1 INTRODUCTION

1.1 Overview

Woodside Energy Ltd (Woodside), as Titleholder under the Offshore Petroleum and Greenhouse Gas Storage (Environment) Regulations 2023 (Cth) (referred to as the Environment Regulations), on behalf of the North West Shelf (NWS) Joint Venture detailed in **Section 1.6**, is operator of the Angel facility. The Angel facility commenced operation in 2008. The facility consists of subsea hydrocarbon gathering systems, a riser platform and an export pipeline. This Environment Plan (EP) is being revised and resubmitted to integrate drilling, subsea installation, commissioning (drilling and tie-back) and production from the Lambert West reservoir (Lambert West tie-back) into the existing Angel production systems. The activities proposed to occur within Production Licences WA-16-L and WA-3-L and Pipeline Licences WA-31-PL and WA-14-PL are:

- routine production and associated activities
- routine inspection, monitoring, maintenance and repair (IMMR) of the platform and associated subsea infrastructure
- well clean up and commissioning
- drill new well in the Lambert West field
- subsea infrastructure installation
- pre-commissioning and commissioning activities

These activities will hereafter be referred to as the Petroleum Activities Program and form the scope of this EP. A more detailed description of the activities is provided in **Section 3.1**.

This EP has been prepared as part of the requirements under the Environment Regulations, as administered by the National Offshore Petroleum Safety and Environmental Management Authority (NOPSEMA). In accordance with the requirements of regulation 39(1) of the Environment Regulations, Woodside has revised the Angel Operations EP, as a new stage of the activity, to incorporate the tie-back, commissioning and operation of the Lambert West well as a new stage under the Angel Operations EP.

Key components of the Lambert West activity which can be attributed to a new stage of the Angel Operations Environment Plan activity include:

- The activity is a single well therefore the Lambert west well and tie-back are proposed to form part of an existing production system.
- The activity would be conducted within the spatial area described in the existing Angel Operations EP, with a slight temporary expansion to the Operational Area during construction activities.
- The addition of the Lambert West field and associated reserves forms an orderly continuation of the Angel project (EPBC 2004/1805) within existing timeframes specified in EPBC approval.
- The operation of proposed Lambert West wells and subsea infrastructure is consistent with the activities already described within this Angel Operations EP.

1.2 Purpose of the Environment Plan

In accordance with the objectives of the Environment Regulations, the purpose of this EP is to demonstrate that:

- the potential environmental impacts and risks (planned (routine and non-routine) and unplanned) that may result from the Petroleum Activities Program are identified
- appropriate management controls are implemented to reduce impacts and risks to a level that is 'as low as reasonably practicable' (ALARP) and acceptable
- the Petroleum Activities Program is carried out in a manner consistent with the principles of ecologically sustainable development (ESD) (as defined in Section 3A of the *Environment Protection and Biodiversity Conservation Act 1999* (Cth) (EPBC Act)).

This EP describes the process and resulting outputs of the risk assessment, whereby impacts and risks are managed accordingly.

The EP defines activity-specific environmental performance outcomes, standards and measurement criteria (MC). These form the basis for monitoring, auditing, and managing the Petroleum Activities Program to be undertaken by Woodside and its contractors. The implementation strategy specified in this EP provides Woodside and NOPSEMA with the required level of assurance that impacts and risks associated with the activity are reduced to ALARP and are acceptable.

1.3 Scope of the Environment Plan

The scope of this EP covers the activities that define the Petroleum Activities Program, as described in **Section 3**. The Petroleum Activities Area (PAA), as defined in **Section 3.2.1**, defines the spatial boundary of the Petroleum Activities Program.

This EP addresses potential environmental impacts from planned activities and potential unplanned events that originate from within the PAA. Transit to and from the PAA by project vessels, as well as port activities associated with these vessels, are not within the scope of this EP. Vessels supporting the Petroleum Activities Program operating outside the PAA (e.g., transiting to and from port) are subject to applicable maritime regulations and other requirements and are not managed by this EP.

1.4 Environment Plan Summary

An EP summary will be prepared based on the material provided in this EP. **Table 1-1** summarises the content that will be provided within the EP summary, as required by regulation 35(7).

Table 1-1: Environment Plan summary

EP summary material requirement	Relevant section of this EP containing EP summary material
The location of the activity	**Section 2.10**
A description of the receiving environment	**Section 4**
A description of the activity	**Section 2.10**
Details of the environmental impacts and risks	**Section 6**
The control measures for the activity	**Section 6**
The arrangements for ongoing monitoring of the titleholder's environmental performance	**Section 7.8**
Response arrangements in the oil pollution emergency plan	**Section 7.12**
Consultation already undertaken and plans for ongoing consultation	**Section 5**
Details of the titleholder's nominated liaison person for the activity	**Section 1.7.2**

1.5 Structure of the Environment Plan

The EP has been structured to reflect the process and requirements of the Environment Regulations, as outlined in **Table 1-2**.

Table 1-2: Environment Plan process phases, applicable Environment Regulations and relevant section of Environment Plan

Criteria for acceptance	Content Requirements/Relevant Regulations	Elements	Section of EP
Regulation 34(a): is appropriate for the nature and scale of the activity	Regulation 21: Environmental Assessment Regulation 22: Implementation strategy for the environment plan Regulation 24: Other information in the environment plan	The principle of 'nature and scale' applies throughout the EP	**Section 2** **Section 3** **Section 4** **Section 5** **Section 6** **Section 7**
Regulation 34(b): demonstrates that the environmental impacts and risks of the activity will be reduced to as low as reasonably practicable Regulation 34(c): demonstrates that the environmental impacts and risks of the activity will be of an acceptable level	Regulation 21(1)– 21(7): 21(1) Description of the activity 21(2),(3) Description of the environment 21(4) Requirements 21(5),(6) Evaluation of environmental impacts and risks 21(7) Environmental performance outcomes and standards Regulation 24(a)– 24(c): A statement of the titleholder's corporate environmental policy A report on all consultations between the titleholder and any relevant person	Set the context (activity and existing environment) Define 'acceptable' (the requirements, the corporate policy, relevant persons) Detail the impacts and risks Evaluate the nature and scale Detail the control measures – ALARP and acceptable	**Section 1** **Section 2** **Section 3** **Section 4** **Section 5** **Section 6** **Section 7**
Regulation 34(d): provides for appropriate environmental performance outcomes, EPS and MC.	Regulation 21(7): Environmental performance outcomes and standards	Environmental Performance Objectives (EPOs) Environmental Performance Standards (EPSs) Measurement Criteria (MC)	**Section 6**
Regulation 34(e): includes an appropriate implementation strategy and monitoring, recording, and reporting arrangements	Regulation 22: Implementation strategy for the environment plan	Implementation strategy, including: systems, practices and procedures performance monitoring Oil Pollution Emergency Plan (OPEP) and scientific monitoring ongoing consultation.	**Section 7** **Appendix D**
Regulation 34(f): does not involve the activity or part of the activity, other than arrangements for environmental monitoring or for responding to an emergency, being	Regulation 21(1)-21(3): 21(1) Description of the activity 21(2) Description of the environment 21(3) Without limiting Regulation 21(2)(b), particular relevant values and	No activity, or part of the activity, undertaken in any part of a declared World Heritage property	**Section 2.10** **Section 4** **Section 6**

Criteria for acceptance	Content Requirements/Relevant Regulations	Elements	Section of EP
undertaken in any part of a declared World Heritage property within the meaning of the EPBC Act	sensitivities may include any of the following: (a) the world heritage values of a declared World Heritage property within the meaning of the EPBC Act; (b) the national heritage values of a National Heritage place within the meaning of that Act; (c) the ecological character of a declared Ramsar wetland within the meaning of that Act; (d) the presence of a listed threatened species or listed threatened ecological community within the meaning of that Act; (e) the presence of a listed migratory species within the meaning of that Act; (f) any values and sensitivities that exist in, or in relation to, part or all of: (i) a Commonwealth marine area within the meaning of that Act; or (ii) Commonwealth land within the meaning of that Act.		
Regulation 34(g): (i) the titleholder has carried out the consultations required by Regulation 25 (ii) the measures (if any) that the titleholder has adopted, or proposes to adopt, because of the consultations are appropriate	Regulation 25: • Consultation with relevant authorities, persons and organisations, etc. • Regulation 24(b): • A report on all consultations between the titleholder and any relevant person	Consultation in preparation of the EP	**Section 5**
Regulation 34(h): complies with the Act and the regulations	Regulation 23: Details of the Titleholder and nominated liaison Regulation 24(c): Details of all reportable incidents in relation to the proposed activity.	All contents of the EP must comply with the Act and the regulations	**Section 1.6** **Section 7.10**

1.6 Description of the Titleholder

Woodside is the Titleholder for this activity, on behalf of the NWS Joint Venture comprising Woodside Energy Ltd, Woodside Energy (North West Shelf) Pty Ltd, BP Developments Australia Pty Ltd, Chevron Australia Pty Ltd, Japan Australia LNG (MIMI) Pty Ltd, CNOOC NWS Private Ltd and Shell Australia Pty Ltd.

Woodside is Australia's leading natural gas producer. Woodside's operations are characterised by strong safety and environmental performance in remote and challenging locations. Wherever

Woodside works, it is committed to living its values of one team, we care. innovate every day, results matter and build and maintain trust

Since 1984, the company has been operating the landmark Australian project, the North West Shelf, which is one of the world's premier liquefied natural gas (LNG) facilities.

Woodside has an excellent track record of efficient and safe production. Woodside strives for excellence in safety and environmental performance and continues to strengthen relationships with customers, partners, co-venturers, governments, and communities. Further information about Woodside can be found at http://www.woodside.com.

1.7 Details of Titleholder and Nominated Liaison

In accordance with regulation 23 of the Environment Regulations, details of the titleholder and nominated liaison and arrangements for the notification of changes are described below.

1.7.1 Titleholder

Woodside Energy Ltd

11 Mount Street

Perth, Western Australia

T: 08 9348 4000

ACN: 63 005 482 986

1.7.2 Nominated Liaison

Andrew Winter

Corporate Affairs Manager

11 Mount Street

Perth, Western Australia

T: 08 9348 4000

E: feedback@woodside.com.au

1.7.3 Arrangements for Notifying Change

If the titleholder, titleholder's nominated liaison person, or the contact details for the titleholder or the liaison person change, then NOPSEMA will be notified of the change in writing within two weeks or as soon as practicable.

1.8 Woodside Management System

The Woodside Management System (WMS) provides a structured framework of documentation to set common expectations governing how all employees and contractors at Woodside will work. Many of the standards presented in **Section 6** are drawn from the WMS documentation, which comprises four elements as outlined below (and illustrated in **Figure 1-1**):

- **Compass and Policies**: Set the enterprise-wide direction for Woodside by governing our behaviours, actions, and business decisions and ensuring we meet our legal and other external obligations.
- **Expectations**: Set essential activities or deliverables required to achieve the objectives of the Key Business Activities and provide the basis for developing processes and procedures.
- **Processes and Procedures**: Processes identify the set of interrelated or interacting activities that transforms inputs into outputs, to systematically achieve a purpose or specific

objective. Procedures specify what steps, by whom, and when required to carry out an activity or a process.

- **Guidelines**: Provide recommended practice and advice on how to perform the steps defined in Procedures, together with supporting information and associated tools. Guidelines provide advice on: how activities or tasks may be performed; information that may be taken into consideration; or, how to use tools and systems.

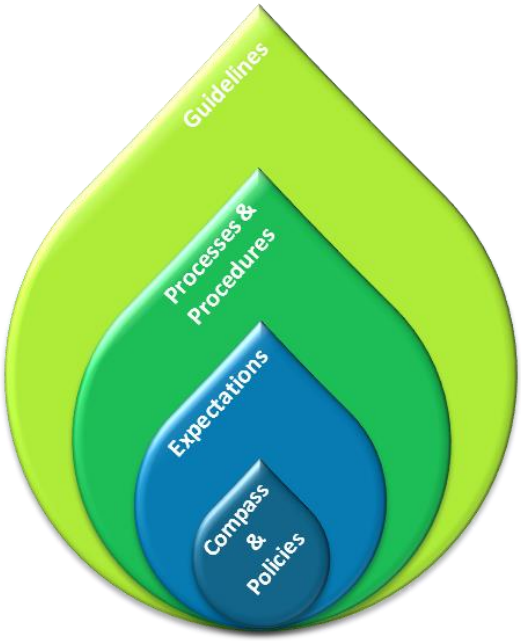

Figure 1-1: The four major elements of the Woodside Management System Seed

The WMS is organised within a Business Process Hierarchy based upon Key Business Activities to ensure the system remains independent of organisation structure, is globally applicable and scalable wherever required. These Key Business Activities are grouped into Management, Support, and Value Stream activities as shown in **Figure 1-2**. The Value Stream activities capture, generate and deliver value through the exploration and production lifecycle. The Management activities influence all areas of the business, while Support activities may influence one or more value stream activities.

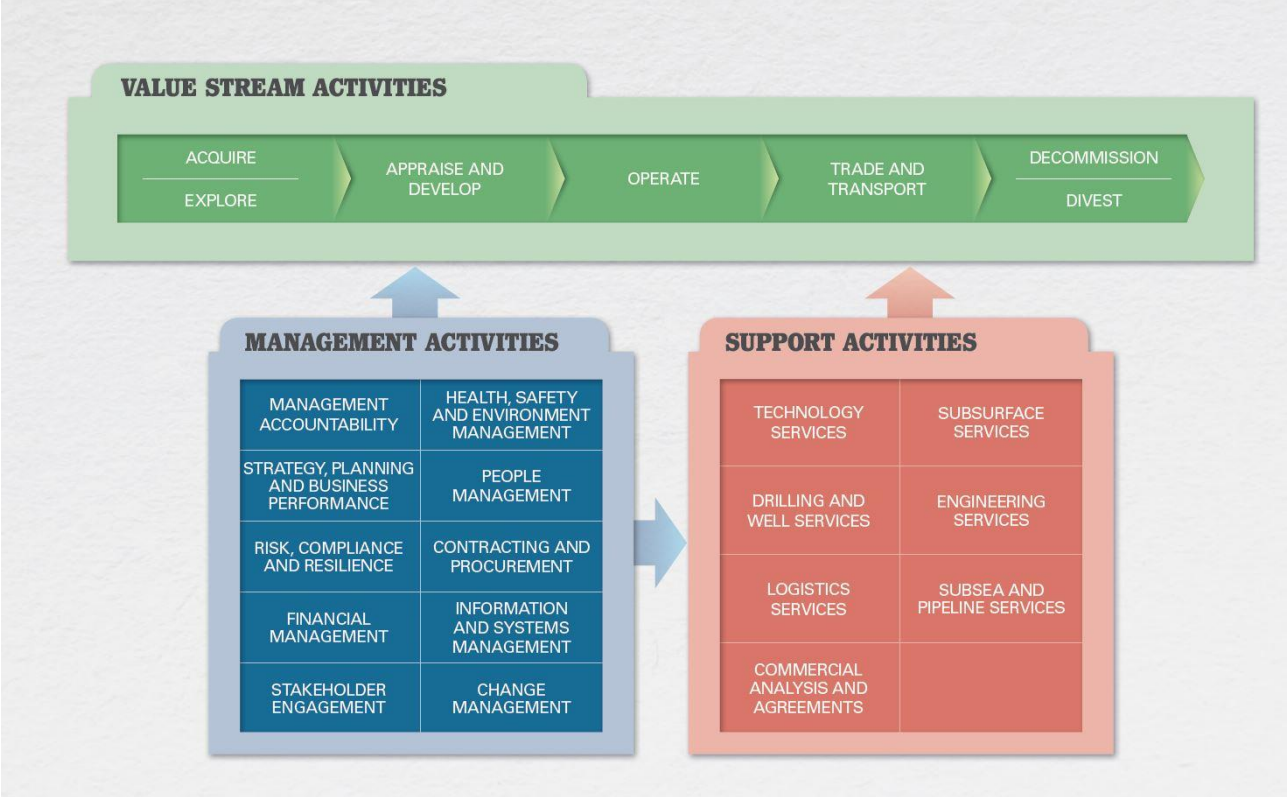

Figure 1-2: The Woodside Management System business process hierarchy

1.8.1 Environment and Biodiversity Policy

In accordance with regulation 24(a) of the Environment Regulations, Woodside's Environment and Biodiversity Policy is provided in **Appendix A** of this EP.

1.9 Description of Relevant Requirements

In accordance with regulation 21(4) of the Environment Regulations, a description of requirements, including legislative requirements, that apply to the activity and are relevant to the management of risks and impacts of the Petroleum Activities Program are detailed in **Appendix B**. This EP will not be assessed under the *Environment Protection Act 1986* (WA) as the activity does not occur on State land or within State Waters.

1.9.1 Offshore Petroleum and Greenhouse Gas Storage Act 2006

The *Offshore Petroleum and Greenhouse Gas Storage Act 2006* (Cth) (OPGGS Act) controls exploration and production activities beyond three nautical miles (nm) of the mainland (and islands) to the outer extent of the Australian Exclusive Economic Zone (EEZ) at 200 nm.

The relevant requirements in Section 572 of the OPGGS Act are detailed in **Table 1-3**.

Table 1-3: Relevant requirements of Section 572 of the *Offshore Petroleum and Greenhouse Gas Storage Act*

Section number	Relevant Requirement	Relevant section of the EP
Section 270 – Consent to surrender title[1]		
	The Joint Authority may consent to the surrender sought by the application only if the registered holder of the permit, lease or licence: c) has: (i) to the satisfaction of NOPSEMA, removed or caused to be removed from the surrender area (defined by subsection (7)) all property brought into the surrender area by any person engaged or concerned in the operations authorised by the permit, lease or licence; or (ii) made arrangements that are satisfactory to NOPSEMA in relation to that property; and	Not applicable
Section 572 – Maintenance and removal of property etc. by titleholder		
2	A titleholder must maintain in good condition and repair all structures that are, and all equipment and other property that is: (a) in the title area; and (b) used in connection with the operations authorised by the permit, lease, licence or authority.	**Section 7.3**
3	A titleholder must remove from the title area all structures that are, and all equipment and other property that is, neither used nor to be used in connection with the operations: (a) in the title area; and (b) used in connection with the operations authorised by the permit, lease, licence or authority.	**Sections 3.4 and 7.3**
7	This section has effect subject to: (a) any other provision of this Act; and (b) the regulations; and (c) a direction given by NOPSEMA or the responsible Commonwealth Minister under: (i) Chapter 3; or (ii) this Chapter; and (d) any other law.	**Section 7.3.4.2**

There is no intent to surrender any titles in the scope of this EP.

Under the OPGGS Act, the Environment Regulations apply to petroleum activities in Commonwealth Waters and are administered by NOPSEMA. The objective of the Environment Regulations is to ensure petroleum activities are performed in a manner:

- consistent with the principles of ESD
- by which the environmental impacts and risks of the activity will be reduced to ALARP
- by which the environmental impacts and risks of the activity will be of an acceptable level.

1.9.2 Environment Protection and Biodiversity Conservation Act 1999 (Cth)

One of the objectives EPBC Act is to protect and manage nationally and internationally important flora, fauna, ecological communities and heritage places in Australia. These are defined under Part 3 of the Act as 'matters of national environmental significance' (MNES). The EPBC Act sets a regime which aims to ensure actions taken on (or impacting upon) Commonwealth land or waters are consistent with the principles of ESD. When a person proposes to take an action that they believe may need approval under the EPBC Act, they must refer the proposal to the Commonwealth Minister for Environment.

In relation to offshore petroleum activities in Commonwealth waters, in accordance with the Streamlining Offshore Petroleum Approvals Program (the Program), requirements under the Act are now administered by NOPSEMA, commencing February 2014. The Program requires any offshore petroleum activities, authorised by the OPGGS Act to be conducted in accordance with an accepted EP. The definition of 'environment' in the Program covers all matters protected under Part 3 of the EPBC Act.

1.9.2.1.1 Offshore Project Approval

The Angel Gas and Condensate Field was referred for assessment under the EPBC Act and was determined to be a Controlled Action. The level of assessment was set at Preliminary Documentation, and the action was subsequently approved with conditions on 27 June 2005.

Consolidated Approval Notice – Angel Gas and Condensate Field (EPBC 2004/1805) dated 14 June 2015 was issued to consolidate the approval conditions, and the approval conditions were subject to variation on the date of the notice. A key element to the variation relates to conditions requiring a plan for managing impacts of the action. The previous conditions required the Minister's approval of such plans, with the variation now automatically deeming the plan to have been approved by the Minister if the measures are included in an EP related to the action that was submitted to NOPSEMA after 27 February 2014 and is in force under the Environment Regulations.

Conditions in relation to the EPBC Act approval that are considered relevant to the scope of this EP are provided in **Table 1-4**.

Table 1-4: Conditions from the Angel gas and condensate field (EPBC 2004/1805) relevant to the Petroleum Activities Program

Condition number	Condition	Relevant section of EP
1[1]	The person taking the action must submit, for the Minister's approval, a plan (or plans) for managing the offshore impacts of the action. The plan (or plans) must include measures for the following individual activities: c) Operations: (i) Produced water monitoring, management and verification; (ii) If naturally occurring radioactive materials (NORMs) are found to be present, measures to manage their collection, handling and disposal; and (iii) Interaction procedures for supply vessels and aircraft that are consistent with Part 8 of the Environment Protection and Biodiversity Conservation Regulations 2000 and cetacean reporting.	(i) – **Section 6.6.5** (ii) – **Section 6.8.7** (iii) – **Section 6.7.3**
2	The person taking the action must submit a decommissioning plan (or plans) for approval by the Minister prior to decommissioning of the development. The plan (or plans) must consider the complete removal of all structures and components above the sea floor. The approved plan (or plans) must be implemented.	Planning for decommissioning is outlined in **Section 7.3**
6	If the person taking the action wishes to carry out any activity otherwise than in accordance with the plans referred to in conditions 1 or 2, the person taking the action may submit for the Minister's approval a revised version of any such plan. If the Minister approves a revised plan so submitted, the person taking the action must implement that plan instead of the plan as originally accepted.	This EP

1 Condition 1a) and 1b) (not shown) have been met through previous plans.

Condition number	Condition	Relevant section of EP
8	A plan required by condition 1, 2 or 6 is automatically deemed to have been submitted to, and approved by, the Minister if the measures (as specified in the relevant condition) are included in an environment plan (or environment plans) relating to the taking of the action that: (a) Was submitted to NOPSEMA after 27 February 2014; and (b) Either: (i) Is in force under the OPGGS Environment Regulations; or (ii) Has ended in accordance with regulation 46 of the OPGGS Environment Regulations.	The implementation of this EP is considered to meet the requirements of this condition
8A	Where a plan required by condition 1 or 6 has been approved by the Minister and the measures (as specified in the relevant condition) are included in an environment plan (or environment plans) that: (a) Was submitted to NOPSEMA after 27 February 2014; and (b) Either: (i) Is in force under the OPGGS Environment Regulations; or (ii) Has ended in accordance with regulation 46 of the OPGGS Environment Regulations. The plan approved by the Minister no longer needs to be implemented.	The implementation of this EP is considered to meet this Condition, and supersedes previously approved plans
8B	Where an environment plan, which includes measures specified in the conditions referred to in conditions 8 and 8A above, is in force under the OPGGS Environment Regulations that relates to the taking of the action, the person taking the action must comply with those measures as specified in that environment plan.	The implementation of this EP is considered to meet the requirements of this condition

1.9.2.1.2 Recovery Plans and Threat Abatement Plans

Under s139(1)(b) of the EPBC Act, the Environment Minister must not act inconsistently with a recovery plan for a listed threatened species or ecological community or a threat abatement plan for a species or community protected under the Act. Similarly, under s268 of the EPBC Act:

"A Commonwealth agency must not take any action that contravenes a recovery plan or a threat abatement plan."

In relation to offshore petroleum activities in Commonwealth waters, these requirements are now administered by NOPSEMA in accordance with commitments set out in the Programs. Relevant recovery plans or threat abatement plans relevant to the scope of this EP have been identified as described in **Section 2.9** and assessed in **Section 6.9**.

1.9.2.1.3 Australian Marine Parks

Under the EPBC Act, Australian Marine Parks (AMPs), formerly known as Commonwealth Marine Reserves, are recognised for conserving marine habitats and the species that live and rely on these habitats. The Director of National Parks (DNP) is responsible for managing AMPs (supported by Parks Australia) and is required to publish management plans for them. Other parts of the Commonwealth Government must not perform functions or exercise powers in relation to these parks that are inconsistent with management plans (s.362 of the EPBC Act). Relevant AMPs are listed in **Section 4.8** and described in **Appendix C**. The North-west Marine Parks Network Management Plan describes the requirements for management.

Specific zones within the AMPs have been allocated conservation objectives as stated below (International Union for Conservation of Nature [IUCN] Protected Area Category) based on the Australian IUCN reserve management principles outlined in Schedule 8 of the Environment Protection and Biodiversity Conservation Regulations 2000 (Cth) (EPBC Regulations 2000).

1.9.2.1.4 World Heritage Properties

Australian World Heritage management principles are prescribed in Schedule 5 of the EPBC Regulations 2000. Management principles that are considered relevant to the scope of this EP are provided in **Table 1-5**.

Table 1-5: Relevant management principles under Schedule 5 – Australian World Heritage management principles of the *Environment Protection and Biodiversity Conservation Act*

Number	Principle	Relevant section of the EP
3	**Environmental impact assessment and approval** 3.01 This principle applies to the assessment of an action that is likely to have a significant impact on the World Heritage values of a property (whether the action is to occur inside the property or not). 3.02 Before the action is taken, the likely impact of the action on the World Heritage values of the property should be assessed under a statutory environmental impact assessment and approval process. 3.03 The assessment process should: • identify the World Heritage values of the property that are likely to be affected by the action; and • examine how the World Heritage values of the property might be affected; and • provide for adequate opportunity for public consultation. 3.04 An action should not be approved if it would be inconsistent with the protection, conservation, presentation or transmission to future generations of the World Heritage values of the property. 3.05 Approval of the action should be subject to conditions that are necessary to ensure protection, conservation, presentation or transmission to future generations of the World Heritage values of the property. 3.06 The action should be monitored by the authority responsible for giving the approval (or another appropriate authority) and, if necessary, enforcement action should be taken to ensure compliance with the conditions of the approval.	3.01 and 3.02: Assessment of significant impact on World Heritage values is included in **Section 6**. Principles are met by the submitted EP. 3.03 (a) and (b): World Heritage values are identified in Section 4 and considered in the assessment of impacts and risks for the Petroleum Activity in **Section 6**. 3.03 (c): Relevant persons consultation and feedback received in relation to impacts and risks to the Ningaloo World Heritage Property are outlined in **Section 5**. 3.04, 3.05 and 3.06: Principles are considered to be met by the acceptance of this EP.

Note that Section 1 – General Principles and 2 – Management Planning of Schedule 5 are not considered relevant to the scope of this EP and, therefore, have not been included.

2 ENVIRONMENT PLAN PROCESS

2.1 Overview

This section outlines the process taken by Woodside to prepare this EP, once the activity was defined as a petroleum activity. The process describes the activity, the existing environment, followed by the environmental risk management methodology used to identify, analyse and evaluate risks to meet ALARP levels and acceptability requirements, and develop EPOs and EPSs. This section also describes Woodside's risk management methodologies as applied to implementation strategies for the activity.

Regulation 21(5) of the Environment Regulations requires the EP to include details of the environmental impacts and risks for the Petroleum Activities Program, and an evaluation of all the impacts and risks, appropriate to the nature and scale of each impact and risk. The objective of the risk assessment process described in this section is to identify risks and associated impacts of an activity, so they can be assessed, and appropriate control measures applied to eliminate, control or mitigate the impact/risk to ALARP, and to determine if the impact or risk level is acceptable.

Environmental impacts and risks include those directly and indirectly associated with the Petroleum Activities Program, and include potential emergency and accidental events:

- **Planned activities** have the inherent potential to cause environmental impacts.
- **Environmental risks** are unplanned events with the potential for environmental impact (termed risk 'consequence').

In this section, potential impacts from planned activities are termed 'impacts', and 'risks' are associated with unplanned events with the potential for environmental impact (should the risk be realised), with such impacts termed potential 'consequences'.

2.2 Environmental Risk Management Methodology

2.2.1 Woodside Risk Management Process

Woodside recognises that risk is inherent to its business and that effective management of risk is vital to delivering on company objectives, success and continued growth. Woodside is committed to managing risk proactively and effectively. The objective of Woodside's risk management system is to provide a consistent process for recognising and managing risks across Woodside's business. Achieving this objective includes ensuring risks consider impacts across these key areas of exposure: health and safety, environment, finance, reputation and brand, legal and compliance, and social and cultural. A copy of Woodside's Risk Management Policy is provided in **Appendix A**.

The environmental risk management methodology used in this EP is based on Woodside's Risk Management Procedure. This procedure aligns to industry standards, such as international standard ISO 31000. WMS risk management procedures, guidelines and tools provide guidance of specific techniques for managing risk, tailored for particular areas of risk within certain business processes. Procedures applied for environmental risk management include (**Section 7.2.4**):

- Health, Safety and Environment Management Procedure
- Impact Assessment Procedure
- Process Safety Management Procedure.

The risk management methodology provides a framework to demonstrate that risks and impacts are continually identified, reduced to ALARP and assessed to be at an acceptable level, as required by the Environment Regulations. The key steps of Woodside's Risk Management Process are shown in **Figure 2-1**. A description of each step and how it is applied to the scopes of this activity is provided in **Section 2.2** to **Section 2.12**.

Figure 2-1: Woodside's risk management process

2.2.2 Health, Safety and Environment Management Procedure

The Health, Safety and Environment Management Procedure provides the structure for managing health, safety and environment (HSE) risks and impacts across Woodside, defines the decision authorities for company-wide HSE management activities and deliverables, and supports continuous improvement in HSE management.

2.2.3 Impact Assessment Procedure

To support effective environmental risk assessment, Woodside's Impact Assessment Procedure (**Figure 2-2**) provides the steps to meet the required environment, health and social standards by ensuring impact assessments are undertaken appropriate to the nature and scale of the activity, the regulatory context, the receiving environment, interests, concerns and rights of relevant persons, and the applicable framework of standards and practices.

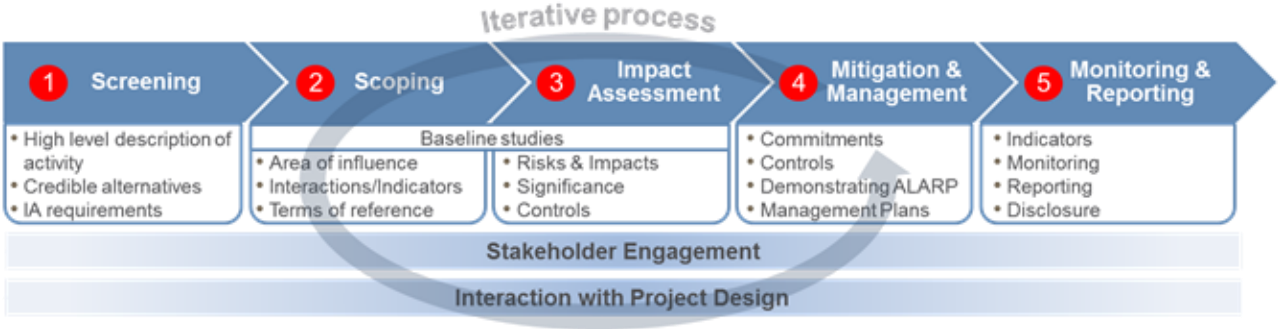

Figure 2-2: Woodside's impact assessment process

2.2.4 Process Safety Management Procedure and Process Safety Risk Assessment Procedure

Due to the nature and scale of petroleum activities, Woodside's Process Safety Management Procedure establishes Woodside's framework for Process Safety Management (**Section 7.2.2**). This framework includes the Process Safety Risk Assessment Procedure (PSRA). The PSRA is a key part of Woodside's process safety management framework for managing the integrity of systems and processes that handle hazardous substances over the exploration and production lifecycle. The PSRA sets out methods to ensure that process safety risks are understood and controlled, including that all process safety hazards are systematically identified, assessed and treated so that the associated risks are reduced to a level that is tolerable and ALARP.

2.3 Environment Plan Development Process

The EP development process is illustrated in **Figure 2-3**. Each element of this process is discussed further in **Section 2.5** to **Section 2.12**.

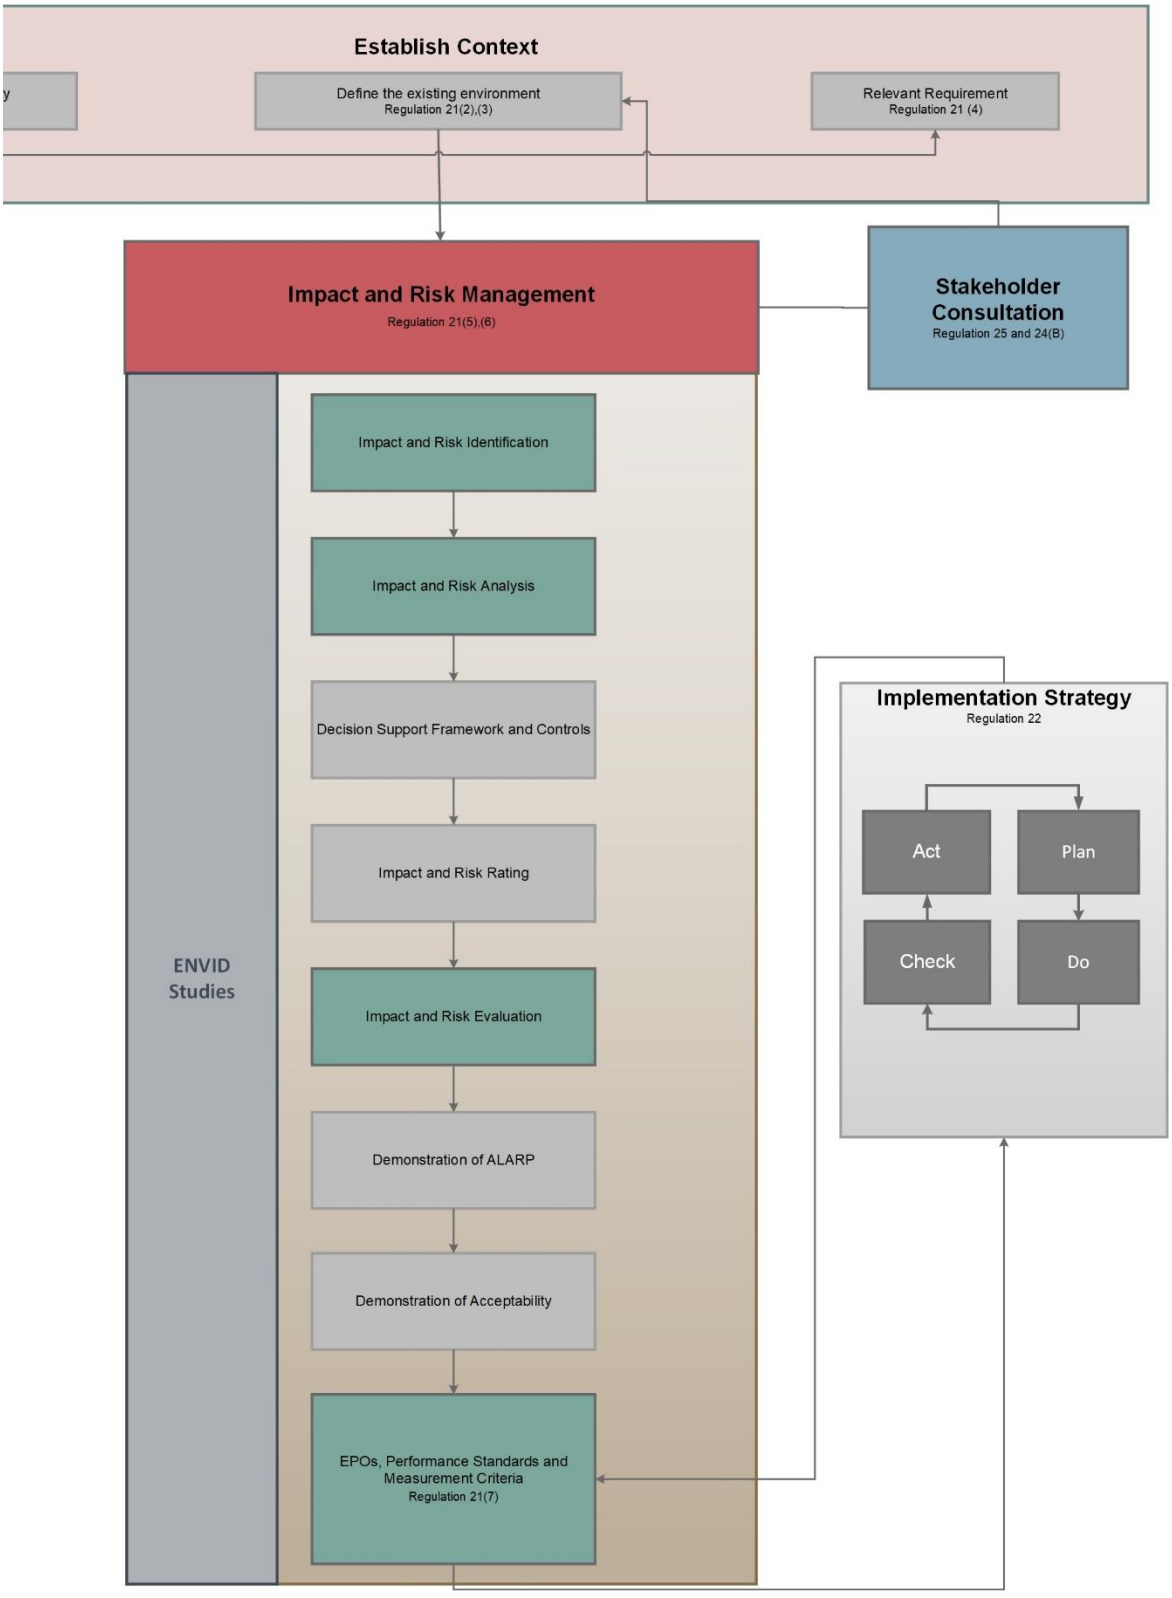

Figure 2-3: Environment Plan development process

2.4 Establish the Context

2.4.1 Define the Activity

This first stage involves evaluating whether the activity meets the definition of a 'petroleum activity' as defined in the Environment Regulations. The activity is described in relation to:

- the location
- what is to be undertaken
- how it is planned to be undertaken, including outlining operational details of the activity and proposed timeframes.

The 'what' and 'how' are described in the context of 'environmental aspects'[2] to inform the risk and impact assessment for planned (routine and non-routine) and unplanned (accidents, incidents, emergency conditions) activities.

The activity is described in **Section 3** and is referred to as the Petroleum Activities Program.

2.4.2 Define the Existing Environment

The context of the existing environment is described and determined by considering the nature and scale of the activity (size, type, timing, duration, complexity, and intensity of the activity), as described in **Section 4**. The purpose is to describe the existing environment that may be impacted by the activity, directly or indirectly, by planned or unplanned[3] events.

The Existing Environment (**Section 4**) is structured into subsections defining the physical, biological, socio-economic and cultural attributes of the area of interest, in accordance with the definition of environment in regulation 5 of the Environment Regulations. These subsections make particular reference to:

- The environmental, and social and cultural consequences as defined by Woodside (refer to **Table 2-1**), which address key physical and biological attributes, as well as social and cultural values of the existing environment. These consequence definitions are applied to the impact and risk analysis (refer **Section 2.2**) and rated for all planned and unplanned activities. Additional detail is provided for unplanned hydrocarbon spill risk evaluation.
- EPBC Act MNES including listed threatened species and ecological communities and listed Migratory species. Defining the spatial extent of the existing environment is guided by the nature and scale of the Petroleum Activities Program (and associated sources of environmental risk). This considers the PAA and wider environment that may be affected (EMBA), as determined by the hydrocarbon spill risk assessments presented in **Section 6.7.2**. MNES, as defined under the EPBC Act, are addressed through Woodside's impact and risk assessment (**Section 6**).
- Relevant values and sensitivities, which may include world or national heritage listed areas, listed Threatened species or ecological communities, listed Migratory species, or sensitive values.

By grouping potentially impacted environmental values by aspect (as presented in **Table 2-1**), the presentation of information about the receiving environment is standardised. This information is then consistently applied to the risk evaluation section to provide a robust approach to the overall environmental risk evaluation and its documentation in the EP.

[2] An environmental aspect is an element of the activity that can interact with the environment.

[3] For each source of risk, the credible worst-case scenario in conjunction with impact thresholds is used to determine the spatial extent of the EMBA. The worst-case unplanned event is considered to be an unplanned hydrocarbon release, further defined for each activity through the risk assessment process. Interpretation of stochastic oil spill modelling determines the EMBA for the release, which defines the spatial scale of the environment that may be potentially impacted by the Petroleum Activities Program and in turn provides context to the 'nature and scale' of the existing environment.

Table 2-1: Example of the environment values potentially impacted which are assessed within the Environment Plan

Environmental Value Potentially Impacted Regulations 21(2), (3)						
Soil and Groundwater	Marine Sediment	Water Quality	Air Quality (incl Odour)	Ecosystems / Habitats	Species	Socio-economic

2.4.3 Relevant Requirements

The relevant requirements in the context of legislation, other environmental approval requirements, conditions and standards that apply to the Petroleum Activities Program are identified and reviewed; and are presented in **Appendix B**.

The Risk Management Climate and Environment and Biodiversity Policies are referenced in **Appendix A**.

2.5 Impact and Risk Identification

Relevant environmental aspects and hazards were identified that support the process to define environmental impacts and risks associated with an activity.

The environmental impact and risk assessment presented in this EP has been informed by recent and historic hazard and environmental risk identification studies (e.g., HAZID/ENVID), consequence modelling studies for high consequence, low probability environmental risks, bowtie risk assessments for MEEs as required by Woodside's PSRA processes, desktop reviews and studies associated with the Petroleum Activities Program. Impacts, risks and potential consequences were identified based on planned and potential interaction with the activity (based on the description in **Section 3**), the existing environment (**Section 4**) and the outcomes of Woodside's consultation process (**Section 6**). The environmental outputs of applicable risk and impact workshops and associated studies are referred to as ENVID in this EP.

An environmental impacts and risks identification and assessment workshop was undertaken by multidisciplinary teams comprising relevant operational and environmental personnel with sufficient breadth of knowledge, training and experience to reasonably assure that risks and impacts were identified, and their potential environmental consequences assessed. Impacts and risks were identified, during the workshop, for both planned (routine and non-routine) activities and unplanned (accidents/incidents/emergency conditions) events. During this process, risks identified as not applicable (not credible) were removed from the assessment.

Impacts and risks were evaluated and tabulated for each planned activity and unplanned events respectively. Environmental impacts and risks were recorded in an environmental impacts and risk register. The output of the workshop is used to present the risk assessment and form the basis of performance outcomes, standards, and measurement criteria. This information is presented in **Section 6**, following the format presented in **Table 2-2**.

Table 2-2: Example of layout of identification of risks and impacts in relation to risk sources

Impacts and Risks Evaluation Summary														
Source of Risk	***Environmental Value Potentially Impacted***							***Evaluation***						
	Soil and Groundwater	Marine Sediment	Water Quality	Air Quality (incl Odour)	Ecosystems / Habitat	Species	Socio-economic	Decision Type	Consequence / Impact	Likelihood	Risk Rating	ALARP Tool	Acceptability	Outcome
Summary of source of impact/risk														

2.6 Impact and Risk Analysis

Risk analysis further develops the understanding of a risk by defining the impacts and assessing appropriate controls, as well as considering previous risk assessments for similar activities, relevant studies, past performance, external consultation feedback, and the existing environment.

The key steps undertaken for each identified risk during the risk assessment were to:

- identify the Decision Type in accordance with the decision support framework
- identify appropriate control measures (preventive and mitigation) aligned with the Decision Type
- assess the risk rating.

2.6.1 Decision Support Framework

To support the risk assessment process and Woodside's determination of acceptability (**Section 2.8.2**), Woodside's HSE risk management procedures include the use of a decision support framework based on principles set out in the Guidance on Risk Related Decision Making (Oil and Gas UK, 2014). This concept is integrated into the environmental impacts and risks identification and assessment workshop to determine the level of supporting evidence that may be required to draw sound conclusions regarding risk level and whether the risk is acceptable and ALARP (**Section 2.8**). Application of the decision support framework confirms:

- activities do not pose an unacceptable environmental risk
- appropriate focus is placed on activities where the impact or risk is anticipated to be acceptable and demonstrated to be ALARP
- appropriate effort is applied to manage risks and impacts based on the uncertainty of the risk, the complexity and risk rating (i.e., potential higher order environmental impacts are subject to further evaluation/assessment).

The framework provides appropriate tools, commensurate to the level of uncertainty or novelty associated with the risk/impact (referred to as the Decision Type A, B, or C). The Decision Type is selected based on an informed discussion around the uncertainty of the risk/impact and is documented in impact and risk register worksheets.

This framework enables Woodside to appropriately understand a risk and determine if the risk or impact is acceptable and can be demonstrated to be ALARP.

2.6.1.1.1 Decision Type A

Decision Type A risks and impacts are well understood and established practice. They are generally recognised as good industry practice and are often embodied in legislation, codes and standards, and utilise professional judgment.

2.6.1.1.2 Decision Type B

Decision Type B risks and impacts typically involve greater uncertainty and complexity; and can include potential higher-order impacts/risks. These risks may deviate from established practice or have some lifecycle implications and therefore require further engineering risk assessment to support the decision and ensure that the risk is ALARP. Engineering risk assessment tools may include:

- risk-based tools such as cost-based analysis or modelling
- consequence modelling
- reliability analysis
- company values.

2.6.1.1.3 Decision Type C

Decision Type C risks and impacts typically have significant risks related to environmental performance. Such risks typically involve greater complexity and uncertainty therefore requiring the adoption of the precautionary approach. The risks may result in significant environmental impact, significant project risk/exposure, or may elicit negative stakeholder concerns. For these risks or impacts, in addition to Decision Type A and B tools, company and societal values need to be considered by undertaking broader internal and external consultation as part of the risk assessment process.

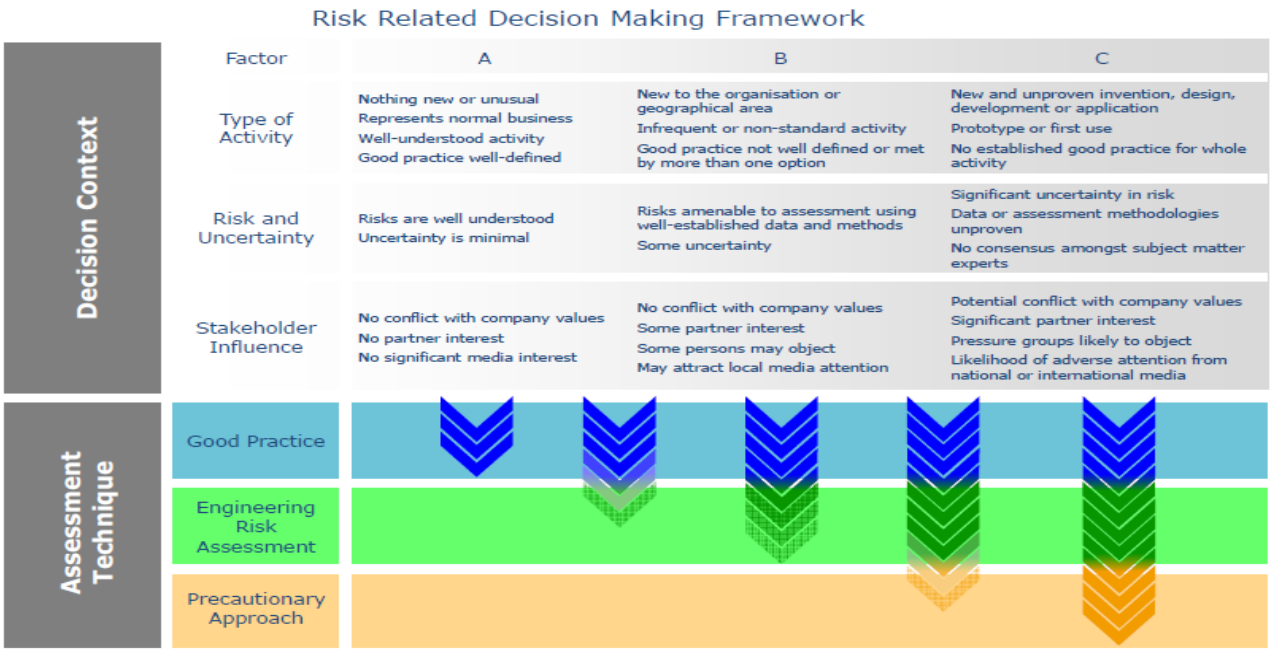

Figure 2-4: Risk-related decision-making framework (Oil and Gas UK, 2014)

2.6.1.1.4 Decision Support Framework Tools

These framework tools are applied, as appropriate, to help identify control measures based on the Decision Type described above:

- **Legislation, Codes and Standards (LCS)** – Identifies the requirements of legislation, codes and standards that are to be complied with for the activity.
- **Good Industry Practice (GP)** – Identifies further engineering control standards and guidelines that may be applied by Woodside above that required to meet the LCS.
- **Professional Judgement (PJ)** – Uses relevant personnel with the knowledge and experience to identify alternative controls. Woodside applies the hierarchy of control as part of the risk assessment to identify any alternative measures to control the risk.
- **Risk-based Analysis (RBA)** – Assesses the results of probabilistic analyses such as modelling, quantitative risk assessment and/or cost–benefit analysis to support the selection of control measures identified during the risk assessment process.
- **Company Values (CV)** – Identifies values identified in Woodside's code of conduct, policies and the Woodside Compass. Views, concerns and perceptions are to be considered from internal Woodside stakeholders directly affected by the planned impact or potential risk.
- **Societal Values (SV)** – Identifies the views, concerns and perceptions of relevant persons and addresses relevant stakeholder views, concerns and perceptions.

2.6.1.1.5 Decision Calibration

To determine that the alternatives selected, and control measures applied are suitable, these tools may be used for calibration (i.e., checking) where required:

- **LCS/Verification of Predictions** – Verification of compliance with applicable LCS and/or good industry practice.
- **Peer Review** – Independent peer review of PJs, supported by RBA, where appropriate.
- **Benchmarking** – Where appropriate, benchmarking against a similar facility or activity type or situation that has been deemed to represent acceptable risk.
- **Internal Consultation** – Consultation undertaken within Woodside to inform the decision and verify company values are met.
- **External Consultation** – Consultation undertaken to inform the decision and verify societal values are considered.

Where appropriate, additional calibration tools may be selected specific to the Decision Type and the activity.

2.6.2 Control Measures (Hierarchy of Controls)

Risk reduction measures are prioritised and categorised in accordance with the hierarchy of controls, where risk reduction measures at the top of the hierarchy take precedence over risk reduction measures further down:

- **Elimination** of the risk by removing the hazard.
- **Substitution** of a hazard with a less hazardous one.
- **Engineering Controls** include design measures to prevent or reduce the frequency of the risk event, or detect or control the risk event (limiting the magnitude, intensity and duration) such as:
  - prevention: design measures that reduce the likelihood of a hazardous event occurring

- detection: design measures that facilitate early detection of a hazardous event
- control: design measures that limit the extent/escalation potential of a hazardous event
- mitigation: design measures that protect the environment if a hazardous event occurs
- response equipment: design measures or safeguards that enable clean up/response after a hazardous event occurs.

- **Procedures and Administration** includes management systems and work instructions used to prevent or mitigate environmental exposure to hazards.
- **Emergency Response and Contingency Planning** includes methods to enable recovery from the impact of an event (e.g., protection barriers deployed near the sensitive receptor).

2.6.3 Impact and Risk Classification

Environmental impacts and risks are assessed to determine the potential impact significance/consequence. The impact significance/consequence considers the magnitude of the impact or risk and the sensitivity of the potentially impacted receptor (**Figure 2-5**).

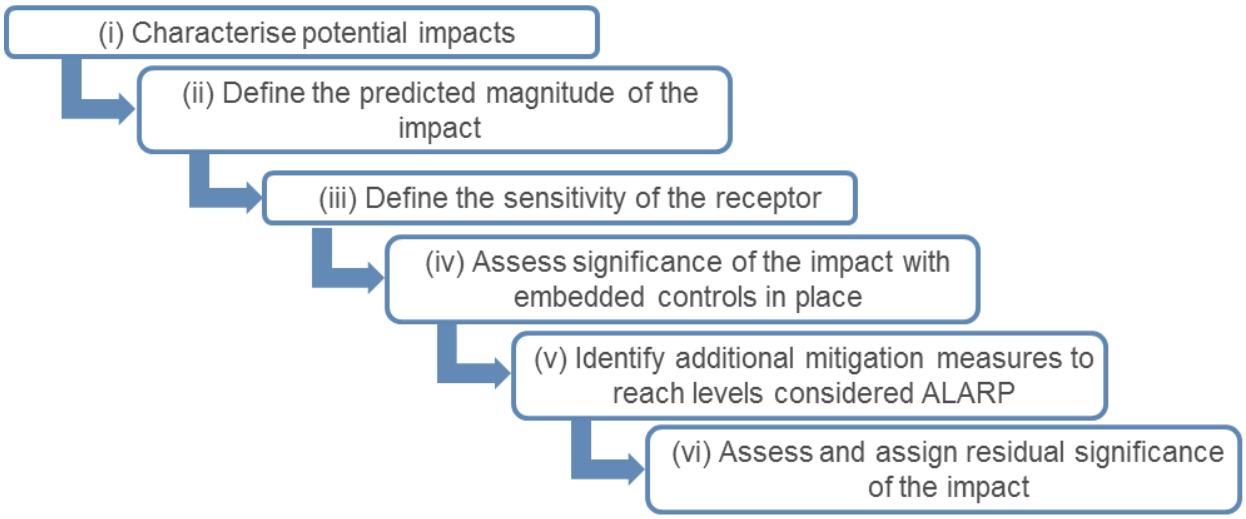

Figure 2-5: Environmental risk and impact analysis

Impacts are classified in accordance with the consequence (**Table 2-3**) outlined in Woodside's Risk Management Procedure and Risk Matrix (**Figure 2-6**). Risks are assessed qualitatively and/or quantitatively in terms of both likelihood and consequence in accordance with this matrix.

The impact and risk information, including classification and evaluation information as shown in the example (**Table 2-2**), are tabulated for each planned activity and unplanned event.

Table 2-3: Woodside risk matrix (environment and social and cultural) consequence descriptions

Environment	Social and cultural	Consequence level
Catastrophic, long-term impact (>50 years) on highly valued ecosystem, species, habitat or physical or biological attribute.	Catastrophic, long-term impact (>20 years) to a community, social infrastructure or highly valued area/item of international cultural significance.	A
Major, long-term impact (10 to 50 years) on highly valued ecosystem, species, habitat or physical or biological attribute.	Major, long-term impact (5 to 20 years) to a community, social infrastructure or highly valued area/item of national cultural significance.	B
Moderate, medium-term impact (2 to 10 years) on ecosystem, species, habitat or physical or biological attribute.	Moderate, medium term impact (2 to 5 years) to a community, social infrastructure or highly valued area/item of national cultural significance.	C
Minor, short-term impact (1 to 2 years) on species, habitat (but not affecting ecosystem function), physical or biological attribute.	Minor, short-term impact (1 to 2 years) to a community or highly valued area/item of cultural significance.	D
Slight, short-term impact (<1 year) on species, habitat (but not affecting ecosystem function), physical or biological attribute.	Slight, short-term impact (<1 year) to a community or area/item of cultural significance.	E
No lasting effect (<1 month). Localised impact not significant to environmental receptor.	No lasting effect (<1 month). Localised impact not significant to area/item of cultural significance.	F

2.6.4 Risk Rating Process

The risk rating process assigns a level of risk to each risk event, measured in terms of consequence and likelihood. The assigned risk rating is determined with controls in place, therefore; the risk rating is determined after identifying the Decision Type and appropriate control measures.

The risk rating process considers the potential environmental consequences and, where applicable, the social and cultural consequences of the risk. The risk ratings are assigned using the Woodside Risk Matrix (refer to **Figure 2-6**).

The risk rating process is done using the steps described in the subsections below.

2.6.4.1.1 Select the Consequence Level

Determine the worst-case credible consequence (**Table 2-3**) associated with the selected event, assuming all controls (preventive and mitigative) are absent or have failed. If more than one potential consequence applies, select the highest severity consequence level.

2.6.4.1.2 Select the Likelihood Level

Determine the description that best fits the chance of the selected consequence occurring, assuming reasonable effectiveness of the prevention and mitigation controls (**Table 2-4**).

Table 2-4: Woodside risk matrix likelihood levels

Likelihood Description						
Frequency	1 in 100,000 to 1,000,000 years	1 in 10,000 to 100,000 years	1 in 1000 to 10,000 years	1 in 100 to 1000 years	1 in 10 to 100 years	>1 in 10 years
Experience	Remote: Unheard of in the industry	Highly Unlikely: Has occurred once or twice in the industry	Unlikely: Has occurred many times in the industry but not at Woodside	Possible: Has occurred once or twice in Woodside or may possibly occur	Likely: Has occurred frequently at Woodside or is likely to occur	Highly Likely: Has occurred frequently at the location or is expected to occur
Likelihood Level	0	1	2	3	4	5

2.6.4.1.3 Calculate the Risk Rating

The risk rating is derived from the consequence and likelihood levels above, in accordance with the Woodside Risk Matrix shown in **Figure 2-6**. A likelihood and risk rating are only applied to environmental risks, not environmental impacts from planned activities.

This risk rating is used as an input into the risk evaluation process and ultimately for prioritising further risk reduction measures. Once each risk is treated to ALARP, the risk rating articulates the ALARP baseline risk as an output of the ENVID studies.

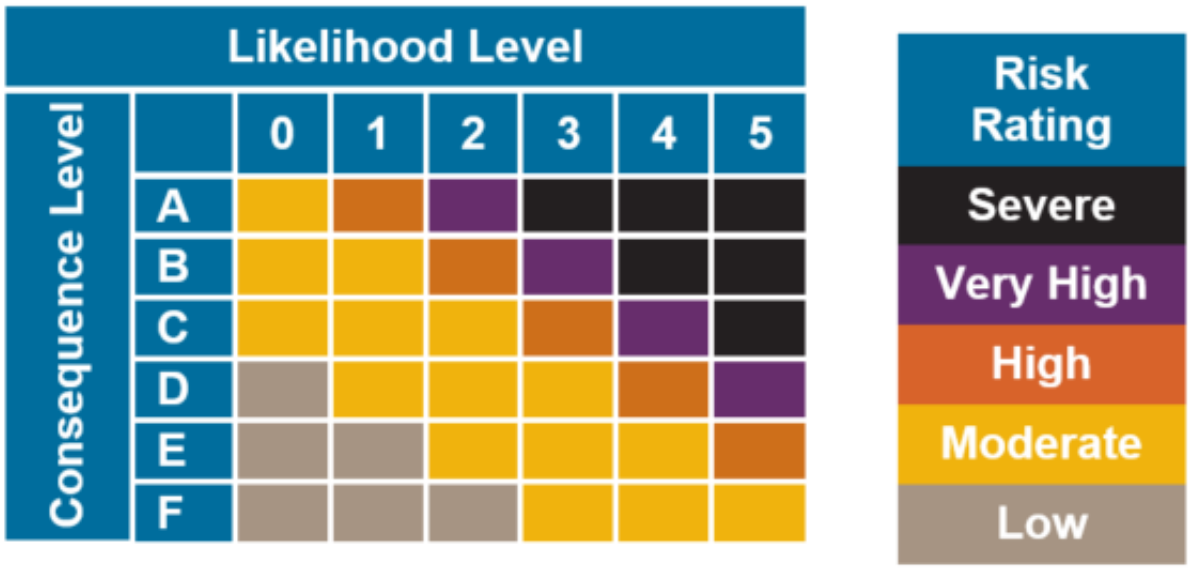

Figure 2-6: Woodside risk matrix – risk level

To support ongoing risk management (as a key component of Woodside's Process Safety Management Framework – refer to the implementation strategy in **Section 7**), Woodside uses the concept of 'current risk' and applies a Current Risk Rating to indicate the current or 'live' level of risk, considering controls that are currently in place and effective on a day-to-day basis. The Current Risk Rating is effective in articulating potential divergence from baseline risk, such as if certain controls fail or could potentially be compromised. Current Risk Ratings aid in communicating and making visible the risk events and ensure the continual management of risk to ALARP by identifying risk reduction measures and assessing acceptability.

2.7 Classification and Analysis of Major Environment Events

For Woodside's production facilities, a further level of analysis is undertaken to identify, classify and analyse MEEs. This extra level of rigour is applied to ensure sufficient controls are in place for risks with potential Level B and above consequences. In the health and safety area, major accident events (MAEs) are identified using a similar process, which supports consistency in managing key risks within Woodside in accordance with Process Safety Risk Management Procedures.

Woodside defines a MEE as an event with potential environment, reputation (pertaining to environment events), social or cultural consequences of level B or higher as per Woodside's Risk Matrix (**Figure 2-6**). MEEs are evaluated against credible worst-case scenarios that may occur when all controls are absent or have failed.

2.7.1 Major Environment Event Identification

The ENVID process identifies numerous sources of risk with differing consequence levels. These risks are screened for those risk events that meet the MEE criteria, and MEE risks are analysed further through detailed consequence modelling and probability/ frequency studies and examined for 'appropriateness' of controls in a bowtie risk assessment.

Risks that do not meet the MEE definition, although screened out of the MEE process, are still evaluated for ALARP and risk acceptability using the methodology described in **Section 2.8**. Some high consequence/low probability events which do not meet the MEE consequence threshold may still undergo additional consequence and probability assessment where they could have a high adverse impact on the company's reputation or relationships with relevant persons, beyond requirement to demonstrate ALARP and acceptable risk levels following application of controls.

2.7.2 Major Environment Event Classification

A standard naming convention has been established for MEEs which is based around ensuring the MEE titles reflect the cause of the event (e.g., subsea system loss of containment) rather than the event itself (e.g., significant hydrocarbon spill to the marine environment). The MEEs are assigned a unique identification code (e.g., MEE-01, MEE-02, etc).

2.7.3 Bowtie Analysis

MEEs are subject to more detailed analysis using the bowtie risk assessment technique, which illustrates cause outcome pathways for each MEE and controls in place to prevent the 'top event' or mitigate the consequences (outcomes). The key drivers for adopting the bowtie technique for MEEs are that it:

- identifies the controls (prevention and mitigation barriers) necessary to ensure the risk is acceptable and ALARP
- supports the process of demonstrating ALARP (described in Section 2.8.1)
- enables verification of and linking to the relevant sections of the WMS that supports barriers
- improves the capacity for lessons learnt and incident prevention by being able to directly relate causes of an incident to those controls that failed
- ensures greater visibility and granularity in the assessment process and enables complex risk scenarios to be presented in an easy to understand format.

The bowtie technique (an example bowtie diagram is shown in **Figure 2-7**) shows the relationships between the 'Causes' that may lead to a particular unwanted event ('Top Event'), together with the range of potential escalation paths that can lead to a variety of 'Outcomes' (or consequences). A bowtie also shows the preventive barriers that may prevent a Top Event from occurring specific to each Cause, and the mitigation barriers in place to limit the potential effects once the Top Event has been realised, specific to each credible MEE Outcome.

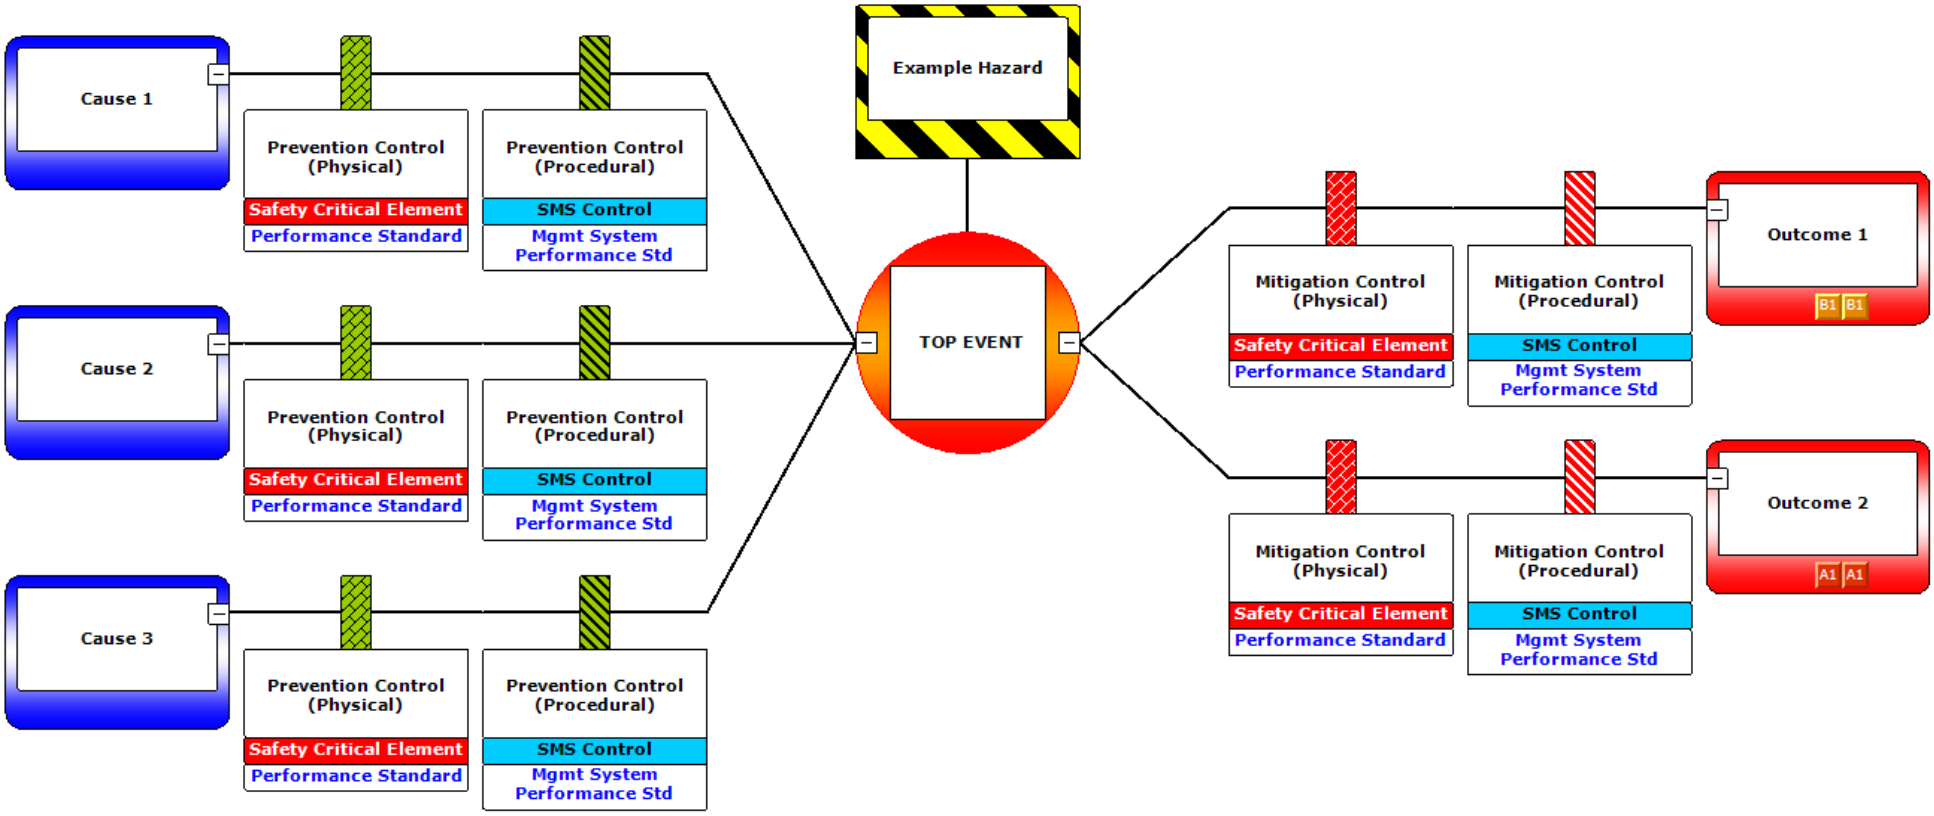

Figure 2-7: Example of bowtie diagram structure

2.7.4 Major Environment Event Register

A MEE Register is prepared for each production facility after completing the bowtie diagrams. The purpose of the MEE Register is to record the MEE identification process, groupings, bowtie diagrams and datasheets in a consolidated format. Datasheets are prepared for each MEE, which summarise the hazard description, hazard management, emergency response, ALARP summary and a list of critical barriers identified on the bowties (known as safety and environment critical elements (SCEs)).

Potential common causes that contribute to MAEs/MEEs, or that can result in failure or degradation of the controls in place to protect against MAEs/MEEs, include some generic mechanisms of SCE failure and generic human error. These are represented in bowties applicable to multiple MEEs and identified in the MEEs applicable to this EP.

2.7.5 Safety and Environment Critical Elements and Technical Performance Standards

Woodside identifies and manages SCEs technical and management system performance standards in accordance with Process Safety Management Procedures, Risk Management Procedures and Change Management Procedures (further described in the implementation strategy in **Section 7**). SCEs are identified for MAEs and MEEs. An SCE is a hardware control, the failure of which could cause or contribute substantially to, or the purpose of which is to prevent or limit the effect of a MAE, MEE or Process Safety Event. In addition, Woodside defines a Safety and Environment Critical Component (SCC) as an item of equipment or structure forming part of a hardware SCE that supports the SCE in achieving the safety function.

Once an SCE is identified as an MEE barrier for the operated facility, technical performance requirements are developed for the facility SCE in accordance with the Global SCE Performance Standards and process described in the SCE Management Procedure and form the SCE Facility Performance Standard. Each SCE Performance Standard represents a statement of the performance required of an SCE (e.g., functionality, availability, reliability, survivability). SCE Performance Standard requirements are used to establish agreed assurance tasks for each SCE, support the management of operations within acceptable safety and/or environment risk levels, and ensure continuous management of risk to ALARP. An assurance task is an activity carried out by the operator to confirm that the SCE meets, or will meet, its SCE Performance Standard. Examples of assurance tasks include inspection routines, maintenance activities, test routines, instrumentation calibration, and reliability monitoring.

SCE Facility Performance Standards do not always align directly with EPSs. They are used in conjunction with the WMS to identify and treat potential step-outs from expected controls performance or integrity envelopes and ensure SCE performance can be optimised. Woodside's HSE Event Reporting Guideline describes the process for identifying 'Failure to meet Facility Performance Standard', which is when the SCE does not meet the goal as stated in the relevant Performance Standard. (see **Section 7.2.6**). Situations where SCEs fail to meet Facility Performance Standards represent a potential increase in risk that, if not addressed immediately, have the potential to result in a process safety event, or worsen the consequences of one. Recording SCE Failure to Meet Performance Standard Events into the Event Reporting Database is important to highlight risk, investigate causes, ensure risks are managed and meet potentially applicable external reporting requirements. For applicable SCEs, 'Failure to meet Facility Performance Standard' represent scenarios that may fail to achieve an EPS presented in this EP.

The results of the MEE classification and analysis for Angel operations are presented in **Section 6.7.2** of this EP. More detail on the SCE and Performance Standards process, and the interrelationships to other parts of the SCE Management Procedures, is described in **Section 7.2.6**.

2.7.6 Safety-critical Management System Barriers

For each MEE, Safety-critical Management System specific measures are also identified. These are management system components (generally WMS processes) that are key barriers to, or measures for, managing MEEs.

2.8 Impact and Risk Evaluation

Environmental impacts and risks cover a wider range of issues, differing species, persistence, reversibility, resilience, cumulative effects, and variability in severity than safety risks. Determining the degree of environmental risk, and the corresponding threshold for whether a risk/impact has been reduced to ALARP and is acceptable, is evaluated to a level appropriate to the nature and scale of each impact or risk. Evaluation includes considering the:

- decision type
- principles of ESD – as defined under the EPBC Act
- internal context – ensuring the proposed controls and risk level are consistent with Woodside policies, procedures and standards (**Section 7** and **Appendix A**)
- external context – the environment consequence (**Section 6**) and stakeholder acceptability (**Section 5**)
- other requirements – ensuring the proposed controls and risk level are consistent with national and international standards, laws and policies.

In accordance with regulations 34(a), 34(b), 34(c) and 21(5)(b), Woodside applies the process described in the subsections below to demonstrate ALARP and acceptability for environmental impacts and risks, appropriate to the nature and scale of each impact or risk.

2.8.1 Demonstration of As Low As Reasonably Practicable

The descriptions in **Table 2-5** articulate how Woodside demonstrates that different risks, impacts and Decision Types identified within the EP are ALARP.

Table 2-5: Summary of Woodside's criteria for demonstrating 'as low as reasonably practicable.

Risk	Impact	Decision Type
Low and Moderate (C, D, E or F level consequence)	***Negligible, Slight, or Minor (D, E or F)***	***A***
Woodside demonstrates these risks, impacts and Decision Types are reduced to ALARP if: • identified controls meet legislative requirements, industry codes and standards, applicable company requirements and industry guidelines, or • further effort towards impact/risk reduction (beyond using opportunistic measures) is not reasonably practicable without sacrifices that are grossly disproportionate to the benefit gained.		
High, Very High or Severe (A or B level consequence)	***Moderate and above (C, B or A)***	***B and C***
Woodside demonstrates these higher-order risks, impacts and Decision Types are reduced to ALARP where it can be shown good industry practice and RBA have been employed, if legislative requirements are met, societal concerns are accounted for, and the alternative control measures are grossly disproportionate to the benefit gained.		

2.8.2 Demonstration of Acceptability

The descriptions in **Table 2-6** articulate how Woodside demonstrates how different risks, impacts and decision types identified within the EP are Acceptable.

Table 2-6: Summary of Woodside's criteria for acceptability

Risk	Impact	Decision Type
Low and Moderate	***Negligible, Slight, or Minor (D, E or F)***	***A***
Woodside demonstrates these risks, impacts and Decision Types are 'Broadly Acceptable' if they meet legislative requirements, industry codes and standards, applicable company requirements and industry guidelines. Further effort towards risk reduction (beyond using opportunistic measures) is not reasonably practicable without sacrifices that are grossly disproportionate to the benefit gained.		
High, Very High or Severe	***Moderate and above (C, B or A)***	***B and C***
Woodside demonstrates these higher order Risks, Impacts and Decision Types are 'Acceptable if ALARP' if it can be demonstrated using good industry practice and risk based analysis (RBA), if legislative requirements are met and societal concerns are accounted for and the alternative control measures are grossly disproportionate to the benefit gained. In undertaking this process for Moderate and High risks, Woodside evaluates: • the Principles of ESD as defined under the EPBC Act • the internal context – the proposed controls and consequence/risk level are consistent with Woodside policies, procedures and standards • the external context – consideration of the environment consequence (**Section 6**) and stakeholder acceptability (**Section 5**) are considered • other requirements – the proposed controls and consequence/risk level are consistent with national and international industry standards, laws and policies ad consideration of applicable plans for management and conservation advices, conventions and significant impact guidelines (e.g., MNES). Additionally, Very High and Severe risks require 'Escalated Investigation' and mitigation. If after further investigation the risk remains in the Very High or Severe category, the risk requires appropriate business engagement with increasing involvement of senior management in accordance with Woodside's Risk Management Procedure to accept the risk. This includes due consideration of regulatory requirements.		

2.9 Recovery Plan and Threat Abatement Plan Assessment

To support the demonstration of acceptability, a separate assessment is undertaken to demonstrate that the EP is not inconsistent with any relevant recovery plans or threat abatement plans (refer **Section 6.9**). The steps in this process are:

- Identify relevant listed threatened species and ecological communities (**Section 4.6**).
- Identify relevant recovery plans and threat abatement plans (**Section 6.9**).
- List all objectives and (where relevant) the action areas of these plans and assess whether these objectives/action areas apply to government, the Titleholder, and the Petroleum Activities Program (**Section 6.9**).
- For those objectives/action areas applicable to the Petroleum Activities Program, identify the relevant actions of each plan, and evaluate whether impacts and risks resulting from the activity are clearly not inconsistent with that action (**Section 6.9**).

2.10 Environmental Performance Outcomes, Environmental Performance Standards and Measurement Criteria

EPOs, EPSs and MC are defined to address the potential environmental impacts and risks. These are explored in **Section 6**.

2.11 Implement, Monitor, Review and Reporting

An implementation strategy for the Petroleum Activities Program describes the specific measures and arrangements to be implemented for the duration of the program. The strategy is based on the principles of AS/NZS ISO 14001 Environmental Management Systems, and demonstrates:

- control measures are effective in reducing the environmental impacts and risks of the Petroleum Activities Program to ALARP and Acceptable levels
- EPOs and EPSs set out in the EP are met through monitoring, recording, auditing, managing non-conformance, and reviewing
- all environmental impacts and risks of the Petroleum Activities Program are periodically reviewed in accordance with Woodside's risk management procedures
- roles and responsibilities are clearly defined, and personnel are competent and appropriately trained to implement the requirements set out in this EP, including in emergencies or potential emergencies
- arrangements are in place for oil pollution emergencies, to respond to and monitor impacts
- environmental reporting requirements are met, including 'reportable incidents'
- appropriate consultation is undertaken throughout the activity.

The implementation strategy is presented in **Section 7**.

2.12 Consultation

Woodside consults relevant persons in the course of preparing an EP in accordance with regulation 25 of the Environment Regulations. Woodside's consultation methodology is presented in **Section 5**. Woodside's consultation record is at **Appendix F**.

3 DESCRIPTION OF THE ACTIVITY

3.1 Overview

This section has been prepared in accordance with regulation 21(1) of the Environment Regulations and describes the activities to be undertaken as part of the Petroleum Activities Program under this EP. It includes the location of the activity, general details of the Angel facility and associated infrastructure, the operational details of the activity, and additional information relevant to consideration of environmental risks and impacts.

The Angel facility currently produces gas and condensate from the Lambert Deep field via one well (LDA-01) and associated subsea infrastructure. This EP includes the ongoing operation of the Angel facility (**Section 3.1.1**) and drilling and tie-back activities associated with a new well (LDA-02) in the Lambert West field (**Section 3.1.2**). The LDA-02 well is to be the final well tied back to the Angel facility. An overview of the Petroleum Activities Program, as defined in **Section 1.1** is provided in **Table 3-1**.

3.1.1 Angel Operations Overview

The Angel facility includes a riser platform consisting of a single processing train, which processes the production fluids via cooling, separation and dehydration. The condensate and gas are then comingled for export, and transported along an export pipeline into the first trunkline (1TL) to the Karratha Gas Plant (KGP) for processing (the operation of 1TL is beyond the scope of this EP).

A single well (LDA-01) produces from the Lambert Deep field via the Lambert Deep two-slot production manifold and 10-inch flowline.

There are a further three production wells tied back to the Angel facility via rigid flowlines that are no longer producing from the Angel reservoir due to high water content. These have been shut-in and are scheduled to be permanently plugged for abandonment. Ongoing preservation of the non-producing Angel infrastructure is covered under this EP. Following plug and abandonment (P&A) the associated subsea infrastructure is planned to be decommissioned. P&A and decommissioning activities will be covered under a separate EP. These activities are outlined in **Table 3-1.**

3.1.2 Lambert West Tie-back Overview

The Lambert West tie-back consists of a subsea tie-back to the Angel facility via the existing Lambert Deep subsea infrastructure. The Lambert West Field lies in 130 m water depth and is located approximately 15 km north-west of the Angel Platform (80 m water depth).

The Lambert West tie-back consists of one well, LDA-02, drilled and connected to the Lambert Deep (LD) two-slot production manifold using a flexible jumper, installation of a controls subsea distribution unit and disconnection of the LDA01 electrical and hydraulic flying leads from the Lambert Deep Umbilical Termination Assembly (UTA) and reconnecting them to the subsea distribution unit.

The well will be drilled and completed using a mobile offshore drilling unit (MODU). Typically, two or three support vessels will support the MODU during drilling activities (**Section 3.5**), with at least one vessel in the vicinity to complete standby duties, if required. Supply vessels from Dampier Port will frequent the MODU at regular intervals throughout drilling operations, as required.

Installation of the subsea infrastructure (**Section 3.5.3**) will be undertaken using an installation vessel. Another installation vessel, similar to vessels used for IMMR, may be used to install the tubing head spool and Xmas tree and for cold commissioning the wells and during Start-up (if required). Support vessels associated with subsea installation activities may transit between the PAA (see **Section 3.5**) and port, however transit activities are not included in the scope of this EP.

The scope for this EP covers the tie-back of the Lambert West field, including drilling, completion, and subsea installation (including minor changes to existing infrastructure) along with pre-commissioning, cold commissioning and start-up. These activities are outlined in **Table 3-1**.

Table 3-1: Petroleum Activities Program overview

Item	Description
Production Licences	WA-16-L and WA-3-L pipeline licenses WA-14-PL and WA-31-PL.
Pipeline Licences	WA-14-PLand WA-31-PL
Platform Location	North West Shelf
Water depth	70 m to 130 m
Key components of platform facilities	Angel fixed riser platform, processing equipment and utilities
Number of wells	• two production wells (one new) • three shut-in production wells • four abandoned with well heads • exploration temporarily abandoned wells
Subsea infrastructure	**Existing:** • Lambert Deep manifold • LDA01 tree and flexible jumper • Lambert Deep umbilical, UTA and flying leads • Angel platform • Angel export pipeline • Angel umbilicals and flowlines (shut in) **Lambert West Proposed:** • one subsea Xmas tree and wellhead (LDA-02) • an 8” ID jumper approximately 300 to 500 m long between the Lambert Deep manifold and the LDA02 well • two sets of flying leads • one subsea distribution unit
MODU	Moored MODU or hybrid moored/DP MODU
Vessels	• Angel Operations: – platform support vessels, subsea support vessels, heavy lift vessels and others appropriate to nature of petroleum activities • Lambert West Tie-back: – installation vessel for installing the subsea infrastructure – IMMR vessel for Xmas tree installation, isolation testing or contingent activities – support vessels including barge(s), heavy lift vessel(s) (HLVs), multi-service construction vessel(s), anchor handling vessel(s) (AHVs) and general supply/support vessels
Key activities	• Angel Operations: – routine production – routine IMMR of the platform and associated subsea infrastructure – well clean-up and commissioning – non-routine and unplanned activities and incidents associated with the above • Lambert West Tie-back: – subsea infrastructure stabilisation – mooring installation for the MODU – development drilling and completions activities via MODU – well intervention, workovers and well kill activities from MODU – site surveys – installation of flowline, flying leads, subsea tree, subsea distribution unit

Item	Description
	– tie-in to existing subsea infrastructure, including disconnecting the LDA-01 well from the Lambert Deep manifold and reconnecting it to the subsea distribution unit – installation of Xmas tree – pre-commissioning of the new subsea infrastructure – cold commissioning of the well and Xmas tree – start-up to the Angel facility including unload of well to host and performance testing – contingent intervention, workover, or re-drill for the existing well (LDA-01) and new well (LDA-02)

3.2 Location

The Angel facility is located in Commonwealth waters on the NWS of Western Australia (WA) and consists of subsea hydrocarbon gathering systems, a riser platform and an export pipeline. The Angel platform is located in Production Licence WA-3-L. Associated subsea production infrastructure is located in Production Licences WA-3-L and WA-16-L, and the Lambert Deep flowline in Pipeline Licence WA-31-PL. The export pipeline, connecting the Angel platform to the North Rankin Complex (NRC), is located in Pipeline Licence WA-14-PL. The LDA-2 well proposed for Lambert West tie-back will be located in Production Licence WA-16-L.

The Angel platform is located approximately 49 km east of the NRC and 123 km north-west of the KGP (**Figure 3-1**). Gas and condensate produced from the Angel facility are exported via the 49 km long export 30-inch pipeline, which ties into the NRC 1TL.

The Angel facility is marked on nautical maps surrounded by a 500 m petroleum safety zone (PSZ). The Angel export pipeline and Lambert Deep flowline are also marked on nautical charts. The coordinates and petroleum titles of the Angel facility infrastructure are presented in **Table 3-2**.

Table 3-2: Approximate location details for the Petroleum Activities Program, including all relevant infrastructure

Structure	Water depth (approx. m LAT)	Latitude	Longitude	Title
Production wells				
LDA-01 well	130	19° 26' 07.220" S	116° 28' 51.314" E	WA-16-L

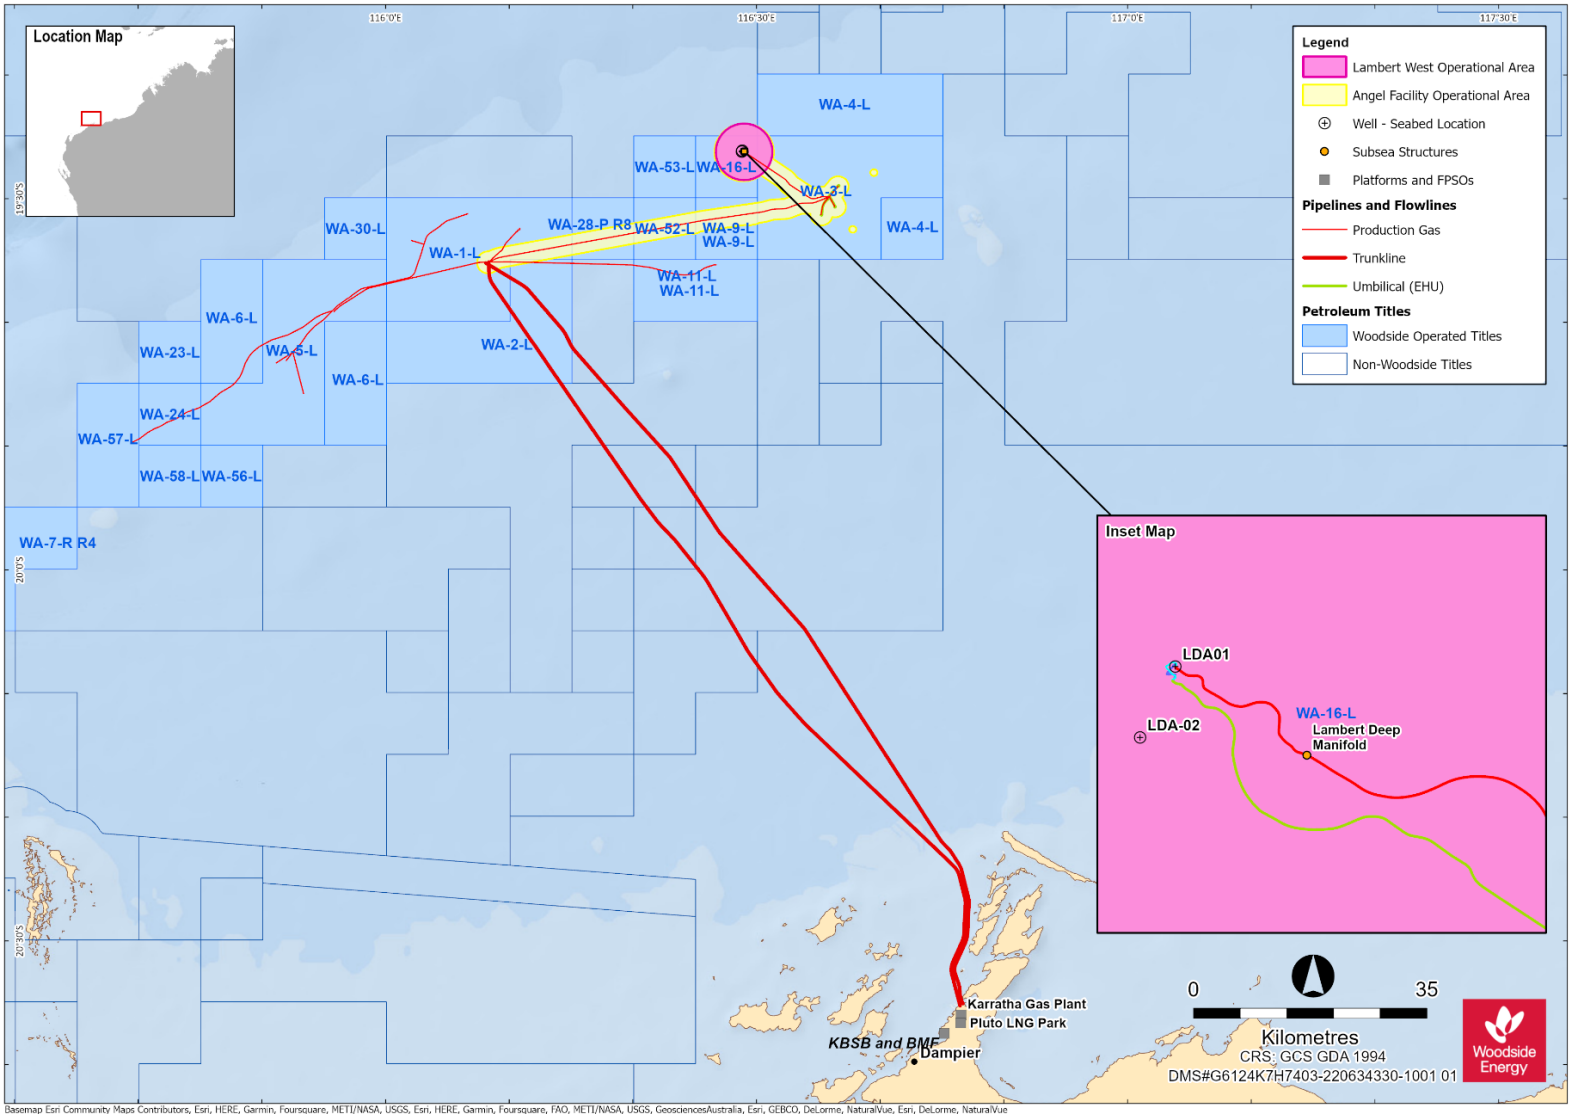

Figure 3-1: Location of the Petroleum Activities Program

3.2.1 Petroleum Activities Area

The spatial boundary of the Petroleum Activities Program (**Figure 3-1)** has been described and assessed using two Operational Areas, the Angel Operational Area and the Lambert West Operational Area.

The Operational Areas are collectively referred to as the Petroleum Activity Area (PAA) in this EP, with specific Operational Areas referred to where relevant.

Vessel-related activities within the PAA will comply with this EP. Vessels transiting to the PAA are outside the scope of this EP and are covered by applicable maritime regulations and other requirements during that time.

3.2.1.1.1 Angel Operational Area

The Angel Operational Area includes:

- the riser platform and the area within a 500 m Petroleum Safety Zone (PSZ) around the Angel facility
- the export pipeline from Angel (WA-14-PL) up to the connection to the barred tee (WA-1-PL) on the NRC 1TL tie-in assembly and an area encompassing 1500 m either side of the WA-14-PL pipeline infrastructure
- Angel subsea hydrocarbon gathering system infrastructure, including Angel production (AP) wells AP-2, AP-3 and AP-4, flowlines, umbilicals and an area within 1500 m around the subsea infrastructure
- Lambert Deep and Lambert West subsea hydrocarbon gathering system infrastructure including wells LDA-01 and LDA-02, flowline (Pipeline Licence WA-31-PL), umbilicals and an area within 1500 m around the subsea infrastructure
- ETA and AW wells and an area of 500 m around each wellhead.

The Angel Operational Area will also include the Lambert West subsea hydrocarbon gathering system infrastructure once tie-back is complete, including the LDA-02 well and an area within 1500 m around the subsea infrastructure.

3.2.1.1.2 Lambert West Operational Area

The Lambert West Operational Area has a radius of 4500 m centred on the Lambert Deep Manifold, to allow for MODU mooring operations, drilling of the LDA-02 well, installation of subsea infrastructure (including disconnection of the LDA-01 well EFLs/HFLs and reconnection to the subsea distribution unit), pre-commissioning and related petroleum activities.

The Lambert West Operational Area allows for MODU mooring operations, including the possible installation of pre-laid moorings and vessel-related petroleum activities. It also includes a 500 m Safety Exclusion Zone (SEZ) around the MODU to manage vessel movements which will be under the control of the MODU Person in Charge. The primary installation vessel, operating within the Lambert West Operational Area, will also be surrounded by a 500 m SEZ when on-location, which will be under the control of the vessel master.

3.3 Timing

The Angel facility commenced production in 2008. AP wells were in production up to late 2020 when they were shut-in. Once production from these wells ceased, Angel topsides processing equipment and subsea infrastructure were placed into preservation mode. Angel topsides processing equipment were recommissioned for the Lambert Deep well (LDA-01) tie-back in 2022.

Decommissioning planning for Angel is underway to meet the requirements of Section 572 and Section 270 of the OPGGS Act. Further information on decommissioning is outlined in detail in **Section 7.3.4** and will be subject to future separate EPs:

- Plug and abandonment activities are currently planned to commence by 1 December 2025 subject to approvals and vessel availability. This work will be covered under the North West Shelf Phase 1 Plug and Abandonment EP, which is due to be submitted to NOPSEMA for assessment in January 2025.
- Subsea infrastructure removal activities are currently planned to commence by 1 December 2026 subject to approvals and vessel availability, this work will be covered under the Angel Flowline and Umbilical Removal EP, due to be submitted to NOPSEMA for assessment in March 2025. Angel Operations.

The Angel facility is designed to operate 24 hours per day, 365 days per year. This EP is intended to remain in force in accordance with Regulation 36 of the Environment Regulations.

3.3.1 Lambert West Tie-back

Lambert West tie-back activities are planned to commence in Q3 2024 with the drilling of the Lambert West (LDA-02) well and related subsea installation is planned to commence from Q4 2024 (**Table 3-3**). Lambert Deep and Lambert West reservoir end of field life (EoFL) is anticipated in 2027 subject to reservoir performance.

Drilling operations for the LDA-02 production well are expected to take about 50 to 60 days to complete, including mobilisation, demobilisation and contingency. Installation of subsea infrastructure and pre-commissioning is anticipated to commence following drilling and is expected to have a cumulative duration of about four weeks (including mobilisation, demobilisation and contingency). Drilling and installation of subsea infrastructure may be performed over multiple campaigns.

When tie-back activities are underway, activities are 24 hours per day, seven days per week. There are no planned concurrent drilling activities under the EP. Simultaneous Operations (SIMOPS) activities with subsea installation may occur. Timing and duration of all activities is subject to change due to project schedule requirements, MODU/vessel availability, unforeseen circumstances and weather.

The EP has risk-assessed activities associated with the drilling and tie-back of the LDA-02 well including if they were to occur at any time during the year. This includes drilling activities, subsea infrastructure installation, pre-commissioning activities and intervention, workover, or re-drilling activities. This provides operational flexibility for requirements and schedule changes and vessel/MODU availability. The timeframes are therefore subject to change within the defined calendar years and, as no particular windows have been nominated for avoidance based on environmental and/or stakeholder sensitivities, changes to the above will not be interpreted as ‘new stages’ against regulation 39(1).

Table 3-3: Summary of timing for tie-back activities

Activity	Approximate timing (and cumulative duration in the field)
Installation and removal of anchors for MODU	2024 (7 to 10 days per activity)
Drilling and completions	2024 (50 to 60 days) 2025 (contingency)
Subsea installation and pre-commissioning/cold commissioning	2024 (~4 weeks) 2025 (contingency)
Well start-up and performance testing	2024 (~3 weeks) 2025 (contingency)

3.4 Angel Operations

3.4.1 Overview

This section provides a description of the Angel facility and the activities that are undertaken during operations.

The Angel facility includes a single processing train on the riser platform, which processes the production fluids via cooling, separation and dehydration. The condensate and gas are then comingled for export and transported along an export pipeline to the NRC.

IMMR activities, and the ongoing preservation of non-producing Angel infrastructure are also covered under this EP.

3.4.2 Angel Facility Layout and Description

This section provides an overview of the Angel facility, including existing and proposed infrastructure, as relevant to consideration of the environmental risks and impacts of the Petroleum Activities Program.

3.4.2.1 Angel Topsides

The Angel platform topside comprises of two decks. The main deck is plated and the cellar deck north of the blast wall is grated. Two grated mezzanine decks are provided in the process area north of the blast wall, and a single plated mezzanine deck is provided south of the blast wall. A pedestal crane is located on the east side of the deck and a boom-rest on the west. A subcellar deck is provided under the northern end of the cellar deck to accommodate the Emergency Shutdown valves and drains tanks. The Angel export riser is located at the base of the riser platform. A flare boom projects northward from the north face of the topside. The helideck is above the south-west corner.

Although the riser platform is not normally crewed (NNC), accommodation facilities are installed on the southern end of the topside for personnel required for campaign maintenance, commissioning, and shutdown activities. **Figure 3-2** shows the layout of the topsides on the Angel facility.

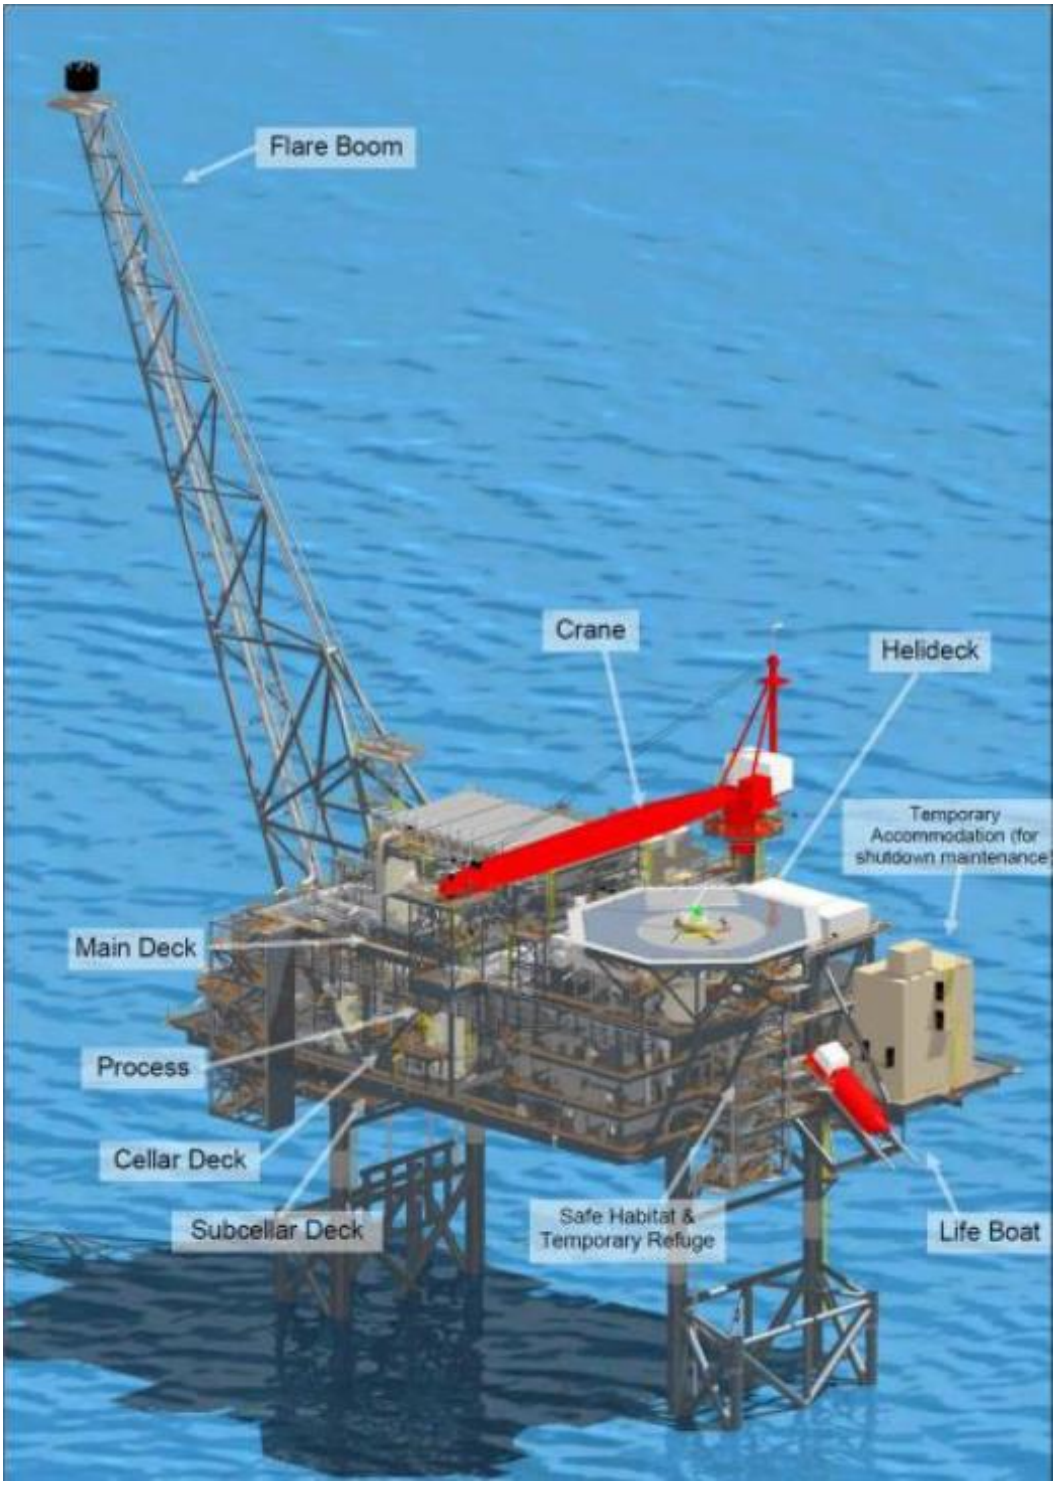

Figure 3-2: Angel facility platform layout

3.4.3 Wells and Reservoirs

The Angel and Lambert Deep wells are managed in accordance with the North Rankin Hub Well Operations Management Plan (WOMP), which provides for current and future wells tied back to the Angel platform, and the associated temporary abandonment of the Angel-3 exploration and appraisal well. The WOMP describes control measures in place to ensure the risks to the well integrity are reduced to ALARP, including during periods of non-operation, before permanent abandonment.

A new well construction WOMP will cover the drilling and management of the new Lambert West well (LDA-02) tie-back.

3.4.3.1 Lambert Deep

LDA-01 is a dual zone open hole gravel pack well that accesses the Lambert Deep reservoir. The well is designed to limit production and isolate unwanted fluids (water) through water shut-off capability. The reservoir upper zone initially flows comingled with the reservoir lower zone. Water shut-off capability will be enabled to isolate the lower zone from the above reservoir intervals once water break through occurs.

3.4.3.2 Lambert West

LDA-02 is a single zone open hole gravel pack well that accesses the Lambert West reservoir. The well is designed to manage gas production and unwanted fluids (water). The various reservoir will be produced as comingled flow.

3.4.3.3 Angel

There are three subsea satellite variant slick big bore wells that access the Angel reservoir currently tied back to the riser platform. Surface controlled sub-surface safety valves (SCSSV) are installed on each well as the primary down hole safety system. The three wells are currently shut in and not producing due to high water content.

Planning for permanent plug and abandonment and decommissioning of the Angel wells is underway and will be covered under a separate EP. See **Section 7.3** for decommissioning planning activities.

3.4.3.4 Exploration Wells with Wellheads

There are ETA and AW wells with wellheads identified in **Table 3-2** that are not tied back to the Angel facility and have no associated infrastructure (i.e., no Xmas tree). The ETA well is managed under an accepted WOMP. Wellheads are being inspected in accordance with WOMPs based on the assessed risk for each well.

In line with the WOMP commitment relating to the ETA well, Woodside continues to undertake detailed subsurface/technical assessments. This is to ensure that the well is abandoned to the relevant regulatory requirements, including permanent downhole barriers. WOMPs to enable final NOPSEMA assessment and subsequent abandonment applications are being continually progressed, with some wells having been accepted as permanently abandoned and have been removed from their respective WOMPs (AW wells).

Decommissioning of the wellheads will progress once the wells have been accepted as permanently abandoned. However, planning for ETA and AW wellhead decommissioning is premised upon the plan for removal as the base case, with consideration of the principles of ALARP and acceptability. Once the wells have been accepted as permanently abandoned and the decommissioning activity is defined, an EP will be submitted for the wellhead decommissioning activity. Decommissioning planning is further described in **Section 7.3.3**). These wells with wellheads continue to be maintained until decommissioned.

3.4.4 Subsea Infrastructure Operations

3.4.4.1 Existing Subsea Infrastructure

The subsea system for both Angel and Lambert Deep is typically controlled from NRC via an integrated power and control cable through:

- umbilicals, which provide hydraulic and electric power, communications and chemical supplies between the platform and Angel and Lambert Deep subsea components through a number of cables and tubes; umbilicals run between the platform and UTA

- well control for the LDA-01 well via a dedicated umbilical from Angel platform, bypassing Lambert Deep manifold and connecting to a subsea distribution unit (SDU) near LDA-01 enhanced horizontal Xmas tree; from the UTA, electrical and hydraulic flying leads carry controls directly to LDA-01 Xmas tree
- for the LDA-01 well, power and communication routers (PCR-X and PCR-D), hydraulic control router (HCR), which are sealed and pressure compensated units linking subsea and surface controls
- valves, which control subsea operations and processes
- chokes, which control pressure and flow rates of hydrocarbons
- a number of subsea valves that may be overridden manually from either a remote operated vehicle (ROV) or by divers on both the Lambert Deep and Angel wells
- a 10” jumper that runs between the LDA-01 Xmas tree and Lambert Deep manifold (~0.34 km), and a 10” jumper (~14.5 km) between Lambert Deep manifold to Angel subcellar deck via existing spare 30” J-tube (no SSIV)
- the 14” diameter corrosion-resistant alloy (CRA) lined, carbon steel rigid flowlines that are 2.04 km (AP2), 1.53 km (AP3) and 2.81 km (AP4) in length that run between the Angel Xmas trees to Angel subcellar deck via individual 14” risers (no SSIVs)
- all flowlines connecting back to Angel Platform being connected to riser emergency shut down valves (RESDVs).

The layout of the Angel and Lambert Deep subsea infrastructure is shown in **Figure 3-3**.

3.4.4.2 Lambert West Subsea Infrastructure

The Lambert West tie-back is primarily supported by the Lambert Deep subsea infrastructure with the following additions:

- From the existing Lambert Deep UTA, EFLs and HFLS will carry controls to the new SDU, then split out via EFLs and HFLs through to both LDA-01 and LDA-02 wells.
- A new 8 to 10” flexible jumper will run between LDA-02 Xmas tree and the existing Lambert Deep manifold (~500 m).
- The layout of the additional Lambert West subsea infrastructure is shown in **Figure 3-3**.

3.4.4.3 Angel Topsides Substructure

The jacket is supported on four pile groups. Each group comprises eight primary and eight insert piles which were drilled and grouted over two stages. The weight of the Angel jacket and piles are 7685 tonnes and 4766 tonnes respectively.

3.4.4.4 Angel Subsea System (Non-producing)

The three Angel wells have subsea control modules (SCM), which are sealed and pressure compensated electro-hydraulic units (typically found on Xmas trees) and link the surface and subsea controls.

Hydrocarbons in the Angel subsea system are depressurised to just above seabed ambient pressure and monitored accordingly. The Angel subsea flowline system commenced operation in 2008 and has a design life of 20 years. The subsea system has been inspected regularly, based on the risk-based inspection (RBI) procedure developed specifically for the Angel facility. The flowlines consist of a 40 mm thick concrete weight coating, protecting and weighting the pipeline down to prevent movement on the seabed. Additional external corrosion protection in the form of anodes placed at regular intervals along each of the flowlines, ensures the flowlines continue to be protected

from corrosion. An in-water inspection undertaken in 2019 of the corrosion protection systems demonstrates that the three flowlines have sufficient integrity forecast until between 2030–2119:

- AP2 flowline – all visible anodes appeared secure with slight depletion, and the field gradient report estimated that the remaining anode lifetimes are 60 years.
- AP3 flowline – all visible anodes appeared secure with slight depletion, and the field gradient report estimated that the remaining anode lifetimes are between 11 years and more than 100 years.
- AP4 flowline – all visible anodes appeared secure with slight depletion and the field gradient report estimated that the remaining anode lifetimes are between 19 years and more than 100 years.

Estimated volumes of hydrocarbons remaining in the AP2, AP3 and AP4 flowlines are presented in **Table 3-4**. Pressure monitoring of the flowlines continues and if the flowlines repressurise via passing subsea valves, the option exists to blowdown the flowlines to seabed ambient pressure again via the flare. Spectacle blinds have been swung closed on the respective RESDVs to provide positive isolation from process equipment and remain in the closed position. IMMR process activities associated with subsea systems are maintained using a RBI methodology and associated plans until they are decommissioned (**Section 3.4.15.1**).

Table 3-4: Estimated hydrocarbon volumes remaining in the AP2, AP3 and AP4 flowlines

Estimated hydrocarbon volumes remaining in Angel flowlines			
Flowlines	AP2	AP3	AP4
Liquid hydrocarbon at seabed Ambient pressure (Am^3)	12	8	15
Gas hydrocarbon at surface pressure (Sm^3)	1520	1230	2220

Section 3.4.15.8 describes subsea flushing operations.

Planning for decommissioning the Angel subsea infrastructure is described in **Section 7.3**.

3.4.4.5 Angel Export Pipeline

Dehydrated export gas and condensate is metered at the outlet of the production train on the riser platform, prior to recombination and subsequent export via the export pipeline. The pipeline route commences at the flange connecting the riser to the riser platform and runs 49 km westwards to the NRC facility. The pipeline ties in to 1TL at the downstream flange of the tie-in assembly to 1TL.

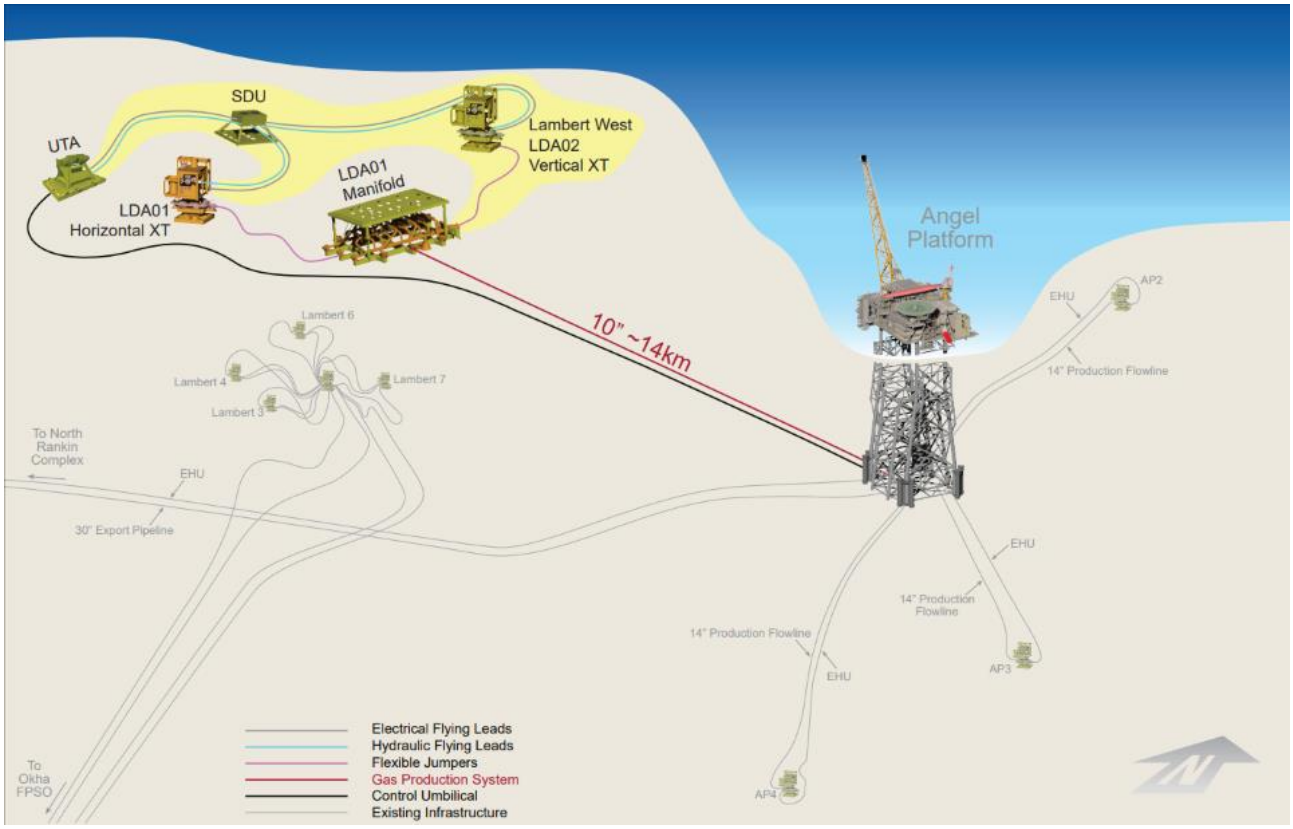

Figure 3-3: Angel facility subsea system layout

3.4.5 Operational Details

3.4.5.1 Staffing and Modes of Operations

The Angel facility is designed to operate without on-platform operator intervention, as a NNC installation. The permanently installed accommodation on the Angel facility can cater for up to 24 personnel on board (POB). Activities which require POB may include:

- projects
- campaign maintenance
- unplanned corrective (breakdown) maintenance
- inspections/audits
- planned facility shutdowns
- well start-up/commissioning.

During routine operations, planned maintenance visits are typically undertaken five times a year, each lasting nominally 14 days, with teams of up to 24 POB. Unplanned maintenance generally requires teams of up to 10, and shutdown maintenance teams including Lambert West initial commissioning activities of up to 24 POB.

The modes Operations fall under are any one of:

- production remote operations
- major projects
- maintenance, including subsea IMMR and removal activities
- well maintenance

- well start-up and commissioning
- suspension
- flowline flushing prior to well plug and abandonment.

When the Angel facility is staffed, primary control is retained by NRC, with personnel on Angel communicating with NRC via the radio communication links. Operational control of equipment is handed to 'local control' on the Angel facility on an as-required basis.

Modes of operation are described below. Production, maintenance and project activities may occur concurrently.

3.4.5.2 Production Remote Operations

The Angel facility is a NNC facility and, therefore, is normally operated, monitored, controlled, restarted and diagnosed from the riser platform or remotely via fibre optic cable from NRC. In the event that NRC personnel are demobilised (e.g., for a cyclone), Angel can be remotely operated from KGP or Perth. The Process Control System (PCS) for the Angel facility provides the monitoring and control functions of:

- basic monitoring of all key performance indicators
- adjustment of devices on the Angel facility, such as control valves, pumps and variable speed drives, to maintain process variables within design limits
- alarm signals to the Human–Machine Interface located on the NRC
- automatically managing duty/standby and lead/lag equipment.

3.4.5.3 Major Projects

Major projects involve refurbishment, modification or major maintenance on the Angel facility. Potential environmental impacts related to projects are managed through the process outlined in **Section 7.2.4.3**. During execution of major projects, such as commissioning of Lambert West, the Angel platform is permanently staffed until the Angel facility is ready to be returned back to remote operations.

3.4.5.4 Maintenance, including Subsea Inspection, Monitoring, Maintenance and Repair Activities

IMMR including those undertaken subsea, are undertaken to maintain production within the platform and subsea infrastructure design constraints. Maintenance teams routinely visit the Angel facility for:

- a nominal 14-day duration with typically five campaigns per year, with teams of up to 24 POB
- unplanned corrective (breakdown) maintenance and restart, executed by a smaller team as required
- shutdown maintenance and restart conducted by a team of up to 24 personnel.

The specific team sizes deployed to the Angel facility are based on planned/unplanned maintenance requirements, helicopter carrying capacity, availability of accommodation and safety considerations.

3.4.5.5 Suspension

Suspension may be implemented for reservoir management purposes. In suspension mode, the Angel facility's process systems are maintained at a positive pressure, flaring is maintained at purge rates and the PW overboard isolated. Implementation for suspension requires minimal intervention,

as it is predominantly achieved through the existing control systems and valves. Implementation activities are summarised as follows:

- shut in the well and open the choke intermittently to ensure the HP and LP flare system remains operational. Close the RESDV on the non-flowing flowline
- minimise topsides liquid inventories, as required
- segregate systems through existing valves
- place non-critical equipment (e.g., fans, coolers, motors) offline
- keep control, Safety Instrumented System and fire and gas live and reconfigured to fit the system requirements.

Facility operations during suspension (post implementation) are as follows:

- facility operations and associated activities as described in this EP are retained
- manual operation of the well production system ensures the HP and LP flares remain operational
- life support, lifesaving equipment, temporary refuge and Safety Instrumented System remain operational and available.

3.4.6 Process Description

3.4.6.1 Production Process

The Angel facility receives well fluids (gas, condensate and associated PW) from the production wells for topside processing via cooling, separation and dehydration prior to export. There is no gas compression.

The Angel facility has a single processing train with an operating capacity of 21.5 kt dry gas per day (kt/day) plus associated condensate.

3.4.7 Flare Systems

The riser platform has two flare systems, the HP flare and the LP flare. The main purpose of the flare systems is to safely discharge gas streams during emergency depressurisation. However, there are also a number of process streams which continuously pass gas to the flare, such as gas flashed from the PW, and stripping gas used in the glycol regeneration process. Other streams intermittently flow to the flare, such as during maintenance activities and when vessels are depressurised and purged.

In line with the Angel facility NNC design philosophy, flare gas recovery is not provided and the system is designed for minimum maintenance. There is no planned venting of hydrocarbons from the Angel facility during normal operations. The flare is monitored via CCTV from NRC CCR. As a contingency, the flare can be manually ignited (in the event the pilots are extinguished) to minimise cold venting.

The amount of gas that may be flared on an annual basis is dependent on continuous and intermittent process sources, planned activities requiring flaring, and unplanned process upsets.

3.4.7.1 High Pressure Flare System

The HP flare system collects vented hydrocarbons from process and utility systems, with design capacity of 2000 kPa or greater. The main HP flare header is routed to the HP flare drum, which is designed to separate liquid droplets by gravity. Liquids collected in the drum are pumped to the oily water treatment system. Vapours from the flare drum are disposed at the flare tip (at the top of the 80 m tower).

3.4.7.2 Low Pressure Flare System

The LP flare system collects vented hydrocarbons from process and utility equipment with design pressures of between 345 kPa and 2000 kPa. There are two separate LP headers, one to accommodate low temperature relief streams and the other to accommodate venting at ambient or higher temperatures. The two LP headers are routed to the LP flare drum, which separates out liquid droplets by gravity. Liquids collecting in the drum (usually condensed water from the glycol regeneration system) are recycled back to the process.

3.4.7.3 Flaring – Normal Operations

A relatively small quantity of gas is required to be continuously flared associated with purge and pilot of the flare system and disposal of waste streams which are not recovered to the process. There is no planned venting of hydrocarbons from the Angel facility during normal operations. The continuous flows to the LP flare are:

- flare pilot
- LP flare header and storage tank purges
- glycol regeneration process, including still column overheads and flash drum
- flash gas from PW degasser
- gas used to blanket the MEG storage vessel
- flash gas from scrubber vessels, and the glycol contactor integral suction scrubbers (under on/off level control).

The continuous flows to the HP flare are:

- flare pilot
- HP flare header purges
- leakage past flare header valves such as pressure safety valves (PSVs) and blowdown valves (BDVs).

3.4.7.4 Flaring – Intermittent Process Upsets and Activities

During process upsets, the process control valves on the main process equipment open to relieve excess pressure to the HP flare. The following sources make up intermittent flaring:

Emergency

The topsides equipment and piping are divided into isolatable sections, each with a dedicated BDV. During an emergency shutdown, each section is separately depressurised to the HP flare. Each section contains a fail-open actuated BDV which allows blowdown of the entire riser platform inventory. Approximately 55 t is flared during each emergency shutdown.

Manual Depressurisation

Typically triggered by routine equipment maintenance, planned emergency shutdown testing and/or depressurisation of equipment and piping to remove the equipment from service. Equipment must be depressurised prior to draining, as the closed drains system is not intended for high pressure service.

Subsea Flowline Depressurisation

The well fluid in the subsea flowlines (which carry hydrocarbons from the subsea wells to the riser platform) may on rare occasions need to be routed to the riser platform flare to allow pressure in the flowlines to be reduced, typically for the reasons of:

- production flowline maintenance and critical leak-off testing
- to facilitate remediation in the event of an unplanned hydrate blockage in the subsea flowlines
- to prevent hydrate formation in the flowlines as the fluids cool after the wells are shut-in
- over-pressurisation of flowlines above integrity limit
- suspension of redundant pipelines/flowlines.

3.4.8 Greenhouse Gas Emissions

The main sources of greenhouse gas (GHG) emissions associated with Angel production are shown in **Table 3-5**. GHG sources that are not part of the Angel facility (e.g., from energy supplied by NRC and onshore processing emissions) are included for completeness. In the context of this EP, the emissions are classified as direct and indirect emissions.

Table 3-5: Direct and indirect emissions greenhouse gas sources from the Angel facility and supply chain

Emission type	Emissions source	Location	Jurisdiction	Process
Direct	Angel facility process	Offshore	Commonwealth	GHG emissions from diesel crane (**Section 3.4.12.7**), flares, fugitives and process vents
Indirect	North Rankin Complex	Offshore	Commonwealth	GHG emissions from gas/diesel turbines generating power for the Angel facility, supplied via subsea cable (**Section 3.4.12.3**)
	Support vessels (on charter)	Offshore	Commonwealth	GHG emissions from engines and fugitives on vessels
	Onshore processing*	Onshore	State	GHG emissions from venting reservoir CO2, combustion of gas as fuel, flares and fugitives associated with processing gas to LNG, LPG, condensate and domestic gas
	Transport	Transit	Subject to consumer location	GHG emissions from transport of products to market, including regasification and distribution of LNG in customer markets
	Regassification, distribution and combustion by third-party user	Market	Subject to consumer location	GHG emissions from combustion of products as part of power generation and other energy solutions within the final market

**ISO 19694:2021 defines indirect GHG emissions as GHG emission that is a consequence of an organisation's operations and activities, but that arises from GHG sources that are not owned or controlled by the organization. For the purposes of this EP, the "organisation" is the Angel facility and therefore NRC power generation, onshore processing and support vessel operations are considered indirect emissions sources.*

3.4.9 Produced Water System

PW is brought to the surface from the reservoirs and separated from the hydrocarbon components during the production process, then discharged to the marine environment. PW can consist of produced formation water (a water reservoir below the hydrocarbon formation), condensed water

(water vapour present within gas/condensate which condenses when brought to the surface), or a combination of both. The PW system is designed to process a maximum of 4,800 m^3/day; however, discharge rates are significantly lower. In 2022, PW discharge ranged from 0 to 123 m^3/day from the Lambert Deep reservoir. Overall PW rates are expected to increase as the fields age but due to low volumes PW is currently being batch discharged and this expected to continue until wells cut water. Current reservoir modelling predicts Lambert Deep may cut water in 2025 and Lambert West is not expected to cut water during field life.

During well clean up and commissioning, drilling and completion fluids may be present in the PW stream. Well clean up and commissioning discharges are described in **Section 3.5.4**.

3.4.9.1 Produced Water System Description

The PW stream is primarily made up of water recovered from the condensate stream by the primary water/condensate separators (PWCS) a lesser quantity of water removed downstream by the condensate coalescers. PW flows under level control from the PWCS and the online condensate coalescer to PW degasser. The PW degasser operates at the LP flare header pressure where liberated flash gas (acid gas, hydrocarbon and nitrogen) is disposed of. Any residual condensate is skimmed to the LP flare knock-out/closed drains drum from the PW degasser. PW from the degasser is discharged overboard above the water line at +8m LAT (**Figure 3-4**).

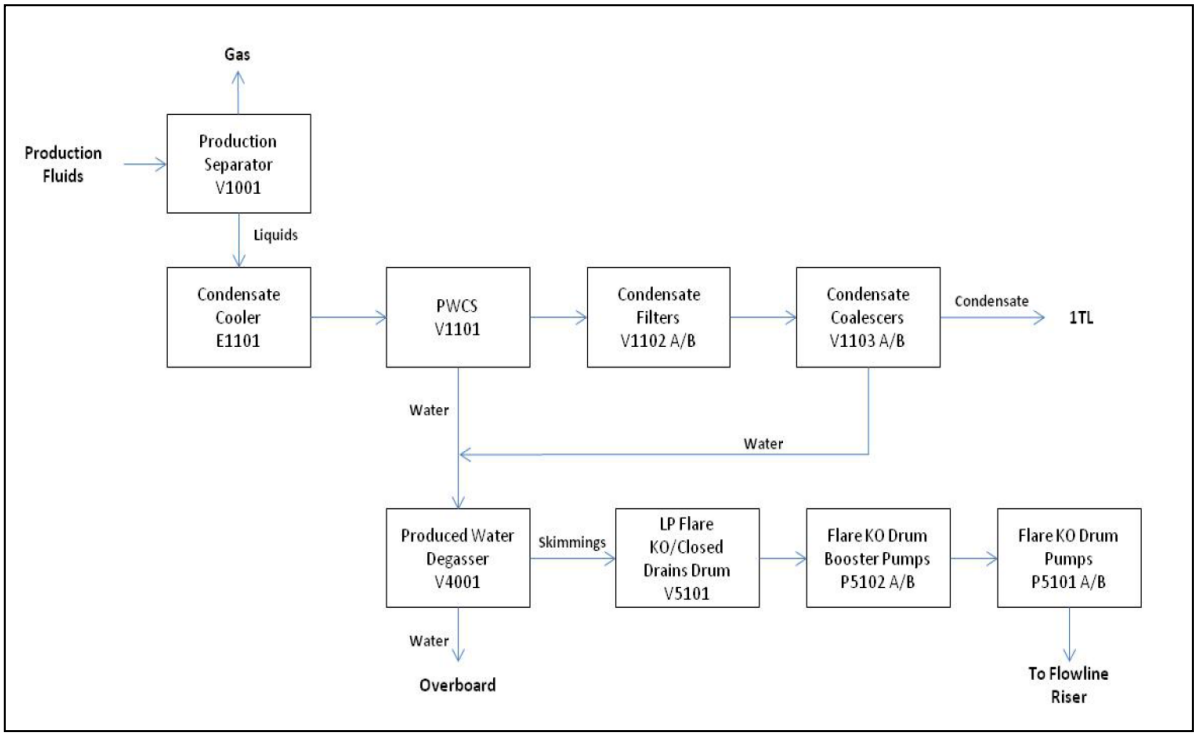

Figure 3-4: Produced water system configuration

3.4.9.2 Produced Water Oil in Water Discharge Monitoring

The measurement of oil in water (OIW) in the PW stream is undertaken prior to discharge to the ocean. OIW is measured using an online OIW analyser. The analyser is designed specifically for offshore operations and measures fluorescence this is calibrated to provide total petroleum hydrocarbon (TPH) in water. Two analysers are currently installed on the facility, with a single analyser on-line at any one time. The analysers can be controlled locally or remotely from the NRC central control room (CCR).

3.4.10 Drainage Systems

The open and closed drains system consists of both hazardous and non-hazardous open drains. The open drains system is required for disposal of water and hydrocarbons which are at atmospheric pressure (e.g., deck water). Drains from hazardous areas are segregated from drains from non-hazardous areas to prevent ingress of gases into a non-hazardous area via the drains system.

3.4.11 Closed Drains

The process closed drains system is used for draining liquids process equipment for maintenance purposes. The drained liquids are routed to the LP flare knock-out/closed drains drum, and from there the recovered liquids are recycled back to the process.

3.4.11.1 Hazardous Open Drains

Operational process and non-process discharges, discharges from some maintenance activities and potential spills are contained within the hazardous open drain system. The drains collect spillage, process drainage and washdown water from equipment/flooring, and rain/deluge water from areas designated as hazardous. Drainage into the system is directed to the collection header which discharges into a horizontal three-phase separator (gas/liquid/liquid).

A 4 m^3 diesel storage tank is always available on the platform so diesel is available during unplanned maintenance visits. The tank is located in a bunded area which drains to the hazardous open drains.

Recovered hydrocarbons/glycol from the open drains separator is skimmed and transferred to waste oil ISO tanks for onshore disposal. The separated water is discharged directly overboard at +22 m LAT from the water disposal compartment of the open drains separator.

During normal operation, there is little flow of liquids through the drains system, with the only continual flow into the hazardous open drains system being the discharge of the sample water from the PW OIW analyser.

3.4.11.2 Glycol Hazardous Open Drains

The Angel facility has a dedicated hazardous open drain system for collecting and containing the glycol and chemical injection areas. The drain is designed to prevent these liquids from being discharged to sea or entering the condensate/water separation process where it may adversely affect the process. The glycol hazardous open drain system also collects triethylene glycol (TEG) and monoethylene glycol (MEG) to prevent recycling into the process via the closed drains system or into the TEG regeneration system (where it may cause corrosive organic acids to form).

The transportable MEG and corrosion inhibitor 4 m^3 ISO tanks are located in common bunded areas on the main deck. The connection provided on the outlet of the bund is normally closed and can be drained to the glycol hazardous open drain system in case of a spill. Drainage into the system is directed to waste oil storage tanks (4 m^3) for onshore disposal.

3.4.11.3 Non-hazardous Open Drains

The non-hazardous open drains system is ‘open’ to the atmosphere and collects, contains and disposes rain, wash water and waste liquids from non-hazardous areas of the decks and from the helideck. The drainage from this system is routed directly overboard. The heating, ventilation and air conditioning (HVAC) condensed water drains also tie into the service water tank overflow in the non-hazardous area of the Angel facility.

3.4.12 Utility Systems

3.4.12.1 Platform Lighting

The riser platform has appropriate lighting to ensure a safe working environment during 24-hour operations. Lighting is split between emergency and normal lighting. Approximately 30% of the

platform lighting is powered from the emergency generator supply. The remainder is fed from the normal supply from NRC. Lighting on the Angel facility may be controlled directly on the facility or remotely from NRC.

The emergency light fittings are located to illuminate the designated escape routes on the Angel facility. Navigational lights are located on the riser platform flare tower and on the booms and towers of the pedestal crane. Helideck lighting is also provided to assist helicopter landing. Unless required to support over-the-side activities (such as re-fuelling and lifting operations), lighting on the riser platform is directed to the work area, which limits light spill to the marine environment.

3.4.12.2 Heating, Ventilation and Air Conditioning System

The HVAC system comprises HVAC equipment, ductwork and associated pipework. It provides independent and interdependent subsystems with pressurised, conditioned, purge and exhaust air services to various areas including accommodation and various modules, which can be operated on an as-required or continuous basis. Ozone-depleting substances are not used on Angel and refrigerants associated with the HVAC system are managed by a licenced refrigerant authority.

3.4.12.3 Power Generation

Power for the Angel facility is supplied from NRC at the 33 kV voltage level via a single submarine cable from the 6.6 kV switchboard. The submarine cable is of a composite type, with power cores as well as fibre optic cores for instrumentation, telecommunication, and electrical interlocking and relaying signals.

The uninterruptible power supply (UPS) is provided by a dual redundant AC and DC battery power system to ensure continuous power to the critical control and safeguarding equipment, even if one UPS or battery in the AC or DC system is shut down for maintenance. On loss of main power supply from NRC, the power control system disconnects and switches to the battery system.

3.4.12.4 Utility Gas System

As the Angel facility does not use gas as a combustion fuel for power generation, utility gas generated from the process system is provided on the facility for:

- stripping gas to the glycol stripping column
- purge gas to the flare headers, glycol storage vessel, MEG storage tank and glycol surge drum
- pilot gas to the flare ignition package
- start-up blanket gas to the glycol flash drum.

3.4.12.5 Sewage and Putrescible Wastes

Sewage from the ablutions is disposed to ocean via the sewage caisson. Putrescible waste (principally food scraps) is either ground to less than 25 mm diameter and disposed overboard, or bagged and transported to shore for disposal as domestic waste.

3.4.12.6 Sand Management

LDA-01 and LDA-02 wells are equipped with sand screens and open hole gravel pack completions and acoustic sand detectors on its subsea Xmas tree. The Angel facility basis of design assumes there is a low probability of sand production from both wells and alarms from the acoustic sand detectors alert operators to any minor sand production. In the event of minor sand/fines production, sand is deposited in the PW system degasser. The piping, layout and valve materials are designed to prevent, handle or easily remove any accumulation of sand as required. In the event of major sand production (i.e., a well completion failure), the well will automatically shut in via the acoustic sand detector signal.

3.4.12.7 Diesel Fuel

Filtered, low sulphur bulk diesel is transported via supply vessels in 4 m^3 ISO tanks. A 4 m^3 diesel ISO tank is provided on the platform so diesel is available during unplanned maintenance visits. The tank is located in a bunded area which drains to the hazardous open drains. Diesel is required for the crane and lifeboat.

3.4.12.8 Routine Lifting from Platform Support Vessels

Routine lifting operations primarily include transferring stores and equipment from a support vessel to the Angel facility. Support vessels are equipped with dynamic positioning (DP) control for holding station during lifting operations.

The types of 'lifted equipment' may vary but generally include containers or skips of various sizes. The stores and equipment required by the Angel facility are secured inside the skip or container. Containers for supply of chemicals and diesel are routinely lifted. Equipment is appropriately rated for offshore lifting.

After offloading from the supply vessel is complete, the Angel facility backloads any items to be returned to shore. These primarily include empty skips or containers or skips containing waste for onshore disposal.

3.4.12.9 Lifting Around the Angel Facility

A pedestal crane is located on the east side of the riser platform at the main deck.

Once lifted to the lay down area, there may be a need to re-position equipment at various locations throughout the Angel facility for operational purposes. This includes lifting stores or equipment to various landing areas throughout the Angel facility for unloading or use and moving waste bins to required areas.

There may be occasions where a non-routine piece of equipment may need to be lifted. On these occasions, the equipment is packed in a container or an approved lifting frame.

3.4.13 Operational Chemicals and Hydrocarbons

3.4.13.1 Hydrocarbons

The main hydrocarbon inventories associated with major topside process equipment is presented in **Table 3-6**. Non-process inventories of hydrocarbons used on the Angel facility are outlined in **Table 3-7**.

Table 3-6: Hydrocarbons inventories of major topside process equipment

Vessel	Gas or two-phase volume (m^3)	Volume liquid (m^3)
Production separator, inlet coolers	105	20
Condensate cooler, PWCS	N/A	30
Glycol contactor	157	2
Condensate filters, condensate coalescers	N/A	7
Export riser to subsea isolation valve (SSIV)	88	N/A

Table 3-7: Inventories of non-process hydrocarbons

Material	Storage volumes
Diesel	Two 4 m^3 ISO tanks
Lube Oil/Hydraulic Fluid	Various sized containers based on type and use 10 m^3 and 205 L drums

3.4.13.2 Chemicals

Chemicals are used on the Angel facility for a variety of purposes and can be divided into two broad categories (operational and non-operational) as described below.

Operational Process Chemicals

A process chemical is the active chemical added to a process or static system, which provides functionality when injected in produced fluid, utility system streams or for pipeline treatment. These chemicals may be present in routine or non-routine discharge streams from the Angel facility.

Operational Non-process Chemicals

Non-process chemicals include chemicals which do not fall into the category described above but which may be required for operational reasons and, by virtue of their use, may be intermittently discharged or have the potential to be discharged (e.g., required as a result of maintenance or intervention activities). Examples include subsea control fluids and dyes.

Non-operational Chemicals

Non-operational chemicals include chemicals which are required for general maintenance or 'housekeeping' activities and are critical for overall maintenance of the Angel facility and its equipment. These may include paints, degreasers, greases, lubricants and domestic cleaning products. They may also include chemicals required for specialty tasks, such as laboratory testing and analysis. Maintenance chemicals generally present negligible risk to the environment as they are not discharged as a result of their use (e.g., paint), or are used intermittently and discharged in low volumes (e.g., domestic cleaning products).

Indicative Chemical Inventories

An indicative list of bulk chemicals commonly used on the Angel facility, and estimated storage quantities, is summarised in **Table 3-8**. In addition to the chemicals listed, the Angel facility may also maintain small volumes of various operational chemicals and facility maintenance chemicals as previously described.

Table 3-8: Indicative bulk inventories of chemicals

Material	Storage means	Storage capacity
Corrosion Inhibitor	Corrosion inhibitor tank	30 m^3 storage vessel (21 m^3 working volume)
TEG	Glycol storage tank	40 m^3 storage vessel 100 m^3 regeneration system
MEG	MEG storage tank	25 m^3 storage vessel
Subsea control fluid	Production hydraulic power unit (HPU) tank	10 m^3 storage vessel

3.4.14 Vessel-based Activities

During planned operations, vessel-based activities will involve the Platform Support Vessel and support vessels during field work such as subsea inspection, maintenance and repair activities.

3.4.14.1 Platform Support Vessel

Platform support vessels are used to transport personnel, material and equipment to and from the Angel facility when staffed. The specifications of the Siem Thiima (**Figure 3-5**) are presented in **Table 3-9** as an example, and represent the typical specifications of a support vessel. Vessels supporting the Angel facility vary depending on vessel schedules and availability. While in the field, the vessel also backloads materials and segregated waste for transport back to the King Bay Supply

Facility (KBSF) in Karratha, as well as carrying out standby duties including during working over the side activities while in the field.

Figure 3-5: Indicative support vessel (Siem Thiima)

Table 3-9: Siem Thiima vessel specifications

Attribute	Details
Type	Facility support vessel
Length overall	89.2 m
Breadth	19.0 m
Draft	7.6 m
Dead weight tonnage	5,500 t
Accommodation	Berthing for 25 personnel
Dynamic positioning system	DP2
Fuel capacity	152 m^3 – largest isolatable tank

3.4.14.2 Support and Other Vessels

Support or project vessels (crewed or remotely operated) are used for field work such as subsea inspection, maintenance and repair activities. Vessels supporting the activities may vary depending on operational requirements, vessel schedules, capability and availability.

Typical support vessels use a DP system to allow manoeuvrability and avoid anchoring when undertaking works, due to the proximity of subsea infrastructure. However, vessels are equipped with anchors which may be deployed in an emergency. Support vessels do not anchor within the PAA during the activities due to water depth.

3.4.15 Inspection, Monitoring, Maintenance and Repair

Subsea infrastructure is designed not to require significant intervention. Inspection and maintenance are undertaken to ensure the integrity of the infrastructure and identify problems before they present a risk of loss of containment. Intervention may be required to repair identified problems.

To manage subsea threats (risks) the IMMR process requires an appropriate response to be selected to manage specific equipment risks. This is typically one of: inspection, maintenance, monitoring or repair.

The IMMR process for subsea infrastructure, including any redundant equipment (**Section 3.4.15.4**), maintains equipment in good condition and repair, for production and to enable future removal.

Subsea activities are typically undertaken from a subsea support vessel or uncrewed surface vessel (USV) and may use ROV with transponders to inspect equipment.

Maintenance and repair activities may require the deployment of frames/baskets which are temporarily placed on the seabed. These typically have a perforated base with a seabed footprint of about 15 m^2. This equipment is removed from field via recovery to the support vessels at the completion of IMMR activities.

Typical IMMR activities are described below.

3.4.15.1 Inspection

Inspection of subsea infrastructure is the process of physical verification and assessment of components in order to detect changes to the as-installed location and condition by comparison to initial state following installation and previous inspections. Details of typical subsea infrastructure inspections/surveys and frequencies are provided in **Table 3-10**. Actual scope and frequency of subsea equipment (operational or redundant) and pipeline inspections are determined using an RBI methodology and associated plans. While the inspection frequency of ETA, AW and non-producing wellheads are determined by the WOMP.

RBI is commonly used within the industry as a method for determining inspection frequencies (Energy Institute, 2009; DNV, 2019). RBI for pipeline systems that have reached cessation of production inherently pose less risk to the environment and may drive a less frequent inspection frequency.

Table 3-10: Typical subsea inspection/surveys and frequencies

Type of inspection/ survey	Subsea infrastructure	Purpose	Approximate frequency
General visual inspection	Structure, wellheads, spools, flowlines, risers and pipelines	Check general infrastructure integrity.	Varied – every 1 to 8 years
Close visual inspections	All subsea infrastructure	Investigate certain subsea infrastructure components.	Varied – every 2 to 6 years
Cathodic protection	All subsea infrastructure	Check for corrosion and renew sacrificial anodes, if required.	Varied – every 2 to 6 years
Wall thickness surveys	Production and crossover manifolds, flowlines and pipelines	Monitor the condition of subsea infrastructure. (i.e., ultrasonic testing).	Typical: Once every 25 years Worst case: Once every 5 years
Acoustic survey (e.g., multibeam echo sounder (MBES), sidescan sonar (SSS), sub bottom profiling (SBP))	Pipelines	Identify buckling, movement, scour and seabed features. Low frequency/ intensity signals undertaken on the flowlines.	Varied – every 1 to 6 years

Type of inspection/ survey	Subsea infrastructure	Purpose	Approximate frequency
Non-destructive testing (NDT)	Pipeline and manifolds (if required)	Evaluates the properties of material/items using electromagnetic, radio graphic, acoustic resonance technology, ultrasonic, or magnetic equipment.	Typical: Once every 25 years Worst Case: Once every 25 years per well
Seabed sampling surveys including minor grabs/cores	NA	Identify benthic fauna, sediment characteristics, determine level of penetration/compaction, etc. Grabs/cores typically disturb 0.1 m² of seabed per sample.	Typical: Once every 25 years Worst Case: Once every 5 years
Anode inspections and/or replacement	Production and crossover manifolds, trees, flowlines and pipelines	Samples taken of anode materials for testing.	Typical: Once every 25 years Worst Case: Once every 25 years
Marine growth sampling	All subsea infrastructure	Samples taken of marine growth for testing.	Typical: Once every 25 years Worst Case: Once every 5 years
Sub bottom profiling	Around subsea components	Low frequency echo sounder undertaken to identify returns of metals under the seabed.	Varied – every 1 to 6 years
Laser surveys	Dimensional check on spools	Used to conduct dimensional checks on spools, etc, and measure proximity.	Varied – every 1 to 6 years
Pigging	Export pipeline, flowline	Inspection, maintenance, repair or to facilitate modifications.	Typical – Once every 12 years Worst case – every 5 years

3.4.15.2 Monitoring

Monitoring of subsea infrastructure refers to the process of surveillance of the physical and chemical environment that a subsea system or component is exposed to, to determine if and when damage may occur, and (where relevant) predict the rate or extent of that damage. Monitoring activities may include process parameters and composition testing, acoustic sand detectors, erosion probes, metocean and geological seismic monitoring, and cathodic protection testing.

3.4.15.3 Maintenance

Planned maintenance activities on subsea infrastructure are undertaken to prevent deterioration or integrity failure of infrastructure. Typical maintenance activities are described in **Table 3-11**.

Table 3-11: Typical subsea maintenance activities

Type of maintenance	Subsea infrastructure	Purpose	Approximate frequency
Cycling of valves via control system	Well	Test functionality of technical integrity valves	Every 6 months
Marine growth removal	Production and cross over manifolds and retrieval components (e.g., chokes)	Reduce weight or gain visual access	Based on outcomes from visual inspections (**Table 3-10**) and marine growth trends on regional infrastructure
Flushing of chemical hydraulic fluid lines	Hydraulic fluid lines	For repair scenarios	When required for repair
Leak and pressure testing	All subsea infrastructure	Test integrity of subsea infrastructure	Following installation of subsea infrastructure components after a repair or intervention, prior to return to service

3.4.15.4 Repair

Repair activities are those required when a subsea system or component is degraded, damaged or has deteriorated to a level outside of acceptance limits. Damage sustained may not necessarily pose an immediate threat to continued system integrity but may present an elevated level of risk to environment or production reliability. Due to the design of subsea infrastructure and materials used, repairs are undertaken on an as needs basis. The requirements and frequency of these repairs are dictated by the outcome of the inspection and maintenance regimes described in **Table 3-10** and **Table 3-11**. Typical subsea repair activities include:

- subsea choke replacement
- chemical injection metering valve insert replacement
- PCR, HCR, SCM, SDU or control distribution unit (CDU) replacement
- hydraulic flying lead (HFL) replacement and/or relocation
- electrical flying lead (EFL) replacement and/or relocation
- tree cap changeout
- logic plate/cap changeout
- pipeline or spool support with grout bag or mattress
- spool disconnection and/or replacement
- flowline/pipeline replacement
- scour prevention installation
- cathodic protection system replenishment/repair
- acoustic sand detector replacement.

When equipment is replaced, the redundant equipment, may remain in situ or be removed from the field. The location of redundant subsea infrastructure items is recorded as part of the ROV as left survey and input into a database for the inventory associated with each title (refer **Section 6.6.2**). The inventory is used to track equipment on the seabed to enable planning for future removal.

3.4.15.5 Subsea Chemical Use

Planned chemical discharges may occur during a range of subsea system operation and IMMR activities. However, these are either small volumes, or discharged intermittently. Operational chemicals to be used in the subsea infrastructure are selected and assessed using Woodside's chemical selection and assessment guideline, as detailed in **Section 3.8**. Typical chemicals used in the subsea infrastructure may be released during IMMR activities. These include:

- control fluid – the subsea control fluid presently used in the subsea systems is Oceanic HW443ND (no dye included), which is a water-based product, with the major component ethylene glycol; HW443ND is dosed with dye to support integrity monitoring, when required
- hydrate control – MEG and TEG are used for hydrate control
- corrosion inhibitor is used to manage and prevent corrosion within pipelines and flowlines
- biocide are used to prevent the bacterial growth in pipelines that may cause corrosion
- acid – where removal of calcium deposits is required, Woodside typically uses sulphamic (or equivalent) acid. Alternatives such as citric acid or calcium wash may be used
- oxygen scavenger is used to reduce/de-oxygenate the pipeline and prevent corrosion and aerobic bacterial growth
- surfactants are formulated to remove water and organic deposits from pipelines
- grout – material used in grout, mattresses and rock is typically concrete-based
- staurolite products – used for abrasive/sand blasting to clean and remove marine growth, the main component is staurolite, which is a naturally forming mineral.

3.4.15.6 Typical Discharges During Inspection, Monitoring, Maintenance and Repair Activities

There are planned environmental discharges during subsea IMMR activities, for example during pressure/leak testing or flushing. Where possible, flushing is performed prior to disconnection of a subsea component to reduce residual hydrocarbon or chemical releases to the subsea environment upon disconnection. The flushing chemicals used for this activity may be supplied from either the Angel facility or a chemical package via a downline from a support vessel. Where possible, flushed fluids are returned to the platform and be processed and treated through the production system. **Table 3-12** shows typical discharge volumes during different IMMR activities.

Table 3-12: Typical discharge volumes during different inspection, monitoring, maintenance and repair activities

Activity	Description
Pressure/leak testing	Chemical dye estimated <10 L
Flushing	Residual hydrocarbon or chemical release volume is dependent upon injection port size, component geometry and pumping rates
Hot stab changeout	Hydrocarbons or control fluid estimated <10 L
Subsea control module changeout	A typical release of diluted acid is estimated to be 400 L and of control fluid is estimated to be 10 L
Jumper and umbilical replacement	Typical releases of hydraulic fluid, MEG and corrosion inhibitor are estimated to be <10 L each, typical acid release of <80 L
Choke changeout	Release of hydrocarbons <10 L and a typical release of MEG is estimated to be 280 L, typical acid release of <80 L
Tree cap changeout	Release of hydrocarbons estimated <50 L and a typical release of MEG is estimated to be <50 L
Logic plate changeout	Release of hydrocarbons estimated <20 L and a typical release of MEG is estimated to be <20 L
Spools repair, replacement and recovery	Typical releases of hydrocarbons, MEG and corrosion inhibitor are estimated to be <10 L each

3.4.15.7 Marine Growth Removal Methods

Due to the relatively high rate of marine growth on the NWS, it is often necessary to remove excess growth prior to undertaking many subsea IMMR activities. Marine growth removal is undertaken with an ROV or a diver. The different techniques are described in **Table 3-13**.

Table 3-13: Typical marine growth removal methods

Activity/equipment	Description
Water jetting	Uses high pressure water to remove marine growth
Brush systems	Uses brushes attached to a ROV to physically remove marine growth
Acid (typically sulphamic acid)	Chemically dissolves calcium deposits
Sand/abrasive blasting	Additional cleaning to allow close visual inspections

3.4.15.8 Flushing and Pigging Operations

During pipeline or flowline lifecycle, there may be a need to conduct flushing and/or pigging for a variety of reasons (e.g., inspection, maintenance, repair, facilitate modifications or to remove hydrocarbon in preparation for decommissioning). Where required, subsea isolation valve operations are carried out from a ROV via a support vessel.

Should pigging of the flowlines and/or export pipeline be required, provision has been made for the installation/recovery of temporary subsea/topsides pig launcher and receivers. The entire flowline and pipeline pigging system, including the launcher, receiver and the respective flowlines and pipeline, is designed for maximum operation pressure of the production system.

Flushing of the Angel subsea flowlines is planned for approximately six months prior to Angel well plug and abandonment to maintain ability:

- for ongoing monitoring and management of subsea wells including ability to carry out leak-off testing (LOT) of valves on Xmas trees prior to plug and abandonment
- to manage any passing hydrocarbon fluids from the shut in Xmas tree valves.

Flushing of the Angel flowlines is from topsides into the wells to achieve an ALARP OIW content. The flowlines are flushed using treated seawater, and once flushed are preserved with treated seawater to prevent corrosion, containing a combination of oxygen scavenger, corrosion inhibitor, and biocide. If required a scale dissolver may also be used to strip and clean any scale build-up. The well integrity barriers on the wells will then be closed, tested and verified, in accordance with the WOMP. The flowlines may then be cut and plugs installed in either end of the cut section. This would result in a release of a quantity of preservation fluids (approximately 100 to 150 L). The plugs installed on the Xmas tree will provide additional isolation and hence minimise the requirement for subsea system inspection frequency in the suspended phase.

As part of a pigging activity for the Angel Export Pipeline, there may be a requirement to flush the subsea pig launch receiver (PLR) after use. Prior to lifting the PLR to the deck of the vessel, flushing to a subsea location may be required to avoid deck risks to the vessel and/or reduce health and safety risks to personnel. Indicative discharge volumes associated with pigging the Angel export pipeline (considered worst case) are provided for in **Table 3-14**. Corrosion product solids are not expected from pigging, based on previous pigging activities, but those generated from the pigging activities would be pushed in front of the pig(s) and into the connecting trunkline (or in the case of the Angel subsea flowlines, into the wells). Remaining solids in the pig receiver will be disposed of onshore. The SSIV may be temporarily locked open for pigging activities.

Table 3-14: Typical subsea discharge volumes associated with pigging for the Angel export pipeline

	Cumulative volume released (by number of receiver recoveries)		
Number of runs	1 (most likely scenario)	2	3
Condensate volume (m^3)	2.9	5.7	8.6
Treated seawater discharge (m^3)	28	57	85
TEG volume (m^3)	4	8	12

3.5 Lambert West Drilling and Tie-back

3.5.1 Overview

This section provides a description of the Lambert West drilling and tie-back activities. The Lambert West tie-back consists of a single well, LDA-02, drilled and connected to the Lambert Deep production manifold, installation of a controls subsea distribution unit, and disconnection of the LDA01 electrical and hydraulic flying leads from the Lambert Deep UTA and reconnecting them to the subsea distribution unit.

The well will be drilled and completed using a MODU. Typically, two or three support vessels will support the MODU during drilling activities (**Section 3.5**), with at least one vessel in the vicinity to complete standby duties, if required. Supply vessels from Dampier Port will frequent the MODU at regular intervals throughout drilling operations, as required.

Installation of the subsea infrastructure (**Section 3.5.3**) will be undertaken using an installation vessel. Another installation vessel, similar to vessels used for IMMR, may be used to install the tubing head spool and Xmas tree and for cold commissioning the wells and during start-up (if required).

3.5.2 Drilling Activities

This EP includes drilling activities for the LDA-02 well in the Lambert West Operational Area and tie-back to the Angel facility. Well construction activities are conducted in a number of stages, as described below. Well design will be optimised for ultimate recovery.

Detailed well design for the LDA-02 well will be submitted to the Well Integrity department of NOPSEMA as part of the Approval to Drill and the accepted WOMP, as required under the Offshore Petroleum and Greenhouse Gas Storage (Resource Management and Administration) Regulations 2011.

3.5.2.1 Cement Unit Test

Upon arrival on location at the PAA, the MODU may need to perform a cement unit test, or 'dummy cement job', to test the functionality of the cement unit and the MODU's bulk cement delivery system before performing an actual cement job. This operation is usually performed after a MODU has been out of operation for an amount of time (warm-stack), if maintenance on the cement unit has been performed, or if it is the first time a MODU is being used in-country and commissioning of the cement unit system is required.

A 'dummy cement job' involves mixing a sacrificial cement slurry at surface which is discharged through the usual cement unit discharge line (which may be up to 10 m above the sea level) or through drill pipe below sea level, and occurs as a cement slurry. The slurry is usually a mix of cement and water; however, it may sometimes contain stabilisers or additives.

3.5.2.2 Top Hole Section Drilling

The Petroleum Activities Program drilling commences with the top hole section as follows:

- The MODU arrives and establishes position over the well site.
- A pilot hole or holes may be drilled close to the intended well location. Pilot holes are used when geology and shallow hazards need to be confirmed or further understanding of the structural integrity of the rock is required. Pilot holes are drilled riserless, as described below, and result in additional cuttings, sweeps and potentially mud deposition to seabed.
- Top hole sections are drilled riserless using seawater with pre-hydrated bentonite sweeps/XC polymer sweeps or drilling fluids to circulate drilled cuttings from the wellbore; these are deposited to the seabed.
- Once the top hole sections of the well have been drilled, steel tubulars (called conductor or casing) are inserted into the wellbore to form the conductor/surface/intermediate casing, and secured in place by pumping cement into the annular space back to about 300 m above the casing shoe or to surface (seabed), which involves discharging excess cement at the seabed.

3.5.2.3 Blowout Preventer and Marine Riser Installation

After setting the surface or intermediate casing, a blowout preventer (BOP) is installed on the wellhead, and the marine riser above it, to provide a physical connection between the well and MODU. This enables a closed circulation system to be maintained, where weighted drilling fluids and cuttings can be circulated from the wellbore back to the MODU, via the riser.

In addition, the BOP provides a means for sealing, controlling, and monitoring the well during drilling operations. The BOP components operate with open hydraulic systems, using water-based BOP control fluids. Each time the BOP is operated (including pressure testing approximately every 21 days and a function test about every seven days, excluding the week a pressure test is conducted), the volume of BOP control fluid released to the marine environment is up to about 3620 L per full BOP test.

Hydraulic fluid used for operating the BOP rams is subject to the chemical assessment process outlined in **Section 3.8**.

3.5.2.4 Bottom Hole Section Drilling

A closed system (riser in place) is used for drilling bottom hole sections to the planned wellbore total depth (TD). The preference is for bottom hole sections to be drilled using water-based mud (WBM) drilling fluids; however, non-water-based mud (NWBM) may be used (**Section 3.5.5.4**).

Protective steel tubulars (casings and liners) are inserted as required. The size, grade, weight, length and inclination of the casing/liner sections within the wellbore are determined by factors such as the geology/subterranean pressures likely to be encountered in the area and any specific information or resource development requirements.

After a string of casing/liner has been installed into the wellbore, it is cemented into place. The casing/liner is then pressure-tested. Once the pressure testing is passed, drilling of the next section can take place, with the riser in place to circulate drill cuttings and drilling fluids back to the MODU.

Cementing operations are also performed to:

- provide annular isolation between hole sections and structural support of the casing/liner as required
- set a plug in an existing well to sidetrack
- plug a well so it can be suspended/abandoned.

Cement is transported as dry bulk to the MODU by the support vessels, mixed as required by the cementing unit on the MODU and pumped by high pressure pumps to the surface cementing head then directed down the well. Excess or contaminated liquid cement that cannot be used down hole and cannot be returned to shore for disposal, as it may solidify in storage tanks, will require discharge. Cement will be mixed and pumped as required from a small mixing tank on the cement unit. This limits the volume of excess or contaminated cement that could potentially require discharge into the ocean. As to excess cement in the form of dry bulk, refer to **Section 3.5.2.11.4**.Cuttings in drilling fluids circulated back to the MODU are separated from the drilling fluids by the solids control equipment (SCoE). The SCoE comprises shale shakers to remove coarse cuttings from the drilling fluid. After processing by the shale shakers, the recovered fluids from the cuttings may be directed to centrifuges, which are used to remove the finer solids (4.5 to 6 µm). Water-based drill cuttings are usually discharged below the water line and the fluids are recirculated into the fluid system.

3.5.2.5 Formation Evaluation

Formation evaluation is the interpretation of a combination of measurements taken inside a wellbore to detect and quantify hydrocarbon presence in the rock adjacent to the well once TD is reached. Formation evaluation while drilling (FEWD) is formation evaluation conducted via tools in the drilling bottom hole assembly. It may include extracting small cores, full diameter cores and other down-hole technologies, as required. FEWD tools are incorporated into the drill string during development drilling and may include gamma ray, directional deep resistivity, callipers, density-neutron, sonic, and tools which can measure formation pressures and take formation fluid samples. Some FEWD tools contain radioactive sources; however, no radioactive material will be released to the environment and radiation fields are not generally detectable outside the tool when the tool is not energised, therefore, they do not present an environmental risk.

3.5.2.6 Wellbore Cleanout

During construction, wells are often displaced from one fluid system to another. Various types of ‘displacement pills’ and ‘cleanout trains’ may be circulated between the two fluid systems to facilitate efficient displacement and/or cleaning of the well. Displacement and cleanout pills will typically be discharged after use. If there is potential for oil within any fluid, it will be captured, tested and discharged only if oil concentration is <1% by volume. It will be returned to shore if discharge requirements cannot be met. Displacement pills and clean out trains are typically between 5 m^3 and 100 m^3, depending on application.

3.5.2.7 Tubing Head Spool Installation (Required for Vertical Xmas Tree Installation)

Before the upper completion is installed into the well, the tubing head spool is installed from an installation vessel (IMMR type), or directly from the MODU. Due to the subsea well layout, if installation was to occur from the installation vessel, the MODU will be required to kedge off or reposition away from the drill centre to allow the installation vessel to install the tubing head spool. Once the tubing head spool has been installed, it is pressure-tested to confirm integrity when the MODU BOP is reconnected to continue with drilling and completions activities.

The tubing head spool is installed with a preservation mixture.

3.5.2.8 Xmas Tree Installation

Following installation of the upper completion, isolations in the upper completion will be tested, and the well suspended. At this point, the vertical Xmas tree may be installed directly from the MODU, or installed from an installation vessel (IMMR Type), immediately, or at a later point in time. Once the Xmas tree has been installed, it is pressure-tested to confirm integrity. A workover control package may be used post Xmas tree installation to facilitate re-opening of tubing isolation valves, which will result in small, localised discharges (<10 L) of MEG/HW443 during downline installation and recover operations. If required, a well control system will be deployed to recover suspension plugs.

An alternate horizontal Xmas tree (HXT) may be utilised which will be installed on the wellhead in place of the tubing head spool (**Section 3.5.2.7**) prior to upper completion deployment. The HXT will be suspended by the rig prior to subsea flowline and control system installation.

The Xmas tree is installed with a preservation mixture in the production and annulus bores.

3.5.2.9 Completions Activities

Once the well has been drilled, completion activities are undertaken including installation of the lower completion, intermediate completion, production tubing, and subsea tree. Throughout construction any safety critical element is tested for integrity. Following construction and completion, the well is suspended with a gas column and tested dual barriers in the subsea tree.

3.5.2.10 Well Unload

3.5.2.10.1 General Description

During well unloading activities, all completion and reservoir fluids will be directed to the Angel facility and be handled by the systems onboard the platform, in accordance with **Sections 3.4.7** and **3.4.9**.

In the event fluids from well unloading cannot be directed to the Angel facility, they may be flared or discharged to the environment via the well test package onboard the MODU. The base oil column, completion fluid, hydrocarbons and produced/condensed water will be measured, handled, separated, treated for overboard discharge (non-hydrocarbon) and flared/burned (hydrocarbon) through the temporary production system on the MODU. Note that the opportunity to unload to the Angel facility is Woodside's preferred option, which could eliminate or reduce well unloading to the MODU.

3.5.2.10.2 Produced/Reservoir Water Disposal

If fluids from well unloading are directed to the MODU, the well test water treatment package will be used to treat produced/reservoir water before discharge. Prior to discharging, the fluids are cycled through an onboard filtration system and gauge tank. Water filtration is standard practice for well unloading operations. Fluids that cannot be treated or flared will be sent onshore in tanks for disposal.

3.5.2.10.3 Emissions

If well unloading is performed to the MODU, it is expected that condensate, diesel and methanol in the wellbore will be flared. The flare may be extinguished due to water ingress, lack of fuel (propane), weather impact or equipment failure resulting in cold venting of gas from the flare for several minutes before the flare can be restarted or venting stopped. After the objectives of the well testing and flowback are achieved, the flow is stopped and the well may be cleaned using a brine that can include several chemicals, such as biocide and surfactant.

3.5.2.11 Drilling Fluid System

In addition to the base fluid, drilling muds contain a variety of chemicals, incorporated into the selected drilling fluid system to meet specific technical requirements (e.g., mud weight required to manage pressure, or for borehole stability). All chemicals selected for use will be assessed under Woodside's internal guidelines to ensure potential impacts are acceptable, ALARP and meet Woodside's expectation for environmental performance.

3.5.2.11.1 Water-based Mud System

A water-based drilling fluid system is the preferred option for the Petroleum Activities Program.

In addition to the base fluid, drilling muds contain a variety of chemicals, incorporated into the selected drilling fluid system to meet specific technical requirements (e.g., mud weight required to manage pressure, or for borehole stability). The WBM drilling fluid will either be mixed on the MODU or received pre-mixed, then stored and maintained aboard the MODU. The top hole sections are drilled riserless with seawater containing pre-hydrated gel sweeps. The bottom hole sections may be drilled using WBM in a closed circulation system which enables reuse of the WBM drilling fluids.

WBM drilling fluids that cannot be reused (e.g., due to bacterial deterioration or if they do not meet required drilling fluid properties) or are mixed in excess of required volumes, may be operationally discharged to the ocean under the MODU's permit to work (PTW) system.

3.5.2.11.2 Mud Pits

There are typically a number of mud pits (tanks) on the MODU that provide a capacity to mix, maintain and store fluids required for drilling activities. The mud pits form part of the drilling fluid circulating system. The mud pits and associated equipment/infrastructure are cleaned out at the end of drilling and completions operations. Mud pit wash residue is discharged overboard with less than 1% oil contamination by volume. Mud pit residue over 1% oil volume is sent to shore for disposal.

3.5.2.11.3 Drill Cuttings

Drill cuttings generated from the well are expected to range from very fine to very coarse (<1 cm) particle/sediment sizes. Cuttings generated during drilling of the top hole sections are discharged at the seabed. Estimated volumes of drill cuttings that may be discharged during the Petroleum Activities Program are presented in **Section 6.6.8**.

The bottom hole sections are drilled with a marine riser that enables cuttings and drilling fluid to be circulated back to the MODU, where the cuttings are separated from the drilling fluids by the SCE. The SCE comprises, but is not limited to shale shakers, cuttings dryers and centrifuges. The SCE uses shale shakers to remove coarse cuttings from the drilling mud. After being processed by the shale shakers, the recovered mud from the cuttings may be directed to centrifuges, which are used to remove fine solids (4.5 to 6 µm). The cuttings are usually discharged below the water line and the mud is recirculated into the fluid system.

If NWBMs are needed to drill a well section (refer to **Section 3.5.5.4**), the cuttings which are separated from the NWBM via the shakers will also pass through a cuttings dryer and associated SCE to reduce the average oil on cuttings for the entire well (only sections using NWBM) to 6.9% wt or less on wet cuttings prior to discharge.

3.5.2.11.4 Dry Bulk Management

Bulk dry products including cement, barite and bentonite is transported to the drill rig via supply vessels and pneumatically transferred to dry bulk storage tanks using compressed air. During the transfer process, the holding tanks are vented to atmosphere to release pressure build up, resulting in small amounts of dry powder being discharged from venting pipes located under the MODU.

Bulk product inventory is managed to minimise excess quantities remaining at the end of the campaign, whilst ensuring adequate stock is available for well integrity and safe operations.

For this activity, it is planned that unused excess dry bulk product at the end of the campaign will be retained for subsequent activities.

Woodside requires that mercury and cadmium concentration in stock barite be below 1 mg/kg and 3 mg/kg, respectively. Documentation of heavy metal analysis is planned to be undertaken for all individual batches of barite and used to verify compliance with these concentrations.

3.5.3 Subsea Installation and Pre-commissioning Activities

The subsea installation scope of work will include installing and pre-commissioning the infrastructure summarised in **Table 3-15**. The Petroleum Activities Program includes directly installing infrastructure from the installation vessels in the relevant location. During hook-up and pre-commissioning of the new and existing facilities there is potential for discharges associated with the testing and connection activities of the subsea systems. The pre-commissioning associated with subsea infrastructure generally includes leak testing of the flexibles, subsea control systems verification and function-testing of valves to verify that the electric and hydraulic flying leads are ready for entry into the commissioning phase.

Table 3-15: Subsea installation component summary

Description	Detail	Dimensions (approx.)
Well (LDA-02)	One wellhead and Xmas tree system	6.0 m (L) × 4.0 m (W) × 6.0 m (H) (typical)
Subsea flowline	8” ID jumper between LDA manifold and the Lambert West well Xmas tree	300-500 m
Subsea control	Two sets of flying leads (1 HFL, 2 EFL per set)	1 set ~70 m 1 set ~300 m
Subsea structures	One subsea distribution unit	5.0 m (L) × 3.5 m (W) × 2.5 m (H) (typical)

3.5.3.1 Underwater Acoustic Positioning

Long base line (LBL) transponders and/or ultrashort baseline transponders (USBL) are commonly used acoustic positioning methods and may be installed on the seabed as required by the installation activities. The USBL subsea transponder transmits an acoustic pulse back to the vessel receiver, hence providing an accurate positioning of the subsea transponder location. The LBL array provides accurate positioning by measuring ranges to three or more transponders deployed at known locations on the seabed and structures.

These transponders are utilised for the correct positioning of the subsea infrastructure. Transmissions are not continuous but consist of short ‘chirps’ with a duration that ranges from three to 40 milliseconds. If used, the LBL transponders are installed in stands on the seabed. Both the transponders and stands are recovered after installation. The USBL transponders are mounted on the subsea infrastructure and removed post installation.

Transponders may also be installed in stands on the seabed for vessel positioning. Both transponders and stands shall be removed post installation.

3.5.3.2 Installation of Structures

Subsea structures (i.e., subsea distribution unit, mudmats) are lowered to the seabed using the installation vessel's main crane to a pre-determined depth before engaging the ROV to guide it to the correct position.

As described above, the structures may be positioned using LBL array or USBL. Additional pre-deployed clump weights or sandbags can potentially be used to provide further assurance that the structures are positioned in the correct location and orientation.

3.5.3.3 Flexible Jumper Initiation/Initiation Anchor Deployment

Commencement of the jumper installation may require using an initiation anchor to pull against in order to provide the required tension to the flexible jumper as it transitions from the installation vessel to the seabed. The initiation anchor, which will be recovered after use, may consist of a clump weight.

Installation aids such as sandbag markers or concrete mattresses may be used for positioning aids or wet storage as required.

3.5.3.4 General Flexible Jumper and Flying Leads Installation

The installation contractor will mobilise an installation vessel to the field to install the flexible jumper and flying leads to the seabed. The installation vessel will operate in DP during installation activities.

The optimum flowline route is selected by considering seabed bathymetry, pre-installation surveys and installation risk management, including dropped object risks.

The indicative installation methodology and principle applied when installing the jumper is as follows:

- The flexible jumper is reeled onto either horizontal or vertical reels.
- VLS are installed on the vessel to lay the flexible jumper.
- During installation, a hydraulically-driven centre reel drive is engaged to the reel to rotate the reel in synchronised speed with the VLS.

Installation sequence for flexible jumper is as follows:

- prepare universal connection system and VLS onboard the vessel
- fit applicable subsea components (anodes, bend restrictors) to flexible jumper, perform tests and pre-deployment checks
- deploy flexible jumper, ROV guide tail end to initiation point and land out
- continue flexible jumper lay as per lay route while monitoring touchdown with ROV
- land out second end to final location and disconnect.

The flexible jumper may also be installed using a lighter installation spread on the installation vessel, via a deck-mounted powered reel system in combination with a deployment chute mounted on the side of the installation vessel and temporary installation aids placed on the seabed.

The flying leads are configured into deployment basket(s) and landed on the seabed using a crane. ROVs will complete the final subsea tie-in. Small volumes of MEG and HW443 will be released to subsea environment during HFL removal and installation. From the existing Lambert Deep UTA, EFLs and HFLS will carry controls to the new SDU, then split out via EFLs and HFLs through to both LDA-01 and LDA-02 wells.

Connection to the existing Lambert Deep manifold may require marine growth removal prior to removing or connecting components. Marine growth removal is described in **Section 3.4.15**.

3.5.3.5 Span/Scouring Rectification and Stabilisation

Spans are undulations in the seabed that do not provide sufficient support to the flowline. Spans are generally mitigated by installing structures, such as concrete mattresses, before installing the flowline. Engineering validation will determine if concrete mattresses need to be installed to mitigate spans. The dimensions for each concrete mattress are typically 6 m by 3 m by 0.3 m.

Post-lay span rectification may also be required after flexible jumper installation. This process typically involves placing grout bags under the span section. The empty bag is moved into position using ROV, then filled with grout supplied from a mixing and pumping spread on the vessel via a downline. Typical grout volumes depend on the size of the span and may vary from about 200 kg to 2000 kg per span.

If grout bags are used, the downline recovery time risks exceeding the grout curing time. If grout cures within the downline and pump, the equipment is likely to be rendered unserviceable, as well as the downline not being safely recoverable in the normal way. Therefore, after grouting activities at each span site, the downline and pump will need to be purged using seawater. This results in an amount of grout, approximately equivalent to the downline volume (5 m^3), being discharged to the ocean. This flushing is required once per grout site. The actual number is not known until the line is laid and need for span rectification determined, if any.

Scouring is the movement of seabed sediment (e.g., silt, sand and gravel) from around the base of a subsea structure to further afield due to prevailing hydrodynamic conditions, potentially compromising the integrity of a structure. Scouring is generally mitigated by installing mattresses along the perimeter of the installed structure. Concrete mattresses may be installed at the Lambert West UTA pending engineering verification.

Stabilisation is a post-lay activity to ensure that items, such as the flying leads remain at their installed positions; i.e., not being shifted due to strong seabed current. Stabilisation of flying leads is generally mitigated by installing sandbags on top of flying leads at a predetermined distance apart. Sandbags generally come in a standard size with 20 kg to 25 kg weight. Concrete mattresses may be used to stabilise the flexible jumper. Sandbags or concrete mattresses may also be used to provide temporary stability of wet stored items if wet storage proves necessary.

Sandbags or concrete mattresses may be installed for crossings over existing umbilicals or jumpers.

3.5.3.6 Pre-commissioning of the Flexible Jumper

Leak testing is performed to test the integrity of subsea infrastructure, test isolations and identify any leaks. Pressure may be applied via a downline from the installation vessel or via ROV. Failure of testing equipment or integrity of the tested infrastructure may lead to a loss of leak test fluids to the marine environment. After the Lambert West leak testing is completed, the system pressurisation volume may be released to the environment to mitigate the risk of hydrocarbons returning to the installation vessel.

During tie-in and pre-commissioning activities, any subsea connection break-outs will be preserved with chemical sticks. A small amount of chemically treated MEG/ water may be discharged to the environment from the structure and tie-in flexible prior to final make up of the connection. All chemicals used in pre-commissioning activities will be subject to the chemical selection assessment process described in **Section 3.8**.

3.5.3.6.1 Flooding

The flexible jumper will be installed filled with chemically treated ~55 wt% MEG/water. MEG is used to prevent formation of hydrates during start-up. Topping up of the flowline will occur when the pulling head is removed to install diverless connectors.

3.5.3.6.2 Leak Testing

Leak test/system pressure tests are performed to confirm the integrity of subsea connections and jumper. During leak testing there may be small volumes of test fluids discharged to environment during connection and disconnection of hot stabs.

3.5.3.7 Tie-in of Flowlines at Lambert Deep Manifold

Prior to tie-in of the LDA-02 jumper to the Lambert Deep manifold, verification testing of any leakage from the manifold isolation valves may be undertaken. This testing will verify that suitable isolations for safe tie-in are available, thereby preventing a major hydrocarbon release during tie-in. This verification may result in the release of hydrocarbons to the environment. The hydrocarbons are predominantly gas with a small quantity of condensate. Additionally, when the flowline tie-ins take place, a quantity of hydrocarbons may be released. A conservative estimate of hydrocarbons that may be released during the flowline tie-in at the manifold is up to 400 L of condensate and residual gas over a 48 hour period. Water jetting and/ or acid injection may be used to clean the connections on the infrastructure prior to tie-in.

3.5.3.8 Cold Commissioning of Subsea Infrastructure

The commissioning associated with subsea infrastructure prior to the introduction of hydrocarbons (referred to as cold commissioning) generally includes subsea control systems verification and function testing of valves to verify that the HFLs and EFLs are ready for entry into the start-up phase.

During cold commissioning, an ROV is deployed from the installation vessel (or similar support vessel) to provide visual confirmation of Xmas tree valve actuation. This activity is typically less than 12 hours in duration.

3.5.3.9 Wet Storage of Equipment

Wet storage of infrastructure may be required intermittently throughout the duration of subsea installation activities (-60 days) as part of the Petroleum Activities Program. There are three categories of equipment that may require wet storage as part of the Petroleum Activities Program, as summarised in **Table 3-16**.

Table 3-16: Wet storage that may be required as part of tie-back activities

Wet storage category	Reason for wet storage	Typical equipment	Retrieval method
Installation aids	To facilitate safe installation of infrastructure	Predominantly installation aids (subsea/ROV baskets, clump weights, etc)	Retrieval will be undertaken using project vessels (**Section 3.5**) and associated equipment such as cranes, ROV, etc
Subsea installation	Prior to connection of infrastructure, wet storage may be necessary to optimise project schedule and support SIMOPs	Items may include flexible jumper, flying leads and wet parking/deployment frames, etc	Retrieval is not required, as infrastructure will be used for production operations and once connected is no longer considered wet stored
Mooring	Mooring chains and anchor may be wet stored for ~ 60 days post MODU disconnection	Mooring chains and anchors	Retrieval will be undertaken using project vessels (**Section 3.5**) and associated equipment such as cranes, ROV, etc

3.5.3.10 Maintenance of Subsea Infrastructure

All subsea structures installed during the Petroleum Activities Program have been designed for full removal. As per **Table 3-16**, wet stored items will be removed during the subsea installation

activities. Due to the design of equipment, the materials selected and short duration of subsea installation activities, all wet stored equipment will be in a condition that allows for removal.

The as-built survey will confirm that structures installed for production operations are in good condition and repair.

3.5.3.11 Site Surveys

Site surveys will be undertaken at various stages throughout the installation of subsea infrastructure. An initial pre-lay survey will be undertaken by the flexible jumper installation contractor before starting installation activities. The pre-lay survey may be performed by a dedicated pre-lay survey vessel which is typically similar in size to support vessels, or potentially by the installation vessel.

The pre-lay survey is a debris and hazard identification survey and not a full geophysical survey along the pre-determined route or proposed design route. While it is not anticipated that any significant debris may need to be removed before flexible jumper installation, if required, these activities will fall under this EP and will be performed by an installation vessel, a support vessel or similar.

Additional surveys, with an ROV, will be undertaken throughout the installation activities. These surveys will identify the location of all items placed on the seabed (including wet stored items and installed infrastructure). The survey data will be input into a computer program to track all subsea equipment and displayed on the 'survey screen' (comprising an AutoCAD file). This file will be progressively updated throughout the activities as items are put down on, and removed from the seabed (and in the title).

An as-built survey will be conducted by ROV at the completion of the installation campaign to ensure installation of equipment is in the designed location. This data will be used to update the 'survey screen' to develop the as-built report, which is considered the inventory of items remaining on the seabed (and in the title). In addition, any material items dropped to the marine environment and not recovered (See **Section 6.8.8**) will be added to the inventory for the title.

3.5.4 Lambert West Commissioning (Initial Start-up) Activities

The commissioning (initial start-up) activities of the LDA-02 well and associated subsea infrastructure are planned to commence in 2024. All activities may be subject to rescheduling, including delay, based on operational requirements of the Angel platform or other production scheduling reasons as well as project schedule changes.

Topsides modifications on the Angel facility for Lambert West are limited to controls updates and installation of temporary equipment for Start-up. This equipment includes a temporary laboratory for manual OIW sampling of the produced water and for analysis of reservoir fluids. A temporary produced water polishing skid is also proposed for start-up.

Once hydrocarbons have been introduced into the system, preservation fluids are displaced to the Angel platform, where they are processed and wells are cleaned-up to maximum rates. Performance testing may be undertaken such as multi-rate testing, simulated emergency shutdown of LW well only, then pressure build-up testing. MEG of up to 100%, or a combination of MEG/treated water initially in the LDA-02 jumper arrives at the separator and is discharged via the produced water (PW) discharge route, along with residual completions fluids and fines from the well as part of well clean-up.

3.5.5 Contingent Activities

The following sections present contingencies that may be required, if operational or technical issues occur during the PAA. These contingencies have been considered within the relevant impact assessment sections and do not represent significant additional risks or impacts but may generate

additional volumes of drilling fluids and cuttings being discharged operationally and may add to the duration of the Petroleum Activities Program.

3.5.5.1 Respud

A respud may be required for a number of reasons, such as if the conductor or wellhead slumps or fails installation criteria (typically during top hole drilling). Re-spudding involves moving the MODU to a suitably close location (e.g., approximately 50 m from the original location, entirely within the Lambert West Operational Area) to recommence drilling. A respud activity would result in repeating top hole drilling (**Section 3.5.6.7**).

The environmental aspects of re-spudding are the same as those for drilling and are considered to be adequately addressed by this EP (**Sections 6.6.8** and **6.6.9**), with no significant changes to existing environmental risks or any additional environmental risks likely. The net environmental effect will be limited to an increase in the volume of cuttings generated (**Section 6.6.8**) and discharged at the seabed, from the repeat drilling of the top hole section, plus an increase in the quantity of cement discharged at seabed from cementing the conductor and surface casing strings along with potential increase in the use of drilling fluids and the additional emissions (atmospheric and waste) associated with an extended drilling program.

3.5.5.2 Sidetrack

The option of a sidetrack instead of a respud may be required if operational issues are encountered. The environmental aspects of a sidetrack well are the same as those for routine drilling activities, which are considered to be adequately addressed by this EP (**Sections 6.6.8** and **6.6.9**), with no significant changes to existing environmental risks or any additional environmental risks likely. The net environmental effect will be limited to an increase in the volume of cuttings generated (**Section 6.6.8**), potential increase in the use of drilling fluids and the additional emissions (atmospheric and waste) associated with an extended drilling program.

3.5.5.3 Workover

The existing production well (LDA-01) and proposed development well (LDA-02) may be worked over. A workover or intervention may be required to restore production or integrity due to a failed completion or component in the well. The environmental aspects of a workover operation are the same as those for well completion activities and are considered to be adequately addressed by this EP, with no significant changes to existing environmental risks or any additional environmental risks likely.

3.5.5.4 Non-water-based Mud System

The LDA-02 well is planned to be drilled entirely using WBM, however NWBM may be required for bottom hole sections as a contingency. The decision to use NWBM drilling fluids for the bottom hole sections of a well is based on a variety of technical factors relevant to wellbore conditions, such as well temperature, well shape and depth, reactivity of the formation to water and well friction. The technical justification to use NWBM includes environment, health, safety and waste management considerations.

The use of NWBM drilling fluids is subject to a formal written commercial and/or technical justification approved in accordance with the Best Practice – Overburden Drilling Fluids Environmental Requirements. The main ingredient of NWBM is base oil, and similar to a WBM system, a range of standard solid and liquid additives may be added in the pits to alter specific mud properties for each section of the well, dependent on the conditions encountered while drilling.

The NWBM drilling fluid will be primarily mixed onshore (new or reuse of existing stock) and transferred to the MODU by a support vessel, where it is stored and maintained in the mud pits. During drilling operations, the NWBM drilling fluid, like the WBM, is pumped by high pressure pumps

down the drill string and out through the drill bit, returning via the annulus between the drill string and the casing back to the MODU via the riser.

The used NWBM pumped back to the MODU contains drill cuttings and is pumped to the solid control equipment (SCE), where the drill cuttings are removed before being pumped back to the pits ready for reuse. The technical properties of the NWBM drilling fluids are maintained/altered (e.g., to increase weight) using additives as required when in the mud pits.

The NWBM drilling fluids that cannot be re-used (i.e., do not meet required drilling fluid properties or are mixed in excess of required volumes) are recovered from the mud pits and returned to the shore base for onshore processing, recycling and/or disposal. The mud pits and associated equipment/infrastructure are cleaned when NWBM is no longer required, with wash water treated onboard through SCE before discharge with mud pit washings, or returned to shore for disposal if discharge criteria cannot be achieved (refer to **Section 3.4.13.2**).

3.5.5.5 Well Suspension

During drilling activities, the well may need to be temporarily suspended. Suspension involves establishing suitable barriers, removing the riser and disconnecting the MODU from the well. The BOP may be left in place to act as a barrier. Suspension may be short term (e.g., in the case of a cyclone) or longer term (more than one year). On return to the well after suspension, the MODU reconnects to the well via the riser, and with BOP in place, barriers are removed and drilling and completions activity resumes.

3.5.5.6 Wireline Logging

Wireline contingencies that may be in place for development drilling include gamma ray and casing collar locator for depth correlation, ultrasonic imaging tool and cement bond log to measure cement integrity, formation pressures (XPT), density, neutron and resistivity and punch perforators/tubing cutters suitable for all tubing sizes. Wireline contingency work will be performed with appropriate isolation barriers in place, i.e., an overbalanced fluid column. If wireline work is required to occur in a live well, or where there is a risk of barrier failure, the operation will be performed with full pressure control equipment at the surface.

Some logging tools may contain low activity radiation sources. Radiation fields are not generally detectable outside the tool when the tool is not energised; therefore, they do not present an environmental risk.

3.5.5.7 Well Intervention

An intervention may be performed on the LDA-01 or LDA-02 wells. Interventions may be performed due to down-hole equipment failure or to address underperformance of a well. Key well intervention methods include wire-line and coiled tubing. Potential environmental impacts from intervention activities have been included in this EP, including discharge of suspension fluids and brines and small volume gas releases subsea due to removal of a tree cap which may be in place if the well was previously suspended.

3.5.5.8 Well Abandonment

The Petroleum Activities Program covers the drilling and intervention of production wells, which are not envisaged to be abandoned until the end of the production field life. For technical reasons, the lower section of the LDA-02 well may need to be abandoned, before side-tracking, or if a respud is required.

Well abandonment activities are conducted in accordance with Woodside's internal standards. Base oil may be used for inflow testing before abandonment, to verify barrier integrity. Base oil may be pumped down the drill string and reverse -circulated back to the rig, with fluids collected for disposal onshore. If stored in a mud pit, the base oil and other fluids associated with the test may result in pit

wash water contaminated with hydrocarbons. If this is the case, mud pit wash water would be discharged in accordance with requirements in this EP; with a hydrocarbon content <1% by volume.

If required, the well will be abandoned with abandonment cement plugs, including verification of the uppermost cement plug through a prescribed program (e.g., directly by tagging and/or pressure testing or indirectly through assessment). A lower section of the well may also be abandoned before side-tracking.

After abandonment activity, the marine riser and BOP will be removed and every reasonable attempt made to retrieve the wellhead (either immediately with the rig or later on a vessel). Conventional wellheads are removed by deploying a cutting device on drill pipe which then cuts through the conductor, allowing the wellhead to be retrieved to the surface. Backup cutting equipment is sent offshore as a contingency should the primary set of equipment fail. The conductor cutting equipment is very reliable with a high success rate of cutting wellheads.

If these recognised removal techniques are ineffective, the wellhead may be left in-situ. The integrity of the wellbore is not affected by the wellhead assembly remaining in-situ.

3.5.5.9 Wellhead Assembly Left In-situ

If a well is abandoned due to the requirement to respud, the wellhead assembly may be left in-situ if recognised removal techniques are ineffective. Well abandonment activities would be performed as outlined in **Section 3.5.5.8** but the well assembly would remain. The integrity of the wellbore is not affected by the wellhead assembly remaining in-situ. The environmental aspects of the wellhead assembly remaining in-situ as a contingent activity are considered to be adequately addressed by this EP (**Section 6.6.2**), with no significant changes to existing environmental risks or any additional environmental risks likely.

Final decommissioning of the development wellhead assembly and other subsea infrastructure at the end of field life will be subject to a separate EP.

3.5.5.10 Sediment Mobilisation and Relocation

If required, an ROV-mounted suction pump/dredging unit may be used to relocate sediment/cuttings around the wellhead or other infrastructure, to keep the area clear and safe for operations and equipment. This activity has the potential to generate plumes of suspended sediment during pumping and disturb benthic fauna in the immediate area.

3.5.5.11 Venting

During drilling of the LDA-02 well, a kick may occur. A kick is an undesirable influx of formation fluid into the wellbore. To maintain well integrity in this situation, a small volume of greenhouse gas is released to the atmosphere via the degasser, in a well control operation known as ‘venting’.

3.5.5.12 Emergency Disconnect Sequence

An emergency disconnect sequence (EDS) may be implemented if the MODU is required to rapidly disengage from the LDA-02 well. The EDS closes the BOP (i.e., shutting in the well) and disconnects the riser to break the conduit between the wellhead/BOP and MODU. Common examples of when this system may be initiated include the movement of the MODU outside of its operating circle (e.g., due to a failure of the DP system) or the movement of the MODU to avoid a vessel collision (e.g., third-party vessel on collision course with the MODU). EDS aims to leave the wellhead and BOP in a secure condition but will result in loss of the drilling fluids/cuttings in the riser after disconnection.

3.5.6 Vessel-based Activities

During Lambert West tie-back, vessel-based activities will involve the MODU, subsea installation vessels and support vessels.

3.5.6.1 Mobile Offshore Drilling Unit

Tie-back activities will be drilled by a moored or hybrid (DP/moored) MODU. Typical specifications for moored MODU types are provided in **Table 3-17**. These are collectively referred to as the MODU for the remainder of the document unless specific risks for different MODU types have been identified. Due to variabilities, such as contractual and operational matters, the MODU used may be subject to change.

Table 3-17: Typical mobile offshore drilling unit specification ranges

Component	Specification Range
Rig type/design/class	Semi-submersible MODU
Accommodation	120 to 200 personnel (maximum persons on board)
Station keeping	Minimum eight-point mooring system
Bulk mud and cement storage capacity	283 to 770 m^3
Liquid mud storage capacity	576 to 2500 m^3
Fuel oil storage capacity	966 to 1400 m^3
Drill water storage capacity	3500 m^3

3.5.6.2 Installation Vessels

The tie-back subsea installation scopes of work may require various installation vessels, with sufficient capacity to accommodate hardware and equipment such as flexible jumpers, SDU and flying leads.

A typical installation vessel for subsea and flowline installation would be a DP vessel (usually DP2 Class) equipped with a primary differential global surface positioning system (DGPS) and an independent secondary DGPS backup. The specification of a typical subsea installation vessel is provided in **Table 3-18**. Another installation vessel, similar to vessels used for inspection, monitoring, maintenance and repair (IMMR), may be used to install the tubing head spool and Xmas tree.

Installation vessels are typically equipped with various material handling equipment, which includes cranes, winches, remotely operated vehicles (ROVs) and ROV launch and recovery systems, vertical lay system (VLS) with either vertical reel drive or horizontal reel drive (carousel) and pre-commissioning spread.

Lifting operations may involve loading and unloading equipment from support and supply vessels onto the installation vessel and subsequently onto the seabed. Cranes are typically equipped with active heave compensation and auto tension, modes and have lifting capacities in excess of lifting loads expected to be encountered during operations.

Table 3-18: Typical DP2 Class subsea installation vessel

Component	Specification range
Vessel type	DP2 Class as a minimum
Crane capacity	250 T active heave compensation crane as minimum
ROVs	Two Work Class ROVs
Deck space	Approximately 1900 m^2
Deck strength	Approximately 15 T/m^2
Accommodation	Approximately 120 people
Fuel oil	Approximately 2200 m^3
Potable water	Approximately 800 m^3

3.5.6.3 Support and Other Vessels

The MODU and installation vessels will be supported by other vessels, such as general support vessel(s), cargo vessel(s), anchor handling vessel(s), barges, multiservice construction and HLVs. During the installation campaign, there may potentially be two HLVs and two platform supply vessels for field support and floating storage facilities.

Support vessels are used to transport equipment and materials between the MODU/installation vessel and port (e.g., Dampier, Onslow, Exmouth). If required, one of the vessels may be at the MODU to perform standby duties, and others will make regular trips between the Lambert West Operational Area and port for routine, non-routine and emergency operations.

3.5.6.4 Holding Station: Mooring Installation and Anchor Hold Testing/Soil Analysis

Mooring uses a system of chains/ropes and anchors, which may be pre-laid before the MODU arrives at the location, to maintain position when drilling. Mooring analysis will be undertaken to determine the appropriate mooring system for the Petroleum Activities Program. The mooring analysis will identify whether the mooring systems are pre-laid or set by the rig, proof tension values, and if synthetic fibre mooring ropes are required. Pre-laid systems are often selected and designed to withstand higher sea states than the rig's mooring system or to provide additional clearance/protection of subsea infrastructure when deemed necessary in the mooring analysis.

Installation and proof tensioning of anchors involves some disturbance to the seabed. AHVs are used in the deployment and recovery of the mooring system.

As part of mooring preparations, anchor hold testing may be conducted at the well locations. Anchor hold testing would be undertaken if Woodside determines that further assurance is required to ensure a robust mooring design.

Anchor hold testing may consist of an AHV or similar vessel deploying an anchor at a potential mooring location. The AHV would then tension the anchor to determine its ability to hold, embed and not drag at location. This may have to be repeated several times at each location. An ROV may also be utilised to evaluate how deep the anchor has embedded and independently verify the seabed condition. Anchor hold testing activities would occur prior to the MODU arriving on location.

Soil analysis may also be necessary to provide data on composition and rock/substrate strength as input into the mooring design and to verify seabed conditions for anchor holding. Soil analysis could include taking a physical sample of the seabed using ROV or other tools, or using measuring devices such as a cone penetrometer. These tests would be carried out up to several months prior to MODU arriving on location, and may occur from a support vessel or anchor handling vessel.

3.5.6.5 Holding Station: Dynamic Positioning Mobile Offshore Drilling Unit

DP uses satellite navigation and radio transponders in conjunction with thrusters to maintain the position of the MODU at the required location. Information about the position of the MODU is provided via a number of seabed transponders, which emit signals that are detected by receivers on the MODU and used to calculate position. The transponders are typically deployed in an array on the seabed, using clump weights comprising concrete, for the duration of the drilling, and are recovered at the end, generally by ROV.

Mooring lines may also be deployed in conjunction with the DP system, acting as a hybrid system, to reduce the loads acting on and improve the reliability of the overall mooring system.

3.5.6.6 Holding Station: Rig Anchor Release Mobile Offshore Drilling Unit

The hybrid MODU scenario is such that the MODU is DP capable though predominantly holds station via pre-laid mooring system. If a hybrid MODU is used to conduct drilling, it will likely have a rig anchor release (RAR) system integrated as a contingency case for cyclone season. A traditional arrangement with no RAR (for lines passing over subsea assets) and rig- or prelay-lines (for lines

clear of subsea assets) will likely be used as the base case in non-cyclone seasons. The moorings are typically pre-laid in an eight-point arrangement, with a RAR device connecting the MODU mooring components with the anchor mooring components. The RAR is an acoustic release connecting link that can be installed in a mooring line to enable a rapid disconnection of a MODU from the mooring system. Each mooring leg would have one RAR installed in the mooring line. The acoustic release process is instigated from a command unit on the MODU that, when activated, transmits a low frequency signal (9 to 11 kHz) that is received by the RAR transducer in the mooring line and activates the primary hydraulic actuator. The hydraulic actuator then releases the locking mechanism of the RAR and the mooring line is disconnected. The MODU then recovers the MODU wire/chain ready for transit (on DP) and the subsea mooring leg remains on the seabed. Anchor lines crossing subsea infrastructure, will be buoyed to maintain clearance from the subsea assets after a disconnection (either on the surface or suspended in the water column).

To reconnect the MODU with the mooring system after a disconnection, the AHV will recover the MODU mooring line (inc. RAR and the trigger sleeve) from the MODU before connecting to the pre-laid line, which is recovered from the seabed or water column by the AHV utilising a ROV.

3.5.6.7 Mobile Offshore Drilling Unit and Support Vessel Activities

A variety of materials are routinely bulk transferred from support vessels to the MODU including drilling fluids (e.g., muds), base fluids, cements, and drill water. A range of dedicated bulk transfer stations and equipment are in place to accommodate the bulk transfer of each type of material. There is also a capacity to bulk transfer waste oil from the MODU to the support vessel, for back-loading and disposal on shore.

The loading and back-loading of equipment, materials and wastes is one of the most common supporting activities conducted during drilling programs. Loading and back-loading is undertaken using cranes on the MODU to lift materials in appropriate offshore rated containers (e.g., ISO tanks, skip bins, containers) between the MODU and support vessel.

Seawater is pumped on board and used as a heat exchange medium for the cooling of machinery engines and high temperature drilling fluid on the MODU. It is subsequently discharged from the MODU to the sea surface at potentially a higher temperature. Alternatively, MODUs may utilise closed-loop cooling systems.

Potable water, primarily for accommodation and associated domestic areas, may be generated on vessels using a reverse osmosis (RO) plant. This process will produce brine, which is diluted and discharged at the sea surface.

The MODU and support vessels will also discharge deck drainage from open drainage areas, bilge water from closed drainage areas, putrescible waste and treated sewage and grey water. Solid hazardous and non-hazardous wastes generated during the Petroleum Activities Program are disposed of onshore by support vessels.

3.5.6.8 Subsea Installation and Support Vessel Activities

The installation vessels may be used for various activities such as pre and post installation survey, installation of subsea structures, installation of subsea infrastructure (e.g., subsea distribution unit), installation of flexible jumper and flying leads, reconfiguration and tie-in to existing infrastructure, pre-commissioning, and cold-commissioning activities.

3.5.6.9 Refuelling

The MODU may be refuelled via support vessels approximately once a month, or as required. This activity will take place within the Lambert West Operational Area and has been included in the risk assessment for this EP. Other fuel transfers that may occur on board the MODU include refuelling of cranes, helicopters or other equipment as required.

The installation vessel is expected to be in the field for relatively short durations and therefore may not require refuelling while in the field. However, this activity has been included in the risk assessment for this EP.

3.6 Vessels

Several vessel types will be required to complete the activities associated with the Petroleum Activities Program. These may include:

- platform support vessel
- a MODU during tie-back (options include a semi-submersible moored MODU or a hybrid MODU with both moorings and DP systems, depending on availability and suitability for the well location (e.g., water depth)
- installation vessels during tie-back
- support vessels, including:
  - AHVs required to set anchors and support the MODU during operations
  - HLVs for providing floating storage facilities to the installation vessel
  - activity support vessels for transportation of hardware from port/staging area to the PAA and installation vessels, and for general re-supply and support for the MODU and the installation vessels.

Typical support vessels use a DP system to allow manoeuvrability and avoid anchoring when undertaking works, due to the proximity of subsea infrastructure. However, vessels are equipped with anchors which may be deployed in an emergency. Support vessels do not anchor within the PAA during the activities due to water depth.

Vessel activities associated with Angel operations and Lambert West tie-back are described in **Section 3.4.14 and Section 3.5.6** respectively.

Description and assessment of project vessel environmental impacts and risks, credible spill scenarios and environmental sensitivities for the activities within the scope of this EP are included in **Section 6**. For power generation, vessels may use diesel-powered generators and/or LNG.

3.6.1 Vessel Mobilisation

Vessels may mobilise from the nearest Australian port or directly from international waters to the PAA, in accordance with biosecurity and marine assurance requirements. Vessel activities while in transit to the PAA are not included in the scope of this EP.

3.6.2 Remotely Operated Vehicles

The MODU and project vessels may be equipped with an ROV system that is maintained and operated by a specialised contractor aboard the vessel. ROVs may be used during drilling operations and subsea installation, for activities such as:

- anchor holding testing
- connection of mooring systems
- pre-drill seabed and hazard survey
- blowout preventer (BOP) land-out and recovery
- BOP well control contingency
- visual observations at seabed during riserless drilling operation
- pre and post installation survey

- subsea Xmas tree control systems hook-up and contingency control
- removal of sediments on or around subsea infrastructure
- installation, testing, pre-commissioning, commissioning and start-up of subsea infrastructure.

An ROV can be fitted with various tools and camera systems that can be used to capture permanent records (both still images and video) of the operations and immediate surrounding environment. Specifically, during installation, the ROV is fitted with hydraulically driven tools to facilitate flowline tie-in.

An ROV may also be used in the event of an incident to deploy the Subsea First Response Toolkit. This is discussed further in **Appendix A**.

3.7 Helicopter Operations

Helicopters are the primary means of transporting passengers and/or urgent freight to/from the Angel facility and vessels. They are also the preferred means of evacuating personnel in an emergency. Helicopter operations within the PAA are limited to helicopter take-off and landing on the helideck. Helicopters may be refuelled on the helideck of the MODU. Helicopter support is principally supplied from Karratha Airport, and transports workers from Karratha for planned maintenance (frequency described in **Section 3.4.5.4**) or from the NRC for breakdown maintenance.

During Lambert West tie-back activities, crew changes may be performed using helicopters. This activity will take place within the Lambert West Operational Area and has been included in the risk assessment for this EP.

3.8 Chemical Selection, Assessment and Approval

Operational chemicals required by the Petroleum Activities Program are selected and approved in accordance with Woodside's process for selecting and assessing chemicals. This process is used to demonstrate that the potential impacts of the chemicals selected are acceptable and ALARP, and that they meet Woodside's corporate requirements, which requires chemicals to be selected with the lowest practicable environmental impacts and risks, subject to technical constraints.

A summary of the environmental requirements of the Chemical Selection and Assessment Environment Guideline is outlined below.

3.8.1.1 Environmental Selection Criteria

Woodside's process for selecting and assessing chemicals follows the principles outlined in the Offshore Chemical Notification Scheme (OCNS), which manages chemical use and discharge in the United Kingdom (UK) and the Netherlands (background on the OCNS scheme is provided below).

Operational chemicals are selected/assessed in compliance with the Woodside's process for selecting and assessing chemicals, specifically:

- Where operational chemicals with an OCNS rating of Gold/Silver/E/D and no OCNS substitution or product warning are selected, or a substance is considered to pose little or no risk to the environment, no further control is required. Such chemicals do not represent a significant impact on the environment under standard use scenarios and therefore are considered ALARP and acceptable.
- If other OCNS-rated or non–OCNS-rated operational chemicals are selected, the chemical is assessed as follows:
  - If there is no planned discharge of the operational chemical to the marine environment, written technical verification of the 'no discharge' fate is provided and no further assessment is required.

- If there is planned discharge of the operational chemical to the marine environment, a further assessment and ALARP justification is conducted.

The ALARP assessment considers chemical toxicity and biodegradation and bioaccumulation potential, using industry standard classification criteria (Centre for Environment, Fisheries and Aquaculture Science scheme criteria).

If a product has no specific ecotoxicity, biodegradation, or bioaccumulation data available:

- environmental data for analogous products can be referred to where chemical ingredients and composition are largely identical
- environmental data may be referenced for each separate chemical ingredient (if known) within the product.

If no environmental data is available for a chemical or if the environmental data does not meet the acceptability criteria outlined above, potential alternatives for the chemical are investigated, with preference for options with a hazard quotient (HQ) band of Gold or Silver, or in OCNS Group E or D with no substitution or product warnings.

If no more environmentally suitable alternatives are available, further risk-reduction measures (e.g., controls related to use and discharge) are considered for the specific context and implemented where relevant to ensure the risk is ALARP and acceptable.

Once the further assessment/ALARP justification has been completed, confirmation that the environmental risk as a result of chemical use is ALARP and acceptable is obtained from the relevant manager.

3.8.1.2 Background Overview of Offshore Chemical Notification Scheme

The OCNS applies the requirements of the Oslo–Paris Convention for the Protection of the Marine Environment of the North East Atlantic (OSPAR Convention). The OSPAR Convention is widely accepted as best practice for chemical management.

All chemical substances listed on the OCNS list of registered products have an assigned ranking based on toxicity and other relevant parameters (e.g., biodegradation, bioaccumulation), in accordance one of two schemes (as shown in **Figure 3-6**):

- **Hazard Quotient (HQ) Colour Band**: Gold, Silver, White, Blue, Orange, and Purple (listed in order of increasing environmental hazard), or
- **OCNS Grouping**: E, D, C, B, or A (listed in order of increasing environmental hazard). Applied to inorganic substances, hydraulic fluids, and pipeline chemicals only.

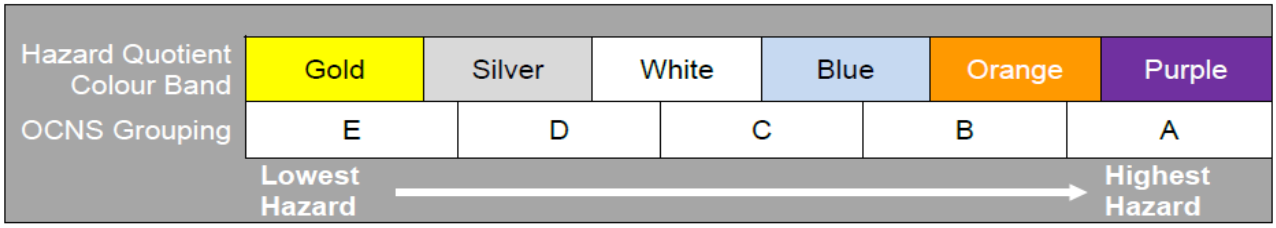

Figure 3-6: Offshore Chemical Notification Scheme ranking

4 DESCRIPTION OF THE EXISTING ENVIRONMENT

4.1 Overview

In accordance with regulations 21(2) and 21(3) of the Environment Regulations, this section describes the existing environment that may be affected (EMBA) by the activity (planned and unplanned, as described in **Section 2.10**), including details of the particular relevant values and sensitivities of the environment, which were used for the risk assessment.

The EMBA is the largest spatial extent where unplanned events could have an environmental consequence on the surrounding environment. For this EP, the EMBA is the potential spatial extent of surface and in-water hydrocarbons at concentrations above ecological impact thresholds, in the event of the worst-case credible spill. The ecological impact thresholds used to delineate the EMBA are defined in **Section 6.7.2**. The worst-case credible spill scenario for this EP is a loss of well integrity. The EMBA also includes any areas that are predicted to experience shoreline contact with hydrocarbons above threshold concentrations.

Woodside recognises that hydrocarbons may be visible beyond the EMBA at lower concentrations than the ecological impact thresholds defined in **Section 6.7.2**. These visible hydrocarbons are not expected to cause ecological impacts. In respect of this, an additional socio-cultural EMBA is defined, as the potential spatial extent within which social-cultural impacts may occur from changes to the visual amenity of the marine environment. Receptors relevant to the socio-cultural EMBA include Commonwealth and State marine protected areas (MPAs), National and Commonwealth Heritage Listed places, areas of tourism and recreation, and commercial and traditional fisheries. The EMBA and socio-economic EMBA are shown in **Figure 4-1** and described in **Table 4-1**.

The EMBA presented does not represent the predicted coverage of any one hydrocarbon spill or a depiction of a slick or plume at any particular point in time. Rather, the areas are a composite of a large number of theoretical paths, integrated over the full duration of the simulations under various metocean conditions.

Table 4-1: Hydrocarbon spill thresholds used to define the environment that may be affected for surface and in-water hydrocarbons

Hydrocarbon type	EMBA[1]	Socio-cultural EMBA[1]	Planning area for scientific monitoring
Surface	10 g/m^2 This represents the minimum oil thickness (0.01 mm) at which ecological impacts (e.g., to birds and marine mammals) are expected to occur.	1 g/m^2 This represents a wider area where a visible sheen may be present on the surface and, therefore, the concentration at which socio-cultural impacts to the visual amenity of the marine environment may occur. However, it is below concentrations at which ecological impacts are expected to occur. This low exposure value also establishes the planning area for scientific monitoring (NOPSEMA Environment bulletin: A652993, April 2019).	
Dissolved	50 ppb This represents potential toxic effects, particularly sublethal effects to highly sensitive species (NOPSEMA Environment bulletin: A652993, April 2019). As dissolved hydrocarbons are within the water column and not visible, impacts to socio-cultural receptors are associated with ecological impacts. Therefore, dissolved hydrocarbons at this threshold also represent the level at which socio-cultural impacts may occur.		10 ppb This low exposure value establishes the planning area for scientific monitoring (based on potential for exceedance of water quality triggers) (NOPSEMA Environment bulletin: A652993, April 2019). This area is described further in **Appendix D** and **Figure 4-1**. In the event of a spill, DNP will be notified of AMPs which may be contacted by hydrocarbons at this threshold.
Entrained	100 ppb This represents potential toxic effects, particularly sublethal effects to highly sensitive species (NOPSEMA Environment bulletin: A652993, April 2019). As entrained hydrocarbons are within the water column and not visible, impacts to socio-cultural receptors are associated with ecological impacts. Therefore, entrained hydrocarbons at this threshold also represent the level at which socio-cultural impacts may occur.		
Shoreline	100 g/m^2 This represents the threshold that could impact the survival and reproductive capacity of benthic epifaunal invertebrates living in intertidal habitat.	10 g/m^2 This represents the volume where hydrocarbons may be visible on the shoreline but is below concentrations at which ecological impacts are expected to occur.	N/A.

[1] *Further details including the source of the thresholds used to define the EMBA in this table are provided in* ***Section 6.7.2****.*

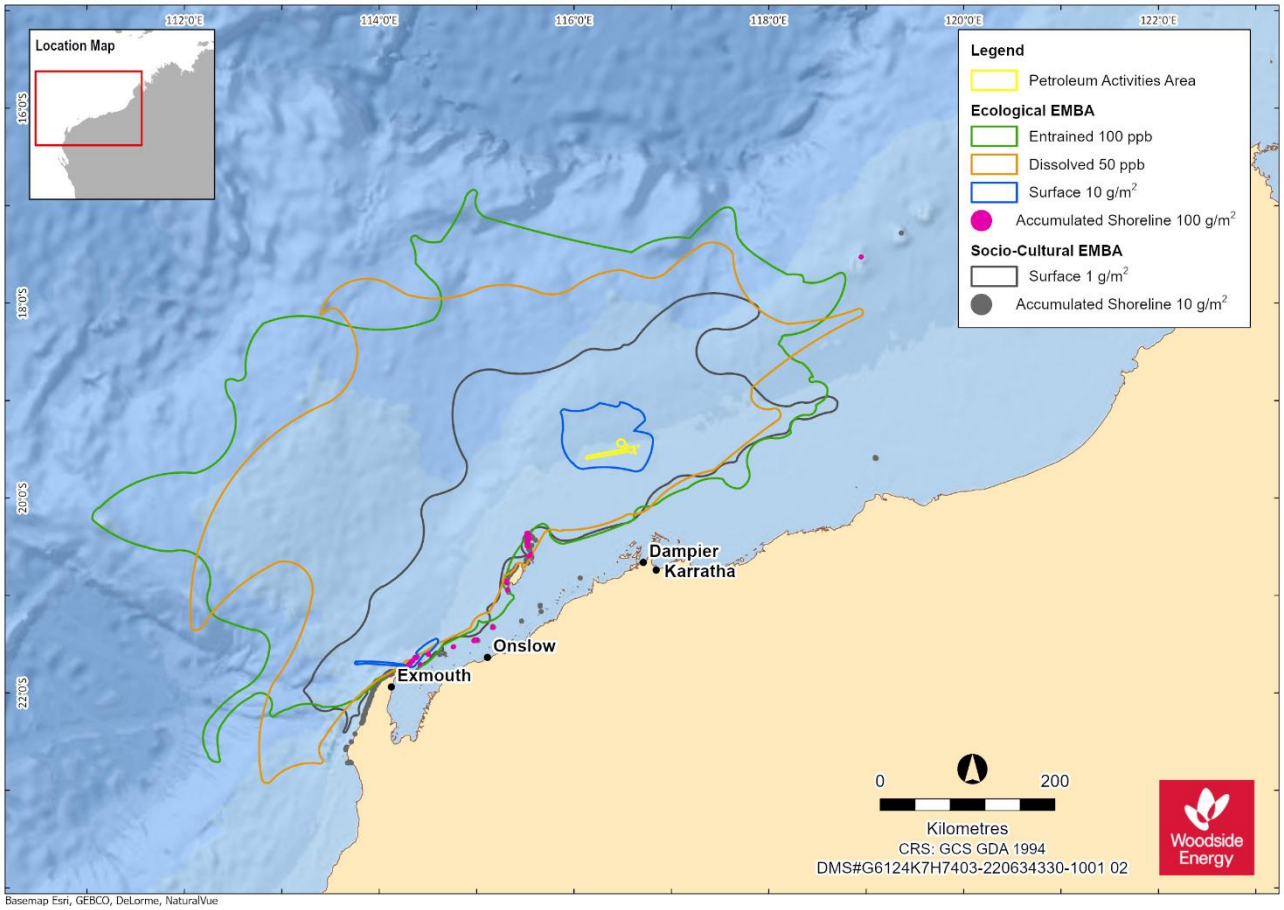

Figure 4-1: Environment that may be affected by the Petroleum Activities Program

4.2 Regional Context

The Petroleum Activities Area (PAA) is located in Commonwealth waters within the North-west Marine Region (NWMR), as defined under the Integrated Marine and Coastal Regionalisation of Australia (IMCRA v4.0) (Commonwealth of Australia, 2006). Within the NWMR, the PAA lies within the Northwest Shelf Province (**Figure 4-2**). Woodside's Description of Existing Environment (**Appendix C-1** and **Section 3**) summarises the characteristics for the relevant marine bioregions.

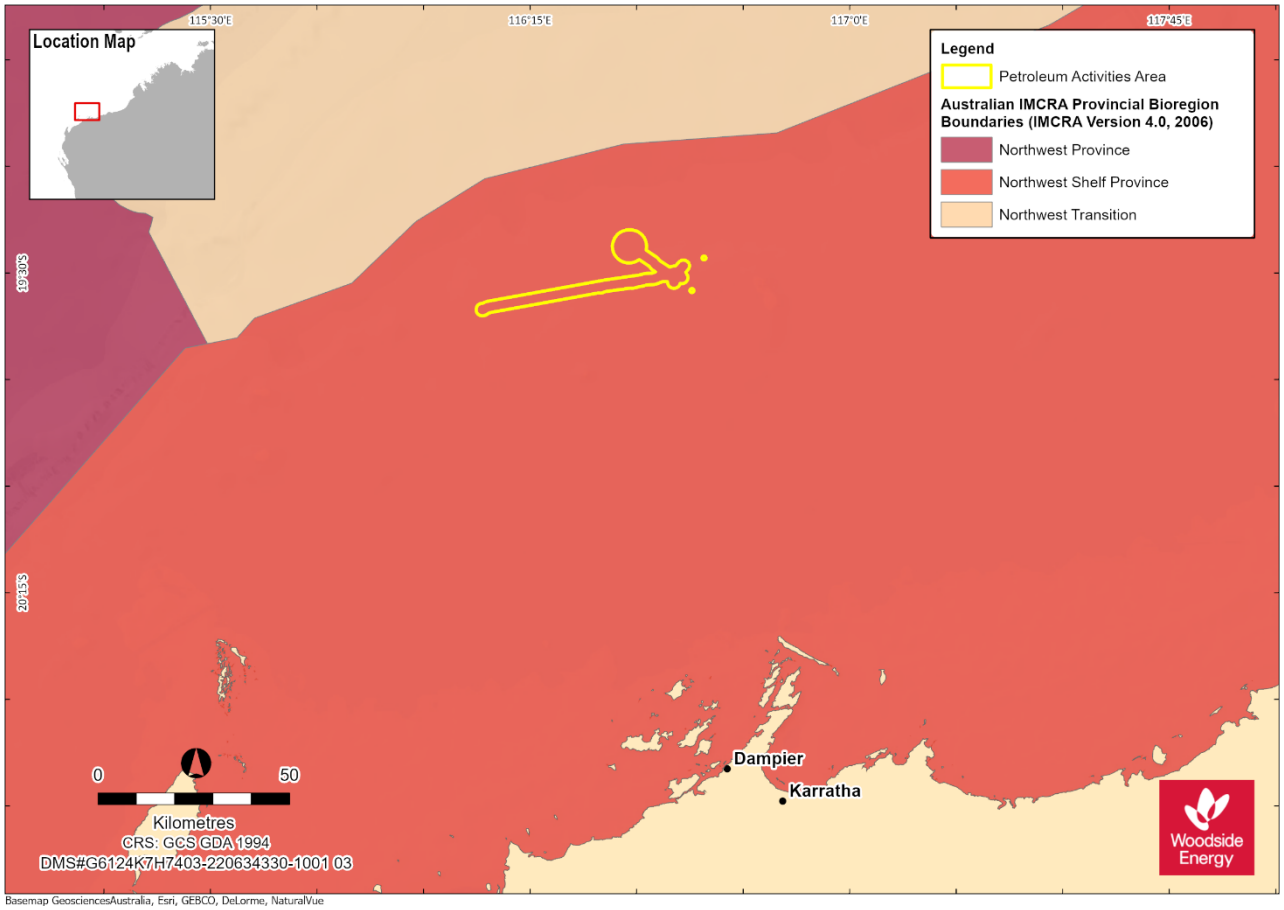

Figure 4-2: Location of the Petroleum Activities Area and relevant marine bioregions

4.3 Matters of National Environmental Significance (Environment Protection and Biodiversity Conservation Act)

Table 4-2 and **Table 4-3** summarise the MNES overlapping the PAA and EMBA, respectively, according to Protected Matters Search Tool (PMST) results (**Appendix C-2**). It should be noted that the EPBC Act PMST is a general database that conservatively identifies areas in which protected species have the potential to occur.

Additional information on these MNES is provided in subsequent sections of this chapter and described in detail in **Appendix C** and **Section 3**.

4.4 Physical Environment

The PAA lies in waters approximately 70 m to 130 m deep on the continental shelf (**Figure 4-3**). The bathymetry within the PAA is generally flat, which is consistent with the broader NWS Province shelf region (Baker et al., 2008). The seabed has a gentle (0.05°) seaward gradient, extending to a relatively steep outer slope approximately 200 to 300 km offshore in water depths of around 200 m (Dix et al., 2005). The continental slope then descends more rapidly from the shelf edge to depths greater than 1000 m to the north-west (James et al., 2004).

Appendix C and **Section 2** provide a summary of the physical characteristics of the environment within the EMBA and broader NWMR.

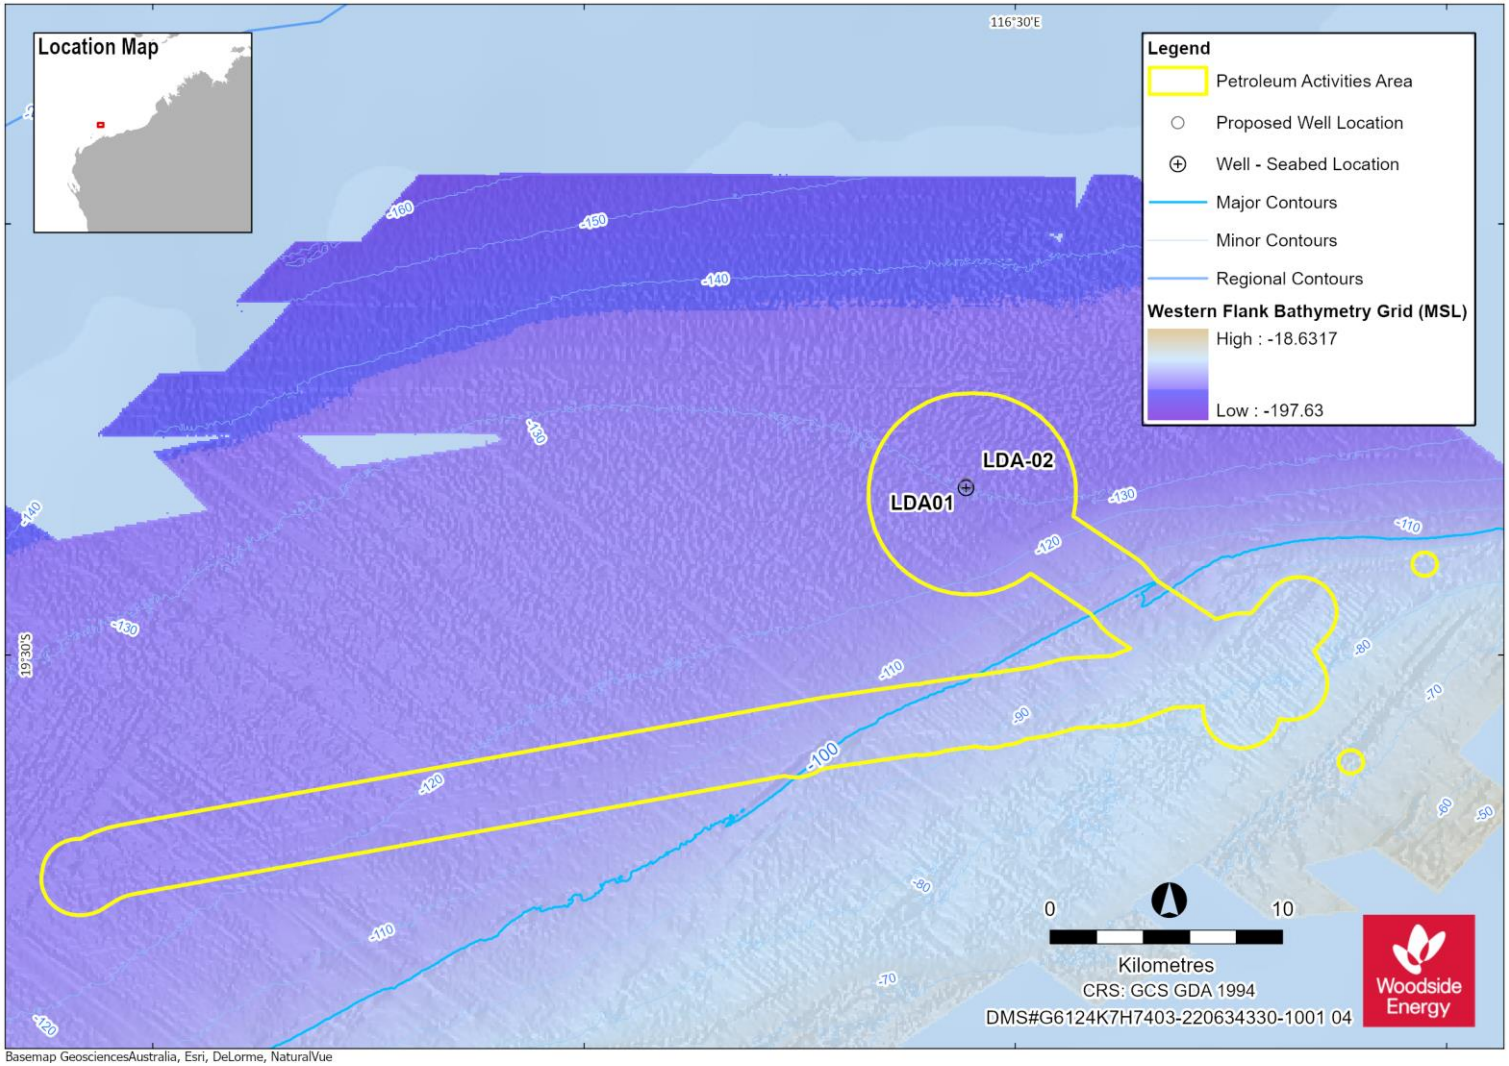

Figure 4-3: Bathymetry of the Petroleum Activities Area

4.5 Habitats and Biological Communities

Sediments in the PAA are broadly consistent with those in the NWS Province, as found in a survey conducted by BMT in 2021 around the Angel facility which found across all sites tested, the sediments collected were predominantly well sorted, yellow/brown coloured fine to coarse sand with large proportions of shell fragments (BMT, 2021). Based on surveys conducted in 2014, as part of the Lambert Deep baseline investigations the sediment surveyed within the PAA are classified as sub-littoral sediments predominantly coarse silt and some shell fragments with burrows, mounds, polychaetes and occasional hydroids, interspersed with areas of muddy sand and occasionally polychaetes and sparse epibiota (Jacobs, 2014).

This is reasonably consistent with the Woodside sampling programs undertaken at Glomar Shoals and the Goodwyn Alpha (GWA) platform (Australian Institute of Marine Science (AIMS), 2014a; BMT Oceanica, 2015a). Sediments in the outer NWS Province are relatively homogenous and are typically dominated by sands and a small portion of gravel (Baker et al., 2008). Fine sediment size classes (e.g., muds) increase with proximity to the shoreline and the shelf break, but are less prominent in the intervening continental shelf (Baker et al., 2008). Carbonate sediments typically account for the bulk of sediment composition, with both biogenic and precipitated sediments present on the outer shelf (Dix et al., 2005). Beyond the shelf break, the proportion of fine sediments increases along the continental slope towards the Exmouth Plateau and the abyssal plain (Baker et al., 2008).

Glomar Shoals KEF itself lies approximately 15 km east of the PAA (**Figure 4-3**). These submerged shoals are large (215 km^2), complex bathymetrical features on the outer continental shelf off the Pilbara. Glomar Shoals rises gently on the south-west side of the reef from 80 m depth to a single plateau at 40 m depth. The north-eastern side of the reef rises steeply from 70 m to 40 m depth. The shoals are relatively shallow, with water depths reaching 22 to 28 m at its shallowest point. Glomar Shoals has been identified as a KEF of the continental shelf within the NWMR, based on its regionally important habitat supporting high biological diversity and high localised productivity (Falkner et al., 2009). On a regional level, the Glomar Shoals KEF is also known to be an important area for commercial and recreational fish species. Approximately 0.015% of the KEF overlaps the PAA (**Figure 4-11**), in water depths between 65 and 72 m. Together with Rankin Bank, these remote shallow water areas represent regionally unique habitats and are likely to play an important role in the productivity of the Pilbara region (AIMS, 2014b; Wahab et al., 2018).

Benthic habitats of the Glomar Shoals KEF vary with depth and are characterised by coarse unconsolidated sediment at depths greater than 60 m to hard substrate supporting benthic communities comprising spare hard and soft corals sponges and macroalgae at depths <40 m. Total cover of benthic taxa (hard coral, soft coral, sponges and other benthic biota) is highest at depths <40 m and decreases with depth (Wahub, 2018). At depths of 60 to 80 m, benthic cover is low and approximately 2%; at depths greater than 80 m, benthic cover is barely present, with baseline survey data indicating 0.1% cover of benthic biota. The results of a baseline survey and habitat modelling undertaken by AIMS in 2013 indicate the portion of the Glomar Shoals KEF overlapping the PAA is composed of soft sediment seabed and not areas of higher, phototrophic benthic biota (AIMS, 2014). Structurally complex biodiverse benthic habitats are mainly found within the north-eastern portion of Glomar Shoals KEF.

Overall, the benthic habitats of the Glomar Shoals KEF are considered pristine and hosts regionally distinct ecological communities. The fish abundance and diversity of the demersal fish communities of the Glomar Shoals KEF are influenced by the seabed habitat type, with genera associated with sandy habitats common, including threadfin breams (Nerripterus spp.) and triggerfish (Abalisters spp.). Species richness and abundance are influenced by habitat depth and the degree of coral cover. In general, the fish abundance and diversity of the Glomar Shoals KEF are considered comparable with other reefs and the submerged shoals and banks in the region, although less diverse and abundant than fish assemblages at Rankin Bank (Wahab et al., 2018).

The PAA overlaps the Ancient Coastline KEF, an ancient submerged coastline, with areas of hard substrate which provides habitat that supports the KEF's higher diversity and enhanced species richness, relative to the surrounding area. The KEF is relatively poorly understood; however, the following fauna are associated with the escarpment: crinoids, molluscs, echinoderms sponges, corals and other benthic invertebrates representative of hard substrate fauna in the region.

Within the Ancient Coastline KEF, several discrete areas of hard substrate exist, which play host to sessile filter feeding communities. However, from five sample locations within the PAA conducted in 2014 as part of the Lambert Deep baseline surveys, two overlap the Ancient Coastline KEF, with no areas of habitat characterised by hard substrate found (Jacobs, 2014). The sediment identified within the samples that are found within both the PAA and the Ancient Coastline KEF are characterised by sublittoral sediment with a mix of coarse silt and fine sand.

Although several areas with sensitive habitat and features are present within the EMBA and PAA, the majority of the seabed is characterised by relatively expansive areas of featureless sandy substrate.

Key habitats and ecological communities within the EMBA are identified in **Table 4-4** and described in **Appendix C** Section 4.4.

Table 4-4: Key sensitive habitats and communities within the environment that may be affected (distance calculated from Petroleum Activities Area)

Habitat/community	Key locations within the EMBA
Seabed characteristics	
Rankin Bank	Rankin Bank is a sedimentary bank located on the continental shelf approximately 59 km west of the PAA and approximately 105 km away from the Angel facility. The bank rises from around 40 to 50 m to 18 m below the sea surface. The formation includes three major shallow banks (18 to 30 m) defined by the 50 m bathymetric contour (Australian Institute of Marine Science (AIMS), 2014a).
Ancient Coastline at 125 m Depth Contour	The Ancient Coastline at 125 m Depth Contour, overlaps the Lambert West Operational Area (DAWE, 2019a). Areas of this KEF comprise hard substrate and may occur within the PAA. Hard substrate seabed habitats present within the Lambert West Operational Area are likely to support filter feeding biota such as sponges and gorgonians (sea whip and fans), as reported for hard substrate seabed habitat in similar water depths along this outer shelf area of the NWS. Seabed habitat comprising hard substrates were not identified during a video benthic habitat and box grab seabed sediment sampling survey of the Lambert Deep development area (Jacobs, 2014). A previous geophysical survey of this area, however, had identified a scarp area in proximity to two of the sample locations (Fugro Survey Pty Ltd, 2002; Jacobs, 2014). Observations of old dead coral fragments and coral rubble were made at these same two sample locations during the 2014 survey (Jacobs, 2014). Hard substrate seabed habitats present within the Lambert West Operational Area are likely to support filter feeding biota such as sponges and gorgonians (sea whip and fans), as reported for hard substrate seabed habitat in similar water depths along this outer shelf area of the NWS. A reconnaissance survey undertaken of the pipeline route linking the Angel platform and NRC indicated occasional outcrops of cemented substrate occur in localised depressions and identified a plateau-like structure up to 4 m higher than the flat, unconsolidated soft sediment seabed habitat of the south-west section of the proposed pipeline route (SKM, 2006). Further supporting the potential for sparse outcrops of hard substrate within the PAA which is predominantly composed of a flat, unconsolidated soft sediment seabed habitat.

Habitat/community	Key locations within the EMBA
Marine primary producers	
Coral	• Glomar Shoals (15 km east) • Rankin Bank (59 km west) • Montebello Islands (106 km south-west) • Barrow Island (139 km south-west) • Muiron Islands (289 km south- west) • Ningaloo Coast (319 km south-west)
Seagrass beds and macroalgae	• Montebello Islands (106 km south-west) • Barrow Island (139 km south-west) • Muiron Islands (289 km south- west) • Ningaloo Coast (319 km south- west) • Exmouth Gulf (352 km south-west)
Mangroves	• Montebello Islands (106 km south-west) • Ningaloo Coast (319 km south- west) • Exmouth Gulf (352 km south-west)
Other communities and habitats	
Plankton	Plankton within the PAA and EMBA are expected to be representative of the wider NWMR, as detailed in **Appendix C** Section 4.3. Peak primary productivity within the EMBA occurs in late summer/early autumn, along the shelf edge of the Ningaloo Reef. It also links to a larger biologically productive period in the area that includes mass coral spawning events, peaks in zooplankton and fish larvae abundance (Department of Conservation and Land Management, 2005a) with periodic upwelling throughout the year. Further detail regarding productivity at other notable locations within the EMBA (e.g., North-west Cape) is provided in **Appendix C** Section 4.3.3.
Pelagic and demersal fish populations	Pelagic and demersal fish populations within the PAA and EMBA are expected to be representative of the NWMR (described in **Appendix C** Section 5.3). Notably, the presence of subsea infrastructure associated with the Angel facility and associated infrastructure has resulted in the development of demersal fish communities that would otherwise not occur in the PAA (McLean et al., 2017). Particular features within the EMBA that are known to support pelagic and demersal fish populations include The Ancient Coastline at 125 m Depth Contour KEF (which is mapped as overlapping the Angel Operational Area), The Continental Slope Demersal Fish Communities KEF, Rankin Bank and Glomar Shoals KEF (including the Glomar Shoals KEF). Detail regarding these features is provided in **Appendix C** Section 9.
Epifauna and infauna	Filter feeders such as sponges, ascidians, soft corals, and gorgonians are animals that feed by actively filtering suspended matter and food particles from water by passing the water over specialised filtration structures (DEWHA, 2008). Filter feeders within the EMBA are expected to be representative of the NWMR, with notable areas of high sponge diversity occurring in the Commonwealth Waters of Ningaloo Marine Park and at shoals within the EMBA. Discrete areas of hard substrate hosting sessile filter feeding communities may also be associated within the Ancient Coastline at the 125 m Depth Contour KEF, which overlaps the Angel Operational Area. However, no areas of hard substrate characteristic of this KEF have been identified within the Angel Operational Area (Jacobs, 2014). Filter feeder communities within the PAA are present on the subsea infrastructure and Angel platform, which provides hard substrate for attachment (Jacobs, 2014).

4.6 Protected Species

A total of 67 EPBC Act listed species considered to be MNES were identified as potentially occurring within the EMBA, of which a subset of 43 species were identified as potentially occurring within the PAA. The full list of marine species identified from the PMST reports is provided in **Appendix C**, including several MNES that are not considered to be credibly impacted (e.g., terrestrial species within the EMBA). Criteria for determining species to be considered for impact assessment is outlined in **Appendix C-1** Section 3.2.

Species identified as potentially occurring within the PAA and EMBA, and relevant biologically important areas (BIAs) and habitat critical to their survival (Habitat Critical) are listed in **Table 4-5** to **Table 4-13**. A description of these species is included in **Appendix C-1** and shows the spatial overlap with relevant BIAs and Habitat Critical areas and the PAA and EMBA.

4.6.1 Fish, Sharks and Rays

Table 4-5: Threatened and migratory fish, shark and ray species predicted to occur within the Petroleum Activities Area and environment that may be affected

Species name	Common name	Threatened status	Migratory status	Potential for interaction	
				PAA	EMBA
Pristis zijsron	Green sawfish	Vulnerable	Migratory	Species or species habitat known to occur within area.	Species or species habitat known to occur within area.
Rhincodon typus	Whale shark	Vulnerable	Migratory	Foraging, feeding or related behaviour known to occur within area.	Foraging, feeding or related behaviour known to occur within area.
Carcharadon carcharias	White shark	Vulnerable	Migratory	Species or species habitat may occur within area.	Species or species habitat known to occur within area.
Pristis pristis	Freshwater sawfish	Vulnerable	Migratory	Species or species habitat may occur within area.	Species or species habitat likely to occur within area.
Carcharias taurus	Grey nurse shark	Vulnerable	N/A	Species or species habitat likely to occur within area.	Species or species habitat known to occur within area.
Pristis clavata	Dwarf sawfish	Vulnerable	Migratory	N/A.	Species or species habitat known to occur within area.
Sphyrna lewini	Scalloped hammerhead	Conservation Dependant	N/A	Species or species habitat likely to occur within area.	Species or species habitat known to occur within area.
Thunnus maccoyii	Southern bluefin tuna	Conservation Dependent	N/A	Breeding known to occur within area.	Breeding known to occur within area.
Anoxypristis cuspidata	Narrow sawfish	N/A	Migratory	Species or species habitat known to occur within area.	Species or species habitat known to occur within area.
Carcharhinus longimanus	Oceanic whitetip shark	N/A	Migratory	Species or species habitat likely to occur within area.	Species or species habitat likely to occur within area.
Manta birostris	Giant manta ray	N/A	Migratory	Species or species habitat likely to occur within area.	Species or species habitat known to occur within area.
Isurus paucus	Longfin mako	N/A	Migratory	Species or species habitat likely to occur within area.	Species or species habitat likely to occur within area.

Species name	Common name	Threatened status	Migratory status	Potential for interaction	
				PAA	EMBA
Manta alfredi	Reef manta ray	N/A	Migratory	Species or species habitat likely to occur within area.	Species or species habitat known to occur within area.
Isurus oxyrinchus	Shortfin mako	N/A	Migratory	Species or species habitat likely to occur within area.	Species or species habitat likely to occur within area.
Lamna nasus	Porbeagle	N/A	Migratory	N/A.	Species or species habitat may occur within area.

Table 4-6: Fish, shark and ray biologically important areas within the Petroleum Activities Area and environment that may be affected

Species	BIA type	Approximate distance and direction of BIA from PAA (km)
Whale shark	Foraging (northward from Ningaloo along 200 m isobath)	Overlaps
	Foraging (high density prey) (Ningaloo Marine Park and adjacent Commonwealth waters)	339 km south-west

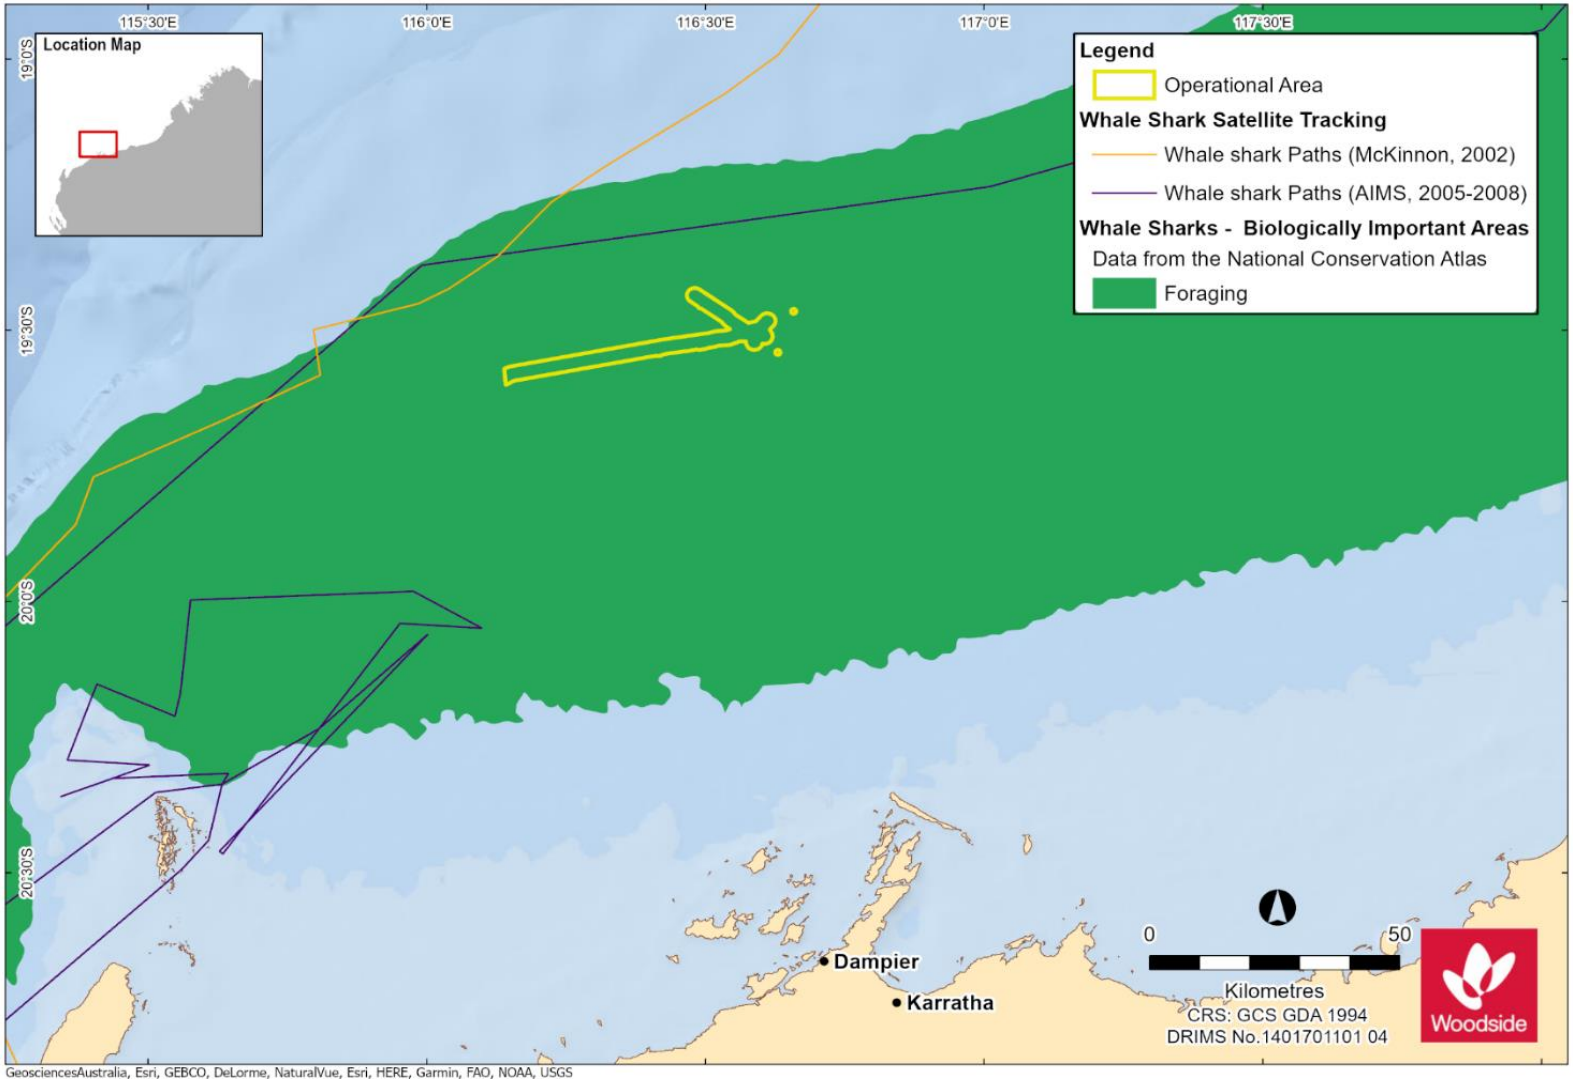

Figure 4-4: Whale shark biologically important areas overlapping the Petroleum Activities Area and satellite tracks of whale sharks tagged between 2005 and 2008 (Double et al., 2012, 2014)

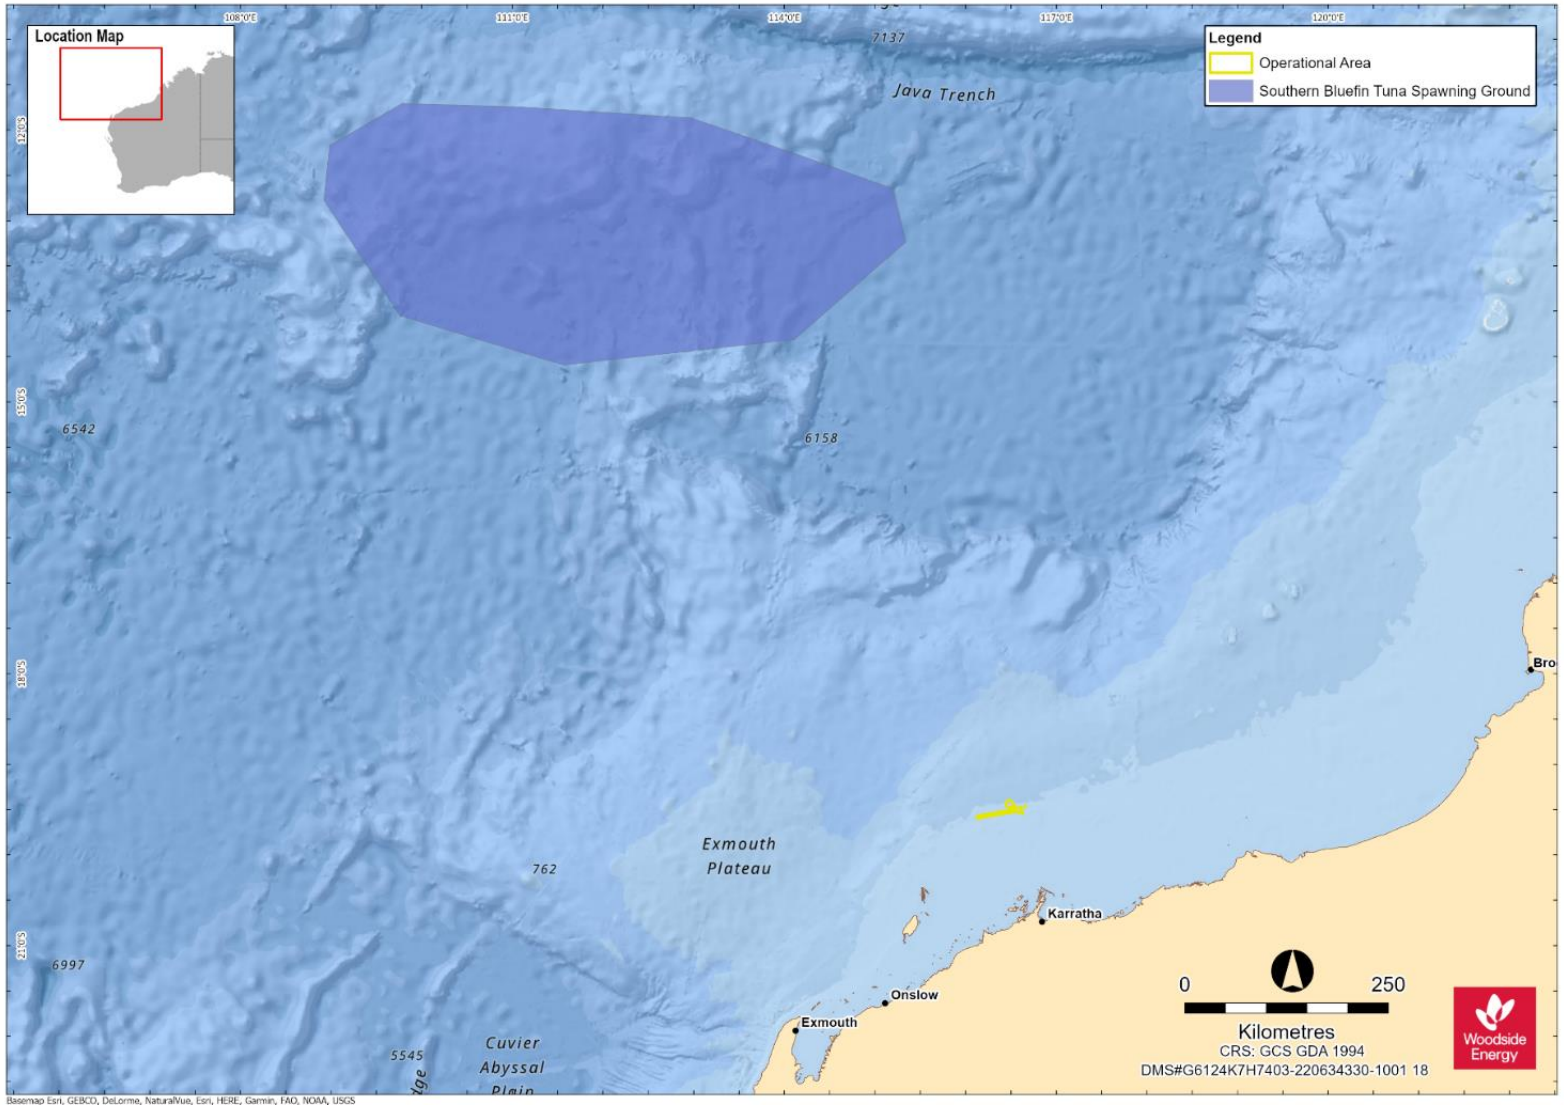

Figure 4-5: Southern blue fin tuna spawning ground

4.6.2 Marine Reptiles

Table 4-7: Threatened and migratory marine reptile species predicted to occur within the Petroleum Activities Area and environment that may be affected

Species name	Common name	Threatened status	Migratory status	Potential for interaction	
				PAA	EMBA
Natator depressus	Flatback turtle	Vulnerable	Migratory	Congregation or aggregation known to occur within area.	Breeding known to occur within area.
Chelonia mydas	Green turtle	Vulnerable	Migratory	Species or species habitat likely to occur within area.	Breeding known to occur within area.
Eretmochelys imbricata	Hawksbill turtle	Vulnerable	Migratory	Species or species habitat likely to occur within area.	Breeding known to occur within area.
Dermochelys coriacea	Leatherback turtle	Endangered	Migratory	Species or species habitat likely to occur within area.	Species or species habitat known to occur within area.
Caretta caretta	Loggerhead turtle	Endangered	Migratory	Species or species habitat likely to occur within area.	Breeding known to occur within area.
Aipysurus foliosquama	Leaf-scaled seasnake	Critically Endangered	N/A	Species or species habitat likely to occur within area.	Species or species habitat known to occur within area.
Aipysurus apraefrontalis	Short-nosed seasnake	Critically Endangered	N/A	Species or species habitat known to occur within area.	Species or species habitat known to occur within area.

Table 4-8: Marine turtle biologically important areas within the environment that may be affected

Species	BIA type (closest location)	Approximate distance and direction of BIA from PAA (km)
Flatback turtle	Internesting Buffer (Dampier Archipelago; Legendre Is, Huay Is, Montebello Is – Hermite Is, NW Is, Trimouille Is, Delambre Is, Intercourse Is, Dixon Island, West of Cape Lambert, Cape Thouin/Mundabullangana/Cowrie Beach, Thevenard Island – South coast, North Turtle Island)	15 km south
	Mating (Montebello Is - Hermite Is, NW Is, Trimouille Is, coral reef habitat west of the Montebello group, Barrow Island)	103 km south-west
	Nesting (Montebello Is - Hermite Is, NW Is, Trimouille Is, Barrow Island, Thevenard Island – south coast)	103 km south-west
	Foraging (Montebello Is - Hermite Is, NW Is, Trimouille Is, Coral reef habitat west of the Montebello group, string of islands between Cape Preston and Onslow, inshore of Barrow Is, Barrow Island)	103 km south-west

Species	BIA type (closest location)	Approximate distance and direction of BIA from PAA (km)
	Aggregation (coral reef habitat west of the Montebello group)	117 km south-west
	Internesting (coral reef habitat west of the Montebello group)	117 km south-west
Green turtle	Internesting Buffer (Montebello Islands, Montebello Is – Hermite Is, NW Is, Trimouille Is, Middle Is. West Coast Barrow Island West Coast and North Coast, North and South Muiron Is and North West Cape)	78 km south-west
	Mating (Montebello Islands, Montebello Is - Hermite Is, NW Is, Trimouille Is, Coral reef habitat west of the Montebello group, Middle Is. West Coast Barrow Island West Coast and North Coast)	98 km south-west
	Nesting (Montebello Islands, Montebello Is – Hermite Is, NW Is, Trimouille Is, Middle Is. West Coast Barrow Island West Coast and North Coast, North and South Muiron Is, North West Cape)	98 km south-west
	Internesting (Montebello Islands, Coral reef habitat west of the Montebello group, Barrow Island)	98 km south-west
	Foraging (Montebello Islands, Montebello Is – Hermite Is, NW Is, Trimouille Is, Coral reef habitat west of the Montebello group, String of islands between Cape Preston and Onslow, inshore of Barrow Is, inshore tidal and shallow subtidal areas around Barrow Island)	98 km south-west
	Aggregation (Coral reef habitat west of the Montebello group)	117 km south-west
	Basking (Middle Is. West Coast Barrow Island West Coast and North Coast)	137 km south-west
Hawksbill turtle	Internesting Buffer (Montebello Is - Hermite Is, NW Is, Trimouille Is, Ah Chong and South East Is, Montebello Is, Trimoulle and NW islands, Lowendal Island Group, Varanus Island, Barrow Island, Thevenard Island, Ningaloo coast and Jurabi coast)	84 km south-west
	Foraging (Montebello Is – Hermite Is, NW Is, Trimouille Is, Lowendal Island Group, String of islands between Cape Preston and Onslow, inshore of Barrow Is, shallow water coral reef and artificial reef (pipeline) habitat)	104 km south-west
	Mating (Montebello Is – Hermite Is, NW Is, Trimouille Is, Lowendal Island Group, Barrow Island)	104 km south-west
	Nesting (Montebello Is – Hermite Is, NW Is, Trimouille Is, Ah Chong and South East Is, Montebello Is, Trimoulle and NW islands, Lowendal Island Group, Barrow Island, Thevenard Island, Ningaloo coast and Jurabi coast)	104 km south-west
	Internesting (Lowendal Island Group)	126 km south-west
Loggerhead turtle	Internesting (Montebello Islands, Lowenthal Island, Muiron Island, Ningaloo coast and Jurabi coast)	92 km south-south-west
	Nesting (Montebello Islands, Lowenthal Island, Muiron Island, Ningaloo coast and Jurabi coast)	112 km south-west
Leatherback turtle	*No BIAs within the EMBA or PAA*	

Table 4-9: Habitat critical to the survival of marine turtle species occurring within the environment that may be affected

Species	Genetic stock	Nesting locations	Approximate distance and direction from PAA (km)	Inter-nesting buffer	Nesting period	Hatching period
Flatback turtle	South-west Kimberley	Eighty Mile Beach, Eco Beach, Lacepede Islands (some within the EMBA)	34 km south-east	60 km	All year (peak: Dec to Jan)	All year
	Pilbara	Montebello Islands, Mundabullangana Beach, Barrow Island, Cemetery Beach, Dampier Archipelago (including Delambre Island and Huay Island), coastal islands from Cape Preston to Locker Island (some within the EMBA)	34 km south	60 km	Oct to Mar (peak: Nov to Jan)	Feb to Mar
Green turtle	North West Shelf	Adele Island, Maret Island, Cassini Island, Lacepede Islands, Barrow Island, Montebello Islands (all with sandy beaches), Serrurier Island, Dampier Archipelago, Thevenard Island, Northwest Cape, Ningaloo coast (some within the EMBA)	86 km south	20 km	Nov to Mar (peak: Dec to Feb)	Jan to May (peak: Feb to Mar)
Hawksbill turtle	Western Australia	Dampier Archipelago (including Rosemary Island and Delambre Island), Montebello Islands (including Ah Chong Island, South East Island and Trimouille Island), Lowendal Islands (including Varanus Island, Beacon Island and Bridled Island), Sholl Island (some within the EMBA)	86 km south	20 km	All year (peak: Oct to Jan)	All year (peak: Dec to Feb)
Loggerhead turtle	Western Australia	Dirk Hartog Island, Muiron Islands, Gnaraloo Bay, Ningaloo coast (some within the EMBA)	300 km south-west	20 km	Nov to Mar (peak: Jan)	Jan to May
Leatherback turtle	*No overlap – nesting located in Northern Territory and North Queensland*

[9] Double et al, 2010

Species	January	February	March	April	May	June	July	August	September	October	November	December
Humpback whale – southern migration [8]												
Sei whale – migration (DEH, 2005)												
East Indian Ocean (EIO) pygmy blue whale – northern migration[10]												
East Indian Ocean (EIO) pygmy blue whale – southern migration [10]												
Seabirds and shorebirds												
Red knot – non-breeding season (NWMR) [11]												
Eastern curlew – non-breeding (NWMR) [12]												
Wedge-tailed shearwater – various breeding sites [13 14]												
	Species may be present in the PAA											
	Peak period. Presence of animals is reliable and predictable each year											

4.7 Key Ecological Features

Two KEFs overlap the PAA (**Figure 4-11**). KEFs within the PAA and EMBA are identified in **Table 4-15** and described in **Appendix C** Section 9.

Table 4-15: Key ecological features within the Petroleum Activities Area and environment that may be affected

Key ecological feature	Distance and direction from PAA to KEF (km)
Ancient Coastline at the 125 m depth contour	Overlaps
Glomar Shoals KEF	Overlaps
Continental Slope Demersal Fish Communities	68 km west
Exmouth Plateau	180 km west
Canyons Linking the Cuvier Abyssal Plain and the Cape Range Peninsula	258 km south-west
Commonwealth Waters Adjacent to Ningaloo Reef	304 km south-west
Mermaid Reef and Commonwealth waters surrounding Rowley Shoals	302 km north-east*

**KEF is outside of EMBA, but given proximity (approximately 800 m) it has been included*

**Conservation objectives for IUCN categories include:*

Ia: Strict Nature Reserve

Ib: Wilderness Area

II: National Park

III: Natural Monument or Feature

IV: Habitat/Species Management Area

V: Protected Landscape

VI: Protected area with sustainable use of natural resources – allow human use but prohibits large scale development.

IUCN categories for the marine park are provided and, in brackets, the IUCN categories for specific zones within each Marine Park as assigned under the North-west Marine Parks Network Management Plan 2018 and South-west Marine Parks Network Management Plan 2018.

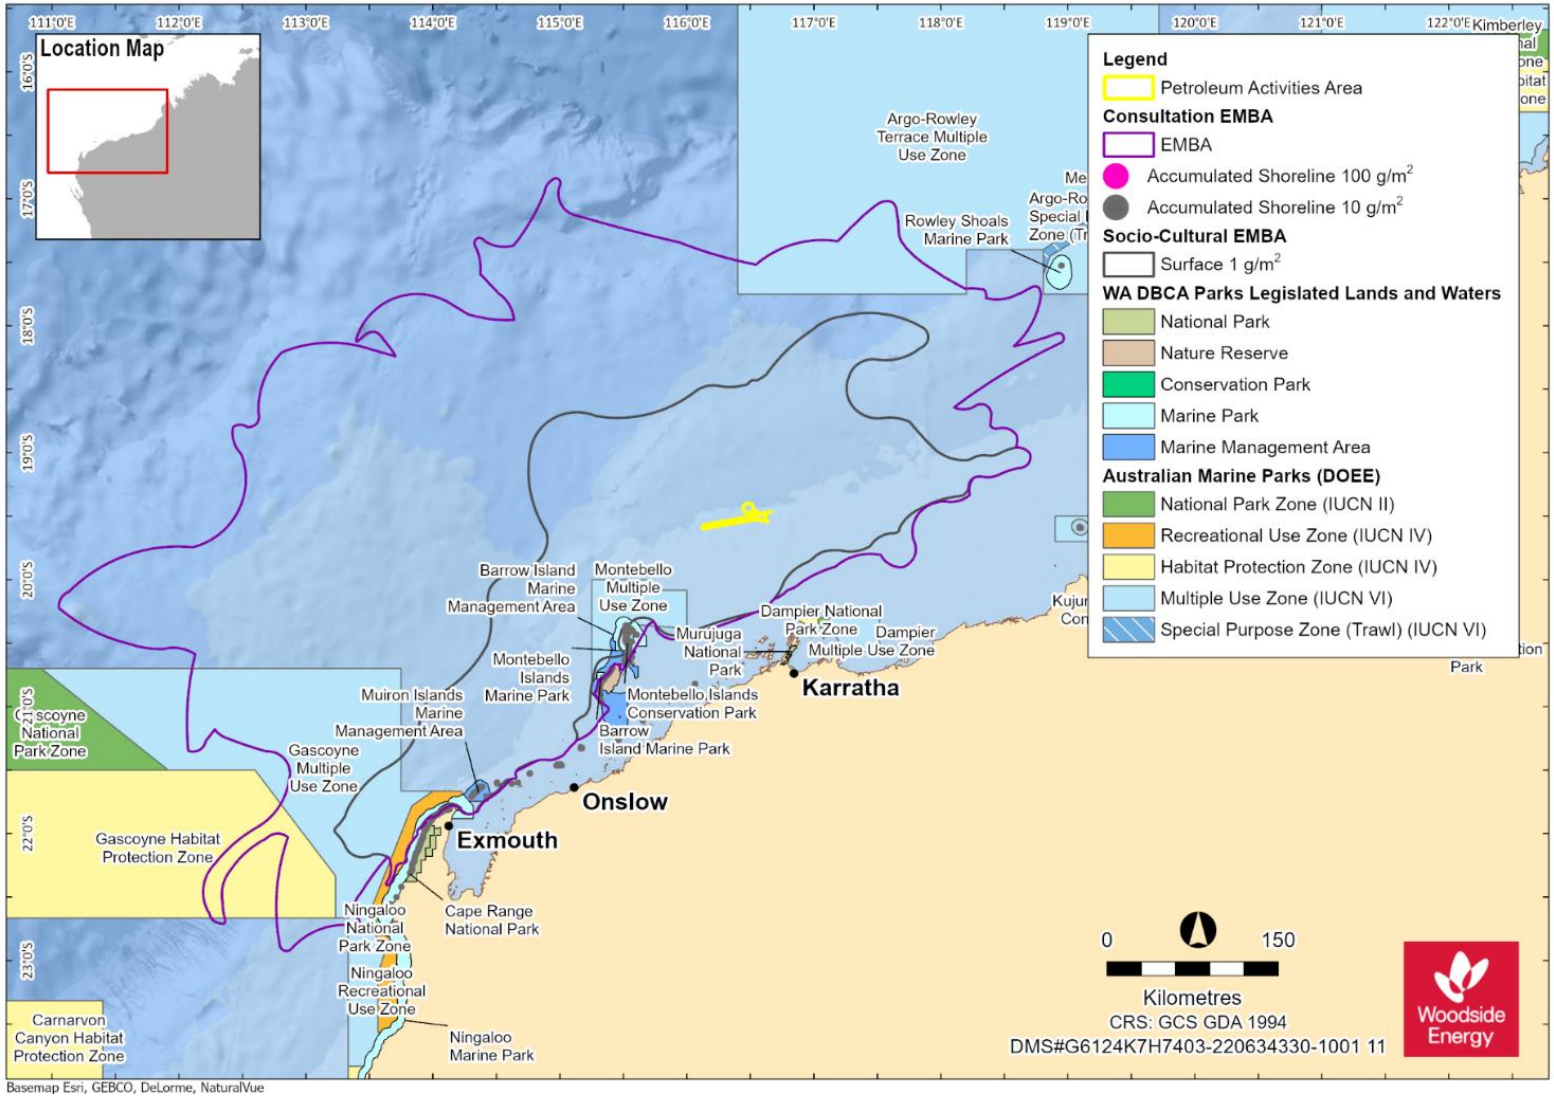

Figure 4-12: Protected Areas adjacent to the Petroleum Activities Area and environment that may be affected

4.9 Socio-economic Environment

4.9.1 Cultural Values and Heritage

4.9.1.1 Background

Woodside recognises the 'environment' for the purpose of the evaluation required under the Environment Regulations includes:

- the heritage value of places
- the social, economic and cultural features of the broader environment.

In this section, the heritage value of places within the PAA and EMBA and the cultural features of the Operational Area and EMBA are described.

In line with The Burra Charter: The Australia ICOMOS Charter for Places of Cultural Significance (ICOMOS, 2013) (Burra Charter) and associated practice notes, Woodside understands heritage value to refer to the cultural significance of a place to an individual group. A cultural feature, by contrast, is understood to be comparable to the Burra Charter term “fabric” and refer to a place’s elements, fixtures, contents and objects which have cultural values. Although these features are necessarily physical, the place they inhabit or comprise may have tangible or intangible dimensions (ICOMOS, 2013).

4.9.1.2 First Nations Peoples

As a starting point for understanding social and cultural features of the environment for Indigenous (First Nations) groups, Woodside uses the existing systems, such as native title, to identify Indigenous groups that may have functions, interests or activities that may be affected. To that end, Woodside identifies native title representative bodies and nominated representative entities (defined in **Section 5.3**), as well as native title claims, determinations and Indigenous Land Use Agreements (ILUAs) which the EMBA overlaps. While acknowledging that cultural features and heritage values may exist outside of the native title framework, Native title claims, determinations and ILUAs are defined under the *Native Title Act 1993 (Cth)*. Woodside considers this to be the broadest extent over which Indigenous groups have claimed native title rights and interests.

Native title claims are applications made to the Federal Court under the *Native Title Act* for a determination or decision about native title in a particular area. A claim is made by a native title claim group which asserts it holds native title rights and interests in an area of land and/or water, according to its traditional laws and customs. By making a claim, the native title claim group seeks a decision that native title exists so that its native title rights and interests are recognised by the common law of Australia. This is called a native title determination. A determination is a decision by a recognised body, such as the Federal Court or High Court of Australia, that native title either does or does not exist in relation to a particular area (National Native Title Tribunal).

A requirement to establish a positive determination of native title in court is proving that there is an organised society that occupied the land and/or waters at the time of British annexation. The requirement of an ‘organised society’ is set out by Justice Toohey in the historic judgment of Mabo v Queensland (No 2) [1992] HCA 23; (1992) 175 CLR 1 (‘Mabo’). Justice Toohey had the following to say (at 187):

it is inconceivable that indigenous inhabitants in occupation of land did not have a system by which land was utilised in a way determined by that society. There must, of course, be a society sufficiently organised to create and sustain rights and duties…

Therefore, Woodside understands native title rights and interests are held communally by an organised society, that native title claims are understood to represent the area over which Indigenous groups are claiming these rights and interests, and that native title determinations provide clarity on

where native title rights and interests are found to either exist or not exist. Where native title rights or interests are determined to exist, they will be held by a Registered Native Title Body Corporate (section 57, *Native Title Act 1993*) in trust or as agent for native title holders.

ILUAs are voluntary agreements between native title parties and other people or bodies about the use and management of land and/or waters and are registered by the Native Title Registrar on the Register of ILUAs. An ILUA can be made over areas where:

- native title has been determined to exist in at least part of the area, or
- a native title claim has been made, or
- where no native title claim has been made.

While registered, ILUAs operate as a contract between the parties, including relevant native title holders (Native Title Tribunal).

The *Native Title Act* provides for a Representative Aboriginal/Torres Strait Islander Body (Native Title Representative Body) to be recognised by the Commonwealth Minister for an area. Native Title Representative Bodies have specialist functions set out in the *Native Title Act* within the area for which they are the Native Title Representative Body. However, the functions of a Native Title Representative Body are such that they do not hold details on the cultural features or heritage values of an area and therefore do not inform Woodside's understanding of heritage values or cultural features.

For the activity in this EP, there are no native title claims or determinations, or ILUAs overlapping the PAA and therefore also no native title rights or interests identified over the PAA (**Table 4-17**). Claims and determinations have not been differentiated in this table, as it is acknowledged that rights and interests may exist within either of these.

There is one native title claim overlapping the EMBA (**Table 4-17**). There are no ILUAs overlapping the EMBA.

4.9.1.3 Coastally Adjacent First Nations Groups

Woodside understands that Indigenous groups are keenly aware of the extent of their rights, interests and responsibilities for Country, and these are generally discrete, defined areas, including areas of sea (Smyth, 2007). To identify cultural features and heritage values which may exist outside of a native title claim, determination and ILUA areas, Woodside considers native title claims, determinations and ILUAs coastally adjacent to the EMBA to be an instructive means of identifying potentially relevant Indigenous groups to be consulted (See **Section 5.3**).

Woodside understands from engagement with relevant persons and/or organisations, that extending a native title group's responsibility to areas which those groups have elected to not include in their claims or ILUAs can have significant cultural consequences for Indigenous groups and individuals. This may also, over time, build expectations in the broader Indigenous community that a group is responsible for maintaining environmental values in areas for which they do not hold traditional knowledge. Woodside also acknowledges that an Indigenous group's relative proximity to any PAA or EMBA is not necessarily a meaningful indicator of the connection of Indigenous groups to the area, and providing advice over such areas can be culturally dangerous. As a result, caution must be used when conducting broader engagement.

A summary of native title claims, determinations and ILUAs overlapping or coastally adjacent to the EMBA is set out in **Table 4-17**. Claims and determinations have not been differentiated in this table, as it is acknowledged that either of these may indicate the existence of rights and interests.

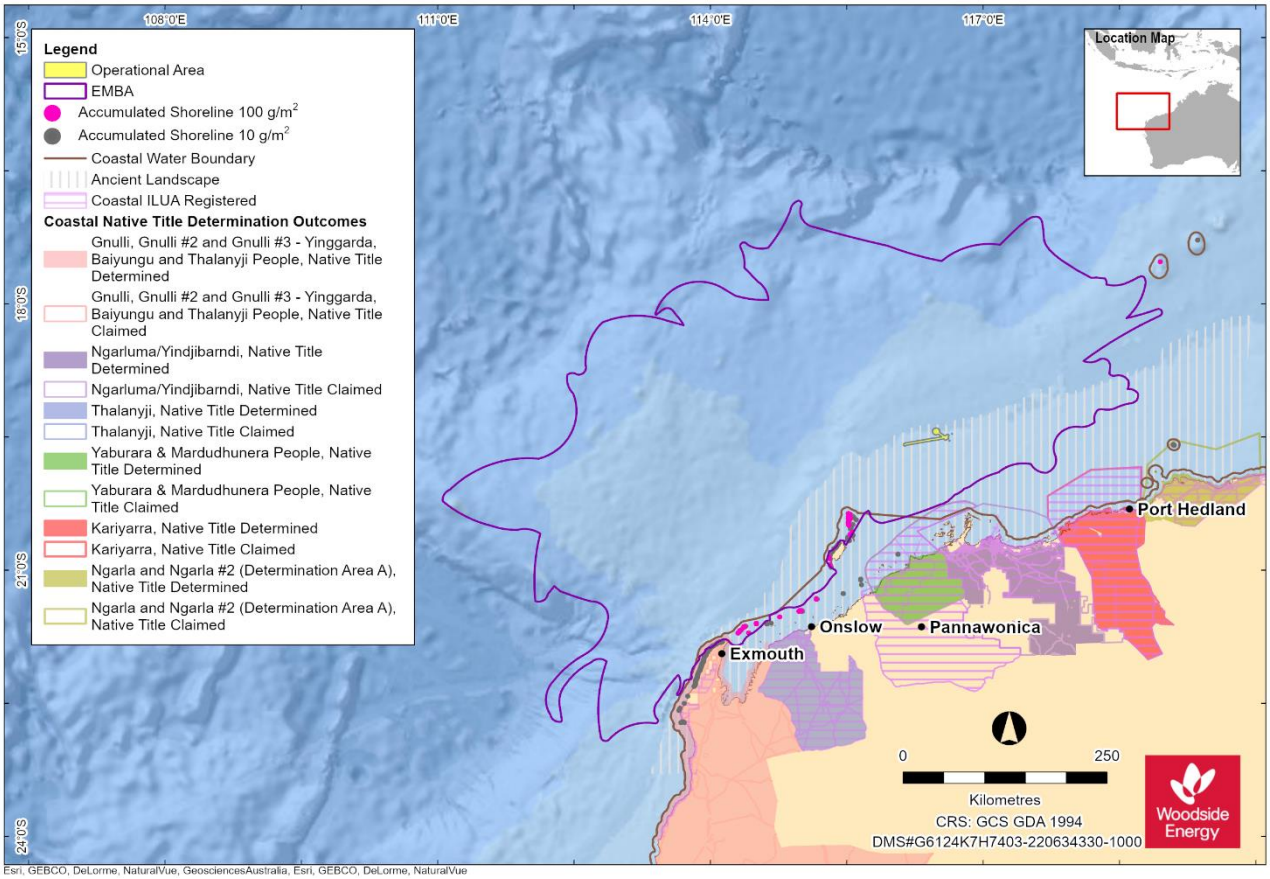

Figure 4-13: Petroleum Activities Area and socio-economic environment that may be affected in relation to native title claims, determinations and Indigenous Land Use Agreements

4.9.1.4 Marine Parks

Woodside acknowledges that Commonwealth and State Marine Park Management Plans have sought to recognise cultural values of Indigenous groups. Australian Marine Parks (AMP) describe this framework in the following way: ‘when making decisions about what can occur in marine parks and what action we will take to protect marine parks, we take values into account’. AMP summarises

these values as natural values, cultural values, heritage values and socio-economic values. Woodside is triggered to undertake an assessment of cultural values within Marine Park Management Plans where the Operational Area or EMBA overlaps a Marine Park. Woodside considers the management plans of marine parks that overlap the Operational Area and the EMBA to determine whether cultural features and heritage values have been identified and whether there are specified Traditional Custodians or representative bodies referenced to contact regarding potential cultural features and heritage values.

The PAA does not overlap any Commonwealth Marine Parks. The EMBA overlaps with features of the Argo-Rowley Terrace, Gascoyne, Montebello and Ningaloo AMPs managed under the North-West Marine Parks Network Management Plan 2018. The EMBA overlaps a further six State Marine Parks. Where these plans specify identifiable representative bodies who may hold knowledge of heritage values or cultural features – including but not limited to Registered Native Title Bodies Corporate – these bodies are consulted (**Section 5.3**). Consultation with these groups may identify heritage values and cultural features beyond those addressed in the marine park management plans. No identifiable representative bodies were specified for the marine parks overlapped by the EMBA (**Table 4-18**).

The Marine Park Management Plans note for the Gascoyne, Montebello and Ningaloo MPs that the Yamatji Marlpa Aboriginal Corporation (YMAC) is the relevant Native Title Representative Body. Consultation with YMAC included discussion of the Traditional Custodians who may hold knowledge of heritage values or cultural features (see **Appendix F** Tables 1 and 2).

Table 4-18: Summary of Commonwealth and State Marine Park Management Plan environment that may be affected overlap

Marine Park Management Plan	PAA Overlap	EMBA Overlap	Specified Bodies
Commonwealth Marine Park Management Plan			
Argo-Rowley Terrace AMP	No	Yes	No identifiable body specified.
Gascoyne AMP	No	Yes	YMAC
Montebello AMP	No	Yes	YMAC
Ningaloo AMP	No	Yes	YMAC
State Marine Park Management Plan			
Barrow Island Marine Management Area	No	Yes	No identifiable body specified.
Barrow Island MP	No	Yes	No identifiable body specified.
Cape Range National Park	No	Yes	No identifiable body specified.
Jurabi Coastal Park	No	Yes	No identifiable body specified.
Montebello Islands MP	No	Yes	No identifiable body specified.
Muiron Islands Marine Management Area	No	Yes	No identifiable body specified.
Muiron Islands Nature Reserve	No	Yes	No identifiable body specified.
Ningaloo MP	No	Yes	NTGAC

Management plans for the AMPs note shipwrecks within the AMPs and overlap with World, National and Commonwealth heritage lists. These are addressed in **Sections 4.9.1.8** and **4.9.1.9** below.

The Management Plan for the Ningaloo Marine Park and Muiron Islands Marine Management Area 2005–2015: Management Plan Number 52 (relating to the Muiron Islands Marine Management Area and Ningaloo Marine Park) notes the aesthetic values of the seascape as a cultural value and that "Panoramic vistas of turquoise lagoon waters, reefs, beaches, breaking surf and the blue open ocean beyond the reef line are major attractions of the reserves." In particular the plan notes that "Inappropriate structures along the coastline, on the islands and in the surrounding waters have the potential to degrade the aesthetic values of the reserves. Coastal developments and maritime infrastructure projects must therefore be planned with careful consideration of this issue." As the activity described in this EP does not include the addition of any structures within these parks, no impacts on the aesthetic values of these parks are anticipated.

A number of management plans for the state marine parks also note Indigenous and maritime heritage within the marine parks. These are addressed in **Sections 4.9.1.5.3** and **4.9.1.9**.

4.9.1.5 Sea Country Values

4.9.1.5.1 General Cultural Values of Marine Ecosystems

Woodside recognises the potential for marine ecosystems to include cultural features as well as environmental values. This is one aspect of the broader concept of "Sea Country", which can be defined as the area of sea over which an Indigenous group has interests, cultural value, connection and use. It has been noted that "the saltwater peoples of the north-west are associated with discrete clan estates or tribal areas, often referred to in contemporary Aboriginal English as 'saltwater country' or 'Sea Country'. 'Country' refers to more than just a geographical area: it is shorthand for all the values, places, resources, stories and cultural obligations associated with that geographical area." (Smyth, 2007). It necessarily follows that an impact to marine ecosystems has the potential to impact cultural features where the impact is detectable within sea country – the seascape which Traditional Custodians view, interact with or hold knowledge of. The link between environmental protection and

cultural heritage protection is illustrated in the Australian Government's Indigenous Protected Areas Program (IPAs). The Indigenous Protected Areas program provides for "areas of land and sea managed by Indigenous groups as protected areas for biodiversity conservation…IPAs deliver environmental benefits…Managing IPAs also helps Indigenous communities protect the cultural values of their country for future generations…" (DCCEEW, 2023). This intrinsic link is also described in MAC (2021, as cited in Woodside, 2023) as it relates to the values of the marine environment that are of cultural importance to MAC based on engagement with their Elders and Murujuga Land and Sea Unit Rangers. Elders were clear that all living things in Mermaid Sound are connected and important. Mermaid Sound and Dampier Archipelago (Murujuga) are considered one place where the entire environment and all ecosystems hold both cultural and environmental value, with these types of values (cultural and environmental) intrinsically linked (MAC, 2021, also cited in Woodside, 2023).

McNiven (2004) suggests that "For those mainland groups whose exploitation of the sea was limited to littoral resources, it is likely that seascapes extended no more than c. 20 to 30 km out to sea, out to the horizon and the limit of human visibility... However, in some coastal places, clouds that can be seen well over 100 km out to sea are imbued with spiritual significance. For those groups with elaborate canoe technology, seascapes extend well over the horizon." While there is some evidence of traditional watercraft in Australia's North West, the recorded evidence is limited to travel across inland rivers (e.g., Barber and Jackson, 2011) or travel between coastal islands (Paterson et al., 2019). The process for identifying Indigenous groups who may have interests and connection in Sea Country are set out in **Section 4.9.1.3**, **Section 4.9.1.4** and **Section 5.3**. The scope of advice Traditional Custodians were encouraged to provide through project consultation was not limited by reference to any particular boundaries or limits of sea country.

Cultural features of coastal areas may include marine species that may travel many thousands of kilometres through areas with similar cultural values to multiple Indigenous language groups. Some species may travel as far as 5000 km from Antarctica to the Kimberley region of Western Australia (Double et al., 2010, 2012), passing Indigenous language groups along the entire west coast of Australia.

As set out above, an impact to marine ecosystems has the potential to impact cultural values where the impact is detectable within Sea Country. Woodside considers that impact to cultural values of marine species will be adequately managed in areas of traditional Sea Country, and therefore management of the environmental values will preserve the cultural values of environmental receptors, as assessed in **Section 6**.

Woodside is triggered to consult on cultural values of Sea Country where Traditional Custodians or representative institutions are identified, or self-identify, as relevant persons.

4.9.1.5.2 Other Identified Cultural Values of Marine Ecosystems

During consultation, BTAC advised it has a cultural obligation to care for the environmental values of Sea Country (see **Appendix G** Table 1). Woodside has put a written proposal to BTAC to support BTAC to undertake an ethnographic assessment (to identify Sea Country values) and involve BTAC in the selection of management strategies of cultural feature and heritage values in the area relevant to BTAC.

Woodside has committed to ongoing engagement to further understand these values. Should feedback be received (including any relevant new information on cultural values), it will be assessed and, where appropriate, Woodside will apply its Management of Change and Revision process (see **Section 7.6**).

Cultural features or heritage values related to marine species within the PAA or EMBA raised by Traditional Custodians in the course of preparing the EP have been outlined in Table 4-20.

4.9.1.5.3 Desktop Assessment of Sea Country Values

Cultural features and heritage values identified in publicly available literature

Publicly available sources were assessed for any records of previously identified Sea Country values or cultural features that may overlap with the EMBA or PAA. Where cultural features or Sea Country values were identified these are summarised in Table 4-19 according to the First Nations groups (where identified or inferable) who hold these values.

All cultural features and heritage values restricted to onshore locations or inland waters have been excluded in Table 4-19, noting that the closest boundary of the PAA is greater than 125 km north-west of Dampier, and greater than 100 km from the closest landfall at North West Cape. Where the geographical extent is not specified or unclear, it has been included for completeness.

Table 4-19: Cultural features and heritage values identified in publicly available literature

First Nations Group	Features and Values	Source	Potential for overlap	
			PAA	***EMBA***
Gnulli (Baiyungu, Thalanyji, Yinggarda)	Feature: resources including marine animals. Value: traditional knowledge holds that ancestors live on the land and in the water. Therefore, people have obligations to access and care for these places (e.g. keeping them clean).	Peck on behalf of the Gnulli Native Title Claim Group v State of Western Australia [2019] FCA 2090	Possible (unspecified) Possible (unspecified)	Possible (unspecified) Possible (unspecified)
	Feature: resources including mangrove crabs, gastropods, shellfish, dugong, turtle.	Morse 1993	Possible (turtle) No (other resources)	Possible (all)
	Feature: heritage sites in the Ningaloo region include shell middens, artefact scatters, skeletal material/burial sites, camps, meeting places, hunting places and water sources.	Deloitte 2020: Economic_contribution_of_Ningaloo_-_FINAL_25_11_2020.pdf (gdc.wa.gov.au) This document also includes information that is marked that cannot be copied, reproduced or used without consent. Juluwarlu 2004	Possible (unspecified)	Possible (unspecified)
	Feature: tangible and intangible heritage. Feature: archaeological evidence of varied occupation and adaptation. Value: a distinct way of life centred around the use of limited water and coastal resources.	Macfarlane and McConnell 2017	Possible (unspecified) No (feature restricted to Ancient Landscape) No	Possible (unspecified) Possible (submerged, highly unlikely for most evidence of faunal use to survive inundation) No

4.9.1.5.4 Indigenous Archaeological Heritage Assessment

Woodside understands that communal cultural connection may exist between Traditional Custodians and land and waters. It is understood from the onshore archaeological record that Aboriginal people have occupied the Australian continent for at least 65,000 years (Clarkson et al., 2017) and in many places maintain a strong continuing connection that is said to extend back in Indigenous cosmology to the beginning of time.

It is understood that the sea level has risen significantly during the 65,000 years of Indigenous occupation, and areas that were once inhabited are now submerged on the continental shelf (Veth et al., 2019; UWA, 2021). Woodside also understands that, at its lowest level during Indigenous occupation, sea level was between 125 m (O'Leary et al., 2020; Veth et al., 2019; Williams et al., 2018) and 130 m below current levels (Benjamin et al., 2020; Benjamin et al., 2023; UWA, 2021). Archaeological material preserved on the Ancient Landscape has the potential to provide further information about the earliest periods of human occupation (Veth et al., 2019; UWA, 2021).

Recent archaeological discoveries demonstrate that the now submerged landscape was occupied and inhabited, and can retain archaeological material from this time (Benjamin et al., 2020; Benjamin et al., 2020; see Ward et al., 2021 for an opposing view).

In recognition of this, Woodside considers the Ancient Landscape between the mainland and the Ancient Coastline KEF (see **Section 4.7**) as an area where potential Indigenous archaeological material may exist on the seabed, as this covers the full extent of this possible Indigenous occupation. Known Indigenous heritage places including archaeological sites may be protected subject to declarations under the *Aboriginal and Torres Strait Islander Heritage Protection Act 1984*, *Underwate*r *Cultural Heritage Act 2018* or EPBC Act 1999. However, these Acts only extend protection to Indigenous heritage places specified by declaration or otherwise included on a statutory list. Woodside understands that there is no Indigenous archaeology known to exist anywhere within Commonwealth waters and no areas subject to declarations or prescriptions under these Acts are located within the EMBA.

The Department of Planning, Lands and Heritage (DPLH) Aboriginal Heritage Inquiry system was searched for the EMBA, which indicated no Registered Aboriginal Sites and 2 Other Heritage Places (**Appendix I**). The exact location, access, and traditional practices for a number of these sites may not be disclosed and if required, such as in the event of a major oil spill, would involve prioritising further consultation with key contacts within DPLH and relevant local Aboriginal communities.

No sites of significance within the PAA or EMBA were identified by Traditional Custodians during consultation in the course of preparing the EP.

The PAA intersects part of the Ancient Landscape but also extends beyond the furthest extent of the Ancient Landscape.

The archaeological potential of the Ancient Landscape is a relevant matter for the proposed activity as there is overlap between the PAA and the Ancient Landscape, and potential for seabed disturbance from planned activities and therefore potential for impact to archaeological material. Woodside has committed to undertake desktop assessment of archaeological potential, based on geophysical and bathymetric data, for any seabed disturbance at depths of less than 130 m (**C 3.1**).

A review will be undertaken by a suitably qualified marine archaeologist for seabed disturbance associated with the Lambert West drilling and tie-back activities, which is not inconsistent with the draft guidelines for working in the near and offshore environment to protect Underwater Cultural Heritage (DCCEEW, 2023) (see **Section 6.6.2**).

4.9.1.5.5 Feedback Received via Consultation to Inform Existing Environment Description

Indigenous cultural values are communally held. This is reflected in Vision 3 of Dhawura Ngilan that "Aboriginal and Torres Strait Islander heritage is managed... according to community ownership" (Heritage Chairs of Australia and New Zealand 2021). Dhawura Ngilan also specifically notes that "Aboriginal and Torres Strait Islander...intangible knowledge systems, which are held in songlines and language, are endangered. This knowledge is held by Elders and the community..." Through consultation with relevant persons, Registered Native Title Bodies Corporate have identified or raised topics relating to environmental values of cultural interest. These include a broad interest in the marine fauna, including whales and turtles (**Appendix F** Table 1).

During consultation, BTAC advised it has a cultural obligation to care for the environmental values of sea country (**Appendix F**). In the course of consultation specific to another Woodside EP, BTAC raised the importance of archaeological sites on nearshore islands. Given the EMBA for this activity extends to nearshore areas coastally adjacent to BTAC native title lands, these values may be relevant in the event of an unplanned hydrocarbon release. BTAC has not provided further detail regarding heritage value of places or cultural features of the PAA or the EMBA.

Wanparta Aboriginal Corporation indicated the connection to water (saltwater and fresh), totemic species including Kestrel, Octopus, Bream and Sting Ray and Solitary Island/Jarrkunpungu are culturally important. In the context of cultural values, these species and islands are assumed to be nearshore where interactions with Traditional Custodians are likely and outside of the EMBA.

Some persons or organisations who identified as a relevant person in relation to First Nations cultural heritage in other Woodside EPs have indicated knowledge of cultural features or heritage values which may be potentially affected by the activities described in this EP.

As a result of feedback received during consultation on other EPs in the region, it is feasible that additional cultural and broader interests in the environment exist. For completeness in describing the Existing Environment, this feedback on potential cultural features and heritage values are tabulated in **Table 4-20**.

Table 4-20: Summary of Feedback received via consultation to inform Existing Environment Description

Relevant First Nations Group / Individuals	Consultation Context	Description of Value / Feature / Interest	Potential for overlap	
			PAA	***EMBA***
Murujuga Aboriginal Corporation (MAC)	Consultation in the course of preparing this EP	• Cultural obligations to care for Country, including Sea Country Interest: Advised MAC are appropriate cultural authority for Murujuga	No (PAA does not overlap the Murujuga National Park)	No (The EMBA does not overlap the Murujuga National Park)
Buurabalayji Thalanyji Aboriginal Corporation (BTAC)	Consultation in the course of preparing this EP	• Cultural obligations to care for Country, including Sea Country Value: Enduring deep connection to Sea Country north of Onslow, extending out to nearshore islands off the Pilbara coast including the Montebello Islands, Barrow Island and the Mackerel Islands	No (PAA does not overlap the cited Sea Country areas)	Possible
Yinggarda Aboriginal Corporation (YAC)	Consultation in the course of preparing this EP	• Whales (including migration patterns) Interest: Potential impact to patterns of whales, and potential collisions	Possible (species unspecified)	Possible (species unspecified)

Relevant First Nations Group / Individuals	Consultation Context	Description of Value / Feature / Interest	Potential for overlap	
			PAA	***EMBA***
		• Ecosystem health (unspecified). Value: Plants, animals and the environment are inexorably linked to their culture Value: Local communities enjoy fishing along the coast	Yes	Yes
		• Seagrass Value: Seagrass is food source for Dugong	No	Yes
		• Dugong Value: Traditional hunting/ fishing and gathering rights	No	Possible
Kariyarra Aboriginal Corporation (KAC)	Consultation in the course of preparing this EP	• Intergenerational knowledge transfer Value: Passing on traditional knowledge to children	Possible (unspecified)	Possible (unspecified)
		• Cultural obligations to care for Country, including Sea Country Value: Having duties to look after and protect all Kariyarra Sea Country.	Possible (unspecified)	Possible (unspecified)
		• Traditional resource collection (hunting, trapping and collecting) Value: Traditional fishing and gathering rights in the ocean	Possible (unspecified)	Possible (unspecified)
		• Songlines and dreaming (unspecified) Feature: Intangible heritage including the Yinta (associated with Sea Country) Feature: Presence of mythic snakes	Possible (unspecified)	Possible (unspecified)
		• Access to Country including visiting offshore islands at low tide (unspecified) Value: Accessing Sea Country (islands) for fishing, trapping, crabbing catching turtle, hunting dugong, using stingray barbs for spears and collecting shellfish. Interest: Visiting offshore islands at low tide	No	Possible
		• Secret habitat totems Value: Cultural obligation to look after and protect sea country and secret habitat totems	Possible (unspecified)	Possible (unspecified)
		• Turtles	Possible	Yes

Relevant First Nations Group / Individuals	Consultation Context	Description of Value / Feature / Interest	Potential for overlap	
			PAA	***EMBA***
		Value: Accessing Sea Country for catching turtle. Interest: Management controls over periods of times (relating to turtles)		
		• Dugongs Value: Accessing Sea Country for hunting dugong.	No	Possible
		• Crabs Value: Accessing Sea Country for crabbing.	No	Possible
		• Stingrays Value: Accessing Sea Country - using stingray barbs for spears.	Possible	Possible
		• Shellfish Value: Accessing Sea Country for collecting shellfish.	No	Possible
		• Ecosystem health (unspecified) Value: General values and interests in Sea Country	Yes	Yes
		• Coastal landforms and coastal native vegetation Value: Cultural (General Significance)	No (PAA does not intersect KAC NTD Coastline)	No (EMBA does not intersect KAC NTD Coastline)
		• Cultural Heritage Values Value: A cultural interest in cultural heritage sites and intangible cultural heritage associated with the coast and the ocean	Possible (unspecified)	Possible (unspecified)
Wanparta Aboriginal Corporation to represent the Ngarla people	Consultation in the course of preparing this EP	• Cultural obligations to care for Country, including Sea Country Value: Responsibility to look after the ocean and lore Value: Ngarla People have a deep spiritual connection to sea country.	Possible (unspecified)	Possible (unspecified)
		• Dreaming Stories (unspecified) Value: Sea people connected through both fresh and salt water with Dreamtime stories that do connect through the sea.	Possible (unspecified)	Possible (unspecified)
		• Totems Value: Emblems and totems reflected on their logo: Kestrel, Octopus, Spiny Bream, Sting Ray	Possible (all)	Possible (all)
Nganhurra Thanardi Garrbu Aboriginal Corporation (NTGAC)	Consultation in the course of preparing this EP	• Whales and Whale Sharks Interest: expressed a general interest in whales and whale sharks	Possible	Possible
		• Ecosystem health	Possible	Possible

Save Our Songlines, [name redacted] and [name redacted]	Consultation in the course of preparing other EP	• Plankton (Unspecified) Interest: Potential impacts on marine species and natural environment	Possible	Possible
		• Energy lines [Songlines] (unspecified)	Possible (unspecified)	Possible (unspecified)
		• Where saltwater and freshwater meet Value: The places where the saltwater from the sea and the freshwater from the land connect are where the biggest energy lines[15] are, and that connection is a core of creation relevant to a Dreaming story	No	Possible

4.9.1.6 Summary of Cultural Features and Heritage Values

Woodside has developed a robust understanding of cultural features and heritage values relevant to the activity through examination of publicly available information, studies and consultation with relevant persons under regulation 25 of the Environment Regulations.

The cultural features and heritage values identified in Section 4.9.1.5.1 to 4.9.1.5.3 confirms whether there is any potential for these to exist within the PAA or EMBA. As previously described topics which have been raised in the context of an interest linked to the natural environment are impact and risk assessed in Section 6.6, 6.7 and 6.8.

As cultural features are physical elements of a place, these can generally be assessed for impacts; where a feature is avoided, it is not impacted. Heritage values relate less to what is significant and more to why something is significant; interaction between heritage values and the PAA can only be reliably informed by consultation with Traditional Custodians where they are willing to share the

[15] Although [name redacted], [name redacted] and Save our Songlines referred to and described Energy Lines, these are understood to be the same as songlines and this document therefore refers to songlines.

necessary knowledge. Assessment of heritage values beyond cultural features alone is addressed in Section 6.10 subject to these caveats.

Table 4-21: Summary of cultural features and heritage values

Identified cultural features and heritage values	Context	EP Source		Potential for overlap	
		Consultation Feedback	***Desktop Literature Assessment***	***PAA***	***EMBA***
Archaeological Heritage and Landscapes					
Coastal/ island archaeological sites	Coastal archaeological sites include shell middens, artefact scatters, skeletal material/burial sites, camps, meeting places, hunting places and water sources.	✓	✓	No	Possible (shoreline accumulation only)
Petroglyphs	Petroglyphs are a form of rock art. Petroglyphs are a prominent feature particularly at Murujuga where it is found on hard, volcanic rock.	x	✓	Possible (submerged)	Possible (submerged)
Fish traps	Stone arrangements constructed in intertidal areas which fill with fish at high tide and trap them at low tide.	x	✓	Possible (submerged)	Possible (submerged)
Submerged archaeological sites	The Ancient Landscape extends between 125m and 130m below current sea level. Ancient occupation of this area may have left traces through now submerged archaeological sites.	x	✓	Possible	Possible
Rivers, waterholes, tidal channels and seeps	Water sources on the Ancient Landscape which may be culturally significant or archeologically prospective. Traditional knowledge retains knowledge of some water sources on the Ancient landscape and some submerged waterholes are related to a Kangaroo songline. Value: Where saltwater and freshwater meet relate to Dreaming stories	✓	✓	Possible (submerged; Ancient Landscape) No (active freshwater systems meeting saltwater)	Possible

Identified cultural features and heritage values	Context	EP Source		Potential for overlap	
		Consultation Feedback	***Desktop Literature Assessment***	***PAA***	***EMBA***
Submerged hills	Hills on the Ancient Landscape which may be culturally significant or archeologically prospective. As sea level rose these hills would have become islands and eventually submerged.	x	✓	Possible	Possible
Intangible values					
Songlines/ Energy lines	Publicly available literature talks to songlines associated with ancestral beings that travelled Sea Country.	✓	✓	Possible (unspecified)	Possible (unspecified)
Creation/ dreaming sites, sacred sites and ancestral beings	Publicly available literature talks to creation/dreaming and ancestral beings, including water serpents, connected to or originating from the sea generally.	✓	✓	Possible (unspecified)	Possible (unspecified)
Ceremonial sites	Places where ceremony (e.g. thalu ceremonies) are performed. All identified ceremonial sites are located onshore.	x	✓	No	Possible (unspecified)
Cultural obligations to care for Country	Cultural obligation to care for the environmental values of Sea Country. Exclusion of Traditional Custodians from Sea Country or decision making processes may inhibit ability to care for Country.	✓	✓	Possible (unspecified)	Possible (unspecified)
Knowledge of Country/ customary law and transfer of knowledge	The preservation and transmission of knowledge is dependent on the preservation of the environment generally. Exclusion of Traditional Custodians from Sea Country may inhibit the transfer of knowledge.	✓	✓	Possible (unspecified)	Possible (unspecified)

Identified cultural features and heritage values	Context	EP Source		Potential for overlap	
		Consultation Feedback	***Desktop Literature Assessment***	***PAA***	***EMBA***
Connection to Country	Connection to Country is described in publicly available literature as "important to the Traditional owners' spirituality and religion". Connection to Country may be damaged where people are displaced or disrupted (e.g. during colonisation) or where there is a loss of technical skills or environmental knowledge	✓	✓	Possible (unspecified)	Possible (unspecified)
Access to Country	Limitations on Traditional Custodians accessing or enjoying areas of Sea Country	✓	✓	No	No (No limitations on access beyond the PAA)
Kinship systems and totemic species	Traditional Custodians have connection to species through kinship and totemic systems. An individual may have obligation to care for or not consume a species to which they are kin.	✓	✓	Possible	Possible
Resource collection	Fishing, hunting, gathering of marine species including marine mammals, marine reptiles, fish and invertebrates.	✓	✓	No	Possible
Marine ecosystems and species					
Water quality	Interest only, raised as a natural environment interest	x	✓	Possible	Possible
Marine species	Generally raised in consultation and literature as an interest	✓	✓	Possible	Possible

Identified cultural features and heritage values	Context	EP Source		Potential for overlap	
		Consultation Feedback	***Desktop Literature Assessment***	***PAA***	***EMBA***
Marine mammals: Whales	Generally raised in consultation and identified in publicly available literature Thalu species of totemic importance Linked to songlines and dreaming stories Humpback whales in particular	✓	✓	Possible	Possible
Marine mammals: Dolphins	Cultural ceremonies associated with communicating with dolphins Culturally important species	x	✓	Possible	Possible
Marine mammals: Dugongs	Culturally important species Used as a resource	✓	✓	No	Possible
Marine reptiles: Marine turtles	Culturally important species and migration There are Thalu ceremonies associated with turtles Turtles and turtle eggs as a resource	✓	✓	Possible	Possible
Fish: Fish, whale sharks, sharks and rays	Culturally important species Used as a resource Law run through the sea, including fish There are Thalu ceremonies associated with increasing fish stocks Fish, including bream and sting rays are totemic species Fish, including sharks and rays raised as a natural environment interest	✓	✓	Possible	Possible
Cephalopods: Squid and Octopus	Thalu species of totemic importance Resource	✓	✓	Possible	Possible

Identified cultural features and heritage values	Context	EP Source		Potential for overlap	
		Consultation Feedback	***Desktop Literature Assessment***	***PAA***	***EMBA***
Intertidal communities: Bivalves, gastropods, echinoderms (sea urchins), crustaceans	Resource.	✓	✓	No	Possible
Seabirds	Culturally important species Birds (including shags, seagulls and osprey) and bird eggs as a resource	✓	✓	Possible	Possible
Plankton	Interest only, raised as a natural environment interest.	✓	×	Possible	Possible
Benthic habitats: Macroalgal communities	Interest only, raised as a natural environment interest.	X	✓	No	Possible
Shoreline habitats: Mangroves	Critical breeding ground for marine and terrestrial wildlife. Mangroves would have provided shelter, crabbing, digging for shellfish, could be turtle nurseries. Mangrove seeds as resource	x	✓	No	Possible
Shoreline habitats: Intertidal sand/ mudflat communities	Interest only, raised as a natural environment interest.	X	✓	No	Possible
Shorelines	Interest only, raised as a natural environment interest.	✓	x	No	Possible
Marine Park/ coastal reserves	Interest and responsibility	x	✓	No	Yes

4.9.1.6.1 Further Context: Archaeological Heritage

Assessment of the PAA has not identified archaeological sites. Consultation with Traditional Custodians has not identified any Aboriginal cultural features or heritage values specifically associated within the PAA.

No coastal areas or islands exist within the PAA. Islands do exist within the EMBA boundary, however given the EMBA is driven by an unplanned loss of well containment, there is no anticipated impact pathway from this activity to onshore archaeological sites above highest astronomical tide (HAT). No archaeological areas have been identified beyond terrestrial or intertidal areas, with the exception of two sites at Murujuga in Cape Bruguieres channel and Flying Foam Passage (Benjamin et al. 2020; Benjamin et al 2023), which are located outside of the EMBA boundary. However, it is recognised that there is the potential for submerged archaeological sites on the Ancient Landscape which is overlapped by the PAA and EMBA.

Archaeological sites identified onshore with the potential to exist in intertidal or submerged locations include petroglyphs, fish traps and artefact scatters or burials contained within sand dunes. As potential archaeological sites, these features would have archaeological value relating to the preservation of their fabric (i.e. the tangible features), and their context (i.e. their location and relationship to other archaeological and natural features). Archaeological sites may also have intangible dimensions (ICOMOS 2013) cultural value that exist in addition to their archaeological or scientific value and are assessed separately.

Certain landscapes have been identified as archaeologically prospective on the submerged Ancient Landscape, including:

- Submerged water sources (rivers, waterholes, tidal channels and seeps) which have an increased likelihood of use or habitation as past generations used the associated resources (UWA 2021).
- Submerged calcarenite ridges younger that human occupation of the continent which may have formed over and protected artefacts in situ (Veth 2019),
- Prominent landscape features (e.g. hills, particularly of igneous rock formations) that may have been foci for cultural activity (UWA 2021),
- Karst depressions and other “catch points” where artefacts may accumulate following disturbances caused by inundation (UWA 2021, Nutley 2022, Nutley 2023a).

4.9.1.6.2 Further Context: Intangible Cultural Heritage:

Cultural knowledge, as expressed through songlines, dreaming, dance and other cultural practices, can be associated with tangible objects and physical sites that are culturally important to First Nations people (Ardler 2021; Bursill et al. 2007). Intangible cultural heritage can also be embodied in the practices, representations, expressions, knowledge, uses and skills associated with physical sites (UNESCO 2003). As a result, physical features may have intangible dimensions (ICOMOS 2013).

In terms of identified cultural features and intangible heritage values, see below some additional context:

- Songlines: Oral Songlines are often described by First Nations people as the law of the land and make up part of the Dreaming (Neale and Kelly, 2020). Songlines are viewed in Western academia as a framework for relating people to land and consist of a series of invisible, interconnected routes along the landscape that mark significant sites for First Nations people (Higgins, 2021). Songlines demonstrate First Nations peoples’ strong connections to land by revealing scared knowledge that is place-specific (Roberts 2023). The land’s physical features are instrumental in maintaining songlines because this is how ancestral spirits journeyed through, and interacted with, the physical landscape leaving sacred knowledge

behind. The interconnection between the physical and spiritual is where songlines become intrinsically tied to significant places across Country. As a result, geographical landforms are recorded within songlines and become sacred places. Such landforms can include inter alia: rocks, mountains, rivers, caves and hills (Higgins, 2021). Songlines can become lost, fragmented or broken when there is a loss of Country or forced removal from Country (Neale and Kelly, 2020). Physical sites that have been identified as comprising a component of a songline are important to protect in order to prevent the fragmenting or breaking apart of songlines and loss of sacred cultural knowledge. No specific details of songlines have been provided by relevant persons during consultation. The PAA overlaps part of the Ancient Landscape where prominent landscape features (e.g. rocks, mountains, rivers, caves and hills) would have been visible or used by Traditional Custodians and therefore likely to be incorporated in songlines.

- In Australia, songlines can stretch thousands of kilometres, making up a complex and organic network of stories containing cultural knowledge of First Nations communities across the land (Neale and Kelly, 2020). Songlines can also extend out to Sea Country and contain cultural knowledge that is tied to geographic features, atmospheric phenomena and marine plants and animals. Often songlines containing references to a seascape or Sea Country make mention of mythical events occurring around marine life, fishing areas, submerged rocks or coral. Songlines that embody seascapes can reflect how a group may relate to, or value, Sea Country—for example connections to nearby islands that they once inhabited in their songlines (Smyth and Isherwood, 2016). Songlines can also be used as proof of long-standing connection to land and support a legal entitlement to land rights (Higgins, 2021). Examples where songlines contain strong references to Sea Country are more common in Pacific Islander and Torres Strait Islander communities, who often refer to seascapes and skylines in their songlines in order to communicate sacred knowledge that assists in safe navigation of the ocean (Neale and Kelly, 2020).
- Creation/dreaming sites, sacred sites and ancestral beings: The only sources identified by Woodside that contained detailed descriptions of the location of ancestral beings or creation/dreaming/ sacred sites placed these locations or sites on land, islands or within inland water sources such as rivers or pools. It is acknowledged that some ancestral beings are noted to live within or originate from the sea generally, and some creation stories talk to the creation of features from or in the sea. Additionally, places on shore or at sea are (without further information or specificity) assumed to have been created on some level in First Nations cosmology.
- Cultural obligations to care for Country: Caring for Country collectively refers to the cultural obligations of individuals and groups, as well as rituals and ceremonies required for the physical and spiritual health of the environment. In the literature reviewed by Woodside, caring for Country was noted to include, but is not limited to, maintenance of the physical environment and ecosystem. It may also have cultural, spiritual and ritual dimensions such as caring for ancestral beings or ensuring cultural safety. Thalu sites are places where increase ceremonies are performed to increase, enhance or maintain populations of plants, animals or phenomena. All references to active ceremonial sites were confined to onshore locations, though the values may extend offshore where e.g., a thalu relates to marine species populations.
- Knowledge of Country/customary law and transfer of knowledge: Knowledge of and familiarity with the features of Sea Country is itself a “value”. The inherent potential for restricted or secret knowledge (or information that is not wished to be shared) makes this difficult to assess even through consultation with Traditional Custodians. However, aspects such as limitations on access to sites or disruption/relocation of First Nations communities may have implications for the preservation of First Nations knowledge. Further, connection to Country may be damaged where people are displaced or disrupted (e.g., during colonisation) or where there is a loss of technical skills or environmental knowledge

(McDonald and Phillips, 2021). Transfer of knowledge includes continuing traditional practices to pass on practical skills. This transfer of knowledge may be integral to managing a group's intangible cultural heritage (UNESCO 2003).

- Connection to Country: Describes the multi-faceted relationship between First Nations people and the landscape, which is envisioned as having personhood and spirit. It is also an aspect of personal identity for many First Nations people. In the case of Sea Country this can mean identifying as a Saltwater person, where "essence of being a 'Saltwater' person is ontological… it is about how people relate spiritually to the sea and engage with spiritual forces that created it, the marine flora and fauna and people" (McDonald and Phillips, 2021).
- Access to Country, including Sea Country: Is necessary for the continuation of other values including caring for Country and the transfer of traditional knowledge. Being on Country can be an important way of expressing or maintaining connection to Country (Australian Indigenous HealthInfoNet n.d.). Access is also a value in its own right, as a continuation of traditional Sea Country access and use.
- Kinship systems and totemic species: Individuals may have kinship to specific species (Smyth 2008, Juluwarlu 2004) and/or a responsibility to care for species (Muller 2008). Kinship arises from totemic associations within First Nations "skin group" systems. It is forbidden for an individual to kill or eat a species who is from the same "skin group" (Juluwarlu 2004). They may also have certain obligations linked to the discussion of caring for Country below. It is assumed that marine species may have kinship/totemic relationships to Traditional Custodians, but it is understood that these relationships do not prohibit people outside of that "skin group" from hunting or eating that same species (Juluwarlu 2004).
- Resource collection: A number of marine species are identified through consultation and literature as important resources, particularly as food sources. In addition to their immediate value as sustenance, the gathering and preparation of these resources is informed by cultural knowledge, and an inability to use these resources may result in a loss of ability to transfer that knowledge to future generations.

4.9.1.6.3 Further Context: Marine Ecosystems and Species

First Nations people have noted through consultation that they have a general interest in environmental management and ecosystem health (i.e., natural environment interest). This was noted in the context of a group/individual seeking further information about potential impacts and risks from the PAA on marine species and benthic communities in the PAA and EMBA. This includes marine mammals, marine reptiles, fish, seabirds, plankton, benthic and shoreline habitats and marine parks, which are described in context of their distribution and populations in Sections 4.5 and 4.6, with further details in Master Existing Environment.

In terms of identified cultural features and heritage values related to marine ecosystems and species summarised in 4.6, see below some additional context:

- Marine mammals: Whales, and in particular humpback whales, have been identified through consultation with First Nations people as culturally important species, with totemic importance including their populations, biodiversity, and migration patterns. Cultural ceremonies associated with communicating with dolphins as well as dugongs identified as a food source have also been raised by Murujuga Aboriginal Corporation through a consultation report on Mermaid Sound (MAC 2021).While Mermaid Sound is outside of the PAA and EMBA, this cultural information informs the cultural heritage features, values and interests that may exist in the area. Details pertaining to marine mammals including whales, dugongs and dolphins, their distribution, migration patterns and populations are described in Section 4.6, with further details in Master Existing Environment.
- Marine reptiles: Turtles and sea snakes have been identified through consultations with First Nations people as culturally important species, with turtles identified as a resource. First

Nations people that identify marine reptiles as species of totemic importance or integral to songlines may place high cultural value on their protection. No specific marine reptiles-related songlines have been identified as per Section Socio-economic Environment that have the potential to interact with the PAA or EMBA. Note the only specific songline related to marine reptiles (turtles) was shared by Murujuga Aboriginal Corporation, and was geographically restricted from Fortescue to Withnell Bay, in Mermaid Sound (MAC 2021). Cultural knowledge of turtles at a population level (turtle migration, behaviour and the related marine environment) may all be important in ensuring the continuation of cultural functions and activities that remain valuable to First Nations people (Fijn 2021:47; Delisle et al.2018). Details pertaining to marine reptiles, their distribution, and populations are described in Section 4.6 with further details in Master Existing Environment.

- Fish and Cephalopods: Fish and squid have been identified through consultation with First Nations people as a culturally important species, with fish generally being identified as a resource. First Nations may identify cultural values associated with fish species as important to maintaining both tangible (physical cultural sites) and intangible (cultural knowledge) cultural heritage. Tangible cultural heritage associated with fish can include important cultural sites such as midden sites, fish traps and Thalu sites. The octopus is an important totem to Ngarla People and features in the creation story of Solitary Island. There are increase ceremonies / rituals for species of squid and octopus to enhance or maintain populations. Thalu are places where these increase ceremonies are performed. Details pertaining to fish and cephalopods are described in Section 4.6, with further details in Master Existing Environment.
- Seabirds: Seabirds, and in particular shags, have been identified through literature as a culturally significant species (Malgana Land and Sea Management et al. (2021), as well as a resource (seabird eggs; Smyth 2007). Details pertaining to seabirds and migratory shorebirds are described in Section 4.6, with further details in Master Existing Environment.
- Benthic habitats: Through consultations for activities not related to this EP, First Nations groups identified benthic habitats as valuable for their ecological values, including corals attracting fish and seagrass providing shelters for fauna, as well as an important resource for dugongs. Additionally, coral is valued by Murujuga Aboriginal Corporation for its aesthetic values. Details pertaining to benthic habitats and communities, including their distribution, are described in Section 4.5, with further details in Master Existing Environment.
- Shoreline habitats: Through consultations for activities not related to this EP, First Nations groups identified shoreline habitats as valuable for their ecological values, including mangroves for providing shelter to marine invertebrates, which are identified resources, and potential nursery for turtles. Literature also notes that mangroves are also valued for the flora and fauna they are associated with and support (Commonwealth of Australia 2002) and Smyth (2007) reports that mangrove seeds are used as a resource by Ngarda-Ngarli. Details pertaining to shoreline and coastal habitats, including their distribution, are described in Section 4.5, with further details in Master Existing Environment.

4.9.1.7 Historic Sites of Significance

There are no known sites of European cultural heritage significance within the PAA. **Appendix C-1** Section 11.1.2 describes cultural heritage sites within the EMBA.

4.9.1.8 Historic Underwater Heritage

A search of the Australian National Shipwreck Database, which records all known Maritime Cultural Heritage (shipwrecks, aircraft, relics and other underwater cultural heritage) in Australian waters indicated that there are no sites within the PAA, or within 50 km of the PAA. There are 34 (shipwrecks) within the EMBA.

4.9.1.9 World, National and Commonwealth Heritage Listed Places

No listed heritage places overlap the PAA. World, National and Commonwealth heritage places within the EMBA are identified in **Table 4-22**. **Appendix C** Section 10.2 outlines the values and sensitivities of these places.

Table 4-22: World Heritage Properties and National/Commonwealth Heritage Listed Places within the environment that may be affected

Listed Place	Distance and direction from PAA to Listed Place (km)
World Heritage Properties	
Ningaloo Coast	286 km south-west
National Heritage Places	
Ningaloo Coast	286 km south-west
Barrow Island and the Montebello-Barrow Islands Marine Conservation Reserves	1000 km south-west
Commonwealth Heritage Places	
Ningaloo Marine Area – Commonwealth Waters	303 km south-west

4.9.2 Commercial Fisheries

A number of Commonwealth and State fishery management areas are located within the PAA and EMBA. A number of Commonwealth and State fishery management areas are located within the Operational Area and EMBA. The Annual Fishery Status Reports published by the Australian Bureau of Agricultural and Resource Economics and Sciences (ABARES) were used to identify if Commonwealth managed fisheries have fished within the Operational Area and EMBA in the last five years. FishCube data were also requested from the WA Department of Primary Industries and Regional Development (DPIRD) for the most recently available five-year period of fishery catch and effort data (2018–2022) to analyse the potential for interaction of fisheries with the PAA. Data was reviewed from the last five years as a subset of past fishing effort. This was deemed an appropriate period to represent potential future fishing effort over the lifecycle of this EP. In addition, any impacts to fish are expected to be temporary in nature (see **Section 6.7** and **Section 6.8**) and therefore not extending beyond the life of the EP.

This information was used to determine relevant fisheries for consultation who may be impacted by the proposed petroleum activities. **Table 4-23** provides an assessment of the potential interaction and **Appendix C** provides further detail on the fisheries that have been identified through desk-based assessment and consultation (**Section 5**). One Commonwealth managed and four State managed fisheries were identified as having a potential interaction with the Petroleum Activities Program, within the PAA (**Figure 4-14**).

Table 4-23: Commonwealth and State commercial fisheries management areas overlapping the Petroleum Activities Area and environment that may be affected and potential for interaction during the Petroleum Activities Program

Fishery	Potential for interaction During Activity × no potential for interaction ✓ potential for interaction		
	Overlap with PAA	Overlap with EMBA	Description
Commonwealth Managed Fisheries			
North West Slope Trawl Fishery	×	✓	The North West Slope Trawl Fishery management area overlaps the EMBA. Between one to six vessels have been active in the fishery since 2005. Fishery Status Reports indicate most recent activity inside the EMBA occurred in the 2021–2022 season (Patterson et al., 2022). Accordingly, Woodside considers it a possibility that interactions with the fishery may occur in the EMBA.
Western Deepwater Trawl Fishery	×	✓	The Western Deepwater Trawl management area overlaps the EMBA. Fishery Status Reports indicate most recent activity inside the EMBA occurred in the 2020–2021 season (Patterson et al., 2022). There has been no fishing effort reported within the PAA in the last 5 years. Accordingly, Woodside considers it a possibility that interactions with the fishery may occur in the EMBA.
Western Tuna and Billfish Fishery	×	×	The Western Tuna and Billfish Fishery management area overlaps the EMBA and PAA; however, the majority of Australian catch has concentrated in south-eastern Australia (ABARES, 2021). There has been no fishing effort reported within the PAA in the last 5 years. Accordingly, Woodside considers there to be no potential for interaction with this fishery and the Petroleum Activities Program.
Southern Bluefin Tuna Fishery	×	×	The Southern Bluefin Tuna Fishery management area overlaps the EMBA and PAA. The Southern Bluefin Tuna Fishery spans the Australian Fishing Zone; however, since 1992, the majority of Australian catch has concentrated in south-eastern Australia (Patterson et al., 2022). There has been no fishing effort reported within the PAA in the last 5 years. Accordingly, Woodside considers there to be no potential for interaction with this fishery and the Petroleum Activities Program.
Western Skipjack Tuna Fishery	×	×	The Western Skipjack Tuna Fishery management area overlaps the PAA and the EMBA. The Western Skipjack Tuna Fishery spans the Australian Fishing Zone west of Victoria and the Torres Strait. The Fishery is not currently active and no fishing has occurred since 2009 (Patterson et al., 2022). Accordingly, Woodside considers there to be no potential for interaction with this fishery and the Petroleum Activities Program.

Fishery	Potential for interaction During Activity ✗ no potential for interaction ✓ potential for interaction		
	Overlap with PAA	Overlap with EMBA	Description
State Managed Fisheries			
Pilbara Line Fishery	✓	✓	The Pilbara Line Fishery licensees are permitted to operate anywhere within Pilbara waters (Newman et al., 2021), overlapping the EMBA and PAA. The fishery is active in the EMBA, with ten 60 nm Catch and Effort System (CAES) blocks reporting up to five vessels across the 2017 to 2022 seasons (DPIRD, 2022). The PAA overlaps 60 nm CAES block 19150. FishCube data for the Pilbara Line Fishery is not provided at the 10 nm scale, therefore it is uncertain if the effort reported in the 60 nm CAES block 19150 overlaps with the PAA. Accordingly, Woodside considers it a possibility that interactions with the fishery may occur within the EMBA and PAA.
Pilbara Crab Managed Fishery	✗	✓	The Pilbara Crab Managed Fishery management area overlaps the EMBA and PAA. The fishery is active in the EMBA, with one 60 nm CAES block reporting less than 3 vessels across the 2017 to 2022 seasons (DPIRD, 2022). FishCube data for the Pilbara Crab Managed Fishery is not provided at the 10 nm scale; however, the 60 nm CAES block does not overlap the PAA. Accordingly, Woodside considers it a possibility that interactions with the fishery may occur within the EMBA.
Pilbara Trap Managed Fishery	✓	✓	The Pilbara Trap Managed Fishery management area overlaps the EMBA and PAA. The fishery is active within the EMBA, with twelve 60 nm CAES blocks reporting up to 3 vessels across the 2017 to 2022 seasons (DPIRD, 2022). FishCube data for the Pilbara Trap Managed Fishery is not provided at the 10 nm scale; therefore, it is uncertain if the effort reported in the 60 nm CAES blocks overlaps with the PAA. Accordingly, Woodside considers it a possibility that interactions with the fishery may occur within the EMBA and PAA.
Pilbara Fish Trawl (Interim) Managed Fishery	✓	✓	The Pilbara Fish Trawl (Interim) Managed Fishery management area overlaps the EMBA and the PAA. The fishery has remained consistently active within the EMBA, with six 60 nm CAES blocks reporting up to four vessels across the 2017 to 2022 seasons (DPIRD, 2022). The fishery is active within the PAA with four 10 nm CAES blocks reporting up to four vessels across the 2017 to 2022 seasons (DPIRD, 2022). Therefore, Woodside considers it a possibility that interactions with the fishery may occur within the EMBA and PAA.

Fishery	Potential for interaction During Activity × no potential for interaction ✓ potential for interaction		
	Overlap with PAA	Overlap with EMBA	Description
Mackerel Managed Fishery (Area 2)	×	✓	The Mackerel Managed Fishery management area overlaps the EMBA and PAA (Area 2 only). The fishery has remained consistently active over the last 5 years, with nine 60 nm CAES blocks reporting up to six vessels across each season between 2017 to 2022 (DPIRD, 2022). FishCube data reported no active fisheries at 10 nm overlapping the PAA over the last 5 years (DPIRD, 2022). Accordingly, Woodside considers it a possibility that interactions with the fishery may occur within the EMBA.
Specimen Shell Managed Fishery	×	✓	The Specimen Shell Managed Fishery management area overlaps the EMBA and PAA. The fishery has remained consistently active within the EMBA between the 2017 to 2022 seasons with five 60 nm CAES blocks overlapping the EMBA reporting up to six vessels (DPIRD, 2022). FishCube data reported no active fisheries at 10 nm overlapping the PAA (DPIRD, 2022). Accordingly, Woodside considers it a possibility that interactions with the fishery may occur in the EMBA.
Marine Aquarium Managed Fishery	×	✓	The Marine Aquarium Managed Fishery management area overlaps the EMBA and the PAA. The fishery is active within the EMBA, with five 60 nm CAES blocks reporting six licences across the 2017 to 2022 seasons (DPIRD, 2022). No activity was recorded for 10 NM CAES blocks reporting across the 2017 to 2022 seasons (DPIRD, 2022). Accordingly, Woodside considers it a possibility that interactions with the fishery may occur within the EMBA.
West Coast Deep Sea Crustacean Managed Fishery	×	✓	The West Coast Deep Sea Crustacean Managed Fishery management area overlaps the EMBA and PAA. The fishery is active within the EMBA, with three 60 NM CAES blocks reporting less than three licences across the 2017 to 2022 seasons (DPIRD, 2022). FishCube data reports no active fishing effort within the PAA at 10 nm over the last 5 years (DPIRD, 2022). Accordingly, Woodside considers it a possibility that interactions with the fishery may occur within the EMBA.
Onslow Prawn Managed Fishery (Areas 2 and 3)	×	✓	The Onslow Prawn Managed Fishery management Areas 2 and 3 overlaps EMBA and PAA (Area 3 only). The fishery is active within the EMBA, with five 60 nm CAES blocks reporting less than three licences across the 2017 to 2022 seasons (DPIRD, 2022). FishCube data reports no active fishing effort within the PAA at 10 nm over the last 5 years (DPIRD, 2022). Accordingly, Woodside considers it a possibility that interactions with the fishery may occur within the EMBA.

Fishery	Potential for interaction During Activity × no potential for interaction ✓ potential for interaction		
	Overlap with PAA	Overlap with EMBA	Description
Western Australian Sea Cucumber Fishery	×	✓	The Western Australian Sea Cucumber Fishery management area overlaps the EMBA. The fishery is permitted to operate throughout all WA waters. The target species typically inhabit nearshore waters. FishCube data reports fishing effort occurs within the EMBA across two 60 NM CAES blocks reporting less than three licenses across 2017 to 2019 seasons (DPIRD, 2022). FishCube data reported no active fisheries at 10 nm CAES blocks overlapping the PAA (DPIRD, 2022). Accordingly, Woodside considers it a possibility that interactions with the fishery may occur within the EMBA.
Nickol Bay Prawn Managed Fishery	×	✓	The Nickol Bay Prawn Managed Fishery management area overlaps the EMBA. FishCube data reports five 60 NM CAES blocks with active fishing effort overlapping the EMBA, with up to eight vessels active across the 2017 to 2022 seasons (DPIRD, 2022). FishCube data reported no active fisheries at 10 nm CAES blocks overlapping the PAA (DPIRD, 2022). Accordingly, Woodside considers it a possibility that interactions with the fishery may occur within the EMBA.
Exmouth Gulf Prawn Managed Fishery	×	✓	The Exmouth Gulf Prawn Managed Fishery management area overlaps the EMBA. FishCube data reports two 60 nm CAES blocks overlapping the EMBA, with up to six vessels active across the 2017 to 2022 seasons (DPRID, 2022). No fishing effort has been reported in the 10 nm CAES blocks overlapping the PAA within the last 5 years (DPIRD, 2022). Accordingly, Woodside considers there to be potential for interaction with this fishery within the EMBA.
South West Coast Salmon Managed Fishery	×	×	The South West Coast Salmon Managed Fishery management area overlaps the EMBA and PAA. Historically, no fishing occurs north of the Perth Metropolitan Area. Therefore, no effort is reported within the EMBA (DPRID, 2022) and Woodside considers there to be no potential for interaction with this fishery within the EMBA.
Land Hermit Crab Fishery	×	✓	The Land Hermit Crab Managed Fishery management area overlaps the EMBA, where shoreline contact is predicted. FishCube data reports fishing effort occurs within the EMBA in one CAES block reporting three licenses across the 2017 to 2018 season (DPIRD, 2022). FishCube data reported no active fisheries at 10 nm CAES blocks overlapping the PAA (DPIRD, 2022). Woodside considers there to be potential for interaction with this fishery within the EMBA, although no shoreline contact is predicted where this overlap occurs.

Fishery	Potential for interaction During Activity × no potential for interaction ✓ potential for interaction		
	Overlap with PAA	Overlap with EMBA	Description
Pearl Oyster Managed Fishery (Zone 1 and 2)	×	×	The Pearl Oyster Managed Fishery management area overlaps the EMBA and the PAA however the main fishing area for Zone 1 is located adjacent to the EMBA, in the nearshore waters of Exmouth Gulf and Port Hedland. No fishing has occurred in Zone 1 from 2017 to 2020 (Hart et al., 2021). FishCube data reported no fishing effort within the EMBA (DPIRD, 2022) and therefore, Woodside considers there to be no potential for interaction with this fishery within the EMBA.
Western Australian Abalone Managed Fishery	×	×	The Western Australian Abalone Managed Fishery management area overlaps the EMBA and the PAA. However, FishCube data reports no fishing effort occurred within the EMBA across 2017 to 2022 (DPIRD, 2022). Similarly, FishCube data reported no active fisheries at 10 nm CAES blocks overlapping the PAA (DPIRD, 2022). Accordingly, Woodside considers there to be no potential for interaction with this fishery within the EMBA.
West Coast Rock Lobster Managed Fishery	×	×	The West Coast Rock Lobster Managed Fishery management area overlaps the EMBA. FishCube data reports no fishing effort occurred within the EMBA across 2017 to 2022 seasons (DPIRD, 2022). FishCube data reported no active fisheries at 10 nm CAES blocks overlapping the PAA (DPIRD, 2022). Accordingly, Woodside considers there to be no potential for interaction with this fishery within the EMBA.
WA North Coast Shark Fishery	×	×	The WA North Coast Shark Fishery management area overlaps the EMBA. The PAA overlaps with the WA North Coast Shark Fishery (WANCSF) management area which extends from longitude 114°06'E to 123°45'E (Patterson et al., 2021). However, fishing activity has not been reported by this fishery since the 2008–2009 fishing season (Patterson et al., 2021). Accordingly, Woodside considers there to be no potential for interaction with this fishery within the EMBA.
Charter based commercial operators			
Tour Operators	×	✓	Fishing Tour Operators are permitted to operate across WA state waters and are required to report monthly logbook records of client fish catches. FishCube data indicate tour operator fishing effort highest around Ningaloo and Muiron Islands and at Barrow Island and the Montebello Islands. FishCube data reports consistent effort across twenty-four 60 nm CAES blocks that overlap the EMBA (DPIRD, 2022). Effort was reported by up to 20 vessels across the 2017 to 2022 seasons (DPIRD, 2022). The FishCube data reported no active tour operators at 10 nm overlapping the PAA within the last 5 years (DPIRD, 2022). Accordingly, Woodside considers it a possibility that interactions with tour operators may occur within the EMBA.

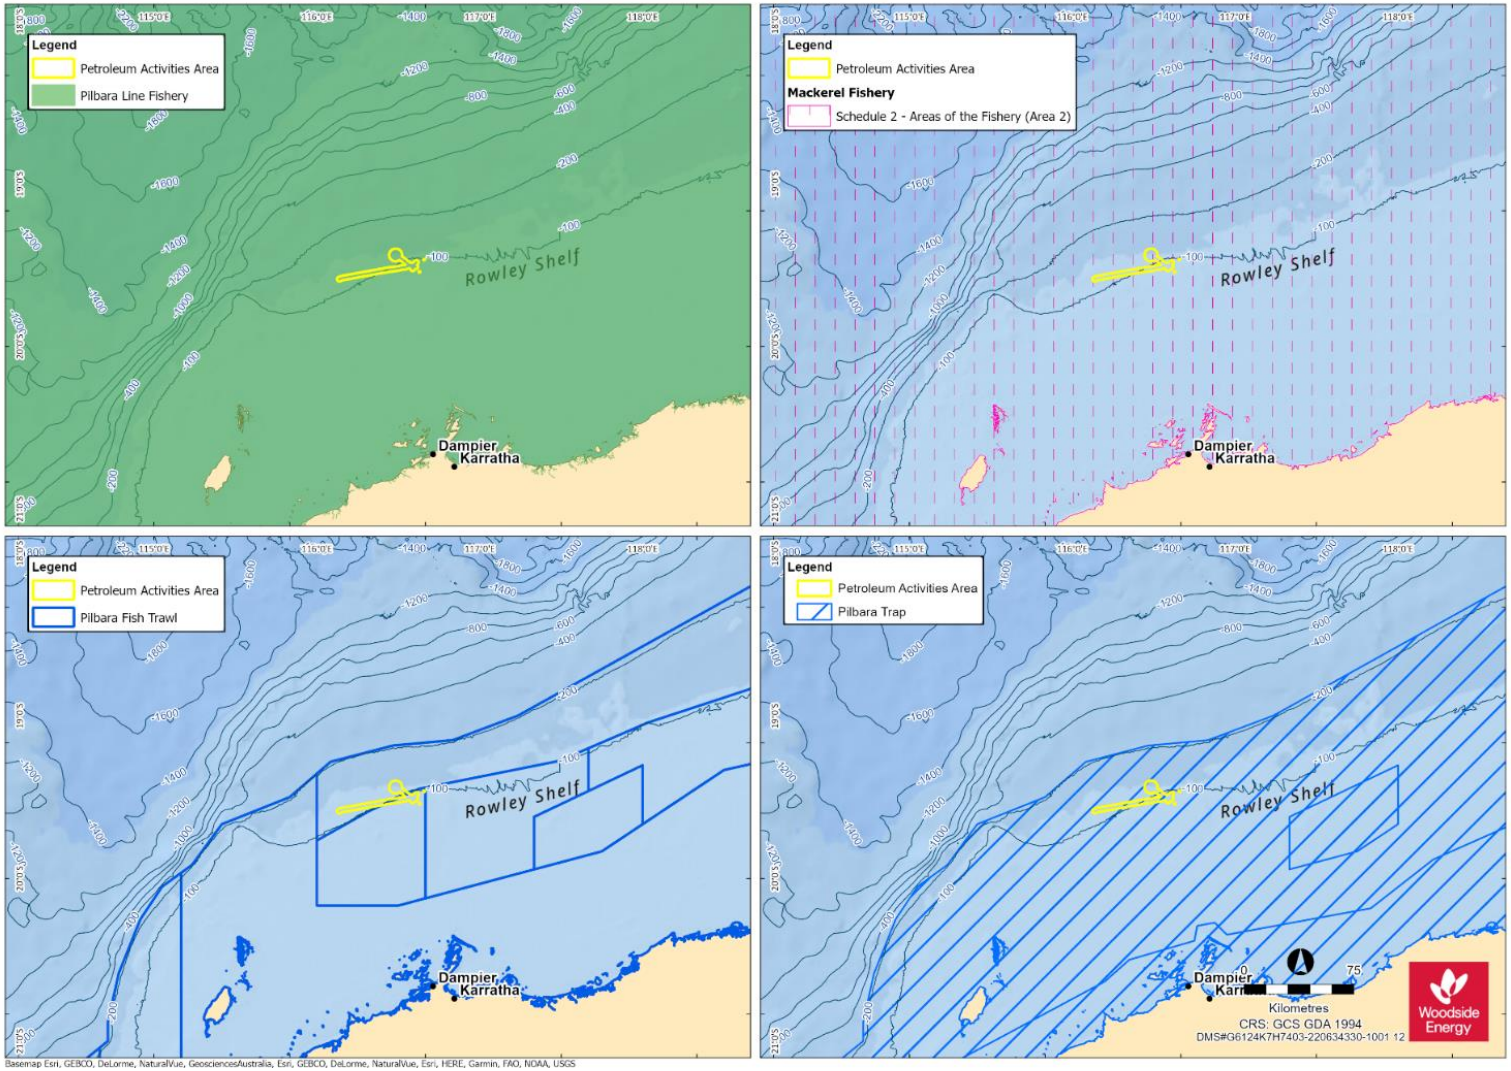

Figure 4-14: Commercial fisheries overlapping the Petroleum Activities Area and environment that may be affected with a potential for interaction with the Petroleum Activities Program

4.9.3 Traditional Fisheries

There are no traditional or customary fisheries within the PAA, as these are typically restricted to shallow coastal waters and/or areas with structures such as reefs. However, it is recognised that Barrow Island, Montebello Islands and Ningaloo Reef, all within the wider EMBA, have a known history of fishing when areas were occupied (as from historical records) (Department of Conservation and Land Management (DCLM), 2005; Department of Environment and Conservation (DEC), 2007). Areas that are covered by registered native title claims are likely to practice Aboriginal fishing techniques at various sections of the Western Australia coastline.

4.9.4 Tourism and Recreation

No tourist activities take place specifically within the PAA; however, it is acknowledged that there are growing tourism and recreational sectors in WA and these sectors have expanded over the last couple of decades. Growth and the potential for further expansion in tourism and recreational activities is recognised for the Pilbara and Gascoyne regions, with the development of regional centres and a workforce associated with the resources sector (SGS Economics and Planning, 2012).

Tourism is one of the major industries of the Gascoyne region and contributes significantly to the local economy in terms of both income and employment. The main marine nature-based tourist activities are concentrated around and within the Ningaloo World Heritage Area (WHA) (approximately 286 km south-west of the PAA). Activities undertaken include recreational fishing, snorkelling and scuba diving and wildlife watching and encounters (including whale sharks, manta rays, humpback whales and turtles) (Schianetz et al., 2009).

The Montebello Islands (located 106 km south-west of the PAA) are the closest location for tourism with some charter boat operators taking visitors to these islands (DEC, 2007).

Recreational fishing in the Pilbara and Gascoyne regions is mainly concentrated around the coastal waters and islands and has grown considerably with the expanding regional centres, seasonal tourism and increasing residential and fly in/fly out work force, particularly in the Pilbara region (Fletcher et al., 2017). Some recreational fishing has historically taken place at Rankin Bank and the Glomar Shoals KEF (approximately 54 km west and 15 km east of the PAA respectively). However, due to the distance from access nodes, such as Dampier and Onslow (approximately 126 km south and 237 km south-south west from the PAA at the closest point respectively) recreational fishing effort is expected to be restricted to relatively large vessels and hence is considered to be low

4.9.5 Commercial Shipping

The Australian Maritime Safety Authority (AMSA) has introduced a network of marine fairways across the NWMR off WA to reduce the risk of vessel collisions with offshore infrastructure. It is noted that none of these fairways intersect with the PAA; the nearest fairway is approximately 19 km east of PAA (**Figure 4-15**). Vessel tracking data suggest shipping is concentrated to the east of the PAA, which is likely associated with ports.

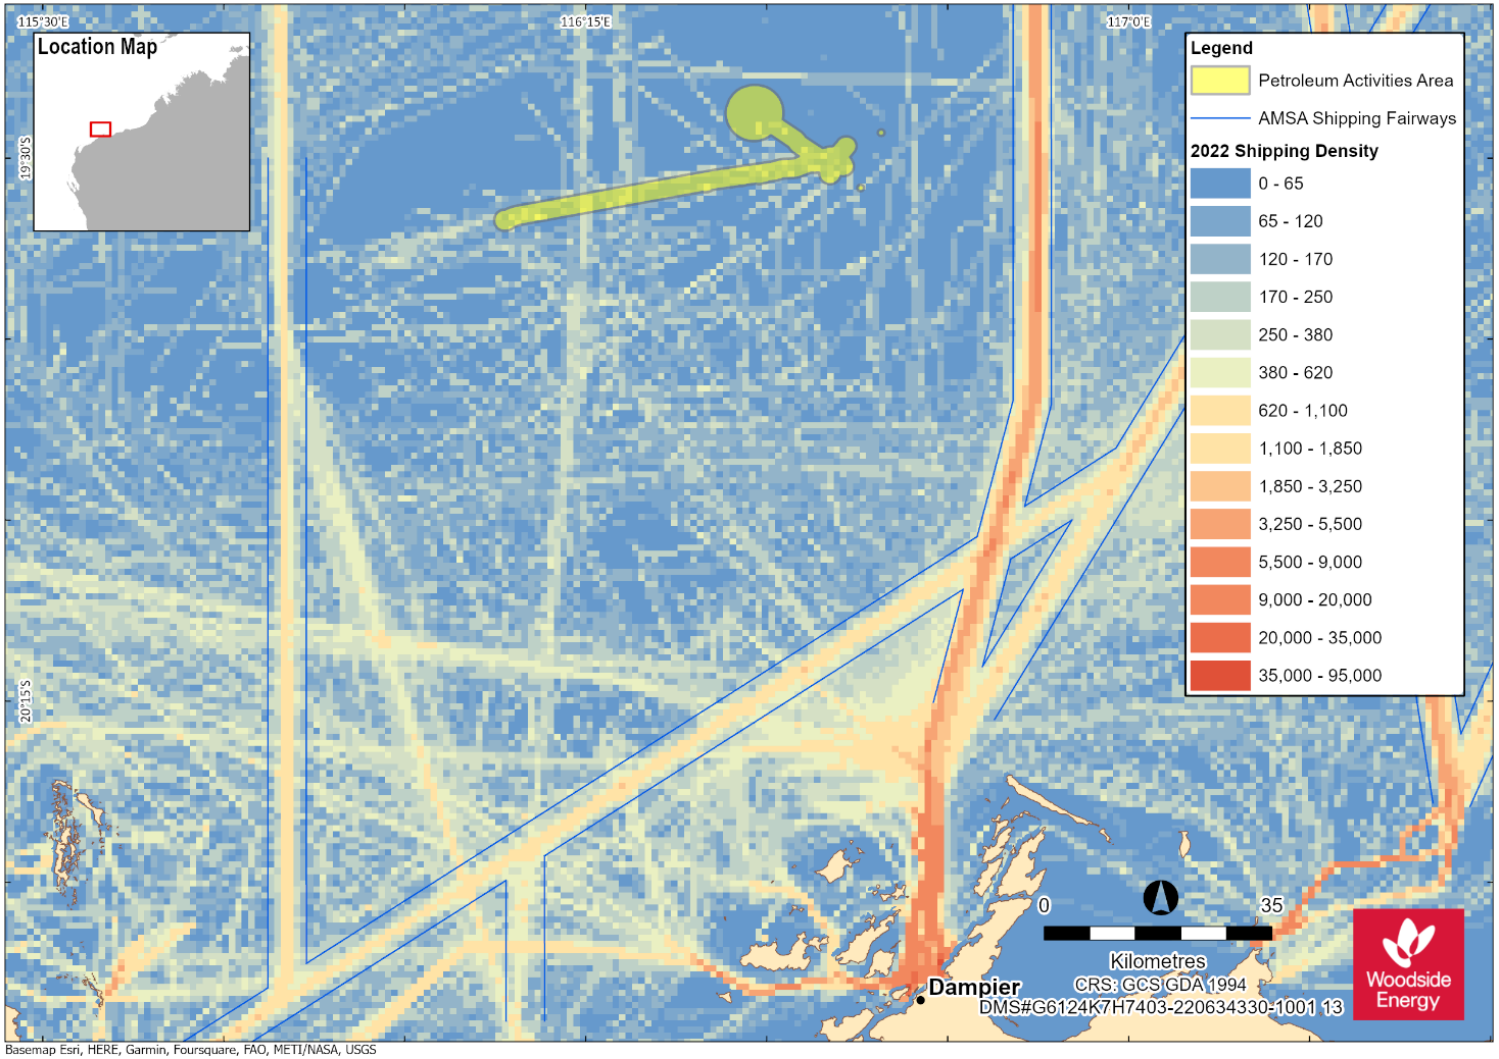

Figure 4-15: Vessel density map for the Petroleum Activities Area and environment that may be affected, derived from Australian Maritime Safety Authority satellite tracking system data; vessels include cargo, liquefied natural gas tanker, passenger vessels, support vessels and others/unnamed vessels

4.9.6 Oil and Gas

Table 4-24 details other oil and gas facilities located within 50 km of the PAA. **Appendix C-1** Section 11.9 describes current oil and gas development within the EMBA, also shown in **Figure 4-16**.

Table 4-24: Other oil and gas facilities located within 50 km of the Petroleum Activities Area

Facility name and operator	Distance and direction from PAA to Listed Place (km)
North Rankin Complex (Woodside)	Overlaps
Okha (Woodside)	5 km south
Goodwyn Alpha (Woodside)	22 km west
Reindeer (Santos)	50 km south-east

4.9.7 Defence

The are no defence areas overlapping the PAA. Defence areas overlapping the EMBA are presented in **Figure 4-17** and **Figure 4-18**.

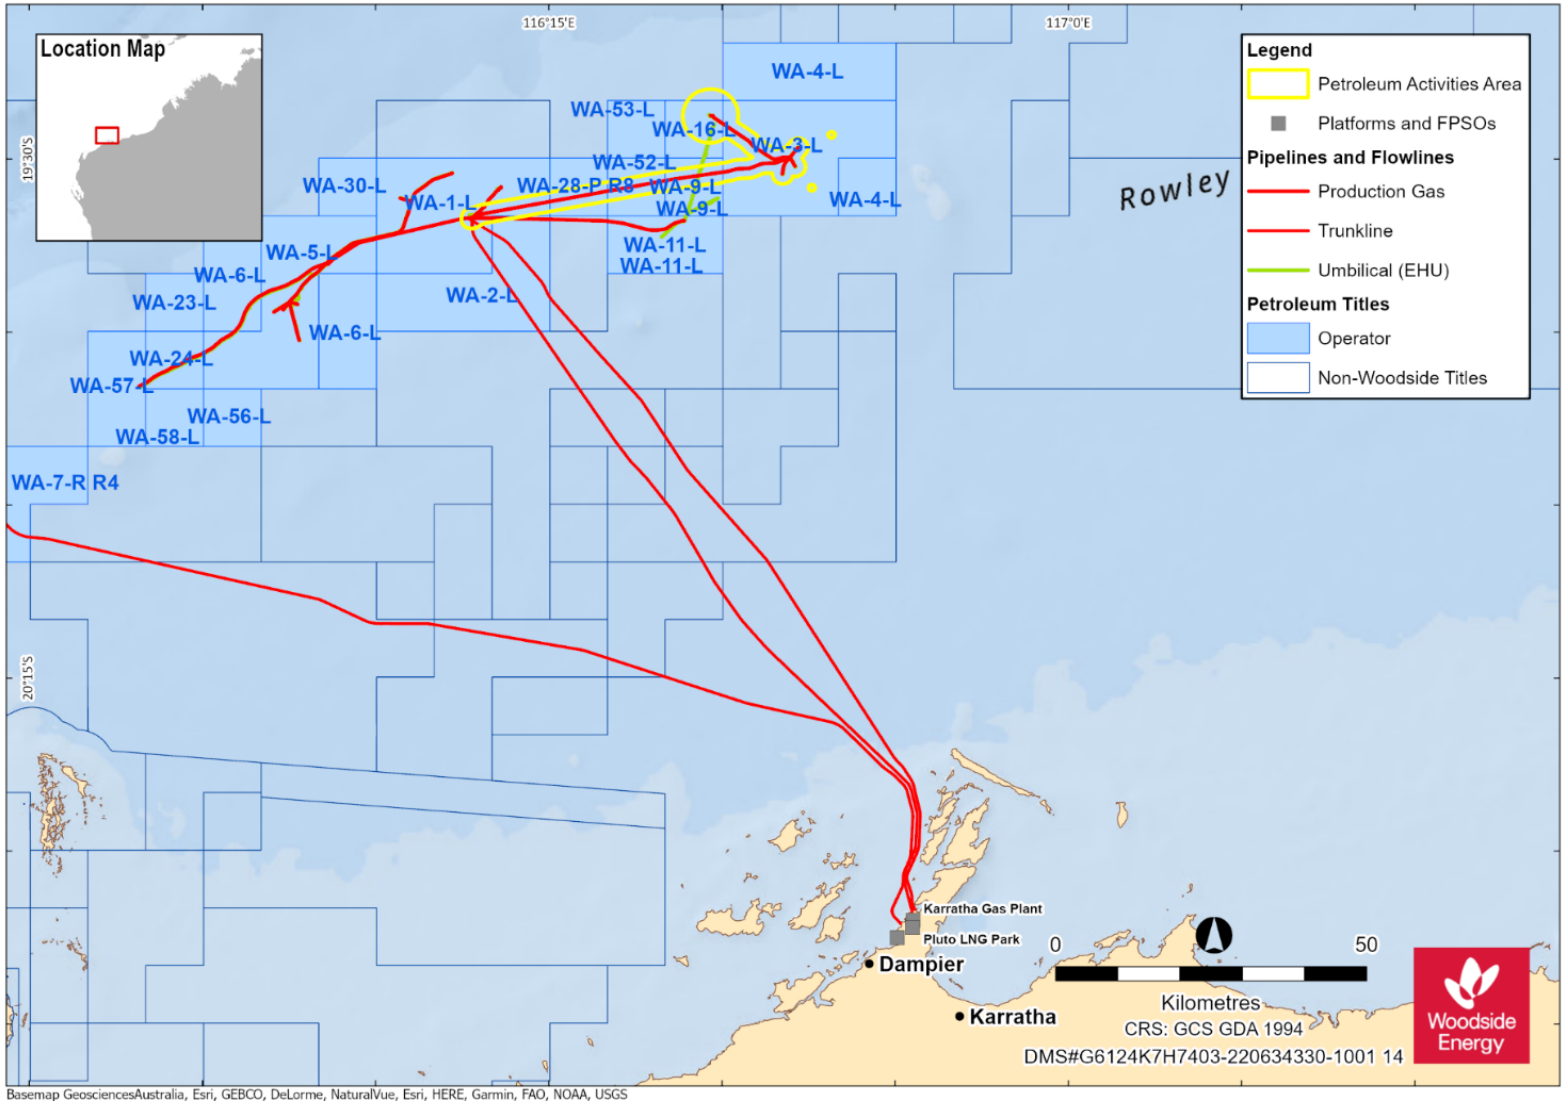

Figure 4-16: Oil and gas Infrastructure within the Petroleum Activities Area and environment that may be affected

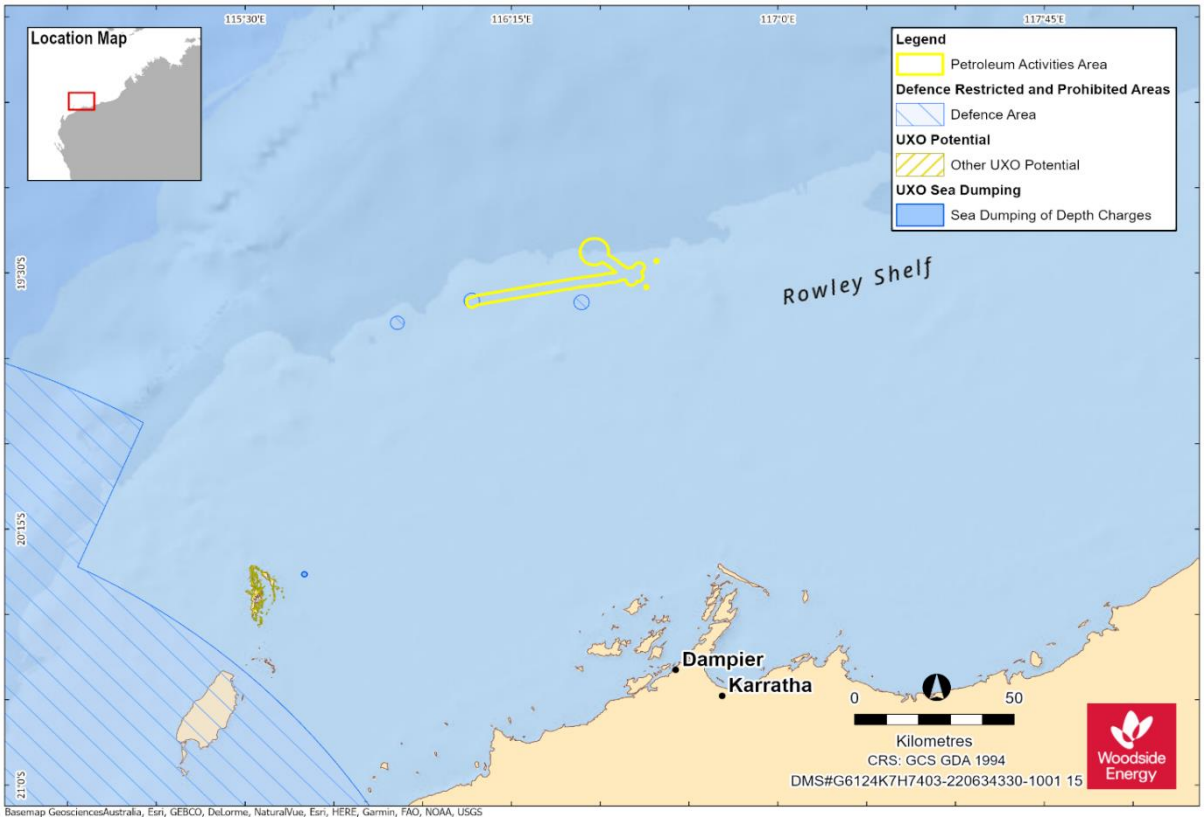

Figure 4-17: Defence areas relative to the Petroleum Activities Area

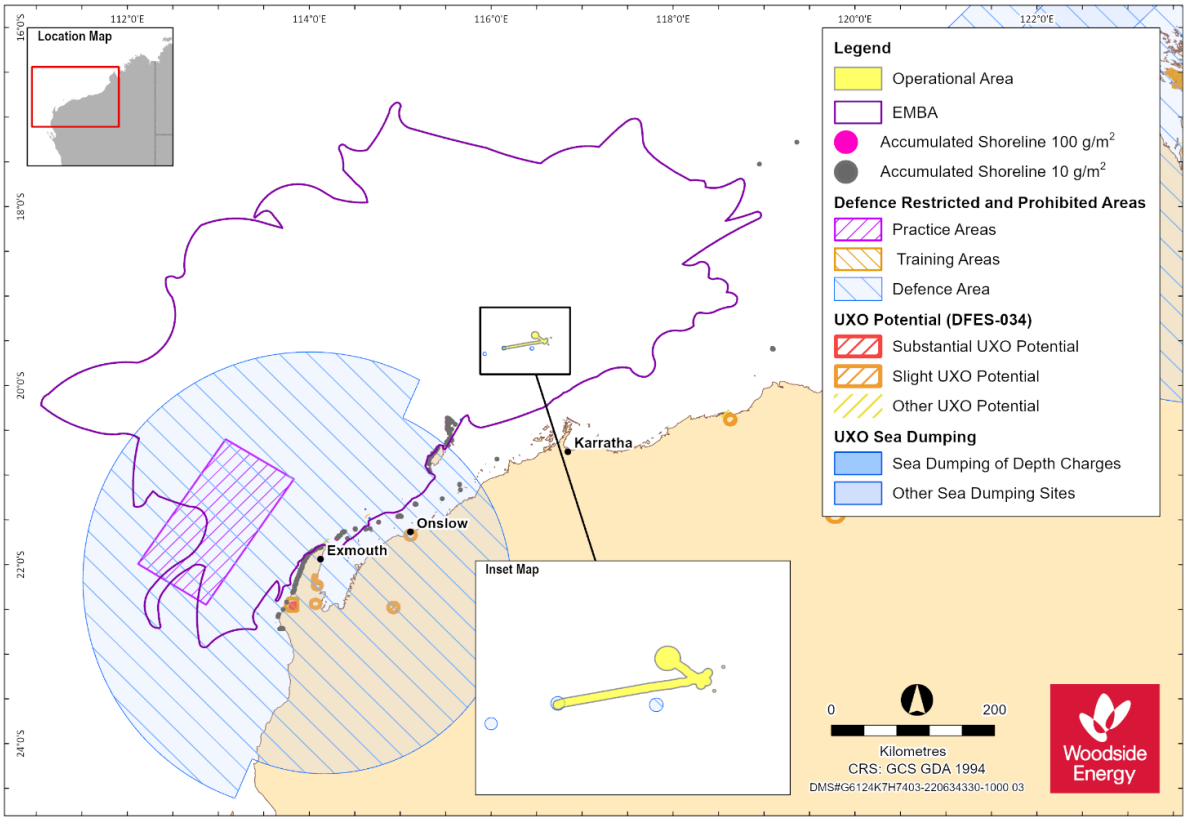

Figure 4-18: Defence areas overlapping the environment that may be affected

5 CONSULTATION

5.1 Summary

Woodside consults relevant persons in the course of preparing an Environment Plan (EP) in accordance with regulation 25 of the Environment Regulations. Consultation is designed to identify relevant persons and provide them with sufficient information and a reasonable period to allow them to make an informed assessment of the possible consequences of the proposed activity on their functions, interests or activities to enable titleholders to consider and adopt appropriate measures in response to the objections or claims received from relevant persons. Consistent with **Section 4** of the Environment Regulations, consultation also supports the objective to ensure that the activity is carried out in a manner by which the environmental impacts and risks of the activity will be reduced to as low as reasonably practicable (ALARP) and will be of an acceptable level.

Woodside acknowledges that a titleholder's approach to consultation is to be informed by both the Environment Regulations and the findings of relevant Courts, including the Full Federal Court in the *Santos NA Barossa Pty Ltd v Tipakalippa* [2022] FCAFC 193 (Tipakalippa Appeal) (see **Section 5.2** and **Section 5.5.1**) delivered on 2 December 2022 and *Munkara v Santos NA Barossa Pty Ltd (No 3)* [2024] FCA 9 (Munkara Case).

For this EP, Woodside has considered both the PAA and the broader EMBA in undertaking consultation (see further discussion in **Section 5.2**). The broadest extent of the EMBA has been determined by reference to the highly unlikely event of a hydrocarbon release resulting from the PAP (see **Section 4**).

Woodside's consultation methodology is divided into two parts:

- The first section (**Section 5.2 to 5.5**) provides an overview of Woodside's consultation methodology for its EPs, including how we apply regulation 25(1) of the Environment Regulations to identify relevant persons.
- The second section (**Section 5.6 to 5.7**) details Woodside's approach to accepting feedback and assessment of the merit of each objection or claim, and engaging in ongoing consultation for this EP.

Woodside's consultation record is at **Appendix F** and includes:

- assessment and identification of relevant persons
- consultation information provided to relevant persons, feedback received and Woodside's assessment of the merits of objections or claims
- engagement with persons or organisations that Woodside chose to contact who are not relevant persons for the purposes of regulation 25(1) of the Environment Regulations (see **Section 5.3.6**)
- opportunities provided to persons or organisations to participate in consultation.

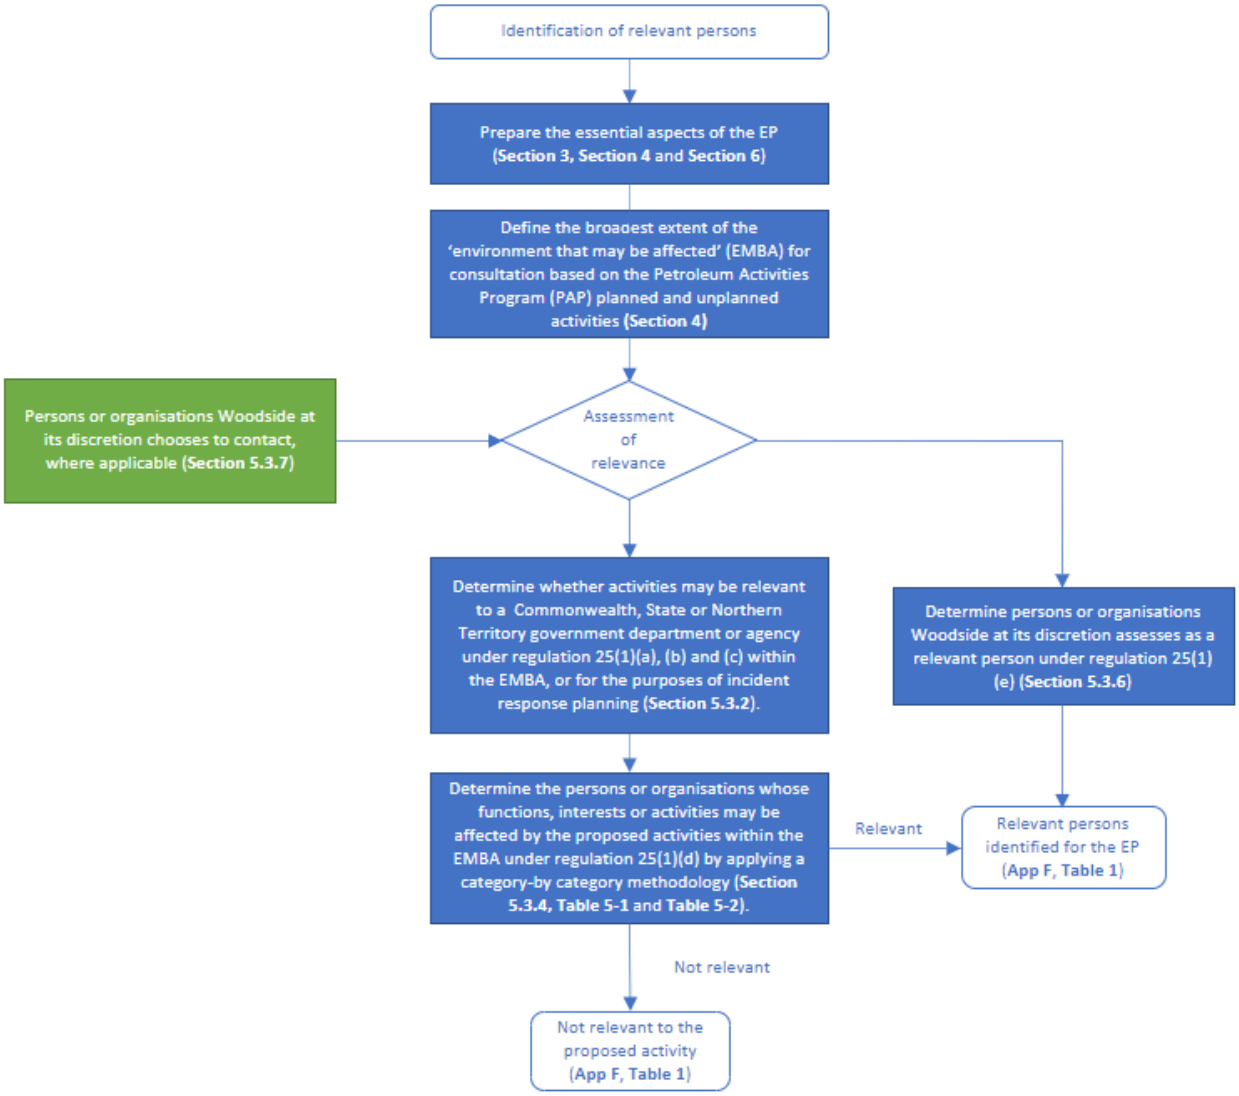

Figure 5-1: Overview of Woodside's methodology to identify relevant persons

5.2 Consultation – General Context

Woodside has a portfolio of quality oil and gas assets and more than 30 years of operating experience. We have a strong history of working with local communities, the relevant regulators and a broad range of persons and organisations to better understand the potential risks and impacts associated with our proposed activities and to develop appropriate measures to manage them.

The length of time that we have operated in Commonwealth and State waters, and the history of continued engagement with a wide range of persons and organisations enables Woodside to develop an extensive consultation list to inform its consultation process. This consultation list is not used as a definitive list of persons to consult, but rather, assists Woodside as an input to its understanding of relevant persons with whom to consult on a proposed petroleum activity. The information in the consultation list has been captured from years of experience, it contains insights relating to the type of information particular persons or organisations want to receive during consultation, the appropriate method of consultation for relevant persons and includes appropriate contact details, which are reviewed and updated periodically.

Woodside acknowledges NOPSEMA's Guideline on *Consultation in the course of preparing an environment plan* (12 May 2023) as well as judicial guidance in the Tipakalippa Appeal on the intent of consultation as follows:

- At paragraph 54 of the appeal decision: … provide a basis for NOPSEMA's considerations of the measures, if any, that a titleholder proposes to take or has taken to lessen or avoid the deleterious effect of its proposed activity on the environment, as expansively defined.
- At paragraph 89 of the appeal decision: …its purpose is to ensure that the titleholder has ascertained, understood and addressed all the environmental impacts and risks that might arise from its proposed activity. Consultation facilitates this outcome because it gives the titleholder an opportunity to receive information that it might not otherwise have received from others affected by its proposed activity. Consultation enables the titleholder to better understand how others with an objective stake in the environment in which it proposes to pursue the activity perceive those environmental impacts and risks. As the Regulations expressly contemplate, it enables the titleholder to refine or change the measures it proposes to address those impacts and risks by taking into account the information acquired through the consultations. Objectively, the scheme intends that this is likely to improve the minimisation of environmental impacts and risks from the activity.

The *Tipakalippa Appeal* and *Munkara Case* have also been further considered in the context of specific methods for consultation with First Nations relevant persons (**Section 5.5.1**).

In order to undertake consultation, Woodside has developed a methodology for identifying relevant persons, in accordance with regulation 25(1) of the Environment Regulations (**Section 5.5.1**). This methodology is consistent with NOPSEMA's guideline and demonstrates that, in order to meet the requirements of regulation 34 (criteria for EP acceptance) when preparing the EP, Woodside understands:

- our planned activities in the PAA, being the area in which our planned activities are proposed to occur (see Section 3.3.1)
- the geographical extent to which the environment may be affected (EMBA) by risks and impacts from our activities (unplanned) (identified in Section 4.1 and assessed in Section 6.8).

Woodside has undertaken consultation in the course of preparing this EP in compliance with regulation 25 of the Environment Regulations, which requires a titleholder to:

- consult with each of the following (a relevant person) in the course of preparing an environment plan:
  - each Commonwealth, State or Northern Territory agency or authority to which the activities to be carried out under the environment plan may be relevant
  - if the plan relates to activities in the offshore area of a State – the Department of the responsible State Minister
  - if the plan relates to activities in the Principal Northern Territory offshore area – the Department of the responsible Northern Territory Minister
  - a person or organisation whose functions, interests or activities may be affected by the activities to be carried out under the EP
  - any other person or organisation that the titleholder considers relevant (regulation 25(1) of the Environment Regulations)
- give each relevant person sufficient information to allow the relevant person to make an informed assessment of the possible consequences of the activity on their functions, interests or activities (regulation 25(2) of the Environment Regulations)

- allow a relevant person a reasonable period for the consultation (regulation 25(3) of the Environment Regulations)
- tell each relevant person that the titleholder consults with that the relevant person may request that particular information it provides in the consultation not be published and any information subject to such a request is not to be published (regulation 25(4) of the Environment Regulations).

Further, Woodside seeks to carry out consultation in a manner that:

- is consistent with the principles of ESD set out in Section 3A of the EPBC Act – see Section 2
- is intended to reduce the environmental impacts and risks from the activity to ALARP (regulation 4 of the Environment Regulations)
- seeks to ensure that the environmental impacts and risks of the activity will be of an acceptable level (regulation 4 of the Environment Regulations)
- is intended to minimise harm to the relevant person and the environment from the proposed petroleum activities and to enable Woodside to consider measures that may be taken to mitigate the potential adverse environmental impacts from the petroleum activity
- is collaborative. Woodside respects that for a relevant person, consultation is voluntary. Where the relevant person seeks to engage, Woodside engages with the relevant person with the aim of seeking genuine and meaningful two-way dialogue
- provides opportunities for relevant persons to provide feedback throughout the life of the EP through its ongoing consultation process (refer to Section 5.7 and Section 7.10).

An overview of Woodside's consultation approach is outlined in **Figure 5-2**.

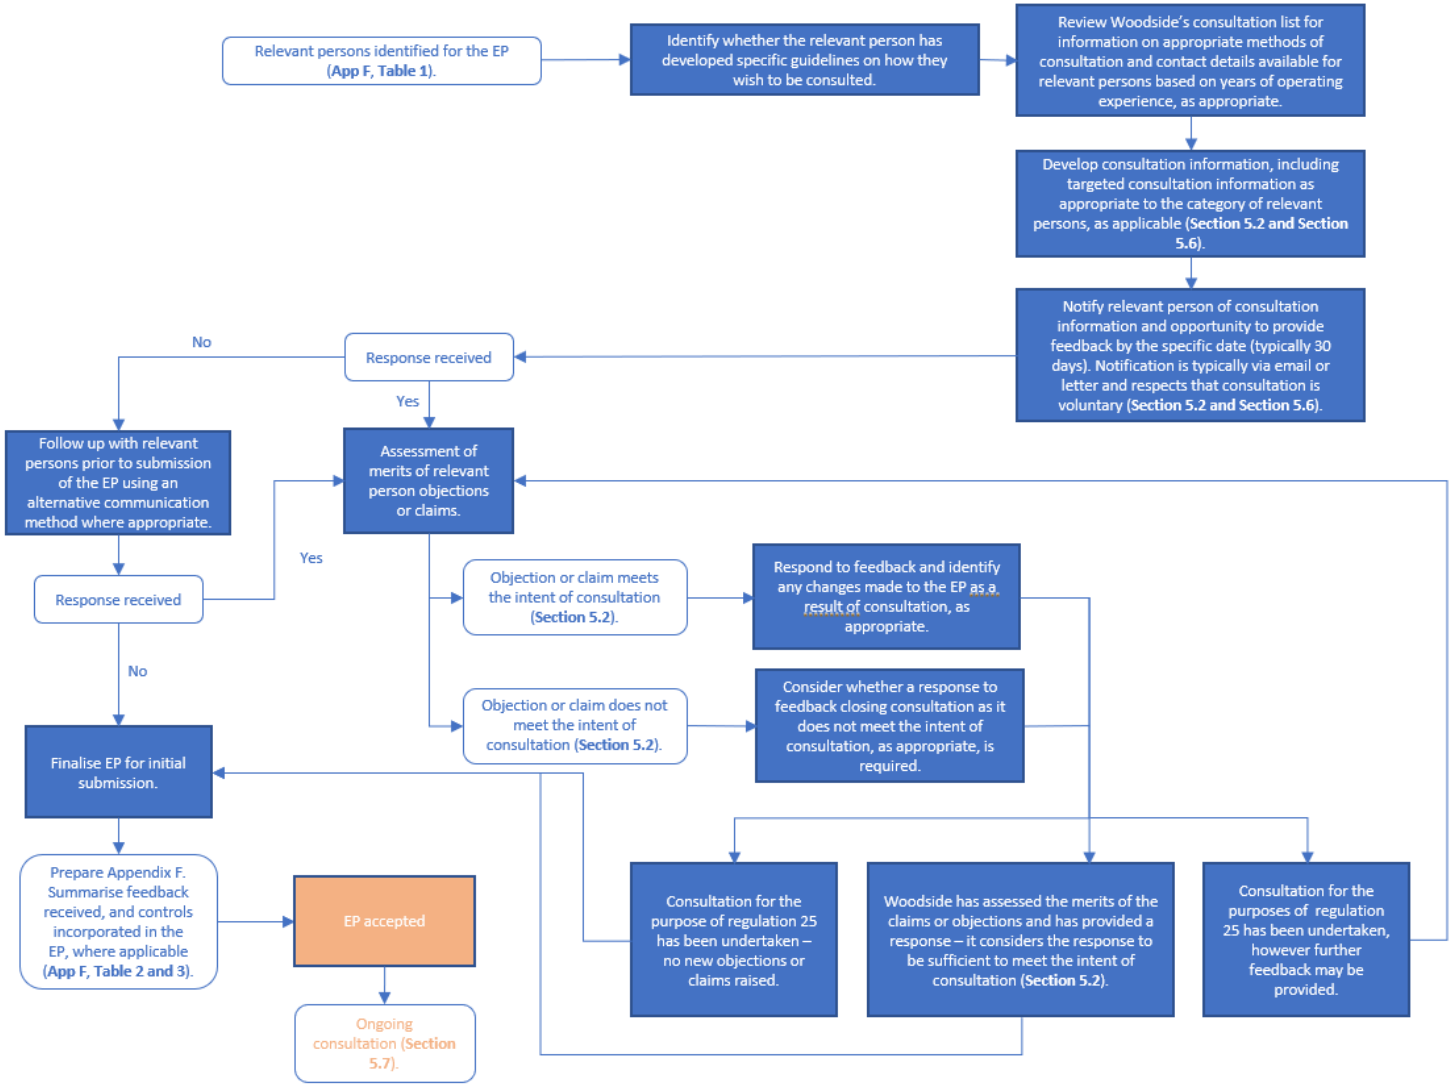

Figure 5-2: Overview of Woodside's consultation approach

The methodology for consultation for this activity has been informed by various guidelines and relevant information for consultation on planned activities, including:

Federal Court:

- Santos NA Barossa Pty Ltd v Tipakalippa [2022] FCAFC 193
- Munkara v Santos NA Barossa Pty Ltd (No 3) [2024] FCA 9

NOPSEMA:

- GL2086 – Consultation in the course of preparing an environment plan – May 2023
- GN1847 – Responding to public comment on environment plans – January 2024
- GN1344 – Environment plan content requirements – September 2020
- GL1721 – Environment Plan decision making – January 2024
- GN1488 – Oil pollution risk management – July 2021
- GN1785 – Petroleum activities and Australian Marine Parks – January 2024
  - GL 1887 – Consultation with Commonwealth agencies with responsibilities in the marine area – January 2024
- PL9028 Managing gender-restricted information – December 2023
- Consultation on offshore petroleum environment plans – Information for the community

Department of Climate Change, Energy, the Environment and Water:

- Sea Countries of the North-West; Literature review on Indigenous connection to and uses of the North West Marine Region

Australian Fisheries Management Authority:

- Petroleum industry consultation with the commercial fishing industry

Commonwealth Department of Agriculture, Fisheries and Forestry:

- Fisheries and the Environment – *Offshore Petroleum and Greenhouse Gas Act 2006*
- Offshore Installations Biosecurity Guide

WA Department of Primary Industries and Regional Development:

- Guidance statement for oil and gas industry consultation with the Department of Fisheries

WA Department of Transport:

- Offshore Petroleum Industry Guidance Note

Good practice consultation:

- IAP2 Public Participation Spectrum
- Interim Engaging with First Nations People and Communities on Assessments and Approvals under the *Environment Protection and Biodiversity Act 1999*.

5.3 Identification of Relevant Persons for Consultation

5.3.1 Regulations 25(1)(a), (b) and (c)

The relevant inquiry for determining relevant persons within the description of regulations 25(1)(a) and (b) of the Environment Regulations is whether the activities to be carried out under the EP may

be relevant to one of the government departments or agencies in those regulations. The government departments and agencies relevant to the EP are listed in **Appendix F, Table 1**. In accordance with regulation 25(1)(b) of the Environment Regulations, Woodside consults with the department of the relevant State Minister.

5.3.2 Identification of Relevant Persons under regulation 25(1)(a), (b) and (c)

- Woodside's methodology for identifying relevant persons under regulations 25(1)(a), (b) and (c) is as follows:
  - Woodside considers the defined responsibilities of each of the departments and agencies to which the activities in the EMBA to be carried out under the EP may be relevant. This list of relevant department and agencies is formulated by reference to the responsibilities of the government departments as set out on their websites, in NOPSEMA's GL1887 – *Consultation with Commonwealth agencies with responsibilities in the marine area guideline* (January 2024), which describes where the Department is a relevant agency under the Environment Regulations, as well as experience and knowledge that Woodside has gained from years of operating. This list is revised from time to time, for example, for the purposes of accommodating government restructures, renaming of departments, shifting portfolios and/or to account for new agencies that might arise.
- Woodside has categorised government department or agency groups as follows:

Government departments / agencies – marine	Agencies with legislated responsibilities for use of the marine environment.
Government departments / agencies – environment	Agencies with legislated responsibilities for the protection of the marine environment.
Government departments / agencies – industry	The legislated Department of the responsible Commonwealth, State or Northern Territory Minister for Industry.

- Woodside considers each of the responsibilities of the departments and agencies and determines whether those responsibilities overlap with potential risks and impacts specific to the proposed petroleum activity in the EMBA. The assessment is both activity and location based.
- Woodside acknowledges the roles and responsibilities of government departments and agencies acting on behalf of various industry participants. For example, AMSA – Marine Safety is responsible for the safety of vessels and the seafarers who are operating in the domestic commercial shipping industry and AHO is responsible for maritime safety and Notices to Mariners. To undertake the PAP in a manner that prevents a substantially adverse effect on the potential displacement of marine users, Woodside therefore consults AMSA – Marine Safety and AHO on its proposed activities. Woodside considers each of the responsibilities of the departments and agencies and determines those that would either be involved in the incident response itself or in relation to the regulatory or decision-making capacity with respect to planning for the unlikely event of a worst-case hydrocarbon release incident response specific to the PAP. Feedback received, if any, is assessed in accordance with the intended outcome of consultation.
- The list of those government departments and agencies assessed as relevant is set out in Appendix F, Table 1.
- Feedback received, if any, is assessed in accordance with the intended outcome of consultation and summarised at Appendix F, Table 2 and Table 3 as appropriate to the relevance assessment.

Woodside does not consult with departments or agencies with interests that do not overlap with risks and impacts specific to the proposed petroleum activity in the EMBA or would not be involved in incident response planning.

5.3.3 Regulation 25(1)(d)

In order to identify a relevant person for the purposes of regulation 25(1)(d), the meaning of "functions, interests or activities" needs to be understood. In regulation 25(1)(d), the phrase "functions, interests or activities" should be construed broadly and consistently with the objects of the Environment Regulations (regulation 4) and the objects of the EPBC Act (section 3A).

In developing its methodology for consultation, Woodside acknowledges that the guidance on the definition of functions, interests and activities is as follows in accordance with NOPSEMA's *GL2086 – Consultation in the course of preparing an environment plan* guideline (May 2023):

Functions	Refers to a power or duty to do something.
Interests	Conforms to the accepted concept of 'interest' in other areas of public administrative law and includes any interest possessed by an individual whether or not the interest amounts to a legal right or is a proprietary or financial interest or relates to reputation.
Activities	Broader than the definition of 'activity' in regulation 5 of the Environment Regulations and is likely be directed to what the relevant person is already doing.

Woodside's methodology for determining 'relevant persons' for the purpose of regulation 25(1)(d) of the Environment Regulations includes consideration of:

- whether a person or organisation has functions interests or activities that overlap with the PAA and EMBA
- whether a person or organisation's functions, interests or activities may be affected by Woodside's proposed planned or unplanned activities.

5.3.4 Identification of Relevant Persons under regulation 25(1)(d)

Relevant persons under regulation 25(1)(d) of the Environment Regulations are defined as a person or organisation whose functions, interests or activities may be affected by the activities to be carried out under the EP. In identifying relevant persons, Woodside considers:

- the planned activities to be carried out under this EP (described in Section 3)
- the EMBA by unplanned activities (identified in Section 4 and assessed in Section 6).

To identify relevant persons who fall within regulation 25(1)(d) of the Environment Regulations, Woodside adopts the following methodology, then undertakes consultation with relevant persons:

- As a general proposition, Woodside assesses whether a person or organisation is a relevant person having regard to:
  - whether a person or organisation has functions, interests or activities that overlap with the PAA and EMBA
  - whether a person or organisation's functions, interests or activities may be affected by Woodside's proposed planned or unplanned activities to be carried out under the EP.
- This assessment includes applying judgement, knowledge and current literature.
- Further, to assist in identifying the full range of relevant persons, Woodside considers the impacts and risks associated with its proposed activities and considers the broad categories of relevant persons who may be affected by the activities proposed to be carried out under the EP. The broad categories are identified in Table 5-1below and identification methodology applied as set out in Table 5-2.

- The list of those persons or organisations assessed as relevant and persons or organisations Woodside separately chose to contact is set out in Appendix F, Table 1.
- Feedback received, if any, is assessed in accordance with the intended outcome of consultation and applying the categories of relevant persons methodology outlined in Table 5-2, as appropriate.
- Feedback from relevant persons is summarised at Appendix F, Table 2. Feedback from persons assessed as "not relevant" but whom Woodside chose to contact or self-identified and Woodside assessed as "not relevant" are summarised at Appendix F, Table 3.

Table 5-1: Categories of relevant persons

Category	Explanation
Commercial fisheries (Commonwealth and State) and peak representative bodies	Commonwealth or State Commercial Fishery with a fishery management plan recognised under the Commonwealth *Fisheries Management Act 1991* and Western Australian *Fish Resources Management Act 1994*, which may be amended from time to time. Commonwealth peak fishery representative bodies are identified by AFMA. WAFIC is the peak representative body for state fishers in Western Australia.
Recreational marine users and peak representative bodies	Charter boat, tourism and dive operators identified by DPIRD specific to the location of the proposed activity. Representative bodies are the recognised peak organisation(s) for recreational marine users.
Titleholders and Operators	Registered holder of an offshore petroleum title or GHG title governed by the *OPGGS Act* and associated regulations.
Peak industry representative bodies	Recognised peak organisation(s) for the oil and gas sector.
Traditional Custodians (individuals and/or groups/entity)	Traditional Custodians are First Nations Australians who hold cultural rights and interests, or have cultural functions or perform cultural activities over particular lands and waters. Where a First Nations person, group or entity self-identifies and asserts cultural rights, functions, interests, or activities they will be considered under the definition of Traditional Custodian for the purpose of this EP (as appropriate).
Nominated Representative Corporations	Nominated representative corporations are Traditional Custodians' nominated representative institutions such as Prescribed Bodies Corporate (PBCs). PBCs are established under the *Native Title Act 1993 (Cth)* by Traditional Custodians to represent their entire Traditional Custodian group (defined broadly by reference to descents from an ancestor set who were known to be the Traditional Custodians at the time of European colonisation) and their interests including, among other things, management and protection of cultural values.
Native Title Representative Bodies	A Representative Aboriginal/Torres Strait Islander Bodies (RATSIB) is a regional organisation appointed under the *Native Title Act* (NTA) with prescribed functions, set out in Part 11 of the *Native Title Act*, which relate to: facilitation and assistance; certification; dispute resolution; notifications; agreement making. They are also known, and referred to here, as Native Title Representative Bodies.
Historical heritage groups or organisations	Legislated or government enlisted groups or organisations responsible for the management of marine heritage.
Local government and recognised local community reference/liaison groups or organisations	Local government governed by the *Local Government Act 1995* (WA) which is responsible for representing the local community. Recognised local community reference/liaison group or organisation in relation to oil and gas matters.

Category	Explanation
Other non-government groups or organisations	Non-government organisation with public website material targeting the proposed activity.
Research institutes and local conservation groups or organisations	Research institutes are government or private institutions that conduct marine or terrestrial research. Local conservation groups are local non-government organisation that regularly conduct conservation activities focused on the local environment or wildlife.

Table 5-2: Methodology for identifying relevant persons within the environment that may be affected undertaken under regulation 25(1)(d) of the Environment Regulations – by category

Category	Relevant person identification methodology
Commercial fisheries (Commonwealth and State) and peak representative bodies	Woodside assesses relevance for commercial fisheries (Commonwealth and State) and their representative bodies using the following next steps in its methodology: • Defining the parameters having regard to timing, location and duration of the proposed petroleum activity. • Confirming whether the EMBA overlaps with the fisheries management area (i.e., the spatial area the fishery is legally permitted to fish in) (see **Section 4.9.2**). • Woodside acknowledges WAFIC's consultation guidance[16], that Titleholders develop separate consultation strategies for significant unplanned events (for example, oil spill) where Titleholders can demonstrate the likelihood of such events occurring is extremely low. WAFIC's guidance is that consultation on unplanned events resulting in an emergency scenario should only be undertaken if an incident occurs (**see Appendix D:** Oil Spill Preparedness and Response Strategy Selection and Evaluation). • For Commonwealth and State commercial fisheries, Woodside assesses the potential spatial and temporal extent for interaction with the fishery by reviewing AFMA ABARES and DPIRD FishCube data within the Operational Area and EMBA (see **Section 4.9.2**). Assessment of relevance: • State commercial fisheries that have been assessed as having a potential for interaction within the Operational Area or EMBA (see **Section 4.9.2**) are assessed as relevant to the proposed activity. Woodside acknowledges WAFIC's consultation guidance (see above) and applies this by: – directly consulting fishery licence holders that are assessed as having a potential for interaction in the Operational Area – consulting fisheries that are assessed as having a potential for interaction in the EMBA . • Commonwealth commercial fisheries that have been assessed as having a potential for interaction within the Operational Area or EMBA (see **Section 4.9.2**) are assessed as relevant to the proposed activity. • If Woodside has identified that a Commonwealth or State fishery is a relevant person, then Woodside also consults the fisheries relevant representative body. For example, WAFIC represents the interests of State fisheries in Western Australia. If a State fishery is identified as relevant, Woodside would also identify WAFIC as relevant. Recognised Commonwealth fishery representative bodies are identified by AFMA via its website. WAFIC is the only recognised State fishery representative body.

16 Consultation Approach for Unplanned Events - WAFIC

Category	Relevant person identification methodology
Recreational marine users and peak representative bodies	Woodside assesses relevance for recreational marine users and peak representative bodies using the following next steps in its methodology: • From Woodside knowledge and operating experience, knowledge of recreational marine users in the area. This assessment is both activity and location based. • Define the parameters having regard to timing, location and duration of the proposed petroleum activity. • Assess the potential spatial and temporal extent for interaction with recreational marine users by reviewing DPIRD FishCube data to assess whether there has been activity within the EMBA in the past 5 years. Assessment of relevance: • Recreational marine users that have been active in the past 5 years within the EMBA are assessed as relevant to the proposed activity. Woodside is provided with the contact details of charter, boat tourism and dive operators specific to the region of the EMBA by DPIRD to consult with the relevant persons. • If Woodside has identified recreational marine users as relevant persons, then Woodside also consults identified peak recreational marine user representative bodies. For example, Recfishwest represents the interests of recreational fishers. These representative bodies are identified via Woodside's existing consultation list, which is updated as appropriate via advice from known groups and DPIRD.
Titleholders and Operators	Woodside assesses relevance for other Titleholders and operators using the following next steps in its methodology: • Use WA Petroleum Titles (DMIRS-011) to determine overlap with other Titleholders or Operators permit areas within the EMBA. • From Woodside knowledge and operating experience, knowledge of other operators in the area. Woodside produces a map showing the outcome of this assessment. Assessment of relevance: • Titleholders and Operators whose permit areas are identified as having an overlap within the EMBA are assessed as relevant.
Peak industry representative bodies	Woodside assesses relevance for peak industry representative bodies using the following next steps in its methodology: • Review peak industry representative bodies responsibilities that Woodside actively participates in, with consideration of overlap between industry focus area and Woodside's proposed activities within the EMBA. • Review Woodside's existing consultation list. • Search websites to identify whether any additional peak industry representative bodies have been created whose responsibilities may overlap with Woodside's proposed activities within the EMBA. Assessment of relevance: • Peak industry representative bodies whose responsibilities are identified as having an overlap with Woodside's proposed activities within the EMBA are assessed as relevant.
Traditional Custodians (individuals and/or groups/entity) and Nominated Representative Corporations	Consistent with its understanding of the matters discussed in **Section 4.9.1**, to identify Traditional Custodian groups or individuals, Woodside: • uses existing systems of recognition to identify First Nations groups who overlap or are coastally adjacent to the EMBA; for example, recognition provided under native title or cultural heritage legislation, or marine park management plans, or identification by other First Nations groups or entities • notifies and invites consultation with First Nations people through their nominated representative corporation (for example, PBCs); or, in the case of native title, and where appropriate, the Native Title Representative Body • requests the nominated representative body to forward the notifications and invitations to consult to their members (members are individual communal rights holders)

Category	Relevant person identification methodology
	• requests advice as to other First Nations groups or individuals that should be consulted • advertises widely so as to invite self-identification and consultation by First Nations groups and/or individuals. Further detail to Woodside's methodology is as follows. Woodside uses the databases of the National Native Title Tribunal to understand: • whether there are any Native Title Claims (historical or current) or determinations overlapping or coastally adjacent to the EMBA • whether there are any relevant ILUAs, registered with the National Native Title Tribunal that overlap or are adjacent to the EMBA that may identify Traditional Custodians or representative bodies to contact regarding potential cultural values. Where there is a positive determination of native title, contacting the PBC or, where there representative is a Native Title Representative Body, contacting the Native Title Representative Body. Where appropriate, contacting the relevant Native Title Representative Body to request a list of any First Nations groups asserting Traditional Custodianship over an area of coastline adjacent to the EMBA. Review of Commonwealth and State Marine Park Management Plans that overlap the EMBA which may identify Traditional Custodians or representative bodies to contact regarding potential cultural values. First Nations groups or individuals identified by a Traditional Custodian, nominated representative corporation, Native Title Representative Body. Request to the PBC to distribute Woodside consultation materials through its membership. Woodside is unable to contact this membership through any other means. Woodside has a number of public notification and information sharing processes by which individual Traditional Custodians can become aware of the proposed activity, its risks and impacts, and self identify. Individuals that consider their functions, interests or activities may be affected by a proposed activity are provided an opportunity to self-identify for each EP. Woodside does not presume that self-identification for an activity, covered by another EP, automatically means that an individual/s functions, interest and activities may be affected by other activities where EMBAs overlap. This decision is for the individual to make. The public notification, information sharing, and consultation processes Woodside puts in place enables Traditional Custodians to become aware of proposed activities, assess any risks and impacts to their values, and enable individuals to self-identify. Assessment of relevance: • Traditional Custodian groups, entities or individuals and Nominated Representative Corporations who are identified through the above methodology and overlap or are coastally adjacent to the EMBA are assessed as relevant.
Native Title Representative Bodies	Woodside assesses relevance for Native Title Representative Bodies using the following steps in its methodology: • Consult a Representative Aboriginal/Torres Strait Islander Body (RATSIB), which is a regional organisation appointed under the *Native Title Act* with prescribed functions set out in Part 11 of the *Native Title Act*, which relate to: facilitation and assistance; certification; dispute resolution; notifications; agreement making. They are also known, and referred to here, as Native Title Representative Bodies. • Review National Native Title Tribunal RATSIB areas that overlap or are coastally adjacent to the EMBA. Assessment of relevance: • Where the area for which a Native Title Representative Body is recognised under the *Native Title Act* overlaps with the EMBA or is coastally adjacent to the EMBA, Woodside will assess the Native Title Representative Body as relevant.

Category	Relevant person identification methodology
Historical heritage groups or organisations	Woodside assesses relevance for groups or organisations whose responsibilities are focused on historical heritage using the following next steps in its methodology: • Use the Australasian Underwater Cultural Heritage Database to assess any known records Maritime Cultural Heritage sites (shipwrecks, aircraft and relics) within the EMBA (see **Section 4.9.1**). Assessment of relevance: • Where there is a known underwater heritage site (shipwrecks, aircraft and relics) within the EMBA, the relevant group or organisation that manages the site will be assessed as relevant.
Local government and recognised local community reference/liaison groups or organisations	Woodside assesses relevance for local government and recognised local community reference/liaison groups or organisations using the following next steps in its methodology: • Reviews Woodside maps (developed based on data from the WA Local Government, Sport and Cultural Industries My Council database and WA Local Government Association (WALGA) Local Government Directory maps) to assess any overlap between the local government's defined area of responsibility and the EMBA. • Host regular community reference/liaison group meetings. Members represent a cross-section of the community and local towns interests. Representatives are from community and industry and generally include, Woodside, State Government (for instance relevant Regional Development Commissions), Local Government, Indigenous Groups, Industry representative bodies, Community and industry organisations. Woodside considers these reference/liaison groups to be the appropriate recognised representatives of the local community for the oil and gas sector. • Review the community reference/liaison group's terms of reference to determine its area of responsibility and any overlap with the EMBA. For example, the Exmouth Community Liaison Group's area of responsibility in relation to Woodside's operational, development and planning activities, is defined in the terms of reference as the Exmouth sub-basin. Comparatively, the Karratha Community Liaison Group's area of responsibility is the Pilbara region (i.e., onshore). Assessment of relevance: • The local government whose defined area of responsibility overlaps the EMBA is assessed as relevant. • The community reference/liaison group whose defined area of responsibility overlaps the EMBA is assessed as relevant and consulted collectively via the relevant reference/liaison group.
Other non-government groups or organisations	Woodside assesses relevance for other non-government groups or organisations using the following next steps in its methodology: • Review Woodside's existing consultation list. • Search the websites of registered non-government groups or organisations (i.e., registered with an Australian Business Number (ABN) and publicly available contact information) that may have public website material specific to the proposed activity at the time of development of the EP. The organisation should have a publicly available mission statement (or purpose) that clearly describes their collective functions, interests or activities. • Review current website material to identify targeted information which demonstrates functions, interests or activities relevant to the potential risks and impacts associated with planned activities. Assessment of relevance: • Registered non-government groups or organisations with current targeted public website material specific to the proposed activity at the time of developing the EP and who have demonstrated functions, interests or activities relevant to the potential risks and impacts associated with planned activities in accordance with the intended outcome of consultation will be assessed as relevant.

Category	Relevant person identification methodology
Research institutes and local conservation groups or organisations	Woodside assesses relevance for research institutes and local conservation groups or organisations using the following next steps in its methodology: • Review Woodside's existing consultation list. • Search the websites for research institutes that may operate within the EMBA. This assessment is both activity and location based. • Search the websites for local conservation groups or organisations that regularly conduct conservation activities within the EMBA. Assessment of relevance: • Where there is known research being undertaken by a research institute within the EMBA, the research institute that is conducting the research will be assessed as relevant. • Local environmental conservation groups who regularly conduct conservation activities or have demonstrated conservation functions, interests or activities within the EMBA are assessed as relevant. This assessment is both activity and location based.

5.3.5 Regulation 25(1)(e)

In addition to assessing relevance under regulation 25(1)(d) of the Environment Regulations, Woodside has discretion to categorise any other person or organisation as a relevant person under regulation 25(1)(e) of the Environment Regulations.

5.3.6 Identification of Relevant Persons Under Regulation 25(1)(e)

Woodside adopts a case-by-case approach for each EP to assess relevance under regulation 25(1)(e) of the Environment Regulations.

5.3.7 Persons or organisations Woodside chooses to contact

In addition to undertaking consultation with relevant persons under regulation 25(1) of the Environment Regulations there are persons or organisations that Woodside chooses to contact, from time to time, in relation to a proposed activity. For example, these are persons or organisations:

- that are 'not relevant' pursuant to regulation 25(1) of the Environment Regulations but that Woodside has chosen to seek additional guidance from, for example, to inform the correct contact person that Woodside should consult, or engage with
- that are 'not relevant' pursuant to regulation 25(1) of the Environment Regulations but have been contacted as a result of consultation requirements changing or updated guidance from the Regulator
- where it is unclear what their functions, interests or activities are, or whether their functions, interests or activities may be affected. In this circumstance, engagement is required to inform relevance under Woodside's methodology. Woodside follows the same methodology for assessing a person or organisations relevance as it does during its initial assessment (as described in Figure 5-2 and **Section 5.3**). The result of Woodside's assessment of relevance during the development of the EP is outlined in **Appendix F,** Table 1.

5.3.8 Assessment of Relevant Persons for the Proposed Activity

The result of Woodside's assessment of relevant persons in accordance with regulation 25(1) is outlined in **Appendix F,** Table 1 and **Appendix F,** Table 2.

Persons or organisations that Woodside assessed as not relevant but chose to contact at its discretion in accordance with **Section 5.3.4** or self-identified and Woodside assessed as not relevant are summarised in **Appendix F,** Tables 1 and 3.

5.4 Consultation Material and Timing

Regulation 25(2) of the Environment Regulations provides that a titleholder must give each relevant person sufficient information to allow the relevant person to make an informed assessment of the possible consequences of the activity on the functions, interests or activities of the relevant person. Regulation 25(3) of the Environment Regulations provides that the titleholder must allow a relevant person a reasonable period for the consultation.

As set out in **Section 5.2**, Woodside notifies relevant persons, of the proposed activities, respecting that consultation is voluntary (for the relevant person) and collaborates on a consultation approach where further engagement is sought by the relevant person. Woodside understands that the consultation process should be appropriate for the category of relevant persons and that not all persons or organisations will require the same level of engagement. Woodside recognises that the level of engagement is dependent on the nature and scale of the PAP. Woodside recognises published guidance for good practice consultation relevant to different sectors and disciplines. Woodside's methodology for providing relevant persons with sufficient information as well as a reasonable period of time to provide feedback is set out in this section.

5.4.1 Sufficient Information

Woodside produces a Consultation Information Sheet for each EP. This is provided to relevant persons and organisations and is also available on Woodside's website for interested parties to access and to provide feedback on. The Consultation Information Sheet typically includes a description of the proposed petroleum activity, the PAA where the activity will take place, the timing and duration of the activity, a location map of the PAA and EMBA, a description of the EMBA, relevant exclusion zones as well as a summary of relevant risks and mitigation and/or management control measures relevant to the proposed petroleum activity. It also sets out contact details to provide feedback to Woodside.

Woodside recognises that the level of information necessary to assist a person or organisation to understand the impacts of the proposed activity on their functions, interests or activities may vary and, also may depend on the degree to which a relevant person is affected. For example, Woodside considers that relevant persons who may be impacted by planned activities in the Operational Area as a result of temporary displacement due to exclusion zones, may require more targeted information relevant to their functions, interests or activities. Woodside also acknowledges NOPSEMA's brochure entitled *Consultation on offshore petroleum environment plans information for the community*, which advises consultees that they may inform titleholders that they only want to be consulted in the very unlikely event of an oil spill.

Woodside places advertisements in selected local, state and national newspapers. This typically includes the name of the EP Woodside is seeking feedback on, an overview of the activity, the consultation feedback date and the ways in which a person or organisation can provide feedback. Advertising in the local paper in the area of the activity is also consistent with the public notification process under section 66 of the *Native Title Act* for native title applications. Woodside typically aligns advertisement feedback timeframes with the timing described below. Feedback received is assessed in accordance with **Section 5.3** to determine relevance and evidenced in **Appendix F** Table 1 as appropriate.

Woodside utilises a range of tools to provide sufficient materials to relevant persons, which may include one or more of:

- Consultation Information Sheet available on Woodside's website
- Summary Consultation Information Sheet, presentations or summaries specific to a particular relevant person group
- subscription available on Woodside's website to receive notification of new Consultation Information Sheets for Woodside EPs

- emails
- letters
- phone calls
- face-to-face meetings (virtual or in person) with presentation slides or handouts as appropriate
- maps outlining a persons or organisations defined area of responsibility in relation to the proposed activity, for example a fisheries management area or defence training area
- community meetings, as appropriate.

Woodside recognises that information may need to be provided to relevant persons in an iterative manner during the consultation process. Woodside considers that genuine two-way engagement may be demonstrated via information on incorporation of controls, where applicable, being provided to the relevant person so that the relevant persons understands how their input has been considered in the development of the EP.

Woodside communicates with relevant persons in different ways. Woodside recognises that as part of genuine two-way dialogue, these forms of communication may evolve, including for example due to changes to organisation representation, as relationships are further established, or an alternative form of communication is expressed by a person or organisation. Woodside acknowledges that there might be limitations in how it can consult with relevant persons.

Typical forms of communications for categories of relevant persons are set out in **Table 5-3**.

Table 5-3: Forms of communication with 'relevant persons'

Category of relevant person	Typically accepted form of communication
Government departments/ agencies – marine	Woodside applies NOPSEMA's guideline for engagement with Commonwealth government departments or agencies in line with *GL1887 – Consultation with Commonwealth agencies with responsibilities in the marine area – January 2023* by using email for its consultation unless another form of communication is requested. Other forms of communication, such as phone calls, and meetings and/or presentation briefings are used on request.
Government departments/ agencies – environment	
Government departments/ agencies – industry	
Commercial fisheries and peak representative bodies	**Commonwealth commercial fisheries**: Email is used as the primary form of communication with Commonwealth commercial fisheries in the ordinary course of business. Other forms of communication, such as phone calls, and meetings and/or presentation briefings are used on request. **State commercial fisheries and recreational marine users:** The Western Australian Department of Primary Industries and Regional Development (DPIRD) has responsibility for managing the *Fish Resources Management Act 1994* and *Aquatic Resources Management Act 2016*, which limits the provision of contact details from the register to the name and business address of licence holders. Alternative forms of communication are at the licence holder's discretion. Other forms of communication, such as phone calls, and meetings and/or presentation briefings are used on request. **Peak representative bodies**: Email is used as the primary form of communication with commercial fishery and recreational marine user peak representative bodies in the ordinary course of business. Other forms of communication, such as phone calls, and meetings and/or presentation briefings are used on request.
Recreational marine users and peak representative bodies	
Titleholders and Operators	Email is used as the primary form of communication between titleholders and operators in the ordinary course of business. Other forms of communication, such as phone calls, and meetings and/or presentation briefings are used on request.
Peak industry representative bodies	Email is used as the primary form of communication with peak representative bodies in the ordinary course of business. Other forms of communication, such as phone calls, and meetings and/or presentation briefings are used on request.

Category of relevant person	Typically accepted form of communication
Traditional Custodians and nominated representative corporations	There are many forms of communication that Woodside uses on a case-by-case basis and as appropriate to or requested by the specific group, such as email, phone calls, meetings and community forums. Other forms of communication are used on request.
Native Title Representative Bodies	There are many forms of communication that Woodside uses on a case-by-case basis and as appropriate to or requested by the specific group, such as email, phone calls, meetings and community forums. Other forms of communication are used on request.
Historical heritage groups or organisations	NOPSEMA's guideline (*GL1887 – Consultation with Commonwealth agencies with responsibilities in the marine area – January 2023*) for engagement with government departments or agencies is used as a reference for Woodside's approach for communicating with historical heritage groups or organisations. Other forms of communication, such as phone calls, and meetings and/or presentation briefings are used on request.
Local government and recognised local community reference/liaison groups or organisations	**Local government:** NOPSEMA's guideline (*GL1887 – Consultation with Commonwealth agencies with responsibilities in the marine area – January 2023*) for engagement with local government is used as a reference for Woodside's approach for communicating with historical heritage groups or organisations. **Community reference/liaison groups and chambers of commerce:** Email is used as the primary form of communication with local community reference/liaison groups or organisations in the ordinary course of business. Other forms of communication, such as phone calls, and meetings and/or presentation briefings are used on request.
Other non-government groups or organisations	Email is used as the primary form of communication with Other non-government groups or organisations. Other forms of communication, such as phone calls, and meetings and/or presentation briefings are used on request.
Research Institutes and Local conservation groups or organisations	Email is used as the primary form of communication with research institutes and local conservation groups or organisations. Other forms of communication, such as phone calls, and meetings and/or presentation briefings are used on request.

Information which is provided to relevant persons for the purposes of consultation on this EP is summarised at **Appendix F,** Table 2.

Appendix F, Table 3 sets out the information which is provided to persons or organisations that are not relevant for the purposes of regulation 25 of the Environment Regulations but which Woodside has chosen to contact.

When engaging in consultation, Woodside notifies relevant persons that, in accordance with regulation 25(4) of the Environment Regulations, the relevant person may request that particular information the person or organisation provides in the consultation not be published and that information subject to that request will not be published.

5.4.2 Reasonable Period for Consultation

Woodside seeks to consult in order to support preparation of its Environment Plan. Woodside recognises that what constitutes a reasonable period for consultation should be considered on a case-by-case basis, with reference to the nature, scale and complexity of the activity.

Woodside recognises that information may need to be provided to relevant persons in an iterative manner during the consultation process. Woodside considers that genuine two-way engagement may be demonstrated via information on incorporation of controls, where applicable, being provided to the relevant person so that the relevant person understands how their input has been considered in the development of the EP.

Woodside considers its methodology allows relevant persons a reasonable period for consultation (regulation 25(3) of the Environment Regulations). A reasonable period for all relevant persons,

including Traditional Custodian relevant persons, to participate in consultation for this EP has been provided.

The consultation period under this EP has satisfied benchmark periods under other relevant legislative processes:

- regulation 30 of the Environment Regulations sets out a public consultation period of 30 days.
- The Department of Mines and Petroleum "Guidelines for Consultation with Indigenous People by Mineral Explorers" directs a period of 21 to 30 days of consultation with traditional owners.
- While repealed, guidance taken from the Aboriginal Cultural Heritage Act 2021 – Consultation Guidelines (Government of Western Australia, 2023) suggests that up to 12 weeks may be a reasonable period of time to allow identification, contact, and response, from First Nations peoples (subject to any alternative timeframe being agreed through co-design of consultation).

This period of consultation demonstrates that Woodside has provided a "reasonable period" for relevant persons to consult in accordance with regulation 25(3). Commentary in the Tipakalippa Appeal judgment limits consultation to a process that must be capable of being discharged within a reasonable time:

"it must be taken to be the regulatory intention that the consultation requirement cannot be one that is incapable of being complied with within a reasonable time..."[17]

Woodside seeks feedback in order to support preparation of its environment plan. What constitutes a reasonable period for consultation is considered on a case-by-case basis, with reference to the person being consulted with and the nature, scale and complexity of the activity.

Woodside's typical approach to enable a reasonable period for consultation is:

- advertising in a selected local, state and national newspapers to give persons or organisations the opportunity to understand the activity and identify whether their functions, interests or activities may be affected
- providing consultation materials directly to identified relevant persons as well as persons who are not relevant but Woodside chose to contact, and providing a target date for feedback; Woodside acknowledges feedback may be received from relevant persons following the target date
- acknowledging that the way in which Woodside provides consultation information may vary depending on the relevant person or organisation and, may depend on the degree to which a relevant person or organisation is affected; different consultation processes may be required for relevant persons and organisations depending on the information requirements
- following up with relevant persons prior to EP submission, where possible, Woodside will endeavour to use an alternative method of communication to contact the relevant person
- engaging in two-way dialogue with relevant persons or organisations where feedback is received.

Appendix F Tables 2 and 3 set out a history of consultation and demonstrate a reasonable period of consultation has been afforded for each relevant person.

Woodside considers that the "reasonable period" of consultation for this EP has closed.

17 Santos NA Barossa Pty Ltd v Tipakalippa [2022] FCAFC 193 at paragraph [136].

As detailed in **Section 5.6**, if comments and feedback are received after the EP has been submitted, Woodside will consider those comments and update controls as appropriate, at all stages during the life of the EP as per Woodside's ongoing consultation approach as described in **Section 5.7**.

5.4.3 Discharge of Regulation 25

The Full Federal Court made clear in the Tipakalippa Appeal that consultation should be approached in a "*reasonable*", "*pragmatic*" and "*not so literal*" way, so that consultation obligations were capable of being met by titleholders (**Section 5.5.1**)[18]. Consultation is a "*real world activity*" and must be capable of reasonable discharge.[19] The Full Federal Court referred to Native Title cases as an illustration that reasonable limits should be applied to consultation efforts to ensure the process is workable.[20]

When the titleholder demonstrates that it has provided sufficient information and a reasonable period for consultation, the regulation 25 of the Environment Regulations consultation requirements are met.[21] Meeting these obligations requires evaluative judgment to determine reasonable satisfaction of the consultation obligation, and as such, the regulator uses its discretion to determine if these criteria are met. The nature of the person being consulted, and their function, interest and activity that may be affected, will inform the manner of consultation and the reasonable period to be afforded.[22]

While a titleholder is required to provide an opportunity to consult, the titleholder is not required to obtain consent to engage in the activity from a person being consulted or confirmation from a person being consulted that consultation is complete.

The Federal Court has commented that a "reasonable opportunity" for consultation must be afforded to relevant persons.[23] A reasonable opportunity may not be every opportunity requested and is limited to reasonable opportunities to consult.

Woodside has completed steps required to discharge its consultation obligations. Woodside has provided sufficient information and a reasonable period of time to enable relevant persons to make an informed assessment of the possible consequences of the activity on their functions, interests or activities, and sufficient time to provide relevant feedback for Woodside to assess relevant persons' objections or claims and action the assessment and response. Woodside has also provided a reasonable opportunity for there to be genuine two-way dialogue on a person's claims or objections.

Woodside has discharged its duty under regulation 25 of the Environment Regulations. Woodside considers that consultation under regulation 25 is complete.

Appendix F Tables 2 and 3 of this EP set out the history of consultation under regulation 25. To the extent a relevant person says that it has further information to share or claims that consultation under regulation 25 has not been completed, **Appendix F** Tables 2 and 3 provide reasons specifically why Woodside considers consultation under regulation 25 has been met in relation to that relevant person.

5.5 Context of Consultation Approach with First Nations

To comply with regulation 25, Woodside identifies and consults Traditional Custodians whose functions, interests or activities may be affected by the activities under an environment plan.

5.5.1 Approach to Methodology − Woodside's Interpretation of Tipakalippa Appeal

Woodside has implemented a consultation methodology consistent with regulation 25 and guidance provided in the Tipakalippa Appeal (**Section 5.2**). Woodside's consultation methodology allows for a sufficiently broad capture of Traditional Custodian relevant persons, provides for informed consultation, follows cultural protocols and allows a reasonable opportunity for consultation with Traditional Custodians whose functions, interests or activities may be affected by the activity described in this EP (**Section 5.5.2.1** to **5.5.2.4**).

Woodside notes the Full Federal Court discussed several *Native Title Act 1993* (Cth) (NTA) cases in response to a submission made in that case that a requirement under regulation 25 to consult "*each and every*" relevant person would be "*unworkable*". The reference to native title cases dealt with how decision-making processes under the NTA requiring "*all*" members of a group to be contacted for communal approval are interpreted by courts in a "*reasonable*", "*pragmatic*" and "*not so literal*" way,[24] and how obligations to consult "*each and every*" person under regulation 25 of the Environment Regulations should be interpreted in a similarly pragmatic way so that consultation is workable. The reference to NTA authorities was made by analogy:

"It can be seen that the terms of [the native title legislation] are somewhat absolute – "all". However, [the native title legislation] has consistently been construed in a way that is not so literal … The cases concerning [the native title legislation] … have reiterated … that [the native title legislation] does not require that "all" of the members of the relevant claim group be involved in the decision. The key question will be whether a reasonable opportunity to participate in the decision-making process has been afforded by the notice for a relevant meeting."[25]

"We consider the authorities in relation to processes under the NTA to be ***illustrative*** *of how a seemingly rigid statutory obligation to consult persons holding a communal interest may operate in a workable manner" (emphasis added).*[26]

"there is no definition of what constitutes "consultation for the purpose of ref 11A [now regulation 25]... A titleholder will need to "demonstrate" to NOPSEMA that what it did constituted consultation appropriate and adapted to the nature of the interests of the relevant persons"[27] (emphasis added).

The Judgment in the Tipakalippa Appeal makes it clear that a Titleholder will have some decisional choice in identifying which natural person(s) are to be approached, how the information will be given to allow the "relevant person" to assess the possible consequence of the proposed activities on their functions, interests or activities, and how the requisite consultation is undertaken.[28] Woodside takes this to mean that consultation is not fixed to a rigid process, and indeed, will need to be adapted so that it is informed by the relevant person or group. Woodside has met its regulation 25 requirements through its consultation methodology (**Section 5.2**).

Consistent with the Tipakalippa Appeal, Woodside considers NTA-style "full group" meetings are not the only way for there to be compliance with regulation 25 in relation to Traditional Custodian relevant persons. Nominated representative corporations (such as PBCs established under the NTA) have a designated role of representing the views of their member Traditional Custodians. They have established methods for engaging with their own members. Woodside will not undermine the purpose and authority of nominated representative corporations by requiring full group meetings where the nominated representative corporations have not requested engagement of members via full group meetings. We do not consider it appropriate for titleholders to direct or challenge the nominated representative corporations on how to engage with their members.

25 Santos NA Barossa Pty Ltd v Tipakalippa [2022] FCAFC 193 at paragraph [98].
26 Santos NA Barossa Pty Ltd v Tipakalippa [2022] FCAFC 193 at paragraph [96].
27 Santos NA Barossa Pty Ltd v Tipakalippa [2022] FCAFC 193 at paragraph [104].
28 Santos NA Barossa Pty Ltd v Tipakalippa [2022] FCAFC 193 at paragraph [47] and [48].

Woodside's approach described below demonstrates that sufficient information and a reasonable opportunity is provided to individual Traditional Custodians to provide feedback on Woodside activities beyond the opportunity provided to nominated representative corporations.

5.5.2 Consultation Method

Woodside's First Nations team has experience in engaging and working with First Nations organisations and individuals, including having worked within the Commonwealth native title and cultural heritage systems and state and territory cultural heritage and land rights systems, for several decades. The team understands the complexities of making information accessible to groups and individuals and engaging in accordance with First Nations groups' established channels of communication and methods of consultation. The First Nations team exercises its professional judgement and is deeply respectful of long-standing relationships (where in place) when considering consultation with First Nations groups. The First Nations team's approach is also informed by the established systems of recognition for First Nations groups and their nominated representative corporations within particular jurisdictions.

For example, the methodology for engaging with First Nations groups in the Northern Territory (not relevant for this EP) tends to centre around engagement through Aboriginal land councils (under the *Aboriginal Land Rights (Northern Territory) Act 1976* (Cth)) as well as community meetings that target clan groups where they do not have PBCs or other nominated representative corporations to represent them. By contrast, recognition for First Nations groups and their nominated representative corporations in Western Australia falls under the *Native Title Act* (Cth) because the vast majority of the Western Australian coastline is settled under the native title regime. This means the methodology and process for consultation in Western Australia places greater emphasis on, but is not limited to, Native Title Representative Bodies and PBCs. Native title determinations provide certainty about the appropriate Traditional Custodian groups that have the cultural authority to speak for country adjacent to the EMBA, and help Woodside to identify Traditional Custodian persons and groups asserting Traditional Custodianship. The Judgment in the Tipakalippa Appeal endorses methods of consultation with groups of relevant persons that are appropriate and adapted to the characteristics of groups.[29] Woodside's consultation methodology is adapted and appropriate to the recognised systems of communal interests in Western Australia.

In Western Australia (relevant for this EP), Woodside has sought to follow the established, effective and respectful means of communication used by Native Title Representative Bodies and nominated representative corporations (including PBCs) with their respective First Nations communities. Woodside follows these processes for the appropriate broad capture of individuals' awareness of our activities, to self-identify (**Section 5.5.2.2**), and to provide feedback to inform the management of environmental impacts and risks.

Using these tools, Woodside communicates information about Environment Plans in these ways:

- advertising in relevant newspapers encourages self-identification, by advertising proposed activities widely through newspapers that have national and intra-state circulation; i.e., Koori Mail, National Indigenous Times, The West Australian

  creating carefully considered Consultation Summary Sheets, with information developed by an Indigenous member of the First Nations Team to remove jargon, provides relevant information for people to have informed understandings about the activities

- direct contact through nominated representative corporations
- utilising social media (i.e., Facebook/Instagram), texts and emails. These mediums are the preferred communication methods used by Traditional Custodians throughout Western Australia and, on that basis, used by Native Title Representative Bodies and other government agencies and industry to engage with Traditional Custodians or call meetings.

29 Santos NA Barossa Pty Ltd v Tipakalippa [2022] FCAFC 193 at paragraph [95].[104].[153].

First Nations woman, Professor Bronwyn Castle through 10 years of research found "*Social media is an intrinsic part of daily life. The use of Facebook is around 20 per cent higher [among First Nations people] than the national average across all geographical locations*" (Social media mob: being Indigenous online, Professor Bronwyn Carlson (2018)).

- For ongoing consultation post regulation 25 of the Environment Regulations consultation, Woodside introduced a Program of Ongoing Engagement with Traditional Custodians which sets out Woodside's commitment to ongoing engagement and support to care for and manage country, including Sea Country. The program was developed in response to Traditional Custodian feedback.
- Woodside has members of its First Nations team who are based in Karratha and Roebourne and who serve as on-Country points of contact for First Nations organisations and individuals. These team members have broad local knowledge and established, on-the-ground relationships within communities. This helps contribute to positive outcomes including encouraging First Nations attendance and involvement at Woodside's information sessions and Community roadshows. Team members on the ground engage in a great deal of preparatory work including by distributing information and providing notice to the community to support First Nations attendance at information sessions and Community roadshows.
- From the commencement of engagement with Traditional Custodians, Woodside seeks direction on how they prefer to be consulted and has consulted accordingly. Consultation processes that are informed by Traditional Custodians and co-designed on a case-by-case basis and includes their direction as to cultural protocols, structure of consultation and whom to appropriately consult with (such as elders).
- Woodside holds meetings on Country at a place and time agreed with the Traditional Custodians, offering and providing financial assistance for meeting expenses (as appropriate).

- Woodside provides information specifically designed to be easily understood, to reach all relevant people, and gives a reasonable period of time for those people to make an informed assessment of the possible consequences of the proposed activity on them.

The First Nations teams' approach to consultation is also consistent with the Federal Court's decision in the Munkara Case. The Munkara Case notes that the word "culture" (and hence the word "cultural") has a communal aspect to it. In order to establish cultural features, it is necessary that the beliefs and values are held by the *relevant* people *as a people*. In order for values, features or beliefs that are expressed by an individual to be "cultural" they cannot simply be an individual's belief - the belief must have a communal aspect to, and demonstrate that the "individual beliefs are broadly representative of the beliefs of other members of the group"[30]. The phrase "cultural features", when applied to "people" as constituent parts of an ecosystem, is not directed to idiosyncratic views or beliefs of an individual[31]. When the First Nations team is told that a particular value is cultural by a Traditional Owner, that information is taken back to the relevant cultural authority to test its broad acceptance. In the case of gender sensitive information, that information would be restricted to the specific gender within the community.

5.5.2.1 Identification of Relevant Persons

In order to undertake consultation, Woodside has developed a methodology for identifying relevant persons, in accordance with regulation 25(1) of the Environment Regulations (**Sections 5.2** and **5.3**).

Specific to Woodside's approach for identifying relevant Traditional Custodians, Woodside's First Nations Communities Policy and consultation approach is guided by Traditional Custodians by

[30] *Munkara v Santos NA Barossa Pty Ltd* (No 3) [2024] FCA 9 at [205]
[31] *Munkara v Santos NA Barossa Pty Ltd* (No 3) [2024] FCA 9 at [205]

directing consultations through their nominated representative corporation. This has been implemented by Woodside through consultation with a nominated representative corporation where that corporation has advised Woodside that it acts as the representative body for a Traditional Custodian group and has requested that Woodside engage with it as the representative body for that Traditional Custodian group.

Woodside asks nominated representative corporations (such as PBCs) and Native Title Representative Bodies to identify individuals that should be consulted, and enables individuals to self-identify in response to national and local advertising, social media and community engagement opportunities (**Section 5.5.2.4**). Where there is a nominated representative corporation for an area, unless directed by the nominated representative corporation, Woodside does not directly approach individuals for consultation, because this has the potential to undermine the role of the nominated representative corporations. Approaching individuals directly is a practice that is no longer considered acceptable because of divisions it has been shown to cause in communities. In addition to asking for the identification of individuals, Woodside also asks nominated representative corporations to distribute consultation information to whomever the nominated representative corporations deem appropriate including members of the nominated representative corporations who are communal rights holders.

Having said this, as set out in further detail in **Section 5.5.2.4**, individuals are also given the opportunity to self-identify, consult and provide their own feedback on the proposed activity. When approached in this way, Woodside will engage individuals as relevant persons and will also (subject to any confidentiality or cultural restrictions) advise the nominated representative body of the consultation where it relates to cultural values. These methods of consultation are consistent with requirements for notification under the *Native Title Act* (Cth), such as under the future act provisions (section 29), which requires notification of the Native Title Representative Body, the PBC (or nominated representative) and notification through newspapers. The notification process has been selected as a respectful, practical and pragmatic analogue for consultation with First Nations peoples, rather than requiring members to be notified via a formal authorisation process which aims to seek, from members, authorisation of agreements and native title/compensation claims under the *Native Title Act 1993* (Cth)[32].

In this consultation, Woodside requested nominated representative corporations to identify any potential individual relevant persons for consultation. Woodside requests nominated representative corporations to distribute consultation materials to their members, however, Woodside recognises that the process is voluntary and that it cannot compel nominated representative corporations (such as PBCs) to do so. Woodside also recognises that it would not be appropriate to seek to audit the nominated representative corporations for compliance with any member consultation request.

5.5.2.2 Opportunity to Self-identify and Identifying Other Individuals

Woodside requests nominated representative corporations and Native Title Representative Bodies to identify other individuals to consult with or individuals who may seek to self-identify for a proposed activity. Woodside also advertises broadly through Indigenous, national and local advertising, social media and community engagement opportunities to provide individuals with an opportunity to consult. Woodside does not directly approach individuals for consultation, as this undermines the role of the nominated representative corporations (**Section 5.5.2.1**). Woodside's approach to providing individual Traditional Custodians the opportunity to self-identify and consult for an Environment Plan is as follows:

- Woodside applies the principles of self-determination when consulting with Traditional Custodians by consulting through the Traditional Owners' authorised representative entities.
- Recognising the function of nominated representative corporations (such as PBCs) and Native Title Representative Bodies to represent communal interests and manage cultural

32 Santos NA Barossa Pty Ltd v Tipakalippa [2022] FCAFC 193, at [104]

values, Woodside requests that the information provided to representative entities is provided to their members but Woodside recognises the process is voluntary and Woodside cannot compel them to do so nor seek to audit the representative entities for compliance with any request.

- Representative entities cannot provide membership details to Woodside due to individual confidentiality requirements.
- Woodside requests advice as to who else Woodside should be consulting but recognises the process is voluntary and cannot compel nominated representative corporations to provide this information.
- Modern Indigenous engagement practices rely on the building and maintaining of respectful relationships. Most nominated representative corporations to date have requested the building of that relationship, where one is not already in place.
- While Woodside has, in some cases, approached individual directors and elders outside of this process due to requirements imposed in Environment Plan consultation, this approach is considered inappropriate by modern Indigenous engagement standards, fundamentally undermining the authority of the authorised representative entity and can be detrimental to the relationship.

For this proposed activity, Woodside requested nominated representative corporations (including PBCs) and Native Title Representative Bodies to identify any potential individual relevant persons for consultation, and to distribute consultation materials to their member base. However, Woodside recognises the process is voluntary and it cannot compel them to do so nor seek to audit the representative entities for compliance with any request. Woodside has not been directed to engage individual Traditional Custodians by nominated representative corporations for this proposed activity. Woodside has nevertheless provided reasonable opportunity for individual Traditional Custodians to engage in consultation through appropriate and adapted consultation methods.

5.5.2.3 Sufficient Information

Woodside recognises that the information sufficient to allow a person or organisation to make an informed assessment of the possible consequences of the proposed activity on their functions, interests or activities may vary and also may depend on the degree to which a relevant person is potentially affected.

Woodside produces a Consultation Information Sheet for each Environment Plan which is provided to relevant persons and organisations to provide the opportunity for feedback on the activity (**Section 5.4.1**). In response to Traditional Custodians' feedback, Woodside has tailored effective consultation methods for its activities, specifically designed for Traditional Custodians, so that information is provided in a form that is readily accessible and appropriate. The targeted Consultation Summary Sheet developed and reviewed by Indigenous representatives so that content is appropriate to the intended recipients, is then provided to relevant Traditional Custodian groups. Phone calls are made to provide context to the consultation.

Where face to face consultation meetings are requested, Woodside coordinates engagement at the Traditional Custodians' location of choice (where practicable) and with their nominated attendees. Key project personnel, environmental and First Nations relations experts are typically present to enable effective communication and prompt response to questions. Materials for these sessions incorporate visual aids such as photos, maps and videos, and plain language suitable for people with a non-technical background.

During consultation, Woodside provides relevant persons with additional information as appropriate in response to requests. There is no requirement to provide relevant persons with all information or documents requested and a titleholder will have provided sufficient information even where it has not provided all information or documents requested.

Woodside has sought to provide sufficient information to individual members of nominated representative corporations (such as PBCs) by providing information to representative bodies and requesting dissemination with members. However, Woodside recognises consultation is voluntary and it cannot compel them to do so nor would it be appropriate to seek to audit the representative entities for compliance with any request.

5.5.2.4 Reasonable Period for Consultation

Woodside seeks to consult in order to support preparation of its Environment Plan. Woodside recognises that what constitutes a reasonable period for consultation should be considered on a case-by-case basis, with reference to the nature, scale and complexity of the activity (**Section 5.4.2**).

5.5.2.5 Discharge of Regulation 25

Woodside's consideration and approach to discharging regulation 25 of the Environment Regulations for relevant persons is discussed in **Section 5.4.3**. In addition to this, Woodside has considered the application of regulation 25 specifically to First Nations based on the Tipakalippa Appeal.

In relation to Traditional Custodian relevant persons (and all relevant persons), Woodside has discharged its duty under regulation 25. Woodside considers that consultation under regulation 25 is complete (**Section 5.4.3**).

5.6 Providing Feedback and Assessment of Merit of Objections or Claims

There are a number of ways in which feedback can be provided. Feedback can be provided through the Woodside feedback email or via the Woodside feedback toll free phone line as outlined in the Consultation Information Sheet and the Woodside website. Where appropriate, consultation may also be supported by phone calls or meetings. An environment plan feedback form is also available on Woodside's website enabling stakeholders to provide feedback on proposed activities, or to request additional information.

Woodside consults widely on its EPs and notes that feedback is received in various forms. Feedback that is considered inappropriate or that puts the environment, health, safety or wellbeing of Woodside employees or operations at risk will not be tolerated. Woodside respects people's rights to protest peacefully and lawfully but actions that put the environment, health, safety or wellbeing of Woodside employees or operations at risk go beyond those boundaries.

Woodside accepts feedback and engages in consultation in order to achieve the aims set out in **Section 5.2**. Woodside recognises that there are persons and organisations that take a view that Woodside's operations and/or growth projects should be stopped or at least delayed as far as possible. While Woodside assesses the merits of objections or claims received, it acknowledges NOPSEMA's guidance in its brochure entitled *Consultation on offshore petroleum environment plans information for the community*, which states that relevant persons are free to respond on any matter and raise any concern, however this may not be able to be considered if it is outside the scope or purpose of the environment plan and approval process, for example, statements of fundamental objection to offshore petroleum activities or information containing personal threats or profanities. Under Regulation 34(g) of the Environment Regulations, there is no requirement for a relevant person to agree or confirm that they have been adequately consulted.

Feedback from relevant persons is reviewed and an assessment of the merits is made of information provided as well as objections or claims about the adverse impact of each activity to which the EP relates. This might, for instance, be done through a review of data and literature and for relevance to the nature and scale of the activity outlined in the EP. Consistent with the aim of consultation in **Section 5.2**, Woodside will consider information received when reviewing and designing measures to put in place to minimise harm to relevant persons and where reasonable or practical to further manage impacts and risks to ALARP and acceptable levels.

Woodside considers feedback during consultation from relevant persons and other persons Woodside chose to contact (see **Section 5.3.6**). This information is summarised in **Appendix F** Tables 1 and 2 of the EP and includes a statement of Woodside's response, or proposed response, if any, to each objection and claim.

In accordance with regulation 26(8) of the Environment Regulations, sensitive information (if any) in an EP, and the full text of any response by a relevant person to consultation under regulation 25, must be contained in the sensitive information part of the plan and not anywhere else in the plan.

5.7 Ongoing Consultation

Consultation can continue to occur during the life of an EP, including after an EP has been accepted by NOPSEMA.

As per Woodside's ongoing consultation approach (refer to **Section 7.10**), feedback and comments received from relevant persons continue to be assessed and responded to, as required, throughout the life of an EP, including during its assessment and once accepted, in accordance with the intended outcome of consultation (as set out in **Section 5.2**).

Should consultation feedback be received following the acceptance of an EP that identifies a measure or control that Woodside considers requires implementation or updates to meet the intended outcome of consultation, Woodside will apply its Management of Change and Review process as appropriate (see **Section 7.2.5**).

6 ENVIRONMENTAL IMPACT AND RISK ASSESSMENT, PERFORMANCE OUTCOMES, STANDARDS AND MEASUREMENT CRITERIA

6.1 Overview

This section presents the impact and risk analysis and evaluation, EPOs, EPSs and MC for the Petroleum Activities Program, using the methodology described in **Section 2**. MEEs require a further level of analysis and are assessed separately in **Section 6.7**.

6.2 Analysis and Evaluation

As required by regulations 21(5) and 21(6) of the Environment Regulations, the analysis and evaluation demonstrate that the identified risks and impacts associated with the Petroleum Activities Program are reduced to ALARP, are of an acceptable level and consider all operations of the activity, including potential emergency conditions.

Impacts and risks identified during the ENVID (including Decision Type, current risk level, acceptability of risk and tools used to demonstrate acceptability and ALARP) have been divided into two broad categories:

- planned (routine and non-routine) activities
- unplanned events (accidents, incidents or emergency situations).

Within these categories, impact and risk assessment groupings are based on environmental aspect[33] (e.g., emissions, physical presence, etc). For all hazardous events considered, the worst credible consequence was assumed.

The ENVID identified 11 impacts and 17 risks associated with the Petroleum Activities Program. Planned activities and unplanned events are summarised in **Table 6-1** and **Table 6-2**.

The analysis and evaluation for the Petroleum Activities Program indicate that current environmental risks and impacts associated with the activity are reduced to ALARP and are of an acceptable level, as discussed further in **Sections 6.6**, **6.7** and **6.8**.

33 An environmental aspect is an element of the activity that can interact with the environment.

Table 6-1: Environmental impact and risk analysis summary table – planned activities (routine and non-routine)

Aspect	EP section	Source of impact	Key potential environmental impacts (refer to relevant EP section for details)	Controlled impact classification	Residual impact level (ALARP controls in place)	Acceptability of impact
Physical Presence: Interaction with other Marine Users	**6.6.1**	Presence of facility excluding and/or displacing other users from PSZ and PAA respectively.	Potential isolated social impact resulting from interference with other sea users (e.g., commercial and recreational fishing, and shipping).	F	Social and Cultural – No lasting effect (<1 month). Localised impact not significant to areas/items of cultural significance.	Broadly Acceptable
		Presence of MODU, installation vessels and other support vessels excluding and/or displacing other users during tie-back activities.				
		Presence of subsea infrastructure interfering with or displacing third party vessels (commercial fishing).				
Physical Presence: Disturbance to Seabed	**6.6.2**	Presence of facility and subsea infrastructure modifying marine habitats.	Localised modification of seabed habitat (formation of artificial reef) within PAA.	E	Environment – Slight, short-term impact (< 1 year) on species, habitat (but not affecting ecosystem function), physical or biological attributes.	Broadly Acceptable
		Subsea operations, inspection, maintenance and repair activities including installation of pig receivers at the subsea wells resulting in disturbance to seabed.	Potential minor, localised modification of seabed habitat within PAA.	E	Environment – Slight, short-term impact (<1 year) on species, habitat (but not affecting ecosystem function), physical or biological attributes.	
		Presence of redundant infrastructure remaining infield until Facility EOFL.	Potential slight, short-term loss or damage to benthic habitats, including benthic communities and marine primary producers.	E	Environment – Slight, short-term impact (<1 year) on species, habitat (but not affecting ecosystem function), physical or biological attributes.	
		Disturbance to seabed from drilling operations.		F	Environment – No lasting effect (<1 month). Localised impact not significant to environmental receptors.	
		Disturbance to seabed from subsea installation of infrastructure (flowlines, umbilicals, flying leads, etc.) and span rectification (concrete mattresses, etc).		E	Environment – Slight, short-term impact (<1 year) on species, habitat (but not affecting ecosystem function), physical or biological attributes.	
		Disturbance to seabed from ROV operation (including localised sediment relocation from sediment mobilisation techniques and marine growth removal).		F	Environment – No lasting effect (<1 month). Localised impact not significant to environmental receptors.	
		Disturbance to seabed from mooring installation.		F	Environment – No lasting effect (<1 month). Localised impact not significant to environmental receptors.	
		Placement and retrieval of seabed transponders and temporary installation aids.		F	Environment – No lasting effect (< 1month). Localised impact not significant to environmental receptors.	
Routine Acoustic Emissions: Generation of Noise during Routine Operations	**6.6.3**	Noise generated within the PAA from: • Angel facility and associated infrastructure • vessel • helicopters • IMMR activities.	Potential localised behavioural impacts to marine fauna around and within the PAA.	F	Environment – No lasting effect (< 1month). Localised impact not significant to environmental receptors.	Broadly Acceptable
Routine Acoustic Emissions: Generation of Noise during Tie-Back Activities	**6.6.4**	Generation of acoustic signals from project vessels (MODU, installation vessels), AHVs and support vessels) during tie-back operations.	Slight, short-term impacts to marine mammals, reptiles and fish, varying from behavioural responses to physiological impact (TTS).	E	Environment – Slight, short-term impact (<1 year) on species, habitat (but not affecting ecosystem function), physical or biological attributes.	Broadly Acceptable
		Generation of acoustic signals from DP systems on project vessels.				
		Generation of noise from cutting of well infrastructure and contingency activities.		F	Environment – No lasting effect (< 1 month). Localised impact not significant to environmental receptors.	
Routine and Non-Routine Discharges: Discharge of Hydrocarbons and Chemicals during Subsea Precommissioning,	**6.6.5**	Discharge of subsea control fluids.	Localised decrease in water quality around subsea system within PAA with no lasting effect.	F	Environment – No lasting effect (<1 month). Localised impact not significant to environmental receptors.	Broadly Acceptable
		Discharge of hydrocarbons remaining in subsea pipelines/flowlines and equipment as a result of subsea intervention works.	Slight short-term decrease in water quality at release location during IMMR activities.	E	Environment – Slight, short-term impact (<1 year) on species, habitat (but not affecting ecosystems function), physical or biological attributes.	

Aspect	EP section	Source of impact	Key potential environmental impacts (refer to relevant EP section for details)	Controlled impact classification	Residual impact level (ALARP controls in place)	Acceptability of impact
Operations and Intervention Activities		Discharge of chemicals remaining in subsea pipeworks and equipment or the use of chemicals for subsea IMMR activities.	Localised decrease in water quality at release location during IMMR activities.	F	Environment – No lasting effect (<1 month). Localised impact not significant to environmental receptors.	
		Discharge of minor fugitive hydrocarbon from subsea equipment.	Potential slight short-term, localised decrease in water quality around subsea system within PAA with no lasting effect.	F	Environment – No lasting effect (<1 month). Localised impact not significant to environmental receptors.	
		Discharge of flowline and subsea installation fluids to the marine environment.	Potential slight, short-term toxic effects on marine biota.	E	Environment – Slight, short-term impact (<1 year) on species, habitat (but not affecting ecosystems function), physical or biological attributes.	
		Discharge of subsea fluids during well intervention activities.	Potential slight, short-term toxic effects on marine biota.	F	Environment – No lasting effect (<1 month). Localised impact not significant to environmental receptors.	
Routine and Non-Routine Wastewater Discharges: Utility Systems, Drains and Project Vessels	**6.6.6**	Discharge of sewage, grey water and putrescible waste from the facility, MODU and project vessels to the marine environment.	Potential localised, short-term decrease in water quality (increased nutrients and biological oxygen demand) at the discharge location.	F	Environment – No lasting effect (<1 month). Localised impact not significant to environmental receptors.	Broadly Acceptable
		Discharge of deck, bilge and drain water from the facility, MODU and project vessels to the marine environment.	Potential localised, short-term decrease in water quality (increased hydrocarbon and chemical concentrations) at the discharge location.			
		Discharge brine and cooling water from MODU and project vessels to the marine environment.	Negligible, localised increase in salinity at the discharge location.			
Routine and Non-Routine Discharges: Produced Water	**6.6.7**	Discharge of produced water during routine and non-routine operations.	Potential slight short-term, localised decrease in water quality (increased hydrocarbon and chemical concentrations) at discharge location and within mixing zone, with potential impacts to marine fauna (toxicity).	E	Environment – Slight, short-term impact (<1 year) on species, habitat (but not affecting ecosystem function), physical or biological attributes.	Broadly Acceptable
Routine and Non-Routine Discharges: Drill Cuttings, Drilling Fluids and Well Removal Fluids	**6.6.8**	Routine discharge of WBM drill cuttings to the seabed and the marine environment.	Potential slight, short-term toxic effects to marine biota, as well as localised reduction in water quality with potential effects on both water quality and benthic communities.	E	Environment – Slight, short-term impact (<1 year) on species, habitat (but not affecting ecosystem function), physical or biological attributes.	Broadly Acceptable
		Routine discharge of drilling muds (WBM) to the seabed and the marine environment.				
		Routine discharge of treated NWBM drill cuttings to the marine environment.				
		Non-routine discharge of wash water from mud pits and vessel tank wash fluids.				
		Routine discharge of well clean-out fluids.				
		Non-routine discharge of well annular fluids.				
		Non-routine discharge of WBM and cement cuttings to the marine environment during drilling out of a cement plug.				
		Non-routine discharge of grit and flocculant during removal of well infrastructure.				
Routine and Non-Routine Discharges: Cement, Cementing Fluids, Subsea Well Fluids, Unused Bulk Product and Subsea Chemicals	**6.6.9**	Routine discharge of cement and cementing fluids, to the seabed and the marine environment.	Potential slight, short term toxic effects to marine biota, as well as localised reduction in water quality with potential effects on both water quality and benthic communities.	E	Environment – Slight, short-term impact (< 1 year) on species, habitat (but not affecting ecosystem function), physical or biological attributes.	Broadly Acceptable
		Routine discharge of subsea well fluids (inc. BOP and well construction activity control fluids).				
		Produced/reservoir water disposal.				
		Non-routine discharge of unused bulk products.				
	6.6.10	Operational flaring, fugitive emissions and vessel emissions.		F		Broadly Acceptable

Aspect	EP section	Source of impact	Key potential environmental impacts (refer to relevant EP section for details)	Controlled impact classification	Residual impact level (ALARP controls in place)	Acceptability of impact
Routine and Non-routine Atmospheric and GHG Emissions: Fuel Combustion, Flaring and Fugitives		Exhaust emissions from internal combustion engines and incinerators on project vessels and helicopters.	Potential short-term localised decrease in air quality, limited to the airshed local to the facility.		Environment – No lasting effect (< 1 month). Localised impact not significant to environmental receptors.	
		Contingent flaring (well test non-routine) during well unloading for pressure test and clean up.				
		Contingent venting of gas during drilling (e.g., well kick).				
Routine Light Emissions: Light Emissions from the Facility, MODU and Project Vessels	**6.6.11**	Light emissions from the facility, MODU and project vessels.	Negligible, localised potential for behavioural disturbance of species in close proximity to riser platform and vessels.	F	Environment – No lasting effect (< 1 month). Localised impact not significant to environmental receptors.	Broadly Acceptable

		Marine environment footprint and associated hydrocarbon and chemical release associated with structural collapse of riser platform.		B	Environment – Major, long-term impact (10 to 50 years) on highly valued ecosystems, species, habitat or physical or biological attributes.	0	M	
		Surface release from support vessel diesel tank.		D	Environment – Minor short-term impact (1 to 2 years) on species, habitat (but not affecting ecosystem function), physical or biological attributes.	1	M	
Unplanned Hydrocarbon Release: Loss of Control of Suspended Load from Platform (MEE-05)	**6.7.7**	Surface or subsea release from flowline, pipeline and riser to the marine environment and atmosphere (MEE-02).	Potential significant impacts to the marine environment: • medium-term impacts to sensitive offshore and nearshore areas • disruption to marine fauna, including protected species. • potential short-term interference with or displacement of other sea users.	B	Environment – Major, long-term impact (10 to 50 years) on highly valued ecosystems, species, habitat or physical or biological attributes.	1	M	Broadly Acceptable
		Hydrocarbon release from topsides equipment to the marine environment and atmosphere (not an MEE).	Potential minor short-term impacts to the marine environment including disruption to marine fauna, including protected species, and/or temporary impacts to water quality.	D	Environment – Minor short-term impact (1 to 2 years) on species, habitat (but not affecting ecosystem function), physical or biological attributes.	1	M	
Unplanned events (accidents/incidents)								
Unplanned Hydrocarbon Release: Loss of Well Integrity during Drilling Operations	**6.8.1**	Loss of hydrocarbons to marine environment due to loss of well containment.	Potential significant impacts to the marine environment: • medium-term impacts to sensitive offshore and nearshore areas • disruption to marine fauna, including protected species. • potential short-term interference with or displacement of other sea users.	B	Environment – Major, long-term impact (10 to 50 years) on highly valued ecosystems, species, habitat or physical or biological attributes.	1	M	Acceptable if ALARP
Unplanned Hydrocarbon Release: Topsides Loss of Containment	**6.8.2**	Hydrocarbon release from topsides process equipment to the marine environment and atmosphere.	Potential minor short-term impacts to the marine environment including disruption to marine fauna, including protected species, and/or temporary impacts to water quality.	D	Environment – Minor short-term impact (1 to 2 years) on species, habitat (but not affecting ecosystem function), physical or biological attributes.	1	M	Acceptable if ALARP

Aspect	EP section	Source of risk	Key potential environmental impacts (refer to relevant EP section for details)	Risk rating				Acceptability of impact
				Controlled impact classification	Residual impact level (ALARP controls in place)	Likelihood	Residual risk rating	
Unplanned Hydrocarbon Release: Vessel Collision	**6.8.3**	Loss of hydrocarbons to marine environment due to a vessel collision (e.g., project vessels or other marine users).	Potential minor short-term impacts to the marine environment: • short-term impacts to sensitive offshore and nearshore areas • disruption to marine fauna, including protected species. • potential short-term interference with or displacement of other sea users.	D	Environment – Minor short-term impact (1 to 2 years) on species, habitat (but not affecting ecosystem function), physical or biological attributes.	1	M	Broadly Acceptable
Unplanned Discharge: Release of Hydrocarbons during Bunkering, Transfer, Storage and Use	**6.8.4**	Accidental discharge of marine diesel to the marine environment during transfer, storage or use.	Potential slight short-term impacts to marine water quality with no lasting effect.	E	Environment – Slight, short-term impact (<1 year) on species, habitat (but not affecting ecosystem function), physical or biological attributes.	1	L	Broadly Acceptable
Unplanned Discharges: Deck and Subsea Spills	**6.8.5**	Accidental discharge of chemicals from MODU and project vessels deck activities and equipment, from subsea ROV hydraulic leaks.	Potential minor short-term impacts to the marine environment including disruption to marine fauna, including protected species, and/or temporary impacts to water quality.	F	Environment – No lasting effect (<1 month). Localised impact not significant to environmental receptors.	2	L	Acceptable if ALARP
Unplanned Discharge: Drilling/Project Fluids	**6.8.6**	Accidental discharge of project fluids (WBM/NWBM/base oil) and cement to marine environment due to failure of slip joint packers, bulk transfer hose/fitting, emergency disconnect system or from routine MODU operations.	Potential slight short-term impacts to the marine environment including disruption to marine fauna, including protected species, and/or temporary impacts to water quality.	E	Environment – Slight, short-term impact (<1 year) on species, habitat (but not affecting ecosystem function), physical or biological attributes.	1	L	Broadly Acceptable
Unplanned Discharges: Hazardous and Non-hazardous Waste Management	**6.8.7**	Incorrect disposal or accidental discharge of non-hazardous and hazardous waste to the marine environment.	Potential slight short-term impacts to the marine fauna, and localised temporary impacts to water quality and marine sediments.	E	Environment – Slight, short-term impact (<1 year) on species, habitat (but not affecting ecosystem function), physical or biological attributes.	2	M	Broadly Acceptable
Physical Presence: Seabed Disturbance from Dropped Objects or Loss of Station Keeping Leading to Anchor Drag	**6.8.8**	Dropped objects resulting in the disturbance of benthic habitat.	Potential minor localised impact to benthic habitat as well as potential seabed infrastructure damage.	D	Environment – Minor short-term impact (1 to 2 years) on species, habitat (but not affecting ecosystem function), physical or biological attributes.	1	L	Broadly Acceptable
		Loss of station keeping of the MODU leading to anchor drag and the disturbance of benthic habitat.		D	Environment – Minor short-term impact (1 to 2 years) on species, habitat (but not affecting ecosystem function), physical or biological attributes.	1		
Physical Presence: Interactions with Marine Fauna	**6.8.9**	Physical presence of support vessels resulting in collision with marine fauna.	Potential injury or death of marine fauna (single animal), including protected species.	E	Environment – Slight, short-term impact (<1 year) on species, habitat (but not affecting ecosystem function), physical or biological attributes.	1	L	Broadly Acceptable
		Physical presence of bird proofing/exclusion devices resulting injury to seabirds.	Potential injury of seabird (single animal), including protected species.	F	Environment – No lasting effect (<1 month). Localised impact not significant to environmental receptors.	1	L	Broadly Acceptable
Physical Presence: Introduction of Invasive Marine Species	**6.8.10**	Invasive species in vessel ballast tanks or on vessels/submersible equipment.	Potential introduction of invasive marine species possibly resulting in an alteration of the localised environment.	E	Environment – Slight, short-term impact (<1 year) on species, habitat (but not affecting ecosystem function), physical or biological attributes.	1	L	Broadly Acceptable

6.2.1 Cumulative Impacts

Woodside has assessed the cumulative impacts of the Petroleum Activities Program in relation to other relevant petroleum activities that could realistically result in overlapping temporal and spatial extents. Other facilities located close to the PAA consist of NRC, which lies within the western end of the PAA where the export pipeline terminates, and Okha, which is approximately 5 km from the PAA. However, given the concentration of sources of environmental risks and impacts from the Petroleum Activities Program are localised, the potential for cumulative impacts is considered to be low. Cumulative impacts are discussed for sources of risk and impacts where such impacts were deemed to be credible.

6.3 Environmental Performance Outcomes, Standards and Measurement Criteria

Regulation 21(7) of the Environment Regulations requires that an EP includes EPOs, EPSs and MC that address legislative and other controls to manage the environmental risks and impacts of the activity to ALARP and Acceptable levels.

EPOs, EPSs and MC for the Petroleum Activities Program have been identified to allow Woodside's environmental performance to be measured and through the implementation of this EP, to determine whether the EPOs and EPSs have been met.

The EPOs, EPSs and MC specified are consistent with legislative requirements and Woodside's standards and procedures. They have been developed based on the legislation, codes and standards, good industry practices and professional judgement outlined in **Sections 2.6.1.1.4** and **2.8**, as part of the acceptability and ALARP justification process.

The EPOs, EPSs and MC are presented throughout this section and in **Appendix D**. A breach of these EPOs or EPSs constitutes a 'Recordable Incident' under the Environment Regulations (refer to **Section 7.11.4**).

6.4 Presentation

The analysis and evaluation (ALARP and acceptability), EPOs, EPSs and MC are presented in tabular form throughout this section, as shown in the sample below. Italicised text in this example table denotes the purpose of each part of the table, with reference to the relevant sections of the Regulations and/or this EP.

Environmental Performance Outcomes	***Controls***	***Environmental Performance Standards***	***Measurement Criteria***
EPO No. *S: Specific performance that addresses the legislative and other controls that manage the activity, and against which performance by Woodside in protecting the environment will be measured.* *M: Performance against the outcome will be measured through implementation of the controls via the MC.* *A: Achievability/feasibility of the outcome demonstrated via discussion of feasibility of controls in ALARP demonstration. Controls are directly linked to the outcome.* *R: The outcome will be relevant to the source of risk/impact and the potentially impacted environmental value[35]* *T: The outcome will state the timeframe during which the outcome will apply or by which it will be achieved.*	***C No.*** *Identified control adopted to ensure that the impacts and risks are continuously reduced to ALARP.* *Regulation 21(5)(c).*	***PS No.*** *Statement of the performance required of a control measure. Regulation 21(7)(a).*	***MC No.*** *Measurement criteria for determining whether the outcomes and standards have been met. Regulation 21(7)(c).*

35 Where impact/consequence descriptors are capitalised and presented within EPOs in **Section 6**; performance level corresponds with those aligned with the Woodside Risk Matrix (refer **Section 2.6.3**).

6.5 Environment Risk/Impacts not Deemed Credible

The ENVID identified a source of environmental risk / impact that was assessed as not being applicable (not credible) within or outside the PAA as a result of the Petroleum Activities Program. It therefore does not form part of this EP. This is described in the following sections for information only.

6.5.1 Shallow/Near-shore Activities

The Petroleum Activities Program is located in water depths of approximately between 71 and 130 m and at a distance approximately 94 km from nearest landfall (Dampier Archipelago), consequently risks/impacts associated with shallow activities such as anchoring, and vessel grounding were assessed as not credible. It is noted that the Glomar Shoals KEF overlaps the PAA; however, the Glomar Shoals themselves (<50 m depth) lie approximately 15 km east of the PAA and will not credibly be impacted by anchoring and vessel grounding.

6.6 Planned Activities

6.6.1 Physical Presence: Interaction with other Marine Users and Values

Context		
Facility Layout and Description – **Section 3.4** Project Vessels – **Section 3.5** Subsea IMMR Activities – **Section 3.4.15** Tie-back Activities – **Section 3.5**	Socio-economic– **Section 4.9** Cultural Values and Heritage – **Section 4.9.1**	Consultation – **Section 5**

Impacts and Risks Evaluation Summary

Presence of facility excluding and/or displacing other users from Petroleum Safety Zone and routine/ IMMR activities within the PAA respectively							✓	A	F	-	-	LC S GP PJ	Broadly Acceptable	**EPO 1**
Presence of MODU, installation vessels and other support vessels excluding and/or displacing other users during tie-back activities							✓							
Presence of subsea infrastructure interfering with or displacing third party vessels (commercial fishing)							✓							

Description of Source of Impact

Operations

The facility was commissioned in 2008 and is marked on nautical charts. The facility is surrounded by a 500 m radius PSZ, which vessels are prohibited from entering unless authorised by Woodside. The PSZ is a critical safety control intended to reduce the likelihood of interactions between vessels and the facility, which increases safety for both vessels and the facility. Implementation of the PSZ excludes other users from a small area (approximately 0.79 km^2). The riser platform is highly visible under most conditions and is lit to meet operational requirements and navigational codes and regulations, and the nature of the facility (large steel structure) ensures a clear radar return to alert ships fitted with anti-collision radars.

Routine vessel activities associated with operational activities are mostly concentrated within the PSZ (e.g., activities performed by platform support vessels at the Angel facility). Subsea support vessels may undertake activities (e.g., IMMR activities, removing redundant equipment) within the PAA at any time, including within parts of the PAA which are beyond the PSZ. The duration and location of these activities varies depending on the activity being undertaken.

There is a series of subsea infrastructure associated with operations that may have interactions with other marine users. The AHO has been notified of the location of all existing subsea infrastructure, including all infrastructure maintained for decommissioning and not normally producing, for marking on nautical charts. Water depths of the existing subsea infrastructure range between 70 and 130 m.

Tie-back activities will include the addition of new infrastructure within the PAA. The proposed LDA-02 wellhead, subsea Xmas tree and other subsea infrastructure will remain for the duration of field life. The footprint of new infrastructure remains within the footprint of the existing Angel facility and will not constitute a significant increase in the physical presence of the facility.

The AHO will be notified of the LDA-02 well and associated subsea infrastructure locations.

Tie-back Activities

The Lambert West tie-back consists of one well, LDA-02 tied back to existing Lambert Deep infrastructure, and the installation of associated subsea infrastructure (~300 to 500 m flexible jumper and a subsea distribution unit).

A MODU is planned be present for approximately 50 to 60 days, including mobilisation, demobilisation and contingency activities. When underway, activities will be 24 hours per day, seven days per week. The MODU will have a 500 m diameter SEZ around it within the PAA for the duration of the drilling activity. An offshore support vessel (OSV) would be present in proximity to the MODU, which would also be supported periodically by another OSV to facility resupply.

Installation vessels will be used to install, pre-commission and cold commission the flexible jumper, subsea distribution unit, and other subsea infrastructure following completion of drilling of the new well, as described in **Section 3.5**. This is expected to take approximately four weeks. Installation is expected to be predominantly undertaken by the primary installation vessel (PIV), which will be surrounded by a 500 m SEZ when on-location within the Lambert West Operational Area. A smaller vessel (IMMR type) may be utilised to undertake components of the installation activity before or after primary installation has been completed.

Drilling and installation activities are expected to be temporally discrete (i.e., conducted at different times), however they may overlap. If these activities coincide, a vessel (IMMR or PIV type) would be active in the tie-back Operational Area while the MODU (supported by two OSVs) is present. A SIMOPS Plan would be in place to manage interaction between vessels in the field.

Once Lambert West infrastructure is operational, potential interactions with other marine users will be managed as per all other subsea infrastructure associated with Angel operations.

Impact Assessment

Exclusion and Displacement of Other Users

Interaction with other marine users due to the physical presence of in the Petroleum Activities Program may result in localised changes to the functions, interests or activities of other users. The duration of change will be for the period of the Petroleum Activities Program.

Commercial Fishing

The PAA overlaps five Commonwealth and 13 State managed commercial fisheries management areas. However, historical fisheries data indicate that only one Commonwealth fishery and four State managed fisheries have the potential for interaction with the Petroleum Activities Program (**Section 4.9.2**).

The Commonwealth managed North West Slope Trawl Fishery, and State-managed Pilbara Line Fishery, Pilbara Crab Managed Fishery, Pilbara Fish Trawl (Interim) Managed Fishery and Pilbara Trap Managed Fishery are considered to have limited potential for interaction with project activities in the PAA (**Table 4-23**).

The PAA is located within 60 NM CAES block 19160, and 10 NM CAES blocks 193160, 193161, 193162, 193163, 192162 and 192163. The Pilbara Fish Trawl (Interim) Managed Fishery reported up to 4 vessels active in the overlapping 10 nm CAES blocks 192163, 193161, 193162, 193163 across the 2017 to 2022 seasons respectively. The Pilbara Line, Trap and Crab Managed Fisheries have remained consistently active in the 60 nm CAES block that overlaps the PAA between 2017 to 2022; however, FishCube data for these fisheries is not reported at the 10 NM scale therefore it is uncertain if the effort reported in the 60 nm CAES blocks overlaps with the PAA. FishCube data indicates the effort is concentrated east of the PAA, around the Southern Pilbara Islands. Given the overlap of the PAA with the fishing block and the annual fishing effort, interactions with these Pilbara Line, Trap and Crab Managed Fisheries and Pilbara Fish Trawl (Interim) Managed Fishery may occur.

Fisheries Status Reports indicate that the North West Slope Trawl Fishery has remained active in the PAA over the last five years, and subsequently interactions with this fishery are considered possible.

Continued Presence of the Angel Facility and Subsea Infrastructure

The potential impact to commercial fisheries in the PAA is limited to the navigational hazard of the facility and localised displacement/avoidance by commercial fishing vessels within the immediate vicinity. As such, the potential impact is considered to be localised with no lasting effect.

The continued presence of subsea infrastructure, over the field life could present a hazard to bottom trawl fisheries due to the risk of equipment entanglement and subsequent equipment damage/loss. The presence of subsea infrastructure could present a hazard to bottom trawl fisheries due to risk of equipment entanglement and subsequent

equipment damage/loss. The Pilbara Trap and Fish Trawl Managed Fisheries and the North West Slope Trawl Fishery employs several gear types, including trawling and are active in the 10 NM blocks that overlap the PAA.

However, **Section 4.9.2** indicated that trawl fisheries are not active in the PAA and therefore, are not at risk of interference. The magnitude of potential impacts to commercial fisheries from activities associated with the ongoing presence of the Angel facility and subsea infrastructure are assessed as having no lasting effect, given the historically lower fishing effort in the region as a result of relatively high density of oil and gas infrastructure in the North West Shelf region.

Tie-back Activities

During tie-back activities, vessels will be temporarily present in the PAA and may restrict the use of the area by the commercial fisheries and tour operators that have been identified as having potential to use the PAA. Use will particularly be restricted within the 500 m safety exclusion zone (temporary) that will be established around the MODU and installation vessel when undertaking drilling and installation activities, which represents a relatively small area when compared to the extent of the individual fishery boundaries that overlap. The MODU is planned to only be present for approximately 50-60 days, and the installation vessels for up to four weeks. Potential impacts to commercial fisheries include damage to fishing equipment and physical displacement from fishing grounds.

Given the distance offshore, the PAA is not an area of high commercial fishing activity. Furthermore, the 500 m temporary exclusion zones around the MODU and installation vessel comprise a relatively small area when compared to the extent of the individual fishery boundaries that overlap. As such, any displacement of commercial fisheries due to tie-back activities in the PAA are not expected to impact commercial fishing activities or the economic viability of the fisheries.

If the subsea installation and drilling activities coincide, a SIMOPS plan will be in place to manage vessel interaction in the field.

Tourism and Recreation

Tourism and recreation activity in the PAA is expected to be infrequent. Recreational and charter fishing from vessels are the only tourism and recreation activities identified as potentially occurring in the PAA. These are most likely to occur around the Glomar Shoals KEF (approximately 15 km east of the PAA) and Rankin Bank (approximately 59 km west of the PAA at the closest point).

Recreational and charter fishing from vessels is largely undertaken using lines. Given the distance from boating facilities, lack of natural attractions and water depth of the PAA, very little recreational or charter fishing is expected to occur. As such, impacts to recreational and charter fishing are expected to be localised and of no lasting effect.

Shipping

To reduce the likelihood of interactions between commercial vessels and offshore facilities, AMSA has introduced a series of shipping fairways, within which commercial vessels are advised to navigate. The fairways are not mandatory, but AMSA strongly recommends commercial vessels remain within the fairway when transiting the region. While no shipping fairways overlap the PAA, several fairways are located within the vicinity. The closest shipping fairway is approximately 19 km east of the PAA. The use of shipping fairways is considered to be good seafaring practice, with Australian Ship Reporting System (AUSREP) data from AMSA indicating cargo ships and tankers routinely navigate within the established fairways.

As the facility has been operational since 2008, is marked on nautical charts and is surrounded by a 500 m PSZ, the likelihood of interactions between commercial vessels and the facility is inherently low. Similarly, the MODU and installation vessel utilised for tie-back activities will also be surrounded by a 500 m SEZ.

The presence of the facility and project vessels will not result in impacts to commercial shipping beyond a localised exclusion of shipping traffic from the PSZ and SEZs, and the limited potential for temporary displacement of commercial shipping from vessels undertaking activities in the PAA. This is considered to be a localised impact, and of no lasting effect.

Oil and Gas

The nearest facility to Angel is the Okha FPSO operated by Woodside; impacts from the Petroleum Activities Program to Okha do not affect third parties. The nearest facility not operated by Woodside is the Santos-operated Reindeer platform, which lies approximately 50 km south-east of the PAA. Given the distance between the PAA and petroleum activities undertaken by other operators, no impacts are expected to other operators.

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Legislation, Codes and Standards				
Contract vessels compliant with Marine Orders for safe vessel operations: • Marine Order 21 (Safety of navigation and emergency procedures) 2016 • Marine Order 27 (Safety of navigation and radio equipment) 2016 • Marine Order 30 (Prevention of Collisions) 2016. Complying with Marine Orders 21, 27 and 30 reduces the likelihood of interaction of vessels with the facility.	F: Yes CS: Minimal cost. Standard practice.	Marine Orders 21, 27 and 30 are required under Australian regulations; implementation is standard practice for commercial vessels as applicable to vessel size, type and class.	Control based on legislative requirement – must be adopted.	Yes **C 1.1**
Implementation of a 500 m PSZ around riser platform reduces the likelihood of interaction of vessels with the facility.	F: Yes. CS: Minimal cost. Standard practice.	The PSZ is a requirement under Australian regulations and reduces the likelihood of interactions with third parties and the riser platform.	Control based on legislative requirement – must be adopted. ALARP Statement:

On the basis of the environmental impact assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the potential impacts of the physical presence of the facility, subsea infrastructure, MODU and project vessels on other users. As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.

Demonstration of Acceptability

Acceptability Statement:

The impact assessment has determined that, given the adopted controls, physical presence of the Petroleum Activities Program represents a negligible impact that is unlikely to result in a potential impact greater than an isolated social impact to commercial fishing, recreational fishing and shipping, and other oil and gas titleholders. Further opportunities to reduce the impacts have been investigated above. The adopted controls are considered good oil-field practice/industry best practice and meet requirements of Australian Marine Orders, and expectations of AMSA and AHO provided in consultation with relevant persons.

The potential impacts and risks are considered broadly acceptable, if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the impacts and risks of physical presence of the Angel facility, subsea infrastructure, MODU and project vessels to a level that is broadly acceptable.

Description of Source of Impact

Seabed disturbance associated with the Petroleum Activities Program can occur during operations and associated activities including:

- physical presence of the facility and subsea infrastructure (operational and redundant)
- drilling and tie-back activities associated with LDA-02
- scour, spans, and flowline movement inherent in design
- subsea IMMR activities.

Operations

Subsea infrastructure has been installed throughout the PAA (**Section 3.4**) and impacts to the seabed during installation of this equipment has been subject to separate EPs. The seabed disturbance from installation of infrastructure associated with the proposed LDA-02 well is outlined in the tie-back activities section below.

The facility and associated subsea infrastructure provides hard substrate habitat; extending from the sea surface through the water column to the seabed (e.g., jacket and risers), as well as along the seabed (e.g., pipelines, flowlines, manifolds, etc).

The presence of subsea infrastructure may result in localised scouring around the infrastructure due to currents, subsurface waves and seabed sediment fluid dynamics. Scour around subsea infrastructure may necessitate IMMR activities as part of integrity management practices.

Flowline movement may occur as per design and within integrity margins along the flowline corridor. Normal flowline operational movement occurs due to factors such as unexpected metocean conditions. Lateral movement can occur within the flowline corridor. Lateral movement which is larger than expected may necessitate IMMR activities. Flowline lateral buckling and walking are no longer expected to occur due to the cessation of gas production from the Angel wells.

Refer to MEE-02 Subsea equipment loss of containment (**Section 6.7.4**) which includes controls to limit scour and flowline movement within integrity requirements. To maintain the integrity of subsea infrastructure, Woodside may be required to undertake routine subsea IMMR activities, as described in **Section 3.4.15**. Activities that constitute IMMR may impact the benthic environment in the vicinity of the activity. IMMR activities identified as impacting the benthic environment include, but are not limited to:

- inspections – localised sediment resuspension by ROV
- marine growth removal – localised resuspension of sediment; removal of marine biota from subsea infrastructure and the Angel facility jacket
- sediment relocation – localised modification of benthic habitat and sediment resuspension
- span rectification, pipeline protection and stabilisation – minor, localised modification of benthic habitat within footprint of area subject to rectification/protection/stabilisation
- jumper and umbilical replacement – minor, localised modification of benthic habitat in the vicinity of the jumper/umbilical
- spool repair/replacement – minor, localised modification of benthic habitat in the vicinity of the spool
- temporary placement of tools on the seabed, e.g., baskets – minor localised modification of the benthic habitat in the vicinity of the items

- pig launcher/receiver installation and retrieval - minor, localised modification of benthic habitat and sediment resuspension in the vicinity of the receiver.

The area of benthic habitat predicted to be impacted varies depending on the nature and scale of the IMMR activity, however no impact is expected beyond the PAA. Span rectification is the IMMR activity with the greatest potential to modify benthic habitats, due to the alteration of the existing soft sediment habitat to hard substrate. Woodside's operational experience on the North West Shelf indicates these activities (e.g., span rectification, pipeline protection and stabilisation) are typically restricted to relatively short (tens of metres) linear sections of pipeline, with areas of up to approximately 100 m^2 impacted.

Tie-back Activities

Drilling and MODU Operations

Drilling activities may result in intermittent or discontinuous direct physical or mechanical disturbance to the seabed up to an approximate 100 m radial distance around the LDA-02 well location due to the installation of the BOP and conductor.

Potential impacts to the seabed from the generation and discharge of cuttings and drilling fluids are not considered in this section; refer to **Section 6.6.8** for an assessment of drill cuttings and drilling fluids and **Section 6.6.9** for an assessment of cement and cementing fluids.

Mooring Installation and Anchor Hold Testing

The LDA-02 well may be drilled using a moored or hybrid MODU. Seabed disturbance will result from the MODU anchor mooring system, including placement of anchors and chain/wire on the seabed, potential dragging during tensioning, and recovery of anchors. Mooring may require an 8 --point pre-laid mooring system, with RAR and buoyed arrangements an option, depending on the time of year.

Although the exact anchoring configurations are /not finalised, a semi-submersible MODU with an 8- to 12-point anchoring system could disturb up to 0.013 km^2 (13,000 m^2), allowing for anchor footprint and disturbance from anchor chains (NERA, 2018).

The area of seabed affected by mooring installation depends upon water depth, currents, size of the vessels and anchors, and length of anchor chain (NERA, 2018). Seabed disturbance from mooring installation and anchor hold testing will result in localised, small scale seabed disturbance relating to the benthic habitats described in **Section 4.5**.

The planned anchoring activities are to be within the parameters defined in the Anchoring of Vessels and Floating Facilities Environment Plan Reference Case (Department of Industry, Innovation and Science, undated) for all anchoring activities performed by vessels and floating facilities (excluding FPSOs and Floating LNG vessels) during the Petroleum Activities Program, including:

- installation of moorings, buoys, equipment or other infrastructure for a period of up to two years
- wet storage on seabed of anchor chains, etc. during activities up to two years
- activities with total areas of seabed disturbance less than 13,000 m^2
- locations of water depth greater than 70 m. This boundary is set to exclude areas of sensitive primary producer habitats (e.g., corals, seagrass) that occur in shallower waters.

Subsea Installation Activities

Subsea installation will include the installation of subsea infrastructure (including placement of materials/equipment on the seabed), supporting structures (including wellhead, flowline, flying leads, subsea distribution unit, mudmats) and installation aids (clump weights, concrete mattresses, sandbags). Subsea infrastructure components are described in **Section 3.5.3**. The total footprint of the LDA-02 well is 24 m^2, with additional subsea infrastructure including the 500 m jumper, subsea distribution unit and flying leads.

Subsea structures (subsea distribution unit, mudmats) will be deployed to the seabed by the installation vessel's primary crane and guided to final position by ROV. Commencement of the flowline installation generally requires tension to the flowline as it transitions from the installation vessel to the seabed. Therefore, commencement of the flowline installation may start with landing the end of flowline termination head into the manifold connection system or on the seabed attached to the initiation anchor (drag anchor or clump weight/dead anchor). This will cause small, localised and temporary impacts to water quality in the vicinity of flowline landout.

Once the termination end is fully landed, the jumper is to be continuously laid using vertical lay system and at the same time, the ROV monitors the touch-down point on the seabed as well as the flexible lay back radius. Flying leads will be deployed to the seabed in deployment baskets, and final subsea tie-in will be completed using ROVs.

Span Rectification

The optimum flexible jumper route will be selected by considering seabed bathymetry, pre-installation ROV surveys and installation risk management, including dropped object risks and buckling/walking impacts. This reduces the potential for spanning and therefore the need for span rectification, while avoiding potential hard substrate habitats.

Where span rectification is required, concrete mattresses may be positioned at the identified free span location by the use of the vessel crane and ROV. The dimensions for each concrete mattress are expected to be 6 m by 3 m by 0.3 m. Post-lay span rectification may involve placing grout bags (multiple ~25 kg) on the seabed, with the extent of any impact limited to the footprint of the installed flexible jumper.

Scouring

Scouring is the movement of sediment around the base of subsea structures due to prevailing wind conditions. Concrete mattresses may be installed at the Lambert West UTA if required, to mitigate scouring.

Stabilisation

Stabilisation is a post lay activity to ensure light items, such as HFL, EFL and jumpers, remain at their installed positions; i.e., not being shifted due to strong seabed current, by installing sand bags on top of HFLs, EFLs and jumpers at a predetermined distance apart. Sand bags generally come in a standard size with 20 kg to 40 kg weight. Concrete mattresses may also be used for stabilisation of some sections of the Lambert West flexible jumper subject to detailed design.

Crossings

Sandbags or concrete mattresses may be installed for crossings over existing umbilicals or jumpers.

Wet Storage of Equipment

Temporary wet storage of installation aids may be required intermittently during tie-back activities. Installation aids will be recovered at the completion of tie-back activities by ROV and project vessels (**Section 3.5.3.9**).

ROV Operations

The use of an ROV during drilling and subsea installation activities as described in **Section 3.6.2** may result in temporary seabed disturbance and suspension of sediment as a result of working close to, or occasionally on, the seabed. ROV use close to or on the seabed is limited to that required for effective and safe subsea activities. The footprint of a typical ROV is about 2.5 m × 1.7 m (4.25 m²).

Additionally, the ROV may be used to relocate small amounts of sediment material (**Section 3.5.5.10**) to create a stable, level surface and reduce the potential for scouring from subsea equipment (e.g., BOP).

Marine Growth Removal

Excess marine growth may need to be removed following return to well after a period of suspended drilling. Removing marine growth is undertaken via a high-pressure water and/or brushes or acid, by ROV.

Underwater Transponders

An array of long base line (LBL) transponders may be installed on the seabed as required to support drilling and subsea installation activities. Transponders may be moored to the seabed either by a clump weight or mounted on a seabed frame. The standard clump weights used, made of cement or steel, will likely weigh about 80 kg. A typical seabed frame is 1.5 m × 1.5 m × 1.5 m in dimension and weighs about 40 kg. On completion of the positioning operation, the array transponders moored by clump weight will be recovered by means of a hydrostatic release and the clump weights removed from the seabed. The transponders mounted on seabed frames will be removed by ROV.

Contingency Activities

Woodside may need to intervene or workover wells within the PAA. Any seabed disturbance would be the same as those described for drilling operations and MODU operations. In addition, in the event of a respud of the LDA-02 well, the base case would be to remove the wellhead. However, if reasonable attempts at wellhead removal are unsuccessful, a wellhead may remain in situ until the end of field life. If this is the case, it will be recorded in a database and monitored and maintained until decommissioned. If a wellhead is left in-situ, there would be localised seabed disturbance at the wellhead location.

Impact Assessment

Drilling, subsea installation, IMMR activities and physical presence of subsea infrastructure can be categorised into two potential impacts, being:

- direct physical disturbance of benthic habitat
- indirect disturbance to benthic habitats from sedimentation.

ROVs working well above the seabed do not have an impact on the seabed.

Water and Sediment Quality

Seabed disturbance may include localised and temporary decline in water quality due to increased suspended sediment concentrations and increased sediment deposition caused by drilling, subsea installation and IMMR activities near the seabed. Similarly, removal of marine growth from the Angel jacket to maintain structural integrity on an as-required basis would cause localised temporary decrease in water quality and suspended sediment from water jetting activities.

Benthic Habitats

The seabed of the PAA is characterised by soft sediments, with sparse epifauna (**Section 4.5**). Discrete areas of hard substrate hosting sessile filter feeding communities may also be associated within the Ancient Coastline at the 125 m Depth Contour KEF, which overlaps the PAA. However, no areas of hard substrate characteristic of this KEF have been identified within the PAA (Jacobs, 2014).

Direct seabed disturbance, including permanent modification of benthic communities, may result as a consequence of IMMR activities such as span rectification, pipeline protection and stabilisation. These activities may disturb a small

area (typically <100 m^2) of soft sediment habitat. Scour and flowline movement may result in localised impacts to soft sediment habitats, typically on the scales of metres to tens of metres. To prevent or remediate scour or flowline movement, soft sediment habitat is replaced by hard substrate (e.g., concrete mattresses, rocks, etc), which is generally uncommon in the middle and outer NWS Province. Over time, this hard substrate is expected to be colonised by sessile benthic biota (e.g., sponges, gorgonians, etc), which may support higher biodiversity than surrounding soft sediment habitats.

Marine life such as deepwater benthic communities epifauna and infauna (living on and in the sediment dominated habitat), may be impacted from the placement of project infrastructure (i.e., LDA-02 wellhead, flowline and subsea distribution unit), or placement of temporary supporting infrastructure (anchors, installation aids) and equipment (e.g., mud mats) on the seabed. Potential impacts include burial or smothering of benthic biota from localised sediment deposition, particularly to sessile epifauna such as sea pens and infauna (polychaetes); and potential clogging or damage to the physiological functioning of certain biota (sea pens, polychaetes) reliant on external respiratory and feeding structures from elevated suspended sediment load (turbidity). Secondary impacts may include highly localised alterations to epifauna and infauna communities (Newell et al., 1998).

If required, mooring installation activities are likely to result in localised physical modification to a small area of the seabed and disturbance to soft sediment. An anchor must travel a certain horizontal distance before penetrating and embedding into the seabed. The drag length of the anchors may be up to a linear distance of 100 m from the drop location (NERA, 2018). The disturbance footprint extends beyond this distance with the anchor chain. The maximum disturbance radius of each anchor drop will therefore not exceed the drag length, plus the additional length of the anchor chain that comes into contact with the sea floor (4000 m). Following recovery of the anchors, impacts from the disturbance (estimated at up to 0.013 km^2) are expected to be localised and short-term, with the underlying conditions present to support re-colonisation and recovery after the activity has been completed (Ingole et al., 2005).

Seabed disturbance will be limited to the wellhead (100 m radial distance), subsea infrastructure and anchoring physical footprint (estimated at up to 0.013 km^2); a small proportion of the benthic habitat and associated communities of the PAA will be affected.

The epifauna and infauna benthic communities associated with the predominantly soft sediment habitats of the PAA are likely to be well represented elsewhere in the vicinity, with impacts restricted to a highly localised proportion of benthic communities. No threatened or migratory species, or ecological communities (as defined under the EPBC Act), were identified in the benthic communities during studies completed in the region (Jacobs, 2014). Potential impacts to epifauna and infauna are likely to be highly localised, and temporary in nature.

ROV activities near the seafloor and small amounts of sediment relocation may result in slight and short-term impacts to deepwater biota, detailed above, as a result of elevated turbidity and localised sedimentation. However, elevated turbidity and sedimentation would only be expected to be slight and short-term, and is therefore, not expected to have any consequential impact to environment receptors.

The use of water jetting to remove marine growth on wellheads and subsea infrastructure will result in temporary suspension of organic matter and localised increase in turbidity. Water jetting will be limited to what is necessary to clean infrastructure prior to intervention or other necessary activity.

The contingent cutting and removal of a wellhead, including the laydown of mud mats, may affect a relatively small footprint of the seabed and lead to localised, temporary suspension of sediments. As such, no significant impacts to benthic fauna are expected should wellhead removal be required.

In the unlikely event that the wellhead cannot be removed following abandonment, over time the cement surrounding the wellhead will likely become buried in sediment as a result of prevailing ocean currents. The steel wellhead structure will also corrode over time and marine fouling is expected to accumulate, whereby a marine life structure may remain above the seafloor. If the wellhead remains in-situ, it is expected to have a localised impact not significant to environment receptors. No further impacts to benthic habitats are likely.

Artificial Habitat

The presence of the facility and subsea infrastructure provides hard substrate for the settlement of marine organisms; the availability of hard substrate is often a limiting factor in benthic communities. As such, the presence of the facility and subsea infrastructure has led to the development of ecological communities which would not have existed otherwise. For example, pipeline infrastructure has been shown to support more diverse fish assemblages and benthic biota (McLean et al., 2017; Bond, 2018). These communities are relatively diverse compared to the open water and soft sediment habitats in the broader PAA.

The provision of artificial habitat associated with the facility and subsea infrastructure has either no adverse environmental impact or a low level of positive environmental impact through increasing biological diversity.

Values and Sensitivities

Glomar Shoals KEF

Benthic habitats of the Glomar Shoals (the KEF that overlaps with the eastern extent of the PAA) are characterised by sand/silt substrate and low epibenthic cover (approximately 53% total cover), with soft corals and sponges the most abundant fauna (AIMS, 2014a). While the PAA overlaps the Glomar Shoals KEF (approximately 0.89 km^2 of the Glomar Shoals KEF lies within the Angel Operational Area), the Glomar Shoals KEF feature is over 15 km from the PAA and 17 km from the Angel facility). The majority of suspended sediments from drilling, subsea installation and IMMR activities are expected to remain localised adjacent to infrastructure (i.e., potentially depositing in a small area

of the Glomar Shoals KEF but not impact Glomar Shoals itself). The NWS Province experiences naturally high episodic sediment resuspension due to events such as tidal movements and cyclones, and the biota in the region are adapted to such conditions. Thus, impacts to Glomar Shoals KEF due to seabed disturbance are not expected to occur.

Cultural Heritage

As described in **Section 4.9.1**, the PAA overlaps the Ancient Coastline at 125 m depth contour KEF and therefore there is the potential that Indigenous Cultural features may exist and these may potentially be impacted during seabed disturbance resulting from operations and associated activities. While no cultural features have been identified in the PAA, further archaeological studies will be undertaken prior to the activity commencing to understand any potential cultural features.

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Legislation, Codes and Standards				
A ROV as left survey is undertaken at the end of activity, to confirm all temporary equipment has been removed and to record location of new subsea infrastructure.	F: Yes. CS: Minimal cost. ROV as-left survey is standard practice.	In accordance with OPGGS Act Section 572 all equipment is removed when no longer in use.	Legislative requirement.	Yes **C 2.1**
Location of subsea infrastructure brought into the PAA, is tracked and recorded.	F: Yes. CS: Minimal cost. Standard practice.	In accordance with OPGGS Act Section 572 the location of equipment is tracked to enable future removal.	Benefits outweigh cost/sacrifice.	Yes **C 2.2**
Monitoring and maintenance of redundant infrastructure is undertaken in accordance with the IMMR process.	F: Yes. CS: Minimal cost. Standard practice.	Monitoring and maintenance of redundant subsea infrastructure undertaken to enable cost efficient and safe removal and meet Section 572(2) and (3) of the OPGGS Act.	Legislative requirement.	Yes **C 2.3**

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Remove redundant infrastructure as soon as it is no longer used, nor to be used.	F: Yes. CS: Removal of property throughout the operational life where it is incorporated within or located close to live infrastructure introduces additional complexities and HSE risk that can be avoided if removed during EOFL decommissioning.	While subsea equipment is in-situ, risks and impacts to the seabed are considered to be low, so only a minor reduction in sediment/ habitat disturbance from less infrastructure in the PAA would be achieved.	Cost of standalone retrieval work scopes are considered disproportionate to the benefit gained when considering the risks of retrieval during current operations versus risk of extending duration in-situ. Wet stored subsea infrastructure is also RBI assessed and managed while preserved to ensure integrity and retrieval options are maintained for potential full removal.	No
Reasonable attempt(s) at removal of wellhead will be undertaken in the event of a respud and if unable to be removed, is monitored and maintained (**C 3.3** above).	F: Yes. CS: Additional cost. Standard practice.	In accordance with OPGGS Act Section 572.	Benefits outweigh cost/ sacrifice.	Yes **C 2.4**
Good Practice				
Subsea infrastructure will be positioned within planned footprint to reduce seabed disturbance.	F: Yes. CS: Standard practice.	Ensures risks appropriately addressed for seabed disturbance.	Benefits outweigh cost/sacrifice.	Yes **C 2.5**
LDA-02 well site location as planned within the Well Location and Site Appraisal Data Sheet (WLSADS).	F: Yes. CS: Minimal cost. Standard practice	Ensures risks appropriately addressed for seabed disturbance.	Benefits outweigh cost/sacrifice.	Yes **C 2.6**

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Project-specific Basis of Well Design, which includes an assessment of seabed sensitivity.	F: Yes. CS: Minimal cost. Standard practice.	Reduces the likelihood of anchoring occurring in areas of high sensitivity. Assessment of seabed topography reduces the likelihood of anchor drag leading to seabed disturbance.	Benefits outweigh cost/sacrifice.	Yes **C 2.7**
Project-specific MODU Mooring Design Analysis.	F: Yes. CS: Additional costs associated with upgraded MODU mooring design.	The mooring design analysis determines the number and spread of anchors required based on sediment type and seabed topography, reducing the likelihood of anchor drag leading to seabed disturbance.	Benefits outweigh cost/sacrifice.	Yes **C 2.8**
Positioning technology used to place seabed infrastructure within the design footprint to reduce seabed disturbance	F: Yes. CS: Minimal cost. Standard practice.	Use of positioning technology to position infrastructure on the seabed with accuracy will reduce seabed disturbance.	Benefits outweigh cost/sacrifice.	Yes **C 2.9**

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Review of existing survey data by a suitably qualified maritime archaeologist to inform areas for laydown and/or installation of equipment to avoid or where not possible, minimise physical impacts to cultural heritage areas or prospective areas.	F: Yes. CS: Minimal costs associated with review of data and avoidance or minimisation options.	Review of data by suitably qualified maritime archaeologist will inform potential exclusion or avoidance areas for seabed disturbance. Implementing this process will protect and minimise any physical impacts to underwater cultural heritage. Additionally, this process is not inconsistent with the draft guidelines for working in the near and offshore environment to protect Underwater Cultural Heritage (DCCEEW, 2023).	Benefits outweigh cost/ sacrifice.	Yes **C 3.1**

Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Unexpected finds of potential Underwater Cultural Heritage sites/ features, including First Nations UCH are managed in accordance with an Unexpected Finds Procedure set out in **Section 7.6**.	F: Yes. CS: Cost of implementation.	Allows management of Unexpected Finds in accordance with legislative requirements, (including Underwater *Cultural Heritage Guidance for Offshore Developments and the DRAFT Guidelines to Protect Underwater Cultural Heritage under the UCH Act*, expert advice and community expectations.	Benefits outweigh cost/ sacrifice.	Yes **C 3.2**
Report any potential underwater cultural heritage finds to relevant stakeholders and authorities in accordance with the Unexpected Finds Procedure, *Underwater Cultural Heritage Act 2018* and the *Aboriginal and Torres Strait Islander Heritage Protection Act 1984* (ATSIHP Act).	F: Yes. CS: Minimal costs associated with reporting process.	Meets legislative requirements and community expectations.	Benefit outweighs cost/ sacrifice.	Yes **C 3.3**
Relevant vessel crew and ROV operators will be advised in an induction of the potential to encounter UCH and requirement to follow the Unexpected Finds Procedure (**C 3.2**).	F: Yes. CS: Minimal cost.	Ensures workforce are suitably aware of legal and process requirements for managing cultural features and heritage values.	Benefits outweigh cost/ sacrifice.	Yes **C 3.4**
Professional Judgement – Eliminate				
Vessels used for IMMR activities will not anchor under routine operations.	F: Yes. CS: Minimal. Subsea support vessels undertaking IMMR activities typically do not anchor.	By not anchoring, the potential impacts to benthic habitat are reduced.	Benefits outweigh cost/sacrifice.	Yes **C 2.10**

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Do not use ROV close to, or on, the seabed.	F: No. The use of ROVs (including work close to or occasionally landed on the seabed) is critical as the ROV is an integral part of IMMR activities. CS: Not assessed, control not feasible.	Not assessed, control not feasible.	Not assessed, control not feasible.	No
Do not complete anchor hold testing for the MODU.	F: No. Anchor hold testing is a requirement for a moored MODU and it is not technically feasible for the MODU to use DP in the water depth of the well location (about 130 m). Woodside has a demonstrated capacity to manage the environmental risks and impacts from mooring to a level that is ALARP and acceptable. CS: Not assessed, control not feasible.	Not assessed, control not feasible.	Not assessed, control not feasible.	No
Professional Judgement – Substitute				
None identified.				
Professional Judgement – Engineered Solution				
Monitoring and maintenance of subsea infrastructure to manage scour and flowline movement to within integrity envelope.	F: Yes, subsea inspection maintenance and integrity monitoring is undertaken which inherently controls extent of scour and flowline movement. CS: Minimal cost. Standard practice.	Monitoring and maintenance of subsea infrastructure confirms benthic seabed disturbance is limited to design flowline corridor.	Control is WMS requirement – must be adopted.	Yes **C 2.11** Refer also MEE-02

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Monitoring of seabed surrounding riser platform and subsea infrastructure.	F: Yes. ROV footage collected as part of subsea integrity surveys could be reviewed to observe and detect changed in benthic habitats. CS: Costs associated with the review of collected footage.	Limited environmental benefit (information) gained from monitoring benthic habitats.	Given the sparsely populated infauna habitat and low sensitivity of the environment surrounding the facility and associated subsea infrastructure, any environmental benefit gained is outweighed by costs associated with implementing control.	No
ALARP Statement: On the basis of the environmental impact assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts of seabed disturbance from tie-back activities and subsea IMMR activities. As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.				
Demonstration of Acceptability				
Acceptability Statement: The impact assessment has determined that, given the adopted controls, seabed disturbance from subsea activities represents a slight short-term impact that is unlikely to result in a potential impact greater than slight, short-term impact to benthic habitats. Further opportunities to reduce the impacts have been investigated above. The adopted controls are considered good oil-field practice/industry best practice. The potential impacts are considered broadly acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the impacts of tie-back activities and subsea IMMR activities to a level that is broadly acceptable.

Noise generated within the PAA from: • Angel facility and associated infrastructure • vessels • helicopters • IMMR activities						✓		A	F	-	-	GP PJ	Broadly Acceptable	EPO 4

Description of Source of Impact

The Angel facility, vessels and helicopters generate noise both in the air and underwater, due to the operation of machinery noise, propeller movement, etc. These noises contribute to and can exceed ambient noise levels, which range from around 90 dB re 1 µPa sound pressure level (SPL) under very calm, low wind conditions, to 120 dB re 1 µPa (SPL) under windy conditions (McCauley, 2005).

Continuous (Non-Impulsive) Sources

Platform Machinery

Production platforms have machinery mounted on decks raised above the sea, hence, most noise is transmitted to the marine environment from air. Normal platform operations generate sound at 162 dB SPL (Hannay. et al., 2004). Machinery noise onboard the Angel facility may be radiated into the underwater environment via the jacket legs and risers, which may act as transducers. Underwater noise generated by the Angel facility is expected to be minimal, with monitoring programs indicating that underwater noise from platforms is typically very low or not detectable (McCauley, 2002).

Flaring

The HP and LP flare system generate noise from combustion. Noise from flaring is emitted at the top of the flare tower, which is approximately 115 m above sea level. Noise from the tip of the flare is not constrained and spreads spherically in all directions.

Received levels from airborne propagation modelling were used to ascertain the underwater received levels during flaring activities for a drilling and subsea installation activity (Woodside, 2019). Only a very small fraction of the acoustic energy produced from flaring will transmit through the air/water boundary due to the surface of water acting as a reflective plane and a significant component of acoustic energy reflecting back into the air. While underwater received sound pressure level during flaring is estimated to be 136 dB re 1µPa at 1m (SPL) below the sea surface it is estimated to attenuate to ambient levels within a very short distance (e.g., metres) and therefore is not considered further in the impact assessment.

Wellhead, Pipelines and Subsea infrastructure

The noise produced by an operational wellhead was measured by McCauley (2002). The broadband noise level was very low, 113 dB re 1 µPa SPL, which is only marginally above rough sea condition ambient noise. For a number of nearby wellheads, the sources would have to be in very close proximity (< 50 m apart) before their signals summed to increase the total noise field (with two adjacent sources only increasing the total noise field by three dB). Hence for multiple wellheads in an area, the broadband noise level in the vicinity of the wellheads would be expected to be of the order of 113 dB re 1 µPa SPL and this would drop very quickly to ambient conditions on moving away from the wellhead, falling to background levels within 200 m from the wellhead.

Based on the measurements of wellhead noise discussed in McCauley (2002), which included flow noise in pipelines, noise produced along a pipeline may be expected to be similar to that described for wellheads, with the radiated noise field falling to ambient levels within a hundred meters of the pipeline.

Woodside has undertaken acoustic measurements on the noise generated by the operation of choke valves associated with the Angel facility (JASCO, 2015). These measurements indicated choke valve noise is continuous, and the frequency and intensity of noise emitted is dependent on the rate of production from the well. Noise intensity at low production rates (16% and 30% choke positions) were approximately 154 to 155 dB re 1 µPa (SPL), with higher production rates (85% and 74% choke positions) resulting in lower noise levels (141 to 144 dB re 1 µPa SPL). Noise from choke valve operation was broadband in nature, with the majority of noise energy concentrated above 1 kHz. Noise from choke valve operation was considered minor compared to noise generated by vessels using thrusters in the area.

Given the low levels of noise emitted by subsea infrastructure such as wellheads, choke valves and flowlines, no impacts to marine fauna from these noise sources are expected. Measurements of noise generated by choke valves indicated it is relatively high frequency (>1 kHz), and hence it attenuates over relatively short distances in the water column; significant impacts to marine fauna are not considered credible and therefore not considered further in the impact assessment.

Vessels and Operation of Dynamic Positioning Systems

Vessels used for routine operations are detailed in **Section 3.5**, and include DP capable vessels. The sound levels and frequencies generated by vessels varies with the size of the vessel, speed, engine type and the activity being undertaken. Vessels produce low frequency sound (i.e., below 1 kHz) from the operation of machinery, hydrodynamic flow sound around the hull and from propeller cavitation, which is typically the dominant source of sound (Ross, 1987, 1993).

Vessels in the 50 to 100 m size class (e.g., supply ships, crew boats, research vessels) produce broadband source levels in the 165 to 180 dB re 1 µPa (SPL) range (Gotz et al., 2009). In comparison, underwater sound levels generated by large ships can produce levels exceeding 190 dB re 1 µPa (Gotz et al., 2009), and small vessels up to the 20 m size class typically produce sound at source levels of 151 to 156 dB re 1 µPa (Richardson et al., 1995). McCauley (1998) measured underwater broadband noise equivalent to about 182 dB re 1 µPa at 1 m (SPL) from a support vessel holding station in the Timor Sea; it is expected that similar noise levels will be generated by support vessels used for routine operations.

Helicopter Transfers

Helicopter activities occur in the PAA, including landing and take-off on the facility or vessel helidecks. Sound emitted from helicopter operations is typically below 500 Hz (Richardson et al., 1995). The peak received level diminishes with increasing helicopter altitude, but the duration of audibility often increases with increasing altitude. Richardson et al. (1995) reports that helicopter sound is audible in air for four minutes before it passed over underwater hydrophones, but detectable underwater for only 38 seconds at 3 m depth and 11 seconds at 18 m depth. Noise levels reported for a Bell 212 helicopter during fly-over was reported at 162 dB re 1 µPa (SPL) and for Sikorsky-61 is 108 dB re 1 µPa (SPL) at 305 m (Simmonds et al., 2004). Water has a very high acoustic impedance contrast compared to air, and the sea surface is a strong reflector of noise energy (i.e., very little noise energy generated above the sea surface crosses into and propagates below the sea surface (and vice versa) – the majority of the noise energy is reflected). The angle at which the sound path meets the surface influences the transmission of noise energy from the atmosphere through the sea surface, angles >13° from vertical being almost entirely reflected (Richardson et al., 1995). Given this, and the typical characteristics of helicopter flights within the PAA (duration, frequency, altitude and air speed), the opportunity for underwater noise levels to exceed the behavioural thresholds is not considered credible and is not assessed further.

Non-routine Impulsive Sources

Subsea Inspection, Monitoring, Maintenance and Repair Activities

MBES and SSS are low-energy, high-resolution geophysical survey instruments that may be required for IMMR every 1 to 6 years to identify buckling, movement, scour and seabed features. MBES have operating frequencies ranging from 12 kHz to 700 kHz (Jimenez-Arranz et al., 2017) with peak pressure (PK) source levels between approximately 210 and 245 dB re 1 µPa at 1 m (Jimenez-Arranz et al., 2017; Zykov, 2013; MacGillivray et al., 2013). MBES generate micro-pulses of high frequency sound in a highly focused beam directed towards the seabed, which attenuates rapidly underwater compared to lower frequency sound sources. Due to this directionality and short pulse duration, there is relatively low sound energy and very limited horizontal sound propagation. The high operating frequencies of many MBES are typically above the hearing range of the low frequency (LF) cetacean (7 Hz to 35 kHz; Southall et al., 2019)

and high frequency (HF) cetacean (150 Hz to 160 kHz; Southall et al. 2019) species that may occur in the Petroleum Activities Area. The high operating frequencies of MBES are also above the hearing ranges of marine turtles (<2 kHz, Finneran et al., 2017) and the majority of fish species (100 Hz to several kHz; Ladich, 2000, Popper et al., 2014). Additionally, sound sources generated closer to the seabed have a lower received noise level in the horizontal direction due to seafloor scattering and absorption.

Similar to MBES, SSS produce micro-pulses of sound in a focussed swath directed at the seabed. SSS operating frequencies may range between 75 kHz and 900 kHz, with sound energy attenuating rapidly with horizontal distance from the main swath (Jimenez-Arranz et al., 2017; Zykov, 2013). Representative source levels range between 200 and 235 dB re 1 µPa PK at 1 m (Jimenez-Arranz et al., 2017; Zykov, 2013). The high operating frequencies of SSS places the dominant sound frequencies above the hearing range of most marine fauna species, including LF cetaceans, turtles and fish, although some of the lower frequency devices may be audible to HF cetaceans (MacGillivray et al., 2013; Zykov, 2013).

Sub-bottom profiling may also be undertaken every 1-6 years to identify features under the seabed. Most commercial SBPs are small, low-powered, high-resolution and shallow-penetrating systems, producing electrical pulses across a range of frequencies (Salgado Kent et al., 2016; Jiménez-Arranz et al., 2017). The instruments proposed for the survey produce pulses of sound between approximately 2 kHz and 30 kHz with source levels between approximately 170 and 230 dB re 1 µPa PK at 1 m.

Positioning Equipment

An array of long baseline (LBL) and/or ultra-short baseline (USBL) transponders may be used for positioning during IMMR activities. Transponders typically emit pulses of medium frequency sound, generally within the range 21 to 31 kHz. The estimated SPL at source ranges from 180 to 202 dB re 1 µPa SPL at 1 m (Jiménez-Arranz et al., 2017).

Impact Assessment

Receptors

Fauna associated with the PAA is predominantly pelagic species of fish, with migratory species such as turtles, whale sharks and cetaceans potentially present in the area seasonally. Noise interference is a key threat to a number of migratory and threatened cetaceans and marine turtles identified as occurring within the PAA (**Section 4.6)**.

The PAA overlaps BIAs for whale sharks (foraging) and wedge-tailed shearwaters (breeding). Whale sharks are present between March and November. Cetaceans, such as pygmy blue and humpback whales, and marine turtle species may also be present within the PAA seasonally; however, no BIAs or other important areas for these species overlap the PAA. While the Ancient Coastline KEF may be associated with outcroppings of hard substrate, limited areas of hard substrate were identified in the PAA, with no evidence of significant reef habitats associated with such outcroppings (Jacobs, 2014). Some demersal fish are likely to be associated with subsea infrastructure such as pipelines (McLean et al., 2017).

Potential Impacts of Noise

Elevated underwater noise can affect marine fauna, including cetaceans, fish, turtles, sharks and rays, in three main ways (Richardson et al., 1995; Simmonds et al., 2004):

- by causing direct physical effects on hearing or other organs. Hearing loss may be temporary (temporary threshold shift (TTS) referred to as auditory fatigue), or permanent threshold shift (PTS) (injury)
- by masking or interfering with other biologically important sounds (including vocal communication, echolocation, signals and sounds produced by predators or prey)
- through disturbance leading to behavioural changes or displacement from important areas (e.g., BIAs). The occurrence and intensity of disturbance is highly variable and depends on a range of factors relating to the animal and situation.

Sound Propagation

Increasing the distance from the noise source usually results in the level of noise reducing, due primarily to the spreading of the sound energy with distance. The way that the noise spreads (geometrical divergence) depends upon several factors such as water column depth, pressure, temperature gradients, and salinity, as well as surface and bottom conditions.

Cetaceans

Species Sensitivity and Exposure Thresholds

Marine mammals and especially cetaceans rely on sound for important life functions including individual recognition, socialising, detecting predators and prey, navigation and reproduction (Weilgart, 2007; Erbe et al., 2015; Erbe et al., 2018). Underwater noise can affect marine mammals in various ways including interfering with communication (masking), behavioural changes, a shift in the hearing threshold (PTS and TTS), physical damage and stress (Erbe, 2012; Rolland et al., 2012). Frequency-specific hearing sensitivity differs among marine mammals, influencing how they are affected by noise exposure. For the purposes of predicting the effects of noise exposure on different groups of cetaceans, blue whales, humpback whales and other large mysticete (baleen) whales are categorised as LF cetaceans, while odontocetes (toothed whales and dolphins) are categorised as HF or VHF cetaceans (Southall et al., 2019).

The thresholds that could result in behavioural response for cetaceans is expected to be 120 dB re 1 µPa (SPL) for continuous noise sources, and 160 dB re 1 µPa (SPL) for impulsive noise sources (**Table 6-3**). These thresholds have been adopted by the United States National Oceanic and Atmospheric Administration (NOAA) (National Marine Fisheries Service [NMFS], 2014, 2018; Southall et al., 2019; NOAA, 2019). The adopted thresholds are based on best data available and published in peer-reviewed literature and represent conservative internationally accepted and applied impact evaluation thresholds.

Table 6-3: Thresholds for permanent threshold shift, temporary threshold shift and behavioural response onset for low frequency, high-frequency and very high frequency cetaceans for continuous and impulsive noise

SEL_{24h} expressed as dB re 1 µPa².s; Peak pressure (PK) and SPL expressed as dB re 1 µPa.

The *Conservation Management Plan for the Blue Whale (BWCMP)* (Commonwealth of Australia, 2015a), a recovery plan made under the EPBC Act, defines important areas for pygmy blue whales and these are also described with reference to BIAs in the National Conservation Values Atlas (NCVA), with particular emphasis placed on foraging areas and migration corridors. As noted above and in **Section 4.6.3**, the PAA is located approximately 37 km south of the pygmy blue whale migration BIA, with the nearest foraging BIA (Ningaloo possible foraging area) approximately 348 km to the south of the PAA. Action Area A.2.3 of the BWCMP states: "Anthropogenic noise in biologically important areas will be managed such that any blue whale continues to utilise the area without injury and is not displaced from a foraging area". Furthermore, the *Guidance on Key Terms within the Blue Whale Conservation Management Plan* (DAWE, 2021), underwater noise emissions from the petroleum activities program must not:

- result in injury[43] (TTS or PTS) to any pygmy blue whale in BIAs, or
- displace a pygmy blue whale from a foraging BIA.

The following assessment of impacts to cetaceans includes consideration of the requirements of the BWCMP with respect to pygmy blue whales.

Predicted Underwater Noise Impacts to Cetaceans

Facility and Support Vessel Noise Impacts

Vessels holding station are considered to be the predominant noise source related to the PAP. McCauley (1998) measured underwater broadband noise equivalent to about 182 dB re 1 µPa SPL (SPL) at 1 m from a support vessel holding station in the Timor Sea. Similar noise levels are expected to be generated by vessels used for the PAP.

PTS and TTS thresholds for LF cetaceans are 199 dB re 1 μPa^2 s (SEL weighted) and 179 dB re 1 μPa^2 s (SEL weighted), respectively for continuous noise sources (refer **Table 6-3**). Typical sound exposures generated by the facility and a support vessel using DP would not exceed these levels (except at extremely close ranges to the source), so PTS and TTS in LF cetaceans, such as large baleen whales, is not anticipated.

Potential impacts to cetaceans may instead include behavioural disturbance from vessels. The thresholds that could result in behavioural response for cetaceans is expected to be 120 dB re 1 µPa (SPL) for continuous noise sources such as vessels (refer **Table 6-3**). Acoustic modelling undertaken for an operating FPU and support vessel on DP predicted that sound from each sound source individually would exceed the 120 dB threshold up to a maximum distance of 670 m, while combined sound sources exceeded the threshold to a distance of 1.07 km (McPherson et al., 2019). Although some site and facility-specific differences may exist, 1 km is considered broadly indicative of the range at which underwater sound propagating from the Angel facility and PSV may cause a behavioural response in cetaceans.

Cetaceans are capable of moving away from potential noise sources, and there are no constraints to their movement within the PAA. LF cetaceans such as humpback whales and pygmy blue whales may be seasonally present in the PAA, though limited to individuals infrequently transiting through the area. Interactions between pygmy blue whales or humpback whales with vessels typically result in avoidance behaviour, with whales generally moving away from

43 For the purpose of interpreting and applying Action Area A.2 of the Blue Whale CMP, injury is both permanent and temporary hearing impairment (Permanent Threshold Shift and Temporary Threshold Shift) and any other form of physical harm arising from anthropogenic sources of underwater noise (DAWE, 2021).

vessels (Bauer, 1986; Stamation et al., 2010). Because the PAA is approximately 37 km from the blue whale migration BIA and 34 km from the humpback whale migration BIA, no impacts are predicted to occur from project vessel noise on individuals using these areas. In summary, potential impacts to blue whales, humpback whales and other cetaceans from predicted noise levels are expected to be limited to behavioural impacts within a localised area around vessels with no lasting effect.

IMMR Activities

Zykov (2013) conducted acoustic modelling for five low energy survey instruments off the coast of California, including MBES, SSS and sub-bottom profiler. All equipment types were modelled in the sandy bottom environment, similar to that of the PAA. Although the bathymetry, salinity, water temperature and sub-seafloor sediment type may differ, given the similarities in equipment type and seafloor habitat, the modelling is considered comparable for the nature and scale of the low energy IMMR survey equipment.

The high operating frequencies of MBES and SSS places the majority of sound frequencies above the auditory range of LF cetaceans. Dolphins and other HF cetaceans, which have peak hearing sensitivity up to 110 kHz, with potential for some limited hearing ability up to approximately 160 kHz (NMFS, 2018; Southall et al., 2019), may be able to detect a small amount of the sound energy from some instruments in the lower operating frequency ranges available for MBES and SSS (MacGillivray et al., 2013; Zykov, 2013).

The modelling by Zykov (2013) indicates that the sound emissions from MBES and SSS do not exceed PTS and TTS accumulated sound exposure criteria for LF cetaceans at any distance, and do not exceed criteria for HF cetaceans beyond 2 to 3 m horizontal distance from the source, which is not considered to be a credible exposure scenario for mobile marine fauna. Zykov (2013) also estimated the maximum distance at which the unweighted 160 dB re 1 µPa (SPL) behavioural disturbance threshold for impulsive sound was reached was 290 m for MBES and 690 m for SSS. Again, it is emphasised that many MBES and SSS instruments may operate at frequencies outside of the hearing range of cetaceans and so these would not be audible or result in behavioural disturbance. For instruments with frequencies that overlap with the hearing ranges of cetaceans, a significant proportion of the sound energy may still be outside of their hearing ranges; therefore, the perceived sound levels are reduced and the horizontal distances at which behavioural disturbances may occur are less than those inferred by the unweighted 160 dB re 1 µPa (SPL) behavioural disturbance threshold. For example, modelling of weighted SPLs by Zykov (2013) for MBES indicated that the 160 dB re 1 µPa (SPL) behavioural threshold was not exceeded for LF cetaceans at any distance and was limited to approximately 205 m horizontal distance for HF cetaceans. For SSS, the modelling of weighted SPLs indicated that the 160 dB re 1 µPa (SPL) behavioural threshold was exceeded at horizontal distances of 110 m for LF cetaceans and 611 m for HF cetaceans.

Acoustic modelling of sub-bottom profilers by Zykov (2013) and McPherson and Wood (2017), indicates limited horizontal sound propagation outside of the main directional field of sound. The modelling studies also indicate that PK and SEL_{24h} thresholds for PTS are not exceeded. The potential for TTS resulting from SEL_{24h} is limited to within a few metres from the moving sound source (Zykov, 2013; McPherson and Wood, 2017), which is not considered to be a credible exposure for mobile marine fauna. Exceedance of the 160 dB re 1 µPa SPL behavioural response threshold for impulsive sound is limited to within a few metres in most instances, or up to a maximum of 50 m depending upon which SBP instrument is used, water depth and the seabed sediment characteristics (Zykov, 2013; McPherson and Wood, 2017).

Potential impacts to cetaceans from MBES, SSS and sub-bottom profiler may, therefore, include behavioural disturbance if in close proximity to the survey instruments, but ranges to disturbance are less than or equivalent to disturbance ranges for the IMMR vessel itself. PTS or TTS are not considered credible, given individuals would need to be directly next to the noise sources for prolonged duration.

Transponders used for positioning during IMMR activities have the potential to cause some temporary behavioural disturbance to cetaceans. The typical frequencies of 21 to 31 kHz produced by the transponders are most audible to HF cetaceans such as toothed whales and dolphins rather than LF cetaceans, and the source levels (180 to 202 dB re 1 µPa at 1 m SPL) rapidly attenuate within a very short distance from the source, such that PTS or TTS are not considered credible. Based on empirical spreading loss estimates measured by Warner and McCrodan (2011), received levels from USBL transponders are expected to exceed the cetacean behavioural response threshold for impulsive sources out to about 42 m.

Transmissions are not continuous but consist of short ‘chirps’ with a duration that ranges from 3 to 40 milliseconds. Transponders do not emit sound when on standby. When required for general positioning, they emit one chirp every five seconds (estimated to be required for 4 hrs at a time). When required for precise positioning, they emit one chirp every second (estimated to be required for 2 hrs at a time). Due to the short duration chirps, the temporary and intermittent use and the mid frequencies used by positioning equipment, the acoustic noise from the transponders is unlikely to have a substantive effect on the behavioural patterns of cetaceans.

Potential impacts from predicted noise levels from the operating facility, project vessels, and IMMR survey activities are not considered to be ecologically significant at a population level.

Marine Turtles

Species Sensitivity and Exposure Thresholds

There is a paucity of data regarding responses of marine turtles to underwater noise. The Recovery Plan for Marine Turtles (Commonwealth of Australia, 2017) notes there is limited information available on the impact of noise on

marine turtles and that the impact of noise on turtle stocks may vary depending on whether exposure is short (acute) or long-term (chronic). However, turtles have been shown to respond to low frequency sound, with indications that they have the highest hearing sensitivity in the frequency range 100 to 700 Hz (Bartol and Musick, 2003).

McCauley et al. (2000) observed the behavioural response of caged green and loggerhead turtles to impulsive sound (an approaching seismic airgun). For received levels above 166 dB re 1 µPa SPL, the turtles increased their swimming activity and above 175 dB re 1 µPa they began to behave erratically, which was interpreted as an agitated state. The 166 dB re 1 µPa SPL has been used as the threshold level for a behavioural disturbance response by the US NMFS (NSF, 2011) and is applied to this impact assessment. No quantitative (numerical) thresholds have been developed for behavioural effects from continuous sources (e.g., vessel noise) on marine turtles. However, Popper et al. (2014) propose qualitative impact criteria for near-field, intermediate and far-field exposures (Popper et al., 2014). Finneran et al. (2017) presents thresholds for turtle PTS and TTS for both impulsive and continuous sound exposures.

The thresholds listed in **Table 6-4** are considered appropriate for the assessment of effects from impulsive and continuous sound sources during the Petroleum Activities Program.

Table 6-4: Thresholds for permanent threshold shift, temporary threshold shift and behavioural response onset in marine turtles for continuous and impulsive noise

Hearing group	***Impulsive***			***Continuous***		
	PTS onset thresholds: SEL_{24h} (dB re 1 µPa².s)	***TTS onset thresholds: SEL_{24h} (dB re 1 µPa².s)***	***Behavioural response (dB re 1 µPa)***	***PTS onset thresholds: SEL_{24h} (dB re 1 µPa².s)***	***TTS onset thresholds: SEL_{24h} (dB re 1 µPa².s)***	***Behavioural response (dB re 1 µPa)***
Marine turtles	204	189	166* 175^{+}	220	200	(N) High (I) Moderate (F) Low$^{\#}$

*Source: PTS and TTS thresholds (Finneran et al., 2017), * behavioural response threshold (impulsive) (NSF 2011), $^{+}$ behavioural disturbance threshold (impulsive) (McCauley et al., 2000), $^{\#}$ behavioural response threshold (continuous) (Popper et al., 2014).*

Note: The sound units provided in the table above for continuous noise include: relative risk (high, medium and low) is given for marine turtles at three distances from the source defined in relative terms as near (N – tens of metres), intermediate (I – hundreds of metres) and far (F – thousands of metres) (after Popper et al., 2014).

Predicted Underwater Noise Impacts to Turtles

Facility and Support Vessel Noise Impacts

As noted above, vessels holding station are considered to be the predominant noise source related to the PAP, with source levels of approximately 182 dB re 1 µPa SPL at 1 m from a support vessel holding station considered to be representative of noise levels generated by vessels used for the PAP.

Although there are no quantitative sound exposure thresholds for impacts on marine turtles resulting from continuous noise sources, the relative risk for behavioural response is expected to be high within tens of metres of the source, medium within hundreds of metres and low within kilometres from the source (refer **Table 6-4**). PTS and TTS thresholds for turtles are 220 dB re 1 μPa^2 s (SEL weighted) and 200 dB re 1 μPa^2 s (SEL weighted), respectively (refer **Table 6-4**). Typical noise levels generated by the facility and a support vessel using DP would not exceed these levels (except at extremely close ranges to the source), and prolonged exposure of transient marine turtles at close range is not considered a credible scenario.

As outlined above, marine turtles are not expected to be in the area in high numbers even during nesting and internesting periods. Marine turtles are also capable of moving away from potential noise sources, and there are no constraints to their movement within the PAA. Therefore, impacts to marine turtles from project vessels or the platform are expected to be of no lasting effect.

IMMR Activities

As outlined above for cetaceans, Zykov (2013) conducted noise modelling for low energy survey instruments, with the modelling for MBES, SSS and sub-bottom profiler considered comparable for the nature and scale of the low energy IMMR survey equipment. The operating frequencies of MBES (12 to 700 kHz) and SSS (75 to 900 kHz) are well above the hearing range of turtles (0.1 to 2 kHz) and so no disturbance is expected. It is possible that some of the lower frequency sound emitted by sub-bottom profilers (2 to 30 kHz) may be audible to turtles, but again, a large proportion of the sound energy may be at frequencies that are outside of their normal auditory range. Modelling of impulsive sub-bottom profiler sound emissions by Zykov (2013) and McPherson and Wood (2017) indicates that the 166 dB re 1 µPa (SPL) behavioural disturbance threshold for turtles may only be exceeded within metres or tens of metres of the survey instruments. Therefore, behavioural impacts would be highly localised. PTS or TTS is not considered to be credible given the rapid attenuation of sound close to the source and a large proportion of the sound energy is produced at frequencies outside the peak hearing frequency range of turtles.

Transponders used for positioning during IMMR activities typical operate at frequencies of 21 to 31 kHz which is well outside the peak hearing frequency range of turtles (0.1 to 2 kHz). Therefore, no impacts are considered credible.

Potential impacts from predicted noise levels from the operating facility, project vessels, and IMMR survey activities are not considered to be ecologically significant at a population level.

Fish, Sharks and Rays

Species Sensitivity and Exposure Thresholds

Fishes are primarily sensitive to the particle motion component of sound at close range to a sound source, while the presence of the swim bladder results in a varying degree of sensitivity of some fishes to sound pressure (Popper and Hawkins, 2018; Popper et al., 2019). Consequently, fishes are broadly categorised into three groups with respect to their hearing capabilities that are relevant to the types of fishes and sharks that may be present in the Operational Area (Popper et al., 2014):

- Fishes with no swim bladder or other gas chamber (e.g., sharks, mackerels) – Sensitive only to particle motion, not sound pressure changes.
- Fishes with swim bladders, but without a direct connection between the swim bladder and the inner ear (e.g., demersal snappers and emperors) – Hearing primarily involves particle motion with some limited ability to indirectly detect changes in sound pressure.
- Fishes with a swim bladder or other gas volume connected directly to the inner ear (e.g., herrings, sardines, pilchards, shads) – These fishes are able to detect both sound pressure as well as particle motion.

Sound exposure criteria applicable to continuous sound sources are presented in **Table 6-5**. Popper et al. (2014) propose relative risk criteria (high, moderate, low) for injury, impairment and behavioural effects to fishes at three distance categories, near (N) (tens of metres from the source), intermediate (I) (hundreds of metres from the source), and far (F) (kilometres from the source).

Table 6-5: Impact thresholds to fish, sharks and rays for continuous noise

Receptor	***Mortality and potential mortal injury***	***Impairment***			***Behaviour***
		Recoverable Injury	***TTS***	***Masking***	
Fish: no swim bladder	(N) Low (I) Low (F) Low	(N) Low (I) Low (F) Low	(N) Moderate (I) Low (F) Low	(N) High (I) High (F) Moderate	(N) Moderate (I) Moderate (F) Low
Fish: swim bladder not involved in hearing	(N) Low (I) Low (F) Low	(N) Low (I) Low (F) Low	(N) Moderate (I) Low (F) Low	(N) High (I) High (F) Moderate	(N) Moderate (I) Moderate (F) Low
Fish: swim bladder involving hearing	(N) Low (I) Low (F) Low	170 dB SPL for 48-hours	158 dB SPL for 12-hours	(N) High (I) High (F) High	(N) High (I) Moderate (F) Low
Fish eggs and fish larvae	(N) Low (I) Low (F) Low	(N) Low (I) Low (F) Low	(N) Low (I) Low (F) Low	(N) High (I) Moderate (F) Low	(N) Moderate (I) Moderate (F) Low

Note: The sound units provided in the table above include relative risk (high, medium and low) is given for fish (all types) at three distances from the source defined in relative terms as near (N – tens of metres), intermediate (I – hundreds of metres) and far (F – thousands of metres) (after Popper et al., 2014).

Predicted Underwater Noise Impacts to Fish

Facility and Support Vessel Noise Impacts

Vessels holding station using DP are expected to produce sound equivalent to about 182 dB re 1 µPa SPL at 1 m. Modelling undertaken by McPherson et al. (2019) of sound produced by facility and vessel operations found that recoverable injury to some types of fish would only be possible if they remained within a distance of less than 10 m for 48 hours, and TTS if fishes remained within 10 m for at least 12 hours. Pelagic fish are highly mobile and the types of demersal fishes known to occur in the vicinity of the Angel facility (e.g., snappers, emperors, cods and groupers) will exhibit some fidelity to the area but are still relatively free-swimming and are not constrained to such close ranges (i.e., 10 m). Therefore, free-swimming fish remaining in close range to sound sources for periods that subject themselves to TTS and injury is not considered to be a credible scenario.

There are no quantitative sound exposure thresholds for impacts on fish, sharks and rays resulting from continuous noise sources. The relative risk for behavioural response is expected to be high within tens of metres of the source, medium within hundreds of metres and low within kilometres from the source (refer **Table 6-4**). In the context of the riser platform, the largest contribution to operational noise is from the topside and near the surface, with lower sound levels produced from subsea infrastructure such as choke valves. Similarly, sound from the PSV would be at the surface. While some localised behavioural avoidance and masking in the vicinity of the loudest sound sources from

the riser platform, choke valves and PSV may occur in some fishes, no lasting effect is anticipated. Fish are also known to habituate to continuous noise sources, which is consistent with fish congregating around operating offshore oil and gas structures.

Considering the overlap of the whale shark foraging BIA with the PAA, it is likely there may be increased numbers of individuals during migratory periods. Currently, there are no quantitative sound exposure thresholds relevant to whale sharks. It is expected that the potential effects of noise on whale sharks are the same as for other fish species, resulting in minor, localised and temporary behavioural change such as avoidance. Therefore, impacts to whale sharks from project vessels or the platform are expected to have no lasting effect. Other fauna associated with the PAA includes predominantly pelagic species of fish, with migratory species such as rays transiting through the PAA; these species may be similarly affected by noise from project vessels/facility.

IMMR Activities

As outlined above, Zykov (2013) conducted noise modelling for low energy survey instruments, with the modelling for MBES, SSS and sub-bottom profiler considered comparable for the nature and scale of the low energy IMMR survey equipment. The operating frequencies of MBES (12 to 700 kHz) and SSS (75 to 900 kHz) are well above the peak hearing ranges of fish (100 Hz to several kHz) and so no disturbance is expected. It is possible that some of the lower frequency sound emitted by sub-bottom profilers (2 to 30 kHz) will be audible to fish, but again, a large proportion of the sound energy may be at frequencies that are outside of their normal auditory range. Therefore, behavioural impacts would be highly localised. PTS or TTS is not considered to be credible given the rapid attenuation of sound close to the source and a large proportion of the sound energy is produced at frequencies outside the peak hearing frequency range of fish.

Transponders used for positioning during IMMR activities typical operate at frequencies of 21 to 31 kHz which is well outside the hearing frequency range of fish. Therefore, no impacts are considered credible.

Potential impacts from predicted noise levels from the operating facility, project vessels, and IMMR survey activities are not considered to be ecologically significant at a population level.

Cultural Values and Heritage

Through consultation and review of available literature (**Section 4.9.1**), Woodside understands that marine fauna that may be affected by noise emissions, such as marine mammals and turtles, are culturally important to Traditional Custodians. Traditional Custodians value these species both tangibly as well intangibly as they can be considered a resource or linked to songlines and dreaming stories. Traditional Custodians also have connection to many marine species through kinship and totemic systems; an individual may have obligation to care for a species to which they are kin. Traditional Custodians may also have a cultural obligation to care for the environmental values of Sea Country.

For example, activities that impact turtle populations and their marine environment may have an indirect impact on some Indigenous communities if they deplete hunting areas and threaten local food security (Delisle et al., 2018:251). Whale species are subject of First Nations' increase ceremonies/rituals which are performed to enhance or maintain populations. As these thalu ceremonies are performed to maintain and increase populations of marine species, it is considered that management applies at the species/population level and not to individuals. For example, it is anticipated the thalu site on Murujuga which "brings in whales to beach" will continue to serve its purpose so long as whales continue to migrate through Mermaid Sound.

Related intangible cultural heritage may include the transmission of cultural knowledge about whales and whale behaviour, including birthing areas, whale communication and migratory patterns. Such cultural knowledge may be associated with various cultural functions and activities that support the social and economic life of a community (Fijn, 2021). Inter-generational transmission of cultural knowledge (including songlines) relating to marine reptiles may be impacted where changes results in reduced sightings (e.g., through population decline, changes to migration routes or changes to migration seasonality). This transfer of knowledge may be integral to managing a group's intangible cultural heritage (UNESCO, 2003).

As described, potential impacts to marine fauna are predicted to be at an individual level, which are not considered to be ecologically significant at a population level. Impacts are not expected to occur to ecologically significant proportions of the populations of the species, nor expected to result in a decrease of the quality of the habitat such that the extent of these species is likely to decline. As such, cultural values and intangible cultural heritage associated with these species are expected to be maintained.

Demonstration of ALARP

Legislation, Codes and Standards				
EPBC Regulations 2000 – Part 8 Division 8.1 Interacting with cetaceans, including the following measures[44]: • Support vessels will not travel greater than 6 knots within 300 m of a cetacean or turtle (caution zone) and not approach closer than 100 m from a whale. • Support vessels will not approach closer than 50 m for a dolphin or turtle and/or 100 m for a whale (with the exception of animals bow riding). • If the cetacean or turtle shows signs of being disturbed, support vessels will immediately withdraw from the caution zone at a constant speed of less than 6 knots. • Support vessels will not travel greater than 8 knots within 250 m of a whale shark and not allow the vessel to approach closer than 30 m of a whale shark.	F: Yes. CS: Minimal cost. Standard practice.	Implementation of these controls is primarily intended to reduce the likelihood of a collision between a cetacean, whale shark or turtle occurring. However, implementation may also provide some reduction in the potential for exposure of these fauna to sound levels in direct proximity to vessels.	Controls based on legislative requirements – must be adopted.	Yes **C 4.1**

44 *For safety reasons, the distance requirements below are not applied for a vessel holding station or with limited manoeuvrability e.g. anchor handling, loading, back-loading, bunkering, close standby cover for overside working and emergency situations.*

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Good Practice				
Vary the timing of the Petroleum Activities Program to avoid migration periods.	F: No. The Petroleum Activities Program occurs continuously, modifying the timing of the Petroleum Activities Program is not feasible. CS: Not considered, control not feasible.	Not considered, control not feasible.	Not considered, control not feasible.	No
Implement a shutdown zone around MBES, SSS and sub-bottom profiler for: • whales • marine turtles • whale sharks.	F: Yes. However, as equipment is underwater, effective implementation of zones is challenging from topside observation. CS: Moderate. Requires the provision of a dedicated suitably trained crew member to undertake Marine Fauna Observations.	Limited. The areas of disturbance for these devices are limited and injury/PTS/TTS is not expected to occur. In addition, it is noted that for many MBES and SSS, the frequency range of these devices are outside the estimated frequency hearing range of identified protected species (whales, turtles and whale sharks).	Acoustic MBES, SSS and sub-bottom profiler surveys are infrequently conducted (every 1 to 6 years) as part of the Petroleum Activities Program. The source levels and frequency range of these devices are mostly outside the estimated frequency hearing range of identified protected species (whales, turtles and whale sharks), so costs are considered disproportionate to benefits.	No
Have a dedicated experienced and trained Marine Fauna Observer (MFO) onboard vessels to undertake marine fauna observations.	F: Yes, however additional cost for dedicated and experienced MFO to be present during IMMR CS: Moderate, requires the provision of a dedicated experienced MFO to undertake Marine Fauna Observations.	Use of an MFO may detect fauna in the area, however control provides limited benefit when managing impacts associated with vessel noise alone.	Given limited benefit associated with the management of vessel noise impacts and costs associated with control implementation an experienced MFO is not considered necessary.	No

Professional Judgement – Eliminate				
Eliminate the use of DP on vessels during the Petroleum Activities Program.	F: No. Both platform and subsea support vessels are required to reliably hold station during the Petroleum Activities Program. Failure to do so may lead to loss of separation between vessels and infrastructure. This would result in unacceptable safety and environmental risk (loss of vessel separation has been identified as a MEE – **Section 6.7.6**). CS: Not considered, control not feasible.	Not considered, control not feasible.	Not considered, control not feasible.	No
Professional Judgement – Substitute				
None identified.				
Professional Judgement – Engineered Solution				
Application of bubble curtains to reduce noise propagation.	F: No. Bubble curtain installation and operation in offshore open water not feasible due to technical operation constraints i.e., water depth/current.	Not considered, control not feasible.	Not considered, control not feasible.	No
ALARP Statement: On the basis of the environmental impact assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the potential impacts from routine acoustic emissions from vessels, helicopters, wellheads, pipelines and the Angel platform (including machinery). As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.				
Demonstration of Acceptability				
Acceptability Statement: The impact assessment has determined that, given the adopted controls, impacts from routine acoustic emissions from vessels, helicopters, wellheads, pipelines and the Angel platform represent a negligible impact /disturbance to marine fauna within the PAA. Further opportunities to reduce the impacts and risks have been investigated above. The impacts are consistent with good oil-field practice/industry best practice. The potential impacts and risks are considered broadly acceptable, if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the impacts of acoustic emissions to a level that is broadly acceptable.				

EPOs, EPSs and MC for Angel Facility Operations			
Environmental Performance Outcomes	***Controls***	***Environmental Performance Standards***	***Measurement Criteria***
EPO 4 Limit adverse impacts on fauna from noise emissions (no impact greater than F[45]) during the Petroleum Activities Program.	**C 4.1** EPBC Regulations 2000 – Part 8 Division 8.1 Interacting with cetaceans, which include the following measures[46]: • Vessels will not travel greater than 6 knots within 300 m of a cetacean or turtle (caution zone) and not approach closer than 100 m from a whale. • Vessels will not approach closer than 50 m for a dolphin or turtle and/or 100 m for a whale (with the exception of animals bow riding). • If the cetacean or turtle shows signs of being disturbed, activity support vessels will immediately withdraw from the caution zone at a constant speed of less than 6 knots. • Vessels will not travel greater than 8 knots within 250 m of a whale shark and not allow the vessel to approach closer than 30 m of a whale shark.	**PS 4.1** Vessels will comply with the EPBC Regulations 2000 – Part 8 Division 8.1 (Regulation 8.05 and 8.06) Interacting with cetaceans to manage the risk of fauna collision.	**MC 4.1.1** Records demonstrate no breaches with EPBC Regulations 2000 – Part 8 Division 8.1 Interacting with cetaceans and Woodside Marine Charterers Instructions. **MC 4.1.2** Records demonstrate reporting cetacean ship strike incidents to the DCCEEW.

45 Defined as 'No lasting effect (< 1 month); localised impact not significant to environmental receptors' as in **Table 2-3**, **Section 2.6.3**.
46 For safety reasons, the specified distances requirements are not applied for a vessel holding station or with limited manoeuvrability (e.g., loading, back-loading, close standby cover for overside working and emergency situations).

6.6.4 Routine Acoustic Emissions: Generation of Noise During Tie-back Activities

Context

Generation of acoustic signals from DP systems on project vessels					✓			F					
Generation of noise from, cutting of well infrastructure and contingency activities					✓			F					

Description of Source of Impact

During tie-back activities, sound will be generated from a number of sources including MODU drilling operations, vessels, and contingency activities such as respud, sidetrack, well removal and associated underwater acoustic positioning systems. These noise sources will contribute to and have the potential to exceed ambient noise levels which range from around 90 dB re 1 µPa (SPL) under very calm, low wind conditions, to 120 dB re 1 µPa (SPL) under windy conditions (McCauley, 2005).

Vessel Noise

A range of project vessels may be used to complete tie-back activities associated with the Petroleum Activities Program including moored/DP MODU,, subsea installation vessels and other support vessels (**Section 3.5.6**).

The MODU (DP or moored) is expected to be on location for drilling operations for approximately 50-60 days including mobilisation, demobilisation and contingency. Vessels associated with subsea installation, pre-commissioning and cold commissioning activities may be on location for up to 4 weeks.

The project vessels will generate noise both in the air and underwater, due to the operation of thrusters, engines, propeller movement, etc (as described in **Section 6.6.3**). Vessels, including the MODU (optional), installation vessels, AHVs, general support vessels will use DP where propellers and thrusters are used to hold position, rather than anchoring.

MODU Drilling Operations (moored)

During drilling operations, a moored MODU will produce low-intensity continuous sound. Sound produced from an active MODU is predominantly below 2 kHz, with peak frequencies below 500 Hz.

A range of broadband values, 59 to 185 dB re 1 µPa at 1 m (SPL), have been quoted for various MODUs (Simmonds et al., 2004). McPherson et al. (2021) recorded the source level spectrum of the Ocean Onyx, which is considered representative of a moored MODU considered for the tie-back campaign. The Ocean Onyx was measured to have a broadband (10 Hz to 31 kHz) source level of 175.4 dB re 1 µPa m while anchored and drilling and is considered representative drilling activity for this EP. The measured source level for the Ocean Onyx is consistent with or slightly higher than levels recorded for other moored MODUs during drilling operations. For example, McCauley (1998) recorded source noise levels for moored MODUs from 149 to 154 dB re 1 µPa at 1 m while actively drilling (with support vessel on anchor) and Greene (1987) recorded source levels of two moored drillships from 145 to 158 dB re 1 µPa at 1 m during drilling (with support vessels idling nearby). Austin et al. (2018) recorded broadband source levels from MODU operations (excluding DP thrusters) to be 170.7 dB re 1 µPa.

Project Vessels and MODU Operation of DP

Vessels used for the tie-back activities are detailed in **Section 3.5.6**, and include a number of DP capable vessels. As discussed in **Section 6.6.3,** sound levels and frequencies generated by vessels varies with the size of the vessel, speed, engine type and the activity being undertaken.

A DP MODU or IMMR vessel may be used as described above. Indicative DP MODU underwater noise measurements were taken for the West Aquarius MODU by JASCO on the Scotian Shelf in Canada (Wecker et al., 2022). The 90th percentile of the broadband radiated sound levels was 186.3 dB re 1 µPa (Martin et al., 2019). This is similar to measurements taken for the Maersk Discoverer drill rig on the North West Shelf (Woodside Energy Limited, 2011), where the system emitted tonal signals between 200 Hz to 1.2 kHz, at a source level between 176 and 185 dB re 1 µPa SPL at 1 m.

Noise levels generated by support vessels on standby is expected to be similar to levels discussed in **Section 6.6.3**.

Sound Transmission Loss Modelling

Noise modelling was commissioned from JASCO by Woodside for the Julimar Appraisal Drilling and Surveys activities (Julimar South-1 well) (Stroot et al., 2022) and Pyxis Drilling and Subsea Installation activities (XNA02 well) (Wecker, et al., 2022), which are considered broadly comparable in terms of MODU and vessel activities, and the water depths and seabed substrates at the LDA-02 well location.

For moored MODU scenarios, noise modelling for the Julimar Appraisal Drilling and Surveys activities (Stroot et al., 2022) provides a suitable analogue to the size and type of moored MODU and support vessels planned for use during tie-back activities. A number of moored MODU scenarios were modelled including with an offshore supply vessel (OSV) in ~166 m at the Julimar South-1 well location (**Table 6-6**). Given water depth at the LDA-02 location is 130 m and similar seabed substrate, the modelling of the moored MODU and OSV are regarded as a suitable analogue for similar vessels and activities at the LDA-02 location.

For DP vessel activities, noise modelling for Pyxis Drilling and Subsea Installation activities (Wecker et al., 2022) provides a similar analogue to the size and type of DP MODU and support vessels planned for use during tie-back activities. Several DP MODU scenarios were modelled, including with an OSV in ~172 m at the XNA02 well location (**Table 6-7**). As above, this modelling is considered a suitable analogue for similar vessels and activities at the LDA-02 location.

These scenarios included several permutations of support vessels and the MODU undertaking drilling activities, used to inform the worst-case credible noise propagation scenarios (including concurrent activities).

Table 6-6: Summary of modelled scenarios for drilling activities at the Julimar South-1 well location as an analogue for moored operations (source: Stroot et al., 2022).

Scenario number	*Description*
1	Anchored MODU Drilling (24h)
2	Anchored MODU Drilling (24h) + OSV on standby (24h)
3	Anchored MODU Drilling + OSV resupply, under DP (2h)
4	Anchored MODU Drilling (24h) + OSV resupply, under DP (8h)
5	Anchored MODU Drilling (24h) + OSV resupply, under DP (8h) + OSV on standby (24h)

Table 6-7: Summary of modelled scenarios at the Xena (XNA02) field as an analogue for DP operations (source: Wecker et al., 2022).

Scenario number	*Description*
6	MODU under DP, drilling at XNA02 (24 hr)
7	MODU under DP, drilling at XNA02 (24 hr) + support vessel resupply, under DP (2 hr)

8	MODU under DP, drilling at XNA02 (24 hr) + support vessel resupply, under DP (8 hr)
9	MODU under DP, drilling at XNA02 (24 hr) + support vessel on standby (24 hr)
10	MODU under DP, drilling at XNA02 (24 hr) + support vessel resupply, under DP (8 hr) + support vessel resupply on standby (24 hr)

Source levels representative of drilling and subsea installation scenarios

Source levels for relevant vessels that were used to inform the sound transmission loss modelling (Stroot et al., 2022; Wecker et al., 2022) are presented in **Table 6-8**.

The source sounds were applied to the modelling scenarios for drilling and subsea installation activities.

Table 6-8: Vessel source levels used in the acoustic modelling for the Petroleum Activities Program tie-back activities.

Vessel	***Sound Level (dB re 1 µPa².m².s)***	***Reference***
Moored MODU	175.4	Stroot et al., 2022
MODU under DP	187.7	Wecker et al., 2022
OSV stationary under DP (resupply scenario)	187.6	Stroot et al., 2022
OSV slow transit	177.8	Stroot et al., 2022

Sound Transmission Loss Modelling Scenarios

The acoustic modelling scenarios used in this assessment are presented in **Table 6-6** and **Table 6-7**. Vessel scenarios during Lambert West tie-back may differ slightly from those modelled from time to time in terms of precise vessel types, proximity and number. However, the magnitude and extent of potential sound propagation and the resultant effects on marine fauna from the modelled worst-case scenario are expected to be comparable to the worst-case scenario or are conservative.

The acoustic modelling studies assessed distances from operations where underwater sound levels were predicted to drop below thresholds corresponding to behavioural response and injury (temporary reduction in hearing sensitivity or TTS and permanent threshold shift or PTS) for marine fauna. The animals considered included marine mammals, turtles, and fish. Due to the variety of species considered, several different thresholds were used for evaluating effects.

The modelling methodologies considered scenario specific source levels and range-dependent environmental properties. Estimated underwater acoustic levels for non-impulsive (continuous) noise sources presented as sound pressure levels (SPL, L_p), and as accumulated sound exposure levels (SEL, L_E) as appropriate for different noise effect criteria, behavioural response and injury (TTS and TPS), respectively. In this report, the duration of the SEL accumulation is defined as integrated over a 24-hour period.

The SEL_{24h} is a cumulative metric that reflects the dosimetric impact of noise levels within 24 hours based on the assumption that an animal is consistently exposed to such noise levels at a fixed position. The corresponding SEL_{24h} radii represent an unlikely worst-case scenario. More realistically, marine mammals (as well as pelagic fish and turtles) would not stay in the same location for 24 hours. Therefore, a reported radius for SEL_{24h} criteria does not mean that marine fauna travelling within this radius of the source will be injured, but rather that an animal could be exposed to the sound level associated with injury (TTS or PTS) if it remained in that location for 24 hours.

Contingency Activities (Respud, Sidetrack, Well Removal)

Contingency activities include a well respud or sidetrack and will involve the use of a MODU and vessels, plus drilling operations. Any acoustic emissions generated will be the same as those expected from the planned activities described above.

In the event the wellhead is removed under this EP scope, additional noise from the cutting of the surface casing and conductors is likely to be generated. Underwater noise associated with cutting (diamond wire) of subsea infrastructure is generally indistinguishable above background noise levels at lower frequencies, primarily detected at noise frequencies above 5 kHz (Pangerc et al., 2016). Quijano and McPherson (2021) estimated the source level of a diamond wire saw cutter at 169 dB re 1 µPa at 1 m. The casings and conductors will be cut below the mudline to enable wellhead recovery using either abrasive water jet cutting method, or mechanical cutting method.

Twachtman et al. (2004) concluded that mechanical cutting and abrasive water jetting, as well as diamond wire cutting methods, are generally considered harmless to marine life and the environment. Similarly, Pangerc et al. (2016) found that the sound radiated from the diamond wire cutting of the conductor was not easily discernible above the background noise at the closest recorder located at 100 m from the source. The sound that could be associated with the diamond wire cutting was primarily detectable above the background noise at the higher acoustic frequencies (above Around 5 kHz) (Pangerc et. al., 2016) above the hearing range of low frequency cetaceans. Background noise was attributed to surface vessel activity such as DP. Any noise propagating at seabed from either abrasive water jet cutting or mechanical cutting of the wellhead casing and conductors is likely to attenuate to levels at, or close to

background ambient levels within <100 m of the source, with ambient levels being significantly elevated by the concurrent presence of a DP vessel immediately above the wellhead location. As such, noise from the cutting of the casing and conductors will not add to significantly to noise levels for the tie-back activities and are not assessed further.

Generation of Underwater Noise from Positioning Equipment

An array of long baseline (LBL) and/or ultra-short baseline (USBL) transponders may be installed on the seabed for metrology and positioning. An array of transponders is proposed within a radius of 500 m from the proposed location of the well and will be in place for a period of about three months. During Xmas tree installation, USBL transponders may be installed on the seabed or mounted to the wellhead as required by the subsea installation activities. Transmissions from USBL transponders are similar to LBL transponders.

Transponders typically emit pulses (impulsive noise) of medium frequency sound, generally within the range 21 to 31 kHz. The estimated SPL would be 180 to 206 dB re 1 µPa at 1 m (Jiménez-Arranz et al., 2017). Transmissions are not continuous but consist of short 'chirps' with a duration that ranges from 3 to 40 milliseconds. Transponders will not emit any sound when on standby and are planned to only actively emit sound for about six hours per well. When required for general positioning they will emit one chirp every five seconds (estimated to be required for four hours at a time). When required for precise positioning they will emit one chirp every second (estimated to be required for two hours at a time). An array of transponders will be active while the DP MODU is on location.

Cumulative Noise Sources

Underwater noise generated during tie-back activities has the potential for cumulative impacts with acoustic emissions from routine operations (e.g., machinery, flaring, IMMR activities etc), which may result in slightly elevated acoustic levels.

As described above, tie-back activities are likely to include a MODU and installation vessel and support vessels. SIMOPS with drilling and installation are not planned but are considered as a contingency. During concurrent activities, a number of vessels may be operating, as described in **Table 6-9**. The worst-case credible scenario is considered to be if the MODU, support vessel and installation vessel are required to be in proximity. This is the case used for the following cumulative assessment of potential impacts.

Table 6-9: Concurrent activities considered in the assessment of cumulative underwater vessel noise.

Concurrent Activities	*Approx. Duration[1]*	*Vessels*	*Approximate distance between vessels*
MODU drilling Subsea installation – tubing head spool installation (or similar activity)	2 days	DP MODU + supply vessel Installation or IMMR vessel (DP)	<3 km
Pre-commissioning and start-up of Lambert West tie back Platform operations and supply	5 days	Commissioning (IMMR class) vessel (DP) Platform + DP supply vessel	~13 km

1. Relates to period of overlap, not entire duration of activity.

Impact Assessment

Potential impacts to environmental values

Receptors

The PAA is located in water depths of approximately 70 to 130 m (**Section 3.2**). The fauna associated with this area will be predominantly pelagic species of fish and cetaceans, with migratory species such as cetaceans, marine turtles and whale sharks occurring in the area seasonally (**Section 4.6**). Anthropogenic noise interference is a key threat to a number of migratory and threatened cetaceans, marine turtles and whale sharks identified as potentially occurring within the PAA. Relevant actions included in recovery plans for these species are outlined in **Section 6.9**.

A pygmy blue whale migration BIA is located 37 km north of the PAA and a humpback whale migration BIA 34 km south (**Section 4.6.3**). Migration periods for pygmy blue whales are April to July and October to January. The migration period for humpback whale is June to November. It is possible that individuals may transit through the PAA during these periods of higher abundance, though it is expected that the majority will be transit within or near to the respective BIAs.

No marine turtle BIAs or Habitat Critical overlaps the PAA, the closest located 15 km south (flatback turtle internesting BIA/flatback turtle Habitat Critical). Given the water depths and distance from shore, the PAA does not represent suitable foraging or internesting habitat. Satellite tracking of flatback turtle nesting populations (Barrow Island and mainland sites) indicates this species travels to the east of Barrow Island between nesting events, within WA mainland coastal waters less than 70 m deep (Chevron Australia Pty Ltd, 2015).

A whale shark foraging BIA overlaps with the PAA. Peak whale shark numbers are expected in the region from March to July.

Two KEFs overlap the PAA: The Glomar Shoals KEF and the Ancient Coastline at 125 m depth contour KEF (**Section 4.7**). The Glomar Shoals KEF is identified as regionally important for high biological diversity and localised productivity (DEWHA, 2008). The Ancient Coastline KEF is valued as a unique seafloor feature, with ecological properties of regional significance (DEWHA, 2008).

Potential Impacts of Noise

Elevated underwater noise can affect marine fauna, including cetaceans, fish, turtles, sharks and rays, in three main ways (Richardson et al., 1995; Simmonds et al., 2004):

- by causing direct physical effects on hearing or other organs. Hearing loss may be temporary (TTS, referred to as auditory fatigue), or PTS (injury)
- by masking or interfering with other biologically important sounds (including vocal communication, echolocation, signals and sounds produced by predators or prey)
- through disturbance leading to behavioural changes or displacement from important areas (e.g., BIAs). The occurrence and intensity of disturbance is highly variable and depends on a range of factors relating to the animal and situation.

Sound Propagation

Increasing the distance from the noise source usually results in the level of noise reducing, due primarily to the spreading of the sound energy with distance. The way that the noise spreads (geometrical divergence) depends upon several factors such as water column depth, pressure, temperature gradients, and salinity, as well as surface and bottom conditions.

Cetaceans

Species Sensitivity and Thresholds

As identified in **Section 6.6.3**, protected species including migratory humpback whales and pygmy blue whales may be encountered near the PAA, and therefore could be impacted by acoustic emissions associated with tie-back activities. Thresholds that could result in a behavioural response, TTS and PTS for cetaceans as a result of continuous and impulsive noise sources are presented in **Table 6-3** in **Section 6.6.3** above.

Predicted Underwater Noise Impacts to Cetaceans

Results – Modelling of a Moored Mobile Offshore Drilling Unit

A sound transmission loss modelling study was conducted by JASCO for several scenarios at the analogous Julimar South-1 well location (water depth – 166.6 m) as well as a nominated OSV standby location (water depth – 150.2 m), as outlined in **Table 6-6** above (Stroot et al., 2022). The modelling study indicated that exceedances of the PTS and TTS thresholds for low frequency (LF) cetaceans, such as humpback whale and pygmy blue whale, may occur out to a maximum of 0.07 km and 0.92 km respectively (**Table 6-10**)**.** For HF and VHF cetaceans (toothed whales and dolphins), the maximum distances at which sound levels dropped below PTS and TTS thresholds were 0.21 km and 2.76 km respectively.

During normal operations (the moored MODU drilling with an OSV on standby – Scenario 2), the minimum distance to the TTS threshold is 0.23 km, 0.09 km and 2.57 km for LF, HF and VHF cetaceans respectively. The PTS threshold was only exceeded for VHF for Scenario 2, at a maximum distance of 0.15 km (**Table 6-10**). Scenario descriptions are given in **Table 6-6**.

As described above, the PTS and TTS thresholds are based on a cumulative metric that that reflects the dosimetric impact of noise levels over a 24 hour period based on the assumption that an animal is consistently exposed to such noise levels at a fixed position. It is not considered credible that individual LF and HF cetaceans that may pass through the PAA during the drilling program would experience PTS or TTS, given individuals would need to remain within 70 m (PTS) and <1 km (TTS) of the drilling activity for a period of 24 hours. It is also considered highly unlikely that any VHF cetaceans would experience PTS or TTS.

The behavioural response threshold may be exceeded at a maximum of 3.57 km during normal drilling operations, and at a maximum of 8.85 km at times when an additional OSV is present and operating DP.

Table 6-10: Thresholds for permanent threshold shift, temporary threshold shift and behavioural response onset thresholds for cetaceans and marine turtles based on Southall et al. (2019) and Finneran et al. (2017)

Hearing group	*Frequency-weighted SEL_{24h} threshold ($L_{E,24h}$; dB re 1 µPa²·s)*	*Scenario 1*	*Scenario 2*	*Scenario 3*	*Scenario 4*	*Scenario 5*

Scenario 4 has been omitted from **Table 6-10 because Scenario 4 differs to Scenario 3 only by the time duration, and the SPL sound footprints represent the instantaneous sound field, independent on accumulation time. A dash indicates the level was not reached within the limits of the modelled resolution (20 m).*

Source: Stroot et al (2022)

Results – Modelling of a Dynamically Positioned Mobile Offshore Drilling Unit

The analogous sound transmission loss modelling study by JASCO for a MODU on DP (Wecker et al., 2022) indicated that the PTS and TTS thresholds for low frequency (LF) cetaceans, such as humpback whale and pygmy blue whale, may be exceeded out to a maximum of 0.13 km and 2.66 km respectively across the scenarios modelled (**Table 6-11**). Scenario descriptions are given in **Table 6-7**. For HF and VHF cetaceans, the maximum distances at which sound levels dropped below PTS and TTS thresholds were 0.15 km (PTS) and 2.63 km respectively. During normal operations (MODU on DP with a support vessel on standby - Scenario 9), the maximum distance at which the TTS threshold is exceeded is 2.17 km, 0.09 km and 2.44 km for LF, HF and VHF cetaceans respectively. For PTS, the maximum distance at which the threshold is exceeded is 0.08 km, 0.02 km and 0.11 km for LF, HF and VHF cetaceans respectively.

As described above, the radii that represent potential for PTS and TTS onset are based on a 24-hour period of exposure and therefore represent an unlikely worst-case scenario since, more realistically, cetaceans would not stay in the same location or at the same range for 24 hours. It is not considered credible that individual LF, HF and VHF cetaceans that may pass through the PAA during DP vessel operations, would experience PTS, given individuals would need to remain within 150 m of the drilling activity for a period of 24 hours. TTS onset is also considered highly unlikely given the known movement behaviour of cetaceans including key migrating LF whale species such as the pygmy blue whale and humpback whale transiting through the PAA. The PAA is not known to represent significant foraging/aggregation habitat for cetaceans and individuals are not expected to dwell within the PAA for extended periods.

The behavioural response threshold may be exceeded at a maximum of 17.2 km during normal drilling operations and a maximum of 20.7 km at times when an additional support vessel is present and operating DP.

Impact Assessment

Potential behavioural disturbance to pygmy blue whales within the distribution range is limited to any overlap with the northbound (April to July) and southbound (October to January) migratory seasons. Migrating humpback whales have shown avoidance behaviours (increased movement rate and dive frequency) when exposed to underwater noise generated by a vessel (Dunlop et al., 2015), and pygmy blue whales may exhibit similar responses.

There is limited data to indicate that the PAA represents an area where opportunistic foraging by pygmy blue whales occurs. Based on an overlap of three different metrics (occupancy, number of whales in a cell and move persistence), Thums et al. (2022) identified the most important foraging areas for pygmy blue whales offshore from Western Australia but also recognised such areas are not static but dependent on the interplay of oceanographic and prey dynamics. The included areas encompassed the shelf edge from Ningaloo Reef to the Rowley Shoals, but none of the important foraging areas identified were on the shelf edge or slope offshore from where the PAA is located. Hence, it cannot be reasonably predicted that pygmy blue whale foraging is probable in the PAA. Furthermore, all of the identified important pygmy blue whale foraging areas identified by Thums et al. (2022) in offshore NW Australian waters are located beyond the maximum range (km) at which the TTS and behavioural impact thresholds for cetaceans are predicted to be exceeded based on modelling presented above.

Humpback whales occur in the region, with a migration BIA located 34 km south of the PAA. Aerial surveys of migrating humpback whales in the region showed that the majority of migrating humpbacks occur in the mid- and inner-continental shelf waters, rather than the outer part of the migration BIA (RPS Environment and Planning, 2010).

The PAA is surrounded by open water, with no restrictions (e.g., shallow waters, embayment's) to an animal's ability to avoid the activities. Behavioural responses by cetaceans (such as pygmy blue whales and humpback whales) may result in a deviation in course during migration, which is expected to be insignificant in the context of the long distances over which individuals migrate (thousands of kilometres). Cetaceans that are frequently exposed to sounds such as vessel noise may also habituate and adapt to this noise (Richardson et al., 1995; NRCC, 2003). This may be the case for the humpback whale population that regularly passes through areas of significant shipping traffic during their migrations. Furthermore, MODU activities are expected to occur over approximately 50 to 60 days.

Transponders used for positioning have the potential to cause some temporary behavioural disturbance to cetaceans; however, noise levels will be well below injury thresholds. Based on empirical spreading loss estimates measured by Warner and McCrodan (2011), received levels from USBL transponders are expected to exceed the cetacean behavioural response threshold for impulsive sources out to about 42 m. Given the short-duration chirps and the mid frequencies used by positioning equipment, the acoustic noise from a single transponder is unlikely to have any substantial effect on the behavioural patterns of marine fauna. Therefore, potential impacts from transponder noise are likely to be restricted to temporary and localised avoidance behaviour of individuals transiting through the PAA, and therefore are considered localised with no lasting effect.

Potential impacts from predicted noise levels from the MODU, project vessels and transponders are not considered to be ecologically significant at a population level.

Marine Turtles

Species Sensitivity and Thresholds

As discussed in **Section 6.6.3**, turtles have been shown to respond to low frequency sound, with indications that they have the highest hearing sensitivity in the frequency range 100 to 700 Hz (Bartol and Musick, 2003). Lenhardt (1994) observed marine turtles avoiding low-frequency sound.

Acute noise, or temporary exposure to loud noise, may result in the avoidance of important habitats and in some situations physical damage to marine turtles. McCauley et al. (2000) observed the behavioural response of caged sea turtles – green (*Chelonia mydas*) and loggerhead (*Caretta caretta*) – to an approaching seismic airgun. For received levels above 166 dB re 1 µPa, the turtles increased their swimming activity and above 175 dB re 1 µPa (SPL) they began to behave erratically, which was interpreted as an agitated state. No numerical thresholds have been developed for behavioural impacts of continuous sources (e.g., vessel noise) on marine turtles. A Popper et al. (2014) review assessed thresholds for marine turtles and found qualitative results that the risk of behavioural disturbance was high for near field exposure, moderate for intermediate exposure and low for far field exposure (Popper et al., 2014).

Sound exposure thresholds and criteria for continuous sound sources (e.g., vessel noise) and impulsive sources (e.g., transponders) applicable to marine turtles are summarised in **Table 6-4**.

Impact Assessment

Marine turtles may be present in the region, with a flatback turtle internesting BIA located 15 km south of the PAA. The Recovery Plan for Marine Turtles (Commonwealth of Australia, 2017) notes there is limited information available on the impact of noise on marine turtles and that the impact of noise on turtle stocks may vary depending on whether exposure is short (acute) or long-term (chronic). However, given the thresholds outlined in **Table 6-4,** it is reasonable to expect that marine turtles may demonstrate avoidance or attraction behaviour to the noise generated by the Petroleum Activities Program. Sound transmission loss modelling indicated that the potential for PTS and TTS onset would be limited to within tens of meters of drilling activity, and up to 140 m (TTS) during DP vessel activities (**Table 6-10** and **Table 6-11**). However, marine turtles within the PAA are expected to be transient individuals, and unlikely to remain within 140 m of the vessels for 24 hours, and therefore PTS and TTS thresholds are not expected to be reached. Behavioural impacts to marine turtles from continuous noise sources generated by the Petroleum Activities Program are expected to be short-term and localised.

Given the water depths and distance from shore, the PAA does not represent suitable foraging or internesting habitat. The PAA does not overlap BIAs or Habitat Critical and it is noted that the defined BIA and Habitat Critical are considered very conservative as they are based on the maximum range of internesting females rather than direct studies that show marine turtles are more likely to remain near their nesting beaches. For example, tracking studies at Barrow and Thevenard islands suggest the majority of internesting flatback turtles remain in shallow water, close (<3 km) to nesting beaches (Whittock et al., 2014). Studies of flatback turtle nesting in the Pilbara region also found that the average distance travelled at each of the beaches ranged between approximately 10 km and 27 km, and typically in water depths of less than 25 m (RPS, 2010; Whittock et al., 2014; Whittock et al., 2016; Waayers and Stubbs, 2016). Hence it is considered highly unlikely that the PAA is utilised by internesting flatback turtles.

Marine turtle presence in general is expected to be infrequent, and potential impacts from predicted noise levels from the project vessels (including MODU and support vessels) are expected to be short-term, intermittent and localised, if they occur and are not considered to be ecologically significant at a population level.

Fish, Sharks and Rays

Species Sensitivity and Thresholds

Fish perceive sound through the ears and the lateral line, which are sensitive to vibration. Some species of teleost or bony fish (e.g., herring) have a structure linking the gas-filled swim bladder and ear, and these species usually have increased hearing sensitivity. These species are considered to be more sensitive to anthropogenic underwater noise sources than species such as cod (*Gadus* sp.), which do not possess a structure linking the swim bladder and inner ear. Fish species that either do not have a swim bladder (e.g., elasmobranchs (sharks and rays) and scombrid fish (mackerel and tunas)) or have a much-reduced swim bladder (e.g., flat fish) tend to have a relatively low auditory sensitivity.

Considering these differences in fish physiology, Popper et al. (2014) developed sound exposure guidelines for fish; these are presented in **Table 6-12** and are considered appropriate to assess continuous acoustic discharges to fish from the Petroleum Activities Program.

Table 6-12: Impact thresholds to fish, sharks and rays for continuous noise

Receptor	*Mortality and potential mortal injury*	*PTS*	*TTS*	*Masking*	*Behaviour*
Fish: no swim bladder	(N) Low (I) Low (F) Low	(N) Low (I) Low (F) Low	(N) Moderate (I) Low (F) Low	(N) High (I) High (F) Moderate	(N) Moderate (I) Moderate (F) Low
Fish: swim bladder not involved in hearing	(N) Low (I) Low (F) Low	(N) Low (I) Low (F) Low	(N) Moderate (I) Low (F) Low	(N) High (I) High (F) Moderate	(N) Moderate (I) Moderate (F) Low
Fish: swim bladder involving hearing	(N) Low (I) Low (F) Low	170 dB rms SPL for 48-hours	158 dB rms SPL for 12-hours	(N) High (I) High (F) High	(N) High (I) Moderate (F) Low
Fish eggs and fish larvae	(N) Low (I) Low (F) Low	(N) Low (I) Low (F) Low	(N) Low (I) Low (F) Low	(N) High (I) Moderate (F) Low	(N) Moderate (I) Moderate (F) Low

Note: The sound units provided in the table above include relative risk (high, medium and low) is given for fish (all types) at three distances from the source defined in relative terms as near (N – tens of metres), intermediate (I – hundreds of metres) and far (F – thousands of metres) (after Popper et al. 2014).

Impact Assessment

Given the thresholds outlined in **Table 6-12**, it is reasonable to expect that fish, sharks and rays may demonstrate avoidance or attraction behaviour to the noise generated by the Petroleum Activities Program. However, potential impacts from predicted noise levels from the project vessels (including MODU and support vessels) are not considered to be ecologically significant at a population level.

A number of demersal and pelagic fish species will be present within the PAA which overlaps the Glomar Shoals KEF and Ancient Coastline at 125 m depth contour KEF. However, given species richness has been shown to correlate with habitat complexity (Gratwicke and Speight, 2005), it is unlikely that the sand/silt sediments that comprise the largest proportion of the PAA will support a wide diversity of species.

Maximum-over-depth horizontal distances to PTS and TTS thresholds for fish with a swim bladder involved in hearing as a result of underwater noise from a support vessel are approximately 10 m or less from the source based on modelling from JASCO for the Scarborough field (McPherson et al., 2019). For fish with a swim bladder not involved in hearing, and fish without a swim bladder (including whale sharks) the likelihood of PTS or TTS is low. Based on an intermediate spreading equation to estimate sound propagation loss from the MODU (15Log(R)), noise levels would drop below PTS and TTS thresholds for fish with a swim bladder involved in hearing within 15 m and 78 m respectively. It is expected that potential impact to demersal and pelagic fish and sharks/rays will be limited to a behavioural response. Behavioural responses are expected to be short-lived, with duration of effect less than or equal to the duration of exposure.

Whale sharks do frequent the wider NWS outside their seasonal aggregation period (peak: April and May) within the high-density prey foraging BIA at Ningaloo. The PAA overlaps a foraging BIA for whale sharks (**Section 4.6.1**); however, it is over 200 km from the Ningaloo high density prey foraging BIA and therefore likelihood of whale shark encounters is not considered high but is possible. Acoustic detections of tagged whale sharks at the North Rankin A and GWA platforms during two periods – June to July and October to January – were recorded (Thomson et al., 2021) and supported anecdotal evidence of whale shark presence on NWS. Behavioural disturbance to whale sharks as a result of vessel noise may result in a temporary deviation on their migration route. However, any deviation is considered to be insignificant in the context of the long distances over which whale sharks migrate and normal variation in their movements in the region.

Given the thresholds outlined in **Table 6-12**, it is reasonable to expect that fish, sharks and rays may demonstrate avoidance or attraction behaviour to the noise generated by the Petroleum Activities Program. However, potential impacts from predicted noise levels from the project vessels (including MODU and support vessels) are not considered to be ecologically significant at a population level.

Cultural Values and Heritage

Through consultation and review of available literature (**Section 4.9.1**), Woodside understands that marine fauna that may be affected by noise emissions, such as marine mammals and turtles, are culturally important to Traditional Custodians. Traditional Custodians value these species both tangibly as well intangibly as they can be considered a resource or linked to songlines and dreaming stories. Traditional Custodians also have connection to many marine species through kinship and totemic systems; an individual may have obligation to care for a species to which they are kin. Traditional Custodians may also have a cultural obligation to care for the environmental values of Sea Country.

For example, activities that impact turtle populations and their marine environment may have an indirect impact on some Indigenous communities if they deplete hunting areas and threaten local food security (Delisle et al., 2018:251). Whale species are subject of First Nations' increase ceremonies/rituals which are performed to enhance or maintain populations. As these thalu ceremonies are performed to maintain and increase populations of marine species, it is considered that management applies at the species/population level and not to individuals. For example, it is anticipated the thalu site on Murujuga which "brings in whales to beach" will continue to serve its purpose so long as whales continue to migrate through Mermaid Sound.

Related intangible cultural heritage may include the transmission of cultural knowledge about whales and whale behaviour, including birthing areas, whale communication and migratory patterns. Such cultural knowledge may be associated with various cultural functions and activities that support the social and economic life of a community (Fijn, 2021). Inter-generational transmission of cultural knowledge (including songlines) relating to marine reptiles may be impacted where changes results in reduced sightings (e.g., through population decline, changes to migration routes or changes to migration seasonality). This transfer of knowledge may be integral to managing a group's intangible cultural heritage (UNESCO, 2003).

As described, potential impacts to marine fauna are predicted to be at an individual level, which are not considered to be ecologically significant at a population level. Impacts are not expected to occur to ecologically significant proportions of the populations of the species, nor expected to result in a decrease of the quality of the habitat such that the extent of these species is likely to decline. As such, cultural values and intangible cultural heritage associated with these species are expected to be maintained.

Cumulative Impacts

As identified above, tie-back activities will coincide with routine operations of the Angel facility and may result in cumulative impacts from underwater noise emissions. The combined sound fields are likely to result in an increase in the maximum range to the behavioural response threshold for LF cetaceans described above (i.e., ~20 km). However, as described above, the PAA is surrounded by open water, with no restrictions (e.g., shallow waters, embayment's) to an animal's ability to avoid the activities. Consequently, if concurrent activities occur and coincide with seasonal migrations, any pygmy blue whales, humpback whales or whale sharks transiting through the area, may deviate, but can continue on their pathway. Biologically significant impacts at a population level are not anticipated. Modelling outlined above predicted PTS onset in LF cetaceans within a maximum of 150 m and TTS onset within a maximum of 2.66 km for a combination of three vessels in close proximity. Therefore, PTS and TTS impacts to pygmy blue whales are not expected given to the distance from the migratory BIA (37 km).

Any cumulative impacts will be limited to the duration of tie-back activities (~12 weeks) and would be discontinuous over this time.

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)[47]***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Legislation, Codes and Standards				
EPBC Regulations 2000 – Part 8 Division 8.1 Interacting with cetaceans, including the following measures[48]: • Project vessels will not travel greater than 6 knots within 300 m of a cetacean or turtle (caution zone) and not approach closer than 100 m from a whale. • Project vessels will not approach closer than 50 m for a dolphin or turtle and/or 100 m for a whale (with the exception of animals bow riding). • If the cetacean or turtle shows signs of being disturbed, project vessels will immediately withdraw from the caution zone at a constant speed of less than 6 knots. • Vessels will not travel greater than 8 knots within 250 m of a whale shark and not allow the vessel to approach closer than 30 m of a whale shark.	F: Yes. CS: Minimal cost. Standard practice.	Implementation of controls for reduced vessel speed around cetaceans can potentially reduce the underwater noise footprint of a vessel and lower the likelihood of interaction above significant thresholds.	Controls based on legislative requirements – must be adopted.	Yes **C 4.1**
Good Practice				
The use of dedicated marine fauna observers (MFOs) on support vessels for the duration of the Petroleum Activities Program to watch for whales and provide direction on and monitor compliance with Part 8 of the EPBC Regulations.	F: Yes. However, support vessel bridge crews already maintain a constant watch during operations. CS: Additional cost of MFOs.	Given that support vessel bridge crews already maintain a constant watch during operations, additional MFOs would not further reduce the likelihood of an individual being within close proximity of the acoustic source during start-up or during operations.	Disproportionate. The cost/sacrifice outweighs the benefit gained.	No

47 Qualitative measure

48 For safety reasons, the distance requirements below are not applied for a vessel holding station or with limited manoeuvrability e.g. anchor handling, loading, back-loading, bunkering, close standby cover for overside working and emergency situations.

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)[47]***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Develop SIMOPS Management Plan where multiple campaigns occur concurrently within the PAA.	F: Yes. CS: Minimal cost. Standard practice.	SIMOPS management plans between Woodside operated vessels in the PAA will assist in the management of cumulative noise sources.	Benefits outweigh cost/sacrifice.	Yes **C 4.2**
Professional Judgement – Eliminate				
Remove support vessel on standby at the Petroleum Activities Program location.	F: No. Activity support vessel required as per MODU Safety Case, particularly for maintaining the 500 m petroleum safety zone around the MODU/ installation vessel. CS: Introduces unacceptable safety risk.	Not considered – control not feasible.	Not considered – control not feasible.	No
Eliminate generation of noise from the MODU, installation vessel, support vessels or positioning equipment.	F: No. The generation of noise from these sources cannot be eliminated due to operating requirements. Note that vessels operating on DP may be a safety critical requirement. CS: Inability to conduct the Petroleum Activities Program. Loss of project.	Not considered – control not feasible.	Not considered – control not feasible.	No
Professional Judgement – Substitute				
Management of vessel noise by varying the timing of the Petroleum Activities Program to avoid migration periods.	F: Yes. Migration periods for cetaceans that may occur in the PAA (pygmy blue and humpback whales) are well known. CS: Significant cost and schedule impacts if activities avoid specific timeframes.	Avoiding migration periods would reduce the likelihood of impacts to cetaceans. However, given that the predicted impacts from noise sources associated with the Petroleum Activities Program are considered to be localised with no lasting effect, the overall benefit is minimal.	Disproportionate. The cost/ sacrifice outweighs the benefit gained.	No

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)[47]***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Professional Judgement – Engineered Solution				
Passive Acoustic Monitoring (PAM).	F: No. PAM has limited ability to detect calls from baleen whales such as the pygmy blue whale, particularly with added background noise from drilling/ installation vessel activities and known reliability and practicality limitations of the technology. CS: Costs associated with PAM technology acquisition and implementation.	Not considered – control not feasible.	Not considered – control not feasible.	No
Use of thermal imaging equipment at night or periods of low visibility to identify cetacean presence.	F: Yes. Feasible to install on support vessel. CS: Costs associated with infrared technology acquisition and implementation.	Can increase likelihood of identifying cetacean presence; however, limitations on detection distance/depth, interpretation of data (identification of cetacean type for example) and practicality.	Cost/sacrifice outweighs benefit. Lack of proven application in detection of cetaceans in deep water environment and limitations of the technology reduce potential benefit gained when compared with low likelihood of expected cetacean activity and low likelihood of MODU/ installation vessel movement at night.	No

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)[47]***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Use of autonomous underwater vehicle (AUV) to monitor for presence of pygmy blue whales using detection of their vocalisations.	F: Yes. Could be deployed from support vessel. CS: Costs associated with obtaining and operating the technology. Schedule delays while data is collected and interpreted (not real-time monitoring).	Limited benefit as the technology relies on pygmy blue whale vocalisation, which is currently not well understood, particularly during foraging activities. Technology and applications still under development and not widely tested in field. Application limited due to lack of real time capability.	Cost/sacrifice outweighs benefit. Due to distance of PAA from PBW migration and foraging BIAs, presence of PBWs carrying out opportunistic foraging activities in the area is expected to be low. Adequate observations are able to be made from the MODU Bridge due to height and surveillance by a trained crew. It is not expected that an AUV would add significantly more value than this, to warrant deployment.	No
ALARP Statement: On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts and risks of noise emissions from tie-back activities. As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.				
Demonstration of Acceptability				
Acceptability Statement The impact assessment has determined that the generation of noise from project vessels, MODU, and positioning equipment during tie-back activities is unlikely to result in an impact significance level greater than slight. Relevant recovery plans and conservation advice have been considered during the impact assessment, and the Petroleum Activities Program is not considered to be inconsistent with the overall recovery objectives and actions of these recovery plans and conservation advice (**Section 6.9**). In particular, the Conservation Management Plan for the Blue Whale (Commonwealth of Australia, 2015a) and associated guidance on key terms requires that pygmy blue whales not be displaced from a foraging area. The nearest recognised foraging BIA is off the Ningaloo Coast, approximately 336 km south-west of the PAA at the closest point. The sound transmission loss modelling studies by JASCO (Stroot et al., 2022; Wecker et al., 2022) predicted that behavioural responses (a conservative surrogate for displacement) could occur up to 8.85 km from the noise source during moored drilling activities (**Table 6-10**) or up to 20.7 km from the noise source during DP vessel activities (**Table 6-11**; less than one tenth of the distance to the foraging BIA). Hence, displacement of pygmy blue whales from this foraging BIA as a result of the Petroleum Activities Program will not occur. The potential impacts are considered broadly acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the impacts of acoustic emissions to a level that is broadly acceptable.

Description of Source of Impact

Operations

Hydrocarbons and chemicals may be discharged as a result of planned routine and non-routine operations and activities for:

Operational discharges including:

- discharge of subsea control fluids – subsea control fluid is used to control valves remotely from the facility. It is an open-loop system, designed to release control fluid from the control system during valve operations (e.g., up to about 6 L per valve actuation)
- potential non-routine hydraulic fluid discharge associated with umbilical system losses/weeps.
- discharge of minor fugitive hydrocarbon from wells and subsea equipment (e.g., weeps/seeps/bubbles)
- discharge of chemicals introduced into subsea infrastructure and the production stream, either as process or non-process chemicals (e.g., corrosion inhibitors, biocides, scale inhibitors); chemicals flow through the production process, with residual hydrophilic chemicals discharged as a component of PW discharged overboard.

IMMR activities (nominal discharges described in **Section 3.4.15.6**) including:

- discharge of residual hydrocarbons in subsea lines and equipment and small gas releases associated with isolation testing and breaking containment.
- discharge of residual chemicals in subsea lines and equipment, or the use of chemicals, intermittently and in small volumes; small quantities of chemicals may remain in the flushed infrastructure, which may be released to the environment after disconnection.
- discharge of hydrocarbons associated with pigging activities required as shown in **Table 3-10**
- discharge of approximately 100 to 150 L of preservation fluids from flowlines following flushing when the flowlines are cut and plugs installed in either end of the cut section; **Section 3.4.15.8**.

Tie-back Activities

The activities that may result in the discharges of small quantities of flowline and subsea installation preservation and pre-commissioning fluids are:

- discharges during barrier testing
- discharges during disconnection of caps from installed structures (manifold, Xmas tree, UTA, SDU)
- discharges from flexible jumper, and flying leads during tie-in and reconfiguration activities
- discharges from installation vessel's pre-commissioning equipment or subsea infrastructure during leak testing activities
- discharges post leak test, during depressurisation to marine environment.

In addition, there is potential for discharge of minor fugitive hydrocarbons from the suspended LDA-02 well prior to Xmas tree installation (e.g., weeps/seeps/bubbles).

Flexible Jumper Fluids

The flexible jumper and subsea distribution unit will be installed filled with a chemically treated mixture of up to 55 wt% MEG/water. The MEG concentration must be fibre-grade (99.9 wt%) before mixing with water. The flexible jumper will not require further flooding post-installation, but pressure test top-up fluid may be required in the event of test failure.

Installation and tie-in of the flexible jumper to the manifold and Xmas tree may result in small quantities of fluids within the jumper being released to the environment. These volumes are expected to be small (1 m^3 per tie in point) as the pressure within the jumper is equal to the hydrostatic pressure and the jumper is uncapped for a short duration during tie-in. Water jetting and/or acid injection (~400 L acid) may be used to clean the connections on the infrastructure prior to tie-in.

A leak test/system pressure test will be performed to test the integrity of the subsea connections, flowline and jumpers, which may result in ~ 1 to 2 m^3 of MEG/treated potable water and ~0.6 to 1.2 L of treatment chemicals (including corrosion inhibitor, biocide, oxygen scavengers and dye) being released to the environment at the locality of the subsea infrastructure. A contingency secondary leak test may also be required, with similar discharge volumes.

Xmas Tree

The Xmas tree will be installed with a preservation mixture in the production and annulus bore. There will be a small discharge of preservation fluid associated with testing after connection to the tubing head spool (estimated 100 to 150 L).

Hydrocarbons

Testing of manifold isolations may be undertaken to verify that suitable isolations are available for safe tie-in to the subsea distribution unit and flexible jumper. The testing and tie-in may release gas and condensate (up to 400 L) over a 48-hour period. This testing is required to verify that suitable isolations are available for safe tie-in and cannot reasonably be eliminated. The estimated mass of hydrocarbons is considered to be a worst-case, with the actual release volume expected to be smaller.

Well Unload

During well unloading activities, all completion and reservoir fluids will be directed to the Angel facility and be handled by the systems onboard the platform, in accordance with **Sections 3.4.7** and **3.4.9**. All non-hydrocarbon fluids will be discharged overboard with the produced water.

Should well unloading fluids not be directed to the Angel facility, they may be flared or discharged to the environment via the well test package onboard the MODU. The base oil column, completion fluid, hydrocarbons and produced/condensed water will be measured, handled, separated, treated for overboard discharge (non-hydrocarbon) and flared/burned (hydrocarbon) through the temporary production system on the MODU.

Well Intervention

During intervention activities, including post Xmas tree installation testing and TIV valve operations, local control of the Xmas tree may be required. Valve actuation of the trees may be required, which will result in small releases of subsea control fluids to be released to the environment.

All subsea chemicals will be selected, assessed and approved in accordance with a defined framework and set of tools to ensure the potential impacts are acceptable, ALARP and meet Woodside's expectation for environmental performance, outlined in **Section 7.2.1**. This procedure is used to demonstrate that the potential impacts of the chemicals selected are acceptable and ALARP (subject to technical and economic constraints).

Impact Assessment

There is potential for localised water column pollution and adverse effects on marine biota as a result of planned routine and non-routine hydrocarbon and chemical discharges during operations and tie-back activities. However, planned discharges of hydrocarbons and chemicals are minor and are minimised as far as practicable via flushing of the lines during IMMR activities. Discharge locations during routine operations are either the PW stream, subsea valves (subsea control fluid), at dis/connection points in subsea infrastructure, including during installation of pig receivers or launchers, or via the AEP to onshore process. During tie-back activities, discharges may also occur at connection points and during leak testing.

Water Quality

During operations, subsea control fluids are discharged at relatively small volumes during valve actuations (typically <6 L) and IMMR activities at or near the seabed. On release the subsea control fluids are expected to mix rapidly and dilute in the water column. Pigging activities are infrequent and result in relatively small releases of hydrocarbon (indicative discharge volumes associated with pigging the AEP are provided for in **Table 3-14**).

During tie-back activities, leak testing and tie in of new infrastructure may result in small amounts of MEG and hydrotest fluids as described above. Contingency activities, such as well intervention may result in minor discharges of subsea control fluids from the Xmas tree, similar to valve actuation releases discussed above. On release, impacts of MEG and hydrotest fluids will be localised to the immediate vicinity of the release location with short-lasting impacts. This is based on the low potential for toxicity and bioaccumulation of MEG, small volumes/rates of discharge and rapid dilution in the marine environment.

Gas and condensate may be released during IMMR activities that break containment of isolated subsea infrastructure or during verification testing of the subsea distribution unit. Hydrocarbons will become dispersed as bubbles in the water column, which will rise to the surface. Methane is the principal component of the gas and is relatively insoluble in water. As such, methane is expected to rise until it reaches the sea surface, where it will be readily dispersed in the atmosphere. The concentration of methane will not be sufficient to form an explosive atmosphere or result in asphyxiation. Water-soluble components of the gas, such as carbon dioxide and sulphur dioxide will dissolve in the seawater as the gas bubbles rise in the water column. These soluble gasses occur naturally and are present in relatively low amounts. No measurable impacts to water quality are expected to occur as a result of the gas release.

The insoluble condensate release during verification testing will be buoyant and rise in the water column. The condensate will be released with gas which will act to disperse the condensate within the water column as it rises to the sea surface. The resulting condensate droplets will rise slowly in the water column and may be transported away from the release location by currents. Upon reaching the sea surface, the condensate will almost entirely evaporate, with a relatively small portion remaining entrained in the water column. Condensate droplets are not expected to reach the surface in sufficient quantities to result in surface slicks above thicknesses that result in biological impacts, although a sheen may be visible. Any condensate reaching the surface will spread and weather rapidly, as described in **Section 6.7.2**. Soluble hydrocarbons will be distributed in the water column through natural water movement and the buoyancy of the condensate droplets and are expected to drop below concentrations recognised as causing biological impacts within tens to hundreds of metres of the release location.

There is potential for slight, localised decrease in water quality at planned discharge locations and potential impacts on marine biota. Impacts to pelagic fish are expected to be limited to avoidance of the localised area of the discharge and short-term, localised decline in planktonic organisms in the immediate vicinity of the discharge.

Ecosystems

Sediments in the PAA are expected to be broadly consistent with those in the NWS Province (as described in **Section 4.5**), with filter feeders such as sponges, ascidians, soft corals and gorgonians associated with areas of hard substrate. The only areas of hard substrate expected in the vicinity are artificial habitat associated with subsea infrastructure. Subsea control fluids and installation fluids are non-toxic and do not have the potential to bioaccumulate.

Receptors that may be impacted by a condensate release during verification testing are in-water receptors within the vicinity of the release location.

These receptors include plankton, pelagic fishes and potentially cetaceans. A detailed assessment of the impacts to these receptors is provided in **Section 6.7** and **Section 6.8.1**. Impacts include:

- acute toxic effects to planktonic organisms near the release location from soluble hydrocarbons
- temporary displacement of pelagic fishes.

Only a very small portion of the planktonic community at a bioregional scale would credibly be impacted. Planktonic communities have high turnover rates, and recovery from any impacts would occur rapidly. Given the small volume of soluble hydrocarbons, the planktonic community in the upper part of the water column will not be impacted.

Large-scale oil spills in open water typically do not result in fish kills, and it is assumed that fishes in open water will actively avoid harmful concentrations of hydrocarbons. Given the relatively small volume of hydrocarbons released and the resulting localised impact, it is unlikely that displacement of pelagic fishes will occur.

Given the nature and scale of planned discharges, potential impacts are considered to be slight and short term (expected to recover once routine discharges cease).

KEFs

Two KEFs overlap the PAA; the Ancient Coastline at 125 m Depth Contour and Glomar Shoals KEF. Glomar Shoals itself is more than 10 km from the PAA; therefore, planned routine and non-routine subsea releases will not impact on the KEF. No significant escarpments, species of conservation significance, emergent features or areas of high biological productivity characteristically associated with the Ancient Coastline at 125 m KEF have been observed in the PAA. Therefore, potential impacts to these regional-scale KEFs are not expected.

Cumulative Impacts

Given that only localised, short term and negligible impacts are predicted to water quality and marine biota, cumulative impacts affecting marine biota from the discharge of subsea installation fluids including MEG and hydrocarbons are considered unlikely.

Demonstration of ALARP

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Good Practice				
Implement Woodside's Chemical Selection and Assessment Environment Guideline: • Where Gold/Silver/E/D OCNS rating (and no OCNS substitution or product warning), chemicals are selected – no further control required. • If chemicals with a different OCNS rating, sub warning or non-OCNS rated chemicals are required chemicals will be assessed in accordance with the guideline prior to use.	F: Yes. Routinely implemented to the chemical selection process for Woodside facilities. CS: Minimal cost. Standard practice.	Selection and assessment of chemicals in accordance with the Woodside process, reduces environmental impacts associated with planned chemical discharge.	Control is a WMS requirement – must be adopted.	Yes **C 5.1**
Subsea infrastructure flushed where practicable prior to disconnection to reduce volume/ concentration of hydrocarbons released to the environment.	F: Yes. Subsea infrastructure has been designed such that much of the hydrocarbon containing elements can be flushed back to the riser platform. CS: Minor. Flushing may prolong the cessation of production required for subsea IMMR activities, leading to reduced production.	Flushing reduces the volumes/ concentration of hydrocarbons released to the environment.	Benefit outweighs cost/sacrifice.	Yes **C 5.2**
Monitoring subsea control fluid use, investigate material discrepancies, and using control fluid with dye marker to support identification of potential integrity failures.	F: Yes. The use of control fluid is monitored to maintain adequate fluid in the system. CS: Minimal cost.	Limits the volumes of subsea control fluid discharged to the marine environment.	Benefit outweighs cost/sacrifice.	Yes **C 5.3**

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Implement Woodside *Engineering Operating Standard - Subsea Isolation*). Proven isolation in place for relevant IMMR activities.	F: Yes CS: Minimal cost. Standard practice.	Maintaining and testing the ability to isolate wells and pipelines will ensure barriers are in place and verified limiting the volume of hydrocarbon released.	Control is a WMS requirement – must be adopted.	Yes **C 5.4**
Chemical reviews will be performed on all previously approved chemicals to confirm potential chemical impacts are reduced to ALARP.	F: Yes. CS: Minimal cost. Standard practice.	Reviews will ensure chemicals selected remain ALARP.	Benefits outweigh cost/sacrifice.	Yes **C 5.5**
ROV inspection during leak test.	F: Yes. CS: Minimal cost. Standard practice.	A procedure for leak testing work that includes inspection (including by ROV) during testing to identify leakage and trigger activity to stop will reduce likelihood of impacts.	Benefits outweigh cost/sacrifice.	Yes **C 5.6**
Test subsea manifold isolation valves prior to flexible jumper tie-in.	F: Yes. CS: Minimal cost. Standard practice.	Testing of the isolation valves will provide a valve pass rate to be used to assess isolation requirements and determine the isolations required to confirm to the relevant internal Woodside standards.	Benefits outweigh cost/sacrifice.	Yes **C 5.7**
Pre-commissioning and flexible jumper subsea installation procedures developed.	F: Yes. CS: Minimal cost. Standard practice.	A procedure for pre-commissioning and subsea installation will reduce likelihood of impacts.	Benefits outweigh cost/sacrifice.	Yes **C 5.8**
Flexible jumper installation procedure (DP alarm system, tensioner alarms, touch down position monitoring).	F: Yes. CS: Minimal cost. Standard practice.	A procedure for subsea installation will reduce likelihood of impacts.	Benefits outweigh cost/sacrifice.	Yes **C 5.9**
Subsea isolations conform to the relevant internal Woodside standards which include: • using a double block isolation. If it is not practicable to establish a double block isolation, then: • one effective, proven and monitored barrier (single block isolation) shall be in	F: Yes. CS: Minimal cost. Standard practice.	Pass rate (≤0.05 kg/s) across valve with proven single block isolation. Conditions for single block isolation reduce the likelihood and consequence of an uncontrolled release.	If valve testing confirms proven barrier (≤0.05 kg/s pass rate), slight environmental impact associated with hydrocarbon release is disproportionate to requirement to shut in the well to achieve double isolation. Benefit for additional conditions for single isolation outweighs	Yes **C 5.10**

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
place, with the following conditions: – It must be possible to isolate the reservoir by remote operation of tree isolation valves. – The residual risks must be shown to be ALARP by a documented isolation risk assessment. – Procedures and response plans for the activity must be developed and implemented and address all applicable hazards appropriately, including provision for closing tree isolation valves.			cost. Benefit outweighs cost.	
Professional Judgement – Eliminate				
Reduce volume or not use preservation and pre-commissioning chemicals including MEG.	F: No. Preservation and pre-commissioning fluids are required to verify the structural integrity of the subsea infrastructure and avoidance of hydrate formation. The volumes selected are required to achieve verification. CS: Potential loss of production due to loss of integrity, possibly leading to a larger environmental incident.	Not considered – control not feasible.	Disproportionate. The cost/sacrifice outweighs the benefit gained.	No

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Do not conduct leak testing activities.	F: No. Leak testing activities are required to control the potential for corrosion of the flexible jumper and to determine if any unacceptable restrictions and/or obstructions exist in the line. CS: Potential loss of production due to loss of integrity, possibly leading to a larger environmental incident.	This would eliminate any potential impacts from the leak testing activities but increases the likelihood of loss of integrity during operation and potentially greater environmental impacts.	Disproportionate. The cost/sacrifice outweighs the benefit gained.	No
Professional Judgement – Substitute				
Installing closed-loop subsea valve control system.	F: Yes. Closed-loop subsea valve control systems can be installed; however, they may not perform as quickly/reliably as open-loop systems. CS: Significant. The design, procurement and retrofitting of a closed-loop valve control system would result in considerable offshore logistics, exposure to safety hazards during installation, and significant financial burden through direct costs and lost production.	The potential consequence of the discharges is ranked as incidental, based on the volume, frequency, location, and types of fluid discharged in an open-ocean environment, and avoiding the discharges would provide little or no environmental benefit.	When considering the negligible effect from the release of control fluids, the risk and costs of retrofitting a closed-loop subsea valve control system is considered to be grossly disproportionate to the environmental benefit.	No
Professional Judgement – Engineered Solution				
Poppetted hydraulic lines in control connections (to minimise release of control/preservation fluids).	F: Yes. CS: Minimal cost. Standard practice.	Poppetted connections minimise discharge to marine environment in pressurised hydraulic lines.	Benefits outweigh cost/sacrifice.	Yes **C 5.11**
Chemical control lines fitted with isolation valves within UTA (to minimise release of chemicals).	F: Yes. CS: Minimal cost. Standard practice.	Isolated valve connections minimise discharge to the marine environment in chemical control lines.	Benefits outweigh cost/sacrifice.	Yes **C 5.12**

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Angel subsea infrastructure flushed/pigged during isolation activities to reduce volume/ concentration of hydrocarbons released to the environment during decommissioning.	F: Yes. Subsea infrastructure has been designed such that much of the hydrocarbon containing elements can be flushed. CS: Minor. Flushing may prolong the cessation of production required for subsea IMMR activities, leading to reduced production.	Flushing reduces the volumes/concentration of hydrocarbons released to the environment.	Benefit outweighs cost/sacrifice.	Yes **C 5.13**
Subsea isolations conform to the relevant internal Woodside standards which include: • well isolations in place are tested and proved following pigging/flushing activities.	F: Yes. CS: Minimal cost. Standard practice.	Tested and proven well isolation barriers in place reduces the likelihood of hydrocarbon migration from the wells in the environment during preservation period, prior to permanent plug and abandonment.	Benefit outweighs cost/sacrifice.	Yes **C 5.14**
Routing hydrocarbons to vessel during disconnection of subsea infrastructure.	F: Yes. However, to do so would introduce significant safety risks to the vessel crew (fire, explosion, asphyxiation). CS: Significant. Equipping and training crew on-board subsea support vessels to safely route hydrocarbons to the vessel would result in significant additional costs (in addition to the increased safety risk identified above).	Small environmental benefit from preventing low concentration hydrocarbon discharge.	Given the increased safety risk and the very low environmental impact from hydrocarbon releases during subsea IMMR activities, the cost of routing hydrocarbons to the vessel is grossly disproportionate to the environmental benefit.	No

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Decreasing the frequency of valve actuation.	F: Yes. However, decreasing the frequency of valve actuation may adversely impact the safe functionality and reliability of valves. Reducing the performance of subsea valves may introduce operability impacts, and increased safety and environmental risk associated with loss of containment events. CS: Minimal cost.	The potential consequence of the discharges is ranked as incidental, based on the volume, frequency, location and types of fluid discharged in an open-ocean environment, and reducing the number of discharges would provide little or no environmental benefit.	Decreasing the frequency of valve actuations would lead to a potential decrease in safe functionality and reliability of valves. When considering the potential safety and environmental risks from such a performance degradation, along with the minor impact from the release of control fluids, the cost of decreasing the frequency of valve actuations is considered to be grossly disproportionate to the environmental benefit.	No
ALARP Statement: On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts of planned routine and non-routine hydrocarbon and chemical discharges. As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.				
Demonstration of Acceptability				
Acceptability Statement: The impact assessment has determined that, given the adopted controls, planned routine and non-routine hydrocarbon and chemical discharge represents a localised short-term impact that is unlikely to result in a potential impact greater than slight short-term effects on water quality, marine sediment or ecosystem habitat. Further opportunities to reduce the impacts have been investigated above. Fluid discharges from the subsea system during operations, IMMR activities, flexible jumper commissioning and well intervention are routine in the oil and gas industry. The adopted controls are considered good oil-field practice/industry best practice. The potential impacts are considered broadly acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the impacts of planned routine and non-routine hydrocarbon and chemical discharges to a level that is broadly acceptable.

Discharge of sewage, grey water and putrescible waste from the facility, MODU and project vessels to the marine environment			✓					A	F	-	-	LCS GP PJ	Broadly acceptable	**EPO 6**
Discharge of deck, bilge and drain water from the facility, MODU and project vessels to the marine environment			✓					A	F	-	-			
Discharge brine and cooling water from MODU and project vessels to the marine environment			✓					A	F	-	-			

Description of Source of Impact

Sewage, Putrescible Waste and Grey Water

No sewage is discharged from the facility when it is uncrewed. When staffed, sewage from the ablutions is macerated then disposed to the marine environment via the sewage caisson (3 m below LAT). Putrescible waste (principally food scraps) is either ground to less than 25 mm diameter and disposed overboard as per above or bagged and transported to shore for disposal as domestic waste.

The volume of sewage and grey water generated is estimated to be in the order of 1.8 m^3 per day (based on an average volume of 75 L/person/day), from the facility when staffed. The actual volume of discharge varies depending on personnel requirements on the facility. Refer to Section **3.4.5.1** for POB estimates under different activities.

Treatment systems on the facility may require routine maintenance or repair during operations, requiring infrequent short periods in which sewage is directly discharged overboard.

Vessels may also discharge sewage, grey water and putrescible wastes within the Operational Area, but outside of the facility PSZ. Sewage on-board operational vessels is routinely treated (either sewage treatment plant or macerator) prior to discharge.

The MODU and project vessels routinely generate/discharge small volumes of treated sewage, putrescible wastes and grey water to the marine environment (impact assessment based on approximate discharge of 15 m^3 per vessel/MODU per day), using an average volume of 75 L/person/day and a maximum of 200 persons on board. However, it is noted that vessels such as the AHV and support vessels will have considerably less persons on board. Discharge of waste may occur within the PAA, but outside of the facility PSZ.

During tie-back activities the facility will be manned during the commissioning phase, in addition to the presence of the MODU, installation vessels and other support vessels, resulting in cumulative volumes of sewerage, putrescible waste and grey water. The expected duration of cumulative discharges is approximately four weeks (**Section 3.3.1**).

Drain and Bilge Water

Angel's hazardous open drains system collects wash water and waste liquids from major process and utility equipment and diesel/chemical storage areas, including plated area deck drains, drain tundishes and equipment drip trays in hazardous areas. Drainage into the hazardous open drains system discharges into a horizontal three-phase separator (gas/liquid/liquid). Recovered oil and/or glycol from the open drains' separator is skimmed and transferred to the transportable waste oil storage tank for onshore disposal. The separated water is discharged directly overboard at +22 m LAT from the water disposal compartment of the open drains' separator.

The non-hazardous open drains system is 'open' to the atmosphere and collects, contains and disposes rain, wash water and waste liquids from non-hazardous areas of the decks and from the helideck. The drainage from this system is routed directly overboard. The HVAC condensed water drains also tie into the service water tank overflow in the non-hazardous area of the facility.

The non-hazardous areas do not include any hydrocarbon containing equipment or process vessels, accordingly there is little potential for hydrocarbon or chemical spills in the non-hazardous area. The non-hazardous open drains are segregated from the hazardous open drains to prevent migration of hydrocarbons from hazardous areas to non-hazardous areas.

MODU and project vessels routinely generate and discharge relatively small volumes of bilge water. Bilge tanks receive fluids from many parts of the vessel, including machinery spaces. Bilge water can contain water, oil, detergents, solvents, chemicals, particles and other liquids, solids or chemicals. MODU and project vessels may also discharge drainage water from decks directly overboard or via deck drainage systems; deck drainage may also contain traces of chemicals. Water sources could include rainfall events and/or from deck activities such as cleaning/wash-down of equipment/decks.

Cooling Water and Brine

No brine water is produced on the facility as potable water is supplied from onshore. Additionally, no seawater cooling is undertaken on the facility.

Potable water, primarily for accommodation and associated domestic areas, may be generated on MODU and project vessels during drilling and tie-back activities using a reverse osmosis (RO) plant. This process will produce brine, which is diluted and discharged at the sea surface.

During the distillation process, relatively small volumes of reject brine is produced and discharged. Reject brine discharge is typically 20 to 50% higher in salinity than the intake seawater (depending on the desalination process used) and may contain low concentrations of scale inhibitors and biocides, which are used to avoid fouling of pipework (Woodside, 2014).

Models developed by the US EPA (Frick et al., 2001) for temporary brine discharges from vessels assuming no ocean current (i.e., 0 m/s) found that brine discharges from the surface dilute 40–fold at 4 m from the source. This modelling can be used as an indicator for predicting horizontal attenuation and diffusion of reject brine; and suggests that the salinity concentration drops below environmental impact thresholds within 4 m of the discharge point.

Seawater is pumped on board and used as a heat exchange medium for the cooling of machinery engines and high temperature drilling fluid on the MODU. Seawater is drawn up from the ocean, where it is subsequently deoxygenated and sterilised by electrolysis (by release of chlorine from the salt solution) and then circulated as coolant for various equipment through the heat exchangers (in the process transferring heat from the machinery), prior to discharge to the ocean. It is subsequently discharged from the MODU to the sea surface at potentially a higher temperature. Cooling water is often treated with additives including scale inhibitors and biocide to avoid fouling of pipework. Scale inhibitors and biocide are usually used at low dosages, and are usually consumed in the inhibition process, so there is little or no residual chemical concentration remaining upon discharge. In addition, the scale inhibitors and brine are selected and assessed using the Woodside chemical selection process.

Alternatively, MODUs may utilise closed-loop cooling systems. In these systems, fresh water is used in a closed circuit to cool down the engine room machinery, and then further cooled by sea water in a seawater cooler. Seawater used for cooling purposes would be routinely discharged at a temperature expected to be less than 70°C and rates ~50 m³/d.

Impact Assessment

Sewage, Putrescible Waste and Grey Water

The environmental impact associated with ocean disposal of sewage, grey water and putrescible waste is eutrophication. Eutrophication occurs when the addition of nutrients, such as nitrates and phosphates, causes adverse changes to the ecosystem, such as oxygen depletion and phytoplankton blooms. Other contaminants of concern occurring in these discharges may include ammonia, E. coli, faecal coliform, volatile and semi-volatile organic compounds, phenol, hydrogen sulphide, metals, surfactants and phthalates.

No significant impacts from planned (routine and non-routine) discharges to the marine environment are anticipated, given the minor volumes involved, the localised mixing zone (as indicated by dilution modelling at the facility and high level of dilution into the open water marine environment of the PAA. This is supported by historical water quality and sewage discharge monitoring undertaken by Woodside around the nearby GWA platform. The GWA platform is approximately 22 km west of the PAA, therefore conditions are comparable. Water quality monitoring around the GWA platform (which is a staffed platform) indicates there was no detectable decrease in oxygen saturation, nutrients or

increase in oxygen demand at the GWA platform (BMT Oceanica, 2015a). In addition, monitoring of sewage discharges demonstrated that a 10 m^3 sewage discharge reduces to approximately 1% of its original concentration within 50 m of the discharge location (Woodside, 2008).

The tie-back is expected to take up to 12 weeks including mobilisation, demobilisation and contingency with subsea installation and pre-commissioning. MODU and project vessel routine discharges are expected to be intermittent in nature for the duration of the tie-back activity. Therefore, impacts to water quality within the PAA are expected to be localised with no lasting effect due to the small mass, relative to daily turnover, the assimilative capacity of the receiving environment, intermittent nature of discharges, and the variable discharge location due to project vessel movement.

Although the NWS Province is characterised as a low nutrient environment (DEWHA, 2008), studies of adjacent shelf water have found the area to be "a highly productive ecosystem in which nutrients and organic matter are rapidly recycled" (Furnas and Mitchell, 1999). The estimated daily loading from sewage and putrescible waste (Facility ~ 1.8 m^3 per day; MODU/project vessels ~ 15 m^3 per day) is not significant in comparison to the daily turnover of nutrients in the area. Furthermore, project vessels are typically moving when in the PAA, which facilitates mixing of sewage, putrescible wastes and grey water when discharged.

The impact of nutrients associated with discharge of sewage, grey-water and putrescible waste is considered to have a localised impact with no lasting effect due to the small mass, relative to daily turnover, and the assimilative capacity of the receiving environment.

Drain and Bilge Water

Drain water from the facility and bilge and deck drainage water from the MODU and project vessels is expected to mix rapidly in the marine environment upon discharge. Deck drainage and treated bilge may contain a range of chemicals, oil, grease and solid material. This particulate matter can cause an increase in the turbidity of the receiving waters close to the point of discharge. The addition of these substances into the marine environment will result in a change ambient water quality; however, these discharges will disperse and dilute rapidly, with concentrations significantly dropping with distance from the discharge point. The PAA is located more than 12 nm from land exceeding the exclusion zones required by Marine Order 96 (Marine pollution prevention – sewage) 2018 and Marine Order 95 (Marine pollution prevention – garbage) 2013.

No significant impacts from the planned routine discharges are anticipated, because of the minor quantities involved, the expected localised mixing zone and high level of dilution into the open water marine environment of the PAA. Based on the detailed evaluation and low levels of potential contaminants, the magnitude of potential impact of a change in water quality is considered highly localised with no lasting effects.

Cooling Water and Brine

The key physicochemical stressors that are associated with reject brine and cooling water discharge from MODU and project vessels include salinity, pH, temperature and chemical toxicity.

The potential impacts on water quality due to cooling water discharge include chlorine toxicity and increased water temperatures. Woodside undertook modelling of continuous wastewater discharges (including cooling water) for its Torosa South-1 drilling program in the Scott Reef complex (Woodside, 2014). This study predicted that discharge water temperature decreases quickly as it mixes with the receiving waters, with the discharge water temperature being <1 °C above ambient within 100 m (horizontally) of the discharge point, and 10 m vertically (Woodside, 2014). As such, any potential impacts to water quality are expected to occur within approximately 100 m of the source of the discharge, where concentrations are highest.

Reject brine will sink through the water column, owing to the 20% to 50% increase in salinity (Frick et al., 2001), where it will be rapidly mixed with receiving waters and dispersed by ocean currents, decreasing in salinity rapidly as distance from source increases.

The scale inhibitors used in the prevention of fouling within cooling systems are typically low in molecular weight and phosphorous compounds that are water-soluble, and only have acute toxicity to marine organisms approximately two orders of magnitude higher than typically used in the water phase (Black et al., 1994). The biocides typically used in the industry are highly reactive and degrade rapidly (Black et al., 1994).

Based on the detailed risk evaluation, the magnitude of the potential impact of a change in water quality from routine and non-routine brine and cooling water discharges is assessed as having no lasting effect on the receiving environment.

Cumulative Impacts

Given the activities that may be conducted during the Petroleum Activities Program, there is the potential for cumulative impacts from routine discharges of sewage, putrescible waste, grey water, bilge water or drain water, due to staffing of the facility and the presence of the MODU, installation vessels and other activity support vessels during tie-back activities. Given the minor quantities involved, the expected localised mixing zone and the rapid dilution in the open water environment, the potential for cumulative impacts to water quality would be restricted to within approximately 100 m of the discharge location. Hence, cumulative impacts are expected to be slight and short term (i.e., Environment Impact – E).

No cumulative impacts from similar discharges from support vessels and other production facilities in the vicinity (e.g., NRC) are expected given the distance from the PAA.

Legislation, Codes and Standards				
Contract vessels complying with Marine Orders for safe vessel operations: • Marine Order 91 (Oil) • Marine Order 95 (Pollution prevention – garbage) • Marine Order 96 (Pollution prevention – sewage). Marine Orders 91, 95 and 96 (pollution prevention) reduce the potential impact of marine wastewater discharges on water quality.	F: Yes. CS: Minimal cost. Standard practice.	Marine Orders required under Australian regulations; implementation is standard practice for commercial vessels as applicable to vessel size, type and class.	Controls based on legislative requirements – must be adopted.	Yes **C 6.1**
Good Practice				
Chemical Selection and Assessment Environment Guideline: • Where Gold/Silver/E/D OCNS rating (and no OCNS substitution or product warning), chemicals are selected, no further control required. • If chemicals with a different OCNS rating, sub-warning or non-OCNS rated chemicals are required, chemicals will be assessed in accordance with the guideline prior to use.	F: Yes. Woodside routinely implements a chemical selection process based on the OCNS at the facility. CS: Minimal. The OCNS is widely used throughout the industry, and chemical suppliers are aware of the requirements of the scheme.	Selection and assessment of chemicals in accordance with the Woodside process reduces environmental impacts associated with planned chemical discharge.	Woodside's chemical selection process is used to ensure chemicals are selected with the lowest practicable environmental risks while still providing the required technical capability.	Yes **C 5.1**
Facility sewage system macerator maintained.	F: Yes. CS: Minimal cost. Standard practice.	Treating and macerating sewage is standard industry practice, ensuring the substance disperses in the receiving environment with minimal effects to water quality.	Benefits outweigh cost/sacrifice.	Yes **C 6.2**
Where there is potential for loss of primary containment of oil and chemicals on the MODU, deck drainage must be collected via a closed drainage system, e.g., drill floor.	F: Yes. CS: Minimal cost. Standard practice.	Reduces the likelihood of contaminated deck drainage water being discharged to the marine environment. No change in consequence would occur.	Benefits outweigh cost/sacrifice.	Yes **C 6.3**

Facility open hazardous drain system integrity maintained as far as practicable.	F: Yes. CS: Minimal cost. Standard practice.	The open hazardous drain system is maintained to support appropriate disposal of environmentally hazardous liquids.	Benefits outweigh cost/sacrifice.	Yes **C 6.5**
ALARP Statement: On the basis of the environmental impact assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts of discharge of sewage, putrescible waste, grey water, bilge water, drain water, cooling water and brine from the facility, MODU and project vessels. As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.				
Demonstration of Acceptability				
Acceptability Statement: The impact assessment has determined that, given the adopted controls, routine and non-routine discharges of sewage, putrescible waste, grey water, bilge water, drain water, cooling water and brine from the facility, MODU and project vessels are not expected to result in potential impacts greater than localised contamination not significantly above background levels outside a localised mixing zone. Further opportunities to reduce the impacts have been investigated above. The adopted controls are considered good oil-field practice/industry best practice and meet legislative requirements under Marine Orders 91, 95 and 96. The potential impacts and risks are considered broadly acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the impacts and risks of these discharges to a level that is broadly acceptable.

Description of Source of Impact

Produced water (PW) is condensed water (water vapour present within gas/condensate that condenses when brought to the surface) or formation water (derived from a water reservoir below the hydrocarbon formation), or a combination of both. Separation of water from reservoir fluids is not 100% effective and therefore, PW often contains small amounts of naturally occurring contaminants including dispersed oil, dissolved organic compounds (aliphatic and aromatic hydrocarbons, organic acids and phenols), inorganic compounds (e.g., soluble inorganic chemicals or dissolved metals) and residual process chemicals (including MEG on a non-routine basis). A description of the PW system has been provided in **Section 3.4.9**.

In 2022 discharge rates ranged from 0 to 123 m^3/day PW discharge rates are expected to increase once wells cut water until such time the facility will batch discharge. The maximum daily discharge is 4800 m^3.

Monitoring and Management Framework

Overview

This section describes the monitoring and management framework which Woodside has developed to support the monitoring of PW discharges from offshore assets. The Commonwealth ANZG for fresh and Marine water quality have been implemented and are consistent with the principles of the National Water Quality Management Strategy.

Environmental values are defined as particular values or uses of the environment that are important for a healthy ecosystem or for public benefit, welfare, safety or health and that require protection from the effects of pollution, waste discharges and deposits (ANZG, 2018). The relevant environmental values considered are:

- ecosystem integrity – maintaining ecosystem processes (primary production, food chains) and the quality of water, biota and sediment.
- cultural and spiritual – in the absence of any specific environmental quality requirements for protection of this value, it is assumed that if water quality is managed to protect ecosystem integrity, this value is achieved in line with the guideline. The link between environmental protection and cultural heritage protection is described further in **Section 4.9.1.5**.

The relationship between key elements of ecosystem integrity, indicators and relevant monitoring activities undertaken on a routine and non-routine basis are shown in **Figure 6-1**. As per the State *waters Technical Guidance: Protecting*

the quality of Western Australia's marine environment (EPA, 2016)[55] key elements to maintain ecosystem integrity have been identified as water quality, sediment quality and biological indicators (biota). By limiting the changes to these key elements to acceptable levels there is high confidence ecosystem integrity is maintained. Monitoring changes in water quality as well as investigating potential toxicity via whole effluent toxicity (WET) testing and implementing management to maintain acceptable levels of change is standard industry practice in Commonwealth and State waters. The relevant indicators to understand changes in key elements and therefore potential for impact to ecosystem integrity are physio-chemical stressors, toxicants in water and biological indicators. Trigger values for each indicator have been defined and are monitored to detect changes. Trigger values serve as an early warning that potential changes may occur.

The approved mixing zone, protects 95% of species, as calculated using the ANZG (2018) statistical distribution methodology on the results of direct toxicity assessment using sub-lethal chronic endpoints. The protection of 95% of species guidelines have been adopted for a slightly to-moderately disturbed system at the approved mixing zone boundary given the discharge location (as per ANZG, 2018).

Formation and condensed water have historically been discharged from the platform. Although currently the Lambert Deep reservoir has not cut water (predicted ~2025) a dual zone well was provided so that the zone producing water can be shut off when water cut is too high for the topsides to process. A single zone well is proposed for Lambert West which is also expected to produce water at some time in the well life. However, when Lambert West starts producing water the well is expected to discontinue flowing. The approved mixing zone boundary is 500 m. The justification for these limits of change being 'acceptable' is provided in the impact assessment section below.

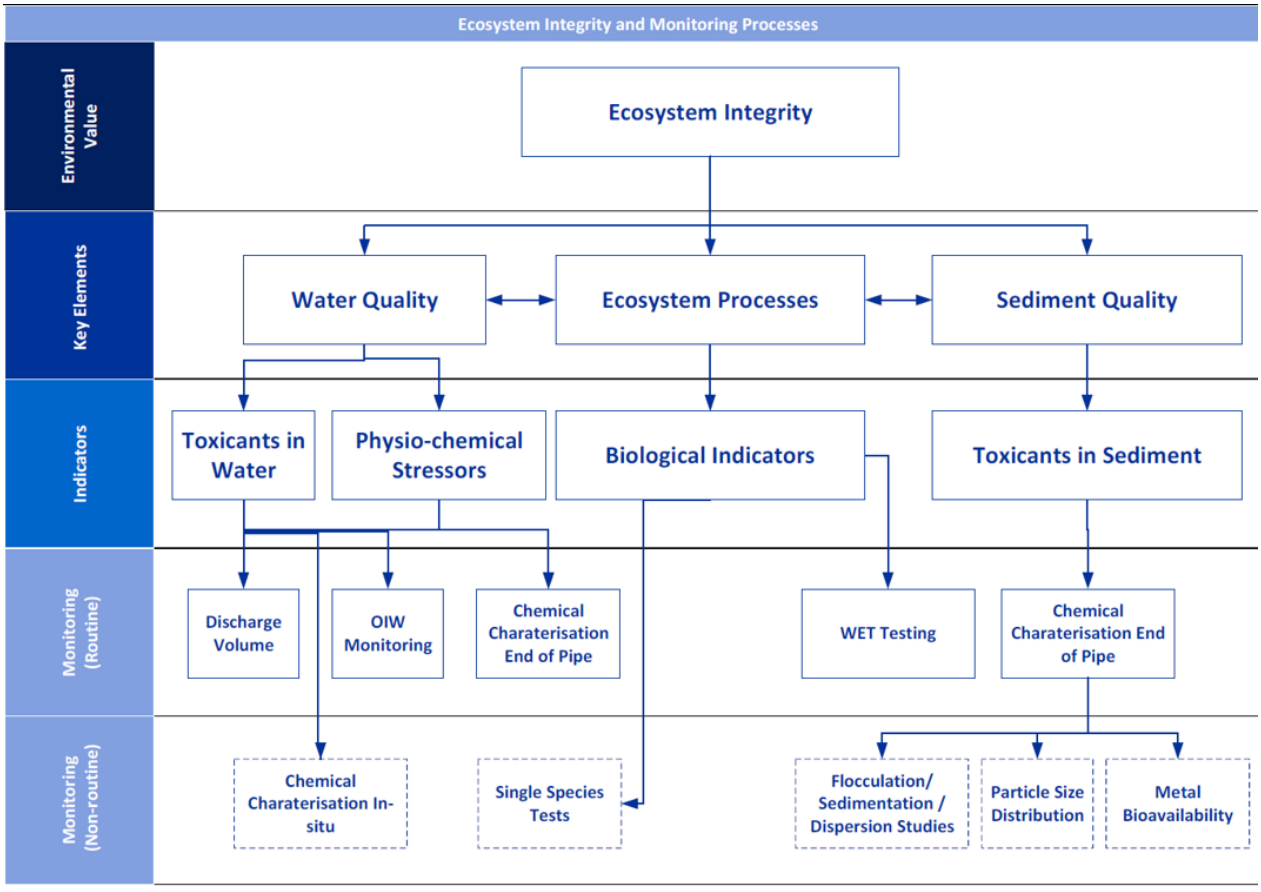

Figure 6-1: Ecosystem integrity and monitoring process

Operational Monitoring

OIW is monitored during routine operations via an online analyser. Online analyser information is sent via transmitter and reported to the NRC control system (DCS) and is also captured within the process historian database (PHD). The DCS facilitates visibility in the NRC control room, for manual or automated process control changes to be made, and/or alarms enunciated (e.g., high OIW specification). PHD information is available onshore for analysis and trending. During each intervention visit approximately 8-weekly basis, or five times per year, operators manually

55 In the absence of any Commonwealth guidelines, the State waters Technical Guidance: Protecting the quality of Western Australia's marine environment (EPA, 2016) has been considered and is consistent with the principles of the National Water Quality Management Strategy.

sample PW and send onshore via helicopter at the start of the visit for analyser QC checks at the onshore lab. The results are sent back to the operator to allow calibration of both analysers during the visit.

Loss of Signal Management

If there is a loss of signal from both OIW analysers, operators attempt to reset analysers remotely and monitor process stability for changes with the potential to result in an increase in the OIW concentration. If analysers cannot be restored, there are no observable changes to a stable operating process, and proof of reliable results below 30 mg/L, the next intervention visit will include restart of the analyser if the next planned intervention is within seven days. If the next planned intervention is greater than seven days away, a 'react' visit is undertaken.

If there is a lack of certainty around results risking OIW measurements exceeding 30 mg/L for more than six consecutive hours, and a risk of OIW exceedance (24-hour rolling average) is anticipated, the asset may undertake a 'react' visit to verify results.

High Oil in Water Management

If the analyser is online and the OIW measurement exceeds 30 mg/L for more than six consecutive hours, and risk of OIW exceedance (24-hour rolling average) is anticipated, the asset may undertake a 'react' visit to verify results. In either case, a helicopter is deployed to the platform for the react visit within 12 hours, weather and time-of-day permitting.

Routine Monitoring

PW is monitored and managed in accordance with the Offshore Marine Discharges Adaptive Management Plan (OMDAMP). The OMDAMP details routine monitoring, trigger values as per **Table 6-13**, analytical methods, assessment against trigger values, and actions when a trigger value is exceeded.

The trigger values are applied through a risk-based approach that is intended to capture uncertainty around the level of impact by staging monitoring and management responses according to the degree of risk to ecosystem integrity. The approach provides a level of confidence that management responses are not triggered too early (i.e., when there is no actual impact) or too late after significant or irreversible damage to the surrounding ecosystem (EPA, 2016). Routine monitoring applicable to the facility, is undertaken to compare against trigger values (described in **Table 6-13**). Unacceptable changes in water quality and raw PW toxicity can be detected early and can indicate the potential for an impact to biota and sediment prior to it occurring. WET testing confirms if there is a potential for impact on biota. It is not appropriate to monitor for changes in species composition, diversity, etc, as there are limited receptors in the direct impact zone (a surface buoyant plume), and such changes may be detected after an impact occurs, and therefore are not considered appropriate for early detection. PW samples should represent normal operations and be undertaken during periods of normal production at the facility. Where practicable, samples are taken soon after new wells are brought online or after wells cut water.

The WET tests are undertaken on a broad range of taxa of ecological relevance for which accepted standard test protocols are well-established. WET tests are mainly focused on the early life stages of test organisms, when organisms are typically at their most sensitive to contaminants are designed to represent local trophic level receptors. Mainly tropical Australian marine species were selected based on their ecological relevance, known sensitivity to contaminants, availability of robust test protocols, and known reproducibility and sensitivity as test species. The dilutions required to protect 95% of species, is calculated using the Warne et al. (2018) methodology.

Table 6-13: Trigger values and frequency of routine monitoring

Parameter	***Trigger value***	***Frequency***
Review of continuous operational OIW monitoring results	Increase in the average monthly OIW concentration by 5 mg/L over a six-month period or by 10 mg/L over a two month period	Monthly
Chemical characterisation: end of pipe sample – physio chemical and toxicants	Results that are predicted to be higher than the 95% species protection trigger value at the approved mixing zone boundary and are above the results from the earlier toxicity year OR above the toxicity year when no guideline is available	Annually timed to consider if sample is representative
WET testing	The 95% species protection safe dilutions derived from the WET testing species sensitivity distributions are not predicted to be achieved at the boundary of the approved mixing zone and are higher than previous years	Three yearly Conducted in parallel with annual chemical characterisation where feasible

Note: earlier toxicity year means the year in which the most recent WET test occurred.

*If a trigger value is exceeded, there is uncertainty around whether the environmental value is being protected and further investigation is required (**Figure 6-2**).*

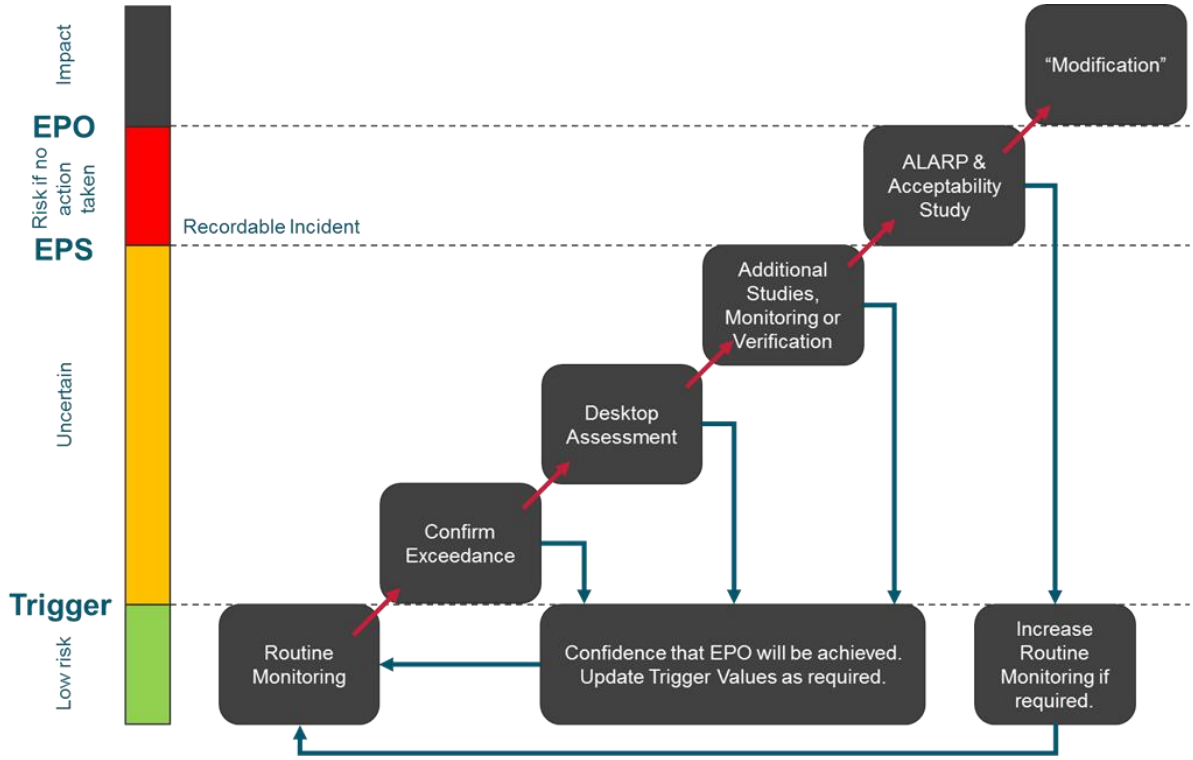

Figure 6-2: Routine monitoring and adaptive management framework for produced water

Further Investigations

Detectable exceedances in trigger values may occur without impacting ecosystem integrity. To provide confidence that ecosystem integrity has been achieved, further investigation would be required in the form of a desktop study to initially assess the exceedance in context of available data (multiple lines of evidence) and confirm if there is potential for impact to the environmental value. A desktop assessment is necessary before undertaking additional in-field monitoring. This ensures monitoring programs are designed and implemented to provide robust findings based on good survey design.

A range of methods can be used to detect trigger value exceedances (e.g., relative percentage difference, control charts, multivariate analysis, etc.) depending on the dataset available. An appropriate method is selected as described in the OMDAMP due to the variable nature of environmental data. If critical data are not available, the desktop study identifies potential data gaps and may recommend additional non-routine studies and/or monitoring to ensure the assessment is appropriately undertaken. The purpose of the 'further investigations' step is to provide certainty that the EPS has been achieved, if a trigger value has been exceeded. The key investigation steps are described below:

1. **Confirm the trigger value has been exceeded** – Review quality assurance and quality control, methodology and possible sources of contamination to determine if the results are reliable, or if any factors have occurred that may compromise the integrity of the monitoring or data.
2. **Desktop assessment to understand whether the EPS is at risk** – If a trigger value is confirmed to be exceeded, multiple lines of evidence are considered including historical and current data from routine and non-routine monitoring and studies. This assessment shall consider whether there is adequate evidence to demonstrate that acceptability criteria have been met and ecological integrity is not at risk (EPS not breached). If the desktop assessment determines that the existing body of evidence is insufficient, it shall outline what additional monitoring or studies are required. The desktop assessment is needed before undertaking any additional infield monitoring. It ensures monitoring programs are designed and implemented to provide robust findings based on good survey design. Potential additional monitoring/studies may include but is not limited to:
   - single species test (collected annually in parallel with routine chemical characterisation should further investigation be required)
   - dilution modelling and or studies
   - flocculation, sedimentation, settling velocity and/or dispersion analysis.
   - metal bioavailability
   - scanning electron microscopy and particle size distribution analyses
   - in-situ monitoring (water quality and/or sediments).

Routine monitoring activities may be required ahead of schedule and additional monitoring not listed may be undertaken as appropriate. Field monitoring is undertaken in accordance with a plan that details timing, locations and objectives of monitoring.

3. **Conduct additional studies to confirm the EPS is not at risk** – Monitoring results provide additional lines of evidence to determine whether there is a risk to ecosystem integrity due to unacceptable changes in water quality sediment, or biological indicators. Given the significant health, safety and technical risks, logistics and planning required, monitoring of the receiving environment is typically only considered when all other sources of evidence are insufficient to demonstrate that ecological integrity is not at risk. The OMDAMP provides detailed guidance on the steps and actions required to be undertaken if a trigger value is exceeded and this may include additional non-routine monitoring to verify that ecological integrity is maintained.

If environmental impact is deemed to be within acceptable limits of change the desktop assessment may consider a review of trigger values to ensure they are appropriate If the environmental impact is deemed to be outside of the acceptable limits of change, an ALARP/Acceptability study is required to determine what additional controls can be implemented to ensure the impacts are acceptable. An EPS breach is a Recordable Incident, which is reported and managed as outlined in **Section 7.11.5**.

Impact Assessment – Routine PW Discharge

Potential impacts of PW discharge include:

- changes to water quality
- toxicity to biota
- changes to sediment quality.

To understand potential impacts from PW discharges, Woodside has undertaken a suite of comprehensive in-situ testing and sampling representing long-term operational periods from its offshore production facilities. The details of this testing and resultant understanding of potential environmental impacts are outlined below.

Potential Impacts to Water Quality

PW is discharged from the platform directly overboard above the sea surface (8 m above LAT). The plume initially plunges and then rises to the surface as positively buoyant plume. Potential impacts to water quality have been assessed through chemical characterisation of PW and potential discharge volumes.

Chemical Characterisation of PW (Physio-chemical Parameters and Toxicants in Water)

Monitoring indicates the approved mixing zone has not been exceeded historically and provides high confidence that impacts from PW discharge are highly localised and pose negligible effects to environmental receptors. Samples of undiluted PW were collected annually from the end of pipe between 2011 to 2020 prior to shutdown and in 2022 following tie-back of Lambert Deep and restart of operations. The samples were analysed for key physio-chemical parameters and toxicants. In most cases, results are below trigger values, or similar to the results of chemical characterisation when the previous year's WET testing was undertaken (i.e., previous toxicity year).

Since restart two metals (nickel and cobalt), benzene, toluene, ethylbenzene and xylenes (BTEX), phenol and polycyclic aromatic hydrocarbons (PAHs) were present at levels above the ANZG (2018) guideline values at the end of the pipe. To achieve the 99% species protection guideline values, the highest dilution required was 82 for phenol. Modelling predicts 2853 and 14,526 dilutions were achieved 500 m from discharge point at 4800 m^3/day and 962 m^3/day respectively. Routine chemical characterisation has indicated condensed water since tie-back is higher in BTEX, napthalene and phenol than condensed water previously sampled in 2015 and 2016. No non-routine monitoring was triggered as routine WET testing was conducted in 2022.

There is potential for slight, localised decrease in water quality at the discharge location within the mixing zone and adverse effects on marine biota. Within the approved mixing zone impacts to pelagic fish are expected to be limited to avoidance of the localised area of the plume and short-term, localised decline in planktonic organisms in the immediate vicinity of the discharge plume.

Discharge Volumes

The max daily volume of PW discharged from the facility in 2022 (see **Figure 6-3**) is lower than the maximum capacity of the PW system (4800 m^3/day). Future discharges are expected to increase due to the Lambert West tie-back and as wells cut water.

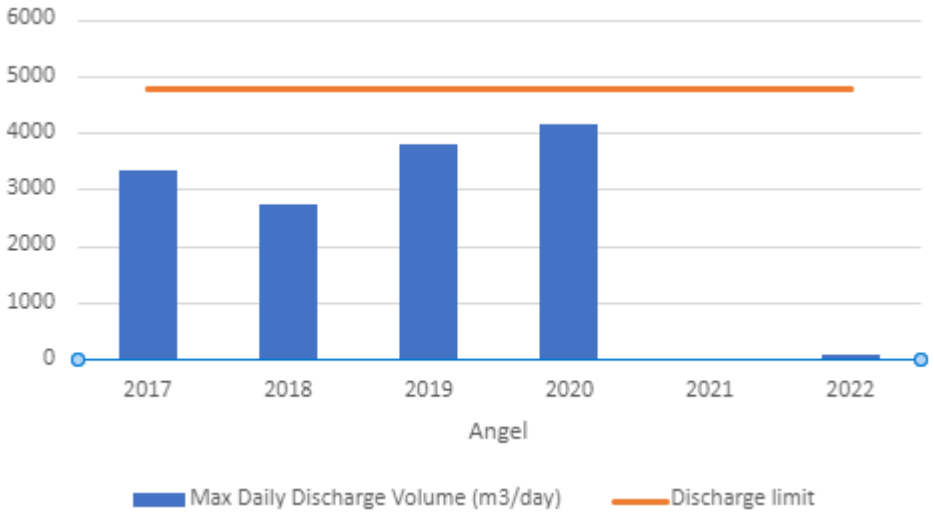

Figure 6-3: Historical maximum daily discharge rates of produced water from Angel facility

Potential Impacts to Biological Indicators

Most treated PW has low to moderate toxicity (Neff et al., 2011), with actual toxicity of discharge dependant on the chemical constituents of the PW and any added process chemicals, the level of treatment and dilution with condensed water prior to release, and the dilution of the discharge as it mixes with seawater. Most hydrocarbons in PW are considered non-specific narcotic toxins with additive toxicities; therefore, the toxicity of a PW does, in part, depend on the total concentration and range of bioavailable hydrocarbons (Neff, 2002). Potential impacts of PW to biological indicators have historically been assessed through WET testing and dilution modelling to verify the approved mixing zone is achieved.

WET Testing

WET testing is undertaken to allow for interactions between toxicants and to consider toxicants that cannot readily be measured or are not known to be present in the sample. Routine WET testing was completed in 2022 and historically in 2011, 2014 and 2017 (**Table 6-14**). The number of dilutions required to achieve 95% species protection safe dilutions since restart is within the bounds of historic discharges. Noting historical discharges are not directly comparable (different reservoirs, separation process and test species).

Table 6-14: PC99 and PC95 concentrations and safe dilutions

Species Protection Level	***Predicted No Effect Concentration***				
PCx	***2011***	***2014***	***2017***	***2020***	***2022***
PC99 (50)	0.38 (1 in 260)	0.053 (1 in 1900)	0.61 (1 in 164)	0.090 (1 in 1111)	0.24 (1 in 417)
PC95 (50)	0.53 (1 in 190)	0.35 (1 in 290)	0.86 (1 in 116)	0.26 (1 in 385)	0.36 (1 in 278)

Determination of Approved Mixing Zone

To determine the potential impact of the PW to the marine environment, modelling has been conducted to predict the distance at which 95% species protection safe dilutions are achieved, using the most recent WET testing results available at the time to reflect the current potential toxicity (**Table 6-14**). The latest modelling study was carried out in 2018 and informs this impact assessment (Jacobs, 2018). Model simulations were undertaken for the three main seasons prevalent on the NWS, based on measured current and wind data supplied by Woodside. Ocean current data was collected at multiple depths through the water column at NRC. Conditions at NRC are considered representative of Angel due to their proximity to each other (approximately 49 km) and open ocean conditions. As the modelling of ocean current speed and direction varies substantially within each season, the full current records were analysed to select periods typical of the three seasons on the NWS but erring on the side of low current speeds to give conservative model results (Jacobs, 2018).

Further to these hydrodynamic inputs, the PW discharge model was validated in 2006 using the results from a dye dispersion study (Oceanic Field Services, 2006) undertaken from the North Rankin A platform. The predicted plume dilutions reasonably matched those measured.

The results from the WET testing undertaken in 2017 were used to develop predicted no-effect concentration (PNEC) values that were inputs to the model. The four-day predicted effects concentration (PEC) value is used to determine the PEC/PNEC ratios and the distances from the discharge point at which 95% species protection safe dilutions (PC95) are achieved. Based on the 2017 average discharge rate (962 m^3/day) and maximum discharge rate

(4800 m^3/day). The modelling shows a surface buoyant plume that is readily diluted to 95% species protection safe dilution within 20 m of the discharge location under worst-case conditions at actual and maximum discharge rates.

Remodelling was not undertaken as discharge is within the parameters modelled in 2018. Although discharge rates since restart have been significantly lower it is not proposed to reduce the approved mixing zone further as discharge rates are predicted to increase and future monitoring and management should consider potential historic contamination.

Impacts to Australian Marine Parks, KEFs and Biologically Important Areas

There is potential for slight, localised decrease in water quality at the discharge location and within the surface water with potential adverse effects on marine biota in the surface water. Potential impacts to pelagic fish are expected to be limited to avoidance of the localised area of the plume and short-term, localised decline in planktonic organisms in the immediate vicinity of the discharge plume. Therefore, while the discharge location of PW overlaps with a small proportion the foraging BIA for whale sharks, given the localised area of impact and that whale sharks are transitory, no impacts are expected to the whale sharks' ability to forage.

During PW discharge these impacts are anticipated to be within the approved mixing zone (500 m). At lower discharge rates, dilution levels are expected to be achieved closer to the discharge point resulting in a reduced loading to the environment.

The facility (and PW discharge point) is ~2.8 km from the nearest KEF, Glomar Shoal, which modelling predicts is outside of the approved mixing zone (500 m). Given PW forms a buoyant plume and the distance from the discharge source, no impacts to the KEF are anticipated.

Bioaccumulation

Bioaccumulation refers to the amount of a substance taken up by an organism through all routes of exposure (water, diet, inhalation, epidermal). The Bioaccumulation Factor is the ratio of the steady-state tissue concentration and the steady-state environmental concentration (assuming uptake is from food and water). The test developed to measure the ability of a substance to bioaccumulate, namely, the octanol-water partition (Pow), is based on the preferential partitioning of lipophilic organic compounds into the octanol phase. Partitioning into octanol can be correlated with the attraction for such compounds to the fatty tissue (lipid) of organisms.

Bioaccumulation of BTEX compounds found in PW has been observed to occur in the laboratory, at concentrations far in excess of that discharged from facilities on the NWS and the worst case data used as analogues for the Angel PW discharge (**Table 6-13**) (for example refer to Berry, 1980); hence it is unlikely that BTEX would bioaccumulate at the exposure concentrations that may be experienced by biota around the Angel facility.

In contrast to BTEX compounds, PAH compounds also found in PW have high Pow values indicative of the potential for bioaccumulation (Vik et al, 1996). Neff and Sauer (1996) reviewed the available literature for laboratory and field studies investigating the bioaccumulation of PAHs. The bioaccumulation values for PAHs in marine organisms collected near PW discharges in the Gulf of Mexico indicate that the highest bioaccumulation factor was in the tissues of bivalve molluscs and the lowest in the muscle tissue of fish (Neff and Saur, 1996).

The most comprehensive field study assessing bioaccumulation of hydrocarbons and metals from PW discharged into offshore waters is that by Neff et al (2011). At the request of the United States Environmental Protection Agency (USEPA), the Gulf of Mexico Offshore Operators Committee sponsored a study of bioconcentration of selected PW chemicals by marine invertebrates and fish around several offshore production facilities discharging more than 731 m^3 per day of PW to outer continental shelf waters of the western Gulf of Mexico (by comparison Angel discharges are estimated to be up to ~1300 m^3/day). The target chemicals identified by USEPA included five metals (As, Cd, Hg, 226Ra and 228Ra), three volatile monocyclic aromatic hydrocarbons (MAH), benzene, toluene, and ethylbenzene, and four semi-volatile organic chemicals, phenol, fluorene, benzo(a)pyrene, and di (2-ethylhexyl) phthalate. Additional MAH (m-, p-, and o-xylenes) and a full suite of 40 parent and alkyl-PAH and dibenzothiophenes were also analysed by Neff et al (2011) in PW, ambient water, and tissues at some platforms.

Concentrations of MAH, PAH, and phenol as determined by Neff and colleagues were orders of magnitude higher in PW than in ambient seawater. There was no evidence of MAH or phenol being bioconcentrated. All MAH and phenol were either not detected (> 95% of tissue samples) or were present at trace concentrations in all invertebrate and fish tissue samples. Concentrations of several petrogenic PAHs, including alkyl naphthalene's and alkyl dibenzothiophenes, were slightly, but significantly higher in some bivalve molluscs, but not fish, from discharging than from non-discharging platforms. These PAH could have been derived from PW discharges or from tar balls or small fuel spills. Concentrations of individual and total PAH in mollusc, crab, and fish tissues were well below concentrations that might be harmful to the marine animals or to humans who might collect them for food at offshore platforms (Neff et. al., 2011).

Bioaccumulation is therefore unlikely to result in increased levels of BTEX in biota surrounding Angel; however, there may be an elevation in PAH levels). The results from Neff et al. (2011) can be used to infer the very low potential for adverse bioaccumulation effects to marine organisms, or to humans, if they were to consume any affected fish, molluscs or crabs found on upper near-surface legs of the facility. The potential environmental impact associated with bioaccumulation of PW constituents in the water column and in the sediments, is considered to be very low, and limited to a potential localised effect on a small number of non-threatened species in waters immediately surrounding the facility as described below.

Potential health risks are unlikely as a result of negligible exposure: the PSV prohibits fishing from or near the platform as there is very little or no activity within the Operational Area. Given the similarity of the chemical characterisation of PW discharges from the facility and other nearby platforms to those elsewhere in the world, including those in the Gulf of Mexico (Jacobs, 2017), the results from Neff et al. (2011) can be used to infer the very low potential for adverse bioaccumulation effects to marine organisms, or to humans, if they were to consume any affected fish, molluscs or crabs found on upper near-surface legs of the facility.

Field studies completed in 2015 at GWA (BMT Oceanica, 2015) confirmed potential environmental impact associated with bioaccumulation of PW constituents in the water is considered to be very low and limited to a potential localised effect on a small number of non-threated species in waters immediately surrounding each facility.

Given the nature of the PW discharge from the riser platform, the potential for bioaccumulation of PW contaminants (in particular, BTEX) is considered to be minor and restricted to sessile organisms growing on the legs of the riser platform.

The potential environmental impact associated with bioaccumulation of PW constituents in the water column is considered to be very low and limited to a potential localised effect on a small number of non-threatened species in waters immediately surrounding the facility. Given the nature of the PW discharge from the riser platform, the potential for bioaccumulation of PW contaminants (in particular, BTEX) is considered to be slight, localised, short term.

Potential Impacts to Sediment Quality

Potential impacts to sediment quality were assessed through sediment surveys and supported by the results of flocculation studies and potential impacts to water quality.

Toxicants in Sediments

Accumulation of PW contaminants in sediments depends primarily on the volume/concentration of particulates in PW discharges or constituents that sorb onto seawater particulates, the area over which those particulates could settle onto the seabed (dominated by current speeds and water depths) and re-suspension, bioturbation and microbial decay of those particulates in the water column and on the seabed. As described above, the potential for PW to impact sediment, based on chemical characterisation, is unlikely due to the concentrations observed.

Studies into potential sediment accumulation from PW discharge found that the PW at all facilities had very small amounts of solid material, with very little potential of settling or flocculation due to small particle sizes (Jacobs, 2016; BMT, 2021). Dr Graeme Hubbert categorised particulate behaviour based on oceanographic experience and mathematical calculations using settling rates and resuspension velocities for various particle sizes. He determined that particles of a size 1 to 5 µm would never permanently settle out of the water column, and that particles of a size 5 to 40 µm would not permanently settle out of the water column, unless they were in very deep water (>5000 m) or in areas where hydrodynamic conditions were very weak and did not continuously resuspend the particles (SKM, 2013).

Sediment sampling undertaken in 2020 verified that concentrations of contaminants were below their respective ANZG (2018) DGVs inside and outside the approved mixing zone. Although measurable concentrations of hydrocarbons were found in the raw PW (BMT, 2021), all hydrocarbon concentrations in surface (top 2 cm) samples were below their LoR, suggesting that there has been no accumulation of hydrocarbons in these sediments following the discharge of PW. The survey demonstrated compliance with approved criteria at the approved PW mixing zone boundary indicating no adverse impacts to sediments are expected from PW discharge outside of the approved mixing zone.

Due to the relatively short duration of field life, low volumes of PW discharge and similar characteristics of PW since tie-back of Lambert Deep it is not proposed to conduct ongoing routine sediment sampling. Instead, sediment sampling would be triggered under the OMDAMP if required.

Management and Impact Assessment – Non-Routine Activities

Management During Commissioning (Initial Start-up) of Lambert West and Restart

Commissioning of the Lambert West field requires flexibility to allow for OIW elevation while the wells are started up and flow rates vary while the system is optimised. It is expected that within 7 to 10 days of sequentially commissioning the reservoir, the process will allow for effective OIW separation with OIW concentrations reflective of steady-state conditions. During restarts OIW may be elevated due to the low volumes for up to 3 days.

The complexities involved in commissioning this process are the limited knowledge of PW chemistry, the pressure drops across the process and impact on separation across each PW treatment stages, and the chemical interactions and effectiveness. In order to provide the required flexibility during commissioning the following OIW levels are required:

- initial commissioning: 100 mg/L 24-hr rolling average.
- restart 100 mg/L 24-hour rolling average.

During commissioning, well jumper preservation fluids in the 500 m long 8" well jumper to LD manifold containing MEG and residual drilling and completion fluids will be produced back to the Angel facility, potentially impacting OIW concentrations in PW discharges. Preservation fluid volumes are low, however, the primary cause of potential higher OIW concentrations is from residual well completions fluids and condensed water potentially containing fines coated in condensate being produced to the facility. Unloading to the Angel facility is the preferred option; however, if well unload fluids cannot be directed to the facility, the well test water treatment package onboard the MODU will be used to treat produced/reservoir water before discharging as per **Section 3.5.2.10**. Upon start-up, the production process requires heating to temperatures which promote effective OIW separation. During the initial commissioning period, defined by the requirement to discharge produced water overboard, manual sampling for OIW will be required until such time the online OIW analysers have been calibrated and proven to be operating in line with their functional requirement. A temporary polishing skid will be run during this initial commissioning period to reduce the OIW concentration and load during this period and maintaining flexibility for optimisation.

Impact Assessment

The PW discharge modelling was based on the system design maximum possible flow rate of 4,800 m^3 per day. The maximum design rate is based on a few wells producing water, the rate during commissioning is expected to be significantly less due to no wells having cut water. The OSPAR (2014) dispersed oil concentration of 70 µg/L was used as the PNEC rather than the ANZECC/ARMCANZ (2000) guideline value (low reliability) of 7 µg/L. The PNEC of 70 µg/L derived by Smit et al (2009) is considered more appropriate than the Tsvetnenko (1998) derived 7 µg/L as all tests used in the Species Sensitivity Distribution (SSD) were chronic as opposed to acute converted to chronic values with an acute chronic ratio (ACR) of 25 as used by Tsvetnenko (1998).

Modelling considered minimum dilutions achieved across all months of the year. According to the modelling results, the distance from the discharge location in which the PNEC of 70 µg/l is achieved (1429 dilutions required) is within the 500 m mixing zone. No approved mixing zone is proposed during commissioning. The commissioning discharge will be of short duration and expected to be of slight short-term impact. use of the polishing skid during the initial commissioning period will minimise the OIW concentrations being discharged to the environment. Further justification that the environmental impact is both ALARP and acceptable have been incorporated into the Demonstration of ALARP and Demonstration of Acceptability sections below.

Professional Judgement – Eliminate				
Reinjecting PW into reservoirs.	As part of the 2015 PW study into treatment, Woodside examined the potential for reinjection of PW at similar NWS facilities. Woodside has not identified a suitable reservoir, and such an option would likely require additional drilling activities to be undertaken. Angel is not capable of supporting platform-based drilling. Reinjection is not feasible unless a suitable reservoir is identified. It is not feasible to reinject into a shut-in Angel subsea well because the wells continue to have high reservoir pressure, which would require significant facility modifications to overcome. Drilling and subsea work activities to establish a reliable PW reinjection well and subsea infrastructure also introduce significant complexity, risk and cost. Retrofitting PW topsides reinjection equipment to Angel introduces significant modifications which pose safety risks on an operational gas facility. There is also very little deck space available at Angel for any such equipment. Together, the significant retrofit risks, associated environmental impact (drilling and subsea construction, greenhouse gas emissions associated with 7 to 15 MW based on known requirements for Enfield - Laverda) is considered significantly disproportionate to the potential slight environmental impact improvement. As such, no further engineering design or screening studies reporting is considered reasonably practicable. For type B impacts, it is appropriate to consider case-specific drivers to ALARP management. The lack of a suitable reservoir contrasts with Woodside's facilities that currently reinject PW. At Nganhurra (NGA), for example, water reinjection was required to maintain reservoir pressure for production and was a key part of the Field Development Plan to optimise overall field recovery. As PW alone is not sufficient to maintain reservoir pressure, seawater is used to make up the balance. Therefore, given the significant economic benefits associated with reinjection at NGA, the ALARP outcome was different from NGA to Angel. The reinjection of PW would also introduce additional sources of environmental risks and impacts, such as those associated with drilling injection wells (e.g., drill cuttings) and maintaining injection capability (e.g., increased greenhouse gas emissions from power generation for pumps, increased chemical usage, etc). Given the localised, slight non-significant impact of PW discharges, and the considerable costs involved in developing a PW reinjection capability for the Angel facility, implementation risks and environmental impacts (greenhouse gas, chemical use), the costs are grossly disproportionate to the potential environmental benefit gained.			No

Professional Judgement – Engineered Solution				
Chemical injection of water clarifier to reduce OIW concentration.	F: Potentially feasible. CS: Moderate. Initial cost of modifying production system to include chemical dosing point. Ongoing cost of chemical procurement.	Potential minor reduction in OIW concentration; however, does not reduce the overall consequence rating. Further, this results in additional chemical load, and lifecycle environmental footprint associated with packaging, logistics, waste management and potential process upsets.	The discharge of clarifying agent with the PW stream may result in additional toxic effects. Ongoing chemical consumption would also incur Operational expenditure (OPEX). Given the nature and scale of impacts forming the current PW discharge, the cost of developing a chemical injection is disproportional to the environmental benefit.	No
Adoption of a permanent tertiary treatment stage to reduce OIW concentration.	F: Potentially feasible. Large deck space would be needed which is not currently available. CS: Significant cost. Deck reinforcement or cantilevers required, as well as high cost associated with these maintenance intensive technologies.	Potential minor reduction in OIW concentration; however, does not reduce the overall consequence rating. Further, there is very little deck space available at Angel for additional treatment equipment.	Centrifuges and macro porous polymer extraction (MPPE) are large and heavy, requiring deck reinforcement or cantilevers. They are also maintenance intensive, which is incompatible with the Angel NNM philosophy. This introduces significant costs and additional risk from exposure of personnel. Additionally, these options tend to have high power consumption. The adoption of secondary treatment is not currently considered ALARP because the additional costs and risks associated with this option are considered disproportionate to the OIW benefit for a field with relatively low condensed water rates and relatively short duration of formation water that is expected to be yielded.	No
Temporary OIW polishing skid (secondary treatment) during initial	F: Yes. Control Considered	***Control Feasibility (F) and Cost/ Sacrifice (CS)[56]***	***Benefit in Impact/ Risk Reduction***	***Proportionality***	***Control Adopted***
	and service provider costs.	sacrifice with regard to execution risks and costs for limited gain.	discharge OIW analysis in place to detect performance variations. Further, Woodside maintains a routine OIW monitoring program for the PW stream (including adaptive management via the OMDAMP, which assesses the need for in situ monitoring). The work undertaken to date provides Woodside with a sound understanding of the nature and scale of the environmental impacts from PW discharge, which would not be further improved by increasing the frequency of in situ monitoring. The execution risks and cost of implementing this control is grossly disproportionate to the environmental benefit.	
Risk Based Analysis				
Application of Woodside's Risk Management Procedures and implementation of the OMDAMP ensures the routine assessment of PW impacts, identification of changes to discharges, systematic assessment of risks and ongoing assessment/monitoring of discharge streams to reduce risk to ALARP, that includes: • ongoing hazard identification, risk assessment and the identification of control measures • ongoing PW discharge monitoring.				
Company Values				
Corporate values require all personnel at Woodside to comply with appropriate policies, standards, procedures and processes while being accountable for their actions and holding others to account in line with the Woodside Compass. As detailed above, the Petroleum Activities Program is undertaken in line with these policies, standards and procedures that include suitable controls to manage PW discharge.				
Societal Values				
Due to the Petroleum Activities Program's proximity to sensitive receptors and potential uncertainty around PW discharges, the PW discharge consequence rating presents a Decision Type B in accordance with the decision support framework described in **Section 2.6.1**. Consultation was undertaken for this program to identify the views and concerns of relevant stakeholders, as described in **Section 5**. Woodside has sent an Activity Factsheet to all identified relevant stakeholders regarding the Petroleum Activities Program (**Section 5** and **Appendix F**); no specific concerns around PW discharge were identified through this process.				

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/ Sacrifice (CS)[56]***	***Benefit in Impact/ Risk Reduction***	***Proportionality***	***Control Adopted***

ALARP Statement:

On the basis of the environmental impact and risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts of PW discharge. Woodside has completed additional PW treatment studies, treatment trials, use of a temporary polishing skid for tie-back commissioning, OIW and discharge volume monitoring, and risk-based analysis (PW discharge modelling) to inform the evaluation and assessment of environmental impacts and risks. Woodside also implements a risk based adaptive OMDAMP which includes annual and triennial end of pipe monitoring. The outcomes of both the modelling studies and long-term monitoring have been considered in determining the ALARP position. In-situ water quality and sediment sampling has demonstrated no impact outside of the approved mixing zone.

As no reasonable additional/alternative controls are currently identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts are considered ALARP.

Demonstration of Acceptability

To assess and determine the acceptable limits of impacts from PW discharges, Woodside has considered the following criteria, appropriate guidelines, principles of ESD, company values and societal values.

Other Requirements (includes Laws, Polices, Standards and Conventions)

The adopted controls and acceptability assessment has considered regulatory guidance, in particular WA EPA (2016) Technical Guidance: Protecting the Quality of Western Australia's Marine Environment and the ANZG (2018) guidelines. Both sources of Regulatory Guidance provide that environmental values should be identified and levels of ecological protection should then be set. To ensure ecosystem health is maintained overall, the cumulative size of the areas where lower levels of ecological protection apply should be proportionally small compared to the areas designated high and maximum. The ANZG (2018) guidelines similarly provide guidance that levels of protection should be identified, based on the environmental values to be protected.

The Monitoring and Management Framework aligns to the levels of protection described by both WA EPA (2016) and the ANZG (2018) guidelines through the acceptable limits of change.

The level of ecological protection provided to sensitive receptors is consistent with the North-west Network Management Plan (2018). By monitoring and managing to the 99% species protection safe dilutions 500 m, there can be high confidence that potential impacts can be detected and managed via the OMDAMP.

Principles of Ecologically Sustainable Development

Woodside has established several research projects to understand the marine environments in which we operate, notably in the Exmouth Region and the Kimberley Region, including Rankin Bank, Glomar Shoals, Enfield Canyon and Scott Reef. Woodside's corporate values require that we consider the environment and communities in which we operate when making decisions.

Woodside looks after the communities and environments where we operate. Risks are inherent in petroleum activities; however, through sound management, systematic application of policies, standards, procedures and processes, Woodside considers that despite this potential impact, the extremely low impact of PW is acceptable.

Internal Context

The Petroleum Activities Program is consistent with Woodside corporate policies, standards, procedures, and processes as outlined in the Demonstration of ALARP and Environmental Performance Outcomes, including:

- Woodside Environment and Biodiversity Policy **(Appendix A)**
- Woodside Risk Management Policy **(Appendix A)**
- Woodside Environmental Performance Procedure (that specifies maximum mixing zones and minimum sampling requirements).

Woodside corporate values include working sustainably, with respect to the environment and communities in which we operate, listening to internal and external stakeholders (below) and considering HSE when making decisions.

External Context

Woodside recognises that its licence to operate from a regulator and societal perspective is based on historical performance, complying with appropriate policies, standards and procedures, and understanding the expectations of external stakeholders. External stakeholder consultation was undertaken with relevant stakeholders (**Section 5**), prior to the Petroleum Activities Program and feedback was incorporated into this EP where appropriate. There was no feedback from stakeholders relevant to PW.

By providing PW monitoring and control measures that are commensurate with the risk rating, location and sensitivity of the receiving environment (including social and aesthetic values), Woodside believes this addresses broad societal concerns to an acceptable level.

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/ Sacrifice (CS)[56]***	***Benefit in Impact/ Risk Reduction***	***Proportionality***	***Control Adopted***
Acceptability Statement: Routine and non-routine discharges of PW have been evaluated as representing potential slight, localised, short-term impacts to water quality, marine sediment, marine fauna and ecosystem/habitat. As per **Section 2.6.1**, Woodside considers 'high order impacts' (Decision Type B impacts such as PW discharge) as acceptable if ALARP is demonstrated using good industry practice, consideration of company and societal values and RBA, if legislative requirements are met and societal concerns are accounted for, and the alternative control measures are grossly disproportionate to the benefit gained. In addition, acceptability is assessed against the above criteria. The adopted controls are considered good oil-field practice/industry best practice, are consistent with WA EPA (2016), ANZG (2018) and Woodside's internal requirements. Further opportunities to reduce the impacts have been investigated (refer ALARP demonstration) and considered to be grossly disproportionate to the benefit gained. Woodside considers the adopted controls appropriate to manage the impacts of PW discharge to an acceptable level.

Description of Source of Impact

Drilling Operations

The Petroleum Activities Program will involve the drilling of the LDA-02 well, drilled over a period of approximately 50 to 60 days (including mobilisation, demobilisation and contingency). Drilling activities generate drill cuttings, require cementing of the casing, and require the use of a range of fluids. Throughout the drilling program several different fluids are to be run through the closed circulation system including, but not limited to, drilling fluids (water-based muds and non-water-based muds), sea water and kill-weight brine.

Routine drilling discharges will include:

- drill cuttings

- drilling fluids direct to seabed (WBMs only), retained on cuttings and bulk discharge of mud pits (WBMs only).

Non-routine drilling discharges may include:

- drill cuttings and fluids generated due to respud or side tracking.
- WBM, swarf and cement cuttings
- well abandonment and use of fluids (subsea control, completions and well annular fluids).

Drilling activities are described in **Section 3.5.2**. The well will be drilled as a series of sections, as detailed in **Section 3.5.2**. The top hole section of the well will be drilled without a riser in place (i.e., riserless drilling). Drill cuttings and unrecoverable WBMs are discharged at the seabed for the top-hole sections, which are drilled riserless (i.e., no closed loop with the MODU). This results in a localised area of sediment deposition (known as a cuttings pile) around and in proximity to the well site influenced by prevailing seabed currents.

Upon drilling of the top hole section, a casing will be cemented in place, a BOP installed and a riser put in place between the BOP and the MODU. The riser remains in place during drilling of the bottom hole sections and facilitates the circulation of drilling fluids and cuttings between the well bore and the MODU. This enables cuttings and drilling fluids to be circulated back to the MODU, where the cuttings are separated from the drilling fluids by the solids control equipment (SCE) and typically re-used in the closed loop system between the well bore and the MODU. The cuttings (with adhered residual fluids) are, in typical circumstances, discharged below the water line, with their fate and dispersion determined by cuttings particle size and the density of the unrecoverable fluids. In contrast the fluids are recirculated into the fluid system where there are a number of mud pits (tanks) on the MODU that provide a capacity to mix, maintain and store fluids required for drilling activities. The mud pits form part of the drilling fluid circulating system and may be discharged at the end of specific well sections, where there is a requirement to change the drilling fluid system or the drilling fluid cannot be re-used (due to deterioration/contamination). Bulk discharge of this type is only permitted for WBMs.

Base oil may be used for inflow testing prior to abandonment of the well, to verify barrier integrity. Base oil would be pumped down the drill string and reverse circulated back to the rig, with fluids collected for disposal onshore. If stored in a mud pit, the base oil and other fluids associated with the test may result in pit wash water contaminated with hydrocarbons. If this is the case, mud pit wash water would be discharged in accordance with requirements in this EP; with a hydrocarbon content <1% by volume. Well abandonment activities are conducted in accordance with Woodside's internal standards.

Drill Cuttings and Fluids

As described above, the primary discharges used as the basis of the impact assessment for this Petroleum Activities Program are as follows:

- Drill cuttings: drilling generates drill cuttings due to the breakup of solid material from within the borehole. The resultant drill cuttings are basically rock particles of various shapes, with sizes typically ranging from very fine to very coarse.
- Drilling fluids: serve many purposes including maintaining borehole stability and hydrostatic pressure, reducing friction and cleaning/ cooling of the drill bit, in addition to acting as a medium to carry cuttings from the well bore and return them to the surface at seabed or on the MODU. There are two main types of drilling fluids as follows:
  - WBMs consists mainly of fresh water or seawater with the addition of chemical and mineral additives to aid in its function. Drilling additives typically used may include chlorides (e.g., sodium, potassium), bentonite (clay), cellulose polymers, guar gum, barite or calcium carbonate. These additives are either completely inert in the marine environment, naturally occurring benign materials, or readily biodegradable organic polymers with a very fast rate of biodegradation in the marine environment. Bentonite and guar gum are listed as 'E' category fluids under the OCNS and is included on the Oslo Paris (OSPAR) Commission PLONOR (chemicals that 'pose little or no risk to the environment') list (OSPAR Commission, 2021). WBMs can be discharged to sea as fluids retained on cuttings and as bulk discharge from mud pits.
  - NWBMs refers to drill fluids that are hydrocarbon rather than water-based fluid. NWBM may contain a range of synthetic hydrocarbons, such as paraffins and olefins; however, such additives are designed to be low in toxicity and biodegradable, as well as not being readily bioavailable or likely to bioaccumulate, particularly in deeper water areas. No bulk discharge of NWBMs will occur offshore, only NWBMs retained on cuttings can be discharged from the MODU. If a NWBM system is required to drill a well section, the cuttings from the NWBM drilling fluid system will pass through the SCE (centrifuge and dryers) to reduce the average residual oil on cuttings (OOC). An OOC discharge limit of 6.9% wt/wt or less on wet cuttings will be averaged over well sections drilled with NWBM for the well. It is noted that microbial biodegradation can result in oxygen reduction within sediments; however, Nedwed et al. (2006) found that depth is an important factor for residual concentrations of NWBF once they reach the seabed, suggesting that loss of base fluid during settling acted to significantly reduce chemical effects from discharges. It is also noted that NWBM cuttings tend to clump and settle to the seabed rapidly adding to the cuttings pile in proximity to the well site.

For the purposes of this impact assessment, the indicative dimensions, discharge locations and approximate drill cuttings and drilling fluid volumes provided in **Table 6-15** represent the estimated discharges for the tie-back activities.

Table 6-15: Estimated discharge of cuttings and volumes of drilling fluids used for tie-back activities.

	Well section width (inches)	*Cuttings ~volume (m^3)*	*Drilling fluid type*	*Drilling fluid ~ volume (m^3)*	*Hole section*	*Discharge point*
	42	64	Seawater[1] with pre-hydrated bentonite (PHB) sweeps/XC polymer	469	Top hole	Seabed
	26	44	Seawater[1] with pre-hydrated bentonite (PHB) sweeps/XC polymer	626		
	17.5	304	WBM	1908	Production hole #1	Surface
	13.5 or 12.25	163	WBM	1590	Production hole #2	
	9.875	15	WBM	954	Reservoir section	
Total planned activities		***591 m^3***		***5573 m^3***		
If NWBM required, these volumes will replace WBM volumes for production hole #2	13.5 or 12.25	163	NWBM	670 (retained fluid on cuttings)	Production hole #2	Surface
Indicative Contingent Activities – one top-hole respud	42" + 26" + 17.5" sections	412	Seawater[1] with PHB sweeps/XC polymer for 42"/26" sections. WBM for 17.5" sections.	3030	Top hole + production hole #1	As above for each section
Indicative Contingent Activities – sidetrack one section (WBM or NWBM, not both)	~12.5 to 13.5" section	163	WBM	1590	Production hole #2	Surface
	~12.25 to 13.5" section	163	NWBM	670	Production hole #2	Surface

1. Seawater volume is not included in the estimated 'drilling fluid volume'.

Subsea – Displacement, Completion and Well-bore Cleanout Fluids

Reservoir drilling and completion fluids are usually brines (i.e., a mixture of seawater or formation water) with additives that can include:

- chlorides (often sodium, potassium or calcium)
- bromides
- hydrate inhibitor (mono-ethylene glycol (MEG))
- biocide
- oxygen scavenger.

They are designed to have the proper density and flow characteristics to be compatible with the reservoir formation. Completion fluids are used to run well completions, and during wellbore clean up and flowback during drilling.

Wellbore and casing clean-up are required at various stages of the drilling operations to ensure the contents of the well are free of contaminants before the next stage of drilling. A chemical wellbore cleanout fluid train may be used to remove residual fluids from the wellbore. The wellbore cleanout fluid is usually brine (similar to completion fluid) that

can include several chemicals, such as biocide and surfactant. During the clean-up process, fluids are circulated back to the MODU.

Cleanout fluids and completion brine will be captured and stored on the MODU and discharged if oil concentration is less than 1% by volume or returned to shore if discharge requirements cannot be met. Discharge volume would be ~400 m^3.

Contingent Drilling Activities

Respud

It is unlikely that the well would be required to respud. If required, the most likely scenario is that the decision to respud is made during drilling of the top hole section of the well; therefore, the incremental increase in cuttings and fluids discharges is associated with the repeat drilling of the same top hole sections for the respudded well with the same associated discharges. A respud once drilling of the bottom hole sections has commenced is far less likely, given the time and effort already committed to the well. However, if this was to occur, the associated discharges would also be a repeat of the discharges as per **Table 6-15** to re-drill the same sections of the respudded well.

Permanent Plugging Program and Removal of Well Infrastructure

If required as a contingency activity, the base case for permanently plugging the well includes the use of WBM and wet cement and will produce well annulus fluids (residual hydrocarbons and residual produced formation water). These fluids/cuttings will be generated during the well bore clean-out, drilling of existing cement barriers, installation of permanent abandonment barriers, circulation of the annulus and washing out of the mud pit.

Potential additional activities that may be required as part of the Petroleum Activities Program includes milling, which will produce metal swarf, drilled cement and formation rock. All of the downhole plugging for permanent abandonment activities are conducted through the marine riser. This is a closed system, meaning there are no planned discharges directly to sea during these activities. Planned discharges of the above fluids are only planned to occur after they have been received on the MODU.

The following describes the source of impact with respect to discharge of clean-up fluids, well kill fluids, grit and flocculent only. See **Section 6.6.9** for cement, cementing fluids and subsea control fluids. For the purposes of this impact assessment, the indicative dimensions, discharge locations and approximate volumes are provided in **Table 6-16**.

Table 6-16: Estimated discharges of solids and volumes of drilling fluids used for contingency plugging and well infrastructure removal.

Description	***Discharge Point***	***Discharge***	***Approximate Solids Discharged (m^3)***	***Approximate Fluid Discharged (m^3)***	***Potential Additional Solids (m^3)***	***Potential Additional Fluid Discharge (m^3)***
Drill out cement plug	Below sea level	WBM and cement cuttings	2	1	0	0
Kill well	Below sea level	Well kill fluid	0	0	0	Discharged if oil concentration is less than 1% by volume or returned to shore if discharge requirements cannot be met.
End of well discharge	Below sea level	WBM, brine, mud pit and vessel tank was fluids	0	600	0	0
Milling (potential activity using WBM)	Below sea level	WBM, swarf, cement and formation rock	0	0	2 (swarf) 3 (cement) 3.5 (formation rock)	1600
Milling (potential activity using NWBM)	Below sea level	NWBM, swarf, cement and	0	0	2 (swarf) 3 (cement)	5

		formation rock			3.5 (formation rock)	
Mechanical cutting	Within the well, below the mudline	Metal and cement cuttings from well infrastructure and lubrication for the cutting tool	0	0	Negligible volumes may be released to surface sediments if cut is made at or close to the mudline	
ABWJ cutting	Within the well, below the mudline	Flocculant and grit	4 tonnes (planned to be released within the well, above the top permanent plug with small volumes entering sediments at cutting depth)	250 L (planned to be released within the well, above the top permanent plug with small volumes entering sediments at cutting depth)	Small volumes may be released to surface sediments if cut is made at or close to the mudline	

Drilled Cement

Indicative volumes of drilled cement for the well are outlined in **Table 6-16**. The shallow cement plug will preferentially be drilled out with WBM. The drilling fluids will pass through shakers to remove the cement cuttings from the drilling fluid before discharging the cement cuttings. Impacts of cement and cementing fluids are outlined further in **Section 6.6.9**.

Well Annular Fluids

Well annular fluids refer to the fluids that remain in the wellbore, or annular spaces between the casing. They may consist of weighted drilling fluid and cement-contaminated mud, seawater, barite, cement polymer, and may include small amounts of hydrocarbon. Upon wellhead removal small volumes (~1.5 m^3) of fluid exchange between the annular spaces and the ocean may occur. The exchange will not be instantaneous as the annular spaces are small and the fluids are typically heavier than seawater. In the unlikely event routine wellhead removal techniques are unsuccessful, this fluid exchange is expected to occur over time following sufficient corrosion of the wellhead.

The small volumes and non-instantaneous nature of the release of the well annular fluids is expected to result in rapid dilution to a no-effect concentration within metres of the release location.

Well Bore Clean-out and Well Kill Fluids

If permanent plugging activities are required, the well will generally be displaced from well kill brine to viscosified brine, or cleaned, which may include residual annulus fluid. A chemical clean-out pill or fluids train will be circulated between the two fluids. This will result in a discharge of fluids in accordance with Woodside's internal guidelines to ensure the potential impacts of the chemicals selected are acceptable.

Should there be clean-up brine contaminated with base oil or NWBM, it will be captured and stored on the MODU for discharge if oil concentration is less than 1% by volume, or returned to shore if discharge requirements cannot be met.

If well kill fluid fails to be bullhead pumped into the well, reservoir fluids may need to be bled off at the MODU through well control equipment (dedicated bleed off/well test spread). In this event, well control equipment will be used to separate the well kill fluids from the hydrocarbons and direct the hydrocarbons to be flared, vented or incinerated, depending on a number of factors including the volume, weather conditions, and safety requirements as documented in relevant procedures for this activity. The well kill fluids will be captured and stored on the MODU and discharged overboard if oil concentration is less than 1% by volume or returned to shore if discharge requirements cannot be met.

Milling

If permanent plugging activities are required, there is a potential additional activity where the well casing needs to be milled out (up to 100 m). This will produce milled swarf (2 m^3), drilled cement cuttings (~3 m^3) and formation rock (~3.5 m^3) and will preferentially be completed using WBM. There may be instances where NWBM is required for operational purposes to manage well stability to safe levels. The solids from the WBM or NWBM drilling fluid system (including the swarf, drilled cement cuttings and formation rock) will also pass through the shakers, to separate these solids before discharging them. Given the small volumes of solids and only limited drilling into formation rock, no oil on cuttings (OOC) discharge limits have been applied, as would be the case for a drilling activity. The estimated volume of solids discharged with residual NWBM on them is expected to be about 5 m^3 (per 100 m milled interval).

Removal (Cutting) of Well Infrastructure (Contingency)

The planned cutting depth for removal of the wellhead is approximately 3 to 5 m below the mudline. Discharges from cutting of well infrastructure using either an abrasive water jet cutting method of a mechanical cutting tool are therefore expected to be confined predominantly within the well and settle on the top of the permanent plug. During final cut through the conductor pipe, small amounts of flocculant and grit will be released below the mudline to sediments immediately surrounding the well.

Should cutting at a shallower depth be required, these discharges may be released to the seabed surface. For the mechanical cutting tool, discharges will be limited to small quantities of metal and cement cuttings from the infrastructure itself as well as small quantities of lubricant. For the abrasive water jet cutting method, discharges include a small amount of grit and flocculant. Depending on the cutting depth, pressure from the jet cutting could push some of the material up to the seabed surface causing localised smothering of benthic communities as well as create localised and temporary increases in turbidity around the well.

Impact Assessment

Potential Impacts to Environmental Values

Routine and non-routine drilling-related discharges may result in the following impacts:

- change in water quality.
- change in seabed sediment quality.
- change in seabed habitat.
- injury/mortality to marine fauna (benthic communities).

Some fluids are discharged at the sea surface (or just below); and some are discharged at the seabed. Due to water depth in the PAA (70 to 130 m), this will determine the exposure pathway, and hence potential impacts and receptors.

Drill Cuttings and Retained Fluids

Water Quality and Planktonic Communities

Drill cuttings and retained drilling fluid discharges are expected to increase turbidity and TSS levels above ambient concentrations above the seabed (top-hole well section) or in the upper surface layers (bottom-hole well sections with discharge below the water line from the MODU). Drill cuttings discharge will be generally intermittent and of short duration (over a total period of about 15 days) during drilling of the well.

Top-hole well section drill cuttings and drilling fluids (WBM) will be discharged at the seabed. The coarser material (drill cuttings) will deposit on the seabed and the finer sediment material (the WBM) will cause localised elevated TSS in the water column above the seabed surrounding the well. This reduction in water quality will be temporary (limited to the operational discharges during drilling) and subject to rapid dispersion and dilution by prevailing seabed currents.

During bottom-hole well sections, when drill cuttings with retained drilling fluids (WBM) are discharged below the water line (from the MODU), the larger particles, representing about 90% of the mass of the solids, form a plume that drops out of suspension in the water column rapidly and, deposits on the seabed. About 10% of the mass of the solids (the fines predominantly composed of drilling fluid) form a plume in the upper surface layer (depending on the depth of discharge from the MODU) that will be transported by prevailing currents away from the MODU and is diluted rapidly in the receiving waters (Neff, 2005, 2010). There is a large body of knowledge indicating a discharge of cuttings with adhered fluids diluting rapidly, finding that within 100 m of the discharge point, a drilling cuttings and fluid plume released at the surface will have diluted by a factor of at least 10,000. Further to that, Neff (2005) states that in well mixed oceans waters, the plume is diluted by more than 100-fold within 10 m of the discharge site.

Dispersion of the cuttings plume is influenced by a number of factors: particle sized distribution of the cuttings and fluids, operational discharge events and rates and metocean conditions such as ocean current speed. The case studies described in Neff (2005) used WBMs and surface current speeds of 0.15 to 0.3 m/s. As currents in the PAA are expected to be within this range, and WBMs (bulk discharge) will contribute the largest input to elevated TSS/turbidity during drilling discharges, the dispersion extent as determined by Neff (2005) is considered representative for LDA-02 tie-back activities.

Using the widely accepted dilution factor of 10,000 (Neff, 2005), cuttings (and adhered fluids) are expected to reach 100 mg/L TSS within 100 m of the MODU. Using a conservative ocean current speed of 0.1 m/s, these discharges are expected to disperse to 100 mg/L within ~16 minutes.

Given the generally low concentration of TSS outside the immediate vicinity of the discharge point, due to rapid dispersion of sediment and the short period of intermittent discharge, the plume is not expected to have more than a very highly localised reduction in water quality and area of potential ecological impact. It is not predicted to impact productivity of the water column.

The combination of low toxicity and rapid dilution of unrecoverable NWBMs discharged in association with drill cuttings are of little risk of direct toxicity to water-column biota (Neff et al., 2000).

Injury/mortality to planktonic species may occur due to a change in water quality following discharges of drill cuttings and fluids. Impacts to these organisms can be as a product of both physical and chemical alterations of water quality, predominantly in the water column.

As outlined above, using the widely accepted dilution factor of 10,000 (Neff, 2005), cuttings (and adhered fluids) are expected to reach 100 mg/L TSS within 100 m of the MODU over a period of ~16 minutes. Minimal impact to plankton (phytoplankton, zooplankton and meroplankton (larvae of invertebrates and fish) is therefore expected from the discharge of drill cuttings. Neff (2010) explains that the lack of toxicity and low bioaccumulation potential of the drilling muds means that the effects of the discharges are highly localised and are not expected to spread through the food web (of which planktonic species are the basis).

Impacts to zooplankton from turbidity are associated with variations in predator prey dynamics, which favours planktonic feeders over visual feeders (Gophen, 2015), while impacts to phytoplankton occur due to decreases in available light, therefore reducing productivity (Dokulil, 1994).

Jenkins and McKinnon (2006) reported that levels of suspended sediments greater than 500 mg/L are likely to produce a measurable impact upon larvae of most fish species, and that levels of 100 mg/L will affect the larvae of some species if exposed for periods greater than 96 hours. Jenkins and McKinnon (2006) also indicated that levels of 100 mg/L may affect the larvae of several marine invertebrate species, and that fish eggs and larvae are more vulnerable to suspended sediments than older life stages. However, dilution estimates (e.g., Hinwood et al., 1994; Neff, 2005) suggest suspended sediment concentrations caused by the discharge of drill cuttings will be well below the levels required to cause an effect on fish or invertebrate larvae (i.e., predicted levels are well below a 96-hour exposure at 100 mg/L, or instantaneous 500 mg/L exposure), beyond the immediate vicinity of the discharge.

Due to the low levels of planktonic productivity in the offshore area, plankton populations on a regional scale are not expected to be affected by drilling or well abandonment activities. In addition, due to the open nature of the marine environment of the PAA and associated environmental conditions (i.e., windy, strong currents, etc), the content and dispersive nature of drilling muds within the marine environment and the high population replenishment of these organisms, it is expected that impacts to plankton species will be limited to within tens of metres of the discharge point and return to previous conditions within a relatively short period of time. On this basis, the impacts to plankton from routine and non-routine discharges during drilling activities is slight.

Sediment Quality and Benthic Communities

Accumulation of drill cuttings, grit and flocculent on the seabed causes changes in the physical properties of the seabed sediment such as the particle size distribution (PSD), the introduction of contaminants (metals such as barium) from retained drilling fluids (WBM) and associated ecological effects.

The discharge of drill cuttings and unrecoverable fluids at the seabed during riserless top hole drilling results in a localised area of sediment deposition (known as a cuttings pile) surrounding the well site. The cuttings pile distribution may reflect prevailing seabed currents and spread predominantly downstream of the well site but overall extent from the well site is typically tens of metres. The dimensions of the cuttings pile depend on several factors, including volume (approximately 110 m^3 of top hole cuttings; **Table 6-15**) and composition of cuttings, and oceanographic conditions at the discharge location. The top-hole well section drill cuttings and retained drilling fluids (WBM) to seabed have the greatest impact to sediment quality and modification of the habitat in proximity to the well, as the solids tend to clump and settle rapidly around the discharge point (Neff, 2010).

Indicative components of the WBM system outlined in **Section 3.5.2.11** have a low toxicity. Bentonite and chemicals from the family of XC polymers (Xanthan Gum or similar) are listed as 'E' category fluids under the OCNS and considered to 'pose little or no risk to the environment'. Metals such as barium from these additives will be present in the drilling fluid, primarily as insoluble mineralised salts, and consequently are not released in significant amounts to the pore water of marine sediments and have low bioavailability to those benthic fauna which may come into contact with the discharged barite (Crecelius et al., 2007; Neff, 2008). The XC polymer and bentonite sweeps have very low toxicities and are considered by OSPAR to pose little or no risk to the environment.

As described above, the bottom hole sections are drilled after the riser is fitted. Cuttings and unrecoverable fluids are discharged below the water line at the MODU site, resulting in drill cuttings and retained drilling fluids rapidly dispersing through the water column. The larger cuttings particles will drop out of suspension and deposit in proximity to the well site (tens to hundreds of metres distance) with potential for localised spreading downstream, while the finer fluid particles will remain in suspension and will be transported further away from the well site, rapidly diluting and eventually depositing over a larger area (hundreds of metres to several kilometres) downstream of the well site. Drill cuttings from the bottom-hole sections will be smaller in volume (approximately 480 m^3; **Table 6-15**) and as determined by surface discharge, depth of seabed and time to reach seabed, result in an extended area of deposition, but a much thinner cuttings pile depth (IOGP, 2016). The fines associated with the retained drilling fluids or mud pit bulk discharge of WBM will settle over a greater extended distance as a thin, undetectable veneer on the seabed. Predicted impacts for bottom hole cuttings are generally confined to a maximum of 500 m from the discharge point (IOGP, 2016). The final deposition of drill cuttings and drilling fluids is largely determined by seabed depth and the time to drop out of suspension within the water column and deposit on the seabed. This leads to the coarser cuttings material being deposited at a location offset but closest to the well site in an area downstream and a distance up to of several hundreds of metres, with associated ecological effects within this area and the fines (predominantly drilling fluids) dispersed over a greater distance from the discharge site, typically several kilometres but with no associated ecological effects.

Benthic organisms below the cuttings pile will be buried and smothered; however, the cuttings pile is expected to be recolonised over time. Ecological impacts to benthic biota are predicted when sediment deposition is equal to or greater than 6.5 mm in thickness (IOGP, 2016). This amount of sediment deposition from top hole and bottom hole cuttings is expected to be confined to within a few hundred metres around the well location, although this depends on the nature of the cuttings, the water depth and currents of the receiving environment (IOGP, 2016). A conservative radius of 500 m representing a zone of potential ecological impact has been applied to each well location for this impact assessment. Mobile benthic fauna, such as demersal fish, may be temporarily displaced from where cuttings discharges accumulate. Furthermore, ecological impacts are not expected for mobile benthic fauna such as crabs and shrimps or pelagic and demersal fish, given their mobility (IOGP, 2016). Balcom et al. (2012) concluded that impacts associated with discharging cuttings and base fluids are minimal, with impacts highly localised to the area of the discharge deposition on the seabed. Changes to benthic communities are normally not severe. Organic enrichment can occur, leading to anoxic conditions in the surface sediments and a loss of infauna species that have a low tolerance to low oxygen concentrations, and to a lesser extent chemical toxicity near the well location. These impacts are highly localised with short-term recovery that may include changes in community composition with the replacement of infauna species that are hypoxia-tolerant (IOGP, 2016). Recovery of affected benthic infauna, epifauna and demersal communities is expected to occur, given the short duration of sediment deposition and the widely represented benthic and demersal community composition.

It is acknowledged that transport of fines (associated with the drilling fluids) will disperse beyond the zone of potential ecological impact but there are no associated ecological effects expected beyond this zone (500 m distance from each well site). Low levels of sediment deposition away from the immediate area of each well site would represent a thin layer of settled drill cuttings and drilling fluids, which will likely be naturally reworked into surface sediment layers through bioturbation (US Environmental Protection Agency, 2000). Metals such as barium from the drilling fluid additives are used as a tracer of dispersion and are typically detected beyond the zone of ecological impact but as discussed for sediment quality (above), the insoluble mineralised salts (the source of barium) have low bioavailability to benthic biota.

Impacts associated with routine and non-routine drilling discharges will be largely limited to an area surrounding the well. The low sensitivity of the benthic communities/habitats within and in the vicinity of the PAA, combined with the low toxicity of WBMs and residual NWBMs, no bulk discharges of NWBM and the highly localised nature and scale of predicted physical impacts to seabed biota, affirm that any predicted impact is considered likely but of a slight environmental consequence.

KEFs

The Lambert West Operational Area overlaps the Ancient Coastline at 125 m depth contour KEF. There is potential for interaction with drill cuttings within the KEF. However, as described above, the sediment deposition from the discharge of drill cuttings and drilling fluids will be highly localised around the well location. Within the conservatively applied zone of potential ecological impact (500 m radius) burial or smothering of epifauna and infauna will be largely confined to close proximity to the wellhead. Recovery of affected benthic infauna, epifauna and demersal fish communities is expected to occur, given the short duration of sediment deposition and the widely represented benthic and demersal community composition. The small portion of the overall KEF area that overlaps the Lambert West Operational Area, in combination with the predicted recovery of the affected benthic communities, affirms that any predicted impact is considered to be a slight, short-term effect.

Cultural Heritage

As described in **Section 4.9.1** the PAA overlaps the Ancient Coastline at 125 m depth contour KEF and, therefore, there is the potential that Indigenous Cultural features may exist and these may potentially be impacted by the discharge of drill cuttings and drilling fluids. While no cultural features have been identified in the PAA, further archaeological studies will be undertaken prior to the activity commencing to understand any potential cultural features (refer **C 4.1**).

Drilling Fluids (Bulk Discharge)

WBM may be bulk discharged at the end of specific well sections, as described above, where there is a requirement to change the drilling fluid system or the drilling fluid cannot be re-used (due to deterioration/contamination). A small quantity of WBM and NWBM residue (<1%) may also be discharged at the sea surface while cleaning the mud pits, typically at the conclusion of drilling activities or when changing between mud types.

Discharge of WBM will result in a buoyant plume of fine materials that will rapidly dilute and decrease in turbidity levels immediately away from the discharge point. WBM samples collected by Jones et al. (2021) from the mud pits just before discharge during the Greater Western Flank-2 drilling campaign were ~90% silt sized (<62.5 µm) with a mean diameter of 12 µm (gel-polymer) and 33 µm (KCl-polymer). Total suspended solid (TSS) levels in the gel-polymer mud and KCl-polymer mud were 257 g/L and 245 g/L respectively. Jones et al. (2021) used an ROV to observe mud pit discharges and reported the discharge to exit the discharge outlet as a jet of material in a distinctive cloud-like plume descending rapidly to the seabed and growing in diameter with increasing depth.

The subsea plume can be expected to disperse over a wide area (up to several kilometres), with no discernible sediment deposition on the seabed and no physical or biological impacts, particularly given the water depth of the PAA (70 to 130 m). Impacts beyond the 500 m zone of ecological impact for the well as described for drill cuttings and retained fluids discharge is not expected.

Subsea – Displacement, Completion and Well-bore Cleanout Fluids

Discharges such as displacement, completion and wellbore cleanout fluids are typically inert and of low-toxicity. These fluids are mostly brine, with a small proportion of chemical additives such as surfactants, biocide, corrosion inhibitor, oxygen scavenger, MEG and guar gum. The volume of one wellbore and subsequent discharge volume would be ~400 m³. Any change to water quality is expected to be localised and temporary. Rapid dilution due to prevailing ocean currents in the open water environment would lead to any changes in water quality such as low toxicity contaminants being temporary (only for the duration of the discharge) and reducing water quality within a short distance of the discharge location.

Removal (Cutting) of Well Infrastructure (Contingency)

The planned cutting depth is approximately 3 to 5 m below the mudline, therefore discharges from cutting of well infrastructure using either an abrasive water jet cutting method of a mechanical cutting tool are expected to be confined predominantly within the well and settle on the top of the permanent plug. During final cut through the conductor pipe, small amounts of flocculent and grit will be released below the mudline to sediments immediately surrounding the well.

Should cutting at a shallower depth be required, however, these discharges may be released to the seabed surface. For the mechanical cutting tool, discharges will be limited to small quantities of metal and cement cuttings from the infrastructure itself as well as small quantities of lubricant. For the abrasive water jet cutting method, discharges include a small amount of grit and flocculent. Depending on the cutting depth, pressure from the jet cutting could push some of the material up to the seabed surface causing localised smothering of benthic communities as well as create localised and temporary increases in turbidity around the well.

All chemicals used for infrastructure removal are assessed in accordance with the Woodside Chemical Selection and Assessment Environment Guideline.

Summary of Potential Impacts to Environmental Values(s)

Given the adopted controls, it is considered that routine discharges of drill cuttings and drilling fluids described will not result in a potential impact greater than slight, short-term impact (less than one year) on species, habitat (but not affecting ecosystems function), physical or biological attributes (i.e., Environment Impact – E).

Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)[57]***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Legislation, Codes and Standards				
No additional controls identified.				
Good Practice				
Implement Woodside's Chemical Selection and Assessment Environment Guideline: • Where Gold/Silver/E/D OCNS rating (and no OCNS substitution or product warning), chemicals are selected – no further control required. • If chemicals with a different OCNS rating, sub warning or non-OCNS rated chemicals are required chemicals will be assessed in accordance with the guideline prior to use.	F: Yes. Routinely implemented to the chemical selection process for Woodside facilities. CS: Minimal cost. Standard practice.	Selection and assessment of chemicals in accordance with the Woodside process, reduces environmental impacts associated with planned chemical discharge.	Control is a WMS requirement – must be adopted.	Yes **C 5.1**

57 Qualitative measure

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)[57]***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Chemical reviews will be performed on all previously approved chemicals to confirm potential chemical impacts are reduced to ALARP.	F: Yes. CS: Minimal cost. Standard practice.	Regular reviews will ensure chemicals selected for drilling fluids remain ALARP.	Benefits outweigh cost/sacrifice.	Yes **C 5.5**
Written NWBM justification process followed.	F: Yes. CS: Minimal cost. Standard practice.	The written justification takes onboard the technical need for NWBM use, receiving environment, cost and additional controls that may be required. By undertaking formal assessment, the potential impacts are well understood, allowing for development of control measures to reduce the consequence of NWBM use. This provides an overall environmental benefit.	Benefits outweigh cost/sacrifice.	Yes **C 8.1**
NWBM base oils selected based on expected toxicity.	F: Yes. CS: Minimal cost.	By selecting a base oil with lower toxicity, the consequence of the release on the environment is reduced.	Benefits outweigh cost/sacrifice.	Yes **C 8.2**
Backload bulk NWBM or maintain on rig for re-use.	F: Yes. CS: Minimal cost. Standard practice.	By restricting the volume of NWBM for overboard discharge, the consequence of the release on the environment is reduced. Although no change in likelihood is provided, the decrease in consequence results in an environmental benefit.	Benefits outweigh cost/sacrifice.	Yes **C 8.3**
Bulk operational discharges conducted under MODU's Permit to Work (PTW) system (to operate discharge valves/pumps).	F: Yes. CS: Minimal cost. Standard practice.	The MODU's PTW may slightly reduce the volumes of bulk discharges occurring, but it is unlikely to be significant given that bulk discharges are often operationally required and cannot be eliminated.	Benefits outweigh cost/sacrifice.	Yes **C 8.4**

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)[57]***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Displacement, brine, workover or intervention fluids contaminated with hydrocarbons will be treated prior to discharge or containment. If discharge specification is not met the fluid will be returned to shore.	F: Yes. CS: Minimal cost. Standard practice.	Ensuring <1% oil content will provide a small reduction in consequence when fluids are discharged to the environment.	Benefits outweigh cost/sacrifice.	Yes **C 8.5**
SCE used to treat NWBM cuttings prior to discharge.	F: Yes. CS: Minimal – more frequent cuttings sampling and testing.	Achieving average oil on cuttings (sections using NWBM only) discharge limit of 6.9% or less oil on wet cuttings will have a small reduction in consequence.	Benefits outweigh cost/sacrifice.	Yes **C 8.6**
In event of SCE failure (including auger) while drilling with NWBM, the initial action will be to cease drilling and determine whether to repair SCE or drill ahead until next practicable opportunity to trip out of the hole. If cuttings are discharged during dryer or auger failure, measurement of OOC to occur more frequently from shakers.	F: Yes. CS: Cost and schedule implications due to cessation of drilling.	Ceasing of drilling in the event of equipment failure will allow for time to assess feasibility of drilling ahead while still meeting residual OOC discharge requirements.	Benefits outweigh cost/sacrifice.	Yes **C 8.7**
Professional Judgement – Eliminate				
No additional controls identified.				
Professional Judgement – Substitute				
No additional controls identified.				
Professional Judgement – Engineered Solution				
Mud pit wash residue will be measured for oil content prior to discharge.	F: Yes. CS: Minimal cost. Standard practice.	Ensuring <1% oil content will provide a small reduction in consequence when residue is discharged to the environment.	Benefits outweigh cost/sacrifice.	Yes **C 8.8**
WBM drill cuttings returned to the MODU will be processed using SCE equipment.	F: Yes. CS: Minimal cost. Standard practice.	Limiting the discharge of WBMs through reuse will reduce the consequence of the using WBM.	Benefits outweigh cost/sacrifice.	Yes **C 8.9**
Drill cuttings returned to the MODU will be discharged below the water line.	F: Yes. CS: Minimal cost. Standard practice.	Discharge of drill cuttings below the water line will reduce carriage and dispersion of cuttings,	Benefits outweigh cost/sacrifice.	Yes **C 8.10**

Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)[57]***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
		thereby reducing the consequence of cuttings discharges during the Petroleum Activities Programme.		
Cuttings reinjection into formation. Cuttings are crushed, slurrified and pumped to a desired geological structure with a suitable seal, below the seabed through an annulus or tubing.	F: No. No concurrent drilling or direct sequential drilling planned which would require cuttings to be stored prior to re-injection. CS: Not considered – control not feasible.	Not considered – control not feasible.	Not considered – control not feasible.	No
Riserless mud recovery (RMR) system to return top-hole cuttings/mud from the riserless section of the well to the MODU prior to treatment onboard and discharge from the MODU (below the water line).	F: Not technically feasible due to water depth. CS: Not considered – control not feasible.	Not considered – control not feasible.	Not considered – control not feasible.	No
RMR system to return top hole cuttings from the riserless section of the well to the MODU prior to transport to an alternative discharge location or back to shore for disposal.	F: Not technically feasible due to water depth. CS: Not considered – control not feasible.	Not considered – control not feasible.	Not considered – control not feasible.	No
Return riser-in-place cuttings for disposal at another marine location or onshore for processing and land disposal (skip and ship) for whole well to reduce risk of benthic disturbance. OR Return riser-in-place cuttings for all sections drilled with NWBM for disposal onshore (to reduce potential residual oil on cuttings to environment).	F: Yes. CS: Primary cost/sacrifice of this option is the additional handling required in transporting cuttings to alternative disposal location. Particularly the health and safety risks associated with high frequency of support vessel activity alongside the rig and the amount of crane lifting required if a cuttings skip/drilling waste container system were employed. Other cost/sacrifice elements which are considered include: • Further treatment of cuttings onshore is required to	Compared to adopted control, return riser in place cuttings would achieve a reduction in cuttings/mud discharged (although discharge would still occur during riserless drilling on the basis this control is not adopted) at the well location; however, given current impact assessment and controls adopted, this would not result in a significant reduction on consequence.	Disproportionate. Given the adopted controls and low current risk rating, the high cost/sacrifice outweighs the benefit gained over the duration of the Petroleum Activities Program. Impact assessment has determined no sensitive benthic receptors in the vicinity and a low level of impact potential from overall cuttings/mud discharge therefore benefit to be gained from cuttings/mud recovery is disproportionate	No

Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)[57]***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
	ensure a standard suitable for landfill. Class II disposed locally (e.g., Karratha). Class III landfill requires transport to Geraldton or Perth. • Increased risk of unplanned vessel collision or loss of cuttings during transfer activities. • Environmental impact (suspended sediment/ sedimentation) of discharging cuttings at new location and other regulatory approvals may also be required (e.g., sea dumping permit). • Potential halt to drilling activity if transfer operations are delayed due to weather or operational issues. • Additional environmental impact incurred (air emissions) from vessel use and onshore trucking for transportation of cuttings. • Disposal via landfill and/or treatment does not eliminate an environmental impact. These options have their own impacts and therefore disadvantages if implemented.		to the risks introduced by cuttings relocation (including if an alternative system which doesn't use transport containers was implemented).	

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)[57]***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Reduce total drill cuttings by implementing slim well design.	F: No. Slim well design is not considered feasible based on the following factors: • The well design is optimised to minimise the size of hole drilled while still being able to reach the targets and meet development objectives safely. CS: Not considered – control not feasible.	Not considered – control not feasible.	Not considered – control not feasible.	No
Water quality and/or sediment monitoring of drill cuttings or drilling fluids to verify impact during activity.	F: Yes. CS: For in-water sampling utilising ROV – time and logistics for tool change out from operational tools to specialised scientific sampling tools. Additional POB to operate ROV and coordinate sampling program. Low ROV availability due to operations can limit time to perform environment monitoring. If additional ROV is required on the MODU, deck space and resources to run/store/service ROV. Resources for sample processing (space/ equipment/ personnel).	No environmental benefit would be gained by implementation of monitoring during the activity. Monitoring could be used to inform additional control measures in future drilling activities; however, there is a considerable body of existing scientific literature on potential impacts of drill cuttings and impacts are generally well understood. Furthermore, it is not guaranteed that additional controls would be feasible, or if they would provide any environmental benefit.	Disproportionate. Cost/sacrifice outweighs benefit to be gained in the context of existing environment (deepwater, open ocean communities with no proximity to sensitive benthic communities or receptors). Although adoption of this control could be used to verify EPOs associated with drilling mud and cutting discharge, alternative controls identified achieve an appropriate outcome.	No
Use SCE with secondary treatment for NWBM: Thermomechanical systems (to achieve <1% average oil on cuttings).	F: Yes – with associated infrastructure including vessels for offline storage and delivery to thermomechanical dryer. CS: The primary cost/sacrifice of this option is the monetary outlay for	A reduction in consequence would be achieved by reducing the average oil on cuttings discharged.	Disproportionate. Cost/sacrifice outweighs benefit to be gained in the context of existing environment and drilling campaign.	No

Selection of smaller core size to reduce volume of drilling cuttings.	F: No. Cannot undertake the required test. CS: Not considered – control not feasible.	Not considered – control not feasible.	Not considered – control not feasible.	No
ALARP Statement: On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts and risks of drill cuttings and fluids discharges to the marine environment. As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.				
Demonstration of Acceptability				
Acceptability Statement: The impact assessment has determined that, given the adopted controls, routine discharges of drilling cuttings and fluids to the marine environment are unlikely to result in a potential impact greater than slight, short-term impact (less than one year) on species, habitat (but not affecting ecosystems function), cultural heritage, physical or biological attributes. Further opportunities to reduce the impacts and risks have been investigated above. The adopted controls are considered good oil-field practice/industry best practice. The potential impacts and risks are considered broadly acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the impacts and risks of these discharges to a level that is broadly acceptable.

Description of Source of Impact

Cement, Cementing Fluids, Grout, Subsea Well Fluids

Cementing Fluids, Cement and Grout

Cementing fluids, including cementing mix water, may require discharge to the marine environment under various scenarios during drilling activities for the LDA-02 well.

At the commencement of the drilling campaign there may be a requirement to run a cement unit test to ensure the functionality of the cement unit and the cement bulk delivery system prior to performing an actual cement job. This test would result in a small volume of approximately 10 m^3 of cement slurry being discharged at the sea surface. The slurry is usually a mix of cement and water however may contain stabilisers or chemical additives.

When cementing the conductor and surface casings after top hole sections of a well have been drilled, cement must be circulated to the seabed to ensure structural integrity of the well. Excess cement is pumped to ensure structural integrity is achieved. If the hole is completely in-gauge and there are no downhole losses while pumping the cement, a maximum volume of 80 m^3 is estimated to be circulated to the seabed at the well location, which forms a thin concrete film on the seabed in close proximity to the well.

Wherever possible, the cement line flush volumes are included in the planned cement jobs. After each cement job, leftover cement slurry in the cement pump unit and the surface lines is flushed and discharged to the sea to prevent clogging of the lines and equipment. This is estimated at about 10 m^3 discharged. In the unlikely event a respud event is required, it would result in additional cement jobs. Also, in the rare event that the cement products become contaminated, the entire volume (~180 m^3) may need to be discharged to sea.

Cement spacers can be used as part of the cementing process, within the well casing, to assist with cleaning of the casing sections prior to cement flow through. The spacers may consist of either seawater or a mixture of seawater

and dye. The dye is used to provide a pre-indicator of cement overflow to the seabed surface, to ensure adequate cement height.

Excess dry bulks, after well operations are completed will be retained at the end of this drilling program and are planned for use during subsequent Woodside campaigns, currently anticipated to take place on this MODU immediately following the conclusion of Lambert West drilling.

Dry bulk materials generally pose little or no risk to the environment (PLONOR)[59], but barite may contain traces of heavy metals, such as mercury and cadmium. Woodside requires that concentrations of mercury and cadmium in barite be <1 mg/kg and <3 mg/kg, respectively. This conforms to the American Petroleum Institute (API) specification for drilling barite. Heavy metal analysis is conducted on individual batches of stock barite prior to mobilisation offshore. This sampling confirms that heavy metals of concern (cadmium and mercury) are within limits prescribed by API Standards.

As described in **Section 3.5.3**, if grout bags are used, after grouting activities at each span site, the downline and pump will need to be purged using seawater. This will result approximately 5 m³ (downline volume) of grout discharged to the ocean. This flushing is required once per grout site.

Subsea Fluids – Blow Out Preventors (BOP) and Well Construction Activity Control Fluids

Subsea fluids are likely to be released during drilling, including the release of BOP control fluids. Subsea control fluids are water-based hydraulic control fluids used in control systems on the subsea trees and BOPs. The BOP is required, by legislation, to be regularly function tested when subsea.

Subsea control fluids will be discharged during function testing of the BOP on installation and pressure testing.

The BOP is function tested during assembly and maintenance and during operation on the seabed as described in **Section 3.5.2.3**. As part of this testing, small volumes of BOP control fluid (generally consisting of water mixed with a glycol based detergent or equivalent water-based anti-corrosive additive) are released to the marine environment.

Each time a pressure and function test is undertaken, approximately 3620 L of water-based fluid is released to the marine environment, of this approximately 4% is control fluid additive. BOP operation includes function and pressure testing approximately every 21 days, and a function test (approx. 2665 L) approximately every seven days, excluding the week a pressure test is conducted.

Subsea Fluids – Displacement Fluids

As required throughout activities with the riser connected, the well will be displaced from one drilling fluid system to another. A chemical clean-out pill or fluids train will be circulated between the different fluids. This will result in a discharge of operational fluids in accordance with the Woodside internal guidelines.

Produced/Reservoir Water

If well unloading activities were to occur, a temporary production system water filtration treatment package will be used to treat produced/reservoir water before discharge. Prior to discharging, the fluids are cycled through an oilbond filtration system and gauge tank. Water filtration is standard practice for well unloading operations and the produced water will be treated to meet 30 ppm OIW. Fluids that cannot be treated or flared will be sent onshore in tanks for disposal.

Impact Assessment

Potential Impacts to Environmental Values

Pelagic and benthic habitats and communities in the PAA are considered to be of low sensitivity and reflective of the wider NWMR. No known regionally significant benthic or infauna habitat occur in the area. The Continental Slope Demersal Fish Communities and Ancient Coastline at 125 m depth contour KEF overlaps the PAA, (**Section 4.7**); however, impacts to values and sensitivities of these KEF are not expected due to the small physical footprint of the discharges, coupled with the low toxicity of cementing and subsea fluids used for the Petroleum Activities Program. The likelihood of any significant impact to marine biota is subsequently considered to be low.

Cement and Grout

Sediment Quality and Benthic Communities

Impacts of cement and grout on the marine environment are predominantly associated with localised burial of benthic biota in the direct physical footprint of deposition. Cement operations and grout discharge during drilling involve routine and non-routine discharges that can result in turbidity in the water column. Reduction in water quality will be temporary (limited to the cement operational discharges during drilling) and subject to rapid dispersion and dilution by prevailing currents. Modelling of cement discharges for another offshore project (BP Azerbaijan, 2013) was used because it provides an appropriate, but conservative, comparison of the potential extent of exposure from this activity. In this study, two hours after the start of discharge, plume concentrations were determined to be between 5 and 50 ppm with the horizontal and vertical extents of the plume ~150 m and 10 m, respectively (BP Azerbaijan, 2013).

59 Barite (as barium sulphate) is on the OSPAR List of Substances Used and Discharged Offshore which are Considered to Pose Little or No Risk to the Environment (PLONOR). The List is available at: https://www.cefas.co.uk/media/p3sbu3bn/ospar-list-of-substances-used-and-discharged-offshore-which-are-considered-to-pose-little-or-no-risk-to-the-environment-plonor-update-2021.pdf

Five hours after ceasing the discharge, modelling indicates that the plume will have dispersed to concentrations <5 ppm.

Cement is the most common material currently used in artificial reefs around the world and is inert. The potential for toxicity is associated with chemical additives that may be added to cement mixtures. Therefore, the toxicity associated with the discharge of cement is limited to the subsurface release of cement (not discharge of slurrified or dry cement). Once the cement has hardened, chemical additives are locked into the cement (Terrens et al., 1998) and not expected to pose any toxicological risk to benthic biota from leaching or direct contact. Most cement discharges that will occur during the drilling activities will be at the seabed during cementing of the casing. Once overspill from cementing activities hardens, the physical sediment properties of the area directly adjacent to the well (10 to 50 m) will be permanently altered (Terrens et.al., 1998). The potential disturbance area is an estimated 0.007 km². Cement discharges at the seabed will overlap with the highest deposition of drill cuttings and drilling fluids. The highly localised physical footprint at the well site is not expected to affect the overall diversity or ecosystem function of the benthic communities of the area.

The potential impacts to benthic communities caused by smothering from a surface release of cement or a seabed release of grout are expected to be significantly less, due to small volumes, intermittent nature of these discharges, and high potential for dispersal by ocean currents. This impact on soft sediment communities is not expected to affect the diversity or ecosystem function in this area and is only considered a short-term impact.

KEFs

The Lambert West Operational Area overlaps the Ancient Coastline at 125 m depth contour KEF. There is potential for interaction with a surface release of cement within the KEF. However, as described above, the surface release of cement or the seabed release of grout will be highly localised around the well location. Recovery of affected benthic infauna, epifauna and demersal fish communities is expected to occur, given the small volume and dispersion, and the widely represented benthic and demersal community composition. The small portion of the overall KEF area that overlaps the Lambert West Operational Area, in combination with the predicted recovery of the affected benthic communities, affirms that any predicted impact is considered to be a slight, short-term effect.

Cultural Heritage

As described in **Section 4.9.1**, the PAA overlaps the Ancient Coastline at 125 m depth contour KEF and therefore there is the potential that Indigenous Cultural features may exist and these may potentially be impacted by the surface release of cement or seabed release of grout. While no cultural features have been identified in the PAA, further archaeological studies will be undertaken prior to the activity commencing to understand any potential cultural features (refer **C 4.1**).

Cementing Fluids, Subsea Well Fluids (BOP Control Fluids and Well Displacement Fluids) and Other Unused Bulk Products

All chemicals that may be operationally released or discharged to the marine environment by the Petroleum Activities Program are evaluated using a defined framework and set of tools to ensure the potential impacts of the chemicals selected are acceptable, ALARP and meet Woodside's expectation for environmental performance. Therefore, any chemicals selected and potentially released are expected to be of low toxicity and biodegradable. Additionally, where cements have been mixed in excess and cannot be reused or returned to shore, these will be turned into a slurry. As chemicals have initially been chosen based on the environmental performance and based on an ALARP assessment, additional dilution prior to discharge further reduces the environment impact to water quality, sediment quality and marine benthic and/or infauna communities. Given the minor quantities of routine and non-routine planned discharges, short discharge durations and the low toxicity and high dispersion in the open, offshore environment, any impacts on the marine environment are expected to be slight and short-term.

Summary of Potential Impacts to Environmental Values(s)

The overall impact significance level for routine and non-routine discharges of cement, cementing fluids, and subsea well fluids is E based on slight, short-term impact (less than one year) on species, habitat (but not affecting ecosystems function), physical or biological attributes.

Good Practice				
Implement Woodside's Chemical Selection and Assessment Environment Guideline: • Where Gold/Silver/E/D OCNS rating (and no OCNS substitution or product warning), chemicals are selected – no further control required. • If chemicals with a different OCNS rating, sub warning or non-OCNS rated chemicals are required chemicals will be assessed in accordance with the guideline prior to use.	F: Yes. Routinely implemented to the chemical selection process for Woodside facilities. CS: Minimal cost. Standard practice.	Selection and assessment of chemicals in accordance with the Woodside process, reduces environmental impacts associated with planned chemical discharge.	Control is a WMS requirement – must be adopted.	Yes **C 5.1**
Chemical reviews will be performed on all previously approved chemicals to confirm potential chemical impacts are reduced to ALARP.	F: Yes. CS: Minimal cost. Standard practice.	Regular reviews will ensure chemicals selected for drilling fluids remain ALARP.	Benefits outweigh cost/sacrifice.	Yes **C 5.5**
Bulk operational discharges conducted under MODU's Permit to Work (PTW) system (to operate discharge valves/pumps).	F: Yes. CS: Minimal cost. Standard practice.	The MODU's PTW may slightly reduce the volumes of bulk discharges occurring, but it is unlikely to be significant given that bulk discharges are often operationally required and cannot be eliminated.	Benefits outweigh cost/sacrifice.	Yes **C 8.4**
Displacement, brine, workover or intervention fluids contaminated with hydrocarbons will be treated prior to discharge or contained. If discharge specification is not met the fluid will be returned to shore.	F: Yes. CS: Minimal cost. Standard practice.	Ensuring <1% oil content will provide a small reduction in consequence when fluids are discharged to the environment.	Benefits outweigh cost/sacrifice.	Yes **C 8.5**
Professional Judgement – Eliminate				
Do not use BOP control fluids.	F: No. BOP and Xmas tree control fluids are critical to the operation of the BOP and Xmas trees. CS: Not considered, control not feasible.	Not considered, control not feasible.	Not considered, control not feasible.	No
Return bulk cement, barite and bentonite for onshore disposal.	F: No. The technical requirements to be able to undertake this safely are unresolved due to:	Not considered, control not feasible.	Not considered, control not feasible.	No

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)[60]***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
	significant health and safety risks with tank high pressure differentials to transfer material onshore. high health and safety risk with the vessel to waste truck transfer due to tank corrosion concerns and pressure relief valve issues. CS: Not considered. Control not feasible.			
Excess dry bulks retained on MODU.	F: Yes. Contract in place for subsequent offshore operations therefore dry bulk retained onboard. CS: Minor.	Retaining excess dry bulks onboard for subsequent works would eliminate the bulk discharge to the marine environment and eliminate the consequence of impacts from such activities.	Benefits outweigh cost/sacrifice.	Yes **C 9.1**
Sampling/analysis of stock barite to ensure acceptable levels of heavy metals (cadmium and mercury).	F: Yes. CS: Minimal cost. Standard practice.	Barite may contain heavy metals, such as cadmium and mercury, depending on their geological origin. Limiting the concentrations of cadmium and mercury is consistent with industry good practice. Limiting cadmium and mercury concentrations in barite reduces the environmental risk from discharges of barite to the environment.	Benefits outweigh cost/sacrifice.	Yes **C 9.2**
Unused MEG/brine will be transferred for future use or returned to port/staging point for disposal where possible.	F: Yes. CS: Minor.	Transfer of excess MEG/brine package for alternate project use or onshore disposal would eliminate the bulk discharge to the marine environment and eliminate the likelihood and consequence of impacts from such activities.	Benefits outweigh cost/sacrifice.	Yes **C 9.3**

ALARP Statement: On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts and risks of cement, cementing fluids, and subsea well fluids. As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.				

Demonstration of Acceptability

Acceptability Statement

The impact assessment has determined that, given the adopted controls, cement, cementing fluids, subsea well fluids and unused bulk products discharges are unlikely to result in an impact greater than slight, short-term impact (less than one year) on species, habitat (but not affecting ecosystems function), physical or biological attributes. Further opportunities to reduce the impacts have been investigated above. The adopted controls are considered good practice.

The potential impacts are considered broadly acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the impacts of these discharges to a level that is broadly acceptable.

Table 6-17: Consideration of control measures outlined in Article 9(5) of the Minamata Convention

Measures in Article 9(5) of the Minamata Convention	***Justification for Implementation or Rejection***
Release limit values to control and, where feasible, reduce releases from relevant sources.	The performance standard limiting the concentration of mercury in barite aligns with API standards and limits the release of mercury to the environment. Woodside will only discharge dry bulk barite if it cannot be used for subsequent drilling activities. In this instance, contracts are in place for subsequent operations and dry bulks will be retained onboard.
The use of best available techniques and best environmental practices to control releases from relevant sources.	Woodside has reviewed the *Guidance on Best Available Techniques and Best Environmental Practices - Minamata Convention on Mercury* (United Nations Environment Program, 2019). The best available techniques described in this document only apply to facilities listed in Annex D[61] of the Minamata Convention, which excludes offshore oil and gas drilling facilities; none of the best available techniques are applicable to the waste generation activity. Using best available techniques is intended to prevent or limit the release of mercury to the environment. This intent is met by the performance standard limiting the concentration of mercury in barite.
A multi-pollutant control strategy that would deliver co-benefits for control of mercury releases.	Woodside has identified a subsequent contract at the conclusion of this drilling activity and will retain dry bulk onboard. This eliminates dry bulk discharges of barite to the environment from this campaign. Woodside's performance standard limiting mercury concentrations in barite also limits the concentration of cadmium, which is also a recognized toxicant. This performance standard hence is a multi-pollutant strategy.
Alternative measures to reduce releases from relevant sources.	No other opportunities to reduce releases of mercury were identified.

61 Facilities listed in Annex D of the Minamata Convention comprise coal-fired power plants, coal-fired industrial boilers, smelting, and roasting processes used in the production of non-ferrous metals, waste incineration facilities, and cement clinker production facilities.

Description of Source of Impact

Atmospheric emissions generated during the Petroleum Activities Program can be classified into two categories:

- Atmospheric pollutants (non-greenhouse gas emissions) are gases and particulates from an activity, or piece of machinery, which have a recognised adverse effect on human health and/or flora and fauna. The main emissions responsible for these effects include carbon monoxide (CO), oxides of nitrogen (NO_x), sulphur dioxide (SO_2), particulate matter less than 10 microns (PM10), non-methane volatile organic compounds (VOCs), BTEX (benzene, toluene, ethylbenzene and xylenes), which are specific VOCs of interest.
- Greenhouse gas (GHG) emissions refer to gases that trap heat within the atmosphere through the adsorption of longwave radiation reflected from the earth's surface. The main gases associated with this effect include carbon dioxide (CO_2), methane (CH_4) and nitrous oxide (N_2O). Other greenhouse gases include perfluorocarbons (PFCs), hydrofluorocarbons (HFCs) and sulphur hexafluoride (SF_6). There are considered to be both direct and indirect GHG emissions (**Table 3-5**).

In this section greenhouse gases are estimated using the National Greenhouse and Energy Reporting (NGER) Measurement Determination 2008 (as amended including 100-year Global Warming Potential).

Direct Atmospheric and Greenhouse Gas Emissions

Direct atmospheric emissions from the Angel facility during the Petroleum Activities Program include emissions from equipment and generators, flares, fugitives and process vents. Direct emissions and combustion products typically include CO_2, water vapour, NO_x, SO_2, methane, refrigerant gases, particulates and VOCs.

The emissions estimates presented in **Table 6-18**, **Table 6-19**, **Table 6-20** and **Table 6-21** are derived from data collected during the 2022/23 financial year and adjusted for the next 5-year period. They are considered representative of the next 5-year period of the Angel Operations EP, approximately 2024 up to 2029[63]. The 2022/23 year using Lambert Deep is considered an appropriate baseline year because it included the startup of Lambert Deep, and as the decline in Lambert Deep occurs, will be replaced with production from Lambert West and therefore, the overall production and emissions rates are expected to be within that of 2022/23. Variance within the period may occur, for example, reduced hydrocarbon throughput from field decline is expected to proportionally decrease the emissions from flaring. Alternatively, increased platform visitation could increase emissions.

Fuel Emissions

No fuel gas is used on the Angel facility for the generation of power, since electricity is supplied from NRC. During staffed operations, diesel is used on the riser platform for the operation of the crane and survival craft.

Diesel use on the facility (excluding support vessels) in 2022/23 was 8 m³, the combustion of which equated to the emission of ~22 tonnes of CO_2 equivalent. It is estimated that up to 15 m³ of diesel will be combusted per year over the EP period and until EOFL. Diesel use during extended, continuously crewed periods may result in up to 75 m³ per annum.

The forecast annual emissions from fuel combustion on the facility has been estimated using emissions factors (as per National Pollutant Inventory (NPI) Emission Estimation Techniques (EET)) and are presented in **Table 6-18**.

Table 6-18: Estimated annual emissions from diesel combustion at the facility under steady state operations (excluding support vessels)

Emission type	***Estimated annual CO_2 eq. emissions from diesel combustion (tonnes)[1]***
CO_2	40.5
CH_4	0.06
N_2O	0.12
Total CO_2 eq	40.6
NOx	0.80
SOx	0

[1] Based on combustion of 15m³ of diesel per year.

Flaring

During normal operations, hydrocarbon gas is flared from the Angel facility via the HP and LP flare systems. Gas flaring emits gases to atmosphere and consumes natural gas, a non-renewable resource. Emissions and combustion products include CO_2, NO_x, SO_2, methane, particulates, and VOCs. Incomplete combustion under certain scenarios may also generate dark smoke.

The release of hydrocarbon gas to atmosphere by flaring is an essential practice, primarily for safety requirements. Operational flaring is comprised of two elements, being:

- normal operational flaring associated with flare system purge and pilot, process flows and glycol regeneration.
- non-routine flaring that may result from activities such as planned shutdowns and emergency shutdown testing, and unplanned shutdowns and emergency shutdowns, production restarts, equipment outage/failures, subsea flowline depressurisation and commissioning activities (**Section 3.5.4**).

During flaring, the burnt gas generates mainly water vapour and CO_2. Based on 2022/2023 flaring from production of Lambert Deep, it is estimated that up to 9000 t of gas is flared per year including water vapour, inert gas and hydrocarbon gas in routine and non-routine activities, such as planned shutdowns or production trips could be flared from Angel Facility once Lambert West is tied in. Flaring volumes vary as a result of production rates and non-routine activities. HP flaring may occur periodically during suspension, with reduced LP flaring. The forecast annual atmospheric emissions from flaring were estimated using the NPI EET (**Table 6-19**). The Lambert West start up is expected to have no planned impact to flaring.

Table 6-19: Estimated annual emissions from flaring at the facility.

Component	Estimated flaring emissions (tonnes CO_{2eq})
Flared gas quantity	9000
CO_2	24,300
CH_4	1197
N_2O	234
Total CO_{2eq}	25,731
NO_x	13.5
SO_x	0
CO	78.3

Reference: NGER Measurement Determination 2008 and NPI EET Manual for Oil and Gas v2.0 2013, Table 8.

Note: SO_x emissions have not been estimated, as the estimation technique from the NPI EET does not account for SO_x. Additionally, the diesel used at Angel is very low in total sulphur and therefore SO_x is not a contaminant of concern in the regional airshed.

Non-routine Venting of Process Hydrocarbons via Flare System

In the unlikely event the flares are extinguished (for example during a cyclone) or unavailable (such as after a major shutdown prior to system ramp-up), the hydrocarbon gas discharged via the flare system may initially not be combusted during the period required to purge the flare and re-establish flare ignition. This may result in the short-term (days) low-rate release of methane to atmosphere. The flare is monitored via CCTV from NRC CCR. As a contingency, the flare can be manually ignited (in the event the pilots are extinguished) to minimise cold venting. However, the flare is not known to have unintentionally extinguished during the asset life (since 2008). Intermittent venting from the facility represents a minor source of atmospheric emissions and is not considered to pose a risk beyond the routine air emissions described in this section.

Fugitive Emissions

Fugitive emissions can occur from pressurised equipment, and are inherent in design, emitted by infrequent operational activities, or can be caused by unintentional equipment leaks. Sources can include valves, flanges, pump seals, relief valves, vents, sampling connections, process drains, open-ended lines, casing, tanks and other potential leak sources from pressurised equipment. Fugitive emissions are, by their nature difficult to quantify. An approach specified by the National Greenhouse and Energy Reporting Scheme (NGERS), is to indirectly estimate the amount of emissions based on platform type (i.e., shallow water or deep water).

As much of the safe operation of the facility relies on the effective containment of hydrocarbons, the volumes of routine and non-routine fugitive emissions are considered to be small (refer to **Section 6.7.3** for potential atmospheric unplanned hydrocarbon releases associated with accidents, incidents and emergency situations). The National Greenhouse and Energy Reporting (Measurement) Determination 2008 estimates fugitive emissions from shallow water offshore platforms (e.g. Angel platform) to be 1,747.1 t CO_2e p.a. of methane and 7.1 t CO_2e p.a. of carbon dioxide.

Discrete relatively small volumes of packed gases and charged systems, including non-ozone depleting refrigerant gases, are used across the facility and vessels which have potential for small volume leaks (typically less than 100 kg per isolatable inventory). Such gases are used in the HVAC and refrigerant systems on the facility and vessels.

The facility is fitted with several portable fire extinguishing units utilising CO_2. The facility does not have any gaseous fire extinguishing systems containing synthetic greenhouse gases or ozone depleting substances.

Indirect Emissions

Tie-back Activities

MODU, Vessel and Helicopter Operations

Atmospheric emissions during tie-back activities are generated by project vessels from internal combustion engines (including all equipment and generators) and incineration activities (including onboard incinerators) during the Petroleum Activities Program for standard operations, excluding drilling waste.

Atmospheric emissions generated during these operations will include SO_x, NO_x, particulates and VOCs. SO_x and particulate matter emissions are heavily influenced by the fuel used and its relative sulphur content, MGO usually having a lower sulphite content than marine diesel oil (MDO) or heavy fuel oil (HFO).

NO_2 emissions from routine MODU power generation for an offshore project were modelled previously by another operator (BP Azerbajan, 2013). NO_2 was the focus of the modelling, on account of the larger predicted emission

63 End of field life is estimated to be 2027, however is dependent on reservoir performance, therefore up to five years of operations is included.

volumes compared to the other atmospheric emissions, and the potential for NO_2 to impact on human health (as a proxy for environmental receptors). The model demonstrated that atmospheric emissions generated by MODU operations may increase ambient NO_2 concentrations by 1 µg/m^3 (0.001 ppm) within 10 km of the source and 0.1 µg/m^3 (0.0001 ppm) within 40 km of the source. This represents an increase of 2% over typical background concentrations within 40 km, with air quality remaining well below the WHO air quality guideline for NO_2 of 40 µg/m^3 annual mean. As NO_2 is the main emission that poses a threat to receptor health, it is considered conservative to use the above studies to justify potential impacts to receptors. As such, studies into the attenuation of other gasses emitted are not evaluated.

A moored MODU may be used for the drilling campaign resulting in less fuel needed for station keeping, however DP or hybrid DP MODU may be used due to the depth of the PAA or in the event of adverse weather conditions. Other vessels required for the Petroleum Activities Program (e.g., installation vessels) may use DP to conduct installation or intervention activities. Based on fuel consumption information from the DPS-1 MODU on previous Woodside drilling campaigns and the expected activity duration plus mobilisation, it is estimated that a DP MODU will consume approximately 44 t/d when compared to similar scenarios. Based on the information available it is expected that up to approximately 13,060 tonnes of fuel may be used from MODU activities (70 total days for the drilling and completions of the single well. Other DP vessels associated with the subsea installation and contingent well intervention activities may use up to 315 t (based on 21 days and a rate of 15 t/day). GHG emissions from the MODU, vessel and helicopter operations are expected to be approximately 10,418t CO_2-e (**Table 6-20**).

Support vessels, refuelling vessel and helicopters will support the Petroleum Activities Program, although emissions produced will be substantially less than those produced by the MODU/installation vessels. Total fuel consumption for support vessel activities (based on four general offshore supply vessels on standby at 2.5 t/day) is expected to be up to 2814 t CO_2-e for drilling activities, subsea installation and contingent well intervention activities. Helicopter operations during drilling activities may consume up to 286t CO_2-e, based on ~1.5 t/day. The potential for multiple helicopter runs has been considered in greenhouse gas summations (**Table 6-20**).

Well Kick

During drilling of the well and contingent well intervention activities, a kick may occur. A kick is an undesirable influx of formation fluid into the wellbore. The resultant effect would be a release of a small volume of greenhouse gases via the degasser to the atmosphere during well control operations, known as 'venting'. Venting is required to ensure well integrity is maintained in the event of a kick, thereby avoiding an emergency condition. The total volume of GHG emissions from well kicks and venting is estimated to be approximately 378t CO_2-e (**Table 6-20**).

Well Flowback (Flaring) and Contingency Activities (Venting)

The preferred well unloading method for the tie-back activities is to direct all fluids to the Angel facility. However, if this activity is not practicable, contingent well unloading to the MODU may result in gas, condensate, base oil and methanol in the wellbore to be flared and efficiently burned. The flare may be extinguished due to water ingress, lack of pilot (propane), weather impact or equipment failure resulting in cold venting of gas from the flare for several minutes. After the objectives of the well testing and flowback are achieved, the flow is stopped and the well may be cleaned using a brine that can include several chemicals, such as biocide and surfactant. Approximately 48 hours ~1.5 mmscf of gas, 534 bbl condensate may be flared, or 529t CO_2-e.

Mud Degassing

Methane emissions may be released during the period of intersection with the reservoir. Small amounts of gases such as methane may dissolve in drilling fluids and be released to the atmosphere as fluids are degassed and recirculated. These emissions have been estimated using American Petroleum Institute factors and are negligible over the activity.

Cold Venting of Residual Gas

During well intervention activities there are several scenarios that may cause small amounts of gas to be vented directly to atmosphere in an intrinsically safe manner via the choke manifold onboard the WIV. Due to the small quantities of gas, it is not viable to flare this gas. These sources of direct gas emissions include:

- Riser disconnect – Riser will be disconnected at the end well intervention activities. Pressurised gas will be vented to the atmosphere.
- Wireline tool string and tool change – During the well intervention activities it is estimated that there will be 3 to 5 tool changes per well requiring intervention. Tool changes will cause a small quantity of venting to the atmosphere via the wireline lubricator.
- Surface returns – Small volumes of hydrocarbon gas from annular spaces will be cold vented via a choke manifold in a controlled and safe manner from the WIV.

Table 6-20: Greenhouse gas emissions and sources from tie-back activities

Source	*GHG Emissions (CO2-e t)*
MODU Activities	
MODU operations	8330
4 support vessel operations	1908

Helicopter operations	286
Well kick - drilling operations (60bbl Cold vent)	0.5
Subsea Installation and Commissioning	
4 support vessels	763
Primary installation vessel	763
Intervention/Contingency Scenarios	
Intervention Vessel	858
2 support vessel operations	143
Contingent flaring	3.5
Well kick and flowback	529
Vented per well	378
Cold venting – riser disconnect (~1800PSI)	176
Cold venting – tool change (5 changes)	<1
Cold venting – surface returns	<1
Cold venting – removal of tree cap	<1
Total GHG Emissions	**13,231**

GHG and Atmospheric emissions from North Rankin Complex

NRC provides power to the Angel Facility via a subsea cable. NRC has three producing trains and 100% compression. For the Angel Facility indirect emissions attributed to NRC include gas/diesel turbines generating power. Flaring, venting and fugitive emissions from NRC are excluded from consideration of Angel indirect emissions, as the main sources of those emissions are from production of gas.

Indicative energy use by the Angel facility when producing between 2022-2023 was 0.8 to 1.2 MW, a reduction from approximately 0.9 to 2 MW over 2016 to 2020. When production is offline and the platform is staffed, the approximate baseload energy consumption of the platform use is 0.2 MW, which is approximately 1.7% of typical NRC generation.

GHG emissions from NRC attributed to Angel based on a percentage of production are listed in **Table 6-21**.

Greenhouse Gas and Atmospheric Emissions from Support Vessels and Helicopters

GHG and atmospheric emissions are generated by vessels and helicopters supporting Angel. Vessel emissions include those from internal combustion engines and fugitives. Atmospheric and GHG emissions from support vessels vary depending on the nature of activities being undertaken; for example, travelling or “steaming” to a destination at low speed uses less fuel and generates lower atmospheric and GHG emissions than high speed steaming. Emissions generated during safety related vessel standby activities, holding station using DP during loading and unloading of materials to the facility or undertaking subsea IMMR work also vary. Vessel Masters control day to day operations that determine support vessel emissions. Woodside has the potential to influence fleet level approach to support vessel emissions through contracting activities. Refrigerant gases are used onboard supply vessels in small quantities.

Expected annual GHG emissions for vessel and helicopter activities have been estimated to be:

- 2500 t CO_2-e for support vessels, based on diesel consumption in 2020 (some vessels are dual-fuel and can use LNG, if using LNG as fuel, combustion emissions are expected to be lower)
- 300 t CO_2-e for IMMR vessels, based on diesel consumption.
- 200 t CO_2-e for helicopters, based on Jet A1 fuel consumption in 2022/23

Indirect emissions from these sources are expected to be relatively constant throughout the EP period and until EOFL.

GHG Emissions from Processing and Product End-use associated with Angel

Indirect emissions associated with Angel result from hydrocarbon processing (onshore), third party transport of products, regassification, distribution and combustion by end users. Indirect GHG emissions associated with Angel operations were estimated using historical emissions intensity methods (**Table 6-21**). Key influences impacting indirect GHG from Angel include:

- Total production – indirect emissions are proportional to total production, which varies with shutdown activity, new field tiebacks or gradual reservoir decline.
- Composition of produced gas – onshore emissions are proportional to reservoir CO_2.

- Split of saleable products from KGP – the proportion of hydrocarbons from Angel sold as LNG, condensate, domestic gas and LPG varies. Each product requires differing amounts of energy to process to the point of sale and varies based on reservoir composition, field contribution and commercial reasons.

Indirect emissions associated with annual Lambert Deep and Lambert West production via Angel, including those apportioned at KGP, and from transport and customer combustion, are estimated to be approximately 4.8 Mt CO_2-e per annum, totalling up to 23.8 Mt CO_2-e at expected EOFL. This is based on operational data for production from Lambert Deep and expanded to include production from Lambert West. Emissions associated with power generation from NRC are estimated to be up to 0.010 Mt CO_2-e per annum and 0.051 Mt CO_2-e at full production rates until the estimated EOFL.

Woodside's current forecast is that the reservoir produced via Angel will decline toward EOFL. Overall, the trend of hydrocarbon production and indirect emissions from onshore processing and third-party transport, regasification, distribution, and end use are expected to also decline.

Table 6-21: Indirect and direct greenhouse gas emissions associated with Angel production.

Source of Impact	*Annual estimated emissions (Mt CO_2-e)*	*Total possible emissions for EP period (Mt CO_2-e)*
Direct Emissions		
Fuel, flaring and fugitives	0.028	0.14
Indirect Emissions		
North Rankin Complex (electrical generation)	0.010	0.051
Onshore hydrocarbon processing	0.47[1]	2.37
Vessels and helicopters	0.003	0.015
Third party transport of products, regassification, distribution and end use	4.30[2]	21.48

[1] Based on 2022/2023 maximum monthly production and KGP emissions intensity apportionment calculation.

[2] Source: EcoInvent 3.5 database and National Greenhouse and Energy Reporting (Measurement) Determination 2008. EcoInvent v3.5 represents a large collection of inventory data. It has been recognised as emission factor source for the European Union Renewable Energy Direction greenhouse gas methodology and is aligned to the principles of the NGERs methodology.

The precise shape and pace of the energy transition is uncertain. It is expected to vary across countries because they have different starting points, development requirements, resources and capabilities. However, the scale of the transition is clearer, as it will take many trillions of dollars, invested over decades. Today, Woodside has a portfolio of oil and gas assets. We are also diversifying our portfolio by investing in new energy products and lower-carbon services that can avoid or reduce customer emissions. We see an ongoing role for gas from the Angel facility to support our customers' plans to secure their energy needs, while they reduce their emissions.

Impact Assessment

Air Quality

Facility, tie-back activities and vessel routine and non-routine emissions, predominantly routine flaring, have the potential to result in localised, temporary reduction in air quality, generation of dark smoke and contribution to greenhouse gas emissions. Potential impacts of emissions depend on the nature of the emissions, as well as the location and nature of the receiving environment.

Facility design (including the rapidly dispersive characteristics of the gas turbine exhausts, flare and other emissions), the estimated level of pollutants in the emissions, and the absence of elevated background ambient levels have been considered in estimating the potential for interaction with human and environmental sensitivities. The PAA is in a remote offshore location, with no expected adverse interaction with populated areas or sensitive environmental receptors associated with air emissions.

There is a foraging BIA for the wedge-tailed shearwater overlapping the PAA; as such, wedge-tailed shearwaters may occur near to the facility airshed. Birds (including migratory birds) are also known to opportunistically roost on the riser platform. Given the highly dispersed nature of facility air emissions, no adverse impacts to birds are anticipated due to air emissions.

Potential impacts are expected to be temporary, localised air quality changes, limited to the airshed local to the riser platform. Air emission impacts are not expected to have direct or cumulative impacts on sensitive environmental receptors, or above National Environmental Protection (Ambient Air Quality) measures and are expected to disperse well before the nearest populated area (Dampier).

The flare and potential black smoke resulting from emissions may impact visual amenity. The offshore location of the Petroleum Activities Program is not directly visible from the nearest landfall (Dampier Archipelago, 94 km south of the

PAA at the closest point). Hence, no impacts to visual amenity for residential communities are expected. Visual amenity impairment to tourism activities is not expected.

Greenhouse Gas Emissions – Habitat and Biological Communities, Protected Species, Key Ecological Features, Protected Places, Socioeconomic and Cultural Environment

This impact assessment considers the potential impacts of climate change on sensitive receptors, including MNES within Australian jurisdictions. Climate change impacts cannot be attributed to any one activity or one project, including the Angel Facility or tie-back of LDA-02, as they are instead the result of global GHG emissions, minus global GHG sinks, that have accumulated in the atmosphere since the industrial revolution started. They do not take into account the net impact of each project or activity. There is no direct link between greenhouse gas emissions from the Angel facility, Angel project or NRC and climate change impacts.

Climate change impacts upon Australian receptors cannot be linked to the Angel facility but are instead the result of the accumulation of net greenhouse gas emissions in the atmosphere. The accumulation of net greenhouse gas emissions in the atmosphere is, in turn, influenced by global energy demand and the composition of the global energy mix. Although the Angel facility cannot be linked to climate change impacts; the following contextual evaluation is provided.

Greenhouse gas emissions associated with Angel are estimated to be ~24.06 Mt CO2-e till EOFL, which ~3.23 Mt CO2-e may originate in Australia. For the purposes of comparison, assuming this total was split evenly across operational years (2024 to 2029; up to 5 years) the ~0.8 Mtpa CO2-e would represent ~0.17% of national Australian emissions (463.9 Mt CO2-e during 2022) (DCCEEW, 2023f). These emissions will not materially or substantially contribute to either Australia's GHG emissions or global GHG emissions.

Climate science is a rapidly evolving field in which new observations continue to deepen understanding of the current and potential impacts of global warming, and the possible pathways for mitigation and adaptation (Woodside, 2023a).

The IPCC is the United Nations body for assessing the science related to climate change and finalised the Sixth Assessment Report (AR6) in 2023. This consists of three Working Group contributions and a Synthesis Report. A summary of outcomes of the working group's contributions comprises a range of matters, which amongst others include:

- The AR6 Working Group I (AR6-WG1) report stated that it is unequivocal that there is human-induced warming. It also stated that increased atmospheric carbon dioxide (CO2) levels, generated by human activity, are the largest driver of warming over the longer term, and that there are a range of factors, including emissions of methane, which increase warming in the short-term.
- The AR6-WG2 report stated that human-induced climate change, including more frequent and intense extreme events, has caused widespread adverse impacts and related losses and damages to nature and people, beyond natural climate variability. It stated that global warming, reaching 1.5°C in the near-term, would cause unavoidable increases in multiple climate hazards and present multiple risks to ecosystems and humans. The report noted that societal choices and actions implemented in the next decade will determine the extent to which medium- and long-term pathways will deliver climate resilient development.
- The AR6 Working Group III (AR6-WG3) report provided an updated global assessment of climate change mitigation progress and pledges and examined the sources of global emissions. It explained developments in emissions reduction and mitigation efforts and assessed the impact of national climate pledges in relation to long-term emissions goals. More than 2000 quantitative emissions pathways were submitted to the IPCC, of which 1202 scenarios included sufficient information for assessing the associated warming. The report found that there are many pathways in the literature that likely limit global warming to 2°C with no overshoot, or to 1.5°C with limited overshoot. These variations occur because, while climate science is able to calculate a 'carbon budget' of net emissions before any particular temperature outcome is reached, the allocation of this budget between different human activities requires additional judgements about for example technology, economics, consumer preferences and policy choices.

For further information related to Woodside's approach to climate change, please see Section 5.3 'Managing Physical Risk' and Section 6.3 'A Just Transition' of Woodside's Climate Transition Action Plan and 2023 Progress Report.

The AR6 Working Group I (AR6-WGI) report states "climate change is a global phenomenon but manifests differently in different regions" (IPCC 2021b). IPCC projections for climate change in Australia from the AR6 Working Group II (AR6-WGII) report include:

- further climate change is inevitable, with the rate and magnitude largely dependent on the emission pathway (very *high confidence*)[64]

64 A level of confidence is expressed using five qualifiers: very low, low, medium, high, and very high. For a given evidence and agreement statement, different confidence levels can be assigned, but increasing levels of evidence and degrees of agreement are correlated with increasing confidence (Lawrence et al., 2022).

- ongoing warming is projected, with more hot days and fewer cold days (*very high confidence*)
- further sea level rise, ocean warming, and ocean acidification are projected (*very high confidence*)
- less winter and spring rainfall is projected in southern Australia, with more winter rainfall in Tasmania, less autumn rainfall in southwestern Victoria and less summer rainfall in western Tasmania (*medium confidence*), with uncertain rainfall changes in northern Australia.
- more extreme fire weather is projected in southern and eastern Australia (*high confidence*)
- increased drought frequency is projected for southern and eastern Australia (*medium confidence*)
- increased heavy rainfall intensity is projected, with fewer tropical cyclones and a greater proportion of severe cyclones (*medium confidence*) (Lawrence et al., 2022).

The AR6-WGII report identified nine key climate risks for the Australasian region:

- loss and degradation of coral reefs and associated biodiversity and ecosystem service values in Australia due to ocean warming and marine heatwaves (*very high confidence*)
- loss of alpine biodiversity in Australia due to less snow (*high confidence*)
- transition or collapse of alpine ash, snowgum woodland, pencil pine and northern jarrah forests in southern Australia due to hotter and drier conditions with more fires (*high confidence*)
- loss of kelp forests in southern Australia due to ocean warming, marine heatwaves, and overgrazing by climate-driven range extensions of herbivore fish and urchins (*high confidence*)
- loss of natural and human systems in low-lying coastal areas due to sea level rise (*high confidence*)
- disruption and decline in agricultural production and increased stress in rural communities in south-western, southern and eastern mainland Australia due to hotter and drier conditions (*high confidence*)
- increase in heat-related mortality and morbidity for people and wildlife in Australia due to heatwaves (*high confidence*)
- cascading, compounding and aggregate impacts on cities, settlements, infrastructure, supply-chains and services due to wildfires, floods, droughts, heatwaves, storms and sea level rise (*high confidence*)
- inability of institutions and governance systems to manage climate risks (*high confidence*) (Lawrence et al., 2022).

An earlier report by Australia's Biodiversity and Climate Change Advisory Group summarised the potential impacts of climate change to marine and terrestrial species, habitats and ecosystems across Australia (Steffen et al., 2009). The 2009 report identified examples of observed changes in Australia's biota that were considered consistent with the emerging climate change 'signal', as genetic constitution, geographic ranges, lifecycles, populations, ecotonal boundaries, ecosystems, and disturbance regimes (Steffen et al., 2009). The report also stated:

- "Biodiversity is one of the most vulnerable sectors to climate change".
- "Australia's biodiversity is not distributed evenly over the continent but is clustered in a small number of hotspots with exceptionally rich biodiversity", and that these "include the Great Barrier Reef, south-west Western Australia, the Australian Alps, the Queensland Wet Tropics and the Kakadu wetlands".

Further, it was stated that "many of the most important impacts of climate change on biodiversity will be the indirect ones at the community and ecosystem levels, together with the interactive effects with existing stressors (Steffen et al., 2009). Future climate change (e.g., increased temperature and decreased, but more variable, rainfall) has the potential to have a range of impacts on ecological factors and threaten biodiversity in the Australian Mediterranean ecosystem (CSIRO, 2017).

Extensive modelling and monitoring studies over the last twenty years provide considerable evidence that global climate change is already affecting and will continue to affect species (Hoegh-Guldberg et al., 2018); however, these impacts are likely to be highly species-dependent and spatially variable. The most frequently observed and cited ecological responses to climate change include species distributions shifting towards the poles, upwards in elevation and shifts in phenology (earlier and later autumn life-history events) (M. Dunlop et al., 2012). Climate change may not only change species distribution patterns but also life-history traits such as migration patterns, reproductive seasonality and sex ratios (Steffen et al., 2009).

Impacts of climate change such as altering temperature, rainfall patterns and fire regimes, are likely to lead to changes in vegetation structure across all terrestrial ecosystems within Australia (M. Dunlop et al., 2012; Steffen et al., 2009). Increases in fire regimes will impact Australian ecosystems altering composition structure, habitat heterogeneity and ecosystem processes. Changes in climate variability, as well as averages, could also be important drivers of altered species interactions, both endemic and invasive species (M. Dunlop et al., 2012). Climate change could result in significant ecosystem shifts, as well as alterations to species ranges and abundances within those ecosystems (Hoegh-Guldberg et al., 2018).

The 'loss of climatic habitat caused by anthropogenic emissions of greenhouse gases' has been listed as a key threatening process under the EPBC Act (DCCEEW, 2021). The threatening process consists of reductions in the bioclimatic range within which a given species or ecological community exists due to emissions induced by human activities of greenhouse gases (DCCEEW, 2021). The process is considered to have a continental distribution,

including both terrestrial and marine areas. Ecosystems in which the process occurs include: alpine habitats, coral reefs, wetlands and coastal ecosystems, polar communities, tropical forests, temperate forests, and arid and semi-arid environments (DCCEEW, 2021).

Coral reefs were recognised by both IPCC and the Australian Government as being at risk of climate change (Lawrence et al., 2022; DCCEEW, 2021). Protected coral reef areas in Australia include those within World Heritage listed sites, such as Ningaloo Coast, Shark Bay, or the Great Barrier Reef. Climate change has been identified as a threat for each of these World Heritage areas, with potential risks to coral reef as well as other environmental values (such as marine fauna) within these ecosystems (IUCN, 2020b, 2020c, 2020a).

Climate variability and change has been identified as a threat to some EPBC Act protected species, including marine turtles, whales, seabirds and migratory shorebirds:

- The Recovery Plan for Marine Turtles in Australia (CoA 2017) states that "climate change is of particular concern to marine turtles because it is likely to have impacts across their entire range and at all life stages. Climate change is expected to cause changes in dispersal patterns, food webs, species range, primary sex ratios, habitat availability, reproductive success and survivorship".
- The Conservation Management Plan for the Blue Whale (CoA 2015a) states: climate change is expected to cause changes in migratory timing and destinations, population range, breeding schedule, reproductive success and survival of baleen whales, including blue whale species and subspecies".
- The Wildlife Conservation Plan for Seabirds (CoA 2022) states that "consequences to seabirds could include negative impacts from an increase in extreme weather events, reduced or changed prey abundance and distribution, and decrease in nesting habitat".
- The Wildlife Conservation Plan for Migratory Shorebirds (CoA 2015) states that 'such changes have the potential to affect migratory shorebirds and their habitats by reducing the extent of coastal and inland wetlands or through a poleward shift in the range of many species".

The North-west Marine Parks Network Management Plan 2018 (DNP, 2018) identifies climate change as a pressure that may impact marine park values. The management plan states that "[t]he impacts of climate change on the marine environment are complex and may include changes in sea temperature, sea level, ocean acidification, sea currents, increased storm frequency and intensity, species range extensions or local extinctions, all of which have the potential to impact on marine park values" (DNP, 2018).

Within the Marine Bioregional Plan for the NWMR (DSEWPaC, 2012), pressures related to climate change are assessed as 'of potential concern' for species of marine turtle, inshore dolphins, sawfish, sea snakes, whale shark, dugong, and seabird and shorebird, as well as the KEFs and shipwrecks known to occur in the NWMR.

Emissions associated with Angel are not predicted to contribute materially or substantially to Australia's total GHG emissions, and there is no link between indirect greenhouse gas emissions associated with the Angel facility and climate change impacts upon Australian receptors.

GHG emissions (in accordance with NGERS/NPI) to inform optimisation management practices and minimise environmental impact of direct Angel and indirect NRC and KGP emissions.	CS: Minimal cost. Standard practice.	governance and optimisation. It combines with good operating practice to maximise production and reduce flaring emissions (Angel) and fuel emissions at NRC and KGP, which improves energy intensity (e.g., cleaner production), optimising emissions from the NWS. Fuel and flared gas are potential product streams, as such, Woodside applies routine short and long term optimisation and opportunity management framework to identify and prioritise enhancement opportunities. On Angel to date this has been limited to reduced flaring (e.g., flare purge rates); however, NRC opportunities are also considered in this process. Annual flare target setting and monthly review of performance is completed for Angel. NRC and KGP also apply fuel and flare target setting and tracking for indirect emissions management. Daily production meetings allow for optimisation of NWS as an integrated production system, considering impacts of variables such as maintenance activities and temperature influence on production rates.	must be adopted.	
Implement relevant methane management at Angel.	F: Yes. CS: Some cost associated with implementation of commitments. Can be managed by proving technology application and process at onshore facilities and applying, where appropriate, to Angel.	Methane management activities are aligned with environment, social and governance expectations, and Woodside's approach to methane emissions management and are consistent with OGMP 2.0 and Near-Zero, consistent with industry recognised practice. Angel methane management practices include: • CCTV monitoring of the flare ignition from NRC CCR to reduce	Control is committed – will be adopted.	Yes **C 10.10**

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)[65]***	***Benefit in Impact Reduction***	***Proportionality***	***Control Adopted***
		incomplete combustion in flaring. • Regular visitation (every 8-10 weeks) to facilitate inspection and maintenance, which may include methane reduction work. • Angel methane inventory developed by 2025 to identify, evaluate methane sources in accordance with Woodside's Production Optimisation and Opportunity Management Procedure (POOMP) (Section 7.2.4.7) and current OGMP framework. This framework requires reduction priority according to the materiality of the emissions across Woodside's portfolio of methane emissions. • Safety-driven LDAR - start-up leak checks reduce methane emissions. • Operational gas detection fixed and mobile, to identify hydrocarbon leak sources, predominantly methane. These management measures at Angel, align with Woodside's corporate approach to methane emissions management as appropriate including current OGMP and Near-Zero requirements to deliver appropriate and proportional identification and reduction effort of methane for a platform of this nature and scale.		
Maintaining CCTV monitoring systems to prevent/respond to unplanned venting.	F: Yes. CS: Standard practice.	Minimises environmental impact through the reduction of unplanned venting. Monitoring of the flare is conducted via CCTV from the NRC CCR. In the event the flare is extinguished the	Benefits potentially outweigh cost/ sacrifice.	Yes **C 10.14**

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)[65]***	***Benefit in Impact Reduction***	***Proportionality***	***Control Adopted***
		flare can be manually reignited via the reignition panel. A platform visit would be required and can be performed outside of regular visitation to reduce the duration of venting and restore blowdown safety. Note: Since commissioning, the Angel flare has not extinguished unintentionally.		
Leak Detection and Repair (LDAR) activities	F: Yes. CS: LDAR via fixed gas detection is considered industry standard practice, which is expected to detect material methane leaks and maintain platform safety. Operational LDAR for fugitive methane leaks using handheld equipment or top-down / remote sensing, e.g., via drone, is feasible. There is cost associated with additional personnel and specialist vendors, transport, helicopters, technology qualification and extended visitation impacts for LDAR work for NNC facilities like Angel. LDAR targeting small leaks may be cost effective on a portfolio approach, or at larger facilities with more repeatability and fewer constraints.	Continuous fixed gas detection and operator inspections upon platform arrival, detect and enable repair of material methane emissions. Post-shutdown start-up infrared and portable gas detection identify leaks for evaluation and repair. Benefits likely outweigh minor cost/sacrifice. LDAR campaigns during operations targeting fugitive emissions may identify opportunities for repair, resulting in emissions reduction.	Process safety-driven gas detection is good industry practice. Implemented in design and operation. Cost/sacrifice of executing LDAR campaigns during operations likely outweighs benefits of emissions reduction at Angel. However, may be adopted to achieve portfolio materiality approaches of methane emissions management and current OGMP and Near-Zero frameworks.	Yes **C 10.10**
Contracting strategy and evaluation for hire of support vessels includes consideration of vessel emissions parameters and low carbon/alternate fuels.	F: Yes. CS: Fuel cost over the five year contract is considered in the evaluation of responses, allowing for competitive consideration of low carbon alternatives.	Minimises costs and emissions through eco-efficiency approach recognising cost of fuel and carbon emissions over the contract term.	Control effectively allocates a cost to emissions to recognise that higher emitting fuel sources with other lower operating costs do not represent	Yes **C 10.11**

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)[65]***	***Benefit in Impact Reduction***	***Proportionality***	***Control Adopted***
			overall best value.	
Well unloading acceptance criteria that define the well objectives will be established.	F: Yes. CS: Standard practice.	Eliminates unnecessary flared volumes and corresponding emissions (light and GHG).	Benefits outweigh cost/ sacrifice.	Yes **C 10.12**
Assess opportunities to eliminate well flowback flaring to MODU. The assessment will consider factors such as: • HSE considerations • well performance • proof of completions success • solids and liquids handling • potential eventual other impacts to the topsides.	F: To be decided. The decision on whether to unload to the MODU or Angel will be based on technical study outcomes. CS: Cost effective but introduces additional risks to the production facility (i.e., risk of equipment and subsea system failures due to solids).	Minimises environmental impact through the reduction of GHG emissions Well flowback may be avoided entirely for some or all wells. In this case the wells are instead flowed back to the eventual host facility (the Angel Facility), resulting in a small increase to expected bean-up flaring for the well but resulting in a net overall flaring decrease. The decision on whether to unload to the host will be based on the outcome of ongoing studies and operational data gathered during the drilling activity.	Benefits potentially outweigh cost/ sacrifice.	Yes **C 10.13**
Professional Judgement – Elimination				
Eliminating flaring by venting un-combusted hydrocarbons.	F: No. Routine hydrocarbon venting is not considered good industry practice, as unburnt methane poses potential for greater environment impact compared to combustion emissions. The ability to flare hydrocarbons is a key safety feature on the facility. Removing the ability to flare hydrocarbons may result in unacceptable safety risks on the facility. CS: Not assessed, control not feasible.	Not assessed, control not feasible.	Not assessed, control not feasible.	No
Eliminate flaring by reinjecting un-combusted hydrocarbons.	F: No. Routine hydrocarbon reinjection, as opposed to transport to onshore facilities, would not be consistent with the approved Angel Field Development Plan, which seeks to optimize	Not assessed, control not feasible.	Not assessed, control not feasible	No

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)[65]***	***Benefit in Impact Reduction***	***Proportionality***	***Control Adopted***
	hydrocarbon recovery while fulfilling NWS gas supply commitments. As such, gas reinjection would not meet concept screening criteria to warrant option evaluation. CS: Not assessed, control not feasible.			
Do not vent during well kick.	F: No. Venting is a critical safety activity required in the event of a kick to reduce pressure build-up. CS: Not considered – control not feasible.	Not considered – control not feasible.	Not considered – control not feasible.	No
Professional Judgement – Substitution				
Fuel for energy generation on NRC is selected for lowest indirect emissions generation practicable: Fuel gas used in preference to diesel for power generation.	F: Yes. Fuel gas is the primary fuel source on NRC, with diesel as back up fuel used when gas production is shut down. CS: Cost effective.	Gas turbines reduce CO_2 emissions for a given unit of power and reduce spill risk associated with diesel bunkering activities.	Cost effective. Minimises fuel bunkering risks.	Yes. Solution permanently implemented.
Professional Judgement – Engineered Solution				
Maintaining flare to maximise efficiency of combustion and minimise venting, incomplete combustion waste products and smoke emissions.	F: Yes. CS: Minimal cost. Standard practice.	Flare tip integrity and ignition system functionality minimises potential for venting, incomplete combustion waste products and smoke emissions.	Benefits potentially outweigh cost/ sacrifice.	Yes **C 10.15**
Manage vessel speed to reduce fuel combustion.	F: Yes. CS: Standard practice.	Reducing fuel combustion reduces atmospheric emissions.	Benefits outweigh cost/sacrifice.	Yes **C 10.16**
Installation of flare gas recovery systems to reduce emissions entering the atmosphere from flaring.	F: Yes. CS: Significant additional cost associated with the design and installation of flare gas recovery systems, including significant retrofitting of multiple stages of compression systems, coupled with associated ancillaries, valving and piping, platform modification and weight considerations. The safe addition of required	Small to negligible environmental benefit from reducing atmospheric emissions from flaring. The environmental benefit gained from the recovery of flaring emissions would be limited to only a portion of flare system flows due to process safety constraints and flare system operation over a wide design envelope (associated with flow variations). Furthermore, required retrofitting of	Given the increased safety risk and the very low, if any, environmental benefit provided when increased power generation emissions are taken into consideration, the installation of flare gas recovery	No

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)[65]***	***Benefit in Impact Reduction***	***Proportionality***	***Control Adopted***
	rotating equipment also poses significant production sacrifice and potential domestic gas supply impacts due to the initial design layout and space safety constraints.	multiple stages of compressions (e.g., for LP/HP streams) would offset any environmental benefits through increased power generation emissions. The retrofitting interaction with the safety critical flare system and continued operation of gas compression would also increase platform safety risks.	systems is considered grossly disproportionate to the environmental benefit it would provide.	
Upgrade flare equipment to allow remote (uncrewed) reignition of flare in the case the flare is extinguished.	A remote flare ignition system is feasible. A brownfield modification of this nature would incur cost and risk the operational performance of the flare ignition system. Operation and maintenance of this system is also additional cost.	A remote flare ignition system could reduce methane venting from flare in the event the flare is extinguished. Benefits would be minor, given the Angel flare is not known to have unintentionally extinguished since commissioning. Methane reduction from remote flare ignition upgrade would be offset by the commissioning and operational testing requirement to extinguish the flare and re-light. This would vent hydrocarbons.	Cost of a remote flare ignition upgrade and operation would outweigh the irregular and minor emissions reduction.	No

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)[65]***	***Benefit in Impact Reduction***	***Proportionality***	***Control Adopted***

Discussion of ALARP

Atmospheric Emissions

On the basis of the environmental risk assessment outcomes and the use of the relevant tools appropriate to decision type A, Woodside considers the adopted controls appropriate to manage the impacts of Angel facility, tie-back activities and vessel atmospheric emissions. As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.

GHG Emissions

Risk Based Analysis

Application of Woodside's Risk Management Procedures, implementation of the Emissions and Energy Management Procedure and Production Optimisation and Opportunity Management Procedure reduces GHG emissions risk to ALARP (**Section 7.2**). This includes a system of continual review and improvement of key emissions sources from NWS assets as an integrated system, including Angel, e.g., flaring reduction was implemented, resulting in reduction of flared gas of 140 tpa (395 tCO2e). Further opportunities are implemented at KGP and NRC to reduce indirect emissions associated with production of Angel and combined emissions from the NWS assets.

Societal Values

Consultation was undertaken for this program to identify the views and concerns of relevant persons, as described in **Section 5**. No specific concerns around air emissions, resulting in changes to air quality and greenhouse gas emissions, were identified through this process.

ALARP Statement:

On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type (i.e., Decision type A and B for direct and indirect emissions respectively), Woodside considers the adopted controls appropriate to manage GHG emissions from the Angel facility and indirect emissions sources that Woodside can practicably influence, including support vessels, during the term of this EP. The adopted controls meet legislative requirements including:

Marine Order 97 for support vessels

NGERS and NPI reporting for direct emissions attributed to Angel, NRC and KGP.

National Greenhouse and Energy Reporting (Safeguard Mechanism) Rule 2015.

Indirect GHG emissions from onshore processing at KGP are managed under Ministerial Statement 536. As part of the North West Shelf Project Extension approvals process (currently under assessment) a draft Greenhouse Gas Management Plan has been submitted to the EPA that includes an emissions limit.

As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.

Demonstration of Acceptability

Acceptability Statement: Atmospheric Emissions

Given the adopted controls, atmospheric emissions represent a negligible impact that is unlikely to result in greater than isolated impacts with close proximity of the Angel facility, in an unpopulated area approximately 94 km from the nearest community receptor. The adopted controls are considered good oil-field practice/industry best practice and meet requirements of Australia Marine Orders and National Pollutant Inventory reporting.

The predicted GHG emissions associated with Angel are considered negligible and as such, below acceptable levels and will not materially or substantially contribute to Australia's net GHG emissions or net global emissions levels.

The potential impacts and risks are considered broadly acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the impacts and risks of atmospheric emissions to a level that is broadly acceptable.

Acceptability Statement: GHG emissions

Principles of Ecologically Sustainable Development

Giving consideration to economic development that safeguards the welfare of future generations, Angel is considered to align with the following core objectives of ESD by:

Responding to the global energy transition, providing a clean and reliable energy source as gas is expected to play a key role in the future energy mix (e.g., partner with renewables). In addition, gas has the potential to contribute to an incremental reduction in global GHG emissions by displacing more carbon intensive power generation (e.g., coal), firming up renewables, or in hard-to-abate sectors.

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)[65]***	***Benefit in Impact Reduction***	***Proportionality***	***Control Adopted***

Committing to management and mitigation measures for GHG emissions within operational control of the facility, given the uncertainty about future climate change trajectories.

Committing to mitigation measures for GHG emissions that are controlled or influenced by Operator and associated with the operations of the Angel facility.

Providing gas to customers within countries that have ratified the Paris agreement, where each country is responsible for accounting for, reporting and reducing emissions that physically occur in its jurisdiction.

Internal Context

The Petroleum Activities Program is consistent with Woodside corporate polices, culture, processes, standards, structure and systems as outlined in the Demonstration of ALARP and Environmental Performance Outcomes, including:

- Woodside Environment and Biodiversity Policy (**Appendix A)**
- Woodside Risk Management Policy (**Appendix A)**
- Woodside Climate Policy (**Appendix A)**

For more information, please see Woodside's Climate Transition Action Plan and 2023 Progress Report (Woodside 2023a).

WMS requirements such as the GHG emissions and Energy Management Procedure, Production Optimisation and Opportunity Management Procedure and Woodside's corporate approach to methane emissions management (**Section 7.2**), which require continuous improvement and demonstration of ALARP in the context of the asset. This is achieved by implementing tools to identify, evaluate, implement and review emissions reductions projects and develop, govern and report on plans to reduce methane fugitive emissions.

External Context

Woodside recognises that our licence to operate from a regulator and societal perspective is based on historical performance, complying with appropriate policies, standards and procedures, and understanding the expectations of external stakeholders. GHG emissions are a global concern, and as such Woodside has undertaken an impact assessment of GHG associated with the Angel facility and identified key measures to manage GHG emissions to an acceptable level.

According to Wood Mackenzie Energy Research Consultancy, LNG from Woodside operated facilities is amongst the lowest carbon intensity in the world delivered into North Asia.[66]

The global consensus on climate change led to the implementation of the Paris Agreement. The aim of the Paris Agreement, as stated in the Article 2.1(a), is to hold the increase in global average temperature to well below 2°C above pre-industrial levels. The Agreement also aims to pursue efforts to limit the temperature increase to 1.5°C above pre-industrial levels, recognising that this would significantly reduce the risks and impacts of climate change.

Paris Agreement text extract[67]:

> "Article 2
>
> 1. This Agreement, in enhancing the implementation of the Convention, including its objective, aims to strengthen the global response to the threat of climate change, in the context of sustainable development and efforts to eradicate poverty, including by:
>
> (a) Holding the increase in the global average temperature to well below 2 °C above pre-industrial levels and pursuing efforts to limit the temperature increase to 1.5 °C above pre-industrial levels, recognizing that this would significantly reduce the risks and impacts of climate change;"

This was reaffirmed in December 2023 in the COP28 decision text on the First global stocktake.[68] The text further recognised that the transition away from fossil fuels in energy systems is to be done in a just, orderly and equitable manner accelerating action in this critical decade, so as to achieve net zero by 2050 in keeping with the science.[69] It

66 Export from the Wood Mackenzie LNG Carbon Emissions Tool available from: https://www.woodside.com/docs/default-source/our-business---documents-and-files/pluto---documents-and-files/wood-mackenzie-lng-carbon-emissions-tool.pdf

Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)[65]***	***Benefit in Impact Reduction***	***Proportionality***	***Control Adopted***

also recognises that transitional fuels can play a role in facilitating the energy transition while ensuring energy security[70].

The Paris Agreement establishes a framework where countries make Nationally Determined Contributions (NDCs) to manage and reduce their own emissions.

Australia has ratified the Paris Agreement and has set a target to reduce emissions by 43% below 2005 levels by 2030 and to reach net-zero emissions by 2050. Australia's emissions projections under a 'with additional measures' scenario is projected to be 43% below 2005 levels by 2030 and to reach net zero emissions by 2050 (DISER, 2022a). Australia's emissions projections demonstrate that it is on track to reduce emissions by up to 43% below 2005 levels by 2030 (DCCEEW, 2022; DISER, 2022a).

Australia's Long-Term Emissions Reduction Plan (DISER, 2021) presents Australia's whole-of-economy plan to achieving net zero emissions by 2050 with priority technologies estimated to achieve 85% reduction and yet-to-be identified emerging technologies abating the remainder. The plan identified LNG as a critical transition fuel and expects growth in the sector with higher use in 2030 than it is today but acknowledging that growth will depend on the preferences of customers and the pace of international action (DISER, 2021).

Climate science has drawn a robust link between cumulative emissions of greenhouse gases and global temperature levels. The link between cumulative emissions and temperature levels allows a carbon budget to be calculated. This is the remaining amount of net emissions (i.e., all global sources of emissions minus all global sinks of emissions) that can occur before today's concentration of greenhouse gases increases to the concentration associated with potential temperature outcomes.

However, the distribution of this carbon budget across different human activities requires additional judgements about a wider range of social, economic and technological factors and consumer and policy choices. Strategies to achieve emissions reductions include transitioning from fossil fuels without CCS to very low-or zero-carbon energy sources, such as renewables or fossil fuels with CCS, demand side measures and improving efficiency, reducing non-CO2 emissions, and deploying carbon dioxide removal (CDR) methods to counterbalance residual greenhouse gas emissions. Pathways to limit warming therefore show different combinations of sectoral mitigation strategies consistent with a given warming level.

As a result, the demand for oil and gas in climate-related scenarios that could limit global warming to 1.5°C or 2°C is uncertain. For example, in the AR6-WG3 report, the IPCC stated that in pathways that limit warming to 1.5°C (with a greater than 50% probability and with no or limited overshoot) the potential global use of gas in 2050 ranges from 30% above 2019 levels to 85% below them with a median 45% decline.

Woodside considers that a stable energy transition will be one in which energy is affordable and reliable, as well as lower carbon. The Angel facility, together with the new well at Lambert West (LDA-02), will provide an incremental volume of hydrocarbons to Australian and international markets during its estimated remaining field life (to 2027). Woodside considers that this development is aligned with their goals for supporting the energy transition and is compatible with the Paris Agreement goal to limit global warming to below 2°C. Further, field life of the reservoirs comprising the Angel facility shall not extend beyond estimated field life (estimated as 2027, and up to 2028 to allow for uncertainty in reservoir performance), which contributes to global emissions reductions from beyond this point in time.

Woodside is a signatory to several global initiatives which are complementary to our corporate approach to methane emissions management, which include OGMP (2024), Oil and Gas Climate Initiative Aiming for Zero Methane Emissions (OGCI Near-Zero) and the Methane Guiding Principles (MGP, 2022), which are voluntary, international multi-stakeholder partnerships between industry and non-industry organisations. Woodside will pursue compliance with these commitments at the Angel facility in line with the control measures (C.10.10) (refer to Internal Context above, and key control measure.

Other Requirements (Includes Laws, Polices, Standards and Conventions)

Legislation and other requirements considered relevant for this aspect, and a demonstration of how these requirements are met, are described below.

Requirement	***Demonstration***
Marine Order 97 Gives effect to Annex VI of MARPOL 73/78	The requirements of Marine Order 97 are incorporated into the key control measures.

Acceptability Statement: Greenhouse Gas Emissions

As per **Section 2.6.1**, decision type B, GHG emissions are acceptable if "ALARP" is demonstrated using good industry practice and risk-based analysis, if legislative requirements are met and societal concerns are accounted for and the alternative control measures are grossly disproportionate to the benefit gained. In addition, acceptability is assessed against the above criteria. Further opportunities to reduce the impacts have been investigated (refer ALARP demonstration discussion).

Indirect GHG emissions associated with the Angel facility are managed to an acceptable level by meeting (where they exist) legislative requirements, industry codes and standards, applicable company requirements, and industry guidelines, and these have been adopted as key controls. The adopted controls are considered good oil-field practice/industry best practice and are consistent with Woodside's internal requirements. The potential impacts are considered acceptable if ALARP is demonstrated. As described above, the predicted GHG emissions associated with the Angel facility are considered negligible and as such, below the acceptable levels and will not materially or substantially contribute to Australia's net GHG emissions or net Global GHG emissions levels.

Light emissions from the facility, MODU and project vessels						✓		A	F	-	-	GP PJ	Broadly Acceptable	**EPO 12**
Light emissions during flaring						✓		A	F	-	-			

Description of Source of Impact

Operations

When staffed (about 14 days/eight times a year for planned maintenance visits; and more constantly at start-up of LDA-02 (see **Section 3.4.5.1**), appropriate lighting is used to ensure a safe working environment at night as well as to communicate the presence of the facility and vessels to other marine users (i.e., navigation lights). Lighting is required for safe operation and cannot reasonably be eliminated. When unstaffed, minimum lighting is maintained on the facility for navigational and safety requirements.

External lighting is located over the entire facility, as well as vessels, with external lighting directed towards working areas such as the production deck of the facility, or the back deck of support vessels. This limits light spill to the marine environment. The production deck is approximately 25 m above sea level, with the highest point of the facility (the top of the flare tower) reaching approximately 115 m above sea level.

During IMMR activities, underwater light is generated over short periods of time while ROVs are in use, as well as from deck lighting. Given the typical intensity of ROV lights and the attenuation of light in seawater, light from ROVs is localised to the vicinity of the ROV and vessels.

A relatively small quantity of gas is required to be continuously flared associated with purge and pilot of the flare system and disposal of waste streams which are not recovered to the process. There is no planned venting of hydrocarbons from the facility during normal operations. Intermittent flaring may occur via the HP flare during emergency, manual depressurisation, and subsea flowline depressurisation.

Tie-back Activities

The MODU and project vessels will have external lighting to support safe navigation and safe operations at night. This lighting typically consists of bright white (i.e., metal halide, halogen, fluorescent) lights, and is not dissimilar to lighting used for other offshore activities, including fishing and shipping. Lighting is required for the safe operation of the MODU and project vessels cannot be reasonably eliminated.

The extent of potential impact for this activity is restricted to the line of sight for each source emitting light. Based on other previous work undertaken by Woodside this is about 30 km from the MODU during drilling activities and 30 km from vessels (Woodside, 2014). For contingent well flowback, specifically flaring, the distance at which the flare will be visible is expected to be less than 50 km from the source, and potentially around a further 10 km during emergency flaring (Woodside Energy Limited, 2011).

While the line of sight may extend tens of kilometres from the source, the light density (measured in Lux – which represents the intensity of light that arrives at or leaves a surface, as perceived by the human eye) rapidly decreases as distance increases from the source of the light. Monitoring undertaken as a part of Woodside's 2014 study indicated that light density (from navigational lighting) attenuated to below 1.00 Lux and 0.03 Lux at distances of 300 m and 1.4 km, respectively, from the source (a MODU). Light densities of 1.00 and 0.03 Lux are comparable to natural light densities experienced during deep twilight and during a quarter moon. Navigational lighting from vessels is less than lighting on a MODU. Therefore, light emissions from the MODU and project vessels are expected to be below 1.00 Lux within 300 m from the source.

Cumulative Light Sources

Cumulative impacts from light sources will occur during the tie-back activities and commissioning/maintenance visits where the facility will be staffed and there will be additional lighting for safe operations and the MODU and project vessels present in these periods. These scenarios will be short term (facility staffed during commissioning – 4 weeks; MODU – 50 to 60 day duration).

Light impacts are also likely to occur from flaring, IMMR activities and project vessel lighting from the nearby Okha FPSO, North Rankin Complex, and GWA Platform (collectively ~ 10 to 72 km from the Angel Platform) which may result in slightly elevated ambient light levels.

Impact Assessment

Lighting from the facility, MODU and project vessels may appear from direct unshielded light sources or through skyglow. Where direct light falls upon the ocean, this area of light is referred to as light spill. Skyglow is the diffuse glow caused by light that is screened from view, but through reflection and refraction creates a glow in the atmosphere. The distance at which direct light and skyglow may be visible from the source is dependent on the lighting on the facility/vessel and environmental conditions.

Receptors that have important habitat present within a 20 km buffer of the PAA were considered as having potential for interaction, based on recommendations of the National Light Pollution Guidelines for Wildlife Including Marine Turtles, Seabirds and Migratory Shorebirds (NLPG). The 20 km threshold provides a precautionary limit based on observed effects of sky glow on marine turtle hatchlings (15 to 18 km) and fledgling seabirds grounded in response to artificial light 15 km away (Commonwealth of Australia, 2020).

Light emissions can affect fauna in two main ways:

Behaviour: many organisms are adapted to natural levels of lighting and the natural changes associated with the day and night cycle as well as the phase of the moon. Artificial lighting has the potential to create a constant level of light at night that can override these natural levels and cycles.

Orientation: organisms such as marine turtles and birds may use lighting from natural sources to orient themselves in a certain direction at night. In instances where an artificial light source is brighter than a natural source, the artificial light may act to override natural cues, leading to disorientation.

The marine fauna within the PAA are predominantly pelagic fish and zooplankton, with a low abundance of species such as turtles and large whales transiting through the area. Additionally, there is no known critical habitat within the PAA for EPBC listed species, although there are BIAs listed in **Section 4.6** that overlap the PAA. The PAA overlaps with the whale shark foraging BIA so individuals are likely to transit the area.

Seabirds

Artificial lighting can attract and disorient seabird species resulting in species behavioural changes (e.g., circling light sources or disrupted foraging), injury or mortality near the light source as a result of collision (Longcore and Rich, 2004; Gaston et al., 2014). The PAA may be occasionally visited by seabirds and migratory shorebirds. There is no emergent land that could be used for roosting or nesting habitat in the PAA or close proximity; however, the Angel facility is known to be used seasonally as a resting place for birds (occasionally in large numbers), especially when unstaffed. The nearest landfall is the Dampier Archipelago, which is 94 km south of the PAA at the closest point and the Montebello Islands, 106 km to the south west. One BIA for wedge-tailed shearwater breeding overlaps the PAA with the breeding period occurring from August to April (**Section 4.6.5**). Adult shearwaters are vulnerable to artificial lighting during the breeding cycle, when returning to and leaving the nesting colony to maintain nesting sites or forage. Foraging wedge-tailed shearwaters may be attracted to sources of light emissions to feed on fish drawn to the light, however, the species feeds predominantly during the day (Catry et al., 2009). Migratory shorebirds may be present in or fly through the region between July and December, and again between March and April as they complete migrations between Australia and offshore locations (Commonwealth of Australia, 2015). The risk associated with collision from seabirds or migratory shorebirds attracted to artificial lighting is considered to be low, impacts are expected to be limited to localised behavioural disturbance to isolated individuals, with no displacement from important habitat.

The most vulnerable life stages for seabirds and migratory shorebirds are nesting adults or fledglings. Nesting or fledgling seabirds and migratory shorebirds are vulnerable to artificial lighting within 20 km of the nesting location (Commonwealth of Australia, 2020). For shearwater species, fledglings are predominantly impacted by onshore lighting sources, which can override sea finding cues and attract fledglings further inland, preventing them from reaching the sea (Mitkus et al., 2018; Telfer et al., 1987). Artificial light can also impact important behaviour of nesting adults (e.g., adult nest attendance, maintaining nest sites) or confuse shearwater species, resulting in injury or mortality as a result of birds colliding with structures (Cianchetti-Benedetti et al., 2018; Rodriguez et al., 2017). As the PAA is 106 km from the nearest emergent land, impacts to adult nesting or fledgling seabirds and migratory shorebirds are not expected. No nesting activity has been identified on the Angel facility. Artificial light from the Petroleum Activities Program is not predicted to disrupt critical breeding behaviours within important nesting habitat or displace seabirds from nesting habitat.

Marine Turtles

Hatchlings

Turtle hatchlings emerge from the nest and orient towards the sea. After entering the water, hatchlings use a combination of cues (wave direction and currents) to orient and travel into offshore waters. Impacts to the sea-finding behaviour of hatchlings are more common for light sources behind a beach, as lighting offshore will orient emerging hatchlings towards the sea. Artificial light at close distances can also impact hatchling dispersal once they are in the water. Light spill may ‘entrap’ hatchling swimming behaviour, reducing the success of their seaward dispersion and potentially increasing their exposure to predators via silhouetting (Salmon et al., 1992).

The PAA does not contain any known Habitat Critical for the Survival of the Species for any species of marine turtle with the nearest location at Montebello Islands (34 km south for flatback turtles). No BIAs overlap the PAA; however, several overlap the EMBA. The closest are internesting buffers for flatback turtles, green turtles, hawksbill turtles and loggerhead turtles (15 km south, 78 km south-west, 84 km south-west and 92 km south-south-west respectively).

The production deck is approximately 25 m above sea level, with the highest point of the facility (the top of the flare tower) reaching approximately 115 m above sea level. The distance to visible horizon is ~39 km – i.e., anything beyond this distance is below the horizon and direct light would not be visible. Therefore, direct light from facility will not reach any nesting location. Sky glow (particularly from flaring) is also unlikely to be visible at the closest nesting locations resulting in no behavioural impact (i.e., not biologically relevant). Even in the scenarios where these areas may be affected, the light source is located directly offshore in the same direction that emerging hatchlings would be heading in during normal sea-finding behaviour, meaning that no significant misorientation or disorientation would occur.

The maximum likely height for a derrick on a MODU contracted for the Petroleum Activities Program is 50 m, so will have a far smaller visible reach than the facility flare tower. In turn, external lighting on vessels is typically lower than the facility lights, with vessel lighting usually reduced to improve night vision of bridge crew.

Since the PAA is located ~106 km from turtle nesting beaches in the Montebello Islands, the risk of significant numbers of dispersing hatchlings becoming attracted to direct light or sky glow from MODU and project vessels is not considered credible. This is supported by the findings of a desktop lighting impact assessment for the Scarborough Project, demonstrating that at a range of 50 km, the density of dispersing hatchlings is expected to be low and very few individuals will be at risk of attraction (PENV, 2020). For any isolated individuals potentially attracted to light spill

from MODU and project vessels, following sunrise, any effect of these light sources on hatchlings will be eliminated allowing dispersal behaviour to resume.

As such, light emissions from the facility, MODU and project vessels are unlikely to result in behavioural changes to individuals in this life stage.

Adults

Artificial lighting may affect the location that turtles emerge to the beach, the success of nest construction, whether nesting is abandoned, and even the seaward return of adults (Salmon et al., 1995a, 1995b; Salmon and Witherington, 1995). However, such lighting is typically from residential and industrial development overlapping the coastline, rather than offshore from nesting beaches. As the PAA does not overlap any marine turtle BIAs or Habitat Critical, it is unlikely to affect nesting adults. Given the water depth of the PAA (70 to 130 m), turtles are unlikely to be foraging. It is acknowledged that marine turtles may be present transiting the PAA in low densities, however light cues aren't used to guide this behaviour.

Fish

Lighting from the presence of the facility, MODU or project vessels may result in the localised aggregation of fish. These aggregations of fish are considered localised and temporary and any long-term changes to fish species composition or abundance is considered highly unlikely. This localised increase in fish extends to those comprising the whale shark's diet. However, given that a large proportion of the diet comprises krill and other planktonic larvae, it is unlikely that a light source would lead to a significant increase in whale shark abundance in the vicinity of the facility or vessels. Similarly, any localised impacts to marine fish are not expected to impact on any commercial fishers in the area.

Cultural Values and Heritage

Through consultation and review of available literature (**Section 4.9.1**), Woodside understands that marine fauna that may be affected by light emissions, such as turtles and plankton, are culturally important to Traditional Custodians. Traditional Custodians value these species both tangibly as well intangibly as they can be considered a resource or linked to songlines and dreaming stories. Traditional Custodians also have connection to many marine species through kinship and totemic systems; an individual may have obligation to care for a species to which they are kin. Traditional Custodians may also have a cultural obligation to care for the environmental values of Sea Country.

For example, activities that impact turtle populations and their marine environment may have an indirect impact on some Indigenous communities if they deplete hunting areas and threaten local food security (Delisle et al., 2018:251). Inter-generational transmission of cultural knowledge (including songlines) relating to marine reptiles may be impacted where changes results in reduced sightings (e.g., through population decline, changes to migration routes or changes to migration seasonality). This transfer of knowledge may be integral to managing a group's intangible cultural heritage (UNESCO, 2003).

As described above, potential impacts to marine fauna are predicted to be at an individual level, which are not considered to be ecologically significant at a population level. Impacts are not expected to occur to significant proportions of the populations of the species, nor expected to result in a decrease of the quality of the habitat such that the extent of these species is likely to decline. As such, cultural values and intangible cultural heritage associated with these species are expected to be maintained.

Cumulative Impacts

There is potential for overlap when the Angel facility becomes staffed (during commissioning) and tie-back activities where cumulative light emissions would occur from lighting required for safe operations from the facility, MODU and project vessels. As outlined above, these scenarios will be short term (facility staffed during commissioning – 4 weeks; MODU – 50 to 60 day duration). The cumulative impact is likely to be minor, due to the low light intensities of the vessel navigational lighting, MODU and facility lighting, short and intermittent nature of the impact, and is not anticipated to adversely affect any sensitive receptors.

Furthermore, cumulative light impacts have the potential to occur from flaring, IMMR activities and project vessel lighting from the nearby Okha FPSO, North Rankin Complex, and GWA Platform (collectively ~ 10 to 72 km from the Angel Platform). However, negligible detrimental impact to biological communities is expected.

Good Practice				
Implement a Seabird Management Plan that includes: • standardisation and maintenance of record keeping and reporting of seabird interactions • procedures on seabird intervention, care and management • regulatory reporting requirements for seabirds (unintentional death of or injury to seabirds that constitute MNES).	F: Yes. CS: Minimal.	Potential for slight reduction in the likelihood of seabird attraction to vessels and facility resulting in a reduced likelihood of bird strikes.	Potential benefits outweigh cost/sacrifice.	Yes **C 12.1**
Lighting will be limited to the minimum required for navigational and safety requirements, with the exception of emergency events.	F. Yes. Lighting is typically appropriate for navigation and safety.	Given the potential impacts to turtles during this activity is insignificant, implementation of this control would not result in a reduction in consequence.	While the control does not result in significant reduction of impacts, it is good practice and not at significant cost.	Yes **C 12.2**
Well unloading acceptance criteria that define the well objectives will be established.	F: Yes. CS: Standard practice.	Eliminates unnecessary flared volumes and corresponding emissions (light and GHG).	Benefits outweigh cost/sacrifice.	Yes **C 12.3**
Professional Judgement – Eliminate				
No external lighting during Petroleum Activities Program.	F: No. Light management is consistent with that required to provide a safe working environment on-board the facility and support vessels. Lighting is required to enable monitoring of the platform from NRC. CS: Not considered – control not feasible.	Not considered – control not feasible.	Not considered – control not feasible.	No

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)[74]***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Variation of the timing of the tie-back activities to avoid peak turtle internesting periods (December to January).	F: Yes CS: Significant cost and schedule impacts due to delays in securing vessels/MODU for specific timeframes.	Not considered – control not feasible.	Not considered, control not feasible.	No
Substitute external lighting with light sources designed to minimise impacts to seabirds, shorebirds and marine turtles: • Use flashing/ intermittent lights instead of fixed beam. • Use motion sensors to turn lights on only when needed. • Use luminaires with spectral content appropriate for the species present. • Avoid high intensity light of any colour.	F: Yes. Replacement of external lighting with lighting appropriate for turtles and seabirds is technically feasible, although is not considered to be practicable. CS: Significant cost/sacrifice. The retrofitting of all external lighting on the facilities, etc, would result in considerable cost and time expenditure. Considerable logistical effort to source sufficient inventory of the range of light types onboard the facilities.	Given the potential impacts to turtles, nesting seabirds and fledglings during this activity are insignificant, implementation of this control would not result in a reduction in consequence. Potential for minor reduction in impact to individual foraging seabirds that may transit the PAA, as outlined in the NLPG.	Grossly disproportionate. Implementation of the control requires considerable cost/sacrifice for minimal environmental benefit. The cost/sacrifice outweighs the benefit gained.	No
No flaring during Petroleum Activities Program.	F: No. While not a routine activity, the ability to flare hydrocarbons is a safety critical requirement on-board the facility. Note, Woodside is committed to reducing flaring, and has developed annual internal facility flare targets against which progress is monitored (see **Section 6.6.10**). ALARP Statement: On the basis of the environmental impact assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the potential impacts from routine light emissions from the facility, MODU and vessels to be ALARP. As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.				
Demonstration of Acceptability				
Acceptability Statement: The impact assessment has determined that, given the adopted controls, routine light emissions from external lighting on the Angel facility, MODU and project vessels represent a localised impact /disturbance to marine fauna within the PAA. BIAs for whale shark foraging and wedge-tailed shearwater breeding areas overlap the PAA. Conservation advice and the NLPG were taken into consideration during the impact evaluation. The Petroleum Activities Program is deemed consistent with the conservation advice and guideline. Further opportunities to reduce the impacts have been investigated above. The potential impacts are consistent with good oil-field practice/industry best practice and are considered to be broadly acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the impacts of light emissions to a level that is broadly acceptable.

6.7 Unplanned Activities (Accidents, Incidents, Emergency Situations) – Major Environmental Events

For Woodside's production facilities, an analysis is undertaken to identify, classify and analyse major environmental events (MEEs), as described in **Section 2.7**. This extra level of rigour is applied to ensure sufficient controls for operational activities are in place for risks with potential Level B and above consequences as per Woodside's Risk Matrix. MEEs are evaluated against credible worst-case scenarios that may occur when all controls are absent or have failed. The risks considered in this section have therefore been identified as MEEs due to the potential for significant consequence. These sources of risk are subject to additional consideration in accordance with the process described in **Section 2.6.4**. Risks associated with the Petroleum Activities Program that have been classified as MEE's are summarised in **Section 6.7.1** and include a range of hydrocarbon spills. The quantitative spill risk assessment methodology used to assess the potential consequence of credible spills is outlined in **Section 6.7.2**. Credible hydrocarbon spills that have not been classified as MEE's are assessed in **Section 6.8**. Risks that do not meet the MEE definition, although screened out of the MEE process, are still evaluated for ALARP and risk acceptability using the methodology described in **Section 2.8**. These include credible hydrocarbon spills during drilling and tie-back activities, which are not classified as MEEs for the following reasons:

- Drilling and subsea installation activities are performed outside of asset controls and ownership. Ownership is only handed over in cold commissioning when the asset gains control of subsea systems and well control, as such a different set of controls and safety systems are used in the lead up to pre-commissioning.
- The vessel safety case contains safety systems that prevent the occurrence of hydrocarbon spills during drilling and subsea installation.
- Hydrocarbon spills assessed for the drilling and subsea installation phase align with vessel safety case risk assessments and mitigation to reflect controls proportionate to the short duration high risk activities.
- Drilling and subsea installation activities conclude with the hand over to the asset along with the subsequent risk and consequence from the activities.

6.7.1 Major Environmental Events Overview

Section 2.7 outlines the process for additional analysis and evaluation of MEEs. **Sections 6.7.3** to **6.7.8** present the bowtie output for each MEE identified (**Table 6-22**).

Table 6-22: Major environmental events for the Angel facility

No.	Hazard	Top Event
MEE-01	Hydrocarbons in reservoirs, wells, wellheads and Xmas trees	Well loss of containment
MEE-02	Hydrocarbons in subsea equipment (pipelines, flowlines and risers)	Subsea equipment loss of containment
MEE-03	Hydrocarbons in subsea and topsides equipment	Loss of structural integrity
MEE-04	Hydrocarbons in subsea and topsides equipment and marine vessels	Loss of marine vessel separation
MEE-05	Hydrocarbons in wells, subsea and topsides equipment	Loss of control of suspended load from platform

Each section includes a summary of the hazard description, hazard management, emergency response, ALARP summary and a list of SCE barriers identified on the bowties. Each group of SCEs is listed under Technical Performance Standards, with consistent naming conventions used across Woodside's process safety management processes (e.g., pipeline integrity SCEs are captured as P09 – Pipeline Systems).

Section 6.7.8 presents the generic SCE Failure and generic Human Error bowties that illustrate the causes, outcomes and controls/barriers in place to manage potential common cause event (CCE) failure mechanisms for MEE controls associated with generic SCE equipment failure (CCE-01), and also human error (CCE-02). Controls and specific measures are listed for both bowties. Human Error is managed via the WMS and the Generic Human Error bowtie is included in the MEE section for completeness.

ALARP is demonstrated through controls and barriers being analysed for selection based on their independence, prioritised in accordance with the Hierarchy of Controls where controls further up the hierarchy take precedence over controls further down, and further analysed to consider the type of effect the control provides. ALARP controls presented for MEE bowties are labelled in accordance with Type of Effect classifications presented in **Table 6-23**.

Woodside has developed a tailored ALARP position for hydrocarbon spill response, including EPOs, EPSs and MC for preparedness and response. The response arrangements are a mitigative control that applies to all MEEs where a hydrocarbon release may credibly occur. The hydrocarbon spill response arrangements are described in **Appendix D**.

Table 6-23: Barrier hierarchy and type of effect

Type of effect	Legend	Description
Elimination (Technical)		Elimination controls form the 'first line of defence'. They eliminate the underlying hazard and therefore are the most effective category of control measure. If practicable, they should be selected in preference to any other type, as their existence removes the need for any other controls (e.g., a corrosion-resistant metal could replace the original material of construction).
Elimination (Administration)		
Prevention (Technical)		Prevention controls are intended to remove certain causes of incidents or reduce their likelihood. The corresponding hazard remains, but the frequency of incidents involving the hazard is lowered (e.g., introduction of regular maintenance programs can prevent the development of events involving the hazard). Where hazards and causes could not be 'eliminated', controls are required to prevent them from leading to unwanted events and consequences.
Prevention (Administration)		
Detection (Technical)		Detection controls are those that identify a potentially hazardous scenario (e.g., a change in operating parameters), allowing initiation of procedures or systems to prevent the cause occurring. Controls that detect the occurrence of events are often critical to being able to respond with other control measures that reduce the propagation of the events. Detection controls themselves often provide no actual control other than the awareness of the need to respond.
Detection (Administration)		
Reduction/Control (Technical)		Reduction controls are intended to limit the scale and consequence of incidents. They include systems that detect incidents and take some action (e.g., to reduce the rate of leakage of a toxic gas) and also aspects such as inter-unit separation that prevent escalation of fire and explosion incidents. As there is always potential for controls to fail, additional measures are required to limit the scale and severity of any unwanted event or outcome that may arise, by providing the ability to intervene and limit the propagation of the events.
Reduction/Control (Administration)		
Mitigation (Technical)		Mitigation controls take effect in response to an incident. They include controls that lessen the significance or damage caused by an unwanted event. Such controls only take effect after the hazardous event and outcomes occur. Mitigation controls are generally those designed to protect personnel against the consequences of a hazard or to aid in recovering from the effects of the hazard.
Mitigation (Administration)		

6.7.2 Quantitative Spill Risk Assessment Methodology

As part of the risk identification process, Woodside identified the range of credible hydrocarbon spill scenarios that may occur during the Petroleum Activities Program. Scenarios that have been classified as MEEs are assessed in **Sections 6.7.3** to **6.7.8**. Scenarios that are not classified as MEEs (as explained in **Section 6.7.1**) are assessed in **Section 6.8**.

Quantitative hydrocarbon spill modelling was undertaken by RPS, on behalf of Woodside, using a three-dimensional (3D) hydrocarbon spill trajectory and weathering model, SIMAP (Spill Impact Mapping and Analysis Program), which is designed to simulate the transport, spreading and weathering of specific hydrocarbon types under the influence of changing meteorological and oceanographic forces.

A stochastic modelling scheme was followed in this study, whereby SIMAP was applied to repeatedly simulate the defined credible spill scenarios using different samples of current and wind data. These data samples were selected randomly from an historic time-series of wind and current data representative of the study area. Results of the replicate simulations were then statistically analysed and mapped to define contours of percentage probability of contact at identified thresholds around the hydrocarbon release point.

The model simulates surface releases and uses the unique physical and chemical properties of a hydrocarbon type to calculate rates of evaporation and viscosity change, including the tendency to form oil in water emulsions. Moreover, the unique transport and dispersion of surface slicks and in water components (entrained and dissolved) are modelled separately. Thus, the model can be used to understand the wider potential consequences of a spill, including direct contact of hydrocarbons due to surface slicks (floating hydrocarbon) and exposure of organisms to entrained and dissolved aromatic hydrocarbons in the water column.

During each simulation, the SIMAP model records the location (by latitude, longitude and depth) of each of the particles (representing a given mass of hydrocarbons) on or in the water column, at regular time steps. For any particles that contact a shoreline, the model records the accumulation of hydrocarbon mass that arrives on each section of shoreline over time, less any mass that is lost to evaporation and/or subsequent removal by current and wind forces.

The collective records from all simulations are then analysed by dividing the study region into a 3D grid. For surface hydrocarbons (floating oil), the sum of the mass in all hydrocarbon particles located within a grid cell, divided by the area of the cell, provides hydrocarbon concentration estimates in that grid cell at each model output time interval. For entrained and dissolved aromatic hydrocarbon particles, concentrations are calculated at each time step by summing the mass of particles within a grid cell and dividing by the volume of the grid cell. The process is also subject to the application of spreading filters that represent the expected mass distribution of each distinct particle. The concentrations of hydrocarbons calculated for each grid cell, at each time step, are then analysed to determine whether concentration estimates exceed defined threshold concentrations.

Hydrocarbon spill modelling assessments undertaken by RPS undergo initial sensitivity modelling to determine appropriate time to add to the simulation after the cessation of the spill. The amount of time following the spill is based on the time required for the modelled concentrations to practically drop below threshold concentrations anywhere in the model domain in the test cases. This assessment is done by post-processing the sensitivity test results and analysing time-series of median and maximum concentrations in the water and on the surface.

6.7.2.1 Hydrocarbon Characteristics

A summary of the characteristics of the hydrocarbons used as the basis for the modelling studies and subsequently used to inform the assessment of credible hydrocarbon spills is provided in **Table 6-24**.

Additional detail on the characteristics of these hydrocarbons is also provided below.

Table 6-24: Characteristics of the hydrocarbon types used for modelling and ecotoxicological studies

Hydrocarbon Type	Density (g/cm^3) at 25°C	Viscosity (cP) at 25°C	Component	Volatile (%)	Semi-volatile (%)	Low volatility (%)	Residual (%)	Aromatics (%)
			Boiling point (°C)	<180	180-265	265-380	>380	Of whole oil <380
Angel Condensate	0.733	0.205	% of total	67.0	23.8	5.4	3.8	8.3
			% aromatics	5.8	2.0	0.5	-	-
Lambert Deep Rich Fluid	0.736	2.952	% of total	52.9	41.8	4.3	0.9	13.3
			% aromatics	7.1	5.6	0.6	-	-

			% aromatics	1.8	1.0	0.2	-	-

** at 15°C*

*** at 20°C*

6.7.2.2 Angel Condensate

Angel condensate is a mixture of volatile and persistent hydrocarbons with high proportions of volatile and semi-volatile components. In favourable evaporation conditions, about 67.0% of the oil mass should evaporate within the first 12 hours, a further 23.8% should evaporate within the first 24 hours, and a further 5.4% should evaporate over several days. Only about 3.8% of the oil is shown to be persistent (RPS, 2021).

The whole oil has a low asphaltene content (< 0.5%), indicating a low propensity for the mixture to take up water to form water-in-oil emulsion over the weathering cycle.

Soluble, aromatic, hydrocarbons contribute approximately 8.3% by mass of the whole oil. Around 5.8% by mass is highly soluble and highly volatile. A further 2.5% by mass has semi-to-low volatility. These compounds dissolve more slowly but tend to persist in soluble form for longer. Discharge onto the water surface will favour the process of evaporation over dissolution under calm sea conditions, but increased entrainment of oil and dissolution of soluble compounds can be expected under breaking wave conditions (RPS, 2021).

The mass balance forecast for the constant-wind case (see **Figure 6-4** for Angel Condensate) shows that approximately 90.8% of the oil is predicted to evaporate within 24 hours. Under calm conditions, the majority of the remaining oil on the water surface will weather at a slower rate due to being comprised of the longer-chain compounds with higher boiling points. Evaporation of the residual compounds will slow significantly, and they will then be subject to more gradual decay through biological and photochemical processes (RPS, 2021).

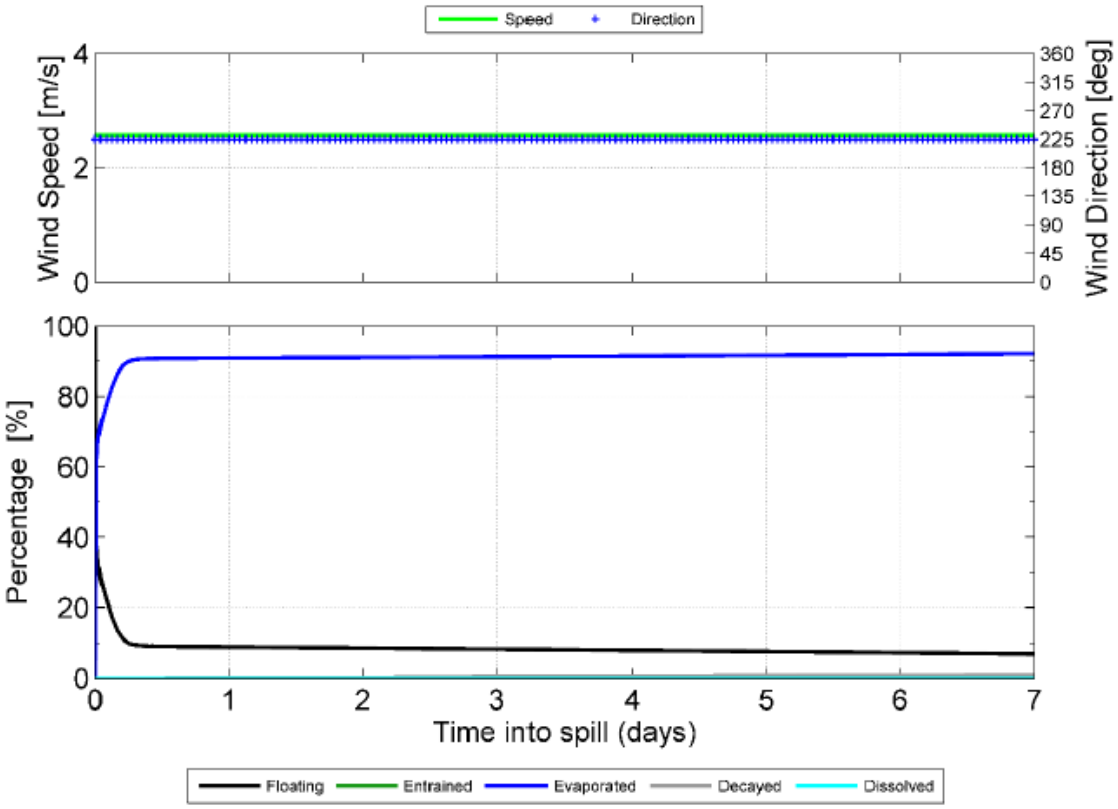

Figure 6-4: Proportional mass balance plot representing the weathering of Angel Condensate spilled onto the water surface as a one-off instantaneous release and subject to a constant 5 kn (2.6 m/s) wind at 27°C water temperature and 25°C air temperature

Under the variable-wind case (see **Figure 6-5**), where the winds are of greater strength on average, entrainment of Angel condensate into the water column is predicted to increase. Approximately 24 hours after the spill, around 14.5% of the oil mass is forecast to have entrained and a further 83.5% is forecast to have evaporated, leaving only a small proportion of the oil floating on the water surface (<1%). The residual compounds will tend to remain entrained beneath the surface under conditions that generate wind waves (approximately >6 m/s) (RPS, 2021).

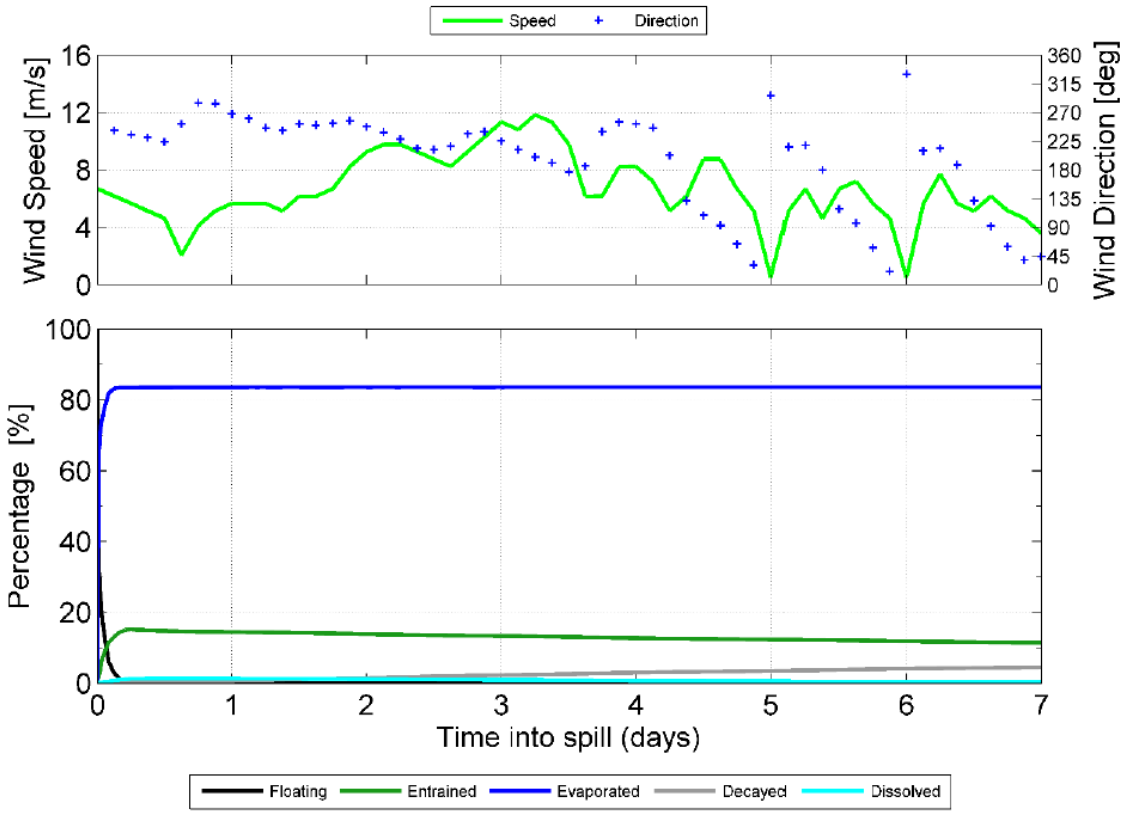

Figure 6-5: Proportional mass balance plot representing the weathering of Angel condensate spilled onto the water surface as a one-off instantaneous release and subject to variable wind at 27°C water temperature and 25°C air temperature.

6.7.2.3 Lambert Deep Rich Fluid

Lambert Deep rich fluid is a mixture of volatile and persistent hydrocarbons with high proportions of volatile and semi-volatile components. In favourable evaporation conditions, about 52.9% of the oil mass should evaporate within the first 12 hours, a further 41.8% should evaporate within the first 24 hours, and a further 4.3% should evaporate over several days. Only about 0.9% of the oil is shown to be persistent (RPS, 2021).

The whole oil has no asphaltenes, indicating no propensity for the mixture to take up water to form water-in-oil emulsion over the weathering cycle.

Soluble, aromatic, hydrocarbons contribute approximately 13.3% by mass of the whole oil. Around 7.1% by mass is highly soluble and highly volatile. A further 5.6% by mass has semi-to-low volatility. These compounds dissolve more slowly but tend to persist in soluble form for longer. Discharge onto the water surface will favour the process of evaporation over dissolution under calm sea conditions, but increased entrainment of oil and dissolution of soluble compounds can be expected under breaking wave conditions (RPS, 2021).

The mass balance forecast for the constant-wind case (see **Figure 6-6**) for Lambert Deep rich fluid shows that approximately 94.8% of the oil is predicted to evaporate within 24 hours. Under calm conditions, the majority of the remaining oil on the water surface will weather at a slower rate due to being comprised of the longer-chain compounds with higher boiling points. Evaporation of the residual compounds will slow significantly, and they will then be subject to more gradual decay through biological and photochemical processes (RPS, 2021).

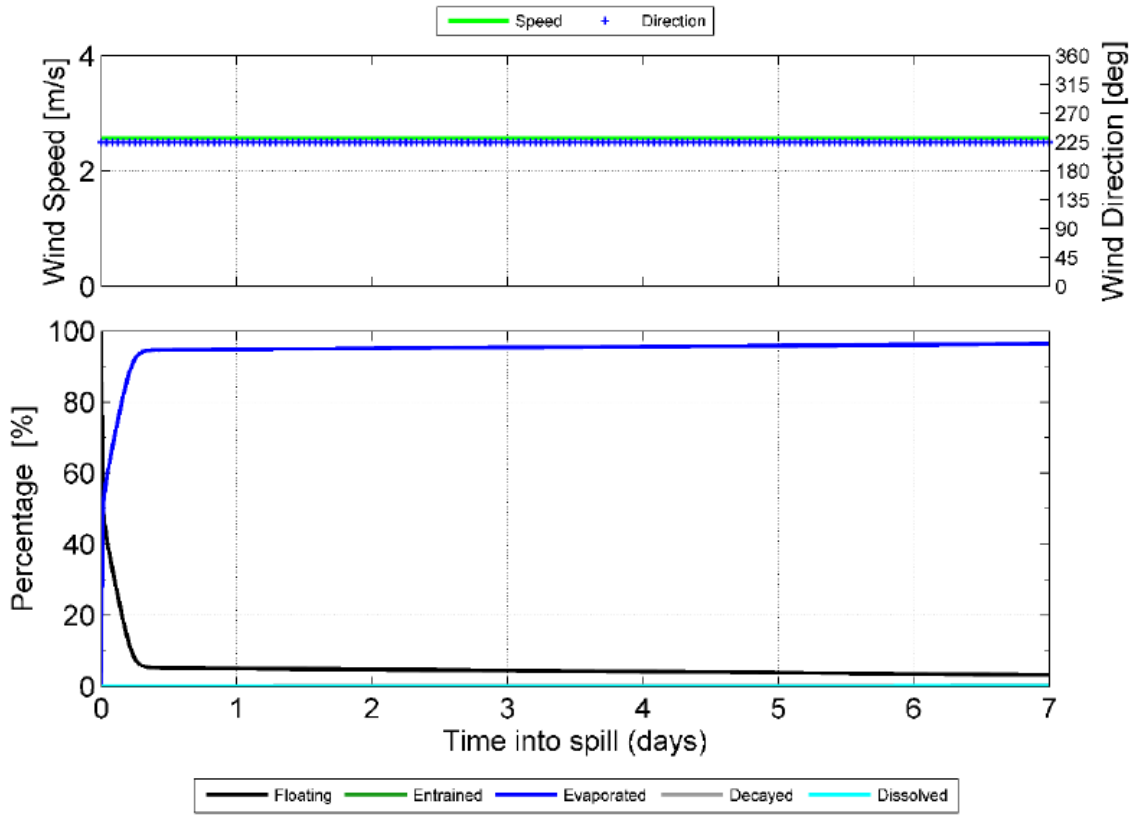

Figure 6-6: Proportional mass balance plot representing the weathering of Lambert Deep rich fluid spilled onto the water surface as a one-off instantaneous release and subject to a constant 5 kn (2.6 m/s) wind at 27°C water temperature and 25°C air temperature

Under the variable-wind case (see **Figure 6-7**), where the winds are of greater strength on average, entrainment of Lambert Deep rich fluid into the water column is predicted to increase. Approximately 24 hours after the spill, around 14.3% of the oil mass is forecast to have entrained and a further 81.8% is forecast to have evaporated, leaving only a small proportion of the oil floating on the water surface (<1%). The residual compounds will tend to remain entrained beneath the surface under conditions that generate wind waves (approximately >6 m/s) (RPS, 2021).

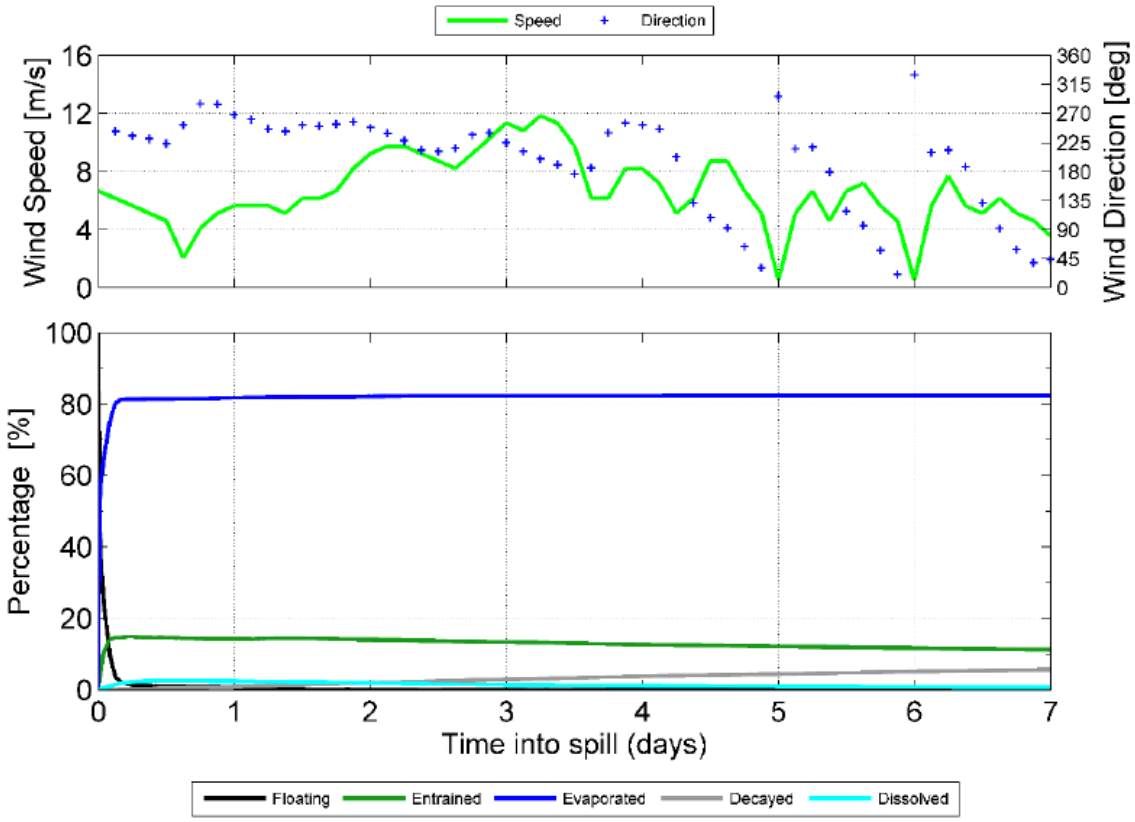

Figure 6-7: Proportional mass balance plot representing the weathering of Lambert Deep rich fluid spilled onto the water surface as a one-off instantaneous release and subject to variable wind at 27°C water temperature and 25°C air temperature

6.7.2.4 Lambert Deep Condensate

Lambert Deep condensate is a mixture of volatile and persistent hydrocarbons with high proportions of volatile and semi-volatile components. In favourable evaporation conditions, about 41.8% of the oil mass should evaporate within the first 12 hours (BP < 180°C); up to a further 24.6% could evaporate within the first 24 hours (BP 180°C to 265°C); and a further 23.8% should evaporate over several days (BP 265°C to 380°C). Approximately 9.9% of the oil is shown to be persistent.

The whole oil has a low asphaltene content (< 0.1%), indicating a low propensity for the mixture to take up water to form water-in-oil emulsion over the weathering cycle.

Soluble, aromatic hydrocarbons contribute approximately 26.1% by mass of the whole oil. 10.5% by mass is highly soluble and highly volatile. A further 15.6% by mass has semi-to-low volatility. These compounds dissolve more slowly but tend to persist in soluble form for longer. Discharge onto the water surface will favour the process of evaporation over dissolution under calm sea conditions, but increased entrainment of oil and dissolution of soluble compounds can be expected under breaking wave conditions.

The mass balance forecast for the constant-wind case for Lambert Deep Condensate shows that approximately 64.3% of the oil is predicted to evaporate within 12 hours. Under these calm conditions the majority of the remaining oil on the water surface will weather at a slower rate due to being comprised of the longer-chain compounds with higher boiling points. Evaporation of the residual compounds will slow significantly, and they will then be subject to more gradual decay through biological and photochemical processes.

Under the variable-wind case, where the winds are of greater strength, entrainment of Lambert Deep Condensate into the water column is indicated to be significant. Approximately 12 hours after the

spill, around 35.8% of the oil mass is forecast to have entrained and a further 53.2% is forecast to have evaporated, leaving only a small proportion of the oil floating on the water surface (<1%). The residual compounds will tend to remain entrained beneath the surface under conditions that generate wind waves (approximately >6 m/s).

The increased level of entrainment in the variable-wind case (**Figure 6-8**) will result in a higher percentage of biological and photochemical degradation, where the decay of the floating slicks and oil droplets in the water column occurs at an approximate rate of 2.3% per day with an accumulated total of ~14.9% after seven days, in comparison to a rate of ~0.24% per day and an accumulated total of 1.7% after seven days in the constant-wind case. Given the considerable proportion of entrained oil and the tendency for it to remain mixed in the water column, the remaining hydrocarbons will decay and/or evaporate over time scales of several weeks to a few months. This long weathering duration will extend the area of potential effect, requiring the break-up and dispersion of the slicks and droplets to reduce concentrations below the thresholds considered in this study.

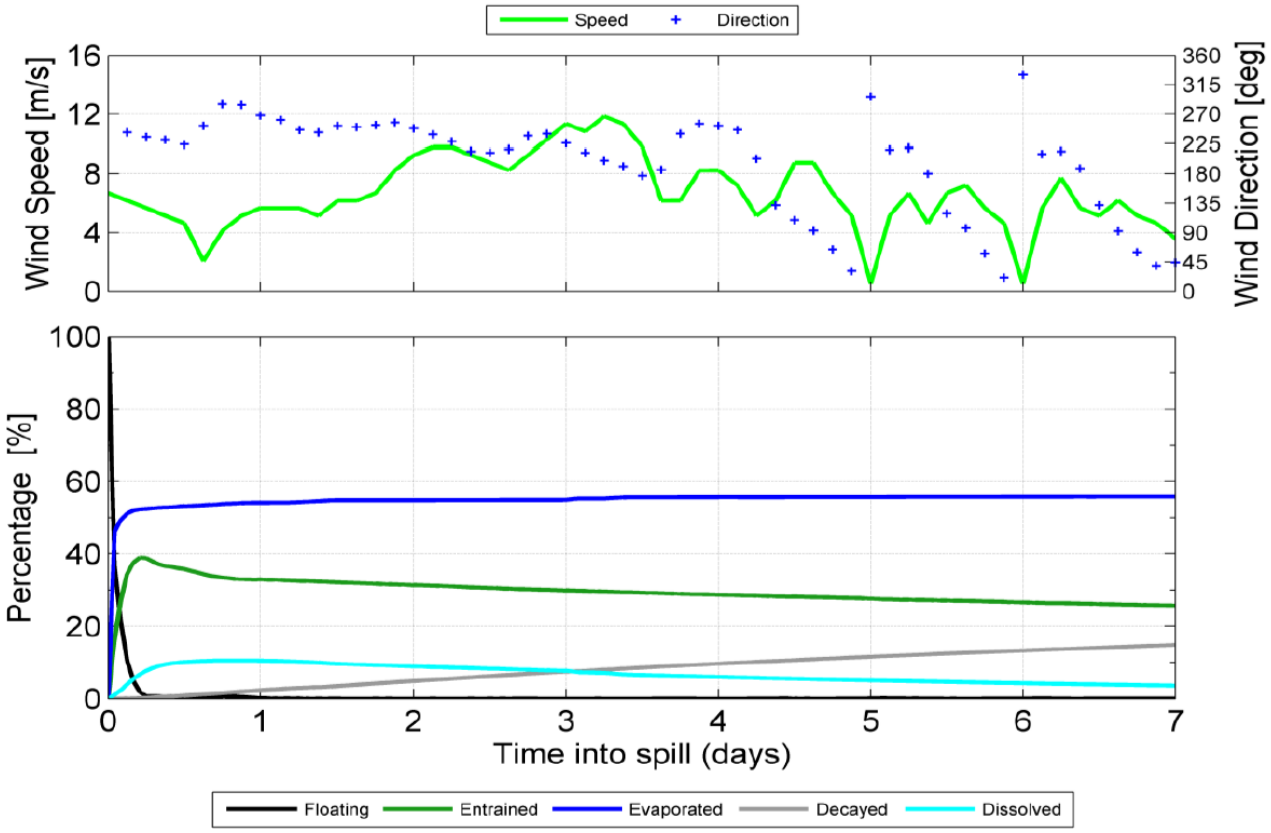

Figure 6-8: Proportional mass balance plot representing the weathering of Lambert Deep condensate spilled onto the water surface as a one-off release (50 m^3 over one hour) and subject to variable wind at 27°C water temperature and 25°C air temperature

6.7.2.5 Marine Diesel

Marine diesel is a mixture of volatile and persistent hydrocarbons with low proportions of highly volatile and residual components. In general, about 6% of the oil mass should evaporate within the first 12 hours (boiling point < 180°C); a further 35% should evaporate within the first 24 hours (180°C < boiling point < 265°C); and a further 54% should evaporate over several days (265°C < boiling point < 380°C). About 5% of the oil is shown to be persistent. The aromatic content of the oil is about 3% (RPS, 2019).

The mass balance forecast for the constant-wind case for marine diesel shows that about 41% of the oil is predicted to evaporate within 24 hours. Under these calm conditions the majority of the remaining oil on the water surface weathers at a slower rate due to comprising the longer-chain

compounds with higher boiling points. Evaporation of the residual compounds slows significantly and is then subject to more gradual decay through biological and photochemical processes (RPS, 2019).

Under the more realistic variable-wind case **Figure 6-9**, where the winds are of greater strength, entrainment of marine diesel into the water column is indicated to be significant. About 24 hours after the spill, around 72% of the oil mass is forecast to have entrained and a further 24% is forecast to have evaporated, leaving only a small proportion of the oil floating on the water surface (<1%). The residual compounds tend to remain entrained beneath the surface under conditions that generate wind waves (about >6 m/s).

The increased level of entrainment in the variable-wind case results in a higher percentage of biological and photochemical degradation, where the decay of the floating slicks and oil droplets in the water column occurs at an approximate rate of 2.4% per day with an accumulated total of ~16% after seven days, in comparison to a rate of ~0.2% per day and an accumulated total of 1.3% after seven days in the constant-wind case. Given the large proportion of entrained oil and the tendency for it to remain mixed in the water column, the remaining hydrocarbons decay and/or evaporate over time scales of several weeks to a few months. This long weathering duration extends the area of potential effect (RPS, 2019).

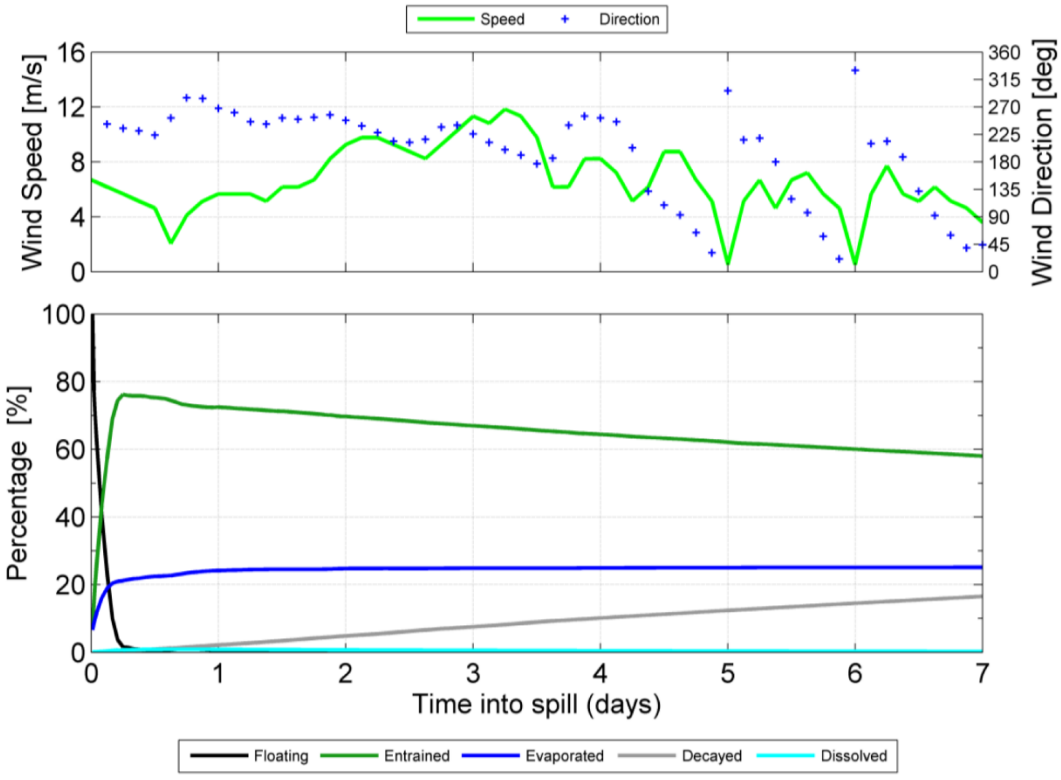

Figure 6-9: Proportional mass balance plot representing the weathering of marine diesel spilled onto the water surface as a one-off release (50 m^3 over one hour) and subject to variable wind at 27°C water temperature and 25°C air temperature

6.7.2.6 Environment that May Be Affected and Hydrocarbon Contact Thresholds

The outputs of the quantitative hydrocarbon spill modelling are used to assess the environmental consequence by delineating which areas of the marine environment could be exposed to hydrocarbon levels exceeding selected hydrocarbon threshold concentrations if a credible hydrocarbon spill scenario occurred. The summary of the locations where hydrocarbon thresholds could be exceeded by any of the simulations modelled is defined as the EMBA. The EMBA covers a larger area than the area that is likely to be affected during any single spill event, as the model

was run for a variety of weather and metocean conditions, and the EMBA represents the total extent of all the locations where hydrocarbon thresholds could be exceeded from all modelling runs.

As the weathering of different fates of hydrocarbons (surface, entrained and dissolved) differs due to the influence of the metocean mechanism of transportation, a different EMBA is presented for each hydrocarbon fate. Together, these EMBA have defined the spatial extent for the existing environment described in **Section 4**.

The spill modelling outputs are presented as areas that meet threshold concentrations for surface, entrained and dissolved hydrocarbons for the modelled scenarios. Surface spill concentrations are expressed as grams per square metre (g/m^2), with entrained and dissolved aromatic hydrocarbon concentrations expressed as parts per billion (ppb). A conservative approach to selecting thresholds was taken by adopting the guideline impact thresholds (NOPSEMA, 2019) for surface, entrained, dissolved and accumulated hydrocarbons to define the EMBA for condensate spills from a loss of well control and marine diesel spills. An additional threshold has been included to define the boundary within which socio-cultural impacts may occur, based on visible surface oil (1 g/m^2) impacting on the visual amenity of the marine environment. Each of these hydrocarbon thresholds are presented in **Table 6-25** and described in the sub-sections below.

Table 6-25: Summary of thresholds applied to the quantitative hydrocarbon spill risk modelling results

Hydrocarbon type	EMBA				Socio-cultural EMBA
	Dissolved hydrocarbon (ppb)	Entrained hydrocarbon (ppb)	Surface hydrocarbon (g/m^2)	Accumulated / shoreline hydrocarbon (g/m^2)	Surface hydrocarbon (g/m^2)
Condensate	50	100	10	100	1
Marine Diesel	50	100	10	100	1

6.7.2.7 Scientific Monitoring

A planning area for scientific monitoring is also described in **Section 5.7** of the Oil Spill Preparedness and Response Mitigation Assessment (**Appendix D**). This planning area has been set with reference to the low exposure entrained value of 10 ppb detailed in the NOPSEMA (2019) bulletin Oil Spill Modelling.

A scientific monitoring program may be activated following a release event with the potential to contact sensitive environmental receptors. This would consider receptors at risk (ecological and socio-economic) and in particular, any identified pre-emptive baseline areas (PBAs) for the worst-case credible spill scenario or other identified unplanned hydrocarbon releases associated with the operational activities.

6.7.3 Unplanned Hydrocarbon Release: Loss of Well Containment from Operating Wells (MEE-01)

Context		
Reservoir and Wells – **Section 3.4.3**	Physical Environment – **Section 4.4** Habitats and Biological Communities – **Section 4.5** Protected Species **– Section 4.6** Protected Places – **Section 4.8** Socio-economic and Cultural – **Section 4.9**	Consultation – **Section 5**

Release of hydrocarbons resulting from loss of subsea well containment from operating wells (MEE-01)		✓	✓	✓	✓	✓	✓	B	A	1	H	LCS GP PJ RBA CV SV	Acceptable if ALARP	**EPO 13**

Description of Source of Risk

During operations, the facility will receive hydrocarbons via the Lambert Deep flowline, from the LDA-01 and LDA-02 wells, as described in **Section 3.4**. The three Angel wells, AP2, AP3 and AP4, have been shut-in due to high water cut, with no further plans to produce hydrocarbons from the field. The surface-controlled sub surface safety valve (SCSSSV) located down each of the three Angel wells has been closed and leak off tested, however; because the wells are not yet plugged and abandoned, loss of containment was considered during risk assessment activities for the Angel facility. Loss of well containment can lead to an uncontrolled release of reservoir hydrocarbons and well fluids to the environment (i.e., well blowout). Woodside has identified a well blowout as the scenario with the worst-case credible environmental outcome as a result of this event. Due to the potential consequences, a loss of well containment during operations is considered to be an MEE (MEE-01).

This MEE scenario applies only after the flowing of well fluids into production infrastructure (as explained in **Section 6.7.1**). The Loss of Well Containment MEE scenario during the drilling and any MODU-based well test of LDA-02 is considered separately in **Section 6.8.1**.

- A loss of well containment during operations could occur due to a variety of causes including:
- internal corrosion
- external corrosion
- erosion
- overpressure of the annuli
- fatigue
- loss of control of suspended load from vessel (operating near subsea wells) (MEE-04; **Section 6.7.6**)
- anchor drag.

A number of common failure causes due to human error and SCQ failures are presented in the generic Human Error and SCE Failure bowties in **Section 6.7.8**.

Loss of Well Control – Credible Scenario

The credible worst-case loss of well containment scenario identified for the Petroleum Activities Program is a well blowout of the AP3 well, chosen because it is the most crestal and recently producing of the Angel wells. A blowout scenario could occur if the SCSSSV fails or is opened and there has been a loss of the Xmas tree or failure of the tree valves (Production Master Valve and Production Wing Valve).

The loss of well containment scenario was assumed to have a release duration of 68 days. This duration is based on the estimated time required to successfully drill an intervention well (refer to **Appendix D** for additional discussion of relief well timing). The relief well drilling time shown in **Table 6-26** is for a rig with pre-lay moorings, however; using rig anchors would reduce drilling time by a further 14 days.

The characteristics of the release scenario are summarised in **Table 6-27**. Refer to **Section 6.7.2** for additional information on modelling methods, environmental impact thresholds and hydrocarbon characteristics.

Table 6-26: Relief well drilling duration

Description	***Time for completion (days)***	
	Moored days – AP3	***Moored days – LDA02***
Rig mobilisation		
Secure and suspend well. Complete Relief well design. Secure relief well materials	8	8
Transit to location based on mobilisation from within the region	2	2

Execute well-specific ranging plan to accurately intersect wellbore in minimum timeframe	9.5	9.5
Pump kill weight drilling fluid per the relief well plan. Confirm well is static with no further flow	0.5	0.5
Contingency for unforeseen technical issues	2.5	2.5
Total days	**68**	**77**

Table 6-27: Summary of worst-case loss of well containment hydrocarbon release scenarios

Scenario	Hydrocarbon	Rate (m^3/day)	Duration (days)	Depth (m)	Latitude	Longitude	Total Condensate Release Volume (m^3)
Scenario 2A Well blowout at seabed (AP3)	Angel Condensate	1,585	68	79	19° 3'' 38.51" S	116° 3'' 18.57" E	107,779

Decision Type, Risk Analysis and ALARP Tools

Woodside implements industry standard practice in well design and construction. In the company's recent history, it has not experienced any well integrity events that have resulted in significant releases or significant environmental impacts. Woodside has never experienced a worst-case loss of well containment in its operational history.

Decision Type

Decision Type B has been applied to this risk under the Guidance on Risk Related Decision Making (Oil and Gas UK, 2014). This reflects the complexity of the risk, the higher potential consequence and stakeholder implications should the event be realised. To align with this decision type, a further level of analysis has been applied using risk based tools including the bowtie methodology (described in **Section 2.6.3**) and hydrocarbon spill trajectory modelling

(described in **Section 6.7.2**). Company and societal values were also considered in the demonstration of ALARP and acceptability, through peer review, benchmarking and consultation (**Section 5**).

The release of hydrocarbons as a result of well loss of containment is considered a Major Environment Event (MEE-01). The hazard associated with this MEE is hydrocarbons in reservoirs, wells, wellheads and Xmas trees tied back to the facility.

Quantitative Spill Risk Assessment

Spill modelling of the worst-case credible loss of well containment spill scenario was undertaken by RPS, to determine the fate of hydrocarbons released based on the assumptions in **Section 6.7.2**. Modelling was undertaken over all seasons to address year-round operations. This is considered to provide a conservative estimate of the EMBA and the potential impacts from the identified worst-case credible release volumes for all loss of well containment scenarios.

Hydrocarbon Characteristics

Hydrocarbon characteristics of Angel condensate are provided in **Table 6-24** and described in more detail in **Section 6.7.2.1**.

Subsea Plume Dynamics

The subsea loss of well containment scenario would result in a buoyant plume of hydrocarbons, which has been modelled using the OILMAP-Deep numerical model (summarised in **Table 6-28**).

Table 6-28: Near-field subsurface discharge model parameters for loss of well containment scenario

Scenario	Hydrocarbon	Rate (m^3/hr)	Duration (days)	Depth (m)
Well blowout at seabed (AP3)	Angel Condensate	66	68	79

Likelihood

In accordance with the Woodside Risk Matrix, a worst-case loss of well containment has been defined as a 'highly unlikely' event as it 'has occurred once or twice in the industry' (experience-based likelihood) and aligns with a frequency of a '1 in 10,000 to 1 in 100,000 year' event. Information to support this likelihood determination is outlined below. Review of industry statistics indicates the probability of a loss of well containment for production wells is low (10.6% of blowouts) relative to other activities in other hydrocarbon provinces (Gulf of Mexico and the North Sea), such as exploration drilling (31.5% of blowouts), development drilling (23.6% of blowouts) and well workovers (20.5% of blowouts) (SINTEF, 2017).

Consequence

The spatial extent and fate (including weathering) of the spilled hydrocarbon were considered during the impact assessment for a worst-case loss of well containment (presented in the following section). These considerations were informed primarily by the outputs from the numerical modelling studies undertaken by RPS, available information on environmental sensitivities that may credibly be impacted in the event of a worst-case spill, and relevant literature and studies considering the effects of hydrocarbon exposure.

Consequence Assessment

Environment that May Be Affected

Surface Hydrocarbons

Hydrocarbon spill modelling for surface hydrocarbons indicated that concentrations equal to or greater than the 10 g/m^2 ecological threshold could potentially be found, in the form of slicks, up to 382 km (south-west) from the release location. There is minimal surface hydrocarbon contact with receptors for the worst-case scenario; receptors contacted were limited to the Gascoyne AMP (2%), Muiron Islands (1%) and associated Muiron Islands MMA (1%).

Entrained Hydrocarbons

Entrained oil concentrations equal to or greater than the 100 ppb ecological thresholds are predicted to be found up to 442 km (south-west) from the release location. A number of receptors were predicted to be contacted by entrained hydrocarbons (full list provided in **Table 6-29**). The greatest probabilities of contact were at the Gascoyne AMP (14%), Montebello AMP (23%), Ningaloo MP (16%), Muiron Islands (15%), Muiron Islands MMA (17%) and Ningaloo Coast WHA (16%).

Dissolved Hydrocarbons

Dissolved aromatic hydrocarbon concentrations equal to or greater than the 50 ppb ecological threshold are predicted to be found up to about 305 km (south-west) from the release location. Five receptors were predicted to be contacted by dissolved hydrocarbons; Montebello AMP (18%), Montebello Island MP (1%), Glomar Shoals (30%), Rankin Bank (7%) and Tryal Rocks (1%).

Accumulated Hydrocarbons

A number of receptors were predicted to receive shoreline hydrocarbons in the spill modelling. Those receptors with the highest probability of contact at the 100 g/m^2 ecological threshold are the Muiron Islands (26%) (including the Muiron Islands MMA; 26%), Peak Island (14%) and the Southern Pilbara Islands (14%).

Summary of Potential Impacts to Environmental Value(s)

Figure 4-1 presents the full extent of the EMBA for loss of well containment (within which all other credible hydrocarbon spill EMBAs are contained); i.e., the sensitive receptors and their locations that may be exposed to hydrocarbons (surface, entrained, dissolved and accumulated) at or above the set threshold concentrations in the unlikely event of a loss of well containment during the Petroleum Activities Program. Details of these receptors are outlined in **Section 4**. The potential biological and ecological impacts of an unplanned hydrocarbon release as a result of a loss of well containment during the Petroleum Activities Program are discussed in the following sections.

Table 6-29: Environment that may be affected – key receptor locations and sensitivities potentially contacted above impact thresholds by the loss of well containment scenario with summary hydrocarbon spill contact

Open Water Environment (Near Spill Area)

Air Quality

A hydrocarbon release during a loss of well containment has the potential to result in localised, temporary reduction in air quality and contribution of greenhouse gases to the global concentration of these gases in the atmosphere. Potential impacts from reduced air quality are expected to be minor, short-term and predominantly localised.

There is potential for human health effects for workers in the immediate vicinity of atmospheric emissions. The ambient concentrations of methane and VOCs released from diffuse sources is difficult to accurately quantify, although the behaviour and fate is predictable in open offshore environments as it is dispersed rapidly by meteorological factors such as wind and temperature. Methane and VOC emissions from a hydrocarbon release in such environments are rapidly degraded in the atmosphere by reaction with photochemically-produced hydroxyl radicals.

Due to the unlikely occurrence of a loss of well containment; the temporary nature of any methane or VOC emissions (from either gas surfacing or weathering of liquid hydrocarbons from a loss of well containment); the predicted behaviour and fate of methane and VOCs in open offshore environments; and the significant distance from the PAA to the nearest sensitive air shed (town of Dampier, about 126 km away), the potential impacts are expected to be minor and short-term.

Water Quality

Water quality would be affected in the offshore environment within the EMBA due to hydrocarbon contamination from entrained, dissolved and surface hydrocarbons. Due to the weathering processes of the hydrocarbons, impacts to water quality are anticipated to be minor long term and/or significant short term as a result of hydrocarbon contamination above background levels.

Marine Sediment Quality

Studies of hydrocarbon concentrations in deep sea sediments in the vicinity of a catastrophic well blowout indicate hydrocarbon from the blowouts can be incorporated into marine sediments (Romero et al., 2015). Proposed mechanisms for hydrocarbon contamination of sediments include sedimentation of hydrocarbons and direct contact between submerged plumes and the seabed (Romero et al., 2015). In the event of a major hydrocarbon release at the seabed, modelling indicates that a pressurised release of condensate would atomise into droplets that would be transported into the water column to the surface. As a result, the extent of potential impacts to the seabed area at and surrounding the release site would be confined to a localised footprint. Marine sediment quality would be reduced as a consequence of hydrocarbon contamination for a small area within the immediate release site for a long to medium term.

Benthic Fauna Communities

In the event of a loss of well containment at the seabed, the spill modelling predicted hydrocarbon droplets would be entrained in a gas plume, transporting them through the water column and to the sea surface. As a result, the low sensitivity benthic communities associated with the unconsolidated, soft sediment habitat within the PAA are generally not expected to be exposed to released hydrocarbons. A localised area of impact relating to the hydrocarbon plume at the point of release is however predicted, which would result in a small area of seabed and any associated epifauna and infauna being exposed to hydrocarbons. Impacts to benthic communities within the PAA would subsequently be limited to the immediate area around the release site and may include lethal or sub-lethal impacts.

Within the offshore waters of the EMBA, impacts to benthic fauna on the seafloor are not anticipated as hydrocarbons are not expected to gravitate toward the seafloor (as described above).

Benthic fauna at geomorphic features located within the water column such as shoals and banks may be impacted by dissolved and/or entrained hydrocarbons (refer to receptors in **Table 6-29**). Spill modelling indicates that Glomar Shoals KEF and Rankin Bank, for example, would be contacted by dissolved hydrocarbons. These features support benthic communities that may be impacted by these hydrocarbons. Notably, given the depths of Rankin Bank and Glomar Shoals KEF, the potential for impacts to benthic communities is considered to be significantly reduced given hydrocarbons will primarily feature in the upper water column.

Demersal and pelagic fish species are associated with the following offshore features within the PAA and/or EMBA (described in **Appendix C**):

- ancient coastline at the 125 m depth contour KEF– overlaps the PAA
- Glomar Shoals KEF– overlaps the PAA
- continental slope demersal fish communities KEF – 68 km west of the PAA
- Glomar Shoals KEF – about 10 km east of the PAA (and 17 km east of the Angel facility)
- Rankin Bank – about 54 km west of the PAA.

These KEFs and geomorphic features may host relatively diverse or abundant fish assemblages compared to the otherwise relatively featureless continental shelf habitats of the NWMR. Impacts to KEFs are discussed below. In summary, impacts to these features are considered to be unlikely. Indirect impacts due to decreased habitat quality at

these KEFs to pelagic and demersal fish communities are, therefore, considered unlikely. Impacts to pelagic fish (associated with receptors such as Glomar Shoals and Rankin Bank) from hydrocarbons are described herein.

Fish mortalities are rarely observed to occur as a result of hydrocarbon spills (International Tanker Owners Pollution Federation, 2011b). This has generally been attributed to the possibility that pelagic fish are able to detect and avoid surface waters underneath hydrocarbon spills by swimming into deeper water or away from the spill affected areas. Fish that have been exposed to dissolved aromatic hydrocarbons are capable of eliminating the toxicants once placed in clean water. Hence individuals exposed to a spill are likely to recover (King et al., 1996). Where fish mortalities have been recorded historically, the spills (resulting from the groundings of the tankers Amoco Cadiz in 1978 and the Florida in 1969) have occurred in sheltered bays.

Laboratory studies have shown that adult fish are able to detect hydrocarbons in water at very low concentrations, and large numbers of dead fish have rarely been reported after hydrocarbon spills (Hjermann et al., 2007). This suggests that juvenile and adult fish are capable of avoiding water contaminated with high concentrations of hydrocarbons. However, sub-lethal impacts to adult and juvenile fish may be possible, given long-term exposure (days to weeks) to polyaromatic hydrocarbon (PAH) concentrations (Hjermann et al., 2007). While modelling of the loss of well containment indicates the potential EMBA for dissolved hydrocarbons is relatively extensive, no time-integrated exposure metrics were modelled; given the oceanographic environment within the EMBA, PAH exposures in the order of weeks for pelagic fish are not considered credible.

The effects of exposure to oil on the metabolism of fish appears to vary according to the organs involved, exposure concentrations and route of exposure (waterborne or food intake). Oil reduces the aerobic capacity of fish exposed to aromatics in the water and to a lesser extent affects fish consuming contaminated food (Cohen et al., 2005). The liver, a major detoxification organ, appears to be the organ where anaerobic activity is most impacted, probably increasing anaerobic activity to facilitate the elimination of ingested oil from the fish (Cohen et al., 2005).

Fish are perhaps most susceptible to the effects of spilled oil in their early life stages, particularly during egg and planktonic larval stages, which can become entrained in spilled oil. Contact with oil droplets can mechanically damage feeding and breathing apparatus of embryos and larvae (Fodrie and Heck, 2011). The toxic hydrocarbons in water can result in genetic damage, physical deformities and altered developmental timing for larvae and eggs exposed to even low concentrations over prolonged timeframes (days to weeks) (Fodrie and Heck, 2011). More subtle, chronic effects on the life history of fish as a result of exposure of early life stages to hydrocarbons include disruption to complex behaviours such as predator avoidance, reproductive and social behaviour (Hjermann et al., 2007). Prolonged exposure of eggs and larvae to weathered concentrations of hydrocarbons in water has also been shown to cause immunosuppression and allows expression of viral diseases (Hjermann et al., 2007). PAHs have also been linked to increased mortality and stunted growth rates of early life history (pre-settlement) of reef fishes, as well as behavioural impacts that may increase predation of post-settlement larvae (Johansen et al., 2017). However, the effect of a hydrocarbon spill on a population of fish in an area with fish larvae and/or eggs, and the extent to which any of the adverse impacts may occur, depends greatly on prevailing oceanographic and ecological conditions at the time of the spill and its contact with fish eggs or larvae.

Hydrocarbons above ecological thresholds may subsequently impact populations located near to the release location for the worst-case spill scenario, with lethal impacts not considered likely in this offshore environment.

Protected Places

Receptors

The Australian Marine Parks (AMPs) listed in **Section 4.8** may be affected by a worst-case spill scenario. The AMPs were predicted to potentially be contacted by surface (Gascoyne Marine Park), entrained (Gascoyne, Montebello and Ningaloo Marine Parks) and dissolved (Montebello Marine Parks) hydrocarbons in the event of a worst-case spill scenario. The Argo-Rowley Terrace Marine Park was also predicted to be contacted by entrained hydrocarbons in spill Scenarios 2 and 3 (MEE-02).

Impacts

The Montebello Marine Park is the closest AMP to the PAA (55 km south) predicted to be contacted by hydrocarbons. Impacts to this AMP are discussed below. Impacts to the natural, cultural, heritage and socio-economic values of the other three AMPs predicted to be contacted by hydrocarbons in a worst case spill scenario are expected to be similar, however, of lower severity and duration due to their being at least 100 km further from the PAA.

Montebello Marine Park

The Montebello Marine Park comprises an area about 3413 km², all of which is zoned as a Multiple Use Zone (IUCN VI). The AMP ranges in water depths from less than 15 m up to 150 m.

The Montebello Marine Park is significant as it contains habitats, species and ecological communities representative of the Northwest Shelf Province. It overlaps with The Ancient Coastline at the 125 m Depth Contour KEF (see 'Key Ecological Features' above for a discussion of impacts to KEFs). The AMP provides connectivity between the deeper waters of the continental shelf and slope, and the adjacent Barrow Island and Montebello Islands State Marine Parks. A prominent seafloor feature in the AMP is Trial Rocks, which consists of two close coral reefs that are emergent at low tide. There is subsequently potential for impacts to shallow coral reef communities at Trial Rocks, as discussed in the section 'Marine Primary Producers – Coral Reef' above. The specific values of the AMP and associated impacts are summarised here.

Natural values – The AMP includes diverse benthic and pelagic fish communities and ancient coastline thought to be an important seafloor feature (KEF) and a migratory pathway for humpback whales (BIA). The AMP supports a range of species, including those listed as threatened, migratory, marine and/or cetacean under the EPBC Act. BIAs within the AMP include breeding habitat for seabirds, internesting, foraging, mating and nesting habitat for marine turtles, a migratory pathway for humpback whales and foraging habitat for whale sharks. Impacts to the relevant species and BIAs are discussed in the sections above.

Cultural values – There is limited information about the cultural significance of this AMP, however, it is noted that sea country is valued for Indigenous cultural identity, health and wellbeing. Across Australia, Indigenous people have been sustainably using and managing their sea country for tens of thousands of years. Potential impacts to cultural values of the AMP will closely tie in with the impacts to the natural values of the Marine Park, as addressed above and below; and range from moderate mid-term potential impacts to major long-term potential impacts.

Heritage values – There are no World, National or Commonwealth heritage listings that apply to the AMP. Two historic shipwrecks are located within the Marine Park. Impacts to shipwrecks are discussed below under 'Cultural Heritage'.

Social and economic values – Tourism, commercial fishing, mining and recreation are important activities in the AMP. These activities contribute to the wellbeing of regional communities and the prosperity of the nation. Impacts to tourism and recreation within the AMP are discussed with regard to offshore and nearshore waters in the sections 'Tourism and Recreation' below.

A worst-case hydrocarbon spill scenario has the potential to result in impacts to these AMPs that range from moderate, medium-term to major, long-term, with the consequence severity dependent on the actual timing, duration and extent of a spill.

Key Ecological Features

Ancient coastline at 125 m depth contour

KEFs located within the EMBA are listed in **Section 4.7** (described in **Appendix C**) and may be impacted by a worst-case hydrocarbon spill.

The Ancient Coastline, Continental Slope Demersal Fish Communities, Exmouth Plateau and Canyons linking the Cuvier Abyssal Plane and the Cape Range Peninsula are KEFs primarily defined by seabed geomorphological features and have been classified as KEFs in recognition of the potential for increased biological productivity and, therefore, ecological significance. Potential impacts to these KEFs include the direct and indirect impacts to benthic fauna / habitats and associated impacts to demersal fish populations described in the sections above.

Notably, other than some small outcrops of hard substrate, no features indicative of the ancient coastline have been identified within the portion of this KEF overlapping the PAA (as per **Section 4.7**). The other KEFs are also quite a significant distance from the PAA (68 to 304 km) and given the nature of the hydrocarbon, it is likely to be significantly weathered prior to reaching these receptors.

Glomar Shoals KEF (essentially a buffer applied to Glomar Shoals KEF which has been discussed above) features marine primary producer habitat and site attached fishes, and provides foraging habitat for a number of species, as discussed under the respective sections above. The Commonwealth waters adjacent to Ningaloo Reef are similarly important habitat for these animal groups. Impacts to water quality due to contamination from entrained and dissolved hydrocarbons may cause flow on effects within these ecosystems.

These KEFs cover extensive areas (as listed in **Appendix C**) and, should impacts to receptors within the KEFs (e.g., benthic communities) occur, these would be anticipated to be short lived with no permanent impacts to the KEF.

Protected Species

A number of cetaceans were identified as potentially occurring with the PAA and the EMBA (see **Section 4**). In the event of a loss of well containment; surface, entrained and dissolved hydrocarbons exceeding environmental impact threshold concentrations may drift across habitat for oceanic cetacean species and the migratory routes and/or BIAs of cetaceans considered to be MNES (e.g., humpback whale and pygmy blue whale north and southbound migrations).

Cetaceans that have direct physical contact with surface, entrained or dissolved aromatic hydrocarbons may suffer surface fouling, ingestion of hydrocarbons (including from prey, water and sediments), aspiration of oily water or droplets and inhalation of toxic vapours (Deepwater Horizon Natural Resource Damage Assessment Trustees, 2016). This may result in the irritation of sensitive membranes such as the eyes, mouth, digestive and respiratory tracts and organs, impairment of the immune system, neurological damage (Helm et al., 2015), reproductive failure, adverse health effects (e.g., lung disease, poor body condition) and, potentially, mortality (Deepwater Horizon Natural Resource Damage Assessment Trustees, 2016).

Given cetaceans maintain thick skin and blubber, external exposure to hydrocarbons is more likely to result in irritation to the more exposed skin and eyes. Entrained hydrocarbons may also be ingested, particularly by baleen whales which feed by filtering large volumes of water. Fresh hydrocarbons (i.e., typically in the vicinity of the release location) may have a higher potential to cause toxic effects when ingested, while weathered hydrocarbons are considered to be less likely to result in toxic effects.

Given the non-persistent nature of the relevant hydrocarbons, Angel condensate and Lambert Deep rich fluid (see **Section 6.7.2.1**) and the relatively small floating hydrocarbon EMBA (see **Figure 4-1**), the area where potential

impacts from inhalation and physical contact with surface slicks may occur would primarily be localised around the release location and impacts would most likely be expected to be limited to individuals that contact the slick, as discussed above. Notably, there was minor modelled overlap of surface hydrocarbons (about 295 to 375 km) south-west of the release location, within the humpback whale migration BIA and migration BIA; and the EIO pygmy blue whale foraging (high density) BIA offshore of Ningaloo Reef.

In a review of the impacts of large-scale hydrocarbon spills on cetaceans, it was found that exposure to oil from the Deepwater Horizon resulted in increased mortality to cetaceans in the Gulf of Mexico (DHNRDT, 2016), and long-term population level impacts to killer whales were linked to the Exxon Valdez tanker spill (Matkin et al., 2008). Given the nature of the condensate (compared with crude oil from these two spills) and relatively small nature of the surface slick, such exposure impacts to cetaceans may not eventuate.

Geraci (1988) has identified behavioural disturbance (i.e., avoiding spilled hydrocarbons) in some instances for several species of cetacean, suggesting that cetaceans have the ability to detect and avoid surface slicks. However, observations during spills have also recorded larger whales (both mysticetes and odontocetes) and smaller delphinids traveling through and feeding in oil slicks. During the Deepwater Horizon spill cetaceans were routinely seems swimming in surface slicks offshore (and nearshore) (Aichinger Dias et al., 2017).

Suitable habitat for oceanic toothed whales (e.g., sperm whales) and dolphins (e.g., long-snouted spinner dolphin) is broadly distributed throughout the NWMR and, as such, while these species may be present within the EMBA, impacts from a spill are unlikely to affect an entire population. Notably, there are no known aggregation areas or BIAs for dolphins or whales within the PAA.

East Indian Ocean Pygmy Blue Whale and Humpback Whale

EIO pygmy blue whales and humpback whales are known to migrate seasonally through the EMBA. Notably, the migration BIAs in the NWMR for both species do not overlap the PAA. A major spill event in June through to November would coincide with the humpback whale migration through the waters off the Pilbara, North West Cape and Shark Bay (outside the EMBA). A major spill in April to July or October to January would coincide with EIO pygmy blue whale migration. Both the pygmy blue and humpback whales are baleen whales and are therefore most likely to be significantly impacted by toxic effects when feeding. However, feeding during migrations is typically low level and opportunistic, with most feeding for both species occurring in the Southern Ocean. Subsequently the risk of ingestion of hydrocarbons through feeding is low.

Migrations of both pygmy blue whales and humpback whales are protracted through time and space (i.e., the whole population will not be within the EMBA at any one time), and as such, a spill from a loss of well integrity (MEE-01) is not considered likely to affect an entire population.

Dugong

There are no BIAs or known areas of aggregation in the offshore waters of the EMBA for the dugong.

Summary

A worst-case hydrocarbon spill scenario has the potential to result in moderate, medium-term impacts to offshore cetacean species, with consequence severity dependent on the actual timing, duration and extent of a spill in relation to species' migratory movements and distributions.

Marine Turtles

Five of the six marine turtle species were identified as potentially occurring within the EMBA, with a number of BIAs and Habitat Critical areas identified within the EMBA (see **Section 4.6.2**).

Adult marine turtles exhibit no avoidance behaviour when they encounter hydrocarbon spills (National Oceanic and Atmospheric Administration, 2010). Contact with surface slicks, or entrained hydrocarbon can therefore result in hydrocarbon adherence to body surfaces (Gagnon and Rawson, 2010) causing irritation of mucous membranes in the nose, throat and eyes leading to inflammation and infection (National Oceanic and Atmospheric Administration, 2010). Oiling can also irritate and injure skin, which is most evident on pliable areas such as the neck and flippers (Lutcavage et al., 1995). A stress response associated with this exposure pathway includes an increase in the production of white blood cells and even a short exposure to hydrocarbons may affect the functioning of their salt glands (Lutcavage et al., 1995).

Hydrocarbons in surface waters may also impact turtles when they surface to breathe and inhale toxic vapours. Their breathing pattern, involving large 'tidal' volumes and rapid inhalation before diving, results in direct exposure to petroleum vapours which are the most toxic component of the hydrocarbon spill (Milton and Lutz, 2003). This can lead to lung damage and congestion, interstitial emphysema, inhalant pneumonia and neurological impairment (National Oceanic and Atmospheric Administration, 2010).

Given the hydrocarbon is expected to weather rapidly when released to the environment, relatively fresh entrained hydrocarbons (which are typically relatively close to the release location) are considered to have the greatest potential for impact. Given the non-persistent nature of the hydrocarbons and the relatively small floating hydrocarbon EMBA, the area where potential impacts from inhalation may occur would be localised around the release location. There is also minimal surface hydrocarbon contact with the marine turtle BIAs and Habitat Critical areas listed in **Section 4.6.2**.

Due to the offshore location and water depths within the PAA, this area is unlikely to represent important habitat for marine turtles. There are also no known areas of aggregation (i.e., BIAs, Habitat Critical to Survival) for marine turtles within the PAA.

The EMBA overlaps a number of BIAs and some Habitat Critical to Survival areas for marine turtles (see **Section 4.6.2**). Marine turtles are, therefore, likely to be present in the offshore waters of the EMBA, particularly as they are a migratory species which often travel large distances during migration periods. Important areas of aggregation for foraging, nesting and mating are typically associated with nearshore islands along the Pilbara and Gascoyne coastlines, as opposed to offshore waters.

Summary

In the event of a loss of well containment, there is potential that surface, entrained and dissolved hydrocarbons exceeding environmental impact threshold concentrations will be present in offshore waters. Therefore, a hydrocarbon spill may disrupt a portion of marine turtle populations for the green, flatback, hawksbill, loggerhead and/or leatherback turtle. However, there is considered to be no threat to overall population viability given the non-persistent nature of predicted hydrocarbons.

Seasnakes

A number of seasnake species which are listed Marine under the EPBC Act were identified by the PMST as potentially occurring within the EMBA. No listed Threatened and/or Migratory seasnake species were identified.

Impacts to seasnakes from direct contact with hydrocarbons are likely to result in similar physical effects to those recorded for marine turtles and may include potential damage to the dermis and irritation to mucus membranes of the eyes, nose and throat (International Tanker Owners Pollution Federation, 2011a). They may also be impacted when they return to the surface to breathe and inhale the toxic vapours associated with the hydrocarbons, resulting in damage to their respiratory system.

In general, seasnakes frequent the waters of the continental shelf area around offshore islands and potentially submerged shoals (water depths <100 m) (impacts described below). However, it is acknowledged that seasnakes may be present in the PAA and within the EMBA. Their abundance is not expected to be high in the offshore environment, however. Exclusions may apply to the yellow-bellied seasnake which is known to be pelagic.

In summary, a hydrocarbon spill may have a minor disruption to some individuals in the offshore environment. Population level impacts to seasnake species are not, however, considered credible.

Sharks and Rays

A number of shark and ray species were identified as potentially occurring within the PAA and/or EMBA (see **Section 4.6.1**). Two foraging BIAs for one of these, the whale shark, overlap with the EMBA; foraging (northward from Ningaloo along the 200 m isobath; PAA, EMBA) and foraging (high prey density – Ningaloo Marine Park; EMBA). Whale sharks are, therefore, likely to transit the open offshore waters within the EMBA while they migrate to and from Ningaloo Reef between July and November.

Other listed Threatened pelagic species identified in the PMST report as potentially occurring within the EMBA include the white shark and grey nurse shark. There are no known areas of aggregation for these species in the offshore waters of the EMBA.

Impacts to sharks and rays may occur through direct contact with hydrocarbons and contaminate the tissues and internal organs either through direct contact or via the food chain (i.e., consumption of prey). As gill breathing organisms, sharks and rays may be vulnerable to toxic effects of dissolved hydrocarbons (entering the body via the gills) and entrained hydrocarbons (coating of the gills inhibiting gas exchange). In the offshore environment, it is probable that pelagic shark species, such as the whale shark, are able to detect and avoid surface waters underneath hydrocarbon spills by swimming into deeper water or away from the affected areas.

Impacts to whale sharks from a hydrocarbon spill will depend on the timing of the spill; however, whale sharks as a pelagic species are expected to demonstrate avoidance behaviour and population level impacts are not anticipated.

Seabirds

A number of EPBC Act listed Threatened and/or Migratory seabird and shorebird species were identified by the PMST as potentially occurring within the PAA and/or EMBA (see **Section 4.6.4**), including the wedge-tailed shearwater, fairy tern, lesser crested tern, lesser frigatebird and roseate tern which have BIAs within the EMBA (see **Table 4-13**).

Seabirds and migratory shorebirds are particularly vulnerable to contact with floating hydrocarbons, which may mat their feathers. This may lead to hypothermia from loss of insulation and ingestion of hydrocarbons when preening to remove hydrocarbons; both impacts may result in mortality (Hassan and Javed 2011). Notably, the credible loss of well containment scenarios result in a relatively small floating hydrocarbon EMBA which is primarily centred around the release location, with some sporadic surface hydrocarbons near to the Muiron Islands and offshore waters of Ningaloo Reef. Subsequently, the potential for seabird exposure to floating hydrocarbons is considered to be low. Migratory shorebirds are considered unlikely to interact with spilled hydrocarbons as they are not expected to stop over within the offshore waters surrounding the PAA during their migrations between mainland/island areas. Many seabirds and migratory shorebirds forage over extensive areas (some hundreds of kilometres out to sea) so individuals may be present. Seabirds which are roosting or resting on the Angel platform may also be impacted; however; these would be individuals and not populations.

Seabirds which plunge dive to feed on prey may contact entrained or dissolved hydrocarbons, most likely through ingestion of prey which are contaminated. Impacts to prey abundance as a result of hydrocarbons may also indirectly impact individuals.

There are several breeding BIAs for seabirds and migratory shorebirds that overlap with the EMBA, which are associated with breeding and nesting at locations along the Gascoyne and Pilbara coastlines (including near-shore islands). The outer edge of a breeding BIA for the wedge-tailed shearwater overlaps with the PAA, and another is less than a kilometre away. It is likely that individual birds may, therefore, transit the PAA. Other species' BIAs are at least 47 km away and these species are less likely to occur within the PAA.

Given the relatively low area of floating hydrocarbons and the lack of key aggregation areas for migratory shorebirds and seabirds within the PAA, impacts at the population level are not anticipated. Individual animals may, however, be impacted with potential fatalities occurring from oiling.

Nearshore Waters (Mainland and Islands)

Marine Sediment Quality

Entrained and dissolved hydrocarbons (at or above the defined thresholds) are predicted to potentially contact shallow, nearshore waters of identified islands and mainland coastlines (see **Table 6-29**). Shoreline hydrocarbons may also reach a number of islands, including the Muiron and Montebello Islands (full list of receptors provided in **Table 6-29**). Such hydrocarbon contact may lead to reduced marine sediment quality by several processes, such as adherence to sediment and deposition shores or seabed habitat.

Protected Species

Cetaceans

Coastal populations of small cetaceans (e.g., the spotted dolphin) and dugongs are known to reside or frequent nearshore waters along the WA coastline and nearshore islands, including the Ningaloo Coast and at the Muiron Islands, Montebello and Barrow Island groups, and the Pilbara Southern Island Groups. These species may be impacted by entrained and dissolved hydrocarbons exceeding threshold concentrations, as well as sporadic areas of surface hydrocarbons near to Muiron Islands and Ningaloo Reef, in the event of a loss of well containment.

The potential impacts of exposure from hydrocarbons for cetaceans and dugongs are as discussed above. More specifically, nearshore populations of cetaceans and dugongs are known to exhibit site fidelity and are often resident populations. Therefore, avoidance behaviour displayed by cetaceans and dugongs in nearshore areas may have greater impacts to population functioning. Geraci (1988) observed relatively little impacts beyond behavioural disturbance for nearshore species.

Humpback Whale

The humpback whale resting area in the Exmouth Gulf lies just within the EMBA (due to modelled contact by entrained hydrocarbons at 100 ppb); however, it is about 306 km south-west of the PAA and the EMBA is not representative of any one hydrocarbon spill. The likelihood of impacts occurring within this BIA are, therefore, considered low.

Dugong

Impacts in addition to those noted above include ingestion of hydrocarbons by dugongs that feed on oiled seagrass and indirect impacts to dugongs should seagrass habitats be damaged by a hydrocarbon spill. As noted for the humpback whale resting BIA, the EMBA just includes a small northern portion of the Exmouth Gulf and it is considered a low likelihood that the dugong BIAs (and associated seagrass meadows) located here and along the Ningaloo Coast (BIAs for calving, nursing, breeding and foraging) would be impacted by a hydrocarbon spill. No surface or shoreline hydrocarbons are predicted within the Exmouth Gulf or associated dugong BIAs within the EMBA.

Summary

A hydrocarbon spill may impact coastal cetaceans through site displacement and damage to food source; however, due to the non-persistent nature of the hydrocarbon it is not predicted to result in impacts on overall population viability of either dugongs or coastal cetaceans.

Marine Turtles

Marine turtles are known to utilise nearshore waters and shorelines for foraging and breeding activities (including internesting), with significant nesting beaches along the WA mainland coast and nearshore islands in locations that may be impacted by a loss of well containment spill scenario (including the Ningaloo Coast, Muiron Islands, Montebello and Barrow Islands, and Pilbara Southern Islands Group).

Seasonal timings for breeding, nesting and hatchling dispersal for each marine turtle species is provided in **Section 4.6.5**, as are the known BIAs and habitat critical areas. The nearshore waters of these marine turtle habitat areas may be exposed to surface, entrained or dissolved hydrocarbons exceeding threshold concentrations. In addition, a number of islands along the WA coastline are predicted to be contacted by accumulated hydrocarbons above the ecological impact threshold; including the Muiron Islands, Thevenard Island, Barrow Island and the Montebello Islands (see **Table 6-29** and **Table 6-33** for full list of receptors).

The potential impacts of exposure are as previously discussed. In the nearshore environment, turtles can ingest hydrocarbons when feeding and/or can be indirectly affected by loss of a food source (e.g., seagrass due to dieback from hydrocarbon exposure) (Gagnon and Rawson, 2010). In addition, hydrocarbon exposure can impact on turtles during the breeding season at nesting beaches. Contact with gravid adult females or with hatchlings may occur on nesting beaches (accumulated hydrocarbons) or in nearshore waters (entrained hydrocarbons) where hydrocarbons are predicted to make shoreline contact. Males waiting in nearshore areas to mate with adult females may also be impacted by entrained hydrocarbons.

Marine turtles aggregating near nesting beaches within the EMBA during the mating and nesting seasons are most vulnerable to hydrocarbons, due to greater turtle densities and the possible disruption to important life cycle behaviours. Potential impacts may occur at the population level due to the presence of a high number of breeding individuals and hatchlings (during hatchling dispersal) and may impact on overall population viability of marine turtle species. However, given the volatile nature of the hydrocarbons population level impacts are not anticipated to occur.

Sea Snakes

Impacts to sea snakes for the mainland and island nearshore waters from direct contact with hydrocarbons may occur and may include potential damage to the dermis and irritation to mucous membranes of the eyes, nose and throat (ITOPF, 2011a). Due to the time to impact in the nearshore environment, the hydrocarbons are considered to be weathered and less likely to result in toxic effects in comparison to fresh hydrocarbons (i.e., typically in the vicinity of the release location).

Therefore, a worst-case hydrocarbon spill scenario has the potential to result in major long-term impacts to sea snakes, with consequence severity dependent on the duration and extent of a spill in relation to the distribution of sea snakes.

Sharks and Rays

Whale sharks and manta rays (reef manta ray and giant manta ray) are known to frequent Ningaloo Reef (forming feeding aggregations March through July) and the nearshore waters of the Muiron Islands (located 294 km south-west of the PAA). Whale sharks and manta rays generally transit along the nearshore coastline in these areas and are vulnerable to surface, entrained and dissolved aromatic hydrocarbon spill impacts, with both taxa having similar modes of feeding.

Whale sharks are versatile feeders, filtering large amounts of water over their gills, catching planktonic and nektonic organisms (Jarman and Wilson, 2004). Whale sharks at Ningaloo Reef have been observed using two different feeding strategies, including passive sub-surface ram-feeding and active surface feeding (Taylor, 2007). Passive feeding consists of swimming slowly at the surface with the mouth wide open. During active feeding, sharks swim high in the water with the upper part of the body above the surface with the mouth partially open (Taylor, 2007). These feeding methods would result in the potential for individuals that are present in worse affected spill areas to ingest potentially toxic amounts of entrained or dissolved aromatic hydrocarbons into their body. Large amounts of ingested hydrocarbons may affect their endocrine and immune system in the longer term.

The presence of hydrocarbons may also cause displacement of whale sharks from important feeding and resting areas at Ningaloo Reef, potentially disrupt migration and aggregations to these areas in subsequent seasons. Whale sharks may also be affected indirectly by entrained or dissolved aromatic hydrocarbons through the contamination of their prey. The preferred food of whale sharks are planktonic organisms which are abundant in the coastal waters of Ningaloo Reef in late summer/autumn, driving the annual arrival and aggregation of whale sharks in this area. If a worse-case spill event were to occur during the spawning season, this important food supply (in worse spill affected areas of the reef) may be diminished or contaminated. The contamination of their food supply and the subsequent ingestion of this prey by the whale shark may also result in long term impacts as a result of bioaccumulation.

There is the potential for other coastal shark species (e.g., dwarf, narrow and/or green sawfish) to be impacted directly from hydrocarbon contact and/or indirectly through contaminated prey or loss of habitat. Excluding sawfish, which may exhibit high site fidelity, it is most likely that shark species (as mobile animals) will move away from spill affected areas and suffer minimal direct impact.

A spill reaching the Ningaloo coastline during key aggregation periods and impacting important whale shark foraging areas may have severe impacts to the local whale shark population, including possible mortality of individuals and impacts to life cycle habitats such as migration patterns. Most species of shark and ray (including whale sharks) are, however, expected to move away from spill affected areas with minimal impacts.

Seabirds

In the event of a loss of well containment, there is the potential for seabirds, and resident/non-breeding overwintering shorebirds that use the nearshore waters within the EMBA for foraging and resting, to be exposed to hydrocarbons above ecological impact thresholds. Impacts may include both lethal or sub-lethal effects, as discussed above and in more detail below.

Although breeding oceanic seabird species can travel long distances to forage in offshore waters, most breeding seabirds tend to forage in nearshore waters near to their breeding colony, resulting in intensive feeding by higher seabird densities in these areas during the breeding season and making these areas particularly sensitive in the event of a spill.

Migratory shorebirds may be exposed to stranded hydrocarbon when foraging or resting in intertidal habitats, however, direct oiling is typically restricted to relatively small portion of birds, and such oiling is typically restricted to the birds' feet. Unlike seabirds, shorebird mortality due to hypothermia from matted feathers is relatively uncommon (Henkel et al., 2012). Indirect impacts, such as reduced prey availability, may occur (Henkel et al., 2012).

Notably, no surface hydrocarbon contact with receptors was predicted by spill modelling. As mentioned, predicted surface hydrocarbons are also relatively restricted to the release location and some sporadic surface contact offshore Ningaloo Reef and near to the Muiron Islands. This latter contact may impact birds nesting at the Muiron Islands, where there is also predicated shoreline contact. Shoreline hydrocarbon contact above ecological thresholds may also occur at the Barrow, Montebello and Thevenard Islands, as well as at Imperieuse Reef (part of the Rowley Shoals). All of these islands are known to support seabird colonies (see **Appendix C**). Impacts may, therefore, occur at the population level for species breeding at these locations should a spill occur during the relevant species breeding seasons.

Impacts are likely to occur through the ingestion of contaminated fish (nearshore waters) or invertebrates (intertidal foraging grounds such as beaches, mudflats and reefs) which have been exposed to surface, shoreline, entrained or dissolved hydrocarbons within the EMBA. Ingestion of contaminated prey can also lead to internal injury to sensitive membranes and organs (International Petroleum Industry Environmental Conservation Association, 2004). Whether the toxicity of ingested hydrocarbons is lethal or sub-lethal will depend on the weathering stage and its inherent toxicity. Exposure to hydrocarbons may have longer term effects, with impacts to population numbers due to decline in reproductive performance and malformed eggs and chicks, affecting survivorship and loss of adult birds. Seabirds also typically nest above the high water mark, meaning nesting areas would not be expected to be directly impacted.

Notably, the nearest receptor to the release location that is predicted to receive shoreline hydrocarbons above threshold concentrations is the Montebello Islands. Shoreline hydrocarbons were modelled to take a minimum of 700 hours to arrive at this location. Hydrocarbons will be significantly weathered after this period and toxic impacts unlikely to occur. Birds utilising the nearshore waters and intertidal areas for foraging and resting at locations of shoreline contact may, therefore, suffer sub-lethal and, less likely, lethal impacts.

Submerged Shoals and Banks

Protected Species

Marine Turtles

While there are no shoal, bank or reef features within the PAA, there is the potential for marine turtles to be present at submerged shoals and banks within the EMBA, including Rankin Bank and Glomar Shoals which are located 54 and 10 km from the PAA, respectively (described in **Appendix C**, **Section 4.4**). These shoals and banks may, at times, be foraging habitat for marine turtles, given the coral and filter feeding biota associated with these areas.

Notably, there are no known key aggregation areas (i.e., BIAs or habitat critical areas) for marine turtles associated with Glomar Shoals or Rankin Bank.

Impacts to marine turtles at submerged shoals and banks are as previously discussed above. Marine turtles would be expected to be foraging, resting and breathing at the surface at these geomorphic features. Ingestion of hydrocarbons while foraging through prey is also possible.

Summarily, marine turtles may be present at shoals and banks within the EMBA and, therefore, may be impacted by entrained and/or dissolved hydrocarbons present at concentrations greater than the relevant thresholds. Impacts would be expected to be limited to the individuals that may be transiting these areas. Subsequently, impacts at the population level are not anticipated for any of the five marine turtle species that may frequent shoals and banks within the EMBA.

Seasnakes

It is likely that seasnakes will be present at submerged shoals and banks within the EMBA, such as Rankin Bank and Glomar Shoal. While there are no known areas of aggregation for seasnakes within the EMBA, individual seasnakes may be impacted by shoreline and surface hydrocarbons predicted at and near to the Muiron, Barrow and Montebello Islands due to their habitat preferences.

The potential impacts of exposure to hydrocarbons are as discussed above.

Seasnake species in Australia generally show strong habitat preferences (Heatwole and Cogger, 1993); species that have preferred habitats associated with submerged shoals and oceanic atolls may be disproportionately affected by a hydrocarbon spill affecting such habitat. However, population level impacts are not anticipated.

Sharks and Rays

Pelagic sharks and rays may frequent submerged shoals and banks (such as Rankin Bank and Glomar Shoal) within the EMBA to feed. Some species may also exhibit site fidelity to these geomorphic features. There is the potential for resident shark and ray populations to be impacted directly from hydrocarbon contact or indirectly through contaminated prey or loss of habitat.

Spill modelling results indicated that Glomar Shoals (located 10 km south-east from the PAA) and Rankin Bank (located 54 km west from the PAA) may be contacted by dissolved hydrocarbons above ecological thresholds. No contact for entrained, surface or shoreline hydrocarbons was predicted for these submerged features. Species which are resident to or exhibit site-fidelity to Glomar Shoals may experience sub-lethal impacts and/or become displaced. Indirect impacts through ingestion of prey that has been exposed to hydrocarbons and/or the loss of marine flora habitats may also impact sharks and rays.

Pelagic sharks and rays are expected to move away from areas affected by spilled hydrocarbons. Impacts to such species are expected to be limited to behavioural responses/displacement. Shark and ray species that have associations with submerged shoals and banks may or may not be displaced/exhibit behavioural avoidance in response to such habitat being contacted by spilled hydrocarbons. Such species may be more susceptible to a reduction in habitat quality resulting from a hydrocarbon spill. It is expected that there will be no impacts at the population level.

All Settings

Coral Reefs

Receptors

There are no coral reef habitats located within the PAA. Within the EMBA, coral reef habitats exist at Rankin Bank, Glomar Shoal, Muiron Islands, the Montebello Islands, Barrow Island and numerous receptors associated with Ningaloo Reef, including the reef itself.

As discussed in 'Benthic Fauna', dissolved hydrocarbons are anticipated to contact Rankin Bank and Glomar Shoal. Impacts to coral reef habitat at these features are anticipated to be similar in nature to benthic communities and of similarly low probability due to the water depths they exist at. However, potential biological impacts to sensitive corals could include sub-lethal stress and in some instances total or partial mortality of corals.

Hydrocarbons were modelled to reach Barrow Island (entrained, shoreline); Barrow Island Marine Management Area (entrained); and Boodie and Middle Islands (shoreline). Entrained and dissolved hydrocarbons were also modelled to contact the nearby Montebello Islands (entrained, shoreline), Montebello AMP (entrained, dissolved), Montebello State Marine Park (entrained, shoreline) and Montebello Shoals (entrained).

Hydrocarbons were predicted at the Muiron Islands (surface, entrained, shoreline), including the surrounding State Marine Park (entrained, shoreline) and Marine Management Area (surface, entrained, shoreline). Spill modelling indicated that hydrocarbons would also reach the Ningaloo Reef, Commonwealth and State Ningaloo MPs, as well as the Ningaloo Coast World Heritage Area (entrained hydrocarbons only at these receptors).

Impacts

Exposure to entrained hydrocarbons (≥100 ppb)/dissolved aromatic hydrocarbons (≥50 ppb) has the potential to result in lethal or sub-lethal toxic effects to corals and other sensitive sessile benthos within the upper water column, including upper reef slopes (subtidal corals), reef flat (intertidal corals) and lagoonal (back reef) coral communities (with reference to Ningaloo Coast). Mortality in a number of coral species is possible and this would result in the reduction of coral cover and change in the composition of coral communities. Sub-lethal effects to corals may include polyp retraction, changes in feeding, bleaching (loss of zooxanthellae), increased mucous production resulting in reduced growth rates and impaired reproduction (Negri and Heyward, 2000).

This could result in impacts to the shallow water fringing coral communities/reefs of the nearshore islands (e.g., Muiron Islands, Barrow and Montebello Island groups). With reference to Ningaloo Reef, wave-induced water circulation flushes the lagoon and may promote removal of entrained and dissolved hydrocarbons from this particular reef habitat. Under typical conditions, breaking waves on the reef crest induce a rise in water level in the lagoon creating a pressure gradient that drives water in a strong outward flow through channels.

Shoreline Accumulation

As mentioned, shoreline accumulation was modelled to occur at a number of receptors (see **Table 6-29**), including at the Muiron Islands, Thevenard Island, Barrow Island and Montebello Islands.

Shallow coral habitats (i.e., nearshore and intertidal waters) are most vulnerable to hydrocarbons through coating by direct contact with surface slicks during periods when corals are tidally-exposed at spring low tides. Water soluble hydrocarbon fractions associated with surface slicks are known to cause high coral mortality (Shigenaka, 2001) via direct physical contact of hydrocarbon droplets to sensitive coral species (such as the branching coral species).

There is, therefore, potential for lethal impacts due to the physical hydrocarbon coating of sessile benthos (including by entrained hydrocarbons), with likely significant mortality of corals (adults, juveniles and established recruits) at the small spill affected areas. These impacts are particularly applicable to branching corals which are reported to be more sensitive than massive corals (Shigenaka, 2001).

Recruitment/Spawning

In the unlikely event of a spill occurring at the time of coral spawning at potentially affected coral locations or in the general peak period of biological productivity, there is the potential for a significant reduction in successful fertilisation and coral larval survival due to the sensitivity of coral early life stages to hydrocarbons (Negri and Heyward, 2000). Such impacts are likely to result in the failure of recruitment and settlement of new population cohorts. In addition, some non-coral species may be affected via direct contact with entrained and dissolved aromatic hydrocarbons, resulting in sub-lethal impacts and in some cases mortality. This is with particular reference to the early life-stages of coral reef animals (reef attached fishes and reef invertebrates), which can be relatively sensitive to hydrocarbon exposure. Coral reef fish are site attached, have small home ranges and as reef residents they are at higher risk from hydrocarbon exposure than non-resident, more wide-ranging fish species. The exact impact on resident coral communities (which may include fringing reefs of the offshore islands and/or the Ningaloo reef system) will be entirely dependent on actual hydrocarbon concentration, duration of exposure and water depth of the affected communities. Coral live cover, structure and composition may reduce in hydrocarbon impacted areas, manifested by loss of corals and associated sessile biota.

Recovery of impacted reef areas from a range of stressors typically relies on coral larvae from neighbouring coral communities that have either not been affected or only partially impacted. For example, there is evidence that Ningaloo Reef corals and fish are partly self-seeding (Underwood, 2009) with the supply of larvae from locations within Ningaloo Reef of critical importance to the healthy maintenance of the coral communities. Recovery at other coral reef areas, may not be aided by a large supply of larvae from other reefs, with levels of recruits after a disturbance event only returning to previous levels after the numbers of reproductive corals had also recovered (Gilmour et al., 2013).

A hydrocarbon spill may subsequently result in large-scale impacts to coral reefs within the EMBA, particularly at the Montebello and Muiron Islands, with long-term effects (recovery >10 years) likely.

Productivity

Primary production by plankton (supported by sporadic upwelling events in the offshore waters of the NWS) is an important component of the primary marine food web. Planktonic communities are generally mixed, including phytoplankton (cyanobacteria and other microalgae) and secondary consuming zooplankton, such as crustaceans (e.g., copepods), and the eggs and larvae of fish and invertebrates (meroplankton).

Plankton exposure to hydrocarbons in the water column can result in changes in species composition with declines or increases in one or more species or taxonomic groups (Batten et al., 1998). Phytoplankton may also experience decreased rates of photosynthesis (Tomajka,1985). For zooplankton, direct effects of contamination may include toxicity, suffocation, changes in behaviour, or environmental changes that make them more susceptible to predation.

Impacts on plankton communities are likely to occur in areas where entrained or dissolved aromatic hydrocarbon threshold concentrations are exceeded, but communities are expected to recover relatively quickly (within weeks or months). This is due to high population turnover with copious production within short generation times that also buffers the potential for long-term (i.e., years) population declines (International Tanker Owners Pollution Federation, 2011a). Therefore, any impacts to exposed planktonic communities present within the EMBA are anticipated to be short-term.

Filter Feeders

Hydrocarbon exposure to filter feeding communities (e.g., Montebello Islands) may occur, depending on the depth of the entrained and dissolved aromatic hydrocarbons. See discussion above on potential impacts.

Nearshore filter feeders that are present in shallower water <20 m may potentially be impacted by entrained hydrocarbon through lethal/sublethal effects (see discussion for Offshore Filter Feeders). However, due to the time to impact in the nearshore environment, the hydrocarbons are considered to be weathered and less likely to result in toxic effects in comparison to fresh hydrocarbons (i.e., typically in the vicinity of the release location). Such impacts may result in localised, long-term effects to community structure and habitat.

Seagrass Beds, Macroalgae and Mangroves

Depending on the trajectory of the entrained and dissolved hydrocarbon plume, macroalgal / seagrass communities including those along the Ningaloo Coast (patchy and low cover associated with the shallow limestone lagoonal platforms), Muiron Islands (associated with limestone pavements), the Barrow and Montebello Island groups, the Pilbara Southern Island Group (documented as low and patchy cover) have the potential to be exposed (refer **Table 6-29**).

Seagrass in the subtidal and intertidal zones have different degrees of tolerance to exposure of hydrocarbons. Subtidal seagrass is generally considered much less vulnerable to hydrocarbon spills than intertidal seagrass, primarily because freshly spilled hydrocarbons, including crude oil, float under most circumstances. Dean et al. (1998) found that hydrocarbons mainly affect flowering, therefore, species that are able to spread through apical meristem growth are not as affected (e.g., Zostera, Halodule and Halophila species).

Seagrass and macroalgal beds occurring in the intertidal and subtidal zone may be susceptible to impacts from entrained hydrocarbons. Toxicity effects can also occur due to absorption of soluble fractions of hydrocarbons into tissues (Runcie et al., 2010). The potential for toxicity effects of entrained hydrocarbons may be reduced by weathering processes that should serve to lower the content of soluble aromatic components before contact occurs.

Minimum time to contact for entrained hydrocarbons with the nearest receptor that may host seagrasses is 677 hours (Montebello Islands). As such, hydrocarbons released in the event of a loss of well containment are expected to be weathered prior to any credible contact with seagrasses. Exposure to entrained hydrocarbons may result in mortality, depending on actual entrained hydrocarbon concentration received and duration of exposure. Physical contact with entrained hydrocarbon droplets could cause sub-lethal stress, causing reduced growth rates and a reduction in tolerance to other stress factors (Zieman et al., 1984). Impacts on seagrass and macroalgal communities are likely to occur in areas where hydrocarbon threshold concentrations are exceeded.

As mentioned, mangrove habitat and associated mud flats and salt marsh at Ningaloo Coast (small habitat areas) and the Montebello Islands have the potential to be exposed to entrained hydrocarbons. Hydrocarbon coating of the prop roots of mangroves can occur when entrained hydrocarbons are deposited on the aerial roots. Hydrocarbons deposited on the aerial roots can block the pores used to breathe or interfere with the trees' salt balance, resulting in sub-lethal and potential lethal effects. Mangroves can also be impacted by entrained/dissolved hydrocarbons that may adhere to the sediment particles. In low energy environments, such as in mangroves, deposited sediment-bound hydrocarbons are unlikely to be removed naturally by wave action and may be deposited in layers by successive tides (National Oceanic and Atmospheric Administration, 2014). Given the non-persistent nature of the hydrocarbons, however, no significant effects to mangrove habitat are expected to occur.

Entrained/dissolved hydrocarbon impacts may include sub-lethal stress and mortality to certain sensitive biota in these habitats, including infauna and epifauna. Larval and juvenile fish, and invertebrates that depend on these shallow subtidal and intertidal habitats as nursery areas, may be indirectly impacted due to the loss of habitats and/or lethal and sub-lethal in-water toxic effects. This may result in mortality or impairment of growth, survival and reproduction (Heintz et al., 2000). In addition, there is the potential for secondary impacts on shorebirds, fish, sea turtles, rays, and crustaceans that utilise these intertidal habitat areas for breeding, feeding and nursery habitat purposes.

Summary of Potential Impacts to Socio-economic Values	
Setting	***Receptor Group***
All Settings	***Cultural Values and Heritage*** Through consultation and review of available literature (**Section 4.9.1**), Woodside understands that sea country, including marine ecosystems and species, archaeological heritage and heritage sites, marine parks, as well as intangible cultural heritage may be impacted in the event of a hydrocarbon release from a vessel collision. Cultural features and heritage values that have the potential to be impacted include: Marine ecosystems and species: Marine ecosystems may hold both cultural and environmental value to Traditional Custodians (see **Section 4.9.1**), with cultural and environmental values intrinsically linked (DCCEEW 2023, MAC 2021 as cited in Woodside 2023b). It necessarily follows that an impact to marine ecosystems has the potential to impact cultural features where the impact is detectable within Sea Country – the seascape which Traditional Custodians view, interact with or hold knowledge of. The EMBA is known to include habitat for culturally important species such as whales, whale sharks, turtles, dugongs, plankton, and seagrass (**Sections 4.6** and **4.9.1**). In the event of a worst-case release of hydrocarbon individual fauna may be directly impacted or impacted through temporary degradation of their habitats, however, no population level impacts are expected. Impacts are not expected to occur to ecologically significant proportions of the populations of the species, nor expected to result in a decrease of the quality of the habitat such that the extent of these species is likely to decline. As such, cultural values and intangible cultural heritage associated with these species are expected to be maintained. Heritage Sites: The EMBA overlaps no Registered Aboriginal Sites and 2 Other Heritage Places. Any oil that reaches the shoreline has potential to impact on indigenous heritage places along the coastline. In the unlikely event of a hydrocarbon release, shoreline accumulation may affect sensitive artefacts or areas, which could damage their heritage value. Marine Parks: The EMBA overlaps five AMPs under North-West Marine Parks Network Management Plan 2018 and six State Marine Parks. Management Plans for these parks recognise cultural values of Indigenous groups (**Section 4.8**). Due to the low maximum concentrations predicted to reach any marine park, it is not anticipated that their values will be compromised. Intangible cultural heritage: Impacts may occur to intangible cultural values such as songlines; creation/dreaming sites, sacred sites, ancestral beings; cultural obligations to care for Country; knowledge of Country/customary law and transfer of knowledge; connection to Country; Access to Country; kinship systems and totemic species, resource collection. Related intangible cultural heritage may include the transmission of cultural knowledge about whales and whale behaviour, including birthing areas, whale communication and migratory patterns. Such cultural knowledge may be associated with various cultural functions and activities that support the social and economic life of a community (Fijn, 2021). Inter-generational transmission of cultural knowledge (including songlines) relating to marine reptiles may be impacted where changes results in

	reduced sightings (e.g., through population decline, changes to migration routes or changes to migration seasonality). This transfer of knowledge may be integral to managing a group's intangible cultural heritage (UNESCO, 2003). In the unlikely event of a hydrocarbon release, intangible cultural heritage values may be impacted.
Offshore Waters	***Fisheries – Commercial*** Please refer to **Section 4.9.2** for a list of the fisheries occurring within the EMBA, and for those considered to have potential for impact with the Petroleum Activities Program. A worst-case hydrocarbon spill, as modelled for this EP, is not considered likely to cause significant direct impacts on the target species of these commercial fisheries, as discussed below. Refer to above sections for a discussion of impacts to spawning. Fish exposure to hydrocarbon can result in 'tainting' of their tissues. Even very low levels of hydrocarbons can impart a taint or 'off' flavour or smell in seafood. Tainting is reversible through the process of depuration which removes hydrocarbons from tissues by metabolic processes, although it is dependent upon the magnitude of the hydrocarbon contamination. Fish have a high capacity to metabolise these hydrocarbons while crustaceans (such as prawns) have a comparably reduced ability (Yender et al., 2002). Seafood safety is a major concern associated with spill incidents. Therefore, actual or potential contamination of seafood can affect commercial and recreational fishers and can impact seafood markets long after any actual risk to seafood from a spill has subsided (Yender et al., 2002). A major hydrocarbon spill would result in the establishment of an exclusion zone around the spill affected area. There would also be a temporary prohibition on fishing activities for a period of time. Subsequently, there is potential for economic impacts to the affected commercial fishing operators. Additionally, hydrocarbon can foul fishing equipment such as traps and trawl nets, requiring cleaning or replacement. Impact to fishers would subsequently be dependent on the extent of the spill and resulting exclusion zone and may cause economic impacts due to fishing bans, damaged equipment and/or consumer perception of seafood safety. These impacts would not be expected to be long term or affect the viability of the fishery.
	Tourism and Recreation Recreational fishers predominantly target tropical species, such as emperor, snapper, grouper, mackerel, trevally and other game fish. Recreational angling activities include shore-based fishing, private boat and charter boat fishing, with the peak in activity between April and October (Smallwood et al., 2011). Limited recreational fishing takes place in the offshore waters of the PAA due to the distance from land mass, however; fishing may take place at nearby Rankin Bank and also at Glomar Shoal. Recreational diving within the offshore waters of the EMBA may be impacted through spill exclusion zones should a spill occur and also as a result of perceived health impacts by the community. It is considered that recreational diving is more likely to occur within nearshore waters and in water depths less than 40 m deep, however. Impacts on species that are recreationally fished are described above under 'Commercial Fisheries' and 'Pelagic and Demersal Fish'. A worst-case spill may lead to the exclusion of marine nature-based tourist activities, resulting in a loss of revenue for tour operators. These impacts would not be expected to be long term.
	Offshore Oil and Gas Infrastructure Surface hydrocarbons from a worst-case spill may affect production from existing offshore petroleum facilities (e.g., platforms and FPSOs). For example, facility water intakes for cooling and fire hydrants could be shut off which could in turn lead to the temporary cessation of production activities. Spill exclusion zones established to manage the spill could also prohibit activity support vessel access as well as tankers approaching facilities on the NWS. The impact on ongoing operations of regional production facilities would be determined by the nature and scale of the spill and the metocean conditions at the time. Furthermore, decisions on the operation of production facilities in the event of a spill would be based primarily on health and safety considerations. The closest oil and gas operation is the NRC platform (operated by Woodside). Other nearby facilities include the Woodside-operated Okha FPSO, GWA and the Santos operated Reindeer platform (**Section 4.9.6)**. Operation of these facilities is likely to be affected in the event of a worst-case loss of well containment.

Nearshore Island and Mainland Coastal Areas (Nearshore Waters)	***Fisheries – Commercial*** Nearshore fisheries that do not overlap with the EMBA comprising of entrained, dissolved and surface hydrocarbon thresholds but that are predicted to be contacted by shoreline hydrocarbons are the pearling leases (state fisheries) located at the Montebello Islands. There are a number of contact locations within the island group at both ecological and socio-economic shoreline hydrocarbon thresholds. Impacts to these fisheries would include possible direct mortality or sub-lethal impacts to the target species, as well as indirect financial and reputational impacts from possible fishing exclusion zones and perceived health impacts by the community/consumers as a result of the spill event. Impacts to fish stocks would depend on the time of the year the spill event was to occur, and the maturity of the fishery. Impacts are, however, expected to be restricted to mid-term for both direct and indirect impacts.
	Fisheries – Traditional Although no designated traditional fisheries have been identified within the PAA or EMBA, it is recognised that Indigenous communities fish in the shallow coastal and nearshore waters of Ningaloo Reef and therefore may be impacted if a worst-case hydrocarbon spill were to occur. Impacts would be similar to those identified for commercial fishing, in the form of a potential fishing exclusion zone and possible contamination/tainting of fish stocks.
	Tourism and Recreation In the unlikely event of a major spill, the nearshore waters of the Ningaloo Coast (including the Ningaloo Coast State and Commonwealth Marine Park and World Heritage Area) could be contacted by entrained hydrocarbons at ecological thresholds, as well as surface (Ningaloo AMP) and shoreline (Ningaloo Coast WHA and State Marine Park) hydrocarbons at socio-economic thresholds, depending on the prevailing wind and current conditions. The Ningaloo coastal waters offer a number of amenities, such as fishing, swimming, snorkelling, diving and other water-based activities, and utilisation of beaches and surrounds have a recreational value for local residents and visitors (regional, national and international). If a major spill resulted in hydrocarbon contact within this area, there could be restricted access to beaches for a period of days to weeks, until natural weathering or tides and currents remove the hydrocarbons. In the event of a major spill, tourists and recreational users may also avoid areas due to perceived impacts, including after the hydrocarbon spill has dispersed. There is also the potential for stakeholder perception that this remote environment will be contaminated over a larger area and for the longer term resulting in a prolonged period of tourism decline. Oxford Economics (2010) assessed the duration of hydrocarbon spill related tourism impacts and found that on average, it took 12 to 28 months to return to baseline visitor spending. There is likely to be significant impacts to the tourism industry, wider service industry (hotels, restaurants and their supply chain) and local communities in terms of economic loss as a result of spill impacts to tourism. Recovery and return of tourism to pre-spill levels will depend on the size of the spill, effectiveness of the spill clean-up and change in any public misconceptions regarding the spill (Oxford Economics, 2010). Other areas modelled to receive shoreline and/or surface hydrocarbons greater than the socio-economic threshold (≥10 g/m^2 and 1 g/m^2, respectively) which are used for tourism and recreation activities include the Muiron Islands, Southern, Middle and Northern Pilbara Islands, Exmouth Coastline, Barrow Island, Lowendal Islands, Montebello islands and Thevenard Island. Impacts to these receptors would be as discussed above, although less significant due to the lower levels of tourism and recreation activities undertaken at these locations compared with the Ningaloo Coast.

MEE-01 Well Loss of Containment – Risk Analysis
A bowtie risk analysis was undertaken to assess MEE-01; refer to **Figure 6-10**, **Figure 6-11** and **Figure 6-12** for bowtie diagrams which were an output of Woodside's risk analysis process.

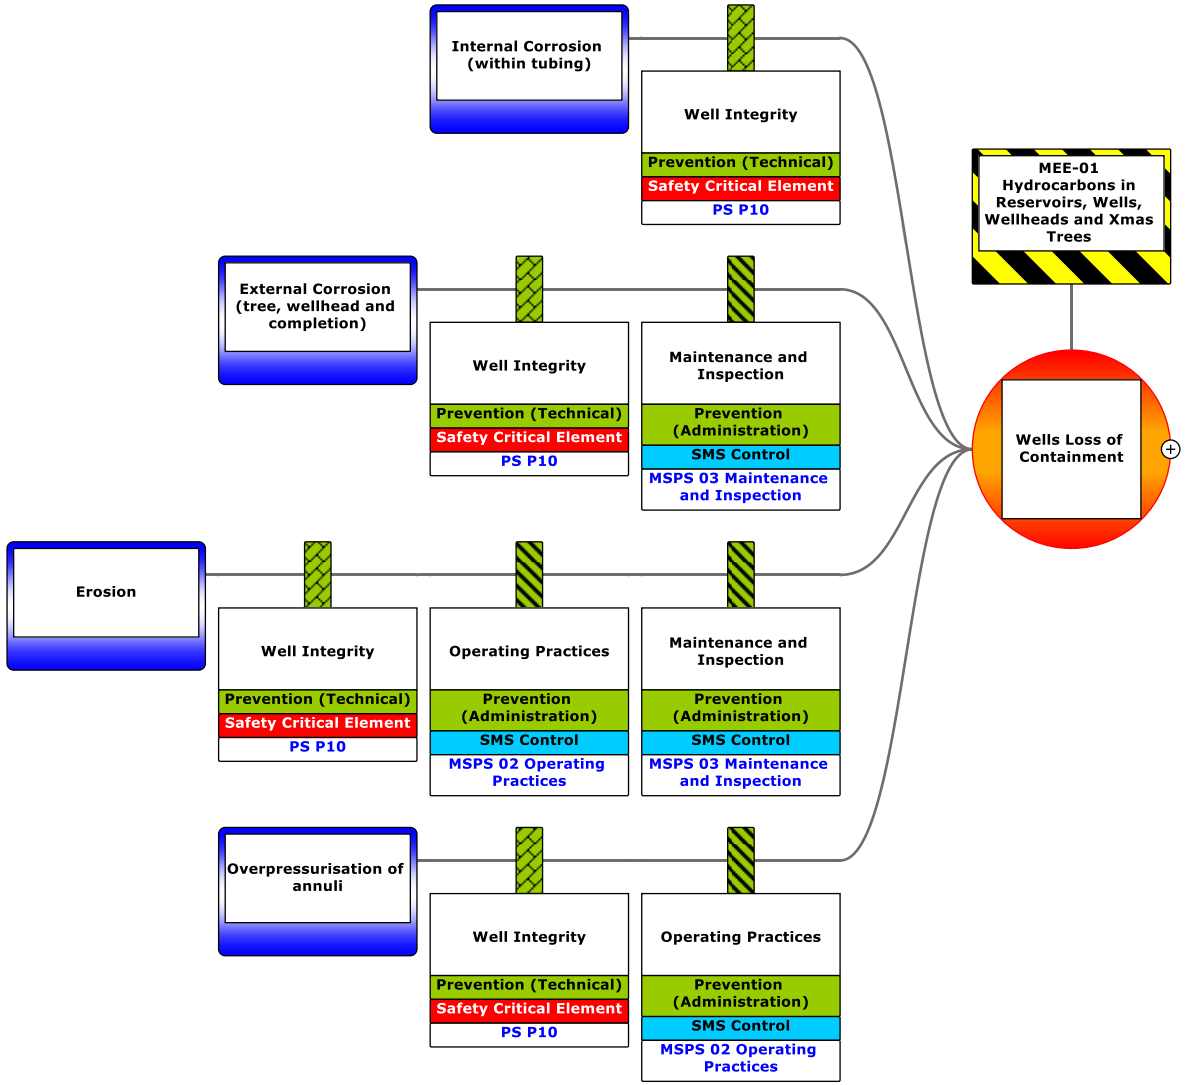

Figure 6-10: MEE-01 wells loss of containment (Causes 1 to 4)

MEE-01 Loss of Well Containment – Demonstration of ALARP ALARP Control Measures				
Hierarchy	***Control/barrier***	***SCE/management system reference***	***Type of effect (refer to Table 6-23)***	***Control adopted***
Risk Based Analysis				
For risks identified as MEEs, a detailed risk-based bowtie analysis (as outlined in **Section 2.7.3)** has been used to identify, analyse and demonstrate that controls in place reduce the risk associated with each MEE to ALARP. Controls have been selected following hierarchy of control principles and consider independence of each barrier and their type of effect in controlling the hazardous event. Application of Woodside's Risk Management Procedures and implementation of the WOMP ensures the continuous identification of hazards, systematic assessment of risks, and ongoing assessment of alternative control measures to reduce risk to ALARP, which includes: ongoing hazard identification, risk assessment and the identification of control measures ongoing integrity management of hardware control measures in accordance with the operational performance standards which define requirements to be suitably maintained, such that they retain effectiveness, functionality, availability and survivability well integrity codes and standards. For each SCE, detailed requirements for equipment functionality, availability, reliability and survivability are incorporated into SCE Performance Standards which also include the relevant assurance tasks (e.g., inspection, maintenance, testing and monitoring requirements) to ensure technical integrity. A quantitative spill risk assessment was undertaken (refer **Section 6.7.2** for details of the method used).				
Company Values				
Corporate values require all personnel at Woodside to comply with appropriate policies, standards, procedures and processes while being accountable for their actions and holding others to account in line with the Woodside Compass. As detailed above, the Petroleum Activities Program is undertaken in line with these policies, standards and procedures that include suitable controls to prevent loss of well containment, and response should a loss of well containment occur.				
Societal Values				
Due to the Petroleum Activities Program's proximity to sensitive receptors (e.g., Glomar Shoal, Ningaloo Coast) and the potential extent of the wider EMBA, the loss of well containment risk rating presents a Decision Type B in accordance with the decision support framework described in **Section 2.6.1**. Extensive consultation was undertaken for this program to identify the views and concerns of relevant persons, as described in **Section 5**. Woodside has sent an Activity Factsheet to all identified relevant persons regarding the Petroleum Activities Program (**Section 5**). Woodside has consulted with AMSA and the WA Department of Transport (DoT) on spill response strategies. In accordance with the MoU between Woodside and AMSA, a copy of the Oil Pollution First Strike Plan was provided to AMSA.				

MEE-01 Loss of Well Containment – Demonstration of ALARP ALARP Control Measures				
Hierarchy	***Control/barrier***	***SCE/management system reference***	***Type of effect (refer to Table 6-23)***	***Control adopted***

ALARP Statement:

On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts and risks of a very low likelihood unplanned hydrocarbon release as a result of a loss of well containment.

The principle of inherent safety and environmental protection is based on prevention of the MEE through design of well integrity, ensuring the wells are operated within their design envelope through operating practices, and assurance through maintenance and inspection. If hydrocarbon loss of containment occurs, mitigation measures are in place to minimise the consequence, by limiting the inventory which can be released and implementing remediation.

The controls in place for prevention and mitigation of MEEs are specified and assured through implementing the WOMP, SCE management procedures including performance standards for SCEs, and Management System Performance Standards (MSPSs) for Safety Critical Management System Controls.

The application of Woodside Risk Management Procedures and implementation of the WOMP ensures the continuous identification of hazards, systematic assessment of risks and ongoing assessment of alternative control measures to reduce risk to ALARP, which includes:

- ongoing hazard identification, risk assessment and the identification of control measures
- ongoing integrity management of hardware control measures in accordance with the technical performance standards which define requirements to be suitably maintained, such that they retain effectiveness, functionality, availability and survivability
- well integrity codes and standards.

Given the controls in place to prevent and control loss of containment events and mitigate their consequences, it is considered that MEE risk associated with loss of well containment is managed to ALARP.

Demonstration of Acceptability

Acceptability Statement:

Loss of well containment has been evaluated as having a 'high' (A1) current risk rating. As per **Section 2.6.3**, Woodside considers 'high' (A1) risk ratings as acceptable if ALARP is demonstrated using good industry practice, company and societal values and risk based analysis are considered, if legislative requirements are met and societal concerns are accounted for, and the alternative control measures are grossly disproportionate to the benefit gained.

Acceptability is demonstrated with regard to the considerations below.

Principles of Ecologically Sustainable Development

Woodside is a proud Australian company that is here for the long term. Woodside has a strong history of exploration and development of oil and gas reserves in the north west of Western Australia with an excellent environmental record, while providing revenue to State and Commonwealth Governments, returns to shareholders, jobs and support to local communities. Titles for oil and gas exploration are released based on commitments to explore with the aim of uncovering and developing resources. It is under the lease agreement that Woodside has determined the potential to develop the hydrocarbon fields for which acceptance of this EP is sought under the Environment Regulations.

Woodside has established a number of research projects in order to understand the marine environments in which they operate, notably in the Exmouth Region and the Kimberley Region, including Rankin Bank, Glomar Shoal, Enfield Canyon and Scott Reef. Where scientific data does not exist, Woodside assumes a pristine natural environment exists, and therefore implements all practicable steps to prevent damage. Woodside's corporate values (**Appendix A**) require that we consider the environment and communities in which we operate when making decisions.

Woodside looks after the communities and environments in which it operates. Risks are inherent in petroleum activities; however, through sound management and systematic application of policies, standards, procedures and processes, Woodside considers that despite this risk, the extremely low likelihood of loss of well containment is acceptable.

Internal Context

The Petroleum Activities Program is consistent with Woodside corporate policies, standards, procedures, processes and training requirements as outlined in the Demonstration of ALARP and EPOs, including:

- Woodside Environment and Biodiversity Environment Policy (Appendix A)
- Woodside Risk Management Policy (Appendix A)
- the SCE Performance Standards developed and implemented for the facility
- Hydrocarbon spill preparedness and response strategies are considered applicable to the nature and scale of the risk, and associated impacts of the response are reduced to ALARP (Section 2.8.1)

Woodside corporate values include working sustainably, with respect to the environment and communities in which we operate, listening to internal and external stakeholders and considering HSE when making decisions. Consultation, outlined below, has been undertaken prior to the Petroleum Activities Program.

External Context – Societal Values

Woodside recognises that its licence to operate from a regulatory and societal perspective is based on historical performance, complying with appropriate policies, standards and procedures, and understanding the expectations of external stakeholders. External stakeholder consultation, outlined below, has been undertaken prior to the Petroleum Activities Program:

- Woodside has consulted with AMSA and WA DoT on spill response strategies. In accordance with the Memorandum of Understanding between Woodside and AMSA, a copy of the Oil Pollution First Strike Plan was provided to AMSA and DoT.
- Other relevant persons were consulted (**Section 5**) and their feedback incorporated into this EP where appropriate.

By providing hydrocarbon spill response measures that are commensurate with the risk rating, location and sensitivity of the receiving environment (including social and aesthetic values), Woodside believes this addresses societal concerns to an acceptable level.

Other Requirements (includes Laws, Policies, Standards and Conventions)

The Petroleum Activities Program is consistent with laws, policies, standards and conventions, including:

- accepted Safety Case (as per the requirements of the OPGGS (Safety) Regulations 2009
- Mutual Aid MoU for relief well drilling is in place
- accepted WOMP as per the requirements of the OPPGS (Resource Management and Administration) Regulations 2011
- notification of reportable and recordable incidents to NOPSEMA, if required, in accordance with **Section 7.11.5**.

The Petroleum Activities Program is consistent with the objectives in the Ningaloo management plans (Management Plan for Ningaloo Marine Park and Muiron Islands Marine Management Areas, Ningaloo Marine Park Management Plan) in relation to water quality, coral, shoreline and intertidal, macroalgal, seagrass, mangroves, seabirds and social and economic values.

Acceptability Statement:

The impact assessment has determined that an accidental hydrocarbon release as a result of a loss of well integrity represents a high current risk rating and may result in catastrophic, long-term impacts (>50 years) on highly valued ecosystems, species, habitat or physical or biological attributes. A number of BIAs for protected species overlap with the PAA and EMBA. Relevant recovery plans and conservation advice have been considered during the impact assessment, and the Petroleum Activities Program is not considered to be inconsistent with the overall recovery objectives and actions of these recovery plans and conservation advice.

The likelihood of a loss of well integrity from operating wells occurring is highly unlikely, given the adopted controls. The adopted controls are considered consistent with industry legislation, codes and standards, and professional judgement and a risk-based assessment has been conducted to better understand the potential consequences and plan oil spill response. The adopted controls also meet the requirements and expectations of Australian Marine Orders, AMSA and AHO identified during impact assessment and consultation. As demonstrated in **Section 6.9** the potential impacts of hydrocarbon release from loss of well integrity is not inconsistent with the relevant objectives and actions of any applicable recovery plans or threat abatement plans. Regard has been given to relevant conservation advice during the assessment of potential risks. On the basis of the environmental impact assessment outcomes and Woodside's criteria for acceptability outlined in **Section 2.8.2** this is considered an acceptable level of risk.

On the basis of the environmental impact assessment outcomes and Woodside's criteria for acceptability outlined in **Section 2.8.2**, this is considered an acceptable level of risk.

Release of hydrocarbons resulting from loss of containment of subsea flowlines and infrastructure		✓	✓	✓	✓	✓	✓	A	D	2	M			

Description of Source of Risk

Hydrocarbons are transported from the Lambert Deep and Lambert West wells to the facility via a ~15 km long jumper with associated subsea hardware. Hydrocarbons are exported from the facility to 1TL via the 49 km export pipeline. A loss of containment from the AEP may result in the release of large volumes of hydrocarbon inventory to the environment, through the riser or through the tie-in location at NRC. Due to the potential consequence of a worst-case subsea equipment loss of containment, this risk is considered to be an MEE (MEE-02).

For redundant Angel flowlines, the worst-case subsea condensate loss of containment scenario is an instantaneous release of approximately 15 m^3. This assumes that all of the possible liquid volume in the flowline is released, based on the volume of AP 4, which is the longest flowline. Maximum release volumes of liquid hydrocarbons from AP2 and AP3 would be around 12 m^3 and 8 m^3 respectively.

The potential hazard sources that could instigate a loss of containment from the riser or export pipeline are:

- internal corrosion
- external corrosion
- erosion (for flowlines)
- overpressure

- equipment fatigue (risers and structural supports)
- pipeline stability and freespans
- anchor impact/dragging
- loss of control of suspended load from visiting vessel.

Although anchor impact and dragging are potential hazard sources, the risk of pipeline loss of containment as a result of commercial trawling practice is not considered credible according to design risk based analysis, as structural protection frames are in place for key subsea infrastructure. Maintenance of subsea infrastructure structural protection frames are included in mechanical integrity controls set out for pipeline integrity performance standard P09 – Pipeline system. Escalation from other MEEs can cause subsea equipment loss of containment:

- loss of structural integrity (MEE-03; Section 6.7.5)
- loss of marine vessel separation (MEE-04; Section 6.7.6)
- loss of control of suspended load from facility lifting operations (MEE-05; **Section 6.7.7**).

Subsea/Riser Equipment Loss of Containment – Credible Scenarios

The credible worst-case hydrocarbon release caused by subsea loss of containment is a release from the AEP, including its full inventory as well as backflow of the inventory of 1TL.

The location of a loss of containment of the export pipeline and associated riser will influence the potential environmental consequence. Woodside has evaluated two locations for a pipeline and riser loss of containment:

- The subsea tie-in point of the export pipeline with 1TL located at NRC: this location is the nearest point to a number of sensitive receptors (e.g., Montebello Islands, Barrow Island) and is also deeper (125 m) than the Angel tie-in location (80.6 m) which maximises potential fluid accumulation and subsequent loss volume.
- A surface release of the export pipeline riser: this location would result in a greater portion of floating hydrocarbons as the release point is above the water; a subsea release is likely to result in much of the liquid-phase hydrocarbons becoming entrained in the water column.

The characteristics of the release scenarios are summarised in **Table 6-30**.

Flowline Loss of Containment – Credible Scenario

A loss of containment from the redundant Angel flowlines was considered a credible scenario and modelled. Notably, the redundant flowlines have been depressurized via flare to ambient pressure and the topsides positively isolated. To ensure modelling was conservative, the last known flowing conditions were modelled to inform liquid hydrocarbon content in the lines and it is assumed that the whole volume would be lost should the flowline be ruptured. The characteristics of the scenario are summarised in **Table 6-30**.

Refer to **Section 6.7.2.1** for additional information on modelling methods and environmental impact, thresholds and hydrocarbon characteristics.

Table 6-30: Summary of worst-case subsea/riser equipment loss of containment release scenario

Scenario	*Hydrocarbon*	*Duration (hrs)*	*Depth (m)*	*Latitude*	*Longitude*	*Total condensate release volume (m^3)*
Scenario 3A Loss of Containment of the export pipeline at tie-in location with NRC (MEE-02)	Lambert Deep rich fluid	12	125	19°35’09’’ S	116°08’22’’ E	6100
Scenario 3B Loss of Containment of the export pipeline riser at the surface (MEE-02)	Lambert Deep rich fluid	42	Surface	19°29’54’’ S	116°35’52’’ E	5600
Scenario 7 Redundant Angel Flowlines release (AP4)	Angel condensate	Instantaneous	85	19°31' 16.44"S	116°35' 12.62"E	15

Decision Type, Risk Analysis and ALARP Tools

Woodside has a good history of implementing industry standard practice in subsea system design and construction. In the company's recent history, it has not experienced any pipeline and riser integrity events that have resulted in significant releases or significant environmental impacts. The facility has never experienced a worst-case loss of pipeline and riser containment in its operational history.

Decision Type

Decision Type B has been applied to this risk under the Guidance on Risk Related Decision Making (Oil and Gas UK, 2014). This reflects the complexity of the risk, the higher potential consequence and stakeholder implications should the event be realised. To align with this decision type, a further level of analysis has been applied using risk based tools including the bowtie methodology (described in **Section 2.7.3**) and hydrocarbon spill trajectory modelling (described in **Section 6.7.2**). Company and societal values were also considered in the demonstration of ALARP and acceptability, through peer review, benchmarking and consultation (**Section 5**).

The release of hydrocarbons as a result of subsea equipment loss of containment is considered a Major Environment Event (MEE-02). The hazard associated with this MEE is hydrocarbons in subsea infrastructure (pipelines, flowlines, risers, etc.) tied to or originating from the facility.

Quantitative Spill Risk Assessment

Spill modelling of each of the subsea loss of containment credible spill scenarios was undertaken by RPS (RPS, 2021), on behalf of Woodside, to determine the fate of hydrocarbon released in each scenario based on the assumptions in **Section 6.7.2** and **Table 6-30** to **Table 6-32**. Modelling was undertaken over all seasons to address year-round operations. This is considered to provide a conservative estimate of the EMBA, and the potential impacts from the identified worst-case credible release volumes for all subsea loss containment scenarios.

Hydrocarbon Characteristics

Refer to **Section 6.7.2** for a discussion of Lambert Deep rich fluid and Angel condensate characteristics.

Subsea Plume Dynamics

The loss of subsea containment scenarios will result in a buoyant plume of hydrocarbons, which has been modelled using the OILMAP-Deep numerical model for Scenarios 3A and 7 (summarised in **Table 6-31** and **Table 6-32**, respectively).

Table 6-31: Near-field subsurface discharge model parameters, OILMAP deep model, for the loss of containment of the export pipeline at tie-in location scenario (Lambert Deep rich fluid)

	Parameter	***Scenario 3A***
Inputs	Release depth (m below sea level)	125
	Oil density (g/cm^3) (at 25°C)	0.736
	Oil viscosity (cP) (at 25°C)	2.952
	Oil temperature (°C)	25
	Gas:Oil ratio (m^3/m^3) [scf/bbl]	1, 244
	Oil flow rate (m^3/d)	4,340
	Hole diameter (m) [in]	0.724
Outputs	Plume diameter (m)	16
	Plume height (m above seabed	125 (at surface)
	Plume initial rise velocity (m/s)	27.6
	Plume terminal rise velocity (m/s)	20.6
Predicted oil droplet size distribution	20% droplets of size (µm)	41
	20% droplets of size (µm)	60
	20% droplets of size (µm)	78
	20% droplets of size (µm)	101
	20% droplets of size (µm)	147

Table 6-32: Near-field subsurface discharge model parameters, OILMAP deep model, for the loss of containment of the redundant Angel flowline (AP4) scenario (Angel condensate)

	Parameter	Scenario 7
Inputs	Release depth (m below sea level)	77
	Oil density (g/cm^3) (at 25°C)	0.733
	Oil viscosity (cP) (at 25°C)	0.205
	Oil temperature (°C)	25
	Gas:oil ratio (m^3/m^3) [scf/bbl]	3627
	Oil flow rate (m^3/d)	15
	Hole diameter (m) [in]	0.321
Outputs	Plume diameter (m)	11.2
	Plume height (m above seabed	77
	Plume initial rise velocity (m/s)	2.5
	Plume terminal rise velocity (m/s)	1.1
Predicted oil droplet size distribution	20% droplets of size (µm)	146.6
	20% droplets of size (µm)	214.0
	20% droplets of size (µm)	278.1
	20% droplets of size (µm)	361.5
	20% droplets of size (µm)	527.9

Likelihood

In accordance with the Woodside Risk Matrix, given prevention and mitigation measures in place (i.e., design, inspection and maintenance, pipeline marked on marine charts), the likelihood has been taken as 1 (Highly Unlikely). Within the riser platform 500 m PSZ, dropped object protection is applied to the pipeline, and as such the risk of dropped object impact leading to a release has also been assessed as 0 (Remote).

Consequence

The spatial extent and fate (including weathering) of the spilled hydrocarbon were considered during the impact assessment for a worst-case subsea or riser loss of containment (presented in the following section). These considerations were informed primarily by the outputs from the numerical modelling studies undertaken by RPS, available information on environmental sensitivities that may credibly be impacted in the event of a worst-case spill (**Section 6.7.2**), and relevant literature and studies considering the effects of hydrocarbon exposure.

Consequence Assessment

Environment that May Be Affected

Scenario 3A

Surface Hydrocarbons

The hydrocarbon spill modelling indicated that concentrations of floating hydrocarbons equal to or greater than the 10 g/m^2 threshold could potentially be found, in the form of slicks, up to 20 km north and north-east from the release location. However, no receptors are predicted to be contacted by surface hydrocarbons at ecological thresholds.

Dissolved Hydrocarbons

Dissolved aromatic hydrocarbon concentrations equal to or greater than the 50 ppb threshold are predicted to be found up to around 419 km south-west from the release location. Receptors with the highest probability of contact at the ecological threshold (50 ppb) include Montebello AMP and Rankin Bank.

Entrained Hydrocarbons

Entrained oil concentrations equal to or greater than the 100 ppb threshold are predicted to be found up to 375 km south-west from the release location.

Receptors with the highest probability of contact at the ecological threshold (100 ppb) include Montebello AMP, Tryal Rocks, Muiron Islands and the Muiron Islands MMA.

Accumulated Hydrocarbons

No shoreline accumulation was predicted at or above 10 g/m^2.

Scenario 3B

Surface Hydrocarbons

The hydrocarbon spill modelling indicated that concentrations of floating hydrocarbons equal to or greater than the 10 g/m^2 threshold could potentially be found, in the form of slicks, 25 km north-east and south, from the release location. However, no receptors are predicted to be contacted by surface hydrocarbons at ecological thresholds.

Dissolved Hydrocarbons

Dissolved aromatic hydrocarbon concentrations equal to or greater than the 50 ppb threshold are predicted to be found up to around 338 km south-west from the release location. Receptors with the highest probability of contact at the ecological threshold (50 ppb) include Montebello AMP and Rankin Bank.

Entrained Hydrocarbons

Entrained oil concentrations equal to or greater than the 100 ppb threshold are predicted to be found up to 398 km south-west from the release location.

Receptors with the highest probability of contact at the ecological threshold (100 ppb) include Montebello AMP, Tryal Rocks, Muiron Islands and the Muiron Islands MMA.

Accumulated Hydrocarbons

No shoreline accumulation at the ecological threshold, at or above 100 g/m^2, was predicted. Contact at the socioeconomic threshold, 100 g/m^2, was predicted at the Muiron Islands.

Scenario 7

No receptors were contacted by hydrocarbons at the ecological thresholds for this scenario. The spill is restricted to a radius of about 35 km (entrained hydrocarbons) from the release location. Any impacts to biological and physical receptors within this area are addressed within the impacts discussion for MEE-01 (**Section 6.7.3**).

Consequence Assessment Summary

The credible worst-case hydrocarbon spill scenario that may arise from MEE-02 may impact upon a range of environmental receptors; refer to **Table 6-33** for a summary of receptors identified by the stochastic spill modelling studies. Potential impacts of a hydrocarbon spill to these receptors are considered in MEE-01; refer to **Section 6.7.3** for a description of potential impacts.

The credible worst-case hydrocarbon volumes that can credibly be released by MEE-02 are significantly smaller than the credible worst-case loss of well containment volumes considered in MEE-01. Additionally, the credible release durations are significantly shorter.

Risk Based Analysis				
For risks identified as MEEs, a detailed risk based Bowtie Analysis (as outlined in **Section 2.7.3**) has been used to identify, analyse and demonstrate that controls in place reduce the risk associated with each MEE to ALARP. Controls have been selected following hierarchy of control principles and consider independence of each barrier and their type of effect in controlling the hazardous event. Application of Woodside's Risk Management Procedures and implementation of the Angel and NWS Pipelines Safety Cases ensures the continuous identification of hazards, systematic assessment of risks and ongoing assessment of alternative control measures to reduce risk to ALARP, which includes: ongoing hazard identification, risk assessment and the identification of control measures ongoing integrity management of hardware control measures in accordance with the operational performance standards which define requirements to be suitably maintained, such that they retain effectiveness, functionality, availability and survivability. For each SCE, detailed requirements for equipment functionality, availability, reliability and survivability are incorporated into SCE Performance Standards which also include the relevant assurance tasks (e.g., inspection, maintenance, testing and monitoring requirements) to ensure technical integrity. A quantitative spill risk assessment was undertaken (refer **Section 6.7.2** for details of the method used).				

MEE-02 Subsea Equipment Loss of Containment – Demonstration of ALARP ALARP Control Measures				
Hierarchy	***Control/barrier***	***SCE/Management System reference***	***Type of effect (refer to Table 6-23)***	***Control adopted***
Company Values				
Corporate values require all personnel at Woodside to comply with appropriate policies, standards, procedures and processes while being accountable for their actions and holding others to account in line with the Woodside Compass. As detailed above, the Petroleum Activities Program is undertaken in line with these policies, standards and procedures that include suitable controls to prevent subsea flowline and riser loss of containment, and response should a loss of containment occur.				
Societal Values				
Due to the Petroleum Activities Program's proximity to sensitive receptors (e.g., Montebello Islands) and the potential extent of the wider EMBA, the pipeline and riser loss of containment risk rating presents a Decision Type B in accordance with the decision support framework described in **Section 2.6.1**. Consultation was undertaken for this program to identify the views and concerns of relevant persons, as described in **Section 5**. Woodside has sent an Activity Factsheet to all identified relevant persons regarding the Petroleum Activities Program (**Section 5**). Woodside has consulted with AMSA and WA DoT on spill response strategies. In accordance with the MoU between Woodside and AMSA, a copy of the Oil Pollution First Strike Plan was provided to AMSA.				
ALARP Statement: On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts and risks of a very low likelihood unplanned hydrocarbon release as a result of a pipeline and riser loss of containment. The principle of inherent safety and environmental protection is based on the prevention of the MEE through design of pipelines and risers, ensuring the export pipeline and risers are operated within their design envelope through operating practices, and assurance through maintenance and inspection. If hydrocarbon loss of containment occurs, mitigation measures are in place to minimise the consequence by limiting the inventory which can be released and implementing remediation. The controls in place for prevention and mitigation of MEEs are specified and assured through implementing the Safety Cases, SCE management procedures including performance standards for SCEs and MSPSs for Safety Critical Management System Controls. The application of Woodside Risk Management Procedures ensures the continuous identification of hazards, systematic assessment of risks and ongoing assessment of alternative control measures to reduce risk to ALARP, which includes: • ongoing hazard identification, risk assessment and the identification of control measures • ongoing integrity management of hardware control measures in accordance with the technical performance standards which define requirements to be suitably maintained, such that they retain effectiveness, functionality, availability and survivability. Given the controls in place to prevent and control loss of containment events and mitigate their consequences and the reduction in likelihood of a loss of containment from the redundant Angel flowlines as the mechanisms for erosion and corrosion are greatly reduced it is considered that MEE risk associated with a pipeline and riser loss of containment is managed to ALARP.				
Demonstration of Acceptability				
Acceptability Statement: Worst case loss of subsea equipment containment has been evaluated as having a 'moderate' (B0) level of risk rating. As per **Section 2.6.3**, Woodside considers 'moderate' (B0) risk ratings as acceptable if ALARP is demonstrated using good industry practice, company and societal values and risk based analysis are considered, legislative requirements are met and societal concerns are accounted for, and the alternative control measures are grossly disproportionate to the benefit gained. Acceptability is demonstrated with regard to the considerations described in **Section 6.7.3** (MEE-01). The considerations include principles of Ecological Sustainable Development, internal context, external context and other requirements (including laws, policies, standards and conventions). On the basis of the environmental impact assessment outcomes and Woodside's criteria for acceptability outlined in **Section 2.8.2**, this is considered an acceptable level of risk.

Marine environment footprint and associated hydrocarbon and chemical release associated with structural collapse of riser platform (MEE-03)		✓	✓	✓	✓	✓	✓	B	B	0	M			

Description of Source of Risk

Extreme environmental conditions or other causes which result in an exceedance of the design criteria and a catastrophic failure of the facility and individual equipment (e.g., cranes, flare tower, etc) has been identified as a

potential MEE (MEE-03). Catastrophic structural failure of the facility could lead to the release of hydrocarbons to the environment.

The identified causes, including escalation from other MEEs, include:

- internal corrosion
- external corrosion
- fatigue
- extreme weather (cyclone, high waves)
- seismic events/seabed instability
- fire/overpressure event
- operation outside of design.

Escalation from other MEEs can also cause loss of structural integrity:

- subsea equipment hydrocarbon loss of containment (MEE-02; Section 6.7.4)
- loss of marine vessel separation (refer to MEE-04; Section 6.7.6)
- loss of control of suspended load from facility lifting operations (refer to MEE-05; Section 6.7.7).

There is a possibility of riser platform collapse ('slow' or 'rapid') caused by the extreme loads induced by strong winds and extreme waves.

A number of common failure causes due to human error and SCQ failures are presented in the generic Human Error and generic SCE Failure bowties in **Section 6.7.8**.

Loss of Structural Integrity – Credible Scenarios

A loss of structural integrity could result in a significant release of hydrocarbons. A loss of structural integrity may result in credible hydrocarbon spill scenarios consistent with:

- subsea equipment loss of containment (MEE-02; Section 6.7.4)
- loss of marine vessel separation (MEE-04; Section 6.7.6)
- topsides loss of containment (not a MEE; Section 6.8.2).

The worst-case credible spill scenarios associated with these MEEs/sources of risk are discussed in the relevant sections above; refer to these sections for further information.

Decision Type, Risk Analysis and ALARP Tools

Woodside has a good history of implementing industry standard practice in structural design, construction and operation. In the company's 60-year history, it has not experienced any loss of structural integrity events that have resulted in significant releases or significant environmental impacts. The facility has never experienced a worst-case loss of containment in its operational history.

Decision Type

Decision Type B has been applied to this risk under the Guidance on Risk Related Decision Making (Oil and Gas UK, 2014). This reflects the complexity of the risk, the higher potential consequence and stakeholder implications should the event be realised. To align with this decision type, a further level of analysis has been applied using risk-based tools including the bowtie methodology (described in **Section 2.7.3**) and hydrocarbon spill trajectory modelling. Company and societal values were also considered in the demonstration of ALARP and acceptability through peer review, benchmarking and consultation.

The release of hydrocarbons from a loss of structural integrity is considered an MEE (MEE-03). The hazard associated with this MEE is hydrocarbons in pipelines, risers, process and non-process inventories and potentially vessels, well, and the riser platform itself.

Quantitative Spill Risk Assessment

Credible worst-case stochastic spill modelling for the scenarios associated with MEE-01 (**Section 6.7.3**), MEE-02 (**Section 6.7.4**) and MEE-04 (**Section 6.7.6**) has been undertaken. Results of these modelling studies have been used to inform the consequence assessment for these MEEs; these assessments are applicable to the consequence assessment for a loss of structural integrity event.

Likelihood

In accordance with the Woodside Risk Matrix (**Section 2.6.3**), the following likelihoods have been assigned to the sources of risk:

- release of hydrocarbons resulting from loss of export pipeline containment (AEP including 1TL inventory) (MEE-02): Highly Unlikely (refer to Section 6.7.4)
- release of hydrocarbons resulting from loss of containment of subsea flowlines and infrastructure (MEE-02): Highly Unlikely (refer to Section 6.7.4)
- hydrocarbon release from topsides equipment to the marine environment and atmosphere: Highly Unlikely (refer to **Section 6.8.2**)

marine environment footprint and associated hydrocarbon and chemical release associated with structural collapse of riser platform: Remote.

Consequence

The spatial extent and fate (including weathering) of the spilled hydrocarbon was considered during the impact assessment for a loss of structural integrity. These considerations were informed primarily by the outputs from the stochastic modelling studies undertaken by RPS, available information on environmental sensitivities that may credibly be impacted in the event of a worst-case spill (**Section 6.7.3**), and relevant literature and studies considering the effects of hydrocarbon exposure.

Consequence Assessment

Environment that May Be Affected

As discussed above, the potential impacts from hydrocarbon release caused by a loss of structural integrity are those which would result from:

- subsea equipment loss of containment (MEE-02; Section 6.7.4)
- loss of marine vessel separation (MEE-04; Section 6.7.6)
- topsides loss of containment (Section 6.8.2).

The potential impacts associated with these impacts are therefore discussed in the above-mentioned sections.

Seabed Disturbance

In the event of loss of structural integrity, there is the potential for collapse of the riser platform leading to an incremental increase of the facility's footprint on the seabed. The potential area that would be affected can conservatively be defined as the existing riser platform footprint plus 100 m in all directions; that is, approximately 237 m by 267 m (0.063 km^2). The benthic habitats surrounding the riser platform have been subject to historical disturbance (e.g., facility construction and operation) and are considered to be of low ecological value (although it is acknowledged the facility provides artificial hard substrate which has formed the basis of relatively high biodiversity communities at this location when compared to the surrounding seabed). Subsequently, the physical disturbance to the seabed resulting from the collapse of the riser platform would be localised but may result in long-term disturbance to benthic communities.

The riser platform could also act as a source of environmental contaminants due to material on board the platform (e.g., chemical/hydrocarbon inventories, corrosion of structural materials, debris, etc). The potential for contamination would diminish over time, as the structure degrades. Depending on the nature of the loss of structural integrity, complete or partial salvage of the riser platform may not be feasible. These structures are expected to be colonised by marine organisms, and a reef habitat will develop over time on the structures.

While the PAA overlaps the Glomar Shoals KEF and Ancient Coastline at 125 m Depth Contour KEFs, neither of these are in close proximity to the riser platform.

MEE-03 Loss of Structural Integrity – Risk Analysis

A bowtie risk analysis was undertaken to assess MEE-03; refer to the **Figure 6-18**, **Figure 6-19 and Figure 6-20** for bowtie diagrams which were an output of Woodside's risk analysis process.

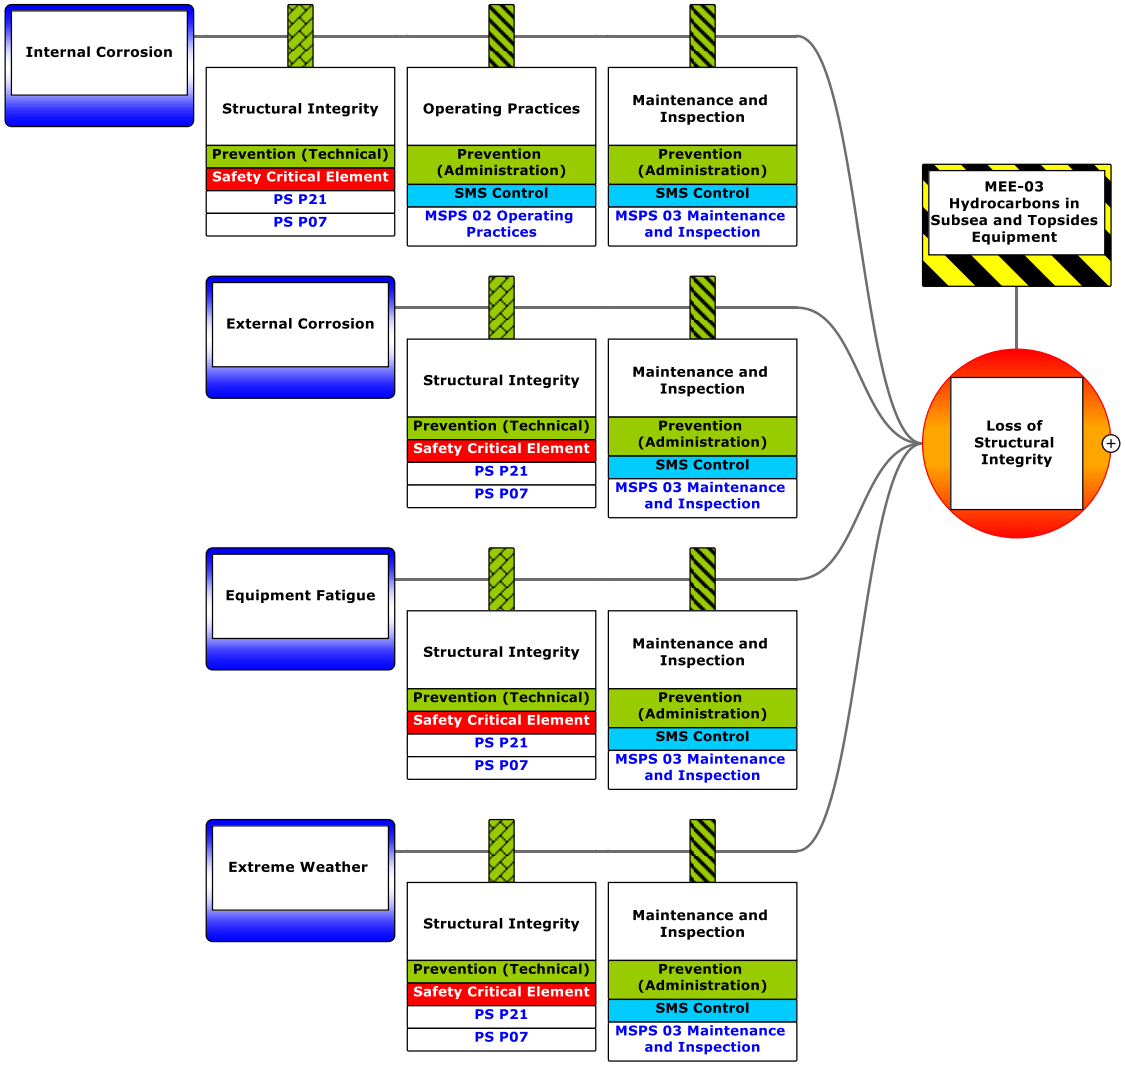

Figure 6-18: MEE-03 loss of structural integrity (Causes 1 to 4)

Risk Based Analysis

For risks identified as MEEs, a detailed risk based Bowtie Analysis (as outlined in **Section 2.7.3**) has been used to identify, analyse and demonstrate that controls in place reduce the risk associated with each MEE to ALARP. Controls have been selected following hierarchy of control principles and consider independence of each barrier and their type of effect in controlling the hazardous event.

Application of Woodside's Risk Management Procedures and implementation of the Angel Safety Case ensures the continuous identification of hazards, systematic assessment of risks and ongoing assessment of alternative control measures to reduce risk to ALARP, which includes:

- ongoing hazard identification, risk assessment and the identification of control measures
- ongoing integrity management of hardware control measures in accordance with the operational performance standards which define requirements to be suitably maintained, such that they retain effectiveness, functionality, availability and survivability.

For each SCE, detailed requirements for equipment functionality, availability, reliability and survivability are incorporated into SCE Performance Standards which also include the relevant assurance tasks (e.g., inspection, maintenance, testing and monitoring requirements) to ensure technical integrity.

A quantitative spill risk assessment was undertaken (refer **Section 6.7.2** for details of the method used).

ALARP Statement:

On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts and risks of a very low likelihood of a loss of structural integrity.

The principle of inherent safety and environmental protection is based on the prevention of the MEE through design of the facility, ensuring the equipment is operated within the design envelope through operating practices, and assurance through maintenance and inspection. If a loss of structural integrity occurs, mitigation measures are in place to minimise the consequence by limiting the inventory which can be released and implementing remediation.

The controls in place for prevention and mitigation of MEEs are specified and assured through implementing the Angel Safety Case, SCE management procedures including performance standards for SCEs, and MSPSs for Safety Critical Management System Controls.

The application of Woodside Risk Management Procedures and implementation of the Angel Safety Case ensures the continuous identification of hazards, systematic assessment of risks and ongoing assessment of alternative control measures to reduce risk to ALARP.

Given the controls in place to prevent and control loss of containment events and mitigate their consequences, alongside procedural control of facility operations, it is considered that MEE risk associated a loss of structural integrity is managed to ALARP.

Demonstration of Acceptability
Acceptability Statement: A loss of structural integrity has been evaluated as having a 'Moderate' (B0 to D1) risk rating (including the consideration of applicable MEEs). As per **Section 2.6.1**, Woodside considers 'Moderate' (B0) risk ratings as acceptable if managed to ALARP. Due to the consequence associated with MEE-03, Decision Type B has been applied, and ALARP is demonstrated using good industry practice and risk based analysis, if legislative requirements are met and societal concerns are accounted for, and the alternative control measures are grossly disproportionate to the benefit gained. Acceptability is demonstrated with regard to the considerations described in **Section 6.7.3** (MEE-01). The considerations include principles of Ecological Sustainable Development, and other requirements (including laws, policies, standards and conventions). On the basis of the environmental impact assessment outcomes and Woodside's criteria for acceptability outlined in **Section 2.8.2** this is considered an acceptable level of risk.

Description of Source of Risk

A loss of marine vessel separation between a vessel and the riser platform may result in a loss of hydrocarbon containment from the Angel facility and/or the release of fuel from the vessel. A loss of marine vessel separation has been identified as a potential MEE (MEE-04). Loss of marine vessel separations can arise from:

visiting vessel collisions associated with platform support vessels – ships which are visiting the riser platform can accidentally collide with the platform during approach to, or manoeuvring alongside, the platform

errant passing vessel collision – ships which are not visiting the riser platform (i.e., passing vessels) can, for one reason or another, move off-course and collide with the platform.

The different collision hazards involve significantly different sized vessels and collision speeds; hence, differing impact energies and consequences have been assessed.

Visiting Vessels

Visiting vessels are defined as those which are routinely used to service the facility. Operating procedures dictate how vessels are operated, loaded and unloaded, but it will generally occur so that the prevailing winds move the vessel away from the facility. The primary causes of visiting vessel collisions are failure to follow safe procedures and communication errors between the marine vessels and riser platform operations. These errors could be worsened by:

- vessel station keeping failures
- vessel operations in adverse weather conditions.

Given the facility is NNC, the frequency of visits by vessels is inherently lower than those for a staffed facility.

Errant Passing Vessels

Errant passing vessels are defined as third party vessels that enter the riser platform's 500 m PSZ, but do not call at the facility (i.e., not support vessels). The collision can be powered or drifting. Either has the potential to cause significant damage to the riser platform.

The causes of errant passing vessel collisions include:

- failure of propulsion or steering systems
- adverse weather conditions resulting in poor visibility
- rough seas
- human error.

Woodside implements a range of control measures to mitigate the risk of errant vessel collision (**Section 6.6.1**). The riser platform is NNC, so monitoring and control (and isolation) of the platform and associated flowlines and export pipeline takes place from NRC.

A number of common failure causes due to human error and SCQ failures are presented in the generic Human Error and SCE Failure bowties in **Section 6.7.8**.

Errant Mobile Offshore Drilling Unit Collision

An errant MODU is a drilling unit that has a broken/failed mooring system and is drifting uncontrolled in the ocean. It may be a MODU contracted to Woodside, drilling in the area proximate to Angel, particularly during tie-back activities, or a unit contracted to a third party. High energy weather events such as cyclones, while a MODU is on station, can lead to excessive loads on the mooring lines resulting in failure (either anchor(s) dragging or mooring lines parting). A failure of mooring integrity may lead to the mooring lines and anchors attached to the MODU being trailed across the seabed. If mooring failure is sufficient, the MODU may move off station, increasing the likelihood of collision with other assets or infrastructure.

For a moored MODU, personnel on-board the MODU are typically evacuated during cyclones (and hence response capabilities in the event of a mooring failure may be limited). Woodside, for example, implements a risk-based assessment process to aid in decision making for cyclone evacuations, with the well suspended prior to MODU evacuation. Operational experience indicates cyclone evacuations typically last for seven days.

Note that single and double mooring line failures do not typically result in the loss of station keeping. In the event of partial or complete mooring failures that are sufficient to result in a loss of station keeping, industry experience indicates that MODUs may drift considerable distances from their initial position (Offshore: Risk & Technology Consulting Inc., 2002). Partial mooring failures leading to a loss of station keeping resulted in smaller MODU displacements due to the remaining anchors dragging along the seabed when compared to complete mooring failures; complete mooring failures resulted in a freely drifting MODU (Offshore: Risk & Technology Consulting Inc., 2002). NOPSEMA has recorded four cases of anchor drag due to loss of MODU holding station during cyclone activity between 2004 and 2015 (NOPSEMA, 2015).

Vessel Collision

A collision between a support vessel with a third-party vessel (i.e., commercial shipping, other petroleum related vessels and commercial fishing vessels) was considered the only credible event that could release a significant quantity of marine diesel to the environment, during operations. This was assessed as being credible, but highly unlikely, given:

- the platform support vessels typically operate in the PAA
- the presence of subsea vessels in the PAA is typically temporary (e.g., while undertaking IMMR activities)
- vessels undertaking the Petroleum Activities Program typically operate at low speeds or are stationary
- the standard vessel operations and equipment in place to prevent collision at sea
- the construction and placement of storage tanks.

An unplanned loss of hydrocarbons resulting from vessel collision during tie-back activities is not considered under the typical Operations MEE framework primarily due to safety case scopes. Typically, the MEE register associated with operations sits with the asset and aligns with the asset safety case to ensure appropriate coverage and risk management for the duration of facility operations. During drilling operations, the responsibility and risk is limited to and covered under the vessel safety case responsible for performing the activities. As such the risk associated with vessel collisions under this circumstance only exists for the duration that this limited time activity is performed and will have its own unique controls to manage this risk to an ALARP level.

The largest tank of a platform support vessel (**Section 3.4.14.1**) or subsea support vessel (**Section 3.5.6.3**) may range up to ~150 m^3. A review of previous modelling identified an instantaneous release of 105 m^3 of diesel at the Angel platform that is considered representative of a loss of containment from a support vessel. Release characteristics for fuel tank loss of containment scenario are summarised in **Table 6-34.**

Table 6-34: Summary of worst-case support vessel fuel tank loss of containment during operations scenario

Scenario	*Hydrocarbon*	*Duration (minutes)*	*Depth (m)*	*Latitude*	*Longitude*	*Total hydrocarbon release volume (m^3)*
Support vessel fuel tank loss of containment	Marine Diesel	< 10	Surface	19° 29’ 54.60” S	116° 35’ 52.80” E	105

Loss of Vessel Separation – Credible Hydrocarbon Spill Scenario

The loss of marine vessel separation during operations is considered a Major Environment Event (MEE-04). A loss of structural integrity could result in a significant release of hydrocarbons. A loss of structural integrity may result in credible spill scenarios consistent with:

- subsea equipment loss of containment, including loss from risers (MEE-02; Section 6.7.4)
- topsides loss of containment (Section 6.8.2; not an MEE).

In addition, vessel cargo, including diesel inventory, could be spilled if the cause of the loss of platform integrity was a collision from a support vessel.

Worst-case hydrocarbon release scenarios for subsea equipment loss of containment (MEE-02) that could result from loss of marine vessel separation are discussed in the relevant sections referenced above. Relevant trajectory modelling, as applicable to these scenarios, is also discussed above.

A loss of vessel separation may lead to the accidental release of marine diesel from the fuel tanks on the vessel(s) involved. For a vessel collision to result in the worst-case scenario of a hydrocarbon spill potentially impacting an environmental receptor, several factors must align as follows:

- Vessel interaction must result in a collision.
- The collision must have enough force to penetrate the vessel hull.
- The collision must be in the exact location of the fuel tank.
- The fuel tank must be full, or at least of volume which is higher than the point of penetration.

The probability of the chain of events described above aligning, to result in a breach of fuel tanks resulting in a spill that could potentially affect the marine environment, is considered highly unlikely. Given the offshore location of the PAA, vessel grounding in relation to the Petroleum Activities Program is not considered a credible risk.

Decision Type, Risk Analysis and ALARP Tools

Woodside has not experienced any loss of marine vessel separation events that have resulted in significant environmental impacts. The facility has never experienced a worst-case loss of containment due to loss of vessel separation in its operational history.

Decision Type

Decision Type B has been applied to this risk under the Guidance on Risk Related Decision Making (Oil and Gas UK, 2014). This reflects the complexity of the risk, the higher potential consequence and stakeholder implications should the event be realised. To align with this decision type, a further level of analysis has been applied using risk-based tools including the bowtie methodology (described in **Section 2.7.3**) and hydrocarbon spill trajectory modelling. Company and societal values were also considered in the demonstration of ALARP and acceptability, through peer review, benchmarking and consultation.

Quantitative Spill Risk Assessment

Stochastic spill modelling of the worst-case credible spill of the support vessel fuel tank loss of containment scenario was undertaken by RPS, on behalf of Woodside. The simulation was based on the assumptions in **Section 6.7.2**. Modelling was undertaken over all seasons to address year-round operations. This is considered to provide a conservative estimate of the EMBA and the potential impacts from the identified worst-case credible release volume for a support vessel fuel tank loss of containment.

Credible worst-case stochastic spill modelling for the scenarios associated with MEE-02 (**Section 6.7.4**) has been undertaken. Results of these modelling studies have been used to inform the consequence assessment for these MEEs; these assessments are applicable to the consequence assessment for a loss of structural integrity event.

Likelihood

In accordance with the Woodside Risk Matrix (**Section 2.6.3**), the following likelihoods have been assigned to the sources of risk:

- release of hydrocarbons resulting from loss of export pipeline containment (AEP including 1TL inventory) (MEE-02): Highly Unlikely (refer to Section 6.7.4)
- release of hydrocarbons resulting from loss of containment of subsea flowlines and infrastructure (MEE-02): Highly Unlikely (refer to Section 6.7.4)
- hydrocarbon release from topsides equipment to the marine environment and atmosphere: Highly Unlikely (refer to Section 6.8.2; not an MEE)
- marine environment footprint and associated hydrocarbon and chemical release associated with structural collapse of riser platform (MEE-03): Remote (refer to Section 6.7.5)
- surface release from support vessel fuel tank: Highly Unlikely.

Consequence

The spatial extent and fate (including weathering) of the spilled hydrocarbon from the support vessel was considered during the impact assessment for a worst-case loss of marine vessel separation. These considerations were informed primarily by the outputs from the numerical modelling studies undertaken by, available information on environmental sensitivities that may credibly be impacted in the event of a worst-case spill (**Section 6.7.2**), and relevant literature and studies considering the effects of hydrocarbon exposure.

Consequence Assessment

Environment that May Be Affected

As discussed above, the potential impacts from a hydrocarbon release caused by a loss of vessel separation include those which would result from:

- subsea equipment loss of containment (MEE-02; Section 6.7.4)
- topsides loss of containment (Section 6.8.2).

The potential impacts are therefore discussed in the above-mentioned sections.

Marine Diesel

No contact at the ecological impact thresholds defined in **Table 6-25** for all hydrocarbon fates was predicted for the modelled scenario. The marine diesel spill would be highly localised with no impacts to receptors within the EMBA anticipated. Impacts to water quality and air quality in the immediate location of the spill would be expected to be minor and short term.

MEE-04 Loss of Marine Vessel Separation – Risk Analysis

A bowtie risk analysis was undertaken to assess MEE-04; refer to **Figure 6-21** and **Figure 6-22** for bowtie diagrams which were an output of Woodside's risk analysis process.

Risk Based Analysis

For risks identified as MEEs, a detailed risk based bowtie analysis (as outlined in **Section 2.7.3**) has been used to identify, analyse and demonstrate that controls in place reduce the risk associated with each MEE to ALARP. Controls have been selected following hierarchy of control principles and consider independence of each barrier and their type of effect in controlling the hazardous event.

Application of Woodside's Risk Management Procedures and implementation of the Angel and NWS Pipelines Safety Cases ensures the continuous identification of hazards, systematic assessment of risks and ongoing assessment of alternative control measures to reduce risk to ALARP, which includes:

- ongoing hazard identification, risk assessment and the identification of control measures
- ongoing integrity management of hardware control measures in accordance with the operational performance standards which define requirements to be suitably maintained, such that they retain effectiveness, functionality, availability and survivability.

For each SCE, detailed requirements for equipment functionality, availability, reliability and survivability are incorporated into SCE Performance Standards which also include the relevant assurance tasks (e.g., inspection, maintenance, testing and monitoring requirements) to ensure technical integrity.

A quantitative spill risk assessment was undertaken (refer **Section 6.7.2** for details of the method used).

ALARP Statement:

On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts and risks of a very low likelihood of a loss of marine vessel separation.

The principle of inherent safety and environmental protection is based on the prevention of the MEE through design of the facility, ensuring the equipment is operated within the design envelope through operating practices, and assurance through maintenance and inspection. If a loss of marine vessel separation occurs, mitigation measures are in place to minimise the consequence by limiting the inventory which can be released and implementing remediation.

The controls in place for prevention and mitigation of MEEs are specified and assured through implementing the Angel and NWS Pipelines Safety Cases, SCE management procedures including performance standards for SCEs and MSPSs for Safety Critical Management System Controls.

The application of Woodside Risk Management Procedures and implementation of the Angel and NWS Pipelines Safety Cases ensures the continuous identification of hazards, systematic assessment of risks and ongoing assessment of alternative control measures to reduce risk to ALARP.

Given the controls in place to prevent and control loss of containment events and mitigate their consequences, alongside procedural control of facility operations, it is considered that MEE risk associated with a loss of marine vessel separation is managed to ALARP.

Demonstration of Acceptability			
Acceptability Statement: A loss of marine vessel separation during operations has been evaluated as having 'moderate' (B0 to D1) risk rating (via the consideration of applicable MEEs). As per **Section 2.6.3**, Woodside considers 'moderate' (B0) risk ratings as acceptable if managed to ALARP. Due to the consequence associated with MEE-04, Decision Type B has been applied; ALARP is demonstrated using good industry practice and risk-based analysis, if legislative requirements are met and societal concerns are accounted for, and the alternative control measures are grossly disproportionate to the benefit gained. Acceptability is demonstrated with regard to the considerations described in **Section 6.7.3** (MEE-01). The considerations include principles of Ecological Sustainable Development and other requirements (including laws, policies, standards and conventions). On the basis of the environmental impact assessment outcomes and Woodside's criteria for acceptability outlined in **Section 5.4**, this is considered an acceptable level of risk.

Surface or subsea release from flowline, pipeline and riser to the marine environment and atmosphere (MEE-02)		✓	✓	✓	✓	✓	✓	B	B	1	M	LCS GP PJ RBA CV SV	Acceptable if ALARP	**EPO 17**
Hydrocarbon release from topsides equipment to the marine environment and atmosphere (**Section 6.8.2**; not an MEE)			✓	✓		✓		A	D	1	M			

Description of Source of Risk

Lifting activities on the riser platform can take place from the pedestal crane on the east side of the platform. Lifts may occur between supply vessels and laydown areas, primarily to transfer stores and equipment to or from the riser platform. Lifting operations could potentially lead to dropped objects impacting assets (topsides equipment, subsea infrastructure) inside the PSZ. This may lead to a hydrocarbon loss of containment from topsides or subsea infrastructure. Loss of suspended load has been identified as an MEE (MEE-05).

- A loss of suspended load may arise from:
- lifting equipment failure
- incorrectly slung loads
- excessive loads.
- crane operator error; dropped anchor/object from supply/standby or work vessel
- adverse weather conditions.

A number of common failure causes due to human error and SCQ failures are presented in the generic Human Error and SCE Failure bowties in **Section 6.7.8**.

Loss of Control of Suspended Load – Credible Scenarios

The potential outcome of a loss of control of a suspended load is a topsides and/or subsea flowlines and riser loss of containment. Refer to **Section 6.7.4** (MEE-02) and **Section 6.8.2** for a description of subsea and topsides loss of containments scenarios, respectively.

Decision Type, Risk Analysis and ALARP Tools

Woodside has a good history of implementing industry standard practice in subsea system design and construction. In the company's recent history, it has not experienced any loss of suspended load events that have resulted in significant releases or significant environmental impacts.

Decision Type

Decision Type B has been applied to this risk under the Guidance on Risk Related Decision Making (Oil and Gas UK, 2014). This reflects the complexity of the risk, the higher potential consequence and stakeholder implications should the event be realised. To align with this decision type, a further level of analysis has been applied using risk-based tools including the bowtie methodology (described in **Section 2.7.3**) and hydrocarbon spill trajectory modelling. Company values were also considered in the demonstration of ALARP and acceptability through peer review, benchmarking and consultation.

A loss of control of a suspended load is considered an MEE (MEE-05). The hazard associated with this MEE is the hydrocarbon inventory of flowlines and risers, or topsides process and non-process hydrocarbons.

Quantitative Spill Risk Assessment

The credible worst-case hydrocarbon scenario for MEE-02 is considered to apply to a loss of control of suspended load, as they may credibly arise from damage to hydrocarbon containing subsea infrastructure within the 500 m PSZ. Refer to **Section 6.7.2** for additional information on quantitative spill risk assessments for this scenario. A quantitative spill risk assessment was not conducted for the topsides loss of containment scenario due to the relatively small credible release volume; refer to **Section 6.8.2** for additional information.

Likelihood

In accordance with the Woodside Risk Matrix, given prevention and mitigation measures in place (i.e., design, inspection and maintenance), the likelihood assigned to the worst-case risk events are considered 1 (Highly Unlikely).

Consequence

The spatial extent and fate (incl. weathering) of the spilled hydrocarbons were considered during the impact assessment for a loss of control of suspended load. These considerations were informed primarily by the outputs from the numerical modelling studies undertaken by RPS, available information on environmental sensitivities that may credibly be impacted in the event of a worst-case spill, and relevant literature and studies considering the effects of hydrocarbon exposure. Refer to **Section 6.7.4** (MEE-02) and **Section 6.8.2** for a description of the consequence potentially resulting from subsea and topsides loss of containment scenarios, respectively.

MEE-05 Loss of Control of Suspended Load from Platform – Risk Analysis

A bowtie risk analysis was undertaken to assess MEE-05; refer to **Figure 6-23** and **Figure 6-24** for bowtie diagrams which were an output of Woodside's risk analysis process.

Risk Based Analysis				
For risks identified as MEEs, a detailed risk based Bowtie Analysis (as outlined in **Section 2.7.3**) has been used to identify, analyse and demonstrate that controls in place reduce the risk associated with each MEE to ALARP. Controls have been selected following hierarchy of control principles and consider independence of each barrier and their type of effect in controlling the hazardous event. Application of Woodside's Risk Management Procedures and implementation of the Angel and NWS Pipelines Safety Cases ensures the continuous identification of hazards, systematic assessment of risks and ongoing assessment of alternative control measures to reduce risk to ALARP, which includes: • ongoing hazard identification, risk assessment and the identification of control measures • ongoing integrity management of hardware control measures in accordance with the operational performance standards which define requirements to be suitably maintained, such that they retain effectiveness, functionality, availability and survivability. • For each SCE, detailed requirements for equipment functionality, availability, reliability and survivability are incorporated into SCE Performance Standards which also include the relevant assurance tasks (e.g., inspection, maintenance, testing and monitoring requirements) to ensure technical integrity. • A bowtie analysis was undertaken to assess MEE-05, refer to **Figure 6-23** and **Figure 6-24** for bowtie diagrams. • A quantitative spill risk assessment was undertaken (refer **Section 6.7.2** for details of the method used).				
Company Values				
Refer to **Section 6.7.4** for a discussion of company values in relation to the pipeline and riser loss of containment scenario.				
Societal Values				
Refer to **Section 6.7.4** for a discussion of societal values in relation to the pipeline and riser loss of containment scenario.				

MEE-05 Loss of Control of Suspended Load from Platform – Demonstration of ALARP				
ALARP Control Measures				
Hierarchy	***Control/barrier***	***SCE/Management System reference***	***Type of effect (refer to Table 6-23)***	***Control adopted***

ALARP Statement:

On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts and risks of a very low likelihood of a loss of control of suspended loads.

The principle of inherent safety and environmental protection is based on the prevention of the MEE through design of the facility, ensuring the equipment is operated within the design envelope through operating practices, and assurance through maintenance and inspection. If a loss of control of suspended load occurs, mitigation measures are in place to minimise the consequence by limiting the inventory which can be released and implementing remediation.

The controls in place for prevention and mitigation of MEEs are specified and assured through implementing the Angel and NWS Pipelines Safety Cases, SCE management procedures including performance standards for SCEs and MSPSs for Safety Critical Management System Controls.

The application of Woodside Risk Management Procedures, and implementation of the Angel and NWS Pipelines Safety Cases ensures the continuous identification of hazards, systematic assessment of risks and ongoing assessment of alternative control measures to reduce risk to ALARP.

Given the controls in place to prevent and control loss of containment events and mitigate their consequences, alongside procedural control of facility operations, it is considered that MEE risk associated with a loss of control of suspended load is managed to ALARP.

Demonstration of Acceptability

Acceptability Statement:

A loss of marine vessel separation has been evaluated as having 'moderate' (B1 to D1) risk rating (via the consideration of applicable MEEs). As per **Section 2.2.1.** Woodside considers 'moderate' (B1) risk ratings as acceptable if managed to ALARP. Due to the consequence associated with MEE-05, Decision Type B has been applied; ALARP is demonstrated using good industry practice and risk-based analysis, if legislative requirements are met and societal concerns are accounted for, and the alternative control measures are grossly disproportionate to the benefit gained.

Acceptability is demonstrated with regard to the considerations described in **Section 6.7.3** (MEE-01). The considerations include principles of Ecological Sustainable Development, company and societal values, and other requirements (including laws, policies, standards and conventions).

On the basis of the environmental impact assessment outcomes and Woodside's criteria for acceptability outlined in **Section 5.4**, this is considered an acceptable level of risk.

Angel: Major Environment Event Datasheet	
MEE Number	All
Hazard Description	Generic Human Errors

Hazard Description

Hazard Overview and Scope

There are a number of causes of human errors which contribute to MEEs, or which can result in failure or degradation of the barriers in place to protect against MEEs. These are presented in the following bowtie pages and include:

- task issues; e.g., poor task design; time pressures, task complexity
- poor physical interfaces/working environment
- provision of inappropriate tools for the task
- communication errors; i.e., poor-quality information, lack of clarity in instructions
- operator failings; e.g., competence, fitness, impairment or fatigue
- organisational issues; e.g., peer pressure, poor safety culture, inadequate supervision, lack of clarity on roles and expectations.

The generic human errors bowtie (**Figure 6-27**, **Figure 6-28** and **Figure 6-29**) illustrates the causes, outcomes and the barriers in place for these failure mechanisms. Human errors are managed solely via the WMS (no SCEs) and the bowtie is included in this section for completeness. Refer to **Section 7** Implementation Strategy for applicable Management System Procedures.

Loss of hydrocarbons to marine environment due to loss of well containment during drilling of the LDA-02 well	✓	✓	✓	✓	✓	✓	B	B	1	M	LCS GP PJ RB A CV SV	Acceptable if ALARP	**EPO 19**

Description of Source of Impact

Woodside has identified a subsea well blowout as the scenario with the worst-case credible environmental outcome as a result of loss of well containment during drilling of the LDA-02 well. A loss of well containment is an uncontrolled release of reservoir hydrocarbon or other well fluids to the environment. A blowout is an incident where formation fluid flows out of the well or between formation layers after all the predefined technical well barriers (e.g., the BOP) or activation of the same has failed. Woodside has identified one well blowout scenario:

- 'swab' blowout – full reservoir open to flow in the 12.375" hole section.

The Loss of Well Containment MEE scenario from all Angel wells during operations is considered separately in **Section 6.7.3**.

Industry Experience

A risk assessment by AMSA of oil spills in Australian ports and waters (Det Norske Veritas, 2011) concluded that:

- overall national exceedance frequency for oil spills from offshore drilling in Australia is 0.033 for spills >1 tonne/year decreasing to 0.008 for spills > 100 tonnes/year
- probability of a blow-out from a well intervention is 1 × 10-4 (0.0001, or 0.01%), considerably lower than drilling activities (International Association of Oil and Gas Producers, 2010).

Woodside has a good history of implementing industry standard practice in well design and construction. In the company's 60-year history, it has not experienced any well containment events that have resulted in significant releases or significant environmental impacts.

Therefore, in accordance with the Woodside Risk Matrix, a loss of well containment and resulting blowout event corresponds to a 'highly unlikely' event as it has occurred many times in the industry, but not in the Company.

Credible Scenario – Loss of Well Containment

The credible worst-case scenario to be considered during drilling of the LDA-02 well is an uncontrolled subsea release to environment lasting <77 days (Refer to **Section 6.7.3**). This timeframe has been selected because:

- the Mutual Aid Memorandum of Understanding informed a likely relief well drilling and response time following the Montara well loss of containment in 2009 (77 days)
- internal Woodside guidelines and procedures indicate that appropriate modelling and response times for well based spill scenarios is reservoir-specific, and reliant on drilling times.

Quantitative Hydrocarbon Spill Modelling – Loss of Well Containment

Spill modelling was undertaken by RPS, on behalf of Woodside, to determine the fate of hydrocarbon released from the loss of well containment scenario, based on the Lambert Deep condensate characteristics (**Table 6-24)**. The modelled release rate provided assumes the worst-case scenario for the largest oil volume release (**Table 6-35**). Modelling considered metocean conditions throughout the year; this was done to inform the determination of consequence of loss of well control during intervention at any time of the year.

Table 6-35: Summary of modelled credible scenario – well blowout

	Loss of well integrity
Total discharge[84] at surface	5 days 2187 m^3
Total discharge at seabed	72 days 28,998 m^3
Water depth	130 m
Fluid	Lambert Deep condensate

Subsea Plume Dynamics

The well blowout surface/subsea release that has been modelled forecasts the size of the hydrocarbon droplets that would be released from the well as determined by the OILMAP model. The results of the OILMAP simulation predict that the discharge will generate a cone of rising gas that will entrain the oil droplets and ambient sea water up to the water surface. The mixed plume is initially forecast to jet towards the water surface with a vertical velocity of around 8 m/s, gradually slowing and increasing in plume diameter as more ambient water is entrained. The diameter of the central cone of rising water and oil at the point of surfacing is predicted to be about 16.7 m.

Given the discharge velocity and turbulence generated by the expanding gas plume, the release is predicted to generate droplet sizes ranging from approximately 3179 µm to 11,452 µm. The results suggest that beyond the immediate vicinity of the blowout, the majority of the released hydrocarbons will be present in the upper layers of the ocean, with the potential for oil to form floating slicks under sufficiently calm local wind conditions.

The ongoing nature of the release combined with the potential for the plume to breach the water surface may present other hazards, including conditions that may lead to high local concentrations of atmospheric volatiles. These issues should be considered when evaluating the practicality of the response operations at or near the blowout site.

Impact Assessment

Potential Impacts Overview

EMBA

Quantitative hydrocarbon spill modelling results are shown in **Table 6-36** and have been used to define the EMBA (**Section 4.1**).

Surface Hydrocarbons

Quantitative hydrocarbon spill modelling results for surface hydrocarbons are shown in **Figure 4-1**. In the event of the loss of well containment scenario occurring, surface hydrocarbons at or above 1 g/m^2 and 10 g/m^2 are forecast to potentially occur up to 391 km and 19 km respectively from the release site. Floating oil concentrations greater than 1 g/m^2 are predicted to contact Gascoyne AMP at a 3% probability. No receptors are predicted to be in contact with floating oil above 10 g/m^2 (**Table 6-36**).

Entrained Hydrocarbons

Entrained hydrocarbons at concentrations equal to or greater than the 100 ppb threshold are predicted to be found up to 406 km from the release site. Contact by entrained hydrocarbons at concentrations equal to or greater than 100 ppb is predicted at the Montebello AMP (6%), with a worst-case entrained concentration of 240 ppb. Several other

84 The discharge volumes in **Table 6-35** are predicted using reservoir modelling software packages that consider a number of factors (well design, reservoir properties and environmental conditions such as water depth, temperature and pressure) to provide a production profile over the oil spill modelling period.

sensitive receptors are predicted to be contacted at concentrations equal to or greater than 100 ppb with probabilities of 1 to 2% (**Table 6-36**).

Dissolved Hydrocarbons

Dissolved aromatic hydrocarbons at concentrations equal to or greater than the 50 ppb thresholds are predicted to be found up to around 552 km from the release site. Contact by dissolved aromatic hydrocarbons at concentrations equal to or greater than 50 ppb is predicted to be greatest at the Montebello AMP (9%), with a worst-case dissolved concentration of 447 ppb. Several other sensitive receptors are predicted to be contacted at concentrations equal to or greater than 50 ppb with probabilities of 1 to 2% (**Table 6-36**).

Accumulated Hydrocarbons

Shoreline oil concentrations above 10 g/m^2 are predicted to contact Muiron Islands with 18% probability. No shoreline oil impact is predicted at 100 g/m^2 (**Table 6-36**).

Summary of Potential Impacts to Environmental Values(s)

The potential impacts of spilled hydrocarbons to species (protected and otherwise), marine primary producers, other habitats and communities, water quality, marine sediment quality, air quality, protected areas and socio-economic values are described in **Section 6.7.3**. Potential impacts specific the loss of well containment during drilling of the LDA-02 well are summarised below.

Marine Mammals

A range of cetaceans were identified as potentially occurring within the PAA and wider EMBA (**Section 4.6.3**). In the event of a loss of well containment during drilling of LDA-02, surface, entrained, and dissolved hydrocarbons exceeding environmental impact threshold concentrations may drift across habitat for cetacean species. Migratory routes and BIAs of cetaceans considered to be MNES may be affected, including humpback whales and pygmy blue whales (northbound and southbound migrations). As described in **Section 4.6.3** cetaceans that have direct physical contact with surface, entrained, or dissolved aromatic hydrocarbons may suffer surface fouling, ingestion of hydrocarbons (from prey, water and sediments), aspiration of oily water or droplets, and inhalation of toxic vapours (Deepwater Horizon Natural Resource Damage Assessment Trustees [DHNRDT], 2016).

Pygmy blue whales and humpback whales are known to migrate seasonally through the wider EMBA. A major spill in May to November would coincide with humpback whale migration through the waters off the Pilbara and North West Cape (**Section 4.6.3**). A major spill in April to August or October would coincide with pygmy blue whale migration (**Section 4.6.5**). Both pygmy blue and humpback whales are baleen whales, so are most likely to be significantly impacted by toxic effects when feeding. However, feeding during migrations is low level and opportunistic, with most feeding for both species occurring in the Southern Ocean. Fresh hydrocarbons (i.e., typically in the vicinity of the release location) may have a higher potential to cause toxic effects when ingested, while weathered hydrocarbons are considered to be less likely to result in toxic effects. As such, the risk of ingestion of hydrocarbons is low. Pygmy blue whale and humpback whale migrations are protracted through time and space (i.e., the whole population will not be within the EMBA), and as such, a spill from the loss of well integrity is unlikely to affect an entire population.

Coastal populations of small cetaceans and dugongs are known to reside or frequent nearshore waters, including the Ningaloo Coast, Muiron Islands, Montebello/Barrow Islands and Pilbara Southern Island Group (see **Table 6-36**) which may be potentially impacted by entrained or dissolved hydrocarbons exceeding threshold concentrations in the event of a loss of well containment. The Exmouth Gulf is a known humpback whale aggregation area on the annual southern migration (September to December), as well as overlapping foraging, breeding, nursing and calving BIAs for dugongs (~181 km south of the PAA).; therefore, migratory humpbacks moving into the Gulf, or more residential dugongs, may be exposed to entrained or dissolved hydrocarbons above thresholds levels. However, entrained and dissolved hydrocarbons concentrations above the threshold are not expected within Exmouth Gulf itself. No hydrocarbon contact at or above threshold concentrations for the ecological EMBA is expected for Camden Sound, an important calving area for humpback whales.

The potential impacts of exposure are discussed above. However, nearshore populations of cetaceans and dugongs are known to exhibit site fidelity and are often resident populations. Therefore, avoidance behaviour may have greater impacts to population functioning. Nearshore dolphin species (e.g., spotted bottlenose dolphins) may exhibit higher site fidelity than oceanic species, although Geraci (1988) observed relatively little impacts beyond behavioural disturbance. Additional potential environment impacts may also include the potential for dugongs to ingest hydrocarbons when feeding on oiled seagrass stands, or indirect impacts to dugongs due to loss of this food source due to dieback in worst-affected areas.

In summary, a loss of well containment during drilling of LDA-02 has the potential to result in major long-term impacts to cetacean species and dugongs, with consequence severity dependent on the actual timing, duration and extent of a spill in relation to species' migratory movements and distributions.

Marine Reptiles

The PAA is unlikely to represent an important habitat for marine turtles as there is an absence of potential nesting or foraging habitat (i.e., no emergent islands, reef habitat or shallow shoals) and the water is deep (70 to 130 m). There is the potential for marine turtles to be present at submerged shoals within the EMBA, such as Rankin Bank and Glomar Shoals; however, these receptors have a low probability of being contacted by dissolved hydrocarbons only above the threshold concentration (8% and 1% respectively).

There are no overlapping BIAs with the PAA (**Section 4.6.2**). However, there are significant nesting and foraging sites along the mainland coast and islands of the region, including the Montebello Islands, and a number of BIAs and habitat critical for the survival of marine turtles overlap the EMBA (**Section 4.6.2**). In particular, the internesting BIAs and habitat critical to the survival of a species for green, loggerhead and hawksbill turtles extend for ~20 km from known nesting locations, and for ~60 km for flatback turtles. It is noted that the drilling of the LDA-02 well is proposed to be undertaken in Q3 2024, which coincides with hawksbill turtle nesting and hatching, but is outside the peak nesting period (October to January) (refer to **Section 4.6.5**). Oil from an ongoing loss of containment could be present during nesting season for all hawksbill, flatback and green turtles depending on the timing of a spill. No floating or accumulated hydrocarbons above ecological threshold concentrations are predicted at shoreline locations, although the nearshore waters of these turtle habitat areas have a low probability (1 to 2%) of contact with dissolved and/or entrained hydrocarbons (**Table 6-36**).

In summary, a loss of well containment during drilling of LDA-02 has the potential to result in major long-term impacts to offshore foraging and nesting marine turtles, with consequence severity dependent on the actual timing, duration and extent of a spill in relation to species' migratory movements and distributions.

In general, sea snakes are found in continental shelf waters around offshore islands and potentially submerged shoals (water depths <100 m. Sea snakes may be present in the wider EMBA at the submerged shoals, Rankin Bank and Glomar Shoals, as well as the submerged reefs and shoals of Barrow Island and southern Pilbara islands. Sea snakes may also be present in nearshore waters of the mainland and islands which, along with submerged reefs and shoals, have the potential to be contacted by entrained and/or dissolved hydrocarbons above the threshold concentrations. Their abundance is not expected to by high given the water depth and offshore environment. However, sea snake species in Australia generally show strong habitat preferences (Heatwole and Cogger, 1993); species that have preferred habitats associated with submerged shoals may be disproportionally affects by a hydrocarbon spill affecting such habitat.

Therefore, a loss of well containment during drilling of LDA-02 has the potential to result in major long-term impacts to sea snakes, with consequence severity dependent on the duration and extent of a spill in relation to the distribution of sea snakes.

Fish, Sharks and Rays

Shark and ray species may occasionally transit through the area and may potentially be exposed to hydrocarbons from a loss of well containment during drilling of the LDA-02 well, including species such as whale sharks and manta rays. Whale sharks may transit offshore open waters when migrating to and from Ningaloo Reef, where they aggregate for feeding from March to July. Both the PAA and EMBA overlap the whale shark foraging BIA identified in **Section 4.6.1.** Should sharks or rays be present in offshore waters near the PAA during the spill, direct impacts may occur if foraging within surface slicks or in the upper 20 to 30 m of the water column containing entrained hydrocarbons and dissolved aromatics. Contamination of their food supply and the subsequent ingestion of this prey may also result in long term impacts as a result of bioaccumulation. Impacts are predicted to be limited to a small number of animals given the absence of key habitat and the low numbers of animals that may transit through the area during the short period when spilled hydrocarbons are present.

Seabirds and Migratory Shorebirds

Offshore waters of the PAA are potential foraging grounds for seabirds associated with the coastal roosting and nesting habitat (e.g., Ningaloo, Muiron Islands and the Barrow/Montebello Islands). Foraging and breeding BIAs for a number of seabirds and migratory shorebirds overlap with the EMBA (**Section 4.6.4).** A hydrocarbon spill may result in surface slicks disrupting a significant portion of the foraging habitat for seabirds, including foraging BIAs, which are generally associated with breeding habitats. Seabird distributions are typically concentrated around islands, so hydrocarbons near nesting/roosting areas may result in increased numbers of seabirds being impacted, with many species of seabirds, such as the wedge-tailed shearwater and the various species of tern, foraging relatively close to breeding islands/colonies. Refer to **Table 6-36** for locations within the predicted extent of the EMBA that are identified as habitat for seabirds/migratory shorebirds. Potential impacts on seabirds and shorebirds are expected to be major and long-term in the unlikely event of a loss of well control. However, given the volatile and non-persistent nature of the hydrocarbons and lack of shoreline accumulation predicted, the extent of impacts is not expected to result in a threat to the overall viability of seabird or shorebird populations in the wider region.

Other Habitats, Species and Communities

Within the EMBA resulting from a loss of well containment during drilling of the LDA-02 well, there is the potential for plankton communities to potentially be impacted where entrained hydrocarbon threshold concentrations are exceeded. A range of lethal and sublethal impacts may occur to plankton exposed to entrained or dissolved hydrocarbons within the EMBA. Communities are expected to recover quickly (weeks/months) due to high population turnover (ITOPF, 2011). It is therefore considered that any potential impacts would be low magnitude and temporary in nature.

Pelagic fish populations in the open water offshore environment of the EMBA are highly mobile and have the ability to move away from a marine diesel spill. It is therefore unlikely that fish populations would be exposed to widespread hydrocarbon contamination. Pelagic fish populations are distributed over a wide geographical area so impacts on populations or species level are considered to be limited. Combined with these factors and the rapid dispersion of condensate, it is considered that any potential impacts will be minor.

Other communities (e.g., demersal fish, benthic infauna and epifauna) and key sensitivities (e.g., KEFs identified in **Section 4.7**) occur within the EMBA and may potentially be exposed to entrained hydrocarbons from a loss of well containment.

Water Quality

It is likely that water quality will be reduced at the release location of the spill; however, such impacts to water quality would be temporary and localised in nature due to the rapid dispersion and weathering of marine diesel. The potential impact is therefore expected to be low.

Protected Areas

Entrained and/or dissolved hydrocarbons at or exceeding the 100 ppb and 50 ppb threshold respectively have a low probability of contacting the Argo-Rowley Terrace AMP, Montebello AMP, Gascoyne AMP and Ningaloo AMP and WHA. Entrained and dissolved hydrocarbons are only predicted within the surface waters of the deep open waters of

these protected areas, with no contact to seabed habitats or to shoreline contact. Potential impacts to water quality and the natural values (e.g., mobile protected species) in these areas would be temporary and localised in nature due to the rapid dispersion and weathering of the condensate, as described above. Visible surface hydrocarbons (at or exceeding 1 g/m^2) are not predicted to reach any protected areas.

Socio-economic

A spill resulting from a loss of well containment during drilling of the LDA-02 well is considered unlikely to cause significant direct impacts on the target species fished by Commonwealth State active fisheries identified in **Section 4.9.2** which overlap with the EMBA. The fisheries that operate within the EMBA predominantly target demersal fish species (demersal finfish and crustaceans) that inhabit waters in the range of >60 to 200 m depth, or pelagic species which are highly mobile. Therefore, a spill from a loss of well control is expected to only result in negligible impacts, considering that hydrocarbons are confined to the upper layers of the water column beyond the immediate area of the spill. Visible surface hydrocarbons at or exceeding 1 g/m^2 may also occur up to 391 km from the release site, which may result in fouling of fishing gear and a perception of impacts to fish stocks by fisheries stakeholders and the public. There is the potential that a fishing exclusion zone would be applied in the area of the spill, which would put a temporary ban on fishing activities and therefore potentially lead to subsequent economic impacts on commercial fishing operators if they were planning to fish within the area of the spill. Such measures would likely be in place for less than a week and would not result in widespread or long term impacts to fishing activities.

Cultural Values and Heritage

Through consultation and review of available literature (**Section 4.9.1**), Woodside understands that sea country, including marine ecosystems and species, archaeological heritage and heritage sites, marine parks, as well as intangible cultural heritage may be impacted in the event of a hydrocarbon release from a vessel collision. Cultural features and heritage values that have the potential to be impacted include:

Marine ecosystems and species: Marine ecosystems may hold both cultural and environmental value to Traditional Custodians (see **Section 4.9.1**), with cultural and environmental values intrinsically linked (DCCEEW, 2023; MAC, 2021, as cited in Woodside, 2023b). It necessarily follows that an impact to marine ecosystems has the potential to impact cultural features where the impact is detectable within Sea Country – the seascape which Traditional Custodians view, interact with or hold knowledge of. The EMBA is known to include habitat for culturally important species such as whales, whale sharks, turtles, dugongs, plankton, and seagrass (**Sections 4.6 and 4.9.1**). In the event of a worst-case release of MDO individual fauna may be directly impacted or impacted through temporary degradation of their habitats; however, no population level impacts as expected. Impacts are not expected to occur to ecologically significant proportions of the populations of the species, nor expected to result in a decrease of the quality of the habitat such that the extent of these species is likely to decline. As such, cultural values and intangible cultural heritage associated with these species are expected to be maintained.

Heritage sites: The EMBA overlaps no Registered Aboriginal Sites and two Other Heritage Places. Any oil that reaches the shoreline has potential to impact on indigenous heritage places along the coastline. In the unlikely event of a hydrocarbon release, shoreline accumulation may affect sensitive artefacts or areas, which could damage their heritage value. are assessed in Section 6.10

Marine parks: The EMBA overlaps five AMPs under North-West Marine Parks Network Management Plan 2018 and six State Marine Parks. Management Plans for these parks recognise cultural values of Indigenous groups (**Section 4.8**). Due to the low maximum concentrations predicted to reach any marine park, these values are expected to be maintained.

Intangible cultural heritage: Impacts may occur to intangible cultural values such as songlines; creation/dreaming sites, sacred sites, ancestral beings; cultural obligations to care for Country; knowledge of Country/customary law and transfer of knowledge; connection to Country; Access to Country; kinship systems and totemic species, resource collection. Related intangible cultural heritage may include the transmission of cultural knowledge about whales and whale behaviour, including birthing areas, whale communication and migratory patterns. Such cultural knowledge may be associated with various cultural functions and activities that support the social and economic life of a community (Fijn, 2021). Inter-generational transmission of cultural knowledge (including songlines) relating to marine reptiles may be impacted where changes results in reduced sightings (e.g., through population decline, changes to migration routes or changes to migration seasonality). This transfer of knowledge may be integral to managing a group's intangible cultural heritage (UNESCO, 2003). In the unlikely event of a hydrocarbon release, intangible cultural heritage values may be impacted.

There are a number of historic shipwrecks identified within the EMBA, but none identified within 50 km of the PAA (**Section 4.9.1**).

The modelling results do not predict surface slicks contacting the identified wrecks, and the majority of entrained hydrocarbons are expected to occur close to the surface. However, shipwrecks in the subtidal zone could be exposed to entrained and dissolved hydrocarbons. Marine life that shelter and take refuge in and around these wrecks may be affected by in-water toxicity of dispersed hydrocarbons. The consequences of such hydrocarbon exposure may include large fish species moving away and resident fish species and sessile benthos such as hard corals exhibiting sub-lethal and lethal impacts (which may range from physiological issues to mortality).

Within the wider EMBA are several designated heritage places (**Section 4.9.1**). These places are also covered by other designations such as WHA. Potential impacts are discussed in the sections above.

Summary of Potential Impacts to Environmental Value(s)
In the highly unlikely event of a major hydrocarbon spill due to a loss of well integrity during drilling of the LDA-02 well, the EMBA includes the areas listed in **Table 6-36**. This incorporates AMPs as well as other sensitive marine environments and associated receptors of the Muiron Islands, Ningaloo Coast, Rankin Bank, Montebello/Barrow Islands and the Pilbara Southern Islands Group. Long term impacts may occur at these locations, including socio cultural effects as a result of a major spill of condensate from drilling activities within the PAA. The overall environmental consequence is defined as 'B – Major, long term impact (10 to 50 years) on highly valued ecosystem, species, habitat, physical or biological attributes'.

Professional Judgement – Eliminate				
Do not drill well.	F: No. CS: Inability to achieve program objectives.	A hydrocarbon release would not be credible.	Disproportionate. Given the extremely low likelihood of a loss of well control due to the systematic implementation of Woodside's policies, standards, procedures and processes relating to drilling activities, the cost/sacrifice outweighs the benefit gained.	No
Professional Judgement – Substitute				
No additional controls identified.				
Professional Judgement – Engineered Solution				
No additional controls identified.				
Risk Based Analysis				
A quantitative spill risk assessment was performed (refer **Section 6.7.2**)				
Company Values				
Corporate values require all personnel at Woodside to comply with appropriate policies, standards, procedures and processes while being accountable for their actions and holding others to account in line with the Woodside Compass. As detailed above, the Petroleum Activities Program will be performed in line with these policies, standards and procedures that include suitable controls to prevent loss of well integrity, and response should a loss of well integrity occur.				
Societal Values				
Due to the Petroleum Activities Program's potential extent of the EMBA, the loss of well integrity current risk rating presents a Decision Type B, in accordance with the decision support framework described in **Section 2.6.1**. Consultation was conducted for this program to identify the views and concerns of relevant persons, as described in **Section 5**. Woodside has consulted with AMSA and WA DoT on spill response strategies. In accordance with the MoU between Woodside and AMSA, a copy of the Oil Pollution First Strike Plan was provided to AMSA.				
ALARP Statement: On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type (i.e., Decision Type B, **Section 2.6.1**), Woodside considers the adopted controls appropriate to manage the risks and consequences of a highly unlikely unplanned hydrocarbon release as a result of a loss of well integrity. As no reasonable additional/alternative controls were identified that would further reduce the risks and consequences without grossly disproportionate sacrifice, the risks and consequences are considered ALARP.				
Demonstration of Acceptability				
Acceptability Criteria and Assessment				
Loss of well integrity during drilling of the LDA-02 well has been evaluated as having a high level of current risk rating due to the scale of potential environmental impacts. However, the likelihood of a loss of well integrity occurring is considered extremely low. As outlined in **Section 2.6.1,** Woodside considers the current risk ratings for a Decision Type B to be acceptable, if ALARP is demonstrated using good industry practice, consideration of company and				

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)[86]***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***

societal values and RBA, if legislative requirements are met and societal concerns are accounted for, and the alternative control measures are grossly disproportionate to the benefit gained.

Principles of ESD

The impact and risk evaluation has taken into account the relevant principles of ESD, being:

- decision-making processes should effectively integrate both long-term and short-term economic, environmental, social and equitable considerations
- the principle of inter-generational equity—that the present generation should ensure that the health, diversity and productivity of the environment is maintained or enhanced for the benefit of future generations
- the conservation of biological diversity and ecological integrity should be a fundamental consideration in decision-making.

Internal Context

The PAP is consistent with Woodside corporate policies, culture, processes, standards, structure and systems as outlined in the Demonstration of ALARP and Environmental Performance Outcomes, including:

- Woodside Environment and Biodiversity Policy (**Appendix A**)
- Woodside Risk Management Policy (Appendix A)
- Engineering Standards – Well Barriers
- Well Acceptance Criteria Procedure
- Global, Wells and Seismic – Well Control Procedure
- Woodside Engineering Standard – Rig Equipment
- Source Control Emergency Response Planning Guideline (SCERP Guidelines).
- Oil spill preparedness and response strategies are considered applicable to the nature and scale of the risk and associated impacts of the response are reduced to ALARP (**Appendix D**).
- Monitoring and Evaluation (operational monitoring) as a key response in the unlikely event of a hydrocarbon release will assess and track the extent of the hydrocarbon contact and revise the predicted extent of impact.

In addition, the Planning Area for scientific monitoring (refer to Section 5.8 of the Oil Spill Assessment and Mitigation Plan) can be re-assessed in the unlikely event of hydrocarbon release with consideration of the conservation values and social-cultural values of state and commonwealth protected areas (including AMPs), National and Commonwealth Heritage Listed places; tourism and recreation; and fisheries. The post-response SMP will consider assessment and monitoring in line with the affected receptors such as habitat and species, AMPs and fisheries. Woodside corporate values include working sustainably with respect to the environment and communities in which we operate, listening to internal and external stakeholders, and considering HSE when making decisions. consultation, outlined below, has been performed prior to the Petroleum Activities Program.

External Context

During consultation with relevant persons, DoT requested to be consulted on spill risks with a potential to impact State Waters (**Section 5**). Woodside has also consulted with AMSA on spill response strategies. In accordance with the MoU between Woodside and AMSA, a copy of the Oil Pollution First Strike Plan was provided to AMSA and DoT. No additional queries or concerns relating to a loss of well integrity hydrocarbon spill risk during drilling of the LDA-02 well were raised during consultation.

Other Requirements

Impact assessment has been informed by risk-based analysis, including hydrocarbon spill modelling. The proposed control measures are consistent with industry legislation, codes and standards, good practice and professional judgement including:

- API Standard 53 for subsea BOP function testing
- APPEA Memorandum of Understanding: Mutual Assistance for relief well drilling; Woodside develops an activity SCERP, including the Relief Well Plan, which is signed off by the Drilling Engineering Manager and maintains a list of rigs that are currently operating in Australia (refer also to Appendix D)
- OPGGS (Resource Management and Administration) Regulations 2011 to have an accepted WOMP and application to permanently plug for abandonment of the wells.

NOPSEMA will be notified of reportable and recordable incidents, if required, in accordance with **Section 7.10**. A mutual aid MoU for relief well drilling is in place and the Drilling Engineering Manager maintains a list of rigs that are currently operating in WA.

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)[86]***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
The EMBA overlaps a number of BIAs for threatened and migratory species, as well as a number of State and Commonwealth MPAs and the Ningaloo Coast WHA. As demonstrated in **Section 6.9**, the residual risk of accidental hydrocarbon release from loss of well integrity during drilling of the LDA-02 well is not inconsistent with the relevant objectives and actions of any applicable recovery plans or threat abatement plans. Regard has been given to relevant conservation advice and wildlife conservation plans during the assessment of potential impacts. The Petroleum Activities Program is not considered to be inconsistent with the overall recovery objectives and actions of these recovery plans and conservation advice (**Section 6.9**).				
Acceptability Statement: The impact assessment has determined that an accidental hydrocarbon release as a result of a loss of well integrity represents a moderate current risk rating and may result in major, long-term impacts (10 to 50 years) on highly valued ecosystems, species, habitat or physical or biological attributes. A number of BIAs for protected species overlap with the BIA and EMBA. Relevant recovery plans and conservation advice have been considered during the impact assessment, and the Petroleum Activities Program is not considered to be inconsistent with the overall recovery objectives and actions of these recovery plans and conservation advice. The likelihood of a loss of well integrity during drilling of the LDA-02 well occurring is highly unlikely, given the adopted controls. The adopted controls are considered consistent with industry legislation, codes and standards, and professional judgement and a risk-based assessment has been conducted to better understand the potential consequences and plan oil spill response. The adopted controls also meet the requirements and expectations of Australian Marine Orders, AMSA and AHO identified during impact assessment and consultation. As demonstrated in **Section 6.9** the potential impacts of hydrocarbon release from loss of well integrity is not inconsistent with the relevant objectives and actions of any applicable recovery plans or threat abatement plans. Regard has been given to relevant conservation advice during the assessment of potential risks. On the basis of the environmental impact assessment outcomes and Woodside's criteria for acceptability outlined in **Section 2.8.2** this is considered an acceptable level of risk.

Hydrocarbon release from topsides process equipment to the marine environment and atmosphere			✓	✓		✓		A	D	1	M	LC S GP PJ	Acceptable if ALARP	**EPO 20**

Description of Source of Risk

The facility has a range of topsides process and non-process equipment. A loss of containment from the topsides includes hydrocarbon inventories that could be released to the environment from high pressure process gas equipment and piping manifolds, and non-process hydrocarbon and chemical inventories.

Hazards that could lead to loss of containment from the topsides are:

- corrosion
- erosion
- material defect
- welding defect
- piping/equipment repair/defect
- vibration fatigue failure
- equipment overpressure
- extreme weather.
- Escalation from MEEs can cause topsides loss of containment:
- loss of structural integrity (MEE-03; Section 6.7.5)
- loss of marine vessel separation (MEE-04; Section 6.7.6)
- loss of control of suspended load from facility lifting operations (MEE-05; Section 6.7.7).

A number of common failure causes due to human error and SCQ failures are presented in the generic human error and SCE failure bowties in Section 6.7.8.

Topsides Loss of Containment – Credible Scenarios

Topsides process and non-process hydrocarbon inventories, and therefore, worst case credible spill scenarios, are relatively low for the riser platform in comparison to other facilities on the NWS. This is due to the lower production rate from single train Angel facility, the provision of a remote power supply from NRC, and the facility's NNC status.

The worst credible hydrocarbon release volume is 30 m^3 condensate from the condensate cooler/PWCS, although there are several smaller condensate inventories also present on the topsides (**Table 3-6**). Small volumes of diesel, hydraulic oil and waste oil may also be released (**Table 3-7**) refer to **Section 6.8.4**. While a number of hydrocarbon

release scenarios were determined to constitute MEEs, the consequence assessment for a topsides loss of containment determined this source of risk is not an MEE.

Consequence Assessment

Once released to the open offshore marine environment around the riser platform (refer to **Section 4**), Angel condensate is expected to weather rapidly. As a consequence, the potential for impacts to environmental receptors is limited to those in the immediate vicinity. Hydrocarbon weathering modelling indicates approximately 67.0% of the mass should evaporate within the first 12 hours (RPS, 2021)

Spill modelling has been undertaken for a smaller surface spill of 21 m^3 of condensate (released in under ten minutes) from the Angel platform (APASA, 2012). In summary, the modelling indicated the released condensate would disperse rapidly and the EMBA impact would be confined to open ocean. No contact with sensitive receptors above impact thresholds for any hydrocarbon type was predicted to occur.

Based on modelling for a much larger surface release of 5600 m^3 (RPS, 2021), it is likely that given the density of the hydrocarbon, decrease in water quality would be restricted to the top few metres of the water column. As such, impacts to demersal or benthic receptors (e.g., Glomar Shoal) are not credible. Refer to **Section 6.7.4** for a description of potential impacts from this larger release.

Water Quality

There may be a minor short-term decrease in water quality in the immediate vicinity of the release location. The soluble fraction of condensate may cause acute toxic effects to planktonic organisms. Given the short generation times and high productivity of planktonic communities, this impact would be localised and have no lasting effect on planktonic species populations.

Air Quality

A topsides release of Angel condensate would be accompanied by a gas plume of methane and ethane released to atmosphere. The gas plume is expected to mix and disperse rapidly in the atmosphere. Hence, it has limited potential to impact fauna in the vicinity of the release location. Impacts, such as asphyxiation, would be highly localised and of no lasting effect to species populations.

Marine Fauna

A range of marine species may be present around the riser platform, such as cetaceans, marine turtles, whale sharks, fishes and birds. These species are widely distributed relative to the potential EMBA that would result from a topsides loss of containment (due to the relatively small volume of hydrocarbons compared to the scenarios considered in **Section 6.7.2**). Many large marine fauna in the region are migratory and are seasonally present in the PAA, which reduces the likelihood of exposure. Air breathing marine species may be impacted by the reduction in air quality (refer above); however, the potential for this impact is very limited. Marine fauna at or near the sea surface may be contacted by liquid-phase hydrocarbons, resulting in oiling. This may lead to impacts such as irritation of sensitive mucous membranes (e.g., eyes, mouth and digestive tract), matting of feathers (leading to inability to fly and loss of insulation) or clogging of filtering structures (e.g., gills). Pelagic and site attached fish (i.e., those resident around risers and jackets) may be exposed to spilled hydrocarbons, but are expected to avoid areas of high concentrations. Depending on the degree of exposure and the sensitivity of the receptor, these impacts may lead to injury or death. Mortality of larger fauna is not expected to occur. No impacts to ecosystem function are expected. Given the volatile nature of the hydrocarbons and the relatively small release volume, the potential for these impacts is largely constrained to the initial 12 hours immediately after the release. Hence, the potential impacts to species would be localised and of no lasting effect to species populations.

Demonstration of ALARP

While the loss of topsides containment does not constitute an MEE, it is considered to be a potential MAE in the Safety Case for the facility. As such, this source of risk is managed under the SCE management system (**Section 7.2.6**) for the facility. Specific measures and controls presented below are drawn from this management system.

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Legislation, Codes and Standards				
Offshore Petroleum and Greenhouse Gas Storage (Safety) Regulations 2009: Accepted Safety Case for the Angel facility.	F: Yes. CS: Minimal cost. Standard practice.	Offshore Petroleum and Greenhouse Gas Storage (Safety) Regulations 2009: Accepted Safety Case for the Angel facility to: • identify hazards that have the potential to cause an MAE • detail assessment of MAE risks • describe the physical barriers SCEs and the safety management systems identified as being required to reduce the risk to personnel associated with an MAE to ALARP, thus contributing to management of associated potential environmental consequences of MAEs.	Control based on legislative requirements – must be adopted.	Yes **C 14.4**
Good Practice				
Incident reports are raised for unplanned releases within event reporting system.	F: Yes. CS: Minimal cost. Standard practice.	Good practice that operators identify, report and learn from unplanned release events. Supports compliance with regulatory reporting requirements.	Control based on Woodside standard and regulatory requirements.	Yes **C 13.6**
Professional Judgement – Elimination				
None identified.				
Professional Judgement – Substitute				
None identified.				

Demonstration of ALARP				
Professional Judgement – Engineered Solution				
Maintain topsides hydrocarbon-containing infrastructure integrity.	F: Yes. CS: Minimal cost. Standard practice.	Reduces the likelihood of topsides loss of containment through inspection and assurance of key hydrocarbon containing vessels.	Benefits outweigh cost/sacrifice.	Yes **C 20.1**
Maintaining Safety Instrumented Systems to prevent/respond to hydrocarbon loss of containment.	F: Yes. CS: Minimal cost. Standard practice.	Safety instrumented systems reduce the risk of topsides loss of containment by detecting and responding to pre-defined conditions and/or initiate responses that put the process plant and equipment in a safe condition so as to prevent or mitigate the effects of an MAE/MEE.	Benefits outweigh cost/sacrifice.	Yes **C 20.2**
Facility open hazardous drain system integrity maintained as far as practicable.	F: Yes. Drain systems in place as far as practicable to suit NNC facility safety design requirements. CS: Some safety philosophy sacrifice. Installed as far as reasonably practicable.	Reduces the likelihood of environmental harm by: • limiting escalation of an incident following loss of containment, fire and/or explosion by removing or containing flammable liquid from hazardous areas • supporting appropriate containment and disposal of environmentally hazardous liquids.	Benefits outweigh cost/sacrifice.	Yes **C 6.5**
In the event of a spill, emergency response activities implemented in accordance with the OPEP.	F: Yes. CS: Costs associated with implementing response strategies, vary dependant on nature and scale of spill event. Standard practice.	Potentially reduces consequence by implementing response to reduce impacts to the marine environment.	Control based on regulatory requirement – must be adopted.	Yes **C 13.7**

Demonstration of ALARP				
Arrangements supporting the activities in the OPEP will be tested to ensure the OPEP can be implemented as planned.	F: Yes. CS: Moderate costs associated with exercises. Standard practice	No change to impact or risk; however, ensures OPEP can be implemented in the event of a hydrocarbon spill thereby potentially reducing the consequence.	Benefits outweigh the cost/sacrifice. Control is also standard practice.	Yes **C 13.8**
ALARP Statement: The controls for the Process Topsides Loss of Containment are based on the controls identified for MEE-03, MEE-04 and MEE-05 (**Sections 6.7.5** to **6.7.7**). On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the risks of a topsides loss of containment. As no reasonable additional/alternative controls were identified that would further reduce the consequences and risks without grossly disproportionate sacrifice, the risks are considered ALARP.				
Demonstration of Acceptability				
Acceptability Statement: The consequence assessment has determined that, given the adopted controls, a topsides loss of containment represents a moderate risk rating that is highly unlikely to result in a consequence greater than minor, short-term impacts that are localised to the release location. Further opportunities to reduce the risks have been investigated above. The adopted controls are considered good oil-field practice/industry best practice and meet requirements of the facility Safety Case. The potential risks are considered broadly acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the risks of a topsides loss of containment to a level that is acceptable if ALARP.

Loss of hydrocarbons to marine environment due to a vessel collision during drilling and tie-back of the LDA-02 well (e.g., project vessels or other marine users)		✓		✓	✓	✓	A	D	1	M	LCS GP PJ	Broadly Acceptable	**EPO 21**

Description of Source of Risk

Background

The temporary presence of the MODU and project vessels in the PAA during drilling and tie-back activities will result in a navigational hazard for commercial shipping within the immediate area. This navigational hazard could result in a third party vessel colliding with the MODU or a project vessel which could release hydrocarbons.

Spill scenarios involving the MODU are not considered likely for a hydrocarbon release given the collision points, vessel speeds and locations of the vessel tanks. MODU fuel tanks are located in the MODU pontoons, typically located on the inner sides of pontoons and can be over 10 m below the waterline.

A typical project vessel (e.g., a support or survey vessel) is likely to have multiple isolated marine diesel tanks distributed throughout the hull of the vessel. The marine diesel storage capacity of a support vessel can be in the order of 1000 m^3 (total) that is distributed through multiple isolated tanks typically located mid-ships and can range in typical size from 22 to 105 m^3. Support vessels can have fuel tank sizes ranging from 111m^3 to 247m^3. The AHV is considered to have a maximum fuel tank size of 264 m^3, and the survey vessel a maximum of 275 m^3.

In the unlikely event of a vessel collision involving a project vessel during drilling and tie-back activities, the vessel will have the capability to pump marine diesel from a ruptured tank to a tank with spare volume in order to reduce the potential volume of fuel released to the environment.

It is noted that a hydrocarbon spill from a loss of vessel separation during operational activities is assessed in **Section 6.7.6**.

Industry Experience

Registered vessels or foreign flag vessels in Australian waters are required to report events to the Australian Transport Safety Bureau (ATSB), AMSA or Australian Search and Rescue (AusSAR).

From a review of the ATSB marine safety and investigation reports, one vessel collision occurred in 2011/12 that resulted in a spill of 25 to 30 L of oil into the marine environment as a result of a collision between a tug and support

vessel off Barrow Island. Two other vessel collisions occurred in 2010, one in the port of Dampier, where a support vessel collided with a barge being towed. Minor damage was reported and no significant injury to personnel or pollution occurred. The second 2010 vessel collision involved a vessel under pilot control in port connecting with a vessel alongside a wharf, causing it to sink. No reported pollution resulted from the sunken vessel. These incidents demonstrate the likelihood of only minor volumes of hydrocarbons being released during the highly unlikely event of a vessel collision.

From 2010 to 2011, the ATSB's annual publication defines the individual safety action factors identified in marine accidents and incidents: 42% related to navigation action (2011). Of those, 15% related to poor communication and 42% related to poor monitoring, checking and documentation (ATSB, 2011). The majority of these related to the grounding instances.

Credible Scenario

For a vessel collision to result in the worst-case scenario of a hydrocarbon spill potentially impacting an environmental receptor, several factors must align as follows:

- The identified causes of vessel interaction must result in a collision.
- The collision must have enough force to penetrate the vessel hull.
- The collision must be in the exact location of the fuel tank.
- The fuel tank must be full, or at least of volume which is higher than the point of penetration.

The environmental risk analysis and evaluation identified and assessed a range of potential scenarios that could result in a loss of vessel structural integrity, resulting in damage to fuel storage tank(s) and a loss of marine diesel to the marine environment (**Table 6-37**). Spill scenarios involving the MODU are not considered likely for a hydrocarbon release given collision points, vessel speeds and locations of the vessel tanks. Instead, the most credible scenarios are associated with the collision of an installation vessel with a refuelling vessel in the event that one should be used within the field.

In summary:

- It is not a credible scenario that the total storage volume of the MODU would be lost, as fuel is stored in more than one tank.
- It is not a credible scenario that a storage tank on the MODU would be damaged due to the location of the tanks within the hull, behind the bilge tanks, below the waterline.
- It is highly unlikely that the full volume of the largest storage tank on a support vessel would be lost.

The last scenario considered was a collision between a project vessel with a third-party vessel (i.e., commercial shipping, other petroleum related vessels and commercial fishing vessels). This was assessed as being credible but highly unlikely, given the standard vessel operations and equipment in place to prevent collision at sea, the standby role of a support vessel (low vessel speed) and its operation in close proximity to the MODU (exclusion areas), and the construction and placement of storage tanks. Potential spill volumes for these scenarios are summarised in **Table 6-37**. Given the offshore location of the PAA, vessel grounding is not considered a credible risk.

Table 6-37: Summary of credible hydrocarbon spill scenario as a result of vessel collision

Scenario	*Hydrocarbon Volumes*	*Preventative and Mitigation Controls*	*Credibility*
Loss of containment from MODU as a result of vessel collision.	Submerged marine diesel tanks up to an individual capacity of 500 m^3.	Fuel tanks are located on the inside of pontoons and protected by location below water line, protection from other tanks, e.g. bilge tanks. The draught of vessel and location of tanks in terms of water line prevent the tanks from being breached.	**Not credible** Due to location of tanks.
Breach of support vessel fuel tanks due to support vessel – other vessel collision including commercial, shipping/fisheries.	Activity support vessel has multiple marine diesel tanks typically ranging between 22 to 105 m^3 each.	Typically, double wall, tanks which are located midship (not bow or stern). Vessels are not anchored and steam at low speeds when relocating within the PAA or providing stand-by cover. Normal maritime procedures would apply during such vessel movements.	**Credible** Activity support vessel – other vessel collision could potentially result in the release from a fuel tank.

Breach of installation vessel fuel tanks due to collision with another vessel including commercial shipping/fisheries.	The installation vessel has multiple isolated tanks, largest volume of a single tank is unlikely to exceed 500 to 1000 m³	Tank locations midship (not bow or stern). Installation vessel will be holding station during installation activities or steaming at low speeds when relocating within the PAA.	**Credible – Worst Case** installation vessel – third party vessel collision could potentially result in the release from a fuel tank.

Quantitative Hydrocarbon Risk Assessment

Analogous modelling was performed by RPS, on behalf of Woodside to determine the fate of marine diesel released from a collision within the PAA. The modelling assessed the extent of a marine diesel spill volume of 1000 m³ for all seasons, using an historic sample of wind and current data for the region. The results of the modelling can be used to demonstrate that a marine diesel spill within the PAA has an EMBA that is not predicted to include any shoreline contact or accumulation at impact thresholds. A total of 200 replicate simulations were modelled over an annual period (50 per quarter).

Hydrocarbon Characteristics

Marine diesel is a mixture of both volatile and persistent hydrocarbons. Predicted weathering of marine diesel, based on typical conditions in the region, indicates that around 72% of the oil mass is forecast to have entrained and a further 24% is forecast to have evaporated over the first 24 hours (**Figure 6-30**) (RPS, 2023). After this time the majority of the remaining hydrocarbon is entrained into the upper water column, leaving only a small proportion of the oil floating on the water surface (<1%). Given the large proportion of entrained oil and the tendency for it to remain mixed in the water column, the remaining hydrocarbons will decay and/or evaporate over time scales of several weeks to a few months, thereby extending the area of potential effect.

Given the environmental conditions experienced in the PAA, marine diesel is expected to undergo rapid spreading and this, together with evaporative loss, is likely to result in a rapid dissipation of the spill. Marine diesel distillates tend not to form emulsions at the temperatures found in the region. The characteristics of the marine diesel are given in **Table 6-38**.

Table 6-38: Characteristics of the marine diesel

Hydrocarbon type	***Initial density (g/cm³) at 25 ºC***	***Viscosity (cP @ 25 ºC)***	***Component BP (ºC)***	***Volatiles % <180***	***Semi volatiles % 180 to 265***	***Low volatility (%) 265 to 380***	***Residual (%) >380***
				Non-Persistent			**Persistent**
Marine diesel	0.829	4.0	% of total	6	34.6	54.4	5

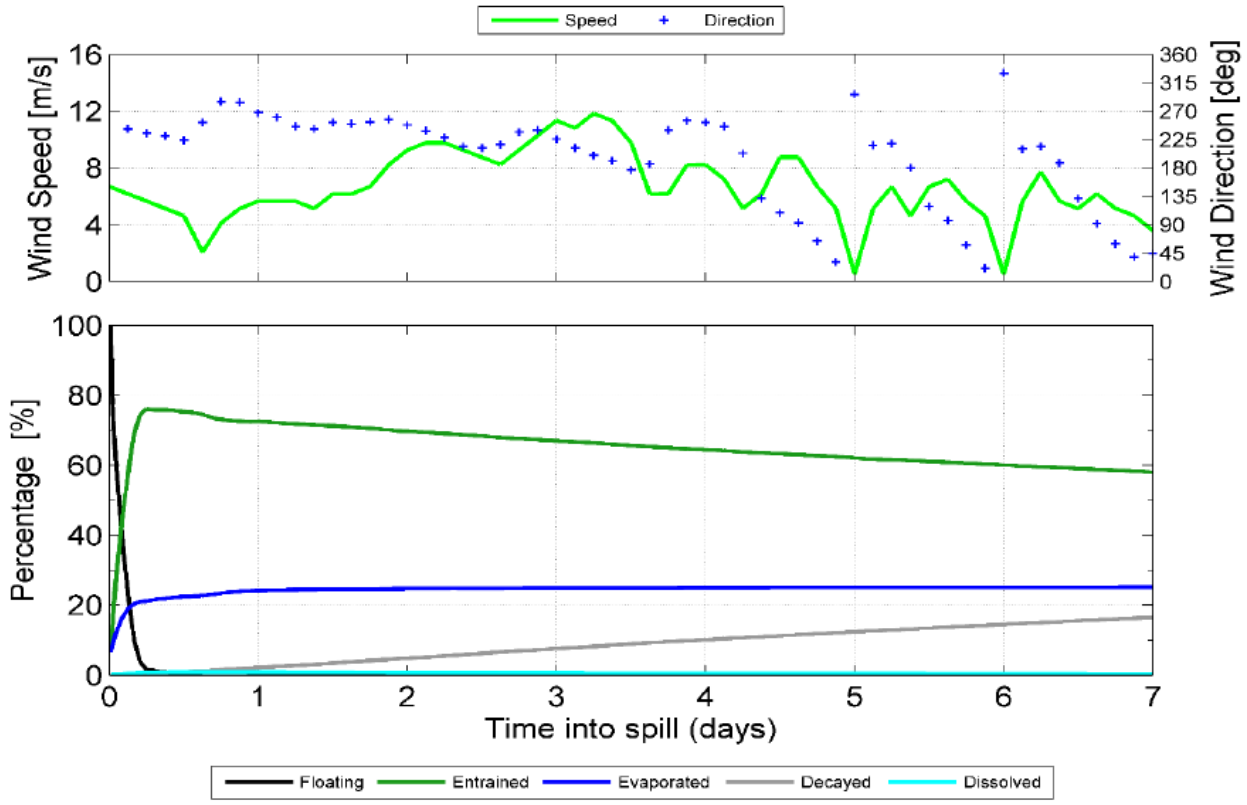

Figure 6-30: Proportional mass balance plot representing weathering of a 1000 m³ surface spill of marine diesel as a one-off release (at a rate of 50 m³/hr) and subject to variable wind at 27°C water temperature and 25°C air temperature (RPS, 2023)

Consequence Assessment

Potential Impacts Overview

Environment that May Be Affected

Surface Hydrocarbons

Quantitative hydrocarbon spill modelling results for surface hydrocarbons are shown in **Table 6-39**. If this scenario occurred, a surface hydrocarbon slick would form down-current of the release location, with the trajectory dependent on prevailing wind and current conditions at the time. The modelling indicates that the EMBA would be confined to open water, with surface hydrocarbons extending up to about 105 km and 65 km from the release location at or above the 1 g/m² and 10 g/m² impact threshold. A socio-cultural EMBA for surface hydrocarbons which includes the threshold for visible surface hydrocarbons of 1 g/m^2 may extend beyond the EMBA in which ecological impacts may occur.

Entrained Hydrocarbons

Quantitative hydrocarbon spill modelling results are shown in **Table 6-39**. If this vessel collision scenario occurred, a plume of entrained hydrocarbons would form down-current of the release location, with the trajectory dependent on prevailing current conditions at the time. The modelling indicates that locations exposed to entrained hydrocarbons at or above the threshold concentration of 100 ppb are restricted to offshore areas, islands, and reefs. **Table 6-39** provides details of receptors potentially contacted by entrained diesel at or above 100 ppb.

Dissolved Hydrocarbons

Dissolved aromatic hydrocarbons at concentrations equal to or greater than the 50 ppb threshold are predicted to be confined to offshore areas and reefs. Dissolved hydrocarbon concentrations above 400 ppb are not predicted to contact any sensitive receptor locations.

Accumulated Hydrocarbons

Accumulated hydrocarbons above threshold concentrations (≥100 g/m²) were not predicted by the modelling to occur at any location. Potential for accumulation of oil on shorelines is predicted to be low, with the worst-case maximum local accumulation of oil on any surrounding shoreline being 1.7 g/m^2 at Barrow Island.

Taking into consideration the EMBA derived from hydrocarbon spill modelling for a marine diesel spill, the environment that may be affected will fall within the EMBA of the spill from a loss of well integrity outlined in **Section 6.7.3**.

88 Note: hydrocarbons cannot accumulate on open ocean, submerged receptors, or receptors not fully emergent.

Potential Impacts to Environmental Values(s)

In the event of a 1000 m³ release of marine diesel spill due to vessel collision, the modelling predicts a low probability of receptors being contacted by entrained hydrocarbons >100 ppb or dissolved aromatic hydrocarbons >50 ppb. The greatest likelihood of contact is at the Montebello AMP and Montebello Islands (5.5% probability for entrained and 0.5% for dissolved). All other sensitive locations identified in **Table 6-39** are predicted to have a 1% probability or less of contact at threshold concentrations. Further, entrained hydrocarbons reaching these environments will be highly weathered, with the volatile and water soluble (often the most toxic) components expected to have dissipated. No surface hydrocarbons above 10 g/m^2 are predicted to contact sensitive receptors and no shoreline oiling above 100 g/m^2 is predicted.

The potential impacts of spilled hydrocarbons to species (protected and otherwise), marine primary producers, other habitats and communities, water quality, marine sediment quality, air quality, protected areas and socio-economic values are described in detail in **Section 6.7.3**.The potential impacts of entrained hydrocarbons provided in **Section 6.7.3**, and the scale of impact described provides a suitable assessment for potential impacts of a 1000 m³ release of marine diesel. Impacts specific to a spill of marine diesel are summarised below. It is noted that the toxic components in marine diesel include alkylated naphthalene's which can be rapidly accumulated by marine biota including invertebrates such as marine oysters, clams, shrimp, as well as a range of vertebrates, such as finfish. Marine diesel also contains additives that contribute to its toxicity.

Given the localised area of the potential EMBA and the rapid dispersion, dilution and weathering of a marine diesel spill, it is expected that any potential impacts will be low magnitude and temporary in nature.

Protected Species

As identified in **Section 4.6**, protected species including migrating pygmy blue whales may be encountered near the PAA, and therefore could be impacted in close proximity to the marine diesel spill location, where the volatile, water soluble and most toxic components of the diesel may be present. However, the window for exposure to hydrocarbons with the potential for any toxicity effects in these waters would be limited to a few days following the spill. Potential impacts may include behavioural impacts (e.g., avoidance of impacted areas), sub-lethal biological effects (e.g., skin irritation, irritation from ingestion or inhalation, reproductive failure) and, in rare circumstances, organ or neurological damage leading to death. Given the absence of critical habitats or aggregation areas, cetaceans in the area are expected to be transient, and impacts are expected to be limited to individuals or small groups of animals. Impact on the overall population viability of cetaceans are not predicted.

There is also the potential for migrating humpback whales, dugongs and coastal dolphin populations to be exposed in nearshore waters, however, the low concentrations and advanced degree of weathering of hydrocarbons in these nearshore waters is not expected to result in any discernible sublethal or lethal impacts to cetaceans.

The EMBA overlaps with BIAs for marine turtle internesting habitat, as identified in **Section 4.6.2**. Turtle internesting habitats, such as those in waters adjacent to the Montebello Islands, are predicted to have very limited or no exposure to surface or dissolved hydrocarbons above their respective impact threshold concentrations. Some marine turtles in these areas may be exposed to patchy occurrences of entrained hydrocarbons, which would be in an advanced state of weathering with reduced toxicity. Low concentrations are only capable of causing sublethal impacts to the most sensitive marine organisms and no lethal or sub-lethal impacts to marine turtles are expected in the BIAs. The potential for lethal and sub-lethal impacts to marine turtles is limited to small numbers of transient individuals that may be present in offshore waters near the release location.

Seabirds may also be exposed to marine diesel on the sea surface or upper water column, if resting or foraging in waters near to the spill. Impacts may include mortality due to oiling of feathers or the ingestion of hydrocarbons. However, due to the limited spatial extent of a marine diesel spill and limited window for exposure, population level impacts are not expected.

Other protected species that may occasionally transit through the area and may potentially be exposed to a marine diesel spill, include shark and ray species such as whale sharks and manta rays. Should sharks or rays be present in offshore waters near the PAA during the spill, direct impacts may occur if foraging within surface slicks or in the upper 20 to 30 m of the water column containing entrained hydrocarbons and dissolved aromatics. Contamination of their food supply and the subsequent ingestion of this prey may also result in long term impacts as a result of bioaccumulation. Impacts are again predicted to be limited to a small number of animals given the absence of key habitat and the low numbers of animals that may transit through the area during the short period when spilled hydrocarbons are present.

Given the limited number of animals that may be impacted and the rapid dispersion of marine diesel, it is considered that any potential impacts will be minor.

Other Habitats, Species and Communities

Within the EMBA for a marine diesel spill resulting from a vessel collision, there is the potential for plankton communities to potentially be impacted where entrained hydrocarbon threshold concentrations are exceeded. A range of lethal and sublethal impacts may occur to plankton exposed to entrained or dissolved hydrocarbons within the EMBA. Communities are expected to recover quickly (weeks/months) due to high population turnover (ITOPF, 2011). It is therefore considered that any potential impacts would be low magnitude and temporary in nature.

Pelagic fish populations in the open water offshore environment of the EMBA are highly mobile and have the ability to move away from a marine diesel spill. The spill-affected area would be confined to the surface layer and upper 20 to 30 m of the water column. It is therefore unlikely that fish populations would be exposed to widespread hydrocarbon contamination. Pelagic fish populations are distributed over a wide geographical area so impacts on populations or species level are considered to be negligible. Combined with these factors and the rapid dispersion of marine diesel, it is considered that any potential impacts will be minor.

Other communities (e.g., demersal fish, benthic infauna and epifauna) and key sensitivities (e.g., KEFs identified in **Section 4.7**) occur within the EMBA, however will not be directly exposed or impacted by a marine diesel spill as hydrocarbons are confined to the upper layers of the water column.

Water Quality

It is likely that water quality will be reduced at the release location of the spill; however, such impacts to water quality would be temporary and localised in nature due to the rapid dispersion and weathering of marine diesel. The potential impact is therefore expected to be low.

Protected Areas

Entrained hydrocarbons at or exceeding the 100 ppb threshold have a low probability of contacting the Montebello AMP, Gascoyne AMP, Argo-Rowley Terrace AMP and Ningaloo WHA. Entrained hydrocarbons are only predicted within the surface waters of the deep open waters of these protected areas, with no contact to seabed habitats or to shoreline contact. Potential impacts to water quality and the natural values (e.g., mobile protected species) in these areas would be temporary and localised in nature due to the rapid dispersion and weathering of the marine diesel, as described above. Dissolved and visible surface hydrocarbons (at or exceeding 1 g/m^2) are not predicted to reach any other protected areas.

Socio-economic

A marine diesel spill is considered unlikely to cause significant direct impacts on the target species fished by the Commonwealth and State active fisheries identified in **Section 4.9.2** which overlap with the EMBA. The fisheries that operate within the EMBA predominantly target demersal fish species (demersal finfish and crustaceans) that inhabit waters in the range of >60 to 200 m depth, or pelagic species which are highly mobile. Therefore, a marine diesel spill is expected to only result in negligible impacts, considering that hydrocarbons are confined to the upper layers of the water column. Visible surface hydrocarbons at or exceeding 1 g/m^2 may also occur up to 105 km from the release site, which may result in fouling of fishing gear and a perception of impacts to fish stocks by fisheries stakeholders and the public. There is the potential that a fishing exclusion zone would be applied in the area of the spill, which would put a temporary ban on fishing activities and therefore potentially lead to subsequent economic impacts on commercial fishing operators if they were planning to fish within the area of the spill. Such measures would likely be in place for less than a week and would not result in widespread or long-term impacts to fishing activities.

Cultural Values and Heritage

Through consultation and review of available literature (**Section 4.9.1**), Woodside understands that sea country, including marine ecosystems and species, archaeological heritage and heritage sites, marine parks, as well as intangible cultural heritage may be impacted in the event of a hydrocarbon release from a vessel collision. Cultural features and heritage values that have the potential to be impacted are considered in **Section 6.8.1**.

Summary of Potential Impacts to Environmental Values(s)

Given the adopted controls, the overall risk rating for an unplanned hydrocarbon release resulting from a vessel collision during drilling and tie-back activities is Moderate based on a Minor consequence (short term impact: 1 to 2 years), to the high value receptors (marine fauna, AMPs, KEFs and commercial fishing), and a highly unlikely likelihood.

Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)[89]***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Legislation, Codes and Standards				
Contract vessels complying with Marine Orders for safe vessel operations: • Marine Order 21 (Safety of navigation and emergency procedures) 2016	F: Yes. CS: Minimal cost. Standard practice.	Legislative requirements to be followed, reduces the likelihood of interference with other marine users resulting in a collision.	Controls based on legislative requirements – must be adopted.	Yes **C 1.1**

89 Qualitative measure.

• Marine Order 27 (Safety of navigation and radio equipment) 2016 • Marine Order 30 (Prevention of collisions) 2016.				
Establishment of a 500 m petroleum safety zone around MODU and 500 m exclusion zone around the installation vessel and communicated to marine users.	F: Yes. CS: Minimal cost. Standard practice.	Legislative requirements to be followed reduce the likelihood of a collision.	Controls based on legislative requirements – must be adopted.	Yes **C 1.3**
In the event of a spill, emergency response activities implemented in accordance with the OPEP (per **Appendix D**).	F: Yes. CS: Costs associated with implementing response strategies, vary dependant on nature and scale of spill event. Standard practice.	This control would not reduce the likelihood, but response activities may reduce the consequence.	Benefits outweigh cost/sacrifice.	Yes **C 13.7**
Arrangements supporting the activities in the OPEP (per **Section 7.12**) will be tested to ensure the OPEP can be implemented as planned.	F: Yes. CS: Minimal cost. Standard practice.	Legislative requirement based on vessel class. Unlikely to have a significant reduction in consequence.	Controls based on legislative requirements – must be adopted.	Yes **C 13.8**
Good Practice				
Support vessel on standby as required during the Petroleum Activities Program to assist in third-party vessel interactions. When a support vessel is designated for standby it will undertake actions to prevent unplanned interactions, such as: • maintain a 24-hour radio watch on designated radio channel(s) • undertake continuous surveillance and warn the MODU/ installation vessel of any approaching vessels reaching 500 m petroleum safety zone. • Surveillance shall be conducted by a combination of: – visual lookout – radar watch – other electronic systems available including Automatic Identification System (AIS) – monitoring any additional/ agreed radio	F: Yes. CS: Minimal cost – support vessels available routinely in PAA during Petroleum Activities Program. Standard practice.	Given the legislative controls in place, use of a support vessel, as defined in the One Marine Charterers Instructions, will provide a small reduction in likelihood of a collision with a third-party vessel.	Benefits outweigh cost/sacrifice.	Yes **C 21.1**

communications channels – all other means available. While complying with the International Regulations for Preventing Collisions at Sea (COLREGS), approach any vessel attempting to transit through the 500 m zone and contact vessel by all available means. Monitor and advise the MODU if: • MODU navigation signals are defective • visibility becomes restricted • any buoys in the area are not holding position or are not working as expected.				
Notify AHO of activities where vessels will be in the Operational Area, but outside of the Petroleum Safety Zone >3 weeks, no less than four working weeks prior to scheduled activity commencement date.	F: Yes. CS: Minimal cost. Standard practice.	Notification of AHO will enable them to update maritime charts thereby reducing the likelihood of a collision with a third-party vessel.	Benefits outweigh cost/sacrifice. Control is also standard practice.	Yes **C 1.9**
Notify relevant persons of activities three months prior to commencement and upon completion of activities.	F: Yes. CS: Minimal cost. Standard practice. Professional Judgement – Engineered Solution				
No additional controls identified.				

ALARP Statement:

On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type (i.e., Decision Type A, **Section 2.6.1**), Woodside considers the adopted controls appropriate to manage the risks and consequences of an unplanned loss of hydrocarbon as a result of a vessel collision during drilling and tie-back activities. As no reasonable additional/alternative controls were identified that would further reduce the risks and consequences without grossly disproportionate sacrifice, the risks and consequences are considered ALARP.

Demonstration of Acceptability

Acceptability Statement:

The impact assessment has determined that an accidental hydrocarbon release as a result of a vessel collision during drilling and tie-back activities represents a moderate current risk rating and is unlikely to result in a risk consequence greater than Minor. Relevant recovery plans and conservation advice have been considered during the impact assessment, and the Petroleum Activities Program is not considered to be inconsistent with the overall recovery objectives and actions of these recovery plans and conservation advice. The adopted controls are considered consistent with industry legislation, codes and standards, good practice and professional judgement and meet the requirements and expectations of Australian Marine Orders, AMSA and AHO identified during impact assessment and consultation.

The potential risks and consequences are considered acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the risks and consequences of a loss of vessel structural integrity to a level that is broadly acceptable.

Accidental discharge of marine diesel to the marine environment during transfer, storage or use			✓			✓		A	E	1	L	LC S GP PJ	Broadly Acceptable	**EPO 22**

Description of Source of Risk

Marine Diesel Transfer, Storage and Use

Operations

Marine diesel is transferred to the riser platform via containers (e.g., ISO tanks), as no bunkering of marine diesel (either vessel to vessel, or vessel to riser platform) occurs in the PAA.

Transfer of diesel from the storage area to the crane diesel tank is by hose; transfer from the storage area to the lifeboat is by jerry can. The crane and lifeboat are refilled as required when the riser platform is staffed.

Marine diesel containers (2×4 m^3) are stored in a bunded storage area on the riser platform. The bund drains to the hazardous open drains system, which features hydrocarbon separation and recovery. Drain water is discharged to the sea following hydrocarbon recovery (refer to **Section 6.6.6**). Diesel storage volumes beyond the bund are small and associated with equipment on the riser platform, such as the lifeboat (0.2 m^3) and crane diesel tank (1.2 m^3). Small volumes of diesel may also be used on platform and subsea support vessels to fuel equipment on deck (typically <0.2 m^3).

The worst-case credible loss of marine diesel during transfer, storage and use is the loss of a single ISO container during transfer operations (e.g., via lifting equipment failure). The volume of marine diesel transferred in ISO containers is 4 m^3.

Tie-back Activities

Bunkering of marine diesel between the MODU and project vessels as well as the possible refuelling of cranes, and other equipment may take place on the MODU.

Three credible scenarios for the loss of containment of marine diesel during bunkering operations have been identified:

- Partial or total failure of a bulk transfer hose or fittings during bunkering, due to operational stress or other integrity issues could spill marine diesel to the deck and/or into the marine environment. This would be in the order of less than 200 L, based on the likely volume of a bulk transfer hose (assuming a failure of the dry break and complete loss of hose volume).
- Partial or total failure of a bulk transfer hose or fittings during bunkering, combined with a failure in procedure to shutoff fuel pumps, for a period of up to fifteen minutes, resulting in approximately 24 m3 marine diesel lost to the deck and/or into the marine environment.
- Partial or total failure of a bulk transfer hose or fittings during helicopter refuelling could spill aviation jet fuel to the helicopter deck and/or into the marine environment. All helicopter refuelling activities are closely supervised and

leaks on the helideck are considered to be easily detectable. In the event of a leak, transfer would cease immediately. The credible volume of such a release during helicopter refuelling would be in the order of <100 L.

Quantitative Spill Risk Assessment

Small diesel spills rapidly spread on the water surface, with the diesel expected to evaporate and disperse rapidly (National Oceanic and Atmospheric Administration (NOAA) 2006). Woodside commissioned RPS to model several small marine diesel spills, including surface spill volumes of 8 m^3 in the offshore waters of northwest WA. The results of these models have indicated that exposure to surface hydrocarbons above the 10 g/m^2 threshold defined in **Section 4.1** is limited to the immediate vicinity of the release site, with little potential to extend beyond 1 km. Based on these modelling results, the potential impacts of the credible marine diesel spill scenario described above are reasonably expected to occur within 1 km of the release location.

The impact assessment assumes this release location to be the riser platform, as this is where all platform-based and most vessel-based spills would potentially occur. Given the nature and scale of the risk, along with the relatively low sensitivity of the receiving environment, no additional modelling studies were considered necessary to inform the impact assessment of unplanned discharges of hydrocarbons during transfer, storage and use.

Given the limited volume of the potential release and offshore location no modelling has been undertaken as it is within significantly less than the 1000 m^3 of MDO assessed under the Vessel Collision scenario in **Section 6.8.3**.

Hydrocarbon Characteristics

Refer to **Section 6.7.2** for a description of the characteristics of marine diesel, including detail on the predicted fate and weathering of a spill to the marine environment.

Impact Assessment

Given the low viscosity of marine diesel, along with the high portion of volatile components, a spill of up 4 m^3 of marine diesel during transfer, storage or use during operations would spread and weather rapidly. A spill at the surface of up to 24 m^3 from bunkering activities related to the MODU and project vessels associated with tie-back activities is likely to be localised with limited potential contact with sensitive receptor locations. The potential biological and ecological impacts associated with much larger hydrocarbon spills are presented in **Section 6.8.3**; further detail on impacts specific to a spill of marine diesel from a bunkering loss are provided below.

Environmental receptors at risk would be restricted to those in the immediate vicinity and may include:

- marine fauna, particularly fauna associated with the sea surface (e.g., seabirds, air breathing vertebrates)
- plankton.

Given the relatively small worst-case credible release volume, the non-persistent nature of marine diesel and the low sensitivity of the receiving environment within the PAA (i.e., offshore open water environment, refer to **Section 4**), potential impacts are expected to be short term (<1 year) and confined to less than 1 km from the release location. Such impacts may include:

- localised decrease in water quality
- acute toxic effects to planktonic organisms in the immediate area of the spill.

Impacts to plankton may include acute toxicity resulting in mortality of planktonic organisms. Given the rapid turnover of plankton communities, these impacts would be short-lived (hours to days).

Impacts to fish are expected to be of no lasting effect, as fish species are mobile and expected to avoid the area affected by a marine diesel spill. Impacts to larger fauna such as cetaceans and marine turtles are expected to be light fouling, potentially resulting in irritation of sensitive membranes such as the eyes, mouth and digestive system (Helm et al., 2015). Mortality of larger fauna is not expected to occur.

No impacts to ecosystem function are expected.

No impacts are predicted to Glomar Shoals or the Ancient Coastline KEF. Although, they do overlap the PAA (**Figure 4-11**), due to the nature of the spill (i.e., surface spill) and the reduced likelihood of diesel components interacting with the seafloor where the KEF values (i.e., unique hard substrate and associated demersal finfish and benthic fauna) are situated, it is unlikely there will be impacts with the Glomar Shoals or Ancient Coastline KEFs.

Minor, short term impacts may occur to other marine users (e.g., commercial fisheries); however, given the small scale of a worst-case marine diesel spill, fishing vessel exclusion within the PSZ, it is unlikely there would be any significant impact to commercial fishers.

Summary of Potential Impacts to Environmental Values(s)

Given the adopted controls, it is considered that spills to the marine environment from bunkering, transfer, storage and use of hydrocarbons will not result in a potential impact greater than slight, short-term impacts on species, habitat (but not affecting ecosystems function), physical and biological attributes (i.e., Environment Impact – E).

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Legislation, Codes and Standards				
Contract vessels complying with Marine Order 91 (Marine pollution prevention – oil) for safe vessel operations.	F: Yes. CS: Minimal cost. Standard practice.	Marine Order 91 is required under Australian regulations; implementation is standard practice for commercial vessels as applicable to vessel size, type and class. Helicopter fuel storage areas are bunded or secondarily contained when they are not being handled/moved temporarily in accordance with the Australian Government Civil Aviation Safety Authority CAAP 92-4(0) 'Guidelines for the development and operation of offshore helicopter landing sites, including vessels.	F: Yes. CS: Minimal cost. Standard practice.	Reduced the likelihood of an unplanned release during helicopter operations. The consequence is unchanged.	Controls based on legislative requirements – must be adopted.	Yes **C 22.2**
Implementation of bunkering procedures to reduce the risk of a hydrocarbon release as a result of a bunkering incident.	F: Yes. CS: Minimal cost. Standard practice.	Reduced the likelihood of an unplanned release.	Benefits outweigh cost/sacrifice.	Yes **C 22.3**
DP specific ASOGS procedure.	F: Yes. CS: Minimal cost. Standard practice.	Reduced the likelihood of an unplanned release.	Benefits outweigh cost/sacrifice.	Yes **C 21.2**
Bunkering is completed in accordance with: • Woodside's Engineering Standard Rig Equipment requirements for MODUs • Engineering Operating Standard: Standard for Construction Vessels for IMMR support vessels (ISVs).	F: Yes. CS: Minimal cost. Standard practice.	Reduced the likelihood of an unplanned release.	Benefits outweigh cost/sacrifice.	Yes **C 22.4**
Good Practice				
Bunkering equipment controls: • All hoses that have a potential environmental risk following damage or failure shall be placed on a hose register that is linked to the MODU's preventative maintenance system.	F: Yes. CS: Minimal cost. Standard practice.	By ensuring the appropriate equipment is in place, tested and maintained appropriately, the likelihood of a spill occurring is reduced. Although no significant reduction in	Benefits outweigh cost/sacrifice.	Yes **C 22.5**

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
• All bulk transfer hoses shall be pressure-rated at purchase to reduce the risk of accidental hydrocarbon release during bunkering. • There shall be dry-break couplings and flotation on fuel hoses. • There shall be an adequate number of appropriately stocked, located and maintained spill kits.		consequence could result, the overall risk is reduced.		
Contractor procedures include requirements to be implemented during bunkering/refuelling operations, including: • A completed PTW and/or job safety analysis (JSA) shall be implemented for the hydrocarbon bunkering/refuelling operation. • Visually monitoring of gauges, hoses, fittings and the sea surface during the operation. • Hoses will be checked before starting. • Bunkering/refuelling will commence in daylight hours. If the transfer is to continue into darkness, the JSA risk assessment must consider lighting and the ability to determine if a spill has occurred. • Hydrocarbons shall not be transferred in marginal weather conditions.	F: Yes. CS: Minimal cost. Standard practice.	By ensuring the appropriate equipment is in place, tested and maintained appropriately, the likelihood of a spill occurring is reduced. Although no significant reduction in consequence could result, the overall risk is reduced.	Benefits outweigh cost/sacrifice.	Yes **C 22.6**
Chemicals and diesel stored safely to prevent the release to the marine environment.	F: Yes. CS: Minimal cost. Standard practice.	Reduces risk of unplanned chemical/diesel release.	Benefits outweigh cost/sacrifice.	Yes **C 22.7**

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Incident reports are raised for unplanned releases within event reporting system.	F: Yes. CS: Minimal cost. Standard practice.	Good practice that operators identify, report and learn from unplanned release events. Supports compliance with regulatory reporting requirements.	Control based on Woodside standard and regulatory requirements.	Yes **C 13.6**
Implement Woodside Engineering Operating Standard – Subsea Isolation). Proven isolation in place for relevant IMMR activities.	F: Yes CS: Minimal cost. Standard practice.	Maintaining and testing the ability to isolate wells and pipelines will ensure barriers are in place and verified limiting the volume released.	Benefits outweigh cost/sacrifice.	Yes **C 5.4**
Professional Judgement – Elimination				
No refuelling of helicopter on MODU.	F: No. Given the distance of the PAA from the airports suitable for helicopter operations, and the endurance of available helicopters, eliminating helicopter refuelling is not feasible. Helicopter flights cannot be eliminated and may be required in emergency situations. CS: Not assessed, control cannot feasibly be implemented.	Not considered – control not feasible.	Not considered – control not feasible.	No
The MODU and project vessels brought into port to refuel.	F: No. Does not eliminate the fuel transfer risk. It is not operationally practical to transit MODU/installation vessel back to port for refuelling based on the frequency of the refuelling requirements and distance from the nearest port. CS: Significant due to schedule delay and vessel transit costs and day rates.	Eliminates the risk in the PAA. However, moves risk to another location. Therefore, no overall benefit.	Disproportionate. The cost/sacrifice outweighs the benefit gained.	No
Professional Judgement – Substitute				
None identified.

Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Professional Judgement – Engineered Solution				
None identified.				
Emergency Response				
None identified.				
ALARP Statement: On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts of accidental spills of hydrocarbons during bunkering, transfer, storage and use. As no reasonable additional/alternative controls were identified that would further reduce the consequences and risks without grossly disproportionate sacrifice, the risks are considered ALARP.				

Demonstration of Acceptability
Acceptability Statement: The consequence assessment has determined that, given the adopted controls, accidental spills of hydrocarbons during bunkering, transfer, storage and use represent a moderate risk rating that is unlikely to result in a consequence greater than minor short term impacts. Further opportunities to reduce the risks have been investigated above. The adopted controls are considered good oil-field practice/industry best practice and meet requirements of Australian Marine Orders. Consultation with relevant persons has not indicated any concerns in relation to accidental spills of hydrocarbons during bunkering, transfer, storage and use. The potential risks are considered broadly acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the risks of accidental spills of hydrocarbons during transfer, storage and use to a level that is broadly acceptable.

EPOs, EPSs and MC for Angel Facility Operations

Description of Source of Risk

Operations

Chemical Transfer

Bulk transfer of TEG via hose between platform support vessels and the facility occurs as required. Potential glycol spill volumes during transfer are less than 0.2 m^3, based on the volume of the transfer hose and the immediate shut-off of the pumps by personnel involved in the bulk transfer process. The worst-case credible TEG spill scenario during transfer could result in up to 8 m^3 of glycol being discharged. This unlikely scenario represents a complete failure of the bulk transfer hose combined with a failure to follow procedures (which require transfer activities to be monitored), coupled with a failure to immediately shut off pumps (i.e., pumping continues for up to five minutes).

Other chemicals (e.g., corrosion inhibitor, hydraulic oil, control fluid, facility maintenance chemicals, etc) are transferred to the facility in containers of various volume (e.g., ISO tanks, drums, etc). The typical largest chemical transfer container is approximately 4.5 m^3 ISO tanks (used for transferring MEG and corrosion inhibitor).

Chemical Storage and Use

Spills can originate from stored chemicals or equipment on the facility and support vessel decks or subsea (refer to **Section 6.6.5** for an assessment of the impacts of planned chemical discharges).

Selection of operational chemicals is undertaken in accordance with the Woodside Chemical Selection and Assessment Environment Guideline.

Operational chemicals on the Angel facility that are kept in larger quantities are typically stored in dedicated vessels which have similar controls to those related to mitigating hydrocarbon releases (e.g., dedicated tanks, permanent piping to the process, isolatable by valves, etc). The chemicals stored in the largest volumes on the facility are TEG (40 m^3), corrosion inhibitor (30 m^3), MEG (25 m^3) and subsea control fluid (10m^3). The MEG, TEG and corrosion inhibitor tanks are classified as pressure vessels. MEG and TEG vessels are considered SCEs (primarily for MAE) and the corrosion inhibitors are managed via RBI. As the MEG and TEG are provided with a hydrocarbon gas blanket from the LP gas system inherent to the nature of explosion/gas loss of containment risks, and as such are covered under P01 – Pressure Vessels technical performance standard. The design of the vessel and associated integrity SCE assurance provides a robust prevention regime associated with the potential loss of containment to sea risk, along

with safe-guarding under the facility Safety Case (refer to see **Section 6.8.2** for additional information). However, the worst-case credible chemical spill scenario could result in up to 30 m^3 of corrosion inhibitor being discharged.

Chemical storage areas are typically set up in cabinets or bunded storage areas to contain releases to deck from transportable containers (e.g., bulk containers, barrels, drums, pails, etc). Releases from equipment are predominantly from the failure of hydraulic hoses or minor leaks from process components, or spills during refuelling of equipment, which can either be located within bunded/drained areas or outside of bunded/drained areas (e.g., over grating on cranes).

All chemical storage areas for transportable chemical containers drain to the hazardous open drains system, which features hydrocarbon separation and recovery.

The facility and support vessels also store other non-process chemicals and hydrocarbons, in various volumes (**Table 3-7** and **Table 3-8**). Operational non-process chemicals and maintenance chemicals present on the facility and support vessels are generally held in low quantities (usually less than 50 L isolatable volumes).

Tie-back Activities

MODU, Project Vessel and ROV Operations

Deck spills can result from spills from stored chemicals or equipment. Project vessels typically store chemicals in various volumes (20 L, 205 L; up to approximately 4000 to 6000 L). Storage areas are typically set up with effective primary and secondary bunding to contain any deck spills. Releases from equipment are predominantly from the failure of hydraulic hoses, which can either be located within bunded areas or outside of bunded or deck areas (e.g., over water on cranes). Helicopter refuelling may also take place within the PAA, on the helipad of the MODU and project vessels.

Chemicals that will be used and may be accidentally released include:

- non process chemicals (maintenance and cleaning chemicals)
- non process hydrocarbons; i.e., hydraulic fluids used in machinery (including cranes, winches, ROVs), small volumes of fuel
- drilling and well fluids
- pre-commissioning chemicals used for leak testing (MEG/treated water mixture).

Non-Process Chemicals

Non-process chemicals, such as wash chemicals, cleaning chemicals, maintenance and solvents, are generally held onboard in low quantities (typically <50 L containers) and are located within chemical cabinets or bunded storage areas on the project vessels and MODU. Non-process chemical spills may result from human error or damage to a chemical container during handling. Spills are generally captured by the drain system and routed to a holding tank for treatment or disposal onshore. In the event that a spill is not contained on deck or within a bunded area, there would be a release to the marine environment of up to 50 L.

Non-Process Hydrocarbons

Woodside's operational experience demonstrates that spills are most likely to originate from hydraulic hoses and have been less than 100 L, with an average volume <10 L.

Non-process hydrocarbons (hydraulic fluids) are used in hydraulic-powered machinery, such as winches, cranes and ROVs, and are hydrocarbon-based with added chemical component additives. Unplanned discharges are predominantly due to failure of hydraulic hoses or minor leaks from process components, or spills during periodic refuelling of hydraulic hoses. Spills or leaks from hydraulic hoses are usually very small volumes (~1 L) and are typically contained within a bunded or drained area under the equipment mounted on deck. These small on-deck spills are unlikely to reach the marine environment. A burst hydraulic hose on an extended crane could potentially result in hydraulic fluid being sprayed in a fine jet out over the water. However, this would only result in a small volume (~25 L) being released, due to the small capacity of hydraulic hoses.

Subsea spills can result from a loss of containment of fluids from subsea equipment including the BOP or ROVs. Subsea chemical use is described in **Section 3.4.15.5**. A review of these spills to the marine environment in the past 12 months showed subsea spills did not exceed approximately 26 L in Woodside's Drilling function.

The ROV hydraulic fluid is supplied through hoses containing approximately 20 L of fluid. Hydraulic lines to the ROV arms and other tooling may become caught resulting in minor leaks to the marine environment. Small volume hydraulic leaks may occur from equipment operating via hydraulic controls subsea (subsea control fluid).

Hydraulic fluids are medium oils of light to moderate viscosity. They have a relatively rapid spreading rate and will dissipate quickly, particularly in high sea states. Lubricating oils may also be held onboard, typically stored with the non process chemicals and held in low quantities. These hydrocarbons are more viscous, so in the event of an unplanned discharge, the spreading rate of a slick of these oils would be slightly slower.

Contingency Activities

Wireline Operations

Minor leaks during wireline activities with a live well are described to include leaks such as:

- leaks from the lubricator, stuffing box and hose or fitting failure, which are expected to be less than 10 L (0.01 m^3)

- loss of containment – fluids – surface holding tanks
- backloading of raw slop fluids in an IBC
- stuffing box leak/under pressure
- draining of lubricator contents
- excess grease/lubricant leaking from the grease injection head
- wind-blown lubricant dripping from cable/on deck
- lubricant used to lubricate hole.

Consequence Assessment

Potential Impacts to Environmental Values

Water Quality

Unplanned discharges of non-process chemicals and hydrocarbons may decrease the water quality in the immediate vicinity of the release. Only small volumes (<0.2 m^3) are anticipated, resulting in very short-term impacts to water quality, and limited to the immediate release location.

As discussed in **Section 6.6.5**, MEG and TEG are miscible in water, non- hazardous and biodegradable; both are rated OCNS Group E and MEG is considered PLONOR. A maximum credible spill of MEG or TEG is expected to mix with the receiving environment with no lasting environmental impact.

Accidental releases of chemicals (including corrosion inhibitor, a PLONAR Group E substance; non-toxic) or non-process hydrocarbons decrease the water quality in the immediate area of the release. The consequence is expected to be a minor short-term impact given the open ocean mixing environment, distance from sensitive receptors and relatively low credible release volumes.

Marine Fauna

Depending on the chemical released, the toxicity and/or potential to bioaccumulate may potentially result in localised impacts to pelagic fish or other marine species in the vicinity of the discharge. Given that surface discharges are rapidly dispersed, and subsea discharges (from ROVs) would be of very small volumes, potential impacts would be highly localised and temporary. Potential impacts to plankton from an accidental chemical spill may include acute toxicity, resulting in mortality of planktonic organisms. Given the rapid turnover of plankton communities and nature and scale of the credible releases, these impacts would be short-lived (hours to days). Impacts to fish are expected to be of no lasting effect, as fish species are mobile and expected to avoid the area affected by an accidental chemical spill. Impacts to air-breathing fauna such as cetaceans, birds and marine turtles are expected to be restricted to irritation of sensitive membranes, such as the eyes, mouth and digestive system. The magnitude of potential impact to marine fauna is no lasting effect, which results in a consequence of F.

Summary of Potential Impacts to Environmental Values(s)

Given the adopted controls, it is considered that deck and subsea spills to the marine environment will have no lasting effect with localised impacts (<1 month) on species, habitat (but not affecting ecosystems function), physical and biological attributes (i.e., Environment Impact – F).

Demonstration of ALARP

• mud tanks • mud tank room • transfer hoses • NWBM base fluid transfer lines • NWBM base fluid transfer station • base fluid storage.		limiting volume released).		
Spill kits positioned in high risk locations around the rig (near potential spill points such as transfer stations).	F: Yes. CS: Minimal cost. Standard practice.	Spill kits would reduce the likelihood of a deck spill from entering the marine environment. The consequence is unchanged.	Benefits outweigh cost/sacrifice.	Yes **C 23.4**
Installation and support vessels have self-containing hydraulic oil drip tray management system.	F: Yes. CS: Minimal cost. Standard practice.	Requirements for self-containing hydraulic oil drip tray management system would reduce the likelihood of contaminants being discharged to the marine environment. No change in consequence would occur.	Benefits outweigh cost/sacrifice.	Yes **C 23.5**
Spill response procedures; e.g., Oil Pollution First Strike Plan, SOPEP and Emergency Response Plan.	F: Yes. CS: Minimal cost. Standard practice.	Will not reduce the likelihood but may reduce the consequence of spill.	Benefits outweigh cost/sacrifice.	Yes **Appendix G** and **Appendix H**
Hoses and fittings carry an appropriate pressure rating.	F: Yes. CS: Minimal cost. Standard practice.	Reduce likelihood of deck spills.	Benefits outweigh cost/sacrifice.	Yes **C 23.7**
Personnel controlling the subsea equipment are competent to undertake the activity.	F: Yes. CS: Minimal cost. Standard practice.	Personnel are trained, reducing likelihood of spill events.	Benefits outweigh cost/sacrifice.	Yes **C 23.8**

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)[92]***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Chemical Selection and Assessment Environment Guideline: • Where Gold/Silver/E/D OCNS rating (and no OCNS substitution or product warning), chemicals are selected, no further control required. • If chemicals with a different OCNS rating, sub warning or non OCNS rated chemicals are required, chemicals will be assessed in accordance with the guideline prior to use.	F: Yes. Woodside routinely implements a chemical selection process based on OCNS at the facility. CS: Minimal. The OCNS is widely used throughout the industry and chemical suppliers are aware of the requirements of the scheme.	Selection and assessment of chemicals in accordance with Woodside process reduces environmental impacts associated with planned chemical discharge.	Benefits outweigh cost/sacrifice.	Yes **C 5.1**
Limiting unplanned volume of subsea control fluid discharged to the marine environment through monitoring subsea control fluid use, investigating material discrepancies.	F: Yes. The use of control fluid is monitored to maintain adequate fluid in the system. CS: Minimal cost.	Limits the volumes of subsea control fluid discharged to the marine environment.	Benefits outweigh cost/sacrifice.	Yes **C 23.9**
Implement Woodside Engineering Operating Standard – Subsea Isolation). Proven isolation in place for relevant IMMR activities.	F: Yes CS: Minimal cost. Standard practice.	Maintaining and testing the ability to isolate wells and pipelines will ensure barriers are in place and verified limiting the volume released.	Benefits outweigh cost/sacrifice.	Yes **C 23.10**
Chemicals and diesel stored safely to prevent the release to the marine environment.	F: Yes. CS: Minimal cost. Standard practice.	Reduces risk of unplanned chemical/diesel release.	Benefits outweigh cost/sacrifice.	Yes **C 22.7**
Professional Judgement – Eliminate				
No additional controls identified.				
Professional Judgement – Substitute				
No additional controls identified.				

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)[92]***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Professional Judgement – Engineered Solution				
Below-deck storage of all hydrocarbons and chemicals.	F: No. During operations there is a need to keep small volumes near activities and within equipment requiring use of hydrocarbons and chemicals and can result in increased risk of leaks from transfers via hose or smaller containers. CS: Not considered – control not feasible.	Not considered – control not feasible.	Not considered – control not feasible.	No
A reduction in the volumes of chemicals and hydrocarbons stored onboard MODU/ project vessels.	F: Yes. Increases the risks associated with transportation and lifting operations. CS: Project delays if required chemicals not on board. Increases the risks associated with transportation and lifting operations.	No reduction in likelihood or consequence since chemicals will still be required to enable drilling activities to occur.	Disproportionate. The cost/sacrifice outweighs the benefit gained.	No
ALARP Statement: On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts and risks of unplanned release of chemicals and hydrocarbons from deck and subsea spills. As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.				
Demonstration of Acceptability				
Acceptability Statement: The impact assessment has determined that accidental discharge of chemicals represents a low current risk rating and is unlikely to result in a risk consequence greater than localised with no lasting effect. BIAs within the PAA include the whale shark foraging and wedge-tailed shearwater breeding. Relevant recovery plans and conservation advice have been considered during the impact assessment, and the Petroleum Activities Program is not considered to be inconsistent with the overall recovery objectives and actions of these recovery plans and conservation advice. The adopted controls are considered consistent with industry legislation, codes and standards, good practice and professional judgement and meet the requirements and expectations of Australian Marine Orders identified during impact assessment. The potential risks and consequences are considered acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the risks and consequences of an unplanned discharge of chemicals /hydrocarbons to a level that is broadly acceptable.

Accidental discharge of project fluids (WBM/NWBM/base oil) and cement to marine environment		✓		✓	✓	✓	A	E	1	L	LCS GP	Broadly Acceptable	**EPO 24**

Description of Source of Impact

Drilling Fluids – Transfers

A project vessel will undertake bulk transfer of drilling muds or base oil to the MODU, if and when required during tie-back activities. Failure of a transfer hose or fittings during a transfer or backload, as a result of an integrity or fatigue issue, could result in a spill of mud or base oil to either the bunded deck or into the marine environment.

The most likely spill volume of mud is likely to be less than 0.2 m^2 based on the volume of the transfer hose and the immediate shutoff of the pumps by personnel involved in the bulk transfer process. However, the worst-case credible spill scenario could result in up to 8 m^3 of mud being discharged. This scenario represents a complete failure of the bulk transfer hose combined with a failure to follow procedures requiring transfer activities to be monitored, coupled with a failure to immediately shut off pumps (e.g., mud pumped through a failed transfer hose for a period of about five minutes).

Drilling Fluids – Slip Joint Packer Failure

The slip joint packer enables compensation for the dynamic movement of the MODU (heave) in relation to the static location of the BOP. A partial or total failure of the slip joint packer could result in a loss of mud to the marine environment. The likely causes of this failure include a loss of pressure in the pneumatic (primary) system combined with loss of pressure in the back up (hydraulic) system.

Catastrophic sequential failure of both slip joint packers (pneumatic and hydraulic) would trigger the alarm and result in a loss of the volume of fluid above the slip joint (conservatively 1.5 m^3) plus the volume of fluid lost in the one minute (maximum) taken to shut down the pumps. At a flow rate of 1000 gallons per minute this volume would equate to an additional 3.8 m^2. In total, it is expected that this catastrophic failure would result in a loss of 5.3 m^2.

Failure of either of the slip joint packers at a rate not large enough to trigger the alarms could result in an undetected loss of 20 bbl (3 m^3) maximum assuming a loss rate of 10 bbl/hr and that MODU personnel would likely walk past the moon pool at least every two hours.

Loss of a drilling chemical container or drum during transfer from the supply vessel to the MODU may occur due to crane operator error or machinery failure. The maximum container that could be lost is an intermediate Bulk Container (IBC) which can hold 1 m^3 of chemicals. In the event that an IBC or drum is lost to the marine environment and cannot be recovered the contents will discharge, either immediately or over a period depending on the damage to the drum or container.

NWBM Drilling Fluid System

The selection of a NWBM drilling fluid system (if required) will be based on Woodside processes; however, for the purposes of this risk assessment, an example base oil (Saraline 185V) has been used. Saraline 185V is a mixture of volatile to low volatility hydrocarbons. Predicted weathering of base oil, based on typical conditions in the region, indicates that about 50% by mass is predicted to evaporate over the first day or two (refer to **Table 6-40**). At this time,

most of the remainder could be entrained into the water column. In calm conditions, entrained hydrocarbons are likely to resurface with up to 100% able to evaporate over time.

Table 6-40: Characteristics of the non-water-based mud base oil

Oil type	*Initial density (kg/m³)*	*Viscosity (cP @ 20 °C)*	*Volatiles (%) <180*	*Semi volatiles (%) 180–265*	*Low volatility (%) 265–380*	*Residual (%) >380*	*Aromatic (%) of whole oil <380 °C BP*
			Non-Persistent		*Persistent*		
Base oil (Saraline 185V)	0.7760	2.0 @ 40 °C	8.5	41.1	50.4	0	0

Cement

Bulk cement is transferred as powder from the supply vessel to the MODU prior to being mixed into a slurry in the cement unit. Additives are required to form a cement slurry; these are transferred to the MODU in drums from the supply vessel to the MODU. Unplanned discharge to the marine environment may occur due to crane operator error or machinery failure resulting in loss of a drum of cement additive, which cannot be recovered. Cement additives are typically stored in drums <100 litres.

Contingency Activities

Activation of the Emergency Disconnect Sequence

The EDS is an emergency system that provides a rapid means of shutting in the well (i.e., BOP closed) and disconnecting the MODU from the BOP. The EDS could be manually activated due to an identified threat to the safety of the MODU, including loss of MODU station keeping resulting from loss of multiple moorings, potential collision by a third-party vessel or a loss of well control. During operations, this could result in a subsurface release of a combination of WBM and/or NWBM and solids at the seabed and a release of base fluid. The volume of material released depends on the water depth and, hence, the length of the riser (i.e., the entire riser volume would be lost). The base oil of the NWBM would remain in an emulsion with the other components of the mud system. Approximately 103 m^3 of base oil could be released in the event of the riser being disconnected when drilling with NWBM.

Impact Assessment

Potential impacts to environmental values

Some drilling fluids/cement may be spilt at the sea surface (e.g., transfer failure) and some in the water column potentially close to the seabed (e.g., in the event of an EDS or slip joint packer failure). Due to water depth in the PAA (70-130 m), this will determine the exposure pathway, and hence potential impacts and receptors.

Water Quality

The worst-case drilling fluid or cement unplanned discharge is 8 m^2 which could occur during bulk transfer from the supply vessel to the MODU during drilling and may decrease the water quality in the immediate vicinity of the release. These discharges would be to the sea surface and would rapidly dilute through mixing by surface currents and wave action. All chemicals that may be operationally released or discharged to the marine environment by the Petroleum Activities Program are evaluated using a defined framework and set of tools to ensure the potential impacts of the chemicals selected are acceptable, ALARP and meet Woodside's expectation for environmental performance. Therefore, any chemicals selected and potentially released are expected to be of low toxicity and biodegradable.

Base oil has a high volatile to semi-volatile fraction. A surface spill would typically evaporate within 48 hours, with the remaining portion to weather at a slow rate. The example base oil, Saraline 185V, is readily biodegradable, non-toxic in the water column and has low sediment toxicity (Shell, 2014). Due to its volatility and small worst-case credible spill scenario, there would be a very localised footprint unlikely to reach any sensitive receptors.

Given the occasional nature of unplanned chemical discharge, the small volumes, and the offshore location of the PAA, the change to water quality resulting from unplanned discharge of chemicals will not be substantial.

Therefore, any potential impact of a change in water quality would be localised. Receptor sensitivity of water quality is low (low value, open ocean), and therefore the consequence of a release of hydrocarbons/chemicals on water quality would be no lasting effect (F).

Marine Fauna

Injury or Mortality to Marine Fauna

The small footprint of a worst-case base oil spill would mean traversing marine fauna such as marine mammals, marine reptiles and fish would unlikely come into direct contact during an unplanned release, thus it is anticipated any impacts would be negligible and temporary in nature.

As a result of a change in water quality, further impacts to receptors may occur, which include injury or mortality to marine fauna resulting from exposure to toxins in the released drilling fluids. Neff (2010) explains that the lack of toxicity and low bioaccumulation potential of the drilling muds means that the effects of the discharges are highly

localised and are not expected to spread through the food web (of which planktonic species are the basis). Given that surface discharges are rapidly dispersed, potential impacts would be highly localised and temporary.

Local increases in turbidity from cement spills may affect zooplankton with variations in predator prey dynamics, which favours planktonic feeders over visual feeders (Gophen, 2015), while impacts to phytoplankton may occur due to decreases in available light, therefore reducing productivity (Dokulil, 1994). The magnitude of potential impact to marine fauna is no lasting effect, which results in a consequence of Slight (E) based on the high receptor sensitivity.

Suspended sediment levels greater than 500 mg/L are likely to produce a measurable impact on larvae of most fish species, and levels of 100 mg/L may affect the larvae of some species if exposed for periods greater than 96 hours (Jenkins and McKinnon, 2006). In addition, levels of 100 mg/L may affect the larvae of several marine invertebrate species. Dilution estimates (e.g., Hinwood et al., 1994; Neff, 2005) would suggest that suspended sediment concentrations from unplanned cement discharge, loss of drilling mud from slip joint packer failure, or activation of the EDS, would dilute rapidly with instantaneous exposures of 500 mg/L unlikely and exposure times of 100 mg/L well below 96 hours.

Due to the low levels of planktonic productivity in the offshore area, the fact that the PAA (70 to 130 m depth) is outside of the highly productive shelf break situated on the 200 m isobath, plankton populations on a regional scale are not expected to be adversely affected by drill and project fluid spills. In addition, due to the open nature of the marine environment of the PAA and associated environmental conditions (i.e., windy, strong currents, etc), the content and dispersive nature of drilling muds within the marine environment and the high population replenishment of these organisms, it is expected that impacts to plankton species will be limited to within tens of metres of the discharge point and return to previous conditions within a relatively short period of time. On this basis, the impacts to plankton from unplanned discharges during tie-back activities is slight and short-term.

Seafloor Receptors (Benthic Communities and Cultural Heritage Sites)

The impact area associated with release of NWBM from activation of the EDS would be small, limited to the seabed surrounding the well. Base fluids for NWBM are designed to be biodegradable in offshore marine sediments. Biodegradation can result in a low oxygen (anoxic) environment resulting in changes in benthic community structure. NWBMs are designed to be low in toxicity and are not readily bioavailable, based on their physical/chemical properties, for bioaccumulation to infauna and epifauna. Deleterious impacts to the infauna may still occur to a limited extent, together with increased hydrocarbon and metal concentrations in the area of deposition. The ability for the infauna communities to recolonise following a small disturbance, localised extent of impact, and low sensitivity deep water benthos within the PAA would mean impacts are short-term and slight.

Drill cuttings from unplanned loss of used drilling fluids would increase turbidity and TSS levels above ambient, where coarser material will deposit on the seabed and finer sediment material (WBM) will temporarily cause elevated TSS above the seabed surrounding the well. This would rapidly disperse and dilute with the prevailing seabed currents.

Accumulation of drill cuttings, grit and flocculent on the seabed causes changes in the physical properties of the seabed sediment such as the PSD, the introduction of contaminants (metals such as barium) from retained drilling fluids (WBM) and associated ecological effects.

Impacts associated with unplanned drill and project fluid discharges will be largely limited to an area surrounding the well. The low sensitivity of the benthic communities/habitats within and in the vicinity of the PAA, combined with the low toxicity of WBMs and residual NWBMs, insoluble mineralised salts (the source of barium) having low bioavailability to benthic biota, and the highly localised nature and scale of predicted physical impacts to seabed biota, affirm that any predicted impact is considered likely but of a short-term environmental consequence.

Cultural Heritage

As described in **Section 4.9.1**, the PAA overlaps the Ancient Coastline at 125 m depth contour KEF and therefore there is the potential that Indigenous Cultural features may exist and these may potentially be impacted during seabed disturbance resulting from operations and associated activities. While no cultural features have been identified in the PAA, further archaeological studies will be undertaken prior to the activity commencing to understand any potential cultural features (see **C 4.1**).

Summary of Potential Impacts to Environmental Values(s)

Given the adopted controls, it is considered that unplanned discharges of drilling fluids or cement to the marine environment will not result in a potential impact greater than slight and short-term impacts on species, habitat (but not affecting ecosystems function), physical and biological attributes (i.e., Environment Impact – E).

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)[95]***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Legislation, Codes and Standards				
Marine Order 91 (marine pollution prevention – oil) 2014, requires SOPEP (as appropriate to vessel class).	F: Yes. CS: Minimal cost. Standard practice.	Legislative requirements to be followed reduce the likelihood of an unplanned release. The consequence is unchanged.	Controls based on legislative requirements – must be adopted.	Yes **C 22.1**
Good Practice				
Marine riser's telescopic joint to be: • comprised of a minimum of two packers (one hydraulic and one pneumatic) • pressure tested in accordance with manufacturers recommendations.	F: Yes. CS: Minimal cost. Standard practice.	Reduces the likelihood of equipment failure leading to an unplanned release of drilling fluids. Although the consequence of an unplanned release would be reduced, the reduction in likelihood reduces the overall risk providing an overall environmental benefit.	Benefits outweigh cost/sacrifice.	Yes **C 24.1**
Implement Woodside's Chemical Selection and Assessment Environment Guideline: • Where Gold/Silver/E/D OCNS rating (and no OCNS substitution or product warning), chemicals are selected – no further control required. • If chemicals with a different OCNS rating, sub warning or non-OCNS rated chemicals are required chemicals will be assessed in accordance with the guideline prior to use.	F: Yes. CS: Minimal cost. Standard practice.	Environmental assessment of chemicals will reduce the consequence of impacts resulting from discharges to the marine environment by ensuring chemicals have been assessed for environmental acceptability. Planned discharges are required for the safe execution of activities and therefore no reduction in likelihood can occur.	Benefits outweigh cost/sacrifice.	Yes **C 5.1**

95 Qualitative measure

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)[95]***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Chemical reviews will be performed on previously approved chemicals to confirm potential chemical impacts are reduced to ALARP.	F: Yes. CS: Minimal cost. Standard practice.	Reduces the consequence of impacts resulting from discharges to the marine environment by confirming chemicals have been assessed for environmental acceptability. Planned discharges are required for safely executing activities; therefore, no reduction in likelihood can occur.	Benefits outweigh cost/sacrifice.	Yes **C 5.5**
Contractor procedure for managing project fluids transfers onto, around and off the MODU, which requires: • emergency shutdown systems for stopping losses of containment (e.g., burst hoses) • break-away dry-break couplings for oil-based mud hoses • transfer hoses to have floatation devised to allow detection of a leak • the valve line-up will be checked prior to commencing mud transfers • constant monitoring of the transfer process • direct radio communications • completed PTW and JSA showing contractor procedures are implemented • recording and verification of volumes moved to identify any losses • mud pit dump valves locked closed when not in use for mud transfers and operated under a PTW.	F: Yes. CS: Minimal cost. Standard practice for Woodside to review contractor systems prior to performing activity.	Reduces the likelihood of an unplanned release occurring. Although no change in consequence would occur, the reduction in likelihood decreases the overall risk, providing environmental benefit.	Benefits outweigh cost/sacrifice.	Yes **C 24.2**

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)[95]***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Check for the functionality of: • additional SCE (augers and cuttings dryers) • mud tanks • mud tank room • transfer hoses • NWBM base fluid transfer lines • NWBM base fluid transfer station • base fluid storage.	F: Yes. CS: Minimal cost. Standard practice.	Reduces the likelihood of an event occurring and reduces the potential consequences (by limiting volume released).	Benefits outweigh cost/sacrifice.	Yes **C 24.3**
Mud pits contaminated with hydrocarbons will be treated prior to discharge or contained. If discharge specification not met the fluid will be returned to shore.	F: Yes. CS: Minimal cost. Standard practice.	Reduces the consequence of the release to the environment, resulting in an environmental benefit.	Benefits outweigh cost/sacrifice.	Yes **C 24.4**
Bulk base oil will not be disposed overboard.	F: Yes. CS: Minimal cost. Standard practice.	Reduces the consequence of the release to the environment. Although no change in likelihood is provided, the decrease in consequence results in an environmental benefit.	Benefits outweigh cost/sacrifice.	Yes **C 24.5**
Professional Judgement – Eliminate				
No additional controls identified.				
Professional Judgement – Substitute				
Only use WBM during drilling.	F: Not feasible. While the base case is to use WBM, a contingent NWBM drilling fluid system is required for safety and technical reasons; therefore, option to use must be maintained. CS: Not considered – control not feasible.	Not considered – control not feasible.	Not considered – control not feasible.	No

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)[95]***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Professional Judgement – Engineered Solution				
Use a MODU which may have a larger tank storage capacity for WBM. As such, there would be fewer bulk transfer movements.	F: Not feasible. The use of a MODU with greater storage capacity cannot be confirmed. CS: Significant cost and schedule delay would occur if the MODU was limited to greater storage capacity.	Not considered – control not feasible.	Not considered – control not feasible.	No
ALARP Statement: On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts and risks of unplanned release of project fluids. As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.				
Demonstration of Acceptability				
Acceptability Statement: The impact assessment has determined that accidental discharge of project fluids represents a low current risk rating and is unlikely to result in a risk consequence greater than Slight. BIAs within the PAA include the whale shark foraging and wedge-tailed shearwater breeding. Relevant recovery plans and conservation advice have been considered during the impact assessment, and the Petroleum Activities Program is not considered to be inconsistent with the overall recovery objectives and actions of these recovery plans and conservation advice. The adopted controls are considered consistent with industry legislation, codes and standards, good practice and professional judgement and meet the requirements and expectations of Australian Marine Orders identified during impact assessment. The potential risks and consequences are considered acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the risks and consequences of an unplanned discharge of chemicals /hydrocarbons to a level that is broadly acceptable.

Incorrect disposal or accidental discharge of non-hazardous and hazardous waste to the marine environment		✓	✓			✓		A	F	2	L	LCS GP	Broadly Acceptable	**EPO 25**

Description of Source of Risk

Non-hazardous and Hazardous Waste

Normal operations on the facility, the MODU and support vessels generate a variety of hazardous and non-hazardous wastes. These materials could potentially impact the marine environment, if incorrectly disposed of, lost overboard or discharged in significant quantities.

Non-hazardous wastes include domestic and industrial wastes such as paper and cardboard, aluminium cans, bottles, polystyrene, organics and scrap steel. Hazardous wastes include recovered solvents, excess or spent chemicals, oil contaminated materials (e.g., sorbents, filters and rags), batteries and used lubricating oils. Sand and sludges may be periodically generated during process and vessel maintenance. Many waste streams are only generated on the riser platform and support vessels during deployment of personnel to the facility for IMMR activities.

All waste materials not suitable for discharge to the environment, including hazardous wastes (i.e., liquid and solid wastes), generated during the Petroleum Activities Program are transported to shore for disposal or recycling by Woodside's licenced waste contractor.

Consequence Assessment

The potential impacts of hazardous or non-hazardous solid waste/equipment accidentally discharged to the marine environment include contamination of the environment as well as secondary impacts relating to potential contact of marine fauna with wastes. This could result in entanglement or ingestion and lead to injury and death of individual animals. The temporary or permanent loss of waste materials into the marine environment is not likely to have a significant environmental impact, based on the location of the PAA, the types, size and frequency of wastes that could occur, and species present.

Water and Sediment Quality

Hazardous solid wastes such as paint cans, oily rags, etc., can cause localised contamination of the water and sediment through a release of toxins and chemicals. Given likely small volumes of any unplanned solid waste discharge, and the occasional nature of the event, these would result in temporary and highly localised changes to the water quality.

Seabirds and Migratory Shorebirds, Fish, Marine Reptiles and Marine Mammals

The unplanned discharge of solid wastes can result in mortality to fauna, either through contamination or physical injury depending on the nature of the waste. Marine fauna, including fish, seabirds and shorebirds, marine mammals and marine reptiles may be impacted through ingestion or entanglement of waste or through exposure to toxic chemicals. Ingestion or entanglement of marine fauna has the potential for physical harm which may limit feeding/foraging behaviours and thus can result in mortalities. Injury and fatality to vertebrate marine life caused by ingestion of, or entanglement in, harmful marine debris was listed as a key threatening process under the EPBC Act in August 2003 (DoEE, 2018). The Threat Abatement Plan for the impacts of marine debris on the vertebrate wildlife of Australia's coasts and oceans (DoEE, 2018) identifies EPBC Act-listed species for which there are scientifically

documented adverse impacts resulting from marine debris. Marine turtles and seabirds in particular may be at risk from plastics which may cause entanglement or be mistaken for food (e.g., DoEE, 2018; Commonwealth of Australia, 2017) and ingested causing damage to internal tissues and potentially preventing feeding activities. In the worst instance this could have a lethal affect to an individual. Marine debris has been identified as threat in the Recovery Plan for Marine Turtles in Australia (2017–2027).

Impacts to species including fish, birds, marine mammals and marine reptiles from the unplanned discharge of solid waste is unlikely given low occurrence of unplanned discharges. Significant impacts are unlikely to occur at an individual level and will not occur at a population level, nor result in the decrease of the quality of the habitat such that the extent of these species is likely to decline.

The temporary or permanent loss of waste materials into the marine environment is not likely to have a significant environmental impact, based on the nature and scale of activities that may generate wastes, the types, size and frequency of wastes that could occur.

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Legislation, Codes and Standards				
Contract vessels complying with Marine Orders for safe vessel operations, Marine Order 94 (Marine pollution prevention – packaged harmful substances) 2014.	F: Yes. CS: Minimal cost. Standard practice.	Implementation of Marine Order 94 reduces the likelihood of a harmful substance being released to the environment. Implementation is standard practice for commercial vessels as applicable to vessel size, type and class.	Controls based on legislative requirements – must be adopted.	Yes **C 25.1**
Contract vessels complying with Marine Order for safe vessel operations, Marine Order 95 (Pollution prevention – garbage).	F: Yes. CS: Minimal cost. Standard practice.	Implementation of Marine Order 95 reduces the likelihood of a harmful substance being released to the environment. Implementation is standard practice for commercial vessels as applicable to vessel size, type and class.	Controls based on legislative requirements – must be adopted.	Yes **C 25.2**
Good Practice				
Storing, handling and transporting wastes in accordance with the Waste Management Plan for Offshore Facilities.	F: Yes. CS: Minimal cost. Standard practice.	Reduces the likelihood of a release of waste to the environment by providing guidance on storage, handling and transport of waste streams.	Benefit outweighs cost/sacrifice.	Yes **C 25.3**

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
If safe and practicable to do so, using MODU, vessels, ROV or crane to attempt recovery of material[97] environmentally hazardous or non-hazardous solid object/waste container lost overboard.	F: Yes. CS: Minimal cost. Standard practice.	Potentially reduces consequence by recovering object/waste container from the environment.	Benefit outweighs cost/sacrifice.	Yes **C 25.4**
Incident reports are raised for unplanned releases within event reporting system.	F: Yes. CS: Minimal cost. Standard practice.	Good practice that operators identify, report and learn from unplanned release events. Supports compliance with regulatory reporting requirements.	Control based on Woodside standard and regulatory requirements.	Yes **C 13.6**

97 For the purposes of this control/performance standard "material" is defined as unplanned releases of environmentally hazardous or non-hazardous solid object/waste events with an environmental consequence of >F.

ALARP Statement: On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts and risks of accidental discharge of non-hazardous and hazardous wastes. As no reasonable additional/alternative controls were identified that would further reduce the impacts and risks without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.				

Demonstration of Acceptability
Acceptability Statement: The consequence assessment has determined that, given the adopted controls, the accidental discharge of non-hazardous waste and hazardous waste represents a low risk rating and is unlikely to result in a consequence greater than localised impacts to water quality, marine sediment and marine species with no lasting effects. Woodside, across its operations (including the facility), has a well-established waste management culture which underpins a strong performance and limits the potential for accidental releases to the marine environment. Opportunities to reduce waste management impacts and risks are employed through standard practices such as job planning, implementation of the Waste Management Plan and job hazard analysis practices. The adopted controls are considered good oil-field practice/industry best practice and meet requirements of Australian Marine Orders. The potential impacts and risks are considered broadly acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the impacts and risks of accidental discharge of non hazardous and hazardous waste to a level that is broadly acceptable.

Loss of station keeping of the MODU leading to anchor drag and the disturbance of benthic habitat	✓			✓		✓							

Description of Source of Impact

During MODU and project vessel operations, the primary cause for unplanned seabed disturbance is through dropped objects from the MODU or project vessels. Additional unplanned disturbance to the seabed may occur from a loss of station keeping and subsequent anchor drag during MODU operations if a moored MODU is used for tie-back activities.

Dropped Objects

There is the potential for objects to be dropped overboard from the MODU and project vessels to the marine environment. Objects that have been dropped during previous offshore activities include small numbers of personal protective gear (e.g., glasses, gloves, hard hats), small tools (e.g., spanners) hardware fixtures (e.g., riser hose clamp) and drill equipment (e.g., drill pipe); however, there is also potential for larger equipment to also be dropped during the activity, particularly during recovery of infrastructure from the seabed. The spatial extent in which dropped objects can occur is restricted to the PAA.

Anchor Drag

A moored MODU may be used for drilling the LDA-02 well, secured on station by an 8-point pre-laid mooring system deployed to the seabed, as dictated by the mooring analysis. High energy weather events such as cyclones, occurring while the MODU is on station, can lead to excessive loads on the mooring lines, resulting in failure (either anchor(s) dragging or mooring lines parting). A failure of mooring integrity may lead to the mooring lines and anchors attached to the MODU being trailed across the seabed. If mooring failure is sufficient, the MODU may move off station, increasing the likelihood of anchor drag across the seafloor. A hybrid MODU that uses DP in conjunction with a pre-laid mooring system to hold station, may be used to conduct the drilling. In this scenario, there may be an opportunity to disconnect the RAR (See **Section 3.5.6**), which would allow the rig to avoid the cyclone and for the anchor drag risk to be reduced.

For a moored MODU, personnel on-board are typically evacuated during cyclones. Woodside implements a risk-based assessment process to aid in decision-making for cyclone evacuations, with the well suspended prior to MODU evacuation. Support vessels also demobilise from the PAA during the passage of a cyclone. While the MODU is temporarily abandoned, the position of the MODU is monitored remotely for any deviation. Support vessels and

MODU personnel return to the PAA as soon as safe to do so after a cyclone evacuation. Operational experience indicates cyclone evacuations typically last for seven days.

Industry statistics from the North Sea show that a single mooring line failure for MODUs is the most common failure mechanism (33 × 10-4 per line per year), followed by a double mooring line failure (11 × 10-4 per line per year) (Petroleumstilsynet, 2014). Note that single and double mooring line failures do not typically result in the loss of station keeping. If partial or complete mooring failures are sufficient to result in a loss of station keeping, industry experience indicates that MODUs may drift considerable distances from their initial position (Offshore: Risk & Technology Consulting Inc., 2002). Partial mooring failures leading to a loss of station keeping resulted in smaller MODU displacements, due to the remaining anchors dragging along the seabed when compared to complete mooring failures; complete mooring failures resulted in a freely drifting MODU (Offshore: Risk & Technology Consulting Inc., 2002).

NOPSEMA has recorded four cases of anchor drag due to loss of MODU holding station during cyclone activity between 2004 and 2015 (NOPSEMA, 2015). Seabed disturbance area size from anchor drag will depend on the extent of the drag.

Impact Assessment

Potential Impacts to Environmental Values

In the unlikely event of an object being dropped into the marine environment or failed mooring, potential environmental effects would be limited to minor physical impacts on benthic communities. In most cases, objects will be able to be recovered and therefore these impacts will also be temporary in nature. However, there may be instances where objects are unable to be recovered due to health and safety, operational constraints or other factors such as the difficulty of recovering dropped objects at depth. When dropped objects are unable to be recovered, the impact will continue to be minor but permanent.

KEFs and Cultural Heritage

The temporary or permanent loss of dropped objects into the marine environment and mooring failure is likely to result in a minor impact only, as the benthic communities associated with the PAA are of low sensitivity and are broadly represented throughout the NWMR. As described in **Section 4.7**, the Glomar Shoals and the Ancient Coastline at 125 m depth contour KEFs overlaps the PAA. Benthic communities in the PAA are representative of the deep water soft sediment habitats reported in the wider region, and is likely to consist of soft sediment seabed habitat, characterised by sparse, widely represented epifauna and infauna (Woodside, 2004; Brewer et al., 2007).

Given the nature and scale of risks and consequences from dropped objects and mooring failure, slight impacts are expected to seabed sensitivities within the PAA. Furthermore, the PAA overlaps a relatively minor proportion of both KEFs (**Section 4.7**). Further, considering the types, size, scale and frequency of dropped objects that could occur, it is unlikely that a dropped object would have a significant impact on any benthic community.

The Ancient Coastline at the 125 m depth contour KEF is also an area where potential Indigenous archaeological material may exist on the seabed (**Section 4.9.1**), therefore dropped objects or mooring failure have the potential to impact cultural heritage sites if present within the PAA. While no cultural features have been identified in the PAA, further archaeological studies will be undertaken prior to the activity commencing to understand any potential cultural features.

Any unplanned seabed disturbance within the KEF would be minor and relatively small compared to the size of the KEF. There will be no substantial adverse effect on the KEF, communities or cultural heritage sites within it. On this basis, the magnitude of potential impacts to KEFs from unplanned seabed disturbance during activities is Minor. Receptor sensitivity for the KEF is high, leading to a Minor (D) risk consequence.

Epifauna and Infauna

As a result of a change in water quality and change in habitat, injury or mortality to marine fauna resulting from an increase in turbidity may occur. Given a change to water quality is unlikely, the only receptors that would potentially be at risk of unplanned seabed disturbance are bottom dwelling species including epifauna and infauna. Benthic communities, including epifauna and infauna may be impacted by the dropped objects, or the drag of anchors on the seabed. If not recovered, dropped objects may result in the permanent loss of a small area under the object.

If anchor drag occurs, habitat impact will span the extent of the drag area, leading to a localised change in communities; however, substantial adverse effect is not anticipated, given the sparse marine life that are well represented elsewhere in the region.

Given generally sparse benthic communities in the PAA, no threatened or migratory benthic species or ecological communities were identified, and those epifauna and infauna communities observed are likely to be well represented elsewhere in the region, impacts are expected to be restricted to a localised proportion of epifauna and infauna communities.

Based on the detailed evaluation, the magnitude of potential impacts to epifauna and infauna from unplanned seabed disturbance during activities associated with the Petroleum Activities Program is evaluated to be slight. Sensitivity for epifauna and infauna is low, leading to a slight (E) risk consequence.

Summary of Potential Impacts to Environmental Values(s)
Given the adopted controls, the predicted small footprint of a dropped object and the unlikely nature of anchor drag, it is considered that unplanned seabed disturbance will result in minor, short-term impact (one to two years) on species, habitat (but not affecting ecosystems), physical or biological attributes, and cultural heritage (i.e., Environment Impact – D).

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)[102]***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
ALARP Statement: On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts and risks of unplanned seabed disturbance. As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.				
Demonstration of Acceptability				
Acceptability Statement: The impact assessment has determined that disturbance to seabed from dropped objects or a loss of station keeping of the MODU represents a moderate current risk rating and is unlikely to result in a risk consequence greater than Minor. The adopted controls are considered industry good practice. The potential risks and consequences are considered broadly acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the risks of seabed disturbance from dropped objects/anchor drag to an acceptable level.

Description of Source of Risk

Activities associated with the Petroleum Activities Program will require vessels for tie-back activities, support operations and supply/transport. The type and number of vessels in the PAA at any one time, and the duration of presence, will differ depending on the activities being undertaken. However, indicative timeframes for tie-back activities at Lambert West are anticipated for Q3 2024.

Vessels operating in and around the PAA may present a potential hazard to cetaceans and other protected marine fauna such as whale sharks and marine reptiles. Vessel movements can result in collisions between the vessel (hull and propellers) and marine fauna, potentially resulting in superficial injury, serious injury that may affect life functions (e.g., movement and reproduction) and mortality. The frequency and severity of impacts due to collisions vary greatly due to vessel type, vessel operation (specific activity, speed), physical environment (e.g., water depth), and the type of marine fauna potentially present and their behaviours.

Seasonally seabirds roost on the facility, if maintenance, process safety and/or health risks are identified associated with the presence of birds, it may be necessary to deter them from roosting on the facility by installing bird proofing/exclusion devices (e.g., work area humpies).

Consequence Assessment

Marine Mammals, Reptiles and Sharks

The likelihood of vessel/whale collision being lethal is influenced by vessel speed; the greater the speed at impact, the greater the risk of mortality (Jensen and Silber, 2004; Laist et al., 2001). Vanderlaan and Taggart (2007) found that the chance of lethal injury to a large whale as a result of a vessel strike increases from about 20% at 8.6 knots to 80% at 15 knots. According to the data of Vanderlaan and Taggart (2007), it is estimated that the risk is less than 10% at a speed of four knots. Vessel–whale collisions at this speed are uncommon and, based on reported data contained in the US NOAA database (Jensen and Silber, 2004), there only two known instances of collisions when the vessel was travelling at less than six knots. Both of these were from whale watching vessels that were deliberately placed among whales.

Support vessels undertaking the Petroleum Activities Program within the PAA are likely to be travelling less than eight knots (and will often be stationary). Therefore, the risk of a vessel collision with protected species resulting in death is inherently low. No known key aggregation areas (resting, breeding or feeding) are located within or immediately adjacent to the PAA.

The nearest recognised BIAs for cetaceans (considered to be at risk due to relatively slow movement and proportion of time spent at or near the sea surface) is the humpback whale migration BIA, which lies 35 km south of the PAA

(refer to **Section 4.6.3**). The pygmy blue whale migration BIA also lies beyond the PAA (37 km north-west). Adverse interactions between vessels and humpback or pygmy blue whales are considered to be unlikely. Both humpback whales and pygmy blue whales are only expected to be present during their seasonal migrations; refer to **Table 4-14** for information on migration timing.

Whale sharks are at risk from vessel strikes when feeding at the surface. Whale sharks may traverse offshore NWS waters including the PAA during their migrations to and from Ningaloo Reef, and a BIA for foraging whale sharks overlaps the PAA. However, given the main aggregation area for whale sharks is approximately 340 km off the coast of Ningaloo (designated as a foraging BIA with high density prey) (**Section 4.6.1**), it is expected that whale shark presence within the PAA would not comprise significant numbers, and their presence would be transitory and of a short duration. There are no constraints preventing whale sharks from moving away from vessels to avoid injury (e.g., shallow water or shorelines).

The PAA is unlikely to represent important habitat for marine turtles, given the absence of potential nesting or foraging habitat (i.e., no emergent islands, reef habitat or shallow shoals) and the water depth (approximately 70 to 130 m). The closest identified marine turtle BIA or critical habitat to the PAA is an internesting buffer for flatback turtles, which lies 15 km from the PAA. The nearest potential turtle nesting habitats are the islands of the Dampier Archipelago (approximately 94 km south). As such, the presence of marine turtles within the PAA is likely to be restricted to individual turtles infrequently transiting the area. It is acknowledged that there are significant nesting sites along the mainland coast and islands of the region. As with cetaceans, the risk of collisions between turtles and vessels increases with vessel speed (Hazel et al., 2007). The typical response from turtles on the surface to the presence of vessels is to dive (a potential 'startle' response), which decreases the risk of collisions (Hazel et al., 2007). Given the low speeds of vessels undertaking the Petroleum Activities Program, along with the expected low numbers of turtles within the PAA, interactions between vessels and turtles are considered to be highly unlikely.

It is not deemed credible that vessel movement associated with the Petroleum Activities Program could have a significant impact on marine fauna populations given (1) the low presence of transiting individuals, (2) avoidance behaviour commonly displayed by marine fauna, and (3) low operating speed of the activity support vessels (generally less than eight knots or stationary, unless operating in an emergency). Activities are considered unlikely to result in a consequence greater than slight, short-term disruption to individuals or a small proportion of the population, and no impact on critical habitat or fauna activity.

Seabirds

While the presence of the facility provides an opportunistic resting location for seabirds, the installation of temporary bird proofing exclusion devices poses the potential risk of entanglement for individual birds. If deterrents are installed, birds will likely relocate to previous ranges (i.e., rather than landing on the Angel platform); therefore, no lasting effect is anticipated.

Cultural Values and Heritage

Through consultation and review of available literature (**Section 4.9.1**), Woodside understands that marine fauna that may be affected by a collision with a project vessel, such as marine mammals, whale sharks and turtles, are culturally important to Traditional Custodians. Traditional Custodians value these species both tangibly as well intangibly as they can be considered a resource or linked to songlines and dreaming stories. Traditional Custodians also have connection to many marine species through kinship and totemic systems; an individual may have obligation to care for a species to which they are kin. Traditional Custodians may also have a cultural obligation to care for the environmental values of Sea Country.

For example, activities that impact turtle populations and their marine environment may have an indirect impact on some Indigenous communities if they deplete hunting areas and threaten local food security (Delisle et al., 2018:251). Whale species may be subject of First Nations' increase ceremonies / rituals which are performed to enhance or maintain populations. As these thalu ceremonies are performed to maintain and increase populations of marine species, it is considered that management applies at the species/population level and not to individuals. For example, it is anticipated the thalu site on Murujuga which "brings in whales to beach" will continue to serve its purpose so long as whales continue to migrate through Mermaid Sound.

Related intangible cultural heritage may include the transmission of cultural knowledge about whales and whale behaviour, including birthing areas, whale communication and migratory patterns. Such cultural knowledge may be associated with various cultural functions and activities that support the social and economic life of a community (Fijn, 2021). Inter-generational transmission of cultural knowledge (including songlines) relating to marine reptiles may be impacted where changes results in reduced sightings (e.g., through population decline, changes to migration routes or changes to migration seasonality). This transfer of knowledge may be integral to managing a group's intangible cultural heritage (UNESCO, 2003).

As described, potential impacts to marine fauna are predicted to be at an individual level, which are not considered to be ecologically significant at a population level. Impacts are not expected to occur to ecologically significant proportions of the populations of the species, nor expected to result in a decrease of the quality of the habitat such that the extent of these species is likely to decline. As such, cultural values and intangible cultural heritage associated with these species are expected to be maintained.

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)[105]***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Legislation, Codes and Standards				
Implementing EPBC Regulations 2000 – Part 8 Division 8.1 Interacting with cetaceans to reduce the likelihood of collision with whales and dolphins.	F: Yes. CS: Minimal cost. Standard practice.	Reductions in speed around protected cetaceans reduce the likelihood of collision.	Controls based on legislative requirements – must be adopted.	Yes **C 4.1**
Good Practice				
Implement a Seabird management plan – to reduce likelihood of interaction with seabirds.	F: Yes. CS: Minimal.	Potential for slight reduction in the likelihood of seabird attraction to vessels and facility resulting in a reduced likelihood of bird strikes.	Potential benefits outweigh cost/sacrifice.	Yes **C 12.1**
Professional Judgement - Elimination				
Not using vessels.	F: No. No alternative to the use of vessels during the Petroleum Activities Program was identified. Given vessels must be used to undertake the Petroleum Activities Program, there is no feasible means to eliminate the source of risk. CS: Not assessed, control not feasible.	Not assessed, control not feasible.	Not assessed, control not feasible.	No
Professional Judgement – Substitute

ALARP Statement: On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the risk of interactions with marine fauna. As no reasonable additional/alternative controls were identified that would further reduce the impacts and risks without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.				

105 Qualitative measure

Demonstration of Acceptability
Acceptability Statement: The consequence assessment has determined that, given the adopted controls, interaction with marine fauna represents a low risk rating that is unlikely to result in a consequence greater than slight, short-term disruption to individuals or a small proportion of the population, and no impact on critical habitat or activity. Further opportunities to reduce the impacts and risks have been investigated above. The adopted controls are considered good oil-field practice/industry best practice and meet the requirements of Part 8 (Division 8.1) of the EPBC Regulations 2000. The management of interactions with marine fauna is consistent with the objectives of approved conservation advice and recovery plans for marine fauna, including cetaceans and whale sharks, where human interference has been identified as a threat. The potential impacts and risks are considered broadly acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the impacts and risks of vessel collision with marine fauna to a level that is broadly acceptable.

Description of Source of Risk

During the Petroleum Activities Program, vessels will be transiting to and from the PAA, potentially including traffic mobilising from beyond Australian waters. These project vessels may include the MODU, IMMR vessel, installation vessels or general support vessels (**Section 3.5**). Vessels may be sourced from the local area (Dampier, Port Hedland, etc.) or from further afield, depending on the type of vessel required and availability. In addition, infrequent import of materials (e.g., spares) from international suppliers may be required. Vessels arriving from international waters typically call into Dampier, where quarantine clearance including ballast log reviews is conducted in accordance with the *Biosecurity Act 2015*.

All vessels are inherently subject to some level of marine fouling. Organisms attach to the vessel hull, particularly in areas where organisms can find a good surface (e.g., seams, strainers and unpainted surfaces) or where turbulence is lowest (e.g., niches, sea chests, etc). Organisms can also be drawn into ballast tanks during on-boarding of ballast water as cargo is unloaded or to balance vessels under load. Biofouling organisms can become established in an area through the release of propagules (e.g., eggs or larvae), or by attaching to substrate after becoming detached from the host vessel.

Non-indigenous marine species (NIMS) have been introduced into a region beyond their natural biogeographic range and have the ability to survive, reproduce and establish founder populations. Not all NIMS introduced into an area thrive or cause demonstrable impacts. Indeed, the majority of NIMS around the world are relatively benign and few have spread widely beyond sheltered ports and harbours. Only a subset of NIMS that become abundant and impact on social/cultural, human health, economic and/or environmental values can be considered invasive marine species (IMS).

During the Petroleum Activities Program, vessel activities that have the potential to lead to the introduction of IMS are:

- discharge of ballast water from vessels
- vessel interactions with the facility
- cross contamination between vessels (e.g., when vessels need to be alongside each other).

Consequence Assessment

IMS have historically been introduced and translocated around Australia by a variety of human means including biofouling and ballast water. Species of concern are those that:

- are not native to the region
- are likely to survive and establish in the region
- are able to spread by human mediated or natural means.

Species of concern vary from one region to another, depending on various environmental factors such as water temperature, salinity, nutrient levels and habitat type. These factors dictate their survival and invasive capabilities.

Introducing IMS into the local marine environment may alter the ecosystem, as IMS have characteristics that make them superior (in a survival and/or reproductive sense) to indigenous species. They may prey upon local species (which had previously not been subject to this kind of predation and therefore not have evolved protective measures against the attack), they may outcompete indigenous species for food, space or light and can also interbreed with local species, creating hybrids such that the endemic species is lost.

IMS have also proven economically damaging to areas where they have been introduced and established. Such impacts include direct damage to assets (fouling of vessel hulls and infrastructure) and depletion of commercially harvested marine life (e.g., shellfish stocks). IMS have proven particularly difficult to eradicate from areas, once established. If the introduction is captured early, eradication may be effective but is likely to be expensive, disruptive and, depending on the method of eradication, harmful to other local marine life.

Despite the potential high consequence of the establishment of a marine pest within a high value environment as a result of introduction, unlike coastal or sheltered nearshore waters, the deep offshore open waters of the PAA are not conducive to the settlement and establishment of IMS (Geiling, 2016), due to the lack of light or suitable habitat to sustain growth or survival. **Table 6-41** provides an assessment of the IMS impacts and risks associated with the Petroleum Activity Program.

Epifauna and Infauna

Epifauna and infauna are susceptible to impacts from IMS due to the risk of changes to the ecosystem dynamics such as competition for resources and predation.

Approximately 0.89 km^2 of the Glomar Shoals KEF overlaps the PAA, in water depths between 65 to 72 m depth. This KEF contains regionally important habitat supporting high biological diversity and high localised productivity (Falkner et al. 2009). Benthic taxa including hard and soft corals, sponges and macroalgae is highest at depths <40 m, decreasing with depth within the KEF (Wahub, 2018). At depths of 60 to 80 m, benthic cover is low and approximately 2%; at depths greater than 80 m, benthic cover is barely present, with baseline survey data indicating 0.1% cover of benthic biota.

Discrete areas of hard substrate hosting sessile filter feeding communities such as sponges and gorgonians may also be associated within the Ancient Coastline at the 125 m Depth Contour KEF, of which ~84.6 km^2 overlaps the PAA. However, no areas of hard substrate characteristic of this KEF have been identified within the PAA (Jacobs, 2014).

Filter feeder communities within the PAA are present on the subsea infrastructure and Angel platform, which provides hard substrate for attachment (Jacobs, 2014).

While the MODU and project vessels have the potential to introduce IMS into the PAA, the deep offshore open waters of the PAA (70 to 130 m) are not conducive to the settlement and establishment of IMS. Furthermore, the PAA are away from shorelines and/or critical habitat. The likelihood of IMS being introduced and establishing viable populations within the PAA or immediate surrounds is considered unlikely, with the potential settlement on subsea infrastructure not expected. Accordingly, impact to epifauna/infauna in the PAA is not considered credible. Receptor sensitivity for epifauna and infauna is low, leading to a Slight (E) risk consequence. **Table 6-41** provides an assessment of the IMS impacts and risks associated with the Petroleum Activity Program.

Industry, Shipping, Defence

The establishment of IMS has the potential to cause changes to the functions, interests or activities of other users through indirect impact such as changes to fisheries target species resulting in economic and social implications, or due to compromised reputation to the oil and gas industry.

Given the low likelihood of IMS translocation to, and colonisation of environments within the PAA, project activities will not result in establishment of IMS, and as such not adversely affect other marine user activities in the region.

Based on the impact evaluation, the magnitude of potential impacts of a change to the functions, interests or activities of other users is slight (see **Table 6-41**). Receptor sensitivity for industry, shipping and defence is medium, leading to a Slight (E) risk consequence. The likelihood of the risk event occurring is Remote, therefore the risk is assessed as Low.

Summary of Potential Impacts to Environment Values

In support of Woodside's assessment of the impacts and risks of IMS introduction associated with the Petroleum Activities Program, a risk and impact evaluation of the different aspects of marine pest translocation associated with the activity was conducted. The results of this assessment are presented in **Table 6-41**.

As a result of this assessment, Woodside has presented the highest potential environment consequence as B 'a major long term impact on highly valued ecosystems' and a likelihood as Remote (0), resulting in an overall moderate risk following the implementation of identified controls.

Table 6-41: Assessment of the impacts and risks of invasive marine species introduction associated with the Petroleum Activity Program

IMS introduction aspect	*Credibility of introduction*	*Consequence of introduction*	*Likelihood*
Transfer of IMS from infected vessel to PAA and establishment on the seafloor or subsea infrastructure.	**Not Credible** The deep offshore open waters of the PAA away from shorelines and/or critical habitat, more than 12 nm from a shore and in waters 70 to 130 m deep, are not conducive to the settlement and establishment of IMS.		
Transfer of IMS from infected vessel to and subsequent establishment on the Angel Platform.	**Credible** There is potential for the transfer of marine pests to occur.	If IMS were to establish this would potentially result in fouling of intakes (depending on the pest introduced), and would likely result in the quarantine of the Angel facility until eradication could occur (through cleaning and treatment of infected areas), which would be costly to undertake. **Minor (D) – Reputation and Brand** Such introduction would be expected to have Minor (D) impact to Woodside's reputation and brand, and close scrutiny of asset level operations or future proposals. **Slight (E) – Environment** Environmental consequence of introduction of IMS to the Angel platform is considered Slight (E), localised and would relate to habitat directly on the Angel facility.	**Highly Unlikely (1)** Interactions between the Angel facility and support vessels is limited during the petroleum activity program, with a 500 m safety exclusion zone being adhered to. Spread of marine pests via ballast water or spawning in these open ocean environments is considered Highly Unlikely (1).
Introduced to PAA and establishment on a project vessel.	**Credible** There is potential for the transfer of marine pests between project vessels within the PAA.	**Environment – Not Credible** The translocation of IMS from a colonised MODU or project vessel to shallower environments via natural dispersion is not considered credible given the distances of the PAA from nearshore environments (i.e., greater than 12 nm/50 m water depth). There is therefore	**Remote (0)** Interactions between project vessel will be limited during the Petroleum Activities Program, with minimum 500 m safety exclusion zones being adhered to around the MODU and installation vessel, and interactions limited short periods of time alongside (i.e., during backloading,

		no credible environmental risk and the assessment is limited to Woodside's reputation. **Reputation – E** If IMS were to establish on a project vessel (i.e., MODU, installation vessel, activity project vessels) this could potentially impact the vessel operationally through the fouling of intakes, result in translocation of an IMS into the PAA and, depending on the species, potentially transfer of an IMS to other project vessels, which would likely result in the quarantine of the vessel until eradication could occur (through cleaning and treatment of infected areas), which would be costly to perform. Such introduction would be expected to have slight impact to Woodside's reputation, particularly with Woodside's contractors, and would likely have a reputational impact on future proposals.	bunkering activities). There is also no direct contact (i.e., they are not tied up alongside) during these activities. Spread of marine pests via ballast water or spawning in these open ocean environments is also considered remote.
Transfer of IMS from infected vessel to and subsequent establishment on riser platform, then transfer of IMS to a secondary vessel from the facility.	**Not Credible** Risk is considered so remote that it is not credible for the purposes of the Petroleum Activity Program. The transfer of a marine pest from an infected activity vessel to the facility is considered highly unlikely given the offshore open ocean environment. For a marine pest to then establish into a mature spawning population on the facility and then transfer to another support vessel is not considered credible (i.e., beyond the Woodside risk matrix). The facility is located in an offshore, open ocean, deep environment. Support vessels only spend short periods of time alongside the riser platform (i.e., during		

	backloading or bunkering activities). There is also no direct contact (i.e., they are not tied up alongside) during these activities. It is also noted that Woodside has been conducting marine vessel movements between the facility and WA ports (such as Dampier) for a long period of time, and no IMS has been detected in these ports (Department of Fisheries, 2017).		

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Legislation, Codes and Standards				
On arrival in Australia, all vessels will manage their ballast water using one of the approved ballast water management options, as specified in the Australian Ballast Water Management Requirements.	F: Yes. CS: Minimal cost. Standard practice.	Reduction in the likelihood that ballast water will host IMS.	Controls based on legislative requirements under the *Biosecurity Act 2015* – must be adopted.	Yes **C 29.1**
Internationally sourced project vessels will manage their biosecurity risk associated with biofouling as specified in the Australian Biofouling Management Requirements.	F: Yes. CS: Minimal cost. Standard practice.	Reduces the likelihood of transfer of marine pests between vessels within the PAA. No change in consequence would occur.	Controls based on legislative requirements under the *Biosecurity Act* 2015 – must be adopted.	Yes **C 29.2**
Good Practice				
Woodside's IMS risk assessment process[106] will be applied to the MODU, project vessels and relevant immersible equipment undertaking the Petroleum Activities Program. Assessment will consider these risk factors: For MODU and project vessels: • vessel/MODU/type	F: Yes. CS: Minimal cost. Good practice implemented across all Woodside Operations.	Identifies potential risks and additional controls implemented accordingly. In doing so, the likelihood of transferring marine pests between project vessels within the PAA is reduced. No change in consequence would occur.	Benefits outweigh cost/sacrifice.	Yes **C 29.3**

106 Qualitative measure

[45] Woodside's IMS risk assessment process was developed with regard to the national biofouling management guidelines for the petroleum production and exploration industry and guidelines for the control and management of a ships' biofouling to minimise the transfer of invasive aquatic species (IMO Guidelines, 2011).

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
• recent IMS inspection and cleaning history, including for internal niches • out-of-water period before mobilisation • age and suitability of antifouling coating at mobilisation date • internal treatment systems and history • origin and proposed area of operation • number of stationary/slow speed periods >7 days • region of stationary or slow periods • type of activity – contact with seafloor. • For immersible equipment: • region of deployment since last thorough clean, particularly coastal locations • duration of deployments • duration of time out of water since last deployment • transport conditions during mobilisation • post-retrieval maintenance regime. Based on the outcomes of each IMS risk assessment, management measures commensurate with the risk (such as treating internal systems, IMS inspections or cleaning) will be implemented to minimise the likelihood of IMS being introduced.				
Diver based monitoring of the riser platform for IMS.	F: Potentially. Diver based surveys are technically feasible for the facility but are not approved under the in-force Safety Case.	Riser platform monitoring does not prevent the potential for translocation (i.e., only as a mitigation measure). Detection	Disproportionate. Interactions between the facility and support/subsea vessels posing IMS translocation risk is limited, and the	No

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
	CS: Significant. IMS inspections of in-water assets typically require vessel logistics and diver-based inspection teams to reliably detect IMS. This is a costly, time-consuming process that would likely require facility simultaneous operational constraints, and invariably introduces a series of significant safety risks in a hazardous offshore environment. Monetary cost of IMS survey for facility-sized infrastructure would be comparable to safe diver campaign arrangements in the order of $200,000/day plus mob/demob costs. Costs of ROV to support survey are in the order of $150,000/day plus mob/demob costs (based on subsea ROV hire costs). Health and safety exposure includes those of personnel while conducting diver based surveys – four days of two to three people (based on subsea ROV surveys of similar size), as well as offshore vessel and facility simultaneous operations hazards.	may facilitate subsequent development of options to manage IMS. Subsequent success may be limited due to structure complexity and hazardous environment.	vessels involved will have been managed through the implementation of Woodside's Invasive Marine Species Management Plan (IMSMP), a verified process which provides Woodside confidence in the verification of environmental performance**.** Consequently, any additional benefit gained through the implementation of this control is considered disproportionate, given material execution safety risks and controls already adopted (and noting already incurred cost through implementation of IMSMP (i.e., inspections and cleaning where risk warrants)), and the unlikely likelihood of a translocation event.	
Professional Judgement – Elimination				
Not using MODU and project vessels.	F: No. No alternative to the use of vessels during the Petroleum Activities Program was identified, given vessels must be used to undertake the Petroleum Activities	Not assessed, control not feasible.	Not assessed, control not feasible.	No

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
	Program. There is no feasible means to eliminate the source of risk. CS: Not assessed, control not feasible.			
No discharge of ballast water during the Petroleum Activities Program.	F: No. Ballast water discharges are critical for maintaining vessel stability. Given the nature of the Petroleum Activities Program, the use of ballast (including the potential discharge of ballast water) is considered to be a safety critical requirement. CS: Not assessed, control not feasible.	Not assessed, control not feasible.	Not assessed, control not feasible.	No
Professional Judgement – Substitute				
Sourcing vessels based in Australia only.	F: Potentially. Limiting activities to only use local project vessels could potentially pose a significant risk in terms of time and duration of sourcing a vessel, as well as the ability of the local vessels to perform the required tasks. For example, there are limited installation vessels based in Australian waters. While the project will attempt to source project vessels locally it is not always possible. Availability cannot always be guaranteed when considered competing Oil and Gas activities in the region. In addition, sourcing Australian based vessels only will cause increases in cost due to pressures of vessel availability. CS: Significant cost and schedule impacts due to restrictions of	Sourcing vessels from within Australian will reduce the likelihood of IMS from outside Australian waters, however, it does not reduce the likelihood of introduction of species native to Australia but alien to the PAA and NWMR, or of IMS that have established elsewhere in Australia. The consequence is unchanged.	Disproportionate. Sourcing vessels from Australian waters may result in a reduction in the likelihood of IMS introduction to the PAA; however, the potential cost of implementing this control is grossly disproportionate to the minor environmental gain (or reducing an already remote likelihood of IMS introduction) potentially achieved by using only Australian based vessels, consequently this risk is considered not reasonably practicable.	No

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
	vessel hire opportunities.			
Inspecting all vessels for IMS.	F: Yes. Approach to inspect vessels is feasible. CS: Significant cost and schedule impacts. Thorough inspections require vessels to be removed from the sea (e.g., slipped or dry docked) and examined by an IMS expert. This process incurs significant financial and schedule sacrifices. Timely vessel based support is integral to the safe and efficient operation of the facility and subsea infrastructure.	Reduction in the likelihood that a vessel will host IMS.	Disproportionate. The cost/sacrifice is grossly disproportionate to the benefit gained.	No
Professional Judgement – Engineered Solution				
None identified.				
ALARP Statement: On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts and risks of IMS introduction and establishment. As no reasonable additional/alternative controls were identified that would further reduce the impacts and risks without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.				
Demonstration of Acceptability				
Acceptability Statement: The risk assessment has determined that, given the adopted controls, introduction of IMS represent a moderate risk rating that has a remote likelihood to result in an environmental consequence greater than major long-term impact on marine communities within the PAA. Further opportunities to reduce the impacts and risks have been investigated above. The adopted controls are considered good oil-field practice/industry best practice and meet Australian legislative requirements, including the *Biosecurity Act 2015*. The potential impacts and risks are considered broadly acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the impacts and risks of invasive marine species to an acceptable level.

Environmental Performance Outcomes	***Controls***	***Environmental Performance Standards***	***Measurement Criteria***
	• duration of deployments • duration of time out of water since last deployment • transport conditions during mobilisation • post-retrieval maintenance regime. Based on the outcomes of each IMS risk assessment, management measures commensurate with the risk (such as treating internal systems, IMS inspections or cleaning) will be implemented to minimise the likelihood of IMS being introduced.		

6.9 Recovery Plan and Threat Abatement Plan Assessment

This section describes the assessment that Woodside has undertaken to demonstrate that the Petroleum Activities Program is not inconsistent with any relevant recovery plans or threat abatement plans. For the purposes of this assessment, the relevant Part 13 statutory instruments (recovery plans and threat abatement plans) are:

- Recovery Plan for Marine Turtles in Australia 2017–2027 (Commonwealth of Australia, 2017).
- Conservation Management Plan for the Blue Whale 2015–2025 (Commonwealth of Australia, 2015a).
- Recovery Plan for the Grey Nurse Shark (Carcharias taurus) 2014 (Commonwealth of Australia, 2014b).
- Sawfishes and River Sharks Multispecies Recovery Plan (Commonwealth of Australia, 2015b).
- Threat Abatement Plan for the impacts of marine debris on the vertebrate wildlife of Australia's coasts and oceans 2018 (Commonwealth of Australia, 2018).

Table 6-42 lists the objectives and (where relevant) the action areas of these plans, and describes whether these objectives/action areas are applicable to government, the Titleholder, and/or the Petroleum Activities Program. For those objectives/action areas applicable to the Petroleum Activities Program, the relevant actions of each plan have been identified, and an evaluation has been conducted as to whether impacts and risks resulting from the activity are not inconsistent with that action. The results of this assessment against relevant actions are presented in **Table 6-43** to **Table 6-46**.

EPBC Act Part 13 Statutory Instrument	Applicable to:		
	Government	***Titleholder***	***Petroleum Activities Program***
B. Enabling and measuring recovery			
B1. Determine trends in index beaches	Y	Y	
B2. Understand population demographics at key foraging grounds	Y		
B3. Address information gaps to better facilitate the recovery of marine turtle stocks	Y	Y	Y
Blue Whale Conservation Management Plan			
Long-term recovery objective: Minimise anthropogenic threats to allow for their conservation status to improve so that they can be removed from the EPBC Act threatened species list	Y	Y	Y
Interim Recovery Objectives			
The conservation status of blue whale populations is assessed using efficient and robust methodology	Y		
The spatial and temporal distribution, identification of biologically important areas, and population structure of blue whales in Australian waters is described	Y	Y	Y
Current levels of legal and management protection for blue whales are maintained or improved and an appropriate adaptive management regime is in place	Y		
Anthropogenic threats are demonstrably minimised	Y	Y	Y
Action Areas			
A. Assessing and addressing threats			
A.1: Maintain and improve existing legal and management protection	Y		
A.2: Assessing and addressing anthropogenic noise	Y	Y	Y
A.3: Understanding impacts of climate variability and change	Y		
A.4: Minimising vessel collisions	Y	Y	Y
B. Enabling and measuring recovery			
B.1: Measuring and monitoring population recovery	Y		
B.2: Investigating population structure	Y		
B.3: Describing spatial and temporal distribution and defining biologically important habitat	Y	Y	Y

EPBC Act Part 13 Statutory Instrument	Applicable to:		
	Government	***Titleholder***	***Petroleum Activities Program***
Grey Nurse Shark Recovery Plan			
Overarching Objective			
To assist the recovery of the grey nurse shark in the wild, throughout its range in Australian waters, with a view to: • improving the population status, leading to future removal of the grey nurse shark from the threatened species list of the EPBC Act • ensuring that anthropogenic activities do not hinder the recovery of the grey nurse shark in the near future, or impact on the conservation status of the species in the future	Y	Y	Y
Specific Objectives			
Develop and apply quantitative monitoring of the population status (distribution and abundance) and potential recovery of the grey nurse shark in Australian waters	Y		
Quantify and reduce the impact of commercial fishing on the grey nurse shark through incidental (accidental and/or illegal) take, throughout its range	Y		
Quantify and reduce the impact of recreational fishing on the grey nurse shark through incidental (accidental and/or illegal) take, throughout its range	Y		
Where practicable, minimise the impact of shark control activities on the grey nurse shark	Y		
Investigate and manage the impact of ecotourism on the grey nurse shark	Y		
Manage the impact of aquarium collection on the grey nurse shark	Y		
Improve understanding of the threat of pollution and disease to the grey nurse shark	Y	Y	Y
Continue to identify and protect habitat critical to the survival of the grey nurse shark and reduce the impact of threatening processes within these areas	Y	Y	
Continue to develop and implement research programs to support the conservation of the grey nurse shark	Y	Y	
Promote community education and awareness in relation to grey nurse shark conservation and management	Y		

EPBC Act Part 13 Statutory Instrument	Applicable to:		
	Government	***Titleholder***	***Petroleum Activities Program***
Sawfish and River Sharks Recovery Plan			
Primary Objective			
To assist the recovery of sawfish and river sharks in Australian waters with a view to: • improving the population status leading to the removal of the sawfish and river shark species from the threatened species list of the EPBC Act • ensuring that anthropogenic activities do not hinder recovery in the near future, or impact on the conservation status of the species in the future	Y	Y	Y
Specific Objectives			
Reduce and, where possible, eliminate adverse impacts of commercial fishing on sawfish and river shark species	Y		
Reduce and, where possible, eliminate adverse impacts of recreational fishing on sawfish and river shark species	Y		
Reduce and, where possible, eliminate adverse impacts of Indigenous fishing on sawfish and river shark species	Y		
Reduce and, where possible, eliminate the impact of illegal, unregulated and unreported fishing on sawfish and river shark species	Y		
Reduce and, where possible, eliminate adverse impacts of habitat degradation and modification on sawfish and river shark species	Y	Y	Y
Reduce and, where possible, eliminate any adverse impacts of marine debris on sawfish and river shark species noting the linkages with the Threat Abatement Plan for the Impact of Marine Debris on Vertebrate Marine Life	Y	Y	Y
Reduce and, where possible, eliminate any adverse impacts of collection for public aquaria on sawfish and river shark species	Y		
Improve the information base to allow the development of a quantitative framework to assess the recovery of, and inform management options for, sawfish and river shark species	Y		
Develop research programs to assist conservation of sawfish and river shark species	Y	Y	
Improve community understanding and awareness in relation to sawfish and river shark conservation and management	Y		

EPBC Act Part 13 Statutory Instrument	Applicable to:		
	Government	***Titleholder***	***Petroleum Activities Program***
Marine Debris Threat Abatement Plan			
Objectives			
Contribute to long-term prevention of the incidence of marine debris	Y	Y	
Understand the scale of impacts from marine plastic and microplastic on key species, ecological communities and locations	Y	Y	Y
Remove existing marine debris	Y		
Monitor the quantities, origins, types and hazardous chemical contaminants of marine debris, and assess the effectiveness of management arrangements for reducing marine debris	Y		
Increase public understanding of the causes and impacts of harmful marine debris, including microplastic and hazardous chemical contaminants, to bring about behaviour change	Y		

Table 6-43: Assessment against relevant actions of the Marine Turtle Recovery Plan

Part 13 Statutory Instrument	Relevant action areas/objectives	Relevant actions	Evaluation	EPO, controls and PS
Marine Turtle Recovery Plan	Action Area A3: Reduce the impacts from marine debris.	Action: Support the implementation of the Marine Debris Threat Abatement Plan (TAP). Priority actions at stock level: G-NWS – Understand the threat posed to this stock by marine debris. LH-WA – Determine the extent to which marine debris is impacting loggerhead turtles. F-Pil – No relevant actions.	Refer **Section 6.8.7**. Not inconsistent assessment: The assessment of the accidental release of solid hazardous and non-hazardous wastes has considered the potential risks to marine turtles. Controls have been implemented to reduce the likelihood of accidental release of solid wastes for the duration of the Petroleum Activities Program.	**EPO 25** **C 25.1** **PS 25.1**

Part 13 Statutory Instrument	Relevant action areas/objectives	Relevant actions	Evaluation	EPO, controls and PS
	Action Area A4: Minimise chemical and terrestrial discharge.	**Action:** Ensure spill risk strategies and response programs adequately include management for marine turtles and their habitats, particularly in reference to 'slow to recover habitats'; e.g., nesting habitat, seagrass meadows or coral reefs. Priority actions at stock level: G-NWS – Ensure that spill risk strategies and response programs include management for turtles and their habitats. LH-WA & F-Pil – Ensure that spill risk strategies and response programs include management for turtles and their habitats, particularly in reference to slow to recover habitats, e.g. seagrass meadows or corals.	Refer **Sections 6.7 and 6.8**. **Not inconsistent assessment:** The assessment of accidental release of chemicals/hydrocarbons has considered the potential risks to marine turtles. Spill risk strategies and response program include management measures for turtles and their nesting habitats.	Refer **Sections 6.7** and **6.8**. Detailed oil spill preparedness and response performance outcomes, standards and measurement criteria for the Petroleum Activities Program are present in **Appendix D**.
	Action Area A8: Minimise light pollution.	**Action:** Artificial light within or adjacent to habitat critical to the survival of marine turtles will be managed such that marine turtles are not displaced from these habitats. Priority actions at stock level: G-NWS – As above. LH-WA – No relevant actions. F-Pil – Manage artificial light from onshore and offshore sources to ensure biologically important behaviours of nesting adults and emerging/dispersing hatchlings can continue.	Refer **Section 6.6.11**. **Not inconsistent assessment:** The assessment of light emissions has considered the potential impacts to marine turtles. Internesting, mating, foraging or migrating turtles are not impacted by light from offshore vessels. Based on the frequency and nature of IMMR activities, the impacts to adult turtles moving through the PAA from vessel lighting are expected to be localised and temporary with no lasting effect.	**EPO 12** **C 12.1, 12.2, 12.3** **PS 12.1, 12.2, 12.3**

Part 13 Statutory Instrument	Relevant action areas/objectives	Relevant actions	Evaluation	EPO, controls and PS
	Action Area B1: Determine trends at index beaches.	**Action:** Maintain or establish long-term monitoring programs at index beaches to collect standardised data critical for determining stock trends, including data on hatchling production Priority actions at stock level: G-NWS – Continue long-term monitoring of index beaches LH-WA – Continue long-term monitoring of nesting and foraging populations F-Pil – no relevant actions	**Not inconsistent assessment:** Woodside contributes to Action Area B1 via its support of the Ningaloo Turtle Program 1.	N/A
	Action Area B3: Address information gaps to better facilitate the recovery of marine turtle stocks.	**Action:** Understand the impacts of anthropogenic noise on marine turtle behaviour and biology Priority actions at stock level: G-NWS – Given this is a relatively accessible stock that is likely to be exposed to anthropogenic noise – Investigate the impacts of anthropogenic noise on turtle behaviour and biology and extrapolate findings from the North West Shelf stock to other stocks. LH-WA – No relevant actions. F-Pil – No relevant actions.	Refer **Sections 6.6.3** and **6.6.4**. **Not inconsistent assessment:** The assessment of acoustic emissions has considered the potential impacts to marine turtles. Noise related to the Petroleum Activities Program is not expected to result in behavioural response, injury or mortality of individuals, or any other lasting effect.	**EPO 4** **C 4.1** **PS 4.1**
Assessment Summary: The Marine Turtle Recovery Plan has been considered during the assessment of impacts and risks, and the Petroleum Activities Program is not considered to be inconsistent with the relevant actions of this plan.				

Table 6-44: Assessment against relevant actions of the Blue Whale Conservation Management Plan

Part 13 Statutory Instrument	*Relevant Action Areas/Objectives*	*Relevant Actions*	*Evaluation*	*EPO, Controls and PS*
Blue Whale Conservation Management Plan	**Action Area A.2:** Assessing and addressing anthropogenic noise.	**Action 2:** Assessing the effect of anthropogenic noise on blue whale behaviour. **Action 3:** Anthropogenic noise in biologically important areas will be managed such that any blue whale continues to use the area without injury, and is not displaced from a foraging area.	Refer **Sections 6.6.3** and **6.6.4**. **Not inconsistent assessment:** The assessment of acoustic emissions has considered the potential impacts to pygmy blue whales. Acoustic emissions from project vessels will not cause injury to any pygmy blue whale. There are no known or possible foraging areas for pygmy blue whales within or adjacent to the PAA. If the Petroleum Activities Program within the PAA overlaps with an individual northbound or southbound migration, they may deviate slightly from the migratory route, but will continue on their migration.	**EPO 4** **C 4.1** **PS 4.1**
	Action Area A.4: Minimising vessel collisions.	**Action 3:** Ensure the risk of vessel strikes on blue whales is considered when assessing actions that increase vessel traffic in areas where blue whales occur and, if required, appropriate mitigation measures are implemented.	Refer **Section 6.8.9**. **Not inconsistent assessment:** The assessment of vessel collision with marine fauna has considered the potential risks to pygmy blue whales. If the Petroleum Activities Program within the PAA overlaps with an individual northbound or southbound migration, they may deviate slightly from the migratory route, but will continue on their migration. Vessel collisions with pygmy blue whales are highly unlikely to occur, given the low operating speed of support vessels.	**EPO 27** **C 4.1** **PS 4.1**
	Action Area B.3: Describing spatial and temporal distribution and defining biologically important habitat.	**Action 2:** Identify migratory pathways between breeding and feeding grounds. **Action 3:** Assess timing and residency within biologically important areas.	**Not inconsistent assessment:** Woodside contributes to Action Area B3 via its support of targeted research initiatives (e.g., satellite tracking of pygmy blue whale migratory movements).	N/A
Assessment Summary: The Blue Whale Conservation Management Plan has been considered during the assessment of impacts and risks, and the Petroleum Activities Program is not considered to be inconsistent with the relevant actions of this plan.				

Table 6-45: Assessment against relevant actions of the Grey Nurse Shark Recovery Plan

Part 13 Statutory Instrument	Relevant Action Areas/Objectives	Relevant Actions	Evaluation	EPO, Controls and PS
Grey Nurse Shark Recovery Plan	**Objective 7:** Improve understanding of the threat of pollution and disease to the grey nurse shark.	**Action 7.1:** Review and assess the potential threat of introduced species, pathogens and pollutants.	Refer **Section 6.8.7**. **Not inconsistent assessment:** This EP includes an assessment of the impacts from accidental release of solid wastes as well as planned discharges of drilling waste on marine species.	N/A
			Refer **Sections 6.7** and **6.8**. **Not inconsistent assessment:** The assessment of accidental release of chemicals / hydrocarbons has considered the potential risks to grey nurse sharks. Spill risk strategies and response program include management measures, as identified and required.	Refer **Sections 6.7** and **6.8**. Detailed oil spill preparedness and response performance outcomes, standards and measurement criteria for the Petroleum Activities Program are present in Appendix D.
Assessment Summary: The Grey Nurse Shark Recovery Plan has been considered during the assessment of impacts and risks, and the Petroleum Activities Program is not considered to be inconsistent with the relevant actions of this plan.				

Table 6-46: Assessment against relevant actions of the Sawfish and River Shark Recovery Plan

Part 13 Statutory Instrument	Relevant Action Areas/Objectives	Relevant Actions	Evaluation	EPO, Controls and PS
Sawfish and River Shark Recovery Plan	**Objective 5:** Reduce and, where possible, eliminate adverse impacts of habitat degradation and modification on sawfish and river shark species.	**Action 5c:** Identify risks to important sawfish and river shark habitat and measures needed to reduce those risks.	Refer **Sections 6.7** and **6.8**. **Not inconsistent assessment:** The assessment of accidental release of chemicals / hydrocarbons has considered the potential risks to sawfish and river shark. Spill risk strategies and response program include management measures, as identified and required.	Refer **Sections 6.7** and **6.8**. Detailed oil spill preparedness and response performance outcomes, standards and measurement criteria for the Petroleum Activities Program are presented in **Appendix D**.
	Objective 6: Reduce and, where possible, eliminate any adverse impacts of marine debris on sawfish and river shark species noting the linkages with the Threat Abatement Plan for the Impact of Marine Debris on Vertebrate Marine Life.	**Action 6a:** Assess the impacts of marine debris including ghost nets, fishing gear and plastics on sawfish and river shark species.	Refer **Section 6.8.7**. **Not inconsistent assessment:** The assessment of the accidental release of solid hazardous and non-hazardous wastes has considered the potential risks to sawfish. Controls have been implemented to reduce the likelihood of accidental release of solid wastes for the duration of the petroleum activities program.	N/A
Assessment Summary: The Sawfish and River Shark Recovery Plan has been considered during the assessment of impacts and risks, and the Petroleum Activities Program is not considered to be inconsistent with the relevant actions of this plan.				

Table 6-47: Assessment against relevant actions of the Marine Debris Threat Abatement Plan

Part 13 Statutory Instrument	Relevant Action Areas/Objectives	Relevant Actions	Evaluation	EPO, Controls and PS
Marine Debris TAP	**Objective 2:** Understand the scale of marine plastic and microplastic impact on key species, ecological communities and locations.	**Action 2.04:** Build understanding related to plastic and microplastic pollution.	Refer **Section 6.8.7**: **Not inconsistent assessment:** The assessment of the accidental release of solid hazardous and non-hazardous wastes has considered the potential risks to the marine environment. Controls have been implemented to reduce the likelihood of accidental release of solid wastes for the duration of the petroleum activities program.	N/A
Assessment Summary: The Marine Debris TAP has been considered during the assessment of impacts and risks, and the Petroleum Activities Program is not considered to be inconsistent with the relevant actions of this plan.				

6.10 Cultural Values and Heritage Values Assessment

As described in Section 4, the identification of cultural features and heritage values of the environment as well as the social, economic and cultural features important to First Nation's people is integral to understanding the environment and any potential impacts and risks to the environment.

In line with Woodside's First Nations Communities Policy (Woodside 2022), Woodside seeks to avoid damage or disturbance to cultural heritage (including intangible heritage) and, if avoidance is not possible, minimise and mitigate the impacts, in consultation with First Nation communities and Traditional Custodians. Mitigation can include any measure or control aimed at ensuring the viability of the intangible cultural heritage and its intergenerational transmission. This can include reducing impacts and risks to environmental features that are associated with intangible cultural heritage (UNESCO 2003; ICOMOS 2013).

It is important to note that not all topics raised by First Nations groups / individuals through consultation are considered values for the purpose of the cultural features and heritage values impact assessment below. A number of topics were raised in the context of a general interest in environmental management and ecosystem health (i.e., natural environment interest), where the group/individual was seeking further information about potential impacts and risks from the PAP on a receptor. As these interests relate to the maintenance of the natural environment, these are adequately addressed through impact and risk assessments described in Sections 6.6, 6.7 and 6.8 respectively and not further assessed below.

Aspect	Cultural Features and Heritage Values
Description of source impact/ risk (key aspects)	***Physical presence of vessels*** The PAP involves drilling LDA 02 and may also involve intervention or workover if required. The MODU will be present within the PAA for 50-60 days, including mobilisation, demobilisation and contingency. Installation of subsea infrastructure and pre-commissioning is anticipated to commence following drilling and is expected to have a cumulative duration of about four weeks (including mobilisation, demobilisation and contingency). When underway, activities will be 24 hours per day, seven days per week. Flowlines and subsea infrastructure will remain in place and be operated under this Operations EP. Safety exclusion zones will be established around the MODU and installation vessels. Refer to Section 6.6.1 for more details. ***Acoustic emissions from vessels*** MODUs, installation vessels and support vessels undertaking the PAP will generate noise both in the air and underwater, due to the operation of thrusters' engines, propeller movement, drilling operations, etc. During drilling operations, the MODU will produce low-intensity continuous sound. In addition, the PAP will be supported by a number of DP capable vessels including; installation and light well intervention vessels, and offshore support vessels (OSVs) used for standby and resupply services. These noises will contribute to and can exceed ambient noise levels which range from around 90 dB re 1 µPa (root square mean sound pressure level (RMS SPL)) under very calm, low wind conditions, to 120 dB re 1 µPa (RMS SPL) under windy conditions. Refer to Section 6.6.3 for more details. ***Unplanned hydrocarbon release from loss of well containment (basis of EMBA)*** Woodside has identified a well blowout from operating wells as the scenario with the worst-case credible environmental outcome as a result of loss of well containment. Well intervention and workover activities may also result in a loss of well containment. The EMBA is the largest spatial extent where unplanned events could have an environmental consequence on the surrounding environment. For this EP, the EMBA is the potential spatial extent of surface and in-water hydrocarbons at concentrations above ecological impact thresholds, in the highly unlikely event of the worst-case credible spill modelled at the well location. The EMBA therefore covers a larger area than the area that would be affected during any one single spill event. In the event of a spill the EMBA would be much smaller and is intermittent e.g., plume travels away from the release location based on prevailing currents and winds directions. The EMBA is driven by the distribution of entrained hydrocarbon above ecological thresholds and hence although Islands such as Barrow and Montebello Islands, and mainland coastlines are within the EMBA, these are not expected to be affected unless there is shoreline contact above thresholds. Refer to 6.7.3 for more details.

Planned Activity Aspect	*The potential environmental impact from the PAP to species that have a cultural feature or heritage value have been summarised below to provide the context related cumulative impact on the cultural feature or heritage value.*						
	Impact Significance Level

Impact and Risk Assessment

The PAP has the potential to impact cultural features and heritage values through the following ways:

Archaeological heritage:

Places that are identified in the literature for their value as archaeological sites can be assumed to be impacted where there is an impact to the archaeological or scientific values of its tangible elements. This could include damage or disturbance of archaeological material or to the archaeological context.

Intangible cultural heritage:

Songlines: Songlines can become lost, fragmented, or broken when there is a loss of Country or forced removal from Country (Neale and Kelly 2020:30). Physical sites that have been identified as comprising a component of a songline are important to protect to prevent the fragmenting or breaking apart of songlines and loss of sacred cultural knowledge. It is noted that oil and gas infrastructure exists in many areas of the North West Shelf, and that songlines are still acknowledged and recognised. It is inferred that if there were to be any impacts to surviving songlines these would be significantly more likely to be described as qualitative (i.e. “weaken” a songline) rather than binary or absolute (i.e. destroy a songline).

Creation/dreaming sites; sacred sites; ancestral beings: Activities that physically alter landscape features may be assumed to potentially impact values of creation/dreaming sites, sacred sites or ancestral beings.

Ceremonial sites: Activities that prevent the performance of ceremony at these sites will directly impact its values.

Cultural obligations to care for Country: Environmental impacts may be assumed to impact rights and obligations to care for Sea Country. Exclusion of Traditional Custodians from Sea Country (e.g., by restricting access) or decision-making processes (e.g., by not conducting ongoing consultation) are other potential sources of impact.

Knowledge of Country/customary law and transfer of knowledge: Direct impact to communities practicing these skills will inherently occur when relevant aspects of the environment disappear, are displaced or suffer a reduction in population. Therefore, the transmission of these skills is expected to be impacted where there are impacts at the species/population level. Limitations on access to sites or disruption/relocation of First Nations communities may have implications for the preservation of First Nations knowledge.

Connection to Country: Where people are displaced or disrupted (e.g., during colonisation) or where there is a loss of technical skills or environmental knowledge this may damage connection to Country (McDonald and Phillips, 2021).

Access to Country: Impacts to access to Country may be classified as temporary (e.g. where exclusion zones exist around activities for safety reasons) or permanent (e.g. where infrastructure obstructs access or navigation). Impacts to access to Country can only occur in areas that were traditionally accessed by Traditional Custodians. As described in Section 4.9.1 this is anticipated to be focussed on areas adjacent to the coast.

Kinship systems and totemic species: It is assumed that marine species may have kinship/totemic relationships to Traditional Custodians, but it is understood that these relationships do not prohibit people outside of that “skin group” from hunting or eating that same species (Juluwarlu 2004). It is therefore inferred that the management of totemic or kinship species applies at the species/population level and not to individual plants and animals.

Resource collection: Direct impact to communities using these resources will inherently occur when the resource disappears, is displaced or suffers a reduction in population. Therefore, marine species (as resources) will be impacted where there is an impact at the species/population level.

Marine ecosystems and species:

Marine ecosystems may hold both cultural and environmental value (see Section 4.9), with cultural and environmental values intrinsically linked (DCCEEW 2023, MAC 2021 as cited in Woodside 2023a). It necessarily follows that an impact to marine ecosystems has the potential to impact cultural features where the impact is detectable within sea country—the seascape which Traditional Custodians view, interact with or hold knowledge of.

Archaeological Heritage

Onshore / intertidal archaeological sites

No coastal areas or islands exist within the PAA. A review of the of DPLH’s Aboriginal Heritage Inquiry System identified Registered Aboriginal Sites and 2 Other Heritage Places in the EMBA. These Other Heritage Places do exist within the EMBA boundary, however given the EMBA is driven by an unplanned hydrocarbon release there is no anticipated impact pathway from this activity to onshore archaeological sites above highest astronomical tide (HAT).

Archaeological sites may exist in intertidal landscapes within the EMBA and may be exposed to hydrocarbon from an unplanned release, however there is no anticipated impact pathway from the

presence of hydrocarbons on archaeological values, as this is not expected to impact the fabric or context of sites on an exposed shoreline site. Impacts to the heritage value of fish traps from hydrocarbons in an unplanned release may occur indirectly through impacts to fish. However, it is expected that continued use of fish traps beyond their archaeological value will be preserved where fish species and distribution are maintained at a population level. With regard to fish, refer to species specific assessment below for further information, in addition to the impact and risk assessment in Sections 6.6, 6.7 and 6.8 respectively.

Submerged archaeological sites

No submerged archaeological sites have been identified beyond terrestrial or intertidal areas, with the exception of two sites at Murujuga in Cape Bruguieres channel and Flying Foam Passage (Benjamin et al. 2020; Benjamin et al 2023), which are outside of the EMBA. Nevertheless, there is the potential for submerged archaeological sites on the Ancient Landscape. Consultation with Traditional Custodians has not identified cultural information about potential submerged cultural heritage or associated intangible cultural elements in the PAA or EMBA. Publicly available literature (Kearney et al.) identified a potential connection between a songline and submerged waterholes but these lay outside of the PAA and EMBA. No known submerged archaeological sites are anticipated to be impacted by the activity.

Given that the PAA intersects part of the Ancient Landscape but also extends beyond the furthest extent of the Ancient Landscape, submerged archaeological sites (locations undefined) may exist on the Ancient Landscape within the PAA and broader EMBA (Leach 2020). An archaeological desktop review has been undertaken and no archaeological sites were identified (refer to Section 4.9). A desktop assessment of submerged archaeological heritage and landscape features will be undertaken in the PAA as an additional control, by a maritime archaeologist, prior to starting work in water depths <130m, to further inform the cultural environment within the PAA. New cultural information will be assessed as part of the Change Management Procedure and Revision process in the EP (Section 7.2.5). Unexpected finds of potential underwater cultural heritage will also be adopted as an additional control in order to appropriately manage unknown impacts and risks to submerged archaeological sites to a level that is acceptable and ALARP. Given the EMBA is driven by an unplanned hydrocarbon release potential impact to the seabed or archaeological material on or within it would be confined to a localised area in the immediate vicinity of the release and shoreline accumulation. .

Rivers, waterholes, tidal channels and seeps

Oceanographic studies indicate that both the open ocean and coastal zone off Western Australia are well-mixed and saline. Submerged former water sources (e.g. river beds) may exist within the EMBA which are archaeologically prospective or culturally significant.

It has been asserted in consultation that locations where saltwater and freshwater meet “are where the biggest energy lines are”. Energy lines are understood by Woodside to be the same as songlines which are addressed below. The EMBA is driven by an unplanned hydrocarbon release, potential impacts to the seabed or archaeological material on or within it would be confined to a localised area in the immediate vicinity of the release and shoreline accumulation. As such, impacts from this activity to submerged water sources in the broader EMBA are considered unlikely. In the highly unlikely and unmitigated worst case, unplanned hydrocarbons may contact shorelines and receptors such as mangroves, and shoreline habitats. These habitats may contain brackish or fresh water due to runoff from land. Given hydrocarbon characteristics and rapid weathering, an unplanned release is expected to have no lasting effect on any freshwater sources along the shoreline.

General Intangible values

Songlines

Management of intangible cultural heritage can include reducing impacts and risks to environmental features that are associated with intangible cultural heritage (UNESCO 2003; ICOMOS 2013). Impacts to marine plants, animals and other cultural features associated with songlines might impact the intergenerational transmission of knowledge of songlines when individuals can no longer witness or interact with the cultural features tied to songlines on Country. Therefore, managing songlines may require environmental controls protecting species at a population level, including migratory routes. Refer to species specific assessment below for further information, in addition to the impact and risk assessment in Sections 6.6, 6.7 and 6.8 respectively.

Physical features comprising a component of a songline are important to protect to prevent the fragmenting or breaking apart of songlines and loss of sacred cultural knowledge. Songlines can become lost, fragmented, or broken when there is a loss of Country or impact to culturally important physical features (Neale and Kelly 2020:30). No specific details of songlines within the EMBA have been provided by relevant persons during consultation for this Activity, and no landforms typical of songlines (e.g. mountains, rivers, caves and hills (Higgins 2021)) are anticipated to be impacted by the Activity.

In publicly available literature, Murujuga is acknowledged as a starting point for songlines, including the flying fox songline (MAC 2023a). Precise location of this songline, and features of this songline that might be impacted, are not clearly articulated in the reviewed sources, but it is stated that "the sea is a source of creation for flying foxes" (DEC 2013). Although this does not provide the specificity required to determine the location of the flying fox songline or associated sites. Consultation with MAC and other Traditional custodians has not identified the flying fox songline as overlapping the EMBA, and flying foxes do not occur within the EMBA.

Kearney et al (2023) notes a connection between the Kangaroo songline and a pair of submerged waterholes identified through seabed mapping by the Deep History of Sea Country project, which later found submerged artefacts in Flying Foam passage. Noted that due to the water depth it is not expected that active or former freshwater sources that may connect to the Kangaroo or other songlines would be within the PAA. Consultation with MAC and other Traditional Custodians has not identified these songlines as overlapping the EMBA, and these species do not occur within the EMBA.

In publicly available literature, Murujuga is acknowledged as the starting point for the Seven Sisters songline (Bainger 2021). Precise location of this songline, and features of this songline that might be impacted, are not clearly articulated in the reviewed sources. Consultation with MAC and other Traditional Custodians has not identified the Seven Sisters songline as overlapping the PAA or EMBA.

While the presence of songlines are generally raised in the literature across several relevant communities, no specific details have been identified. The literature review has also identified culturally important features, which are known to be commonly associated with songlines (e.g. marine species and landforms; Section 4.9), and these have been separately assessed in this section. Further assessment of intangible values and marine species are provided below, in addition to the impact and risk assessment in Sections 6.6, 6.7 and 6.8 respectively.

Creation/dreaming sites; sacred sites; ancestral beings

Woodside has undertaken all reasonable steps to identify creation and dreaming sites, and places associated with ancestral beings within the EMBA. No such sites have been identified. Consultation with KAC has identified the presence of spiritual beings including belief in 'Yinta' that is associated with Sea Country but no further detail was specified and consultation has not identified the presence of Yinta as overlapping the EMBA. A review of relevant literature has been undertaken which has identified creation, dreaming and ancestral narratives related to the sea more broadly without confirming where (if anywhere) these overlap the EMBA (see Section 4.9.1.6.2). These references are of a general nature, and do not identify any features or values requiring specific protection or management from the proposed activities.

Sea serpents or water serpents are common in Aboriginal creation narratives, and several references were identified in the reviewed literature. The majority of these refer to serpents residing within inland rivers or pools outside of the EMBA (Barber and Jackson 2011, Hayes v Western Australia [2008] FCA 1487, Water Corporation 2019, Zaunmayr 2016). In some versions, the serpent originates from the sea or coast and creates the rivers as it heads inland. Barber and Jackson (2011) also recount a story where a freshwater serpent pushes a sea serpent back into the ocean where it presumably continues to reside. This does not provide the specificity required to determine the location of sea serpents within the sea, and it is possible that the ocean as a whole (out to and beyond other continents) should be viewed generally as housing the sea serpent(s). Consultation with Traditional Custodians have not identified activities of this PAP as having an impact on sea serpents. However, by analogy to other water serpent narratives across Australia, possible impact pathways may include interruption of its path by blocking or reducing flows of water, damaging sacred sites such as thalu or rock art sites or depleting water sources. While there is potential for shoreline accumulation of hydrocarbons within the EMBA, relevant cultural authorities will be engaged in the event of a release that may affect them, as specified in **Appendix H.**

No impacts to water flows (either tidal movement or ocean currents) or depletion of water sources are anticipated from this PAP. Features of the landscape with the potential for connection to creation/dreaming stories and ancestral beings may exist on the Ancient Landscape. Given the EMBA is designed around an unplanned hydrocarbon release, potential impacts to the seabed or archaeological material on or within it would be confined to a localised area in the immediate vicinity of the release and shoreline accumulation. Desktop assessments will be undertaken to further inform the cultural environment in Section 4.9 including submerged cultural features and Change Management Procedure (Section 7.2.5) applied if new information is assessed to impact creation/dreaming stories and ancestral beings located on the Ancient Landscape.

Ceremonial sites

All mentions of active ceremonial sites were confined to onshore locations and no direct impacts to onshore ceremonial sites are anticipated from the PAP. However, indirect impacts may occur where ceremonies cannot be performed due to limitations on access, loss of knowledge or impacts to the environment, which are further described below.

Cultural obligations to care for Country

Caring for Country collectively refers to the cultural obligations of individuals and groups, as well as rituals and ceremonies required for the physical and spiritual health of the environment. Lack of access to coastally located cultural sites that carry songlines or remain ceremonially important can impact First Nations people's livelihoods and impact their ability to carry out cultural obligations on Country. While there is potential for shoreline accumulation of hydrocarbons within the EMBA, relevant cultural authorities will be engaged in the event of a spill that may affect them, as specified in **Appendix H.**

Knowledge of Country/ customary law and transfer of knowledge

Cultural knowledge about Sea Country/customary law and the intergenerational transmission of knowledge are important values identified through consultation, assessments and the literature review.

Transfer of knowledge includes continuing traditional practices to pass on practical skills. Direct impact to communities practicing these skills will inherently occur when relevant aspects of the environment disappear, are displaced or suffer a reduction in population—for example traditional fishing methods require the survival of traditional fish resources. Therefore, ensuring the transmission of cultural knowledge may require environmental controls protecting species and migratory pathways at a population level. Refer to species specific assessment below for further information, in addition to the impact and risk assessment in Sections 6.6, 6.7 and 6.8 respectively.

Connection to Country

Connection to Country describes the multi-faceted relationship between First Nations people and the landscape, which is envisioned as having personhood and spirit. Connection to Country may be damaged where people are displaced or disrupted (e.g. during colonisation) or where there is a loss of technical skills or environmental knowledge (McDonald and Phillips, 2021). No impacts of this nature are considered to arise from this PAP. Access to Country is discussed below.

Access to Country

Access to Country, including Sea Country, is necessary for the continuation of other values including caring for Country and the transfer of traditional knowledge. Access is also a value in its own right, as a continuation of traditional Sea Country access and use.

Access to areas within the PAP may be limited where exclusion zones are established around vessels for safety purposes. However due to the location offshore this is not expected to impact on Access to Country. Access to Country within the EMBA would be limited to temporary exclusion in areas where there are hydrocarbons present, including shoreline accumulation. However relevant cultural authorities will be engaged in the event of a release that may affect them, as specified in **Appendix H.**

Kinship systems and totemic species

Individuals may have kinship to specific species (Smyth 2008, Juluwarlu 2004) and/or a responsibility to care for species (Muller 2008). KAC, through consultation, identified secret habitat totems but no further detail or locations were identified. Regarding this EP, KAC did not identify any secret habitat totems overlapping the PAP or EMBA. Kinship relationships are understood to impose obligations on Traditional Custodians. It is understood that these obligations do not impose restrictions on other people generally, but it is considered that impacts to species at a population level may inhibit Traditional Custodians with kinship relationships' ability to perform their obligations where this results in reduced or displaced populations. It is therefore considered that the management of totemic or kinship species applies at the species/population level and not to individual plants and animals. As such, impacts to individual marine fauna is not expected to impact on the totemic or kinship cultural connection.

Totemic species identified during consultation include whales, fish, stingrays and octopuses. Refer to species specific assessment below for further information, in addition to the impact and risk assessment in **Sections 6.6, 6.7 and 6.8** respectively. In the highly unlikely event of a hydrocarbon release relevant cultural authorities will be engaged in the event of a release that may affect them, as specified in **Appendix H**.

Resource collection

A suite of marine species have been identified through consultation and literature as important resources, particularly as food sources. For example, Sea Country resources of noted relevance to Thalanyji people which may be present in the vicinity of the Montebello Islands include dugongs, majun (marine turtles), turtle eggs, fish and shellfish. Other resource species include marine mammals, fish, molluscs including bivalves, gastropods and cephalopods and seabirds, sea urchins and mangrove seeds.

In addition to their immediate value as sustenance, the gathering and preparation of these resources are informed by cultural knowledge, and an inability to use these resources may result in a loss of ability to transfer that knowledge to future generations. Direct impact to communities using these

resources will inherently occur when the resource disappears, is displaced or suffers a reduction in population. Therefore, these communities may be impacted where there is an impact at the species/population level.

As assessed in Section 6.6, impacts from planned activities on the marine environment, including resources important to First Nations people, is expected to be limited to negligible or slight and therefore impacts that result in population effects (e.g., population decline, changes in migration routes, etc) are not expected. Impacts to potential resources within the EMBA, in the highly unlikely event of hydrocarbon release, are described and risk assessed in Sections 6.7 and 6.8 but are not expected to result in species / population level impacts. There may be potential impacts to resource collection along the coastlines where there is shoreline accumulation of hydrocarbons. Given hydrocarbon characteristic and rapid weathering an unplanned release is not expected to have a substantial adverse impact resulting in population level changes. Therefore, impacts to resource collection would be limited to temporary exclusion in areas where there are hydrocarbons present, including shoreline accumulation. Further relevant cultural authorities will be engaged in the event of a release that may affect them, as specified in **Appendix H**.

Marine Ecosystems and Species

Marine mammals (whale, dolphins, dugongs)

There are increase ceremonies / rituals for species of animals and plants important to First Nations, to enhance or maintain populations. Thalu are places where these increase ceremonies are performed. All mentions of active ceremonial sites in the reviewed literature were confined to onshore locations, though the values may extend offshore where, for example, the thalu relates to marine species populations. As thalu ceremonies are performed to maintain and increase populations of marine species, it is inferred that management applies at the species/population level and not to individuals. Reviewed literature (Deloitte 2020) also includes information that is marked as information that cannot be copied, reproduced or used without consent. The values described in the literature are environmental in nature, apply to marine mammal behaviours at a population level and are managed through existing environmental controls in **Sections 6.6.3, 6.6.4, 6.7.3 and 6.8.9.**

Related intangible cultural heritage may include the transmission of cultural knowledge about whales and whale behaviour, including birthing areas, whale communication and migratory patterns. Such cultural knowledge may be associated with various cultural functions and activities that support the social and economic life of a community (Fijn 2021). Whale symbology expressed through stories, music, and dance can reflect a group's connections with the sea, as well as marine fauna, which then comprise a group's cultural values (Ardler 2021; Bursill et al. 2007; Cressey 1998). Whales also speak to a broader connection that exists between First Nation people and their surrounding environment. Beyond mythology and symbolism, whales can be connected with various economic and social functions associated with everyday life. Cultural knowledge of whales, whale migration, behaviour and the related marine environment may all be important in ensuring the continuation of these socio-economic functions and other related activities that remain valuable to First Nations people (Fijn 2021). No impacts to communities' ability to perform or transmit stories, music or dance are anticipated from the PAP. Where timing or performance is linked to sighting or engaging with these species, impacts may occur where numbers or migration behaviours are impacted at a population level.

First Nations groups have expressed interest about whale migratory routes and studies. Inter-generational transmission of cultural knowledge (including songlines) relating to marine mammals may be impacted where changes to population or behaviour at a population level results in reduced sightings (e.g. through population decline, changes to migration routes or changes to migration seasonality). This transfer of knowledge may be integral to managing a group's intangible cultural heritage (UNESCO 2003).

As described in the relevant environmental impact assessments in Section 6.6, potential impacts to cetaceans from planned activities are limited to behavioural impact, which may include temporary and localised deviations from migratory pathways for cetaceans. However, no permanent impacts preventing cetaceans from entering or occupying the areas have been identified. These impacts and risks are not considered to be ecologically significant at a population level, and hence are not expected to impact the value of marine mammals, including the transmission of cultural knowledge. As such, cultural values and intangible cultural heritage associated with these species are expected to be maintained.

Marine reptiles (turtles, sea snakes, crocodiles)

Turtles and crocodiles have been identified through consultation and existing literature as an important resource, particularly as food sources. Direct impact to communities using these resources will inherently occur when the resource disappears, is displaced or suffers a reduction in population. Therefore, these species (as resources) will be impacted where there is an impact at the species/population level.

Intangible cultural heritage may also include the transmission of cultural knowledge about marine reptiles, such as nesting areas, hunting areas and migratory patterns. Cultural knowledge may also be conveyed through stories, such as the turtle being trapped in the sea as a result of its greed for berries as recounted by Capewell (2020). Such cultural knowledge may be associated with various cultural functions and activities that support the social and economic life of a community (Fijn 2021). First Nations groups have expressed an interest regarding turtle monitoring programs and migration patterns. Activities that impact turtle / crocodile populations and their marine environment may have an indirect impact on some Aboriginal communities as this can limit access to cultural sites or deplete hunting areas that would threaten local food security (Dortch et al. 2019, Delisle et al. 2018:251). Inter-generational transmission of cultural knowledge (including songlines) relating to marine reptiles may be impacted where changes to population or behaviour results in reduced sightings (e.g. through population decline, changes to migration routes or changes to migration seasonality). This transfer of knowledge may be integral to managing a group's intangible cultural heritage (UNESCO 2003).

As described in the relevant environmental impact assessments in Section 6.6 potential impacts to marine reptiles from planned activities are likely to be restricted to temporary behavioural changes, which are not considered to be ecologically significant at a population level, and hence not expected to impact the value of marine reptiles, including the transmission of cultural knowledge or use as a resource. As such, cultural values and intangible cultural heritage associated with these species are expected to be maintained.

Fish and Cephalopods

Fish and squid have been identified through consultation and existing literature as an important resource, particularly as food sources. Direct impact to communities using these resources will inherently occur when the resource disappears, is displaced or suffers a reduction in population. Therefore these species (as resources) will be impacted where there is an impact at the species/population level.

Through consultation, fish were identified as important agents in the management of the broader ecosystem. It may be assumed that inter-generational transmission of cultural knowledge relating to fish may be impacted where changes to population or behaviour results in reduced sightings (e.g. through population decline). In addition, MIAC (2019) identified whale sharks as a culturally important species associated with stories which describe them as guardians of the sea. This transfer of knowledge may be integral to managing a group's intangible cultural heritage (UNESCO 2003). Intangible cultural heritage associated with fish and whale sharks, including inter-generational knowledge regarding fishing techniques and migratory patterns, can be managed by reducing impacts to fish in nearshore marine environments to which this cultural knowledge is intrinsically connected.

The octopus is an important totem to Ngarla People and features in the creation story of Solitary Island. There are increase ceremonies / rituals for species of squid and octopus to enhance or maintain populations. Thalu are places where these increase ceremonies are performed. All mentions of active ceremonial sites in the reviewed literature were confined to onshore locations, though the values may extend offshore where, for example, the thalu relates to marine species populations. As thalu ceremonies are preformed to maintain and increase populations of marine species, it is inferred that management applies at the species/population level and not to individuals.

As described in the relevant environmental impact assessment in Section 6.6, the potential impacts from planned activities on fish[108] are considered to be localised and with slight, short-term (<1-year) impact potential on species (or lower), but not affecting ecosystem function, physical or biological attributes. Impact potential is not considered to be ecologically significant at a population level. As such, cultural values and intangible cultural heritage associated with these species are expected to be maintained.

Seabirds

Seabirds, specifically shags, have been identified through literature as a culturally significant species (Malgana Land and Sea Management et al. 2021), as well as a resource (seabird eggs; Smyth 2007). Direct impact to communities using these resources will inherently occur when the resource disappears, is displaced or suffers a reduction in population. Therefore, these species (as resources) will be impacted where there is an impact at the species/population level. Intangible cultural heritage may also include the transmission of cultural knowledge about seabirds, such as nesting areas, hunting areas and migratory patterns. Such cultural knowledge may be associated with various cultural functions and activities that support the social and economic life of a community (Fijn 2021) Inter-generational transmission of cultural knowledge relating to seabirds may be impacted where changes to population or behaviour results in reduced sightings (e.g. through population decline, changes to migration routes or changes to migration seasonality). This transfer of knowledge may be integral to managing a group's intangible cultural heritage (UNESCO 2003).

[108] Squid and octopus are considered to be impacted through similar impact pathways as fish, and hence the conclusion represented here are considered appropriate for cephalopods.

As described in the relevant environmental impact assessments in Section 6.6 the potential impacts from planned activities on seabirds is limited to slight. The potential for temporary behavioural disturbance localised around vessels from light is not expected to result in a substantial adverse effect on species' population, and light emissions will not seriously disrupt the lifecycle of an ecologically significant proportion any migratory bird species. In terms of risk, as described in Section 6.7.3 a change in marine fauna behaviour or injury/mortality to seabirds and migratory shorebirds may occur due to hydrocarbon contact as well as a change in water or sediment quality following an unplanned hydrocarbon release. Given hydrocarbon characteristics, expected rapid weathering to below impact thresholds, and the mobile transient nature of individuals, unplanned hydrocarbon releases are not expected to substantially modify important habitat for migratory species. As such, cultural values and intangible cultural heritage associated with these species are expected to be maintained.

Benthic habitats (coral, seagrass)

Benthic habits are important environments that house marine fauna that may be considered to be culturally important, including corals attracting fish and seagrass providing shelters for fauna, as well as serving as an important habitat for dugongs. Through consultation, no First Nations group identified benthic habitats as valuable for their ecological values. The reviewed literature similarly did not reveal any new cultural values, features or interests related to benthic habitats for the relevant First Nations groups.

There is no overlap between the PAA and coral / seagrass habitats as water depth is more than 120 m, and no planned impacts to coral / seagrass habitats from planned activities.

In terms of risk, as described in Section 6.7.3, a change in habitat may occur following an unplanned hydrocarbon release. In the unlikely event of a hydrocarbon release may result in large-scale impacts to coral reefs within the EMBA, particularly at the Montebello and Muiron Islands. Potential impacts to benthic habitats are managed by controls listed in Sections 6.6,6.7 and 6.8. Relevant cultural authorities will be engaged in the event of a release that may affect them, as specified in **Appendix. H.**

Shoreline Habitats (mangroves / salt marshes)

Through consultation, First Nations groups identified shoreline habitats as valuable for their ecological values, including mangroves for providing shelter to marine invertebrates, which are identified resources, and potential nursery for turtles. Literature also notes that mangroves are also valued for the flora and fauna they are associated with and support (Commonwealth of Australia 2002) and Smyth (2007) reports that mangrove seeds are used as a resource by Ngarda-Ngarli.

There is no overlap between the PAA and mangrove / salt marsh habitat, and no planned impacts to mangroves from the PAP.

In terms of risk, as described in Section 6.7.3 a change in habitat may occur due to a change in water or sediment quality following an unplanned hydrocarbon release. Given hydrocarbon characteristics, rapid weathering, as well as the response strategies planned to be deployed an unplanned release may result in localised impacts to mangroves and saltmarshes . As such, cultural values and intangible cultural heritage associated with shoreline habitats are expected to be maintained.

Marine Park / coastal reserves

A number of marine parks and coastal reserves (e.g. Ningaloo Coastal Reserve) are jointly managed with First Nation groups. The groups are responsible for sharing management decisions and also for sharing in the overall responsibility of making sure the marine park fulfils its purpose.

There is no overlap between the PAA and any marine parks.

In terms of risk, as described in Sections 6.7 and 6.8, shoreline accumulation may occur in some of these marine parks. The relevant cultural authorities will be engaged in the event of a release that may affect them, as specified in Appendix H.

Conclusion

The impact and risk assessment for cultural features and heritage values has determined that the planned activities are unlikely to result in an impact greater than negligible (F). The highest risk is to coral from the unlikely event of an unplanned hydrocarbon release from operating wells.

ALARP Demonstration	*As marine ecosystems may hold both cultural and environmental value (see Section 4.9), with cultural and environmental values intrinsically linked, in addition to the specific controls for cultural features and heritage values, the controls and performance standards in sections 6.6, 6.7 and 6.8 will reduce impacts to cultural features and heritage values, including marine species and habitats.*				
	Control considered	Feasibility (F) & Cost/	Benefit in Impact/Risk Reduction	Proportionality	Adopted

		Sacrifice (Cs)			
	Apply a 'living heritage[109] management approach. Woodside seeks advice and incorporates Traditional Custodian cultural knowledges across our activities. Cultural safety considerations are factored for our workforce and the Traditional Custodian community.	F: Yes CS: Minimal	Implementation of the 'living heritage' approach pays acknowledgement and respect to Traditional Custodian communities. It supports the transfer of cultural knowledges and is an effective strategy to manage intangible cultural values.	Benefits outweigh cost/ sacrifice.	Yes C 30.1
	Project inductions to all relevant marine crew, prior to the individual commencing the activity, will include information on cultural features and heritage values, including tangible and intangible cultural heritage.	F: Yes CS: Minimal	Ensures workforce is suitably aware of cultural features and heritage values in the area they are operating.	Benefits outweigh cost/ sacrifice.	Yes C 30.2
	Should it be identified that relevant cultural authorities may be affected in the unlikely event of a spill, Woodside will engage with those parties as appropriate and in alignment with the FSP.	F: Yes CS: Minimal	Engaging with relevant cultural authorities that may be impacted by a spill will allow the Traditional Custodians to identify areas of concern.	Benefits outweigh cost/sacrifice	Yes Adopted, see Appendix H
	Review of existing survey data by a suitably qualified maritime archaeologist to inform areas for laydown and/or installation of equipment to avoid or where not possible, minimise physical impacts to cultural heritage areas or prospective areas.	F: Yes. CS: Cost of paying an external consultant to undertake a desktop assessment.	Review of data by suitably qualified maritime archaeologist will inform potential exclusion or avoidance areas for seabed disturbance. Implementing this process will protect and minimise any physical impacts to underwater cultural heritage.	Benefits outweigh cost/ sacrifice.	Yes **C 3.1**

[109] Living heritage supports community and individual identity. Intangible cultural heritage is 'living heritage' that is inherited from ancestors and passed on to their descendants. It is comprised of many influences, including oral traditions, art, social practices, rituals and ceremonies, cultural knowledge and practices. It is transmitted from generation to generation, and evolves in response to the environment. Woodside applies a 'living heritage' approach to its cultural heritage management. This includes ensuring that Traditional Custodians are given voice to identify interests, transmit information and express concerns. Woodside works with Traditional Custodians to support and follow appropriate cultural protocols, including calling to Country, conducting smoking ceremonies (in areas where this custom is appropriate) and undertaking cultural awareness. Woodside will collaborate and provide relevant information it holds to groups such as Heritage Management Committees where they are established.

			Additionally, this process is not inconsistent with the draft guidelines for working in the near and offshore environment to protect Underwater Cultural Heritage (DCCEEW, 2023).		
	Unexpected finds of potential Underwater Cultural Heritage[110] sites/features, including First Nations UCH are managed in accordance with the Unexpected Finds Procedure set out in **Section 7.6**	F: Yes CS: Costs of implementation	Allows management of Unexpected Finds in accordance with legislative requirements, (including *Underwater Cultural Heritage Guidance for Offshore Developments and the DRAFT Guidelines to Protect Underwater Cultural Heritage under the Underwater Cultural Heritage Act 2018* (Cth) (UCH Act), expert advice and community expectations	Benefits outweigh cost/sacrifice.	Yes **C 3.2**
	Report any potential UCH finds to relevant stakeholders and authorities in accordance with the Unexpected Finds Procedure, UCH Act and the *ATSIHP Act*.	F: Yes CS: Minimal costs associated with reporting process.	Meets legislative requirements and community expectations.	Benefits outweigh cost/sacrifice.	Yes **C 3.3**
	Relevant vessel crew and ROV operators will be advised in an induction of the potential to encounter UCH and requirement to follow the Unexpected Finds Procedure (**C 3.2**).	F: Yes. CS: Minimal cost.	Ensures workforce are suitably aware of legal and process requirements for managing cultural features and heritage values.	Benefits outweigh cost/sacrifice.	Yes **C 3.4**
ALARP Statement	On the basis of the impact and risk assessment outcomes and use of the relevant tools appropriate to the decision type (i.e. Decision Type A, Section 2.6.1), Woodside considers the adopted controls appropriate to manage the potential impacts and risks to cultural features and heritage values. As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts are considered ALARP.				
Acceptability Statement	The impact and risk assessment has determined that planned activities are unlikely to result in an impact greater than negligible. Impacts to corals from an unplanned loss of well containment has been evaluated as having a 'high' risk rating. As per Section 2.6.3, 'high' (A1) risk ratings are considered acceptable if ALARP is demonstrated using good industry practice, company and societal values and risk based analysis are considered, if legislative requirements are met and societal concerns are				

[110] Underwater Cultural Heritage is defined as any trace of human existence that has a cultural, historical or archaeological character and is located under water, in accordance with the UCH Act.

accounted for, and the alternative control measures are grossly disproportionate to the benefit gained. Refer to section 6.7.3 for a detailed description of acceptability.

The PAP and the EMBA are not expected to have a significant impact (e.g. changes in population levels) on MNES including marine fauna with a First Nations connection with, or traditional use in nearshore areas as defined in **Section 4.9**. While the EMBA may overlap the Ancient Landscape impacts are predicted to be localised in the release area with the majority of hydrocarbons expected to remain within the upper water column. While the PAA overlaps the Ancient Landscape, Woodside has:

- consulted with Traditional Owners to identify concerns associated with activities of this EP in Commonwealth waters and none were identified, including no concerns raised over the PAA overlap on the Ancient Landscape (see **Appendix F, Table 2**).
- implemented additional controls **(C 30.1)** and performance standards (**30.1.1**) into the EP to further manage potential risks and impacts to cultural heritage.
- undertaken an archaeological desktop review (refer to **Section 4.9** and **C 3.1**) and implemented an unexpected finds procedure **(C 3.2).** Prior to starting work in water depths <130m, a desktop assessment will be undertaken by a suitably qualified marine archaeologist using existing survey data, to identify known or potential underwater cultural heritage in parts of the PAA. Therefore, the activity is not inconsistent with *Underwater Cultural Heritage Guidance for Offshore Developments* and the *DRAFT Guidelines to Protect Underwater Cultural Heritage* under the *UCH* Act.

In addition, Woodside has engaged with Traditional Custodians adjacent to the EMBA to understand the cultural features and heritage values that may occur and potential impacts from the activity. In the event of an unplanned loss of hydrocarbons Woodside has committed to engaging with relevant cultural authorities that may be affect (**Appendix H**).

Further opportunities to reduce the impacts have been investigated above. The potential impacts and risks are considered acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the impacts and risks to cultural features and heritage values to a level that is acceptable, if ALARP.

Key Environmental Performance Outcomes, Standards and Measurement Criteria related to Cultural Features and Heritage Values[111]

EPO	Adopted Control(s)	EPS	MC
EPO 30 No impact to cultural features and heritage values, as stated in Table 4-21, greater than a consequence level of F from planned activities.	**C 30.1** Apply a 'living heritage management approach. Woodside seeks advice and incorporates Traditional Custodian cultural knowledge across our activities. Cultural safety considerations are factored for our workforce and the Traditional Custodian community.	**PS 30.1.1** Woodside will continue to give voice to Traditional Custodians to identify interests, transmit information and express concern.	**MC 30.1.1** Records demonstrate Change Management and Management of Knowledge processes have been followed where new controls or management measures identified.
		PS 30.1.2 Woodside will assess and where deemed practicable will implement appropriate cultural protocols where requested by Traditional Custodians.	**MC 30.1.2** Records demonstrate Woodside implemented cultural protocols as requested.
	C 30.2 Project inductions to all relevant marine crew, prior to the individual commencing the activity, will include information on cultural features and heritage values,	**C 30.2.1** All relevant marine crew have completed Project inductions that include information on cultural values, including tangible	**MC 30.2.1** Records demonstrate all relevant marine crew have completed inductions that include cultural material.

[111] As marine ecosystems may hold both cultural and environmental value (see Section 4.9), with cultural and environmental values intrinsically linked, in addition to the specific controls for cultural features and heritage values, the controls and performance standards in Section 6.6, 6.7 and 6.8 will reduce impacts to cultural features and heritage values including marine species and habitats.

	including tangible and intangible cultural heritage.	and intangible cultural heritage for awareness.

7 IMPLEMENTATION STRATEGY

7.1 Overview

Regulation 22 of the Environment Regulations requires an EP to contain an implementation strategy for the activity. The implementation strategy for the Petroleum Activities Program confirms fit-for-purpose systems, practices and procedures are in place to direct, review and manage the activities so that environmental risks and impacts are continually being reduced to ALARP and are acceptable, and that EPOs and EPSs outlined in this EP are achieved.

Woodside, as Operator, is responsible for ensuring that the Petroleum Activities Program is managed in accordance with this Implementation Strategy and the WMS (see **Section 1.8**).

7.2 Systems, Practice and Procedures

All operational activities are planned and carried out in accordance with relevant legislation and internal environment standards, management measures (i.e., controls) identified in this EP and internal environment standards and procedures (**Section 6**).

The systems, practices and procedures that are implemented are listed in the Performance Standards (PS) contained in this EP. Document names and reference numbers may be subject to change during the statutory duration of this EP and is managed through a Change Register and update process.

7.2.1 Woodside Management System Operate Processes

Under the WMS Operate Activity (see **Section 1.8** for an overview of the WMS), there are four overarching processes; those directly relevant to the implementation of this EP and environmental management during the Petroleum Activities Program are described below (Operate Plant Process and the Maintain Assets Process).

7.2.1.1 Operate Plant

The objective of the Operate Plant Process is to ensure production is carried out in a safe, efficient, reliable and economic manner, and that all required process variables are within allowable limits. This ensures the potential for unplanned (accident/incident) events that may impact the environment are minimised.

The Operate Plant Process develops key activities to support ongoing production activities to ensure the facility is operated within the Basis of Design. The process also identifies required production routines, routine execution, recording of data gathered and formulation of remedial activities. The Operate Plant Process includes the Integrated Safe System of Work (ISSoW) system (described below).

In addition, the Operating Practice MSPS (M02) is in place to assure operating practices are in place, such that:

- integrity critical operating procedures are available, accurate, up to date, understood and used
- safe operating and technical integrity limits are defined, understood and the process is managed within these limits.

7.2.1.2 Integrated Safe System of Work

The ISSoW Procedure outlines the key activities required to achieve effective management of permit-controlled work on the facility. The ISSoW process is a management system for all work and is a key element in ensuring the safety of personnel, protection of the environment and technical integrity of the facility.

Work within the facility 500 m PSZ and operations within the vicinity of the connected flowlines is controlled in accordance with ISSoW.

The ISSoW system takes a risk-based approach to activities, thus tasks with higher levels of risk are subjected to greater scrutiny and control. The ISSoW system also allows for low risk routine tasks to be carried out with adequate but minimal administration. The prime objective of ISSoW is to ensure work other than normal operations is properly planned, risk assessed, controlled, coordinated, and safely executed. It provides a methodical approach to identifying hazards, assessing risks, and creating and supporting permits to work and associated certificates.

In keeping with ALARP principles, this system is critical to ensuring the appropriate level of hazard identification and risk assessment is carried out for activities performed on the facility.

In addition, the Safe Work Control MSPS (M04) is in place to assure effective safe work control, permit to work and task risk management arrangements are in place and followed to control the risks arising from work activities.

7.2.1.3 Maintain Assets

The Maintain Assets Process aims to improve the reliability and availability of plant and equipment (which includes that required for safe operation) through well managed and planned execution of maintenance that promotes a proactive maintenance culture.

Maintenance, inspection and testing systems and procedures are in place to safeguard the integrity of the facility. The maintenance strategy for the facility is based on optimising safety, minimising environmental impact and maximising production. Maintenance practices used to establish well managed maintenances strategies, planned execution and improvement are described in the Maintenance of Assets Procedure.

A risk-based approach is used as the basis for establishing and prioritising inspection, maintenance and testing requirements at the facility. Equipment is assessed to establish equipment criticality with respect to the consequences and likelihood of equipment failure. This informs determination of appropriate maintenance and inspection activities. Maintenance activities are allocated risk rankings according to the criticality of equipment, to ensure high risk maintenance work orders are completed as a priority.

A computerised maintenance management system (CMMS) provides a database called SAP-PM that contains facility registers, equipment details, spare parts data and associated planned maintenance tasks. This system is used to plan, monitor and record maintenance activities. The system provides a variety of reports that enable monitoring and assessment of maintenance activities.

SCE Technical Performance Standards identify SCEs and associated assurance activities. These activities are identified in the CMMS and given the appropriate priority (Technical Integrity status). Refer to **Sections 2.7.5** and **7.2.6** for more detail on SCE Technical Performance Standards and how they differ from EPSs required by the Environment Regulations. SCE Technical Performance Standards form a key component in the processes and systems implemented by Woodside to maintain safety and environment critical plant and equipment.

In addition, the Maintenance and Inspection MSPS (M03) is in place to assure that the necessary inspection and maintenance requirements are identified and carried out to maintain the integrity of SCEs and SCQs.

7.2.2 Process Safety Management

To ensure that Woodside protects the safety, security and health of its employees, contractors, the environment and assets, Woodside has adopted the Energy Institute's Process Safety Management (PSM) framework within its Process Safety Management Procedure which sets out a disciplined framework for managing the integrity of systems and processes that handle hazardous substances

over the production (and exploration) lifecycle. It deals with the prevention and control of events that have potential to release hazardous materials and energy.

PSM consists of four main focus areas. Each focus area contains a number of PSM requirements that define key aspects required to ensure that PSM is integrated through the organisation. There are twenty PSM requirements. The focus areas and requirements are shown in **Figure 7-1**.

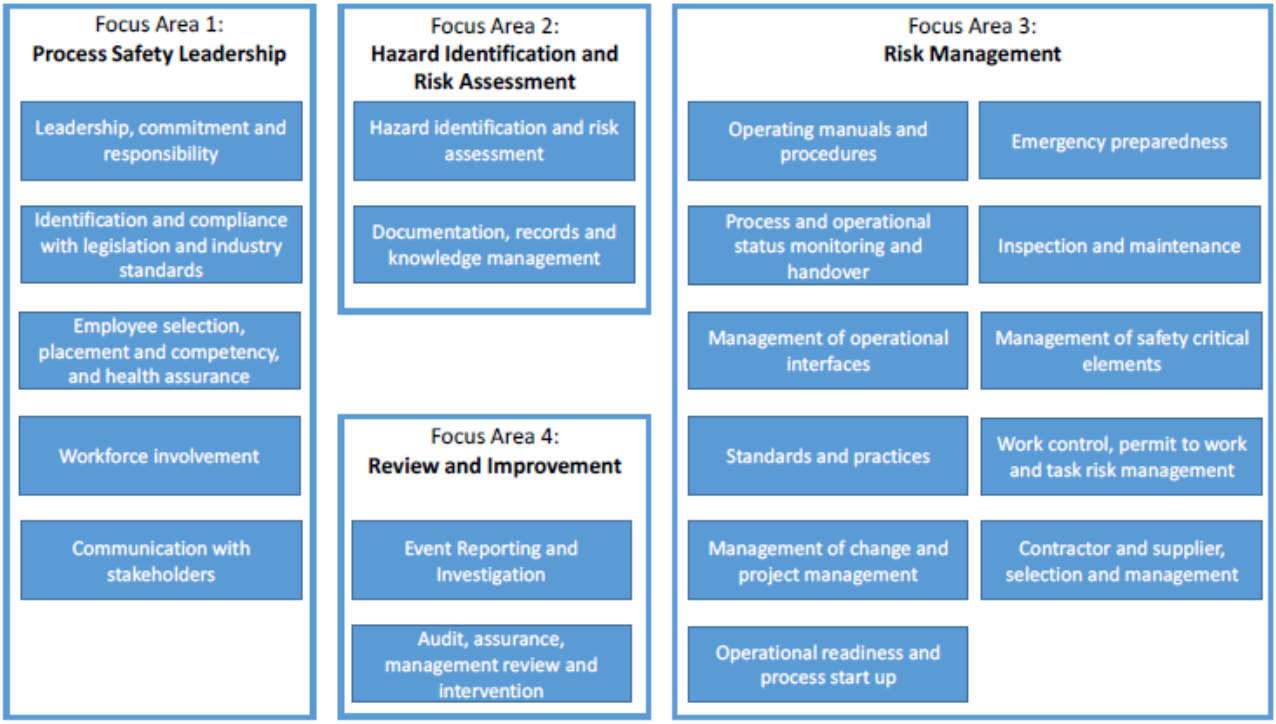

Figure 7-1: Process safety management focus area

7.2.2.1 Woodside Safety Culture Framework

Woodside's 'Our Safety Culture' framework (shown in **Figure 7-2**) promotes a strong HSE culture and is a key enabler for effective process safety management. This framework outlines the expected behaviours for everyone including supervisors and managers/executives, and is openly discussed as part of inductions, training and development.

Theme	Everyone	Supervisors	Managers/Executives
Standards	Follow rules	Ensure compliance	Set high standards
Communication	Speak up	Encourage the team	Communicate openly
Risk management	Be mindful	Promote risk awareness	Confront risk
Involvement	Get involved	Involve the team	Involve the workforce

Figure 7-2: Woodside 'Our Safety Culture' framework

7.2.3 Woodside Invasive Marine Species Risk Assessment Process

7.2.3.1 Objective and Scope

To minimise the risk of introducing IMS as a result of the Petroleum Activities Program, all applicable vessels and immersible equipment will be subject to Woodside's IMS risk assessment process (unless exempt as outlined below).

The objective of the risk assessment process is to identify the level of threat a contracted vessel, or immersible equipment poses if no additional risk reduction management measures are implemented. This allows Woodside (and its contractors) to apply management options that are commensurate to the identified level of risk.

In context of the activities specified in **Section 3**, the IMS risk assessment process does not apply to:

- vessels or immersible equipment that do not plan to enter the IMS Management Area (IMSMA)112 or PAAs defined in environmental approvals
- 'new build' vessels launched less than 14 days prior to mobilisation
- vessels or immersible equipment which have been inspected by a suitably qualified IMS inspector who has classified the vessels or immersible equipment as acceptably low risk no more than 14 days prior to mobilisation
- locally sourced vessels or immersible equipment from within the Pilbara locally sourced zone113. Vessels, or immersible equipment are defined as locally sourced when the same supply facilities/port have been used since their last IMS inspection, full hull clean in dry dock or application of antifouling coating (AFC114).

7.2.3.2 Risk Assessment Process

Woodside's IMS risk assessment process was developed with regard to the national biofouling management guidelines for the petroleum production and exploration industry and guidelines for the control and management of a ships' biofouling to minimise the transfer of invasive aquatic species (IMO Guidelines, 2011).

To effectively evaluate the potential for vessels and immersible equipment to introduce IMS, a risk assessment process has been developed to score and evaluate the risk posed by each Project vessel, or immersible equipment planning to undertake activities within the IMSMA/PAA. The risk assessment process considers a range of factors, as listed in **Table 7-1** and **Table 7-2**.

The IMS risk assessments will be undertaken by a trained environment adviser who has completed relevant Woodside IMS training or by a qualified and experienced IMS inspector. A QA/QC process is implemented for all Woodside conducted IMS risk assessments where a secondary trained environment adviser verifies the assessment to minimise the risk of misapplication and errors within the risk assessment process.

112 MSMA is based on current legal framework and includes all nearshore waters around Australia, extending from the lowest astronomical tide (LAT) mark to 12 nm from land (including Australian territorial islands). The IMSMA also includes all waters within 12 nm from the 50 metre depth contour outside of the 12 nm boundary (i.e., Submerged reefs and atolls).
113 The Pilbara Zone includes Port, nearshore and offshore movements between Exmouth and Port Hedland (excluding high environmental value areas, World Heritage Areas, Commonwealth Marine Reserve Sanctuary Zones and State Marine Management Areas and Marine Parks).
114 Vessels and immersible equipment can still be classified as locally sourced even if the AFC application occurred in a different port provided the amount of time between AFC application and departure to the locally sourced area (i.e., period of time in waters <12 nm/50m water depth) did not exceed consecutive 7 days or the period of time the vessel or immersible equipment has spent within the locally sourced zone exceeds 1 year (i.e., the risk of introducing a species from a different location has already passed).

Table 7-1: Key factors considered as a part of the risk assessment process for vessels

Factors	Details
Vessel type	The risk of IMS infection varies depending on the type of vessel undertaking the activity. A higher risk rating is applied for more complex, slow-moving vessels (e.g., dredges) in comparison to simple vessels (e.g., crew transfer vessel).
Recent IMS inspection and cleaning history, including for internal niches	In the case of biofouling on external hull niches, different risk ratings are applied dependant on whether out-of-water or in-water IMS inspections by qualified IMS inspectors and cleaning (if required) have been undertaken prior to contract commencement. If an IMS inspection (and clean if required) has not been undertaken in the past six months (from the time of contract commencement), the highest risk factor is applied. The risk factor then lessens for vessels as the time between inspection and mobilisation reduces.
Out-of-water period before mobilisation	A risk reduction factor can be applied for vessels that are hauled out and then mobilised as deck cargo or by road during mobilisation, therefore becoming air dried over an extended period. Risk reduction factor increases with exposure time out of water.
Age and suitability of AFC at mobilisation date	AFC manufacturers provide a range of coatings, each designed to avoid premature coating failure if it is correctly applied and matched to the vessel's normal speeds and activity profile (i.e., proportion of time spent stationary or below three knots), and its main operational region (i.e., tropical, sub-tropical temperate). If the AFC type is deemed to be unknown, unsuited or absent, the highest risk value is applied. If the AFC type is suitable the risk factor applied reduces with age since application.
Internal treatment systems	A risk reduction factor applied if the vessel has an internal biological fouling control system in place at the time of assessment, or evidence of manual dosing.
Vessel origin and proposed area of operation	Differing risk ratings are assigned in relation to the climatic relationship between the vessel's origin and the proposed climatic region of the proposed area of operation. Highest risk rating is applied to similar climatic regions.
Number of stationary/slow speed periods >7 days	A risk factor is calculated based on the number of 7-day periods that the vessel has operated at stationary or at low speed (less than three knots) in port or coastal waters which is any waters less than 50 metres deep outside 12 nautical miles from land or any waters within 12 nm of land. The greater the number of periods, the higher the risk factor applied.
Region of stationary or slow periods	A further multiplier is applied depending on the location of the stationary/slow speed periods. The highest risk rating applied if the stationary or slow speed periods occurred within ports or coastal waters of the same climatic region,
Type of activity – contact with seafloor	The potential for the introduction of IMS varies on the planned vessel activity taking place. Those activities that come in contact with sediments and thus have the potential to accumulate and harbour IMS in areas such as hoppers (dredges) and spud cans (drilling rigs) are considered to have a greater risk of infection.

Table 7-2: Key factors considered as a part of the risk assessment process for immersible equipment

Factors	Details
Region of deployment since last thorough clean, particularly coastal locations	Climatic region of use since last overhaul, thorough cleaning or prolonged period out of water (>28 day). Highest risk rating is applied to similar climatic regions. Activities occurring in nearshore areas (less than 50 metres deep and/or within 12 nautical miles from land) are given the highest risk rating.
Duration of deployments	Maximum duration of deployment (maximum time in water) since last overhaul or thorough cleaning. The longer the period of immersion the higher the risk rating applied.
Duration of time out of water since last deployment	A further risk reduction factor can be applied for immersible equipment that has been out of the water for an extended period.
Transport conditions during mobilisation	If the equipment is stored in damp conditions then a high risk factor is applied, while if equipment is stored in dry and well ventilated (low humidity) conditions then a low risk factor is applied.
Post-retrieval maintenance regime	A risk reduction factor is applied if the equipment/item of interest is routinely washed, cleaned, checked and/or dissembled between project sites, while a higher risk rating is applied where no routine cleaning occurs.

Following implementation of the risk assessment process, vessels and/or immersible equipment are classified as one of three risk categories, as defined below:

- 'Low' – Low risk of introducing IMS of concern and hence no additional management required, or management options have been applied to reduce the risk
- 'Uncertain' – Risk of introducing IMS is not apparent and as such the precautionary approach is adopted, and additional management options may be required
- 'High' – High risk of introducing IMS means additional management options are required prior to this vessel mobilising to the PAA.

Following the allocation of a 'low' risk rating for a vessel or immersible equipment, the information provided by the vessel operator for the purposes of risk assessment must be confirmed prior to mobilisation. For vessels or equipment classified as posing an 'uncertain' or 'high' theoretical risk, a range of management options are presented to reduce this theoretical risk to acceptable levels and achieve a low risk status. These management options have been developed with the intention of reducing IMS risk to levels that are as low as reasonably practicable (i.e., ALARP). It is a flexible approach that allows for a range of management actions to be tailored for a specific vessel movement. These will be assessed on a case-by-case basis and may include:

- having a suitably qualified and experienced IMS inspector inspect (desktop, in-water or dry dock) to verify risk status; where practicable, the inspection shall occur within seven days (but not more than 14 days) prior to final departure to the PAA
- applying in-water or dry dock cleaning of the hull and other niche areas, typically applied where the risk assessment outcome is High risk driven by the age of the AFC on the vessel and its time spent in similar climatic region ports
- treating vessels. internal seawater systems, typically applied in isolation for vessels with AFC applied to their hull within the last 12 months and where subsequent assessment through the process achieves a Low risk rating
- limiting the duration that the vessel spends within the IMSMA to a maximum of 48 hours (cumulative entries); applicable for Uncertain risk vessels only
- rejecting the vessel.

Project vessels and immersible equipment are required to be a low risk of introducing IMS prior to entering the PAA.

7.2.4 Risk Management

Risk management processes and practices are applied on an ongoing basis to design, production and maintenance activities at the Angel facility to manage risks to personnel, assets and the environment.

Potential environmental consequences and impacts from the Angel facility are risk assessed and controlled in accordance with the Woodside risk management processes described in **Section 2** of this EP (Environmental Risk Management Methodology).

The results of the Angel facility ENVID are described in **Section 6** and in the facility Environmental Impacts and Risk Register. This register, in conjunction with the EP, provides a demonstration that environmental risks have been identified, and that appropriate controls are in place to manage those risks to a level that is acceptable and ALARP throughout the life of the facility.

A number of other risk management tools and techniques are used by the Angel facility to manage environmental and other risks on a routine basis during operational, maintenance and inspection tasks. Examples include:

- the processes outlined in Section 2.2

- risk management tools including: ISSoW tools; e.g., Hazard Identification and Risk Assessments, Level 2 Risk Assessments, Operational Risk Assessments, the technical MoC system (Section 7.2.5), and Step Back 5 × 5
- integrity review studies, HAZIDs and Hazard Operability studies.

These tools, risk and integrity management practices are described further in the Angel Facility Safety Case, WOMP, and the Control of Operational Risk Procedure.

In addition, other risk sub-processes and practices are also applied within Woodside on an ongoing basis to manage different types of risk. A summary of those relevant to the Petroleum Activities Program is provided below. Woodside's risk management processes (refer to **Section 2.2.1**), along with the supporting risk sub-processes and practices discussed in this section, ensure the environmental impacts and risks of the activity continue to be identified and reduced to a level that is ALARP.

7.2.4.1 Management of Risks – Contracting and Procurement

Suppliers and contractors play a significant role in meeting the resource needs of Woodside's operations, including the facility operations. Effective management of environmental risks in contracts is achieved by setting clear expectations and managing environmental risks throughout the duration of the contract. Environmental risks in contracts are managed under the Contracting and Procurement Procedure supported by the Health, Safety and Environment in Contracting Guideline. The guideline provides a risk-based approach to contractor selection and management and is aligned with 'HSE Management – Guidelines for Working Together in a Contract Environment' (International Association of Oil and Gas Producers, Report No. 423).

The Engineering Standard: Quality Requirements for Supply of Products and Services defines specific quality requirements for engineering contracts and purchase orders. The specified quality control requirements in the Standard are required to be complied with as applicable to the scope of supply.

7.2.4.2 Management of Risks – Subsea Activities

Subsea activities are managed in line with the Subsea and Pipelines Integrity Management Procedure which defines the practices and technical requirements that must be applied to deliver and safeguard integrity of the subsea equipment and pipelines during the facility lifecycle. It provides the relationship between the PSM Framework (including management of change) and Subsea and Pipelines Group services processes.

IMMR activities are managed under the Manage IMMR Work Procedure. Risk assessments are conducted as required under this procedure.

These requirements are supported by implementation of the Subsea Construction and Inspection, Maintenance and Repair Environment Screening Questionnaire tool. The screening questionnaire is used to understand the scope of the activity, potential environmental impact and if additional regulatory approvals are required. To achieve this, the questionnaire captures key project information such as seabed disturbance, chemical use and waste. This information is used by an environment focal point to determine if further assessment is required. For projects that have the potential for environmental impact, an assessment is undertaken against this EP and other Woodside environmental requirements. If determined by the Subsea and Pipeline Environment Screening Questionnaire process, an EP MoC review (as per **Section 7.2.5.2**) is undertaken to confirm if the level of environmental risk warrants revision and resubmission of an EP.

Key environmental requirements and regulatory commitments are communicated to project teams and incorporated into key project documentation where applicable and required (i.e., not addressed via existing Woodside practices).

7.2.4.3 Management of Risks – Major Projects

Major projects are required to follow the Appraise and Develop Management Procedure and the Investment Management Framework. This procedure defines the requirements to deliver a commercially valuable production facility or modify to an existing facility. The process workflow requires integration of work from various functions utilising their people and processes, including Environment, for example HSE philosophy and regulatory approval requirements.

These requirements are supported by implementation of the Brownfields Environment Screening Questionnaire tool. The screening tool is used to determine if a project has the potential for environmental impact or requires additional regulatory approvals. For projects that have the potential for environmental impact, an environmental focal point is assigned and the risks and impacts assessed against the facility EP and other Woodside environmental requirements.

Key environmental requirements and regulatory commitments are communicated to project teams and incorporated into key project documentation where applicable and required (i.e., not addressed via existing Woodside practices).Where it is identified that the project scope has the potential to result in modification or change to the facility description provided in the EP, or where potential new environmental risks or impacts or increases in an existing environmental risk or impact are identified, an EP MoC review (as per **Section 7.2.5.2**) is undertaken to confirm if the level of environmental risk warrants revision and resubmission of an EP.

7.2.4.4 Management of Risks – Well Integrity

Wells are managed throughout their lifecycle in line with the Well Lifecycle Management Procedure. This procedure provides the basis for ensuring well integrity in accordance with the Process Safety Management Procedure.

In addition, wells are required to have a regulator accepted Well Operations Management Plan to demonstrate that well integrity risks are managed to ALARP levels. Wells tied back to the facility are managed under a WOMP.

7.2.4.5 Management of Risks – Marine Services

Woodside's Marine Services Function provides a platform for the conduct of safe and efficient Marine Operations across Woodside through the Marine Services Management. A set of procedures that support vessel assurance and management (including HSE and quality [HSEQ] management) are in place to ensure marine operations are conducted in a safe and efficient manner, and in accordance with regulatory requirements.

More details on vessel assurance and the communication of environment requirements to vessels are provided in **Section 7.8.2**.

Vessel masters are required to request clearance from the facility OIM delegate prior to entering the 500 m PSZ.

7.2.4.6 Management of Risks – Emissions and Energy Management

Emissions generation and energy use is managed in line with the GHG Emissions and Energy Management Procedure which defines the minimum mandatory requirements to manage and deliver continuous improvement in energy efficiency and reduction in GHG emissions. The procedure supports the implementation of the Climate Policy and aligns with the requirements of the Environmental Performance Procedure, applicable to assets in Operate phase. It supports the "operate out" component of limiting net emissions, as shown in the Woodside Climate Change Strategy.

Implementation of the GHG Emissions and Energy Management Procedure assists in meeting external expectations, such as Woodside's 2025 (-15%) and 2030 (-30%) emissions reductions targets and aspiration to be net zero by 2050. It also aligns with corporate commitments, such as the Zero Routine Flaring Initiative for oil assets and the OGMP, OGCI Near-Zero and Methane

Guiding Principles. These methane reduction commitments aim to improve methane emissions inventorisation, materiality assessments, evaluation, reduction implementation and increased transparency through reporting. The Woodside Flare Framework is an optional WMS tool that seeks to improve awareness of flaring-related issues and influence for reduced flaring.

The GHG Emissions and Energy Management Procedure links to the annual review of opportunities to improve energy performance through identification and evaluation as described in the Production Optimisation and Opportunity Management Procedure. It also requires measurement, analysis and communication of energy performance across the Operations Division and consideration of actual or potential impacts to energy efficiency in company decision making, such as management of change, operational decisions, issue resolution options analysis and facility optimisation plans.

The Environmental Performance Procedure requires that assets measure, monitor or estimate direct air and GHG emissions, and that such emissions and energy intensities are minimised to ALARP. The requirement to set, measure and track fuel and flare targets for assets help manage the emissions to meet the EPS requirements in **Section 6.6.10**.

7.2.4.7 Production Optimisation and Opportunity Management

Woodside's Production and Opportunity Management Procedure outlines the process for identification, prioritisation and management of production opportunities that maximise production revenue or reduce emissions intensity across Woodside operated assets. Opportunities are identified throughout the year in various meetings, forums and teams. In addition, formal opportunity identification takes place through annual workshops, which complement the identification of improvement opportunities. These opportunities are prioritised and managed according to the workflow shown in **Figure 7-3**.

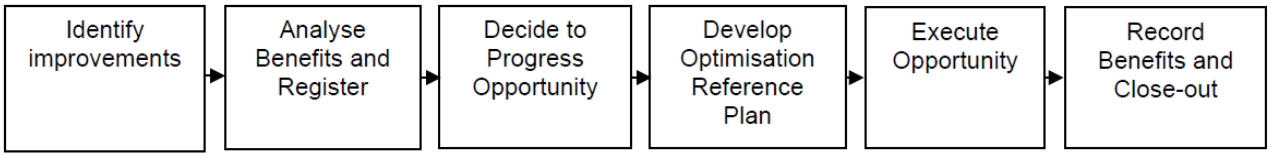

Figure 7-3: Opportunity management workflow

Production opportunities are evaluated and progressed, based on value and confidence of return, within the constraints of technical feasibility, cost and other factors. Implemented opportunities are validated and recorded before close out.

7.2.4.8 Flare Target Setting

In demonstrating the risks and impacts relating to flaring have been reduced to ALARP, flare targets for the facility are set annually in accordance with Woodside's Greenhouse Gas, Energy and Flare Target Setting Guideline. Targets are estimated based on operating experience and forecast activities; e.g., shutdowns. Consideration is also given to the flaring estimates contained within this EP.

The flare target is tracked against flare performance through the year. Where achieving a flare target is in question, an internal flare target deviation is developed, which requires an ALARP justification. A flare target deviation considers EP flare estimates. If estimate is likely to be exceeded, an EP management of change assessment (see **Section 7.2.5**) is undertaken to determine if a revision and resubmission is required.

7.2.4.9 Management of Human Factor Related Risks

The term 'human factors' is used to describe the consideration of people as part of complex systems. Woodside defines 'human factors' as follows: 'human factors uses what we know about people, organisation and work design to influence performance'.

As outlined in **Section 6.7.8**, human factors can contribute to MEEs, or result in failure or degradation of the controls in place to protect against MEEs. The WMS includes a number of procedures designed to manage human factors related risks and prevent incident causation.

7.2.5 Change Management

Woodside's Change Management Procedure describes Woodside's requirements for change management at Woodside owned or controlled operations/sites.

Change management is used where there is no existing approved business baseline, such as a process, procedure or accepted practice, or where conformance with an approved baseline is not possible or intended; for example, due to equipment fault or failure or a recently discovered issue which will take time to rectify. Change management is also used when the baseline is changed (e.g., the process is modified). It applies to management of temporary, permanent, planned or unplanned change encompassing one or more of:

- plant (equipment, plant, technology, facilities, operations or materials)
- projects (budget, schedule)
- people (organisation structure, performance, roles)
- process (WMS content, processes, procedures, standards, legislation, information).

Woodside's change management process hierarchy is depicted in **Figure 7-4**. The hierarchy has been developed with sub-processes to address the different types of change performed at Woodside.

Figure 7-4: Change management hierarchy

To help manage the day to day operation of the facility, Woodside has developed a Golden Safety Rules Booklet, which provides a summary of mandatory requirements for safety in the workplace and includes guidance for managing changes that have a Health, Safety, Integrity and/or Environment impact.

7.2.5.1 Technical Change Management

Technical changes within the Operations Division are managed using the Management of Change – Assets Procedure. The objective of the procedure is to ensure HSE risks associated with both realised and potential changes, including any failure to meet the facility SCE Technical Performance Standards, are identified, assessed and reduced to ALARP (**Section 7.2.6** provides further information on management of SCE Technical Performance Standards).

Assessed changes must be recommended, agreed and decided upon based on the assessed current level of risk, as defined by Woodside's Technical Decision Authority matrices.

The management of change requirements contained in the Process Safety Management Procedure and Management System Performance Standard M05 Management of Change are considered when conducting any changes with the potential to impact process safety.

The Engineering Management Procedure specifies key requirements of engineering related changes, and requires that engineering Technical Decisions are agreed, recommended and decided

at the appropriate engineering authority level according to the risk. Change management and risk assessment include consideration of applicable legislation/regulation.

Change is also managed under management system requirements set out as part of major projects (Brownfields), wells integrity, subsea and pipelines integrity management and marine management system. Change management includes consideration of regulatory requirements, managed in accordance with the Regulatory Compliance Management Procedure.

In addition, the Management of Change MSPS (M05) is in place to assure process safety risks arising from change (temporary and permanent) are systematically identified, assessed and managed.

7.2.5.2 Environment Plan Management of Change and Revision

Management of changes are managed in accordance with Woodside's Environmental Approval Requirements Australia Commonwealth Guideline. Management of changes relevant to this EP, concerning the scope of the activity description (**Section 2.10**) including: review of advances in technology at stages where new equipment may be selected such as vessel contracting; changes in understanding of the environment, DCCEEW EPBC Act listed threatened and migratory species status, Part 13 statutory instruments (recovery plans, threat abatement plans, conservation advice, wildlife conservation plans) and current requirements for AMPs (**Section 4.8**); and potential new advice from external stakeholders (**Section 5**), will be managed in accordance with regulation 39 of the Environment Regulations.

Risk will be assessed in accordance with the environmental risk management methodology (**Section 2.8** to determine the significance of any potential new environmental impacts or risks not provided for in this EP. Risk assessment outcomes are reviewed in compliance with regulation 38 and 39 of the Environment Regulations.

Minor changes where a review of the activity and the environmental risks and impacts of the activity do not trigger a requirement for a formal revision under regulation 38 or 39 of the Environment Regulations, will be considered a 'minor revision'. Minor administrative changes to this EP, where an assessment of the environmental risks and impacts is not required (e.g., document references, phone numbers, etc), will also be considered a 'minor revision'. Minor revisions as defined above will be made to this EP using Woodside's document control process. Minor revisions will be tracked in an MOC Register to ensure visibility of cumulative risk changes, as well as enable internal EP updates/reissuing as required. This document will be made available to NOPSEMA during regulator environment inspections.

7.2.5.3 Oil Pollution Emergency Plan Management of Change

Relevant documents from the OPEP will be reviewed in the circumstances of:

- implementation of improved preparedness measures
- a change in the availability of equipment stockpiles
- a change in the availability of personnel that reduces or improves preparedness and the capacity to respond
- the introduction of a new or improved technology that may be considered in a response for this activity
- to incorporate, where relevant, lessons learned from exercises or events
- if national or state response frameworks and Woodside's integration with these frameworks changes.

Where changes are required to the OPEP, based on the outcomes of the reviews described above, they will be assessed against regulation 38 and 39 to determine if EP, including OPEP, resubmission is required (see **Section 7.2.5.2**). Changes with potential to influence minor or technical changes to

the OPEP are tracked in management of change records, project records and incorporated during internal updates of the OPEP or revisions to the EP.

7.2.6 Management of Safety and Environment Critical Element Technical Performance Standards and Management System Performance Standards

7.2.6.1 Management System Performance Standards

Woodside ensures safety critical management processes function as required through the application of management system performance standards. MSPS are developed and owned at non-facility-specific level (i.e., pan Woodside) and include assurance checks for the key requirements of the applicable management system.

Individual facilities demonstrate conformance against the MSPS through the conduct of reviews. Non-conformances against an MSPS are internally managed in accordance with the Woodside Management System.

7.2.6.2 Safety and Environment Critical Element Technical Performance Standards

An SCE is defined by Woodside as a hardware barrier, the failure of which could cause or contribute substantially to, or the purpose of which is to prevent or limit the effect of a MAE/MEE, or Process Safety Event.

Woodside identifies/develops, implements, monitors/assures and verifies/optimises SCEs by applying SCE technical Performance Standards as described in the Safety and Environment Critical Element (SCE) Management Procedure. Key elements of the procedure are summarised in **Table 7-3**.

Table 7-3: Safety and environment critical element management procedure summary

Identify/Develop	**Identify SCE** – SCEs must be identified from the facilities PSRAs (e.g., Formal Safety Assessments) (**Section 2.2**). The identification of SCEs for which Performance Standards are required are part of the formal safety and environmental risk assessment processes. Woodside's Global Performance Standards (based on industry and Woodside Standards) should be used for preliminary selection of SCEs. **Complete Engineering Design Studies** – Engineering design studies must be completed to demonstrate that SCE Performance Criteria specified in the global Performance Standard and/or determined by PSRA will be met by the facility design, allowing for normal SCE degradation in operation. The studies must establish the testing and inspection tasks required to assess performance against the criteria. The scope and frequency of SCE Assurance Tasks are guided by the Global Performance Standard and may require designated Engineering Design Studies. Studies should include Reliability Centred Maintenance, Risk Based Inspection and Safety Instrumented Function studies to determine the Assurance Task scope and frequencies, RBI plans, and classification and implementation requirements for instrumented safeguarding. **Develop Performance Standards** – Facilities must develop Performance Standards for all SCEs by: • selecting the applicable Global Performance Standard (including Assurance Tasks) • considering facility specific requirements and applicable regulatory requirements • adding the specific data from the facility Engineering Design Studies and PSRA to compile scope and frequency of SCE assurance activities.
Implement	**Identify SCE in Asset Register** – SCEs must be uniquely identified on the asset register and assigned Performance Standard flags. **Develop Testing, Inspection and Maintenance Programs** – SCE assurance tasks are developed into maintenance procedures. **Implement Testing, Inspection and Maintenance Programs** – SCE testing, inspection and maintenance requirements must be implemented in the CMMS (**Section 7.2.1.3**).
Maintain/Assure	**Execute Testing, Inspection and Maintenance Programs** – On completion of SCE assurance tasks, results must be recorded with all relevant detail, assessed for conformance with the Performance Criteria and any follow-on correction work identified. **Conduct Fitness for Service (FFS) Assessment** – In some instances, an engineering FFS assessment may be required to determine whether equipment has failed its performance standard requirements; e.g., assessment of corrosion defects following inspection of piping. Detailed results of FFS assessment may be recorded out of CMMS. **Response to SCE Failure** – SCE failure (technical Performance Standard non-conformance) is a failure to achieve the given Performance Criteria. SCE failures must be managed in accordance with a structured review process. This process may require the application of the facility MOPO which provides prescriptive guidelines to be followed in the event of a reduction in the performance of an SCE, or managed in accordance with the Management of Change – Assets Procedure (**Section 7.1.4**). **Internal Reporting** – SCE failure/damage and SCE demands must be reported in accordance with the Health Safety and Environment Event Reporting and Investigation Procedure (**Section 7.11.4**). **External Reporting** – External notification obligations for SCE failure/damage must be understood (i.e., based on local regulatory requirements). External communications must be in accordance with the health safety and environment event reporting and investigation procedure (**Section 7.11.5**). **Manage and Analyse Results** – The results from assurance tasks must be accurately recorded to support data analysis. Analysis will enable appropriate action to be taken to minimise future failure recurrences, and enable assessment of overall system performance and reliability to verify SCE effectiveness in revealing failures and to allow predictive maintenance.
Verify/Optimise	**Review SCE Performance** – SCE performance reviews must be conducted to ensure requirements for maintaining SCE performance are being met. **Manage Change** – Any change to the Performance Standards must be conducted in accordance with the Change Management Procedure (**Section 7.2.5**).

SCE Technical Performance Standards are a statement of the performance required of an SCE (e.g., functionality, availability, reliability, survivability), which is used as the basis for establishing agreed assurance tasks and managing the hazard. An assurance task is an activity carried out by the operator to confirm that the SCE meets, or will meet, its SCE technical Performance Standard.

Examples of assurance tasks include inspection routines, maintenance activities, test routines, instrumentation calibration and reliability monitoring.

These assurance tasks are identified in the CMMS, flagged against their associated technical Performance Standard, and given the appropriate priority (defined as Technical Integrity). Management systems are in place to manage the completion of maintenance including that required for Technical Integrity assurance.

Events where the SCC/SCE have not met their specified performance criteria must be managed in accordance with a structured review process. This process may require the application of the facility MOPO which provides prescriptive guidelines to be followed in the event of a reduction in the performance of an SCE in specific defined circumstances; or, if the MOPO does not cover the event, according to procedures for the assessment and management of operational risk.

Internal notification of SCC failures must be made in accordance with maintenance management workflows. Failures to meet a Facility Performance Standard occur where SCC events lead to the functional objectives (goal and/or key requirement statements) of the facility Performance Standard for the SCE not being met (i.e., lost or unavailable), taking into account any redundancy inherent within the SCE. These events are reported in the Event Reporting Database as potential SCE Failure to Meet Facility Performance Standard Events.

These are internally reported as Hazard Events. Where ‘Failure to meet a Facility Performance Standard’ leads to a loss of hydrocarbon containment, or a release of energy, it is internally reported (and externally where relevant) as a Loss of Primary Containment or Environmental Spill event, depending on the nature of the release.

Additionally, confirmed “Failure to meet a Facility Performance Standard’’ events for the SCEs identified in the MEE bowties may equate to a breach of EPOs and/or EPSs. The review to identify such events for external reporting considers whether the hazard event is relevant to environmental SCE functional objectives (goal and/or key requirements) of the SCE Facility Performance Standard and whether the event poses a risk to achieving EPOs and EPSs. The WMS Regulator Event Reporting Guideline provides additional information regarding external SCE related reporting obligations.

There may also be planned changes/deviations from SCE Technical Performance Standards, these are managed via procedures for the assessment and management of operational risk, and endorsed in accordance with the engineering management procedures (described further within **Section 7.2.5**). This management process ensures risks (including environment) are managed so that the planned change/deviation does not result in unacceptable impact or risk, remains ALARP and regulatory requirements are met.

7.3 Woodside’s Decommissioning Framework

Decommissioning is normal, planned activity for the offshore oil and gas industry. Current best practice for decommissioning includes:

- designing for decommissioning during the development phase of projects/facilities
- removing property, equipment and infrastructure, such as a facility or a pipeline, and plugging wells associated with a petroleum activity
- assessing decommissioning options and opportunities during the operational life of the facility leading up to cessation of production
- selecting, developing and planning the selected decommissioning option
- executing decommissioning plans
- restoring the marine environment.

This is aligned with Section 572 (3) of the OPGGS Act, which requires titleholders to remove property from the title area when it is neither used, nor to be used, in connection with the operations. Planning for complete removal is generally the base case for offshore decommissioning operations. Section 572 (7) and Section 270 (3) of the OPGGS Act provide scope for in situ decommissioning or other arrangements to be made where it can be demonstrated that the risks and impacts are ALARP and acceptable. If complete removal or other arrangements for decommissioning are planned, the proposed alternative presented in an EP must comply with all other Acts and legislation.

7.3.1 Decommissioning in Operations

Asset specific decommissioning plans are typically developed prior to cessation of production. Planning includes redundant infrastructure as well as structures coming to the end of production and, decommissioning critical systems to enable, as a base case, full removal.

7.3.2 Facility Decommissioning Planning

Decommissioning planning generally commences two to 10 years prior to cessation of production (**Figure 7-5**). The timeframe selected for decommissioning planning depends on the complexity of the facility and infrastructure requiring decommissioning.

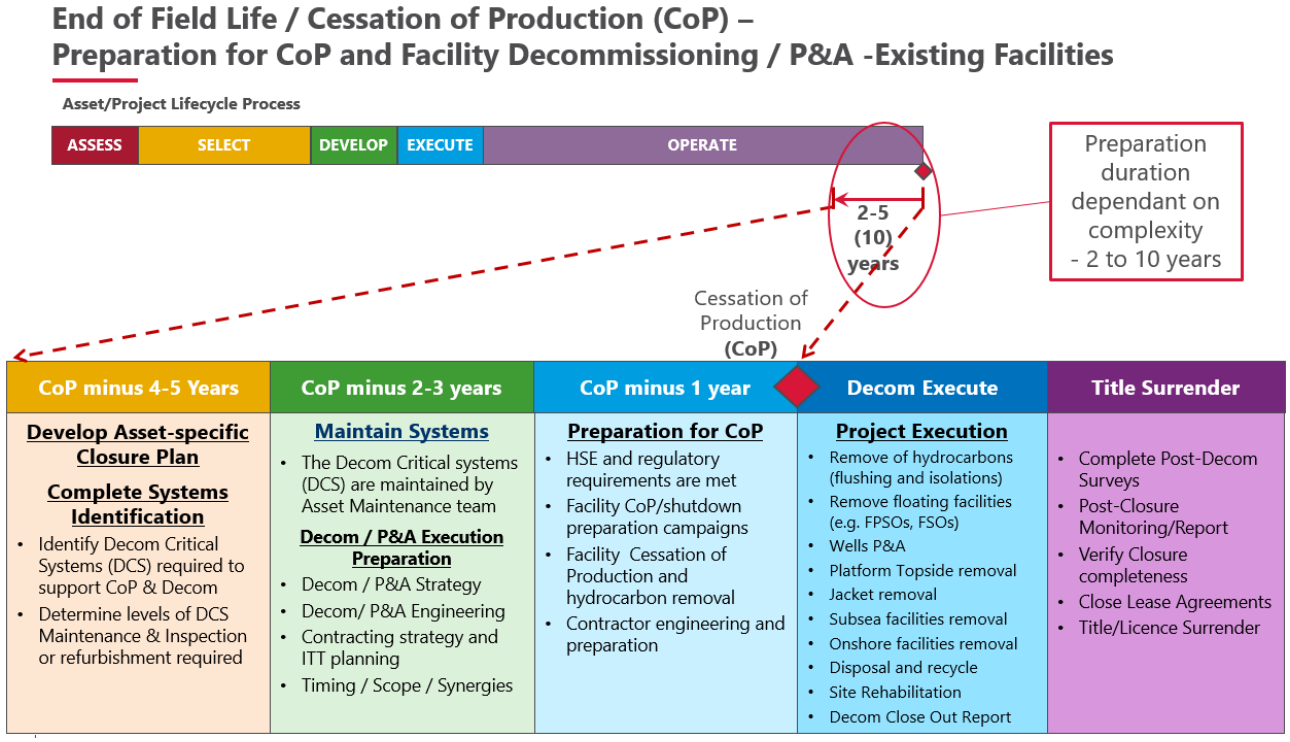

Figure 7-5: Woodside's process for decommissioning planning

7.3.3 Angel Field Inventory

The layout of Angel subsea infrastructure is shown in **Figure 7-6** and detailed in **Table 7-4**. Decommissioning planning for infrastructure no longer in use is described in **Section 7.3.4**.

Table 7-4: Inventory of subsea wells and key infrastructure, including status

Infrastructure	Quantity/length	Details	Status	Removed under this EP?	Subject to Future EP?
Stage 1 Decommissioning					
Wells	3 development wells (AP2, AP3, AP4)	Wellheads and trees	Maintained for decommissioning	No	Yes – NWS P&A EP
Rigid pipeline	3 14-inch with asphalt enamel coating (6.5 mm)	Total length = 6.5 km		No	Yes – Angel Flowline & Umbilical Removal EP
Rigid spools	8			No	
Umbilicals	3	Total length = 7.3 km		No	
Umbilical termination assembly (UTA)	3	Weight = 6740 kg each		No	
Hydraulic and electrical flying leads (HFL/EFL)	9			No	
Stage 2 Decommissioning					
Angel Export Pipeline	1 30-inch rigid pipeline 4 rigid spools 1 power umbilical 1 pig launcher/receiver 1 valve station	Total length 49 km	Maintained for production	No	Yes – future EP yet to be determined
Lambert Deep Subsea Equipment	3 14-inch rigid pipeline 8-inch flexible jumper 1 umbilical 2-slot manifold 1 UTA 3 HFL/EFL	Total length 14.9 km		No	Yes – future EP yet to be determined
Angel Platform	Topside Jacket Risers	Total weight = 16,405 tonnes		No	Yes – future EP yet to be determined

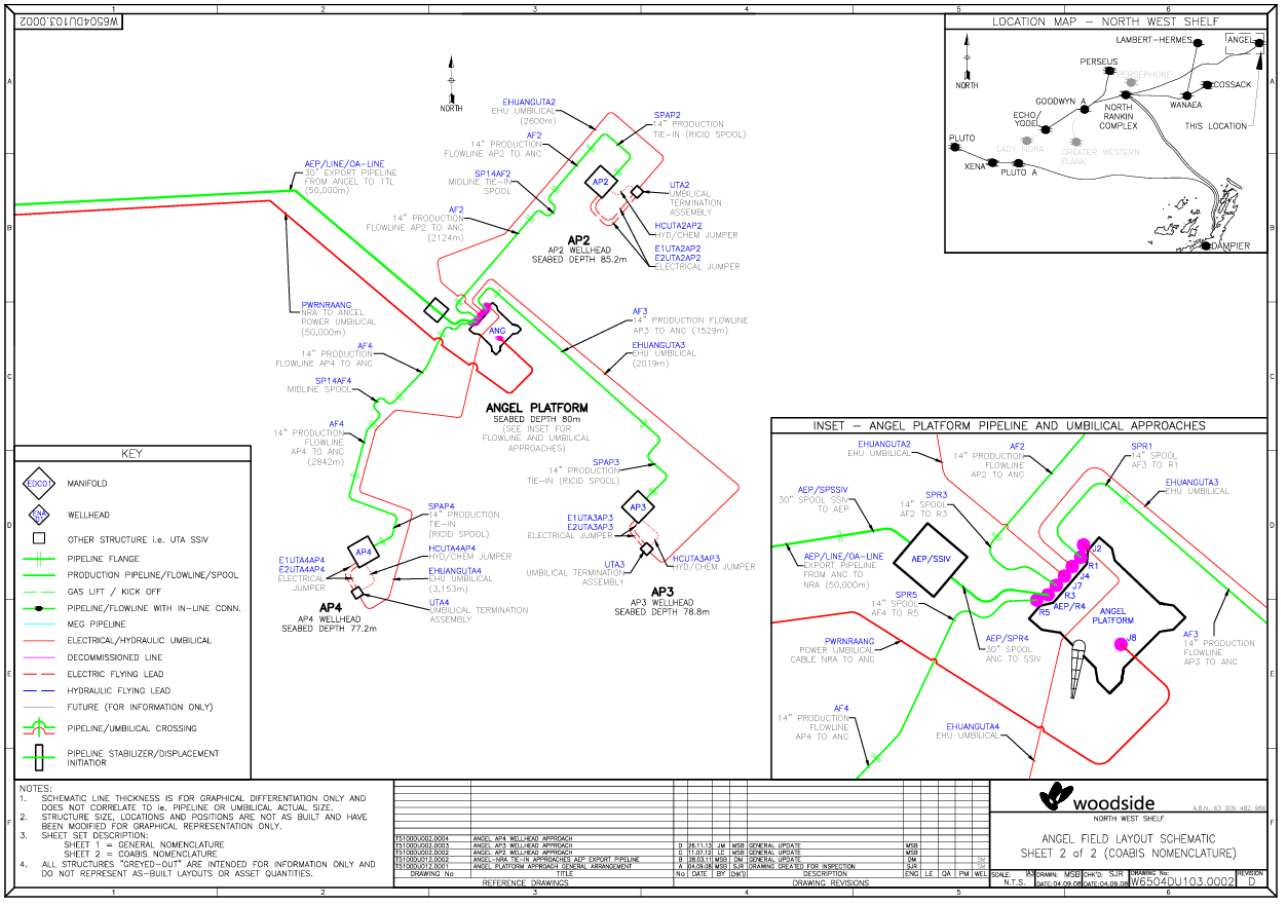

Figure 7-6: Angel subsea infrastructure layout

7.3.4 Angel Decommissioning Phasing

The decommissioning of the Angel asset is being considered in two stages:

- Stage 1: covers the decommissioning of the Angel subsea wells (AP2, AP3 and AP4) and the associated subsea infrastructure with these three wells.
- Stage 2: considers the decommissioning of the Angel platform and Lambert Deep and Lambert West wells and subsea infrastructure.

In December 2020, production ceased from the Angel subsea wells. The three wells and subsea system have been shut in, and their pressure integrity is being monitored to manage the risk of Loss of Containment. Woodside is progressing studies in support of the Stage-1 decommissioning of those subsea wells and associated subsea infrastructure.

The platform remains a production asset, with brownfield modifications undertaken to enable tie in of the Lambert Deep field. This stage is then being divided up into different phases.

The key milestones for Stage 1 in accordance with decommissioning planning process (**Figure 7-5**) are described below and in the following sections. An indicative overarching Angel decommissioning planning lifecycle and schedule is presented in **Figure 7-8**.

Stage 1 of Angel decommissioning has been incorporated into the North West Shelf (NWS) Gas Decommissioning Program to plug and abandon redundant wells and removal redundant equipment. Further information is outlined in the 2023 NWS Gas Offshore Asset Closure Management Plan.

Stage 1 (Angel subsea wells and subsea infrastructure) – Key Milestones

2022

- Systems Identification & Maintain Systems:
  - completed identification of decommissioning critical systems.
- Decommissioning Execution Preparation:
  - commenced Concept Definition for the permanent plug and abandonment of the Angel subsea wells (AP2, AP3 and AP4)
  - completed technical engineering studies in support of assessing removal options, timing and synergies with other planned decommissioning activities, including consideration of removal over live infrastructure.

2023/24

- Decommissioning Execution Preparation:
  - complete Concept Definition for the plug and abandonment of the Angel subsea wells (early 2024)
  - commenced contracting in support of target execution windows for both plug and abandonment of Angel subsea wells and Angel flowlines flushing (separate contracts)
  - develop NWS Phase 1 Plug and Abandonment EP (which includes the plug and abandonment of three Angel wells AP2, AP3 and AP4). Submission of this EP to NOPSEMA for assessment is currently scheduled for January 2025.

2024/25

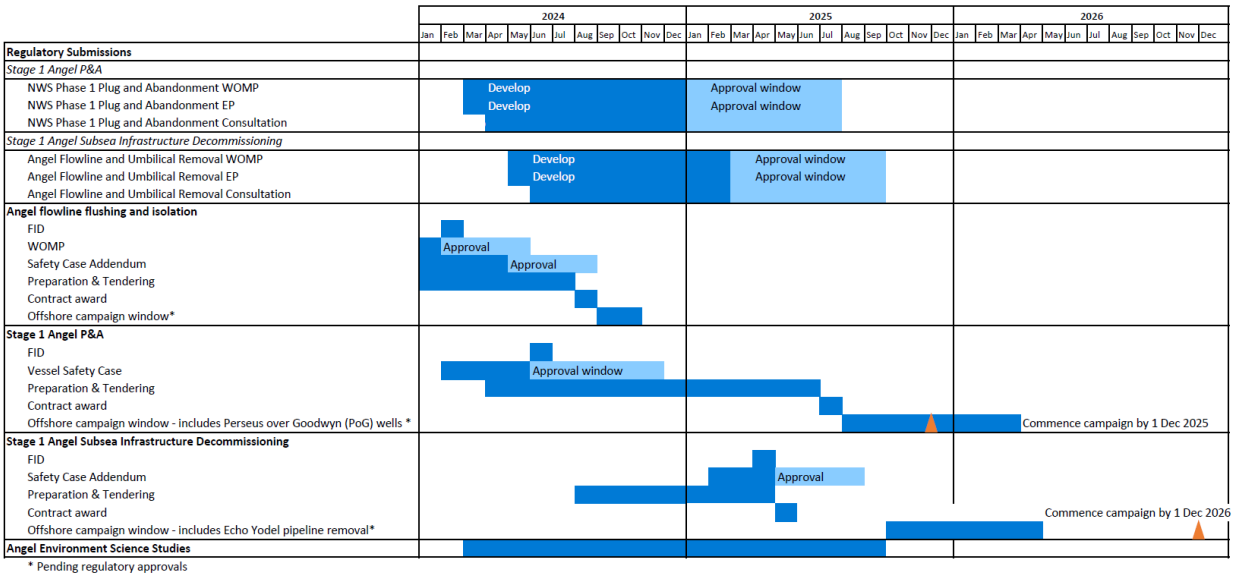
- Decommissioning Execution Preparation:
  - complete contracting for Angel flowline flushing and plug and abandonment of Angel subsea wells

    plan for executing subsea infrastructure removal and waste disposal
  - develop Angel Flowline and Umbilical Removal EP. Submission of this EP to NOPSEMA for assessment is currently scheduled for March 2025.
- Project Execution:
  - flush and preserve Angel flowlines (Section 3.4.15.8)
  - target execution window for plug and abandonment campaign for Angel wells AP2, AP3 and AP4, shown in Figure 7-7 below, currently planned to commence by 1 December 2025.

2025/26

- Decommissioning Execution Preparation:
  - complete contracting for NWS Rigid Flowline Removal Campaign, which includes Angel flowline and umbilical removal and Echo Yodel pipeline removal.
- Project Execution:
  - target execution window for Angel flowline and umbilical removal campaign shown in **Figure 7-7** below, currently planned to commence by 1 December 2026.

Figure 7-7: Current Angel Stage 1 decommissioning schedule (subject to change)



Stage 2 (Angel platform, Lambert Deep and Lambert West wells and associated subsea infrastructure and Angel Export Pipeline) – Early Milestones

It is anticipated the Develop/FEED phase for Stage 2 of Angel Decommissioning will commence in 2024, three years before expected cessation of production (**Section 3.3**), with the commencement of early studies (planned for 2023/24) to comprise of:

2022/23/24

- Systems Identification and Maintain Systems:
  - identified decommissioning critical systems and development of Angel Decommissioning Maintenance Plan.
- Decommissioning Execution Planning:
  - environmental and scientific studies on the impact of the infrastructure on the marine environment.
  - assessment of options in support of decommissioning activities including:
    - topsides removal
    - jacket decommissioning in-situ or removal
    - subsea equipment preservation and removal options
    - study for isolation, flushing, preservation and decommissioning of the Angel export pipeline (AEP)115.

115 If permanent isolation of the AEP from the 1TL could be safely achieved at 1TL Isolation Skid, then the decommissioning of the AEP will be included into the targeted Angel Subsea Infrastructure decommissioning campaign. If the permanent isolation to 1TL could not be safely achieved then the AEP will be flushed, preserved, capped and left in place for decommissioning with 1TL, after NRC cessation of production (CoP); the NRC CoP is estimated to be around 2038.

7.3.4.1 Stage 1 – Angel Plug and Abandonment Planning

Prior to ceasing production from the Angel wells (AP2, AP3 and AP4), Woodside initiated studies on the permanent plug and abandonment of the three wells. The following engineering and study outputs are underway to inform Concept Definition for Stage 1 – Angel plug and abandonment planning:

- Angel Environmental Science Program: demonstration and quantification of habitat retention to provide insights to inform Stage 2 decommissioning decisions
- Angel Facilities Removal studies: pre-assess scope to gain insights into decommissioning methodology, costs, schedule, risks and opportunities for removal of the Angel platform to support future project initiation
- North West Shelf Redundant Wells Plug and Abandonment Define (includes Angel and Perseus over Goodwyn wells): P&A of redundant wells planned as an option on the TransOcean Endurance campaign
- North West Shelf Redundant Equipment Flushing and Removal Define (includes Angel flowline and umbilical removal): flushing subsea ahead of redundant wells P&A, removal post P&A.

The subsurface studies in support of the abandonment design have been completed, along with technical well engineering studies for well re-entry and abandonment. The plug and abandonment project is currently in the Decommissioning Execution Preparation phase (**Figure 7-5**).

Execution of the Angel plug and abandonment campaign is anticipated to start no later than 1 December 2025, with options being assessed to accelerate this schedule. This timing is aligned with Industry Good Practice (OGA, 2018; OGUK, 2018, 2019), is supported by ongoing well integrity monitoring and consistent with previous decommissioning commitments. Permanent plugging of the Angel wells is expected to be part of a larger, five to seven well campaign. Exact timing of the activity will be determined by a number of factors including commercial negotiations and rig availability.

The wells are monitored and maintained in accordance with the Woodside Well Integrity Management Process for production wells, also described in **Section 3.4.15**. Monitoring of the three Angel wells continues as per the approved WOMP and well integrity management procedure (**Section 3.4.15**).

7.3.4.2 Stage 1 – Angel Subsea Infrastructure Decommissioning Planning

7.3.4.2.1 Systems Identification and Maintain Systems

In accordance with Section 572 (2) of the OPGGS Act, all infrastructure in the title area and used in connection with the operations must be maintained in good condition and repair. Equipment associated with the Angel wells and subsea system will continue to be inspected, monitored and maintained in accordance with the Woodside Asset Maintenance and Inspection regime for producing infrastructure, as described in **Section 3.4.15**.

The Angel subsea flowline system commenced operation in 2008 and has a design life of 20 years. The subsea system has been inspected regularly, based on the RBI procedure developed specifically for the Angel facility to facilitate a plan for full removal in accordance with Section 572 (3) of the OPGGS Act. Inspections undertaken in 2019 of the corrosion protection systems confirms that the three flowlines have sufficient integrity forecast until between 2030 to 2119.

7.3.4.2.2 Decommissioning Execution Planning

Woodside is in the early planning phase for decommissioning Angel subsea infrastructure: progressing technical engineering studies. These studies assess removal options, timing of removal options and synergies with other planned decommissioning activity (**Figure 7-7**). The decommissioning of redundant Angel subsea infrastructure is the subject of a separate

decommissioning EP, Angel Flowline and Umbilical Removal EP. Wells, wellheads and Xmas trees are expected to be covered by the NWS Phase 1 Plug and Abandonment EP. Inspection and maintenance regimes will continue until the timeframe for removal is agreed in a future EP.

7.3.4.2.3 Preparation for Cessation of Production

Preservation Activities

Flushing of Angel flowlines is planned to occur in late 2024 prior to Angel wells permanent plug and abandonment activities (**Figure 7-7**). Flowlines flushing is expected to be conducted from Angel topsides to the reservoir, leaving flowlines temporarily preserved with treated seawater. Although not planned, pigging activities, including provision for installation and recovery of a pig launcher/ receiver, are in scope of this EP if required (**Section 3.4.15.8**).

Flushing and cleaning the flowlines, prior to permanent plugging of the wells, leads to the internal fluid being replaced with preservation fluid. This typically consists of seawater treated with an oxygen scavenger (to inhibit corrosion and prevent chloride stress corrosion cracking (CSCC) in the CRA) and a biocide (to inhibit microbial growth which can lead to corrosion). The concentration of the fluids is calculated to provide internal corrosion protection for the flowlines for an extended duration so flowlines are maintained until they are decommissioned.

Leaving the Angel subsea infrastructure *in situ* under these conditions and meeting these maintenance requirements, satisfies the requirements of Section 572 of the OPGGS Act.

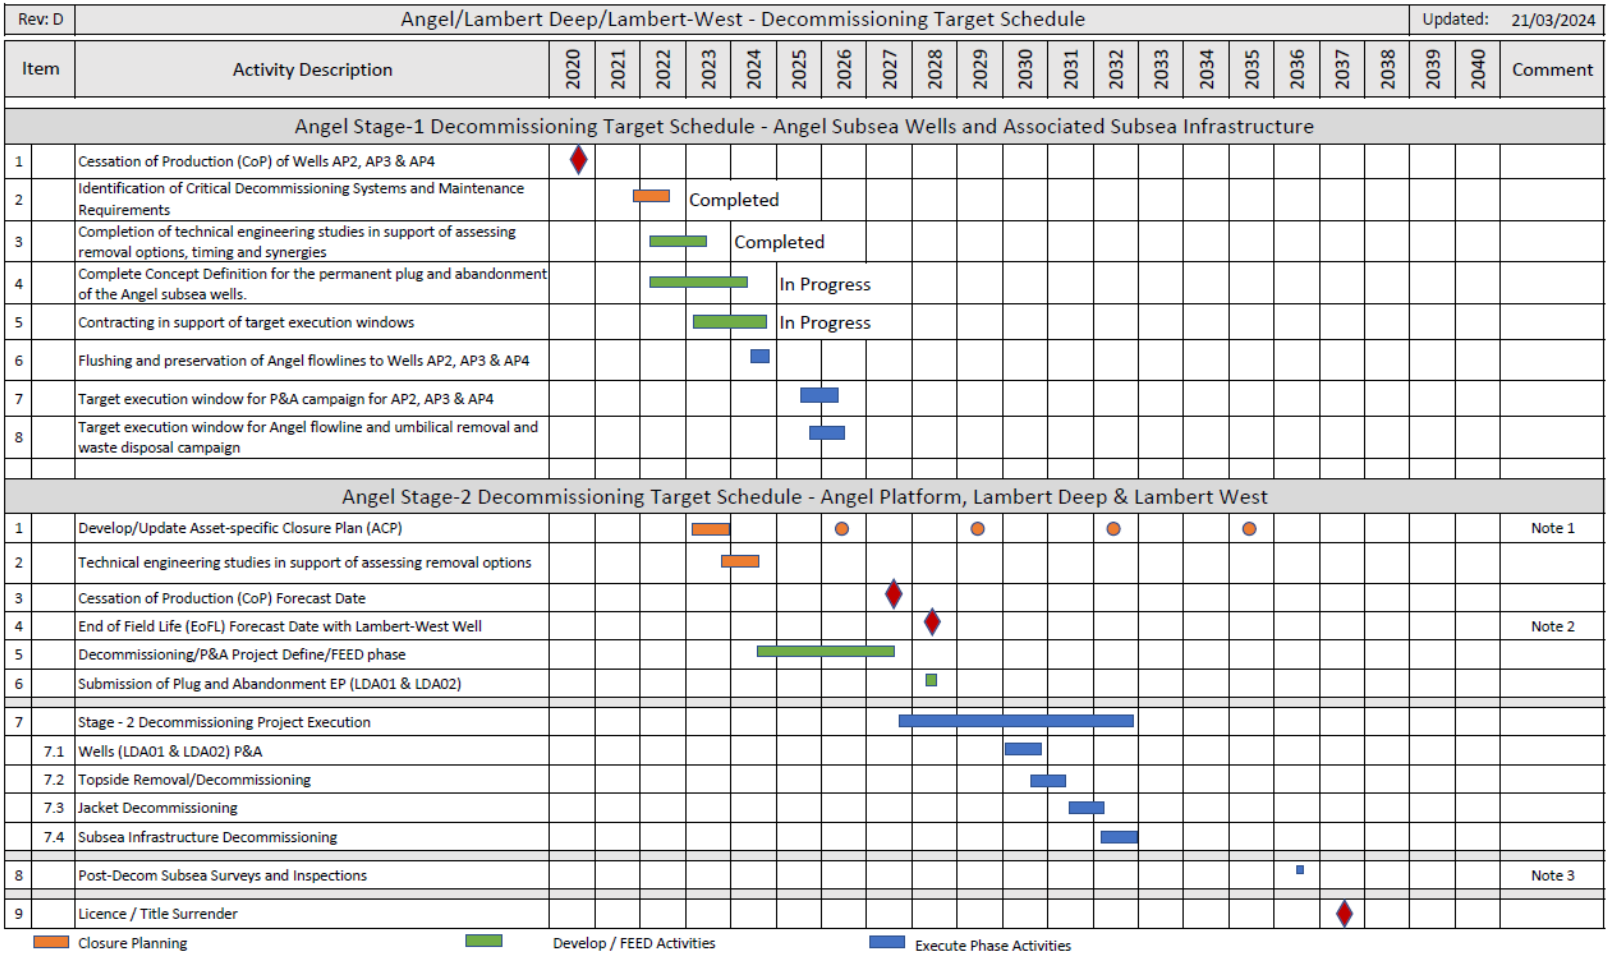
7.3.4.3 Stage 2 – Angel Facility Decommissioning Planning

Production from the Lambert Deep and Lambert West reservoirs is expected to continue until ~2027[116], thereby extending the life of the Angel Platform until that time (**Figure 7-8**). Woodside proposes to decommission the Angel Platform (including Lambert Deep and Lambert West infrastructure) with an indicative field implementation start date shortly after cessation of production. Decommissioning planning has commenced, which is four to five years prior to Lambert Deep and Lambert West reservoir cessation of production.

7.3.4.3.1 Systems Identification and Maintain Systems

Woodside is developing an Angel Decommissioning Maintenance Plan, to identify decommissioning critical systems as well as any additional maintenance and inspection requirements to comply with the requirements of Section 572(2), (3) and (7) and 270(3) of the OPGGS Act. The Angel Decommissioning Maintenance Plan will aim to ensure decommissioning critical systems and any additional maintenance and inspection requirements are in place until Angel facilities are decommissioned.

116 Expected end of field life will be updated post drilling of Lambert West, and is continuously reviewed during production life.



Notes:

1) The Angel Asset Closure Plan (ACP) is updated regularly, every three years, or more frequently if major changes to the Asset occur.
2) Project for Lambert-West development (1 Well) is in pre-FID phase. When developed it may slightly extend the Angel EoFL /CoP, to mid-2028.
3) Post closure monitoring plan assumes that final survey is completed within 2 to 5 years post completion of all decommissioning activities.

Figure 7-8: Holistic Angel decommissioning planning lifecycle and schedule

7.4 Organisation Structure

The following Woodside organisational structure provides leadership and direction for operation of the Angel facility and environmental performance:

- The Executive Vice President Operations (EVP) reports to the Chief Executive Officer.
- The NWS Vice President (VP) reports to the EVP Operations.
- The Asset Manager reports to the NWS VP.
- Angel PIC reports to the Asset Manager.
- The functional support teams report to the corresponding Functional VP.
- All production facilities are supported by a team of environmental professionals who report to the Environment Manager Australian Operations.
- All facilities are supported by other Woodside functional teams, including:
  - **HSE** – provides specific guidance and access to specialist HSE resources including assistance for governance and training, as well as guidance on Woodside HSE standards
  - **Subsea** – responsible for the installation and IMMR activities on subsea infrastructure including facility structures, flowlines, manifolds and subsea isolation valves to ensure integrity
  - **Global Wells and Seismic** – ensures the safe planning and execution of drilling, completion and work over operations
  - **Projects** – responsible for the engineering, construction and execution of small projects on operational facilities to ensure ongoing integrity and safe operation
  - **Marine Group** – responsible for chartering vessels to support Woodside's offshore production facilities including vessels to aid emergency response
  - **Aviation Group** – provides personnel transport, material transport, emergency evacuation and search and rescue capabilities.

7.5 Roles and Responsibilities

Key roles and responsibilities for Woodside and contractor personnel in relation to implementing, managing and reviewing this EP are described in **Table 7-5**. Roles and responsibilities for hydrocarbon spill preparation and response are outlined in **Table 7-5**, **Appendix D** and the *Woodside Oil Pollution Emergency Arrangements (Australia)*.

It is the responsibility of all Woodside employees and contractors to apply the Woodside *Corporate Health, Safety, Environment and Quality Policy* (**Appendix A**) in their areas of responsibility and that the personnel are suitably trained and competent in their respective roles.

Table 7-5: Roles and responsibilities

Title (role)	Environmental responsibilities
All Personnel	
All offshore-based personnel and onshore support personnel	• Understand the Woodside standards and procedures that apply to their area of work. • Understand the environmental risks and control measures that apply to their area of work. • Carry out assigned activities in accordance with approved procedures and the EP. • Follow instructions from relevant supervisor with respect to environmental protection. • Cease operations which are deemed to present an unacceptable risk to the environment. • Participate in environmental assurance activities and inspections as required. • Prompt reporting of environmental hazards/incidents to their supervisor and assist in event investigation. • Attend HSE meetings, training and drills when required.
Office-based Personnel	
Woodside Project Manager	• Monitor and manage the activity so it is undertaken as per the relevant standards and commitments in this EP. • Notify the Woodside Environment Adviser of any scope changes in a timely manner. • Liaise with regulatory authorities as required. • Review this EP as necessary and manage change requests. • Ensure all project and support vessel crew members complete an HSE induction. • Verify that contractors meet environmental related contractual obligations. • Confirm environmental incident reporting meets regulatory requirements (as outlined in this EP) and Woodside's Health, Safety and Environment Reporting and Investigation Procedure. • Monitor and close out corrective actions identified during environmental monitoring or audits.
Woodside Head of Projects/Region (Global Wells and Seismic)	• Ensure drilling operations are undertaken as per this EP and approval conditions. • Provide sufficient resources to implement the drilling-related management measures (i.e., controls, EPOs, PSs and MC) in this EP. • Confirm controls and performance standards in this EP are actioned, as required, before drilling commences. • Ensure the MODU start-up meets the requirements of the Drilling and Managing Rig Operations Process.

Title (role)	Environmental responsibilities
Subsea Delivery Lead	• Ensure the subsea installation activities are undertaken as per this EP and approval conditions. • Provide sufficient resources to implement the subsea installation-related management measures (i.e., controls, EPOs, PSs and MC) in this EP. • Ensure installation vessel personnel are given an Environmental Induction as per Section 7.7.1 of this EP at the start of the installation activities. • Confirm controls and performance standards in this EP are actioned, as required, before installation activities commence. • Ensure relevant vessels meet the requirements of Woodside's Marine Operations Operating Standard. • Manage change requests for the activity and notify the Woodside Environment Adviser of any scope changes in a timely manner. • Confirm that site-based personnel are given an Environmental Induction as per Section 7.7.1 of this EP at the start of the activity. • Ensure all chemicals and drill fluids proposed to be discharged are assessed and approved as per the requirements of the EP.
Woodside Drilling Superintendent	• Ensure the drilling program meets the requirements detailed in this EP. • Ensure changes to the drilling program are communicated to the Woodside Environmental Adviser. • Ensure the Woodside's Well Site Manager is provided with the resources required to ensure the management measures (i.e., controls, EPOs, EPs and MC) in this EP are undertaken. • Confirm environmental incident reporting meets regulatory requirements (as outlined in this EP) and Woodside's Health, Safety and Environment Reporting and Investigation Procedure. • Monitor and close out corrective actions identified during environmental monitoring or audits. • Ensure MODU and project vessel personnel are given an Environmental Induction as per Section 7.7.1 of this EP at the start of the drilling programs.
Woodside Drilling Engineers	• Ensure changes to the drilling program are communicated to the Woodside Environmental Adviser. • Ensure all drill and completions fluid chemical components and other fluids that may be used downhole have been reviewed by the Drilling and Completions Environmental Adviser.

Title (role)	Environmental responsibilities
Woodside Projects/GWS Environmental Adviser	• Verify relevant Environmental Approvals for the activities exist prior to commencing activity. • Track compliance with performance outcomes and performance standards as per the requirements of this EP. • Prepare environmental component of relevant Induction Package. • Assist with the review, investigation and reporting of environmental incidents. • Ensure environmental monitoring and inspections/audits are undertaken as per the requirements of this EP. • Liaise with relevant regulatory authorities as required. • Assist in preparation of external regulatory reports required, in line with environmental approval requirements and Woodside incident reporting procedures. • Monitor and close out corrective actions (Campaign Action Register (CAR)) identified during environmental monitoring or audits. • Provide advice to relevant Woodside personnel and contractors to assist them to understand their environment responsibilities. • Liaise with primary installation contractors to ensure communication and understanding of environment requirements as outlined in this EP and in line with Woodside's Compass values and management systems.
Asset Manager	• Be accountable for ensuring all necessary regulatory approvals are in place to operate. • Approve (decide on) the content to be contained in the Environment Plan. • Be accountable for managing the asset throughout its operations in accordance with legislative/regulatory requirements (including this EP) and WMS requirements. • Agree facility key performance indicators (KPIs), including environment KPIs and is accountable for their achievement. • Be responsible for continuous improvement of operations of the facility, including environmental performance. • Decide on technical decisions where required based on assessed current level of risk. • Be accountable for incident notification, reporting and investigation in line with regulatory requirements, the WMS and EP requirements.
Asset Superintendent	• Be responsible for the operation of the facility in accordance with legislative/regulatory requirements (including this EP) and the WMS. • Decide on technical decisions where required based on assessed current level of risk. • Be accountable for aspects of integrity management. • Communicate changes relevant to the EP to the Production Environment team. • Be accountable for conformance to production Operations processes including ISSoW.
Technical Support Lead	• Be responsible for safeguarding process safety with respect to the asset. • Ensure technical integrity risks are identified, managed and reduced to ALARP. • Recommend technical decisions where required based on assessed current level of risk.

Title (role)	Environmental responsibilities
Integrity Authorities (Technical Integrity Custodians, Technical Authorities and Engineering Authorities)	• Agree technical integrity decision based on assessed current level of risk when discipline owner • Undertake process safety responsibilities as defined under the Woodside process safety framework.
Environment Manager Australian Operations	• Facilitate operations environmental approval documentation and timely submission in accordance with regulatory requirements. • Ensure Asset and supporting personnel understand and adhere to legislative and regulatory environment requirements, EP requirements and the environmental requirements of the WMS. • Develop and maintain appropriate Production environmental processes and procedures. • Monitor and communicate to internal stakeholders all relevant changes to legislation, policies, regulator organisation that may impact the EP or business. • Facilitate review of the EP, including revision to the EP and in relation to any technical decisions or proposed changes to operations.
Environment Adviser Australian Operations	• Manage change relevant to the EP in accordance with the Regulations and the EP. • Ensure environmental monitoring, offshore inspections, and reporting is undertaken as per the requirements of this EP. • Coordinate and monitor closeout of corrective actions. • Ensure environmental inspections/audits are undertaken as per the requirements of the EP. • Ensure environmental incident reporting meets regulatory requirements (as described within the EP) and WMS.
Subsea and Pipelines (IMMR) Activity Manager	• Ensure IMMR activities undertaken in line with EP commitments. • Manage IMMR change requests for the activity and notify the Subsea and Pipelines Environment Adviser of any scope changes in a timely manner. • Be responsible for governance of IMMR related activities for subsea support vessels. • Provide sufficient resources to implement the EP requirements. • Monitor and close out corrective actions raised from IMMR environmental inspections/audits or incidents.
Corporate Affairs Adviser	• Prepare and implement the Consultation Plan for the Petroleum Activities Program. • Report on consultation. • Perform ongoing liaison and notification as required as per Section 7.9.
Woodside Marine Assurance Superintendent	• Conduct relevant audit and inspection to confirm vessels comply with relevant Marine Orders and Woodside Marine Charters Instructions requirements to meet safety, navigation and emergency response requirements.

Title (role)	Environmental responsibilities
Woodside CIMT Deputy Incident Commander	• On receiving notification of an incident, the Woodside CIMT Deputy Incident Commander shall: • establish and take control of the IMT and establish an appropriate command structure for the incident • assess situation, identify risks and actions to minimise the risk • communicate incident progress to relevant persons within the organisation • develop the incident action plan (IAP) including setting objectives for action • approve, implement and manage the IAP • communicate within and beyond the incident management structure • manage and review safety of responders • address the broader public safety considerations • conclude and review activities.
Contractor Sponsors	• Ensure implementation of EP for the contractor's scope of work. • Ensure contractors have adequate environmental capability in order to execute their respective scopes of work. • Review contractor environmental performance as required.
MODU-based Personnel	
MODU Offshore Installation Manager (OIM)	• Ensure the MODU's management system and procedures are implemented. • Ensure personnel starting work on the MODU receive an environmental induction that meets the requirements specified in this EP. • Ensure personnel are competent to undertake the work they have been assigned. • Verify that emergency drills are conducted as per the MODU's schedule. • Ensure the MODU's Emergency Response Team has been given sufficient training to implement the MODU's SOPEP. • Ensure any environmental incidents or breaches of outcomes or standards are reported immediately to the Well Site Manager. • Ensure corrective actions for incidents or breaches are developed, communicated to the Well Site Manager, and tracked to close out in a timely manner. Close out of actions is communicated to the Well Site Manager.

Title (role)	Environmental responsibilities
Woodside Well Site Manager	• Ensure the drilling program is undertaken as detailed in this EP. • Ensure the management measures (i.e., controls, EPOs, PSs and MC) detailed in this EP (relevant to offshore activities) are implemented on the MODU (other controls will be implemented onshore). • Ensure environmental incidents or breaches of outcomes or standards are reported as per the Woodside Corporate Event Notification Matrix. Corrective actions for incidents and breaches are developed, tracked and closed out in a timely manner. • Ensure actions in the Drilling and Completions HSE Improvement Plan are undertaken. • Ensure periodic environmental inspections/reviews are completed. Corrective actions from inspections are developed, tracked and closed out in a timely manner.
Woodside Offshore HSE Adviser	• Support the Well Site Manager to ensure the controls detailed in this EP relevant to offshore activities are implemented on the MODU and help collect and record evidence of implementation (other controls are implemented, and evidence collected onshore). • Support the Well Site Manager to ensure the Environmental Performance Outcomes are met and the performance standards detailed in this EP are implemented on the MODU. • Confirm actions in the Drilling and Completions HSE Improvement Plan are undertaken. • Support the Well Site Manager to ensure environmental incidents or breaches of outcomes or standards outlined in this EP, are reported, and corrective actions for incidents and breaches are developed, tracked and closed out in a timely manner. • Ensure periodic environmental inspections/reviews are completed and corrective actions from inspections are developed, tracked and closed out in a timely manner. • Review Contractors procedures, input into Toolbox talks and JSAs. • Provide day to day environmental support for activities in consultation with the Woodside Environment Adviser.
Drilling Logistics Coordinator	• Ensure waste is managed on the MODU and sent to shore as per the Drilling and Completions Waste Management Plan.

Title (role)	Environmental responsibilities
Offshore-based Personnel	
NRC Offshore Installation Manager (OIM)	• Be in charge of the Angel facility and the field. • Be accountable for implementation of the EP at the facility. • Ensure offshore personnel comply with regulatory/legislative requirements (including the EP) and the WMS. • Be responsible for Area Operations compliance with Technical Integrity requirements including Management of Change process, Permit to Work process and MOPO and process safety requirements. • Be the single point responsible person for the coordination of simultaneous activities. • Implement relevant offshore environment initiatives and review environmental performance to drive continuous improvement. • Ensure effective communication with workforce on environmental performance. • Ensure incidents are reported and investigated in line with WMS and EP requirements, with appropriate actions initiated and closed out. • Decide on technical decisions where required based on assessed current level of risk. • Communicate changes relevant to the EP to the Environment team. • Be accountable for the performance and development of direct reports, ensuring operator capability and competency across all shifts and ensuring the skill requirements of the Operations division are being met. • Lead response efforts (as Level 1 Incident Controller, refer Section 7.12) in managing emergency or crisis scenarios. • Ensure exercises and drills are conducted in a manner to assure the facility's ability to respond effectively to an emergency.
Angel Person in Charge (PIC) (offshore staffed mode)	• Manage work in accordance with the Offshore Safety Manual. • Control and execute all facility activities within the Angel PAA. • Provide and apply the EP for all work scopes. • Manage and coordinate the permit to work process and Work Permit Authority. • Be responsible for leading and coordinating a multi-disciplined team to perform specific duties required to support the technical integrity of the facility. • Be Level 1 Incident Controller during staffed mode (refer Section 7.12). • Manage and coordinate during emergencies.

Title (role)	Environmental responsibilities
Operations Advisor/ Operations Team Leader/ Execution Superintendent	• Be accountable for the day-to-day operations of the facility including effective shift handover; completion and logging of operator routine. • Be responsible for operations shift compliance to all legislative and regulatory requirements as defined in the EP. • Be responsible for permitting and isolation for all frontline work activities. • Be responsible for leading and coordinating a multi-disciplined team performing specific duties required to support the facility, including helicopter operations, vessel movements and consumable controls. • Be responsible for following emergency response protocols in accordance with the emergency response procedure and fulfilling allocated emergency response roles.
Angel/NRC Operations and Maintenance Technicians	• Be responsible for daily operations on the facility within their operational control. • Undertake daily operational and maintenance tasks in accordance with approved standards and procedures to ensure compliance with the EP. • Manage day-to-day environmental risks through use of ISSoW and other risk management tools. • Identify opportunities for continuous improvement and communicate these to their Supervisor. • Complete training requirements to maintain competence and knowledge in operating and maintaining equipment, and manage environmental risks and impacts. • Participate in environmental assurance activities and inspections as required. • Report all environmental hazards and incidents and assist in investigations.
NRC Health, Safety and Environment Coordinator (HSEC)	• Liaise with managers/supervisors on day to day management of environmental risks and issues. • Assist in the ongoing promotion of environmental performance at the facilities and day-to-day management HSE risks and issues. • Identify opportunities for continuous improvement and communicate these to the OIM and Environment Team. • Implement environmental improvement plans. • Support operational personnel to understand the EP requirements applicable to their role, • Communicate environmental performance information and training material to offshore personnel and maintain associated records.

Title (role)	Environmental responsibilities
Vessel-based Personnel	
Vessel Master (Installation Vessel Master, Activity Support Vessel Master, Support Vessel (Platform and Subsea Support Vessels))	• Ensure the vessel management system and procedures are implemented. • Ensure personnel commencing work on the vessel receive an environmental induction that meets the relevant requirements specified in this EP. • Ensure personnel are competent to undertake the work they have been assigned. • Verify SOPEP drills are conducted as per the vessel's schedule. • Ensure the vessel Emergency Response Team (ERT) has been given sufficient training to implement the SOPEP. • Ensure any environmental incidents or breaches of relevant Environmental Performance Outcomes or performance standards detailed in this EP, are reported immediately to the Woodside Representative. • Ensure corrective actions for incidents or breaches are developed, communicated to the Woodside Representative, and tracked to close out in a timely manner. Close out of actions is communicated to the Woodside Representative.
Vessel Logistics Coordinators	• Ensure waste is managed on the relevant support vessels or installation vessel and sent to shore as per the relevant Waste Management Plan.
Vessel HSE Advisers	• Refer to Woodside HSE Offshore Adviser responsibilities detailed above under MODU-based personnel.
Contractor Project Manager	• Confirm that activities are undertaken in accordance with this EP, as detailed in the Woodside approved Contactor Environmental Management Plan. • Ensure personnel commencing work on the project receive a relevant environmental induction that meets the requirements specified in this EP. • Ensure personnel are competent to undertake the work they have been assigned. • Ensure any environmental incidents or breaches of objectives, standards or criteria outlined in this EP, are reported immediately to the Woodside Responsible Engineer or Vessel Master.
Woodside Site Representative/ Resident Engineer	• Ensure activities are undertaken as detailed in this EP. • Ensure the management measures made in this EP are implemented on the vessel. • Ensure environmental incidents or breaches of objectives, standards or criteria outlined in this EP, are reported as per the Woodside Corporate Event Notification Matrix. • Verify HSE improvement actions identified during the project are implemented where practicable. • Ensure periodic environmental inspections are completed.

It is the responsibility of all Woodside employees and contractors to implement the Woodside Corporate Health, Safety, Environment and Quality Policy (**Appendix A**) in their areas of responsibility and that the personnel are suitably trained and competent in their respective roles.

7.6 Unexpected Finds Procedure

In the event of the discovery of what appears to be Underwater Cultural Heritage (defined as 'any trace of human existence that has a cultural, historical or archaeological character and is located under water'); the following Unexpected Finds Procedure will apply:

- All activities with the potential to impact the suspected Underwater Cultural Heritage must cease immediately. Retain all records of the potential Underwater Cultural Heritage, including any imagery, description and location.
- Person who discovers the heritage object must inform the Activity Supervisor.
- Activity Supervisor must notify Woodside's Principal Heritage Adviser.
- Woodside will specify an appropriate buffer around the potential Underwater Cultural Heritage, taking into consideration the nature and scale of the potential Underwater Cultural Heritage and the activities to be managed.
- No seabed disturbance may occur within the buffer area around the potential Underwater Cultural Heritage until approved by Woodside's Principal Heritage Adviser.
- Woodside's Principal Heritage Adviser must notify a qualified underwater archaeologist and provide all available documentation of the potential Underwater Cultural Heritage.
- If the potential Underwater Cultural Heritage appears to be Aboriginal underwater cultural heritage, Woodside's Principal Heritage Adviser must notify the appropriate Traditional Custodians to determine whether it is a heritage site and if so, how the site should be managed.
- If the potential Underwater Cultural Heritage appears to be a shipwreck or aircraft that has been wrecked for more than 75 years, or is otherwise reportable under Section 40 of the UCH Act, Woodside's Principal Heritage Advisor must notify the Minister responsible for the UCH Act, the DCCEEW underwater archaeology section through the Australasian Underwater Cultural Heritage Database, and the Western Australian Museum.
- If the suspected heritage object includes human remains, Woodside's Principal Heritage Adviser must also notify:
  - the Australian Federal Police (phone: 131 444) of the location of the remains, that the remains are likely to be historic or Aboriginal in origin, and that it may be appropriate that Traditional Custodians and a maritime archaeologist are present during any handling of the remains
  - the Office of the Federal Environment Minister in accordance with Section 20 of the ATSIHP Act.
- Work must not recommence in the vicinity of the potential heritage object until Woodside's Principal Heritage Adviser provides written approval. Woodside's Principal Heritage Adviser must only provide written approval once agreed management measures are implemented consistent with approvals and legislation or where the potential Underwater Cultural Heritage is confirmed to not be Underwater Cultural Heritage.

7.7 Training and Competency

Woodside as part of its contracting process undertakes assessments of a proposed Contractor's environmental management system to determine the level of compliance with the standard

AS/NZS ISO 14001. This assessment is undertaken for the Petroleum Activities Program as part of the pre-mobilisation process. The assessment determines whether there is a clearly defined organisational structure that clearly defines the roles and responsibilities for key positions. The assessment also assesses whether there is an up-to-date training matrix that defines any corporate and site/activity-specific environmental training and competency requirements.

As a minimum, environmental awareness during inductions is required for all Angel facility and MODU personnel, detailing awareness and compliance with the Angel facility, MODU and project vessel Contractor's environmental policy and environmental management system.

7.7.1 Inductions and Training

Inductions are provided to all relevant personnel (e.g., contractors and Company representatives) before mobilising to or on arrival at the activity location. The induction covers the HSE requirements and environmental information specific to the activity location. Attendance records will be maintained.

The Petroleum Activities Program induction may cover information about:

- description of the activity
- ecological and socio-economic values of the activity location (including underwater cultural heritage)
- regulations relevant to the activity
- Woodside's Environmental Management System – Health, Safety and Environment Policy
- EP importance/structure/implementation/roles and responsibilities
- main environmental aspects/hazards and potential environmental impacts and related performance outcomes
- oil spill preparedness and response
- monitoring and reporting on performance outcomes and standards using MC
- incident reporting
- inductions for offshore facility workers and visitors
- operations competency framework training
- permit to work training (ISSoW)
- production environmental leadership training and environment awareness training
- emergency and hydrocarbon spill response training
- inductions for subsea IMMR (vessel based) personnel
- Unexpected Finds Procedure and reporting requirements (Section 7.6).

Records for Woodside operations personnel, in relation to the above-listed training, are maintained in Woodside's learning management system. Contractor training records are also maintained.

Competence of operations personnel can be reviewed via online dashboards.

7.7.2 Activities Program Specific Environmental Awareness

Before petroleum activities begin, a pre-activity meeting will be held on-board the MODU and project vessels with all relevant personnel. The pre-activity meeting provides an opportunity to reiterate specific environmental sensitivities or commitments associated with the activity. Relevant sections of the pre-activity meeting will also be communicated through to the support vessel personnel. Attendance lists are recorded and retained.

During operations, regular HSE meetings will be held on the Angel facility, MODU and project vessels which cover all crew. During these meetings, recent environmental incidents are regularly reviewed, and awareness material presented.

7.7.3 Inductions for Offshore Facility Workers and Visitors

A comprehensive induction process is in place for personnel working on or visiting Woodside's offshore production facilities. The induction process is designed to equip personnel with the HSE awareness and skills necessary for them to manage their own safety and environmental performance and contribute to others working around them. The induction process includes:

- Common Production Induction – All employees and contractors who have not accessed a production facility within 12 months are required to undertake this induction prior to mobilisation. It includes Woodside's values, HSEQ and Process Safety, continuous improvement, risk management and ISSoW.
- Facility Specific Induction – All employees and contractors that have not accessed the production facility within six months are required to undertake this induction on arrival at the facility. This induction covers the HSE and emergency response issues specific to each facility. For environment, this induction covers the Facility EP, prevention of spills, waste management, fauna interactions, hazard identification and risk assessment, and incident reporting.
- Production Offshore Environmental Leadership Training – Key operations leadership roles (as specified within the Operations Competency Framework) are required to complete this competency on commencement of the new role and three yearly thereafter. The training covers Woodside's policies and standards, environmental legislative requirements, the EP, key environmental risk and impacts, environmental reporting, environmental management tools (e.g., improvement planning, compliance reviews and audits), hydrocarbon spill response and environmental accountabilities.
- Production Offshore Environmental Awareness Training – All new offshore operational personnel are required to undertake this online training on commencement of the new role and two yearly thereafter. This training covers environmental legislative requirements, the facility EP, key environmental hazards and control measures (including waste management, spill prevention, chemical storage, wildlife interactions), environmental management tools, hazard and incident reporting, spill response, and environmental responsibilities.

7.7.4 Operations Competency Framework Training

The Operations Competency Guideline defines a framework to make sure all personnel on operating facilities are competent to perform their work and that competency is managed. By doing this, the potential for unplanned (accident/incident) type events that could result in environmental impact is minimised.

Operational Area Licence to Operate (LTO) roles are those roles related to oil and gas processing, equipment maintenance, marine regulations, emergency response and any other roles involved with safeguarding the facility integrity, including all roles where high-risk work licences are required. Additionally, roles mandated by Woodside such as HSEC and helicopter landing officer are included in the LTO roles process.

The requisite competency and training for each LTO role has been defined. Competencies for these LTO roles are stipulated by the governance group for each respective position and are based on the relevant Australian or International standards which apply. In cases where no Australian or International standards are available or applicable, training is based on the relevant Woodside Standard as determined by the respective governance group.

Contractors working on Woodside facilities are required to verify the competency of their personnel through the contractor's own verification systems. Additionally, contractor personnel working on

Woodside facilities are required to be registered in Woodside's Contractor Verification Service (CVS) beforehand. Personnel registered in CVS have had their skills and qualifications independently verified on behalf of Woodside thereby confirming that contractor personnel hold the required competencies before mobilisation to the facility.

The LTO Roles Report (available online on the Woodside Competency Reporting Dashboard on the Production Academy Intranet page) provides the conformance status of the facility against the LTO roles requirements.

7.7.5 Permit to Work System Training

The ISSoW permit to work (i.e., participation in crisis or emergency management exercises). Roles based training is further described in **Section 7.12**.

An overview of Woodside's hydrocarbon spill response training and competency requirements are provided in dashboards for key responder roles. The roles are consistent with Woodside's crisis and emergency management incident control structure. system (see **Section 7.2.1**) is a key element in ensuring that all necessary steps are taken to ensure the safety of personnel, protection of the environment and technical integrity of the facility. The ISSoW system takes a risk-based approach to all activities, thus tasks with higher levels of risk are subjected to greater scrutiny and control.

All members of the workforce that are required to work with ISSoW (**Section 7.2.1**) receive training commensurate with the level of authority and responsibility they hold in ISSoW.

7.7.6 Emergency and Hydrocarbon Spill Response Training

All operations personnel involved in crisis and emergency management are required to commit to ongoing training, process improvement and participation in emergency and crisis response (both real and simulated), including emergency drills specific to potential incidents at the Angel facility. Training includes task specific training and role based training and 'on the job' experience

Woodside Hydrocarbon Spill Preparedness Advisor(s) are responsible for maintaining hydrocarbon spill preparedness competency. This includes the identification and development of approved competency and non-competency-based courses, identification of relevant personnel required to undertake training and ensuring training records are maintained. Minimum Woodside capabilities will continue to be identified and documented.

7.7.7 Subsea Inspection, Monitoring, Maintenance and Repair Activity Environmental Awareness

At the beginning of, and during a new Subsea IMMR activity, the Subsea Support Vessel crew including contractor crew, Woodside representatives and other relevant personnel are required to undertake a vessel induction before commencing work. This induction covers HSE requirements for the vessel and IMMR activities, and as required environmental information specific to the activity location. The induction may cover the following environmental information:

- adherence to standards and procedures, and the use of Job Safety Analysis and permit to work hazard identification and management process
- spill management including prevention, response and clean-up, location of spill kits and reporting requirements
- waste management requirements and location of bins
- reporting of marine fauna, location of forms and charts
- chemical management requirements.

All personnel who undertake the project induction are required to sign an attendance sheet which is retained.

Regular HSE meetings are held on subsea support vessels with crew. During these meetings, any environmental incidents are reviewed, and environmental awareness material presented.

7.7.8 Management of Training Requirements

All personnel on the Angel facility, MODU and project vessels are required to be competent to perform their assigned positions. This may be in the form of external or 'on the job' training. The vessel Safety Training Coordinator (or equivalent) is responsible for identifying training needs, keeping records of training performed and identifying minimum training requirements.

7.8 Monitoring, Auditing, Management of Non-conformance and Review

Regulation 22(5) states that the implementation strategy is to provide for the monitoring, audit, management of non-conformance and review of operator's environmental performance and the implementation strategy itself.

This section of the EP outlines the measures undertaken by Woodside to regularly monitor the management of environmental risks and impacts of the Angel facility against the EPOs, EPSs and MCs, with a view to continuous improvement of environmental performance. The effectiveness of the implementation strategy is also reviewed periodically as part of the monitoring and assurance process.

7.8.1 Monitoring

Woodside and its contractors will perform a program of periodic monitoring during the Petroleum Activities Program – starting at mobilisation of each activity and continuing through the duration of each activity to activity completion. This information will be collected using the tools and systems outlined below, developed based on the EPOs, controls, standards and MC in this EP. The tools and systems will collect, as a minimum, the data (evidence) referred to in the MC in **Section 6** and **Appendix D**.

The collection of this data (against the MC) will form part of the permanent record of compliance maintained by Woodside and will form the basis for demonstrating that the EPOs and standards are met, which will be summarised in a series of routine reporting documents.

7.8.1.1 Source-based Impacts and Risks

The tools and systems to monitor environmental performance, where relevant, will include:

- daily reports which include leading indicator compliance
- periodic review of waste management and recycling records
- use of contractor's risk identification program that requires recording and submitting safety and environment risk observation cards routinely (frequency varies with contractor)
- collection of evidence of compliance with the controls detailed in the EP relevant to offshore activities by the Woodside Offshore HSE Adviser (other compliance evidence is collected onshore)
- environmental discharge reports that record volumes of planned and unplanned discharges downhole (in the well), to ocean and atmosphere
- monitoring of progress against the Drilling and Completions function and Operations Division scorecards for KPIs
- internal auditing and assurance program as described in **Section 7.8.2**.

Throughout this activity, Woodside will continuously identify new source-based risks and impacts through the Monitoring and Auditing systems and tools described above and in **Section 7.8.2**.

Other examples of assurance tasks implemented through the EP include (as an example):

- start of shift operator walk arounds
- permit to work hazard, risk management check list, area sign-on, and permit audits (ISSoW – Section 7.2.1)
- technical integrity SCE performance reviews (daily, weekly, monthly) (Section 2.7.5)
- ongoing maintenance performance assurance (e.g., conformance dashboard)
- management system performance audits reviews (e.g., MSPSs) (Section 7.8.2)
- data gathering and governance dashboard presentations (e.g., Woodside Integrated Risk and Compliance System).

7.8.1.2 Management of Knowledge

Review of knowledge relevant to the existing environment is undertaken in order to identify changes relating to the understanding of the environment or legislation that supports the risk and impact assessments for EPs (in-force and in-preparation). New knowledge checks take place both routinely primarily via quarterly and annual knowledge reviews and ad hoc (as information is obtained), and encompasses the following topics:

- Environmental science – update checks conducted via desktop reviews: scientific literature, government publications and Woodside supported publications and studies relating to existing environment topics (including but not limited to species and habitats) as well as EPBC Act Matters of National Environmental Significance (Part 3) and Part 13 statutory instruments.
- Socio-economic environment and stakeholder information – update checks conducted via desktop reviews: scientific literature, government publications and Woodside consultation; and,
- Environmental legislation – monitoring of emerging regulatory changes and the subsequent management of regulatory change (as outlined in the WMS Regulatory Compliance Management Procedure).

A management of knowledge tracker is maintained to record reviews and updates. Communication of relevant new knowledge is addressed at the EP Consolidation meetings where changes in knowledge prompt a consideration of management of change, this is actioned and documented appropriately.

The frequency and documentation of reviews, communication of relevant new knowledge and consideration of management of change are documented in the WMS Environment Plan Guideline.

Any relevant new information on cultural values and heritage will be assessed using the EP Management of Change Process (refer to **Section 7.2.5**).

Under the Oil Spill Scientific Monitoring Program preparedness, an annual review and update to the environmental baseline studies database is completed and documented. Periodic location-focused environmental studies and baseline data gap analyses are completed and documented. Any subsequent studies scoped and executed as a result of such gap analysis are managed by the Environment Science Team and tracked via the Corporate Environment Baseline Database.

7.8.1.3 Management of Newly Identified Impacts and Risks

New sources of receptor based impacts and risks identified through monitoring and auditing systems and tools and the Woodside Environment Knowledge Management System are assessed using the Change Management Process (**Section 7.2.5**).

Table 7-6: Summary of emissions and discharges monitoring for the Petroleum Activities Program

Category	Parameter to be Monitored/Reported	Monitoring Frequency	Monitoring Equipment/Methodology	EP Reference
Planned Emissions				
Atmospheric emissions	Greenhouse, energy and criteria pollutants	Normally continuous process metering/annual reporting	NGERS and NPI reporting estimation methods (e.g., fuel/flare flow meters, throughput meters, process estimation)	**Section 6.6.10**
	Fuel gas and flare intensity	Normally continuous process metering/monthly reviews	Fuel and flare flowmeters inform intensity profiles – tracked against optimisation targets	**Section 6.6.10**
Planned Discharges				
Discharge of subsea control fluids during valve actuations	Subsea control fluid consumption	Normally continuous process indication/monthly review	Subsea control fluid consumption surveillance. Process indication for gross leaks/ruptures	**Section 6.6.4**
Discharge of hydrocarbons and chemicals during subsea IMMR activities	Volumes of hydrocarbons and chemicals released subsea	As required, during IMMR activities (activity specific)	Estimates based on known volumes pumped and ROV observation	**Section 6.6.4**
Discharge of produced water	Volume discharged overboard	Normally continuous process indication/monthly review	PW flow meter(s), process estimation	**Section 6.6.7**
	OIW concentration of discharged PW	Normally continuous process indication/monthly review	Normally continuous process metering/monthly review	
	Chemical characterisation	Annually	Characterisation of end of pipe sample	
	WET testing	Three yearly	PW ecotoxicity testing	
Waste recycling and disposal	Quantities of solid and liquid wastes disposed of onshore	Ongoing	Facility waste manifest	**Section 6.8.7**
Unplanned Emissions and Discharges				
Unplanned emissions and discharges	Nature of release	As required	HSEQ Event Reporting System (First Priority)	**Sections 6.7 and 6.8**

7.8.2 Auditing

Environmental performance auditing will be performed to:

- identify potential new or changes to existing environmental impacts and risk, and methods for reducing those to ALARP
- confirm that mitigation measures detailed in this EP are effectively reducing environmental impacts and risk, that mitigation measures proposed are practicable and provide appropriate information to verify compliance
- confirm compliance with the Performance Outcomes, Controls and Standards detailed in this EP.

Internal auditing will be performed to cover each key project activity as summarised.

7.8.2.1 Mobile Offshore Drilling Unit Activities

Internal auditing is performed on a MODU-specific schedule, rather than a schedule to align with the well. This enables continuous review and improvement of environmental performance over the term of the MODU contract. The following internal audits, inspections and reviews will be performed to review the environmental performance of the activities:

- Survey environment rig equipment for a newly contracted MODU (if not previously contracted to Woodside within the last two years) against Woodside's Engineering Standard – Rig Equipment. This standard covers functional and technical requirements for Woodside contracted rigs and their associated equipment. An environment rig equipment survey scope typically includes mud and solids control systems, environmental discharge control (including drainage management), and loss of containment management.
- Complete a minimum of monthly environmental inspection (conducted by offshore Woodside personnel or a delegate) which may include verifying:
  - bunkering/transfers between support vessels and MODU/project vessels
  - environment containment including chemical storage, spill response equipment and housekeeping
  - general MODU environment risks including waste management, drilling fluids oil/water separation, and inspection of subsea and moonpool areas.
- Perform environment audits quarterly during the Petroleum Activities Program, while the MODU is on location (by a Woodside Environment Adviser or delegate), which may include:
  - operational compliance audits relevant to environmental risk of activities, which may include compliance with training commitments, discharge requirements, bunkering activities, verification of use of approved chemicals, and satisfactory close out of items from previous audits
  - inspection of selected risk areas/activities (which may include shaker house, drill floor and mud management while commencing riser drilling or reservoir interception) during routine MODU visits throughout the MODU campaign, determined by risk, previous incidents or operation specification requirements
  - audit findings relevant to continuous improvement of environmental performance tracked through the MODU or vessel compliance action register, a contractor register between the MODU operator or vessel contractor and Woodside.

7.8.2.2 Subsea Scope Activities

The following internal assurance will be performed for the subsea scope activities:

- Pre-mobilisation inspection/audit report will be conducted by a relevant person (before commencing). The scope of the audits are risk-based and specific to the relevant activity, but will generally focus on aspects relating to ensuring appropriate understanding of environmental commitments and the operational readiness of the activity scope, including appropriate environmental controls in place. All installation vessels associated with the above scopes will be audited by Woodside. Support or transport vessels will be assessed on a risk-based approach, but will be audited via the primary subsea installation contractor's process.
- At least one operational compliance audit relevant to applicable EP commitments will be conducted by a Woodside Environment Adviser for the subsea campaign. The audit may be conducted offshore or office-based, subject to the duration of the activity and logistics of performing the audit offshore for short duration scopes (e.g., pipelay).
- Contractor-specific HSE audits will also be conducted of the associated support vessels. The audits will consider the implementation of HSE management, risk management, as well as pre-mobilisation and offshore readiness.
- Vessel based HSE inspections will be conducted fortnightly by vessel HSE personnel. Each inspection will focus on a specific risk area relevant to the project activity and a formal report will be issued (for example, bunkering controls, chemical and discharge management, cetacean reporting, etc).
- Annual inspection of Woodside's long term hire subsea support vessels are undertaken to ensure compliance with both the EP and the approved Contractor Management system.

The internal audits and reviews, combined with the ongoing monitoring described in **Section 7.8.1**, and collection of evidence for MC are used to assess EPOs and standards.

As part of Woodside's EMS and/or assurances processes, activities may also be periodically selected for environmental audits as per Woodside's internal auditing process. Audit, inspection and review findings relevant to continuous improvement of environmental performance are tracked through the Environmental Commitments and Actions Register.

This Environmental Commitments and Actions Register is used to track subsea support vessel and subsea activity compliance with EP commitments, including any findings and corrective actions.

Non-conformances identified will be reported and/or tracked in accordance with **Section 7.8.3**.

7.8.2.3 Operations Assurance

To provide confidence, based on evidence commensurate with risk, that business objectives are met, business activities are performed and risks are managed, assurance is performed as described in the Provide Assurance Procedure and the Provide Assurance Guideline. The Guideline aims to explain how the Operations Division Assurance Team implement WMS Assurance requirements, while concurrently satisfying the Operations Division's specific objectives.

Operations Assurance Assignments are contained within the Operations Division Integrated Assurance Assignment Plan.

Environmental assurance activities are conducted on a regular basis to help:

- verify environmental risks and potential impacts are being managed in accordance with the EPOs and EPSs detailed in this EP
- monitor, review and evaluate the effectiveness of the performance outcomes and standards detailed in this EP

- verify effectiveness of the EP implementation strategy
- identify potential non-conformances.

The outputs of the assurance process are corrective actions that feed the improvement process. Therefore, assurance is a key driver of continuous improvement.

7.8.2.4 Annual Offshore Inspection/Desktop Review

An inspection/review of the Angel facility is undertaken every calendar year by the Production Environment Team, via either an offshore inspection or desktop review. Selected risk areas/activities are inspected to review environmental performance against the EPOs and EPSs, and verify that control measures are effective in reducing the environmental risks and impacts of the activity to an ALARP and acceptable level.

The inspection/review also includes review of conformance with selected aspects of the EP implementation strategy. All risk sources/activities applicable to the offshore facility will be reviewed over a three-year rolling period. Records of findings and records of close-out of any corrective or improvement actions are maintained (close-out is tracked in Woodside's action tracking system).

7.8.2.5 Marine Assurance

Woodside's marine assurance is managed by the Marine Assurance Team of the Logistics Function in accordance with Woodside's Marine Offshore Vessel Assurance Procedure. The Woodside process is based on industry standards and consideration of guidelines and recommendations from recognised industry organisations such as Oil Companies International Marine Forum and International Maritime Contractors Association.

Woodside's Marine Offshore Assurance process is mandatory for all vessels (other than Tankers and Floating Production Storage and Offloading vessels) that are chartered directly by or on behalf of Woodside, including for short term hires (i.e., <3 months in duration). It defines applicable marine offshore assurance activities, ensuring all vessel operators operate seaworthy vessels that meet the requirements for a defined scope of work and are managed with a robust Safety Management System.

The process is multi-faceted and encompasses the marine assurance activities of:

- safety management system assessment
- DP system verification
- vessel inspections
- project support for tender review, evaluation and pre/post contract award.

Vessel inspections are used to verify actual levels of compliance with the company's Safety Management System, the overall condition of the vessel and the status of the planned maintenance system onboard. Woodside Marine Assurance Specialist will conduct a risk assessment on the vessel to determine the level of assurance applied and the type of vessel inspection required.

Methods of vessel inspection may include, and are not limited to:

- Woodside marine vessel inspection
- Oil Companies International Marine Forum (OCIMF) Offshore Vessel Inspection Database (OVID) inspection
- IMCA CMID inspection
- marine warranty survey.

Upon completion of the marine assurance process, to confirm that identified concerns are addressed appropriately and conditions imposed are managed, the Woodside Marine Assurance Team will

issue the vessel a statement of approval. Should a vessel not meet the requirements of the Woodside Marine Offshore Vessel Assurance Process and be rejected, there does exist an opportunity to further scrutinise the proposed vessel.

Where a vessel inspection and/or OVMSA Verification Review is not available and all reasonable efforts based on time and resource availability to complete an vessel inspection and/or OVMSA Verification Review are performed (i.e., short term vessel hire), the Marine Assurance Specialist Offshore may approve the use of an alternate means of inspection, known as a risk assessment (**Section 7.8.2.6**).

Environmental requirements specific to offshore facility support vessel contractors are communicated via Woodside marine charterers instructions. This document provides the Master of a vessel on hire to Woodside, with a clearly defined set of requirements and procedures for operating the vessel in the vicinity of the Woodside's operating facilities. This includes the management of environmental risks and impacts from the Angel facility. The document includes information on:

- applicable legislation and guidelines
- roles and responsibilities
- marine fauna interaction guidance
- incident reporting requirements.

Environmental requirements specific to Subsea Support Vessels are communicated via the Subsea Environmental Compliance Package. This document outlines mandatory environmental management requirements for Subsea Support Vessels and associated contractors.

7.8.2.6 Risk Assessment

Woodside conducts a risk assessment of vessels where either an OVMSA Verification Review and/or vessel inspection cannot be completed. This is not a regular occurrence and is typically used when the requirements of the assurance process are unable to be met or the processes detailed are not applicable to a proposed vessel(s). The Marine Vessel Risk Assessment will be conducted by the Marine Assurance Specialist, where the vessel meets the short term hire prerequisites.

The risk assessment is a semi-quantitative method of determining what further assurance process activity, if any, is required to assure a vessel for a particular task or role. The process compares the level of management control a vessel is subject to against the risk factors associated with the activity or role.

Several factors are assessed as part of a vessel risk assessment, including:

- management control factors:
  - Company audit score (i.e., management system)
  - vessel HSE incidents
  - vessel Port State Control deficiencies
  - instances of Port State Control vessel detainment
  - years since previous satisfactory vessel inspection
  - age of vessel
  - contractors' prior experience operating for Woodside
- activity risk factors:
  - people health and safety risks (a function of the nature of the work and the area of operation)

- environmental risks (a function of environmental sensitivity, activity type and magnitude of potential environment damage (e.g., largest credible oil spill scenario))
- value risk (likely time and cost consequence to Woodside if the vessel becomes unusable)
- reputation risk
- exposure (i.e., exposure to risk based on duration of project)
- industrial relations risk.

The acceptability of the vessel or requirement for further vessel inspections or audits is based on the ratio of vessel score to activity risk. If the vessel management control is not deemed to appropriately manage activity risk, a satisfactory company audit and/or vessel inspection may be required before awarding work.

The risk assessment is valid for the period a vessel is on hire and for the defined scope of work.

7.8.3 Management of Non-conformance

Woodside classifies non-conformances with EPOs and standards in this EP as environmental incidents. Woodside employees and contractors are required to report all environmental incidents, and these are managed as per Woodside's internal event recording, investigation and learning requirements.

An internal computerised database called First Priority is used to record and report these incidents. Details of the event, immediate action taken to control the situation, investigation outcomes and corrective actions to prevent reoccurrence are all recorded. Corrective actions are monitored using First Priority and closed out in a timely manner.

Woodside uses a consequence matrix for classification of environmental incidents, with the significant categories being A, B and C (as detailed in **Section 2.3**). Detailed investigations are completed for all categories A, B, C and high potential environmental incidents.

7.8.4 Review

7.8.4.1 Management Review

Within the Environment Function, senior management regularly monitor and review environmental performance and the effectiveness of managing environmental risks and performance. Within each Function and Business Unit Leadership Team (e.g., Drilling and Completions, Subsea and Developments/Projects), managers review environmental performance regularly, including through quarterly HSE review meetings.

Woodside's Global, Wells and Seismic Environment Team will perform six-monthly reviews of the effectiveness of the implementation strategy and associated tools. This will involve reviewing the:

- Drilling and Completions team environment KPIs (leading and lagging)
- tools and systems to monitor environmental performance (detailed in Section 7.8.1)
- lessons learned about implementation tools and throughout each campaign.

Reviews of oil spill arrangements and testing are performed in accordance with **Section 7.12.7**.

Woodside's Operations Division Environment Team will perform routine reviews of the effectiveness of the implementation strategy and associated tools. This will involve reviewing the:

- Operations Division environment KPIs (leading and lagging)
- tools and systems to monitor environmental performance (detailed in **Section 7.8.1**)

Reviews of oil spill arrangements and testing are performed in accordance with **Section 7.12.7**.

7.8.4.2 Program of Ongoing Engagement with Traditional Custodians

Woodside will undertake an annual review of the Program of Ongoing Engagement with Traditional Custodians (**Appendix I**) to determine its effectiveness and adapt the program accordingly. The annual review will also include an assessment of appropriateness of the methods used to undertake ongoing consultation with Traditional Custodians.

7.8.4.3 Learning and Knowledge Sharing

Learning and knowledge sharing occurs via a number of different methods including:

- event investigations
- event bulletins
- after action review conducted at the end of each well, including review of environmental incidents as relevant
- ongoing communication with MODU and facility operators
- formal and informal industry benchmarking
- cross asset learnings
- engineering and technical authorities discipline communications and sharing
- review of impacts, risks and controls across the life of the EP.

In the event that activities described in this EP do not occur continuously or sequentially, before recommencing activities after a cessation period greater than 12 months, impacts, risks and controls will be reviewed.

The process will identify or review impacts and risks associated with the newly-commencing activity, and will identify or review controls to ensure impacts and risks remain/are reduced to ALARP and acceptable levels. Information learned from previous activities conducted under this EP will be considered. Controls which have previously been excluded on the basis of proportionality will be reconsidered. Any required changes will be managed by the MOC process outlined below (**Section 7.2.5**).

7.8.4.4 Continuous Improvement

Continuous improvement (CI) projects to improve production or environmental performance that involve refurbishment, modification or major maintenance on the facility are typically managed by Brownfields Engineering, and required to follow appraise and develop management procedures. Currently, the Procedure requires that all projects be managed in accordance with the Opportunity Management Framework which supports the progressive maturation of an opportunity through value creation in the Assess and Select Phases and the maintenance of value in the Develop and Execute phases.

To support the accountable executive to make a decision on whether a CI Project should proceed to the next phase in the Opportunity Management Framework, it is sometimes necessary to conduct a trial of the modification to determine the outcomes that can be expected if the modification is implemented. Due to prioritisation of resources, the phased progress of opportunities, competition between different solutions and long-term strategic and financial considerations, it is not possible to set quantitative success criteria to determine whether a modification will be implemented based on the results of trials. Instead, the results of a trial are used to inform a decision on whether to progress the CI Project to the next phase in the Opportunity Management Framework. Decisions are typically made with two key considerations; whether the business is ready to proceed which has a technical/functional focus and whether there is a business case for progressing to the next phase. The business case may consider the ALARP position for the CI Project, if relevant.

7.9 Record Keeping

Compliance records (outlined in MCs in **Section 6**) are maintained.

Record keeping is in accordance with regulation 22(6) that addresses maintaining records of emissions and discharges.

7.10 Ongoing Consultation

Although consultation for the purpose of regulation 25 is complete, in accordance with regulation 22(15) of the Environment Regulations, the implementation strategy must provide for appropriate consultation with relevant authorities of the Commonwealth, a State or Territory and other relevant interested persons or organisations.

Woodside proposes to undertake the engagements with directly impacted relevant persons and additional persons listed in **Table 7-7**. Relevant new information identified during ongoing consultation will be assessed using the EP Management of Knowledge (refer to **Section 7.8** and Management of Change Process (refer to **Section 7.2.5**).

Woodside hosts community forums at which members are provided updates on Woodside activities on a regular basis (for example community reference group meetings). Representatives who present at those meetings are from community and industry and include Woodside, State Government (for instance relevant Regional Development Commissions), Local Government, Indigenous Groups, industry representative bodies, Community and industry organisations.

Relevant persons and those who are simply interested in the activities, can otherwise remain up to date on this activity through subscribing to our website the Woodside website, or by reading the publicly available version of the EP on NOPSEMA's website, where available.

Should consultation feedback be received following EP acceptance that identifies relevant new information or a measure or control that requires implementation or update to meet the intended outcome of consultation (see **Section 5.2**), Woodside will apply its EP Management of Knowledge process (refer to **Section 7.8.1.2**) and Management of Change process (refer to **Section 7.2.5**), as appropriate.

Woodside has developed a Program of Ongoing Engagement with Traditional Custodians (**Appendix I**)**,** which is compliant with Corporate Woodside Policies Strategies and procedures and directly informed by feedback from Traditional Custodians. It provides a mechanism for ongoing dialogue so that Traditional Custodians can, on an ongoing basis, provide Woodside with feedback relating to the activity and in relation to caring for and managing country, including Sea Country. The Program will be tailored to each Traditional Custodian group and may include, as agreed with relevant Traditional Custodians:

- social investment to support Indigenous ranger programs
- support for Indigenous oil spill response capabilities
- support for recording Sea Country values
- support to Traditional Custodian groups to build capabilities and capacity with respect to ability to engage with Woodside and the broader O&G industry on activities
- development of ongoing relationships with Traditional Custodian groups
- any other initiatives proposed for the purpose of protecting Country including cultural values.

At the time of EP submission, a number of specific activities as part of ongoing consultation regarding the activity are planned with Traditional Custodian Relevant Persons. These are described in **Appendix I**. Where Traditional Custodian relevant persons have requested information or further engagement considered as ongoing consultation, but have not requested a framework agreement,

these requests have been captured in **Table 7-7**. However, a framework agreement may still be initiated by these groups at any time.

Table 7-7: Ongoing consultation engagements

Report/ information	Recipient	Purpose	Frequency	Content
Notification (email)	AHO	As requested by AMSA during consultation	No less than 4 weeks prior to commencement.	**PS 1.9** (**Section 6.6.1**) Date of activity start.
Updates (email)			As required.	Changes to planned activities.
Notification (email)	AMSA	As requested by AMSA during consultation	At least 24-48 hours before operations commence.	**PS 1.10** (**Section 6.6.1**) Date of activity start.
Update (email)			Provide updates to the AHO and JRCC should there be changes to the activity.	Changes to planned activities.
Notification (email) Updates (email)	AFMA, DAFF – Fisheries, DPIRD, CFA, WAFIC, Recfishwest, Searcher Seismic, and Wanparta	As requested during consultation	No less than 10 days prior to commencement and on completion of activities.	**PS 1.11** (**Section 6.6.1**) Date of activity start and end.
			As required.	Changes to planned activities.
Notification (email)	Other relevant persons	Notification of significant change	As required.	Notification of significant change.
Emails/ Meetings	Persons or organisations who provide feedback to Woodside post EP submission	Identification, assessment and consideration of feedback, claims and/or objections	As appropriate.	Assessment of claims and/ or objections. Relevant new information will be assessed using the EP Management of Knowledge (**Section 7.8**) and Management of Change Process (refer to **Section 7.2.5**).
Notification (email)	Australasian Underwater Cultural Heritage Database Any other stakeholders as required in the Unexpected Finds Procedure (**Section 7.6**)	Report any unexpected finds of potential Underwater Cultural Heritage	If triggered by Unexpected Finds Procedure (**Section 7.6**).	Refer to Unexpected Finds Procedure (**Section 7.6** and **C 3.2**).

Report/ information	Recipient	Purpose	Frequency	Content
Program of ongoing engagement with Traditional Custodians (**Appendix I**)	Relevant cultural authorities (**Appendix I**)	Ongoing engagement	Ongoing. Responses to any feedback received by Traditional Custodian groups will be provided by Woodside within four weeks of receipt. Progress on the Program will be reported in line with annual sustainability reporting via the Woodside website.	Assessment of cultural values. Any relevant new information on cultural values will be assessed using the EP Management of Knowledge (**Section 7.8**) and Management of Change Process (refer to **Section 7.2.5**).

7.11 Reporting

7.11.1 Overview

To meet the EPOs and EPSs outlined in this EP, Woodside reports at a number of levels, as outlined in the next sections.

7.11.2 Routine Reporting (Internal)

7.11.2.1 Daily Progress Reports and Meetings

The following daily reports, containing environmental performance information are issued:

- Daily reports for drilling activities provide performance information about drilling activities, heath, safety and environment, and current and planned work activities.
- Pan-Woodside Daily Production Report – The report includes facility performance information on production and a log of any HSE events.
- Subsea support vessel Daily Progress Report(s) – During subsea IMMR activities, daily reports are issued by the Woodside Site Representative. The reports provide performance information on HSE events, diesel use, together with equipment information, current and planned work activities.

Meetings between key personnel are used to transfer information, discuss incidents, agree plans for future activities and develop plans and accountabilities for resolving issues.

7.11.2.2 Regular Health, Safety and Environment Meetings

Regular dedicated HSE meetings are held with the offshore and Perth-based management and advisers to address targeted HSE incidents and initiatives. Minutes of these meetings are produced and distributed as appropriate.

7.11.2.2.1 Performance Reporting

Monthly and quarterly performance reports are developed and reviewed by the Function and Business Unit Leadership Teams (e.g., Drilling and Completions, Operations). These reports cover a number of subject matters, including:

- HSE incidents (including high potential incidents and those related to this EP) and recent activities
- corporate KPI targets, which include environmental metrics
- outstanding actions as a result of audits or incident investigations

- technical high and low lights
- status of subsea IMMR activities.

7.11.3 Routine Reporting (External)

7.11.3.1 Start and End Notifications of the Petroleum Activities Program

7.11.3.1.1 Angel Operations

In accordance with regulation 54, Woodside will notify NOPSEMA within ten days of the completion of the Petroleum Activities Program.

The EP will end when Woodside notifies NOPSEMA that the Petroleum Activities Program has ended, all of the obligations identified in this EP have been completed, and NOPSEMA has accepted the notification, in accordance with regulation 46 of the Environment Regulations.

7.11.3.1.2 Lambert West Drilling and Tie-back

In accordance with regulation 54, Woodside will notify NOPSEMA of the commencement of the Petroleum Activities Program at least ten days before the activity commences, and will notify NOPSEMA within ten days of completing the activity.

7.11.3.2 Environmental Performance Review and Reporting

In accordance with applicable environmental legislation for the activity, Woodside is required to report information on environmental performance to the appropriate regulator. Regulatory reporting requirements are summarised in **Table 7-8**.

Table 7-8: Routine external reporting requirements

Report	Recipient	Frequency	Content
Monthly Recordable Incident Reports	NOPSEMA	Monthly, by 15th of each month	Details of recordable incidents that have occurred during the Petroleum Activities Program for previous month (if applicable).
Annual Environment Plan Performance Report	NOPSEMA	Annual, by 30 April of the year following reporting period	Compliance with EPOs, controls and standards outlined in this EP, in accordance with the Environment Regulations.
National Pollutant Inventory (NPI) Report	DAWE	Annual, by 30 September each year	Summary of the emissions to land, air and water including those from the facility. Reporting period 1 July to 30 June each year.
National Greenhouse and Energy Reporting (NGERS)	Clean Energy Regulator	Annual, by 31 October each year	Summary of energy use and greenhouse gas emissions including those from the facility. Reporting period is 1 July to 30 June each year.

7.11.3.3 End of the Petroleum Activities Program Notification

In accordance with regulation 54, Woodside will notify NOPSEMA within ten days of the completion of the Petroleum Activities Program.

7.11.3.4 End of the Environment Plan

The EP will end when Woodside notifies NOPSEMA that the Petroleum Activities Program has ended, all of the obligations identified in this EP have been completed, and NOPSEMA has accepted the notification, in accordance with regulation 46 of the Environment Regulations.

7.11.4 Incident Reporting (Internal)

The process for reporting environmental incidents is described in **Section 7.8.3** of this EP. It is the responsibility of the Woodside Project Manager to ensure reporting of environmental incidents meets

Woodside and regulatory reporting requirements as detailed in the Woodside HSE Event Reporting and Investigation Procedure and this section of this EP.

7.11.5 Incident Reporting (External) – Reportable and Recordable

7.11.5.1 Reportable Incidents

A reportable incident is defined under regulation 5 of the Environment Regulations as:

- 'an incident relating to the activity that has caused, or has the potential to cause, moderate to significant environmental damage'.

A reportable incident for the Petroleum Activities Program is:

- an incident that has caused environmental damage with a Consequence Level of Moderate C+ or above (as defined under Woodside's Risk Table; refer to Section 2.2)
- an incident that has the potential to cause environmental damage with a Consequence Level of Moderate C+ or above (as defined under Woodside's Risk Table – refer to **Section 2.6**).

The environmental risk assessment (**Section 6**) for the Petroleum Activities Program identifies those risks with a potential consequence level of C+ for environment. The incidents that have the potential to cause this level of impact include hydrocarbon loss of containment events to ocean resulting from:

- loss of well containment (MEE-01)
- pipeline and riser loss of containment (MEE-02)
- loss of structural integrity (MEE-03)
- loss of marine vessel separation (MEE-04)
- loss of control of suspended load from Platform (MEE-05)
- unplanned hydrocarbon release: loss of well integrity during drilling operations.

Any such incidents represent potential events which would be reportable incidents. Reporting of incidents is undertaken with consideration of NOPSEMA (2014) guidance stating, 'if in doubt, notify NOPSEMA', and assessed on a case-by-case basis to determine if they trigger a reportable incident as defined in this EP and by the regulations.

7.11.5.1.1 Notification

NOPSEMA will be notified of all reportable incidents, according to the requirements of regulations 47, 48 and 49 of the Environment Regulations. Woodside will:

- report all reportable incidents to the regulator (orally) as soon as practicable (ASAP), but within two hours of the incident or of its detection by Woodside
- provide a written record of the reported incident to NOPSEMA, the National Offshore Petroleum Titles Administrator (NOPTA) and the Department of the responsible State Minister (DMIRS) ASAP after orally reporting the incident
- complete a written report for all reportable incidents using a format consistent with the NOPSEMA Form FM0831 – Reportable Environmental Incident (Appendix E) which must be submitted to NOPSEMA ASAP, but within three days of the incident or of its detection by Woodside
- provide a copy of the written report to the NOPTA and DMIRS, within seven days of the written report being provided to NOPSEMA.

AMSA will be notified of oil spill incidents ASAP after their occurrence, and DCCEEW notified if MNES are to be affected by the oil spill incident.

7.11.5.2 Recordable Incidents

A recordable incident is defined under regulation 5 of the Environment Regulations as a 'breach of an EPO or EPS, in the EP that applies to the activity, that is not a reportable incident'.

Any breach of the EPOs or EPSs (as presented within **Section 6**) will be raised as a recordable incident and managed as per the notification and reporting requirements outlined below and internal requirements outlined in **Section 7.10**.

7.11.5.2.1 Notification

NOPSEMA will be notified of all recordable incidents, according to the requirements of regulation 50(2), no later than 15 days after the end of the calendar month using the NOPSEMA Form – Recordable Environmental Incident Monthly Summary Report (**Appendix E**) detailing:

- all recordable incidents that occurred during the calendar month
- all material facts and circumstances concerning the recordable incidents that the operator knows or is able, by reasonable search or enquiry, to find out
- any action taken to avoid or mitigate any adverse environment impacts of the recordable incidents
- the corrective action that has been taken, or is proposed to be taken, to prevent similar recordable incidents
- the action that has been taken, or is proposed to be taken, to prevent a similar incident occurring in the future.

7.11.5.3 Other External Reporting Requirements and Notifications

In addition to the notification and reporting of environmental incidents defined under the Environment Regulations and Woodside requirements, **Table 7-9** describes the incident reporting requirements that also apply in the PAA.

Table 7-9: External incident reporting requirements

Event	Responsibility	Notifiable party	Notification requirements	Contact	Contact details
Any marine incidents during Petroleum Activities Program	Vessel Master	AMSA	Incident Alert Form 18 as soon as reasonably practicable Within 72 hours after becoming aware of the incident, submit Incident Report Form 19	AMSA	reports@amsa.gov.au
Oil pollution incidents in Commonwealth waters	Vessel Master	AMSA Rescue Coordination Centre (RCC)	As per Article 8 and Protocol I of MARPOL within two hours via the national emergency 24-hour notification contacts and a written report within 24 hours of the request by AMSA	AMSA RCC Australia	If the ship is at sea, reports are to be made to: Free call: 1800 641 792 Phone: 08 9430 2100 (Fremantle)
Oil pollution incidents in Commonwealth waters	Vessel Master	AMSA	Without delay as per *Protection of the Sea Act*, part II, section 11(1), AMSA RCC notified verbally via the national emergency 24-hour notification contact of the hydrocarbon spill; follow up with a written Pollution Report ASAP after verbal notification	RCC Australia	Phone: 1800 641 792 or +61 2 6230 6811 AFTN: YSARYCYX
Any oil pollution incident which has the potential to enter a National Park or requires oil spill response activities to be conducted within a National Park	Vessel Master	DCCEEW	Reported verbally, ASAP	Director of National Parks	Phone: 02 6274 2220
Activity causes unintentional death of or injury to fauna species listed as Threatened or Migratory under the EPBC Act	Vessel Master	DCCEEW	Within seven days of becoming aware	Secretary of the DCCEEW	Phone: 1800 803 772 Email: protected.species@environment.gov.au

7.12 Emergency Preparedness and Response

7.12.1 Overview

Under regulation 22(8), the implementation strategy must contain an oil pollution emergency plan (OPEP) and provide for the updating of the OPEP. Regulation 22(9) outlines the requirements for the OPEP which must include adequate arrangements for responding to and monitoring of oil pollution.

A summary of how this EP and supporting documents address the various requirements of Environment Regulations relating to oil pollution response arrangements is shown in **Table 7-10**.

Table 7-10: Oil pollution preparedness and response overview

Content	Environment Regulations Reference	Document/Section Reference
Details (oil pollution response) control measures that will be used to reduce the impacts and risks of the activity to ALARP and an acceptable level	Regulation 21(5), (6), 22(2)	Oil Spill Preparedness and Response Mitigation Assessment (**Appendix D**).
Describes the OPEP	Regulation 22 (8)	EP: Woodside's oil pollution emergency plan has the following components: • Woodside Oil Pollution Emergency Arrangements (Australia) • Angel Operations Oil Pollution First Strike Plan (Appendix G) • Lambert West Drilling Oil Pollution First Strike Plan (Appendix H) • Oil Spill Preparedness and Response Mitigation Assessment (**Appendix D**). In accordance with Regulation 56 of the Environmental Regulations the Woodside Oi Pollution Emergency Arrangements (Australia) was provided with the Scarborough Drilling and Completions EP, accepted by NOPSEMA on 1 December 2023.
Details the arrangements for responding to and monitoring oil pollution (to inform response activities), including control measures	Regulation 22 (9)	Oil Spill Preparedness and Response Mitigation Assessment (**Appendix D**). Angel Operations Oil Pollution First Strike Plan (**Appendix G**). Lambert West Drilling Oil Pollution First Strike Plan (**Appendix H**).
Details the arrangements for updating and testing the oil pollution response arrangements	Regulation 22(8)(12),(13)(14)	Environment Plan: **Section 7.12.7**. Oil Spill Preparedness and Response Mitigation Assessment (**Appendix D**).
Details provisions for monitoring impacts to the environment from oil pollution and response activities	Regulation 22(10)	Oil Spill Preparedness and Response Mitigation Assessment (**Appendix D**).
Demonstrates that the oil pollution response arrangements are consistent with the national system for oil pollution preparedness and control	Regulation 22(11)	Oil Pollution Emergency Arrangements (Australia).

7.12.2 Emergency Response Training

Regulation 22(4) requires that the implementation strategy includes measures to ensure that employees and contractors have the appropriate competencies and training. Woodside has conducted a risk based training needs analysis on positions required for effective emergency response (**Table 7-11**).

Table 7-11: Emergency response training requirements

IMT Position	Minimum Competency
Corporate Incident Management Team (CIMT) Incident Commander and Deputy Incident Commander	• IMT Fundamentals Course (internal course) or equivalent • ICS 100/200 • IMO3 or equivalent spill response specialist level with an oil spill response organisation (OSRO) Participation in L2 activation, exercise or skills maintenance
Operations, Planning, Logistics and Finance Sections, and other rostered members of the CIMT	• IMT Fundamentals Course or equivalent • ICS 100/200 • Oil spill theory Participation in L2 activation, exercise or skills maintenance
Environment Unit Leader	• IMT Fundamentals Course • ICS 100/200 • IMO2 or equivalent spill response specialist level with an OSRO Participation in L2 activation, exercise or skills maintenance
Note on competency/equivalency	
In 2023 Woodside undertook a review of incident and crisis systems, processes and tools to assess whether these were fit-for purpose and has rolled out a change to the Crisis and Emergency Management training and the oil spill response training requirements for IMT roles. The revised IMT Fundamentals training Program aligns with the performance requirements of the *PMAOMIR320 – Manage Incident Response Information* and *PMAOM0R418 - Coordinate Incident Response.* In 2023, Woodside took the decision to align its global incident command arrangements to the Incident Command System (ICS). As such all rostered members of the Incident Management Team are trained up to ICS 200. In addition to baseline incident management training, all rostered members of the CIMT undertake a level of hydrocarbon spill response training. Depending upon the role, this may take the form of IMO training or completion of Woodside's internal oil spill training course (OSREC) which involves the completion of two online AMSA Modules (Introduction to National Plan and Incident Management; and Introduction to Oil Spills) and face-to-face training. Woodside Learning Services is responsible for collating and maintaining personnel training records. The HSP Dashboard reflects the competencies required for each oil spill role (IMT/operational).	

7.12.3 Emergency Response Preparation

The Corporate Incident Management Team (CIMT) based in Woodside's head office in Perth, is the onshore coordination point for an offshore emergency. The CIMT is staffed by a roster of appropriately skilled personnel available on call 24 hours a day. The CIMT, under the leadership of the CIMT Leader, supports the site-based Incident Management Team by providing additional support in areas such as operations, logistics, planning, people management and public information (corporate affairs). A description of Woodside's Incident Command Structure and arrangements is further detailed in the Woodside Oil Pollution Emergency Arrangements (Australia).

Woodside will have a number of Emergency Response Plans (ERP) in place relevant to the PAP. The ERP provides procedural guidance specific to the asset and location of operations to control, coordinate and respond to an emergency or incident.

For the tie-back activity, the ERP will be a bridging document to the contracted rig's emergency documentation. This document summarises the emergency command, control and communications

processes for the integrated operation and management of an emergency. It is developed in collaboration with the contracted rig and ensures roles and responsibilities between the contracted rig and Woodside personnel are identified and understood. The ERPs will contain instructions for vessel emergency, medical emergency, search and rescue, reportable incidents, incident notification, contact information and activation of the contractor's emergency centre and Woodside Communication Centre (WCC). Electronic copies of the ERPs are available on the facility Virtual Bookshelves and the Security and Emergency Management intranet page. Hard controlled copies are available on the facilities.

In addition, the Emergency Preparedness MSPS (M06) is in place to assure that in the event of an incident, the organisation is appropriately prepared for all necessary actions which may be required for the protection of People, Environment, Asset, Reputation and Livelihood.

7.12.3.1 Emergency Event During Tie-back Activity

In the event of an emergency of any type:

- On the MODU the OIM will assume overall onsite command and act as the Incident Controller (IC). All persons aboard the MODU will be required to act under the IC's directions. The MODU/vessels will maintain communications with the onshore Drilling Superintendent and/or other emergency services in the event of an emergency. Emergency response support can be provided by the contractor's emergency centre or WCC if requested by the IC.
- Vessel Master (depending on the location of the emergency) will assume overall onsite command and act as the IC. All persons will be required to act under the IC's directions. The vessels will maintain communications with the onshore project manager and/or other emergency services in the event of an emergency. Emergency response support can be provided by the contractor's emergency centre or WCC if requested by the IC.
- The MODU and project vessels will have on-board equipment for responding to emergencies including medical equipment, fire-fighting equipment and oil spill response equipment.

7.12.3.2 Initial Response to Facility Incident

The facility is equipped with emergency shutdown systems designed to protect personnel, the facility and the environment from unsafe operating conditions and catastrophic situations.

Emergency shutdown systems are provided as a means of isolation in response to process upsets and facility conditions (including associated flowlines and risers) that could result in loss of hydrocarbon inventories, or to reduce the potential impact from a hydrocarbon loss of containment event on the facility. Provision has been made for process and facility alarm systems to provide early indication of any process upset conditions and potential hazardous events, including fire and gas alarms.

The key ERP relevant to the facility and subsea infrastructure (excluding the export pipeline) is the Angel Emergency Response Plan. This plan covers health, safety, asset and environmental risks (including fire, structural integrity, sabotage, etc) to ensure the range of occupational, asset and environmental risk exposures from incidents have been considered and plans are in place for their management. The plan provides specific details on the initial response required during events with potential significant environmental consequences such as a hydrocarbon spill, subsea hydrocarbon leak or potential collision.

The Pipelines Emergency Response Plan covers key ERP relevant to the export pipeline, as well as other major pipelines on Woodside's NWS facilities. The Angel Operations Oil Pollution First Strike Plan provides immediate actions required to commence a response (**Appendix G**). Vessels will have SOPEPs in accordance with the requirements of MARPOL 73/78 Annex I. These plans outline responsibilities, specify procedures and identify resources available in the event of a hydrocarbon or chemical spill from vessel activities. The Angel Operations Oil Pollution First Strike Plan is intended

to work in conjunction with the SOPEPs, if hydrocarbons are released to the marine environment from a vessel.

Woodside has established EPOs, EPSs and MCs to be used for hydrocarbon spill response during the Petroleum Activities Program, as detailed in **Appendix D**.

7.12.4 Oil and Other Hazardous Materials Spill

A significant hydrocarbon spill during the Petroleum Activities Program is unlikely, but should such an event occur, it has the potential to cause serious environmental and reputational damage if not managed properly. The Woodside Oil Pollution Emergency Arrangements (Australia) document, supported by the Oil Pollution First Strike Plan which provides tactical response guidance to the activity/area (**Appendix G** and **Appendix H**), and Oil Spill Preparedness and Response Strategy Selection and Evaluation (**Appendix D)** of this EP, cover spill response for this Petroleum Activities Program.

The Security and Emergency Management Function is responsible for the management of Woodside's hydrocarbon spill response equipment and for the maintenance of hydrocarbon spill preparedness and response documentation. In the event of a major spill, Woodside will request that AMSA (administrator of the National Plan) provides support to Woodside through advice and access to equipment, people and liaison. The interface and responsibilities, as defined under the National Plan, are described in the Oil Pollution Emergency Arrangements (Australia). AMSA and Woodside have a Memorandum of Understanding in place to support Woodside in the event of a hydrocarbon spill.

The Oil Pollution First Strike Plan provides immediate actions required to commence a response (**Appendix G** and **Appendix H**).

The MODU and project vessels will have SOPEPs in accordance with the requirements of MARPOL 73/78 Annex I. These plans outline responsibilities, specify procedures and identify resources available in the event of a hydrocarbon or chemical spill from vessel activities. The Oil Pollution First Strike Plan is intended to work in conjunction with the SOPEPs, if hydrocarbons are released to the marine environment from a vessel.

Woodside has established EPOs, performance standards and MC to be used for oil spill response during the Petroleum Activities Program, as detailed in (**Appendix D**).

7.12.5 Emergency and Spill Response

Woodside categorises incidents in relation to response requirements as follows:

Level 1 Incident

A Level 1 incident can be resolved through the use of existing resources, equipment and personnel. A Level 1 incident is contained, controlled and resolved by site/regionally based teams using existing resources and functional support services.

Level 2 Incident

A Level 2 incident is characterised by a response that requires external operational support to manage the incident. It is triggered in the event the capabilities of the tactical level response are exceeded. This support is provided to the activity via the activation of all, or part of, the responsible CIMT.

Level 3 Incident

A Level 3 incident or crisis is identified as a critical event that seriously threatens the organisation's People, the Environment, company Assets, Reputation, or Livelihood. At Woodside, the Crisis Management Team (CMT) manages the strategic impacts in order to respond to and recover from

the threat to the company (material impacts, litigation, legal and commercial, reputation, etc). The CIMT may also be activated as required to manage the operational incident response.

7.12.6 Emergency and Spill Response Drills and Exercises

Woodside's capability to respond to incidents will be tested periodically, in accordance with the Emergency and Crisis Management Procedure. The scope, frequency and objective of these tests is described in **Table 7-12**. Emergency response testing is aligned to existing or developing risks associated with Woodside's operations and activities. Corporate hazards/risks outlined in the corporate risk register, respective Safety Cases or project Risk Registers, are reference points developing and scheduling emergency and crisis management exercises. External participants may be invited to attend exercises (e.g., government agencies, specialist service providers, oil spill response organisations, or industry members with which Woodside has mutual aid arrangements).

The overall objective of exercises is to test procedures, skills and the teamwork of the Emergency Response and Command Teams in their ability to respond to major accident/major environment events. After each exercise, the team holds a debriefing session, during which the exercise is reviewed. Any lessons learned or areas for improvement are identified and incorporated into revised procedures, where appropriate.

Table 7-12: Testing of response capability

Response Category	Scope	Response Testing Frequency – tie-back activities	Response Testing Frequency – Operations	Response Testing Objective
Level 1 Response	Exercises are project-/ activity-specific	One Level 1 'First Strike' drill conducted within two weeks of commencing activity. For campaigns with an operational duration of greater than one month this will occur within the first two weeks of commencing the activity and then at least every 6-month hire period thereafter.	Two comprehensive Level 1 'First Strike' drills conducted per year, per asset. Additional Level 1 emergency drills routinely conducted (approximately one per fortnight).	**Operations:** Comprehensive exercises test elements of the Oil Pollution First Strike Plan (**Appendix G**). **Tie-back activities:** Comprehensive exercises test elements of the Oil Pollution First Strike Plan (**Appendix H**). Emergency drills are scheduled to test other aspects of the Emergency Response Plan.
Level 2 Response	Exercises are facility-/ vessel-specific	Level 2 Emergency Management exercises are relevant to activities with an operational duration of one month or greater. At least one Emergency Management exercise per vessel per campaign must be conducted within the first month of commencing the activity and then at every 6-month hire period thereafter, where applicable based on duration.	A minimum of one Emergency Management exercise is conducted biennially.	Testing both the facility IMT response and/or that of the CIMT following handover of incident control.
Level 3 Response	Exercises are relevant to all Woodside assets	The number of CMT exercises conducted each year is determined by the Chief Executive Officer, in consultation with the Vice President of Security and Emergency Management.		Test Woodside's ability to respond to and manage a crisis level incident.

7.12.7 Hydrocarbon Spill Response Testing of Arrangements

There are a number of arrangements which, in the event of a spill, will underpin Woodside's ability to implement a response across its petroleum activities. In order to ensure these arrangements are adequately tested, the Capability Development Team within Security and Emergency Management ensures tests are conducted in alignment with the Hydrocarbon Spill Testing of Arrangements Schedule.

Woodside's arrangements for spill response are common across its Australian operating assets and activities to ensure the controls are consistent. The overall objective of testing these arrangements is to ensure that Woodside maintains an ability to respond to a hydrocarbon spill, specifically to:

- ensure relevant responders, contractors and key personnel understand and practise their assigned roles and responsibilities
- test response arrangements and actions to validate response plans
- ensure lessons learned are incorporated into Woodside's processes and procedures and improvements are made where required.

If new response arrangements are introduced, or existing arrangements significantly amended, additional testing is undertaken accordingly. Additional activities or activity locations are not anticipated to occur; however, if they do, testing of relevant response arrangements will be undertaken as soon as practicable.

In addition to the testing of response capability described in **Table 7-11**, up to eight formal exercises are planned annually, across Woodside, to specifically test arrangements for responding to a hydrocarbon spill to the marine environment.

7.12.7.1.1 Testing of Arrangements Schedule

Woodside's Testing of Arrangements Schedule (**Figure 7-9**) aligns with international good practice for spill preparedness and response management; the testing is compatible with the International Petroleum Industry Environmental Conservation Association Good Practice Guide and the Australian Institute for Disaster Resilience (AIDR) Australian Emergency Management Arrangements Handbook. If a spill occurs, enacting these arrangements will underpin Woodside's ability to implement a response across its petroleum activities.

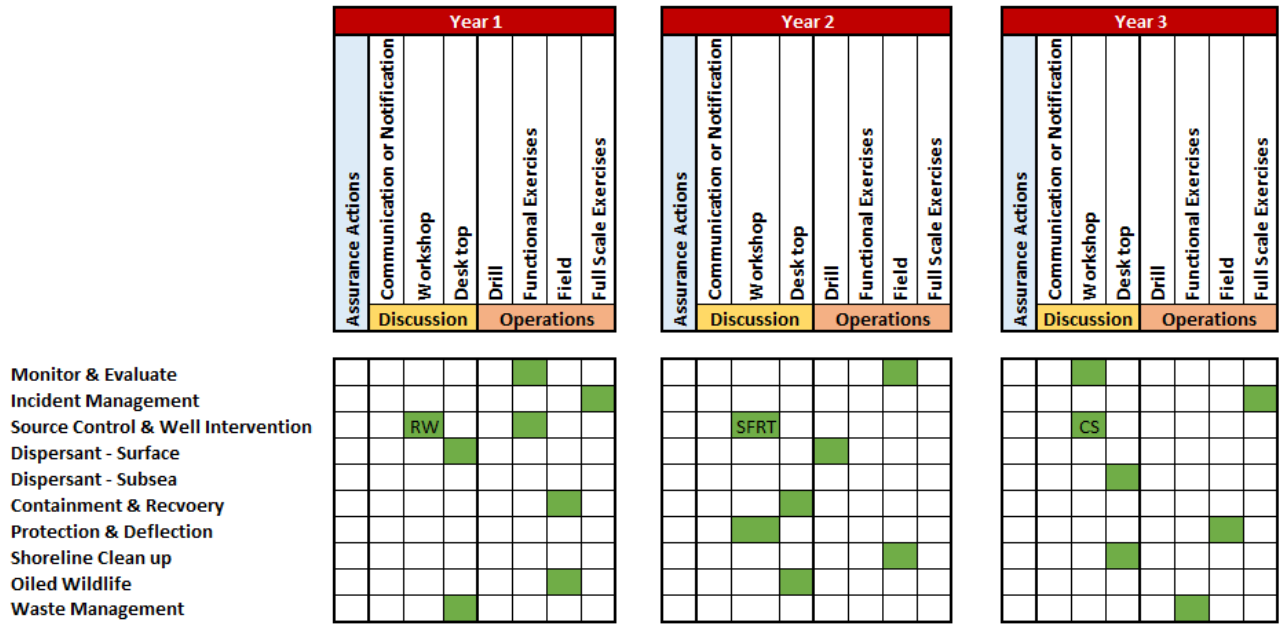


Figure 7-9: Indicative three-yearly testing of arrangements schedule

The hydrocarbon spill arrangements shown in the rows of the schedule are tested against Woodside's regulatory commitments. Each arrangement has a support agency/company and an area to be tested (e.g., capability, equipment and personnel). For example, an arrangement could be to test Woodside's personnel capability for conducting scientific monitoring, or the ability of the Australian Marine Oil Spill Centre to provide response personnel and equipment.

The vertical columns relate to how hydrocarbon spill arrangements will be tested over the three-year rolling schedule. The sub-heading for the column describes the standard method of testing likely to be undertaken (e.g., discussion exercise, desktop exercise), and the green cells indicate the arrangements that could be tested for each method.

Some arrangements may be tested across multiple exercises (e.g., critical arrangements) or via other 'additional assurance' methods outside the formal Testing of Arrangements Schedule that also constitute sufficient evidence of testing of arrangements (e.g., audits, no-notice drills, internal exercises, assurance drills).

7.12.8 Cyclone and Dangerous Weather Preparation

Tropical cyclones and other severe weather events are a potential risk to the safety and health of personnel and can potentially cause spills of hazardous materials into the environment from infrastructure and/or damaged vessels.

Facilities and relevant support vessels on hire to Woodside receive regular forecasts from Woodside Meteorologists, who liaise closely with the Bureau of Meteorology (BOM). If a cyclone (or severe weather event) is forecast, the path and its development is plotted and monitored using the BoM data. If there is the potential for the cyclone (severe weather event) to affect the Petroleum Activities Program, the asset Cyclone Contingency Plan and the vessel's Cyclone Contingency Plan will be actioned. If required, vessels can transit from the proposed track of the cyclone (severe weather event).

9 GLOSSARY AND ABBREVIATIONS

Acronym	Description
1TL	first trunkline
AC	alternating current
AEP	Angel export pipeline
AFMA	Australian Fisheries Management Authority
AHV	anchor handling vessel
AHO	Australian Hydrographic Office
AIMS	Australian Institute of Marine Science
ALARP	as low as reasonably practicable
AMOSC	Australian Marine Oil Spill Centre
AMP	Australian Marine Park
AMSA	Australian Maritime Safety Authority
ARMCANZ	Agriculture and Resource Management Council of Australia and New Zealand
ANZECC	Australian and New Zealand Environment and Conservation Council
AP	Angel production
APPEA	Australian Petroleum Production and Exploration Association
ATSIHP Act	Aboriginal and Torres Strait Islander Heritage Protection Act 1984
AUSREP	Australian Ship Reporting System
AUV	autonomous underwater vehicles
AW	abandoned wells with wellhead
BDV	blowdown valve
BIA	biologically important area
BoM	Bureau of Meteorology
BTEX	benzene, toluene, ethylbenzene and xylenes
CAES	Catch and Effort System
CAPEX	capital expenditure
CCR	central control room
CDU	control distribution unit
CEFAS	Centre for Environment, Fisheries and Aquaculture Science
CEO	Chief Executive Officer
CFA	Commonwealth Fisheries Association
CI	continuous improvement
CIMT	Corporate Incident Management Team
CMMS	Computerised Maintenance Management System
CMT	Crisis Management Team
CoP	cessation of production
CRA	corrosion-resistant alloy
CS	cost/sacrifice

Acronym	Description
CV	company values
CVS	Contractor Verification Service
DAA	Department of Aboriginal Affairs
DAWE	Department of Agriculture, Water and the Environment
D&C	drilling and completions
DC	direct current
DCCEEW	Department of Climate Change, Energy, the Environment and Water
DCS	NRC control system
DISER	Department of Industry, Science, Energy and Resources

APPENDIX A: WOODSIDE ENVIRONMENT AND BIODIVERSITY, CLIMATE AND RISK MANAGEMENT POLICIES

Environment and Biodiversity Policy

OBJECTIVE

Woodside recognises the intrinsic value of nature and the importance of conserving biodiversity and ecosystem services to support the sustainable development of our society. We are committed to doing our part. We understand and embrace our responsibility to undertake activities in an environmentally sustainable way.

PRINCIPLES

Woodside commits to:

- Implementing a systematic approach to the management of the impacts and risks of our operating activities on an ongoing basis, including emissions and air quality, discharge and waste management, water management, biodiversity and protected areas.
- Applying the mitigation hierarchy principle (avoid, minimise, restore) and a continuous improvement approach to ensure we maintain compliance, improve resource use efficiency and reduce our environmental impacts.
- Embedding environmental and biodiversity management, and opportunities, in our business planning and decision making processes.
- Complying with relevant laws and regulations and applying responsible standards where laws do not exist.
- Not undertaking new exploration or development of hydrocarbons within the boundaries of natural sites on the UNESCO World Heritage List (as specified at 1 December 2022). Existing activity may continue if compatible with maintenance of the listed outstanding universal values.
- Not undertaking new exploration or development of hydrocarbons within IUCN Protected Areas (as specified at 1 December 2022) unless compatible with management plans in place for the area. Existing activity may continue if compatible with management plans in place for the area.
- Achieving net zero deforestation1 associated with new projects that take a Final Investment Decision (FID) after 1 December 2022.
- Developing Biodiversity Action Plans for all new major projects (CAPEX >USD$2 billion) that take a FID after 1 December 2022.
- Supporting positive biodiversity outcomes in regions and areas in which we operate.
- Setting targets and publicly reporting on our environmental and biodiversity performance.

APPLICABILITY

Responsibility for the application of this Policy rests with all Woodside employees, contractors and joint venturers engaged in activities under Woodside operational control. Woodside managers are also responsible for promotion of this Policy in non-operated joint ventures.

This Policy will be reviewed regularly and updated as required.

Approved by the Woodside Energy Group Ltd Board in December 2022.

[1] Definition of Forest: 'trees higher than 5 meters and a canopy cover of more than 10 percent on the land to be cleared'

BACKGROUND

The Intergovernmental Panel on Climate Change has stated that “it is unequivocal that human influence has warmed the atmosphere, ocean and land”. An objective of the Paris Agreement is to hold “the increase in the global average temperature to well below 2ºC above pre-industrial levels” and to pursue “efforts to limit the temperature increase to 1.5ºC”. Many countries have set targets to reduce greenhouse gas emissions, including by changing the way they produce and consume energy.

OBJECTIVE

Woodside’s objective is to thrive in this energy transition as a low cost, lower carbon energy provider.

PRINCIPLES

Woodside aims to achieve the objective by:

- Setting science-based[1] near, mid, and long-term net emissions reduction targets that are consistent with Paris-aligned[2] scenarios, covering equity scope 1 and 2 emissions, both operated and non-operated.[3]
- Developing and operating oil and gas projects in a manner that is consistent with these targets. This includes the deployment of lower-emission technologies (Design Out), supporting efficient operations (Operate Out) and use of robust offsets (Offset) as methods to reduce and offset greenhouse gas emissions.
- Investing in new energy products and lower carbon services to reduce customers’ emissions (part of Woodside’s Scope 3 emissions), including but not limited to hydrogen, ammonia and carbon capture, utilisation and storage.
- Publishing transparent climate-related disclosures aligned to the recommendations of the Task Force on Climate-related Financial Disclosures (TCFD) or other recognised global reporting standards.
- Aligning our advocacy to the principles of this Climate Policy.

[1] Woodside is using the draft Prototype IFRS Sustainability Disclosure Standard definition of “science-based” (published 2021) which states “targets are considered ‘science-based’ if they are in line with what the most recent climate science sets out is necessary to meet the goals of the Paris Agreement—limiting global warming to below 2 degrees Celsius above pre-industrial levels and pursuing efforts to limit warming to 1.5 degrees Celsius.”. See https://www.ifrs.org/content/dam/ifrs/groups/trwg/trwg-climate-related-disclosures-prototype.pdf (Appendix A).

[2] Woodside is using the draft Prototype IFRS Sustainability Disclosure Standard definition of “Paris-aligned scenarios” (published 2021) which states “scenarios consistent with limiting global warming to below 2 degrees Celsius above pre-industrial levels and pursuing efforts to limit warming to 1.5 degrees Celsius.” See https://www.ifrs.org/content/dam/ifrs/groups/trwg/trwg-climate-related-disclosures-prototype.pdf (Appendix A).

[3] Equity emissions means the share of the total emissions arising from an activity that are attributable to Woodside in proportion to Woodside’s ownership interest in the activity, irrespective of whether Woodside operates the activity. Operated emissions are the total emissions arising from an activity that Woodside operates, irrespective of Woodside’s ownership interest.

APPLICABILITY

Responsibility for the application of this Policy rests with all Woodside employees, contractors and joint venture participants engaged in activities under Woodside operational control. Woodside managers are also responsible for promotion of this Policy in non-operated joint ventures.

This Policy will be reviewed regularly and updated as required.

Reviewed by the Woodside Energy Group Ltd Board in December 2023.

Risk Management Policy

OBJECTIVES

Woodside recognises that risk is inherent in our business and the effective management of risk is vital to deliver our strategic objectives, continued growth and success. We are committed to managing risks in a proactive and effective manner as a source of competitive advantage.

Our approach protects us against potential negative impacts, enables us to take risk for reward and improves our resilience against emerging risks. The objective of our risk management framework is to provide a single consolidated view of risks across the company to understand our full risk exposure and prioritise risk management and governance.

The success of our approach lies in the responsibility placed on everyone at all levels to proactively identify, assess and treat risks relating to the objectives they are accountable for delivering.

PRINCIPLES

Woodside achieves these objectives by:

- Applying a structured and comprehensive framework for the identification, assessment and treatment of current risks and response to emerging risks;
- Ensuring line of sight of financial and non-financial risks at appropriate levels of the organisation;
- Demonstrating leadership and commitment to integrating risk management into our business activities and governance practices;
- Recognising the value of stakeholder engagement, best available information and proactive identification of potential changes in external and internal context;
- Embedding risk management into our critical business processes and control framework;
- Understanding our exposure to risk and tolerance for uncertainty to inform our decision making and assure that Woodside is operating with due regard to the risk appetite endorsed by the Board; and
- Evaluating and improving the effectiveness and efficiency our approach.

APPLICABILITY

The Managing Director of Woodside is accountable to the Board of Directors for ensuring this Policy is effectively implemented.

Responsibility for the application of this Policy rests with all Woodside employees, contractors and joint venturers engaged in activities under Woodside operational control. Woodside managers are also responsible for promotion of this Policy in non-operated joint ventures.

This Policy will be reviewed regularly and updated as required.

APPENDIX B: RELEVANT REQUIREMENTS

The below table refers to Commonwealth Legislation related to the project.

Commonwealth Legislation	Legislation Summary
Air Navigation Act 1920 Air Navigation Regulations 1947 Air Navigation (Aerodrome Flight Corridors) Regulations 1994 Air Navigation (Aircraft Engine Emissions) Regulations 1995 Air Navigation (Aircraft Noise) Regulations 1984 Air Navigation (Fuel Spillage) Regulations 1999	This Act relates to the management of air navigation.
Australian Maritime Safety Authority Act 1990	This Act establishes a legal framework for the Australian Maritime Safety Authority (AMSA), which represents the Australian Government and international forums in the development, implementation and enforcement of international standards including those governing ship safety and marine environment protection. AMSA is responsible for administering the Marine Orders in Commonwealth waters.
Australian Radiation Protection and Nuclear Safety Act 1998	This Act relates to the protection of the health and safety of people, and the protection of the environment from the harmful effects of radiation.
Biosecurity Act 2015 Quarantine Regulations 2000 Biosecurity Regulation 2016 Australian Ballast Water Management Requirements 2017 Biosecurity Amendment (Biofouling Management) Regulations 2021	This Act provides the Commonwealth with powers to take measures of quarantine, and implement related programs as are necessary, to prevent the introduction of any plant, animal, organism or matter that could contain anything that could threaten Australia's native flora and fauna or natural environment. The Commonwealth's powers include powers of entry, seizure, detention and disposal. This Act includes mandatory controls on the use of seawater as ballast in ships and the declaration of sea vessels voyaging out of and into Commonwealth waters. The Regulations stipulate that all information regarding the voyage of the vessel and the ballast water is declared correctly to the quarantine officers. The Biofouling Management Regulations requires ships to report information about biofouling management and the voyage history of the ship in the past 12 months through a pre-arrival report.
Environment Protection and Biodiversity Conservation Act 1999 Environment Protection and Biodiversity Conservation Regulations 2000	This Act protects matters of national environmental significance (NES). It streamlines the national environmental assessment and approvals process, protects Australian biodiversity and integrates management of important natural and culturally significant places. Under this Act, actions that may be likely to have a significant impact on matters of NES must be referred to the Commonwealth Environment Minister.
Environment Protection (Sea Dumping) Act 1981 Environment Protection (Sea Dumping) Regulations 1983	This Act provides for the protection of the environment by regulating dumping matter into the sea, incineration of waste at sea and placement of artificial reefs.
Industrial Chemicals (Notification and Assessment Act) 1989 Industrial Chemicals (Notification and Assessment) Regulations 1990	This Act creates a national register of industrial chemicals. The Act also provides for restrictions on the use of certain chemicals which could have harmful effects on the environment or health.

Commonwealth Legislation	Legislation Summary
National Environment Protection Measures (Implementation) Act 1998 National Environment Protection Measures (Implementation) Regulations 1999	This Act and Regulations provide for the implementation of National Environment Protection Measures (NEPMs) to protect, restore and enhance the quality of the environment in Australia and ensure that the community has access to relevant and meaningful information about pollution. The National Environment Protection Council has made NEPMs relating to ambient air quality, the movement of controlled waste between states and territories, the national pollutant inventory, and used packaging materials.
National Greenhouse and Energy Reporting Act 2007 National Greenhouse and Energy Reporting (Safeguard Mechanism) Rule 2015	This Act and associated Rule establishes the legislative framework for the NGER scheme for reporting greenhouse gas emissions and energy consumption and production by corporations in Australia.
Navigation Act 2012 Marine order 12 – Construction – subdivision and stability, machinery and electrical installations Marine order 30 - Prevention of collisions Marine order 47 – Offshore Industry units Marine order 57 - Helicopter operations Marine order 91 - Marine pollution prevention—oil Marine order 93 - Marine pollution prevention—noxious liquid substances Marine order 94 - Marine pollution prevention—packaged harmful substances Marine order 96 - Marine pollution prevention—sewage Marine order 97 - Marine pollution prevention—air pollution	This Act regulates navigation and shipping including Safety of Life at Sea (SOLAS). The Act will apply to some activities of the MODU and project vessels. This Act is the primary legislation that regulates ship and seafarer safety, shipboard aspects of marine environment protection and pollution prevention.
Offshore Petroleum and Greenhouse Gas Storage Act 2006 Offshore Petroleum and Greenhouse Gas Storage (Environment) Regulations 2023 Offshore Petroleum and Greenhouse Gas Storage (Resource Management and Administration) Regulations 2011 Offshore Petroleum and Greenhouse Gas Storage (Safety) Regulations 2009	This Act is the principal Act governing offshore petroleum exploration and production in Commonwealth waters. Specific environmental, resource management and safety obligations are set out in the Regulations listed.
Ozone Protection and Synthetic Greenhouse Gas Management Act 1989 Ozone Protection and Synthetic Greenhouse Gas Management Regulations 1995	This Act provides for measures to protect ozone in the atmosphere by controlling and ultimately reducing the manufacture, import and export of ozone depleting substances (ODS) and synthetic greenhouse gases, and replacing them with suitable alternatives. The Act will only apply to Woodside if it manufactures, imports or exports ozone depleting substances.
Protection of the Sea (Powers of Intervention) Act 1981	This Act authorises the Commonwealth to take measures for the purpose of protecting the sea from pollution by oil and other noxious substances discharged from ships and provides legal immunity for persons acting under an AMSA direction.
Recycling and Waste Reduction (Mandatory Product Stewardship—Mercury-added Products) Rules 2021 (Minamata Convention on Mercury 2017)	This Convention is an agreement to protect human and environmental health from the effects of releases of mercury and mercury-containing compounds to the environment. The Convention was ratified by Australia in December 2021 and is implemented in Commonwealth law under the *Recycling and Waste Reduction (Mandatory Product Stewardship – Mercury added Products) Rules 2021*).

Commonwealth Legislation	Legislation Summary
Protection of the Sea (Prevention of Pollution from Ships) Act 1983 Protection of the Sea (Prevention of Pollution from Ships) (Orders) Regulations 1994 Marine order 91 - Marine pollution prevention—oil Marine order 93 - Marine pollution prevention—noxious liquid substances Marine order 94 - Marine pollution prevention—packaged harmful substances Marine order 95 - Marine pollution prevention—garbage Marine order 96 - Marine pollution prevention—sewage *Maritime Legislation Amendment (Prevention of Air Pollution from Ships) Act 2007* MARPOL Convention	This Act relates to the protection of the sea from pollution by oil and other harmful substances discharged from ships. Under this Act, discharge of oil or other harmful substances from ships into the sea is an offence. There is also a requirement to keep records of the ships dealing with such substances. The Act applies to all Australian ships, regardless of their location. It applies to foreign ships operating between 3 nautical miles (nm) off the coast out to the end of the Australian Exclusive Economic Zone (200 nm). It also applies within the 3 nm of the coast where the State/Northern Territory does not have complementary legislation. All the Marine Orders listed, except for Marine Order 95, are enacted under both the *Navigation Act 2012* and the *Protection of the Sea (Prevention of Pollution from Ships) Act 1983*. This Act is an amendment to the *Protection of the Sea (Prevention of Pollution from Ships) Act 1983*. This amended Act provides the protection of the sea from pollution by oil and other harmful substances discharged from ships.
Protection of the Sea (Harmful Antifouling Systems) Act 2006 Marine order 98—(Marine pollution—anti-fouling systems)	This Act relates to the protection of the sea from the effects of harmful anti-fouling systems. It prohibits the application or reapplication of harmful anti-fouling compounds on Australian ships or foreign ships that are in an Australian shipping facility.
Aboriginal and Torres Strait Islander Heritage Protection Act 1984	This Act seeks “to preserve and protect places, areas and objects of particular significance” to Aboriginal people. Under the Section 9 and 10 provisions of the Act, the Minister for the Environment may declare significant Aboriginal areas temporarily or permanently protected if they are considered under threat. Similar declarations regarding Aboriginal objects can be made under Section 12. Under Section 22 of the Act, the contravention of any of these declarations is an offence. Additionally, the discovery of any Aboriginal remains must be reported to the Minister under Section 20. Damage or interference with Aboriginal objects or places is not an offence under the ATSIHO Act except within Victoria under Section 21U.
Underwater Cultural Heritage Act 2018 Underwater Cultural Heritage Guidance for Offshore Developments DRAFT Guidelines to Protect Underwater Cultural Heritage	The Act prescribes penalties for damage to protected Underwater Cultural Heritage without a permit under Section 30 or in contravention of a permit under Section 28. Protected Underwater Cultural Heritage is prescribed in Section 16 to automatically include the remains and associated artefacts of any vessel or aircraft that has been in Australian waters for 75 years, whether known or unknown. This protection is also extended to Underwater Cultural Heritage in Commonwealth waters specified by the Environment Minister under Section 17. Without a declaration under this section, Aboriginal Underwater Cultural Heritage is not protected under the UCH Act.

APPENDIX C-1: WOODSIDE MASTER EXISTING ENVIRONMENT DOCUMENT

Description of the Existing Environment

THIS PAGE HAS BEEN INTENTIONALLY LEFT BLANK

TABLE OF CONTENTS

TABLE OF FIGURES

TABLE OF TABLES

1. INTRODUCTION

1.1 Purpose

This document applies, where indicated in the relevant Environment Plan, to Woodside Energy Ltd. (Woodside) activities and operations.

1.2 Scope

This document describes the existing environment within the Woodside areas of activity located in Commonwealth waters off north-western Western Australia (WA), with a focus on the North-west Marine Region (NWMR) (**Figure 1-1**). This document includes details of the particular and relevant values and sensitivities of the environment as required by the Commonwealth Offshore Petroleum and Greenhouse Gas Storage (Environment) Regulations 2009 in order to inform the impact and risk evaluation of Woodside's activities within the NWMR. Furthermore, the key values of the South-west Marine Region (SWMR) and the North Marine Region (NMR) are summarised to encompass areas outside the NWMR. This is with reference to the environment that may be affected (EMBA), as defined and described in individual EPs, for unplanned hydrocarbon spill risks. Additional information appropriate to the nature and scale of the impacts and risks of activities that may interact with the environment will be used to further inform impact and risk assessments and included in the Description of the Existing Environment of individual EPs.

This document is informed by a variety of resources that includes: a search of the Department of Agriculture, Water and the Environment (DAWE) Protected Matters Search Tool (PMST) for the marine bioregions (NWMR, SWMR and NMR) and the three PMST reports provided in **Appendix A**; State (WA)/Commonwealth Marine Park Management Plans, the *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act) Species Profile and Threats Database (SPRAT), Part 13 statutory instruments (recovery plans, conservation advices and wildlife conservation plans for listed threatened and migratory species); and peer reviewed scientific publications, as well as Woodside and Joint Venture (JV) funded studies and other titleholder funded study findings available in the public domain.

1.3 Review and Revision

The information presented in this document is reviewed and updated, where relevant, on at least an annual basis to address any relevant changes, which includes but is not limited to the status of EPBC Act listed species, Part 13 Instruments, policies and guidelines and recently published scientific literature.

1.4 Regional Context

Where relevant, the physical, biological and social environments within the areas of interest are discussed with reference to the three marine bioregions of Australia—NWMR, SWMR and NMR (**Table 1-1)**. The NWMR is the focal marine bioregion for the Description of the Existing Environment as this is currently the location of most of Woodside's activities.

Table 1-1. Description of the Marine Bioregions

Marine Bioregion	Description
North-west	The NWMR includes all Commonwealth waters (from 3 nautical mile [nm] from the Territorial Sea Baseline [TSB] to the 200 nm Exclusive Economic Zone [EEZ] boundary) extending from the WA/Northern Territory (NT) border to Kalbarri, south of Shark Bay in WA, covering an area of approximately 1.07 million square kilometres and includes extensive areas of shallower waters on the continental shelf, as well as deep areas of abyssal plain where water depths are 5000 m or greater.
South-west	The SWMR comprises Commonwealth waters from the eastern end of Kangaroo Island in SA to Shark Bay in WA. The region spans approximately 1.3 million square kilometres of temperate and subtropical waters and abuts the coastal waters of SA and WA.
North	The NMR comprises Commonwealth waters from west Cape York Peninsula to the NT/WA border). The region covers approximately 625,689 square kilometres of tropical waters in the Gulf of Carpentaria and Arafura and Timor seas, and abuts the coastal waters of Queensland and the NT.

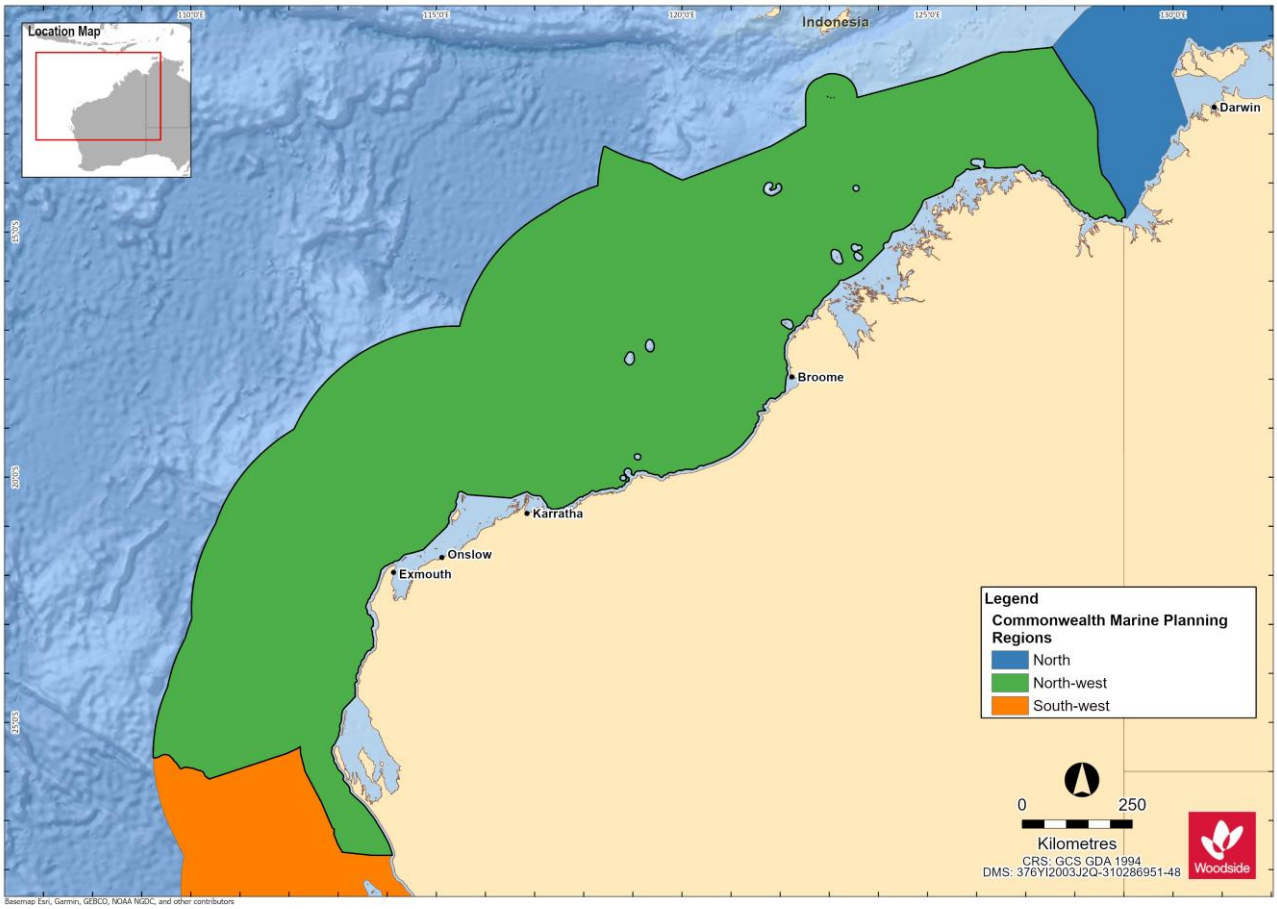

Figure 1-1. Marine Bioregions: North-west (NWMR), South-west (SWMR) and North (NMR)

2. PHYSICAL ENVIRONMENT

2.1 Regional Context

The key physical characteristics of the NWMR, SWMR and NMR are presented in **Table 2-1**.

Table 2-1 Key physical characteristics of the NWMR, SWMR and NMR

Bioregion	Key Characteristics
North-west Marine Region	The NWMR experiences a tropical monsoonal climate towards the northern extent of the region, transitioning to tropical arid and subtropical arid within the central and southern areas of the region (DSEWPAC, 2012a).
	The NWMR is part of the Indo-Australian Basin, the ocean region between the north-west coast of Australia and the Indonesian islands of Java and Sumatra. Dominant currents in the Region include: the South Equatorial Current, the Indonesian Throughflow; the Eastern Gyral Current, and the Leeuwin Current (DEWHA, 2007a).
	The seafloor of the NWMR consists of four general feature types: continental shelf; continental slope; continental rise; and abyssal plain and is distinguished by a range of topographic features including canyons, plateaus, terraces, ridges, reefs, and banks and shoals.
South-west Marine Region	The SWMR contains both subtropical and temperate climates, with overall light climatic cycles.
	The SWMR experiences complex and unusual oceanographic patterns, driven largely by the Leeuwin Current and its associated currents that have a significant influence on biodiversity distribution and abundance.
	The major seafloor features of the SWMR include a narrow continental shelf on the west coast to the waters off south-west WA, and a wide continental shelf dominated by sandy carbonate sediments of marine origin in the Great Australian Bight, the region also contains a steep, muddy continental slope, many canyons and large tracts of abyssal plains (DSEWPAC, 2012b).
North Marine Region	The NMR experiences a tropical monsoonal climate with complex weather cycles, including high temperatures and heavy seasonal yet variable rainfall and cyclones, which can be both destructive (loss of seagrass and mangroves) and constructive (mobilisation of sediment into coastal habitats).
	The NMR comprises Commonwealth waters from west Cape York Peninsula to the NT–WA border, covering tropical waters in the Gulf of Carpentaria and Arafura and Timor seas. Currents in the NMR are driven largely by strong winds and tides, with only minor influences from oceanographic currents such as the Indonesian Throughflow and the South Equatorial Current (DSEWPAC, 2012c).
	The seafloor of the NMR consists mainly of a wide continental shelf, as well as other geomorphological features such as shoals, banks, terraces, valleys, shallow canyons and limestone pinnacles.

2.2 Marine Systems of the North-west Marine Region.

The NWMR can be divided into three large scale ecological marine systems on the basis of the influence of major ocean currents, seafloor features and eco-physical processes (e.g. climate, tides, freshwater inflow) upon the Region (DSEWPAC, 2012a). The three large scale marine systems approximate the Woodside activity areas within the NWMR (**Figure 2-1**). The key characteristics of each marine system are outlined below in **Table 2-2**.

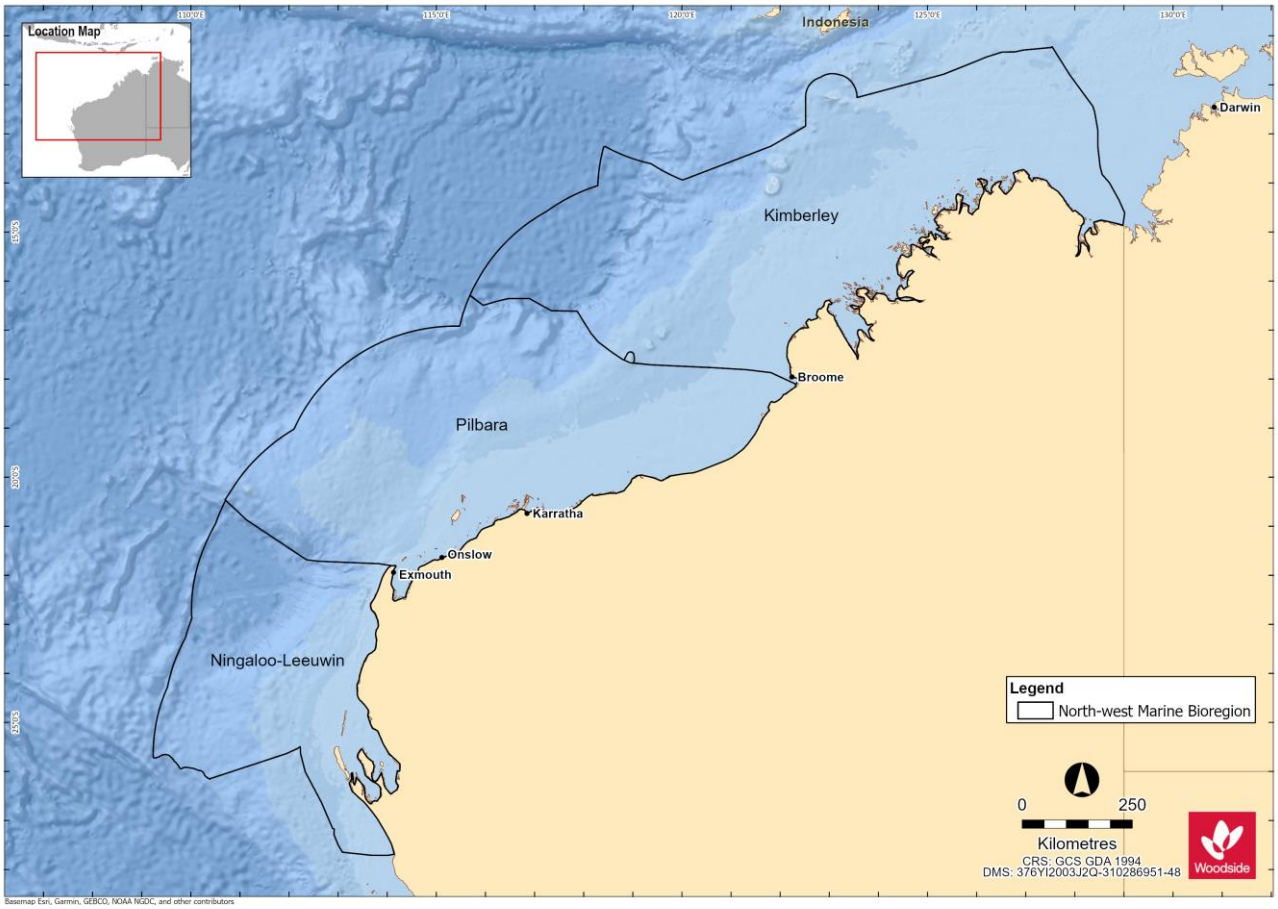

Figure 2-1. The marine systems of the North-west Marine Region (NWMR)

Table 2-2. Key characteristics of the Marine Systems of the NWMR

Note: Woodside areas align with the marine systems as described in DEWHA (2007a)

Marine System	Woodside Activity Area	Key Characteristics
Kimberley	Browse	Tropical monsoonal climate Strong influence from Indonesian Throughflow Predominantly tropical Indo-Pacific species Subject to episodic offshore cyclonic activity, rarely crossing the coast Large tidal regimes Freshwater input from terrestrial monsoonal run-off Turbid coastal waters (i.e. light limited systems) Dominated by shelf environments Predominantly hard substrates in inner to mid-shelf environments Includes a number of shelf-edge atolls (i.e. Scott Reef, Rowley Shoals)
Pilbara	North-west Shelf (NWS) / Scarborough	Tropical arid climate Transition between Indonesian Throughflow and Leeuwin Current dominated areas Predominantly tropical species High cyclone activity with frequent crossing of the coast Transitional tidal zone Internal tide activity Large areas of shelf and slope Dry coast with ephemeral freshwater inputs
Ningaloo-Leeuwin	North-west Cape	Subtropical arid climate Leeuwin Current consolidates Transitional tropical/temperate faunal area Higher water clarity in near-shore and offshore environments Narrow shelf and slope Marginal tidal range Seasonal wind forcing more dominant influence on marine environment

2.3 Meteorology and Oceanography

This section describes the general meteorological conditions and oceanography for the NWMR and provides further detail for the three Woodside activity areas. The NWMR is influenced by a complex system of ocean currents that change between seasons and between years, which generally result in its surface waters being warm and nutrient-poor, and of low salinity (DEWHA, 2007a). The mix of bathymetric features, complex topography and oceanography across the whole north-west marine environment has created and supports a globally important marine biodiversity hotspot (Wilson, 2013).

Table 2-3 NWMR climate and oceanography summary

Receptor	Description
Meteorology	
Seasonal patterns	The NWMR associated land mass of the Australian continent is characterised as a hot and humid summer climate zone. The broader NWMR experiences variations of a tropical or monsoon climate. In the far north-west (Kimberley), there is a hot summer season from December to March and a milder winter season between April and November. The Pilbara area is described as having a tropical arid climate with high cyclone activity (DEWHA, 2007a). The Pilbara and North-west Cape has a hot summer season from October to April and a milder winter season between May and September with transition periods between the summer and winter regimes.
Air temperature and rainfall	In summer (between September and March), maximum daily temperatures range from 31ºC to 33ºC. During winter (May to July), mean daily temperatures range from 18ºC to 31ºC (BOM[1]), refer to **Figure 2-2a** and **b**. Rainfall in the region typically occurs during the summer, with highest falls observed late in the season. This is often associated with the passage of tropical low-pressure systems and cyclones.
Wind	Wind patterns in north-west WA are dictated by the seasonal movement of atmospheric pressure systems. During summer, high-pressure cells produce prevailing winds from the north-west and south-west, which vary between 10 and 13 ms^{-1}. During winter, high-pressure cells over central Australia produce north-easterly to south-easterly winds with average speeds of between 6 and 8 ms^{-1}. Refer to **Figure 2-3a** and **b**.
Tropical cyclones	The NWS and Pilbara coast (within the NWMR) experiences more cyclonic activity than any other region of the Australian mainland coast (BOM, 2021a). Tropical cyclone activity typically occurs between November and April and is most frequent in the region during December to March (i.e. considered the peak period), with an average of about one cyclone per month (BOM, 2021a). Refer to **Figure 2-4**.
Oceanography	
Ocean temperature	Waters in NWMR are tropical year-round, with sea surface temperature in open shelf waters reaching ~26°C in summer and dropping to ~22°C in winter. Nearshore temperatures (as recorded for the NWS area) fluctuate more widely on an annual basis from ~17°C in winter to ~31°C in summer (Chevron Australia, 2010). Refer to **Figure 2-5a** and **b**.
Currents	The major surface currents influencing north-west WA flow towards the poles and include the Indonesian Throughflow, the Leeuwin Current, the South Equatorial Current, and the Eastern Gyral Current. The Ningaloo Current, the Holloway Current, the Shark Bay Outflow, and the Capes Current are seasonal surface currents in the region. Below these surface currents are several subsurface currents, the most important of which are the Leeuwin Undercurrent and the West Australian Current. These subsurface currents flow towards the equator in the opposite direction to surface currents (DEWHA, 2007a). Refer to **Figure 2-6**. The offshore waters of the NWMR are characterised by surface and subsurface boundary currents that flow along the continental shelf/slope and are enhanced through inflows from the ocean basins and are an important conduit for the poleward heat and mass transport along the west coast (Wijeratne *et al.*, 2018). Local physical oceanography is strongly influenced by the large-scale water movements of the Indonesian Throughflow (Liu *et al*. 2015; Sutton *et al*. 2019). Typically, a warm and well-mixed oligotrophic surface layer and a cooler and more nutrient rich, deeper water layer (Menezes *et al*. 2013).
Waves	Sea surface waves within the NWMR, generally reflect the direction of the synoptic winds and flow predominately from the south-west in the summer and east in winter (Pearce *et al.*, 2003). The NWS within the NWMR is a known area of internal wave generation. Both internal tides and internal waves are thought to be more prevalent during summer months due to the increased stratification of the water column (DEWHA, 2007a). Along the continental slope of the NWMR, strong internal waves and interaction between semi-diurnal tidal currents and seabed topographic features facilitates upwelling events and localised productivity events (Holloway, 2001).
Tides	Tides on the NWS (NWMR) increase as the water moves from deep towards the shallower coast. The highest offshore tides are experienced at the border of the Browse and Canning basins. The smallest tides are experienced at the Exmouth Plateau, near the coast. Tides of NWS (NWMR) are predominantly semi-diurnal (two highs and two lows each day), but with increasing importance of the diurnal (once per day) inequality at the southern and northern extremities of the NWS.

Receptor	Description
	The tide range—represented by the Mean Spring Range (MSR)—increases northwards along the coast from 1.4 m at North-west Cape (Point Murat) to 7.7 m at Broome, before decreasing again (apart from local amplification in King Sound and Collier Bay) to about 5 m off Cape Londonderry. The MSR then increases again through Joseph Bonaparte Gulf and on up 5.5 m at Darwin (RPS, 2016).

2.3.1 Browse

Table 2-4 Summary meteorology and oceanography for Browse (refer to Appendix B for supporting metocean figures)

Receptor	Description
Meteorology	
Seasonal patterns	The Browse area overlapping the Kimberley marine system experiences tropical monsoon climate with two distinct seasons: the wet season from December to March and dry season from April to November.
Air temperature	The mean annual air temperature recorded at Troughton Island between 2010 and 2020 ranged from 30.1ºC in 2011 to 32.6ºC in 2016 and highest mean monthly air temperatures were recorded for the months of November and December (BOM, 2021b).
Rainfall	Rainfall recorded from Troughton Island in the Browse basin ranged from barely detectable (<1 mm) mean monthly level to >100 mm in December to March, with the highest rainfall recorded for January. Reflecting the wet monsoon season of the Kimberley marine system (BOM, 2021c).
Wind	The dry season experiences high pressure systems that bring east to south-easterly winds with average wind speeds during the season of approximately 16.6 km/hr and maximum wind gusts of 65 km/hr. In contrast the wet season brings predominately westerly winds with average wind speeds approximately 17 km/hr and maximum gusts exceeding 100 km/hr (generally associated with tropical cyclones (MetOcean Engineers, 2005).
Oceanography	
Currents	Surface currents exhibit seasonal directionality, with flow to the south-west during March to June and more variable outside this period (Woodside, 2019). This is consistent with the stronger Leeuwin Current flow during winter months, with more variable currents driven by local wind stress during periods of weaker Leeuwin Current flow.

2.3.2 North West Shelf / Scarborough

Table 2-5 Summary meteorology and oceanography for the North West Shelf and Scarborough (refer to Appendix B for supporting metocean figures)

Receptor	Description
Meteorology	
Seasonal patterns	The NWS and Scarborough areas experience the monsoonal climate of the wider NWMR with a distinct wet and dry seasonal regime and transitions periods between seasons.
Air temperature	Air temperatures as measured at the North Rankin A platform on NWS ranged from a maximum average of 39.5ºC in summer to a minimum average temperature of 15.6ºC in winter (Woodside, 2012).
Rainfall	Rainfall patterns annually reveal the wet season with highest rainfalls during the late summer, often associated with the passage of tropical low-pressure systems and cyclones. Rainfall in the dry season is typically extremely low. (Pearce *et al.* 2003).
Wind	Winds are typically from the southwest during the wet season (summer) and tending from the south-east during the dry season (winter). The summer south-westerly winds are driven by high pressure cells that pass from west to east over the Australian continent. During the winter period, the relative position of the high-pressure cells shifts further north, leading to prevailing south-easterly winds from the mainland (Pearce *et al.* 2003).
Oceanography	
Currents	The large-scale ocean currents of the NWMR, primarily the Indonesian Throughflow and Leeuwin Current (and Holloway Current), are the primary influence on the NWS and Scarborough areas. The ITF and Leeuwin Current are strongest during the late summer and winter and flow reversals to the north-east, typically short-lived and weak, when there are strong south-westerly winds can generate localised upwelling on the shelf edge (Holloway and Nye, 1985; James *et al.* 2004 and Condie *et al.* 2006).

2.3.3 North-west Cape

Table 2-6 Summary meteorology and oceanography for the North-west Cape (refer to Appendix B for supporting metocean figures)

Receptor	Description
Meteorology	
Seasonal patterns	The climate of the NWMR is dry tropical exhibiting a hot summer season and a mild winter season. There are often distinct transition periods between the summer and winter regimes, characterised by periods of relatively low winds.
Air temperature	Air temperatures in the North-west Cape area range from high summer temperatures (maximum average of 37.5ºC) and mild winter temperatures (minimum average of 12.2ºC).
Rainfall	Rainfall typically occurs during the summer, with highest rainfall during later summer and autumn, often associated with the passage of tropical low-pressure systems and cyclones. Rainfall is typically low in winter.
Wind	Winds vary seasonally, generally from the south-west quadrant during summer months and the south, south-east quadrant during the autumn and winter months. The summer south-westerly winds are driven by high pressure cells that pass from west to east over the Australian continent. Winds typically weaken and are more variable during the transitional period between the summer and winter seasons, generally between April to August.
Oceanography	
Currents	Surface currents exhibit seasonal directionality, with flow to the south-west during March to June and more variable outside this period (Woodside, 2016). This is consistent with the stronger Leeuwin Current flow during winter months, with more variable currents driven by local wind stress during periods of weaker Leeuwin Current flow.

2.4 Physical Environment of NWMR

Based on the Integrated Marine and Coastal Regionalisation of Australia (IMCRA) Version 4.0, there are eight provincial bioregions that occur within the NWMR, which are based on patterns of demersal fish diversity, benthic habitat and oceanographic data (Commonwealth of Australia, 2006), **Figure 2-7**. Of the eight provincial bioregions that occur within the NWMR, these include four offshore (~65% of total NWMR area) and four shelf (~35% of total NWMR area) bioregions (Baker *et al.,* 2008).

The NWMR is a tropical carbonate margin that comprises an extensive area of shelf, slope and abyssal plain/deep ocean floor, as well as complex areas of bathymetry such as plateau, terraces and major canyons (Harris *et al.*, 2005). A series of reefs are located on the outer shelf/slope of the NWMR, including Ashmore, Cartier, Scott and Seringapatam reefs (Baker *et al*., 2008). The distribution of seafloor geomorphic features has been systematically mapped over much of the Australian margin and adjacent seafloor. The mapped area can be divided into 10 geomorphic regions, of which the NWMR overlays two; the Western Margin and Northern Margin (Harris *et al.*, 2005). Most of the region consists of either continental slope (61%) or continental shelf (28%) (DEWHA, 2007a) with more than 40% of the NWMR having a water depth less than 200 m. The shallow shelf is contrasted by features such as the Cuvier and Argo abyssal plains, which reach depths more than five kilometres. A unique feature of the region is the significant narrowing of the continental shelf around North-west Cape (approximately 7 km wide) from the broad continental shelf in the north of the region (approximately 400 km wide at Joseph Bonaparte Gulf) (DEWHA, 2007a), **Figure 2-8.**

The geological history of the region, as well as its geomorphology and oceanography, has influenced the composition and distribution of sediments (DEWHA, 2007a). The sedimentology of the NWMR is dominated by marine carbonates, which show a broad zoning and fining with water depth. Main trends of the NWMR sediments include a tropical carbonate shelf that is dominated by sand and gravel, an outer shelf/slope zone that is dominated by mud and a relatively homogenous rise and abyssal plain/deep ocean floor that is dominated by non-carbonate mud (Baker *et al.,* 2008), **Figure 2-9**.

The distribution and resuspension of sediments on the inner shelf is strongly influenced by the strength of tides across the continental shelf as well as episodic events such as cyclones. Further offshore, on the mid to outer shelf and on the slope itself, sediment movement is primarily influenced by ocean currents and internal tides (DEWHA, 2007a).

This variation in bathymetry and interactions with oceanographic processes provides a diversity of habitats to marine fauna and flora within the NWMR.

2.5 Air quality

The ambient air quality of all three marine regions is largely unpolluted due to the extent of the open ocean area, the activities currently carried out in each and the relative remoteness of each region.

3.2 Part 13 Statutory Instruments for EPBC Act Listed Threatened and Migratory Species in the NWMR, SWMR and NMR

A screening process was conducted to identify which EPBC Act listed threatened and migratory species, and associated Part 13 statutory instruments, are relevant in the context of the assessment of impacts and risks associated with petroleum activities in each of the Woodside activity areas, using the following criteria:

- overlap between the Woodside activity areas with habitat critical for the survival of marine turtles, and with BIAs (overlapping the marine environment) for any listed threatened species as reported in the PMST searches;
- published literature, unpublished reports and/or credible anecdotal information (e.g. feedback from stakeholders) indicating species presence/occurrence within the Woodside activity areas;
- temporal overlap between the likely timing of petroleum activities and peak periods for key behaviours (e.g. breeding, nesting, calving, resting, foraging, migration); and
- environmental aspects associated with petroleum activities have been identified as a key threat to a species in a Part 13 statutory instrument (e.g. anthropogenic noise, light emissions, marine debris).

Relevant EPBC Act threatened and migratory species and their Part 13 statutory instruments are listed in **Table 3-4**. For the full list of EPBCA Act listed species for each marine bioregion refer to the PMST reports (**Appendix A**).

Table 3-4 Summary of MNES identified by the EPBC Act Protected Matters Search Tool (PMST) to be considered for impact or risk evaluation for Woodside operations

Species	EPBC Act Part 13 Statutory Instrument
All vertebrate marine fauna	Threat Abatement Plan for the impacts of marine debris on vertebrate marine life (Commonwealth of Australia, 2018)
Marine Mammals	
Blue whale	Conservation Management Plan for the Blue Whale: A Recovery Plan under the *Environment Protection and Biodiversity Conservation Act 1999* 2015–2025 (Commonwealth of Australia, 2015a)
Southern right whale	Conservation Management Plan for the Southern Right Whale: A Recovery Plan under the *Environment Protection and Biodiversity Conservation Act 1999* 2011–2021 (DSEWPAC, 2012d)
Sei whale	Conservation Advice *Balaenoptera borealis* sei whale (Threatened Species Scientific Committee, 2015a)
Humpback whale	Conservation Advice *Megaptera novaeangliae* humpback whale (Threatened Species Scientific Committee, 2015b)
Fin whale	Conservation Advice *Balaenoptera physalus* fin whale (Threatened Species Scientific Committee, 2015c)
Australian sea lion	Recovery Plan for the Australian Sea Lion (*Neophoca cinerea*) 2013 (DSEWPAC, 2013a) (due to expire in October 2023) Conservation Advice *Neophoca cinerea* Australian Sea Lion (Threatened Species Scientific Committee, 2020a) (in effect under the EPBC Act from 23-Dec-2020)
Marine Reptiles	
All marine turtle species (loggerhead, green, leatherback, hawksbill, flatback, olive ridley)	Recovery Plan for Marine Turtles in Australia 2017-2027 (Commonwealth of Australia, 2017)
Short-nosed sea snake	Approved Conservation Advice for *Aipysurus apraefrontalis* (Short-nosed Sea Snake) (DSEWPAC, 2011a)
Leaf-scaled sea snake	Approved Conservation Advice for *Aipysurus foliosquama* (Leaf-scaled Sea Snake) (DSEWPAC, 2011b)
Fishes, Sharks, Rays and Sawfishes	
Grey nurse shark (west coast population)	Recovery Plan for the Grey Nurse Shark (*Carcharias taurus*) 2014 (DOE, 2014)
White shark	Recovery Plan for the White Shark (*Carcharodon carcharias*) 2013 (DSEWPAC, 2013b)
Whale shark	Conservation Advice *Rhincodon typus* whale shark (Threatened Species Scientific Committee, 2015d)
All sawfishes (largetooth, green, dwarf, speartooth, narrow)	Sawfish and River Sharks Multispecies Recovery Plan (Commonwealth of Australia, 2015b)

Species	EPBC Act Part 13 Statutory Instrument
Seabirds	
Migratory seabird species	Draft Wildlife Conservation Plan for Migratory Seabirds (Commonwealth of Australia, 2019)
Southern giant petrel	National recovery plan for threatened albatrosses and giant petrels 2011–2016 (DSEWPAC, 2011c)
Indian yellow-nosed albatross	National recovery plan for threatened albatrosses and giant petrels 2011–2016 (DSEWPAC, 2011c)
Abbott's booby	Conservation Advice for the Abbott's booby - *Papasula abbotti* (Threatened Species Scientific Committee, 2020b)
Australian fairy tern	Approved Conservation Advice for *Sterna nereis nereis* (Fairy Tern) (DSEWPAC, 2011d)
Australian lesser noddy	Conservation Advice *Anous tenuirostris melanops* Australian lesser noddy (Threatened Species Scientific Committee, 2015e)
Soft-plumaged petrel	Conservation Advice *Pterodroma mollis* soft-plumaged petrel (Threatened Species Scientific Committee, 2015f)
Shorebirds	
Migratory shorebird species	Wildlife Conservation Plan for Migratory Shorebirds (Commonwealth of Australia, 2015c)
Eastern curlew, far eastern curlew	Conservation Advice *Numenius madagascariensis* eastern curlew (DOE, 2015a)
Curlew sandpiper	Conservation Advice *Calidris ferruginea* curlew sandpiper (DOE, 2015b)
Great knot	Conservation Advice *Calidris tenuirostris* Great knot (Threatened Species Scientific Committee, 2016a)
Red knot, knot	Conservation Advice *Calidris canutus* Red knot (Threatened Species Scientific Committee, 2016b)
Bar-tailed godwit (*menzbieri*)	Conservation Advice *Limosa lapponica menzbieri* Bar-tailed godwit (northern Siberia) (Threatened Species Scientific Committee, 2016c)
Greater sand plover	Conservation Advice *Charadrius leschenaultii* Greater sand plover (Threatened Species Scientific Committee, 2016d)
Lesser sand plover	Conservation Advice *Charadrius mongolus* Lesser sand plover (Threatened Species Scientific Committee, 2016e)

4. HABITAT AND BIOLOGICAL COMMUNITIES

4.1 Regional context

The NWMR habitats range from nearshore benthic primary producer habitats such as seagrass beds, coral communities and mangrove forests, to offshore soft sediment seabed habitats and submerged and emergent reef systems. These habitats support biological communities that range from low density sessile and mobile benthos, such as sponges, molluscs and echinoids (with noted areas of sponge hotspot diversity) in offshore soft sediment habitat (DSEWPAC, 2012a) to complex, diverse, remote coral reef systems.

Benthic primary producer habitats, such as seagrass beds, coral communities and mangrove forests within the SWMR, are described as a mixture of tropical and temperate species, due to the seasonal influences of the tropical waters carried south by the Leeuwin Current and the temperate waters carried north by the Capes Current (DSEWPAC, 2012b).

The NMR shares similar habitat types to the NWMR. The predominant habitat of the region includes soft muddy sediments on relatively flat terrain. Other habitat types include seagrasses, reefs, shoals and coastal habitats such as mangroves and coastal wetlands (Rochester *et al.*, 2007).

The summary of key habitats and biological communities provided in the following sub-sections is focused on the primary features of relevance to the activity areas within the NWMR – primarily the offshore habitats of the continental shelf and slope, submerged shoals and banks, and remote oceanic reef systems of recognised conservation value.

4.2 Biological Productivity of NWMR

Primary productivity of the NWMR is generally low and appears to be largely driven by offshore influences (Brewer *et al.*, 2007), with periodic upwelling events and cyclonic influences driving coastal productivity with nutrient recycling and advection. Seasonal weather patterns also influence the delivery of nutrients from deep-water to shallow water. Cyclones and north-westerly winds during the North-west monsoon (approximately November–March) and the strong offshore winds of the South-east monsoon (approximately April–September) facilitate the upwelling and mixing of nutrients from deep-water to shallow water environments (Brewer *et al.*, 2007).

The Indonesian Throughflow (ITF) has an important effect on productivity in the northern areas of the Region. Generally, its deep, warm and low nutrient waters suppress upwelling of deeper comparatively nutrient-rich waters, thereby forcing the highest rates of primary productivity to occur at depths associated with the thermocline. When the ITF is weaker, the thermocline lifts bringing deeper, more nutrient-rich waters into the photic zone and hence resulting in conditions favourable to increased productivity (DEWHA, 2007a). Similarly, the Leeuwin Current has a significant role in determining primary productivity in the southern areas of the NWMR. As with the ITF, the overlying warm oligotrophic waters of the Leeuwin Current suppress upwelling. A subsurface chlorophyll maximum is therefore formed at a depth in the water column where nutrients and light are sufficient for photosynthesis to proceed. Seasonal changes in the strength of the Leeuwin Current influence primary productivity levels and seasonal interactions between the Leeuwin and Ningaloo currents in the south of the NWMR are believed to be particularly important (DEWHA, 2007a).

Internal tides (defined as internal waves generated by the barotropic tide) are a striking characteristic of many parts of the NWMR and are associated with highly stratified water columns. Internal waves (solitons), which can raise cooler, generally more nutrient rich water higher in the water column, are generated between water depths of 400 m and 1000 m where bottom topography results in a significant change in water depth over a relatively short distance. Cyclones are episodic events in the NWMR that contribute to spikes in productivity through enrichment of surface water layers due to enhanced vertical mixing of the water column. Temporary increases in primary productivity as a result of cyclones generally last between one and two weeks, and it is believed that the impacts of

cyclones are generally limited to waters less than 100 m deep and affect benthic communities more substantially than pelagic systems (DEWHA, 2007a).

Water depth also has a significant overriding influence over productivity in the marine environment, due to its influence on light availability. This is reflected by distinct onshore and offshore assemblages of major pelagic groups of phytoplankton, microzooplankton, mesoplankton and ichthyoplankton. Productivity booms are thought to be triggered by seasonal changes to physical drivers or episodic events, as detailed above, which result in rapid increases in primary production over short periods, followed by extended periods of lower primary production. The trophic systems in the NWMR are able to take advantage of blooms in primary production, enabling nutrients generated to be used by different groups of consumers over long periods (DEWHA, 2007a).

Little detailed information is available about the trophic systems in the NWMR. The utilisation of available nutrients is thought to differ between pelagic and benthic environments, influenced by water depth and vertical migration of some species groups in the water column. In the pelagic system, it is thought that approximately half of the nutrients available are utilised by microzooplankton (e.g. protozoa) with the remainder going to macro/meso-zooplankton (e.g. copepods). As primary and secondary consumers, gelatinous zooplankton (e.g. salps, coelenterates) and jellyfish are thought to play an important role in the food web, contributing a significant proportion of biomass in the marine system during and for periods after booms in primary productivity. Salps are semi-transparent, barrel-shaped marine animals that can reproduce quickly in response to bursts in primary productivity and provide a food source for many pelagic fish species (DEWHA, 2007a).

4.3 Planktonic Communities in the NWMR

The NWMR has two distinct phytoplankton assemblages; a tropical oceanic community in offshore waters and a tropical shelf community confined to the NWS (Hallegraeff, 1995). MODIS (Moderate Resolution Imaging Spectrometer) satellite datasets from the NWMR indicates that chlorophyll (and thus phytoplankton) levels are low in summer months (December to March) and higher in the winter months (Schroeder *et al.*, 2009). Low chlorophyll levels during summer months may be a result of lower plankton productivity during the wet season or lower nutrient inputs from warm surface waters dominant during summer. However, it is likely that much of the primary production is taking place below the surface, where the MODIS imagery does not penetrate (Schroeder *et al.*, 2009). The winter months are relatively cloud free and surface chlorophyll is high throughout most of the region.

Zooplankton and may include organisms that complete their lifecycle as plankton (e.g. copepods, euphausiids) as well as larval stages of other taxa such as fishes, corals and molluscs. Peaks in zooplankton such as mass coral spawning events (typically in March and April) (Rosser and Gilmour, 2008) and fish larvae abundance (CALM, 2005a) can occur throughout the year. Spatial and temporal patterns in the distribution and abundance of macro-zooplankton on the North-west Shelf are influenced by sporadic climatic and oceanographic events, with large inter-annual changes in assemblages (Wilson *et al.*, 2003). Amphipods, euphausiids, copepods, mysids and cumaceans are among the most common components of the zooplankton in the region (Wilson *et al.*, 2003).

4.3.1 Browse

Phytoplankton within the Browse activity area is expected to reflect the conditions of the NWMR. There is a tendency for offshore phytoplankton communities in the NWMR to be characterised by smaller taxa (e.g. bacteria), whereas shelf waters are dominated by larger taxa such as diatoms (Hanson *et al.*, 2007).

Zooplankton within the activity area may include organisms that complete their lifecycle as plankton (e.g. copepods, euphausiids) as well as larval stages of other taxa such as fishes, corals and molluscs. Peaks in zooplankton such as mass coral spawning events (typically in March and April) (Rosser and Gilmour, 2008; Simpson *et al.*, 1993) and fish larvae abundance (CALM, 2005a) can occur throughout the year.

The influence of the Indonesian Throughflow restricts upwelling across the Kimberley System (approximately equates to the Browse activity area). However, small-scale topographically associated current movements and upwellings are thought to occur, which inject nutrients into specific locations within the system and result in 'productivity hot-spots'. Similarly, internal waves, generated at the shelf break (e.g. west of Browse Island and around submerged cliffs) play a role in making nutrients available in the photic zone. Productivity within shallow nearshore waters is driven primarily by tidal movement and terrestrial runoff whereby nutrients are mixed by tidal action and new inputs of organic matter come from the land.

4.3.2 North-west Shelf / Scarborough

Plankton communities within the NWS / Scarborough activity area are expected to reflect conditions of the NWMR. Within the Pilbara system of the NWMR (approximately equates to the NWS / Scarborough activity area). Internal tides along the NWS and Exmouth Plateau result in the drawing of deeper cooler waters into the photic zone, stirring up nutrients and triggering primary productivity. Broadly the greatest productivity within this sub-system is found around the 200 m isobath associated with the shelf break.

4.3.3 North-west Cape

Waters of the North-west Cape experience a relatively high diversity of phytoplankton groups including diatoms, coccolithophorids and dinoflagellates. During the warmer months blooms of *Trichodesmium* occur in the region, these have been observed particularly on the frontal systems around Point Murat (Heyward *et al*., 2000).

Average Leeuwin Current phytoplankton biomass is characteristic of low productivity oceanic waters like the Indian, Pacific and Atlantic Oceans (Hanson *et al.*, 2005). However, the Canyons linking the Cuvier Abyssal Plain and Cape Range Peninsula KEF are connected to the Commonwealth waters adjacent to Ningaloo Reef, and may also have connections to Exmouth Plateau. The canyons are thought to interact with the Leeuwin Current to produce eddies inside the heads of the canyons, resulting in waters from the Antarctic intermediate water mass being drawn into shallower depths and onto the shelf (Brewer *et al.* 2007). These waters are cooler and richer in nutrients and strong internal tides may also aid upwelling at the canyon heads (Brewer *et al.* 2007). The narrow shelf width (about 10 kilometres) near the canyons facilitates nutrient upwelling and relatively high productivity. This high primary productivity leads to high densities of primary consumers, such as micro and macro-zooplankton, such as amphipods, copepods, mysids, cumaceans, euphausiids (Brewer *et al.*, 2007).

4.4 Habitats and Biological Communities in the NWMR

4.4.1 Offshore Habitats and Biological communities

The NWMR has a large area of continental shelf and continental slope, with a range of bathymetric features such as canyons, plateaus, terraces, ridges, reefs, banks and shoals. The marine environment in this region is typified by tropical to sub-tropical marine ecosystems with diverse habitats from soft sediments, canyons, remote coral reefs and limestone pavement.

The key habitats and biological communities representative of the broader NWMR are summarised in **Table 4-1**.

The key habitats and biological communities representative of the broader SWMR and NMR are summarised in **Table 4-2** and **Table 4-3**.

4.4.2 Shoreline habitats and biological communities

The NWMR encompasses offshore and coastal waters, islands and mainland shoreline habitats typified by mangroves, tidal flats, saltmarshes, sandy beaches, and smaller areas of rocky shores. Each of these shoreline types has the potential to support different flora and fauna assemblages due to the different physical factors (e.g. waves, tides, light, etc.) influencing the habitat.

The key shoreline habitats representative of the broader NWMR are summarised in **Table 4-1**.

The key shoreline habitats representative of the broader SWMR and NMR are summarised in **Table 4-2** and **Table 4-3**.

Table 4-1 Habitats and biological communities within the NWMR

Habitat/Community	Browse	NWS / Scarborough	North-west Cape	Reference
Offshore habitats and biological communities				
Soft sediment with infauna	The offshore environment of the NWMR comprises predominately of seabed habitats dominated by soft sediments (sandy and muddy substrata with occasional patches of coarser sediments) and sparse benthic biota. The benthic communities inhabiting the predominantly soft, fine sediments of the offshore habitats are characterised by infauna such as polychaetes, and sessile and mobile epifauna such as crustacea (shrimp, crabs and squat lobsters) and echinoderms (starfish, cucumbers).The density of benthic fauna is typically lower in deep-sea sediment habitats (greater than 200 m) than in shallower coastal sediment habitats, but the diversity of communities may be similar.			
Soft sediment with hard substrate outcropping	A unique seafloor feature combining both soft sediment and hard substrates, including outcrops, terraces, continental slope, and escarpments. This habitat is found in offshore areas of the NWMR, often associated with key ecological features such as the Ancient coastline at 125 m depth contour KEF.			**Section 9**
	Ancient Coastline at 125 m Depth Contour KEF Continental Slope Demersal Fish Communities KEF	Ancient Coastline at 125 m Depth Contour KEF Continental Slope Demersal Fish Communities KEF	Ancient Coastline at 125 m Depth Contour KEF Continental Slope Demersal Fish Communities KEF	**Section 9**
Coral Reef	Coral reef habitats within the NWMR have a high species diversity that includes corals, and associated reef species such as fishes, crustaceans, invertebrates, and algae. Coral reef habitats of the offshore environment of the NWMR include remote oceanic reef systems, large platform reefs, submerged banks and shoals.			
	Browse Island Scott Reef Seringapatam Reef Ashmore Reef Cartier Island Hibernia Reef	Rowley Shoals (including Mermaid Reef, Clerke Reef, Imperieuse Reef) Glomar Shoal Rankin Bank	-	**Section 10**
Seagrass and Macroalgae communities	Seagrass beds and benthic macroalgae reefs are a main food source for many marine species and also provide key habitats and nursery grounds (Heck Jr. *et al.*, 2003; Wilson *et al.*, 2010). In the northern half of Western Australia, these habitats are restricted to sheltered and shallow waters, including around offshore reef systems, due to large tidal movement, high turbidity, large seasonal freshwater run-off and cyclones.			
	Scott Reef Seringapatam Reef Ashmore Reef	Rowley Shoals (including; Mermaid Reef, Clerke Reef, Imperieuse Reef)		**Section 10**
Filter Feeders/ heterotrophic	Filter feeder epifauna such as sponges, ascidians, soft corals and gorgonians are animals that feed by actively filtering suspended matter and food particles from water, by passing the water over specialised filtration structures (DEWHA, 2008). Filter feeders generally live in areas that have strong currents and hard substratum, often associated with deeper environments of the shoals and banks in the offshore NWMR.

Habitat/Community	Browse	NWS / Scarborough	North-west Cape	Reference
	systems such as Scott Reef	Ancient coastline at 125 m depth contour KEF		
Sandy Beaches	Sandy beaches are dynamic environments, naturally fluctuating in response to external forcing factors (e.g. waves, currents, etc). Sandy beaches vary in length, width and gradient, and in sediment type, composition, and grain size throughout the NWMR, being found around islands and reefs in the offshore areas of the region.			
	Browse Island Scott Reef (Sandy Islet) Ashmore Reef Cartier Island	Montebello Islands Lowendal Islands Barrow Island	Muiron Islands	**Section 10**
Nearshore/coastal habitats and biological communities				
Coral Reef	Coral reef habitats typically found in nearshore regions of the NWMR include the fringing reefs around coastal islands and the mainland shore.			
	Kimberley East Holothuria and Long reefs Bonaparte and Buccaneer Archipelagos Montgomery Reef Adele complex (Beagle, Mavis, Albert, Churchill reefs, Adele Island)	Dampier Archipelago Montebello, Lowendal and Barrow Island Groups	Ningaloo Reef Exmouth Gulf Shark Bay	**Section 10**
Seagrass and Macroalgae communities	Seagrass beds and benthic macroalgae reefs are a main food source for many marine species and also provide key habitats and nursery grounds (Heck Jr. *et al.*, 2003; Wilson *et al.*, 2010). In the nearshore areas of the NWMR, these habitats are restricted to sheltered and shallow waters due to large tidal movement, high turbidity, large seasonal freshwater run-off and cyclones. These areas include in bays and sounds and around reef and island groups.			
	King Sound	Roebuck Bay Dampier Archipelago Montebello, Lowendal and Barrow Island Groups	Ningaloo Reef Exmouth Gulf Shark Bay	**Section 10**
Filter Feeders/ heterotrophic	Filter feeder epifauna such as sponges, ascidians, soft corals and gorgonians are animals that feed by actively filtering suspended matter and food particles from water, by passing the water over specialised filtration structures (DEWHA, 2007a). Filter feeders generally live in areas that have strong currents and hard substratum. Conversely, higher diversity infauna are mainly associated with soft unconsolidated sediment and infauna communities are considered widespread and well represented along the continental shelf and upper slopes of the NWMR. In nearshore areas of the NWMR, these species are generally found around reef systems.			
	-	Deeper habitats of Rankin Bank and Glomar Shoal	Deeper habitats of Ningaloo Reef and the protected sponge zone in the south	

Habitat/Community	Browse	NWS / Scarborough	North-west Cape	Reference
Mangroves	Mangroves grow in intertidal mud and sand, with specially adapted aerial roots (pneumatophores) that provide for gas exchange during low tide (McClatchie *et al.*, 2006). Mangrove forests can help stabilise coastal sediments, provide a nursery ground for many species of fish and crustacean, and provide shelter or nesting areas for seabirds (McClatchie *et al.*, 2006). Mangroves are confined to shoreline habitats, in nearshore areas of the NWMR.			
	Dampier Peninsula (including Carnot Bay, Beagle Bay and Pender Bay)	Pilbara Coastline (including; Ashburton River Delta, Coolgra Point, Robe River Delta, Yardie Landing, Yammadery Island and the Mangrove Islands) Montebello, Lowendal and Barrow Island Groups Roebuck Bay	Shark Bay Mangrove Bay, Cape Range Peninsula Exmouth Gulf	
Saltmarshes	Saltmarshes communities are confined to shoreline habitats and are typically dominated by dense stands of halophytic plants such as herbs, grasses, and low shrubs. The diversity of saltmarsh plant species increases with increasing latitude (in contrast to mangroves). The vegetation in these environments is essential to the stability of the saltmarsh, as they trap and bind sediments. The sediments are generally sandy silts and clays and can often have high organic material content.			
	-	Eighty Mile Beach Roebuck Bay	Shark Bay	
Sandy Beaches	Sandy beaches are dynamic environments, naturally fluctuating in response to external forcing factors (e.g. waves, currents, etc). Sandy beaches vary in length, width and gradient, and in sediment type, composition, and grain size throughout the NWMR. Sandy beaches are important for both resident and migratory seabirds and shorebirds and can also provide an important habitat for turtle nesting and breeding. They are located along many coastlines of the nearshore environments of the NWMR.

Table 4-2 Habitats within the SWMR

Habitat/Community	Location
Offshore	
Soft sediment with infauna	Most of the SWMR seafloor is composed of soft unconsolidated sediments, but due to large variations in bathymetry there are marked differences in sedimentary composition and benthic assemblage structure across the region. Despite the prevalence of these habitats in the SWMR, very little is known about the composition or distribution of the region's sedimentary infauna (DEWHA, 2008b)
Soft sediment with hard substrate outcropping	A unique seafloor feature combining both soft sediment and hard substrates, including outcrops, terraces, continental slope, and escarpments.
	Perth Canyon Marine Park Ancient coastline at 90-120 m depth contour KEF Diamantina Fracture Zone Naturaliste Plateau
Coral Reef	To date, studies and understanding of the corals within the SWMR have concentrated on the shallow water areas in State Waters. Within the deeper Commonwealth waters of the SWMR little is known of the distribution of corals.
Filter Feeders/ heterotrophic	Filter feeder epifauna such as sponges, ascidians, soft corals and gorgonians are animals that feed by actively filtering suspended matter and food particles from water, by passing the water over specialised filtration structures (DEWR, 2007). Filter feeders generally inhabit deeper habitat (below the photic zone) that have strong currents and hard substratum
	Ancient coastline at 90-120 m depth Diamantina Fracture Zone Naturaliste Plateau Perth Canyon Marine Park South-west Corner Marine Park
Nearshore	
Coral Reef	The northern extent of the SWMR coincides loosely with the disappearance of abundant and diverse coral from coastal habitats. To the south of Shark Bay, abundant corals occur predominantly around offshore islands, with corals at inshore sites occurring in very isolated patches of non-reef coral communities, usually of reduced species richness.
	Houtman Abrolhos Islands Rottnest Island
Seagrass and Macroalgae communities	Within the SWMR, macroalgae and seagrass communities are noted for their extent, species richness and endemism. The clear waters of the region allow light to reach greater depths, with some species found at much greater depths than usual (down to 120 m) (DEWR, 2007). Of the known species there are more than 1000 species of macro-algae and 22 species of seagrass consisting of tropical and temperate species. Seagrass and macro-algae occur in areas with sheltered bays and in the inter-reef lagoons along exposed sections of the coast.

Filter Feeders/ heterotrophic	Filter feeder epifauna such as sponges, ascidians, soft corals and gorgonians are animals that feed by actively filtering suspended matter and food particles from water, by passing the water over specialised filtration structures (DEWR, 2007). Filter feeders generally live in areas that have strong currents and hard substratum.
	Houtman Abrolhos Islands Recherche Archipelago
Mangroves	Mangroves grow in intertidal mud and sand, with specially adapted aerial roots (pneumatophores) that provide for gas exchange during low tide (McClatchie *et al.*, 2006). Mangrove forests can help stabilise coastal sediments, provide a nursery ground for many species of fish and crustacean, and provide shelter or nesting areas for seabirds (McClatchie *et al.*, 2006). Mangroves are confined to shoreline habitats, in nearshore areas of the SWMR.
	Houtman Abrolhos Islands
Sandy Beaches	Sandy beaches within the SWMR are important for both resident and migratory seabirds and shorebirds and can also host breeding populations of the Australian sea lion. They are found along many coastlines of the nearshore environments of the SWMR. In addition to this, beaches in the SWMR provide a variety of socio-economic values including tourism, commercial and recreational fishing, and support other recreational activities.
	Houtman Abrolhos Islands Marmion Marine Park Ngari Capes Marine Park Walpole and Nornalup Inlets Marine Park

Table 4-3 Habitats and Biological Communities within the NMR

Habitat/Community	Location
Offshore habitats and biological communities	
Soft sediment with infauna	Most of the offshore environment of the NMR is characterised by relatively flat expanses of soft sediment seabed. The soft sediments of the region are characterised by moderately abundant and diverse communities of infauna and mobile epifauna dominated by polychaetes, crustaceans, molluscs, and echinoderms.
Soft sediment with hard substrate outcropping	A unique seafloor feature combining both soft sediment and hard substrates, including outcrops, terraces, continental slope, and escarpments. The variability in substrate composition may contribute to the presence of unique ecosystems. Species present include sponges, soft corals and other sessile filter feeders associated with hard substrate sediments.
	Carbonate bank and terrace system of the Van Diemen Rise KEF Pinnacles of the Bonaparte Basin KEF
Coral Reef	Offshore coral reefs within the NMR is generally associated with a series of submerged shoals and banks. The shoals/banks in the region support tropical marine biota consistent with that found on emergent reef systems of the Indo West Pacific region such as Ashmore Reef, Cartier Island, Seringapatam Reef and Scott Reef (Heyward *et al.,* 1997)
	Pinnacles of the Bonaparte Basin KEF Evans Shoal Tassie Shoal Blackwood Shoal
Filter Feeders/ heterotrophic	Filter feeder epifauna such as sponges, ascidians, soft corals and gorgonians are animals that feed by actively filtering suspended matter and food particles from water, by passing the water over specialised filtration structures (DEWHA, 2007b). Filter feeders generally live in areas that have strong currents and hard substratum and typically associated with the deeper habitats of the submerged shoals and banks, and canyon features.
	Carbonate bank and terrace system of the Van Diemen Rise KEF Pinnacles of the Bonaparte Basin KEF Tributary Canyons of the Arafura Depression KEF Evans Shoal Tassie Shoal Goodrich Bank
Nearshore	
Coral Reef	Within the NMR corals occur both as reefs and in non-reef coral communities. Nearshore reefs include patch reefs and fringing reefs sparsely distributed within the region. Coral reefs within the NMR provides breeding and aggregation areas for many fish species including mackerel and snapper and offer refuges for sea snakes and apex predators such as sharks.
	Submerged coral reefs of the Gulf of Carpentaria KEF Darwin Harbour
Seagrass and Macroalgae communities	Seagrasses provide key habitats in the NMR. They stabilise coastal sediments and trap and recycle nutrients. They provide nursery grounds for commercially harvested fish and prawns and provide feeding grounds for dugongs and green turtles. Seagrass distribution in the region is largely associated with sheltered small bays and inlets including shallow waters surrounding inshore islands.
	Field Island The mainland coastline adjacent to Kakadu National Park

Habitat/Community	Location
Filter Feeders/ heterotrophic	Filter feeder epifauna such as sponges, ascidians, soft corals, and gorgonians are animals that feed by actively filtering suspended matter and food particles from water, by passing the water over specialised filtration structures (DEWHA, 2007b). Filter feeders generally live in areas that have strong currents and hard substratum.
	Cape Helveticus
Mangroves	Mangroves grow in intertidal mud and sand, with specially adapted aerial roots (pneumatophores) that provide for gas exchange during low tide (McClatchie *et al.*, 2006). Mangroves provide habitat for waterbirds and support many commercially and recreationally important fish and crustacean species for parts of their life cycles. They buffer the coast from large tidal movements, storm surges and flooding.
	Tiwi Islands Darwin Harbour The mainland coastline adjacent to the Daly River
Sandy Beaches	Sandy beaches vary in length, width and gradient, and in sediment type, composition, and grain size throughout the NMR and are important for both resident and migratory seabirds and shorebirds. Sandy beaches can also provide an important habitat for turtle nesting. They are located along many coastlines of the nearshore environments of the islands and mainland shores of the NMR.
	Tiwi Islands Cobourg Peninsula Joseph Bonaparte Gulf

5. FISHES, SHARKS AND RAYS

5.1 Regional Context

Western Australian waters provide important habitat for listed fishes, sharks, and rays including areas that support key life stages such as breeding, foraging, and migration routes for fish species. Pelagic and demersal fishes occupy a range of habitats throughout each of the regions, from coral reefs to open offshore waters, and are an extremely important component of ecosystems, providing a link between primary production and higher predators, with many species being of conservation value and important for commercial and recreational fishing.

The fish fauna in the NWMR is diverse. Of the approximately 500 shark species found worldwide, 94 are found in the region (DEWHA, 2008). Approximately 54 species of syngnathids (seahorses, seadragons, pipehorses and pipefishes) and one species of solenostomids (ghostpipefishes) are also known to occur in the NWMR or adjacent State waters (DSEWPAC, 2012a).

The fish fauna of the SWMR includes more than 900 species occupying a large variety of habitats. However, only three species of bony fishes known to occur in the region are listed under the EPBC Act as threatened or marine species, and seven listed species of shark (DSEWPAC, 2012b).

The NMR is considered an important area for the sawfish and river shark species group, with five species of sawfishes and river sharks listed under the EPBC Act known to occur in the region (DSEWPAC, 2012c). Approximately 28 species of syngnathids and two species of solenostomids are listed marine and known to occur in the NMR, however there is a paucity of knowledge on the distribution, relative abundance and habitats of these species in the region (DEWHA, 2008).

The following sections focus on the fish species (including sharks and rays) listed as threatened or migratory that are known to occur within the NWMR. In addition, listed, conservation dependent fish and shark species for the NWMR are described. A detailed account of commercial and recreational fisheries that operate in the region is provided in **Section 11**.

Table 5-1 outlines the threatened and migratory fish species that may occur within the NWMR, with their conservation status and relevant recovery plans and/or conservation advice. **Table 5-2** provides information for species of fish that are listed as conservation dependent that may occur within the NWMR, NMR and SWMR. Note that currently there are no approved Conservation Advices in place for any of these five species.

Table 5-1 Fish species (including sharks and rays) identified by the EPBC Act PMST for the NWMR

Species Name	Common Name	*Environment Protection and Biodiversity Conservation Act 1999*			WA *Biodiversity Conservation Act 2016*	EPBC Act Part 13 Statutory Instrument

Table 5-2 EPBC Act listed Conservation Dependent species of fishes and sharks that may occur in the NWMR, NMR and SWMR

Species Name	Common Name	Likely Occurrence / Distribution	Listing Advice
Hoplostethus atlanticus	Orange roughy, Deep-sea perch, Red roughy	SWMR	No conservation listing advice for this species. Refer to the Marine bioregional plan for the SWMR (DSEWPAC, 2012b) for further information
Thunnus maccoyii	Southern bluefin tuna	NWMR and SWMR	Threatened Species Scientific Committee (2010)
Sphyrna lewini	Scalloped hammerhead	NWMR, NMR and SWMR	Threatened Species Scientific Committee (2018)
Centrophorus zeehaani	Southern dogfish, Endeavour dogfish, Little gulper shark	SWMR	Threatened Species Scientific Committee (2013)
Galeorhinus galeus	School shark, Eastern school shark, Snapper shark, Tope, Soupfin shark	SWMR	Threatened Species Scientific Committee (2009)

5.2 Protected Sharks, Sawfishes and Rays in the NWMR

The EPBC Act Protected Matters search (**Appendix A**) identified seven species of shark and five species of river shark or sawfish listed as threatened and/or migratory within the NWMR. In addition, two species of ray (the reef manta ray and giant manta ray) are listed as migratory within the region (refer **Table 5-2**).

5.2.1 Sharks and Sawfishes

The shark species known to occur within the NWMR include: the whale shark, grey nurse shark, white shark, shortfin mako, and longfin mako (**Table 5-2**).

Five species of river shark or sawfish known to occur in the NWMR and include: the narrow sawfish, northern river shark, freshwater sawfish, green sawfish and dwarf sawfish (**Table 5-2**).

There are identified BIAs within the NWMR for the whale shark, freshwater sawfish, green sawfish, and dwarf sawfish (refer **Section 5.3.2**).

Table 5-2 Information on the threatened shark and sawfish species within the NWMR

Species	Preferred Habitat and Diet	Habitat Location
Whale shark	Preferred habitat: They have a widespread distribution in tropical and warm temperate seas, both oceanic and coastal (Last and Stevens, 2009). The species is widely distributed in Australian waters. Diet: Whale sharks are planktivorous sharks and feed on a variety of planktonic organisms including krill, jellyfish, and crab larvae (Last and Stevens, 2009).	Ningaloo Reef is the main known aggregation site for whale sharks in Australian waters and has the largest density of whale sharks per kilometre in the world (Martin, 2007). Refer **Table 5-3** for the BIA summary for the whale shark.
Grey nurse shark (west coast population)	Preferred habitat: Most commonly found in temperate waters on, or close to, the bottom of the continental shelf, from close inshore to depths of about 200 m (McAuley, 2004). Diet: A variety of teleost and elasmobranch fishes and some cephalopods (Gelsleichter *et al.*, 1999; Smale, 2005).	Details of movement patterns of the western sub-population are unclear (McAuley, 2004) and key aggregation sites have not been formally identified within the NWMR (Chidlow *et al.*, 2006). The NWMR represents the northern limit of the west coast population.

Species	Preferred Habitat and Diet	Habitat Location
White shark	Preferred habitat: The species typically occurs in temperate coastal waters between the shore and the 100 m depth contour; however, adults and juveniles have been recorded diving to depths of 1000 m (Bruce *et al.*, 2006; Bruce, 2008). Diet: Smaller white sharks (less than 3 m in length) feed primarily on teleost and elasmobranch fishes, broadening their diet as larger sharks to include marine mammals (Last and Stevens, 2009).	There are no known aggregation sites for white sharks in the NWMR, and this species is most often found south of North-west Cape, in low densities (DSEWPAC, 2012a). Given the migratory nature of the species, most likely has a broad distribution within the NWMR. No BIAs identified for NWMR.
Shortfin mako	Preferred habitat: The shortfin mako shark is a pelagic species with a circumglobal, wide-ranging oceanic distribution in tropical and temperate seas (Mollet *et al.*, 2000). Tagging studies indicate shortfin makos spend most of their time in water less than 50 m deep but with occasional dives up to 880 m (Abascal *et al.*, 2011; Stevens *et al.*, 2010). Diet: Feeds on a variety of prey, such as teleost fishes, other sharks, marine mammals, and marine turtles (Campana *et al.*, 2005).	Given the migratory nature of the species, most likely has a broad distribution within the NWMR. No BIAs identified for NWMR.
Longfin mako	Preferred habitat: A pelagic species with a wide-ranging oceanic distribution in tropical and temperate seas (Mollet *et al.*, 2000). Diet: Primarily teleost fishes and cephalopods (primarily squid) (Last and Stevens, 2009).	Records on longfin mako sharks are sporadic and their complete geographic range is not well known (Reardon *et al.*, 2006). Given the migratory nature of the species, most likely has a broad distribution within the NWMR. No BIAs identified for NWMR.
Mackerel/Porbeagle shark	Preferred habitat: The porbeagle shark primarily inhabits offshore waters around the edge of the continental shelf. They occasionally move into coastal waters, but these movements are temporary (Campana and Joyce, 2004; Francis *et al.*, 2002). The porbeagle shark is known to dive to depths exceeding 1300 m (Campana *et al.*, 2010; Saunders *et al.*, 2011). Diet: Primarily teleost fish, elasmobranchs, and cephalopods (primarily squid) (Joyce *et al.*, 2002; Last and Stevens, 2009).	In Australia, the species occurs in waters from southern Queensland to south-west Australia (Last and Stevens, 2009). Distribution within the NWMR is unknown, but there are several records for this species on the NWS in the Atlas of Living Australia (ALA).
Oceanic whitetip shark	Preferred habitat: The oceanic whitetip shark is globally distributed in warm-temperate and tropical oceans (Andrzejaczek *et al.*, 2018). The species may occur in tropical and sub-tropical offshore and coastal waters around Australia. They primarily occupy pelagic waters in the upper 200 m of the water column; however, they have been observed diving to depths of around 1000 m, potentially associated with foraging behaviour (Howey-Jordan *et al.*, 2013; D'Alberto *et al.*, 2017). The species is highly migratory, travelling large distances between shallow reef habitats in coastal waters and oceanic waters (Howey-Jordan *et al.*, 2013). The species does exhibit a strong preference for warm and shallow waters above 120 m. Diet: Opportunistic feeders and generally target a variety of finfishes and pelagic squid, depending on habitat. Target pelagics such as tuna in open ocean as noted by the large bycatch numbers in the long line fisheries.	Given the migratory nature of the species, most likely has a broad distribution within the NWMR. No BIAs identified for NWMR.

Species	Preferred Habitat and Diet	Habitat Location
Narrow sawfish	Preferred habitat[1]: Shallow coastal, estuarine, and riverine habitats, however it may occur in waters up to 40 m deep (D'Anastasi *et al.*, 2013). Diet: Shoaling fishes, such as mullet, as well as molluscs and small crustaceans (Cliff and Wilson, 1994).	Shallow coastal waters of the Pilbara and Kimberly coasts (Last and Stevens, 2009).
Northern river shark	Preferred habitat[1]: Rivers, tidal sections of large tropical estuarine systems and macrotidal embayments, as well as inshore and offshore marine habitats (Pillans *et al.*, 2009; Thorburn and Morgan, 2004). Adults have been recorded only in marine environments. Juveniles and sub-adults have been recorded in freshwater, estuarine and marine environments (Pillans *et al.*, 2009). Diet: Variety of fish and crustaceans (Stevens *et al.*, 2005)	Within the NWMR records have come from both the west and east Kimberley, including King Sound, the Ord and King rivers, West Arm of Cambridge Gulf and also from Joseph Bonaparte Gulf (Thorburn and Morgan, 2004; Stevens *et al.*, 2005; Thorburn, 2006; Field *et al.*, 2008; Pillans *et al.*, 2008, Whitty *et al.*, 2008; Wynen *et al.*, 2008).
Largetooth (Freshwater) sawfish	Preferred habitat: Sandy or muddy bottoms of shallow coastal waters, estuaries, river mouths and freshwater rivers, and isolated water holes. Diet: Shoaling fishes, such as mullet, as well as molluscs and small crustaceans (Cliff and Wilson, 1994).	Refer **Table 5-3** for the BIA summary for the freshwater sawfish.
Green sawfish	Preferred habitat[1]: Inshore coastal environments including estuaries, river mouths, embayments, and along sandy and muddy beaches, as well as offshore marine habitat (Stevens *et al.*, 2005; Thorburn *et al.*, 2003). Diet: Schools of baitfish and prawns (Poganoski *et al.*, 2002), molluscs and small crustaceans (Cliff and Wilson, 1994).	Refer **Table 5-3** for the BIA summary for the green sawfish.
Dwarf sawfish	Preferred habitat[1]: Shallow (2 to 3 m) silty coastal waters and estuarine habitats, occupying relatively restricted areas and moving only small distances (Stevens *et al.*, 2008) Diet: Shoaling fish such as mullet, molluscs, and small crustaceans (Cliff and Wilson, 1994).	Refer **Table 5-3** for the BIA summary for the dwarf sawfish.

1 Preferred habitat as described within the Sawfish and River Sharks Multispecies Recovery Plan (Commonwealth of Australia, 2015b).

5.2.2 Rays

Rays are commonly found in the NWMR. Two listed and migratory species of ray known to occur within the NWMR: the reef manta ray and giant manta ray.

No BIAs for either the reef or giant manta ray species have been identified in the NWMR.

Table 5-3 Information on migratory ray species within the NWMR

Species	Preferred Habitat and Diet	Habitat Location
Reef manta ray	Preferred habitat: The reef manta ray is commonly sighted within productive nearshore environments, such as island groups, atolls or continental coastlines. However, the species has also been recorded at offshore coral reefs, rocky reefs, and seamounts (Marshall *et al.*, 2009). Diet: Feed on planktonic organisms including krill and crab larvae.	A resident population of reef manta rays has been recorded at Ningaloo Reef. No BIAs identified for NWMR.
Giant manta ray	Preferred habitat: The species primarily inhabits near-shore environments along productive coastlines with regular upwelling, but they appear	The Ningaloo Coast is an important area for giant manta rays from March to August (Preen *et al.*, 1997).

Species	Preferred Habitat and Diet	Habitat Location
	to be seasonal visitors to coastal or offshore sites including offshore island groups, offshore pinnacles and seamounts (Marshall *et al.*, 2011). Diet: Feed on planktonic organisms including krill and crab larvae.	No BIAs identified for NWMR.

5.3 Fish, Shark and Sawfish Biological Important Areas in the NWMR

A review of the National Conservation Values Atlas identified Biologically Important Areas (BIAs) for four species of shark and sawfish (whale shark, freshwater sawfish, green sawfish and dwarf sawfish) within the NWMR. The BIAs for the whale shark and the sawfish species include foraging, nursing and pupping areas. These are described in **Table 5-4**.

Table 5-4 Fish, whale shark and sawfish BIAs within the NWMR

Species	Woodside Activity Area			BIAs		
	Browse	NWS/S	NWC	Pupping	Nursing	Foraging
Whale shark	✓	✓	✓	No pupping BIA identified within the NWMR	No nursing BIA identified within the NWMR	Foraging (high density) in Ningaloo Marine Park and adjacent Commonwealth waters (March–July) Foraging northward from Ningaloo along the 200 m isobath (July – Nov).
Green sawfish	✓	✓	-	Pupping in Cape Keraudren (pupping occurs in summer in a narrow area adjacent to shoreline) Pupping in Willie Creek Pupping in Roebuck Bay Pupping in Cape Leveque Pupping in waters adjacent to Eighty Mile Beach Pupping (likely) in Camden Sound. Figure 5-2 Sawfish BIAs for the NWMR

5.4 Fish Assemblages of the NWMR

5.4.1 Regional Context for Fish Assemblages of NWMR

The NWMR contains a diverse range of fishes of tropical Indo-west Pacific affinity (Allen *et al.*, 1988). The region is characterised by the highest level of endemism and species diversity compared with other areas of the Australian continental slope. Last *et al.* (2005) recorded 1431 species from the three bioregions encompassing the continental slope, whilst also acknowledging some information gaps.

The NWMR is known for its demersal slope fish assemblages; the continental slope of the Timor Province and the North-west Transition supports more than 418 and 505 species of demersal fishes respectively, of which 64 are considered to be endemic. This is the second richest area for demersal fish species across the entire Australian continental slope. Conversely, the broad Southern Province, which covers most of southern Australia, supports 463 species, only 26 possibly being endemic. The continental slope demersal fish assemblages of the NWMR have been identified as a KEF (DEWHA, 2008), as described in **Section 9**.

The NWMR also features a diversity of pelagic fishes (those living in the pelagic zone) and bentho-pelagic fishes, including tuna, billfish, bramids, lutjanids, serranids and some sharks (DEWHA, 2007a). These species feed on salps and jellyfish, and more often on secondary consumers such as squid and bait fish. Water depth provides an indication of the level of interaction between pelagic and benthic communities within the NWMR; in waters deeper than 1000 m, for instance, the trophic system is pelagically-driven and benthic communities rely on particulates that fall to the seafloor (DEWHA, 2007a).

Pelagic fishes play an important ecological role within the NWMR; small pelagic fishes, such as lantern fish, inhabit a range of marine environments, including inshore and continental shelf waters and form a vital link in and between many of the region's trophic systems, feeding on pelagic phytoplankton and zooplankton and providing a food source for a wide variety of predators including large pelagic fishes, sharks, seabirds and marine mammals (Bulman, 2006; Mackie *et al.*, 2007). Large pelagic fishes, such as tuna, mackerel, swordfish, sailfish and marlin, are found mainly in oceanic waters and occasionally on the continental shelf (Brewer *et al.*, 2007). Both juvenile and adult phases of the large pelagic species are highly mobile and have a wide geographic distribution, although the juveniles more frequently inhabit warmer or coastal waters (DEWHA, 2008).

5.4.2 Listed Fish Species in the NWMR

The family Syngnathidae is a group of bony fishes that includes seahorses, pipefishes, pipehorses and seadragons. Along with syngnathids, members of the related Solenostomidae family (ghost pipefishes) are also found in the NWMR (DSEWPAC, 2012a).

There are 44 solenostomid and syngnathid species that are listed marine species that may occur within the NWMR, although no species is currently listed as threatened or migratory, according to the PMST report (**Appendix A**).

Syngnathids live in nearshore and inner shelf habitats, usually in shallow coastal waters, among seagrasses, mangroves, coral reefs, macroalgae dominated reefs, and sand or rubble habitats (Dawson, 1985; Lourie *et al.*, 1999, Lourie *et al.*, 2004; Vincent, 1996). Two species, the winged seahorse (*Hippocampus alatus*) and western pipehorse (*Solegnathus sp. 2*) have been identified in deeper waters of the NWMR (up to 200 m) (DSEWPAC, 2012a), however, these species were not identified by the Protected Matters search of the NWMR.

Knowledge about the distribution, abundance and ecology of both syngnathids and solenostomids in the NWMR is limited. No BIAs for syngnathids and solenostomids have been identified in the NWMR.

5.4.3 Browse

The proposed Browse activity area includes biologically important habitat for the whale shark and three sawfish species:

- whale shark (foraging northward from Ningaloo along the 200 m isobath (July – Nov),
- freshwater sawfish (pupping, nursing and foraging areas),
- green sawfish (pupping, nursing and foraging areas); and
- dwarf sawfish (pupping, nursing and foraging areas).

BIAs for the shark and sawfish species are outlined in **Table 5-4** and **Figure 5-1**.

The proposed Browse activity area has partial overlap with the Continental slope demersal fish communities KEF.

5.4.4 NWS / Scarborough

The NWS / Scarborough activity area includes biologically important habitat for the whale shark and three sawfish species:

- whale shark (foraging northward from Ningaloo along the 200 m isobath (July – Nov),
- freshwater sawfish (pupping, nursing and foraging areas),
- green sawfish (pupping, nursing and foraging areas); and
- dwarf sawfish (pupping, nursing and foraging areas).

BIAs for the whale shark and sawfish species are outlined in **Table 5-4** and **Figure 5-1**.

The NWS / Scarborough activity area has partial overlap with the Continental slope demersal fish communities KEF. The continental slope between North-west Cape and the Montebello Trough has more than 500 fish species, 76 of which are endemic, which makes it the most diverse slope bioregion in Australia (Last *et al.*, 2005).

5.4.5 North-west Cape

The North-west Cape activity area includes biologically important foraging habitat for the whale shark:

- whale shark, including:
  - Foraging (high density) in Ningaloo Marine Park and adjacent Commonwealth waters (March–July); and
  - Foraging northward from Ningaloo along the 200 m isobath (July – Nov).

BIAs for the whale shark are outlined in **Table 5-4** and **Figure 5-1**.

The North-west Cape activity area coincides with part of the Continental slope demersal fish communities KEF.

6. MARINE REPTILES

6.1 Regional Context for Marine Reptiles

The NWMR contains important habitat for listed marine reptiles, including areas that support key life stages such as nesting, internesting, migration and foraging for marine turtle species, and habitats supporting resident sea snake and crocodile populations.

Six of the seven marine turtle species occur in Australian waters, and all six (the green turtle, hawksbill turtle, loggerhead turtle, flatback turtle, leatherback turtle and olive ridley turtle) occur in the NWMR and NMR.

There are 25 listed species of sea snake reported within or adjacent to the NWMR (Guinea, 2007a; Udyawer *et al*., 2016), of which four are endemic to reef habitats in the remote parts of the region. Nineteen (19) listed sea snake species are known to occur in the NMR, as reported in the Protected Matters search (**Appendix A**).

There are significantly fewer marine reptile species that frequently occur within the SWMR and presently include three species of listed marine turtle and one sea snake species. Other species of sea snake may occur because of the southward-flowing Leeuwin Current, as vagrants in the region (DSEWPAC, 2012b).

The following sections focus on the listed marine reptile species known to occur within the NWMR.

Table 6-1 outlines the threatened and migratory marine reptile species that occur within the NWMR, with their conservation status and relevant recovery plans and/or conservation advice.

Table 6-1 Marine reptile species identified by the EPBC Act PMST as potentially occurring within or utilising habitats in the NWMR for key life cycle stages

Species Name	Common Name	*Environment Protection and Biodiversity Conservation Act 1999*			WA *Biodiversity Conservation Act 2016*	EPBC Act Part 13 Statutory Instrument

Aipysurus foliosquama	Leaf-scaled sea snake	Critically endangered	N/A	Marine	Critically endangered	Approved Conservation Advice for *Aipysurus foliosquama* (Leaf-scaled Sea Snake) (DSEWPAC, 2011b)
Crocodylus porosus	Salt-water crocodile	N/A	Migratory	Marine	Other protected fauna	N/A

6.2 Marine Turtles in the NWMR

According to the Protected Matters search (**Appendix A**) six species of marine turtle known to occur within the NWMR are listed as threatened and migratory (three Vulnerable and three Endangered) under the EPBC Act—the green (*Chelonia mydas*), hawksbill (*Eretmochelys imbricata*), flatback (*Natator depressus*), loggerhead (*Caretta caretta*), leatherback (*Dermochelys coriacea*) and olive ridley (*Lepidochelys olivacea*) turtle (DSEWPAC, 2012a) (refer **Table 6-1**).

The NWMR supports globally significant breeding populations of four marine turtle species: the green, hawksbill, flatback and loggerhead turtle. Olive ridley turtles are known to forage within the NWMR, but there are only occasional records of the species nesting in the region. Leatherback turtles regularly forage over Australian continental shelf waters within the NWMR but there are also no records of the species nesting in the region (DSEWPAC, 2012a).

The six marine turtle species reported for the NWMR also occur within the NMR.

Three marine turtle species; the green, loggerhead, and leatherback turtle, have presumed feeding areas within the SWMR; however, no known nesting areas exist within the region (DSEWPAC, 2012b).

Discrete genetic stocks have evolved within each marine turtle species. This is the result of marine turtles returning to the location where they hatched. These genetically distinct stocks are defined by the presence of regional breeding aggregations. Stocks are composed of multiple rookeries in a region and are delineated by where there is little or no migration of individuals between nesting areas. Turtles from different stocks typically overlap at feeding grounds (Commonwealth of Australia, 2017). There are 17 genetic stocks across both the NWMR and NMR (nine in the NWMR, six in the NMR, and two overlapping both regions). Of these 17 genetic stocks, nine are known to occur within Woodside's three areas of activity (**Table 6-2**).

6.2.1 Life Cycle Stages

Marine turtles are highly migratory during non-reproductive life phases and have high site fidelity during breeding and nesting life phases. Majority of their lives are spent in the ocean, but the adult female marine turtles will come ashore to lay eggs in the sand above the high water mark on natal beaches (Commonwealth of Australia, 2017). **Figure 6-1** summarises the generalised life cycle of marine turtles. Species-specific life cycle information is outlined within the Recovery Plan for Marine Turtles of Australia (Commonwealth of Australia, 2017).

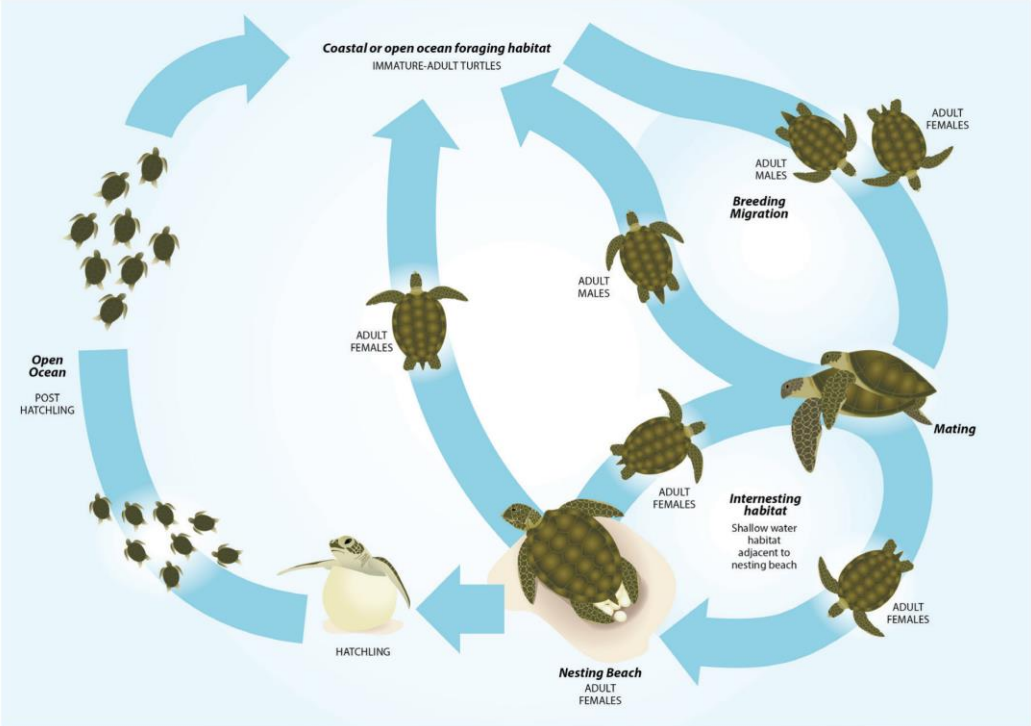

Figure 6-1 Generalised life cycle of marine turtles (Commonwealth of Australia, 2017)

6.2.2 Habitat Critical to Survival for Marine Turtles in the NWMR

The Recovery Plan for Marine Turtles of Australia (Commonwealth of Australia, 2017) identifies habitat critical to the survival of a species for marine turtle stocks under the EPBC Act. Habitat critical to survival is defined by the EPBC Act *Significant Impact Guidelines 1.1 – Matters of National Environmental Significance* as areas necessary:

- for activities such as foraging, breeding or dispersal;
- for the long-term maintenance of the species (including the maintenance of species essential to the survival of the species);
- to maintain genetic diversity and long term evolutionary development; and
- for the reintroduction of populations or recovery of the species.

The Recovery Plan for Marine Turtles of Australia (Commonwealth of Australia, 2017) has identified nesting locations and associated internesting areas as habitat critical to survival for four marine turtle species within the NWMR and these are identified, described and mapped in **Table 6-2** and **Figure 6-2**. No habitat critical to survival has been identified within the NWMR for olive ridley or leatherback turtles.

Table 6-2 outlines the relevant genetic stock, habitat critical to survival and key life cycle stage seasonality of the four species of marine turtles within the NWMR.

Table 6-2 Genetic stock, habitat critical to survival and key life cycle stage seasonality of the four species of marine turtles within the NWMR

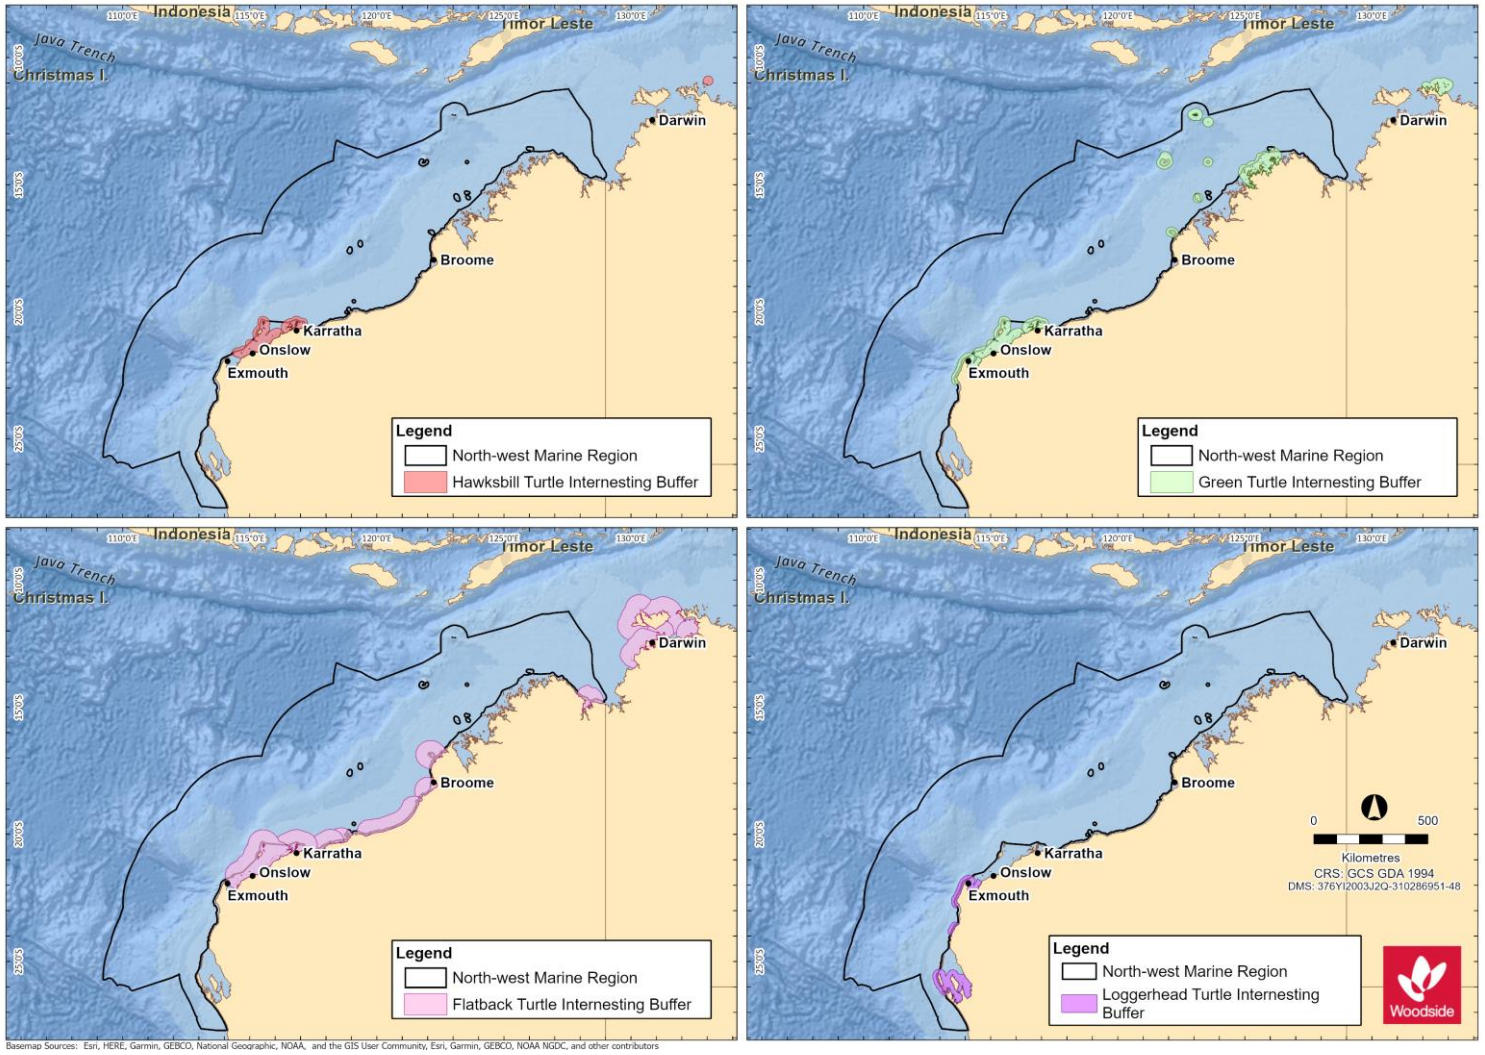

Figure 6-2 Marine turtle species habitat critical to survival (nesting beaches and internesting buffers) for the NWMR

6.3 Marine Turtle Biological Important Areas in the NWMR

A review of the National Conservation Values Atlas (DAWE, 2020[2]) identified BIAs for the four marine turtle species that occur within the NWMR. These are described in **Table 6-3**. Note that nesting and internesting BIAs are not listed in **Table 6-3** as they are defined as in the Recovery Plan as habitat critical to survival for marine turtles nesting beaches and internesting areas (refer **Table 6-2**).

Individual turtles foraging in the same area do not necessarily take the same migration route (Limpus *et al.*, 1992). Ferreira et al. (2021) broadly identified two migratory corridors, one used by the NWS stock-Pilbara and another used by the NWS stock-Kimberley and the Scott-Browse stock with some overlap at the northern and southern extents respectively. This study showed that the foraging distribution of green turtles from two stocks in WA expands throughout north-west and northern Australian coastal waters, including the NT and Queensland.
Hawksbill turtle	✓	✓	✓	No mating BIA identified within the NWMR.	Foraging around the Lowendal Island group Foraging at Delambre Island Foraging around Dixon Island Foraging in the De Grey River area to Bedout Island Foraging around the islands between Cape Preston and	Individuals may migrate up to 2400 km between their nesting and foraging grounds (DSEWPAC, 2012a).

[3] Migration BIA does not exist for Marine Turtles – general information provided.

Species	Woodside Activity Area			BIAs		
	Browse	NWS/S	NWC	Mating	Foraging	Migration[3]
					Onslow and inshore of Barrow Island Foraging around the islands of the Dampier Archipelago (to the west of the Burrup Peninsula) Foraging at Ashmore Reef	
Flatback turtle	✓	✓	-	Lacepede Islands Mating at Montebello Islands Mating at Dampier Archipelago (islands to the west of the Burrup Peninsula) Mating at Barrow Island A year-round internesting buffer biologically important area (BIA) of 80 km is located north and north-west of the Montebello Islands, extending 20 km further than the habitat critical to survival. However, use level for this BIA has been defined as very low (Commonwealth of Australia, 2017) and the habitat critical to survival internesting buffer is the legally recognised area of protection under the EPBC Act *Significant Impact Guidelines 1.1 – Matters of National Environmental Significance* Refer to the Marine Bioregional Plan for the North-west Marine Region (DSEWPAC, 2012a) for locations of seasonal 80 km internesting buffer BIAs for flatback turtles	Foraging at the islands between Cape Preston and Onslow and inshore of Barrow Island. Foraging at Montebello Islands Foraging at Dampier Archipelago (islands to the west of the Burrup Peninsula) Foraging at Legendre Island and Huay Island Foraging at Delambre Island Foraging in the Joseph Bonaparte Depression Foraging in waters adjacent to James Price Point	There is evidence that some flatback turtles undertake long-distance migrations between breeding and feeding grounds (Limpus *et al.*, 1983). However, flatback turtles generally do not have a pelagic phase to their lifecycle. Instead, hatchlings grow to maturity in shallow coastal waters thought to be close to their natal beaches (DSEWPAC, 2012a).

Species	Woodside Activity Area			BIAs		
	Browse	NWS/S	NWC	Mating	Foraging	Migration[3]
Loggerhead turtle	✓	✓	-	No mating BIA identified within the NWMR	Foraging in the De Grey River area to Bedout Island Foraging on the Western Joseph Bonaparte Depression Foraging in the waters adjacent to James Price Point	Adult loggerhead turtles dispersing from Dirk Hartog Island beaches (near Shark Bay) have remained within WA waters from southern WA to the Kimberley. Turtles dispersing from the North-west Cape–Muiron Islands nesting area have ranged north as far as the Java Sea and the north-western Gulf of Carpentaria, and to south-west WA (DSEWPAC, 2012).
Olive ridley turtle	✓	✓	-	No mating BIA identified within the NWMR	Foraging in the Western Joseph Bonaparte Depression and Gulf Foraging in the Dampier Archipelago (islands to the west of the Burrup Peninsula)	Migration routes and distances between nesting beaches and foraging areas are not known for Australian olive ridley turtles.

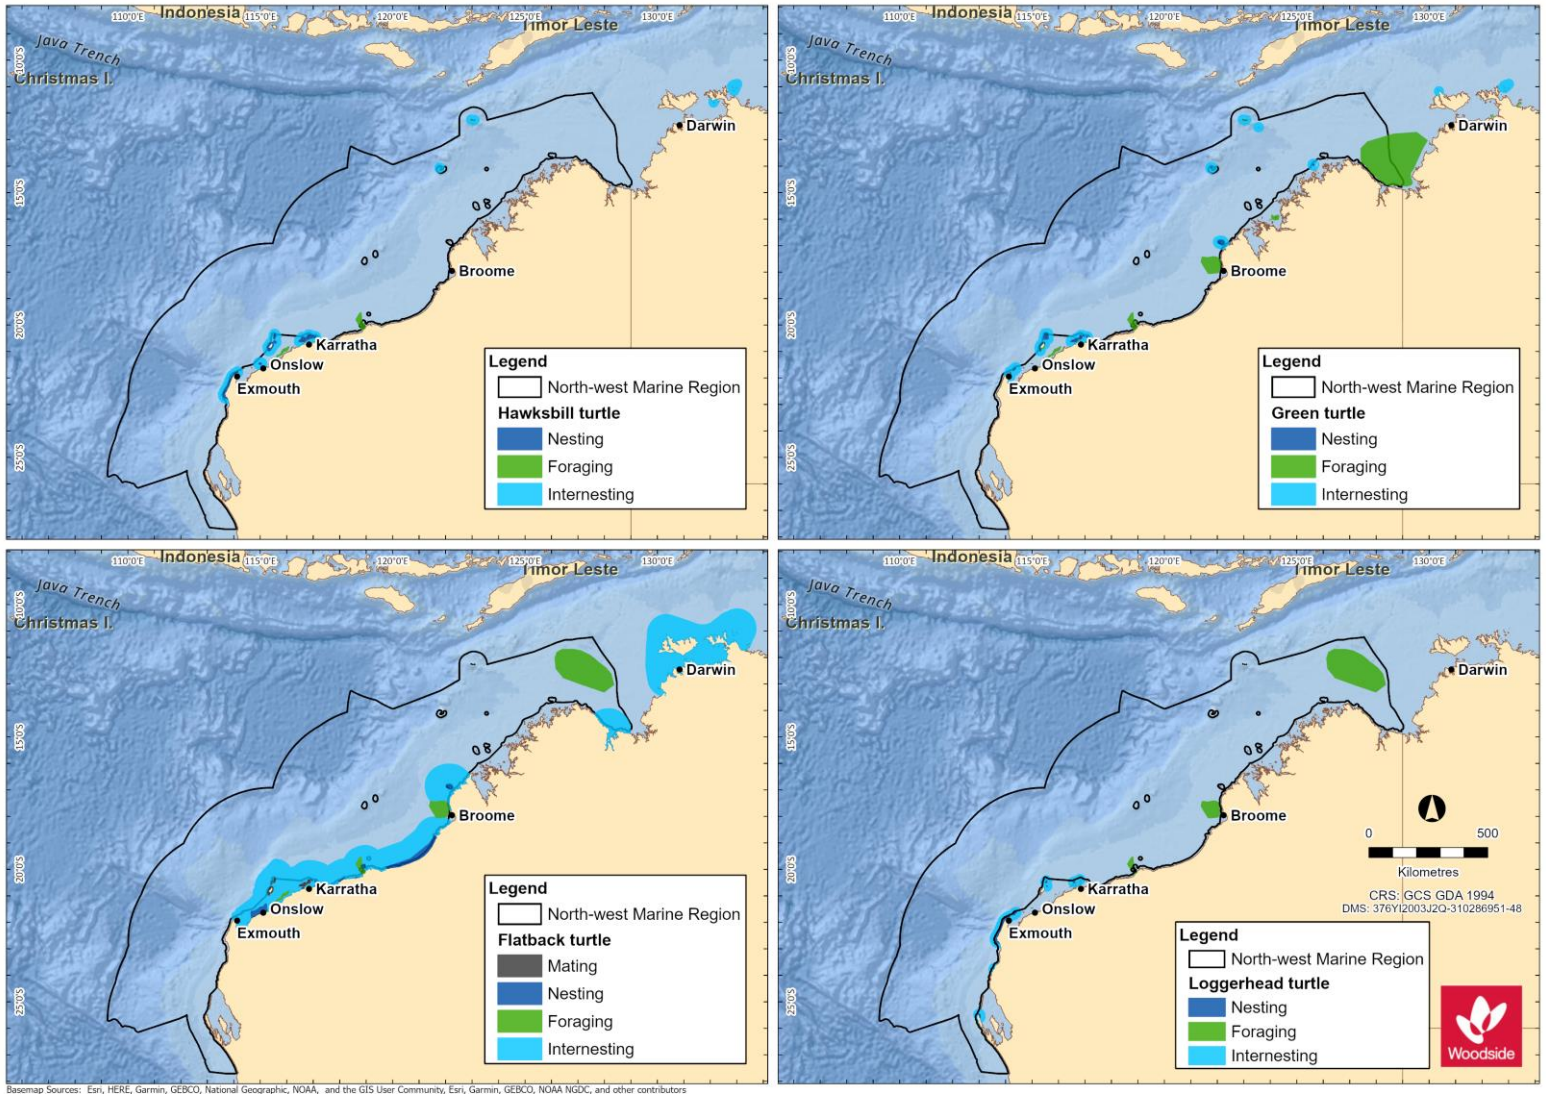

Figure 6-3 Marine turtle species BIAs within the NWMR

6.4 Marine Turtle Summary for NWMR

Six of the seven marine turtle species occur within the Woodside activity areas. Across all three areas, globally significant breeding populations of four marine turtle species; the green, hawksbill, flatback and loggerhead turtle, have been recorded.

However, offshore waters do not represent biologically important habitat for marine turtles in any of the three Woodside activity areas. Isolated records of transient individuals (on post-nesting migration) are expected, but there is no evidence of important habitat or behaviours for marine turtles in offshore, open water environment of the NWS, in general.

6.4.1 Browse

The proposed Browse activity area includes major nesting areas that support globally significant breeding populations of two marine turtle species:

- the green turtle, including two distinct genetic stocks (Ashmore Reef and Scott Reef-Browse Island); and
- the flatback turtle, Cape Domett genetic stock.

Locations of habitat critical for each of the two species are outlined in **Table 6-2** and **Figure 6-2**.

BIAs for the green and flatback turtle are outlined in **Table 6-3** and **Figure 6-3**.

Table 6-4 Marine turtle key information for Browse activity area

Species / Genetic Stock	Key Information
Green Turtle	
Ashmore Reef Stock (G-AR)	The G-AR stock nests in a localised area of the Indian Ocean in the Ashmore Reef and Cartier Island AMP areas. Population estimates are not available for Ashmore Reef, although annual breeding numbers are thought to be in the low hundreds (Whiting, 2000). Designated habitat critical for the G-AR stock are the nesting locations of Ashmore Reef and Cartier Reef, and an internesting buffer of 20 km radius around these rookeries, year-round with peak internesting activity occurring December to January (refer Table 6 of the Recovery Plan). Juvenile and adult turtles forage within the tidal/sub-tidal habitats of offshore islands and coastal waters with coral reef, mangrove, sand, rocky reefs, and mudflats where there are algal turfs or seagrass meadows present (Commonwealth of Australia, 2017).
Scott Reef-Browse Island Stock (G-ScBr)	The G-ScBr stock is a discrete unit known to nest at only two locations within the north-east Indian Ocean—Sandy Islet and Browse Island. There is currently very limited data available for the G-ScBr stock, therefore population numbers are not known. Designated habitat critical for the G-ScBr stock are the nesting locations of Sandy Islet and Browse Island, and an internesting buffer of 20 km radius around these rookeries, for the period November to March (refer Table 6 of the Recovery Plan). Surveys conducted at Scott Reef in 2006, 2008 and 2009 indicate that the summer months from late November to February are the preferred breeding season for green turtles at Sandy Islet (Guinea, 2009). Satellite tagging studies (Pendoley, 2005; Guinea, 2011) have provided an indication of the behaviour and migratory routes of adult green turtles leaving Scott Reef. Most animals appear to swim through South Reef lagoon and disperse toward the Western Australian mainland via two distinct post-nesting migration pathways; travelling east and north toward the Bonaparte Archipelago and then north along the coast to foraging areas in NT waters, or travelling south to Cape Leveque and then south along the coast to the Turtle Islands off the mouth of the De Grey River in the Pilbara region (Ferreira *et al*., 2021).

Species / Genetic Stock	Key Information
Flatback Turtle	
Cape Domett Stock (F-CD)	Cape Domett is an important high density nesting area. Combined with a smaller site at Lacrosse Island, the F-CD stock is one of the largest flatback turtle stocks in Australia. Average nesting abundance at Cape Domett is estimated at 3250 females per year (Whiting *et al.*, 2008). Designated habitat critical for the F-CD stock are the nesting locations of Cape Domett and Lacrosse Island, and an internesting buffer of 60 km radius around these rookeries, year-round with peak internesting activity occurring July to September. Extending further than the habitat critical internesting buffer, an internesting buffer BIA of 80 km is located at Cape Domett and Lacrosse Island.

6.4.2 North-west Shelf / Scarborough

The NWS / Scarborough activity area includes major nesting areas that support globally significant breeding populations of three marine turtle species, representing four discreet genetic stocks:

- the green turtle, NWS genetic stock;
- the hawksbill turtle, WA genetic stock; and
- the flatback turtle, South-west Kimberley stock and Pilbara genetic stocks.

Locations of habitat critical for each of the four species are outlined in **Table 6-2** and **Figure 6-2**.

BIAs for the green, hawksbill, and flatback are outlined in **Table 6-3** and **Figure 6-3**.

Table 6-5 Marine turtle key information for NWS / Scarborough activity area

Species / Genetic Stock	Key Information
Green Turtle	
NWS Stock (G-NWS)	The G-NWS stock is one of the largest green turtle stocks in the world and the largest in the Indian Ocean. The G-NWS stock is estimated at approximately 20,000 individuals (DSEWPAC, 2012a) and the trend for the stock is reported as stable (Commonwealth of Australia, 2017). Major rookeries of the G-NWS stock within the NWS / Scarborough activity area are located at Barrow Island and the Montebello Islands. These areas are designated habitat critical for the stock and include an internesting buffer of 20 km radius around these rookeries, November to March.
Hawksbill Turtle	
Western Australia Stock (H-WA)	The H-WA stock is the largest in the Indian Ocean. The majority of the nesting for this stock is located in the Pilbara. The Dampier Archipelago has the largest nesting aggregation recorded. In particular, Rosemary Island supports the most significant hawksbill turtle rookery in the WA region and one of the largest in the Indian Ocean; approximately 500-1000 females nest on the island annually, more than at any other WA rookery (Pendoley, 2005; Pendoley *et al*., 2016). Major rookeries of the H-WA stock within the NWS / Scarborough activity area are located at Rosemary Island, Delambre Island and the Montebello Islands. These areas are designated habitat critical for the stock and include an internesting buffer of 20 km radius around these rookeries, October to February.
Flatback Turtle	
South-west Kimberley Stock (F-swKim)	The genetic relationship between this nesting aggregation and the Cape Domett and Pilbara stocks is currently under review. Population numbers of the F-swKim stock are unknown. Major rookeries of the F-swKim stock are located at Eighty Mile Beach and Eco Beach. These areas are designated habitat critical for the stock and include an internesting buffer of 60 km radius around these rookeries, October to March.

Species / Genetic Stock	Key Information
Pilbara Stock (F-Pil)	The extent of genetic relatedness of flatback turtles along the WA coast is currently under review. Population numbers of the F-Pil stock are unknown. This stock nests on many islands in the Pilbara and southern Kimberley, with major rookeries at Mundabullangana Beach, Delambre Island and Barrow Island. These areas are designated habitat critical for the F-Pil stock and include an internesting buffer of 60 km radius around these rookeries, October to March. Extending further than the habitat critical internesting buffer, a year-round internesting buffer BIA of 80 km is located north and north-west of the Montebello Islands. However, use level for this BIA has been defined as very low (Commonwealth of Australia, 2017) and the habitat critical internesting buffer is the legally recognised area of protection under the EPBC Act *Significant Impact Guidelines 1.1 – Matters of National Environmental Significance*. Post-nesting satellite tracking indicates foraging occurs along the WA coast in water shallower than 130 m and within 315 km of shore (Commonwealth of Australia, 2017).

6.4.3 North-west Cape

The North-west Cape activity area includes major nesting areas that support globally significant breeding populations of two marine turtle species, representing two discreet genetic stocks:

- the green turtle, NWS genetic stock; and
- the loggerhead turtle, Western Australia genetic stock.

Locations of habitat critical for each of the two species are outlined in **Table 6-2** and **Figure 6-2**.

BIAs for the green and loggerhead turtles are outlined in **Table 6-3** and **Figure 6-3**.

A 2018 survey, including on-beach monitoring of the Muiron Islands and Ningaloo Coast from North-west Cape to Bungelup (Rob *et al.*, 2019), supports the concept that North-west Cape and the Muiron Islands are major important nesting areas for green and loggerhead turtles, as identified in the Recovery Plan (Commonwealth of Australia, 2017).

Table 6-6 Marine turtle key information for North-west Cape activity area

Species / Genetic Stock	Key Information
Green Turtle	
NWS Stock (G-NWS)	The G-NWS stock is one of the largest green turtle stocks in the world and the largest in the Indian Ocean. The G-NWS stock is estimated at approximately 20,000 individuals (DSEWPAC, 2012a) and the trend for the stock is reported as stable (Commonwealth of Australia, 2017). There is one major rookery of the G-NWS stock located within the North-west Cape activity area. Located on the mainland coast of the North-west Cape, this area is designated habitat critical for the stock and includes an internesting buffer of 20 km radius around the rookery, November to March.
Loggerhead Turtle	
Western Australia Stock (LH-WA)	The LH-WA stock is one of the largest in the world (Limpus, 2009). The trend for the stock is reported as stable (Commonwealth of Australia, 2017). Major rookeries of the LH-WA stock are located at Dirk Hartog Island, Muiron Islands and Gnaraloo Bay. These areas are designated habitat critical for the stock and include an internesting buffer of 20 km radius around these rookeries, November to May. Dirk Hartog Island in the Shark Bay Marine Park, with an average of 122 nests per day over 2.1 km (Reinhold and Whiting, 2014), is recognised as the most important loggerhead turtle rookery in WA (Commonwealth of Australia, 2016; as cited in Rob *et al.*, 2019).

6.5 Sea Snakes

Sea snakes are commonly found in the NWMR and NMR, but less so in the SWMR, and occupy three broad habitat types: shallow water coral reef and seagrass habitats, deepwater soft bottom habitats away from reefs, and surface water pelagic habitats (Guinea, 2007a).

There are 25 listed species of sea snake reported within or adjacent to the NWMR (Guinea, 2007a; Udyawer *et al*., 2016), of which four are endemic to reef habitats in the remote parts of the region:

- dusky sea snake (*Aipysurus fuscus*);
- large headed sea snake (*Hydrophis pacificus*);
- short-nosed sea snake (*Aipysurus apraefrontalis*); and
- leaf-scaled sea snake (*Aipysurus foliosquama*).

The short-nosed sea snake and the leaf-scaled sea snake are listed threatened species (Critically Endangered) under the EPBC Act **(Table 6-7**).

There is currently limited knowledge about the ranges and distribution patterns of sea snake species in the NWMR, in addition to a lack of understanding of population status and threats. Recent findings of *A. apraefrontalis* and *A. foliosquama* in locations outside of their previously defined ranges have highlighted the lack of information on species distributions in the NWMR (Udyawer *et al.*, 2016). Udyawer *et al.* (2020) used a correlative modelling approach to understand habitat associations and identify suitable habitats for five sea snake species (*A. apraefrontalis, A. foliosquama, A. fuscus, A. l. pooleorum* and *A. tenuis*). Species-specific habitat suitability was modelled across 804,244 km^2 of coastal waters along the NWS, and the resulting habitat suitability maps enabled the identification of key locations of suitable habitat for these five species (refer **Table 6-6**).

No habitat critical to survival or BIAs for sea snake species have been identified in the NWMR. While the Ashmore Reef and Cartier Island AMPs have been recognised for their high diversity and density of sea snakes (DSEWPAC, 2012a), surveys have revealed a steep decline in sea snake numbers at Ashmore Reef (Guinea, 2007b; Lukoschek *et al.*, 2013). Leaf-scaled and short-nosed sea snakes have been absent from surveys at Ashmore Reef since 2001, despite an increase in survey intensity (Guinea, 2006, 2007b; Guinea and Whiting, 2005; Lukoschek *et al.*, 2013). The reason for the decline is unknown.

Table 6-7 Information on the two threatened sea snake species within the NWMR

Species	Preferred Habitat and Diet	Habitat Location
Short-nosed sea snake	Preferred habitat: Primarily on the reef flats or in shallow waters of the outer reef edges to depths of 10 m (Minton *et al*., 1975). Typically, movement is restricted to within 50 m of reef flat habitat (Guinea and Whiting, 2005). Diet: Primarily fishes and eels.	The short-nosed sea snake has been recorded from Exmouth Gulf to the reefs of the Sahul Shelf, although most records come from Ashmore and Hibernia reefs (Guinea and Whiting, 2005). Key locations of suitable habitat: Ashmore Reef, Exmouth Gulf, Muiron Islands, Montebello Islands (Udyawer *et al.*, 2020).
Leaf-scaled sea snake	Preferred habitat: The leaf-scaled sea snake occurs in shallow protected areas of reef flats, typically in water depth less than 10 m. Diet: Primarily shallow water coral-associated wrasse, gudgeons, clinids and eels (McCosker, 1975; Voris, 1972; Voris and Voris, 1983)	The leaf-scaled sea snake has only been recorded at Ashmore and Hibernia reefs (Guinea and Whiting, 2005), indicating it has a very limited distribution. Key locations of suitable habitat: Ashmore Reef, Shark Bay, Exmouth Gulf, Barrow Island and Montebello Islands (Udyawer *et al.*, 2020).

6.6 Crocodiles

The salt-water crocodile (*Crocodylus porosus*) is a listed migratory species under the EPBC Act known to occur within the NWMR. The species is found in most major river systems of the Kimberley, including the Ord, Patrick, Forrest, Durack, King, Pentecost, Prince Regent, Lawley, Mitchell, Hunter, Roe and Glenelg rivers. The largest populations occur in the rivers draining into the Cambridge Gulf and the Prince Regent River and Roe River systems. There have also been isolated records in rivers of the Pilbara region, around Derby near Broome and as far south as Carnarvon on the mid-west coast.

No BIAs for salt-water crocodile have been identified in the NWMR.

7. MARINE MAMMALS

7.1 Regional Context

The offshore waters of WA include important habitat for marine mammals, including areas that support key life stages such as breeding, foraging, and migration. Of the 45 species of cetacean occurring in Australian waters, 27 species occur regularly in the waters of the NWMR, nine species in the waters of the NMR and 33 species in the SWMR. The waters of the NWMR and the NMR also support significant populations of dugong (DSEWPAC, 2012a, c).

The NWMR is an important migratory pathway between feeding grounds in the Southern Ocean and breeding grounds in tropical waters of the NWMR for several cetacean species (DSEWPAC, 2012a). Numerous large mysticetes (baleen whale) species, in particular the humpback whale, are known to utilise the region for migration and calving, and the pygmy blue whale for foraging and as a migration pathway between southern feeding and northern breeding/feeding areas, north of the equator.

The SWMR is an important area for numerous marine mammal species including pinniped species, large, migratory whale species and resident coastal whale and dolphin species (DSEWPAC, 2012b).

The NMR and adjacent areas are important for several species of cetacean, particularly inshore dolphin species. These species, and other marine mammals, rely on the waters of the NMR and adjacent coastal areas for breeding and foraging. However, there is little knowledge of the seasonal movements, migrations and breeding seasonality for many of the marine mammal species in the NMR due to lack of extensive surveys (DSEWPAC, 2012c).

Table 7-1 outlines the threatened and migratory marine mammal species that may occur within the NWMR, with their conservation status and relevant recovery plans and/or conservation advice.

Table 7-1 Marine mammal species identified by the EPBC Act PMST as occurring within the NWMR

Species Name	Common Name	*Environment Protection and Biodiversity Conservation Act 1999*			WA *Biodiversity Conservation Act 2016*	EPBC Act Part 13 Statutory Instrument
		Threatened Status	Migratory Status	Listed	Conservation Status

7.2 Cetaceans in the NWMR

Cetaceans are generally widely distributed and highly mobile. In general, distribution patterns reflect seasonal feeding areas, characterised by high productivity, and migration routes associated with reproductive patterns. The NWMR is thought to be an important migratory pathway between feeding grounds in the Southern Ocean and breeding grounds in tropical waters for several cetacean species (DSEWPAC, 2012a).

From the Protected Matters search, 34 EPBC Act listed species were recorded as potentially occurring or having habitat within the NWMR (**Appendix A**). Of those, 12 cetacean species are listed as threatened and/or migratory, including baleen whales, toothed whales and dolphins that occur within the NWMR (**Table 7-2**).

7.3 Dugongs in the NWMR

The dugong is listed as migratory under the EPBC Act. Dugongs inhabit seagrass meadows in coastal waters, estuarine creeks and streams, and reef systems (DSEWPAC, 2012a).

Some of the coastal waters adjacent to the NWMR support significant populations of dugongs, including Shark Bay, Exmouth Gulf, in and adjacent to Ningaloo Reef, in coastal waters along the Kimberley coast, and on the edge of the continental shelf at Ashmore Reef (DEWHA, 2008).

Although the patterns of dugong movement in WA are not well understood, it is thought that dugongs move in response to availability of seagrass (Marsh *et al.*, 1994; Preen *et al.*, 1997) and water temperature.

There are a number of BIAs for dugong within and adjacent to waters of the NWMR (refer **Section 7.5**).

7.4 Pinnipeds in the NWMR

The Australian sea lion is listed as a species that may occur, or may have habitat within the NWMR (Protected Matters search - **Appendix A**). It is included here as the Australian sea lion is the only pinniped endemic to Australia (Strahan, 1983) and has been recorded within the southern extent of the NWMR at Shark Bay, WA (Kirkwood *et al.*, 1992). The most northern known breeding colony is at the Houtman Abrolhos Islands in the SWMR. The Australian sea lion's breeding range extends from the Houtman Abrolhos Islands, WA to The Pages Island, east of Kangaroo Island, SA. The Australian sea lion was listed as endangered in 2020 (Threatened Species Scientific Committee, 2020a). An assessment of the status and trends in abundance of this endemic, coastal pinniped species (Goldsworthy *et al.* 2021) documented an overall reduction in pup abundance over three generations, providing strong evidence that the species meets IUCN endangered criteria.

There are no BIAs for the Australian sea lion in the NWMR.

Table 7-2 Information on the threatened/migratory marine mammal species within the NWMR

Species	Key Information
Baleen whales (Mysticeti)	
Humpback whale	In Australian waters two genetically distinct populations migrate annually along the west (Group IV) and east coasts (Group V) between May and November. In WA, the migration pathway for the Group IV population (also known as Breeding Stock D) extends from Albany to the Kimberley coastline, passing through the NWMR (Threatened Species Scientific Committee, 2015b). Since the 1982 moratorium on commercial whaling population numbers have recovered significantly; from approximately 2000 to 3000 individuals in 1991, to between 19,200–33,850 individuals in 2008 (Bannister and Hedley, 2001; Bejder *et al.*, 2019; Hedley *et al.*, 2011). Aerial surveys off the WA coast undertaken between 2000 and 2008 produced a population estimate for the Group IV population of 26,100 individuals (CI 20,152–33,272) in 2008 (Salgado Kent *et al.*, 2012). Current population growth for the Group IV population is estimated to be between 9.7 and 13% per annum (Threatened Species Scientific Committee, 2015b). Using the Salago-Kent *et al.* (2012) estimate of 26,100 individuals and an annual population growth rate of ~10%, current population size could be in excess of 75,000 individuals (Woodside, 2019). The Group IV population migrates northward from their Antarctic feeding grounds around May each year, reaching the NWMR around early June. The southward migration subsequently starts in mid-September, around the time of breeding and calving (typically August to September) (Threatened Species Scientific Committee, 2015b). Within the NWMR there are key calving areas between Broome and the northern end of Camden Sound, and resting areas in the southern Kimberley region, Exmouth Gulf and Shark Bay. In particular, high numbers of humpback whales are observed in Camden Sound and Pender Bay from June to September each year (Threatened Species Scientific Committee, 2015b). There are reports of neonates further south, suggesting that the calving areas may be poorly defined. Aerial photogrammetric surveys in 2013 and 2015 recorded large numbers of humpback whale calves along North-west Cape, with estimated minimum relative calf abundance of 463–603 in 2013 and 557–725 in 2015 (Irvine *et al.*, 2018). The majority of calves sighted in both years (85% in 2013; 94% in 2015) were neonates, and these observations indicate that a minimum of approximately 20% of the expected number of calves of this population are born near, or south of, North-west Cape. Thus, the calving grounds for the Group IV population extend south from Camden Sound to at least North-west Cape, 1000 km south-west of the currently recognized calving area (Irvine *et al.*, 2018). There are BIAs for migration and breeding and calving for the humpback whale along the WA coast and within the NWMR (refer **Table 7-3** and **Figure 7-1**).
Blue whale	There are two recognised sub-species of blue whale in the Southern Hemisphere, both of which are recorded in Australian waters. These are the southern (or 'true') blue whale (*Balaenoptera musculus*) and the 'pygmy' blue whale (*Balaenoptera musculus brevicauda*) (Commonwealth of Australia, 2015a). In general, southern blue whales occur in waters south of 60°S and pygmy blue whales occur in waters north of 55°S (i.e. not in the Antarctic). On this basis, nearly all blue whales sighted in the NWMR are likely to be pygmy blue whales. The East Indian Ocean (EIO) pygmy blue whale population is seasonally distributed from Indonesia (a potential breeding ground) to south-west of Australia and east across the Great Australian Bight and Bonney Upwelling to beyond the Bass Strait (Blue Planet Marine, 2020). Migration seems to be variable, with some individuals appearing as resident to areas of high productivity and others undertaking migrations across long distances (Commonwealth of Australia, 2015a). McCauley *et al.* (2018) describe three migratory stages around Australia for the EIO pygmy blue whale population: a 'southbound migratory stage' where whales travel southwards from Indonesian waters offshore from the WA coastline, mostly from October to December but possibly into January of the following year; a protracted 'southern Australian stage' (January to June) where animals spread across southern waters of the Indian Ocean and south of Australia; and a 'northbound migratory stage' (April to August) where animals travel north back to Indonesia again. There are currently insufficient data to accurately estimate population numbers of the pygmy blue whale in Australian waters (Blue Planet Marine, 2020; Commonwealth of Australia, 2015a). There are, however, two estimates of population size of the EIO pygmy blue whale for WA. McCauley and Jenner (2010) calculated the population to be between 662 and 1559 individuals in 2004 based on passive acoustics (whale vocalisations), and Jenner *et al.* (2008) (based on photographic mark and recapture) calculated between 712 and 1754 individuals, but both estimates did not account for animals

Species	Key Information
	travelling further west into the Indian Ocean (McCauley *et al.*, 2018). More recent passive acoustic data estimates a 4.3% growth rate that applies to the proportion of EIO pygmy blue whales seasonally present in offshore water of the south-eastern Australia and may not reflect the full population but does imply an increasing population (McCauley *et al.*, 2018). The pygmy blue whale is typically present in the Perth Canyon from November to June, with an observed peak between March and May (Commonwealth of Australia, 2015a; Blue Planet Marine, 2020). The pygmy blue whale feeds in the Perth Canyon at depths of 200 to 300 m, which overlaps the typical distribution of krill (200–500 m water depth (day) to surface (night) (McCauley *et al.*, 2004; Commonwealth of Australia, 2015a). Other possible feeding grounds off the WA coast include the wider area around the Perth Canyon, and possible foraging areas off the Ningaloo Coast and at Scott Reef (Commonwealth of Australia, 2015a). Refer **Table 7-3** and **Figure 7-2** for the location and type of BIAs for blue whales in the NWMR. There is a migratory BIA for the pygmy blue whale within WA waters, which extends for most of the length of the NWMR within offshore waters.
Bryde's whale	The Bryde's whale is the least migratory of its genus and is restricted geographically from the equator to approximately 40°N and S, or the 20° isotherm (Bannister *et al.*, 1996). The species is known to exhibit inshore and offshore forms in other international locations that vary in morphology and migratory behaviours (Bannister *et al.*, 1996). This appears to also be the case within Australian waters. Bryde's whales have been identified as occurring in both oceanic and inshore waters, with the only key localities recognised in WA being in the Houtman Abrolhos Islands and north of Shark Bay (Bannister *et al.*, 1996). Data suggests offshore whales migrate seasonally, heading towards warmer tropical waters during the winter; however, information about migration within the NWMR is not well known (McCauley and Duncan, 2011). McCauley (2011) detected Bryde's whales using acoustic loggers deployed in and around Scott Reef from 2006 to 2009. Other acoustic logger data of Bryde's whale vocalisations recorded between Ningaloo and north of Darwin showed no apparent trends or seasonality (McCauley, 2011). There are no identified BIAs for this species in the National Conservation Values Atlas.
Southern right whale	The southern right whale occurs primarily in waters between about 20°S and 60°S and moves from high latitude feeding grounds in summer to warmer, low latitude, coastal locations in winter (Bannister *et al.*, 1996). Southern right whales aggregate in calving areas along the south coast of WA outside of the NWMR. However, there have been sightings in waters of the NWMR as far north as Ningaloo (Bannister and Hedley, 2001), and a stranding record exists for the far north Kimberley coast (ALA, 2020). Southern right whale calving grounds are found at mid to lower latitudes and are occupied during the austral winter and early-mid spring. They are regularly present on the southern Australian coast from about mid-May to mid-November, and peak periods for mating are from mid-July through August. Mating occurs within these breeding grounds as evidenced by many observations of intromission and mating behaviours. Southern right whales in south-western Australia appear to be increasing at the maximum biological rate but there is limited evidence of increase in south-eastern Australian waters (DSEWPAC, 2012d). There are no identified BIAs for this species in the NWMR.
Antarctic minke whale	The Antarctic minke whale is distributed worldwide and has been recorded off all Australian states (but not in the NT), feeding in cold waters and migrating to warmer waters to breed. It is thought that the Antarctic minke whale migrates up the WA coast to about 20°S to feed and possibly breed (Bannister *et al.*, 1996); however, detailed information about timing and location of migrations and breeding grounds within the NWMR is not well known. In the high latitudinal winter breeding grounds in other regions, the species appears to be distributed off the continental shelf edge. No population estimates are available for Antarctic minke whales in Australian waters. There are no identified BIAs for this species in the National Conservation Values Atlas.
Sei whale	The sei whale is a baleen whale with a worldwide oceanic distribution and is expected to seasonally migrate between low latitude wintering areas and high latitude summer feeding grounds (Bannister *et al.*, 1996; Prieto *et al.*, 2012). There are no known mating or calving areas in Australian waters. The species has a preference for deep waters, typically occurs in oceanic basins and continental slopes (Prieto *et al.*, 2012), and exhibits a migration pathway influenced by seasonal feeding and breeding patterns. Sei whales have been infrequently recorded in Australian waters (Bannister *et al.*, 1996). Reliable estimates of the sei whale population size in Australian waters are currently not possible due to a lack of dedicated surveys and their elusive characteristics. Similarly, the extent of occurrence and area of occupancy of sei whales in Australian waters cannot be calculated due to the

Species	Key Information
	rarity of sighting records. They will typically travel in small pods of three to five individuals, with some segregation by age, sex and reproductive status. Calving grounds are presumed to exist in low latitudes with mating and calving potentially occurring during winter months (Threatened Species Scientific Committee, 2015a). There are no known mating or calving areas in Australian waters, and there are no identified BIAs for this species in the National Conservation Values Atlas.
Fin whale	The fin whale is a large baleen whale distributed worldwide. Fin whales migrate annually between high latitude summer feeding grounds and lower latitude over-wintering areas (Bannister *et al.*, 1996) and follow oceanic migration paths. The species is uncommonly encountered in coastal or continental shelf waters. Australian Antarctic waters are important feeding grounds for fin whales but there are no known mating or calving areas in Australian waters (Morrice *et al.*, 2004). The species has been observed in groups of six to 10 individuals, as well as in pairs and alone (Threatened Species Scientific Committee, 2015c). Accurate distribution patterns are not known within Australian waters and the majority of data are from stranding events. Fin whales have been recorded vocalising off the Perth Canyon, WA, between January and April 2000 (McCauley *et al.*, 2000). It is currently not possible to accurately estimate the population size of fin whales in Australian waters predominantly due to the species' behaviour and local ecology, as the proportion of time they spend at the surface varies greatly depending on these factors. In addition, natural fluctuations of fin whales in Australian waters are unknown; however, long-range movements do appear to be prey-related. A recent study by Aulich *et al.* (2019) used passive acoustic monitoring as a tool to identify the migratory movements of fin whales in Australian waters. On the west coast, the earliest arrival of these animals occurred at Cape Leeuwin in April, and between May and October they migrated along the WA coastline to the Perth Canyon, which likely acts as a way-station for feeding (Aulich *et al.*, 2019). Some whales were found to continue migrating as far north as Dampier (Aulich *et al.*, 2019). There are no identified BIAs for this species in the National Conservation Values Atlas.
Toothed whales (Odontoceti)	
Sperm whale	Sperm whales are the largest of the toothed whales and are distributed worldwide in deep waters (greater than 200 m) off continental shelves and sometimes near shelf edges (Bannister *et al.*, 1996). The species tends to inhabit offshore areas at depths of 600 m or more and is uncommon in waters less than 300 m deep (Ceccarelli *et al.*, 2011). There is limited information about sperm whale distribution in Australian waters, however, they are usually found in deep offshore waters, with more dense populations close to continental shelves and canyons. In the open ocean, there is a generalised movement of sperm whales southwards in summer, and corresponding movement northwards in winter, particularly for males. Detailed information about the distribution and migration patterns of sperm whales off the WA coast is not available. Females with young may reside within the NWMR all year round, males may migrate through the region and the species may be associated with canyon habitats (Ceccarelli *et al.*, 2011). Sperm whales have been recorded in deep waters off North-west Cape and appear to occasionally venture into shallower waters in other areas. Twenty-three (23) sightings of sperm whales (variable pod sizes, ranging from one to six animals) were recorded by marine mammal observers (MMOs) during the North West Cape MC3D marine seismic survey (December 2016 to April 2017) (Woodside, 2020). These animals were observed in deep, continental slope waters of the Montebello Saddle (maximum distance of approximately 90 km from North-west Cape), and the waters overlying the Canyons linking the Cuvier Abyssal Plain and the Cape Range Peninsula KEF. The deep waters above the gully/saddle on the inner edge of the plateau (the Montebello Saddle) are thought to be important for sperm whales that may feed in the region (based on 19th Century whaling records; Townsend, 1935). There are no identified BIAs for this species in the NWMR.
Killer whale	The preferred habitat of killer whales includes oceanic, pelagic and neritic (relatively shallow waters over the continental shelf) regions, in both warm and cold waters. Killer whales appear to be more common in cold, deep waters; however, they have been observed along the continental slope and shelf, particularly near seal colonies, as well as in shallow coastal areas of WA (Bannister *et al.*, 1996; Thiele and Gill, 1999). The total number of killer whales in Australian waters is unknown, however, it may be that the total number of mature animals within waters around the continent is less than 10,000. Killer whales are known to make seasonal movements, and probably follow regular migratory routes, but no information is available for the

Species	Key Information
	species in Australian waters. Killer whales are top-level carnivores, and there are reports from around Australia of attacks on dolphins, juvenile humpback whales, blue whales, sperm whales, dugongs and Australian sea lions (Bannister *et al.*, 1996). Killer whales are known to target humpback whales, particularly calves, off Ningaloo Reef during the humpback southern migration season (Pitman *et al.*, 2015). Overall, observations suggest that humpback calves are a predictable, plentiful, and readily taken prey source for killer whales off Ningaloo Reef for at least five months of the year. Additionally, there are records of killer whales attacking dugongs in Shark Bay (Anderson and Prince, 1985). However, there are no recognised key localities or important habitats for killer whales within the NWMR (DSEWPAC, 2012a). There are no identified BIAs for this species in the NWMR.
Australian snubfin dolphin	Stranding and museum specimen records indicate that Australian snubfin dolphins occur only in waters off northern Australia, from approximately Broome on the west coast to the Brisbane River on the east coast (Parra *et al.*, 2002). Aerial and boat-based surveys indicate that Australian snubfin dolphins occur mostly in protected shallow waters close to the coast, and close to river and creek mouths (Parra, 2006; Parra *et al.*, 2006; Parra *et al.*, 2002). Within the NWMR, species has been found in the shallow coastal waters and estuaries along the Kimberley coast. Beagle and Pender bays on the Dampier Peninsula, and tidal creeks around Yampi Sound and between Kuri Bay and Cape Londonderry are important areas for Australian snubfin dolphins (DEWHA, 2008). Roebuck Bay has generally been considered the south-western limit of snubfin dolphin distribution across northern Australia, but the species has been recorded in Port Hedland harbour, the Dampier Archipelago, Montebello Islands, Exmouth Gulf and off North-west Cape (Allen *et al.*, 2012). A first comprehensive catalogue of snubfin dolphin sightings has been compiled for the Kimberley, north-west Western Australia (Bouchet *et al.* 2021) and documented that snubfin dolphins are consistently encountered in shallow water (<21 m depth) close to (<15 km) freshwater inputs with high detection rates in known hotspots such as Roebuck Bay and Cygnet Bay as well as suitable coastal habitat in the wider Kimberley region. Refer **Table 7-3** and **Figure 7-3** for the location and type of BIAs for Australian snubfin dolphins in the NWMR.
Indo-Pacific humpback dolphin (Australian humpback dolphin)	Previously included with *Sousa chinensis*, the Australian humpback dolphin (*S. sahulensis*) was elevated to a species in 2014. *S. chinensis* is now applied for humpback dolphins in the eastern Indian and western Pacific Oceans and *S. sahulensis* for humpback dolphins in the waters of the Sahul Shelf from northern Australia to southern New Guinea (Jefferson and Rosenbaum, 2014). The Australian humpback dolphin is listed as *S. chinensis* under EPBC Act. The Australian humpback dolphin (referred to as 'humpback dolphin' hereafter) inhabits the tropical/subtropical waters of the Sahul Shelf across northern Australia and southern Papua New Guinea (Jefferson and Rosenbaum, 2014). Based on historical stranding data, museum specimens and opportunistic sightings collected during aerial and boat-based surveys for other fauna it has been inferred that humpback dolphins occur from the WA/NT border south-west to Shark Bay (Hanf *et al.*, 2016). Allen *et al.* (2012) suggested that humpback dolphins use a range of inshore habitats, including both clear and turbid coastal waters across northern WA. The waters surrounding North-west Cape are an important area for the species. Boat-based surveys up to 5 km out from the coast (Brown *et al.*, 2012) recorded humpback dolphins from 0.3 to 4.5 km away from shore and in depths ranging from 1.2 to 20 m, with a mean of ~8 m. Other studies around North-west Cape, surveying waters up to 5 km from the coast, recorded humpback dolphins in water depths of up to 40 m (Hanf *et al.*, 2016). Based on density, site fidelity and residence patterns, North-west Cape is clearly an important habitat toward the south-western limit of this species' range (Hunt *et al.*, 2017). Aerial surveys targeting dugongs over the western Pilbara have recorded humpback dolphins more than 60 km from the mainland in shallow shelf waters (i.e. <30 m deep) near Barrow Island and the western Lowendal Islands (Hanf, 2015). The species has also been recorded in fringing coral reef and shallow, sheltered sandy lagoons at the Montebello Islands (Raudino *et al.*, 2018). Over the past ten years a number of studies have focused on populations of humpback dolphins along the Kimberley coast, including Roebuck Bay, the Dampier Peninsula, Cone Bay, Yampi Sound, Prince Regent River and the Cambridge Gulf (Brown *et al.*, 2016). Refer Table **Table 7-3** and **Figure 7-4** for the location and type of BIAs for Indo-Pacific humpback dolphins in the NWMR.
Indo-Pacific bottlenose dolphin (Spotted bottlenose dolphin)	There are four known sub-populations of spotted bottlenose dolphins, of which the Arafura/Timor Sea populations were identified as potentially occurring within the NWMR. The species is restricted to inshore areas such as bays and estuaries, nearshore waters, open coast environments, and shallow offshore waters including coastal areas around oceanic islands, from Shark Bay to the western edge of the Gulf of Carpentaria. The species

Species	Key Information
	forages in a range of habitats but is generally restricted to water depths of less than 200 m (DSEWPAC, 2012a). Important foraging/breeding areas include the shallow coastal waters and estuaries along the Kimberley coast and Roebuck Bay. Refer **Table 7-3** the location and type of BIAs for spotted bottlenose dolphins in the NWMR.
Sirenians	
Dugong	Dugongs are distributed along the WA coast throughout the Gascoyne, Pilbara and Kimberley. Specific areas supporting dugong populations include: Shark Bay; Ningaloo and Exmouth Gulf; the Pilbara coast (Exmouth Gulf to De Grey River [Marsh *et al.*, 2002]); and Eighty Mile Beach and the Kimberley coast, including Roebuck Bay (Brown *et al.*, 2014). Dugong distribution is correlated with the seagrass habitats upon which it feeds, although water temperature has also been correlated with dugong movements and distribution (Preen *et al.*, 1997; Preen, 2004). Dugongs are known to migrate between seagrass habitats (hundreds of kilometres) (Sheppard *et al.*, 2006), and in Shark Bay they exhibit seasonal movements as a behavioural thermoregulatory response to winter water temperatures (Holley *et al.*, 2006; Marsh *et al.*, 2011). Aerial surveys since the mid-1980s indicate that dugong populations are now stable at a regional scale in Shark Bay and in the Exmouth/Ningaloo Reef. Refer **Table 7-3** and **Figure 7-5** for the location and type of BIAs for dugong in the NWMR.
Pinnipeds	
Australian sea lion	The Australian sea lion is the only endemic pinniped (true seals, fur seals and sea lions) in Australian waters. It is a member of the Otariidae (eared seals) family. The birth interval in Australian sea lions is around 17–18 months. The Australian sea lion is unique among pinnipeds in being the only species that has a non-annual breeding cycle that is also temporally asynchronous across its range (DSEWPAC, 2013a; Threatened Species Scientific Committee, 2020a). This means the breeding period (copulation and birthing) in one colony will occur at different times to breeding in another colony. The Australian sea lion is considered to be a specialised benthic forager—that is, it feeds primarily on the sea floor. Studies have shown that the species will eat a range of prey, including fish, cephalopods (squid, cuttlefish and octopus), sharks, rays, rock lobsters and penguins (DSEWPAC, 2013a; Threatened Species Scientific Committee, 2020a). The Australian sea lion feeds on the continental shelf, most commonly in depths of 20–100 m, and they typically travel up to about 60 km from their colony on each foraging trip, with a maximum distance of around 190 km when over shelf waters. The current breeding distribution of the Australian sea lion extends from the Houtman Abrolhos Islands on the west coast of WA to the Pages Islands in SA. Sites for the 58 breeding colonies occurring in WA and SA are designated as habitat critical to the survival of the species under the Recovery Plan for the Australian sea lion (DSEWPAC, 2013a). Of these, four are located in the SWMR along the west coast of WA: Abrolhos Islands (Easter Group), Beagle Island, North Fisherman Island and Buller Island. There are also a number of foraging BIAs for both males and females along the west coast, extending from the Abrolhos Islands south to Rockingham. There is no designated habitat critical to survival or identified BIAs for this species in the NWMR. **Figure 7-6** shows the foraging BIAs for the Australian sea lion to the south of the NWMR.

7.5 Biological Important Areas in the NWMR

BIAs representing important life cycle stages and behaviours for six species of marine mammal in the NWMR: the humpback whale, the pygmy blue whale, Australian snubfin dolphin, Australian humpback dolphin, spotted bottlenose dolphin and dugong, are presented in **Table 7-3**.

7.6 Marine Mammal Summary for the NWMR

7.6.1 Browse

The Browse activity area includes biologically important habitat for five threatened and/or migratory marine mammal species:

- blue whale and pygmy blue whale (foraging and migration areas);
- humpback whale (breeding, calving and migration areas);
- Indo-Pacific humpback dolphin (foraging, breeding and calving areas);
- Australian snubfin dolphin (foraging, breeding and calving areas); and
- dugong (foraging).

BIAs for the marine mammal species are outlined in **Table 7-3**.

7.6.2 North-west Shelf / Scarborough

The NWS / Scarborough activity area includes biologically important habitat for five threatened and/or migratory marine mammal species:

- blue whale and pygmy blue whale (foraging and migration areas);
- humpback whale (resting and migration areas);
- Indo-Pacific humpback dolphin (foraging, breeding and calving areas);
- Australian snubfin dolphin (foraging, breeding and calving areas); and
- dugong (foraging and calving areas).

BIAs for the marine mammal species are outlined in **Table 7-3**.

7.6.3 North-west Cape

The North-west Cape activity area includes biologically important habitat for three threatened and/or migratory marine mammal species:

- blue whale and pygmy blue whale (foraging and migration areas);
- humpback whale (resting and migration areas); and
- dugong (foraging and calving areas).

BIAs for the marine mammal species are outlined in **Table 7-3**.

8. SEABIRDS AND MIGRATORY SHOREBIRDS OF THE NWMR

8.1 Regional Context

The NWMR supports high numbers and species diversity of seabirds and migratory shorebirds including many that are EPBC Act listed, threatened and migratory. The NWMR marine bioregional plan reported 34 seabird species (listed as threatened, migratory and/or marine) that are known to occur, and 30 of 37 species of migratory shorebird species that regularly occur in Australia, are recorded at Ashmore Reef in the NWMR (DSEWPAC, 2012e). The NWMR marine bioregional plan also noted that Roebuck Bay and Eighty Mile Beach are internationally significant and recognised migratory shorebird locations.

Many migratory seabirds and shorebirds are protected through bilateral agreements between Australia and Japan (JAMBA), China (CAMBA) and the Republic of Korea (ROKAMBA), recognising the migratory route and important stopover and resting habitats of the East Asian-Australasian Flyway (EAAF). Important migratory bird habitats are also recognised as part of protected wetlands of the internationally significance under the Ramsar Convention. Important Bird Areas (IBAs) for the NWMR, which are also recognised as global Key Biodiversity Areas (KBAs) (BirdLife Australia[4]), include:

- Roebuck Bay KBA (and Ramsar site): Internationally significant migratory shorebird species.
- Mandora Marsh and Anna Plains KBA (adjacent to Eighty Mile Beach, Ramsar site): Internationally significant migratory shorebird species.
- Dampier Saltworks KBA: Internationally significant migratory shorebird species.
- Montebello Islands KBA: Shorebird and seabird species.
- Barrow Island KBA: Shorebird and seabird species.
- Exmouth Gulf Mangroves KBA: Internationally significant migratory shorebird species.

Table 8-1 presents a list of the threatened and migratory seabird and shorebird species that occur within the NWMR, with their conservation status and relevant recovery plans and/or conservation advice.

8.2 Seabirds in the NWMR

Seabirds are birds that are adapted to life within the marine environment (oceanic and coastal) and are generally long-lived, have delayed breeding and have fewer young than other bird species (Commonwealth of Australia, 2019). At least 34 seabird species listed as threatened, migratory and/or marine under the EPBC Act are known to occur regularly in the NWMR and include a variety of species of terns, noddies, petrels, shearwaters, frigatebirds, and boobies. Many of these species spend most of their lives at sea (predominately pelagic species), ranging over large distances to forage. These pelagic species only come onshore to breed and raise chicks at natal or high-fidelity breeding colonies on remote, offshore island locations in and adjacent to the NWMR. Many species are ecologically significant to the NWMR, as they are endemic to the region, can be present in large numbers in breeding seasons and non-breeding seasons, and many exhibit extensive annual migrations that include marine areas outside the Australian EEZ (DSEWPAC, 2012e).

The presence of seabirds within the NWMR is influenced by seabird species that migrate and forage in the area during the non-breeding season and this includes many seabird species that breed on the Houtman Abrolhos in the SWMR. Pelagic seabirds have been documented foraging at current boundaries and seasonal upwellings within the NWMR (refer to Sutton *et al*., 2019). The Houtman Abrolhos Islands National Park located in the SWMR, is one of the most significant seabird breeding locations in the eastern Indian Ocean. Sixteen (16) species of seabirds breed there. Eighty percent of common (brown) noddies, 40% of sooty terns and all the lesser noddies found in Australia nest at the Houtman Abrolhos (Surman, 2019). Important seabird areas in the NWMR are as identified by the KBAs (refer to **Section 8.1**) and the information on a select number of seabird species documented for the NWMR (based on the screening criteria presented in **Section 3**), as presented in **Table 8-2**.

Table 8-2 Information on threatened/migratory seabird species of the NWMR

Species	Key Information
Seabirds	
Southern giant petrel	This species is included in the National recovery plan for threatened albatrosses and giant petrels. Habitat critical to survival is defined for breeding and foraging. There are six known breeding localities under Australian jurisdiction (for all species giant petrels) and all are located in the Southern Ocean including islands off Tasmania and within the Australian Antarctic Territory (DSEWPAC, 2011c). Habitat critical to survival identified for foraging is defined as waters south of 25 degrees latitude. The giant petrel species distribution is mainly within the Southern Ocean but this species does migrate into subtropical waters during the winter and its distribution includes the southern extent of the NWMR. No BIAs for this species are located in the NWMR.
Abbott's booby	The Abbott's booby is a large, long-lived seabird known to nest only at Christmas Island. The recovery of this species is strongly dependent on the protection of breeding habitat defined habitat critical to the survival of this species on Christmas Island (Threatened Species Scientific Committee, 2020b). This species spends much of its time at sea and known to forage over large distances offshore when nesting and its range includes off the coast of Java, near the Chagos and in the Banda Sea, and may possibly extend into the north-western extent of the NWMR. No BIAs for this species are located in the NWMR.
Soft-plumaged petrel	This petrel species breeds only at two locations in Australian waters within the Southern Ocean (one off Tasmania and Macquarie Island) (Threatened Species Scientific Committee, 2015f). As a mainly sub-Antarctic species they are usually distributed in cooler seas but distribution extents into subtropical waters and its known distribution includes the southern extent of the NWMR. No BIAs for this species are located in the NWMR.
Australian fairy tern	The Australian fairy tern is listed as Vulnerable for the sub-species only recorded for WA. It has a coastal distribution from Sydney, south to Tasmania and around southern WA up to the Dampier Archipelago and out on the offshore island groups of Barrow, Montebello and the Lowendals (DSEWPAC, 2011d). The Australian fairy tern feeds on small baitfish and roosts and nests on sandy beaches below vegetation. These behaviours, generally, occur in inshore waters of island archipelagos and on the Australian mainland shores and adjacent wetlands. Fairy terns breed from August to February. The Australian fairy tern is unlikely to be present

Species	Key Information
	within the offshore environment of the NWMR. The largest breeding colony in Western Australia for this species is in the Houtman Abrolhos Islands, SWMR (Surman, 2019). For the description and location of BIAs in the NWMR, refer to **Table 8-3** and **Figure 8-2**.
Australian lesser noddy	The Houtman Abrolhos, WA is an important breeding habitat for the Australian lesser noddy in the eastern Indian Ocean. This species exhibits nesting habitat specialisation (white mangrove stands) and has a limited foraging range during the breeding season. Furthermore, the lesser noddy forages over shelf waters and appears not to disperse over their non-breeding period as they remain largely in the general vicinity or slightly to the south of the colony in the non-breeding season (February to September; Surman *et al*., 2018). No BIAs for this species are located in the NWMR.
Indian yellow-nosed albatross	This species is included in the National recovery plan for threatened albatrosses and giant petrels. Habitat critical to survival is defined for breeding and foraging. There are six known breeding localities under Australian jurisdiction (for all species of albatrosses) and all are located in the Southern Ocean including islands off Tasmania and within the Australian Antarctic Territory (DSEWPAC, 2011c). Habitat critical to survival identified for foraging is defined as waters south of 25 degrees latitude. All albatross species distribution (including the Indian yellow-nose albatross) is mainly within the Southern Ocean but this species does migrate into subtropical waters during the winter and its distribution includes the southern extent of the NWMR. No BIAs for this species are located in the NWMR.
Common noddy	This species is listed as migratory and marine. The common (or brown) noddy is the largest species of noddy found in Australian waters. The species is widespread in tropical and subtropical areas beyond Australia. This seabird species is gregarious and normally occurs in flocks, up to hundreds of individuals, when feeding or roosting. The Houtman Abrolhos, WA is the primary breeding habitat for the common noddy in the Eastern Indian Ocean. This species spends their non-breeding season (March to August) in the NWS area, around 950 km north from the breeding colony (Surman *et al*. 2018). The species occurs within NWMR waters, particularly around offshore islands such as the Montebello Island group. This species is recorded on unmanned oil and gas platforms within the NWS. No BIAs for this species are located in the NWMR.
Lesser frigatebird **Great frigatebird**	Both species of frigatebird are listed as migratory and marine. Within the NWMR, the lesser frigatebird is known to breed on Adele, Bedout and West Lacepede islands, Ashmore Reef and Cartier Island (Commonwealth of Australia, 2019). The lesser frigatebird feeds mostly on fish and sometimes cephalopods, and all food is taken while the bird is in flight. Lesser frigatebirds generally forage close to breeding colonies. Breeding/foraging BIAs for the lesser frigatebird are located in the NWMR; refer to **Table 8-3**.
Brown booby	The brown booby is the most common booby, occurring throughout all tropical oceans bounded by latitudes 30º N and 30º S. There are large colonies on offshore islands within the NWMR such as the Lacepede Islands (one of the largest colonies in the world), Ashmore Reef, and other offshore Kimberley islands. This seabird species is a specialised plunge diver, mostly eating fish and some cephalopods (Commonwealth of Australia, 2019). Breeding/foraging BIAs for the brown booby are located in the NWMR; refer to **Table 8-3** and **Figure 8-3**.
Red-footed booby	Within the NWMR, its known breeding sites for this species include Ashmore Reef and Cartier Island. It is a pelagic species and generally occurs away from land. It mainly eats flying fish and squid. Prey abundance is reliant on the high productivity in slope areas off remote islands where the birds breed (Commonwealth of Australia, 2019). Breeding/foraging BIAs for the red-footed booby are located in the NWMR; refer to **Table 8-3** and **Figure 8-3**.
Greater crested tern	The greater crested tern has a widespread distribution recorded on islands and coastlines of tropical and subtropical areas, ranging from the Atlantic coast of South Africa, Indian Ocean and through south-east Asia and Australia. Outside the breeding season it can be found at sea throughout its range, with the exception of the central Indian Ocean (Commonwealth of Australia, 2019). The largest breeding colony in WA for this species is the Houtman Abrolhos Islands, SWMR (Surman, 2019). No BIAs for this species are located in the NWMR.
Little tern	There are three sub-populations of this species in Australia and two of these occur in the NWMR: northern Australian breeding sub-population occurring around Broome and extending across in to the NMR, and an east Asian breeding sub-population, with the terns present from Shark Bay to south-eastern Queensland during the austral summer. Little terns

Species	Key Information
	usually forage close to breeding colonies in the shallow water of estuaries (Commonwealth of Australia, 2019). For the description and location of BIAs in the NWMR, refer to **Table 8-3** and **Figure 8-2**.
Roseate tern	This species is generally tropical in distribution and there are many breeding populations in the NWMR, including Ashmore Reef, Napier Broome Bay, Bonaparte Archipelago, Lacepede Islands, Dampier Archipelago and the Lowendal Islands. A large number of non-breeding roseate terns have been observed at several remote locations in the Kimberley and there are high numbers also recorded for Eighty Mile Beach Ramsar site. The Kimberley colonies are likely to be another sub-species that breeds in east Asia. Roseate terns predominately eat small pelagic fish (Commonwealth of Australia, 2019). The largest breeding colony in Western Australia for this species is in the Houtman Abrolhos Islands, SWMR (Surman, 2019). For the description and location of BIAs in the NWMR, refer to **Table 8-3** and **Figure 8-2**.
Wedge-tailed shearwater	The wedge-tailed shearwater is a pelagic, marine seabird known from tropical and subtropical waters. Its distribution is widespread across the Indian and Pacific oceans. It is known to breed on the east and west coasts (and offshore islands) of Australia. This species is known to consume fish, cephalopods, and other biota primarily via contact-dipping. Wedge-tailed shearwaters are now understood to undertake extensive foraging trips (over thousands of kilometres over periods of days when chicking and provisioning young) and much longer and extensive pelagic travels over the north-west Indian Ocean during the non-breeding season, targeting current boundaries and upwellings. The species breeds throughout its range, mainly on vegetated islands, atolls and cays and excavates burrows in the ground where chicks are raised (Commonwealth of Australia, 2019). Large breeding colonies of the wedge-tailed shearwater are located on the Houtman Abrolhos islands (SWMR) (Surman *et al*., 2018) and several locations in the NWMR including: Muiron Islands (North-west Cape), Varanus Island and the Dampier Archipelago in the Pilbara where burrow numbers were estimated to several hundred thousand to half a million such as on the Muiron Islands, though it is not known if all burrows are utilised on an annual basis (Birdlife Australia, 2018; Surman *et al.*, 2018). Cannell *et al* (2019) satellite tracked adult wedge-tailed shearwaters during egg incubation and chick rearing on the Muiron Islands in January 2018. For the incubation trips, there was a strong consistency for the birds to travel towards seamounts, typically located north-west of the Muiron Islands, between Australia and Indonesia. One bird however remained south-west of the islands, in the Cape Range Canyon. A similar pattern to utilise areas associated with sea mounts was also observed for the long foraging trips during chick rearing, though some of the foraging was concentrated in deeper waters. A bimodal foraging strategy during chick-rearing was observed, with adults undertaking long foraging trips after a series of shorter foraging trips within the NWMR. Surman *et al*. (2018) reported most wedge-tailed shearwaters from the breeding colonies on the Houtman Abrolhos undertook extensive non-breeding migrations. This seabird species occupied waters adjacent or to the north of their nesting sites or migrated 4200 km north-west into the equatorial central Indian Ocean near the Ninety East Ridge during the non-breeding season (later April to mid-November). For the description and location of BIAs in the NWMR, refer to **Table 8-3** and **Figure 8-1**.
Flesh-footed shearwater	The species mainly occurs in the subtropics, over continental shelves and slopes and occasionally inshore waters, with individual birds pass through the tropics and over deeper waters during migration to the North Pacific and Indian oceans (Commonwealth of Australia, 2019). They are a common visitor to the waters off southern Australia, from south-western WA to south-eastern Queensland. The fleshy-footed shearwater is a trans-equatorial migrant, breeding from late September to May off south-western Australia, and migrating north by early May, across the southern Indian and possibly Indonesia to the northern Pacific Ocean. No BIAs for the flesh-footed shearwater are located in the NWMR.
Streaked shearwater	The streaked shearwater has a broad distribution in the western Pacific Ocean, breeding on the coast and offshore islands of Japan, Russia, China and the Korean Peninsula. During winter months (non-breeding season), the species undertakes trans-equatorial migration to the coasts of Vietnam, New Guinea, the Philippines, Australia, southern India and Sri Lanka. The streaked shearwater feeds mainly on fish and squid that it catches by surface-seizing and shallow plunges (Commonwealth of Australia, 2019). No BIAs for the streaked shearwater are located in the NWMR.
White-tailed tropicbird	Tropicbirds are predominately pelagic species and the white-tailed tropicbird forages in warm waters and over long distances (pan-tropical). The species is most common off north-west Australia. In the NWMR, this species is considered a sub-species and are limited in number and distribution. Nesting sites are known for Clerke Reef (Rowley Shoals) and Ashmore

Species	Key Information
	Reef. Christmas Island is also a known nesting site and the species can disperse several thousand kilometres during foraging trips. This species feeds mainly on fish and cephalopods, captured by deep plunge diving (Commonwealth of Australia, 2019). There are breeding BIAs at the Rowley Shoals and Ashmore Reef within the NWMR for the white-tailed tropicbird; refer to **Table 8-3**.
Silver gull	The silver gull is typically described as an inshore and coastal foraging seabird and has an Australian-wide distribution including locations within the NWMR. It is noted as it has been recorded on unmanned oil and gas platforms located within the NWS.

8.2.1 Biologically Important Areas in the NWMR

BIAs representing important life cycle stages and behaviours for eight species of seabird in the NWMR are presented in **Table 8-3**.

Table 8-3 Seabird BIAs within the NWMR
