1. INTRODUCTION

1.1 Overview

Woodside Burrup Pty. Ltd. (Woodside) is operator of the Pluto offshore facility and export pipeline on behalf of the Pluto Liquefied Natural Gas (LNG) Joint Venture Participants. The Pluto offshore facility (the facility), including the riser platform and subsea hydrocarbon gathering system, has been in production since 2012 and is operated by Woodside under the Petroleum Titles listed in Table 3-1. The facility is located offshore approximately 160 km northwest of Dampier, in WA-1-IL and WA-34-L, while the associated export pipeline and flowline are within WA-17-PL and WA-16-PL, respectively. The operation of the facility, Xena-03 Drilling and Tie-back activities, and recovery of well fluids from associated fields and subsea infrastructure is hereafter, collectively referred to as the Petroleum Activities Program. Well fluids are recovered from a series of fields via pipelines and subsea infrastructure, which are produced by the facility and exported to the onshore LNG plants for processing. Subsea tiebacks relevant to the facility include:

- Pluto
- Xena-03
- Pyxis.

The Pluto-Alpha platform (PLA) combines accommodation, utilities, operation of production facilities and the water treatment module (see Section 3). The platform is designed to be operated in both not-normally crewed and minimally crewed states. The offshore facilities are remotely operated from the Central Control Room (CCR), either from the CCR at Pluto LNG Park (PLP) or Remote CCR in Perth.

This Environment Plan (EP) has been prepared as part of the requirements under the Offshore Petroleum and Greenhouse Gas Storage (Environment) Regulations 2023 (Cth) (referred to as the Environment Regulations), as administered by the National Offshore Petroleum Safety and Environmental Management Authority (NOPSEMA).

In accordance with the requirements of Regulation 41 of the Environment Regulations, Woodside has submitted a revision to the Pluto Facility Operations EP to NOPSEMA at least 14 days prior to the end of the five-year period from the original acceptance under what is now regulation 35 of the Environment Regulations. At the time of the original acceptance, the relevant provision was regulation 11 of the Offshore Petroleum and Greenhouse Gas Storage (Environment) Regulations 2009 (Cth).

In accordance with the requirements of Regulation 39 of the Environment Regulations, Woodside has revised the Pluto Facility Operations EP to incorporate a new stage of the activity which is the tie-back, commissioning and operation of the Xena-03 well. Key components of the Xena-03 tie back activity that represent a new stage of the Pluto Facility Operations EP include:

- The activity is a single well therefore the Xena-03 well and tie-back are proposed to form part of an existing production system.
- The activity would be conducted within the spatial area described in the existing Pluto Facility Operations EP, with a slight temporary expansion to the Operational Area during construction activities.
- The addition of the Xena-03 well forms an orderly continuation of the Pluto project (EPBC 2006/2968) within existing timeframes specified in EPBC approval.
- The operation of proposed Xena-03 well and subsea infrastructure is consistent with the activities already described within this Pluto Facility Operations EP.

- No further increase to the active number of wells producing to the Pluto offshore facility is planned[1].

1.2 Purpose of the Environment Plan

In accordance with the objectives of the Environment Regulations, the purpose of this EP is to demonstrate that:

- The potential environmental impacts and risks (planned (routine and non-routine) and unplanned) that may result from the Petroleum Activities Program are identified.
- Appropriate management controls are implemented to reduce impacts and risks to a level that is 'as low as reasonably practicable' (ALARP) and acceptable.
- The Petroleum Activities Program is carried out in a manner consistent with the principles of ecologically sustainable development (ESDev) (as defined in Section 3A of the Environment Protection and Biodiversity Conservation Act 1999 (Cth) (EPBC Act)).

This EP describes the process and resulting outputs of the risk assessment, whereby impacts and risks are managed accordingly.

The EP defines activity-specific environmental performance outcomes, standards, and measurement criteria (MC). These form the basis for monitoring, auditing, and managing the Petroleum Activities Program to be undertaken by Woodside and its contractors. The implementation strategy specified in this EP provides Woodside and NOPSEMA with the required level of assurance that impacts and risks associated with the activity are reduced to ALARP and are acceptable.

1.3 Scope of the Environment Plan

The scope of this EP covers the activities that define the Petroleum Activities Program, as described in Section 3, for a period of up to five years. The Petroleum Activities Area (PAA), as defined in Section 3.2.1, defines the spatial boundary of the Petroleum Activities Program.

This EP addresses potential environmental impacts from planned activities and potential unplanned events that originate from within the PAA. Transit to and from the PAA by project vessels, as well as port activities associated with these vessels, are not within the scope of this EP. Vessels supporting the Petroleum Activities Program operating outside the PAA (e.g. transiting to and from port) are subject to applicable maritime regulations and other requirements and are not managed by this EP.

1.4 Environment Plan Summary

An EP summary will be prepared based on the material provided in this EP. Table 1-1 summarises the content that will be provided within the EP summary, as required by Regulation 35(7).

Table 1-1: EP Summary

EP Summary material requirement	Relevant section of this EP containing EP Summary material
The location of the activity	Section 3.2
A description of the receiving environment	Section 4
A description of the activity	Section 3
Details of the environmental impacts and risks	Section 6
The control measures for the activity	Section 6

[1] Accurate at the time of writing. Should development opportunities be identified during the validity of this EP, Woodside will engage with NOPSEMA to determine the appropriate environmental approval pathway prior to pursuit of the opportunity.

EP Summary material requirement	Relevant section of this EP containing EP Summary material
The arrangements for ongoing monitoring of the titleholder's environmental performance	Section 7.10
Response arrangements in the oil pollution emergency plan	Section 7.14
Consultation already undertaken and plans for ongoing consultation	Section 5
Details of the titleholder's nominated liaison person for the activity	Section 1.7.2

1.5 Structure of the Environment Plan

The EP has been structured to reflect the process and requirements of the Environment Regulations, as outlined in Table 1-2.

Table 1-2: EP process phases, applicable Environment Regulations and relevant section of EP

Criteria for acceptance	Content Requirements/Relevant Regulations	Elements	Section of EP
Regulation 34(a): is appropriate for the nature and scale of the activity	Regulation 21: Environmental Assessment Regulation 22(1): Implementation strategy for the environment plan Regulation 24: Other information in the environment plan	The principle of 'nature and scale' applies throughout the EP	Section 2 Section 3 Section 4 Section 5 Section 6 Section 7
Regulation 34(b): demonstrates that the environmental impacts and risks of the activity will be reduced to as low as reasonably practicable Regulation 34(c): demonstrates that the environmental impacts and risks of the activity will be of an acceptable level	Regulation 21(1)–21(7): 21(1) Description of the activity 21(2)(3) Description of the environment 21(4) Requirements 21(5)(6) Evaluation of environmental impacts and risks 21(7) Environmental performance outcomes and standards Regulation 24a)–24(c): A statement of the titleholder's corporate environmental policy A report on all consultations between the titleholder and any relevant person	Set the context (activity and existing environment) Define 'acceptable' (the requirements, the corporate policy, relevant persons) Detail the impacts and risks Evaluate the nature and scale Detail the control measures – ALARP and acceptable	Section 1 Section 2 Section 3 Section 4 Section 5 Section 6 Section 7
Regulation 34(d): provides for appropriate environmental performance outcomes, EPS and MC.	Regulation 21(7): Environmental performance outcomes and standards	Environmental Performance Objectives (EPOs) Environmental Performance Standards (EPSs) Measurement Criteria (MC)	Section 6
Regulation 34(e): includes an appropriate implementation strategy and monitoring,	Regulation 22: Implementation strategy for the environment plan	Implementation strategy, including: systems, practices and procedures performance monitoring	Section 7

Criteria for acceptance	Content Requirements/Relevant Regulations	Elements	Section of EP
recording, and reporting arrangements		Oil Pollution Emergency Plan (OPEP) and scientific monitoring ongoing consultation.	
Regulation 34(f): does not involve the activity or part of the activity, other than arrangements for environmental monitoring or for responding to an emergency, being undertaken in any part of a declared World Heritage property	Regulation 21 (1)–21(3): 21(1) Description of the activity 21(2) Description of the environment 21(3) Without limiting [Regulation 21(2)(b)], particular relevant values and sensitivities may include any of the following: the world heritage values of a declared World Heritage property within the meaning of the EPBC Act; the national heritage values of a National Heritage place within the meaning of that Act; the ecological character of a declared Ramsar wetland within the meaning of that Act; the presence of a listed threatened species or listed threatened ecological community within the meaning of that Act; the presence of a listed migratory species within the meaning of that Act; any values and sensitivities that exist in, or in relation to, part or all of: a Commonwealth marine area within the meaning of that Act; or Commonwealth land within the meaning of that Act.	No activity, or part of the activity, undertaken in any part of a declared World Heritage property	Section 3 Section 4 Section 6
Regulation 34(g): (i) the titleholder has carried out the consultations required by Section 25 (ii) the measures (if any) that the titleholder has adopted, or proposes to adopt, because of the consultations are appropriate	Regulation 25: Consultation with relevant authorities, persons and organisations, etc. Regulation 24(b): A report on all consultations under Regulation 25 of any relevant person by the titleholder, that contains: a summary of each response made by a relevant person; and an assessment of the merits of any objection or claim about the adverse impact of each activity to which the environment plan relates; and a statement of the titleholder's response, or proposed response, if any, to each objection or claim; and (iv) a copy of the full text of any response by a relevant person;	Consultation in preparation of the EP	Section 5
Regulation 10A(h): Complies with the Act, this instrument and any other	Regulation 23: Details of the Titleholder and liaison person Regulation 24(c):	All contents of the EP must comply with the Act and the regulations	Section 1.6 Section 7.12

Criteria for acceptance	Content Requirements/Relevant Regulations	Elements	Section of EP
regulations made under the Act	Details of all reportable incidents in relation to the proposed activity.		

1.6 Description of the Titleholder

Woodside is the operator of the facility and associated infrastructure on behalf of itself and its Pluto LNG joint venture partners, MidOcean Pluto Pty Ltd and Kansai Electric Power Australia Pty Ltd. The Titleholder for this activity is Woodside (refer to Table 3-2 for a list of petroleum titles associated with the Petroleum Activities Program).

Woodside is Australia's leading natural gas producer. Woodside's operations are characterised by strong safety and environmental performance in remote and challenging locations. Wherever Woodside works, it is committed to living its values of integrity, respect, ownership, sustainability, courage, and working together.

Since 1984, the company has been operating the landmark Australian project, the North West Shelf, which is one of the world's premier liquefied natural gas (LNG) facilities.

Woodside has an excellent track record of efficient and safe production. Woodside strives for excellence in safety and environmental performance and continues to strengthen relationships with customers, partners, co-venturers, governments, and communities. Further information about Woodside can be found at https://www.woodside.com/who-we-are/our-story.

1.7 Details of Titleholder and Nominated Liaison

In accordance with Regulation 23 of the Environment Regulations, details of the titleholder and nominated liaison and arrangements for the notification of changes are described below.

1.7.1 Titleholder

Woodside Burrup Ltd

11 Mount Street

Perth, Western Australia

T: 08 9348 4000

ACN: 120 237 416

1.7.2 Nominated Liaison Person

Andrew Winter

Corporate Affairs Manager

11 Mount Street

Perth, Western Australia

T: 08 9348 4000

E: feedback@woodside.com

1.7.3 Arrangements for Notifying Change

If the titleholder, titleholder's nominated liaison person, or the contact details for the titleholder or the liaison person change, then NOPSEMA will be notified of the change in writing within two weeks or as soon as practicable.

1.8 Woodside Management System

The Woodside Management System (WMS) provides a structured framework of documentation to set common expectations governing how all employees and contractors at Woodside will work. Many of the standards presented in Section 6 are drawn from the WMS documentation, which comprises four elements as outlined below (and illustrated in Figure 1-1):

- Our Values and Policies: Set the enterprise-wide direction for Woodside by governing our behaviours, actions, and business decisions and ensuring we meet our legal and other external obligations.
- Expectations: Set essential activities or deliverables required to achieve the objectives of the Key Business Activities and provide the basis for developing processes and procedures.
- Processes and Procedures: Processes identify the set of interrelated or interacting activities that transforms inputs into outputs, to systematically achieve a purpose or specific objective. Procedures specify what steps, by whom, and when required to carry out an activity or a process.
- Guidelines: Provide recommended practice and advice on how to perform the steps defined in Procedures, together with supporting information and associated tools. Guidelines provide advice on: how activities or tasks may be performed; information that may be taken into consideration; or, how to use tools and systems.

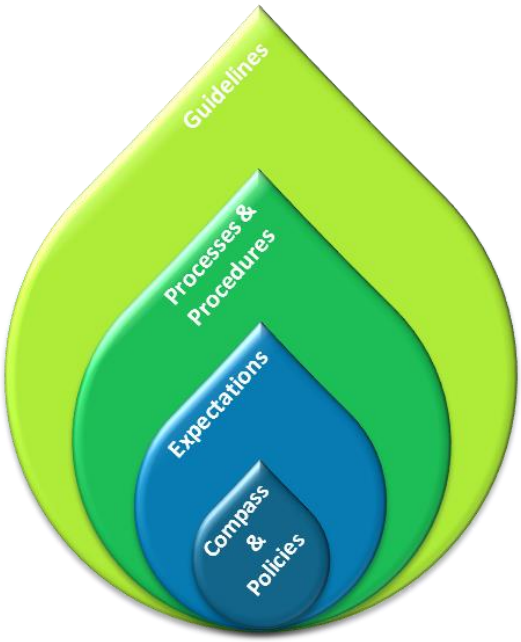

Figure 1-1: The four major elements of the Woodside Management System Seed

The WMS is organised within a Business Process Hierarchy based upon Key Business Activities so that the system remains independent of organisation structure, is globally applicable and scalable wherever required. These Key Business Activities are grouped into Management, Support, and Value Stream activities as shown in Figure 1-2. The Value Stream activities capture, generate and deliver value through the exploration and production lifecycle. The Management activities influence all areas of the business, while Support activities may influence one or more value stream activities.

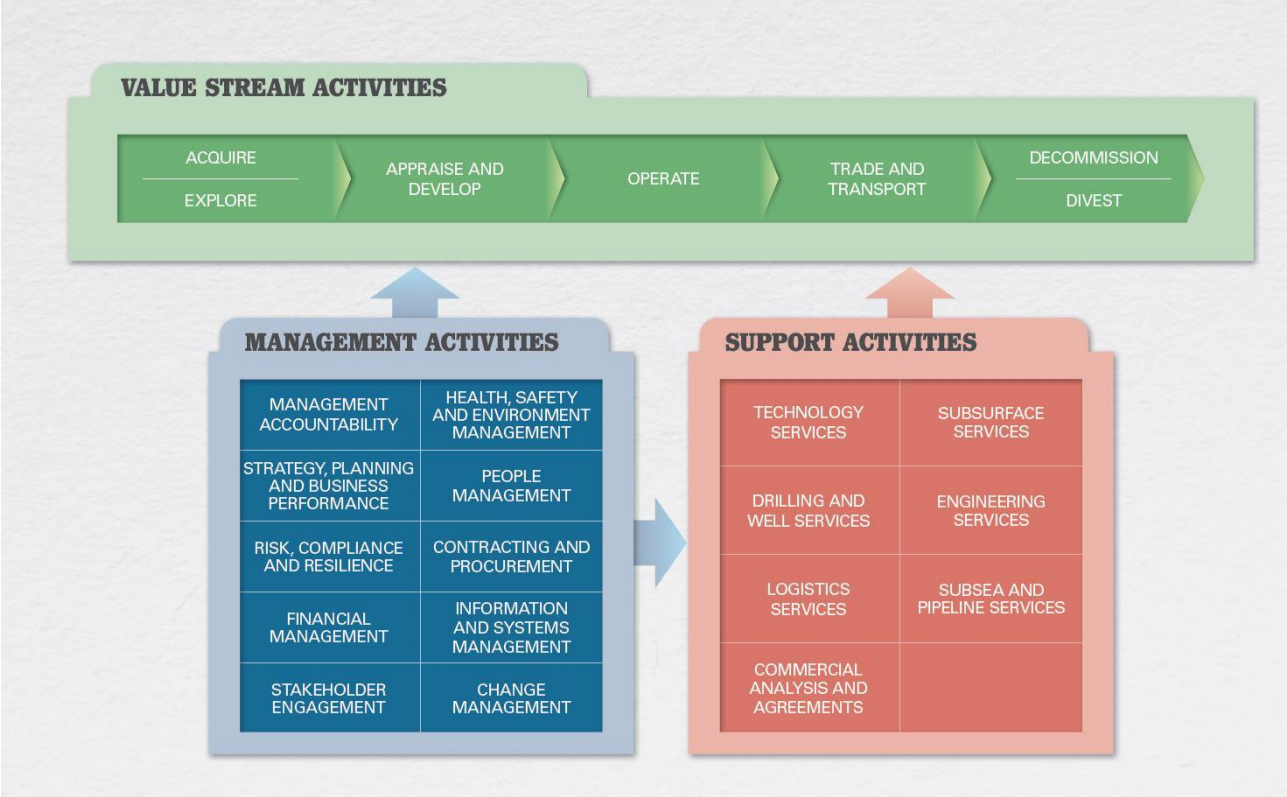

Figure 1-2: The Woodside Management System business process hierarchy

1.8.1 Environment and Biodiversity Policy

In accordance with Regulation 24(a) of the Environment Regulations, Woodside's Environment and Biodiversity Policy is provided in Appendix A of this EP.

As the objective of the policy, Woodside recognises the intrinsic value of nature and the importance of conserving biodiversity and ecosystem services to support the sustainable development of our society. We are committed to doing our part. We understand and embrace our responsibility to undertake activities in an environmentally sustainable way.

As part of the policy's principles, Woodside commits to:

- Implementing a systematic approach to the management of the impacts and risks of our operating activities on an ongoing basis, including emissions and air quality, discharge and waste management, water management, biodiversity and protected areas.
- Applying the mitigation hierarchy principle (avoid, minimise, restore) and a continuous improvement approach to ensure we maintain compliance, improve resource use efficiency and reduce our environmental impacts.
- Embedding environmental and biodiversity management, and opportunities, in our business planning and decision making processes.
- Complying with relevant laws and regulations and applying responsible standards where laws do not exist.
- Not undertaking new exploration or development of hydrocarbons within the boundaries of natural sites on the UNESCO World Heritage List (as specified at 1 December 2022). Existing activity may continue if compatible with maintenance of the listed outstanding universal values.

- Not undertaking new exploration or development of hydrocarbons within IUCN Protected Areas (as specified at 1 December 2022) unless compatible with management plans in place for the area. Existing activity may continue if compatible with management plans in place for the area.
- Achieving net zero deforestation1 associated with new projects that take a Final Investment Decision (FID) after 1 December 2022.
- Developing Biodiversity Action Plans for all new major projects (CAPEX >USD$2 billion) that take a FID after 1 December 2022.
- Supporting positive biodiversity outcomes in regions and areas in which we operate.
- Setting targets and publicly reporting on our environmental and biodiversity performance.

The application of the policy is the responsibility of all Woodside employees, contractors and joint venturers engaged in activities under Woodside operational control. Woodside managers are also responsible for promotion of the policy in non-operated joint ventures.

The policy is reviewed regularly and updated as required. The version applicable to the activity covered in this EP was reviewed in December 2023.

1.9 Description of Relevant Requirements

In accordance with Regulation 21(4) of the Environment Regulations, a description of requirements, including legislative requirements, that apply to the activity and are relevant to the management of risks and impacts of the Petroleum Activities Program are detailed in Appendix B. This EP will not be assessed under the Environment Protection Act 1986 (WA) as the activity does not occur on State land or within State Waters.

1.9.1 Offshore Petroleum and Greenhouse Gas Storage Act 2006

The Commonwealth Offshore Petroleum and Greenhouse Gas Storage Act 2006 (OPGGS Act) controls exploration and production activities beyond three nautical miles (nm) of the mainland (and islands) to the outer extent of the Australian Exclusive Economic Zone (EEZ) at 200 nm.

The relevant requirements in Section 572 of the OPGGS Act are detailed in Table 1-3.

Table 1-3: Relevant requirements of Section 572 of the OPGGS Act

Section Number	Relevant Requirement	Relevant Section of the EP
Section 270 – Consent to surrender title[1]		
	The Joint Authority may consent to the surrender sought by the application only if the registered holder of the permit, lease or licence: c) has: (i) to the satisfaction of NOPSEMA, removed or caused to be removed from the surrender area (defined by subsection (7)) all property brought into the surrender area by any person engaged or concerned in the operations authorised by the permit, lease or licence; or (ii) made arrangements that are satisfactory to NOPSEMA in relation to that property; and	Not applicable
Section 572 - Maintenance and removal of property etc. by titleholder		
2	A titleholder must maintain in good condition and repair all structures that are, and all equipment and other property that is: (a) in the title area; and (b) used in connection with the operations authorised by the permit, lease, licence or authority.	Section 7.5

Section Number	Relevant Requirement	Relevant Section of the EP
3	A titleholder must remove from the title area all structures that are, and all equipment and other property that is, neither used nor to be used in connection with the operations: (a) in the title area; and (b) used in connection with the operations authorised by the permit, lease, licence or authority.	Section 3 and 7.5
7	This section has effect subject to: (a) any other provision of this Act; and (b) the regulations; and (c) a direction given by NOPSEMA or the responsible Commonwealth Minister under: (i) Chapter 3; or (ii) this Chapter; and (d) any other law	Section 7.5

1. There is no intent to surrender any titles in the scope of this EP.

Under the OPGGS Act, the Environment Regulations apply to petroleum activities in Commonwealth Waters and are administered by NOPSEMA. The objective of the Environment Regulations is to ensure petroleum activities are performed in a manner:

- consistent with the principles of ESDev
- by which the environmental impacts and risks of the activity will be reduced to ALARP
- by which the environmental impacts and risks of the activity will be of an acceptable level.

1.9.2 Environment Protection and Biodiversity Conservation Act 1999 (Cth)

One of the objectives EPBC Act is to protect and manage nationally and internationally important flora, fauna, ecological communities and heritage places in Australia. These are defined under Part 3 of the Act as “Matters of National Environmental Significance” (MNES). The EPBC Act sets a regime which aims to ensure actions taken on (or impacting upon) Commonwealth land or waters are consistent with the principles of ESD. When a person proposes to take an action that they believe may need approval under the EPBC Act, they must refer the proposal to the Commonwealth Minister for Environment.

In relation to offshore petroleum activities in Commonwealth waters, in accordance with the “Streamlining Offshore Petroleum Approvals Program” (the Program), requirements under the Act are now administered by NOPSEMA, commencing February 2014. The Program requires any offshore petroleum activities, authorised by the OPGGS Act to be conducted in accordance with an accepted EP. The definition of ‘environment’ in the Program covers all matters protected under Part 3 of the EPBC Act.

1.9.3 Offshore Project Approval

The Pluto LNG Project (including both offshore and onshore infrastructure) was referred for assessment under the EPBC Act (EPBC 2006/2968) and the level of assessment was set as Public Environment Report (PER). The action was approved 12 October 2007 with conditions.

It should be noted that a Consolidated Approval Notice for EPBC 2006/2968 dated 14 June 2015 was issued to consolidate the approval conditions, and the approval conditions were subject to variation on the date of the notice. A key element to the variation relates to conditions requiring a plan for managing impacts of the action. The previous conditions required the Minister’s approval of such plans, with the variation now automatically deeming the plan to have been approved by the

Minister if the measures are included in an environment plan related to the action submitted to NOPSEMA after 27 February 2014 and in force under the Environment Regulations.

Conditions in relation to the EPBC Act approval that are considered relevant to the scope of this EP are provided in Table 1-4. See also Section 1.1 for further details.

Table 1-4: Conditions from Pluto Gas condensate field (EPBC 2006/2968) relevant to the Petroleum Activities Program

Condition Number	Condition	Relevant Section of EP
1[2]	The person taking the action must submit, for the Minister's approval, a plan (or plans) for managing the offshore impacts of the action. The plan (or plans) must include measures for: b) Construction and installation: design and construction that allow for the decommissioning of all structures and components on the sea floor impacts and management measures for reuse of any spoil ground material details of the final selection of wells, anchor type and placements and flowline paths hydrotest fluid type, handling and risk assessment of disposal impacts interaction procedures for supply vessels and aircraft that are consistent with Part 8 of the Environment Protection and Biodiversity Conservation Regulations 2000 cetacean and whale shark sightings reporting.	The Xena-03 tie-back project is the only planned construction and installation activity covered under this EP. Relevant sub-conditions are addressed in the following sections: i. Section 3.11 and 7.5 ii. Not relevant iii. Section 3.11 iv. Section 3.11.4 and 6.7.5 v. Section 6.7.3, 6.7.4 and 6.9.9 vi. Section 6.7.3, 6.7.4, 6.9.9 and 7.13.3.2
1	c) Operations: trading tanker vetting procedures the monitoring and disposal of produced water (PW), including the analysis of expected PW chemistry, baseline biological and physical information at the PW outfall site, toxic impacts of PW on marine flora and fauna based on ecotoxicological, bioaccumulation and biodegradation studies, industry best practice disposal of PW monitoring and reporting of biological and physical indicators and contingency measures if adverse impacts are indicated monitoring and management the collection, handling and disposal of naturally occurring radioactive materials (NORMs) interaction procedures for supply vessels and aircraft that are consistent with Part 8 of the Environment Protection and Biodiversity Conservation Regulations 2000 cetacean and whale shark sightings reporting. Individual offshore activities may not commence until the plan (or plans) for that specific activity has been approved. The approved plan (or plans) must be implemented.	i. Not applicable ii. Sections 6.7.5 and 6.7.7 iii. Sections 3.6.8 iv. Section 6.7.3, 6.7.4 and 6.9.9 v. Sections 6.7.3, 6.7.4 and 6.9.9.
4	The person taking the action must submit for the Minister's approval an oil spill contingency plan to mitigate the environmental effects of any hydrocarbon spills. The oil spill contingency plan must include: the types of dispersants, protective booms, clean up gear, and related equipment to be used in the event of an oil spill and the storage arrangements	Woodside's Emergency Preparedness and Response arrangements (refer to Section 7.14 and associated documents).

[2] Condition 1a), 2 and 3 (not shown) have been met through previous plans

Condition Number	Condition	Relevant Section of EP
	training of staff in oil spill response measures identification of sensitive areas, and specific response measures for these areas details of the insurance arrangements that have been made in respect of the costs associated with repairing any environmental damage arising from potential oil spills the reporting of oil spill incidents. Offshore construction may not commence until the plan is approved. The approved plan must be implemented.	
8	At least twelve months before the expiry of the period for which this approval has effect, the person taking the action Limited must submit a decommissioning plan for approval by the Minister that considers the removal of all structures and components above the sea floor, including subsea wells, manifolds and flowlines and any other associated infrastructure and the disposal and management of any NORMs. Decommissioning may not commence until the plan is approved. The approved plan must be implemented.	Decommissioning is beyond the scope of this EP.
11	If the person taking the action proposes to undertake any subsea tie-in[3] not included in approved plans pursuant to condition 1, the person taking the action must revise such plans or submit a new plan or plans to address the activities associated with, and potential environmental impacts of, the subsea tie-in. Activities associated with subsea tie-ins may not be commenced until each such plan or revised plan has been approved by the Minister. Each plan or revised plan that has been approved by the Minister must be implemented.	The resubmission and subsequent implementation of this EP is considered to meet this Condition (i.e. This EP is submitted as the 'revised plan' to address aspects of condition 1 applicable to the Xena-03 subsea tie-in operation).
12	If the person taking the action wishes to carry out any activity otherwise than in accordance with the plans referred to in conditions 1 ,3, 4, 5, 6 and 8 the person taking the action may submit for the Minister's approval a revised version of any such plan. If the Minister approved a revised plan so submitted the person taking the action must implement that plan instead of the plan as originally approved.	The Implementation of this EP is considered to meet this Condition (i.e. This EP is submitted as the 'revised plan' to address aspects of conditions applicable to the Xena-03 subsea tie-in operation).
15	A plan required by condition 1, 4, 8, 11 or 12 is automatically deemed to have been submitted to, and approved by, the Minister if the measures (as specified in the relevant condition) are included in an environment plan (or environment plans) relating to the taking of the action that: was submitted to NOPSEMA after 27 February 2014, and either: is in force under the OPGGS Environment Regulations, or has ended in accordance with Regulation 46 of the OPGGS Environment Regulations	The implementation of this EP is considered to meet this Condition.
15A	Where a plan required by condition 1, 4, 11 or 12 has been approved by the Minister and the measures (as specified	The implementation of this EP is considered to meet this Condition and supersedes previously approved plans.

[3] Subsea tie-ins: means the construction and operation of subsea wells, flowlines and other related infrastructure for the purpose of extracting gas from hydrocarbon reserves (other than the Pluto gas reservoir) within that area and conveying that petroleum to the platform located at the site of the Pluto hydrocarbon reservoir.

Condition Number	Condition	Relevant Section of EP
	in the relevant condition) are included in an environment plan (or environment plans) that: was submitted to NOPSEMA after 27 February 2014, and either: is in force under the OPGGS Environment Regulations, or has ended in accordance with regulation 46 of the OPGGS Environment Regulations, the plan approved by the Minister no longer needs to be implemented.	
15B	Where an environment plan, which includes measures specified in the conditions referred to in conditions 15 and 15A above, is in force under the OPGGS Environment Regulations that relates to the taking of the action, the person taking the action must comply with those measures as specified in that environment plan.	The implementation of this EP is considered to meet this Condition.

1.9.4 Recovery Plans and Threat Abatement Plans

Under s139(1)(b) of the EPBC Act, the Environment Minister must not act inconsistently with a recovery plan for a listed threatened species or ecological community or a threat abatement plan for a species or community protected under the Act. Similarly, under s268 of the EPBC Act:

"A Commonwealth agency must not take any action that contravenes a recovery plan or a threat abatement plan."

In relation to offshore petroleum activities in Commonwealth waters, these requirements are now administered by NOPSEMA in accordance with commitments set out in the Programs. Relevant recovery plans or threat abatement plans relevant to the scope of this EP have been identified as described in Section 2.9 and assessed in Section 6.10.

1.9.5 Australian Marine Parks

Under the EPBC Act, Australian Marine Parks (AMPs), formerly known as Commonwealth Marine Reserves, are recognised for conserving marine habitats and the species that live and rely on these habitats. The Director of National Parks (DNP) is responsible for managing AMPs (supported by Parks Australia) and is required to publish management plans for them. Other parts of the Commonwealth Government must not perform functions or exercise powers in relation to these parks that are inconsistent with management plans (s.362 of the EPBC Act). Relevant AMPs are listed in Section 4.8 and in the Master Existing Environment (Woodside 2022; under Regulation 56 of the Environment Regulations, this Master Existing Environment was accepted on 3 March 2022 as Appendix C in the Goodwyn Alpha (GWA) Facility Operations Environment Plan). The North-west Marine Parks Network Management Plan describes the requirements for management.

- Specific zones within the AMPs have been allocated conservation objectives as stated below (International Union for Conservation of Nature [IUCN] Protected Area Category) based on the Australian IUCN reserve management principles outlined in Schedule 8 of the Environment Protection and Biodiversity Conservation Regulations 2000 (Cth) (EPBC Regulations 2000).
- Special Purpose Zone (IUCN category VI)—managed to allow specific activities though special purpose management arrangements while conserving ecosystems, habitats and native species. The zone allows or prohibits specific activities.
- Sanctuary Zone (IUCN category Ia)—managed to conserve ecosystems, habitats and native species in as natural and undisturbed a state as possible. The zone allows only authorised scientific research and monitoring.

- National Park Zone (IUCN category II)—managed to protect and conserve ecosystems, habitats and native species in as natural a state as possible. The zone only allows non-extractive activities unless authorised for research and monitoring.
- Recreational Use Zone (IUCN category IV)—managed to allow recreational use, while conserving ecosystems, habitats and native species in as natural a state as possible. The zone allows for recreational fishing, but not commercial fishing.
- Habitat Protection Zone (IUCN category IV)—managed to allow activities that do not harm or cause destruction to seafloor habitats, while conserving ecosystems, habitats and native species in as natural a state as possible.
- Multiple Use Zone (IUCN category VI)—managed to allow ecologically sustainable use while conserving ecosystems, habitats and native species. The zone allows for a range of sustainable uses, including commercial fishing and mining where they are consistent with park values.

Two planned activities are proposed within the Montebello Marine Park Multiple Use Zone (IUCN category VI): Subsea Inspection Maintenance and Repair activities along the existing pipeline (Section 3.4.5.2) and produced water discharge with associated environmental monitoring (Section 3.5.5). The principles for each zone determine what activities are acceptable within a protected area under the EPBC Act. The Australian IUCN Reserve Management Principles for Multiple Use Zone (IUCN category VI) are considered relevant to the scope of this EP are provided in Table 1-5.

Table 1-5: Australian IUCN Reserve Management Principles relevant to the Petroleum Activities Program

Condition number	Principle
7.01	The reserve or zone should be managed mainly for the sustainable use of natural ecosystems based on the following principles.
7.02	The biological diversity and other natural values of the reserve or zone should be protected and maintained in the long term.
7.03	Management practices should be applied to ensure ecologically sustainable use of the reserve or zone.
7.04	Management of the reserve or zone should contribute to regional and national development to the extent that this is consistent with these principles.

For the North West Marine Parks Network Management Plan (2018) petroleum activities including transportation of minerals by pipeline, and oil spill response are permittable subject to approval in Multiple Use Zone (IUCN category VI) and Special Purpose Zone Trawl (IUCN category VI). Proposed mining operations conducted under usage rights that existed immediately before the declaration of a marine park do not require approval.

Petroleum Activities (including environmental monitoring in connection with a particular petroleum activity) occurring within these zones are approved by a class approval (Director of National Parks 2018a). Conditions of the Class Approval that are considered relevant to the scope of this EP are provided in Table 1-6.

Table 1-6: Conditions of Class Approval relevant to the Petroleum Activities Program

Condition number	Condition	Relevant section of the EP
1	The Approved Actions must be conducted in accordance with: (a) an Environment Plan accepted under the Offshore Petroleum and Greenhouse Gas Storage (Environment) Regulations 2023; - (b) the EPBC Act; (c) the EPBC Regulations (d) the North-west Network Management Plan; (e) any prohibitions, restrictions or determinations made under the EPBC Regulations by the Director of National Parks; and (f) all other applicable Commonwealth and state laws (to the extent those laws are capable of operating concurrently with the laws and instruments described in paragraphs (a) to (e)).	Conditions 1a, b, c, f are met by the submitted EP (Section 1.2) 1d The impacts on the marine park values have been considered in Section 6.7.2, 6.7.5 and 6.7.7. 1e Consultation has been undertaken with the Director of National Parks and no prohibitions, restrictions or determinations have been made (Section 5).
2	If requested by the Director of National Parks, an Approved Person must notify the Director prior to conducting Approved Actions within Approved Zones.	Section 5 describes requirements to notify the DNP prior to activities within the Montebello Multiple Use Zone.
3	If requested by the Director of National Parks, an Approved Person must provide the Director with information relating to undertaking the Approved Actions (or gathered while undertaking the Approved Actions), that is relevant to the Director's management of the Approved Zones.	If requested by the Director of National Parks, information relating to undertaking the Approved Actions (or gathered while undertaking the Approved Actions), that is relevant to the Director's management of the Approved Zones will be provided.

1.9.6 World Heritage Properties

Australian World Heritage management principles are prescribed in Schedule 5 of the EPBC Regulations 2000. Management principles that are considered relevant to the scope of this EP are provided in Table 1-7.

Table 1-7: Relevant Management Principles under Schedule 5—Australian World Heritage management principles of the EPBC Act.

Number	Principle	Relevant Section of the EP
3	Environmental impact assessment and approval 3.01 This principle applies to the assessment of an action that is likely to have a significant impact on the World Heritage values of a property (whether the action is to occur inside the property or not). 3.02 Before the action is taken, the likely impact of the action on the World Heritage values of the property should be assessed under a statutory environmental impact assessment and approval process. 3.03 The assessment process should: identify the World Heritage values of the property that are likely to be affected by the action; and examine how the World Heritage values of the property might be affected; and provide for adequate opportunity for public consultation. 3.04 An action should not be approved if it would be inconsistent with the protection, conservation, presentation or transmission to future generations of the World Heritage values of the property. 3.05 Approval of the action should be subject to conditions that are necessary to ensure protection, conservation, presentation or transmission to future generations of the World Heritage values of the property. 3.06 The action should be monitored by the authority responsible for giving the approval (or another appropriate authority) and, if necessary, enforcement action should be taken to ensure compliance with the conditions of the approval.	3.01 and 3.02: Assessment of significant impact on World Heritage values is included in Section 6. Principles are met by the submitted EP. 3.03 (a) and (b): World Heritage values are identified in Section 4.8 and considered in the assessment of impacts and risks for the Petroleum Activity in Section 6. 3.03l): Relevant persons consultation and feedback received in relation to impacts and risks to the Ningaloo World Heritage Property are outlined in Section 5 3.04, 3.05 and 3.06: Principles are considered to be met by the acceptance of this EP.

Note that Section 1 – General Principles and 2 – Management Planning of Schedule 5 are not considered relevant to the scope of this EP and, therefore, have not been included.

2. ENVIRONMENT PLAN PROCESS

2.1 Overview

This section outlines the process taken by Woodside to prepare this EP, once the activity was defined as a petroleum activity. The process describes the activity, the existing environment, followed by the environmental risk management methodology used to identify, analyse and evaluate risks to meet ALARP levels and acceptability requirements, and develop EPOs and EPSs. This section also describes Woodside's risk management methodologies as applied to implementation strategies for the activity.

Regulation 21(5) of the Environment Regulations requires the EP to include details of the environmental impacts and risks for the Petroleum Activities Program, and an evaluation of all the impacts and risks, appropriate to the nature and scale of each impact and risk. The objective of the risk assessment process described in this section is to identify risks and associated impacts of an activity, so they can be assessed, and appropriate control measures applied to eliminate, control or mitigate the impact/risk to ALARP, and to determine if the impact or risk level is acceptable.

Environmental impacts and risks include those directly and indirectly associated with the Petroleum Activities Program, and include potential emergency and accidental events:

- Planned activities have the inherent potential to cause environmental impacts
- Environmental risks are unplanned events with the potential for environmental impact (termed risk 'consequence').

In this Section, potential impacts from planned activities are termed 'impacts', and 'risks' are associated with unplanned events with the potential for environmental impact (should the risk be realised), with such impacts termed potential 'consequences'.

2.2 Environmental Risk Management Methodology

2.2.1 Woodside Risk Management Process

Woodside recognises that risk is inherent to its business and that effective management of risk is vital to delivering on company objectives, success and continued growth. Woodside is committed to managing risk proactively and effectively. The objective of Woodside's risk management system is to provide a consistent process for recognising and managing risks across Woodside's business. Achieving this objective includes ensuring risks consider impacts across these key areas of exposure: health and safety, environment, finance, reputation and brand, legal and compliance, and social and cultural.

The environmental risk management methodology used in this EP is based on Woodside's Risk Management Procedure. This procedure aligns to industry standards, such as international standard ISO 31000. WMS risk management procedures, guidelines and tools provide guidance of specific techniques for managing risk, tailored for particular areas of risk within certain business processes. Procedures applied for environmental risk management include (Section 0):

- Health, Safety and Environment Management Procedure
- Impact Assessment Procedure
- Process Safety Management Procedure.

The risk management methodology provides a framework to demonstrate that risks and impacts are continually identified, reduced to ALARP and assessed to be at an acceptable level, as required by the Environment Regulations. The key steps of Woodside's Risk Management Process are shown in Figure 2-1. A description of each step and how it is applied to the scopes of this activity is provided in Section 2.2 to Section 2.12.

Figure 2-1: Woodside's Risk Management Process

2.2.2 Health, Safety and Environment Management Procedure

The Health, Safety and Environment Management Procedure provides the structure for managing health, safety and environment (HSE) risks and impacts across Woodside, defines the decision authorities for company-wide HSE management activities and deliverables, and supports continuous improvement in HSE management.

2.2.3 Impact Assessment Procedure

To support effective environmental risk assessment, Woodside's Impact Assessment Procedure (Figure 2-2) provides the steps to meet the required environment, health and social standards by ensuring impact assessments are undertaken appropriate to the nature and scale of the activity, the regulatory context, the receiving environment, interests, concerns and rights of relevant persons, and the applicable framework of standards and practices.

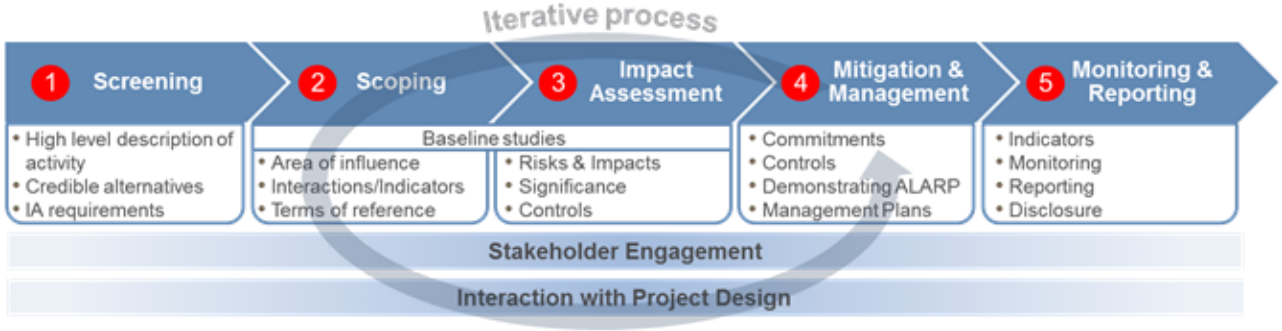

Figure 2-2: Woodside's Impact Assessment Process

2.2.4 Process Safety Management Procedure and Process Safety Risk Assessment Procedure

Due to the nature and scale of petroleum activities, Woodside's Process Safety Management Procedure establishes Woodside's framework for Process Safety Management (Section 7.2.5). This framework includes the Process Safety Risk Assessment Procedure (PSRA). The PSRA is a key part of Woodside's process safety management framework for managing the integrity of systems and processes that handle hazardous substances over the exploration and production lifecycle. The PSRA sets out methods so that process safety risks are understood and controlled, including that all process safety hazards are systematically identified, assessed and treated so that the associated risks are reduced to a level that is tolerable and ALARP.

2.3 Environment Plan Development Process

The EP development process is illustrated in Figure 2-3. Each element of this process is discussed further in Section 2.5 to Section 2.12.

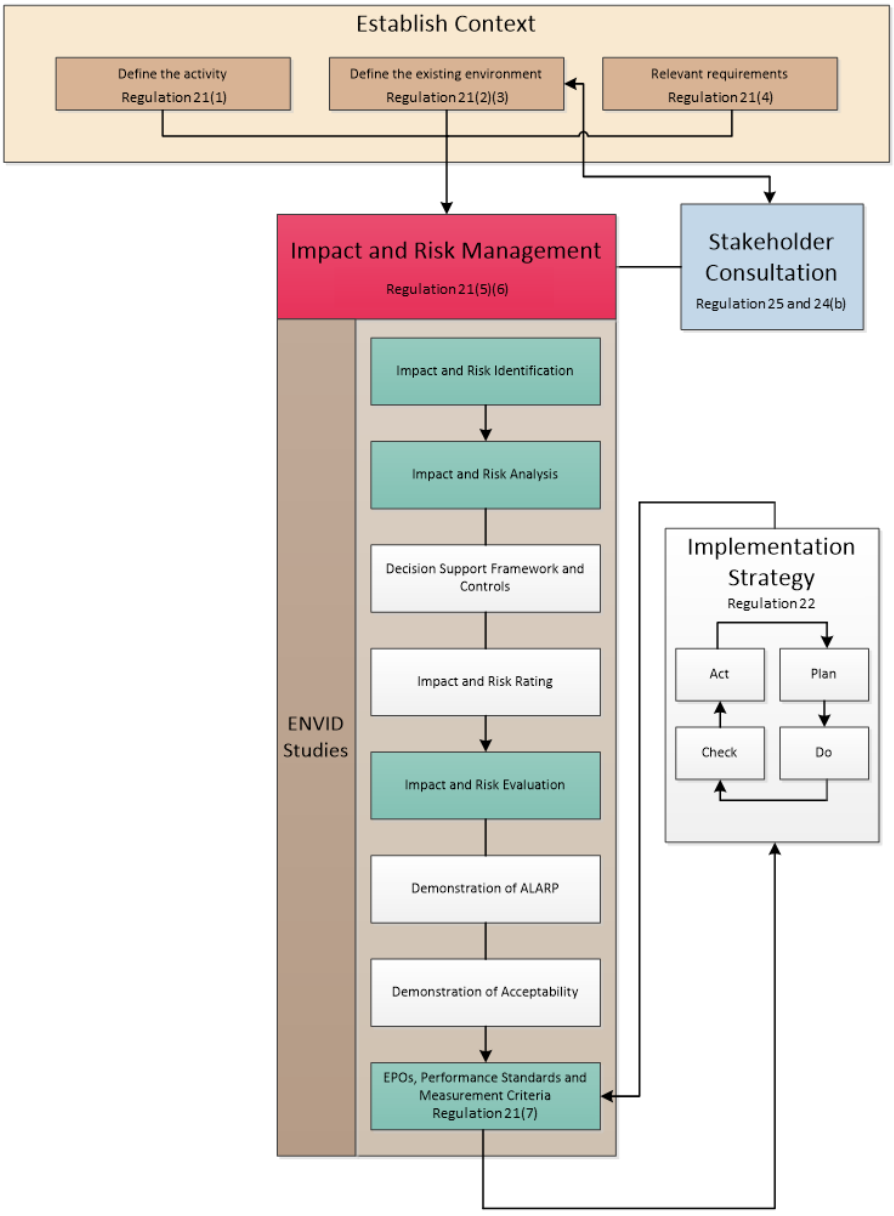

Figure 2-3: Environment Plan Development Process

2.4 Establish the Context

2.4.1 Define the Activity

This first stage involves evaluating whether the activity meets the definition of a 'petroleum activity' as defined in the Environment Regulations. The activity is described in relation to:

- the location
- what is to be undertaken
- how it is planned to be undertaken, including outlining operational details of the activity and proposed timeframes.

The 'what' and 'how' are described in the context of 'environmental aspects'[4] to inform the risk and impact assessment for planned (routine and non-routine) and unplanned (accidents/ incidents/ emergency conditions) activities.

The activity is described in Section 3 and is referred to as the Petroleum Activities Program.

2.4.2 Define the Existing Environment

The context of the existing environment is described and determined by considering the nature and scale of the activity (size, type, timing, duration, complexity, and intensity of the activity), as described in Section 4. The purpose is to describe the existing environment that may be impacted by the activity, directly or indirectly, by planned or unplanned[5] events.

The Existing Environment (Section 4) is structured into subsections defining the physical, biological, socio-economic and cultural attributes of the area of interest, in accordance with the definition of environment in Regulation 5 of the Environment Regulations. These subsections make particular reference to:

- The environmental, and social and cultural consequences as defined by Woodside (refer to Table 2-1), which address key physical and biological attributes, as well as social and cultural values of the existing environment. These consequence definitions are applied to the impact and risk analysis (refer Section 2.2) and rated for all planned and unplanned activities. Additional detail is provided for unplanned hydrocarbon spill risk evaluation.
- EPBC Act MNES including listed threatened species and ecological communities and listed Migratory species. Defining the spatial extent of the existing environment is guided by the nature and scale of the Petroleum Activities Program (and associated sources of environmental risk). This considers the PAA and wider environment that may be affected (EMBA), as determined by the hydrocarbon spill risk assessments. MNES, as defined under the EPBC Act, are addressed through Woodside's impact and risk assessment (Section 6).
- Relevant values and sensitivities, which may include world or national heritage listed areas, listed Threatened species or ecological communities, listed Migratory species, or sensitive values.

By grouping potentially impacted environmental values by aspect (as presented in Table 2-1), the presentation of information about the receiving environment is standardised. This information is then

[4] An environmental aspect is an element of the activity that can interact with the environment.

[5] For each source of risk, the credible worst-case scenario in conjunction with impact thresholds is used to determine the spatial extent of the EMBA. The worst-case unplanned event is considered to be an unplanned hydrocarbon release, further defined for each activity through the risk assessment process. Interpretation of stochastic oil spill modelling determines the EMBA for the release, which defines the spatial scale of the environment that may be potentially impacted by the Petroleum Activities Program and in turn provides context to the 'nature and scale' of the existing environment.

consistently applied to the risk evaluation section to provide a robust approach to the overall environmental risk evaluation and its documentation in the EP.

Table 2-1: Example of the Environment Values Potentially Impacted which are Assessed within the Environment Plan

Environmental Value Potentially Impacted Regulations 21(2)(3)						
Soil and Groundwater	Marine Sediment	Water Quality	Air Quality (incl Odour)	Ecosystems / Habitats	Species	Socio-economic

2.4.3 Relevant Requirements

The relevant requirements in the context of legislation, other environmental approval requirements, conditions and standards that apply to the Petroleum Activities Program are identified and reviewed; and are presented in Appendix B.

The Woodside Risk Management Policy, Climate Policy as well as Environment and Biodiversity Policy are presented in Appendix A.

2.5 Impact and Risk Identification

Relevant environmental aspects and hazards were identified that support the process to define environmental impacts and risks associated with an activity.

The environmental impact and risk assessment presented in this EP has been informed by recent and historic hazard and environmental risk identification studies (e.g. HAZID/ENVID), consequence modelling studies for high consequence, low probability environmental risks, bowtie risk assessments for MEEs as required by Woodside's PSRA processes, desktop reviews and studies associated with the Petroleum Activities Program. Impacts, risks and potential consequences were identified based on planned activities and unplanned events (based on the description in Section 3), the existing environment (Section 4) and the outcomes of Woodside's consultation process (Section 5). The environmental outputs of applicable risk and impact workshops and associated studies are referred to as ENVID in this EP.

An environmental impacts and risks identification and assessment workshop was undertaken by multidisciplinary teams comprising relevant operational and environmental personnel with sufficient breadth of knowledge, training and experience to reasonably assure that risks and impacts were identified, and their potential environmental consequences assessed. Impacts and risks were identified, during the workshop, for both planned (routine and non-routine) activities and unplanned (accidents/incidents/emergency conditions) events. During this process, risks identified as not applicable (not credible) were removed from the assessment.

Impacts and risks were evaluated and tabulated for each planned activity and unplanned events respectively. Environmental impacts and risks were recorded in an environmental impacts and risk register. The output of the workshop is used to present the risk assessment and form the basis of performance outcomes, standards, and measurement criteria. This information is presented in Section 6, following the format presented in Table 2-2.

Table 2-2: Example of Layout of Identification of Risks and Impacts in Relation to Risk Sources

Impacts and Risks Evaluation Summary														
Source of Risk	***Environmental Value Potentially Impacted***							***Evaluation***						
	Soil and Groundwater	Marine Sediment	Water Quality	Air Quality (incl Odour)	Ecosystems / Habitat	Species	Socio-economic	Decision Type	Consequence / Impact	Likelihood	Risk Rating	ALARP Tool	Acceptability	Outcome
Summary of source of impact / risk														

2.6 Impact and Risk Analysis

Risk analysis further develops the understanding of a risk by defining the impacts and assessing appropriate controls, as well as considering previous risk assessments for similar activities, relevant studies, past performance, external consultation feedback, and the existing environment.

These key steps were undertaken for each identified risk during the risk assessment:

- identify the Decision Type in accordance with the decision support framework.
- identify appropriate control measures (preventive and mitigation) aligned with the Decision Type
- assess the risk rating.

2.6.1 Decision Support Framework

To support the risk assessment process and Woodside's determination of acceptability (Section 2.8.2), Woodside's HSE risk management procedures include the use of a decision support framework based on principles set out in the Guidance on Risk Related Decision Making (Oil and Gas UK, 2014). This concept is integrated into the environmental impacts and risks identification and assessment workshop to determine the level of supporting evidence that may be required to draw sound conclusions regarding risk level and whether the risk is acceptable and ALARP (Section 2.8). Application of the decision support framework confirms:

- activities do not pose an unacceptable environmental risk.
- appropriate focus is placed on activities where the impact or risk is anticipated to be acceptable and demonstrated to be ALARP.
- appropriate effort is applied to manage risks and impacts based on the uncertainty of the risk, the complexity and risk rating (i.e., potential higher order environmental impacts are subject to further evaluation/assessment).

The framework provides appropriate tools, commensurate to the level of uncertainty or novelty associated with the risk/impact (referred to as the Decision Type A, B, or C). The Decision Type is selected based on an informed discussion around the uncertainty of the risk/impact and is documented in impact and risk register worksheets.

This framework enables Woodside to appropriately understand a risk and determine if the risk or impact is acceptable and can be demonstrated to be ALARP.

2.6.1.1 Decision Type A

Decision Type A risks and impacts are well understood and established practice. They are generally recognised as good industry practice and are often embodied in legislation, codes and standards, and utilise professional judgment.

2.6.1.2 Decision Type B

Decision Type B risks and impacts typically involve greater uncertainty and complexity; and can include potential higher-order impacts/risks. These risks may deviate from established practice or have some lifecycle implications and therefore require further engineering risk assessment to support the decision and so that the risk is ALARP. Engineering risk assessment tools may include:

- risk-based tools such as cost-based analysis or modelling
- consequence modelling
- reliability analysis
- company values.

2.6.1.3 Decision Type C

Decision Type C risks and impacts typically have significant risks related to environmental performance. Such risks typically involve greater complexity and uncertainty therefore requiring the adoption of the precautionary approach. The risks may result in significant environmental impact, significant project risk/exposure, or may elicit negative stakeholder concerns. For these risks or impacts, in addition to Decision Type A and B tools, company and societal values need to be considered by undertaking broader internal and external consultation as part of the risk assessment process.

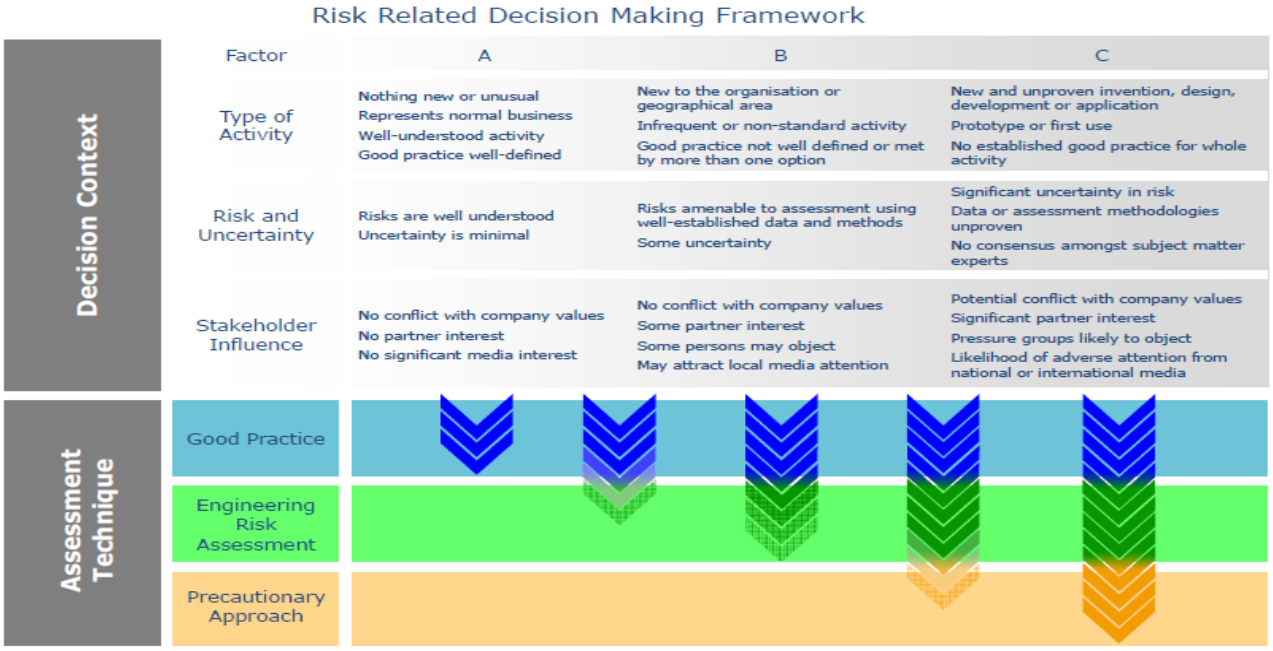

Figure 2-4: Risk-related Decision-making Framework (Oil and Gas UK, 2014)

2.6.1.4 Decision Support Framework Tools

These framework tools are applied, as appropriate, to help identify control measures based on the Decision Type described above:

- Legislation, Codes and Standards (LCS) – identifies the requirements of legislation, codes and standards that are to be complied with for the activity.
- Good Industry Practice (GP) – identifies further engineering control standards and guidelines that may be applied by Woodside above that required to meet the LCS.
- Professional Judgement (PJ) – uses relevant personnel with the knowledge and experience to identify alternative controls. Woodside applies the hierarchy of control as part of the risk assessment to identify any alternative measures to control the risk.
- Risk-based Analysis (RBA) – assesses the results of probabilistic analyses such as modelling, quantitative risk assessment and/or cost–benefit analysis to support the selection of control measures identified during the risk assessment process.
- Company Values (CV) – identifies values identified in Woodside's code of conduct, policies and Our Values. Views, concerns and perceptions are to be considered from internal Woodside stakeholders directly affected by the planned impact or potential risk.
- Societal Values (SV) – identifies the views, concerns and perceptions of relevant persons and addresses relevant stakeholder views, concerns and perceptions.

2.6.1.5 Decision Calibration

To determine that the alternatives selected, and control measures applied are suitable, these tools may be used for calibration (i.e., checking) where required:

- LCS/Verification of Predictions – Verification of compliance with applicable LCS and/or good industry practice.
- Peer Review – Independent peer review of PJs, supported by RBA, where appropriate.
- Benchmarking – Where appropriate, benchmarking against a similar facility or activity type or situation that has been deemed to represent acceptable risk.
- Internal Consultation – Consultation undertaken within Woodside to inform the decision and verify company values are met.
- External Consultation – Consultation undertaken to inform the decision and verify societal values are considered.

Where appropriate, additional calibration tools may be selected specific to the Decision Type and the activity.

2.6.2 Control Measures (Hierarchy of Controls)

Risk reduction measures are prioritised and categorised in accordance with the hierarchy of controls, where risk reduction measures at the top of the hierarchy take precedence over risk reduction measures further down:

- Elimination of the risk by removing the hazard.
- Substitution of a hazard with a less hazardous one.
- Engineering Controls include design measures to prevent or reduce the frequency of the risk event, or detect or control the risk event (limiting the magnitude, intensity and duration) such as:
- Prevention: design measures that reduce the likelihood of a hazardous event occurring.
- Detection: design measures that facilitate early detection of a hazardous event.
- Control: design measures that limit the extent/escalation potential of a hazardous event.

- Mitigation: design measures that protect the environment if a hazardous event occurs.
- Response Equipment: design measures or safeguards that enable clean-up/response after a hazardous event occurs.
- Procedures and Administration includes management systems and work instructions used to prevent or mitigate environmental exposure to hazards.
- Emergency Response and Contingency Planning includes methods to enable recovery from the impact of an event (e.g., protection barriers deployed near the sensitive receptor).

2.6.3 Impact and Risk Classification

Environmental impacts and risks are assessed to determine the potential impact significance/consequence. The impact significance/consequence considers the magnitude of the impact or risk and the sensitivity of the potentially impacted receptor (Figure 2-5).

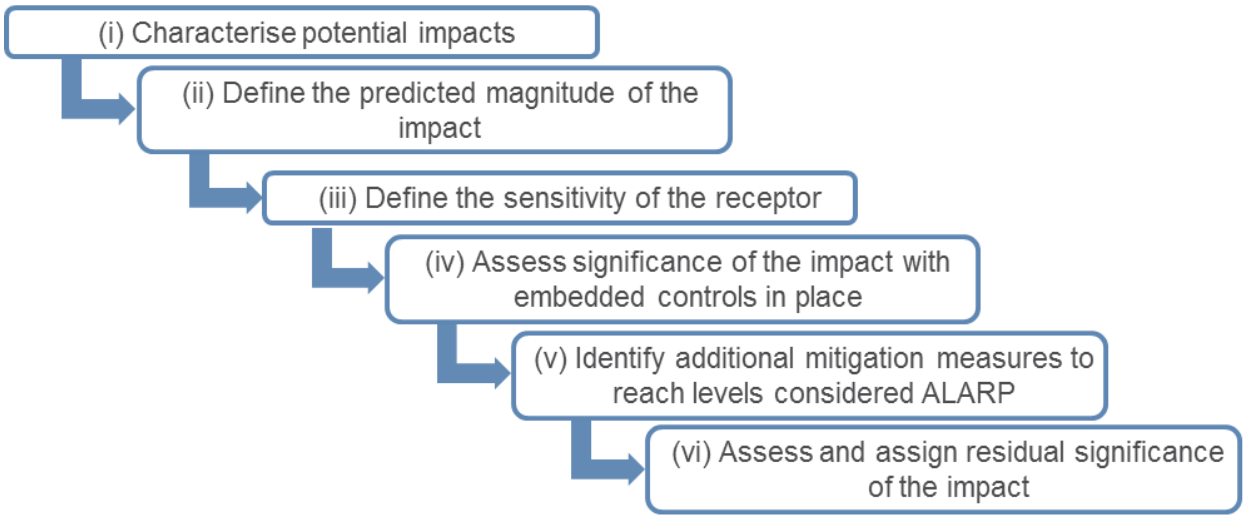

Figure 2-5: Environmental Risk and Impact Analysis

Impacts are classified in accordance with the consequence (Table 2-3) outlined in Woodside's Risk Management Procedure and Risk Matrix (Figure 2-6). Risks are assessed qualitatively and/or quantitatively in terms of both likelihood and consequence in accordance with this matrix.

The impact and risk information, including classification and evaluation information as shown in the example (Table 2-2), are tabulated for each planned activity and unplanned event.

Table 2-3: Woodside Risk Matrix (Environment and Social and Cultural) Consequence Descriptions

Environment	Social and Cultural	Consequence Level
Catastrophic, long-term impact (>50 years) on highly valued ecosystem, species, habitat or physical or biological attribute.	Catastrophic, long-term impact (>20 years) to a community, social infrastructure or highly valued area/item of international cultural significance.	A
Major, long-term impact (10–50 years) on highly valued ecosystem, species, habitat or physical or biological attribute.	Major, long-term impact (5–20 years) to a community, social infrastructure or highly valued area/item of national cultural significance.	B
Moderate, medium-term impact (2–10 years) on ecosystem, species, habitat or physical or biological attribute.	Moderate, medium-term impact (2–5 years) to a community, social infrastructure or highly valued area/item of national cultural significance.	C

Environment	Social and Cultural	Consequence Level
Minor, short-term impact (1–2 years) on species, habitat (but not affecting ecosystem function), physical or biological attribute.	Minor, short-term impact (1–2 years) to a community or highly valued area/item of cultural significance.	D
Slight, short-term impact (<1 year) on species, habitat (but not affecting ecosystem function), physical or biological attribute.	Slight, short-term impact (<1 year) to a community or area/item of cultural significance.	E
No lasting effect (<1 month). Localised impact not significant to environmental receptor.	No lasting effect (<1 month). Localised impact not significant to area/item of cultural significance.	F

2.6.4 Risk Rating Process

The risk rating process assigns a level of risk to each risk event, measured in terms of consequence and likelihood. The assigned risk rating is determined with controls in place, therefore; the risk rating is determined after identifying the Decision Type and appropriate control measures.

The risk rating process considers the potential environmental consequences and, where applicable, the social and cultural consequences of the risk. The risk ratings are assigned using the Woodside Risk Matrix (refer to Figure 2-6).

The risk rating process is done using the steps described in the subsections below.

2.6.5 Select the Consequence Level

Determine the worst-case credible consequence (Table 2-3) associated with the selected event, assuming all controls (preventive and mitigative) are absent or have failed. If more than one potential consequence applies, select the highest severity consequence level.

2.6.6 Select the Likelihood Level

Determine the description that best fits the chance of the selected consequence occurring, assuming reasonable effectiveness of the prevention and mitigation controls (Table 2-4).

Table 2-4: Woodside Risk Matrix Likelihood Levels

Likelihood Description						
Frequency	1 in 100,000–1,000,000 years	1 in 10,000–100,000 years	1 in 1,000–10,000 years	1 in 100–1,000 years	1 in 10–100 years	>1 in 10 years
Experience	Remote: Unheard of in the industry	Highly Unlikely: Has occurred once or twice in the industry	Unlikely: Has occurred many times in the industry but not at Woodside	Possible: Has occurred once or twice in Woodside or may possibly occur	Likely: Has occurred frequently at Woodside or is likely to occur	Highly Likely: Has occurred frequently at the location or is expected to occur
Likelihood Level	0	1	2	3	4	5

2.6.7 Calculate the Risk Rating

The risk rating is derived from the consequence and likelihood levels above, in accordance with the Woodside Risk Matrix shown in Figure 2-6. A likelihood and risk rating are only applied to environmental risks, not environmental impacts from planned activities.

This risk rating is used as an input into the risk evaluation process and ultimately for prioritising further risk reduction measures. Once each risk is treated to ALARP, the risk rating articulates the ALARP baseline risk as an output of the ENVID studies.

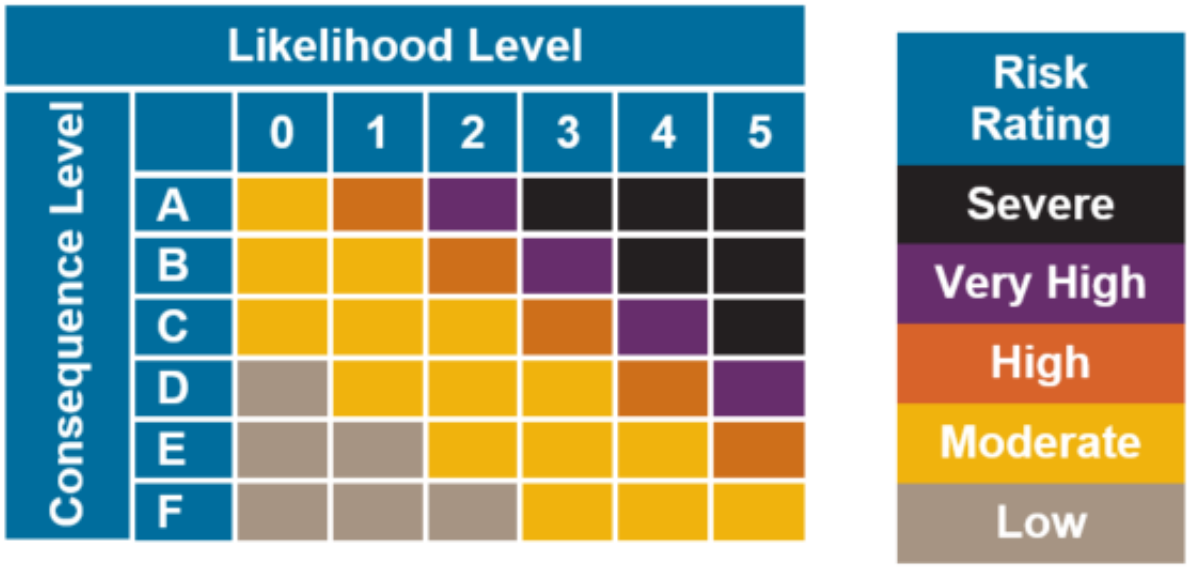

Figure 2-6: Woodside Risk Matrix – Risk Level

To support ongoing risk management (as a key component of Woodside's Process Safety Management Framework – refer to the implementation strategy in Section 7), Woodside uses the concept of 'current risk' and applies a Current Risk Rating to indicate the current or 'live' level of risk, considering controls that are currently in place and effective on a day-to-day basis. The Current Risk Rating is effective in articulating potential divergence from baseline risk, such as if certain controls fail or could potentially be compromised. Current Risk Ratings aid in communicating and making visible the risk events and for the continual management of risk to ALARP by identifying risk reduction measures and assessing acceptability.

2.7 Classification and Analysis of Major Environment Events

For Woodside's production facilities, a further level of analysis is undertaken to identify, classify and analyse MEEs. This extra level of rigour is applied so that sufficient controls are in place for risks with potential Level B and above consequences. In the health and safety area, Major Accident Events (MAEs) are identified using a similar process, which supports consistency in managing key risks within Woodside in accordance with Process Safety Risk Management Procedures.

Woodside defines a MEE as an event with potential environment, reputation (pertaining to environment events), social or cultural consequences of level B or higher as per Woodside's Risk Matrix (Figure 2-6). MEEs are evaluated against credible worst-case scenarios that may occur when all controls are absent or have failed.

2.7.1 Major Environment Event Identification

The ENVID process identifies numerous sources of risk with differing consequence levels. These risks are screened for those risk events that meet the MEE criteria, and MEE risks are analysed further through detailed consequence modelling and probability/ frequency studies and examined for 'appropriateness' of controls in a bowtie risk assessment.

Risks that do not meet the MEE definition, although screened out of the MEE process, are still evaluated for ALARP and risk acceptability using the methodology described in Section 2.8. Some high consequence/low probability events which do not meet the MEE consequence threshold may still undergo additional consequence and probability assessment where they could have a high

adverse impact on the company's reputation or relationships with relevant persons, beyond requirement to demonstrate ALARP and acceptable risk levels following application of controls.

2.7.2 MEE Classification

A standard naming convention has been established for MEEs which is based around ensuring the MEE titles reflect the cause of the event (e.g. 'subsea system loss of containment') rather than the event itself (e.g. significant hydrocarbon spill to the marine environment). The MEEs are assigned a unique identification code (e.g. MEE-01, MEE-02, etc).

2.7.3 Bowtie Analysis

MEEs are subject to more detailed analysis using the bowtie risk assessment technique, which illustrates cause outcome pathways for each MEE and controls in place to prevent the 'top event' or mitigate the consequences (outcomes). The key drivers for adopting the bowtie technique for MEEs are that it:

- identifies the controls (prevention and mitigation barriers) necessary so that the risk is acceptable and ALARP.
- supports the process of demonstrating ALARP (described in Section 2.8.1).
- enables verification of and linking to the relevant sections of the WMS that supports barriers.
- improves the capacity for lessons learnt and incident prevention by being able to directly relate causes of an incident to those controls that failed.
- ensures greater visibility and granularity in the assessment process and enables complex risk scenarios to be presented in an easy to understand format.

The bowtie technique (an example bowtie diagram is shown in Figure 2-7) shows the relationships between the 'Causes' that may lead to a particular unwanted event ('Top Event'), together with the range of potential escalation paths that can lead to a variety of 'Outcomes' (or consequences). A bowtie also shows the preventive barriers that may prevent a Top Event from occurring specific to each Cause, and the mitigation barriers in place to limit the potential effects once the Top Event has been realised, specific to each credible MEE Outcome.

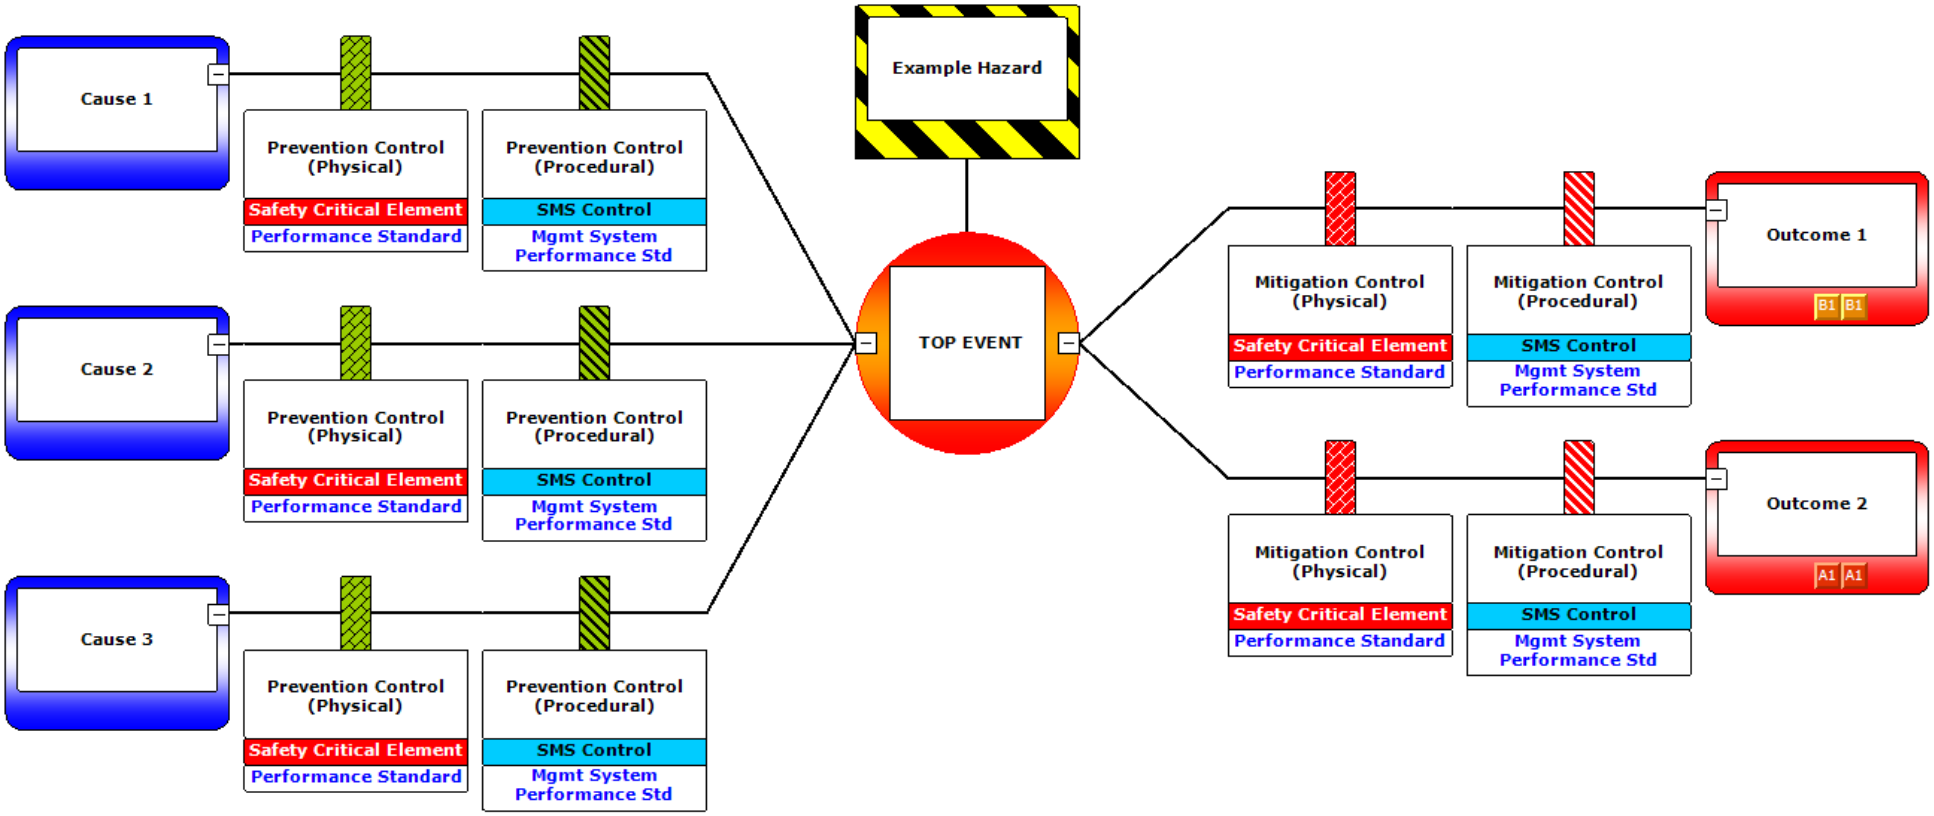

Figure 2-7: Example of Bowtie Diagram Structure

2.7.4 MEE Register

A MEE Register is prepared for each production facility after completing the bowtie diagrams. The purpose of the MEE Register is to record the MEE identification process, groupings, bowtie diagrams and datasheets in a consolidated format. Datasheets are prepared for each MEE, which summarise the hazard description, hazard management, emergency response, ALARP summary and a list of critical barriers identified on the bowties (known as Safety and Environment Critical Elements (SCEs)).

Potential common causes that contribute to MAEs/MEEs, or that can result in failure or degradation of the controls in place to protect against MAEs/MEEs, include some generic mechanisms of SCE failure and generic human error. These are represented in bowties applicable to multiple MEEs and identified in the MEEs applicable to this EP.

2.7.5 Safety and Environment Critical Elements and Technical Performance Standards

Woodside identifies and manages SCEs technical and management system performance standards in accordance with Process Safety Management Procedures, Risk Management Procedures and Change Management Procedures (further described in the implementation strategy in Section 7). SCEs are identified for MAEs and MEEs. An SCE is a hardware control, the failure of which could cause or contribute substantially to, or the purpose of which is to prevent or limit the effect of a MAE, MEE or Process Safety Event. In addition, Woodside defines Safety and Environment Critical Component (SCC) as an item of equipment or structure forming part of a hardware SCE that supports the SCE in achieving the safety function.

Once an SCE is identified as an MEE barrier for the operated facility, technical performance requirements are developed for the facility SCE in accordance with the Global SCE Performance Standards and process described in the SCE Management Procedure and form the SCE Facility Performance Standard. Each SCE Performance Standard represents a statement of the performance required of an SCE (e.g., functionality, availability, reliability, survivability). SCE Performance Standard requirements are used to establish agreed assurance tasks for each SCE, support the management of operations within acceptable safety and/or environment risk levels, and for the continuous management of risk to ALARP. An assurance task is an activity carried out by the operator to confirm that the SCE meets, or will meet, its SCE Performance Standard. Examples of assurance tasks include inspection routines, maintenance activities, test routines, instrumentation calibration, and reliability monitoring.

SCE Facility Performance Standards do not always align directly with EPSs. They are used in conjunction with the WMS to identify and treat potential step-outs from expected controls performance or integrity envelopes and so that SCE performance can be optimised. Woodside's HSE Event Reporting Guideline describes the process for identifying 'Failure to meet Facility Performance Standard', which is when the SCE does not meet the goal as stated in the relevant Performance Standard. (see Section 7.4). Situations where SCEs fail to meet Facility Performance Standards represent a potential increase in risk that, if not addressed immediately, have the potential to result in a process safety event, or worsen the consequences of one. Recording SCE Failure to Meet Performance Standard Events into the Event Reporting Database is important to highlight risk, investigate causes, manage risks and meet potentially applicable external reporting requirements. For applicable SCEs, 'Failure to meet Facility Performance Standard' represent scenarios that may fail to achieve an EPS presented in this EP.

The results of the MEE classification and analysis for Pluto Offshore operations are presented in Section 6.8.1 of this EP. More detail on the SCE and Performance Standards process, and the interrelationships to other parts of the SCE Management Procedures, is described in Section 7.4.

2.7.6 Safety-critical Management System Barriers

For each MEE, Safety-critical Management System specific measures are also identified. These are management system components (generally WMS processes) that are key barriers to, or measures for, managing MEEs.

2.8 Impact and Risk Evaluation

Environmental impacts and risks cover a wider range of issues, differing species, persistence, reversibility, resilience, cumulative effects, and variability in severity than safety risks. Determining the degree of environmental risk, and the corresponding threshold for whether a risk/impact has been reduced to ALARP and is acceptable, is evaluated to a level appropriate to the nature and scale of each impact or risk. Evaluation includes considering the:

- decision type
- principles of ESDev – as defined under the EPBC Act
- internal context – ensuring the proposed controls and risk level are consistent with Woodside policies, procedures and standards (Section 6 and Section 7)
- external context – the environment consequence (Section 6) and stakeholder acceptability (Section 5)
- other requirements – ensuring the proposed controls and risk level are consistent with national and international standards, laws and policies.

In accordance with Regulations 34(a), 34(b), 34(c) and 34(b), Woodside applies the process described in the subsections below to demonstrate ALARP and acceptability for environmental impacts and risks, appropriate to the nature and scale of each impact or risk.

2.8.1 Demonstration of ALARP

The descriptions in Table 2-5 articulate how Woodside demonstrates that different risks, impacts and Decision Types identified within the EP are ALARP.

Table 2-5: Summary of Woodside's Criteria for ALARP Demonstration

Risk	Impact	Decision Type
Low and Moderate	***Negligible, Slight, or Minor (D, E or F)***	***A***
Woodside demonstrates these risks, impacts and Decision Types are reduced to ALARP if: identified controls meet legislative requirements, industry codes and standards, applicable company requirements and industry guidelines, or further effort towards impact/risk reduction (beyond using opportunistic measures) is not reasonably practicable without sacrifices that are grossly disproportionate to the benefit gained.		
High, Very High or Severe	***Moderate and above (C, B or A)***	***B and C***
Woodside demonstrates these higher order Risks, Impacts and Decision Types are reduced to ALARP (where it can be demonstrated using good industry practice and risk-based analysis) that: legislative requirements, applicable Woodside requirements and industry codes and standards are met; societal concerns are accounted for; and the alternative control measures are grossly disproportionate to the benefit gained.		

2.8.2 Demonstration of Acceptability

The descriptions in Table 2-6 articulate how Woodside demonstrates how different risks, impacts and Decision Types identified within the EP are Acceptable.

Table 2-6: Summary of Woodside's Criteria for Acceptability

Risk	Impact	Decision Type
Low and Moderate	***Negligible, Slight, or Minor (D, E or F)***	***A***
Woodside demonstrates these risks, impacts and Decision Types are 'Broadly Acceptable' if they meet legislative requirements, industry codes and standards, applicable company requirements and industry guidelines. Further effort towards risk reduction (beyond using opportunistic measures) is not reasonably practicable without sacrifices that are grossly disproportionate to the benefit gained.		
High, Very High or Severe	***Moderate and above (C, B or A)***	***B and C***
Woodside demonstrates these higher order Risks, Impacts and Decision Types are 'Acceptable if ALARP' if it can be demonstrated using good industry practice and risk based analysis (RBA), if legislative requirements are met and societal concerns are accounted for and the alternative control measures are grossly disproportionate to the benefit gained. In undertaking this process for Moderate and High risks, Woodside evaluates: • the Principles of ESD as defined under the EPBC Act • the internal context – the proposed controls and consequence/risk level are consistent with Woodside policies, procedures and standards • the external context – consideration of the environment consequence (Section 6) and stakeholder acceptability (Section 5) are considered • other requirements – the proposed controls and consequence/risk level are consistent with national and international industry standards, laws and policies ad consideration of applicable plans for management and conservation advices, conventions and significant impact guidelines (e.g. MNES). For potential C or above consequence/impact levels where significant uncertainty exists in analysis of the risk or impact (such as, for predicted or potential high risk of significant environmental impacts, significant project risk/exposure, novel activities, lack of consensus on standards, and significant stakeholder concerns e.g. Decision Type C), acceptability may be required to be conducted separately for key receptors. This is not applicable for risks, given the consequence of an unplanned risk event occurring may not be acceptable and, therefore, acceptability is demonstrated in the context of the residual likelihood of an event occurring and subsequent impacts. Additionally, Very High and Severe risks require 'Escalated Investigation' and mitigation. If after further investigation the risk remains in the Very High or Severe category, the risk requires appropriate business engagement with increasing involvement of senior management in accordance with Woodside's Risk Management Procedure to accept the risk. This includes due consideration of regulatory requirements.		

2.9 Recovery Plan and Threat Abatement Plan Assessment

A separate assessment is undertaken to demonstrate that the EP is not inconsistent with any relevant recovery plans or threat abatement plans (refer Section 6.10). An assessment of associated national objectives and action areas contribute to the demonstration of acceptability. The steps in this process are:

- Identify relevant listed threatened species and ecological communities (Section 4).
- Identify relevant recovery plans and threat abatement plans (Section 6.10).
- List all objectives and (where relevant) the action areas of these plans and assess whether these objectives/action areas apply to government, the Titleholder, and the Petroleum Activities Program (Section 6.9).
- For those objectives and action areas applicable to the Petroleum Activities Program, identify the relevant actions of each plan, and evaluate whether impacts and risks resulting from the activity are clearly not inconsistent with that action (Section 6.10).

2.10 Environmental Performance Outcomes, Environmental Performance Standards, and Measurement Criteria

EPOs, EPSs and MC are defined to address the potential environmental impacts and risks. These are explored in Section 6.

2.11 Implement, Monitor, Review and Reporting

An implementation strategy for the Petroleum Activities Program describes the specific measures and arrangements to be implemented for the duration of the program. The strategy is based on the principles of AS/NZS ISO 14001 Environmental Management Systems, and demonstrates:

- control measures are effective in reducing the environmental impacts and risks of the Petroleum Activities Program to ALARP and Acceptable levels
- EPOs and EPSs set out in the EP are met through monitoring, recording, auditing, managing non-conformance, and reviewing
- all environmental impacts and risks of the Petroleum Activities Program are periodically reviewed in accordance with Woodside's risk management procedures
- roles and responsibilities are clearly defined, and personnel are competent and appropriately trained to implement the requirements set out in this EP, including in emergencies or potential emergencies
- arrangements are in place for oil pollution emergencies, to respond to and monitor impacts
- environmental reporting requirements are met, including 'reportable incidents'
- appropriate consultation is undertaken throughout the activity.

The implementation strategy is presented in Section 7.

2.12 Consultation

Woodside consults relevant persons in the course of preparing an EP in accordance with regulation 25 of the Environment Regulations. Woodside's consultation methodology is presented in Section 5. Woodside's consultation record is at Appendix F.

3. DESCRIPTION OF THE ACTIVITY

3.1 Overview

This section has been prepared in accordance with Regulation 21(1) of the Environment Regulations and describes the activities to be undertaken as part of the Petroleum Activities Program under this EP. It includes the location of the activity, general details of the facility associated infrastructure, the operational details of the activity, and additional information relevant to consideration of environmental risks and impacts.

The Pluto facility currently produces gas and condensate from the Pluto, Pyxis and Xena fields via the Pluto subsea hydrocarbon gathering system (Section 3.4). This EP includes the ongoing operation of the Pluto facility and Xena-03 Drilling and tie-back activities associated with the Xena-03 well, in the Xena field. An overview of the Petroleum Activities Program (PAP) is provided for in Section 1.1 and Table 3-1..

3.1.1 Pluto Facility Operations Overview

The Pluto offshore facility (the facility) and export pipeline is outlined in Figure 3-1. The facility produces wet gas and condensate from the Pluto, Pyxis and Xena fields in Production Licence WA-34-L. The platform is designed to be operated in both not-normally-crewed (NNC) and minimally crewed states. The offshore facilities are remotely operated from the Central Control Room (CCR), either from the Central Control Room at Pluto LNG Park or Remote Central Control Room in Perth. Gas and condensate are transported onshore for processing via a 180 km long export pipeline.

A water handling module has been installed on the riser platform to enable the processing and discharge of produced water at the platform. Wet gas will be processed through the water handling module, with gas and condensate transported to the onshore LNG Plant for processing. These activities are outlined in Table 3-1.

3.1.2 Xena-03 Tie-back Overview

Woodside is resuming plans to drill and complete the Xena-03 infill production well within the Petroleum Activities Program in this EP revision. The work includes drilling one new well in the Xena field, installing an associated wellhead and xmas tree, and connecting the well to the existing Pyxis Hub subsea infrastructure (Section 3.4). The well will be located at approximately 177 m water depth.

The well will be drilled and completed using a moored or hybrid mobile offshore drilling unit (MODU). Typically, two or three support vessels will support the MODU during drilling activities, with at least one vessel in the vicinity to complete standby duties, if required. Supply vessels from Dampier Port will frequent the MODU at regular intervals throughout drilling operations, as required.

Installation of the subsea infrastructure will be undertaken using an installation vessel. Another installation vessel, similar to vessels used for IMMR, may be used to install the xmas tree and for cold commissioning the wells and during start-up (if required). Support vessels associated with subsea installation activities may transit between the PAA and port, however transit activities are not included in the scope of this EP.

The scope for this EP covers the tie-back of the Xena-03 well, including drilling, completion, and subsea installation (including minor changes to existing infrastructure) along with pre commissioning, cold commissioning and start-up. These activities are outlined in Table 3-1 and described in detail in Section 3.4.2.3.

Table 3-1: Petroleum Activities Program overview

Item	Description
Production Licences	WA-1-IL, WA-34-L
Pipeline Licences	WA-16-PL, WA-17-PL
Platform Location	115° 22' 5.582" E 19° 59' 46.476' S
Water depth (lowest astronomical tide (LAT)) at Pluto topsides location	85 m
Key components of the facilities	Fixed platform, processing equipment, pipelines; subsea infrastructure Pluto, Xena and Pyxis wells, wellheads, manifolds, umbilicals, chemical supply lines, risers, flowlines, flexible jumpers.
Key components of pipeline subsea infrastructure	Xmas trees, flowlines/pipelines and umbilicals
Number of wells	11 existing production wells (PLA01, PLA02, PLA03, PLA04, PLA05, PLA06, PLA07, XNA01, XNA02, PYA01, and PL-PYA02) 1 new well to be constructed in 2024 (PLA08) 1 new well proposed to be constructed in 2025 (XNA03)
Subsea infrastructure	Existing: Pluto riser platform Pluto Export Pipeline Pluto/Xena-03/Pyxis subsea infrastructure (including umbilicals and flowlines) Xena-03 Proposed (planned installation Q3, 2025): One subsea xmas tree and wellhead One flexible flowline One set of flying leads One electrohydraulic umbilical (EHU) and associates umbilical termination assemblies (UTAs).
MODU	Moored MODU or hybrid MODU.
Vessels	Pluto Operations: Platform support vessels, ASV, subsea support vessels Xena-03 Tie-back: MODU, MODU support vessels including AHVs, installation vessel/s
Key activities	Pluto Operations: routine production routine inspection, maintenance, monitoring and repair of the platform and associated subsea infrastructure. well unloading and clean-up installation and operation of the water handling unit non-routine and unplanned activities and incidents associated with the above. Xena-03 Tie-back: subsea infrastructure stabilisation mooring installation for the MODU development drilling and completions activities via MODU installation of xmas tree site surveys installation of flowline, flying leads, subsea tree, subsea distribution unit tie-in to existing subsea infrastructure

Item	Description
	pre-commissioning of the new subsea infrastructure cold commissioning of the well and xmas tree start-up to the Pluto facility including unload of well to onshore LNG Plant and performance testing contingent intervention, workover, or re-drill for the new well

3.2 Location

The riser platform is located in Commonwealth waters off WA, in Production Licence Area WA-1-IL approximately 160 km north west of Dampier and 75 km north of Barrow Island (Figure 3-1). Gas and condensate produced from the facility are exported via the 180 km long pipeline and associated 6-inch chemical supply line, to onshore for processing. Currently, gas is produced from two wells in the Xena field (Xena-01 and Xena-02) which are tied into the Pluto flowlines, ~16 km from the riser platform. An additional well in the Xena field (Xena-03) is proposed in this EP, 11 km from the riser platform. Additional wells are planned for Pyxis, Pluto and Xena as part of field development (the drilling of these wells and associated activities will be subject to a separate EP).

The riser platform is marked on nautical charts and surrounded by a 500 m petroleum safety zone (PSZ). The riser platform is marked on general aviation maps and categorised as a Danger Area for civil aircraft. The danger-type is listed in the General Pilots Manual as “avoid flight over facility between surface and 1500 feet”. The export pipeline is also marked on nautical charts.

The coordinates and permit areas of the facility and associated infrastructure are presented in Table 3-2.

Table 3-2: Approximate location details for the Petroleum Activities Program including all relevant infrastructure.

Structure	Water depth (approx. m LAT)	Latitude	Longitude	Title

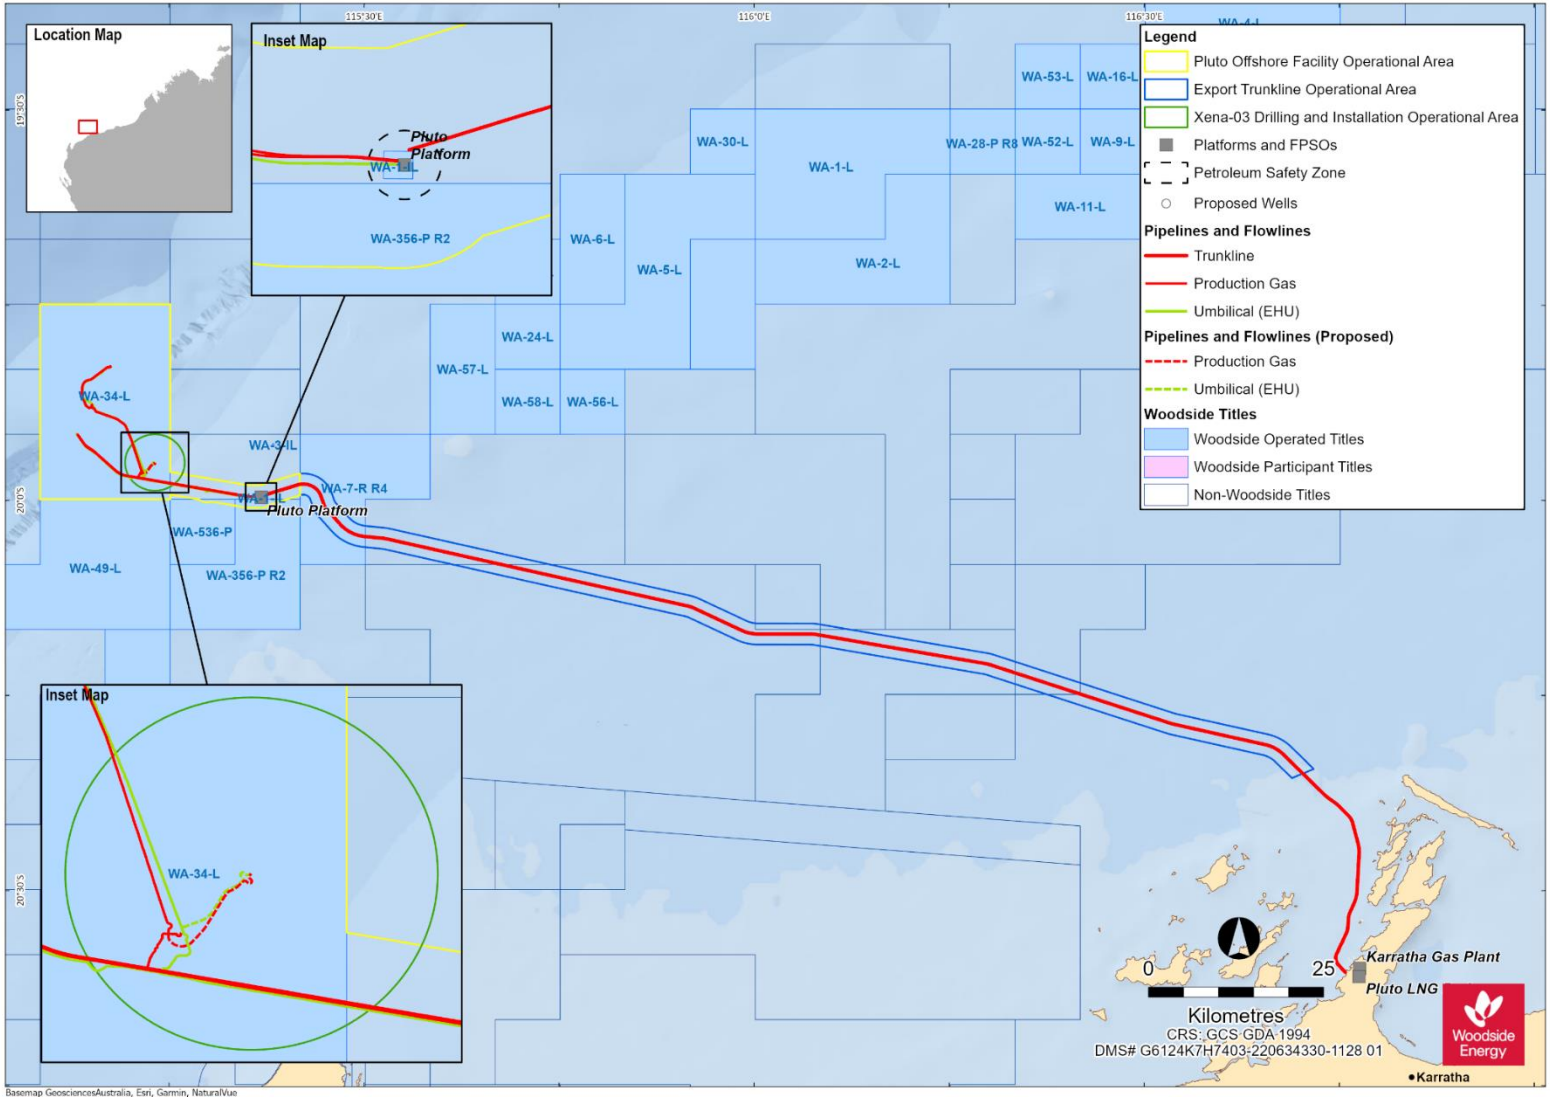

Figure 3-1: Location of the Petroleum Activities Program.

3.2.1 Petroleum Activities Area

The spatial boundary of the Petroleum Activities Program has been described and assessed using three Operational Areas, the Pluto Facility Operational Area, Export Pipeline Operational Area (collectively referred to as the Pluto Operational Area), and the Xena-03 Operational Area. The Operational Areas are collectively referred to as the Petroleum Activity Area (PAA) in this EP, with specific Operational Areas referred to where relevant.

Vessel-related activities within the PAA will comply with this EP. Vessels transiting to the PAA are outside the scope of this EP and are covered by applicable maritime regulations and other requirements during that time.

3.2.2 Pluto Operational Area

The Pluto Operational Area, risk assessed and managed by this EP, includes vessel-related petroleum activities within the PAA and includes:

- the riser platform and the area within a 500 m PSZ around the riser platform.
- the export pipeline (P1TL) and associated 6-inch chemical supply line covered by Pipeline Licence WA-17-PL and an area encompassing 1500 m around the subsea pipeline infrastructure.
- Pluto, Xena and Pyxis subsea facilities (including wells, production and pigging manifolds, production jumpers, spools, flowlines and flexible jumpers) and an area within 1500 m around the subsea infrastructure.

For the purposes of the Description of the Existing Environment (Section 4) and for the Environmental Impact and Risk Assessments (Section 6) the Pluto Operational Area has been divided into two sections where relevant:

the Facility Operational Area (all elements of the Pluto platform and subsea hydrocarbon gathering system (wells, xmas trees, flowlines, spools, jumpers, umbilicals, etc.)).

the Export Pipeline Operational Area (pipeline to the boundary between Commonwealth and WA State waters).

3.2.3 Xena-03 Operational Area

The Xena-03 Operational Area has a radius of 4000 m centred on the Xena-03 well location, to allow for MODU mooring operations, drilling of the Xena-03 well, installation of subsea infrastructure (including installation and connection of the Xena-03 flowline), pre-commissioning and related petroleum activities.

The Xena-03 Operational Area allows for MODU mooring operations, including the possible installation of pre-laid moorings and vessel-related petroleum activities. It also includes a 500 m Safety Exclusion Zone (SEZ) around the MODU to manage vessel movements, which will be under the control of the MODU Person in Charge. The Primary Installation Vessel (PIV), operating within the Xena-03 Operational Area, will also be surrounded by a 500 m SEZ when on-location, which will be under the control of the vessel master.

For the purposes of the Description of the Existing Environment (Section 4) and for the Environmental Impact and Risk Assessments (Section 6) the Xena-03 Tie-back Operational Area has been referred to where relevant.

3.3 Timing

3.3.1 Pluto Operations

The facility commenced production in 2012. The riser platform is designed to be operated with minimal crewing, thus minimising risk exposure to personnel. Maintenance activities are undertaken to support the day-to-day operations of the facility as required.

Mid case estimated end of life of the Pluto, Xena and Pyxis fields is expected in 2032, beyond the life of this EP. Tie-back opportunities are continuously being reviewed for Woodside's offshore facilities, which have the potential to extend the life of the fields. Any future decommissioning or drilling will be subject to a separate EP.

3.3.2 Xena-03 Tie-back Activities

Drilling of the Xena-03 well is anticipated to commence in Q2 2025 and take around 60 days to complete (Table 3-3). Subsea installation is anticipated to follow in Q3 2025 and to have a cumulative duration of around 3 weeks (including mobilisation, demobilisation and contingency). Drilling and installation of subsea infrastructure may be performed over multiple campaigns.

Timing and duration of activities is subject to change due to project schedule requirements, MODU/vessel availability, unforeseen circumstances and weather constraints.

When tie-back activities are underway, activities are 24 hours per day, seven days per week. There are no planned concurrent drilling activities under the EP. Simultaneous Operations (SIMOPS) activities with subsea installation may occur. Timing and duration of all activities is subject to change due to project schedule requirements, MODU/vessel availability, unforeseen circumstances and weather.

The EP has risk-assessed activities associated with the drilling and tie-back of the Xena-03 well as if they were to occur at any time during the year, this includes drilling activities, subsea infrastructure installation, pre-commissioning activities and intervention, workover, or re-drilling activities. This provides operational flexibility for requirements and schedule changes and vessel/MODU availability. The timeframes are therefore subject to change within the defined calendar years and, as no particular windows have been nominated for avoidance based on environmental and/or stakeholder sensitivities, changes to the above will not be interpreted as 'new stages' against Regulation 39(1).

Table 3-3: Summary of timing for Tie-back Activities

Activity	Approximate timing (and cumulative duration in the field)
Installation and removal of anchors for MODU	2025 (7 – 10 days per activity)
Drilling and completions	Q2 2025 (~60 days) 2026 (contingency)
Subsea installation and pre-commissioning / cold commissioning	Q3 2025 (~3 weeks) 2026 (contingency)
Well start-up and performance testing	2025 (~3 weeks) 2026 (contingency)

3.4 Facility Layout and Description

This section provides a high-level overview of the facility and associated infrastructure, as relevant to consideration of the environmental risks and impacts of the Petroleum Activities Program.

3.4.1 PLA Topsides

The riser platform topsides comprise of five decks with separated by two major vertical trusses (Figure 3-2). A pedestal crane is located on the northeast end of the facility. The flare boom is inclined and located at the northern end of the facility. A water handling module has been installed on the western side of the riser platform. The helideck is located above the southern corner. Figure 3-3 shows the riser platform topsides layout and layout of the water handling unit (new infrastructure in yellow and green).

Other facilities include pig launchers and receivers for the flowlines and export pipeline, vessels for handling pigging fluids, metering for inflow streams, chemical injection facilities (for monoethylene glycol (MEG), water clarifier and corrosion inhibitors), diesel power generators, emergency flare, pedestal crane, temporary waste storage, helideck, bunkering facility, telecommunications, monitoring, control and safety systems and marine navigational aids.

Power generation was upgraded during installation of the water handling module, including a gas engine utilising fuel gas as the primary fuel source, supported by two diesel generators. Chemical storage and injection facilities (corrosion inhibitors and water clarifier) are also part of the water handling module.

Although the riser platform is NNC, permanently installed accommodation facilities are provided on the southern end of the topsides to accommodate personnel required for campaign maintenance, significant modifications and pigging activities.

The potential environmental impacts from planned and unplanned activities are discussed in Section 6.

Figure 3-2: Photograph of the PLA riser platform

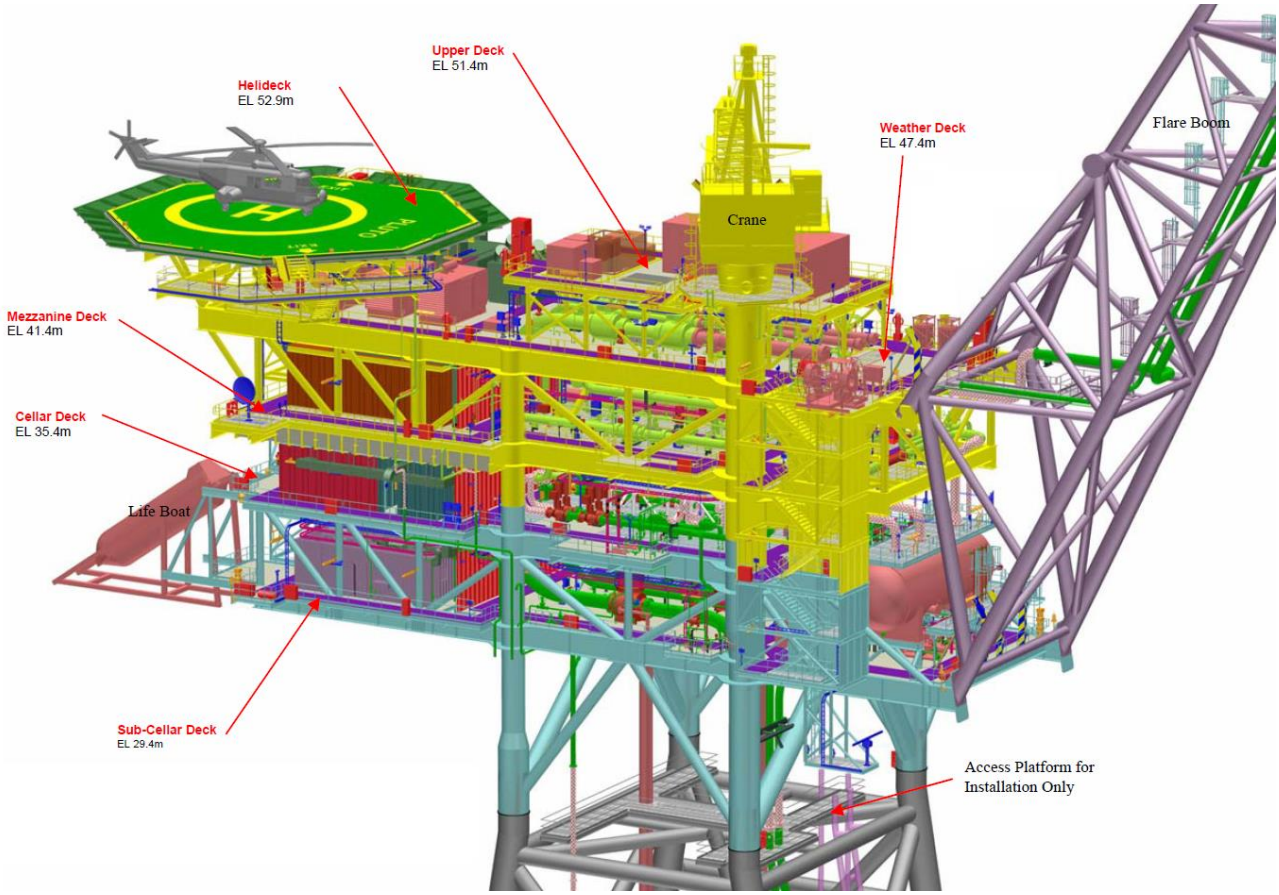

Figure 3-3: PLA Facility Platform Layout

3.4.2 Wells and Reservoirs

3.4.2.1 Pluto Wells

Gas and condensate from the Pluto reservoir are currently produced through eight big bore gas production wells (PLA01-07 and PL-PYA02) which are configured in a cluster arrangement around a central manifold at the drill centre (Figure 3-4). The primary reservoir isolations are provided by the actuated valves within the tree, and a down-hole Surface Controlled Sub-Surface Safety Valve (SCSSV) is included in the well design as emergency barrier in the event of tree / wellhead catastrophic failure. The wells are completed with a subsea tree system. An additional well (PLA-08), is planned to be drilled in the Pluto field with completions planned for Q3 2024, and is proposed to be operated during the life of this EP.

3.4.2.2 Xena Wells

Condensate and gas from the Xena reservoir are currently produced through two gas production wells (XNA01 and XNA02). The wells are independently isolated and controlled via a spur tie-in to the existing Pluto electro-hydraulic umbilical, located close to the existing tee locations. MEG and other chemicals as required are distributed to the wells via a dedicated flowline between an existing MEG Pipeline End Termination (PLET) on the chemical supply line. The existing wells are completed with a subsea tree system, similar to those installed on the Pluto wells. The primary reservoir isolations are provided by the actuated valves within the tree, and a down-hole SCSSV is included in the well design as emergency barrier in the event of tree / wellhead catastrophic failure.

An additional infill well from the Xena reservoir (Xena-03) is proposed to be operated during the life of this EP.

3.4.2.3 Pyxis Wells

Condensate and gas from the Pyxis reservoir is produced through one gas production well (PYA01), approximately 25 km north north-east of the existing Pluto A flow line tie-in PL-PYA02 exploits the Pluto gas field but is considered part of the Pyxis development.

The wells are independently isolated and controlled via a spur tie-in to the existing Pluto electro-hydraulic umbilical, located close to the existing tee locations (Figure 3-4). MEG and other chemicals are distributed to the well via a new integrated service umbilical supplied from an existing MEG PLET on the chemical supply line. The wells were completed with a subsea tree system, similar to those installed on the Pluto wells. The primary reservoir isolations are provided by the actuated valves within the tree, and a down-hole SCSSV is included in the well design as emergency barrier in the event of tree / wellhead catastrophic failure.

3.4.3 Flowline and Riser System

Production from the Pluto wells is routed approximately 27 km through dual 20-inch flowlines with an adjacent chemical supply line, up the continental slope to the riser platform (Figure 3-4).

During water production through the water handling module, Flowline B operates in wet mode, with Flowline A remaining unchanged as a dry flowline. The Xena well (and proposed future Xena-03 well) is connected to the production flowline via the following subsea infrastructure:

- a flexible production jumper
- mid-line connector system (MLCS) to the existing flowline tees.
- The Pluto and Pyxis wells are connected to the production flowlines via the following subsea infrastructure:
- an approximately 25 km flexible flowline up to 12-inch
- an 8” flexible production jumper from the flowline end terminal to existing MLCS-A and Pluto flowline A in-line tee.

The flowlines are configured as loops to allow round trip pigging of the flowlines from either end, with flowline pig launcher/receivers installed on the topsides. The flowlines and subsea system are sized to match the peak offtake rate required by the onshore LNG plant.

3.4.4 Pipeline and 6-inch Chemical Supply Line

Gas, condensate and other fluids (process chemicals and produced water) are currently transported from the riser platform to the LNG Plant via a 36-inch pipeline. Flow assurance is aided by the supply of MEG and other process chemicals in small concentrations (including corrosion inhibitor, biocide, oxygen scavenger, scale inhibitor, etc.) as required to protect the integrity of the pipeline. These chemicals are supplied from onshore storage and MEG regeneration infrastructure and pumped via the 6-inch chemical supply line piggy-backed to the pipeline from onshore to the riser platform. MEG, containing supporting chemicals are then supplied from the riser platform to the wells via a 4-inch chemical supply line.

The offshore gas pipeline and 6-inch chemical supply line route between the shore and the facility is approximately 180 km in length with a shore crossing at Holden Point, just north of the Pluto export jetty. The portion of the pipeline in State waters is not included in the scope of this EP. The offshore pipeline route is shown in Figure 3-1.

3.4.5 Subsea Infrastructure

The scope of this EP includes all subsea infrastructure associated with facility. The main components of subsea infrastructure include wells, xmas trees, umbilicals, spools, jumpers, manifolds, flowlines,

riser, chemical supply lines and the export pipeline. The layout of Pluto existing and proposed subsea infrastructure is shown in Figure 3-4.

The subsea system is remotely operated via satellite links and includes:

- rigid spools transporting hydrocarbons from the wells to the manifold/MLCS where the fluids flow through the 20-inch flowlines to the riser platform for onwards processing at the onshore facility
- jumpers and umbilicals which provide hydraulic and electric power, communications and chemical supplies
- valves which control subsea operations and processes
- chokes which control pressure and flow rates of hydrocarbon
- subsea control module (SCM) which contain sealed and pressure compensated electro-hydraulic units (typically found on manifold and/or wellheads) and links the surface and subsea controls.

Emergency shutdown (ESD) valves exist at various locations in the offshore facilities, including at the top of each flowline and pipeline riser to the riser platform. A non-return valve (NRV) is also provided on the 36-inch pipeline close to the riser platform as an emergency barrier to reduce the potential for uncontrolled backflow from the pipeline to the riser platform.

A number of subsea valves may also be overridden manually from either a Remotely Operated Vehicle (ROV) or by divers.

3.4.5.1 Flowlines Interactions

The following facilities and equipment are near the Pluto flowlines:

- The 44” Wheatstone pipeline was installed in 2014 and crosses the Pluto flowlines at approximately KP 19.1. It also crosses the 4” MEG line and subsea umbilical.
- The 18” Julimar and Brunello flowlines were also installed over the Pluto flowlines, 4” MEG line and subsea umbilical crossing at flowline KP21 in 2014
- The Scarborough 36” trunkline (under construction) crosses both Pluto flowlines and MEG/umbilical lines in 152m water depth, and the Scarborough trunkline 32” section crosses the Pyxis flexible flowline in 1007m water depth.

The design of the crossings ensures that the safety and integrity of any new infrastructure can be assured over its design life whilst not compromising the safety, integrity and operability of the existing facilities.

3.4.5.2 Export Pipeline Interactions

Connected on each side of the Pluto Export Pipeline are the PLA platform and the Pluto LNG Park. The following facilities and equipment are also in the vicinity of the Commonwealth waters section of the Pluto Export Pipeline:

- 36-inch export pipeline runs adjacent to the 40-inch 1TL within Mermaid Sound (for ~40km); and
- the 36-inch Scarborough Trunkline runs adjacent to the Pluto 36-inch export pipeline from the shore-crossing in Mermaid Sound for approximately 161 km.
- 16-inch Reindeer gas pipeline crossing at KP 75.

3.4.5.2.1 Reindeer Pipeline Crossing

The Santos Reindeer pipeline was installed in late 2010 and crosses the 36-inch pipeline and 6-inch MEG pipeline at KP 75. The design of the Reindeer crossing incorporates sufficient stabilisation of the pipelines, sufficient clearance and was subject to independent validation by DNV.

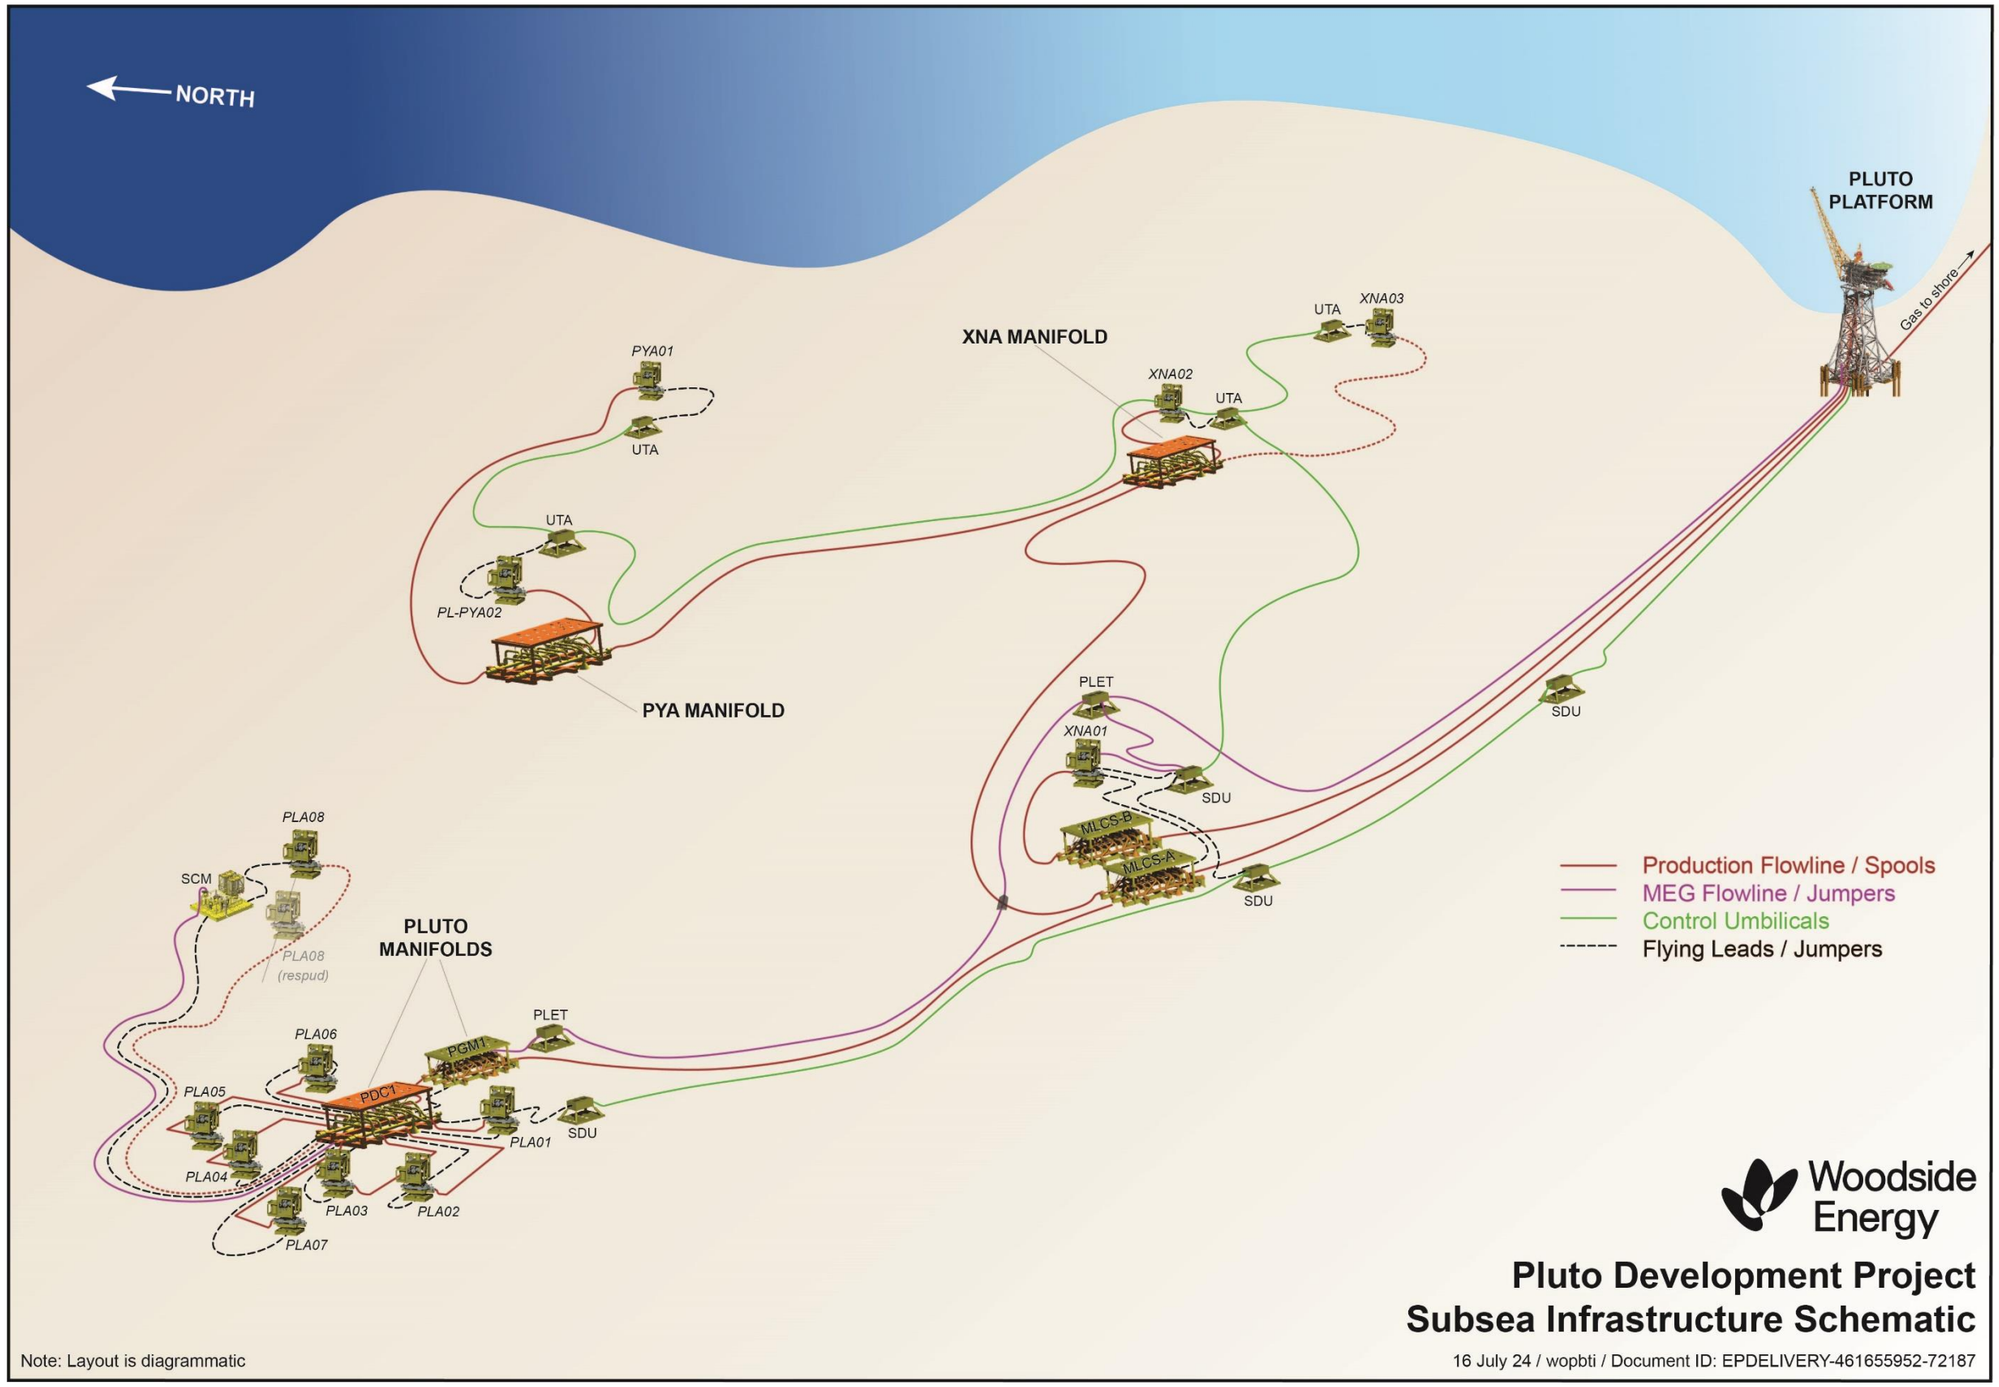

Figure 3-4: Layout of the Pluto facility subsea infrastructure

3.4.6 Field Inventory

The layout of the Pluto subsea infrastructure, including location of the fields, is shown in Figure 3-4 and described in Table 3-4.

Table 3-4: Inventory of subsea wells and key infrastructure, including status

Infrastructure[1]	Status[2]	Decommissioning Planning
Pluto		
7 x wells, 2 x active pipe support, 2 x flowline termination assembly, 2 x manifolds, 7 x SDU, 3 x PLET	Maintained for production	**Section 7.3**
17 x rigid spools (2 x 6", 7 x 8", 2 x 14", 4 x 20", 2 x 36" - total length ~2.0 km), 5 x flowlines (2 x 4", 1 x 6", 2 x 20" - total length ~263 km), 1 x 36" trunkline (~181 km)	Maintained for production	
5 x umbilicals (total length ~28 km), 25 x flying leads, 65 x jumpers	Maintained for production	
1 x well (PL08), 1 x SCM control skid, 2 x 8" flowlines – total length ~433 m), 10 x jumpers	To be commissioned	
Pyxis		
2 x wells, 1 x manifold, 2 x SDU/UTAs	Maintained for production	**Section 7.3**
3 x flowlines (1 x 8", 1 x 10", 1 x 12" - total length ~22 km)	Maintained for production	
2 x umbilicals (total length ~21 km), 11 x jumpers	Maintained for production	
Xena (existing)		
2 x wells, 3 x manifolds, 3 x SDUs, 1 x skid sensor	Maintained for production	**Section 7.3**
2 x 8" rigid spools - total length ~800 m, 3 x flowlines (2 x 8", 1 x 10" - total length ~1.8 km)	Maintained for production	
1 x umbilical (~1.4 km), 29 x jumpers	Maintained for production	
1 x jumper	Maintained for decommissioning	
Xena-03 (proposed)		
1 x well, 2 x UTAs	To be commissioned	**Section 7.3**
1 x 10" flowline (~3.0 km)	To be commissioned	
1 x umbilical (~2.2 km), 6 x jumpers	To be commissioned	

[1] Inventory of subsea infrastructure in the title areas or proposed to be installed in the title areas at time of submission of this EP
[2] Status at time of submission of this EP

The subsea infrastructure is recorded and tracked using a database. This database is updated as equipment is brought into title, which may include new or replacement equipment. Remotely Operated Vehicle (ROV) as found and as left surveys are undertaken to identify the location of items placed on the seabed. At the completion of an IMMR campaign this data is used to update the inventory for the title. Material items dropped to the marine environment and not recovered are added to the inventory for the title.

The subsea system has been designed, fabricated and installed in accordance with best practice and international standards. The pipelines, flowlines and wells are marked on nautical charts. Decommissioning planning for infrastructure no longer in use**.**

3.5 Operational Details

This section provides a description of the main operations associated with the facility. It includes key elements in relation to interaction between the activity and the environment, described under the following headings:

- Process Description (Section 3.5.4)
- Utility Systems (Section 3.6)
- Facility Operations (Section 3.7)
- Support Vessel Operations (Section 3.8)

The facility is designed to operate without operator intervention. Normal operations are controlled remotely via satellite links from the Pluto Remote Operations Centre (PROC). Activities which require manning are:

- engineering projects
- campaign maintenance
- unplanned corrective (breakdown) maintenance
- inspections/audits
- planned facility shutdowns.

Operations fall under any one of the following modes of operation:

- production remote operations
- major projects
- maintenance, including subsea inspection, maintenance, monitoring and repair (IMMR) activities
- well maintenance.

These modes of operation are described below. Production, maintenance and project activities may occur concurrently.

3.5.1 Production Remote Operations

The platform is designed to be operated with minimal/NNC crewing and is remotely operated, monitored, controlled, restarted and diagnosed from the Central Control Room (CCR), either from the Central Control Room at Pluto LNG Park or Remote Central Control Room in Perth.

The Process Control System for the facility provides the following monitoring and control functions:

- basic monitoring of key performance indicators
- adjustment of devices on the facility such as control valves, pumps, and variable speed drives
- alarm signals
- automatic management of duty/standby and lead/lag equipment.

3.5.2 Major Projects

Major projects involve refurbishment, modification or major maintenance on the facility. The Projects function is responsible for undertaking these projects. Potential environmental impacts related to projects are managed through the process outlined in Section 0.

3.5.3 Maintenance including IMMR Subsea Activities

Inspection, monitoring, maintenance and repairs, including those undertaken subsea, are intended to maintain safe and sustainable production within the platform.

Maintenance teams routinely visit the facility for:

- planned maintenance campaigns undertaken during routine interventions. Campaigns typically last for 14 days, with ten campaigns planned per year;
- unplanned corrective (breakdown) maintenance, as required;
- shutdown maintenance;
- pigging of the pipeline/flowlines for sand and debris removal, liquid management, inline inspection, well clean up and hydrate remediation. The frequency of pigging operations is defined in Pluto Pipeline System Inspection, Monitoring and Maintenance (IMM) Plan; and
- contingent manning on the riser platform involving continuous manning for indefinite periods to address low probability equipment failures, operational issues or major projects, such as maintenance of the water handling module.

The specific team sizes deployed to the facility are based on maintenance requirements, helicopter carrying capacity, availability of accommodation and safety considerations.

When the facility is crewed, primary control is retained by the PROC, with personnel on Pluto communicating with the PROC. Operational control of equipment is handed to ‘local control’ on the facility on an as-required basis.

3.5.4 Process and Production Description

The riser platform receives well fluids (gas, condensate, associated produced water and other fluids such as process chemicals) from the Pluto, Xena and Pyxis production wells. The facility then exports gas and condensate from the riser platform via the pipeline to the onshore gas plant for processing. With the installation of water handling module, the facility has the ability to separate and discharge PW. The riser platform also receives chemicals from the 6-inch chemical supply line, and transports these to the wells via the 4-inch chemical supply flowlines.

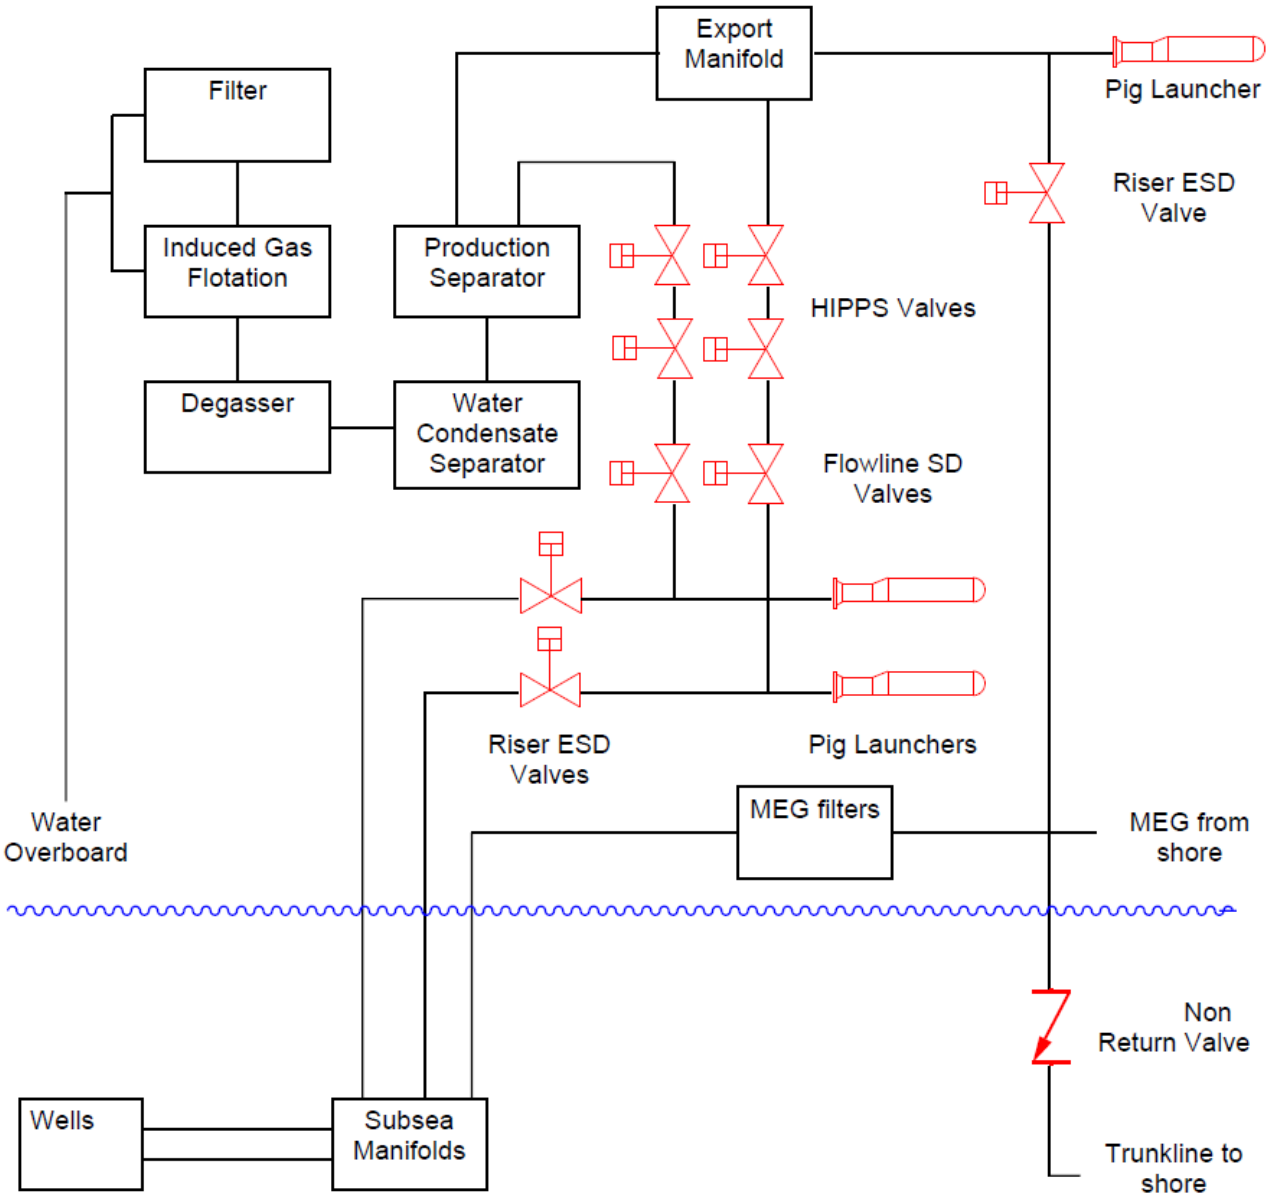

Figure 3-5: High-level Process flow diagram

3.5.5 Produced Water System

Due to the increasing ingress of water in the Pluto reservoir towards the production wells, PW treatment and disposal is required on the Pluto facility, as the volumes exceed the treatment capacity of the onshore facility. Woodside has recently installed a water handling module on the riser platform to treat PW. The maximum design case for water treatment is 3500 m3/day. The rate of PW is forecast to range from as low as 30 m3/day up to a maximum of 3500 m3/day, dependent on the number of wells producing water and their associated flowrate. As the operation of the module is dependent on volumes of PW, its operating times may vary.

The Pluto water handling module includes a two-phase production separator, water condensate separator, degasser and a secondary horizontal induced gas floatation (HIGF) vessel, to aid oil in water (OIW) separation. To safeguard from any excursions or process upsets, coalescing filters have been installed prior to the end of the process for intermittent use, where OIW concentrations from the HIGF outlet do not meet the required specification for overboard discharge. The filters are in

place to manage high OIW without process disruption. They are not suitable for permanent use due to NNC philosophy, as described in Section 6.7.7.

3.5.5.1 Produced Water Treatment System

The PW treatment module directs all wet production fluids from Flowline B through a two-phase production separator and water condensate separator to the PW system, which operates at a low pressure to maximise the removal of dissolved gas. The system consists of a degasser which separates dissolved gas followed by a HIGF unit, which distributes small gas bubbles through the PW in the vessel to enhance OIW separation. In this process, oil and fine solids particles present in the water adhere to the gas bubbles and float to the surface where they are skimmed off as a reject stream to the Oily Water Separator (OWS). PW is then discharged overboard in accordance with OIW monitoring requirements above the water line at +8 m LAT.

If water exiting the HIGF exceeds discharge limits due to excursion or process upset, the water can be routed through a set of coalescing filters for further treatment prior to being discharged overboard. This mitigation stage has been provided to minimise the requirement for reactive platform visits (increased safety risk) in the event of a process upset or excursion of produced water and will allow remote troubleshooting of the process, while maintaining the oil in water specification within operational discharge limits.

The water treatment system includes provision for injection of water clarifier chemical injection if increased efficiency in OIW separation is required. Contingency for demulsifier chemical injection upstream of the inlet separator has also been provided. Use of either is circumstantial based on engineering/operations judgement. In addition, the PW stream can also be routed via coalescing filters, which can be used in upset or non-routine scenarios to reduce OIW concentrations.

Reject streams with residual condensate from the Degasser, HIGF and coalescing filters will flow to the Oily Water Separator (OWS). Separated condensate is pumped to the pipeline and water is routed back to the main PW stream either upstream of the PW Pumps or upstream of the HIGF. The evolved gas from the degasser and HIGF is routed to the high pressure (HP) flare; the flowrate will be proportional to the PW rate. Water from the OWS can also be comingled with Produced Water Pump discharge (downstream of filters) and discharged overboard.

3.5.5.2 PW Discharge Oil in Water Monitoring

The measurement of OIW in the PW stream is undertaken prior to discharge to the ocean. OIW will be measured using online OIW analysers. The analysers are designed specifically for offshore operations and reports total petroleum hydrocarbons (TPH), where TPH is defined as all hydrocarbons that are soluble in the extraction solution and are present in the solvent extract after filtration through Florisil. Two OIW analysers will be installed on the module, with at least one analyser online at any one time in case of instrument failure.

Woodside has contracted external studies to advise on suitable OIW analyser technologies. Lessons from other Woodside assets were also heeded. The application of the analyser in a low aromatic, gas condensate field like Pluto has been verified with other operators of the selected analyser technology.

3.5.5.3 PW Discharge Monitoring

PW discharge on the facility is managed in accordance with the Offshore Marine Discharges Adaptive Management Plan (OMDAMP). This plan has been developed to detail the disposal of routine marine discharges from Woodside's offshore production facilities in accordance with Woodside's Environmental Performance Procedure. Implementation of the plan also verifies the discharges are managed in a way that reduces the potential environmental risks and impacts to ALARP.

In addition to continuous OIW monitoring, PW discharge monitoring includes routine chemical characterisation and ecotoxicity assessments of the PW. This information, combined with dilution modelling is used so that the discharge of PW is in accordance with the required standards outlined in Section 6.7.7. Refer to Section 6.7.7 for a detailed discussion and ALARP justification regarding PW discharge from the Pluto facility.

3.5.6 Utility Gas and Flare System

The riser platform currently has a combined high-pressure flare and utility gas system. A schematic showing the utility gas and flare system is presented in Figure 3-6.

With the water handling module installed, fuel gas is the primary fuel source for the gas engine. The fuel gas conditioning facilities (filtering and super heating) have been installed as part of the module.

Utility gas is required:

- for continuous purging of the flare header to prevent air ingress
- to supply pilot gas for the flare tip pilots
- to supply to the induced gas floatation unit for gas injection to maximise oil in water separation.

The flare system safely collects, contains and disposes relief, blowdown and vent flows from the topsides (pressure safety valves, manual and automatic blowdowns). A flare header collects relieved, entrained or condensed liquids and routes them into a knock-out drum. Liquids in the drum are periodically pumped into the export pipeline. The vapour flows via a riser, mounted on a cantilever boom to the elevated flare tip for burning.

The water handling module introduces additional process waste streams directed to the flare including the degasser, Induced Gas Floatation vessel and oily water separation tank.

The utility gas system is equipped with a meter that records total utility gas used and a meter that detects the volume of gas purging the flare. Remote operational monitoring of the flare system is in place via:

- flare gas flow metering
- monitoring of the pilot flare operation through ionisation detectors at each of the three tips
- monitoring of the utility gas pressure (with back-up systems activating on low pressure)
- closed circuit TV for visual checks.

The system allows for sustained flaring up to 100 MMscfd, when the flowlines are pigged or in the event depressurisation of the flowlines is necessary.

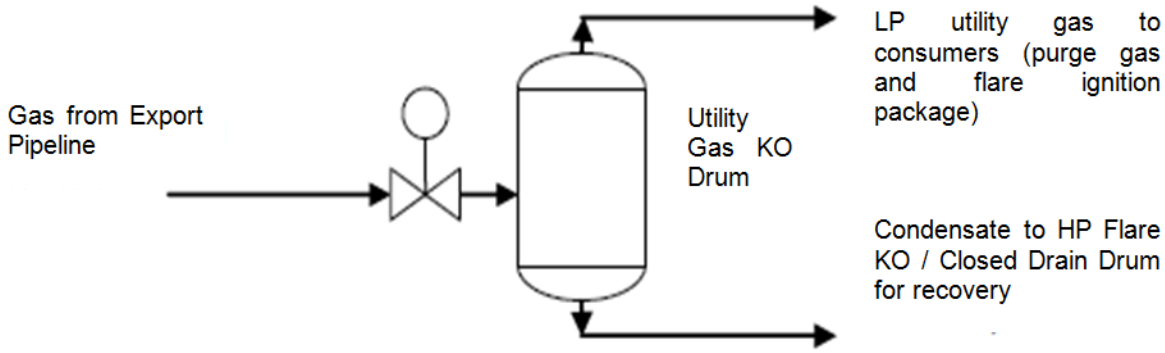

Figure 3-6: Riser Platform Utility Gas System

3.5.7 Drainage Systems

The open and closed drains system consists of both hazardous and non-hazardous open drains. The open drains system is required for disposal of water and hydrocarbons, which are at atmospheric pressure (e.g., deck water). Drains from hazardous areas are totally segregated from drains from non-hazardous areas, to prevent ingress of gases into a non-hazardous area via the drains system.

3.5.7.1 Closed Drains

The closed drain system is designed to safely collect, contain and recycle depressurized hydrocarbons, chemicals and other liquids from normally pressurized and hazardous equipment and is fully contained. The drained liquids are routed to the flare knock-out drum during normal operations and then pumped into the export pipeline for transfer to shore.

3.5.7.2 Hazardous Open Drains

The hazardous open drains system collects non-pressurised spillage, overflows, contaminated deck wash-down and some rainwater from the open drain boxes, tundishes and equipment drip trays in areas designated as hazardous. The PLA hazardous open drains flow to the hazardous open drains collection tank (working volume 11.6 m3) when the facility is crewed and work is being undertaken in the area. Areas of the facility have secondary spill protection (bunding) depending on the location, protection and spill risk of each component of the facility to contain and direct flows to the hazardous open drains system.

The hazardous open drains collection tanks are periodically pumped to a waste oil storage tank (capacity 4 m3) then transported onshore for disposal. The transfer of liquids from the collection tanks to the waste oil storage tank is a manual operation only undertaken while the facility is crewed.

The collection tanks are provided with a submerged centrifugal pump to transfer liquids from the tank at the sub-cellar deck to the waste oil storage tank located in a bunded area on the upper deck.

As part of installation of the water handling module to the facility, an additional open drains collection tank (working volume 10.7 m3) was added below the sub cellar deck of the module, designed to contain spillage (such as during chemical decant), leakage or washdown during maintenance activities on the module. Pump-out from the module open drain collection tank can be remotely operated to decant to the PLA open drain tank collection tank if required, or transferred directly during crewed activities for disposal onshore via the waste oil storage tank.

3.5.7.3 Non-hazardous Open Drains

The non-hazardous area open drains system collects liquids from open drain boxes, tundishes and equipment drip trays in areas designated as non-hazardous. It is segregated from all other drainage systems to eliminate the risk of hydrocarbon vapour transmission from hazardous to non-hazardous areas. Drains from the diesel generator bunds/tanks are part of the non-hazardous area open drains system. Water and any contamination are routed to the non-hazardous area open drains collection tank. This tank is sized for containing in excess of the full volume from a diesel generator day tank and has a working volume of 2 m3 (with max capacity of 2.6 m3).

The collected liquids are manually drained to the hazardous area open drains collection tank during every facility campaign maintenance visit (if it contains any liquid) so that the full working volume of the non-hazardous area collection tank is available for spill capture.

3.6 Utility Systems

3.6.1 Platform Lighting

The riser platform has appropriate lighting for there to be a safe working environment during 24-hour operations. Lighting is split between emergency and normal lighting. The emergency light fittings

have been located to illuminate the designated escape routes on the facility. Navigational lights are located on the riser platform flare tower and on the booms and towers of the pedestal crane. Helideck lighting is also provided to assist helicopter landing.

Unless required to support over the side activities (such as bunkering and lifting operations), lighting on the facility is directed to the work area when crewed, which limits light spill to the marine environment.

3.6.2 Heating, Ventilation and Air Conditioning System

The heating, ventilation and air conditioning (HVAC) system comprises HVAC equipment, ductwork and associated pipework. It provides independent and interdependent sub-systems with pressurised, conditioned, purge and exhaust air services to all living to various areas including accommodation and various modules which can be operated on an as required basis or continuous basis.

3.6.3 Potable Water

Commercially supplied water from onshore is provided for drinking and domestic use on the riser platform, which is bunkered by support vessels and transferred into a storage tank. The service water passes through a UV disinfection unit to ensure water quality for users.

3.6.4 MEG System

Lean MEG is filtered onshore, then transferred to the riser platform via the 6-inch subsea chemical supply line. The lean MEG concentration is selected as 90% by weight, which is the optimum concentration to maximise capacity of the distribution system. The topsides arrival pressure of the MEG from the 6-inch chemical supply line is 22 Mpa(g) under normal operations. Once on the riser platform, the MEG is again filtered and distributed to the Pluto/Xena/Pyxis wells via the 4-inch chemical supply line. The MEG flow is controlled by manual adjustments in subsea injection chokes, which are controlled via the PROC.

MEG ensures the water in the flowlines is inhibited against hydrates. Other chemicals, such as corrosion inhibitors, biocides, oxygen scavengers, and scale inhibitors, may be mixed with the MEG to aid in integrity and asset protection. These chemicals are injected into the wells in dilute concentrations as required for technical requirements. Chemicals used on the riser platform are discussed further in Section 3.9.

Injected (rich) MEG normally flows back from the wells with the production fluids in the flowlines to the riser platform, then via the pipeline to the onshore processing facility. It is then separated from the production fluids and stored and regenerated at the onshore processing facility for re-use.

The MEG supply lines have the following size and capacity:

- six-inch chemical supply line (onshore to the riser platform) – 715 m3/day
- four-inch chemical supply line (riser platform to Pluto subsea manifolds) – 354 m3/day.

When MEG is required to be injected into the Wet flowline for hydrate management, this diluted MEG will be processed through the water processing module and discharged overboard via the PW discharge pipe, these volumes are limited and frequency intermittent as detailed in Section 3.5.5. Continuous low rate MEG discharge to the flowlines and production system and PW discharge may be seen up to 2 m3/day associated with MEG injection bleed into the production system.

If required for intervention purposes, MEG or methanol may also be transferred onto the facility via iso-tanks to a 10 m^3 storage vessel.

3.6.5 Wet Flowline Conversions

To segregate wet wells for processing through the water handling module, the Pluto flowline B may need to be converted between dry flowline mode and wet flowline modes. Prior to flowline pigging operations (approximately four-yearly) and in case of infrequent planned/proactive shutdown management; the flowline may be required to be converted between wet and dry modes to treat the flowline with MEG for integrity management and prevent hydrate blockages. Upon restart, the flowline is required to be converted from dry mode back to wet mode. As part of this, up to 52 tonnes of diluted MEG will be displaced from the flowlines and wells, which will enter the water treatment process on the facility and be discharged overboard.

If the wet flowline is shut down, MEG is required to be dosed into in each wet well (~1.6 tonnes) and uninsulated sections of the flowlines subsea (14 tonnes) which will be displaced to the separation and PW treatment process on the facility and discharged overboard.

3.6.6 Power Generation

As the riser platform is NNC and includes no processing, the power demand of the facility is characterised by long periods of very low power demand and short duration peaks in demand. Continuous power during normal operations is required by the utility gas pre-heater, to maintain charge in the uninterruptible power supply (UPS) batteries, and for lighting and navigational aids. Peaks in demand occur during flowline pigging (which requires running of the flare knock-out drum pumps) and recovery from an extended blackout (which requires the UPS batteries to be heavily recharged).

Historically, power for the facility was provided by three small diesel generators located on the platform, with capacity of 240 kW per generator. One out of the three diesel generators remained online during normal operating mode, with the other two on standby. For operations requiring additional power, one of the standby generators was brought online.

Operation of the water handling module increases the operating requirements of the production equipment, thus increasing the base load for the facility. Peaks in demand occur during flowline pigging and process upset conditions (such as restart activities) and recovery from an extended blackout. The generator tanks are located in a bunded area which drains into the non-hazardous open drains system (refer Section 3.5.7).

Following installation of the water handling module, power for the facility is provided by two diesel-fuelled generators, one gas-fuelled generator and a Grid Stability Module (GSM) located on the water handling module. The fundamental components of the GSM are a rectifier/inverter and a battery supply. The generators are integrated with a GSM to eliminate the requirement for a hot standby generator and increase fuel efficiency. The gas-fuelled engine generator is the preferred unit for operation. If fuel gas is not available, or the unit is unavailable, the other diesel units will be started. In the event of a generator trip, the GSM shall maintain the load with no breaks (i.e. seamless) during the transition to an alternate generator supply. When a generator supply is restored, the GSM shall re-commence charging. The generators and GSM shall be capable of online changeover, synchronisation and load sharing. For operations requiring additional power, one of the standby generators is brought online.

3.6.7 Sewage and Putrescible Wastes

No sewage or putrescible wastes are produced from the riser platform during uncrewed periods. When the facility is crewed, the sanitary drainage system is a combined black and grey water system, with black and grey water discharged to the marine environment as untreated, un-macerated waste. Sewage is disposed via a dedicated overboard caisson. The caisson is a 300 mm carbon steel pipe that discharges at approximately 7.5 m below LAT. A rodding point is also provided at the top of the disposal caisson.

When the facility is crewed, putrescible waste (principally food scraps) are bagged and transported to shore for disposal as domestic waste, in accordance with the requirements of Woodside's Waste Management Plan for Offshore Facilities. During planned maintenance campaigns, shutdown maintenance or major projects additional crew will be present at the Pluto facility. During these times of increased personnel, an accommodation support vessel (ASV) may also be utilised on station to accommodate crew. Sewerage and putrescible discharges associated with the ASV are discussed in Section 3.8.3.

3.6.8 Sand Management

Subsea wells are equipped with downhole sand control (expandable sand screens or open hole gravel pack), acoustic sand detectors and erosion probe located on the subsea xmas trees. The facility basis of design assumes there is a low probability of sand production. Hence, any sand produced in normal operation should not cause any significant erosion or corrosion impact in the flowlines. In the event of sand production and depending on the mode of production (wet or dry), produced sand is expected to accumulate in the onshore facilities (dry mode) or Pluto Water Handling equipment (wet mode).

Sand and other material (sludge, scale, etc.) with the potential to be contaminated with NORMs is tested and disposed of in accordance with Woodside's Waste Management Plan for Offshore Facilities.

3.6.9 Diesel Fuel System

Low sulphur diesel is transferred to the riser platform in bulk from supply vessels via a hose reel located at the dedicated bunker station on the platform. Diesel is bunkered directly into the crane pedestal diesel bulk storage tank which has a maximum storage capacity of 80 m3. Filters provided on the diesel inlet assist in preventing blockage of the tank level devices. Diesel is metered and distributed to users via a continuously pressurised ring main. Unused diesel is recycled back to the crane pedestal. The tank is equipped with level fall alarms and remote shut-off systems to allow shutdown of the system locally or from the PROC.

Diesel is required for:

- crane tank
- lifeboat tank
- diesel generators.

With the installation of the water handling module and the change to fuel gas being the primary source for power generation, diesel consumption is forecast to reduce which is expected to reduce the bunkering frequencies.

3.6.10 Hydraulic Fluid System

The riser platform is provided with a hydraulic power unit (HPU) hydraulic fluid storage tank of 4 m3 capacity. A glycol based hydraulic fluid is supplied to actuate valves on the topsides and subsea facilities including shutdown valves, blowdown valves, high integrity pressure protection system (HIPPS) valves, control valves and subsea xmas tree, surface-controlled sub surface safety valve and choke valves.

Hydraulic fluid is supplied in high- and low-pressure modes with two independent headers. A common production hydraulic power unit is located on the sub-cellar deck to provide both low pressure (LP) and HP hydraulic power for operation of both subsea and topsides valves. The topsides hydraulic system has a supply reservoir and a return reservoir (closed loop), four hydraulic supply pumps and a reservoir pump. Hydraulic fluid supplied to the subsea facilities is in an open-loop configuration, and each actuation of a valve will release a small quantity of the fluid at the SCM vent port.

All safety critical valves are designed for fail safe operation, in the case of the HPU losing pressure (e.g. in the highly unlikely event of a major platform or umbilical failure).

Oceanic HW443, typically is used in the hydraulic system, which is a MEG-based hydraulic fluid and rated D under the non-Chemical Hazard and Risk Management (CHARM) Offshore Chemical Notification Scheme (OCNS) rating system but carries a CEFAS substitution warning. Chemical selection and use is detailed in Section 3.9.

The water handling module will feature an independent closed loop topsides HPU located on the sub-cellar deck for supplying fluid power to the module actuated on/off valves and control valves. The HPU is proposed to have a total system capacity of 2 m3 in the supply reservoir, with an additional 1 m3 storage tank permanently connected to the HPU. This system will utilise an oil based fluid; this is required due to the lubrication requirements of the valve solenoids, which improves the reliability and reduces maintenance requirements on the NNC platform.

Hydraulic power is the only instrument utility available for motive power on the facility. If an activity requires the use of an air powered tool, then portable air compressors will be transported from shore as required. Maintenance of this equipment occurs onshore.

3.7 Facility Operations

3.7.1 Operational Flaring

Flaring is expected to occur during a range of operational circumstances; key operational flaring events are explained in further detail in the following sections. Annual internal facility flare targets are set based on operational activities planned for the year. This target is used to assess facility flare performance.

3.7.2 Normal Operations

A relatively small quantity of gas is required to be continuously flared associated with purge and pilot of the flare system and disposal of waste streams that are not suitable to be recovered to the process.

Continuous flows to the flare are approximately 4000 tpa. Sources include:

- flare header purges
- flare pilot
- PW degasser
- PW induced gas floatation
- leakage past flare header values such as pressure safety valves (PSVs) and blowdown valves (BDVs)
- oily water separator tank.

3.7.3 Intermittent Process Upsets and Activities

During process upsets or blowdowns, the process control valves on the main process equipment open to relieve topsides system pressure to the flare. The following sources make up intermittent flaring.

3.7.3.1 Operational Pigging

Flaring to facilitate round-trip pigging of the flowlines is an integral part of operation of the facility and occurs as required (approximately once every four years). Produced gas is flared during flowline pigging operations, with liquids exiting the flowlines stored in the flare knock-out drum. Pipeline gas is used to propel the pig in the first half of the flowline loop. Well fluid is used to propel the pig in the

second half of the flowline loop, with produced gas and liquids from flowline pigging directed to the pipeline.

The system is sized to flare at a rate of 100 MMscf per day gas during flowline pigging. Additionally, initial depressurisation of the flowlines to flare is required for approximately two hours prior to pig launch to reduce the flowline pressure sufficiently to successfully launch the pigs using pipeline pressure. Each pigging campaign requires three pigging runs each for gauging, cleaning and inspection. The pigging activity typically results in an additional 8300 tonnes (approx.) in years that flowlines are pigged.

3.7.3.2 Emergency Blowdown

The topsides equipment and piping are divided into isolatable sections, each with a dedicated BDV. During an ESD, each section is separately depressurised to the flare. Each section contains actuated BDVs which allows blowdown of the riser platform inventory. The total volume depressurised is 7 tonnes. With the water handling module on the platform, this has increased to approximately 8 tonnes as a result of additional process vessels and pipework.

3.7.3.3 Manual Depressurisation

Manual depressurisations will result in intermittent flaring of hydrocarbons, triggered by routine equipment maintenance, planned ESD testing and/or depressurisation of equipment and piping to remove the equipment from service. Furthermore, equipment must be depressurised prior to draining as the closed drains system is not intended for high pressure service.

3.7.3.4 Subsea Flowline Depressurisation

The well fluid in the subsea flowlines (which carry hydrocarbons from the subsea wells to the riser platform) may on rare occasions need to be routed to the flare to allow the pressure in the flowlines to be reduced. The flowlines may require depressurisation for the following reasons:

- for flowline hydrate management: depressuring must be completed prior to flowlines cooling to seabed temperature when the production system is offline
- over-pressurisation of flowlines above integrity limit
- leak-off testing of well or subsea isolation valves
- production flowline maintenance (if required)
- to facilitate remediation in the event of an unplanned hydrate blockage in the subsea equipment

3.7.3.5 Estimated Flare Volumes

The amount of gas that may be flared on an annual basis is a dependent of continuous and intermittent process sources, planned activities requiring flaring, and unplanned process upsets. The estimated annual amount of gas flared ranges between approximately 8,500 tpa and 16,800 tpa.

3.7.4 Greenhouse Gas Emissions

The main sources of greenhouse gas (GHG) emissions associated with Pluto production are shown in Table 3-5. GHG sources that are not part of the Pluto facility (e.g. from onshore processing emissions) are included for completeness. In the context of this EP, the emissions are classified as direct and indirect emissions.

Table 3-5: Direct and indirect GHG emissions sources from the Pluto facility and supply chain

Emission type	Emissions source	Location	Jurisdiction	Process
Direct	Pluto facility process	Offshore	Commonwealth	GHG emissions from fuel, flares, fugitives and process vents
Indirect	Support vessels (on charter)	Offshore	Commonwealth	GHG emissions from engines and fugitives on vessels
	Onshore processing*	Onshore	State (WA)	GHG emissions from venting reservoir CO2, combustion of gas as fuel, flares and fugitives associated with processing gas to products such as LNG, LPG, condensate and domestic gas
	Transport	Transit	Subject to consumer location	GHG emissions from transport of products to market, including regassification and distribution of LNG in customer markets
	Regassification, distribution and combustion by third party user	Market	Subject to consumer location	GHG emissions from combustion of products as part of power generation and other energy solutions within the final market

**ISO 19694:2021 defines indirect GHG emissions as GHG emission that is a consequence of an organization's operations and activities, but that arises from GHG sources that are not owned or controlled by the organization. For the purposes of this EP the "organization" is the Pluto facility and therefore onshore processing and support vessel operations are considered indirect emissions sources.*

3.7.5 Lifting Operations

A pedestal crane is located on the east side of the riser platform at the weather deck, providing the necessary coverage for all on-deck material handling requirements and lifting between the riser platform and supply vessels. The pedestal crane is powered by diesel.

3.7.5.1 Routine Lifting from Platform Support Vessels

Routine lifting operations primarily include transferring stores and equipment from a support vessel to the facility. Support vessels are equipped with dynamic positioning (DP) control for holding station during lifting operations. The types of 'lifted equipment' may vary but generally include containers or skips of various sizes. The stores and equipment required by the facility are secured inside the skip or container. Containers for supply of chemicals are routinely lifted. Equipment is to be appropriately rated for offshore lifting.

After offloading from the supply vessel is complete, the facility then backloads to the supply vessel any items to be returned to shore. These primarily include empty skips or containers or skips containing waste for onshore disposal.

3.7.5.2 Lifting Around the Facility

Once lifted to the lay down area, there may be a need to re-position equipment at various locations throughout the facility for operational purposes. This includes lifting stores or equipment to various landing areas throughout the facility for unloading or use, and moving waste bins to required areas.

There may be occasions where a non-routine piece of equipment may need to be lifted. On these occasions, the equipment is packed up in a container or an approved lifting frame.

3.7.5.3 Operational Lifting (Non-crane Based)

There is also a requirement to undertake operational lifting utilising rigging, chain blocks or electric hoists. This lifting is primarily undertaken for maintenance or repairs and involves lifting and removing equipment such as valves, spools and motors.

Maintenance areas are in close proximity to all major equipment. Material handling corridors are provided to allow transportation of materials and equipment.

Once lifted to the lay down area, there may be a need for re-positioning of equipment at various locations throughout the facility for operational purposes. Where required, lifting of material and equipment in/out is achieved via beam clamps. General purpose floor trolleys and skates are used for moving material and equipment to/from laydown areas. Pad-eyes are provided for equipment requiring regular or frequent maintenance, where there is no direct pedestal crane access, or where runway beams are impractical.

3.7.6 Safety Features and Emergency Systems

A range of safety features and emergency systems have been integrated into the design and operation of the Offshore Facility to manage safety risk. Based on Woodside's Health and Safety Design Premises for Hydrocarbon Facilities, risk management measures have been grouped into the categories of:

- prevention
- detection
- control
- mitigation.

The safety features and emergency measures in place on the facility are listed in Table 3-6. Specific details of these and other safety systems can be found in the Pluto A Operations Safety Case.

Table 3-6: The Pluto facility safety features and emergency systems

Category	Description
Prevention	Inherently safe design (leak minimisation, layout) Dropped object/impact protection (including vessel collision avoidance) Structural design Material selection and corrosion control
Detection	Fire, gas and smoke detection (including manual alarm callpoints)
Control	Process control system Ignition control Depressurisation systems Passive fire protection Heating, ventilation and air conditioning
Mitigation	Escape and evacuation routes Temporary refuge Emergency power and UPS Emergency and escape lighting Critical communications systems Evacuation and rescue facilities and equipment

3.8 Support Vessel Operations

3.8.1 Platform Support Vessels

Platform support vessels are used to transport material and equipment to and from the riser platform when crewed. The specifications of the Mermaid Strait are presented in Table 3-7 as an example, and represent typical specifications of a platform support vessel. Vessels supporting the facility may vary depending on vessel schedules and availability.

While in the field, the vessel also backloads materials and segregated waste for transportation back to the King Bay Supply Facility in Karratha. If the vessel has Fast Rescue Craft (FRC) capability it can be utilised to carry out standby duties including during helicopter operations and working over the side activities while in the field. PLA also utilises the Standby Vessel (SBV) located at the nearby Wheatstone Platform which can be called upon to render assistance in the event of a platform emergency and rescue response for helicopter operations.

Figure 3-7: Indicative facility support vessel (Mermaid Strait)

Table 3-7: Indicative platform support vessel specifications (Mermaid Strait)

Particulars	
Type	Diesel Electric, Azimuth, AHT, OSV, DP1
Length overall (LOA)	52.35 metres
Breadth	14.6 metres
Draft	4.9 metres
Dead weight tonnage (DWT)	930 tonnes
Accommodation	Berthing for 24 personnel
Dynamic positioning system	Kongsberg Simrad DP1 with Poscon joystick control
Capacities	
Fuel	592 m3
Pollution Control	
Spray booms	Nil
Dispersant pump	Nil
Dispersant storage	Woodside issued dispersant kit: tank volume 350 gallons.

3.8.2 Subsea Support Vessels

Subsea support vessels, including uncrewed surface vessels (USVs), are also used for field work such as subsea IMMR activities. Vessels supporting offshore activities may vary depending on operational requirements, vessel schedules, capability and availability.

Subsea activities are typically undertaken from a subsea support vessel or USV and may use an ROV with transponders. For some activities, ROVs may also be deployed from the Pluto riser platform. Typical subsea support vessels use a DP system to allow manoeuvrability and avoid anchoring when undertaking works, due to the close proximity of subsea infrastructure. However, vessels are equipped with anchors which may be deployed in an emergency.

The DP system requires the temporary deployment of up to six transponders on the seabed. Transponders are also used for monitoring the location of infrastructure/equipment during a repair. The transponders are attached to small recoverable moorings (metal clump weight or tripod) that are lowered to the seabed and placed in position by ROV. The transponders have a small footprint; less than 0.5 m2. The transponders and moorings are recovered using ROVs at the end of the activity.

ROV operations often require tool baskets which are temporarily placed on the seabed. These baskets typically have a mesh base with a seabed footprint of approximately 15 m2. The baskets are recovered to the vessel at the end of the activity.

3.8.3 Accommodation Support Vessel

An Accommodation Support Vessel (ASV) may be required for short periods to support planned maintenance campaigns, shutdown maintenance or major projects. Typically, these campaigns would last up to 90 days with possible extensions due to unforeseen factors like weather. During the life of this EP, an ASV could be required at any time of the year and would be located next to the facility, inside the PSZ.

ASV vessel specifications may vary depending on operational requirements, vessel schedules, capability and availability. Typical ASVs use a DP system so as to allow manoeuvrability and avoid anchoring when in close proximity of the platform. However, vessels are equipped with anchors which may be deployed in an emergency. Indicative ASV specifications are provided in Table 3-8.

Table 3-8: Indicative accommodation supply vessel specifications (Floatel Triumph ASV)

Particulars	
Type	Semi-submersible Accommodation Support Vessel
Length overall (LOA)	125 m
Breadth	80 m
Dead weight tonnage (DWT)	27,111 t
Accommodation	500 persons approx.
Dynamic Positioning System	DP 3
Capacities	
Fuel	Largest tank 297 m3 Total capacity 1,800 m3

3.8.4 Remotely Operated Vehicles

The MODU and project vessels may be equipped with an ROV system that is maintained and operated by a specialised contractor aboard the vessel. ROVs may be used during drilling operations and subsea installation, for activities such as:

- anchor holding testing
- connection of mooring systems
- pre-drill seabed and hazard survey
- blowout preventer (BOP) land-out and recovery
- BOP well control contingency
- visual observations at seabed during riserless drilling operation
- pre and post installation survey
- subsea xmas tree control systems hook-up and contingency control

- removal of sediments on or around subsea infrastructure
- installation, testing, pre-commissioning, commissioning and start-up of subsea infrastructure.

An ROV can be fitted with various tools and camera systems that can be used to capture permanent records (both still images and video) of the operations and immediate surrounding environment. Specifically, during installation, the ROV is fitted with hydraulically driven tools to facilitate flowline tie-in. An ROV may also be used in the event of an incident to deploy the Subsea First Response Toolkit.

3.8.5 Helicopter Operations

Helicopters are the primary means of transporting passengers and/or urgent freight to/from the Pluto facility and vessels. They are also the preferred means of evacuating personnel in an emergency. Helicopter operations within the PAA are limited to helicopter take-off and landing on the helideck. Helicopters may be refuelled on the helideck of the MODU. Helicopter support is principally supplied from Karratha Airport, and transports workers from Karratha for planned maintenance.

3.9 Hydrocarbon and Chemical Inventories and Selection

3.9.1 Hydrocarbons

The main hydrocarbon inventories associated with major topside process and non-process equipment is summarised in Table 3-8. In addition to the chemicals listed, the riser platform may also maintain small volumes of various facility maintenance chemicals as previously described.

Table 3-9: Hydrocarbon Inventories of process and non-process equipment

Material	Storage Means	Capacity/Storage Volume
Hydrocarbons		
Condensate	Knock-out drum	Usual volume 5 to 10 m^3, with capacity 90 m^3
Diesel	Crane pedestal diesel storage tank	80 m
	Generator set day tanks	3 x 1.8 m^3
Oily water and chemical waste	Hazardous Drain Collection Tank	14 m^3 (working volume 11.6 m3)
	Non-Hazardous Drain Collection Tank	2.3 m^3
	Waste Oil Storage Tank (transportable ISO container)	4 m^3
Water Handling Module– indicative potential hydrocarbon inventories		
Production separator	Vertical gas/liquid separator	~30 m^3 (normally also incl. PW)
Liquid-liquid separator	Produced water/condensate separator	~40 m^3 (normally also incl. PW)
Degasser	Produced water vessel	40 m^3
Induced gas floatation vessel	Produced water vessel	30 m^3
Oily water separation tank	Oily water storage tank	4 m^3

3.9.2 Chemical Usage

Chemicals are utilised for a variety of purposes and can be divided into two broad categories (operational and maintenance), as described below.

3.9.3 Operational Chemicals

3.9.3.1 Operational Process Chemicals

An operational process chemical is the active chemical added to a process or static system, which provides functionality when injected in produced fluid, utility system streams or for pipeline treatment. These chemicals may be present in routine or non-routine discharge streams from the facility.

Installation of the WHM, has introduced operational process chemicals corrosion inhibitors (up to 100 ppm dependent on water flow rate due to wet flowline operation) and water clarifiers (up to 50 ppm), some of which will be present in the routine discharge of produced water.

3.9.3.2 Operational Non-Process Chemicals

Operational non-process chemicals include chemicals which do not fall into the category described above but which may be required for operational reasons and, by virtue of their use, may be intermittently discharged or have the potential to be discharged (e.g., required as a result of maintenance or intervention activities). Examples include subsea control fluids, dyes and well intervention/workover chemicals.

Operational non-process chemicals such as hydraulic fluids required for operation of the water handling module HPU, have been introduced and included in this EP.

3.9.4 Maintenance Chemicals

Maintenance chemicals include chemicals which are required for general maintenance or 'housekeeping' activities and are critical for overall maintenance of the riser platform and its equipment. These may include paints, degreasers, greases, lubricants and domestic cleaning products. They may also include chemicals required for specialty tasks, such as laboratory testing and analysis. Maintenance chemicals generally present negligible risk to the environment, as they are not discharged as a result of their use (e.g., paint) or are used intermittently and discharged in low volumes (e.g. domestic cleaning products).

3.9.5 Indicative Chemical Inventories

An indicative list of bulk chemicals commonly used (or planned to be used on the facility) and estimated storage quantities, is summarised in Table 3-10. Other chemicals may be used in the future if chemical requirements change, for example, during start-up of new wells, there may be also be temporary well clean-up skid which may include water clarifiers. In addition to the chemicals listed, the riser platform may also maintain other small volumes of various operational chemicals and facility maintenance chemicals as previously described.

Table 3-10: Indicative bulk inventories of chemicals

Material	Storage Means	Storage Capacity
MEG	Hydrate inhibitor storage vessel[1] Transportable ISO container	12 m^3 (working volume 10 m^3)
Methanol (if required)	Hydrate inhibitor storage vessel [1] Transportable ISO container	Typically 4-6 m3 ISO containers
Subsea control fluid	Hydraulic power unit storage tank	4 m^3
Water Handling Module – indicative inventories		
Water clarifier (if required)	Water clarifier storage tank	4 m^3
Demulsifier	Demulsifier storage tank	4 m^3
Corrosion inhibitor	Corrosion inhibitor storage tank (stainless steel)	28 m^3 4 m^3

Material	Storage Means	Storage Capacity
	Lifted from vessels in IBC's and gravity drained into storage tank.	
Subsea control fluid	Hydraulic power unit storage tank for water handling module	3 m^3

[1] *Only a single hydrate inhibitor storage vessel is provided on the platform; however, the utility fluid may vary between methanol and MEG depending on operations requirements.*

3.9.6 Environmental Consideration during Selection, Assessment and Approval of Chemicals

As part of Woodside's chemical approval process, operational chemicals required by the Petroleum Activities Program are selected and approved in accordance with the Woodside Chemical Selection and Assessment Environment Guideline. This guideline is used to demonstrate that the potential impacts of the chemicals selected are acceptable and ALARP, and meet Woodside's corporate requirements (as outlined in Woodside's Environmental Performance Procedure, which requires chemicals to be selected with the lowest practicable environmental impacts and risks subject to technical constraints.

A summary of the environmental requirements of the guideline is outlined below.

3.9.7 Environmental Selection Criteria

The Woodside Chemical Selection and Assessment Environment Guideline follows the principles outlined in the OCNS which manages chemical use and discharge in the United Kingdom (UK) and the Netherlands (background on the OCNS scheme provided is below).

Operational chemicals will be selected/assessed in compliance with the Woodside Chemical Selection and Assessment Environment Guideline, specifically:

- Where operational chemicals with an OCNS rating of Gold/Silver/E/D and no OCNS substitution or product warning are selected, or a substance is considered to pose little or no risk to the environment (PLONOR), no further control is required. (Such chemicals do not represent a significant impact on the environment under standard use scenarios and therefore, are considered ALARP and acceptable).
- If other OCNS rated or non-OCNS rated operational chemicals are selected, the chemical will be assessed as follows:
  - If there is no planned discharge of the operational chemical to the marine environment, written technical verification of the 'no discharge' fate must be provided, and no further assessment is required.
  - If there is planned discharge of the operational chemical to the marine environment, a further assessment/ALARP justification will be conducted.

The ALARP assessment will include consideration of chemical toxicity, biodegradation and bioaccumulation potential, using industry standard classification criteria (CEFAS scheme criteria).

If a product has no specific ecotoxicity, biodegradation or bioaccumulation data available, the following options are considered:

- Environmental data for analogous products can be referred to where chemical ingredients and composition are largely identical.
- Alternatively, environmental data may be referenced for each separate chemical ingredient (if known) within the product.

If no environmental data is available for a chemical or if the environmental data does not meet the acceptability criteria outlined above, potential alternatives for the chemical will be investigated, with

preference for options with a Hazard Quotient (HQ) band of Gold or Silver, or are OCNS Group E or D with no substitution or product warnings.

If no more environmentally suitable alternatives are available, further risk reduction measures (e.g. controls related to use and discharge) will be considered for the specific context and implemented where relevant so that the risk is ALARP and acceptable.

Once the further assessment/ALARP justification has been completed, concurrence from the relevant manager that the environmental risk as results of chemical use is ALARP and acceptable is obtained.

3.9.8 Background Overview of the OCNS Scheme

The OCNS Scheme applies the requirements of the Convention for the Protection of the Marine Environment of the North-East Atlantic (OSPAR Convention). The OSPAR Convention is widely accepted as best practice for chemical management.

All chemical substances listed on the OCNS ranked list of registered products have an assigned ranking based on toxicity and other relevant parameters such as biodegradation, and bioaccumulation, in accordance one of two schemes (as shown in Figure 3-8):

Hazard Quotient Colour Band: Gold, Silver, White, Blue, Orange and Purple (listed in order of increasing environmental hazard), or

OCNS Grouping: E, D, C, B or A (listed in order of increasing environmental hazard). Applied to inorganic substances, hydraulic fluids and pipeline chemicals only.

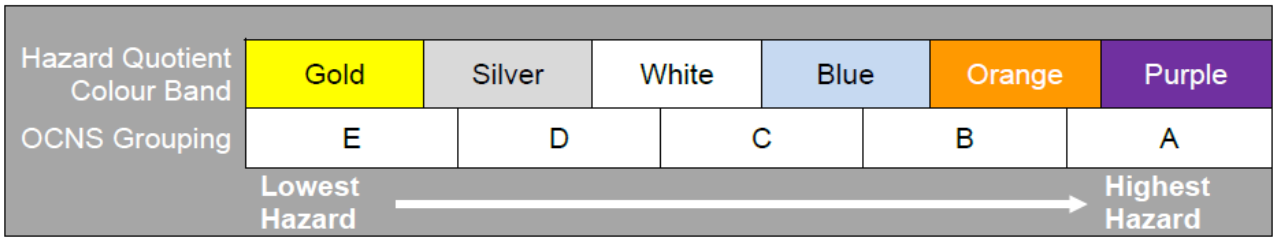

Figure 3-8: OCNS ranking scheme

3.10 Subsea Inspection, Maintenance, Monitoring and Repair (IMMR) Activities

3.10.1 Overview

Subsea infrastructure, including the platform substructure, is designed not to require significant intervention. Inspection and maintenance are undertaken to ensure the integrity of the infrastructure and identify problems before they present a risk of loss of containment. Maintaining infrastructure integrity also supports decommissioning planning. Intervention may be required to repair identified problems.

To manage subsea threats (risks) the IMMR process requires an appropriate response to be selected to manage specific equipment risks. This is typically one of: Inspection, Maintenance, Monitoring and Repair (IMMR).

The IMMR process for subsea infrastructure maintains equipment in good condition and repair, for production and to enable future removal.

Subsea activities are typically undertaken from a subsea support vessel or Uncrewed Surface Vessel (USV) and may use an ROV to inspect equipment. For some activities, ROVs may also be deployed from the PLA platform.

Maintenance and repair activities may require the deployment of frames/baskets which are temporarily placed on the seabed. These typically have a perforated base with a seabed footprint of

about 15 m^2. This temporary equipment is removed from field via recovery to project vessels at the completion of IMR activities.

3.10.2 Typical IMR activities are described below.

3.10.2.1 Inspection

Inspection of subsea infrastructure is the process of physical verification and assessment of components in order to detect changes to the as-installed location and condition by comparison to initial state following installation and previous inspections. Details of typical subsea infrastructure inspections/surveys and indicative frequencies are provided in Table 3-11. Scope and frequency of subsea equipment (operational and redundant) and pipeline inspections are determined using a Risk Based Inspection (RBI) methodology and associated plans.

RBI is commonly used within the industry as a method for determining inspection frequencies (Energy Institute, 2009; DNV, 2019).

Table 3-11: Typical subsea infrastructure inspections and surveys, their purpose and approximate frequencies.

Type of inspection/ survey	Subsea infrastructure	Purpose	Approximate frequency
General visual inspection	All subsea infrastructure	Check general infrastructure integrity.	Varied – every 1 to 8 years
Close visual inspections	All subsea infrastructure	Investigate certain subsea infrastructure components.	Varied – every 2 to 6 years
Cathodic protection	All subsea infrastructure	Check for corrosion and renew sacrificial anodes, if required.	Varied – every 2 to 6 years
Wall thickness surveys	Production and crossover manifolds, flowlines and pipelines	Monitor the condition of subsea infrastructure. (i.e., ultrasonic testing). Typically only performed if a specific threat is identified through other means.	Typical: Once every 25 years Worst case: Once every 5 years
Acoustic survey (e.g., multibeam echo sounder (MBES), sidescan sonar (SSS)	Pipelines	Identify buckling, movement, scour and seabed features. Low frequency/ intensity signals undertaken on the flowlines.	Varied – every 1 to 6 years
Non-destructive testing (NDT)	Pipeline and manifolds (if required)	Evaluates the properties of material/items using electromagnetic, radio graphic, acoustic resonance technology, ultrasonic, or magnetic equipment.	Typical: Once every 25 years Worst Case: Once every 25 years per well
Seabed sampling surveys including minor grabs/cores	NA	Identify benthic fauna, sediment characteristics, determine level of penetration/compaction, etc. Grabs/cores typically disturb 0.1 m^2 of seabed per sample.	Typical: Once every 25 years Worst Case: Once every 5 years

Anode inspections and/or replacement	Production and crossover manifolds, trees, flowlines and pipelines	Samples taken of anode materials for testing.	Typical: Once every 25 years
Marine growth sampling	All subsea infrastructure	Samples taken of marine growth for testing.	Typical: Once every 25 years Worst Case: Once every 5 years
Sub bottom profiling	Around subsea components	Low frequency echo sounder undertaken to identify returns of metals under the seabed.	Varied – every 1 to 6 years
Laser surveys	Dimensional check on spools	Used to conduct dimensional checks on spools, etc, and measure proximity.	Varied – every 1 to 6 years
Pigging	Export pipeline, flowline	Inspection, maintenance, repair or to facilitate modifications.	Typical – Once every 4 years Worst case – every 4 months
Type of inspection/ survey	Subsea infrastructure	Purpose	Approximate frequency
General visual inspection	Structure, wellheads, spools, flowlines, risers and pipelines	Check general infrastructure integrity.	Varied – every 1 to 8 years
Close visual inspections	All subsea infrastructure	Investigate certain subsea infrastructure components.	Varied – every 2 to 6 years
Cathodic protection	All subsea infrastructure	Check for corrosion and renew sacrificial anodes, if required.	Varied – every 2 to 6 years
Wall thickness surveys	Production and crossover manifolds, flowlines and pipelines	Monitor the condition of subsea infrastructure. (i.e., ultrasonic testing).	Typical: Once every 25 years Worst case: Once every 5 years
Acoustic survey (e.g., multibeam echo sounder (MBES), sidescan sonar (SSS), sub bottom profiling (SBP))	Pipelines	Identify buckling, movement, scour and seabed features. Low frequency/ intensity signals undertaken on the flowlines.	Varied – every 1 to 6 years
Non-destructive testing (NDT)	Pipeline and manifolds (if required)	Evaluates the properties of material/items using electromagnetic, radio graphic, acoustic resonance technology, ultrasonic, or magnetic equipment.	Typical: Once every 25 years Worst Case: Once every 25 years per well
Seabed sampling surveys including minor grabs/cores	NA	Identify benthic fauna, sediment characteristics, determine level of penetration/compaction, etc. Grabs/cores typically disturb 0.1 m^2 of seabed per sample.	Typical: Once every 25 years Worst Case: Once every 5 years
Anode inspections and/or replacement	Production and crossover manifolds, trees, flowlines and pipelines	Samples taken of anode materials for testing.	Typical: Once every 25 years Worst Case: Once every 25 years

Marine growth sampling	All subsea infrastructure	Samples taken of marine growth for testing.	Typical: Once every 25 years Worst Case: Once every 5 years
Sub bottom profiling	Around subsea components	Low frequency echo sounder undertaken to identify returns of metals under the seabed.	Varied – every 1 to 6 years
Laser surveys	Dimensional check on spools	Used to conduct dimensional checks on spools, etc, and measure proximity.	Varied – every 1 to 6 years
Pigging	Export pipeline, flowline	Inspection, maintenance, repair or to facilitate modifications.	Typical – Once every 12 years Worst case – every 5 years
Cycling of valves via control system	Well	Test functionality of technical integrity valves	Every 6 months
Marine growth removal	Production and cross over manifolds and retrieval components (e.g., chokes)	Reduce weight or gain visual access	Based on outcomes from visual inspections and marine growth trends on regional infrastructure
Flushing of chemical hydraulic fluid lines	Hydraulic fluid lines	For repair scenarios	When required for repair
Leak and pressure testing	All subsea infrastructure	Test integrity of subsea infrastructure	Following installation of subsea infrastructure components after a repair or intervention, prior to return to service

3.10.2.2 Monitoring

Monitoring of subsea infrastructure refers to the process of surveillance of the physical and chemical environment that a subsea system or component is exposed to, in order to determine if and when damage may occur, and (where relevant) predict the rate or extent of that damage. Monitoring activities may include process composition testing, corrosion probes, corrosion mitigation checks, metocean and seismic monitoring, and cathodic protection testing. Other monitoring activities include process monitoring (temperature, pressure, etc.), cyclone weather monitoring, and hydraulic fluid usage.

3.10.2.3 Maintenance

Maintenance activities on subsea infrastructure are those required at regular or planned intervals to prevent deterioration or integrity failure of infrastructure. Typical maintenance activities are described in Table 3-12.

Table 3-12: Typical maintenance activities, their purpose and approximate frequencies

Type of maintenance	Subsea infrastructure	Purpose	Approximate Frequency
Cycling of valves via control system	Wells and manifolds	Test functionality of technical integrity valves	Every 6 months for well barriers during operations
Marine growth removal	Production and cross over manifolds and retrieval components (e.g. chokes) and jacket cleaning	Reduce weight or gain visual access	Based on outcomes from visual inspections (Table 3-11) and marine growth trends on regional infrastructure

Flushing of chemical hydraulic fluid lines	Hydraulic fluid lines	For repair scenarios	When required for repair
Leak and pressure testing	All subsea infrastructure	Test integrity of subsea infrastructure	Following installation of subsea infrastructure components after a repair or intervention, prior to return to service
Pigging	Export pipeline	Cleaning of trunkline or liquids management	Typically every year for cleaning and liquids management pigging not required at current export rates but would be performed on as needs basis

3.10.2.4 Repair

Repair activities are those required when a subsea system or component is degraded, damaged or has deteriorated to a level outside of acceptance limits as defined by design codes. Damage sustained may not necessarily pose an immediate threat to continued system integrity, but may present an elevated level of risk to environment or production reliability. Due to the design of subsea infrastructure and materials used, repairs are undertaken on an as needs basis. The requirements and frequency of these repairs are dictated by the outcome of the inspection and maintenance regimes described in Table 3-11 and Table 3-12. Typical subsea repair activities included but not limited to, are described below.

- subsea choke and/or battery module replacement
- chemical injection throttling valve (CITV) replacement
- subsea control module (SCM) or electrical distribution unit (EDU) replacement
- power and communications router, tree and downhole replacement
- multi-phase flow meter (MPFM) or wet gas flow meter (WGM) replacement
- acoustic sand detector (ASD) replacement
- hydraulic control router (HCR) replacement
- hydraulic flying lead (HFL) replacement
- electrical flying lead (EFL) replacement
- pipeline or spool support with grout bag, mattress, anchors or rock dumping
- spool disconnection and/or replacement
- umbilical jumper replacement and/or relocation
- flowline/pipeline replacement
- scour prevention installation
- cathodic protection system replenishment/repair.

When equipment is replaced, the redundant equipment, may remain in-situ or be removed from the field. The location of redundant subsea infrastructure items is recorded as part of the ROV as left survey and included in a database for Pluto subsea inventory.

3.10.2.5 Subsea Chemical Usage

Planned chemical discharges may occur during a range of subsea system operation and IMMR activities. The chemicals and volumes released will be specific to each activity. Releases are discussed and provided in the specific activity sections below and, where practical, typical and approximate worst-case volumes provided. Typical volumes are the expected releases associated with the activity following depressurisation and flushing activities.

Operational chemicals to be used within Pluto subsea infrastructure are selected and assessed using Woodside's chemical selection and assessment procedures as detailed in Section 3.9.

Typical chemicals which are used in subsea infrastructure and may be released during IMMR activities include those described below.

- Subsea Control Fluid – The subsea control fluid presently used in the facility subsea systems is HW443. HW443 is a water-based product.
- Hydrate Control – MEG is used for hydrate control.
- Corrosion Inhibitor – Corrosion inhibitor is generally used to manage and prevent corrosion in pipes and tanks.
- Biocide – Biocides are generally used to prevent the bacterial growth in pipelines that may cause corrosion.
- Dye – Chemical dyes are used to identify the source of a leak.
- Acid – Where removal of calcium deposits is required, Woodside typically uses sulphamic (or equivalent) acid. Alternatives such as citric acid may be used.
- Oxygen Scavenger – Oxygen scavenger is used to de-oxygenate the flowlines and prevent corrosion and aerobic bacterial growth.
- Grout – The material used in grout, mattresses and rock is typically concrete-based.
- Staurolite Products – Staurolite products are used for abrasive/sand blasting to clean and remove marine growth. The main component is staurolite, which is a naturally forming mineral.

3.10.2.6 Marine Growth Removal

Due to the relatively high rate of marine growth on the NWS, it is often necessary to remove excess growth prior to undertaking many subsea IMMR activities. Marine growth removal is undertaken with a ROV or a diver. The different techniques are described in Table 3-13..

Table 3-13: Marine growth removal techniques

Activity/Equipment	Description
Water jetting	Uses high pressure water to remove marine growth.
Brush systems	Uses brushes attached to a ROV to remove marine growth.
Acid (typically sulphamic acid)	Dissolving of calcium deposits between interfaces on subsea infrastructure.
Sand/abrasive blasting	Additional cleaning to allow close visual inspections.

3.10.2.7 Intervention Isolations

The Woodside Engineering Operating Standard – Subsea Isolation defines a proven isolation to be a valved isolation where the effectiveness of the isolation has been confirmed via vent, bleed, or instrumentation points. An activity specific philosophy/procedure must be developed in line with this standard for each isolation. Isolation testing will result in a planned release of hydrocarbons to the environment.

3.10.2.8 Pipeline Pigging Operations

Pipeline cleaning pigging occurs approximately once every 20 weeks to manage liquid hold-up and solids generation, and as part of the planned inspection programme. Pipeline maintenance and monitoring requirements may increase pipeline pigging frequency with time, to monitor pipeline integrity more closely as the facilities age and/or in response to findings from intelligent pigging campaigns.

3.10.2.9 Sediment Relocation

If sediment builds up around a pipeline or other subsea infrastructure, a ROV-mounted suction pump/dredging unit may be used to relocate the sediment to allow inspection/works to be undertaken. This activity is limited to the relocation of small amounts of sediment material in the immediate vicinity of the subsea infrastructure (i.e. within the existing footprint). Sediment relocation typically results in minor seabed disturbance and some localised turbidity.

3.10.2.10 Corrosion Protection

The aim of corrosion protection is to preventor limit the chemical reactions that cause corrosion and to manipulate them in such a way that corrosion is avoided or mitigated. Corrosion prevention techniques used are:

- corrosion protection layers to provide a barrier of corrosion-resistant material between the subsea environment and the structural material.
- anode skids where an anode is attached to the subsea asset to act as ‘sacrificial metal’ which is more easily corroded.

Measurements may be undertaken using probes (e.g., electrical resistance probes) to assess the effectiveness of these techniques. If a measurement identifies the corrosion protection layer requires repairs, appropriate remediation options will be investigated.

If additional anode skids are required, they will be placed on the seabed using a support vessel crane. A typical anode skid will have a seabed footprint of approximately 8 m2. It is necessary to remove marine growth around the point where the anode skid is to be connected in order to establish good continuity through clamping and/or welding.

Activities may result in some minor disturbance due to placement of skids, removal of marine growth from equipment, sediment relocation, the placement of ROV tool baskets and DP transponders on the seabed.

3.10.2.11 Span Rectification, Pipeline Protection and Stabilisation

Due to tidal currents or other scouring processes, sections of pipelines, spool flowlines and umbilicals may become unsupported by the seabed (span) and/or become unstable on the seabed. Spanning or instability may expose the component to risk of stress beyond design parameters, increasing risk of failure.

A number of techniques may be used for span rectification or component stabilisation and protection, including grout bags, mattresses, anchors, piling or rock placement. All techniques require the use of a support vessel crane to deploy the material and a ROV so that it is accurately placed on the seabed. In addition, a subsea component may require protection from additional activities (e.g., supply vessel lifts onto the facility and pipeline crossings).

3.10.2.11.1 Grout Bags

Span rectification typically involves placement of a grout bag with anti-scouring skirts under the spanned component. Grout is pumped into the grout bag from a support vessel via a downline. Once

the bag is inflated it acts as a pillow with the pipe resting on top (Figure 3-10). Typical grout volumes will depend on the size of the span and may vary from 200 kg to greater than 2000 kg.

Figure 3-9: Grout bags in position

3.10.2.11.2 Mattresses

Mattresses are typically made of concrete and may be used for span rectification or pipeline protection and stabilisation. An example of a mattress over a pipeline is provided in Figure 3-11. Mattresses are typically 3 m by 6 m in size, and therefore may disturb 18 m2 of the seabed.

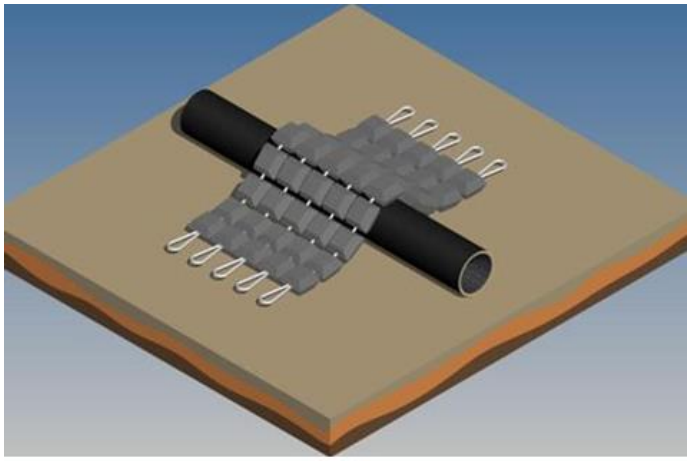

Figure 3-10: Concrete mattress for span rectification or pipeline protection or stabilisation

3.10.2.11.3 Rock Placement

Rock placement for span rectification is typically small scale and involves the use of one tonne bulker bags filled with rock, with the number of bags varying to suit the application. This activity will cause seabed disturbance due to placement of material on the seabed; however, the area of seabed affected will be small and localised and is unlikely to extend beyond the area originally impacted during the laying of the pipeline.

In addition, the activity may result in some minor disturbance from removal of marine growth, sediment relocation, the placement of ROV tool baskets and DP transponders on the seabed.

3.10.2.12 Suspension and Preservation of Redundant Equipment

In the event equipment is degraded, damaged or has deteriorated to a level outside of acceptance limits, equipment may be repaired, replaced, or preserved and suspended until decommissioning. A risk assessment will be undertaken considering level of risk to safety, health, and environment or production reliability and will determine if the infrastructure will be repaired, replaced or suspended and preserved.

A typical program to suspend and preserve redundant equipment is as follows:

- Complete an as-found ROV survey of the umbilical/jumper and adjacent infrastructure.
- Remove marine growth, if required.
- Relocate any sediment build-up in the area surrounding infrastructure, if required.
- Flush prior to disconnection.
- Isolate equipment.
- Install caps/flanges.
- Relocate infrastructure to a safe location (if required).

3.10.2.13 Well Management and Maintenance Activities

The facility subsea well interventions, workovers and well kills require a suitable vessel or MODU to accommodate and support intervention packages. Therefore, these activities do not form part of the scope of this EP. Unloading and clean-up from subsea wells via the facility may be required infrequently. Unloading and clean-up discharges are routed via the process facilities to be cleaned of any remaining chemicals and fluids in the wellbore or reservoir.

3.10.2.13.1 Well Unloading and Clean-up

Following subsea interventions, workovers and well kills, the well may be unloaded and flowed via the process facilities to be cleaned of any remaining chemicals and fluids in the wellbore or reservoir. During this phase, the products may be processed, as follows:

- Gas: will be routed into the production process where possible, or flared if unsuitable.
- Fluids: will be routed to the HP flare knock-out drum which discharges liquids to the closed drain system.
- Wastes (may include fluids and sand/solids): will be managed as appropriate based on composition. Solids will be separated for onshore disposal as required following Woodside's Waste Management Plan for Offshore Facilities. An additional strainer may be placed in the flowlines prior to the main separators to remove any large debris that may be in the wellbore.

3.11 Xena-03 Drilling and Tie-back Activities

3.11.1 Drilling Activities

This EP includes drilling activities for the Xena-03 well in the Xena-03 Operational Area and tie-back to the Pluto facility, in the PAA. Well construction activities are conducted in a number of stages, as described below. Well design will be optimised for ultimate recovery.

Detailed well designs will be submitted to NOPSEMA as part of the Approval to Drill and the accepted Well Operation Management Plan (WOMP), as required under the Offshore Petroleum and Greenhouse Gas Storage (Resource Management and Administration) Regulations 2011.

For clarity, all activities specific to the Xena-03 Drilling and Tie-back campaign (Section 3.11) will herein be referred to as the Xena-03 Tie-back activities.

3.11.1.1 Cement Unit Test

Upon arrival on location at the Xena-03 Operational Area, the MODU may need to perform a cement unit test, or 'dummy cement job', to test the functionality of the cement unit and the MODU's bulk cement delivery system before performing an actual cement job. This operation is usually performed after a MODU has been out of operation for an amount of time (warm-stack), if maintenance on the

cement unit has been performed, or if it is the first time a MODU is being used in-country and commissioning of the cement unit system is required.

A 'dummy cement job' involves mixing a sacrificial cement slurry at surface, and once functionality of the cement unit and delivery system has been confirmed, the slurry is discharged through the usual cement unit discharge line (which may be up to 10 m above the sea level) or through drill pipe below sea level as a cement slurry. The slurry is usually a mix of cement and water; however, may sometimes contain stabilisers or additives. The indicative volume of cement that may be discharged to sea during a cement unit test is approximately 100 bbl.

3.11.1.2 Top Hole Section Drilling

Petroleum Activities Program drilling commences with the top hole section as follows:

- The MODU arrives and establishes position over the well site.
- Top-hole sections are drilled riserless using seawater with pre-hydrated bentonite sweeps/XC Polymer sweeps or drilling fluids to circulate drilled cuttings from the wellbore. As a contingency, Water Based Mud (WBM) may be used in the presence of a shallow gas anomaly.

Once the top hole sections of the well have been drilled, steel tubulars (called conductor or casing) are inserted into the wellbore to form the surface/intermediate casing and secured in place by pumping cement into the annular space above the casing shoe or to surface (seabed), which will involve discharging excess cement at the seabed.

3.11.1.3 Blowout Preventer and Marine Riser Installation

After setting the surface or intermediate casing, a BOP is installed on the wellhead, and the marine riser above it, to provide a physical connection between the well and MODU. This enables a closed circulation system to be maintained, where weighted drilling fluids and cuttings can be circulated from the wellbore back to the MODU, via the riser.

In addition, the BOP provides a means for sealing, controlling and monitoring the well during drilling operations. The BOP components operate using open hydraulic systems, using water-based BOP control fluids.

Each time a BOP pressure and function test schedule is undertaken approximately 3620 L of water-based fluid is released to the marine environment, of this approximately 4% is control fluid additive. BOP operation includes function and pressure testing approximately every 21 days, and a function test (approximately 2665 L) approximately every seven days, excluding the week a pressure test is conducted.

3.11.1.4 Bottom Hole Section Drilling

A closed system (riser in place) is used for drilling bottom hole sections to the planned wellbore Total Depth (TD). The bottom hole sections will be drilled using water-based mud (WBM) drilling fluids, although contingency non-water-based muds (NWBM) may be used if WBM cannot meet technical requirements (Section 3.11.5).

Protective steel tubulars (casings and liners) are inserted as required. The size, grade, weight, length and inclination of the casing/liner sections within the wellbore are determined by factors such as the geology/subterranean pressures likely to be encountered in the area and any specific information or resource development requirements.

After a string of casing/liner has been installed into the wellbore, it is cemented into place. The casing/liner is then pressure tested. Once the pressure testing is passed, drilling of the next section can resume with the riser in place to circulate drill cuttings and drilling fluids back to the MODU.

Cementing operations can be performed to:

- provide annular isolation between hole sections and structural support of the casing/liner as required.
- set a plug in an existing well to sidetrack.
- plug a well so it can be suspended/abandoned.

Cement is transported as dry bulk to the MODU by the support vessels, mixed as required by the cementing unit on the MODU and pumped by high pressure pumps to the surface cementing head then directed down the well.

3.11.1.5 Formation Evaluation

Formation evaluation is the interpretation of a combination of measurements taken inside a wellbore to detect and quantify hydrocarbon presence in the rock adjacent to the well. Formation Evaluation While Drilling (FEWD) is the process by which the presence and quantity of hydrocarbon in a reservoir is measured according to its response to radioactive and electrical input. It may include extracting small cores, wireline logging, full diameter cores and other down-hole technologies, as required. FEWD tools will be incorporated into the drillstring during development drilling and may include gamma ray, directional deep resistivity, callipers, density-neutron, sonic and tools which can measure formation pressures. Some FEWD tools contain radioactive sources; however, no radioactive material will be released to the environment and radiation fields are not generally detectable outside the tool when the tool is not energised. Therefore, they do not present an environmental risk.

3.11.1.6 Wellbore Clean Out

As required throughout activities with the riser connected, wells will be displaced from one drilling fluid system to another, or from the drilling fluid system to completion brine. A chemical clean out pill or fluids train will be circulated between the two fluids. Brine is typically a filtered brine with < 70 NTU or < 0.05% total suspended solids (TSS). This results in a brine and seawater discharge after this operation.

Clean out fluids and completion brine will be captured and stored on the MODU and discharged if oil concentration is < 1% by volume or returned to shore if discharge requirements cannot be met.

3.11.1.7 Xmas Tree Installation

Before the upper completion is installed into the well, the horizontal xmas tree will be installed from either an installation vessel or directly from the MODU. Due to the subsea well layout, if installation was to occur from an installation vessel, the MODU will be required to reposition away from the drill centre to allow the installation vessel to install the xmas tree. Once the xmas tree has been installed, the tree-to-wellhead interface will be pressure tested to confirm integrity. The MODU BOP will then be reconnected to continue with drilling and completions activities.

The xmas tree will be installed with a preservation mixture in the production and annulus bore.

3.11.1.8 Completions Activities

Once the well has been drilled, well completion activities will be performed which may include the installation of the lower completion, intermediate completion, production tubing and subsea tree. The well is then pressure tested for integrity before well suspension.

The well will be completed with a conventional upper completion. The well will be suspended with two crown plugs installed in the tubing hanger. Crown plugs will be individually pressure tested to verify suspension barriers before removing the BOP.

3.11.1.9 Well Unload

3.11.1.9.1 General Description

During well unloading activities, all completion and reservoir fluids will be directed through the Pluto facility to the onshore LNG plant.

In the event that fluids from well unloading cannot be directed to the Pluto facility, they may be flared or discharged to the environment via the well test package onboard the MODU. The base oil column, completion fluid, hydrocarbons and produced/condensed water will be measured, handled, separated, treated for overboard discharge (non-hydrocarbon) and flared/burned (hydrocarbon) through the temporary production system on the MODU. Note that the opportunity to unload to the Pluto facility is Woodside's preferred option, which could eliminate or reduce well unloading to the MODU.

3.11.1.9.2 Produced/Reservoir Water Disposal

If fluids from well unloading are directed to the MODU, the well test water treatment package will be used to treat produced/reservoir water before discharge. Prior to discharging, the fluids are cycled through an onboard filtration system and gauge tank. Water filtration is standard practice for well unloading operations. Fluids that cannot be treated or flared will be sent onshore in tanks for disposal.

3.11.1.9.3 Emissions

If well unloading is performed to the MODU, it is expected that condensate, diesel and methanol in the wellbore will be flared. The flare may be extinguished due to water ingress, lack of fuel (propane), weather impact or equipment failure resulting in cold venting of gas from the flare for several minutes before the flare can be restarted or venting stopped. After the objectives of the well testing and flowback are achieved, the flow is stopped and the well may be cleaned using a brine that can include several chemicals, such as biocide and surfactant.

3.11.2 Drilling Fluid System

In addition to the base fluid, drilling muds contain a variety of chemicals, incorporated into the selected drilling fluid system to meet specific technical requirements (e.g., mud weight required to manage pressure, or for borehole stability). All chemicals selected for use will be assessed under Woodside's internal guidelines so that potential impacts are acceptable, ALARP and meet Woodside's expectation for environmental performance.

3.11.2.1 Water-based Mud System

A water-based drilling fluid system is the preferred option for the Petroleum Activities Program.

In addition to the base fluid, drilling muds contain a variety of chemicals, incorporated into the selected drilling fluid system to meet specific technical requirements (e.g., mud weight required to manage pressure, or for borehole stability). The WBM drilling fluid will either be mixed on the MODU or received pre-mixed, then stored and maintained aboard the MODU. The top hole sections are drilled riserless with seawater containing pre-hydrated gel sweeps. The bottom hole sections may be drilled using WBM in a closed circulation system which enables reuse of the WBM drilling fluids.

WBM drilling fluids that cannot be reused (e.g., due to bacterial deterioration or if they do not meet required drilling fluid properties) or are mixed in excess of required volumes, may be operationally discharged to the ocean under the MODU's Permit to Work (PTW) system.

A number of factors unique to each drilling program will determine the quantities of WBM drilling fluids required and subsequent discharge volumes if no suitable reuse option is available.

3.11.2.2 Mud Pits

There are typically a number of mud pits (tanks) on the MODU that provide a capacity to mix, maintain and store fluids required for drilling activities. The mud pits form part of the drilling fluid circulating system. The mud pits and associated equipment/infrastructure are cleaned out at the end of drilling and completions operations. Mud pit wash residue is discharged overboard with less than 1% oil contamination by volume. Mud pit residue over 1% oil volume is sent to shore for disposal.

3.11.2.3 Drill Cuttings

Drill cuttings generated from the well are expected to range from very fine to very coarse (<1 cm) particle/sediment sizes. Cuttings generated during drilling of the top hole sections are discharged at the seabed. Estimated volumes of drill cuttings that may be discharged during the Petroleum Activities Program are presented in Section 6.7.8.

The bottom hole sections are drilled with a marine riser that enables cuttings and drilling fluid to be circulated back to the MODU, where the cuttings are separated from the drilling fluids by the SCE. The SCE comprises, but is not limited to shale shakers, cuttings dryers and centrifuges. The SCE uses shale shakers to remove coarse cuttings from the drilling mud. After being processed by the shale shakers, the recovered mud from the cuttings may be directed to centrifuges, which are used to remove fine solids (4.5 to 6 µm). The cuttings are usually discharged below the water line and the mud is recirculated into the fluid system.

If contingency NWBM is needed to drill a well section, the cuttings which are separated from the NWBM via the shakers will also pass through a cuttings dryer and associated SCE to reduce the average oil on cuttings for the entire well (only sections using NWBM) to 6.9% wt or less on wet cuttings prior to discharge. Woodside is not planning to use NWBM and their use is retained as a contingency only. The approval process within Woodside to permit the use of NWBM is described in Section 3.11.5.4.

3.11.2.4 Cement, Barite and Bentonite Discharge

Excess cement, barite and bentonite (dry bulk) after well operations are completed, will either be held onboard and used for subsequent wells, provided to the next operator at the end of the program, or if these options are not feasible, discharged to the marine environment. Toward the end of the campaign, if re-use, transfer or on-sale of the dry bulk stocks becomes not feasible, Woodside will implement stock reduction measures to reduce the volume dry bulk stock requirement, to that necessary for well control, as defined in relevant well control procedures.

Excess cement, barite and bentonite that does not meet technical requirements during the Petroleum Activities Program may also be bulk discharged to the environment. Bulk discharges of cement, barite and bentonite may occur as a slurry through the usual cement discharge line or blown as dry bulk and discharged. Woodside requires that mercury and cadmium concentration in stock barite be below 1 mg/kg and 3 mg/kg, respectively. Documentation of heavy metal analysis is planned to be undertaken for all individual batches of barite and used to verify compliance with these concentrations.

3.11.3 Subsea Installation and Pre-commissioning Activities

The subsea installation scope of work will include installing and pre-commissioning the infrastructure summarised in Table 3-14. The Petroleum Activities Program includes directly installing infrastructure from the installation vessels in the relevant location. During hook-up and pre-commissioning of the new and existing facilities there is potential for discharges associated with the testing and connection activities of the subsea systems. The pre-commissioning associated with subsea infrastructure generally includes leak testing of the flexibles, subsea control systems verification and function-testing of valves to verify that the electric and hydraulic flying leads are ready for entry into the commissioning phase.

Table 3-14: Subsea installation component summary

Description	Detail	Dimensions (approximate)
Well (Xena-03)	1x wellhead and xmas tree system	6.0 m (L) x 4.0 m (W) x 6.0 m (H) (typical)
Subsea flowline	10” ID flexible flowline	3000 m
Subsea control	1 x electrohydraulic umbilical (EHU)	2500 m
	Umbilical termination assembly x 2	4 m x 3m
Stabilisation	Concrete mattresses x ~10	6 m x 3 m

3.11.3.1 Underwater Acoustic Positioning

Long base line (LBL) transponders and/or Ultra Short Baseline transponders (USBL) are commonly used acoustic positioning methods and may be installed on the seabed as required by the installation activities. The USBL subsea transponder transmits an acoustic pulse back to the vessel receiver, hence providing an accurate positioning of the subsea transponder location. The LBL array provides accurate positioning by measuring ranges to three or more transponders deployed at known locations on the seabed and structures.

These transponders are utilised for the correct positioning of the subsea infrastructure. Transmissions are not continuous but consist of short ‘chirps’ with a duration that ranges from three to 40 milliseconds. If used, the LBL transponders are installed in stands on the seabed. Both the transponders and stands are recovered after installation. The USBL transponders are mounted on the subsea infrastructure and removed post installation.

Transponders may also be installed in stands on the seabed for vessel positioning. Both transponders and stands shall be removed post installation.

3.11.3.2 Installation of Structures

Subsea structures (i.e., subsea distribution unit, mudmats) are lowered to the seabed using the main crane positioned on an installation vessel to a pre-determined depth before engaging an ROV to guide it to the correct position.

As described above, the structures may be positioned using LBL array or USBL. Additional pre-deployed clump weights or sandbags can potentially be used to provide further assurance that the structures are positioned in the correct location and orientation.

3.11.3.3 Flexible Flowline Initiation/Initiation Anchor Deployment

Commencement of the flowline installation may require using an initiation anchor to pull against in order to provide the required tension to the flexible flowline as it transitions from the installation vessel to the seabed. The initiation anchor, which will be recovered after use, may consist of a clump weight.

Installation aids such as sandbag markers or concrete mattresses may be used for positioning aids or wet storage as required.

3.11.3.4 General Flexible Flowline and flying leads Installation

The installation contractor will mobilise an installation vessel to the field to install the flexible flowline and flying leads to the seabed. The installation vessel will operate in DP during installation activities.

The optimum flowline route is selected by considering seabed bathymetry, pre-installation surveys and installation risk management, including dropped object risks.

The indicative installation methodology and principle applied when installing the flowline is as follows:

- The flexible flowline is reeled onto either horizontal or vertical reels.
- VLS are installed on the vessel to lay the flexible flowline.
- During installation, a hydraulically driven centre reel drive is engaged to the reel to rotate the reel in synchronised speed with the VLS.
- Installation sequence for flexible flowline is as follows:
- Prepare universal connection system and VLS onboard the vessel.
- Fit applicable subsea components (anodes, bend restrictors) to flexible flowline, perform tests and pre-deployment checks.
- Deploy flexible flowline, ROV guide tail end to initiation point and land out
- Continue flexible flowline lay as per lay route while monitoring touchdown with ROV.
- Land out second end to final location and disconnect.

The flexible flowline may also be installed using a lighter installation spread on the installation vessel, via a deck-mounted powered reel system in combination with a deployment chute mounted on the side of the installation vessel and temporary installation aids placed on the seabed.

The flying leads are configured into deployment basket(s) and landed on the seabed using a crane. ROVs will complete the final subsea tie-in. Small volumes of MEG and HW443 will be released to subsea environment during HFL removal and installation.

3.11.3.5 Span/Scouring Rectification and Stabilisation

Spans are undulations in the seabed that do not provide sufficient support to the flowline. Spans are generally mitigated by installing structures, such as concrete mattresses, before installing the flowline. Engineering validation will determine if concrete mattresses need to be installed to mitigate spans. The dimensions for each concrete mattress are typically 6 m by 3 m by 0.3 m.

Post-lay span rectification may also be required after flexible flowline installation. This process typically involves placing grout bags under the span section. The empty bag is moved into position using ROV, then filled with grout supplied from a mixing and pumping spread on the vessel via a downline. Typical grout volumes depend on the size of the span and may vary from about 200 kg to 2000 kg per span.

If grout bags are used, the downline recovery time risks exceeding the grout curing time. If grout cures within the downline and pump, the equipment is likely to be rendered unserviceable, as well as the downline not being safely recoverable in the normal way. Therefore, after grouting activities at each span site, the downline and pump will need to be purged using seawater. This results in an amount of grout, approximately equivalent to the downline volume (5 m^3), being discharged to the ocean. This flushing is required once per grout site. The actual number is not known until the line is laid and need for span rectification determined, if any.

Scouring is the movement of seabed sediment (e.g., silt, sand and gravel) from around the base of a subsea structure to further afield due to prevailing hydrodynamic conditions, potentially compromising the integrity of a structure. Scouring is generally mitigated by installing mattresses along the perimeter of the installed structure. Concrete mattresses may be installed pending engineering verification.

Stabilisation is a post-lay activity to ensure that items, such as the flying leads remain at their installed positions, i.e. not being shifted due to strong seabed current. Stabilisation of flying leads is generally mitigated by installing sandbags on top of flying leads at a predetermined distance apart. Sandbags generally come in a standard size with 20 kg to 25 kg weight. Concrete mattresses may be used to stabilise the flexible flowline. Sandbags or concrete mattresses may also be used to provide temporary stability of wet stored items if wet storage proves necessary.

Sandbags or concrete mattresses may be installed for crossings over existing umbilicals or jumpers/flowlines.

3.11.3.6 Pre-commissioning of the Flexible Flowline

Leak testing is performed to test the integrity of subsea infrastructure, test isolations and identify any leaks. Pressure may be applied via a downline from the installation vessel or via ROV. Failure of testing equipment or integrity of the tested infrastructure may lead to a loss of leak test fluids to the marine environment. After the leak testing is completed, the system pressurisation volume may be released to the environment to mitigate the risk of hydrocarbons returning to the installation vessel.

During tie-in and pre-commissioning activities, any subsea connection break-outs will be preserved with chemical sticks. A small amount of chemically treated MEG/ water may be discharged to the environment from the structure and tie-in flexible prior to final makeup of the connection. All chemicals used in pre-commissioning activities will be subject to the chemical selection assessment process described in Section 3.9.

3.11.3.6.1 Flooding

The flexible flowline will be installed filled with chemically treated ~50 wt% MEG/water. MEG is used to prevent formation of hydrates during start-up. Topping up of the flowline will occur when the pulling head is removed to install diverless connectors.

3.11.3.6.2 Leak Testing

Leak test/system pressure tests are performed to confirm the integrity of subsea connections and flowline. During leak testing there may be small volumes of test fluids discharged to environment during connection and disconnection of hot stabs.

3.11.3.7 Tie-in of Flowlines at Pluto Manifold

Prior to tie-in of the Xena-03 flowline to the Pluto manifold, verification testing of any leakage from the manifold isolation valves may be undertaken. This testing will verify that suitable isolations for safe tie-in are available, thereby preventing a major hydrocarbon release during tie-in. This verification may result in the release of hydrocarbons to the environment. The hydrocarbons are predominately gas with a small quantity of condensate. Additionally, when the flowline tie-ins take place, a quantity of hydrocarbons may be released. A conservative estimate of hydrocarbons that may be released during the flowline tie-in at the manifold is up to 400 L of condensate and residual gas over a 48 hour period. Water jetting and/ or acid injection may be used to clean the connections on the infrastructure prior to tie-in.

3.11.3.8 Cold Commissioning of Subsea Infrastructure

The commissioning associated with subsea infrastructure prior to the introduction of hydrocarbons (referred to as cold commissioning) generally includes subsea control systems verification and function testing of valves to verify that the Hydraulic Flying Leads (HFLs) and Electric Flying Leads (EFLs) are ready for entry into the start-up phase.

During cold commissioning, an ROV is deployed from the installation vessel (or similar support vessel) to provide visual confirmation of xmas tree valve actuation. This activity is typically less than 12 hours in duration.

3.11.3.9 Wet Storage of Equipment

Wet storage of infrastructure may be required intermittently throughout the duration of subsea installation activities as part of the Petroleum Activities Program. There are two categories of equipment that may require wet storage as part of the Petroleum Activities Program, as summarised

in Table 3-15. At completion of Xena-03 Tie-back activities there will be no wet stored infrastructure remaining on the seabed.

Table 3-15: Wet storage that may be required as part of Xena-03 Tie-back activities.

Wet Storage Category	Reason for wet storage	Typical equipment	Retrieval method
Installation Aids	To facilitate safe installation of infrastructure.	Predominately installation aids (subsea/ROV baskets, clump weights, etc)	Retrieval will be undertaken using project vessels (Section 3.12) and associated equipment such as cranes, ROV, etc.
Subsea installation	Prior to connection of infrastructure, wet storage may be necessary to optimise project schedule and support SIMOPs	Items may include flexible flowline, flying leads and wet parking/deployment frames etc	Retrieval is not required, as infrastructure will be used for production operations and once connected is no longer considered wet stored.

3.11.3.10 Maintenance of Subsea Infrastructure

All subsea structures installed during the Petroleum Activities Program have been designed for full removal. et stored items will be removed during the subsea installation activities. Due to the design of equipment, the materials selected and short duration of subsea installation activities, all wet stored equipment will be in a condition that allows for removal.

The as-built survey will confirm that structures installed for production operations are in good condition and repair.

3.11.3.11 Site Surveys

Site surveys will be undertaken at various stages throughout the installation of subsea infrastructure. An initial pre-lay survey will be undertaken by the flexible flowline installation contractor before starting installation activities. The pre-lay survey may be performed by a dedicated pre-lay survey vessel which is typically similar in size to support vessels, or potentially by the installation vessel.

The pre-lay survey is a debris and hazard identification survey and not a full geophysical survey along the pre-determined route or proposed design route. While it is not anticipated that any significant debris may need to be removed before flexible flowline installation, if required, these activities will fall under this EP and will be performed by an installation vessel, a support vessel or similar.

Additional surveys, with an ROV, will be undertaken throughout the installation activities. These surveys will identify the location of all items placed on the seabed (including wet stored items and installed infrastructure). The survey data will be input into a computer program to track all subsea equipment and displayed on the ‘survey screen’ (comprising an auto-cad file). This file will be progressively updated throughout the activities as items are placed and removed from the seabed (and in the title).

An as-built survey will be conducted by ROV at the completion of the installation campaign so that installation of equipment is in the designed location. This data will be used to update the ‘survey screen’ to develop the as-built report, which is considered the inventory of items remaining on the seabed (and in the title). In addition, any material items dropped to the marine environment and not recovered (See Section 6.9.8) will be added to the inventory for the title.

3.11.4 Xena-03 Commissioning (initial start-up) Activities

The commissioning (initial start-up) activities of the Xena-03 well and associated subsea infrastructure are planned to commence in 2025. All activities may be subject to rescheduling,

including delay, based on operational requirements of the Pluto platform or other production scheduling reasons as well as project schedule changes. Topsides modifications on the Pluto facility are limited to controls updates.

Once hydrocarbons have been introduced into the system, preservation fluids are displaced to the Pluto platform, where they are processed and wells are cleaned-up to maximum rates. Performance testing may be undertaken such as Multi-Rate Testing, simulated ESD of Xena-03 well only, then Pressure Build-up testing. MEG of up to 100%, or a combination of MEG/ treated water initially in the Xena-03 flowline arrives at the separator and is discharged via the produced water (PW) discharge route, along with residual completions fluids and fines from the well as part of well clean-up.

3.11.5 Contingent Activities for the Xena-03 Tie-back

The following sections present contingencies that may be required, if operational or technical issues occur during the Petroleum Activities Program. These contingencies have been considered within the relevant impact assessment sections and do not represent significant additional risks or impacts but may generate additional volumes of drilling fluids and cuttings being discharged operationally.

3.11.5.1 Respud

A respud may be required for a number of reasons, such as if the conductor or well head slumps or fails installation criteria (typically during top hole drilling). Re-spudding involves moving the MODU to a suitably close location (e.g., ~50 m from the original location) to recommence drilling. A respud activity would result in repeating top hole drilling (Section 3.11.1).

The environmental aspects of re-spudding are the same as those for drilling and are considered to be adequately addressed by this EP (Section 6.7), with no significant changes to existing environmental risks or any additional environmental risks likely. The net environmental effect will be limited to an increase in the volume of cuttings generated (Section 6.7.8) and increased volumes discharged.

3.11.5.2 Sidetrack

The option of a sidetrack instead of a respud may be required if operational issues are encountered. The environmental aspects of a sidetrack well are the same as those for routine drilling activities, which are considered to be adequately addressed by this EP (Section 6.7), with no significant changes to existing environmental risks or any additional environmental risks likely. The net environmental effect will be limited to an increase in the volume of cuttings generated (Section 6.7.8), potential increase in the use of drilling fluids and the additional emissions (atmospheric and waste) associated with an extended drilling program.

3.11.5.3 Workover

A workover may be performed on the Xena-03 well. A workover or intervention may be required to restore production or integrity due to a failed completion or component in the well. The environmental aspects of a workover operation are the same as those for well completion activities and are considered to be adequately addressed by this EP, with no significant changes to existing environmental risks or any additional environmental risks likely.

3.11.5.4 Non-water Based Mud System

The Xena-03 well is planned to be drilled entirely using WBM, however NWBM may be required for bottom hole sections as a contingency. The decision to use NWBM drilling fluids for the bottom hole sections of a well is based on a variety of technical factors relevant to wellbore conditions, such as well temperature, well shape and depth, reactivity of the formation to water and well friction. The

technical justification to use NWBM includes environment, health, safety and waste management considerations.

The use of NWBM drilling fluids is subject to a formal written commercial and/or technical justification approved in accordance with the Best Practice – Overburden Drilling Fluids Environmental Requirements. The main ingredient of NWBM is base oil, and similar to a WBM system, a range of standard solid and liquid additives may be added in the pits to alter specific mud properties for each section of the well, dependent on the conditions encountered while drilling.

The NWBM drilling fluid will be primarily mixed onshore (new or reuse of existing stock) and transferred to the MODU by a support vessel, where it is stored and maintained in the mud pits. During drilling operations, the NWBM drilling fluid, like the WBM, is pumped by high pressure pumps down the drill string and out through the drill bit, returning via the annulus between the drill string and the hole/casing back to the MODU via the riser.

The used NWBM pumped back to the MODU contains drill cuttings and is pumped to the solid control equipment (SCE), where the drill cuttings are removed before the NWBM is pumped back to the pits ready for reuse. The technical properties of the NWBM drilling fluids are maintained/altered (e.g., to increase weight) using additives as required when in the mud pits.

The NWBM drilling fluids that cannot be re-used (i.e., do not meet required drilling fluid properties or are mixed in excess of required volumes) are recovered from the mud pits and returned to the shore base for onshore processing, recycling and/or disposal. The mud pits and associated equipment/infrastructure are cleaned when NWBM is no longer required, with wash water treated onboard through SCE before discharge with mud pit washings, or returned to shore for disposal if discharge criteria cannot be achieved (refer to Section 3.5).

3.11.5.5 Well Suspension

During drilling activities, a well may need to be temporarily suspended. Suspension involves establishing suitable barriers, removing the riser and disconnecting the MODU from the well. The BOP may be left in place to act as a barrier. Suspension may be short term (e.g., in the case of a cyclone) or longer term (more than one year). On return to a well after suspension, the MODU reconnects to the well via the riser, and with BOP in place, barriers are removed and drilling and completions activity resumes.

3.11.5.6 Wireline Logging

Wireline contingencies that may be in place for development drilling include gamma ray and casing collar locator for depth correlation, ultrasonic imaging tool and cement bond log to measure cement integrity, formation pressures (XPT), density, neutron and resistivity and punch perforators/tubing cutters suitable for all tubing sizes. Wireline contingency work will be performed with appropriate isolation barriers in place, i.e., an overbalanced fluid column. If wireline work is required to occur in a live well, or where there is a risk of barrier failure, the operation will be performed with full pressure control equipment at the surface.

Some logging tools may contain low activity radiation sources. Radiation fields are not generally detectable outside the tool when the tool is not energised; therefore, they do not present an environmental risk.

3.11.5.7 Well Intervention

An intervention may be performed on the Xena-03 well. Interventions may be performed due to down-hole equipment failure or to address underperformance of a well. Key well intervention methods include wire-line and coiled tubing. Potential environmental impacts from intervention activities have been included in this EP, including discharge of suspension fluids and brines and small volume gas releases subsea due to removal of a tree cap which may be in place if the well was previously suspended.

3.11.5.8 Well Abandonment

The Petroleum Activities Program covers the drilling and intervention of the Xena-03 well, which is not envisaged to be abandoned until the end of the production field life. For technical reasons, the lower section of a well may need to be abandoned, before sidetracking, or if a respud is required.

Well abandonment activities are conducted in accordance with Woodside's internal standards. Base oil may be used for inflow testing before abandonment, to verify barrier integrity. Base oil would be pumped down the drill string and reverse circulated back to the rig, with fluids collected for disposal onshore. If stored in a mud pit, the base oil and other fluids associated with the test may result in pit wash water contaminated with hydrocarbons. If this is the case, mud pit wash water would be discharged in accordance with requirements in this EP; with a hydrocarbon content <1% by volume.

If required, wells will be abandoned with abandonment cement plugs, including verification of cement plug by tagging and/or pressure testing through a prescribed program. A lower section of a well may also be abandoned before sidetracking.

After abandonment activity, the marine riser and BOP will be removed and every reasonable attempt made to retrieve the wellhead. Conventional wellheads are removed by deploying a cutting device on drill pipe which then cuts through the casing and conductor, allowing the wellhead to be retrieved to the surface. Backup cutting equipment is sent offshore as a contingency should the primary set of equipment fail. The conductor cutting equipment is very reliable with a high success rate of cutting wellheads.

If these recognised removal techniques are ineffective, the wellhead may be left in-situ. The integrity of the wellbore is not affected by the wellhead assembly remaining in-situ.

3.11.5.9 Wellhead Assembly Left In-situ

If a well is abandoned due to the requirement to respud, the wellhead assembly may be left in-situ if recognised removal techniques are ineffective. Well abandonment activities would be performed as outlined in Section 3.11.5.8 but the well assembly would remain. The integrity of the wellbore is not affected by the wellhead assembly remaining in-situ. The environmental aspects of the wellhead assembly remaining in-situ as a contingent activity are considered to be adequately addressed by this EP (Section 6.7.2) with no significant changes to existing environmental risks or any additional environmental risks likely.

Final decommissioning of the development wellhead assembly and other subsea infrastructure at the end of field life will be subject to a separate EP. Woodside's Decommissioning Framework is discussed further in Section 7.5.

3.11.5.10 Sediment Mobilisation and Relocation

If required, an ROV-mounted suction pump/dredging unit may be used to relocate sediment/cuttings around the wellhead or other infrastructure, to keep the area clear and safe for operations and equipment. This activity has the potential to generate plumes of suspended sediment during pumping and disturb benthic fauna in the immediate area.

3.11.5.11 Venting

During drilling of the well, a kick may occur. A kick is an undesirable influx of formation fluid into the wellbore. To maintain well integrity in this situation, a small volume of greenhouse gas is released to the atmosphere via the degasser, in a well control operation known as 'venting'.

3.11.5.12 Emergency Disconnect Sequence

An emergency disconnect sequence (EDS) may be implemented if the MODU is required to rapidly disengage from the well. The EDS closes the BOP (i.e., shutting in the well) and disconnects the riser to break the conduit between the wellhead/BOP and MODU. Common examples of when this

system may be initiated include the movement of the MODU outside of its operating circle (e.g., due to a failure of the DP system) or the movement of the MODU to avoid a vessel collision (e.g., third-party vessel on collision course with the MODU). EDS aims to leave the wellhead and BOP in a secure condition but will result in loss of the drilling fluids/cuttings in the riser after disconnection.

3.12 Vessel-based Activities for the Xena-03 Tie-back

During the Xena-03 Tie-back activities, vessel-based activities will involve the MODU, subsea installation vessels and support vessels such as Anchor Handling Vessels (AHVs).

All project vessels are subject to the Marine Offshore Assurance process and review of the Offshore Vessel Inspection Database (OVID). All required audits and inspections will assess compliance with the laws of the international shipping industry, which includes safety and environmental management requirements, and maritime legislation including International Convention for the Prevention of Pollution from Ships 1973 as modified by the Protocol of 1978 (MARPOL) and other International Maritime Organization (IMO) standards.

For power generation, vessels may use diesel-powered generators and/or LNG. All vessels will display navigational lighting and external lighting, as required for safe operations. Lighting levels will be determined primarily by operational safety and navigational requirements under relevant legislation, specifically the Navigation Act 2012. The MODU and support vessels will be lit to maintain operational safety on a 24-hour basis.

3.12.1 MODU

The Xena-03 well will be drilled by a moored, or hybrid MODU. Contingent well intervention activities may also be performed by a moored or hybrid MODU. Typical specifications for a moored and hybrid MODU are provided in Table 3-16 and Table 3-17, respectively. Moored and hybrid MODU types are collectively referred to as MODU for the remainder of the document unless specific risks for different MODU types have been identified. Due to variabilities such as contractual and operational matters, the MODU used may be subject to change.

Table 3-16: Typical moored MODU specifications for Ocean Apex

Component	Specification Range
Rig Type/Design/Class	Semi-submersible MODU
Accommodation	120 to 200 personnel
Station Keeping	Eight-point or twelve-point mooring system
Bulk Mud and Cement Storage Capacity	283 to 770 m³
Liquid Mud Storage Capacity	576 to 2500 m³
Fuel Oil Storage Capacity	966 to 1400 m³
Drill Water Storage Capacity	3500 m³

Table 3-17: Typical hybrid MODU specifications for Transocean Endurance

Component	Specification
Rig Type/Design/Class	Semi-submersible MODU
Accommodation	130 persons (maximum persons on board)
Station Keeping	Eight-point or twelve-point mooring system with thrusters for Dynamic Positioning (DP3)
Bulk Mud and Cement Storage Capacity	340 m³
Liquid Mud Storage Capacity	1445 m³
Fuel Oil Storage Capacity	2600 m³

Component	Specification
Drill Water Storage Capacity	1508 m³

3.12.2 Installation Vessels

The Petroleum Activities Program subsea installation scopes of work may require various installation vessels, with sufficient capacity to accommodate hardware and equipment such as flowlines, flexible flowlines, umbilicals and the cold commissioning/dewatering spreads.

A typical installation vessel for subsea and flowline installation would be a DP vessel (usually DP2 Class) equipped with a primary differential global surface positioning system (DGPS) and an independent secondary DGPS backup. The specification of a typical subsea installation vessel is provided in Table 3-18.

Installation vessels are typically equipped with various material handling equipment, which includes cranes, winches, remotely operated vehicles (ROVs) and ROV launch and recovery systems, vertical lay system (VLS) with either vertical reel drive or horizontal reel drive (carousel) and cold commissioning spread.

Lifting operations may involve loading and unloading equipment from support and supply vessels onto the installation vessel and subsequently onto the seabed. Cranes are typically equipped with active heave compensation and auto tension, modes and have lifting capacities in excess of lifting loads expected to be encountered during operations.

Table 3-18: Typical DP2 Class subsea installation vessel for Deep Orient

Component	Specification Range
Vessel Type	DP2 Class as a minimum
Crane Capacity	250 T active heave compensation crane as minimum
ROVs	Two Work Class ROVs
Deck Space	Approximately 1900 m²
Deck Strength	Approximately 15 T/m²
Accommodation	Approximately 120 people
Fuel Oil	Approximately 2200 m³
Potable Water	Approximately 800 m³

3.12.3 Support and Other Vessels

During the Petroleum Activities Program, the MODU and installation vessel will be supported by other vessels, such as general support vessel(s) and AHVs.

Support vessels are used to transport equipment and materials between the MODU/installation vessel and port (e.g., Dampier, Onslow, Exmouth). When required, a support vessel will perform standby duties at the MODU. At any given time, support vessels will make regular trips between the Operational Area to port for routine, non-routine and emergency operations.

Support vessels will be using their DP system within the Operational Area.

The support vessels are also available to assist in implementing the Oil Pollution First Strike Plan , should an environmental incident occur (e.g., spills).

3.12.4 Subsea Support Vessel for LWI Activities

During the Petroleum Activities Program, a subsea support vessel for light well intervention (LWI) operations may be used as an option for contingent well intervention, subsea installation and other activities. An example of this vessel type is the Sapura Constructor, which is a 117 m long subsea

support vessel equipped with a saturation dive system, two Work Class ROVs, well intervention equipment, a helideck, moon pool and accommodation for 120 persons. The final vessel selection, if required, will be subject to commercial and/or operational considerations.

3.12.5 Holding Station: Mooring Installation and Anchor Hold Testing/Soil Analysis

Mooring uses a system of chains/ropes and anchors, which may be pre-laid before the MODU arrives at the location, to maintain position when drilling. Mooring analysis will be undertaken to determine the appropriate mooring system for the Petroleum Activities Program. The mooring analysis will identify whether the mooring systems are pre-laid or set by the rig, proof tension values, and if synthetic fibre mooring ropes are required. Pre-laid systems are often selected and designed to withstand higher sea states than the rig's mooring system or to provide additional clearance/protection of subsea infrastructure when deemed necessary in the mooring analysis.

Installation and proof tensioning of anchors involves some disturbance to the seabed. Anchor Handling Vessels (AHVs) are used in the deployment and recovery of the mooring system.

As part of mooring preparations, anchor hold testing may be conducted at the well locations. Anchor hold testing would be undertaken if Woodside determines that further assurance is required to ensure a robust mooring design.

Anchor hold testing may involve an AHV or similar vessel deploying an anchor at a potential mooring location. The AHV would then tension the anchor to determine its ability to hold, embed and not drag at location. This may have to be repeated several times at each location. An ROV may also be utilised to evaluate how deep the anchor has embedded and independently verify the seabed condition. Anchor hold testing activities would occur prior to the MODU arriving on location.

Soil analysis may also be necessary to provide data on composition and rock/substrate strength as input into the mooring design and to verify seabed conditions for anchor holding. Soil analysis could include taking a physical sample of the seabed using ROV or other tools, or using measuring devices such as a cone penetrometer. These tests would be carried out up to several months prior to MODU arriving on location and may occur from a support vessel or an AHV.

3.12.6 Holding Station: Rig Anchor Release MODU

The hybrid MODU scenario is such that the MODU is DP capable though predominantly holds station via a pre-laid mooring system. If a hybrid MODU is used to conduct drilling, it will likely have a rig anchor release (RAR) system integrated as a contingency case for cyclone season. A traditional arrangement with no RAR (for lines passing over subsea assets) and rig- or prelay-lines (for lines clear of subsea assets) will likely be used as the base case in non-cyclone seasons. The moorings are typically pre-laid in an eight-point arrangement, with a RAR device connecting the MODU mooring components with the anchor mooring components. The RAR is an acoustic release connecting link that can be installed in a mooring line to enable a rapid disconnection of a MODU from the mooring system. Each mooring leg would have one RAR installed in the mooring line. The acoustic release process is instigated from a command unit on the MODU that, when activated, transmits a low frequency signal (9 – 11 kHz) that is received by the RAR transducer in the mooring line and activates the primary hydraulic actuator. The hydraulic actuator then releases the locking mechanism of the RAR and the mooring line is disconnected. The MODU then recovers the MODU wire/chain ready for transit (on DP) and the subsea mooring leg remains on the seabed. Anchor lines crossing subsea infrastructure, will be buoyed to maintain clearance from the subsea assets after a disconnection (either on the surface or suspended in the water column).

To reconnect the MODU with the mooring system after a disconnection, the AHV will recover the MODU mooring line (including RAR and the trigger sleeve) from the MODU before connecting to the pre-laid line, which is recovered from the seabed or water column by the AHV utilising a ROV.

3.12.7 MODU and Support Vessel Activities

A variety of materials are routinely bulk transferred from support vessels to the MODU including drilling fluids (e.g., muds), base fluids, cements and drill water. A range of dedicated bulk transfer stations and equipment are in place to accommodate the bulk transfer of each type of material. There is also a capacity to bulk transfer waste oil from the MODU to the support vessel, for back loading and disposal on shore.

The loading and back-loading of equipment, materials and wastes is one of the most common supporting activities conducted during drilling programs. Loading and back-loading is performed using cranes on the MODU to lift materials in appropriate offshore rated containers (e.g., ISO tanks, skip bins, containers) between the MODU and support vessel.

Seawater is pumped on board and used as a heat exchange medium for cooling machinery engines and high temperature drilling fluid on the MODU. It is subsequently discharged from the MODU at the sea surface at potentially a higher temperature. Alternately, MODUs may use closed loop cooling systems.

Potable water, primarily for accommodation and associated domestic areas, may be generated on vessels using a reverse osmosis plant. This process will produce brine, which is diluted and discharged at the sea surface.

The MODU and support vessels will also discharge deck drainage from open drainage areas, bilge water from closed drainage areas, putrescible waste and treated sewage and grey water. Solid hazardous and non-hazardous wastes generated during the Petroleum Activities Program are disposed of onshore by support vessels.

The MODU and support vessels may also take on or discharge ballast water in order to maintain vessel stability. All ballast water exchanges will be undertaken in accordance with relevant requirements, such as the Australian Ballast Water Management Requirements.

3.12.8 Subsea Installation and Support Vessel Activities

An installation vessel may be used for various subsea installation activities such as pre- and post-installation survey, installation of subsea structures, installation of the flowline, installation of interconnecting HFL, EFL and MEG jumper, tie-in to existing infrastructure, and cold commissioning activities.

Other support vessels may also be used to transport equipment, hardware and MEG from shore to the installation vessel.

3.12.9 Refuelling

The MODU will be refuelled via support vessels approximately once a month, or as required. Refuelling will occur within the Xena-03 Operational Area and has been included in the risk assessment for this EP. Other fuel transfers that may occur on board the MODU may include refuelling of cranes, helicopters or other equipment as required.

As the base case, refuelling of installation vessels is planned to occur outside of the Operational Area during interim mobilisation/demobilisation.

3.12.10 Vessel Mobilisation

Vessels may mobilise from the nearest Australian port or directly from international waters to the PAA, in accordance with biosecurity and marine assurance requirements. Vessel activities whilst in transit to the PAA are not included in the scope of this EP.

4. DESCRIPTION OF THE EXISTING ENVIRONMENT

4.1 Overview

In accordance with Regulations 21(2) and 21(3) of the Environment Regulations, this section describes the existing environment that may be affected (EMBA) by the activity (planned and unplanned, as described in Section 2.10), including details of the particular relevant values and sensitivities of the environment, which were used for the risk assessment.

The EMBA is the largest spatial extent where unplanned events could have an environmental consequence on the surrounding environment. For this EP, the EMBA is the potential spatial extent of surface and in-water hydrocarbons at concentrations above ecological impact thresholds, in the event of the worst-case credible spill. The worst-case credible spill scenarios for this EP are a loss of well integrity and potential marine diesel loss of containment release in the offshore area, and a nearshore subsea loss of containment scenario. The EMBA also includes any areas that are predicted to experience shoreline contact with hydrocarbons above threshold concentrations.

Woodside recognises that hydrocarbons may be visible beyond the EMBA at lower concentrations than the ecological impact thresholds. These visible hydrocarbons are not expected to cause ecological impacts. In respect of this, an additional socio-cultural EMBA is defined, as the potential spatial extent within which social-cultural impacts may occur from changes to the visual amenity of the marine environment. Receptors relevant to the socio-cultural EMBA include Commonwealth and State marine protected areas (MPAs), National and Commonwealth Heritage Listed places, areas of tourism and recreation, and commercial and traditional fisheries. The EMBA and socio-economic EMBA are described in Table 4-1.

The EMBA presented does not represent the predicted coverage of any one hydrocarbon spill or a depiction of a slick or plume at any particular point in time. Rather, the areas are a composite of a large number of theoretical paths, integrated over the full duration of the simulations under various metocean conditions.

Table 4-1: Hydrocarbon spill thresholds used to define EMBA for surface and in-water hydrocarbons

Hydrocarbon Type	EMBA1	Socio-cultural EMBA[1]	Planning Area for Scientific Monitoring
Surface	10 g/m2 This represents the minimum oil thickness (0.01 mm) at which ecological impacts (e.g. to birds and marine mammals) are expected to occur.	1 g/m2 This represents a wider area where a visible sheen may be present on the surface and, therefore, the concentration at which socio-cultural impacts to the visual amenity of the marine environment may occur. However, it is below concentrations at which ecological impacts are expected to occur. This low exposure value also establishes the planning area for scientific monitoring (NOPSEMA Environment bulletin: A652993, April 2019).	
Dissolved	50 ppb This represents potential toxic effects, particularly sublethal effects to highly sensitive species (NOPSEMA Environment bulletin: A652993, April 2019). As dissolved hydrocarbons are within the water column and not visible, impacts to socio-cultural receptors are associated with ecological impacts. Therefore, dissolved hydrocarbons at this threshold also represent the level at which socio-cultural impacts may occur.		10 ppb This low exposure value establishes the planning area for scientific monitoring (based on potential for exceedance of water quality triggers) (NOPSEMA Environment bulletin: A652993, April 2019). This area is described in Figure 4-1. In the event of a spill, DNP will be notified of AMPs which may be contacted by hydrocarbons at this threshold.
Entrained	100 ppb This represents potential toxic effects, particularly sublethal effects to highly sensitive species (NOPSEMA Environment bulletin: A652993, April 2019). As entrained hydrocarbons are within the water column and not visible, impacts to socio-cultural receptors are		

Hydrocarbon Type	EMBA1	Socio-cultural EMBA[1]	Planning Area for Scientific Monitoring
	associated with ecological impacts. Therefore, entrained hydrocarbons at this threshold also represent the level at which socio-cultural impacts may occur.		
Shoreline	100 g/m2 This represents the threshold that could impact the survival and reproductive capacity of benthic epifaunal invertebrates living in intertidal habitat.	10 g/m2 This represents the volume where hydrocarbons may be visible on the shoreline but is below concentrations at which ecological impacts are expected to occur.	N/A

[1] *Further details including the source of the thresholds used to define the EMBA in this table are provided in Section 6.8.3*

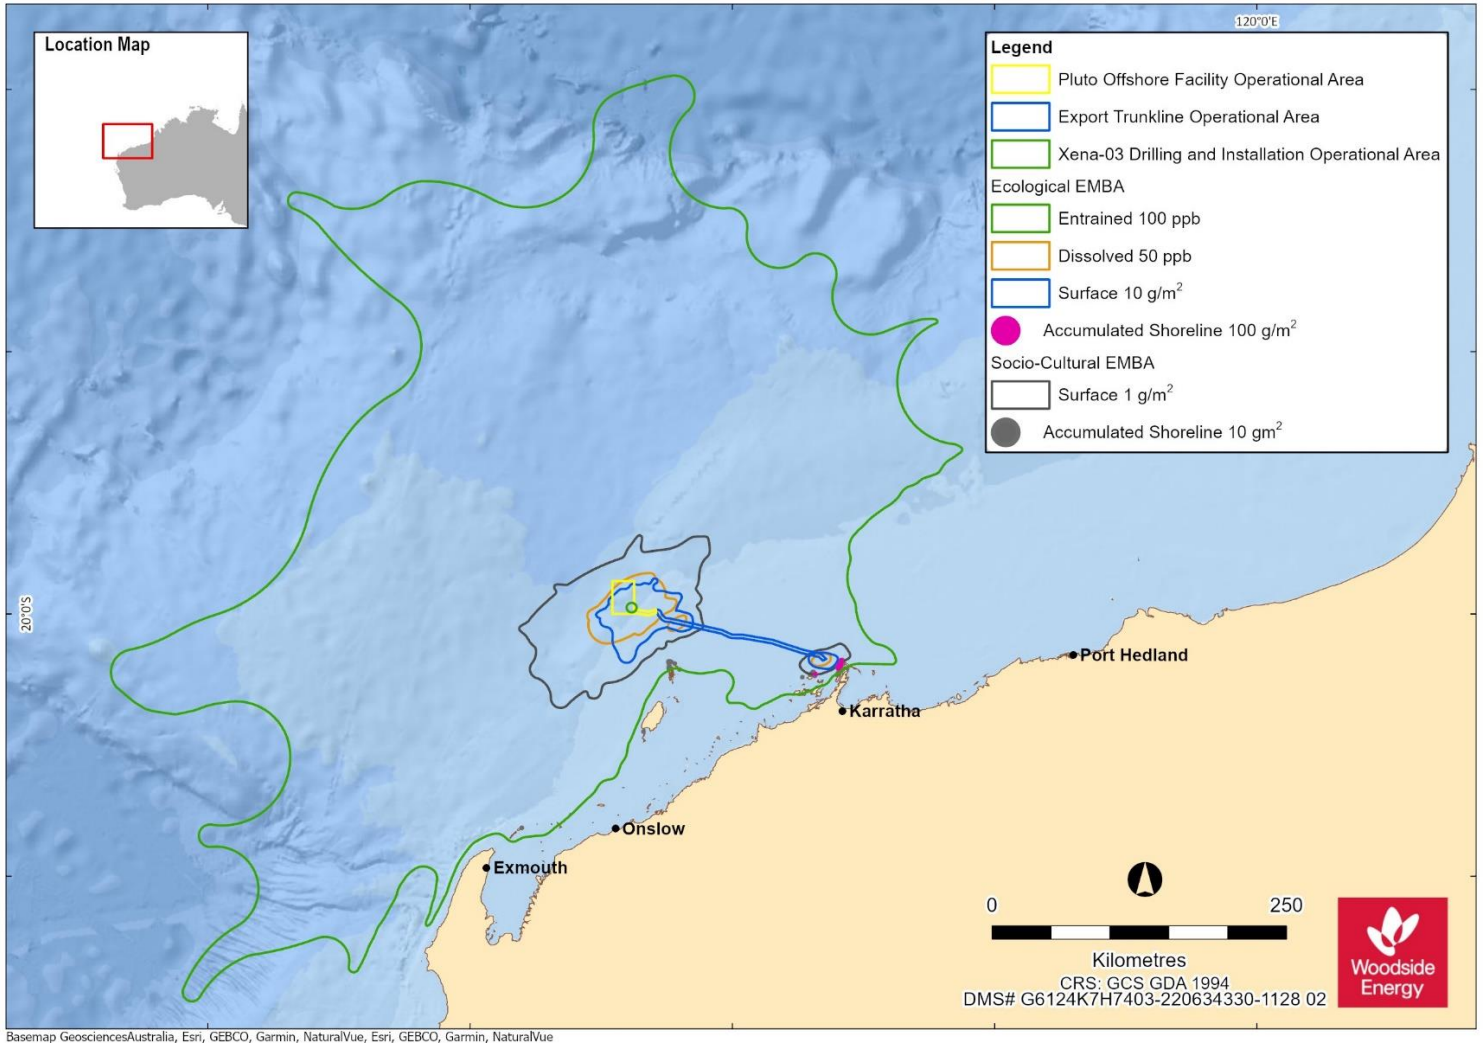

Figure 4-1:Environment that may be affected (EMBA) by the Petroleum Activities Program

4.2 Regional Context

The Petroleum Activities Area (PAA) is located in Commonwealth waters within the North-west Marine Region (NWMR), as defined under the Integrated Marine and Coastal Regionalisation of Australia (IMCRA v4.0) (Commonwealth of Australia, 2006). Within the NWMR, the export pipeline lies within the North West Shelf Province, while the facility lies across the boundary of the North West Shelf Province and the Northwest Province. Section 1 of Woodside's Master Existing Environment (Woodside, 2022) summarises the characteristics for the relevant marine bio-regions.

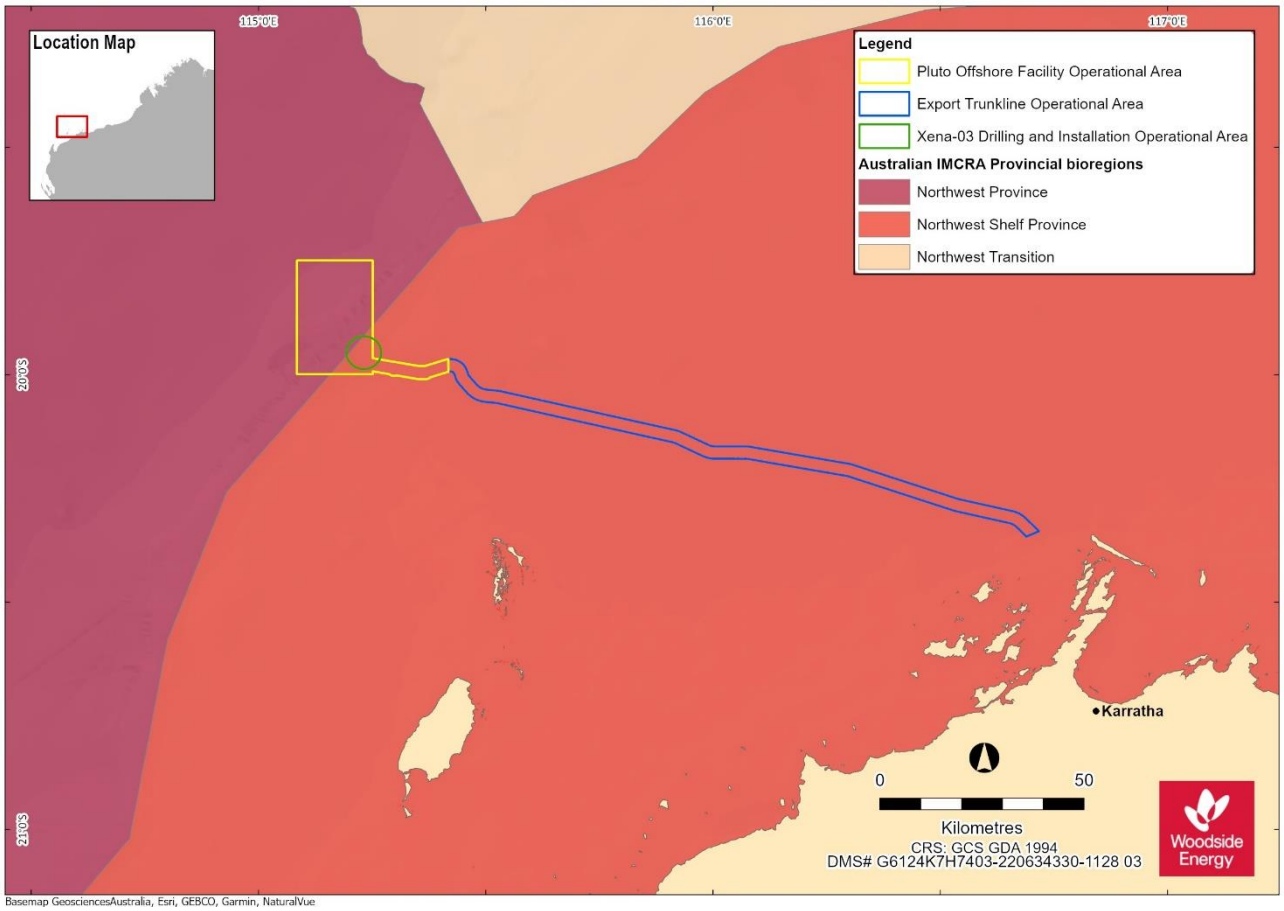

Figure 4-2: Location of the PAA and relevant marine bio-regions

4.3 Matters of National Environmental Significance (EPBC Act)

Table 4-2 and Table 4-3 summarise the MNES overlapping the PAA and EMBA, respectively, according to Protected Matters Search Tool (PMST). It should be noted that the EPBC Act PMST is a general database that conservatively identifies areas in which protected species have the potential to occur.

Additional information on these MNES is provided in subsequent sections of this chapter and described in detail in the Master Existing Environment (Woodside, 2022).

Table 4-2: Summary of MNES identified by the EPBC Act PMST as potentially occurring within the PAA

MNES	Number	Relevant Section
World Heritage Properties	0	Section 4.9.8
National Heritage Places	0	Section 4.9.8
Wetlands of International Importance (Ramsar)	0	Master Existing Environment (Woodside, 2022)

Listed Migratory Species	62	Section 4.6

4.4 Physical Environment

The PAA is characterised by both the continental shelf and the continental slope of the NWMR. The export pipeline lies entirely in continental shelf waters from the State waters boundary to the facility. Water depth along the export pipeline is between 40 and 85 m. Water depth at the Pluto Offshore Facility (at the riser platform) is 85 m and the subsea gathering system extends downslope to depths of 962 m.

The bathymetry within the continental shelf section of the PAA is generally flat, which is consistent with the broader NWS Province (Baker et al., 2008). Bathymetry around the riser platform is relatively flat and featureless (Woodside, 2006). Across the shelf, the seabed has a gentle (approximately 0.05°) seaward gradient to where it transitions to a steep distal slope approximately 200 to 300 km offshore, in water depths of around 200 m (Dix et al., 2005). The continental slope descends relatively rapidly from the shelf edge to depths greater up to 5,000 m within the Northwest Province (James et al., 2004; Woodside, 2006).

Within the broader Northwest Province, the continental slope comprises seven major geomorphic features, including plateaus, deeps/holes/valleys, terraces, trenches/troughs and canyons (Baker et al., 2008). Key features overlapping the subsea hydrocarbon gathering system section of the facility include:

- a number of canyon systems which trend east-west across the continental slope and have an increased seafloor gradient of up to 80°
- approximately 20 m high cliff-like structures at 1000 m depth where the continental slope meets the abyssal plain

- mudstone outcrops at 900 to 1000 m
- a field of rock pinnacles (2 to 3 m tall and 1 m wide and in an area covering approximately 4 x 1 km) of biogenic origin located at a depth of 300 to 500 m on the continental slope within WA-34-L.

The Master Existing Environment (Woodside, 2022) provides a summary of the physical characteristics of the environment within the EMBA and broader NWMR (Appendix K).

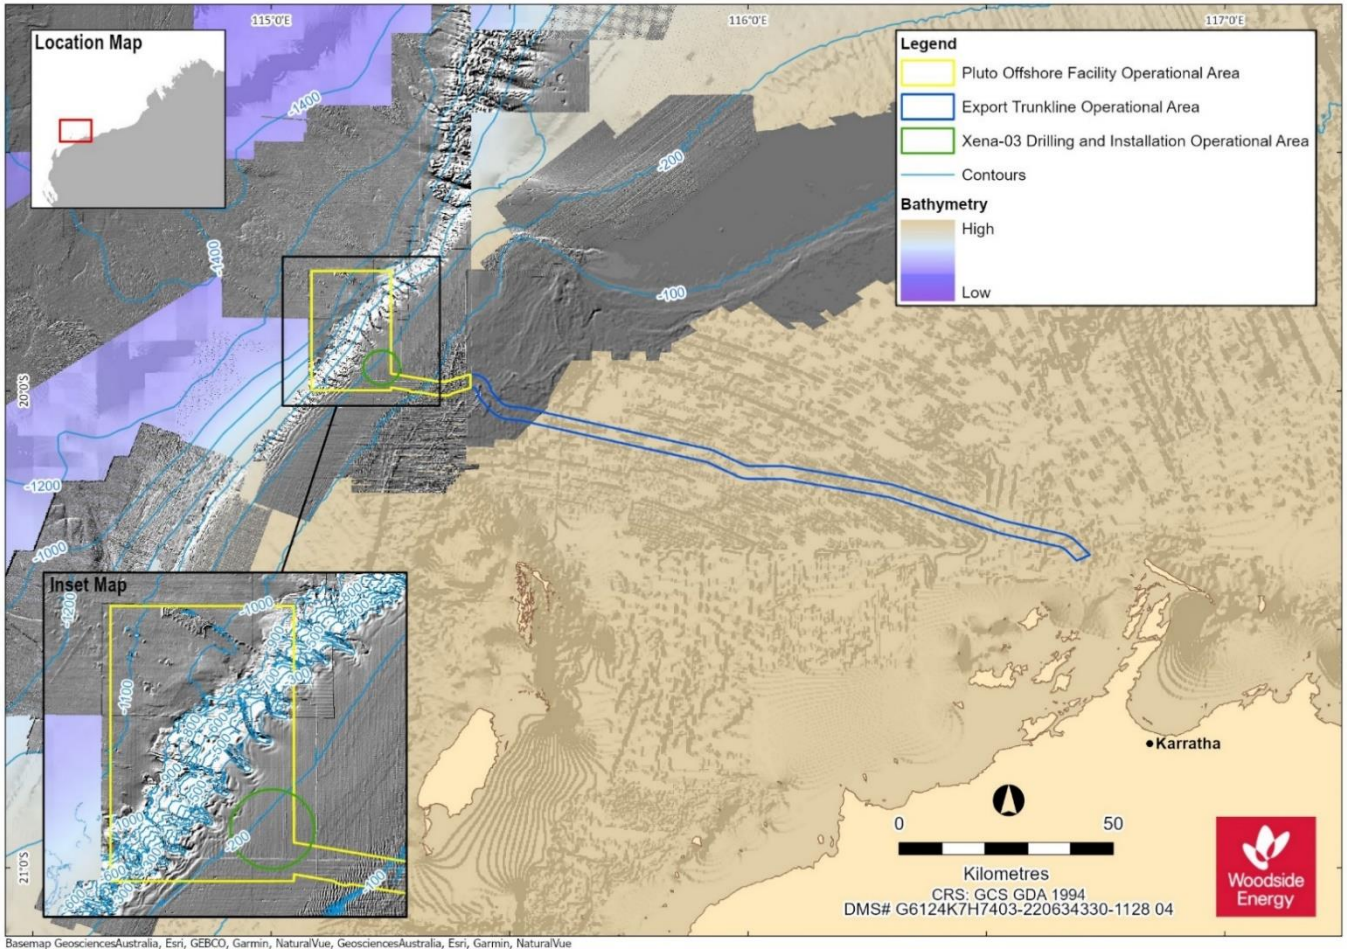

Figure 4-3: Location and bathymetry for the PAA

4.5 Habitats and Biological Communities

Sediments in the outer NWMR are relatively homogenous and are typically dominated by sands and a small portion of gravel (Baker et al., 2008). Fine sediment size classes (e.g. muds) increase with proximity to the shoreline and the shelf break, but are less prominent in the intervening continental shelf (Baker et al., 2008). Carbonate sediments typically account for the bulk of sediment composition, with both biogenic and precipitated sediments present on the outer shelf (Dix et al., 2005). Beyond the shelf break within the NWMR (200 m depth contour), the proportion of fine sediments increases along the continental slope towards the abyssal plain (Baker et al., 2008).

Prior to commissioning of the facility, seabed surveys of the Facility Operational Area were completed. The survey revealed that the seabed around the riser platform comprised soft sediments, with surface layer of sand between 1–4 m thick overlying cemented sands, typical of the region (SKM, 2007; Woodside, 2006). Seabed surveys along the export pipeline route found sediments were predominantly fine sand with variable proportions of coarser sand fractions, silt, shells and shell fragments, coral cemented materials (including calcarenite gravel and cobbles) (SKM, 2006; Woodside, 2006).

Within WA-34-L on the continental slope, sediments ranged from fine sands to silts, with sediments generally becoming finer with increasing water depth down to 600 m for both slope and canyon transects. Below 600 m, sediment became slightly coarser, but still relatively fine compared to continental shelf sediments (between 150–200 m) (SKM, 2007). This is expected to be characteristic of the sediment across the subsea hydrocarbon gathering system section of the facility.

While the PAA comprises of mainly soft sediments, two Key Ecological Features (KEFs) overlap the Facility Operational Area, including the Ancient Coastline at 125 m Depth Contour KEF and the Continental Slope Demersal Fish Communities KEF (Figure 4-10). The Xena-03 Operational Area also overlaps the Continental Slope Demersal Fish Communities KEF. Areas of hard substrate may be associated with these KEFs, which are considered to support more diverse benthic communities that are characteristic of the wider region. Refer to Section 4.7 and the Master Existing Environment (Woodside, 2022) for information on the environmental values of KEFs overlapping the PAA and EMBA.

Key habitats and ecological communities within the EMBA are identified in Table 4-4 and described in the Master Existing Environment (Woodside, 2022).

Table 4-4: Key Sensitive Habitats and Communities within the EMBA (distance calculated from PAA)

Habitat/Community	Key locations within the EMBA
Seabed characteristics	
Ancient Coastline at 125 m Depth Contour	Several steps and terraces as a result of Holocene sea level changes occur in the region with the most prominent of these features occurring as an escarpment along the NWMR and Sahul Shelf at a water depth of 125 m, which forms the Ancient Coastline at 125 m depth contour KEF (the Ancient Coastline). The Ancient Coastline KEF overlaps the Facility Operational Area, extending along a line approximated by the 125 m isobath Section 4.7. The Ancient Coastline is not continuous throughout the NWMR and coincides with a well-documented eustatic stillstand at approximately 130 m worldwide (Falkner et al., 2009). Where the Ancient Coastline provides areas of hard substrate, it may contribute to higher diversity and enhanced species richness relative to soft sediment habitat (Falkner et al., 2009). Parts of the Ancient Coastline, represented as rocky escarpment, are considered to provide biologically important habitat in an area predominantly made up of soft sediment. The escarpment type features may also potentially facilitate mixing within the water column due to upwelling, providing a nutrient rich environment. Although the Ancient Coastline adds additional habitat types to a representative system, the habitat types are not unique to the coastline as they are widespread on the upper shelf (Falkner et al., 2009). Detail regarding these features are provided in Section 4.7 and the Master Existing Environment (Woodside, 2022).
Continental Slope Demersal Fish Communities	The continental slope demersal fish communities in the region have been identified as a KEF of the NWMR (DSEWPaC, 2012), and overlaps the Facility Operational Area and Xena-03 Operational Area. The continental slope between North West Cape and the Montebello Trough has been identified as one of the most diverse slope assemblages in Australian waters, with over 508 fish species and the highest number of endemic species (76) of any Australian slope habitat (DEWHA, 2008). Detail regarding these features is provided in Section 4.7 and the Master Existing Environment (Woodside, 2022).
Marine primary producers (distances from the PAA)	
Coral	Rankin Bank (29 km north-east) Montebello Islands State Marine Park (25 km south) Barrow Island State Nature Reserve (43 km south) Dampier Archipelago Island Reserves – Rosemary Island (13 km south) Lowendal Islands (61 km south-west) Muiron Islands (195 km south-west) Ningaloo Coast World Heritage Area (WHA) (incl. Muiron Islands) (195 km south-west).
Seagrass beds and macroalgae	Montebello Islands (25 km south-west) Barrow Island (67 km south-west) Muiron Islands (195 km south-west) Ningaloo Coast (195 km south-west) Exmouth Gulf (225 km south-west)
Mangroves	Montebello Islands (32 km south) Ningaloo Coast (195 km south-west) Exmouth Gulf (225 km south-west)

Habitat/Community	Key locations within the EMBA
Other communities and habitats	
Plankton	Plankton within the PAA and EMBA are expected to be representative of the wider NWMR, as detailed in the Master Existing Environment (Woodside, 2022). Primary productivity of the NWMR appears to be largely driven by offshore influences (as reported by Brewer et al., 2007), with periodic upwelling events and cyclonic influences driving coastal productivity with nutrient recycling and advection. There is a tendency for offshore phytoplankton communities in the NWMR to be characterised by smaller taxa (e.g. bacteria), whereas, shelf waters are dominated by larger taxa such as diatoms (Hanson et al., 2007). Within the wider EMBA, peak primary productivity occurs in late summer/early autumn, along the shelf edge of the Ningaloo Reef. It also links to a larger biologically productive period in the area that includes mass coral spawning events, peaks in zooplankton and fish larvae abundance (Department of Conservation and Land Management, 2005) with periodic upwelling throughout the year.
Pelagic and demersal fish populations	Pelagic and demersal fish populations within the PAA and EMBA are expected to be representative of the NWMR (described in the Master Existing Environment (Woodside, 2022)). The presence of subsea infrastructure with the facility and export pipeline has likely resulted in the development of demersal fish communities that would otherwise not occur within the PAA (McLean et al. 2017). Given continental shelf waters overlap the majority of the Operational Area, pelagic species will also be present. The Continental Slope Demersal Fish Communities KEF and Ancient Coastline at 125 m Depth Contour KEF overlap the Facility Operational Area. These KEFs include areas of hard substrate that are known or likely to support a higher diversity of demersal fish assemblages. Rankin Bank (29 km north-east of the PAA) has also been identified as supporting high demersal fish richness and abundance (Australian Institute of Marine Science, 2014). Further information KEFs is provided in Section 4.7. Fish species in the NWMR (including the PAA and the EMBA) comprise small and large pelagic and demersal species. Small pelagic fish inhabit a range of marine habitats, including inshore and continental shelf waters. They feed on pelagic phytoplankton and zooplankton and represent a food source for a wide variety of predators including large pelagic fish, sharks, seabirds and marine mammals (Mackie et al., 2007). Large pelagic fish in the NWMR include commercially targeted species such as mackerel, wahoo, tuna, swordfish and marlin. Large pelagic fish are typically widespread, found mainly in offshore waters (occasionally on the shelf) and often travel extensively. Detail regarding these features is provided in the Master Existing Environment (Woodside, 2022).
Epifauna and infauna	Filter feeders such as sponges, ascidians, soft corals, and gorgonians are animals that feed by actively filtering suspended matter and food particles from water by passing the water over specialised filtration structures (DEWHA 2008). Filter feeders within the EMBA are expected to be representative of the NWMR, with notable areas of high sponge diversity occurring in the Commonwealth Waters of Ningaloo Marine Park and at shoals within the EMBA. Filter feeders generally live in areas that have strong currents and hard substratum and are closely associated with substrate type, with areas of hard substrate typically supporting more diverse

Habitat/Community	Key locations within the EMBA
	epibenthic communities (Heyward et al., 2001a). Conversely, higher diversity infauna is mainly associated with soft unconsolidated sediment and infauna communities are considered widespread and well represented along the continental shelf and upper slopes of the NWMR (Brewer et al., 2007a; Rainer, 1991; SKM, 2007b; Woodside Energy Limited, 2004). A number of targeted surveys investigating epibenthos and infauna within offshore NWSP shelf and slope environments have been carried out by Woodside. Woodside has collected survey data from numerous sampling locations within and surrounding the Operational Area using ROV/video investigations of benthic habitats and infauna and epifauna sampling using sediment grabs and epibenthic sled (SKM, 2007). Elsewhere on the NWSP, surveys have included grab samples of seabed sediments from around North Rankin Complex, Goodwyn A, Angel facilities and their export pipeline routes (SKM, 2007), as well as additional sampling throughout the broader region (SKM, 2007b). Benthic grab sampling in the vicinity of the continental slope region of the Operational Area revealed a sparse abundance, high variability and high diversity of infauna dominated by polychaetes with other fauna including nemerteans and sipunculids and crustaceans (mainly amphipods) (SKM, 2007). Higher, albeit low, infauna density was reported at the shelf break (200 m) compared to deeper areas on the continental slope. Epifaunal sled samples to 800 m depth including from inside and outside the canyon systems on the continental slope found deepwater solitary cnidarians were the most common fauna in samples, followed by crustaceans (mostly decapods), bony fish and sponges, with urchins, sea stars and brittle stars also recorded (SKM, 2007). Epifauna, cnidarians and demersal fish were also more common in samples taken at 200 m compared to deeper depths and it was noted other epifauna groups showed some variation in abundance with depth (SKM, 2007). These survey findings at the facility were typical of other surveys in the region which revealed deep water habitats consist primarily of bare unconsolidated carbonate sediments supporting a sparse assemblage of deposit and filter feeding organisms, including glass sponges, urchins, sea cucumbers, sea stars and crustaceans (Mobil, 2011; Heyward et al., 2001; URS, 2010). Only limited areas of deepwater hard substrate have been observed over the continental slope, namely rock pinnacles on the upper continental slope and exposed cliff-like features and relatively soft expanses of mudstone outcrops on the mid continental slope. Benthic fauna is closely associated with substrate type, with areas of hard substrate typically supporting more diverse epibenthic communities (Heyward et al., 2001a). Rock pinnacles possibly formed by the deep-water coral Lophelia spp. (few live specimens were observed with low cover) were found in a small portion of the Pluto reservoir (4 x 1 km area) at a depth of 300–500 m and observed to provide habitat for fish, shrimp, hydroids and anemones (SKM, 2007). Exposed cliff-like features of banded sedimentary rock (approximately 20 m in height) were observed at around 1000 m deep. ROV survey findings showed no epifauna on exposed rock, possibly due to their vertical orientation and water flow which may impede settlement (SKM, 2007). However, anemones and fish were observed in areas on more sloping areas among the cliff-like features where sediment had accumulated. At approximately 900–1000 m, mudstone outcrops were also observed dominated by glass sponges. Discrete areas of hard substrate hosting sessile filter feeding communities may also be associated within the Ancient Coastline at the 125 m Depth Contour KEF, which overlaps the PAA. However, Falkner et al. (2009) concluded the Ancient Coastline

Habitat/Community	Key locations within the EMBA
	may not represent different habitat type compared to the surrounding areas and suggested that associated faunal communities may be similar. Refer to Section 4.7 for additional information on KEFs overlapping the Operational Area and wider EMBA. Filter feeder communities within the PAA are present on the subsea infrastructure and Pluto platform, which provides hard substrate for attachment (Jacobs, 2014). Within the wider EMBA, the NWMR has been identified as a sponge diversity hotspot with a variety of areas of potentially high and unique sponge biodiversity, particularly in the Commonwealth waters of Ningaloo Marine Park (CALM, 2005b; Rees et al., 2004). Detail regarding these features is provided in the Master Existing Environment (Woodside, 2022).

4.6 Protected Species

A total of 100 EPBC Act listed species considered to be MNES were identified as potentially occurring within the EMBA, of which a subset of 47 species were identified as potentially occurring within the PAA. The full list of marine species identified from the PMST reports is provided in Appendix C, including several MNES that are not considered to be credibly impacted (e.g., terrestrial species within the EMBA). Criteria for determining species to be considered for impact assessment is outlined in the Master Existing Environment (Woodside, 2022).

Species identified as potentially occurring within the PAA and EMBA, and relevant Biologically Important Areas (BIAs) and Habitat Critical to their Survival (Habitat Critical) are listed in Table 4-4 to Table 4-12. A description of these species is included in the Master Existing Environment (Woodside, 2022), which also shows the spatial overlap with relevant BIAs and Habitat Critical areas and the PAA and EMBA.

4.6.1 Fish, Sharks and Rays

A total of eight EPBC-listed Threatened and an additional seven Migratory fish species have been identified to potentially occur within the EMBA, of which 14 occur in the PAA (Table 4-5). For additional detail, the PAA is presented here in two parts; the Export Pipeline Operational Area and the combined Facility and Xena-03 Drilling Operational Areas. Two threatened species, identified in the PMST were identified to occur within the EMBA, however are not considered to inhabit shorelines, or rely on the marine environment for their diet, and therefore are not included. There are also 35 EPBC- listed Marine species in the EMBA, which do not have a Threatened or Migratory status and include a variety of pipefish and sea dragons. These species are described in the Master Existing Environment (Woodside, 2022).

The PAA overlaps the foraging BIA for the whale shark as outlined in Figure 4-4. The BIAs are detailed further in the Master Existing Environment (Woodside, 2022).

Table 4-5: Threatened and Migratory Fish, Shark and Ray Species predicted to occur within the Export Pipeline Operational Area, Facility and Xena-03 Operational Areas and the EMBA

Species name	Common name	Threatened status	Migratory status	Potential for interaction		
				Export Pipeline OA	***Facility and Xena-03 OA***	***EMBA***
Carcharadon carcharias	White shark	Vulnerable	Migratory	Species or species habitat may occur within area.	Species or species habitat may occur within area.	Species or species habitat known to occur within area
Pristis clavata	Dwarf sawfish	Vulnerable	Migratory	Species or species habitat known to occur within area	Species or species habitat known to occur within area	Species or species habitat known to occur within area
Pristis zijsron	Green sawfish	Vulnerable	Migratory	Species or species habitat known to occur within area.	Species or species habitat known to occur within area.	Species or species habitat known to occur within area
Pristis pristis	Freshwater sawfish	Vulnerable	Migratory	Species or species habitat may occur within area	Species or species habitat may occur within area	Species or species habitat likely to occur within area
Rhincodon typus	Whale shark	Vulnerable	Migratory	Foraging, feeding or related behaviour known to occur within area.	Foraging, feeding or related behaviour known to occur within area.	Foraging, feeding or related behaviour known to occur within area
Carcharias taurus	Grey nurse shark	Vulnerable	N/A	Species or species habitat likely to occur within area.	Species or species habitat likely to occur within area.	Species or species habitat likely to occur within area
Sphyrna lewini	Scalloped hammerhead	Conservation Dependant	N/A	Species or species habitat known to occur within area	Species or species habitat known to occur within area	Species or species habitat known to occur within area
Thunnus maccoyii	Southern bluefin tuna	Conservation Dependent	N/A	Breeding known to occur within area	Breeding known to occur within area	Breeding known to occur within area
Anoxypristis cuspidata	Narrow sawfish	N/A	Migratory	Species or species habitat likely to occur within area.	Species or species habitat may occur within area.	Species or species habitat known to occur within area
Carcharhinus longimanus	Oceanic whitetip shark	N/A	Migratory	Species or species habitat likely to occur within area.	Species or species habitat likely to occur within area.	Species or species habitat likely to occur within area

Species name	Common name	Threatened status	Migratory status	Potential for interaction		
				Export Pipeline OA	*Facility and Xena-03 OA*	*EMBA*
Isurus oxyrinchus	Shortfin mako	N/A	Migratory	Species or species habitat likely to occur within area.	Species or species habitat likely to occur within area.	Species or species habitat likely to occur within area
Isurus paucus	Longfin mako	N/A	Migratory	Species or species habitat likely to occur within area.	Species or species habitat likely to occur within area.	Species or species habitat likely to occur within area
Manta alfredi	Reef manta ray	N/A	Migratory	Species or species habitat known to occur within area.	Species or species habitat likely to occur within area.	Species or species habitat known to occur within area
Manta birostris	Giant manta ray	N/A	Migratory	Species or species habitat likely to occur within area.	Species or species habitat likely to occur within area.	Species or species habitat known to occur within area
Lamna nasus	Porbeagle shark	N/A	Migratory	N/A	N/A	Species or species habitat may occur within area

Table 4-6: Fish, Shark and Ray BIAs within the PAA and EMBA

Species	BIA type	Approximate Distance (closest) and Direction of BIA from PAA (km)
Whale shark	Foraging (northward from Ningaloo along 200 m isobath)	Overlaps the Facility and Xena-03 Operational Areas and Export Pipeline Operational Area
	Foraging (high density prey) (Ningaloo Marine Park and adjacent Commonwealth waters)	228 km south-west (Facility and Xena-03 Operational Area)

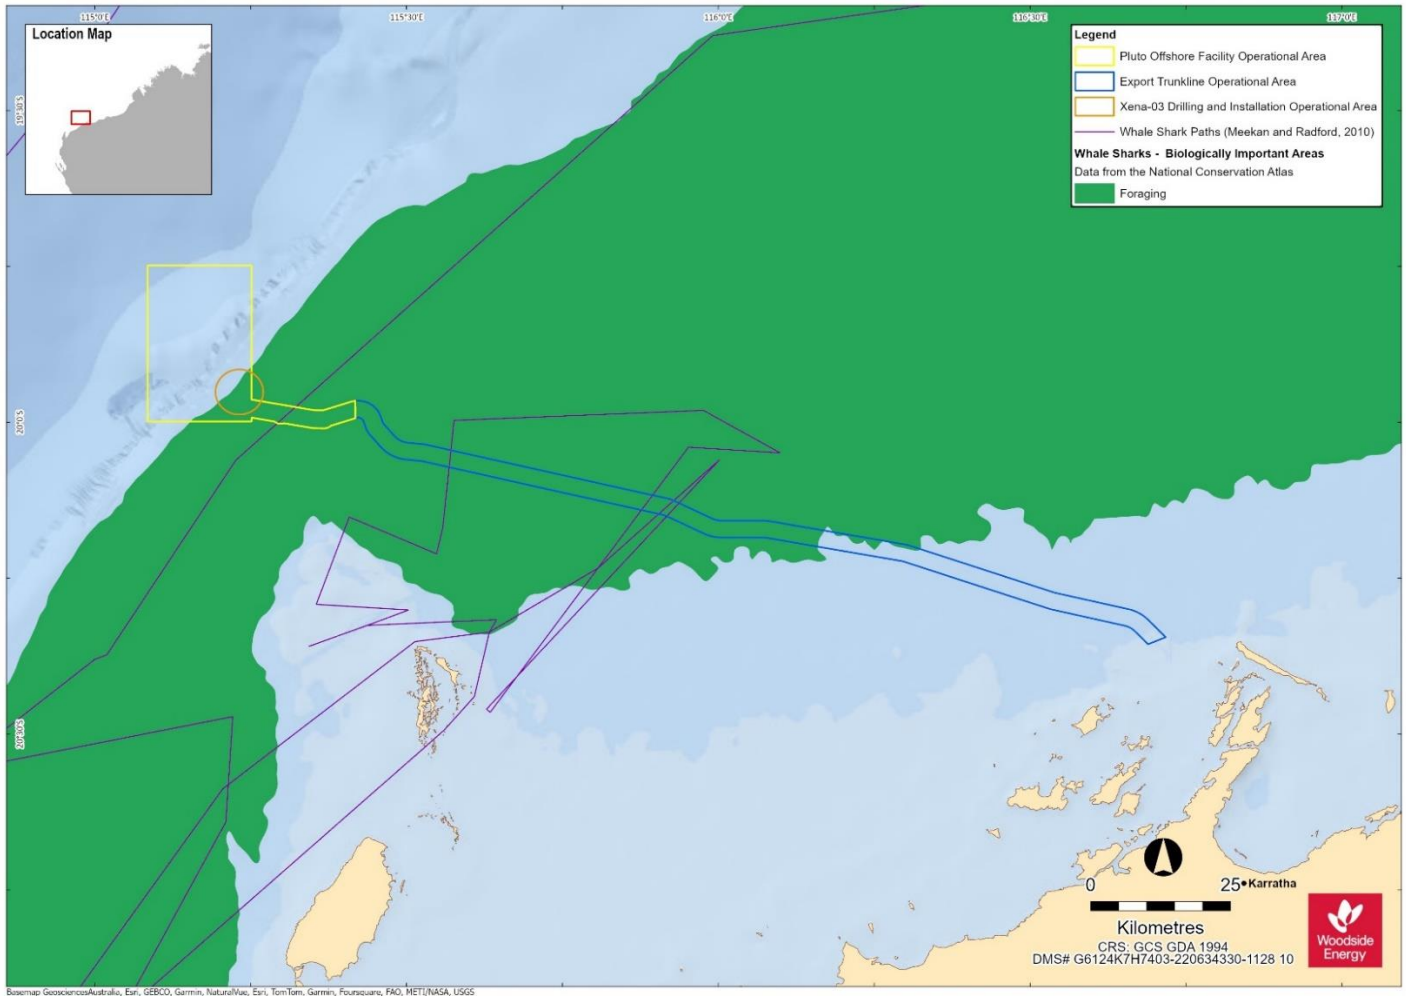

Figure 4-4: Whale Shark BIAs overlapping the PAA and satellite tracks of whale sharks tagged between 2005 and 2008 (Double et al. 2012, 2014)

4.6.2 Marine Reptiles

All seven EPBC listed marine reptiles are and five of these are also listed Migratory species (Table 4-7). For additional detail, the PAA is presented here in two parts; the Export Pipeline Operational Area and the combined Facility and Xena-03 Drilling Operational Areas. Two threatened species, identified in the PMST were identified to occur within in the EMBA, however are not considered to inhabit shorelines, or rely on the marine environment for their diet, and therefore are not included in Table 4-6.

BIAs for the green turtle, hawksbill turtle, and flatback turtle overlap the PAA and the loggerhead turtle only overlaps the Export Pipeline Operational Area as described in Table 4-7 and shown in Figure 4-5.

Habitat critical to the survival of the green turtle, hawksbill turtle, and loggerhead turtle is overlapped by, or adjacent to the PAA as shown in Figure 4-5. An additional 16 EPBC-listed Marine reptiles species occur in the EMBA, which do not have Threatened or Migratory status. The majority of these are sea snake species. These listed Marine species are described in the Master Existing Environment (Woodside, 2022).

Table 4-7: Threatened and Migratory Marine Reptile Species predicted to occur within the Export Pipeline Operational Area, Facility and Xena-03 Operational Areas and the EMBA

Species name	Common name	Threatened status	Migratory status	Potential for interaction		
				Export Pipeline OA	Facility and Xena-03 OA	EMBA
Caretta caretta	Loggerhead turtle	Endangered	Migratory	Congregation or aggregation known to occur within the area	Species or species habitat known to occur within the area	Breeding known to occur within area
Dermochelys coriacea	Leatherback turtle	Endangered	Migratory	Species or species habitat likely to occur within the area	Species or species habitat likely to occur within the area	Species or species habitat known to occur within area
Chelonia mydas	Green turtle	Vulnerable	Migratory	Congregation or aggregation known to occur with the area	Species or species habitat known to occur within the area	Breeding known to occur within area
Eretmochelys imbricata	Hawksbill turtle	Vulnerable	Migratory	Congregation or aggregation known to occur with the area	Species or species habitat known to occur within the area	Breeding known to occur within area
Natator depressus	Flatback turtle	Vulnerable	Migratory	Congregation or aggregation known to occur with the area	Congregation or aggregation known to occur with the area	Breeding known to occur within area
Aipysurus apraefrontalis	Short-nosed seasnake	Critically Endangered	N/A	Species or species habitat likely to occur within the area	Species or species habitat may occur within the area	Species or species habitat known to occur within area
Aipysurus foliosquama	Leaf-scaled seasnake	Critically Endangered	N/A	Species or species habitat known to occur within the area	N/A	Species or species habitat known to occur within area

Table 4-8: Marine Turtle BIAs within the EMBA

Species	BIA type (closest location)	Approximate Distance and Direction of BIA from PAA (km)
Flatback turtle	Internesting Buffer (Montebello Island, Hermite Island, NW Island, Trimouille Island; Dampier Archipelago (islands to the west of the Burrup Peninsula); Intercourse Island; Legendre Island, Huay Island; Delambre Island; Dixon Island; West of Cape Lambert; Thevernard Island – South coast)	Overlaps the Facility and Xena-03 Operational Areas and Export Pipeline Operational Area
	Mating (Dampier Archipelago (islands to the west of the Burrup Peninsula); Montebello Island, Hermite Island, NW Island, Trimouille Island; coral reef habitat west of the Montebello group (extends the entire length of Montebello's); Barrow Island; Coral reef habitat west of the Montebello group (extends the entire length of the Montebellos)	10 km south-east (Export Pipeline Operational Area)
	Nesting (Dampier Archipelago (islands to the west of the Burrup Peninsula); Legendre Island, Huay Island; Delambre Island; Montebello Island, Hermite Island, NW Island, Trimouille Island)	10 km south-east (Export Pipeline Operational Area)
	Foraging (Dampier Archipelago (islands to the west of the Burrup Peninsula); Legendre Island, Huay Island; Montebello Island, Hermite Island, NW Island, Trimouille Island; coral reef habitat west of the Montebello)	10 km south-east (Export Pipeline Operational Area)
	Aggregation (Coral reef habitat west of the Montebello group. Extends the entire length of Montebello's)	40 km south-west (Export Pipeline Operational Area)
	Internesting (Dampier Archipelago (islands to the west of the Burrup Peninsula); coral reef habitat west of the Montebello group (extends the entire length of Montebello's))	10 km south-east (Export Pipeline Operational Area)
	Migration corridor (Dampier Archipelago (islands to the west of the Burrup Peninsula)	10 km south-east (Export Pipeline Operational Area)
Green turtle	Internesting Buffer (Dampier Archipelago (islands to the west of the Burrup Peninsula); Legendre Island, Huay Island; Montebello Island, Hermite Island, NW Island, Trimouille Island; Delambre Island; north and south Muiron Island; north-west Cape)	Overlaps the Facility and Xena-03 Operational Areas and Export Pipeline Operational Area
	Mating (Dampier Archipelago (islands to the west of the Burrup Peninsula); Montebello Islands; Hermite Island, NW Island, Trimouille Island; coral reef habitat west of the Montebello group (extends the entire length of Montebello's))	10 km south-east (Export Pipeline Operational Area)
	Nesting (Dampier Archipelago (islands to the west of the Burrup Peninsula); Legendre Island, Huay Island; Montebello Islands; Hermite Island, NW Island, Trimouille Island; north and south Muiron Island)	10 km south-east (Export Pipeline Operational Area)
	Internesting (Dampier Archipelago (islands to the west of the Burrup Peninsula); Montebello Islands; coral reef habitat west of the Montebello group (extends the entire length of Montebello's))	10 km south-east (Export Pipeline Operational Area)

Species	BIA type (closest location)	Approximate Distance and Direction of BIA from PAA (km)
	Foraging (Dampier Archipelago (islands to the west of the Burrup Peninsula); Legendre Island, Huay Island; Delambre Island; Montebello Island, Hermite Island, NW Island, Trimouille Island; coral reef habitat west of the Montebello group (extends the entire length of Montebellos))	10 km south-east (Export Pipeline Operational Area)
	Aggregation (Coral reef habitat west of the Montebello group (extends the entire length of Montebello's))	40 km south-west (Export Pipeline Operational Area)
	Migration corridor (Dampier Archipelago (islands to the west of the Burrup Peninsula)	10 km south-east (Export Pipeline Operational Area)
Hawksbill turtle	Internesting Buffer (Rosemary Island; Dampier Archipelago (islands to the west of the Burrup Peninsula); Delambre Island; Montebello Island; Hermite Island, NW Island, Trimouille Island; Ah chong and South East Island; Lowendal Island; Thevenard Island; Ningaloo coast and Jurabi coast)	Overlaps the Facility and Xena-03 Operational Areas and Export Pipeline Operational Area
	Foraging (Dampier Archipelago (islands to the west of the Burrup Peninsula); Montebello Island, Hermite Island, NW Island, Trimouille Island	10 km south-east (Export Pipeline Operational Area)
	Mating (Dampier Archipelago (islands to the west of the Burrup Peninsula); Montebello Island; Hermite Island; NW Island; Trimouille Island)	10 km south-east (Export Pipeline Operational Area)
	Nesting (Delambre Island (and other Dampier Archipelago Islands); Dampier Archipelago (islands to the west of the Burrup Peninsula); Rosemary Island; Montebello Island; Hermite Island; NW Island; Trimouille Island; Ah chong and South East Island)	9 km south-east (Export Pipeline Operational Area)
	Internesting (Dampier Archipelago (islands to the west of the Burrup Peninsula))	10 km south-east (Export Pipeline Operational Area)
	Migration corridor (Dampier Archipelago (islands to the west of the Burrup Peninsula))	10 km south-east (Export Pipeline Operational Area)
Loggerhead turtle	Internesting buffer (Rosemary Island; Montebello Islands; Muiron Island; Ningaloo coast and Jurabi coast)	Overlaps Export Pipeline Operational Area only
	Nesting (Cohen Island; Rosemary Island; Montebello Islands; Muiron Island)	10 km south-east (Export Pipeline Operational Area)
Leatherback turtle	No BIAs within the EMBA or PAA	

Table 4-9: Habitat Critical to the Survival of Marine Turtle Species occurring within the EMBA

Species	Genetic Stock	Nesting Locations	Approximate Distance and Direction from PAA (km)	Inter-nesting buffer	Nesting period	Hatching period
Flatback turtle	Northwest Shelf	Dampier Archipelago (including Delambre Island and Huay Island), Barrow Island, Montebello Islands, coastal islands from Cape Preston to Locker Island, Cemetery Beach, Port Headland, Mundabullangana Beach	Overlaps the Facility and Xena-03 Operational Areas and Export Pipeline Operational Area	60 km	All year (peak: Au– - Sep)	All year
Green turtle	Northwest Shelf	Dampier Archipelago (including Delambre Island and Rosemary Island, Barrow Island, Montebello Islands, Serrier Island and Thevenard Island, Cape Preston to mourh of Exmouth Gulf (including Moneteblo Islands and Lowendal Islands)	Overlaps Export Pipeline Operational Area only	20 km	Nov–Mar (peak: Dec–Jan)	Jan–May (peak: Feb–Mar)
Hawksbill turtle	Northwest Shelf	Dampier Archipelago (including Rosemary Island and Delambre Island), Cape Preston to north of Exmouth Gulf (including Monteeblo Islands and Lowendal Islands),	Overlaps Export Pipeline Operational Area only	20 km	All year (peak: No– - May)	All year (peak: Dec–Feb)
Loggerhead turtle	Northwest Shelf	Exmouth Gulf and Ningaloo coast, Gnaraloo Bay and beaches.	200 km south-west (Facility and Xena-03 Operational Areas)	20 km	Nov–Mar (peak: Jan)	Jan–May
Leatherback turtle	No overlap – nesting located within the EMBA and PAA

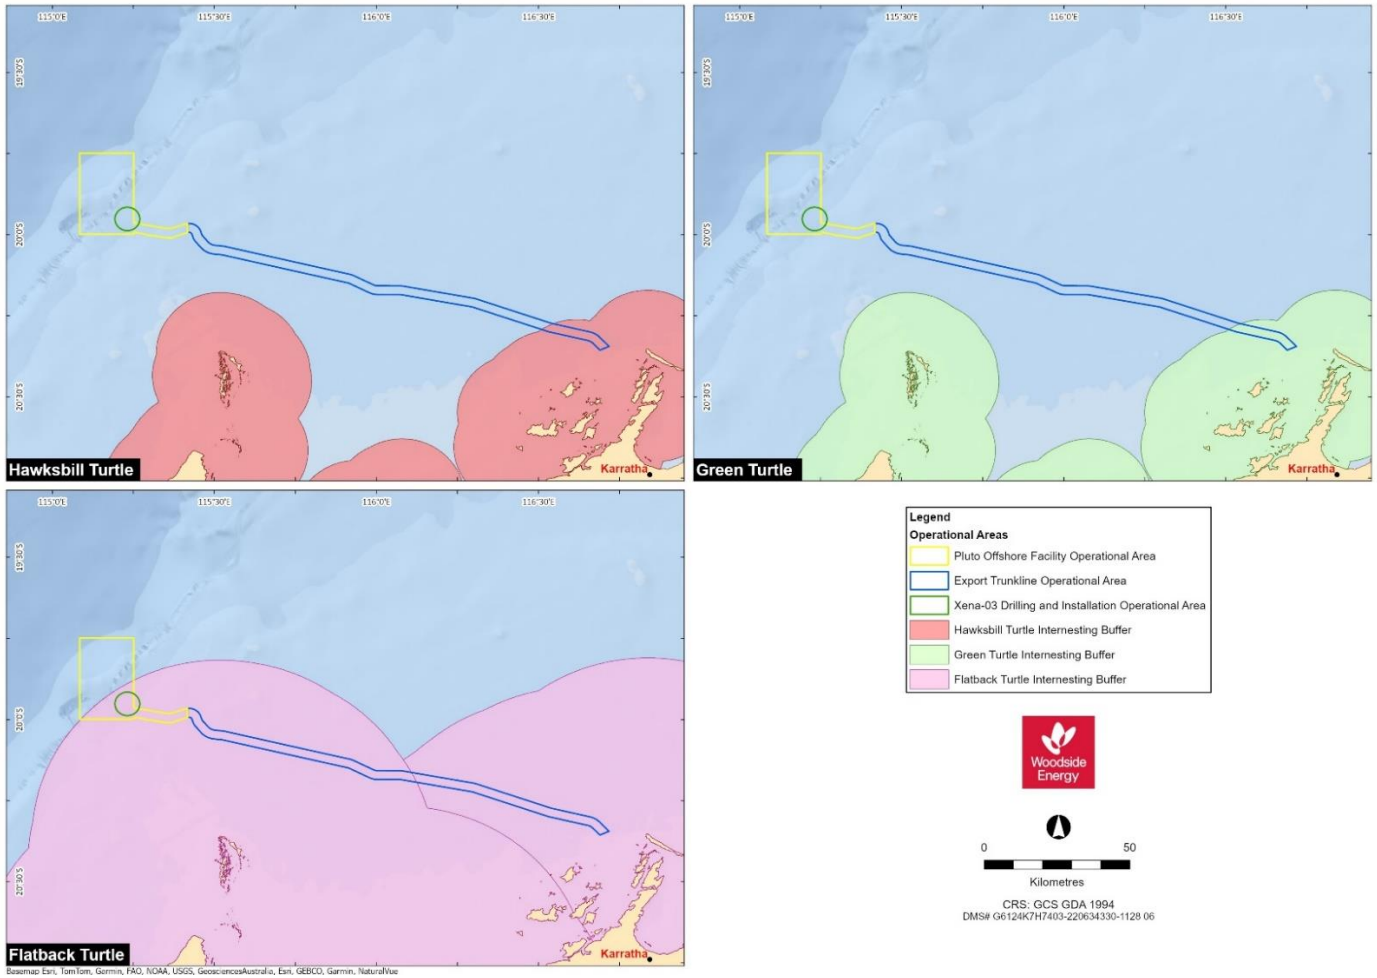

Figure 4-6: Habitat Critical to the Survival of Marine Turtles overlapping the PAA

4.6.3 Marine Mammals

A total of four EPBC Listed Threatened and an additional nine Migratory marine mammal species have been identified to potentially occur within the EMBA, of which 11 occur in the PAA (Table 4-10). For additional detail, the PAA is presented here in two parts; the Export Pipeline Operational Area and the combined Facility and Xena-03 Drilling Operational Areas. Nine threatened species, identified in the PMST were identified to occur within in the EMBA, however are not considered to inhabit shorelines, or rely on the marine environment for their diet, and therefore are not included.

The PAA overlaps with the distribution and migration BIAs for the pygmy blue whale and migration (north and south) BIA for the humpback whale. Two other species of marine mammal species have BIAs within the EMBA and are described in Table 4-10.

Table 4-10: Threatened and Migratory Marine Mammal Species predicted to occur within the Export Pipeline Operational Area, Facility and Xena-03 Operational Areas and the EMBA

Species name	Common name	Threatened status	Migratory Status	Potential for interaction		
				Export Pipeline OA	Facility and Xena-03 OA	EMBA
Balaenoptera musculus	Blue whale	Endangered	Migratory	Migration route known to occur within the area	Migration route known to occur within the area	Migration route known to occur within area
Balaenoptera physalus	Fin whale	Vulnerable	Migratory	Species or species habitat likely to occur within the area	Species or species habitat likely to occur within the area	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera borealis	Sei whale	Vulnerable	Migratory	Species or species habitat likely to occur within the area	Species or species habitat likely to occur within the area	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera edeni	Bryde's whale	N/A	Migratory	Species or species habitat likely to occur within the area	Species or species habitat likely to occur within the area	Species or species habitat likely to occur within area
Dugong dugon	Dugong	N/A	Migratory	Species or species habitat known to occur within the area	N/A	Breeding known to occur within area
Megaptera novaeangliae	Humpback whale	N/A	Migratory	Breeding known to occur with in the area	Breeding known to occur with in the area	Breeding known to occur within area
Orcaella heinsohni	Australian snubfin dolphin	N/A	Migratory	Species or species habitat may occur within the area	Species or species habitat may occur within the area	Species or species habitat known to occur within area
Orcinus orca	Killer whale	N/A	Migratory	Species or species habitat may occur within the area	Species or species habitat may occur within the area	Species or species habitat may occur within area

Species name	Common name	Threatened status	Migratory Status	Potential for interaction		
				Export Pipeline OA	Facility and Xena-03 OA	EMBA
Physeter macrocephalus	Sperm whale	N/A	Migratory	Species or species habitat may occur within the area	Species or species habitat may occur within the area	Species or species habitat may occur within area
Sousa chinensis	Australian humpback dolphin	N/A	Migratory	Species or species habitat may occur within the area	Species or species habitat may occur within the area	Species or species habitat known to occur within area
Tursiops aduncus (Arafura/Timor Sea populations)	Spotted bottlenose dolphin	N/A	Migratory	Species or species habitat likely to occur within the area	Species or species habitat likely to occur within the area	Species or species habitat known to occur within area
Eubalaena australis	Southern right whale	Endangered	Migratory	N/A	N/A	Species or species habitat likely to occur within area
Balaenoptera bonaerensis	Antarctic minke whale	N/A	Migratory	N/A	N/A	Species or species habitat likely to occur within area

Table 4-11: Marine Mammal BIAs within the EMBA

Species	BIA type	Approximate Distance and Direction from PAA (km)
Dugong	Calving (Exmouth Gulf)	207 km south-west (Facility and Xena-03 Operational Areas)
	Nursing (Exmouth Gulf)	207 km south-west (Facility and Drilling Operational Area)
	Breeding (Exmouth Gulf)	207 km south-west (Facility and Xena-03 Operational Areas)
	Foraging (high density seagrass beds) (Exmouth Gulf)	207 km south-west (Facility and Xena-03 Operational Areas)
Pygmy Blue Whale	Migration (Augusta to Derby. Tend to pass along the shelf edge at depths of 500m to 1000m; appear close to coast in the Exmouth-Montebello Islands area on southern migration.)	Overlaps the Facility and Xena-03 Operational Areas and Export Pipeline Operational Area
	Distribution	Overlaps the Facility and Xena-03 Operational Areas and Export Pipeline Operational Area
	Foraging (Ningaloo)	232 km south-west (Facility and Xena-03 Operational Areas)
Humpback whale	Migration (north and south) (The migration corridor extends from the coast to out to approximately 100km offshore in the Kimberley region extending south to North-west Cape. From North-west Cape to south of shark Bay the migration corridor is reduced to approximately 50 km.)	Overlaps the Facility and Xena-03 Operational Areas and Export Pipeline Operational Area
Southern Right Whale	Reproduction (Exmouth Gulf and Ningaloo)	Abuts the EMBA

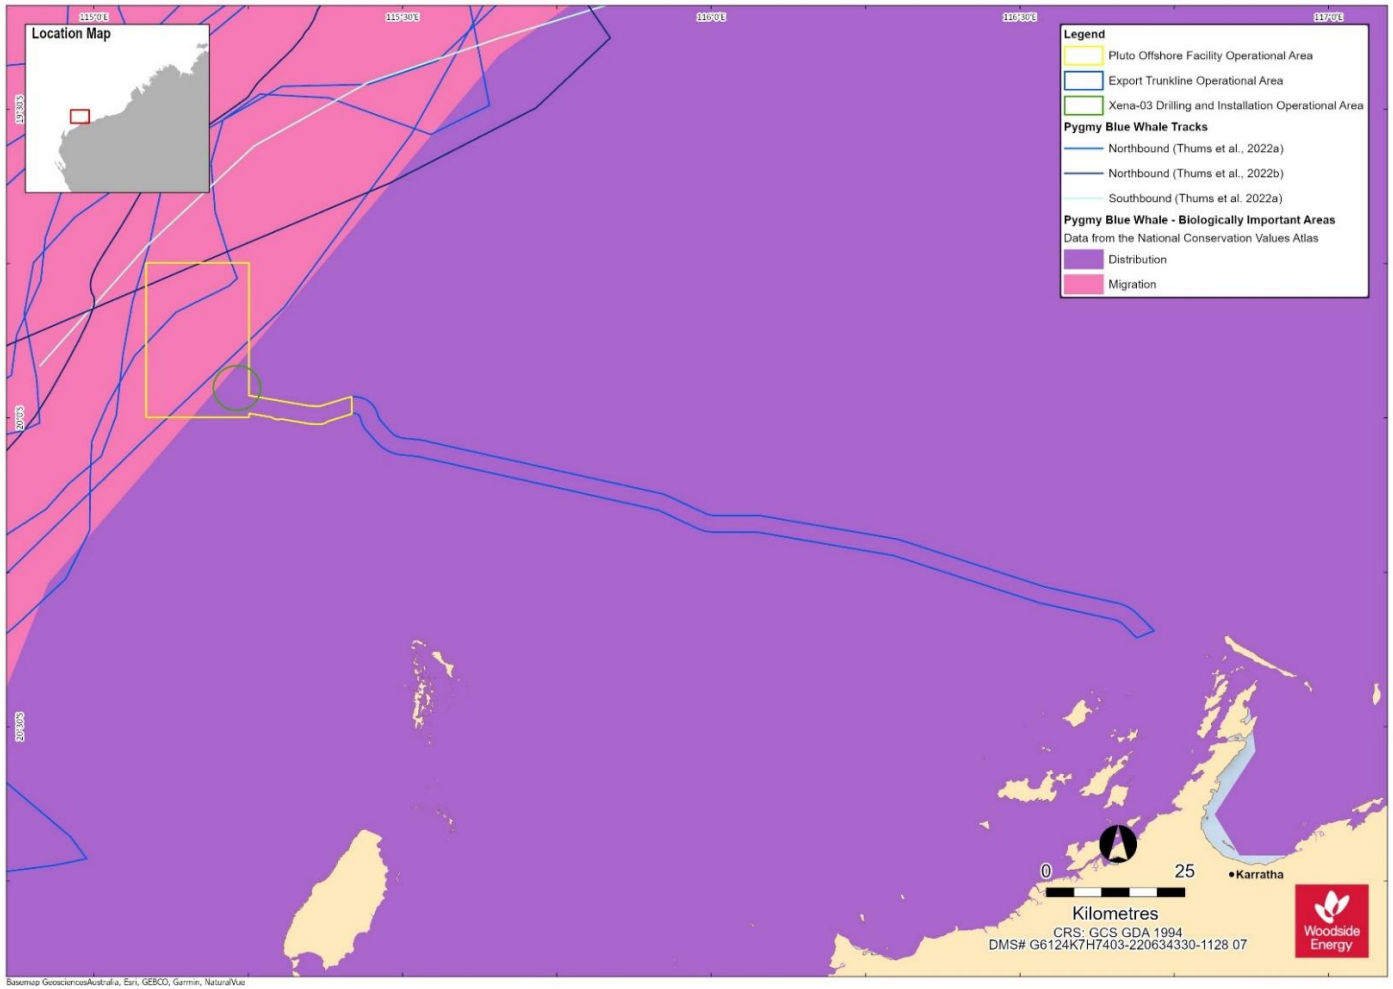

Figure 4-7:Pygmy blue whale BIAs overlapping the PAA and satellite tracks of tagged whales (Double et al., 2012, 2014)

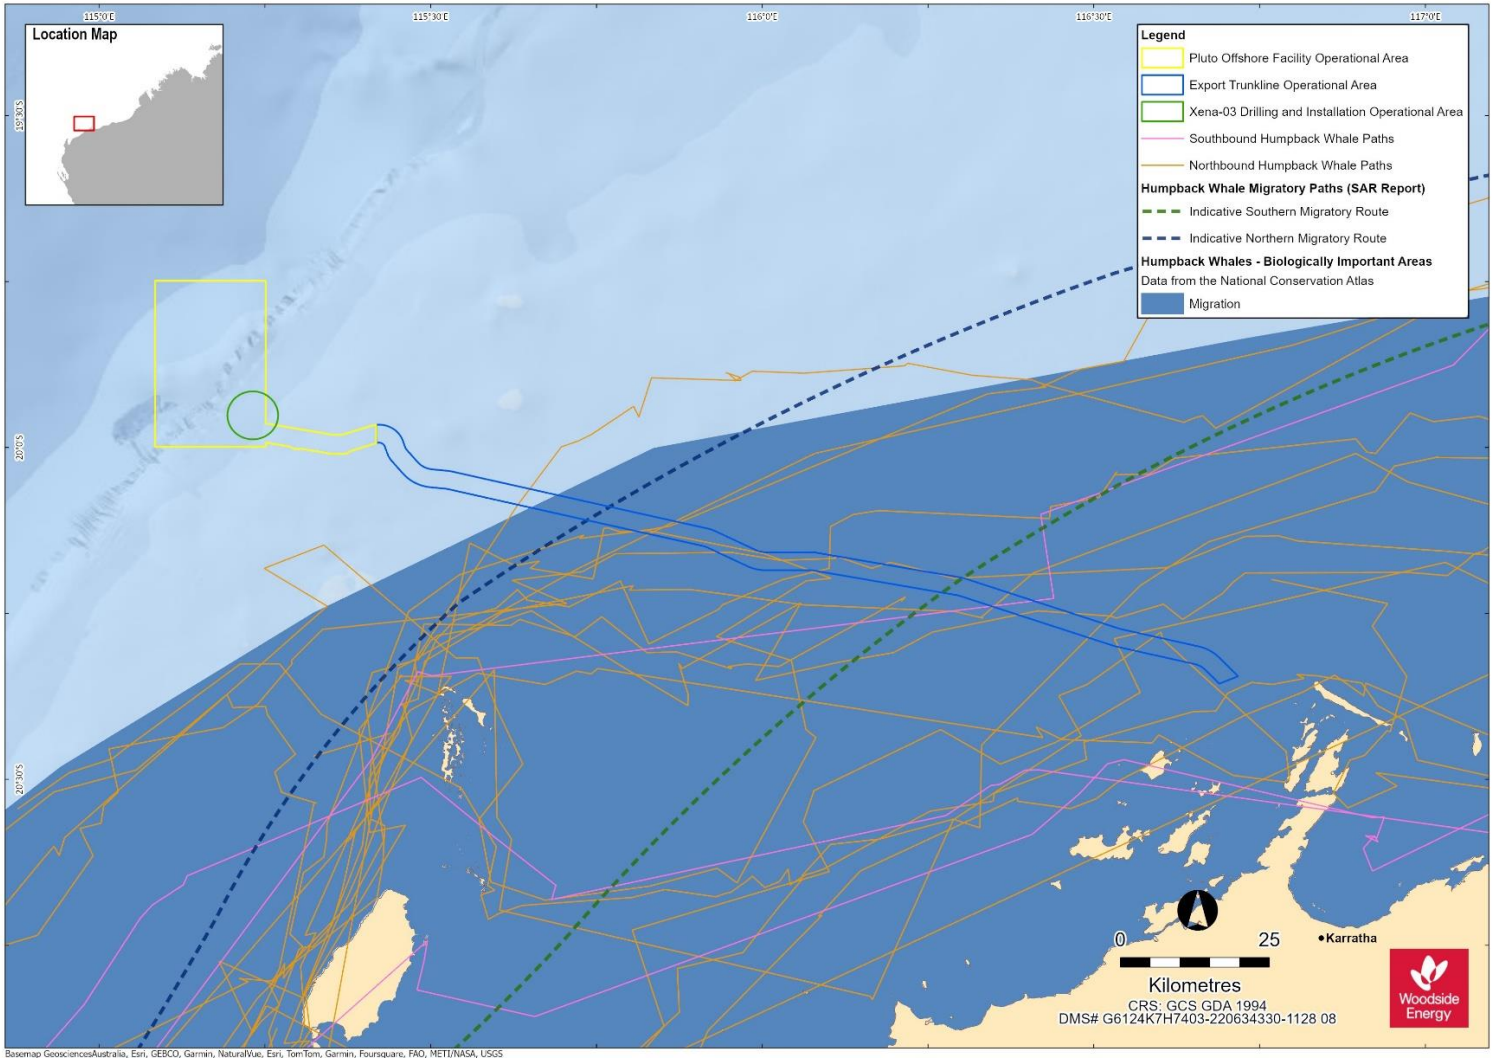

Figure 4-8: Humpback whale BIAs overlapping the PAA and satellite tracks of tagged whales (Double et al., 2012, 2010)

4.6.4 Seabirds and Migratory Shorebirds

A total of 17 EPBC-listed Threatened and additional 21 Migratory seabird and shorebird species have been identified to potentially occur within the EMBA, of which 15 occur in the PAA (Table 4-12). For additional detail, the PAA is presented here in two parts; the Export Pipeline Operational Area and the combined Facility and Xena-03 Drilling Operational Areas. There are 2 migratory bird species (fork-tailed swift and roseate turn) occurring within the Export Pipeline Operational Area that are not present within the Facility and Xena-03 Drilling Operational Areas. An additional 6 EPBC-listed Marine bird species are identified to occur within the EMBA, none of which are listed as Threatened or Migratory.

The PAA overlaps the BIA (Breeding) for the wedge-tailed shearwater. The roseate tern, and fairy tern only overlap the Export Pipeline Operational Area, as shown in Figure 4-9. The lesser crested tern breeding BIA is overlapped by the EMBA. Seabird and Migratory shorebirds which BIAs within the PAA and EMBA are outlined in Table 4-13.

Table 4-12: Threatened and Migratory Seabird and Migratory Shorebird Species predicted to occur within the Export Pipeline Operational Area, Facility and Xena-03 Operational Area and the EMBA

Species name	Common name	Threatened status	Migratory status	Potential for interaction		
				Export Pipeline OA	Facility and Xena-03 OA	EMBA
Calidris ferruginea	Curlew sandpiper	Critically Endangered	Migratory	Species or species habitat may occur within the area	Species or species habitat may occur within the area	Species or species habitat known to occur within area
Numenius madagascariensis	Eastern curlew	Critically Endangered	Migratory	Species or species habitat may occur within the area	Species or species habitat may occur within the area	Species or species habitat known to occur within area
Macronectes giganteus	Southern-giant petrel	Endangered	Migratory	Species or species habitat may occur within the area	Species or species habitat may occur within the area	Species or species habitat may occur within area
Calidris acuminata	Sharp-tailed sandpiper	Vulnerable	Migratory	Species or species habitat may occur within the area	Species or species habitat may occur within the area	Species or species habitat known to occur within area
Calidris canutus	Red knot	Vulnerable	Migratory	Species or species habitat may occur within the area	Species or species habitat may occur within the area	Species or species habitat known to occur within area
Phaethon lepturus fulvus	Christmas Island white-tailed tropicbird	Endangered	N/A	Species or species habitat may occur within the area	Species or species habitat may occur within the area	Species or species habitat may occur within area
Phaethon rubricauda	Red-tailed tropicbird	Endangered	N/A	Species or species habitat likely to occur within area	Species or species habitat likely to occur within area	Species or species habitat known to occur within area
Sternula nereis nereis	Australian fairy tern	Vulnerable	N/A	Breeding known to occur within the area	Foraging, feeding or related behaviour likely to occur within the area	Breeding known to occur within area

4.6.5 Seasonal Sensitivities for Protected Species

Seasonal sensitivities for protected migratory species identified as potentially occurring within the PAA are identified in Table 4-14. Movement patterns of all protected species identified in Section 4.6 are described in the Master Existing Environment (Woodside, 2022).

Table 4-14: Key seasonal sensitivities for protected migratory species identified as occurring within the PAA and EMBA

Species	January	February	March	April	May	June	July	August	September	October	November	December
Fish, sharks and rays												
Whale shark – northern and southern migration (NWMR)[8]												
Whale shark – foraging/ aggregation (Ningaloo Coast)[8]												
Great white shark – northern migration (to Northwest Cape) [9]												
Marine reptiles[10]												
Flatback turtle, Pilbara Coast genetic stock – nesting												
Flatback turtle, Pilbara Coast genetic stock – hatching												
Green turtle, Northwest Shelf genetic stock – nesting												
Green turtle, Northwest Shelf genetic stock– - hatching

4.7 Key Ecological Features

Two KEFs overlap the PAA (Figure 4-10). KEFs within the PAA and EMBA are identified in Table 4-15 and described in the Master Existing Environment (Woodside, 2022).

Table 4-15: KEFs within the PAA and EMBA

Key Ecological Feature	Distance (closest) and Direction from PAA to KEF (km)
Ancient Coastline at the 125 m depth contour	Overlaps (Export Pipeline Operational Area)
Continental Slope Demersal Fish Communities	Overlaps (Facility and Xena-03 Operational Areas)
Glomar Shoal KEF	56 km north-east (Export Pipeline Operational Area)
Exmouth Plateau	74 km west (Facility and Xena-03 Operational Areas)
Canyons Linking the Cuvier Abyssal Plain and the Cape Range Peninsula	164 km south-west (Facility and Xena-03 Operational Areas)
Commonwealth Waters Adjacent to Ningaloo Reef	207 km south-west (Facility and Xena-03 Operational Areas)

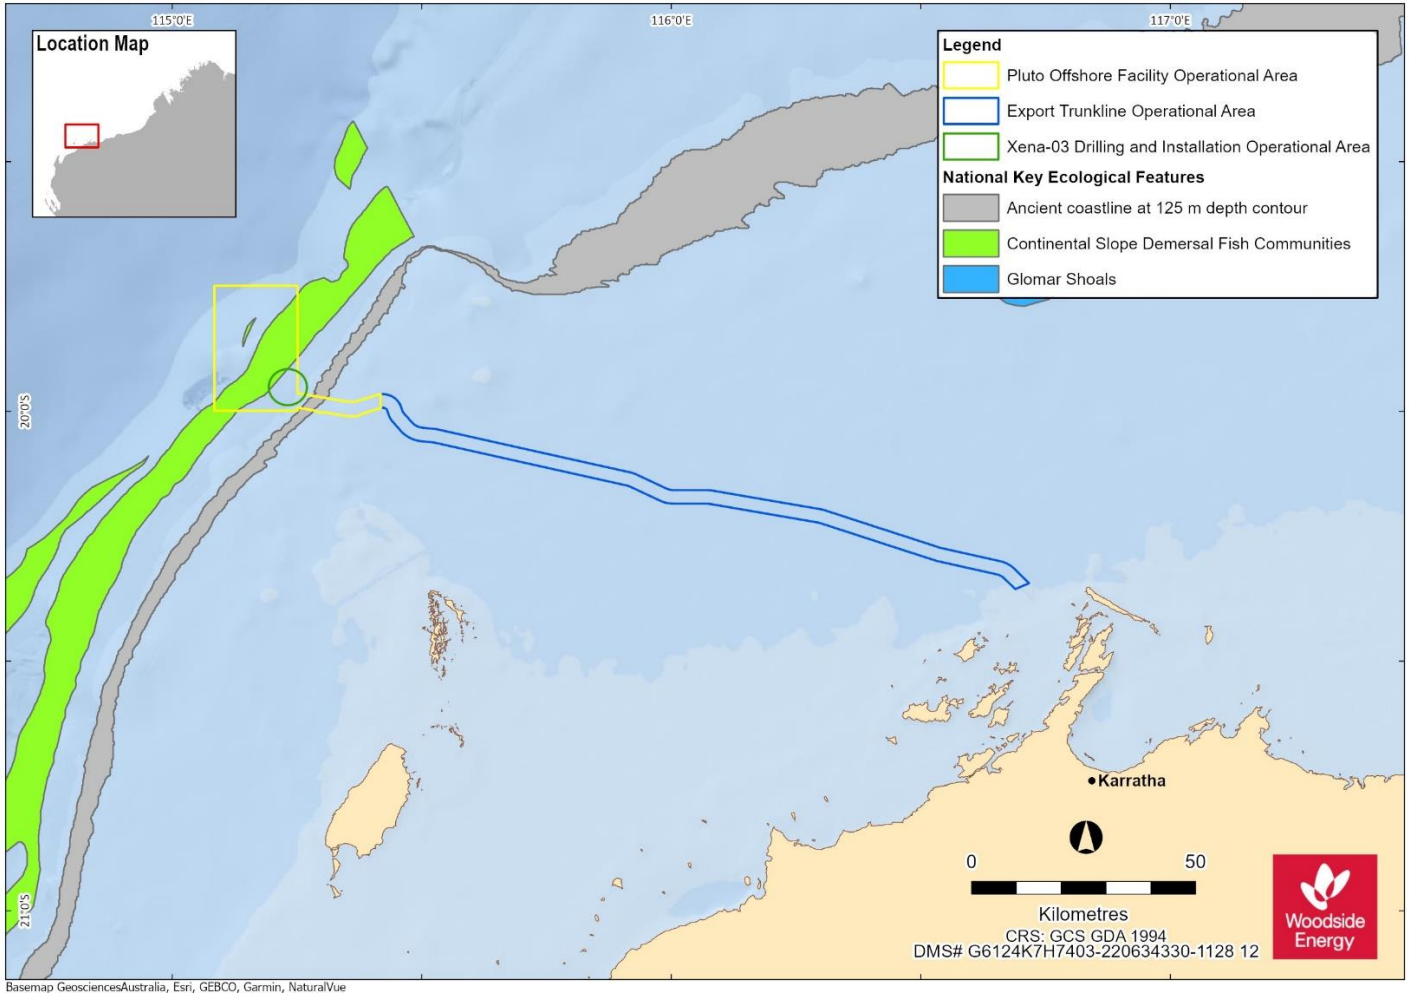

Figure 4-10: Key Ecological Features overlapping and near the PAA

4.8 Protected Places

The Montebello Marine Park Overlaps the PAA. Protected places within the EMBA are identified in Table 4-16 and presented in Figure 4-11 and Figure 4-12. The Master Existing Environment (Woodside, 2022) outlines the values and sensitivities of protected places and other sensitive areas in the EMBA.

Table 4-16: Established protected places and other sensitive areas overlapping the EMBA

Protected places and other sensitive areas	Distance (closest) and Direction from PAA to protected place or sensitive area (km)	Park zone and IUCN category* overlapping PAA and/or EMBA

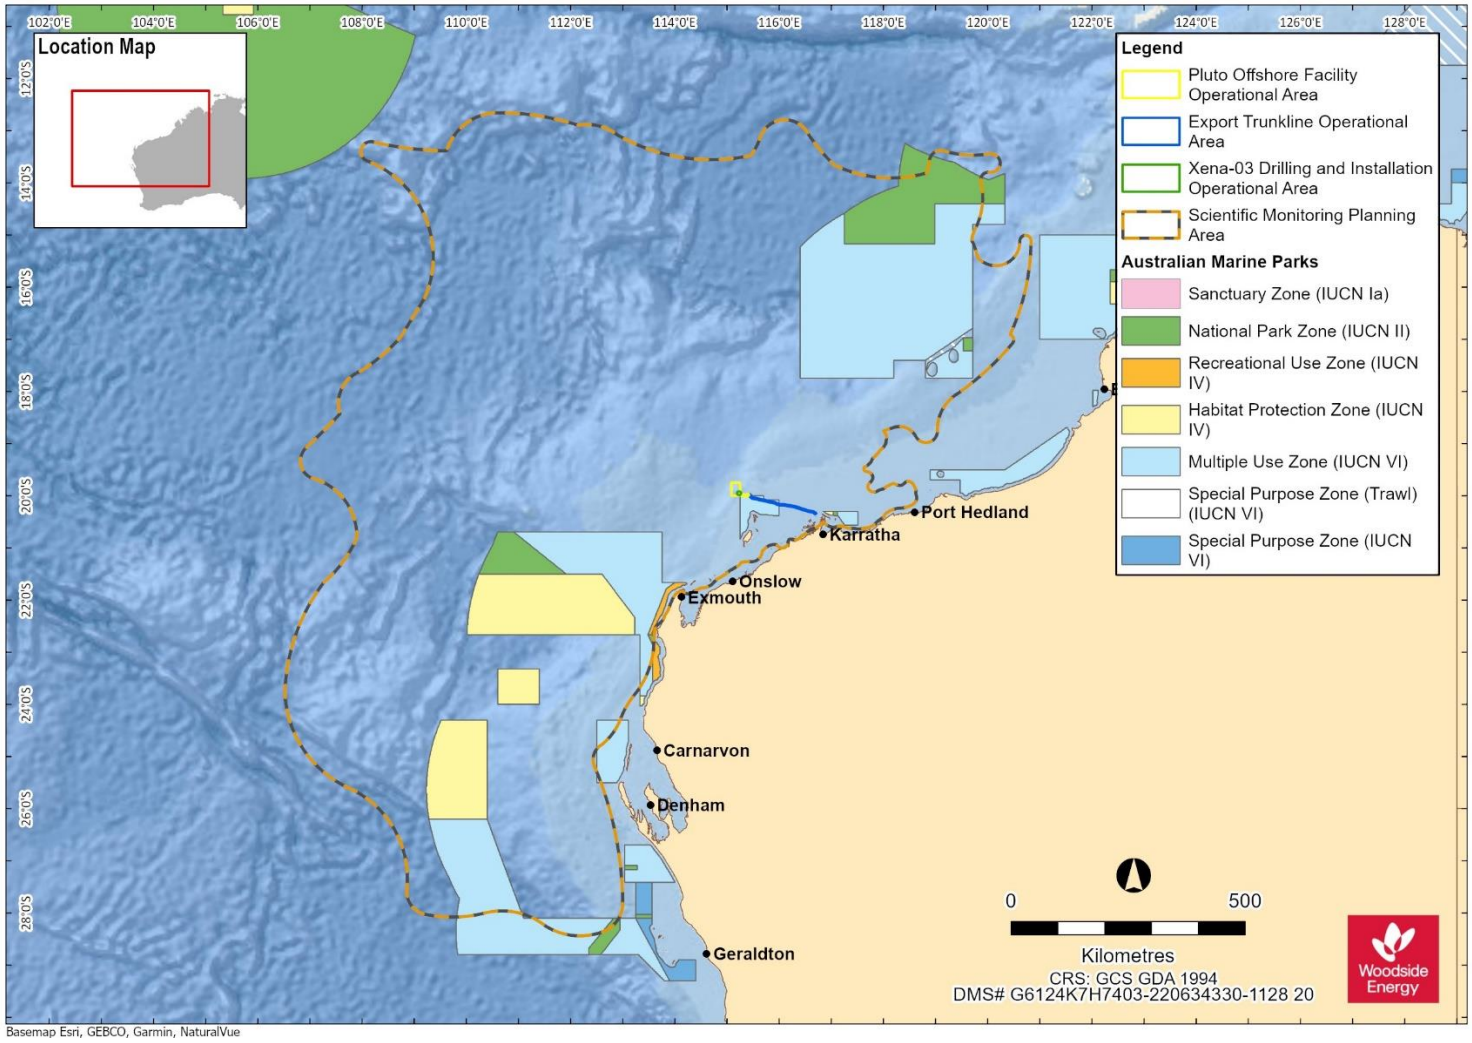

Figure 4-12: Australian Marine Parks adjacent to the PAA, Scientific Monitoring Area and EMBA

4.9 Cultural Features and Heritage Values

4.9.1 Background

Woodside recognises the 'environment' for the purpose of the evaluation required under the Environment Regulations includes:

- the heritage value of places; and
- the social, economic, and cultural features of the broader environment.

In this section, the heritage value of places within the PAA and EMBA and the cultural features of the PAA and EMBA are described.

In line with The Burra Charter: The Australia ICOMOS Charter for Places of Cultural Significance (Australia ICOMOS 2013) (Burra Charter) and associated practice notes, Woodside understands heritage value to refer to the cultural significance of a place to an individual or group. A cultural feature, by contrast, is understood to be comparable to the Burra Charter term “fabric” and refer to a place’s elements, fixtures, contents and objects which have cultural values. Although these features are necessarily physical, the place they inhabit or comprise may have tangible or intangible dimensions (Australia ICOMOS 2013). Woodside has undertaken heritage assessment to identify potential cultural values or features that may be impacted by the PAA. This assessment has not identified heritage places, objects or values which will be impacted by the activities planned under this EP (discussed in Section). However, Woodside recognises the deep spiritual and cultural connection to the environment[19] that First Nations peoples hold and is committed to ensuring appropriate management through on-going consultation.

4.9.2 First Nations People

Woodside uses established systems managed and maintained by government at State and/or Federal level where possible to identify First Nations groups that may have functions, interests or activities that may be affected by the PAP. Woodside identifies native title representative bodies and nominated representative entities, as well as native title claims, determinations and Indigenous Land Use Agreements (ILUAs) which the EMBA overlaps. Native title claims, determinations and ILUAs are defined under the Native Title Act 1993 (Cth). While acknowledging that cultural features and heritage values may exist outside of the native title framework, Woodside considers this to be the broadest extent over which Indigenous groups have claimed native title rights and interests.

Native title claims are applications made to the Federal Court under the Native Title Act 1993 for a determination or decision about native title in a particular area. A claim is made by a native title claim group which asserts it holds native title rights and interests in an area of land and/or water, according to its traditional laws and customs. By making a claim, the native title claim group seeks a decision that native title exists so that its native title rights and interests are recognised by the common law of Australia. This is called a native title determination. A determination is a decision by a recognised body, such as the Federal Court or High Court of Australia, that native title either does or does not exist in relation to a particular area (National Native Title Tribunal).

A requirement to establishing a positive determination of native title in court is proving that there is an organised society that occupied the land and/or waters at the time of British annexation. The requirement of an ‘organised society’ is set out by Justice Toohey in the historic judgment of Mabo

[19] Definition of ‘Environment’ in Regulation 4 of the OPGGS (Environment) Regulations are defined as:
Ecosystems and their constituent parts, including people and communities; and
Natural and physical resources; and
The qualities and characteristics of locations, places and areas; and
The heritage values of places; and includes
The social, economic and cultural features of the matters mentioned in paragraphs (a), (b), (c) and (d)

v Queensland (No 2) [1992] HCA 23; (1992) 175 CLR 1 ('Mabo'). Justice Toohey had the following to say (at 187):

it is inconceivable that indigenous inhabitants in occupation of land did not have a system by which land was utilized in a way determined by that society. There must, of course, be a society sufficiently organized to create and sustain rights and duties…

Therefore, Woodside understands that native title rights and interests are held communally by an organised society, that native title claims are understood to represent the area over which First Nations groups are claiming these rights and interests, and that native title determinations provide clarity on where native title rights and interests are found to either exist or not exist. Where native title rights or interests are determined to exist they will be held by a Registered Native Title Body Corporate (section 57, Native Title Act 1993) in trust or as agent for native title holders.

ILUAs are voluntary agreements between native title parties and other people or bodies about the use and management of land and/or waters and are registered by the Native Title Registrar in the Register of ILUAs. An ILUA can be made over areas where:

- native title has been determined to exist in at least part of the area; or
- a native title claim has been made; or
- where no native title claim has been made.

While registered, ILUAs operate as a contract between the parties, including relevant native title holders (National Native Title Tribunal).

The Native Title Act 1993 provides for a Representative Aboriginal/Torres Strait Islander Body (Native Title Representative Body) to be recognised by the Commonwealth Minister for an area. Native Title Representative Bodies have specialist functions set out in the Native Title Act 1993 within the area for which they are the Native Title Representative Body. However, the functions of a Native Title Representative Body are such that they do not hold details on the cultural features or heritage values of an area and therefore do not inform Woodside's understanding of heritage values or cultural features.

For the activity in this EP, there are no native title claims or determinations, ILUAs overlapping the PAA and therefore also no native title rights or interests and/or cultural values identified over the PAA (Figure 4-13).

There are three native title claims overlapping the EMBA and areas of potential shoreline accumulation. A further two native title claims are coastally adjacent to the EMBA. There are three ILUAs overlapping the in-water EMBA and areas of potential shoreline accumulation. A further 9 ILUAs are coastally adjacent to the EMBA (Figure 4-13).

4.9.3 Coastally adjacent First Nations groups

Woodside understands that First Nations groups are keenly aware of the extent of their rights, interests and responsibilities for Country, and these are generally discrete, defined areas, including areas of sea (Smyth 2007). To identify cultural features and heritage values which may exist outside of native title claim, determination and ILUA areas, Woodside considers native title claims, determinations and ILUAs coastally adjacent to the EMBA to be an instructive means of identifying potentially relevant First Nations groups to be consulted.

Woodside understands from engagement with relevant persons and/ or organisations, that extending a native title group's responsibility to areas which those groups have elected to not include in their claims or ILUAs can have significant cultural consequences for First Nations groups and individuals. This may also, over time, build expectations in the broader First Nations community that a group is responsible for maintaining environmental values in areas for which they do not hold traditional knowledge. Woodside also acknowledges that a First Nations group's relative proximity to any PAA or EMBA is not necessarily a meaningful indicator of the connection of First Nations groups to the

area, and providing advice over such areas can be culturally dangerous. As a result, caution must be used when conducting broader engagement.

A summary of native title claims, determinations and ILUAs overlapping or coastally adjacent to the EMBA is set out in Table 4-17. Claims and determinations have not been differentiated in this table, as it is acknowledged that either of these may indicate the existence of rights and interests.

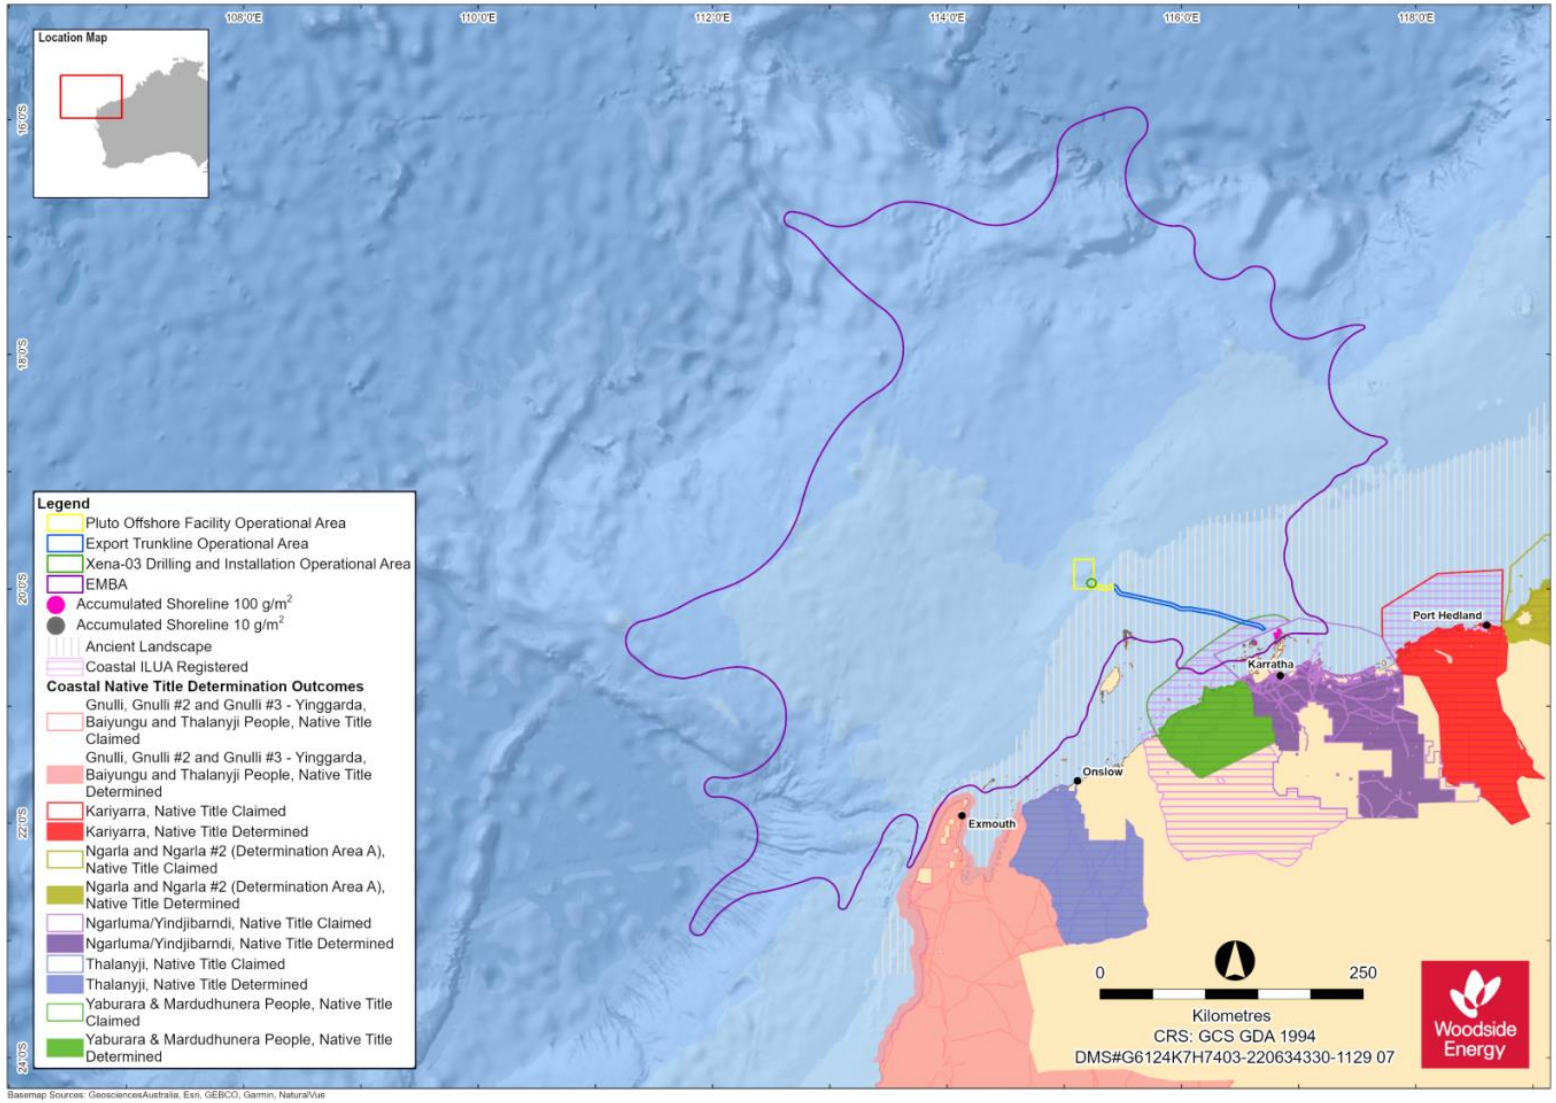

Figure 4-13: PAA and EMBA in relation to native title claims, determinations and ILUA

4.9.4 Sea Country Values

Woodside recognises the potential for marine ecosystems to include cultural features as well as environmental values. This is one aspect of the broader concept of "sea country", which can be defined as the area of sea over which a First Nations group has interests, cultural value, connection and use. It has been noted that "the saltwater peoples of the north-west are associated with discrete clan estates or tribal areas, often referred to in contemporary Aboriginal English as 'saltwater country' or 'sea country'. 'Country' refers to more than just a geographical area: it is shorthand for all the values, places, resources, stories and cultural obligations associated with that geographical area." (Smyth, 2007). It necessarily follows that an impact to marine ecosystems has the potential to impact cultural values where the impact is detectable within sea country—the seascape which Traditional Custodians view, interact with or hold knowledge of. The link between environmental protection and cultural heritage protection is illustrated in the Australian Government's Indigenous Protected Areas Program. The Indigenous Protected Areas program provides for "areas of land and sea managed by Indigenous groups as protected areas for biodiversity conservation…IPAs deliver environmental benefits…Managing IPAs also helps Indigenous communities protect the cultural values of their country for future generations…" (DCCEEW, 2023).

McNiven (2004) suggests that "For those mainland groups whose exploitation of the sea was limited to littoral resources, it is likely that seascapes extended no more than c. 20–30km out to sea, out to the horizon and the limit of human visibility. ... However, in some coastal places, clouds that can be seen well over 100km out to sea are imbued with spiritual significance. For those groups with elaborate canoe technology, seascapes extend well over the horizon." While there is some evidence of traditional watercraft in Australia's North West, the recorded evidence is limited to travel across inland rivers (e.g. Barber and Jackson 2011) or travel between coastal islands (Paterson et al 2019). The process for identifying First Nations groups who may have interests and connection in Sea Country are set out in Section 4.9.4.1. The scope of advice Traditional Custodians were encouraged to provide through project consultation was not limited by reference to any particular boundaries or limits of Sea Country.

Cultural features of coastal areas may include marine species that may travel many thousands of kilometres through areas with similar cultural values to multiple First Nations groups. Some species may travel as far as 5,000 km from Antarctica to the Kimberley region of Western Australia (Double et al., 2010, 2012), passing First Nations groups along the entire west coast of Australia. For a further description of whale distribution and whale migration patterns, see Section 4.6.3. For a further description on turtles, see Section 4.6.2.

As set out above, an impact to marine ecosystems has the potential to impact cultural values where the impact is detectable within Sea Country. Woodside considers that impact to cultural values of marine species will be adequately managed in areas of traditional Sea Country, and therefore management of the environmental values will preserve the cultural values of environmental receptors, as assessed in Section 6.

Sea country values have been defined using multiple lines of evidence including:

- Desktop assessment of sea country values from publicly available sources
- Indigenous archaeological heritage assessments
- Consultation with First Nations groups and individuals

4.9.4.1 Desktop Assessment of Sea Country Values

4.9.4.1.1 Cultural Features and Heritage Values Identified in Publicly Available Literature

Publicly available sources were assessed for any records of previously identified Sea Country values or cultural features that may overlap with the EMBA or PAA. Where cultural features or Sea Country

values were identified these are summarised in Table 4-18 according to the First Nations groups (where identified or inferable) who hold these values.

All cultural features and heritage values restricted to onshore locations or inland waters have been excluded in Table 4-17, noting that the closest boundary of the PAA is approximately 13 km to islands of the Dampier Archipelago and 22 km north-west of the coastal mainland, while the boundary of the EMBA is about 6 km from closest landfall with no shoreline contact. Where the geographical extent is not specified or unclear it has been included for completeness.

Table 4-18: Cultural features and heritage values identified in publicly available literature

First Nations Group	Features and Values	Source	Potential for overlap	
			PAA	***EMBA***
Gnulli (Baiyungu, Thalanyji, Yinggarda)	Feature: resources including marine animals. Value: traditional knowledge holds that ancestors live on the land and in the water. Therefore, people have obligations to access and care for these places (e.g. keeping them clean).	Peck on behalf of the Gnulli Native Title Claim Group v State of Western Australia [2019] FCA 2090	Possible (unspecified) Possible (unspecified)	Possible (unspecified) Possible (unspecified)
	Feature: resources including mangrove crabs, gastropods, shellfish, dugong, turtle.	Morse 1993	Possible (turtle) No (other resources)	Possible (all)
	Feature: heritage sites in the Ningaloo region include shell middens, artefact scatters, skeletal material/burial sites, camps, meeting places, hunting places and water sources.	Deloitte 2020	No	Possible (Shoreline accumulation areas on offshore islands)
	Feature: resources including gajalbu (emu), bundgurdi (kangaroo), bardurra (bush turkey), majun (marine turtles), turtle eggs, bilygurumarda (osprey), fish, shellfish and plants.		Possible (turtles, fish) No (other resources)	Possible (turtles, turtle eggs, fish, shellfish) No (other resources)
	Feature: mudflats, mangroves and sand dunes provide a critical breeding ground for marine and terrestrial wildlife.		No	Possible (mangroves)
	Value: the Ningaloo region contains cultural heritage dating back at least 32,000 years, including ceremonial Thalu sites.		No	Possible (unspecified, but likely refers to onshore areas outside the EMBA)
	Value: connection to Country is important to the Traditional Owners' spirituality and religion.		Possible Unspecified	Possible (unspecified, but likely due to location of EMBA)
	Value: caring for Country– "The southern coastal reserves along the Ningaloo Coast are jointly managed by Traditional Owners and the DBCA. The Joint Management Body ensures that the Traditional Owners have an opportunity to make decisions about environmental management and land use". 4.9.4.1.2 First Nations Archaeological Heritage Assessment

Woodside understands that communal cultural connection may exist between Traditional Custodians and land and waters. It is understood from the onshore archaeological record that Aboriginal people have occupied the Australian continent for at least 65,000 years (Clarkson et al 2017) and in many places maintain a strong continuing connection that is said to extend back in Indigenous cosmology to the beginning of time.

It is understood that the sea level has risen significantly during the 65,000 years of Indigenous occupation, and areas that were once inhabited are now submerged on the continental shelf (Veth et al 2019; UWA 2021). Woodside also understands that, at its lowest level during First Nations occupation, sea level was between 125 m (O'Leary et al 2020, Veth et al 2019, Williams et al 2018) and 130 m below current levels (Benjamin et al 2020, Benjamin et al 2023, UWA 2021). Archaeological material preserved on the Ancient Landscape has the potential to provide further information about the earliest periods of human occupation (Veth et al 2019; UWA 2021).

Recent archaeological discoveries demonstrate that the now submerged landscape was occupied and inhabited, and can retain archaeological material from this time (Benjamin et al, 2020; Benjamin et al 2023, see Ward et al 2021 for an opposing view).

In recognition of this, Woodside considers the Ancient Landscape between the mainland and the Ancient Coastline KEF as an area where potential First Nations archaeological material may exist on the seabed, as this covers the full extent of this possible First Nations occupation. Known Indigenous heritage places including archaeological sites may be protected subject to declarations under the Aboriginal and Torres Strait Islander Heritage Protection Act 1984, Underwater Cultural Heritage Act 2018 or EPBC Act 1999. However, these Acts only extend protection to heritage places specified by declaration or otherwise included on a statutory list. Woodside understands that there is no First Nations archaeology known to exist anywhere within Commonwealth waters and no declarations or prescriptions under these Acts are located within the EMBA.

The PAA is located beyond the Ancient Landscape. The EMBA overlaps the ancient landscape, but no impacts to the seabed are anticipated. Archaeological material on the Ancient Landscape is not a relevant matter for the proposed activity as there is no overlap between the PAA or areas of potential seabed disturbance and the Ancient Landscape.

The Department of Planning, Lands and Heritage (DPLH) Aboriginal Heritage Inquiry system was searched for the EMBA, which indicated 55 Registered Aboriginal Sites and Other Heritage Places (Appendix D). The exact location, access, and traditional practices for a number of these sites may not be disclosed and if required, such as in the event of a major oil spill, would involve prioritising further consultation with key contacts within DPLH and relevant local Aboriginal communities.

No sites of significance within the PAA or EMBA were identified by Traditional Custodians during the course of preparing the EP.

Should feedback be received (including any relevant new information on cultural values), it will be assessed and, where appropriate, Woodside will apply its Management of Change and Revision process.

Where Indigenous archaeological material is identified within the EMBA, Woodside will discuss the management of this material with appropriate Traditional Custodian group(s), starting with any adjacent Native Title Body Corporate.

4.9.4.1.3 Consultation Feedback to Inform Existing Environment

First Nations cultural values are communally held. This is reflected in Vision 3 of Dhawura Ngilan that "Aboriginal and Torres Strait Islander heritage is managed according to community ownership" (Heritage Chairs of Australia and New Zealand 2021). Dhawura Ngilan also specifically notes that "Aboriginal and Torres Strait Islander... intangible knowledge systems, which are held in songlines

and language, are endangered. This knowledge is held by Elders and the community..." Through consultation with relevant persons, Registered Native Title Bodies Corporate have identified or raised topics relating to environmental values of cultural interest. These include a broad interest in the marine fauna.

Additional cultural values and broader interests in the environment are known and have been shared with Woodside in the course of consultation on this activity and other Environment Plans. These cultural values and broader interests that are known to exist within the EMBA are identified below:

The marine ecosystem description (Section 4.5) encompasses the description of the cultural features and Section 4.6 provide a description of turtles and marine cetaceans respectively.

Woodside has committed to ongoing engagement to further understand these values. The Program of Ongoing Engagement with Traditional Custodians provides a mechanism for ongoing dialogue between Woodside and Traditional Custodians. The program enables Woodside to manage uncertainty on the impacts and risks to cultural values which may be identified at any time during Woodside's activities via ongoing dialogue with Traditional Custodians. Should feedback be received (including any relevant new information on cultural values), it will be assessed and, where appropriate, Woodside will apply its Management of Change and Revision process.

A summary of the topics/interests and values raised by First Nations groups through consultation relevant to this PAP, or raised in context of general Project activities or other activities are provided in Table 4-19.

4.9.4.2 Summary of cultural features and heritage values

Woodside has developed a robust understanding of cultural features and heritage values relevant to the activity through examination of publicly available information, studies and consultation with relevant persons under regulation 25.

The cultural features and heritage values identified in Section 4.9.4.1 to Section 4.9.4.4 confirms whether there is any potential for these to exist within the PAA or EMBA. As previously described, topics which have been raised in the context of an interest linked to the natural environment are impact and risk assessed in Section 6.

As cultural features are physical elements of a place, these can generally be assessed for impacts; where a feature is avoided, it is not impacted. Heritage values relate less to what is significant and more to why something is significant; interaction between heritage values and the PAA can only be reliably informed by consultation with Traditional Custodians where they are willing to share the necessary knowledge. Assessment of heritage values beyond cultural features alone is addressed in Section 6.11 subject to these caveats.

Table 4-19: Summary of cultural features and heritage values

Identified cultural features and heritage values	Context	EP Source		Potential for overlap	
		Consultation Feedback	Desktop Literature Assessment	PAA	EMBA
Archaeological Heritage and Landscapes					
Coastal/ island archaeological sites	Coastal archaeological sites include shell middens, artefact scatters, skeletal material/burial sites, camps, meeting places, hunting places and water sources.	×	✓	No	Possible (shoreline accumulation only)
Petroglyphs	Petroglyphs are a form of rock art. Petroglyphs are a prominent feature particularly at Murujuga where it is found on hard, volcanic rock.	×	✓	No	Possible (submerged)
Fish traps	Stone arrangements constructed in intertidal areas which fill with fish at high tide and trap them at low tide.	×	✓	No	Possible (submerged)
Submerged archaeological sites	The Ancient Landscape extends between 125m and 130m below current sea level. Ancient occupation of this area may have left traces through now submerged archaeological sites.	×	✓	No	Possible
Rivers, waterholes, tidal channels and seeps	Water sources on the Ancient Landscape which may be culturally significant or archeologically prospective. Traditional knowledge retains knowledge of some water sources on the Ancient landscape and some submerged waterholes are related to a Kangaroo songline.	×	✓	No	Known to occur
Submerged hills	Hills on the Ancient Landscape which may be culturally significant or archeologically prospective. As sea level rose these hills would have become islands and eventually submerged.	×	✓	No	Possible
Intangible values					

Identified cultural features and heritage values	Context	EP Source		Potential for overlap	
		Consultation Feedback	Desktop Literature Assessment	PAA	EMBA
Songlines	Consultation and publicly available literature talks to songlines associated with ancestral beings that travelled Sea Country. Energy lines were raised in consultation. Energy lines are understood by Woodside to be the same as songlines.	✓	✓	Possible (unspecified)	Possible (unspecified)
Creation/ dreaming sites, sacred sites and ancestral beings	Publicly available literature talks to creation/dreaming and ancestral beings, including water serpents, connected to or originating from the sea generally.	✓	✓	Possible (unspecified)	Possible (unspecified)
Ceremonial sites	Places where ceremony (e.g. thalu ceremonies) are performed. All identified ceremonial sites are located onshore.	×	✓	No	Possible (unspecified)
Cultural obligations to care for Country	Cultural obligation to care for the environmental values of Sea Country. Exclusion of Traditional Custodians from Sea Country or decision making processes may inhibit ability to care for Country.	✓	✓	Possible (unspecified)	Possible (unspecified)
Cultural Safety	Respecting local Lore and culturally significant areas to protect individuals from cultural harm.	×	✓	No	Possible (unspecified)
Knowledge of Country/ customary law and transfer of knowledge	The preservation and transmission of knowledge is dependent on the preservation of the environment generally. Exclusion of Traditional Custodians from Sea Country may inhibit the transfer of knowledge.	✓	✓	Possible (unspecified)	Possible (unspecified)

Identified cultural features and heritage values	Context	EP Source		Potential for overlap	
		Consultation Feedback	Desktop Literature Assessment	PAA	EMBA
Connection to Country	Connection to Country is described in publicly available literature as “important to the Traditional owners’ spirituality and religion”. Connection to Country may be damaged where people are displaced or disrupted (e.g. during colonisation) or where there is a loss of technical skills or environmental knowledge	×	✓	Possible (unspecified)	Possible (unspecified)
Access to Country	Limitations on Traditional Custodians accessing or enjoying areas of Sea Country	✓	✓	No	No (No limitations on access beyond the PAA)
Kinship systems and totemic species	Traditional Custodians have connection to species through kinship and totemic systems. An individual may have obligation to care for or not consume a species to which they are kin.	✓	✓	Possible	Possible
Resource collection	Fishing, hunting, trapping, crabbing, gathering of marine species including marine mammals, marine reptiles, fish and invertebrates including molluscs.	✓	✓	No	Possible
Marine ecosystems and species					
Marine species	Generally raised in consultation and literature as an interest	✓	✓	Possible	Possible

Identified cultural features and heritage values	Context	EP Source		Potential for overlap	
		Consultation Feedback	Desktop Literature Assessment	PAA	EMBA
Marine mammals: Whales	Generally raised in consultation and identified in publicly available literature. Thalu species of totemic importance Linked to songlines and dreaming stories Humpback whales in particular	✓	✓	Possible	Possible
Marine mammals: Dugongs	Culturally important species Used as a resource	✓	✓	No	Possible
Marine reptiles: Marine turtles	Culturally important species and migration There are Thalu ceremonies associated with turtles Turtles and turtle eggs as a resource	✓	✓	Possible	Possible
Fish: Fish, whale sharks, sharks and rays	Culturally important species Used as a resource There are Thalu ceremonies associated with increasing fish stocks Whale sharks are known as guardians of the sea by the Mayala People. Fish, including bream and sting rays are totemic species Fish, including sharks and rays raised as a natural environment interest	✓	✓	Possible	Possible
Cephalopods: Squid and Octopus	Octopus are a species of totemic importance Resource	✓	✓	Possible	Possible

Identified cultural features and heritage values	Context	EP Source		Potential for overlap	
		Consultation Feedback	Desktop Literature Assessment	PAA	EMBA
Intertidal communities: Bivalves, Gastropods, echinoderms, sea urchins, crustaceans	Resource. Bivalve and gastropod shells such as pearl shells, baler shells and trochus shells used in traditional trading practices and in resource collection. Molluscs are collected as a resource.	×	✓	No	Possible
Seabirds	Culturally important species Birds (including shags, seagulls and osprey) and bird eggs as a resource Bird feathers also used as a resource Kestrel are a species of totemic importance	✓	✓	Possible	Possible
Plankton	Interest only, raised as a natural environment interest	×	×	Possible	Possible
Benthic habitats: Coral and Reefs	Publicly available literature identified coral and reefs as culturally important with regard to connection with fish and important for food gathering.	×	✓	No	Possible
Benthic habitats: Seagrass	Publicly available literature identified seagrass as a culturally important species, providing for the protection of other marine species (e.g. turtles, dugongs).	×	✓	No	Possible
Benthic habitats: Macroalgal communities	Interest only, raised as a natural environment interest.	×	✓	No	Possible
Benthic habitats: Epifauna and infauna	Interest only, subtidal soft bottom communities raised as a natural environment interest.	×	✓	No	Yes

Identified cultural features and heritage values	Context	EP Source		Potential for overlap	
		Consultation Feedback	Desktop Literature Assessment	PAA	EMBA
Shoreline habitats: Mangroves and saltmarsh communities	Mangrove seeds as resource Critical breeding ground for marine and terrestrial wildlife. Mangroves would have provided shelter, crabbing, digging for shellfish, could be turtle nurseries. Saltmarshes would have provided an environment for crabbing and digging for shellfish. Coastal vegetation, raised as an interest	✓	✓	No	Possible
Shoreline habitats: Intertidal sand/ mudflat communities	Interest only, raised as a natural environment interest.	×	✓	No	Possible
Shorelines and coastal landforms	Interest only, raised as a natural environment interest.	✓	×	No	Possible
Estuarine crocodiles	Publicly available literature identified estuarine crocodiles as a culturally important species Resource	×	✓	No	Possible
Marine Park/ coastal reserves	Interest and responsibility	×	×	No	Yes
Nearshore and offshore islands	Interest in protection of islands and species that inhabit the islands, including Rosemary Island and Solitary Island Interest in access to nearshore islands Offshore islands are culturally significant	✓	×	No	Yes (Rosemary Island, other islands) No (Solitary Island)

4.9.4.2.1 Further context: Archaeological heritage

The PAA is in water depths of 40 to 960 m, some of which overlaps the Ancient Landscape. No coastal areas or islands exist within the PAA. Islands do exist within the EMBA boundary, however given the EMBA is driven by an unplanned loss of well containment there is no anticipated impact pathway from this activity to onshore archaeological sites above highest astronomical tide (HAT).

Archaeological sites identified onshore with the potential to exist in intertidal or submerged locations include petroglyphs, fish traps and artefact scatters or burials contained within sand dunes. As archaeological sites, these features have archaeological value which relates to the preservation of their fabric (i.e. the tangible features) and their context (i.e. their location and relationship to other archaeological and natural features). Archaeological sites may also have intangible dimensions (ICOMOS 2013) cultural value that exist in addition to their archaeological or scientific value and are assessed separately.

Certain landscapes have been identified as archaeologically prospective on the submerged Ancient Landscape, including:

- submerged water sources (rivers, waterholes, tidal channels and seeps) which have an increased likelihood of use or habitation as past generations used the associated resources (UWA 2021).
- submerged calcarenite ridges younger that human occupation of the continent which may have formed over and protected artefacts in situ (Veth 2019),
- prominent landscape features (e.g. hills, particularly of igneous rock formations) that may have been foci for cultural activity (UWA 2021),
- Karst depressions and other “catch points” where artefacts may accumulate following disturbances caused by inundation (UWA 2021, Nutley 2022, Nutley 2023a).

4.9.4.2.2 Further context: Intangible Cultural Heritage

Cultural knowledge, as expressed through songlines, dreaming, dance and other cultural practices, can be associated with tangible objects and physical sites that are culturally important to First Nations people (Ardler 2021; Bursill et al. 2007). Intangible cultural heritage can also be embodied in the practices, representations, expressions, knowledge, uses and skills associated with physical sites (UNESCO 2003). As a result, physical features may have intangible dimensions (ICOMOS 2013).

In terms of identified cultural features and heritage values related to intangible values, see below some additional context:

- Songlines: Oral Songlines are often described by First Nations people as the law of the land and make up part of the Dreaming (Neale and Kelly, 2020). Songlines are viewed in Western academia as a framework for relating people to land and consist of a series of invisible, interconnected routes along the landscape that mark significant sites for First Nations people (Higgins, 2021). Songlines demonstrate First Nations peoples’ strong connections to land by revealing scared knowledge that is place-specific (Roberts 2023). The land’s physical features are instrumental in maintaining songlines because this is how ancestral spirits journeyed through, and interacted with, the physical landscape leaving scared knowledge behind. The interconnection between the physical and spiritual is where songlines become intrinsically tied to significant places across Country. As a result, geographical landforms are recorded within songlines and become sacred places. Such landforms can include inter alia: rocks, mountains, rivers, caves and hills (Higgins, 2021). Songlines can become lost, fragmented or broken when there is a loss of Country or forced removal from Country (Neale and Kelly, 2020). Physical sites that have been identified as comprising a component of a songline are important to

protect in order to prevent the fragmenting or breaking apart of songlines and loss of sacred cultural knowledge. No specific details of songlies have been provided by relevant persons during consultation for this Activity. The Activity is located beyond the Ancient Landscape where prominent landscape features (e.g. rocks, mountains, rivers, caves and hills) would have been visible or used by Traditional Custodians and therefore likely to be incorporated in songlines. In Australia, songlines can stretch thousands of kilometres, making up a complex and organic network of stories containing cultural knowledge of First Nations communities across the land (Neale and Kelly, 2020). Songlines can also extend out to Sea Country and contain cultural knowledge that is tied to geographic features, atmospheric phenomena and marine plants and animals. Often songlines containing references to a seascape or Sea Country make mention of mythical events occurring around marine life, fishing areas, submerged rocks or coral. Songlines that embody seascapes can reflect how a group may relate to, or value, Sea Country—for example connections to nearby islands that they once inhabited in their songlines (Smyth and Isherwood, 2016). Songlines can also be used as proof of long-standing connection to land and support a legal entitlement to land rights (Higgins, 2021). Examples where songlines contain strong references to Sea Country are more common in Pacific Islander and Torres Strait Islander communities, who often refer to seascapes and skylines in their songlines in order to communicate sacred knowledge that assists in safe navigation of the ocean (Neale and Kelly, 2020).

- Creation/dreaming sites, sacred sites and ancestral beings: The only sources identified by Woodside that contained detailed descriptions of the location of ancestral beings or creation/dreaming/ sacred sites placed these locations or sites on land, islands or within inland water sources such as rivers or pools. It is acknowledged that some ancestral beings are noted to live within or originate from the sea generally, and some creation stories talk to the creation of features from or in the sea. Additionally, places on shore or at sea are (without further information or specificity) assumed to have been created on some level in First Nations cosmology.
- Cultural obligations to care for Country: Caring for Country collectively refers to the cultural obligations of individuals and groups, as well as rituals and ceremonies required for the physical and spiritual health of the environment. In the literature reviewed by Woodside, caring for Country was noted to include, but is not limited to, maintenance of the physical environment and ecosystem. It may also have cultural, spiritual and ritual dimensions such as caring for ancestral beings or ensuring cultural safety. Thalu sites are places where ceremonies are performed to increase, enhance or maintain populations of plants, animals or phenomena. All references to active ceremonial sites were confined to onshore locations, though the values may extend offshore where e.g., a thalu relates to marine species populations.
- Knowledge of Country/customary law and transfer of knowledge: Knowledge of and familiarity with the features of Sea Country is itself a “value”. The inherent potential for restricted or secret knowledge (or information that is not wished to be shared) makes this difficult to assess even through consultation with Traditional Custodians. However, aspects such as limitations on access to sites or disruption/relocation of First Nations communities may have implications for the preservation of First Nations knowledge. Further, connection to Country may be damaged where people are displaced or disrupted (e.g., during colonisation) or where there is a loss of technical skills or environmental knowledge (McDonald and Phillips, 2021). Transfer of knowledge includes continuing traditional practices to pass on practical skills. This transfer of knowledge may be integral to managing a group’s intangible cultural heritage (UNESCO 2003).
- Connection to Country: Describes the multi-faceted relationship between First Nations people and the landscape, which is envisioned as having personhood and spirit. It is also an aspect of personal identity for many First Nations people. In the case of Sea Country this can mean identifying as a Saltwater person, where “essence ‘f being a''Saltwater' person is ontological…

it is about how people relate spiritually to the sea and engage with spiritual forces that created it, the marine flora and fauna and people" (McDonald and Phillips, 2021).

- Access to Country, including Sea Country: Is necessary for the continuation of other values including caring for Country and the transfer of traditional knowledge. Being on Country can be an important way of expressing or maintaining connection to Country (Australian Indigenous HealthInfoNet n.d.). Access is also a value in its own right, as a continuation of traditional Sea Country access and use.
- Cultural Safety: refers to respecting local Lore and culturally significant areas to protect individuals from cultural harm. There are many cultural implications for those (Aboriginal and non-Aboriginal) who do not follow cultural advice or access Country in culturally inappropriate ways. Cultural safety may include observing gender restricted areas, respecting significant places and restricted areas as well as following the advice from those with cultural authority.
- Kinship systems and totemic species: Individuals may have kinship to specific species (Smyth 2008, Juluwarlu 2004) and/or a responsibility to care for species (Muller 2008). Kinship arises from totemic associations within First Nations "skin group" systems. It is forbidden for an individual to kill or eat a species who is from the same "skin group" (Juluwarlu 2004). They may also have certain obligations linked to the discussion of caring for Country below. It is assumed that marine species may have kinship/totemic relationships to Traditional Custodians, but it is understood that these relationships do not prohibit people outside of that "skin group" from hunting or eating that same species (Juluwarlu 2004).
- Resource collection: A number of marine species are identified through consultation and literature as important resources, particularly as food sources. In addition to their immediate value as sustenance, the gathering and preparation of these resources is informed by cultural knowledge, and an inability to use these resources may result in a loss of ability to transfer that knowledge to future generations.

4.9.4.2.3 Further context: Marine ecosystems and species

First Nations people have noted through consultation that they have a general interest in environmental management and ecosystem health (i.e., natural environment interest). This was noted in the context of a group/individual seeking further information about potential impacts and risks from the Petroleum Activities Program on marine species and benthic communities in the PAA and EMBA. This includes marine mammals, marine reptiles, fish, seabirds, plankton, benthic and shoreline habitats and marine parks, which are described in context of their distribution and populations in Section 4.6 to 4.8, with further details in Master Existing Environment (Woodside, 2022).

In terms of identified cultural features and heritage values related to marine ecosystems and species summarised in Section 4.9, see below some additional context:

- Marine mammals: Whales, and in particular humpback whales, have been identified through consultation with First Nations people as culturally important species, with totemic importance including their populations, biodiversity, and migration patterns. Cultural ceremonies associated with communicating with dolphins have also been raised by MAC through consultation and dugongs predominantly as a resource. Details pertaining to whales, dugongs and dolphins, their distribution, migration patterns and populations are described in Section 4.6.3, with further details in the Master Existing Environment (Woodside, 2022).
- Marine reptiles: Turtles and sea snakes have been identified through consultation with First Nations people as culturally important species, with turtles identified as a resource. First Nations people that identify marine reptiles as species of totemic importance or integral to songlines may place high cultural value on their protection. No specific marine reptiles-related songlines have been identified as per Section 4.9 that have the potential to interact with the

PAA or EMBA. Note the only specific songline related to marine reptiles (turtles) was shared by MAC, and was geographically restricted from Fortescue to Withnell Bay, in Mermaid Sound (MAC 2021). Cultural knowledge of turtles at a population level (turtle migration, behaviour and the related marine environment) may all be important in ensuring the continuation of cultural functions and activities that remain valuable to First Nations people (Fijn 2021:47; Delisle et al.2018). Details pertaining to marine reptiles, their distribution, and populations are described in Section 4.6.2, with further details in the Master Existing Environment (Woodside, 2022).

- Fish and Cephalopods: Fish and squid have been identified through consultation with First Nations people as a culturally important species, with fish generally being identified as a resource. First Nations may identify cultural values associated with fish species as important to maintaining both tangible (physical cultural sites) and intangible (cultural knowledge) cultural heritage. Tangible cultural heritage associated with fish can include important cultural sites such as midden sites, fish traps and thalu sites. While the octopus is an important totem to Ngarla People and features in the creation story of Solitary Island. There are increase ceremonies / rituals for species of squid and octopus to enhance or maintain populations. Thalu are places where these increase ceremonies are performed. Details pertaining to fish and cephalopods are described in Section 4.9, with further details in the Master Existing Environment (Woodside, 2022).
- Seabirds: Seabird eggs have been identified through literature as a culturally significant resource (Smyth 2007). Details pertaining to seabirds and migratory shorebirds are described in Section 4.6.4, with further details in the Master Existing Environment (Woodside, 2022).
- Benthic habitats: Through consultation, First Nations groups identified benthic habitats as valuable for their ecological values, including corals attracting fish and seagrass providing shelters for fauna, as well as an important resource for dugongs. Additionally, coral is valued by MAC for its aesthetic values. Details pertaining to benthic habitats and communities, including their distribution, with further details in the Master Existing Environment (Woodside, 2022).
- Shoreline habitats: Through consultation, First Nations groups identified shoreline habitats as valuable for their ecological values, including mangroves for providing shelter to marine invertebrates, which are identified resources, and potential nursery for turtles. Literature also notes that mangroves are also valued for the flora and fauna they are associated with and support (Commonwealth of Australia 2002) and Smyth (2007) reports that mangrove seeds are used as a resource by Ngarda-Ngarli. Details pertaining to shoreline and coastal habitats, including their distribution, with further details in the Master Existing Environment (Woodside, 2022).

4.9.5 Summary of Existing Research on Murujuga Petroglyphs and Anthropogenic Air Emissions

Murujuga (Burrup Peninsula), including the Murujuga National Park, is most widely known for its large collection of rock art (petroglyphs). The Traditional Owners of Murujuga have a deep cultural and spiritual connection to the rock art of the Burrup Peninsula, which provides a record of Aboriginal lore, dreamtime stories, customs, and local knowledge of the land and its resources (MAC 2019).

The presence of industry on the Burrup Peninsula has generated concerns from some stakeholders that these emissions may lead to an accelerated weathering of rocks on which rock art is present which may reduce the visibility or destroy the rock art. This is based on a hypothesis that deposition of compounds such as NOx, SOx and ammonia (NH_3) from anthropogenic industrial sources have the potential to increase the acidity of the rock surface through chemical

and/or biological processes and that acidic conditions may then accelerate the weathering of rock patina, eroding or affecting the contrast of the rock art. There have been several independent studies and rock art monitoring initiatives since the mid-2000s, none of which have conclusively demonstrated a causal link between degradation of rock art and industrial activity. There are therefore also no applicable environmental air quality standards or guidelines available that can be applied to engraved rock art (Government of Western Australia, 2023).

Nevertheless, relevant persons have raised through consultation (**Appendix F, Table 2**) the possibility that emissions from the processing of LNG onshore at Murujuga may have an impact on the preservation of rock art. While these onshore emissions are not within the scope of the PAP, the research related to this topic is summarised in this section and evaluated to consider the potential for indirect impact (**Section 6.7.11**).

Further research continues to be undertaken by the Murujuga Rock Art Monitoring Program (MRAMP), run by the Traditional Custodians of the petroglyphs, the Murujuga Aboriginal Corporation, and Western Australian Department of Water and Environmental Regulation (DWER). MRAMP is described as "A best practice monitoring and analysis program" by the Western Australian Government which "will provide reliable information on changes and trends in the condition of the rock art and whether the rock art is showing signs of accelerated change… The results from these studies will guide management and protection of the rock art" (Government of Western Australia, 2023). MRAMP will provide the necessary certainty to guide management and protection of the rock art. The MRAMP website also describes the role of MRAS as part of the proposed World Heritage listing for Murujuga:
"The Department of Biodiversity, Conservation and Attractions (DBCA) works with MAC to lead the development of the World Heritage nomination of the Murujuga Cultural Landscape, as well as joint management of the Murujuga National Park. The World Heritage nomination for Murujuga includes a comprehensive and effective management framework that outlines how the potential 'Outstanding Universal Value' of the area will be protected, conserved and monitored. As part of this framework, the State Government and MAC will demonstrate how they are working closely together to protect the rock art through the Murujuga Rock Art Strategy and the Murujuga Rock Art Monitoring Program". (Government of Western Australia, 2023)

Refer to **Section 6.7.11** for further information on Murujuga cultural heritage management framework.

4.9.5.1 Research, Monitoring and Publications

Bednarik (2002) speculates the existence of several possible impact pathways for industrial emissions to impact rock art, including acidification of rain and promotion of microbial activity. A key indicator for this is identified as colour change in the rock surfaces. The data provided by Bednarik is not sufficient to demonstrate that industrial emissions have negative impacts on the rock art, but did warrant further study.

In 2002, the Western Australian Government established the Burrup Rock Art Monitoring Management Committee (BRAMMC) to assess the possible impacts of industrial emissions on the rock art of Murujuga. Research conducted by the BRAMMC included measurements of colour change as well as air quality, microclimate, dust deposition, mineral spectrometry, microbiological analyses, air dispersion modelling, and laboratory simulations of chemical impacts at contemporary, predicted and 10-times predicted pollutant estimates.

During the course of the BRAMMC studies, several further publications were produced including:

MacLeod 2005, which found that acidity of rockfaces on Murujuga is higher than samples kept in museum conditions. The paper does not demonstrate that the museum samples, which have been subject to decades of museum preservation conditions, are representative of the natural pH of Murujuga's rocks nor does it draw any conclusions on the impacts of acidity on rock art preservation.

Bednarik 2006 and 2007a were editorials, which did not include any original research. Bednarik 2007b argued that industrial emissions were impacting rock art but provided no evidence beyond analogy to bird droppings and expert advice that the absence of rock patina near trees was not the result of any known process caused by plants. The data provided by Bednarik is not sufficient to demonstrate that industrial emissions have negative impacts on the rock art but did warrant further study (which was already underway at that time).

In 2009, the BRAMMC reviewed the results of studies conducted under their program and concluded that "there is no scientific evidence to indicate that there is any measurable impact of emissions on the rate of deterioration of the Aboriginal rock art in the Burrup" and recommended that a technical working group be established to continue long-term monitoring.

In 2010, the Burrup Rock Art Technical Working Group (BRATWG) was established. Under the BRATWG, the CSIRO continued to monitor potential colour change on the rock art (Markley et al 2015). In 2016, an unpublished paper by Black and Diffey concluded, contrary to CSIRO analysis at the time, that colour change was detected but that "a cause for the colour changes cannot be properly determined" and "the colour changes at the southern [non-control] sites are not readily explained by the concentrations of NOx and SOx compounds in the air."

These criticisms of the statistical methods used by CSIRO prompted the Department of Environment Regulation to commission Data Analysis Australia (DAA) to review the CSIRO research. The DAA report found that "superficially our analyses and those of Black and Diffey suggest that some changes may have taken place, but… we have substantial doubts about the reliability of the data and hence any conclusions drawn" and, in relation to the conclusions of Black and Diffey, "it would not be appropriate for the Draft paper to be published in its current form – the findings are based on highly doubtful data rendering any discussion of statistical significance moot" (DAA, 2016). The final CSIRO report includes a reassessment using more robust methods informed by the DAA report. The result of this analysis was "not fully conclusive" (Duffey et al 2017).

In 2016, the BRATWG commissioned an extreme condition weathering study to investigate the effects of different concentrations of acids on weathered rock surfaces. This study found that the dissolution of chemicals began at lower pH levels than previously estimated (pH 3 for aluminium, manganese and iron), but was recognised as a preliminary study and did not provide definitive results (Ramanaidou et al 2017). These results cannot be relied on as a meaningful threshold for determining whether rock art is being impacted by emissions.

Since the 2016 BRATWG extreme weathering study, several additional papers have been produced, including:

- Black et al 2017a provides a review of the conclusions of earlier studies into emissions impacts by the CSIRO, specifically those undertaken with regards to the fumigation of rock samples with acid gasses, emersion of iron-rich rocks in acids, air pollution modelling and colour change. This review concluded that a number of errors and inaccuracies prevent any

meaningful conclusion being drawn from the CSIRO data. This review did not demonstrate impacts to rock art from industrial emissions.

- Black et al 2017b provides a theoretical evaluation of MacLeod 2005 research. It provides no data that links industrial air emissions or subsequent deposition to changes in pH on Murujuga rock surfaces. There are practical limitations that prevent the MacLeod data from being adapted to the paper's purpose, including variation in sample dilution and the arbitrary exclusion of data.
- Black et al 2018 speculates the existence of several possible impact pathways, including acidification of rain and promotion of microbial activity. The paper recognises, however, that "there is no proof yet that the patina on Murujuga rocks is dissolving" and asserts that "there has not been credible research to determine" whether rock art is being degraded. In drawing conclusions regarding changes in acidity this paper assumes, without evidence, that geological samples which have been subject to decades of preservation in a museum are representative of the natural pH of Murujuga's rocks. The key conclusions of this paper are that further, more robust research is required, and that the precautionary principle should be applied in the interim.
- Gleeson et al 2018 primarily discusses microbial organisms that may be responsible for the formation of rock varnish. The paper briefly speculates on the possible impacts of industrial emissions but does not purport to provide evidence of impacts to Murujuga's rock art.
- In 2019 the Department of Water and Environmental Regulation (DWER) produced the Murujuga Rock Art Strategy, which built on the research to that date, and according to DWER will establish a world's best practice program to monitor, evaluate and report on factors that could affect the condition of rock art. This will be undertaken in consultation with a team of national and international experts in relevant disciplines and funded by industry including from Woodside. Research by this program is led independently by MAC and DWER working with leading research groups.
- CBG Solutions 2020 repurposes previous pH records from 2003 and 2004 (as a baseline) and data collected between 2017 and 2019 to assess changes in acidity on rock surfaces. The report repurposes historical and inconsistent pH data and acknowledges a number of resulting statistical issues which "makes determination of long-term pH changes problematic." The report states that "there appears to be no detrimental (acidification) impact that can be statistically supported regarding proximity to either the NW Gas plant or to the Pluto plant" and "owing to the many variables that determine the surface pH of the Burrup rocks and the significant impact of periodic cyclonic heavy rain and the lack of historic data on all the tested sites, it is not possible to claim that there is sufficient evidence for the statement that there is a continuing increase in acidity across Murujuga since measurements commenced in 2003."
- Dorn 2020 discusses competing theories of desert varnish growth and how chemical changes to desert varnish result from human sources, such as lead concentration following the addition of lead to petrol. The chapter predominantly focusses on North America, but uncritically restates the conclusions of Black et al 2017b. Only one other example in the paper, regarding an apparent change in varnish texture from near Los Angeles, appears to have even tangential relevance to industry on Murujuga. Acid fog is proposed as one *possible* cause, but this suggestion is not supported by any provided data and is based on examinations from an area with significantly higher acid gas concentration than Murujuga experiences.
- MacLeod 2020 provided results of a study commissioned by Yara Pilbara Nitrates. This report observes a variability of the relationship between colour difference and pH, with colour difference diminishing with increasing pH at some points, and diminishing with decreasing pH at other points although the final sentence of the report claims "there is unequivocal evidence that the changes in colour contrast are affected by the changes in the

mean and in the minimum pH observed on the rock art sites at the reference positions." At several points this report notes that rainfall events—particularly cyclonic events—appear to substantially reduce the acidity. The executive summary states that "there is a clear link between the minimum pH and the amount of sulphate on the rock surfaces, *which indicates some of the sulphate comes from anthropogenic sources*" (emphasis added) though the report does not articulate how a link between pH and sulphate contributes to an understanding of sulphate origin. MacLeod (2020) comments in relation to the two sites that are closest to Pluto LNG Plant and Karratha Gas Plant that the observed low sulphate concentrations "strongly supports that these exhaust sources are not resulting in any significant SOx deposition on the rock surfaces."

- MacLeod 2021 provides an update to this previous work which found that pH had increased during the study period but pH changes were affected by microclimate at each site including seasonal variations, microbial activity, and localised rainfall events. Any relationship between anthropogenic NOx and SOx emissions and acidity was not established and "just as the mechanisms of adsorption of NOx and SOx onto the moistened rock surfaces are yet to be unequivocally established, the presence of a direct relationship between the concentration of sulphate in the wash solutions with the underlying acidity can be regarded as a de-facto correlation." Once again the report states that "there is unequivocal evidence that the changes in colour contrast are affected by the changes in the mean and in the minimum pH observed on the rock art sites at the reference positions."
- Also in 2021, MacLeod and Fish (2021) published results of the studies commissioned by Yara Pilbara Nitrates, including that "there is presently no adverse impact on the rock engravings from industrial pollution owing to a lower NOx level than when the studies commenced 14 years ago". This conclusion was critiqued by Smith et al 2022a, who correctly noted that this conclusion is based on limited data and makes a number of key assumptions without adequate peer-reviewed research.
- Gagan et al 2022 is an investigation of anthropogenic air-borne sulphur on rock art on limestone in Sulawesi, Indonesia. This is not comparable to the Murujuga petroglyphs as the Murujuga petroglyphs are not on a limestone substrate. The research notes that "the bulk of the damage was present before 1950 CE" for example due to biomass burning ~3,500 years ago; current threats include "vandalism and sulphur emissions from diesel-powered traffic and cement-based infrastructure"; and that "the rate of rock art loss may be on the decline."
- Smith et al 2022a is a review of the Fish and McLeod report; the review does not contain original research and therefore does not further the existing scientific understanding of the subject. Claims that Smith et al 2022a demonstrate that emissions from industry are impacting rock art are incorrect.
- Smith et al 2022b does provide evidence of impacts to rock art and attributes these to three sources: mechanical removal and damage, chemicals emitted by industry, and an increased unsympathetic human presence in the landscape – examples provided include "rock scratching from off-road vehicles and graffiti, broken rocks from inappropriate trampling… rock splitting and discolouration from non-traditional burning practices". Evidence of the first and third of these is apparent and easily demonstrated from the photographic record, yet the paper itself notes that the use of photographic records to assess chemical impacts through colour change are subject to considerable errors including distortion and degradation of early photographs, variable lighting conditions and other factors. The researchers do note that several petroglyphs (numbered 2, 5, 6, 9, 16, 17, 21, 22 and 24) appear to have lightened over time in line with a hypothesis that emissions have played a role in this, while one petroglyph (1) appears to have darkened and at least 13 do not demonstrate any change, including several in close proximity to

industry. The paper appropriately notes that further research is required to determine the causes of these perceived changes.

- Neumann et al 2022 is an important proof-of-concept for analytical techniques, but is clear in its conclusion that:

Although our data clearly demonstrate that acidic rain has measurable effects on the varnish surface, including its colour and increased dissolution of Fe and Mn compounds, it should be stressed here that this does not necessarily mean that natural weathering of the petroglyphs is accelerated by anthropogenic pollution.

- Ruffolo et al 2023 review the formation of "black crusts", accumulation of materials on the surface of stone buildings, in highly polluted urban environments, and intervention strategies to mitigate damage to built heritage from black crusts. The study notes "the research outcomes have established some correlations between black crusts and the surrounding air pollution, leading to them being considered as a "record" and also a "passive sampler" of past pollution patterns. However, in this case, there is not yet a well-defined procedure to obtain accurate and unambiguous information." This paper does not provide new science applicable to the Murujuga petroglyphs due to its focus on built heritage and urban pollution.
- In December 2023 the first interim report of MRAMP was published. An accompanying summary report notes that "data collected in the first year of observation do not permit any firm conclusions to be drawn about trends in rock surface condition and any relationship to air quality over time." However, several techniques were considered promising for future analysis, including spectral measurement of rock art condition, geological studies and mineralogical studies. Though requiring more data to draw any conclusions, the report and summary both note that the correlation observed between acid-producing emissions and pH were the inverse of predictions if these gasses were causing acidification of rock surfaces (that is, higher concentrations of these gasses were associated with *less* acidic rock surfaces). These results are not definitive and recognise that further work by MRAMP is required. Final results by MRAMP are scheduled for publication in December 2025 with interim Environmental Quality Criteria anticipated to be published in the preceding years. This will provide the relevant data to guide management and protection of the rock art for industry on Murujuga.
- Smith 2024 provides the results of laboratory studies on Murujuga rock samples. The methodology for these experiments is not provided. The reported results are that particles of weathering rind begin to detach from the rock samples when the pH of rocks reach 6 or lower—significantly higher than, for example, the level suggested in Ramanaidou et al 2017. This report also reinterprets results from the MRAMP program (although excluding results from the first campaign of this work from consideration). This reinterpretation requires cautious consideration, noting the MRAMP interim report's caveats that the available data is insufficient for drawing meaningful conclusions. The conclusions of Smith 2024 state that "the rock surfaces of Murujuga have become increasingly acidic *due to the nitric and sulphuric dusts emitted by industry in the area.*" (emphasis added). This causal link is not supported in the report by reference to any other study, and as the report does not provide a clearly stated methodology it is unclear that this is supported by the laboratory work performed. A correlation may, perhaps, be implied by reference to historic trends reported in reports discussed elsewhere in this section, which have noted methodological issues. Smith 2024 also fails to address, in its reinterpretation of MRAMP data, the preliminary observation that higher levels of acid-producing emissions were found to correlate with less acidic rock surfaces.
- The MRAMP is a "best practice monitoring and analysis program" which "will provide reliable information on changes and trends in the condition of the rock art and whether the rock art is showing signs of accelerated change" (Government of Western Australia 2024).

As a basic principle of managing First Nations cultural heritage, as reflected in Woodside's First Nations Communities Policy, the involvement of MAC as representatives of Traditional Custodians in this project is also important so that the broader values of Murujuga are appropriately managed. Further results from the MRAMP are expected periodically until its conclusion in 2025, and relevant findings as applicable to the Pluto PAA will be managed through Woodside's Management of Change process.

4.9.6 Historic Sites of Significance

Historic sites of significance and heritage value are found along adjacent foreshores of the NWMR. Heritage places are protected in Western Australia under the Heritage Act 2018.

There are no known sites of Historic cultural heritage significance within the PAA.

4.9.7 Historic Underwater Heritage

A search of the Australian National Shipwreck Database, which records all known Maritime Cultural Heritage (shipwrecks, aircraft, relics and other underwater cultural heritage) in Australian waters indicated there are no sites within the PAA; however, a number of shipwrecks exist within the EMBA and detailed in the Master Existing Environment (Woodside, 2022).

Table 4-20: Historic shipwrecks within 100 km of the PAA

Shipwreck	Distance from PAA to Shipwreck (km)
Curlew	<1
Marietta	<1
Wild Wave (China)	<1
Vianen	<1
McDermott Derrick Barge No 20	14
Zelma	17
Tanami	28
Trial	28
HMS Plym	36
Tropic Queen	41
Parks Lugger	45

4.9.8 World, National and Commonwealth Heritage Listed Places

No World, National or Commonwealth heritage listed places overlap the PAA. World, National and Commonwealth heritage places within the EMBA are identified in Table 4-21. The Master Existing Environment (Woodside, 2022) outlines the values and sensitivities of these places.

Table 4-21: World, National and Commonwealth Heritage Listed places within the EMBA

Listed Place	Distance and Direction from PAA to Listed Place (km)
World Heritage Places	
The Ningaloo Coast	208 south-west (Facility and Xena-03 Operational Areas)
National Heritage Places	
The Ningaloo Coast	194 south-west (Facility and Xena-03 Operational Areas)
Dampier Archipelago	9 km south-east (Export Pipeline Operational Area)

4.10 Socio-Economic Environment

4.10.1 Commercial Fisheries

Five Commonwealth and eighteen State fishery management areas are located within the PAA and EMBA. For additional detail, the PAA is presented here in two parts; the Export Pipeline Operational Area and the combined Facility and Xena-03 Drilling Operational Areas.

The Annual Fishery Status Reports published by the Australian Bureau of Agricultural and Resource Economics and Sciences (ABARES) were used to identify whether Commonwealth-managed fisheries were active within the PAA and EMBA in the last five years. FishCube data were also requested from the WA Department of Primary Industries and Regional Development (DPIRD) for the most recently available 5-year period for each fishery (2019-2023). Data obtained from the catch and effort system (CAES) was analysed to assess the potential for fisheries interaction with the PAA and Petroleum Activities Program. Data was reviewed from the last 5 years as a subset of past fishing effort. This was deemed an appropriate period to represent potential future fishing effort over the lifecycle of this EP (5 years from NOPSEMA acceptance). In addition, any impacts to fish are expected to be temporary in nature (See Section 6) and therefore not extend beyond the life of the EP.

This information was used to determine relevant fisheries for consultation who may be impacted by the proposed petroleum activities Table 4-22 provides an assessment of the potential interaction and the Master Existing Environment (Woodside, 2022) provides further detail on the fisheries that have been identified through desk-based assessment and consultation (Section 5). One Commonwealth managed, and ten (10) State managed fisheries were identified as having a potential interaction with the Petroleum Activities Program, within the PAA (Figure 4-14).

Table 4-22: Commonwealth and State commercial fisheries management areas overlapping the PAA and EMBA and potential for interaction during the Petroleum Activities Program.

Fishery	PAA/EMBA			Description
	Facility and Xena-03 Operational Area	Export Pipeline Operational Area	EMBA	Potential for interaction during Petroleum Activity Program ✗ no spatial overlap ✓ spatial overlap Blue shading possibility for interaction with the PAA
Commonwealth Managed Fisheries				
North West Slope Trawl Fishery	✓	✗	✓	The North West Slope Trawl Fishery management area overlaps the Facility and Xena-03 Operational Area and the EMBA. The fishery operates off north-western Australia from 114oE to 125 oE roughly between the 200 m isobath and the outer boundary of the Australian Fishing Zone (Keller and Curtotti, 2023). Fishing effort commenced in 1985 with vessel numbers between 1 and 6 vessels per year since 2005-2006 (Keller and Curtotti, 2023). Three vessels operated in the 2021-2022 season, decreasing from 4 in 2020-2021 season (Keller and Curtotti, 2023). Woodside considers it a possibility that interactions with the fishery may occur in the Facility and Xena-03 Operational Area and the EMBA.

Fishery	PAA/EMBA			Description
	Facility and Xena-03 Operational Area	Export Pipeline Operational Area	EMBA	Potential for interaction during Petroleum Activity Program ✗ no spatial overlap ✓ spatial overlap Blue shading possibility for interaction with the PAA
Southern Bluefin Tuna Fishery	✓	✓	✓	The Southern Bluefin Tuna Fishery management area overlaps the PAA and the EMBA. The Southern Bluefin Tuna Fishery spans the Australian Fishing Zone, however since 1992, the majority of Australian catch has concentrated in south-eastern Australia (Patterson and Dylewski, 2023a). Woodside considers there to be no potential for interaction with this fishery and the Petroleum Activities Program.
Western Deepwater Trawl Fishery	✗	✗	✓	The Western Deepwater Trawl management area overlaps the EMBA. The fishery operates off the coast between the western boundary off the Southern and Eastern Scalefish and Shark Fishery in the south, and the western boundary of the North West Slope Trawl Fishery in the north (Kell et al., 2023). Fishing effort has been relatively low since 2005-2006, with 1 to 3 vessels active in the fishery since 2004-2005, and 2 active vessels recorded in 2021-2022 (Keller et al., 2023). Woodside considers it a possibility that interactions with the fishery may occur in the EMBA.
Western Tuna and Billfish Fishery	✓	✓	✓	The Western Tuna and Billfish Fishery management area overlaps the PAA and the EMBA. However, the majority of Australian catch has concentrated off south-west Western Australia with occasional activity off South Australia (Patterson et al., 2023). Woodside considers there to be no potential for interaction with this fishery and the Petroleum Activities Program.
Western Skipjack Tuna Fishery	✓	✓	✓	The Western Skipjack Tuna Fishery management area overlaps the PAA and the EMBA. The Western Skipjack Tuna Fishery spans the Australian Fishing Zone west of Victoria and the Torres Strait. The Fishery is currently not active, and no fishing has occurred since 2009 (Patterson and Dylewski, 2023b).
State Managed Fisheries				

Fishery	PAA/EMBA			Description
	Facility and Xena-03 Operational Area	Export Pipeline Operational Area	EMBA	Potential for interaction during Petroleum Activity Program ✗ no spatial overlap ✓ spatial overlap Blue shading possibility for interaction with the PAA
Exmouth Gulf Prawn Managed Fishery	✗	✗	✓	The Exmouth Gulf Prawn Fishery is a prawn trawl fishery operating in Exmouth Gulf. Target species generally < 50 m water depth. Fishing effort has been stable in the last 5 years with 6 vessels active during the 2020-2021 and 2021-2022 season (Wilkin et al., 2023a). The fishery management area overlaps with the EMBA. The fishery is limited to the spatial extent within the Exmouth Gulf and Muiron Islands. Woodside considers there to be a potential for interaction with this fishery in the EMBA.
Hermit Crab Fishery	✗	✓	✓	The Hermit Crab Fishery management area overlaps the Export Pipeline Operational Area and the EMBA. The Land Hermit Crab Fishery is a shoreline fishery active North of Exmouth, with crabs taken onshore at night by hand. The fishery is active within the Export Pipeline Operational Area, with 60 NM CAES blocks only (DPIRD, 2023) with 2 licences active during the 2021-2022 fishing season (Newman et al., 2023). The activity is likely to occur predominantly in coastal waters outside of the Export Pipeline Operational Area. Woodside considers it a possibility that interactions with the fishery may occur in the Export Pipeline Operational Area and the EMBA.
Mackerel Managed Fishery	✓	✓	✓	The Mackerel Managed Fishery management area(Area 2) overlaps the PAA and the EMBA (Area 2 and 3). The fishery is active within the Facility and Xena-03 Operational Areas, and the Export Pipeline Operational Area. FishCube data for the Mackerel Managed Fishery reported less than 3 vessels active during the 2020-2021 season under 10 NM, and up to 6 vessels active over the last 5 years under 60 NM CAES blocks (DPIRD, 2023). The fishery is managed through designated Areas, and extends from coastal waters to the EEZ, in waters northwards of Cape Leeuwin to the NT border. Nominal catch rates in Area 2 (Pilbara) have been generally decreasing since 2004 (Lewis and Watt, 2023). Woodside considers it a possibility that interactions with the fishery may occur within the PAA and the EMBA.

Fishery	PAA/EMBA			Description		
	Facility and Xena-03 Operational Area	Export Pipeline Operational Area	EMBA	Potential for interaction during Petroleum Activity Program		
				✖ no spatial overlap	✓ spatial overlap	Blue shading possibility for interaction with the PAA
Marine Aquarium Managed Fishery	✓	✓	✓			The Marine Aquarium Managed Fishery management area overlaps the PAA and the EMBA. The Marine Aquarium Fishery is a diver-based fishery and therefore typically restricted to relatively shallow waters. FishCube data for the fishery from within the EMBA is provided at 10 NM and 60 NM CAES blocks reporting a maximum of 4 licences under 10 NM and 7 licences active under 60 NM across the 2017-2023 seasons (DPIRD, 2023). Woodside considers it a possibility that interactions with the fishery may occur within the Export Trunkline Operations Area and the EMBA.
Nickol Bay Prawn Managed Fishery	✖	✖	✓			The Nickol Bay Prawn Managed Fishery management area overlaps the EMBA. The fishery is active in State waters and the EMBA with fishing effort at 10 NM CAES blocks recording 3 vessels active during the 2021-2022 fishing season, a decrease from 8 vessels in 2021-2022 (Wilkin et al., 2023b). Woodside considers it a possibility that interactions with this fishery may occur within the EMBA.
Onslow Prawn Managed Fishery	✓	✓	✓			The Onslow Prawn Managed Fishery management area overlaps the PAA and the EMBA. The fishery is active within the Export Pipeline Operational Area and EMBA with 60 NM CAES blocks reporting less than 3 vessels active during the 2021-2022 season (DPIRD, 2023). Woodside considers it a possibility that interactions with the fishery may occur in the Export Pipeline Operational Area and EMBA.

Fishery	PAA/EMBA			Description
	Facility and Xena-03 Operational Area	Export Pipeline Operational Area	EMBA	Potential for interaction during Petroleum Activity Program ✖ no spatial overlap ✓ spatial overlap Blue shading possibility for interaction with the PAA
Pearl Oyster Managed Fishery (Zone 1 and 2)	✓	✓	✓	The Pearl Oyster Managed Fishery management area overlaps the PAA and the EMBA. Fishing effort is mostly focused within coastal waters (10-15 m depth) with a maximum depth of 35 m (Lulofs et al., 2002), collecting wild oysters for use in the aquaculture production of pearls. These are collected from fishing grounds primarily off the coast of Eighty Mile Beach with smaller catches from the Lacepede Islands. Woodside considers there to be no potential for interaction with this fishery and the Petroleum Activities Program.
Pilbara Line Fishery (Condition)	✓	✓	✓	The Pilbara Line Fishery (Condition) licensees are permitted to operate anywhere within Pilbara waters (Wakefield et al., 2023), overlapping the PAA and the EMBA. The fishery is active in the PAA and the EMBA, with 60 NM CAES blocks reporting up to 5 vessels active across the 2017-2023 seasons (DPIRD, 2023). Fishing effort has decreased form 7 vessels activin in 2020-2021 to 6 vessels active in 2021-2022 (Wakefield, et al., 2023).
Pilbara Crab Managed Fishery	✓	✓	✓	The Pilbara Crab Managed Fishery management area overlaps the PAA and the EMBA. The fishery operates via trap-based fishery methods up to 50 m and is concentrated around Dampier. The fishery is active in the Export Pipeline Operational Area and the EMBA, with 60 NM CAES blocks reporting less than 3 vessels active across the 2017-2023 seasons (DPIRD, 2023). Fishing effort has remained stable from 2020-2022 with 2 vessels active within the EMBA (Johnston et al., 2023). Woodside considers it a possibility that interactions with the fishery may occur within the Export Pipeline Operational Area and the EMBA.

Fishery	PAA/EMBA			Description
	Facility and Xena-03 Operational Area	Export Pipeline Operational Area	EMBA	Potential for interaction during Petroleum Activity Program ✖ no spatial overlap ✓ spatial overlap Blue shading possibility for interaction with the PAA
Pilbara Trap Managed Fishery	✓	✓	✓	The Pilbara Trap Managed Fishery management area overlaps the PAA and EMBA. The fishery is active within the Facility and Xena-03 Operational Areas, Export Pipeline Operational Area and the EMBA, with 60 MN CAES blocks reporting less than 3 vessels active across the 2017-2023 seasons (DPIRD, 2023). Fishing effort has increased from 7 active vessels during 2020-2021 to 8 vessels active in 2021-2022 (Wakefield et al., 2023). Woodside considers it a possibility that interactions with the fishery may occur within the PAA as well as the EMBA.
Pilbara Fish Trawl (Interim) Managed Fishery	✖	✓	✓	The Pilbara Fish Trawl (Interim) Managed Fishery management area (Area 1) overlaps the Export Pipeline Operational Area and the EMBA. The fishery is active within the Export Pipeline Operational Area and EMBA with four 10NM CAES blocks reporting up to four vessels across the 2017–2023 seasons (DPIRD, 2023). Fishing effort within the EMBA has been stable with 2 vessels active between 2018 and 2022 (Wakefield et al., 2023). Woodside considers it a possibility that interactions with the fishery may occur within the EMBA and the Export Pipeline Operational Area.
Specimen Shell Managed Fishery	✓	✓	✓	The Specimen Shell Managed Fishery management area overlaps the PAA and the EMBA. The fishery is active within the Export Pipeline Operational Area and the EMBA. FishCube data for the fishery is provided at 10 NM and 60 NM CAES blocks reporting less than 3 licences under 10 NM and up to 3 licences under 60 NM CAES blocks active across 2017-2023 seasons (DPIRD, 2023). The fishery is largely diver-based, targeting specimen shells in water depths mostly < 30 m. Given the depth of the Export Pipeline Operational Area at its shallowest, it is not likely to interact with the fishery. Woodside considers it a possibility that interactions with the fishery may occur in the Export Pipeline Operational Area and the EMBA.

Fishery	PAA/EMBA			Description
	Facility and Xena-03 Operational Area	Export Pipeline Operational Area	EMBA	Potential for interaction during Petroleum Activity Program ✖ no spatial overlap ✓ spatial overlap Blue shading possibility for interaction with the PAA
West Coast Deep Sea Crustacean Managed Fishery	✓	✓	✓	The West Coast Deep Sea Crustacean Managed Fishery management area overlaps the PAA and the EMBA. The fishery is prohibited to fish landwards of the 150m isobath, restricting any potential interactions to activities within the Facility and Xena-03 Operational Area. Most of the commercial crab catch is taken in depth of 500 m – 800 m (WAFIC 2024). The fishery is active within the EMBA, with 5 vessels active during the 2021-2022 season (Tuffley, et al., 2023). Woodside considers it a possibility that interactions with the fishery may occur within the EMBA only.
Western Australian Sea Cucumber Fishery	✓	✓	✓	The Western Australian Sea Cucumber Fishery management area overlaps the PAA and the EMBA. The fishery is active within the EMBA, with 60 NM CAES blocks reporting less than 3 vessels active across 2017-2019 seasons. The fishery operates as a wader and diver-based fishery in the Kimberley region and therefore would typically be restricted to coastal waters outside of the Export Pipeline Operational Area. Woodside considers it a possibility that interactions with the fishery may occur in the Export Pipeline Operational Area and the EMBA.
South West Coast Salmon Managed Fishery	✓	✓	✓	The South West Coast Salmon Managed Fishery management area overlaps the PAA and EMBA. Historically, no fishing has occurred north of the Perth Metropolitan Area. Therefore, no effort is reported within the EMBA (Duffy et al., 2023) and Woodside considers there to be no potential for interaction with this fishery within the PAA and EMBA.

Fishery	PAA/EMBA			Description
	Facility and Xena-03 Operational Area	Export Pipeline Operational Area	EMBA	Potential for interaction during Petroleum Activity Program ✖ no spatial overlap ✓ spatial overlap Blue shading possibility for interaction with the PAA
Western Australian Abalone Managed Fishery	✓	✓	✓	The Abalone Fishery management area overlaps the PAA and the EMBA. The fishery operates in shallow coastal waters off the south-west and south coasts of WA (Strain et al., 2023). Given the fishery method (shore-based and hand caught) and water depths of the PAA there are no CAES blocks reporting fishing effort within the PAA. Woodside considers there to be no potential for interactions with the fishery within the EMBA or PAA.
West Coast Rock Lobster Managed Fishery	✖	✖	✓	The Western Rock Lobster Fishery management area overlaps the EMBA. The fishery mainly operates off the west coast of WA between Shark Bay and Cape Leeuwin (de Lestang and Walsh, 2023). There are no CAES block reporting fishing effort within the EMBA. Woodside considers there to be no potential for interactions with the fishery within the EMBA.
WA North Coast Shark Fishery	✓	✓	✓	The North Coast Shark Fishing area overlaps the PAA and the EMBA. The northern shark fisheries comprise of the North Coast Shark Fishery in the Pilbara and Western Kimberly (closed since 1998), and the Joint Authority of Northern Shark Fishery in the eastern Kimberly, which has not been active since 2008-2009 season (AFMA 2021). Woodside considers there to be no interaction with the fishery and the Petroleum Activities Program.
Charter based commercial operators				
Tour Operators	✓	✓	✓	Fishing Tour Operators are permitted to operate across WA state waters and are required to report monthly logbook records of client fish catches. The fishery is active within the Facility and Xena-03 Operational Areas and Export Pipeline Operational Area as well as the EMBA. FishCube data indicates fishing effort across the 10 NM and 60 NM CAES blocks overlap the PAA. Fishing effort at 10 NM scale has been consistent over the last 5 years reporting no more than 3 licence holders (DPIRD,

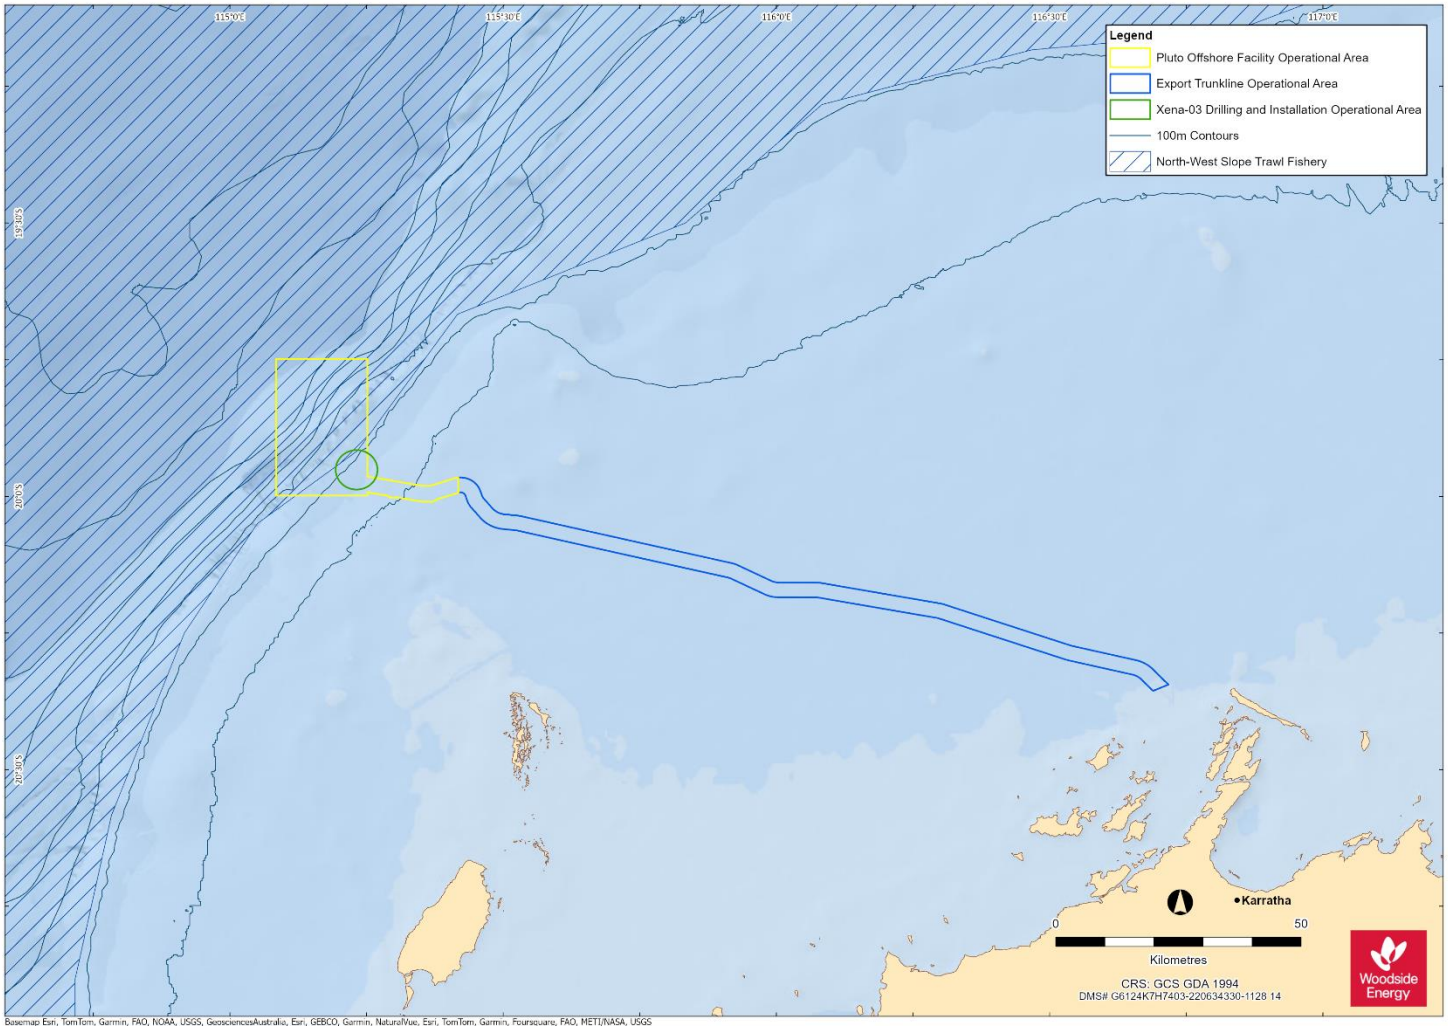

Figure 4-14: Commonwealth managed Commercial Fisheries overlapping the PAA with a potential for Interaction with the Petroleum Activities Program

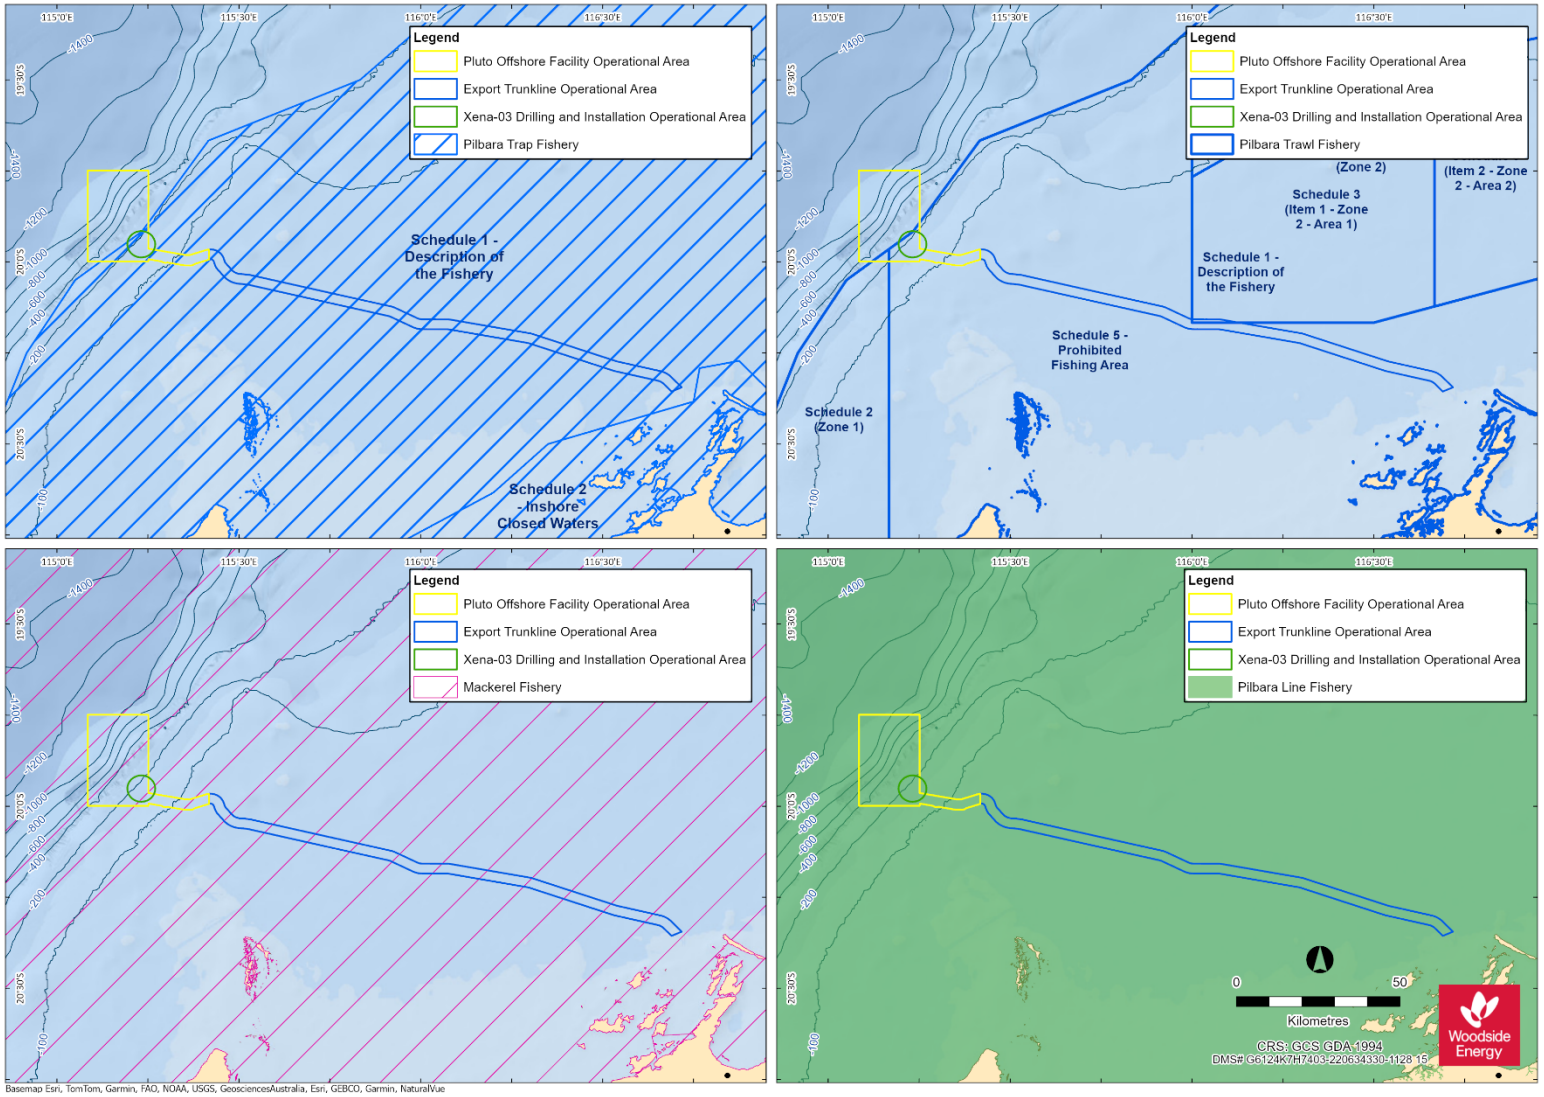

Figure 4-15: State managed (WA) Commercial Fisheries overlapping the PAA with a potential for Interaction with the Petroleum Activities Program

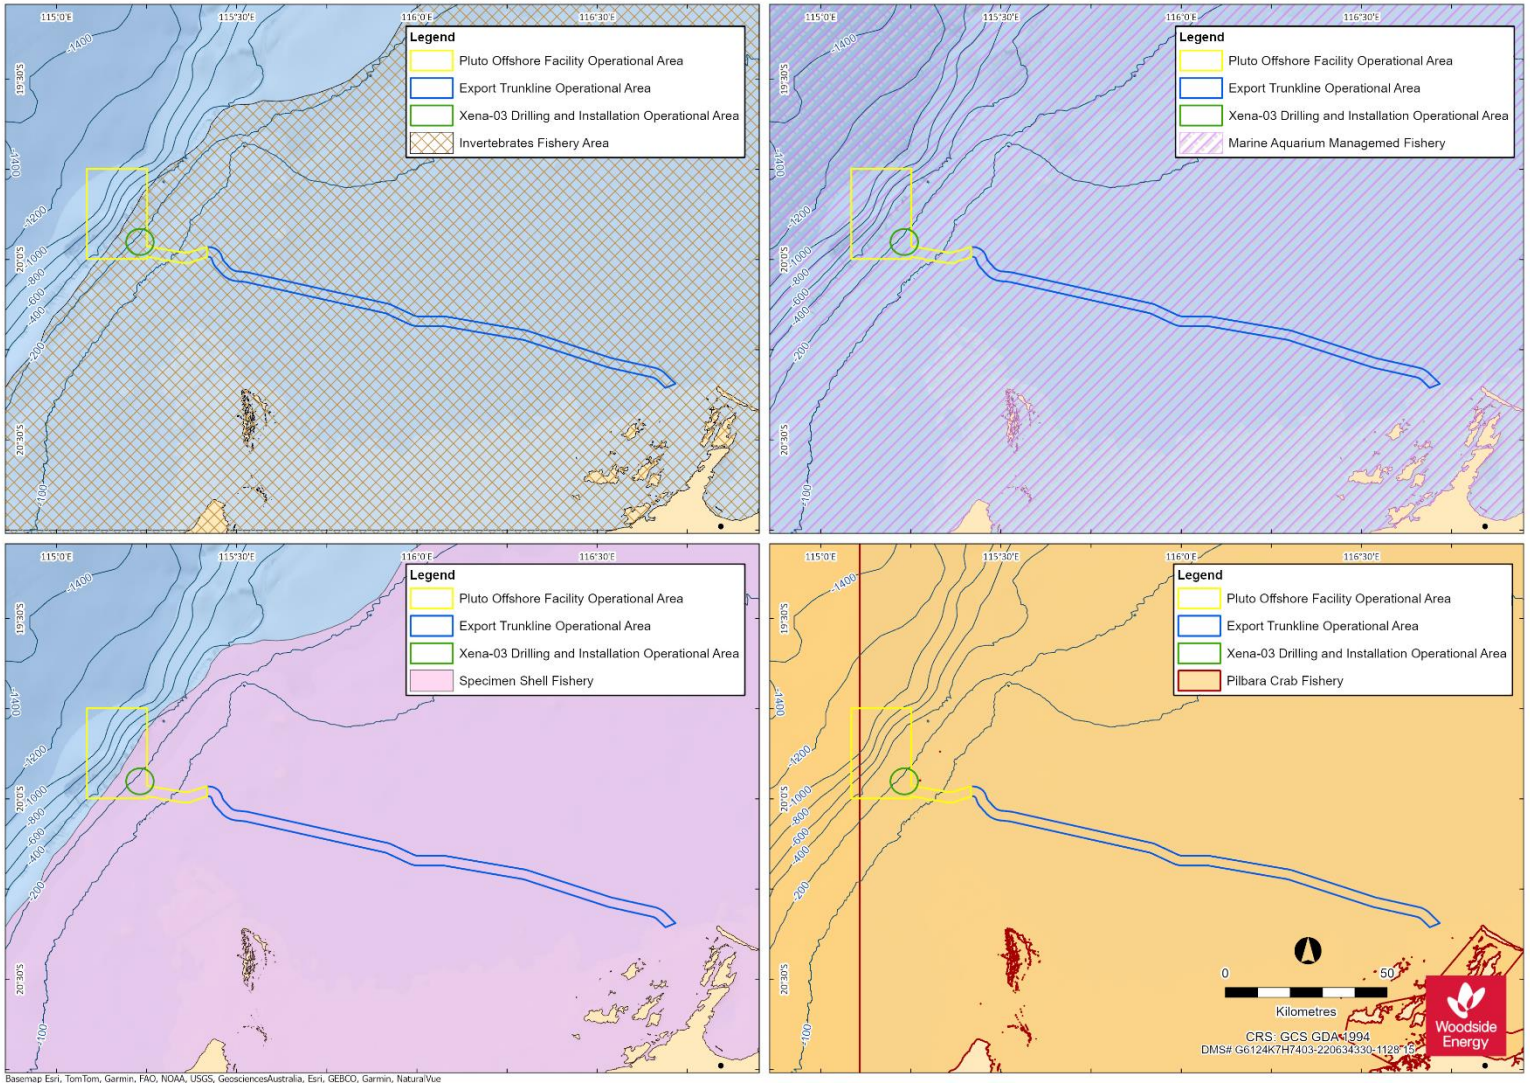

Figure 4-16: State managed (WA) Commercial Fisheries overlapping the PAA with a potential for Interaction with the Petroleum Activities Program

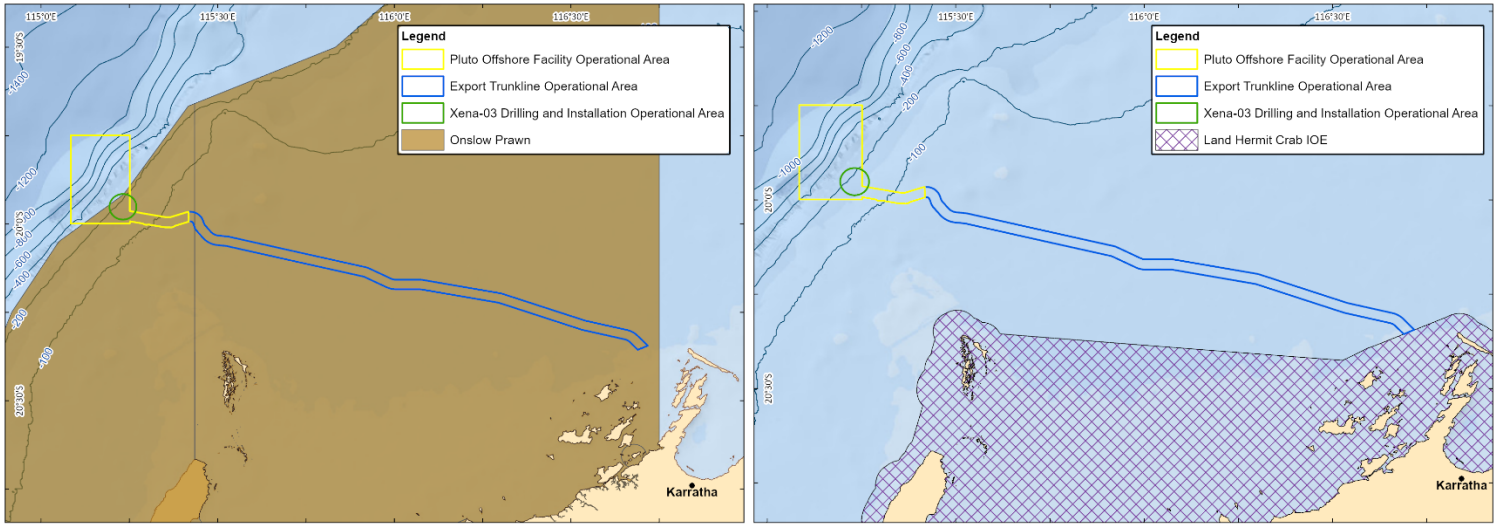

Figure 4-17: State managed (WA) Commercial Fisheries overlapping the PAA with a potential for Interaction with the Petroleum Activities Program

4.10.2 Traditional Fisheries

There are no traditional or customary fisheries within the PAA, as these are typically restricted to shallow coastal waters and/or areas with structures such as reefs. However, it is recognised that Barrow Island, Montebello Islands and Ningaloo Reef, all within the wider EMBA, have a known history of fishing when areas were occupied (as from historical records) (Department of Conservation and Land Management (DCLM), 2005, Department of Environment and Conservation (DEC), 2007). Areas that are covered by registered native title claims are likely to practice Aboriginal fishing techniques at various sections of the Western Australia coastline.

Further information on traditional fishing activity that is likely to occur in the EMBA is provided in the Master Existing Environment (Woodside, 2022).

4.10.3 Tourism and Recreation

The recreation and tourism industries in the Pilbara are of high social value with approximately 965,000 visitors over the last 5 years (Tourism Western Australia, 2023). Tourism continued to grow in 2022, with over 1 million visitors (Tourism Western Australia, 2023). Growth and the potential for further expansion in tourism and recreational activities are recognised for the Pilbara region, with the development of regional centres and a workforce associated with the resources sector (SGS Economics and Planning 2012).

The PAA is located offshore of the North West tourism region, which includes parts of the Gascoyne, Pilbara, and Kimberley region. Tourism is concentrated in the vicinity of population centres such as Broome, Dampier, Exmouth, Coral Bay, and Shark Bay. The population centre closest to the PAA is the town of Dampier (31 km from the Export Pipeline Operational Area and 157 km from the Facility and Xena-03 Operational Areas). No tourist activities take place specifically within the PAA.

The nearest tourism areas include the Montebello State Marine Park (25 km from the Export Pipeline Operational Area and 34 km from the Facility and Xena-03 Operational Areas), as well as the Montebello Marine Park, which is located in deeper offshore waters and overlaps the PAA. These tourism areas have some charter boat operators taking visitors to islands (Department of Environment and Conservation, 2007). Recreational fishing in the Pilbara and Gascoyne regions is mainly concentrated around the coastal waters and islands and has grown considerably with the expanding regional centres, seasonal tourism and increasing residential and fly in/fly out work force, particularly in the Pilbara region (Fletcher et al., 2017). Some recreational fishing has historically taken place at Rankin Bank (approximately 29 km north-east of the PAA at the closest point). However, due to the distance from access nodes, such as Dampier and Onslow (approximately 31 km south and 180 km southwest from the PAA at the closest point respectively) recreational fishing effort is expected to be restricted to relatively large vessels and hence is considered to be low.

4.10.4 Commercial Shipping

The Australian Maritime Safety Authority (AMSA) has introduced a network of marine fairways across the NWMR off WA to reduce the risk of vessel collisions with offshore infrastructure. Two fairways overlap the Export Pipeline Operational Area, and none overlap with the Facility and Xena-03 Operational Areas (Figure 4-188). Ports in the region are nodes of increased vessel activities. Active ports within the vicinity of the PAA include:

- Dampier (approximately 31 km south)
- Barrow Island (approximately 84 km south)
- Port Walcott (approximately 160 km south)
- Onslow (approximately 180 km south)

- Port Headland (approximately 207 km south-east)

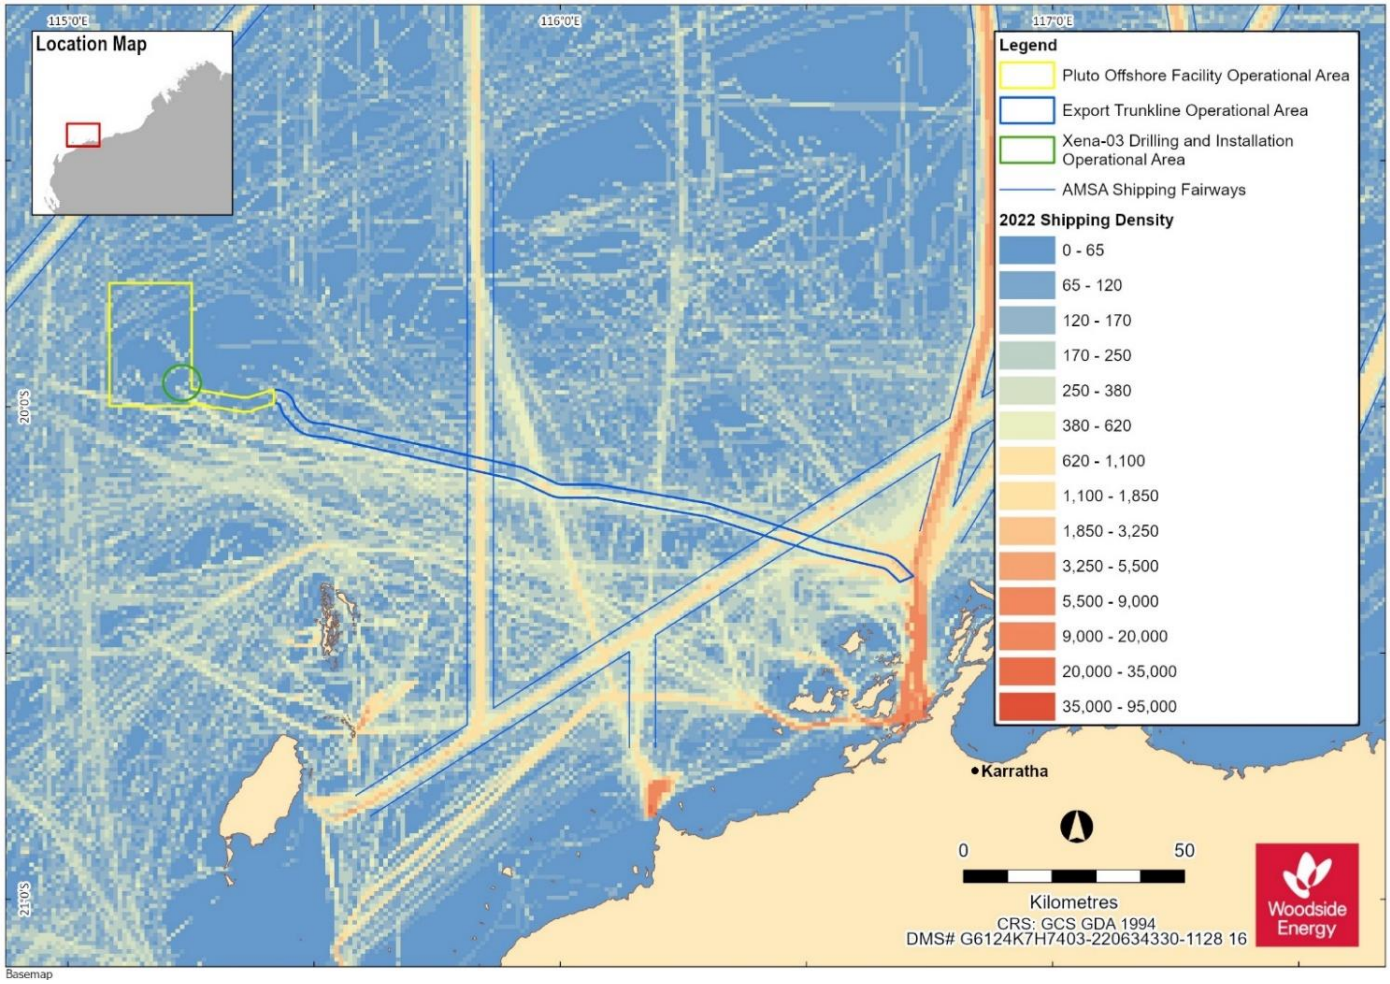

Figure 4-18: Vessel density map for the PAA, derived from AMSA satellite tracking system data (vessels include cargo, LNG tanker, passenger vessels, support vessels, and others/unnamed vessels

4.10.5 Oil and Gas

The PAA is located within an area of established oil and gas operations in the broader NWMR. Table 4-22 details the proximity of other oil and gas facilities within the region to the operational areas within the PAA. The Master Existing Environment (Woodside, 2022) describes current oil and gas development within the EMBA, also shown in Figure 4-199.

There are also facilities with intersecting subsea infrastructure including:

- Julimar Brunello production pipeline (Woodside)
- Wheatstone pipeline (Chevron)
- Reindeer offshore gas supply pipeline (Santos)
- Scarborough export trunkline (Woodside)

Table 4-22: Other Oil and Gas Facilities located within 70 km of the Facility and Xena-03 combined Operational Areas and the Export Pipeline Operational Area

Facility Name and Operator	Distance and direction from Facility and Xena-03 OA	Distance and direction from Export pipeline OA
Wheatstone platform (Chevron)	5 km north	5 km north
Angel platform (Woodside)	48 km north	48 km north
John Brookes (Santos)	50 km south	57 km south-west
Goodwyn Alpha platform (Woodside)	72 km north-east	51 km north
North Rankin Complex (Woodside)	86 km north-east	64 km north
Reindeer wellhead platform (Santos)	109 km east	12 km north
Stag A (Jadestone)	112 km south-east	8 km south
Wandoo B (VOGA)	123 km south-east	12 km south

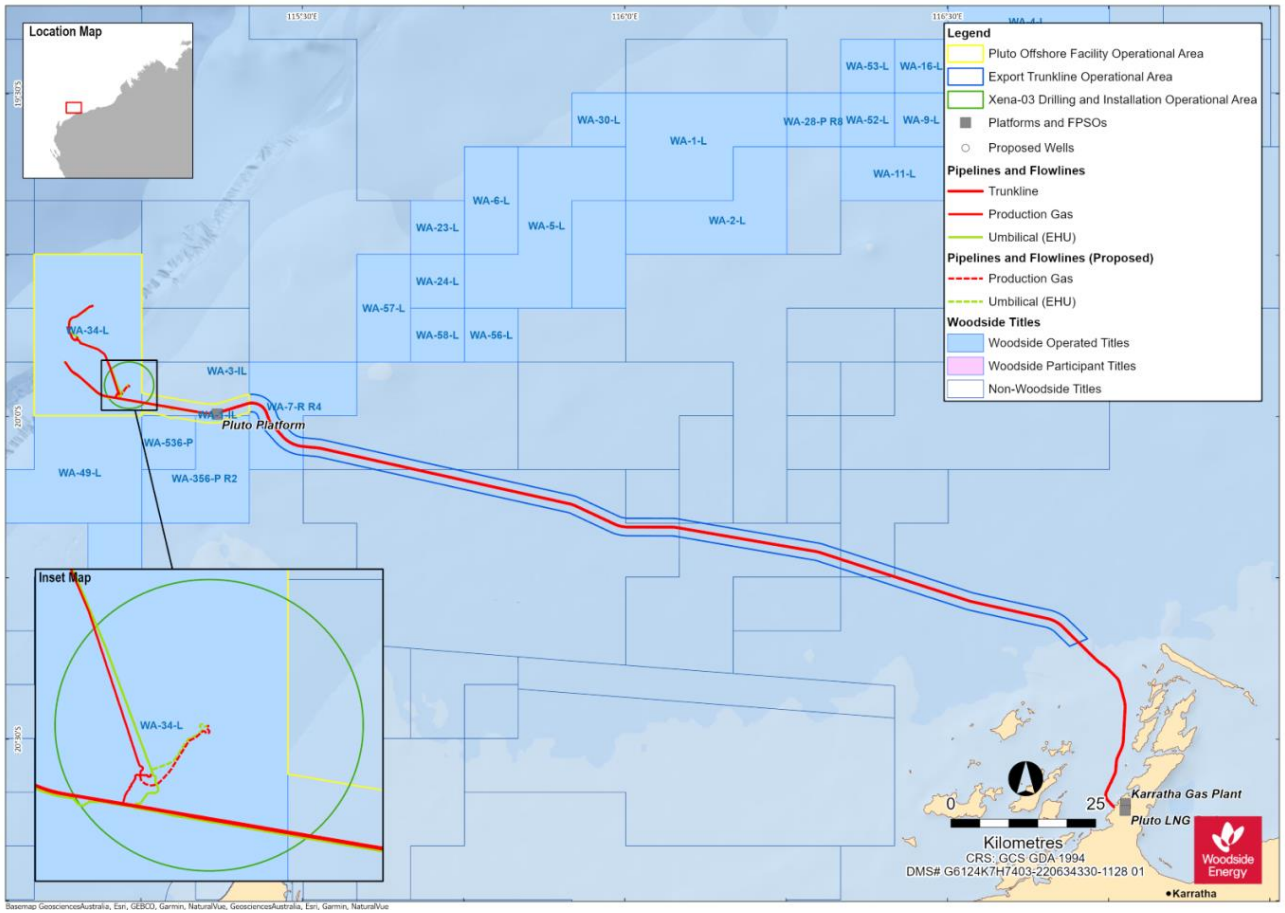

Figure 4-19: Oil and Gas Facilities located within the EMBA

4.10.6 Defence

Department of Defence (DoD) areas, facilities and UXOs near the PAA and within the EMBA are outlined in Table 4-23. There are no DoD areas overlapping the PAA. The Master Existing Environment (Woodside, 2022) describes key DoD areas and facilities.

Table 4-23: Defence areas, facilities and UXOs overlapping the Operational Area and/or EMBA.

Defence area/ facility	Presence	
	PAA	EMBA
UXO SDG096 Sea Dumping: Anchor Island. This site is an area used for the dumping at sea of ordnance and other items.		✓
Potential Depth Charge UXO DEP022: Northwest of Bessieres Island. This site was an area where Depth Charges were used in WWII and where some depth charges failed to function.		✓
Potential Depth Charge UXO DEP027: East of Montebello Islands. This site was an area where Depth Charges were used in WW2 and where some depth charges failed to function.		✓

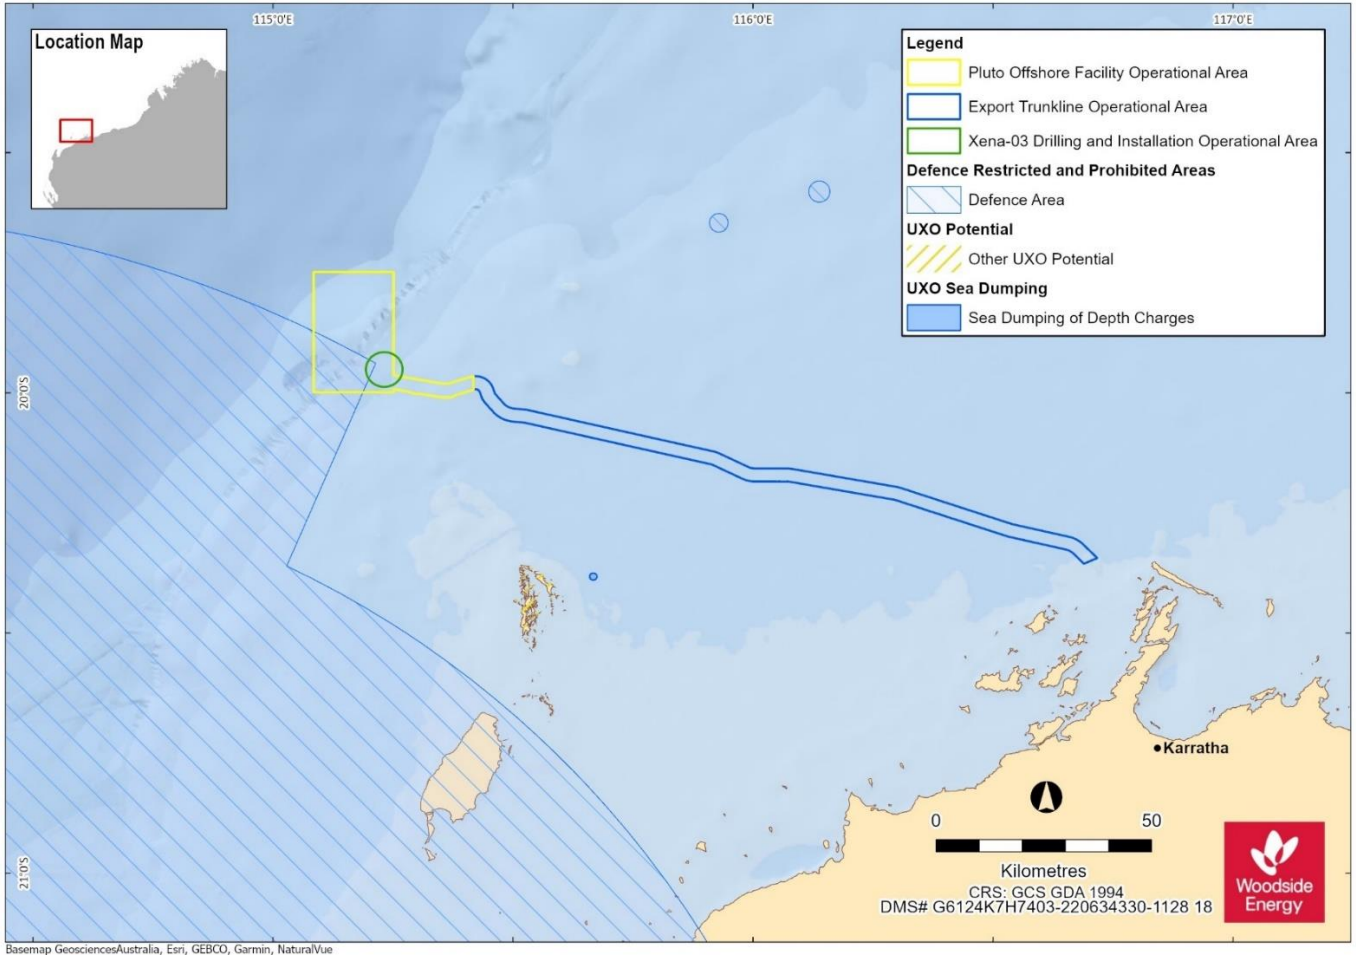

Figure 4-20: Defence areas relative to the PAA

5. CONSULTATION

5.1 Summary

Woodside consults relevant persons in the course of preparing an Environment Plan (EP) in accordance with regulation 25 of the Environment Regulations. (In this Section, references to 'regulations' are to regulations of the Environment Regulations, unless otherwise stated).

Consultation is designed to identify relevant persons and provide them with sufficient information and a reasonable period to allow them to make an informed assessment of the possible consequences of the proposed activity on their functions, interests or activities. This enables Woodside to consider and assess claims or objections received from relevant persons and for Woodside to adopt appropriate measures in response to those objections or claims so that the activity is carried out in a manner by which the environmental impacts and risks of the activity will be reduced to as low as reasonably practicable (ALARP) and will be of an acceptable level.

Consultation is to be informed by both the Environment Regulations and the findings of relevant Courts, including the Full Federal Court in the Santos NA Barossa Pty Ltd v Tipakalippa [2022] FCAFC 193 (Tipakalippa Appeal) (see Section 5.2 and 5.5.1) and Munkara v Santos NA Barossa Pty Ltd (No 3) [2024] FCA 9 (Munkara Case).

For this EP, Woodside has considered both the PAA and the broader EMBA in undertaking consultation (see further discussion in Section 5.2). The broadest extent of the EMBA has been determined by reference to the highly unlikely event of a hydrocarbon release resulting from the activities in the PAA (see Section 4).

Woodside's consultation methodology is divided into two parts:

- The first section (Section 5.2 to 5.5) provides an overview of Woodside's consultation methodology for its EPs, including how we apply regulation 25(1) to identify relevant persons.
- The second section (Section 5.6 to Section 5.7) details Woodside's approach to accepting feedback and assessment of the merit of each objection or claim, and engaging in ongoing consultation for this EP.

Woodside's consultation record is at Appendix F and includes a summary of the following:

- assessment and identification of relevant persons
- consultation information provided to relevant persons, feedback received, Woodside's assessment of the merits of objections or claims and Woodside's response to relevant persons and other stakeholders Woodside chose to consult
- engagement with persons or organisations that Woodside chose to contact who are not relevant persons for the purposes of regulation 25(1) (see Section 5.3.4)
- opportunities provided to persons or organisations to participate in consultation.

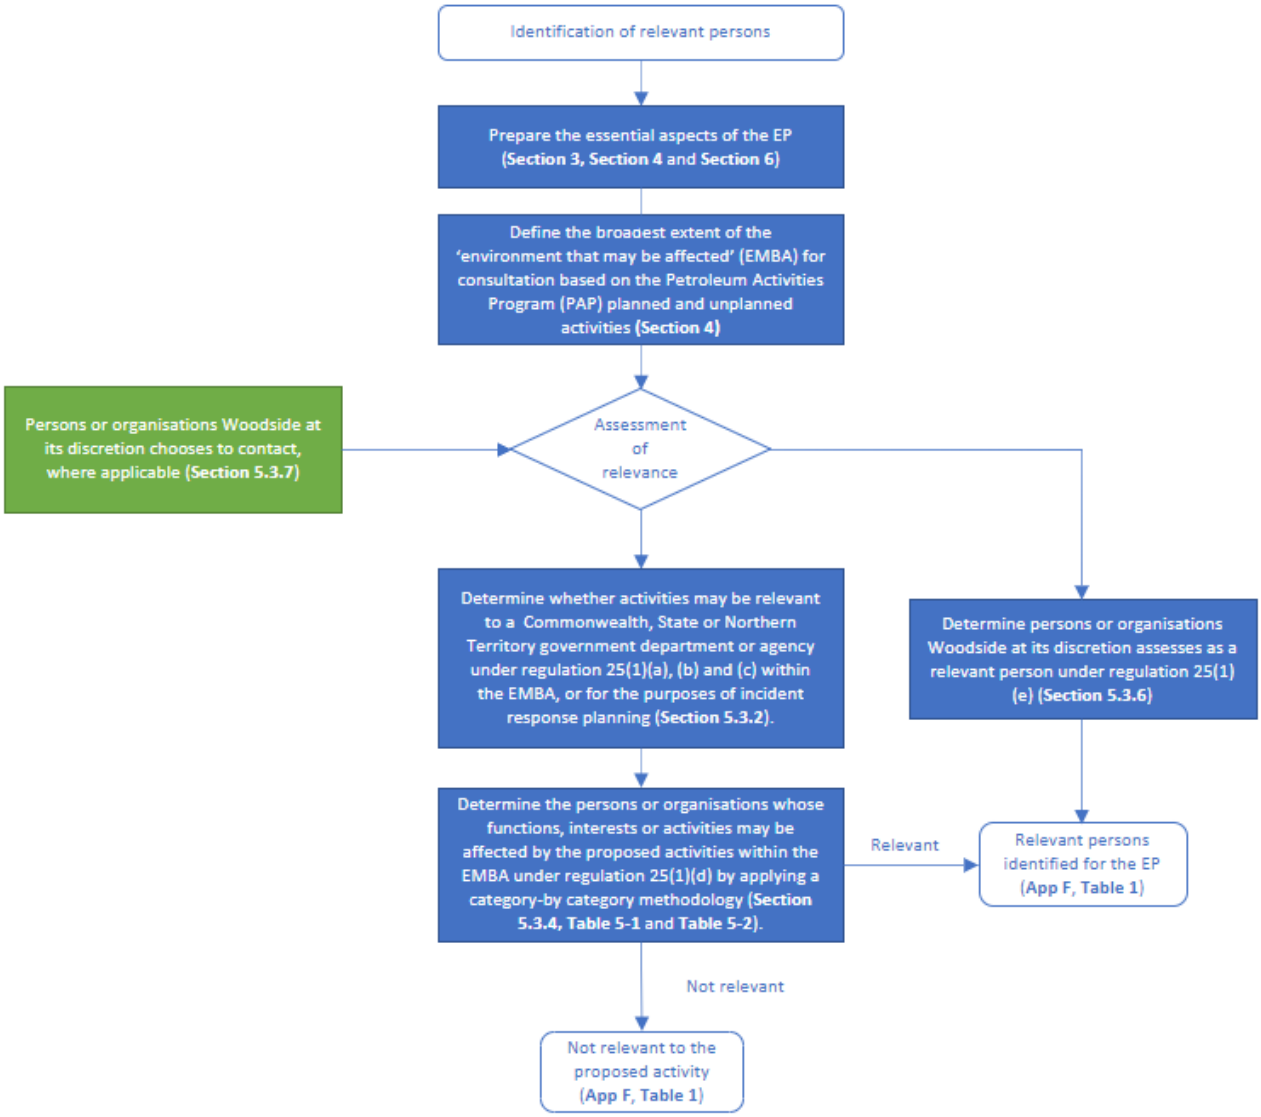

Figure 5-1: Overview of Woodside's methodology to identify relevant persons

5.2 Consultation – General Context

Woodside has a portfolio of quality oil and gas assets and more than 30 years of operating experience. We have a strong history of working with local communities, the relevant regulators and a broad range of persons and organisations, to better understand the potential risks and impacts associated with our proposed activities and to develop appropriate measures to manage them.

The length of time that we have operated in Commonwealth and State waters, and the history of continued engagement with a wide range of persons and organisations, enables Woodside to develop an extensive consultation list to inform its consultation process. This consultation list is not used as a definitive list of persons to consult but, rather, assists Woodside as an input to its understanding of relevant persons with whom to consult on a Petroleum Activities Program (PAP). The information in the consultation list has been captured from years of experience: it contains insights relating to the type of information particular persons or organisations want to receive during consultation, the appropriate method of consultation for relevant persons and includes appropriate contact details, which are reviewed and updated periodically.

Woodside acknowledges NOPSEMA's Guideline on Consultation in the course of preparing an environment plan (12 May 2023) as well as judicial guidance in the Tipakalippa Appeal on the intent of consultation, as follows:

- At paragraph 54 of the appeal decision: … provide a basis for NOPSEMA's considerations of the measures, if any, that a titleholder proposes to take or has taken to lessen or avoid the deleterious effect of its proposed activity on the environment, as expansively defined.
- At paragraph 89 of the appeal decision: …its purpose is to ensure that the titleholder has ascertained, understood and addressed all the environmental impacts and risks that might arise from its proposed activity. Consultation facilitates this outcome because it gives the titleholder an opportunity to receive information that it might not otherwise have received from others affected by its proposed activity. Consultation enables the titleholder to better understand how others with an objective stake in the environment in which it proposes to pursue the activity perceive those environmental impacts and risks. As the Regulations expressly contemplate, it enables the titleholder to refine or change the measures it proposes to address those impacts and risks by taking into account the information acquired through the consultations. Objectively, the scheme intends that this is likely to improve the minimisation of environmental impacts and risks from the activity.

The *Tipakalippa Appeal* and *Munkara Case* have also been further considered in the context of specific methods for consultation with First Nations' relevant persons (Section 5.5.1).

To undertake consultation, Woodside has developed a methodology for identifying relevant persons in accordance with regulation 25(1) (Section 5). This methodology is consistent with NOPSEMA's Guideline and demonstrates that, to meet the requirements of regulation 34 (criteria for EP acceptance) when preparing the EP, Woodside understands:

- our planned activities in the PAA, being the area in which our planned activities are proposed to occur (see Section 3.3.2)
- the geographical extent to which the environment may be affected (EMBA) by risks and impacts from our activities (unplanned) (identified in Section 4.1 and assessed in Section 6.8).

Woodside has undertaken consultation in the course of preparing this EP in compliance with regulation 25, which requires a titleholder to:

- consult with each of the following (a relevant person):
  - each Commonwealth, State or Northern Territory agency or authority to which the activities to be carried out under the EP may be relevant
  - if the plan relates to activities in the offshore area of a State – the Department of the responsible State Minister
  - if the plan relates to activities in the Principal Northern Territory offshore area – the Department of the responsible Northern Territory Minister
  - a person or organisation whose functions, interests or activities may be affected by the activities to be carried out under the EP
  - any other person or organisation that the titleholder considers relevant (regulation 25(1)).
- give each relevant person sufficient information to allow the relevant person to make an informed assessment of the possible consequences of the activity on their functions, interests or activities (regulation 25(2))
- allow a relevant person a reasonable period for the consultation (regulation 25(3))

- tell each relevant person that the titleholder consults with, that the relevant person may request that particular information it provides in the consultation not be published and any information subject to such a request is not to be published (regulation 25(4)).

Further, Woodside seeks to carry out consultation in a manner that:

- is consistent with the principles of ecologically sustainable development (ESDev) set out in section 3A of the EPBC Act – see Section 2
- is intended to reduce the environmental impacts and risks from the activity to ALARP and an acceptable level (regulation 4)
- is intended to minimise harm to the relevant person and the environment from the proposed petroleum activities and to enable Woodside to consider measures that may be taken to mitigate the potential adverse environmental impacts from the petroleum activity
- is collaborative. Woodside respects that, for a relevant person, consultation is voluntary. Where the relevant person seeks to engage, Woodside engages with the relevant person with the aim of seeking genuine and meaningful two-way dialogue
- provides opportunities for relevant persons to provide feedback throughout the life of the EP through its ongoing consultation process (refer to Section 5.7 and Section 7.8.2.1).

An overview of Woodside's consultation approach is outlined at Figure 5-2.

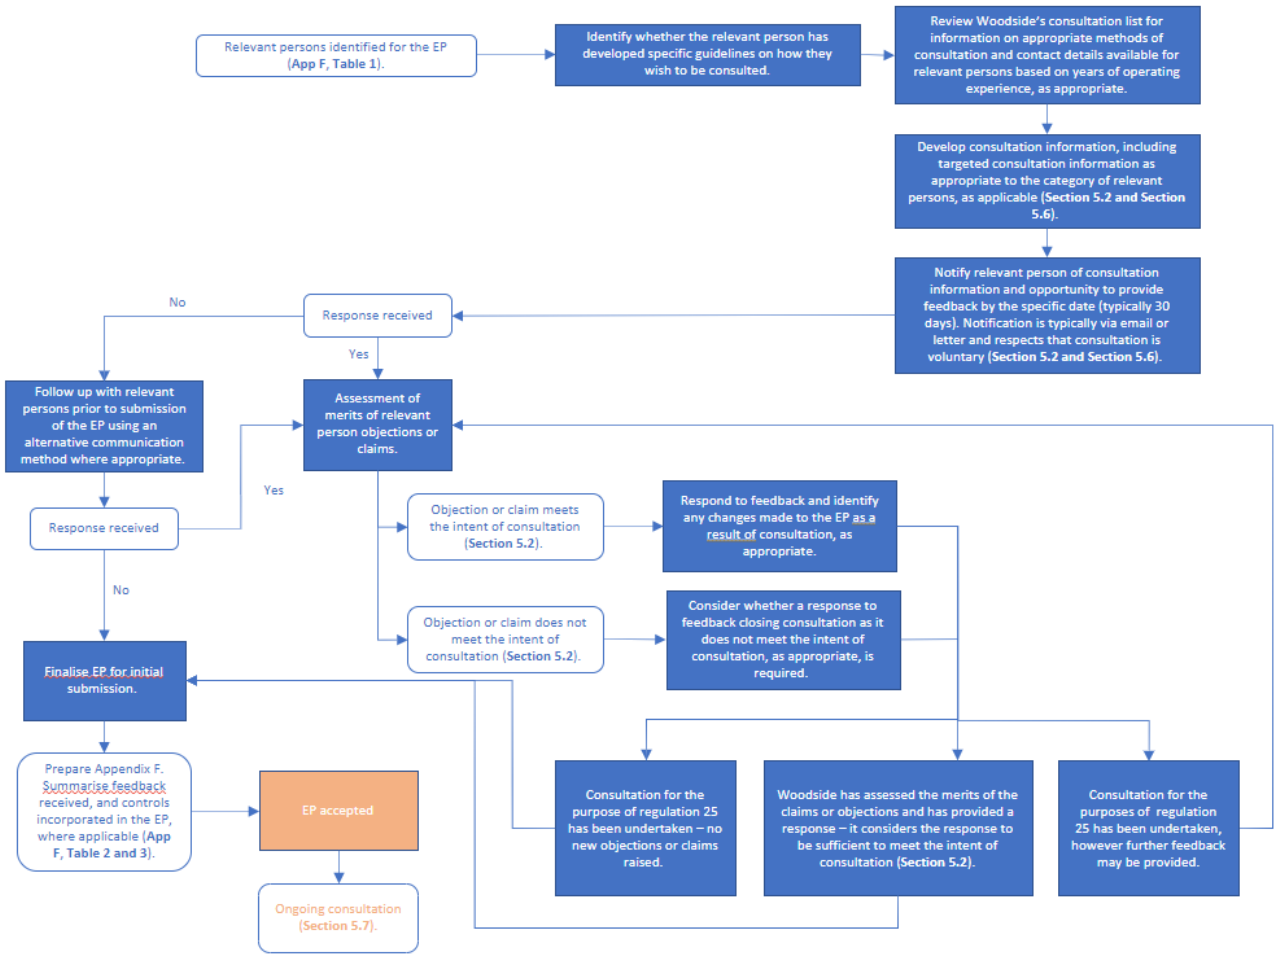

Figure 5-2: Overview of Woodside's consultation approach.

The methodology for consultation for this activity has been informed by various guidelines and relevant information for consultation on planned activities, including:

Federal Court:

5.3 Identification of Relevant Persons for Consultation

5.3.1 Regulations 25(1)(a), (b) and (c)

The relevant inquiry for determining relevant persons under regulations 25(1)(a) and (b) is whether the activities to be carried out under the EP may be relevant to one of the government departments or agencies in those regulations. The government departments and agencies relevant to the EP are listed in Appendix F, Table 1. In accordance with Regulation 25(1)(b), Woodside consults with the Department of the relevant State Minister.

5.3.2 Identification of Relevant Persons under Regulations 25(1)(a), (b) and (c)

Woodside's methodology for identifying relevant persons under regulations 25(1)(a), (b) and (c) is as follows:

- Woodside considers the defined responsibilities of each of the departments and agencies to which the activities to be carried out in the EMBA under the EP may be relevant. This list of relevant departments and agencies is formulated by reference to the responsibilities of the government departments, as set out on their websites, in NOPSEMA's GL1887 – Consultation with Commonwealth agencies with responsibilities in the marine area guideline (January 2024), which describes where the Department is a relevant agency under the Environment Regulations, as well as experience and knowledge that Woodside has gained from years of operating. This list is revised from time to time, for example, for the purposes of accommodating government restructures, renaming of departments, shifting portfolios and/or to account for new agencies that might arise.

Woodside has categorised government department or agency groups as follows:

Government departments / agencies – marine	Agencies with legislated responsibilities for use of the marine environment.
Government departments / agencies – environment	Agencies with legislated responsibilities for the protection of the marine environment.
Government departments / agencies – industry	The legislated Department of the responsible Commonwealth, State or Northern Territory Minister for Industry.

- Woodside considers each of the responsibilities of the departments and agencies, determining whether those responsibilities overlap with potential risks and impacts specific to the PPA in the EMBA. The assessment is both activity and location based.
- Woodside acknowledges the roles and responsibilities of government departments and agencies acting on behalf of various industry participants. For example, AMSA – Marine Safety is responsible for the safety of vessels and the seafarers who are operating in the domestic commercial shipping industry; and AHO is responsible for maritime safety and Notices to Mariners. To undertake the PAP in a manner that prevents a substantially adverse effect on the potential displacement of marine users, Woodside therefore consults AMSA – Marine Safety and AHO on its proposed activities. Woodside considers each of the responsibilities of the departments and agencies and determines those that would either be involved in the incident response itself or in relation to the regulatory or decision-making capacity with respect to planning for the unlikely event of a worst-case hydrocarbon release incident response specific to the OA. Feedback received, if any, is assessed in accordance with the intended outcome of consultation.
- The list of government departments and agencies assessed as relevant is set out in Appendix F, Table 1.
- Feedback received, if any, is assessed in accordance with the intended outcome of consultation and summarised at Appendix F, Table 2 and Table 3 as appropriate to the relevance assessment.

Woodside does not consult with departments or agencies with interests that do not overlap with risks and impacts specific to the PPA in the EMBA or would not be involved in incident response planning.

5.3.3 Regulation 25(1)(d)

To identify a relevant person for the purposes of regulation 25(1)(d), the meaning of “functions, interests or activities” needs to be understood. In regulation 25(1)(d), the phrase “functions, interests or activities” should be construed broadly and consistently with the objects of the Environment Regulations (regulation 4) and the objects of the EPBC Act (section 3A).

In developing its methodology for consultation, Woodside acknowledges the guidance below from NOPSEMA’s GL2086 – Consultation in the course of preparing an environment plan guideline (May 2023):

Functions	Refers to a power or duty to do something.
Interests	Conforms to the accepted concept of ‘interest’ in other areas of public administrative law and includes any interest possessed by an individual whether or not the interest amounts to a legal right or is a proprietary or financial interest or relates to reputation.
Activities	Broader than the definition of ‘activity’ in regulation 5 of the Environment Regulations and is likely be directed to what the relevant person is already doing.

Woodside’s methodology for determining ‘relevant persons’ for the purpose of regulation 25(1)(d) includes consideration of:

- whether a person or organisation has functions interests or activities that overlap with the OA or PAA, and EMBA

- whether a person or organisation's functions, interests or activities may be affected by Woodside's proposed planned or unplanned activities.

5.3.4 Identification of Relevant Persons under Regulation 25(1)(d)

Relevant persons under regulation 25(1)(d) are defined as a person or organisation whose functions, interests or activities may be affected by the activities to be carried out under the EP. In identifying relevant persons, Woodside considers:

- the planned activities to be carried out under the EP (described in Section 3)
- the EMBA by unplanned activities (identified in Section 4 and assessed in Section 6).
- To identify relevant persons who fall within regulation 25(1)(d), Woodside adopts the following methodology, and then undertakes consultation with relevant persons.
- As a general proposition, Woodside assesses whether a person or organisation is a relevant person having regard to:
- whether a person or organisation has functions, interests or activities that overlap with the OA or PAA, and EMBA
- whether a person or organisation's functions, interests or activities may be affected by Woodside's proposed planned or unplanned activities to be carried out under the EP.
- This assessment will include applying judgement, knowledge and considering available, relevant literature.
- To assist in identifying the full range of relevant persons, Woodside considers the impacts and risks associated with its proposed activities and considers the broad categories of relevant persons who may be affected by the activities to be carried out under the EP. The broad categories are identified in Table 5-1 below and identification methodology applied as set out in Table 5-1.
- The list of those persons or organisations assessed as relevant persons or organisations Woodside separately chose to contact is set out in Appendix F, Table 1.
- Feedback received, if any, is assessed in accordance with the intended outcome of consultation and applying the categories of relevant persons methodology outlined in Table 5-2, as appropriate.
- Feedback from relevant persons is summarised at Appendix F, Table 2. Feedback from persons assessed as "not relevant" but whom Woodside chose to contact, or self-identified and Woodside assessed as "not relevant", are summarised at Appendix F, Table 3.

Table 5-1: Categories of relevant persons

Category	Explanation
Commercial fisheries (Commonwealth and State) and peak representative bodies	Commonwealth or State Commercial Fishery with a fishery management plan recognised under the Commonwealth Fisheries Management Act 1991 (Cth) and the Western Australian Fish Resources Management Act 1994 (WA), which may be amended from time to time. Commonwealth peak fishery representative bodies are identified by AFMA. WAFIC is the peak representative body for state fishers in Western Australia.
Recreational marine users and peak representative bodies	Charter boat, tourism and dive operators identified by DPIRD specific to the location of the proposed activity. Representative bodies are the recognised peak organisation(s) for recreational marine users.

Titleholders and Operators	Registered holder of an offshore petroleum title or GHG title under the OPGGS Act and associated regulations.
Peak industry representative bodies	Recognised peak organisation(s) for the oil and gas sector.
Traditional Custodians (individuals and/or groups/entity)	Traditional Custodians are First Nations Australians with cultural rights and interests or cultural functions or who perform cultural activities over particular lands and waters. Where a First Nations person, group or entity self-identifies and asserts cultural rights, functions, interests or activities they will be considered under the definition of Traditional Custodian for the purpose of this EP (as appropriate).
Nominated Representative Corporations	Nominated representative corporations are Traditional Custodians' nominated representative institutions such as Prescribed Body Corporates (PBC). PBCs are established under the Native Title Act 1993 (Cth) by Traditional Custodians to represent their entire Traditional Custodian group (defined broadly by reference to descents from an ancestor set who were known to be the Traditional Custodians at the time of European colonisation) and their interests including, among other things, management and protection of cultural values.
Native Title Representative Bodies	A Representative Aboriginal/Torres Strait Islander Bodies (RATSIB) is a regional organisation appointed under the Native Title Act 1993 with prescribed functions, set out in Part 11 of the Native Title Act 1993, which relate to: facilitation and assistance; certification; dispute resolution; notifications; agreement making. They are also known, and referred to here, as Native Title Representative Bodies.
Historical heritage groups or organisations	Legislated or government enlisted groups or organisations responsible for the management of marine heritage.
Local government and recognised local community reference/liaison groups or organisations	Local government body formed under the Local Government Act 1995 (WA) which is responsible for representing the local community. Recognised local community reference or liaison group or organisation in relation to oil and gas matters.
Other non-government groups, organisations or individuals	Non-government organisation with public website material targeting the proposed activity. Individual who demonstrates the proposed activity could potentially impact their interests, functions or activities.
Research institutes and local conservation groups or organisations	Research institutes are government or private institutions that conduct marine or terrestrial research. Local conservation groups are local non-government organisation that regularly conduct conservation activities focused on the local environment or wildlife.

Table 5-2: Methodology for identifying relevant persons within the EMBA undertaken under Regulation 25(1)(d) – by category

Category	Relevant person identification methodology
Commercial fisheries (Commonwealth and State) and peak representative bodies	Woodside assesses relevance for commercial fisheries (Commonwealth and State) and their representative bodies using the following next steps in its methodology: • Defining the parameters having regard to timing, location and duration of the proposed petroleum activity. • Confirming whether the EMBA overlaps with the fisheries management area (i.e., the spatial area the fishery is legally permitted to fish in) (see Section 4.10.1).

	• Woodside acknowledges WAFIC's consultation guidance20, that Titleholders develop separate consultation strategies for significant unplanned events (for example an oil spill) where titleholders can demonstrate the likelihood of such events occurring is extremely low. WAFIC's guidance is that consultation on unplanned events resulting in an emergency scenario should only be undertaken if an incident occurs. • For Commonwealth and State commercial fisheries, Woodside assesses the potential spatial and temporal extent for interaction with the fishery by reviewing AFMA, ABARES and DPIRD Fishcube data within the Operational Area and EMBA (see Section 4.10.2). Assessment of relevance: • State commercial fisheries that have been assessed as having a potential for interaction within the Operational Area or EMBA (see Section 4.10.2) are assessed as relevant to the proposed activity. However, to avoid over consulting and as requested in WAFIC's guidance, Woodside only consults individual licence holders based on WAFIC's advice. Woodside also utilises WAFIC's consultation service whereby WAFIC: - directly consults fishery licence holders that are assessed as having a potential for interaction in the Operational Area - consults fisheries that are assessed as having a potential for interaction in the EMBA only in the event of an unplanned emergency scenario. • Commonwealth commercial fisheries that have been assessed as having a potential for interaction within the Operational Area or EMBA (see Section 4.10.2) are assessed as relevant to the proposed activity. • If Woodside has identified that a Commonwealth or State fishery is a relevant person, then Woodside also consults the fisheries relevant representative body. For example, WAFIC represents the interests of State fisheries in Western Australia. If a State fishery is identified as relevant, Woodside would also identify WAFIC as relevant. Recognised Commonwealth fishery representative bodies are identified by AFMA via its website. WAFIC is the only recognised State fishery representative body.
Recreational marine users and peak representative bodies	Woodside assesses relevance for recreational marine users and peak representative bodies using the following next steps in its methodology: • Using Woodside knowledge and operating experience, applying knowledge of recreational marine users in the area. This assessment is both activity and location based. • Defining the parameters having regard to timing, location and duration of the proposed petroleum activity. • Assessing the potential spatial and temporal extent for interaction with recreational marine users by reviewing DPIRD Fishcube data to assess whether there has been activity within the EMBA in the past 5 years. Assessment of relevance: • Recreational marine users that have been active in the past 5 years within the EMBA are assessed as relevant to the proposed activity. Woodside is provided with the contact details of charter, boat tourism and dive operators specific to the region of the EMBA by DPIRD to consult with the relevant persons. • If Woodside has identified recreational marine users as relevant persons, then Woodside also consults identified peak

[20] Consultation Approach for Unplanned Events - WAFIC

	recreational marine user representative bodies. For example, Recfishwest represents the interests of recreational fishers. These representative bodies are identified via Woodside's existing consultation list, which is updated as appropriate via advice from known groups and DPIRD.
Titleholders and Operators	Woodside assesses relevance for other Titleholders and operators using the following steps in its methodology: • Using GPInfo to determine overlap with other Titleholders or Operators permit areas within the EMBA. • Using Woodside knowledge and operating experience, applying knowledge of other operators in the area. • Woodside produces a map showing the outcome of this assessment. Assessment of relevance: • Titleholders and Operators whose permit areas are identified as having an overlap within the EMBA are assessed as relevant.
Peak industry representative bodies	Woodside assesses relevance for peak industry representative bodies using the following steps in its methodology: • Review of peak industry representative bodies responsibilities that Woodside actively participates in, with consideration of overlap between industry focus area and Woodside's proposed activities within the EMBA. • Review of Woodside's existing consultation list. • Website search to identify whether any additional peak industry representative bodies have been created whose responsibilities may overlap with Woodside's proposed activities within the EMBA. Assessment of relevance: Peak industry representative bodies whose responsibilities are identified as having an overlap with Woodside's proposed activities within the EMBA are assessed as relevant.
Traditional Custodians (individuals and/or groups/entity) and Nominated Representative Corporations	Consistent with its understanding of the matters discussed in Section 4.9, to identify Traditional Custodian groups or individuals, Woodside: • uses existing systems of recognition to identify First Nations groups who overlap or are coastally adjacent to the EMBA (for example, recognition provided under native title or cultural heritage legislation, or marine park management plans, or identification by other First Nations groups or entities) • notifies and invites consultation with First Nations people through their nominated representative corporation (for example PBCs); or, in the case of native title and where appropriate, the Native Title Representative Body • requests the nominated representative body to forward the notifications and invitations to consult to their members (members are individual communal rights holders; • requests advice as to other First Nations groups or individuals that should be consulted • advertises widely so as to invite self-identification and consultation by First Nations groups and individuals. Further detail to Woodsides methodology is as follows. Woodside uses the databases of the National Native Title Tribunal: • to understand whether there are any Native Title Claims (historical or current) or determinations overlapping or coastally adjacent to the EMBA • to understand whether there are any relevant Indigenous Land Use Agreements (ILUA), registered with the National Native Title Tribunal that overlap or are adjacent to the EMBA that may

	identify Traditional Custodians or representative bodies to contact regarding potential cultural values. Where there is a positive determination of native title, contacting the PBC or, where their representative is a Native Title Representative Body, contacting the Native Title Representative Body. Where appropriate, contacting the relevant Native Title Representative Body to request a list of any First Nations groups asserting Traditional Custodianship over an area of coastline adjacent to the EMBA. Review of Commonwealth and State Marine Park Management Plans that overlap the EMBA which may identify Traditional Custodians or representative bodies to contact regarding potential cultural values. In Victoria, using the Victorian Aboriginal Heritage Council data to determine whether there are any Registered Aboriginal Parties (RAP) appointed under the Aboriginal Heritage Act 2006 (Vic), that overlap or are adjacent to the EMBA. First Nations groups or individuals identified by a Traditional Custodian, nominated representative corporation, Native Title Representative Body. Request to the PBC to distribute Woodside consultation materials through its membership. Woodside is unable to contact this membership through any other means. Woodside has a number of public notification and information sharing processes by which individual Traditional Custodians can become aware of the proposed activity, its risks and impacts, and self-identify. Individuals that consider their functions, interests or activities may be affected by a proposed activity are provided an opportunity to self-identify for each EP. Woodside does not presume that self-identification for an activity, covered by another EP, automatically means that an individual/s functions, interests and activities may be affected by other activities where EMBAs overlap. This decision is for the individual to make. The public notification, information sharing, and consultation processes Woodside puts in place enables Traditional Custodians to become aware of proposed activities, assess risks and impacts to their values, and enable individuals to self-identify. Assessment of relevance: Traditional Custodian groups, entities or individuals and Nominated Representative Corporations who are identified through the above methodology and overlap or are coastally adjacent to the EMBA are assessed as relevant.
Native Title Representative Bodies	Woodside assesses relevance for Native Title Representative Bodies using the following steps in its methodology: • A Representative Aboriginal/Torres Strait Islander Body (RATSIB) is a regional organisation appointed under the Native Title Act 1993 with prescribed functions set out in Part 11 of the Native Title Act 1993, which relate to: facilitation and assistance; certification; dispute resolution; notifications; agreement making. They are also known, and referred to here, as Native Title Representative Bodies. • Review of National Native Title Tribunal RATSIB areas that overlap or are coastally adjacent to the EMBA. Assessment of relevance: • Where the area for which a Native Title Representative Body is recognised under the Native Title Act 1993, overlaps with the EMBA or is coastally adjacent to the EMBA, Woodside will assess the Native Title Representative Body as relevant.
Historical heritage groups or organisations	Woodside assesses relevance for groups or organisations whose responsibilities are focused on historical heritage using the following steps in its methodology: • Using the Australasian Underwater Cultural Heritage Database to assess known records Maritime Cultural Heritage sites

	(shipwrecks, aircraft and relics) within the EMBA (see Section 4.9.1). Assessment of relevance: • Where there is a known underwater heritage site (shipwrecks, aircraft and relics) within the EMBA, the relevant group or organisation that manages the site will be assessed as relevant.
Local government and recognised local community reference/liaison groups or organisations	Woodside assesses relevance for local government and recognised local community reference/liaison groups or organisations using the following steps in its methodology: • Review of Woodside maps (developed based on data from the WA Local Government, Sport and Cultural Industries 'My Council' database and WA Local Government Association (WALGA) Local Government Directory maps to assess overlap between the local government's defined area of responsibility and the EMBA. • Woodside hosts regular community reference/liaison group meetings. Members represent a cross-section of the community and local towns interests. Representatives are from community and industry and generally include, Woodside, State Government (for instance relevant Regional Development Commissions), Local Government, Indigenous Groups, Industry representative bodies, community and industry organisations. Woodside considers these reference/liaison groups to be the appropriate recognised representatives of the local community for the oil and gas sector. • Woodside reviews the community reference/liaison group's terms of reference to determine its area of responsibility and overlap with the EMBA. For example, the Exmouth Community Liaison Group's area of responsibility in relation to Woodside's operational, development and planning activities, is defined in the terms of reference as the Exmouth sub-basin. Comparatively, the Karratha Community Liaison Group's area of responsibility is the Pilbara region (i.e., onshore). Assessment of relevance: • The local government whose defined area of responsibility overlaps the EMBA is assessed as relevant. • The community reference/liaison group whose defined area of responsibility overlaps the EMBA is assessed as relevant and consulted collectively via the relevant reference/liaison group.
Other non-government groups, organisations or individuals	Woodside assesses relevance for other non-government groups, organisations or individuals using the following steps in its methodology: • Review of Woodside's existing consultation list. • Website search of registered non-government groups or organisations (i.e., registered with an Australian Business Number (ABN) and publicly available contact information) that may have public website material specific to the proposed activity at the time of development of the EP. • Organisation has a publicly available mission statement (or purpose) that clearly describes their collective functions, interests or activities. • Review of current website material to identify targeted information which demonstrates functions, interests or activities relevant to the potential risks and impacts associated with planned activities. • Review of an individual's feedback to consider whether their functions, interests or activities could be impacted. Assessment of relevance:

	• Registered non-government groups or organisations with current targeted public website material specific to the proposed activity at the time of developing the EP and who have demonstrated functions, interests or activities relevant to the potential risks and impacts associated with planned activities in accordance with the intended outcome of consultation will be assessed as relevant. • Individual demonstrates their functions, interests or activities could be impacted will be assessed as relevant.
Research institutes and local conservation groups or organisations	Woodside assesses relevance for research institutes and local conservation groups or organisations using the following steps in its methodology: • Review of Woodside's existing consultation list. • Website search for research institutes that may operate within the EMBA. This assessment is both activity and location based. • Website search for local conservation groups or organisations that regularly conduct conservation activities within the EMBA. Assessment of relevance: • Where there is known research being undertaken by a research institute within the EMBA, the research institute that is conducting the research will be assessed as relevant. • Local environmental conservation groups who regularly conduct conservation activities or have demonstrated conservation functions, interests or activities within the EMBA are assessed as relevant. This assessment is both activity and location based.

5.3.5 Regulation 25(1)(e)

In addition to assessing relevance under regulation 25(1)(d), Woodside has discretion to categorise any other person or organisation as a relevant person under regulation 25(1)(e).

5.3.6 Identification of Relevant Persons under Regulation 25(1)(e)

Woodside adopts a case-by-case approach for each EP to assess relevance under regulation 25(1)(e).

5.3.7 Persons or Organisations Woodside Chooses to Contact

In addition to undertaking consultation with relevant persons under regulation 25(1), from time to time there are persons or organisations that Woodside chooses to contact in relation to a proposed activity. For example, these are persons or organisations:

- that are 'not relevant' pursuant to regulation 25(1) but that Woodside has chosen to seek additional guidance from, for example, to inform the correct contact person that Woodside should consult, or engage with
- that are 'not relevant' pursuant to regulation 25(1) but have been contacted as a result of consultation requirements changing or updated guidance from the Regulator
- where it is unclear what their functions, interests or activities are, or whether their functions, interests or activities may be affected. In this circumstance, engagement is used to inform relevance under Woodside's methodology. Woodside follows the same methodology for assessing a person or organisations relevance as it does during its initial assessment (as described in Figure 5-1 and Section 5.3). The result of Woodside's assessment of relevance during the development of the EP is outlined at Appendix F, Table 1.

5.3.8 Assessment of Relevant Persons for the Proposed Activity

The result of Woodside's assessment of relevant persons in accordance with regulation 25(1) is outlined at Appendix F, Table 1 and Appendix F, Table 2.

Persons or organisations that Woodside assessed as not relevant but chose to contact at its discretion in accordance with Section 5.3.4, or self-identified and Woodside assessed as not relevant, are summarised at Appendix F, Table 1 and Appendix F, Table 3.

5.4 Consultation Material and Timing

Regulation 25(2) provides that a titleholder must give each relevant person sufficient information to allow the relevant person to make an informed assessment of the possible consequences of the activity on the functions, interests or activities of the relevant person. Regulation 25(3) provides that the titleholder must allow a relevant person a reasonable period for the consultation.

As set out in Section 5.2, Woodside notifies relevant persons of the proposed activities, respecting that consultation is voluntary, and collaborates on a consultation approach where further engagement is sought by the relevant person. The consultation process aims to be appropriate for the category of relevant persons and not all persons or organisations will require the same level of engagement. Woodside recognises that the level of engagement is dependent on the nature and scale of the PAA and PAP. Woodside acknowledges published guidance for good practice consultation, relevant to different sectors and disciplines. Woodside's methodology for providing relevant persons with sufficient information as well as a reasonable period of time to provide feedback is set out in this section.

5.4.1 Sufficient Information

Woodside produces a Consultation Information Sheet for each EP. This is provided to relevant persons and organisations and is also available on Woodside's website for interested parties to access and to provide feedback on. The Consultation Information Sheet typically includes:

- a description of the proposed petroleum activity
- the OA or PAA, dependent on the EP
- where the activity will take place
- the timing and duration of the activity
- a location map of the OA or PAA, and EMBA
- a description of the EMBA
- relevant exclusion zones
- a summary of relevant risks and mitigation and management control measures relevant to the proposed petroleum activity (PPA).

It also sets out contact details to provide feedback to Woodside.

The level of information necessary to assist a person or organisation to understand the impacts of the proposed activity on their functions, interests or activities may vary and may depend on the degree to which a relevant person is affected. For example, Woodside considers that relevant persons who may be impacted by planned activities in the PAA, as a result of temporary displacement due to exclusion zones, may require more targeted information relevant to their functions, interests or activities. Sufficient information may have been provided to a relevant person even where all documents requested by a relevant person have not been provided. Woodside acknowledges NOPSEMA's brochure entitled Consultation on offshore petroleum environment plans

information for the community, which advises persons being consulted that they may inform titleholders that they only want to be consulted in the very unlikely event of an oil spill.

Woodside places advertisements in selected local, state and national newspapers. This typically includes:

- the name of the EP Woodside is seeking feedback on
- an overview of the activity
- the consultation feedback date
- the ways in which a person or organisation can provide feedback.

Advertising in the local paper in the area of the activity is also consistent with the public notification process under section 66 of the Native Title Act 1993 for native title applications. Woodside typically aligns advertisement feedback timeframes with the timing described below. Feedback received is assessed in accordance with Section 5.3 to determine relevance and evidenced in Appendix F, Table 1 as appropriate.

Woodside utilises a range of tools to provide sufficient information to relevant persons, which may include one or more of the following:

- Consultation Information Sheet available on Woodside's website and shared directly with relevant persons
- Summary Consultation Information Sheet, presentations or summaries specific to a particular relevant person group
- subscription available on Woodside's website to receive notification of new Consultation Information Sheets for Woodside EPs
- emails
- letters
- phone calls
- face-to-face meetings (virtual or in person) with presentation slides or handouts as appropriate
- Let's Talk newsletter – digital and hard copy
- maps outlining a person or organisation's defined area of responsibility in relation to the proposed activity, for example a fisheries management area or defence training area
- community meetings, as appropriate
- attendance at on-the-ground community events or planned regional roadshows
- broader awareness campaigns on the how to be involved in the EP consultation process.

Woodside recognises that information may be provided to relevant persons in an iterative manner during the consultation process. Woodside considers that genuine two-way engagement may be demonstrated via information on incorporation of controls, where applicable, being provided to the relevant person so that the relevant persons understand how their input has been considered in the development of the EP.

Woodside communicates with relevant persons in different ways. Woodside recognises that, as part of genuine two-way dialogue, these forms of communication may evolve including, for example due to changes to organisation representation, as relationships are further established, or a preference for an alternative form of communication is expressed by a person or organisation. There might be limitations in how Woodside can consult with relevant persons.

Typical forms of communications for categories of relevant persons are set out below.

Category of relevant person	Typically accepted form of communication
Government departments / agencies – marine	Woodside applies NOPSEMA's guideline for engagement with Commonwealth government departments or agencies GL1887 – Consultation with Commonwealth agencies with responsibilities in the marine area – January 2023 by using email for its consultation unless another form of communication is requested. Other forms of communication, such as phone calls, meetings and/or presentation briefings are used on request.
Government departments / agencies – environment	
Government departments / agencies – industry	
Commercial fisheries and peak representative bodies	Commonwealth commercial fisheries: Email is used as the primary form of communication with Commonwealth commercial fisheries in the ordinary course of business. Other forms of communication, such as phone calls, and meetings and/or presentation briefings are used on request. State commercial fisheries and recreational marine users: The Western Australian Department of Primary Industries and Regional Development (DPIRD) has responsibility for managing the Fish Resources Management Act 1994 and Aquatic Resources Management Act 2016, which limits the provision of contact details from the register to the name and business address of licence holders. Alternative forms of communication are at the licence holder's discretion. Other forms of communication, such as phone calls, and meetings and/or presentation briefings are used on request. Peak representative bodies: Email is used as the primary form of communication with commercial fishery and recreational marine user peak representative bodies in the ordinary course of business. Other forms of communication, such as phone calls, and meetings and/or presentation briefings are used on request.
Recreational marine users and peak representative bodies	
Titleholders and Operators	Email is used as the primary form of communication between titleholders and operators in the ordinary course of business. Other forms of communication, such as phone calls, and meetings and/or presentation briefings are used on request.
Peak industry representative bodies	Email is used as the primary form of communication with peak representative bodies in the ordinary course of business. Other forms of communication, such as phone calls, and meetings and/or presentation briefings are used on request.
Traditional Custodians and nominated representative corporations	There are many forms of communication that Woodside uses on a case-by-case basis and as appropriate to or requested by the specific group, such as email, phone calls, meetings and community forums. Other forms of communication are used on request.
Native Title Representative Bodies	There are many forms of communication that Woodside uses on a case-by-case basis and as appropriate to or requested by the specific group, such as email, phone calls, meetings and community forums. Other forms of communication are used on request.
Historical heritage groups or organisations	NOPSEMA's guideline (GL1887 – Consultation with Commonwealth agencies with responsibilities in the marine area – January 2023) for engagement with government departments or agencies is used as a reference for Woodside's approach for communicating with historical heritage groups or organisations. Other forms of communication, such as phone calls, and meetings and/or presentation briefings are used on request.
Local government and recognised local community reference/liaison groups or organisations	Local government: NOPSEMA's guideline (GL1887 – Consultation with Commonwealth agencies with responsibilities in the marine area – January 2023) for engagement with local government is used as a reference for Woodside's approach for communicating with historical heritage groups or organisations. Community reference/liaison groups and chambers of commerce: Email and presentations are used as the primary form of communication with local community reference/liaison groups or organisations in the ordinary course of business. Other forms of communication, such as phone calls, and meetings and/or presentation briefings are used on request.
Other non-government groups or organisations	Email is used as the primary form of communication with Other non-government groups or organisations. Other forms of communication, such as phone calls, and meetings and/or presentation briefings are used on request.

Research Institutes and Local conservation groups or organisations	Email is used as the primary form of communication with research institutes and local conservation groups or organisations. Other forms of communication, such as phone calls, and meetings and/or presentation briefings are used on request.

Information which is provided to relevant persons for the purposes of consultation on this EP is summarised at Appendix F, Table 2.

Appendix F, Table 3 sets out the information which is provided to persons or organisations that are not relevant for the purposes of regulation 25 but which Woodside has chosen to contact.

When engaging in consultation, Woodside notifies relevant persons that, in accordance with regulation 25(4), the relevant person may request that the titleholder notifies NOPSEMA that particular information the person or organisation provides in the consultation not be published, and that information subject to that request will not be published under the Environment Regulations.

5.4.2 Reasonable Period for Consultation

Woodside seeks to consult in order to support preparation of its EP. Woodside recognises that what constitutes a reasonable period for consultation should be considered on a case-by-case basis, with reference to the nature, scale and complexity of the activity.

Woodside recognises that information may need to be provided to relevant persons in an iterative manner during the consultation process. Woodside considers that genuine two-way engagement may be demonstrated via information on incorporation of controls, where applicable, being provided to the relevant person so that the relevant person understands how their input has been considered in the development of the EP.

Woodside's methodology allows relevant persons a reasonable period for consultation (regulation 25(3)). A reasonable period for all relevant persons, including Traditional Custodians, to participate in consultation for this EP has been provided.

The consultation period under this EP has satisfied benchmark periods under other relevant legislative processes:

- Regulation 30 sets out a public consultation period of 30 days.
- The Department of Mines, Energy and Petroleum (DEMIRS) "Guidelines for Consultation with Indigenous People by Mineral Explorers" directs a period of 21-30 days of consultation with traditional owners.
- While repealed, guidance taken from the Aboriginal Cultural Heritage Act 2021—Consultation Guidelines (Government of Western Australia, 2023) suggests that up to 12 weeks may be a reasonable period to allow identification, contact and response from First Nations peoples (subject to any alternative timeframe being agreed through co-design of consultation).

This period of consultation demonstrates that Woodside has provided a "reasonable period" for relevant persons to consult in accordance with regulation 25(3). Commentary in the Tipakalippa Appeal judgment limits consultation to a process that must be capable of being discharged within a reasonable time:

"it must be taken to be the regulatory intention that the consultation requirement cannot be one that is incapable of being complied with within a reasonable time..."[21]

Woodside seeks feedback in order to support preparation of its EP. What constitutes a reasonable period for consultation is considered on a case-by-case basis, with reference to the person being consulted and the nature, scale and complexity of the activity.

[21] Santos NA Barossa Pty Ltd v Tipakalippa [2022] FCAFC 193 at paragraph [136].

Woodside's typical approach to providing a reasonable period for consultation is as follows:

- advertising in selected local, state and national newspapers to give persons or organisations the opportunity to understand the activity and identify whether their functions, interests or activities may be affected
- providing consultation materials directly to identified relevant persons as well as persons who are not relevant but Woodside chose to contact and providing a target date for feedback. Woodside acknowledges that feedback may be received from relevant persons following the target date
- acknowledging that the way in which Woodside provides consultation information may vary depending on the relevant person or organisation and, may depend on the degree to which a relevant person or organisation is affected. Different consultation processes may be required for relevant persons and organisations depending on the information requirements
- following up with relevant persons prior to EP submission. Where possible, Woodside will endeavour to use an alternative method of communication to contact the relevant person
- engaging in two-way dialogue with relevant persons or organisations where feedback is received.

Appendix F, Table 2 and Table 3 sets out a history of ongoing consultation and demonstrates that a reasonable period of consultation has been provided.

Woodside considers that consultation for this EP has closed.

As detailed in Section 5.6, if comments and feedback are received after the EP has been submitted, Woodside will consider those comments and update controls as appropriate and at all stages of the life of the EP as per Woodside's ongoing consultation approach described in Section 5.7.

5.4.3 Discharge of Regulation 25

The Full Federal Court made clear in the Tipakalippa Appeal that consultation should be approached in a "reasonable", "pragmatic" and "not so literal" way, so that consultation obligations were capable of being met by titleholders (Section 5.5.1).22 Consultation is a "real world activity" and must be capable of reasonable discharge.23 The Full Federal Court referred to Native Title cases as an illustration that reasonable limits should be applied to consultation efforts to ensure the process is workable.[24]

When the titleholder demonstrates that it has provided sufficient information and a reasonable period for consultation, then regulation 25 consultation requirements are met.25 Meeting these obligations requires evaluative judgement to determine reasonable satisfaction of the consultation obligation and, as such, the Regulator uses its discretion to determine if this criteria are met. The nature of the person being consulted and their function, interest and activity that may be affected, will inform the manner of consultation and the reasonable period to be afforded.26

While a titleholder is required to provide an opportunity to consult, the titleholder is not required to obtain consent to engage in the activity from a person being consulted, or confirmation from a person being consulted, that consultation is complete. The Federal Court has commented that a "reasonable

[22] Santos NA Barossa Pty Ltd v Tipakalippa [2022] FCAFC 193 [89], [98], [103]-[104] and [109].
[23] Santos NA Barossa Pty Ltd v Tipakalippa [2022] FCAFC 193 at [89].

[26] Explanatory Statement, Offshore Petroleum and Greenhouse Gas Storage (Environment) Regulations 2023, page 30 and Santos NA Barossa Pty Ltd v Tipakalippa [2022] FCAFC 193 at [153].

opportunity" for consultation must be afforded to relevant persons.[27] A reasonable opportunity may not be every opportunity requested and is limited to reasonable opportunities to consult.

Woodside has completed steps required to discharge its consultation obligations. Woodside has provided sufficient information and a reasonable period of time to enable relevant persons to make an informed assessment of the possible consequences of the activity on their functions, interests or activities; and sufficient time to provide relevant feedback for Woodside to assess relevant persons objections or claims. Woodside has also provided a reasonable opportunity for there to be genuine two-way dialogue on a person's claims or objections.

Woodside has discharged its duty under regulation 25 and considers that is complete.

Appendix F, Table 2 and Table 3 of this EP sets out the history of consultation under regulation 25. To the extent a relevant person says that they have further information to share or claims that consultation under regulation 25 has not been completed, Appendix F, Table 2 and Table 3 provide reasons why Woodside considers consultation under regulation 25 has been met, in relation to that relevant person.

5.5 Context of Consultation Approach with First Nations

To comply with regulation 25, Woodside identifies and consults Traditional Custodians whose functions, interests or activities may be affected by the activities under an EP.

5.5.1 Approach to Methodology − Woodside's Interpretation of Tipakalippa Appeal

Woodside has implemented a consultation methodology consistent with regulation 25 and guidance provided in the Tipakalippa Appeal. Woodside's consultation methodology allows for a sufficiently broad capture of Traditional Custodian relevant persons, provides for informed consultation, follows cultural protocols and allows a reasonable opportunity for consultation with Traditional Custodians whose functions, interests or activities may be affected by the activity described in this EP.

Woodside notes the Full Federal Court discussed several Native Title Act 1993 (Cth) cases in response to a submission made in that case that a requirement under regulation 25 to consult "each and every" relevant person would be "unworkable". The reference to native title cases dealt with how decision-making processes under the NTA requiring "all" members of a group to be contacted for communal approval are interpreted by courts in a "reasonable", "pragmatic" and "not so literal" way,[28] and how obligations to consult "each and every" person under regulation 25 should be interpreted in a similarly pragmatic way, so that consultation is workable. The reference to NTA authorities was made by analogy:

"It can be seen that the terms of [the native title legislation] are somewhat absolute – "all". However, [the native title legislation] has consistently been construed in a way that is not so literal … The cases concerning [the native title legislation] … have reiterated … that [the native title legislation] does not require that "all" of the members of the relevant claim group be involved in the decision. The key question will be whether a reasonable opportunity to participate in the decision-making process has been afforded by the notice for a relevant meeting." [29]

"We consider the authorities in relation to processes under the NTA to be illustrative of how a seemingly rigid statutory obligation to consult persons holding a communal interest may operate in a workable manner"[30] *(emphasis added).*

[27] Cooper v National Offshore Petroleum Safety and Environmental Management Authority (No 2) [2023] FCA 1158 at paragraph [11]; Santos NA Barossa Pty Ltd v Tipakalippa [2022] FCAFC 193 at [153].
[28] Santos NA Barossa Pty Ltd v Tipakalippa [2022] FCAFC 193 at paragraph [95], [98], [103]-[104] and [109].
[29] Santos NA Barossa Pty Ltd v Tipakalippa [2022] FCAFC 193 at paragraph [98].
[30] Santos NA Barossa Pty Ltd v Tipakalippa [2022] FCAFC 193 at paragraph [96].

"there is no definition of what constitutes "consultation for the purpose of Reg11A [now regulation 25] ... A titleholder will need to "demonstrate" to NOPSEMA that what it did constituted consultation appropriate and adapted to the nature of the interests of the relevant persons"[31] *(emphasis added).*

The Judgment in the *Tipakalippa Appeal* makes it clear that a titleholder will have some decisional choice in identifying which person(s) are to be approached, how the information will be given to allow the "relevant person" to assess the possible consequence of the proposed activities on their functions, interests or activities, and how the requisite consultation is undertaken.[32] Consultation is not fixed to a rigid process and will be adapted so that it is informed by the relevant person or group. Woodside has met its regulation 25 requirements through its consultation methodology (Section 5.5.2).

Consistent with the *Tipakalippa Appeal*, Woodside considers NTA-style "full group" meetings are not required for there to be compliance with regulation 25. Nominated representative corporations (such as PBCs established under the NTA) have a designated role of representing the views of their member Traditional Custodians. They have established methods for engaging with their own members. Woodside will not undermine the purpose and authority of nominated representative corporations by requiring full group meetings where the nominated representative corporations have not requested engagement of members via full group meetings. It is not appropriate for titleholders to direct or challenge the nominated representative corporations on how to engage with their members.

Woodside's approach described below demonstrates that sufficient information and a reasonable opportunity is provided to individual Traditional Custodians to provide feedback on Woodside activities beyond the opportunity provided to nominated representative corporations.

5.5.2 Consultation Method

Woodside's First Nations team has experience in engaging and working with First Nations organisations and individuals, including within the Commonwealth native title and cultural heritage systems, and state and territory cultural heritage and land rights systems. The team understands the complexities of making information accessible to groups and individuals and engaging in accordance with First Nations groups' established channels of communication and methods of consultation. The First Nations team exercises its professional judgement and is respectful of long-standing relationships (where in place) when considering consultation with First Nations groups. The First Nations team's approach is also informed by the established systems of recognition for First Nations groups and their nominated representative corporations within particular jurisdictions. For example, the methodology for engaging with First Nations groups in the Northern Territory (not relevant for this EP) tends to centre around engagement through Aboriginal land councils (under the Aboriginal Land Rights (Northern Territory) Act 1976 (Cth)) as well as community meetings that target clan groups where they do not have PBCs or other nominated representative corporations to represent them.

By contrast, recognition for First Nations groups and their nominated representative corporations in Western Australia falls under the Native Title Act 1993 (Cth) because the vast majority of the Western Australian coastline is settled under the native title regime. This means that the methodology and process for consultation in Western Australia places greater emphasis on, but is not limited to, Native Title Representative Bodies and PBCs.

Native title determinations provide certainty about the appropriate Traditional Custodian groups that have the cultural authority to speak for country adjacent to the EMBA and help Woodside to identify Traditional Custodian persons and groups asserting Traditional Custodianship. The Judgment in the

[31] Santos NA Barossa Pty Ltd v Tipakalippa [2022] FCAFC 193 at paragraph [104].
[32] Santos NA Barossa Pty Ltd v Tipakalippa [2022] FCAFC 193 at paragraph [47] and [48].

Tipakalippa Appeal endorses methods of consultation with groups of relevant persons that are appropriate and adapted to the characteristics of groups.33 Woodside's consultation methodology is adapted and appropriate to the recognised systems of communal interests in Western Australia.

In Western Australia (relevant for this EP), Woodside has sought to follow the established, effective and respectful means of communication used by Native Title Representative Bodies and nominated representative corporations (including PBCs) with their respective First Nations communities. Woodside follows these processes for the appropriate broad capture of individuals' awareness of our activities, to self-identify (Section 5.5.2.2), and to provide feedback to inform the management of environmental impacts and risks.

Using these processes, Woodside communicates information about EPs by:

- advertising in relevant newspapers. This encourages self-identification, by advertising proposed activities widely through newspapers that have national and intra-state circulation, i.e., Koori Mail, National Indigenous Times, The West Australian
- creating carefully considered Consultation Summary Sheets with information developed by an Indigenous member of the First Nations Team to remove jargon and provide relevant information for people to have informed understandings about the activities
- direct contact through nominated representative corporations
- utilising social media (i.e. Facebook/Instagram), texts and emails. These mediums are the preferred communication methods used by Traditional Custodians throughout Western Australia and, on that basis, used by Native Title Representative Bodies and other government agencies and industry, to engage with Traditional Custodians or call meetings. First Nations woman, Professor Bronwyn Castle, through 10 years of research found "Social media is an intrinsic part of daily life. The use of Facebook is around 20 per cent higher [among First Nations people] than the national average across all geographical locations" (Social media mob: being Indigenous online, Professor Bronwyn Carlson (2018))
- For ongoing consultation post regulation 25 consultation, Woodside has a Program of Ongoing Engagement with Traditional Custodians which sets out Woodside's commitment to ongoing engagement and support to care for and manage country, including Sea Country. The program was developed in response to Traditional Custodian feedback.
- Woodside has members of its First Nations team who are based in Karratha and Roebourne and who serve as on-Country points of contact for First Nations organisations and individuals. These team members have broad local knowledge and established, on-the-ground relationships within communities. This helps contribute to positive outcomes including encouraging First Nations attendance and involvement at Woodside's information sessions and Community roadshows. Team members on the ground engage in a great deal of preparatory work including by distributing information and providing notice to the community to support First Nations attendance at information sessions and Community roadshows.
- From the commencement of engagement with Traditional Custodians, Woodside seeks direction on how they prefer to be consulted and has consulted accordingly. Consultation processes that are informed by Traditional Custodians and co-designed on a case-by-case basis and includes their direction as to cultural protocols, structure of consultation and who to appropriately consult with (such as elders)
- Holding meetings on country at a place and time agreed with Traditional Custodians and offering and providing financial assistance for meeting expenses (as appropriate)

[33] Santos NA Barossa Pty Ltd v Tipakalippa [2022] FCAFC 193 at paragraph [95].[104].[153].

- Providing information specifically designed to be easily understood, to reach all relevant people, and give a reasonable period of time for those people to make an informed assessment of the possible consequences of the proposed activity on them.

The First Nations team approach to consultation is also consistent with the Federal Court's decision in the *Munkara Case.* The *Munkara Case* notes that the word "culture" (and hence the word "cultural") has a communal aspect to it. To establish cultural features, it is necessary that the beliefs and values are held by the relevant people as a people. For values, features or beliefs that are expressed by an individual to be "cultural" they cannot simply be an individual's belief - the belief must have a communal aspect too, and demonstrate that the "individual beliefs are broadly representative of the beliefs of other members of the group"[34]. The phrase "cultural features", when applied to "people" as constituent parts of an ecosystem, is not directed to idiosyncratic views or beliefs of an individual35. When the First Nations team is told that a particular value is cultural by an individual Traditional Owner, that information is taken back to the relevant cultural authority to test its broad acceptance. In the case of gender sensitive information, that information would be restricted to the specific gender within the community.

5.5.2.1 Identification of Relevant Persons

To undertake consultation, Woodside has developed a methodology for identifying relevant persons, in accordance with regulation 25(1) (Section 5.2 and 5.3).

Specific to Woodside's approach for identifying relevant Traditional Custodians, Woodside's First Nations Communities Policy and consultation approach is guided by Traditional Custodians by directing consultations through their nominated representative corporation. This has been implemented by Woodside through consultation with a nominated representative corporation, where that corporation has advised Woodside that it acts as the representative body for a Traditional Custodian group and has requested that Woodside engage with it as the representative body for that Traditional Custodian group.

Woodside asks nominated representative corporations (such as PBCs) and Native Title Representative Bodies to identify individuals that should be consulted, and enables individuals to self-identify in response to national and local advertising, social media and community engagement opportunities (Section 5.5.2.54). Where there is a nominated representative corporation for an area, unless directed by the nominated representative corporation, Woodside does not directly approach individuals for consultation, because this has the potential to undermine the role of the nominated representative corporation. Approaching individuals directly is a practice that is no longer considered acceptable because of divisions it has been shown to cause in communities. In addition to asking for the identification of individuals, Woodside also asks nominated representative corporations to distribute consultation information to whomever the nominated representative corporations deem appropriate, including members of the nominated representative corporations who are communal rights holders.

Having said this, as set out in further detail in Section 5.5.2.54 below, individuals are also given the opportunity to self-identify, consult and provide their own feedback on the proposed activity. When approached in this way, Woodside will engage individuals as relevant persons and will also (subject to any confidentiality or cultural restrictions) advise the nominated representative body of the consultation where it relates to cultural values. These methods of consultation are consistent with requirements for notification under the Native Title Act 1993 (Cth), such as under the future act provisions (section 29), which requires notification of the Native Title Representative Body, the PBC (or nominated representative) and notification through newspapers. The notification process has been selected as a respectful, practical and pragmatic analogue for consultation with First Nations

[34] Munkara v Santos NA Barossa Pty Ltd (No 3) [2024] FCA 9 at [205]
[35] Munkara v Santos NA Barossa Pty Ltd (No 3) [2024] FCA 9 at [205]

peoples, rather than requiring members to be notified via a formal authorisation process which seeks, from members, authorisation of agreements and native title/compensation claims under the Native Title Act 1993 (Cth)36.

In this consultation, Woodside requested nominated representative corporations to identify any potential individual relevant persons for consultation. Woodside requests nominated representative corporations to distribute consultation materials to their members. However, Woodside recognises that the process is voluntary and that it cannot compel nominated representative corporations (such as PBCs) to do so. Woodside also recognises that it would not be appropriate to seek to audit the nominated representative corporations for compliance with any member consultation request.

5.5.2.2 Opportunity to Self-identify and Identifying Other Individuals

Woodside requests nominated representative corporations and Native Title Representative Bodies to identify other individuals to consult with or individuals who may seek to self-identify for a proposed activity. Woodside also advertises broadly through Indigenous, national and local advertising, social media and community engagement opportunities to provide individuals with an opportunity to consult. Woodside does not directly approach individuals for consultation, as this undermines the role of the nominated representative corporations (Section 5.5.2.1). Woodside's approach to providing individual Traditional Custodians the opportunity to self-identify and consult for an EP is as follows:

- Woodside applies the principles of self-determination when consulting with Traditional Custodians by consulting through the Traditional Owners authorised representative entities.
- Recognising the function of nominated representative corporations (such as PBCs) and Native Title Representative Bodies to represent communal interests and manage cultural values, Woodside requests that the information provided to representative entities is provided to their members but Woodside recognises the process is voluntary and Woodside cannot compel them to do so, nor seek to audit the representative entities for compliance with any request.
- Representative entities cannot provide membership details to Woodside due to individual confidentiality requirements.
- Woodside requests advice as to who else Woodside should be consulting but recognises the process is voluntary and cannot compel nominated representative corporations to provide this information.
- Modern Indigenous engagement practises rely on the building and maintaining of respectful relationships. To date, most nominated representative corporations have requested the building of that relationship, where one is not already in place.
- While Woodside has, in some cases, approached individual directors and Elders outside of this process due to requirements imposed in EP consultation, this approach is considered inappropriate by modern Indigenous engagement standards, fundamentally undermining the authority of the authorised representative entity and can be detrimental to the relationship.

For this proposed activity, Woodside requested nominated representative corporations (including PBCs) and Native Title Representative Bodies to identify any potential individual relevant persons for consultation, and to distribute consultation materials to their member base. However, Woodside recognises the process is voluntary and it cannot compel them to do so nor seek to audit the representative entities for compliance with any request. Woodside has not been directed to engage individual Traditional Custodians by nominated representative corporations for this proposed activity.

[36] Santos NA Barossa Pty Ltd v Tipakalippa [2022] FCAFC 193, at [104]

Woodside has nevertheless provided reasonable opportunity for individual Traditional Custodians to engage in consultation through appropriate and adapted consultation methods.

5.5.2.3 Sufficient Information

Woodside recognises that the information sufficient to allow a person or organisation to make an informed assessment of the possible consequences of the proposed activity on their functions, interests or activities may vary and may depend on the degree to which a relevant person is potentially affected.

Woodside produces Consultation Information Sheets for each EP which is provided to relevant persons and organisations for the purpose of seeking feedback on the activity (Section 5.4.1). In response to feedback from Traditional Custodians' feedback on information provisions, Woodside has tailored effective consultation methods for its activities, specifically designed for Traditional Custodians, so that information is provided in a form that is readily accessible and appropriate. The targeted Summary Information Sheet developed and reviewed by Woodside's First Nations Engagement Team and First Nations staff to ensure that content is appropriate to the intended recipients, which is then provided to relevant Traditional Custodian groups. Phone calls are made to provide context to the consultation.

Where face-to-face consultation meetings are requested, Woodside coordinates engagement at the Traditional Custodians location of choice (where practicable) and with their nominated attendees. Key project personnel, environmental and First Nations relations experts are typically present to enable effective communication and prompt response to questions. Materials for these sessions incorporate visual aids such as photos, maps and videos, and plain language suitable for people with a non-technical background.

During consultation, Woodside provides relevant persons with additional information as appropriate in response to requests. There is no requirement to provide relevant persons with all information or documents requested and a titleholder will have provided sufficient information even where it has not provided all information or documents requested.

Woodside has sought to provide sufficient information to individual members of nominated representative corporations (such as PBCs) by providing information to representative bodies and requesting dissemination with members. However, Woodside recognises consultation is voluntary and it cannot compel them to do so, nor would it be appropriate to seek to audit the representative entities for compliance with any request.

5.5.2.4 Reasonable Period for Consultation

Woodside seeks to consult in order to support preparation of its EP. Woodside recognises that what constitutes a reasonable period for consultation should be considered on a case-by-case basis, with reference to the nature, scale and complexity of the activity (Section 5.4.2).

5.5.2.5 Discharge of Regulation 25

Woodside's consideration and approach to discharging regulation 25 for relevant persons is discussed in Section 5.4.3. In addition to this, Woodside has considered the application of regulation 25 specific to First Nations based on the *Tipakalippa Appeal*.

In relation to Traditional Custodian relevant persons (and all relevant persons), Woodside has discharged its duty under regulation 25 of the Environment Regulations. Woodside considers that consultation under regulation 25 is complete.

5.6 Providing Feedback and Assessment of Merit of Objections or Claims

There are a number of ways in which feedback can be provided. Feedback can be provided through the Woodside feedback email or via the Woodside feedback toll free phone line as outlined in the

Consultation Information Sheet and the Woodside website. Where appropriate, consultation may also be supported by phone calls or meetings. An EP feedback form is also available on Woodside's website enabling stakeholders to provide feedback on proposed activities, or to request additional information.

Woodside consults widely on its EPs and notes that feedback is received in various forms. Feedback that is considered inappropriate or that puts the environment, health, safety or wellbeing of Woodside employees or operations at risk will not be tolerated. Woodside respects people's rights to protest peacefully and lawfully but actions that put the environment, health, safety or wellbeing of Woodside employees or operations at risk go beyond those boundaries.

Woodside accepts feedback and engages in consultation in order to achieve the aims set out in Section 5.2. Woodside recognises that there are persons and organisations that take a view that Woodside's operations and/or growth projects should be stopped or at least delayed as far as possible. Whilst Woodside assesses the merits of objections or claims received, it acknowledges NOPSEMA's guidance in its brochure entitled Consultation on offshore petroleum environment plans information for the community, which states that relevant persons are free to respond on any matter and raise any concern, however this may not be able to be considered if it is outside the scope or purpose of the EP and approval process, for example, statements of fundamental objection to offshore petroleum activities or information containing personal threats or profanities. Under regulation 34(g), there is no requirement for a relevant person to agree or confirm that they have been adequately consulted.

Feedback from relevant persons is reviewed and an assessment of the merits is made of information provided as well as objections or claims about the adverse impact of each activity to which the EP relates. This might, for instance, be done through a review of data and literature and for relevance to the nature and scale of the activity outlined in the EP. Consistent with the aim of consultation in Section 5.2, Woodside will consider information received when reviewing and designing measures to put in place to minimise harm to relevant persons and where reasonable or practical to further manage impacts and risks to ALARP and acceptable levels.

Woodside considers feedback during consultation from relevant persons and other persons Woodside chose to contact (see Section 5.3.4). This information is summarised in Appendix F, Table 1 and Table 2 of the EP and includes a statement of Woodside's response, or proposed response, if any, to each objection and claim.

In accordance with regulation 26(8), sensitive information (if any) in an EP, and the full text of any response by a relevant person to consultation under regulation 25, must be contained in the sensitive information part of the plan and not anywhere else in the plan.

5.7 Ongoing Consultation

Consultation can continue to occur during the life of an EP, including after an EP has been accepted by NOPSEMA.

As per Woodside's ongoing consultation approach (refer to Section 7.8.2.1), feedback and comments received from relevant persons continue to be assessed and responded to, as required, throughout the life of an EP, including during its assessment and once accepted, in accordance with the intended outcome of consultation.

Should consultation feedback be received following the acceptance of an EP that identifies a measure or control that Woodside considers requires implementation or updates to meet the intended outcome of consultation, Woodside will apply its Management of Change and Review process as appropriate (see Section 7.6).

6. ENVIRONMENTAL IMPACT AND RISK ASSESSMENT, PERFORMANCE OUTCOMES, STANDARDS AND MEASUREMENT CRITERIA

6.1 Overview

This section presents the impact and risk analysis and evaluation, EPOs, EPSs and MC for the Petroleum Activities Program, using the methodology described in Section 2. MEEs require a further level of analysis and are assessed separately in Section 6.8.

6.2 Analysis and Evaluation

As required by Regulation 21(5) and 21(6) of the Environment Regulations, the analysis and evaluation demonstrate that the identified risks and impacts associated with the Petroleum Activities Program are reduced to ALARP, are of an acceptable level and consider all operations of the activity, including potential emergency conditions.

Impacts and risks identified during the ENVID (including Decision Type, current risk level, acceptability of risk and tools used to demonstrate acceptability and ALARP) have been divided into two broad categories:

- planned (routine and non-routine) activities; and
- unplanned events (accidents, incidents or emergency situations).

Within these categories, impact and risk assessment groupings are based on environmental aspect[37] (e.g. emissions, physical presence, etc.). For all hazardous events considered, the worst credible consequence was assumed.

The ENVID identified 11 impacts and 15 risks associated with the Petroleum Activities Program. Planned activities and unplanned events are summarised in Table 6-1 and Table 6-2.

The analysis and evaluation for the Petroleum Activities Program indicate that current environmental risks and impacts associated with the activity are reduced to ALARP and are of an acceptable level, as discussed further in Section 6.

[37] An environmental aspect is an element of the activity that can interact with the environment.

Table 6-1: Environmental impact and risk analysis summary table – planned activities

Aspect	EP Section	Source of Impact	Key Potential Environmental Impacts (Refer to relevant EP section for details)	Controlled Impact Classification	Residual Impact Level (ALARP controls in place)	Acceptability of Impact
Planned Activities (Routine and Non-routine)						
Physical Presence: Interaction with other Marine Users	6.7.1	Presence of facility displacing and/or excluding other users from PSZ during routine and IMMR activities within the PAA, respectively.	Potential isolated social impact resulting from interference with other sea users (e.g. commercial and recreational fishing, and shipping).	F	Socio-Economic – No lasting effect (<1 month). Localised impact not significant to area/item of cultural significance.	Broadly Acceptable
		Presence of MODU, AHVs, installation vessels and other support vessels displacing and/or excluding other users during Xena-03 Tie-back activities.				
		Presence of subsea infrastructure interfering with or displacing third party vessels (commercial fishing).				
Physical Presence: Disturbance to the Seabed	6.7.2	Presence of Pluto Facility and subsea infrastructure	Localised modification of seabed habitat (formation of artificial reef) within PAA.	E	Environment – Slight, short-term impact (< 1 year) on species, habitat (but not affecting ecosystem function), physical or biological attributes.	Broadly Acceptable
		Subsea operations, inspection, maintenance and repair activities including installation of pig receivers/launchers at the subsea wells.	Potential minor, localised modification of seabed habitat within PAA.	E	Environment – Slight, short-term impact (< 1 year) on species, habitat (but not affecting ecosystem function), physical or biological attributes.	
		Presence of redundant infrastructure remaining infield until Facility EOFL.	Potential slight, short-term loss or damage to benthic habitats, including benthic communities and marine primary producers.	F	Environment – No lasting effect (<1 month). Localised impact not significant to environmental receptor.	
		Disturbance to seabed from drilling operations.		F	Environment – No lasting effect (<1 month). Localised impact not significant to environmental receptor.	
		Disturbance to seabed from subsea installation of infrastructure (e.g. flowlines, umbilicals, flying leads) as well as rectification and stabilisation activities (e.g. installation of concrete mattresses).		F	Environment – No lasting effect (<1 month). Localised impact not significant to environmental receptor.	
		Disturbance to seabed from ROV operation (including localised sediment relocation from sediment mobilisation techniques and marine growth removal).		E	Environment – Slight, short-term impact (<1 year) on species, habitat (but not affecting ecosystem function), physical or biological attribute.	
		Disturbance to seabed from mooring installation.		E	Environment – Slight, short-term impact (<1 year) on species, habitat (but not affecting ecosystem function), physical or biological attribute.	
		Placement and retrieval of seabed transponders and temporary installation aids.		E	Environment – Slight, short-term impact (<1 year) on species, habitat (but not affecting ecosystem function), physical or biological attribute.	
Acoustic Emissions: Generation of Noise for Facility Operations	6.7.3	Noise generated within the PAA from: Pluto Facility and associated infrastructure Vessels (ASV and support vessels) Helicopters Subsea IMMR activities	Potential localised behavioural impacts to marine fauna around and within the PAA.	F	Environment – No lasting effect (<1 month). Localised impact not significant to environmental receptor.	Broadly Acceptable
Acoustic Emissions: Generation of Noise during Xena-03 Tie-Back Activities	6.7.4	Generation of noise from MODU, AHVs and support vessels.	Slight, short-term impacts to marine mammals, reptiles and fish, varying from behavioural responses to physiological impact (TTS).	F	Environment – Slight, short-term impact (< 1 year) on species, habitat (but not affecting ecosystem function), physical or biological attributes.	Broadly Acceptable
		Generation of noise from DP systems on support vessels		F	Environment – Slight, short-term impact (< 1 year) on species, habitat (but not affecting ecosystem function), physical or biological attributes.	

Aspect	EP Section	Source of Impact	Key Potential Environmental Impacts (Refer to relevant EP section for details)	Controlled Impact Classification	Residual Impact Level (ALARP controls in place)	Acceptability of Impact
		Generation of noise from cutting of well infrastructure and contingency activities		F	Environment – No lasting effect (< 1 month). Localised impact not significant to environmental receptors.	
Routine and Non-Routine Discharges: Discharge of Hydrocarbons and Chemicals	6.7.5	Discharge of subsea control fluids.	Localised decrease in water quality around subsea system within PAA with no lasting effect.	F	Environment – No lasting effect (< 1 month). Localised impact not significant to environmental receptors.	Broadly Acceptable
		Discharge of hydrocarbons remaining in subsea pipeworks and equipment as a result of subsea intervention works (including pigging).	Slight short term decrease in water quality at release location during IMMR activities.	E	Environment – Slight, short-term impact (< 1 year) on species, habitat (but not affecting ecosystems function), physical or biological attributes.	
		Discharge of chemicals remaining in subsea pipeworks and equipment or the use of chemicals for subsea IMMR activities.	Localised decrease in water quality at release location during IMMR activities.	F	Environment – No lasting effect (< 1 month). Localised impact not significant to environmental receptors.	
		Discharge of minor fugitive hydrocarbons from subsea equipment.	Potential slight short-term, localised decrease in water quality around subsea system within PAA with no lasting effect.	F	Environment – No lasting effect (< 1 month). Localised impact not significant to environmental receptors.	
		Discharge of chemicals (e.g. MEG) during installation and leak testing of new infrastructure.	Localised decrease in water quality at discharge location during installation and leak testing of new infrastructure.	F	Environment – No lasting effect (< 1 month). Localised impact not significant to environmental receptors.	
Routine and Non-Routine Marine Wastewater Discharges: Utility Systems and Drains	6.7.6	Discharge of sewage, grey water and putrescible waste from the Pluto Facility, MODU, ASV, installation and support vessels to the marine environment.	Potential localised, short-term decrease in water quality (increased nutrients and biological oxygen demand) at the discharge location.	F	Environment – No lasting effect (< 1 month). Localised impact not significant to environmental receptors.	Broadly Acceptable
		Discharge of deck, bilge and drain water from the Pluto Facility, MODU, ASV, installation and support vessels to the marine environment.	Potential localised, short-term decrease in water quality (increased hydrocarbon and chemical concentrations) at the discharge location.	F	Environment – No lasting effect (< 1 month). Localised impact not significant to environmental receptors.	
		Discharge of brine and cooling water from the Pluto Facility, MODU, ASV, installation and support vessels to the marine environment.	Negligible, localised increase in salinity at the discharge location.	F	Environment – No lasting effect (< 1 month). Localised impact not significant to environmental receptors.	
Routine and Non-Routine Discharges: Produced Water	6.7.7	Discharge of produced water during routine and non-routine operations.	Potential slight short-term, localised decrease in water quality (increased hydrocarbon and chemical concentrations) at discharge location and within mixing zone, with potential impacts to marine fauna (toxicity).	E	Environment – Slight, short-term impact (< 1 year) on species, habitat (but not affecting ecosystem function), physical or biological attributes.	Broadly Acceptable
Routine and Non-Routine Discharges: Drill Cuttings, Drilling Fluids and Well Removal Fluids	6.7.8	Routine discharge of WBM drill cuttings to the seabed and the marine environment	Potential slight, short-term toxic effects to marine biota, as well as localised reduction in water quality with potential effects on both water quality and benthic communities	E	Environment – Slight, short-term impact (< 1 year) on species, habitat (but not affecting ecosystem function), physical or biological attributes.	Broadly Acceptable
		Routine discharge of drilling muds (WBM) to the seabed and the marine environment		D		
		Non-routine discharge of treated NWBM drill cuttings to the marine environment		D		
		Non-routine discharge of wash water from mud pits and vessel tank wash fluids		E		
		Routine discharge of well clean-out fluids		E		
		Non-routine discharge of well annular fluids		F		
Routine and Non-Routine Discharges: Cement,	6.7.9	Routine discharge of cement and cementing fluids, to the seabed and the marine environment.	Potential slight, short term toxic effects to marine biota, as well as localised reduction in water quality	F		Broadly Acceptable

Aspect	EP Section	Source of Impact	Key Potential Environmental Impacts (Refer to relevant EP section for details)	Controlled Impact Classification	Residual Impact Level (ALARP controls in place)	Acceptability of Impact
Cementing Fluids, Subsea Well Fluids, Unused Bulk Product and Subsea Chemicals from Xena-03 Tie-back Activities		Routine discharge of subsea well fluids (including BOP and well construction activity control fluids).	with potential effects on both water quality and benthic communities.		Environment – No lasting effect (< 1 month). Localised impact not significant to environmental receptors.	
		Produced / reservoir water disposal				
		Non-routine discharge of unused bulk products at campaign end.				
Routine and Non-routine Atmospheric (direct) and GHG Emissions (direct and indirect)	6.7.10	Operational flaring, exhaust emissions from fuel combust–on, fugitive emissions from the Pluto facility.	Potential short-term localised decrease in air quality, limited to the airshed local to the facility.	F	Environment – No lasting effect (< 1 month). Localised impact not significant to environmental receptors.	Broadly Acceptable
		Exhaust emissions from fuel combustion and incinerators on the ASV, MODU, installation and support vessels and helicopters				
		Contingent MODU flaring (well test non-routine) during well unloading for pressure test and clean up.				
		Contingent venting of gas during drilling (e.g. well kick)				
		Consideration of indirect emissions associated onshore processing, third party transportation, regassification and combustion by end users				
Routine Atmospheric Emissions: Indirect Emissions from Gas Processing Onshore	6.7.11	Consideration of potential indirect impact from atmospheric emissions associated with onshore processing of Pluto gas.	Negligible, small contribution to cumulative air quality relative to defined air quality criteria. Risk of processing of Pluto gas at onshore facilities adversely impacting rock art on Murujuga is considered to be low, and no impact classification assigned.	F	Environment – No lasting effect (< 1 month). Localised air quality impact not significant to environmental receptors.	Broadly Acceptable
Routine Light Emissions: Light Emissions from Facility Operations and Xena-03 Tie-back Activities	0	Light emissions from the Pluto Facility, ASV, MODU, installation and support vessels.	Negligible, localised potential for behavioural disturbance of species in close proximity to riser platform and vessels.	F	Environment – No lasting effect (< 1 month). Localised impact not significant to environmental receptors.	Broadly Acceptable
		Light emissions during flaring.	Negligible, localised potential for behavioural disturbance of species in close proximity to riser platform and vessels.	F	Environment – No lasting effect (< 1 month). Localised impact not significant to environmental receptors.	

Table 6-2: Environmental impact and risk analysis summary table – unplanned events (including MEEs)

Aspect	EP Section	Source of Risk	Key Potential Environmental Impacts (Refer to relevant EP section for details)	Risk Rating				Acceptability of Impact
				Controlled Impact Classification	Residual Impact Level (ALARP controls in place)	Likelihood	Residual Risk Rating	
Unplanned Events (Accidents / Incidents) - MEEs								
Unplanned Hydrocarbon Release: Loss of Well Containment from Operating Wells (MEE-01)	6.8.5	Release of hydrocarbons resulting from subsea loss of well containment.	Potential significant impacts to the marine environment: medium-term impacts to sensitive nearshore areas of offshore islands and coastal shorelines disruption to marine fauna, including protected species potential short-term interference with or displacement of other sea users.	C	Environment - Moderate, medium-term impact (2–10 years) on ecosystem, species, habitat or physical or biological attribute.	1	M	Acceptable if ALARP
Unplanned Hydrocarbon Release: Subsea Equipment Loss of Containment (MEE-02)	6.8.6	Surface or subsea release from flowline, pipeline and riser to the marine environment and atmosphere within PSZ and to mid-point of export pipeline	Potential significant impacts to the marine environment: medium-term impacts to sensitive offshore and nearshore areas disruption to marine fauna, including protected species potential short-term interference with or displacement of other sea users	C	Environment - Moderate, medium-term impact (2–10 years) on ecosystem, species, habitat or physical or biological attribute.	1	M	Acceptable if ALARP
		Subsea release from export pipeline to the marine environment and atmosphere between mid-point of export pipeline to shore		B	Environment - Major, long-term impact (10–50 years) on highly valued ecosystem, species, habitat or physical or biological attribute.	1	M	
Unplanned Hydrocarbon Release: Loss of Structural Integrity (MEE-03)	6.8.7	Marine environment footprint and associated hydrocarbon and chemical release associated with structural collapse of riser platform	Potential significant impacts to the marine environment: medium-term impacts to sensitive offshore and nearshore areas disruption to marine fauna, including protected species potential short-term interference with or displacement of other sea users.	C	Environment - Moderate, medium-term impact (2–10 years) on ecosystem, species, habitat or physical or biological attribute.	1	M	Acceptable if ALARP
		Surface or subsea release from flowline, pipeline and riser to the marine environment and atmosphere within PSZ (MEE-02) – caused by loss of structural integrity		C	Environment - Moderate, medium-term impact (2–10 years) on ecosystem, species, habitat or physical or biological attribute.	1	M	
Unplanned Hydrocarbon Release: Loss of Marine Vessel Separation (MEE-04)	6.8.8	Hydrocarbon release of marine diesel to the marine environment from vessel due to collision within the PSZ.	Potential significant impacts to the marine environment: medium-term impacts to sensitive offshore and nearshore areas disruption to marine fauna, including protected species potential short-term interference with or displacement of other sea users.	C	Environment - Moderate, medium-term impact (2–10 years) on ecosystem, species, habitat or physical or biological attribute.	1	M	Acceptable if ALARP
		Hydrocarbon release from pipeline, flowline(s) and riser(s) to the marine environment and atmosphere (MEE-02/03) caused by collision and structural integrity failures.		C	Environment - Moderate, medium-term impact (2–10 years) on ecosystem, species, habitat or physical or biological attribute.	1	M	
		Marine environment footprint and associated hydrocarbon and chemical release associated with platform loss of structural integrity (MEE-03) caused by collision.		C	Environment - Moderate, medium-term impact (2–10 years) on ecosystem, species, habitat or physical or biological attribute.	1	M	
Unplanned Hydrocarbon Release: Loss of Control	6.8.9	Surface or subsea release from flowline, pipeline and riser to the marine environment and atmosphere within PSZ	Potential significant impacts to the marine environment:	C	Environment - Moderate, medium-term impact (2–10 years) on ecosystem,	1	M	Acceptable if ALARP

Unplanned Discharge: Drilling Fluids	6.9.6	Accidental discharge of project fluids (WBM/NWBM/base oil) and cement to marine environment	Potential slight short-term impacts to the marine environment including disruption to marine fauna, including protected species, and/or temporary impacts to water quality.	E	Environment – Slight, short-term impact (< 1 year) on species, habitat (but not affecting ecosystem function), physical or biological attributes.	1	L	Broadly Acceptable
Unplanned Discharges: Hazardous and Non-hazardous Waste Management	6.9.7	Incorrect disposal or accidental discharge of non-hazardous and hazardous waste to the marine environment.	Potential slight short-term impacts to the marine fauna, and localised temporary impacts to water quality and marine sediments.	E	Environment – No lasting effect (< 1 month). Localised impact not significant to environmental receptors.	2	M	Broadly Acceptable
Physical Presence: Seabed Disturbance from Dropped Objects or Loss of Station Keeping Leading to Anchor Drag	6.9.8	Dropped objects resulting in the disturbance of benthic habitat	Potential minor localised impact to benthic habitat as well as potential seabed infrastructure damage.	D	Environment - Minor, short-term impact (1–2 years) to a community or highly valued area/item of cultural significance.	1	L	Broadly Acceptable
		Loss of station keeping of the MODU leading to anchor drag and the disturbance of benthic habitat		D	Environment - Minor, short-term impact (1–2 years) to a community or highly valued area/item of cultural significance.	1	L	
Physical Presence: Interactions with Marine Fauna	6.9.9	Physical presence of MODU, ASV, installation and support vessels resulting in collision with marine fauna.	Potential injury or death of marine fauna (single animal), including protected species.	E	Environment – Slight, short-term impact (< 1 year) on species, habitat (but not affecting ecosystem function), physical or biological attributes.	1	L	Broadly Acceptable
Physical Presence: Introduction of Invasive Marine Species	6.9.10	Invasive species in vessel ballast tanks or on vessels/submersible equipment	Potential introduction of invasive marine species possibly resulting in an alteration of the localised environment.	E	Environment – Slight, short-term impact (< 1 year) on species, habitat (but not affecting ecosystem function), physical or biological attributes.	1	L	Broadly Acceptable

6.2.1 Cumulative Impacts

Woodside has assessed the cumulative impacts of the Petroleum Activities Program in relation to other relevant petroleum activities that could realistically result in overlapping temporal and spatial extents. The closest facilities to the Pluto Riser Platform and Pluto Export Pipeline include the Wheatstone platform, 5 km north, and the Stag A platform 8 km south, respectively (Section 4.10.5). However, given the concentration of sources of environmental risks and impacts from the Petroleum Activities Program are localised, the potential for cumulative impacts is considered to be low. Cumulative impacts are discussed for sources of risk and impacts where such impacts were deemed to be credible.

6.3 Environmental Performance Outcomes, Standards and Measurement Criteria

Regulation 21(7) of the Environment Regulations requires that an EP includes EPOs, EPSs and MC that address legislative and other controls to manage the environmental risks and impacts of the activity to ALARP and Acceptable levels.

The EPOs, EPSs and MC specified are consistent with legislative requirements and Woodside's standards and procedures. They have been developed based on the Codes and Standards, Good Industry Practices and Professional Judgement outlined in Section 2.6, as part of the acceptability and ALARP justification process.

As defined in regulation 5 of the Environment Regulations, an EPO "for an activity, means a measurable level of performance required for the management of environmental aspects of the activity to ensure that environmental impacts and risks of the activity will be of an acceptable level".

EPOs are set so that they are consistent with the principles of ESD as defined in the section 3A of the EPBC Act and demonstrated through the acceptability process (described in Section 2.8.2), which is applied to the aspects in Section 6, taking into consideration the principles of ESD. The EPOs for planned activities have been set at a level of environmental performance that is equal to the identified environmental impact.

Impact based EPOs, where qualitative terms (e.g. prevent, limit) are used in EPOs, are supported by detailed impact assessment in Section 6 such that they can be interpreted as meaning "impact and risk greater than that predicted in this EP".

A risk-based EPO ties in with Woodside's risk management processes so that risk is maintained within a level that has been evaluated as being appropriate to the nature and scale of the risk. WMS and relevant controls are used to identify and treat potential step-outs (resulting in an increased likelihood) from expected controls performance or integrity envelopes.

EPSs and MC are defined to measure environment performance against the EPOs:

EPS are statements of performance required of a control measure in order to manage risk and/or impacts to ALARP and an acceptable level. EPS are used as a basis for environmental performance reporting and demonstrates compliance against the EPO.

MCs are outlined defining how environmental performance is measured and sets the criteria to determine whether the EPO and EPS have been met during the activity.

For planned activities, where the activity is undertaken as described and the relevant EPS are implemented it confirms that the EPOs are being met.

The EPOs, EPSs and MC are presented throughout this section for both operations and Xena-03 tie-back activities, as relevant. A breach of these EPOs or EPSs constitutes a 'Recordable Incident' under the Environment Regulations (refer to Section 7.13.5).

6.4 Presentation

The analysis and evaluation (ALARP and acceptability), EPOs, EPSs and MC are presented in tabular form throughout this section, as shown in the sample below. Italicised text in this example table denotes the purpose of each part of the table, with reference to the relevant sections of the Regulations and/or this EP.

Context Description of the context for the impact/risk. Regulation 21(1), 21(2) and 21(3)

ALARP/Hierarchy of Control Tools Used – Section 2.6.2				

[38] Qualitative measure

Demonstration of ALARP				
Summary of control considered to ensure the impacts and risks are continuously reduced to ALARP. Regulation 21(5)(c).	Technical/logistical feasibility of the control. Cost/sacrifice required to implement the control (qualitative measure).	Qualitative commentary of impact/risk that could be averted/ environmental benefit gained if the cost/ sacrifice is made and the control is adopted.	Proportionality of cost/sacrifice vs environmental benefit. If proportionate (benefits outweigh costs), the control will be adopted. If disproportionate (costs outweigh benefits), the control will not be adopted.	If control is adopted, reference to Control No. provided.
Major Environmental Events				
MEEs are subject to additional analysis and evaluation as outlined in Sections 2.7. ALARP is demonstrated through controls being analysed for selection, based on their independence, and prioritised in accordance with hierarchy of controls, and further analysed to consider the type of effect the control provides.				
ALARP Statement Made on the basis of the environmental risk/impact assessment outcomes, use of the relevant tools appropriate to the Decision Type (Section 2.6.1) and a proportionality assessment. Regulation 34(b).				

Demonstration of Acceptability
Acceptability Statement Made on the basis of applying the process described in Section 2.8.2 and taking into account internal and external expectations, risk/impact to environmental thresholds and use of environment decision principles. Regulation 34(c)

EPOs, EPSs and MC			
Environmental Performance Outcomes	***Controls***	***Environmental Performance Standards***	***Measurement Criteria***
EPO No. S: Specific performance that addresses the legislative and other controls that manage the activity, and against which performance by Woodside in protecting the environment will be measured. M: Performance against the outcome will be measured through implementation of the controls via the MC. A: Achievability/feasibility of the outcome demonstrated via discussion of feasibility of controls in ALARP demonstration. Controls are directly linked to the outcome. R: The outcome will be relevant to the source of risk/impact and the potentially impacted environmental value[39] T: The outcome will state the timeframe during which the outcome will apply or by which it will be achieved.	C No. Identified control adopted to ensure that the impacts and risks are continuously reduced to ALARP. Regulation 21(5c).	PS No. Statement of the performance required of a control measure. Regulation 21(7)(a).	MC No. Measurement criteria for determining whether the outcomes and standards have been met. Regulation 21(7)(c).

6.5 Environment Risk/Impacts not Deemed Credible

The ENVID identified a source of environmental risk / impact that was assessed as not being applicable (not credible) within or outside the PAA as a result of the Petroleum Activities Program. It therefore does not form part of this EP. This is described in the following sections for information only.

6.5.1 Shallow/Near-shore Activities

The Petroleum Activities Program is located in water depths of approximately between 40 m at the state-waters boundary of the Pluto Export Pipeline and 962 m at the greatest depths of the hydrocarbon gathering system. The closest land is 12 km from the Export Pipeline Operational Area at Legendre Island and 32 km from the Facility and Xena-03 Operational Area at Montebello Islands. Consequently risks/impacts associated with shallow/near-shore activities such as anchoring and vessel grounding were assessed as not credible.

6.6 Indirect Impacts

For the proposed Petroleum Activities Program, potential 'indirect' environmental impacts and risks are those associated with waste brought onshore, mobilisation/demobilisation of vessels to the PAA, and related to emissions associated with the extraction of Pluto gas for onshore processing and third party transport, regassification, distribution and use. Due to the nature and scale of these potential indirect environmental impacts and risks which could be reasonably attributed to the PAP, and the regulatory frameworks in place to manage them, Woodside considers the potential indirect impacts and risks from these activities to be inherently managed to ALARP and acceptable in its current state.

[39] Where impact/consequence descriptors are capitalised and presented within EPOs in Section 6; performance level corresponds with those aligned with the Woodside Risk Matrix (refer Section 2.6.3).

However, recognising stakeholder and regulatory interest with the processing of Pluto gas onshore and concern regarding the potential for indirect impacts from atmospheric emissions; and GHG emissions from third party use, further information and evaluation has been provided in Section 6.7.10 and 6.7.11.

6.7 Planned Activities

6.7.1 Physical Presence: Interaction with other Marine Users

Context		
Facility Layout and Description – Section 3.4 Support Vessel Operations – Section 3.8 Subsea Inspection, Maintenance & Repair Activities – Section 3.10 Xena-03 Drilling &Tie-back Activities – Section 3.11 Vessel-based Activities for the Xena-03 Tie-back – Section 3.12	Socio-economic Environment – Section 4.10	Consultation – Section 5

Impacts and Risks Evaluation Summary

Source of Impact	***Environmental Value Potentially Impacted***							***Evaluation***						
	Soil and Groundwater	Marine Sediment	Water Quality	Air Quality (incl Odour)	Ecosystems / Habitat	Species	Socio-economic	Decision Type	Consequence / Impact	Likelihood	Risk Rating	ALARP Tool	Acceptability	Outcome
Presence of facility displacing and/or excluding other users from PSZ during routine and IMMR activities within the PAA, respectively.							x	A	F	-	-	LCS GP PJ	Broadly Acceptable	EPO 1
Presence of MODU, AHVs, installation vessels and other support vessels displacing and/or excluding other users during Xena-03 Tie-back activities.							x							
Presence of subsea infrastructure interfering with or displacing third party vessels (commercial fishing)							x							

Description of Source of Impact

Operations

The facility commenced operation in 2012 and is marked on nautical charts. The riser platform is surrounded by a 500 m radius PSZ, which vessels are prohibited from entering unless authorised by Woodside. The PSZ is a critical safety control intended to reduce the likelihood of interactions between vessels and the platform, which increases safety for both vessels and the facility. Implementation of the PSZ around the riser platform excludes other users from a small area of the sea (approximately 0.079 km2). The riser platform is highly visible under most conditions and is well lit, and the nature of the riser platform (large steel structure) ensures a clear radar return to alert ships fitted with anti-collision radars.

Routine support vessel operations (Section 3.8) associated with the Pluto facility operations activities are concentrated within the PSZ (e.g. platform support vessels during crewed mode), with the exception of IMMR activities. Subsea support vessels may undertake activities (e.g. IMMR, removal of redundant equipment) within the PAA at any time, including within parts of the PAA which are beyond the PSZ. The duration and location of these activities varies

depending on the activity being undertaken. Planned maintenance campaigns undertaken during routine intervention activities typically occur ten times per year, lasting approximately 14 days per campaign. Vessels required for major projects, including AHV and subsea installation vessels may undertake activities within the PAA as required.

Subsea infrastructure associated with operations activities may have the potential for interactions with other marine users. The AHO has been notified of the location of all existing subsea infrastructure, for marking on nautical charts. Water depths of the existing subsea infrastructure range between 40 m at the export pipeline state boundary and 180-962 m, at the hydrocarbon gathering system. The Pluto riser platform itself, is located at the edge of the continental shelf at 85 m depth.

Presence of MODU, Xena-03 Tie-back Activities and associated Subsea Infrastructure

The activity includes mooring system installation, drilling of one well, installation of a wellhead and xmas tree, and connection of the well to the existing Pyxis Hub subsea infrastructure.

Support vessels including ASVs will be used for MODU mooring system installation activities before the arrival of the MODU, and for retrieval of anchors following completion of drilling when the MODU departs. Each of these phases are intended to last 7-10 days.

A MODU is planned to be present for approximately 60 days, including mobilisation, demobilisation and contingency activities. When underway, activities will be 24 hours per day, seven days per week. A 500 m Safety Exclusion Zone (SEZ) will be applied to the MODU within the Xena-03 Operational Area for the duration of the drilling activity. An support vessel would be present in proximity to the MODU, which would also be supported periodically by another support vessel to facilitate resupply.

Installation vessels will be used to install, pre-commission and cold commission the flexible flowline, subsea distribution unit, and other subsea infrastructure following completion of drilling of the new well, as described in Section 3.11. This is expected to take approximately three weeks. Installation is expected to be predominantly undertaken by the Primary Installation Vessel (PIV), which will be surrounded by a 500 m SEZ when on-location within the Xena-03 Operational Area. A smaller vessel (IMMR type) may be utilised to undertake components of the installation activity before or after primary installation has been completed.

Mooring installation, drilling and subsea installation activities are expected to be temporally discrete (i.e. conducted at different times), however they may overlap. If these activities coincide, a vessel (IMMR or PIV type) would be active in the Xena-03 Operational Area while the MODU (supported by two OSVs) is present. A SIMOPS plan would be in place to manage interaction between vessels in the field.

Xena-03 Tie-back activities will include the addition of new infrastructure within the PAA. The proposed Xena-03 wellhead, subsea xmas tree and other subsea infrastructure will remain for the duration of field life. All new infrastructure will be contained within the existing Facility Operational Area and will not constitute a significant increase in the physical presence of the facility.

The AHO will be notified of the Xena-03 well and associated subsea infrastructure locations. Further, once Xena-03 infrastructure is operational, potential interactions with other marine users will be managed as per all other subsea infrastructure associated with Pluto operations.

Impact Assessment

Exclusion and Displacement of Other Users

Interaction with other marine users due to the physical presence of activity-related vessels in the Petroleum Activities Program may result in localised changes to the functions, interests or activities of other users.

The duration and extent of potential for interaction, will depend on the activity undertaken, and are outlined below:

- Pluto facility operations – on-going, for the period of the Petroleum Activities Program, limited to the Facility Operational Area.
- Xena-03 Tie-back activities – Approximately 60 days, limited to the Xena-03 Operational Area.
- IMMR – Typically 14 days, throughout the PAA. Approximately 10 IMMR activities are planned per year, with additional IMMR campaigns carried out as required.

Commercial Fishing

The PAA overlaps 4 Commonwealth and 15 State managed commercial fisheries management areas. Historical fisheries data indicate that only 1 Commonwealth fishery and ten (10) State managed fisheries have been active within the PAA over the last 5 years. To identify active fisheries with the potential for interaction, ABARES and FishCube data at the 10 NM and 60 NM CAES reporting blocks, overlapping the PAA were identified and fishery effort assessed (Section 4.10.1). ***Routine Operations***

The Commonwealth managed North West Slope Trawl Fishery, and ten (10) State managed fisheries are considered to have potential for interaction with project activities in the PAA. There potential to interact with the activity is based on their catch effort drawn from ABARES (Commonwealth) and FishCube (WA State) data. The catch effort is described for each fishery in Table 4-22 in Section 4.10.1.

Continued presence of the Pluto facility and subsea infrastructure

The potential impact to commercial fisheries in the PAA is limited to the navigational hazard of the facility and localised displacement/avoidance by commercial fishing vessels within the immediate vicinity. As such, the potential impact is considered to be localised with no lasting effect.

The continued presence of subsea infrastructure over the field life could present a hazard to bottom trawl fisheries due to the risk of equipment entanglement and subsequent equipment damage/loss. The presence of subsea infrastructure could present a hazard to bottom trawl fisheries due to risk of equipment entanglement and subsequent equipment damage/loss.

Given the catch effort of commercial fisheries outlined in Table 4.22, anticipated impacts from activities associated with the ongoing presence of the Pluto facility and subsea infrastructure are assessed as having no lasting effect.

Xena-03 Tie-back activities

During Xena-03 Tie-back activities, additional vessels will be temporarily present in the Xena-03 Operational Area and may restrict the use of the area by the commercial fisheries and tour operators that have been identified as having potential to use the region. Use will particularly be restricted within the 500 m SEZ (temporary) that will be established around the MODU and installation vessel while undertaking drilling and installation activities. The exclusions represent a relatively small area when compared to the extent of the fishery boundaries that overlap. The MODU is planned to be present for approximately 60 days, and the installation vessels for up to three weeks. Potential impacts to commercial fisheries include damage to fishing equipment and physical displacement from some parts of the managed fishery areas for the duration of the Xena-03 Tie-back activities.

Given the distance offshore and previous fishing effort within the Facility Operational Area (discussed above), the Xena-03 Operational Area is not considered to be an area of high commercial fishing activity. Furthermore, the 500 m temporary exclusion zones around the MODU and installation vessel comprise a relatively small area when compared to the extent of the individual fishery boundaries that overlap. As such, any displacement of commercial fisheries due to the Xena-03 Tie-back activities in the Xena-03 Operational Area are not expected to impact commercial fishing activities or the economic viability of the fisheries.

Tourism and Recreation

Tourism and recreation activity in the PAA is expected to be infrequent, with recreational and charter fishing from vessels the only tourism and recreational activities identified as potentially occurring.

The Montebello Islands State Marine Park (~25 km from the PAA), is the closest location for tourism with some charter boat operators taking visitors to these islands. Reported fishing charter catch effort (at 10 NM CAES blocks) within the PAA, is predominantly located along the Export Pipeline. There may be recreational fishing at Rankin Bank, which is ~29 km from the PAA. The Export Pipeline Operational Area is 13 km from the Dampier Archipelago at the state boundary and therefore, low numbers of recreational vessels may be encountered within that nearshore area.

Given the distance from boating facilities, lack of natural attractions and water depth (~85 m) of the Facility Operational Area, very little recreational or charter fishing is expected to occur. In nearshore waters where the Export Pipeline Operational Area has the potential for greater interaction with tourism and recreational activities, given the infrequent and transient nature of IMMR activities and the known presence of current infrastructure, any impacts are not likely to be of significance. Collectively, activities in the PAA are not likely to significantly impact recreational and tourism activities and are expected to be localised with no lasting effect.

Shipping

Commercial shipping occurs in high numbers across the NWS, based on the proximity to key export ports. Commercial shipping traffic comprises vessels including:

- bulk carriers (e.g. mineral ore, salt) from Port Hedland, Port Walcott and Dampier
- offtake tankers
- support vessels for offshore oil and gas activities
- LNG carriers from Dampier, Barrow Island and Ashburton North.

To reduce the likelihood of interactions between commercial vessels and offshore facilities, AMSA has introduced a series of shipping fairways, within which commercial vessels are advised to navigate. The fairways are not mandatory, but AMSA strongly recommends commercial vessels remain within the fairway when transiting the region. The use of shipping fairways is considered to be good seafaring practice, with AUSREP data from AMSA indicating cargo ships and tankers routinely navigate within the established fairways.

No shipping fairways interact with the Facility and/or Xena-03 operational areas, however two fairways overlap the Export Pipeline Operational Area:

- A fairway directs north/south-bound vessel traffic from Barrow Island and the southern Montebello Islands.
- A fairway travels parallel to the coast, from Barrow Island to the Dampier Shipping Fairways.

In addition, most vessel activity in the vicinity of the PAA is associated with nodes such as offshore facilities (e.g. Wheatstone) and ports; no such nodes occur within the PAA (aside from the Pluto facility).

The presence of the Pluto riser platform, vessels and subsea infrastructure does not result in impacts to commercial shipping beyond a localised exclusion of shipping traffic from the PSZ and the temporary displacement of commercial shipping from subsea support vessels as a result of vessels undertaking activities in the PAA.

Oil and Gas

Several oil and gas facilities are located within 50 km of the PAA (see Section 4.10.5), the nearest being the Wheatstone platform 5 km north of the Pluto riser platform. Operational history of the facility has shown that interactions with other titleholders has not been an issue to date.

Cumulative Impacts

Given the presence of the riser platform, subsea infrastructure and export pipeline as well as support vessels there is the potential for cumulative impacts due to the presence of the Wheatstone platform, subsea infrastructure and support vessels. Additionally, a MODU and support vessels will also be present during Xena-03 Tie-back activities which may incrementally increase cumulative impacts for a shorter period of time ~12 weeks.

Other marine users will be restricted from exclusion zones established around the Pluto riser platform for the duration of this EP and from around the MODU and installation vessels for ~12 weeks. These exclusion zones in combination remain negligible, and partially temporary, relative to the area of overlapping fisheries zones.

Vessel activities in support of both Pluto Facility operations and Xena-03 tie-back activities are usually of a short duration. Any impacts arising from presence of additional vessels in connection with Xena-03 tieback activities are expected to be localised and short-lived with limited, if any, cumulative impacts anticipated.

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Legislation, Codes and Standards				
Contract vessels compliant with Marine Orders for safe vessel operations: Marine Order 21 (Safety of navigation and emergency procedures) 2016 Marine Order 27 (Safety of navigation and radio equipment) 2016 Marine Order 30 (Prevention of Collisions) 2016. Compliance with Marine Orders 21, 27 and 30 reduces the likelihood of interaction of vessels with the facility.	F: Yes CS: Minimal cost. Standard practice.	Marine Orders 21, 27 and 30 are required under Australian regulations; implementation is standard practice for commercial vessels as applicable to vessel size, type and class.	Control based on legislative requirement – must be adopted.	Yes C 1.1
Implementation of a 500 m PSZ around riser platform reduces the likelihood of interaction of vessels with the facility.	F: Yes. CS: Minimal cost. Standard practice.	The PSZ is a requirement under Australian regulations and reduces the likelihood of interactions with third parties and the riser platform.	Control based on legislative requirement – must be adopted.	Yes C 1.2

Establishment of a 500 m safety exclusion zone around MODU and primary installation vessel and communicated to marine users.	F: Yes. CS: Minimal cost. Standard practice.	Establishment of a 500 m safety exclusion zone around MODU and the primary installation vessel reduces the likelihood of interaction with other marine users.	Benefits outweigh cost/sacrifice. Control is also Standard Practice.	Yes C 1.3
For Xena-03 tieback activities, reasonable attempts at removal of wellhead(s) will be made in the event of a respud.	F: Yes. CS: Additional cost. Standard practice.	In accordance with OPGGS Act Section 572.	Benefits outweigh cost/ sacrifice. Control is also standard practice.	Yes C 1.4
MODU mooring systems (chains/wires and anchors) will be removed.	F: Yes CS: Additional cost. Standard Practice.	In accordance with OPGGS Act Section 572.	Benefits outweigh cost/sacrifice.	Yes C 1.5
Good Practice				
Location of permanent Pluto infrastructure shown on AHO marine charts.	F: Yes. CS: Minimal cost. Standard practice.	Include location of permanent Pluto infrastructure on maritime charts.	Benefits outweigh cost sacrifice.	Yes C 1.6
Consultation undertaken in support of the Petroleum Activities Program, so that marine users are informed and aware.	F: Yes. CS: Minimal cost. Standard practice.	Consultation ensures marine users are informed and aware.	Benefits outweigh cost sacrifice.	Yes C 1.7
Notify AHO of activities no less than four working weeks prior to scheduled activity commencement date, where vessels will be in the Operational Area, but outside of the Petroleum Safety Zone >3 weeks.	F: Yes CS: Minimal cost. Standard Practice.	Notification of AHO will enable them to issue a Maritime Safety Information Notifications (MSIN) and Notice to Mariners (NTM) thereby reducing the likelihood of unplanned interactions with other vessels.	Benefits outweigh cost sacrifice.	Yes C 1.8
Notify AMSA Joint Rescue Coordination Centre (JRCC) of activities where vessels will be in the field >3 weeks, 24 to 48 hrs before activities.	F: Yes CS: Minimal cost. Standard Practice.	Communicating the Petroleum Activities Program to other marine users ensures they are informed and aware should emergency response be required.	Benefits outweigh cost sacrifice.	Yes C 1.9
Notify relevant persons for XNA03 tieback activities within the Petroleum Activities Program that commence more than a year after EP acceptance.	F: Yes. CS: Minimal cost. Standard practice.	Communicating the Petroleum Activities Program to other marine users ensures they are informed and aware, thereby reducing the likelihood of interference with other marine users.	Benefits outweigh cost/ sacrifice. Control is also standard practice.	Yes C 1.10
Notify DoD no less than four weeks before Xena-03 Tie-back activities commence.	F: Yes CS: Additional cost. Standard practice.	In accordance with request made by DoD during consultation.	Benefits outweigh cost/sacrifice	Yes C 1.11

Notify government departments, fishing industry representative bodies and licence holders of activities prior to commencement and upon completion of the Xena-03 Tie-back activities.	F: Yes. CS: Minimal cost. Standard practice.	Communication of the Petroleum Activities Program to other marine users ensures they are informed and aware, thereby reducing the likelihood of interference with other marine users.	Benefits outweigh cost/sacrifice. Control is also Standard Practice.	Yes C 1.12
Notify AMSA Joint Rescue Coordination Centre (JRCC) of IMMR activities within shipping lanes.	F: Yes CS: Minimal. The control will only apply to IMMR activities undertaken within a shipping lane.	Notification of AMSA ensures they are informed and aware, thereby reducing the risk of unplanned interactions within shipping lanes.	Benefits outweigh cost sacrifice	Yes C 1.13
Develop a SIMOPS Plan to manage rig interactions with other facilities/vessels, where multiple campaigns occur within the PAA (i.e. during xmas tree installation). SIMOPS Plan to contain information on: minimum separation distances communications MODU/vessels/ activities involved in SIMOPS exclusion zone entry and exit processes ROV operations helicopter operations key roles, responsibilities and emergency contacts PTW arrangements incident reporting and investigation management of change.	F: Yes. CS: Minimal cost. Standard practice.	SIMOPS Management Plans between Woodside operated vessels in the PAA will provide for efficient delivery of the activity.	Benefits outweigh cost/sacrifice.	Yes C 1.14
Professional Judgement – Eliminate				
Reducing the PSZ.	F: No. PSZ is mandated by the OPGGS Act and is an SCE; it cannot be reduced. CS: Not assessed, control not feasible.	Not assessed, control not feasible.	Not assessed, control not feasible.	No

Limit the Petroleum Activities Program to avoid peak shipping and commercial fishing activities.	F: No. Shipping occurs year-round and cannot be avoided. SIMOPS with fishing seasons cannot be eliminated as exact timings for all activities are not confirmed. CS: Not considered – control not feasible.	Not considered – control not feasible.	Not considered – control not feasible.	No
Professional Judgement – Substitute				
None identified				
Professional Judgement – Engineered Solution				
Pluto's collision prevention system is implemented to alert marine vessels of the facility location, which reduces the likelihood of adverse interaction with other marine users.	F: Yes. CS: Minimal cost. Standard practice.	Pluto's collision prevention system equipment has the ability to alert marine vessels of the facility location, which reduces the likelihood of adverse interaction with other marine users.	Control is SCE requirement – must be adopted.	Yes C1.15
Over-trawl protection on subsea infrastructure.	F: Yes. Over-trawl protection on subsea infrastructure could be fitted to Pluto subsea infrastructure. CS: Significant additional cost associated with designing and installing trawl protection on subsea infrastructure.	Over-trawl protection on subsea infrastructure could mitigate the potential for commercial fishing trawl gear to damage infrastructure or result in gear loss.	Given the PAA only overlies a small portion of the fisheries management area open to trawl fishing, the cost of installing over-trawl protection is considered grossly disproportionate to the environmental benefit.	No

ALARP Statement:

On the basis of the environmental impact assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the potential impacts of the physical presence of the facility, subsea infrastructure, MODU and project vessels on other users.

Identified controls comprehensively cover all legislative requirements, relevant industry codes, standards and guidelines as well as company requirements.

Efforts towards reducing potential for impacts by identifying additional or alternative controls was a key feature of HAZID/ENVID studies informing this EP. As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.

Demonstration of Acceptability
Acceptability Statement: The approach to risk assessment and implementation strategy is consistent with Woodside policies, procedures and standards ensuring consistency and reliability in our environmental management practices. The management of risk and potential impacts of the activity to other marine users and values are also consistent with legislative and other regulatory requirements including relevant policy documents, guidelines and conservation plans. This ensures our activities are aligned with national standards and objectives. Woodside has comprehensively considered the socio-economic context relevant to the activity allowing us to understand and respect the inherent values and sensitivities of other users of the operational area of the activity. We have assessed, responded to and adopted controls from objections and claims received from relevant persons, ensuring community concerns are addressed in our management strategies of the activity. This includes expectations of AMSA and AHO provided in consultation with relevant persons. The potential impacts are considered broadly acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the impacts from the physical presence of the Petroleum Activities Program to a level that is broadly acceptable; and demonstrates the EPOs are met.

EPOs, EPSs and MC for Pluto Facility Operations			
Environmental Performance Outcomes	***Controls***	***Environmental Performance Standards***	***Measurement Criteria***
EPO 1a Prevent adverse interactions between operational vessels/ facility/subsea infrastructure and other marine users during the Petroleum Activities Program.	C 1.1 Contract vessels complying with Marine Orders for safe vessel operations: Marine Order 21 (Safety of navigation and emergency procedures) 2016 Marine Order 27 (Safety of navigation and radio equipment) 2016 Marine Order 30 (Prevention of Collisions) 2016.	PS 1.1 Vessels contracted whose practices comply with Marine Orders as applicable to vessel size, type and class (Marine Orders 21, 27 and 30).	MC 1.1.1 Marine verification records demonstrate compliance with standard maritime safety procedures (Marine Orders 21, 27 and 30).
	C 1.2 Implementation of a 500 m Petroleum Safety Zone around riser platform.	PS 1.2 Petroleum Safety Zone maintained and monitored for incursions.	MC 1.2.1 Records of adverse interactions in 500 m Petroleum Safety Zone with other marine users are recorded.
	C 1.6 Permanent infrastructure shown on AHO maritime charts.	PS 1.6 Woodside to notify AHO of location of permanent infrastructure.	MC 1.6.1 Records demonstrate that permanent Pluto infrastructure is shown on AHO maritime charts.
	C 1.7 Undertaking consultation program to advise relevant persons of the Petroleum Activities Program.	PS 1.7 Implement a consultation process that conforms to the requirements of the Environment Regulations.	MC 1.7.1 Records demonstrate a consultation program that conforms to the requirements of the Environment Regulations has been undertaken (refer to Section 5).

EPOs, EPSs and MC for Pluto Facility Operations			
	C 1.8 Notify AHO of activities no less than four working weeks prior to scheduled activity commencement date, where vessels will be in the Operational Area, but outside of the Petroleum Safety Zone >3 weeks.	PS 1.8 Woodside to notify AHO of activities where vessels will be in the Operational Area, but outside of the Petroleum Safety Zone >3 weeks.	MC 1.8.1 Records demonstrate that AHO notifications complete.
	C 1.9 Notify AMSA Joint Rescue Coordination Centre (JRCC), of activities where vessels will be in the Operational Area, but outside of the Petroleum Safety Zone >3 weeks, 24 to 48 hrs before activities commence.	PS 1.9 AMSA's JRCC is notified 24 to 48 hrs before mobilisation, for activities in the Operational Area, but outside of the Petroleum Safety Zone >3 weeks, for awareness should emergency response be required.	MC 1.9.1 Records demonstrate a once-off notification provided to AMSA's JRCC within required timeframes before mobilisation.
	C 1.13 Notify AMSA Joint Rescue Coordination Centre (JRCC) of IMMR activities within shipping lanes.	PS 1.13 Woodside to notify AMSA Joint Rescue Coordination Centre (JRCC) of IMMR activities within shipping lanes 24-48 hours before activity commencement	MC 1.13.1 Records demonstrate AMSA Joint Rescue Coordination Centre (JRCC) has been notified of IMMR activities within shipping lanes.

Description of Source of Impact

Seabed disturbance associated with the Petroleum Activities Program can occur during operations and Xena-03 Tie-back activities including:

- physical presence of the facility and subsea infrastructure (operational and redundant)
- scour, spans, and flowline movement inherent in design
- subsea IMMR activities
- Xena-03 tie-back activities

Operations

Physical presence

The physical presence of the Pluto facility provides hard substrate habitats from the surface to the seabed via jackets and risers, as well as along the seabed from pipelines, flowlines and manifolds. The presence of subsea infrastructure and the interaction with hydrodynamic processes may result in localised scouring to the seabed and localised sedimentation of fine substrates around infrastructure.

Flowline movement may occur as per design and within integrity margins along the flowline corridors. Normal flowline operational movement occurs due to factors such as flowline buckling, walking and varying metocean conditions. Lateral movement can occur within the flowline corridor. Management of flowline buckling and walking, and scouring around subsea infrastructure may necessitate IMMR activities, as part of integrity management practices.

Subsea IMMR activities

Woodside may be required to undertake routine subsea IMMR activities within the PAA, to maintain the integrity of subsea infrastructure. IMMR activities identified as impacting the benthic environment include, but are not limited to:

- inspections – localised sediment resuspension by ROV
- marine growth removal – localised resuspension of sediment; removal of marine biota from subsea infrastructure and the Pluto facility jacket
- sediment relocation – localised modification of benthic habitat and sediment resuspension
- span rectification, pipeline protection and stabilisation – minor, localised modification of benthic habitat within footprint of area subject to rectification/protection/stabilisation
- flowline and umbilical replacement – minor, localised modification of benthic habitat in the vicinity of the flowline/umbilical
- spool repair/replacement – minor, localised modification of benthic habitat in the vicinity of the spool
- temporary placement of tools on the seabed e.g. baskets – minor localized modification of the benthic habitat in the vicinity of the items.
- pig launcher/receiver installation and retrieval - minor, localised modification of benthic habitat and sediment resuspension in the vicinity of the receiver.

The area of benthic habitat predicted to be impacted varies depending on the nature and scale of the IMMR activity, however no impact is expected beyond the PAA. Span rectification is the IMMR activity with the greatest potential to modify benthic habitats, due to the alteration of the existing soft sediment habitat to hard substrate. Woodside's operational experience on the North West Shelf indicates these activities (e.g. span rectification, pipeline protection and stabilisation) are typically restricted to relatively short (tens of metres) linear sections of pipeline, with areas of up to approximately 200 m2 impacted. Refer to MEE-02 Subsea equipment loss of containment which includes controls to limit scour and flowline movement within integrity requirements.

Drilling and MODU Operations

Drilling activities may result in intermittent or discontinuous direct physical or mechanical disturbance to the seabed up to an approximate 100 m radial distance around the Xena-03 well location due to the installation of the BOP and conductor. Potential impacts to the seabed from the generation and discharge of cuttings and drilling fluids are considered in Section 6.7.8 and Section 6.7.9 respectively.

Mooring Installation and Anchor Hold Testing

The Xena-03 well may be drilled using a moored or hybrid MODU. Seabed disturbance will result from installation of the MODU anchor mooring system (supported by AHVs), including placement of anchors and chain/wire/fibre lines on the seabed, potential dragging during tensioning, and recovery of anchors. Mooring may require an 8 to 12 point pre-laid mooring system, with RAR and buoyed arrangements an option, depending on the time of year. Although the exact anchoring configurations are not finalised, a semi-submersible MODU with an 8 to 12-point anchoring system

could disturb up to 0.013 km2 (13,000 m2), allowing for anchor footprint and disturbance from anchor chains (NERA, 2018).

The area of seabed affected by mooring installation depends upon water depth, currents, size of the vessels and anchors, and length of anchor chain (NERA, 2018). Seabed disturbance from mooring installation and anchor hold testing will result in localised, small scale seabed disturbance relating to the benthic habitats described in Section 4.5.

The planned anchoring activities are to be within the parameters defined in the Anchoring of Vessels and Floating Facilities Environment Plan Reference Case (Department of Industry, Innovation and Science, undated) for all anchoring activities performed by vessels and floating facilities (excluding FPSOs and Floating LNG vessels) during the Petroleum Activities Program, including:

- installation of moorings, buoys, equipment or other infrastructure for a period of up to two years
- wet storage on seabed of anchor chains, etc. during activities up to two years
- activities with total areas of seabed disturbance less than 13,000 m2
- locations of water depth greater than 70 m. This boundary is set to exclude areas of sensitive primary producer habitats (e.g. corals, seagrass) that occur in shallower waters.

Subsea Installation Activities

Subsea installation will include the installation of subsea infrastructure (including placement of materials/equipment on the seabed), supporting structures (including wellhead, flowline, flying leads, subsea distribution unit, mudmats) and installation aids (clump weights, concrete mattresses, sandbags). Subsea infrastructure components are described in Section 3.4. The estimated total footprint of the Xena-03 Tie-back is 1405 m2, with additional subsea infrastructure including the 500 m flowline, wellhead, EHU, concrete mats and UTAs.

Subsea structures (subsea distribution unit, mudmats) will be deployed to the seabed by the installation vessel's primary crane and guided to final position by ROV. Commencement of the flowline installation generally requires tension to the flowline as it transitions from the installation vessel to the seabed. Therefore, commencement of the flowline installation may start with landing the end of flowline termination head into the manifold connection system or on the seabed attached to the initiation anchor (drag anchor or clump weight/dead anchor). This will cause small, localised and temporary impacts to water quality in the vicinity of flowline landout.

Once the termination end is fully landed, the flowline is to be continuously laid using vertical lay system and at the same time, the ROV monitors the touch-down point on the seabed as well as the flexible lay back radius. Flying leads will be deployed to the seabed in deployment baskets, and final subsea tie-in will be completed using ROVs.

Span rectification

The optimum flexible flowline route will be selected by considering seabed bathymetry, pre-installation ROV surveys and installation risk management, including dropped object risks and buckling/walking impacts. This reduces the potential for spanning and therefore the need for span rectification, while avoiding potential hard substrate habitats.

Where span rectification is required, concrete mattresses may be positioned at the identified free span location using the vessel crane and ROV. The dimensions for each concrete mattress are expected to be 6 m x 3 m x 0.3 m. Post-lay span rectification may involve placing grout bags (multiple ~25 kg) on the seabed, with the extent of any impact limited to the footprint of the installed flexible flowline.

Scouring

Scouring is the movement of sediment around the base of subsea structures due to prevailing wind conditions. Concrete mattresses may be installed at the Xena-03 UTA if required, to mitigate scouring.

Stabilisation

Stabilisation is a post lay activity so that light items, such as HFL, EFL and flowlines, remain at their installed positions; i.e., not being shifted due to strong seabed current, by installing sand bags on top of HFLs, EFLs and flowlines at a predetermined distance apart. Sandbags generally come in a standard size with 20 kg to 40 kg weight. Concrete mattresses may also be used for stabilisation of some sections of the Xena-03 flexible flowline subject to detailed design.

Crossings

Sandbags or concrete mattresses may be installed for crossings over existing umbilicals or flowlines.

Wet Storage of Equipment

Temporary wet storage of installation aids may be required intermittently during Xena-03 Tie-back activities. Installation aids will be recovered at the completion of the Xena-03 Tie-back activities by ROV and project vessels.

ROV Operations

The use of an ROV during drilling and subsea installation activities may result in temporary seabed disturbance and suspension of sediment as a result of working close to, or occasionally on, the seabed. ROV use close to or on the seabed is limited to that required for effective and safe subsea activities. The footprint of a typical ROV is about 2.5 m × 1.7 m (4.25 m²).

Additionally, an ROV may be used to relocate small amounts of sediment material to create a stable, level surface and reduce the potential for scouring from subsea equipment (e.g. BOP).

Marine Growth Removal

Excess marine growth may need to be removed following return to well after a period of suspended drilling. Removing marine growth is undertaken via a high-pressure water and/or brushes or acid, by ROV.

Underwater Transponders

An array of long base line (LBL) transponders may be installed on the seabed as required to support drilling and subsea installation activities. Transponders may be moored to the seabed either by a clump weight or mounted on a seabed frame. The standard clump weights used, made of cement or steel, will likely weigh about 80 kg. A typical seabed frame is 1.5 m × 1.5 m × 1.5 m in dimension and weighs about 40 kg. On completion of the positioning operation, the array transponders moored by clump weight will be recovered by means of a hydrostatic release and the clump weights removed from the seabed. The transponders mounted on seabed frames will be removed by ROV.

Contingency Activities

Woodside may need to intervene or workover the Xena-03 well. Any seabed disturbance would be the same as those described for drilling operations and MODU operations. In addition, in the event of a respud of the Xena-03 well, the base case would be to remove the wellhead. However, if reasonable attempts at wellhead removal are unsuccessful, a wellhead may remain in situ until the end of field life. If this is the case, it will be recorded in a database and monitored and maintained until decommissioned. If a wellhead is left in-situ, there would be localised seabed disturbance at the wellhead location.

Impact Assessment

Drilling, subsea installation, IMMR activities and physical presence of subsea infrastructure can be categorised into two potential impacts:

- direct physical disturbance of benthic habitat
- indirect disturbance to benthic habitats from sedimentation.

ROVs working well above the seabed do not have an impact on the seabed.

Water and Sediment QualitySeabed disturbance may include localised and temporary decline in water quality due to increased suspended sediment concentrations and increased sediment deposition caused by drilling, subsea installation and IMMR activities near the seabed. Similarly, removal of marine growth from the Pluto jacket for structural integrity maintenance, carried out on an as required basis, would cause localised temporary decrease in water quality and suspended sediment from water jetting activities.

Each discrete IMMR activity near the seabed is likely to cause a single brief disturbance resulting in a transient plume of suspended sediment. This plume will subsequently be deposited down current as particles settle out. Such localised and short-term events may affect small areas of the seabed and consequently, impact the associated biota (typically sparsely distributed infauna and sessile fauna). Given the expected nature and scale of resuspension resulting from IMMR activities, impacts such as smothering or burial are not expected. Rather, impacts are likely to be restricted to increased ingestion of sediments by filter feeders. Biota in the region are well adapted to periodic turbidity events caused by cyclones and tidal movements. As such, impacts from turbidity caused by IMMR activities are not expected to have any lasting effect on benthic biota.

Benthic Habitats

The Pluto facility is located within deeper offshore waters (~85 m) approximately 152 km north-west of Dampier and includes the riser platform, hydrocarbon gathering system and export pipeline, extending through shallower waters to the state-waters boundary. The benthic habitat within the PAA is predominantly soft sediment (Section 4.5) with sparsely associated epifauna, which is broadly represented throughout the NWSP and NP Provinces.

Benthic communities in the soft sediment seabed are characterised by burrowing infauna such as polychaetes, with biota such as sessile filter feeders occurring on areas of hard substrate (such as subsea infrastructure).

Direct seabed disturbance, including permanent modification of benthic communities, may result as a consequence of IMMR activities such as span rectification, pipeline protection and stabilisation. These activities typically disturb a small area (typically < 200 m2) of soft sediment habitat, which is broadly represented in the Operational Area and wider NWMR region.

Drilling

Physical impacts from drilling activities (excluding impacts from routine and non-routine discharges such as drill cuttings assessed in Section 6.7.8) are expected to be for the most part confined to sediment burrowing infauna and surface epifauna invertebrates, particularly filter feeders, inhabiting the seabed directly around the Xena-03 well. Impacts from the installation of subsea infrastructure are expected to be confined to sediment burrowing infauna and surface epifauna invertebrates, particularly filter feeders, inhabiting the seabed directly around the installation site. Impacts to these broadly represented communities are expected to be highly localised with no significant impact.

Seabed disturbance will be limited to the wellhead (100 m radial distance), subsea infrastructure and anchoring physical footprint (estimated at up to 0.013 km2); a small proportion of the benthic habitat and associated communities

of the PAA will be affected. Marine life such as deep water benthic communities epifauna and infauna (living on and in the sediment dominated habitat), may be impacted from the placement of project infrastructure (i.e. Xena-03 wellhead, flowline and subsea infrastructure), or placement of temporary supporting infrastructure (anchors, installation aids) and equipment (e.g. mud mats) on the seabed. Potential impacts include; burial or smothering of benthic biota from localised sediment deposition, particularly to sessile epifauna such as sea pens and infauna (polychaetes); and potential clogging or damage to the physiological functioning of certain biota (sea pens, polychaetes) reliant on external respiratory and feeding structures from elevated suspended sediment load (turbidity). Secondary impacts may include highly localised alterations to epifauna and infauna communities (Newell et al., 1998).

Mooring installation activities (MODU) are likely to result in localised physical modification to a small area of the seabed and disturbance to soft sediment. An anchor must travel a certain horizontal distance before penetrating and embedding into the seabed. The drag length of the anchors may be up to a linear distance of 100 m from the drop location (NERA, 2018). The disturbance footprint extends beyond this distance with the anchor chain. The maximum disturbance radius of each anchor drop will therefore not exceed the drag length, plus the additional length of the anchor chain that comes into contact with the sea floor (4000 m). Following recovery of the anchors, impacts from the disturbance (estimated at up to 0.013 km2) are expected to be localised and short-term, with the underlying conditions present to support re-colonisation and recovery after the activity has been completed (Ingole et al. 2005).

ROV activities associated with IMMR and Xena-03 Tie-back operations, near the seafloor and small amounts of sediment relocation may result in slight and short-term impacts to deepwater biota, detailed above, as a result of elevated turbidity and localised sedimentation. However, elevated turbidity and sedimentation would only be expected to be slight and short-term, and is therefore, not expected to have any consequential impact to environment receptors.

Values and Sensitivities

Ancient Coastline at 125 m Depth Contour

The Facility Operational Area overlaps approximately 9 km2 of the 16,190 km2 Ancient Coastline, which is about 0.06% of the KEF. The Facility Operational Area represents a 1500 m2 buffer around the Pluto subsea infrastructure to facilitate vessel operations; the potential for seabed disturbance is much more localised (i.e. within tens of metres of the subsea infrastructure).

Benthic habitat surveys in the region (including within the Ancient Coastline at 125m depth contour KEF) indicate that benthic habitats within the KEF are characterised by sand interspersed with areas of rubble and outcroppings of limestone pavement (AIMS 2014b, RPS 2011). Such habitats are widely distributed in the NWMR. No significant escarpments, species of conservation significance, emergent features or areas of high biological productivity characteristically associated with the Ancient Coastline at 125 m KEF have been observed in the Facility Operational Area. As noted in Section 4.7, the geomorphic feature associated with this KEF is represented worldwide and represents the coastline during a previous glacial period. These impacts are discussed in relation to filter feeders above. Therefore, potential impacts to this regional-scale KEF are expected to be negligible.

Continental Slope Demersal Fish Communities

The Facility Operational Area and the Xena-03 Operational Area overlap the Continental Slope Demersal Fish Communities KEF. Seabed disturbance will have no adverse environmental impact on this KEF and the presence of the riser platform and subsea infrastructure may provide habitat for demersal fish communities potentially having a low level positive environmental impact.

Montebello Australian Marine Park (IUCN IV)

A small portion of the Pluto Export Pipeline Operational Area overlaps the Montebello Marine Park Multiple Use Zone. The Marine Park includes values associated with the shallow shelf environment, however no pinnacle or terrace seafloor features are found within the Operational Areas.

Direct loss of sediments in the Marine Park may be possible if IMMR activities include the placement of materials on the seabed. In addition, indirect impacts may occur as a result of sedimentation. These impacts are discussed in relation to soft sediment benthic habitats above.

Cultural Heritage

As described in Section 4.10, the PAA overlaps the Ancient Coastline at 125 m depth contour KEF. The wider Xena-03 Operational Area overlaps the Ancient Coastline KEF, the targeted well location and installation activities for the Xena-03 well are not within the Ancient Coastline KEF. Therefore, there may be the potential that Indigenous Cultural features may exist, and these may potentially be impacted during seabed disturbance resulting from operations and associated activities. While no cultural features have been identified in the PAA, consultations with First Nations groups have been undertaken for the Petroleum Activities Program.

Cumulative Impacts

Seabed disturbance may arise from the Pluto facility, subsea infrastructure and IMMR activities as well as Xena-03 tie-back activities at a localised level limited to well within the PAA. At a regional scale, cumulative impacts also arise from the presence of the Wheatstone platform and associated subsea infrastructure and activities. The activities are expected to incur localised and temporary declines in water quality and modification of soft sediment habitat where infrastructure has a physical footprint. These impacts are considered to be temporary and, in the case of benthic habitat modification, limited relative to the vast representation of similar habitat in the PAA and surrounds as well as

regionally. Cumulative impacts are considered to be localised and temporary, or in the case of physical footprints, to be slight relative to the presence of similar habitat in the PAA and regionally.

movement to within integrity envelope.	monitoring is undertaken which inherently controls extent of scour and flowline movement CS: Minimal cost. Standard practice	limited to design flowline corridor.		Refer also MEE-02
Monitoring of seabed surrounding riser platform and subsea infrastructure.	F: Yes. ROV footage collected as part of subsea integrity surveys could be reviewed to observe and detect changed in benthic habitats. CS: Costs associated with the review of collected footage.	Limited environmental benefit (information) gained from monitoring benthic habitats.	Given the sparsely populated infauna habitat and low sensitivity of the environment surrounding the facility and associated subsea infrastructure, any environmental benefit gained is outweighed by costs associated with implementing control.	No
ALARP Statement: On the basis of the environmental impact assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts of seabed disturbance from Xena-03 Tie-back activities and subsea IMMR activities. As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.				
Demonstration of Acceptability				
Acceptability Statement: The impact assessment has determined that, given the adopted controls, seabed disturbance from subsea activities is unlikely to result in a potential impact greater than slight, short-term impact to benthic habitats and marine sediments and water quality. Further opportunities to reduce the impacts have been investigated above. The adopted controls are considered good oil-field practice/industry best practice. The potential impacts are considered broadly acceptable if the adopted controls are implemented. The inclusion of C2.1, C2.5, C2.9 and C2.17 will confirm the activity is undertaken as described. Therefore, Woodside considers the adopted controls appropriate to manage the impacts of Xena-03 Tie-back activities and subsea IMMR activities to a level that is broadly acceptable; and demonstrate the EPOs are met.

Noise generated within the PAA from: • Pluto Facility and associated infrastructure • Vessels (ASV and support vessels) • Helicopters • Subsea IMMR activities						x		A	F	-	-	LCS GP PJ	Broadly Acceptable	EPO 3

Description of Source of Impact

The facility, vessels, IMMR activities and helicopters will generate noise both in the air and underwater, due to normal operation of machinery noise, propeller movement, and infrequent non-routine activities. Typical noise levels for these sources are provided in Table 6-3, with more detailed descriptions provided below. This noise will contribute to and can exceed ambient noise levels which range from around 90 dB re 1 µPa sound pressure level (SPL) under very calm, low wind conditions, to 120 dB re 1 µPa SPL under windy conditions (McCauley, 2005).

Table 6-3: Indicative source characteristics of underwater noise associated with the Petroleum Activities Program as reported in Jiménez-Arranz et al. (2017) and by McCauley (2005) and McCauley (2002)

Acoustic Noise Sources	Estimated SPL (dB re 1 µPa SPL) @1 m unless otherwise stated	Frequency Range (kHz)
Vessels (Continuous)		
Support vessels, ASV using DP	182	Broadband
IMMR Activity Noise (Pulsed)		

Multibeam Echo Sounder (MBES)	210–247	12–675
Side Scan Sonar (SSS)	200–234	9–675
Sub-bottom Profiler (SBP) (Pinger)	167–212	4–12
SBP (Chirp)	161–205	2–23
SBP (Boomer)	205–225	0.3–6
Wellhead, Flowlines and Subsea Infrastructure (Continuous)		
Wellhead	113	Broadband
Choke valve	155	Broadband
Production platforms		
Riser platform	110–130 @100 m	Broadband (mainly < 100 Hz)

** Range provided was not measured at the noise source; therefore, this should be used as an indicative estimate only and cannot be used to estimate exposure thresholds closer to the source.*

Continuous (Non-Impulsive) Noise Sources

Platform Machinery and Flaring

Production platforms have machinery mounted on decks raised above the sea, hence, most noise is transmitted to the marine environment from air (i.e., power generation and operational flaring). Machinery noise on-board the riser platform may be radiated into the underwater environment via the jacket legs and risers, which may act as transducers. Monitoring programs have indicated that underwater noise from platforms is typically very low or not detectable (Jiménez-Arranz et al., 2017; McCauley, 2002).

The flare system will generate noise from combustion. Noise from flaring represents a health and safety risk to personnel, and noise from flaring was considered in the design of the facility to manage the occupational health and safety risks associated with noise (e.g. height specification of flare tower). Noise from flaring is emitted at the top of the flare tower, which has a flare boom length of 87 m. Noise from the tip of the flare is not constrained and will spread spherically in all directions.

Gales (1982) assessed noise from 18 oil and gas platforms, including 11 bottom-standing fixed platforms during production operations (i.e. consistent with the Pluto riser platform). The study found the strongest noise levels were relatively low frequency (< 100 Hz, and mostly between 4 and 38 Hz), with sound levels of 110 to 130 dB re 1 µPa @100 m (Gales, 1982). Noise from the platforms was found to be lower than levels recorded from support vessels, with a cumulative increase in overall underwater noise of 20–30 dB from the noise produced by a support vessel operating in the vicinity of an operations platform (Gales, 1982).

Noise emitted from machinery on the riser platform is limited relative to other operating facilities due to its NNC status, smaller size and the lack of processing facilities on the riser platform. Therefore, it is likely that the range provided by Gales (1982) is a conservative estimate. Noise from the riser platform is not expected to significantly increase from operation of the water handling unit given the nature and duration of the installation and commissioning activities. In summary, noise emissions generated by the facility are expected to be minimal.

Wellheads, Pipelines and Subsea Infrastructure

The noise produced by an operational wellhead was measured by McCauley (2002). The broadband noise level was very low, 113 dB re 1 µPa, which is only marginally above rough sea condition ambient noise. For a number of nearby wellheads, the sources would have to be in very close proximity (< 50 m apart) before their signals summed to increase the total noise field (with two adjacent sources only increasing the total noise field by 3 dB). Hence, for multiple wellheads in an area, the broadband noise level in the vicinity of the wellheads would be expected to be of the order of 113 dB re 1 µPa and this would drop very quickly to ambient conditions on moving away from the wellhead, falling to background levels within < 200 m from the wellhead.

Based on the measurements of wellhead noise discussed in McCauley (2002), which included flow noise in flowlines, noise produced along a flowline or the export pipeline may be expected to be similar to that described for wellheads, with the radiated noise field falling to ambient levels within a hundred metres of the flowline. Woodside has undertaken acoustic measurements on noise generated by the operation of choke valves associated with the Angel facility (JASCO 2015) similar to the design employed across Pluto subsea valves. These measurements indicated choke valve noise is continuous, and the frequency and intensity of noise emitted is dependent on the rate of production from the well. Noise intensity at low production rates (16% and 30% choke positions) were approximately 154–155 dB re 1 µPa, with higher production rates (85% and 74% choke positions) resulting in lower noise levels (141–144 dB re 1 µPa). Noise from choke valve operation was broadband in nature, with the majority of noise energy concentrated above 1 kHz.

Vessels and operations of Dynamic Positioning Systems

The main source of noise from vessels (platform support, subsea support, ASV) relates to the use of DP thrusters (i.e. cavitation from thruster propellers). Thruster noise is typically high intensity and broadband in nature, with sound pressure levels of 137 dB re 1 µPa at 405 m from a typical offshore support vessel holding station in strong currents (McCauley 1998). McCauley (2005) measured underwater broadband noise up to approximately 182 dB re 1 µPa at 1 m (SPL) from a support vessel holding station in the Timor Sea; it is expected that noise levels up to this level may be generated by vessels using DP during the Petroleum Activities Program. Thruster noise from vessels holding station is typically the most intense underwater noise source from vessel activities; other sources of underwater noise from vessels (e.g. main engines when underway, machinery noise transmitted through the hull, etc.) are typically considerably lower intensity noise (McCauley 1998). Note that vessels undertaking the Petroleum Activities Program inherently minimise the use of DP, and there is little potential to reduce DP use further.

For planned operations and maintenance activities, vessels are expected to be in the field operating 24 hours per day for approximately 14 days, approximately 10 times per year. However, vessels will be present for longer durations or at a higher frequency during pigging operations, corrective maintenance and interventions, major/shutdown maintenance, contingent manning (refer to Section 3.5.3). For example, the ASV may be utilised for campaigns of approximately 90 days duration (Section 3.8.3).

Helicopter Transfers

Helicopter activities occur in the PAA, including landing and take-off on the facility or vessel helidecks. Helicopters land and take-off on the riser platform (which occurs typically twice every 10 weeks during normal operations but may occur more often during unplanned maintenance activities) and potentially on subsea support vessels. Sound emitted from helicopter operations is typically below 500 Hz (Richardson et al., 1995). The peak received level diminishes with increasing helicopter altitude, but the duration of audibility often increases with increasing altitude. Richardson et al. (1995) reports that helicopter sound is audible in air for four minutes before it passed over underwater hydrophones, but detectable underwater for only 38 seconds at 3 m depth and 11 seconds at 18 m depth. Noise levels reported for a Bell 212 helicopter during fly-over was reported at 162 dB re 1 µPa (SPL) and for Sikorsky-61 is 108 dB re 1 µPa (SPL) at 305 m (Simmonds et al. 2004). Water has a very high acoustic impedance contrast compared to air, and the sea surface is a strong reflector of noise energy (i.e., very little noise energy generated above the sea surface) crosses into and propagates below the sea surface (and vice versa) – the majority of the noise energy is reflected). The angle at which the sound path meets the surface influences the transmission of noise energy from the atmosphere through the sea surface, angles >13° from vertical being almost entirely reflected (Richardson et al., 1995). Given this, and the typical characteristics of helicopter flights within the PAA (duration, frequency, altitude and air speed), the opportunity for underwater noise levels to exceed the behavioural thresholds is not considered credible and is not assessed further.

Impulsive Noise Sources

Subsea Inspection, Monitoring, Maintenance and Repair Activities

MBES and SSS are low-energy, high-resolution geophysical survey instruments that may be required for IMMR every 1-6 years to identify buckling, movement, scour and seabed features. MBES have operating frequencies ranging from 12 kHz to 700 kHz (Jimenez-Arranz et al. 2017) with peak pressure (PK) source levels between approximately 210 and 245 dB re 1 µPa at 1 m (Jimenez-Arranz et al. 2017; Zykov 2013; MacGillivray et al. 2013). MBES generate micro-pulses of high frequency sound in a highly focused beam directed towards the seabed, which attenuates rapidly underwater compared to lower frequency sound sources. Due to this directionality and short pulse duration, there is relatively low sound energy and very limited horizontal sound propagation. The high operating frequencies of many MBES are typically above the hearing range of the low frequency (LF) cetacean (7 Hz to 35 kHz; Southall et al. 2019) and high frequency (HF) cetacean (150 Hz to 160 kHz; Southall et al. 2019) species that may occur in the Petroleum Activities Area. The high operating frequencies of MBES are also above the hearing ranges of marine turtles (<2 kHz, Finneran et al. 2017) and the majority of fish species (100 Hz to several kHz; Ladich 2000, Popper et al. 2014). Additionally, sound sources generated closer to the seabed have a lower received noise level in the horizontal direction due to seafloor scattering and absorption.

Similar to MBES, SSS produce micro-pulses of sound in a focussed swath directed at the seabed. SSS operating frequencies may range between 75 kHz and 900 kHz, with sound energy attenuating rapidly with horizontal distance from the main swath (Jimenez-Arranz et al. 2017; Zykov 2013). Representative source levels range between 200 and 235 dB re 1 µPa PK at 1 m (Jimenez-Arranz et al. 2017; Zykov 2013). The high operating frequencies of SSS places the dominant sound frequencies above the hearing range of most marine fauna species, including LF cetaceans, turtles and fish, although some of the lower frequency devices may be audible to HF cetaceans (MacGillivray et al. 2013; Zykov 2013).

Sub-bottom profiling may also be undertaken every 1-6 years to identify features under the seabed. Most commercial SBPs are small, low-powered, high-resolution and shallow-penetrating systems, producing electrical pulses across a range of frequencies (Salgado Kent et al., 2016; Jiménez-Arranz et al., 2017). The instruments proposed for the survey produce pulses of sound between approximately 2 kHz and 30 kHz with source levels between approximately 170 and 230 dB re 1µPa PK at 1 m. Indicative source characteristics for typical acoustic survey equipment are provided in Table 6-3.

Positioning Equipment

An array of long baseline (LBL) and/or ultra-short baseline (USBL) transponders may be used for positioning during IMMR activities. Transponders typically emit pulses of medium frequency sound, generally within the range 21 to 31 kHz. The estimated SPL at source ranges from 180 to 202 dB re 1 µPa SPL at 1 m (Jiménez-Arranz et al. 2017).

Impact Assessment

Receptors

Fauna associated with the PAA is predominantly pelagic species of fish, with migratory species such as turtles, whale sharks and cetaceans potentially present in the area seasonally. Noise interference is a key threat to a number of migratory and threatened cetaceans and marine turtles identified as occurring within the PAA (Section 4.6).

The PAA overlaps BIAs for whale sharks (foraging), pygmy blue whale (migration and distribution), humpback whale (migration), roseate tern (breeding), fairy tern (breeding) and wedge-tailed shearwaters (breeding). Whale sharks are present between March and November. Marine turtle species may also be present within the PAA seasonally; however, no BIAs or other important areas for these species overlap the PAA.

Two key ecological features feature within the PAA. The Pluto Offshore Facility Operational Area overlaps the Continental Slope Demersal Fish Communities KEF, and the export pipeline route within the Pluto Offshore Facility Operational Area; overlaps the Ancient Coastline at 125 m KEF. This indicates that operational activities at the Pluto Facility have the potential for impact on the Continental Slope Demersal Fish Communities KEF and operational activities relevant to the export pipeline may have the potential for impact on the Ancient Coastline at 125 m KEF (Figure 4-10).

Demersal fish from these KEFs may be impacted by noise emissions. While the Ancient Coastline at 125 m KEF may be associated with outcroppings of hard substrate, no evidence of significant reefs has been found in the Pluto Offshore Facility Operational Area. Note some demersal fish are also likely to be associated with subsea infrastructure such as the export pipeline (McLean et al., 2017).

Potential Impacts of Noise

Elevated underwater noise can affect marine fauna, including cetaceans, fish, turtles, sharks and rays, in three main ways (Richardson et al., 1995; Simmonds et al. 2004):

by causing direct physical effects on hearing or other organs. Hearing loss may be temporary (temporary threshold shift (TTS) referred to as auditory fatigue), or permanent threshold shift (PTS) (injury);

by masking or interfering with other biologically important sounds (including vocal communication, echolocation, signals and sounds produced by predators or prey); and

through disturbance leading to behavioural changes or displacement from important areas (e.g., BIAs). The occurrence and intensity of disturbance is highly variable and depends on a range of factors relating to the animal and situation.

Increasing the distance from the noise source usually results in the level of noise reducing, due primarily to the spreading of the sound energy with distance. The way that the noise spreads (geometrical divergence) depends upon several factors such as water column depth, pressure, temperature gradients, and salinity, as well as surface and bottom conditions.

Cetaceans

Species Sensitivity and Exposure Thresholds

Marine mammals and especially cetaceans rely on sound for important life functions including individual recognition, socialising, detecting predators and prey, navigation and reproduction (Weilgart. 2007; Erbe et al. 2015; Erbe et al. 2018). Underwater noise can affect marine mammals in various ways including interfering with communication (masking), behavioural changes, a shift in the hearing threshold (PTS and TTS), physical damage and stress (Erbe, 2012; Rolland et al. 2012). Frequency-specific hearing sensitivity differs among marine mammals, influencing how they are affected by noise exposure. For the purposes of predicting the effects of noise exposure on different groups of cetaceans, blue whales, humpback whales and other large mysticete (baleen) whales are categorised as low frequency (LF) cetaceans, while odontocetes (toothed whales and dolphins) are categorised as high frequency (HF) or very high frequency (VHF) cetaceans (Southall et al. 2019).

The thresholds that could result in behavioural response for cetaceans is expected to be 120 dB re 1 µPa (SPL) for continuous noise sources, and 160 dB re 1 µPa (SPL) for impulsive noise sources (Table 6-4). These thresholds have been adopted by the United States National Oceanic and Atmospheric Administration (NOAA) (National Marine Fisheries Service [NMFS], 2014, 2018; Southall et al. 2019; NOAA, 2019). The adopted thresholds are based on best data available and published in peer-reviewed literature and represent conservative internationally accepted and applied impact evaluation thresholds.

Table 6-4: Thresholds for PTS, TTS and behavioural response onset for low-frequency (LF), high-frequency (HF) and very high frequency (VHF) cetaceans for continuous and impulsive noise.

Hearing group	Impulsive					Continuous		
	PTS onset		TTS onset		Behavioural response	PTS onset	TTS onset	Behavioural response
	SEL24h	PK	SEL24h	PK	SPL	SEL24h	SEL24h	SPL
LF cetaceans	183	219	168	213	160	199	179	120
HF cetaceans	185	230	170	224	160	198	178	120
VHF cetaceans	155	202	140	196	160	173	153	120

Source: NMFS (2014, 2018; Southall, 2019; NOAA, 2019).

SEL24h expressed as dB re 1 µPa².s; Peak pressure (PK) and SPL expressed as dB re 1 µPa.

The Conservation Management Plan for the Blue Whale (BWCMP) (Commonwealth of Australia, 2015a), a recovery plan made under the EPBC Act, defines important areas for pygmy blue whales and these are also described with reference to BIAs in the National Conservation Values Atlas (NCVA), with particular emphasis placed on foraging areas and migration corridors. As noted above and in Section 4.6.3, the PAA overlaps the pygmy blue whale migration BIA, with the nearest foraging BIA (Ningaloo possible foraging area) approximately 232 km to the south of the PAA. Action Area A.2.3 of the BWCMP states: "Anthropogenic noise in biologically important areas will be managed such that any blue whale continues to utilise the area without injury, and is not displaced from a foraging area". Furthermore, the Guidance on Key Terms within the Blue Whale Conservation Management Plan (DAWE, 2021), underwater noise emissions from the petroleum activities program must not:

- Result in injury[43] (TTS or PTS) to any pygmy blue whale in BIAs; or
- Displace a pygmy blue whale from a foraging BIA.

The following assessment of impacts to cetaceans includes consideration of the requirements of the BWCMP with respect to pygmy blue whales.

The National Recovery Plan for the Southern Right Whale (DCCEEW, 2024b) also identified anthropogenic noise as a threat, however the BIAs and habitat critical to the survival are over 250km away, well outside the area where behavioural responses are expected to extend from the Operational Area and as such, there is not expected to be any anthropogenic noise from the petroleum activity that could displace or interfere with life cycle activities within, or near, the reproduction or migration BIAs and habitat critical to the survival.

Predicted Underwater Noise Impacts to Cetaceans

Facility and Support Vessel Noise Impacts

Vessels holding station are considered to be the predominant noise source related to the Petroleum Activities Program. Using thruster noise, McCauley (1998) measured underwater broadband noise equivalent to about 182 dB re 1 µPa SPL (SPL) at 1 m from a support vessel holding station in the Timor Sea. Similar noise levels are expected to be generated by vessels used for the Petroleum Activities Program.

PTS and TTS thresholds for LF cetaceans are 199 dB re 1 µPa2 s (SEL weighted) and 179 dB re 1 µPa2 s (SEL weighted), respectively for continuous noise sources (refer Table 6-4). Typical sound exposures generated by the facility and a support vessel using DP would not exceed these levels (except at extremely close ranges to the source), so PTS and TTS in LF cetaceans, such as large baleen whales, is not anticipated.

Potential impacts to cetaceans may instead include behavioural disturbance from vessels. The thresholds that could result in behavioural response for cetaceans is expected to be 120 dB re 1 µPa (SPL) for continuous noise sources such as vessels (refer Table 6-4).

Acoustic modelling undertaken for an operating FPU and support vessel on DP predicted that sound from each sound source individually would exceed the 120 dB threshold up to a maximum distance of 670 m, while combined sound sources exceeded the threshold to a distance of 1.07 km (McPherson et al. 2019). Although some site and facility-specific differences may exist, 1 km is considered broadly indicative of the range at which underwater sound propagating from the Pluto facility and support vessels may cause a behavioural response in cetaceans.

The Pluto facility is located in ~85 m water depth and is located outside of the pygmy blue whale (PBW) migration biologically important area (BIA) (platform is ~17 km south-east of the boundary and outside of the humpback whale migration BIA (platform is ~24 km north-west of the boundary, see Figure 4-8).

Based on underwater noise modelling and monitoring results for a similar DP-3 thruster system44 (the West Aquarius MODU), sound levels would drop below permanent threshold shift (PTS) and temporary threshold shift (TTS) (i.e., injury) exposure thresholds for low frequency cetaceans (including PBW and humpback whales) within a few hundred metres of the thrusters. Therefore, there is no possibility of underwater noise emissions from the ASV resulting in TTS onset within the PBW migration BIA or humpback whale migration BIA, even with additional cumulative noise from the presence of additional Production Support Vessels on DP adjacent to the ASV and Pluto facility.

Cetaceans are capable of moving away from potential noise sources, and there are no constraints to their movement within the PAA. LF cetaceans such as humpback whales and pygmy blue whales may be seasonally present in the PAA, though limited to individuals infrequently transiting through the area. Interactions between pygmy blue whales or humpback whales with vessels typically result in avoidance behaviour, with whales generally moving away from vessels (Bauer 1986; Stamation et al. 2010).

Given the migration corridor BIAs for pygmy blue whales and humpback whales overlap the PAA (pygmy blue whale BIA overlaps the Facility Operational Area and humpback whales BIA overlaps the Export Pipeline Operational Area), there is the potential for these species to be exposed to underwater noise from vessels associated with the Petroleum Activities Program when they are present in the region during seasonal migrations. However, as the underwater noise levels that may be generated by DP vessels and IMMR activities are below those resulting impairment or mortality, only behavioural impacts are credible. Impacts are expected to be limited to localised avoidance of the noise source as there are no physical barriers in or near the operational areas that may prevent cetaceans from moving away from vessels.

Aerial surveys of humpback whales show the majority of humpback whales migrate within continental shelf waters along Western Australia (Double et al., 2010, 2012; Jenner et al., 2001). Humpback whales are expected to transit the Export Pipeline Operational Area during their annual north and south migrations between May and November, where vessel activity will be limited to during intermittent IMMR activities. These activities are relatively short-term and occur relatively infrequently and, therefore, are unlikely to impact humpback whales.

Pygmy blue whales are likely to be present when migrating north between April and August and south between October and December. Tagging studies of pygmy blue whales showed tagged animals were typically in water depths of > 1000 m. Pygmy blue whales are expected to transit the subsea hydrocarbon gathering system section of the facility and are unlikely to occur within proximity to the riser platform.

Mid and high frequency cetaceans are known to show behavioural disturbance at a range of received noise levels (Southall et al., 2007a). Mid- and high frequency cetaceans may exhibit short-term behavioural responses to increased levels of underwater noise, such as avoidance or attraction. This is expected to occur mainly within the Export Pipeline Operational Area during IMMR activities, but is unlikely to significantly impact these species (e.g., spotted bottlenose dolphins). In summary, potential impacts to blue whales, humpback whales and other cetaceans from predicted noise levels are expected to be limited to behavioural impacts within a localised area around vessels with no lasting effect.

IMMR Activities

Zykov (2013) conducted acoustic modelling for five low energy survey instruments off the coast of California, including MBES, SSS and sub-bottom profiler. All equipment types were modelled in the sandy bottom environment, similar to that of the PAA. Although the bathymetry, salinity, water temperature and sub-seafloor sediment type may differ, given the similarities in equipment type and seafloor habitat, the modelling is considered comparable for the nature and scale of the low energy IMMR survey equipment.

The high operating frequencies of MBES and SSS places the majority of sound frequencies above the auditory range of LF cetaceans. Dolphins and other HF cetaceans, which have peak hearing sensitivity up to 110 kHz, with potential for some limited hearing ability up to approximately 160 kHz (NMFS 2018, Southall et al. 2019), may be able to detect a small amount of the sound energy from some instruments in the lower operating frequency ranges available for MBES and SSS (MacGillivray et al., 2013; Zykov, 2013).

The modelling by Zykov (2013) indicates that the sound emissions from MBES and SSS do not exceed PTS and TTS accumulated sound exposure criteria for LF cetaceans at any distance, and do no– exceed criteria for HF cetaceans beyond 2 - 3 m horizontal distance from the source, which is not considered to be a credible exposure scenario for mobile marine fauna. Zykov (2013) also estimated the maximum distance at which the unweighted 160 dB re 1 µPa (SPL) behavioural disturbance threshold for impulsive sound was reached was 290 m for MBES and 690 m for SSS. Again, it is emphasised that many MBES and SSS instruments may operate at frequencies outside of the hearing range of cetaceans and so these would not be audible or result in behavioural disturbance. For instruments with frequencies that overlap with the hearing ranges of cetaceans, a significant proportion of the sound energy may still be outside of their hearing ranges, therefore, the perceived sound levels are reduced and the horizontal distances at which

[44] The Floatel Triumph uses a DP-3 system for station keeping that comprises six azimuth thrusters, each 3200 kW. Therefore, the ASV has 19,200 kW total installed thruster power, which is similar thruster configuration and power to the West Aquarius (eight azimuth thrusters with a total of 28,002 kW installed power)

behavioural disturbances may occur are less than those inferred by the unweighted 160 dB re 1 µPa (SPL) behavioural disturbance threshold. For example, modelling of weighted SPLs by Zykov (2013) for MBES indicated that the 160 dB re 1 µPa (SPL) behavioural threshold was not exceeded for LF cetaceans at any distance and was limited to approximately 205 m horizontal distance for HF cetaceans. For SSS, the modelling of weighted SPLs indicated that the 160 dB re 1 µPa (SPL) behavioural threshold was exceeded at horizontal distances of 110 m for LF cetaceans and 611 m for HF cetaceans.

Acoustic modelling of sub-bottom profilers by Zykov (2013) and McPherson and Wood (2017), indicates limited horizontal sound propagation outside of the main directional field of sound. The modelling studies also indicate that PK and SEL24h thresholds for PTS are not exceeded. The potential for TTS resulting from SEL24h is limited to within a few metres from the moving sound source (Zykov, 2013; McPherson and Wood 2017), which is not considered to be a credible exposure for mobile marine fauna. Exceedance of the 160 dB re 1 µPa SPL behavioural response threshold for impulsive sound is limited to within a few metres in most instances, or up to a maximum of 50 m depending upon which SBP instrument is used, water depth and the seabed sediment characteristics (Zykov, 2013; McPherson and Wood 2017).

Potential impacts to cetaceans from MBES, SSS and sub-bottom profiler may, therefore, include behavioural disturbance if in close proximity to the survey instruments, but ranges to disturbance are less than or equivalent to disturbance ranges for the IMMR vessel itself. PTS or TTS are not considered credible, given individuals would need to be directly next to the noise sources for prolonged duration.

Transponders used for positioning during IMMR activities have the potential to cause some temporary behavioural disturbance to cetaceans. The typical frequencies of 21 to 31 kHz produced by the transponders are most audible to HF cetaceans such as toothed whales and dolphins rather than LF cetaceans, and the source levels (180 to 202 dB re 1 µPa at 1 m SPL) rapidly attenuate within a very short distance from the source, such that PTS or TTS are not considered credible. Based on empirical spreading loss estimates measured by Warner and McCrodan (2011), received levels from USBL transponders are expected to exceed the cetacean behavioural response threshold for impulsive sources out to about 42 m.

Transmissions are not continuous but consist of short ‘chirps’ with a duration that ranges from three to 40 milliseconds. Transponders do not emit sound when on standby. When required for general positioning, they emit one chirp every five seconds (estimated to be required for 4 hrs at a time). When required for precise positioning, they emit one chirp every second (estimated to be required for 2 hrs at a time). Due to the short duration chirps, the temporary and intermittent use and the mid frequencies used by positioning equipment, the acoustic noise from the transponders is unlikely to have a substantive effect on the behavioural patterns of cetaceans.

Potential impacts from predicted noise levels from the operating facility, project vessels, and IMMR survey activities are not considered to be ecologically significant at a population level for cetaceans.

Marine Turtles

Species Sensitivity and Exposure Thresholds

The Recovery Plan for Marine Turtles (Commonwealth of Australia, 2017) notes there is limited information available on the impact of noise on marine turtles and that the impact of noise on turtle stocks may vary depending on whether exposure is short (acute) or long-term (chronic). However, turtles have been shown to respond to low frequency sound, with indications that they have the highest hearing sensitivity in the frequency range 100–700 Hz (Bartol and Musick, 2003).

McCauley et al. (2000) observed the behavioural response of caged green and loggerhead turtles to impulsive sound (an approaching seismic airgun). For received levels above 166 dB re 1 µPa SPL, the turtles increased their swimming activity and above 175 dB re 1 µPa they began to behave erratically, which was interpreted as an agitated state. The 166 dB re 1 µPa SPL has been used as the threshold level for a behavioural disturbance response by the US NMFS (NSF, 2011) and is applied to this impact assessment. No quantitative (numerical) thresholds have been developed for behavioural effects from continuous sources (e.g., vessel noise) on marine turtles. However, Popper et al. (2014) propose qualitative impact criteria for near-field, intermediate and far-field exposures (Popper et al. 2014). Finneran et al., (2017) presents thresholds for turtle PTS and TTS for both impulsive and continuous sound exposures.

The thresholds listed in Table 6-5 are considered appropriate for the assessment of effects from impulsive and continuous sound sources during the Petroleum Activities Program.

Table 6-5: Thresholds for PTS, TTS and behavioural response onset in marine turtles for continuous and impulsive noise

Hearing group	Impulsive			Continuous		
	PTS onset thresholds: SEL24h (dB re 1 µPa².s)	TTS onset thresholds: SEL24h (dB re 1 µPa².s)	Behavioural response (dB re 1 µPa)	PTS onset thresholds: SEL24h (dB re 1 µPa².s)	TTS onset thresholds: SEL24h (dB re 1 µPa².s)	Behavioural response (dB re 1 µPa)

Marine turtles	204	189	166* 175+	220	200	(N) High (I) Moderate (F) Low#

*Source: PTS and TTS thresholds (Finneran et al., 2017), * behavioural response threshold (impulsive) (NSF 2011), + behavioural disturbance threshold (impulsive) (McCauley et al. 2000), # behavioural response threshold (continuous) (Popper et al. 2014).*

Note: The sound units provided in the table above for continuous noise include: relative risk (high, medium and low) is given for marine turtles at three distances from the source defined in relative terms as near (N – tens of metres), intermediate (I – hundreds of metres) and far (F – thousands of metres) (after Popper et al. 2014).

Predicted Underwater Noise Impacts to Turtles

Facility and Support Vessel Noise Impacts

As noted above, vessels holding station are considered to be the predominant noise source related to the Petroleum Activities Program, with source levels of approximately 182 dB re 1 µPa SPL at 1 m from a support vessel holding station considered to be representative of noise levels generated by vessels used for the Petroleum Activities Program.

Although there are no quantitative sound exposure thresholds for impacts on marine turtles resulting from continuous noise sources, the relative risk for behavioural response is expected to be high within tens of metres of the source, medium within hundreds of metres and low within kilometres from the source (refer Table 6-5). PTS and TTS thresholds for turtles are 220 dB re 1 µPa2 s (SEL weighted) and 200 dB re 1 µPa2 s (SEL weighted), respectively (refer Table 6-5). Typical noise levels generated by the facility and a support vessel using DP would not exceed these levels (except at extremely close ranges to the source), and prolonged exposure of transient marine turtles at close range is not considered a credible scenario.

As outlined above, marine turtles are not expected to be in the area in high numbers even during nesting and internesting periods. Marine turtles are also capable of moving away from potential noise sources, and there are no constraints to their movement within the PAA. Therefore, impacts to marine turtles from project vessels or the platform are expected to be of no lasting effect.

IMMR Activities

As outlined above for cetaceans, Zykov (2013) conducted noise modelling for low energy survey instruments, with the modelling for MBES, SSS and sub-bottom profiler considered comparable for the nature and scale of the low energy IMMR survey equipment. The operating fr–quencies of MBES (12 -700 kHz) and SSS (75 - 900 kHz) are w–ll above the hearing range of turtles (0.1 - 2 kHz) and so no disturbance is expected. It is possible that some of the lower frequen–y sound emitted by sub-bottom profilers (2 - 30 kHz) may be audible to turtles, but again, a large proportion of the sound energy may be at frequencies that are outside of their normal auditory range. Modelling of impulsive sub-bottom profiler sound emissions by Zykov (2013) and McPherson and Wood (2017) indicates that the 166 dB re 1 µPa (SPL) behavioural disturbance threshold for turtles may only be exceeded within metres or tens of metres of the survey instruments. Therefore, behavioural impacts would be highly localised. PTS or TTS is not considered to be credible given the rapid attenuation of sound close to the source and a large proportion of the sound energy is produced at frequencies outside the peak hearing frequency range of turtles.

Transponders used for positioning during IMMR activities typical operate at frequencies of 21 to 31 kHz which is well outside the p–ak hearing frequency range of turtles (0.1 - 2 kHz). Therefore, no impacts are considered credible.

Potential impacts from predicted noise levels from the operating facility, project vessels, and IMMR survey activities are not considered to be ecologically significant at a population level for turtles.

Fish, Sharks and Rays

Species Sensitivity and Exposure Thresholds

Fishes are primarily sensitive to the particle motion component of sound at close range to a sound source, while the presence of the swim bladder results in a varying degree of sensitivity of some fishes to sound pressure (Popper & Hawkins, 2018; Popper et al., 2019). Consequently, fishes are broadly categorised into three groups with respect to their hearing capabilities that are relevant to the types of fishes and sharks that may be present in the Operational Area (Popper et al., 2014):

- Fishes with no swim bladder or other gas chamber (e.g., sharks, mackerels) – Sensitive only to particle motion, not sound pressure changes.
- Fishes with swim bladders, but without a direct connection between the swim bladder and the inner ear (e.g., demersal snappers and emperors) – Hearing primarily involves particle motion with some limited ability to indirectly detect changes in sound pressure.

Fishes with a swim bladder or other gas volume connected directly to the inner ear (e.g. herrings, sardines, pilchards, shads) – These fishes are able to detect both sound pressure as well as particle motion.

Sound exposure criteria applicable to continuous sound sources are presented in Table 6-6. Popper et al. (2014) propose relative risk criteria (high, moderate, low) for injury, impairment and behavioural effects to fishes at three distance categories, near (N) (tens of metres from the source), intermediate (I) (hundreds of metres from the source), and far (F) (kilometres from the source).

Table 6-6: Impact thresholds to fish, sharks and rays for continuous noise

Receptor	Mortality and potential mortal injury	Impairment			Behaviour
		Recoverable Injury	TTS	Masking	
Fish: no swim bladder	(N) Low (I) Low (F) Low	(N) Low (I) Low (F) Low	(N) Moderate (I) Low (F) Low	(N) High (I) High (F) Moderate	(N) Moderate (I) Moderate (F) Low
Fish: swim bladder not involved in hearing	(N) Low (I) Low (F) Low	(N) Low (I) Low (F) Low	(N) Moderate (I) Low (F) Low	(N) High (I) High (F) Moderate	(N) Moderate (I) Moderate (F) Low
Fish: swim bladder involving hearing	(N) Low (I) Low (F) Low	170 dB SPL for 48-hours	158 dB SPL for 12-hours	(N) High (I) High (F) High	(N) High (I) Moderate (F) Low
Fish eggs and fish larvae	(N) Low (I) Low (F) Low	(N) Low (I) Low (F) Low	(N) Low (I) Low (F) Low	(N) High (I) Moderate (F) Low	(N) Moderate (I) Moderate (F) Low

Note: The sound units provided in the table above include relative risk (high, medium and low) is given for fish (all types) at three distances from the source defined in relative terms as near (N – tens of metres), intermediate (I – hundreds of metres) and far (F – thousands of metres) (after Popper et al. 2014).

Predicted Underwater Noise Impacts to Fish

Facility and Support Vessel Noise Impacts

Vessels holding station using DP are expected to produce sound equivalent to about 182 dB re 1 µPa SPL at 1 m. Modelling undertaken by McPherson et al. (2019) of sound produced by facility and vessel operations found that recoverable injury to some types of fish would only be possible if they remained within a distance of less than 10 m for 48 hours, and TTS if fishes remained within 10 m for at least 12 hours. Pelagic fish are highly mobile, and the types of demersal fishes known to occur in the vicinity of the Pluto facility (e.g. snappers, emperors, cods and groupers) will exhibit some fidelity to the area but are still relatively free-swimming and are not constrained to such close ranges (i.e. 10 m). Therefore, free-swimming fish remaining in close range to sound sources for periods that subject themselves to TTS and injury is not considered to be a credible scenario.

There are no quantitative sound exposure thresholds for impacts on fish, sharks and rays resulting from continuous noise sources. The relative risk for behavioural response is expected to be high within tens of metres of the source, medium within hundreds of metres and low within kilometres from the source (refer Table 6-5). In the context of the riser platform, the largest contribution to operational noise is from the topside and near the surface, with lower sound levels produced from subsea infrastructure such as choke valves. Similarly, sound from the PSV would be at the surface. While some localised behavioural avoidance and masking in the vicinity of the loudest sound sources from the riser platform, choke valves and PSV may occur in some fishes, no lasting effect is anticipated. Fish are also known to habituate to continuous noise sources, which is consistent with fish congregating around operating offshore oil and gas structures.

Considering the overlap of the whale shark foraging BIA with the PAA, it is likely there may be increased numbers of individuals during migratory periods. Currently, there are no quantitative sound exposure thresholds relevant to whale sharks. It is expected that the potential effects of noise on whale sharks are the same as for other fish species, resulting in minor, localised and temporary behavioural change such as avoidance. Therefore, impacts to whale sharks from project vessels or the platform are expected to have no lasting effect. Other fauna associated with the PAA includes predominantly pelagic species of fish, with migratory species such as rays transiting through the PAA; these species may be similarly affected by noise from project vessels/facility. Potential impacts from predicted noise levels from the operating facility, project vessels, and IMMR survey activities are not considered to be ecologically significant at a population level for fish, sharks and rays.

Demonstration of ALARP				
Control Considered	**Control Feasibility (F) and Cost/Sacrifice (CS)**	**Benefit in Impact/Risk Reduction**	**Proportionality**	**Control Adopted**
Legislation, Codes and Standards				
EPBC Regulations 2000 – Part 8 Division 8.1 Interacting with cetaceans, including the following measures45: Support vessels will not travel greater than 6 knots within 300 m of a cetacean or turtle (caution zone) and not approach closer than 100 m from a whale. Support vessels will not approach closer than 50 m for a dolphin or turtle and/or 100 m for a whale (with the exception of animals bow riding). If the cetacean or turtle shows signs of being disturbed, support vessels will immediately withdraw from the caution zone at a constant speed of less than 6 knots. Support vessels will not travel greater than 8 knots within 250 m of a whale shark and not allow the vessel to approach closer than 30 m of a whale shark.	F: Yes. CS: Minimal cost. Standard practice.	Implementation of these controls is primarily intended to reduce the likelihood of a collision between a cetacean, whale shark or turtle occurring. However, implementation may also provide some reduction in the potential for exposure of these fauna to sound levels in direct proximity to vessels.	Controls based on legislative requirements – must be adopted.	Yes C 3.1
Good Practice				
Vary the timing of the Petroleum Activities Program to avoid migration periods.	F: No. The Petroleum Activities Program occurs continuously over a five year period, modifying the timing of the Petroleum Activities Program is not feasible. CS: Not considered, control not feasible.	Not considered, control not feasible.	Not considered, control not feasible.	No
Implement a shutdown zone around MBES, SSS and sub-bottom profiler for the following fauna: whales marine turtles whale sharks.	F: Yes. However, as equipment is underwater, effective	Limited. The areas of disturbance for these devices are limited and injury /	Acoustic MBES, SSS and sub-bottom profiler surveys are infrequently	No

[45] For safety reasons, the distance requirements below are not applied for a vessel holding station or with limited manoeuvrability e.g. anchor handling, loading, back-loading, bunkering, close standby cover for overside working and emergency situations.

Application of bubble curtains to reduce noise propagation.	F: No, Bubble curtain installation and operation in offshore open water not feasible due to technical operation constraints i.e. water depth/current.	Not considered, control not feasible.	Not considered, control not feasible.	No
ALARP Statement: On the basis of the environmental impact assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the potential impacts from acoustic emissions from vessels, helicopters, wellheads, pipelines and the Pluto platform (including machinery). As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.				

EPOs, EPSs and MC for Pluto Facility Operations			
Environmental Performance Outcomes	***Controls***	***Environmental Performance Standards***	***Measurement Criteria***
EPO 3 Limit adverse impacts on fauna from noise emissions during the Petroleum Activities Program to those with No lasting effect	C 3.1 EPBC Regulations 2000 – Part 8 Division 8.1 Interacting with cetaceans, which include the following measures : vessels will not travel greater than 6 knots within 300 m of a cetacean or turtle (caution zone) and not approach closer than 100 m from a whale; vessels will not approach closer than 50 m for a dolphin or turtle and/or 100 m for a whale (with the exception of animals bow riding); if the cetacean or turtle shows signs of being disturbed, activity support vessels will immediately withdraw from the caution zone at a constant speed of less than 6 knots; and vessels will not travel greater than 8 knots within 250 m of a whale shark	PS 3.1 Vessels will comply with the EPBC Regulations 2000 – Part 8 Division 8.1 (Regulation 8.05 and 8.06) Interacting with cetaceans to manage the risk of fauna collision.	MC 3.1.1 Records demonstrate no breaches with EPBC Regulations 2000 – Part 8 Division 8.1 Interacting with cetaceans and Woodside Marine Charterers Instructions. MC 3.1.2 Records demonstrate reporting cetacean ship strike incidents to DCCEEW.

	and not allow the vessel to approach closer than 30 m of a whale shark.		

Demonstration of Acceptability
Acceptability Statement:
The impact assessment has determined that, given the adopted controls, impacts from acoustic emissions from vessels, helicopters, wellheads, pipelines and the Pluto platform represent a negligible impact /disturbance to marine fauna within the Export Pipeline and Pluto Facility Operational Areas. Further opportunities to reduce the impacts and risks have been investigated above. The impacts are consistent with good oil-field practice/industry best practice.
The potential impacts and risks are considered broadly acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the impacts of acoustic emissions to a level that is broadly acceptable and demonstrate the EPOs are met.

6.7.4 Acoustic Emissions: Generation of Noise during Xena-03 Tie-Back Activities

Context		
Xena-03 Drilling &Tie-back Activities – Section 3.11 Vessel-based Activities for the Xena-03 Tie-back – Section 3.12	Protected Species – Section 4.6	Consultation – Section 5

Impact Evaluation Summary

Generation of noise from DP systems on project vessels.					x			F					
Generation of noise from cutting of well infrastructure and contingency activities.					x			F					

Description of Source of Impact

During Xena-03 Tie-back activities, sound will be generated from a number of sources including from vessels involved with installation of the mooring system, the MODU during drilling operations, support vessels, and retrieval of anchors. Noise may also be generated from contingency activities such as respud, sidetrack, well removal and associated underwater acoustic positioning systems. These noise sources will contribute to and have the potential to exceed ambient noise levels which range from around 90 dB re 1 µPa (sound pressure level [SPL]) under very calm, low wind conditions, to 120 dB re 1µPa (SPL) under windy conditions (McCauley, 2005).

Vessel Noise

A range of vessels may be used to complete the Xena-03 Tie-back activities, including AHVs, MODU, subsea installation vessels and other support vessels (Section 3.12).

The MODU (hybrid or moored) is expected to be on location for drilling operations for approximately 60 days including mobilisation, demobilisation and contingency. Vessels associated with installation of the mooring system will be on location for up to 10 days prior to arrival of the MODU. Subsea installation and commissioning activities may be on location for up to 3 weeks. Mooring system anchor retrieval may also take up to 10 days once the MODU departs.

The vessels will generate noise both in the air and underwater, due to the operation of thrusters, engines, propeller movement, etc. Vessels, including the MODU (unless moored/ hybrid), installation vessels, AHVs, general support vessels will use DP where propellers and thrusters are used to hold position, rather than anchoring, unless in an emergency.

MODU Drilling Operations (moored)

During drilling operations, a moored MODU will produce low-intensity continuous sound. Sound produced from an active MODU is predominantly below 2 kHz, with peak frequencies below 500 Hz.

A range of broadband values, 59 to 185 dB re 1 µPa at 1 m (SPL), have been quoted for various MODUs (Simmonds et al., 2004). McPherson et al. (2021) recorded the source level spectrum of the Ocean Onyx, which is considered representative of a moored MODU considered for the tie-back campaign. The Ocean Onyx was measured to have a broadband (10 Hz to 31 kHz) source level of 175.4 dB re 1 µPa m whilst anchored and drilling and is considered representative drilling activity for this EP. The measured source level for the Ocean Onyx is consistent with or slightly higher than levels recorded for other moored MODUs during drilling operations. For example, McCauley (1998) recorded source noise levels for moored MODUs from 149-154 dB re 1 µPa at 1 m while actively drilling (with support vessel on anchor) and Greene (1987) recorded source levels of two moored drillships from 145-158 dB re 1 µPa at 1 m during drilling (with support vessels idling nearby). Austin et al. (2018) recorded broadband source levels from MODU operations (excluding DP thrusters) to be 170.7 dB re 1 µPa.

Project Vessels and MODU Operation of DP

Vessels used for the Xena-03 Tie-back activities are detailed in Section 3.12, and are DP capable, as required. As discussed in Section 6.7.3, sound levels and frequencies generated by vessels varies with the size of the vessel, speed, engine type and the activity being undertaken.

Indicative MODU underwater noise measurements were taken for the West Aquarius MODU by JASCO on the Scotian Shelf in Canada (Wecker et al., 2022). The 90th percentile of the broadband radiated sound levels was 186.3 dB re 1 µPa (Martin et al., 2019). This is similar to measurements taken for the Maersk Discoverer drill rig on the North West Shelf (Woodside Energy Limited, 2011), where the system emitted tonal signals between 200 Hz to 1.2 kHz, at a source level between 176 and 185 dB re 1 µPa SPL at 1 m.

Noise levels generated by support vessels on standby is expected to be similar to levels discussed in Section 6.7.3.

Sound Transmission Loss Modelling

Noise modelling was commissioned from JASCO by Woodside for the Julimar Appraisal Drilling and Surveys activities (Julimar South-1 well) (Stroot et al., 2022) and Pyxis Drilling and Subsea Installation activities (Xena-02 well) (Wecker, et al., 2022), which are considered broadly comparable in terms of MODU and vessel activities, and the water depths and seabed substrates at the Xena-03 well location.

For moored MODU scenarios, noise modelling for the Julimar Appraisal Drilling and Surveys activities (Stroot et al., 2022) provides a suitable analogue to the size and type of moored MODU and support vessels planned for use during Xena-03 tie-back activities. A number of moored MODU scenarios were modelled including with an offshore supply vessel (OSV) in ~166 m at the Julimar South-1 well location. Given water depth at the Xena-03 location is 177 m and similar seabed substrate, the modelling of the moored MODU and OSV are regarded as a suitable analogue for similar vessels and activities at the Xena-03 location.

For DP vessel activities, noise modelling for Pyxis Drilling and Subsea Installation activities (Wecker, et al., 2022) provides a similar analogue to the size and type of hybrid MODU and support vessels planned for use during the Xena-03 Tie-back activities. Several DP MODU scenarios were modelled, including with an OSV in ~172 m at the Xena-02 well location. As above, this modelling is considered a suitable analogue for similar vessels and activities at the Xena-03 location.

These scenarios included several permutations of support vessels and the MODU undertaking drilling activities, used to inform the worst-case credible noise propagation scenarios (including concurrent activities).

Table 6-7: Summary of modelled scenarios for drilling activities at the Julimar South-1 well location as an analogue for moored operations (source: Stroot et al., 2022).

Scenario Number	Description
1	Anchored MODU Drilling (24h)
2	Anchored MODU Drilling (24h) + OSV on standby (24h)
3	Anchored MODU Drilling + OSV resupply, under DP (2h)
4	Anchored MODU Drilling (24h) + OSV resupply, under DP (8h)
5	Anchored MODU Drilling (24h) + OSV resupply, under DP (8h) + OSV on standby (24h)

Table 6-8: Summary of modelled scenarios at the Xena (Xena-02) field as an analogue for DP operations (source: Wecker et al., 2022).

Scenario Number	Description
6	MODU under DP, drilling at Xena-02 (24 hr)
7	MODU under DP, drilling at Xena-02 (24 hr) + support vessel resupply, under DP (2 hr)

Source levels representative of drilling and subsea installation scenarios

Source levels for relevant vessels that were used to inform the sound transmission loss modelling (Stroot et al., 2022; Wecker et al., 2022) are presented in Table 6-10. The source sounds were applied to the modelling scenarios for drilling and subsea installation activities.

Table 6-9: Vessel source levels used in the acoustic modelling for the Xena-03 Tie-back activities.

Vessel	Sound Level (dB re 1 µPa².m2.s)	Reference
Moored MODU	175.4	(Stroot et al., 2022)
MODU under DP	187.7	(Wecker et al., 2022)
OSV stationary under DP (resupply scenario)	187.6	(Stroot et al., 2022)
OSV slow transit	177.8	(Stroot et al., 2022)

Sound Transmission Loss Modelling Scenarios

The acoustic modelling scenarios used in this assessment are presented in Table 6-8 and Table 6-9. Vessel scenarios during Xena-03 tie-back activities may differ slightly from those modelled from time to time in terms of precise vessel types, proximity and number. However, the magnitude and extent of potential sound propagation and the resultant effects on marine fauna from the modelled worst-case scenario are expected to be comparable to the worst-case scenario or are conservative.

The acoustic modelling studies assessed distances from operations where underwater sound levels were predicted to drop below thresholds corresponding to behavioural response and injury (temporary reduction in hearing sensitivity or TTS and permanent threshold shift or PTS) for marine fauna. The animals considered included marine mammals, turtles, and fish. Due to the variety of species considered, several different thresholds were used for evaluating effects.

The modelling methodologies considered scenario specific source levels and range-dependent environmental properties. Estimated underwater acoustic levels for non-impulsive (continuous) noise sources presented as sound pressure levels (SPL, Lp), and as accumulated sound exposure levels (SEL, LE) as appropriate for different noise effect criteria, behavioural response and injury (TTS and TPS), respectively. In this report, the duration of the SEL accumulation is defined as integrated over a 24-hour period.

The SEL24h is a cumulative metric that reflects the dosimetric impact of noise levels within 24 hours based on the assumption that an animal is consistently exposed to such noise levels at a fixed position. The corresponding SEL24h radii represent an unlikely worst-case scenario. More realistically, marine mammals (as well as pelagic fish and turtles) would not stay in the same location for 24 hours. Therefore, a reported radius for SEL24h criteria does not mean that marine fauna travelling within this radius of the source will be injured, but rather that an animal could be exposed to the sound level associated with injury (TTS or PTS) if it remained in that location for 24 hours.

Contingency Activities (Respud, Sidetrack, Well Removal)

Contingency activities include a well respud or sidetrack and will involve the use of a MODU and vessels, plus drilling operations. Any acoustic emissions generated will be the same as those expected from the planned activities described above.

In the event the wellhead is removed under this EP scope, additional noise from the cutting of the surface casing and conductors is likely to be generated. Underwater noise associated with cutting (diamond wire) of subsea infrastructure is generally indistinguishable above background noise levels at lower frequencies, primarily detected at noise frequencies above 5 kHz (Pangerc et al., 2016). Quijano and McPherson (2021) estimated the source level of a

diamond wire saw cutter at 169 dB re 1 µPa at 1 m. The casings and conductors will be cut below the mudline to enable wellhead recovery using either abrasive water jet cutting method, or mechanical cutting method.

Twachtman et al. (2004) concluded that mechanical cutting and abrasive water jetting, as well as diamond wire cutting methods, are generally considered harmless to marine life and the environment. Similarly, Pangerc et al. (2016) found that the sound radiated from the diamond wire cutting of the conductor was not easily discernible above the background noise at the closest recorder located at 100 m from the source. The sound that could be associated with the diamond wire cutting was primarily detectable above the background noise at the higher acoustic frequencies (above around 5 kHz) (Pangerc et. al., 2016) above the hearing range of low frequency cetaceans. Background noise was attributed to surface vessel activity such as DP. Any noise propagating at seabed from either abrasive water jet cutting or mechanical cutting of the wellhead casing and conductors is likely to attenuate to levels at, or close to background ambient levels within <100 m of the source, with ambient levels being significantly elevated by the concurrent presence of a DP vessel immediately above the wellhead location. As such, noise from the cutting of the casing and conductors will not add to significantly to noise levels for the Xena-03 Tie-back activities and are not assessed further.

Generation of Underwater Noise from Positioning Equipment

An array of long baseline (LBL) and/or ultra-short baseline (USBL) transponders may be installed on the seabed for metrology and positioning. An array of transponders is proposed within a radius of 500 m from the proposed location of the well and will be in place for a period of about three months. During xmas tree installation, ultra-short baseline transponders (USBL) may be installed on the seabed or mounted to the wellhead as required by the subsea installation activities. Transmissions from USBL transponders are similar to LBL transponders.

Transponders typically emit pulses (impulsive noise) of medium frequency sound, generally within the range 21 to 31 kHz. The estimated SPL would be 180 to 206 dB re 1 µPa at 1 m (Jiménez-Arranz et al., 2017). Transmissions are not continuous but consist of short ‘chirps’ with a duration that ranges from 3 to 40 milliseconds. Transponders will not emit any sound when on standby and are planned to only actively emit sound for about six hours per well. When required for general positioning they will emit one chirp every five seconds (estimated to be required for four hours at a time). When required for precise positioning they will emit one chirp every second (estimated to be required for two hours at a time). An array of transponders will be active whilst the DP MODU is on location.

Rig Anchor Release system

Should a hybrid MODU be utilised, Rig Anchor Release (RAR) moorings may be installed to allow the DP capable rig rapidly disengage from a mooring system. An RAR device will couple each of the moorings to the MODU (8 – 12 devices depending on mooring spread).

RAR devices typically emit pulses (impulsive noise) of low frequency, in the range of 9-11 kHz. Transmissions are expected to be limited to short pulses with a duration of minutes, during weekly testing. When activated to release moorings, they are expected to emit pulses of ~two minutes duration for each RAR.

Cumulative noise sources

Underwater noise generated during Xena-03 Tie-back activities (~12 weeks) havethe potential for cumulative impacts with routine Pluto Facility Operations (Section 6.7.3) with acoustic emissions from routine operations (e.g. machinery, flaring, IMMR activities etc), which may result in slightly elevated acoustic levels.

As described above, Xena-03 Tie-back activities are likely to include AHVs, a MODU and PIV as well as installation and support vessels. SIMOPS with drilling and installation are not planned but are considered as a contingency. During concurrent activities, a number of vessels may be operating. The worst-case credible scenario is considered to be if the MODU, support vessel and installation vessel are required to be in proximity. This is the case used for the following cumulative assessment of potential impacts.

Table 6-10: Concurrent activities considered in the assessment of cumulative underwater vessel noise

Concurrent Activities	Approx. Duration1	Vessels	Approximate distance between vessels
MODU drilling. Subsea tree installation from installation vessel (or similar activity)	2 days	MODU + supply vessel Installation or IMMR vessel (DP)	<3 km
Pre-Commissioning and start-up of Xena-03 tie back Platform operations and supply	5 days	Commissioning (IMMR class) vessel (DP) Platform + DP supply vessel	~11 km

Notes:

Relates to period of overlap, not entire duration of activity.

Impact Assessment

Potential impacts to environmental values

Receptors

The Xena-03 Operational Area is located in waters at ~177m depth (Section 3.2). The fauna associated with this area will be predominantly pelagic species of fish and cetaceans, with migratory species such as cetaceans, marine turtles and whale sharks occurring in the area seasonally (Section 4.6). Anthropogenic noise interference is a key threat to a number of migratory and threatened cetaceans, marine turtles and whale sharks identified as potentially occurring within the Xena-03 Operational Area.

The migration and distribution BIA for the pygmy blue whale partially overlaps the Xena-03 Operational Area (Section 4.6.3). Migration periods for pygmy blue whales are April to July and October to January, and some whales can be expected to pass by the Xena-03 Tieback activities.

The migration BIA for the humpback whale is ~30 km east of the Xena-03 Operational Area with no overlap. The migration period for humpback whale is June to November and the majority of the migrating population will be found further inshore than the Xena-03 Tie-back activities, inside the BIA.

The internesting buffer BIA for the flatback turtle overlaps the Xena-03 Operational Area. Habitat Critical for the flatback turtle is ~10 kms from the Xena-03 Operational Area (~12 kms from the Xena-03 well location). Given the water depths and distance from shore, the Xena-03 Operational Area, does not represent suitable foraging or internesting habitat. Satellite tracking of flatback turtle nesting populations (Barrow Island and mainland sites) indicates this species travels to the east of Barrow Island between nesting events, within WA mainland coastal waters less than 70 m deep (Chevron Australia Pty Ltd, 2015).

The whale shark foraging BIA overlaps with the Xena-03 Operational Area. Peak whale shark numbers are expected in the region from March to July.

The Continental Slope Demersal Fish Communities KEF overlaps the wider Xena-03 Operational Area (Section 4.7) and is recognised for its biodiversity values, including high levels of species endemism (DCCEEW 2023b). The targeted well location is not within the Continental Slope Demersal Fish Communities KEF (Figure 4-10).

Potential Impacts of Noise

Elevated underwater noise can affect marine fauna, including cetaceans, fish, turtles, sharks and rays, in three main ways (Richardson et al., 1995; Simmonds et al. 2004):

by causing direct physical effects on hearing or other organs. Hearing loss may be temporary (temporary threshold shift (TTS) referred to as auditory fatigue), or permanent threshold shift (PTS) (injury);

by masking or interfering with other biologically important sounds (including vocal communication, echolocation, signals and sounds produced by predators or prey); and

through disturbance leading to behavioural changes or displacement from important areas (e.g. BIAs). The occurrence and intensity of disturbance is highly variable and depends on a range of factors relating to the animal and situation.

Sound Propagation

Increasing the distance from the noise source usually results in the level of noise reducing, due primarily to the spreading of the sound energy with distance. The way that the noise spreads (geometrical divergence) depends upon several factors such as water column depth, pressure, temperature gradients, and salinity, as well as surface and bottom conditions.

Cetaceans

Species Sensitivity and Thresholds

Protected species including migratory pygmy blue whales may be encountered near the Xena-03 Operational Area and therefore could be impacted by acoustic emissions associated with Xena-03 Tie-back activities. Thresholds that could result in a behavioural response, TTS and PTS for cetaceans as a result of continuous and impulsive noise sources are presented in Table 6-6.

Predicted Underwater Noise Impacts to Cetaceans

Results - Modelling of a Moored MODU

A sound transmission loss modelling study was conducted by JASCO for several scenarios at the analogous Julimar South-1 well location (water depth – 166.6 m) as well as a nominated OSV standby location (water depth – 150.2 m), (Stroot et al., 2022). The modelling study indicated that exceedances of the PTS and TTS thresholds for low frequency (LF) cetaceans, such as humpback whale and pygmy blue whale, may occur out to a maximum of 0.07 km and 0.92 km respectively. For HF and VHF cetaceans (toothed whales and dolphins), the maximum distances at which sound levels dropped below PTS and TTS thresholds were 0.21 km and 2.76 km respectively.

During normal operations (the moored MODU drilling with an OSV on standby – Scenario 2), the minimum distance to the TTS threshold is 0.23 km, 0.09 km and 2.57 km for LF, HF and VHF cetaceans respectively. The PTS threshold was only exceeded for VHF for Scenario 2, at a maximum distance of 0.15 kmTable 6-11.

As described above, the PTS and TTS thresholds are based on a cumulative metric that that reflects the dosimetric impact of noise levels over a 24 hours period based on the assumption that an animal is consistently exposed to such noise levels at a fixed position. It is not considered credible that individual LF and HF cetaceans that may pass through the Xena-03 Operational Area during the drilling program would experience PTS or TTS, given individuals would need to remain within 70 m (PTS) and <1 km (TTS) of the drilling activity for a period of 24 hours. It is also considered highly unlikely that any VHF cetaceans would experience PTS or TTS.

The behavioural response threshold may be exceeded at a maximum of 3.57 km during normal drilling operations, and at a maximum of 8.85 km at times when an additional OSV is present and operating DP.

Table 6-11: Thresholds for PTS, TTS and behavioural response onset thresholds for cetaceans and marine turtles based on Southall et al. (2019) and Finneran et al. (2017).

Hearing group	Frequency-weighted SEL24h threshold (LE,24h; dB re 1 µPa²·s)	Scenario 1	Scenario 2	Scenario 3	Scenario 4	Scenario 5

Cetaceans	120	1.07	3.57	8.25*		8.85

**Scenario 4 has been omitted from Table 6-12 because Scenario 4 differs to Scenario 3 only by the time duration, and the SPL sound footprints represent the instantaneous sound field, independent on accumulation time. A dash indicates the level was not reached within the limits of the modelled resolution–(20 m).Source: Stroot et al (2022)*

Results - Modelling of a DP MODU

The analogous sound transmission loss modelling study by JASCO for a MODU on DP (Wecker et al., 2022) indicated that the PTS and TTS thresholds for low frequency (LF) cetaceans, such as humpback whale and pygmy blue whale, may be exceeded out to a maximum of 0.13 km and 2.66 km respectively across the scenarios modelled. For HF and VHF cetaceans, the maximum distances at which sound levels dropped below PTS and TTS thresholds were 0.15 km (PTS) and 2.63 km respectively. During normal operations (MODU on DP with a support vessel on standby - Scenario 9), the maximum distance at which the TTS threshold is exceeded is 2.17 km, 0.09 km and 2.44 km for LF, HF and VHF cetaceans respectively. For PTS, the maximum distance at which the threshold is exceeded is 0.08 km, 0.02 km and 0.11 km for LF, HF and VHF cetaceans respectively.

As described above, the radii that represent potential for PTS and TTS onset are based on a 24-hour period of exposure and therefore represent an unlikely worst-case scenario since, more realistically, cetaceans would not stay in the same location or at the same range for 24-hours. It is not considered credible that individual LF, HF and VHF cetaceans that may pass through the Xena-03 Operational Area during DP vessel operations, would experience PTS, given individuals would need to remain within 150 m of the drilling activity for a period of 24 hours. TTS onset is also considered highly unlikely given the known movement behaviour of cetaceans including key migrating LF whale species such as the pygmy blue whale transiting through the Xena-03 Operational Area. The Xena-03 Operational

Area is not known to represent significant foraging/aggregation habitat for cetaceans and individuals are not expected to dwell within the area for extended periods.

The behavioural response threshold may be exceeded at a maximum of 17.2 km during normal drilling operations and a maximum of 20.7 km at times when an additional support vessel is present and operating DP.

Table 6-12: Thresholds for PTS, TTS and behavioural response onset thresholds for cetaceans and marine turtles based on Southall et al. (2019) and Finneran et al. (2017).

Impact Assessment

Potential behavioural disturbance to pygmy blue whales within the distribution range is limited to any overlap with the northbound (April to July) and southbound (October to January) migratory seasons. Migrating humpback whales have shown avoidance behaviours (increased movement rate and dive frequency) when exposed to underwater noise generated by a vessel (Dunlop et al., 2015), and pygmy blue whales may exhibit similar responses.

There is limited data to indicate that the Xena-03 Operational Area represents an area where opportunistic foraging by pygmy blue whales occurs. Based on an overlap of three different metrics (occupancy, number of whales in a cell and move persistence), Thums et al. (2022) identified the most important foraging areas for pygmy blue whales offshore from Western Australia but also recognised such areas are not static but dependent on the interplay of oceanographic and prey dynamics. The included areas encompassed the shelf edge from Ningaloo Reef to the Rowley Shoals, but none of the important foraging areas identified were on the shelf edge or slope offshore from where the Xena-03 Operational Area is located. Hence, it cannot be reasonably predicted that pygmy blue whale foraging is probable in the Xena-03 Operational Area. Furthermore, all of the identified important pygmy blue whale foraging areas identified by Thums et al. (2022) in offshore NW Australian waters are located beyond the maximum range (km) at which the TTS and behavioural impact thresholds for cetaceans are predicted to be exceeded based on modelling presented above.

Humpback whales occur in the region, with the migration BIA ~30 km east of the Xena-03 Operational Area. Aerial surveys of migrating humpback whales in the region showed that the majority of migrating humpbacks occur in the mid- and inner-continental shelf waters, rather than the outer part of the migration BIA (RPS Environment and Planning, 2010). The Xena-03 Operational Area is surrounded by open water, with no restrictions (e.g., shallow waters, embayments) to an animal's ability to avoid the activities. Behavioural responses by cetaceans (such as pygmy blue whales and humpback whales) may result in a deviation in course during migration, which is expected to be insignificant in the context of the long distances over which individuals migrate (thousands of kilometres). Cetaceans that are frequently exposed to sounds such as vessel noise may also habituate and adapt to this noise (Richardson et al. 1995; NRCC, 2003). This may be the case for the humpback whale population that regularly passes

through areas of significant shipping traffic during their migrations. Furthermore, MODU activities are expected to occur over approximately 50-60 days.

Transponders used for positioning have the potential to cause some temporary behavioural disturbance to cetaceans; however, noise levels will be well below injury thresholds. Based on empirical spreading loss estimates measured by Warner and McCrodan (2011), received levels from USBL transponders are expected to exceed the cetacean behavioural response threshold for impulsive sources out to about 42 m. Given the short-duration chirps and the mid frequencies used by positioning equipment, the acoustic noise from a single transponder is unlikely to have any substantial effect on the behavioural patterns of marine fauna. Therefore, potential impacts from transponder noise are likely to be restricted to temporary and localised avoidance behaviour of individuals transiting through the PAA, and therefore are considered localised with no lasting effect.

Potential impacts from predicted noise levels from the MODU, project vessels and transponders are not considered to be ecologically significant at a population level.

The National Recovery Plan for the Southern Right Whale (DCCEEW, 2024) also identified anthropogenic noise as a threat, however the BIAs and habitat critical to the survival are over 250km away, well outside the area where behavioural responses are expected to extend from the Operational Area and as such, there is not expected to be any anthropogenic noise from the petroleum activity that could displace or interfere with life cycle activities within, or near, the reproduction or migration BIAs and habitat critical to the survival.

Marine Turtles

Species Sensitivity and Thresholds

Turtles have been shown to respond to low frequency sound, with indications that they have the highest hearing sensitivity in the frequency range 100–700 Hz (Bartol and Musick, 2003). Lenhardt (1994) observed marine turtles avoiding low-frequency sound.

Acute noise, or temporary exposure to loud noise, may result in the avoidance of important habitats and in some situations physical damage to marine turtles. McCauley et al. (2000) observed the behavioural response of caged sea turtles—green (Chelonia mydas) and loggerhead (Caretta caretta)—to an approaching seismic airgun. For received levels above 166 dB re 1 µPa, the turtles increased their swimming activity and above 175 dB re 1 µPa (SPL) they began to behave erratically, which was interpreted as an agitated state. No numerical thresholds have been developed for behavioural impacts of continuous sources (e.g. vessel noise) on marine turtles. A Popper et al. (2014) review assessed thresholds for marine turtles and found qualitative results that the risk of behavioural disturbance was high for near field exposure, moderate for intermediate exposure and low for far field exposure (Popper et al., 2014).

Sound exposure thresholds and criteria for continuous sound sources (e.g. vessel noise) and impulsive sources (e.g. transponders) applicable to marine turtles are summarised in Table 6-5.

Impact Assessment

Marine turtles may be present in the region, with a flatback turtle internesting BIA, overlapping the Xena-03 Operational Area. Habitat Critical for the flatback turtle is present ~10 km south west of the Xena-03 Operational Area. The Recovery Plan for Marine Turtles (Commonwealth of Australia, 2017) notes there is limited information available on the impact of noise on marine turtles and that the impact of noise on turtle stocks may vary depending on whether exposure is short (acute) or long-term (chronic). However, given the thresholds outlined it is reasonable to expect that marine turtles may demonstrate avoidance or attraction behaviour to the noise generated by the Xena-03 Tie-back activities. Sound transmission loss modelling indicated that the potential for PTS and TTS onset would be limited to within tens of meters of drilling activity, and up to 140 m (TTS) during DP vessel activities. However, marine turtles within the Xena-03 Operational Area are expected to be transient individuals, and unlikely to remain within 140 m of the vessels for 24-hours, and therefore PTS and TTS thresholds are not expected to be reached. Behavioural impacts to marine turtles from continuous noise sources generated by the Xena-03 Tie-back activities are expected to be short-term and localised.

Given the water depths and distance from shore, the Xena-03 Operational Area does not represent suitable foraging or internesting habitat. The defined BIA and Habitat Critical are considered very conservative as they are based on the maximum range of internesting females rather than direct studies that show marine turtles are more likely to remain near their nesting beaches. For example, tracking studies at Barrow and Thevenard islands suggest the majority of internesting flatback turtles remain in shallow water, close (< 3 km) to nesting beaches (Whittock et al., 2014). Studies of flatback turtle nesting in the Pilbara region also found that the average distance travelled at each of the beaches ranged between approximately 10 km and 27 km, and typically in water depths of less than 25 m (RPS 2010; Whittock et al. 2014; Whittock et al. 2016; Waayers and Stubbs, 2016). Hence it is considered highly unlikely that the Xena-03 Operational Area is utilised by internesting flatback turtles.

Marine turtle presence in general is expected to be infrequent, and potential impacts from predicted noise levels from the project vessels (including MODU and support vessels) are expected to be short-term, intermittent and localised, if they occur and are not considered to be ecologically significant at a population level.

Fish, Sharks and Rays

Species Sensitivity and Thresholds

Fish perceive sound through the ears and the lateral line, which are sensitive to vibration. Some species of teleost or bony fish (e.g., herring) have a structure linking the gas-filled swim bladder and ear, and these species usually have increased hearing sensitivity. These species are considered to be more sensitive to anthropogenic underwater noise sources than species such as cod (Gadus sp.), which do not possess a structure linking the swim bladder and inner ear. Fish species that either do not have a swim bladder (e.g., elasmobranchs (sharks and rays) and scombrid fish (mackerel and tunas)) or have a much-reduced swim bladder (e.g. flat fish) tend to have a relatively low auditory sensitivity.

Considering these differences in fish physiology, Popper et al. (2014) developed sound exposure guidelines for fish; these are presented in Table 6-13 and are considered appropriate to assess continuous acoustic discharges to fish from the Petroleum Activities Program.

Table 6-13: Impact thresholds to fish, sharks and rays for continuous noise

Receptor	Mortality and potential mortal injury	PTS	TTS	Masking	Behaviour
Fish: no swim bladder	(N) Low (I) Low (F) Low	(N) Low (I) Low (F) Low	(N) Moderate (I) Low (F) Low	(N) High (I) High (F) Moderate	(N) Moderate (I) Moderate (F) Low
Fish: swim bladder not involved in hearing	(N) Low (I) Low (F) Low	(N) Low (I) Low (F) Low	(N) Moderate (I) Low (F) Low	(N) High (I) High (F) Moderate	(N) Moderate (I) Moderate (F) Low
Fish: swim bladder involving hearing	(N) Low (I) Low (F) Low	170 dB rms SPL for 48-hours	158 dB rms SPL for 12-hours	(N) High (I) High (F) High	(N) High (I) Moderate (F) Low
Fish eggs and fish larvae	(N) Low (I) Low (F) Low	(N) Low (I) Low (F) Low	(N) Low (I) Low (F) Low	(N) High (I) Moderate (F) Low	(N) Moderate (I) Moderate (F) Low

Note: The sound units provided in the table above include relative risk (high, moderate and low) is given for fish (all types) at three distances from the source defined in relative terms as near (N – tens of metres), intermediate (I – hundreds of metres) and far (F – thousands of metres) (after Popper et al. 2014).

Impact Assessment

Given the thresholds outlined in Table 6-13, it is reasonable to expect that fish, sharks and rays may demonstrate avoidance or attraction behaviour to the noise generated by the Xena-03 Tie-back activities.. However, potential impacts from predicted noise levels from the project vessels (including MODU and support vessels) are not considered to be ecologically significant at a population level.

A number of demersal and pelagic fish species will be present within the Xena-03 Operational Area which overlaps the Continental Slope Demersal Fish Communities KEF. However, given species richness has been shown to correlate with habitat complexity (Gratwicke and Speight, 2005), it is unlikely that the sand/silt sediments that comprise the largest proportion of the Xena-03 Operational Area will support a wide diversity of species.

Maximum-over-depth horizontal distances to PTS and TTS thresholds for fish with a swim bladder involved in hearing as a result of underwater noise from a support vessel are approximately 10 m or less from the source based on modelling from JASCO for the Scarborough field (McPherson et al. 2019). For fish with a swim bladder not involved in hearing, and fish without a swim bladder (including whale sharks) the likelihood of PTS or TTS is low. Based on an intermediate spreading equation to estimate sound propagation loss from the MODU (15Log(R)), noise levels would drop below PTS and TTS thresholds for fish with a swim bladder involved in hearing within 15 m and 78 m respectively. It is expected that potential impact to demersal and pelagic fish and sharks/rays will be limited to a behavioural response. Behavioural responses are expected to be short-lived, with duration of effect less than or equal to the duration of exposure.

Whale sharks do frequent the wider NWS outside their seasonal aggregation period (peak: April and May) within the high-density prey foraging BIA at Ningaloo. The Xena-03 Operational Area overlaps a foraging BIA for whale sharks (Section 0), however it is over 200 km from the Ningaloo high density prey foraging BIA and therefore likelihood of whale shark encounters is not considered high but is possible. Acoustic detections of tagged whale sharks at the North Rankin A and GWA platforms during two periods—June to July and October to January were recorded

(Thomson et al. 2021) and supported anecdotal evidence of whale shark presence on NWS. Behavioural disturbance to whale sharks as a result of vessel noise may result in a temporary deviation on their migration route. However, any deviation is considered to be insignificant in the context of the long distances over which whale sharks migrate and normal variation in their movements in the region.

It is reasonable to expect that fish, sharks and rays may demonstrate avoidance or attraction behaviour to the noise generated by the Xena-03 Tie-back activities. However, potential impacts from predicted noise levels from the project vessels (including MODU and support vessels) are not considered to be ecologically significant at a population level.

Cumulative Impacts

As identified above, Xena-03 Tie-back activities will coincide with routine operations of the Pluto facility and may result in cumulative impacts from underwater noise emissions. The combined sound fields are likely to result in an increase in the maximum range to the behavioural response threshold for LF cetaceans described above (i.e. ~20 km). However, as described above, the Xena-03 Operational Area is surrounded by open water, with no restrictions (e.g. shallow waters, embayments) to an animal's ability to avoid the activities. Consequently, if concurrent activities occur and coincide with seasonal migrations, any pygmy blue whales, humpback whales or whale sharks transiting through the area, may deviate, but can continue on their pathway. Biologically significant impacts at a population level are not anticipated. Modelling outlined above predicted PTS onset in LF cetaceans within a maximum of 150 m and TTS onset within a maximum of 2.66 km for a combination of three vessels in close proximity. Any cumulative impacts arising from the Pluto Facility Operations will be limited to the duration of Xena-03 Tie-back activities (~12 weeks) and would be discontinuous over this time.

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)9F[46]***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Legislation, Codes and Standards				
EPBC Regulations 2000 – Part 8 Division 8.1 Interacting with cetaceans, including the following measures[47]: Project vessels will not travel greater than 6 knots within 300 m of a cetacean or turtle (caution zone) and not approach closer than 100 m from a whale. Project vessels will not approach closer than 50 m for a dolphin or turtle and/or 100 m for a whale (with the exception of animals bow riding). If the cetacean or turtle shows signs of being disturbed, project vessels will immediately withdraw from the caution zone at a constant speed of less than 6 knots. Vessels will not travel greater than 8 knots within 250 m of a whale shark and not allow the	F: Yes. CS: Minimal cost. Standard practice.	Implementation of controls for reduced vessel speed around cetaceans can potentially reduce the underwater noise footprint of a vessel and lower the likelihood of interaction above significant thresholds	Controls based on legislative requirements – must be adopted.	Yes C 3.1

[46] *Qualitative measure*

[47] *For safety reasons, the distance requirements below are not applied for a vessel holding station or with limited manoeuvrability e.g. anchor handling, loading, back-loading, bunkering, close standby cover for overside working and emergency situations.*

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)9F[46]***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
vessel to approach closer than 30 m of a whale shark.				
Good Practice				
Develop a SIMOPS Plan to manage rig interactions with other facilities/vessels, where multiple campaigns occur within the PAA (i.e. during xmas tree installation).	F: yes CS: Minimal cost. Standard practice.	SIMOPS management plans between Woodside operated vessels in the PAA will reduce the acoustic emissions from concurrent vessels.	Benefits outweigh cost/sacrifice.	Yes C 1.16
Implement adaptive management procedure prior to: resupply vessel moving alongside the MODU with PIV within the PAA, during daylight hours MODU departing well location (excludes kedging).	F: Yes CS: Time / Cost associated with person used for observations. Schedule delays associated with waiting on pygmy blue whale activity to cease / move on.	Implementation of adaptive management where pygmy blue whales (or large unidentified whales) are observed means a new noise source (vessel) is not introduced while pygmy blue whales are sighted. Restricting the introduction of new noise sources when pygmy blue whale presence is detected could lower likelihood of disturbance to pygmy blue whales so as to not be inconsistent with the Blue Whale Conservation Management Plan.	Benefits outweigh cost/sacrifice	Yes C 4.1
Collect data on opportunistic sightings of pygmy blue whales to gauge presence and behaviour.	F: Yes CS: Time / Cost associated with person used for observations and in data collection.	Collecting data on pygmy blue whale presence and behaviour may assist in increasing understanding of their activity in the PAA to inform future activities and support environmental knowledge.	Benefits outweigh cost/sacrifice.	Yes C 4.2
Implement speed limitations when safe[48] to do so for MODU and PIV within the Xena-03 Operational Area.	F: Yes, within the limits of navigational safety. CS: Time / Cost associated with slower transit speed.	Given the Xena-03 Operational Area overlaps the pygmy blue whale migration BIA and introduction of vessel noise may present behavioural disturbance risk to migrating pygmy blue whales, reducing vessel speed can result in reduced underwater noise emissions and overall	Benefit outweighs cost/sacrifice.	Yes C 4.3

[48] Vessel speeds are at the ultimate discretion of the vessel master, noting speed limitations may be exceeded from time to time to maintain safe navigation.

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)9F[46]***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
		reduction in potential behavioural disturbance. Additionally, reducing speed to 6 knots is consistent with the EPBC Regs 2000 – Part 8 Division 8.1, interacting with cetaceans, under which project vessels are not to travel greater than 6 knots within 300 m of a cetacean. Application of this speed restriction for the MODU and PIV within the Xena-03 Operational Area is considered to be a precautionary approach to reducing vessel noise and potential disturbance to cetaceans.		
Stop or deviate from course[49] if pygmy blue whale (or large unidentified whale) observed during entry of a hybrid MODU and PIV to the Xena-03 Operational Area.	F: Yes. If a whale is observed during mobilisation into the Xena-03 Operational Area, the MODU (if under own propulsion) and PIV could deviate course away from the whale and delay mobilisation. CS: Time/ cost associated with deviating and delay to mobilisation into the Xena-03 Operational Area.	Deviating course may reduce potential behavioural disturbance associated with vessel noise.	Benefit outweighs cost/sacrifice.	Yes C 4.4
Stop or deviate from course if pygmy blue whale (or large unidentified whale) observed during entry of a moored MODU into the Xena-03 Operational Area.	F: No. Stopping or deviating the MODU in an unplanned manner if a pygmy blue whale or large unidentified whale is observed may reduce potential behavioural disturbance associated with vessel noise. However, the action would significantly increase the safety risk profile of the mobilisation activity through reactive interruption of planned course by vessels towing MODU into field. CS: Introduces unacceptable safety risk.	Not considered – introduces unacceptable safety risk.	Not considered – introduces unacceptable safety risk.	No

[49] Unless deemed navigationally unsafe by the vessel master.

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)9F[46]***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
The use of dedicated Marine Fauna Observers (MFOs) on project vessels for the duration of the PAP to watch for whales and provide direction on and monitor compliance with Part 8 of the EPBC Regulations.	F: Yes. However, support vessel bridge crews already maintain a constant watch during operations. CS: Additional cost of MFOs.	Given that support vessel bridge crews already maintain a constant watch during operations and trained crew as MFOs will monitor for pygmy blue whale presence prior to resupply/support vessel moves alongside the MODU and PIV, additional MFOs would not further reduce the likelihood of an individual being within close proximity of the acoustic source during introduction of sounds related to DP or during operations.	Disproportionate. The cost/sacrifice outweighs the benefit gained.	No
Implement adaptive management procedure prior to: Hybrid MODU energising (turning on) DP system within the Xena-03 Operational Area.	F: No, a DP assist, or thruster assist rig is held into position by a mooring spread and may be supplemented by a thruster assisted mooring system. the DP system will be energised and available for emergency use but not planned for use in regular operations. The system operates such that thrusters engage automatically in response to metocean conditions using feedback (signals) from the mooring system. Therefore, it is not feasible to predict when this will occur and hence, pre-emptively apply adaptive management procedures. CS: N/A	Not considered – control not feasible.	Not considered – control not feasible.	No
Use professional MFOs in lieu of trained crew to observe for pygmy blue whales.	F: Yes CS: The cost of implementing dedicated MFOs during vessel activities would be tens of thousands of dollars and expose additional personnel to the health and safety risks of working at sea. The cost is grossly disproportionate to the environmental benefit.	The environmental benefit of having dedicated professional MFOs is a potential increase in the likelihood of detecting pygmy blue whales at the species level, which then permits actions to maintain separation as per the adaptive management procedure. Trained crew will watch for marine fauna during the petroleum activity. Trained	Disproportionate. The cost/ sacrifice outweighs the benefit gained.	No.

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)9F[46]***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
		crew will implement adaptive management measures if a pygmy blue whale or large unidentified whale is observed. Therefore whilst there is an increased likelihood for professional MFO's to detect pygmy blue whales from other large whale species, the ability to identify marine fauna in comparison with trained crew is negligible.		
Professional Judgement – Eliminate				
Remove support vessel on standby at the Petroleum Activities Program location.	F: No. Activity support vessel required as per MODU Safety Case, particularly for maintaining the 500 m petroleum safety zone around the MODU/ installation vessel. CS: Introduces unacceptable safety risk.	Not considered – control not feasible.	Not considered – control not feasible.	No
Eliminate generation of noise from the MODU, installation vessel, support vessels or positioning equipment.	F: No. The generation of noise from these sources cannot be eliminated due to operating requirements. Note that vessels operating on DP may be a safety critical requirement. CS: Inability to conduct the Petroleum Activities Program. Loss of project.	Not considered – control not feasible.	Not considered – control not feasible.	No
Professional Judgement – Substitute				
Management of vessel noise by varying the timing of the Petroleum Activities Program to avoid migration periods.	F: Yes. Migration periods for cetaceans that may occur in the PAA (pygmy blue and humpback whales) are well known. CS: Significant cost and schedule impacts if activities avoid specific timeframes	Avoiding migration periods would reduce the likelihood of impacts to cetaceans. However, given that the predicted impacts from noise sources associated with the Petroleum Activities Program are considered to be localised with no lasting effect, the overall benefit is minimal.	Disproportionate. The cost/sacrifice outweighs the benefit gained.	No
Professional Judgement – Engineered Solution				
Use of additional detection controls (e.g., drones for aerial observations, Passive Acoustic Monitoring for	F: Yes CS: Time / cost associated with additional personnel and	May increase likelihood of detection of whales, particularly during periods of poor visibility. Additional detection technologies can	Disproportionate. The cost/ sacrifice outweighs the benefit gained.	No

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)9F[46]***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
use at night, thermal imaging for use at night) to Identify cetacean presence.	technology onboard vessels. Due to distance offshore actual obse–vation times are limited by fuel availability - larger fuel capacity associated with larger aircraft increases cost of the exercise.	be degraded by metocean conditions (e.g., sea state). Additional detection methods would not result in a reduction in the potential consequence level.	Adequate observations are able to be made from the MODU bridge due to the height and surveillance by trained crew. It is not expected that additional technologies would add significantly more value than this to warrant deployment.	
ALARP Statement On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts and risks of noise emissions from Xena-03 Tie-back activities. As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.				
Demonstration of Acceptability				
Acceptability Statement The impact assessment has determined that the generation of noise from project vessels, MODU, and positioning equipment during Xena-03 Tie-back activities is unlikely to result in an impact significance level greater than slight. Relevant recovery plans and conservation advice have been considered during the impact assessment, and the Petroleum Activities Program is not considered to be inconsistent with the overall recovery objectives and actions of these recovery plans and conservation advice. In particular, the Conservation Management Plan for the Blue Whale (Commonwealth of Australia, 2015a) and associated guidance on key terms requires that pygmy blue whales not be displaced from a foraging area. The nearest recognised foraging BIA is off the Ningaloo Coast, approximately 232 km south-west of the PAA at the closest point. The sound transmission loss modelling studies by JASCO (Stroot et al., 2022; Wecker et al., 2022) predicted that behavioural responses (a conservative surrogate for displacement) could occur up to 8.85 km from the noise source during moored drilling activities or up to 20.7 km from the noise source during DP vessel activities; less than one tenth of the distance to the foraging BIA). Hence, displacement of pygmy blue whales from this foraging BIA as a result of the Xena-03 Tie-back Activities will not occur. The potential impacts are considered broadly acceptable if the adopted controls are implemented and EPO 5 has been applied to demonstrate the activities are not inconsistent with the Blue Whale Conservation Management Plan. Therefore, Woodside considers the adopted controls appropriate to manage the impacts of acoustic emissions to a level that is broadly acceptable and demonstrate the EPOs are met.

Description of Source of Impact

Operations

Hydrocarbons and chemicals may be discharged as a result of planned routine and non-routine operations and activities for:

Operational discharges including:

- discharge of subsea control fluids – subsea control fluid is used to control valves remotely from the facility. It is an open-loop system, designed to release control fluid from the control system during valve operations (e.g., up to about 6 L per valve actuation)
- potential non-routine hydraulic or chemical fluid discharge associated with umbilical system losses/weeps.
- discharge of minor fugitive hydrocarbon from wells and subsea equipment (e.g., weeps/seeps/bubbles)
- discharge of chemicals introduced into subsea infrastructure and the production stream, either as process or non-process chemicals (e.g., corrosion inhibitors, biocides, scale inhibitors). Chemicals flow through the production process, with residual hydrophilic chemicals discharged as a component of PW discharged overboard.

IMMR activities (nominal discharges described in Section 3.8.5) including:

- discharge of residual hydrocarbons in subsea lines and equipment and small gas releases associated with isolation testing and breaking containment.
- discharge of residual chemicals in subsea lines and equipment, or the use of chemicals. These chemicals are used and discharged intermittently in small volumes. Small quantities of chemicals may remain in the flushed infrastructure, which may be released to the environment after disconnection.
- discharge of hydrocarbons associated with pigging activities required as shown in Section 3.10.2.8.
- discharge of approximately 100–150 L of preservation fluids from flowlines following flushing when the flowlines are cut and plugs installed in either end of the cut section.

Xena-03 Tie-back Activities

The following activities may result in the discharges of small quantities of flowline and subsea installation preservation and pre-commissioning fluids:

- discharges during barrier testing
- discharges during disconnection of caps from installed structures (manifold, xmas tree, UTA)
- discharges from flexible flowline and flying leads during tie-in and reconfiguration activities.
- discharges from installation vessel's pre-commissioning equipment or subsea infrastructure during leak testing activities
- discharges post leak test, during depressurisation to marine environment.

In addition there is potential for discharge of minor fugitive hydrocarbons from the suspended Xena-03 well prior to xmas tree installation (e.g. weeps/seeps/bubbles).

Flexible Flowline Fluids

The flexible flowline and subsea distribution unit will be installed filled with a chemically treated mixture of up to 50 wt% MEG/water. The MEG concentration must be fibre-grade (99.9 wt%) before mixing with water. The flexible flowline will not require further flooding post-installation but pressure test top-up fluid may be required in the event of test failure.

Installation and tie-in of the flexible flowline to the manifold and xmas tree may result in small quantities of fluids within the flowline being released to the environment. These volumes are expected to be small (1 m3 per tie in point) as the pressure within the flowline is equal to the hydrostatic pressure and the flowline is uncapped for a short duration during tie-in. Water jetting and/ or acid injection (~400 L acid) may be used to clean the connections on the infrastructure prior to tie-in.

A leak test/system pressure test will be performed to test the integrity of the subsea connections, flowline and flowlines, which may result in ~4 m3 of MEG/treated potable water and ~0.6-1.2 L of treatment chemicals (including corrosion inhibitor, biocide, oxygen scavengers and dye) being released to the environment at the locality of the subsea infrastructure. A contingency secondary leak test may also be required, with similar discharge volumes.

Xmas Tree

The xmas tree will be installed with a preservation mixture in the production and annulus bore. There will be a small discharge of preservation fluid associated with testing after connection to the THS (estimated 100 to 150 L).

Hydrocarbons

Testing of manifold isolations may be undertaken to verify that suitable isolations are available for safe tie-in to the subsea distribution unit and flexible flowline. The testing and tie-in may release gas and condensate (up to 400L) over a 48 hour period. This testing is required to verify that suitable isolations are available for safe tie-in and cannot

reasonably be eliminated. The estimated mass of hydrocarbons is considered to be a worst-case, with the actual release volume expected to be smaller.

Well Unload

During well unloading activities, all completion and reservoir fluids will be directed to the Pluto facility and be handled by the systems onboard the platform, in accordance with Sections 3.5.5. All non-hydrocarbon fluids will be discharged overboard with the produced water.

Should well unloading fluids not be directed to the Pluto facility, they may be flared or discharged to the environment via the well test package onboard the MODU. The base oil column, completion fluid, hydrocarbons and produced/condensed water will be measured, handled, separated, treated for overboard discharge (non-hydrocarbon) and flared/burned (hydrocarbon) through the temporary production system on the MODU.

Well Intervention (contingency)

Well intervention activities have been considered within the Petroleum Activities Program, for contingency purposes. During intervention activities, including post xmas tree installation testing and TIV valve operations, local control of the xmas tree may be required. Valve actuation of the trees may be required, which will result in small releases of subsea control fluids to be released to the environment.

All subsea chemicals will be selected, assessed and approved in accordance with a defined framework and set of tools so that the potential impacts are acceptable, ALARP and meet Woodside's expectation for environmental performance, outlined in Section 7.2.1. This procedure is used to demonstrate that the potential impacts of the chemicals selected are acceptable and ALARP (subject to technical and economic constraints).

Impact Assessment

There is potential for localised water column pollution and adverse effects on marine biota as a result of planned routine and non-routine hydrocarbon and chemical discharges during operations and Xena-03 Tie-back activities. However, planned discharges of hydrocarbons and chemicals are minor and are minimised as far as practicable via flushing of the lines back to the facility during IMMR activities, and unloading wells to host during tie-back activities. Discharge locations during routine operations are either the PW stream, subsea valves (subsea control fluid), at dis/connection points in subsea infrastructure, including during installation of pig receivers or launchers, or via the export pipeline to the onshore process. During tie-back activities, discharges may also occur at connection points and during leak testing.

Water Quality

During operations, subsea control fluids are discharged at relatively small volumes during valve actuations (typically <6 L) and IMMR activities at or near the seabed. On release the subsea control fluids are expected to mix rapidly and dilute in the water column. Pigging activities are infrequent and result in relatively small releases of hydrocarbon.

During Xena-03 Tie-back activities, leak testing and tie in of new infrastructure may result in discharges of small amounts of MEG and hydrotest fluids as described above. Contingency activities, such as well intervention may result in minor discharges of subsea control fluids from the xmas tree, similar to valve actuation releases discussed above. On release, impacts of MEG and hydrotest fluids will be localised to the immediate vicinity of the release location with short-lasting impacts. This is based on the low potential for toxicity and bioaccumulation of MEG, small volumes/rates of discharge and rapid dilution in the marine environment.

Gas and condensate may be released during IMMR activities that break containment of isolated subsea infrastructure or during verification testing of the subsea distribution unit. Hydrocarbons will become dispersed as bubbles in the water column, which will rise to the surface. Methane is the principal component of the gas and is relatively insoluble in water. As such, methane is expected to rise until it reaches the sea surface, where it will be readily dispersed in the atmosphere. The concentration of methane will not be sufficient to form an explosive atmosphere or result in asphyxiation. Water-soluble components of the gas, such as carbon dioxide and sulphur dioxide will dissolve in the seawater as the gas bubbles rise in the water column. These soluble gasses occur naturally and are present in relatively low amounts. No measurable impacts to water quality are expected to occur as a result of the gas release.

The insoluble condensate release during verification testing will be buoyant and rise in the water column. The condensate will be released with gas which will act to disperse the condensate within the water column as it rises to the sea surface. The resulting condensate droplets will rise slowly in the water column and may be transported away from the release location by currents. Upon reaching the sea surface, the condensate will almost entirely evaporate, with a relatively small portion remaining entrained in the water column. Condensate droplets are not expected to reach the surface in sufficient quantities to result in surface slicks above thicknesses that result in biological impacts, although a sheen may be visible. Any condensate reaching the surface will spread and weather rapidly. Soluble hydrocarbons will be distributed in the water column through natural water movement and the buoyancy of the condensate droplets and are expected to drop below concentrations recognised as causing biological impacts within tens to hundreds of metres of the release location.

There is potential for slight, localised decrease in water quality at planned discharge locations and potential impacts on marine biota. Impacts to pelagic fish are expected to be limited to avoidance of the localised area of the discharge and short-term, localised decline in planktonic organisms in the immediate vicinity of the discharge.

Ecosystems

Sediments in the PAA are expected to be broadly consistent with those in the NWS Province (as described in Section 4.5), with filter feeders such as sponges, ascidians, soft corals and gorgonians associated with areas of hard substrate. Subsea control fluids and installation fluids are non-toxic and do not have the potential to bioaccumulate.

Receptors that may be impacted by a condensate release during verification testing are in-water receptors within the vicinity of the release location. These receptors include plankton, pelagic fishes and potentially cetaceans. Potential impacts to these receptors include:

acute toxic effects to planktonic organisms near the release location from soluble hydrocarbons. Only a very small portion of the planktonic community at a bioregional scale would credibly be impacted. Planktonic communities have high turnover rates, and recovery from any impacts would occur rapidly. Given the small volume of soluble hydrocarbons, the planktonic community in the upper part of the water column will not be impacted.

temporary displacement of pelagic fishes. Large-scale oil spills in open water typically do not result in fish kills, and it is assumed that fishes in open water will actively avoid harmful concentrations of hydrocarbons. Given the relatively small volume of hydrocarbons released and the resulting localised impact, it is unlikely that displacement of pelagic fishes will occur.

Given the nature and scale of planned discharges, potential impacts are considered to be slight and short term (expected to recover once routine and non-routine discharges cease).

KEFs

The Ancient Coastline at 125 m Depth Contour and Continental Slope Demersal Fish Communities KEF, overlap the PAA (Figure 4-10). The Continental Slope Demersal Fish Communities KEF overlaps the wider Xena-03 Operational Area and the Pluto Facility Operational Area. No significant escarpments, species of conservation significance, emergent features or areas of high biological productivity characteristically associated with the Ancient Coastline at 125 m KEF have been observed in the PAA. Therefore, potential impacts to these regional-scale KEFs are not expected.

A small portion of the Pluto Export Operational Area overlaps the Ancient Coastline at 125 m Depth Contour KEF. Potential impacts to this KEF would be limited to IMMR activities. Given the infrequent and small volumes of discharges associated with IMMR activities, potential impacts to the KEF are not expected.

Cumulative Impacts

Given the adopted controls, the overall impacts from the discharge of hydrocarbons and chemicals to the marine environment is Slight (E) based on short term (<1 year) on species, habitat (but not affecting ecosystems function), physical or biological attributes.

Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
	open-loop systems. CS: Significant. The design, procurement and retrofitting of a closed-loop valve control system would result in considerable offshore logistics, exposure to safety hazards during installation, and significant financial burden through direct costs and lost production.	ocean environment, and avoiding the discharges would provide little or no environmental benefit.	considered to be grossly disproportionate to the environmental benefit.	
Professional Judgement – Engineered Solution				
Poppetted hydraulic lines in control connections (to minimise release of control/preservation fluids).	F: Yes CS: Minimal cost. Standard Practice	Poppeted connections minimise discharge to marine environment in pressurised hydraulic lines	Benefits outweigh cost/sacrifice.	Yes C 5.10
Routing hydrocarbons to vessel during disconnection of subsea infrastructure.	F: Yes. However, to do so would introduce significant safety risks to the vessel crew (fire, explosion, asphyxiation). CS: Significant. Equipping and training crew on-board subsea support vessels to safely route hydrocarbons to the vessel would result in significant additional costs (in addition to the increased safety risk identified above).	Small environmental benefit from preventing low concentration hydrocarbon discharge.	Given the increased safety risk and the very low environmental impact from hydrocarbon releases during subsea IMMR activities, the cost of routing hydrocarbons to the vessel is grossly disproportionate to the environmental benefit.	No

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Decreasing the frequency of valve actuation.	F: Yes. However, decreasing the frequency of valve actuation may adversely impact the safe functionality and reliability of valves. Reducing the performance of subsea valves may introduce operability impacts, and increased safety and environmental risk associated with loss of containment events. CS: Minimal cost.	The potential consequence of the discharges is ranked as incidental, based on the volume, frequency, location and types of fluid discharged in an open-ocean environment, and reducing the number of discharges would provide little or no environmental benefit.	Decreasing the frequency of valve actuations would lead to a potential decrease in safe functionality and reliability of valves. When considering the potential safety and environmental risks from such a performance degradation, along with the minor impact from the release of control fluids, the cost of decreasing the frequency of valve actuations is considered to be grossly disproportionate to the environmental benefit.	No
ALARP Statement: On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts of planned routine and non-routine hydrocarbon and chemical discharges. As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.				
Demonstration of Acceptability				
Acceptability Statement: The impact assessment has determined that, given the adopted controls, planned routine and non-routine hydrocarbon and chemical discharge represents a localised short-term impact that is unlikely to result in a potential impact greater than slight short-term effects on water quality, marine sediment or ecosystem habitat. Further opportunities to reduce the impacts have been investigated above. Fluid discharges from the subsea system during operations, IMMR activities, flexible flowline commissioning and well intervention are routine in the oil and gas industry. The adopted controls are considered good oil-field practice/industry best practice. The potential impacts are considered broadly acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the impacts of planned routine and non-routine hydrocarbon and chemical discharges to a level that is broadly acceptable and demonstrates the EPOs are met.

Description of Source of Impact

Sewage, Putrescible Waste and Grey Water

No sewage is discharged from the facility when it is uncrewed. When the facility is crewed, the sanitary drainage system is a combined black and grey water system, with black and grey water discharged to the marine environment as untreated, un-macerated waste. Sewage is disposed via a dedicated overboard caisson (7.5 m below LAT). Putrescible waste (principally food scraps) bagged and transported to shore for disposal as domestic waste.

The volume of sewage and greywater generated is estimated to be in the order of 1.8 m3 per day (based on an average volume of 75 L/person/day), from the facility when crewed. The actual volume of discharge varies depending on personnel requirements on the facility. Refer to Section 3.6.7 for POB estimates under different activities.

Treatment systems on the facility may require routine maintenance or repair during operations, requiring infrequent short periods in which sewage is directly discharged overboard.

During maintenance campaigns or major projects, an ASV may be utilised inside the PSZ for periods of approximately 90 days to accommodate crews of around 100 POB. The ASV will discharge sewage, putrescible waste and grey water, managed in accordance with MARPOL requirements.

Vessels may also discharge sewage, grey water and putrescible wastes within the Operational Area, but outside of the facility PSZ. Sewage on-board operational vessels is routinely treated (either sewage treatment plant or macerator) prior to discharge.

The MODU and project vessels routinely generate/discharge small volumes of treated sewage, putrescible wastes and grey water to the marine environment (impact assessment based on approximate discharge of 15 m3 per vessel/MODU per day), using an average volume of 75 L/person/day and a maximum of 200 persons on board. However, it is noted that vessels such as the AHV and support vessels will have considerably fewer persons on board. Discharge of waste may occur within the PAA, but outside of the facility PSZ.

During tie-back activities the facility will be crewed during the commissioning phase, in addition to the presence of the MODU, installation vessels and other support vessels, resulting in cumulative volumes of sewerage, putrescible waste and grey water over approximately 12 weeks (Section 3.3.2).

Drain and Bilge Water

Pluto's hazardous open drains system collects wash water and waste liquids from major process and utility equipment and diesel/chemical storage areas, including plated area deck drains, drain tundishes and equipment drip trays in hazardous areas. Drainage into the hazardous open drains system discharges into a collection tank (working volume 11.6 m3), which is periodically pumped to a waste oil storage tank (capacity 4 m3) then transported onshore for disposal. The transfer of liquids from the collection tank to the waste oil storage tank is a manual operation only undertaken while the facility is crewed.

The non-hazardous area open drains system collects liquids from areas designated as non-hazardous. It is segregated from all other drainage systems to eliminate the risk of hydrocarbon vapour transmission from hazardous to non-hazardous areas. Water and any contamination are routed to the non-hazardous area open drains collection tank, which is 2 m3 (with max capacity of 2.6 m3). The collected liquids are manually drained to the hazardous area open drains collection tank during every facility campaign maintenance visit.

The MODU, ASV, installation and support vessels routinely generate and discharge relatively small volumes of bilge water. Bilge tanks receive fluids from many parts of the vessel, including machinery spaces. Bilge water can contain water, oil, detergents, solvents, chemicals, particles and other liquids, solids or chemicals. The MODU and vessels may also discharge drainage water from decks directly overboard or via deck drainage systems; deck drainage may also contain traces of chemicals. Water sources could include rainfall events and/or from deck activities such as cleaning/wash-down of equipment/decks.

Cooling Water and Brine

No brine water is produced on the facility as potable water is supplied from onshore. Additionally, no seawater cooling is undertaken on the facility.

Potable water, primarily for accommodation and associated domestic areas, may be generated on the MODU, ASV, installation and support vessels using a reverse osmosis (RO) plant. This process will produce brine, which is diluted and discharged at the sea surface.

During the distillation process, relatively small volumes of reject brine is produced and discharged. Reject brine discharge is typically 20 to 50 percent higher in salinity than the intake seawater (depending on the desalination process used) and may contain low concentrations of scale inhibitors and biocides, which are used to avoid fouling of pipework (Woodside, 2014).

Models developed by the US EPA (Frick et al., 2001) for temporary brine discharges from vessels assuming no ocean current (i.e. 0 m/s) found that brine discharges from the surface dilute 40–fold at 4 m from the source. This modelling can be used as an indicator for predicting horizontal attenuation and diffusion of reject brine; and suggests that the salinity concentration drops below environmental impact thresholds within 4 m of the discharge point.

Seawater is pumped on board and used as a heat exchange medium for the cooling of machinery engines and high temperature drilling fluid on the MODU. Seawater is drawn up from the ocean, where it is subsequently de-oxygenated and sterilised by electrolysis (by release of chlorine from the salt solution) and then circulated as coolant for various equipment through the heat exchangers (in the process transferring heat from the machinery), prior to discharge to the ocean. It is subsequently discharged from the MODU to the sea surface at potentially a higher temperature. Cooling water is often treated with additives including scale inhibitors and biocide to avoid fouling of pipework. Scale inhibitors and biocide are usually used at low dosages, and are usually consumed in the inhibition process, so there is little or no residual chemical concentration remaining upon discharge .In addition, the scale inhibitors and brine are selected and assessed using the Woodside chemical selection process.

Alternatively, MODUs may utilise closed-loop cooling systems. In these systems, fresh water is used in a closed circuit to cool down the engine room machinery, and then further cooled by sea water in a seawater cooler. Seawater used for cooling purposes would be routinely discharged at a temperature expected to be less than 70°C and rates ~50 m^3/d.

Impact Assessment

Sewage, Putrescible Waste and Grey Water

The environmental impact associated with ocean disposal of sewage, grey water and putrescible waste is eutrophication. Eutrophication occurs when the addition of nutrients, such as nitrates and phosphates, causes adverse changes to the ecosystem, such as oxygen depletion and phytoplankton blooms. Other contaminants of concern occurring in these discharges may include ammonia, E. coli, faecal coliform, volatile and semi-volatile organic compounds, phenol, hydrogen sulphide, metals, surfactants and phthalates.

No significant impacts from planned (routine and non-routine) discharges to the marine environment are anticipated, given the minor volumes involved, the localised mixing zone (as indicated by dilution modelling at the facility and high level of dilution into the open water marine environment of the PAA. This is supported by historical water quality and sewage discharge monitoring undertaken by Woodside around the nearby Goodwyn Alpha platform. The Goodwyn Alpha platform is approximately 72 km northeast of the PAA, therefore conditions are comparable. Water quality monitoring around the Goodwyn Alpha platform (which is a crewed platform) indicates there was no detectable decrease in oxygen saturation, nutrients or increase in oxygen demand at the Goodwyn Alpha platform (BMT Oceanica 2015a). In addition, monitoring of sewage discharges demonstrated that a 10 m3 sewage discharge reduces to approximately 1% of its original concentration within 50 m of the discharge location (Woodside, 2008).

The tie-back is expected to take up to 12 weeks including mobilisation, demobilisation and contingency with subsea installation and pre-commissioning. MODU and installation and support vessel routine discharges are expected to be intermittent in nature for the duration of the tie-back activity. Therefore, impacts to water quality within the PAA are expected to be localised with no lasting effect due to the small mass, relative to daily turnover, the assimilative capacity of the receiving environment, intermittent nature of discharges, and the variable discharge location due to project vessel movement.

Although the NWS Province is characterised as a low nutrient environment (DEWHA 2008), studies of adjacent shelf water have found the area to be “a highly productive ecosystem in which nutrients and organic matter are rapidly recycled” (Furnas and Mitchell 1999). The estimated daily loading from sewage and putrescible waste (Facility ~1.8 m3 per day; MODU/project vessels ~15 m3 per day) is not significant in comparison to the daily turnover of nutrients in the area. Furthermore, installation and support vessels are typically moving when in the PAA, which facilitates mixing of sewage, pulrescible wastes and grey water when discharged.

The impact of nutrients associated with discharge of sewage, grey-water and putrescible waste is considered to have a localised impact with no lasting effect due to the small mass, relative to daily turnover, and the assimilative capacity of the receiving environment.

Drain and Bilge Water

Drain water from the facility and bilge and deck drainage water from the MODU and installation and support vessels is expected to mix rapidly in the marine environment upon discharge. Deck drainage and treated bilge may contain a range of chemicals, oil, grease and solid material. This particulate matter can cause an increase in the turbidity of the receiving waters close to the point of discharge. The addition of these substances into the marine environment will result in a change ambient water quality; however, these discharges will disperse and dilute rapidly, with concentrations significantly dropping with distance from the discharge point. The PAA is located more than 12 nm from land exceeding the exclusion zones required by Marine Order 96 (Marine pollution prevention – sewage) 2018 and Marine Order 95 (Marine pollution prevention – garbage) 2013.

No significant impacts from the planned routine discharges are anticipated, because of the minor quantities involved, the expected localised mixing zone and high level of dilution into the open water marine environment of the PAA. Based on the detailed evaluation and low levels of potential contaminants, the magnitude of potential impact of a change in water quality is considered highly localised with no lasting effects.

Cooling Water and Brine

The key physicochemical stressors that are associated with reject brine and cooling water discharge from MODU and project vessels include salinity, pH, temperature and chemical toxicity.

The potential impacts on water quality due to cooling water discharge include chlorine toxicity and increased water temperatures. Woodside undertook modelling of continuous wastewater discharges (including cooling water) for its Torosa South-1 drilling program in the Scott Reef complex (Woodside, 2014). This study predicted that discharge water temperature decreases quickly as it mixes with the receiving waters, with the discharge water temperature being <1°C above ambient within 100 m (horizontally) of the discharge point, and 10 m vertically (Woodside, 2014). As such, any potential impacts to water quality are expected to occur within approximately 100 m of the source of the discharge, where concentrations are highest.

Reject brine will sink through the water column, owing to the 20% to 50% increase in salinity (Frick et al., 2001), where it will be rapidly mixed with receiving waters and dispersed by ocean currents, decreasing in salinity rapidly as distance from source increases.

The scale inhibitors used in the prevention of fouling within cooling systems are typically low in molecular weight and phosphorous compounds that are water-soluble, and only have acute toxicity to marine organisms approximately

two orders of magnitude higher than typically used in the water phase (Black et al., 1994). The biocides typically used in the industry are highly reactive and degrade rapidly (Black et al., 1994).

Based on the detailed risk evaluation, the magnitude of the potential impact of a change in water quality from routine and non-routine brine and cooling water discharges is assessed as having no lasting effect on the receiving environment.

Cumulative Impacts

Given the activities that may be conducted during the Petroleum Activities Program, there is the potential for cumulative impacts from routine discharges of sewage, putrescible waste, grey water, PW, bilge water or drain water, due to:

- periodic, repeated discharges at the same location (riser platform) over the course of the Petroleum Activities Program
- cumulative discharges from differing point sources (riser platform and various vessels, e.g. ASV, MODU, installation vessels).

Because of the nature of these routine discharges, normal operations are unmanned (and therefore no discharges), the localised spatial extent of impacts and the well mixed receiving environment, the cumulative impacts from these discharges are not considered to result in impacts more than slight short-term impact (i.e. Environment Impact – E). Given the highly localised nature of the impacts of routine discharges, no cumulative impacts are expected from similar discharges from other production facilities (e.g. Wheatstone), Xena-03 drilling and tieback activities, or support vessels.

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)[56]***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
ALARP Statement: On the basis of the environmental impact assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts of discharge of sewage, putrescible waste, grey water, bilge water, drain water, cooling water and brine from the Pluto Offshore facility, MODU, ASV, installation and support vessels. As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.				
Demonstration of Acceptability				
Acceptability Statement: The impact assessment has determined that, given the adopted controls, routine and non-routine discharges of sewage, putrescible waste, grey water, bilge water, drain water, cooling water and brine from the Pluto Offshore facility, MODU, ASV, installation and support vessels are not expected to result in potential impacts greater than localised contamination not significantly above background levels outside a localised mixing zone. Further opportunities to reduce the impacts have been investigated above. The adopted controls are considered good oil-field practice/industry best practice and meet legislative requirements under Marine Orders 91, 95 and 96. The potential impacts and risks are considered broadly acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the impacts and risks of these discharges to a level that is broadly acceptable and demonstrate the EPOs are met.

Description of Source of Impact

Produced water (PW) consists of formation water (derived from a water reservoir below the hydrocarbon formation) and condensed water (water vapour present within gas/condensate that condenses when brought to the surface). As described in Section 3.5.4 a water handling module has been installed on the riser platform to treat and discharge PW offshore. Water production from each reservoir is not expected to occur initially, as the reservoir ages wells will begin to cut water. It is difficult to anticipate with high confidence when wells will begin to produce water from each reservoir.

Separation of water from reservoir fluids is not practicable to achieve 100%-effectiveness and therefore, PW often contains small amounts of naturally occurring contaminants including dispersed oil, dissolved organic compounds (aliphatic and aromatic hydrocarbons, organic acids and phenols), inorganic compounds (e.g., soluble inorganic chemicals or dissolved metals) and residual process chemicals (including MEG on a non-routine basis) as well as production chemicals such as MEG, water clarifier and corrosion inhibitor. A description of the PW system has been provided in Section 3.5. Potential environmental impacts of PW discharge include changes in water quality, sediment quality and biota potentially reducing ecosystem integrity. The ratio of PW to hydrocarbon and therefore volume of PW each well produces is expected to increase over the field life. It is difficult to anticipate with high confidence when the volumes will require offshore discharge but is predicted to commence in 2024. The maximum possible daily discharge is 3500 m3/day (constrained by process equipment capacity); actual discharge rates during the Petroleum Activities Program fluctuate in line with production rates however are expected to be well below the maximum capacity.

Monitoring and Management Framework

Overview

This section describes the monitoring and management framework which Woodside has developed to support the monitoring of PW discharges from offshore assets. The Australian and New Zealand Guidelines (ANZG) for Fresh and Marine water quality have been implemented and are consistent with the principles of the National Water Quality Management Strategy.

Environmental values are defined as particular values or uses of the environment that are important for a healthy ecosystem or for public benefit, welfare, safety or health and that require protection from the effects of pollution, waste discharges and deposits (ANZG, 2018). The relevant environmental values considered are:

- ecosystem integrity – maintaining ecosystem processes (primary production, food chains) and the quality of water, biota and sediment.
- cultural and spiritual – in the absence of any specific environmental quality requirements for protection of this value, it is assumed that if water quality is managed to protect ecosystem integrity, this value is achieved in line with the guideline.

The relationship between key elements of ecosystem integrity, indicators and relevant monitoring activities undertaken on a routine and non-routine monitoring basis are shown in Figure 6-1. As per State Waters Technical Guidance: Protecting the quality of Western Australia's marine environment (EPA 2016) key elements to maintain ecosystem integrity have been identified as water quality, sediment quality and biological indicators (biota). By limiting the changes to these key elements to acceptable levels there is high confidence ecosystem integrity is maintained. For each of these elements an indicator has been identified and monitoring designed to identify changes. Monitoring changes in water quality and sediment quality as well as investigating potential toxicity via whole effluent toxicity (WET) testing and implementing management to maintain acceptable levels of changes is standard industry practice in Commonwealth and State waters. The relevant indicators to understand changes in key elements and therefore potential for impact to ecosystem integrity are physio-chemical stressors; toxicants in water; biological indicators and toxicants in sediment. A number of default and/or derived guideline values for each indicator have been defined and are monitored to detect changes. Guideline values serve as an early warning that potential changes beyond the acceptable limits may occur. Further investigation is then required to confirm whether there is potential to exceed the acceptable limit of change.

The approved mixing zone boundary for the facility is 1300 m. The approved mixing zone protects 95% of species, as calculated using the species sensitivity distribution (SSD) statistical method on the results of direct toxicity assessment. The protection of 95% of species guidelines have been adopted for a slightly to moderately disturbed system at the approved mixing zone boundary given the discharge location (ANZG 2018).

Given the proximity of the discharge point to the Montebello Marine Park Multiple Use Zone (~416 m from the facility) the acceptable limit at the boundary of the Multiple Use Zone is to protect 95% of species. The justification for these limits of change being "acceptable" is provided in the impact assessment section.

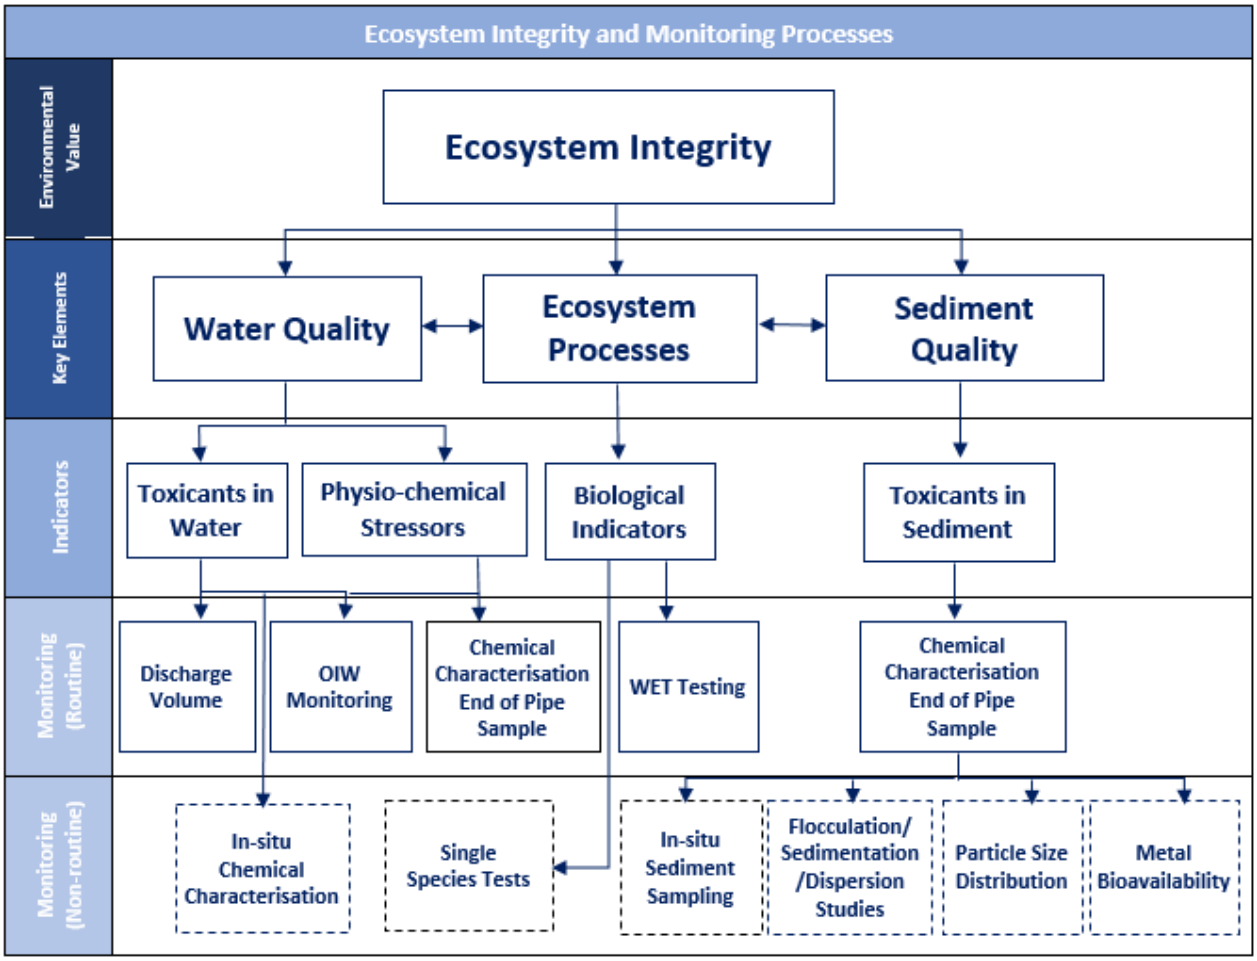

Figure 6-1: Ecosystem Integrity and Monitoring Process

Operational Monitoring

OIW monitoring during routine operations is undertaken via an online analyser. Online analyser information is sent via transmitter instantaneously and reported to the control system (CS) and is also captured within the process historian database (PHD). The CS facilitates visibility in the Central Control Room (either from Local Central Control Room at PLP or Remote Central Control Room in Perth), for manual or automated process control changes to be made, and/or annunciate alarms (e.g. high oil in water specification). PHD information is available onshore for analysis and trending. During each intervention visit on an approximately eight-weekly basis or six times per year operators manually sample PW and undertake manual analyser QC checks either at the onshore lab or on the facility.

Any discrepancies that are identified between instrument readings and CS/PHD that are outside of expected tolerance are investigated to determine the cause. As discussed in the Section 3.5.5.2, two analysers have been installed on the facility. If an analyser is faulty or breaks down, any anomalies that are identified are investigated to determine the cause and may be addressed by corrective maintenance during the next intervention visit.

Loss of Signal Management

If there is a loss of signal from both OIW analysers, operators attempt to troubleshoot remotely and monitor process stability for changes. If analysers cannot be restored and there are no observable changes to a stable operating process, low water cut, and high confidence of results below 30 mg/L, the next intervention visit will include reinstatement of the analyser operation if the next planned intervention is within seven days. If the next planned intervention is greater than seven days away, a 'reactive intervention' visit takes place to repair the analysers. Similarly, if analysers cannot be restored and there are no observable changes to a stable operating process, low water cut, and high confidence of results below 30 mg/L the reactive intervention visit will be performed within 7 days.

If there is a lack of certainty around results risking OIW measurements exceeding 30 mg/L for more than six consecutive hours, and a risk of OIW exceedance (24-hour rolling average) is anticipated, the asset may undertake a 'reactive intervention visit' via helicopter to verify results. A react visit if required is deployed to the platform within 48 hours, weather and time-of-day permitting.

High OIW Management

If the analyser is online and the OIW measurement exceeds 30 mg/L for more than six consecutive hours, an Operational Risk Assessment will be performed to determine if the high OIW could have occurred as a result of faulty equipment. If the risk of OIW exceedance (24-hour rolling average) is anticipated, the asset may undertake a 'reactive intervention visit' via helicopter to verify results.

For both loss of signal and high OIW management, a Standard Operating Procedure has been developed. It will display decision criteria to allow clear interpretation and facilitate compliance with OIW standards. Any EPS breaches are reported as Recordable Incidents.

Baseline Monitoring

As per EPBC Act condition requirements for the Pluto Gas condensate field (EPBC 2006/2968, condition 1(c) ii), Woodside undertook a baseline monitoring program in 2021 which included water, sediment, biological and physical monitoring. The assessment determined that ambient conditions meet the ANZG 2018 default guidelines values prior to discharge of PW and that benthic habitats present were typical of the North West Shelf in similar depths (BMT 2022).

Initial Monitoring

Initial samples of PW will be collected during the first intervention visit after reaching steady state conditions (at the end of the commissioning, optimisation and validation period) when the facility is operating (i.e., not during shutdown conditions) to characterise the discharge stream and potential toxicity. PW samples should represent normal operations, so sampling should only be undertaken during periods of normal production for the facility. Sampling should as far as reasonably practicable provide a representative sample. Representative samples are taken at a time when all PFW-producing wells are online (or as many as reasonably possible) with a consideration of chemicals that may be present in the discharge stream. Monitoring includes the following:

Chemical characterisation to identify if toxicants with the potential to bioaccumulate exceed the 80% species protection guideline value at end of pipe. If toxicants with the potential to bioaccumulate are predicted to exceed guideline values at end of pipe further investigations are required as described in the monitoring and management framework.

Chemical characterisation of the PW will be completed to verify 99% species protection safe dilutions for comparison with the approved mixing zone. If 99% safe dilutions are not predicted to be achieved at the boundary of the approved mixing zone, further investigations are required as described in the monitoring and management framework.

WET testing will be conducted to verify 95% species protection safe dilutions (as per SSD) for comparison with the approved mixing zone dilutions. If 95% safe dilutions are not predicted to be achieved at the boundary of the approved mixing zone, further investigations are required as described in the monitoring and management framework.

If 99% safe dilutions of chemical characterisation are not predicted to be achieved at the boundary of the marine park, further investigations are required as described in the monitoring and management framework. WET testing will be conducted (in parallel with chemical characterisation) to verify 95% species protection safe dilutions for comparison with the mixing zone dilutions at the Marine Park boundary at 416 m.

Settling velocity and particle size distribution analysis will be completed to ascertain the potential for contaminants to flocculate and settle out of solution and impact sediment quality. If an exceedance in water quality occurs, the results of these studies will inform if non routine sediment sampling is required prior to the next routine monitoring event.

Quarterly chemical characterisation and single species toxicity testing (initial sampling plus three events) is proposed during the first 12 months after reaching steady state conditions. WET testing will be completed to develop a robust understanding of variability in effluent toxicity. Results of chemical characterisation, single species toxicity tests will be compared against Offshore Marine Discharges Adaptive Management Plan (OMDAMP59) guideline values. Exceedances of guideline values require further investigation including multiple lines of evidence. If further investigation confirms the guideline value has been exceeded, a review of single species testing is conducted and if required additional WET testing. The single specie test proposed is a bacteria (Vibrio fischeri, Microtox® luminescence 5 and 15-min). This acute test is consistent with other Woodside PW discharging facilities and targets the lowest trophic level and most sensitive species. Initial monitoring will be conducted in accordance with the OMDAMP and where appropriate routine monitoring triggers, methods and standards applied (e.g. requirements for WET testing) so that there is consistency and comparability of data.

Routine Monitoring

PW is monitored and managed in accordance with the OMDAMP. The OMDAMP details routine monitoring assessment against guideline values, analytical methods and actions when a guideline value is exceeded.

The guideline values are applied through a risk-based approach that is intended to capture any uncertainty around the level of impact by staging monitoring and management responses according to the degree of risk to ecosystem integrity. The approach provides a level of confidence that management responses are not triggered too early (i.e., when there is no actual impact) or too late after significant or irreversible damage to the surrounding ecosystem" (EPA 2016). Routine monitoring applicable to the facility, is undertaken to compare against guideline values (described in Table 6-14). Changes in water quality can be detected early and can indicate the potential for an impact to sediments or biota prior to it occurring. WET testing provides additional lines of evidence if there is a potential for impacts.

PW samples should represent normal operations, so sampling should only be undertaken during periods of normal production for the facility. Where possible, samples are taken at a time when all PFW-producing wells are online (or as many as reasonably possible) with a consideration of chemicals that may be present in the discharge stream. The WET tests are undertaken on a broad range of taxa of ecological relevance for that accepted standard test protocols are well-established. WET tests are mainly focused on the early life stages of test organisms, when organisms are typically at their most sensitive to contaminants and are designed to represent local trophic level receptors. A minimum of eight toxicity tests are carried out with each PW sample during WET testing. The toxicity tests include a range of tropical and temperate Australian marine species and are selected based on their ecological relevance, known sensitivity to contaminants, availability of robust test protocols and known reproducibility and sensitivity as test species for assessing PW in marine environments. Specific tests are listed in the OMDAMP however other tests can be exchanged over time if tests are not available, or become obsolete, however, preference would be for tests that mimic the receiving environment as closely as possible (i.e., for most facilities this would be tropical, marine water tests) and for at least eight mainly chronic tests (Warne et al. 2015). The dilutions required to protect 95% of species is calculated using the ANZECC/ARMCANZ (2000) statistical distribution methodology on the results of direct toxicity assessment using sub-lethal chronic endpoints. The protection of 95% of species at the boundary of the Montebello Marine Park protects ecosystem integrity and associated values.

Settling velocity and particle size distribution analysis is proposed as part of the initial monitoring of representative discharge to confirm potential for sediment impacts. Results of these studies will inform if non-routine sediment sampling is required prior to the next routine monitoring event.

Table 6-14 Trigger values and frequency of routine monitoring

Routine Monitoring	Trigger Value	Frequency
Chemical characterisation End of pipe sample – toxicants	Results that are predicted to be higher than the 99% species protection guideline value at boundary of the approved mixing zone.	Annual.
	Results that are predicted to be higher than the 99% species protection guideline value at boundary of the marine park.	Annual.

[59] *The OMDAMP is reviewed annually. As such, it is important to note the OMDAMP information presented in this EP is subject to update to reflect new methodologies and adaptive management. Any changes in the OMDAMP are subject to the Change Management requirements.*

	Toxicants with the potential to bioaccumulate are predicted to be higher than the 80% species protection guideline value at end of pipe.	Annual if initial monitoring indicates 80% guideline values for toxicants with the potential to bioaccumulate are not met at end of pipe.
Chemical characterisation End of pipe sample – physio-chemical	Results that are predicted to be higher than the 99% species protection guideline value at boundary of approved mixing zone.	Annual.
WET testing	The 99% species protection safe dilutions derived from the WET testing species sensitivity distributions are not predicted to be achieved at boundary of approved mixing zone.	Three yearly. Conducted in parallel with annual chemical characterisation.
	The 95% species protection safe dilutions derived from the WET testing species sensitivity distributions are not predicted to be achieved prior to the boundary of marine park zone.	Three yearly. Conducted in parallel with annual chemical characterisation.
Review of continuous operational monitoring results	Increases in the average monthly OIW concentration by 5 mg/L for more than six consecutive months or by 10 mg/L for two consecutive months.	Monthly.
Discharge volume	Mean discharge volume (m3/day) is equal to or below the level required to meet approved mixing zone based on WET testing.	Monthly volume review.

Note: earlier toxicity year means the year in which the most recent WET test occurred.

If a guideline value is exceeded, there is uncertainty around whether the environmental value is being protected and further investigation is required.

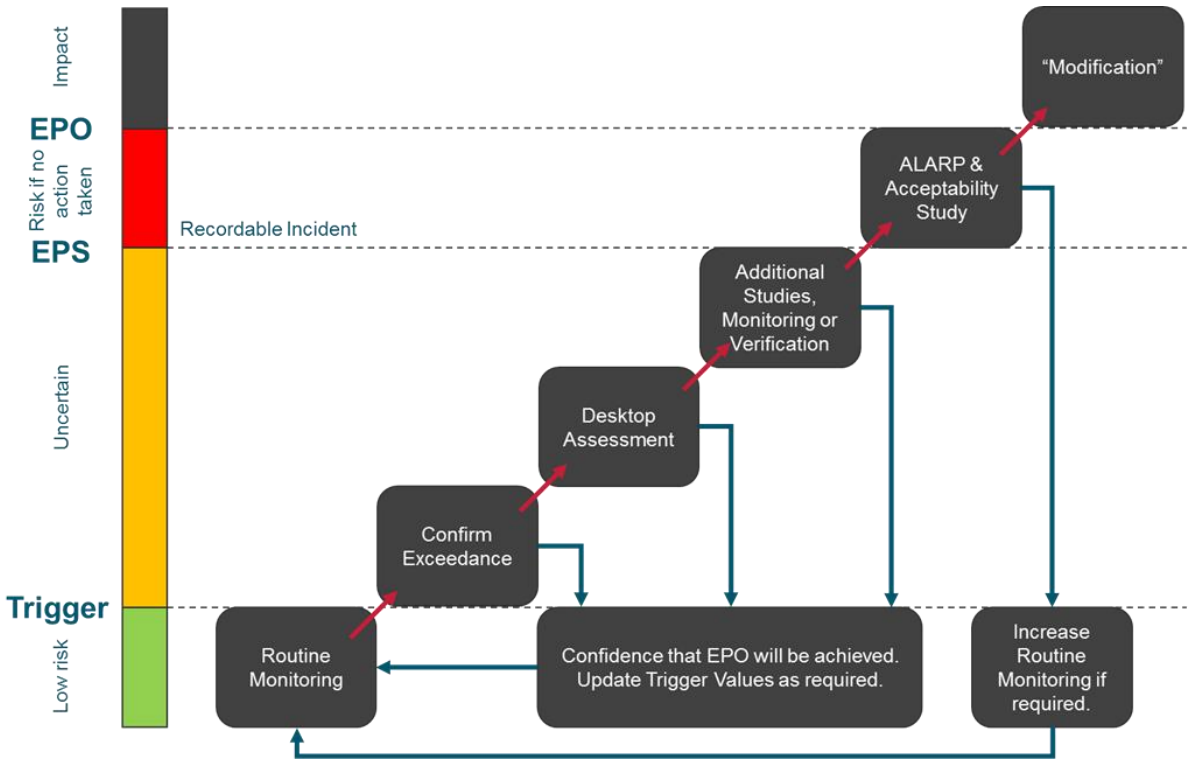

Figure 6-2: Routine Monitoring and Adaptive Management Framework for Produced Water

Further Investigations and non-routine exceedance monitoring

Detectable exceedances in guideline values may occur without impacting ecosystem integrity. To provide confidence that ecosystem integrity has been achieved, further investigation (per the OMDAMP) will be required in the form of a desktop study to initially assess the exceedance in context of available data (multiple lines of evidence) and confirm if there is potential for impact to the environmental value. A desktop assessment is necessary before undertaking any additional non-routine or in-situ monitoring. This ensures monitoring programs are designed and implemented to provide robust findings based on appropriate survey design.

A range of methods can be used to detect guideline value exceedances (e.g., relative percentage difference, control charts, multivariate analysis, etc.) depending on the dataset available. An appropriate method is selected as described in the OMDAMP due to the variable nature of environmental data. If critical data is not available, the desktop study will identify potential data gaps and may recommend additional non-routine studies and/or monitoring to ensure the assessment is appropriately undertaken. The purpose of the 'further investigations' step is to provide certainty that the EPS has been achieved, if a guideline value has been exceeded. The key investigation steps are described below:

Confirm the guideline value has been exceeded – Review quality assurance and quality control, methodology and possible sources of contamination to determine if the results are reliable, or if any factors have occurred that may compromise the integrity of the monitoring or data.

Desktop assessment to understand whether the EPS is at risk – If a guideline value is confirmed to be exceeded, multiple lines of evidence are considered including historical and current data from routine and non-routine monitoring and studies. This assessment shall consider whether there is adequate evidence to demonstrate that acceptability criteria have been met and ecological integrity is not at risk (EPS not breached). If the desktop assessment determines that the existing body of evidence is insufficient, it shall outline what additional monitoring or studies are required. The desktop assessment is needed before undertaking any additional infield monitoring. It ensures monitoring programs are designed and implemented to provide robust findings based on good survey design. Potential additional monitoring/studies may include but is not limited to:

- single species toxicity testing (collected annually in parallel with routine chemical characterisation should further investigation be required)
- WET test (collected in parallel with routine chemical characterisation should further investigation be required)
- dilution modelling and or studies
- flocculation, sedimentation, settling velocity and/or dispersion analysis
- metal bioavailability
- scanning electron microscopy and particle size distribution analyses
- in-situ monitoring (water quality and/or sediments).

Routine monitoring activities may be required ahead of schedule and additional monitoring not listed may be undertaken as appropriate. Field monitoring is undertaken in accordance with a plan that details timing, locations and objectives of monitoring.

Conduct additional studies to confirm the EPS is not at risk – Monitoring results provide additional lines of evidence to determine whether there is a risk to ecosystem integrity due to unacceptable changes in water quality, sediment, or biological indicators. Given the significant health, safety and technical risks, logistics and planning required, monitoring of the receiving environment is typically only considered when all other sources of evidence are insufficient to demonstrate that ecological integrity is not at risk. The OMDAMP provides detailed guidance on the steps and actions required to be undertaken if a guideline value is exceeded and this may include additional non-routine monitoring to verify that ecological integrity is maintained.

If an environmental impact is deemed to be within acceptable limits of change, the desktop assessment may consider a review of guideline values to ensure they are appropriate. If the environmental impact is deemed to be outside of the acceptable limits of change, an ALARP/Acceptability study is required to determine what additional controls can be implemented to ensure the impacts are acceptable. An EPS breach is a Recordable Incident, which is reported and managed as outlined in Section 7.13.5.

ALARP/Acceptability Study

An ALARP/Acceptability study is conducted once it has been determined, as a result of further investigations, that there is potential for an impact that exceeds the acceptable limits of change. The ALARP/Acceptability study shall be conducted in accordance with the ALARP Demonstration Procedure, to determine additional controls that may be necessary to reduce the potential impacts. Additional management measures (controls) may include technology or process upgrades, and reservoir management. Woodside will implement the additional controls identified in the ALARP/Acceptability study, that are required to give confidence that the acceptable limits on environmental impact can be achieved. Field validation of model assumptions and additional monitoring to assess whether impacts have been realised using a gradient monitoring design will be considered.

Impact Assessment

Potential impacts of PW discharge include:

- changes to water quality
- toxicity to biota
- changes to sediment quality.

To understand potential impacts from PW discharges, Woodside has undertaken a suite of comprehensive in-situ testing and sampling representing long-term operational periods from its offshore production facilities. The details of this testing and resultant understanding of potential environmental impacts are outlined below.

Potential Impacts to Water Quality

Potential impacts to water quality are to be assessed through chemical characterisation of the end of pipe discharge. Variability in the chemical composition is managed via the Monitoring and Management Framework.

Although reservoir fluids are available from the current production at the Pluto LNG Plant onshore, these are not deemed to be representative of PW characteristics at the offshore facility. The export pipeline transports hydrocarbons, condensed water and rich MEG to the Pluto LNG Plant onshore. There is significant difference between the natural compositions of PW associated with the reservoir compared to that condensed from the gas. Condensed water has low levels of dissolved salts while PW from the reservoir contains varying levels of salts. The presence of residual process chemicals further complicates any comparisons between onshore and offshore PW. Given the natural difference onshore PW samples are deemed to not be representative for the purposes of this assessment. It is not possible to collect a sample of PW that is representative of the discharge prior to treatment facilities achieving stable operation.

The discharge stream is expected to comprise primarily of PW from the Pluto reservoir. PW may also be derived from the Pyxis reservoir and Xena reservoir. Naturally Occurring Radioactive Materials (NORM's) have not been detected previously. Given PW will continue to be primarily from the Pluto reservoir increased NORMs are not expected and increased monitoring beyond that described above is not proposed.

Woodside has successfully managed impacts from PW from six facilities via the OMDAMP and intends to implement this Monitoring and Management Framework to manage variability in PW at this facility.

Chemical Characterisation of PW (Physio-chemical Parameters and Toxicants in Water)

During appraisal drilling for the Pluto project, samples of the formation water were obtained from three wells at various locations and depths within the reservoir with trace elements measured from each well in order to establish a basis for the process design (Table 6-15). The reported concentrations of metals were based on the highest levels measured from any of the three wells sampled (two Pluto, one Xena). The concentrations of metals within the three wells were highly variable. Metals with the potential to bioaccumulate (e.g., lead, mercury) were an order of magnitude lower in the other two wells compared to the worst case well used for the basis of design. Mercury concentrations measured from the three wells were 0.03, and <0.002 mg/L. Lead concentration measured from the three wells were 0.11, 0.03 and <0.02 mg/L. During routine operations a number of wells will be produced at any given time therefore the produced water will be comprised of formation water from a number of wells. The maximum toxicant concentrations from a single well will be diluted by wells with lower concentrations resulting in lower concentrations prior to discharge. Therefore, it is expected that lower concentrations will originate in the produced water and that these lower concentrations will be below the guideline values. The formation water will also be diluted by condensed water in the process further reducing concentrations. There have been no further opportunities to analyse PW from the reservoir to date. No ANZG 2018 guideline values are available for the ions listed within Table 6-15, as such dilution requirements are not listed. Dilutions to reach ANZG 2018 99% species protection guideline values are provided where applicable.

Table 6-15 Pluto Development Basis of Design Data Predicted PW Characteristics

a 99% species protection guideline value (ANZG 2018) ranking of reliability is shown in parenthesis.

b Golding et al. (2015) and draft submission paper to the Council of Australian Government's Standing Council on Environment and Water (SCEW).

c No guideline value or low reliability guideline value only available.

d Draft submission paper to the Council of Australian Government's Standing Council on Environment and Water (SCEW 2014).

The metal concentrations in the PW of the other Woodside offshore facilities are either lower than the ANGZ (2018) 99% species protection guideline values or between the 99% and 95% species protection guideline values at end of pipe. However, initial monitoring is proposed to confirm toxicants with the potential to bioaccumulate are below 80% species protection at end of pipe.

The composition of PW is complex and may consist of additional components such as volatile aromatic compounds Benzene, Toluene, Ethylbenzene, Xylenes (BTEX) and Polycyclic Aromatic Hydrocarbons (PAHs), concentrations of which vary throughout the field life. The chemical characterisation of the discharged PW will be verified by initial monitoring.

There is potential for slight, localised decrease in water quality at the discharge location and within the mixing zone with potential adverse effects on marine biota. Within the approved mixing zone impacts to pelagic fish are expected to be limited to avoidance of the localised area of the plume and short-term, localised decline in planktonic organisms in the immediate vicinity of the discharge plume.

Discharge Volumes

The maximum expected discharge rate is 3,500 m3/day (integrity limit). The average daily PW discharge rate is expected to be significantly less than the maximum rate as demonstrated on other Woodside facilities. However, as the total volume of PW is expected to increase as the field ages, environmental impacts have been assessed against maximum expected discharge rates and monitored as per the OMDAMP.

Residual Process Chemicals

Residual process chemicals may be present in the PW stream. Process chemicals are subject to Woodside's chemical selection and approval process. The largest chemical by volume, MEG is rated OCNS Group E (lowest hazard) and is considered PLONOR. Corrosion inhibitor required for the operation of the PW module and subsea system is assessed as having a CHARM assessment calculation rating of Gold. Chemicals will decrease the water quality in the immediate area of the release (i.e. surface waters at the release location); however, the consequence is expected to be temporary and localised due to dilution with the PW stream and the open ocean mixing environment, distance from sensitive receptors and relatively low and or non-routine discharge volumes.

Potential Impacts to Biological Indicators

Upon achieving steady state PW processing, chemical characterisation and WET testing of the PW will be completed in order to establish actual toxicity and to verify the approved mixing zone.

WET Testing

Most treated PW has low to moderate toxicity (Neff et al. 2011), with actual toxicity of discharge dependant on the chemical constituents of the PW and any added process chemicals, the level of treatment and dilution with condensed water prior to release, and the dilution of the discharge as it mixes with seawater. Most hydrocarbons in PW are considered non-specific narcotic toxins with additive toxicities; therefore, the toxicity of a PW will, in part, depend on the total concentration and range of bioavailable hydrocarbons (Neff, 2002).

WET testing is undertaken to allow for interactions between toxicants and take into account toxicants that cannot readily be measured or are not known to be present in the sample. For the WET testing a range of tropical and temperate Australian marine species are selected based on their ecological relevance, known sensitivity to contaminants, availability of robust test protocols, and known reproducibility and sensitivity as test species (ANGZ 2018).

The partitioning of contaminants between PW and condensate is unknown for the Pluto reservoir, therefore using the toxicity of the Pluto condensate as a surrogate for PW discharge is not appropriate. Woodside has extensive operational experience with PW characterisation from gas condensate facilities on the North West Shelf of Western Australia. Actual 99% and 95% species protection safe dilutions will be provided from initial monitoring WET testing to verify the approved mixing zone is being achieved.

During design of the PW handling module, the then available suite of Woodside PW WET testing results guided the conservative selection of the GWA species protection level (SPL) safe dilutions as 1:2,000 – which is basis for Pluto QSRA studies, and informing the approved mixing zone (2019 Environment Plan). This value has been retained for consistency in the 2024 Pluto EP assessment, and is appropriately more conservative than more recent worst-case dilutions required for similar assets as shown below in Table 6-31.

Recent WET testing data collected in 2022 and 2023 from existing operating facilities Table 6-31 was reviewed to verify a reasonable level of conservatism is included in impact assessment to ensure that 99% species protection safe dilutions, will be met within the approved mixing zone.

Table 6-17: Actual 99% and 95% species protection level (SPL) safe dilutions at Woodside's current PW discharge facilities

Facility	99% SPL safe dilutions	95% SPL safe dilutions
Angel	1:417	1:278
Goodwyn Alpha	1:1,388	1:205
North Rankin	1:63	1:44
Okha FPSO	1:102	1:67

In addition to this, in the context of assessing short-term non-routine OIW discharges with varied initial OIW concentration assumptions, the OSPAR (2014) dispersed oil concentration of 70 µg/L was used as the PNEC rather than the ANZECC/ARMCANZ (2000) guideline value (low reliability) of 7 µg/L. The PNEC of 70 µg/L derived by Smit et al (2009) is considered more appropriate than the Tsvetnenko (1998) derived 7 µg/L as all tests used in the Species Sensitivity Distribution (SSD) were chronic as opposed to acute converted to chronic values with an acute chronic ratio (ACR) of 25 as used by Tsvetnenko (1998). Further information on assessment of non-routine PW discharges is provided in modelling summary and Non-routine Activities Impact Assessment sections below.

Determination of Approved Mixing Zone

The principal aim of the modelling was to quantify the likely extents of the near-field and far-field mixing zones and therefore the potential impact of the PW to the marine environment. Three modelling methods were integrated to simulate the potential dispersion, an oceanic hydrodynamic model (HDROMAP) for current data, a near-field discharge model (PDS surface discharge model), and a far-field advection and dispersion model (MUDMAP) (APASA, 2017). The dispersion of contaminants will depend, initially, on the geometry and hydrodynamics of the discharge itself, where the induced momentum and buoyancy effects dominate over background processes. This region is

generally referred to as the near-field zone and is characterised by variations over short time and space scales. As the discharge mixes with the ambient waters, the momentum and buoyancy signatures are eroded, and the background, or ambient, processes become dominant.

The far-field modelling expands on the near-field work by allowing the time-varying nature of currents to be included, and the potential for recirculation of the plume back to the discharge location to be assessed. The near-field simulations consider steady-state unidirectional currents, while the far-field simulations account for currents that vary in speed and direction over time and space, far field modelling represents minimum dilutions achieved 95% of the time. Validation of the current data used for the modelling was performed using infield current measurements located approximately 30 km to the southwest of the Pluto riser platform location, two-point current measurements nearest to the surface, at depths of approximately 10 m and 70 m were used to evaluate the modelled current data. The outcome of the comparison was good agreement at all current speeds, and the modelled data product was suitable for PW discharge modelling. Validation of tidal predictions was performed using the model output and independent predictions of tides. All comparisons demonstrated that the model produces a very good match to the known tidal behaviour for a wide range of tidal amplitudes and clearly represents the varying diurnal and semi-diurnal nature of the tidal signal.

The dilution modelling results are based on the maximum design flow rates of 3,500 m3/day representing the worst-case load to the environment. At lower actual discharge rates, dilutions levels are expected to be achieved closer to the discharge point than those predicted by the modelling due to reduced loading to the environment.

Near Field

Modelling indicated that, irrespective of the season, given the elevation of the discharge above the water surface, the plume will initially plunge downward into the water column creating a turbulent mixing zone. Once the initial jet momentum ceased, the plume would remain sufficiently buoyant to rise to the surface to continue to mix with ambient waters, though at a slower rate. As a result of the mixing during the initial plunge and buoyant rise, the salinity and temperature of the discharge plume are predicted to reach background level over a short distance.

During low current speeds, the discharge will plunge the deepest (~11.5 m below sea level) and resurface closest to the riser platform (within approximately 10-11 m), with average dilution levels of 1:137-1:142 predicted at the end of the near field zone. Under medium and high current, the plunge depth becomes progressively shallower (approximately 7.5 and 5.5 m below sea level, respectively) due to the increasing deflection of the plume as it enters the water. The subsequent resurfacing of the plume under medium and high current occurs around 32 m and 63 m from the riser platform discharge location, respectively, regardless of season. Average dilution levels at the end of the near field zone under medium and high currents are predicted to be 1:135-1:237 and 1:277-1:283, respectively. Under all current conditions, the plume is predicted to resurface and remain in the upper layer of the water column (5-10 m).

Far Field

The far field modelling for all simulations indicated that the discharge plume would drift horizontally with the currents prevailing in the near surface layer while undergoing vertical and horizontal dispersion. Variable and patchy concentrations were predicted within the plume, attributed to large variation in current flows past the discharge point. The annual dilutions are provided below in

Generally, the overall plume footprints were observed to vary between season, with a noticeable north to north-westerly drift during the summer months and a south to south-westerly drift during the winter months. In the transitional months, more variation in the transport patterns was evident.

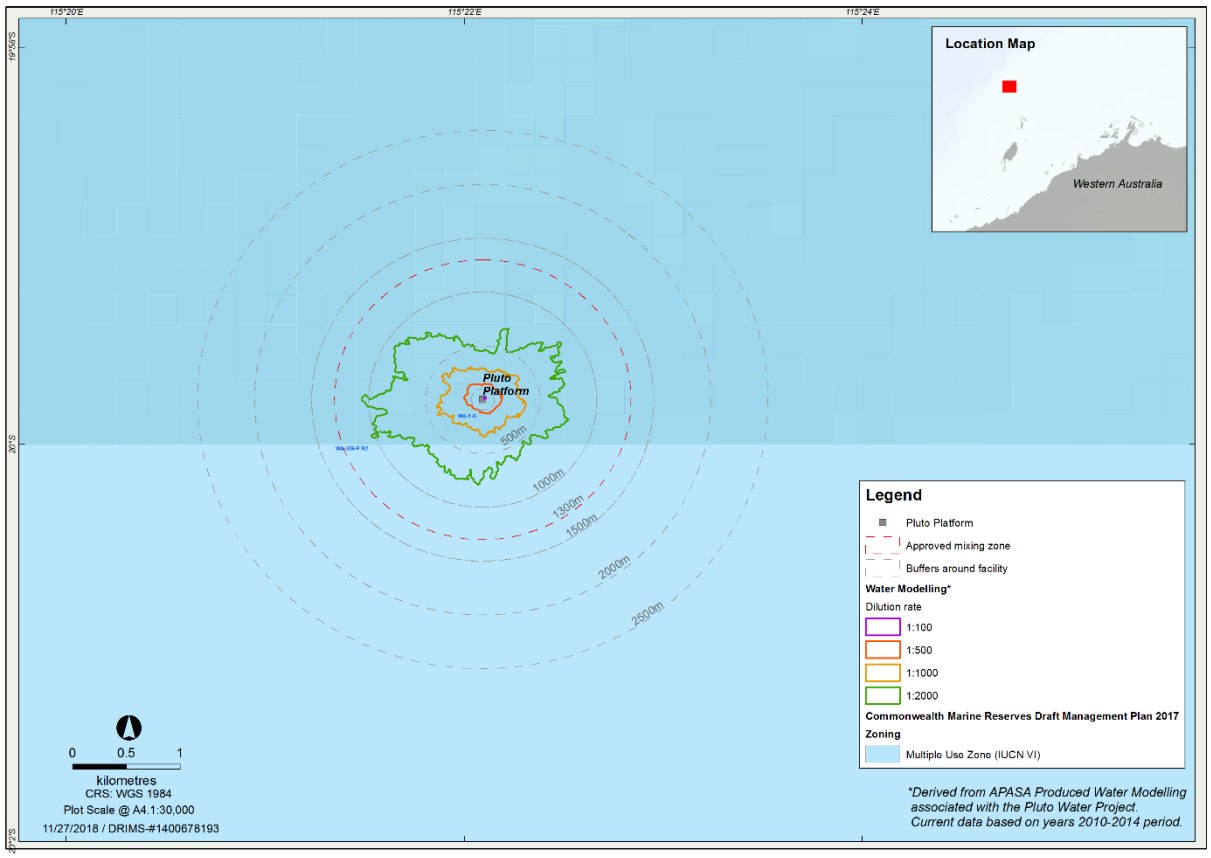

Figure 6-3: Annual dilution contours for a 3,500 m3 discharge from the Pluto Riser Platform

Modelling shows 2,000 dilutions can be achieved at maximum discharge rates in all conditions at 1300 m; therefore, this has been selected as the approved mixing zone boundary. This approved mixing zone will be reviewed and potentially adjusted after results of initial monitoring are received. Additionally, modelling predicts that 99% species protection safe dilutions can be achieved at the AMP boundary under all conditions. PW discharge rates are likely to vary up to a maximum rate of 3,500 m3 per day throughout field life.

Additional modelling was undertaken in 2024 (RPS,2023) to assess the potential impact of possible lower-rate discharges including those during non-routine activities such as production system restarts and water cut well start-ups. These intermittent activities have potential for short term variations in OIW specification which require system flexibility to optimise and stabilise the PW process, and hence may see short periods of elevated OIW concentration, not more than 50mg/L and 100mg/L 24-hour rolling average, for discharge rates limited to those lower than the design basis - as 1,900 m3/day and 795 m3/d respectively.

Bioaccumulation

Bioaccumulation refers to the amount of a substance taken up by an organism through all routes of exposure (water, diet, inhalation, epidermal). The Bioaccumulation Factor is the ratio of the steady-state tissue concentration and the steady-state environmental concentration (assuming uptake is from food and water). The test developed to measure the ability of a substance to bioaccumulate, namely, the octanol-water partition (Pow), is based on the preferential partitioning of lipophilic organic compounds into the octanol phase. Partitioning into octanol can be correlated with the attraction for such compounds to the fatty tissue (lipid) of organisms.

Bioaccumulation of BTEX compounds has been observed to occur in the laboratory, only at concentrations far in excess of that discharged from facilities on the NWS (for example refer to Berry, 1980); hence it is unlikely that BTEX would bioaccumulate at the exposure concentrations that may be experienced by biota around the Pluto facility. Baseline characterisation of the PW discharge will verify BTEX levels in the PW from the facility.

In contrast to BTEX compounds, PAH compounds have high Pow values indicative of the potential for bioaccumulation (Vik et al, 1996). Neff and Sauer (1996) based on available literature for laboratory and field studies investigating the bioaccumulation of PAHs. The bioaccumulation values for PAHs in marine organisms collected near PW discharges in the Gulf of Mexico reported by Neff and Saur (1996) indicate that the highest bioaccumulation factor was in the tissues of bivalve molluscs and the lowest in the muscle tissue of fish.

The most comprehensive field study assessing bioaccumulation of hydrocarbons and metals from PW discharged into offshore waters is that by Neff et al (2011). At the request of the United States Environmental Protection Agency (USEPA), the Gulf of Mexico Offshore Operators Committee sponsored a study of bioconcentration of selected PW

chemicals by marine invertebrates and fish around several offshore production facilities discharging more than 731 m3 per day of PW to outer continental shelf waters of the western Gulf of Mexico (by comparison Pluto discharges will be up to 3500 m3/day). The target chemicals identified by USEPA included five metals (As, Cd, Hg, 226Ra and 228Ra), three volatile Monocyclic Aromatic Hydrocarbons (MAH), benzene, toluene, and ethylbenzene, and four semi-volatile organic chemicals, phenol, fluorene, benzo(a)pyrene, and di (2 ethylhexyl) phthalate. Additional MAH (m-, p-, and o-xylenes) and a full suite of 40 parent and alkyl PAH and dibenzothiophenes were also analysed by Neff et al (2011) in PW, ambient water, and tissues at some platforms.

Concentrations of MAH, PAH, and phenol as determined by Neff et al were orders of magnitude higher in PW than in ambient seawater. There was no evidence of MAH or phenol being bioconcentrated. All MAH and phenol were either not detected (> 95% of tissue samples) or were present at trace concentrations in all invertebrate and fish tissue samples. Concentrations of several petrogenic PAHs, including alkyl naphthalene's and alkyl dibenzothiophenes, were slightly, but significantly higher in some bivalve molluscs, but not fish, from discharging than from non-discharging platforms. These PAH could have been derived from PW discharges or from tar balls or small fuel spills. Concentrations of individual and total PAH in mollusc, crab, and fish tissues were well below concentrations that might be harmful to the marine animals or to humans who might collect them for food at offshore platforms (Neff et. al., 2011).

It is expected that bioaccumulation is unlikely to result in increased levels of BTEX in biota surrounding the riser platform; however, there may be an elevation in PAH levels. Given the similarity of the chemical characterisation of PW discharges from Woodside facilities to those elsewhere in the world including those in the Gulf of Mexico (Rob Phillips Consulting 2016), the results from Neff et al (2011) can be used to infer the very low potential for adverse bioaccumulation effects to marine organisms, or to humans, if they were to consume any affected fish, molluscs or crabs found on upper near-surface legs of the facility.

The potential environmental impact associated with bioaccumulation of PW constituents in the water column is considered to be slight and a localised effect on a small number of non-threatened species in waters immediately surrounding the facility. The potential risk to fisheries is further reduced to ALARP as a result of negligible exposure given the PSZ that prohibits fishing from or near the platform. Given the nature of the PW discharge from the riser platform, the potential for bioaccumulation of PW contaminants (in particular BTEX) is considered to be minor and restricted to sessile organisms growing on the legs of the platform.

Impacts to Australian Marine Parks, KEFs and Biologically Important Areas

The facility is located approximately 416 m from the boundary of the Multiple Use Zone (IUCN Category VI) of the Montebello Marine Park. This zone is managed to allow ecologically sustainable use while conserving ecosystems, habitats and native species (Section 4.8).

The approved mixing zone overlaps 0.05% (1.6 km2 of the 3412 km2) Multiple Use Zone. Potential to impact the values of the Montebello Marine Park are expected to be very localised and are considered below.

Table 6-18 Values of the Montebello Marine Park

Value	Potential Impact
Ancient Coastline at the 125 m depth contour	The KEF is located approximately 6.5 km from the PW discharge point and is outside of the approved mixing zone. Modelling predicts the PW will form a buoyant plume extending less than 1,300 m from the discharge point, therefore, no contact and no impacts to biological indicators associated with the KEF are expected from the plume. Potential for impacts are monitored and managed to the approved mixing zone boundary; therefore, no impacts to the KEF situated outside the approved mixing zone are anticipated.
Species including species listed as threatened, migratory, marine or cetacean under the EPBC Act	A number of threatened migratory, marine or cetacean species may be in the approved mixing zone (Section 4.6). Species are primarily migratory and are not anticipated to spend long durations within the approved mixing zone. Toxicants are expected to rapidly dilute and are not considered to cause acute toxicity. By monitoring and managing water quality and sediment quality impacts to the approved mixing zone boundary, no impacts are expected to threatened migratory, marine or cetacean species.

BIA flatback turtle internesting buffer around the Montebello Islands (Oct – Mar)	The Montebello Islands, located approximately 41 km from the PW discharge, are the nearest emergent land and potential nesting habitat (minor) for flatback turtles. During internesting turtles remain close to the nesting beach or rookery (DOEE, 2017). Typically, internesting habitat is located immediately seaward of designated nesting habitat (DOEE, 2017). The approved mixing zone is within the Pilbara flatback turtle 60 km internesting buffer zone (October – March) however given the approved mixing zone is over 40 km from the nearest nesting beach internesting turtles are not anticipated to remain in the approved mixing zone for prolonged periods of time or in large numbers. Chronic discharge is identified as a moderate risk threat in the Recovery Plan for Marine Turtles for the Pilbara flatback population (DOEE, 2017). Given the localised area of impact, 95% species protection safe dilutions will be achieved by the boundary of the marine park and the distance to nesting habitat no impacts are expected to this value.
BIA foraging for whale sharks along the 200 m isobath, with seasonally high use (April–June)	The 200 m isobath is located about 17 km outside the approved mixing zone. Given the localised area of impact and that whale sharks are transiting the area, no impacts are expected.
BIA breeding habitat for seabirds	There is no nesting habitat within the approved mixing zone, therefore aggregations of breeding birds are unlikely to be present in the approved mixing zone. Foraging areas are located outside the approved mixing zone. No impacts are expected to this value.
BIA pygmy blue whale migration corridor (northern migration April to August; southern migration October to January) from Indonesian Waters to southwest Australia	The pygmy blue whale migration is thought to follow deep oceanic routes (DEWHA, 2008). In the NWMR, pygmy blue whales migrate along the 500 m to 1000 m depth contour on the continental slope where they are likely to opportunistically feed on ephemeral krill aggregations (DEWHA, 2008). Given the BIA is located outside the approved mixing zone and that PW forms a surface buoyant plume, no impacts are expected to this value.
Cultural Values	Cultural and spiritual values have been identified by the monitoring and management framework. In the absence of any specific environmental quality requirements for protection of this value, it is assumed that if water quality is managed to protect ecosystem integrity (95% species protection safe dilutions), this value is achieved in line with the EPA technical guideline.
Heritage values	No international, Commonwealth or national listings apply to the Montebello Marine Park currently. The Western Australia Barrow Island and the Montebello–Barrow Island Marine Conservation Reserves are outside of the approved mixing zone and therefore are not predicted to be impacted. Two historic shipwrecks, the Trial and Tanami, are located about 30 km outside of the approved mixing zone and therefore are not impacted by PW.

Information about the adaptive management program in place to address changes in routine discharge rates and other factors that may alter the assessment of risk is outlined within the OMDAMP. The Montebello Marine Park special protection zone for benthic habitat and sanctuary zone boundaries are located approximately 36 km to the south of the riser platform. As such, there are no impacts anticipated in these zones.

There are no impacts anticipated to the values of the Montebello Marine Park (including natural, cultural, heritage and socio-economic values). Wider water quality and sediment impacts are considered in respective sections above. Discharges are monitored and managed to achieve a 95% species protection safe dilution to protect ecosystem integrity via the OMDAMP at the AMP boundary.

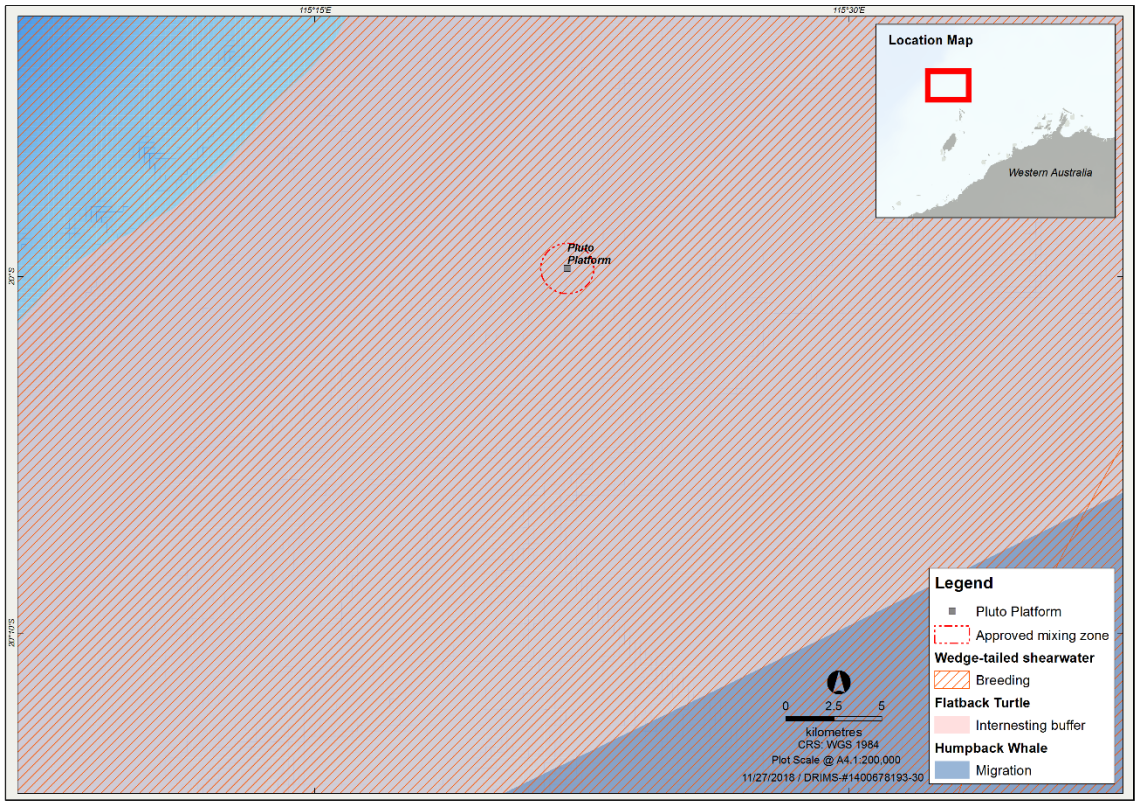

Figure 6-5 Biologically important areas

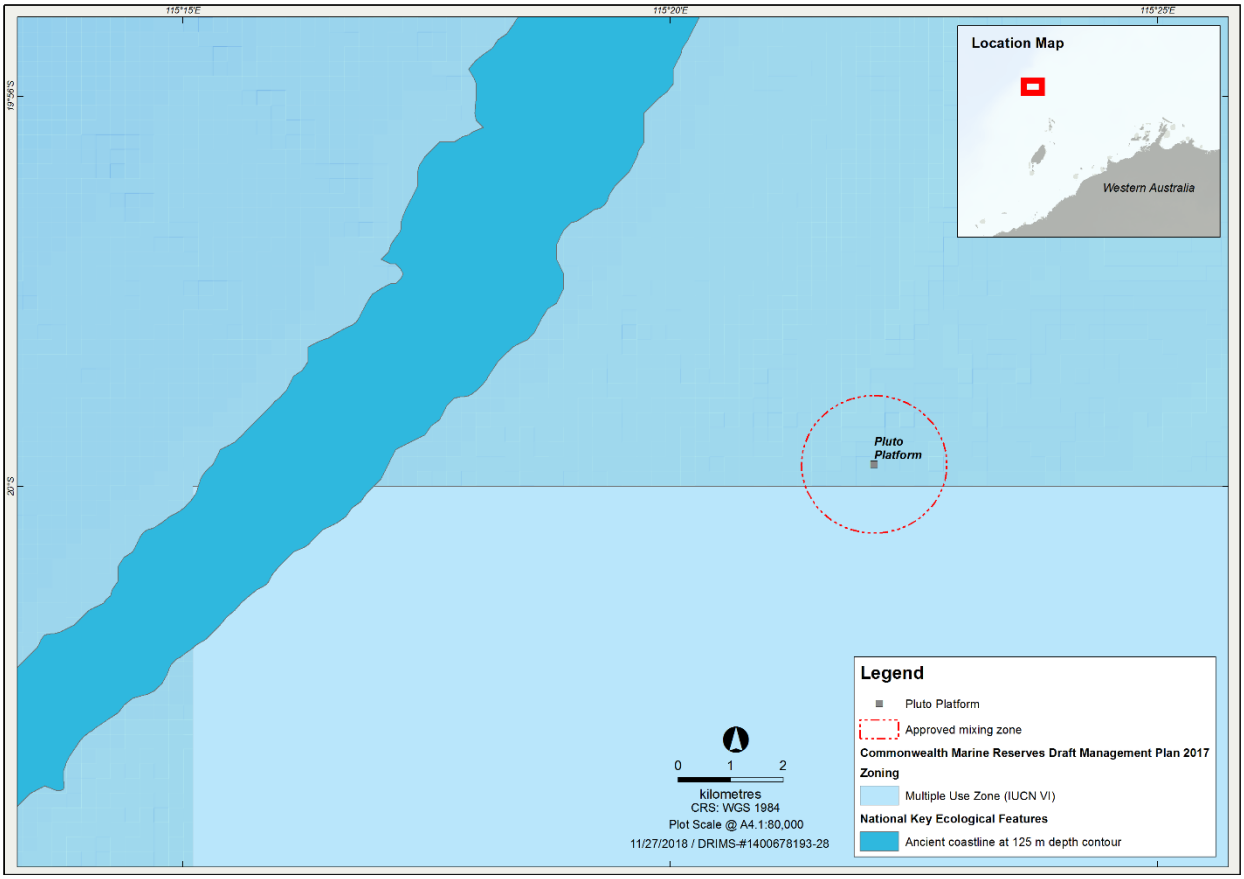

Figure 6-6 Key Ecological Features

Potential Impacts to Sediment Quality

Potential impacts to sediment quality were assessed through sediment surveys and supported by the results of flocculation studies and potential impacts to water quality.

Toxicants in Sediments

Accumulation of PW contaminants in sediments depends primarily on the volume and concentration of particulates in PW discharges or constituents that sorb onto seawater particulates the area over which those particulates could settle onto the seabed (dominated by current speeds and water depths) and re-suspension, bioturbation and microbial decay of those particulates in the water column and on the seabed.

Baseline sediment surveys were completed to provide a baseline monitoring prior to the discharge of PW from the riser platform. The benthic habitat within the approved mixing zone is predominantly soft sediment with sparsely associated epifauna, which is broadly represented throughout the NWS Province (Section 4.2). Benthic communities of soft sediment are characterised by burrowing infauna such as polychaetes, with biota such as sessile filter feeders occurring on areas of hard substrate (such as subsea infrastructure). Benthic grab sampling in the vicinity of the continental slope region of the Operational Area revealed a sparse abundance, high variability and high diversity of infauna dominated by polychaetes with other fauna including nemerteans and sipunculids and crustaceans (mainly amphipods) (SKM, 2007). Higher, albeit low, infauna density was reported at the shelf break (200 m) compared to deeper areas on the continental slope.

Within the approved mixing zone potential impacts to sediment quality may result in localised impacts to benthic communities. The potential extent of such impacts is extremely small in relation to the extent of the soft sediment habitats that are broadly represented within the Operational Area and the wider NWS Province. As such, impacts to benthic communities are expected to be localised with no lasting effect. There is no history of drilling with oil-based muds at the riser platform.

The PW plume is predicted to be buoyant, due to lower salinity and/or higher temperature than surrounding seawater. Therefore, potential contaminants in the PW discharge may be introduced into sediments around the riser platform through precipitations of soluble contaminants and flocculation and sedimentation of the particles in the PW plume. Studies into potential sediment accumulation from PW discharge have been undertaken by Woodside (Jacobs 2016). The study found that the PW at all facilities had very small amounts of solid material, with very little potential of settling or flocculation due to the very small particle sizes.

Initial monitoring is described above and includes settling velocity and particle size distribution to confirm potential for precipitation and flocculation.

Dr Graeme Hubbert categorised particulate behaviour based on oceanographic experience and mathematical calculations using settling rates and resuspension velocities for various particle sizes. He determined that particles of a size 1 to 5 µm would never permanently settle out of the water column, and that particles of a size 5 to 40 µm would not permanently settle out of the water column, unless they were in very deep water (> 5000 m) or in areas where hydrodynamic conditions were very weak and did not continuously resuspend the particles.

It is anticipated PW will not impact sediment quality to an unacceptable level; however, this will be verified via initial monitoring and results considered and managed by the OMDAMP. Should initial routine monitoring indicate the potential for impact to sediment quality to an unacceptable level, it will be necessary to undertake further investigations. This may include additional chemical characterisation, sedimentation studies, non-routine sediment sampling and/or bioavailability testing.

Non-Routine PW Discharges Impact Assessment

Production Restarts

There is the potential for the facility to experience high OIW during production restarts. Wells that have been shut in are required to be MEG and corrosion inhibitor dosed to maintain pipeline integrity, this may in part cause emulsions to form and OIW management issues. Wells that are either condensed water or have less associated produced water are expected to experience similar high OIW issues.

During production restart events, the modelled discharge rate of 5,000 bbl/day (795 m3/day) achieves 2,000 dilutions within 425 m from the platform in all directions and 3,719 dilutions are achieved at the AMP boundary as absolute worst-case (RPS 2023). With the additional controls, and non-routine discharge criteria of up to 100 mg/L 24hour rolling average (see Demonstration of ALARP table below) with lower-than-design discharge rates it is expected that OIW Predicted-No-Effect-Concentrations (PNEC) of 70 µg/L will be readily achieved for daily and monthly average timescales within an approximate 200-425 m radius of discharge (worse-case), and well before the AMP Multiple Use Zone at 416 m in a southerly direction.

Water Cut Well Restarts

Water cut wells that have been shut in for extended periods of time, may have varied produced water profiles on restart which can impact process stability until stable rates are achieved. It is expected that this can take a number of days for water rates to plateau from each individual water cut well when restarted.

During water cut well restart events, the modelled discharge rate of 12,000 bbl/day (1,900 m3/day) achieves 2,000 dilutions within 606 m from the platform in all directions and 2,107 dilutions are achieved at the AMP boundary (RPS 2023). With the additional controls, and non-routine discharge criteria of up to 50 mg/L 24hour rolling average (see Demonstration of ALARP table below) with lower-than-design discharge rates it is expected that OIW Predicted-No-Effect-Concentrations (PNEC) of 70 µg/L will be readily achieved for daily and monthly average timescales within an approximate 300 m radius of discharge (worse-case minimum dilution), and well before the AMP Multiple Use Zone at 416 m in a southerly direction.

Based on modelling and the non-routine short duration of elevated OIW, the non-routine discharge during production restarts and restarts of water cut wells is considered to have a short term, temporary and localised impact to water quality, and not predicted to result in impacts beyond the approved mixing zone, or AMP boundary.

Demonstration of ALARP

Control Considered	***Control Feasibility (F) and Cost/ Sacrifice (CS)[60]***	***Benefit in Impact/ Risk Reduction***	***Proportionality***	***Control Adopted***
Legislation, Codes and Standards				
None identified.				
Good Practice				
Implement Woodside's Chemical Selection and Assessment Environment Guideline:	F: Yes. Routinely implemented to the chemical selection process for Woodside facilities.	Selection and assessment of chemicals in accordance with the Woodside process, reduces	Benefits outweigh cost/sacrifice.	Yes C 5.1

[60] Qualitative measure

• Where Gold/Silver/E/D OCNS rating (and no OCNS substitution or product warning), chemicals are selected, no further control required; and • If chemicals with a different OCNS rating, sub warning or non-OCNS rated chemicals are required, chemicals will be assessed in accordance with the procedure prior to use.	CS: Minimal cost. Standard practice.	environmental impacts associated with planned chemical discharge.		
Monitoring of OIW concentrations in accordance with PARCOM 1997/16 Annex 3 methodology. Limiting average PW OIW during routine operations to less than 30 mg/L (over a 24hr rolling average (ra.)). During non-routine production restart and water cut well re-start activities: limit PW OIW to less than 100 mg/L 24hr rolling average (<5000 bbl/day ra.), for the first 7 days following re-starts; OR limit PW OIW to a 50 mg/L 24hr rolling average (<12,000 bbl/day ra.), for up to 7 days. PW OIW is limited to a 30 mg/L monthly rolling average for all activities. Tertiary coalescing filter separation will be used for all non-routine activities where this aligns with achieving beneficial	F: Yes. CS: Monitoring and implementation costs. Standard practice. The 30 mg/L 24-hour rolling average limit proposed is a legacy of the former Environment Regulations 29 and 29A repealed in 2014. Reduction of this limit is not considered feasible or practicable. The current limit is effective in managing potential impact of PW discharge. Short-term non-routine criteria support ensuring PW operations achieve environmental outcomes (EPO) with ALARP management of start-up constraints which could otherwise resulting in frequent flaring, system upsets, and/or addition of process chemicals for integrity management	Limiting OIW concentrations within PW reduces impacts to the environment.	Benefits outweigh cost/sacrifice.	Yes C 7.1.1

OIW concentration objectives.	(potentially adversely affecting overall outcomes and OIW separation performance)			
Monitoring routine and implementation of the Adaptive Monitoring and Management Framework for PW discharges including: Monitoring of PW discharge volume Chemical characterisation WET testing; and Timing of annual / triennial sampling to be representative aiming to detect change, considering when the reservoir cuts formation water.	F: Yes. CS: Monitoring costs. Standard practice.	The OMDAMP provides for detection of significant changes to the PW discharge characteristics (i.e. volumes, OIW concentration, chemical characterisation) that may cause an increased impact or risk to the marine environment. Monitoring is designed to detect if 95% species protection is achieved at the approved mixing zone boundary. Through the implementation of the OMDAMP, potential risks to the environment are reduced.	Woodside has developed the OMDAMP based on operational experience from relevant offshore assets. The OMDAMP considers risk-based adaptive management measures.	Yes C 7.2
Online monitoring and/or procedural controls in place to monitor and control PW discharge volume and OIW concentrations, and prevent discharge of PW with high OIW concentrations through OIW analyser, or off spec/outage procedures. Process performance monitored by OIW concentration analyser and volume meter(s).	F: Yes. CS: Minimal cost. Standard practice.	The OIW analysers and flow meter provides optimal process control and safeguarding to monitor, control and prevent discharge of PW with high OIW concentration to the environment.	Online monitoring control is WMS requirement– must be adopted.	Yes C 7.3
The online analyser is calibrated with a manual sample in accordance with Offshore Laboratory Determination of Oil in Water Standard Operating Procedure.	F: Yes CS: Monitoring and implementation costs. Standard practice.	Calibration of equipment to maintain quality control.	Calibrations undertaken at appropriate frequency to maintain quality control and in line with procedures.	Yes C 7.4

Professional Judgement – Eliminate		
Reinjecting PW into reservoirs.	F: No. Some technical risk associated with reservoir uncertainty and ultimate reservoir recovery. Economically not feasible. CS: Significant. The reinjection of PW would require significant modification to the PLA facility, including drilling of injection wells. This would require considerable design and construction costs. Previous studies indicate a cost in excess of $400 million CAPEX for a PW reinjection solution on-board the Pluto facility. Benefit in Impact reduction The environmental impacts in the approved mixing zone around the facility would be eliminated. Long term biological impacts from PW that are outside of the acceptable limits of change (i.e. impacts to ecosystem integrity from contaminant accumulation in sediment and bioaccumulation effects over time) are prevented by the PW Monitoring and Management Framework. Proportionality As part of the possible solutions for managing PW from the Pluto operations, Woodside examined the potential for reinjection of PW. Woodside did not identify a suitable reservoir, and such an option would require additional drilling activities to be undertaken. Reinjection is not feasible unless a suitable reservoir is identified. It is not feasible to reinject into a previous Pluto appraisal well, or future shut-in well because this would further accelerate the production of PW from the reservoir and reduce the overall recoverable volume from the reservoir. Given the limited space available on the platform, subsea separation would be required, this is novel technology with limited operational experience. Drilling and Subsea work activities to establish a reliable PW reinjection well and subsea infrastructure also introduce significant complexity, risk and cost. Together the significant technological and operational risks, associated environmental impact (drilling and subsea construction, greenhouse gas emissions associated with 7–15 MW based on known requirements for Enfield–Laverda) is considered significantly disproportionate to the potential slight environmental impact improvement. As such, no further engineering design or screening studies reporting is considered reasonably practicable. It is not necessary to conduct a reservoir-by-reservoir analysis to understand these costs. For Type B impacts, it is appropriate to consider case specific drivers to ALARP management. The lack of a suitable reservoir contrasts with Woodside's facilities that currently reinject PW. At Nganhurra, for example, water re-injection was required to maintain reservoir pressure for production and was a key part of the FDP to optimise overall field recovery. As PW alone is not sufficient to maintain reservoir pressure, seawater is used to make up the balance. Therefore, given the significant economic benefits associated with reinjection at NGA, the ALARP outcome is different from NGA to Pluto. The reinjection of PW would also introduce additional sources of environmental risks and impacts, such as those associated with drilling injection wells (e.g. drill cuttings) and maintaining injection capability (e.g. increased greenhouse gas emissions from power generation for pumps, increased chemical usage, etc.). Given the localised, slight non-significant impact of PW discharges, and the considerable costs involved in developing a PW reinjection capability for the Pluto facility, implementation risks and environmental impacts (greenhouse gas, chemical use), the costs are grossly disproportionate to the potential environmental benefit gained.	No

Professional Judgement – Substitute				
None identified.				
Professional Judgement – Engineered Solution				
Chemical injection of water clarifier, demulsifier to reduce OIW concentration, if required.	F: Potentially feasible. CS: Moderate. Initial cost of modifying production system to include chemical dosing point. Ongoing cost of chemical procurement.	Potential minor reduction in OIW concentration; however, does not reduce the overall consequence rating. Further, this results in additional chemical load, and lifecycle environmental footprint associated with packaging, logistics, waste management and potential process upsets.	Benefits outweigh cost/sacrifice.	Yes C 7.5
Secondary treatment stage (HIGF) to reduce OIW concentration.	F: Yes. Process design adopts an HIGF unit. CS: Moderate. Integrated in to process design. Ongoing cost of maintenance.	Installation of a secondary treatment stage (HIGF) has been provided on the NNC facility to ensure OIW remains below 30 mg/L (24-hour rolling average) during routine operations.	As part of the possible solutions for managing PW from the Pluto operations, Woodside examined the potential for installation of various secondary treatment technologies. The HIGF was identified as the optimal secondary treatment stage in order to maximise OIW separation prior to discharge overboard during routine operations.	Yes C 7.1.3
Adoption of a permanent tertiary treatment stage to reduce OIW concentration. Filters are used during the initial commissioning period and non-routine activities if required to minimise OIW concentration of PW discharged.	F: Potentially feasible. CS: Moderate. Integrated in to process design. Ongoing cost of maintenance.	Potential minor reduction in OIW concentration.		Yes C 7.1.3
Professional Judgement – Procedures and Administration				
Routine in situ monitoring beyond the requirements of Woodside's OMDAMP for an existing asset	F: Yes. CS: Increasing the frequency of field based monitoring would result in additional offshore demand on resources, safety	In situ monitoring following release is not an effective control to manage the nature of PW discharges and results no impact reduction. Increases to in situ monitoring	Long term monitoring of water and sediment) characteristics at the facilities indicate the PW discharge is not detectable beyond	No

	hazards and costs associated with an offshore environmental monitoring program, such as vessel activities, logistics, manual labour, analytical laboratory and service provider costs.	beyond the adaptive management approach outlined in the OMDAMP does not follow good application of the hierarchy of controls and results in disproportionate sacrifice with regard to execution risks and costs for limited gain.	the approved mixing zone. No sediment contamination has been detected. PW separation process design, optimisation, monitoring and surveillance offer the primary controls, with discharge OIW analysis in place to detect performance variations. Further, Woodside maintains a routine OIW monitoring program for the PW stream (including adaptive management via the OMDAMP, which assesses the need for in situ monitoring). The work undertaken to date provides Woodside with a sound understanding of the nature and scale of the environmental impacts from PW discharge, which would not be further improved by increasing the frequency of in situ monitoring. The execution risks and cost of implementing this control is grossly disproportionate to the environmental benefit.	

Risk Based Analysis

Application of Woodside's Risk Management Procedures and implementation of the OMDAMP ensures the routine assessment of PW impacts, identification of changes to discharges, systematic assessment of risks and ongoing assessment/monitoring of discharge streams to reduce risk to ALARP, that includes:

ongoing hazard identification, risk assessment and the identification of control measures

ongoing PW discharge monitoring.

Company Values

Corporate values require all personnel at Woodside to comply with appropriate policies, standards, procedures and processes while being accountable for their actions and holding others to account in line with the Woodside Values. As detailed above, the Petroleum Activities Program will be undertaken in line with these policies, standards and procedures that include suitable controls to manage PW discharge.

Societal Values

Due to the Petroleum Activities Program's proximity to sensitive receptors and potential uncertainty around PW discharges, the PW discharge consequence rating presents a Decision Type B in accordance with the decision

support framework described in Section 2.6.1. Consultation was undertaken for this program to identify the views and concerns of relevant stakeholders, as described in Section 5.

Woodside has sent an Activity Factsheet to all identified relevant stakeholders regarding the Petroleum Activities Program (Section 5 and Appendix F), no specific concerns around PW discharge were identified through this process.

ALARP Statement

Based on the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts of PW discharge. Woodside has undertaken extensive PW process studies, trials (emulsions) and risk-based analysis (PW discharge modelling) to inform the evaluation and assessment of environmental impacts and risks. Woodside also implements a risk-based adaptive OMDAMP. The outcomes of the modelling studies and process engineering have been considered in determining the ALARP position.

As no reasonable additional/alternative controls are currently identified that would further reduce the impacts and risks without grossly disproportionate sacrifice, the impacts are considered ALARP.

Demonstration of Acceptability

To assess and determine the acceptable limits of impacts from PW discharges, Woodside has considered the following criteria, appropriate guidelines, principles of Ecologically Sustainable Development, Company Values and Societal Values.

Other Requirements (includes Laws, Polices, Standards and Conventions)

The adopted controls and acceptability assessment has considered regulatory guidance, in particular WA EPA (2016) Technical Guidance: Protecting the Quality of Western Australia's Marine Environment and the ANZG (2018) guidelines. Both sources of Regulatory Guidance provide that environmental values should be identified, and levels of ecological protection should then be set. To ensure ecosystem health is maintained overall, the cumulative size of the areas where lower levels of ecological protection apply should be proportionally small compared to the areas designated high and maximum. The ANZG (2018) guidelines similarly provide guidance that levels of protection should be identified, based on the environmental values to be protected. The Monitoring and Management Framework aligns to the levels of protection described by both WA EPA (2016) Technical Guidance and the ANZG 2018 guidelines through the acceptable limits of change.

The level of ecological protection provided to sensitive receptors is consistent with the North-west Network Management Plan (2018). By monitoring and managing to the 95% species protection safe dilutions at 1300 m, there can be high confidence that any potential for impacts will be detected and managed via the OMDAMP.

Principles of Ecologically Sustainable Development

Woodside has established several research projects to understand the marine environments in which we operate, notably in the Exmouth Region and the Kimberley Region, including Rankin Bank, Glomar Shoals, Enfield Canyon and Scott Reef. Woodside's corporate values require that we consider the environment and communities in which we operate when making decisions.

Woodside looks after the communities and environments where we operate. Risks are inherent in petroleum activities; however, through sound management, systematic application of policies, standards, procedures and processes, Woodside considers that despite this potential impact, the extremely low impact of PW is acceptable.

The proposed activity has been assessed and considered in accordance with Australian IUCN Reserve Management Principles, conditions of the class approval (Section 1.9), objectives of the IUCN category VI zone (Section 1.9), the North West Marine Park Management Plan and the values of the Montebello Marine Park. Discharge of PW is acceptable providing that 95% species protection safe dilutions are met at the Montebello Marine Park boundary. This removes potential to adversely impact on biodiversity, ecological integrity, social amenity or human health. Activities will not be conducted in a manner inconsistent with the Objectives of the respective zones of the AMPs, the Principles of the IUCN Area Categories of the Values of the AMPs.

Internal Context

The Petroleum Activities Program is consistent with Woodside corporate policies, standards, procedures, and processes as outlined in the Demonstration of ALARP and Environmental Performance Outcomes, including:

- Woodside Environment and Biodiversity Policy (Appendix A);
- Woodside Risk Management Policy; and
- Woodside Environmental Performance Procedure (which specifies maximum mixing zones and minimum sampling requirements).

Woodside corporate values include working sustainably, with respect to the environment and communities in which we operate, listening to internal and external stakeholders (below) and considering HSE when making decisions.

External Context

Woodside recognises that its licence to operate from a regulator and societal perspective is based on historical performance, complying with appropriate policies, standards and procedures, and understanding the expectations of

external stakeholders. External stakeholder consultation was undertaken with relevant stakeholders (Section 5), prior to the Petroleum Activities Program and feedback was incorporated into this EP where appropriate. In particular, the Director of National Parks (DNP) was consulted as part of the 5-yearly update for this document. In addition, Woodside undertook additional consultation (2022) specific to PW discharge monitoring and management and other activities including baseline data collection on sediment quality during the engagement process.

By providing PW monitoring and control measures that are commensurate with the risk rating, location and sensitivity of the receiving environment (including social and aesthetic values), Woodside believes this addresses broad societal concerns to an acceptable level.

Acceptability Statement

Routine and non-routine discharges of PW have been evaluated as representing potential slight, localised, short-term impacts to water quality, marine sediment, marine fauna and ecosystem/habitat. As per Section 2.6.1, Woodside considers 'high order impacts' (Decision Type B impacts such as PW discharge) as acceptable if ALARP is demonstrated using good industry practice, consideration of company and societal values and RBA, if legislative requirements are met and societal concerns are accounted for, and the alternative control measures are grossly disproportionate to the benefit gained. In addition, acceptability is assessed against the above criteria.

The adopted controls are considered good oil-field practice/industry best practice, are consistent with WA EPA (2016), ANZG (2018) and Woodside's internal requirements. Further opportunities to reduce the impacts have been investigated (refer ALARP demonstration) and considered to be grossly disproportionate to the benefit gained. Woodside considers the adopted controls appropriate to manage the impacts of PW discharge to an acceptable level.

Description of Source of Impact

Drilling Operations

The Petroleum Activities Program will involve the drilling of the Xena-03 well, drilled over a period of approximately 60 days (including mobilisation, demobilisation and contingency). Drilling activities generate drill cuttings, require cementing of the casing, and require the use of a range of fluids. Throughout the drilling program several different fluids are to be run through the closed circulation system including, but not limited to, drilling fluids (water-based muds and non water-based muds), sea water, and kill-weight brine.

Routine drilling discharges will include:

- drill cuttings
- drilling fluids direct to seabed (WBMs only), retained on cuttings and bulk discharge of mud pits (WBMs only)

- Non-routine drilling discharges may include:
- drill cuttings and fluids generated due to respud or side tracking
- WBM, swarf and cement cuttings
- well abandonment and use of fluids (subsea control, completions and well annular fluids).

Drilling activities are described in Section 3.11.1. The well will be drilled as a series of sections, as detailed in Section 3.11.1. The top hole section of the well will be drilled without a riser in place (i.e. riserless drilling). Drill cuttings and unrecoverable WBMs are discharged at the seabed for the top-hole sections, which are drilled riserless (i.e. no closed loop with the MODU). This results in a localised area of sediment deposition (known as a cuttings pile) around and in proximity to the well site influenced by prevailing seabed currents.

Upon drilling of the top hole section, a casing will be cemented in place, a BOP installed and a riser put in place between the BOP and the MODU. The riser remains in place during drilling of the bottom hole sections and facilitates the circulation of drilling fluids and cuttings between the well bore and the MODU. This enables cuttings and drilling fluids to be circulated back to the MODU, where the cuttings are separated from the drilling fluids by the solids control equipment (SCEt) and typically re-used in the closed loop system between the well bore and the MODU. The cuttings (with adhered residual fluids) are, in typical circumstances, discharged below the water line, with their fate and dispersion determined by cuttings particle size and the density of the unrecoverable fluids. In contrast the fluids are recirculated into the fluid system where there are a number of mud pits (tanks) on the MODU that provide a capacity to mix, maintain and store fluids required for drilling activities. The mud pits form part of the drilling fluid circulating system and may be discharged at the end of specific well sections, where there is a requirement to change the drilling fluid system or the drilling fluid cannot be re-used (due to deterioration/contamination). Bulk discharge of this type is only permitted for WBMs.

Base oil may be used for inflow testing prior to abandonment of the well, to verify barrier integrity. Base oil would be pumped down the drill string and reverse circulated back to the rig, with fluids collected for disposal onshore. If stored in a mud pit, the base oil and other fluids associated with the test may result in pit wash water contaminated with hydrocarbons. If this is the case, mud pit wash water would be discharged in accordance with requirements in this EP; with a hydrocarbon content <1% by volume. Well abandonment activities are conducted in accordance with Woodside's internal standards.

Drill Cuttings and Fluids

As described above, the primary discharges used as the basis of the impact assessment for this Petroleum Activities Program are as follows:

- Drill cuttings: drilling generates drill cuttings due to the breakup of solid material from within the borehole. The resultant drill cuttings are basically rock particles of various shapes, with sizes typically ranging from very fine to very coarse.
- Drilling fluids: serve many purposes including maintaining borehole stability and hydrostatic pressure, reducing friction and cleaning/ cooling of the drill bit, in addition to acting as a medium to carry cuttings from the well bore and return them to the surface at seabed or on the MODU. There are two main types of drilling fluids as follows:

- WBMs consists mainly of fresh water or seawater with the addition of chemical and mineral additives to aid in its function. Drilling additives typically used may include chlorides (e.g. sodium, potassium), bentonite (clay), cellulose polymers, guar gum, barite or calcium carbonate. These additives are either completely inert in the marine environment, naturally occurring benign materials, or readily biodegradable organic polymers with a very fast rate of biodegradation in the marine environment. Bentonite and guar gum are listed as 'E' category fluids under the OCNS and is included on the Oslo Paris (OSPAR) Commission PLONOR (chemicals that 'pose little or no risk to the environment') list (OSPAR Commission, 2021). WBMs can be discharged to sea as fluids retained on cuttings and as bulk discharge from mud pits.

For the purposes of this impact assessment, the indicative dimensions, discharge locations and approximate drill cuttings and drilling fluid volumes provided in Table 6-19 represent the estimated discharges for the Xena-03 Tie-back activities.

Table 6-19: Estimated discharge of cuttings and volumes of drilling fluids used for Xena-03 Tie-back activities.

Well section width (inches)	Cuttings ~volume (m^3)	Drilling fluid type	Drilling fluid ~ volume (m^3)	Hole section	Discharge point
42	72	Seawater1 with pre-hydrated bentonite (PHB) sweeps/XC polymer	157	Top hole	Seabed

	~12.25 - 13.5" section	163	NWBM	670	Production hole #2	Surface

1 seawater volume is not included in the estimated 'drilling fluid volume'

Subsea – Displacement, Completion and Well-bore Cleanout Fluids

Reservoir drilling and completion fluids are usually brines (i.e. a mixture of seawater or formation water) with additives that can include:

- chlorides (often sodium, potassium or calcium)
- bromides
- hydrate inhibitor (mono-ethylene glycol (MEG))
- biocide
- oxygen scavenger.

They are designed to have the proper density and flow characteristics to be compatible with the reservoir formation. Completion fluids are used to run well completions, and during wellbore clean up and flowback during drilling.

Wellbore and casing clean-up are required at various stages of the drilling operations so that the contents of the well are free of contaminants before the next stage of drilling. A chemical wellbore cleanout fluid train may be used to remove residual fluids from the wellbore. The wellbore cleanout fluid is usually brine (similar to completion fluid) that can include several chemicals, such as biocide and surfactant. During the clean-up process, fluids are circulated back to the MODU.

Cleanout fluids and completion brine will be captured and stored on the MODU and discharged if oil concentration is less than 1% by volume or returned to shore if discharge requirements cannot be met. Discharge volume would be ~400 m³.

Contingent Drilling Activities

Non-water Based Muds

NWBM are not planned to be used but may be required as a contingency during drilling should the offset history, geohazards assessment and borehole stability studies indicate that NWBM is required to manage well stability to safe levels. Where NWBM is needed to drill a well section, the cuttings from the NWBM drilling fluid system will also pass through a cuttings dryer to reduce the average residual oil on cuttings (OOC) for the well (only sections using NWBM) to ALARP, prior to discharge. In the event of SCE failures, cuttings may be discharged without having passed through the dryer; however, this will only occur for a short duration while the drill string is being moved to a safe location in the well and existing cuttings are circulated out of hole. A decision will then be made on the case for drilling ahead without the failed SCE, while still meeting residual OOC discharge limits. Drilling ahead while SCE breakdown assessment and repairs occur is a contingent activity subject to additional controls; however, the standard mode of operation for the management of cuttings to ALARP is to treat cuttings through a dryer. An OOC discharge limit of <6.9% on wet cuttings will be averaged over well sections drilled with NWBM for the well.

Should NWBM be used, mud pit residue may be discharged to the sea where the residue contains <1% oil volume. Where the mud pit residue exceeds 1% by volume, the residue will be retained and disposed of onshore.

Base oil and chemicals used in NWBM are assessed in accordance with the Chemical Selection and Assessment Environment Guideline.

Respud

It is unlikely that the well would be required to respud. If required, the most likely scenario is that the decision to respud is made during drilling of the top hole section of the well; therefore, the incremental increase in cuttings and fluids discharges is associated with the repeat drilling of the same top hole sections for the respudded well with the same associated discharges. A respud once drilling of the bottom hole sections has commenced is far less likely, given the time and effort already committed to the well. However, if this was to occur, the associated discharges would also be a repeat of the discharges required to re-drill the same sections of the respudded well.

Permanent Plugging Program and Removal of Well Infrastructure

If required as a contingency activity, the base case for permanently plugging the well includes the use of WBM and wet cement and will produce well annulus fluids (residual hydrocarbons and residual produced formation water). These fluids/cuttings will be generated during the well bore clean-out, drilling of existing cement barriers, installation of permanent abandonment barriers, circulation of the annulus and washing out of the mud pit.

Potential additional activities that may be required as part of the Petroleum Activities Program includes milling, which will produce metal swarf, drilled cement and formation rock. All of the downhole plugging for permanent abandonment activities are conducted through the marine riser. This is a closed system, meaning there are no planned discharges directly to sea during these activities. Planned discharges of the above fluids are only planned to occur after they have been received on the MODU.

The following describes the source of impact with respect to discharge of clean-up fluids, well kill fluids, grit and flocculent only. See Section 6.7.9 for cement, cementing fluids and subsea control fluids. For the purposes of this impact assessment, the indicative dimensions, discharge locations and approximate volumes are provided in Table 6-20.

Table 6-20: Estimated discharges of solids and volumes of drilling fluids used for contingency plugging and well infrastructure removal

Description	Discharge Point	Discharge	Approximate Solids Discharged (m^3)	Approximate Fluid Discharged (m^3)	Potential Additional Solids (m^3)	Potential Additional Fluid Discharge (m^3)
Drill out cement plug	Below sea level	WBM and cement cuttings	2	1	0	0
Kill well	Below sea level	Well kill fluid	0	0	0	Discharged if oil concentration is less than 1% by volume or returned to shore if discharge requirements cannot be met.

End of well discharge	Below sea level	WBM, brine, mud pit and vessel tank was fluids	0	600	0	0
Milling (potential activity using WBM)	Below sea level	WBM, swarf, cement and formation rock	0	0	2 (swarf) 3 (cement) 3.5 (formation rock)	1600
Milling (potential activity using NWBM)	Below sea level	NWBM, swarf, cement and formation rock	0	0	2 (swarf) 3 (cement) 3.5 (formation rock)	5
Mechanical cutting	Within the well, below the mudline	Metal and cement cuttings from well infrastructure and lubrication for the cutting tool.	0	0	Negligible volumes may be released to surface sediments if cut is made at or close to the mudline	
ABWJ cutting	Within the well, below the mudline	Flocculant and grit	4 tonnes (planned to be released within the well, above the top permanent plug with small volumes entering sediments at cutting depth).	250 L (planned to be released within the well, above the top permanent plug with small volumes entering sediments at cutting depth).	Small volumes may be released to surface sediments if cut is made at or close to the mudline	

Drilled Cement

Indicative volumes of drilled cement for the well are outlined in Table 6-21. The shallow cement plug will preferentially be drilled out with WBM. The drilling fluids will pass through shakers to remove the cement cuttings from the drilling fluid before discharging the cement cuttings.

Well Annular Fluids

Well annular fluids refer to the fluids that remain in the wellbore, or annular spaces between the casing. They may consist of weighted drilling fluid and cement-contaminated mud, seawater, barite, cement polymer, and may include small amounts of hydrocarbon. Upon wellhead removal small volumes (~1.5 m^3) of fluid exchange between the annular spaces and the ocean may occur. The exchange will not be instantaneous as the annular spaces are small and the fluids are typically heavier than seawater. In the unlikely event routine wellhead removal techniques are unsuccessful, this fluid exchange is expected to occur over time following sufficient corrosion of the wellhead.

The small volumes and non-instantaneous nature of the release of the well annular fluids is expected to result in rapid dilution to a no-effect concentration within metres of the release location.

Well Bore Clean-out and Well Kill Fluids

If permanent plugging activities are required, the well will generally be displaced from well kill brine to viscosified brine, or cleaned, which may include residual annulus fluid. A chemical clean-out pill or fluids train will be circulated between the two fluids. This will result in a discharge of fluids in accordance with Woodside's internal guidelines to ensure the potential impacts of the chemicals selected are acceptable.

Should there be clean-up brine contaminated with base oil or NWBM, it will be captured and stored on the MODU for discharge if oil concentration is less than 1% by volume, or returned to shore if discharge requirements cannot be met.

If well kill fluid fails to be bullhead pumped into the well, reservoir fluids may need to be bled off at the MODU through well control equipment (dedicated bleed off/well test spread). In this event, well control equipment will be used to separate the well kill fluids from the hydrocarbons and direct the hydrocarbons to be flared, vented or incinerated,

depending on a number of factors including the volume, weather conditions, and safety requirements as documented in relevant procedures for this activity. The well kill fluids will be captured and stored on the MODU and discharged overboard if oil concentration is less than 1% by volume or returned to shore if discharge requirements cannot be met.

Milling

If permanent plugging activities are required, there is a potential additional activity where the well casing needs to be milled out (up to 100 m). This will produce milled swarf (2 m^3), drilled cement cuttings (~3 m^3) and formation rock (~3.5 m^3) and will preferentially be completed using WBM. There may be instances where NWBM is required for operational purposes to manage well stability to safe levels. The solids from the WBM or NWBM drilling fluid system (including the swarf, drilled cement cuttings and formation rock) will also pass through the shakers, to separate these solids before discharging them. Given the small volumes of solids and only limited drilling into formation rock, no oil on cuttings (OOC) discharge limits have been applied, as would be the case for a drilling activity. The estimated volume of solids discharged with residual NWBM on them is expected to be about 5 m^3 (per 100 m milled interval).

Removal (Cutting) of Well Infrastructure (Contingency)

The planned cutting depth for removal of the wellhead is approximately 3-5 m below the mudline. Discharges from cutting of well infrastructure using either an abrasive water jet cutting method of a mechanical cutting tool are therefore expected to be confined predominately within the well and settle on the top of the permanent plug. During final cut through the conductor pipe, small amounts of flocculant and grit will be released below the mudline to sediments immediately surrounding the well.

Should cutting at a shallower depth be required, these discharges may be released to the seabed surface. For the mechanical cutting tool, discharges will be limited to small quantities of metal and cement cuttings from the infrastructure itself as well as small quantities of lubricant. For the abrasive water jet cutting method, discharges include a small amount of grit and flocculant. Depending on the cutting depth, pressure from the jet cutting could push some of the material up to the seabed surface causing localised smothering of benthic communities as well as create localised and temporary increases in turbidity around the well.

Impact Assessment

Potential impacts to environmental values

Routine and non-routine drilling-related discharges may result in the following impacts:

- change in water quality
- change in seabed sediment quality
- change in seabed habitat
- injury/mortality to marine fauna (benthic communities).

Some fluids are discharged at the sea surface (or just below); and some are discharged at the seabed. Due to water depth at the drilling location (177 m), this will determine the exposure pathway, and hence potential impacts and receptors.

Drill Cuttings and Retained Fluids

Water Quality and Planktonic Communities

Drill cuttings and retained drilling fluid discharges are expected to increase turbidity and TSS levels above ambient concentrations above the seabed (top-hole well section) or in the upper surface layers (bottom-hole well sections with discharge below the water line from the MODU). Drill cuttings discharge will be generally intermittent and of short duration (over a total period of about 15 days) during drilling of the well.

Top-hole well section drill cuttings and drilling fluids (WBM) will be discharged at the seabed. The coarser material (drill cuttings) will deposit on the seabed and the finer sediment material (the WBM) will cause localised elevated TSS in the water column above the seabed surrounding the well. This reduction in water quality will be temporary (limited to the operational discharges during drilling) and subject to rapid dispersion and dilution by prevailing seabed currents.

During bottom-hole well sections, when drill cuttings with retained drilling fluids (WBM) are discharged below the water line (from the MODU), the larger particles, representing about 90% of the mass of the solids, form a plume that drops out of suspension in the water column rapidly and, deposits on the seabed. About 10% of the mass of the solids (the fines predominately composed of drilling fluid) form a plume in the upper surface layer (depending on the depth of discharge from the MODU) that will be transported by prevailing currents away from the MODU and is diluted rapidly in the receiving waters (Neff 2005, 2010). There is a large body of knowledge indicating a discharge of cuttings with adhered fluids diluting rapidly, finding that within 100 m of the discharge point, a drilling cuttings and fluid plume released at the surface will have diluted by a factor of at least 10,000. Further to that, Neff (2005) states that in well mixed oceans waters, the plume is diluted by more than 100-fold within 10 m of the discharge site.

Dispersion of the cuttings plume is influenced by a number of factors: particle sized distribution of the cuttings and fluids, operational discharge events and rates and metocean conditions such as ocean current speed. The case studies described in Neff (2005) used WBMs and surface current speeds of 0.15–0.3 m/s. As currents in the PAA are

expected to be within this range, and WBMs (bulk discharge) will contribute the largest input to elevated TSS/turbidity during drilling discharges, the dispersion extent as determined by Neff (2005) is considered representative for Xena-03 tie-back activities.

Using the widely-accepted dilution factor of 10,000 (Neff, 2005), cuttings (and adhered fluids) are expected to reach 100 mg/L TSS within 100 m of the MODU. Using a conservative ocean current speed of 0.1 m/s, these discharges are expected to disperse to 100 mg/L within ~16 minutes.

Given the generally low concentration of TSS outside the immediate vicinity of the discharge point, due to rapid dispersion of sediment and the short period of intermittent discharge, the plume is not expected to have more than a very highly localised reduction in water quality and area of potential ecological impact. It is not predicted to impact productivity of the water column.

The combination of low toxicity and rapid dilution of unrecoverable NWBMs discharged in association with drill cuttings are of little risk of direct toxicity to water-column biota (Neff et al., 2000).

Injury/mortality to planktonic species may occur due to a change in water quality following discharges of drill cuttings and fluids. Impacts to these organisms can be as a product of both physical and chemical alterations of water quality, predominantly in the water column.

As outlined above, using the widely-accepted dilution factor of 10,000 (Neff, 2005), cuttings (and adhered fluids) are expected to reach 100 mg/L TSS within 100 m of the MODU over a period of ~16 minutes. Minimal impact to plankton (phytoplankton, zooplankton and meroplankton (larvae of invertebrates and fish) is therefore expected from the discharge of drill cuttings. Neff (2010) explains that the lack of toxicity and low bioaccumulation potential of the drilling muds means that the effects of the discharges are highly localised and are not expected to spread through the food web (of which planktonic species are the basis).

Impacts to zooplankton from turbidity are associated with variations in predator prey dynamics, which favours planktonic feeders over visual feeders (Gophen, 2015), while impacts to phytoplankton occur due to decreases in available light, therefore reducing productivity (Dokulil, 1994).

Jenkins and McKinnon (2006) reported that levels of suspended sediments greater than 500 mg/L are likely to produce a measurable impact upon larvae of most fish species, and that levels of 100 mg/L will affect the larvae of some species if exposed for periods greater than 96 hours. Jenkins and McKinnon (2006) also indicated that levels of 100 mg/L may affect the larvae of several marine invertebrate species, and that fish eggs and larvae are more vulnerable to suspended sediments than older life stages. However, dilution estimates (e.g. Hinwood et al., 1994; Neff, 2005) suggest suspended sediment concentrations caused by the discharge of drill cuttings will be well below the levels required to cause an effect on fish or invertebrate larvae (i.e. predicted levels are well below a 96-hour exposure at 100 mg/L, or instantaneous 500 mg/L exposure), beyond the immediate vicinity of the discharge.

Due to the low levels of planktonic productivity in the offshore area, plankton populations on a regional scale are not expected to be affected by drilling or well abandonment activities. In addition, due to the open nature of the marine environment of the PAA and associated environmental conditions (i.e. windy, strong currents, etc.), the content and dispersive nature of drilling muds within the marine environment and the high population replenishment of these organisms, it is expected that impacts to plankton species will be limited to within tens of metres of the discharge point and return to previous conditions within a relatively short period of time. On this basis, the impacts to plankton from routine and non-routine discharges during drilling activities is slight.

Sediment Quality and Benthic Communities

Accumulation of drill cuttings, grit and flocculent on the seabed causes changes in the physical properties of the seabed sediment such as the particle size distribution (PSD), the introduction of contaminants (metals such as barium) from retained drilling fluids (WBM) and associated ecological effects.

The discharge of drill cuttings and unrecoverable fluids at the seabed during riserless top hole drilling results in a localised area of sediment deposition (known as a cuttings pile) surrounding the well site. The cuttings pile distribution may reflect prevailing seabed currents and spread predominately downstream of the well site but overall extent from the well site is typically tens of metres. The dimensions of the cuttings pile depend on several factors, including volume (approximately 641 m3 of top hole cuttings) and composition of cuttings, and oceanographic conditions at the discharge location. The top-hole well section drill cuttings and retained drilling fluids (WBM) to seabed have the greatest impact to sediment quality and modification of the habitat in proximity to the well, as the solids tend to clump and settle rapidly around the discharge point (Neff, 2010).

Indicative components of the WBM system outlined in Section 3.11.2 have a low toxicity. Bentonite and chemicals from the family of XC polymers (Xanthan Gum or similar) are listed as ‘E’ category fluids under the OCNS and considered to ‘pose little or no risk to the environment’. Metals such as barium from these additives will be present in the drilling fluid, primarily as insoluble mineralised salts, and consequently are not released in significant amounts to the pore water of marine sediments and have low bioavailability to those benthic fauna which may come into contact with the discharged barite (Crecelius et al., 2007; Neff, 2008). The XC polymer and bentonite sweeps have very low toxicities and are considered by OSPAR to pose little or no risk to the environment.

As described above, the bottom hole sections are drilled after the riser is fitted. Cuttings and unrecoverable fluids are discharged below the water line at the MODU site, resulting in drill cuttings and retained drilling fluids rapidly dispersing through the water column. The larger cuttings particles will drop out of suspension and deposit in proximity

to the well site (tens to hundreds of metres distance) with potential for localised spreading downstream, while the finer fluid particles will remain in suspension and will be transported further away from the well site, rapidly diluting and eventually depositing over a larger area (hundreds of metres to several kilometres) downstream of the well site. Drill cuttings from the bottom-hole sections will be smaller in volume (approximately 482 m3Table 6-19) and as determined by surface discharge, depth of seabed and time to reach seabed, result in an extended area of deposition, but a much thinner cuttings pile depth (IOGP, 2016). The fines associated with the retained drilling fluids or mud pit bulk discharge of WBM will settle over a greater extended distance as a thin, undetectable veneer on the seabed. Predicted impacts for bottom hole cuttings are generally confined to a maximum of 500 m from the discharge point (IOGP, 2016). The final deposition of drill cuttings and drilling fluids is largely determined by seabed depth and the time to drop out of suspension within the water column and deposit on the seabed. This leads to the coarser cuttings material being deposited at a location offset but closest to the well site in an area downstream and a distance up to of several hundreds of metres, with associated ecological effects within this area and the fines (predominately drilling fluids) dispersed over a greater distance from the discharge site, typically several kilometres but with no associated ecological effects.

Benthic organisms below the cuttings pile will be buried and smothered; however, the cuttings pile is expected to be recolonised over time. Ecological impacts to benthic biota are predicted when sediment deposition is equal to or greater than 6.5 mm in thickness (IOGP, 2016). This amount of sediment deposition from top hole and bottom hole cuttings is expected to be confined to within a few hundred metres around the well location, although this depends on the nature of the cuttings, the water depth and currents of the receiving environment (IOGP, 2016). A conservative radius of 500 m representing a zone of potential ecological impact has been applied to each well location for this impact assessment. Mobile benthic fauna, such as demersal fish, may be temporarily displaced from where cuttings discharges accumulate. Furthermore, ecological impacts are not expected for mobile benthic fauna such as crabs and shrimps or pelagic and demersal fish, given their mobility (IOGP, 2016). Balcom et al., (2012) concluded that impacts associated with discharging cuttings and base fluids are minimal, with impacts highly localised to the area of the discharge deposition on the seabed. Changes to benthic communities are normally not severe. Organic enrichment can occur, leading to anoxic conditions in the surface sediments and a loss of infauna species that have a low tolerance to low oxygen concentrations, and to a lesser extent chemical toxicity near the well location. These impacts are highly localised with short-term recovery that may include changes in community composition with the replacement of infauna species that are hypoxia-tolerant (IOGP, 2016). Recovery of affected benthic infauna, epifauna and demersal communities is expected to occur, given the short duration of sediment deposition and the widely represented benthic and demersal community composition.

It is acknowledged that transport of fines (associated with the drilling fluids) will disperse beyond the zone of potential ecological impact but there are no associated ecological effects expected beyond this zone (500 m distance from each well site). Low levels of sediment deposition away from the immediate area of each well site would represent a thin layer of settled drill cuttings and drilling fluids, which will likely be naturally reworked into surface sediment layers through bioturbation (US Environmental Protection Agency, 2000). Metals such as barium from the drilling fluid additives are used as a tracer of dispersion and are typically detected beyond the zone of ecological impact but as discussed for sediment quality (above), the insoluble mineralised salts (the source of barium) have low bioavailability to benthic biota.

Impacts associated with routine and non-routine drilling discharges will be largely limited to an area surrounding the well. The low sensitivity of the benthic communities/habitats within and in the vicinity of the PAA, combined with the low toxicity of WBMs and residual NWBMs, no bulk discharges of NWBM and the highly localised nature and scale of predicted physical impacts to seabed biota, affirm that any predicted impact is considered likely but of a slight environmental consequence.

KEFs

The Xena-03 Operational Area overlaps the Continental Slope Demersal Fish Communities KEF (Section 4.7). While drill cuttings will be discharged within the KEF, the highly localised turbidity and sediment deposition effects will not affect demersal fish communities, beyond temporary avoidance behaviour for some individual fish. Within the conservatively applied zone of potential ecological impact (500 m radius) burial or smothering of epifauna and infauna will be largely confined to close proximity to the wellhead. Recovery of affected benthic infauna, epifauna and demersal fish communities is expected to occur, given the short duration of sediment deposition and the widely represented benthic and demersal community composition. The small portion of the overall KEF area that overlaps the Xena-03 Operational Area, in combination with the predicted recovery of the affected benthic communities, affirms that any predicted impact is considered to be a slight, short-term effect.

Cultural Heritage

The Xena-03 Operational Area is located further offshore than the Ancient Coastline at 125 m depth contour KEF (Section 4.7). The Xena-03 Tie-back activities do not pose a risk to Indigenous Cultural features on the Ancient Landscape between the mainland and the Ancient Coastline KEF.

Drilling Fluids (Bulk Discharge)

WBM may be bulk discharged at the end of specific well sections, as described above, where there is a requirement to change the drilling fluid system or the drilling fluid cannot be re-used (due to deterioration/contamination). A small

quantity of WBM and NWBM residue (<1%) may also be discharged at the sea surface while cleaning the mud pits, typically at the conclusion of drilling activities or when changing between mud types.

Discharge of WBM will result in a buoyant plume of fine materials that will rapidly dilute and decrease in turbidity levels immediately away from the discharge point. WBM samples collected by Jones et al. (2021) from the mud pits just before discharge during the Greater Western Flank-2 drilling campaign were ~90% silt sized (<62.5 µm) with a mean diameter of 12 µm (gel-polymer) and 33 µm (KCl-polymer). Total suspended solid (TSS) levels in the gel-polymer mud and KCl-polymer mud were 257 g/L and 245 g/L respectively. Jones et al. (2021) used an ROV to observe mud pit discharges and reported the discharge to exit the discharge outlet as a jet of material in a distinctive cloud-like plume descending rapidly to the seabed and growing in diameter with increasing depth.

The subsea plume can be expected to disperse over a wide area (up to several kilometres), with no discernible sediment deposition on the seabed and no physical or biological impacts, particularly given the water depth at the drilling location (176 m). Impacts beyond the 500 m zone of ecological impact for the well as described for drill cuttings and retained fluids discharge is not expected.

Subsea – Displacement, Completion and Well-bore Cleanout Fluids

Discharges such as displacement, completion and wellbore cleanout fluids are typically inert and of low-toxicity. These fluids are mostly brine, with a small proportion of chemical additives such as surfactants, biocide, corrosion inhibitor, oxygen scavenger, MEG and guar gum. The volume of one wellbore and subsequent discharge volume would be ~400 m3. Any change to water quality is expected to be localised and temporary. Rapid dilution due to prevailing ocean currents in the open water environment would lead to any changes in water quality such as low toxicity contaminants being temporary (only for the duration of the discharge) and reducing water quality within a short distance of the discharge location.

Removal (Cutting) of Well Infrastructure (Contingency)

The planned cutting depth is approximately 3-5 m below the mudline, therefore discharges from cutting of well infrastructure using either an abrasive water jet cutting method of a mechanical cutting tool are expected to be confined predominately within the well and settle on the top of the permanent plug. During final cut through the conductor pipe, small amounts of flocculent and grit will be released below the mudline to sediments immediately surrounding the well.

Should cutting at a shallower depth be required, however, these discharges may be released to the seabed surface. For the mechanical cutting tool, discharges will be limited to small quantities of metal and cement cuttings from the infrastructure itself as well as small quantities of lubricant. For the abrasive water jet cutting method, discharges include a small amount of grit and flocculent. Depending on the cutting depth, pressure from the jet cutting could push some of the material up to the seabed surface causing localised smothering of benthic communities as well as create localised and temporary increases in turbidity around the well. All chemicals used for infrastructure removal are assessed in accordance with the Woodside Chemical Selection and Assessment Environment Guideline.

Cumulative Impacts

The seabed around the Xena-03 well is in close proximity to other wells and hence the discharge of drill cuttings and drilling fluids from the well may result in cumulative impacts. The benthic habitats and communities that may be impacted by the discharge of drill cuttings and fluids are widely represented in the region and not of high conservation value. The area within which cumulative impacts may occur is relatively small and would be substantially smaller than the area impacted directly by drill cuttings and fluids discharges. Other aspects of the Petroleum Activities Program that may impact upon benthic habitats will be localised around the Xena-03 wellhead and subsea infrastructure, hence the potential area impacts by cumulative impacts from other aspects is very small. Recovery is expected to occur through natural processes. Hence cumulative impacts will be slight and of no lasting effect (i.e., Environment Impact – F).

Summary of Potential Impacts to environmental values(s)

Given the adopted controls, it is considered that routine discharges of drill cuttings and drilling fluids described will not result in a potential impact greater than slight, short-term impact (less than one year) on species, habitat (but not affecting ecosystems function), physical or biological attributes (i.e. Environment Impact – E).

No additional controls identified				
Professional Judgement – Substitute				
No additional controls identified				
Professional Judgement – Engineered Solution				
Mud pit wash residue will be measured for oil content prior to discharge.	F: Yes. CS: Minimal cost. Standard practice.	Ensuring <1% oil content will provide a small reduction in consequence when residue is discharged to the environment.	Benefits outweigh cost/sacrifice.	Yes C 8.8
WBM drill cuttings returned to the MODU will be processed using SCEt equipment.	F: Yes. CS: Minimal cost. Standard practice.	Limiting the discharge of WBMs through reuse will reduce the consequence of the using WBM.	Benefits outweigh cost/sacrifice.	Yes C 8.9
Drill cuttings returned to the MODU will be discharged below the water line.	F: Yes. CS: Minimal cost. Standard practice.	Discharge of drill cuttings below the water line will reduce carriage and dispersion of cuttings thereby reducing the consequence of cuttings discharges during the Petroleum Activities Programme.	Benefits outweigh cost/sacrifice.	Yes C 8.10
Cuttings reinjection into formation. Cuttings are crushed, slurrified and pumped to a desired geological structure with a suitable seal, below the seabed through an annulus or tubing.	F: No. No concurrent drilling or direct sequential drilling planned which would require cuttings to be stored prior to re-injection. CS: Not considered – control not feasible.	Not considered – control not feasible.	Not considered – control not feasible.	No
Riserless Mud Recovery (RMR) system to return top-hole cuttings/mud from the riserless section of the well to the MODU prior to treatment onboard and discharge from the MODU (below the water line).	F: Not technically feasible due to water depth. CS: Not considered – control not feasible.	Not considered – control not feasible.	Not considered – control not feasible.	No

Demonstration of ALARP				
Control Considered	**Control Feasibility (F) and Cost/Sacrifice (CS)9F[61]**	**Benefit in Impact/Risk Reduction**	**Proportionality**	**Control Adopted**
Riserless Mud Recovery (RMR) system to return top hole cuttings from the riserless section of the well to the MODU prior to transport to an alternative discharge location or back to shore for disposal.	F: Not technically feasible due to water depth. CS: Not considered – control not feasible.	Not considered – control not feasible.	Not considered – control not feasible.	No
Return riser-in-place cuttings for disposal at another marine location or onshore for processing and land disposal (skip and ship) for whole well to reduce risk of benthic disturbance. OR Return riser-in-place cuttings for all sections drilled with NWBM for disposal onshore (to reduce potential residual oil on cuttings to environment).	F: Yes. CS: Primary cost/sacrifice of this option is the additional handling required in transporting cuttings to alternative disposal location. Particularly the health and safety risks associated with high frequency of support vessel activity alongside the rig and the amount of crane lifting required if a cuttings skip/drilling waste container system were employed. Other cost/sacrifice elements which are considered include: Further treatment of cuttings onshore is required to ensure a standard suitable for landfill. Class II disposed locally (e.g. Karratha). Class III landfill requires transport to Geraldton or Perth Increased risk of unplanned vessel collision or loss of cuttings during transfer activities Environmental impact (suspended sediment/ sedimentation) of discharging cuttings at new location and	Compared to adopted control, return riser in place cuttings would achieve a reduction in cuttings/mud discharged (although discharge would still occur during riserless drilling on the basis this control is not adopted) at the well location; however, given current impact assessment and controls adopted, this would not result in a significant reduction on consequence.	Disproportionate. Given the adopted controls and low current risk rating, the high cost/sacrifice outweighs the benefit gained over the duration of the Petroleum Activities Program. Impact assessment has determined no sensitive benthic receptors in the vicinity and a low level of impact potential from overall cuttings/mud discharge therefore benefit to be gained from cuttings/mud recovery is disproportionate to the risks introduced by cuttings relocation (including if an alternative system which doesn't use transport containers was implemented).	No

Demonstration of ALARP				
Control Considered	**Control Feasibility (F) and Cost/Sacrifice (CS)9F[61]**	**Benefit in Impact/Risk Reduction**	**Proportionality**	**Control Adopted**
	other regulatory approvals may also be required (e.g. sea dumping permit). Potential halt to drilling activity if transfer operations are delayed due to weather or operational issues Additional environmental impact incurred (air emissions) from vessel use and onshore trucking for transportation of cuttings. Disposal via landfill and/or treatment does not eliminate an environmental impact. These options have their own impacts and therefore disadvantages if implemented.			
Reduce total drill cuttings by implementing slim well design.	F: No. Slim well design is not considered feasible based on the following factors: The well design is optimised to minimise the size of hole drilled while still being able to reach the targets and meet development objectives safely. CS: Not considered – control not feasible.	Not considered – control not feasible.	Not considered – control not feasible.	No
Water quality and/or sediment monitoring of drill cuttings or drilling fluids to verify impact during activity.	F: Yes. CS: For in-water sampling utilising ROV - Time and logistics for tool change out from	No environmental benefit would be gained by implementation of monitoring during the activity. Monitoring could be used to inform additional control measures in future	Disproportionate Cost/sacrifice outweigh benefit to be gained in the context of existing environment (deep water,	No

Demonstration of ALARP				
Control Considered	**Control Feasibility (F) and Cost/Sacrifice (CS)9F[61]**	**Benefit in Impact/Risk Reduction**	**Proportionality**	**Control Adopted**
	operational tools to specialised scientific sampling tools. Additional POB to operate ROV and coordinate sampling program. Low ROV availability due to operations can limit time to perform environment monitoring. If additional ROV is required on the MODU, deck space and resources to run/store/service ROV. Resources for sample processing (space/ equipment/ personnel).	drilling activities; however, there is a considerable body of existing scientific literature on potential impacts of drill cuttings and impacts are generally well understood. Furthermore, it is not guaranteed that additional controls would be feasible, or if they would provide any environmental benefit.	open ocean communities with no proximity to sensitive benthic communities or receptors). Although adoption of this control could be used to verify EPOs associated with drilling mud and cutting discharge, alternative controls identified achieve an appropriate outcome.	
Use SCE with secondary treatment for NWBM: Thermomechanical systems (to achieve <1% average oil on cuttings).	F: Yes – with associated infrastructure including vessels for offline storage and delivery to thermomechanical dryer. CS: The primary cost/sacrifice of this option is the monetary outlay for acquisition and implementation which is estimated at $800,000 to mobilise, install and demobilise, along with a running cost of about $32,000/day. Other factors considered include: It is estimated that it would take a minimum of seven months to mobilise, install and commission the	A reduction in consequence would be achieved by reducing the average oil on cuttings discharged.	Disproportionate. Cost/sacrifice outweighs benefit to be gained in the context of existing environment and drilling campaign.	No

Demonstration of ALARP				
Control Considered	**Control Feasibility (F) and Cost/Sacrifice (CS)9F[61]**	**Benefit in Impact/Risk Reduction**	**Proportionality**	**Control Adopted**
	system on to the MODU. Complex and unfamiliar system to integrate with the rig systems. Increased health and safety exposure due to: crew of nine engineers and technicians required to run the plant. multiple crane lifting operations, during installation, operations and demobilisation. rotating machinery heat illness deck congestion due to large footprint of the plant.			
Time restricted discharge of WBM and/or cuttings to align with tide/current or other oceanographic events.	F: Yes. CS: Disruption to drilling operations in having to stop drilling at time when discharge of WBM and/or cuttings might not be permitted. Additional mud storage volume required.	Given the offshore location, oceanographic changes are unlikely to significantly affect the dispersion of cuttings and therefore no environmental benefit would be gained.	Disproportionate. The cost/sacrifice outweighs the benefit gained – No hard coral or other photo-sensitive benthic communities in the vicinity of the well to rationalise phased/ timed discharge.	No
ALARP Statement On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts and risks of drill cuttings and fluids discharges to the marine environment. As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.				
Demonstration of Acceptability				
Acceptability Statement The impact assessment has determined that, given the adopted controls, routine discharges of drilling cuttings and fluids to the marine environment are unlikely to result in a potential impact greater than slight, short-term impact (less than one year) on species, habitat (but not affecting ecosystems function), cultural heritage, physical or biological attributes. Further opportunities to reduce the impacts and risks have been investigated above. The adopted controls are considered good oil-field practice/industry best practice. The potential impacts and risks are considered broadly acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted				

Demonstration of ALARP				
Control Considered	**Control Feasibility (F) and Cost/Sacrifice (CS)9F[61]**	**Benefit in Impact/Risk Reduction**	**Proportionality**	**Control Adopted**
controls appropriate to manage the impacts and risks of these discharges to a level that is broadly acceptable and demonstrates the EPO has been met.

Description of Source of Impact

Cement, Cementing Fluids, Grout, Subsea Well Fluids and Unused Bulk Products at End of Drilling Campaign

Cementing Fluids, Cement and Grout

Cementing fluids, including cementing mix water, may require discharge to the marine environment under various scenarios during drilling and tie-back activities for the Xena-03 well.

At the commencement of the drilling campaign there may be a requirement to run a cement unit test to ensure the functionality of the cement unit and the cement bulk delivery system prior to performing an actual cement job. This test would result in a small volume of approximately 10 m3 of cement slurry being discharged at the sea surface. The slurry is usually a mix of cement and water however may contain stabilisers or chemical additives.

When cementing the conductor and surface casings after top hole sections of a well have been drilled, cement must be circulated to the seabed to ensure structural integrity of the well. Excess cement is pumped so that structural integrity is achieved. If the hole is completely in-gauge and there are no downhole losses while pumping the cement, a maximum volume of 80 m³ is estimated to be circulated to the seabed at the well location, which forms a thin concrete film on the seabed in close proximity to the well.

Wherever possible, the cement line flush volumes are included in the planned cement jobs. After each cement job, leftover cement slurry in the cement pump unit and the surface lines is flushed and discharged to the sea to prevent clogging of the lines and equipment. This is estimated at about 10 m³ discharged. In the unlikely event a respud event

is required it would result in additional cement jobs. Also, in the rare event that the cement products become contaminated, the entire volume (~180 m³) may need to be discharged to sea.

Cement spacers can be used as part of the cementing process, within the well casing, to assist with cleaning of the casing sections prior to cement flow through. The spacers may consist of either seawater or a mixture of seawater and dye. The dye is used to provide a pre-indicator of cement overflow to the seabed surface, to ensure adequate cement height.

If grout bags are used, after grouting activities at each span site, the downline and pump will need to be purged using seawater. This will result approximately 5 m3 (downline volume) of grout discharged to the ocean. This flushing is required once per grout site.

Subsea Fluids – Blow Out Preventors (BOP) and Well Construction Activity Control Fluids

Subsea fluids are likely to be released during drilling, including the release of BOP control fluids. Subsea control fluids are water-based hydraulic control fluids used in control systems on the subsea trees and BOPs. The BOP is required, by legislation, to be regularly function tested when subsea.

Subsea control fluids will be discharged during function testing of the BOP on installation and pressure testing.

The BOP is function tested during assembly and maintenance and during operation on the seabed as described in Section 3.11. As part of this testing, small volumes of BOP control fluid (generally consisting of water mixed with a glycol based detergent or equivalent water-based anti-corrosive additive) are released to the marine environment.

Each time a pressure and function test is undertaken approximately 3620 L of water-based fluid is released to the marine environment, of this approximately 4% is control fluid additive. BOP operation includes function and pressure testing approximately every 21 days, and a function test (approx. 2665 L) approximately every seven days, excluding the week a pressure test is conducted.

Subsea Fluids – Displacement Fluids

As required throughout activities with the riser connected, the well will be displaced from one drilling fluid system to another. A chemical clean-out pill or fluids train will be circulated between the different fluids. This will result in a discharge of operational fluids in accordance with the Woodside internal guidelines.

Produced / Reservoir Water

If well unloading activities were to occur, a temporary production system water filtration treatment package will be used to treat produced/reservoir water before discharge. Prior to discharging, the fluids are cycled through an oilbond filtration system and gauge tank. Water filtration is standard practice for well unloading operations and the produced water will be treated to meet 30 ppm OIW. Fluids that cannot be treated or flared will be sent onshore in tanks for disposal.

Non-Routine Discharge of Unusued Dry Bulk Products at the End of the Drilling Campaign:

Adequate stocks of dry bulk product are required to be stored on the MODU for the duration of the drilling activity for safe operations and well control purposes, as defined in the Woodside Well Control Bridging Document. Approximate quantities typically required are as follows:

- Cement: approximately 100 tonnes
- Barite: approximately 120 tonnes
- Bentonite: approximately 120 tonnes

At the end of the drilling activity and prior to demobilisation, Woodside is contractually obliged to remove the dry bulk product from the MODU. A number of options for removing excess product from the MODU exist, with the last option being to discharge to the marine environment. Woodside have developed a process to assess all safe and technically feasible options for the excess product before a decision is made to discharge overboard, this includes the considering the following options, as described below and illustrated in Figure 6-7:

- Retaining products on the MODU to be used for subsequent Woodside drilling activities where the activity is not the last in the Woodside MODU sequence, or
- Retaining products on the MODU to be used by the next titleholder who has the MODU on hire, or
- Transfer to another Woodside contracted MODU operating in the region, or
- Transferring to another titleholder-contracted MODU operating in the region, or
- Returning to shore for onshore storage and/or disposal if a facility is available that is both safe and technically feasible to transfer dry bulk products to, and
- Discharged to the marine environment as a slurry as a last resort, if it is concluded that no other options outlined in Figure 6 1 are feasible and that concentrations of mercury and cadmium in barite are <1 mg/kg and <3 mg/kg, respectively.

Woodside's base plan is to retain dry bulk products on board the MODU at the end of the campaign, either for reuse by Woodside (if a subsequent Woodside drilling activity is contracted after the petroleum activity), or transfer the dry bulks to the next titleholder who has the MODU on hire. At the time this EP was written it was not yet confirmed

whether Woodside would be contracting the MODU for subsequent petroleum activities or if there was another titleholder who planned to contract it.

If there are no available options to leave the dry bulk products on the MODU, Woodside would look to transfer excess dry bulk product to another MODU operating in the region, either for Woodside use or for another titleholder. MODU schedules and regional activities are closely monitored to identify these transfer opportunities early, allowing sufficient time to coordinate transfer arrangements. At the time this EP was written it was not yet confirmed if there was another MODU to transfer dry bulk product to, and this opportunity typically presents towards the end of a drilling activity. Woodside has a proven record of transferring dry bulk materials for reuse between operators and offshore facilities within these timeframes.

The backload of dry bulks to shore at the end of the campaign has been explored with Woodside's fluids providers. However, current onshore infrastructure does not support the safe transfer of bulk product at high pressure. When the MODU receives bulk product from a shore base, it involves the pneumatic transfer of product from a lower pressure container/tank to the higher pressure MODU or supply vessel container/tank. However, transfer of bulk product from the MODU to shore would involve the transfer of that material, which is powder, from a high pressure to low pressure mobile tank. These high to low pressure transfers of dry powder carry safety risk as the pressure differential between the two systems can result in an uncontrolled, or rapid fluid flow causing pressure build up, beyond safe limits. Dry bulk products can be transported from shore when initially processed given the manufacturing locations have necessary infrastructure to package bulks in bags for transportation and sale, including bagging machines. These dry bulk products cannot be returned to shore in this same manner. Once the product is transported offshore, it is stored in tanks under high pressure conditions. To return product to shore in the same manner it is initially transported from manufacturing location, the product would need to be high-pressure transferred from the MODU or support vessel tanks to bags, which is not considered to be feasible.

During the PAP Woodside will continue exploring the feasibility of installing appropriate infrastructure including pressure release valves and other transfer equipment to enable safe transfer of dry bulk product to shore.

If reuse of excess bulks for subsequent activities in the region is not possible and no feasible options for safe transfer of dry bulk product are identified by completion of the campaign, excess dry bulk will be discharged to the marine environment in the form of a slurry. This will only occur if it can be demonstrated that there are no other options identified in Figure 6-7. Use and discharge of all chemicals and products will be conducted in line with Woodside's internal guidelines (Section 7.2).

Dry bulk materials generally pose little or no risk to the environment (PLONOR)[63], though barite may contain traces of heavy metals, such as mercury and cadmium. Woodside requires that concentrations of mercury and cadmium in barite be <1 mg/kg and <3 mg/kg, respectively. This conforms to the American Petroleum Institute (API) specification for drilling barite. Heavy metal analysis is conducted on individual batches of stock barite prior to mobilisation offshore. This sampling confirms that heavy metals of concern (cadmium and mercury) are within limits prescribed by API standards.

[63] Barite (as barium sulphate) is on the OSPAR List of Substances Used and Discharged Offshore which are Considered to Pose Little or No Risk to the Environment (PLONOR). The List is available at: https://www.cefas.co.uk/media/p3sbu3bn/ospar-list-of-substances-used-and-discharged-offshore-which-are-considered-to-pose-little-or-no-risk-to-the-environment-plonor-update-2021.pdf

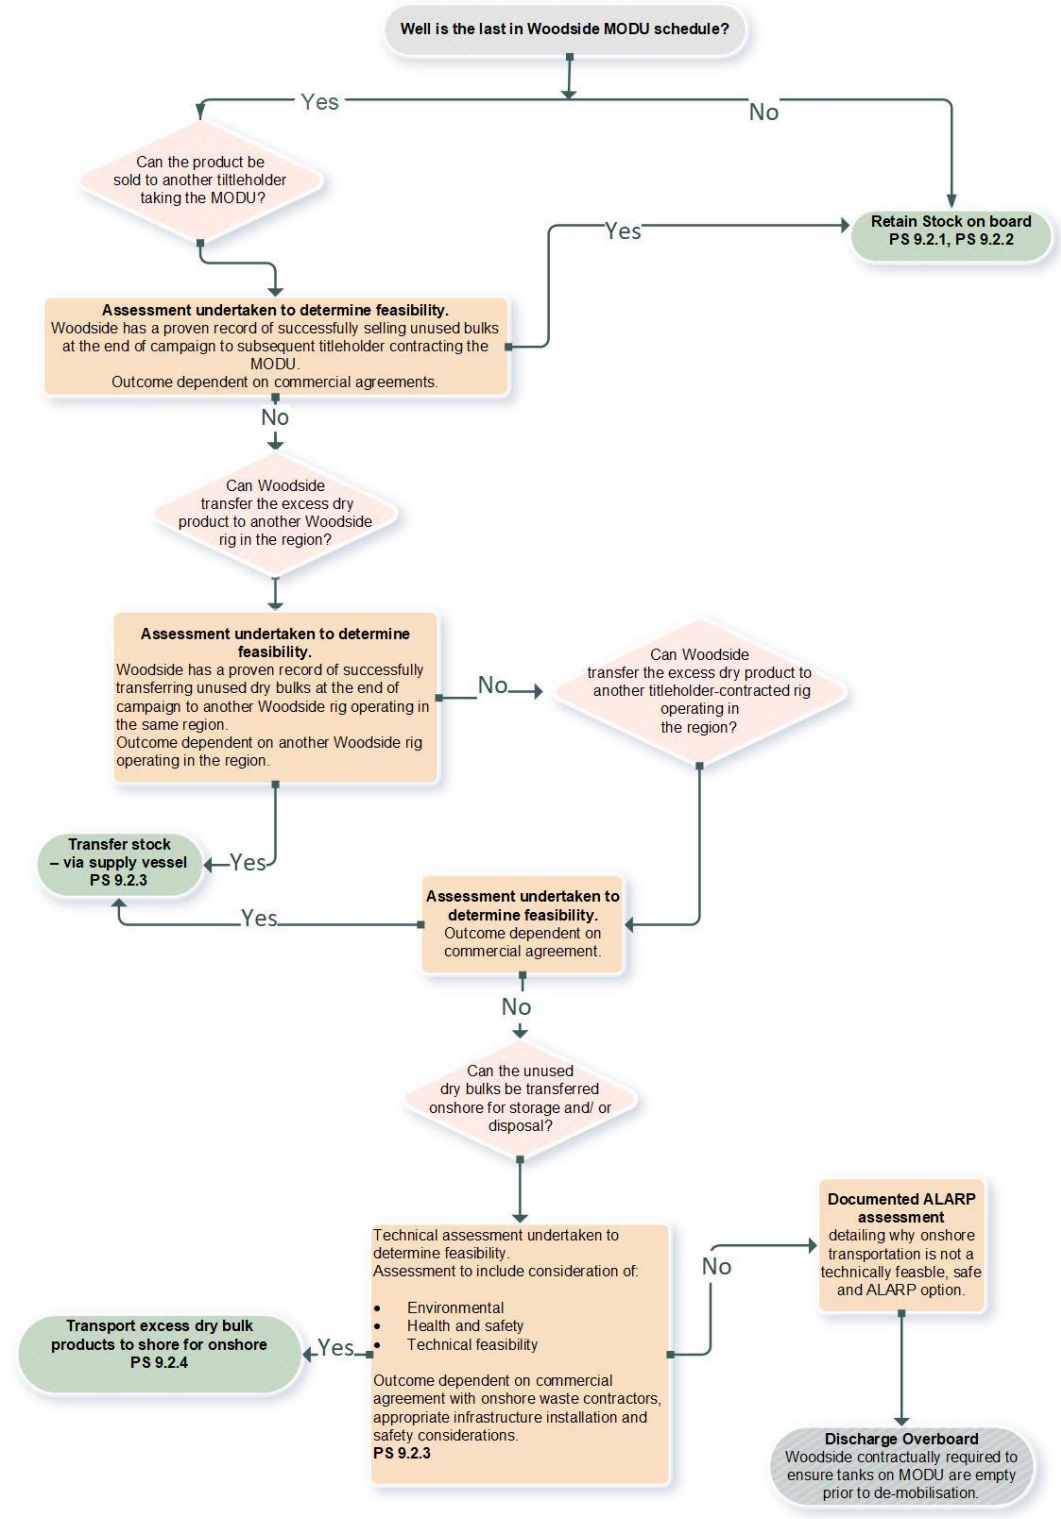

Figure 6-7: Management process for excess bulk product

Impact Assessment

Potential impacts to environmental values

Pelagic and benthic habitats and communities in the Xena-03 Operational Area are considered to be of low sensitivity and reflective of the wider NWMR. No known regionally significant benthic or infauna habitat occur in the area. The Continental Slope Demersal Fish Communities KEF overlaps the Xena-03 Operational Area (Section 4.7), however the targeted well location is not located within the KEF. Impacts to values and sensitivities of this KEF are not expected due to the location of the well, small physical footprint of the discharges, coupled with the low toxicity of cementing and subsea fluids used for the Petroleum Activities Program. The likelihood of any significant impact to marine biota is subsequently considered to be low.

Cement and Grout

Sediment Quality and Benthic Communities

Impacts of cement and grout on the marine environment are predominantly associated with localised burial of benthic biota in the direct physical footprint of deposition. Cement operations and grout discharge during drilling involve routine and non-routine discharges that can result in turbidity in the water column. Reduction in water quality will be temporary (limited to the cement operational discharges during drilling) and subject to rapid dispersion and dilution by prevailing currents. Modelling of cement discharges for another offshore project (BP Azerbaijan, 2013) was used because it provides an appropriate, but conservative, comparison of the potential extent of exposure from this activity. In this study, two hours after the start of discharge, plume concentrations were determined to be between 5 and 50 ppm with the horizontal and vertical extents of the plume ~150 m and 10 m, respectively (BP Azerbaijan, 2013). Five hours after ceasing the discharge, modelling indicates that the plume will have dispersed to concentrations <5 ppm.

Cement is the most common material currently used in artificial reefs around the world and is inert. The potential for toxicity is associated with chemical additives that may be added to cement mixtures. Therefore, the toxicity associated with the discharge of cement is limited to the subsurface release of cement (not discharge of slurrified or dry cement). Once the cement has hardened, chemical additives are locked into the cement (Terrens et al., 1998) and not expected to pose any toxicological risk to benthic biota from leaching or direct contact. Most cement discharges that will occur during the drilling activities will be at the seabed during cementing of the casing. Once overspill from cementing activities hardens, the physical sediment properties of the area directly adjacent to the well (10–50 m) will be permanently altered (Terrens et.al., 1998). The potential disturbance area is an estimated 0.007 km². Cement discharges at the seabed will overlap with the highest deposition of drill cuttings and drilling fluids. The highly localised physical footprint at the well site is not expected to affect the overall diversity or ecosystem function of the benthic communities of the area.

The potential impacts to benthic communities caused by smothering from a surface release of cement or a seabed release of grout are expected to be significantly less, due to small volumes, intermittent nature of these discharges, and high potential for dispersal by ocean currents. This impact on soft sediment communities is not expected to affect the diversity or ecosystem function in this area and is only considered a short-term impact.

KEFs

The Xena-03 Operational Area overlaps the Continental Slope Demersal Fish Communities KEF. The targeted Xena-03 well location is ~2.5 km from the Continental Slope Demersal Fish Communities KEF. The potential for interaction is limited to a surface release of cement within the KEF. However, as described above, the surface release of cement or the seabed release of grout will be highly localised around the well location. Recovery of affected demersal fish communities is expected to occur, given the small volume and dispersion, and the widely represented benthic and demersal community composition. The small portion of the overall KEF area that overlaps the Xena-03 Operational Area, in combination with the predicted recovery of the affected benthic communities, affirms that any predicted impact is considered to be a slight, short-term effect.

Cultural Heritage

The targeted Xena-03 well location (~176m) and Xena-03 Operational Area is not located within the Ancient Coastline at 125 m depth contour KEF, which extends from the 115-130 m isobath (Section 4.7). The targeted well location is ~4.5 km from the Ancient Coastline at 125 m depth contour KEF, The Xena-03 Tie-back activities do not pose a risk to Indigenous Cultural features on the Ancient Landscape between the mainland and the Ancient Coastline KEF.

Cementing Fluids, Subsea Well Fluids (BOP Control Fluids and Well Displacement Fluids) and Other Unused Bulk Products

All chemicals that may be operationally released or discharged to the marine environment by the Petroleum Activities Program are evaluated using a defined framework and set of tools to ensure the potential impacts of the chemicals selected are acceptable, ALARP and meet Woodside's expectation for environmental performance. Therefore, any chemicals selected and potentially released are expected to be of low toxicity and biodegradable. Additionally, where cements have been mixed in excess and cannot be reused or returned to shore, these will be turned into a slurry. As chemicals have initially been chosen based on the environmental performance and based on an ALARP assessment, additional dilution prior to discharge further reduces the environment impact to water quality, sediment quality and marine benthic and/or infauna communities. Given the minor quantities of routine and non-routine planned discharges, short discharge durations and the low toxicity and high dispersion in the open, offshore environment, any impacts on the marine environment are expected to be slight and short-term.

Summary of Potential Impacts to environmental values(s)
The overall impact significance level for routine and non-routine discharges of cement, cementing fluids, subsea well fluids and unused bulk product is E based on slight, short-term impact (less than one year) on species, habitat (but not affecting ecosystems function), physical or biological attributes.

Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)9F[64]***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
If discharge specification not met the fluid will be returned to shore.				
During well unloading and completions activities, if PW is not flared, it will be processed through the well test water treatment package prior to discharge to the environment.	F: Yes. CS: Minimal cost. Standard practice.	Reduced toxicity to the marine environment when discharged.	Benefits outweigh cost/ sacrifice	Yes C 9.1
Professional Judgement – Eliminate				
Do not use BOP control fluids.	F: No. BOP and xmas tree control fluids are critical to the operation of the BOP and xmas trees. CS: Not considered, control not feasible.	Not considered, control not feasible.	Not considered, control not feasible.	No
Excess dry bulk products will be managed as per Figure 6-7.	F: Yes. However, the cement may not meet the required technical specifications, and hence not be usable. CS: Minor administrative costs associated with coordinating reuse opportunities. Cost savings associated with the re-use or onsell of the dry bulk products. Moderate cost associated with onshore transportation and/ or disposal, if deemed feasible.	Reusing bulk products or identifying an opportunity for it to be returned to shore may eliminate any environmental impacts associated with discharge to the marine environment, where these options are safe and technically feasible. Furthermore, following the process outlined in Figure 6-7 confirms that discharge to the marine environment only occurs when there are no other safe or technically feasible options and therefore when ALARP.	Benefits outweigh cost/sacrifice	Yes C 9.2
Sampling/analysis of stock barite to ensure acceptable levels of heavy metals (i.e. concentrations of mercury and cadmium in barite are <1 mg/kg and <3 mg/kg, respectively)	F: Yes. CS: Minimal cost. Standard practice.	Barite may contain heavy metal such as cadmium and mercury, depending on its geological origin. Limiting the concentrations of cadmium and mercury is consistent with industry good practice.	Benefits outweigh cost/sacrifice.	Yes C 8.8

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)9F[64]***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
		Limiting cadmium and mercury concentrations in barite reduces the environmental risk from discharges of barite to the environment.		
Professional Judgement – Substitute				
No additional controls identified.				
Professional Judgement – Engineered Solution				
No additional controls identified				
ALARP Statement On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts and risks of cement, cementing fluids, subsea well fluids and unused bulk products. As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.				

Demonstration of Acceptability
Acceptability Statement The impact assessment has determined that, given the adopted controls, cement, cementing fluids, subsea well fluids and unused bulk products discharges are unlikely to result in an impact greater than slight, short-term impact (less than one year) on species, habitat (but not affecting ecosystems function), physical or biological attributes. Further opportunities to reduce the impacts have been investigated above. The adopted controls are considered good practice. When considering the broader acceptability of the potential impacts consideration has been given to the legislative context, including International Conventions such as the Minamata Convention. Woodside has undertaken an assessment of the PAP and the Minamata Convention (including measures in Article 9(5), and considers that the PAP is not inconsistent with the Minamata Convention. The potential impacts are considered broadly acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the impacts of these discharges to a level that is broadly acceptable and demonstrates the EPO will be met.

Description of Source of Impact

Atmospheric emissions generated during the Petroleum Activities Program can be classified into two categories:

- Atmospheric pollutants (non-greenhouse gas emissions) are gases and particulates from an activity, or piece of machinery, which have a recognised adverse effect on human health and/or flora and fauna. The main emissions responsible for these effects include carbon monoxide (CO), oxides of nitrogen (NOx), sulphur dioxide (SO2), particulate matter less than 10 microns (PM10), non-methane volatile organic compounds (VOCs) including BTEX (benzene, toluene, ethylbenzene and xylenes).
- Greenhouse gas (GHG) emissions. GHG emissions refers to those gases within the atmosphere that absorb long-wave radiation, and thus trap heat reflected from the Earth's surface. The main gases associated with this effect include carbon dioxide (CO2), methane (CH4) and nitrous oxide (N2O). Other GHGs include perfluorocarbons (PFCs), hydrofluorocarbons (HFCs) and sulphur hexafluoride (SF6). There are considered to be both direct and indirect GHG emissions.

In this section, atmospheric emissions estimates are developed in line with the National Pollutant Inventory (NPI) Emission Estimation Techniques (EET). GHG emissions are estimated using the National Greenhouse and Energy Reporting (NGER) Measurement Determination 2008 (Cth). The following section has been separated into Direct Emissions (Scope 1 & 2) and Indirect Emissions (Scope 3), aligned with the definitions of the GHG Protocol Corporate Standard (GHG Protocol 2015) and NGERS.

The main sources of GHG emissions associated with the PAP are shown in Table 3-5. GHG emissions sources that are not part of the PAP (e.g. GHG emissions from the onshore processing of Pluto gas) are included for consideration as indirect emissions. In the context of this EP, GHG emissions are classified as Direct and Indirect Emissions, as shown in Table 3-5.

The GHG Protocol 2015 defines indirect GHG emissions as emissions that are a consequence of the activities of the reporting entity but occur at sources owned or controlled by another entity. For the purposes of this EP the "reporting entity" is the Pluto offshore facility and therefore, onshore processing and support vessel/helicopter operations are considered indirect emissions sources.

Direct Atmospheric and Greenhouse Gas Emissions – Pluto Operations

Direct atmospheric emissions from the Pluto facility during the Petroleum Activities Program include emissions from flaring, equipment and generators, fugitives and process vents. Direct emissions and combustion products typically include CO_2, water vapour, NO_x, SO_2, methane, refrigerant gases, particulates and VOCs.

The emissions estimates presented provide a representative estimate of activities and operations over the next 5-year period of the Pluto Facility Operations EP. Direct GHG emissions are estimated to average approximately 37,700 t CO_2-e p.a during this period.

Variance within the period may occur, due to a number of factors such as reservoir and production system performance outcomes, planned activities including shutdowns and maintenance activities and unplanned reliability events. Emissions estimates below are provided as a reasonable estimate to inform an impact and risk assessment associated with activities requiring emissions to air.

Greenhouse gas emissions associated from XNA-03 drilling and tie-back activities is estimated to be approximately 13,300 t CO_2-e.

Atmospheric Emissions – Flaring: Historical emissions, prior to Water Handling Module

Prior to the water handling module start up, flaring has been the largest source of combustion emissions from the riser platform. The combustion of hydrocarbon gas by flaring is an essential practice, primarily for safety requirements. Operational flaring is comprised of two elements:

- normal operational flaring typically associated with flare system purge and pilot and process flows from produced water separation system.
- non-routine flaring that may result from activities such as planned shutdowns, ESD testing and pigging, and un-planned shutdowns and ESDs, production restarts, equipment outage/failures, subsea flowline depressurisation and well remediation activities.

During flaring, the burnt gas generates mainly water vapour and CO2. Gas flaring has the potential to increase the volumes of GHGs emitted to the atmosphere. Flaring also consumes natural gas, a non-renewable resource. The efficiency of the facility flare is estimated to be approximately 98%. Incomplete combustion under certain scenarios may also generate dark smoke.

During normal operations, approximately 540 tonnes of gas are flared per year due to purging and maintenance of a pilot (based on data between 2020 - 2024).

Atmospheric Emissions – Flaring: Water Handling Module Normal Operations

Additional sources will be routed to flare as a result of normal water handling module operations with sources from the produced water degasser and the Horizontal Induced Gas Flotation (HIGF) processes. Following commencement of water handling module operations, combined continuous low pressure flows to flare are estimated to result in approximately 3500 tonnes flaring per annum.

Atmospheric Emissions – Intermittent flaring required to operate of the Water Handling Module and integrated subsea system

It is estimated that intermittent flaring may total approximately 4500 tonnes of gas per year associated with operation of the water handling module and integrated subsea system. Flaring will vary as a result of production rates and non-routine activities, outages and shutdowns, and is key to safe operation of the facility and integrity management of the subsea system (particularly pressure management in case of upset to prevent hydrate formation) as outlined in Section 3.7.1.

Atmospheric Emissions – Flaring: Non-routine Flowline Pigging

Flaring to facilitate round-trip pigging of the flowlines is an integral part of operation and maintenance of the facility and occurs as required (approximately once every four years). Non-routine flowline pigging is expected to result in approximately 8300 tonnes of flaring in order to transport flowline pig(s) through the subsea flowline system.

Atmospheric Emissions – Fuel Consumption

Diesel for fuel combustion has been used for the operation of the crane, power generators and survival craft prior to the installation of the water handing module. Diesel usage on the facility (excluding support vessels) between 2016 and 2023 ranged between 202 tonnes and 488 tonnes. The 2016-2017 period (330 tonnes) represented a typical NNC year, while the 2022-2023 period reflects an increased diesel use year as a result of ongoing topside modifications and continuous crewing of the NNC facility associated with the tie-in of the water handling module.

The installation of the water handling unit requires additional power generation and fuel usage when operational. To accommodate this, installation of the Water Handling Module during 2023 included adding a fuel gas generator, and changed the main source of power on PLA from the two existing diesel generators to the gas engine generator. The two existing diesel engine generators remain on the platform for backup power generation. Once under stable operation with the PWH module operating, the fuel gas generator is expected to consume an estimated 147 kg/hr (1286t/y fuel gas).

Diesel use will continue for operation of supporting diesel generators, the crane and survival craft. Upon achieving stable operation of the Water Handling Module, annual emissions from diesel combustion are expected to decrease.

The current arrangement for power generation is as follows:

- Gas Engine Generator
- Diesel Engine Generators

Grid Stability Module (contingent power supply)

There are several operating conditions that will use various arrangements for power generation as outlined in Table 6-21 below. Emissions estimates from these different modes and sources are summarised in Table 6-22 and Table 6-23.

Table 6-21: Power generation configuration list

No.	Scenarios	Configuration
1	Uncrewed Normal Production	Gas Engine Generator priority 1 x generator online 2 x generators offline standby 1 x grid stability module online
2	Flowline depressurised	Gas Engine Generator priority 2 x generators online
3	Production recovery	
4	Start-Up (warm-up) Production Recovery from ESD	

5	Normal Production Pumping	1 x generator offline standby 1 x grid stability module online
6	Campaign Maintenance	
7	Campaign Maintenance, UPS discharge test	
8	Shutdown Maintenance	

Emissions Estimates

The following sections provide direct emissions estimates associated with annual fuel combustion for power generation, routine and non-routine flaring, and fugitives required in the operation of the Pluto offshore facility.

Table 6-22: Estimated annual atmospheric emissions consumed in PLA operations for power generation

Emission Type	Estimated annual emissions from diesel combustion	Estimated total annual emissions from gaseous fuel combustion[1]
Source / Fuel	330	1,286
CO_2 (t/yr)	1,032	3,558
CH4 (tCO_2-e/yr)	1	7
N2O (tCO_2-e/yr)	3	2
Total CO_2-e (t/yr)	1,036	3,567
NO_x (t/yr)	5	120
SO_x (t/yr)	0	0
VOCs (t/yr)	2	3
PM10 (t/yr)	2	0
CO (t/yr)	5	16

1 Based on combustion of 1286 tonnes of fuel gas required for gas engine generator operation during normal operations (yearly).

Table 6-23: Estimated annual atmospheric emissions from routine and non-routine flaring sources

Activity	Routine	Non-routine	
	Routine operations flared gas combustion	Flaring during shutdown, blowdown and start-up events (includes blowdown, warm-up, and infrequent flowline depressurisation)	Estimated emissions from flared gas combustion required for infrequent flowline pigging
Total Gas (t/yr)	3,957	4,532	8,300
CO_2 (t/yr)	10,684	12,236	22,410
CH_4 (tCO_2-e/yr)	526	603	1,104
N_2O (tCO_2-e/yr)	103	118	216
Total CO_2-e (t/yr)	11,313	12,957	23,730
NO_x (t/yr)	6	7	12
SO_x (t/yr)	n/a (NPI EETM)		
VOCs (t/yr)	59	68	25
PM10 (t/yr)	n/a (NPI EETM)		

CO (t/yr)	34	39	72

Non-Routine Venting of Process Hydrocarbons via Flare System

During normal operations, hydrocarbon gas is flared via the flare system. The system is maintained to effectively combust hydrocarbons as a critical component for the safe operation of the facility. In the unlikely event that the flare is extinguished or unavailable (such as following a major shutdown prior to system ramp-up), the hydrocarbon gas discharged via the flare system may initially not be combusted during the period required to maintain safety purge flows to the flare system and intervention to re-establish flare ignition. This may result in the short term (days) low-rate contingent release of hydrocarbon gas to the atmosphere. Intermittent non-routine venting from the riser platform represents only a minor source of atmospheric emissions and is not considered to pose a risk beyond the routine air emissions described in this section.

Fugitive Emissions

Fugitive emissions can occur from pressurised equipment and are inherent in design. Fugitive emissions may occur due to infrequent operational activities or unintentional equipment leaks. Sources can include valves, flanges, pump seals, relief valves, vents, sampling connections, process drains, open-ended lines, casing, tanks, produced water and other potential leak sources from pressurised equipment. Fugitive emissions are quantified and reported as requirements set under the National Greenhouse and Energy Reporting Scheme (NGERS).Fugitive methane emissions are anticipated to be a very small GHG contributor at Pluto-A as safe operation of the facility relies on the effective containment of hydrocarbons. The amount of routine and non-routine fugitive emissions are considered to be small, and is inherently controlled by design and operations/maintenance practices. The facility has limited topsides processing and relatively few potential leak-points, is well-maintained using good practice operations and maintenance tightness validation. Furthermore, the facility is monitored with safety gas detection systems, and produced water discharges are processed through a degasser to remove associated entrained methane. Facility safety-related controls, produced water operations and implementation strategy measures provide proportional management of potential fugitive emissions for PLA. Potential unplanned hydrocarbon releases to the atmosphere associated with accidents, incidents and emergency situations are described in Sections 6.7 and 6.8). The National Greenhouse and Energy Reporting (Measurement) Determination 2008 estimates fugitive emissions based on typical 'shallow water offshore platforms' to be 1,747 t CO_2-e/yr of methane and 7 t CO_2-e/yr of carbon dioxide. Fugitive emissions associated with produced water production at the PLA PWH module maximum design rate is estimated to be approximately 1,140 t CO_2-e/yr based on accepted NGERs methodologies. Discrete relatively small volumes of packed gases and charged systems, including non-ozone depleting refrigerant gases, are used across the facility and vessels which have potential for small volume leaks (typically less than 100 kg per isolatable inventory). Such gases are used in the HVAC and refrigerant systems on the facility and vessels.

The facility is fitted with several portable fire extinguishing units utilising CO_2. The facility does not have any gaseous fire extinguishing systems containing synthetic GHGs or ozone depleting substances.

Indirect Emissions

Tie-back Activities: MODU, Vessel and Helicopter Operations

Atmospheric emissions during tie-back activities are generated by installation and support vessels from internal combustion engines (including all equipment and generators) and incineration activities (including onboard incinerators) during the Petroleum Activities Program for standard operations, excluding drilling waste.

Atmospheric emissions generated during these operations will include SO_x, NO_x, particulates and VOCs. SOx and particulate matter emissions are heavily influenced by the fuel used and its relative sulphur content, MGO usually having a lower sulphite content than marine diesel oil (MDO) or heavy fuel oil (HFO).

NO_2 emissions from routine MODU power generation for an offshore project were modelled previously by another operator (BP Azerbajan, 2013). NO_2 was the focus of the modelling, on account of the larger predicted emission volumes compared to the other atmospheric emissions, and the potential for NO_2 to impact on human health (as a proxy for environmental receptors). The model demonstrated that atmospheric emissions generated by MODU operations may increase ambient NO_2 concentrations by 1 µg/m^3 (0.001 ppm) within 10 km of the source and 0.1 µg/m^3 (0.0001 ppm) within 40 km of the source. This represents an increase of 2% over typical background concentrations within 40 km, with air quality remaining well below the WHO air quality guideline for NO_2 of 40 µg/m^3 annual mean. As NO_2 is the main emission that poses a threat to receptor health, it is considered conservative to use the above studies to justify potential impacts to receptors. As such, studies into the attenuation of other gasses emitted are not evaluated.

A moored MODU may be used for the drilling campaign resulting in less fuel needed for station keeping, however a hybrid MODU may be used. Other vessels required for the Petroleum Activities Program (e.g. installation vessels) may use DP to conduct installation or intervention activities. Based on fuel consumption information from the DPS-1 MODU on previous Woodside drilling campaigns and the expected activity duration plus mobilisation, it is estimated that a hybrid MODU will consume approximately 44 t/d of fuel when compared to similar scenarios. Based on the information available it is expected that up to approximately 2,640 tonnes of fuel may be used from MODU activities (60 total days for the drilling and completions of the single well). Other DP vessels associated with the subsea

installation and contingent well intervention activities may use up to 315 t (based on 21 days and a rate of 15 t/day). GHG emissions from the MODU, vessel and helicopter operations are expected to be approximately 8,042 t CO_2-e.

Support vessels, refuelling vessel and helicopters will support the Petroleum Activities Program, although emissions produced will be substantially less than those produced by the MODU/installation vessels. Total fuel consumption for support vessel activities (based on four general offshore supply vessels on standby at 2.5 t/day) is expected to be up to 1,669 tCO_2-e for anchor handling, drilling activities, subsea installation, well start-up and contingent well intervention activities. Helicopter operations during drilling activities may consume up to 84 tCO_2-e, based on ~1.5 t/day. The potential for multiple helicopter runs has been considered in GHG emissions summations.

Well Kick

During drilling of the well and contingent well intervention activities, a kick may occur. A kick is an undesirable influx of formation fluid into the wellbore. The resultant effect would be a release of a small volume of GHGs via the degasser to the atmosphere during well control operations, known as 'venting'. Venting is required to ensure well integrity is maintained in the event of a kick thereby avoiding an emergency condition. The total estimated, expected volume of GHG emissions from well kicks and venting is estimated to be approximately 378 tCO_2-e.

Well Flowback (Flaring) and Contingency Activities (Venting)

The preferred well unloading method for the tie-back activities is to direct all fluids to the onshore LNP plant via the Pluto facility. However, if this activity is not practicable, contingent well unloading to the MODU may result in gas, condensate, base oil and methanol in the wellbore to be flared and efficiently burned. The flare may be extinguished due to water ingress, lack of pilot (propane), weather impact or equipment failure resulting in cold venting of gas from the flare for several minutes. After the objectives of the well testing and flowback are achieved, the flow is stopped and the well may be cleaned using a brine that can include several chemicals, such as biocide and surfactant. Across approximately 48 hours a volume of ~31 mmscf of gas, 534 bbl condensate may be flared, or 1918 tCO_2-e.

Mud Degassing

Methane emissions may be released during the period of intersection with the reservoir. Small amounts of gases such as methane may dissolve in drilling fluids and be released to the atmosphere as fluids are degassed and recirculated. These emissions have been estimated using American Petroleum Institute factors and are negligible over the activity.

Venting of residual gas

During well intervention activities there are several scenarios that may cause small amounts of gas to be vented directly to atmosphere in an intrinsically safe manner via the choke manifold onboard the WIV. Due to the small quantities of gas, it is not viable to flare this gas. These sources of direct gas emissions include:

- Riser disconnect – Riser will be disconnected at the end of well intervention activities. Pressurised gas will be vented to the atmosphere.
- Wireline tool string and tool change – During the well intervention activities it is estimated that there will be 3 to 5 tool changes per well requiring intervention. Tool changes will cause a small quantity of venting to the atmosphere via the wireline lubricator.
- Surface returns – Small volumes of hydrocarbon gas from annular spaces will be cold vented via a choke manifold in a controlled and safe manner from the WIV.

Table 6-24: Greenhouse gas emissions and sources associated with tie-back activities

Source	GHG Emissions (t CO_2-e)
Anchor handling Activities	
Anchor Handling Operations	273
Support Vessel (Anchor handling)	136
MODU Activities	
MODU Operations	7140
Support Vessel (MODU Operations)	818
Helicopter Operations	84
Subsea Installation activities	
Primary Installation Vessel Operations	858
Support Vessel (PIV Operations)	286
Well Start Up and performance testing	
Support Vessel	286

Contingent Scenarios - Intervention / IMMR activities	
Intervention Vessel / IMMR vessel	858
Support vessel Operations	143
Contingent flaring	4
Well Kick & Flowback	1918
Vented per well	378
Venting – Riser disconnect (~1800PSI)	176
Venting - Tool change (5 changes)	<1
Venting – Surface returns	<1
Venting – Removal of tree cap	<1

Greenhouse Gas and Atmospheric Emissions associated with Support Vessels and Helicopters

Indirect GHG and atmospheric emissions will be generated by various support vessels, and helicopters supporting Pluto. Vessel emissions include those from internal combustion engines and fugitives. Incinerators may be used onboard vessels to dispose of flammable domestic wastes such as cardboard. Incinerators are typically used infrequently, with wastes generally segregated and transported to shore for disposal.

The figures provided below are estimates of key vessel and helicopter emissions. Atmospheric and GHG emissions from support vessels vary depending on the nature of activities being undertaken; for example, travelling or "steaming" to a destination at low speed uses less fuel and generates lower atmospheric and GHG emissions than high speed steaming. Emissions generated during safety related vessel standby activities, holding station using DP during loading and unloading of materials to the facility or undertaking subsea IMMR work also vary. PLA is not expected to require routine vessel support except on occasion when an intervention visit is required (planned or reactive maintenance). This is estimated to occur as frequently as 6 – 8 times per year.

Vessel Masters control day to day operations that determine support vessel emissions. Woodside has the potential to influence fleet level approaches to support vessel emissions through contracting activities. Refrigerant gases are used onboard supply vessels in small quantities.

Expected annual GHG emissions for vessel and helicopter activities have been estimated to be:

- 827 tCO_2-e for support vessels, based on MDO consumption.
- 1035 tCO_2-e for IMMR vessels, based on MDO consumption.
- 80 tCO_2-e for helicopters, based on Jet A1 fuel consumption.

Indirect emissions from these sources are expected to be relatively constant throughout the EP period.

Greenhouse Gas Emissions associated with Accommodation Support Vessels

Accommodation support vessels generate emissions dependent on several factors including: Sea state conditions, size of the vessel, environmental conditions and crewing and activity requirements. It is expected that there is variation in the fuel requirements dependent on these factors, ranging from ~6 to ~48 tonnes per day. Estimated ASV GHG emissions is approximately 12,760 tCO_2-e for ASVs, based on a 90-day campaign.

GHG Emissions associated with Processing Onshore and Product End-use associated with Pluto

Indirect emissions associated with Pluto Operations result from hydrocarbon processing (onshore), third party transport of products, regassification, distribution and combustion by end users. Key influences impacting indirect GHG associated with Pluto production include:

- Total production – indirect emissions are proportional to total production, which varies reservoir, well and production system performance, maintenance and shutdown activities, and well tie-backs and technical and commercial operating requirements.
- Composition of produced gas – such as variability due to technical constraints, inert gas optimisation, and separation of reservoir CO_2.

Downstream feed gas and product demands – the proportion of hydrocarbons attributed to Pluto sold as LNG, condensate, domestic gas and other products varies. Each product requires differing amounts of energy to process to the point of sale and varies based on reservoir composition, field contribution and commercial reasons.

End location, and use of sold products by third parties varies with national and international pathways for valuable energy and resource produces. Wide potential for end use of sold products can result in variable emissions intensities.

For the purposes of framing potential indirect emissions, the total assumed GHG emissions associated with annual production and from transport and customer combustion are estimated in Table 6-25 below. Estimates are conservatively framed, as they do not include possible abatement or offsets applied voluntarily or through regulatory

mechanisms in Australia and across the value chain and product lifecycle, including international. Indirect atmospheric emissions (non-GHG) are discussed in **Section 6.7.11.**

Table 6-25:Estimated direct and potential indirect GHG emissions associated with Pluto offshore activity production

Source of emissions	Annual estimated emissions (MtCO2-e)	Total possible emissions for EP period (MtCO2-e)
Direct Emissions		
Pluto Offshore Operations (including fuel, flaring and fugitives)	0.038	0.189
Indirect Emissions		
Project vessels, MODU and helicopters during XNA03 drilling, Installation, Hook-up and Commissioning	0.013	0.013
Vessels and helicopters during Operations	0.002	0.01
Onshore hydrocarbon processing[1]	2.36	9.52
Third party transport of products, regassification, distribution and end use[2]	23.1	91.3

[1] Estimated onshore processing emissions envelope based on potential positive reservoir and production outcomes, processed through onshore PLP and KGP LNG facilities. Typical of most oil and gas activities, reservoir performance carries a wide uncertainty range, and production varies with market demand and downstream processing performance. The annual estimated emissions presented in Table 6-26 represent the year with highest expected production/GHG emissions in the duration of the 5 year prior to acceptance of this EP. Total emissions presented do not consider net reduction by way of voluntary and regulatory abatement/offsets.

[2] Source: EcoInvent 3.5 database and National Greenhouse and Energy Reporting (Measurement) Determination 2008. EcoInvent v3.5 represents a large collection of inventory data, used as an approximation of third-party lifecycle LNG use for cargos delivered to China. It has been recognised as emission factor source for the European Union Renewable Energy Direction greenhouse gas methodology and is aligned to the principles of the NGERs methodology. Total emissions presented do not consider potential third-party net reduction by way of voluntary and regulatory abatement/offsets.

The precise shape and pace of the energy transition is uncertain. It is expected to vary across countries because they have different starting points, development requirements, resources and capabilities. However, the scale of the transition is clearer, as it will take many trillions of dollars, invested over decades. Today, Woodside has a portfolio of oil and gas assets. We are also diversifying our portfolio by investing in new energy products and lower carbon services that can avoid or reduce customer emissions. We see an ongoing role for gas from the Pluto facility to support our customers' plans to secure their energy needs, while they reduce their emissions.

Impact/Risk Assessment

Air Quality

Facility, tie-back activities and vessel routine and non-routine emissions, predominantly flaring, have the potential to result in localised, temporary reduction in air quality, generation of dark smoke and contribution to GHG emissions. Potential impacts of emissions depend on the nature of the emissions, as well as the location and nature of the receiving environment.

Facility design (including the rapidly dispersive characteristics of the gas turbine exhausts, flare and other emissions), the estimated level of pollutants in the emissions, and the absence of elevated background ambient levels have been considered in estimating the potential for interaction with human and environmental sensitivities. The PAA is in a remote offshore location, with no expected adverse interaction with populated areas or sensitive environmental receptors associated with air emissions.

The PAA overlaps the breeding BIA for the wedge-tailed shearwater, roseate tern, and fairy tern (see Section 4.6.4); as such, these seabirds may occur near to the facility airshed. Birds (including migratory birds) are also known to opportunistically roost on the riser platform. Given the highly dispersed nature of facility air emissions, no adverse impacts to birds are anticipated due to air emissions.

Potential impacts are expected to be temporary, localised air quality changes, limited to the airshed local to the riser platform. Air emission impacts are not expected to have direct or cumulative impacts on sensitive environmental

receptors, or above National Environmental Protection (Ambient Air Quality) measures and are expected to disperse well before reaching the nearest populated area (Dampier).

The flare and potential black smoke resulting from emissions may impact visual amenity. The offshore location of the Platform is not directly visible from the nearest landfall (Montebello Islands, 43 km south). Hence, no impacts to visual amenity for residential communities are expected. Visual amenity impairment to tourism activities is not expected.

Assessment of Potential Climate Change Impacts

Greenhouse gas emissions associated with Pluto are estimated to be up to 180 Mt CO2-e till EOFL, of which approximately 17 Mt CO2-e may originate from extraction and processing in Australia. Peak projected annual extraction and processing GHG of approximately 2.4 MtCO2-e would represent ~0.5% of national Australian emissions (463.9 Mt CO2-e during 2022) (DCCEEW, 2023d). These emissions will not materially or substantially contribute to either Australia's GHG emissions or global GHG emissions. Further, net emissions associated with Pluto in Australia are set to be lower than these totals - with ongoing abatement via implementation of the NGERS Safeguard Mechanism which sets out an abatement trajectory consistent with achieving Australia's emission reduction targets of 43% below 2005 levels by 2030 and net zero by 2050 (DCCEEW, 2023e). In view of the direct and indirect GHG emissions associated with Pluto Facility and tie-back of Xena-03, Woodside considers it appropriate to include contextual evaluation relating to the accumulation of GHGs in the atmosphere and relationship with potential climate change impacts on the environment. Climate change impacts cannot be attributed to any one activity as they are instead the result of global GHG emissions, minus global GHG sinks, that have accumulated in the atmosphere since the industrial revolution started. They do not take into account the net impact of each project or activity. Even if discounting the potential positive role gas can play towards customer commitments and plans to decarbonise through the energy transition; emissions associated with the project are negligible in the context of existing and future predicted global GHG emissions. The accumulation of net GHG emissions in the atmosphere is, in turn, influenced by global energy demand and the composition of the global energy mix. Although the direct and indirect GHG emissions associated with Pluto (as described above) cannot be linked to climate change impacts to the environment, the following context is provided:

GHG Emissions – Global and Australian Context

Climate science is a rapidly evolving field in which new observations continue to deepen understanding of the current and potential impacts of global warming, and the possible pathways for mitigation and adaptation (Woodside, 2023a). The IPCC is the United Nations body for assessing the science related to climate change, and is finalising the Sixth Assessment Report (AR6) which consists of three Working Group contributions and a Synthesis Report. A summary of outcomes of the working group's contributions comprises a range of matters, which amongst others include:

The AR6 Working Group I (AR6-WG1) report stated that it is unequivocal that there is human-induced warming. It also stated that increased atmospheric carbon dioxide (CO2) levels, generated by human activity, are the largest driver of warming over the longer term, and that there are a range of factors, including emissions of methane, which increase warming in the short-term.

The AR6 Working Group II (AR6-WG2) report stated that human-induced climate change, including more frequent and intense extreme events, has caused widespread adverse impacts and related losses and damages to nature and people, beyond natural climate variability. It stated that global warming, reaching 1.5°C in the near-term, would cause unavoidable increases in multiple climate hazards and present multiple risks to ecosystems and humans. The report noted that societal choices and actions implemented in the next decade will determine the extent to which medium- and long-term pathways will deliver climate resilient development.

The AR6 Working Group III (AR6-WG3) report provided an updated global assessment of climate change mitigation progress and pledges, and examined the sources of global emissions. It explained developments in emissions reduction and mitigation efforts, and assessed the impact of national climate pledges in relation to long-term emissions goals. More than 2000 quantitative emissions pathways were submitted to the IPCC, of which 1202 scenarios included sufficient information for assessing the associated warming. The report found that there are many pathways in the literature that likely limit global warming to 2°C with no overshoot, or to 1.5°C with limited overshoot. These variations occur because, while climate science is able to calculate a 'carbon budget' of net emissions before any particular temperature outcome is reached, the allocation of this budget between different human activities requires additional judgements about for example technology, economics, consumer preferences and policy choices.

The AR6 Working Group I (AR6-WGI) report states "climate change is a global phenomenon, but manifests differently in different regions" (IPCC 2021b). IPCC projections for climate change in Australia from the AR6 Working Group II (AR6-WGII) report include:

- further climate change is inevitable, with the rate and magnitude largely dependent on the emission pathway (very high confidence)[66]
- ongoing warming is projected, with more hot days and fewer cold days (very high confidence)
- further sea level rise, ocean warming, and ocean acidification are projected (very high confidence)
- less winter and spring rainfall is projected in southern Australia, with more winter rainfall in Tasmania, less autumn rainfall in southwestern Victoria and less summer rainfall in western Tasmania (medium confidence), with uncertain rainfall changes in northern Australia
- more extreme fire weather is projected in southern and eastern Australia (high confidence)
- increased drought frequency is projected for southern and eastern Australia (medium confidence)
- increased heavy rainfall intensity is projected, with fewer tropical cyclones and a greater proportion of severe
- cyclones (medium confidence) (Lawrence et al., 2022).

The AR6-WGII also contains information about projected impacts to health and well-being for the Australasian region including, amongst others:

- detrimental effects on human health due to heat stress, changing rainfall patterns including floods and drought climate-sensitive air pollution (including that caused by wildfires) (high confidence) and vector-borne diseases (medium confidence)
- vulnerability to detrimental effects of climate change will vary with socioeconomic conditions (high confidence) (Lawrence et al. 2022).

For further information related to Woodside's approach to climate change, please see Section 5.3 'Managing Physical Risk' and Section 6.3 'A Just Transition' of Woodside's Climate Transition Action Plan and 2023 Progress Report (Woodside, 2024).

The AR6-WGII report identified nine key climate risks for the Australasian region:

- loss and degradation of coral reefs and associated biodiversity and ecosystem service values in Australia due to
- ocean warming and marine heatwaves (very high confidence)
- loss of alpine biodiversity in Australia due to less snow (high confidence)
- transition or collapse of alpine ash, snowgum woodland, pencil pine and northern jarrah forests in southern Australia due to hotter and drier conditions with more fires (high confidence)
- loss of kelp forests in southern Australia due to ocean warming, marine heatwaves, and overgrazing by climate-driven range extensions of herbivore fish and urchins (high confidence)
- loss of natural and human systems in low-lying coastal areas due to sea level rise (high confidence)
- disruption and decline in agricultural production and increased stress in rural communities in south-western, southern and eastern mainland Australia due to hotter and drier conditions (high confidence)
- increase in heat-related mortality and morbidity for people and wildlife in Australia due to heatwaves (high confidence)
- cascading, compounding and aggregate impacts on cities, settlements, infrastructure, supply-chains and services due to wildfires, floods, droughts, heatwaves, storms and sea level rise (high confidence)
- inability of institutions and governance systems to manage climate risks (high confidence) (Lawrence et al., 2022).

An earlier report by Australia's Biodiversity and Climate Change Advisory Group summarised the potential impacts of climate change to marine and terrestrial species, habitats and ecosystems across Australia (Steffen et al., 2009). The 2009 report identified examples of observed changes in Australia's biota that were considered consistent with the emerging climate change 'signal', as genetic constitution, geographic ranges, lifecycles, populations, ecotonal boundaries, ecosystems, and disturbance regimes (Steffen et al., 2009). The report also stated:

- "Biodiversity is one of the most vulnerable sectors to climate change".
- "Australia's biodiversity is not distributed evenly over the continent but is clustered in a small number of hotspots with exceptionally rich biodiversity", and that these "include the Great Barrier Reef, south-west Western Australia, the Australian Alps, the Queensland Wet Tropics and the Kakadu wetlands".

Further, it was stated that "many of the most important impacts of climate change on biodiversity will be the indirect ones at the community and ecosystem levels, together with the interactive effects with existing stressors" (Steffen et

[66] A level of confidence is expressed using five qualifiers: very low, low, medium, high, and very high. For a given evidence and agreement statement, different confidence levels can be assigned, but increasing levels of evidence and degrees of agreement are correlated with increasing confidence (Lawrence et al., 2022).

al., 2009). Future climate change (e.g., increased temperature and decreased, but more variable, rainfall) has the potential to have a range of impacts on ecological factors and threaten biodiversity in the Australian Mediterranean ecosystem (CSIRO, 2017).

Extensive modelling and monitoring studies over the last 20 years provide considerable evidence that global climate change is already affecting and will continue to affect species (Hoegh-Guldberg et al., 2018) however these impacts are likely to be highly species-dependent and spatially variable. The most frequently observed and cited ecological responses to climate-change include species distributions shifting towards the poles, upwards in elevation and shifts in phenology (earlier and later autumn life history events) (M. Dunlop et al., 2012). Climate change may not only change species distribution patterns but also life-history traits such as migration patterns, reproductive seasonality and sex ratios (Steffen et al., 2009).

Impacts of climate change such as altering temperature, rainfall patterns and fire regimes, are likely to lead to changes in vegetation structure across all terrestrial ecosystems within Australia (M. Dunlop et al., 2012; Steffen et al., 2009) . Increases in fire regimes will impact Australian ecosystems altering composition structure, habitat heterogeneity and ecosystem processes. Changes in climate variability, as well as averages, could also be important drivers of altered species interactions, both endemic and invasive species (M. Dunlop et al., 2012). Climate change could result in significant ecosystem shifts, as well as alterations to species ranges and abundances within those ecosystems (Hoegh-Guldberg et al., 2018).

The 'loss of climatic habitat caused by anthropogenic emissions of greenhouse gases' has been listed as a key threatening process under the EPBC Act (DCCEEW, 2021). The threatening process consists of reductions in the bioclimatic range within which a given species or ecological community exists due to emissions induced by human activities of greenhouse gases (DCCEEW, 2021). The process is considered to have a continental distribution, including both terrestrial and marine areas. Ecosystems in which the process occurs include: alpine habitats, coral reefs, wetlands and coastal ecosystems, polar communities, tropical forests, temperate forests, and arid and semi-arid environments (DCCEEW, 2021).

Coral reefs were recognised by both IPCC and the Australian Government as being at risk of climate change (Lawrence et al., 2022; DCCEEW, 2021). Protected coral reef areas in Australia include those within World Heritage listed sites, such as Ningaloo Coast, Shark Bay, or the Great Barrier Reef. Climate change has been identified as a threat for each of these World Heritage areas, with potential risks to coral reef as well as other environmental values (such as marine fauna) within these ecosystems (IUCN, 2020b, 2020c, 2020a).

Climate variability and change has been identified as a threat to some EPBC Act protected species, including marine turtles, whales, seabirds and migratory shorebirds:

The Recovery Plan for the Southern Right Whale (DCCEEW, 2024) states that 'modelling the links between krill and whale population dynamics with climate change, including changes in ocean temperature, primary productivity, and sea ice, suggests future ocean conditions are likely to have a negative impact on krill populations and in association the baleen whale species that feed on them.'

The Recovery Plan for Marine Turtles in Australia (CoA 2017) states that climate change is of particular concern to marine turtles because it is likely to have impacts across their entire range and at all life stages. Climate change is expected to cause changes in dispersal patterns, food webs, species range, primary sex ratios, habitat availability, reproductive success and survivorship".

The Conservation Management Plan for the Blue Whale (CoA 2015a) states: climate change is expected to cause changes in migratory timing and destinations, population range, breeding schedule, reproductive success and survival of baleen whales, including blue whale species and subspecies".

The Wildlife Conservation Plan for Seabirds (CoA 2022) states that "consequences to seabirds could include negative impacts from an increase in extreme weather events, reduced or changed prey abundance and distribution, and decrease in nesting habitat".

The Wildlife Conservation Plan for Migratory Shorebirds (CoA 2015) states that "such changes have the potential to affect migratory shorebirds and their habitats by reducing the extent of coastal and inland wetlands or through a poleward shift in the range of many species".

The North-west Marine Parks Network Management Plan 2018 (DNP, 2018) identifies climate change as a pressure that may impact marine park values. The management plan states that "the impacts of climate change on the marine environment are complex and may include changes in sea temperature, sea level, ocean acidification, sea currents, increased storm frequency and intensity, species range extensions or local extinctions, all of which have the potential to impact on marine park values" (DNP, 2018).

Within the Marine Bioregional Plan for the NWMR (DSEWPaC, 2012), pressures related to climate change are assessed as 'of potential concern' for species of marine turtle, inshore dolphins, sawfish, sea snakes, whale shark, dugong, and seabird and shorebird, as well as the KEFs and shipwrecks known to occur in the NWMR.

Summary

The availability of gas from Pluto to markets is anticipated to have a role to play towards customer commitments and plans to decarbonise through the energy transition. Emissions associated with Pluto are not predicted to contribute materially or substantially to Australia's total GHG emissions.

Climate change impacts cannot be attributed to any one activity or one project, including Pluto, as they are instead the result of global GHG emission, minus global GHG sinks, that have accumulated in the atmosphere since the industrial revolution started. Therefore, the impact level of GHG emissions associated with Pluto operations has not been assigned.

Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)67***	***Benefit in Impact Reduction***	***Proportionality***	***Control Adopted***
sufficient pressure to counter pore pressure during well construction (cementing barriers, including conductor, casing and liners) conform to the relevant minimum standards set out in the Woodside Engineering Standard – Well Cementation. Verification: effectiveness of primary and secondary barriers shall be verified (physical evidence of the correct placement and performance) during the drilling of the well.				
XNA-03 Drilling: As-built checks that shall be completed during well operations to establish a minimum acceptable standard of well integrity is achieved.	F: Yes CS: Minimal cost. Standard practice	Reduces the likelihood of occurrence. No reduction in consequence will occur.	Benefits outweigh cost/sacrifice	Yes C 10.5
XNA-03 Drilling: Subsea BOP installed and tested during drilling operations. The BOP shall include: • one annular preventer • two pipe rams (excluding the test rams) • a minimum of two sets of shear rams, one of which must be capable of sealing • deadman functionality • the capability of ROV intervention • independent power systems.	F: Yes CS: Standard practice. Required by Woodside standards.	BOP testing reduces the volume of gas vented in the event of a well kick.	Benefits outweigh cost/sacrifice	Yes C 10.6
XNA-03 Drilling: Process conducted to calculate, update and monitor kick tolerance for use in well design	F: Yes CS: Standard practice. Required by Woodside standards.	Processes will reduce the volume of gas vented in the event of a well kick.	Benefits outweigh cost/sacrifice	Yes C 10.7

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)67***	***Benefit in Impact Reduction***	***Proportionality***	***Control Adopted***
and while drilling, including: The BOP shall be closed upon detecting a positive well influx. The shut in procedure shall be according the rig contractor procedures or as the well conditions dictate. Kick tolerance calculations will be made for drilling all hole sections based on the weakest known point in the well. Kick detection techniques will be adjusted based on the level of kick tolerance through a management of change (MOC). The manual also includes requirements for kick tolerance management in the event of down-hole losses.				
XNA-03 Drilling: Well control bridging document (WCBD) for alignment of Woodside and the MODU Contractor in order to manage the equipment and procedures for preventing and handling a well kick.	F: Yes CS: Standard practice. Required by Woodside standards.	Implementing equipment and procedures in the well control bridging document will reduce the volume of gas vented in the event of a well kick.	Benefits outweigh cost/sacrifice	Yes C 10.8
Good Practice				
Forecast, measure, monitor and/or estimate facility GHG emissions (in accordance with NGERS/NPI) to inform optimisation management practices and minimise environmental impact of direct Pluto and indirect onshore processing emissions.	F: Yes CS: Minimal cost. Standard practice.	Minimises environmental impact of emissions through planning, ongoing review, governance and optimisation. It combines with good operating practice to maximise production and reduce flaring emissions (Pluto) and fuel emissions at the LNG plant to manage cost, which improves energy intensity (e.g. cleaner production), optimising emissions from the project. Fuel and flared gas are potential product streams,	Control is WMS requirement – must be adopted.	Yes 10.9

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)67***	***Benefit in Impact Reduction***	***Proportionality***	***Control Adopted***
		as such, Woodside applies routine short and long term optimisation and opportunity management framework to identify and prioritise enhancement opportunities. On Pluto to date this has been limited to reduced flaring (e.g. flare purge rates); however overall system efficiencies (such as well and composition optimisation) and LNG Plant opportunities are also considered in this process. Annual flare and emissions target setting and monthly review of performance is completed for Pluto. The LNG Plant also applies flare and emissions target setting and tracking for emissions management. Daily production meetings allow for optimisation as an integrated production system, considering impacts of variables such as maintenance activities and temperature influence on production rates.		
Contracting strategy and evaluation for hire of support vessels includes consideration of vessel emissions parameters and low carbon/alternate fuels	F: Yes CS: Fuel cost over the five year contract is considered in the evaluation of responses, allowing for competitive consideration of low carbon alternatives	Minimises costs and emissions through eco-efficiency approach recognising cost of fuel and carbon emissions over the contract term	Control effectively allocates a cost to emissions to recognise that higher emitting fuel sources with other lower operating costs do not represent overall best value.	Yes C 10.10
XNA-03 Drilling: Well unloading acceptance criteria that define the well objectives will be established	F: Yes. CS: Standard practice.	Eliminates unnecessary flared volumes and corresponding emissions (light and GHG).	Benefits outweigh cost/ sacrifice.	Yes C 10.11
XNA-03 Drilling: Assess opportunities to eliminate well flowback flaring to MODU. The assessment will consider factors such as: HSE considerations	F: To be decided. The decision on whether to unload to the MODU or Pluto will be based on technical study outcomes. CS: Cost effective but introduces	Minimises environmental impact through the reduction of GHG emissions. Well flowback may be avoided entirely. In this case the wells are instead flowed back to the eventual host facility (the Pluto	Benefits potentially outweigh cost/ sacrifice.	Yes C 10.12

Well performance Proof of completions success Solids and liquids handling Potential eventual other impacts to the topsides.	additional risks to the production facility (i.e. risk of equipment and subsea system failures due to solids).	Facility), resulting in a small increase to expected bean-up flaring for the well but resulting in a net overall flaring decrease.		
Woodside supporting customers and suppliers to reduce their GHG emissions by: Promote global measurement and reporting by participating in industry collaboration initiatives to mature, harmonise and advocate for transparent measurement and reporting Advocacy for policy frameworks that enable a stable approach to carbon emissions management. Working with the natural gas value chain to reduce methane emissions in third party systems (e.g. regasification and distribution), such as through the adoption of the Methane Guiding Principles. Promoting the role of LNG in displacing higher carbon intensity fuels. Supporting the development of new technologies to reduce higher carbon intensive energy sources. Monitoring the global energy outlook including the demand for lower carbon intensive energy such as LNG and displacing higher carbon intensive fuels.	F: Yes CS: Moderate cost. Standard practice	Woodside to support customers and suppliers to reduce their GHG emissions.	Potential benefit outweighs cost/sacrifice.	Yes C 11.1

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)67***	***Benefit in Impact Reduction***	***Proportionality***	***Control Adopted***
Professional Judgement – Elimination				
Eliminate flaring by venting un-combusted hydrocarbons.	F: No. Routine hydrocarbon venting is not considered good industry practice, as unburnt methane poses potential for greater environment impact compared to combustion emissions. The ability to flare hydrocarbons is a key safety feature on the facility. Removing the ability to flare hydrocarbons may result in unacceptable safety risks on the facility. CS: Not assessed, control not feasible.	Not assessed, control not feasible.	Not assessed, control not feasible.	No
Eliminate flaring by reinjecting un-combusted hydrocarbons	F: No. Routine hydrocarbon reinjection, as opposed to transport to onshore facilities, would not be consistent with the approved Pluto Field Development Plan (FDP) which seeks to optimize hydrocarbon recovery while fulfilling gas supply commitments. As such, gas reinjection would not meet concept screening criteria to warrant option evaluation. CS: not assessed, control not feasible.	Not assessed, control not feasible	Not assessed, control not feasible	No
XNA-03 Drilling: Do not vent during well kick.	F: No. Venting is a critical safety activity required in the event of a kick to reduce pressure build up.	Not considered – control not feasible.	Not considered – control not feasible.	No

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)67***	***Benefit in Impact Reduction***	***Proportionality***	***Control Adopted***
	CS: Not considered – control not feasible.			
Professional Judgement – Substitution				
Fuel for energy generation on the riser platform is selected for lowest indirect emissions generation practicable: Fuel gas used in preference to diesel for power generation	F: Yes, fuel gas is the primary fuel source, with diesel as back up fuel used when gas production is shut down. CS: Cost effective	Gas turbines reduce CO2 emissions for a given unit of power and reduces spill risk associated with diesel bunkering activities.	Cost effective. Minimises fuel bunkering risks	Yes. Solution permanently implemented. This improvement was made as part of the recent produced-water-handling module upgrades, with gas engine commissioned in 2023.
Professional Judgement – Engineered Solution				
Maintain flare to maximise efficiency of combustion and minimise venting, incomplete combustion waste products and smoke emissions.	F: Yes. CS: Minimal cost. Standard practice.	Flare tip integrity and ignition system functionality minimises potential for venting, incomplete combustion waste products and smoke emissions.	Fuel	Yes C 10.13
Installation of flare gas recovery systems to reduce emissions entering the atmosphere from flaring	F: Yes CS: Significant additional cost associated with the design and installation of flare gas recovery systems, including significant retrofitting of multiple stages of compression systems, coupled with associated ancillaries, valving and piping, platform modification and weight considerations. The safe addition of required rotating equipment also poses significant production sacrifice and potential domestic gas supply impacts due to the initial design	Small to negligible environmental benefit from reducing atmospheric emissions from flaring. The environmental benefit gained from the recovery of flaring emissions would be limited to only a portion of flare system flows due to process safety constraints and flare system operation over a wide design envelope (associated with flow and pressure variations and related flowline integrity management). Furthermore, required retrofitting of multiple stages of compressions (e.g. for LP/HP streams) would offset any environmental benefits through increased power generation emissions. The retrofitting interaction with the safety critical flare system and continued	Given the increased safety risk and the very low, if any, environmental benefit provided when increased power generation emissions are taken into consideration, the installation of flare gas recovery systems is considered grossly disproportionate to the environmental benefit it would provide.	No

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)67***	***Benefit in Impact Reduction***	***Proportionality***	***Control Adopted***
	layout, space and safety constraints.	operation and maintenance of gas compression would also increase the NNC'd platform safety risks.		

Discussion of ALARP

Atmospheric emissions

On the basis of the environmental risk assessment outcomes and the use of the relevant tools appropriate to decision type A, Woodside considers the adopted controls appropriate to manage the impacts of Pluto facility, tie-back activities and vessel atmospheric emissions. As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.

GHG emissions

Risk Based Analysis

Application of Woodside's Risk Management Procedures, implementation of the GHG Emissions and Energy Management Procedure and Production Optimisation and Opportunity Management Procedure reduces GHG emissions risk to ALARP (Section 7.2). This includes a system of continual review and improvement of key emissions sources from the Pluto assets as an integrated system, including the Pluto-A offshore platform, e.g. installation of a gas engine on PLA which replaces the primary method of power generation from diesel to gas. Further opportunities are implemented at the Pluto LNG Plant to reduce indirect emissions associated with production from Pluto offshore fields.

Societal Values

Consultation was undertaken for this program to identify the views and concerns of relevant persons, as described in Section 5 and Appendix F Consultation Summary Tables. Some stakeholders expressed strong views on GHG emissions associated with Pluto operations, which were responded to accordingly. This included provision of further information on direct and indirect GHG emissions, discussion of controls and Woodside's corporate position, targets and controls via the 2024 Climate Transition Action Plan and 2023 Progress Report (Woodside, 2024).

ALARP Statement

On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type (i.e. Decision type A and B for direct and indirect emissions respectively), Woodside considers the adopted controls appropriate to manage GHG emissions from the Pluto facility and indirect emissions sources that Woodside can practicably influence, including support vessels, during the five year term of this EP. The adopted controls meet legislative requirements including:

- Marine Order 97 for support vessels
- NGERS and NPI reporting for direct emissions attributed to Pluto
- National Greenhouse and Energy Reporting (Safeguard Mechanism) Rule 2015.

Indirect GHG emissions from onshore processing at PLP are managed under the Pluto Greenhouse Gas Abatement Program, and at Karratha Gas Plant (KGP) are managed under the Karratha Gas Plant Greenhouse Gas Management Plan. These facilities are also subject to complying with the Federal Safeguarding Mechanism (SGM) to manage net emissions under the scheme in line with Australia's emission reduction targets of 43% below 2005 levels by 2030 and net zero by 2050.

The Federal Safeguarding Mechanism (SGM)68 requires Australia's highest greenhouse gas emitting facilities to reduce or limit their emissions in line with Australia's emission reduction targets of 43% below 2005 levels by 2030 and net zero by 2050. Direct GHG emissions from the Pluto Offshore Facility, indirect emissions associated with onshore processing of gas from Pluto as well as indirect emissions associated with the transportation and end use of gas within Australian safeguard facilities are subject to the SGM, and net emissions from these sources must be kept below a specified limit or baseline.

Safeguard facilities that exceed their baseline must manage their excess emissions, such as by surrendering acceptable quality offsets suitably classified as Australian Carbon Credit Units (ACCUs) or Safeguard Mechanism

[68] Further information about the SGM and SGM Baselines can be found at the Clean Energy Regulator website: https://cer.gov.au/schemes/safeguard-mechanism and https://cer.gov.au/schemes/safeguard-mechanism/safeguard-baselines

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)67***	***Benefit in Impact Reduction***	***Proportionality***	***Control Adopted***
Credits (SMCs) which is the other eligible compliance unit. Each are representative of one tonne of CO2-e per credit, so that net emissions under the scheme are brought in line with the baseline. So that sufficient credits are available and that there is a means to comply, safeguard facilities that exceed their baseline are able to buy Government-held ACCUs from the Clean Energy Regulator via the Cost Containment Measure implemented as part of recent reforms. Safeguard Mechanism (SGM) obligations for the Pluto facility as defined under SGM will be met by emissions abatement via operational controls as first preference (described above). Options to manage residual net emissions in excess of baseline include surrendering ACCUs or SMCs, applying to become a trade-exposed baseline-adjusted facility, applying to borrow baseline from the following year or applying for a multi-year monitoring period. Surrendered carbon credits may be generated from Woodside projects, purchased from the market or purchased from the Government through the Cost-Containment Mechanism. Woodside is supporting customers and suppliers at a corporate level to manage indirect emissions associated with customer use of gas from the Pluto offshore fields. As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.				

Demonstration of Acceptability
Atmospheric Emissions Given the adopted controls, atmospheric emissions represent a negligible impact that is unlikely to result in greater than isolated impacts with close proximity of the Pluto facility, in an unpopulated area approximately 160 km northwest of the nearest community receptor, Dampier. The adopted controls are considered good oil-field practice/industry good practice and meet requirements of Australia Marine Orders and National Pollutant Inventory reporting. The potential impacts and risks are considered broadly acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the impacts and risks of atmospheric emissions to a level that is broadly acceptable. ***Greenhouse Gas Emissions*** To assess and determine that impacts from GHG emissions will be of an acceptable level, Woodside considered corporate commitments, principles of Ecologically Sustainable Development, Company Values and Societal Values. Principles of Ecologically Sustainable Development Giving consideration to economic development that safeguards the welfare of future generations, Pluto offshore operations is considered to align with the following core objectives of ESDev (e.g. intergenerational equity) by: • gas having the potential to contribute to an incremental reduction in global GHG emissions by displacing more carbon intensive power generation (e.g., coal), firming up renewables, or in hard-to-abate sectors • committing to management and mitigation measures for GHG emissions within operational control of the facility, given the uncertainty about future climate change trajectories • committing to mitigation measures for direct GHG emissions • continue to provide LNG as a source of fuel for global markets and pursue the development of lower carbon energy sources with reference to the UN Sustainable Development Goal 7, Affordable and Clean Energy • Marketing gas to customers within countries that have ratified the Paris agreement, where each country is responsible for accounting for, reporting and reducing emissions that physically occur in its jurisdiction. ***Internal Context*** The Petroleum Activities Program is consistent with Woodside corporate polices, culture, processes, standards, structure and systems as outlined in the Demonstration of ALARP and Environmental Performance Outcomes, including: • Woodside Environment and Biodiversity Policy • Woodside Risk Management Policy • Woodside Climate Policy • Woodside Climate Transition Action Plan and Progress Report • Woodside being a signatory to several global initiatives which are complementary to our corporate approach to methane emissions management, which include OGMP 2.0 (2024), Oil and Gas Climate Initiative Aiming

for Zero Methane Emissions (OGCI Near-Zero) and the Methane Guiding Principles (MGP, 2022), which are voluntary, international multi-stakeholder partnerships between industry and non-industry organisations.

- WMS requirements such as the GHG emissions and Energy Management Procedure, Production Optimisation and Opportunity Management Procedure and Methane Guiding Principles Management Guideline (Section 7.2). Deployment is being applied on a risk-based approach at portfolio level. This is achieved by implementing tools to identify, evaluate, implement and review emissions reductions projects and develop, govern and report on plans to reduce methane fugitive emissions.

External Context

GHG emissions are a global concern, and as such Woodside has undertaken an impact assessment of GHG associated with the Pluto facility and identified key measures to manage GHG emissions to an acceptable level.

According to Wood Mackenzie Energy Research Consultancy, LNG from Woodside operated facilities is amongst the lowest carbon intensity in the world delivered into North Asia69.

The global consensus on climate change led to the implementation of the Paris Agreement. The aim of the Paris Agreement, as stated in the Article 2.1(a) is to hold the increase in global average temperature to well below 2°C above pre-industrial levels. The Agreement also aims to pursue efforts to limit the temperature increase to 1.5°C above pre-industrial levels, recognising that this would significantly reduce the risks and impacts of climate change.

Paris Agreement text extract70:

“Article 2

1. This Agreement, in enhancing the implementation of the Convention, including its objective, aims to strengthen the global response to the threat of climate change, in the context of sustainable development and efforts to eradicate poverty, including by:

(a) Holding the increase in the global average temperature to well below 2°C above pre-industrial levels and pursuing efforts to limit the temperature increase to 1.5°C above pre-industrial levels, recognizing that this would significantly reduce the risks and impacts of climate change; This was reaffirmed in December 2023 in the COP28 decision text on the First global stocktake71. The text further recognised that the transition away from fossil fuels in energy systems is to be done in a just, orderly and equitable manner accelerating action in this critical decade, so as to achieve net zero by 2050 in keeping with the science72. It also recognises that transitional fuels can play a role in facilitating the energy transition while ensuring energy security73.

The Paris Agreement establishes a framework where countries make Nationally Determined Contributions (NDCs) to manage and reduce their own emissions.

Australia has ratified the Paris Agreement and has set a target to reduce emissions by 43% below 2005 levels by 2030 and to reach net-zero emissions by 2050. Australia’s emissions projections under a ‘with additional measures’ scenario is projected to be 43% below 2005 levels by 2030 and to reach net zero emissions by 2050 (DISER, 2022a). Australia’s emissions projections demonstrate that it is on track to reduce emissions by up to 43% below 2005 levels by 2030 (DCCEEW, 2022; DISER, 2022a). Pluto Offshore (direct GHG) and indirect onshore 3rd party processing facilities are also subject to complying with the Federal Safeguarding Mechanism (SGM) to manage net emissions under the scheme in line with Australia’s emission reduction targets of 43% below 2005 levels by 2030 and net zero by 2050.

Australia’s Long-Term Emissions Reduction Plan (DISER, 2021) presents Australia’s whole-of-economy plan to achieving net zero emissions by 2050 with priority technologies estimated to achieve 85% reduction and yet-to-be identified emerging technologies abating the remainder. The plan identified LNG as a critical transition fuel and expects growth in the sector with higher use in 2030 than it is today but acknowledging that growth will depend on the preferences of customers and the pace of international action (DISER, 2021).

Climate science has drawn a link between cumulative emissions of greenhouse gases and global temperature levels. The link between cumulative emissions and temperature levels allows a carbon budget to be calculated. This is the remaining amount of net emissions (i.e. all global sources of emissions minus all global sinks of emissions) that can occur before today’s concentration of greenhouse gases increases to the concentration associated with potential temperature outcomes.

[72] FCCC/PA/CMA/2023L.17 (Draft decision distributed 13 December 2023) First global stocktake text extracts https://unfccc.int/sites/default/files/resource/cma2023_L17_adv.pdf (Section II, Subsection A, Clause 28 (d))

[73] FCCC/PA/CMA/2023L.17 (Draft decision distributed 13 December 2023) First global stocktake text extracts https://unfccc.int/sites/default/files/resource/cma2023_L17_adv.pdf (Section II, Subsection A, Clause 29)

However, the distribution of this carbon budget across different human activities requires additional judgements about a wider range of social, economic and technological factors and consumer and policy choices. Strategies to achieve emissions reductions include transitioning from fossil fuels without CCS to very low-or zero-carbon energy sources, such as renewables or fossil fuels with CCS, demand side measures and improving efficiency, reducing non-CO2 emissions, and deploying carbon dioxide removal (CDR) methods to counterbalance residual greenhouse gas emissions. Pathways to limit warming therefore show different combinations of sectoral mitigation strategies consistent with a given warming level.

As a result the demand for oil and gas in climate-related scenarios that could limit global warming to 1.5°C or 2°C is uncertain. For example in the AR6-WG3 report, the IPCC stated that in pathways that limit warming to 1.5°C (with a greater than 50% probability and with no or limited overshoot) the potential global use of gas in 2050 ranges from 30% above 2019 levels to 85% below them with a median 45% decline.

The demand for oil and gas remains through the remainder of this century in all of these pathways, but to varying degrees. The Pluto Facility will provide an incremental volume of hydrocarbons to Australian and international markets during its estimated remaining field life. Woodside considers that this development is aligned with the goals for supporting the energy transition and is compatible with the Paris Agreement goal to limit global warming to below 2°C.

To complement the approach to methane emissions management across the natural gas supply chain, Woodside is a member of, and aligns to the following global initiatives which are multi-stakeholder partnerships between industry and non-industry organisations.

- Oil and Gas Decarbonisation Charter (signed at COP28, OGDC, 2023). The charter reflects principles that we believe will contribute to supporting the aims of the Paris Agreement.
- OGMP2.0 (2024). Supports accurate, transparent, measurement-based methane emission reporting.
- Oil and Gas Climate Initiative Aiming for Zero Methane Emissions (Near-Zero, 2022). Initiative focuses on avoiding methane venting and flaring, repair of detected leaks, and supports development of methane detection and quantification technologies.
- Methane Guiding Principles (MGP, 2018). MGP focuses on the following priority areas for action along the natural gas supply chain:
    - Continually reducing methane emissions at our operational assets through delivery of Methane Action Plan activities.
    - Advancing strong methane performance across gas value chains via outreach and collaboration with other organisations.
    - Improving accuracy of methane emissions data via technology trials.
    - Increasing transparency through improved reporting.

The integrated Pluto facility operations embody the above principles.

Other requirements (includes laws, polices, standards and conventions):

Legislation and other requirements considered relevant for this aspect, and a demonstration of how these requirements are met, are described below.

Requirement	Demonstration
Marine Order 97 Gives effect to Annex VI of MARPOL 73/78	The requirements of Marine Order 97 are incorporated into the key control measures.

Acceptability Statement: Greenhouse Gas Emissions

As per Section 2.6.1 decision type B, GHG emissions are acceptable if "ALARP" is demonstrated using good industry practice and risk-based analysis, if legislative requirements are met and societal concerns are accounted for and the alternative control measures are grossly disproportionate to the benefit gained. In addition, acceptability is assessed against the above criteria. Further opportunities to reduce the impacts have been investigated (refer ALARP demonstration discussion).

Indirect GHG emissions associated with the Pluto facility are managed to an acceptable level by meeting (where they exist) legislative requirements, industry codes and standards, applicable company requirements, and industry guidelines, and these have been adopted as key controls.

The adopted controls are considered good oil-field practice/industry best practice and are consistent with Woodside's internal requirements. The potential impacts are considered acceptable if ALARP is demonstrated. As described above, the predicted GHG emissions associated with the Pluto Facility are considered negligible, and will not materially or substantially contribute to Australia's net GHG emissions or net Global GHG emissions levels.

Routine Atmospheric Emissions – Indirect emissions from gas processing onshore

Description of Source of Impact/Risk

Background

The processing of gas from Pluto at onshore processing facilities will result in the release of atmospheric emissions. These emissions, and their potential indirect effects, have been raised by stakeholders as a concern and as such are evaluated within the Pluto Facility Operations EP.

This section provides contextual evaluation of consideration for potential indirect impacts, particularly the potential for air emissions associated with the PAA to cause a reduction in ambient air quality impacting human health and the potential to contribute to accelerated weathering of rock art on the Burrup Peninsula and within the Dampier Archipelago (i.e. Murujuga). These potential indirect impacts cannot be considered in isolation as they are the result of cumulative airshed conditions generated from various sources.

No other indirect impacts or risks from the release of atmospheric emissions are considered within this Environment Plan.

Murujuga Rock Art Strategy

The WA State Government (DWER) have established a Murujuga Rock Art Strategy (MRAS) in partnership with MAC as the Traditional Owners and custodians of Murujuga.

DWER has primary responsibility for the day-to-day implementation of the strategy in partnership with MAC. This includes working with MAC to oversee the development and implementation of a world's best practice monitoring and

analysis program that will determine whether the rock art on Murujuga is subject to accelerated change (for further information see Murujuga Rock Art | Western Australian Government (www.wa.gov.au)).

The results from studies underway will guide management and protection of Murujuga rock art, with State environmental protection and heritage legislation in place as the applicable regulatory framework.

The MRAS states that:

"The data currently available from previous monitoring projects does not allow for a conclusive answer on whether anthropogenic emissions are impacting Murujuga's rock art. The Murujuga Rock Art Strategy is therefore essential to fill these gaps in knowledge.

Although it is not known whether the rock art is being impacted currently, there are feasible impact pathways by which emissions from industrial activities and other local sources could cause accelerated weathering of the rock art. The strategy is examining these potential pathways and the condition of the rock art to understand whether change is occurring, and whether there is a need to set a future limit on emissions to ensure accelerated weathering does not occur."

As a causal link between industrial air emissions and anthropogenic-induced change to rock art on Murujuga has not been established, nor sources and potential pathways defined, it is not yet practicable to attribute impact and risk level posed by the Pluto Offshore Operations PAA. The scientific uncertainty that persists is addressed by an adaptive and precautionary management framework in place by way of the MRAS and the associated Murujuga Rock Art Monitoring Program (MRAMP) / together with the State *Environmental Protection Act 1986* (WA) and associated regulatory framework, approvals and licences.

Onshore processing emission context

Gas from Pluto is transported to shore through the trunkline to be processed at the Pluto LNG Facility. A portion of annual gas supply from Pluto offshore may also be processed at the Karratha Gas Plant (KGP) via the interconnector pipeline. Products from Pluto gas are then sold as LNG and delivered to customers via ship or road, or distributed to customers via pipeline for domestic consumption for purposes such as heating, electricity generation or industrial processes such as the production of LNG, ammonia, urea or hydrogen.

This section relates to atmospheric emissions that are associated with the processing of gas exported from Pluto to onshore facilities. While the operation of these onshore processing facilities are outside the scope of this Environment Plan, the atmospheric emissions associated with processing Pluto gas at these facilities is addressed in this section. The processing facilities addressed in this section are considered as the primary recipients of Pluto gas, being the Pluto LNG facility, and a smaller portion of gas supplied to KGP.

Source of Atmospheric Emissions from Onshore Processing

The principal atmospheric emissions from onshore processing in terms of potential for air quality impacts arise from the combustion of gas in fuel turbine generators and compressors as well as gas conditioning process vents at onshore facilities. Gas processing and liquefaction can also result in flaring of some gas and incidental venting of un-combusted gas. The most significant by-products of gas combustion, flaring and venting of gas from Pluto will include oxides of nitrogen (NOx), carbon monoxide (CO), methane and non-methane volatile organic compounds (VOCs) including BTEX (benzene, toluene, ethylbenzene and xylenes).

Ozone is not typically emitted directly from gas consumption or processing but is formed through anthropogenic sources via chemical reactions between oxides of nitrogen and other emissions such as VOCs and CO in the presence of ultraviolet light. Ventilation readily disperses CO emissions relative to criteria. There may also be traces of particulate matter (PM) and sulphur dioxide (SO_2) but such emissions are generally considered negligible from the onshore processing of Pluto gas, due to the fact it has a very low sulphur content and absence of products that are precursors to the formation of particulate pollution. Emissions of PM from the consumption of gas from Pluto is negligible in comparison to background and other industrial sources.

Sources of Emissions within the Murujuga Airshed

Potential indirect impacts from processing of gas from Pluto could arise via a contribution to the cumulative effect of all emissions in the airshed. The Murujuga airshed encompasses the entire Burrup Peninsula and includes the population centres of Dampier and Karratha and surrounding areas. Industrial facilities that currently release or have approval to emit into the Murujuga airshed include[76] :

[76] https://www.epa.wa.gov.au/sites/default/files/EPA_Report/EPA%20Report%201727%20-%20North%20West%20Shelf%20Extension%20Project%20-%20assessment%20report.pdf

- Woodside Operated North West Shelf Venture's Karratha Gas Plant (KGP)

- Yara Pilbara Fertilisers Pty Ltd Ammonia Plant
- Yara Pilbara Nitrates Pty Ltd Technical Ammonium Nitrate Production Facility (TANPF)
- Perdaman Urea Project
- Pilbara Iron Yurralyi Maya Power Station
- Santos Devil Creek Power Station
- ATCO Karratha Power Station
- EDL West Kimberley Power Plant (Maitland LNG Plant).

Atmospheric Emissions into the Murujuga Airshed from Onshore Processing of Gas from Pluto

Emissions associated with onshore processing of gas from Pluto are emitted and combined with similar emissions from natural sources and other industrial activities in proximity of the Murujuga region. Assessment of potential impacts considers cumulative impacts within the airshed rather than estimating emissions influence associated with processing gas from Pluto in isolation. Further, estimating ground level concentrations of atmospheric constituents as related to human health and deposition relies on complex non-linear photochemical modelling, underpinned by biochemical and physical forcing systems such as regional meteorological forcing model.

Therefore, risk assessment is based on a cumulative airshed modelling inclusive of contribution from onshore processing of Pluto gas, and other material sources.

In 2021, DWER commissioned Ramboll Australia Pty Ltd to undertake a *Study of the Cumulative Impacts of Air Emissions in the Murujuga Airshed*[77]. The resulting report, (Ramboll 2022) considered a "complete emission inventory" including air emissions from existing and proposed future industries, shipping, and aggregated sources in the Pilbara region. The air dispersion modelling was used to obtain predicted maximum ground level concentrations (GLCs) for a range of air pollutants of concern, including NO_x, Ozone, SO_x, CO, VOCs, particulates and others.

Emission estimates in the Ramboll 2022 study were based on a range of data sources, including publicly available datasets, engineering design estimates (maximum and averages) and facility level monitoring data. The scenarios investigated as part of this study included a baseline (2014) scenario that included all industrial, mobile, domestic and commercial as well as natural sources, a scenario that included point and area sources for heavy industry including railways and shipping in the region, and a proposed future scenario indicative of all 2030 emissions. Both the baseline and 2030 scenarios included operation of onshore processing facilities at capacity which covers the portion associated with ongoing processing of Pluto gas.

Woodside provided inputs to the Ramboll 2022 study aligned with DWER's original data request and the scenario descriptions and assumptions described in the North West Shelf Project Extension Environmental Review Document Appendix E Air Quality Impact Assessment[78], Section 4, Scenarios 3 and 4 with existing, approved and referred facilities operating - which included (amongst others):

- Airshed baseline;
- NWS Extension Project with NO_x improvement opportunities;
- Pluto LNG as operating, and future expansion of Pluto (Train 2, and T1 backfill) fed by Scarborough gas;
- Perdaman Urea project; and
- Indicative Methanol Plant in the region.

Ramboll (2022) indicated that NO_x loads to the airshed from industrial sources are estimated to be 13,937 tonnes per year and are forecast to reduce to 12,052 tonnes per year by 2030, when calculated over a 1.33 km grid. A significant contribution to this cumulative airshed reduction is associated with commitments by the NWSJV to reduce NO_x emissions from the Karratha Gas Plant by 40% by 2030. Ramboll (2022) did not predict NO_x air concentrations in excess of current air quality standards in any modelled scenario.

The assumptions for Murujuga airshed NO_x emissions underpinning the Ramboll (2022) study are suitably conservative for reviewing KGP and Plutos' contribution for the onshore processing of Pluto gas using information provided by the respective facilities and are aligned with latest information.

Based on the estimated total regional airshed emissions used in Ramboll (2022) and NO_x contribution to the airshed outlined within the Pluto Air Quality Management Plan (approved in accordance with Ministerial Statement 757), it is estimated that NO_x emissions associated with the processing of Pluto gas via the Pluto LNG facility, and an

[77] Study of the Cumulative Impacts of Air Emissions in the Murujuga Airshed: https://www.wa.gov.au/system/files/2023-03/Study-of-the-cumulative-impacts-of-air-emissions-in-the-Murujuga-airshed.pdf

[78] NWS Extension Environment Review Document Appendices: https://www.woodside.com/docs/default-source/current-consultation-activities/australian-activties/north-west-shelf-project-extension---appendices.pdf

approximate 1/5th proportion supply of Train 4 or Train 5 capacity at KGP accounts for approximately 13% currently, declining to less than 6% of the total estimated 2030 NO_x load in the Murujuga region

Where Pluto gas is processed at KGP, it proportionally displaces other sources of gas processed at this facility (as assumed in the Ramboll (2022) model, which did not need to account for the source of gas); Pluto gas therefore does not result in a net increase in KGP or total airshed NO_x, relative to those presented in the Ramboll 2030 projections.

Continued processing of gas from Pluto is therefore not anticipated to cause an increase of NO_x within the Murujuga airshed beyond historic maximum levels; which, as described in section 4.9.5 has resulted in no conclusive evidence for anthropogenic change to rock art on Murujuga. The reduction in future NO_x load within the Murujuga airshed presented in Ramboll 2022 is reflective of commitments made by third party proponents that are publicly disclosed either in Ministerial Statements or Air Quality Management Plans.

Existing Regulatory Framework

Facilities associated with the onshore processing of LNG are not subject to the Offshore Petroleum and Greenhouse Gas Storage (Environment) Regulations 2023 (Cth). Assessment and management of these emissions is required pursuant to various State and Commonwealth legislative frameworks. Impacts associated with atmospheric emissions are subject to an appropriate level of independent assessment by regulatory agencies and management measures are in place which are sufficient to ensure the environment performance outcome of this PAP can be achieved.

A summary of the relevant legislation, approvals and governance measures in place to manage atmospheric emissions from onshore processing facilities such as Pluto LNG facility, KGP and Perdaman Urea facility are outlined below.

Environmental Protection (EP) Act 1986 (WA)

The EP Act is the principal legislation in WA that provides for "the prevention, control and abatement of pollution and environmental harm" and for "the conservation, preservation, protection, enhancement and management of the environment".

The object of the EP Act is to protect the environment of Western Australia, having regard to a number of principles, including:

- the precautionary principle, which holds that where there are threats of serious or irreversible damage, lack of full scientific certainty should not be used as a reason for postponing measures to prevent environmental degradation. In the application of the precautionary principle, decisions are to be guided by:
- careful evaluation to avoid, where practicable, serious or irreversible damage to the environment
- an assessment of the risk-weighted consequences of various options
- the principle of intergenerational equity, which holds that the present generation should ensure that the health, diversity and productivity of the environment is maintained or enhanced for the benefit of future generations
- the principle of waste minimisation, which holds that all reasonable and practicable measures should be taken to minimise the generation of waste and its discharge into the environment
- principles relating to improved valuation, pricing and incentive mechanisms, which include the 'polluter pays principle' whereby those who generate pollution and waste should bear the costs of containment, avoidance or abatement.

Assessment of Proposals under Pt IV of the EP Act

In Western Australia, it is the role of the independent Environment Protection Authority (EPA) to assess proposals against the requirements of the EP Act and EPA objectives.

Section 15 of the Act establishes the objectives of the EPA (Authority): It is the objective of the Authority to use its best endeavours to protect the environment; and to prevent, control and abate pollution and environmental harm. The object and principles guide the overall application of the powers of the Act. The principles are matters to which the EPA is required to have regard as a condition of the valid exercise of its powers to assess and report on proposals and schemes under the Act. The EPA only recommends that the Minister approve a proposal if it can be demonstrated the proposal is aligned with the Act including any relevant objectives.

Under the EPA's Air Quality Environmental Factor Guideline, the EPA has an objective to*o maintain air quality and minimise emissions so that environmental values are protected*[79] (Air Quality Objective). The Air Quality Environmental Factor Guideline identifies that this objective recognises the fundamental link between good air quality and the environmental values it supports. It also recognises the principle of waste minimisation as set out in the EP Act. In the context of this factor and objective, the EPA recognises that maintaining good air quality and minimising emissions protects human health and amenity, as well as the broader environment. When considering the significance

[79] EFG - Air Quality - 03.04.2020.pdf (epa.wa.gov.au)

of potential impacts to air quality, the EPA may have regard to the various matters outlined in Section 5 of the Statement of Environmental Principles, Factors and Objectives[80], including the Air Quality Objective.

Environment Protection and Biodiversity Conservation Act 1999 (Cth)

The EPBC Act is the Australian Government's key environmental legislation providing for the protection of the environment and the conservation of biodiversity. The EPBC Act requires approval for activities with a significant impact on a number of matters of national environmental significance including for example, National Heritage places and listed threatened species or endangered communities.

The NWS Project Extension (a proposal to extend operation of the NWS Project beyond 2030) has been assessed under the EPBC Act by the WA EPA under an accredited process and recommended for approval (Refer EPA Report 1727). The controlling provision for the proposed action is 'National heritage places', and the Project is subject to assessment by accredited assessment under Part IV of the EP Act at the level of Public Environment Review. The Commonwealth Minister for the Environment will make an approval decision once the State process has completed.

Aboriginal Heritage

Aboriginal sites are of cultural heritage importance to both the Aboriginal and wider community. The Aboriginal Heritage Act 1972 (AH Act) is the principal legislation providing for the preservation of Aboriginal sites and objects in WA. All Aboriginal heritage sites or places to which s.5 of the AH Act applies are protected, whether or not they are registered with the Department of Planning, Lands and Heritage (DPLH). It is an offence under the AH Act to excavate, destroy, damage, conceal or in any way alter any Aboriginal site unless the consent of the Registrar or the Minister for Aboriginal Affairs is first obtained.

Approvals under Pt V of the EP Act

DWER regulates certain premises through a works approval and licensing process to prevent, control, abate and mitigate pollution and environmental harm, under Part V of the EP Act.

Woodside currently holds the following licences for facilities operated on the Burrup Peninsula:

- Pluto Liquefied Natural Gas (LNG) Project (L8752/2013/2)[81]
- Woodside Onshore Gas Treatment Plant (L5491/1984/18)[82]

The abovementioned licences specify air emission limits for individual emission points, Woodside is required under these licences to submit an Annual Audit Compliance Report identifying compliance with the conditions of the licences. Copies of the Annual Audit Compliance Reports are available on the DWER's website.

Other Regulatory Measures in Place for Management of Atmospheric Emissions

National Environmental Protection (Ambient Air Quality) Measure (Cth)

The National Environment Protection Council (NEPC), comprising Commonwealth, State, and Territory Ministers, finalised the NEPM (Ambient Air Quality), on 26 June 1998. The National Environment Protection Council Act 1994 (Cth) allows the National Environment Protection Council to make National Environment Protection Measures (NEPMs). NEPMs are a special set of national objectives designed to assist in protecting or managing particular aspects of the environment. The NEPM [Ambient Air Quality] outlines ambient air quality monitoring protocol that allows for the adequate protection of human health and well-being.

National Environment Protection (National Pollutant Inventory) Measure 1998 (Cth)

The National Pollutant Inventory (NPI) is a public database that provides information on 93 selected air pollutants and their emissions, produced as a result of industry, transport, commercial premise, and household activities, and emitted to air, land, and water in Australia. The NPI is a Commonwealth Government initiative and each state and territory is responsible for implementing the program. The objective of the NPI is to inform the community about emissions to water, air, and land and acceptable emissions levels. It also provides information for policy and decision making, environmental planning and management, and minimising waste.

The Woodside operated facilities on the Burrup Peninsula have been reporting emission data to the NPI from the NWS Project since the 1998/1999 reporting period and Pluto since the commencement of operations in 2012. Other facilities located on the Burrup Peninsula including Yara Pilbara Fertilisers Pty Ltd have reported since 2005.'

Other Relevant Frameworks and Programs

Program: Murujuga Rock Art (Western Australian Government)

The Western Australian Government publish on their aboriginal heritage conservation website a summary of their Murujuga Rock Art Program, the partnership with Murujuga Aboriginal Corporation, and the Murujuga Rock Art Strategy. The description of the program is provided in the box below, courtesy of Govt of Western Australia Website: https://www.wa.gov.au/service/aboriginal-affairs/aboriginal-heritage-conservation/program-murujuga-rock-art

Program Murujuga Rock Art

Background:

Murujuga (which means 'hip bone sticking out' in the Ngarluma-Yaburara language) comprises the Burrup Peninsula and the Dampier Archipelago 1,300 km north of Perth, Western Australia. The Government of Western Australia (State Government) recognises Murujuga as a unique ecological and archaeological area containing one of the largest collections of Aboriginal engraved rock art in the world.

Murujuga is also home to industry that contributes to the local, state and national economy and employment. Concerns the rock art could be damaged by industrial air emissions have led to several independent scientific studies and rock art monitoring initiatives since the mid 2000s.

Murujuga Rock Art Strategy:

The purpose of the Murujuga Rock Art Strategy (MRAS) is to protect the Aboriginal rock art by providing a long-term framework that builds on previous work to deliver an improved approach to monitoring, analysis and management.
The Murujuga Rock Art Strategy will be reviewed at least every five years. This will ensure it remains current, supports appropriate governance arrangements, and that the best scientific knowledge and management practices are used to protect the rock art.

Scope:

The department has primary responsibility for the day-to-day implementation of the strategy in partnership with MAC. This includes working with MAC to oversee the development and implementation of a world's best practice monitoring and analysis program that will determine whether the rock art on Murujuga is subject to accelerated change.
The scope of this strategy is to:

1. *establish an environmental quality management framework, including the derivation and implementation of environmental quality criteria*
2. *develop and implement a robust program of monitoring and analysis to determine whether change is occurring to the rock art on Murujuga*
3. *identify and commission scientific studies to support the implementation of the monitoring and analysis program and management*
4. *establish governance arrangements to ensure that:*
    - *monitoring, analysis and reporting are undertaken in such a way as to provide confidence to Traditional Owners, the community, industry scientists and other stakeholders about the integrity, robustness, repeatability and reliability of the monitoring data and results*
    - *government is provided with accurate and appropriate recommendations regarding the protection of the rock art, consistent with legislative responsibilities*
5. *develop and implement a communication strategy in consultation with stakeholders.*

The consultation summary report summarises the comments received on the draft strategy. The consultation ran from September 2017 to May 2018. There were 27 written submissions received.

[continues over…]

[…continued]

Monitoring Program [Murujuga Rock Art Monitoring Program – MRAMP]:

A best practice monitoring and analysis program commenced in 2020. It will provide reliable information on changes and trends in the condition of the rock art and whether the rock art is showing signs of accelerated change.
The program includes:

- *installation of air quality monitoring stations across Murujuga*
- *regular field measurements of selected rock art panels using a variety of methods*
- *detailed laboratory investigation of rock samples, including the microorganisms living on the rock surface.*

The results from these studies will guide management and protection of the rock art. Reports produced as part of the monitoring program are regularly published in the Murujuga Rock Art Strategy document collection.

The monitoring program is overseen by the department and MAC, in consultation with national and international subject matter experts, a panel of independent peer reviewers and stakeholders.
MAC has developed the Murujuga Research Protocols as a set of governing principles and guidelines to ensure research is conducted in a respectful and culturally appropriate manner.

The monitoring program is being implemented by Calibre Group and experts from Curtin University until early 2026. Curtin University has also developed a training program for MAC Rangers to build their skills and knowledge in monitoring and analysis techniques. Once Rangers are qualified, MAC will be well placed to implement the monitoring from 2026 onwards.

Conceptual models of the rock art system were published in 2021 to share the current understanding of the system and interactions that are likely to be occurring. These models inform the development of the monitoring studies plans and the development of an environmental quality management framework.
The monitoring studies data collection and analysis plan, published in April 2022, is crucial to the design of the Murujuga Rock Art Monitoring Program, and the scope and quality of the science to monitor, evaluate and report on changes and trends in the integrity of the rock art on Murujuga.

The first Monitoring Studies Technical Report was published in December 2023, following an independent peer review process. View the Summary Monitoring Studies Report. View all reports from the Murujuga Rock Art Monitoring Program.

Key milestones and status:

Year	***Program key milestone and status***
2020-2021	• *Review of weathering/alteration/degradation processes that have the potential to cause change in the rock art* ***(completed)*** • *Delivery of a stakeholder workshop* ***(completed)*** • *Development of conceptual models and monitoring studies plan* ***(completed)*** • *Determination of optimal monitoring sites* ***(completed)*** • *Peer review of conceptual model and monitoring studies plan* ***(completed)***
2022	• *MAC and the department's approval of the monitoring studies plan* ***(completed)*** • *State Government commitment to funding dedicated MAC Ranger positions and to support training and capacity building for MAC* ***(announced May 2022)*** • *Completion of fieldwork and laboratory monitoring studies* ***(2022 studies completed)*** • *Commencement of Ranger training needs analysis, Ranger training and capacity building* ***(completed)***

[…]	
2023	• *Continuation of fieldwork and laboratory monitoring studies **(2023 fieldwork completed)*** • *Procurement and installation of air quality monitoring stations **(completed)*** • *Continuation of Ranger training and capacity building **(completed)*** • *Development of report on monitoring studies March 2022−March 2023 (peer reviewed) **(completed)*** • *Delivery of a stakeholder workshop **(completed)***
2024	• *Continue fieldwork and laboratory monitoring studies* • *Report on monitoring studies April 2023–April 2024 (peer reviewed)* • *Design ongoing monitoring program* • *Develop interim Environmental Quality Criteria (EQC) based on field and laboratory (chamber) studies* • *Implement the ongoing monitoring program* • *Commence reporting against interim EQC* • *Continue Ranger training and capacity building (Curtin University micro credentials)* • *Develop Environmental Monitoring Programme Regulations under the Environmental Protection Act 1986* • *Independent review of the Murujuga Rock Art Strategy*
2025	• *Report on monitoring studies April 2024–April 2025 (peer reviewed)* • *Design final monitoring program* • *Develop final EQC* • *Report on monitoring program 2024–2025* • *Commence progressive handover monitoring and reporting program to Murujuga Aboriginal Corporation (with support from the department)* • *Independent review of the monitoring program*
2026 (and beyond)	• *Ongoing monitoring program managed by the Murujuga Aboriginal Corporation and the Department of Water and Environmental Regulation* • *Ongoing monitoring and reporting against final EQC*

Stakeholder Reference Group:

The Murujuga Rock Art Stakeholder Reference Group is an advisory group that was established by the previous Minister for Environment, Hon. Stephen Dawson MLC, in September 2018. The group facilitates engagement between the Murujuga Aboriginal Corporation (MAC) and key government, industry and community representatives on the development and implementation of the strategy.
Professor Stephen van Leeuwen is the independent chair of the stakeholder reference group, which meets on a quarterly basis. Visit the document collection to read summaries of meetings and community forums.
The Terms of Reference are reviewed regularly in consultation with MAC and the Independent Chair to ensure the group remains effective in achieving its purpose.

[end]

Murujuga Rock Art Monitoring Program

In recognising the high level of stakeholder concern and scientific uncertainty regarding the links between anthropogenic emissions and risks to rock art (see Appendix F), in 2019 the Department of Water and Environmental Regulation (DWER) produced the Murujuga Rock Art Strategy[83] (MRAS), which builds on the research to date, and according to DWER will establish a world's best practice program to monitor, evaluate and report on factors that could affect the condition of Murujuga rock art. This is being undertaken in consultation with the Murujuga Aboriginal Corporation, a team of national and international experts in relevant disciplines and is funded by industry, including Woodside. The MRAS describes a risk-based approach for the management of impacts to the rock art that is consistent with the State Government's responsibilities under the EP Act.

A program being executed as part of the MRAS is the Murujuga Rock Art Monitoring Program (MRAMP) which will monitor, evaluate, and report on changes and trends in the integrity of the rock art, specifically to determine whether anthropogenic emissions are accelerating the natural weathering, alteration, or degradation of the rock art. This will enable timely and appropriate management responses by the Western Australian Government, industry and other stakeholders to emerging issues and risks. The following extract from the WA Government website MRAS website outlines this. (Govt of Western Australia (December 2023) https://www.wa.gov.au/service/aboriginal-affairs/aboriginal-heritage-conservation/program-murujuga-rock-art#frequently-asked-questions):

How will the Murujuga Rock Art Strategy provide protection for the rock art?

The initial studies will allow the scientific team to determine the levels of various air emissions that may cause accelerated weathering of the rock art. These levels will not necessarily be identified during the field studies on Murujuga Country, in which case they will be informed by laboratory tests.

The research will inform an environmental quality management framework. Specifically, the levels of air emissions at which accelerated weathering is deemed to occur will be used to inform environmental quality criteria. The ongoing monitoring program, administered by MAC and the department, will gather data and ensure that emissions do not exceed the criteria. Industry will also be regulated to ensure their emissions will not cause the criteria to be exceeded.

There are two types of environmental quality criteria under the framework: environmental quality standards and environmental quality guidelines. Guidelines provide early warning of potential environmental effects, while standards indicate where the level of risk is no longer acceptable, triggering a management response to prevent environmental harm. In the case of the rock art, an exceedance of the standard means there is a high risk of permanent loss or damage to the rock art.

While environmental quality criteria have been used successfully in other contexts, it is important to remember that there are no environmental quality standards or guidelines values currently available anywhere in the world that can be applied to engraved rock art.

[… and…]

What is the connection with World Heritage listing?

The World Heritage nomination for Murujuga includes a comprehensive and effective management framework that outlines how the potential 'Outstanding Universal Value' of the area will be protected, conserved and monitored. As part of this framework, the State Government and MAC will demonstrate how they are working closely together to protect the rock art through the Murujuga Rock Art Strategy and the Murujuga Rock Art Monitoring Program.

The DBCA website has more information on the World Heritage nomination

In recent EPA assessment reports for industrial facilities on the Burrup Peninsula, the EPA has recommended a condition mandating relevant facilities to comply with air quality standards such as those derived from the MRAMP.

In the EPA's North West Shelf Project Extension Assessment Report 1727 (EPA Report 1727), the EPA recommends the 'Air Quality Outcome' for recommended condition 3 be 'to ensure that no air emissions from the proposal have an adverse impact accelerating the weathering of rock art within Murujuga beyond natural rates.'

[83] https://www.wa.gov.au/system/files/2020-07/DWER-Murujuga-rock-art-strategy.pdf

Recommended condition 3-3 states that if the Minister notifies the proponent in writing of one or more air quality standards to be met (including standards derived from the results of the Murujuga Rock Art Monitoring Program) and the proponent complies with all those standards, and any amendments to the standards the proponent is taken to have achieved the Air Quality Outcome.

EPA Report 1727[84] specifies that the proponent is to achieve compliance with any detailed air quality standards to ensure that there are no adverse impacts accelerating the weathering of rock art within Murujuga beyond natural rates. The EPA expects that this will include environmental quality objectives and environmental quality standards derived from the results of the MRAMP. While the North West Shelf Project Extension Proposal has not yet been approved, the Ministerial Statement for the Perdaman Urea Project (MS 1180) includes the same air quality outcome condition that is proposed in EPA Report 1727.

The Pluto LNG Facility has a Cultural Heritage Management Plan and Air Quality Management Plan (AQMP) (required under Ministerial Statement 757). Statements and commitments made by Woodside within the North West Shelf Air Quality Management Plan and the Pluto LNG Facility Air Quality Management Plan commit to manage potential impacts to Aboriginal rock art on the Burrup Peninsula in accordance with the MRAS and as a member of the Murujuga Rock Art Stakeholder Reference Group. Woodside actively supports the implementation of the Murujuga Rock Art Strategy through membership of the Murujuga Rock Art Reference Group and provides funding associated with the Murujuga Rock Art Monitoring Program. Woodside also supports the coordinated approach for an atmospheric deposition monitoring program to be established under the Strategy, and currently provides data to the program from the Woodside Atmospheric and Ambient Air Quality Monitoring Programs.

Onshore Facility Air Emission Design Mitigations

Under the regulatory Conditions and Part IV Air Quality Management Plans of onshore processing facilities on the Burrup, operators are required to implement a number of controls and risk management practices related to air emissions, including the demonstration of best practice design, and monitoring and abatement programs.

Condition 11-1 of Ministerial Statement 757 required the development of an Assessment of Best Practice for Minimising Emissions to Air from Major Plant (Best Practice Report) for the Pluto LNG Facility and condition 11-2 required the development of the Pluto LNG Facility Air Quality Management Plan to demonstrate that best available practicable and efficient technologies are used to minimise and monitor air emissions from the plant. This demonstration was required to meet the requirements of the Minister for the Environment on advice of the EPA prior to Woodside applying for and obtaining a Works Approval to construct the Pluto LNG facility. In 2019, these reports were updated to include Pluto Train 2 and subject to an independent peer review commissioned by the EPA, before being approved by the Minister for Environment in 2020 on advice of the EPA.

Best practice technologies to minimise air emissions implemented in Pluto LNG design and operation include:

- Dry Low NO_x emissions control systems on gas turbines
- Specification of activated methyldiethanolamine (aMDEA) in the acid gas removal system to reduce co-absorption of benzene, toluene and xylene (BTX) and other hydrocarbons.
- installation of a regenerative thermal oxidiser on the acid gas removal unit
- flare design integrated smokeless flaring technologies implemented for the storage and loading flare system, cold dry flare, warm wet flare and common spare flare.

The NWS Extension Environment Review Document[85] details how the most recent LNG trains (trains 4 and 5) constructed at the existing North West Shelf Project are already equipped with lower NO_x technology for gas turbines than trains 1-3. In addition, EPA Report 1727 includes recommended conditions requiring the minimisation of air emissions from the NWS Project Extension proposal by the adoption of practicable technologies, and, as a minimum, a substantial reduction of both total NO_x and VOC emissions from the proposal baseline by 31 December 2030

Detailed Impact Assessment

Indirect Emissions from Gas Processing Onshore – Assessment of Potential Impacts

Contribution to Accelerated Weathering of Murujuga Rock Art

The Dampier Archipelago, including the Burrup Peninsula and surrounds, traditionally referred to as Murujuga (which means 'Hip Bone Sticking Out' in the Ngarluma-Yaburara language) is located in the Pilbara region of WA. With more than one million images, Murujuga is home to one of the largest, densest and most diverse collections of rock art in the world[86] .

[84] North West Shelf Project Extension Proposal (epa.wa.gov.au)
[85] https://www.epa.wa.gov.au/sites/default/files/PER_documentation2/NWS%20Project%20Extension%20-%20Environmental%20Review%20Document.pdf
[86] https://www.wa.gov.au/system/files/2020-07/DWER-Murujuga-rock-art-strategy.pdf

The presence of industry on the Burrup Peninsula has generated concerns from some stakeholders that these emissions may lead to an accelerated weathering of rocks on which rock art is present which may reduce the visibility or destroy the rock art. Research to date on the impacts of emissions on rock art has not been conclusive, and there are currently no set air quality thresholds for the protection of rock art.

As outlined in **Section 4.9.5**, industrial emissions on the Burrup Peninsula are subject to extensive scientific studies to understand any potential pathway to impact on rock art, including wet and dry deposition which may alter the pH of rocks as well as the supply of nutrients which may promote microbial activity, the metabolic by-products of which may interact with rock surfaces.

The history of research on this subject, set out in more detail in **Section 4.9.5** may be broadly divided into four periods. The earliest period, from 2002 to 2009, aligns with the studies conducted by the Burrup Rock Art Monitoring Management Committee (BRAMMC) but also includes work conducted by others, primarily Bednarik who identified potential impact pathways through acid formation and microbial impacts. During this period MacLeod (2005) also took some comparative pH samples between in-situ rocks and museum samples. None of this parallel work established that industrial emissions were impacting rock art, or the levels of emissions at which impacts may be expected to occur. This period concluded with the 2009 BRAMMC report which stated that "there is no scientific evidence to indicate that there is any measurable impact of emissions on the rate of deterioration of the Aboriginal rock art in the Burrup" (BRAMMC 2009) but recommended the establishment of the Burrup Rock Art Technical Working Group (BRATWG) to conduct ongoing monitoring.

The second period of research aligns with this monitoring from 2010 to 2017. A significant component of this monitoring involved the monitoring of rock art colour. In 2016 Black and Diffey produced an unpublished paper critiquing the statistical methods applied by the CSIRO, which led to a review by Data Analysis Australia (DAA) which also raised "substantial doubts about the reliability of the data". A final report from the CSIRO adapted its statistical methods to respond where possible to the conclusions from DAA but the results were described as "not fully conclusive". Also during this period, the BRATWG also commissioned an extreme condition weathering study which found that the dissolution of chemicals began at lower pH levels than previously estimated, however this work was only preliminary and should not be relied upon in setting thresholds for potential impacts.

The third research period, although overlapping with the conclusion of the BRATWG and initial years of the MRAS and MRAMP, is marked by the absence of any results from a coordinated, well-resourced research program and instead comprises a number of independent studies between 2017 and 2023. As a result, it is difficult to characterise these studies consistently. Some (Black et al 2017a, Dorn 2020; Smith 2022a) critiqued or re-stated conclusions of previous studies. Black et al 2017b repurposes historic pH data and concludes that "theoretical evaluation using electrochemical equilibrium principles" indicates impacts to rock art will result from an decreased pH since pre-industrial times; CGB Solutions 2020's analysis of historic pH and contemporary measurements found that pH was not decreasing and that any correlation between acidity and LNG production sites could not be statistically supported. Both studies suffer from significant issues with the available data.

Other studies (Black et al 2018; Gleeson et al 2018) discuss possible impact pathways but stop short of drawing conclusions on whether impacts to rock art are resulting from industrial emissions. Smith et al (2022b) does hypothesise that industrial emissions may be responsible for some reported impacts but acknowledges that the methodologies applied are subject to considerable errors that prevent a definitive conclusion being drawn. A series of studies by MacLeod (2020, 2021, MacLeod and Fish 2021) report on the results of monitoring conducted for Yara Pilbara Nitrates. The outcomes of these reports are inconsistent. Solo reports by MacLeod (2020, 2021) both state that "There is unequivocal evidence that the changes in colour contrast are affected by the changes in the mean and in the minimum pH observed on the rock art sites at the reference positions" though the results include increased acidity correlating in some places with increased contrast and elsewhere with decreased contrast. MacLeod and Fish (2021) then state that "there is presently no adverse impact on the rock engravings from industrial pollution owing to a lower NO_x level than when the studies commenced 14 years ago". This conclusion is critiqued by Smith et al (2022a).

As noted in the MRAMP conceptual model, "*while many of these studies form useful datasets to include in subsequent analyses, in general these studies have been inconclusive or failed to show any significant impact of anthropogenic impact on the rock art or chemical/biological species composition and abundance (Commonwealth of Australia, 2018). Nor have they produced any definitive relationships to inform a conceptual impact model, which is instead reliant on fundamental scientific studies in other regions to inform the likely processes occurring at Murujuga (e.g. Dorn, 2020*[87]*)."*

In December 2023, the first interim report of MRAMP[88] was published (refer to **Section 4.9.5**), marking the start of a fourth period of research. The report states that results remain inconclusive with regards to whether industrial air emissions are resulting in anthropogenic change to rock art and recommends that further scientific studies are required. The MRAMP report noted that while some spatial trends in electrochemical parameters (such as pH) and rock surface elemental composition have been found, more work is required to determine causal relationships for

[87] https://www.wa.gov.au/system/files/2023-12/murujuga-rock-art-monitoring-program-conceptual-models.pdf
[88] https://www.wa.gov.au/system/files/2023-12/murujuga-rock-art-monitoring-program-monitoring-studies-repo2023.pdf

these trends (as relationships were not as expected). Spatial trends were also identified as appearing for several measured air pollutants such as NO_2 that are generally consistent with earlier air quality modelling by Ramboll (2022).

The MRAMP monitoring report outlined that similar trends exist for the pH measurements taken in March–April 2022 and the measured NO_2 levels generally. This relationship was the reverse of what would be expected to confirm the acid deposition hypothesis in previous literature as MRAMP found pH values in March–April 2022 were highest where NO_2 concentrations are highest; whereas with acid deposition, pH is expected to be lower where NO_2 is higher, as NO_2 is often a precursor to the formation of nitric acid, which has a low pH. Neutral pH is around 7, with low pH indicating potentially acidic conditions. The results in the MRAMP monitoring report have been reinterpreted by Smith (2024) in addition to original research but fails to address this unexpected correlation. Smith (2024) claims that "the damaging impact of acidic emissions on the rock surfaces is not in doubt" but does not provide adequate detail on the original research to allow its reliability to be considered, nor does it provide reason to question the conclusions of the MRAMP report, which stress that the available data is insufficient to draft any meaningful conclusions.

Throughout this ongoing period of research, new information will continue to be considered and responded to. However, the resourcing, scope and expertise available to MRAMP make it by far the most significant source of research on the cultural impacts of industrial emissions on Murujuga. MRAMP is also co-managed by MAC and emphasises Indigenous decision making and management, aligned with international guidance and standards, including the United Nations Declaration on the Rights of Indigenous Peoples and ICOMOS Charter for the Protection and Management of the Archaeological Heritage. For these reasons, the results of the MRAMP are prioritised in understanding the potential for emission to impact Murujuga's rock art.

The contribution of emissions from processing of Pluto gas to the Murujuga airshed is relatively small over the remaining life of Pluto Offshore Operations. Further, there is inconclusive evidence for any causal link between industrial air emissions and anthropogenic change to rock art on Murujuga. Given this, and that downstream facilities are subject to separate regulatory assessment outcomes, the risk of processing of Pluto gas at onshore facilities adversely impacting rock art on Murujuga is considered to be low, and no impact classification assigned.

Potential Impacts to Human Health

It is recognised that gaseous emissions causing a reduction in ambient air quality have the potential to impact human health as regulated by the NEPM. Both the Pluto LNG Facility and NWS Project Air Quality Management Plans have modelled and assessed the potential impacts of industrial emissions on human health in accordance with the requirements of Western Australian regulatory requirements and international standards (e.g. World Health Organisation). Ambient air quality monitoring programs are in place which demonstrate that current air pollution levels were well below standards set to protect human health and well-being[89]. The magnitude of emissions from processing Pluto gas are insufficient to lead to the exceedance of any relevant health criteria on the Burrup Peninsula or surrounding region.

Both Pluto LNG facility and the NWS Project have committed to maintaining an ongoing air quality monitoring program that is in place to monitor the ambient ground-level concentrations of relevant gases on the Burrup Peninsula, with comparisons being made against the NEPM standards and reported to DWER.

Ambient air quality monitoring results from Pluto and NWS Project will be summarised in the relevant facilities' Annual Environment Report, including any observed exceedances of ambient air quality standards.

As part of the NWS Extension proposal, the EPA assessed the residual impact to human health and amenity from the proposal's nitrogen dioxide (NO_2), SO_2, NH_3, ozone (O_3), and particulate (as PM_{10} and $PM_{2.5}$) emissions at sensitive receptors both in isolation and in a cumulative context with other existing and future emission sources. Predicted ground level concentrations (GLCs) at Dampier, Karratha, Hearson Cove, and Deep Gorge (Ngajarli) remain below applicable current and future proposed air quality criteria at 'standard operating conditions' and 'worst case' cumulative impact scenarios, with the exception of annual PM_{10} and $PM_{2.5}$ GLCs at Hearson Cove and Deep Gorge (Ngajarli), which slightly exceed the applicable criteria due to high levels of natural background dust. Subject to recommended conditions, the impact of the proposal was considered as being consistent with the EPA's objective for air quality in respect of human health.

Noting the absence of any current impacts to human health from industrial activity on Murujuga and presence of a comprehensive regulatory regime including monitoring program, the risk of processing of Pluto gas to human health is assessed as Negligible (F) based on slight effect to overall cumulative air quality in context of defined air quality criteria.

		applies routine short and long term optimisation and opportunity management framework to identify and prioritise enhancement opportunities. Annual fuel and flare target setting and monthly review of performance will be completed for Pluto which includes onshore LNG processing facilities..		
Professional Judgement – Eliminate				
Professional Judgement – Substitute				
No additional controls identified.				
Professional Judgement – Engineered Solutions				
No additional controls identified beyond best-practice measures demonstrated as required by MS757.				

ALARP Statement:

On the basis of the environmental risk assessment outcomes and the use of the relevant tools appropriate to decision type B for indirect emissions from gas processing onshore, Woodside considers the adopted controls appropriate to manage the risk.

Air emissions from onshore processing at Pluto LNG Facility are managed under Ministerial Statement 757.

Air emissions from onshore processing at the NWS Project have been assessed and approved in accordance with Ministerial Statement 536 (and others). Air emissions from onshore processing at the NWS Project Extension (i.e. an extension of the life the NWSV beyond 2030) have been assessed by the EPA under Assessment Report 1727. Both facilities are subject to the provisions of Commonwealth and State legislation to ensure unacceptable environmental impacts are avoided.

As no reasonable additional/alternative controls were identified that would further reduce the impacts without being grossly disproportionate the impacts and risks are considered ALARP.

Societal Values

Consultation was undertaken for this program to identify the views and concerns of relevant stakeholders. Industrial air emissions on the Burrup Peninsula are being managed by the EPA as part of the EP Act Part IV assessment process and DWER as part of their EP Act Part V process and via the MRAS. It is important to note that operators of the Pluto LNG Facility and Northwest Shelf Karratha Gas Plant have both made public commitments to supporting the outcomes of MRAS.

Summary of ALARP Statement:

On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type (i.e. Decision type B for indirect emissions), the adopted controls are appropriate to manage the indirect impacts of air emissions related with processing Pluto gas onshore. The adopted controls meet legislative requirements including:

- EPBC Act
- EP Act.

As no reasonable additional/alternative controls were identified that would further reduce the impacts without being grossly disproportionate sacrifice, the impacts and risks are considered ALARP.

Demonstration of Acceptability
Acceptability Criteria and Assessment
Acceptability Statement: Indirect Atmospheric Emissions The impact assessment concludes that indirect atmospheric emissions from the onshore processing of Pluto gas contribute only a minor portion to the overall industrial emission airshed load on the Burrup Peninsula. Atmospheric emissions within the Murujuga airshed from both Pluto LNG, NWS Project Extension have undergone independent assessment by the WA and agencies and have been considered acceptable, if subject to conditions. Based on the implemented controls and the inconclusive evidence for any causal link between industrial air emissions and anthropogenic change to rock art, uncertainty and precaution are addressed by the existing State regulatory processes including the MRAS, which can apply adaptive management and mitigation measures as further scientific knowledge of potential pathways and indirect links to rock art are established. Therefore, impacts from indirect air emissions as a result of onshore processing of Pluto gas are considered Negligible and of an ALARP and Acceptable level.

Environmental Performance Outcomes, Standards and Measurement Criteria

Light emissions from the Pluto Facility, ASV, MODU, installation and support vessels.						x		A	F	-	-	GP PJ	Broadly Acceptable	EPO 12
Light emissions during flaring.						x		A	F	-	-			

Description of Source of Impact

Operations

When the riser platform is not crewed, lighting is limited to essential navigational and aviation requirements to communicate the presence of the riser platform and vessels to other marine users (i.e. navigation lights). Navigational lights are also located on the facility's tallest structures (i.e. crane boom). Helideck lighting is provided to assist helicopter landings.

When crewed, which is generally ten times per year for approximately 14 days at a time, the platform and support vessels have adequate lighting to allow safe working conditions during 24-hour operations. Lights are not normally directed outwards away from work areas except when necessary for safe operations outboard, such as lifting operations, and deployment/retrieval of equipment from IMMR activities. A relatively small quantity of gas is required to be continuously flared associated with purge and pilot of the flare system and produced water treatment system low pressure gas streams that are not able to be recovered to the process. Intermittent flaring may occur during facility shutdowns/blowdown, pigging, restart, flowline depressurisation for subsea system integrity management and in case of emergency.

The distance to the horizon at which components of the facility will be directly visible can be estimated using the formula below:

$$horizon\ distance\ = 3.57 \times \sqrt{height}$$

Where horizon distance is the distance to the horizon at sea level in kilometres and height is the height above sea level of the light source in metres. Using this formula, the approximate distances at which the production deck and flare tower top will be visible at sea level are (based on the weather deck height above sea level of 47.4 m and flare tower height of 44 m – given an angle of 30°):

- weather deck: approximately 25 km from riser platform
- flare tower tip: approximately 34 km from riser platform

The ASV has the majority of its lighting sources located on the main accommodation decks below the bridge at heights extending from ~47 m to ~100 m above sea level (whilst at operating draft). Therefore, the majority of the lighting is approximately at, or below, the level of the most significant light source on the riser platform (the flare tower

tip). Accordingly, cumulative light from the ASV and riser platform will not be visible beyond approximately 36 km from the facilities.

During IMMR activities, underwater light is generated over short periods of time while ROVs are in use, as well as from deck lighting. Given the typical intensity of ROV lights and the attenuation of light in seawater, light from ROVs is localised to the vicinity of the ROV and vessels.

Xena-03 Tie-back activities

The MODU and project vessels will have external lighting to support safe navigation and safe operations at night. This lighting typically consists of bright white (i.e. metal halide, halogen, fluorescent) lights, and is not dissimilar to lighting used for other offshore activities, including fishing and shipping. Lighting is required for the safe operation of the MODU and project vessels cannot be reasonably eliminated.

The extent of potential impact for this activity is restricted to the line of sight for each source emitting light. Based on other previous work undertaken by Woodside this is about 30 km from the MODU during drilling activities and 30 km from vessels (Woodside, 2014). For contingent well flowback, specifically flaring, the distance at which the flare will be visible is expected to be less than 50 km from the source, and potentially around a further 10 km during emergency flaring (Woodside Energy Limited, 2011). Contingent well flowback activities would be intermittent and of a short duration, where alternate options for reservoir fluids during well unloading activities cannot be achieved (i.e., directed to the onshore LNG plant via the Pluto Facility).

Whilst the line of sight may extend tens of kilometres from the source, the light density (measured in Lux – which represents the intensity of light that arrives at or leaves a surface, as perceived by the human eye) rapidly decreases as distance increases from the source of the light. Monitoring undertaken as a part of Woodside's 2014 study indicated that light density (from navigational lighting) attenuated to below 1.00 Lux and 0.03 Lux at distances of 300 m and 1.4 km, respectively, from the source (a MODU). Light densities of 1.00 and 0.03 Lux are comparable to natural light densities experienced during deep twilight and during a quarter moon. Navigational lighting from vessels is less than lighting on a MODU. Therefore, light emissions from the MODU and installation vessel are expected to be below 1.00 Lux within 300 m from the source during Xena-03 Tie-back activities.

Cumulative light sources

Cumulative increases in light levels will occur during the tie-back activities and commissioning/maintenance visits where the facility will be crewed and may also be utilising an ASV (up to 90 days per campaign). There will be additional lighting for safe operations of the MODU and installation and support vessels present in these periods. These scenarios will be short term (~12 weeks for tie-back activities). Light emissions are also likely from flaring, IMMR activities and vessel lighting from several nearby platforms including Wheatstone, Reindeer and Goodwyn (see Section 4.10.5) that are located within 50 km of Pluto and may result in slightly elevated ambient light levels.

Impact Assessment

Lighting from the facility, MODU, ASV, installation and support vessels may appear from direct unshielded light sources or through skyglow. Where direct light falls upon the ocean, this area of light is referred to as light spill. Skyglow is the diffuse glow caused by light that is screened from view, but through reflection and refraction creates a glow in the atmosphere. The distance at which direct light and skyglow may be visible from the source is dependent on the lighting on the facility / vessel and environmental conditions.

Receptors that have important habitat present within a 20 km buffer of artificial light sources were considered as having potential for interaction, based on recommendations of the National Light Pollution Guidelines for Wildlife Including Marine Turtles, Seabirds and Migratory Shorebirds (NLPG). The 20 km threshold provides a precautionary limit based on observed effects of sky glow on marine turtle hatchlings (15 to 18 km) and fledgling seabirds grounded in response to artificial light 15 km away (Commonwealth of Australia, 2020).

Light emissions can affect fauna in two main ways:

- Behaviour: many organisms are adapted to natural levels of lighting and the natural changes associated with the day and night cycle as well as the phase of the moon. Artificial lighting has the potential to create a constant level of light at night that can override these natural levels and cycles.
- Orientation: organisms such as marine turtles and birds may use lighting from natural sources to orient themselves in a certain direction at night. In instances where an artificial light source is brighter than a natural source, the artificial light may act to override natural cues, leading to disorientation.

The marine fauna within the PAA are predominantly pelagic fish and zooplankton, with a low abundance of species such as turtles and large whales transiting through the area. The Facility Operational Area and the Xena-03 Operational Area overlap the whale shark foraging BIA, flatback turtle internesting BIA and the wedge-tailed shearwater breeding BIA.

The Export Pipeline Operational Area is nearer the coastline and overlaps more BIAs (BIAs for the loggerhead turtle, green turtle, hawksbill turtle, and flatback turtle, and Habitat Critical to the green turtle, hawksbill turtle, and loggerhead turtle. Also the breeding BIA for the wedge-tailed shearwater, roseate tern, and fairy tern; see Section 4.6), but lighting in this region will be restricted to short-term periodic lighting from vessels conducting IMMR activities.

Seabirds

Artificial lighting can attract and disorient seabird species resulting in species behavioural changes (e.g. circling light sources or disrupted foraging), injury or mortality near the light source as a result of collision (Longcore and Rich, 2004; Gaston et al. 2014). Foraging wedge tailed shearwaters may be attracted to artificial light sources to feed upon fish drawn to the light; however, the species feeds predominantly during the day in association with pelagic predators (Catry et al., 2009; Whittow, 1997). The majority of foraging trips are short, with single day foraging trips significantly more common than any other length trip, with birds returning to nesting/roosting sites between trips (Congdon et al., 2005). As such, the numbers of wedge-tailed shearwaters present in the Facility Operational Area or Xena-03 Operational Area at night is expected to be low relative to daylight hours, and any potential changes to behaviour would only affect a relatively low number of birds. Given the species' global distribution and primarily diurnal foraging behaviour, impacts to wedge-tailed shearwaters from artificial lighting are considered to be negligible.

The nearest potential seabird roosting habitat on natural emergent land, the Montebello Islands, lie approximately 32 km south of the Export Pipeline Operational Area and 64 km from the riser platform, at their closest points. The breeding BIA for the wedge-tailed shearwater overlaps the Facility, Xena-03 and Export Pipeline Operational areas, with the breeding period occurring from August to April. Adult shearwaters are vulnerable to artificial lighting during the breeding cycle, when returning to and leaving the nesting colony to maintain nesting sites or forage.

The breeding BIAs for the roseate tern and fairy tern overlap the Export Pipeline Operational Areas, with breeding occurring in June to March for the Australian fairy tern, and breeding varying throughout the year for the roseate tern.

Large numbers of migratory seabirds have been observed opportunistically roosting on the facility. If maintenance, process safety and/or health risks are identified associated with the presence of birds, it may be necessary to deter them from roosting on the riser platform by installing bird proofing/exclusion devices. The installation of bird proofing poses the potential risk of entanglement for individual birds. There have been no reported bird injuries or deaths at the facility, and consequently future adverse interactions are considered highly unlikely with no lasting effects on populations or impacts to critical habitat anticipated. If deterrents are installed birds will be likely to relocate to previous ranges (i.e. rather than landing on the platform), therefore no lasting effect is anticipated. The risk associated with collision from seabirds attracted to the light is considered to be low, given that lighting will be limited, except during intermittent periods when the riser platform is crewed and during IMMR and the Xena-03 Tie-back activities.

Migratory shorebirds may be present in or fly through the region between July and December, and again between March and April as they complete migrations between Australia and offshore locations (Commonwealth of Australia, 2015). The risk associated with collision from seabirds or migratory shorebirds attracted to artificial lighting is considered to be low, impacts are expected to be limited to localised behavioural disturbance to isolated individuals, with no displacement from important habitat.

The most vulnerable life stages for seabirds and migratory shorebirds are nesting adults or fledglings. Nesting or fledgling seabirds and migratory shorebirds are vulnerable to artificial lighting within 20 km of the nesting location (Commonwealth of Australia, 2020). For shearwater species, fledglings are predominantly impacted by onshore lighting sources, which can override sea finding cues and attract fledglings further inland, preventing them from reaching the sea (Mitkus et al., 2018). Artificial light can also impact important behaviour of nesting adults (e.g. adult nest attendance, maintaining nest sites) or confuse shearwater species, resulting in injury or mortality as a result of birds colliding with structures (Cianchetti-Benedetti et al., 2018; Rodriguez et al., 2017). As the PAA is 32 km from the nearest emergent land, impacts to adult nesting or fledgling seabirds and migratory shorebirds are not expected. No nesting activity has been identified on the Pluto facility. Artificial light from the Petroleum Activities Program is not predicted to disrupt critical breeding behaviours within important nesting habitat or displace seabirds from nesting habitat.

Marine Turtles

Hatchlings

Light pollution is listed as a key threat to all marine turtle species, with advice to minimise light. The nearest potential nesting site in relation to the Xena-03 Operational Area is the Montebello Islands, approximately 43 km from the Xena-03 Tie-back and Pluto Facility Operational Area. Given this, platform lighting and the tip of the flare tower will not be directly visible from this potential nesting site.

Light emissions reaching turtle nesting beaches is widely considered detrimental owing to interference with important nocturnal activities including choice of nesting sites and orientation/navigation to the sea by post-nesting females and hatchlings (Lorne and Salmon, 2007; Salmon, 2003; Tuxbury and Salmon, 2005).

Turtle hatchlings emerge from the nest and orient towards the sea. After entering the water, hatchlings use a combination of cues (wave direction and currents) to orient and travel into offshore waters. Impacts to the sea-finding behaviour of hatchlings are more common for light sources behind a beach, as lighting offshore will orient emerging hatchlings towards the sea. Artificial light at close distances can also impact hatchling dispersal once they are in the water. Light spill may 'entrap' hatchling swimming behaviour, reducing the success of their seaward dispersion and potentially increasing their exposure to predators via silhouetting (Salmon et al., 1992).

Sky glow, particularly from flaring on the riser platform, is also unlikely to be visible at the closest nesting locations and is unlikely to cause behavioural impacts. In any case, the light source is located directly offshore in the same direction that emerging hatchlings would be heading in during normal sea-finding behaviour, meaning that no significant misorientation or disorientation would occur.

The weather deck is approximately 47.4 m above sea level, with the highest point of the facility (the top of the flare tower) reaching approximately 91.4 m above sea level. The distance to visible horizon is ~32 km – i.e., anything beyond this distance is below the horizon and direct light would not be visible. Therefore, direct light from facility will not reach any nesting location. Sky glow (particularly from flaring) is also unlikely to be visible at the closest nesting locations resulting in no behavioural impact (i.e., not biologically relevant). Even in the scenarios where these areas may be affected, the light source is located directly offshore in the same direction that emerging hatchlings would be heading in during normal sea-finding behaviour, meaning that no disorientation impacts would occur.

The maximum likely height for a derrick on a MODU contracted for the Petroleum Activities Program is ~50 m, and subsequently have a lesser visible reach than the facility flare tower. External lighting on vessels is typically lower than the facility lights, with vessel lighting usually reduced to improve night vision of bridge crew. During IMMR activities vessels may come closer to turtle nesting beaches, mainly within the Dampier Archipelago. However, given the low frequency and large spatial extent at which these activities occur, there is not likely to be significant impacts. As such, the potential for hatchling turtles to become disorientated by artificial lighting is considered remote.

Adults

Artificial lighting may affect the location that turtles emerge to the beach, the success of nest construction, whether nesting is abandoned, and even the seaward return of adults (Salmon et al., 1995a, 1995b; Salmon & Witherington, 1995). However, such lighting is typically from residential and industrial development overlapping the coastline, rather than offshore from nesting beaches. It is acknowledged that the Facility Operational Area and Xena-03 Operational Area overlaps a 40 km internesting buffer BIA for flatback turtles and that marine turtles may occur in low densities in this area. However, no impacts to nesting flatback turtles will occur due to light generated within this section of the PAA given the riser platform's NNC status and the distance to the nearest landfall.

Within the Export Pipeline Operational Area, a higher abundance of turtles may be present. The Export Pipeline Operational Area overlaps internesting and internesting buffer BIAs for green, hawksbill and loggerhead turtles. Given the very low occurrence of IMMR activities, no impacts to nesting turtles of these species will occur.

Fish

Lighting from the presence of the facility, MODU or project vessels may result in the localised aggregation of fish. These aggregations of fish are considered localised and temporary and any long-term changes to fish species composition or abundance is considered highly unlikely. This localised increase in fish extends to those comprising the whale shark's diet which has a foraging BIA that intersects majority of the PAA. However, given that a large proportion of the diet comprises krill and other planktonic larvae, it is unlikely that a light source would lead to a significant increase in whale shark abundance in the vicinity of the facility or vessels. Similarly, any localised impacts to marine fish are not expected to impact on any commercial fishers in the area.

Cumulative impacts

There is potential for overlap when the Pluto facility becomes staffed during commissioning and tie-back activities where cumulative light emissions would occur from lighting required for safe operations from the facility, MODU and project vessels. As outlined above, these scenarios will be short term. The cumulative impact is likely to be minor, due to the low light intensities of the vessel navigational lighting, MODU and facility lighting, short and intermittent nature of the impact, and is not anticipated to adversely affect any sensitive receptors.

Cumulative light impacts have the potential to occur from flaring, IMMR activities and project vessel lighting from several nearby gas platforms, however negligible detrimental impact to biological communities is expected.

Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)90***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Legislation, Codes and Standards				
None Identified				
Good Practice				

[90] Qualitative measure

Implement a Seabird Management Plan that includes: Standardisation and maintenance of record keeping and reporting of seabird interactions Procedures on seabird intervention, care and management Regulatory reporting requirements for seabirds (unintentional death of or injury to seabirds that constitute MNES)	F: Yes. CS: Minimal.	Potential for slight reduction in the likelihood of seabird attraction to vessels and facility resulting in a reduced likelihood of bird strikes.	Potential benefits outweigh cost sacrifice.	Yes C 12.1
Lighting will be limited to the minimum required for navigational and safety requirements, with the exception of emergency events.	F. Yes. Lighting is typically appropriate for navigation and safety.	Given the potential impacts to turtles during this activity is insignificant, implementation of this control would not result in a reduction in consequence.	While the control does not result in significant reduction of impacts, it is good practice and not at significant cost.	Yes C 12.2
Well unloading acceptance criteria that define the well objectives will be established	F: Yes. CS: Standard practice.	Eliminates unnecessary flared volumes and corresponding emissions (light and GHG).	Benefits outweigh cost/ sacrifice.	Yes C 10.12
Professional Judgement – Eliminate				
No external lighting during Petroleum Activities Program.	F: No. Light management is consistent with that required to provide a safe working environment on-board the facility and support vessels. Lighting is required to enable monitoring of the platform from NRC. CS: Not considered – control not feasible.	Not considered – control not feasible.	Not considered – control not feasible.	No
Variation of the timing of the tie-back activities to avoid peak turtle internesting periods (December to January).	F: Yes CS: Significant cost and schedule impacts due to delays in securing vessels/MODU for specific timeframes.	Not considered – control not feasible.	Not considered, control not feasible.	No

Substitute external lighting with light sources designed to minimise impacts to seabirds, shorebirds and marine turtles: use flashing/ intermittent lights instead of fixed beam use motion sensors to turn lights on only when needed use luminaires with spectral content appropriate for the species present avoid high intensity light of any colour	F: Yes. Replacement of external lighting with lighting appropriate for turtles and seabirds is technically feasible, although is not considered to be practicable. CS: Significant cost sacrifice. The retrofitting of all external lighting on the facilities, etc, would result in considerable cost and time expenditure. Considerable logistical effort to source sufficient inventory of the range of light types onboard the facilities.	Given the potential impacts to turtles, nesting seabirds and fledglings during this activity are insignificant, implementation of this control would not result in a reduction in consequence. Potential for minor reduction in impact to individual foraging seabirds that may transit the PAA, as outlined in the NLPG.	Grossly disproportionate. Implementation of the control requires considerable cost sacrifice for minimal environmental benefit. The cost/sacrifice outweighs the benefit gained.	No
No flaring during Petroleum Program activities.	F: No. The ability to flare hydrocarbons is a safety and integrity critical requirement for the facility. Note, Woodside is committed to reducing flaring, and has developed annual internal facility flare targets against which progress is monitored (see Section 7.2.166.7.10). CS: Not considered – control not feasible.	Not considered – control not feasible.	Not considered – control not feasible.	No
Professional Judgement – Substitute

ALARP Statement: On the basis of the environmental impact assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the potential impacts from routine light emissions from the facility, MODU and vessels to be ALARP. As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.				

Demonstration of Acceptability
Acceptability Statement: The impact assessment has determined that, given the adopted controls, routine light emissions from external lighting on Pluto facility, MODU, ASV, installation and support vessels represent a localised impact /disturbance to marine fauna within the PAA, the majority of which will occur in the Facility Operational Area and Xena-03 Operational Area. The PAA overlaps with the whale shark foraging BIA as well as BIAs for the loggerhead turtle, green turtle, hawksbill turtle, and flatback turtle, and Habitat Critical to the green turtle, hawksbill turtle, and loggerhead turtle. The PAA also overlaps the breeding BIA for the wedge-tailed shearwater, roseate tern, and fairy tern. Conservation advice and the NLPG were taken into consideration during the impact evaluation. The Petroleum Activities Program is deemed consistent with the conservation advice and guideline. Further opportunities to reduce the impacts have been investigated above. The potential impacts are consistent with good oil-field practice/industry best practice and are considered to be broadly acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the impacts of light emissions to a level that is broadly acceptable and demonstrate the EPOs are met.

[92] Defined as 'no lasting effect (< 1 month); localised impact not significant to environmental receptors' as in Table 2-3/ Section 2.6.5.

6.8 Unplanned Activities (Accidents, Incidents, Emergency Situations) – Major Environmental Events

For Woodside's production facilities, an analysis is undertaken to identify, classify and analyse Major Environmental Events (MEEs), as described in Section 2.7. This extra level of rigour is applied so that sufficient controls for operational activities are in place for risks with potential Major and above environment event related consequences as per Woodside's Risk Matrix.

MEEs are evaluated against credible worst-case scenarios that may occur when all controls are absent or have failed. The risks considered in this section have therefore been identified as MEEs due to the potential for significant consequence. These sources of risk are subject to additional consideration in accordance with the process described in Section 2.6.4. Risks associated with the Petroleum Activities Program that have been classified as MEE's are summarised in Section 6.8.1 and include a range of hydrocarbon spills. The quantitative spill risk assessment methodology used to assess the potential consequence of credible spills is outlined in Section 6.8.2. Credible hydrocarbon spills that have not been classified as MEE's have also been assessed in Section 6.8. Risks that do not meet the MEE definition, although screened out of the MEE process, are still evaluated for ALARP and risk acceptability using the methodology described in Section 2.8. These include credible hydrocarbon spills during drilling and tie-back activities, which are not classified as MEE's for the following reasons:

- Drilling and subsea installation activities are performed outside of operations asset controls and ownership. Ownership is only handed over in cold commissioning when the asset gains control of subsea systems and well control, as such a different set of controls and safety systems are used in the lead up to pre-commissioning.
- The vessel safety case contains safety systems that prevent the occurrence of hydrocarbon spills during drilling and subsea installation.
- Hydrocarbon spills assessed for the drilling and subsea installation phase align with vessel safety case risk assessments and mitigation to reflect controls proportionate to the short duration elevated risk activities.

Drilling and subsea installation activities conclude with the hand over to the asset along with the subsequent risk and consequence from the activities.

6.8.1 MEEs Overview

Section 2.7 outlines the process for additional analysis and evaluation of MEEs. The bowtie output for each MEE identified has been provided in Table 6-27.

Table 6-26: MEE events for the Pluto Facility Operations

No.	Hazard	Top Event
MEE-01	Hydrocarbons in reservoirs, wells, wellheads and xmas trees	Well loss of containment
MEE-02	Hydrocarbons in subsea equipment (pipelines, flowlines and risers)	Subsea equipment loss of containment
MEE-03	Hydrocarbons in subsea and topsides equipment	Loss of structural integrity
MEE-04	Hydrocarbons in subsea and topsides equipment and marine vessels	Loss of marine vessel separation with platform
MEE-05	Hydrocarbons in subsea and topsides equipment	Loss of control of suspended load from platform

Each section includes a summary of the hazard description, hazard management, emergency response, ALARP summary and a list of SCE barriers identified on the bowties. Each group of SCEs is listed under Technical Performance Standards, with consistent naming conventions used across

Woodside's process safety management processes (e.g., pipeline integrity SCEs are captured as P09 – Pipeline Systems).

Section 6.8.10 presents the generic SCE Failure and generic Human Error bowties that illustrate the causes, outcomes and controls/barriers in place to manage potential common cause event (CCE) failure mechanisms for MEE controls associated with generic SCE equipment failure (CCE-01), and also human error (CCE-02). Controls and specific measures are listed for both bowties. Human Error is managed via the WMS and the Generic Human Error bowtie is included in the MEE section for completeness.

ALARP is demonstrated through controls and barriers being analysed for selection based on their independence, prioritised in accordance with the Hierarchy of Controls where controls further up the hierarchy take precedence over controls further down, and further analysed to consider the type of effect the control provides. ALARP controls presented for MEE bowties are labelled in accordance with Type of Effect classifications presented.

Woodside has developed a tailored ALARP position for hydrocarbon spill response, including EPOs, EPSs and MC for preparedness and response. The response arrangements are a mitigative control that applies to all MEEs where a hydrocarbon release may credibly occur. The hydrocarbon spill response arrangements are described in Section 7.

Table 6-27: Barrier Hierarchy and Type of Effect

Type of Effect	Legend	Description
Elimination (Technical)		Elimination controls form the 'first line of defence'. They eliminate the underlying hazard and therefore are the most effective category of control measure. If practicable, they should be selected in preference to any other type, as their existence removes the need for any other controls (e.g. a corrosion-resistant metal could replace the original material of construction).
Elimination (Administration)		
Prevention (Technical)		Prevention controls are intended to remove certain causes of incidents or reduce their likelihood. The corresponding hazard remains, but the frequency of incidents involving the hazard is lowered (e.g. introduction of regular maintenance programs can prevent the development of events involving the hazard). Where hazards and causes could not be 'eliminated', controls are required to prevent them from leading to unwanted events and consequences.
Prevention (Administration)		
Detection (Technical)		Detection controls are those that identify a potentially hazardous scenario (e.g. a change in operating parameters), allowing initiation of procedures or systems to prevent the cause occurring. Controls that detect the occurrence of events are often critical to being able to respond with other control measures that reduce the propagation of the events. Detection controls themselves often provide no actual control other than the awareness of the need to respond.
Detection (Administration)		
Reduction/Control (Technical)		Reduction controls are intended to limit the scale and consequence of incidents. They include systems that detect incidents and take some action (e.g. to reduce the rate of leakage of a toxic gas) and also aspects such as inter-unit separation that prevent escalation of fire and explosion incidents. As there is always potential for controls to fail, additional measures are required to limit the scale and severity of any unwanted event or outcome that may arise, by providing the ability to intervene and limit the propagation of the events.
Reduction/Control (Administration)		
Mitigation (Technical)		Mitigation controls take effect in response to an incident. They include controls that lessen the significance or damage caused by

Mitigation (Administration)		an unwanted event. Such controls only take effect after the hazardous event and outcomes occur. Mitigation controls are generally those designed to protect personnel against the consequences of a hazard or to aid in recovering from the effects of the hazard.

6.8.2 Hydrocarbon Characteristics

A summary of the characteristics of the hydrocarbons used as the basis for the modelling studies and subsequently used to inform the assessment of credible hydrocarbon spills is provided in Table 6-28.

Additional detail on the characteristics of these hydrocarbons is also provided below.

Table 6-28: Characteristics of the hydrocarbon types used for modelling and ecotoxicological studies

Hydrocarbon Type	Density (g/cm3) at 15°C	Viscosity (cP) at 15°C	Component	Volatile (%)	Semi-volatile (%)	Low volatility (%)	Residual (%)	Aromatics (%)
			Boiling point (°C)	<180	180-265	265-380	>380	Of whole oil <380

** at 25°C*

6.8.2.1 Pluto Condensate (PLA02 Operations)

Pluto condensate (applicable to PLA02 Operations) is a mixture of volatile and persistent hydrocarbons with high proportions of volatile and semi-volatile components. In favourable conditions, about 68% of the oil mass should evaporate within the first 12 hours (boiling point < 180°C); a further 18.48% should evaporate within the first 24 hours (180°C < boiling point < 265°C); and a further 10.05% should evaporate over several days (265°C < boiling point < 380°C). About 2.5% of the oil is shown to be persistent. The aromatic content of the oil is about 9.83% (RPS Group, 2024b).

Soluble, aromatic, hydrocarbons contribute to approximately 9.83% mass of the total oil. A further 10.05% has low volatility and a further 18.48% is semi-volatile. These compounds dissolve more slowly but tend to persist in soluble form for longer. Discharge onto the water surface will favour the process of evaporation over dissolution under calm sea conditions, but increased entrainment of oil and dissolution of soluble compounds can be expected under breaking wave conditions (RPS Group, 2024b).

The mass balance forecast for the constant-wind case shows that approximately 85% of the oil is predicted to evaporate within 24 hours. Under calm conditions, most of the remaining oil on the water surface will weather at a slower rate due to being comprised of the longer-chain compounds with higher boiling points. Evaporation of the residual compounds will slow significantly, and they will then be subject to more gradual decay through biological and photochemical processes (RPS Group, 2024b).

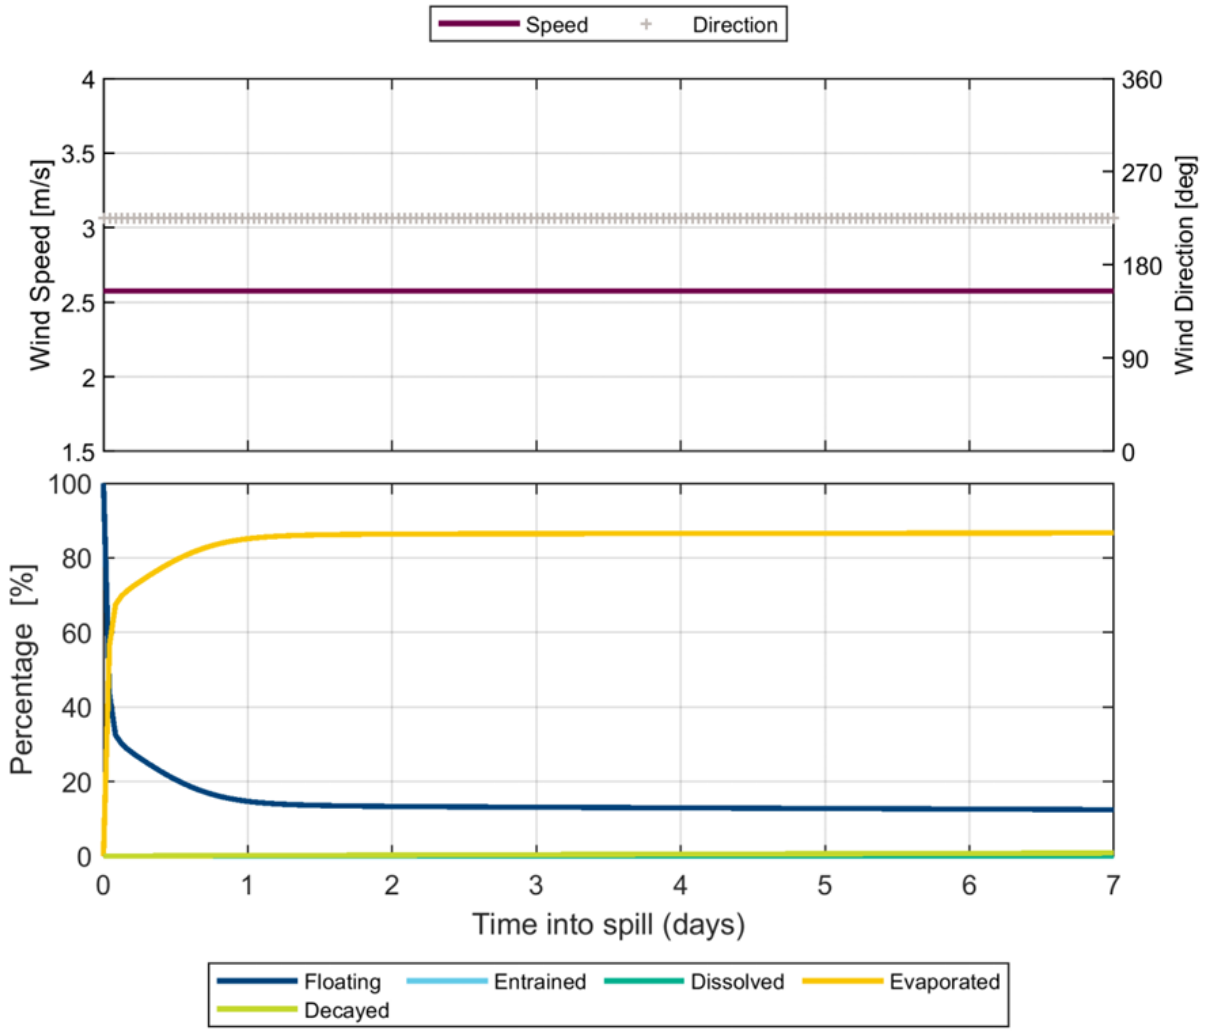

Figure 6-8: Proportional mass balance plot representing the weathering of Pluto Condensate spilled onto the water surface as a one-off instantaneous release (50 m3) and subject to a constant 5 kn (2.6 m/s) wind at 27°C water temperature and 25°C air temperature.

Under the variable-wind case, where the winds are of greater strength on average, entrainment of Pluto condensate into the water column is predicted to increase. Approximately 24 hours after the spill, around 16% of the oil mass is forecast to have entrained and a further 82% is forecast to have evaporated, leaving only a small proportion of the oil floating on the water surface (<0.1%). The residual compounds will tend to remain entrained beneath the surface under conditions that generate wind waves (approximately >6 m/s) (RPS Group, 2024b).

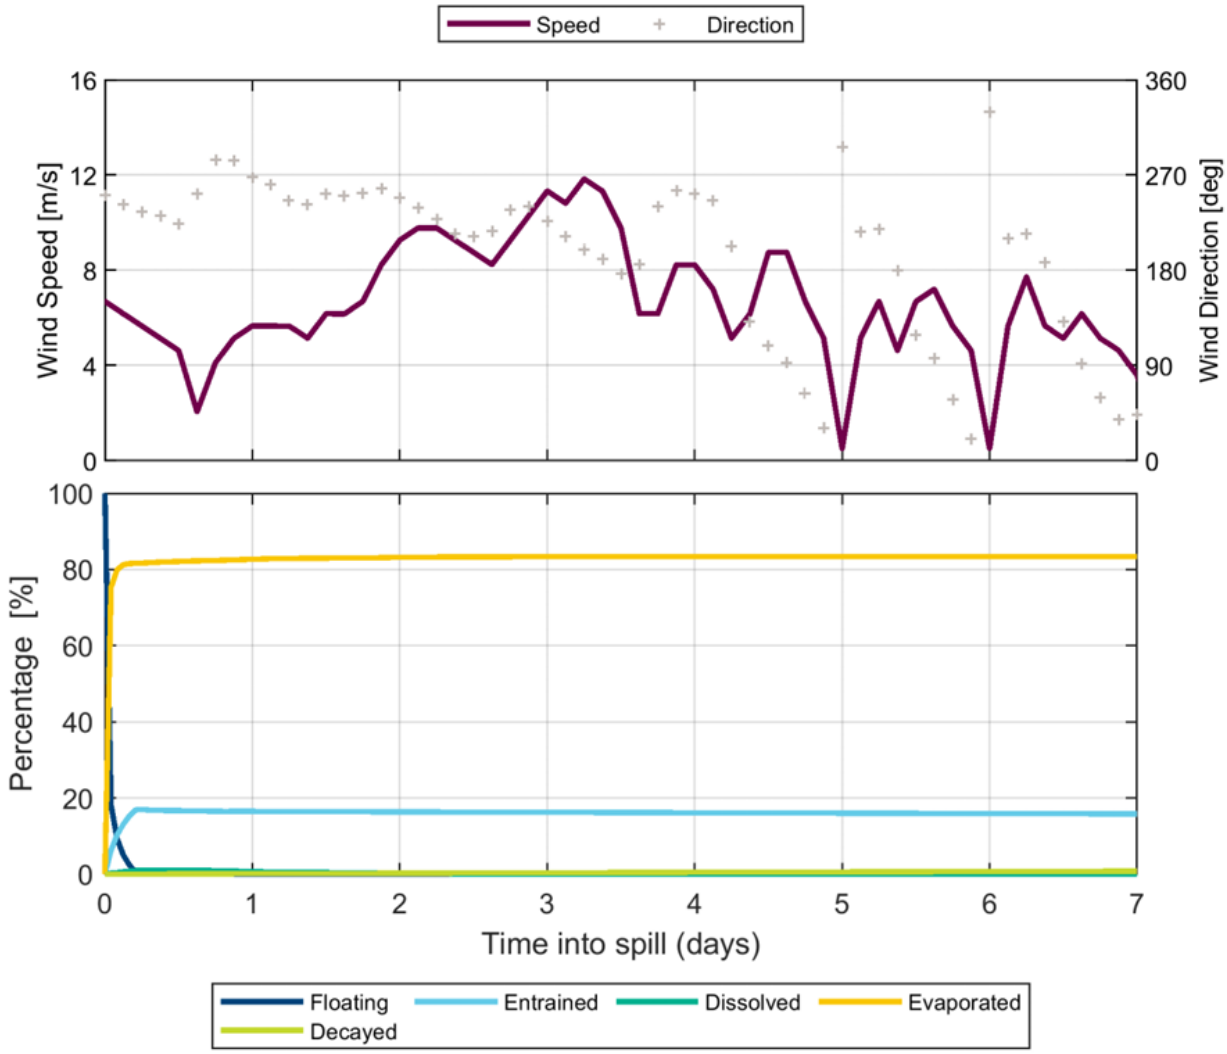

Figure 6-9: Proportional mass balance plot representing the weathering of Pluto condensate spilled onto the water surface as a one-off instantaneous release (50 m3) and subject to variable wind at 27 °C water temperature and 25 °C air temperature.

6.8.2.2 Pluto Condensate (Trunkline Operations)

Pluto condensate is a mixture of volatile and persistent hydrocarbons with high proportions of volatile and semi-volatile components. In favourable conditions, about 76% of the oil mass should evaporate within the first 12 hours (boiling point < 180°C); a further 14% should evaporate within the first 24 hours (180°C < boiling point < 265°C); and a further 9.5% should evaporate over several days (265°C < boiling point < 380°C). About 0.5% of the oil is shown to be persistent (RPS Group, 2024c, 2024d).

Around 76% of the oil is highly soluble and highly volatile. A further 14% is semi-volatile, and a further 9.5% has low volatility. These compounds dissolve more slowly but tend to persist in soluble form for longer. Discharge onto the water surface will favour the process of evaporation over dissolution under calm sea conditions, but increased entrainment of oil and dissolution of soluble compounds can be expected under breaking wave conditions (RPS Group, 2024c, 2024d).

The mass balance forecast for the constant low-wind case for Pluto shows that approximately 90% of the oil should evaporate within 24 hours. Under calm conditions, most of the remaining oil on the water surface will weather at a slower rate due to being comprised of the longer-chain compounds with higher boiling points. Evaporation of the residual compounds will slow significantly, and they will

then be subject to more gradual decay through biological and photochemical processes (RPS Group, 2024c, 2024d).

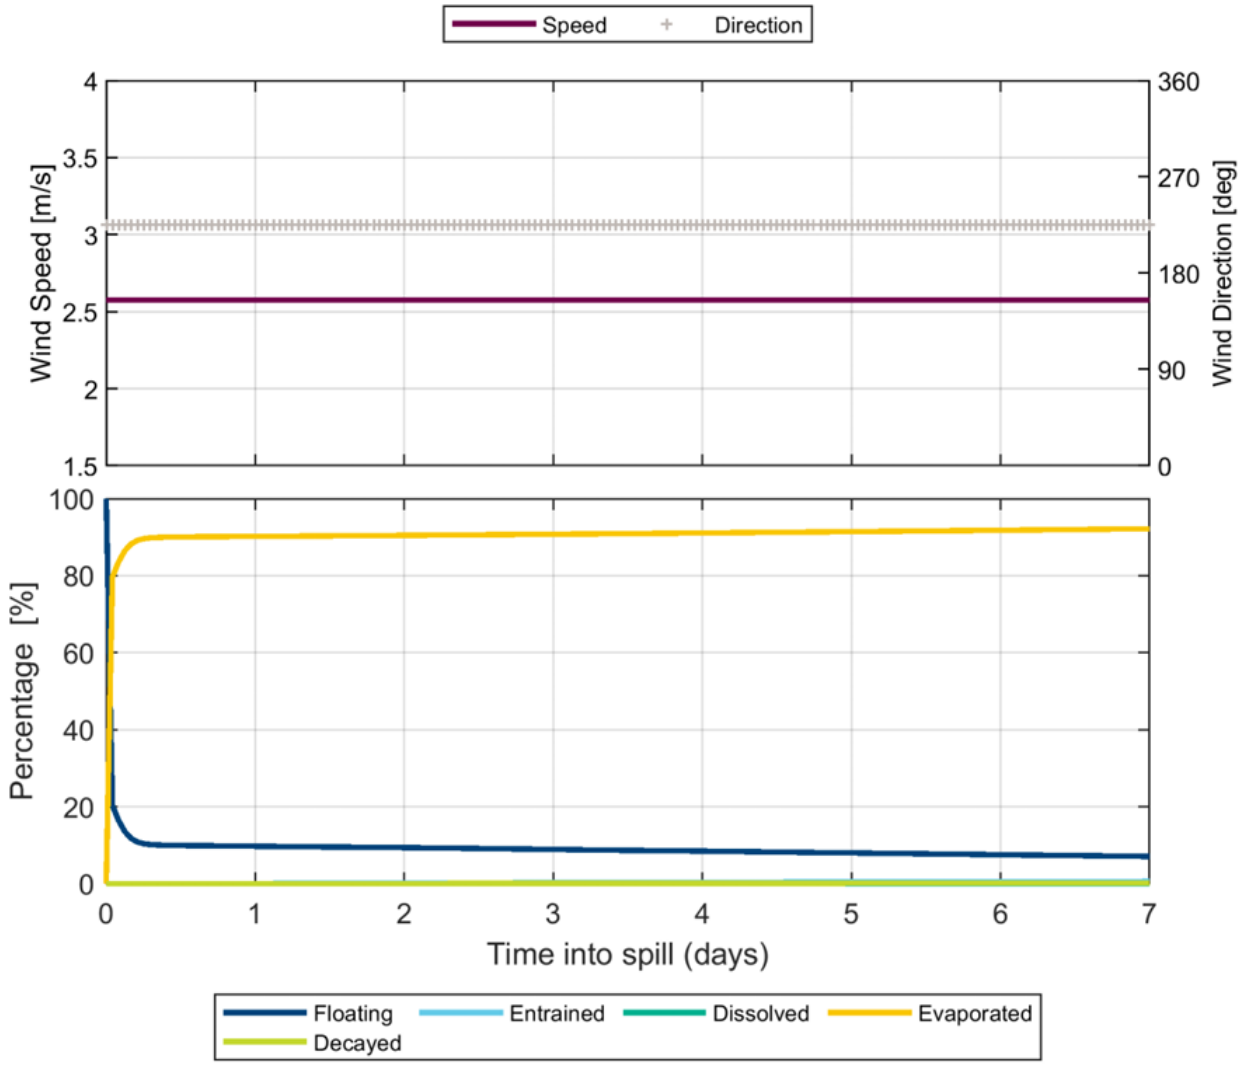

Figure 6-10: Proportional mass balance plot representing the weathering of Pluto Condensate spilled onto the water surface as a one-off instantaneous release (50 m3) and subject to a constant 5 kn (2.6 m/s) wind at 27 °C water temperature and 25 °C air temperature.

Under the variable-wind case, where the winds are of greater strength on average, entrainment of Pluto Condensate into the water column is predicted to increase. Approximately 24 hours after the spill, around 12% of the oil mass is predicted to have entrained and a further 87% is predicted to have evaporated, leaving only a small proportion of oil floating on the water surface (<1%). The residual compounds will tend to remain entrained beneath the surface under conditions that generate wind waves (approximately >6 m/s) (RPS Group, 2024c, 2024d).

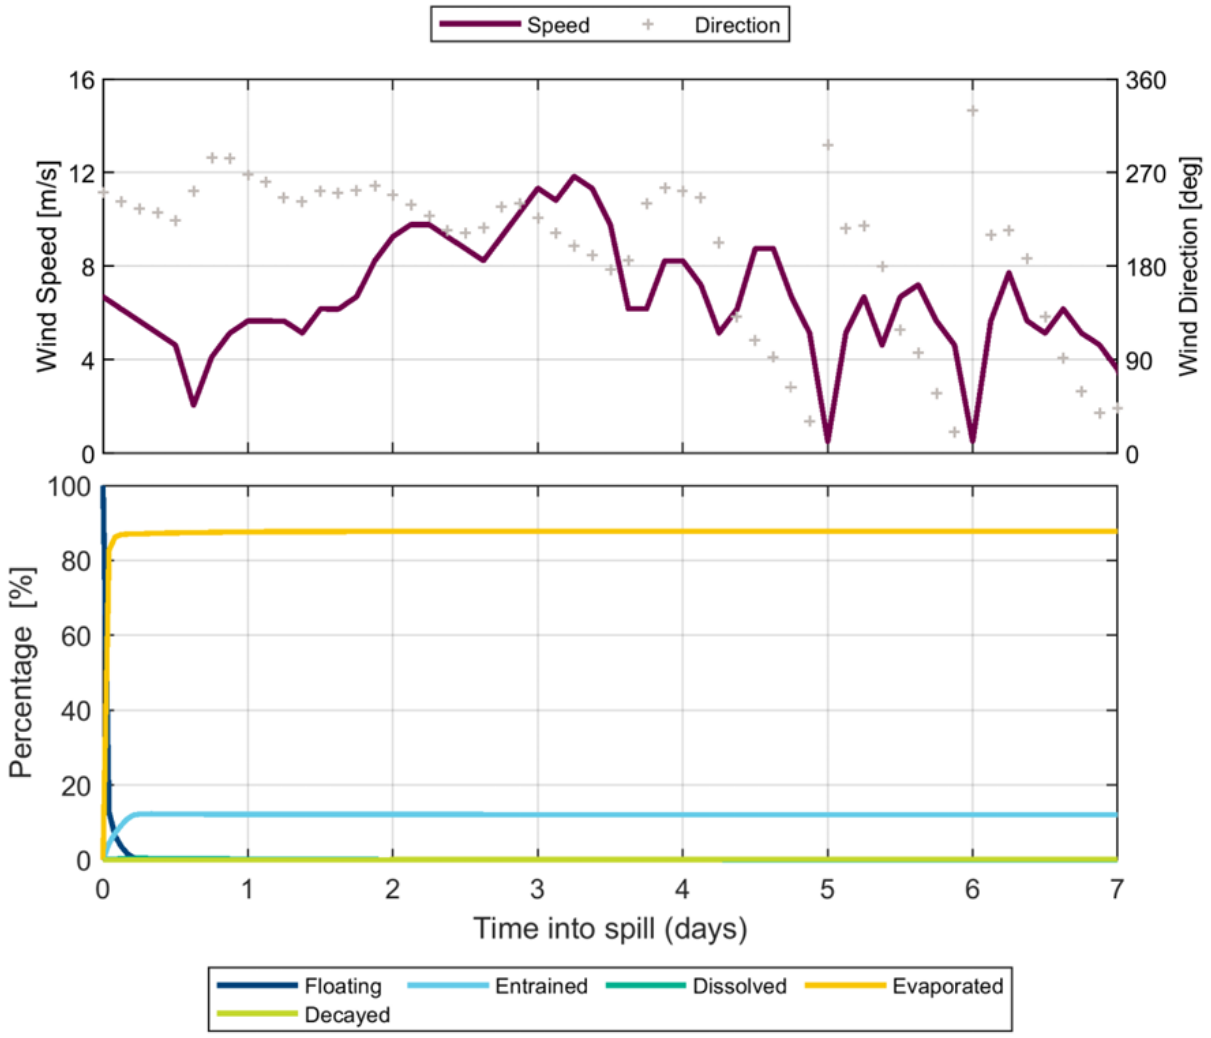

Figure 6-11: Proportional mass balance plot representing the weathering of Pluto Condensate spilled onto the water surface as a one-off instantaneous release (50 m3) and subject to variable wind at 27–°C water temperature and 25 °C air temperature.

6.8.2.3 Condensate - Eris-1 and Pluto analogues (surface and seabed)

Eris-1 and Pluto analogues Condensate (Eris-1), applicable for XNA03 hydrocarbon QSRA is a mixture of hydrocarbon compounds that would condense from the gas-phase on exposure to the lower pressures and temperatures of ambient conditions. As these conditions would differ, the hydrocarbon characteristics of the condensate at the surface and the seabed have both been accounted for.

Eris-1 Condensate released at the surface is a mixture of volatile and persistent hydrocarbons with high proportions of volatile and semi-volatile components. In favourable conditions, about 15% of the oil mass should evaporate within the first 12 hours (boiling point < 180°C); a further 48.43% should evaporate within the first 24 hours (180°C < boiling point < 265°C); and a further 26.6% should evaporate over several days (265°C < boiling point < 380°C). About 10% of the oil is shown to be persistent. The aromatic content of the oil is about 9.85% (RPS Group, 2024a).

Soluble, aromatic, hydrocarbons contribute approximately 9.85% by mass of the whole oil. Around 14.97% is highly soluble and highly volatile. A further 48.43% is semi-volatile and a 26.6% has a low volatility. These compounds dissolve more slowly but tend to persist in soluble form for longer.

Discharge onto the water surface will favour the process of evaporation over dissolution under calm sea conditions, but increased entrainment of oil and dissolution of soluble compounds can be expected under breaking wave conditions (RPS Group, 2024a).

The mass balance forecast for the constant wind case for the Eris-1 Condensate (surface) shows that approximately 64% of the oil should evaporate within 24 hours. Under calm conditions, the majority of the remaining oil on the water surface will weather at a slower rate due to being comprised of the longer-chain compounds with higher boiling points. Evaporation of the residual compounds will slow significantly, and they will then be subject to more gradual decay through biological and photochemical processes (RPS Group, 2024a).

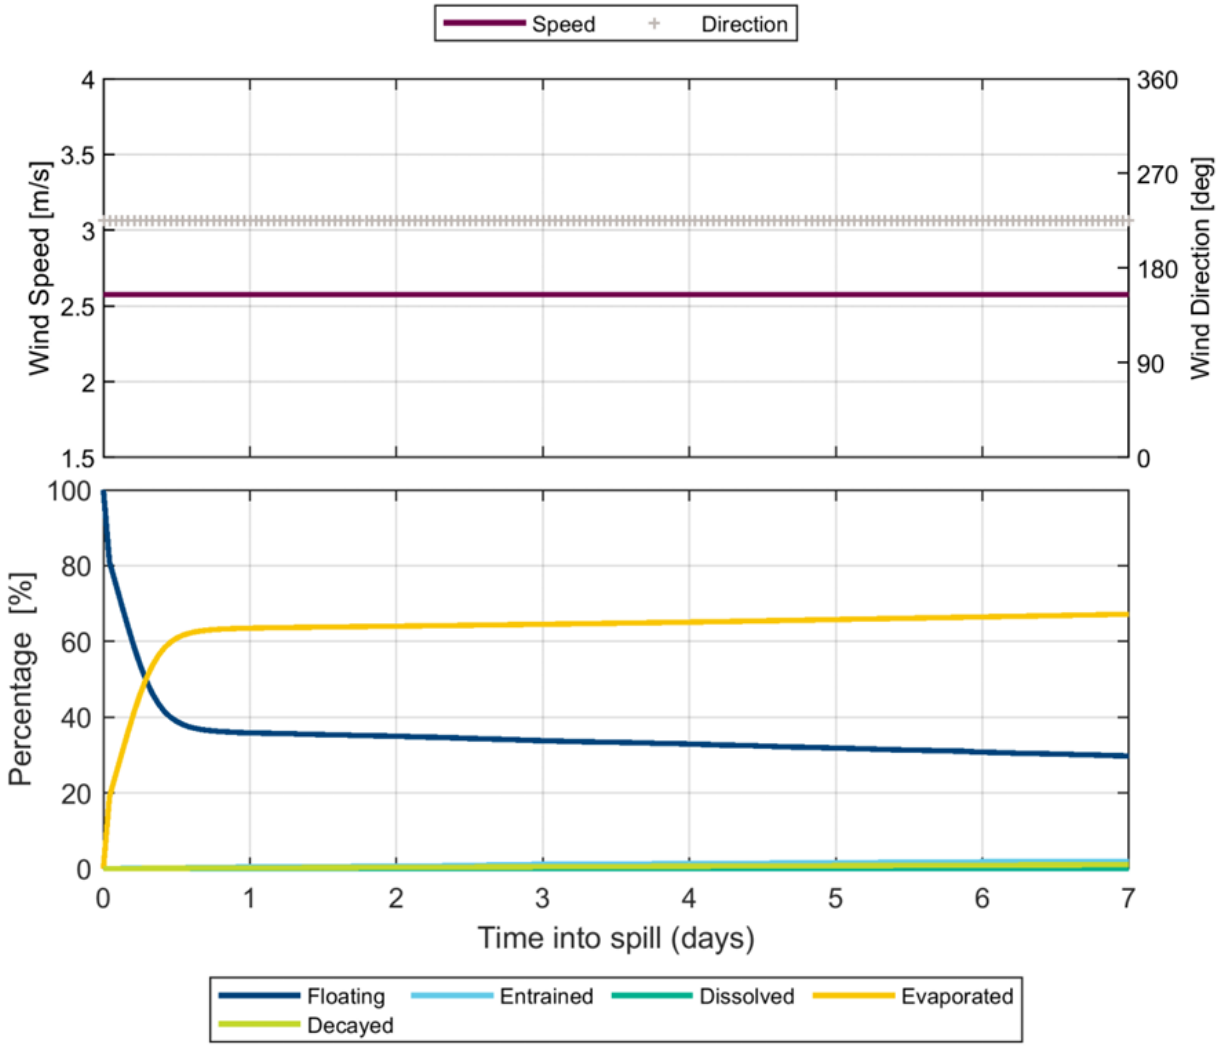

Figure 6-12: Proportional mass balance plot representing the weathering of Eris-1 Condensate spilled onto the water surface as a one-off instantaneous release (50 m3) and subject to a constant 5 kn (2.6 m/s) wind at 27 °C water temperature and 25 °C air temperature.

Under the variable-wind case, where the winds are of greater strength on average, entrainment of Eris-1 Condensate (surface) into the water column is predicted to increase. Approximately 24 hours after the spill, around 54% of the oil mass is expected to have entrained and a further 43% is forecasted to have evaporated, leaving only a small proportion of oil floating on the water surface (<15). The residual compounds will tend to remain entrained beneath the surface under conditions that generate wind waves (approximately >6 m/s) (RPS Group, 2024a).

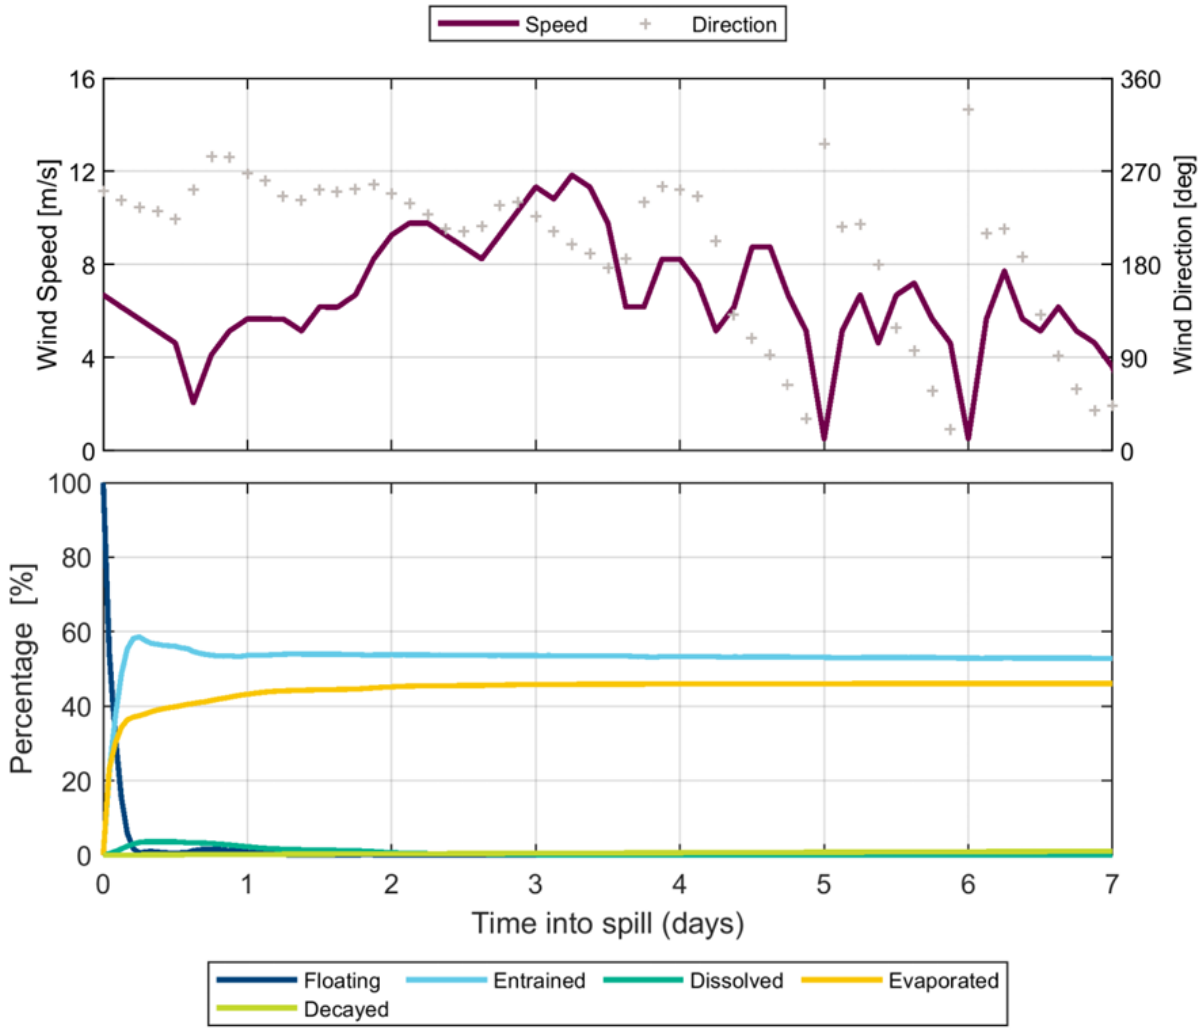

Figure 6-13: Proportional mass balance plot representing the weathering of Xena Fluid spilled onto the water surface as a one-off instantaneous release (50 m3) and subject to variable wind at 27 °C water temperature and 25 °C air temperature.

6.8.2.4 Marine Diesel

Marine diesel, 'Marine Gas Oil' (MGO) is a mixture of volatile and persistent hydrocarbons with low proportions of highly volatile and residual components. Modelling for marine diesel utilised information for a comparable Marine Gas Oil (MGO). In favourable conditions, about 6% of the oil mass should evaporate within the first 12 hours (boiling point < 180°C); a further 34.6% should evaporate within the first 24 hours (180°C < boiling point < 265°C); and a further 54.4% should evaporate over several days (265°C < boiling point < 380°C). About 5% of the oil is shown to be persistent. The aromatic content of the oil is about 3% (RPS Group, 2024e).

The mass balance forecast for the constant-wind case for MGO shows that about 38% of the oil is predicted to evaporate within 24 hours. Under these calm conditions the majority of the remaining oil on the water surface weathers at a slower rate due to comprising the longer-chain compounds with higher boiling points. Evaporation of the residual compounds slows significantly and is then subject to more gradual decay through biological and photochemical processes (RPS Group, 2024e).

Under the more realistic variable-wind case, where the winds are of greater strength, entrainment of MGO into the water column is indicated to be significant. About 24 hours after the spill, around 74% of the oil mass is forecast to have entrained and a further 26% is forecast to have evaporated, leaving only a small proportion of the oil floating on the water surface (<1%). The residual compounds tend to remain entrained beneath the surface under conditions that generate wind waves (about >6 m/s).

The increased level of entrainment in the variable-wind case results in a higher percentage of biological and photochemical degradation. Given the large proportion of entrained oil and the tendency for it to remain mixed in the water column, the remaining hydrocarbons decay and/or evaporate over time scales of several weeks to a few months. This long weathering duration extends the area of potential effect (RPS Group, 2024e).

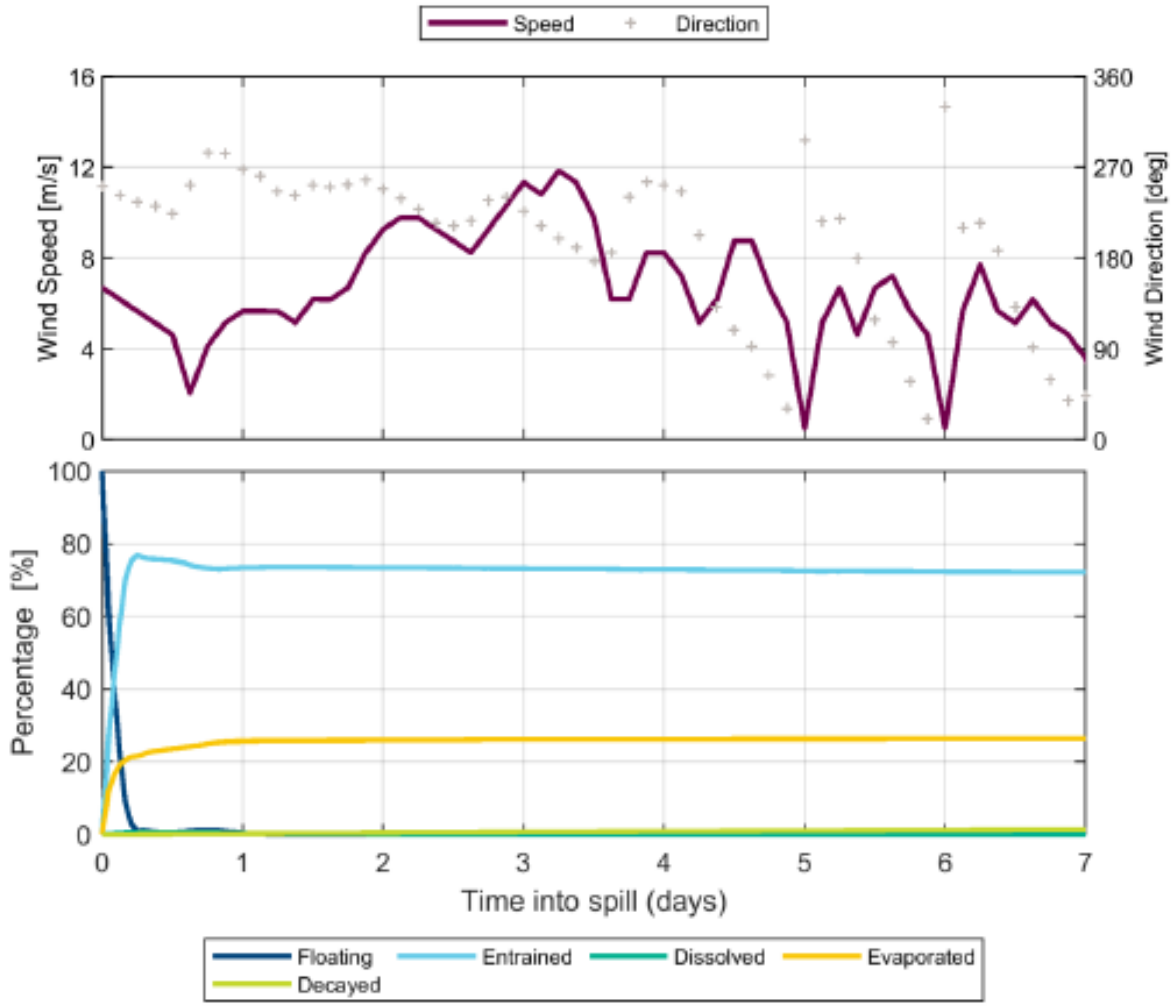

Figure 6-14: Proportional mass balance plot representing the weathering of marine gas oil spilled onto the water surface as a one-off release (50 m3 over one hour) and subject to variable wind at 27°C water temperature and 25°C air temperature.

6.8.3 Quantitative Spill Risk Assessment Methodology

As part of the risk identification process, Woodside identified the range of credible hydrocarbon spill scenarios that may occur during the Petroleum Activities Program. Scenarios that have been classified as MEEs are assessed in Sections 6.8.5 to 6.8.9. Scenarios that are not classified as MEEs are assessed in Section 6.9.

Quantitative hydrocarbon spill modelling was undertaken by RPS, on behalf of Woodside, using a three-dimensional (3D) hydrocarbon spill trajectory and weathering model, SIMAP (Spill Impact Mapping and Analysis Program), which is designed to simulate the transport, spreading and weathering of specific hydrocarbon types under the influence of changing meteorological and oceanographic forces.

A stochastic modelling scheme was followed in this study, whereby SIMAP was applied to repeatedly simulate the defined credible spill scenarios using different samples of current and wind data. These data samples were selected randomly from an historic time-series of wind and current data representative of the study area. Results of the replicate simulations were then statistically analysed and mapped to define contours of percentage probability of contact at identified thresholds around the hydrocarbon release point.

The model simulates surface releases and uses the unique physical and chemical properties of a hydrocarbon type to calculate rates of evaporation and viscosity change, including the tendency to form oil in water emulsions. Moreover, the unique transport and dispersion of surface slicks and in water components (entrained and dissolved) are modelled separately. Thus, the model can be used to understand the wider potential consequences of a spill, including direct contact of hydrocarbons due to surface slicks (floating hydrocarbon) and exposure of organisms to entrained and dissolved aromatic hydrocarbons in the water column.

During each simulation, the SIMAP model records the location (by latitude, longitude and depth) of each of the particles (representing a given mass of hydrocarbons) on or in the water column, at regular time steps. For any particles that contact a shoreline, the model records the accumulation of hydrocarbon mass that arrives on each section of shoreline over time, less any mass that is lost to evaporation and/or subsequent removal by current and wind forces.

The collective records from all simulations are then analysed by dividing the study region into a 3D grid. For surface hydrocarbons (floating oil), the sum of the mass in all hydrocarbon particles located within a grid cell, divided by the area of the cell, provides hydrocarbon concentration estimates in that grid cell at each model output time interval. For entrained and dissolved aromatic hydrocarbon particles, concentrations are calculated at each time step by summing the mass of particles within a grid cell and dividing by the volume of the grid cell. The process is also subject to the application of spreading filters that represent the expected mass distribution of each distinct particle. The concentrations of hydrocarbons calculated for each grid cell, at each time step, are then analysed to determine whether concentration estimates exceed defined threshold concentrations.

Hydrocarbon spill modelling assessments undertaken by RPS undergo initial sensitivity modelling to determine appropriate time to add to the simulation after the cessation of the spill. The amount of time following the spill is based on the time required for the modelled concentrations to practically drop below threshold concentrations anywhere in the model domain in the test cases. This assessment is done by post-processing the sensitivity test results and analysing time-series of median and maximum concentrations in the water and on the surface.

6.8.4 Environment that May Be Affected and Hydrocarbon Contact Thresholds

The outputs of the quantitative hydrocarbon spill modelling are used to assess the environmental consequence by delineating which areas of the marine environment could be exposed to hydrocarbon levels exceeding selected hydrocarbon threshold concentrations if a credible hydrocarbon spill scenario occurred. The summary of the locations where hydrocarbon thresholds could be exceeded by any of the simulations modelled is defined as the EMBA. The EMBA covers a larger area than the area that is likely to be affected during any single spill event, as the model was run for a variety of weather and metocean conditions, and the EMBA represents the total extent of all the locations where hydrocarbon thresholds could be exceeded from all modelling runs.

As the weathering of different fates of hydrocarbons (surface, entrained and dissolved) differs due to the influence of the metocean mechanism of transportation, a different EMBA is presented for each hydrocarbon fate. Together, these EMBA have defined the spatial extent for the existing environment described in Section 4.

The spill modelling outputs are presented as areas that meet threshold concentrations for surface, entrained and dissolved hydrocarbons for the modelled scenarios. Surface spill concentrations are expressed as grams per square metre (g/m2), with entrained and dissolved aromatic hydrocarbon concentrations expressed as parts per billion (ppb). A conservative approach to selecting thresholds was taken by adopting the guideline impact thresholds (NOPSEMA, 2019) for surface, entrained, dissolved and accumulated hydrocarbons to define the EMBA for condensate spills from a loss of well control and marine diesel spills. An additional threshold has been included to define the boundary within which socio-cultural impacts may occur, based on visible surface oil (1 g/m2) impacting on the visual amenity of the marine environment. Each of these hydrocarbon thresholds are presented in Table 6-29 and described in the sub-sections below.

Table 6-29: Summary of thresholds applied to the quantitative hydrocarbon spill risk modelling results

Hydrocarbon Type	EMBA				Socio-cultural EMBA
	Dissolved hydrocarbon (ppb)	Entrained hydrocarbon (ppb)	Surface hydrocarbon (g/m2)	Accumulated / shoreline hydrocarbon (g/m2)	Surface hydrocarbon (g/m2)
Condensate	50	100	10	100	1
Marine Gas Oil	50	100	10	100	1

6.8.4.1 Scientific Monitoring

A planning area for scientific monitoring is also described in the Oil Spill Preparedness and Response Mitigation Assessment. This planning area has been set with reference to the low exposure entrained value of 10 ppb detailed in the NOPSEMA (2019) bulletin Oil Spill Modelling.

A scientific monitoring program may be activated following a release event with the potential to contact sensitive environmental receptors. This would consider receptors at risk (ecological and socio-economic) and in particular, any identified Pre-emptive Baseline Areas (PBAs) for the worst-case credible spill scenario or other identified unplanned hydrocarbon releases associated with the operational activities.

6.8.5 Unplanned Hydrocarbon Release: Loss of Well Containment from Operating Wells (MEE-01)

Context		
Reservoir and Wells – Section 3.4.2	Physical Environment – Section 4.4 Habitats and Biological Communities – Section 4.5 Protected Species – Section 4.6 Protected Places – Section 4.8 Socio-economic and Cultural – Section 4.9	Consultation – Section 5

Impacts and Risks Evaluation Summary

Source of Risk	***Environmental Value Potentially Impacted***							***Evaluation***						
	Soil and Groundwater	Marine Sediment	Water Quality	Air Quality (incl Odour)	Ecosystems / Habitat	Species	Socio-economic	Decision Type	Consequence	Likelihood	Risk Rating	ALARP Tool	Acceptability	Outcome
Release of hydrocarbons resulting from subsea well loss of containment		x	x	x	x	x	x	B	C	1	M	LCS GP PJ RBA CV SV	Acceptable if ALARP	EPO 13

Description of Source of Risk

During operations, the facility will receive hydrocarbons via the Pluto flowline from wells in the Pluto, Xena and Pyxis fields, as described in Section 3.

Loss of well containment can lead to an uncontrolled release of reservoir hydrocarbons and well fluids to the environment. Woodside has identified a loss of well containment (LOWC) as the scenario with the worst-case credible environmental outcome as a result of this event. A loss of well containment during operations could occur due to a variety of causes including:

- internal corrosion;
- external corrosion;
- erosion;
- overpressure of the annuli;
- fatigue;
- loss of control of suspended load from vessel (operating near subsea wells) (MEE-04; Section 6.8.8)
- loss of well system structural integrity.

A number of common failure causes due to human error and SCC failures are presented in the generic Human Error and SCE Failure bowties in Section 6.8.10.

The LOWC scenario that may occur during the drilling and any MODU-based well test of Xena-03 is considered separately in Section 6.9.1.

Loss of Well Control – Credible Scenario

The Petroleum Activities Program includes production from a series of subsea wells (Section 3.4.2). To assess the potential consequences, a worst credible hydrocarbon release scenario has been defined for a Pluto well (PLA02). The Pluto well scenario is based on a loss of containment from a well which represents the overall characteristics of the Pluto reservoir and is a high producing well, thus representing a worst credible volume release and potential

environmental impact, for current Pluto, Pyxis and Xena wells. Future wells (PLA-08 and XNA-03) were considered but the existing PLA02 scenario is considered to be worst case.

The LOWC was assumed to have a release duration of 77 days. This duration is based on the estimated time required to successfully drill an intervention well (refer to Appendix H for additional discussion of relief well timing). The characteristic of the release scenario is summarised in Table 6-30. The characteristics of Pluto condensate was used as the basis in the modelling the LOWC scenario (RPS, 2024b); refer to Section 6.8.2 and 6.8.3 for additional information on modelling methods, hydrocarbon characteristics and environmental impact thresholds.

Table 6-30: Summary of worst-case loss of well containment hydrocarbon release scenarios

Scenario	Hydrocarbon	Average Rate (m3/day)	Duration (days)	Depth (m)	Latitude	Longitude	Total Condensate Release Volume (Sm3)
Scenario 2: Well blowout at seabed PLA02	Pluto Condensate	4,848	77	829	19° 54' 48.266" S	115° 7' 54.151" E	59,459

Decision Type, Risk Analysis and ALARP Tools

Woodside implements industry standard practice in well design and construction. In the company's recent history, it has not experienced any well integrity events that have resulted in significant releases or significant environmental impacts. Woodside has never experienced a worst-case loss of well containment in its operational history.

Decision Type

Decision Type B has been applied to this risk under the Guidance on Risk Related Decision Making (Oil and Gas UK 2014). This reflects the complexity of the risk, the higher potential consequence and stakeholder implications should the event be realised. To align with this decision type, a further level of analysis has been applied using risk based tools including the bowtie methodology (described in Section 2.7.3) and hydrocarbon spill trajectory modelling. Company and societal values were also considered in the demonstration of ALARP and acceptability, considered through internal reviews, and stakeholder consultation (Section 5).

The release of hydrocarbons as a result of well loss of containment is considered a Major Environment Event (MEE-01). The hazard associated with this MEE is hydrocarbons in reservoirs, wells, wellheads and xmas trees tied back to the facility.

Quantitative Spill Risk Assessment

Spill modelling of the worst-case credible loss of well containment spill scenario was undertaken by RPS, to determine the fate of hydrocarbons released based on the assumptions. Modelling was undertaken over all seasons to address year-round operations (RPS, 2024b). This is considered to provide a conservative estimate of the EMBA and the potential impacts from the identified worst-case credible release volumes for all loss of well containment scenarios.

Hydrocarbon Characteristics

Hydrocarbon characteristics of Pluto Condensate are provided and described in more detail in Section 6.8.2.

Subsea Plume Dynamics

The subsea loss of well containment scenario would result in a buoyant plume of hydrocarbons, which has been modelled using the OILMAP-Deep numerical model.

Table 6-31: Near-field subsurface discharge model parameters for loss of well containment scenario

Scenario	Hydrocarbon	Rate (m3/hr)	Duration (days)	Depth (m)
Well blowout at seabed (PLA02)	Pluto Condensate	202	77	829

Likelihood

In accordance with the Woodside Risk Matrix, a worst-case loss of well containment has been defined as a 'highly unlikely' event as it 'has occurred once or twice in the industry' (experience based likelihood) and aligns with a frequency of a '1 in 10,000 to 1 in 100,000 year' event. Information to support this likelihood determination is outlined below.

The blowout likelihood was evaluated using Blowout and Well release Frequencies based on SINTEF offshore blowout database as analysed in the IOGP, 2019 Study "Risk Assessment Data Directory Blowout Frequencies – Report 434-02" (September 2019). This uses data from 1980-2014 to determine likelihood for well blowouts and

releases. For a gas well, the IOGP study calculated gas blowout frequency during production as 7.20 x10-5 per year per well.

Given consideration for up to 13 subsea gas wells and using SINTEF/IOGP database, blowout during production occurs with a frequency of 9.36E-04 per year which gives a likelihood level of 2 “Unlikely” on the Woodside Risk Matrix. An order of magnitude reduction has been taken to reduce the likelihood of significant environmental impacts to Level 1 “Highly Unlikely”, for the following reasons:

SINTEF and Lloyds data presented in the IOGP 2019 Blowout Frequencies study considers Production well integrity events between 1980 and 2011, with some additional data from the North Sea between 2011 and 2014. Frequencies are informed by incidents which occurred in Gulf of Mexico, which occurred prior to standards improvement following the Macondo event. Similarly, improvements in standards have been achieved in the North Sea compared to the pre-Macondo era. External causes are excluded for subsea production wells, as causes discussed appears to only be relevant to dry-tree/platform wells.

For the international blowout incidents analysed, these are expected to have resulted in varied release outcomes with varied flow and environmental consequence outcomes – not all are aligned with a worst case unconstrained full-bore blowout, from the highest flowing well, nor necessarily required a relief well to remediate (which is the basis for this risk assessment)

Woodside have adopted international best practice – the O&G UK Well Lifecycle Integrity Guidelines (post-Macondo industry improvements). Woodside continue to apply a rigorous well integrity management program (refer WOMP) as required under WMS and Australian regulations, including verification, and testing of key barriers including SSSVs.

Additionally, when considering likelihood from an ‘Experience’ perspective, and considering the significant environmental consequence likelihood as the outcome of a blowout event; historical blowouts resulting in major impacts to the environment have not occurred “many times in industry”. Hence, alignment with Highly Unlikely likelihood classification is deemed appropriate.

Consequence

The spatial extent and fate (including weathering) of the spilled hydrocarbon were considered during the impact assessment for a worst-case loss of well containment (presented in the following section). These considerations were informed primarily by the outputs from the numerical modelling studies undertaken by RPS (2024b), available information on environmental sensitivities that may credibly be impacted in the event of a worst-case spill, and relevant literature and studies considering the effects of hydrocarbon exposure.

Consequence Assessment

Environment that May Be Affected

Surface Hydrocarbons

Hydrocarbon spill modelling for surface hydrocarbons indicated that concentrations equal to or greater than the 10 g/m2 ecological threshold could potentially be found, in the form of slicks, up to 20 km (south-west) from the release location. There is minimal surface hydrocarbon contact with receptors for the worst-case scenario. The probability of films arriving at receptors were <1%.

Entrained Hydrocarbons

Entrained oil concentrations equal to or greater than the 100 ppb ecological thresholds are predicted to be found up to 420 km (south-west) from the release location. A number of receptors were predicted to be contacted by entrained hydrocarbons. The greatest probabilities of contact by entrained hydrocarbons were at Gascoyne MP (2%) and Montebello MP (71%).

Dissolved Hydrocarbons

Dissolved aromatic hydrocarbon concentrations equal to or greater than the 50 ppb ecological threshold are predicted to be found up to 80 km (south-west) from the release location. The greatest probabilities of contact by dissolved hydrocarbons were at Montebello MP (3%).

Accumulated Hydrocarbons

A number of receptors were predicted to potentially receive shoreline hydrocarbons in the spill modelling. The hydrocarbon contact is expected to be minimal for all receptors for the worst-case scenario. The probability of shoreline accumulation on receptors at all thresholds were <1%.

Summary of Potential Impacts to Environmental Value(s)

The combined EMBA for loss of well containment within which all other credible hydrocarbon spill EMBAs are contained, i.e. the sensitive receptors and their locations that may be exposed to hydrocarbons (surface, entrained, dissolved and accumulated) at or above the set threshold concentrations in the unlikely event of a loss of well containment during the Petroleum Activities Program are outlined in Section 4. The potential biological and ecological impacts of an unplanned hydrocarbon release as a result of a LOWC during the Petroleum Activities Program are discussed in the following sections.

Table 6-32: Environment that May Be Affected – key receptor locations and sensitivities potentially contacted above impact thresholds by the loss of well containment scenario with summary hydrocarbon spill contact ≥ 1% probability

Environmental Setting	Receptor	Environmental, social, cultural, heritage and economic aspects presented as per the environmental risk definitions (Woodside's Risk Management Procedure)																																Probability of hydrocarbon contact and fate (%)[93]

[93] Worst case probability

Open water Environment (Near Spill Area)
Air Quality A hydrocarbon release during a loss of well containment has the potential to result in localised, temporary reduction in air quality and contribution of greenhouse gases to the global concentration of these gases in the atmosphere. Potential impacts from reduced air quality are expected to be minor, short-term and predominantly localised due to rapid entrainment and dissolution of gas bubbles into the water column. There is potential for human health effects for workers in the immediate vicinity of atmospheric emissions that potentially reach the surface. The ambient concentrations of methane and VOCs released from diffuse sources is difficult to accurately quantify, although the behaviour and fate is predictable in open offshore environments as rapidly dissolved in deep waters, and it is dispersed rapidly by meteorological factors such as wind and temperature. Methane and VOC emissions from a hydrocarbon release in such environments are rapidly degraded in the atmosphere by reaction with photo chemically-produced hydroxyl radicals. Due to the unlikely occurrence of a loss of well containment; the temporary nature of any methane or VOC emissions (from either gas surfacing or weathering of liquid hydrocarbons from a loss of well containment); the predicted behaviour and fate of methane and VOCs in open offshore environments; and the significant distance from the PAA to the nearest sensitive air shed (town of Dampier, about 157 km away), the potential impacts are expected to be minor and short-term.
Water Quality Water quality would be affected in the offshore environment within the EMBA due to hydrocarbon contamination from entrained, dissolved and surface hydrocarbons. Due to the weathering processes of the hydrocarbons, impacts to water quality are anticipated to be minor long term and/or significant short term as a result of hydrocarbon contamination above background levels.
Marine Sediment Quality Studies of hydrocarbon concentrations in deep sea sediments in the vicinity of a catastrophic well blowout indicate hydrocarbon from the blowouts can be incorporated into marine sediments (Romero et al. 2015). Proposed mechanisms for hydrocarbon contamination of sediments include sedimentation of hydrocarbons and direct contact between submerged plumes and the seabed (Romero et al. 2015). In the event of a major hydrocarbon release at the seabed, modelling indicates that a pressurised release of condensate would atomise into droplets that would be transported into the water column to the surface. As a result, the extent of potential impacts to the seabed area at and surrounding the release site would be confined to a localised footprint. Marine sediment quality would be reduced as a consequence of hydrocarbon contamination for a small area within the immediate release site for a long to medium term.
Benthic Fauna Communities In the event of a loss of well containment at the seabed, the spill modelling predicted hydrocarbon droplets would be entrained in a gas plume, transporting them through the water column and to the sea surface. As a result, the low sensitivity benthic communities associated with the unconsolidated, soft sediment habitat within the PAA are generally not expected to be exposed to released hydrocarbons. A localised area of impact relating to the hydrocarbon plume at the point of release is however predicted, which would result in a small area of seabed and any associated epifauna and infauna being exposed to hydrocarbons. Impacts to benthic communities within the PAA would subsequently be limited to the immediate area around the release site and may include lethal or sub-lethal impacts. Within the offshore waters of the EMBA, impacts to benthic fauna on the seafloor are not anticipated as hydrocarbons are not expected to gravitate toward the seafloor (as described above). Benthic fauna at geomorphic features located within the water column such as shoals and banks are not predicted to be impacted by dissolved and/or entrained hydrocarbons above the ecological thresholds. Offshore features such Rankin Bank support benthic communities, however, the modelling indicated that hydrocarbon contact would only occur at low thresholds below the ecological threshold. Notably, given the depths of offshore benthic communities such as Rankin Bank, the potential for impacts to benthic communities is considered to be significantly reduced given hydrocarbons will primarily feature in the upper water column.
The Ancient Coastline at 125 m Depth Contour and Continental Slope Demersal Fish Communities KEF, overlap the PAA (Figure 4-10). The Continental Slope Demersal Fish Communities KEF overlaps the Pluto Facility Operational Area. Other KEFs that overlap and are in proximity to the combined EMBA are listed in Section 4.7. These KEFs and geomorphic features may host relatively diverse or abundant fish assemblages compared to the otherwise relatively featureless continental shelf habitats of the NWMR. Impacts to KEFs are discussed below. In summary, impacts to these features are considered to be unlikely. Indirect impacts due to decreased habitat quality at these KEFs to pelagic and demersal fish communities are, therefore, considered unlikely. Impacts to pelagic fish (associated with receptors such as the Rankin Bank) from hydrocarbons are described herein. The values of these KEFs are described in further details within the Master Existing Environment (Woodside, 2022)):

Fish mortalities are rarely observed to occur as a result of hydrocarbon spills (International Tanker Owners Pollution Federation 2011b). This has generally been attributed to the possibility that pelagic fish are able to detect and avoid surface waters underneath hydrocarbon spills by swimming into deeper water or away from the spill affected areas. Fish that have been exposed to dissolved aromatic hydrocarbons are capable of eliminating the toxicants once placed in clean water. Hence individuals exposed to a spill are likely to recover (King et al. 1996). Where fish mortalities have been recorded historically, the spills (resulting from the groundings of the tankers Amoco Cadiz in 1978 and the Florida in 1969) have occurred in sheltered bays.

Laboratory studies have shown that adult fish are able to detect hydrocarbons in water at very low concentrations, and large numbers of dead fish have rarely been reported after hydrocarbon spills (Hjermann et al. 2007). This suggests that juvenile and adult fish are capable of avoiding water contaminated with high concentrations of hydrocarbons. However, sub-lethal impacts to adult and juvenile fish may be possible, given long-term exposure (days to weeks) to polyaromatic hydrocarbon (PAH) concentrations (Hjermann et al. 2007). While modelling of the loss of well containment indicates the potential EMBA for dissolved hydrocarbons is relatively extensive, no time-integrated exposure metrics were modelled; given the oceanographic environment within the EMBA, PAH exposures in the order of weeks for pelagic fish are not considered credible.

The effects of exposure to oil on the metabolism of fish appears to vary according to the organs involved, exposure concentrations and route of exposure (waterborne or food intake). Oil reduces the aerobic capacity of fish exposed to aromatics in the water and to a lesser extent affects fish consuming contaminated food (Cohen et al. 2005). The liver, a major detoxification organ, appears to be the organ where anaerobic activity is most impacted, probably increasing anaerobic activity to facilitate the elimination of ingested oil from the fish (Cohen et al. 2005).

Fish are perhaps most susceptible to the effects of spilled oil in their early life stages, particularly during egg and planktonic larval stages, which can become entrained in spilled oil. Contact with oil droplets can mechanically damage feeding and breathing apparatus of embryos and larvae (Fodrie and Heck 2011). The toxic hydrocarbons in water can result in genetic damage, physical deformities and altered developmental timing for larvae and eggs exposed to even low concentrations over prolonged timeframes (days to weeks) (Fodrie and Heck 2011). More subtle, chronic effects on the life history of fish as a result of exposure of early life stages to hydrocarbons include disruption to complex behaviours such as predator avoidance, reproductive and social behaviour (Hjermann et al. 2007). Prolonged exposure of eggs and larvae to weathered concentrations of hydrocarbons in water has also been shown to cause immunosuppression and allows expression of viral diseases (Hjermann et al. 2007). PAHs have also been linked to increased mortality and stunted growth rates of early life history (pre-settlement) of reef fishes, as well as behavioural impacts that may increase predation of post-settlement larvae (Johansen et al. 2017). However, the effect of a hydrocarbon spill on a population of fish in an area with fish larvae and/or eggs, and the extent to which any of the adverse impacts may occur, depends greatly on prevailing oceanographic and ecological conditions at the time of the spill and its contact with fish eggs or larvae. Hydrocarbons above ecological thresholds although not predicted to, may subsequently impact populations located near to the release location for the worst-case spill scenario, with lethal impacts not considered likely in this offshore environment. No significant escarpments, species of conservation significance, emergent features or areas of high biological productivity characteristically associated with the Continental Slope Demersal Fish Communities KEF have been observed in the PAA. Therefore, potential impacts to these regional-scale KEFs are not expected.

Protected Places

Receptors

The modelling of the worst-case LOWC indicated that Australian Marine Parks may be impacted by entrained (Gascoyne and Montebello Marine Park) and dissolved (Montebello Marine Park) hydrocarbons. No AMPs were predicted to potentially be contacted by surface hydrocarbons in the event of a worst-case spill scenario (RPS, 2024b).

Impacts

The Montebello Marine Park is the closest AMP to the PAA (overlapped by the facility Operational Area) predicted to be contacted by hydrocarbons. Impacts to this AMP are discussed below. Impacts to the natural, cultural, heritage and socio-economic values of the other three AMPs predicted to be contacted by hydrocarbons in a worst-case spill scenario are expected to be similar, however, of lower severity and duration due to their being at least 100 km further from the PAA.

Montebello Marine Park

The Montebello Marine Park comprises an area of about 3,413 km², all of which is zoned as a Multiple Use Zone (IUCN VI). The AMP ranges in water depths from less than 15 m up to 150 m.

The Montebello Marine Park is significant as it contains habitats, species and ecological communities' representative of the Northwest Shelf Province. It overlaps with The Ancient Coastline at the 125m Depth Contour KEF (see 'Key Ecological Features' above for a discussion of impacts to KEFs). The AMP provides connectivity between the deeper waters of the continental shelf and slope, and the adjacent Barrow Island and Montebello Islands State Marine Parks. A prominent seafloor feature in the AMP is Trial Rocks, which consists of two close coral reefs that are emergent at low tide. There is subsequently potential for impacts to shallow coral reef communities at Tryal Rocks, as discussed in the

section ‘Marine Primary Producers – Coral Reef’ above. The specific values of –he AMP and associated impacts are summarised here.

Natural values - The AMP includes diverse benthic and pelagic fish communities and ancient coastline thought to be an important seafloor feature (KEF) and a migratory pathway for humpback whales (BIA). The AMP supports a range of species, including those listed as threatened, migratory, marine and/or cetacean under the EPBC Act. BIAs within the AMP include breeding habitat for seabirds, internesting, foraging, mating and nesting habitat for marine turtles, a migratory pathway for humpback whales and foraging habitat for whale sharks. Impacts to the relevant species and BIAs are discussed in the sections above.

Cultural values - There is limited information about the cultural significance of this AMP, however, it is noted that sea country is valued for Indigenous cultural identity, health and wellbeing. Across Australia, Indigenous people have been sustainably using and managing their sea country for tens of thousands of years. Potential impacts to cultural values of the AMP will closely tie in with the impacts to the natural values of the Marine Park, as addressed above and below; and range from moderate mid-term potential impacts to major long-term potential impacts.

Heritage values - There are no World, National or Commonwealth heritage listings that apply to the AMP. Two historic shipwrecks are located within the Marine Park. Impacts to shipwrecks are discussed below under ‘Cultural Heritage’.

Social and economic values - Tourism, commercial fishing, mining and recreation are important activities in the AMP. These activities contribute to the wellbeing of regional communities and the prosperity of the nation. Impacts to tourism and recreation within the AMP are discussed with regard to offshore and nearshore waters in the sections ‘Tourism and Recreation’ below.

A worst-case hydrocarbon spill scenario has the potential to result in impacts to these AMPs that range from moderate, medium-term to major, long-term, with the consequence severity dependent on the actual timing, duration and extent of a spill.

Key Ecological Features

KEFs located within the combined EMBA are listed in Section 4.7 (described in the Master Existing Environment (Woodside, 2022)).

The modelling for the worst-case LOWC (MEE-01) predicted an overlap of entrained hydrocarbons above the ecological threshold with the following offshore features:

- Ancient coastline at the 125 m depth contour KEF
- Continental slope demersal fish communities KEF
- Glomar Shoals KEF

The Ancient Coastline, Glomar Shoals and Continental Slope Demersal Fish Communities are KEFs primarily defined by seabed geomorphological features and have been classified as KEFs in recognition of the potential for increased biological productivity and, therefore, ecological significance. Potential impacts to these KEFs include the direct and indirect impacts to benthic fauna / habitats and associated impacts to demersal fish populations described in the sections above.

In-water hydrocarbon exposure (entrained and dissolved) are only predicted to occur within the upper 0–10 m of the water column, therefore, benthic values of these KEFs are not anticipated to be impacted following a LOWC.

Notably, other than some small outcrops of hard substrate, no features indicative of the Ancient Coastline have been identified within the portion of this KEF overlapping the PAA (as per Section 4.7) These KEFs cover extensive areas (as listed in the Master Existing Environment (Woodside, 2022)) and, should impacts to receptors within the KEFs (e.g. benthic communities) occur, these would be anticipated to be short lived with no permanent impacts to the KEF.

Protected Species

A number of cetaceans were identified as potentially occurring with the PAA and the combined EMBA (see Section 4). In the event of a worst-case LOWC; surface, entrained and dissolved hydrocarbons exceeding environmental impact threshold concentrations may drift across habitat for oceanic cetacean species and the migratory routes and/or BIAs of cetaceans considered to be MNES (e.g. humpback whale and pygmy blue whale north and southbound migrations).

Cetaceans that have direct physical contact with surface, entrained or dissolved aromatic hydrocarbons may suffer surface fouling, ingestion of hydrocarbons (including from prey, water and sediments), aspiration of oily water or droplets and inhalation of toxic vapours (Deepwater Horizon Natural Resource Damage Assessment Trustees 2016). This may result in the irritation of sensitive membranes such as the eyes, mouth, digestive and respiratory tracts and organs, impairment of the immune system, neurological damage (Helm et al. 2015), reproductive failure, adverse health effects (e.g. lung disease, poor body condition) and, potentially, mortality (Deepwater Horizon Natural Resource Damage Assessment Trustees 2016).

Given cetaceans maintain thick skin and blubber, external exposure to hydrocarbons is more likely to result in irritation to the more exposed skin and eyes. Entrained hydrocarbons may also be ingested, particularly by baleen whales which feed by filtering large volumes of water. Fresh hydrocarbons (i.e. typically in the vicinity of the release location) may have a higher potential to cause toxic effects when ingested, while weathered hydrocarbons are considered to be less likely to result in toxic effects.

Given the non-persistent nature of the relevant hydrocarbons, such as Pluto condensate, and the relatively small floating hydrocarbon release of the worst-case LOWC EMBA (RPS Group, 2024a, 2024b) the area where potential impacts from inhalation and physical contact with surface slicks may occur would primarily be localised around the release location and impacts would most likely be expected to be limited to individuals that contact the slick, as discussed above. The modelling for surface hydrocarbons above the ecological threshold did not overlap any cetacean BIAs beyond those that are found within the PPA: the EIO pygmy blue whale migration and distribution BIA and the humpback whale migration (north and south) BIA.

There is a small overlap of the southern right whale migration and reproduction BIAs in proximity to the North West Cape with entrained and dissolved oil exceeding thresholds, however no floating oil is present in this area and no hydrocarbons are predicted to enter the Exmouth Gulf, which is used as a resting area by humpback whales during the southern migration and a reproduction area by the Southern Right Whale.

In a review of the impacts of large-scale hydrocarbon spills on cetaceans, it was found that exposure to oil from the Deepwater Horizon resulted in increased mortality to cetaceans in the Gulf of Mexico (DHNRDT 2016), and long-term population level impacts to killer whales were linked to the Exxon Valdez tanker spill (Matkin et al. 2008). Given the nature of the condensate (compared with crude oil from these two spills) and relatively small nature of the surface slick, such exposure impacts to cetaceans may not eventuate.

Geraci (1988) has identified behavioural disturbance (i.e. avoiding spilled hydrocarbons) in some instances for several species of cetacean, suggesting that cetaceans have the ability to detect and avoid surface slicks. However, observations during spills have also recorded larger whales (both mysticetes and odontocetes) and smaller delphinids traveling through and feeding in oil slicks. During the Deepwater Horizon spill cetaceans were routinely seems swimming in surface slicks offshore (and nearshore) (Aichinger Dias et al. 2017).

Suitable habitat for oceanic toothed whales (e.g. sperm whales) and dolphins (e.g. long-snouted spinner dolphin) is broadly distributed throughout the NWMR and, as such, whilst these species may be present within the combined EMBA, impacts from a spill are unlikely to affect an entire population. Notably, there are no known aggregation areas or BIAs for dolphins or whales within the PAA.

East Indian Ocean (EIO) Pygmy Blue Whale and Humpback Whale

EIO pygmy blue whales and humpback whales are known to migrate seasonally through the worst-case LOWC EMBA. A migration and distribution BIA for the pygmy blue whale overlaps the PAA and Facility and Xena-03 Operational Areas. A major spill event in June through to November would coincide with the humpback whale migration through the waters off the Pilbara, North West Cape and Shark Bay (outside the EMBA). A major spill in April to July or October to January would coincide with EIO pygmy blue whale migration (Double et al., 2010). Both the pygmy blue and humpback whales are baleen whales and are therefore most likely to be significantly impacted by toxic effects of the oil which can be engulfed during feeding. However, feeding during migrations is typically low level and opportunistic, with most feeding for both species occurring in the Southern Ocean (Thums et al., 2022). Subsequently the risk of ingestion of hydrocarbons through feeding is low.

Migrations of both pygmy blue whales and humpback whales are protracted through time and space (i.e. the whole population will not be within the worst-case LOWC EMBA at any one time), and as such, a hydrocarbon loss of containment is not considered likely to affect an entire population.

Dugong

There are no BIAs or known areas of aggregation in the offshore waters of either the combined EMBA or worst-case LOWC for the dugong. The BIAs are only found in nearshore waters, which is assessed below.

Summary

A worst-case hydrocarbon spill scenario has the potential to result in moderate, medium-term impacts to offshore cetacean species, with consequence severity dependent on the actual timing, duration and extent of a spill in relation to species' migratory movements and distributions.

Marine Turtles

Five of the six marine turtle species were identified as potentially occurring within the combined EMBA of all spill scenarios, with a number of BIAs and Habitat Critical areas also identified. A flatback turtle internesting BIA intersects the PAA and Facility and Xena-03 Operational Areas (see Section 4.6.2).

Modelling for the worst-case LOWC (MEE-01) predicted a low probability of overlap by entrained hydrocarbons within a number of BIAs; including the green turtle, hawksbill, and flat back turtle internesting buffer (RPS, 2024b). The modelling predicted no exposure to shorelines at any exposure threshold. Therefore, impacts to Habitat Critical areas are not anticipated following a LOWC.

Adult marine turtles exhibit no avoidance behaviour when they encounter hydrocarbon spills (National Oceanic and Atmospheric Administration 2010). Contact with surface slicks, or entrained hydrocarbon can therefore result in hydrocarbon adherence to body surfaces (Gagnon and Rawson 2010) causing irritation of mucous membranes in the nose, throat and eyes leading to inflammation and infection (National Oceanic and Atmospheric Administration 2010). Oiling can also irritate and injure skin, which is most evident on pliable areas such as the neck and flippers (Lutcavage et al. 1995). A stress response associated with this exposure pathway includes an increase in the production of white

blood cells and even a short exposure to hydrocarbons may affect the functioning of their salt glands (Lutcavage et al. 1995).

Hydrocarbons in surface waters may also impact turtles when they surface to breathe and inhale toxic vapours. Their breathing pattern, involving large 'tidal' volumes and rapid inhalation before diving, results in direct exposure to petroleum vapours which are the most toxic component of the hydrocarbon spill (Milton and Lutz 2003). This can lead to lung damage and congestion, interstitial emphysema, inhalant pneumonia and neurological impairment (National Oceanic and Atmospheric Administration 2010).

Given the hydrocarbon is expected to weather rapidly when released to the environment, relatively fresh entrained hydrocarbons (which are typically relatively close to the release location) are considered to have the greatest potential for impact. Given the non-persistent nature of the hydrocarbons and the relatively small floating hydrocarbon EMBA, the area where potential impacts from inhalation may occur would be localised around the release location. There is also minimal surface hydrocarbon contact with the marine turtle BIAs and Habitat Critical areas listed in Section 4.6.2.

Due to the offshore location and water depths within the PAA, this area is unlikely to represent important habitat for marine turtles. There are also no known areas of aggregation (i.e. BIAs, Habitat Critical to Survival) for marine turtles within the PAA.

The d LOWC EMBA only overlapped the outer edges of a few marine turtle internesting BIAs, with no overlap of Habitat Critical to Survival areas for marine turtles (RPS, 2024b). Marine turtles are, therefore, likely to be present in the offshore waters of the EMBA, particularly as they are a migratory species which often travel large distances during migration periods. Important areas of aggregation for foraging, nesting and mating are typically associated with nearshore islands along the Pilbara and Gascoyne coastlines, as opposed to offshore waters.

Summary

In the event of a LOWC, there is potential that surface, entrained and dissolved hydrocarbons exceeding environmental impact threshold concentrations will be present in offshore waters. Therefore, a hydrocarbon spill may disrupt a portion of marine turtle populations for the green, flatback, hawksbill, loggerhead and/or leatherback turtle. However, there is considered to be no threat to overall population viability given the non-persistent nature of predicted hydrocarbons.

Sea Snakes

A number of sea snake species which are listed Marine under the EPBC Act were identified by the PMST as potentially occurring within the combined EMBA. Two critically endangered species were identified as known to occur within the EMBA, the short-nosed sea snake and the leaf-scaled sea snake.

Impacts to seasnakes from direct contact with hydrocarbons are likely to result in similar physical effects to those recorded for marine turtles and may include potential damage to the dermis and irritation to mucus membranes of the eyes, nose and throat (International Tanker Owners Pollution Federation 2011a). They may also be impacted when they return to the surface to breathe and inhale the toxic vapours associated with the hydrocarbons, resulting in damage to their respiratory system. Oiling of the sensory and respiratory areas on the body of the snake is shown to prevent the mouth from opening and obstructing the nares and airway which can interfere with feeding and result in asphyxiation. Oiling of the outer body surface has shown to inhibit their movements which can lead to overexertion and drowning. Sea snakes are also capable of transcutaneous oxygen uptake, therefore oiling to the surface of their cutaneous layer can compromise this ability (Yaghmour et al., 2022).

In general, seasnakes frequent the waters of the continental shelf area around offshore islands and potentially submerged shoals (water depths <100 m) (impacts described below). However, it is acknowledged that seasnakes may be present in the PAA and within the EMBA. Their abundance is not expected to be high, given the water depth and offshore environment.

In summary, a hydrocarbon spill may have a minor disruption to some individuals in the offshore environment. Population level impacts to seasnake species are not, however, considered credible.

Sharks and Rays

A number of shark and ray species were identified as potentially occurring within the PAA and/or combined EMBA (see Section 0). Two foraging BIAs for the whale shark, overlaps the combined EMBA; foraging (northward from Ningaloo along the 200 m isobath; PAA, combined EMBA) and foraging (high prey density - Ningaloo Marine Park; EMBA). Whale sharks are, therefore, likely to transit the open offshore waters within the EMBA whilst they migrate to and from Ningaloo Reef between July and November. Modelling for the worst-case LOWC scenario (MEE-01) predicted exposure to only one of the whale shark foraging BIA; foraging northward from Ningaloo along the 200 m isobath (RPS, 2024b).

Other listed Threatened pelagic species identified in the PMST report as potentially occurring within the combined EMBA include the white shark and grey nurse shark. There are no known areas of aggregation for these species in the offshore waters of the combined EMBA.

Impacts to sharks and rays may occur through direct contact with hydrocarbons and contaminate the tissues and internal organs either through direct contact or via the food chain (i.e. consumption of prey). As gill breathing organisms, sharks and rays may be vulnerable to toxic effects of dissolved hydrocarbons (entering the body via the gills) and entrained hydrocarbons (coating of the gills inhibiting gas exchange). In the offshore environment, it is probable that

pelagic shark species, such as the whale shark, are able to detect and avoid surface waters underneath hydrocarbon spills by swimming into deeper water or away from the affected areas.

Impacts to whale sharks from a hydrocarbon spill will depend on the timing of the spill, however; whale sharks as a pelagic species are expected to demonstrate avoidance behaviour and population level impacts are not anticipated.

Seabirds

A number of EPBC Act listed Threatened and/or Migratory seabird and shorebird species were identified by the PMST as potentially occurring within the PAA and/or combined EMBA (see Section 4.6.4). The EMBA for the worst-case LOWC (MEE-01) also predicted exposure to a number of seabird BIAs; including the wedge-tailed shearwater roseate tern breeding and foraging BIAs.

Seabirds and migratory shorebirds are particularly vulnerable to contact with floating hydrocarbons, which may mat their feathers. This may lead to hypothermia from loss of insulation and ingestion of hydrocarbons when preening to remove hydrocarbons; both impacts may result in mortality (Hassan and Javed 2011). Notably, the credible loss of well containment scenarios result in a relatively small floating hydrocarbon EMBA which is primarily centred around the release location. Subsequently, the potential for seabird exposure to floating hydrocarbons is considered to be low. Migratory shorebirds are considered unlikely to interact with spilled hydrocarbons as they are not expected to stop over within the offshore waters surrounding the PAA during their migrations between mainland/island areas. Many seabirds and migratory shorebirds forage over extensive areas (some hundreds of kilometres out to sea) so individuals may be present. Seabirds which are roosting or resting on the Pluto platform may also be impacted, however; these would be individuals and not populations.

Seabirds which plunge dive to feed on prey may contact entrained or dissolved hydrocarbons, most likely through ingestion of prey which are contaminated. Impacts to prey abundance as a result of hydrocarbons may also indirectly impact individuals.

There are several breeding BIAs for seabirds and migratory shorebirds that overlap with the combined EMBA and breeding BIAs within the LOWC EMBA, which are associated with breeding and nesting at locations along the Gascoyne and Pilbara coastlines (including near-shore islands). The outer edge of a breeding BIA for the wedge-tailed shearwater overlaps with the PAA, and another is less than a kilometre away. It is likely that individual birds may, therefore, transit the PAA.

However, the EMBA for the worst-case LOWC predicted no impact to shorelines at any thresholds, therefore impacts to breeding sites are not anticipated in the event of a LOWC.

Given the relatively low area of floating hydrocarbons and the lack of key aggregation areas for migratory shorebirds and seabirds within the PAA, impacts at the population level are not anticipated. Individual animals may, however, be impacted with potential fatalities occurring from oiling.

Nearshore Waters (Mainland and Islands)

The combined EMBA overlaps the nearshore waters of a few shorelines and islands. However, the modelling for the LOWC scenario EMBA (MEE-01), predicted no shoreline, entrained or dissolved hydrocarbons (at or above the defined ecological thresholds) to potentially contact shallow, nearshore waters of identified islands and mainland coastlines. Therefore, impacts to nearshore waters is not predicted from a MEE-01 scenario.

Submerged Shoals and Banks

The combined EMBA overlaps a few submerged shoals and banks (Section 4.5). However, the modelling for the LOWC scenario EMBA (MEE-01), did not predict entrained or dissolved hydrocarbons (at or above the defined ecological threshold) to contact any submerged shoals and banks. Therefore, impacts are not anticipated for a MEE-01 scenario at these receptors.

All Settings

Coral Reefs

Receptors

There are no coral reef habitats located within the PAA. The closest coral reef habitats exist at Rankin Bank, Muiron Islands, the Montebello Islands, Barrow Island, Dampier Archipelago, Lowendal Island and numerous receptors associated with Ningaloo Reef, including the reef itself (see Section 4.5).

As discussed in ‘Benthic Fauna’, no dissolved or entrained hydrocarbons above the ecological threshold are anticipated to contact these known coral habitat areas for MEE-01. Therefore, impacts to coral reef habitats at these features are not anticipated during this scenario.

Modelling for the vessel separation scenario (MEE-04) also predicted low probability of hydrocarbon contact at the Montebello Shoals, Outtrim Patches, and Tryal Rocks.

Productivity

Primary production by plankton (supported by sporadic upwelling events in the offshore waters of the NWS) is an important component of the primary marine food web. Planktonic communities are generally mixed; including phytoplankton (cyanobacteria and other microalgae) and secondary consuming zooplankton, such as crustaceans (e.g. copepods), and the eggs and larvae of fish and invertebrates (meroplankton).

Plankton exposure to hydrocarbons in the water column can result in changes in species composition with declines or increases in one or more species or taxonomic groups (Batten et al. 1998). Phytoplankton may also experience decreased rates of photosynthesis (Tomajka 1985). For zooplankton, direct effects of contamination may include toxicity, suffocation, changes in behaviour, or environmental changes that make them more susceptible to predation.

Impacts on plankton communities are likely to occur in areas where entrained or dissolved aromatic hydrocarbon threshold concentrations are exceeded, but communities are expected to recover relatively quickly (within weeks or months). This is due to high population turnover with copious production within short generation times that also buffers the potential for long-term (i.e. years) population declines (International Tanker Owners Pollution Federation 2011a). Therefore, any impacts to exposed planktonic communities present within the EMBA are anticipated to be short-term.

Filter Feeders

Hydrocarbon exposure to offshore filter feeding communities may occur, however, due to the hydrocarbon modelling predicting no contact above the ecological threshold and the anticipated depth of the entrained and dissolved aromatic hydrocarbons. See discussion above on potential impacts.

Nearshore filter feeders that are present in shallower water <20 m may potentially are unlikely to be impacted by entrained hydrocarbon based on the predicted modelling.

The released hydrocarbons are predicted to be weathered and less likely to result in toxic effects in comparison to fresh hydrocarbons (i.e. typically in the vicinity of the release location) before they reach any potential filter feeder community. Therefore, impacts such as localised, long-term effects to community structure and habitat, are not predicted.

Seagrass Beds, Macroalgae and Mangroves

No primary macroalgal / seagrass communities identified within the worst-case LOWC EMBA (RPS, 2024b). Therefore, these communities not predicted to be exposed to hydrocarbons above the ecological threshold.

Summary of Potential Impacts to Socio-economic Values	
Setting	***Receptor Group***
All Settings	***Cultural Features and Heritage Values*** Through consultation and review of available literature (Section 4.9), Woodside understands that sea country, including marine ecosystems and species, archaeological heritage and heritage sites, marine parks, as well as intangible cultural heritage may be impacted in the event of a hydrocarbon release from a loss of well containment. Cultural features and heritage values that have the potential to be impacted include: Marine ecosystems and species: Marine ecosystems may hold both cultural and environmental value to Traditional Custodians (see Section 4.9), with cultural and environmental values intrinsically linked (DCCEEW 2023, MAC 2021 as cited in Woodside 2023a). It necessarily follows that an impact to marine ecosystems has the potential to impact cultural features where the impact is detectable within Sea Country— the seascape which Traditional Custodians view, interact with or hold knowledge of. The EMBA is known to include habitat for culturally important species such as whales, whale sharks, turtles, dugongs, plankton, and seagrass (Sections 4.6 and 4.9). In the event of a worst-case release of hydrocarbons individual fauna may be directly impacted or impacted through temporary degradation of their habitats, however, no population level impacts as expected. Impacts are not expected to occur to ecologically significant proportions of the populations of the species, nor expected to result in a decrease of the quality of the habitat such that the extent of these species is likely to decline. As such, cultural values and intangible cultural heritage associated with these species are expected to be maintained. Heritage Sites: The combined EMBA overlaps a number of native features and heritage values (see Section 4.9) Any oil (combined EMBA – not applicable to MEE01) that reaches the shoreline has potential to impact on indigenous heritage places along the coastline. In the unlikely event of a hydrocarbon release, shoreline accumulation may affect sensitive artefacts or areas, which could damage their heritage value. Marine Parks: The combined EMBA overlaps a number of AMPs under North-West Marine Parks Network Management Plan 2018 and a few State Marine Parks. Management Plans for these parks recognise cultural values of Indigenous groups (Section 4.9). Due to the low maximum concentrations predicted to reach any marine park, it is not anticipated that their values will be compromised.

	Intangible cultural heritage: Impacts may occur to intangible cultural values such as songlines; creation/dreaming sites, sacred sites, ancestral beings; cultural obligations to care for Country; knowledge of Country/customary law and transfer of knowledge; connection to Country; Access to Country; kinship systems and totemic species, resource collection. Related intangible cultural heritage may include the transmission of cultural knowledge about whales and whale behaviour, including birthing areas, whale communication and migratory patterns. Such cultural knowledge may be associated with various cultural functions and activities that support the social and economic life of a community (Fijn, 2021). Inter-generational transmission of cultural knowledge (including songlines) relating to marine reptiles may be impacted where changes results in reduced sightings (e.g., through population decline, changes to migration routes or changes to migration seasonality). This transfer of knowledge may be integral to managing a group's intangible cultural heritage (UNESCO, 2003). In the unlikely event of a hydrocarbon release, intangible cultural heritage values may be impacted.
Offshore Waters	***Fisheries – Commercial*** Please refer to Section 4.10.1 for a list of the fisheries occurring within the EMBA, and for those considered to have potential for impact with the Petroleum Activities Program. A worst-case hydrocarbon spill, as modelled for this EP, is not considered likely to cause significant direct impacts on the target species of these commercial fisheries, as discussed below. Refer to above sections for a discussion of impacts to spawning. Fish exposure to hydrocarbon can result in 'tainting' of their tissues. Even very low levels of hydrocarbons can impart a taint or 'off' flavour or smell in seafood. Tainting is reversible through the process of depuration which removes hydrocarbons from tissues by metabolic processes, although it is dependent upon the magnitude of the hydrocarbon contamination. Fish have a high capacity to metabolise these hydrocarbons while crustaceans (such as prawns) have a comparably reduced ability (Yender et al. 2002). Seafood safety is a concern associated with spill incidents. Therefore, actual or potential contamination of seafood can affect commercial and recreational fishers and can impact seafood markets long after any actual risk to seafood from a spill has subsided (Yender et al. 2002). A major hydrocarbon spill would result in the establishment of an exclusion zone around the spill affected area. There would also be a temporary prohibition on fishing activities for a period of time. Subsequently, there is potential for economic impacts to the affected commercial fishing operators. Additionally, hydrocarbon can foul fishing equipment such as traps and trawl nets, requiring cleaning or replacement. Impact to fishers would subsequently be dependent on the extent of the spill and resulting exclusion zone and may cause economic impacts due to fishing bans, damaged equipment and/or consumer perception of seafood safety. These impacts would not be expected to be long term or affect the viability of the fishery.
	Tourism and Recreation Tourism would likely be adversely affected if a visible surface slick entered areas of tourism activity. Spill modelling predicted low probability of hydrocarbon contact to the closest tourism area, such as the Montebello MP, Rankin Bank, and the Dampier AMP. These areas have some seasonal charter boat operators and recreational fishing activities, mainly concentrated around the islands. Recreational fishers predominantly target tropical species, such as emperor, snapper, grouper, mackerel, trevally and other game fish. Recreational angling activities include shore-based fishing, private boat and charter boat fishing, with the peak in activity between April and October (Smallwood et al. 2011). Impacts on species that are recreationally fished are described above under 'Commercial Fisheries' and 'Pelagic and Demersal Fish'. In the event of a major spill, tourists and recreational users may also avoid areas due to perceived impacts, including after the hydrocarbon spill has dispersed. There is also the potential for stakeholder perception that this remote environment will be contaminated over a larger area and for the longer term resulting in a prolonged period of tourism decline. Oxford Economics (2010) assessed the duration of hydrocarbon spill in relation to tourism impacts and found that on average, it took 12 to 28 months to return to baseline visitor spending. There is likely to be significant impacts to the tourism industry, wider service industry (hotels, restaurants and their supply chain) and local communities in terms of economic loss as a result of spill impacts to tourism. Recovery and return of tourism to pre-spill levels will depend on the size of the spill, effectiveness of the spill clean-up and change in any public misconceptions regarding the spill (Oxford Economics 2010).

	However, based on the low levels of tourism and recreation at these locations (compared to other locations such as the Ningaloo Coast), and the low probability of hydrocarbons above the socio-economic thresholds contacting these areas impacts are not expected to be significant.
	Offshore Oil and Gas Infrastructure Surface hydrocarbons from a worst-case spill may affect production from existing offshore petroleum facilities (e.g. platforms and FPSOs). For example, facility water intakes for cooling and fire hydrants could be shut off which could in turn lead to the temporary cessation of production activities. Spill exclusion zones established to manage the spill could also prohibit activity support vessel access as well as tankers approaching facilities on the NWS. However, no petroleum operations are located within the spill EMBA that would likely be affected. The closest oil and gas operation is the Wheatstone platform (operated by Chevron). Other nearby facilities include the Woodside-operated Angel platform, GWA and the Santos operated John Brookes platform (Section 4.10.5). Operation of these facilities is unlikely to be affected in the event of a worst-case loss of well containment.

MEE-01 Well Loss of Containment – Risk Analysis
A bowtie risk analysis was undertaken to assess MEE-01; refer to the below figures for bowtie diagrams which were an output of Woodside's risk analysis process.

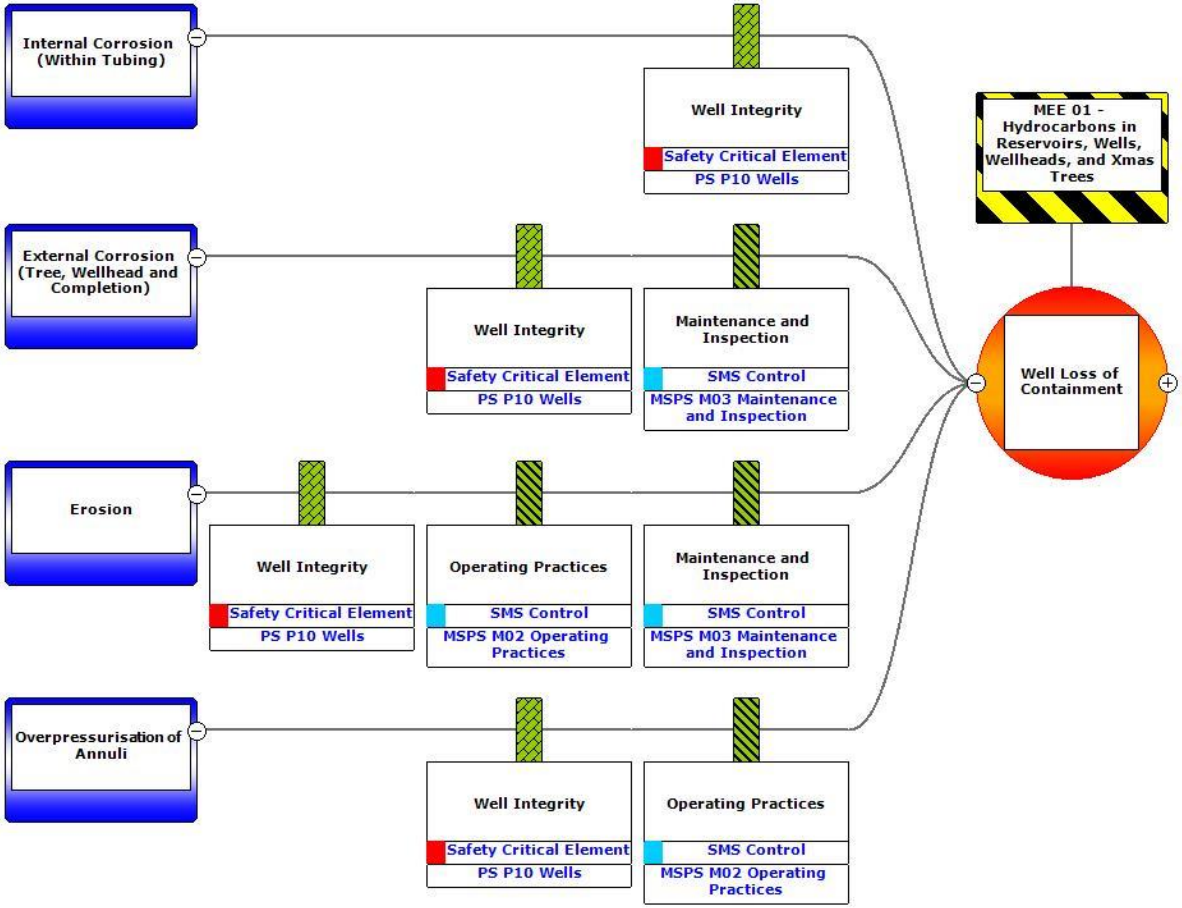

Figure 6-15: MEE-01 Wells Loss of Containment (Causes 1–4)

Risk Based Analysis				
For risks identified as MEEs, a detailed risk-based Bowtie Analysis (as outlined in Section 2.7.3) has been used to identify, analyse and demonstrate that controls in place reduce the risk associated with each MEE to ALARP. Controls have been selected following hierarchy of control principles and consider independence of each barrier and their type of effect in controlling the hazardous event.				

MEE-01 Loss of Well Containment – Demonstration of ALARP ALARP Control Measures				
Hierarchy	***Control / Barrier***	***SCE / Management System Reference***	***Type of Effect***	***Control Adopted***

Application of Woodside's Risk Management Procedures and implementation of the WOMP ensures the continuous identification of hazards, systematic assessment of risks, and ongoing assessment of alternative control measures to reduce risk to ALARP, which includes:

- ongoing hazard identification, risk assessment and the identification of control measures
- ongoing integrity management of hardware control measures in accordance with the operational performance standards which define requirements to be suitably maintained, such that they retain effectiveness, functionality, availability and survivability
- well integrity codes and standards.

For each SCE, detailed requirements for equipment functionality, availability, reliability and survivability are incorporated into SCE Performance Standards which also include the relevant assurance tasks (e.g. inspection, maintenance, testing and monitoring requirements) to ensure technical integrity.

Bowtie analysis was undertaken to assess MEE-01, with review of well integrity formal safety and design studies.

Company Values

Woodside's corporate values require all personnel to comply with appropriate policies, standards, procedures and processes while being accountable for their actions and holding others to account in line with Our Values. As detailed above, the Petroleum Activities Program is undertaken in line with these policies, standards and procedures that include suitable controls to prevent loss of well containment, and response should a loss of well containment occur.

Societal Values

Due to the Petroleum Activities Program's proximity to sensitive receptors (e.g. Barrow Island, Ningaloo Coast) and the potential extent of the wider EMBA, a major hydrocarbon spill could have impacts to a community. However, due to the low maximum concentrations predicted to reach sensitive receptors, it is not anticipated that their values will be compromised. Therefore, the LOWC risk rating presents a Decision Type B in accordance with the decision support framework described in Section 2.6.1. Extensive consultation was undertaken for this program to identify the views and concerns of relevant persons, as described in Section 5.

Woodside has sent an Activity Factsheet to all identified relevant persons regarding the Petroleum Activities Program (Section 5). Woodside has consulted with AMSA and the WA Department of Transport (DoT) on spill response strategies. In accordance with the MoU between Woodside and AMSA, a copy of the Oil Pollution First Strike Plan was provided to AMSA.

ALARP Statement:

On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts and risks of a very low likelihood unplanned hydrocarbon release as a result of a loss of well containment.

The principle of inherent safety and environmental protection is based on prevention of the MEE through design of well integrity, ensuring the wells are operated within their design envelope through operating practices, and assurance through maintenance and inspection. If hydrocarbon loss of containment occurs, mitigation measures are in place to minimise the consequence, by limiting the inventory which can be released and implementing remediation.

The controls in place for prevention and mitigation of MEEs are specified and assured through implementing the WOMP, SCE management procedures including performance standards for SCEs, and Management System Performance Standards (MSPSs) for Safety Critical Management System Controls.

The application of Woodside Risk Management Procedures and implementation of the WOMP ensures the continuous identification of hazards, systematic assessment of risks and ongoing assessment of alternative control measures to reduce risk to ALARP, which includes:

- ongoing hazard identification, risk assessment and the identification of control measures
- ongoing integrity management of hardware control measures in accordance with the technical performance standards which define requirements to be suitably maintained, such that they retain effectiveness, functionality, availability and survivability,
- well integrity codes and standards.

Given the controls in place to prevent and control loss of containment events and mitigate their consequences, it is considered that MEE risk associated with loss of well containment is managed to ALARP.

Demonstration of Acceptability

Acceptability Statement:

Loss of well containment has been evaluated as having a 'moderate' risk rating, based on a C consequence level and a 'highly unlikely' likelihood. As per Section 2.6.3, Woodside considers C+ consequence risks as acceptable if ALARP is demonstrated using good industry practice, consideration of company and societal values and risk based analysis, if legislative requirements are met and societal concerns are accounted for and the alternative control measures are grossly disproportionate to the benefit gained.

Acceptability is demonstrated with regard to the considerations below.

Principles of Ecologically Sustainable Development

Woodside is a proud Australian company that is here for the long term. Woodside has a strong history of exploration and development of oil and gas reserves in the north west of Western Australia with an excellent environmental record, while providing revenue to State and Commonwealth Governments, returns to shareholders, jobs and support to local communities. Titles for oil and gas exploration are released based on commitments to explore with the aim of uncovering and developing resources. It is under the lease agreement that Woodside has determined the potential to develop the hydrocarbon fields for which acceptance of this EP is sought under the Environment Regulations.

Woodside has established a number of research projects in order to understand the marine environments in which they operate, notably in the Exmouth Region and the Kimberley Region, including Rankin Bank, Glomar Shoal, Enfield Canyon and Scott Reef. Where scientific data does not exist, Woodside assumes a pristine natural environment exists, and therefore implements all practicable steps to prevent damage. Woodside's corporate values (Appendix A) require that we consider the environment and communities in which we operate when making decisions.

Woodside looks after the communities and environments in which it operates. Risks are inherent in petroleum activities; however, through sound management and systematic application of policies, standards, procedures and processes, Woodside considers that despite this risk, the extremely low likelihood of loss of well containment is acceptable.

Internal Context

The Petroleum Activities Program is consistent with Woodside corporate policies, standards, procedures, processes and training requirements as outlined in the Demonstration of ALARP and EPOs, including:

- Woodside Environment and Biodiversity Policy (Appendix A)
- Woodside Risk Management Policy (Appendix A)
- the SCE Performance Standards developed and implemented for the facility
- Hydrocarbon spill preparedness and response strategies are considered applicable to the nature and scale of the risk, and associated impacts of the response are reduced to ALARP (Section 2.8.1)

Woodside corporate values include working sustainably, with respect to the environment and communities in which we operate, listening to internal and external stakeholders and considering HSE when making decisions. Consultation, outlined below, has been undertaken prior to the Petroleum Activities Program.

External Context – Societal Values

Woodside recognises that its licence to operate from a regulatory and societal perspective is based on historical performance, complying with appropriate policies, standards and procedures, and understanding the expectations of external stakeholders. External stakeholder consultation, outlined below, has been undertaken prior to the Petroleum Activities Program:

- Woodside has consulted with AMSA and WA DoT on spill response strategies. In accordance with the Memorandum of Understanding between Woodside and AMSA, a copy of the Oil Pollution First Strike Plan was provided to AMSA and DoT.
- Other relevant persons were consulted (Section 5) and their feedback incorporated into this EP where appropriate.
- By providing hydrocarbon spill response measures that are commensurate with the risk rating, location and sensitivity of the receiving environment (including social and aesthetic values), Woodside believes this addresses societal concerns to an acceptable level.

Other Requirements (includes Laws, Policies, Standards and Conventions)

The Petroleum Activities Program is consistent with laws, policies, standards and conventions, including:

- accepted Safety Case (as per the requirements of the OPGGS (Safety) Regulations 2009
- Mutual Aid MoU for relief well drilling is in place
- accepted WOMP as per the requirements of the OPPGS (Resource Management and Administration) Regulations 2011
- notification of reportable and recordable incidents to NOPSEMA, if required, in accordance with Section 7.13.5.

The Petroleum Activities Program is consistent with the objectives in the Ningaloo management plans (Management Plan for Ningaloo Marine Park and Muiron Islands Marine Management Areas, Ningaloo Marine Park Management Plan) in relation to water quality, coral, shoreline and intertidal, macroalgal, seagrass, mangroves, seabirds and social and economic values.

6.8.6 Unplanned Hydrocarbon Release: Subsea Equipment Loss of Containment (MEE-02)

Context		
Flowline and Riser System – Section 3.4.3 Pipeline and 6-inch Chemical Supply Line – Section 3.4.4 Subsea Infrastructure – Section 3.4.5	Physical Environment – Section 4.4 Habitats and Biological Communities – Section 4.5 Protected Species – Section 4.6 Protected Places – Section 4.8 Socio-economic Environment – Section 4.9	Consultation – Section 5

Impacts and Risks Evaluation Summary

Source of Risk	***Environmental Value Potentially Impacted***							***Evaluation***						
	Soil and Groundwater	Marine Sediment	Water Quality	Air Quality (incl Odour)	Ecosystems / Habitat	Species	Socio-economic	Decision Type	Consequence	Likelihood	Risk Rating	ALARP Tool	Acceptability	Outcome
Surface or subsea release from flowline, pipeline and riser to the marine environment and atmosphere within PSZ and to mid-point of export pipeline		x	x	x	x	x	x	B	C	1	M	LCS GP PJ RBA CV SV	Acceptable if ALARP	EPO 14
Subsea release from export pipeline to the marine environment and atmosphere between mid-point of export pipeline to shore		x	x	x	x	x	x	B	B	1	M			

Description of Source of Risk

A loss of containment from subsea equipment, including the export pipeline may result in the release of large volumes of hydrocarbon inventory to the environment. The worst-case scenario is based on a release (such as a major rupture or failure) and assumes depressurisation and release of the pipeline inventory prior to and following activation of the emergency shut down systems. Due to the potential consequence of a worst-case subsea equipment loss of containment, this risk is considered to be an MEE (MEE-02).

The potential hazard sources that could instigate a loss of containment from the export pipeline are:

- internal corrosion
- external corrosion
- erosion (for flowlines)
- overpressure
- equipment fatigue and mechanical failures

- pipeline stability and freespans
- anchor impact/dragging
- loss of control of suspended load from supply/ support boat.

Escalation from other MEEs can cause subsea equipment loss of containment:

- loss of Structural Integrity (MEE-03)
- loss of Marine Vessel Separation (MEE-04)
- loss of Control of Suspended Load from facility lifting operations (MEE-05)

The potential for subsea loss of containment events within the PSZ to escalate due to fire and/or explosion events is considered in Section 6.8.7 Loss of Structural Integrity (MEE-03).

A number of common failure causes due to human error and SCC failures are presented in the generic Human Error and SCE Failure bowties in Section 6.8.10

Subsea Export Pipeline Loss of Containment – Credible Scenarios

The credible worst-case hydrocarbon release caused by subsea loss of containment is a release from the export pipeline.

Woodside evaluated three locations for a loss of containment of the export pipeline, as the location will influence the potential environmental consequence. These included:

- A seabed loss of containment of hydrocarbons from the export pipeline approximately 29 km shorewards along the pipeline from Pluto A. The approximate mid-point location was identified as the point closest to offshore sensitive environmental receptors (i.e. Montebello Islands).
- A seabed loss of containment of hydrocarbons from the export pipeline at the State waters 3nm boundary to consider potential near-shore impacts.
- A surface loss of containment of hydrocarbons from the export pipeline at the riser platform. However, based on the predicted annualised probability and previous modelling studies, the subsea scenario (1) was predicted to be the worst-case scenario within the PSZ, and therefore a surface scenario was not modelled.

The characteristics of the release scenarios modelled are summarised in Table 6-33.

Refer to Section 6.8.2 for additional information on modelling methods and environmental impact, thresholds and hydrocarbon characteristics.

Table 6-33: Summary of worst-case subsea pipeline loss of containment release scenarios

Scenario	Hydrocarbon	Duration (hrs)	Depth (m)	Latitude	Longitude	Total Condensate Release Volume (Sm3)
Scenario 3: Loss of containment of the export pipeline 29 km from Pluto A	Pluto condensate	8	78	20° 3’ 55.1” S	115° 36’ 1.1” E	472
Scenario 4: Loss of containment of the export pipeline at the State Waters boundary	Pluto condensate	8	41	20° 21’ 0.81” S	116° 42’ 12.41” E	662

Decision Type, Risk Analysis and ALARP Tools

Woodside has a good history of implementing industry standard practice in subsea system design and construction. In the company’s recent history, it has not experienced any pipeline integrity events that have resulted in significant releases or significant environmental impacts. The facility has never experienced a worst-case loss of pipeline and riser containment in its operational history.

Prevention and Mitigation

The main measures in place to prevent and mitigate consequences of a subsea equipment loss of containment event are:

- Pipeline design and integrity management.
- Sand management systems.

- Process control and emergency shutdown systems.
- Operating practices.
- Maintenance and inspection
- Emergency and hydrocarbon spill response

Decision Type

Decision Type B has been applied to this risk under the Guidance on Risk Related Decision Making (Oil and Gas UK 2014). This reflects the complexity of the risk, the higher potential consequence and stakeholder implications should the event be realised. To align with this decision type, a further level of analysis has been applied using risk based tools including the bowtie methodology (described in Section 2.7.3) and hydrocarbon spill trajectory modelling (described in Section 6.8.2). Company and societal values were also considered in the demonstration of ALARP and acceptability, considered through internal reviews, and stakeholder consultation (Section 5).

The release of hydrocarbons as a result of subsea equipment loss of containment is considered a Major Environment Event (MEE-02). The hazard associated with this MEE is hydrocarbons in subsea infrastructure tied to or originating from the facility.

Quantitative Spill Risk Assessment

Spill modelling of each of the subsea loss of containment credible spill scenarios was undertaken by RPS (RPS, 2024c, 2024d), on behalf of Woodside, to determine the fate of hydrocarbon released in each scenario based on the assumptions outlined in Section 6.8.2. Modelling was undertaken over all seasons to address year-round operations. This is considered to provide a conservative estimate of the EMBA, and the potential impacts from the identified worst-case credible release volumes for all subsea loss containment scenarios.

Hydrocarbon Characteristics

Refer to Section 6.8.2 for a discussion of Pluto condensate characteristics.

Subsea Plume Dynamics

The loss of subsea containment scenarios will result in a buoyant plume of hydrocarbons, which has been modelled using the OILMAP-Deep numerical model for Scenarios 3A and 7 (summarised in Table 6-34 and Table 6-35, respectively).

Table 6-34: Near-field subsurface discharge model parameters, OILMAP deep model, for the loss of containment of the export pipeline at 29 km from Pluto A for hour 1

	Parameter	Scenario 3
Inputs	Release depth (m below sea level)	78
	Oil density (g/cm3) (at 15°C)	0.733
	Oil viscosity (cP) (at 15°C)	0.58
	Oil temperature (°C)	95
	Gas:Oil ratio (m3/m3) [scf/bbl]	9,264/ 52,016
	Oil flow rate (m3/hr)	2,444
	Hole diameter (m) [in]	1.2 [47.2]
Outputs	Plume diameter (m)	10
	Plume height (m above seabed	78
	Plume initial rise velocity (m/s)	33
	Plume terminal rise velocity (m/s)	27
Predicted oil droplet size distribution	20% droplets of size (µm)	2,586
	20% droplets of size (µm)	3,776
	20% droplets of size (µm)	4,908
	20% droplets of size (µm)	6,380
	20% droplets of size (µm)	9,316

Table 6-35: Near-field subsurface discharge model parameters, OILMAP deep model, for the loss of containment of export pipeline at State Water boundary for 1 hour

	Parameter	Scenario 4
Inputs	Release depth (m below sea level)	41
	Oil density (g/cm3) (at 15°C)	0.733
	Oil viscosity (cP) (at 15°C)	0.58
	Oil temperature (°C)	95
	Gas:Oil ratio (m3/m3) [scf/bbl]	7,495/ 42,082
	Oil flow rate (m3/hr)	3,063
	Hole diameter (m) [in]	1.2 [47.2]
Outputs	Plume diameter (m)	5.3
	Plume height (m above seabed	41
	Plume initial rise velocity (m/s)	50.9
	Plume terminal rise velocity (m/s)	41.8
Predicted oil droplet size distribution	20% droplets of size (µm)	2,024
	20% droplets of size (µm)	2,956
	20% droplets of size (µm)	3,842
	20% droplets of size (µm)	4,994
	20% droplets of size (µm)	7,293

Likelihood

In accordance with the Woodside Risk Matrix, given prevention and mitigation measures in place, worst case subsea loss of containment likelihood has been assessed as 1 (Highly Unlikely).

Subsea loss of containment full bore export pipeline loss of containment events where the zone of contact potentially includes shoreline impact or impact on nearshore Marine Parks / Reserves with low associated probability: Formal safety studies indicate the frequency of this event is calculated to be 3.03E-05, or 1 in 33,000 years. This means with outcome mitigation factored in, the likelihood is considered 1 “Highly Unlikely”

For full bore loss of containment releases from the export riser or pipeline at any point within the platform PSZ, consequences for the worst-case credible spill where the zone of contact does not include predicted shoreline impact or impact on nearshore Marine Parks / Reserves; Likelihood is estimated to be 3.6E-05 per year, or 1 in 27,470 years.

Similarly, for releases at the platform location from the production flowlines or risers; the frequency of this event is estimated to be 9.8E-05, or 1 in 10,200 years. Therefore both scenarios have consequences likelihood considered as 1 “Highly Unlikely”.

Consequence

The spatial extent and fate (including weathering) of the spilled hydrocarbon were considered during the impact assessment for a worst-case subsea or riser loss of containment (presented in the following section). These considerations were informed primarily by the outputs from the numerical modelling studies undertaken by RPS (2024c, 2024d), available information on environmental sensitivities that may credibly be impacted in the event of a worst-case spill and relevant literature and studies considering the effects of hydrocarbon exposure.

Consequence Assessment

Environment that May Be Affected

Scenario 3 - Loss of containment of the export pipeline at 29 km from Pluto A

Surface Hydrocarbons

The hydrocarbon spill modelling indicated that concentrations of floating hydrocarbons equal to or greater than the 10 g/m2 threshold could potentially be found, in the form of slicks, approximately 10 km north-west, from the release location. The only receptor modelled with a probability of contact at the ecological threshold (10 g/m2) was Montebello AMP (90%).

Dissolved Hydrocarbons

Dissolved aromatic hydrocarbon concentrations equal to or greater than the 50 ppb threshold are predicted to be found up to around 10 km south-west from the release location. The only receptor modelled with a probability of contact at the ecological threshold (50 ppb) was Montebello AMP (2%).

Entrained Hydrocarbons

Entrained oil concentrations equal to or greater than the 100 ppb threshold are predicted to be found up to 110 km south-west from the release location. The only receptors modelled with a probability of contact at the ecological threshold (100 ppb) was Montebello AMP (47%) and Tryal Rocks (1%).

Accumulated Hydrocarbons

No shoreline accumulation at the ecological threshold, at or above 100 g/m2, was predicted.

Scenario 4 - Loss of containment of the export pipeline at the State Waters 3nm boundary

Surface Hydrocarbons

The hydrocarbon spill modelling indicated that concentrations of floating hydrocarbons equal to or greater than the 10 g/m2 threshold could potentially be found, in the form of slicks, up to 12 km south-west from the release location. However, no receptors are predicted to be contacted by surface hydrocarbons at or above ecological thresholds.

Dissolved Hydrocarbons

Dissolved aromatic hydrocarbon concentrations equal to or greater than the 50 ppb threshold are predicted to be found up to around 10 km south-west from the release location. However, no receptors are predicted to be contacted by dissolved hydrocarbons at ecological thresholds.

Entrained Hydrocarbons

Entrained oil concentrations equal to or greater than the 100 ppb threshold are predicted to be found up to 80 km south-west from the release location.

Receptors with the highest probability of contact at the ecological threshold (100 ppb) include Dampier AMP (23%), Cape Bruguieres (3%), Dampier Archipelago (16%), Cohen Island (7%), Enderby Island (1%), Gidley Island (1%), Goodwyn Island (1%), Keast Island (5%), Kendrew Island (6%), Legendre Island (13%), Malus Island (1%), Rosemary Island (7%), Courtenay Shoal (1%), Hammersley Shoal (8%), and the Madeline Shoals (25%).

Accumulated Hydrocarbons

Shoreline accumulation was predicted at or above 100 g/m2 was predicted for Cape Bruguieres (1%), Dampier Archipelago (2%), Cohen Island (2%), Keast Island (1%), Legendre Island (1%), and Rosemary Island (1%)

Any impacts to biological and physical receptors within this area are addressed within the impact discussion for MEE-01 (Section 6.8.5).

Summary of Potential Impacts to Environmental Value(s)

The credible worst-case hydrocarbon spill scenario that may arise from MEE-02 may impact upon a range of environmental receptors. Potential impacts of a hydrocarbon spill to the open water environment and receptors has been assessed within the worst-case spill scenario, MEE-01; refer to Section 6.8.5 for a description of potential impacts.

However, the spill scenario that may arise from MEE-02 is the only scenario predicted to impact the shorelines at or above relevant thresholds. Therefore, potential impacts to nearshore waters (including mainlands and islands) have been assessed below.

Table 6-36: Environment that May Be Affected - Key receptor locations and sensitivities potentially contacted above impact thresholds by the export pipeline and riser loss of containment scenarios with summary hydrocarbon spill contact ≥ 1% probability

Nearshore Waters (Mainland and Islands)
Marine Sediment Quality The EMBA modelled for MEE-02 scenarios (RPS, 2024c, 2024d) overlapped the nearshore waters of a few shorelines and islands. Specifically, the modelling for the export pipeline release near State Waters 3nm boundary was the only scenario to predict hydrocarbon accumulation above the ecological threshold at any shoreline. Low probabilities (<2%) of hydrocarbon accumulation were predicted at a few nearshore receptors, such as the Dampier Archipelago, Cape Bruguieres, Keast Island, Cohen Island, Legendre Island, and Rosemary Island. Therefore, hydrocarbon contact from this scenario may lead to reduced marine sediment quality by several processes, such as adherence to sediment and deposition on shores or seabed habitat.
Protected Species
Cetaceans Evaluation of the extent of the spill EMBA modelled for MEE-02 demonstrated an overlap with areas where cetaceans are known to occur, including the BIAs for a number of species. The potential impacts of hydrocarbon exposure upon cetaceans has already been assessed within the offshore environment evaluation above Section 6.8.6. No additional BIAs beyond those already assessed were identified within the EMBA modelled for MEE-02.
Marine Turtles Marine turtles are known to utilise nearshore waters and shorelines for foraging and breeding activities (including internesting), with significant nesting beaches along the WA mainland coast and nearshore islands in locations (such as the Dampier Archipelago and Montebello Island). The combined EMBA overlaps a number of marine turtle BIAs. The modelling for the LOC from the export pipeline scenario in MEE-02 predicted low probabilities of contact by shoreline hydrocarbons above the ecological threshold at a number of these nearshore shorelines; including Dampier Archipelago (2%), Legendre Island (1%) and rosemary Island (1%). In addition, a number of islands and the nearshore waters of these marine turtle habitat areas are also shown to be exposed to entrained hydrocarbons exceeding the threshold concentrations modelled for MEE-02. Seasonal timings for breeding, nesting and hatchling dispersal for each marine turtle species is provided in Section 4.6.5, as are the known BIAs and habitat critical areas. The potential impacts of exposure within the offshore environment has been previously discussed within Section 6.8.5. In the nearshore environment, turtles can ingest hydrocarbons when feeding and/or can be indirectly affected by loss of a food source (e.g. seagrass due to dieback from hydrocarbon exposure) (Gagnon and Rawson 2010). In addition, hydrocarbon exposure can impact on turtles during the breeding season at nesting beaches. Contact with gravid adult females or with hatchlings may occur on nesting beaches (accumulated hydrocarbons) or in nearshore waters (entrained hydrocarbons) where hydrocarbons are predicted to make shoreline contact. Males waiting in nearshore areas to mate with adult females may also be impacted by entrained hydrocarbons. Marine turtles aggregating near nesting beaches within the spill EMBA during the mating and nesting seasons are most vulnerable to hydrocarbons, due to greater turtle densities and the possible disruption to important life cycle behaviours. Potential impacts may occur at the population level due to the presence of a high number of breeding individuals and hatchlings (during hatchling dispersal) and may impact on overall population viability of marine turtle species. However, given the volatile nature of the hydrocarbons population level impacts are not anticipated to occur.
Sea Snakes Impacts to sea snakes for the mainland and island nearshore waters from direct contact with hydrocarbons may occur and may include potential damage to the dermis and irritation to mucous membranes of the eyes, nose and throat (ITOPF, 2011a). Due to the time to impact in the nearshore environment, the hydrocarbons are considered to be weathered and less likely to result in toxic effects in comparison to fresh hydrocarbons (i.e. typically in the vicinity of the release location).
Sharks and Rays Whale sharks and manta rays generally transit along the nearshore coastline in these areas and are vulnerable to surface, entrained and dissolved aromatic hydrocarbon spill impacts, with both taxa having similar modes of feeding. Whale sharks and manta rays (reef manta ray and giant manta ray) are known to frequent Ningaloo Reef (forming feeding aggregations March through July) and the nearshore waters of the Muiron Islands (located 228 km south-west of the PAA). Impacts from hydrocarbon exposure occurring within the nearshore waters of their main foraging areas, such as Ningaloo Reef, has been assessed in more detail below as the spill EMBA for MEE-04 is more relevant for this assessment.
Seabirds

There is the potential for seabirds, and resident/non-breeding overwintering shorebirds that use the nearshore waters for foraging and resting to be exposed to hydrocarbons above ecological impact thresholds within the EMBA modelled for MEE-02. Impacts may include both lethal or sub-lethal effects, as discussed below and above in the offshore environment assessment.

Although breeding oceanic seabird species can travel long distances to forage in offshore waters, most breeding seabirds tend to forage in nearshore waters near to their breeding colony, resulting in intensive feeding by higher seabird densities in these areas during the breeding season and making these areas particularly sensitive in the event of a spill.

Migratory shorebirds may be exposed to stranded hydrocarbons when foraging or resting in intertidal habitats, however, direct oiling is typically restricted to relatively small portion of birds, and such oiling is typically restricted to the birds' feet. Unlike seabirds, shorebird mortality due to hypothermia from matted feathers is relatively uncommon (Henkel et al. 2012). Indirect impacts, such as reduced prey availability, may occur (Henkel et al. 2012).

As mentioned, predicted surface hydrocarbons are relatively restricted to the release location, with only low probabilities of sporadic shoreline contact at certain locations. Shoreline hydrocarbon contact above ecological thresholds may occur at the Dampier Archipelago, Cape Bruguieres and a number of islands, including Cohen Island, Keast Island, Legendre and Rosemary Island during a MEE-02 scenario. Impacts may, therefore, occur at the population level for species breeding at these locations should a spill occur during the relevant species breeding seasons.

Impacts are likely to occur through the ingestion of contaminated fish (nearshore waters) or invertebrates (intertidal foraging grounds such as beaches, mudflats and reefs) which have been exposed to surface, shoreline, entrained or dissolved hydrocarbons within the combined EMBA. Ingestion of contaminated prey can also lead to internal injury to sensitive membranes and organs (International Petroleum Industry Environmental Conservation Association, 2004). Whether the toxicity of ingested hydrocarbons is lethal or sub-lethal will depend on the weathering stage and its inherent toxicity. Exposure to hydrocarbons may have longer term effects, with impacts to population numbers due to decline in reproductive performance and malformed eggs and chicks, affecting survivorship and loss of adult birds. Seabirds also typically nest above the high-water mark, meaning nesting areas would not be expected to be directly impacted.

Notably, the nearest receptor to the release location that is predicted to receive shoreline hydrocarbons above threshold concentrations is the Dampier Archipelago. Shoreline hydrocarbons were modelled to take a minimum of 21 hours to arrive at this location (RPS, 2024d). Hydrocarbons will be weathered after this period and toxic impacts unlikely to occur. Birds utilising the nearshore waters and intertidal areas for foraging and resting at locations of shoreline contact may, therefore, suffer sub-lethal and, less likely, lethal impacts.

Submerged Shoals and Banks

Protected Species

Marine Turtles

While there are no shoal, bank or reef features within the PAA, there is the potential for marine turtles to be present at submerged shoals and banks within the spill EMBA modelled for MEE-02; with modelling predicted relatively low probabilities of contact by entrained hydrocarbons at Madeleine Shoals (25%), Courtnenay Shoal (1%), Hammersely Shoal (8%) and Tryal Rocks (1%). Shoals and banks may, at times, be foraging habitat for marine turtles, given the coral and filter feeding biota associated with these areas.

Notably, there are no known key aggregation areas (i.e. BIAs or habitat critical areas) for marine turtles associated with these submerged receptors (see Section 4.6.2 for further details on key areas).

Impacts to marine turtles at submerged shoals and banks in offshore marine environments have been discussed above. Marine turtles would be expected to be foraging, resting and breathing at the surface at these geomorphic features. Ingestion of hydrocarbons while foraging through prey is also possible.

Marine

turtles that may be present at these submerged shoals and banks within the EMBA may be impacted by entrained hydrocarbons present at concentrations greater than the relevant thresholds. Impacts would be expected to be limited to the individuals that may be transiting these areas. Subsequently, impacts at the population level are not anticipated for any of the five marine turtle species that may frequent shoals and banks within the EMBA.

Sea snakes

It is likely that sea snakes will be present at submerged shoals and banks within the EMBA modelled for MEE-2. Whilst there are no known areas of aggregation for sea snakes within the extended combined EMBA (see Section 4.6.2), individual sea snakes may be impacted by hydrocarbons predicted at and near to their habitat preferences (see Section 4.6.2).

The potential impacts to sea snakes following exposure to hydrocarbons have been discussed above.

Sea snake species in Australia generally show strong habitat preferences (Heatwole and Cogger 1993); species that have preferred habitats associated with submerged shoals and oceanic atolls may be disproportionately affected by a hydrocarbon spill affecting such habitat. However, population level impacts are not anticipated.

Sharks and Rays

Pelagic sharks and rays may frequent submerged shoals and banks to feed within the EMBA modelled for MEE-02. Some species may also exhibit site fidelity to these geomorphic features. There is the potential for resident shark and ray populations to be impacted directly from hydrocarbon contact or indirectly through contaminated prey or loss of habitat.

Species which are resident to or exhibit site-fidelity to impacted Shoals or Banks may experience sub-lethal impacts and/or become displaced. Indirect impacts through ingestion of prey that has been exposed to hydrocarbons and/or the loss of marine flora habitats may also impact sharks and rays.

Pelagic sharks and rays are expected to move away from areas affected by spilled hydrocarbons. Impacts to such species are expected to be limited to behavioural responses/displacement. Shark and ray species that have associations with submerged shoals and banks may or may not be displaced/exhibit behavioural avoidance in response to such habitat being contacted by spilled hydrocarbons. Such species may be more susceptible to a reduction in habitat quality resulting from a hydrocarbon spill. It is expected that there will be no impacts at the population level

All Settings

Coral

Modelling for the pipeline export scenario (MEE-02) was predicted to contact known coral reef habitats above the ecological threshold. The modelling predicted low probability of entrained hydrocarbons to contact the Dampier Archipelago (16%).

Impacts

Exposure to entrained hydrocarbons (≥100 ppb) / dissolved aromatic hydrocarbons (≥50 ppb) has the potential to result in lethal or sub-lethal toxic effects to corals and other sensitive sessile benthos within the upper water column, including upper reef slopes (subtidal corals), reef flat (intertidal corals) and lagoonal (back reef) coral communities. Mortality in a number of coral species is possible and this would result in the reduction of coral cover and change in the composition of coral communities. Sub-lethal effects to corals may include polyp retraction, changes in feeding, bleaching (loss of zooxanthellae), increased mucous production resulting in reduced growth rates and impaired reproduction (Negri and Heyward 2000).

This could result in impacts to the shallow water fringing coral communities/reefs of the nearshore islands.

Shoreline Accumulation

A very low probability of shoreline contact (<2%) above the ecological threshold was predicted at a few receptors for the MEE-02 scenario at the State Waters 3nm boundary including Cape Brugieres, Dampier Archipelago, Cohen Island, rosemary Island, Keast Island, Leagendre Island.

Shallow coral habitats (i.e. nearshore and intertidal waters) are most vulnerable to hydrocarbons through coating by direct contact with surface slicks during periods when corals are tidally-exposed at spring low tides. Water soluble hydrocarbon fractions associated with surface slicks are known to cause high coral mortality (Shigenaka 2001) via direct physical contact of hydrocarbon droplets to sensitive coral species (such as the branching coral species).

There is, therefore, potential for lethal impacts due to the physical hydrocarbon coating of sessile benthos (including by entrained hydrocarbons), with likely significant mortality of corals (adults, juveniles and established recruits) at the small spill affected areas. These impacts are particularly applicable to branching corals which are reported to be more sensitive than massive corals (Shigenaka 2001).

Recruitment / Spawning

In the unlikely event of a spill occurring at the time of coral spawning at potentially affected coral locations or in the general peak period of biological productivity, there is the potential for a significant reduction in successful fertilization and coral larval survival due to the sensitivity of coral early life stages to hydrocarbons (Negri and Heyward 2000). Such impacts are likely to result in the failure of recruitment and settlement of new population cohorts. In addition, some non-coral species may be affected via direct contact with entrained and dissolved aromatic hydrocarbons, resulting in sub-lethal impacts and in some cases mortality. This is with particular reference to the early life-stages of coral reef animals (reef attached fishes and reef invertebrates), which can be relatively sensitive to hydrocarbon exposure. Coral reef fish are site attached, have small home ranges and as reef residents they are at higher risk from hydrocarbon exposure than non-resident, more wide-ranging fish species. The exact impact on resident coral communities (which may include fringing reefs of the offshore islands) will be entirely dependent on actual hydrocarbon concentration, duration of exposure and water depth of the affected communities. Coral cover, structure and composition may be reduced in hydrocarbon impacted areas, manifested by loss of corals and associated sessile biota.

Recovery of impacted reef areas from a range of stressors typically relies on coral larvae from neighbouring coral communities that have either not been affected or only partially impacted. For example, there is evidence that Ningaloo Reef corals and fish are partly self-seeding (Underwood 2009) with the supply of larvae from locations within Ningaloo Reef of critical importance to the healthy maintenance of the coral communities. Recovery at other coral reef areas, may not be aided by a large supply of larvae from other reefs, with levels of recruits after a disturbance event only returning to previous levels after the numbers of reproductive corals had also recovered (Gilmour et al. 2013).

The hydrocarbon modelling for the MEE-02 scenarios predicted only low probability of contact from entrained hydrocarbons at the Dampier Archipelago, Outtrim Patches, submerged Shoals, and Tryal Rocks. Therefore, a worst-case scenario of an export pipeline release near the State Waters boundary may cause impacts to coral reefs with the EMBA, with the potential to cause long-term effects.

Productivity

The potential impacts to plankton and offshore productivity following exposure to entrained hydrocarbons have been discussed above.

Filter Feeders

Nearshore filter feeders that are present in shallower water <20 m may potentially be impacted by entrained hydrocarbon based on the predicted modelling.

However, the released hydrocarbons are predicted to be weathered and less likely to result in toxic effects in comparison to fresh hydrocarbons (i.e. typically in the vicinity of the release location) before they reach any potential filter feeder community. Therefore, impacts such as localised, long-term effects to community structure and habitat, are not predicted.

Seagrass Beds, Macroalgae and Mangroves

The primary macroalgal / seagrass communities identified within the combined EMBA including those along the Ningaloo Coast (patchy and low cover associated with the shallow limestone lagoonal platforms), Muiron Islands (associated with limestone pavements), and the Barrow and Montebello Island groups are not predicted to be exposed to hydrocarbons above the ecological threshold based on the modelling.

The seagrass and macroalgal beds that may be found at other areas of lower coverage, such as the Dampier Archipelago, may be susceptible to impacts from entrained hydrocarbons from a worst-case release near the State Water boundary (MEE-02). Toxicity effects can also occur due to absorption of soluble fractions of hydrocarbons into tissues (Runcie et al. 2010). The potential for toxicity effects of entrained hydrocarbons may be reduced by weathering processes that should serve to lower the content of soluble aromatic components before contact occurs. Furthermore, given the non-persistent nature of the hydrocarbons, however, no significant effects to seagrass and macroalgal habitats are expected to occur.

Mangrove habitats and associated mud flats and salt marsh at Ningaloo Coast (small habitat areas) and the Montebello Islands have were not predicted to be exposed to entrained hydrocarbons. Therefore, impacts are not expected to occur.

Summary of Potential Impacts to Socio-economic Values	
Setting	***Receptor Group***
Nearshore Island and Mainland Coastal Areas (Nearshore Waters)	***Fisheries – Commercial*** A few State managed fisheries have been identified to overlap with the EMBA. Any impacts to these fisheries would include possible direct mortality or sub-lethal impacts to the target species, as well as indirect financial and reputational impacts from possible fishing exclusion zones and perceived health impacts by the community/consumers as a result of the spill event. Impacts to fish stocks would depend on the time of the year the spill event was to occur, and the maturity of the fishery. Impacts are, however, expected to be restricted to mid-term for both direct and indirect impacts. Fishing activities may be hampered if fisheries are restricted from entry to an affected area, however the area potentially affected represents a very small part of available fishery zones and the short duration that diesel would persist limits the potential for significant impacts.
	Fisheries – Traditional Although no designated traditional fisheries have been identified within the PAA or EMBA, it is recognised that Indigenous communities' fish in the shallow coastal and nearshore waters of Ningaloo Reef and therefore may be impacted if a worst-case hydrocarbon spill were to occur. Impacts would be similar to those identified for commercial fishing, in the form of a potential fishing exclusion zone and possible contamination/tainting of fish stocks.

	Tourism and Recreation Tourism would likely be adversely affected if a visible surface slick entered areas of tourism activity. Spill modelling predicted low probability of hydrocarbon contact to the closest tourism area, such as the Montebello MP and Dampier AMP and archipelago. These areas have some seasonal charter boat operators and fishing activities, mainly concentrated around the islands. The Dampier Archipelago was predicted to have low probability of shoreline contact by MEE-02 scenario. This area experiences seasonal charter boats and recreational fishing. In the event of an export pipeline release near the State Water 3nm boundary, there could be restricted access to this area for a period of days to weeks, until natural weathering or tides and currents remove the hydrocarbon.

MEE-02 Subsea Equipment Loss of Well Containment – Risk Analysis
A bowtie risk analysis was undertaken to assess MEE-02; refer to the below figures for bowtie diagrams which were an output of Woodside's risk analysis process.

Risk Based Analysis				

MEE-02 Subsea Equipment Loss of Well Containment – Demonstration of ALARP ALARP Control Measures				
Hierarchy	***Control / Barrier***	***SCE / Management System Reference***	***Type of Effect***	***Control Adopted***

For risks identified as MEEs, a detailed risk-based Bowtie Analysis (as outlined in Section 2.7.3) has been used to identify, analyse and demonstrate that controls in place reduce the risk associated with each MEE to ALARP. Controls have been selected following hierarchy of control principles and consider independence of each barrier and their type of effect in controlling the hazardous event.

Application of Woodside's Risk Management Procedures and implementation of the Pluto A Operations Safety Case and Pluto Export Pipeline Safety Case ensures the continuous identification of hazards, systematic assessment of risks and ongoing assessment of alternative control measures to reduce risk to ALARP, which includes:

ongoing hazard identification, risk assessment and the identification of control measures

ongoing integrity management of hardware control measures in accordance with the operational performance standards which define requirements to be suitably maintained, such that they retain effectiveness, functionality, availability and survivability.

For each SCE, detailed requirements for equipment functionality, availability, reliability and survivability are incorporated into SCE Performance Standards which also include the relevant assurance tasks (e.g. inspection, maintenance, testing and monitoring requirements) to ensure technical integrity.

Bowtie analysis was undertaken to assess MEE-02, with review of formal safety assessments and subsea system design studies.

Company Values

Corporate values require all personnel at Woodside to comply with appropriate policies, standards, procedures and processes while being accountable for their actions and holding others to account in line with Our Values. As detailed above, the Petroleum Activities Program is undertaken in line with these policies, standards and procedures that include suitable controls to prevent subsea flowline and riser loss of containment, and response should a loss of containment occur.

Societal Values

Due to the Petroleum Activities Program's proximity to sensitive receptors (e.g. Montebello Islands) and the potential extent of the wider EMBA, the pipeline and riser loss of containment risk rating presents a Decision Type B in accordance with the decision support framework described in Section 2.6.1. Consultation was undertaken for this program to identify the views and concerns of relevant persons, as described in Section 5.

Woodside has sent an Activity Factsheet to all identified relevant persons regarding the Petroleum Activities Program (Section 5). Woodside has consulted with AMSA and WA DoT on spill response strategies. In accordance with the MoU between Woodside and AMSA, a copy of the Oil Pollution First Strike Plan was provided to AMSA.

ALARP Statement:

On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts and risks of a very low likelihood unplanned hydrocarbon release as a result of a pipeline and riser loss of containment.

The principle of inherent safety and environmental protection is based on the prevention of the MEE through design of pipelines and risers, ensuring the export pipeline and risers are operated within their design envelope through operating practices, and assurance through maintenance and inspection. If hydrocarbon loss of containment occurs, mitigation measures are in place to minimise the consequence by limiting the inventory which can be released and implementing remediation.

The controls in place for prevention and mitigation of MEEs are specified and assured through implementing the Safety Cases, SCE management procedures including performance standards for SCEs and MSPSs for Safety Critical Management System Controls.

The application of Woodside Risk Management Procedures ensures the continuous identification of hazards, systematic assessment of risks and ongoing assessment of alternative control measures to reduce risk to ALARP, which includes:

- ongoing hazard identification, risk assessment and the identification of control measures
- ongoing integrity management of hardware control measures in accordance with the technical performance standards which define requirements to be suitably maintained, such that they retain effectiveness, functionality, availability and survivability.

Given the controls in place to prevent and control loss of containment events and mitigate their consequences it is considered that MEE risk associated with a pipeline and riser loss of containment is managed to ALARP.

MEE-02 Subsea Equipment Loss of Well Containment – Demonstration of ALARP ALARP Control Measures				
Hierarchy	***Control / Barrier***	***SCE / Management System Reference***	***Type of Effect***	***Control Adopted***
Demonstration of Acceptability				
Acceptability Statement Subsea equipment loss of containment has been evaluated as having a 'moderate' level of risk rating. Subsea loss of containment events are risk assessed as Highly Unlikely potential "C – Moderate" consequence for offshore events, and; Export pipeline mid-point to shore section loss of containment events risk assessed as Highly Unlikely , potential "B – Major" consequence. As per Section 2.6.3, Woodside considers 'moderate' risk ratings as broadly acceptable if the adopted controls are implemented. Due to the consequence associated with MEE-02, Decision Type B has been applied, and ALARP is demonstrated using good industry practice, consideration of company and societal values and risk based analysis, if legislative requirements are met and societal concerns are accounted for and the alternative control measures are grossly disproportionate to the benefit gained. Acceptability is demonstrated with regard to the oil spill risk considerations as described in Section 6.8.5 (MEE-01) (the considerations include principles of Ecologically Sustainable Development, internal context, external context and other requirements (includes laws, policies, standards and conventions)). On the basis of the environmental impact assessment outcomes and Woodside's criteria for acceptability outlined in Section 2.8.2, this is considered an acceptable level of risk.				

EPOs, EPSs and MC for Pluto Facility Operations			
Environmental Performance Outcomes	***Controls***	***Environmental Performance Standards***	***Measurement Criteria***

Surface or subsea release from flowline, pipeline and riser to the marine environment and atmosphere within PSZ (MEE-02) – caused by loss of structural integrity		x	x	x	x	x	x	B	C	1	M			

Description of Source of Risk

Extreme environmental conditions or other causes which result in an exceedance of the design criteria and a catastrophic failure of the facility and individual equipment (e.g. cranes, flare tower, etc.) has been identified as a potential MEE (MEE-03). Catastrophic structural failure of the facility could lead to the release of hydrocarbons to the environment.

The identified causes, including escalation from other MEEs, include:

- internal corrosion;
- external corrosion;
- equipment failure;
- extreme weather (cyclone, high waves);
- seismic events/seabed instability; and
- fire/overpressure event (escalation of loss of containment event).

Escalation from other MEEs can also cause loss of structural integrity:

- loss of marine vessel separation (refer to MEE-04, Section 6.8.8); and
- loss of control of suspended load from facility lifting operations (refer to MEE-05).

A number of common failure causes due to human error and SCC failures are presented in the generic Human Error and generic SCE Failure bowties in Section 6.8.10.

There is a possibility of riser platform collapse ('slow' or 'rapid') caused by the extreme loads induced by strong winds and extreme waves. Extreme weather may induce fracture of pipework due to vibration/fatigue and loosen/dislodge objects/projectiles causing impact to equipment/pipework and subsequently, resulting in a loss of containment.

Structural damage to the platform resulting from the causes listed above could be minor or could in the most extreme situation result in total loss of the platform. The type of structural failure considered is restricted to major structural damage (e.g. catastrophic collapse of the jacket or release of hydrocarbons on or adjacent to the platform). Such events are beyond the design basis for the platform.

Loss of Structural Integrity – Credible Scenarios

A loss of structural integrity could result in a significant release of hydrocarbons. A loss of structural integrity may result in credible hydrocarbon spill scenarios consistent with:

- subsea equipment loss of containment (MEE-02)
- loss of marine vessel separation (MEE-04)
- topsides loss of containment (one or more storage inventories) through to total loss of platform hydrocarbon/chemical inventory (bound by MEE-04 impact assessment) (Section 6.8.6).

The worst-case credible spill scenarios associated with these MEEs/sources of risk are discussed in the relevant sections above, with impacts dependent on the extent of structural damage, volume of hydrocarbons released (including cumulative volumes from tanks/vessels), the associated weather conditions, and effectiveness of mitigation and response measures.

Decision Type, Risk Analysis and ALARP Tools

Woodside has a good history of implementing industry standard practice in structural design, construction and operation. In the company's 60-year history, it has not experienced any loss of structural integrity events that have resulted in significant releases or significant environmental impacts.

Decision Type

Decision Type B has been applied to this risk under the Guidance on Risk Related Decision Making (Oil and Gas UK 2014). This reflects the complexity of the risk, the higher potential consequence and stakeholder implications should the event be realised. To align with this decision type, a further level of analysis has been applied using risk-based tools including the bowtie methodology (described in Section 2.7.3) and hydrocarbon spill trajectory modelling. Company and societal values were also considered in the demonstration of ALARP and acceptability, considered through internal reviews, and stakeholder consultation (Section 5).

The potential release of hydrocarbons from a loss of structural integrity is considered an MEE (MEE-03). The hazard associated with this MEE is hydrocarbons in pipelines, risers, process and non-process hydrocarbon and chemical inventories and potentially the physical riser platform/jacket structure itself..

Quantitative Spill Risk Assessment

Credible worst-case stochastic spill modelling for the scenarios associated with MEE-02 Subsea system loss of containment and MEE-04 Loss of Marine Vessel Separation (diesel loss of containment) has been undertaken. Results of these modelling studies have been used to inform the consequence assessment for these MEEs; these assessments are applicable to bounding the worst-case consequence assessment for a loss of structural integrity event. A "C" Moderate consequence is assigned to worst-case releases from the riser platform location for both MEE-02 Subsea system loss of containment, and a conservatively assessed diesel loss of containment scenario (MEE-04) which bounds the worst-case impact potential for cumulative topsides hydrocarbon, chemicals and marine vessel loss of containment in case of a structural collapse.

Likelihood

Formal safety studies inform an assessed frequency of total platform collapse estimated to be 1.08E-04 per year, or 1 in 9,285 years considering seismic factors, weather events and vessel collision risk. Once the low likelihood of cumulative instantaneous release to result in worst-case environmental consequence is considered, together with prevention and mitigation factors - the likelihood is assessed as "Highly Unlikely" in accordance with the Woodside Risk Matrix

Consequence

The spatial extent and fate (including weathering) of the spilled hydrocarbon was considered during the impact assessment for a loss of structural integrity. These considerations were informed primarily by the outputs from the stochastic modelling studies undertaken by RPS (2024c, 2024e), available information on environmental sensitivities that may credibly be impacted in the event of a worst-case spill, and relevant literature and studies considering the effects of hydrocarbon exposure.

Consequence Assessment

Environment that May Be Affected

As discussed above, the potential impacts from hydrocarbon release caused by a loss of structural integrity are analogous to those which would result from:

- loss of containment from subsea equipment (within PSZ) (MEE-02)
- loss of marine vessel separation (MEE-04)
- topsides loss of containment (one or more storage inventories) through to total loss of platform hydrocarbon/chemical inventory (bound by MEE-04 impact assessment) (Section 6.8.6).

The potential impacts associated with these impacts are therefore discussed in the above-mentioned sections.

Seabed Disturbance

In the event of loss of structural integrity, there is the potential for collapse of the riser platform leading to an incremental increase of the facility's footprint on the seabed. The potential area that would be affected can conservatively be defined as the existing facility footprint plus 100 m in all directions, that is approximately 300 m by 350 m (0.105 km2). The benthic habitats surrounding the riser platform have been subject to historical disturbance (e.g. facility construction and operation) and are considered to be of low ecological value (although it is acknowledged the facility provides artificial hard substrate which has formed the basis of relatively high biodiversity communities at this location when compared to the surrounding seabed). Subsequently, the physical disturbance to the seabed resulting from the collapse of the riser platform would be localised but may result in long-term disturbance to benthic communities.

The riser platform could also act as a source of environmental contaminants due to material on board the platform (e.g. chemical/hydrocarbon inventories, corrosion of structural materials, debris, etc.). The potential for contamination would diminish over time, as the structure degrades. Depending on the nature of the loss of structural integrity, complete or partial salvage of the riser platform may not be feasible. These structures are expected to be colonised by marine organisms, and a reef habitat will develop over time on the structures.

While the PAA overlaps the Continental Slope Demersal Fish Communities KEF and Ancient Coastline at 125 m Depth Contour KEFs, neither of these are in close proximity to the riser platform.

MEE-03 Loss of Structural Integrity – Risk Analysis

A bowtie risk analysis was undertaken to assess MEE-03; refer to the below figures for bowtie diagrams which were an output of Woodside's risk analysis process.

MEE-03 Loss of Structural Integrity – Demonstration of ALARP ALARP Control Measures				
Hierarchy	***Control / Barrier***	***SCE / Management System Reference***	***Type of Effect (Refer to Table 6-27)***	***Control Adopted***

For risks identified as MEEs, a detailed risk based Bowtie Analysis (as outlined in Section 2.7.3) has been used to identify, analyse and demonstrate that controls in place reduce the risk associated with each MEE to ALARP. Controls have been selected following hierarchy of control principles and consider independence of each barrier and their type of effect in controlling the hazardous event.

Application of Woodside's Risk Management Procedures and implementation of the Pluto A Operations Safety Case ensures the continuous identification of hazards, systematic assessment of risks and ongoing assessment of alternative control measures to reduce risk to ALARP, which includes:

- ongoing hazard identification, risk assessment and the identification of control measures
- ongoing integrity management of hardware control measures in accordance with the operational performance standards which define requirements to be suitably maintained, such that they retain effectiveness, functionality, availability and survivability.

For each SCE, detailed requirements for equipment functionality, availability, reliability and survivability are incorporated into SCE Performance Standards which also include the relevant assurance tasks (e.g. inspection, maintenance, testing and monitoring requirements) to ensure technical integrity.

Bowtie analysis was undertaken to assess MEE-03, with review of formal safety assessment studies.

ALARP Statement:

On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts and risks of a very low likelihood of a loss of structural integrity.

The principle of inherent safety and environmental protection is based on the prevention of the MEE through design of the facility, ensuring the equipment is operated within the design envelope through operating practices, and assurance through maintenance and inspection. If a loss of structural integrity occurs, mitigation measures are in place to minimise the consequence by limiting the inventory which can be released and implementing remediation.

The controls in place for prevention and mitigation of MEEs are specified and assured through implementing the Pluto A Operations Safety Case, SCE management procedures including performance standards for SCEs, and MSPSs for Safety Critical Management System Controls.

The application of Woodside Risk Management Procedures and implementation of the Pluto A Operations Safety Case ensures the continuous identification of hazards, systematic assessment of risks and ongoing assessment of alternative control measures to reduce risk to ALARP.

Given the controls in place to prevent and control loss of containment events and mitigate their consequences, alongside procedural control of facility operations, it is considered that MEE risk associated a loss of structural integrity is managed to ALARP.

Demonstration of Acceptability

Acceptability Statement:

A loss of structural integrity has been evaluated as having a 'Moderate' risk rating (including the consideration of applicable MEEs). As per Section 2.6.1, Woodside considers 'Moderate' (B0) risk ratings as acceptable if managed to ALARP. Due to the consequence associated with MEE-03, Decision Type B has been applied, and ALARP is demonstrated using good industry practice and risk-based analysis, if legislative requirements are met and societal concerns are accounted for, and the alternative control measures are grossly disproportionate to the benefit gained.

Acceptability is demonstrated with regard to the oil spill risk considerations as described in Section 6.8.5 (MEE-01) (the considerations include principles of Ecologically Sustainable Development, internal context, external context and other requirements (includes laws, policies, standards and conventions)).

On the basis of the environmental impact assessment outcomes and Woodside's criteria for acceptability outlined in Section 2.8.2 this is considered an acceptable level of risk.

Description of Source of Risk

A loss of marine vessel separation between a vessel and the facility, or between vessels may result in a loss of hydrocarbon containment from the facility and/or the release of fuel from the vessel. A loss of marine vessel separation with PLA has been identified as a potential MEE (MEE-04). Loss of marine vessel separations can arise from:

- visiting vessel collisions associated with platform support vessels, IMMR and accommodation vessels – ships which are visiting the riser platform can accidentally collide with the platform or each other during approach to, or manoeuvring alongside, the platform; and

- errant passing vessel collision – ships which are not visiting the riser platform (i.e. passing vessels) can, for one reason or another, move off-course and collide with the platform
- vessel operations during adverse weather.

The different collision hazards involve significantly different sized vessels and collision speeds; hence, differing impact energies and consequences have been assessed.

Visiting Vessels

Visiting vessels are defined as those which are routinely used to service the facility. Operating procedures dictate how vessels are operated, loaded and unloaded, but it will generally occur so that the prevailing winds move the vessel away from the facility. The primary causes of visiting vessel collisions are failure to follow safe procedures and communication errors between the marine vessels and riser platform operations. These errors could be worsened by:

- vessel station keeping failures
- vessel operations in adverse weather conditions.

A number of common failure causes due to human error and SCC failures are presented in the generic Human Error and generic SCE Failure bowties in Section 6.8.10

Errant Passing Vessels

Errant passing vessels are defined as third party vessels that enter the riser platform's 500 m PSZ, but do not call at the riser platform (i.e. not support vessels). The collision can be powered or drifting. Either has the potential to cause significant damage to the riser platform.

The causes of errant passing vessel collisions include:

- failure of propulsion or steering systems
- adverse weather conditions resulting in poor visibility
- rough seas
- human error.

Woodside implements a range of control measures to mitigate the risk of errant vessel collision. In addition to the potential for large hydrocarbon releases following impact by a vessel with the riser platform, powered collisions from large passing vessels or tankers could have sufficient impact energy to breach both skins of the vessel to the extent that there is a loss of containment of cargo or fuel oil with the potential for significant loss of inventory and consequent environmental impact. This is not within the control of Woodside so is not assessed further.

Loss of Vessel Separation – Credible Hydrocarbon Spill Scenario

The loss of marine vessel separation is considered a Major Environment Event (MEE-04). The hazards associated with this MEE is loss of containment of hydrocarbons in subsea equipment, process and non-process hydrocarbon inventories and potentially fuel stored in vessels (such as platform support/IMMR vessels).

A loss of marine vessel separation could result in a significant release of process hydrocarbons. Hydrocarbon releases may result in a spill to the marine environment as described in Section 6.8.6 (MEE-02 – Subsea Equipment Loss of Containment, surface scenario) caused due to mechanical integrity impacts to structures which include flowline/export pipeline riser systems. Escalation events could interact with Loss of Structural Integrity MEE-03 Section 6.8.7 topsides inventories. In addition, vessel cargo, including diesel inventory, could be spilled if the cause of the loss of platform integrity was a collision from a support vessel or other in-field vessel.

Worst case hydrocarbon release scenarios for a subsea equipment loss of containment (MEE-02) that could result from loss of marine vessel separation in the PSZ is discussed in Section 6.8.6. Relevant trajectory modelling as applicable to these scenarios is also discussed above.

A loss of vessel separation may lead to the accidental release of marine diesel from the fuel tanks on the vessel(s) involved. For a vessel collision to result in the worst-case scenario of a hydrocarbon spill potentially impacting an environmental receptor, several factors must align as follows:

- vessel interaction must result in a collision
- the collision must have enough force to penetrate the vessel hull
- the collision must be in the exact location of the fuel tank
- the fuel tank must be full, or at least of volume which is higher than the point of penetration.

The probability of the chain of events described above aligning, to result in a breach of fuel tanks resulting in a spill that could potentially affect the marine environment is considered highly unlikely. Given the offshore location of the Operational Area, vessel grounding in relation to the Petroleum Activities Program is not considered a credible risk.

A collision between a platform, subsea support vessel or ASV with a third-party vessel (i.e. commercial shipping, other petroleum related vessels and commercial fishing vessels) was considered the only credible event that could release a significant quantity of marine diesel to the environment. This was assessed as being credible but highly unlikely given the platform support vessels typically operate in the Operational Area, the presence of vessels in the Operational Area is typically temporary (e.g. while undertaking IMMR activities), vessels undertaking the Petroleum Activities Program typically operate of low speeds or are stationary, the standard vessel operations and equipment in

place to prevent collision at sea, and the construction and placement of storage tanks. For marine vessels, credible spill volume assumptions are taken as the volume of the largest fuel tank in line with AMSA guidelines [Technical Guidelines for Preparing Contingency Plans for Marine and Coastal Facilities].The largest tank of a platform support or subsea support vessel is unlikely to exceed 105 m3. However, non-routine vessel activities may be required with larger tank inventories such as ASV with segregated tank inventories of ~300 m3, with combined capacity of ~1,800 m3. For the purposes of understanding the characteristics of a marine diesel release from a large vessel, a loss of 1000 m3 of marine diesel to sea-surface within the PSZ has been selected as being representative of a worst-case spill scenario.

Decision Type, Risk Analysis and ALARP Tools

Woodside has not experienced any loss of marine vessel separation events that have resulted in significant environmental impacts. The facility has never experienced a worst-case loss of containment due to loss of vessel separation in its operational history.

Decision Type

A decision type 'B' has been applied to this risk under the Guidance on Risk Related Decision Making (Oil and Gas UK 2014). This reflects the complexity of the risk, the higher potential consequence and stakeholder implications should the event be realised. To align with this decision type, a further level of analysis has been applied using risk-based tools including the Bowtie Methodology (described in Section 2.7.3) and hydrocarbon spill trajectory modelling. Company and societal values were also considered in the demonstration of ALARP and acceptability, considered through internal reviews, and stakeholder consultation (Section 5).

Quantitative Spill Risk Assessment

Credible worst-case hydrocarbon spill scenarios subsea equipment loss of containment (MEE-02) applies to a loss of vessel separation (MEE-04) causing structural failures, with PLA facility location noted to be further away (offshore) from key receptors modelled in a mid-point export pipeline loss of containment scenario. Refer to the Section 6.8.6 for a discussion of this credible worst-case spill scenario.

Spill modelling of the worst-case credible loss of marine diesel from a vessel spill scenario was undertaken by RPS (2024e) on behalf of Woodside. Modelling of a diesel fuel tank loss of containment described in Table 6-37: Summary of worst-case vessel fuel tank loss of containment during operations scenario was undertaken over all seasons to address possible year-round vessel operations. This is considered to provide a conservative estimate of the EMBA and the potential impacts from the identified worst-case credible release volumes for marine diesel loss of containment scenarios.

Table 6-37: Summary of worst-case vessel fuel tank loss of containment during operations scenario

Scenario	Hydrocarbon	Duration (minutes)	Depth (m)	Latitude	Longitude	Total Hydrocarbon Release Volume (m3)
Scenario 5: Vessel fuel tank loss of containment	Marine Gas Oil	60	Surface	19° 59' 46.5" S	115° 22' 5.6" E	1,000

Hydrocarbon Characteristics

See Section 6.8.2 for a description of marine diesel.

Likelihood

In accordance with the Woodside Risk Matrix, a likelihood of 'highly unlikely' event as it 'has occurred once or twice in the industry' (experience-based likelihood) and aligns with a frequency of '1 in 10,000 to 1 in 100,000 years' has been assigned to each of the following events:

- hydrocarbon release from subsea equipment to the marine environment and atmosphere
- marine environment footprint and associated hydrocarbon and chemical release associated with structural collapse of riser platform.
- surface release from vessel fuel tank

Consequence

The spatial extent and fate (including weathering) of the spilled hydrocarbon was considered during the impact assessment for MEE-02 Section 6.8.6, and separate diesel modelling scenario. These considerations were informed primarily by the outputs from the stochastic modelling studies undertaken by RPS (2024c, 2024e), available information on environmental sensitivities that may credibly be impacted in the event of a worst-case spill (Section 6.8.5 and 6.8.6), and relevant literature and studies considering the effects of hydrocarbon exposure.

Consequence Assessment

Environment that May Be Affected

As discussed above, the potential impacts from a hydrocarbon release caused by a loss of vessel separation include those which would result from:

- subsea equipment loss of containment (MEE-02 – Scenario 3)
- loss of structural integrity.
- Scenario 5 - Loss of containment of the Marine Diesel within the PSZ
- The potential impacts are –discussed in the above-mentioned sections and below.

Scenario 5 - Loss of containment of the Marine Diesel within the PSZ

Surface Hydrocarbons

The hydrocarbon spill modelling indicated that concentrations of floating hydrocarbons equal to or greater than the 10 g/m2 threshold could potentially be found, in the form of slicks, up to 50 km north and north-east from the release location. Receptors with the highest probability of contact at the ecological threshold include Montebello AMP with a 24% probability.

Entrained Hydrocarbons

Entrained oil concentrations equal to or greater than the 100 ppb threshold are predicted to be found up to 400 km south-west from the release location.

Receptors with the highest probability of contact at the ecological threshold (>100 ppb) include Gascoyne AMP (4%), Montebello AMP (57.5%) and Tryal Rocks (1.5%). Several other sensitive receptors are predicted to be contacted at concentrations equal to or greater than 100 ppb with probabilities of 0.5-2%Table 6-38.

Dissolved Hydrocarbons

Dissolved aromatic hydrocarbon concentrations equal to or greater than the 50 ppb threshold are predicted to be found up to around 26 km south-west from the release location. Receptors with the highest probability of contact at the ecological threshold (>50 ppb) include Montebello AMP (19.5%).

Accumulated Hydrocarbons

The modelling predicted no shoreline hydrocarbon accumulated at any receptor above the ecological threshold.

Summary of Potential Impacts to Environmental Value(s)

The credible worst-case hydrocarbon spill scenario that may arise from MEE-04 may impact upon a range of environmental receptors; refer to Table 6-38 for a summary of receptors identified by the stochastic spill modelling studies. Potential impacts of a hydrocarbon spill to the open water environment and receptors has been assessed within the worst-case spill scenario, MEE-01; refer to Section 6.8.5 for a description of potential impacts.

The modelling for the spill scenario that may arise from MEE-04 predicted some low-probability entrained hydrocarbons that may also impact the environment and receptors within the nearshore waters above the relevant thresholds that were not located within the EMBAs modelled for either the worst-case spill scenario; MEE-01 or MEE-02 assessed above. Therefore, the potential impacts have been assessed further below.

Table 6-38: Environment that May Be Affected - Key receptor locations and sensitivities potentially contacted above impact thresholds by loss of vessel marine diesel inventory at the PLA PSZ for threshold ≥0.5%

Nearshore Waters (Mainland and Islands)

Marine Sediment Quality

The EMBA modelled for MEE-04 scenario overlaps the nearshore waters of a few shorelines and islands (RPS, 2024e).

Low probabilities (<2%) of entrained hydrocarbons were predicted to contact a few nearshore receptors, such as the Ningaloo Coast, Montebello Islands and Shoals, Barrow Island and Muiron Island. Therefore, hydrocarbon contact from this scenario may lead to reduced marine sediment quality by several processes, such as adherence to sediment and deposition seabed habitat.

No shorelines were predicted to be exposed to either shoreline accumulation or floating surface hydrocarbons at any threshold (RPS, 2024e).

Protected Species

Cetaceans and dugongs

Coastal populations of small cetaceans (e.g. the spotted dolphin) and dugongs are known to reside or frequent nearshore waters along the WA coastline and nearshore islands, including the Exmouth Gulf, Ningaloo Coast and at the Muiron Islands, Montebello and Barrow Island groups, and the Pilbara Southern Island Groups. The general impacts of hydrocarbons on cetaceans has been assessed above.

Evaluation of the extent of the spill EMBA modelled for MEE-04 demonstrated an overlap with areas where cetaceans are known to occur, including the BIAs for a number of species. In addition to the BIAs that overlaps the PPA, the EMBA overlaps with the dugong calving, breeding, foraging (high density seagrass beds) and nursing BIAs, the OIE pygmy blue whale foraging BIA (see Section 4.6).

OIE pygmy blue whale

The pygmy blue whale foraging area in the Ningaloo Coast is within the EMBA modelled for the vessel separation scenario (due to contact with entrained hydrocarbons at 100 ppb); however, it is about 232 km south-west of the PAA and the EMBA is not representative of any one hydrocarbon spill. The likelihood of impacts occurring within this BIA are, therefore, considered low.

Dugong

Impacts (in addition to those noted above) include ingestion of hydrocarbons by dugongs that feed on oiled seagrass and indirect impacts to dugongs should seagrass habitats be damaged by a hydrocarbon spill. As noted for the pygmy blue whale foraging BIA, the spill EMBA modelled for MEE-04 scenario only overlaps a small northern portion of the Exmouth Gulf and it is considered a low likelihood that the dugong BIAs (and associated seagrass meadows) located there and along the Ningaloo Coast (BIAs for calving, nursing, breeding and foraging) would be impacted by a hydrocarbon spill. No surface or shoreline hydrocarbons are predicted within the Exmouth Gulf or associated dugong BIAs within this EMBA.

Summary

A hydrocarbon spill following a vessel separation may impact coastal cetaceans through site displacement and damage to food source, however, due to the non-persistent nature of the hydrocarbon it is not predicted to result in impacts on overall population viability of either dugongs or coastal cetaceans.

Marine Turtles

Marine turtles are known to utilise nearshore waters and shorelines for foraging and breeding activities (including internesting), with significant nesting beaches along the WA mainland coast and nearshore islands in locations (such as the Dampier Archipelago and Montebello Island).

The combined EMBA overlaps a number of marine turtle BIAs. The modelling for MEE-04 scenario predicted exposure by to entrained hydrocarbons exceeding the relevant exposure thresholds at a number of islands and the nearshore waters of these marine turtle habitat areas.

The modelling for MEE-04 predicted no hydrocarbon exposure to any shorelines at any threshold. Therefore, impacts to nesting individuals are not expected following a release of hydrocarbons in the event of a vessel separation.

The potential impacts of hydrocarbon exposure within the nearshore environment has been assessed above. Marine turtles aggregating near nesting beaches within the EMBA for MEE-04 during the mating and nesting seasons are most vulnerable to hydrocarbons, due to greater turtle densities and the possible disruption to important life cycle behaviours.

Potential impacts may occur at the population level due to the presence of a high number of breeding individuals and hatchlings (during hatchling dispersal) and may impact on overall population viability of marine turtle species. However, given the volatile nature of the hydrocarbons population level impacts are not anticipated to occur

Sea Snakes

The potential impacts of hydrocarbon exposure within the nearshore environment upon sea snakes has been assessed above.

Sharks and Rays

Whale sharks and manta rays (reef manta ray and giant manta ray) are known to frequent Ningaloo Reef (forming feeding aggregations March through July) and the nearshore waters of the Muiron Islands (located 228 km south-west of the PAA). Whale sharks and manta rays generally transit along the nearshore coastline in these areas and are vulnerable to surface, entrained and dissolved aromatic hydrocarbon spill impacts, with both taxa having similar modes of feeding.

Whale sharks are versatile feeders, filtering large amounts of water over their gills, catching planktonic and nektonic organisms (Jarman and Wilson 2004). Whale sharks at Ningaloo Reef have been observed using two different feeding strategies, including passive sub-surface ram-feeding and active surface feeding (Taylor 2007). Passive feeding consists of swimming slowly at the surface with the mouth wide open. During active feeding, sharks swim high in the water with the upper part of the body above the surface with the mouth partially open (Taylor 2007). These feeding methods would result in the potential for individuals that are present in worse affected spill areas to ingest potentially toxic amounts of entrained or dissolved aromatic hydrocarbons into their body. Large amounts of ingested hydrocarbons may affect their endocrine and immune system in the longer term.

The presence of hydrocarbons may also cause displacement of whale sharks from important feeding and resting areas at Ningaloo Reef, potentially disrupt migration and aggregations to these areas in subsequent seasons. Whale sharks may also be affected indirectly by entrained or dissolved aromatic hydrocarbons through the contamination of their prey. The preferred food of whale sharks are planktonic organisms which are abundant in the coastal waters of Ningaloo Reef in late summer/autumn, driving the annual arrival and aggregation of whale sharks in this area. If a worse-case spill event were to occur during the spawning season, this important food supply (in worse spill affected areas of the reef) may be diminished or contaminated. The contamination of their food supply and the subsequent ingestion of this prey by the whale shark may also result in long term impacts as a result of bioaccumulation.

There is the potential for other coastal shark species (e.g. dwarf, narrow and/or green sawfish) to be impacted directly from hydrocarbon contact and/or indirectly through contaminated prey or loss of habitat. Excluding sawfish, which may exhibit high site fidelity, it is most likely that shark species (as mobile animals) will move away from spill affected areas and suffer minimal direct impact.

A spill reaching the Ningaloo coastline during key aggregation periods and impacting important whale shark foraging areas may have severe impacts to the local whale shark population, including possible mortality of individuals and impacts to life cycle habitats such as migration patterns. Most species of shark and ray (including whale sharks) are, however, expected to move away from spill affected areas with minimal impacts.

Seabirds

The potential impacts of hydrocarbon exposure within the nearshore environment upon seabirds has been assessed above. The modelling for the EMBA for MEE-04 predicted no shoreline accumulation of hydrocarbons at any thresholds. As mentioned above, the area exposed to surface hydrocarbons is also relatively restricted to the release site, therefore impacts to rafting or foraging individuals is anticipated to be low.

Submerged Shoals and Banks

Protected Species

Marine Turtles

Modelling for the MEE-04 spill scenario predicted a very low probability of overlap of submerged shoals and banks by the EMBA; including Montebello Shoals (0.5%), Outram Patches (1%), and Tryal Rocks (1.5%). Shoals and banks may, at times, be foraging habitat for marine turtles, given the coral and filter feeding biota associated with these areas.

Notably, there are no known key aggregation areas (i.e. BIAs or habitat critical areas) for marine turtles associated with these submerged receptors (see Section 4.6.2 for further details on key areas).

Impacts to marine turtles at submerged shoals and banks in offshore marine environments have been discussed above in Section 6.8.5. Marine turtles would be expected to be foraging, resting and breathing at the surface at these geomorphic features. Ingestion of hydrocarbons while foraging through prey is also possible.

Marine turtles that may be present at these submerged shoals and banks within the EMBA may be impacted by entrained hydrocarbons present at concentrations greater than the relevant thresholds. Impacts would be expected to be limited to the individuals that may be transiting these areas. Subsequently, impacts at the population level are not anticipated for any of the five marine turtle species that may frequent shoals and banks within the EMBA.

Sea snakes

It is likely that sea snakes will be present at submerged shoals and banks within the EMBA modelled for MEE-2. Whilst there are no known areas of aggregation for sea snakes within the extended combined EMBA (see Section 4.6.2), individual sea snakes may be impacted by hydrocarbons predicted at and near to their habitat preferences (see Section 4.6.2).

The potential impacts to sea snakes following exposure to hydrocarbons have been discussed above.

Sharks and Rays

Pelagic sharks and rays may frequent submerged shoals and banks to feed within the EMBA modelled for MEE-04. The potential impacts to sharks and rays following exposure to entrained hydrocarbons have been discussed above.
All Settings
Coral
The potential impacts to coral and coral recruitment / spawning following exposure to entrained hydrocarbons have been discussed above.
Productivity
The potential impacts to plankton and offshore productivity following exposure to entrained hydrocarbons have been discussed above.
Seagrass Beds, Macroalgae and Mangroves
The potential impacts to seagrass beds, macroalgae and mangroves following exposure to entrained hydrocarbons have been discussed above.

Summary of Potential Impacts to Socio-economic Values	
Setting	***Receptor Group***
Nearshore Island and Mainland Coastal Areas (Nearshore Waters)	***Fisheries – Commercial*** The potential impacts to commercial fisheries following exposure to hydrocarbons have been discussed above.
	Fisheries – Traditional Although no designated traditional fisheries have been identified within the PAA or EMBA, it is recognised that Indigenous communities' fish in the shallow coastal and nearshore waters of Ningaloo Reef and therefore may be impacted if a worst-case hydrocarbon spill were to occur. Impacts would be similar to those identified for commercial fishing, in the form of a potential fishing exclusion zone and possible contamination/tainting of fish stocks.
	Tourism and Recreation Tourism would likely be adversely affected if a visible surface slick entered areas of tourism activity. Spill modelling predicted low probability of hydrocarbon contact to the closest tourism area, such as the Montebello MP and Dampier AMP and archipelago. These areas have some seasonal charter boat operators and fishing activities, mainly concentrated around the islands. Modelling also predicted low probabilities of entrained hydrocarbon exposure at areas such as the Ningaloo Coast located over 200 km south of the PPA. These areas experience high levels f seasonal tourism and recreational activities. Impacts would be temporary exclusion of these activities within the exposed areas. No long-term impacts are expected due to the distance and weathering and fate of the hydrocarbons exposed to prior to reaching these areas.

MEE-04 Loss of Marine Vessel Separation – Risk Analysis
A bowtie risk analysis was undertaken to assess MEE-04; refer to the below figures for bowtie diagrams which were an output of Woodside's risk analysis process.

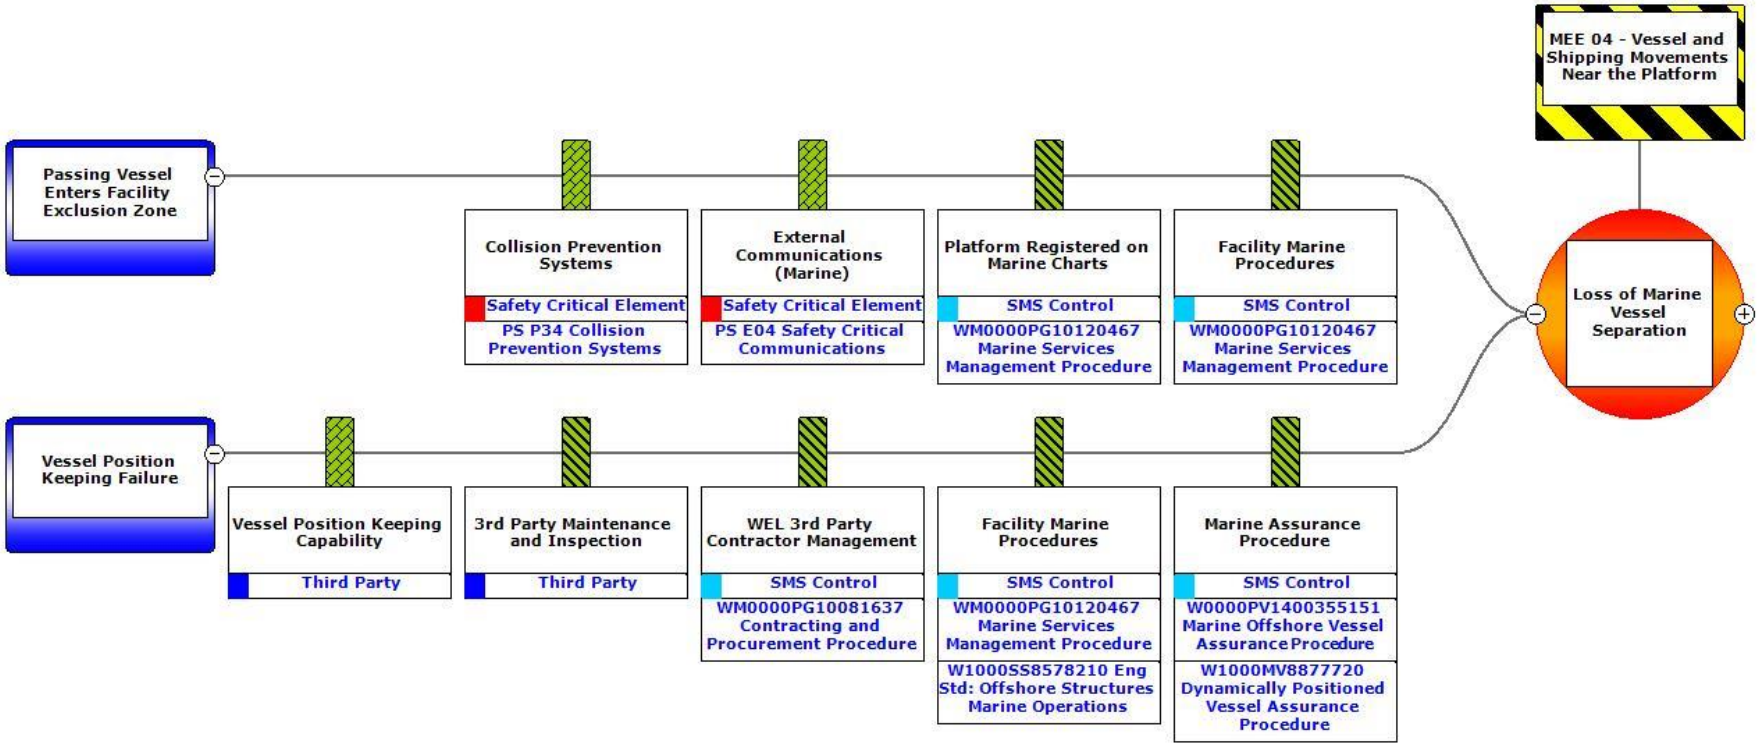

Figure 6-26: MEE-04 Loss of Vessel Separation (Causes 1-2)

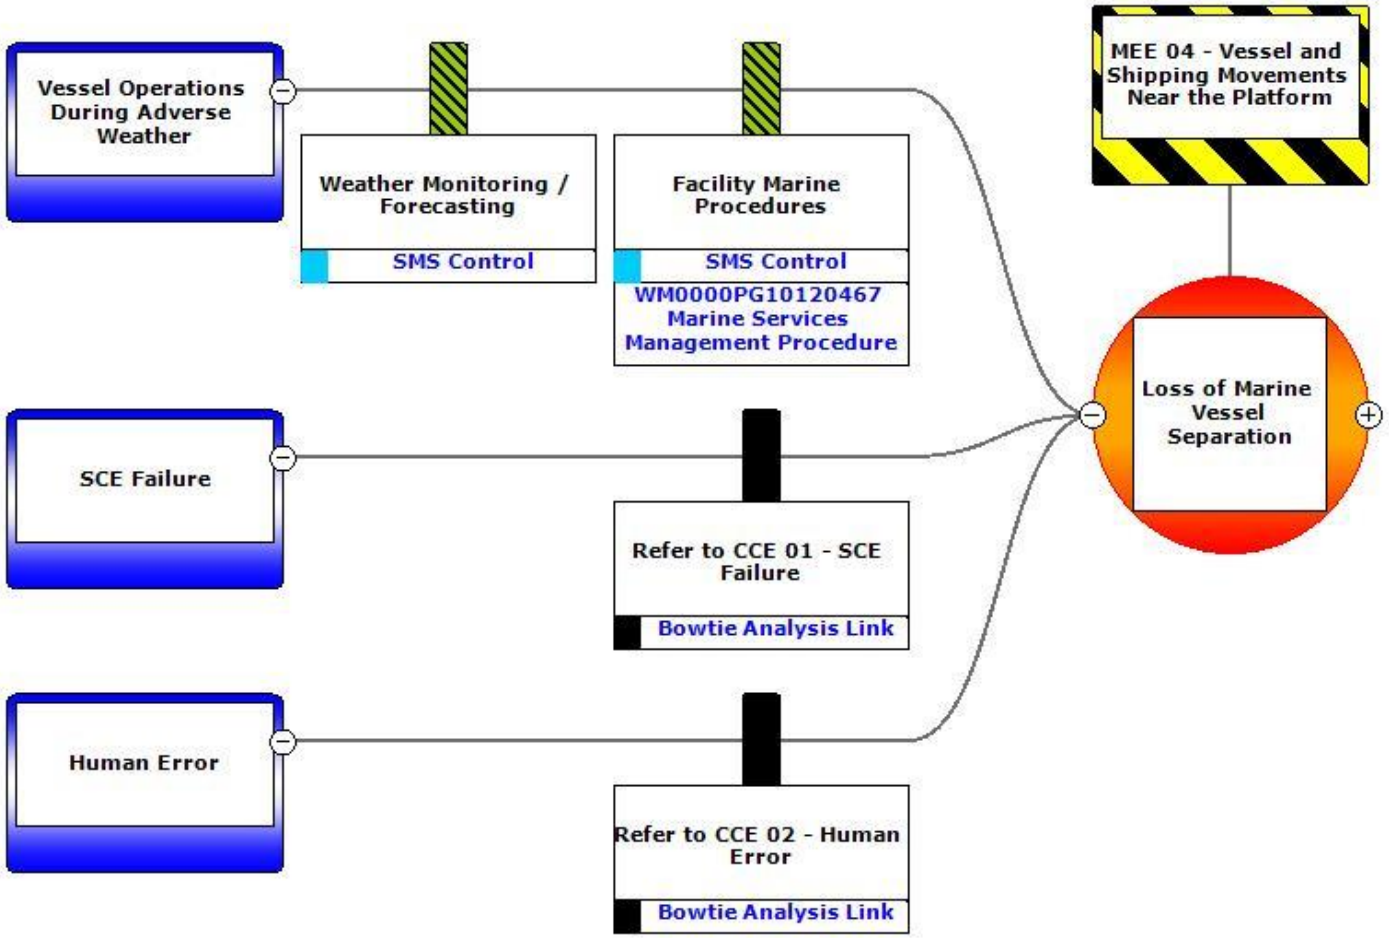

Figure 6-27: MEE 04 Loss of Marine Vessel Separation (Causes 3-5)

Risk Based Analysis				
For risks identified as MEEs, a detailed risk-based Bowtie Analysis (as outlined in Section 2.7.3) has been used to identify, analyse and demonstrate that controls in place reduce the risk associated with each MEE to ALARP. Controls have been selected following hierarchy of control principles and consider independence of each barrier and their type of effect in controlling the hazardous event. Application of Woodside's Risk Management Procedures and implementation of the Pluto A Operations Safety Case and Pluto Export Pipeline Safety Case ensures the continuous identification of hazards, systematic assessment of risks and ongoing assessment of alternative control measures to reduce risk to ALARP, which includes: • ongoing hazard identification, risk assessment and the identification of control measures • ongoing integrity management of hardware control measures in accordance with the operational performance standards which define requirements to be suitably maintained, such that they retain effectiveness, functionality, availability and survivability. For each SCE, detailed requirements for equipment functionality, availability, reliability and survivability are incorporated into SCE Performance Standards which also include the relevant assurance tasks (e.g. inspection, maintenance, testing and monitoring requirements) to ensure technical integrity. Bowtie analysis was undertaken to assess MEE-04, with review of formal safety assessment studies.				

MEE-04 Loss of Marine Vessel Separation – Demonstration of ALARP ALARP Control Measures				
Hierarchy	***Control / Barrier***	***SCE / Management System Reference***	***Type of Effect***	***Control Adopted***

ALARP Statement:

On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts and risks of a remote likelihood unplanned hydrocarbon release as a result of a loss of marine vessel separation.

The principle of inherent safety and environmental protection is based on the prevention of the MEE through design of the facility jacket and pipeline, flowline and riser integrity and ensuring controls are assurance through maintenance and inspection, and safe operating practices applied. If hydrocarbon loss of containment occurs, mitigation measures are in place to minimise the consequence by limiting the inventory which can be released and implementing remediation.

The controls in place for prevention and mitigation of MEEs are specified and assured through implementing the Pluto A Operations Safety Case(s), SCE management procedures including technical performance standards for SCEs and MSPSs for Safety Critical Procedures.

The application of Woodside Risk Management Procedures, and implementation of the Pluto Subsea Pipeline and Pluto A Operations Safety Cases ensures the continuous identification of hazards, systematic assessment of risks and ongoing assessment of alternative control measures to reduce risk to ALARP, which includes:

ongoing hazard identification, risk assessment and the identification of control measures

ongoing integrity management of hardware control measures in accordance with SCE technical performance standards which define requirements to be suitably maintained, such that they retain effectiveness, functionality, availability and survivability.

Given the controls in place to prevent and control loss of containment events and mitigate their consequences, it is considered that MEE risk associated with Loss of Marine Vessel Separation at the riser platform is managed to ALARP

Demonstration of Acceptability

Acceptability Statement

Loss of marine vessel separation has been evaluated as having a ‘moderate’ level of risk rating. Woodside considers ‘moderate’ risk ratings as broadly acceptable if the adopted controls are implemented. Due to the consequence associated with MEE-04, Decision Type B has been applied, and ALARP is demonstrated using good industry practice, consideration of company and societal values and risk-based analysis, if legislative requirements are met and societal concerns are accounted for and the alternative control measures are grossly disproportionate to the benefit gained.

Acceptability is demonstrated with regard to the oil spill risk considerations as described in Section 6.8.5 (MEE-01) (the considerations include principles of Ecologically Sustainable Development, internal context, external context and other requirements (includes laws, policies, standards and conventions)).

Surface or subsea release from flowline, pipeline and riser to the marine environment and atmosphere within PSZ (MEE-02) – caused by loss of control of suspended load		x	x	x	x	x	x	B	C	1	M	LCS GP PJ RBA CV		EPO 17
Hydrocarbon release from topsides equipment to the marine environment and atmosphere – caused by loss of control of suspended load		x	x	x		x		A	D	1	M		Acceptable if ALARP	

Description of Source of Risk

Lifting activities on the riser platform can take place from the platform crane between supply vessels and laydown areas, or between laydown areas. Lifting operations performed using the platform or visiting vessel cranes could potentially lead to dropped objects, impacting assets (topsides equipment, subsea infrastructure) inside the riser platform 500 m PSZ, potentially leading to a hydrocarbon loss of containment from topsides and/or subsea infrastructure. Loss of suspended load has been identified as an MEE (MEE-05). A loss of suspended load may arise from:

- lifting equipment failure
- facility lifting operations
- adverse weather

A number of common failure causes due to human error and SCC failures are presented in the generic Human Error and SCE Failure bowties in Section 6.8.10.

Loss of Control of Suspended Load – Credible Scenarios

The identified outcome of this MEE is a loss of containment of hydrocarbons due to impact of a dropped object on topsides equipment or subsea pipelines resulting in a release of the hydrocarbon inventory to the atmosphere or the marine environment.

Decision Type, Risk Analysis and ALARP Tools

Woodside has a good history of implementing industry standard practice in subsea system design and construction. In the company's recent history, it has not experienced any loss of suspended load events that have resulted in significant releases or significant environmental impacts.

Decision Type

Decision Type B has been applied to this risk under the Guidance on Risk Related Decision Making (Oil and Gas UK 2014). This reflects the complexity of the risk, the higher potential consequence and stakeholder implications should the event be realised. To align with this decision type, a further level of analysis has been applied using risk-based tools including the bowtie methodology (described in Section 2.7.3) and hydrocarbon spill trajectory modelling. Company and societal values were also considered in the demonstration of ALARP and acceptability, considered through internal reviews, and stakeholder consultation (Section 5).

A loss of control of a suspended load is considered an MEE (MEE-05). The hazard associated with this MEE is the hydrocarbon inventory of flowlines and risers, or topsides process and non-process hydrocarbons.

Quantitative Spill Risk Assessment

The credible worst-case hydrocarbon scenario for MEE-02 is considered to apply to a loss of control of suspended load, as they may credibly arise from damage to hydrocarbon containing subsea infrastructure within the 500 m PSZ. A quantitative spill risk assessment was not conducted for the topsides loss of containment scenario due to the relatively small credible release volume. Potential escalation events are considered and previously discussed in Section 6.8.7 Loss of Structural Integrity.

Likelihood

In accordance with the Woodside Risk Matrix a likelihood rating of "Highly Unlikely" is assigned for potential environmental consequences from loss of containment events caused by dropped objects. Formal safety assessment

studies considered the frequency of dropped objects from platform into sea with potential impaction to flowline or export pipeline being limited to 1.0E-05 per year, or 1 in 100,000 years. This aligns with an experience-based likelihood assessment as it 'has occurred once or twice in the industry' and is considered appropriate also for hydrocarbon release from topsides equipment to the marine environment and atmosphere, due to the nature of topsides infrastructure, containment storage design and locations, and lifting protocols in place.

Consequence

The spatial extent and fate (incl. weathering) of the spilled hydrocarbons were considered during the impact assessment for a loss of control of suspended load. These considerations were informed primarily by the outputs from the numerical modelling studies undertaken by RPS, available information on environmental sensitivities that may credibly be impacted in the event of a worst-case spill, and relevant literature and studies considering the effects of hydrocarbon exposure. Refer to Section 6.8.9 (MEE-02) and Section 6.9.2 for a description of the consequence potentially resulting from subsea and topsides loss of containment scenarios, respectively – as applicable worse-case outcomes from loss of control of suspended load events.

Benthic disturbance

In the unlikely event of an object being dropped into the marine environment, potential environmental effects would be limited to slight physical impacts on benthic communities. In most cases, objects will be able to be recovered and therefore these impacts will also be temporary in nature. However, there may be instances where objects are unable to be recovered due to health and safety, operational constraints or other factors such as the difficulty of recovering dropped objects at depth. When dropped objects are unable to be recovered, the impact will continue to be slight but permanent.

MEE-05 Loss of Control of Suspended Load from Platform – Risk Analysis
A bowtie risk analysis was undertaken to assess MEE-05; refer to the below figures for bowtie diagrams which were an output of Woodside's risk analysis process.

MEE-05 Loss of Control of Suspended Load from Platform – Demonstration of ALARP ALARP Control Measures				
Hierarchy	***Control / Barrier***	***SCE / Management System Reference***	***Type of Effect***	***Control Adopted***

For risks identified as MEEs, a detailed risk-based Bowtie Analysis (as outlined in Section 2.7.3) has been used to identify, analyse and demonstrate that controls in place reduce the risk associated with each MEE to ALARP. Controls have been selected following hierarchy of control principles and consider independence of each barrier and their type of effect in controlling the hazardous event.

Application of Woodside's Risk Management Procedures and implementation of the Pluto A Operations Safety Case and Pluto Export Pipeline Safety Case ensures the continuous identification of hazards, systematic assessment of risks and ongoing assessment of alternative control measures to reduce risk to ALARP, which includes:

- ongoing hazard identification, risk assessment and the identification of control measures
- ongoing integrity management of hardware control measures in accordance with the operational performance standards which define requirements to be suitably maintained, such that they retain effectiveness, functionality, availability and survivability.

For each SCE, detailed requirements for equipment functionality, availability, reliability and survivability are incorporated into SCE Performance Standards which also include the relevant assurance tasks (e.g. inspection, maintenance, testing and monitoring requirements) to ensure technical integrity.

A bowtie analysis quantitative spill risk assessment was undertaken to assess MEE-05.

Company Values

Refer to Section 6.8.6 for a discussion of company values in relation to the pipeline and riser loss of containment scenario.

Societal Values

Refer to Section 6.8.6 for a discussion of societal values in relation to the pipeline and riser loss of containment scenario.

ALARP Statement:

On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts and risks of a highly unlikely likelihood unplanned hydrocarbon release as a result of a loss of control of suspended load.

The principle of inherent safety and environmental protection is based on the prevention of the MEE through design of structural integrity and impact protection, and lifting equipment and standards ensuring the systems are operated within their design envelope through operating practices and assurance through maintenance and inspection. If hydrocarbon loss of containment occurs, mitigation measures are in place to minimise the consequence by limiting the inventory which can be released and implementing remediation.

The controls in place for prevention and mitigation of MEEs are specified and assured through implementing the Safety Case(s), SCE management procedures including technical performance standards for SCEs and MSPSs for Safety Critical Procedures.

The application of Woodside Risk Management Procedures, and implementation of the Pluto Export Pipeline and Pluto A Operations Safety Cases ensures the continuous identification of hazards, systematic assessment of risks and ongoing assessment of alternative control measures to reduce risk to ALARP, which includes:

ongoing hazard identification, risk assessment and the identification of control measures

ongoing integrity management of hardware control measures in accordance with the SCE technical performance standards which define requirements to be suitably maintained, such that they retain effectiveness, functionality, availability and survivability.

Given the controls in place to prevent and control loss of containment events and mitigate their consequences, alongside procedural control of facility operations, it is considered that MEE risk associated with a loss of control of suspended load is managed to ALARP.

MEE-05 Loss of Control of Suspended Load from Platform – Demonstration of ALARP ALARP Control Measures				
Hierarchy	***Control / Barrier***	***SCE / Management System Reference***	***Type of Effect***	***Control Adopted***
Demonstration of Acceptability				
Acceptability Statement Loss of suspended load has been evaluated as having a 'moderate' level of risk rating. As per Section 2.2.1., Woodside considers 'moderate' risk ratings as broadly acceptable if the adopted controls are implemented. Due to the consequence associated with MEE-05, Decision Type B has been applied, and ALARP is demonstrated using good industry practice, consideration of company and societal values and risk-based analysis, if legislative requirements are met and societal concerns are accounted for and the alternative control measures are grossly disproportionate to the benefit gained. Acceptability is demonstrated with regard to the oil spill risk considerations as described in Section 6.8.5 (MEE-01) (the considerations include principles of Ecologically Sustainable Development, internal context, external context and other requirements (includes laws, policies, standards and conventions).

Pluto: Major Environment Event Datasheet	
MEE Number	All
Hazard Description	Generic Human Errors
Hazard Description	
Hazard Overview and Scope	

Pluto: Major Environment Event Datasheet
There are a number of causes of human errors which contribute to MEEs, or which can result in failure or degradation of the barriers in place to protect against MEEs. These are presented in the following bowtie pages and include: task issues, e.g. poor task design; time pressures, task complexity; poor physical interfaces/working environment; provision of inappropriate tools for the task; communication errors, i.e. poor-quality information, lack of clarity in instructions; operator failings, e.g. competence, fitness, impairment or fatigue; and organisational issues, e.g. peer pressure, poor safety culture, inadequate supervision, lack of clarity on roles and expectations. The Generic Human Errors bowtie illustrates the causes, outcomes and the barriers in place for these failure mechanisms. Human Errors are managed solely via the WMS (no SCEs) and the bowtie is included in this section for completeness. Refer to Section 7 Implementation Strategy for applicable Management System Procedures.

Loss of hydrocarbons to marine environment due to loss of well containment during drilling of the Xena-03 well	x	x	x	x	x	x	B	B	1	M	LCS GP PJ RBA CV SV	Acceptable if ALARP	EPO 18

Description of Source of Risk

Woodside has identified a subsea well blowout as the scenario with the worst-case credible environmental outcome as a result of loss of well containment (LOWC) during drilling of the Xena-03 well. A LOWC is an uncontrolled release of reservoir hydrocarbon and/or other well fluids to the environment. A blowout is an incident where formation fluid flows out of the well or between formation layers after all the predefined technical well barriers (e.g. the blow out preventer [BOP]) or activation of the same has failed. Woodside has identified one well blowout scenario:

- Well blowout – full reservoir open to flow in the 9-7/8" hole section
- The LOWC MEE scenario from all Pluto wells during operations is considered separately.

Industry Experience

A risk assessment by AMSA of oil spills in Australian ports and waters (Det Norske Veritas 2011) concluded that:

overall national exceedance frequency for oil spills from offshore drilling in Australia is 0.033 for spills > 1 tonne/year decreasing to 0.008 for spills > 100 tonnes/year

probability of a blow-out from a well intervention is 1 x 10-4 (0.0001, or 0.01%), considerably lower than drilling activities (International Association of Oil and Gas Producers 2010).

Woodside has a good history of implementing industry standard practice in well design and construction. In the company's history, it has not experienced any well containment events that have resulted in significant releases or significant environmental impacts.

Credible Scenario – Loss of Well Containment

The credible worst-case scenario to be considered during drilling of the Xena-03 well is an uncontrolled subsea release to environment lasting <64 days. This time frame has been selected because:

- The Mutual Aid Memorandum of Understanding informed a likely relief well drilling and response time following the Montara well loss of containment in 2009 (77 days); and
- Internal Woodside guidelines and procedures indicate that appropriate modelling and response times for well based spill scenarios is reservoir-specific, and reliant on drilling times.

Quantitative Hydrocarbon Spill Modelling – Loss of Well Containment during Drilling at Xena-03

Spill modelling was undertaken by RPS (2024a), on behalf of Woodside, to determine the fate of hydrocarbon released from the loss of well containment scenario, based on the Xena condensate characteristics. The modelled release rate provided assumes the worst-case scenario for the largest oil volume release. Modelling considered metocean conditions throughout the year; this was done to inform the determination of consequence of loss of well control during intervention at any time of the year.

Table 6-39: Summary of modelled credible scenario – well blowout

Loss of well integrity	
Total discharge[104] at surface	5 days 1,880Sm³
Total discharge at seabed	59 days 44,751 Sm³
Water depth	178 m
Fluid	Eris-1 (and Pluto analogues) condensate

Subsea Plume dynamics

The well blowout surface/subsea release that has been modelled forecasts the size of the hydrocarbon droplets that would be released from the well as determined by the OILMAP model. The results of the OILMAP simulation predict that the discharge will generate a cone of rising gas that will entrain the oil droplets and ambient sea water up to the water surface. In the first week, the mixed plume is initially forecast to jet towards the water surface with a vertical velocity of around 12.3 m/s, gradually slowing and increasing in plume diameter as more ambient water is entrained. The diameter of the central cone of rising water and oil at the point of surfacing is predicted to be about 23 m.

Given the discharge velocity and turbulence generated by the expanding gas plume, the release is predicted to generate droplet sizes ranging from approximately 2,500 µm to 12,884 µm. The results suggest that beyond the immediate vicinity of the blowout, the majority of the released hydrocarbons will be present in the upper layers of the ocean, with the potential for oil to form floating slicks under sufficiently calm local wind conditions.

The ongoing nature of the release combined with the potential for the plume to breach the water surface may present other hazards, including conditions that may lead to high local concentrations of atmospheric volatiles. These issues should be considered when evaluating the practicality of the response operations at or near the blowout site.

Consequence Assessment

Potential Impacts Overview

EMBA

Quantitative hydrocarbon spill modelling results have been used to define the EMBA (Section 4.1) (see RPS, 2024a for further details).

Surface Hydrocarbons

In the event of the loss of well containment scenario occurring, surface hydrocarbons at or above 1 g/m^2 and 10 g/m^2 are forecast to potentially occur up to 100 km and 25 km respectively from the release site. Floating oil concentrations greater than 10 g/m^2 are predicted to contact Montebello AMP at 2% probability.

Entrained Hydrocarbons

Entrained hydrocarbons at concentrations equal to or greater than the 100 ppb threshold are predicted to be found up to 600 km from the release site. Contact by entrained hydrocarbons at concentrations equal to or greater than 100 ppb is predicted to be greatest at Montebello AMP with 81% probability of hydrocarbon contact and worst-case entrained concentration of 1,960 ppb. Several other sensitive receptors are predicted to be contacted at

[104] The discharge volumes are predicted using reservoir modelling software packages that consider a number of factors (well design, reservoir properties and environmental conditions such as water depth, temperature and pressure) to provide a production profile over the oil spill modelling period.

concentrations equal to or greater than 100 ppb include Tryal Rocks (4%), Argo-Rowley Terrace MP (1%), and Gascoyne MP (5%).

Dissolved Hydrocarbons

Dissolved aromatic hydrocarbons at concentrations equal to or greater than the 50 ppb thresholds are predicted to be found up to around 45 km from the release site. Contact by dissolved aromatic hydrocarbons at concentrations equal to or greater than 50 ppb is predicted to be at the Montebello AMP (5%), with a worst-case dissolved concentration of 454 ppb.

Accumulated Hydrocarbons

Shoreline oil concentrations above 10 g/m^2 are predicted to contact Muiron Islands with 18% probability. No shoreline oil impact is predicted at 100 g/m^2.

Summary of Potential Impacts to environmental values

The potential impacts of spilled hydrocarbons to species (protected and otherwise), marine primary producers, other habitats and communities, water quality, marine sediment quality, air quality, protected areas and socio-economic values are described in Section 6.8.5. Potential impacts specific the loss of well containment during drilling of the Xena-03 well are summarised below.

Marine Mammals

A range of cetaceans were identified as potentially occurring within the Xena-03 Operational and wider EMBA (Section 4.6.3). In the event of a LOWC during drilling of Xena-03, surface, entrained, and dissolved hydrocarbons exceeding environmental impact threshold concentrations may drift across habitat for cetacean species. Migratory routes and BIAs of cetaceans considered to be MNES may be affected, including humpback whales and pygmy blue whales (northbound and southbound migrations). As described in Section 4.6.3, cetaceans that have direct physical contact with surface, entrained, or dissolved aromatic hydrocarbons may suffer surface fouling, ingestion of hydrocarbons (from prey, water and sediments), aspiration of oily water or droplets, and inhalation of toxic vapours (Deepwater Horizon Natural Resource Damage Assessment Trustees [DHNRDT] 2016).

Pygmy blue whales and humpback whales are known to migrate seasonally through the Xena-03 Operational Area, the PAA and the modelled EMBA. Pygmy Blue Whale migration BIA intersects the Xena-03 Operational Area. A major spill in May to November would coincide with humpback whale migration through the waters off the Pilbara and North West Cape (Section 4.6.3). A major spill in April–August or October would coincide with pygmy blue whale migration (Section 4.6.5). Both pygmy blue and humpback whales are baleen whales, so are most likely to be significantly impacted by toxic effects when feeding. However, feeding during migrations is low level and opportunistic, with most feeding for both species occurring in the Southern Ocean. Fresh hydrocarbons (i.e. typically in the vicinity of the release location) may have a higher potential to cause toxic effects when ingested, while weathered hydrocarbons are considered to be less likely to result in toxic effects. As such, the risk of ingestion of hydrocarbons is low. Pygmy blue whale and humpback whale migrations are protracted through time and space (i.e. the whole population will not be within the EMBA), and as such, a spill from the loss of well integrity is unlikely to affect an entire population.

Coastal populations of small cetaceans and dugongs are known to reside or frequent nearshore waters, including the Ningaloo Coast, Muiron Islands, Montebello/Barrow Islands and Pilbara Southern Island Group which may be potentially impacted by entrained or dissolved hydrocarbons exceeding threshold concentrations in the event of a loss of well containment. The Exmouth Gulf is a known humpback whale aggregation area on the annual southern migration (September to December), as well as overlapping foraging, breeding, nursing and calving BIAs for dugongs (~207 km south of the Xena-03 Operational Area).; therefore, migratory humpbacks moving into the Gulf, or more residential dugongs, may be exposed to entrained or dissolved hydrocarbons above thresholds levels. However, entrained and dissolved hydrocarbons concentrations above the threshold are not expected within Exmouth Gulf itself. No hydrocarbon contact at or above threshold concentrations for the ecological EMBA is expected for Camden Sound, an important calving area for humpback whales.

The potential impacts of exposure are discussed above. However, nearshore populations of cetaceans and dugongs are known to exhibit site fidelity and are often resident populations. Therefore, avoidance behaviour may have greater impacts to population functioning. Nearshore dolphin species (e.g. spotted bottlenose dolphins) may exhibit higher site fidelity than oceanic species, although Geraci (1988) observed relatively little impacts beyond behavioural disturbance. Additional potential environment impacts may also include the potential for dugongs to ingest hydrocarbons when feeding on oiled seagrass stands, or indirect impacts to dugongs due to loss of this food source due to dieback in worst-affected areas.

In summary, a LOWC during drilling of Xena-03 has the potential to result in major long-term impacts to cetacean species and dugongs, with consequence severity dependent on the actual timing, duration and extent of a spill in relation to species' migratory movements and distributions.

Marine Reptiles

The Xena-03 Operational Area is unlikely to represent an important habitat for marine turtles as there is an absence of potential nesting or foraging habitat (i.e. no emergent islands, reef habitat or shallow shoals) and the water is deep (70-130 m). There is the potential for marine turtles to be present at submerged shoals within the EMBA, such as Rankin Bank and Glomar Shoals, however these receptors have a low probability of being contacted by dissolved hydrocarbons only above the threshold concentration (<1%).

An internesting BIA for the flatback turtle overlaps the Xena-03 Operational Area (Section 4.6.2). However, there are significant nesting and foraging sites along the mainland coast and islands of the region, including the Montebello Islands, and a number of BIAs and habitat critical for the survival of marine turtles overlap the EMBA (Section). In particular, the internesting BIAs and habitat critical to the survival of a species for green, loggerhead and hawksbill turtles extend for ~20 km from known nesting locations, and for ~60 km for flatback turtles. It is noted that the drilling of the Xena-03 well is proposed to be undertaken in Q2 2025, indicating species may be present, however avoids the peak nesting period (October to January) (refer to Section 4.6.5). Oil from an ongoing loss of containment could be present during nesting season for all hawksbill, flatback and green turtles depending on the timing of a spill. No floating or accumulated hydrocarbons above ecological threshold concentrations are predicted at shoreline locations,

although the nearshore waters of these turtle habitat areas have a low probability (1-2%) of contact with dissolved and/or entrained hydrocarbons.

In summary, a LOWC during drilling of Xena-03 has the potential to result in major long-term impacts to offshore foraging and nesting marine turtles, with consequence severity dependent on the actual timing, duration and extent of a spill in relation to species' migratory movements and distributions.

In general, sea snakes are found in continental shelf waters around offshore islands and potentially submerged shoals (water depths <100 m. Sea snakes may be present in the wider EMBA at the submerged shoals, Rankin Bank and Glomar Shoals, as well as the submerged reefs and shoals of Barrow Island and southern Pilbara islands. Sea snakes may also be present in nearshore waters of the mainland and islands which, along with submerged reefs and shoals, have the potential to be contacted by entrained and/or dissolved hydrocarbons above the threshold concentrations. Their abundance is not expected to by high given the water depth and offshore environment. However, sea snake species in Australia generally show strong habitat preferences (Heatwole and Cogger, 1993); species that have preferred habitats associated with submerged shoals may be disproportionally affects by a hydrocarbon spill affecting such habitat.

Therefore, a loss of well containment during drilling of Xena-03 may have a minor disruption to some individuals in the offshore environment. Population level impacts to sea snake species are not, however, considered credible.

Fish, Sharks and Rays

Shark and ray species may occasionally transit through the area and may potentially be exposed to hydrocarbons from a loss of well containment during drilling of the Xena-03 well, including species such as whale sharks and manta rays. Whale sharks may transit offshore open waters when migrating to and from Ningaloo Reef, where they aggregate for feeding from March to July. Both the Xena-03 Operational Area and EMBA overlap the whale shark foraging BIA identified in Section 0. Should sharks or rays be present in offshore waters near the PAA during the spill, direct impacts may occur if foraging within surface slicks or in the upper 20 to 30 m of the water column containing entrained hydrocarbons and dissolved aromatics. Contamination of their food supply and the subsequent ingestion of this prey may also result in long term impacts as a result of bioaccumulation. Impacts are predicted to be limited to a small number of animals given the absence of key habitat and the low numbers of animals that may transit through the area during the short period when spilled hydrocarbons are present.

Seabirds and Migratory Shorebirds

Offshore waters of the PAA are potential foraging grounds for seabirds associated with the coastal roosting and nesting habitat (e.g. Ningaloo, Muiron Islands and the Barrow/Montebello Islands). A breeding BIA for the wedge-tailed shearwater overlaps the Xena-03 Operational Area. Foraging and breeding BIAs for a number of seabirds and migratory shorebirds overlap with the EMBA (Section 4.6.4). A hydrocarbon spill may result in surface slicks disrupting a significant portion of the foraging habitat for seabirds, including foraging BIAs, which are generally associated with breeding habitats. Seabird distributions are typically concentrated around islands, so hydrocarbons near nesting/roosting areas may result in increased numbers of seabirds being impacted, with many species of seabirds, such as the wedge-tailed shearwater and the various species of tern, foraging relatively close to breeding islands/colonies. Potential impacts on seabirds and shorebirds are expected to be major and long-term in the unlikely event of a loss of well control. However, given the volatile and non-persistent nature of the hydrocarbons and lack of shoreline accumulation predicted, the extent of impacts is not expected to result in a threat to the overall viability of seabird or shorebird populations in the wider region.

Other Habitats, Species and Communities

There is potential for plankton communities to be impacted where entrained hydrocarbon threshold concentrations are exceeded due to a loss of well containment during drilling of the Xena-03 well. A range of lethal and sublethal impacts may occur to plankton exposed to entrained or dissolved hydrocarbons within the EMBA. Communities are expected to recover quickly (weeks/months) due to high population turnover (ITOPF, 2011). It is therefore considered that any potential impacts would be low magnitude and temporary in nature.

Pelagic fish populations in the open water offshore environment of the EMBA are highly mobile and have the ability to move away from a marine diesel spill. It is therefore unlikely that fish populations would be exposed to widespread hydrocarbon contamination. Pelagic fish populations are distributed over a wide geographical area so impacts on populations or species level are considered to be limited. Combined with these factors and the rapid dispersion of condensate, it is considered that any potential impacts will be minor.

Other communities (e.g. demersal fish, benthic infauna and epifauna) and key sensitivities (e.g. KEFs identified in Section 4.7) occur within the EMBA and may potentially be exposed to entrained hydrocarbons from a loss of well containment.

Water Quality

It is likely that water quality will be reduced at the release location of the spill; however, such impacts to water quality would be temporary and localised in nature due to the rapid dispersion and weathering of condensate. The potential impact is therefore expected to be low.

Protected Areas

Entrained and/or dissolved hydrocarbons at or exceeding the 100 ppb and 50 ppb threshold, respectively, have a low probability of contacting the Argo-Rowley Terrace AMP, Montebello AMP, Gascoyne AMP and Ningaloo AMP and WHA. Entrained and dissolved hydrocarbons are only predicted within the surface waters of the deep open waters of these protected areas, with no contact to seabed habitats or to shoreline contact. Potential impacts to water quality and the natural values (e.g. mobile protected species) in these areas would be temporary and localised in nature due to the rapid dispersion and weathering of the condensate, as described above. Visible surface hydrocarbons (at or exceeding 1 g/m2) are not predicted to reach any protected areas.

Socio-economic

A spill resulting from a loss of well containment during drilling of the Xena-03 well is considered unlikely to cause significant direct impacts on the target species fished by Commonwealth State active fisheries identified in Section 4.10.1 which overlap with the EMBA. The fisheries management areas that overlap with the EMBA are predominantly for demersal fish species (demersal finfish and crustaceans) that inhabit waters in the range of >60–200 m depth, or pelagic species which are highly mobile. Therefore, a spill from a loss of well control is expected to only result in negligible impacts, considering that hydrocarbons are confined to the upper layers of the water column beyond the immediate area of the spill. Visible surface hydrocarbons at or exceeding 1 g/m2 may also occur up to 100 km from the release site, which may result in fouling of fishing gear and a perception of impacts to fish stocks by fisheries stakeholders and the public. There is the potential that a fishing exclusion zone would be applied in the area of the spill, which would put a temporary ban on fishing activities and therefore potentially lead to subsequent economic impacts on commercial fishing operators if they were planning to fish within the area of the spill. Such measures would likely be in place for less than a week and would not result in widespread or long term impacts to fishing activities.

Cultural Heritage

There are a number of historic shipwrecks identified within the EMBA, but none identified within 50 km of the PAA (Section 4.10).

The modelling results do not predict surface slicks contacting the identified wrecks, and the majority of entrained hydrocarbons are expected to occur close to the surface. However, shipwrecks in the subtidal zone could be exposed to entrained and dissolved hydrocarbons. Marine life that shelter and take refuge in and around these wrecks may be affected by in-water toxicity of dispersed hydrocarbons. The consequences of such hydrocarbon exposure may include large fish species moving away and resident fish species and sessile benthos such as hard corals exhibiting sub-lethal and lethal impacts (which may range from physiological issues to mortality).

Within the wider EMBA are several designated heritage places (Section 4.10). These places are also covered by other designations such as WHA. Potential impacts are discussed in the sections above.

Summary of Potential Impacts to Environmental Value(s)

In the highly unlikely event of a major hydrocarbon spill due to a loss of well containment during drilling of the Xena-03 well, the EMBA includes AMPs as well as other sensitive marine environments and associated receptors of the Muiron Islands, Ningaloo Coast, Rankin Bank, Montebello/Barrow Islands and the Pilbara Southern Islands Group. Long term impacts may occur at these locations, including socio cultural effects as a result of a major spill of condensate from drilling activities within the PAA.

Given the adopted controls, the overall risk rating for an unplanned hydrocarbon due to a loss of well containment during drilling of the Xena-03 well is Moderate based on a Major consequence (long-term impact (10–50 years) on highly valued ecosystem, species, habitat or physical or biological attributes, or to a community, social infrastructure or highly valued area/item of cultural significance), and a remote likelihood.

Demonstration of ALARP

No additional controls identified.				
Professional Judgement – Engineered Solution				
No additional controls identified.				
Risk Based Analysis				
A quantitative spill risk assessment was performed (refer Section 6.8.2)				
Company Values				
Woodside's corporate values require all personnel a to comply with appropriate policies, standards, procedures and processes while being accountable for their actions and holding others to account in line with Our Values. As detailed above, the Petroleum Activities Program will be performed in line with these policies, standards and procedures that include suitable controls to prevent loss of well integrity, and response should a loss of well integrity occur.				
Societal Values				
Due to the Petroleum Activities Program's potential extent of the EMBA, the loss of well integrity current risk rating presents a Decision Type B, in accordance with the decision support framework described in Section 2.6.1. Consultation was conducted for this program to identify the views and concerns of relevant persons, as described in Section 5. Woodside has consulted with AMSA and WA DoT on spill response strategies. In accordance with the MoU between Woodside and AMSA, a copy of the Oil Pollution First Strike Plan was provided to AMSA.				

ALARP Statement

On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type (i.e. Decision Type B, Section 2.6.1), Woodside considers the adopted controls appropriate to manage the risks and consequences of a highly unlikely unplanned hydrocarbon release as a result of a loss of well integrity. As no reasonable additional/alternative controls were identified that would further reduce the risks and consequences without grossly disproportionate sacrifice, the risks and consequences are considered ALARP.

Demonstration of Acceptability

Acceptability Criteria and Assessment

Loss of well integrity during drilling of the Xena-03 well was evaluated and the risk was rated as high due to the scale of potential environmental impacts. However, the loss of well integrity occurring is considered highly unlikely. As outlined in Section 2.6.1 , Woodside considers the current risk ratings for a Decision Type B to be acceptable, if ALARP is demonstrated using good industry practice, consideration of company and societal values and RBA, if legislative requirements are met and societal concerns are accounted for, and the alternative control measures are grossly disproportionate to the benefit gained.

Principles of ESDev

The impact and risk evaluation has taken into account the following relevant principles of ESDev:

- decision-making processes should effectively integrate both long-term and short-term economic, environmental, social and equitable considerations
- the principle of inter-generational equity—that the present generation should ensure that the health, diversity and productivity of the environment is maintained or enhanced for the benefit of future generations
- the conservation of biological diversity and ecological integrity should be a fundamental consideration in decision-making.

Internal Context

The Petroleum Activities Program is consistent with Woodside corporate policies, culture, processes, standards, structure and systems as outlined in the Demonstration of ALARP and Environmental Performance Outcomes, including:

- Woodside Environment and Biodiversity Policy
- Engineering Standards – Well Barriers
- Well Acceptance Criteria Procedure
- Global, Wells and Seismic – Well Control Procedure
- Woodside Engineering Standard – Rig Equipment
- Source Control Emergency Response Planning Guideline (SCERP Guidelines)
- Oil spill preparedness and response strategies are considered applicable to the nature and scale of the risk and associated impacts of the response are reduced to ALARP.

Monitoring and Evaluation (operational monitoring) as a key response in the highly unlikely event of a hydrocarbon release will assess and track the extent of the hydrocarbon contact and revise the predicted extent of impact.

In addition, the Planning Area for scientific monitoring can be re-assessed in the unlikely event of hydrocarbon release with consideration of the conservation values and social-cultural values of state and commonwealth protected areas (including AMPs), National and Commonwealth Heritage Listed places; tourism and recreation; and fisheries. The post-response SMP will consider assessment and monitoring in line with the affected receptors such as habitat and species, AMPs and fisheries.Woodside corporate values include working sustainably with respect to the environment and communities in which we operate, listening to internal and external stakeholders, and considering HSE when making decisions. consultation, outlined below, has been performed prior to the Petroleum Activities Program.

External Context

During consultation with relevant persons, DoT requested to be consulted on spill risks with a potential to impact State Waters (Section 5). Woodside has also consulted with AMSA on spill response strategies. In accordance with the MoU between Woodside and AMSA, a copy of the Oil Pollution First Strike Plan was provided to AMSA and DoT. No additional queries or concerns relating to a loss of well integrity hydrocarbon spill risk during drilling of the Xena-03 well were raised during consultation.

Other Requirements

Impact assessment has been informed by risk-based analysis, including hydrocarbon spill modelling. The proposed control measures are consistent with industry legislation, codes and standards, good practice and professional judgement including:

API Standard 53 for subsea BOP function testing

AEP (Australian Energy Producers) Memorandum of Understanding: Mutual Assistance for relief well drilling is in place. Woodside develops an activity SCERP, including the Relief Well Plan, which is signed off by the Drilling Engineering Manager and maintains a list of rigs that are currently operating in Australia.

OPGGS (Resource Management and Administration) Regulations 2011 to have an accepted WOMP and application to permanently plug for abandonment of the wells .

NOPSEMA will be notified of reportable and recordable incidents, if required (Section 7). A mutual aid MoU for relief well drilling is in place and the Woodside Head of Projects/Region (Global Wells and Seismic)maintains a list of rigs that are currently operating in WA.

The EMBA overlaps a number of BIAs for threatened and migratory species, as well as a number of State and Commonwealth MPAs and the Ningaloo Coast WHA. The residual risk of accidental hydrocarbon release from loss of well integrity during drilling of the Xena-03 well is not inconsistent with the relevant objectives and actions of any applicable recovery plans or threat abatement plans. Regard has been given to relevant conservation advice and wildlife conservation plans during the assessment of potential impacts. The Petroleum Activities Program is not considered to be inconsistent with the overall recovery objectives and actions of these recovery plans and conservation advice.

Acceptability Statement

The impact assessment has determined that an accidental hydrocarbon release as a result of a loss of well integrity represents a moderate cu–rent risk rating and may result in major, long-term impacts (10 - 50 years) on highly valued ecosystems, species, habitat or physical or biological attributes. A number of BIAs for protected species overlap with the BIA and EMBA. Relevant recovery plans and conservation advice have been considered during the impact assessment, and the Petroleum Activities Program is not considered to be inconsistent with the overall recovery objectives and actions of these recovery plans and conservation advice.

The likelihood of a loss of well integrity during drilling of the Xena-03 well occurring is highly unlikely, given the adopted controls. The adopted controls are considered consistent with industry legislation, codes and standards, and professional judgement and a risk-based assessment has been conducted to better understand the potential consequences and plan oil spill response. The adopted controls also meet the requirements and expectations of Australian Marine Orders, AMSA and AHO identified during impact assessment and consultation. As demonstrated in Section 6.10 the potential impacts of hydrocarbon release from loss of well integrity is not inconsistent with the relevant objectives and actions of any applicable recovery plans or threat abatement plans. Regard has been given to relevant conservation advice during the assessment of potential risks.

On the basis of the environmental impact assessment outcomes and Woodside's criteria for acceptability outlined in Section 2.8.2 this is considered an acceptable level of risk.

Hydrocarbon release from Pluto-A topsides equipment to the marine environment and atmosphere.			x	x		x	x	A	D	1	M	LCS GP PJ	Broadly Acceptable	EPO 19

Description of Source of Risk

The facility has a range of topsides process and non-process equipment. A loss of containment from the topsides includes hydrocarbon inventories that could be released to the environment from high pressure process gas equipment and piping manifolds, and non-process hydrocarbon and chemical inventories.

Hazards that could lead to loss of containment from the topsides are:

- corrosion
- erosion
- material defect
- welding defect
- piping/equipment repair/defect
- vibration fatigue failure
- equipment overpressure
- uncontrolled transfer

Escalation from MEEs can cause topsides loss of containment:

- Loss of Structural Integrity (MEE-03) (Section 6.8.7)
- Loss of Marine Vessel Separation (MEE-04) (Section 6.8.8)
- Loss of Control of Suspended Load from facility lifting operations (MEE-05) (Section 6.8.9).
- A number of common failure causes due to human error and SCC failures are presented in the generic Human Error and SCE Failure bowties in Section 6.8.10.

Topsides Loss of Containment – Credible Scenarios

Topsides process and non-process hydrocarbon inventories, and therefore, worst case credible spill scenarios, are relatively low for PLA riser platform in comparison to other offshore facilities, due to reservoir composition and the integrated Pluto Development design including NNC offshore philosophy, meaning limited offshore processing and storage inventory. The maximum credible process-hydrocarbon loss scenario includes the loss of the potential

condensate inventory within process vessels such as the production separator and produced water/condensate separator and cooler with potential ~30 m3 condensate inventory. The maximum potential non-process hydrocarbons loss of containment scenario on the topsides is associated with the largest diesel storage inventory in the crane pedestal storage tank (80 m3). While a number of hydrocarbon release scenarios were determined to constitute MEEs, the consequence assessment for a topsides loss of containment determined this source of risk is not an MEE.

Other smaller condensate and hydrocarbon inventories also present on the topsides (Section 3.4.1). Smaller volumes of stored diesel, hydraulic and lube oils and waste oil may also be released in case of loss of containment. While a number of hydrocarbon release scenarios were determined to constitute MEEs, the consequence assessment for a topsides loss of containment determined this source of risk is not an MEE.

Quantitative Hydrocarbon Risk Assessment

Spill modelling was performed by RPS, on behalf of Woodside to determine the fate of marine diesel (modelled as marine gas oil) released from loss of marine vessel separation within the PAA (RPS, 2024e) – as described in Section 6.8.8. The modelling assessed the extent of a marine diesel spill volume of 1000 m^3 for all seasons, using an historic sample of wind and current data for the region. The results of the modelling can be used to demonstrate that a marine diesel spill within the PAA has an EMBA that is not predicted to include any shoreline contact or accumulation at impact thresholds. A total of 200 replicate simulations were modelled over an annual period (50 per quarter). As stated above, the largest topsides loss of containment diesel storage tank volume is 80 m3; therefore, the modelling of 1000 m^3 is considered conservative for Topsides loss of containment scenarios. Historical spill risk assessment modelling undertaken for a smaller diesel spill (105 m3 released in under ten minutes) at the Greater Western Flank Project (GWF) location near the GWA facility, located 75 km north east of the facility (APASA 2016) also provides as an approximate analogue for the topside loss of containment scenario – which indicated floating hydrocarbons may occur above threshold criteria up to 10 km from the release site.

Hydrocarbon Characteristics

Marine diesel oil (MDO) is a mixture of both volatile and persistent hydrocarbons. Modelling conducted on a comparable marine gas oil (MGO) more typical of vessel fuel. Predicted weathering of marine diesel, based on typical conditions in the region, indicates that around 72% of the oil mass is forecast to have entrained and a further 24% is forecast to have evaporated over the first 24 hours (RPS, 2024e). After this time the majority of the remaining hydrocarbon is entrained into the upper water column, leaving only a small proportion of the oil floating on the water surface (<1%). Given the large proportion of entrained oil and the tendency for it to remain mixed in the water column, the remaining hydrocarbons will decay and/or evaporate over time scales of several weeks to a few months, thereby extending the area of potential effect.

Given the environmental conditions experienced in the PAA, marine gas oil is expected to undergo rapid spreading and this, together with evaporative loss, is likely to result in a rapid dissipation of the spill. Marine gas oil distillates tend not to form emulsions at the temperatures found in the region. The characteristics of the marine gas oil are given in Section 6.8.2.

Consequence Assessment

Consequences associated with hydrocarbon release due to a Topsides loss of containment event are similar, however substantially more localised than consequences presented in this EP for diesel loss of containment events detailed in Section 6.8.8 Unplanned Hydrocarbon Release: Loss of Marine Vessel Separation (MEE-04) and Section 6.9.3 Unplanned Hydrocarbon Release: Vessel Collision during Drilling and Tie-back Activities

Once released to the open offshore setting around the riser platform (refer to Section 4), the potential for impacts to environmental receptors is limited to those in the open ocean, up to 10 km from the riser platform.

Given the density of the hydrocarbon, this decrease in water quality will be restricted to the top few metres of the water column. As such, impacts to demersal or benthic receptors (e.g. Ancient Coastline or continental slope demersal fish KEF) are not considered credible.

Water Quality

There may be a minor short-term decrease in water quality in the immediate vicinity of the release location. The soluble fraction of condensate may cause acute toxic effects to planktonic organisms. Given the short generation times and high productivity of planktonic communities, this impact would be localised and have no lasting effect on planktonic species populations.

Air Quality

A topsides release of Pluto condensate may be potentially accompanied by release of a limited volume of methane and ethane released to atmosphere. The gas plume is expected to mix and disperse rapidly in the atmosphere. Hence, it has limited potential to impact fauna in the vicinity of the release location. Impacts, such as asphyxiation, would be highly localised and of no lasting effect to species populations.

Marine Fauna

A range of marine species may be present around the riser platform, such as cetaceans, marine turtles, whale sharks, fishes and birds. These species are widely distributed relative to the potential EMBA that would result from a topsides loss of containment (due to the relatively small volume of hydrocarbons compared to the scenarios considered in

Section 6.8.8). Many large marine fauna in the region are migratory and are seasonally present in the PAA, which reduces the likelihood of exposure. Air breathing marine species may be impacted by the reduction in air quality (refer above); however, the potential for this impact is very limited. Marine fauna at or near the sea surface may be contacted by liquid-phase hydrocarbons, resulting in oiling. This may lead to impacts such as irritation of sensitive mucous membranes (e.g. eyes, mouth and digestive tract), matting of feathers (leading to inability to fly and loss of insulation) or clogging of filtering structures (e.g. gills). Pelagic and site attached fish (i.e. those resident around risers and jackets) may be exposed to spilled hydrocarbons, but are expected to avoid areas of high concentrations. Depending on the degree of exposure and the sensitivity of the receptor, these impacts may lead to injury or death. Mortality of larger fauna is not expected to occur. No impacts to ecosystem function are expected. Given the volatile nature of the hydrocarbons and the relatively small release volume, the potential for these impacts is largely constrained to the initial 12 hours immediately after the release. Hence, the potential impacts to species would be localised and of no lasting effect to species populations.

Socio-economic

Slight, short term impacts may occur to other marine users (e.g. commercial fisheries); however, as the worst case marine diesel spill would weather rapidly, and there is already no fishing within PSZ and limited fishing within the Operational Area, it is unlikely that there would be any significant impact to commercial fishers.

Summary

Given the adopted controls, the overall risk rating for an unplanned hydrocarbon due to a Pluto-A Topsides Loss of Containment is Moderate based on a Minor consequence (short-term impact (1–2 years) on species, habitat (but not affecting ecosystem function), physical or biological attribute, or to a community or highly valued area/item of cultural significance community), and a highly unlikely likelihood.

Demonstration of ALARP

While the loss of topsides containment does not constitute an MEE, it is considered to be a potential MAE in the Pluto A Operations Safety Case. As such, this source of risk is managed under the SCE management system (Section 7.4) for the facility. Specific measures and controls presented below are drawn from this management system.

Control Considered	Control Feasibility (F) and Cost/Sacrifice (CS)	Benefit in Impact/Risk Reduction	Proportionality	Control Adopted
Legislation, Codes and Standards				
Offshore Petroleum and Greenhouse Gas Storage (Safety) Regulations 2009: Accepted Safety Case for the facility.	F: Yes. CS: Minimal cost. Standard practice.	Offshore Petroleum and Greenhouse Gas Storage (Safety) Regulations 2009: Accepted the Pluto A Operations Safety Case to: identify hazards that have the potential to cause an MAE detail assessment of MAE risks describe the physical barriers SCEs and the safety management systems identified as being required to reduce the risk to personnel associated with an MAE to ALARP, thus contributing to management of associated potential environmental consequences of MAEs.	Control based on legislative requirements – must be adopted.	Yes C 19.1
Good Practice				
Incident reports are raised for unplanned releases within event reporting system.	F: Yes. CS: Minimal cost. Standard practice.	Good practice that operators identify, report and learn from unplanned release events. Supports compliance	Control based on Woodside standard and regulatory	Yes C 13.5

Professional Judgement – Elimination				
None identified beyond those integrated within PLA facility design.				
Professional Judgement – Substitute				
None identified beyond those integrated within PLA facility design.				
Professional Judgement – Engineered Solution				
Maintain topsides hydrocarbon-containing infrastructure integrity (P01 – Pressure Vessels, P04 Tanks).	F: Yes. CS: Minimal cost. Standard practice.	Reduces the likelihood of topsides loss of containment through inspection and assurance of key hydrocarbon containing vessels/tanks.	Benefits outweigh cost sacrifice.	Yes C 19.2
Maintaining Safety Instrumented System (Safety Instrumented Functions and ESD actions) and valves to detect and respond to pre-defined initiating conditions, and/or initiating responses that put the process plant, equipment, and the wells in a safe condition to prevent or mitigate the effects of an MEE	F: Yes. CS: Minimal cost. Standard practice.	Safety instrumented systems reduce the risk of topsides loss of containment by detecting and responding to pre-defined conditions and/or initiate responses that put the process plant and equipment in a safe condition so as to prevent or mitigate the effects of an MAE/MEE.	Benefits outweigh cost sacrifice.	Yes C 13.3
Maintaining facility's open hazardous and non-hazardous drain system integrity as far as practicable (F22 – Open Hazardous and Diesel Drains).	F: Yes. The riser platform has been designed with an integral drains system (as practicable to suit NNC facility safety design requirements) to prevent escalation associated with hazardous inventories and support the appropriate containment of environmentally hazardous liquids. CS: Inherent feature of riser platform design ALARP. Some safety philosophy sacrifice.	Reduces the likelihood of environmental harm by: limiting escalation of an incident following loss of containment, fire and/or explosion by removing or containing flammable liquid from hazardous areas; supporting appropriate containment and disposal of environmentally hazardous liquids.	Benefits outweigh cost sacrifice.	Yes C 6.4
Emergency Response				

Mitigation – Emergency and Hydrocarbon Spill Response.	Standard practice to implementing management systems to maintain: Pluto Offshore Facility Emergency Response Plan Pluto Offshore Facility Oil Pollution First Strike Plan Oil Pollution Emergency Arrangements – Australia Refer to Section 7 for discussion around the ALARP assessment of controls related to hydrocarbon spill response

ALARP Statement:

The controls for the Topsides loss of containment are based on the controls similar to those identified for MEE-03, MEE-04 and MEE-05 (Sections 6.8.7 to 6.8.9) and are supported by specific measures presented in Section 7.2. On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the risks of a topsides loss of containment. As no reasonable additional/alternative controls were identified that would further reduce the consequences and risks without grossly disproportionate sacrifice, the risks are considered ALARP.

Demonstration of Acceptability

Acceptability Statement:

The consequence assessment has determined that, given the adopted controls, a highly unlikely worst case hydrocarbon release from topside loss of containment represent a Moderate risk rating. Consequences are unlikely to result in a consequence greater than Minor, short-term impacts. Further opportunities to reduce the risks have been investigated above. The adopted controls are considered good oil-field practice/industry best practice and consistent with the safety case. The potential risks are considered broadly acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the risks of process hydrocarbon release from loss of containment to a level that is broadly acceptable.

Loss of hydrocarbons to marine environment due to a vessel collision during drilling and tie-back of the Xena-03 well		x		x	x	x	A	C	1	M	LCS GP PJ	Broadly Acceptable	EPO 20

Description of Source of Risk

Background

The temporary presence of the MODU, AHVs, installation and support vessels in the Xena-03 Operational Area during Xena-03 Tie-back activities will result in a navigational hazard within the immediate area

Spill scenarios involving the MODU are not considered likely for a hydrocarbon release given the collision points, vessel speeds and locations of the vessel tanks. MODU fuel tanks are located in the MODU pontoons, typically located on the inner sides of pontoons and can be over 10 m below the waterline.

The installation vessel is expected to have a total fuel capacity of 2200 m^3, with the largest tank holding approximately 340 m^3 (Section 3.12.2). AHVs and other support vessels for the Xena-03 Tie-back activities are likely to have multiple isolated marine diesel tanks distributed throughout the hull of the vessel, typically ranging from 22 to 105 m^3.

In the unlikely event of a vessel collision involving the installation vessel or a support vessel during the Xena-03 Tie-back activities, the vessel will have the capability to pump marine diesel from a ruptured tank to a tank with spare volume in order to reduce the potential volume of fuel released to the environment. It is noted that a hydrocarbon spill from a loss of vessel separation during operational activities is assessed in Section 6.8.8.

Industry Experience

Registered vessels or foreign flag vessels in Australian waters are required to report events to the Australian Transport Safety Bureau (ATSB), AMSA or Australian Search and Rescue (AusSAR).

From a review of the ATSB marine safety and investigation reports, one vessel collision occurred in 2011/12 that resulted in a spill of 25–30 L of hydrocarbon into the marine environment as a result of a collision between a tug and support vessel off Barrow Island. Two other vessel collisions occurred in 2010, one in the port of Dampier, where a support vessel collided with a barge being towed. Minor damage was reported and no significant injury to personnel or pollution

occurred. The second 2010 vessel collision involved a vessel under pilot control in port connecting with a vessel alongside a wharf, causing it to sink. No reported pollution resulted from the sunken vessel. These incidents demonstrate the likelihood of only minor volumes of hydrocarbons being released during the highly unlikely event of a vessel collision.

From 2010 to 2011, the ATSB's annual publication defines the individual safety action factors identified in marine accidents and incidents: 42% related to navigation action (2011). Of those, 15% related to poor communication and 42% related to poor monitoring, checking and documentation (ATSB, 2011). The majority of these related to the grounding instances.

Credible Scenario

For a vessel collision to result in the worst-case scenario of a hydrocarbon spill potentially impacting an environmental receptor, several factors must align as follows:

- The identified causes of vessel interaction must result in a collision.
- The collision must have enough force to penetrate the vessel hull.
- The collision must be in the exact location of the fuel tank.
- The fuel tank must be full, or at least of volume which is higher than the point of penetration.

The environmental risk analysis and evaluation identified and assessed a range of potential scenarios that could result in a loss of vessel structural integrity, resulting in damage to fuel storage tank(s) and a loss of marine diesel to the marine environment. Spill scenarios involving the MODU are not considered likely for a hydrocarbon release given collision points, vessel speeds and locations of the vessel tanks. Instead, the most credible scenarios are associated with the collision of an installation vessel with a support vessel in the event that one should be used within the field.

In summary, it is not a credible scenario that the total storage volume of the MODU, installation and support vessels would be damaged or lost, as fuel is stored in more than one tank and stored within the hull, behind the bilge tanks, below the waterline.

The last scenario considered was a collision between a project vessel with a third-party vessel (i.e. other petroleum related vessel or commercial fishing vessel). This was assessed as being credible but highly unlikely, given the standard vessel operations and equipment in place to prevent collision at sea, the standby role of a support vessel (low vessel speed) and its operation in close proximity to the MODU (exclusion areas), and the construction and placement of storage tanks. Potential spill volumes for these scenarios are summarised in Table 6-41. Given the offshore location of the PAA, vessel grounding is not considered a credible risk.

Table 6-41: Summary of credible hydrocarbon spill scenario as a result of vessel collision

Scenario	Hydrocarbon Volumes	Preventative and Mitigation Controls	Credibility
Loss of containment from MODU as a result of vessel collision	Submerged marine diesel tanks up to an individual capacity of 500 m3.	Fuel tanks are located on the inside of pontoons and protected by location below water line, protection from other tanks, e.g. bilge tanks. The draught of vessel and location of tanks in terms of water line prevent the tanks from being breached.	Not credible Due to location of tanks.
Breach of support vessel fuel tanks due to support vessel – other vessel collision including commercial, shipping/fisheries.	Activity support vessel has multiple marine diesel tanks typically ranging between 22– 105 m^3 each.	Typically, double wall, tanks which are located midship (not bow or stern). Vessels are not anchored and steam at low speeds when relocating within the PAA or providing stand-by cover. Normal maritime procedures would apply during such vessel movements.	Credible Activity support vessel – other vessel collision could potentially result in the release from a fuel tank.
Breach of installation vessel fuel tanks due to collision with another vessel including	The installation vessel has multiple isolated tanks, largest volume of a single tank is unlikely to exceed 500 to 1000 m^3.	Tank locations midship (not bow or stern). Installation vessel will be holding station during installation activities or steaming at low speeds when relocating within the PAA.	Credible – Worst Case Installation vessel – third party vessel collision could potentially result in the release from a fuel tank.

commercial shipping/fisheries.			

Quantitative Hydrocarbon Risk Assessment

Spill modelling was performed by RPS, on behalf of Woodside to determine the fate of marine diesel (modelled as marine gas oil) released from a collision within the PAA (RPS, 2024e). The modelling assessed the extent of a marine diesel spill volume of 1000 m³ for all seasons, using an historic sample of wind and current data for the region. The results of the modelling can be used to demonstrate that a marine diesel spill within the PAA has an EMBA that is not predicted to include any shoreline contact or accumulation at impact thresholds. A total of 200 replicate simulations were modelled over an annual period (50 per quarter). As stated above, the largest tank volumes on an installation vessel is expected to be 500 m3; therefore, the modelling of 1000 m³ is considered conservative for a vessel collision scenario during drilling and tie-back activities.

Hydrocarbon Characteristics

Marine diesel oil (MDO) is a mixture of both volatile and persistent hydrocarbons. Modelling conducted on a comparable marine gas oil (MGO) more typical of vessel fuel. Predicted weathering of marine diesel, based on typical conditions in the region, indicates that around 72% of the oil mass is forecast to have entrained and a further 24% is forecast to have evaporated over the first 24 hours (RPS, 2024e). After this time the majority of the remaining hydrocarbon is entrained into the upper water column, leaving only a small proportion of the oil floating on the water surface (<1%). Given the large proportion of entrained oil and the tendency for it to remain mixed in the water column, the remaining hydrocarbons will decay and/or evaporate over time scales of several weeks to a few months, thereby extending the area of potential effect.

Given the environmental conditions experienced in the PAA, marine gas oil is expected to undergo rapid spreading and this, together with evaporative loss, is likely to result in a rapid dissipation of the spill. Marine gas oil distillates tend not to form emulsions at the temperatures found in the region. The characteristics of the marine gas oil are given in Table 6-42.

Table 6-42: Characteristics of the marine gas oil

Hydrocarbon type	Initial density (g/cm³) at 25 ºC	Viscosity (cP @ 25 ºC)	Component BP (ºC)	Volatiles %<180	Semi volatiles % 180–265	Low volatility (%) 265-380	Residual (%) >380
				Non-Persistent			Persistent
Marine Gas Oil	0.829	4.0	% of total	6	34.6	54.4	5

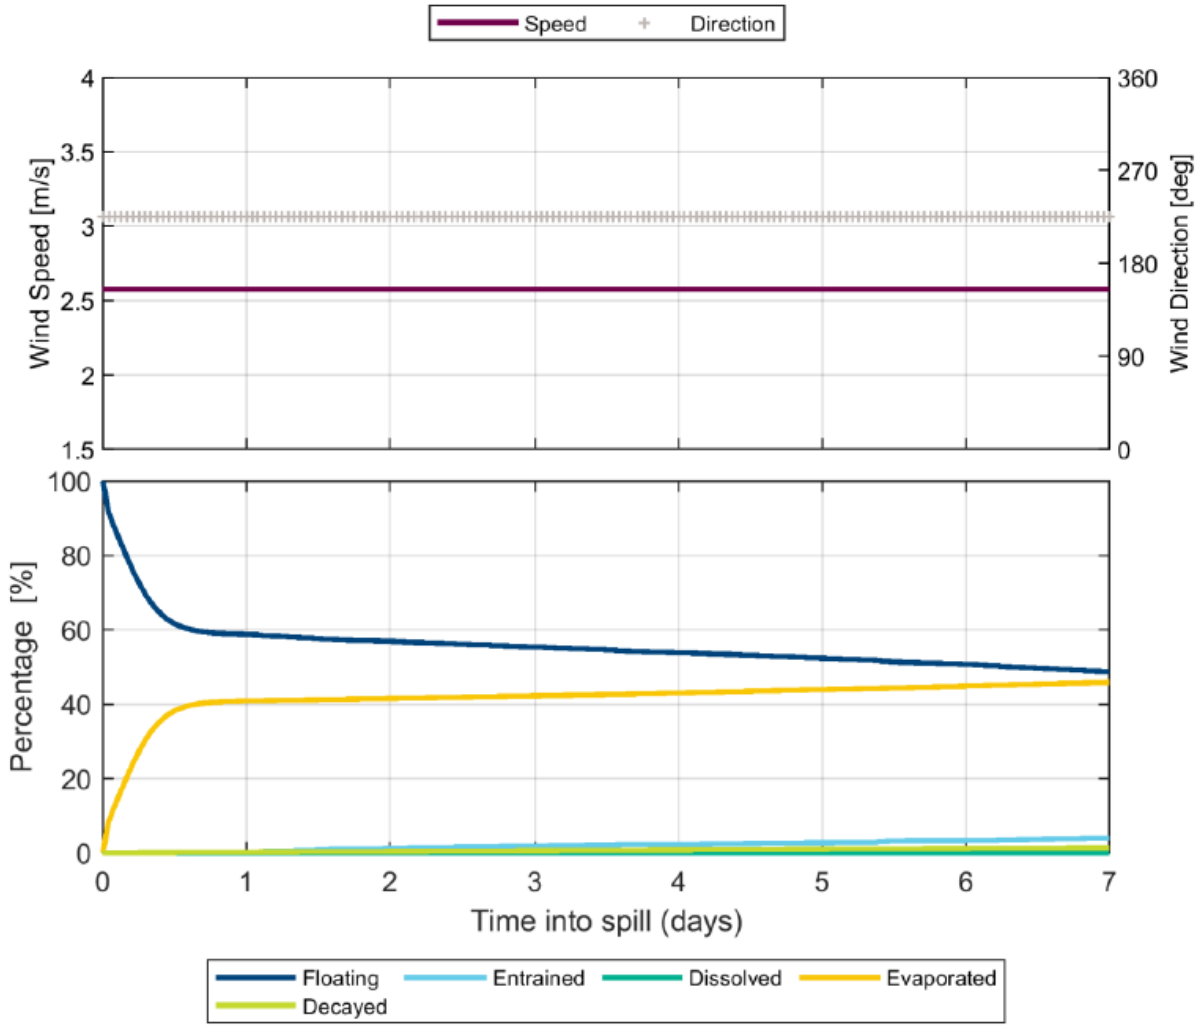

Figure 6-38: Proportional mass balance plot representing the weathering of MGO spilled onto the water surface as a one-off release (50 m3) and subject to a constant 5 kn (2.6 m/s) wind at 27 °C water temperature and 25 °C air temperature. (RPS Group, 2024e)

Consequence Assessment

Environment that May Be Affected

In the event of a 1000 m³ release of marine diesel spill due to vessel collision during drilling and tie-back activities, the modelling predicts a low probability of receptors being contacted by entrained hydrocarbons >100 ppb or dissolved aromatic hydrocarbons >50 ppb (RPS, 2024e).

The greatest likelihood of contact is at the Montebello AMP (24% probability for surface hydrocarbons, 57.5% probability for entrained and 19.5% for dissolved). All other sensitive locations identified are predicted to have a 0.5% probability or less of contact at threshold concentrations. Further, entrained hydrocarbons reaching these environments will be highly weathered, with the volatile and water soluble (often the most toxic) components expected to have dissipated. No surface hydrocarbons above 10 g/m2 are predicted to contact sensitive receptors and no shoreline oiling above 100 g/m2 is predicted (RPS, 2024e).

Potential Impacts to Environmental Value(s)

The potential impacts from a hydrocarbon release caused by a vessel seperation (Pluto Operations) are discussed in Section 6.8.8 (MEE-04). Taking into consideration that the EMBA derived from hydrocarbon spill modelling for a marine diesel spill (during drilling and operations), will fall within the EMBA of the spill from a loss of well containment outlined in Section 6.9.1 Moreover, given the expected maximum fuel tank size of the installation vessel (350 m3) is much lower than the modelled scenario (1000 m3), this assessment is considered to be conservative. A summary of the potential environmental impacts specific to a vessel collision scenario during drilling and tie-back activities are provided below.

Water Quality

There may be a short-term decrease in water quality in the immediate vicinity of the release location. Given the localised area of the potential EMBA and the rapid dispersion, dilution and weathering of a marine diesel spill, it is expected that any potential impacts will be minor and temporary in nature.

Marine Sediment Quality

Low probabilities (<2%) of entrained hydrocarbons were predicted to contact a few nearshore receptors, such as the Ningaloo Coast, Montebello Islands and Shoals, Barrow Island and Muiron Islands. No shorelines were predicted to be exposed to either shoreline accumulation or floating surface hydrocarbons at any threshold (RPS, 2024e). However, hydrocarbon contact from this scenario may lead to reduced marine sediment quality by processes such as adherence to sediment and deposition seabed habitat away from shoreline areas.

Protected Species

Cetaceans

As identified in Section 4, protected species including migrating pygmy blue whales may be encountered near the PAA, and therefore could be impacted in close proximity to the marine diesel spill location, where the volatile, water soluble and most toxic components of the diesel may be present. However, the window for exposure to hydrocarbons with the potential for any toxicity effects in these waters would be limited to a few days following the spill. Potential impacts may include behavioural impacts (e.g. avoidance of impacted areas), sub-lethal biological effects (e.g. skin irritation, irritation from ingestion or inhalation, reproductive failure) and, in rare circumstances, organ or neurological damage leading to death. Given the absence of critical habitats or aggregation areas, cetaceans in the area are expected to be transient, and impacts are expected to be limited to individuals or small groups of animals. Impact on the overall population viability of cetaceans are not predicted.

There is also the potential for migrating humpback whales, dugongs and coastal dolphin populations to be exposed in nearshore waters, however, the low concentrations and advanced degree of weathering of hydrocarbons in these nearshore waters is not expected to result in any discernible sublethal or lethal impacts to cetaceans.

Marine Turtles

The EMBA modelled for a release of hydrocarbons following a vessel collision overlaps with BIAs for marine turtle internesting habitat, as identified in Section 4.6.2. Turtle internesting habitats, such as those in waters adjacent to the Dampier Archipelago Islands, are predicted to have very limited or no exposure to surface or dissolved hydrocarbons above their respective impact threshold concentrations. Some marine turtles in these areas may be exposed to patchy occurrences of entrained hydrocarbons, which would be in an advanced state of weathering with reduced toxicity. Low concentrations are only capable of causing sublethal impacts to the most sensitive marine organisms and no lethal or sub-lethal impacts to marine turtles are expected in the BIAs. The potential for lethal and sub-lethal impacts to marine turtles is limited to small numbers of transient individuals that may be present in offshore waters near the release location.

Seabirds

Seabirds may also be exposed to marine diesel on the sea surface or upper water column, if resting or foraging in waters near to the release in the event of a marine diesel spill during drilling and tie-back activities. Impacts may include mortality due to oiling of feathers or the ingestion of hydrocarbons. However, due to the limited spatial extent of a marine diesel spill and limited window for exposure, population level impacts are not expected.

Other species

Other protected species that may occasionally transit through the area and may potentially be exposed to a marine diesel spill during drilling and tie-back activities, include shark and ray species such as whale sharks and manta rays. Should sharks or rays be present in offshore waters near the PAA during the spill, direct impacts may occur if foraging within surface slicks or in the upper 20 to 30 m of the water column containing entrained hydrocarbons and dissolved aromatics. Contamination of their food supply and the subsequent ingestion of this prey may also result in long term impacts as a result of bioaccumulation. Impacts are again predicted to be limited to a small number of animals given the absence of key habitat and the low numbers of A quickly (weeks/months) due to high population turnover (ITOPF, 2011). It is therefore considered that any potential impacts would be low magnitude and temporary in nature.

Pelagic fish populations in the open water offshore environment of the EMBA are highly mobile and have the ability to move away from a marine diesel spill. The spill-affected area would be confined to the surface layer and upper 20 to 30 m of the water column. It is therefore unlikely that fish populations would be exposed to widespread hydrocarbon contamination. Pelagic fish populations are distributed over a wide geographical area so impacts on populations or species level are considered to be negligible. Combined with these factors and the rapid dispersion of marine diesel, it is considered that any potential impacts will be minor.

Other communities (e.g. demersal fish, benthic infauna and epifauna) and key sensitivities (e.g. KEFs identified in Section 4.7) occur within the combined EMBA, however will not be directly exposed or impacted by a marine diesel spill as hydrocarbons are confined to the upper layers of the water column (0-10m).

Protected Areas

Entrained hydrocarbons at or exceeding the 100 ppb threshold have a low probability of contacting the Montebello AMP, Gascoyne AMP, and Ningaloo MPWHA in the event of a vessel collision during drilling and tie-back activities (RPS, 2024e). Entrained hydrocarbons are only predicted within the surface waters of the deep open waters of these protected areas, with no contact to seabed habitats or to shoreline contact. Potential impacts to water quality and the natural values (e.g. mobile protected species) in these areas would be temporary and localised in nature due to the rapid dispersion and weathering of the marine diesel, as described above. Dissolved and visible surface hydrocarbons (at or exceeding 1 g/m2) are not predicted to reach any other protected areas.

Socio-economic

A marine diesel spill is considered unlikely to cause significant direct impacts on the target species fished by the Commonwealth and State active fisheries identified in Section 4.10.1 which overlap with the combined EMBA. The fisheries that operate within the EMBA predominantly target demersal fish species (demersal finfish and crustaceans) that inhabit waters in the range of >60–200 m depth, or pelagic species which are highly mobile. Therefore, a marine diesel spill is expected to only result in negligible impacts, considering that hydrocarbons are confined to the upper layers of the water column (0-10m). There is the potential that a fishing exclusion zone would be applied in the area of the spill, which would put a temporary ban on fishing activities and therefore potentially lead to subsequent economic impacts on commercial fishing operators if they were planning to fish within the area of the spill. Such measures would likely be in place for less than a week and would not result in widespread or long term impacts to fishing activities.

Demonstration of ALARP

Given the adopted controls, the overall risk rating for an unplanned hydrocarbon release resulting from a vessel collision during drilling and tie-back activities is Moderate based on a Minor consequence (short term impact: 1-2 years), to the high value receptors (marine fauna, AMPs, KEFs and commercial fishing), and a highly unlikely likelihood.

Control Considered	*Control Feasibility (F) and Cost/Sacrifice (CS)9F*[110]	Benefit in Impact/Risk Reduction	Proportionality	Control Adopted

ALARP Statement: On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type (i.e. Decision Type A, Section 2.6.1), Woodside considers the adopted controls appropriate to manage the risks and consequences of an unplanned loss of hydrocarbon as a result of a vessel collision during drilling and tie-back activities. As no reasonable additional/alternative controls were identified that would further reduce the risks and consequences without grossly disproportionate sacrifice, the risks and consequences are considered ALARP.				
Demonstration of Acceptability				
Acceptability Statement The impact assessment has determined that an accidental hydrocarbon release as a result of a vessel collision during drilling and tie-back activities represents a moderate current risk rating and is unlikely to result in a risk consequence greater than Minor. Relevant recovery plans and conservation advice have been considered during the impact assessment, and the Petroleum Activities Program is not considered to be inconsistent with the overall recovery objectives and actions of these recovery plans and conservation advice. The adopted controls are considered consistent with industry legislation, codes and standards, good practice and professional judgement and meet the requirements and expectations of Australian Marine Orders, AMSA and AHO identified during impact assessment and consultation.				

The potential risks and consequences are considered acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the risks and consequences of a loss of vessel structural integrity to a level that is broadly acceptable.

Description of Source of Risk

Operations: Marine Diesel Bunkering and Refuelling

Marine diesel fuel is transferred to the facility (during crewed visits) and ASV by bunkering. Two key scenarios for the loss of containment of marine diesel during bunkering operations were identified:

- Partial or total failure of a bulk transfer hose or fittings during bunkering, due to operational stress or other integrity issues could spill marine diesel to the deck and/or into the marine environment. This would be less

than 200 L, based on the likely volume of a bulk transfer hose (assuming a failure of the dry break and complete loss of hose volume).

- Partial or total failure of a bulk transfer hose or fittings during bunkering or refuelling, combined with a failure in procedure to shutoff fuel pumps, for a period of up to five minutes, resulting in approximately 8 m3 marine diesel loss to the deck and/or into the marine environment.

Mechanisms are available to capture potential topsides diesel spillage from process/piping associated with the PLA bunkering station and manual fuel transfers, enabling drainage flow to be routed inboard to the open drains collections tank when the facility is crewed and during specific activities. The diesel unloading stations have isolation and vent valves to allow draining of bunkering hoses between uses.

Diesel system storage and use risks are covered in Topsides Loss of Containment risk Section 6.9.2.

Chemical Transfer, Bunkering, Storage and Use

Transfer and bunkering

Operational process chemicals are transferred to the facility in a dedicated MEG supply line, or transportable containers. Operational non-process and facility maintenance chemicals, such as subsea control fluid, cleaning products, paint, degreaser, etc., are typically transferred to the facility in containers.

Spills have the potential to occur during transfer to the facility (e.g. transport or lifting incidents). Given the small volumes being handled, the worst credible release volumes are relatively small (e.g. the typical largest chemical transfer is via transportable 4-6 m3 ISO containers of MEG, corrosion inhibitor and water clarifier).

Installation of the produced water handling module provided equipment to facilitate chemical bunkering of corrosion inhibitor and water clarifier, however this is not used - with a long-term isolation in place.

MEG loss of containment risks associated with supply and distribution is discussed below.

Storage and Use

Spills of chemicals (including non-process hydrocarbons stored in transportable containers) can originate from stored hydrocarbons/chemicals or equipment on the platform, vessel decks or subsea (refer to Section 6.7.5 for an assessment of the impacts of planned routine and non-routine chemical discharges).

The chemical planned to be stored in the largest volume on the riser platform is corrosion inhibitor (28 m3 stainless steel tank associated with the water handling module). Therefore, the worst-case credible chemical spill scenario could result in up to 28 m3 of corrosion inhibitor being discharged from the riser platform if all controls were to fail.

Selection of operational chemicals and those used during IMR activities is undertaken in accordance with the Woodside Chemical Selection and Assessment Environment Guideline.

Operational process chemicals are typically stored in dedicated vessels which have similar controls of those related to mitigating hydrocarbon releases, e.g. permanent piping to the process, isolatable by valves, open drain systems and collection tanks, and assurance through risk-based inspection in accordance with the Maintenance and Inspection regimes under the Maintain Assets Process (Section 6.1.1.2).

The riser platform and support vessels also store other non-process chemicals and hydrocarbons, in various volumes. Operational non-process chemicals and facility maintenance chemicals present on the riser platform and support vessels are typically held in low quantities (usually less than 50 L).

Chemical storage areas are typically set up in cabinets, or bunded storage areas to contain any releases to deck from transportable containers (e.g. ISOs, IBCs, barrels, drums, etc.). Releases from equipment are predominantly from the failure of hoses or minor leaks from process components, or spills during decant or refuelling of equipment, which can either be located within bunded/drained areas or outside of bunded/drained areas (e.g. over grating on cranes).

Subsea Support Vessels undertaking IMR activities may also store quantities of chemicals for subsea use. Subsea chemical selection process and use is described in Section 3.9. Accidental releases of small quantities of subsea chemicals may occur (e.g. deck spills). Operational experience indicates potential volumes of such spills is small (< 20 L).

ROV hydraulic fluid is supplied through hoses containing approximately 20 L of fluid. Hydraulic lines to the ROV arms and other tooling may become caught resulting in minor leaks to the marine environment. Small volume hydraulic leaks may occur from equipment operating via hydraulic controls subsea (subsea control fluid). These include the diamond wire cutter, bolt tensioning equipment, ROV tooling, etc.

Six-inch chemical supply and four-inch chemical supply lines

MEG may be released from 6-inch chemical supply and 4-inch chemical supply lines due to a rupture of the lines. Subsea umbilicals transport production chemicals such as corrosion inhibitor for distribution to wells and manifolds. The worst-case credible spill scenario has been determined to be a loss of containment of lean MEG from the 6inch chemical supply line due to a rupture caused by external impact (such as a vessel's anchor). If a rupture occurs the likely volume to be released to the marine environment is 35 m3 through the depressurisation of the MEG pipeline from its operating pressure of 25 MPag to seabed pressure. Additional MEG losses may occur if:

- there are severe tidal movements around the rupture location causing sea water ingress into the chemical supply line and displacing the MEG to the marine environment, or

- there is a downward flow of MEG due to gravity, dependent on the location of the rupture.

In the unlikely event that there is a continuous leak which does not trigger alarms due to flow differential between onshore and offshore, MEG release could be in the order of 30 m3/day resulting in a worst-case release of 420 m3, over two weeks, until detection based on consumption trends.

Surface Spill (Hydrocarbons/Chemicals)

Small diesel spills will rapidly spread on the water surface, with the diesel expected to evaporate and disperse rapidly (National Oceanic and Atmospheric Administration (NOAA) 2006). Woodside has commissioned RPS APASA to model several small marine diesel spills, including surface spill volumes of 8 m3 in the offshore waters of northwest WA. The results of these models have indicated that exposure to surface hydrocarbons above the 10 g/m2 threshold s limited to the immediate vicinity of the release site, with little potential to extend beyond 1 km. Based on these modelling results, the potential impacts of the credible marine diesel and chemical spill scenarios described above are reasonably expected to occur within 1 km of the release location.

The impact assessment assumes this release location to be the riser platform, as this is where all platform-based and most vessel-based spills will potentially occur. Given the nature and scale of the risk, along with the relatively low sensitivity of the receiving environment, no additional modelling studies were considered necessary to inform the impact assessment of unplanned discharges of hydrocarbons or chemicals during transfer, storage and use.

Hydrocarbon Characteristics

Refer to Section 6.8.2 for a description of the characteristics of marine diesel, including detail on the predicted fate and weathering of a spill to the marine environment.

Consequence Assessment

Marine Diesel

Given the low viscosity of marine diesel, along with the high portion of volatile components, a spill of up 8 m3 of marine diesel during transfer, storage or use would spread and weather rapidly. Environmental receptors at risk would be restricted to those in the vicinity (< 1 km from the release location).

Consequences to marine environmental receptors are assessed as consistent with diesel loss of containment impacts described in Section 6.9.2 however with an order of magnitude lower volume potential, and hence spatial extent.

Given the adopted controls, the overall risk rating for an unplanned bunkering loss of containment is Moderate based on a Minor consequence (short-term impact (1–2 years) on species, habitat (but not affecting ecosystem function), physical or biological attribute, or to a community or highly valued area/item of cultural significance community), and a unlikely likelihood.

Chemicals and Non-Process Hydrocarbons

MEG is considered PLONOR; however, very high concentrations of MEG (> 50%) may cause irritation to sensitive areas of larger marine fauna (e.g. eyes, gills). Woodside undertook ecotoxicity testing on the lean Pluto MEG (90% monoethylene glycol, ~10% demineralised water and 0.05% corrosion inhibitor). Seven tests, comprised of five different species representing five different taxonomic groups (algae, echinoderm, crustacea, molluscs and fish), were used. The toxicity of the MEG was found to be low, 240 mg/l for 99% species protection and 780 mg/l for 95% species protection (SKM, 2014). MEG is water soluble and will dilute rapidly in the marine environment to low concentrations. Impacts may occur as described above if marine fauna are within the mixing zone when the MEG is released. However, given MEG's low toxicity impacts, it is unlikely there would be any measurable effects on marine species resident in the vicinity of the release. The maximum credible spill of MEG is expected to mix rapidly with the local receiving environment with short term environmental impact.

Accidental releases of chemicals (including corrosion inhibitor) or non-process hydrocarbons decrease the water quality in the immediate area of the release; however, the worst-case loss of containment consequences are expected to be minor with a short-term impact given the water depths, the open ocean mixing environment, Operational Area distance from sensitive receptors and relatively low credible release volumes. Depending on the chemical released the toxicity and/ or potential to bioaccumulate may potentially result in impacts to pelagic fish or other marine species in the vicinity of the discharge.

Potential impacts to plankton from an accidental chemical spill may include acute toxicity resulting in mortality of planktonic organisms. Given the rapid turnover of plankton communities and nature and scale of the credible releases, these impacts will be short-lived (hours to days). Impacts to fish are expected to be of no lasting effect, as fish species are mobile and expected to avoid the area affected by an accidental chemical spill. Impacts to air-breathing fauna such as cetaceans, birds and marine turtles, are expected to be restricted to irritation of sensitive membranes such as the eyes, mouth, and digestive system.

Slight, short term impacts may occur to other marine users (e.g. commercial fisheries); however, as there is limited fishing within the Operational Area, it is unlikely there would be any significant impact to commercial fishers.

Summary of Potential Impacts to environmental values(s)

Given the adopted controls, the overall risk rating for an unplanned hydrocarbon or chemical release to the marine environment resulting from bunkering, transfer, storage and use is Moderate based on a maximum of Minor

consequence (short term impact: 1-2 years) to species, habitat (but not affecting ecosystems function), physical and biological attributes, or to a community or highly valued area/item of cultural significant, and an unlikely likelihood.

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Legislation, Codes and Standards				
Contract vessels complying with Marine Order 91 (Marine pollution prevention – oil) for safe vessel operations. Compliance with Marine Order 91 reduces the risk of accidental hydrocarbon release during transfer.	F: Yes. CS: Minimal cost. Standard practice.	Marine Order 91 is required under Australian regulations; implementation is standard practice for commercial vessels as applicable to vessel size, type and class.	Control based on legislative requirement – must be adopted.	Yes C 6.1
Vessel or ASV helicopter fuel storage areas (if applicable) are bunded or secondarily contained when they are not being handled/moved temporarily in accordance with the Australian Government Civil Aviation Safety Authority CAAP 92-4(0) 'Guidelines for the development and operation of offshore helicopter landing sites, including vessels. No helicopter refuelling occurs on PLA.	F: Yes. CS: Minimal cost. Standard practice.	Reduced the likelihood of an unplanned release during helicopter operations. The consequence is unchanged.	Controls based on legislative requirements – must be adopted.	Yes C 21.1
Implementation of bunkering procedures to reduce the risk of a hydrocarbon release as a result of a bunkering incident.	F: Yes. CS: Minimal cost. Standard practice.	Reduced the likelihood of an unplanned release	Benefits outweigh cost/sacrifice	Yes C 21.2
Good Practice				
PLA Bunkering equipment controls: All bulk transfer hoses shall be pressure-rated at purchase to reduce the risk of accidental hydrocarbon release during bunkering. There shall be dry-break couplings on fuel hoses. There shall be an adequate number of appropriately stocked, located and maintained spill kits.	F: Yes. CS: Minimal cost. Standard practice.	By ensuring the appropriate equipment is in place, tested and maintained appropriately, the likelihood of a spill occurring is reduced. Although no significant reduction in consequence could result, the overall risk is reduced.	Benefits outweigh cost/sacrifice	Yes C 21.3
Contractor procedures include requirements to be implemented during vessel bunkering/refuelling operations, including:	F: Yes. CS: Minimal cost. Standard practice.	By ensuring the appropriate equipment is in place, tested and maintained	Benefits outweigh cost/sacrifice.	Yes C 21.4

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
A completed PTW and/or job safety analysis (JSA) shall be implemented for the hydrocarbon bunkering/refuelling operation. Visually monitoring of gauges, hoses, fittings and the sea surface during the operation. Hoses will be checked before starting. Bunkering/refuelling will commence in daylight hours. If the transfer is to continue into darkness, the JSA risk assessment must consider lighting and the ability to determine if a spill has occurred. Hydrocarbons shall not be transferred in marginal weather conditions.		appropriately, the likelihood of a spill occurring is reduced. Although no significant reduction in consequence could result, the overall risk is reduced.		
Safely storing chemicals and diesel to prevent the release to the marine environment.	F: Yes. CS: Minimal cost. Standard practice.	Reduces risk of unplanned chemical/diesel release.	Benefits outweigh cost sacrifice.	Yes C 21.5
Chemical Selection and Assessment Environment Guideline (Woodside Doc No. WM0000MG9905057). Where Gold/Silver/E/D OCNS rating (and no OCNS substitution or product warning), chemicals are selected, no further control required If chemicals with a different OCNS rating, sub warning or non-OCNS rated chemicals are required, chemicals will be assessed in accordance with the procedure prior to use.	F: Yes. Woodside routinely implements a chemical selection process based on OCNS at the facility. CS: Minimal. The OCNS is widely used throughout the industry and chemical suppliers are aware of the requirements of the scheme.	Selection and assessment of chemicals in accordance with the Woodside process, reduces environmental impacts associated with planned chemical discharge.	Benefits outweigh cost sacrifice.	Yes C 5.1
Incident reports are raised for unplanned releases within event reporting system.	F: Yes. CS: Minimal cost. Standard practice.	Good practice that operators identify, report and learn from unplanned release events. Supports compliance with regulatory reporting requirements.	Control based on Woodside standard and regulatory requirements.	Yes C 13.5
Inspecting MEG Pipeline by ROV at the same frequency that the hydrocarbon export trunkline is inspected.	F: Yes. CS: Minimal cost. Standard practice.	Good practice to inspect integrity of MEG pipeline.	Benefit outweighs cost sacrifice.	Yes C 21.8

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Monitoring MEG use, investigating material discrepancies, and monitoring flow discrepancy to support identification of potential integrity failures.	F: Yes. The use of MEG is monitored to maintain adequate fluid in the system. CS: Minimal cost.	Chemical inventory monitoring and surveillance limits the volumes of MEG potentially discharged to the marine environment.	Benefit outweighs cost sacrifice.	Yes C 21.9

Facility open hazardous and non-hazardous drain system integrity maintained, as far as practicable.	F: Yes. The riser platform has been designed with an integral drains system (as practicable to suit NNM facility safety design requirements) to prevent escalation associated with hazardous inventories and support the appropriate containment of environmentally hazardous liquids. CS: Inherent feature of riser platform design to ALARP. Some safety philosophy sacrifice.	The drains system can support the appropriate segregation and containment of environmentally hazardous liquids in case of unplanned loss of containment before it reaches the environment.	Benefit outweighs cost sacrifice.	Yes C 6.4
Emergency Response				
Mitigation – Emergency and Hydrocarbon Spill Response.	Standard practice to implementing management systems to maintain: Pluto Offshore Facility Emergency Response Plan Pluto Offshore Facility Oil Pollution First Strike Plan Oil Pollution Emergency Arrangements – Australia Refer to Section 7 for discussion around the ALARP assessment of controls related to hydrocarbon spill response			
ALARP Statement: On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts of accidental spills of hydrocarbons from bunkering/refuelling, chemicals transfer, storage, and use, and accidental release of 6-inch MEG chemical supply line and 4-inch chemical supply lines. As no reasonable additional/alternative controls were identified that would further reduce the consequences and risks without grossly disproportionate sacrifice, the risks are considered ALARP				

Demonstration of Acceptability
Acceptability Statement: The consequence assessment has determined that, given the adopted controls, accidental spills during bunkering/refuelling, or spills from storage, transfer and use and from a release of 6-inch MEG chemical supply line and 4-inch chemical supply lines represent a moderate risk rating that is unlikely to result in a consequence greater than Minor, short-term impacts. Further opportunities to reduce the risks have been investigated above. The adopted controls are considered good oil-field practice/industry best practice and meet requirements of Australian Marine Orders. The potential risks are considered broadly acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the risks of bunkering/refuelling, and storage, transfer and use, and the release of 6-inch MEG chemical supply line and 4-inch chemical supply lines to a level that is broadly acceptable.

Accidental discharge of marine diesel/hydrocarbons to the marine environment during bunkering and/or refuelling.		x			x		A	D	2	M	LCS GP	Broadly Acceptable	EPO 21b
Accidental discharge of other hydrocarbons and chemicals from MODU or project vessels deck activities and equipment (e.g., cranes) including subsea ROV hydraulic leaks		x		x	x		A	F	1	L	LCS GP	Acceptable if ALARP	

Description of Source of Risk

Marine Diesel Bunkering/Refuelling

Bunkering of marine diesel between the MODU and project vessels as well as the possible refuelling of cranes, and other equipment may take place on the MODU.

Three credible scenarios for the loss of containment of marine diesel during bunkering operations have been identified:

- Partial or total failure of a bulk transfer hose or fittings during bunkering, due to operational stress or other integrity issues could spill marine diesel to the deck and/or into the marine environment. This would be in the order of less than 200 L, based on the likely volume of a bulk transfer hose (assuming a failure of the dry break and complete loss of hose volume).
- Partial or total failure of a bulk transfer hose or fittings during bunkering, combined with a failure in procedure to shutoff fuel pumps, for a period of up to fifteen minutes, resulting in approximately 24 m3 marine diesel lost to the deck and/or into the marine environment.

- Partial or total failure of a bulk transfer hose or fittings during helicopter refuelling could spill aviation jet fuel to the helicopter deck and/or into the marine environment. All helicopter refuelling activities are closely supervised and leaks on the helideck are considered to be easily detectable. In the event of a leak, transfer would cease immediately. The credible volume of such a release during helicopter refuelling would be in the order of <100 L.

Quantitative Spill Risk Assessment

Small diesel spills rapidly spread on the water surface, with the diesel expected to evaporate and disperse rapidly (National Oceanic and Atmospheric Administration (NOAA) 2006). Woodside commissioned RPS to model several small marine diesel spills in the offshore waters of northwest WA. The results of these models have indicated that exposure to surface hydrocarbons above the 10 g/m2 threshold is limited to the immediate vicinity of the release site, with little potential to extend beyond 1 km. Therefore, it is considered that exposure to thresholds concentrations from an 24 m3 surface spill from MODU bunkering activities would be well within the EMBA for the vessel collision scenario detailed in Section 6.9.3. Given this, the offshore location of the Xena-03 Operational Area, and the fact that the same hydrocarbon type is involved for both scenarios, specific modelling for an 24 m3 marine diesel release was not undertaken for this Petroleum Activities Program.

Hydrocarbon Characteristics

Refer to Section 6.9.3 for a description of the characteristics of marine diesel (comparable characteristics for marine gas oil used in the modelling), including detail on the predicted fate and weathering of a spill to the marine environment.

Chemical Spills – Deck and Subsea

MODU, Installation Vessel and ROV Operations

Deck spills can result from spills from stored chemicals or equipment. Installation vessels typically store chemicals in various volumes (20 L, 205 L; up to approximately 4000–6000 L). Storage areas are typically set up with effective primary and secondary bunding to contain any deck spills. Releases from equipment are predominantly from the failure of hydraulic hoses, which can either be located within bunded areas or outside of bunded or deck areas (e.g. over water on cranes). Helicopter refuelling may also take place within the PAA, on the helipad of the MODU and project vessels.

Chemicals that will be used and may be accidentally released include:

- non process chemicals (maintenance and cleaning chemicals)
- non process hydrocarbons - i.e. hydraulic fluids used in machinery (including cranes, winches, ROVs), small volumes of fuel
- drilling and well fluids
- pre-commissioning chemicals used for leak testing (MEG / treated water mixture).

Non-Process Chemicals

Non-process chemicals, such as wash chemicals, cleaning chemicals, maintenance and solvents, are generally held onboard in low quantities (typically <50 L containers) and are located within chemical cabinets or bunded storage areas on the project vessels and MODU. Non-process chemical spills may result from human error or damage to a chemical container during handling. Spills are generally captured by the drain system and routed to a holding tank for treatment or disposal onshore. In the event that a spill is not contained on deck or within a bunded area, there would be a release to the marine environment of an estimated up to 50 L.

Non-Process Hydrocarbons

Woodside's operational experience demonstrates that non-process hydrocarbon spills are most likely to originate from hydraulic hoses and are typically less than 100 L, with an approximate average volume <10 L.

Non-process hydrocarbons (hydraulic fluids) are used in hydraulic-powered machinery, such as winches, cranes and ROVs, and are hydrocarbon-based with added chemical component additives. Unplanned discharges are predominantly due to failure of hydraulic hoses or minor leaks from process components, or spills during periodic refuelling of hydraulic hoses. Spills or leaks from hydraulic hoses are usually very small volumes (~1 L) and are typically contained within a bunded or drained area under the equipment mounted on deck. These small on-deck spills are unlikely to reach the marine environment. A burst hydraulic hose on an extended crane could potentially result in hydraulic fluid being sprayed in a fine jet out over the water. However, this would only result in a small volume (~25 L) being released, due to the small capacity of hydraulic hoses.

Subsea leaks or spills can result from a loss of containment of fluids from subsea equipment including the BOP or ROVs. Subsea chemical use is described in Section 3.9. Typically, subsea spills during Woodside drilling activities generally do not exceed 26 L.

The ROV hydraulic fluid is supplied through hoses containing approximately 20 L of fluid. Hydraulic lines to the ROV arms and other tooling may become caught resulting in minor leaks to the marine environment. Small volume hydraulic leaks may occur from equipment operating via hydraulic controls subsea (subsea control fluid).

Hydraulic fluids are medium oils of light to moderate viscosity. They have a relatively rapid spreading rate and will dissipate quickly, particularly in high sea states. Lubricating oils may also be held onboard, typically stored with the non process chemicals and held in low quantities. These hydrocarbons are more viscous, so in the event of an unplanned discharge, the spreading rate of a slick of these oils would be slightly slower.

Contingency Activities

Wireline Operations

Minor unplanned leaks of hydrocarbons or chemicals during wireline activities with a live well include leaks such as:

- leaks from the lubricator, stuffing box and hose or fitting failure, which are expected to be less than 10 L (0.01 m3)
- loss of containment – fluids – surface holding tanks
- backloading of raw slop fluids in an IBC
- stuffing box leak/under pressure
- draining of lubricator contents
- excess grease/lubricant leaking from the grease injection head
- wind-blown lubricant dripping from cable/on deck
- lubricant used to lubricate hole.

Consequence Assessment

Marine Diesel

Given the low viscosity of marine diesel, along with the high portion of volatile components, a surface spill of marine diesel during transfer, storage or use would spread and weather rapidly. Environmental receptors at risk would be restricted to those in the vicinity (< 1 km from the release location). The biological consequences of a small volume diesel spill on identified open water sensitive receptors relate to the potential for minor consequences to megafauna, plankton and fish populations (surface and water column biota). Impacts to plankton may include acute toxicity resulting in mortality of planktonic organisms. Given the rapid turnover of plankton communities, these impacts will be short-lived (hours to days). Impacts to fish are expected to be of no lasting effect, as fish species are mobile and expected to avoid the area affected by a marine diesel spill incident. Impacts to larger fauna such as cetaceans and marine turtles may be light fouling, potentially resulting in irritation of sensitive membranes such as the eyes, mouth and digestive system (Helm et al. 2015). Mortality of larger fauna is not expected to occur. No impacts to ecosystem function are expected.

Hydrocarbons may extend into the Multiple Use Zone of the Montebello Marine Park and impacts would be as described above for open ocean receptors. No impacts are predicted to Continental Slope Demersal Fish Communities and the Ancient Coastline at 125 m Depth Contour KEFs. Although they do overlap the operational area, they are outside the predicted spill impact zone.

Slight, short term impacts may occur to other marine users (e.g. commercial fisheries); however, there is already no fishing within PSZ and limited fishing within the Operational Area it is unlikely that there would be any significant impact to commercial fishers.

Accidental spills of hydrocarbons or chemicals from the MODU, installation vessel and support vessels will decrease the water quality in the immediate area of the spill; however, the impacts are expected to be temporary and very localised due to dispersion and dilution in the open ocean environment.

Given the offshore/open water location, receptors such as marine fauna may be affected if they come in direct contact with a release (i.e., by traversing the immediate spill area). In the event that marine fauna come into contact with a release, they could suffer fouling, ingestion, inhalation of toxic vapours, irritation of sensitive membranes in the eyes, mouth, digestive and respiratory tracts, and organ or neurological damage. Cetaceans may exhibit avoidance behaviour patterns and given they are smooth skinned, hydrocarbons and other chemicals are not expected to adhere. Given the small area of the potential spill and the dilution and weathering of any spill, the likelihood of ecological impacts to marine fauna (protected species), other communities and habitats is expected to be have no lasting effect.

No impacts on socio-economic receptors are expected due to the low levels of fishing activity in the Xena-03 Operational Area, the small volumes of hydrocarbons/chemicals that could be accidentally spilled, and the localised and temporary nature of the impacts.

Summary of Potential Impacts to environmental values(s)

Given the adopted controls, it is considered that hydrocarbon spills to the marine environment from bunkering will not result in a potential impact greater than minor, short term local impacts on species, habitat (but not affecting ecosystems function), physical and biological attributes (i.e., Consequence – D). Further, other hydrocarbon and chemical spills to the marine environment from deck/subsea is expected to have no lasting effect (<1 month), localised impact not significant to environmental receptor (i.e., Consequence – F).

A reduction in the volumes of chemicals and hydrocarbons stored onboard MODU/ project vessels.	F: Yes. Increases the risks associated with transportation and lifting operations. CS: Project delays if required chemicals not on board. Increases the risks associated with transportation and lifting operations	No reduction in likelihood or consequence since chemicals will still be required to enable drilling activities to occur.	Disproportionate. The cost/ sacrifice outweighs the benefit gained	No
ALARP Statement On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the risks and consequences of unplanned release of chemicals and hydrocarbons from bunkering, deck and subsea spills during Xena-03 Tieback activities. As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts and risks are considered ALARP..				

Demonstration of Acceptability
Acceptability Statement: The consequence assessment has determined that, given the adopted controls, accidental spills during bunkering/refuelling from Xena-03 Tieback activities represent a moderate risk rating that is unlikely to result in a consequence greater than Minor, short-term impacts. Other accidental hydrocarbon or chemical spills to Deck/subsea during Xena-03 Tieback activities represent a low risk rating that is unlikely to result in potential impact greater than localised, minor and temporary disruption to a small proportion of the population and no impact on critical habitat or

activity. Further opportunities to reduce the risks have been investigated above. The adopted controls are considered good oil-field practice/industry best practice and meet requirements of Australian Marine Orders.

The potential risks are considered broadly acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the risks of unplanned hydrocarbon or chemical release from bunkering, deck and subsea spills to a level that is broadly acceptable.

Description of Source of Risk

Drilling Fluids - Transfers

A project vessel will undertake bulk transfer of drilling muds or base oil to the MODU, if and when required during tie-back activities. Failure of a transfer hose or fittings during a transfer or backload, as a result of an integrity or fatigue issue, could result in a spill of mud or base oil to either the bunded deck or into the marine environment.

The most likely spill volume of mud is likely to be less than 0.2 m2 based on the volume of the transfer hose and the immediate shutoff of the pumps by personnel involved in the bulk transfer process. However, the worst-case credible spill scenario could result in up to 8 m^3 of mud being discharged. This scenario represents a complete failure of the bulk transfer hose combined with a failure to follow procedures requiring transfer activities to be monitored, coupled with a failure to immediately shut off pumps (e.g. mud pumped through a failed transfer hose for a period of about five minutes).

Drilling Fluids - Slip Joint Packer Failure

The slip joint packer enables compensation for the dynamic movement of the MODU (heave) in relation to the static location of the BOP. A partial or total failure of the slip joint packer could result in a loss of mud to the marine environment. The likely causes of this failure include a loss of pressure in the pneumatic (primary) system combined with loss of pressure in the back up (hydraulic) system.

Catastrophic sequential failure of both slip joint packers (pneumatic and hydraulic) would trigger the alarm and result in a loss of the volume of fluid above the slip joint (conservatively 1.5 m^3) plus the volume of fluid lost in the one minute (maximum) taken to shut down the pumps. At a flow rate of 3800 L (1000 gallons) per minute this volume would equate to an additional 3.8 m^2. In total, it is expected that this catastrophic failure would result in a loss of 5.3 m2.

Failure of either of the slip joint packers at a rate not large enough to trigger the alarms could result in an undetected loss of 20 bbl (3 m^3) maximum assuming a loss rate of 10 bbl/hr and that MODU personnel would likely walk past the moon pool at least every two hours.

Loss of a drilling chemical container or drum during transfer from the supply vessel to the MODU may occur due to crane operator error or machinery failure. The maximum container that could be lost is an intermediate Bulk Container (IBC) which can hold 1 m³ of chemicals. In the event that an IBC or drum is lost to the marine environment and cannot be recovered the contents will discharge, either immediately or over a period depending on the damage to the drum or container.

NWBM Drilling Fluid System

The selection of a NWBM drilling fluid system (if required) will be based on Woodside processes; however, for the purposes of this risk assessment, an example base oil (Saraline 185V) has been used. Saraline 185V is a mixture of volatile to low volatility hydrocarbons. Predicted weathering of base oil, based on typical conditions in the region, indicates that about 50% by mass is predicted to evaporate over the first day or two. At this time, most of the remainder could be entrained into the water column. In calm conditions, entrained hydrocarbons are likely to resurface with up to 100% able to evaporate over time.

Table 6-43: Characteristics of the non water-based mud base oil

Oil type	Initial density (kg/m³)	Viscosity (cP @ 20 °C)	Volatiles (%) <180	Semi volatiles (%) 180–265	Low volatility (%) 265–380	Residual (%) >380	Aromatic (%) of whole oil <380 °C BP
Base oil (Saraline 185V)			***Non-Persistent***		***Persistent***		
	0.7760	2.0 @ 40°C	8.5	41.1	50.4	0	0

Cement

Bulk cement is transferred as powder from the supply vessel to the MODU prior to being mixed into a slurry in the cement unit. Additives are required to form a cement slurry; these are transferred to the MODU in drums from the supply vessel to the MODU. Unplanned discharge to the marine environment may occur due to crane operator error or machinery failure resulting in loss of a drum of cement additive, which cannot be recovered. Cement additives are typically stored in drums <100 litres.

Contingency Activities

Activation of the Emergency Disconnect Sequence

The EDS is an emergency system that provides a rapid means of shutting in the well (i.e. BOP closed) and disconnecting the MODU from the BOP. The EDS could be manually activated due to an identified threat to the safety of the MODU, including loss of MODU station keeping resulting from loss of multiple moorings, potential collision by a third-party vessel or a loss of well control. During operations, this could result in a subsurface release of a combination of WBM and/or NWBM and solids at the seabed and a release of base fluid. The volume of material released depends on the water depth and, hence, the length of the riser (i.e. the entire riser volume would be lost). The base oil of the NWBM would remain in an emulsion with the other components of the mud system. Approximately 103 m3 of base oil could be released in the event of the riser being disconnected when drilling with NWBM.

Consequence Assessment

Potential impacts to environmental values

Some drilling fluids/cement may be spilt at the sea surface (e.g., transfer failure) and some in the water column potentially close to the seabed (e.g., in the event of an EDS or Slip Joint Packer Failure). Due to water depth in the PAA (70-130 m), this will determine the exposure pathway, and hence potential impacts and receptors.

Water Quality

NWBM is made up of a number of components including base oil, which generally has a high volatile to semi-volatile fraction. If released to the marine environment at surface, this generally evaporates within the first 48 hours, with the remaining fraction being on the sea surface and weathering at a slower rate. As a result of this volatility, combined with the worst-case credible spill scenario volumes (8 m3, during bulk transfer from supply vessel to MODU), and based on Woodside's experience of modelling base oil, it is considered there would be an extremely small footprint area associated with any release. Therefore, any surface oil would be confined to open waters with a minor surface slick that would not reach any sensitive receptors. Therefore, impacts on water quality would be minor and temporary in nature. The material safety datasheet for Saraline 185V indicates that it is readily biodegradable, non-toxic in the water column and has low sediment toxicity (Shell, 2014). Marine fauna may be affected if they come in direct contact with a release (i.e., by traversing the immediate spill area), but due to the small footprint of such a spill, it is anticipated that any impacts would be negligible and temporary in nature.

WBM is made up of a number of components including a variety of chemicals, incorporated into the selected drilling fluid system to meet specific technical requirements. If released to the marine environment at surface, there would be an extremely small impact footprint area associated with a release. Any release would be confined to the open waters of the Operational Area that would not reach any sensitive receptors. Components of the WBM would settle out in the

water column and be subject to dilution. Given the low toxicity of WBM and its planned discharge during drilling, any impacts on water quality would be slight and temporary in nature.

The EMBA associated with the release of NWBM from the activation of the EDS would be small and limited to deeper water seabed surrounding the well site (the release point). The environmental consequence of such a release would include a highly localised area at the discharge location. Lethal impacts to the underlying infauna may occur but are considered unlikely, and recolonisation would occur over time. Elevated hydrocarbon and metal concentrations in the localised area of deposition would also occur, with reduction over time. It is likely that any impacts to water and sediment quality and low-sensitivity deeper water benthos would be short term, localised and a full recovery expected.

All chemicals that may be operationally released or discharged to the marine environment by the Petroleum Activities Program are evaluated using a defined framework and set of tools to ensure the potential impacts of the chemicals selected are acceptable, ALARP and meet Woodside's expectation for environmental performance. Therefore, any chemicals selected and potentially released are expected to be of low toxicity and biodegradable.

Base oil has a high volatile to semi-volatile fraction. A surface spill would typically evaporate within 48 hours, with the remaining portion to weather at a slow rate. The example base oil, Saraline 185V, is readily biodegradable, non-toxic in the water column and has low sediment toxicity (Shell, 2014). Due to it's volatility, and small worst-case credible spill scenario, there would be a very localised footprint unlikely to reach any sensitive receptors.

Given the occasional nature of unplanned chemical discharge, the small volumes, and the offshore location of the PAA, the change to water quality resulting from unplanned discharge of chemicals will not be substantial.

Therefore, any potential impact of a change in water and sediment quality and low-sensitivity deeper water benthos would be short-term and localised, with a full recovery expected. Receptor sensitivity of water quality is low (low value, open ocean), and therefore the consequence of a release of hydrocarbons/chemicals on water and sediment quality would be no lasting effect (F).

Marine Fauna

Injury or Mortality to Marine Fauna

As a result of a change in water quality, further impacts to receptors may occur, which may include injury or mortality to marine fauna resulting from exposure to toxins in the released drilling fluids. Neff (2010) explains that the lack of toxicity and low bioaccumulation potential of the drilling muds means that the effects of the discharges are highly localised and are not expected to spread through the food web (of which planktonic species are the basis). Given that surface discharges are rapidly dispersed, potential impacts would be highly localised and temporary.

Local increases in turbidity from cement spills may affect zooplankton with variations in predator prey dynamics, which favours planktonic feeders over visual feeders (Gophen, 2015), while impacts to phytoplankton may occur due to decreases in available light, therefore reducing productivity (Dokulil, 1994). The magnitude of potential impact to marine fauna is no lasting effect, which results in a consequence of Slight (E) based on the high receptor sensitivity.

Suspended sediment levels greater than 500mg/L are likely to produce a measurable impact on larvae of most fish species, and levels of 100 mg/L may affect the larvae of some species if exposed for periods greater than 96 hours (Jenkins and McKinnon, 2006). In addition, levels of 100 mg/L may affect the larvae of several marine invertebrate species. Dilution estimates (e.g. Hinwood et al., 1994; Neff, 2005) would suggest that suspended sediment concentrations from unplanned cement discharge, loss of drilling mud from Slip Joint Packer Failure, or activation of the EDS, would dilute rapidly with instantaneous exposures of 500 mg/L unlikely and exposure times of 100 mg/L well below 96 hours.

Due to the low levels of planktonic productivity in the offshore area, the fact that the Xena-03 Operational Area (70-130 m depth) is outside of the highly productive shelf break situated on the 200 m isobath, plankton populations on a regional scale are not expected to be adversely affected by drill and project fluid spills. In addition, due to the open nature of the marine environment of the Xena-03 Operational Areas and associated environmental conditions (i.e. windy, strong currents, etc.), the content and dispersive nature of drilling muds within the marine environment and the high population replenishment of these organisms, it is expected that impacts to plankton species will be limited to within tens of metres of the discharge point and return to previous conditions within a relatively short period of time. On this basis, the risk to plankton from unplanned discharges during Xena-03 Tie-back activities is low and would result in consequences no greater than slight, short-term effects.

Seafloor receptors (benthic communities and cultural heritage sites)

The impact area associated with release of NWBM from activation of the EDS would be small, limited to the seabed surrounding the well. Base fluids for NWBM are designed to be biodegradable in offshore marine sediments. Biodegradation can result in a low oxygen (anoxic) environment resulting in changes in benthic community structure. NWBMs are designed to be low in toxicity and are not readily bioavailable, based on their physical/chemical properties, for bioaccumulation to infauna and epifauna. Deleterious impacts to the infauna may still occur to a limited extent, together with increased hydrocarbon and metal concentrations in the area of deposition. The ability for the infauna communities to recolonise following a small localised disturbance within the Xena-03 Operational Area would mean impacts are short-term and slight.

Drill cuttings from unplanned loss of used drilling fluids would increase turbidity and TSS levels above ambient, where coarser material will deposit on the seabed and finer sediment material (WBM) will temporarily cause elevated TSS above the seabed surrounding the well. This would rapidly disperse and dilute with the prevailing seabed currents.

Accumulation of drill cuttings, grit and flocculent on the seabed causes changes in the physical properties of the seabed sediment such as the particle size distribution (PSD), the introduction of contaminants (metals such as barium) from retained drilling fluids (WBM) and associated ecological effects.

Impacts associated with unplanned drill and project fluid discharges will be largely limited to an area surrounding the well. The low sensitivity of the benthic communities/habitats within and in the vicinity of the Xena-03 Operational Area, combined with the low toxicity of WBMs and residual NWBMs, insoluble mineralised salts (the source of barium) having low bioavailability to benthic biota, and the highly localised nature and scale of predicted physical impacts to seabed biota, affirm that any predicted impact is considered likely but of a short-term environmental consequence.

Cultural Heritage

As described in Section 4.10, the Xena-03 Operational Area is located further offshore than the Ancient Coastline at 125 m depth contour KEF. Seabed disturbance resulting from Xean-03 Tie-back activities does not pose a threat to Indigenous Cultural features of the Ancient Landscape.

Summary of Potential Impacts to Environmental Values(s)

Given the adopted controls, it is considered that unplanned discharges of drilling fluids or cement to the marine environment will not result in a potential impact greater than slight and short-term impacts on species, habitat (but not affecting ecosystems function), physical and biological attributes (i.e. Environment Impact – E).

Not considered – control not feasible.	Not considered – control not feasible.	No

ALARP Statement

On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts and risks of unplanned release of project fluids. As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.

Demonstration of Acceptability

Acceptability Statement

The impact assessment has determined that, given the adopted controls, unplanned discharges of drilling fluids represent a low current risk rating that is unlikely to result in a potential impact greater than minor and/or temporary contamination above background levels and/or national/international quality standards and/or known biological effect concentrations on a localised scale. Further opportunities to reduce the risks and consequences have been investigated above.

The adopted controls are considered good oil-field practice/industry best practice. The potential risks and consequences are considered broadly acceptable if the adopted controls are implemented. Therefore, Woodside

considers the adopted controls appropriate to manage the risks and consequences of an unplanned discharge of NWBM/base oil or WBM to a broadly acceptable level.

Description of Source of Risk

Non-hazardous and Hazardous Waste

Normal operations on the facility, the MODU and support vessels generate a variety of hazardous and non-hazardous wastes. These materials could potentially impact the marine environment, if incorrectly disposed of, lost overboard or discharged in significant quantities.

Non-hazardous wastes include domestic and industrial wastes such as paper and cardboard, aluminium cans, bottles, polystyrene, organics and scrap steel. Hazardous wastes include recovered solvents, excess or spent chemicals, oil contaminated materials (e.g. sorbents, filters and rags), batteries and used lubricating oils and potentially material containing NORMs. Sand and sludges may be periodically generated during process and vessel maintenance. Many waste streams are only generated on the riser platform and support vessels during deployment of personnel to the facility for IMMR activities.

All waste materials not suitable for discharge to the environment, including hazardous wastes (i.e. liquid and solid wastes), generated during the Petroleum Activities Program are transported to shore for disposal or recycling by Woodside's licenced waste contractor.

Material generated onshore from pigging of the export pipeline has been tested in accordance with the relevant procedures and determined not to be classified as NORM therefore NORMs not expected to be encountered.

Consequence Assessment

The potential impacts of hazardous or non-hazardous solid waste / equipment accidentally discharged to the marine environment include contamination of the environment as well as secondary impacts relating to potential contact of marine fauna with wastes. This could result in entanglement or ingestion and lead to injury and death of individual animals. The temporary or permanent loss of waste materials into the marine environment is not likely to have a significant environmental impact, based on the location of the PAA, the types, size and frequency of wastes that could occur, and species present.

Water and Sediment Quality

Hazardous solid wastes such as paint cans, oily rags, etc., can cause localised contamination of the water and sediment through a release of toxins and chemicals. Given likely small volumes of any unplanned solid waste

discharge, and the occasional nature of the event, these would result in temporary and highly localised changes to the water quality.

In the unlikely event of an object being dropped into the marine environment, potential environmental effects would be limited to slight physical impacts on benthic communities. In most cases, objects will be able to be recovered and therefore these impacts will also be temporary in nature. However, there may be instances where objects are unable to be recovered due to health and safety, operational constraints or other factors such as the difficulty of recovering dropped objects at depth. When dropped objects are unable to be recovered, the impact will continue to be slight but permanent.

Seabirds and Migratory Shorebirds, Fish, Marine Reptiles and Marine Mammals

The unplanned discharge of solid wastes can result in mortality to fauna, either through contamination or physical injury depending on the nature of the waste. Marine fauna, including fish, seabirds and shorebirds, marine mammals and marine reptiles may be impacted through ingestion or entanglement of waste or through exposure to toxic chemicals. Ingestion or entanglement of marine fauna has the potential for physical harm which may limit feeding/foraging behaviours and thus can result in mortalities. Injury and fatality to vertebrate marine life caused by ingestion of, or entanglement in, harmful marine debris was listed as a key threatening process under the EPBC Act in August 2003 (DoEE, 2018). The Threat Abatement Plan for the impacts of marine debris on the vertebrate wildlife of Australia's coasts and oceans (DoEE, 2018) identifies EPBC Act-listed species for which there are scientifically documented adverse impacts resulting from marine debris. Marine turtles and seabirds in particular may be at risk from plastics which may cause entanglement or be mistaken for food (e.g. DoEE, 2018; Commonwealth of Australia, 2017) and ingested causing damage to internal tissues and potentially preventing feeding activities. In the worst instance this could have a lethal affect to an individual. Marine debris has been identified as threat in the Recovery Plan for Marine Turtles in Australia (2017–2027).

Impacts to species including fish, birds, marine mammals and marine reptiles from the unplanned discharge of solid waste is unlikely given low occurrence of unplanned discharges. Significant impacts are unlikely to occur at an individual level and will not occur at a population level, nor result in the decrease of the quality of the habitat such that the extent of these species is likely to decline.

The temporary or permanent loss of waste materials into the marine environment is not likely to have a significant environmental impact, based on the nature and scale of activities that may generate wastes, the types, size and frequency of wastes that could occur.

ALARP Statement: On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts and risks of accidental discharge of non-hazardous and hazardous wastes. As no reasonable additional/alternative controls were identified that would further reduce the impacts and risks without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.				

Demonstration of Acceptability
Acceptability Statement: The consequence assessment has determined that, given the adopted controls, the accidental discharge of non-hazardous waste and hazardous waste represents a low risk rating and is unlikely to result in a consequence greater than localised impacts to water quality, marine sediment and marine species with no lasting effects. Woodside, across its operations (including this facility), has a well-established waste management culture which underpins a strong performance and limits the potential for accidental releases to the marine environment. Opportunities to reduce waste management impacts and risks are employed through standard practices such as job planning, implementation of Waste Management Plans and job hazard analysis practices. The adopted controls are considered good oil-field practice/industry best practice and meet requirements of Australian Marine Orders. The potential impacts and risks are considered broadly acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the impacts and risks of accidental discharge of non hazardous and hazardous waste to a level that is broadly acceptable.

Dropped objects resulting in the disturbance of benthic habitat	x			x		x	A	D	1	L	GP PJ	Broadly Acceptable	EPO 25
Loss of station keeping of the MODU leading to anchor drag and the disturbance of benthic habitat	x			x		x							

Description of Source of Risk

The primary cause for unplanned seabed disturbance during the PAP is through dropped objects from the riser platform and support vessel operations or from installation of the Xena-03 mooring system, the MODU, subsea installation and support vessels. Additional unplanned disturbance to the seabed may occur from a loss of station keeping and subsequent anchor drag during MODU operations if a moored MODU is used. An assessment of the risks of loss of control of suspended loads from the platform, and waste/objects lost to sea is presented in Section 6.8.9 and 6.9.7 and is not considered further here.

Dropped Objects

There is the potential for objects to be dropped overboard from the riser platform and support vessel operations or from installation of the Xena-03 mooring system, the MODU, installation and support vessels to the marine environment. Objects that have been dropped during previous offshore activities include small numbers of personal protective gear (e.g. glasses, gloves, hard hats), small tools (e.g. spanners) hardware fixtures (e.g. riser hose clamp) and drill equipment (e.g. drill pipe); however, there is also potential for larger equipment to also be dropped during the activity, particularly during recovery of infrastructure from the seabed. The spatial extent in which dropped objects can occur is restricted to the PAA.

Anchor Drag

The Xena-03 well may be drilled using a moored or hybrid MODU. If a moored MODU is used for drilling the Xena-03 well, it will be secured on station by an 8 to 12 point pre-laid mooring system deployed to the seabed, as dictated by the mooring analysis. High energy weather events such as cyclones, occurring while the MODU is on station, can lead to excessive loads on the mooring lines, resulting in failure (either anchor(s) dragging or mooring lines parting). A failure of mooring integrity may lead to the mooring lines and anchors attached to the MODU being trailed across the seabed. If mooring failure is sufficient, the MODU may move off station, increasing the likelihood of anchor drag

across the seafloor. A hybrid MODU that uses DP in conjunction with a pre-laid mooring system to hold station, may be used to conduct the drilling. In this scenario, there may be an opportunity to disconnect the RAR (See Section 3.12), which would allow the rig to avoid the cyclone and for the anchor drag risk to be reduced.

For a moored MODU, personnel on-board are typically evacuated during cyclones. Woodside implements a risk-based assessment process to aid in decision-making for cyclone evacuations, with the well suspended prior to MODU evacuation. Support vessels also demobilise from the PAA during the passage of a cyclone. While the MODU is temporarily abandoned, the position of the MODU is monitored remotely for any deviation. Support vessels and MODU personnel return to the Xena-03 Operational Area as soon as safe to do so after a cyclone evacuation. Operational experience indicates cyclone evacuations typically last for seven days.

Industry statistics from the North Sea show that a single mooring line failure for MODUs is the most common failure mechanism (33 × 10-4 per line per year), followed by a double mooring line failure (11 × 10-4 per line per year) (Petroleumstilsynet, 2014). Note that single and double mooring line failures do not typically result in the loss of station keeping. If partial or complete mooring failures are sufficient to result in a loss of station keeping, industry experience indicates that MODUs may drift considerable distances from their initial position (Offshore: Risk & Technology Consulting Inc., 2002). Partial mooring failures leading to a loss of station keeping resulted in smaller MODU displacements, due to the remaining anchors dragging along the seabed when compared to complete mooring failures; complete mooring failures resulted in a freely drifting MODU (Offshore: Risk & Technology Consulting Inc., 2002). NOPSEMA has recorded four cases of anchor drag due to loss of MODU holding station during cyclone activity between 2004 and 2015 (NOPSEMA 2015). Seabed disturbance area size from anchor drag will depend on the extent of the drag.

Consequence Assessment

Potential impacts to environmental values

In the unlikely event of an object being dropped into the marine environment or failed mooring, potential environmental effects would be limited to minor physical impacts on benthic communities. In most cases, objects will be able to be recovered and therefore these impacts will also be temporary in nature. However, there may be instances where objects are unable to be recovered due to health and safety, operational constraints or other factors such as the difficulty of recovering dropped objects at depth. When dropped objects are unable to be recovered, the impact will continue to be minor but permanent.

KEFs and cultural heritage

The temporary or permanent loss of dropped objects into the marine environment and mooring failure is likely to result in a minor impact only, as the benthic communities associated with the Pluto Facility and Xena-03 Operational Areas are of low sensitivity and are broadly represented throughout the NWMR. As described in Section 4.7, the Ancient Coastline at 125 m overlaps with the Pluto Facility Operational area, and the Continental Slope Demersal Fish Communities KEF overlaps the Pluto Facility and Xena-03 Operational Areas. Benthic communities in the Operational Areas are representative of the deep water soft sediment habitats reported in the wider region, and is likely to consist of soft sediment seabed habitat, characterised by sparse, widely represented epifauna and infauna (Woodside, 2004; Brewer et al., 2007).

Given the nature and scale of risks and consequences from dropped objects and mooring failure, slight impacts are expected to seabed sensitivities within the Pluto Facility and Xena-03 Operational Areas. Further, considering the types, size, scale and frequency of dropped objects that could occur, it is unlikely that a dropped object would have a significant impact on any benthic community.

The operational areas overlap a small proportion of the KEFs. Any unplanned seabed disturbance within the KEFs would be minor and relatively small compared to the size of the KEFs. Given the location of the MODU, and likely anchor placement locations outside of the KEFs, impacts from anchor drag are likely to be further reduced. On this basis, the risk to the KEFs from unplanned seabed disturbance during Facility Operations and Xena-03 Tie-back Activities is low and would result in consequences no greater than minor, short-term impacts.

Epifauna and Infauna

As a result of a change in water quality and change in habitat, injury or mortality to marine fauna resulting from an increase in turbidity may occur. Given a change to water quality is unlikely, the only receptors that would potentially be at risk of unplanned seabed disturbance are bottom dwelling species including epifauna and infauna. Benthic communities, including epifauna and infauna may be impacted by the dropped objects, or the drag of anchors on the seabed. If not recovered, dropped objects may result in the permanent loss of a small area under the object. Over time, these hard substrates are expected to be colonised by sessile benthic biota (e.g. sponges, gorgonians, etc.), which is consistent with other small areas of hard substrate throughout the region.

If anchor drag occurs, habitat impact will span the extent of the drag area, leading to a localised change in communities; however, substantial adverse effect is not anticipated, given the sparse marine life that are well represented elsewhere in the region.

Given generally sparse benthic communities in the operational areas, no threatened or migratory benthic species or ecological communities were identified, and those epifauna and infauna communities observed are likely to be well

represented elsewhere in the region, impacts are expected to be restricted to a localised proportion of epifauna and infauna communities.

On this basis, the risk to epifauna and infauna from unplanned seabed disturbance during Xena-03 Tie-back activities is low and would result in consequences no greater than minor, short-term impacts.

Summary of Potential Impacts to environmental values(s)

Given the adopted controls, the predicted small footprint of a dropped object and the highly unlikely nature of anchor drag, it is considered that unplanned seabed disturbance will result in Minor, short-term impact (one to two years) on species, habitat (but not affecting ecosystems), physical or biological attributes, and cultural heritage, with an overall risk rating of Moderate.

ALARP Statement On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts and risks of unplanned seabed				

[126] For the purposes of this control/performance standard, "material" is defined as unplanned releases of environmentally hazardous or non-hazardous solid object/waste events with an environmental consequence of > F.

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)9F[125]***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
disturbance. As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.				

Demonstration of Acceptability
Acceptability Statement
The impact assessment has determined that disturbance to seabed from dropped objects from the Pluto Facility Operations and the Xena-03 Tie-back Activities including a loss of station keeping of the MODU represents a moderate current risk rating and is unlikely to result in a risk consequence greater than Minor. The adopted controls are considered industry good practice.
The potential risks and consequences are considered broadly acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the risks of seabed disturbance from dropped objects / anchor drag to an acceptable level.

6.9.9 Physical Presence: Interactions with Marine Fauna

Context		
Facility Operations– Section 3.7 Xena-03 Drilling and Tie-back Activities – Section 3.11	Protected Species – Section 4.6	Consultation – Section 5

Impacts and Risks Evaluation Summary

Source of Risk	***Environmental Value Potentially Impacted***							***Evaluation***						
	Soil and Groundwater	Marine Sediment	Water Quality	Air Quality (incl Odour)	Ecosystems / Habitat	Species	Socio-economic	Decision Type	Consequence / Impact	Likelihood	Risk Rating	ALARP Tool	Acceptability	Outcome
Physical presence of the Pluto Facility, MODU, ASV, installation and support vessels resulting in collision with marine fauna.						x		A	E	1	L	LCS PJ	Broadly Acceptable	EPO 26

Description of Source of Risk

Activities associated with the Petroleum Activities Program will require vessels IMMR activities, support operations and supply/transport as well as for tie-back activities. The type and number of vessels in the PAA at any one time, and the duration of presence, will differ depending on the activities being undertaken.

Vessels operating in and around the PAA may present a potential hazard to cetaceans and other protected marine fauna such as whale sharks and marine reptiles. Vessel movements can result in collisions between the vessel (hull and propellers) and marine fauna, potentially resulting in superficial injury, serious injury that may affect life functions (e.g. movement and reproduction) and mortality. The frequency and severity of impacts due to collisions vary greatly due to vessel type, vessel operation (specific activity, speed), physical environment (e.g. water depth), and the type of marine fauna potentially present and their behaviours.

Consequence Assessment

Marine mammals, reptiles and sharks

The likelihood of vessel/whale collision being lethal is influenced by vessel speed; the greater the speed at impact, the greater the risk of mortality (Jensen and Silber 2004, Laist et al. 2001). Vanderlaan and Taggart (2007) found that the chance of lethal injury to a large whale as a result of a vessel strike increases from about 20% at 8.6 knots to 80% at 15 knots. According to the data of Vanderlaan and Taggart (2007), it is estimated that the risk is less than 10% at a speed of four knots. Vessel–whale collisions at this speed are uncommon and, based on reported data contained in the US NOAA database (Jensen and Silber 2004), there only two known instances of collisions when the vessel was travelling at less than six knots. Both of these were from whale watching vessels that were deliberately placed among whales.

Support vessels undertaking the Petroleum Activities Program within the PAA are likely to be travelling less than eight knots (and will often be stationary). Therefore, the risk of a vessel collision with protected species resulting in death is inherently low. No known key aggregation areas (resting, breeding or feeding) are located within or immediately adjacent to the PAA.

The PAA overlaps two recognised BIAs for cetaceans; the pygmy blue whale migration and distribution BIA and the humpback whale migration BIA (the humpback whale is considered to be at risk due to relatively slow movement and proportion of time spent at or near the sea surface) (refer to Section 4.6.3). Both humpback whales and pygmy blue

whales are only expected to be present during their seasonal migrations. Refer to Table 4-14 for information on migration timing.

Whale sharks are at risk from vessel strikes when feeding at the surface. Whale sharks may traverse offshore NWS waters including the PAA during their migrations to and from Ningaloo Reef, and a BIA for foraging whale sharks overlaps the PAA. However, given the main aggregation area for whale sharks is approximately 340 km off the coast of Ningaloo (designated as a foraging BIA with high density prey) (Section 0), it is expected that whale shark presence within the PAA would not comprise significant numbers, and their presence would be transitory and of a short duration. There are no constraints preventing whale sharks from moving away from vessels to avoid injury (e.g. shallow water or shorelines).

Vessel strikes have also been identified as a threat to marine turtles; however, no explicit management actions are listed in relevant conservation advices or recovery plans (Table 4 3). The typical response from turtles on the surface to the presence of vessels is to dive (a potential "startle" response), which decreases the risk of collisions (Hazel et al., 2007). As with cetaceans, the risk of collisions between turtles and vessels increases with vessel speed (Hazel et al. 2007). Given the low speeds of vessels undertaking the Petroleum Activities Program, along with the expected low numbers of turtles within the Xena-03 and Facility Operational Areas, interactions between vessels and turtles are considered to be highly unlikely.

The facility section of the PAA overlaps a flatback internesting buffer BIA which extends for 40 km around a nesting BIA at the Montebello Islands and Dampier Archipelago during their summer nesting period. Given the water depth around the facility (between approximately 85 and 960 m) and absence of potential nesting or significant foraging habitat for turtles (i.e. no emergent islands, reef habitat or shallow shoals/banks) the Facility Operational Area is unlikely to represent important habitat for marine turtles.

The Export Pipeline Operational Area also overlaps the aforementioned flatback turtle internesting buffer BIA, as well as internesting BIAs for green, hawksbill and loggerhead turtles. The BIAs for flatback, green and hawksbill turtles have also been designated as habitat critical to the survival of the species in the Recovery plan for marine turtles in Australia 2017–2027 (Commonwealth of Australia, 2017); however, these areas are likely to hold the same significance as the existing BIAs with slightly differing spatial areas. The export pipeline lies in water depths of 40 to 85 m. No potential nesting or significant foraging habitat for turtles (i.e. no emergent islands, reef habitat or shallow shoals/banks) overlap the Export Pipeline Operational Area.

Given there are significant nesting sites along the mainland coast and islands in proximity to the Export Pipeline Operational Area, turtles are likely to transit this area. Individuals may also infrequently forage in some areas of the export pipeline (i.e. flatback turtles), although not in significant numbers given the lack of suitable habitat and distance from emergent land. As vessels are likely to only operate within the PAA infrequently during IMMR activities and when the facility is crewed, interactions with vessels during the Petroleum Activities Program are highly unlikely. Given vessels will be moving at low speeds while in the PAA, turtles are likely to avoid collisions with vessels by diving or swimming away from the area. It is not deemed credible that vessel movement associated with the Petroleum Activities Program could have a significant impact on marine fauna populations given (1) the low presence of transiting individuals, (2) avoidance behaviour commonly displayed by marine fauna, and (3) low operating speed of the activity support vessels (generally less than eight knots or stationary, unless operating in an emergency). Activities are considered unlikely to result in a consequence greater than slight, short-term disruption to individuals or a small proportion of the population, and no impact on critical habitat or fauna activity.

ALARP Statement: On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the risk of interactions with marine fauna. As no reasonable additional/alternative controls were identified that would further reduce the impacts and risks without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.				

Demonstration of Acceptability
Acceptability Statement: The consequence assessment has determined that, given the adopted controls, interaction with marine fauna represents a low risk rating that is unlikely to result in a consequence greater than slight, short-term disruption to individuals or a small proportion of the population, and no impact on critical habitat or activity. Further opportunities to reduce the impacts and risks have been investigated above. The adopted controls are considered good oil-field practice/industry best practice and meet the requirements of Part 8 (Division 8.1) of the EPBC Regulations 2000. The management of interactions with marine fauna is consistent with the objectives of approved conservation advice and recovery plans for marine fauna, including cetaceans and whale sharks, where human interference has been identified as a threat. The potential impacts and risks are considered broadly acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the impacts and risks of vessel collision with marine fauna to a level that is broadly acceptable.

Description of Source of Risk

During the Petroleum Activities Program, vessels will be transiting to and from the PAA, potentially including traffic mobilising from beyond Australian waters. Vessels include those servicing and supporting Pluto operations (Section 3.8) as well as the MODU, ASV, IMMR vessel, installation vessels or general support vessels (Section 3.12). Vessels may be sourced from the local area (Dampier, Port Hedland, etc.) or from further afield, depending on the type of vessel required and availability. In addition, infrequent import of materials (e.g. spares) from international suppliers may be required. Vessels arriving from international waters typically call into Dampier, where quarantine clearance including ballast log reviews is conducted in accordance with Biosecurity Act 2015.

All vessels are inherently subject to some level of marine fouling. Organisms attach to the vessel hull, particularly in areas where organisms can find a good surface (e.g. seams, strainers and unpainted surfaces) or where turbulence is lowest (e.g. niches, sea chests, etc.). Organisms can also be drawn into ballast tanks during on-boarding of ballast water as cargo is unloaded or to balance vessels under load. Biofouling organisms can become established in an area through the release of propagules (e.g. eggs or larvae), or by attaching to substrate after becoming detached from the host vessel.

Non-indigenous Marine Species (NIMS) have been introduced into a region beyond their natural biogeographic range and have the ability to survive, reproduce and establish founder populations. Not all NIMS introduced into an area thrive or cause demonstrable impacts. Indeed, the majority of NIMS around the world are relatively benign and few have spread widely beyond sheltered ports and harbours. Only a subset of NIMS that become abundant and impact on social/cultural, human health, economic and/or environmental values can be considered Invasive Marine Species (IMS).

During the Petroleum Activities Program, vessel activities that have the potential to lead to the introduction of IMS are:

- discharge of ballast water from vessels
- vessel interactions with the facility
- cross contamination between vessels (e.g., when vessels need to be alongside each other)

Consequence Assessment

IMS have historically been introduced and translocated around Australia by a variety of human means including biofouling and ballast water. Species of concern are those that:

- are not native to the region;
- are likely to survive and establish in the region; and
- are able to spread by human mediated or natural means.

Species of concern vary from one region to another, depending on various environmental factors such as water temperature, salinity, nutrient levels and habitat type. These factors dictate their survival and invasive capabilities.

Introducing IMS into the local marine environment may alter the ecosystem, as IMS have characteristics that make them superior (in a survival and/or reproductive sense) to indigenous species. They may prey upon local species (which had previously not been subject to this kind of predation and therefore not have evolved protective measures against the attack), they may outcompete indigenous species for food, space or light and can also interbreed with local species, creating hybrids such that the endemic species is lost.

IMS have also proven economically damaging to areas where they have been introduced and established. Such impacts include direct damage to assets (fouling of vessel hulls and infrastructure) and depletion of commercially harvested marine life (e.g. shellfish stocks). IMS have proven particularly difficult to eradicate from areas, once established. If the introduction is captured early, eradication may be effective but is likely to be expensive, disruptive and, depending on the method of eradication, harmful to other local marine life.

Despite the potential high consequence of the establishment of a marine pest within a high value environment as a result of introduction, unlike coastal or sheltered nearshore waters, the deep offshore open waters of the PAA are not conducive to the settlement and establishment of IMS (Geiling 2016), due to the lack of light or suitable habitat to sustain growth or survival. Table 6-44 provides an assessment of the IMS impacts and risks associated with the Petroleum Activity Program.

Epifauna and Infauna

Epifauna and infauna are susceptible to impacts from IMS due to the risk of changes to the ecosystem dynamics such as competition for resources and predation.

Two KEFs also overlap the PAA; the Ancient Coastline at 125 m KEF and Continental Slope Demersal Fish Communities KEF.

Discrete areas of hard substrate hosting sessile filter feeding communities such as sponges and gorgonians may be associated within the Ancient Coastline at the 125 m Depth Contour KEF, of which 9.1 km2 overlaps the PAA. However, no areas of hard substrate characteristic of this KEF have been identified within the PAA (Jacobs 2014).

Filter feeder communities within the PAA are present on the subsea infrastructure and Pluto platform, which provides hard substrate for attachment (Jacobs, 2014).

Vessels have the potential to introduce IMS into the PAA, however, the deep offshore open waters of the PAA (70 - 130 m) are not conducive to the settlement and establishment of IMS. Furthermore, the PAA are away from shorelines and/or critical habitat. The likelihood of IMS being introduced and establishing viable populations within the PAA or immediate surrounds is considered unlikely, with the potential settlement on subsea infrastructure not expected. Accordingly, impact to epifauna/infauna in the PAA is not considered credible. Receptor sensitivity for epifauna and infauna is low, leading to a Slight (E) risk consequence.

Industry, Shipping, Defence

The establishment of IMS has the potential to cause changes to the functions, interests or activities of other users through indirect impact such as changes to fisheries target species resulting in economic and social implications, or due to compromised reputation to the oil and gas industry.

Given the low likelihood of IMS translocation to, and colonisation of environments within the PAA, project activities will not result in establishment of IMS, and as such not adversely affect other marine user activities in the region.

Based on the impact evaluation, the magnitude of potential impacts of a change to the functions, interests or activities of other users is slight. Receptor sensitivity for industry, shipping and defence is medium, leading to a Slight (E) risk consequence. The likelihood of the risk event occurring is Remote, therefore the risk is assessed as Low.

Summary of Potential Impacts to Environment Values

In support of Woodside's assessment of the impacts and risks of IMS introduction associated with the Petroleum Activities Program, a risk and impact evaluation of the different aspects of marine pest translocation associated with the activity was conducted.

Given the adopted controls, the overall risk rating for unplanned introduction of invasive marine species is Low based on a Slight consequence (short-term impact (<1 year) on species, habitat (but not affecting ecosystem function), physical or biological attribute, or to a community or area/item of cultural significance community), and a highly unlikely likelihood.

Table 6-44: Assessment of the impacts and risks of IMS introduction associated with the Petroleum Activity Program

IMS Introduction Aspect	Credibility of Introduction	Consequence of Introduction	Likelihood
Transfer of IMS from infected vessel to PAA and establishment on the seafloor or subsea infrastructure.	Not Credible The deep offshore open waters of the PAA away from shorelines and/or critical habitat, more than 12 nm from a shore and in waters 40 - 85 m deep, are not conducive to the settlement and establishment of IMS.		
Transfer of IMS from infected vessel to and subsequent establishment on the Pluto Platform.	Credible There is potential for the transfer of marine pests to occur.	If IMS were to establish this would potentially result in fouling of intakes (depending on the pest introduced) and would likely result in the quarantine of the Pluto facility until eradication could occur (through cleaning and treatment of infected areas), which would be costly to undertake. Minor (D) – Reputation and Brand Such introduction would be expected to have Minor (D) impact to Woodside's reputation and brand, and close scrutiny of asset level operations or future proposals. Slight (E) – Environment Environmental consequence of introduction of IMS to the Pluto platform is considered Slight (E), localised and would relate to habitat directly on the facility.	Highly Unlikely (1) Interactions between the Pluto facility and support vessels is limited during the petroleum activity program, with a 500 m safety exclusion zone being adhered too. Spread of marine pests via ballast water or spawning in these open ocean environments is considered Highly Unlikely (1).
Introduced to PAA and establishment on a project vessel.	Credible There is potential for the transfer of marine pests between project vessels within the PAA.	Environment – Not Credible The translocation of IMS from a colonised MODU or project vessel to shallower environments via natural dispersion is not considered credible given the distances of the PAA from nearshore environments (i.e. greater than 12 nm/50 m water depth). There is therefore no credible environmental	Remote (0) Interactions between project vessel will be limited during the Petroleum Activities Program, with minimum 500 m safety exclusion zones being adhered to around the MODU and installation vessel, and interactions limited short periods of time alongside (i.e. during backloading, bunkering activities).

		risk and the assessment is limited to Woodside's reputation. Reputation – E If IMS were to establish on a project vessel (i.e. MODU, installation vessel, activity project vessels) this could potentially impact the vessel operationally through the fouling of intakes, result in translocation of an IMS into the PAA and, depending on the species, potentially transfer of an IMS to other project vessels, which would likely result in the quarantine of the vessel until eradication could occur (through cleaning and treatment of infected areas), which would be costly to perform. Such introduction would be expected to have slight impact to Woodside's reputation, particularly with Woodside's contractors, and would likely have a reputational impact on future proposals.	There is also no direct contact (i.e. they are not tied up alongside) during these activities. Spread of marine pests via ballast water or spawning in these open ocean environments is also considered remote.
Transfer of IMS from infected vessel to and subsequent establishment on riser platform, then transfer of IMS to a secondary vessel from the facility.	Not Credible Risk is considered so remote that it is not credible for the purposes of the Petroleum Activity Program. The transfer of a marine pest from an infected activity vessel to the facility is considered highly unlikely given the offshore open ocean environment. For a marine pest to then establish into a mature spawning population on the facility and then transfer to another support vessel is not considered credible (i.e. beyond the Woodside risk matrix). The facility is located in an offshore, open ocean, deep environment. Support vessels only spend short periods of time alongside the riser platform (i.e. during		

	backloading or bunkering activities). There is also no direct contact (i.e. they are not tied up alongside) during these activities. It is also noted that Woodside has been conducting marine vessel movements between the facility and WA ports (such as Dampier) for a long period of time, and no IMS has been detected in these ports (Department of Fisheries 2017).

Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Legislation, Codes and Standards				
On arrival in Australia all vessels will manage their ballast water using one of the approved ballast water management options, as specified in the Australian Ballast Water Management Requirements	F: Yes. CS: Minimal cost. Standard practice.	Reduction in the likelihood that ballast water will host IMS.	Controls based on legislative requirements under the Biosecurity Act 2015 – must be adopted.	Yes C 28.1
Internationally sourced project vessels will manage their biosecurity risk associated with biofouling as specified in the Australian Biofouling Management Requirements.	F: Yes. CS: Minimal cost. Standard practice.	Reduces the likelihood of transfer of marine pests between vessels within the PAA. No change in consequence would occur.	Controls based on legislative requirements under the Biosecurity Act 2015 – must be adopted.	Yes C 28.2
Good Practice				
Woodside's IMS risk assessment process[133] will be applied to the MODU, and all vessels and relevant immersible equipment undertaking the Petroleum Activities Program. Assessment will consider these risk factors: • For MODU and project vessels:	F: Yes. CS: Minimal cost. Good practice implemented across all Woodside Operations.	Identifies potential risks and additional controls implemented accordingly. In doing so, the likelihood of transferring marine pests between project vessels within the PAA is reduced. No change	Benefits outweigh cost/sacrifice.	Yes C 28.3

[133] Qualitative measure
45 Woodside's IMS risk assessment process was developed with regard to the national biofouling management guidelines for the petroleum production and exploration industry and guidelines for the control and management of a ships' biofouling to minimise the transfer of invasive aquatic species (IMO Guidelines, 2011).

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
• vessel/MODU/ type • recent IMS inspection and cleaning history, including for internal niches • out-of-water period before mobilisation • age and suitability of antifouling coating at mobilisation date • internal treatment systems and history • origin and proposed area of operation • number of stationary/slow speed periods >7 days • region of stationary or slow periods • type of activity – contact with seafloor. • For immersible equipment: • region of deployment since last thorough clean, particularly coastal locations • duration of deployments • duration of time out of water since last deployment • transport conditions during mobilisation • post-retrieval maintenance regime.		in consequence would occur.		

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
• Based on the outcomes of each IMS risk assessment, management measures commensurate with the risk (such as treating internal systems, IMS inspections or cleaning) will be implemented to minimise the likelihood of IMS being introduced.				
Diver based monitoring of the riser platform for IMS.	F: Potentially. Diver based surveys are technically feasible for the facility but are not approved under the in-force Safety Case. CS: Significant. IMS inspections of in-water assets typically require vessel logistics and diver-based inspection teams to reliably detect IMS. This is a costly, time-consuming process that would likely require facility simultaneous operational constraints, and invariably introduces a series of significant safety risks in a hazardous offshore environment. Monetary cost of IMS survey for facility-sized infrastructure would be comparable to safe diver campaign arrangements in the order of $200,000/day plus mob/demob costs. Costs of ROV to support survey are in the order of $150,000/day plus	Riser platform monitoring does not prevent the potential for translocation (i.e. only as a mitigation measure). Detection may facilitate subsequent development of options to manage IMS. Subsequent success may be limited due to structure complexity and hazardous environment.	Disproportionate. Interactions between the facility and support/subsea vessels posing IMS translocation risk is limited, and the vessels involved will have been managed through the implementation of Woodside's Invasive Marine Species Management Plan (IMSMP) (C 13.2), a verified process which provides Woodside confidence in the verification of EPO 13. Consequently, any additional benefit gained through the implementation of this control is considered disproportionate, given material execution safety risks and controls already adopted (and noting already incurred cost through implementation of IMSMP (i.e. inspections and cleaning where risk warrants)), and the unlikely likelihood of a translocation event.	No

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
	mob/demob costs (based on subsea ROV hire costs). Health and safety exposure includes those of personnel while conducting diver-based surveys - four days of two to three people (based on subsea ROV surveys of similar size), as well as offshore vessel and facility simultaneous operations hazards.			
Professional Judgement - Elimination				
Not using MODU and project vessels.	F: No. No alternative to the use of vessels during the Petroleum Activities Program was identified, given vessels must be used to undertake the Petroleum Activities Program. There is no feasible means to eliminate the source of risk. CS: Not assessed, control not feasible.	Not assessed, control not feasible.	Not assessed, control not feasible.	No
No discharge of ballast water during the Petroleum Activities Program.	F: No. Ballast water discharges are critical for maintaining vessel stability. Given the nature of the Petroleum Activities Program, the use of ballast (including the potential discharge of ballast water) is considered to be a safety critical requirement. CS: Not assessed, control not feasible.	Not assessed, control not feasible.	Not assessed, control not feasible.	No
Professional Judgement – Substitute				
Sourcing vessels based in Australia only.	F: Potentially. Limiting activities to only use local project vessels could potentially pose a significant risk in terms of time and duration of sourcing a	Sourcing vessels from within Australian will reduce the likelihood of IMS from outside Australian waters, however, it does not	Disproportionate. Sourcing vessels from Australian waters may result in a reduction in the likelihood of IMS introduction to the PAA; however, the potential cost of	No

Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
	vessel, as well as the ability of the local vessels to perform the required tasks. For example, there are limited installation vessels based in Australian waters. While the project will attempt to source project vessels locally it is not always possible. Availability cannot always be guaranteed when considered competing Oil and Gas activities in the region. In addition, sourcing Australian based vessels only will cause increases in cost due to pressures of vessel availability. CS: Significant cost and schedule impacts due to restrictions of vessel hire opportunities.	reduce the likelihood of introduction of species native to Australia but alien to the PAA and NWMR, or of IMS that have established elsewhere in Australia. The consequence is unchanged.	implementing this control is grossly disproportionate to the minor environmental gain (or reducing an already remote likelihood of IMS introduction) potentially achieved by using only Australian based vessels, consequently this risk is considered not reasonably practicable.	
Inspecting all vessels for IMS.	F: Yes. Approach to inspect vessels is feasible. CS: Significant cost and schedule impacts. Thorough inspections require vessels to be removed from the sea (e.g. slipped or dry docked) and examined by an IMS expert. This process incurs significant financial and schedule sacrifices. Timely vessel-based support is integral to the safe and efficient operation of the facility and subsea infrastructure.	Reduction in the likelihood that a vessel will host IMS.	Disproportionate. The cost/sacrifice is grossly disproportionate to the benefit gained.	No
Professional Judgement – Engineered Solution				
None identified.				
ALARP Statement:				

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts and risks of IMS introduction and establishment. As no reasonable additional/alternative controls were identified that would further reduce the impacts and risks without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.				
Demonstration of Acceptability				
Acceptability Statement: The risk assessment has determined that, given the adopted controls, introduction of IMS represent a moderate risk rating that has a remote likelihood to result in an environmental consequence greater than major long-term impact on marine communities within the PAA. Further opportunities to reduce the impacts and risks have been investigated above. The adopted controls are considered good oil-field practice/industry best practice and meet Australian legislative requirements, including the Biosecurity Act 2015. The potential impacts and risks are considered broadly acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the impacts and risks of invasive marine species to an acceptable level.

	Program. Assessment will consider these risk factors: For all vessels: • vessel/MODU/ type • recent IMS inspection and cleaning history, including for internal niches • out-of-water period before mobilisation • age and suitability of antifouling coating at mobilisation date • internal treatment systems and history • origin and proposed area of operation • number of stationary/slow speed periods >7 days • region of stationary or slow periods • type of activity – contact with seafloor. • For immersible equipment: • region of deployment since last thorough clean, particularly coastal locations • duration of deployments • duration of time out of water since last deployment • transport conditions during mobilisation • post-retrieval maintenance regime. • Based on the outcomes of each IMS risk		MC 28.3.2 Records maintained of management measures which have been implemented where identified through the IMS Vessel Risk Assessment process.

EPOs, EPSs and MC for Pluto Operations and Xena-03 Tie-back Activities			
Environmental Performance Outcomes	***Controls***	***Environmental Performance Standards***	***Measurement Criteria***
	assessment, management measures commensurate with the risk (such as treating internal systems, IMS inspections or cleaning) will be implemented to minimise the likelihood of IMS being introduced.		

6.9.11 Physical Presence (Unplanned): Interaction with Live Infrastructure

Context

Relevant Activities	***Existing Environment***	***Consultation***
Project vessels – Section 3.12 Subsea installation Activities – 3.12 Drilling Activities – 3.11.1	Socio-economic Environment – Section 4.10	Consultation – Section 5

Impact Evaluation Summary

Source of Impact	***Environmental Value Potentially Impacted***						***Evaluation***						
	Marine Sediment	Water Quality	Air Quality (incl Odour)	Ecosystems/Habitat	Species	Socio-economic	Decision Type	Consequence / Impact	Likelihood	Risk Rating	ALARP Tools	Acceptability	Outcome
Interaction with live infrastructure from dropped objects						X	A	E	1	L	LCS GP	Broadly Acceptable	EPO 29
Interaction with live infrastructure from anchor drag						X							

Description of Source of Impact

There is existing live subsea infrastructure in the PAA, which includes components of the Woodside Julimar Brunello Production Pipeline, Chevron Wheatstone Pipeline, Santos Reindeer Offshore Gas Supply Pipeline and Woodside Scarborough Export Pipeline. During the PAP, activities may be conducted that present a risk of dropped objects or anchor drag over the nearby live infrastructure.

Dropped Objects

There is the potential for objects to be dropped overboard from the MODU and project vessels to the marine environment. Objects that have been dropped during previous offshore activities include small numbers of personal protective gear (e.g. glasses, gloves, hard hats), small tools (e.g. spanners), hardware fixtures (e.g. riser hose clamp) and drill equipment (e.g. drill pipe). However, there is potential for larger equipment to be dropped during the activity, particularly during recovery of infrastructure from the seabed. The spatial extent in which dropped objects can occur is restricted to the PAA.

Anchor Drag

A moored/ hybrid MODU may be used for drilling the wells, secured on station by an 8 to 12-point mooring system deployed to the seabed, as dictated by the mooring analysis. High energy weather events such as cyclones, occurring while the MODU is on station, can lead to excessive loads on the mooring lines, resulting in failure (either anchor(s) dragging or mooring lines parting). A failure of mooring integrity may lead to the mooring lines and anchors attached to the MODU being trailed across the seabed and over live infrastructure.

For a moored MODU, personnel on-board are typically evacuated during cyclones. Woodside implements a risk-based assessment process to aid in decision making for cyclone evacuations, with the well suspended prior to MODU evacuation. Support vessels also demobilise from the PAA during the passage of a cyclone. While the MODU is temporarily abandoned, the position of the MODU is monitored remotely for any deviation. Support vessels and MODU personnel return to the PAA as soon as safe to do so after a cyclone evacuation. Operational experience indicates cyclone evacuations typically last for seven days.

Industry statistics from the North Sea show that a single mooring line failure for MODUs is the most common failure mechanism (33 × 10-4 per line per year), followed by a double mooring line failure (11 × 10-4 per line per year) (Petroleumstilsynet, 2014). Note that single and double mooring line failures do not typically result in the loss of station keeping. If partial or complete mooring failures are sufficient to result in a loss of station keeping, industry experience indicates that MODUs may drift considerable distances from their initial position (Offshore: Risk & Technology Consulting Inc., 2002). Partial mooring failures leading to a loss of station keeping resulted in smaller MODU displacements, due to the remaining anchors dragging along the seabed when compared to complete mooring failures; complete mooring failures resulted in a freely drifting MODU (Offshore: Risk & Technology Consulting Inc., 2002).

NOPSEMA has recorded four cases of anchor drag due to loss of MODU holding station during cyclone activity between 2004 and 2015 (NOPSEMA 2015).

Impact Assessment

Potential impacts to environmental values

Interactions with other marine users

In the unlikely event of an object being dropped on, or anchors dragging over, live infrastructure there is potential impacts to the infrastructure and the Operators of that infrastructure.

If interactions with live infrastructure were to occur, Woodside would notify the relevant operations team in accordance with the SIMOPS plan. This would trigger responses from the Operator to assess and respond to any damage caused in accordance with the relevant operations EP for the live infrastructure. Under Regulation 56 of the Environment Regulations, a titleholder may refer NOPSEMA to information previously given to NOPSEMA for another purpose under the OPGGS Act, the Environment Regulations or any other regulations made under the Act, to comply with a requirement on the titleholder under the Environment Regulations to give NOPSEMA information or include information in a document. In accordance with Regulation 56, NOPSEMA is referred to the relevant operations EPs submitted by the Operators of the live infrastructure, and accepted by NOPSEMA, for the detail of the Operators' assessment and response in such a scenario. Potential impacts therefore include time and costs associated with inspecting the infrastructure and time and costs associated with any associated repair, which are expected to be slight and short-term in nature.

Potential subsequent loss of containment

In the unlikely event of an object being dropped on, or anchors dragging over, live infrastructure, and in the further unlikely event of a severe interaction with the infrastructure, there is a possibility that live infrastructure could be ruptured releasing hydrocarbons into the marine environment in such a scenario. In accordance with Regulation 56, NOPSEMA is referred to the relevant operations EPs submitted by the Operators of the live infrastructure, and accepted by NOPSEMA, for the detail of potential impacts, receptors and the extent of the environment that may be affected in such a scenario, being:

Julimar Operations EP (NOPSEMA Doc A771970, https://docs.nopsema.gov.au/A771970)

Wheatstone Project Start-up and Operations EP (NOPSEMA Doc: A853704, https://docs.nopsema.gov.au/A853704)

Reindeer Wellhead Platform and Offshore Gas Supply Pipeline Operations (NOPSEMA Doc: A738138, https://docs.nopsema.gov.au/A738138)

Scarborough Seabed Intervention and Trunkline Installation (NOPSEMA Doc. A1027151, https://docs.nopsema.gov.au/A1027151)

As detailed in this Section above and below, this EP addresses the risks and impacts (interaction with live infrastructure) that arise from the activities under this EP (interaction from dropped objects and interaction from anchor drag). This EP also contains controls to prevent such an event from occurring that are within the operational control of this EP. As detailed in this Section, the operational control, maintenance and incident response associated with the live infrastructure and/or loss of containment from the live infrastructure is not within the operational control of this EP. As detailed below, the risks and impacts of the activities under this EP are managed to ALARP and an acceptable level by implementing the SIMOPS plan and notifying the relevant Operators in the instance of an interaction with live infrastructure to allow the relevant Operator's detailed response strategies under the relevant operations EPs to be triggered, if required. In the event of a loss of containment caused by an interaction with live infrastructure Woodside will follow direction from the relevant Operator and will respond as per the relevant Operator's requirements. In accordance with Regulation 56, NOPSEMA is referred to the relevant operations EPs submitted by the Operators of the live infrastructure, and accepted by NOPSEMA, for the detail of the operational control, maintenance and incident response associated with the live infrastructure and/or loss of containment from the live infrastructure.

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)[135]***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Good Practice				
The MODU/PIV work procedures for lifts, bulk transfers and cargo loading, which require: The security of loads shall be checked prior to commencing lifts. Loads shall be covered if there is a risk of loss of loose materials. Lifting operations shall be conducted using the PTW and JSA systems to manage the specific risks of that lift, including consideration of weather and sea state.	F: Yes. CS: Minimal cost. Standard practice.	Reduces the likelihood of an object being dropped during lifts, bulk transfers and cardo loading.	Benefits outweigh cost/sacrifice.	Yes C 25.1
Specifications and requirements for station keeping equipment (mooring systems), require that: systems are tested and inspected in accordance with API RP 21 systems have sufficient capability such that a failure of any single component will not cause progressive failure of the remaining anchoring arrangement.	F: Yes. CS: Minimal cost. Standard practice.	Reduces the likelihood of mooring failure leading to uncontrolled anchor drag.	Benefit outweighs cost sacrifice.	Yes C 25.2
Project-specific Mooring Design Analysis.	F: Yes. CS: Minimal cost. Standard practice.	By ensuring that a mooring analysis report is undertaken, the likelihood of mooring failure occurring is reduced. The mooring design analysis report specifically considers proximity to live infrastructure and manages potential impacts on that infrastructure accordingly.	Benefit outweighs cost sacrifice.	Yes C 4.3
Mooring system is tested to recommended tension as per API RP 2SK.	F: Yes. CS: Minimal cost. Standard practice	Reduces the likelihood of anchor drag.	Benefit outweighs cost sacrifice.	Yes C 25.3

[135] Qualitative measure

Professional Judgement – Eliminate				
No additional controls identified				
Professional Judgement – Substitute				
No additional controls identified				
Professional Judgement – Engineered Solution				
MODU tracking equipment operational when the MODU unmanned.	F: Yes. CS: Minimal cost. Standard practice.	Although no reduction in consequence would occur, the overall risk is reduced as the location of the MODU would be known at all times and the appropriate response could be deployed in the event of a loss of station keeping.	Benefit outweighs cost sacrifice.	Yes C 25.4
SIMOPS Plan in place when MODU working in vicinity of other facilities, vessels or live infrastructure i.e. during xmas tree installation. SIMOPS Plan will contain information on: Minimum separation distances Communications MODU / vessels / activities involved in SIMOPS Exclusion zone entry and exit processes ROV operations Helicopter operations Key roles, responsibilities and emergency contacts PTW arrangements Incident reporting and investigation Management of Change	F: Yes. CS: Minimal cost. Standard practice.	SIMOPS Plan contains detail such as communications requirements, exclusion zones and entry/exit requirements and roles and responsibilities – which can help reduce likelihood of interactions with live infrastructure, it also contains notification protocols in the event of an interaction with live infrastructure. The SIMOPS plan also requires notification in the event of an incident or interaction with infrastructure thus triggering response strategies in the relevant operations EPs. The detailed response is in the Ops EP and the implementation of that would be triggered by the SIMOPS plan and Woodside will support the response according to the other Operator's requests.	Benefits outweigh cost/sacrifice. Control is also Standard Practice.	Yes C 1.10

ALARP Statement

Woodside considers the adopted controls appropriate to manage the risks of a significant dropped object or anchor drag interacting with live infrastructure within the PAA. As no reasonable additional/alternative controls were identified that would further reduce the risks and consequences without disproportionate sacrifice, the risks and consequences are considered ALARP.

Demonstration of Acceptability

Acceptability Statement

The impact assessment has determined that interaction with live infrastructure from dropped objects or a loss of station keeping of the MODU represents a low current risk rating and is unlikely to result in a risk consequence greater than slight. The adopted controls are considered industry good practice.

The potential risks and consequences are considered broadly acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the risks of seabed disturbance from dropped objects / anchor drag to an acceptable level.

Environmental Performance Outcomes, Standards and Measurement Criteria

Outcomes	*Controls*	*Standards*	*Measurement Criteria*
EPO 29 No interactions with live infrastructure resulting in loss of hydrocarbons to the marine environment during the PAP	C 1.10	PS 1.10	MC 1.10.1
	C 4.3	PS 4.3	MC 4.3.1
	C 25.1 The MODU/PIV work procedures for lifts, bulk transfers and cargo loading, which require: The security of loads shall be checked prior to commencing lifts. Loads shall be covered if there is a risk of loss of loose materials. Lifting operations shall be conducted using the PTW and JSA systems to manage the specific risks of that lift, including consideration of weather and sea state.	PS 25.1 All lifts conducted in accordance with applicable MODU/ installation vessel work procedures to limit potential for dropped objects.	MC 25.1.1 Records show lifts conducted in accordance with the applicable MODU/ installation vessel work procedures.
	C 25.2 Specifications and requirements for station keeping equipment (mooring systems), require that: systems are tested and inspected in accordance with API RP 21 systems have sufficient capability such that a failure of any single component will not cause progressive failure of the remaining anchoring arrangement.	PS 25.2 MODU mooring system tested and in place to ensure no complete mooring failure.	MC 25.2.1 Records demonstrate mooring system tests and inspection.
	C 25.3 Mooring system is tested to recommended tension as per API RP 2SK.	PS 25.3 Monitoring compliant with ISO 19901-7:2013	MC 25.3.1 Records confirm mooring system is tested to recommended tension as per API RP 2SK.
	C 25.4 MODU tracking equipment operational when the MODU unmanned.	PS 25.4 Tracking of the MODU is possible when the MODU is unmanned.	MC 25.4.1 Records show the moored MODU has functional tracking equipment for instances when MODU is unmanned.

6.10 Recovery Plan and Threat Abatement Plan Assessment

This section describes the assessment that Woodside has undertaken to demonstrate that the Petroleum Activities Program is not inconsistent with any relevant recovery plans or threat abatement plans. For the purposes of this assessment, the relevant Part 13 statutory instruments (recovery plans and threat abatement plans) are:

- Recovery Plan for Marine Turtles in Australia 2017–2027 (Commonwealth of Australia, 2017).
- Conservation Management Plan for the Blue Whale 2015–2025 (Commonwealth of Australia, 2015a).
- National Recovery Plan for the Southern Right Whale (DCCEEW, 2024b)
- Recovery Plan for the Grey Nurse Shark (Carcharias taurus) 2014 (Commonwealth of Australia, 2014).

Sawfishes and River Sharks Multispecies Recovery Plan (Commonwealth of Australia, 2015b).

Threat Abatement Plan for the impacts of marine debris on the vertebrate wildlife of Australia's coasts and oceans 2018 (Commonwealth of Australia, 2018).

Table 6-46 lists the objectives and (where relevant) the action areas of these plans, and also describes whether these objectives/action areas are applicable to government, the Titleholder, and/or the Petroleum Activities Program. For those objectives/action areas applicable to the Petroleum Activities Program, the relevant actions of each plan have been identified, and an evaluation has been conducted as to whether impacts and risks resulting from the activity are not inconsistent with that action.

The assessment of potential impacts and risks to pygmy blue whales from underwater noise emissions has taken into account the definitions of terminology in the CMP, as described in the DAWE and NOPSEMA guidance released in September 2021. Similarly, the assessment against relevant actions in the CMP in Table 6-47 has been undertaken in the context of the definitions included in the guidance note.

Table 6-45: Identification of Applicability of Recovery Plan and Threat Abatement Plan Objectives and Action Areas

EPBC Act Part 13 Statutory Instrument	Applicable to:		
	Government	***Titleholder***	***Petroleum Activities Program***
Marine Turtle Recovery Plan			
Long-term Recovery Objective: Minimise anthropogenic threats to allow for the conservation status of marine turtles to improve so they can be removed from the EPBC Act threatened species list	Y	Y	Y
Interim Recovery Objectives			
Current levels of legal and management protection for marine turtle species are maintained or improved, both domestically and throughout the migratory range of Australia's marine turtles	Y		
The management of marine turtles is supported	Y		
Anthropogenic threats are demonstrably minimised	Y	Y	Y
Trends in nesting numbers at index beaches and population demographics at important foraging grounds are described	Y	Y	
Action Areas			
A. Assessing and addressing threats			
A1. Maintain and improve efficacy of legal and management protection	Y		
A2. Adaptatively manage turtle stocks to reduce risk and build resilience to climate change and variability	Y		
A3. Reduce the impacts of marine debris	Y	Y	Y
A4. Minimise chemical and terrestrial discharge	Y	Y	Y
A5. Address international take within and outside Australia's jurisdiction	Y		
A6. Reduce impacts from terrestrial predation	Y		
A7. Reduce international and domestic fisheries bycatch	Y		
A8. Minimise light pollution	Y	Y	Y
A9. Address the impacts of coastal development/infrastructure and dredging and trawling	Y	Y	
A10. Maintain and improve sustainable Indigenous management of marine turtles	Y		

EPBC Act Part 13 Statutory Instrument	Applicable to:		
	Government	***Titleholder***	***Petroleum Activities Program***
B. Enabling and measuring recovery			
B1. Determine trends in index beaches	Y	Y	
B2. Understand population demographics at key foraging grounds	Y		
B3. Address information gaps to better facilitate the recovery of marine turtle stocks	Y	Y	Y
Blue Whale Conservation Management Plan			
Long-term recovery objective: Minimise anthropogenic threats to allow for their conservation status to improve so that they can be removed from the EPBC Act threatened species list	Y	Y	Y
Interim Recovery Objectives			
The conservation status of blue whale populations is assessed using efficient and robust methodology	Y		
The spatial and temporal distribution, identification of biologically important areas, and population structure of blue whales in Australian waters is described	Y	Y	Y
Current levels of legal and management protection for blue whales are maintained or improved and an appropriate adaptive management regime is in place	Y		
Anthropogenic threats are demonstrably minimised	Y	Y	Y
Action Areas			
A. Assessing and addressing threats			
A.1: Maintain and improve existing legal and management protection	Y		
A.2: Assessing and addressing anthropogenic noise	Y	Y	Y
A.3: Understanding impacts of climate variability and change	Y		
A.4: Minimising vessel collisions	Y	Y	Y
B. Enabling and Measuring Recovery			
B.1: Measuring and monitoring population recovery	Y		
B.2: Investigating population structure	Y		

EPBC Act Part 13 Statutory Instrument	Applicable to:		
	Government	***Titleholder***	***Petroleum Activities Program***
B.3: Describing spatial and temporal distribution and defining biologically important habitat	Y	Y	Y
Southern Right Whale Recovery Plan			
Long-term vision: increase population to a level that the conservation status has improved and the species no longer qualifies for listing as threatened under any of the EPBC Act listing criteria.	Y	Y	Y
Interim Recovery Objectives			
• Current levels of Commonwealth and State legislative and management protection for southern right whales are implemented, maintained, or improved, so threats continue to be managed and reduced over the life of the plan	Y		
• Anthropogenic threats are managed consistent with ecologically sustainable principles to facilitate recovery of southern right whales	Y	Y	Y
• Population dynamics, including demographics, distribution, residency, and coastal movement across the species range are monitored and quantified using robust, standardised, best-practice methodology to assess population recovery	Y		
• The population structure in Australian waters is clearly characterised to evaluate the degree to which the western and eastern populations are separate populations and inform the degree of connectivity with other southern right whale populations	Y		
• Capability of First Nation Australians, research, citizen science, and general community groups is improved to assist in addressing recovery actions of southern right whales in Australia.	Y		
Action Areas			
Assess and address key threats			
A1: Maintain, implement and improve efficacy of current legislative and management protection for southern right whales.	Y		
A2: Address habitat degradation impacts from coastal and offshore marine infrastructure developments within the species' range.	Y	Y	Y
A3: Understand impacts of climate variability and anthropogenic climate change on the species biology and population recovery.	Y		

EPBC Act Part 13 Statutory Instrument	Applicable to:		
	Government	***Titleholder***	***Petroleum Activities Program***
A4: Manage and mitigate the threat of entanglements from commercial active or discarded fishing gear throughout the species' range in Australian waters.	Y		
A5: Assess, manage, and mitigate impacts from anthropogenic underwater noise.	Y	Y	Y
A6: Manage, minimise and mitigate the threat of vessel strike.	Y	Y	Y
Measure recovery			
B1: Measure and monitor population demographic and recovery	Y		
B2: Characterise population structure	Y		
B3: Determine migratory paths and offshore distribution	Y		
B4: Improve capability of First Nation Australians, research, citizen science, and general community groups to assist management of southern right whales	Y		
Grey Nurse Shark Recovery Plan			
Overarching Objective			
To assist the recovery of the grey nurse shark in the wild, throughout its range in Australian waters, with a view to: improving the population status, leading to future removal of the grey nurse shark from the threatened species list of the EPBC Act ensuring that anthropogenic activities do not hinder the recovery of the grey nurse shark in the near future, or impact on the conservation status of the species in the future	Y	Y	Y
Specific Objectives			
Develop and apply quantitative monitoring of the population status (distribution and abundance) and potential recovery of the grey nurse shark in Australian waters	Y		
Quantify and reduce the impact of commercial fishing on the grey nurse shark through incidental (accidental and/or illegal) take, throughout its range	Y		
Quantify and reduce the impact of recreational fishing on the grey nurse shark through incidental (accidental and/or illegal) take, throughout its range	Y		
Where practicable, minimise the impact of shark control activities on the grey nurse shark	Y		

EPBC Act Part 13 Statutory Instrument	Applicable to:		
	Government	***Titleholder***	***Petroleum Activities Program***
Investigate and manage the impact of ecotourism on the grey nurse shark	Y		
Manage the impact of aquarium collection on the grey nurse shark	Y		
Improve understanding of the threat of pollution and disease to the grey nurse shark	Y	Y	Y
Continue to identify and protect habitat critical to the survival of the grey nurse shark and reduce the impact of threatening processes within these areas	Y	Y	
Continue to develop and implement research programs to support the conservation of the grey nurse shark	Y	Y	
Promote community education and awareness in relation to grey nurse shark conservation and management	Y		
Sawfish and River Sharks Recovery Plan			
Primary Objective			
To assist the recovery of sawfish and river sharks in Australian waters with a view to: improving the population status leading to the removal of the sawfish and river shark species from the threatened species list of the EPBC Act ensuring that anthropogenic activities do not hinder recovery in the near future, or impact on the conservation status of the species in the future	Y	Y	Y
Specific Objectives			
Reduce and, where possible, eliminate adverse impacts of commercial fishing on sawfish and river shark species	Y		
Reduce and, where possible, eliminate adverse impacts of recreational fishing on sawfish and river shark species	Y		
Reduce and, where possible, eliminate adverse impacts of Indigenous fishing on sawfish and river shark species	Y		
Reduce and, where possible, eliminate the impact of illegal, unregulated and unreported fishing on sawfish and river shark species	Y		
Reduce and, where possible, eliminate adverse impacts of habitat degradation and modification on sawfish and river shark species	Y	Y	Y
Reduce and, where possible, eliminate any adverse impacts of marine debris on sawfish and river shark species noting the linkages with the Threat Abatement Plan for the Impact of Marine Debris on Vertebrate Marine Life	Y	Y	Y

EPBC Act Part 13 Statutory Instrument	Applicable to:		
	Government	***Titleholder***	***Petroleum Activities Program***
Reduce and, where possible, eliminate any adverse impacts of collection for public aquaria on sawfish and river shark species	Y		
Improve the information base to allow the development of a quantitative framework to assess the recovery of, and inform management options for, sawfish and river shark species	Y		
Develop research programs to assist conservation of sawfish and river shark species	Y	Y	
Improve community understanding and awareness in relation to sawfish and river shark conservation and management	Y		
Marine Debris Threat Abatement Plan			
Objectives			
Contribute to long-term prevention of the incidence of marine debris	Y	Y	
Understand the scale of impacts from marine plastic and microplastic on key species, ecological communities and locations	Y	Y	Y
Remove existing marine debris	Y		
Monitor the quantities, origins, types and hazardous chemical contaminants of marine debris, and assess the effectiveness of management arrangements for reducing marine debris	Y		
Increase public understanding of the causes and impacts of harmful marine debris, including microplastic and hazardous chemical contaminants, to bring about behaviour change	Y		

Table 6-46: Assessment against relevant actions of the Marine Turtle Recovery Plan

Part 13 Statutory Instrument	Relevant Action Areas/Objectives	Relevant Actions	Evaluation	EPO, Controls and PS
Marine Turtle Recovery Plan	Action Area A3: Reduce the impacts from marine debris	Action: Support the implementation of the Marine Debris Threat Abatement Plan (TAP) Priority actions at stock level: G-NWS – Understand the threat posed to this stock by marine debris LH-WA – Determine the extent to which marine debris is impacting loggerhead turtles F-Pil – no relevant actions	Not inconsistent assessment: The assessment of the accidental release of solid hazardous and non-hazardous wastes has considered the potential risks to marine turtles. Controls have been implemented to reduce the likelihood of accidental release of solid wastes for the duration of the petroleum activities program.	EPO 24 C 24.1 PS 24.1
	Action Area A4: Minimise chemical and terrestrial discharge	Action: Ensure spill risk strategies and response programs adequately include management for marine turtles and their habitats, particularly in reference to 'slow to recover habitats', e.g. nesting habitat, seagrass meadows or coral reefs Priority actions at stock level: G-NWS – Ensure that spill risk strategies and response programs include management for turtles and their habitats LH-WA & F-Pil – Ensure that spill risk strategies and response programs include management for turtles and their habitats, particularly in reference to slow to recover habitats, e.g. seagrass meadows or corals	Not inconsistent assessment: The assessment of accidental release of chemicals / hydrocarbons has considered the potential risks to marine turtles. Spill risk strategies and response program include management measures for turtles and their nesting habitats.	Detailed oil spill preparedness and response performance outcomes, standards and measurement criteria for the Petroleum Activities Program are present in Sections 6.8 and 6.9

Part 13 Statutory Instrument	Relevant Action Areas/Objectives	Relevant Actions	Evaluation	EPO, Controls and PS
	Action Area A8: Minimise light pollution	Action: Artificial light within or adjacent to habitat critical to the survival of marine turtles will be managed such that marine turtles are not displaced from these habitats Priority actions at stock level: G-NWS – as above LH-WA – no relevant actions F-Pil – Manage artificial light from onshore and offshore sources to ensure biologically important behaviours of nesting adults and emerging/dispersing hatchlings can continue	Not inconsistent assessment: The assessment of light emissions has considered the potential impacts to marine turtles. Internesting, mating, foraging or migrating turtles are not impacted by light from offshore vessels. Based on the frequency and nature of IMMR activities, the impacts to adult turtles moving through the PAA from vessel lighting are expected to be localised and temporary with no lasting effect.	EPO 12 C 12.1, 12.2, C 10.8 PS 12.1, 12.2, 10.8
	Action Area B1: Determine trends at index beaches	Action: Maintain or establish long-term monitoring programs at index beaches to collect standardised data critical for determining stock trends, including data on hatchling production Priority actions at stock level: G-NWS – Continue long-term monitoring of index beaches LH-WA – Continue long-term monitoring of nesting and foraging populations F-Pil – no relevant actions	Not inconsistent assessment: Woodside contributes to Action Area B1 via its support of the Ningaloo Turtle Program1.	N/A
	Action Area B3: Address information gaps to better facilitate the recovery of marine turtle stocks	Action: Understand the impacts of anthropogenic noise on marine turtle behaviour and biology Priority actions at stock level: G-NWS – Given this is a relatively accessible stock that is likely to be exposed to anthropogenic noise – Investigate the impacts of anthropogenic noise on turtle behaviour and biology and extrapolate findings from the North West Shelf stock to other stocks LH-WA – no relevant actions F-Pil – no relevant actions	Not inconsistent assessment: The assessment of acoustic emissions has considered the potential impacts to marine turtles. Noise related to the Petroleum Activities Program is not expected to result in behavioural response, injury or mortality of individuals, or any other lasting effect.	EPO 4 C 4.1 PS 4.1

Part 13 Statutory Instrument	Relevant Action Areas/Objectives	Relevant Actions	Evaluation	EPO, Controls and PS
Assessment Summary The Marine Turtle Recovery Plan has been considered during the assessment of impacts and risks, and the Petroleum Activities Program is not considered to be inconsistent with the relevant actions of this plan.				

Table 6-47: Assessment against relevant actions of the Blue Whale Conservation Management Plan

Part 13 Statutory Instrument	Relevant Action Areas/Objectives	Relevant Actions	Evaluation	EPO, Controls and PS
Blue Whale Conservation Management Plan	Action Area A.2: Assessing and addressing anthropogenic noise.	Action 2: Assessing the effect of anthropogenic noise on blue whale behaviour. Action 3: Anthropogenic noise in biologically important areas will be managed such that any blue whale continues to use the area without injury, and is not displaced from a foraging area	Not inconsistent assessment: The assessment of acoustic emissions has considered the potential impacts to pygmy blue whales. Acoustic emissions from project vessels will not cause injury to any pygmy blue whale. There are no known or possible foraging areas for pygmy blue whales within or adjacent to the PAA. If the Petroleum Activities Program within the PAA overlaps with an individual northbound or southbound migration, they may deviate slightly from the migratory route, but will continue on their migration.	EPO 4 C 4.1 PS 4.1
	Action Area A.4: Minimising vessel collisions	Action 3: Ensure the risk of vessel strikes on blue whales is considered when assessing actions that increase vessel traffic in areas where blue whales occur and, if required, appropriate mitigation measures are implemented	Not inconsistent assessment: The assessment of vessel collision with marine fauna has considered the potential risks to pygmy blue whales. If the Petroleum Activities Program within the PAA overlaps with an individual northbound or southbound migration, they may deviate slightly from the migratory route, but will continue on their migration. Vessel collisions with pygmy blue whales are highly unlikely to occur, given the low operating speed of support vessels.	EPO 26 C 4.1 PS 4.1
	Action Area B.3: Describing spatial and temporal distribution and defining biologically important habitat	Action 2: Identify migratory pathways between breeding and feeding grounds. Action 3: Assess timing and residency within Biologically Important Areas	Not inconsistent assessment: Woodside contributes to Action Area B3 via its support of targeted research initiatives (e.g. satellite tracking of pygmy blue whale migratory movements).	N/A
Assessment Summary The Blue Whale Conservation Management Plan has been considered during the assessment of impacts and risks, and the Petroleum Activities Program is not considered to be inconsistent with the relevant actions of this plan.				

Table 6-48: Assessment against relevant actions of the Southern Right Whale Recovery Plan

Part 13 Statutory Instrument	Relevant Action Areas/Objectives	Relevant Actions	Evaluation	EPO, Controls and PS
National Recovery Plan for the Southern Right Whale	A2: Address habitat degradation impacts from coastal and offshore marine infrastructure developments within the species' range.	Action 1 Coastal and offshore development actions are assessed according to principles of ecological sustainable development to ensure the risk of injury, auditory impairment and/or disturbance to southern right whales is maintained. Action 3 Current information on species' occurrence, particularly in HCTS, BIAs, and historic high use areas, are used to inform planning, assessment, and decision-making on marine infrastructure development actions.	Not inconsistent assessment: This EP assesses the potential impacts of the petroleum activity do not result in the risk of injury, auditory impairment and/or disturbance to southern right whales, particularly within the HCTS and BIAs that are located over 250 km from the Operational Areas.	N/A
	A5: Assess, manage, and mitigate impacts from anthropogenic underwater noise.	Action 2: Actions within and adjacent to southern right whale BIAs and HCTS should demonstrate that it does not prevent any southern right whale from utilising the area or cause auditory impairment. Action 3: Actions within and adjacent to southern right whale BIAs and HCTS should demonstrate that the risk of behavioural disturbance is minimised. Action 4: Ensure environmental assessments associated with underwater noise generating activities include consideration of national policy (e.g., EPBC Act Policy Statement 2.1) and guidelines related to managing anthropogenic underwater noise and implement appropriate mitigation measures to reduce risks to southern right whales to the lowest possible level. Action 5: Quantify risks of anthropogenic underwater noise to southern right whales, including studies aimed to measure physiological effects, behavioural disturbance, and changes to acoustic communication (e.g., masking of vocalisations) to whales.	Not inconsistent assessment: The assessment of acoustic emissions has considered the potential impacts to southern right whales. The nearest BIAs and HCTS for the southern right whale being over 250 km from the Operational Areas therefore it is not expected that noise from the petroleum activity program will impact the southern right whales.	N/A

Part 13 Statutory Instrument	Relevant Action Areas/Objectives	Relevant Actions	Evaluation	EPO, Controls and PS
	A6: Manage, minimise and mitigate the threat of vessel strike.	Action 1: Assess risk of vessel strike to southern right whales in BIAs Action 3: Ensure environmental impact assessments and associated plans consider and quantify the risk of vessel strike and associated potential cumulative risks in BIAs and HCTS/.	Not inconsistent assessment: The assessment of vessel collision with marine fauna has considered the potential risks to southern right whales. The nearest BIAs and HCTS for the southern right whale being over 250 km from the Operational Areas therefore it is not expected that there is a risk of vessel strike.	N/A
Assessment Summary The National Recovery Plan for the Southern Right Whale has been considered during the assessment of impacts and risks, and the Petroleum Activities Program is not considered to be inconsistent with the relevant actions of this plan.				

Table 6-49: Assessment against relevant actions of the Grey Nurse Shark Recovery Plan

Part 13 Statutory Instrument	Relevant Action Areas/Objectives	Relevant Actions	Evaluation	EPO, Controls and PS
Grey Nurse Shark Recovery Plan	Objective 7: Improve understanding of the threat of pollution and disease to the grey nurse shark	Action 7.1: Review and assess the potential threat of introduced species, pathogens and pollutants	Not inconsistent assessment: This EP includes an assessment of the impacts from accidental release of solid wastes as well as planned discharges of drilling waste on marine species.	N/A
			Not inconsistent assessment: The assessment of accidental release of chemicals / hydrocarbons has considered the potential risks to grey nurse sharks. Spill risk strategies and response program include management measures, as identified and required.	Detailed oil spill preparedness and response performance outcomes, standards and measurement criteria for the Petroleum Activities Program are present in Section 6.8 and 6.9.
Assessment Summary The Grey Nurse Shark Recovery Plan has been considered during the assessment of impacts and risks, and the Petroleum Activities Program is not considered to be inconsistent with the relevant actions of this plan.				

Table 6-50: Assessment against relevant actions of the Sawfish and River Shark Recovery Plan

Part 13 Statutory Instrument	Relevant Action Areas/Objectives	Relevant Actions	Evaluation	EPO, Controls and PS
Sawfish and River Shark Recovery Plan	Objective 5: Reduce and, where possible, eliminate adverse impacts of habitat degradation and modification on sawfish and river shark species	Action 5c: Identify risks to important sawfish and river shark habitat and measures needed to reduce those risks	Not inconsistent assessment: The assessment of accidental release of chemicals / hydrocarbons has considered the potential risks to sawfish and river shark. Spill risk strategies and response program include management measures, as identified and required.	Detailed oil spill preparedness and response performance outcomes, standards and measurement criteria for the Petroleum Activities Program are present in Appendix H.
	Objective 6: Reduce and, where possible, eliminate any adverse impacts of marine debris on sawfish and river shark species noting the linkages with the Threat Abatement Plan for the Impact of Marine Debris on Vertebrate Marine Life	Action 6a: Assess the impacts of marine debris including ghost nets, fishing gear and plastics on sawfish and river shark species	Not inconsistent assessment: The assessment of the accidental release of solid hazardous and non-hazardous wastes has considered the potential risks to sawfish. Controls have been implemented to reduce the likelihood of accidental release of solid wastes for the duration of the petroleum activities program.	N/A
Assessment Summary The Sawfish and River Shark Recovery Plan has been considered during the assessment of impacts and risks, and the Petroleum Activities Program is not considered to be inconsistent with the relevant actions of this plan.

Marine Debris TAP	Objective 2: Understand the scale of marine plastic and microplastic impact on key species, ecological communities and locations	Action 2.04: Build understanding related to plastic and microplastic pollution	Not inconsistent assessment: The assessment of the accidental release of solid hazardous and non-hazardous wastes has considered the potential risks to the marine environment. Controls have been implemented to reduce the likelihood of accidental release of solid wastes for the duration of the petroleum activities program.	N/A
Assessment Summary The Marine Debris TAP has been considered during the assessment of impacts and risks, and the Petroleum Activities Program is not considered to be inconsistent with the relevant actions of this plan.				

6.11 First Nations Cultural Features and Heritage Values Assessment

As described in Section 4.9 the identification of cultural features and heritage values of the environment as well as the social, economic and cultural features important to First Nation's people is integral to understanding the environment and any potential impacts and risks to the environment.

In line with Woodside's First Nations Communities Policy (December 2023), Woodside seeks to avoid damage or disturbance to cultural heritage (including intangible heritage) and, if avoidance is not possible, minimise and mitigate the impacts, in consultation with First Nation communities and Traditional Custodians. Mitigation can include any measure or control aimed at ensuring the viability of the intangible cultural heritage and its intergenerational transmission. This can include reducing impacts and risks to environmental features that are associated with intangible cultural heritage (UNESCO 2003; ICOMOS 2013).

It is important to note that not all topics raised by First Nations groups / individuals through consultation are considered values for the purpose of the cultural features and heritage values impact assessment below. A number of topics were raised in the context of a general interest in environmental management and ecosystem health (i.e., natural environment interest), where the group/individual was seeking further information about potential impacts and risks from the Petroleum Activities Program on a receptor. As these interests relate to the maintenance of the natural environment, these are adequately addressed through impact and risk assessments and not further assessed below.

Aspect	Cultural Features and Heritage Values
Description of Source Impact/ Risk	***Physical presence of vessels*** The Petroleum Activities Program involves operation of the Pluto Facility and the drilling and tie-back of one new production well (Xena-03). The MODU will be present within the Operational Area for ~60 days to drill the Xena-03 well. When underway, activities will be 24 hours per day, seven days per week. Subsea installation vessels will be used to install and cold commission the flowlines and subsea infrastructure following the completion of drilling the new well. This is expected to take ~ 3 weeks. Temporary exclusion zones will be established around the MODU. ***Acoustic emissions from vessels*** MODUs, installation vessels and support vessels (including ASV and AHVs) undertaking the Petroleum Activities Program will generate noise both in the air and underwater. During drilling operations, the MODU will produce low-intensity continuous sound. In addition, the Petroleum Activities Program will be supported by DP capable vessels. These noises will contribute to and can exceed ambient noise levels which range from around 90 dB re 1 µPa (root square mean sound pressure level (RMS SPL)) under very calm, low wind conditions, to 120 dB re 1 µPa (RMS SPL) under windy conditions. ***Unplanned hydrocarbon release from loss of well containment (basis of EMBA)*** For each source of risk, the credible worst-case scenario in conjunction with impact thresholds is used to determine the spatial extent of the EMBA. The worst-case unplanned event is considered to be an unplanned hydrocarbon release. The stochastic modelling approach to determining the EMBA involves numerous simulations covering a range of metocean conditions representing currents and winds that typically prevail over the course of a year. The EMBA is generated from a composite of outcomes of each simulation and therefore covers a larger area than the area that could be affected during any one single spill event. In the event of a spill, the area that would be affected would be much smaller than the EMBA. The EMBA is driven by the distribution of entrained hydrocarbon above ecological thresholds and hence although Islands such as Barrow and Montebello Islands, and mainland coastlines are within the EMBA, these are not expected to be affected unless there is shoreline contact above thresholds. Whilst the EMBA is driven by predictions of entrained hydrocarbons, the scenario associated with the most significant consequence involves shoreline contact, which is predicted from the scenario of subsea equipment loss of containment.

Aspect	Cultural Features and Heritage Values
Impact and Risk Assessment	The PAP has the potential to impact cultural features and heritage values through the following ways: ***Intangible Cultural Heritage*** Songlines: Songlines can become lost, fragmented, or broken when there is a loss of Country or forced removal from Country (Neale and Kelly, 2020:30). Physical sites that have been identified as comprising a component of a songline are important to protect to prevent the fragmenting or breaking apart of songlines and loss of sacred cultural knowledge. It is noted that oil and gas infrastructure exists in many areas of the North West Shelf, and that songlines are still acknowledged and recognised. It is inferred that if there were to be any impacts to surviving songlines these would be significantly more likely to be described as qualitative (i.e. "weaken" a songline) rather than binary or absolute (i.e. destroy a songline). Creation/dreaming sites; sacred sites; ancestral beings: Activities that physically alter landscape features may be assumed to potentially impact values of creation/dreaming sites, sacred sites or ancestral beings. Cultural obligations to care for Country: Environmental impacts may be assumed to impact rights and obligations to care for Sea Country. Exclusion of Traditional Custodians from Sea Country (e.g. by restricting access) or decision-making processes (e.g. by not conducting ongoing consultation) are other potential sources of impact. Knowledge of Country/customary law and transfer of knowledge: Direct impact to communities practicing these skills will inherently occur when relevant aspects of the environment disappear, are displaced or suffer a reduction in population. Therefore, the transmission of these skills is expected to be impacted where there are impacts at the species/population level. Limitations on access to sites or disruption/relocation of First Nations communities may have implications for the preservation of First Nations knowledge. Connection to Country: Where people are displaced or disrupted (e.g. during colonisation) or where there is a loss of technical skills or environmental knowledge this may damage connection to Country (McDonald and Phillips, 2021). Access to Country: Impacts to access to Country may be classified as temporary (e.g. where exclusion zones exist around activities for safety reasons) or permanent (e.g. where infrastructure obstructs access or navigation). Impacts to access to Country can only occur in areas that were traditionally accessed by Traditional Custodians. This is anticipated to be focussed on areas adjacent to the coast. Restrictions on Access to Country: Access to the operational area has not been identified as a cultural issue, however some areas within the EMBA may not be culturally appropriate to access. Impacts to this value may occur where spill response access areas that are not appropriate, or in ways that are not consistent with traditional law. Kinship systems and totemic species: It is assumed that marine species may have kinship/totemic relationships to Traditional Custodians, but it is understood that these relationships do not prohibit people outside of that "skin group" from hunting or eating that same species (Juluwarlu, 2004). It is therefore inferred that the management of totemic or kinship species applies at the species/population level and not to individual plants and animals. Resource collection: Direct impact to communities using these resources will inherently occur when the resource disappears, is displaced or suffers a reduction in population. Therefore, marine species (as resources) will be impacted where there is an impact at the species/population level. ***Marine Ecosystems and Species:*** Marine ecosystems may hold both cultural and environmental value with cultural and environmental values intrinsically linked (DCCEEW, 2023; MAC, 2021 as cited in Woodside, 2023a). It necessarily follows that an impact to marine ecosystems has the potential to impact cultural features where the impact is detectable within Sea Country—the seascape which Traditional Custodians view, interact with or hold knowledge of. ***Coastal landforms*** Coastal landforms may have cultural values either through association with intangible values described above (e.g. as features of a songline, physical manifestations of ancestor beings etc.) or as archaeologically prospective locations (e.g. water sources with increased habitation/use, dunes used for burials etc.)

Aspect	Cultural Features and Heritage Values
	Intangible Values ***Songlines*** Management of intangible cultural heritage can include reducing impacts and risks to tangible features that are associated with intangible cultural heritage (UNESCO, 2003; ICOMOS, 2013). Impacts to marine plants, animals and other cultural features associated with songlines might impact the intergenerational transmission of knowledge of songlines when individuals can no longer witness or interact with the cultural features tied to songlines on Country. Therefore, managing songlines may require environmental controls to minimise potential impact to marine fauna at a population level, including migratory routes. Refer to species specific assessment below for further information. Physical features comprising a component of a songline are important to protect to prevent the fragmenting or breaking apart of songlines and loss of sacred cultural knowledge. Songlines can become lost, fragmented, or broken when there is a loss of Country or impact to culturally important physical features (Neale and Kelly, 2020:30). No specific details of songlines within the EMBA have been provided by relevant persons during consultation for this Activity, and no landforms typical of songlines (e.g. rocks, mountains, rivers, caves and hills (Higgins 2021:724)) are anticipated to be impacted by the Activity. ***Creation/Dreaming Sites; Sacred Sites; Ancestral Beings*** Woodside has undertaken all reasonable steps to identify creation and dreaming sites, sacred sites, and places associated with ancestral beings within the EMBA. No such sites have been identified. A review of relevant literature has been undertaken which has identified creation, dreaming and ancestral narratives related to the sea more broadly without confirming where (if anywhere) these overlap the EMBA. These references are of a general nature, and do not identify any features or values requiring specific protection or management from the proposed activities. In the literature reviewed, sea serpents or water serpents are common in Aboriginal creation narratives, and several references were identified. The majority of these refer to serpents residing within inland rivers or pools outside of the EMBA (Barber and Jackson, 2011, Hayes v Western Australia [2008] FCA 1487, Juluwarlu, 2004; Water Corporation, 2019). In some versions, the serpent originates from the sea or coast and creates the rivers as it heads inland. Areas of the current coastline and past coastlines at various points along the Ancient Landscape—where the Serpent would have emerged onto the land—are within the EMBA. Areas of the broader ocean where the serpent may have originally lived are not specified. Barber and Jackson (2011) also recount a story where a freshwater serpent pushes a sea serpent back into the ocean where it presumably continues to reside. This does not provide the specificity required to determine the location of sea serpents within the sea, and it is possible that the ocean as a whole (out to and beyond other continents) should be viewed generally as housing the sea serpent(s). Consultation with Traditional Custodians and ethnographic surveys have not identified impacts on sea serpents from the PAP. However, by analogy to other water serpent narratives across Australia, possible impact pathways may include interruption of its path by blocking or reducing flows of water, damaging sacred sites such as thalu or rock art sites or depleting water sources. No impacts to water flows (either tidal movement or ocean currents) or depletion of water sources are anticipated from this PAP. ***Cultural Obligations to Care for Country*** Caring for Country collectively refers to the cultural obligations of individuals and groups, as well as rituals and ceremonies required for the physical and spiritual health of the environment. Lack of access to coastally located cultural sites that carry songlines or remain ceremonially important can impact First Nations people's livelihoods and impact their ability to carry out cultural obligations on Country. ***Knowledge of Country/Customary Law and Transfer of Knowledge*** Cultural knowledge about Sea Country/customary law and the intergenerational transmission of knowledge are important values identified through consultation, assessments and the literature review. Transfer of knowledge includes continuing traditional practices to pass on practical skills. Direct impact to communities practicing these skills will inherently occur when relevant aspects of the environment disappear, are displaced or suffer a reduction in population—for example traditional fishing methods require the survival of traditional fish resources. Therefore, ensuring the transmission of cultural knowledge may require environmental controls protecting species and migratory pathways at a population level. Refer to species specific assessment below for further information.

Aspect	Cultural Features and Heritage Values
	Connection to Country Connection to Country describes the multi-faceted relationship between First Nations people and the landscape, which is envisioned as having personhood and spirit. No impacts to connection to country are anticipated as a result of exclusion or displacement of Aboriginal communities. Access to Country is discussed below. ***Access to Country*** Access to Country, including Sea Country, is necessary for the continuation of other values including caring for Country and the transfer of traditional knowledge. Access is also a value in its own right, as a continuation of traditional Sea Country access and use. Access to areas within the Operational Area may be limited where exclusion zones are established around vessels for safety purposes. Further the exclusion zones around drilling activities are temporary and presence of subsea infrastructure are not anticipated to affect navigation, particularly given the water depth. Access to Country within the EMBA is also not expected to be affected in the highly unlikely event of an unplanned hydrocarbon release. However relevant cultural authorities will be engaged in the event of a spill that may affect them. ***Restrictions on Access to Country*** No information was received which suggested any part of the Operational Area cannot be accessed in a culturally appropriate way. However, some areas of the EMBA may be subject to cultural restrictions on access or may be culturally dangerous to access in any respect. Access to these areas would only be required in response to an unplanned impact. Kinship Systems and Totemic Species Individuals may have kinship to specific species (Smyth, 2008; Juluwarlu, 2004) and/or a responsibility to care for species (Muller, 2008). These relationships are understood to impose obligations on Traditional Custodians. It is understood that these obligations do not impose restrictions on other people generally, but it is considered that impacts to species at a population level may inhibit Traditional Custodians with kinship relationships' ability to perform their obligations where this results in reduced or displaced populations. It is therefore considered that the management of totemic or kinship species applies at the species/population level and not to individual plants and animals. As such, impacts to individual marine fauna is not expected to impact on the totemic or kinship cultural connection. Refer to species specific assessment below for further information. ***Resource Collection*** A number of marine species are identified through consultation and literature as important resources, particularly as food sources. In addition to their immediate value as sustenance, the gathering and preparation of these resources are informed by cultural knowledge, and an inability to use these resources may result in a loss of ability to transfer that knowledge to future generations. Direct impact to communities using these resources will inherently occur when the resource disappears, is displaced or suffers a reduction in population. Therefore, these communities may be impacted where there is an impact at the species/population level. Refer to species specific assessment below for further information. Relevant cultural authorities will be engaged in the event of a spill that may affect them. **Marine Species** ***Marine Mammals*** There are increase ceremonies/rituals for species of animals and plants, important to First Nations, to enhance or maintain populations. Thalu are places where these increase ceremonies are performed. All mentions of active ceremonial sites were confined to onshore locations, though the values may extend offshore where, for example, the thalu relates to marine species populations. As thalu ceremonies are performed to maintain and increase populations of marine species, it is considered that management applies at the species/population level and not to individuals—for example the thalu site on Murujuga which "brings in whales to beach" will continue to serve its purpose so long as whales continue to migrate through Mermaid Sound. Related intangible cultural heritage may include the transmission of cultural knowledge about whales and whale behaviour, including birthing areas, whale communication and migratory patterns. Such cultural knowledge may be associated with various cultural functions and activities that support the social and economic life of a community (Fijn, 2021). First Nations groups have expressed interest about whale migratory routes and studies. Inter-generational transmission of cultural knowledge (including songlines) relating to marine mammals may be impacted where changes to population or behaviour at a population level results in reduced sightings (e.g. through

Aspect	Cultural Features and Heritage Values
	population decline, changes to migration routes or changes to migration seasonality). This transfer of knowledge may be integral to managing a group's intangible cultural heritage (UNESCO, 2003). As described in the relevant environmental impact and risk assessment, potential impacts to whales are limited to behavioural disturbance to transient individuals, which are not considered to be ecologically significant at a population level, and hence not expected to impact the value of marine mammals, including the transmission of cultural knowledge. The Operational Area does overlap the BIAs for Migration for the Pygmy Blue Whale and Humpback Whale. As such, cultural values and intangible cultural heritage associated with these species are expected to be maintained. ***Marine Reptiles*** Turtles and their eggs have been identified through consultation and existing literature as an important resource, particularly as food sources. Direct impact to communities using these resources will inherently occur when the resource disappears, is displaced or suffers a reduction in population. Therefore, these species (as resources) will be impacted where there is an impact at the species/population level. Intangible cultural heritage may also include the transmission of cultural knowledge about marine reptiles, such as nesting areas, hunting areas and migratory patterns. Such cultural knowledge may be associated with various cultural functions and activities that support the social and economic life of a community (Fijn, 2021). First Nations groups have expressed an interest regarding turtle monitoring programs and migration patterns. Activities that impact turtle populations and their marine environment may have an indirect impact on some Aboriginal communities as this can limit access to cultural sites or deplete hunting areas that would threaten local food security (Delisle et al., 2018:251). Inter-generational transmission of cultural knowledge (including Songlines) relating to marine reptiles may be impacted where changes results in reduced sightings (e.g. through population decline, changes to migration routes or changes to migration seasonality). This transfer of knowledge may be integral to managing a group's intangible cultural heritage (UNESCO, 2003). As described in the relevant environmental impact and risk section, potential impacts to marine reptiles are predicted to be at an individual level, which are not considered to be ecologically significant at a population level. Impacts will not occur to significant proportions of the populations of the species, nor result in a decrease of the quality of the habitat such that the extent of these species is likely to decline. Further, the Operational Area and EMBA do overlap marine turtle BIAs. As such, cultural values and intangible cultural heritage associated with these species are expected to be maintained. ***Fish*** Fish have been identified through consultation and existing literature as an important resource, particularly as food sources. Direct impact to communities using these resources will inherently occur when the resource disappears, is displaced or suffers a reduction in population. Therefore, these species (as resources) will be impacted where there is an impact at the species/population level. During consultation, fish were identified as important agents in the management of the broader ecosystem in Mermaid Sound, and generally to marine environments. Inter-generational transmission of cultural knowledge relating to fish may be impacted where changes to population/behaviour results in reduced sightings (e.g. through population decline). This transfer of knowledge may be integral to managing a group's intangible cultural heritage (UNESCO, 2003). Intangible cultural heritage associated with fish, including inter-generational knowledge regarding fishing techniques and migratory patterns, can be managed by reducing impacts to fish in nearshore marine environments to which this cultural knowledge is intrinsically connected. As described in the relevant environmental impact and risk sections, it is expected that fish, sharks and rays may demonstrate avoidance or attraction behaviour however, potential impacts are not considered to be ecologically significant at a population level. As such, cultural values and intangible cultural heritage associated with these species are expected to be maintained. ***Benthic habitats (coral, seagrass)*** Through consultation, First Nations groups identified benthic habitats as valuable for their ecological values, including corals attracting fish and seagrass providing shelters for fauna, as well as an important habitat for dugongs. Additionally, coral is valued by MAC for its aesthetic values. As described in the relevant environmental impact assessments, the potential impacts from the PAP on benthic habitats is assessed to be no lasting effect.

Aspect	Cultural Features and Heritage Values
	In terms of risk, a change in habitat may occur due to a change in water or sediment quality following an unplanned hydrocarbon release. Given hydrocarbon characteristics, rapid weathering, short-term exposure, as well as the response strategies planned to be deployed, an unplanned release is not expected to result in a level of exposure to coral and seagrass that would cause an adverse impact on marine ecosystem functioning or integrity results. As such, cultural values and intangible cultural heritage associated with benthic habitats are expected to be maintained. ***Shoreline Habitats (coastal vegetation, mangroves)*** Through consultation, First Nations groups identified shoreline habitats as valuable for their ecological values, including coastal vegetation such as mangroves which provide shelter to marine invertebrates, which are identified resources, and potential nursery for turtles. Literature also notes that mangroves are also valued for the flora and fauna they are associated with and support (Commonwealth of Australia 2002) and Smyth (2007) reports that mangrove seeds are used as a resource by Ngarda-Ngarli. There is no overlap between the Operational Area and shoreline habitats, and no planned impacts to shoreline habitats from the PAP. In terms of risk, a change in habitat may occur due to a change in water or sediment quality following an unplanned hydrocarbon release. Given hydrocarbon characteristics, rapid weathering, as well as the response strategies planned to be deployed, an unplanned release is not expected to have a substantial adverse impact on marine ecosystem functioning or integrity. As such, cultural values and intangible cultural heritage associated with shoreline habitats are expected to be maintained. ***Coastal Landforms*** There is no overlap between the Operational Area and coastal landforms, and no planned impacts to coastal landforms from the PAP. For coastal landforms beyond the Operational Area, the EMBA is driven by an unplanned hydrocarbon release. There is no anticipated impact pathway from the presence of marine diesel on the physical existence of coastal landforms such as hills, waterways or dune systems. Access to Country within the EMBA is also not expected to be affected in the highly unlikely event of an unplanned hydrocarbon release. However relevant cultural authorities will be engaged in the event of a spill that may affect them. As such, cultural values and intangible cultural heritage associated with shoreline habitats are expected to be maintained. **Conclusion** The impact and risk assessment has determined that the planned activities are unlikely to result in an impact greater than negligible[136] (F) and unplanned activities are assessed to have a residual risk rating of moderate (or lower). Woodside engages in ongoing consultation throughout the life of an EP. Should feedback be received after the EP has been accepted, it will be assessed and, where appropriate, Woodside will apply its Management of Change and Revision process..
Impact and Risk Assessment	The Petroleum Activities Program has the potential impact cultural features and heritage values through the following ways: **Archaeological heritage:** Places that are identified in the literature for their value as archaeological sites can be assumed to be impacted where there is an impact to the archaeological or scientific values of its tangible elements. This could include damage or disturbance of archaeological material or to the archaeological context. **Intangible cultural heritage:** Songlines: Songlines can become lost, fragmented, or broken when there is a loss of Country or forced removal from Country (Neale and Kelly 2020:30). Physical sites that have been identified as comprising a component of a songline are important to protect to prevent the fragmenting or breaking apart of songlines and loss of sacred cultural knowledge. It is noted that oil and gas infrastructure exists in many areas of the North West Shelf, and that songlines are still acknowledged and recognised. It is inferred that if there were to be any impacts to surviving songlines these would be significantly more likely to be described as qualitative (i.e. “weaken” a songline) rather than binary or absolute (i.e. destroy a songline).

[136] Noting that as the receptor sensitivity is high, the impact significance level is Slight (E).

	Creation/dreaming sites; sacred sites; ancestral beings: Activities that physically alter landscape features may be assumed to potentially impact values of creation/dreaming sites, sacred sites or ancestral beings. Ceremonial sites: Activities that prevent the performance of ceremony at these sites will directly impact its values. Cultural obligations to care for Country: Environmental impacts may be assumed to impact rights and obligations to care for Sea Country. Exclusion of Traditional Custodians from Sea Country (e.g., by restricting access) or decision-making processes (e.g., by not conducting ongoing consultation) are other potential sources of impact. Knowledge of Country/customary law and transfer of knowledge: Direct impact to communities practicing these skills will inherently occur when relevant aspects of the environment disappear, are displaced or suffer a reduction in population. Therefore, the transmission of these skills is expected to be impacted where there are impacts at the species/population level. Limitations on access to sites or disruption/relocation of First Nations communities may have implications for the preservation of First Nations knowledge. Cultural Safety refers to respecting local Lore and culturally significant areas to protect individuals from cultural harm. There are many cultural implications for those (Aboriginal and non-Aboriginal) who do not follow cultural advice or access Country in culturally inappropriate ways. Connection to Country: Where people are displaced or disrupted (e.g., during colonisation) or where there is a loss of technical skills or environmental knowledge this may damage connection to Country (McDonald and Phillips, 2021). Access to Country: Impacts to access to Country may be classified as temporary (e.g. where exclusion zones exist around activities for safety reasons) or permanent (e.g. where infrastructure obstructs access or navigation). Impacts to access to Country can only occur in areas that were traditionally accessed by Traditional Custodians. As described in Section 4.9 this is anticipated to be focussed on areas adjacent to the coast. Kinship systems and totemic species: It is assumed that marine species may have kinship/totemic relationships to Traditional Custodians, but it is understood that these relationships do not prohibit people outside of that “skin group” from hunting or eating that same species (Juluwarlu 2004). It is therefore inferred that the management of totemic or kinship species applies at the species/population level and not to individual plants and animals. Resource collection: Direct impact to communities using these resources will inherently occur when the resource disappears, is displaced or suffers a reduction in population. Therefore, marine species (as resources) will be impacted where there is an impact at the species/population level. **Marine ecosystems and species** Marine ecosystems may hold both cultural and environmental value (see Section 4.9), with cultural and environmental values intrinsically linked (DCCEEW 2023, MAC 2021 as cited in Woodside 2023a). It necessarily follows that an impact to marine ecosystems has the potential to impact cultural features where the impact is detectable within sea country—the seascape which Traditional Custodians view, interact with or hold knowledge of. **Archaeological Heritage** ***Onshore / intertidal archaeological sites*** No coastal areas or islands exist within the Operational Area. A review of the of DPLH’s Aboriginal Heritage Inquiry System identified 55 Registered Aboriginal Sites and Other Heritage Places in the EMBA. These were mainly comprised of sites at Barrow Island, the Ningaloo coast, the Pilbara and then north to the Kimberly. These locations do exist within the EMBA boundary, however given the EMBA is driven by an unplanned hydrocarbon spill there is no anticipated impact pathway from this activity to onshore archaeological sites above highest astronomical tide (HAT). Archaeological sites may exist in intertidal landscapes within the EMBA and may be exposed to hydrocarbon from an unplanned spill, however there is no anticipated impact pathway from the presence of hydrocarbons on archaeological values, as this is not expected to impact the fabric or context of sites on an exposed shoreline site. Impacts to the heritage value of fish traps from hydrocarbons in an unplanned spill may occur indirectly through impacts to fish. However, it is expected that continued use of fish traps beyond their archaeological value will be preserved where fish species and distribution are maintained at a population level. With regard to fish, refer to species specific assessment below for further information. ***Submerged archaeological sites*** No submerged archaeological sites have been identified beyond terrestrial or intertidal areas, with the exception of two sites at Murujuga in Cape Bruguieres channel and Flying Foam Passage

	(Benjamin et al. 2020; Benjamin et al 2023), which are outside of the EMBA. Nevertheless, there is the potential for submerged archaeological sites on the Ancient Landscape. Submerged archaeological sites (locations undefined) may exist on the Ancient Landscape within the broader EMBA. However, given the EMBA is driven by an unplanned hydrocarbon spill, it is not expected to impact the seabed or archaeological material on or within it. Therefore, there is no anticipated impact pathway to submerged archaeological sites in the broader EMBA from the Petroleum Activities Program. ***Rivers, waterholes, tidal channels and seeps*** Oceanographic studies indicate that both the open ocean and coastal zone off Western Australia are well-mixed and saline. Submerged former water sources (e.g. river beds) may exist within the EMBA which are archaeologically prospective or culturally significant. The EMBA is driven by an unplanned hydrocarbon spill, which is not expected to impact the seabed or features on it. As such, there is no anticipated impact pathway from this activity to submerged water sources in the broader EMBA. In the highly unlikely and unmitigated worst case, unplanned hydrocarbons may contact shorelines and receptors such as mangroves, and shoreline habitats. These habitats may contain brackish or fresh water due to runoff from land. Given hydrocarbon characteristics and rapid weathering, an unplanned release is expected to have no lasting effect on any freshwater sources along the shoreline. **General Intangible values** ***Songlines*** Management of intangible cultural heritage can include reducing impacts and risks to environmental features that are associated with intangible cultural heritage (UNESCO 2003; ICOMOS 2013). Impacts to marine plants, animals and other cultural features associated with songlines might impact the intergenerational transmission of knowledge of songlines when individuals can no longer witness or interact with the cultural features tied to songlines on Country. Therefore, managing songlines may require environmental controls protecting species at a population level, including migratory routes. Refer to species specific assessment below for further information, in addition to the impact and risk assessment in Section 6.7 and 6.8, respectively. Energy lines have also been raised during consultation. Energy lines are understood by Woodside to be the same as songlines. Physical features comprising a component of a songline are important to protect to prevent the fragmenting or breaking apart of songlines and loss of sacred cultural knowledge. Songlines can become lost, fragmented, or broken when there is a loss of Country or impact to culturally important physical features (Neale and Kelly 2020:30). No specific details of songlines within the EMBA have been provided by relevant persons during consultation for this Activity, and no landforms typical of songlines (e.g. mountains, rivers, caves and hills (Higgins 2021)) are anticipated to be impacted by the Activity. In publicly available literature, Murujuga is acknowledged as a starting point for songlines, including the flying fox songline (MAC 2023a). Precise location of this songline, and features of this songline that might be impacted, are not clearly articulated in the reviewed sources, but it is stated that “the sea is a source of creation for flying foxes” (DEC 2013). Although this does not provide the specificity required to determine the location of the flying fox songline or associated sites. Consultation with MAC and other Traditional custodians has not identified the flying fox songline as overlapping the EMBA, and flying foxes do not occur within the EMBA. Kearney et al (2023) notes a connection between the Kangaroo songline and a pair of submerged waterholes identified through seabed mapping by the Deep History of Sea Country project, which later found submerged artefacts in Flying Foam passage. Noted that due to the water depth it is not expected that active or former freshwater sources that may connect to the Kangaroo or other songlines would be within the Operational Area. Consultation with MAC and other Traditional custodians has not identified these songlines as overlapping the EMBA, and these species do not occur within the EMBA. In publicly available literature, Murujuga is acknowledged as the starting point for the seven sisters songline (Bainger 2021). Precise location of this songline, and features of this songline that might be impacted, are not clearly articulated in the reviewed sources. Consultation with MAC and other Traditional custodians has not identified the seven sisters songline as overlapping the EMBA. While the presence of songlines are generally raised in the literature across several relevant communities, no specific details have been identified. The literature review has also identified culturally important features, which are known to be commonly associated with songlines (e.g. marine species and landforms; Section 4.8), and these have been separately assessed. Further assessment of intangible values and marine species are provided below, in addition to the impact and risk assessment in Section 6.7 and 6.8, respectively.

	Creation/dreaming sites; sacred sites; ancestral beings Woodside has undertaken all reasonable steps to identify creation and dreaming sites, and places associated with ancestral beings within the EMBA. No such sites have been identified. A review of relevant literature has been undertaken which has identified creation, dreaming and ancestral narratives related to the sea more broadly without confirming where (if anywhere) these overlap the EMBA. These references are of a general nature, and do not identify any features or values requiring specific protection or management from the proposed activities. Sea serpents or water serpents are common in Aboriginal creation narratives, and several references were identified in the reviewed literature. The majority of these refer to serpents residing within inland rivers or pools outside of the EMBA (Barber and Jackson 2011, Dury v Western Australia [2018] FCA 1849, Hayes v Western Australia [2008] FCA 1487, Juluwarlu 2004, Kalbarri Visitor Centre 2023, Water Corporation 2019, Zaunmayr 2016, Department of Parks and Wildlife 2014, Yu 1999, DBCA 2020). In some versions, the serpent originates from the sea or coast and creates the rivers as it heads inland. Barber and Jackson (2011) also recount a story where a freshwater serpent pushes a sea serpent back into the ocean where it presumably continues to reside. This does not provide the specificity required to determine the location of sea serpents within the sea, and it is possible that the ocean as a whole (out to and beyond other continents) should be viewed generally as housing the sea serpent(s). Consultation with Traditional Custodians have not identified activities of this Petroleum Activities Program as having an impact on sea serpents. However, by analogy to other water serpent narratives across Australia, possible impact pathways may include interruption of its path by blocking or reducing flows of water, damaging sacred sites such as thalu or rock art sites or depleting water sources. While there is potential for shoreline accumulation of hydrocarbons within the EMBA, relevant cultural authorities will be engaged in the event of a spill that may affect them, as specified in Appendix I. No impacts to water flows (either tidal movement or ocean currents) or depletion of water sources are anticipated from this Petroleum Activities Program. Features of the landscape with the potential for connection to creation/dreaming stories and ancestral beings are likely within the EMBA on the Ancient Landscape. However, there are no anticipated impact pathways to submerged landscape features within the broader EMBA from the Petroleum Activities Program. ***Ceremonial sites*** All mentions of active ceremonial sites were confined to onshore locations and no direct impacts to onshore ceremonial sites are anticipated from the Petroleum Activities Program. However, indirect impacts may occur where ceremonies cannot be performed due to limitations on access, loss of knowledge or impacts to the environment, which are further described below. ***Cultural obligations to care for Country*** Caring for Country collectively refers to the cultural obligations of individuals and groups, as well as rituals and ceremonies required for the physical and spiritual health of the environment. Lack of access to coastally located cultural sites that carry songlines or remain ceremonially important can impact First Nations people's livelihoods and impact their ability to carry out cultural obligations on Country. While there is potential for shoreline accumulation of hydrocarbons within the EMBA, relevant cultural authorities will be engaged in the event of a spill that may affect them, as specified in Appendix I. ***Knowledge of Country/ customary law and transfer of knowledge*** Cultural knowledge about Sea Country/customary law and the intergenerational transmission of knowledge are important values identified through consultation, assessments and the literature review. Transfer of knowledge includes continuing traditional practices to pass on practical skills. Direct impact to communities practicing these skills will inherently occur when relevant aspects of the environment disappear, are displaced or suffer a reduction in population—for example traditional fishing methods require the survival of traditional fish resources. Therefore, ensuring the transmission of cultural knowledge may require environmental controls protecting species and migratory pathways at a population level. Refer to species specific assessment below for further information, in addition to the impact and risk assessment in Section 6.7 and 6.8 respectively. ***Connection to Country*** Connection to Country describes the multi-faceted relationship between First Nations people and the landscape, which is envisioned as having personhood and spirit. Connection to Country may be damaged where people are displaced or disrupted (e.g. during colonisation) or where there is a loss of technical skills or environmental knowledge (McDonald and Phillips, 2021). No impacts of this nature are considered to arise from this Petroleum Activities Program. Access to Country is discussed below.

	Access to Country Access to Country, including Sea Country, is necessary for the continuation of other values including caring for Country and the transfer of traditional knowledge. Access is also a value in its own right, as a continuation of traditional Sea Country access and use. Access to areas within the Operational Area may be limited where exclusion zones are established around vessels for safety purposes. However due to the location offshore this is not expected to impact on Access to Country. Access to Country within the EMBA would be limited to temporary exclusion in areas where there are hydrocarbons present, including shoreline accumulation. However relevant cultural authorities will be engaged in the event of a spill that may affect them, as specified in Appendix I. ***Cultural Safety*** Cultural Safety refers to respecting local Lore and culturally significant areas to protect individuals from cultural harm. There are many cultural implications for those (Aboriginal and non-Aboriginal) who do not follow cultural advice or access Country in culturally inappropriate ways. Cultural safety may include observing gender restricted areas, respecting significant places and restricted areas as well as following the advice from those with cultural authority. Therefore, relevant cultural authorities will be engaged in the event of a spill that may affect them, as specified in Appendix I. ***Kinship systems and totemic species*** Individuals may have kinship to specific species (Smyth 2008, Juluwarlu 2004) and/or a responsibility to care for species (Muller 2008). These relationships are understood to impose obligations on Traditional Custodians. It is understood that these obligations do not impose restrictions on other people generally, but it is considered that impacts to species at a population level may inhibit Traditional Custodians with kinship relationships' ability to perform their obligations where this results in reduced or displaced populations. It is therefore considered that the management of totemic or kinship species applies at the species/population level and not to individual plants and animals. As such, impacts to individual marine fauna is not expected to impact on the totemic or kinship cultural connection. Totemic species identified during consultation include whales, fish, stingrays and octopuses. In the highly unlikely event of a hydrocarbon spill relevant cultural authorities will be engaged in the event of a spill that may affect them, as specified in Appendix I. ***Resource collection*** A suite of marine species have been identified through consultation and literature as important resources, particularly as food sources. For example, Sea Country resources of noted relevance to Thalanyji people which may be present in the vicinity of the Montebello Islands include dugongs, majun (marine turtles), turtle eggs, fish and shellfish. Other resource species include marine mammals, fish, molluscs including bivalves, gastropods and cephalopods and seabirds, sea urchins and mangrove seeds. In addition to their immediate value as sustenance, the gathering and preparation of these resources are informed by cultural knowledge, and an inability to use these resources may result in a loss of ability to transfer that knowledge to future generations. Direct impact to communities using these resources will inherently occur when the resource disappears, is displaced or suffers a reduction in population. Therefore, these communities may be impacted where there is an impact at the species/population level. As assessed Section 6.7, impacts from planned activities on the marine environment, including resources important to First Nations people, is expected to be limited to negligible or slight and therefore impacts that result in population effects (e.g., population decline, changes in migration routes, etc) are not expected. Impacts to potential resources within the EMBA, in the highly unlikely event of hydrocarbon spill, are described and risk assessed in Section 6.8 and are not expected to result in species / population level impacts. There may be potential impacts to resource collection along the coastlines where there is shoreline accumulation of hydrocarbons. Given hydrocarbon characteristic and rapid weathering an unplanned release is not expected to have a substantial adverse impact resulting in population level changes. Therefore, impacts to resource collection would be limited to temporary exclusion in areas where there are hydrocarbons present, including shoreline accumulation. Further relevant cultural authorities will be engaged in the event of a spill that may affect them, as specified in Appendix I. **Marine Ecosystems and Species** ***Marine mammals (whale, dolphins, dugongs)*** There are increase ceremonies / rituals for species of animals and plants important to First Nations, to enhance or maintain populations. Thalu are places where these increase ceremonies are performed. All mentions of active ceremonial sites in the reviewed literature were confined to

	onshore locations, though the values may extend offshore where, for example, the thalu relates to marine species populations. As thalu ceremonies are performed to maintain and increase populations of marine species, it is inferred that management applies at the species/population level and not to individuals. Reviewed literature (Deloitte 2020) also includes information that is marked as information that cannot be copied, reproduced or used without consent. The values described in the literature are environmental in nature, apply to marine mammal behaviours at a population level and are managed through existing environmental controls in Sections 6.7, 6.8 and 6.9. Related intangible cultural heritage may include the transmission of cultural knowledge about whales and whale behaviour, including birthing areas, whale communication and migratory patterns. Such cultural knowledge may be associated with various cultural functions and activities that support the social and economic life of a community (Fijn 2021). Whale symbology expressed through stories, music, and dance can reflect a group's connections with the sea, as well as marine fauna, which then comprise a group's cultural values (Ardler 2021; Bursill et al. 2007; Cressey 1998). Whales also speak to a broader connection that exists between First Nation people and their surrounding environment. Beyond mythology and symbolism, whales can be connected with various economic and social functions associated with everyday life. Cultural knowledge of whales, whale migration, behaviour and the related marine environment may all be important in ensuring the continuation of these socio-economic functions and other related activities that remain valuable to First Nations people (Fijn 2021). No impacts to communities' ability to perform or transmit stories, music or dance are anticipated from the Petroleum Activities Program. Where timing or performance is linked to sighting or engaging with these species, impacts may occur where numbers or migration behaviours are impacted at a population level. First Nations groups have expressed interest about whale migratory routes and studies. Inter-generational transmission of cultural knowledge (including songlines) relating to marine mammals may be impacted where changes to population or behaviour at a population level results in reduced sightings (e.g. through population decline, changes to migration routes or changes to migration seasonality). This transfer of knowledge may be integral to managing a group's intangible cultural heritage (UNESCO 2003). As described in the relevant environmental impact and risk assessments in Sections 6.7, 6.8 and 6.9, respectively, potential impacts to cetaceans from planned activities are limited to behavioural impact, which may include temporary and localised deviations from migratory pathways for cetaceans. However, no permanent impacts preventing cetaceans from entering or occupying the areas have been identified. These impacts and risks are not considered to be ecologically significant at a population level, and hence are not expected to impact the value of marine mammals, including the transmission of cultural knowledge. As such, cultural values and intangible cultural heritage associated with these species are expected to be maintained. Marine reptiles (turtles, sea snakes, crocodiles) Turtles and crocodiles have been identified through consultation and existing literature as an important resource, particularly as food sources. Direct impact to communities using these resources will inherently occur when the resource disappears, is displaced or suffers a reduction in population. Therefore, these species (as resources) will be impacted where there is an impact at the species/population level. Intangible cultural heritage may also include the transmission of cultural knowledge about marine reptiles, such as nesting areas, hunting areas and migratory patterns. Cultural knowledge may also be conveyed through stories, such as the turtle being trapped in the sea as a result of its greed for berries as recounted by Capewell (2020). Such cultural knowledge may be associated with various cultural functions and activities that support the social and economic life of a community (Fijn 2021). First Nations groups have expressed an interest regarding turtle monitoring programs and migration patterns. Activities that impact turtle / crocodile populations and their marine environment may have an indirect impact on some Aboriginal communities as this can limit access to cultural sites or deplete hunting areas that would threaten local food security (Delisle et al. 2018:251). Inter-generational transmission of cultural knowledge (including songlines) relating to marine reptiles may be impacted where changes to population or behaviour results in reduced sightings (e.g. through population decline, changes to migration routes or changes to migration seasonality). This transfer of knowledge may be integral to managing a group's intangible cultural heritage (UNESCO 2003). As described in the relevant environmental impact and risk assessments in Sections 6.7, 6.8 and 6.9, potential impacts to marine reptiles from planned activities are likely to be restricted to temporary behavioural changes, which are not considered to be ecologically significant at a population level, and hence not expected to impact the value of marine reptiles, including the

	transmission of cultural knowledge or use as a resource. As such, cultural values and intangible cultural heritage associated with these species are expected to be maintained. ***Fish and Cephalopods*** Fish and squid have been identified through consultation and existing literature as an important resource, particularly as food sources. Direct impact to communities using these resources will inherently occur when the resource disappears, is displaced or suffers a reduction in population. Therefore these species (as resources) will be impacted where there is an impact at the species/population level. Through consultation, fish were identified as important agents in the management of the broader ecosystem. It may be assumed that inter-generational transmission of cultural knowledge relating to fish may be impacted where changes to population or behaviour results in reduced sightings (e.g. through population decline). In additional MIAC (2019) identified whale sharks as a culturally important species associated with stories which describe them as guardians of the sea. This transfer of knowledge may be integral to managing a group's intangible cultural heritage (UNESCO 2003). Intangible cultural heritage associated with fish and whale sharks, including inter-generational knowledge regarding fishing techniques and migratory patterns, can be managed by reducing impacts to fish in nearshore marine environments to which this cultural knowledge is intrinsically connected. The octopus is an important totem to Ngarla People and features in the creation story of Solitary Island. There are increase ceremonies / rituals for species of squid and octopus to enhance or maintain populations. Thalu are places where these increase ceremonies are performed. All mentions of active ceremonial sites in the reviewed literature were confined to onshore locations, though the values may extend offshore where, for example, the thalu relates to marine species populations. As thalu ceremonies are preformed to maintain and increase populations of marine species, it is inferred that management applies at the species/population level and not to individuals. As described in the relevant environmental impact and risk assessments in Sections 6.7, 6.8 and 6.9, respectively, the potential impacts from planned activities on fish[137] are considered to be localised and with slight, short-term (<1-year) impact potential on species (or lower), but not affecting ecosystem function, physical or biological attributes. Impact potential is not considered to be ecologically significant at a population level. As such, cultural values and intangible cultural heritage associated with these species are expected to be maintained. ***Seabirds*** Seabirds, specifically shags, have been identified through literature as a culturally significant species (Malgana Land and Sea Management et al. 2021), as well as a resource (seabird eggs; Smyth 2007). Direct impact to communities using these resources will inherently occur when the resource disappears, is displaced or suffers a reduction in population. Therefore, these species (as resources) will be impacted where there is an impact at the species/population level. Intangible cultural heritage may also include the transmission of cultural knowledge about seabirds, such as nesting areas, hunting areas and migratory patterns. Such cultural knowledge may be associated with various cultural functions and activities that support the social and economic life of a community (Fijn 2021) Inter-generational transmission of cultural knowledge relating to seabirds may be impacted where changes to population or behaviour results in reduced sightings (e.g. through population decline, changes to migration routes or changes to migration seasonality). This transfer of knowledge may be integral to managing a group's intangible cultural heritage (UNESCO 2003). As described in the relevant environmental impact assessments in Section 6.7, the potential impacts from the Petroleum Activities Program on seabirds is limited to slight. The potential for temporary behavioural disturbance localised around vessels from light is not expected to result in a substantial adverse effect on species' population, and light emissions will not seriously disrupt the lifecycle of an ecologically significant proportion any migratory bird species. In terms of risk, as described in Section 6.8 and 6.9 a change in marine fauna behaviour or injury/mortality to seabirds and migratory shorebirds may occur due to a change in water or sediment quality following an unplanned hydrocarbon release. Given hydrocarbon characteristics, expected rapid weathering to below impact thresholds, and the mobile transient nature of individuals, unplanned hydrocarbon releases are not expected to substantially modify important habitat for migratory species. As such,

[137] Squid and octopus are considered to be impacted through similar impact pathways as fish, and hence the conclusion represented here are considered appropriate for cephalopods.

	cultural values and intangible cultural heritage associated with these species are expected to be maintained. ***Benthic habitats (coral, seagrass)*** Through consultation, First Nations groups identified benthic habitats as valuable for their ecological values, including corals attracting fish and seagrass providing shelters for fauna, as well as an important habitat for dugongs. There is no overlap between the Operational Area and coral / seagrass habitats as water depth is more than 170 m, and no planned impacts to coral / seagrass habitats from the Petroleum Activities Program. In terms of risk, as described in Section 6.8 and 6.9, a change in habitat may occur following an unplanned hydrocarbon release. Given hydrocarbon characteristics, rapid weathering, short-term exposure, as well as the response strategies planned to be deployed, an unplanned release may result in localised impacts coral and seagrass habitats. As such, cultural values and intangible cultural heritage associated with benthic habitats are expected to be maintained. ***Shoreline Habitats (mangroves / salt marshes)*** Through consultation, First Nations groups identified shoreline habitats as valuable for their ecological values, including mangroves for providing shelter to marine invertebrates, which are identified resources, and potential nursery for turtles. Literature also notes that mangroves are also valued for the flora and fauna they are associated with and support (Commonwealth of Australia 2002) and Smyth (2007) reports that mangrove seeds are used as a resource by Ngarda-Ngarli. There is no overlap between the Operational Area and mangrove / salt marsh habitat, and no planned impacts to mangroves from the Petroleum Activities Program. In terms of risk, as described in Section 6.8 and 6.9, a change in habitat may occur due to a change in water or sediment quality following an unplanned hydrocarbon release. Given hydrocarbon characteristics, rapid weathering, as well as the response strategies planned to be deployed an unplanned release may result in localised impacts coral and seagrass habitats. As such, cultural values and intangible cultural heritage associated with shoreline habitats are expected to be maintained. ***Marine Park / coastal reserves*** A number of marine parks (e.g. Barrow Island Marine Park, Montebello Islands Marine Park, Ningaloo Marine Park) are jointly managed with First Nation groups. The groups are responsible for sharing management decisions and also for sharing in the overall responsibility of making sure the marine park fulfils its purpose. There is no overlap between the Operational Area and any marine parks. In terms of risk, as described in Section 6.8 and 6.9, shoreline accumulation may occur in some of these marine parks. The relevant cultural authorities will be engaged in the event of a spill that may affect them, as specified in Appendix I. ***Nearshore islands*** Nearshore islands (including Rosemary Island and Solitary Island) have been raised in consultation as of interest, for cultural values and for their ecological benefit. There is no overlap between the Operational Area and any islands. ***Solitary Island is outside the EMBA.*** In terms of risk, as described in Section 6.8 and 6.9, shoreline accumulation may occur on some islands. The relevant cultural authorities will be engaged in the event of a spill that may affect them, as specified in Appendix I. ***Murujuga*** Cultural features and heritage values associated with Murujuga petroglyphs are outlined in **Section 4.9.5** and consideration of potential for indirect impact from atmospheric emissions associated with onshore processing of Pluto gas presented in **Section** 6.7.11 **Conclusion** The impact and risk assessment for cultural features and heritage values has determined that the planned activities are unlikely to result in an impact greater than negligible (F) and unplanned activities are assessed to have a residual risk rating of High (or lower).

Demonstration of ALARP				
As marine ecosystems may hold both cultural and environmental value (see Section 4.9.1), with cultural and environmental values intrinsically linked, in addition to the specific controls for cultural features and heritage values, the controls and performance standards in section 6.7 and 6.8 will reduce impacts to cultural features and heritage values, including marine species and habitats.				
Control considered	***Feasibility (F) & Cost/ Sacrifice (Cs)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Adopted***
Apply a 'living heritage[138]' management approach. Woodside seeks advice and incorporates Traditional Custodian cultural knowledges across our activities. Cultural safety considerations are factored for our workforce and the Traditional Custodian community.	F: Yes CS: Minimal	Implementation of the 'living heritage' approach pays acknowledgement and respect to Traditional Custodian communities. It supports the transfer of cultural knowledges and is an effective strategy to manage intangible cultural values.	Benefits outweigh cost/ sacrifice.	Yes C 29.1
Project inductions to all relevant marine crew, prior to the individual commencing the activity, will include information on cultural features and heritage values, including tangible and intangible cultural heritage.	F: Yes CS: Minimal	Ensures workforce is suitably aware of cultural features and heritage values in the area they are operating.	Benefits outweigh cost/ sacrifice.	Yes C 29.2
Should it be identified that relevant cultural authorities may be affected in the unlikely event of a spill, Woodside will engage with those parties as appropriate and in alignment with the FSP.	F: Yes CS: Minimal	Engaging with relevant cultural authorities that may be impacted by a spill will allow the Traditional Custodians to identify areas of concern.	Benefits outweigh cost/sacrifice	Yes Adopted
ALARP Statement				
On the basis of the impact and risk assessment outcomes and use of the relevant tools appropriate to the decision type (i.e. Decision Type A, Section 2.6.1), Woodside considers the adopted controls appropriate to manage the potential impacts and risks to cultural features and heritage values. As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts are considered ALARP.				
Acceptability Statement				
The impact and risk assessment has determined that, given the adopted controls, planned activities are unlikely to result in an impact greater than negligible and unplanned activities are assessed to have a residual risk rating of moderate (or lower).				

[138] Living heritage supports community and individual identity. Intangible cultural heritage is 'living heritage' that is inherited from ancestors and passed on to their descendants. It is comprised of many influences, including oral traditions, art, social practices, rituals and ceremonies, cultural knowledge and practices. It is transmitted from generation to generation, and evolves in response to the environment. Woodside applies a 'living heritage' approach to its cultural heritage management. This includes ensuring that Traditional Custodians are given voice to identify interests, transmit information and express concerns. Woodside works with Traditional Custodians to support and follow appropriate cultural protocols, including calling to Country, conducting smoking ceremonies (in areas where this custom is appropriate) and undertaking cultural awareness. Woodside will collaborate and provide relevant information it holds to groups such as Heritage Management Committees where they are established.

The Petroleum Activities Program and the EMBA are not expected to have a significant impact (e.g. changes in population levels) on MNES including marine fauna with a First Nations connection with, or traditional use in nearshore areas as defined in Section 4.8. While the EMBA may overlap the Ancient Landscape no impacts are predicted as hydrocarbons are expected to remain within the upper water column.

Woodside has engaged with Traditional Custodians adjacent to the EMBA to understand the cultural features and heritage values that may occur and potential impacts from the activity. In the event of an unplanned loss of hydrocarbons Woodside has committed to engaging with relevant cultural authorities that may be affected (Appendix I).

Further opportunities to reduce the impacts have been investigated above. The potential impacts and risks are considered acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the impacts and risks to cultural features and heritage values to a level that is acceptable, if ALARP.

Key Environmental Performance Outcomes, Standards and Measurement Criteria related to Cultural Features and Heritage Values[139]

Environmental Performance Outcomes	***Controls***	***Environmental Performance Standards***	***Measurement Criteria***
EPO 29 No impact to cultural features and heritage values greater than a consequence level of F from the Petroleum Activities Program	C 29.1 Apply a 'living heritage' management approach. Woodside seeks advice and incorporates Traditional Custodian cultural knowledge across our activities. Cultural safety considerations are factored for our workforce and the Traditional Custodian community.	PS 29.2.1 Woodside will continue to give voice to Traditional Custodians to identify interests, transmit information and express concern	MC 29.2.1 Records demonstrate Change Management and Management of Knowledge processes have been followed where new controls or management measures identified
		PS 29.1.2 Woodside will assess and where deemed practicable will implement appropriate cultural protocols where requested by Traditional Custodians	MC 29.1.2 Records demonstrate Woodside implemented cultural protocols as requested
	C 29.2 Project inductions to all relevant marine crew, prior to the individual commencing the activity, will include information on cultural features and heritage values, including tangible and intangible cultural heritage.	C 29.2.1 All relevant marine crew have completed Project inductions that include information on cultural values, including tangible and intangible cultural heritage for awareness	MC 29.2.1 Records demonstrate all relevant marine crew have completed inductions that include cultural material

[139] As marine ecosystems may hold both cultural and environmental value (see Section 4.9.1), with cultural and environmental values intrinsically linked, in addition to the specific controls for cultural features and heritage values, the controls and performance standards in section 6.6 and 6.7 will reduce impacts to cultural features and heritage values including marine species and habitats.

EPOs, EPSs and MC for the Pluto Operations			
Environmental Performance Outcomes	***Controls***	***Environmental Performance Standards***	***Measurement Criteria***
EPO 30 No adverse impact to Underwater Cultural Heritage without a permit.	C 30.1 Review of existing survey data by a suitably qualified maritime archaeologist to inform areas for laydown and/or installation of equipment to avoid or where not possible, minimise physical impacts to cultural heritage areas or prospective areas, where water depths <130m.	PS 30.1 Existing survey data reviewed by a suitably qualified maritime archaeologist to inform areas for laydown and/or installation of equipment.	MC 30.1.1 Records demonstrate review of existing survey data completed prior to laydown and/or installation of equipment.
	C 30.2 Unexpected finds of potential Underwater Cultural Heritage sites/ features, including First Nations UCH are managed in accordance with an Unexpected Finds Procedure set out in b.	PS 30.2 In the event that an Underwater Cultural Heritage site or feature is identified, implement an Unexpected Finds Procedure set out in Section 7.6.	PS 30.2.1 In the event that an Underwater Cultural Heritage site or feature is identified, implement an Unexpected Finds Procedure set out in Section 7.6.
	C 30.3 Report any potential UCH finds to relevant stakeholders and authorities in accordance with the Unexpected Finds Procedure, Underwater Cultural Heritage Act 2018 and the ATSIHP Act.	PS 30.3 Report any finds of potential UCH in accordance with the Unexpected Finds Procedure (b) including to the Australasian Underwater Cultural Heritage Database.	MC 30.3.1 Records of potential UCH finds reported to relevant authorities and stakeholders.
	C 30.4 Relevant vessel crew and ROV operators will be advised in an induction of the potential to encounter UCH, and of their requirement to follow the Unexpected Finds Procedure.	PS 30.4 Relevant vessel crew (including ROV operators) are made aware of the requirements of the Unexpected Finds Procedure through an induction.	MC 30.4.1 Records demonstrate vessel crew are made aware of potential to encounter UCH.

7. IMPLEMENTATION STRATEGY

7.1 Overview

Regulation 22 of the Environment Regulations requires an EP to contain an implementation strategy for the activity. The implementation strategy for the Petroleum Activities Program confirms fit for purpose systems, practices and procedures are in place to direct, review and manage the activities so that environmental risks and impacts are continually being reduced to ALARP and are acceptable, and that EPOs and EPSs outlined in this EP are achieved.

Woodside, as Operator, is responsible for ensuring that the Petroleum Activities Program is managed in accordance with this implementation strategy and the WMS (see Section 1.8).

7.2 Systems, Practice and Procedures

All operational activities are planned and performed in accordance with relevant legislation and internal environment standards and procedures identified in this EP (Section 6).

Processes are implemented to verify controls to manage environmental impacts and risks to:

- a level that is ALARP and acceptable
- meet EPOs
- comply with EPSs defined in this EP.

The systems, practices and procedures that are implemented are listed in the EPSs contained in this EP. Document names and reference numbers may be subject to change during the statutory duration of this EP and is managed through a Change Register and update process. Further information regarding some of the key systems, practices and procedures relevant to implementation of this EP is provided below.

7.2.1 WMS Operate Processes

Under the WMS Operate Activity (see Section 1.8 for an overview of the WMS), there are four overarching processes; those directly relevant to the implementation of this EP and environmental management during the Petroleum Activities Program are described below (Operate Plant Process and the Maintain Assets Process).

7.2.2 Operate Plant

The objective of the Operate Plant Process is for production to be carried out in a safe, efficient, reliable and economic manner, and that all required process variables are within allowable limits. This is so that the potential for unplanned (accident/incident) events that may impact the environment are minimised.

The Operate Plant Process develops key activities to support ongoing production activities so that the facility is operated within the Basis of Design. The process also identifies required production routines, routine execution, recording of data gathered and formulation of remedial activities. The Operate Plant Process includes the Integrated Safe System of Work (ISSoW) system (described below).

In addition, the Operating Practice MSPS (M02) is in place to assure operating practices are in place, such that:

- integrity critical operating procedures are available, accurate, up to date, understood and used.
- safe operating and technical integrity limits are defined, understood and the process is managed within these limits.

7.2.3 Integrated Safe System of Work

The ISSoW Procedure outlines the key activities required to achieve effective management of permit-controlled work on the facility. The ISSoW process is a management system for all work and is a key element in ensuring the safety of personnel, protection of the environment and technical integrity of the facility.

Work within the facility 500 m PSZ and operations within the vicinity of the connected flowlines is controlled in accordance with ISSoW.

The ISSoW system takes a risk-based approach to activities, thus tasks with higher levels of risk are subjected to greater scrutiny and control. The ISSoW system also allows for low risk routine tasks to be carried out with adequate but minimal administration. The prime objective of ISSoW is to ensure work other than normal operations is properly planned, risk assessed, controlled, coordinated and safely executed. It provides a methodical approach to identifying hazards, assessing risks, and creating and supporting permits to work and associated certificates.

In keeping with ALARP principles, this system is critical to ensuring the appropriate level of hazard identification and risk assessment is carried out for activities performed on the facility.

In addition, the Safe Work Control MSPS (M04) is in place to assure effective safe work control, permit to work and task risk management arrangements are in place and followed to control the risks arising from work activities.

7.2.4 Maintain Assets

The Maintain Assets Process aims to improve the reliability and availability of plant and equipment (which includes that required for safe operation) through well managed and planned execution of maintenance that promotes a proactive maintenance culture.

Maintenance, inspection and testing systems and procedures are in place to safeguard the integrity of the facility. The maintenance strategy for the facility is based on optimising safety, minimising environmental impact and maximising production. Maintenance practices used to establish well managed maintenances strategies, planned execution and improvement are described in the Maintenance of Assets Procedure.

A risk-based approach is used as the basis for establishing and prioritising inspection, maintenance and testing requirements at the facility. Equipment is assessed to establish equipment criticality with respect to the consequences and likelihood of equipment failure. This informs determination of appropriate maintenance and inspection activities. Maintenance activities are allocated risk rankings according to the criticality of equipment, so that high risk maintenance work orders are completed as a priority.

A computerised maintenance management system (CMMS) provides a database called SAP-PM that contains facility registers, equipment details, spare parts data and associated planned maintenance tasks. This system is used to plan, monitor and record maintenance activities. The system provides a variety of reports that enable monitoring and assessment of maintenance activities.

SCE Technical Performance Standards identify SCEs and associated assurance activities. These activities are identified in the CMMS and given the appropriate priority (Technical Integrity status). Refer to Sections 2.7.5 and 7.4 for more detail on SCE Technical Performance Standards and how they differ from EPSs required by the Environment Regulations. SCE Technical Performance Standards form a key component in the processes and systems implemented by Woodside to maintain safety and environment critical plant and equipment.

In addition, the Maintenance and Inspection MSPS (M03) is in place to assure that the necessary inspection and maintenance requirements are identified and carried out to maintain the integrity of SCEs and SCCs.

7.2.5 Process Safety Management

So that Woodside protects the safety, security and health of its employees, contractors, the environment and assets, Woodside has adopted the Energy Institute's Process Safety Management (PSM) framework within its Process Safety Management Procedure which sets out a disciplined framework for managing the integrity of systems and processes that handle hazardous substances over the production (and exploration) lifecycle. It deals with the prevention and control of events that have potential to release hazardous materials and energy.

PSM consists of four main focus areas. Each focus area contains a number of PSM requirements that define key aspects required so that PSM is integrated through the organisation. There are twenty PSM requirements. The focus areas and requirements are shown in Figure 7-1.

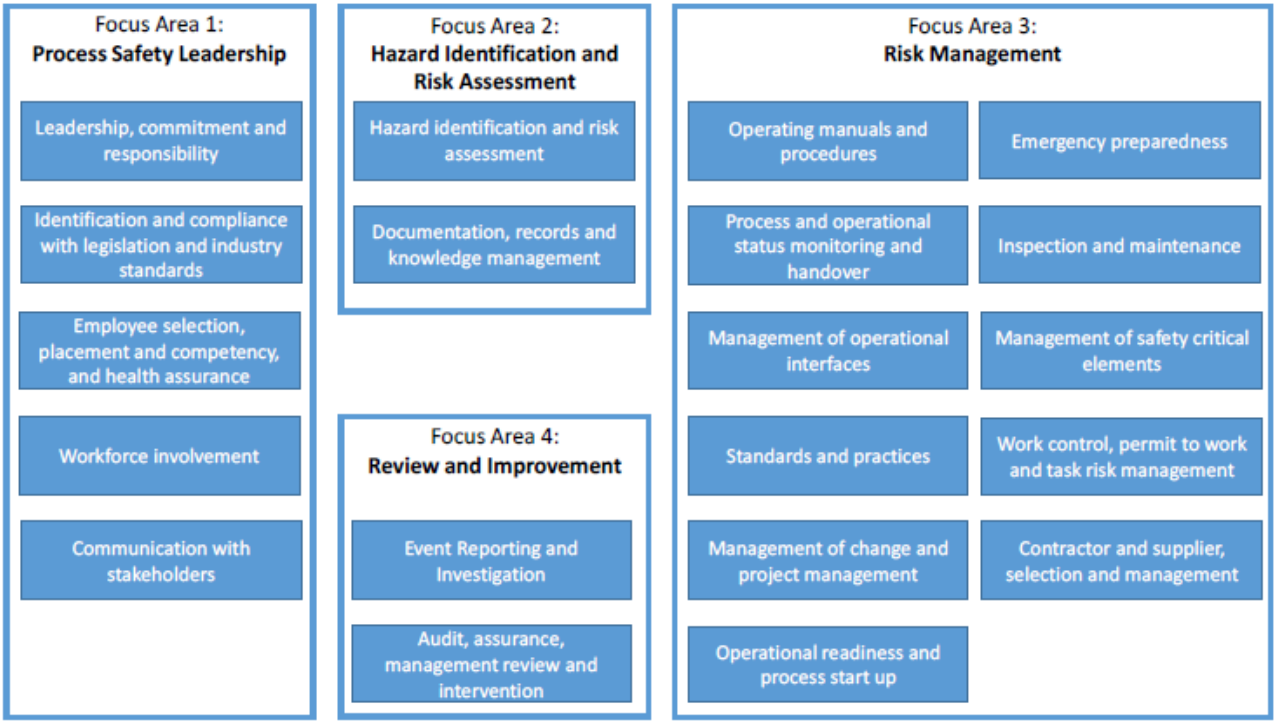

Figure 7-1: Process safety management focus area

7.2.6 Woodside Safety Culture Framework

Woodside's 'Our Safety Culture' framework (shown in Figure 7-2) promotes a strong HSE culture and is a key enabler for effective process safety management. This framework outlines the expected behaviours for everyone including supervisors and managers/executives, and is openly discussed as part of inductions, training and development.

Figure 7-2: Woodside 'Our Safety Culture' framework

7.2.7 Woodside Invasive Marine Species Risk Assessment Process

7.2.7.1 Objective and scope

To minimise the risk of introducing IMS as a result of the Petroleum Activities Program, all applicable vessels and immersible equipment will be subject to Woodside's IMS risk assessment process (unless exempt as outlined below).

The objective of the risk assessment process is to identify the level of threat a contracted vessel, or immersible equipment poses if no additional risk reduction management measures are implemented. This allows Woodside (and its contractors) to apply management options that are commensurate to the identified level of risk.

In context of the activities specified in Section 3, the IMS risk assessment process does not apply to the following:

- Vessels or immersible equipment that do not plan to enter the IMS Management Area (IMSMA)[140] or PAAs defined in environmental approvals.
- 'New build' vessels launched less than 14 days prior to mobilisation.
- Vessels or immersible equipment which have been inspected by a suitably qualified IMS inspector who has classified the vessels or immersible equipment as acceptably low risk no more than 14 days prior to mobilisation.
- Locally sourced vessels or immersible equipment from within the Pilbara locally sourced zone[141] . Vessels, or immersible equipment are defined as locally sourced when the same

[140] MSMA is based on current legal framework and includes all nearshore waters around Australia, extending from the lowest astronomical tide (LAT) mark to 12 nm from land (including Australian territorial islands). The IMSMA also includes all waters within 12 nm from the 50 metre depth contour outside of the 12 nm boundary (i.e. Submerged reefs and atolls).

[141] The Pilbara Zone includes Port, nearshore and offshore movements between Exmouth and Port Headland (excluding high environmental value areas, World Heritage Areas, Commonwealth Marine Reserve Sanctuary Zones and State Marine Management Areas and Marine Parks).

supply facilities/port have been used since their last IMS inspection, full hull clean in dry dock or application of antifouling coating (AFC[142]).

7.2.8 Risk assessment process

Woodside's IMS risk assessment process was developed with regard to the national biofouling management guidelines for the petroleum production and exploration industry and guidelines for the control and management of a ships' biofouling to minimise the transfer of invasive aquatic species (IMO Guidelines, 2011).

In order to effectively evaluate the potential for vessels and immersible equipment to introduce IMS, a risk assessment process has been developed to score and evaluate the risk posed by each Project vessel, or immersible equipment planning to undertake activities within the IMSMA / PAA. The risk assessment process considers a range of factors, as listed in Table 7-1 and Table 7-2.

The IMS risk assessments will be undertaken by a trained environment adviser who has completed relevant Woodside IMS training or by a qualified and experienced IMS inspector. A QA/QC process is implemented for all Woodside conducted IMS risk assessments where a secondary trained environment adviser verifies the assessment to minimise the risk of misapplication and errors within the risk assessment process.

Table 7-1: Key factors considered as a part of the risk assessment process for vessels

Factors	Details
Vessel type	The risk of IMS infection varies depending on the type of vessel undertaking the activity. A higher risk rating is applied for more complex, slow-moving vessels (e.g., dredges) in comparison to simple vessels (e.g., crew transfer vessel).
Recent IMS inspection and cleaning history, including for internal niches	In the case of biofouling on external hull niches, different risk ratings are applied dependant on whether out-of-water or in-water IMS inspections by qualified IMS inspectors and cleaning (if required) have been undertaken prior to contract commencement. If an IMS inspection (and clean if required) has not been undertaken in the past six months (from the time of contract commencement), the highest risk factor is applied. The risk factor then lessens for vessels as the time between inspection and mobilisation reduces.
Out-of-water period before mobilisation	A risk reduction factor can be applied for vessels that are hauled out and then mobilised as deck cargo or by road during mobilisation, therefore becoming air dried over an extended period. Risk reduction factor increases with exposure time out of water.
Age and suitability of AFC at mobilisation date	AFC manufacturers provide a range of coatings, each designed to avoid premature coating failure if it is correctly applied and matched to the vessel's normal speeds and activity profile (i.e., proportion of time spent stationary or below three knots), and its main operational region (i.e., tropical, sub-tropical temperate). If the AFC type is deemed to be unknown, unsuited or absent, the highest risk value is applied. If the AFC type is suitable the risk factor applied reduces with age since application.
Internal treatment systems	A risk reduction factor applied if the vessel has an internal biological fouling control system in place at the time of assessment, or evidence of manual dosing.
Vessel origin and proposed area of operation	Differing risk ratings are assigned in relation to the climatic relationship between the vessel's origin and the proposed climatic region of the proposed area of operation. Highest risk rating is applied to similar climatic regions.
Number of stationary/slow speed periods >7 days	A risk factor is calculated based on the number of 7 day periods that the vessel has operated at stationary or at low speed (less than three knots) in port or coastal waters which is any waters less than 50 metres deep outside 12 nautical miles from land or any

[142] Vessels and immersible equipment can still be classified as locally sourced even if the AFC application occurred in a different port provided the amount of time between AFC application and departure to the locally sourced area (i.e. period of time in waters <12nm/50m water depth) did not exceed consecutive 7 days or the period of time the vessel or immersible equipment has spent within the locally sourced zone exceeds 1 year (i.e. the risk of introducing a species from a different location has already passed).

Factors	Details
	waters within 12 nautical miles of land. The greater the number of periods the higher the risk factor applied.
Region of stationary or slow periods	A further multiplier is applied depending on the location of the stationary/slow speed periods. The highest risk rating applied if the stationary or slow speed periods occurred within ports or coastal waters of the same climatic region,
Type of activity – contact with seafloor.	The potential for the introduction of IMS varies on the planned vessel activity taking place. Those activities that come in contact with sediments and thus have the potential to accumulate and harbour IMS in areas such as hoppers (dredges) and spud cans (drilling rigs) are considered to have a greater risk of infection.

Table 7-2: Key factors considered as a part of the risk assessment process for immersible equipment

Factors	Details
Region of deployment since last thorough clean, particularly coastal locations	Climatic region of use since last overhaul, thorough cleaning or prolonged period out of water (>28 day). Highest risk rating is applied to similar climatic regions. Activities occurring in nearshore areas (less than 50 meters deep and/or within 12 nautical miles from land) are given the highest risk rating.
Duration of deployments	Maximum duration of deployment (maximum time in water) since last overhaul or thorough cleaning. The longer the period of immersion the higher the risk rating applied.
Duration of time out of water since last deployment	A further risk reduction factor can be applied for immersible equipment that has been out of the water for an extended period.
Transport conditions during mobilisation	If the equipment is stored in damp conditions then a high risk factor is applied, while if equipment is stored in dry and well ventilated (low humidity) conditions then a low risk factor is applied.
Post-retrieval maintenance regime.	A risk reduction factor is applied if the equipment/item of interest is routinely washed, cleaned, checked and/or dissembled between project sites. While a higher risk rating is applied where no routine cleaning occurs.

Following implementation of the risk assessment process, vessels and/or immersible equipment are classified as one of three risk categories, as defined below.

‘Low’– Low risk of introducing IMS of concern and hence no additional management required, or management options have been applied to reduce the risk.

‘Uncertain’– Risk of introducing IMS is not apparent and as such the precautionary approach is adopted, and additional management options may be required.

‘High’– High risk of introducing IMS means additional management options are required prior to this vessel mobilising to the PAA.

Following the allocation of a ‘low’ risk rating for a vessel or immersible equipment, the information provided by the vessel operator for the purposes of risk assessment must be confirmed prior to mobilisation. For vessels or equipment classified as posing an ‘uncertain’ or ‘high’ theoretical risk, a range of management options are presented to reduce this theoretical risk to acceptable levels and achieve a low risk status. These management options have been developed with the intention of reducing IMS risk to levels that are as low as reasonably practicable (i.e., ALARP). It is a flexible approach that allows for a range of management actions to be tailored for a specific vessel movement. These will be assessed on a case-by-case basis and may include, but not limited to, the following:

- Inspection (desktop, in-water or dry dock) by a suitably qualified and experienced IMS inspector to verify risk status. Where practicable, the inspection shall occur within seven days (but not more than 14 days) prior to final departure to the PAA.

- In-water or dry dock cleaning of the hull and other niche areas. This is typically applied where the risk assessment outcome is High risk driven by the age of the AFC on the vessel and its time spent in similar climatic region ports.
- Treatment of vessels internal seawater systems. This is typically applied in isolation for vessels with AFC applied to their hull within the last twelve months and where subsequent assessment through the process achieves a low risk rating.
- Limiting the duration that the vessel spends within the IMSMA to a maximum of 48 hours (cumulative entries). This is applicable for Uncertain risk vessels only.
- Reject the vessel.
- Project vessels and immersible equipment are required to be a low risk of introducing IMS prior to entering the PAA.

Risk Management

Risk management processes and practices are applied on an ongoing basis to design, production and maintenance activities at the Pluto facility to manage risks to personnel, assets and the environment.

Potential environmental consequences and impacts from the Pluto facility are risk assessed and controlled in accordance with the Woodside risk management processes described in Section 2 of this EP (Environmental Risk Management Methodology).

The results of the Pluto facility ENVID are described in Section 6 and in the facility Environmental Impacts and Risk Register. This register, in conjunction with the EP, provides a demonstration that environmental risks have been identified, and that appropriate controls are in place to manage those risks to a level that is acceptable and ALARP throughout the life of the facility.

A number of other risk management tools and techniques are used by the Pluto facility to manage environmental and other risks on a routine basis during operational, maintenance and inspection tasks. Examples include:

- the processes outlined in Section 2.2
- risk management tools including: ISSoW tools, e.g. Hazard Identification and Risk Assessments, Level 2 Risk Assessments, Operational Risk Assessments, the technical Management of Change (MoC) system (Section 7.3.2), and Step back 5 x 5
- integrity review studies, HAZIDs and Hazard Operability studies.

These tools, risk and integrity management practices are described further in the Pluto Facility Safety Case, WOMP, and the Control of Operational Risk Procedure.

In addition, other risk sub-processes and practices are also applied within Woodside on an ongoing basis to manage different types of risk. A summary of those relevant to the Petroleum Activities Program is provided below. Woodside's risk management processes (refer to Section 2.2.1), along with the supporting risk sub-processes and practices discussed in this section, so that the environmental impacts and risks of the activity continue to be identified and reduced to a level that is ALARP.

7.2.9 Management of Risks – Contracting and Procurement

Suppliers and contractors play a significant role in meeting the resource needs of Woodside's operations, including the facility operations. Effective management of environmental risks in contracts is achieved by setting clear expectations and managing environmental risks throughout the duration of the contract. Environmental risks in contracts are managed under the Contracting and Procurement Procedure supported by the Health, Safety and Environment in Contracting

Guideline. The guideline provides a risk-based approach to contractor selection and management and is aligned with 'HSE Management – Guidelines for Working Together in a Contract Environment' (International Association of Oil and Gas Producers, Report No. 423).

The Engineering Standard: Quality Requirements for Supply of Products and Services defines specific quality requirements for engineering contracts and purchase orders. The specified quality control requirements in the Standard are required to be complied with as applicable to the scope of supply.

7.2.10 Management of Risks – Subsea Activities

Subsea activities are managed in line with the Subsea and Pipelines Integrity Management Procedure which defines the practices and technical requirements that must be applied to deliver and safeguard integrity of the subsea equipment and pipelines during the facility lifecycle. It provides the relationship between the PSM Framework (including management of change) and Subsea and Pipelines Group services processes.

IMMR activities are managed under the Manage IMMR Work Procedure. Risk assessments are conducted as required under this procedure.

These requirements are supported by implementation of the Subsea Construction and Inspection, Maintenance and Repair Environment Screening Questionnaire tool. The screening questionnaire is used to understand the scope of the activity, potential environmental impact and if additional regulatory approvals are required. To achieve this, the questionnaire captures key project information such as seabed disturbance, chemical use and waste. This information is used by an environment focal point to determine if further assessment is required. For projects that have the potential for environmental impact, an assessment is undertaken against this EP and other Woodside environmental requirements. If determined by the Subsea and Pipeline Environment Screening Questionnaire process, an EP MoC review (as per Section 7.3.2) is undertaken to confirm if the level of environmental risk warrants revision and resubmission of an EP.

Key environmental requirements and regulatory commitments are communicated to project teams and incorporated into key project documentation where applicable and required (i.e. not addressed via existing Woodside practices).

7.2.11 Management of Risks – Major Projects

Major projects are required to follow the Appraise and Develop Management Procedure and the Investment Management Framework. This procedure defines the requirements to deliver a commercially valuable production facility or modify to an existing facility. The process workflow requires integration of work from various functions utilising their people and processes, including Environment, for example HSE philosophy and regulatory approval requirements.

These requirements are supported by implementation of the Brownfields Environment Screening Questionnaire tool. The screening tool is used to determine if a project has the potential for environmental impact or requires additional regulatory approvals. For projects that have the potential for environmental impact, an environmental focal point is assigned and the risks and impacts assessed against the facility EP and other Woodside environmental requirements.

Key environmental requirements and regulatory commitments are communicated to project teams and incorporated into key project documentation where applicable and required (i.e. not addressed via existing Woodside practices). Where it is identified that the project scope has the potential to result in modification or change to the facility description provided in the EP, or where potential new environmental risks or impacts or increases in an existing environmental risk or impact are identified, an EP MoC review (as per Section 7.3.2) is undertaken to confirm if the level of environmental risk warrants revision and resubmission of an EP.

7.2.12 Management of Risks – Well Integrity

Wells are managed throughout their lifecycle in line with the Well Lifecycle Management Procedure. This procedure provides the basis for ensuring well integrity in accordance with the Process Safety Management Procedure.

In addition, wells are required to have a regulator accepted WOMP to demonstrate that well integrity risks are managed to ALARP levels. Wells tied back to the facility are managed under a WOMP.

7.2.13 Management of Risks – Marine Services

Woodside's Marine Services Function provides a platform for the conduct of safe and efficient Marine Operations across Woodside through the Marine Services Management. A set of procedures that support vessel assurance and management (including HSE and quality [HSEQ] management) are in place to ensure marine operations are conducted in a safe and efficient manner, and in accordance with regulatory requirements.

Vessel masters are required to request clearance from the facility OIM or delegate prior to entering the 500 m PSZ.

7.2.14 Management of Risks – Emissions and Energy Management

Emissions generation and energy use is managed in line with the GHG Emissions and Energy Management Procedure which defines the minimum mandatory requirements to manage and deliver continuous improvement in energy efficiency and reduction in GHG emissions. The procedure supports the implementation of the Climate Policy and aligns with the requirements of Woodside's Environmental Performance Procedure. It supports the "operate out" component of limiting net emissions as part of Woodside's Climate Policy (Available: page 14 of the Climate Transition Action Plan (Woodside, 2024) available on the Woodside website).

Implementation of the GHG Emissions and Energy Management Procedure assists in meeting external expectations, such as Woodside's 2025 (-15%) and 2030 (-30%) emissions reductions targets and aspiration to be net zero by 2050. It also maintains consistency with the principles of current corporate initiatives, such as the Zero Routine Flaring Initiative for oil assets and the Methane Guiding Principles. These methane reduction commitments aim to improve methane emissions inventorisation, methane materiality assessments, evaluation, reduction implementation and increased transparency through reporting. The Woodside Flare Framework is an optional WMS tool that seeks to improve awareness of flaring-related issues and influence for reduced flaring.

The GHG Emissions and Energy Management Procedure links to the annual review of opportunities to improve energy performance through identification and evaluation as described in the Production Optimisation and Opportunity Management Procedure. It also requires measurement, analysis and communication of energy performance across the Operations Division and consideration of actual or potential impacts to energy efficiency in Woodside decision making, such as management of change, operational decisions, issue resolution options analysis and facility optimisation plans.

The Environmental Performance Procedure requires that assets measure, monitor or estimate direct air and GHG emissions, and designed such that emissions and energy intensities are minimised to ALARP. Further details including performance standards are defined in Section 6.7.10.

7.2.15 Production Optimisation and Opportunity Management

Woodside's Production and Opportunity Management Procedure outlines the process for identification, prioritisation and management of production opportunities that maximise production revenue or reduce emissions intensity across Woodside operated assets. Opportunities are identified throughout the year in various meetings, forums and teams. In addition, formal opportunity identification takes place through annual workshops, which complement the identification of

improvement opportunities. These opportunities are prioritised and managed according to the workflow shown in Figure 7-3.

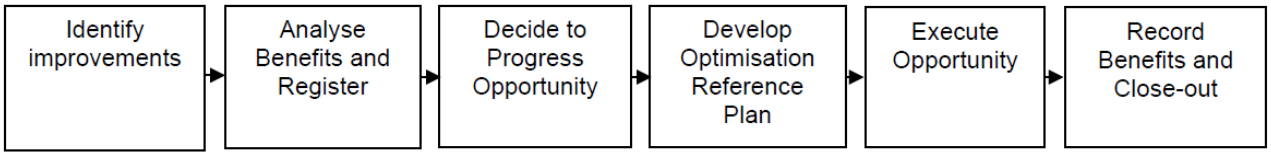

Figure 7-3 Opportunity Management Workflow

Production opportunities are evaluated and progressed, based on value and confidence of return, within the constraints of technical feasibility, cost and other factors. Implemented opportunities are validated and recorded before close out.

7.2.16 Flare Target Setting

In demonstrating the risks and impacts relating to flaring have been reduced to ALARP, flare targets for the facility are set annually. Targets are estimated based on operating experience and forecast activities, e.g. shutdowns. Consideration is also given to the flaring estimates contained within this EP.

The flare target is tracked against flare performance through the year. Where achieving a flare target is in question, an internal flare target deviation is developed, which requires an ALARP justification. A flare target deviation considers the EP flare estimate. If the estimate is likely to be exceeded, an EP MoC assessment (see Section 7.3.2) is undertaken to determine if a revision and resubmission is required.

7.2.17 Management of Risks – Indirect GHG Emissions Management

As stated in the Climate Policy, Woodside's objective is to thrive in this energy transition as a low cost, lower carbon energy provider. To support this policy Woodside undertakes the following measures:

- Set science-based[143] near, mid, and long-term net emissions reduction targets that are consistent with Paris-aligned[144] scenarios, covering equity scope 1 and 2 emissions, both operated and non-operated.[145]
- Develop and operate oil and gas projects in a manner that is consistent with these targets. This includes the deployment of lower-emission technologies (Design Out), supporting efficient operations (Operate Out) and use of robust offsets (Offset) as methods to reduce and offset greenhouse gas emissions.

[143] Woodside is using the draft Prototype IFRS Sustainability Disclosure Standard definition of "science-based" (published 2021) which states "targets are considered 'science-based' if they are in line with what the most recent climate science sets out is necessary to meet the goals of the Paris Agreement—limiting global warming to below 2 degrees Celsius above pre-industrial levels and pursuing efforts to limit warming to 1.5 degrees Celsius." See https://www.ifrs.org/content/dam/ifrs/groups/trwg/trwg-climate-related-disclosures-prototype.pdf.

[144] Woodside is using the draft Prototype IFRS Sustainability Disclosure Standard definition of "Paris-aligned scenarios" (published 2021) which states "scenarios consistent with limiting global warming to below 2 degrees Celsius above pre-industrial levels and pursuing efforts to limit warming to 1.5 degrees Celsius." See https://www.ifrs.org/content/dam/ifrs/groups/trwg/trwg-climate-related-disclosures-prototype.pdf.

[145] Equity emissions means the share of the total emissions arising from an activity that are attributable to Woodside in proportion to Woodside's ownership interest in the activity, irrespective of whether Woodside operates the activity. Operated emissions are the total emissions arising from an activity that Woodside operates, irrespective of Woodside's ownership interest.

- Invest in new energy products and lower carbon services to reduce customers' emissions (part of Woodside's Scope 3 emissions), including but not limited to hydrogen, ammonia and carbon capture, utilisation and storage.
- Publish transparent climate-related disclosures aligned to the recommendations of the Task Force on Climate-related Financial Disclosures (TCFD) or other recognised global reporting standards.
- Align our advocacy to the principles of this Climate Policy.

These measures will be amalgamated into a cohesive program to monitor market developments related to the contribution of hydrocarbons in the energy transition and support suppliers and customers to reduce their GHG emissions. The program will be managed by Woodside's Climate & Sustainability Team and implementation will be in Q1 2024. The progress against each of the measures will be tracked and reported, as part of Woodside's climate-related disclosures.

7.2.17.1 Annual Review

The measures proposed will be Woodside Corporate initiatives targeting indirect emissions which are attributable to production from Woodside operated facilities as a whole. Via the annual review process and consideration of the controls, if they are deemed to be effective at a Corporate implementation level then it will also be deemed that specific impacts and risks at an Asset contribution level (i.e. proportion attributable to Pluto production) is also being managed appropriately.

The review process will also undertake an assessment of the Pluto attributable indirect GHG emissions and consider the EP indirect emission estimates (Table 6-25 in Section 6.7.10). This assessment will include both a review of the total CO_2e estimates and also the methods used to derive the estimates. If the estimate is exceeded, an EP management of change assessment (see Section 7.3.2) is undertaken to determine if a revision and resubmission is required.

7.2.18 Management of Human Factor Related Risks

The term 'human factors' is used to describe the consideration of people as part of complex systems. Woodside defines 'human factors' as follows: 'human factors uses what we know about people, organisation and work design to influence performance'.

As outlined in Section 6.8.10, human factors can contribute to MEEs, or result in failure or degradation of the controls in place to protect against MEEs. The WMS includes a number of procedures designed to manage human factors related risks and prevent incident causation.

7.3 Change Management

Woodside's Change Management Procedure describes Woodside's requirements for change management at Woodside owned or controlled operations/sites.

Change management is used where there is no existing approved business baseline, such as a process, procedure or accepted practice, or where conformance with an approved baseline is not possible or intended; for example, due to equipment fault or failure or a recently discovered issue which will take time to rectify. Change management is also used when the baseline is changed (e.g. the process is modified). It applies to management of temporary, permanent, planned or unplanned change encompassing one or more of the following:

- plant (equipment, plant, technology, facilities, operations or materials)
- projects (budget, schedule)
- people (organisation structure, performance, roles)

- process (WMS content, processes, procedures, standards, legislation, information).

Woodside's change management process hierarchy is depicted in Figure 7-4. The hierarchy has been developed with sub-processes to address the different types of change performed at Woodside.

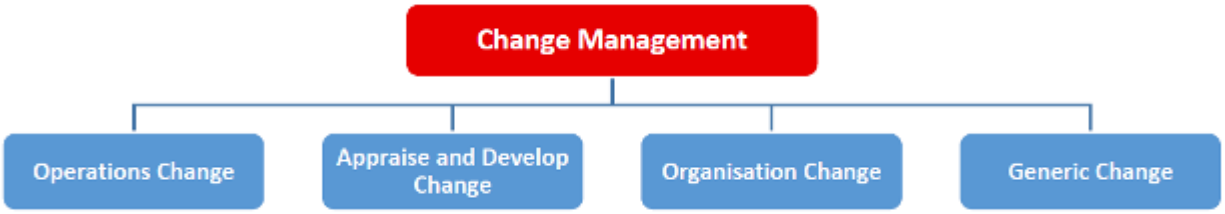

Figure 7-4: Change management hierarchy

To help manage the day-to-day operation of the facility, Woodside has developed a Golden Safety Rules Booklet, which provides a summary of mandatory requirements for safety in the workplace and includes guidance for managing changes that have a Health, Safety, Integrity and/or Environment impact.

7.3.1 Technical Change Management

Technical changes within the Operations Division are managed using the MoC – Assets Procedure. The objective of the procedure is to ensure HSE risks associated with both realised and potential changes, including any failure to meet the facility SCE Technical Performance Standards, are identified, assessed and reduced to ALARP (Section 7.4 provides further information on management of SCE Technical Performance Standards).

Assessed changes must be recommended, agreed and decided upon based on the assessed current level of risk, as defined by Woodside's Technical Decision Authority matrices.

The MoC requirements contained in the PSM Procedure and Management System Performance Standard M05 MoC are considered when conducting any changes with the potential to impact process safety.

The Engineering Management Procedure specifies key requirements of engineering related changes, and requires that engineering Technical Decisions are agreed, recommended and decided at the appropriate engineering authority level according to the risk. Change management and risk assessment include consideration of applicable legislation/regulation.

Change is also managed under management system requirements set out as part of major projects (Brownfields), wells integrity, subsea and pipelines integrity management and marine management system. Change management includes consideration of regulatory requirements, managed in accordance with the Regulatory Compliance Management Procedure.

In addition, the MoC MSPS (M05) is in place to assure process safety risks arising from change (temporary and permanent) are systematically identified, assessed and managed.

7.3.2 Environment Plan Management of Change and Revision

Management of changes are managed in accordance with Woodside's Environmental Approval Requirements Australia Commonwealth Guideline. Management of changes relevant to this EP, concerning the scope of the activity description (Section 2.10) including: review of advances in technology at stages where new equipment may be selected such as vessel contracting; changes in understanding of the environment, DCCEEW EPBC Act listed threatened and migratory species status, Part 13 statutory instruments (recovery plans, threat abatement plans, conservation advice, wildlife conservation plans) and current requirements for AMPs (Section 4.8); and potential new

advice from external stakeholders (Section 5), will be managed in accordance with Regulation 38 and 39 of the Environment Regulations.

Risk will be assessed in accordance with the environmental risk management methodology (Section 2.8 to determine the significance of any potential new environmental impacts or risks not provided for in this EP. Risk assessment outcomes are reviewed in compliance with Regulation 38 and 39 of the Environment Regulations.

Minor changes where a review of the activity and the environmental risks and impacts of the activity do not trigger a requirement for a formal revision under regulation 38 or 39 of the Environment Regulations, will be considered a 'minor revision'. Minor administrative changes to this EP, where an assessment of the environmental risks and impacts is not required (e.g., document references, phone numbers, etc), will also be considered a 'minor revision'. Minor revisions as defined above will be made to this EP using Woodside's document control process. Minor revisions will be tracked in an MOC Register to ensure visibility of cumulative risk changes, as well as enable internal EP updates/reissuing as required. This document will be made available to NOPSEMA during regulator environment inspections.

7.3.3 OPEP Management of Change

Relevant documents from the OPEP will be reviewed in the following circumstances:

- implementation of improved preparedness measures
- a change in the availability of equipment stockpiles
- a change in the availability of personnel that reduces or improves preparedness and the capacity to respond
- the introduction of a new or improved technology that may be considered in a response for this activity
- to incorporate, where relevant, lessons learned from exercises or events
- if national or state response frameworks and Woodside's integration with these frameworks changes.

Where changes are required to the OPEP, based on the outcomes of the reviews described above, they will be assessed against Regulation 38 and 39 to determine if EP, including OPEP, resubmission is required (see Section 7.3.2). Matters arising with potential to influence minor or technical changes to the OPEP are tracked in MoC records, project records and incorporated during internal updates of the OPEP or revisions to the EP.

7.4 Management of Safety and Critical Element Technical Performance Standards and Management System Performance Standards

7.4.1 Management System Performance Standards (MSPS)

Woodside ensures safety critical management processes function as required through the application of MSPS. These standards are developed and owned at non-facility-specific level (i.e., pan-Woodside) and include assurance checks for the key requirements of the applicable management system.

Individual facilities demonstrate conformance against the MSPS through the conduct of reviews. Non-conformances against an MSPS are internally managed in accordance with the WMS.

7.4.2 SCE Technical Performance Standards

An SCE is defined by Woodside as a hardware barrier, the failure of which could cause or contribute substantially to, and the purpose of which is to prevent or limit the effect of a MAE/MEE, or Process Safety Event.

Woodside identifies/develops, implements, monitors/assures and verifies/optimises SCEs by applying SCE technical Performance Standards as described in the SCE Management Procedure. Key elements of the procedure are summarised in Table 7-3.

Table 7-3: Safety and Environment Critical Element Management Procedure Summary

Identify/Develop	Identify SCE – SCEs must be identified from the facilities PSRAs (e.g. Formal Safety Assessments) (Section 2.2). The identification of SCEs for which Performance Standards are required are part of the formal safety and environmental risk assessment processes. Woodside's Global Performance Standards (based on industry and Woodside Standards) should be used for preliminary selection of SCEs. Complete Engineering Design Studies – Engineering design studies must be completed to demonstrate that SCE Performance Criteria specified in the global Performance Standard and/or determined by PSRA will be met by the facility design, allowing for normal SCE degradation in operation. The studies must establish the testing and inspection tasks required to assess performance against the criteria. The scope and frequency of SCE Assurance Tasks are guided by the Global Performance Standard and may require designated Engineering Design Studies. Studies should include Reliability Centred Maintenance, Risk Based Inspection and Safety Instrumented Function studies to determine the Assurance Task scope and frequencies, RBI plans, and classification and implementation requirements for instrumented safeguarding. Develop Performance Standards – Facilities must develop Performance Standards for all SCEs by: selecting the applicable Global Performance Standard (including Assurance Tasks) considering facility specific requirements and applicable regulatory requirements adding the specific data from the facility Engineering Design Studies and PSRA to compile scope and frequency of SCE assurance activities.
Implement	Identify SCE in Asset Register – SCEs must be uniquely identified on the asset register and assigned Performance Standard flags. Develop Testing, Inspection and Maintenance Programs – SCE assurance tasks are developed into maintenance procedures. Implement Testing, Inspection and Maintenance Programs – SCE testing, inspection and maintenance requirements must be implemented in the CMMS (Section 7.2.4).
Maintain/Assure	Execute Testing, Inspection and Maintenance Programs – On completion of SCE assurance tasks, results must be recorded with all relevant detail, assessed for conformance with the Performance Criteria and any follow on correction work identified. Conduct Fitness for Service (FFS) Assessment – In some instances, an engineering FFS assessment may be required to determine whether equipment has failed its performance standard requirements, e.g. assessment of corrosion defects following inspection of piping. Detailed results of FFS assessment may be recorded out of CMMS. Response to SCE Failure – SCE failure (technical Performance Standard non-conformance) is a failure to achieve the given Performance Criteria. SCE failures must be managed in accordance with a structured review process. This process may require the application of the facility MOPO which provides prescriptive guidelines to be followed in the event of a reduction in the performance of an SCE, or managed in accordance with the Management of Change – Assets Procedure (Section 7.1.4). Internal Reporting – SCE failure/damage and SCE demands must be reported in accordance with the Health Safety and Environment Event Reporting and Investigation Procedure (Section 7.13.4). External Reporting – External notification obligations for SCE failure/damage must be understood (i.e. based on local regulatory requirements). External communications must be in accordance with the health safety and environment event reporting and investigation procedure (Section 7.13.5). Manage and Analyse Results – The results from assurance tasks must be accurately recorded to support data analysis. Analysis will enable appropriate action to be taken to minimise future failure recurrences, and enable assessment of overall system performance and reliability to verify SCE effectiveness in revealing failures and to allow predictive maintenance.

Verify/Optimise	Review SCE Performance – SCE performance reviews must be conducted to ensure requirements for maintaining SCE performance are being met. Manage Change – Any change to the Performance Standards must be conducted in accordance with the MoC Procedure (Section 7.3.2).

SCE Technical Performance Standards are a statement of the performance required of an SCE (e.g. functionality, availability, reliability, survivability), which is used as the basis for establishing agreed assurance tasks and managing the hazard. An assurance task is an activity to confirm that the SCE meets, or will meet, its SCE Performance Standard. Examples of assurance tasks include inspection routines, maintenance activities, test routines, instrumentation calibration and reliability monitoring.

These assurance tasks are identified in the CMMS, flagged against their associated technical Performance Standard, and given the appropriate priority. Management systems are in place to manage the completion of maintenance including that required for Technical Integrity assurance.

Events where the SCC/SCE have not met their specified performance criteria must be managed in accordance with a structured review process. This process may require the application of the facility Manual of Permitted Operation (MOPO) which provides prescriptive guidelines to be followed in the event of a reduction in the performance of an SCE in specific defined circumstances; or, if the MOPO does not cover the event, according to procedures for the assessment and management of operational risk.

Internal notification of SCC failures must be made in accordance with maintenance management workflows. Failures to meet a Facility Performance Standard occur where SCC events lead to the functional objectives (goal and/or key requirement statements) of the facility Performance Standard for the SCE not being met (i.e. lost or unavailable), taking into account any redundancy inherent within the SCE. These ‘damage to SCE’ events are reported in the Event Reporting Database as potential SCE Failure to Meet Facility Performance Standard Events.

These are internally reported as Hazard Events. Where ‘Failure to meet a Facility Performance Standard’ leads to a loss of hydrocarbon containment, or a release of energy, it is internally reported (and externally where relevant) as a Loss of Primary Containment or Environmental Spill event, depending on the nature of the release.

Additionally, confirmed “Failure to meet a Facility Performance Standard’’ events for the SCEs identified in the MEE bowties may equate to a breach of EPOs and/or EPSs. The review to identify such events for external reporting considers whether the hazard event is relevant to environmental SCE functional objectives (goal and/or key requirements) of the SCE Facility Performance Standard and whether the event poses a risk to achieving EPOs and EPSs. The WMS Regulator Event Reporting Guideline provides additional information regarding external SCE related reporting obligations.

There may also be planned changes/deviations from SCE Technical Performance Standards, these are managed via procedures for the assessment and management of operational risk, and endorsed in accordance with the engineering management procedures (described further within Section 7.3. This management process ensures risks (including environment) are managed so that the planned change/deviation does not result in unacceptable impact or risk, remains ALARP and regulatory requirements are met.

7.5 Woodside’s Decommissioning Framework

Decommissioning is a planned activity for the offshore oil and gas industry. Current best practice is for decommissioning to include:

- designing for decommissioning during the development phase of projects / facilities
- removing property, equipment and infrastructure, such as a facility or a pipeline, and plugging wells associated with a petroleum activities.
- assessing decommissioning options and opportunities during the operational life of the facility leading up to cessation of production
- selecting, developing and planning the selected decommissioning option
- executing decommissioning plans
- restoring the marine environment.

This is aligned with Section 572 (3) of the OPGGS Act, which requires titleholders to remove property from the title area when it is neither used, nor to be used, in connection with the operations. Planning for complete removal is generally the base case for offshore decommissioning operations. Section 572 (7) and section 270 (3) of the OPGGS Act provide scope for in situ decommissioning or other arrangements to be made where it can be demonstrated that the risks and impacts are ALARP and acceptable. If complete removal or other arrangements for decommissioning are planned, the proposed alternative presented in an EP must comply with all other Acts and legislation.

7.5.1 Decommissioning in Operations

Asset specific decommissioning plans are typically developed prior to cessation of production. Planning includes redundant infrastructure as well as structures coming to the end of production and decommissioning critical systems to enable, as a base case, removal.

7.5.2 Facility Decommissioning Planning

Decommissioning planning generally commences 2-10 years prior to Cessation of Production (CoP) (Figure 7-5). The timeframe selected for decommissioning planning depends on the complexity of the facility and infrastructure requiring decommissioning.

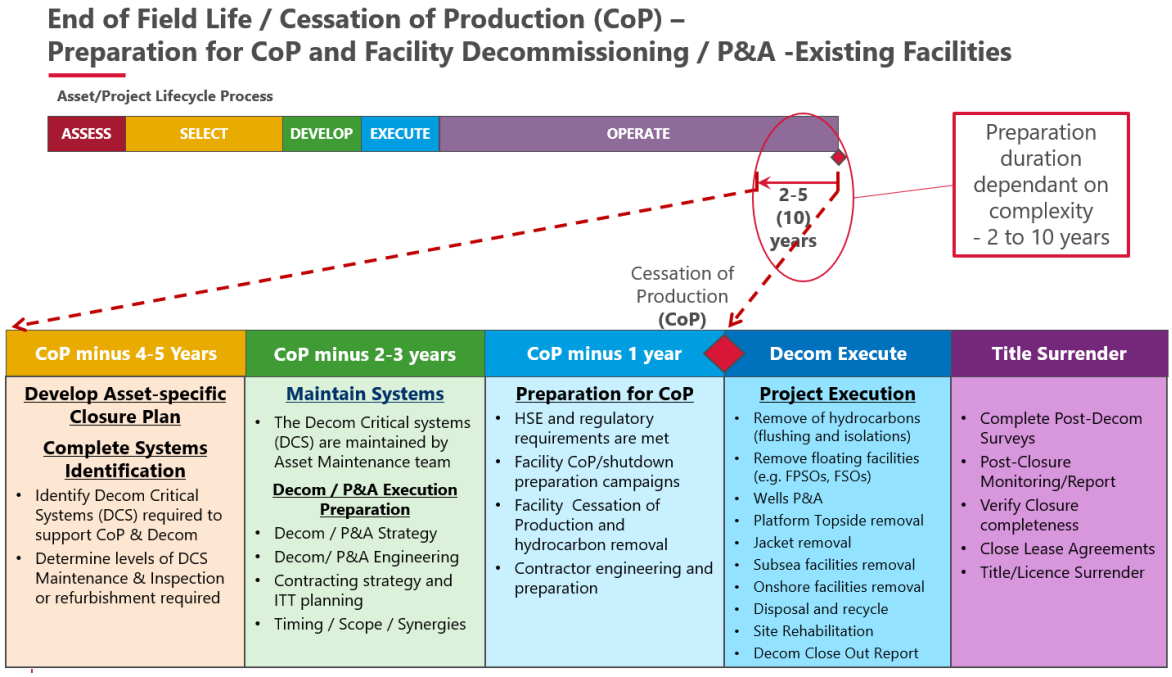

Figure 7-5: Woodside's process for decommissioning planning

7.5.3 Pluto Decommissioning Strategy

The base plan for decommissioning consists of permanent plugging and abandonment (P&A) of wells, removal of trees, wellheads and all other subsea equipment (e.g. XT's, manifolds, Valve stations) by cleaning and flushing and removal to shore.

The Pluto topsides to be cleaned and disconnected then removed via modular reverse lift and transported onshore for recycling/disposal. Alternative decommissioning strategies to full removal will be explored for the Pluto Jacket and rigid pipelines.

The decommissioning strategy will be matured over the time through various studies and data gathering targeted to support that the final proposed Pluto Decommissioning Plan represents an ALARP position in respect of the environmental, safety and the socio-economical outcomes.

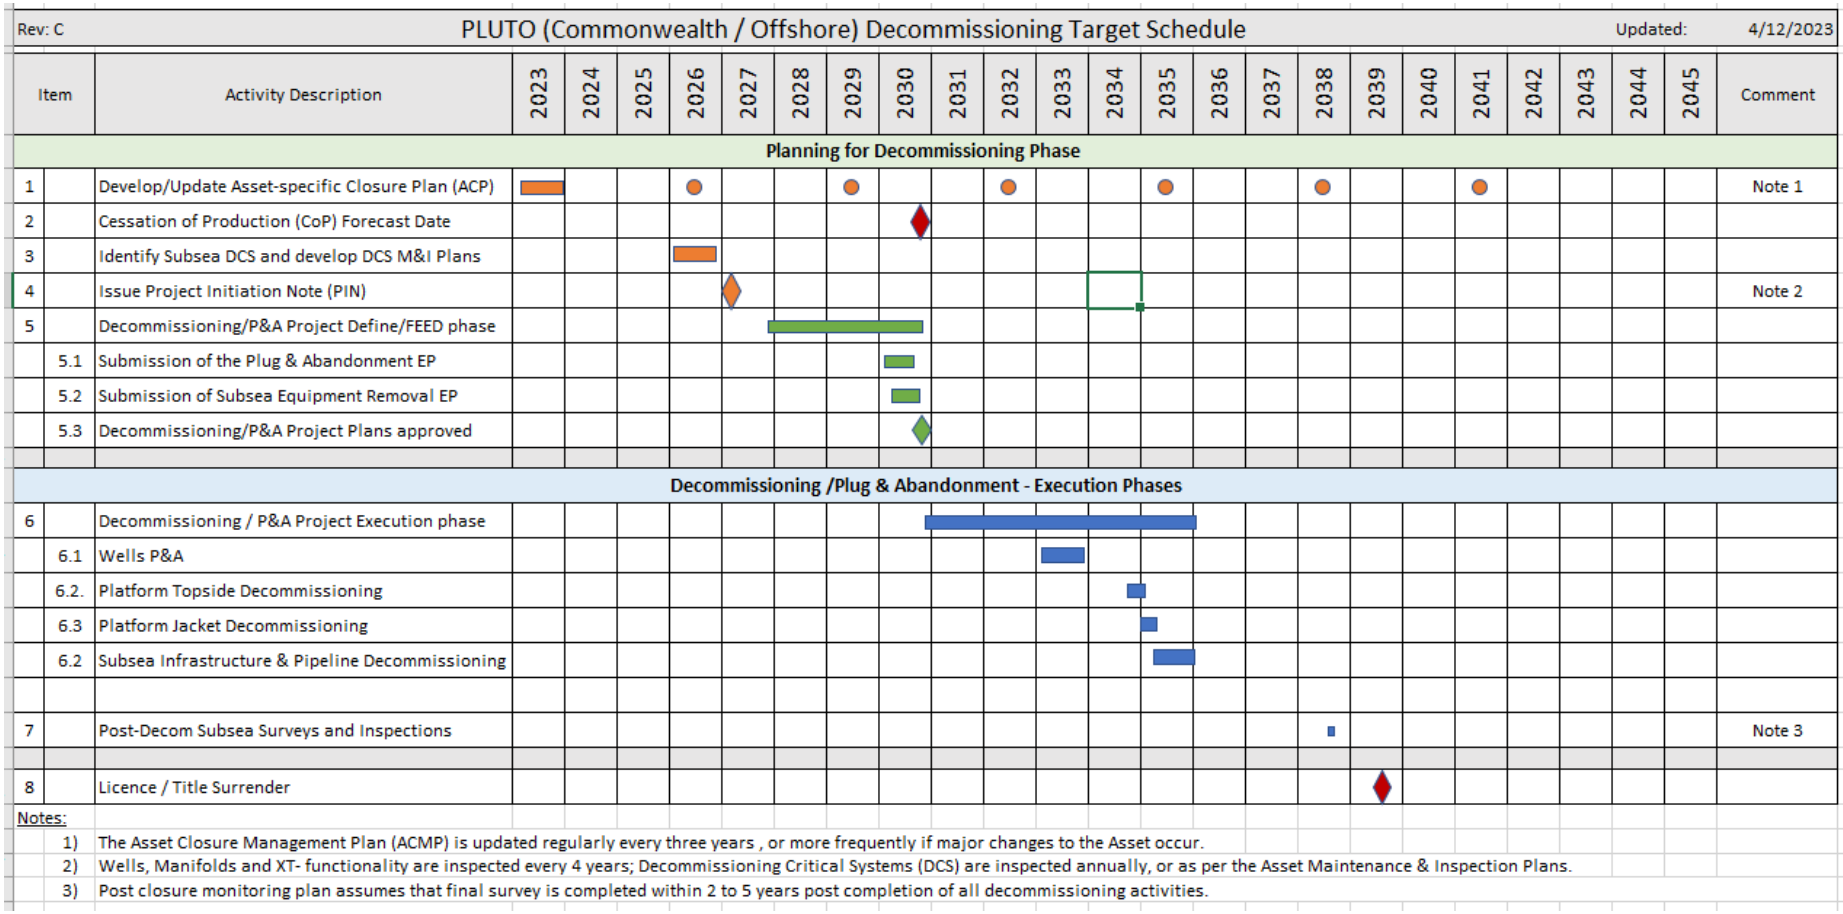
7.5.4 Pluto Decommissioning Phasing

Decommissioning of the Pluto facilities has been planned in two phases:

- Phase-1 - Planning for decommissioning / P&A of the Pluto offshore facilities
- Phase-2 – Execute decommissioning / P&A of the Pluto offshore facilities.

The expected Cessation of Production (CoP) for the Pluto offshore facilities is around 2030.

Currently Woodside is commencing early studies in support of the preparations for the future decommissioning activities to optimise the scope and strategy to deliver safe and effective decommissioning outcomes. The key envisaged activities related to the decommissioning are outlined in the indicative Pluto Decommissioning Planning Lifecycle Schedule shown in Figure 7-6. Timing is indicative - subject to reservoir performance outcomes through the remaining field life.



Rev: C — PLUTO (Commonwealth / Offshore) Decommissioning Target Schedule — Updated: 4/12/2023

Item		Activity Description	2023	2024	2025	2026	2027	2028	2029	2030	2031	2032	2033	2034	2035	2036	2037	2038	2039	2040	2041	2042	2043	2044	2045	Comment
Planning for Decommissioning Phase																										
1		Develop/Update Asset-specific Closure Plan (ACP)																								Note 1
2		Cessation of Production (CoP) Forecast Date																								
3		Identify Subsea DCS and develop DCS M&I Plans																								
4		Issue Project Initiation Note (PIN)																								Note 2
5		Decommissioning/P&A Project Define/FEED phase																								
	5.1	Submission of the Plug & Abandonment EP																								
	5.2	Submission of Subsea Equipment Removal EP																								
	5.3	Decommissioning/P&A Project Plans approved																								
Decommissioning /Plug & Abandonment - Execution Phases																										
6		Decommissioning / P&A Project Execution phase																								
	6.1	Wells P&A																								
	6.2.	Platform Topside Decommissioning																								
	6.3	Platform Jacket Decommissioning																								
	6.2	Subsea Infrastructure & Pipeline Decommissioning																								
7		Post-Decom Subsea Surveys and Inspections																								Note 3
8		Licence / Title Surrender																								

Notes:

1) The Asset Closure Management Plan (ACMP) is updated regularly every three years , or more frequently if major changes to the Asset occur.
2) Wells, Manifolds and XT- functionality are inspected every 4 years; Decommissioning Critical Systems (DCS) are inspected annually, or as per the Asset Maintenance & Inspection Plans.
3) Post closure monitoring plan assumes that final survey is completed within 2 to 5 years post completion of all decommissioning activities.

Figure 7-6: Indicative Pluto Decommissioning Planning Lifecycle and Schedule

7.5.4.1 Phase 1: Planning for Decommissioning - Key Activities

2023: Developed Asset-specific Closure Management Plan (CMP) – (the CMP will be updated regularly to reflect changes to the asset infrastructure, or to address major changes in Regulator requirements).

2026: Complete Decommissioning Critical Systems (DCS) identifications, define DCS Maintenance & Inspection requirements and update the Asset Maintenance & Inspection Plans (if required).

2027: Initiate Define/FEED works for the Pluto Offshore facilities decommissioning program.

2027 to 2030: Complete Define/FEED Phase works for Decommissioning / P&A of the Pluto offshore facilities.

Submission of the Environmental Plan(s) for the activities related to flushing of the subsea systems and for isolations/separation of the wells from the flushed subsea infrastructure.

2030: Commence Pluto Offshore Asset Cessation of Production (CoP) activities.

7.5.4.2 Phase 2: Execute Decommissioning and P&A – Key Activities:

2030 to 2035: Execute P&A of the wells – (target within 3 years from the CoP). Execute decommissioning/removal of the PLA platform and the subsea equipment – (target within 5 years from the CoP date).

7.6 Organisation Structure

The following Woodside organisational structure provides leadership and direction for operation of the Pluto facility and environmental performance:

- The Executive Vice President (EVP) Australian Operations reports to the Chief Executive Officer.
- The Pluto and Scarborough Vice President (VP) reports to the EVP.
- The Asset Manager reports to the Pluto and Scarborough VP.
- The Reliability & Integrity Manager reports to the Pluto and Scarborough VP.
- The PLA Superintendent reports to the Asset Manager.
- The functional support teams report to the corresponding Functional VP.

Production facilities are supported by a team of environmental professionals who report to the Environment and Sustainability Manager – Australian Operations.

All facilities are supported by other Woodside functional teams, including:

- HSE – provides specific guidance and access to specialist HSE resources including assistance for governance and training, as well as guidance on Woodside HSE standards
- Subsea – responsible for the installation and IMMR activities on subsea infrastructure including facility structures, flowlines, manifolds and subsea isolation valves to ensure integrity
- Global Wells and Seismic – ensures the safe planning and execution of drilling, completion and work over operations
- Projects – responsible for the engineering, construction and execution of small projects on operational facilities to ensure ongoing integrity and safe operation
- Marine Group – responsible for chartering vessels to support Woodside's offshore production facilities including vessels to aid emergency response

- Aviation Group – provides personnel transport, material transport, emergency evacuation and search and rescue capabilities.

7.7 Roles and Responsibilities

Key roles and responsibilities for Woodside and contractor personnel in relation to implementing, managing and reviewing this EP are described in Table 7-4. Roles and responsibilities for hydrocarbon spill preparation and response are outlined in Table 7-4 and the Woodside Oil Pollution Emergency Arrangements (Australia).

It is the responsibility of all Woodside employees and contractors to apply the Woodside's Health and Safety Policy, and Environment and Biodiversity Policy in their areas of responsibility and that the personnel are suitably trained and competent in their respective roles.

Table 7-4: Roles and responsibilities

Title (role)	Environmental Responsibilities
All Personnel	
All onshore and offshore personnel	understand the Woodside standards and procedures that apply to their area of work. understand the environmental risks and control measures that apply to their area of work. carry out assigned activities in accordance with approved procedures and the EP. follow instructions from relevant supervisor with respect to environmental protection. cease operations which are deemed to present an unacceptable risk to the environment. participate in environmental assurance activities and inspections as required. prompt reporting of environmental hazards/incidents to their supervisor and assist in event investigation. attend HSE meetings, training and drills when required.
Office-based Personnel	
Woodside Project Manager	Monitor and manage the activity so it is undertaken as per the relevant standards and commitments in this EP. Notify the Woodside Environment Adviser of any scope changes in a timely manner. Liaise with regulatory authorities as required. Review this EP as necessary and manage change requests. Ensure all project and support vessel crew members complete an HSE induction. Verify that contractors meet environmental related contractual obligations. Confirm environmental incident reporting meets regulatory requirements (as outlined in this EP) and Woodside's Health, Safety and Environment Reporting and Investigation Procedure. Monitor and close out corrective actions identified during environmental monitoring or audits.
Woodside Head of Projects/Region (Global Wells and Seismic)	Ensure drilling operations are undertaken as per this EP and approval conditions. Provide sufficient resources to implement the drilling-related management measures (i.e. controls, EPOs, EPSs and MC) in this EP. Confirms controls and performance standards in this EP are actioned, as required, before drilling commences. Ensures the MODU start-up meets the requirements of the Drilling and Managing Rig Operations Process.
Subsea Delivery Lead	Ensure the subsea installation activities are undertaken as per this EP and approval conditions. Provide sufficient resources to implement the subsea installation-related management measures (i.e. controls, EPOs, PSs and MC) in this EP. Ensure installation vessel personnel are given an Environmental Induction as per Section 7.9.1 this EP at the start of the installation activities. Confirm controls and performance standards in this EP are actioned, as required, before installation activities commence. Ensure relevant vessels meet the requirements of Woodside's Marine Operations Operating Standard. Manage change requests for the activity and notify the Woodside Environment Adviser of any scope changes in a timely manner. Confirm that site-based personnel are given an Environmental Induction as per Section 7.9.1 of this EP at the start of the activity. Ensure all chemicals and drill fluids proposed to be discharged are assessed and approved as per the requirements of the EP.
Woodside Drilling Superintendent	Ensure the drilling program meets the requirements detailed in this EP. Ensure changes to the drilling program are communicated to the Woodside Environmental Adviser. Ensure the Woodside's Well Site Manager is provided with the resources required to ensure the management measures (i.e. controls, EPOs, EPs and MC) in this EP are undertaken.

Title (role)	Environmental Responsibilities
	Confirm environmental incident reporting meets regulatory requirements (as outlined in this EP) and Woodside's Health, Safety and Environment Reporting and Investigation Procedure. Monitor and close out corrective actions identified during environmental monitoring or audits. Ensure MODU and project vessel personnel are given an Environmental Induction as per Section 7.9.1 of this EP at the start of the drilling programs.
Woodside Drilling Engineers	Ensure changes to the drilling program are communicated to the Woodside Environmental Adviser. Ensure all drill and completions fluid chemical components and other fluids that may be used downhole have been reviewed by the Drilling and Completions Environmental Adviser.
Woodside Projects/GWS Environmental Adviser	Verify relevant Environmental Approvals for the activities exist prior to commencing activity. Track compliance with performance outcomes and performance standards as per the requirements of this EP. Prepare environmental component of relevant Induction Package. Assist with the review, investigation and reporting of environmental incidents. Ensure environmental monitoring and inspections/audits are undertaken as per the requirements of this EP. Liaise with relevant regulatory authorities as required. Assist in preparation of external regulatory reports required, in line with environmental approval requirements and Woodside incident reporting procedures. Monitor and close out corrective actions (Campaign Action Register (CAR)) identified during environmental monitoring or audits. Provide advice to relevant Woodside personnel and contractors to assist them to understand their environment responsibilities. Liaise with primary installation contractors to ensure communication and understanding of environment requirements as outlined in this EP and in line with Woodside's Compass values and management systems.
Asset Manager	accountable for ensuring all necessary regulatory approvals are in place to operate. approves (decides on) the content to be contained in the Environment Plan accountable for managing the asset throughout its operations in accordance with legislative/regulatory requirements (including this EP) and WMS requirements. agrees facility key performance indicators (KPIs), including environment KPIs and is accountable for their achievement. responsible for continuous improvement of operations of the facility, including environmental performance. decides on technical decisions where required based on assessed current level of risk. accountable for incident notification, reporting and investigation in line with regulatory requirements, the WMS and EP requirements
PLA Superintendent	Responsible for the safe conduct of all activities within the facility 500 m Safety Zone and within the vicinity of the connected pipelines, through the facility team of coordinators, technicians and specialist resources. Accountable for aspects of integrity management including the evaluation and reporting of conditions against performance standard, integrity envelope, reviewing post-incident / legislative or joint venture requirements and planning and executing planned inspections. Accountable for conformance to operations processes including ISSoW. Accountable for compliance with all legislative and regulatory requirements including Safety Case and Environment Plan. Accountable for ensuring all teams operate on the facility in a safe and reliable manner within the defined technical integrity envelope. Responsible for making safe, repairing and raising technical deviations where necessary for abnormal situations. Accountable and responsible for updating changes to production information in site-controlled documents.

Title (role)	Environmental Responsibilities
	Accountable for the performance and development of direct reports, ensuring operator and maintainer capability and competency across all shifts and ensuring the skill requirements are being met. Accountable for effective handovers between shifts and swings. Decider for high risk MOC decisions associated with PLA and pipelines. Custodian of and therefore responsible for ensuring the facility remains in compliance with PLA Safety Case and Environment Plan.Ensures offshore personnel comply with regulatory/legislative requirements (including the EP) and the WMS. Communicates changes relevant to the EP to the Production Environment team. Implement relevant offshore environment initiatives and review environmental performance to drive continuous improvement. Ensure effective communication with workforce on environmental performance. Ensure incidents are reported and investigated in line with WMS and EP requirements, with appropriate actions initiated and closed out.
Technical Support Lead	Champion technology and new ways of working to explore and implement new and efficient ways for managing performance and maintenance for equipment. Champion and embed risk thinking with Engineers and TICs so that effective and proportionate controls are implemented.
Reliability & Integrity Manager	Steward of Reliability and Integrity for the business unit. Lead a team that expertly ensures that strategies for equipment maintenance and operation are set to meet Reliability, Performance and Integrity goals. Ensuring that the Safety Case, Performance Standard, Regulatory and Reliability driven maintenance tasks for all equipment are known and implemented in the most efficient maintenance strategy possible. Ensuring that Very High and Severe risks are assessed and controlled when they appear, and that the right technical expertise, including technical authorities, is engaged to understand, communicate and manage the risk, as part of the 'Agree' role in the Engineering Management Procedure. Ensuring that refresh of facility baseline risk assessments is completed upon trigger of re-assessment. Assuring that reliability and integrity delivery processes in the assets is being done to correct standard and engaging with relevant process owners.
Integrity Authorities (Technical Integrity Custodians, Technical Authorities and Engineering Authorities)	Manage technical integrity within their designated discipline by ensuring the safe and consistent application of integrity management processes and systems, discipline standards and good engineering practices. Agree technical integrity decisions based on assessed current level of risk. Agree to facility specific Performance Standards and confirm that Performance Standard requirements are met.
Subsea and Pipelines (IMMR) Activity Manager	ensure IMMR activities undertaken in line with EP commitments. manage IMMR change requests for the activity and notify the Subsea and Pipelines Environment Adviser of any scope changes in a timely manner. responsible for governance of IMMR related activities for Subsea Support Vessels. provide sufficient resources to implement the EP requirements. monitor and close out corrective actions raised from IMMR environmental inspections/audits or incidents
Environment Manager Australian Operations	facilitate operations environmental approval documentation and timely submission in accordance with regulatory requirements. ensure Asset and supporting personnel understand and adhere to legislative and regulatory environment requirements, EP requirements and the environmental requirements of the WMS. develop and maintain appropriate Production environmental processes and procedures.

Title (role)	Environmental Responsibilities
	Monitor and communicate to internal stakeholders all relevant changes to legislation, policies, regulator organisation that may impact the EP or business. facilitate review of the EP, including five-yearly revision and in relation to any technical decisions or proposed changes to operations
Environment Adviser Australian Operations	manage change relevant to the EP in accordance with the Regulations and the EP ensure environmental monitoring, offshore inspections, and reporting is undertaken as per the requirements of this EP. coordinate and monitor closeout of corrective actions. ensure environmental inspections/audits are undertaken as per the requirements of the EP. ensure environmental incident reporting meets regulatory requirements (as described within the EP) and WMS
Corporate Affairs Adviser	Prepare and implement the Consultation Plan for the Petroleum Activities Program. Report on consultation. Ongoing liaison and notification as required.
Woodside Marine Assurance Superintendent	Conducts relevant audit and inspection to confirm vessels comply with relevant Marine Orders and Woodside Marine Charters Instructions requirements to meet safety, navigation and emergency response requirements.
Woodside CIMT Deputy Incident Commander	On receiving notification of an incident, the Woodside CIMT Deputy Incident Commander shall: establish and take control of the IMT and establish an appropriate command structure for the incident. assess situation, identify risks and actions to minimise the risk. communicate incident progress to relevant persons within the organisation. develop the incident action plan (IAP) including setting objectives for action. approve, implement and manage the IAP. communicate within and beyond the incident management structure. manage and review safety of responders. address the broader public safety considerations. conclude and review activities.
Contractor Sponsors	ensure implementation of EP for the contractor's scope of work ensure contractors have adequate environmental capability in order to execute their respective scopes of work. review contractor environmental performance as required.
PLP-based personnel	
Frontline Superintendent	Onshore roles at Pluto LNG Park which are responsible for ensuring that offshore work scopes are conducted in safe manner when platform is not crewed. Other responsibilities associated with onshore gas plant are described in the Pluto LNG Park Safety Case. Issuing Authority in ISSoW Permit to Work system when platform is uncrewed and/or subsea scope that does not involve work execution on PLA platform and is outside the facility 500m Safety Zone. Responsible for emergency response at or near PLA when platform is uncrewed.
Onshore Installation Manager (OIM)	Normally Site Controller in ISSoW process. Other responsibilities associated with onshore gas plant are described in the Pluto LNG Park Safety Case. Accountable for Permit to Work governance, processes and permit requirements. The OIM, supported by Frontline Superintendent, is the single point responsible person for the coordination of SIMOPS for activities that have ability to impact onshore or its operations.
Environment Advisor	liaise with managers/supervisors on day-to-day management of environmental risks and issues assist in the ongoing promotion of environmental performance at the facilities and day-to-day management HSE risks and issues.

Title (role)	Environmental Responsibilities
	identify opportunities for continuous improvement and communicate these to the PLA Superintendent and Environment Team implement environmental improvement plans. support operational personnel to understand the EP requirements applicable to their role. communicate environmental performance information and training material to offshore personnel and maintain associated records.
PLA-based Personnel (in crewed mode)	
Person in Charge (PIC) (offshore crewed mode)	Offshore roles at PLA which are responsible for ensuring that offshore work scopes are conducted in a safe manner when platform is crewed. Accountable for the day-to-day operations of the platform when crewed including, SIMOPS affecting PLA, effective shift handover; completion and logging of operator routine. Responsible for operations shift compliance to all legislative and regulatory requirements as defined in the Safety Case and Environmental Plan. Issuing Authority in ISSoW Permit to Work systemwhen platform is crewed. Responsible for auditing and maintaining maintenance procedures. Responsible for leading and coordinating a multi-disciplined team that is responsible for the duties required to support the facility, including helicopter operations, vessel movements and consumable controls. Responsible for emergency response at or near PLA when platform is crewed, including ensuring exercises and drills are carried out such that the facility's ability to respond effectively to an emergency is assured.
Production and Maintenance Technicians	responsible for daily operations on the facility within their operational control. undertake daily operational and maintenance tasks in accordance with approved standards and procedures to ensure compliance with the EP. manage day-to-day environmental risks through use of ISSoW and other risk management tools. identify opportunities for continuous improvement and communicate these to their Supervisor. complete training requirements to maintain competence and knowledge in operating and maintaining equipment and manage environmental risks and impacts. participate in environmental assurance activities and inspections as required. report all environmental hazards and incidents and assist in investigations.
MODU-based Personnel	
MODU Offshore Installation Manager (OIM)	Ensure the MODU's management system and procedures are implemented. Ensure personnel starting work on the MODU receive an environmental induction that meets the requirements specified in this EP. Ensure personnel are competent to undertake the work they have been assigned. Verify that emergency drills are conducted as per the MODU's schedule. Ensure the MODU's Emergency Response Team has been given sufficient training to implement the MODU's SOPEP. Ensure any environmental incidents or breaches of outcomes or standards are reported immediately to the Well Site Manager. Ensure corrective actions for incidents or breaches are developed, communicated to the Well Site Manager, and tracked to close out in a timely manner. Close out of actions is communicated to the Well Site Manager.
Woodside Well Site Manager	Ensure the drilling program is undertaken as detailed in this EP. Ensure the management measures (i.e. controls, EPOs, PSs and MC) detailed in this EP (relevant to offshore activities) are implemented on the MODU (other controls will be implemented onshore). Ensure environmental incidents or breaches of outcomes or standards are reported as per the Woodside Corporate Event Notification Matrix. Corrective actions for incidents and breaches are developed, tracked and closed out in a timely manner. Ensure actions in the Drilling and Completions HSE Improvement Plan are undertaken.

Title (role)	Environmental Responsibilities
	Ensure periodic environmental inspections/reviews are completed. Corrective actions from inspections are developed, tracked and closed out in a timely manner.
Woodside Offshore HSE Adviser	Support the Well Site Manager to ensure the controls detailed in this EP relevant to offshore activities are implemented on the MODU and help collect and record evidence of implementation (other controls are implemented, and evidence collected onshore). Support the Well Site Manager to ensure the Environmental Performance Outcomes are met and the performance standards detailed in this EP are implemented on the MODU. Confirm actions in the Drilling and Completions HSE Improvement Plan are undertaken. Support the Well Site Manager to ensure environmental incidents or breaches of outcomes or standards outlined in this EP, are reported, and corrective actions for incidents and breaches are developed, tracked and closed out in a timely manner. Ensure periodic environmental inspections/reviews are completed and corrective actions from inspections are developed, tracked and closed out in a timely manner. Review Contractors procedures, input into Toolbox talks and JSAs. Provide day to day environmental support for activities in consultation with the Woodside Environment Adviser.
Drilling Logistics Coordinator	Waste is managed on the MODU and sent to shore as per the Drilling and Completions Waste Management Plan.
Vessel-based Personnel	
Vessel Master (Installation Vessel Master, Activity Support Vessel Master, Support Vessel (Platform and Subsea Support Vessels)	Ensure the vessel management system and procedures are implemented. Ensure personnel commencing work on the vessel receive an environmental induction that meets the relevant requirements specified in this EP. Ensure personnel are competent to undertake the work they have been assigned. Verify SOPEP drills are conducted as per the vessel's schedule. Ensure the vessel Emergency Response Team (ERT) has been given sufficient training to implement the SOPEP. Ensure any environmental incidents or breaches of relevant Environmental Performance Outcomes or performance standards detailed in this EP, are reported immediately to the Woodside Representative. Ensure corrective actions for incidents or breaches are developed, communicated to the Woodside Representative, and tracked to close out in a timely manner. Close out of actions is communicated to the Woodside Representative.
Vessel Logistics Coordinators	Ensure waste is managed on the relevant support vessels or installation vessel and sent to shore as per the relevant Waste Management Plan.
Vessel HSE Advisers	Refer to Woodside HSE Offshore Adviser responsibilities detailed above under MODU-based personnel.
Contractor Project Manager	Confirm that activities are undertaken in accordance with this EP, as detailed in the Woodside approved Contactor Environmental Management Plan Ensure personnel commencing work on the project receive a relevant environmental induction that meets the requirements specified in this EP. Ensure personnel are competent to undertake the work they have been assigned. Ensure any environmental incidents or breaches of objectives, standards or criteria outlined in this EP, are reported immediately to the Woodside Responsible Engineer or Vessel Master.

Title (role)	Environmental Responsibilities
Woodside Site Representative/ Resident Engineer	Ensure activities are undertaken as detailed in this EP. Ensure the management measures made in this EP are implemented on the vessel. Ensure environmental incidents or breaches of objectives, standards or criteria outlined in this EP, are reported as per the Woodside Corporate Event Notification Matrix Verify HSE improvement actions identified during the project are implemented where practicable. Ensure periodic environmental inspections are completed.

7.8 Unexpected Finds Procedure

In the event of the discovery of what appears to be Underwater Cultural Heritage (defined as 'any trace of human existence that has a cultural, historical or archaeological character and is located under water'); the following Unexpected Finds Procedure will apply:

- All activities with the potential to impact the suspected Underwater Cultural Heritage must cease immediately. Retain all records of the potential Underwater Cultural Heritage, including any imagery, description and location.
- Person who discovers the heritage object must inform the Activity Supervisor.
- Activity Supervisor must notify Woodside's Global Heritage Manager.

Woodside will specify an appropriate buffer around the potential Underwater Cultural Heritage, taking into consideration the nature and scale of the potential Underwater Cultural Heritage and the activities to be managed.

No seabed disturbance may occur within the buffer area around the potential Underwater Cultural Heritage until approved by Woodside's Global Heritage Manager. Woodside's Global Heritage Manager must notify a qualified underwater archaeologist and provide all available documentation of the potential Underwater Cultural Heritage. If the potential Underwater Cultural Heritage appears to be Aboriginal underwater cultural heritage, Woodside's Global Heritage Manager must notify the appropriate Traditional Custodians to determine whether it is a heritage site and if so, how the site should be managed.

If the potential Underwater Cultural Heritage appears to be a shipwreck or aircraft that has been wrecked for more than 75 years or is otherwise reportable under Section 40 of the UCH Act, Woodside's Global Heritage Manager must notify the Minister responsible for the UCH Act, the DCCEEW underwater archaeology section through the Australasian Underwater Cultural Heritage Database, and the Western Australian Museum.

If the suspected heritage object includes human remains, Woodside's Global Heritage Manager must also notify:

- The Australian Federal Police (phone: 131 444) of the location of the remains, that the remains are likely to be historic or Aboriginal in origin, and that it may be appropriate that Traditional Custodians and a maritime archaeologist are present during any handling of the remains; and
- The Office of the Federal Environment Minister in accordance with Section 20 of the ATSIHP Act.

Work must not recommence in the vicinity of the potential heritage object until Woodside's Principal Heritage Adviser provides written approval. Woodside's Global Heritage Manager must only provide written approval once agreed management measures are implemented consistent with approvals and legislation or where the potential Underwater Cultural Heritage is confirmed to not be Underwater Cultural Heritage.

7.9 Training and Competency

Woodside as part of its contracting process undertakes assessments of a proposed Contractor's environmental management system to determine the level of compliance with the standard AS/NZS ISO 14001. This assessment is undertaken for the Petroleum Activities Program as part of the pre-mobilisation process. The assessment determines whether there is a clearly defined organisational structure that outlines the roles and responsibilities for key positions. The assessment also considers whether there is an up-to-date training matrix that defines any corporate and site/activity-specific environmental training and competency requirements.

As a minimum, environmental awareness during inductions is required for all Pluto facility and MODU personnel, detailing awareness and compliance with the Pluto facility, MODU and project vessel Contractor's environmental policy and environmental management system.

Impacts to training roll-out have arisen in the last five years due to major external disruptions beyond Woodside's control, namely associated with the COVID-19 pandemic. In the event of similar future disruptions, the adequacy of training and competency processes and procedures will be subject to Woodside's MoC process for ongoing safe operations of its facilities.

7.9.1 Inductions and Training

Inductions are provided to all relevant personnel (e.g. contractors and Company representatives) before mobilising to or on arrival at the activity location. The induction covers the HSE requirements and environmental information specific to the activity location. Attendance records will be maintained.

The Petroleum Activities Program induction may cover information about:

- Description of the activity
- Ecological and socio-economic values of the activity location (including Underwater Cultural Heritage).
- Regulations relevant to the activity
- Woodside's Environmental Management System – Health and Safety, and Environment and Biodiversity Policies.
- EP importance/structure/implementation/roles and responsibilities
- Main environmental aspects/hazards and potential environmental impacts and related performance outcomes
- Oil spill preparedness and response
- Monitoring and reporting on performance outcomes and standards using MC
- Incident reporting
- Inductions for offshore facility workers and visitors
- Operations competency framework training
- Permit to work training (ISSoW)
- Production environmental leadership training and environment awareness training
- Emergency and hydrocarbon spill response training
- Inductions for subsea IMMR (vessel based) personnel.
- Unexpected Finds Procedure and reporting requirements (Section 7.8).

- Records for Woodside operations personnel, in relation to the above listed training, are maintained in Woodside's learning management system. Contractor training records are also maintained.
- Competence of operations personnel can be reviewed via online dashboards.

7.9.2 Activities Program Specific Environmental Awareness

Before petroleum activities begin, a pre-activity meeting will be held on-board the MODU and project vessels with all relevant personnel. The pre-activity meeting provides an opportunity to reiterate specific environmental sensitivities or commitments associated with the activity. Relevant sections of the pre-activity meeting will also be communicated through to the support vessel personnel. Attendance lists are recorded and retained.

During operations, regular HSE meetings will be held on the Pluto facility, MODU and project vessels which cover all crew. During these meetings, recent environmental incidents are regularly reviewed, and awareness material presented.

7.9.3 Inductions for Offshore Facility Workers and Visitors

A comprehensive induction process is in place for personnel working on or visiting Woodside's offshore production facilities. The induction process is designed to equip personnel with the HSE awareness and skills necessary for them to manage their own safety and environmental performance and contribute to others working around them. The induction process includes:

Common Production Induction – All employees and contractors who have not accessed a production facility within twelve months are required to undertake this induction prior to mobilisation. It includes Woodside's values, HSEQ and Process Safety, continuous improvement, risk management and ISSoW.

Facility Specific Induction – All employees and contractors that have not accessed the production facility within twelve months are required to undertake this induction on arrival at the facility. This induction covers the HSE and emergency response issues specific to each facility. For environment, this induction covers the EP, prevention of spills, waste management, fauna interactions, hazard identification and risk assessment, and incident reporting.

Production Offshore Environmental Leadership Training – Key operations leadership roles (as specified within the Operations Competency Framework) are required to complete this competency on commencement of the new role and three yearly thereafter. The training covers Woodside's policies and standards, environmental legislative requirements, the EP, key environmental risk and impacts, environmental reporting, environmental management tools (e.g. improvement planning, compliance reviews and audits), hydrocarbon spill response and environmental accountabilities.

Production Offshore Environmental Awareness Training – All new offshore operational personnel are required to undertake this online training on commencement of the new role and two yearly thereafter. This training covers environmental legislative requirements, the facility EP, key environmental hazards and control measures (including waste management, spill prevention, chemical storage, wildlife interactions), environmental management tools, hazard and incident reporting, spill response, and environmental responsibilities.

7.9.4 Operations Competency Framework Training

The Operations Competency Guideline defines a framework to make sure all personnel on operating facilities are competent to perform their work and that competency is managed. By doing this, the potential for unplanned (accident/incident) type events that could result in environmental impact is minimised.

Operational Area License to Operate (LTO) roles are those roles related to oil and gas processing, equipment maintenance, marine regulations, emergency response and any other roles involved with safeguarding the facility integrity, including all roles where high-risk work licenses are required. Additionally, roles mandated by Woodside such as HSEC and helicopter landing officer are included in the LTO roles process.

The requisite competency and training for each LTO role has been defined. Competencies for these LTO roles are stipulated by the governance group for each respective position and are based on the relevant Australian or International standards which apply. In cases where no Australian or International standards are available or applicable, training is based on the relevant Woodside Standard as determined by the respective governance group.

Contractors working on Woodside facilities are required to verify the competency of their personnel through the contractor's own verification systems. Additionally, contractor personnel working on Woodside facilities are required to be registered in Woodside's Contractor Verification Service (CVS) beforehand. Personnel registered in CVS have had their skills and qualifications independently verified on behalf of Woodside thereby confirming that contractor personnel hold the required competencies before mobilisation to the facility.

The LTO Roles Report (available online on the Woodside Competency Reporting Dashboard on the Production Academy Intranet page) provides the conformance status of the facility against the LTO roles requirements.

7.9.5 Permit to Work System Training

The ISSoW permit to work (i.e. participation in crisis or emergency management exercises). Roles based training is further described in Section 7.14.

An overview of Woodside's hydrocarbon spill response training and competency requirements are provided in dashboards for key responder roles. The roles are consistent with Woodside's crisis and emergency management incident control structure. system (see Section 7.2.1) is a key element in ensuring that all necessary steps are taken for the safety of personnel, protection of the environment and technical integrity of the facility. The ISSoW system takes a risk-based approach to all activities, thus tasks with higher levels of risk are subjected to greater scrutiny and control.

All members of the workforce that are required to work with ISSoW (Section 7.2.1) receive training commensurate with the level of authority and responsibility they hold in ISSoW.

7.9.6 Emergency and Hydrocarbon Spill Response Training

All operations personnel involved in crisis and emergency management are required to commit to ongoing training, process improvement and participation in emergency and crisis response (both real and simulated), including emergency drills specific to potential incidents at the Pluto facility. Training includes task specific training and role based training and 'on the job' experience.

Woodside Hydrocarbon Spill Preparedness Advisor(s) are responsible for maintaining hydrocarbon spill preparedness competency. For more information see Section 7.14.

7.9.7 Subsea IMMR Activity Environmental Awareness

At the beginning of, and during a new Subsea IMMR activity, the Subsea Support Vessel crew including contractor crew, Woodside representatives and other relevant personnel are required to undertake a vessel induction before commencing work. This induction covers HSE requirements for the vessel and IMMR activities, and as required environmental information specific to the activity location. The induction may cover the following environmental information:

- adherence to standards and procedures, and the use of Job Safety Analysis and permit to work hazard identification and management process.

- spill management including prevention, response and clean-up, location of spill kits and reporting requirements.
- waste management requirements and location of bins
- reporting of marine fauna, location of forms and charts
- chemical management requirements.

All personnel who undertake the project induction are required to sign an attendance sheet which is retained.

Regular HSE meetings are held on Subsea Support Vessels with crew. During these meetings, any environmental incidents are reviewed, and environmental awareness material presented.

7.9.8 Management of Training Requirements

All personnel on the Pluto facility, MODU and project vessels are required to be competent to perform their assigned positions. This may be in the form of external or 'on the job' training. The vessel Safety Training Coordinator (or equivalent) is responsible for identifying training needs, keeping records of training performed and identifying minimum training requirements.

7.10 Monitoring, Auditing, Management of Non-conformance and Review

Regulation 22(5) states that the implementation strategy is to provide for the monitoring, audit, management of non-conformance and review of operator's environmental performance and the implementation strategy itself.

Regulation 22(6) further states that the implementation strategy is to provide for sufficient monitoring of, and maintaining a quantitative record of, emissions and discharges (whether occurring during normal operations or otherwise).

This section of the EP outlines the measures undertaken by Woodside to regularly monitor the management of environmental risks and impacts of the Pluto facility against the EPOs, EPSs and MC, with a view to continuous improvement of environmental performance. The section also outlines records that are to be used to assess whether the EPOs and EPSs in the environment plan are being met.

The effectiveness of the implementation strategy is also reviewed periodically as part of the monitoring and assurance process.

7.10.1 Monitoring

Woodside and its contractors will perform a program of periodic monitoring during the Petroleum Activities Program – starting at mobilisation of each activity and continuing through the duration of the Program. This information will be collected using the tools and systems outlined below, developed based on the EPOs, EPSs and MC in this EP. The tools and systems will collect, as a minimum, the data (evidence) referred to in the relevant measurement criteria.

The collection of this data will form part of the permanent record of compliance maintained by Woodside and will form the basis for demonstrating that the EPOs and EPSs are met, which will be summarised in a series of routine reporting documents.

Source-based Impacts and Risks

The tools and systems to monitor environmental performance, where relevant, will include:

- Daily reports which include leading indicator compliance.
- Periodic review of waste management and recycling records.

- Use of contractor's risk identification program that requires recording and submitting safety and environment risk observation cards routinely (frequency varies with contractor).
- Collection of evidence of compliance with the controls detailed in the EP relevant to offshore activities by the Woodside Offshore HSE Adviser (other compliance evidence is collected onshore).
- Environmental discharge reports that record volumes of planned overboard discharges to the ocean.
- Monitoring of progress against the Global Wells and Seismic and Operations Division scorecards for KPIs.

7.10.1.1 Internal auditing and assurance program

A summary of monitoring and quantitative records of emissions and discharges that will be kept and used to assess environmental performance is provided in Table 7-5.

Table 7-5: Summary of Operations emissions and discharges monitoring for the Petroleum Activities Program

Category	Parameter to be Monitored/Reported	Monitoring Frequency	Monitoring Equipment/Methodology	EP Reference
Planned Emissions				
Atmospheric emissions	Greenhouse, energy and criteria pollutants	Normally continuous process metering/annual reporting	NGERS and NPI reporting estimation methods (e.g. fuel/flare flow meters, throughput meters, process estimation)	Section 6.7.10
	Fuel gas and flare intensity	Normally continuous process metering/monthly reviews	Fuel and flare flowmeters inform intensity profiles – tracked against optimisation targets	Section 6.7.10
Planned Discharges				
Discharge of subsea control fluids during valve actuations	Subsea control fluid consumption	Normally continuous process indication/monthly review	Subsea control fluid consumption surveillance. Process indication for gross leaks/ruptures	Section 6.7.5
Discharge of hydrocarbons and chemicals during subsea IMMR activities	Volumes of hydrocarbons and chemicals released subsea	As required, during IMMR activities (activity specific)	Estimates based on known volumes pumped and ROV observation	Section 6.7.5
Discharge of produced water	Volume discharged overboard	Normally continuous process indication/monthly review	PW flow meter(s), process estimation	Section 6.7.7
	OIW concentration of discharged PW	Normally continuous process indication/monthly review	Online analyser(s) and/or manual sampling	
	Chemical characterisation	Annually	Characterisation of end of pipe sample	
	WET testing	Three yearly	PW ecotoxicity testing	

Category	Parameter to be Monitored/Reported	Monitoring Frequency	Monitoring Equipment/Methodology	EP Reference
Waste recycling and disposal	Quantities of solid and liquid wastes disposed of onshore	Ongoing	Facility waste manifest	Section 6.7.6
Unplanned Emissions and Discharges				
Unplanned emissions and discharges	Nature of release	As required	HSEQ Event Reporting System (First Priority)	Section 6.8 and 6.9.

Throughout this activity, Woodside will continuously identify new source-based risks and impacts through the Monitoring and Auditing systems and tools described above.

Other examples of assurance tasks implemented through the EP include (as an example);

- start of shift operations meetings;
- permit to work hazard, risk management check list, area sign-on, and permit audits (ISSoW – Section 7.2.1);
- technical integrity SCE performance reviews (daily, weekly, monthly) (Section 2.7.5);
- maintenance performance assurance (e.g. conformance dashboards);
- management system performance audits reviews (e.g. MSPSs); and
- data gathering and governance dashboard presentations (e.g. Woodside Integrated Risk and Compliance System).

7.10.1.2 Management of Knowledge

Review of knowledge relevant to the existing environment is undertaken in order to identify changes relating to the understanding of the environment or legislation that supports the risk and impact assessments for EPs (in-force and in-preparation). New knowledge checks take place both routinely primarily via quarterly and annual knowledge reviews and ad hoc (as information is obtained), and encompasses the following topics:

- Environmental science – update checks conducted via desktop reviews: scientific literature, government publications and Woodside supported publications and studies relating to existing environment topics (including but not limited to species and habitats) as well as EPBC Act Matters of National Environmental Significance (Part 3) and Part 13 statutory instruments.
- Cultural Features and Heritage Values science and information – update checks conducted via desktop reviews: scientific literature, government publications and Woodside consultation as well as reporting progress for the Murujuga Rock Art Monitoring Program.
- Socio-economic environment and stakeholder information – update checks conducted via desktop reviews: scientific literature, government publications and Woodside consultation; and,
- Environmental legislation – monitoring of emerging regulatory changes and the subsequent management of regulatory change (as outlined in the WMS Regulatory Compliance Management Procedure).

A management of knowledge tracker is maintained to record reviews and updates. New knowledge identified will prompt a consideration of MoC, which is actioned and documented appropriately.

The frequency and documentation of reviews, communication of relevant new knowledge and consideration of management of change are documented in the WMS Environment Plan Guideline.

Any relevant new information on cultural values and heritage will be assessed using the EP MoC Process (refer to Section 7.3.2).

Under the Oil Spill Scientific Monitoring Program preparedness, an annual review and update to the environmental baseline studies database is completed and documented. Periodic location-focused environmental studies and baseline data gap analyses are completed and documented. Any subsequent studies scoped and executed as a result of such gap analysis are managed by the Environment Science Team and tracked via the Corporate Environment Baseline Database.

Management of Newly Identified Impacts and Risks

New sources of impacts and risks identified through monitoring and auditing systems and tools and the Woodside Environment Knowledge Management System are assessed using the MoC Process (Section 7.3).

7.10.2 Auditing

Environmental performance auditing will be performed to:

- Identify potential new or changes to existing environmental impacts and risk, and methods for reducing those to ALARP.
- Confirm that mitigation measures detailed in this EP are effectively reducing environmental impacts and risk, that mitigation measures proposed are practicable and provide appropriate information to verify compliance.
- Confirm compliance with the Performance Outcomes, Controls and Standards detailed in this EP.

Internal environmental auditing will be performed to cover each key project activity as summarised.

7.10.2.1 Mobile Offshore Drilling Unit Activities

Internal auditing is performed on a MODU-specific schedule, rather than a schedule to align with the well. This enables continuous review and improvement of environmental performance over the term of the MODU contract. The following internal audits, inspections and reviews will be performed to review the environmental performance of the activities:

- Survey environment rig equipment for a newly contracted MODU (if not previously contracted to Woodside within the last two years) against Woodside's Engineering Standard – Rig Equipment. This standard covers functional and technical requirements for Woodside contracted rigs and their associated equipment. An environment rig equipment survey scope typically includes mud and solids control systems, environmental discharge control (including drainage management), and loss of containment management.
- Complete a minimum of monthly environmental inspection (conducted by offshore Woodside personnel or a delegate) which may include verifying:
  - bunkering/transfers between support vessels and MODU/project vessels
  - environment containment including chemical storage, spill response equipment and housekeeping
  - general MODU environment risks including waste management, drilling fluids oil/water separation, and inspection of subsea and moonpool areas.
- Perform environment audits quarterly during the Petroleum Activities Program, while the MODU is on location (by a Woodside Environment Adviser or delegate), which may include:
  - operational compliance audits relevant to environmental risk of activities which may include compliance with training commitments, discharge requirements, bunkering

activities, verification of use of approved chemicals, and satisfactory close out of items from previous audits

- inspection of selected risk areas/activities (which may include shaker house, drill floor and mud management while commencing riser drilling or reservoir interception) during routine MODU visits throughout the MODU campaign, determined by risk, previous incidents or operation specification requirements.
- audit findings relevant to continuous improvement of environmental performance will be tracked through the MODU or vessel compliance action register, a contractor register between the MODU operator or vessel contractor and Woodside.

7.10.2.2 Project Subsea Scope Activities

The following internal assurance will be performed for the subsea scope activities:

- Pre-mobilisation inspection/audit report will be conducted by a relevant person (before commencing). The scope of the audits are risk-based and specific to the relevant activity, but will generally focus on aspects relating to ensuring appropriate understanding of environmental commitments and the operational readiness of the activity scope, including appropriate environmental controls in place. All installation vessels associated with the above scopes will be audited by Woodside. Support or transport vessels will be assessed on a risk-based approach, but will be audited via the primary subsea installation contractor's process.
- At least one compliance audit relevant to applicable EP commitments will be conducted by a Woodside Environment Adviser for the subsea campaign. The audit may be conducted offshore or office-based, subject to the duration of the activity and logistics of performing the audit offshore for short duration scopes (e.g. pipelay).
- Contractor-specific HSE audits will also be conducted of the associated support vessels. The audits will consider the implementation of HSE management, risk management, as well as pre-mobilisation and offshore readiness.
- Vessel based HSE inspections will be conducted fortnightly by vessel HSE personnel. Each inspection will focus on a specific risk area relevant to the project activity and a formal report will be issued (for example, bunkering controls, chemical and discharge management, cetacean reporting, etc).
- Annual inspection of Woodside's long term hire subsea support vessels are undertaken fore compliance with both the EP and the approved Contractor Management system.
- The internal audits and reviews, combined with the ongoing monitoring described in Section 7.10.1, and collection of evidence for MC are used to assess EPOs and standards.
- As part of Woodside's EMS and/or assurances processes, activities may also be periodically selected for environmental audits as per Woodside's internal auditing process. Audit, inspection and review findings relevant to continuous improvement of environmental performance are tracked through the Environmental Commitments and Actions Register.
- This Environmental Commitments and Actions Register is used to track subsea support vessel and subsea activity compliance with EP commitments, including any findings and corrective actions.

Non-conformances identified will be reported and/or tracked in accordance with Section 7.10.3.

7.10.2.3 Operations Assurance

To provide confidence, based on evidence commensurate with risk, that business objectives are met, business activities are performed and risks are managed, assurance is performed as described

in the Provide Assurance Procedure and the Provide Assurance Guideline. The Guideline aims to explain how the Operations Division Assurance Team implement WMS Assurance requirements, while concurrently satisfying the Operations Division's specific objectives.

Operations Assurance Assignments are contained within the Operations Division Integrated Assurance Assignment Plan.

Environmental assurance activities are conducted on a regular basis to help:

- verify environmental risks and potential impacts are being managed in accordance with the EPOs and EPSs detailed in this EP.
- monitor, review and evaluate the effectiveness of the performance outcomes and standards detailed in this EP.
- verify effectiveness of the EP implementation strategy
- identify potential non-conformances.

The outputs of the assurance process are corrective actions that feed the improvement process. Therefore, assurance is a key driver of continuous improvement.

7.10.2.4 Annual Offshore Inspection/Desktop Review

An inspection/review of the Pluto offshore facility is undertaken every calendar year by the Australian Operations Environment Team, via either an offshore inspection or desktop review. Selected risk areas/activities are inspected to review environmental performance against the EPOs and EPSs and verify that control measures are effective in reducing the environmental risks and impacts of the activity to an ALARP and acceptable level.

The inspection/review also includes review of conformance with selected aspects of the EP implementation strategy. All risk sources/activities applicable to the offshore facility will be reviewed over a three-year rolling period. Records of findings and records of close-out of any corrective or improvement actions are maintained (close-out is tracked in Woodside's action tracking system).

7.10.2.5 Marine Assurance

Woodside's marine assurance is managed by the Marine Assurance Team of the Logistics Function in accordance with Woodside's Marine Offshore Vessel Assurance Procedure. The Woodside process is based on industry standards and consideration of guidelines and recommendations from recognised industry organisations such as Oil Companies International Marine Forum and International Maritime Contractors Association.

Woodside's Marine Offshore Assurance process is mandatory for all vessels (other than Tankers and Floating Production Storage and Offloading vessels) that are chartered directly by or on behalf of Woodside, including for short term hires (i.e. <3 months in duration). It defines applicable marine offshore assurance activities, ensuring all vessel operators operate seaworthy vessels that meet the requirements for a defined scope of work and are managed with a robust Safety Management System.

The process is multi-faceted and encompasses the following marine assurance activities:

- Safety Management System Assessment
- Dynamic Positioning (DP) System Verification
- Vessel Inspections
- Project support for tender review, evaluation and pre/post contract award.

Vessel inspections are used to verify actual levels of compliance with the company's Safety Management System, the overall condition of the vessel and the status of the planned maintenance system onboard. Woodside Marine Assurance Specialist will conduct a risk assessment on the vessel to determine the level of assurance applied and the type of vessel inspection required.

Methods of vessel inspection may include, and are not limited to:

- Woodside Marine Vessel Inspection
- Oil Companies International Marine Forum (OCIMF) Offshore Vessel Inspection Database (OVID) Inspection
- IMCA CMID Inspection
- Marine Warranty Survey

Upon completion of the marine assurance process, to confirm that identified concerns are addressed appropriately and conditions imposed are managed, the Woodside Marine Assurance Team will issue the vessel a statement of approval. Should a vessel not meet the requirements of the Woodside Marine Offshore Vessel Assurance Process and be rejected, there does exist an opportunity to further scrutinise the proposed vessel.

Where a vessel inspection and/or OVMSA Verification Review is not available and all reasonable efforts based on time and resource availability to complete an vessel inspection and/or OVMSA Verification Review are performed (i.e. short term vessel hire), the Marine Assurance Specialist Offshore may approve the use of an alternate means of inspection, known as a risk assessment (Section 7.10.2.6).

Environmental requirements specific to offshore facility support vessel contractors are communicated via Woodside marine charterers instructions. This document provides the Master of a vessel on hire to Woodside, with a clearly defined set of requirements and procedures for operating the vessel in the vicinity of the Woodside's operating facilities. This includes the management of environmental risks and impacts from the Pluto facility. The document includes information on:

- applicable legislation and guidelines
- roles and responsibilities
- marine fauna interaction guidance
- incident reporting requirements.

Environmental requirements specific to Subsea Support Vessels are communicated via the Subsea Environmental Compliance Package. This document outlines mandatory environmental management requirements for Subsea Support Vessels and associated contractors.

7.10.2.6 Vessel Risk Assessment

Woodside conducts a risk assessment of vessels where either an OVMSA Verification Review and/or vessel inspection cannot be completed. This is not a regular occurrence and is typically used when the requirements of the assurance process are unable to be met or the processes detailed are not applicable to a proposed vessel(s). The Marine Vessel Risk Assessment will be conducted by the Marine Assurance Specialist, where the vessel meets the short term hire prerequisites.

The risk assessment is a semi-quantitative method of determining what further assurance process activity, if any, is required to assure a vessel for a particular task or role. The process compares the level of management control a vessel is subject to against the risk factors associated with the activity or role.

Several factors are assessed as part of a vessel risk assessment, including:

- Management control factors:
  - Company audit score (i.e. management system)
  - vessel HSE incidents
  - vessel Port State Control deficiencies
  - instances of Port State Control vessel detainment
  - years since previous satisfactory vessel inspection
  - age of vessel
  - contractors' prior experience operating for Woodside.
- Activity risk factors:
  - people health and safety risks (a function of the nature of the work and the area of operation)
  - environmental risks (a function of environmental sensitivity, activity type and magnitude of potential environment damage (e.g. largest credible oil spill scenario))
  - value risk (likely time and cost consequence to Woodside if the vessel becomes unusable)
  - reputation risk
  - exposure (i.e. exposure to risk based on duration of project)
  - industrial relations risk.

The acceptability of the vessel or requirement for further vessel inspections or audits is based on the ratio of vessel score to activity risk. If the vessel management control is not deemed to appropriately manage activity risk, a satisfactory company audit and/or vessel inspection may be required before awarding work.

The risk assessment is valid for the period a vessel is on hire and for the defined scope of work.

7.10.3 Management of Non-conformance

Woodside classifies non-conformances with EPOs and standards in this EP as environmental incidents. Woodside employees and contractors are required to report all environmental incidents, and these are managed as per Woodside's internal event recording, investigation and learning requirements.

An internal computerised database called First Priority is used to record and report these incidents. Details of the event, immediate action taken to control the situation, investigation outcomes and corrective actions to prevent reoccurrence are all recorded. Corrective actions are monitored using First Priority and closed out in a timely manner.

Woodside uses a consequence matrix for classification of environmental incidents, with the significant categories being A, B and C (as detailed in Section 2.3). Detailed investigations are completed for all categories A, B, C and high potential environmental incidents.

7.10.4 Review

7.10.4.1 Management Review

Within the Australian Operations Environment Team, senior management regularly monitor and review environmental performance and the effectiveness of managing environmental risks and performance. Within each Function and Business Unit Leadership Team (e.g. Drilling and

Completions, Subsea and Developments/Projects), managers review environmental performance regularly, including through quarterly HSE review meetings.

Woodside's Global, Wells and Seismic Environment Team will perform six-monthly reviews of the effectiveness of the implementation strategy and associated tools. This will involve reviewing the:

- Drilling and Completions environment KPIs (leading and lagging).
- Tools and systems to monitor environmental performance
- Lessons learned about implementation tools and throughout each campaign.

Reviews of oil spill arrangements and testing are performed in accordance with Section 7.12.9.1.

Woodside's Operations Division Environment Team will perform routine reviews of the effectiveness of the implementation strategy and associated tools. This will involve reviewing the:

- Operations Division environment KPIs (leading and lagging).
- Tools and systems to monitor environmental performance

Reviews of oil spill arrangements and testing are performed in accordance with Section 7.12.9.1.

7.10.4.2 Program of Ongoing Engagement with Traditional Custodians

Woodside will undertake an annual review of the Program of Ongoing Engagement with Traditional Custodians to determine its effectiveness and adapt the program accordingly. The annual review will also include an assessment of appropriateness of the methods used to undertake ongoing consultation with Traditional Custodians (Appendix G).

7.10.4.3 Learning and Knowledge Sharing

Learning and knowledge sharing occurs via a number of different methods including:

- Event investigations.
- Event bulletins.
- After action review conducted at the end of each well, including review of environmental incidents as relevant.
- Ongoing communication with MODU and facility operators.
- Formal and informal industry benchmarking.
- Cross asset learnings.
- Engineering and technical authorities discipline communications and sharing.
- Review of impacts, risks and controls across the life of the EP.

7.10.4.4 Continuous Improvement

Continuous Improvement Projects to improve production or environmental performance that involve refurbishment, modification or major maintenance on the facility are typically managed by Brownfields engineering, and required to follow appraise and develop management procedures. Currently, the Procedure requires that all projects be managed in accordance with the Opportunity Management Framework which supports the progressive maturation of an opportunity through value creation in the Assess and Select Phases and the maintenance of value in the Develop and Execute phases.

To support the accountable executive to make a decision on whether a project should proceed to the next phase in the Opportunity Management Framework, it is sometimes necessary to conduct a

trial of the modification to determine the outcomes that can be expected if the modification is implemented. Due to prioritisation of resources, the phased progress of opportunities, competition between different solutions and long-term strategic and financial considerations, it is not possible to set quantitative success criteria to determine whether a modification will be implemented based on the results of trials. Instead, the results of a trial are used to inform a decision on whether to progress the project to the next phase in the Opportunity Management Framework. Decisions are typically made with two key considerations; whether the business is ready to proceed which has a technical/functional focus and whether there is a business case for progressing to the next phase. The business case may consider the ALARP position for the project, if relevant.

7.11 Record Keeping

Compliance records (outlined in MCs in Section 6) are maintained.

Record keeping is in accordance with Regulation 22(6) that addresses maintaining records of emissions and discharges. See also Table 7-5.

7.12 Ongoing Consultation

Although consultation for the purpose of regulation 25 is complete, in accordance with regulation 22(15) of the Environment Regulations, the implementation strategy must provide for appropriate consultation with relevant authorities of the Commonwealth, a State or Territory and other relevant interested persons or organisations.

Woodside proposes to undertake the engagements with directly impacted relevant persons and additional persons listed in Table 7-7. Relevant new information identified during ongoing consultation will be assessed using the EP Management of Knowledge (refer to Section 7.10 and Management of Change Process (refer to Section 7.2.5).

Woodside hosts community forums at which members are provided updates on Woodside activities on a regular basis (for example community reference group meetings). Representatives who present at those meetings are from community and industry and include Woodside, State Government (for instance relevant Regional Development Commissions), Local Government, Indigenous Groups, industry representative bodies, Community and industry organisations.

Relevant persons and those who are simply interested in the activities, can otherwise remain up to date on this activity through subscribing to our website the Woodside website, or by reading the publicly available version of the EP on NOPSEMA's website, where available.

Should consultation feedback be received following EP acceptance that identifies relevant new information or a measure or control that requires implementation or update to meet the intended outcome of consultation (see Section 5.2), Woodside will apply its EP Management of Knowledge process (refer to Section 7.8.1.2) and MoC process (refer to Section 7.2.5), as appropriate.

Woodside has developed a Program of Ongoing Engagement with Traditional Custodians (Appendix G), which is compliant with Corporate Woodside Policies Strategies and procedures and directly informed by feedback from Traditional Custodians. It provides a mechanism for ongoing dialogue so that Traditional Custodians can, on an ongoing basis, provide Woodside with feedback relating to the activity and in relation to caring for and managing country, including Sea Country. The Program will be tailored to each Traditional Custodian group and may include, as agreed with relevant Traditional Custodians:

- social investment to support Indigenous ranger programs
- support for Indigenous oil spill response capabilities
- support for recording Sea Country values

- support to Traditional Custodian groups to build capabilities and capacity with respect to ability to engage with Woodside and the broader O&G industry on activities
- development of ongoing relationships with Traditional Custodian groups
- any other initiatives proposed for the purpose of protecting Country including cultural values.

At the time of EP submission, a number of activities related to ongoing consultation regarding the activity are planned with Traditional Custodian Relevant Persons. These are described in Appendix G. Where Traditional Custodian relevant persons have requested information or further engagement considered as ongoing consultation, but have not requested a consultation agreement, these requests have been captured in Table 7-7. However, a consultation agreement may still be initiated by these groups at any time.

Table 7-6: Ongoing consultation engagements

Report/ Information	Recipient	Purpose	Frequency	Content
Program of Ongoing Engagement with Traditional Custodians	Relevant cultural authorities	Identification, assessment and consideration of cultural values relevant to the PAA and EMBA.	Ongoing	Assessment of cultural values. Any relevant new information on cultural values will be assessed using the EP Management of Knowledge and Management of Change Process (refer to Section 7.3.2).
Notification (email) Updates (email)	AHO	As requested by AMSA during consultation.	No less than 4 weeks prior to commencement. As required.	PS 1.9 Date of activity start. Changes to planned activities
Notification (email) Update (email)	AMSA	As requested by AMSA during consultation	At least 24-48 hours before operations commence. As required.	PS 1.10 Date of activity start. Changes to planned activities
Notification (email)	Other relevant persons	Notification of significant change	As required	Notification of significant change
Notification (email)	AFMA WAFIC CFA DAFF – Fisheries KUFPEC		No less than 10 days prior to commencement and following completion of activities.	Date of activity start and end.
Emails/ Meetings	Persons or organisations who provide feedback to Woodside post EP submission.	Identification, assessment and consideration of feedback, claims and/ or objections	As appropriate	Assessment of claims and/ or objections. Relevant new information will be assessed using the EP Management of Knowledge and MoC Process (refer to Section 7.3.2).

Notification (email)	Australasian Underwater Cultural Heritage Database Any other stakeholders as required in the Unexpected Finds Procedure	Report any unexpected finds of potential Underwater Cultural Heritage.	If triggered by Unexpected Finds Procedure.	Refer to Unexpected Finds Procedure.

7.13 Reporting

7.13.1 Overview

To meet the EPOs and EPSs outlined in this EP, Woodside reports at a number of levels, as outlined in the next sections.

7.13.2 Routine Reporting (Internal)

7.13.2.1 Daily Progress Reports and Meetings

The following daily reports, containing environmental performance information are issued:

- Daily reports for drilling activities provide performance information about drilling activities, heath, safety and environment, and current and planned work activities.
- Pan-Woodside Daily Production Report – The report includes facility performance information on production and a log of any HSE events.
- Subsea support vessel Daily Progress Report(s) – During subsea IMMR activities, daily reports are issued by the Woodside Site Representative. The reports provide performance information on HSE events, diesel use, together with equipment information, current and planned work activities.

Meetings between key personnel are used to transfer information, discuss incidents, agree plans for future activities and develop plans and accountabilities for resolving issues.

7.13.2.2 Regular HSE Meetings

Regular dedicated HSE meetings are held with the offshore and Perth-based management and advisers to address targeted HSE incidents and initiatives. Minutes of these meetings are produced and distributed as appropriate.

7.13.2.3 Performance Reporting

Monthly and quarterly performance reports are developed and reviewed by the Function and Business Unit Leadership Teams (e.g. Drilling and Completions, Operations). These reports cover a number of subject matters, including:

- HSE incidents (including high potential incidents and those related to this EP) and recent activities.
- Corporate KPI targets, which include environmental metrics.
- Outstanding actions as a result of audits or incident investigations.
- Technical high and low lights.
- status of subsea IMMR activities.

7.13.3 Routine Reporting (External)

7.13.3.1 Start and End Notifications of the Petroleum Activities Program

7.13.3.1.1 Pluto Operations

In accordance with Regulation 54, Woodside will notify NOPSEMA within ten days of the completion of the Petroleum Activities Program.

The EP will end when Woodside notifies NOPSEMA that the Petroleum Activities Program has ended, all of the obligations identified in this EP have been completed, and NOPSEMA has accepted the notification, in accordance with Regulation 46 of the Environment Regulations.

The Petroleum Activities Program is not expected to end within the five-year life of this EP.

7.13.3.1.2 Xena-03 Drilling and Tie-back

In accordance with Regulation 54, Woodside will notify NOPSEMA of the commencement of the Petroleum Activities Program at least ten days before the activity commences, and will notify NOPSEMA within ten days of completing the activity.

7.13.3.2 Cetacean and Whale Shark Sightings Reporting

In accordance with EPBC Act approval conditions for the activity (refer Table 1-4), Woodside will keep a record of any cetacean and whale shark sightings for the life of this EP. A sightings report will be submitted to the Australian Antarctic Division annually with the reporting period being by calendar year (see also Table 7-7).

7.13.3.3 Environmental Performance Review and Reporting

In accordance with applicable environmental legislation for the activity, Woodside is required to report information on environmental performance to the appropriate regulator. Regulatory reporting requirements are summarised in Table 7-7.

Table 7-7: Routine external reporting requirements

Report	Recipient	Frequency	Content
Monthly Recordable Incident Reports	NOPSEMA	Monthly, by 15 of each month	Details of recordable incidents that have occurred during the Petroleum Activities Program for previous month (if applicable).
Annual EP Performance Report	NOPSEMA	Annual, by 30 April of the year following reporting period	Compliance with EPOs, controls and standards outlined in this EP, in accordance with the Environment Regulations (regulation 22(7).
NPI Report	DCCEEW	Annual, by 30 September each year	Summary of the emissions to land, air and water including those from the facility. Reporting period 1 July to 30 June each year.
National Greenhouse and Energy Reporting (NGERS)	Clean Energy Regulator	Annual, by 31 October each year	Summary of energy use and greenhouse gas emissions including those from the facility. Reporting period is 1 July to 30 June each year.
Cetacean and Whale Shark Sightings Report	Australian Antarctic Division	Annually, by 31 January each year	Summary of any sightings of cetaceans or whale sharks. Reporting period is 1 Jan to 31 December.

7.13.3.4 End of the Petroleum Activities Program Notification

In accordance with Regulation 54, Woodside will notify NOPSEMA within ten days of the completion of the Petroleum Activities Program.

7.13.3.5 End of the Environment Plan

The EP will end when Woodside notifies NOPSEMA that the Petroleum Activities Program has ended, all of the obligations identified in this EP have been completed, and NOPSEMA has accepted the notification, in accordance with Regulation 46 of the Environment Regulations. As noted above, the Petroleum Activities Program is not expected to end within the five-year life of this EP.

7.13.4 Incident Reporting (Internal)

All Woodside employees and contractors are required to report environmental incidents and non-conformances with this EP. Incidents are reported using an Event Report Form which includes details of the event, immediate action taken to control the situation, and corrective actions to prevent reoccurrence.

7.13.5 Incident Reporting (External) – Reportable and Recordable

7.13.5.1 Reportable Incidents

A reportable incident is defined under Regulation 5 of the Environment Regulations as:

- ‘an incident relating to the activity that has caused, or has the potential to cause, moderate to significant environmental damage’.

A reportable incident for the Petroleum Activities Program is:

- An incident that has caused environmental damage with a Consequence Level of Moderate C+ or above (as defined under Woodside’s Risk Table; refer to Section 2.2).
- An incident that has the potential to cause environmental damage with a Consequence Level of Moderate C+ or above (as defined under Woodside’s Risk Table – refer to Section 2.6).

The environmental risk assessment (Section 6) for the Petroleum Activities Program identifies those risks with a potential consequence level of C+ for environment. The incidents that have the potential to cause this level of impact include hydrocarbon loss of containment events to ocean resulting from either:

- Well loss of containment (MEE-01)
- Subsea equipment loss of containment (MEE-02)
- Loss of structural integrity (MEE-03)
- Loss of marine vessel separation with platform (MEE-04)
- Loss of control of suspended load from platform (MEE-05)
- Unplanned Hydrocarbon Release: Loss of Well Integrity during Drilling Operations.

Any such incidents represent potential events which would be reportable incidents. Reporting of incidents is undertaken with consideration of NOPSEMA (2014) guidance stating, ‘if in doubt, notify NOPSEMA’, and assessed on a case-by-case basis to determine if they trigger a reportable incident as defined in this EP and by the regulations.

7.13.5.1.1 Notification

NOPSEMA will be notified of all reportable incidents, according to the requirements of Regulations 47, 48 and 49 of the Environment Regulations. Woodside will:

- Report all reportable incidents to the regulator (orally) as soon as practicable (ASAP), but within two hours of the incident or of its detection by Woodside.
- Provide a written record of the reported incident to NOPSEMA, the National Offshore Petroleum Titles Administrator (NOPTA) and the Department of the responsible State Minister (DMIRS) ASAP after orally reporting the incident.
- Complete a written report for all reportable incidents using a format consistent with the NOPSEMA Form FM0831 – Reportable Environmental Incident which must be submitted to NOPSEMA ASAP, but within three days of the incident or of its detection by Woodside.
- Provide a copy of the written report to the NOPTA and DMIRS, within seven days of the written report being provided to NOPSEMA.

AMSA will be notified of oil spill incidents ASAP after their occurrence, and DCCEEW notified if MNES are to be affected by the oil spill incident.

7.13.5.2 Recordable Incidents

A recordable incident is defined under Regulation 5 of the Environment Regulations as a 'breach of an EPO or EPS, in the EP that applies to the activity, that is not a reportable incident'.

Any breach of the EPOs or EPSs (as presented within Section 6) will be raised as a recordable incident and managed as per the notification and reporting requirements outlined below and internal requirements outlined in Section 7.11.4.

7.13.5.2.1 Notification

NOPSEMA will be notified of all recordable incidents, according to the requirements of Regulation 50(2), no later than 15 days after the end of the calendar month using the NOPSEMA Form – Recordable Environmental Incident Monthly Summary Report detailing:

- All recordable incidents that occurred during the calendar month.
- All material facts and circumstances concerning the recordable incidents that the operator knows or is able, by reasonable search or enquiry, to find out.
- Any action taken to avoid or mitigate any adverse environment impacts of the recordable incidents.
- The corrective action that has been taken, or is proposed to be taken, to prevent similar recordable incidents.
- The action that has been taken, or is proposed to be taken, to prevent a similar incident occurring in the future.

7.13.5.3 Other External Reporting Requirements and Notifications

In addition to the notification and reporting of environmental incidents defined under the Environment Regulations and Woodside requirements, Table 7-8 describes the incident reporting requirements that also apply in the PAA if a spill originates from a vessel.

Table 7-8: External Incident Reporting Requirements

Event	Responsibility	Notifiable party	Notification requirements	Contact	Contact detail
Any marine incidents during Petroleum Activities Program	Vessel Master	AMSA	Incident Alert Form 18 as soon as reasonably practicable* Within 72 hours after becoming aware of the incident, submit Incident Report Form 19	AMSA	reports@amsa.gov.au
Oil pollution incidents in Commonwealth waters	Vessel Master	AMSA Rescue Coordination Centre (RCC)	As per Article 8 and Protocol I of MARPOL within two hours via the national emergency 24-hour notification contacts and a written report within 24 hours of the request by AMSA	AMSA RCC Australia	If the ship is at sea, reports are to be made to: Free call: 1800 641 792 Phone: 08 9430 2100 (Fremantle)
Oil pollution incidents in Commonwealth waters	Vessel Master	AMSA	Without delay as per Protection of the Sea Act, part II, section 11(1), AMSA RCC notified verbally via the national emergency 24-hour notification contact of the hydrocarbon spill; follow up with a written Pollution Report ASAP after verbal notification	RCC Australia	Phone: 1800 641 792 or +61 2 6230 6811 AFTN: YSARYCYX
Any oil pollution incident which has the potential to enter a National Park or requires oil spill response activities to be conducted within a National Park	Vessel Master	DCCEEW	Reported verbally, ASAP	Director of National Parks	Phone: 02 6274 2220
Activity causes unintentional death of or injury to fauna species listed as Threatened or Migratory under the EPBC Act	Vessel Master	DCCEEW	Within seven days of becoming aware	Secretary of the DCCEEW	Phone: 1800 803 772 Email: protected.species@environment.gov.au

7.14 Emergency Preparedness and Response

7.14.1 Overview

Under Regulation 22(8), the implementation strategy must contain an oil pollution emergency plan (OPEP) and provide for the updating of the OPEP. Regulation 22(9) outlines the requirements for the OPEP which must include adequate arrangements for responding to and monitoring of oil pollution.

A summary of how this EP and supporting documents address the various requirements of Environment Regulations relating to oil pollution response arrangements is shown in Table 7-9.

Table 7-9: Oil Pollution Preparedness and Response Overview

Content	Environment Regulations Reference	Document/Section Reference
Details (oil pollution response) control measures that will be used to reduce the impacts and risks of the activity to ALARP and an acceptable level	Regulation 21 (5), (6), 22 (2)	Oil Spill Preparedness and Response Mitigation Assessment
Describes the OPEP	Regulation 22 (8)	EP: Section 7.9. Woodside's oil pollution emergency plan has the following components: Woodside Oil Pollution Emergency Arrangements (Australia) Pluto Operations Oil Pollution First Strike Plan Xena-03 Tie-back Oil Pollution First Strike Plan Oil Spill Preparedness and Response Mitigation Assessment
Details the arrangements for responding to and monitoring oil pollution (to inform response activities), including control measures	Regulation 22 (9)	Oil Spill Preparedness and Response Mitigation Assessment Pluto Operations Oil Pollution First Strike Plan Xena-03 Tie-back Oil Pollution First Strike Plan
Details the arrangements for updating and testing the oil pollution response arrangements	Regulation 22 (8)(12)(13)(14)	Environment Plan: Section 7.12.9 Oil Spill Preparedness and Response Mitigation Assessment
Details provisions for monitoring impacts to the environment from oil pollution and response activities	Regulation 22(10)	Oil Spill Preparedness and Response Mitigation Assessment
Demonstrates that the oil pollution response arrangements are consistent with the national system for oil pollution preparedness and control	Regulation 22(11)	Oil Pollution Emergency Arrangements (Australia).

7.14.2 Emergency Response Training

Regulation 22(4) requires that the implementation strategy includes measures to ensure that employees and contractors have the appropriate competencies and training. Woodside has conducted a risk based training needs analysis on positions required for effective emergency response (Table 7-10).

Table 7-10: Emergency Response Training Requirements

IMT Position	Minimum Competency
Corporate Incident Management Team (CIMT) Incident Commander and Deputy Incident Commander	• IMT Fundamentals Course (internal course) or equivalent • ICS 100/200 • IMO3 or equivalent spill response specialist level with an oil spill response organisation (OSRO) • Participation in L2 activation, exercise or skills maintenance
Operations, Planning, Logistics and Finance Sections, and other rostered members of the CIMT	• IMT Fundamentals Course or equivalent • ICS 100/200 • Oil spill theory • Participation in L2 activation, exercise or skills maintenance
Environment Unit Leader	• IMT Fundamentals Course • ICS 100/200 • IMO2 or equivalent spill response specialist level with an OSRO • Participation in L2 activation, exercise or skills maintenance
Note on competency/equivalency	
In 2023, Woodside undertook a review of incident and crisis systems, processes and tools to assess whether these were fit-for purpose and has rolled out a change to the Crisis and Emergency Management training and the oil spill response training requirements for IMT roles. The revised IMT Fundamentals training Program aligns with the performance requirements of the PMAOMIR320 – Manage Incident Response Information and PMAOM0R418 - Coordinate Incident Response. In 2023, Woodside took the decision to align its global incident command arrangements to the Incident Command System (ICS). As such all rostered members of the Incident Management Team are trained up to ICS 200. In addition to baseline incident management training, all rostered members of the CIMT undertake a level of hydrocarbon spill response training. Depending upon the role, this may take the form of IMO training or completion of Woodside's internal oil spill training course (OSREC) which involves the completion of two online AMSA Modules (Introduction to National Plan and Incident Management; and Introduction to Oil Spills) and face-to-face training. Woodside Learning Services (WLS) are responsible for collating and maintaining personnel training records. The HSP Dashboard reflects the competencies required for each oil spill role (IMT/operational).	

7.14.3 Emergency Response Preparation

The Corporate Incident Management Team (CIMT) based in Woodside's head office in Perth, is the onshore coordination point for an offshore emergency. The CIMT is staffed by a roster of appropriately skilled personnel available on call 24 hours a day. The CIMT, under the leadership of the CIMT Leader, supports the site-based Incident Management Team by providing additional support in areas such as operations, logistics, planning, people management and public information (corporate affairs). A description of Woodside's Incident Command Structure and arrangements is further detailed in the Woodside Oil Pollution Emergency Arrangements (Australia).

Woodside will have a number of Emergency Response Plans (ERP) in place relevant to the PAP. The ERP provides procedural guidance specific to the asset and location of operations to control, coordinate and respond to an emergency or incident.

For the tie-back activity, the ERP will be a bridging document to the contracted rig's emergency documentation. This document summarises the emergency command, control and communications processes for the integrated operation and management of an emergency. It is developed in collaboration with the contracted rig so that roles and responsibilities between the contracted rig and Woodside personnel are identified and understood. The ERPs will contain instructions for vessel emergency, medical emergency, search and rescue, reportable incidents, incident notification, contact information and activation of the contractor's emergency centre and Woodside Communication Centre (WCC). Electronic copies of the ERPs are available on the facility Virtual

Bookshelves and the Security and Emergency Management intranet page. Hard controlled copies are available on the facilities.

In addition, the Emergency Preparedness MSPS (M06) is in place to assure that in the event of an incident, the organisation is appropriately prepared for all necessary actions which may be required for the protection of People, Environment, Asset, Reputation and Livelihood.

7.14.4 Emergency Event During Tie-back Activity

In the event of an emergency of any type:

- On the MODU the OIM will assume overall onsite command and act as the Incident Controller (IC). All persons aboard the MODU will be required to act under the IC's directions. The MODU/vessels will maintain communications with the onshore Drilling Superintendent and/or other emergency services in the event of an emergency. Emergency response support can be provided by the contractor's emergency centre or WCC if requested by the IC.
- Vessel Master (depending on the location of the emergency) will assume overall onsite command and act as the IC. All persons will be required to act under the IC's directions. The vessels will maintain communications with the onshore project manager and/or other emergency services in the event of an emergency. Emergency response support can be provided by the contractor's emergency centre or WCC if requested by the IC.
- The MODU and project vessels will have on-board equipment for responding to emergencies including medical equipment, fire-fighting equipment and oil spill response equipment.

7.14.5 Initial Response to Facility Incident

The facility is equipped with emergency shutdown systems designed to protect personnel, the facility and the environment from unsafe operating conditions and catastrophic situations.

Emergency shutdown systems are provided as a means of isolation in response to process upsets and facility conditions (including associated flowlines and risers) that could result in loss of hydrocarbon inventories, or to reduce the potential impact from a hydrocarbon loss of containment event on the facility. Provision has been made for process and facility alarm systems to provide early indication of any process upset conditions and potential hazardous events, including fire and gas alarms.

The key ERP relevant to the facility and subsea infrastructure (excluding the export pipeline) is the Pluto Emergency Response Plan. This plan covers health, safety, asset and environmental risks (including fire, structural integrity, sabotage, etc.) so that the range of occupational, asset and environmental risk exposures from incidents have been considered and plans are in place for their management. The plan provides specific details on the initial response required during events with potential significant environmental consequences such as a hydrocarbon spill, subsea hydrocarbon leak or potential collision.

The Pipelines Emergency Response Plan covers key ERP relevant to the export pipeline, as well as other major pipelines on Woodside's NWS facilities. The Pluto. Vessels will have SOPEPs in accordance with the requirements of MARPOL 73/78 Annex I. These plans outline responsibilities, specify procedures and identify resources available in the event of a hydrocarbon or chemical spill from vessel activities. The Pluto Operations Oil Pollution First Strike Plan is intended to work in conjunction with the SOPEPs, if hydrocarbons are released to the marine environment from a vessel.

Woodside has established EPOs, EPSs and MC to be used for hydrocarbon spill response during the Petroleum Activities Program.

7.14.6 Oil and Other Hazardous Materials Spill

A significant hydrocarbon spill during the Petroleum Activities Program is unlikely, but should such an event occur, it has the potential to cause serious environmental and reputational damage if not managed properly. The Woodside Oil Pollution Emergency Arrangements (Australia) document, supported by the Oil Pollution First Strike Plan which provides tactical response guidance to the activity/area and Oil Spill Preparedness and Response Strategy Selection and Evaluation of this EP, cover spill response for this Petroleum Activities Program.

The Security and Emergency Management Function is responsible for the management of Woodside's hydrocarbon spill response equipment and for the maintenance of hydrocarbon spill preparedness and response documentation. In the event of a major spill, Woodside will request that AMSA (administrator of the National Plan) provides support to Woodside through advice and access to equipment, people and liaison. The interface and responsibilities, as defined under the National Plan, are described in the Oil Pollution Emergency Arrangements (Australia). AMSA and Woodside have a Memorandum of Understanding in place to support Woodside in the event of a hydrocarbon spill.

The Oil Pollution First Strike Plan provides immediate actions required to commence a response.

The MODU and project vessels will have SOPEPs in accordance with the requirements of MARPOL 73/78 Annex I. These plans outline responsibilities, specify procedures and identify resources available in the event of a hydrocarbon or chemical spill from vessel activities. The Oil Pollution First Strike Plan is intended to work in conjunction with the SOPEPs, if hydrocarbons are released to the marine environment from a vessel.

Woodside has established EPOs, performance standards and MC to be used for oil spill response during the Petroleum Activities Program.

7.14.7 Emergency and Spill Response

Woodside categorises incidents in relation to response requirements as follows:

7.14.7.1 Level 1 Incident

A Level 1 incident can be resolved through the use of existing resources, equipment and personnel. A Level 1 incident is contained, controlled and resolved by site / regionally based teams using existing resources and functional support services.

7.14.7.2 Level 2 Incident

A Level 2 incident is characterised by a response that requires external operational support to manage the incident. It is triggered in the event the capabilities of the tactical level response are exceeded. This support is provided to the activity via the activation of all, or part of, the responsible CIMT.

7.14.7.3 Level 3 Incident

A Level 3 incident or crisis is identified as a critical event that seriously threatens the organisation's People, the Environment, company Assets, Reputation, or Livelihood. At Woodside, the Crisis Management Team (CMT) manages the strategic impacts in order to respond to and recover from the threat to the company (material impacts, litigation, legal and commercial, reputation etc.). The CIMT may also be activated as required to manage the operational incident response.

7.14.8 Emergency and Spill Response Drills and Exercises

Woodside's capability to respond to incidents will be tested periodically, in accordance with the Emergency and Crisis Management Procedure. The scope, frequency and objective of these tests

is described in Table 7-11. Emergency response testing is aligned to existing or developing risks associated with Woodside's operations and activities. Corporate hazards/risks outlined in the corporate risk register, respective Safety Cases or project Risk Registers, are reference points developing and scheduling emergency and crisis management exercises. External participants may be invited to attend exercises (e.g. government agencies, specialist service providers, oil spill response organisations, or industry members with which Woodside has mutual aid arrangements).

The overall objective of exercises is to test procedures, skills and the teamwork of the Emergency Response and Command Teams in their ability to respond to major accident / major environment events. After each exercise, the team holds a debriefing session, during which the exercise is reviewed. Any lessons learned or areas for improvement are identified and incorporated into revised procedures, where appropriate.

Table 7-11: Testing of response capability

Response Category	Scope	Response Testing Frequency – tie-back activities	Response Testing Frequency – Operations	Response Testing Objective
Level 1 Response	Exercises are project-/ activity-specific	One Level 1 'First Strike' drill conducted within two weeks of commencing activity*. For campaigns with an operational duration of greater than one month this will occur within the first two weeks of commencing the activity and then at least every 6-month hire period thereafter.	Two Level 1 'First Strike' drills conducted per year, per asset. Additional Level 1 emergency drills routinely conducted (approximately one per fortnight).	Operations: Drills test elements of the Pluto Facility Operations Oil Pollution First Strike Plan. Tie-back activities: Drills test elements of the Xena-03 Drilling and Tie-back Oil Pollution First Strike Plan. Emergency drills are scheduled to test other aspects of the Emergency Response Plan.
Level 2 Response	Exercises are facility specific	Level 2 Emergency Management exercises are relevant to activities with an operational duration of one month or greater. At least one Emergency Management exercise per MODU per campaign must be conducted within the first month of commencing the activity and then at every 6 month hire period thereafter, where applicable based on duration.	A minimum of one Emergency Management exercise is conducted biennially.	Testing both the facility IMT response and/or that of the CIMT following handover of incident control.
Level 3 Response	Exercises are relevant to all Woodside assets	The number of CMT exercises conducted each year is determined by the Chief Executive Officer, in consultation with the Vice President of Security and Emergency Management.		Test Woodside's ability to respond to and manage a crisis level incident

** For drilling and tie-back activities, this applies to the project installation vessel (PIV) and MODU only*

7.14.9 Hydrocarbon Spill Response testing of Arrangements

There are a number of arrangements which, in the event of a spill, will underpin Woodside's ability to implement a response across its petroleum activities. So that these arrangements are adequately tested, the Capability Development Team within Security and Emergency Management ensures tests are conducted in alignment with the Hydrocarbon Spill Testing of Arrangements Schedule.

Woodside's arrangements for spill response are common across its Australian operating assets and activities so that the controls are consistent. The overall objective of testing these arrangements is so that Woodside maintains an ability to respond to a hydrocarbon spill, specifically so that:

- relevant responders, contractors and key personnel understand and practise their assigned roles and responsibilities.
- response arrangements and actions to validate response plans are tested.
- lessons learned are incorporated into Woodside's processes and procedures and improvements are made where required.

If new response arrangements are introduced, or existing arrangements significantly amended, additional testing is undertaken accordingly. Additional activities or activity locations are not anticipated to occur; however, if they do, testing of relevant response arrangements will be undertaken as soon as practicable.

In addition to the testing of response capability described in Table 7-11, up to eight formal exercises are planned annually, across Woodside, to specifically test arrangements for responding to a hydrocarbon spill to the marine environment.

7.14.9.1 Testing of Arrangements Schedule

Woodside's Testing of Arrangements Schedule (Figure 7-7) aligns with international good practice for spill preparedness and response management; the testing is compatible with the IPIECA Good Practice Guide and the Australian Institute for Disaster Resilience (AIDR) Australian Emergency Management Arrangements Handbook. If a spill occurs, enacting these arrangements will underpin Woodside's ability to implement a response across its petroleum activities.

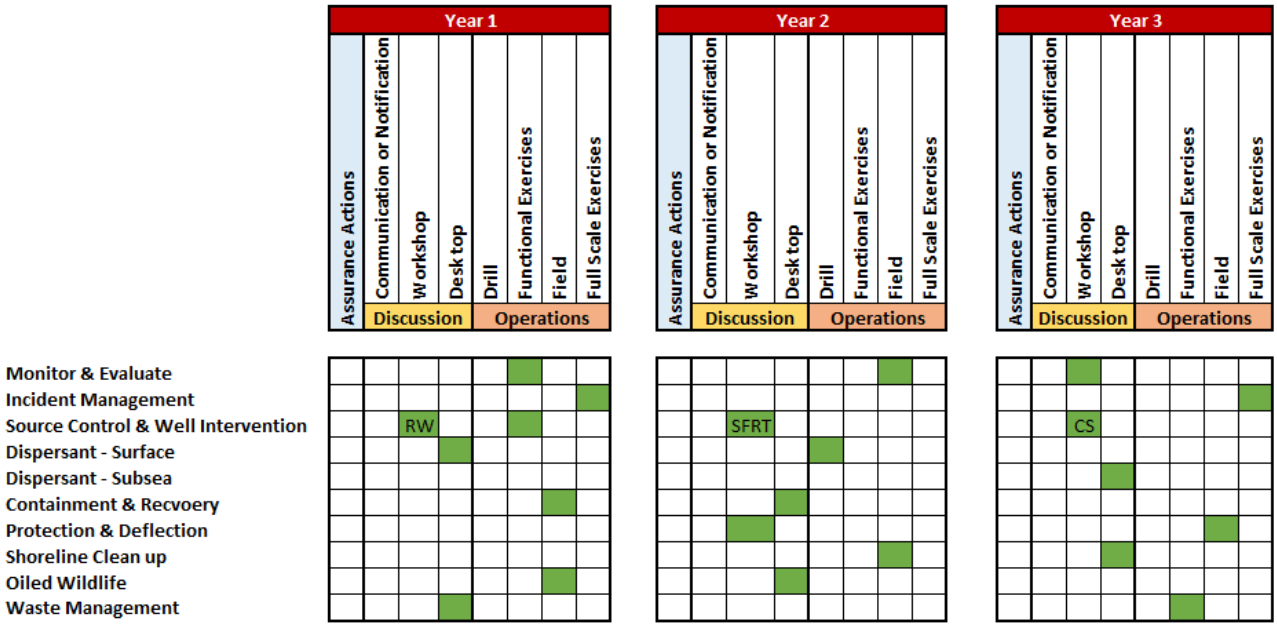


Figure 7-7: Indicative 3-yearly testing of arrangements schedule

The hydrocarbon spill arrangements shown in the rows of the schedule are tested against Woodside's regulatory commitments. Each arrangement has a support agency/company and an area to be tested (e.g., capability, equipment and personnel). For example, an arrangement could be to test Woodside's personnel capability for conducting scientific monitoring, or the ability of the Australian Marine Oil Spill Centre to provide response personnel and equipment.

The vertical columns relate to how hydrocarbon spill arrangements will be tested over the 3-year rolling schedule. The sub-heading for the column describes the standard method of testing likely to be undertaken (e.g., discussion exercise, desktop exercise), and the green cells indicate the arrangements that could be tested for each method.

Some arrangements may be tested across multiple exercises (e.g., critical arrangements) or via other 'additional assurance' methods outside the formal Testing of Arrangements Schedule that also constitute sufficient evidence of testing of arrangements (e.g., audits, no-notice drills, internal exercises, assurance drills).

7.14.10 Cyclone and Dangerous Weather Preparation

Tropical cyclones and other severe weather events are a potential risk to the safety and health of personnel and can potentially cause spills of hazardous materials into the environment from infrastructure and/or damaged vessels.

Facilities and relevant support vessels on hire to Woodside receive regular forecasts from Woodside Meteorologists, who liaise closely with the Bureau of Meteorology (BOM). If a cyclone (or severe weather event) is forecast, the path and its development is plotted and monitored using the BoM data. If there is the potential for the cyclone (severe weather event) to affect the Petroleum Activities Program, the asset Cyclone Contingency Plan and the vessel's Cyclone Contingency Plan will be actioned. If required, vessels can transit from the proposed track of the cyclone (severe weather event).
