

Scarborough Offshore Facility and Trunkline (Operations) Environment Plan

January 2025

Revision 3

This page has been intentionally left blank

TABLE OF CONTENTS

1	INTRODUCTION	23
1.1	Overview.....	23
1.2	Defining the Petroleum Activity	23
1.3	Purpose of the Environment Plan.....	23
1.4	Scope of the Environment Plan.....	24
1.5	Environment Plan Summary	24
1.6	Structure of the Environment Plan	24
1.7	Description of the Titleholder	27
1.8	Details of Titleholder, Nominated Liaison and Public Affairs Contact	27
1.8.1	Titleholder.....	27
1.8.2	Nominated Liaison	27
1.8.3	Arrangements for Notifying of Change	27
1.9	Woodside Management System	27
1.9.1	Environment and Biodiversity Policy	29
1.10	Description of Relevant Requirements.....	29
1.10.1	Offshore Petroleum and Greenhouse Gas Storage Act 2006.....	29
1.10.2	Environment Protection and Biodiversity Conservation Act 1999	30
1.10.2.1	Offshore Project Proposal	31
1.10.2.2	Recovery Plans and Threat Abatement Plans	31
1.10.2.3	Australian Marine Parks	32
2	ENVIRONMENT PLAN PROCESS	33
2.1	Overview.....	33
2.2	Environmental Risk Management Methodology	33
2.2.1	Woodside Risk Management Process.....	33
2.2.2	Establish the Context.....	34
2.2.3	Review of the Significance/Sensitivity of Receptors and Levels of Protection	34
2.2.4	Environmental Legislation and Other Requirements	34
2.2.5	Impact and Risk Identification	34
2.3	Impact and Risk Analysis and Evaluation.....	35
2.3.1	Decision Support Framework.....	35
2.3.1.1	Decision Support Framework Tools.....	37
2.3.1.2	Decision Calibration	37
2.3.2	Control Measures (Hierarchy of Controls)	37
2.3.3	Impact and Risk Classification	38
2.3.4	Risk Rating Process.....	39
2.3.4.1	Select the Consequence Level.....	39
2.3.4.2	Select the Likelihood Level.....	39
2.3.4.3	Calculate the Risk Rating	39
2.3.5	Demonstration of As Low As Reasonably Practicable.....	41

2.3.6 Demonstration of Acceptability..... 41

2.4 Environment Protection and Biodiversity Conservation Act Assessment..... 42

2.4.1 Principles of Ecological Sustainable Development..... 42

2.4.2 Matter of National Environmental Significance: Significant Impact Guidelines 1.1..... 43

2.4.3 Recovery Plan and Threat Abatement Plan Assessment..... 43

2.5 Environmental Performance Objectives/Outcomes, Standards and Measurement Criteria
..... 44

3 DESCRIPTION OF THE ACTIVITY45

3.1 Overview..... 45

3.2 Location..... 47

3.3 Operational Area..... 49

3.4 Timing..... 52

3.5 Future Expansion..... 55

3.6 Floating Production Unit Installation and Hook-up..... 55

3.6.1 Floating Production Unit Mooring Hook-up..... 56

3.6.2 Production and Export Riser Hook-up..... 56

3.7 Offshore Facility Commissioning..... 57

3.7.1 Dewatering of Production and Export Systems 57

3.7.2 Subsea System Commissioning 57

3.7.3 Floating Production Unit Commissioning..... 57

3.7.4 General Facility Maintenance..... 58

3.8 Offshore Facility Initial Start-up 58

3.8.1 Well Cleanup 59

3.9 Scarborough Operations..... 59

3.9.1 Facility Layout and Description 59

3.9.1.1 Topsides 59

3.9.1.2 Process Area..... 60

3.9.1.3 Utilities Area 61

3.9.1.4 Utility Building..... 61

3.9.1.5 Living Quarters..... 61

3.9.1.6 Floating Production Unit Hull 61

3.9.2 Wells and Reservoirs 61

3.9.3 Subsea Infrastructure Operations 62

3.9.4 Export Trunkline..... 63

3.9.5 Moorings..... 67

3.9.6 Operational Details 67

3.9.6.1 Attendance Modes 67

3.9.7 Process Description 68

3.9.7.1 Production Process 68

3.9.7.2 Inlet Facilities 68

3.9.7.3 Gas Conditioning..... 69

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

3.9.7.4	Export Gas Compression	71
3.9.8	Flare Systems.....	71
3.9.8.1	High Pressure Flare System.....	71
3.9.8.2	Low Pressure Flare System	71
3.9.8.3	Flaring – Normal Operations	71
3.9.8.4	Flaring – Intermittent Process Activities and Upsets	71
3.9.9	Monoethylene Glycol Recovery and Storage System.....	73
3.9.10	Produced Water System	74
3.9.10.1	Produced Water System Description	74
3.9.10.2	Produced Water Oil-in-Water Discharge Monitoring	76
3.9.11	Drainage Systems	76
3.9.11.1	Closed Drains.....	76
3.9.11.2	Open Drains	76
3.9.12	Floating Production Unit Utility Systems.....	77
3.9.12.1	Floating Production Unit Lighting.....	77
3.9.12.2	Heating Ventilation and Air Conditioning System.....	77
3.9.12.3	Seawater System	77
3.9.12.4	Fresh, Potable, Utility and Demin Water System	78
3.9.12.5	Power Generation and Distribution.....	78
3.9.12.6	Heating Medium	79
3.9.12.7	Fuel Gas System.....	79
3.9.12.8	Diesel Fuel Supply System.....	79
3.9.12.9	Sand Management	79
3.9.12.10	Sewage and Putrescible Wastes	80
3.9.12.11	Lifting Operations	80
3.9.12.12	Instrument/Utility Air System	81
3.9.12.13	Nitrogen System.....	81
3.9.13	Bunkering	81
3.9.14	Ballast and Bilge System	81
3.9.15	Safety Features and Emergency Systems	82
3.9.16	Hydrocarbon and Chemical Inventories	82
3.9.16.1	Hydrocarbons.....	82
3.9.16.2	Chemical Usage.....	83
3.9.16.3	Operational Chemicals	83
3.9.16.4	Indicative Chemical Inventories	84
3.9.16.5	Chemical Selection, Assessment and Approval.....	84
3.9.17	Inspection, Monitoring, Maintenance, and Repair Activities.....	86

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

3.9.17.1	Inspection.....	86
3.9.17.2	Monitoring	87
3.9.17.3	Maintenance.....	87
3.9.17.4	Repair	88
3.9.17.5	Removal of Equipment	88
3.9.17.6	Pigging Operations.....	89
3.9.17.7	Subsea Chemical Use.....	89
3.9.17.8	Typical Discharges During Inspection, Monitoring, Maintenance and Repair Activities	89
3.9.17.9	Marine Growth Removal.....	90
3.9.17.10	Sediment Relocation	90
3.9.17.11	Underwater Acoustic Positioning	91
3.10	Gravimetry surveys.....	91
3.11	Vessel-based Activities	92
3.11.1	Support Vessels.....	93
3.11.2	Accommodation Support Vessel	94
3.11.3	Anchor Handling Tug/Tow Vessels	95
3.11.4	Light Construction Vessel	95
3.11.5	Uncrewed Surface Vessel.....	95
3.12	Helicopter Operations	96
3.13	Contingent Activities	96
3.13.1	Trunkline Repair and Flooding, Cleaning, Gauging and Testing	96
3.13.2	Wet Storing Equipment.....	97
4	DESCRIPTION OF THE EXISTING ENVIRONMENT	98
4.1	Overview.....	98
4.2	Regional Context	102
4.3	Matters of National Environmental Significance (Environment Protection and Biodiversity Conservation Act)	103
4.4	Physical Environment	103
4.4.1	Offshore Operational Area	103
4.4.2	Trunkline Operational Area	105
4.5	Habitats and Biological Communities.....	107
4.5.1	Offshore Operational Area	107
4.5.2	Trunkline Operational Area	108
4.6	Protected Species.....	110
4.6.1	Fish, Sharks and Rays.....	111
4.6.2	Marine Reptiles.....	114
4.6.3	Marine Mammals	122
4.6.3.1	Pygmy Blue Whales	126
4.6.4	Seabirds and Migratory Shorebirds.....	128
4.6.5	Seasonal Sensitivities for Protected Species	134
4.7	Key Ecological Features	135

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

4.8	Protected Places.....	138
4.9	Cultural Features and Heritage Values	141
4.9.1	Background	141
4.9.2	First Nations Peoples.....	141
4.9.3	Coastally Adjacent First Nations Groups.....	142
4.9.3.1	Marine Parks	144
4.9.4	Sea Country Values	146
4.9.4.1	Desktop Assessment of Sea Country Values	147
4.9.4.2	Studies of Cultural Features and Heritage Values	156
4.9.4.3	Consultation Feedback to Inform Existing Environment.....	165
4.9.4.4	Further Context: Archaeological Heritage.....	188
4.9.4.5	Further Context: Intangible Cultural Heritage.....	188
4.9.4.6	Further Context: Marine Ecosystems and Species	190
4.9.5	Murujuga Cultural Landscape	191
4.9.6	Summary of Existing Research on Onshore Industrial Emissions	196
4.9.6.1	Research, Monitoring and Publications	197
4.9.7	Historic Sites of Significance.....	202
4.9.8	Underwater Heritage.....	202
4.9.9	World, National and Commonwealth Heritage Listed Places.....	204
4.10	Socio-economic Environment	205
4.10.1	Commercial Fisheries	205
4.10.2	Traditional Fisheries.....	215
4.10.3	Tourism and Recreation.....	215
4.10.4	Commercial Shipping.....	215
4.10.5	Oil and Gas.....	216
4.10.6	Submarine Communications Infrastructure	217
4.10.7	Defence	218
5	CONSULTATION	220
5.1	Summary	220
5.2	Consultation – General Context	221
5.3	Identification of Relevant Persons for Consultation	226
5.3.1	Regulations 25(1)(a), (b) and (c).....	226
5.3.2	Identification of Relevant Persons under Regulations 25(1)(a), (b) and (c)	226
5.3.3	Regulation 25(1)(d).....	227
5.3.4	Identification of Relevant Persons under Regulation 25(1)(d)	227
5.3.5	Regulation 25(1)(e).....	234
5.3.6	Identification of Relevant Persons under Regulation 25(1)(e)	234
5.3.7	Persons or Organisations Woodside Chooses to Contact.....	234
5.3.8	Assessment of Relevant Persons for the Proposed Activity	234
5.4	Consultation Material and Timing.....	234
5.4.1	Sufficient Information	235

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

5.4.2 Reasonable Period for Consultation..... 238

5.4.3 Discharge of Regulation 25..... 239

5.5 Context of Consultation Approach with First Nations..... 240

5.5.1 Approach to Methodology – Woodside’s Interpretation of *Tipakalippa Appeal*..... 240

5.5.2 Consultation Method..... 241

5.5.2.1 Identification of Relevant Persons 243

5.5.2.2 Opportunity to Self-identify and Identifying Other Individuals..... 244

5.5.2.3 Sufficient Information..... 245

5.5.2.4 Reasonable Period for Consultation 246

5.5.2.5 Discharge of Regulation 25 246

5.6 Providing Feedback and Assessment of Merit of Objections or Claims..... 246

5.7 Ongoing Consultation 247

6 ENVIRONMENTAL RISK ASSESSMENT, PERFORMANCE OUTCOMES, STANDARDS AND MEASUREMENT CRITERIA..... 248

6.1 Overview..... 248

6.2 Impact and Risk Analysis and Evaluation..... 248

6.2.1 Concurrent Operations and Cumulative Impacts..... 253

6.3 Environmental Performance Outcomes, Standards and Measurement Criteria..... 253

6.4 Presentation 265

6.5 Potential Environment Risks Not Included Within the Scope of this Environment Plan.. 267

6.5.1 Shallow/Near-shore Activities 267

6.5.2 Loss of Containment of Existing or Third-party Subsea Infrastructure 267

6.6 Indirect Impacts 268

6.7 Planned Activities (Routine and Non-routine)..... 269

6.7.1 Physical Presence: Interactions with Other Marine Users 269

6.7.2 Physical Presence: Seabed Disturbance 278

6.7.3 Routine Light Emissions: Floating Production Unit and Vessels..... 287

6.7.4 Routine Acoustic Emissions: Floating Production Unit Hook-up and Commissioning.... 299

6.7.5 Routine Acoustic Emissions: Routine Operations 320

6.7.6 Routine and Non-routine Greenhouse Gas Emissions 335

6.7.7 Routine Atmospheric Emissions: Offshore, and Indirect Emissions from Gas Processing Onshore..... 387

6.7.8 Physical Presence: Interactions between diurnal migratory/foraging seabirds and shorebirds and the FPU..... 410

6.7.9 Routine and Non-routine Discharges: Vessels..... 416

6.7.10 Routine and Non-routine Discharges: Floating Production Unit Operations (Wastewater Streams)..... 423

6.7.11 Routine and Non-routine Discharges: Floating Production Unit Operations (Comingled Produced Water/Seawater Return Stream)..... 431

6.7.12 Routine and Non-Routine Discharges: Subsea Operations, Activities and Contingent Trunkline Dewatering..... 456

6.7.13 Routine and Non-routine Discharges: Floating Production Unit and Subsea Commissioning and Initial Start-up..... 472

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

6.8 Unplanned Activities (Accidents, Incidents, Emergency Situations) 480

6.8.1 Quantitative Spill Risk Assessment Methodology and Floating Production Unit Significant Environment Event Overview 480

6.8.1.1 Quantitative Hydrocarbon Spill Modelling 480

6.8.1.2 Environment that May Be Affected and Hydrocarbon Contact Thresholds..... 482

6.8.1.3 Surface Hydrocarbon Threshold Concentrations 483

6.8.1.4 Accumulated Hydrocarbon Threshold Concentrations 483

6.8.1.5 Dissolved Aromatic Hydrocarbon Threshold Concentrations 484

6.8.1.6 Entrained Hydrocarbon Threshold Concentrations 484

6.8.1.7 Scientific Monitoring 484

6.8.1.8 Classification and Analysis of Significant Environment (Process Safety) Events 484

6.8.1.9 Safety and Environment Critical Elements and Technical Performance Standards... 486

6.8.2 Unplanned Diesel Release: Vessel Collision..... 488

6.8.3 Unplanned Diesel Release: Loss of FPU/ASV Structural Integrity/Stability 512

6.8.4 Unplanned Gas Release: Loss of Well Containment..... 526

6.8.5 Unplanned Gas Release: Subsea Equipment and Trunkline Loss of Containment 534

6.8.6 Unplanned Diesel Release: FPU Topsides Loss of Containment including Bunkering/Refuelling..... 542

6.8.7 Unplanned Discharge: Chemical Release During Transfer, Storage and Use 557

6.8.8 Unplanned Discharge: Loss of Solid Hazardous and Non-hazardous Wastes 564

6.8.9 Physical Presence (Unplanned): Seabed Disturbance 571

6.8.10 Physical Presence (Unplanned): Interactions with Fauna 577

6.8.11 Physical Presence (Unplanned): Introduction and Establishment of Invasive Marine Species..... 585

6.9 Environment Protection and Biodiversity Conservation Act Assessment..... 595

6.9.1 Matters of National Environmental Significance Significant Impact Guidelines..... 595

6.9.2 Principles of Ecologically Sustainable Development 595

6.9.3 Recovery Plan and Threat Abatement Plan Assessment 595

6.10 Cultural Features and Heritage Values Assessment 610

7 IMPLEMENTATION STRATEGY 629

7.1 Overview..... 629

7.2 Systems, Practice and Procedures 629

7.2.1 Woodside Management System Operate Processes 629

7.2.1.1 Operate Plant..... 629

7.2.1.2 Integrated Safe System of Work..... 629

7.2.1.3 Maintain Assets..... 630

7.2.2 Process Safety Management 630

7.2.2.1 Woodside Safety Culture Framework 631

7.2.3 Risk Management..... 632

7.2.3.1 Management of Risks – Contracting and Procurement (Operations) 632

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

7.2.3.2 Management of Risks – Subsea Activities (Operations) 633

7.2.3.3 Management of Risks – Major Projects 633

7.2.3.4 Management of Risks – Well Integrity 634

7.2.3.5 Management of Risks – Marine Services 634

7.2.3.6 Management of Human Factor Related Risks 634

7.2.4 Emissions and Energy Management..... 634

7.2.4.1 GHG Emissions and Energy Management Procedure 635

7.2.4.2 Production Optimisation and Opportunity Management..... 636

7.2.4.3 Greenhouse Gas, Energy and Flare Target Setting - Operations 637

7.2.4.4 Fuel and Flare Target Setting - Initial Start-Up 638

7.2.4.5 Methane Management 639

7.2.5 Offshore Marine Discharge Adaptive Management Plan 640

7.2.5.1 Overview 640

7.2.5.2 Routine Monitoring and Management..... 641

7.2.5.3 Further Investigations 642

7.2.5.4 ALARP/Acceptability Study 643

7.2.5.5 Review and revision 644

7.2.6 Woodside Invasive Marine Species Risk Assessment Process..... 644

7.2.6.1 Objective and Scope 644

7.2.6.2 Risk Assessment Process 645

7.2.6.3 Scarborough FPU Invasive Marine Species Management Plan..... 647

7.2.7 Change Management 647

7.2.7.1 Technical Change Management..... 648

7.2.7.2 Environment Plan Management of Change and Revision..... 649

7.2.7.3 Oil Pollution Emergency Plan Management of Change 649

7.2.8 Management of Safety and Environment Critical Element Technical Performance Standards and Management System Performance Standards (Operations) 650

7.2.8.1 Management System Performance Standards 650

7.2.8.2 Safety and Environment Critical Element Technical Performance Standards 650

7.3 Woodside Decommissioning Framework 652

7.3.1 Decommissioning in Operations..... 652

7.3.2 Facility Decommissioning Planning..... 653

7.3.2.1 Scarborough Decommissioning Planning 653

7.3.2.2 Subsea Infrastructure Decommissioning 653

7.3.2.3 Scarborough Trunkline Decommissioning 656

7.3.2.4 Floating Production Unit Decommissioning 656

7.4 Frontline Offshore Seabird Management Plan 657

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

7.5 Woodside Corporate GHG Emission Targets..... 657

7.5.1 Scope 1 GHG Emission Targets 657

7.5.2 Scope 3 GHG Emission Targets 658

7.6 Organisation Structure 659

7.6.1 Roles and Responsibilities 660

7.7 Heritage Management Committee Implementation 667

7.8 Unexpected Finds Procedure..... 668

7.9 Training and Competency – Project and Vessel Activities..... 669

7.9.1 Inductions and Training..... 669

7.9.2 Activities Program Specific Environmental Awareness..... 670

7.9.3 Inductions for Offshore Facility Workers and Visitors 670

7.9.4 Operations Competency Framework Training..... 670

7.9.5 Permit to Work System Training..... 671

7.9.6 Emergency and Hydrocarbon Spill Response Training 671

7.9.7 Subsea Inspection, Monitoring, Maintenance and Repair Activity Environmental Awareness
..... 671

7.9.8 Marine Fauna Observation Training..... 672

7.9.9 Establishment of seabird handling capabilities 673

7.9.10 Management of Training Requirements 673

7.10 Monitoring, Auditing, Management of Non-conformance and Review 674

7.10.1 Monitoring..... 674

7.10.1.1 Source-based Impacts and Risks 674

7.10.1.2 Management of Newly Identified Impacts and Risks..... 675

7.10.1.3 Management of Knowledge 676

7.10.2 Auditing..... 676

7.10.2.1 Floating Production Unit Hook-up and Commissioning Activities 676

7.10.2.2 Operations Assurance 677

7.10.2.3 Inspection and Audits – Operations..... 677

7.10.2.4 Annual Offshore Inspection/Desktop Review..... 678

7.10.2.5 Marine Assurance 678

7.10.2.6 Risk Assessment..... 679

7.10.3 Management of Non-conformance..... 679

7.10.4 Review..... 680

7.10.4.1 Management Review..... 680

7.10.4.2 Learning and Knowledge Sharing..... 680

7.10.4.3 Review of Impacts, Risks and Controls Across the Life of the Environment Plan 680

7.10.4.4 Program of Ongoing Engagement with Traditional Custodians..... 680

7.10.5 Ongoing Consultation 681

7.11 Record Keeping 683

7.12 Reporting 683

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

7.12.1	Routine Reporting (Internal).....	683
7.12.1.1	Daily Progress Reports and Meetings	683
7.12.1.2	Regular Health, Safety and Environment Meetings	684
7.12.1.3	Performance Reporting	684
7.12.2	Routine Reporting (External).....	684
7.12.2.1	Start and End Notifications of the Petroleum Activities Program.....	684
7.12.2.2	Environmental Performance Review and Reporting	684
7.12.2.3	End of the Environment Plan.....	685
7.12.3	Incident Reporting (Internal).....	685
7.12.4	Incident Reporting (External) – Reportable and Recordable	685
7.12.4.1	Reportable Incidents	685
7.12.4.2	Recordable Incidents.....	686
7.12.4.3	Other External Incident Reporting Requirements	686
7.13	Emergency Preparedness and Response.....	688
7.13.1	Overview.....	688
7.13.2	Emergency Response Training.....	689
7.13.3	Emergency Response Preparation	690
7.13.3.1	Initial Response to Facility Incident	690
7.13.4	Oil and Other Hazardous Materials Spill	691
7.13.5	Emergency and Spills Response	691
7.13.6	Emergency and Spill Response Drills and Exercises	692
7.13.7	Hydrocarbon Spill Response Testing of Arrangements	695
7.13.7.1	Testing of Arrangements Schedule	695
7.13.8	Cyclone and Dangerous Weather Preparation.....	696
8	REFERENCES	697

1 INTRODUCTION

1.1 Overview

The Scarborough gas resource, located in Commonwealth waters approximately 375 km west-northwest of the Burrup Peninsula, forms part of the Greater Scarborough gas fields, comprising the Scarborough, Thebe and Jupiter gas fields. Woodside Energy Scarborough Pty Ltd (Woodside), as a Titleholder under the *Offshore Petroleum and Greenhouse Gas Storage (Environment) Regulations 2023* (Cth) (referred to as the Environment Regulations), proposes to perform petroleum activities within Permit Areas WA-61-L and WA-62-L, specifically:

- hook-up of the Scarborough Floating Production Unit (FPU) (moorings and subsea system)
- startup and commissioning activities of the FPU and associated subsea wells, flowlines and infrastructure
- routine production and associated activities for up to 13 subsea wells (up to eight wells in Phase 1 and five wells in Phase 2)
- export of dry gas to the Pluto onshore gas plant, through the gas export trunkline (ETL)
- inspection, monitoring, maintenance and repair (IMMR) activities for the FPU, subsea infrastructure, and ETL
- gravimetry surveys.

These activities will hereafter be referred to as the Petroleum Activities Program (PAP) and form the scope of this Environment Plan (EP). A more detailed description of the activities is provided in Section 3.

This EP has been prepared by Woodside as part of the requirements under the Environment Regulations, as administered by the National Offshore Petroleum Safety and Environmental Management Authority (NOPSEMA).

The Petroleum Activities Program as defined in this EP is a part of the Scarborough Offshore Project Proposal (OPP) accepted by NOPSEMA on 30 March 2020.

1.2 Defining the Petroleum Activity

The Petroleum Activities Program to be undertaken within Permit Area WA-61-L and WA-62-L comprises petroleum activities, as defined in Regulation 5 of the Environment Regulations.

The Petroleum Activities Program includes pipeline operation, IMMR activities and all such other things in the area specified in the pipeline licence (WA-32-PL) as are necessary for, or incidental, to the operation of a pipeline as defined under section 211(1)(d)(i) of the OPGGS Act, which are petroleum activities as defined in Regulation 5 of the Environment Regulations.

1.3 Purpose of the Environment Plan

In accordance with the objectives of the Environment Regulations, the purpose of this EP is to demonstrate that:

- the environmental impacts and risks (planned (routine and non-routine) and unplanned) of the Petroleum Activities Program are identified;
- appropriate control measures are implemented to reduce environmental impacts and risks of the Petroleum Activities Program to 'as low as reasonably practicable' (ALARP) and an acceptable level; and
- the Petroleum Activities Program is carried out in a manner consistent with the principles of ecologically sustainable development (as set out in section 3A of the *Environment Protection and Biodiversity Conservation Act 1999* (Cth) (EPBC Act)).

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

This EP describes the process and resulting outputs of the risk assessment, whereby impacts and risks are managed accordingly.

The EP defines activity-specific:

- Environmental Performance Outcomes (EPOs)
- Environmental Performance Standards (EPSs)
- Measurement Criteria (MCs).

These form the basis for monitoring, auditing and management of the Petroleum Activities Program to be undertaken by Woodside and its contractors. The implementation strategy (derived from the decision support framework tools) specified within this EP provides Woodside and NOPSEMA with the required level of assurance that the environmental impacts and risks of the Petroleum Activities Program are reduced to ALARP and an acceptable level.

1.4 Scope of the Environment Plan

The scope of this EP covers the activities that define the Petroleum Activities Program, as described in Section 3.

A Combined Offshore Operational Area and a Trunkline Operational Area have been defined (Section 3.3). These areas define the spatial boundary of the Petroleum Activities Program, hereafter referred to as the Petroleum Activity Area (PAA).

This EP addresses environmental impacts and risks from planned activities within the PAA and any potential unplanned events that originate from the Petroleum Activities Program within the PAA.

Transit to and from the PAA by vessels, as well as port activities associated with these vessels, are not within the scope of this EP. Vessels supporting the petroleum activities operating outside the PAA (e.g. transiting to and from port) are subject to all applicable maritime regulations and other requirements and are not managed by this EP.

1.5 Environment Plan Summary

An EP summary will be prepared based on the material provided in this EP, addressing the items listed in Table 1-1 as required by Regulation 35(6) of the Environment Regulations.

Table 1-1: Summary of contents of the Environment Plan

EP summary material requirement	Relevant section of EP containing EP summary material
The location of the activity	Section 3.2
A description of the receiving environment	Section 4
A description of the activity	Section 3
Details of the environmental impacts and risks	Section 6
The control measures for the activity	Section 6
The arrangements for ongoing monitoring of the titleholder’s environmental performance	Section 6
Response arrangements in the oil pollution emergency plan	Section 7.13
Consultation already undertaken and plans for ongoing consultation	Section 5
Details of the titleholders nominated liaison person for the activity	Section 1.8

1.6 Structure of the Environment Plan

This EP has been structured to reflect the process and requirements of the Environment Regulations as outlined in Table 1-2.

Table 1-2: Environment Plan process phases, applicable regulations and relevant section

Criteria for acceptance	Content requirements/relevant regulations	Elements	Section of EP
Regulation 34(a): Is appropriate for the nature and scale of the activity	Regulation 21: Environmental assessment Regulation 22: Implementation strategy for the environment plan Regulation 24: Other information in the environment plan	The principle of 'nature and scale' is applicable throughout the EP	Section 2 Section 3 Section 4 Section 5 Section 6 Section 7
Regulation 34(b): Demonstrates that the environmental impacts and risks of the activity will be reduced to as low as reasonably practicable	Regulations 21(1)–21(7): 21(1) Description of the activity 21(2) and (3) Description of the environment 21(4) Requirements 21(5) and (6) Evaluation of environmental impacts and risks 21(7) Environmental Performance Outcomes and standards Regulations 24(a)–24(c): A statement of the titleholder's corporate environmental policy A report on all consultations between the titleholder and any relevant person	Set the context (activity and existing environment) Define 'acceptable' (the requirements, the corporate policy, relevant persons) Detail the impacts and risks Evaluate the nature and scale Detail the control measures – ALARP and acceptable	Section 1 Section 2 Section 3 Section 4 Section 5 Section 6 Section 7
Regulation 34(c): Demonstrates that the environmental impacts and risks of the activity will be of an acceptable level			
Regulation 34(d): Provides for appropriate Environmental Performance Outcomes, environmental performance standards and measurement criteria	Regulation 21(7): Environmental Performance Outcomes and standards	Environmental Performance Outcomes (EPOs) Environmental performance standards (EPSs) Measurement criteria (MCs)	Section 6
Regulation 34(e): Includes an appropriate implementation strategy and monitoring, recording and reporting arrangements	Regulation 22: Implementation strategy for the environment plan	Implementation strategy, including: Environmental Management System (EMS) Performance monitoring Oil Pollution Emergency Plan (OPEP – per Table 7-11) and scientific monitoring Ongoing consultation	Section 7 Appendix H: Oil Spill Preparedness and Response Mitigation Assessment

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

Criteria for acceptance	Content requirements/relevant regulations	Elements	Section of EP
<p>Regulation 34(f): Does not involve the activity or part of the activity, other than arrangements for environmental monitoring or for responding to an emergency, being undertaken in any part of a declared World Heritage property within the meaning of the Environment Protection and Biodiversity Conservation Act 1999 (EPBC Act)</p>	<p>Regulations 21(1)–21(3): 21(1) Description of the activity 21(2) Description of the environment 21(3) Without limiting Regulation 21(2)(b), relevant values and sensitivities may include any of the following: (a) the world heritage values of a declared World Heritage property within the meaning of the EPBC Act; (b) the national heritage values of a National Heritage place within the meaning of that Act; (c) the ecological character of a declared Ramsar wetland within the meaning of that Act; (d) the presence of a listed threatened species or listed threatened ecological community within the meaning of that Act; (e) the presence of a listed migratory species within the meaning of that Act; (f) any values and sensitivities that exist in, or in relation to, part or all of: (i) a Commonwealth marine area within the meaning of that Act; or (ii) Commonwealth land within the meaning of that Act.</p>	<p>No activity, or part of the activity, undertaken in any part of a declared World Heritage property</p>	<p>Section 2.5 Section 4 Section 6</p>
<p>Regulation 34(g): (i) the titleholder has carried out the consultations required by Regulation 25 (ii) the measures (if any) that the titleholder has adopted, or proposes to adopt, because of the consultations are appropriate</p>	<p>Regulation 25: Consultation with relevant authorities, persons and organisations, etc. Regulation 24(b): A report on all consultations between the titleholder and any relevant person</p>	<p>Consultation undertaken in the preparation of this EP.</p>	<p>Section 5</p>
<p>Regulation 34(h): Complies with the Act and the regulations</p>	<p>Regulation 21(4)(a): Describe the requirements, including legislative requirements, that apply to activity and are relevant to the environmental management of the activity Regulation 23: Details of the Titleholder and liaison person Regulation 24(a): A statement of the titleholder's corporate environmental policy Regulation 24(c): Details of all reportable incidents in relation to the proposed activity</p>	<p>All contents of the EP must comply with the <i>Offshore Petroleum and Greenhouse Gas Storage Act 2006</i> and the Environment Regulations</p>	<p>Section 1 Section 3 Section 6 Appendix B</p>

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

1.7 Description of the Titleholder

Woodside is a Titleholder for this activity on behalf of a joint venture comprising Woodside Energy Scarborough Pty Ltd, Woodside Energy (Australia) Pty Ltd and LJ Scarborough Pty Ltd.

Woodside is the largest Australian natural gas producer with more than 35 years of safe and reliable operating experience in Western Australia.

Woodside recognises that strong environmental performance is essential to success and continued growth. Woodside has an established methodology to identify impacts and risks and assess potential consequences of activities. Strong partnerships, sound research and transparency are the key elements of Woodside's approach to the environment.

1.8 Details of Titleholder, Nominated Liaison and Public Affairs Contact

In accordance with Regulation 23 of the Environment Regulations, details of the relevant titleholder, its nominated liaison and arrangements for the notification of changes are described below.

1.8.1 Titleholder

Woodside Energy Scarborough Pty Ltd

11 Mount Street

Perth, Western Australia

T: 08 9348 4000

ACN: 650 177 227

1.8.2 Nominated Liaison

Andrew Winter

Corporate Affairs Manager

11 Mount Street

Perth, Western Australia

T: 08 9348 4000

E: feedback@woodside.com.au

1.8.3 Arrangements for Notifying of Change

Should the titleholder, the titleholder's nominated liaison or the contact details for either change, then NOPSEMA is to be notified of the change in writing within two weeks or as soon as practicable.

1.9 Woodside Management System

The Woodside Management System (WMS) provides a structured framework of documentation to set common expectations governing how all employees and contractors at Woodside will work. Many of the standards presented in Section 6 are drawn from the WMS documentation, which comprises of four elements: Our Values and Policies, Expectations, Processes and Procedures and Guidelines, outlined below (and illustrated in Figure 1-1):

- **Values and Policies:** Set the enterprise-wide direction for Woodside by governing our behaviours, actions and business decisions and ensuring we meet our legal and other external obligations.

- **Expectations:** Set essential activities or deliverables required to achieve the objectives of the Key Business Activities and provide the basis for development of processes and procedures.
- **Processes and Procedures:** Processes identify the set of interrelated or interacting activities which transforms inputs into outputs, to systematically achieve a purpose or specific objective. Procedures specify what steps, by whom and when are required to carry out an activity or a process.
- **Guidelines:** Provide recommended practice and advice on how to perform the steps defined in Procedures, together with supporting information and associated tools. Guidelines provide advice on:
 - how activities or tasks may be performed;
 - information that may be taken into consideration; or
 - how to use tools and systems.

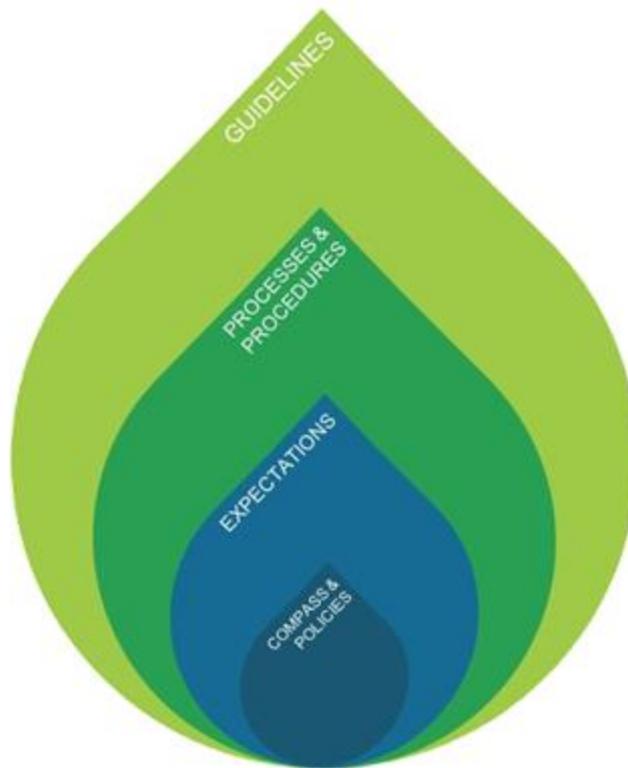

Figure 1-1: The four major elements of the Woodside Management System framework

The WMS is organised within a business process hierarchy based upon key business activities to ensure the system remains independent of organisation structure, is globally applicable and is scalable wherever required. These business activities are grouped into management, support and value stream activities, as shown in Figure 1-1. The value stream activities capture, generate and deliver value throughout the exploration and production (E and P) lifecycle. The management activities influence all areas of the business, while support activities may influence one or more value stream activities.

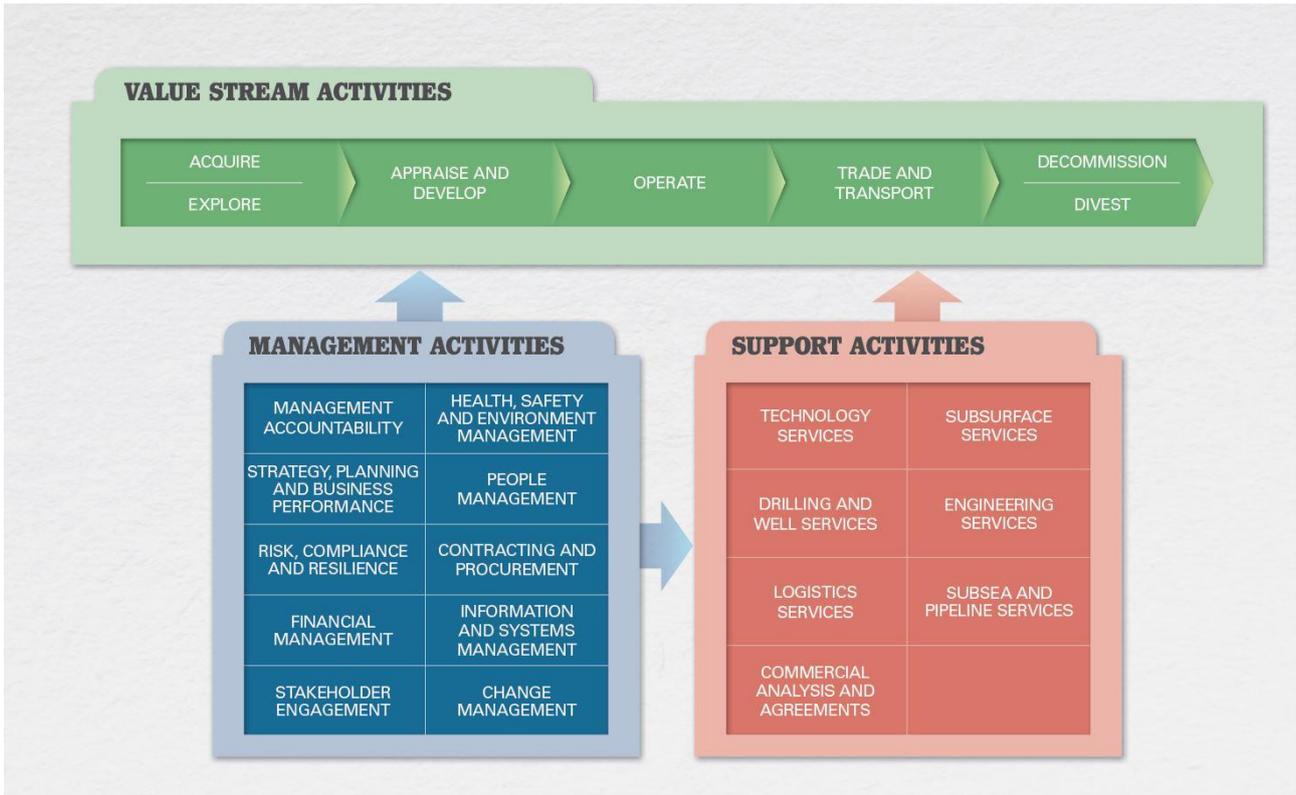

Figure 1-2: The Woodside Management System business process hierarchy

1.9.1 Environment and Biodiversity Policy

In accordance with Regulation 24(a) of the Environment Regulations, Woodside’s Environment and Biodiversity Policy is provided in Appendix A: Woodside Policies. Please note that the Environment and Biodiversity Policy is reviewed regularly and is updated as required. The Environment and Biodiversity Policy is made available on our website, along with the other Board policies: <https://www.woodside.com/who-we-are/corporate-governance-and-policies>

1.10 Description of Relevant Requirements

In accordance with Regulation 21(4) of the Environment Regulations, a description of requirements, including legislative requirements, that apply to the activity and relevant to the management of risks and impacts of the Petroleum Activities Program are detailed in Appendix B: Relevant Requirements.

1.10.1 Offshore Petroleum and Greenhouse Gas Storage Act 2006

The *Offshore Petroleum and Greenhouse Gas Storage Act 2006* (Cth) (OPGGGS Act) provides the regulatory framework for offshore petroleum exploration and production and greenhouse gas activities in Commonwealth waters (beyond three nautical miles (nm) of the mainland (and islands) to the outer extent of the Australian Exclusive Economic Zone at 200 nm).

Relevant requirements in section 572 of the OPGGS Act are detailed in Table 1-3.

Table 1-3: Relevant requirements of the Offshore Petroleum and Greenhouse Gas Storage Act

Section Number	Relevant Requirement	Relevant section of the EP
Section 572 – Maintenance and removal of property etc. by titleholder		
(2)	<p>Maintenance of property etc. A titleholder must maintain in good condition and repair all structures that are, and all equipment and other property that is:</p> <ul style="list-style-type: none"> (a) in the title area; and (b) used in connection with the operations authorised by the permit, lease, licence or authority. 	Section 7.3
(3)	<p>Removal of property etc. A titleholder must remove from the title area all structures that are, and all equipment and other property that is, neither used nor to be used in connection with the operations:</p> <ul style="list-style-type: none"> (a) in which the titleholder is or will be engaged; and (b) that are authorised by the permit, lease, licence or authority. 	Section 7.3

The regulatory framework establishes NOPSEMA as the regulator. Under the OPGGS Act, the Environment Regulations apply to petroleum activities in Commonwealth waters and are administered by NOPSEMA. The object of the Environment Regulations is to ensure that petroleum activities are carried out in a manner:

- consistent with the principles of ecologically sustainable development (as set out in the EPBC Act)
- by which the environmental impacts and risks of the activity will be reduced to ALARP
- by which the environmental impacts and risks of the activity will be of an acceptable level.

1.10.2 Environment Protection and Biodiversity Conservation Act 1999

On 28 February 2014, NOPSEMA’s environmental management authorisation process was endorsed by the then Minister for the Environment as a Program that meets the requirements of Part 10 of the EPBC Act. This ministerial endorsement streamlined environmental approvals for offshore petroleum activities and made NOPSEMA the sole regulator for environmental management of petroleum activities in Commonwealth waters.

The Streamlining Offshore Petroleum Approvals Program (Program) under the EPBC Act requires proponents of an offshore project after 28 February 2014 to submit an Offshore Project Proposal to NOPSEMA for assessment. An accepted Offshore Project Proposal (OPP) must be in place prior to submission and assessment of Environment Plans for the individual component activities. The definition of environment incorporated in the Program encompasses all aspects of the environment including, but not limited to, EPBC Act Part 3 protected matters. As a result, all Program functions relating to protection of the environment apply for EPBC Act Part 3 matters.

One of the objectives of the EPBC Act is to protect and manage nationally and internationally important flora, fauna, ecological communities and heritage places in Australia. These are defined under Part 3 of the EPBC Act as Matters of National Environmental Significance (MNES). The EPBC Act establishes a regime which aims to ensure actions taken on (or impacting upon) Commonwealth land or waters are consistent with the principles of ecological sustainable development.

1.10.2.1 Offshore Project Proposal

Woodside submitted the Scarborough OPP to NOPSEMA for assessment in February 2019 and NOPSEMA accepted the OPP in March 2020. The OPP provided the detail and evaluation of potential impacts and risks from the key components of the Scarborough development. These key components include:

- wells – drilling of the Scarborough and North Scarborough gas fields, with potential for future fields (including Thebe and Jupiter gas fields) to be tied back to the facility
- trunkline installation – installation of a gas trunkline to extend for a total of 430 km using trenching and backfill (for nearshore only)
- surface infrastructure – installation and operation of an FPU in approximately 900 m of water over the Scarborough reservoir
- subsea infrastructure – installation and operation of infield infrastructure, including wellheads, manifolds, flowlines and umbilicals, export trunkline and communications lines
- commissioning – commissioning of the overall production system (to be conducted from the FPU once on location)
- operations – hydrocarbon extraction and processing to take place at the FPU, to meet the export trunkline specifications; gas will be exported via the trunkline
- decommissioning – the facilities are to be decommissioned in accordance with good oilfield practice and relevant legislation at the time.

In accordance with Regulations 26 and 17 of the Environment Regulations, a titleholder must have submitted and have an accepted EP in place before commencing an activity. A staged approach has been undertaken with several EPs developed and submitted to NOPSEMA, to cover components of the Scarborough development approved under the Scarborough OPP.

Each EP has a defined Petroleum Activities Program and will detail and evaluate the risks and impacts, demonstrating they have been reduced to ALARP and an acceptable level for that Petroleum Activity Program. The Scarborough OPP sets out the environmental performance outcomes (EPOs) for the project and the level of performance to be achieved, to ensure that environmental impacts and risks will be of an acceptable level and the project is consistent with the principles of ecologically sustainable development. These EPOs will be adopted into each EP, where relevant to the scope of the EP.

In accordance with Regulation 56 of the Environment Regulations, references to the Scarborough OPP have been made throughout this EP. The accepted OPP is available on the NOPSEMA website: Scarborough Offshore Project Proposal » NOPSEMA.

1.10.2.2 Recovery Plans and Threat Abatement Plans

Under section 139(1)(b) of the EPBC Act, the Minister for the Environment must not act inconsistently with a recovery plan for a listed threatened species or ecological community or a threat abatement plan for a species or community protected under the EPBC Act. Similarly, under section 268 of the EPBC Act:

“A Commonwealth agency must not take any action that contravenes a recovery plan or a threat abatement plan.”

In respect to offshore petroleum activities in Commonwealth waters, these requirements are implemented by NOPSEMA via the commitments included in the Program. Commitments relating to listed threatened species and ecological communities under the EPBC Act are included in the Program Report (Commonwealth of Australia (CoA), 2014a).

1.10.2.3 Australian Marine Parks

Under the EPBC Act, Australian Marine Parks (AMPs), formally known as Commonwealth Marine Reserves, are recognised for conserving marine habitats and the species that live and rely on these habitats. The Director of National Parks (DNP) is responsible for managing AMPs (supported by Parks Australia) and is required to publish management plans for them. Other parts of the Australian Government must not perform functions or exercise powers in relation to these parks that are inconsistent with management plans (section 362 of the EPBC Act). Relevant AMPs are identified in Section 4.8 and described in Section 11.5 of the Master Existing Environment (Appendix L: Woodside Master Existing Environment). The North-west Marine Parks Network Management Plan (DNP, 2018a) describe the requirements for managing the marine parks that are relevant to this EP.

Specific zones within the AMPs have been allocated conservation objectives as stated below (International Union for Conservation of Nature (IUCN) Protected Area Category) based on the Australian IUCN reserve management principles outlined in Schedule 8 of the *EPBC Regulations 2000* (Cth):

- **Special Purpose Zone (IUCN category VI)**—managed to allow specific activities though special purpose management arrangements while conserving ecosystems, habitats and native species. The zone allows or prohibits specific activities.
- **Sanctuary Zone (IUCN category Ia)**—managed to conserve ecosystems, habitats and native species in as natural and undisturbed a state as possible. The zone allows only authorized scientific research and monitoring.
- **National Park Zone (IUCN category II)**—managed to protect and conserve ecosystems, habitats and native species in as natural a state as possible. The zone only allows nonextractive activities unless authorised for research and monitoring.
- **Recreational Use Zone (IUCN category IV)**—managed to allow recreational use, while conserving ecosystems, habitats and native species in as natural a state as possible. The zone allows for recreational fishing, but not commercial fishing.
- **Habitat Protection Zone (IUCN category IV)**—managed to allow activities that do not harm or cause destruction to seafloor habitats, while conserving ecosystems, habitats and native species in as natural a state as possible.
- **Multiple Use Zone (IUCN category VI)**—managed to allow ecologically sustainable use while conserving ecosystems, habitats and native species. The zone allows for a range of sustainable uses, including commercial fishing and mining where they are consistent with park values.

2 ENVIRONMENT PLAN PROCESS

2.1 Overview

This section outlines the process Woodside follows to prepare the EP once an activity has been defined as a petroleum activity. The process describes the environmental risk assessment methodology that is used to identify, analyse and evaluate risks to meet ALARP and acceptability requirements and to develop EPOs and EPSs. This section also describes Woodside's risk management methodologies applicable to implementation strategies applied during the activity.

Regulation 21(5) of the Environment Regulations requires the detailing of environmental impacts and risks, and evaluation appropriate to the nature and scale of each impact and risk associated with the Petroleum Activities Program and potential emergency conditions. The objective of the risk assessment process, described in this section, is to identify the impacts and risks of an activity, so that they can be assessed, and appropriate control measures applied to eliminate, control or mitigate the impacts and risks to ALARP and determine if the impact or risk is of an acceptable level.

Environmental impacts and risks assessed include those directly and indirectly associated with the Petroleum Activities Program and includes potential emergency and accidental events.

- **Planned activities** (routine and non-routine) have the potential for inherent environmental impacts.
- An **environmental risk** is an unplanned event with the potential for impact (termed risk 'consequence').

In this EP, the potential results of planned activities are termed 'impacts', whereas 'risks' are associated with unplanned events with the potential for impact (should the risk be realised); with such potential impacts termed 'consequences'.

2.2 Environmental Risk Management Methodology

2.2.1 Woodside Risk Management Process

The environmental risk management methodology used in this EP is based on Woodside's Risk Management Procedure. This procedure aligns to industry standards, such as International Organization for Standardization (ISO) 31000. Woodside's WMS risk management procedures, guidelines and tools provide guidance of specific techniques for managing risk, tailored for particular areas of risk within certain business processes. Procedures applied for environmental risk management include:

- Health, Safety and Environment Management Procedure
- Impact Assessment Procedure
- Process Safety Management (PSM) Procedure.

An assessment of the impacts and risks associated with the Petroleum Activities Program has been undertaken in accordance with Woodside's Environment Impact Assessment Guideline and Risk Management Procedure. This guideline and procedure set out the broad principles and high-level steps for assessing environmental impacts across the lifecycle of Woodside's activities and managing these during project execution.

The key steps of the Woodside impact and risk management process are comprised of the:

- environmental impact and risk assessment
- communication and consultation that informs the assessment and ongoing environmental performance of the activity
- steps required during implementation of the activity including to monitor, review and report.

2.2.2 Establish the Context

Context is established by considering the proposed activities associated with a Petroleum Activities Program, and the environment in which the activities are planned to take place.

Describing the activity involves the evaluation of whether the activity meets the definition of a “petroleum activity” as defined in the Environment Regulations. The activity is then described in relation to the location, what is to be undertaken and how. This allows for the identification of environmental “aspects” for each activity.

2.2.3 Review of the Significance/Sensitivity of Receptors and Levels of Protection

Sensitivity of receptors relevant to the Scarborough Project and this Petroleum Activities Program was determined during development of the Scarborough OPP. As set out within the OPP, the sensitivity of all project receptors was determined to be either low, medium or high based on qualitative expert judgement.

During development of this EP, OPP receptor sensitivity determinations were reviewed in the context of any changing legislation or changed knowledge regarding the sensitivity of each receptor. No relevant factors were identified that would change receptor sensitivity from that determined in the OPP. Receptor sensitivity determinations from the OPP are used in the risk impact assessment summaries for each environmental risk assessment (refer to Section 6).

2.2.4 Environmental Legislation and Other Requirements

In preparing this EP, Woodside has confirmed the proposed controls and impact and risk levels are consistent with national and international standards, law and policies (including applicable plans for management and conservation advices and significant impact guidelines for MNES).

This has included developing the project in accordance with applicable legislation as identified in **Section 1.10**, and confirming the requirements of the species recovery plans and conservation advices have been considered to identify requirements that may be applicable to the risk assessment.

2.2.5 Impact and Risk Identification

Terminology used for this impact and risk assessment has been taken from the impact and risk management process, which is aligned with ISO 13001:2018 and the requirements of Part 4 (regulations 17 to 46) of the Environment Regulations.

Impacts and risks of the Scarborough Project were identified in the scoping phase of the Scarborough Project (and presented within the OPP). During this phase, the relationships between the environmental aspects identified for the proposed activities and the associated potential impacts and risks for each receptor are established. This EP considers relevant impacts and risks associated with the hook-up of the FPU, startup and commissioning activities of the FPU and associated subsea well and subsea infrastructure, ongoing operations of the FPU and ETL, IMMR activities, and gravimetry surveys.

Using the Scarborough OPP as a guide, impacts and risks associated with the Petroleum Activities Program for this EP were identified during the EP scoping phase by undertaking an Environmental Risk and Impact Identification (ENVID) workshop. Impacts, risks and potential consequences were identified based on planned and potential interaction with the activity (based on the description in Section 3), the existing environment (Section 4) and the outcomes of Woodside’s stakeholder engagement process (Section 5). The ENVID workshop was undertaken by a multidisciplinary team comprising personnel with breadth of knowledge, training and experience to reasonably assure that the hazards that may arise in connection with the Petroleum Activity Program in this EP were identified.

Impacts and risks were identified during the ENVID for both planned (routine and non-routine) activities and unplanned (accidents/incidents/emergency conditions) events. During this process, risks identified as not applicable (not credible) were removed from the assessment.

A further specific ENVID workshop was conducted in September 2024 to evaluate impacts, risks and potential consequences associated with using an Uncrewed Surface Vessel (USV) for gravimetry and IMMR activities (Section 3.11.5). The workshop was attended by personnel who had appropriate breadth of knowledge and experience, including Gravimetry Survey Project Manager, Marine Assurance Manager, Environment Plan Facilitator, Scarborough Project Environment Advisers and Global Wells and Seismic Environment Advisers. The workshop served to identify that any potential hazards associated with the use of a USV.

Outside of the ENVID process, other potential risks may be identified through consultation. When this is the case, some of these risks may be included as a Risk Assessment in Section 6, even though no direct impact pathway exists as a result of the Petroleum Activities Program. These risks, which are included to demonstrate impact potential in the context of the PAP (such as accelerated weathering of rock art as a result of onshore emissions from processing of Scarborough gas; Section 6.7.7) cannot be assigned a consequence magnitude or impact significance level as per the process outlined in Section 2.3.4 because current literature does not identify a credible impact as a result of the PAP.

2.3 Impact and Risk Analysis and Evaluation

After identifying impacts and risks, analysis and evaluation is undertaken to determine the extent of the impacts and risks, whether they are acceptable or not, and to identify the impact and risk treatment (or controls) to be implemented.

Impact and risk evaluation are undertaken by assessing the magnitude (i.e. no lasting effect, slight, minor, moderate, major or catastrophic) of the credible environmental impacts from each aspect based on extent, duration, frequency and scale, and then either:

- assigning an impact significance level to each credible environmental impact based on the receptor sensitivity and the magnitude of the impact, OR
- assigning an environmental risk level to each environmental risk based on the receptor sensitivity, magnitude of the consequence, and the likelihood of occurrence.

2.3.1 Decision Support Framework

To support the risk assessment process Woodside's HSE risk management procedures include the use of a decision support framework based on principles set out in the Guidance on Risk Related Decision Making (Oil and Gas UK, 2014). This concept has been applied during the ENVID or equivalent preceding processes during historical design decisions to determine the level of supporting evidence that may be required to draw sound conclusions regarding risk level and whether the risk is ALARP and of an acceptable level. This is to confirm:

- activities do not pose an unacceptable environmental risk
- appropriate focus is placed on activities where the risk is anticipated to be acceptable and demonstrated to be ALARP
- appropriate effort is applied to the management of risks based on the uncertainty of the risk, the complexity and risk rating (i.e. potential higher order environmental impacts are subject to further evaluation assessment).

The framework provides appropriate tools, commensurate to the level of uncertainty or novelty associated with the risk (referred to as Decision Type A, B or C). The decision type is selected based on an informed discussion around the uncertainty of the risk, then documented in ENVID output.

This framework enables Woodside to appropriately understand a risk, determine if the risk is acceptable and can be demonstrated to be ALARP.

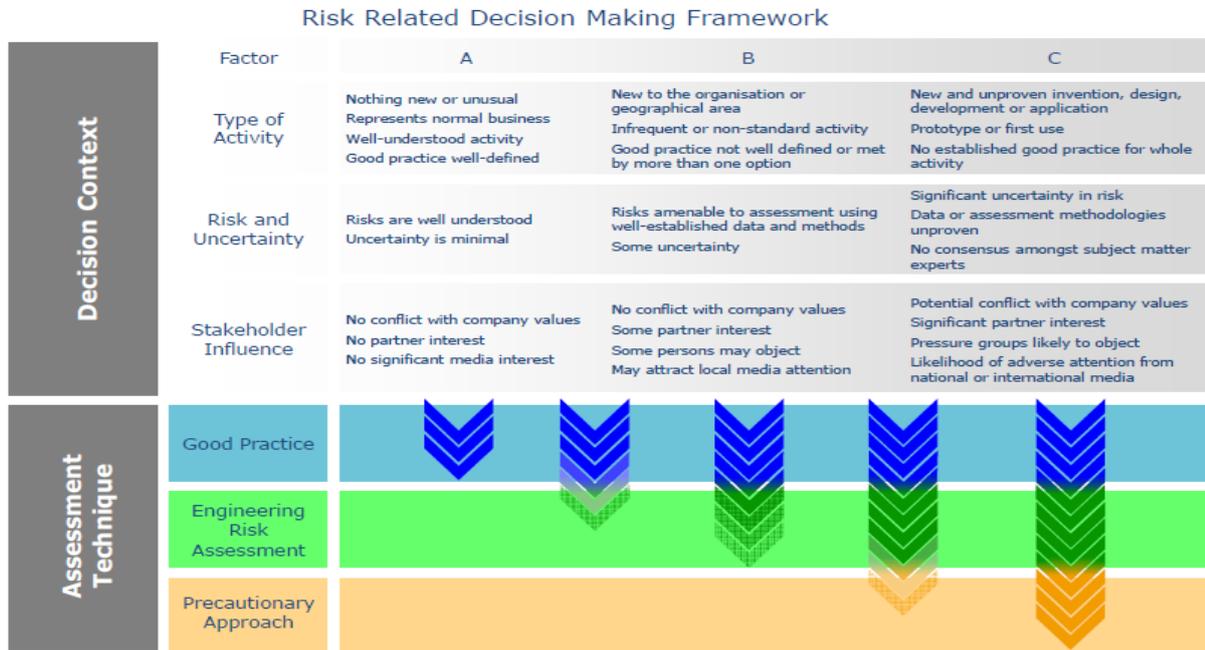

Figure 2-1: Risk related decision-making framework (Oil and Gas UK, 2014)

Decision Type A

Risks classified as a Decision Type A are well understood and established practice, they generally consider recognised good industry practice which is often embodied in legislation, codes and standards and use professional judgement.

Decision Type B

Risks classified as Decision Type B typically involve greater uncertainty and complexity (and can include potential higher order impacts/risks). These risks may deviate from established practice or have some lifecycle implications, and therefore require further engineering risk assessment to support the decision and ensure the risk is ALARP. Engineering risk assessment tools may include:

- risk-based tools such as cost based analysis or modelling
- consequence modelling
- reliability analysis
- company values.

Decision Type C

Risks classified as a Decision Type C typically have significant risks related to environmental performance. Such risks typically involve greater complexity and uncertainty; therefore, requiring adoption of the precautionary approach. The risks may result in significant environmental impact; significant project risk/exposure or may elicit negative stakeholder concerns. For these risks, in addition to Decision Type A and B tools, company and societal values need to be considered by undertaking broader internal and external consultation as part of the risk assessment process.

2.3.1.1 Decision Support Framework Tools

These framework tools are applied, as appropriate, to help identify control measures based on the Decision Type described above:

- **Legislation, Codes and Standards (LCS)** – identifies the requirements of legislation, codes and standards that are to be complied with for the activity.
- **Good Industry Practice (GP)** – identifies further engineering control standards and guidelines that may be applied by Woodside above that required to meet the LCS.
- **Professional Judgement (PJ)** – uses relevant personnel with the knowledge and experience to identify alternative controls. Woodside applies the hierarchy of control as part of the risk assessment to identify any alternative measures to control the risk.
- **Risk-based Analysis (RBA)** – assesses the results of probabilistic analyses such as modelling, quantitative risk assessment and/or cost–benefit analysis to support the selection of control measures identified during the risk assessment process.
- **Company Values (CV)** – identifies values identified in Woodside’s code of conduct, policies and the Woodside Compass. Views, concerns and perceptions are to be considered from internal Woodside stakeholders directly affected by the planned impact or potential risk.
- **Societal Values (SV)** – identifies the views, concerns and perceptions of relevant persons and addresses relevant stakeholder views, concerns and perceptions.

2.3.1.2 Decision Calibration

To determine that the alternatives selected, and control measures applied are suitable, these tools may be used for calibration (i.e. checking) where required:

- **LCS/Verification of Predictions** – Verification of compliance with applicable LCS and/or good industry practice.
- **Peer Review** – Independent peer review of PJs, supported by RBA, where appropriate.
- **Benchmarking** – Where appropriate, benchmarking against a similar facility or activity type or situation that has been deemed to represent acceptable risk.
- **Internal Consultation** – Consultation undertaken within Woodside to inform the decision and verify company values are met.
- **External Consultation** – Consultation undertaken to inform the decision and verify societal values are considered.

Where appropriate, additional calibration tools may be selected specific to the Decision Type and the activity.

2.3.2 Control Measures (Hierarchy of Controls)

Risk reduction measures are prioritised and categorised in accordance with the hierarchy of controls, where risk reduction measures at the top of the hierarchy take precedence over risk reduction measures further down:

- **Elimination** of the risk by removing the hazard.
- **Substitution** of a hazard with a less hazardous one.
- **Engineering Controls** include design measures to prevent or reduce the frequency of the risk event, or detect or control the risk event (limiting the magnitude, intensity and duration) such as:
 - Prevention: design measures that reduce the likelihood of a hazardous event occurring.
 - Detection: design measures that facilitate early detection of a hazardous event.

- Control: design measures that limit the extent/escalation potential of a hazardous event.
- Mitigation: design measures that protect the environment if a hazardous event occurs.
- Response Equipment: design measures or safeguards that enable clean up/response after a hazardous event occurs.
- **Procedures and Administration** includes management systems and work instructions used to prevent or mitigate environmental exposure to hazards.
- **Emergency Response and Contingency Planning** includes methods to enable recovery from the impact of an event (e.g. protection barriers deployed near the sensitive receptor).

2.3.3 Impact and Risk Classification

Environmental impacts and risks are assessed to determine the potential impact significance/consequence. The impact significance/consequence considers the magnitude of the impact or risk and the sensitivity of the potentially impacted receptor (Figure 2-2).

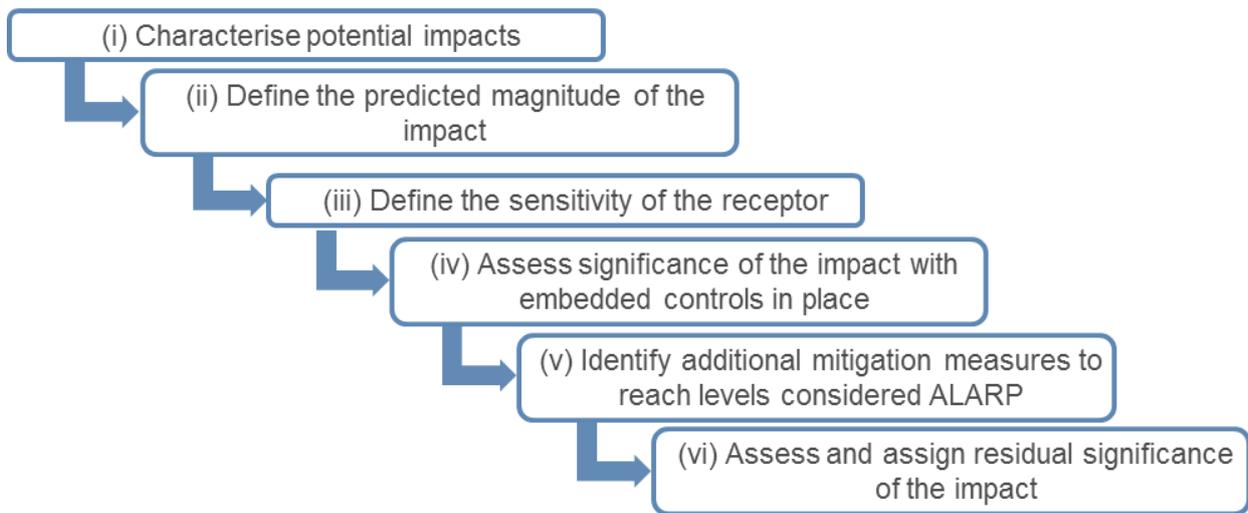

Figure 2-2: Environmental risk and impact analysis

Impacts are classified in accordance with the consequence (Table 2-1) outlined in Woodside’s Risk Management Procedure and Risk Matrix (Figure 2-3). Risks are assessed qualitatively and/or quantitatively in terms of both likelihood and consequence in accordance with this matrix.

The impact and risk information, including classification and evaluation information as shown in the example (Table 2-1), are tabulated for each planned activity and unplanned event.

Table 2-1: Woodside Risk Matrix (environment and social and cultural) consequence descriptions

Environment	Social and Cultural	Consequence Level
Catastrophic, long-term impact (>50 years) on highly valued ecosystem, species, habitat or physical or biological attribute.	Catastrophic, long-term impact (>20 years) to a community, social infrastructure or highly valued area/item of international cultural significance.	A
Major, long-term impact (10–50 years) on highly valued ecosystem, species, habitat or physical or biological attribute.	Major, long-term impact (5–20 years) to a community, social infrastructure or highly valued area/item of national cultural significance.	B
Moderate, medium-term impact (2–10 years) on ecosystem, species, habitat or physical or biological attribute.	Moderate, medium-term impact (2–5 years) to a community, social infrastructure or highly valued area/item of national cultural significance.	C

Environment	Social and Cultural	Consequence Level
Minor, short-term impact (1–2 years) on species, habitat (but not affecting ecosystem function), physical or biological attribute.	Minor, short-term impact (1–2 years) to a community or highly valued area/item of cultural significance.	D
Slight, short-term impact (<1 year) on species, habitat (but not affecting ecosystem function), physical or biological attribute.	Slight, short-term impact (<1 year) to a community or area/item of cultural significance.	E
No lasting effect (<1 month). Localised impact not significant to environmental receptor.	No lasting effect (<1 month). Localised impact not significant to area/item of cultural significance.	F

2.3.4 Risk Rating Process

The risk rating process assigns a level of risk to each risk event, measured in terms of consequence and likelihood. The assigned risk rating is determined with controls in place, therefore; the risk rating is determined after identifying the Decision Type and appropriate control measures.

The risk rating process considers the potential environmental consequences and, where applicable, the social and cultural consequences of the risk. The risk ratings are assigned using the Woodside Risk Matrix (refer to Figure 2-3).

The risk rating process is done using the steps described in the subsections below.

2.3.4.1 Select the Consequence Level

Determine the worst-case credible consequence (Table 2-1) associated with the selected event, assuming all controls (preventive and mitigative) are absent or have failed. If more than one potential consequence applies, select the highest severity consequence level.

2.3.4.2 Select the Likelihood Level

Determine the description that best fits the chance of the selected consequence occurring, assuming reasonable effectiveness of the prevention and mitigation controls (Table 2-2).

Table 2-2: Woodside Risk Matrix likelihood levels

Likelihood Description						
Frequency	1 in 100,000–1,000,000 years	1 in 10,000–100,000 years	1 in 1,000–10,000 years	1 in 100–1,000 years	1 in 10–100 years	>1 in 10 years
Experience	Remote: Unheard of in the industry	Highly Unlikely: Has occurred once or twice in the industry	Unlikely: Has occurred many times in the industry but not at Woodside	Possible: Has occurred once or twice in Woodside or may possibly occur	Likely: Has occurred frequently at Woodside or is likely to occur	Highly Likely: Has occurred frequently at the location or is expected to occur
Likelihood Level	0	1	2	3	4	5

2.3.4.3 Calculate the Risk Rating

The risk rating is derived from the consequence and likelihood levels above, in accordance with the Woodside Risk Matrix shown in Figure 2-3. A likelihood and risk rating are only applied to environmental risks, not environmental impacts from planned activities.

This risk rating is used as an input into the risk evaluation process and ultimately for prioritising further risk reduction measures. Once each risk is treated to ALARP, the risk rating articulates the ALARP baseline risk as an output of the ENVID studies.

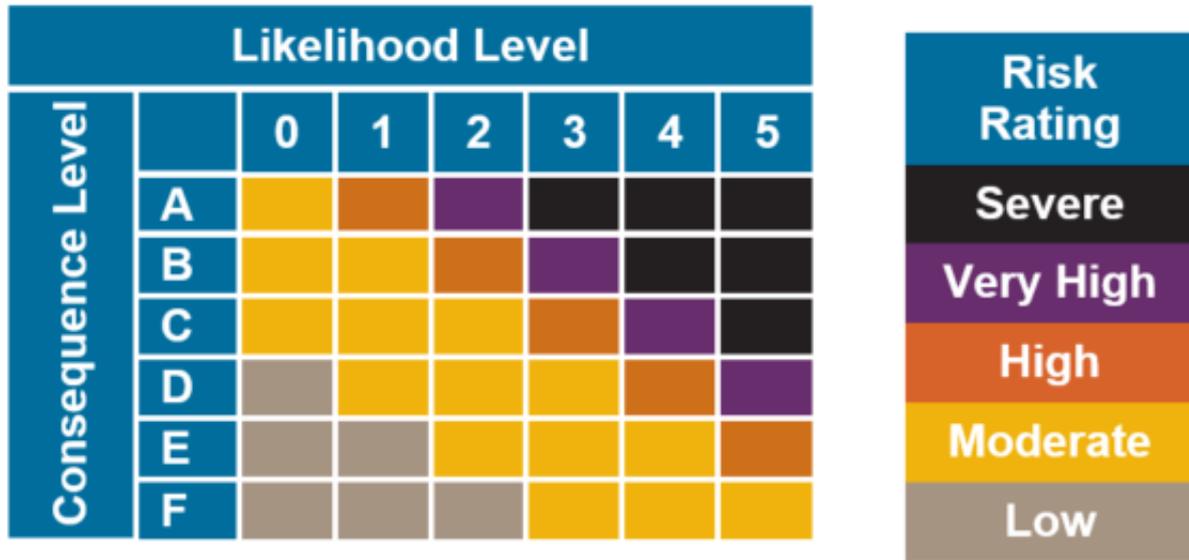

Figure 2-3: Woodside Risk Matrix – risk level

To support ongoing risk management (as a key component of Woodside’s Process Safety Management Framework) – refer to the implementation strategy in Section 7. Woodside uses the concept of ‘current risk’ and applies a Current Risk Rating to indicate the current or ‘live’ level of risk, considering controls that are currently in place and effective on a day-to-day basis. The Current Risk Rating is effective in articulating potential divergence from baseline risk, such as if certain controls fail or could potentially be compromised. Current Risk Ratings aid in communicating and making visible the risk events and ensure the continual management of risk to ALARP by identifying risk reduction measures and assessing acceptability.

2.3.5 Demonstration of As Low As Reasonably Practicable

Descriptions have been provided below (Table 2-3) to articulate how Woodside demonstrates different risks, impacts and Decision Types identified within the EP are ALARP.

Table 2-3: Summary of Woodside’s criteria for demonstrating ‘as low as reasonably practicable’

Risk	Impact	Decision Type
Low and Moderate	Negligible, Slight, or Minor (F, E or D)	A
Woodside demonstrates these Risks, Impacts and Decision Types are reduced to ALARP if: <ul style="list-style-type: none"> controls identified meet legislative requirements, industry codes and standards, applicable Woodside requirements and industry guidelines further effort towards impact/risk reduction (beyond employing opportunistic measures) is not reasonably practicable without sacrifices grossly disproportionate to the benefit gained. 		
High, Very High or Severe	Moderate and above (C, B or A)	B and C
Woodside demonstrates these higher order Risks, Impacts and Decision Types are reduced to ALARP (where it can be demonstrated using good industry practice and risk-based analysis) that: <ul style="list-style-type: none"> legislative requirements, applicable Woodside requirements and industry codes and standards are met societal concerns are accounted for the alternative control measures are grossly disproportionate to the benefit gained. 		

2.3.6 Demonstration of Acceptability

Acceptability of the Scarborough Project, including the Petroleum Activities Program described in this EP, was demonstrated in the Scarborough OPP as required by Regulation 13 of the Environment Regulations. The EPOs set out in the Scarborough OPP demonstrate that the environmental impacts and risks of the project will be managed to an acceptable level.

The impacts and risks of Scarborough were determined to be acceptable in the Scarborough OPP through considering the evaluation criteria of (Scarborough OPP; Section 6.4.4):

- principles of ecologically sustainable development (ESD) as defined under the EPBC Act, whereby:
 - decision-making processes should effectively integrate both long-term and short-term economic, environmental, social and equitable considerations (section 3A(a) of the EPBC Act)
 - if there are threats of serious or irreversible environmental damage, lack of full scientific certainty should not be used as a reason for postponing measures to prevent environmental degradation (section 3A(b) of the EPBC Act)
 - the principle of inter-generational equity—that the present generation should ensure that the health, diversity and productivity of the environment is maintained or enhanced for the benefit of future generations (section 3A(c) of the EPBC Act)
 - the conservation of biological diversity and ecological integrity should be a fundamental consideration in decision-making (section 3A(d) of the EPBC Act)
 - improved valuation, pricing and incentive mechanisms should be promoted (section 3A(e) of the EPBC Act)
 - internal context – the proposed impacts and risk levels are consistent with Woodside policies, procedures and standards

- external context – stakeholder expectations and feedback have been considered and activities do not have a significant impact on MNES including those with an Indigenous connection with, or traditional use in nearshore areas as defined in Section 4.9
- other requirements – the proposed controls and impact and risk levels are consistent with national and international standards, laws, policies and Woodside Standards (including applicable plans for management and conservation advices, and significant impact guidelines for MNES).

In this EP Woodside has demonstrated that the level of acceptability determined in the Scarborough OPP has been met through the criteria of:

- adoption of relevant Scarborough OPP EPOs and controls or equivalent
- adoption of EP specific controls where required
- Impact Significance Level/Risk Consequence levels for receptors are equal to or less than the significant impact level defined in the Scarborough OPP (Section 6.5; Table 6-3) and are therefore consistent with the EPOs and managed to an acceptable level of impact or risk
- consideration of internal/external context and other requirements specific to this EP Petroleum Activities Program (including issues raised during EP Consultation).

A summary of the process as adopted is shown in Table 2-4.

Table 2-4: Summary of Woodside’s criteria for Acceptability for Scarborough Environment Plan

Risk	Impact	Decision Type
<i>Low and Moderate</i>	<i>Negligible, Slight, or Minor (F, E or D)</i>	<i>A</i>
Woodside demonstrates these Risks, Impacts and Decision Types are 'Broadly Acceptable' if they meet the EP criteria listed above in Section 2.3.5 . Further effort towards risk reduction (beyond employing opportunistic measures) is not reasonably practicable without sacrifices disproportionate to the benefit gained.		
<i>High, Very High or Severe</i>	<i>Moderate and above (C, B or A)</i>	<i>B and C</i>
Woodside demonstrates these higher order Risks, Impacts and Decision Types are 'Acceptable if ALARP' if they meet the EP criteria listed above in Section 2.3.5 . In addition, these higher order risks, impacts and decision types are 'Acceptable if ALARP' if it can be demonstrated that the predicted levels of impact and/or residual risk, are managed to ALARP (as described in Section 6).		
For potential C or above consequence/impact levels where significant uncertainty exists in analysis of the risk or impact (such as, for predicted or potential high risk of significant environmental impacts, significant project risk/exposure, novel activities, lack of consensus on standards, and significant stakeholder concerns (e.g. Decision Type C), defined acceptable levels and assessment of acceptability may be required to be conducted separately for key receptors. This may not be applicable for some risks, given the consequence of an unplanned risk event occurring may not be acceptable and, therefore acceptability is demonstrated in the context of the likelihood of an event occurring and subsequent impacts.		

2.4 Environment Protection and Biodiversity Conservation Act Assessment

To support the demonstration of acceptability, a separate assessment is undertaken across the following three legislative requirements incorporated into the EPBC Act.

2.4.1 Principles of Ecological Sustainable Development

As part of the demonstration of acceptability, an assessment is undertaken to demonstrate that the EP is not inconsistent with relevant principles of ESD (refer Section 2.3.6).

2.4.2 Matter of National Environmental Significance: Significant Impact Guidelines 1.1

A separate assessment is undertaken to determine if the potential impacts/risks of the activity trigger any relevant criteria listed in the MNES: Significant Impact Guidelines 1.1.

An action is likely to have a significant impact on a critically endangered or endangered species if there is a real chance or possibility that it will:

- lead to a long-term decrease in the size of a population
- reduce the area of occupancy of the species
- fragment an existing population into two or more populations
- adversely affect habitat critical to the survival of a species
- disrupt the breeding cycle of a population
- modify, destroy, remove, isolate or decrease the availability or quality of habitat to the extent that the species is likely to decline
- result in invasive species that are harmful to a critically endangered or endangered species becoming established in the endangered or critically endangered species' habitat
- introduce disease that may cause the species to decline, or interfere with the recovery of the species.

An action is likely to have a significant impact on a vulnerable species if there is a real chance or possibility that it will:

- lead to a long-term decrease in the size of an important population of a species
- reduce the area of occupancy of an important population
- fragment an existing important population into two or more populations
- adversely affect habitat critical to the survival of a species
- disrupt the breeding cycle of an important population
- modify, destroy, remove or isolate or decrease the availability or quality of habitat to the extent that the species is likely to decline
- result in invasive species that are harmful to a vulnerable species becoming established in the vulnerable species' habitat
- introduce disease that may cause the species to decline, or
- interfere substantially with the recovery of the species.

2.4.3 Recovery Plan and Threat Abatement Plan Assessment

To support the demonstration of acceptability, a separate assessment is undertaken to demonstrate that the EP is not inconsistent with any relevant recovery plans or threat abatement plans (refer Section 1.10.2.2). The steps in this process are:

- identify relevant listed threatened species and ecological communities (Section 4)
- identify relevant recovery plans and threat abatement plans (Section 6.9.3)
- list all objectives and (where relevant) the action areas of these plans, and assess whether these objectives/action areas apply to government, the Titleholder, and the Petroleum Activities Program (Section 6.9.3)
- for those objectives/action areas applicable to the Petroleum Activities Program, identify the relevant actions of each plan, and evaluate whether impacts and risks resulting from the activity are clearly not inconsistent with that action (Section 6.9.3).

2.5 Environmental Performance Objectives/Outcomes, Standards and Measurement Criteria

The Environment Regulations define EPOs to mean: “a measurable level of performance required for the management of environmental aspects of an activity to ensure that environmental impacts and risks will be of an acceptable level”. As such, the process of defining an appropriate EPO, has relied on the required levels of performance set either in:

- legislation (such as the OPGGS Act)
- regulator guidance notes such as the Matters of National Environmental Significance– Significant Impact Guidelines (DoE, 2013), or
- specific agreements or expectations with other relevant persons (e.g. fishers or other marine users).

EPOs for the Scarborough Project have been set within the Scarborough OPP and assessed as meeting the requirements of the Environment Regulations to be appropriate, consistent with the principles of ecologically sustainable development and to demonstrate that the environmental impacts and risks of the project will be managed to an acceptable level. Impact based EPOs, where qualitative terms (e.g. prevent, limit) are used in EPOs, are supported by detailed impact assessments in Section 6 such that they can be interpreted as meaning ‘impact and risk greater than that predicted in this EP’.

EPs for petroleum activities submitted after the OPP process are required to contain EPOs that are appropriate by being consistent with those set out in the OPP. The EPOs presented in a subsequent EP are not required to be identical to those set out in the OPP. However, they should achieve the same environmental outcome (or better) as that described in the OPP. Activity specific EPs will also be required to contain measurement criteria and performance monitoring, auditing and reporting processes relating to the EPOs.

Table 6-2 shows a comparison between EPOs in the Scarborough OPP and this EP.

3 DESCRIPTION OF THE ACTIVITY

3.1 Overview

This section has been prepared in accordance with Regulation 21(1) of the Environment Regulations and describes the activities to be undertaken as part of the Petroleum Activities Program under this EP. This section includes the location of the Petroleum Activities Program, general details of installation and hook-up of the Scarborough FPU to the mooring system (Figure 3-1), the connection of the FPU to preinstalled subsea infrastructure/gas export trunkline, and its subsequent commissioning and start-up. The section also includes general details of the facility's layout, operational details of the Petroleum Activities Program and additional information relevant to considering environmental risks and impacts.

The FPU will be hooked up to the mooring system, connected to subsea infrastructure and commissioned. Once commissioned, the FPU will produce gas from a series of reservoirs and associated subsea infrastructure. The semi-submersible FPU is designed to be locally or remotely operated. The FPU topside processing facilities include gas separation, dehydration, and compression to the export trunkline for processing onshore. Mono-Ethylene Glycol (MEG) is stored and regenerated on the platform and injected both subsea and topsides for hydrate management. The Scarborough gas field is characterised by very low quantities of associated liquid hydrocarbons resulting in the FPU having a simple processing and treatment design due to there being no requirement to separately store, export or re-inject liquid hydrocarbons.

Figure 3-1: Scarborough floating production unit render / artists impression.

An overview of the Petroleum Activities Program is provided in Table 3-1.

Table 3-1: Petroleum Activities Program overview

Item	Description
Production Licence Areas	WA-61-L, WA-62-L
Pipeline Licence	WA-32-PL
Location	Carnarvon Basin, North-West Australia
Water depth (below MSL)	FPU location: ~950 m
	Offshore Operational Area: ~900 m to 1000 m
	Trunkline Operational Area: ~31 m (export trunkline route at State waters boundary) to 1400 m (deepest point at KP 275 of the export trunkline route)
Planned Field Life	Approximately 30 years with potential to be extended
Key components of FPU	<ul style="list-style-type: none"> • Moored FPU with gas processing equipment and utilities. • 20 x suction piles and anchor chains
Key components of subsea infrastructure	<ul style="list-style-type: none"> • Up to 13 wells including wellheads; (8 wells in Phase 1 and 5 wells in Phase 2). • Xmas tree per well • 3 x production risers • 3 x gas export risers • 6 x riser holdback mud mats • 3 x flowlines • 7 x flowline sleepers • 1 x riser base manifold (RBM) and foundation • 13 x mud mats as support to ILTs and FLETS • 7 x in-line structures (in-line T) • 6 x flowline end terminations (FLETS) • 7 x umbilical termination assemblies • 7 x umbilical termination heads • 2 x subsea distribution units • 1 x subsea distribution assembly • 7 x umbilicals • 9 x flexible jumpers (includes 1 spare) • Multiple flying leads • 1 x trunkline spool • Export trunkline (~433km in length) • Pipeline End Termination (PLET) • Up to 265 x concrete pads for gravimetry
Key vessel types	<ul style="list-style-type: none"> • Tow and anchor handling tugs (AHT) • Light construction vessel (LCV) • Support vessels (including supply vessels) (OSV) • Accommodation support vessel (ASV) • Uncrewed Surface Vessel (USV)

Item	Description
<p>Key activities</p>	<p>Offshore facility hookup and commissioning</p> <ul style="list-style-type: none"> • Installation and hook-up of the FPU to the pre-laid 20-point suction-piled mooring system • Production and export riser pull-in, hook-up and connection to subsea infrastructure • Umbilical riser pull-in • Dewatering of production flowlines/risers and export risers/manifold/PLET • Commissioning of the overall subsea production system, including Xmas trees, umbilicals and communication lines • Commissioning the FPU for the introduction of reservoir hydrocarbons • Bunkering Diesel and MEG • Gas export trunkline pressurisation and nitrogen (N₂) removal • Removal of temporary equipment <p>Offshore facility initial start-up</p> <ul style="list-style-type: none"> • Well clean up • Starting-up the subsea production system and FPU to allow the reservoir fluids and processing equipment to reach operational pressures and temperatures, as well as obtaining sufficient and stable equipment inlet flow to enable the equipment to perform to design criteria <p>Offshore facility operations</p> <ul style="list-style-type: none"> • Routine production operations involve conveying reservoir fluids, including gas and produced water from the reservoir, along with MEG injection at the wells, through the subsea infrastructure to the FPU. • Gas export via the gas export trunkline • Routine IMMR activities for the FPU, subsea infrastructure (excluding well intervention or well workover activities) and gas export trunkline. • Well clean-up and commissioning. • Non-routine and unplanned activities and incidents associated with the above <p>Other activities</p> <ul style="list-style-type: none"> • Gravimetry surveys for the purposes of reservoir monitoring • Non-routine and contingent activities associated with the above.

3.2 Location

The Petroleum Activities Program consists of the Scarborough FPU, wells and subsea infrastructure located in Permit Areas WA-61-L and WA-62-L in Commonwealth waters, about 375 km west-north-west of Dampier (Figure 3-2). The Petroleum Activities Program also includes the gas export trunkline (WA-32-PL), which traverses through Commonwealth and State waters through to the Pluto LNG Plant (PLP). Only the portion of the gas export trunkline within Commonwealth waters is within the scope of this EP. The closest landfall to the FPU is the North-West Cape, about 216 km south-south-east at its nearest point. The coordinates and permit areas of the Petroleum Activities Program are presented in Table 3-2.

Table 3-2: Scarborough infrastructure approximate locations and Petroleum Titles

Structure	Water depth (approx. MSL)	Coordinates (GDA 94)		Petroleum Titles
		Latitude	Longitude	
Facility				
Scarborough FPU	953	19° 55' 33.73" S	113° 14' 29.75" E	WA-61-L

* Phase 1 proposed well locations may vary up to 3 km in radius subject to further engineering design. To be installed under Scarborough Drilling and Completions EP.

** Proposed well locations are subject to further engineering design. To be installed under a future EP.

*** SCA11 is a Phase 1 contingency (Option 1 Longitude/Latitude shown). Contingency to be installed under Scarborough Drilling and Completions EP for Phase 1. Installation during Phase 2 is subject to a future EP.

3.3 Operational Area

The PAA defines the spatial boundary of the Petroleum Activities Program as described, risk assessed and managed by this EP, including vessel related petroleum activities within the PAA (Figure 3-2). The PAA is comprised of one overarching Combined Offshore Operational Area (hereafter referred to as the Offshore Operational Area) and one Trunkline Operational Area.

The Offshore Operational Area is made up of the following two Operational Areas specific to the key activities of the Petroleum Activities Program described in Section 3.1 and are shown in Figure 3-3:

- Operational Area 1 applies during FPU hook-up, commissioning, start-up, and routine operations activities: a radius of 2000 m around the location of the FPU and a 1500 m radius from the centre point or from the centreline of subsea infrastructure¹.
- Operational Area 2 applies during gravimetry survey activities only: a radius of 1000 m around Permit Areas WA-61-L and WA-62-L². This allows for the movement and positioning of vessels undertaking gravimetry surveys around the outermost concrete pads of the permit area(s).

The Trunkline Operational Area is 500m either side of the Trunkline centreline, extending ~410 km from the export RBM spool tie-in flange across Commonwealth Waters to the boundary with WA State Waters. This applies throughout the Petroleum Activities Program.

¹ The 1500 m radius excludes gravimetry concrete pads which are covered in Operational Area 2.

² Gravimetry activities (operations related to the recovery of petroleum) will be undertaken within the bounds of title areas WA-61-L and WA-62-L. Extension of the operational area 1000m beyond the title boundary allows for vessel maneuverability on sea surface only and has been discussed with adjacent title holders through consultation (Ref Appendix F, Table 2)

Vessel-related activities within the Trunkline Operational Area and the Offshore Operational Area are managed under this EP. Vessels supporting the Petroleum Activities Program when outside of these Operational Areas (e.g., transiting to and from port) are outside the scope of this EP and must adhere to applicable maritime regulations and other requirements which are not managed under this EP.

3.4 Timing

The Petroleum Activities Program includes number of temporary activities (FPU installation and hook-up, commissioning and start-up), followed by ongoing operations and IMMR. The earliest commencement date for hook up and offshore commissioning is currently estimated to be 2H 2025. Further details and a breakdown of activities are provided in (Table 3-3).

The EP has risk assessed the PAP throughout the year (all seasons) to provide operational flexibility for schedule changes and vessel availability.

Table 3-3: Timing of Petroleum Activities Program

Activity	Vessel Type	Earliest estimated start and duration	Relevant EP Section
FPU Hook-Up and Commissioning			
Pre-laid mooring chain retrieval and hook-up to FPU	Anchor handling tugs (AHTs)	Earliest commencement: 2H 2025 Duration: ~30 days – 45 days	3.6.1
Subsea Production and Export Riser Hook-up	Light construction vessel (LCV)	Commencement: Following completion of mooring hook-up Duration: ~14 days – 30 days	3.6.2
Subsea system dewatering and commissioning	LCV	Commencement: Following completion of Subsea Production and Export Riser Hook-up Duration: ~2 months – 3 months	3.7.1
FPU commissioning	Support Vessel Accommodation Support Vessel (ASV)	Commencement: Upon arrival to the Scarborough field and post hook-up ³ Duration: ~3 – 6 months	3.7.3
FPU Initial Start-up			
Initial start-up including well clean up	Support Vessel LCV	Commencement: At Ready for Start-Up (RFSU) Duration: ~3 – 6 months	3.8
FPU Operations			
FPU operations including maintenance and ongoing support vessel operations	Support Vessel	Following facility final acceptance, and ongoing for the life of the EP. Final Acceptance occurs once for the entire facility (See Section 3.8 for further detail). This is the point at which GHG emissions commissioning and startup controls are planned to be replaced by operations phase controls.	3.9

³ Commissioning of some FPU systems may commence prior to the FPU arrival in the Scarborough field and may remain ongoing concurrently with subsea hook-up, dewatering and commissioning.

		<p>Produced water system controls are planned to switch to Operations phase controls once “steady-state” is achieved (which may or may not be at the same time as Facility Final Acceptance).</p> <p>Because “steady-state” is expected to take around 6 months post RFSU, on Figure 3-4 below this is shown to occur at the same time as Facility Final Acceptance.</p>	
IMMR including contingent flowline and trunkline pigging	Support Vessel LCV Uncrewed Surface Vessel (USV)	<p>May occur any time post-infrastructure installation for the life of this EP.</p> <p>Variable duration: Table 3-8</p>	3.9.17
Gravimetry surveys	Support Vessel LCV USV	<p>~55 days per survey</p> <p>First survey to be completed ~18 month post ready for start-up</p> <p>Subsequent survey every 2-3 years.</p>	3.10

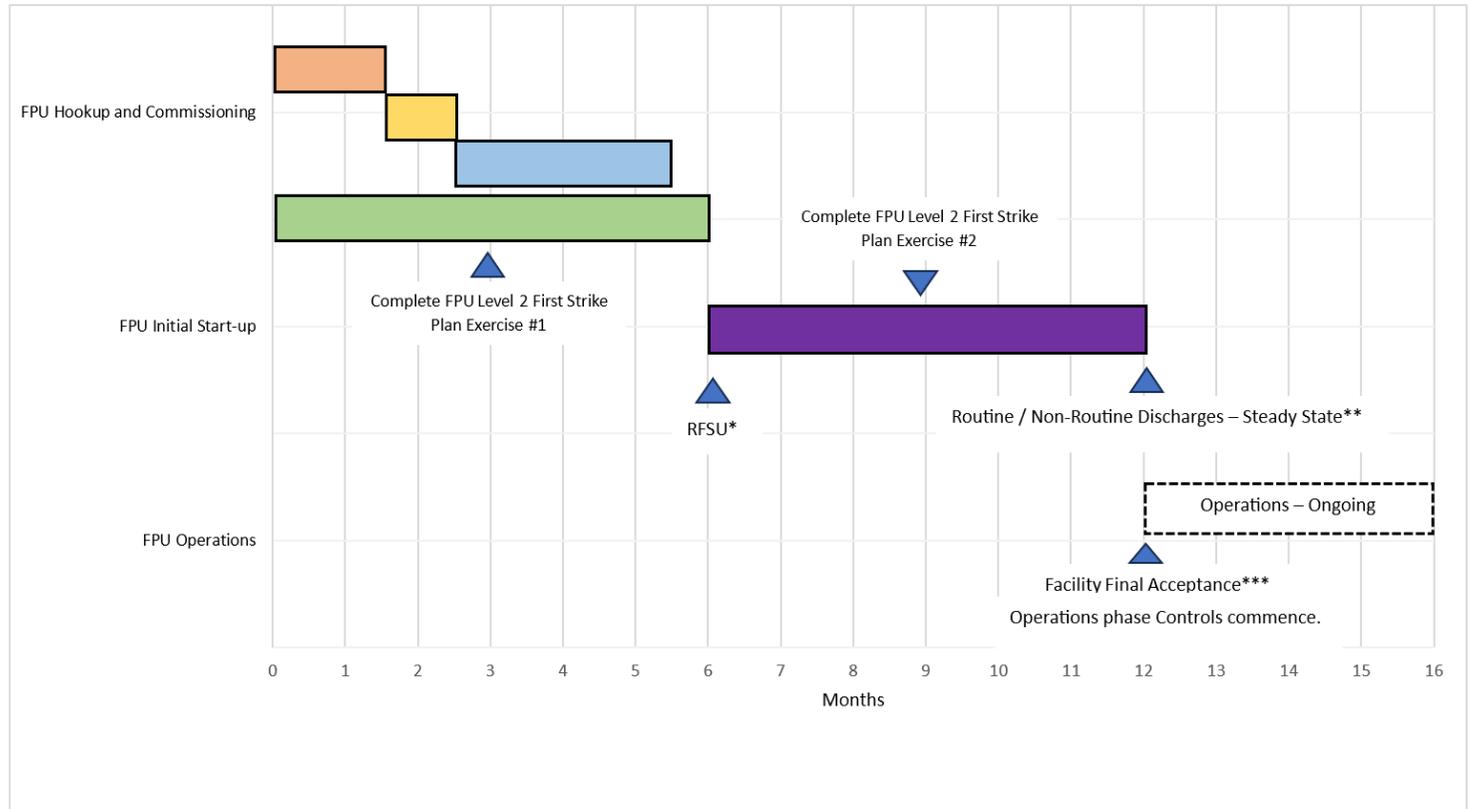

Operation of the FPU will be continuous (24 hours per day, 365 days per year).

Supporting activities, such as both FPU and subsea routine inspection, monitoring, maintenance, and repair (IMMR) (Section 3.9.17), take place as required.

Simultaneous operations (SIMOPS) may occur between activities within the PAA, with timing of some subsea hook-up, commissioning and survey activities overlapping. Timing, duration and vessel selection for all activities is subject to change due to project schedule requirements, vessel availability, unforeseen circumstances, and weather.

The Petroleum Activities Program currently has a planned field life from startup of operations of approximately 30 years, subject to reservoir performance and life extension studies.

This EP is intended to remain in force in accordance with Regulation 36 of the Environment Regulations.

- Pre-laid mooring chain retrieval and hook-up to FPU (30 – 45 days)
- Subsea Production and Export Riser Hook-up (14 – 30 days)
- Subsea system dewatering and commissioning (2 – 3 months)
- FPU Commissioning (3 - 6 months)
- Initial start-up including well clean-up (3 - 6 months)

* RFSU – Ready for Start-Up Well cleanup and introduction of hydrocarbons to the topsides

** Routine / Non-Routine Discharges – Steady State – Operations Controls for discharges such as Produced Water become applicable once steady state is achieved i.e. routine discharge commences, contaminant concentrations and discharge volumes remain steady (Approx. 6 months after startup)

*** Facility Final Acceptance – Successful completion of all performance testing ensuring systems meet design intent, functionality, and operability requirements.

Figure 3-4: FPU Hookup, Commissioning, Start-up and Operations – Planned durations and sequence

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

3.5 Future Expansion

The FPU is designed to be able to accommodate future potential tie-back opportunities including from Thebe and Jupiter gas fields and potentially other resources owned either by Woodside or other Titleholders. Additionally, the export trunkline has provision for future tie-in opportunities. Any future development opportunities (such as additional Phase 2 wells) would be undertaken in accordance with the Scarborough Offshore Project Proposal (the primary approval for the Scarborough Project). The scope of the approved OPP includes 30 wells in total across Scarborough (Phase 1 and 2), Thebe and Jupiter, which includes 10 contingency wells.

Provision for tie-in to the FPU, such as spare riser slots and preinstalled tees in the export trunkline is part of the current design of the Scarborough infrastructure. The infrastructure to support the potential Thebe and Jupiter field development is likely to comprise development wells and subsea infrastructure such as manifolds, possibly subsea compression, and flowlines.

Future Scarborough Phase 2 wells or development of the Thebe and Jupiter fields will require development of Environment Plans specific to these Petroleum Activities Programs. The Acceptable levels of impact from the OPP and relevant EPO's (or develop EPO's commensurate with those from the OPP) will be cascaded into future Scarborough Development EP's. The EP MOC process (Section 7.2.6) will be used to determine if resubmission of this *Scarborough Offshore Facility and Trunkline (Operations)* Environment Plan is required to enable any future developments.

3.6 Floating Production Unit Installation and Hook-up

On arrival in the Offshore Operational Area the FPU will be held in position by tow tugs (with towlines) as shown in Figure 3-5 using dynamic positioning (DP). Once pre-installation inspections and tests have been satisfactorily completed and the marine warranty surveyor (MWS) has issued their certificate of approval, mooring hook-up operations are planned to commence.

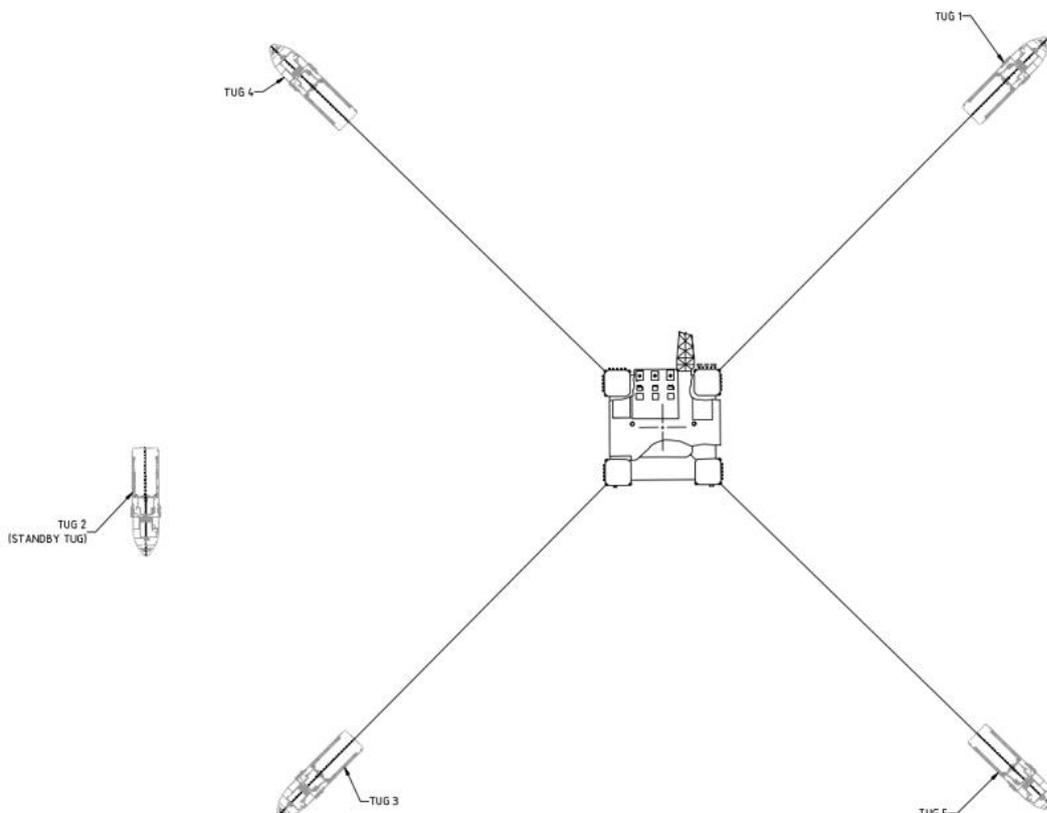

Figure 3-5: Floating production unit pre-mooring installation preparations

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

3.6.1 Floating Production Unit Mooring Hook-up

The FPU will be hooked up to a pre-installed mooring system, comprising 20 suction piles and mooring lines. The FPU is positioned into the prevailing weather direction and brought towards mooring centre. While four tow tugs maintain the position of the FPU, two mooring hook-up anchor handling tugs (AHT) will each begin recovery from the seabed to the deck of each pre-installed mooring line. The pre-laid mooring lines will be recovered from the seabed and connected to chain stoppers on each column of the FPU. The mooring system incorporates a monitoring system, to measure and log horizontal excursions. Once complete, clump weights and installation chain are recovered.

The installation of the suction piles and mooring chains and their wet storage on the seabed is planned to be undertaken under the *WA-61-L and WA-62-L Subsea Infrastructure Installation Environment Plan*.

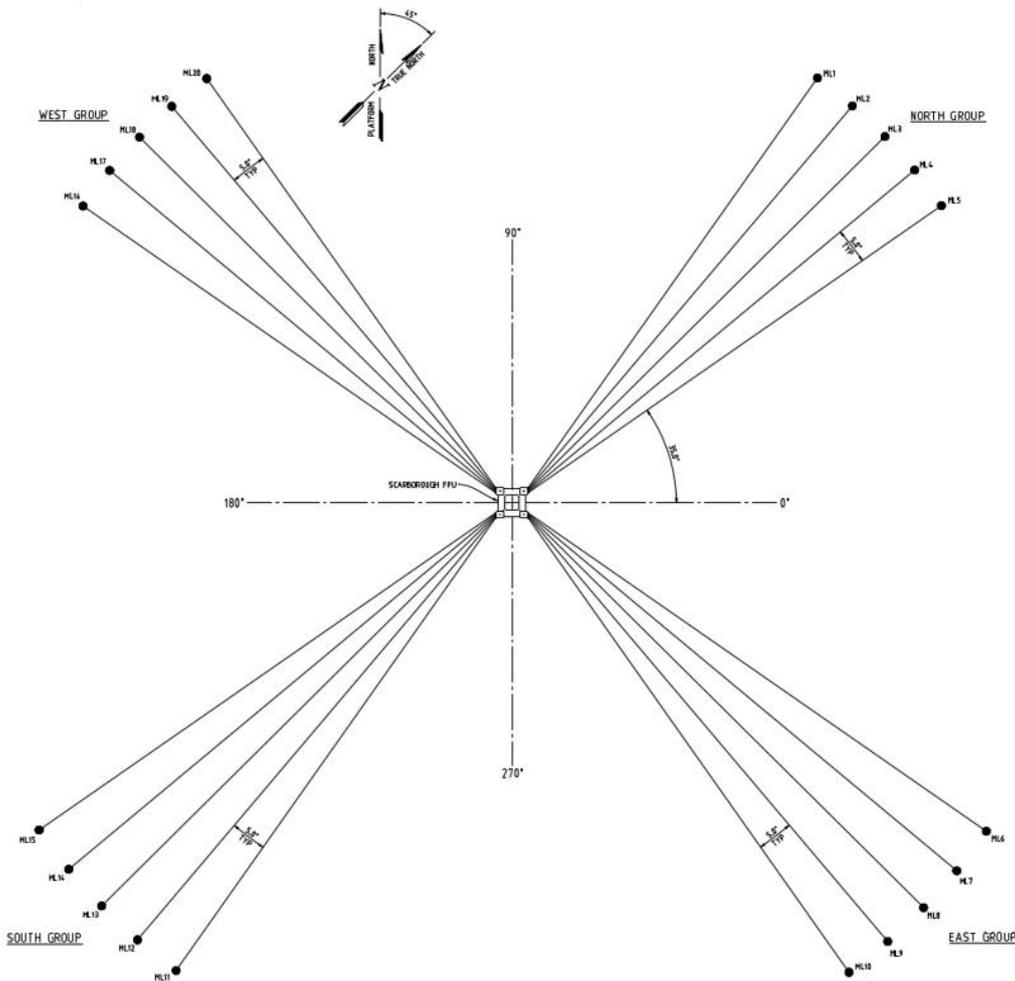

Figure 3-6: Floating production unit mooring lines layout

3.6.2 Production and Export Riser Hook-up

Following the connection of all mooring lines to the FPU, the subsea infrastructure previously installed and wet stored will be pulled-in and hooked-up to the FPU. This includes three production risers, three export risers and one dynamic umbilical to be pulled-in and hung-off the FPU hull. Following pull-in, activities that will be performed are:

- annulus vacuum test to confirm that no water ingress occurred during installation

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

- (contingency only) a structural integrity test performed if damage is suspected or if any of the lay parameters exceed maximum allowable limits
- risers connected to FPU topsides
- leak testing of the topside tie-in spool and riser connection using nitrogen/helium.

Contingent activities that may be required during this process include repair of leakages from topsides/subsea connections, additional flushing of risers and flowlines if damage or contamination is found to have occurred (resulting in additional discharges) and wet storage on the seabed of equipment found to be defective.

3.7 Offshore Facility Commissioning

Once hooked-up to the FPU, the subsea production and export systems will be dewatered and commissioned. This will be conducted in parallel with FPU topsides commissioning, readying the connected facility for start-up (i.e. hydrocarbon introduction).

3.7.1 Dewatering of Production and Export Systems

Following topsides hook-up, dewatering of the production and export systems will be performed from FPU end of the risers using a Nitrogen dewatering spread and pig launcher receivers (PLRs). A series of pigs will be pushed through the production and export risers/flowlines to remove the treated seawater, leaving the systems filled with nitrogen. Dewatering will result in multiple discharges subsea, of filtered and treated seawater and freshwater (with additives including corrosion inhibitor, biocide, oxygen scavenger and dye), MEG and glycol-based gel pigs.

The subsea PLRs will be recovered upon completion of flowline dewatering operations and replaced with high pressure caps. Once installed, the piping between the cap and the isolation valve will be flushed with MEG mixture to displace any seawater ingress. Leak testing will then be performed to check the cap connection.

3.7.2 Subsea System Commissioning

Commissioning of the subsea system will involve testing of subsea controls communications from the FPU to the subsea control modules to confirm system readiness for hydrocarbon introduction. The exercising of valves will result in control fluid discharge.

3.7.3 Floating Production Unit Commissioning

The FPU commissioning process involves activities to confirm the integrity of the interconnected facility, so it is ready for start-up (RFSU) with the introduction of hydrocarbons. There will be no flaring prior to RFSU milestone. Where practicable, commissioning activities will be completed prior to the FPU arriving in the PAA. However, foreseeable activities that may occur after arrival in the PAA include:

- commissioning and start-up of some utilities systems
- installation and reinstatement testing of systems and equipment to operate the FPU that may have been removed or disturbed during the sail-down
- removal of temporary equipment/waste
- function testing (leak testing) of the hydrocarbon processing system
- final calibrations and testing of piping, alignment, hoses, safety systems, emergency shutdown valves, pumps, monitoring systems, heating, venting and air conditioning (HVAC) equipment and telecommunications connections
- safety system testing (e.g. emergency shutdown)
- commissioning of remaining systems that were not commissioned prior to arrival in the PAA.

3.7.4 General Facility Maintenance

During this period, power will be supplied to necessary equipment via diesel generators. Power generation for the facility will remain on diesel until start-up of the fuel gas system is complete and a steady fuel gas supply is available. Nitrogen from various topsides packages will be sent to the flare. Emissions from this activity are considered in Section 6.7.6.

Treated water may be discharged during commissioning activities. Fluids suitable for discharge will be over boarded or routed through the produced water treatment system, while fluids not suitable for discharge (e.g. waste oil) will be captured in a tank and transported onshore.

3.8 Offshore Facility Initial Start-up

Once the FPU is RFSU and before a steady state of production can be achieved, an initial start-up period is required to allow clean-up of the wells and to introduce hydrocarbons to the topsides equipment and pressurise the export trunkline. Start-up is as follows:

- The subsea production choke will be opened slowly to allow the flow of well fluids into the subsea production system, which will displace the nitrogen from the flowline to the FPU. Initially the nitrogen and then reservoir gas will be flared; drilling fluids will be removed and well performance and integrity will be proven (see Section 3.8.1). Flaring will continue until various start-up objectives are met (e.g. steady fuel gas available, trunkline has met minimum pressure requirements, export compressor(s) commissioned).
- As stable gas is established, the first processing train and the fuel gas system will be commissioned.
- The export trunkline can be pressurised, either using FPU export gas or from onshore.
 - If using FPU export gas, gas meeting export specification is directed to the trunkline via the fuel gas system.
 - If using onshore gas, the trunkline will be brought to pressure using gas from onshore, with trunkline nitrogen removed via the FPU high pressure flare.
- Once steady gas on the FPU is established and the trunkline is pressurised, the first export gas compressor start-up can be completed, and gas export can commence. At this point, flaring will be largely reduced, as gas will be directed to the trunkline instead of partially to the flare. It is expected to take 30-60 days from RFSU to reach this point.
- As the start-up sequence progresses, the remaining wells and flowlines can be cleaned up with the subsequent commissioning of the other processing trains and export compressors.

Equipment performance trials will be completed once production rates or equipment is available.

The end of the “initial start-up” phase and the beginning of “operations” phase is marked by successful completion of performance testing, and “Final Acceptance” of the facility. Performance testing confirms that the systems meet their design intent, functionality and operability requirements (i.e. the systems are operating as designed and intended). Performance testing requirements must be met in order to achieve final acceptance, and this milestone occurs for the entire facility at the same time. This means that major systems will be operational, including gas conditioning trains providing on-spec gas for export, the MEG recovery unit, the produced water system, and the flare. Troubleshooting for performance testing issues may continue beyond facility Final Acceptance. If required, (for example if equipment is not operating as intended by design), the EP Change Management Process (Section 7.2.6) will be followed to manage ongoing issues and potential environmental impacts. Initial start-up phase controls for Routine and Non-Routine Greenhouse Gas Emissions will be replaced by operational phase controls at this point. Non-Routine Discharges controls, which will switch to Operations controls once ‘steady state’ is achieved. This occurs once routine discharge commences, and contaminant concentrations and discharge volumes are seen to remain steady. Post start-up, a period of time is required to optimise the PW treatment system and

to confirm how it operates and reacts to changes in the process (pressures, chemical concentrations, flow rates). It is expected that this will take approximately 6 months post facility initial start-up.

Flaring during the initial start-up period will occur while equipment and wells are brought online and emergency shutdown, blowdown and performance testing occurs. Flare pilots will remain on propane until the fuel gas system is commissioned and a stable fuel gas supply has been established. Likewise, topsides systems will be run off diesel until a stable fuel gas supply has been established. Emissions associated with these activities are considered in Section 6.7.6. Emissions estimates include contingency for additional flaring if unexpected issues arise during start-up (e.g. export system commissioning delays).

For discharges during the start-up of the facility, there may be short term peaks in contaminant values as equipment is brought online for the first time, but this is not expected based on the system design. Discharge of sewage and grey water from the FPU may be elevated with an increase in Persons On Board (POB) during this period. Unplanned sources of fluid that are unable to be treated and discharged (e.g. waste oil), will be captured in tanks and transported onshore.

3.8.1 Well Cleanup

Scarborough wells will initially be cleaned up to a temporary well clean-up (WCU) package on the FPU which will be lined up to an individual flowline/train at a time. The WCU package will filter solids carried in the liquid stream. The liquid will be routed to the HP Flare Knock-out Drum, where the liquids will be degassed, and they will be sent to the closed drain drum for further degassing. Due to contamination from drilling and completion chemicals, all the liquid (dirty MEG) will be held in a rich MEG tank, and depending on cleanliness a decision will then be made on whether to process the MEG onboard or send onshore and dispose at an appropriate onshore waste facility. Criteria for reclamation will be based on whether the MEG is contaminated enough to impact the MEG Recovery Unit (MRU). If the MEG is recovered onboard the usual MEG recovery process will be applied and subsequent PW discharges may contain additional chemicals from the drilling and completions process. Additional MEG bunkering may be required to replenish the lean MEG inventory after well clean up. Gas produced during this activity will be flared until the systems required to export gas to the trunkline have been commissioned.

In the scenario, which is considered unlikely, where a well produces formation water during clean up, the formation water, MEG and well clean up liquids will be sent to a dedicated tank (base case for all well clean up liquids). If a well is identified to be producing formation water, it is expected that it will be immediately shut in. In the unlikely event that a water-producing well was kept online for an extended period, the formation water would either be segregated with the other well clean up liquids (for disposal onshore) or alternatively, be sent to a rich MEG tank for processing and discharge as per the usual process. The formation water would only be discharged if it was on spec. The alternative is to re-direct it inboard to the rich MEG tanks if off-spec.

3.9 Scarborough Operations

3.9.1 Facility Layout and Description

This section provides an overview of the Scarborough FPU and associated infrastructure, as relevant to consideration of the environmental risks and impacts of the Petroleum Activities Program.

3.9.1.1 Topsides

The FPU topsides consists of three main decks (lower, middle and upper) and four additional mezzanine and valve decks (Lower Mezzanine Deck, Middle Mezzanine Deck, Lower Valve Deck and Upper Valve Deck). The plan view area is 7,878 m², extending 101 m long and 78 m wide.

The layout of the topsides is configured such that:

- the hydrocarbon processing equipment and flare system are located to the north
- utilities, main laydown, and utilities building) sit between the process areas and the Living Quarters (LQ)
- the process area is segregated from the utilities by a fire and blast rated partition that extends from the Lower Deck to above the Middle Deck
- two pedestal cranes, located on east and west sides of the Middle Deck
- the Flare Boom is located towards the NE corner of the Lower and Middle Decks
- the Platform Crane South crane is located on the west side of the LQ.

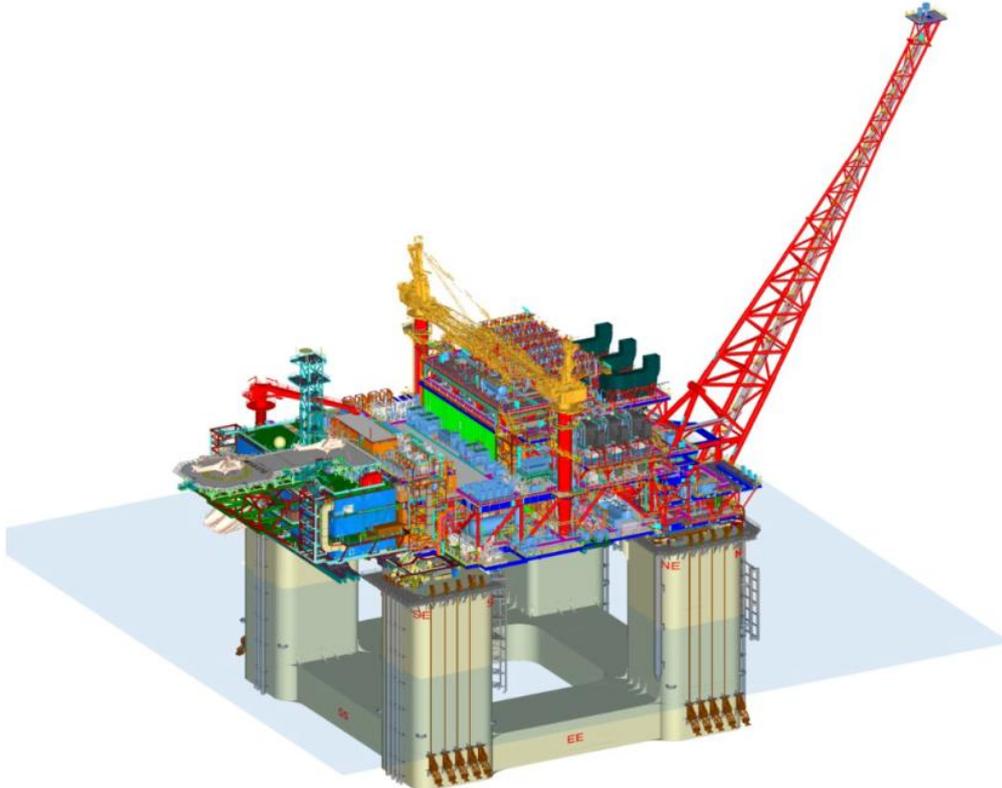

Figure 3-7: Facility topsides overview

3.9.1.2 Process Area

The process areas support the following systems and equipment:

- The Lower Deck process connects to the subsea production and export risers and contains the Inlet Separators, MRU, MEG injection, chemical injection and Flare Knock Out (KO) Drums.
- Temporary pig receiver facilities are located at equivalent elevation as Lower Deck Mezzanine level on the NW corner.
- The Middle Deck contains the Export Gas Compressors (EGCs) and Discharge Coolers, Gas-Gas Heat Exchangers, MRU, Fuel Gas Heaters and Main Power Generators (MPGs).
- The Upper Deck contains the EGC turbine intakes and exhausts, gas blowdown/relief valves and expansion vessels for the cooling systems.
- The Lower and Upper Valve Decks contain the Pressure Safety Valves (PSVs) and expansion vessel for the heating system.

- The Flare Boom is located towards the NE corner of the Lower and Middle Decks.
- Two pedestal cranes are located on east and west sides of the Middle Deck. Diesel storage is within the crane pedestals.

3.9.1.3 Utilities Area

The Lower Deck contains the enclosures for the Firewater Pump (FWP) Generators, Emergency Diesel Generator (EDG) and Black Start Generator (BSG), seawater system, ultraviolet sterilisers for the freshwater system, Fire Water Ringmain and deluge valve skids, instrument air system and FRC.

The Middle Deck provides the main laydown area, Nitrogen Generation, Hypochlorite Generation, Reverse Osmosis (RO) Water Maker, Produced Water Treatment (PWT), Open and Closed Drain Waste Drum, and the chemical storage area.

3.9.1.4 Utility Building

The Utility Building (UB), containing the laboratory and workshop, is located to the south of the Utilities/laydown areas. It is integral to the Lower and Middle Deck structures and extends above the Middle Deck. The largest proportion of the UB is occupied by electrical switchgear and marshalling cabinets.

A Battery Energy Storage System (BESS) and the instrument air receivers and driers are located on the roof of the UB.

3.9.1.5 Living Quarters

The LQ is located to the south of the UB and contains the Local Control Room (LCR), galley/mess, cabins, medical facility and direct access to the lifeboats (located to the south) and the Helideck (located on the roof of the LQ). The roof of the LQ also supports the Heating, Ventilation and Airconditioning (HVAC) equipment, aviation fuel skid, telecommunications radio tower and radar.

3.9.1.6 Floating Production Unit Hull

The FPU's hull structure consists of four columns connected to a ring pontoon containing ballast tanks. Each of the four hull columns is subdivided into a number of compartments (tanks), comprising of:

- void tanks
- access shafts
- freshwater storage tanks and Utility water tank (seawater (SW) column)
- MEG storage tanks (NE and NW columns).

3.9.2 Wells and Reservoirs

The Scarborough wells will be managed in accordance with the Scarborough Well Operations Management Plan – Operate Phase (WOMP). The WOMP describes control measures in place to ensure the risks to the well integrity are reduced to ALARP, including during periods of non-operation, before permanent decommissioning.

During Scarborough Drilling and Completions activities, (under the accepted EP *Scarborough Drilling and Completions Environment Plan*) wells with wellheads that are re-spudded and wellheads unable to be removed will be managed through Woodside's Change Management Processes (Section 7.2.7) under this EP. The Scarborough Drilling and Completions EP includes requirements for wellhead removal attempts and sets out where it may be acceptable to leave a wellhead in-situ post re-spud.

Decommissioning of the wellheads will progress once the wells have been accepted as permanently abandoned wells (AW). However, planning AW wellhead decommissioning is premised upon the plan for removal, with consideration of the principles of ALARP and acceptability. Once the wells have been accepted as permanently abandoned and the decommissioning activity is defined, an EP will be submitted for the wellhead decommissioning activity. Decommissioning planning is further described in Section 7.3).

3.9.3 Subsea Infrastructure Operations

Phase 1 of the Scarborough development consists of eight (plus one contingent) subsea wells tied back to the FPU via three subsea production 16" rigid flowlines.

The subsea infrastructure above the mudline comprises a xmas tree connected to a wellhead at each well location (Table 3-2). Each subsea xmas tree is approximately 5 x 5 x 5 m (Length x Width x Height) and is connected to the flowlines via flexible jumpers. The production flowlines each terminate at a Flowline End Termination (FLET) with subsea isolation valve (SSIV) approximately 1.6 km away from the FPU. The production fluids from each flowline are transported to the FPU by three dedicated 14" flexible production risers with provision for two additional production risers to be installed in the future. The flexible production risers are hung off the top of I-tubes, which are supported by a cantilevered platform at the NW column of the FPU's hull. At the hang-offs, the flexible risers are connected to the rigid riser spools. The other ends of the spools are connected to the Riser Emergency Shutdown Valves (RESRVs) which are located on the NW corner of the Lower Deck of the FPU.

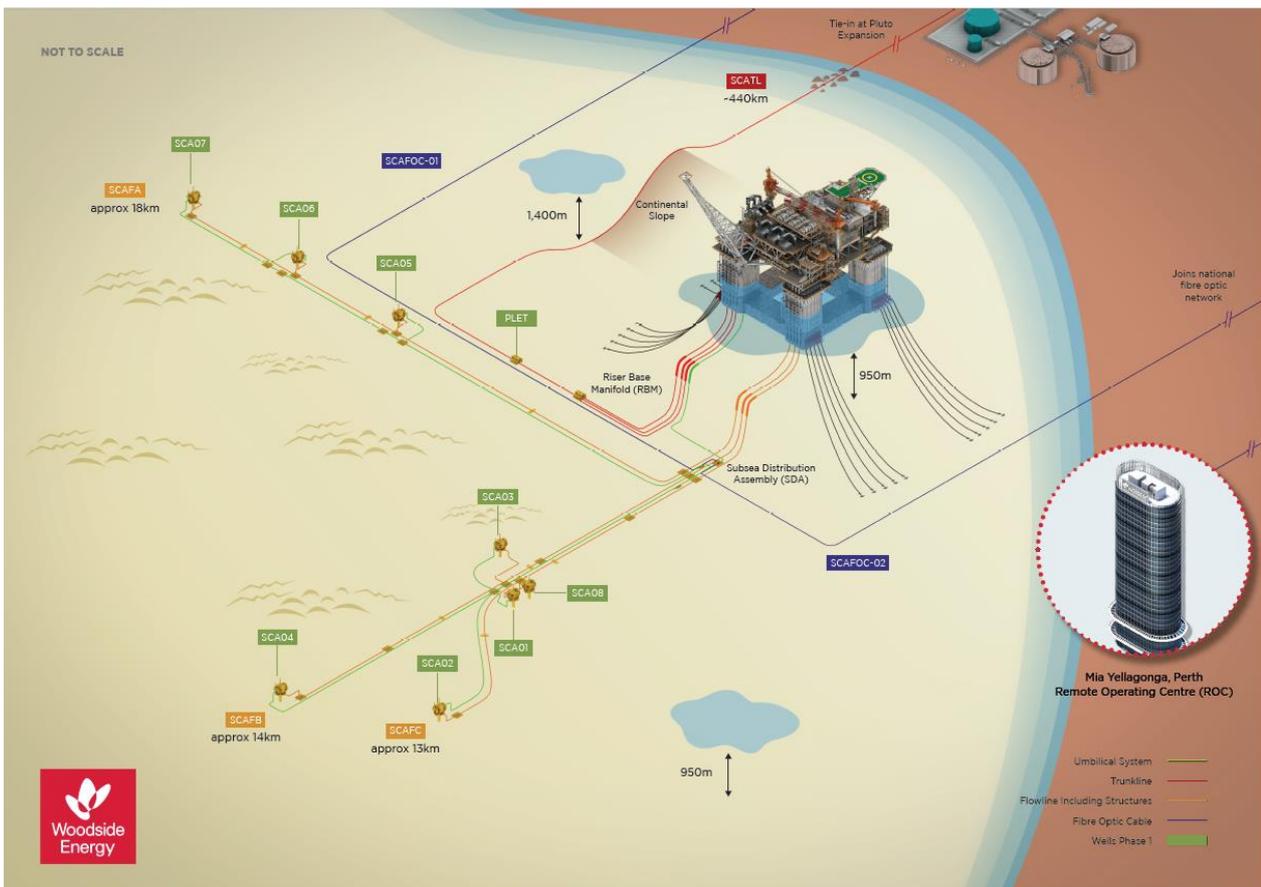

Figure 3-8: Indicative Scarborough field infrastructure layout

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

The three flexible export gas risers which are connected to the North-East column of the FPU, feed dry gas into the Riser Base Manifold (RBM) with non-return valves into a single 32-inch spool and through to the export trunkline (ETL) (Section 3.9.4). The FPU subsea infrastructure consists of:

- Wells/Xmas trees/wellheads
- flowlines
- risers
- flexible jumpers
- umbilicals
- flying leads
- flowline end terminations (FLETs)
- umbilical termination heads and assemblies
- subsea distribution units and assemblies
- export trunkline
- trunkline spool
- pipeline end termination (PLET)
- riser base manifold (RBM) and foundation
- support structures (sleepers, mud mats, in-line structures).

The FPU subsea infrastructure is controlled from the FPU through the:

- umbilical and subsea electro/hydraulic distribution system which provide hydraulic services, electrical power and control services, and chemical injection services as required
- valves which control subsea operations and processes
- chokes which control pressure and flow rates from the production wells
- subsea control modules (SCM), which are sealed, and pressure compensated electrohydraulic units (typically found on the XT), which link the surface and subsea controls.
- subsea valves may be overridden manually/mechanically via a remotely operated vehicle (ROV).

3.9.4 Export Trunkline

The licenced section (WA-32-PL) of the ETL starts at the RBM outboard flange and includes the 32-inch spool, the PLET and the ETL between the PLET and the State Waters boundary. The ETL can be isolated from the FPU export system by the Riser Emergency Shutdown Valves (RESRVs) located on each export riser, and non-return valves are provided in the RBM for each export riser. The trunkline route traverses a deepwater escarpment to the vicinity of the Pluto riser platform and follows the existing Pluto Export Trunkline (WA-17-PL) route to shore. Outside of this EP scope; the trunkline continues through state waters to the onshore Pluto Gas Plant. The Trunkline infrastructure consists of:

- Trunkline:
 - 36-inch Subsea pipeline (KP 32.036 to KP 200),
 - 32-inch Subsea pipeline (KP 200 to KP 433), and
 - Buckle arrestors from KP 208.3 to the PLET;
- In-Line Tee Assembly (ILTA);
- Two identical Hot Tap Tee Assemblies (HTTAs) for future tie-ins;
- PLET;

- 32-inch Spool; and
- Export RBM spool tie-in flange.

The ETL is designed to require minimal maintenance during operating life, with planned IMMR activities as described in Section 3.9.17.

The design and operating parameters for the ETL are detailed in Table 3-4.

Table 3-4: Export Trunkline Design and Operating Parameters

Description	Details
<i>Trunkline</i>	
Length	433.053 km (total)
Diameter, internal	864 mm from KP -0.029 to KP 200 760 mm from KP 200 to KP 433
Wall thickness:	Line pipe: 27.3 mm – 39 mm Buckle Arrestors: 65.0 mm
Coatings: Nearshore/Midwater and Slope Crossing (KP 0.09 to KP 204)	Bituminous Enamel (BE) Concrete Weight Coating (CWC)
Slope Crossing to Deep Water (KP 204 to 433.053)	Three-layer Polypropylene
Weight Coating:	
Material	Concrete (on BE coated sections and at the slope crossing)
Density	3040 kg/m ³
Thickness	40 – 110 mm
Field joints	Heat shrink sleeve with epoxy primer
Design pressure and temperature:	
Pressure	Full Vacuum to (24.2 MPaa) (242 bara) at +30 m mean sea level (MSL)
Temperature	-10 to +60 °C
Maximum Normal Operating Pressure (NOP) at FPU export compression system ¹	21.0 MPaa (210 bara)
Normal Operating pressure range at Offshore Pipeline Termination Point ^{1,2}	70 to 95 bara
FPU Export Normal Operating Temperature Range	37 to 45 °C
Expected Maximum Export Flow Rate	1750 MMscfd
Cathodic Protection (CP): Pipeline (including crossings, transition piece and HTTAs)	Sacrificial bracelet anodes (Al-Zn-In).
ILTA and PLET	Additional anodes attached to these structures
Design Life	25 years
Hydrocarbon Product – Dry gas	
Component	~ Mole Fraction (%)

3.9.5 Moorings

The FPU has a piled anchor mooring system, comprising 20 suction piles and mooring lines (five mooring lines per column) connected to chain stoppers 20 m below the water level on each column of the FPU. Each mooring line is composed of chain and wire segments, extend approximately 1800 m from the FPU and are connected to suction piles that are exposed above the seabed by ~1 to 2 m. The mooring system incorporates a monitoring system, to measure and log horizontal excursions.

3.9.6 Operational Details

This section provides a description of the main operations associated with the FPU.

3.9.6.1 Attendance Modes

Typically, the facility will be operated with a complement of personnel supplemented during times of higher need, for example start up and maintenance campaigns, up to the maximum POB. Control of the facility will be from the Integrated Remote Operations Centre (IROC) onshore in Perth or from the Local Control Room on the facility. Personnel will be removed from the facility during extreme weather events, although the facility will continue to operate.

Operations fall under any one of the modes of:

- hookup and commissioning (HUC)
- initial start-up and turnarounds (i.e. max POB)
- normal operations (attended mode)
- campaign maintenance
- cyclone response
- unattended mode.

During Hookup and Commissioning accommodation utilisation will be maximised. An Accommodation Support Vessel (ASV) could be utilised alongside the FPU to further accommodate up to ~500 people.

After HUC, Initial start-up and maintenance campaigns will have the largest number of personnel on the facility, which has been designed to accommodate around 75 people (subject to future change). During normal operations the facility will be minimally crewed.

As described in Section 3.8, normal operation mode will be entered after successful completion and close out of all performance testing.

Normal, steady-state operations are categorised by:

- production remote operations
- major projects
- maintenance, including subsea IMMR and removal activities
- well maintenance
- well start-up and commissioning
- suspension
- flowline flushing prior to well plug and abandonment.

The FPU is designed to allow for unattended operation for extended periods and is remotely controlled via the IROC. The facility is designed to be operated unattended for approximately 28 days (driven by consumables replenishment timeframes and other operation limitations), after which point an intervention visit / maintenance campaign will occur. Intervention visits are planned to be

~3 weeks long. In the initial years of operation, the FPU will only operate in unattended mode during severe cyclones, when personnel are demobilised as a precautionary safety measure. Operating in unattended mode for the longer durations is not expected to start until facility achieves reliable operations, likely two years post RFSU.

3.9.7 Process Description

3.9.7.1 Production Process

The hydrocarbon processing facilities, represented by the process flow diagram in Figure 3-10 are designed to produce dry gas safely and efficiently for export to Pluto Gas Plant / Karratha Gas Plant for processing.

The production fluids arriving from the subsea production system are processed on the FPU in three parallel gas processing trains, each comprising inlet separation, gas conditioning and export gas compression. The inlet to each gas processing train is aligned to a single production flowline/riser. There is provision (drop out spools) for commingling of multiple production flowline/risers to a single gas processing train if required later in field life.

Each gas processing train ties into a common compressor suction header at the outlet of the gas conditioning system to allow for operational flexibility and redundancy in the event of a compressor outage. Specifically, if one compressor fails, the others can continue to operate, enabling continuous processing.

The gas conditioning trains and compressors can each be isolated for maintenance while the others remain operational. In such cases, gas import rates will be reduced and/or compressor line-up will be altered in a controlled manner to avoid excess flaring. This redundancy minimises the impact of maintenance activities on production.

The production trains are supported by:

- a common liquid handling system that includes a MRU and a produced water treatment (PWT) and disposal system
- MEG storage and injection
- facilities for collection and removal of recovered hydrocarbon liquid, sand/solids and mercury.

In addition, the gas processing trains provide gas to meet FPU fuel gas requirements.

The MPGs on the FPU are dual fuel (i.e. can run on both fuel gas and diesel) and will run on diesel prior to fuel gas becoming available during initial and normal start-up. Diesel will be available for certain uses such as the BSG, EDG and FWP generators, when required for black start or emergency response.

3.9.7.2 Inlet Facilities

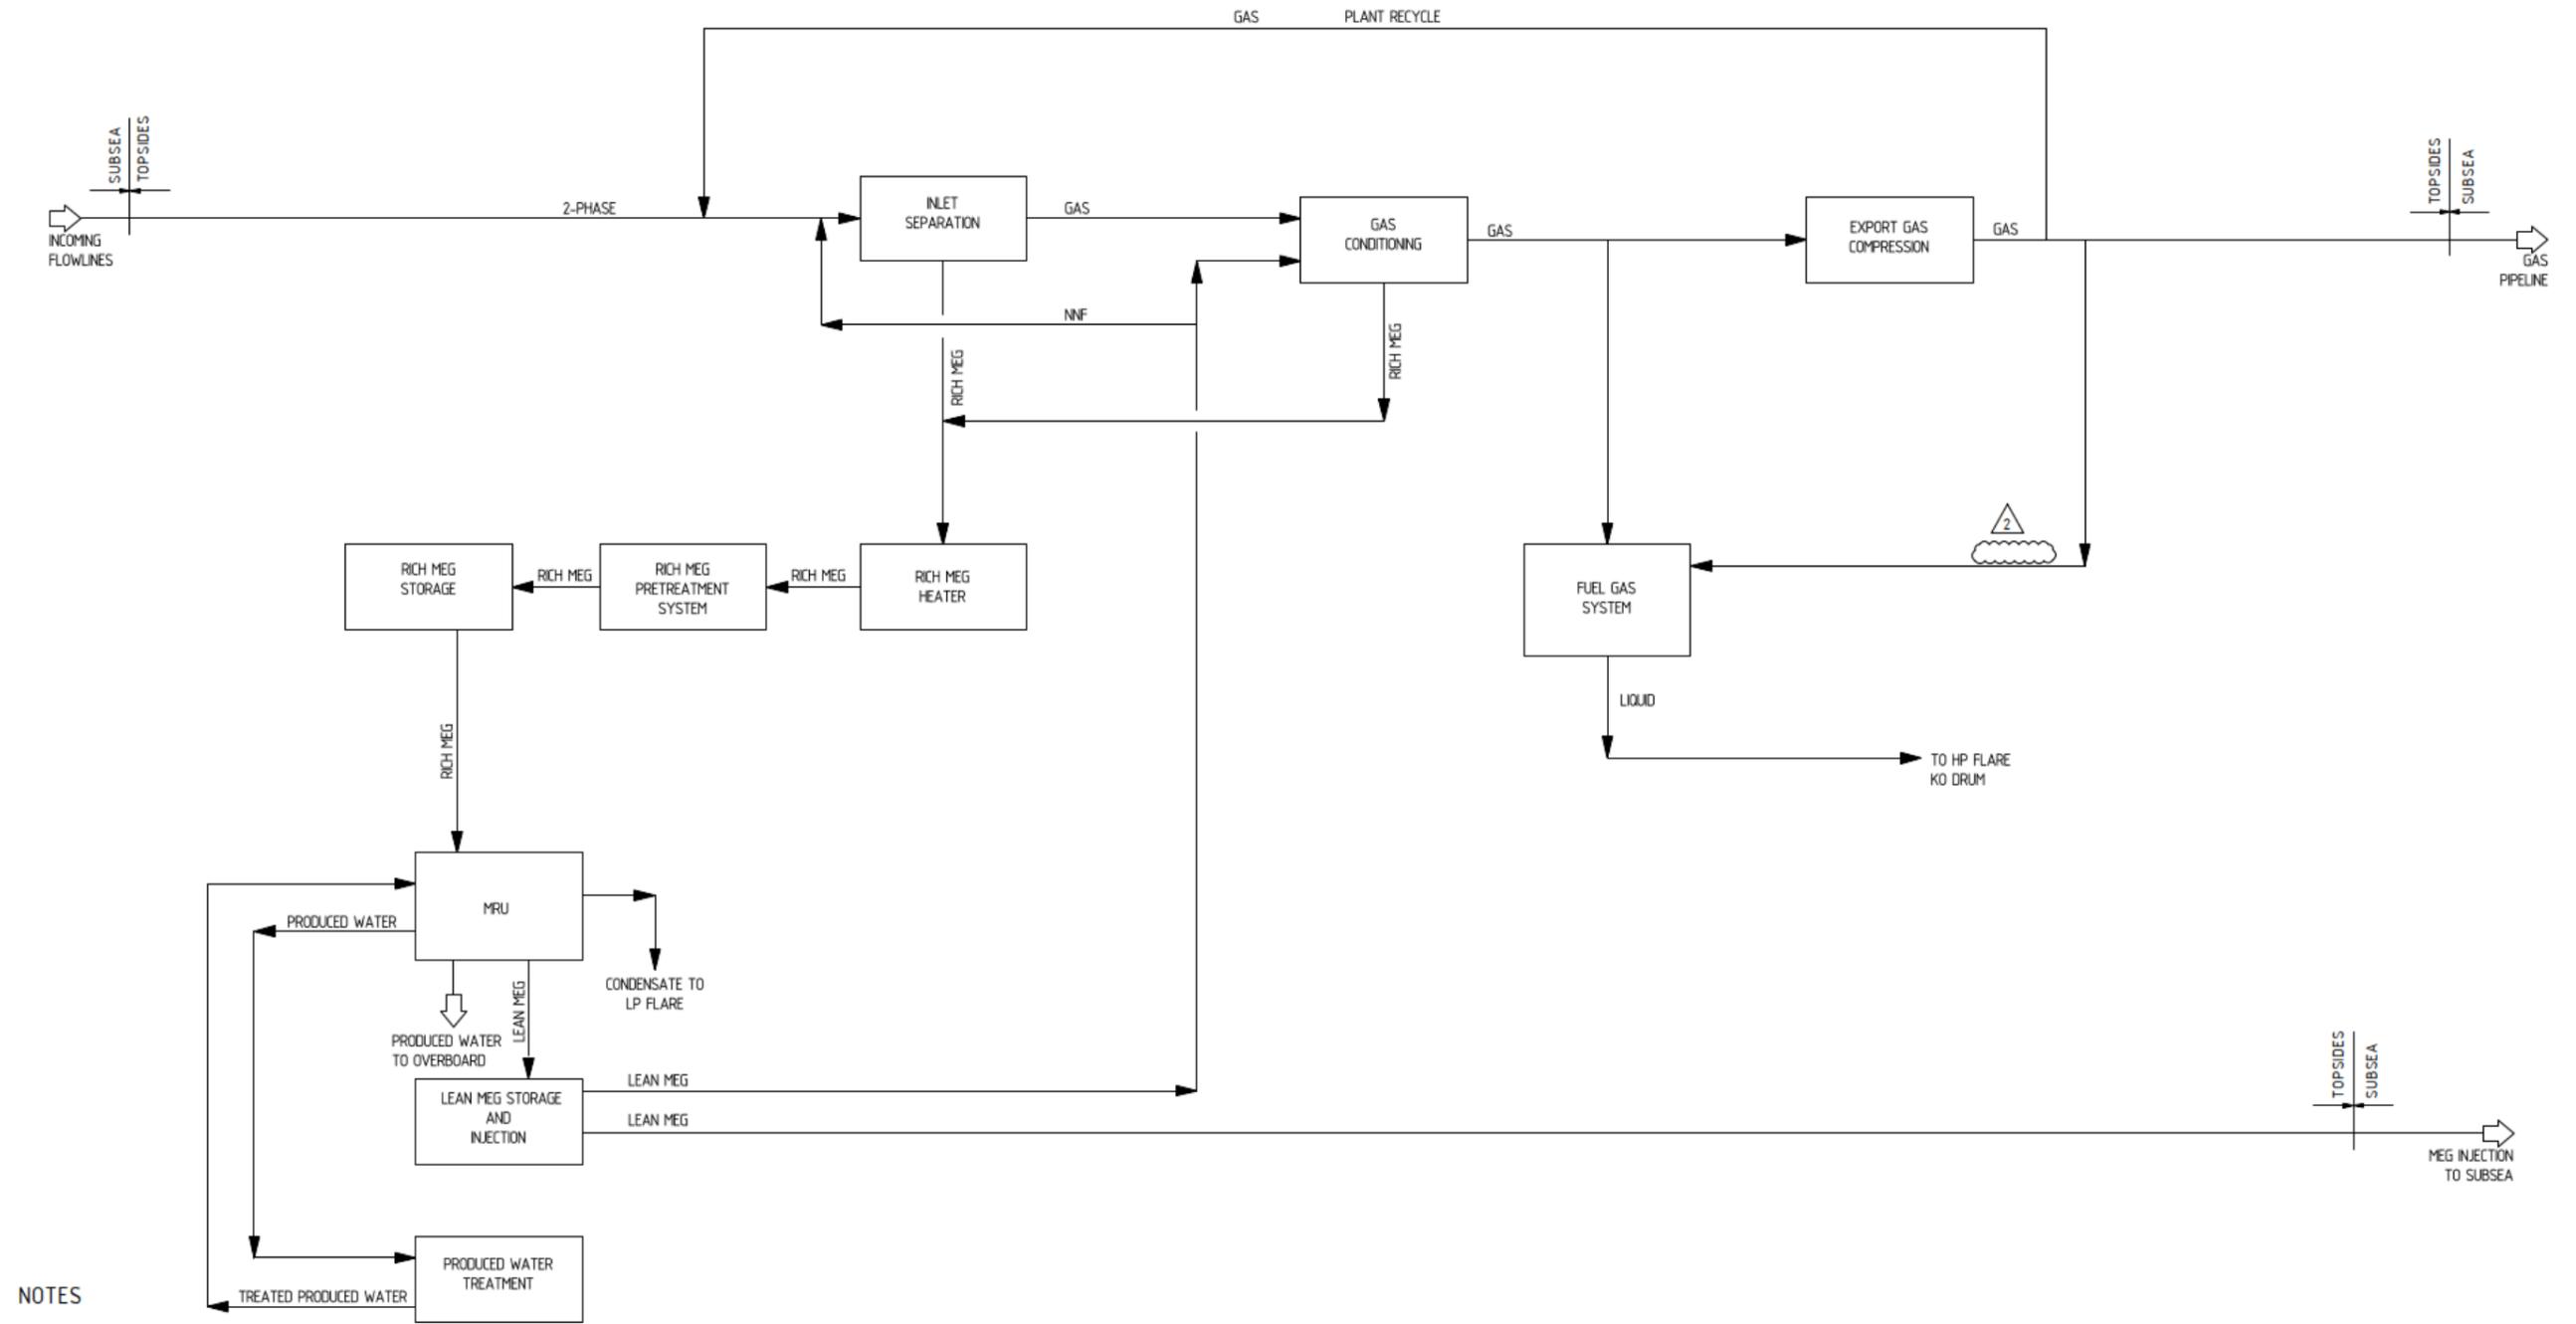

The bulk separation of liquids from the wet gas feed stream takes place at the Inlet Separator for each production flowline/riser system and to allow production fluids from each flowline to be handled and monitored separately. The inlet separation system separates the liquid stream (MEG and water) and solids from the wet gas. Although hydrocarbon liquids are not expected, provisions have been included to separate and direct these liquids towards the flare system/closed drains system for subsequent collection and removal for onshore disposal. Mercury and sand traps are provided in each Inlet Separator to capture elemental mercury and solids from the incoming fluids and to minimise carry over to downstream systems.

It is anticipated that the Scarborough reservoir fluids will contain low levels of mercury. Elemental mercury may condense in the subsea production flowlines and risers and if not removed during normal operation, the mercury is expected to be displaced during pigging operations. On the FPU, mercury is expected to collect in the bottom of the Inlet Separators and Low Temperature

Separators. Accumulated mercury will be drained periodically via dedicated nozzles when the vessels are offline and at low pressure. Mercury waste will be managed by trained personnel and placed in suitable containers for transfer to an approved specialist onshore waste management facility for treatment and disposal.

3.9.7.3 Gas Conditioning

The gas stream from each of the Inlet Separators flow to the gas conditioning system, which consists of a Gas-Gas Heat Exchanger, JT valve and Low Temperature Separator (LTS). The gas conditioning train operating conditions ensure that the water, MEG and liquid hydrocarbons in the wet gas stream are removed to meet the required gas quality specifications for export. Separated hydrocarbon liquids will be directed towards the flare system/closed drains system for subsequent collection and removal for onshore disposal.

NOTES

Figure 3-10: Production system process flow diagram

3.9.7.4 Export Gas Compression

After gas conditioning, dry gas enters the export gas compression and metering system. Three identical gas turbine driven gas compressors are used. At the discharge of the export compressors, the Export Gas Discharge Coolers reduce the gas temperature after which the gas is combined to a Common Export Header before the gas is metered and exported via the three export risers.

3.9.8 Flare Systems

The FPU has two flare systems, the high pressure (HP) flare and the low pressure (LP) flare. The main purpose of the flare systems is to safely discharge gas streams to maintain the safety of the facility, during emergency depressurisation scenarios, planned depressurisations (i.e. for maintenance activities) and overpressure relief disposal. The flare tip will be 136 m above sea level (the highest point on the FPU). Flared gas is metered by flowmeters on source streams.

3.9.8.1 High Pressure Flare System

The HP flare system collects vented hydrocarbons from process and utility systems, with a design pressure of 1400 kPag or above. The HP flare header is routed to the HP flare knockout (KO) drum, to separate liquid from gas. Vapours from the flare KO drum are then sent to the flare tip for combustion, while liquids are sent to the closed drain drum. To prevent air ingress, the HP flare header is purged continuously with a mix of nitrogen and fuel gas, to ensure complete combustion of any unburnt methane.

3.9.8.2 Low Pressure Flare System

The LP flare system collects vented hydrocarbons from process and utility systems, with a design pressure of below 1400 kPag. The LP flare header is routed to the LP flare knockout (KO) drum, to separate liquid from gas. Vapours from the flare drum are then sent through the flare system and combusted at the flare tip, while liquids are sent to the closed drain drum. To prevent air ingress, the LP flare header is purged continuously with fuel gas, to ensure complete combustion of any unburnt methane.

3.9.8.3 Flaring – Normal Operations

Small quantities of gas and nitrogen are required to be flared throughout normal operations, for safety purposes or disposal of waste streams not recovered to the process. These continuous and intermittent flows to the LP flare include flare pilot, flare purge, Low Pressure MEG Flash Vessel (LPMFV) vent, compressor seal gas, MEG vacuum scrubber system, sampling points and analysers. Flows to the HP flare include flare pilot, flare purge, control valves and sampling points. Pilot rates total approximately 110 tpa. Total continuous flows to the flare are approximately 1100 tpa.

3.9.8.4 Flaring – Intermittent Process Activities and Upsets

During periods considered to be 'non-steady state', such as during start-up, upset conditions, or when introducing new wells, increased flaring may occur. This is required to protect the integrity of the facility and to prevent harm to personnel, environment and equipment. It is anticipated that such events may occur for short periods (hours or days at a time), which has been accounted for in the emissions estimates. The following sources make up intermittent flaring:

3.9.8.4.1 Initial Start-up

Flaring during the initial start-up period is described in Section 3.8.

3.9.8.4.2 Emergency Blowdown / Manual Depressurisation

The topsides equipment and piping are divided into isolatable sections, each with a dedicated blowdown valve (BDV). During an emergency shutdown, each section is separately depressurised to the flare. Each section contains a fail-open actuated BDV which allows blowdown of the entire platform inventory.

Manual depressurisations will result in intermittent flaring of hydrocarbons, triggered by restart operations (to avoid export of off-spec gas), routine equipment maintenance, planned emergency shutdown testing and/or depressurisation of equipment and piping to remove the equipment from service. These may involve the entire facility or just parts of it.

It is anticipated that approximately 10 emergency / manual (full or partial) depressurisations will occur within the first 6-months post-RFSU, 7 in the second 6-months, and 18 per-year during normal operations. A total of approximately 630t gas will be flared per event for full facility shutdown and restart (less for partial facility).

3.9.8.4.3 Pigging

Pigging of the production flowlines is planned four times throughout field life, although this may be adjusted based on Risk Based Inspection (RBI) outcomes. Reservoir gas will be used to propel the pigs from the FLETs to the FPU receiver. Flaring will be required for depressurisation of the FPU receiver for pig removal, which will result in an estimated 2 tonnes of flaring in years that flowlines are pigged. In the event that the end well is not available to drive the pig, an alternative fluid (likely nitrogen) will be required to propel the pig to the next available well. If nitrogen is used for pigging, flaring will be required due to incompatibility with FPU and onshore fuel gas systems, estimated at 200t per flowline.

Pigging of the trunkline is planned three times throughout field life, although this may be adjusted based on RBI outcomes. After the temporary subsea pig launcher is attached to the RBM, the preservation fluid (MEG/water) plus any seawater that has entered the pig launcher during installation must be flushed out, resulting in discharge to the environment of ~6m³ of MEG/water mixture and ~2 tonnes of hydrocarbon gas. FPU export gas will be used to propel the pigs from the RBM to the onshore receiver. Flaring will be required for depressurisation of the onshore receiver for pig removal, estimated at 8t per pigging campaign. In the unlikely event of inability to launch a pig via the kickerline, nitrogen may be required. If nitrogen is used for pig launch then this may be required to be flared if it cannot be adequately blended due to incompatibility with the onshore fuel gas systems. Flaring is estimated at 100t.

3.9.8.4.4 Subsea Flowline and Export Riser Depressurisation

The well fluid in the subsea flowlines (which transport hydrocarbon gas, water and MEG from the subsea wells to the FPU) may on occasion need to be routed to the flare to reduce pressure in the flowlines and risers for the following reasons:

- Over-pressurisation (packing) of the flowlines
- Leak-off testing of well and subsea isolation valves
- Repair or replacement intervention/maintenance of subsea system
- Hydrate remediation
- Emergency depressurisation

This would result in ~200-350 kT flared for a single flowline (and associated riser).

The hydrocarbon gas in the export risers may on occasion need to be routed to the flare to reduce pressure for the following reasons:

- Leak-off testing of subsea non-return valves

- Repair or replacement intervention/maintenance of subsea system
- Hydrate remediation
- Emergency depressurisation

This would result in ~35-55 kT flared per riser.

3.9.9 Monoethylene Glycol Recovery and Storage System

The water and MEG mixture (Rich MEG) from the Inlet Separator and LTS, are combined, heated and sent to the MRU. Entrained and dissolved gases including any liquid hydrocarbons and suspended solids are initially removed from the Rich MEG stream in the MRU pre-treatment section before storage in the Rich MEG Storage Tanks.

Two Rich MEG Tanks and two Lean MEG (regenerated MEG with majority of water removed) Tanks are located in the NE and NW FPU hull columns. The MEG storage tanks are standalone tanks which are integrated into the hull structure, surrounded by a void space. The storage volumes of the Rich and Lean MEG Tanks are 620 m³ and 410 m³ respectively.

The MRU operates in two modes, being:

- salt-free mode, when the only water produced from the reservoir is condensed from the gas stream (no formation water)
- salt-mode, where formation water is also produced from the reservoir. This water carries various naturally occurring salts and other contaminants such as organic acids from the reservoir that can build up in the MEG and affect its properties.

The Scarborough production wells are not expected to produce formation water within the first 5 years of operations as they will typically start to cut water toward the end of well life, however this may occur due to reservoir uncertainty and is included in scope of the EP.

The Rich MEG is transferred from the Rich MEG Tanks to the reconcentration/reclamation section of the MRU where the water and salts (when in salt-mode) are removed from the MEG, thereby producing Lean MEG for re-use. The Lean MEG is stored within the previously mentioned Lean MEG Storage Tanks and subsequently pumped to the Subsea and FPU Process System for prevention of hydrate formation and blockages.

The separated water from the MRU is treated in the Produced Water Treatment Package before it is discharged overboard.

In salt-mode, the MRU reclamation process removes monovalent salts (primarily sodium and potassium) and divalent salts (e.g. calcium, magnesium and iron) from the MEG. MEG salts may also contain hydrocarbons, other contaminants such as mercury and elevated MEG levels. This concentrated salt slurry is recombined with treated produced water as a brine and then further diluted in the PW discharge stream before comingling with the much larger seawater return stream before discharge. It is possible that some divalent salts when removed from the MEG are no longer soluble and may be present as precipitated particles.

The MRU is provided with a separate MEG closed drains system to safely collect and dispose of depressurised liquids during maintenance and shutdown (Section 3.9.11.1).

A simplified block diagram of the combined MRU and PW treatment system is provided in Figure 3-11.

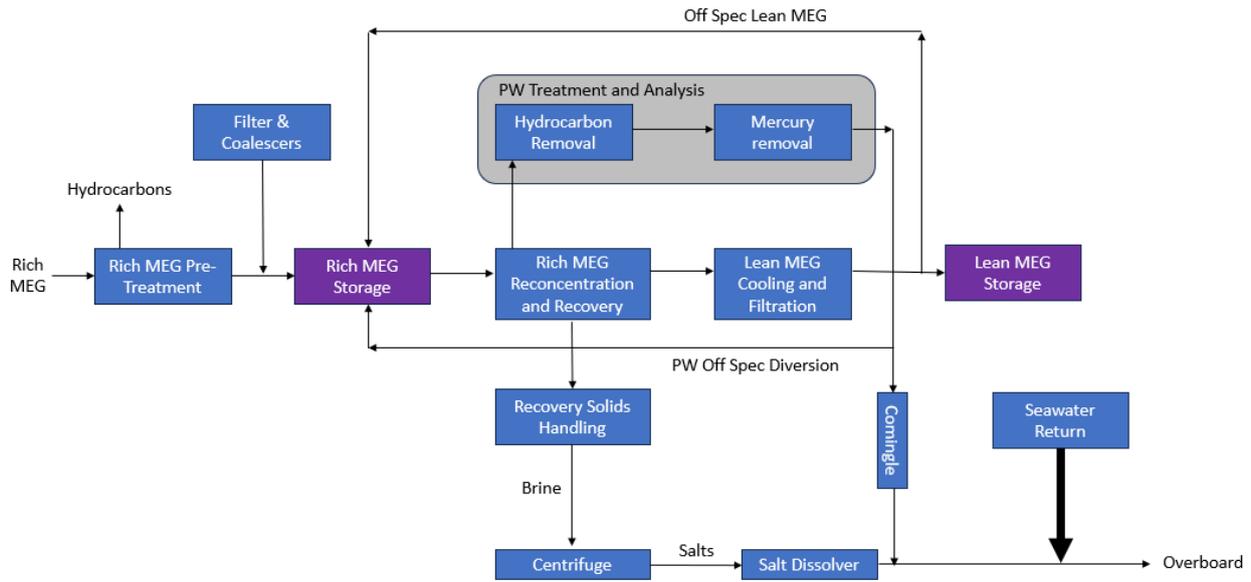

Figure 3-11: Block diagram of combined monoethylene glycol recovery unit and produced water treatment systems

3.9.10 Produced Water System

3.9.10.1 Produced Water System Description

Produced Water (PW) from the reservoirs combines with the lean MEG injected into the subsea system and is brought to the surface from the reservoirs and separated from the hydrocarbon components during the production process, then treated and discharged to the marine environment. PW can consist of produced formation water (a water reservoir below the hydrocarbon formation), condensed water (water vapour present within gas which condenses when brought to the surface), or a combination of both. The untreated PW may also contain dissolved salts, MEG, scale, corrosion inhibitors, total petroleum hydrocarbons (TPH), BTEX, mercury and residual process chemicals.

The PW treatment system is designed to process a maximum of 100 m³/day (integrity limit). Initial flow rates during operations are expected to be much lower, as PW is expected to consist of primarily condensed water. Flow rates will increase once formation water begins to be produced.

The maximum PW generation and discharge rate is 100 m³/day.

The PW will be separated from MEG by distillation in the MRU and directed to the Produced Water Treatment Plant (PWTP) for processing. The PWTP uses hydrocarbon adsorption beds operated in a duty and standby configuration and mercury adsorption beds operated in series with a lead bed and a guard bed to remove hydrocarbon and mercury respectively from the PW stream. The hydrocarbon adsorption beds are designed to achieve <29 mg/L oil in water discharge, subject to operational performance, actual reservoir composition and chemistry.

Mercury may also be present in the PW or salts removed as part of MEG recovery. The PW treatment system described in this section includes technology to remove this in the PW stream to ALARP. The system is in a “plug and play” configuration such that when the media in an adsorption bed becomes saturated, the vessel can be removed from the FPU and transported back to shore for onshore regeneration or decanting and refilling. A process flow diagram of the PWTP is presented in Figure 3-12.

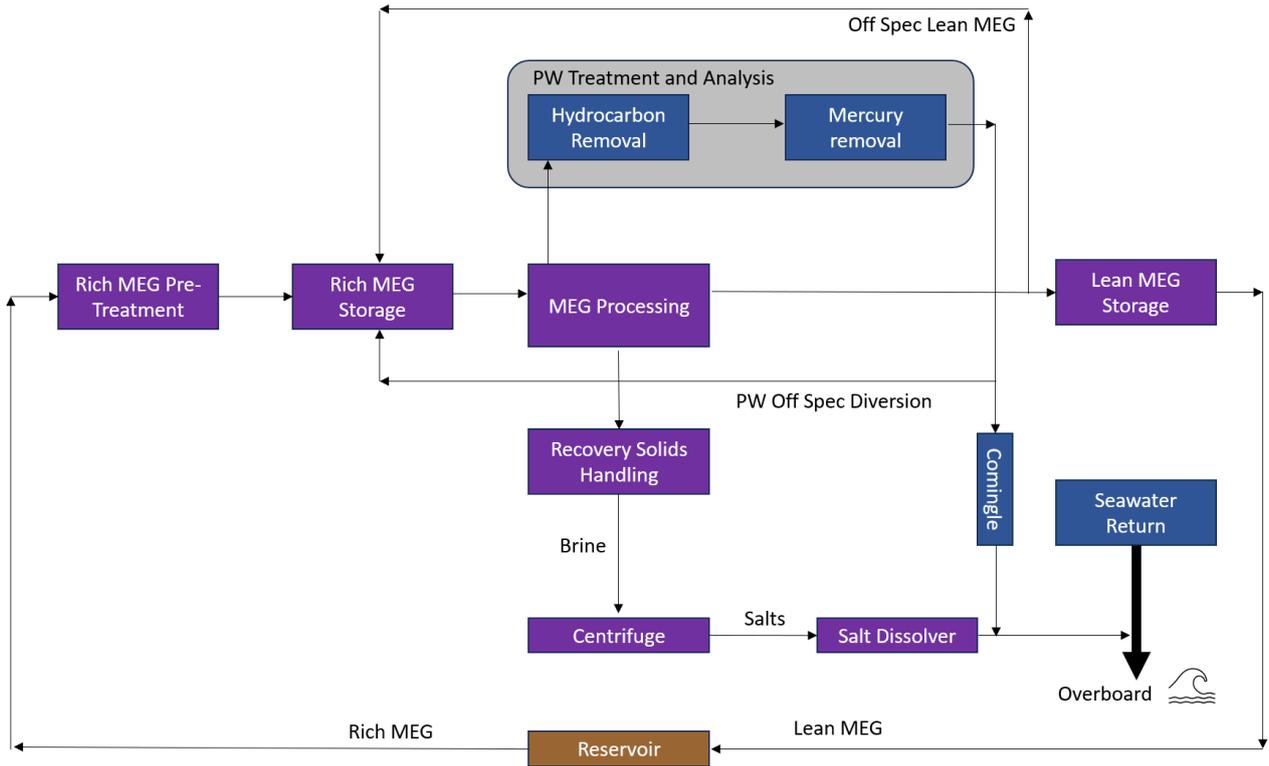

Figure 3-12: Process flow diagram of the produced water treatment plant

The treated produced water stream may be used to re-dissolve monovalent salts or to suspend divalent salts removed from the MRU for overboard disposal (when the MRU is in salt-mode). As part of adaptive management, PW from the MRU may be directed to the rich MEG storage tank for a limited duration.

The produced water discharge stream will be comingled with seawater which has been drawn from the ocean to remove heat from a closed loop cooling water system (see Section 3.9.12.3), prior to discharge overboard via the seawater dump caisson overboard 8 m below the water line. Comingling of the PW stream into the much larger seawater return stream will reduce the concentration of any contaminants remaining after passing through the media beds or associated with salts from the MEG stream by approximately 1000 times, prior to discharge.

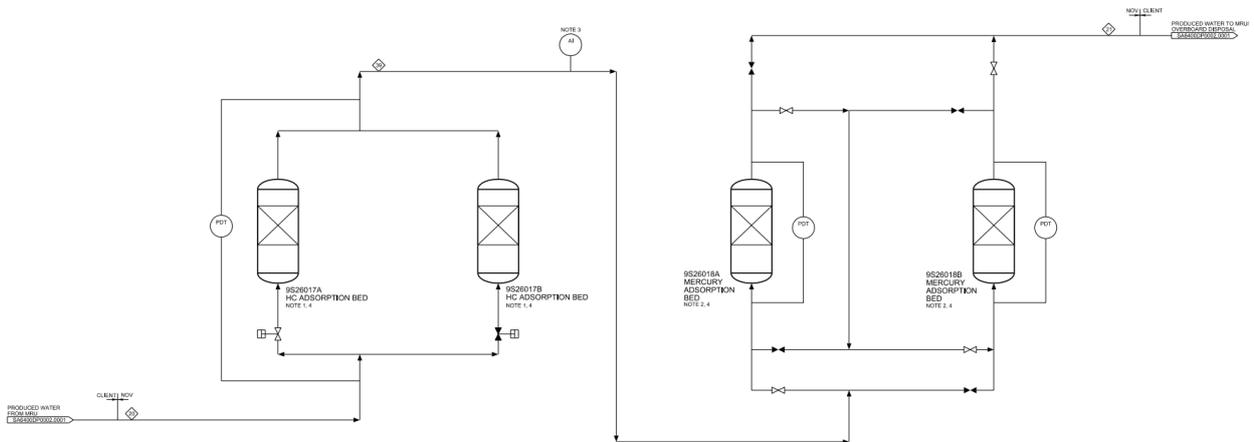

Figure 3-13: Produced water treatment unit

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

3.9.10.2 Produced Water Oil-in-Water Discharge Monitoring

The measurement of Oil in Water (OIW) in the PW stream is undertaken prior to comingling with the seawater return and subsequent discharge to the ocean. OIW is measured using an online OIW analyser. The analyser is designed specifically for offshore operations and measures fluorescence this is calibrated to provide TPH in water.

During commissioning a competent technician/operator will be available on the facility to conduct:

- manual sampling, dependant on OIW concentrations, as described in the relevant commissioning document
- calibration of the online OIW analyser to ensure that OIW analyser is able to measure accurately.

3.9.11 Drainage Systems

3.9.11.1 Closed Drains

The closed drains system is used for draining hydrocarbon liquids from all process equipment except the MRU. A separate closed drain system is provided for the MRU after it has been depressurised. The drained liquids are routed to the closed drain drum. Upon reaching a sufficient volume, liquids can be pumped to the transportable waste drums to allow for onshore treatment and disposal. Alternatively, directed to the LPMFV for processing or to the Rich MEG storage tank. The MEG closed drains collects MEG from the MRU closed drains system and drains from other equipment in MEG service (Lean MEG Injection filters and pumps). MEG can be reprocessed via the LPMFV or if unsuitable for reprocessing pumped to transportable waste drums for onshore disposal. Closed drain piping systems are classed as topsides pressure containing/hazardous pipework.

3.9.11.2 Open Drains

The open drain system consists of hazardous open drains, non-hazardous open drains and machinery open drains. Rainfall on areas with no risk of hydrocarbon contamination are routed directly overboard. A diagram of the open drains system is provided in Figure 3-14.

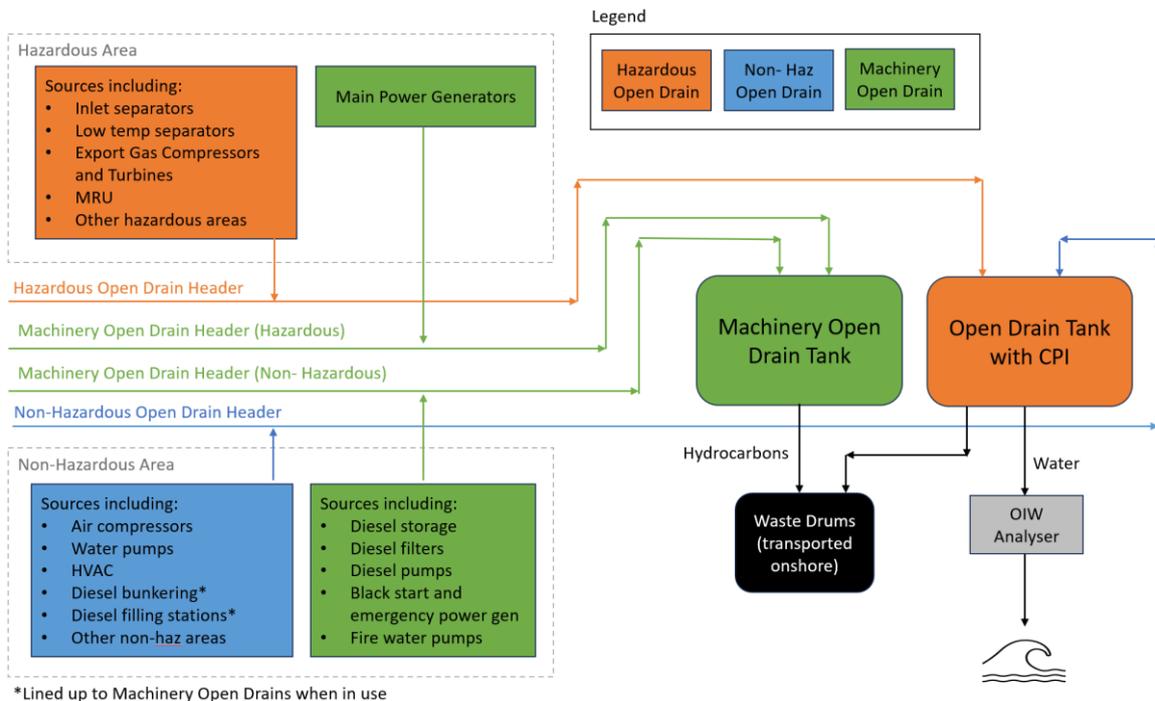

Figure 3-14: Open drains system

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

The machinery open drains headers collect drained fluids from sources defined as “machinery space” under marine legislation, broadly defined as areas which include diesel containing equipment. These spaces are protected from rain ingress, by being under cover or within enclosures. Machinery open drains are sent to the machinery open drains tank for collection and are pumped to the open drains transportable waste drum for disposal onshore. Hazardous and non-hazardous open drains collect potentially contaminated fluids from the hazardous and non-hazardous areas on the FPU. Hazardous and non-hazardous safety zones are routed to separate headers before co-mingling in the open drains tank. The Open Drains Tank separates any residual hydrocarbon liquids (such as lube oil) from the incoming fluids. The oil in water content is managed through an oil in water separation system utilising a corrugated plate interceptor (CPI) to reduce OIW concentration prior to discharge, supported by instrumentation and alarms to detect and respond to potential upsets. Hydrocarbons from the open drains tank are pumped to the open drains transportable waste drum for disposal onshore, and separated water passes through an online OIW analyser prior to being discharged to the ocean via a down pipe.

Liquids such as rainwater, deluge or condensation captured across the FPU which do not have the potential to be contaminated are freely drained overboard. Any rainfall stronger than the design basis will overflow via the drain box overflow, which will be located in all drain boxes (which are exposed to rainwater and fire water) including drain boxes in non-hazardous area. The overflow lines from the drain boxes can be gathered together or routed separately overboard at safe locations below the lower deck.

3.9.12 Floating Production Unit Utility Systems

3.9.12.1 Floating Production Unit Lighting

The FPU has appropriate lighting so that there is a safe working environment to support 24-hour operations. Lighting will be installed across the process area, utilities, accommodation and hull. Lighting is split between emergency and normal lighting.

There are navigational lights on the flare tower via a narrow beam floodlight and on the boom and towers of the pedestal cranes. Helideck lighting is also provided to assist helicopter landing.

Unless required to support over the side activities (such as refuelling and lifting operations), lighting on the FPU is directed to the work area, which aids in limiting light spill to sea.

3.9.12.2 Heating Ventilation and Air Conditioning System

The heating, ventilation and air conditioning (HVAC) system comprises HVAC equipment, ductwork and associated pipework. It provides independent and inter-dependent subsystems with pressurised, conditioned, purge and exhaust air services to various areas including accommodation, and various modules which can be operated on as required basis and others on a continuous basis.

No ozone-depleting substances will be used on the FPU and refrigerants associated with the HVAC system are managed by a licenced refrigerant authority.

3.9.12.3 Seawater System

The primary function of the seawater system is to provide process and HVAC cooling. There are two seawater systems onboard the FPU:

- Seawater for cooling: The purpose of the seawater system is to supply seawater to the topsides to remove heat from the closed circuit cooling medium system. Seawater is supplied by three seawater lift pumps enclosed within protective caissons outside the hull columns. Filtration of the seawater is provided by two coarse filters. During normal operations a single filter will be online at any time. The seawater flows through the seawater side of the heat exchangers and the cooling medium flows on the cooling medium side of the exchangers.

Warm seawater exits from the exchangers where it combines with, brine from the reverse osmosis water maker package and produced water, before being routed to the Seawater Dump Caisson. Seawater rate and temperature are monitored.

- Cooling Medium: Demineralised water (with <1 ppm chloride content) is used as cooling medium. The Cooling Medium system is a closed loop system which provides required cooling in the FPU with heat rejection via cross exchange with the SW system. Cooling Medium Expansion Vessel (9V51001) is provided to accommodate system volume expansion and contraction between ambient and normal operating conditions, and its total volume is 18 m³. Cooling medium (demineralized water) has the potential to be discharged during maintenance.
- Service seawater: The service seawater system supplies seawater to the firewater ringmain, reverse osmosis water maker package, hypochlorite generation package and the hull ballasting system (when required). The seawater service system comprises of two service pumps in dedicated caissons outside of hull columns. The pumped service seawater from the hull is passed through a coarse filter to remove suspended solids to minimise blockage/fouling of downstream systems.

For both systems, concentrated hypochlorite solution is dosed from the Hypochlorite Generation Package into the intake caissons to provide marine bio-fouling growth protection for the internal surfaces of the system. Continuous dosing rate of equivalent chlorine is 1000 ppm approximately to produce sufficient volumes of concentrated sodium hypochlorite for all intake Caissons to target 2 mg/L concentration total residual chlorine in all pump discharges. During normal operation this will be a total design flowrate of about 4000 m³/h.

The Hypochlorite package has the capability to provide hypochlorite dosing when two service seawater lift pumps and two seawater lift pumps are running simultaneously (i.e. During ballasting operations) which is a total design flowrate of about 4500 m³/h to ensure minimum hypochlorite dosing concentration of 2 mg/L is met for all users.

Seawater comingled with produced water and brine will be routinely discharged overboard at a temperature less than 60°C and rates up to 95,000 m³/d.

3.9.12.4 Fresh, Potable, Utility and Demin Water System

Fresh water for the facility is produced in the Reverse Osmosis (RO) water maker package using service seawater. Fresh water is then routed to the either Fresh Water Storage Tanks or Utility Water Storage Tanks and potable water is produced following UV sterilisation. Demin water is not produced on the FPU and is supplied in portable storage tanks.

The FPU has provision for potable water bunkering. Potable water from the support vessel can be bunkered to either Fresh Water Storage Tanks (two at 86 m³) or Utility Water Storage Tank (109 m³) based on the requirement.

3.9.12.5 Power Generation and Distribution

Three dual fuel gas turbine driven generators are installed on the FPU that have the capacity to use diesel if gas is not available (such as during start-up operations). During normal operations only two are expected to be online at any one time, with the third on cold standby. In the event one online GTGs trips, a Battery Energy Storage System (BESS) will come online to provide power to maintain safe production until the Black Start (diesel) Generator starts. Then, once the Black Start Generator is online, this can maintain sufficient power with a single GTG to maintain production to start the cold standby generator. In effect, the BESS (with Black Start Diesel Generator) allows auto switchover between duty and the cold standby GTG. Once the cold standby GTG has been started, the BESS can be turned off and recharged. Critical and emergency utility power generation is provided respectively by a diesel engine driven black start generator and a diesel engine driven emergency

generator. The facility Power Management System (PMS) is designed to automatically start the third GTG when it detects that the BESS is offline.

3.9.12.6 Heating Medium

The FPU has provision for a heating medium which is a closed loop demineralised water system with chemical injection (corrosion inhibitor and oxygen scavenger). This will be discharged overboard during maintenance or for overpressure protection. Waste heat is recovered from power generator gas turbine exhaust to provide process heating requirements.

3.9.12.7 Fuel Gas System

Fuel gas is used in the power generation turbines and gas compression turbines. The system also supplies purge gas to the LP flare system and fuel gas to the flare pilots.

The Fuel Gas System receives dew pointed gas from the Compressor Suction Header during early field life, and from the Export Header during mid and late field life. Fuel gas will be supplied from the export gas compressor suction header during all start-up scenarios where compressor is offline. The Fuel Gas System treats the gas to meet the user's specifications and distributes the gas via the High Pressure (HP), the Medium Pressure (MP) and the Low Pressure (LP) distribution systems.

The Fuel Gas System includes the major equipment of:

- HP Fuel Gas Heaters
- HP Fuel Gas Scrubber
- Fuel Gas Superheater and Electric Fuel Gas Superheater
- HP Fuel Gas Filters.

There are three fuel gas distribution headers, being:

- HP Fuel Gas Header
- MP Fuel Gas Header
- LP Fuel Gas Header.

Total fuel gas consumption on the facility is metered by fuel gas flowmeters. Compressor turbine individual load is approximately 30 MW. Gas turbine driven Main Power Generators have an individual load of around 4.6 MW. GHG emissions estimates related to fuel gas consumption are presented in Section 6.

3.9.12.8 Diesel Fuel Supply System

The diesel fuel supply system includes storage and a distribution system to provide a fuel source for emergency power generation systems, firewater pumps, Fast Rescue Craft (FRC) and as a back-up fuel source for the main power generation system. Diesel is supplied to the FPU by support vessel and stored in two atmospheric Crane Pedestal Diesel Storage Tanks of around 220 m³ each, via a bunkering station, located on West and East side of the FPU. The diesel flows through a strainer on the FPU prior to metering and flow-in to the tanks. Diesel is metered and distributed to the users via a continuously pressured ring main. Unused diesel is recycled back to the crane pedestal tanks. Each user is isolated from diesel supply interruptions by the provision of break tanks.

3.9.12.9 Sand Management

Each production well is completed with downhole sand control and sand production continually monitored at each subsea xmas tree with alarm and trip capability. In addition, sand detection and alarms are installed upstream of the Inlet Separators. A well is only expected to produce solids during initial well clean up, for the first year of well production, or in the event of downhole sand control failure.

Produced sand will mainly collect in the Inlet Separator whilst some sand may reach the LPMFV within the MRU pre-treatment section.

Sand will accumulate in the bottom of the separator. The collected material will be removed periodically and transferred to a suitable transportable container for shipment to an approved onshore waste management facility for treatment and disposal.

3.9.12.10 Sewage and Putrescible Wastes

Sewage and putrescible waste (principally food scraps) produced onboard the FPU when occupied and under normal operating conditions will pass through a macerator to be ground to less than 25 mm particle diameter, before being discharged overboard via a pipe submerged below the water line. The FPU does not contain sewage holding tanks, and in the event that the sewage macerator becomes inoperable, sewage may bypass the macerator for a temporary period whilst maintenance, repairs or replacement is undertaken. Where putrescible waste macerators are not operational, the waste will be retained onboard until the macerator maintenance is completed or the waste is transported to shore for disposal as domestic waste.

3.9.12.11 Lifting Operations

Two pedestal cranes are located on the FPU one on the east side and one on the west sides of the Middle Deck. Both cranes are of 'A' frame design and driven by electric motors. A Platform Crane is located on the South platform.

3.9.12.11.1 Routine Lifting from Platform Support Vessels

Routine lifting operations primarily include transferring stores and equipment from a support vessel to the FPU. Lifts can be conducted from any of the main cranes depending on weather conditions. Support vessels are equipped with dynamic positioning (DP) systems for holding station during lifting operations.

The types of 'lifted equipment' may vary but generally include containers or skips of various sizes. The stores and equipment required by the facility are secured inside the skip or container. Containers for supply of chemicals are also routinely lifted. The equipment is appropriately rated for offshore lifting.

Following the completion of offloading from the support vessel, the FPU backloads any items to be returned to shore to the support vessel. These primarily include empty skips or containers or skips containing waste for onshore disposal.

3.9.12.11.2 Lifting around the Facility

Once lifted to the laydown area, equipment may need to be repositioned at various locations throughout the facility for operational purposes. This includes lifting stores or equipment to various landing areas throughout the facility for unloading or use, moving waste bins to required areas, or relocating ISO containers.

3.9.12.11.3 Operational Lifting (Non-crane Based)

There is also a requirement to undertake operational lifting using other lifting appliances and lifting gear. This lifting is primarily undertaken for major projects, maintenance or repairs, and involves lifting and removing equipment such as valves, spools, and motors.

3.9.12.11.4 Special Lifts

There may be occasions where equipment may need to be lifted to support hook-up, commissioning, and operations using specifically prepared lift plans. On these occasions, the equipment will be

packed up in a container or an approved lifting frame. All relevant lifting procedures will be adhered to, including preparation of an appropriate lift plan.

Lifting operations support the FPU operations and maintenance activities (e.g. transfer of domestic stores, spare and replacement parts/equipment and other marine/process consumables etc.).

The lifting operations are to be performed by cranes, monorails, trolleys and local lifting equipment. The two pedestal cranes (east and west) provide the necessary coverage for on-deck material handling requirements and lifts between the FPU and support vessels. The type of lifted equipment varies but can include containers or skips of various sizes. The stores and equipment required by the facility are secured inside the skip/container. Containers for supply of chemicals are also routinely lifted. Lifting equipment is appropriately rated and inspected for offshore lifting. Following the completion of offloading from a support vessel, the facility backloads any items to be returned to shore to the support vessel. These primarily include empty skips/containers or waste for onshore disposal.

The south platform crane located to the west of the LQ is used for in-board platform lifts and to support maintenance and testing of the lifeboats.

3.9.12.12 Instrument/Utility Air System

Compressed, filtered and dried air is supplied to the instrument and utility air systems using instrument air compressors and driers, located on the roof of the UB.

An air receiver is provided to supply instrument air for a period of time if the instrument air production from the compressors and driers is interrupted. Instrument air users include instrumentation, mainly for control valves and on/off valves and nitrogen generation. Utility air is supplied to the utility stations distributed across the FPU.

3.9.12.13 Nitrogen System

There are three nitrogen (N₂) systems provided on the FPU: the HP N₂ system and two LP N₂ systems. With respect to the two LP N₂ systems, one is classed as Low Quality (97% purity) and the other is classed as High Quality (99.99% purity).

3.9.13 Bunkering

Low sulphur diesel is transferred to FPU in bulk from support vessels via the east bunkering stations. Diesel is stored within the east and west crane pedestal tanks. The diesel is pumped from this location to the diesel pre-filters and diesel coalescing filters for clean-up before distribution to the user areas described in Section 3.9.16.

As described in Section 3.9.12.3 the FPU has provision for potable water bunkering to Fresh Water Storage Tanks or Utility Water Storage Tanks.

MEG will be bunkered to the FPU during commissioning (Section 3.9.16) via a dedicated bunkering station using an Offshore Support Vessel (OSV). A chemical tanker may be positioned outside of the Operational Area and perform ship-to-ship transfer operations between the chemical tanker and OSV. During start-up, rich MEG and well clean up fluids will be removed from the FPU to an OSV, to be disposed onshore. During operations MEG is expected to be topped up using temporary tanks or containers but provision to bunker MEG during operations is included for flexibility. Other chemicals will be transferred to the FPU via containers.

3.9.14 Ballast and Bilge System

The FPU is designed such that stability is maintained in all design conditions without the active use of the ballast system. The ballast system is designed, therefore, to keep the FPU at operational draught and on an even keel by filling and emptying a total of 28 ballast tanks located within the hull columns and in the ring pontoon. Whilst not required for day-to-day operations the ballast system

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

will be required for significant volume and weight movements such as emptying or filling of MEG tanks under a maintenance activity or if a large significant load was placed/moved on the FPU. Seawater from service system which is dosed with chlorine (Section 3.9.12.3) is supplied and gravity fed to the ballast tanks via the dedicated ballast caisson in each column. The weight of water used to achieve the 32 m draft is 33,000 tonnes. Discharged ballast water will contain residual chlorine, required to prevent biofouling of this integrity critical system.

The bilge system provides functionality for removing any liquids collected in the void compartments in the event of flooding from structural or piping failure. A permanent bilge caisson and pump with maximum pump capacity of 510 m³/h is installed in each column. Water that is collected in the column void tanks drains under gravity to the bilge caisson and it is then pumped overboard from top of column.

Local bilge stripping pumps are installed at the bottom of the access shaft. The purpose of the stripping pumps is to remove residual water from the ballast tanks in preparation for entry and to clear any bilge water that may accumulate in the access shaft.

A crossover line from the bilge caisson to the ballast caisson is provided at the bottom of each column so that any tank can be de-ballasted with any one pump inoperable.

3.9.15 Safety Features and Emergency Systems

A range of safety features and emergency systems have been integrated into the design and operation of the FPU to manage safety risk. Maintenance and operation of these systems is key to ensuring safe operability of the facility.

Specific safety systems include:

- control and detection systems
- process control system
- Local Control Room (LCR)
- Remote Control Room (RCR) – onshore
- fire and gas detection system
- emergency and process shutdown systems
- emergency relief and depressurisation systems
- LP and HP flare systems
- ignition control
- emergency alarms and communications
- evacuation and rescue facilities and equipment
- collision avoidance systems
- passive and active fire protection.

Mandatory testing of the FPU helideck active fire deluge and Helifuel storage area foam safety system is undertaken for safety requirements. This discharge is directed overboard to prevent foam contamination of the drain system potentially impacting wastewater oil separation processes. The FPU's fire system uses fluorine free foam.

3.9.16 Hydrocarbon and Chemical Inventories

3.9.16.1 Hydrocarbons

The main liquid hydrocarbon inventories associated with major topside process equipment and non-process inventories of liquid hydrocarbons used on the facility are outlined in Table 3-5. Large volumes of hydrocarbon liquids are not expected due to the composition of the Scarborough well

fluid. The small amount of liquid hydrocarbon produced will be collected and transported onshore for disposal.

Table 3-5: Estimated hydrocarbon inventories of process and non-process equipment

Material	Storage Means	Storage Volumes
Process equipment⁴		
HC liquid condensate	HP Flare and LP Flare Knock-Out (KO) drums ⁵	15 m ³ for HP flare KO drum, 4 m ³ for (volume will contain different liquids including water, MEG and liquid hydrocarbon) – Normal liquid volumes
HC liquid condensate	Inlet separators and Low Temperature Separators (LTS)	Total 7 m ³ (3x inlet separators with 1.4 m ³ skimmed volume design, and 3x LTS with 0.8 m ³)
HC liquid condensate	LPMFV HC bucket	0.2 m ³
HC liquid condensate	Closed drain drum + closed drain waste drums	Total 18 m ³ (2x 8.8 m ³). Volume will contain different liquids including water, MEG and liquid hydrocarbons.
Oily water	Open drain system	Total 21 m ³ Open drains waste drum 8.8 m ³ , open drains tank 2 m ³ , machinery open drains tank 10 m ³
Non-process equipment		
Diesel	2x Diesel storage tanks 4x Day tanks	472 m ³ total (East crane pedestal 219 m ³ , west crane pedestal 219 m ³ , 2x 12 m ³ day tanks and 2x 5 m ³ day tanks)
Lube Oil/Hydraulic Fluid	3x Export Gas Compressor lube oil reservoir tank, and other various size containers based on type and use	135 m ³ total (3x 32 m ³). Various – general 20 L and 205 L drums and 1000-4000 L bulk containers
Heli fuel – Jet A1	2x portable tanks into an aviation fuel package	8 m ³ total (2x 4 m ³ ISO tanks)

3.9.16.2 Chemical Usage

Chemicals are utilised on the facility for a variety of purposes and can be divided into two broad categories (operational and non-operational) as described below.

3.9.16.3 Operational Chemicals

3.9.16.3.1 Operational Process Chemicals

A process chemical is the active chemical added to a process or static system, which provides functionality when injected in produced fluid, utility system streams or for pipeline treatment. These chemicals may be present in routine or non-routine discharge streams from the facility. Examples include corrosion inhibitors, biocides, scale inhibitors, de-emulsifiers, glycols and hydrate inhibitors.

3.9.16.3.2 Operational Non-Process Chemicals

Non-process chemicals include chemicals which do not fall into the category described above but which may be required for operational reasons and, by virtue of their use, may be intermittently discharged or have the potential to be discharged (e.g. required as a result of maintenance or

⁴ Based on Scarborough well fluid composition, HC liquid condensate is not expected in the topside processing facility.

⁵ Liquid from the drum is sent via level control valve to the Closed drain vessel.

intervention activities). Examples include subsea control fluids, workover chemicals, tracer chemicals and dyes.

3.9.16.3.3 Non-operational Chemicals

Non-operational chemicals include chemicals which are required for general maintenance or ‘housekeeping’ activities and are critical for overall maintenance of the facility and its equipment. These may include paints, degreasers, greases, lubricants and domestic cleaning products. They may also include chemicals required for specialty tasks, such as laboratory testing and analysis. Maintenance chemicals generally present negligible risk to the environment as they are not discharged as a result of their use (e.g. paint), or are used intermittently and discharged in low volumes (e.g. domestic cleaning products).

3.9.16.4 Indicative Chemical Inventories

An indicative list of bulk chemicals commonly used on the facility, and estimated storage quantities, is summarised in Table 3-6. In addition to the chemicals listed, the facility may also maintain small volumes of various operational chemicals and facility maintenance chemicals as previously described.

Table 3-6: Indicative bulk inventories of chemicals

Material	Storage Means	Working Capacity
MEG	2 x Lean MEG storage tanks 2 x Rich MEG storage tanks Regeneration System – LPMFV	2 x 396 m ³ 2 x 588 m ³ 25.63 m ³
Subsea control fluid	Hydraulic Power Unit tank: Supply reservoir Return reservoir	3.1 m ³ 2.4 m ³
Oxygen Scavenger	Fixed tank and 1.5 m ³ tote tanks	5.1 m ³
Corrosion Inhibitor	Corrosion Inhibitor tank	4.2 m ³
Sodium Carbonate	Storage tank	18.85 m ³
Kinetic Hydrate Inhibitor (KHI) (contingency)	Storage tank	74 m ³ (contingency)
Firefighting foam	Heli fuel package concentrated foam tank	Approx. 0.7 m ³
Chemical waste	Open Drains Waste drums	Total 16 m ³ (2x 8 m ³)
Citric Acid	MRU Citric Acid Storage Tank and tote tanks MRU Cleaning In Place Tank	Total 8.2 m ³ (4.2 m ³ +4 m ³)
Anti-foam	MRU Anti-foam Storage Tank	1.6 m ³

3.9.16.5 Chemical Selection, Assessment and Approval

Operational chemicals required by the Petroleum Activities Program are selected and approved in accordance with Woodside’s process for selecting and assessing chemicals. This process is used to demonstrate that the potential impacts of the chemicals selected are acceptable and ALARP, and that they meet Woodside’s corporate requirements, which requires chemicals to be selected with the lowest practicable environmental impacts and risks, subject to technical constraints.

A summary of the environmental requirements of the Chemical Selection and Assessment Environment Guideline is outlined below.

3.9.16.5.1 Environmental Selection Criteria

Woodside's process for selecting and assessing chemicals follows the principles outlined in the Offshore Chemical Notification Scheme (OCNS), which manages chemical use and discharge in the United Kingdom (UK) and the Netherlands (background on the OCNS scheme is provided below).

Operational chemicals are selected/assessed in compliance with the Woodside's process for selecting and assessing chemicals, specifically:

- Where operational chemicals with an OCNS rating of Gold/Silver/E/D and no OCNS substitution or product warning are selected, or a substance is considered to pose little or no risk to the environment, no further control is required. Such chemicals do not represent a significant impact on the environment under standard use scenarios and therefore are considered ALARP and acceptable.
- If other OCNS-rated or non-OCNS-rated operational chemicals are selected, the chemical is assessed as follows:
 - If there is no planned discharge of the operational chemical to the marine environment, written technical verification of the 'no discharge' fate is provided and no further assessment is required.
 - If there is planned discharge of the operational chemical to the marine environment, a further assessment and ALARP justification is conducted.

The ALARP assessment considers chemical toxicity and biodegradation and bioaccumulation potential, using industry standard classification criteria (Centre for Environment, Fisheries and Aquaculture Science scheme criteria).

If a product has no specific ecotoxicity, biodegradation, or bioaccumulation data available, these options are considered:

- environmental data for analogous products can be referred to where chemical ingredients and composition are largely identical, or
- environmental data may be referenced for each separate chemical ingredient (if known) within the product.

If no environmental data is available for a chemical or if the environmental data does not meet the acceptability criteria outlined above, potential alternatives for the chemical are investigated, with preference for options with a hazard quotient (HQ) band of Gold or Silver, or in OCNS Group E or D with no substitution or product warnings.

If no more environmentally suitable alternatives are available, further risk-reduction measures (e.g. controls related to use and discharge) are considered for the specific context and implemented where relevant to ensure the risk is ALARP and acceptable.

Once the further assessment/ALARP justification has been completed, confirmation that the environmental risk as a result of chemical use is ALARP and acceptable is obtained from the relevant manager.

3.9.16.5.2 Background Overview of Offshore Chemical Notification Scheme

The OCNS applies the requirements of the Oslo-Paris Convention for the Protection of the Marine Environment of the North East Atlantic (OSPAR Convention). The OSPAR Convention is widely accepted as best practice for chemical management.

All chemical substances listed on the OCNS list of registered products have an assigned ranking based on toxicity and other relevant parameters (e.g. biodegradation, bioaccumulation), in accordance one of two schemes (as shown in Figure 3-15):

- Hazard Quotient (HQ) Colour Band: Gold, Silver, White, Blue, Orange, and Purple (listed in order of increasing environmental hazard), or
- OCNS Grouping: E, D, C, B, or A (listed in order of increasing environmental hazard). Applied to inorganic substances, hydraulic fluids, and pipeline chemicals only.

Hazard Quotient Colour Band	Gold	Silver	White	Blue	Orange	Purple
OCNS Grouping	E	D	C	B	A	
	Lowest Hazard					Highest Hazard

Figure 3-15: Offshore Chemical Notification Scheme ranking

3.9.17 Inspection, Monitoring, Maintenance, and Repair Activities

Subsea infrastructure is designed not to require significant intervention. Inspection and maintenance are undertaken to confirm the integrity of the infrastructure and identify problems before they present a risk of loss of containment. Intervention may be required to repair identified problems.

To manage subsea threats (risks) the IMMR process requires an appropriate response to be selected to manage specific equipment risks. This is typically one of: Inspection, Monitoring, Maintenance, or Repair. The IMMR process for subsea infrastructure, including any redundant equipment (Section 3.9.17.1), maintains equipment in good condition and repair, for production and to enable future removal.

IMMR activities are typically undertaken from a support vessel, light construction vessel (LCV), or an uncrewed surface vessel (USV) and may use an ROV with transponders to inspect equipment. For some activities, ROVs may also be deployed from the FPU.

Maintenance and repair activities may require the deployment of frames/baskets which are temporarily placed on the seabed. These typically have a perforated base with a seabed footprint of about 15 m². Other equipment, materials or tools may need to be temporarily wet stored on the seabed in the Operational Area during installation and operations. This could include, but not be limited to, pig launcher/receiver, scour mattresses, subsea equipment prior to installation etc. Any wet stored items will be removed from the seabed.

Typical IMMR activities are described below.

3.9.17.1 Inspection

Inspection of subsea infrastructure is the process of physical verification and assessment of components to detect changes to the as-installed location and condition by comparison to initial state following installation and previous inspections. Inspections will either be planned or triggered by an event e.g. significant metocean/weather. Details of typical subsea infrastructure inspections/surveys and indicative frequencies are provided in Table 3-7. Inspection of wellheads are determined by the WOMP. Scope and frequency of subsea infrastructure (operational and redundant) inspections are determined using a Risk Based Inspection (RBI) methodology.

RBI is commonly used within the industry as a method for determining inspection frequencies (Energy Institute, 2009; DNV, 2019).

Table 3-7: Typical subsea infrastructure inspections/surveys and frequencies

Type of Inspection/Survey	Purpose	Approximate Frequency
General Visual Inspection	Check general infrastructure integrity.	Varied – every 2-6 years
Close Visual Inspections	Investigate certain subsea infrastructure components.	Varied – every 1-4 years
Hull and Mooring visual inspection	Visual inspection of the Hull and Mooring systems to satisfy class requirements.	Hull – twice every 5 years Mooring system – once every 5 years.
Cathodic Protection	Visual inspection, check cathodic protection and anodes.	Varied – every 2-6 years
Wall Thickness Surveys	Close Visual Inspection. Non-destructive testing e.g. inline inspection pigging. Ultrasonic testing.	Typical 1 yearly Varied 6-12 years Typically once every 25 years, worst case 5 yearly
Side Scan Sonar (SSS) and/or Multibeam Sonar (MBES) and/or laser profiling	Identify buckling, movement, scour and seabed features. Low frequency/intensity signals directed to seafloor, undertaken for approximately five days.	Varied – every 5-12 years
Non-Destructive Testing	Evaluates the properties of material/items using electromagnetic, radio graphic, acoustic resonance technology, ultrasonic, or magnetic equipment.	Typical: Once every 25 years Worst Case: Once every 25 years per well
Seabed sampling surveys including minor grabs/cores	Identify benthic fauna, sediment characteristics, determine level of penetration/compaction, etc. Grabs/cores typically disturb 0.1m ² of seabed per sample.	Typical: Once every 25 years Worst Case: Once every 5 years
Marine growth sampling	Samples taken of marine growth for testing.	Typical: Once every 25 years Worst Case: Once every 5 years
Sub bottom profiling	Low frequency echo sounder undertaken to identify returns of metals under the seabed.	Varied – every 1-6 years
Pigging	Inspection, maintenance, repair or to facilitate modifications.	Typical: Once every 12 years Worst case: every 5 years
Laser surveys	Used to conduct dimensional checks on spools etc. and measure proximity.	Varied: every 1-6 years

3.9.17.2 Monitoring

Monitoring of subsea infrastructure refers to the process of surveillance of the physical and chemical environment that a subsea system or component is exposed to in order to determine if and when damage may occur, and (where relevant) predict the rate or extent of that damage. Monitoring activities may include process composition testing, corrosion mitigation checks, metocean and geological seismic monitoring, and cathodic protection testing.

3.9.17.3 Maintenance

Planned maintenance activities on subsea infrastructure are undertaken to prevent deterioration or integrity failure of infrastructure. Typical maintenance activities are described in Table 3-8

Table 3-8: Typical maintenance activities and frequencies

Type of Maintenance	Purpose	Approximate Frequency
Cycling of valves via control system	Test functionality of technical integrity valves	Every 6 months for well barriers during operations, Annual for SSIVs and NRVs

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

Type of Maintenance	Purpose	Approximate Frequency
Cycling of valves via ROV	Test functionality of isolation valves	Every 2 years
Marine growth removal	Reduce weight or gain visual access	Based on outcomes from visual inspections and marine growth trends on regional infrastructure
Flushing of hydraulic fluid lines	Replenish stagnant hydraulic fluid (SSIV closed loop) or repair scenarios	Every 2-5 years
Leak and pressure testing	Test integrity of subsea infrastructure	Following installation of subsea infrastructure components for performance testing, after a repair or intervention, prior to return to service

3.9.17.4 Repair

Repair activities are those required when a subsea system or component is degraded, damaged or has deteriorated to a level outside of acceptance limits. Damage sustained may not necessarily pose an immediate threat to continued system integrity but may present an elevated level of risk to environment or production reliability. Due to the design of subsea infrastructure and materials used, repairs are undertaken on an as needs basis. The requirements and frequency of these repairs are dictated by the outcome of the inspection and maintenance regimes described in Table 3-7 and Table 3-8. Typical subsea repair activities included:

- subsea choke insert replacement
- chemical injection metering valve replacement
- SCM replacement
- acoustic sand detector replacement
- Xmas tree replacement
- valve actuator replacement
- hydraulic flying lead (HFL) replacement/or relocation
- electrical flying lead (EFL) replacement/or relocation
- export trunkline or spool support with grout bag, mattress, anchors or rock spool disconnection and/or replacement
- umbilical, jumper replacement and/or relocation
- scour prevention installation
- cathodic protection system replenishment/repair.

3.9.17.5 Removal of Equipment

Removal of property will be undertaken in accordance with Section 7.3 (which also includes further detail of Woodside’s decommissioning strategy and compliance with the OPGGS Act).

When equipment is replaced, an assessment of the redundant equipment will be undertaken to assess the feasibility and risks associated with removal. Where removal is deemed to pose an unacceptable risk to existing operational infrastructure, redundant subsea infrastructure items may be left in-situ. Items are recorded as part of the ROV as left survey and included in a database for the inventory associated with each title (refer Section 6.7.2). The inventory is used to track equipment on the seabed to enable planning for future removal. Relevant redundant equipment left in-situ will be maintained as per the IMMR register and plan.

3.9.17.6 Pigging Operations

Pigging involves sending an internal tool through a pipeline using a process medium. During the pipeline lifecycle, the installation/recovery of temporary subsea pig launchers is required for pigging of both the flowlines and trunkline for a variety of reasons (e.g. inspection, maintenance, repair or to facilitate modifications). Where required, subsea isolation valve operations are carried out from a ROV via a support vessel.

Temporary pig launchers will be deployed flooded with MEG/water and require to be de-watered for pigging operations. The base case is to drive the flowline pigs with hydrocarbon gas from an end well. In the event that an end well is not available then the contingency will be to drive the pigs with nitrogen supplied by downline from a support vessel.

High concentrations of nitrogen are not compatible with the FPU and onshore fuel gas systems and therefore may require flaring of hydrocarbon/nitrogen gas if the nitrogen cannot be blended to an acceptable concentration.

The entire pipeline pigging system, including the launcher, receiver and the pipeline, is designed for maximum operation pressure of the production system.

3.9.17.7 Subsea Chemical Use

Planned chemical discharges may occur during a range of IMMR activities. These are planned to be either small volumes or discharged intermittently. Operational chemicals to be used in the Scarborough subsea infrastructure are selected and assessed using Woodside's chemical selection and assessment guideline, as detailed in Section 3.9.16. Typical chemicals which may be used in the Scarborough subsea infrastructure and may be released during IMMR activities include, but are not limited to:

- hydraulic control fluid – the subsea control fluid planned for use in subsea systems is Pelagic 100H, a water-based product, the major component of which is ethylene glycol, a control fluid that contains a dye to support integrity monitoring
- hydrate control – MEG is used for hydrate inhibition of production flowlines
- corrosion inhibitor – corrosion inhibitor is generally used to manage and prevent corrosion within flowlines; corrosion inhibitor is dosed to the MEG on FPU
- biocide – biocides are generally used to prevent the bacterial growth in trunklines and flowlines that may cause corrosion; biocides, oxygen scavenger, surfactant are only used for IMMR activities on the flowlines and trunkline and not during normal operation
- acid – where removal of calcium deposits is required, Woodside typically uses sulphamic (or equivalent) acid; alternatives such as citric acid or calcium wash may be used
- oxygen scavenger – oxygen scavenger is used to reduce/de-oxygenate the trunkline and prevent corrosion and aerobic bacterial growth
- surfactant – surfactants are formulated to remove water and organic deposits from trunklines and flowlines
- grout – the material used in grout, mattresses and rock is typically concrete-based
- staurolite products – used for abrasive/sand blasting to clean and remove marine growth, the main component is staurolite, which is a naturally forming mineral.

3.9.17.8 Typical Discharges During Inspection, Monitoring, Maintenance and Repair Activities

Minor environmental discharges are expected during subsea IMMR activities (e.g. during pressure/leak testing or flushing). Where practicable, flushing is performed before a subsea component is disconnected to reduce residual hydrocarbon or chemical releases to the environment

upon disconnection. The flushing chemicals used for this activity may be supplied from either the facility or a chemical package either via a downline from a support vessel or locally via ROV. Where possible, flushed fluids will return to the platform and be processed and treated through the production system. Table 3-9 shows typical discharge volumes during different IMMR activities.

Table 3-9: Typical discharge volumes during inspection, monitoring, maintenance and repair and subsea activities

Activity	Description
Pressure/Leak testing	Chemical dye estimated <10 L
Flushing	Residual hydrocarbon (gas) or chemical release volume is dependent upon injection port size, component geometry and pumping rates
Flowline PLR installation and purge	Release of hydrocarbon (gas) or nitrogen is estimated to be 1 T and a release of MEG is estimated to be 3 m ³
Export PLR installation and purge	Release of hydrocarbon (gas) or nitrogen is estimated to be 2 T and a release of MEG is estimated to be 6 m ³
Hot stab operations	Hydrocarbon (gas) or control fluid estimated <10 L
Subsea Control Module change out	A typical release of diluted acid is estimated to be 400 L and of control fluid is estimated to be 10 L
Umbilical or hydraulic flying lead replacement	Typical releases of control fluid, MEG with corrosion inhibitor are estimated to be <10 L each, typical acid release of <80 L
SSIV flushing	Release of hydraulic control fluid (mainly MEG) estimated to be 2400 L
Jumper replacement	Release of hydrocarbon (gas) <4 m ³ and a typical release of MEG with corrosion inhibitor is estimated to be 40 L
Choke insert change out	Release of hydrocarbon (gas) <100 L and a typical release of MEG with corrosion inhibitor is estimated to be 280 L, typical acid release of <80 L
Tree cap change out	Release of hydrocarbon (gas) estimated <50 L and a typical release of MEG with corrosion inhibitor is estimated to be <50 L
Logic plate change out	Release of hydrocarbon (gas) estimated <20 L and a typical release of MEG with corrosion inhibitor is estimated to be <20 L

3.9.17.9 Marine Growth Removal

It is often necessary to remove excess marine growth prior to undertaking many subsea IMMR activities if present. Marine growth removal is undertaken with ROV. The different techniques are described in Table 3-10.

Table 3-10: Marine growth removal methods

Activity/Equipment	Description
Water jetting	Uses high-pressure water to remove marine growth
Brush systems	Uses brushes attached to an ROV to physically remove marine growth
Acid (typically citric or sulfamic acid)	Chemically dissolves calcium deposits
Sand/abrasive blasting	Additional cleaning to allow close visual inspections

3.9.17.10 Sediment Relocation

If sediment builds up around trunkline or other subsea infrastructure, an ROV-mounted suction pump unit may be used to relocate the sediment to allow inspection/works to be undertaken. This activity is limited to the relocation of small amounts of sediment material in the immediate vicinity of the subsea infrastructure (i.e. within the existing footprint).

3.9.17.11 Underwater Acoustic Positioning

Long base line (LBL) transponders and/or Ultra Short Baseline Transponders (USBL) are commonly used acoustic positioning methods and may be installed on the seabed as required for vessel positioning. The USBL subsea transponder transmits an acoustic pulse back to the vessel receiver, hence providing an accurate positioning of the subsea transponder location. The LBL array provides accurate positioning by measuring ranges to three or more transponders deployed at known locations on the seabed and structures.

Transmissions are not continuous but consist of short 'chirps' with a duration that ranges from three to 40 milliseconds, when required for positioning. If used, the transponders will be installed in stands on the seabed within the PAA. Transponders and stands shall be removed at work completion.

3.10 Gravimetry surveys

Among the many variables associated with the Scarborough reservoir range, the large regional aquifer and the associated uncertainty of water movement are a material contributor. Gravimetry technology has been identified as a suitable complement to 4D seismic (which would be subject to a future EP) for monitoring field-wide water movement in the reservoir and to reduce uncertainty associated with water movement. The technique delivers a field-wide measurement of gravity, providing direct measurement of water movement / saturation and reservoir compaction / subsidence.

Gravimetry surveys are planned to be completed under this EP as part of this Petroleum Activities Program, at routine intervals over the life of Scarborough operations. The survey duration is approximately 55 days per survey (Section 3.4) and involves the remote surveying of the seabed and concrete pads, and the temporary placement of a passive gravity meter, sequentially on each concrete pad (224 installed previously under the WA-61-L and WA-62-L Subsea Infrastructure Installation EP) by ROV, and temporary deployment of tide gauges on the seabed by a Support Vessel, USV or LCV. The tide gauges will be recovered after the survey is complete. The purpose of the survey is to monitor pressure and saturation changes in the reservoir, to inform decisions regarding reservoir management.

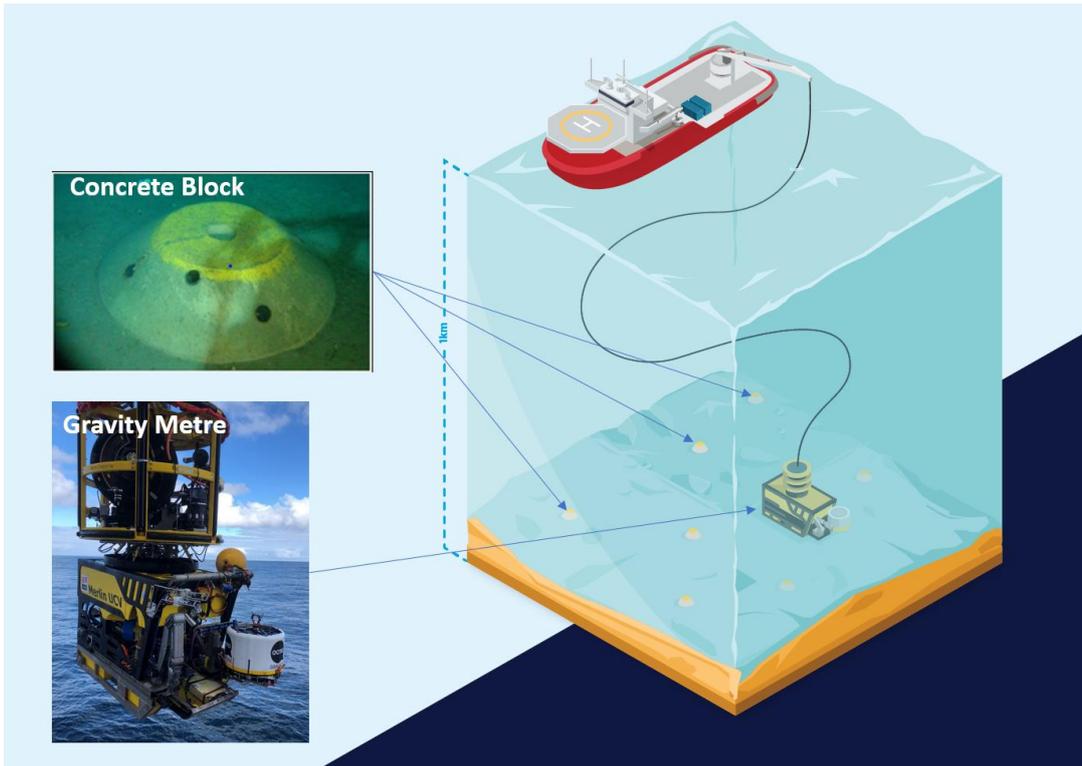

Figure 3-16: Gravimetry activity diagram (not to scale)

During the operation phase, there may be numerous time-lapse gravimetry surveys, subject to reservoir performance. The first time-lapse survey is anticipated within 18-24 months post RFSU. Subsequent surveys may occur every two to three years subject to reservoir performance and field development opportunities identified.

3.11 Vessel-based Activities

Several vessel types (Project Vessels) will be required to complete the activities associated with the Petroleum Activities Program. These include:

- Support vessels (OSV)
- AHTs
- LCV
- ASV
- USV.

Table 3-11 details when each vessel type could be used during the Petroleum Activities Program.

Table 3-11: Summary of vessels

Activity	Vessel type
Routine and Non-Routine Operations	Support Vessels ASV
Hook-up of the pre-laid mooring lines to the FPU	Tow tugs AHTs Support Vessels
Production and export riser pull-in, hook-up and connection to subsea infrastructure Dewatering of production flowlines/risers and export risers/manifold/PLET Cold commissioning of the overall subsea production system, including Xmas trees, umbilicals, and communication lines Commissioning the FPU for the introduction of reservoir hydrocarbons	Support Vessel ASV LCV
Start-up of subsea production system and FPU Well clean-up and commissioning. Gas export trunkline pressurisation and nitrogen (N ₂) removal	Support Vessels
IMMR Activities Gravimetry surveys	Support Vessel, USV or LCV

3.11.1 Support Vessels

Support Vessels are used for field work such as subsea inspection, maintenance and repair and commissioning activities or bunkering. While in field, Support Vessels may be used to backload materials and segregated waste for transport back to shore for further processing at appropriate waste management facilities (located outside of the operational area (Section 3.3). Support Vessels may also be used to transport liquid between moored tankers or onshore port locations. During start-up, rich MEG and well clean up fluids will be removed from the FPU to a Support Vessel, to be disposed of onshore.

The number and type of vessels supporting the activities may vary depending on operational requirements, vessel schedules, capability and availability. The frequency of visits of the Support Vessels is expected to be fortnightly, however, this is subject to increase or decrease depending on IMMR activities and other operational requirements over the life of the EP.

Typical Support Vessels use a dynamic positioning (DP) system to allow manoeuvrability and avoid anchoring when undertaking works, due to the close proximity of subsea infrastructure. However, vessels are equipped with anchors which may be deployed in an emergency. DP uses multiple sources of positioning data (such as satellite navigation and radio transponders) to maintain the position of the vessel at a required location. In some instances, higher levels of accuracy may be required, where satellite information is enhanced via seabed transponders. These transponders emit signals that are detected by receivers on the vessel and used to calculate position. Refer to Section 3.9.17.11 for a full description of the transponders that may be used during the Petroleum Activities Program.

All Support Vessels are required to undergo a Woodside Marine Assurance inspection to review compliance with marine laws and Woodside safety and environment requirements. Vessels may mobilise from an Australian port or directly from international waters to the PAA, in accordance with biosecurity and marine assurance requirements. Vessels will not anchor within the PAA during the activities and instead will maintain position using DP.

Specifications of the vessel *Siem Thiima* are presented in Table 3-12 as an example of the typical Support Vessel.

Table 3-12: Indicative facility support vessel specifications (Siem Thiima)

Parameter	Facility Support Vessel (based on Siem Thiima)
Type	Support Vessel
Length overall (LOA)	89.2 m
Breadth	19.0 m
Draft	7.4 m
Dead weight tonnage (DWT)	5,500 tonnes
Accommodation	Berthing for 25 personnel

3.11.2 Accommodation Support Vessel

An ASV may be required to support commissioning of the FPU, to support planned maintenance campaigns, shutdown maintenance or major projects. The ASV may be alongside the FPU in support of these activities for a period of up to 6 months at a time. . Positioning of the ASV will be determined based on assessment of weather conditions including wind and swell. Transfer of personnel to the FPU will be via a bridge connected to one of two landing platforms installed on either the south-west and south-east corners of the FPU and only connected when safe to do so in accordance with the Activity Specific Operating Guide (ASOG).The ASOG is developed by Woodside in collaboration with the ASV operator, and describes the operating procedures and safe working parameters between the FPU and ASV. Whilst alongside the FPU, the ASV will be required to comply with the requirements of the NOPSEMA accepted ASV facility safety case, and FPU facility safety case. The safety case(s) set out controls to manage potential impacts to people. Bridging documents or safety case(s) may also be required (as well as the ASOG) to support safe operation of both facilities whilst alongside.

The FPU and ASV may be at maximum POB capacity during this time and will be operating utilities such as power, water and sewage systems to enable habitation and commissioning activities. Additionally, the ASV may be used for temporary storage of equipment and supply of services to the FPU such as water and service air/nitrogen. To manage potential risks and impacts associated with the ASV being on station and potential impacts to the environment (including people) a description of the risks impacts and controls to reduce potential impacts to ALARP and acceptable levels is assessed in Section 6.

Typical ASV specifications are provided in Table 3-13 but may vary depending on operational requirements, vessel schedules, capability and availability. Typical ASVs use a DP system to allow manoeuvrability and avoid anchoring when in close proximity to the FPU.

Table 3-13: Indicative accommodation support vessel specifications

Parameter	Typical ASV (Based on Floatel Triumph)
Breadth	80 m
Length	125 m
Gross tonnage	27,211 t
Accommodation	500 POB
Dynamic Positioning	DP3
Fuel Capacity	Total capacity 1800 m ³ Largest tank capacity 267 m ³

3.11.3 Anchor Handling Tug/Tow Vessels

AHTs will be in field during the initial FPU installation and hook-up to mooring lines.

Table 3-14: Indicative anchor handling tug/tow vessel parameters

Parameter	AHT (based on Normand Saracen)
Draft (max)	7.8 m
Length	87.4 m
Gross tonnage	6107 t
Bollard Pull	265 mt
Total fuel volume	1100 m ³
Volume of largest fuel tank	238 m ³

3.11.4 Light Construction Vessel

A Light Construction Vessel (LCV) will be required for pull in of the risers and umbilicals and subsequent subsea infrastructure hook-up and may be utilised for IMMR activities. Key parameters for a typical LCV are presented in Table 3-15.

Table 3-15: Indicative light construction vessel parameters

Parameter	LCV (based on Seven Pegasus)
Draft (max)	6.75 m
Length	131.7 m
Gross tonnage	9494 t
Crane capacity (AHC)	400 t
Total fuel volume	1200 m ³
Volume of largest fuel tank	362 m ³

3.11.5 Uncrewed Surface Vessel

A USV may be utilised to complete gravimetry surveys and/or IMMR activities. The USV will be remotely controlled from an onshore remote operations centre (ROC) in Australia which is staffed 24 hours a day whilst the vessel is in transit or undertaking activities. Key roles in the ROC mirror those on a usual vessel management team and include a Vessel Master, First Officer, Offshore Manager and ROV Supervisor. The vessels are designed with multiple forms of high speed and reliable communication systems to allow connection to the ROC and provide redundancy in the case of disconnection during operations, including an independent emergency low bandwidth satellite communications system.

The USV will be assessed by Woodside Marine (Section 7.10.2.5) to review compliance with marine laws, flag requirements, vessel class and Woodside’s safety and environment requirements. A support vessel may accompany the USV during initial operations in the Scarborough field to monitor the performance of the vessel and provide any assistance if required.

Because there are no facilities to support human occupancy on USV’s, emissions and discharges are typically limited to cooling water and combustion of marine diesel. The vessel is equipped with bilge monitoring systems to monitor the bilge tanks for hydrocarbons (such as leaks from engine machinery spaces or from marine diesel tanks), and where detected the bilge pumps will auto disable and the vessel will be required to immediately return to port.

The USV may be equipped with a built-in work class ROV with the ability to deploy and retrieve equipment from the seabed. Key parameters for a typical USV are presented in Table 3-16.

Table 3-16: Indicative uncrewed surface vessel parameters

Parameter	USV (based on Reach Remote 2)	USV (based on Fugro Maali)
Draft (max)	6 m	2.6 m
Length	23.9 m	12 m
Displacement (Gross Tonnage)	~340 t	14 t
Propulsion System	Diesel-electric hybrid	Diesel-electric hybrid
Total fuel volume	74.1 m ³	3.3 m ³

3.12 Helicopter Operations

Helicopters are the primary means of transporting passengers and/or urgent freight to/from the facility and Support Vessels. They are also the preferred means of evacuating personnel in an emergency. Helicopter support is principally supplied from either Exmouth or Karratha Airports.

Search and Rescue helicopters may be refuelled on the FPU helideck in emergency scenarios.

3.13 Contingent Activities

3.13.1 Trunkline Repair and Flooding, Cleaning, Gauging and Testing

If there is an emergency situation during Trunkline operation (i.e., dragged anchor or dropped object over/on the Trunkline) there may be a need for Trunkline repairs. Repairs may involve the removal of a damaged section of the Trunkline and the remaining good section of trunkline being dewatered. It is usually necessary to carry out dewatering and repairs as soon as possible to minimize damage (corrosion) to the Trunkline internal lining.

The damaged section of trunkline will be cut from the remainder of the trunkline using equipment such as a diamond wire saw and moved out of the trunkline route. A new section of the Trunkline may be installed, or an alternative fix applied to reinstate the Trunklines functionality. Using a contingency water treatment spread, set-up at the shore crossing location within the Pluto Gas Plant, the Trunkline will first be flooded with seawater (treated or untreated, depending on recovery philosophy) for preservation, and then dewatered from shore to offshore using a pig train, potentially separated by chemically treated fresh water (desalination) slugs. The damaged section of the trunkline will then be cut into recoverable lengths (nominally 12 m joints) and recovered by an LCV.

Flood, Clean, Gauge and Test (FCGT) may be used to ensure Trunkline integrity, should there be a need to repair the Trunkline during operations. Flooding and cleaning pigs would be propelled using filtered and chemically treated seawater using an onshore pumping spread. Flooding water would be supplied by a temporary water winning line installed to provide sea water to the onshore pumping spread.

Once flooded, the trunkline would be pressurised using positive displacement pumps from the onshore shore crossing location. Hydrotesting would then be performed to measure the pressure within the trunkline over an extended period of time. Following completion of the test, the trunkline would be depressurised from onshore and left filled with treated seawater. Dewatering of the trunkline would be performed using pigs propelled by compressed air with a combination of freshwater slugs to desalinate the trunkline. The displaced hydrotest water will be discharged offshore through a valve arrangement at the end of the Trunkline. Drying and inerting would then be performed if required. Discharge offshore may occur anywhere along the Trunkline route, depending on the incident location and repair needs.

Activities at the discharge location will be performed with the LCV and may include, but not be limited to, intervention on the PLET (attachment of a pig receiver), which could release small volumes of monoethylene glycol (MEG) used to inert the cavity between the PLET valve and diverless connector, and placement of work baskets on the seabed for storage of ROV tools.

3.13.2 Wet Storing Equipment

Equipment, materials or tools may need to be temporarily wet stored on the seabed in the Operational Area during hook-up or Operations. This could include, but not be limited to, work baskets for ROV tools, pig launcher/receiver prior/after connection, damaged risers or flowlines etc. Removal of wet stored items will be planned for and undertaken when the property is neither used, nor to be used throughout operations authorised by the title.

4 DESCRIPTION OF THE EXISTING ENVIRONMENT

4.1 Overview

In accordance with Regulations 21(2) and 21(3) of the Environment Regulations, this section describes the existing environment that may be affected by the activity (planned and unplanned, as described in Section 6), including details of the particular relevant values and sensitivities of the environment, which were used for the risk assessment. Specific references to supporting information in Appendix L: Woodside Master Existing Environment have been made throughout this section.

The Environment that May Be Affected (EMBA) is the largest spatial extent where unplanned events could have an environmental consequence on the surrounding environment. For this EP, the EMBA is the potential spatial extent of surface and in-water hydrocarbons at concentrations above ecological impact thresholds, in the event of the worst-case credible spill. The ecological impact thresholds used to delineate the EMBA are defined in Section 6.8.1.2. The EMBA also includes areas that are predicted to experience shoreline contact with hydrocarbons above threshold concentrations. The worst-case credible spill scenarios for this EP are highly unlikely loss of marine diesel during a vessel collision

- at the FPU location
- from a vessel conducting activities along the trunkline in the Montebello Australian Marine Park Multi Use Zone
- from a vessel conducting activities along the trunkline at the boundary between State and Commonwealth waters.

Results from each of these scenarios were overlaid to create a combined EMBA, hereafter referred to as the EMBA (Figure 4-2).

Woodside recognises that hydrocarbons may be visible beyond the EMBA at lower concentrations than the ecological impact thresholds defined in Section 6.8.1.2. These visible hydrocarbons are not expected to cause ecological impacts. However, in recognition of this, an additional socio-cultural EMBA is defined as the potential spatial extent within which social-cultural impacts may occur from changes to the visual amenity of the marine environment. Receptors relevant to the socio-cultural EMBA include Commonwealth and State marine protected areas (MPAs), National and Commonwealth Heritage Listed places, areas of tourism and recreation, and commercial and traditional fisheries. For this EP, the socio-cultural EMBA for surface hydrocarbons encompasses an area fully within the boundaries of the EMBA for ecological impacts. The EMBA and socio-economic EMBA is shown in Figure 4-2 and described in Table 4-1.

The EMBA presented does not represent the predicted coverage of any one hydrocarbon spill or a depiction of a slick or plume at any particular point in time. Rather, the areas are a composite of a large number of theoretical paths, integrated over the full duration of the simulations under various metocean conditions, with release from three key locations.

Table 4-1: Hydrocarbon spill thresholds used to define environment that may be affected for surface and in-water hydrocarbons

Hydrocarbon Type	EMBA ₁	Socio-cultural EMBA ₁	Planning Area for Scientific Monitoring
Surface	10 g/m ² This represents the minimum oil thickness (0.01 mm) at which ecological impacts (e.g. to birds and marine mammals) are expected to occur.	1 g/m ² This represents a wider area where a visible sheen may be present on the surface and, therefore, the concentration at which socio-cultural impacts to the visual amenity of the marine environment may occur. However, it is below concentrations at which ecological impacts are expected to occur.	NA
Dissolved	50 ppb This represents potential toxic effects, particularly sublethal effects to highly sensitive species (NOPSEMA guidance note: A652993, April 2019). As dissolved hydrocarbons are within the water column and not visible, impacts to socio-cultural receptors can be associated with ecological impacts. Therefore, dissolved hydrocarbons at this threshold also represent the level at which socio-cultural impacts may occur.		10 ppb This low exposure value establishes the planning area for scientific monitoring (based on potential for exceedance of water quality triggers) (NOPSEMA guidance note: A652993, April 2019). This area is described further in Appendix H: Oil Spill Preparedness and Response Mitigation Assessment: Figure 5-1. In the event of a spill, DNP will be notified of AMPs which may be contacted by hydrocarbons at this threshold.
Entrained	100 ppb This represents potential toxic effects, particularly sublethal effects to highly sensitive species (NOPSEMA guidance note: A652993, April 2019). As entrained hydrocarbons are within the water column and not visible, impacts to socio-cultural receptors can be associated with ecological impacts. Therefore, entrained hydrocarbons at this threshold also represent the level at which socio-cultural impacts may occur.		
Shoreline	100 g/m ² This represents the threshold that could impact the survival and reproductive capacity of benthic epifaunal invertebrates living in intertidal habitat.	10 g/m ² This represents the volume where hydrocarbons may be visible on the shoreline but is below concentrations at which ecological impacts are expected to occur.	N/A

¹ Further details, including the source of the thresholds used to define the EMBA in this table, are provided in **Section 6.8.1.2**.

4.2 Regional Context

The PAA occurs in Commonwealth waters off the north-west coast of Western Australia (WA), located in the North-west Marine Bioregion (NWMR) (IMCRA 4.0). Within the NWMR, the Offshore Operational Area lies within the Northern Carnarvon Basin on the Exmouth Plateau, about 375 km offshore from the Burrup Peninsula. The Trunkline Operational Area is situated in water depths from ~31 m (export trunkline route at State waters boundary) to 1400 m (KP 275 of the trunkline route). The Offshore Operational Area overlaps with the Northwest Province whilst the Trunkline Operational Area overlaps the Northwest Shelf Province and the Northwest Province. The EMBA partially overlaps with the Central Western Shelf Transition, Central Western Shelf Transition, Northwest Shelf Province, Northwest Province and Northwest Transition. Appendix L: Woodside Master Existing Environment summarises the characteristics for the relevant marine bioregions.

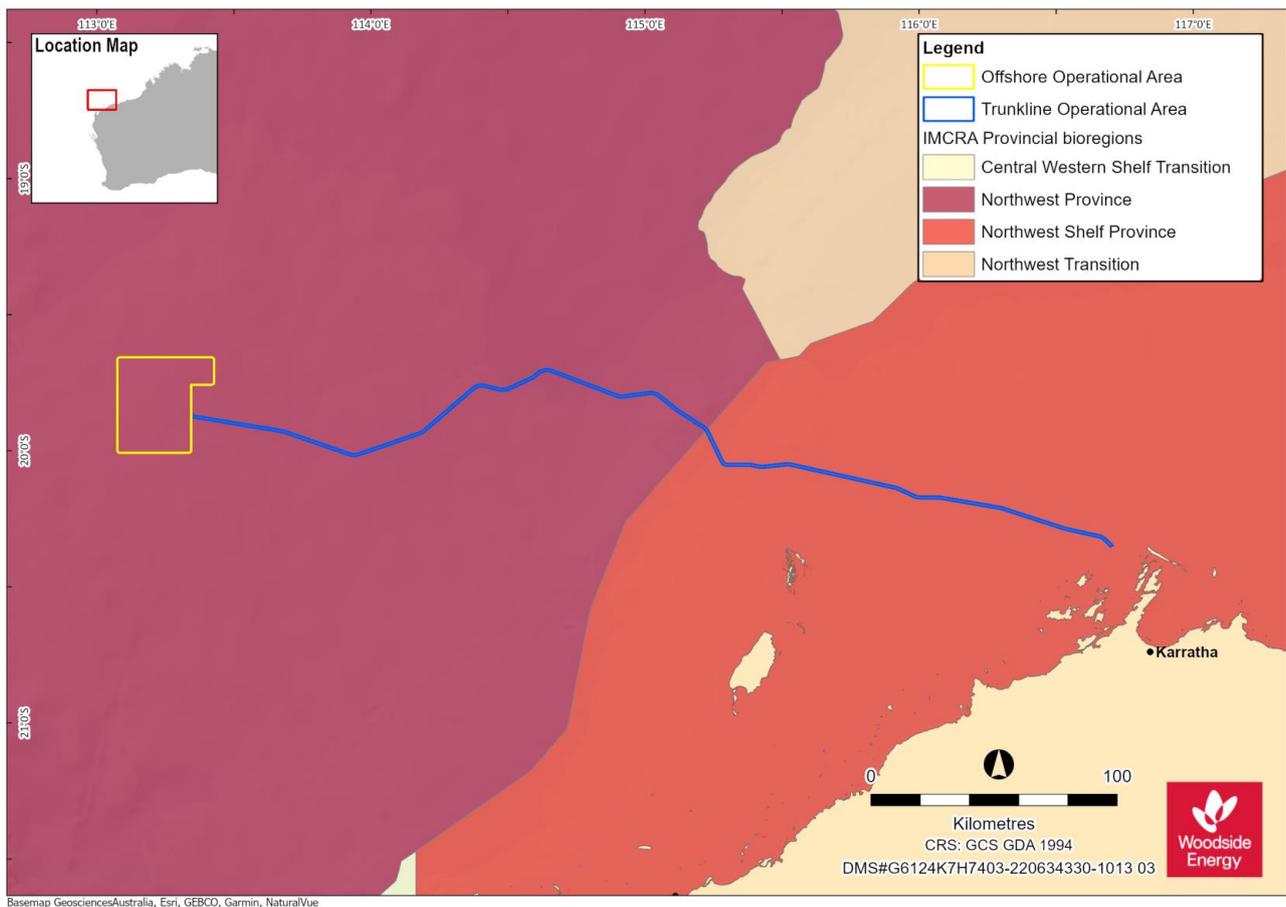

Figure 4-3: Location of the Petroleum Activities Area and relevant marine bioregions

4.3 Matters of National Environmental Significance (Environment Protection and Biodiversity Conservation Act)

Table 4-2 and Table 4-3 summarise the matters of national environmental significance (MNES) overlapping the PAA and EMBA, respectively, according to results of Appendix C: Environment Protection and Biodiversity Conservation Act Protected Matters Search. It should be noted that the EPBC Act PMST is a general database that conservatively identifies areas in which protected species have the potential to occur.

Additional information on these MNES is provided in subsequent sections of this chapter.

Table 4-2: Summary of matters of national environmental significance identified by the Environment Protection and Biodiversity Conservation Act Protected Matters Search Tool as potentially occurring within the Petroleum Activities Area

MNES	Number	Relevant Section
World Heritage Properties	0	Section 4.9
National Heritage Places	0	Section 4.9

4.4 Physical Environment

4.4.1 Offshore Operational Area

Water depths of the Offshore Operational Area range from 900 m to 1000 m. The shallowest waters are approximately in the centre of the Offshore Operational Area, with a gradual increase in depth to the north/north-west and also to the south/south-east (Figure 4-4). To the centre and west of the PAA, craters (up to 400 m across and 10 m deep) and similar pockmarks (metres to tens of metres across) have been identified through geophysical surveys (Fugro, 2010). The seafloor exhibits gradients less than 1° but extends to about 15° on the edge of craters (Fugro, 2010). These crater and pockmark formations may be associated with hydrocarbon seeps and associated authigenic carbonate formations (Fugro, 2010).

Marine sediment quality surveys within the Scarborough titles were undertaken during the 2012/2013 wet and dry seasons (ERM, 2013). The ERM marine investigation included sampling at a number of sampling sites, to:

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

- provide a broad characterisation of the habitats within WA-61-L
- achieve spatial coverage across WA-61-L
- provide a representative selection of the various topographic features and corresponding benthic habitats (i.e. crater/pockmark versus non-crater areas).

Key results included:

- All the sediment samples collected were predominantly ($\geq 97\%$ w/w) composed of clay and silt; and only small amounts (1–3% w/w) of sand and shell were detected.
- Generally, low concentrations of metals and nutrients were detected. Except for nickel, metal concentrations were below the sediment default guideline values (DGVs) (Simpson, 2013) for analytes with defined DGVs (arsenic, cadmium, chromium, copper, mercury, nickel, lead and zinc). Nickel concentrations were below the high guideline value (GV).
- No hydrocarbons were detected.
- Although crater and pockmark formations have been identified in the EMBA, which have been associated with hydrocarbon seeps and authigenic carbonate formations (Fugro, 2010), the absence of hydrocarbons in sediment samples indicates the lack of recent hydrocarbon seep activity in the locations sampled (ERM, 2013).
- Water quality in the Offshore Operational Area is typical of a tropical offshore environment. Much of the surface water in this area is nutrient poor, transported from the Indonesian Throughflow (ITF) and has low primary productivity.
- The marine water quality of the offshore environment of the Exmouth Plateau was measured by collecting triplicate water samples at three stations per 15 sampling sites (across two seasons) (ERM, 2013). Water profiling and water quality sampling was undertaken in the 2012/2013 wet and dry seasons.
- The deeper waters had significantly lower dissolved oxygen concentrations (about 23%) compared to the oxygen-saturated ($\geq 100\%$) surface waters.
- Generally low concentrations of metals, nutrients and chlorophyll-a were detected. Except for cobalt, copper and zinc, mean metal concentrations throughout WA-61-L during both the wet and dry season studies were below the ANZECC guidelines trigger value for 95% species protection (ANZECC and ARMCANZ 2000).
- Total suspended solid mean concentrations were higher during the wet season (22,450 $\mu\text{g/L}$) than the dry season study (4000 $\mu\text{g/L}$) and showed variability across sites and throughout the water column.

Results from the studies indicated the water quality within the WA-61-L title is generally typical of the NWMR's tropical deep-water environment (ERM, 2013).

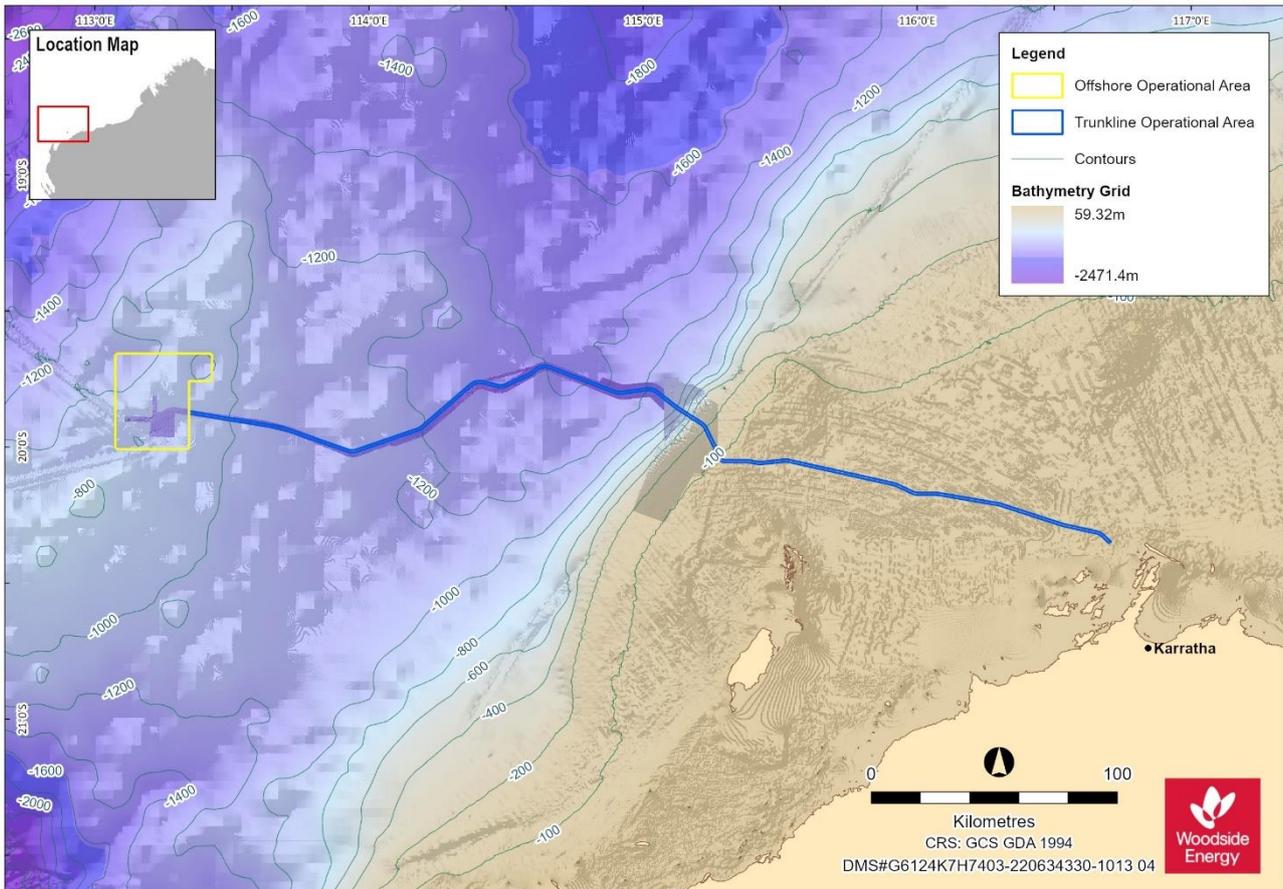

Figure 4-4: Bathymetry of the Offshore Operational Area

4.4.2 Trunkline Operational Area

The Trunkline Operational Area extends from the State-Commonwealth waters boundary on the inner continental shelf, onto the continental slope where it traverses the continental slope westwards to the Exmouth Plateau (Figure 4-5). The eastern half of the Trunkline Operational Area is adjacent to the existing Pluto trunkline. The water depth ranges from ~31 m (export trunkline route at State waters boundary) to 1400 m (KP 275 of the export trunkline route).

Table 4-4 provides a summary description of the seabed along the export trunkline route, including seabed features and along the export trunkline route from the State waters boundary (KP 32) to the intersection of the export trunkline route with the north-western limit of the Montebello Marine Park (approximately KP 191). Beyond KP 191 the seabed is located on the Exmouth Plateau, which is characterised by a thick Triassic sequence overlain by a Jurassic, Cretaceous and Cainozoic sediment sequence; and fine-grained carbonate ooze (Fugro, 2010). Sediment samples collected at the end of the export trunkline route were predominantly composed of clay and silt; and only small amounts (1–3% w/w) of sand and shell (ERM, 2013).

Appendix L: Woodside Master Existing Environment provides a summary of the physical characteristics of the environment within the EMBA in Section 2.

Table 4-4: Summary of seabed features, sediments, epifauna and infauna along the trunkline route

Section of Trunkline	Seabed features and sediments	Epifauna and infauna
KP 32 – KP 43.1	<ul style="list-style-type: none"> The seabed is predominantly flat, smooth and featureless Sediments comprise carbonate sands with some finer components. 	<p>Sparse ascidians, sponges, invertebrate communities, burrowing organisms and octocorals were observed from the drop camera study. This benthos is considered representative of the area and is similar to that observed in other regional studies (Keesing, 2019; Advisian, 2019a).</p>
KP 43.1 – KP 52.5	<ul style="list-style-type: none"> Seabed expected to comprise carbonate sand and shell gravel The seabed is predominantly flat and featureless between KP 43.1 and KP 52.5 Minor accumulations of coarser sediments between KP 43.9 and KP 44.9 and KP 47.1 to KP 50 KP 50 to KP 52 there are a number of isolated depressions visible on the seafloor. 	
KP 52.5 – KP 108.4	<ul style="list-style-type: none"> Seabed sediments are expected to comprise carbonate sands with shell gravel Depressions appear throughout the route corridor it seems that the clusters of depressions mostly occur when the calcarenite is outcropping at seafloor. These depressions run perpendicular to the proposed export trunkline route Geotechnical sampling within this section recovered carbonate sands with some silt content. 	<p>The predominantly featureless seabed is not expected to support abundant or diverse benthic communities and is considered typical of the North West Shelf.</p> <p>The presence of oil and gas infrastructure may artificially increase habitat complexity in areas of featureless seabed, resulting in higher species richness and abundance of fish species and epifauna associated with infrastructure, compared to adjacent natural habitats (McLean et al., 2020; McLean et al., 2018; McLean et al., 2017; Bond et al., 2018).</p>
KP 108.4 – KP117.6 (Montebello Marine Park MUZ)	<ul style="list-style-type: none"> Seabed sediments are expected to comprise carbonate sands with shell gravel which was confirmed by geotechnical sampling Localised increases in reflectivity tend to be associated with the presence of numerous depressions and exposure of the underlying calcarenite unit Shallow soils isopach occur along the corridor and tends to show a cover of sand which suggests that these areas are more likely to represent accumulations of coarse material or disturbed seabed rather than outcrop. 	<p>The results of previous benthic studies in the Montebello Marine Park are largely in alignment with the geophysical data (i.e. typically low relief sandy seafloor (with various bedforms) with occasional rubbly areas increasing at sites more inshore) and dominant benthic organisms identified (which varied in diversity and density within and between survey areas, but typically included a wide variety of sponges and soft corals including whips and gorgonians, hydroids, seapens and crinoids) (Advisian, 2019a).</p> <p>The harder areas of calcarenite have the potential to support more abundant and diverse benthic communities, however the patchiness of the exposure of the underlying hard substrate is expected to limit the potential to support significant epifaunal habitats.</p>
KP 164.1 – KP 173.6 (Montebello Marine Park MUZ)	<ul style="list-style-type: none"> Seabed sediments are expected to comprise carbonate sands with shell gravel The underlying calcarenite is expected to outcrop at seabed within the majority of this area, however, apart from appearing marginally less smooth and sometimes slightly mottled, the seafloor otherwise appears very uniform without any noticeable increase in reflectivity. 	
KP 173.6 – KP 191.6 (Montebello Marine Park MUZ)	<ul style="list-style-type: none"> Seabed appears moderately reflective and predominantly featureless. Isolated features and clusters are noted. These depressions often show associated small mounds

Section of Trunkline	Seabed features and sediments	Epifauna and infauna
	<ul style="list-style-type: none"> Between KP 173.4 and KP 178.1 the seafloor appears more irregular and slightly mottled. Lineations in the calcarenite are oriented approximately north-east to south-west, and this area is thought to represent the outer reef which is characterised by linear ridges and relict sandwaves Relict sandwaves are present between KP 184.7 to KP 190.6. The sandwaves exhibit an approximate north-south orientation, have wavelengths of between 150 m to 300 m, and measure up to 10 m in height. Surficial seabed sediments are expected to comprise carbonate sands with shell gravel. 	

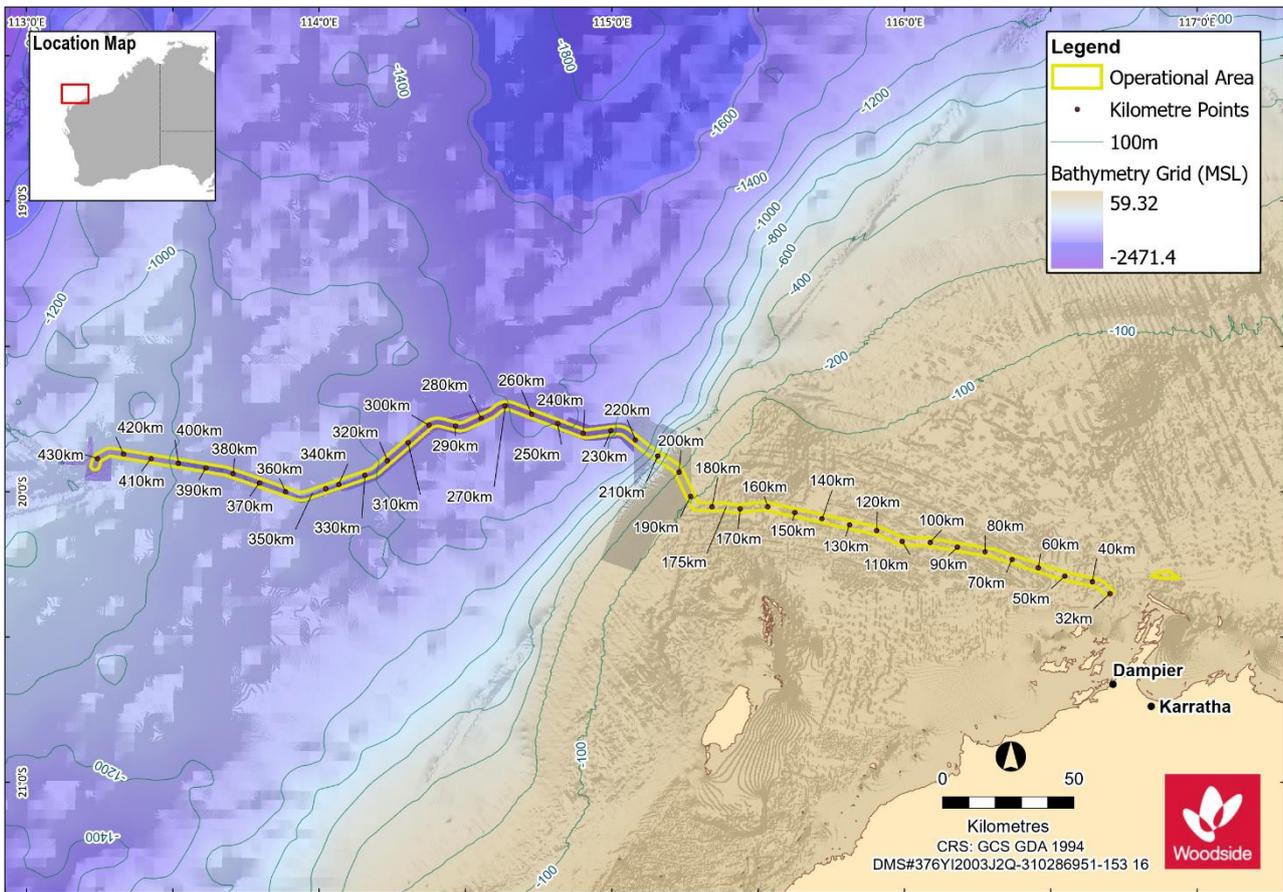

Figure 4-5: Bathymetry of the Export Trunkline Operational Area

4.5 Habitats and Biological Communities

4.5.1 Offshore Operational Area

The seafloor in the Offshore Operational Area is characterised by sparse marine life dominated by motile organisms (ERM, 2013). This soft bottom habitat also supports patchy distributions of mobile epibenthos, such as sea cucumbers, ophiuroids, echinoderms, polychaetes and sea-pens (DEWhA,

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

2008a). Bivalve shell debris and bacterial mats (both with low percent cover) were the only identified features that may be indicative of historic hydrocarbon seep activity. A benthic infauna analysis reported by ERM in 2013 provided no evidence of the presence of unique hydrocarbon seep chemosynthetic benthic communities, which are typically characterised by species from the family Dorvilleidae (ERM, 2013; Thornhill et al., 2012).

Seabed habitat is characterised by sparse marine life dominated by mobile benthic biota (ERM, 2013). The benthic biota are predominantly deposit feeders such as epifauna (living on the seabed): shrimp (crustaceans) and sea cucumbers (echinoderms), and infauna (living within the surface sediments) small, burrowing worms (polychaetes) and crustaceans (ERM, 2013). Bioturbation traces (seabed surface sediment animals trails, mounds and burrows) are characteristic of such deepwater benthic habitats and were recorded during baseline survey work (ERM, 2013) and are thought to be common within the PAA and EMBA. The seabed bioturbation indicates the presence of benthic biota (epifauna and infauna) including echinoderms, crustaceans and echiurans (spoon worms) and annelids (polychaetes) (ERM, 2013).

Sampling within the Offshore Operational Area returned low phytoplankton densities (ERM, 2013). Seasonal variation was observed in the samples with total recorded taxa, species richness and species diversity (Shannon-Weiner) being significantly greater in the dry season than in the wet season (ERM, 2013). Dinoflagellates were the most abundant group within wet season study, and diatoms were generally the most abundant group in dry season study (ERM, 2013).

Similarly, greater species abundance and diversity was recorded in zooplankton samples during the dry season compared to the wet season (ERM, 2013). Copepods were the most dominant taxonomic group during both studies in terms of abundance and concentrations, with other zooplankton including ostracods, molluscs (pteropods), euphausiids (krill) and larvaceans also being identified in relatively abundant amounts (ERM, 2013).

Concentrations of fish larvae were similar in both wet and dry season samples. For both seasons ichthyoplankton communities largely comprised the larvae of meso-pelagic fishes (Myctophidae [lantern fishes] and Gonostomatidae [bristlemouths]) (ERM, 2013).

It is noted that these survey findings do not reflect the productivity trends reported in scientific literature for the region (DEWHA, 2008a; Brewer et al., 2007), whereby productivity is typically greater during the wet season when the weakening of surface currents allows for increased upwelling. However, the findings do indicate that productivity remains low across the seasons and that while seasonal variations in plankton species composition potentially occurs, overall variations in abundance are likely to be minor (ERM, 2013).

4.5.2 Trunkline Operational Area

Primary productivity in the region is typically low, driven by offshore influences, with periodic upwelling and cyclonic events driving coastal productivity (Brewer et al., 2007). Localised upwelling generally occurs as a result of the changing strength of the ITF, internal tides, cyclones, and their interaction with the complex seafloor topography.

The planktonic communities that drive primary productivity in the region are comprised of phytoplankton and zooplankton (protozoa, copepods, ichthyoplankton etc.). Phytoplankton abundance increases as a result of an increase in nutrient availability, in turn supporting an increase in zooplankton. Mass coral spawning events in the NWMR during March and April contribute to peaks in zooplankton abundance.

The planktonic communities of the Trunkline Operational Area are likely to be representative of the wider region. Offshore planktonic communities feature smaller taxa, whereas inshore communities are dominated by larger taxa such as diatoms. The greatest productivity is likely to be around the 200 m isobath, associated with the shelf break. Further information regarding the planktonic communities of the PAA and the NWMR are detailed in Sections 4.2 and 4.3 of Appendix L: Woodside Master Existing Environment and in the Scarborough OPP.

The NWMR is characterised by diverse nearshore primary producer habitats such as seagrass meadows, coral reefs and mangrove forests, to offshore soft sediment seabed habitats and submerged and emergent reef systems. Benthic communities range from infauna and low density sessile filter feeders of soft sediments and deeper waters, mobile macrobenthos and diverse hard coral communities in shallower habitats.

The EMBA is likely representative of the wider region, featuring sparse mobile epifauna (i.e., arthropods and echinoderms) and sessile filter feeders (sponges, soft corals etc.). Hard coral assemblages are generally found in shallower waters (< 50 m) on the seaward slopes of outer islands of the Dampier Archipelago, as well as fringing reefs around the Montebello Islands, Barrow Island, Muiron Islands and Ningaloo Reef. Regionally significant Rankin Bank and Glomar Shoal (~114 km north-west and ~84 km north of the Trunkline Operational Area, respectively), are present within the EMBA, hosting diverse benthic assemblages across complex seafloor features. Seagrass meadows and benthic macroalgae reefs are located in shallow waters surrounding the Dampier Archipelago, Muiron and Barrow islands in sheltered areas and subtidal habitats. This is detailed in Table 4-1 of Appendix L: Woodside Master Existing Environment.

The Trunkline Operational Area is likely to feature sparse ascidians, sponges, invertebrates, infauna and burrowing organisms and octocorals, representative of the area as detailed in Table 4-3 of Appendix L: Woodside Master Existing Environment. No primary producer communities (hard corals, seagrass, macroalgae) are expected to occur due to the lack of light.

Key habitats and ecological communities within the EMBA are identified in Table 4-5 and described in Section 4 of Appendix L: Woodside Master Existing Environment.

Table 4-5: Habitats and communities within the environment that may be affected

Habitat/community	Key locations within the EMBA
Marine primary producers	
Coral	Key locations for coral/habitat communities within the EMBA are at Rankin Bank, approximately 226 km east of the Offshore Operational Area (33 km north of the Trunkline Operational Area). The EMBA overlaps the Commonwealth waters adjacent to Ningaloo Reef KEF, known for its extensive coral reef communities, soft corals and gorgonians. Refer to Section 4 of Appendix L: Woodside Master Existing Environment for a description of coral communities in the NWMR.
Seagrass beds and macroalgae	Ningaloo Marine Park and soft-bottom substrates along the Pilbara coast support seagrass communities. Protected waters around the Dampier Archipelago, Thevenard Island, Barrow and Montebello Islands also contain seagrass communities.
Mangroves	Regionally significant mangrove communities can be found in the Montebello Islands and Enderby Island Complex (within the Dampier Archipelago).
Sandy beaches	Occur on shorelines of island groups throughout the EMBA (e.g., Barrow Island).
Salt marshes	Occur on some island groups throughout the EMBA.
Other communities and habitats	
Plankton	Plankton within the EMBA is expected to reflect the conditions of the NWMR. Primary productivity of the NWMR appears to be largely driven by offshore influences, with periodic upwelling events and cyclonic influences driving coastal productivity with nutrient recycling and advection. Refer to Section 4.3 of Appendix L: Woodside Master Existing Environment for a description of planktonic communities in the NWMR.
Pelagic and demersal fish populations	In the EMBA, fish diversity and abundance is typically correlated with habitat distribution, with complex habitats, such as coral and rocky reefs, hosting more diverse and abundant assemblages. Notable habitats hosting diverse

Habitat/community	Key locations within the EMBA
	fish assemblages include the Continental slope demersal fish communities KEF. Refer to Section 5 of Appendix L: Woodside Master Existing Environment for a description of pelagic and demersal fish populations in the NWMR.
Epifauna and infauna	The EMBA contains deep water habitats dominated by soft, fine grain sediments and sparse benthic biota. The benthic communities are characterised by benthic filter feeders and other epifauna, and infaunal bioturbators. Refer to Section 4.4 of Appendix L: Woodside Master Existing Environment for a description of epifauna and infauna in the NWMR.

4.6 Protected Species

A total of 67 EPBC Act listed species considered to be MNES were identified as potentially occurring within the EMBA, of which a subset of 49 species were identified as potentially occurring within the PAA. The full list of marine species identified from the PMST reports is provided in Appendix C: Environment Protection and Biodiversity Conservation Act Protected Matters Search, including several MNES that are not considered to be credibly impacted (e.g., terrestrial species within the EMBA). One conservation dependent species have also been identified with a potential to occur within the PAA and EMBA.

Species identified as potentially occurring within the PAA and EMBA, Biologically Important Areas (BIAs) and Habitat Critical to their Survival (Habitat Critical) that overlap the PAA and EMBA are listed in Table 4-6 to Table 4-14. A description of these species is included in Sections 5 to 8 of Appendix L: Woodside Master Existing Environment. Figure 4-6 to Figure 4-12 show the spatial overlap of relevant BIAs and Habitat Critical areas within the PAA.

4.6.1 Fish, Sharks and Rays

Table 4-6: Threatened and Migratory fish, shark and ray species predicted to occur within the Petroleum Activities Area and environment that may be affected

Species name	Common name	Threatened status	Migratory status	Potential for interaction	
				PAA	EMBA

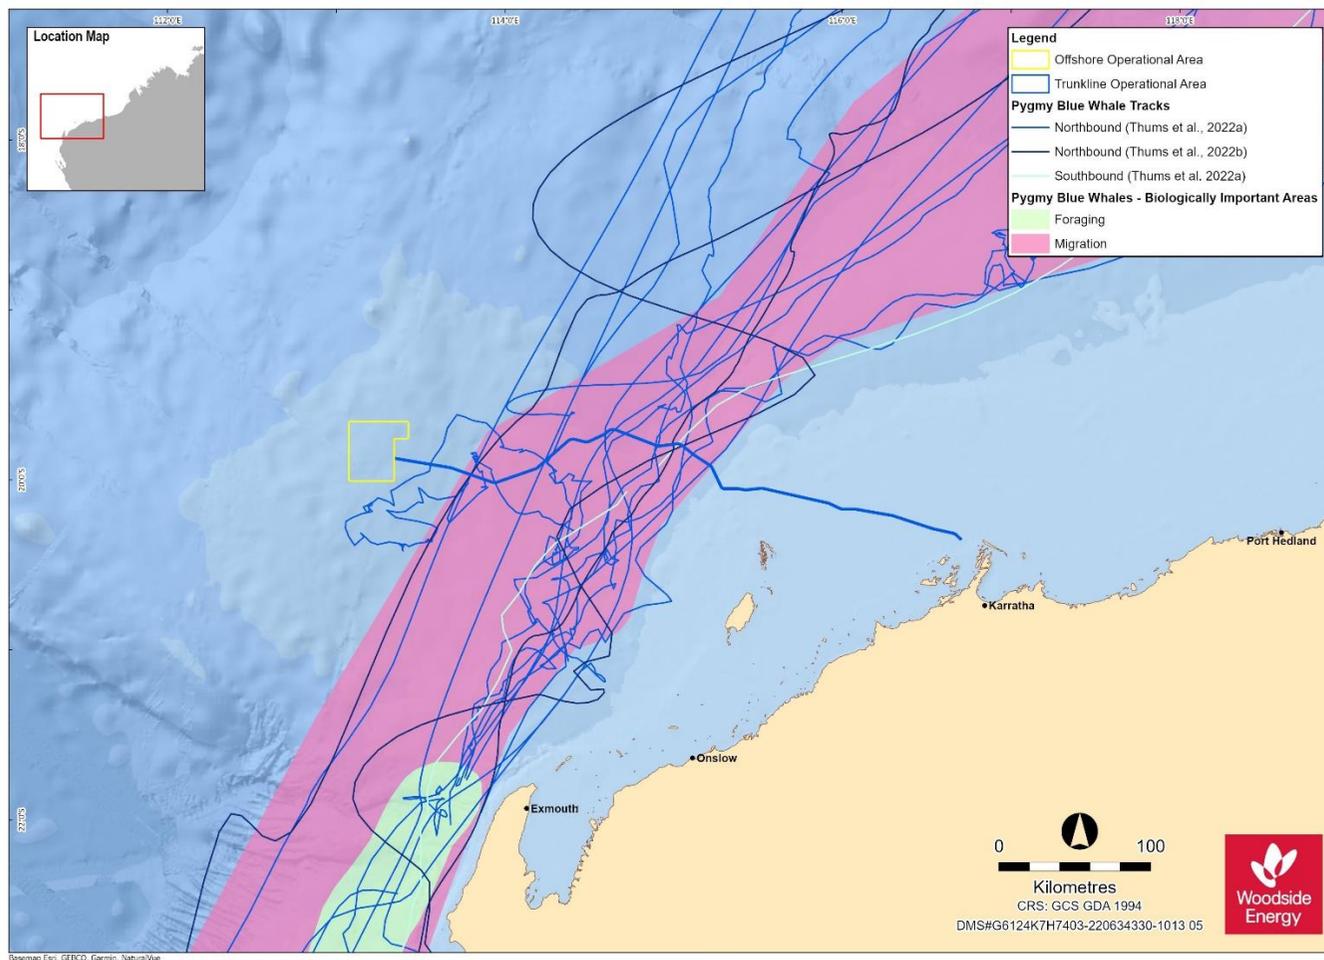

Figure 4-10: Pygmy blue whale biologically important areas and distribution range (as per the National Conservation Values Atlas and Blue Whale Conservation Management Plan, respectively) with reference to the Petroleum Activities Area and the 20 tracks of satellite tagged pygmy blue whales recorded in the NWMR, of the 22 tracks presented in Thums et al. (2022)

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

4.6.3.1 Pygmy Blue Whales

The blue whale (*Balaenoptera musculus*) is currently listed as Endangered, Migratory and Cetacean under the EPBC Act and Endangered under the WA Biodiversity Conservation Act 2016 (BC Act, September 2018).

The important biological habitats for critical life stages of the pygmy blue whale life cycle are presented in the Blue Whale Conservation Management Plan (CMP) (CoA, 2015a) and the National Conservation Values Atlas (NCVA). The foraging areas correspond to blue whale biologically important areas (BIAs) based on foraging of varying density and likelihood. The NCVA also includes an area of offshore waters in Western Australia that represents the migratory corridor or Migratory BIA for pygmy blue whales; refer to Figure 4-10.

The pygmy blue whale migration BIA overlaps the Trunkline Operational Area and is approximately 35 km to the east of the Offshore Operational Area (Figure 4-10). Both the Trunkline and Offshore Operational Areas overlap the broader pygmy blue whale distribution BIA (Figure 4-11), a spatially defined area representing presence certainty and not biologically important behaviour (e.g. breeding, foraging, migration). The distribution range acknowledges the migratory movement of pygmy blue whales to the west of the Migratory BIA, though the majority of the important migration areas for north-west Australia are within the migratory BIA (Thums et al. 2022) and telemetry data also indicates north of the North West Cape pygmy blue whales transit through deeper and further offshore waters (Thums et al., 2022; Double et al., 2014).

Considering the pygmy blue whale migration BIA overlaps the Trunkline Operational Area, migrating whales are expected to be present during the north and south bound migratory seasons (April to July and October to January, respectively) (McCauley, 2011; Gavrillov et al., 2018; Thums et al., 2022). It is likely that individuals may also transit it and around the Offshore Operational Area; however, only transient individuals or small groups are expected occasionally due to the distance from the migration BIA (35 km). The Exmouth Plateau KEF (refer to Section 4.7) is an area of localised upwelling and may be a source of food for occasional pygmy blue whale foraging. Migrating pygmy blue whales (northbound) display predominately relatively fast, directed travel interspersed with relatively short periods of low move persistence indicative of foraging (Thums et al., 2022) and acoustic detection (McCauley, 2011) indicated a short, sharp pulse of southbound migrating pygmy blue whales.

Thums et al. (2022) acknowledge that the majority of important migration areas for north-west Australia were encompassed by the pygmy blue whale migration BIA, as indicated by 20 tracks for northbound pygmy blue whale (presented in Figure 4-10). Furthermore, the analysis identified areas from Ningaloo Reef to the Rowley Shoals as important for foraging (and/or breeding/resting) using the overlay of three modelled metrics (occupancy, number of whales and move persistence) by Thums et al. (2022). These include areas within and to the west of the migration BIA, indicating there is some but most likely low likelihood of foraging whales being present in the Offshore Operational Area.

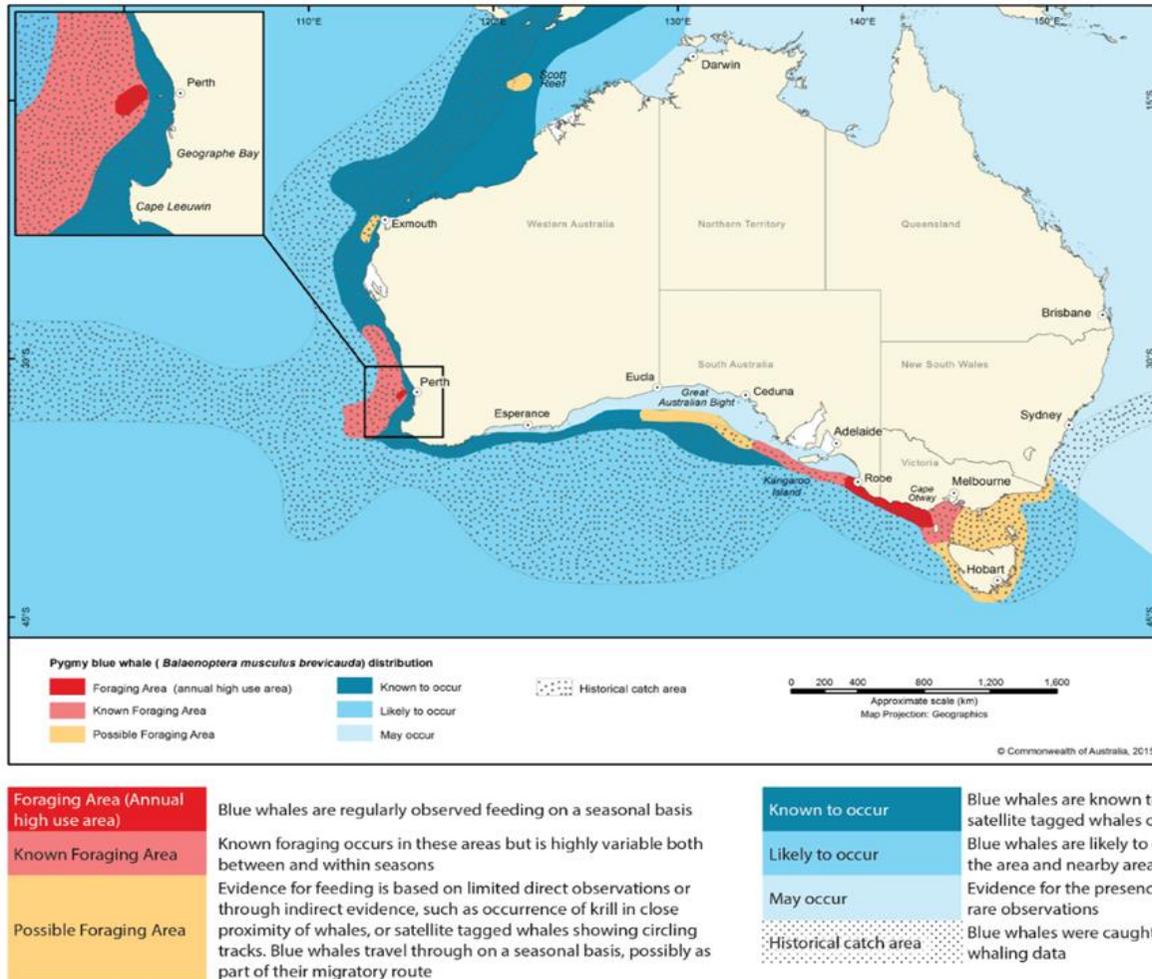

Figure 4-11: Important foraging and areas of occurrence for pygmy blue whales as presented in the Blue Whale Conservation Plan (Commonwealth of Australia, 2015a); note: known to occur area in the Blue Whale Conservation Management Plan is the same as the distribution range presented in the National Conservation Values Atlas

4.6.4 Seabirds and Migratory Shorebirds

Table 4-13: Threatened and Migratory seabird and shorebird species predicted to occur within the Petroleum Activities Area⁶ and environment that may be affected⁷

Species name	Common name	Threatened status	Migratory status	Potential for interaction	
				PAA	EMBA
<i>Macronectes giganteus</i>	Southern giant petrel	Endangered	Migratory	Species or species habitat may occur within area	Species or species habitat may occur within area
<i>Phethon lepturus fulvus</i>	Christmas island white-tailed tropicbird	Endangered	N/A	Species or species habitat may occur within area	Species or species habitat may occur within area
<i>Phaethon lepturus</i>	White-tailed tropicbird	N/A	Migratory	Species or species habitat may occur within area	Species or species habitat likely to occur within area
<i>Fregata ariel</i>	Lesser frigatebird	N/A	Migratory	Species or species habitat may occur within area	Species or species habitat known to occur within area
<i>Anous stolidus</i>	Common noddy	N/A	Migratory	Species or species habitat may occur within area	Species or species habitat likely to occur within area
<i>Thalassarche steadi</i>	White-capped albatross	Vulnerable	Migratory	N/A	Species or species habitat may occur within area
<i>Thalassarche carteri</i>	Indian yellow-nosed albatross	Vulnerable	Migratory	N/A	Species or species habitat may occur within area

⁶ N.B. The wedge-tailed shearwater was not identified in the PMST as potentially occurring within the PAA. However, given its BIA overlaps the eastern end of the Trunkline Operational Area, it is considered likely that the species may be encountered within the PAA.

⁷ N.B. The Lesser Crested Tern was not identified in the PMST as potentially occurring within the EMBA. However, given it has several BIAs south of the Trunkline Operational Area, it is considered likely that the species may be encountered within the EMBA.

Species name	Common name	Threatened status	Migratory status	Potential for interaction	
				PAA	EMBA
<i>Thalassarche impavida</i>	Campbell albatross	Vulnerable	Migratory	N/A	Species or species habitat may occur within area
<i>Pterodroma mollis</i>	Soft-plumaged petrel	Vulnerable	N/A	N/A	Foraging, feeding or related behaviour likely to occur within area
<i>Sternula nereis nereis</i>	Australian fairy tern	Vulnerable	N/A	Breeding known to occur within area	Breeding known to occur within area
<i>Fregata minor</i>	Great frigatebird	N/A	Migratory	Species or species habitat may occur within area	Species or species habitat may occur within area
<i>Ardenna carneipes</i>	Flesh-footed shearwater	N/A	Migratory	N/A	Species or species habitat likely to occur within area
<i>Calonectris leucomelas</i>	Streaked shearwater	N/A	Migratory	Species or species habitat likely to occur within area	Species or species habitat likely to occur within area
<i>Onychoprion anaethetus</i>	Bridled tern	N/A	Migratory	N/A	Breeding known to occur within area
<i>Sterna dougallii</i>	Roseate tern	N/A	Migratory	Breeding likely to occur within area	Breeding known to occur within area
<i>Pandion haliaetus</i>	Osprey	N/A	Migratory	N/A	Breeding known to occur within area
<i>Apus pacificus</i>	Fork-tailed Swift	N/A	Migratory	Species or species habitat likely to occur within area	Species or species habitat likely to occur within area
<i>Hydroprogne caspia</i>	Caspian Tern	N/A	Migratory	N/A	Breeding known to occur within area

Table 4-14: Seabird biologically important areas within the environment that may be affected

Species	BIA type	Approximate distance (km) a direction from PAA
Wedge-tailed shearwater	Breeding (Kimberley, Pilbara and Gascoyne coasts and islands including Ashmore Reef)	Overlaps Trunkline Operational Area from KP 32 to ~KP 220. Occurs throughout EMBA across fringing islands of Dampier Archipelago to Cape Range and to Barrow Island.
Roseate Tern	Breeding (Kimberley, Pilbara and Gascoyne coasts and islands including Ashmore Reef)	Numerous BIAs: 2 x BIAs overlap the PAA; 117 km, 97 km, 44 km, 23 km south of Trunkline Operational Area; 12 km; 7km east of Trunkline Operational Area (State Waters)
Fairy Tern	Breeding (Gascoyne and Pilbara coasts and islands)	Numerous BIAs: 1 x BIA overlaps the PAA; 3km south-east of Trunkline Operational Area (State Waters); 52 km, 58 km, 47 km south of Trunkline Operational Area (State Waters); 141 km, 137 km, 54 km, 30 km, 25 km south of Trunkline Operational Area; 200 km, 195 km south of Trunkline Operational Area (FPU end)
Lesser Crested Tern	Breeding (Kimberley, Pilbara and Gascoyne coasts and islands including Ashmore Reef)	Numerous BIAs: 125 km, 52 km, 30 km south of Trunkline Operational Area

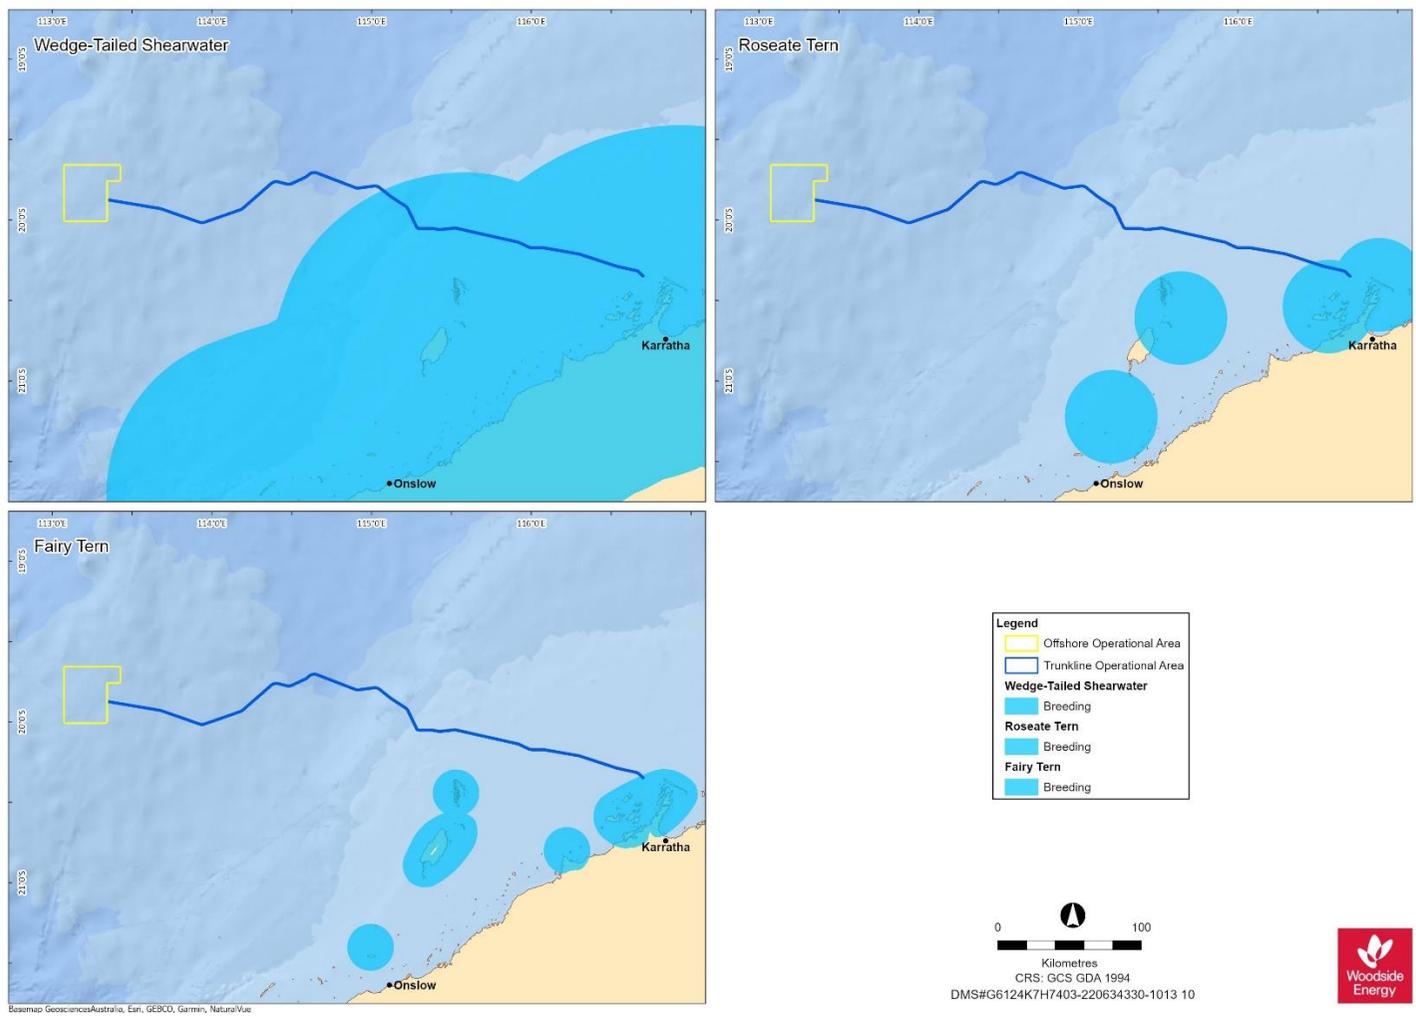

Figure 4-12: Seabird biologically important areas overlapping the Petroleum Activities Area

4.6.5 Seasonal Sensitivities for Protected Species

Seasonal sensitivities for protected migratory species identified as potentially occurring within the PAA are identified in Table 4-15.

As shown in Figure 4-10, the Trunkline Operational Area overlaps the pygmy blue whale migratory corridor and the PAA lies 183 km from the possible pygmy blue whale foraging area off North-west Cape/Ningaloo Coast.

In September 2021, DAWE (now DCCEEW) and NOPSEMA released guidance on key terms within the Conservation Management Plan for the Blue Whale CMP⁸. This guidance recognises the potential for whale foraging and feeding to occur in areas of high primary productivity outside of designated foraging areas. Migrating pygmy blue whales are not necessarily confined to the designated migratory corridor, and there is the potential for individuals to undertake opportunistic foraging within and adjacent to the PAA, particularly during the northbound migration.

⁸ <https://www.environment.gov.au/epbc/publications/guidance-key-terms-blue-whale-conservation-management-plan>

Table 4-15: Key seasonal sensitivities for protected migratory species

Species	Life stage/Activity**	J	F	M	A	M	J	J	A	S	O	N	D

Humpback whale	Northbound					*	*						
	Southbound								*				
Southern Right Whale	Calving/Presence					*	*						
Fish/Elasmobranchs													
Whale shark	Foraging – north of Ningaloo along 200 m Isobath												
Manta rays	Presence/aggregation-breeding (Ningaloo)												
Seabirds													
Wedge-tailed shearwater	Foraging/breeding				**								
Roseate tern	Breeding												
Lesser Frigatebird	Breeding												
Lesser Crested Tern	Breeding												
Fairy tern	Foraging/breeding												
Migratory shorebirds													
General	Peak presence (non-breeding)												

* Asterisk denotes peak periods.

** Note given the offshore location of the PAA, and distance from islands/mainland, specific life stages such as nesting do not occur in the PAA.

*** Wedge-tail shearwater rookeries have been confirmed on Goodwyn Island and Malus Island (Pendoley Environmental, 2022) and Malus Satellite, Lady Nora and northeast Enderby Island have had rookeries detected post survey (Pendoley Environmental, 2022). Peak breeding period denoted by fledging synchronised exodus period occurs in April (Advisian, 2022).

4.7 Key Ecological Features

Key ecological features (KEFs) are not MNES, however are considered components of a Commonwealth marine area. They are considered important for a marine region’s biodiversity or ecosystem-based functioning. Five KEFs overlap the EMBA, of which three overlap the PAA (Figure 4-13). KEFs within the EMBA are identified in Table 4-16.

Table 4-16: Key ecological features within the Petroleum Activities Area or environment that may be affected

Key Ecological Feature	Distance (km) and direction from PAA to KEF	Overlaps with EMBA	Description
Exmouth Plateau	Overlaps PAA (Offshore Operational Area and Trunkline Operational Area)	✓	Water depth: 500–5000 m. Unique seafloor features with regional ecological significance. Believed to affect deep water flow and associated with internal tides, contributing to localised upwelling.
Continental Slope Demersal Fish Communities	Overlaps PAA (Trunkline Operational Area only)	✓	High biodiversity values, hosting more than 500 fish species, 76 of which are endemic.
Ancient coastline at 125 m depth contour	Overlaps PAA (Trunkline Operational Area only)	✓	Water depths 115–135 m. Provides some hard benthic substrate for regionally significant biodiversity hotspots and localised upwelling. Recent surveys suggest less hard substrate may now exist that once thought, with prevalence of soft sediment that has infilled parts of the palaeo shoreline (Wakeford et al., 2023).
Canyons linking the Cuvier Abyssal Plain and the Cape Range Peninsula	131 km south of Offshore Operational Area	✓	Interacts with Leeuwin Current to create localised upwellings and support aggregations of marine megafauna, migratory fish and seabirds.
Commonwealth waters adjacent to Ningaloo Reef	182 km south of Trunkline Operational Area	✓	Defined as the waters contained within the Ningaloo AMP and thus shares the same ecological values and integrity.

4.9 Cultural Features and Heritage Values

4.9.1 Background

Woodside recognises that the 'environment' for the purpose of the evaluation under the Environment Regulations includes:

- the heritage value of places
- the social, economic, and cultural features of the broader environment.

In this section, the heritage value of places within the PAA and EMBA and the cultural features of the PAA and EMBA are described.

In line with The Burra Charter: The Australia ICOMOS Charter for Places of Cultural Significance (ICOMOS 2013) (Burra Charter) and associated practice notes, Woodside understands heritage value to refer to the cultural significance of a place to an individual or group. A cultural feature, by contrast, is understood to be comparable to the Burra Charter term “fabric” and refer to a place’s elements, fixtures, contents and objects which have cultural values. Although these features are necessarily physical, the place they inhabit or comprise may have tangible and intangible dimensions (ICOMOS 2013).

Woodside has undertaken archaeological assessments and ethnographic surveys to identify potential cultural values or features that may be impacted by Scarborough activities. These works have not identified heritage places, objects or values which will be impacted by the activities planned under this EP. However, through consultation with relevant persons, Woodside recognises the spiritual and cultural connection to the environment⁹ that First Nations people hold.

4.9.2 First Nations Peoples

As a starting point for understanding cultural features of the environment for First Nations groups, Woodside uses the existing systems, such as native title, to identify First Nations groups that may have functions, interests or activities that may be affected. To that end, Woodside identifies native title representative bodies and nominated representative entities (defined in Section 5), as well as native title claims, determinations and Indigenous Land Use Agreements (ILUAs) which the EMBA overlaps. Native title claims, determinations and ILUAs are defined under the *Native Title Act 1993* (Cth). While acknowledging that cultural features and heritage values may exist outside of the native title framework, Woodside considers this to be the broadest extent over which First Nations groups have claimed native title rights and interests.

Native title claims are applications made to the Federal Court under the *Native Title Act 1993* (Cth) for a determination or decision about native title in a particular area. A claim is made by a native title claim group which asserts it holds native title rights and interests in an area of land and/or water, according to its traditional laws and customs. By making a claim, the native title claim group seeks a decision that native title exists so that its native title rights and interests are recognised by the common law of Australia. This is called a native title determination. A determination is a decision by a recognised body, such as the Federal Court or High Court of Australia, that native title either does or does not exist in relation to a particular area (National Native Title Tribunal).

⁹ Regulation 5 of the Environment Regulations defines “environment” to mean:

- a) ecosystems and their constituent parts, including people and communities
- b) natural and physical resources
- c) the qualities and characteristics of locations, places and areas
- d) the heritage values of places, and includes
- e) the social, economic and cultural features of the matters mentioned in paragraphs (a), (b), (c) and (d).

A requirement to establishing a positive determination of native title in court is proving that there is an organised society that occupied the land and/or waters at the time of British annexation. The requirement of an 'organised society' is set out by Justice Toohey in the historic judgment of *Mabo v Queensland (No 2)* [1992] HCA 23; (1992) 175 CLR 1 ('Mabo'). Justice Toohey had the following to say (at 187):

it is inconceivable that indigenous inhabitants in occupation of land did not have a system by which land was utilized in a way determined by that society. There must, of course, be a society sufficiently organized to create and sustain rights and duties...

Therefore, Woodside understands that native title rights and interests are held communally by an organised society, that native title claims are understood to represent the area over which First Nations groups are claiming these rights and interests, and that native title determinations provide clarity on where native title rights and interests are found to either exist or not exist. Where native title rights or interests are determined to exist, they will be held by a Registered Native Title Body Corporate (section 57 of the *Native Title Act 1993* (Cth)) in trust or as agent for native title holders.

ILUAs are voluntary agreements between native title parties and other people or bodies about the use and management of land and/or waters and are registered by the Native Title Registrar in the Register of ILUAs. An ILUA can be made over areas where:

- native title has been determined to exist in at least part of the area, or
- a native title claim has been made, or
- where no native title claim has been made.

While registered, ILUAs operate as a contract between the parties, including relevant native title holders (National Native Title Tribunal).

The Native Title Act provides for a Representative Aboriginal/Torres Strait Islander Body (Native Title Representative Body) to be recognised by the Commonwealth Minister for an area. Native Title Representative Bodies have specialist functions set out in the Native Title Act within the area for which they are the Native Title Representative Body. However, the functions of a Native Title Representative Body are such that they do not hold details on the cultural features or heritage values of an area and therefore do not inform Woodside's understanding of heritage values or cultural features.

For the activity in this EP, there are 16 ILUAs and six native title claims or determinations overlapping or adjacent to the EMBA (see Figure 4-15).

4.9.3 Coastally Adjacent First Nations Groups

Woodside understands that First Nations groups are keenly aware of the extent of their rights, interests and responsibilities for Country, and these are generally discrete, defined areas, including areas of sea (Smyth 2007). To identify cultural features and heritage values which may exist outside of native title claim, determination and ILUA areas, Woodside considers native title claims, determinations and ILUAs coastally adjacent to the EMBA to be an instructive means of identifying potentially relevant First Nations groups to be consulted (See Table 5-2).

That said, Woodside understands from engagement with stakeholders that extending a native title group's responsibility to areas which those groups have elected not to include in their claims or ILUAs can have significant cultural consequences for First Nations groups and individuals. This may also, over time, build expectations in the broader First Nations community that a group is responsible for maintaining environmental values in areas for which they do not hold traditional knowledge. Woodside also acknowledges that a First Nations group's relative proximity to Operational Areas or EMBA is not necessarily a meaningful indicator of the connection of First Nations groups to the area and that providing advice over such areas can be culturally dangerous. As a result, caution must be used when conducting broader engagement.

There are no native title claims, determinations or ILUAs, native title rights or interests identified overlapping the PAA.

A summary of native title claims, determinations and ILUAs overlapping or coastally adjacent to the EMBA is illustrated in Figure 4-15 and set out in Table 4-18. Claims and determinations have not been differentiated in this table, as it is acknowledged that either of these may indicate the existence of rights and interests.

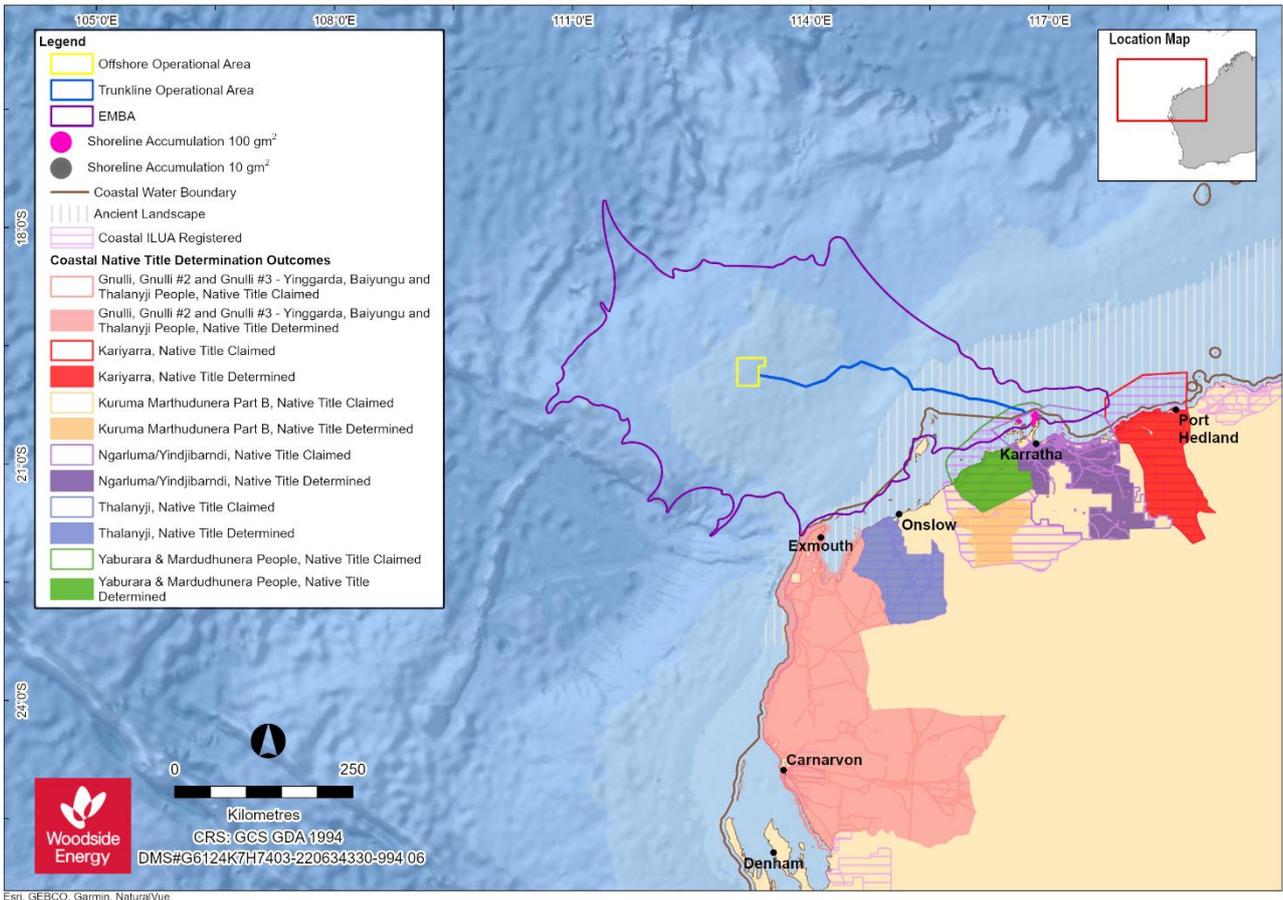

Figure 4-15: Petroleum Activities Area and environment that may be affected in relation to native title claims, determinations and Indigenous Land Use Agreements

Table 4-18: Summary of Native Title Claim or Determination and Indigenous Land Use Agreements that overlap or are coastally adjacent to the Environment that May be Affected

4.9.3.1 Marine Parks

Woodside acknowledges that Commonwealth and State Marine Park Management Plans have sought to recognise cultural values of First Nations groups. Australian Marine Parks (AMP) describe this framework in the following way: ‘when making decisions about what can occur in marine parks and what action we will take to protect marine parks, we take values into account’. AMP summarises these values as natural values, cultural values, heritage values and socio-economic values. Woodside undertakes an assessment of cultural values within Marine Park Management Plans where the operational area or EMBA overlaps an AMP. Woodside considers the management plans of marine parks that overlap the Operational Area and the EMBA to determine whether cultural features and heritage values have been identified and whether there are specified representative bodies referenced to contact regarding potential cultural features and heritage places.

The Trunkline Operational Area overlaps features of the Montebello AMP. The EMBA overlaps features of a further three AMPs under the North-West Marine Parks Network Management Plan 2018. The PAA does not overlap any State Marine Parks, however the EMBA overlaps two State Marine Parks. Where these plans specify identifiable representative bodies who may hold knowledge of heritage values or cultural features—including but not limited to Registered Native Title Bodies Corporate—these bodies are consulted (Appendix F: Consultation, Table 1). Consultation with these groups may identify heritage values and cultural features beyond those addressed in the marine park management plans. Four identifiable representative bodies were specified for the AMPs overlapped by the EMBA (see Table 4-19).

The marine park management plans note for the Dampier, Gascoyne, Montebello and Ningaloo AMPs that the Yamatji Marlpa Aboriginal Corporation (YMAC) is the relevant Native Title Representative Body. Consultation with YMAC included discussion of the Traditional Custodians who may hold knowledge of heritage values or cultural features (see Appendix F: Consultation, Table 2).

Table 4-19: Summary of Commonwealth and State Marine Park Management Plan overlap with the environment that may be affected

Marine Park Management Plan	PAA Overlap	EMBA Overlap	Specified Bodies
Commonwealth Marine Park Management Plan			
Gascoyne AMP	No	Yes	NTGAC, YAC
Dampier AMP	No	Yes	NAC, YAC, YMAC
Ningaloo AMP	No	Yes	NTGAC, YMAC
Montebello AMP	Yes	Yes	YMAC
State Marine Park Management Plan			
Montebello/Barrow Islands Marine Conservation Reserves	No	Yes	No identifiable body specified
Ningaloo Marine Park and Muiron Islands Marine Management Area	No	Yes	Yamatji Marlpa Barna Baba Maaja Aboriginal Corporation (now renamed to YMAC)

In the management plans for the AMPs it is noted that “Sea country is valued for Indigenous cultural identity, health and wellbeing.” Cultural identity is understood to refer to the fact that “essence of being a 'Saltwater' person is ontological rather than merely technological. That is, it is about how people relate spiritually to the sea and engage with spiritual forces that created it, the marine flora and fauna and people.” (McDonald and Phillips, 2021).

The North-West Marine Parks Network Management Plan 2018 notes shipwrecks within the AMPs and overlap with World, National and Commonwealth heritage lists. These are addressed in Sections 4.9.8 and 4.9.9.

The Management Plan for the Ningaloo Marine Park and Muiron Islands Marine Management Area 2005 – 2015: Management Plan Number 52 (relating to the Muiron Islands Marine Management Area and Ningaloo Marine Park) notes the aesthetic values of the seascape as a cultural value and that “Panoramic vistas of turquoise lagoon waters, reefs, beaches, breaking surf and the blue open ocean beyond the reef line are major attractions of the reserves.” In particular, the plan notes that “Inappropriate structures along the coastline, on the islands and in the surrounding waters have the potential to degrade the aesthetic values of the reserves. Coastal developments and maritime infrastructure projects must therefore be planned with careful consideration of this issue.” As the Petroleum Activities Program described in this EP does not include the addition of any structures within these parks, no impacts on the aesthetic values of these parks are anticipated.

A number of management plans for the state marine parks also note Indigenous and maritime heritage within the marine parks. These are addressed in Section 4.9.4 and Section 4.9.8.

4.9.4 Sea Country Values

'Sea Country' can be defined as the area of sea over which a First Nations group has interests, cultural value, connection and use. It has been noted that "the saltwater peoples of the north-west are associated with discrete clan estates or tribal areas, often referred to in contemporary Aboriginal English as 'saltwater country' or 'sea country'. "Country refers to more than just a geographical area: it is shorthand for all the values, places, resources, stories and cultural obligations associated with that geographical area." (Smyth 2007). "Sea country is valued for Indigenous cultural identity, health and wellbeing" (DNP 2018a, 2018b). Cultural identity is understood to refer to the fact that "essence of being a 'Saltwater' person is ontological rather than merely technological. That is, it is about how people relate spiritually to the sea and engage with spiritual forces that created it, the marine flora and fauna and people" (McDonald and Phillips, 2021).

In terms of seascape extent, McNiven (2004) suggests that "For those mainland groups whose exploitation of the sea was limited to littoral resources, it is likely that seascapes extended no more than c. 20–30 km out to sea, out to the horizon and the limit of human visibility. ... However, in some coastal places, clouds that can be seen well over 100 km out to sea are imbued with spiritual significance. For those groups with elaborate canoe technology, seascapes extend well over the horizon." While there is some evidence of traditional watercraft in Australia's North West, the recorded evidence is limited to travel across inland rivers (e.g. Barber and Jackson, 2011) or travel between coastal islands (Paterson et al 2019).

Woodside recognises the potential for marine ecosystems to include cultural features as well as environmental values. The link between environmental protection and cultural heritage protection is illustrated in the Australian Government's Indigenous Protected Areas Program. The Indigenous Protected Areas program provides for "areas of land and sea managed by Indigenous groups as protected areas for biodiversity conservation...IPAs deliver environmental benefits...Managing IPAs also helps Indigenous communities protect the cultural values of their country for future generations..." (NIAA, 2024). This intrinsic link concept is also described by MAC (2021) as it relates to the values of the marine environment that are of cultural importance to MAC based on engagement with their Elders and Murujuga Land and Sea Unit Rangers. Elders were clear that all living things in Mermaid Sound are connected, and that Mermaid Sound and Dampier Archipelago (Murujuga) are considered one place where the entire environment and all ecosystems hold both cultural and environmental value, with these types of values (cultural and environmental) intrinsically linked (MAC, 2021 as cited in Woodside, 2023a).

Cultural features of coastal areas may include marine species that may travel many thousands of kilometres through areas with similar cultural values to multiple Indigenous language groups. Some species may travel as far as 5,000 km from Antarctica to the Kimberley region of Western Australia (Double et al., 2010, 2012), passing Indigenous language groups along the entire west coast of Australia. Distribution and migratory patterns of migratory species are described in Section 4.6.

Sea country values have been defined using multiple lines of evidence including:

- desktop assessment of sea country values from publicly available sources
- specific studies including ethnographic surveys and archaeological heritage assessments
- consultation with First Nations groups and individuals.

The process for identifying First Nations groups who may have interests and connection in Sea Country are set out in Section 4.9.3 and Section 5. The scope of advice Traditional Custodians were encouraged to provide through ethnographic surveys (see Section 4.9.4) or through project consultation was not limited by reference to any particular boundaries or limits of Sea Country.

4.9.4.1 Desktop Assessment of Sea Country Values

4.9.4.1.1 Cultural Features and Heritage Values Identified in Publicly Available Literature

Publicly available sources were assessed for records of previously identified Sea Country values or cultural features that may overlap with the PAA or EMBA. Where cultural features or Sea Country values were identified these are summarised in Table 4-20 according to the First Nations groups (where identified or inferable) who hold these values.

Cultural features and heritage values are restricted to onshore locations above the highest astronomical tide (HAT) or inland waters and where the geographical extent is not specified or unclear it has been included for completeness.

Table 4-20: Cultural features and heritage values identified in publicly available literature

First Nations Group	Features and Values	Source	Potential for overlap	
			Operational Area	EMBA
Gnulli (Baiyungu, Thalanyji, Yinggarda)	Feature: resources including marine animals. Value: traditional knowledge holds that ancestors live on the land and in the water. Therefore, people have obligations to access and care for these places (e.g., keeping them clean).	Peck on behalf of the Gnulli Native Title Claim Group v State of Western Australia [2019] FCA 2090	Possible (unspecified) Possible (unspecified)	Possible (unspecified) Possible (unspecified)
	Feature: heritage sites in the Ningaloo region include shell middens, artefact scatters, skeletal material/burial sites, camps, meeting places, hunting places and water sources. Feature: resources including gajalbu (emu), bundgurdi (kangaroo), bardurra (bush turkey), majun (marine turtles), turtle eggs, bilygurumarda (osprey), fish, shellfish and plants. Feature: mudflats, mangroves and sand dunes provide a critical breeding ground for marine and terrestrial wildlife. Value: the Ningaloo region contains cultural heritage dating back at least 32,000 years, including ceremonial thalu sites. Value: connection to Country is important to the Traditional owners' spirituality and religion. Value: caring for Country - "The southern coastal reserves along the Ningaloo Coast are jointly managed by Traditional Owners and the DBCA. The Joint Management Body ensures that the Traditional Owners have an opportunity to make decisions about environmental management and land use". 4.9.4.1.2 Cultural Features and Heritage Values Identified in Other Assessments

In addition to publicly available literature, Woodside has reviewed its own publicly available Cultural Heritage Management Plan (CHMP) which was developed in consultation with MAC for the nearshore installation of the export trunkline. The CHMP identifies a list of features which may hold heritage values. Not all features on this list, included in Table 5-7 of the CHMP, exist in the area relevant to the CHMP or in the EMBA for this EP (Woodside, 2023a).

The features listed in the CHMP include, at the highest level:

- A Tangible Heritage
- B Ethnographic Sites
- C Intangible Heritage
- D Heritage Landscapes
- E Features with National Heritage Values
- F Features with Outstanding Universal Values
- G Submerged Heritage
- H Features with Values to Neighbouring Groups.

Features described by items A to G are discussed for the purposes of this EP elsewhere in Section 4.9. Item H in the CHMP recognises that Traditional Custodians of Country beyond Murujuga may hold values such as those in items A-G. Given the scope of relevant persons considered under this EP (relevant persons consulted in the course of preparing this EP have interests in the EMBA which extends well beyond Murujuga), the distinction between cultural heritage on Murujuga and beyond Murujuga is not considered meaningful. Where features were noted to exist in or near the area relevant to the CHMP, Table 4-21 considers their relevance to the EMBA.

Table 4-21: Values identified in the Scarborough Cultural Heritage Management Plan (Woodside, 2023a)

Feature		Identification in the CHMP	Relevance to the EMBA
A.1.a	Petroglyphs	Noted onshore only.	The EMBA overlaps the Ancient Landscape where these features may exist.
A.1.b	Artefact scatters	Archaeological assessment of the submerged landscape (UWA 2021) assessed the likelihood of impacting potential archaeological Indigenous heritage such as artefact scatters/middens in the nearshore or offshore Development Envelope as low to nil.	The EMBA overlaps the Ancient Landscape where these features may exist.
A.1.d	Middens		
D.3	Submerged calcarenite ridges	Calcarenite features at the edge of the continental shelf are young enough that they may include artefacts, but these features are covered by modern sediments and marine growth, and the export trunkline will be installed over this. These calcarenite ridges will be crossed by the export trunkline.	Exists within EMBA
A.1.b.i	Site 19675 (Tool Shed)	Noted onshore only.	Outside of EMBA
B.1	Features with spiritual values	It was concluded that ethnographic sites with spiritual values exist outside	No ethnographic sites have been identified within the EMBA.

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

Feature		Identification in the CHMP	Relevance to the EMBA
B.2	Features with social/cultural values	of the Development Envelope (Mott 2019, McDonald and Phillips 2021). No impacts from the Project to ethnographic sites were foreseen during these consultations. It was concluded that ethnographic sites which may have social and cultural values exist outside of the Development Envelope (Mott 2019, McDonald and Phillips 2021). No impacts from the Project to ethnographic sites were foreseen during these consultations.	
B.1.a	Songlines	It was concluded that ethnographic sites and features connected to songlines exist outside of the Development Envelope (Mott 2019, McDonald and Phillips 2021). No impacts from the Project to ethnographic sites were identified during these surveys. Woodside notes that trunklines and other infrastructure including shipping channels already exist in close proximity to the proposed export trunkline route, and if there were to be any impacts to surviving songlines these would be significantly more likely to be described as qualitative (i.e. “weaken” a songline) rather than binary or absolute (i.e. destroy a songline).	Areas identified in the CHMP with connection to songlines or stories were limited to onshore locations and islands not included within the EMBA.
C.1.b	Stories		
B.2.a	Places for which access must be preserved	Noted onshore only.	Limitation of access is a relevant consideration within the EMBA.
C.1	Living culture	The continuous living culture of Murujuga is a component of the Outstanding Universal Values proposed as a justification for World Heritage Listing.	Ongoing access, connection to Country and transfer of knowledge are relevant considerations for the EMBA.
C.1.a	Customs	Consultation with MAC has identified concerns about the movement of rocks to and from Country as requiring consultation with representatives of other areas.	Relevant consideration for PPA where rocks are locally sourced. Not relevant to internationally sourced rocks.
C.2.a	Animals of medicinal/food/economic value	Miscellaneous values as identified in MAC 2021.	The relevant values of MAC 2021 are considered in Section 4.9.4.1 .
C.2.c	Plants		
C.2.c.i-vi	Plants (misc values)		
D.1	Conservation zones	Noted onshore only.	Outside of EMBA
D.4	Submerged hills	Archaeological assessment of the submerged landscape (UWA 2021) identified submerged hills which may have archaeological or other heritage values.	Exists within EMBA

Feature		Identification in the CHMP	Relevance to the EMBA
D.5.a	Rivers	<p>Archaeological assessment of the submerged landscape (UWA 2021) identified a submerged river which may have archaeological or other heritage values but confirmed that the export trunkline does not cross this feature.</p> <p>Review of SSS data (Nutley 2022b) concluded that “In the middle shelf and outer shelf there were no indicators of former riverbeds, creek lines or lakes with which [any archaeological] feature may be associated.”</p>	The EMBA overlaps the Ancient Landscape where these features may exist.

4.9.4.2 Studies of Cultural Features and Heritage Values

4.9.4.2.1 First Nations Archaeological Heritage Assessment

Woodside understands that communal cultural connection may exist between Traditional Custodians and land and waters. It is understood from the onshore archaeological record that First Nations people have occupied the Australian continent for at least 65,000 years (Clarkson et al 2017) and in many places maintain a strong continuing connection that is said to extend back in First Nations cosmology to the beginning of time.

It is understood that the sea level has risen significantly during the 65,000 years of First Nations occupation, and areas that were once inhabited are now submerged on the continental shelf (Veth et al., 2019; UWA, 2021). Woodside also understands that, at its lowest level during First Nations occupation, sea level was between 125 m (O’Leary et al., 2020; Veth et al., 2019; Williams et al., 2018) and 130 m below current levels (Benjamin et al., 2020; Benjamin et al., 2023; UWA, 2021). Archaeological material preserved on the Ancient Landscape has the potential to provide further information about the earliest periods of human occupation (Veth et al., 2019; UWA, 2021).

Recent archaeological discoveries demonstrate that the now submerged landscape was occupied and inhabited and can retain archaeological material from this time (Benjamin et al., 2020; Benjamin et al., 2023; see Ward et al., 2022 for an opposing view).

In recognition of this, Woodside considers the Ancient Landscape between the mainland and the Ancient Coastline KEF (see Table 4-16) as an area where potential First Nations archaeological material may exist on the seabed, as this covers the full extent of this possible First Nations occupation. The PAA intersects part of the Ancient Landscape but also extends beyond the furthest extent of the Ancient Landscape.

Archaeological material on the Ancient Landscape is a relevant matter for the proposed activity given the overlap, and potential for seabed disturbance related to planned IMMR activities along the export trunkline and therefore potential for impacts to archaeological material. Woodside undertakes desktop assessments of archaeological potential, based on geophysical and bathymetric data, for any seabed disturbance at depths of less than 130 m. These assessments did not identify any archaeological sites or values in Commonwealth waters that may be impacted by the Petroleum Activities Program.

Known First Nations heritage places including archaeological sites may be protected subject to declarations under the *Aboriginal and Torres Strait Islander Heritage Protection Act 1984* (Cth), *Underwater Cultural Heritage Act 2018* (Cth) or EPBC Act. However, these Acts only extend protection to First Nations heritage places specified by declaration or otherwise included on a statutory list. Woodside understands that there is no First Nations archaeology known to exist

anywhere within Commonwealth waters and no areas subject to declarations or prescriptions under these Acts are located within the EMBA.

For this EP, a search of DPLH's Aboriginal Heritage Inquiry System was undertaken, which showed 58 Registered Aboriginal Sites and 5 Lodged Aboriginal Sites in the EMBA (see Appendix D: Aboriginal Cultural Heritage Inquiry System Searches).

Woodside has conducted extensive assessments described below (along with consultation) to adequately understand and describe the existing environment. If further relevant information on cultural values is received, it will be assessed and, where appropriate, Woodside will apply its Management of Change and Revision process (see Section 7.2.7).

Where First Nations archaeological material is identified within the EMBA, Woodside will discuss the management of this material with appropriate Traditional Custodian group(s), starting with any adjacent Native Title Body Corporate.

Existing Research and Desktop Assessment

In Australia until recently, the consideration of submerged archaeological sites has generally focused on the sub-discipline of maritime archaeology with connection to Australian Indigenous archaeology through studies of Indigenous fish-traps, whaling stations and shipwreck survivor camps. However, except for Indigenous fish traps in intertidal zones, the consideration of Indigenous heritage sites submerged by post-glacial sea-level rise has only recently been considered (Mott, 2019).

There has been long and continuous occupation of the coastal Pilbara region as evidenced by scientific studies (Balme et al., 2009; McDonald et al., 2018; Veth et al., 2017). Petroglyph motifs feature a range of subject matter with many examples depicting extinct fauna and early stylistic techniques (McNickle, 1984; McDonald, 2005; Mulvaney, 2009, 2010, 2013).

To assess and define potential for preservation of submerged Late Pleistocene and Holocene sediment bodies that may contain preserved archaeological deposits, modelling on continental shelf development in the Dampier Archipelago has been undertaken. Analysis and modelling between the Last Glacial Maximum, through the Holocene marine transgression and up to the present day has shown that archaeological materials, if present, would most likely be evident in deposits associated with the early phases of inundation of the Dampier Archipelago, dating from around 9 to 7 ka before present (BP) (Ward et al., 2013). In contrast, the study proposes that coastal archaeology older than about 12 ka BP, when the post-glacial sea levels were below about 50 m, will have been exposed to a phase of faster tidal currents on the continental shelf, and hence eroded or poorly preserved (Ward et al., 2013). These areas of hypothesised lower preservation potential include most of the PAA relevant to this EP (see Table 3-2).

A paper examining terrestrial analogy as a predictive tool for targeting submerged archaeological sites, provides several key elements to consider when examining the potential for identifying and managing submerged Indigenous heritage sites (Veth et al., 2019). Analysis of more than 2,500 known archaeological sites from the Dampier Archipelago reveals that the vast majority are rock art sites, but these are interspersed by a significant number of artefact scatters, myriad stone structures, shell middens, and quarry and reduction areas. Most of these sites are focused on coastal and interior valleys, associated uplands, and coastal embayments. While over two thirds of sites occur on granophyre and basalt substrates, the others are located on quaternary sediments. Regional research on nearby continental islands shows that use of these environments can be expected to pre-date sea-level rise (Veth et al., 2019).

Through the Deep History of Sea Country (DHSC) project, researchers undertook a systematic and hierarchical approach to underwater investigation of the submerged landscapes at Murujuga (Dampier Archipelago). The researchers looked at the previously recorded Indigenous heritage sites from terrestrial surveys and used principles of geological, geomorphological and environmental associations to extrapolate to submerged landscapes. Where possible, the research considered submerged landscape principles as comparable but recognised that a range of factors may affect

direct comparisons. A major constraint to any comparative studies is the shortage of marine stratigraphic, paleo-environmental, or geochronological data, and thus comparisons were initially divided into hard (crystalline) rock and soft (sedimentary) rock contexts, with the relative age of a potential site or deposit based on bathymetry (i.e., depth below modern sea level) and morphological setting. These essentially inform and delineate prospective target areas for broad-scale underwater mapping (Veth et al., 2019).

The sites considered most likely to survive inundation, based on the review of existing literature, were logically the more robust forms including:

- midden and artefacts within cemented dunes, relict water holes, and beach rock deposits
- quarry outcrops, extraction pits, and associated reduction debris in fine-grained volcanic outcrops
- curvilinear stone structures and standing stones sitting on volcanic pavements and jammed into volcanic rock piles
- lag deposits of artefacts and possibly midden on hardpan in suitable landscape contexts with good preservation conditions (e.g. shallow declination shorelines in sheltered passages of the inner archipelago or on the leeward side of hard-rock/fringing reef cause-ways adjacent to the outer islands)
- small overhangs and shelters with preserved deposits, facing away from the dominant wave and wind action. (Veth et al., 2019).

Geotechnical sampling along the export trunkline route has shown that sediments are predominantly comprised of soft silty sands and therefore those landforms other than the first are highly unlikely to be present along the export trunkline alignment. Rocks such as the dolerites, gabros and other volcanic rocks on which Murujuga rock art is found are not present in the PAA.

Integrated Heritage Services was engaged by Woodside to conduct an Indigenous heritage desktop investigation and initial ethnographic consultations with Traditional Custodian representatives, for the offshore and landfall component of the project (Mott, 2019). After the finalisation of Mott (2019), the conclusions of Veth et al (2019) were tested through direct inspection with DHSC divers which led to the discovery of two locations with Indigenous underwater cultural heritage (Benjamin et al., 2020) in Flying Foam Passage and Cape Bruigeres in State waters outside the EMBA. This demonstrated the potential for underwater cultural heritage (UCH) to exist on the NW Shelf and highlighted the need to assess the potential impacts of offshore developments on submerged heritage landscapes (UWA, 2021).

MAC was consulted during the development of the Scarborough Project (Nearshore Component) Dredging and Spoil Disposal Management Plan (DSDMP) which included Commonwealth activities associated with Scarborough project construction activity for full activity context. As a part of the DSDMP consultation, MAC advised that DHSC had identified two areas considered “culturally prospective”:

The first is the Madeline [sic] Shoals, which... is formed of the same igneous geology as the other areas of the archipelago where sub-tidal archaeological sites have been found. The second area is a 3 km wide relict submerged paleo beach barrier system that extends across the northern entrance to Mermaid Sound, over which the proposed trunk line route passes. This is an area of hard grounds... with high potential to contain Aboriginal lithic materials cemented within the deposits.

Scarborough Export Trunkline Cultural Heritage Assessment (UWA, 2021)

Following the recommendations of Mott (2019), Woodside engaged with the DHSC project from mid-2019. Woodside subsequently engaged researchers from the then-concluded DHSC project based at the University of Western Australia (UWA) to assess the prospectivity for archaeological sites along the Scarborough export trunkline route and adjacent areas, beginning at the Burrup Peninsula and ending at the edge of the continental shelf in consultation with MAC (UWA, 2021).

The UWA Indigenous UCH assessment along the proposed export trunkline route developed a predictive model for the potential for UCH to be located within the submerged landscapes along the Scarborough export trunkline route (UWA, 2021). The study concluded that the export trunkline route is likely to have “low to nil impacts” to Indigenous archaeological values across the project footprint in Commonwealth waters (UWA, 2021).

The middle shelf landscape crossed by the export trunkline was determined to be of very low or no likelihood of impact to Indigenous archaeological values and “The current development envelope is the preferred pipeline route within mid shelf” (UWA, 2021). The assessment noted that “The mid shelf is flat, relatively featureless and covered by a thick layer of recent marine sediments. The absence of definable landscape features, exacerbated by marine sediment cover observed along the 300 m wide survey corridor makes this 30 m wide export trunkline development corridor low prospectivity for any residual, in-situ, surface manifestations of Indigenous heritage” (UWA, 2021). Two “low relief beach ridge and beach barrier features” that were identified were considered to predate the 65,000 years of scientifically verified occupation of the Australian continent and “Therefore, they are likely to have a low prospectivity for cultural heritage being captured in these durable surfaces at formation, and similarly low potential for subsequently deposited cultural material having survived initial inundation and subsequent marine pedogenic forces.” (UWA, 2021). The assessment also identified within the EMBA “two mounds which are interpreted as low relief hills of an unknown geology, each more than 15 km from the proposed pipeline envelope” (UWA, 2021).

Although the outer shelf possesses a highly prospective cultural landscape, the assessment concluded “Scarborough pipeline development is likely to have nil to low impact on any potential heritage values and the current development envelope is the preferred pipeline route here” (UWA, 2021). Within the EMBA, “There are several locations at the outer edge of the continental shelf where the reconstructed submerged landscapes are assessed as having high potential for significant heritage being present... These high potential landscape features are especially notable to the north of the proposed pipeline. If submerged heritage was to be encountered here, it would be of high significance, and we have identified several sections of the route where this possibility is greater than elsewhere.” For clarity, the assessment also notes that “While there are landforms and features that were identified on the seabed as having a higher probability of hosting indigenous UCH and would benefit from direct observations via ROV/AUV, these have not been identified within the proposed pipeline route.” (UWA, 2021) and “The current pipeline alignment avoids several higher value landforms which increased heritage sensitivity (i.e., karst depressions, tidal channels) in proximity to the pipeline.” (UWA, 2021).

The EMBA also includes areas of the inner shelf where “development proposal is likely to have nil or very low impact on any places with heritage values. The identification of more prospective submerged landscapes across this inner shelf, make the current proposal the preferred pipeline route within Mermaid Sound.” (UWA 2021). The inner shelf includes “submerged barrier systems which outcrop at the seabed.” (UWA 2021). The assessment noted these were dated “between 80,000 to 130,000 years BP and 186,000 to 245,000 years BP. Given these early ages it is unlikely that these barriers formed as an active cultural landscape and therefore these are unlikely to be prospective for encapsulated archaeological evidence. While it is possible that people may have occupied these exposed landscapes at any time in the last 65,000 years, the absence of water or other attractors associated with these identified low relief limestone-ridge landscapes lowers this potential, while their exposed nature makes for low survival chances of artefactual deposits laid on these exposed hard surfaces” (UWA, 2021).

The inner shelf includes “no palaeochannels, relict waterholes, clay pan features, or igneous rock outcrops – such as can be observed in other parts of the Dampier Archipelago – that have been identified has hosting or potentially hosting cultural heritage sites” (UWA, 2021). While “The palaeochannels of the Maitland River and Nicoll River are identifiable on the seabed to the south of Enderby Island and the east of the Archipelago on the inner shelf... The proposed pipeline transects neither of these palaeochannels – nor any submerged mounds/hills (i.e., features of potential

mythological significance to the Ngarda ngarli) that can be identified from the bathymetric reconstruction.” (UWA, 2021).

Side Scan Sonar Review (Nutley, 2022)

At the request of MAC, a review of existing side scan sonar data for the PAA on the Ancient Landscape was undertaken by a maritime archaeologist (Nutley, 2022), with a particular but not exclusive focus on submerged fish traps. Although the remote sensing data was not targeted specifically at underwater cultural heritage when originally collected, the review noted the data was sufficient to provide a platform for assessing features that may require further investigation (Nutley, 2022). This review included the barrier systems identified in UWA (2021) in the mid- and inner shelf.

This review identified numerous clusters of depressions which are “certainly naturally occurring features” and “none of them appear to be archaeological in nature” but requested further advice on what these represented to better understand the landscape and whether these were permanent features such as karsts. Woodside considers from existing data and previous investigation that these depressions in sandy sediments are a result of marine life and moving fluids. The report concluded: “No indication of stone structures such as fish traps, or hut foundations could be detected in the inner reef, middle shelf or outer shelf areas. In the middle shelf and outer shelf there were no indicators of former riverbeds, creek lines or lakes with which such feature may be associated.” (Nutley, 2022).

ROV Inspection of Barrier Systems (Nutley, 2023a)

MAC requested that calcarenite ridges on the inner shelf be directly inspected where the export trunkline would be installed in State Waters. This installation is subject to separate approvals outside this EP, although the EMBA for activities under this EP does extend into State waters. Direct inspection in these areas was completed by ROV with the participation of a qualified marine archaeologist and representative of MAC (Nutley, 2023a). No instances of potential cultural heritage material were detected during these inspections (Nutley, 2023a).

The investigation “confirmed the presence of the former calcarenite, coastal barrier ridgelines that would have been exposed prior to inundation following global warming and substantial melting of the icecaps” (Nutley, 2023a). It was noted that any stone tools “would have been subject to tidal movements, currents and storm waves and to have been redeposited into the ravines and valleys between the ridges. The geodetic data for the area shows that such ravines and valleys are filled with post-inundation marine sediments of up to five or more metres in depth.” (Nutley, 2023a). The assessment also found “No evidence of former waterways or subsea springs or river valleys were present at the surface of the seabed.” (Nutley, 2023a).

4.9.4.2.2 First Nations Ethnographic Heritage Assessment

Ethnographic surveys are a form of heritage survey conducted by anthropologists or ethnographers to understand cultural features of heritage significance and heritage values within a landscape. This is distinguished from archaeological survey (which focusses on the material remains of human culture) and consultation (which is not confined to an assessment of heritage, is not limited to values of a landscape and may be conducted without an ethnographic methodology).

Ethnographic surveys are “*undertaken to identify Aboriginal cultural heritage sites and values that are identifiable as tangible and intangible elements that are important to the Aboriginal people of the State, and are recognised through social, spiritual, historical, scientific or aesthetic values, as part of Aboriginal tradition.*”

“To achieve this, an ethnographic survey is undertaken with an Aboriginal person or persons who in accordance with Aboriginal tradition, holds particular knowledge about the Aboriginal cultural heritage and has traditional rights, interests and responsibilities in respect of the Aboriginal cultural heritage (Mott, 2023).”

Woodside seeks to undertake ethnographic surveys where planned impacts overlap an area where First Nations group has an established cultural jurisdiction over an area of land or sea. Cultural

jurisdiction confirms ethnographic survey participants “in accordance with Aboriginal tradition, hold particular knowledge about the Aboriginal cultural heritage”, and may be established through a number of mechanisms, including prescription under heritage legislation (e.g. the *Aboriginal Heritage Act 1972* and subsidiary legislation), recognition through the determination of Native Title rights, or through land access agreements including ILUAs or ILUA-like agreements.

Where ethnographic surveys are requested during broader consultation in which a relevant person articulates their cultural jurisdiction, Woodside will assess this request and, where appropriate, undertake surveys. Surveys may not be appropriate, for example, where another party has established cultural jurisdiction or an adequate ethnographic survey has already been carried out over the area.

As ethnographic surveys are dependent on the participation of traditional knowledge holders, it is not possible to meaningfully conduct ethnographic surveys proactively over areas for which cultural jurisdiction is not established or unclear.

To supplement understanding of the area subject to MAC’s cultural jurisdiction, Woodside commissioned ethnographic surveys in 2019 and 2020 to support the Scarborough Project (Mott, 2019, McDonald and Phillips, 2021). Woodside has committed to support MAC with further ethnographic work, but MAC has not yet elected to progress this work.

An ethnographic survey may determine both the tangible and intangible cultural heritage which may be associated with cultural features. Importantly, ethnographic surveys are only one tool in identifying cultural features and heritage values; Woodside has supplemented this work with archaeological assessments described in Section 4.9.4 and extensive consultation with Traditional Custodians described in Section 5. Typical results from ethnographic surveys may include the identification of songlines, ceremonial places such as ‘thalu’ sites for managing environmental resources, or places where activities such as birthing, initiation or other significant activities are performed. As a form of heritage survey, distinct from more general consultation, surveys were limited to discussions of the relevant landscape. However, participants were not restricted in the types of tangible and intangible cultural heritage they were encouraged to identify.

Preliminary Desktop Assessment and Ethnographic Inspection (Mott, 2019)

The 2019 survey was undertaken due to the potential planned impact of offshore, nearshore and onshore activities associated with the Scarborough project within the cultural jurisdiction of Ngarda Ngarli people, traditional custodians of Murujuga. The survey was conducted with members of all five Traditional Custodian groups of Murujuga (Mardudhunera, Ngarluma, Wong-Goo-Tt-Oo, Yaburara and Yindjibarndi) invited through Prescribed Bodies Corporate for Ngarda Ngarli people (including NAC and WAC) and MAC, who met on country with heritage consultants.

The aim of this aspect of the work was “to undertake an initial ethnographic site visit to consult with traditional owners to discuss the current research undertaken by others on submerged landscapes generally, and to seek specific feedback on the nature of the proposed export trunkline pipeline plans including the pipe landfall area, adjacent to a significant Aboriginal heritage site” (Mott, 2019). Participants were provided with a map of the Scarborough development (Figure 4-16) and asked to identify any values in the surrounding landscape.

No cultural features or heritage values were identified in the Operational Area or EMBA through this survey (Mott 2019).

Within the recommendations arising from this work, it was advised “If any deviations from the current Project Area footprints are made, addendum desktop heritage assessment and consultation with traditional owners should be undertaken.” The desktop component of Mott (2019) related to archaeological heritage, and subsequent archaeological assessments are described in Section 4.9.4.

Consultation with Traditional Custodians for the project, have been undertaken as described in Section 4.9.4 and Section 5.

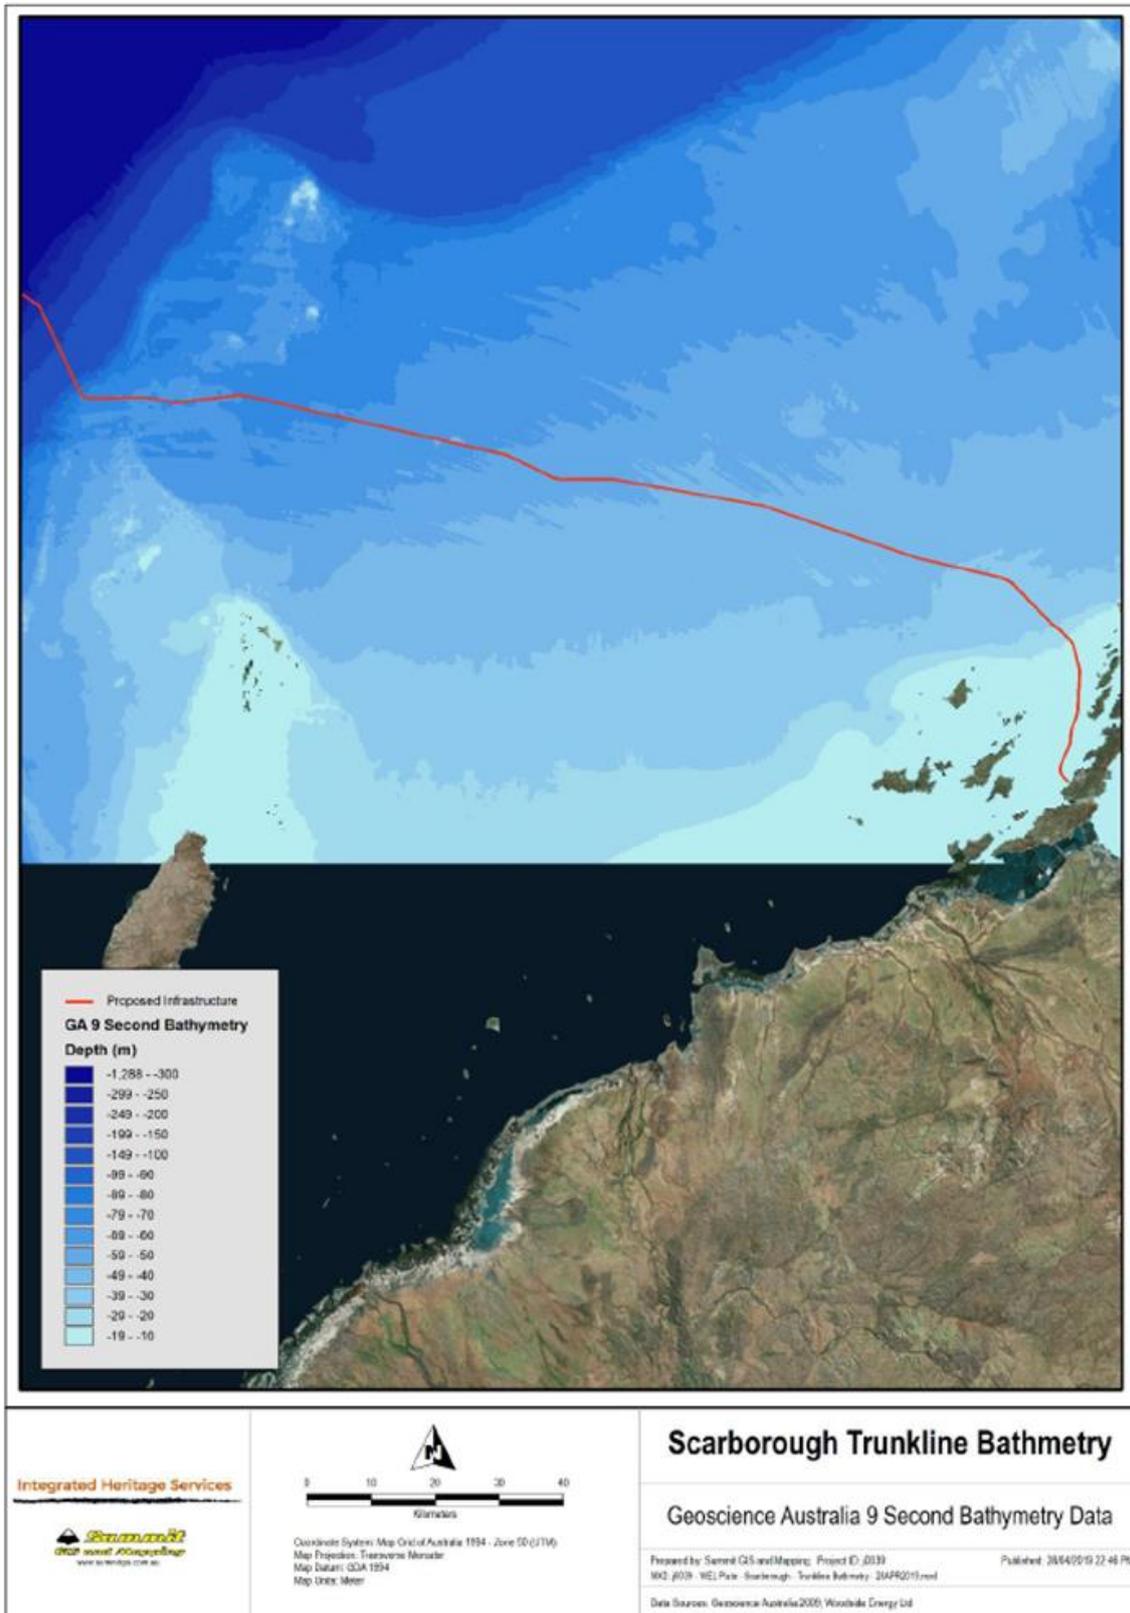

Figure 4-16: Scarborough development extent considered in the 2019 ethnographic survey (Mott, 2019)

Ethnographic Consultation (McDonald and Phillips, 2021)

The 2020 survey was undertaken due to the potential planned impact of offshore, nearshore and onshore activities associated with the Scarborough project within the cultural jurisdiction of Ngarda Ngarli people, traditional custodians of Murujuga. The survey was conducted by MAC as representatives of Traditional Custodians for the onshore and nearshore aspects of the Scarborough Project. MAC appointed their preferred heritage consultants to meet on Country with the MAC Circle of Elders to discuss the project and identify any cultural values (McDonald and Phillips 2021). The resulting report is owned by MAC and was approved by the Circle of Elders prior to being provided to Woodside. Representatives from the Mardudhunera, Ngarluma, Yaburara, Yindjibarndi and Wong-Goo-Tt-Oo Peoples—all five Indigenous groups represented by MAC (MAC 2022)—participated in this survey (McDonald and Phillips 2021).

The scope of works for this survey defines the purpose of this survey as follows:

The ethnographic consultation aims at providing an understanding of the cultural heritage values associated with the submerged landscape.

Specifically, the survey and reporting will provide Woodside an understanding of the cultural values within the coastal, nearshore and offshore proposed Scarborough export trunkline and associated works areas.

The scope of the assessment was informed by the Scarborough project's development footprint as provided in Figure 4-17 . A landscape-scale approach was undertaken, considering heritage values that may be identified by participants well beyond this footprint. No boundary was imposed on the participants, and participants were not restricted in the types of heritage value they were encouraged to identify. As an indication of the breadth of the cultural landscape that the survey considered, cultural features and heritage values were identified more than 60km from the development footprint.

Participants were shown an introductory video explaining the key parameters of the Scarborough project including the proposed export trunkline (McDonald and Phillips 2021). The survey identified ethnographic sites onshore, but these are outside the Operational Area and EMBA and scope of this EP (McDonald and Phillips, 2021).

It is not appropriate or practical to request Traditional Custodians to list all ethnographic values onshore which they have not identified as potentially impacted, however some identified in the report included stories related to Eaglehawk Island and several sites at Withnell Bay several kilometres from the project footprint in State waters, outside of the EMBA and exclusively onshore. Some of these sites have spiritual connections and songlines throughout the landscape including to Cape Preston and Depuch Island. It was not proposed in the report that the Project would pose any risk to these sites or values, which are located well outside the EMBA. It was noted that some traditional knowledge of ethnographic values may have been lost through the effects of colonisation generally, and as a result of the Flying Foam Massacre in particular (McDonald and Phillips 2021).

Figure 4-17: Scarborough Development Location considered in the 2020 ethnographic survey (McDonald and Phillips, 2021)

4.9.4.2.3 Future Ethnographic Surveys

McDonald and Phillips (2021) represents the findings of Phase I of a planned two-part ethnographic survey, and recommends that the Phase II ethnographic survey be initiated. The second phase goes beyond industry standard by engaging with neighbouring First Nations groups to identify potential ethnographic values that traverse traditional group boundaries. Per Appendix F: Consultation, Table 2, Woodside has communicated its commitment to the Phase II survey to MAC. MAC has not yet elected to progress this work.

Phase I of the ethnographic survey was run by MAC, and the scope of this survey required “Full recording and significance assessment. The consultant is to provide advice as to whether there are cultural values within and nearby the footprint area...” Discussion with MAC’s then CEO has confirmed that MAC does not consider that they have failed to deliver on this scope. The survey was conducted with members of MAC’s Circle of Elders, who are recognised as cultural authorities for Murujuga, and the final report was approved by the Circle of Elders prior to being provided to Woodside.

Therefore, the Phase I survey adequately describes and assesses the cultural, spiritual, aesthetic and social values held by Traditional Custodians for the project area and surrounding land and seascape. Given the nature of the proposed Phase 2 survey, it is not necessary to complete Phase II survey before or in order to commence the operation of the Scarborough Project.

Woodside has also conducted extensive engagement with appropriate representatives as determined by MAC over the course of several years as well as a number of neighbouring Indigenous First Nations groups and representatives as detailed in Section 5. As reported in Section 4.9.4, this consultation with MAC has resulted in the detailing of cultural values beyond the heritage values that

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

may be identified through ethnographic survey, and in greater detail than the results of ethnographic survey to date. On 21 July 2023, MAC advised by letter that MAC “have no concerns at this point in time” regarding the proposed activities subject to this EP.

Beyond MAC, no Indigenous group has articulated cultural jurisdiction over any area of waters subject to impacts from planned activities. BTAC has stated that their Sea Country extends “out to the vast islands off the coast of the Pilbara, including the Monte Bello Islands, Barrow Island, and the Mackerel Islands.” These locations are outside of the extent of planned impacts. A review of publicly available literature has been undertaken to seek clarity on the extent of Sea Country for Thalanyji people in Section 4.9.4.1 and has not identified any areas recorded as Thalanyji Sea Country which overlap the extent of proposed impacts.

Woodside has offered support, through ongoing consultation, for initiatives proposed by Traditional Custodians to record Sea Country values (see Appendix G: Program of Ongoing Engagement with Traditional Custodians).

Woodside engages in ongoing consultation throughout the life of an EP. Should feedback be received (including any relevant new information on cultural values from the Phase II survey or other sources), it will be assessed and, where appropriate, Woodside will apply its Management of Change and Revision process (see Section 7.2.7).

4.9.4.3 Consultation Feedback to Inform Existing Environment

4.9.4.3.1 Summary of Values Raised During Consultation

A summary of the topics/interests and values raised by First Nations groups through consultations on this Petroleum Activities Program, or raised in context of general Scarborough Project activities or other activities are provided in Table 4-22.

First Nations cultural values are communally held. This is reflected in Vision 3 of Dhawura Ngilan that “Aboriginal and Torres Strait Islander heritage is managed... according to community ownership” (Heritage Chairs of Australia and New Zealand 2021). Dhawura Ngilan also specifically notes that “Aboriginal and Torres Strait Islander... intangible knowledge systems, which are held in songlines and language, are endangered. This knowledge is held by Elders and the community...” Through consultation Registered Native Title Bodies Corporate and nominated representative corporations have identified or raised topics relating to environmental values of cultural interest. Woodside recognises the spiritual and cultural connection to the environment¹⁰ that First Nations people hold.

Appendix G: Program of Ongoing Engagement with Traditional Custodians provides a mechanism for ongoing dialogue between Woodside and Traditional Custodians, beyond that required by Regulation 25. The program enables Woodside to manage the potential impacts and risks to cultural values which may be identified during Woodside’s activities via ongoing dialogue with Traditional Custodians. Should feedback be received (including any relevant new information on cultural values), it will be assessed and, where appropriate, Woodside will apply its Management of Change and Revision process (see Section 7.2.7).

¹⁰ Definition of ‘Environment’ in Regulation 4 of the OPPGS (Environment) Regulations are defined as:

- a) ecosystems and their constituent parts, including people and communities, and
- b) natural and physical resources, and
- c) the qualities and characteristics of locations, places and areas, and
- d) the heritage values of places, and includes
- e) the social, economic and cultural features of the matters mentioned in paragraphs (a), (b), (c) and (d).

Table 4-22: Feedback received via consultation to inform Existing Environment Description

Relevant First Nation Group/Individuals	Consultation context	Description of Value/Interest	Potential for overlap	
			Operational Area	EMBA
BTAC representing some of the Gnulli native title claimants (Baiyungu and Thalanyji people)	Raised in context of general Scarborough Project activities	Value: Cultural obligation to care for the environmental values of sea country Sea country extends “out to the vast islands off the coast of the Pilbara, including the Monte Bello Islands, Barrow Island, and the Mackerel Islands”	Possible (unspecified) No	Possible (unspecified) Possible (unspecified)
Kariyarra Aboriginal Corporation	Raised in context of general Scarborough Project activities	Interest: Assertion of sea rights in native title claim area <i>Interpreted as general connection to country, assertion of rights to access country and cultural obligation to care for environmental values of sea country</i>	No	Yes
	Raised in context of general EP consultation	Value: Coastal resource collection - fishing, trapping, crabbing, catching turtles, dugong, stingray (barbs) and collecting shellfish.	No	Possible
		Value: On Country access - visiting offshore islands at low tide and intergenerational knowledge transfer.	No	Possible
		Value: Cultural obligations to care for Country, including Sea Country. Value: Secret Habitat Totems associated with Sea Country	Possible (unspecified)	Possible (unspecified)
		Value: The existence of intangible cultural heritage including the Yinta (associated with Sea Country). <i>From Kariyarra Native Title documents it is clear that Yinta are significant cultural/spiritual sites, often a pool or water source but possibly a hill or other feature. These are, at least generally, associated with creation beings and are a core part of cultural rights to land in determining who can use or speak for an area.</i>	Possible (unspecified)	Possible (unspecified)
		Interest: Coastal landforms	No	Possible (unspecified)
		Interest: Coastal native vegetation	No	Possible (unspecified)
		Feature: Tangible cultural heritage (sites) associated with the coast/ocean.	No	Possible (unspecified)
		Value: Intangible cultural heritage associated with the coast/ocean.	Possible (unspecified)	Possible (unspecified)
		Interest: Shark Bay environment is unique and has the largest living organism in the world	No	No

Relevant First Nation Group/Individuals	Consultation context	Description of Value/Interest	Potential for overlap	
			Operational Area	EMBA
Malgana Aboriginal Corporation ¹¹	Raised in context of general Scarborough Project activities	Feature: Stromatolites Interest: Shark Bay contains stromatolites and microbial mats which are amongst the oldest living in the world.	No	No
		Interest: Seagrass For Shark Bay Malgana Aboriginal Corporation stated that they had observed a nearly 25% loss of seagrass from a hypersaline discharge into the bay	No	No
Murujuga Aboriginal Corporation representing Ngarda-Ngarli people (Mardudhunera, Ngarluma, Wong-Goo-Tt-Oo, Yaburara and Yindjibarndi)	Raised in context of Nearshore Scarborough Project activities (MAC 2021 as cited in Woodside 2023)	Value: Mermaid Sound ecosystem health	No	Possible
		Feature: Whale Value: A whale thalu is an increase at a totemic site that brings whales into beach Value: Whales and other species of totemic importance need to be protected, including their populations, biodiversity, and migration patterns Value: Whales are culturally important species that migrate through Mermaid Sound. Humpback whales in particular.	Possible (whale) Possible (unspecified) Possible (whales) Possible (unspecified; other species) No (based on defined location)	Possible (whale) Possible (unspecified) Possible (whales) Possible (unspecified; other species) Possible
		Feature: Dolphins Value: There are cultural ceremonies associated with communicating with dolphins	Possible (dolphins) Possible (unspecified)	Possible (dolphins) Possible (unspecified)
		Feature: Dugongs Value: Are a food source associated with seagrasses near Gidley Island	Possible (dugongs) No (based on defined location)	Possible (dugongs) No (based on defined location)

¹¹ While Malgana is not a relevant person under regulation 25 of the Environment Regulations they have been included in this table as they provided feedback during consultation.

Relevant First Nation Group/Individuals	Consultation context	Description of Value/Interest	Potential for overlap	
			Operational Area	EMBA
		<p>Feature: Fish</p> <p>Value: There are thalu ceremonies associated with increasing fish stocks</p>	<p>Possible (fish)</p> <p>Possible (unspecified)</p>	<p>Possible (fish)</p> <p>Possible (unspecified)</p>
		<p>Feature: Sea snakes</p> <p>Specifically mentioned as culturally important species</p>	<p>Possible (sea snakes)</p>	<p>Possible (sea snakes)</p>
		<p>Feature: Flatback, green, hawksbill, loggerhead and leatherback turtles</p> <p>Turtles are culturally important species that moves through Mermaid Sound. Turtles are most often seen in shallower areas and where there are seagrasses</p> <p>Most beaches are nesting sites for turtles, including those on Gidley and Legendre Islands</p> <p>Value: The songline associated with the turtle comes from Fortescue to Withnell Bay. This song is sung by four or five tribes for day and night without consuming food or water</p>	<p>Possible (turtles)</p> <p>No (based on defined location)</p> <p>No (based on defined location)</p> <p>No (songline geographically restricted nearshore)</p>	<p>Possible (turtles)</p> <p>Possible</p> <p>Possible</p> <p>No (songline geographically restricted nearshore)</p>
		<p>Feature: Coral</p> <p>Fish are attracted to areas with coral</p> <p>Concerned about coral bleaching because corals are important. Beautiful colours. They also attract a lot of other things</p> <p>Fish carry coral spawn like bees pollinate flowers. If fish were looked after, the corals would get brighter and brighter (by transmitting nutrients and performing other ecosystem services, fish can be symbiotic with corals)</p> <p>Spawning events should be avoided (associated with full moon). Locations identified during consultation include Withnell Bay; Conzinc Bay; south west of Legendre Island</p>	<p>No</p>	<p>Possible</p> <p>No (based on defined location)</p>

4.9.4.3.2 Murujuga Aboriginal Corporation Cultural Values of Marine Ecosystems

Murujuga Aboriginal Corporation (MAC) was consulted during the development of the Scarborough Project (Nearshore Component) Dredging and Spoil Disposal Management Plan (DSDMP) which included Commonwealth activities for full activity context (e.g., trenching and spoil disposal; and borrow ground dredging and associated backfill) that are pertinent to this EP. As a part of the DSDMP consultation, MAC proactively engaged the Circle of Elders to identify places, areas and values of the marine environment that are of cultural importance. MAC prepared a report titled “Cultural Values of the Environment for Scarborough DSDMP” which identified values of the marine environment that are of cultural importance to MAC. This work was an outcome of consultation further described in Section 5. This work is not considered an ethnographic survey, as it did not employ ethnographic survey methodology or the participation of a qualified anthropologist or ethnographer.

No specific environmental values of cultural importance were identified within the export trunkline Project Area (KP32 to KP50). Rather, values were identified within Mermaid Sound, which is directly relevant for the EMBA and for specific values can be inferred within the PAA.

4.9.4.3.3 Further Information Regarding Buurabalayji Thalanyji Aboriginal Corporation’s Sea Country values

During consultation, BTAC, on behalf of the Thalanyji People, advised it has a cultural obligation to care for the environmental values of Sea Country (refer to Appendix F: Consultation)

In correspondence from 20 February 2023 relating to the Scarborough Project, BTAC advised that:

- BTAC seeks support from Woodside to enable BTAC to define and articulate its values on Sea Country in a manner that could be more clearly understood by the offshore sector, government, and the community. This would enable BTAC and Woodside to collaborate to develop effective management plans that can provide adequate protection to Sea Country values.
- BTAC seeks support from Woodside to obtain technical support to review the information and provide BTAC and its members with feedback on the project risks to Sea Country and help BTAC contemplate the potential management controls that could be developed to protect its values and interests.

These requests do not constitute a request for an ethnographic survey. Woodside has agreed to BTAC’s request, and the resulting offer of technical support is detailed in Appendix F: Consultation. BTAC’s Sea Country has been identified as relating to nearshore islands and in nearshore areas which are not relevant to this EP.

BTAC noted that this Sea Country extends “out to the vast islands off the coast of the Pilbara, including the Monte Bello Islands, Barrow Island, and the Mackerel Islands.” In the absence of further advice from BTAC, Woodside understands from this description that BTAC’s interests extend to the Montebello Marine Park Multiple Use Zone in the vicinity of the islands.

While an ethnographic survey has not been requested, a review of publicly available literature has been undertaken to seek clarity on the extent of Sea Country for Thalanyji people. This review identified a number of heritage research projects undertaken for the Montebello and Barrow Islands which acknowledge the support of BTAC (e.g., Manne and Veth 2015, Veth et al. 2017), though no information regarding Sea Country values, or the extent of Sea Country, were identified.

Publicly available heritage assessment reports elsewhere on Thalanyji Country tend to rely on established native title boundaries (e.g., Chisholm 2013) or draw on historic maps, particularly those compiled by Norman Tindale and published in 1947 (e.g., Hook et al. 2020).

An early 1940’s map by Tindale shows “Talaindji” (Thalanyji) Country as exclusively terrestrial and further west than areas typically recognised today as Thalanyji Country (Tindale 1940). This map also shows the Noala people as custodians of the Onslow area and defines Barrow and the

Montebello Islands as “Mardudunera” (Mardudhunera) Country—it is unclear from the map if the boundary of Mardudhunera is proposed to represent an extent of Sea Country, or merely note that these islands are part of Mardudhunera Country.

A further refined version of this map was produced in 1974 which shows “Talandji” in a location more closely aligned with contemporary understanding of Thalanyji Country and removes the apparent extent of Mardudhunera over Barrow and the Montebello Islands (Tindale 1947). This definition of Thalanyji Country is still confined to the mainland in this map.

A more contemporary attempt at mapping traditional country is shown in The AIATSIS Map of Indigenous Australia (Horton 1996). This map similarly confines Thalanyji Country to terrestrial areas west of Onslow and leaves Barrow and the Montebello Islands unmarked as an area with “[n]o published information available”. It is also noted that “[t]his map is based on data collected up to 1994 and is not intended to show precise areas or boundaries” (Horton 1996).

Collective assessments of Sea Country in the Pilbara (Lincoln and Hedge 2019, YMAC et al. 2010) were also found to rely on existing native title boundaries. It is noted in the Pilbara Sea Country Plan (YMAC et al. 2010) that:

Although some differences remain, between and among native title groups, there is now a general sense that most groups have coalesced into final forms that will, in future, be the groups that exercise rights and interests in their respective areas. many of these rights and interests will relate directly to native title. however, there is also a more broadly based appreciation of the need to accept and discharge responsibilities for land and marine management within native title areas regardless of whether native title per se is affected. (YMAC et al. 2010, emphasis added).

The office of the Registrar of Indigenous Corporations records four corporations using the name Thalanyji, specifically:

- Buurabalayji Thalanyji Aboriginal Corporation
- Buurabalayji Thalanyji Aboriginal Corporation RNTBC
- Onslow Thalanyji Aboriginal Corporation
- Wurrumalu Thalanyji Aboriginal Corporation.

The only currently operative organisation, and the only organisation with an identified website, is Buurabalayji Thalanyji Aboriginal Corporation RNTBC. This website states that “Thalanyji Country spreads out across the Ashburton River coastal plain south to Tubridji Point, then across to Yannarie River and upstream to Emu Creek, across the range hills of southwest Pilbara to Henry River and Cane River in the north.” (BTAC 2021) This description includes coastal areas but provides no description of the extent of Sea Country.

A search of the National Native Title Tribunal register of applications and determinations identified four historic Native Title claims with the name Thalanyji, specifically:

- Thalanyji People (WC1995/002)
- Thalanyji People #2 (WC1996/082)
- Thalanyji (WC1999/045)
- Thalanyji 2 (WC2010/004)

Most of these claims were dismissed, and Woodside makes no assessment of the merits of these claims.

The area of WC1995/002, as defined in the map forming Attachment 1 to the Native Title Application,¹³ does not include any areas of Sea Country.

WC1996/082 does not include a publicly available map on the National Native Title Tribunal website. The Native Title Application¹⁴ does describe the area covered by the claim, including "This country extends from the Tubridji Point on the coast south west of Onslow and tracking south to Yanarrie River." and "The area also includes the waters and associated islands between Tubridji point and Cane River. These islands were visited by Thalanyji People." The extent of this Sea Country from the coast is unclear, but would presumably include islands as distant as Airlie Island, approximately 30 km from the shore.

The area of WC1999/045, as defined in the map forming Attachment C to the Native Title Application,¹⁵ includes an area of water extending approximately 30 km from the mainland coast in encompassing a number of islands, including:

- Airlie Island
- Ashburton Island
- Bessieres Island
- Direction Island
- Flat Island
- Locker Island
- Round Island
- Serrurier Island
- Table Island
- Thevenard Island
- Tortoise Island
- the Twin Islands.

The area also includes the southern-most of the Mangrove Islands, but does not include the other Mangrove Islands.

The area of WC2010/004, as defined in the map forming Attachment C to the Native Title Application¹⁶ includes localised areas of sea up to approximately 5 km beyond the coast.

Woodside has developed a robust understanding of Thalanyji Sea Country cultural values and heritage features through publicly available information (Section 4.9.4.1) and consultation with BTAC under Regulation 25. Reasonable and practicable steps have been taken to identify cultural features and heritage values of Thalanyji people in the EMBA.

If further guidance from BTAC is received as part of ongoing consultation which changes Woodside's understanding of the extent of Thalanyji Sea Country, then, if applicable, Woodside's Management of Change and Management of Knowledge process with EPO 28 will be applied to manage potential impact to newly identified cultural values or features to ALARP and an acceptable level. This estimation does not limit the extent of consultation with BTAC or the features and values they are encouraged to identify and communicate.

4.9.4.3.4 Summary of Cultural Features and Heritage Values

Woodside has developed a robust understanding of cultural features and heritage values relevant to the activity through examination of publicly available information, studies and consultation with relevant persons under Regulation 25.

Table 4-23 consolidates the cultural features and heritage values identified in Sections 4.9.4.1, 4.9.4.2 and 4.9.4.3 and confirms whether there is potential for these to exist within the PAA or EMBA. As previously described, topics which have been raised in the context of an interest linked to the natural environment are impact and risk assessed in Section 6.7 and 6.7.13.

As cultural features are physical elements of a place, these can generally be assessed for impacts; where a feature is avoided, it is not impacted. Heritage values relate less to what is significant and more to why something is significant; interaction between heritage values and the PAA can only be reliably informed by consultation with Traditional Custodians where they are willing to share the necessary knowledge. Assessment of heritage values beyond cultural features alone is addressed in Section 6.10 subject to these caveats.

Table 4-23: Summary of cultural features and heritage values

Identified cultural features and heritage values	Context	EP Source				Potential for overlap	
		Consultation Feedback	Indigenous Archaeological Heritage Assessment	Ethnographic Heritage Assessment	Desktop Literature Assessment	Operational Area	EMBA
Archaeological Heritage and Landscapes							
Coastal/island archaeological sites	Coastal archaeological sites include shell middens, artefact scatters, skeletal material/burial sites, camps, meeting places, hunting places and water sources.	✓	x	✓	✓	No	Possible (shoreline accumulation only)
Petroglyphs	Petroglyphs are a form of rock art. Petroglyphs are a prominent feature particularly at Murujuga where it is found on hard, volcanic rock.	✓	x	✓	✓	No	Possible (submerged)
Fish traps	Stone arrangements constructed in intertidal areas which fill with fish at high tide and trap them at low tide/	✓	✓	x	✓	No	Possible (submerged)
Submerged archaeological sites	The Ancient Landscape extends between 125m and 130m below current sea level. Ancient occupation of this area may have left traces through now submerged archaeological sites.	✓	x	x	✓	No	None identified; Possible (Unknown)
Rivers, waterholes, tidal channels and seeps	Water sources on the Ancient Landscape which may be culturally significant or archeologically prospective. Traditional knowledge retains knowledge of some water sources on the ancient landscape and some submerged waterholes are related to a Kangaroo songline.	x	✓	x	✓	No	Known to occur
Submerged calcarenite ridges/paleo beach barrier systems	Calcarenite ridges that have formed at former coastal sand dunes have the potential to encase and preserve artefacts from disturbance during inundation where these formed following human occupation.	x	✓	x	✓	Known to occur	Known to occur

Identified cultural features and heritage values	Context	EP Source				Potential for overlap	
		Consultation Feedback	Indigenous Archaeological Heritage Assessment	Ethnographic Heritage Assessment	Desktop Literature Assessment	Operational Area	EMBA
Submerged hills	Hills on the Ancient Landscape which may be culturally significant or archeologically prospective. As sea level rose these hills would have become islands and eventually submerged.	x	✓	x	✓	No	Known to occur
Madeleine Shoals	Archaeologically prospective location on the submerged landscape, including igneous geology which has the potential to include rock art.	x	x	x	✓	No	Known to occur
Karst depressions/Ravines and valleys between submerged ridges	Natural depressions with the potential to contain artefacts displaced during inundation.	x	✓	x	✓	No	Possible
Intangible values							
Songlines	Ethnographic survey noted dreaming tracks from locations onshore and to islands outside of the EMBA but was not able to determine the routes of any dreaming tracks that may extend across the submerged landscape.	✓	x	✓	✓	Possible (unspecified)	Possible (unspecified)
Creation/dreaming sites, sacred sites and ancestral beings	Ethnographic survey noted some sites associated with creation/dreaming or ancestral beings are known on land outside the EMBA. Publicly available literature talks to creation/dreaming and ancestral beings, including water serpents, connected to or originating from the sea generally.	✓	x	✓	✓	Possible (unspecified)	Possible (unspecified)
Ceremonial sites	Places where ceremony (e.g. thalu ceremonies) are performed. All identified ceremonial sites are located onshore.	x	x	x	✓	No	Possible (unspecified)

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

Identified cultural features and heritage values	Context	EP Source				Potential for overlap	
		Consultation Feedback	Indigenous Archaeological Heritage Assessment	Ethnographic Heritage Assessment	Desktop Literature Assessment	Operational Area	EMBA
Cultural obligations to care for Country	Cultural obligation to care for the environmental values of Sea Country. Exclusion of Traditional Custodians from Sea Country or decision-making processes may inhibit ability to care for Country.	✓	x	x	✓	Possible (unspecified)	Possible (unspecified)
Knowledge of Country/customary law and transfer of knowledge	The preservation and transmission of knowledge is dependent on the preservation of the environment generally. Exclusion of Traditional Custodians from Sea Country may inhibit the transfer of knowledge.	✓	x	✓	✓	Possible (unspecified)	Possible (unspecified)
Connection to Country	Connection to Country is described in publicly available literature as “important to the Traditional owners’ spirituality and religion”. Connection to Country may be damaged where people are displaced or disrupted (e.g. during colonisation) or where there is a loss of technical skills or environmental knowledge.	✓	x	x	✓	Possible (unspecified)	Possible (unspecified)
Access to Country	Limitations on Traditional Custodians accessing or enjoying areas of Sea Country.	✓	x	x	✓	Possible (unspecified)	No (No limitations on access beyond the Operational Area)
Kinship systems and totemic species	Traditional Custodians have connection to species through kinship and totemic systems. An individual may have obligation to care for or not consume a species to which they are kin.	✓	x	x	✓	Possible	Possible

		Consultation Feedback	Indigenous Archaeological Heritage Assessment	Ethnographic Heritage Assessment	Desktop Literature Assessment	Operational Area	EMBA
Fish: Fish, sharks and rays	Culturally important species. Used as a resource. Law run through the sea, including fish. There are thalu ceremonies associated with increasing fish stocks. Fish, including bream and sting rays are totemic species. Fish, including sharks and rays raised as a natural environment interest.	✓	x	x	✓	Possible	Possible
Cephalopods: Squid and Octopus	Thalu species of totemic importance. Resource.	✓	x	x	✓	Possible	Possible
Seabirds	Culturally important species. Birds (including shags, seagulls and osprey) and bird eggs as a resource.	✓	x	x	✓	Possible	Possible
Plankton	Interest only, raised as a natural environment interest.	✓	x	x	x	Possible	Possible
Benthic habitats: Coral	Culturally important with regard to connection with fish. Coral spawning specifically raised.	✓	x	x	x	No	Possible
Benthic habitats: Seagrass	Culturally important species. Protection of animals.	✓	x	x	x	No	Possible
Benthic habitats: Macroalgal communities	Interest only, raised as a natural environment interest.	✓	x	x	x	No	Possible
Benthic habitats: Epifauna and infauna	Interest only, subtidal soft bottom communities raised as a natural environment interest.	✓	x	x	x	Yes	Yes

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

Identified cultural features and heritage values	Context	EP Source				Potential for overlap	
		Consultation Feedback	Indigenous Archaeological Heritage Assessment	Ethnographic Heritage Assessment	Desktop Literature Assessment	Operational Area	EMBA
Shoreline habitats: Mangroves	Mangrove seeds as resource. Critical breeding ground for marine and terrestrial wildlife. Mangroves would have provided shelter, crabbing, digging for shellfish, could be turtle nurseries.	✓	x	x	✓	No	Possible
Shoreline habitats: Intertidal sand/mudflat communities	Interest only, raised as a natural environment interest.	✓	x	x	✓	No	Possible
Shoreline habitats: Rocky shores	Interest only, raised as a natural environment interest.	✓	x	x	x	No	Possible
Shorelines	Including coastal landform. Interest only, raised as a natural environment interest.	✓	x	x	✓	No	Possible
Marine Park/coastal reserves	Interest only.	✓	x	x	x	Yes	Yes

4.9.4.4 Further Context: Archaeological Heritage

Assessment of the Operational Area has not identified archaeological sites within the Operational Area.

No coastal areas or islands exist within the Operational Area. Islands do exist within the EMBA boundary, however given the EMBA is based on various models of an unplanned marine diesel spill there is no anticipated impact pathway from this activity to onshore archaeological sites above highest astronomical tide (HAT). No archaeological sites have been identified beyond terrestrial or intertidal areas, with the exception of two sites at Murujuga in Cape Bruguieres channel and Flying Foam Passage (Benjamin et al. 2020; Benjamin et al 2023), which are outside of the EMBA. However, it is recognised that there is the potential for submerged archaeological sites on the Ancient Landscape which is overlapped by the EMBA.

Archaeological sites identified onshore with the potential to exist in intertidal or submerged locations include petroglyphs, fish traps and artefact scatters or burials contained within sand dunes. As archaeological sites, these features have archaeological value which relates to the preservation of their fabric (i.e. the tangible features) and their context (i.e. their location and relationship to other archaeological and natural features). Archaeological sites may also have intangible dimensions (ICOMOS, 2013) cultural value that exist in addition to their archaeological or scientific value and are assessed separately.

Certain landscapes have been identified as archaeologically prospective on the submerged Ancient Landscape, including:

- submerged water sources (rivers, waterholes, tidal channels and seeps) which have an increased likelihood of use or habitation as past generations used the associated resources (UWA 2021)
- submerged calcarenite ridges younger than human occupation of the continent which may have formed over and protected artefacts in-situ (Veth 2019)
- prominent landscape features (e.g. hills, particularly of igneous rock formations) that may have been foci for cultural activity (UWA 2021)
- karst depressions and other “catch points” where artefacts may accumulate following disturbances caused by inundation (UWA 2021, Nutley 2022, Nutley 2023a).

Madeleine Shoals has been specifically identified by MAC as a prospective due to its igneous rock formations which have the potential to contain petroglyphs.

4.9.4.5 Further Context: Intangible Cultural Heritage

Intangible cultural heritage has been identified through consultation with First Nations people as culturally important (refer to Section 4.9.4.3). Cultural knowledge, as expressed through songlines, dreaming, dance and other cultural practices, can be associated with tangible objects and physical sites that are culturally important to First Nations people (Ardler 2021; Bursill et al. 2007). Intangible cultural heritage can also be embodied in the practices, representations, expressions, knowledge, uses and skills associated with physical sites (UNESCO 2003). As a result, physical features may have intangible dimensions (ICOMOS 2013).

In terms of identified cultural features and heritage values related to intangible values summarised in Table 4-23, see below for some additional context:

Songlines: Oral Songlines are often described by First Nations people as the law of the land and make up part of the Dreaming (Neale and Kelly 2020:30). Songlines are viewed in Western academia as a framework for relating people to land and consist of a series of invisible, interconnected routes across the landscape that mark significant sites for First Nations people (Higgins 2021:723). Songlines demonstrate First Nations peoples’ strong connections to land by revealing sacred knowledge that is place-specific (Roberts 2023:5). The land’s physical features are instrumental in

maintaining songlines because this is how ancestral spirits journeyed through, and interacted with, the physical landscape leaving sacred knowledge behind. The interconnection between the physical and spiritual is where songlines become intrinsically tied to significant places across Country. As a result, geographical landforms are recorded within songlines and become sacred places. Such landforms can include inter alia: rocks, mountains, rivers, caves and hills (Higgins 2021:724). Songlines can become lost, fragmented or broken when there is a loss of Country or forced removal from Country (Neale and Kelly 2020:30). Physical sites that have been identified as comprising a component of a songline are important to protect to prevent the fragmenting or breaking apart of songlines and loss of sacred cultural knowledge.

In Australia, songlines can stretch thousands of kilometres, making up a complex and organic network of stories containing cultural knowledge of First Nations communities across the land (Neale and Kelly 2020:35). Songlines can also extend out to Sea Country and contain cultural knowledge that is tied to geographic features, atmospheric phenomena and marine plants and animals. Often songlines containing references to a seascape or Sea Country make mention of mythical events occurring around marine life, fishing areas, submerged rocks or coral. Songlines that embody seascapes can reflect how a group may relate to, or value, Sea Country—for example connections to nearby islands that they once inhabited in their songlines (Smyth and Isherwood 2016:307). Songlines can also be used as proof of long-standing connection to land and support a legal entitlement to land rights (Higgins 2021:74). Examples where songlines contain strong references to Sea Country are more common in Pacific Islander and Torres Strait Islander communities, who often refer to seascapes and skylines in their songlines in order to communicate sacred knowledge that assists in safe navigation of the ocean (Neale and Kelly 2020:83-84). The routes of any songlines in the EMBA have not been provided by Traditional Custodians through consultation relevant to this EP.

Creation/dreaming sites, sacred sites and ancestral beings: The sources located by Woodside with detailed descriptions of the location of ancestral beings or creation/dreaming/sacred sites placed these on land or within inland water sources such as rivers or pools. Some ancestral beings are noted to live within or originate from the sea generally, and some creation stories talk to the creation of features from or in the sea. Additionally, every place on shore or at sea is generally assumed to have been created on some level in First Nations' cosmology.

Cultural obligations to care for Country: Caring for Country collectively refers to the cultural obligations of individuals and groups, as well as rituals and ceremonies directed to the physical and spiritual health of the environment. In the literature reviewed by Woodside, caring for Country was noted to include, but is not limited to, maintenance of the physical environment and ecosystem. It may also have cultural, spiritual and ritual dimensions such as caring for ancestral beings or ensuring cultural safety. Thalu are places where what are known as "increase ceremonies" are performed to enhance or maintain populations of plants, animals or phenomena. All mentions of active ceremonial sites were confined to onshore locations, though the values may extend offshore where e.g., a thalu relates to marine species populations.

Knowledge of Country/customary law and transfer of knowledge: Knowledge of and familiarity with the features of Sea Country is itself a value. The inherent potential for restricted or secret knowledge makes this difficult to assess even through consultation with Traditional Custodians. However, aspects such as limitations on access to sites or disruption/relocation of First Nations communities may have implications for the preservation of First Nations knowledge. Further, connection to Country may be damaged where people are displaced or disrupted (e.g., during colonisation) or where there is a loss of technical skills or environmental knowledge (McDonald and Phillips, 2021). Transfer of knowledge includes continuing traditional practices to pass on practical skills. This transfer of knowledge may be integral to managing a group's intangible cultural heritage (UNESCO 2003).

Connection to Country: Describes the multi-faceted relationship between First nations people and the landscape, which is envisioned as having personhood and spirit. It is also an aspect of personal

identity for many First Nations people. In the case of Sea Country this can mean identifying as a Saltwater person, where “essence of being a 'Saltwater' person is ontological... it is about how people relate spiritually to the sea and engage with spiritual forces that created it, the marine flora and fauna and people” (McDonald and Phillips, 2021).

Access to Country, including Sea Country: Access is necessary for the continuation of other values including caring for Country and the transfer of traditional knowledge. Being on Country can be an important way of expressing or maintaining connection to Country (Australian Indigenous HealthInfoNet n.d.). Access is also a value in its own right, as a continuation of traditional Sea Country access and use.

Kinship systems and totemic species: Individuals may have kinship to specific species (Smyth 2008, Juluwarlu 2004) and/or a responsibility to care for species (Muller 2008). Kinship arises from totemic associations within First Nations “skin group” systems. It is forbidden for an individual to kill or eat a species who is from the same “skin group” (Juluwarlu 2004). They may also have certain obligations linked to the discussion of caring for Country below. It is assumed that marine species may have kinship/totemic relationships to Traditional Custodians, but it is understood that these relationships do not prohibit people outside of that “skin group” from hunting or eating that same species (Juluwarlu 2004).

Resource collection: A number of marine species are identified through consultation and literature as important resources, particularly as food sources. In addition to their immediate value as sustenance, the gathering and preparation of these resources is informed by cultural knowledge, and an inability to use these resources may result in a loss of ability to transfer that knowledge to future generations.

4.9.4.6 Further Context: Marine Ecosystems and Species

First Nations people have raised through consultation that they have a general interest in environmental management and ecosystem health (i.e., natural environment interest), where a group/individual was seeking further information about potential impacts and risks from the Petroleum Activities Program on marine species and benthic communities in the Operational Area and EMBA. This includes marine mammals, marine reptiles, fish, seabirds, plankton, benthic and shoreline habitats and marine parks, which are described in context of their distribution and populations in Section 4.5 and 4.6.

In terms of identified cultural features and heritage values related to marine ecosystems and species summarised in Table 4-23, see below for some additional context:

Marine mammals: Whales, and in particular humpback whales, have been identified through consultation with First Nations people as culturally important species, with totemic importance including their populations, biodiversity, and migration patterns. Cultural ceremonies associated with communicating with dolphins have also been raised by MAC through consultation and dugongs predominantly as a resource. Details pertaining to whales, dugongs and dolphins, their distribution, migration patterns and populations are described in Section 4.6.3.

Marine reptiles: Turtles and sea snakes have been identified through consultation with First Nations people as culturally important species, with turtles identified as a resource. First Nations people that identify marine reptiles as species of totemic importance or integral to songlines may place high cultural value on their protection. No marine reptiles-related songlines have been identified as per Section 4.9.4.3.4 that have the potential to interact with the PAA or EMBA. Note the only specified songline related to marine reptiles (turtles) was shared by MAC, and was geographically restricted from Fortescue to Withnell Bay, in Mermaid Sound (MAC 2021). Cultural knowledge of turtles at a population level (turtle migration, behaviour and the related marine environment) may all be important in ensuring the continuation of cultural functions and activities that remain valuable to First Nations people (Fijn 2021:47; Delisle et al.2018). Details pertaining to marine reptiles, their distribution, and populations are described in Section 4.6.2.

Fish and Cephalopods: Fish and squid have been identified through consultation with First Nations people as a culturally important species, with fish generally being identified as a resource. First Nations may identify cultural values associated with fish species as important to maintaining both tangible (physical cultural sites) and intangible (cultural knowledge) cultural heritage. Tangible cultural heritage associated with fish can include important cultural sites such as midden sites, fish traps and thalu sites. The octopus is an important totem to Ngarla People and features in the creation story of Solitary Island. There are “increase ceremonies/rituals” for species of squid and octopus to enhance or maintain populations. Thalu are places where these “increase ceremonies” are performed. Details pertaining to fish and cephalopods are described in Section 4.6.1.

Seabirds: Seabirds, and in particular shags, have been identified through literature as a culturally significant species (Malgana Land and Sea Management et al. (2021), as well as a resource (seabird eggs; Smyth 2007). Details pertaining to seabirds and migratory shorebirds are described in Section 4.6.4.

Benthic habitats: Through consultation, First Nations groups identified benthic habitats as valuable for their ecological values, including corals attracting fish and seagrass providing shelters for fauna, as well as an important resource for dugongs. Additionally, coral is valued by MAC for its aesthetic values. Details pertaining to benthic habitats and communities, including their distribution, are described in Section 4.5.

Shoreline habitats: Through consultation, First Nations groups identified shoreline habitats as valuable for their ecological values, including mangroves for providing shelter to marine invertebrates, which are identified resources, and potential nursery for turtles. Literature also notes that mangroves are also valued for the flora and fauna they are associated with and support (Commonwealth of Australia 2002) and Smyth (2007) reports that mangrove seeds are used as a resource by Ngarda-Ngarli. Details pertaining to shoreline and coastal habitats, including their distribution, are described in Section 4.5.

4.9.5 Murujuga Cultural Landscape

Murujuga is a significant cultural landscape rich with heritage values, included on Australia’s National Heritage list and World Heritage tentative list. It contains one of the largest, densest and most diverse collections of rock art in the world, estimated to contain over a million engravings (petroglyphs) covering a broad range of styles and subjects. The landscape also contains quarries, middens, fish traps, rock shelters, ceremonial sites, artefact scatters, grinding patches and stone arrangements that evidence tens of thousands of years of human occupation. These places are linked through the stories, knowledge and customs that are still held by Traditional Custodians and have significance beyond their archaeological value.

This Cultural Landscape has global significance and is on the UNESCO World Heritage Tentative List. As stated on the UNESCO World Heritage website¹⁷:

The Traditional Custodians of Murujuga, the Ngarluma, Yindjibarndi, Yaburara, Mardudhunera and Wong-Goo-Tt-Oo groups, collectively referred to as Ngurra-ra Ngarli, have taken the lead in proposing the inclusion of the Murujuga Cultural Landscape on Australia’s World Heritage Tentative List. Ngurra-ra Ngarli, represented by the Murujuga Aboriginal Corporation, have prepared this Tentative List Submission in partnership with the Western Australian Government and with the support of the Australian Government.

Murujuga, the Aboriginal traditional name for the Dampier Archipelago and surrounds, including the Burrup Peninsula, is located in the Pilbara region of Western Australia. When the Ngurra-ra Ngarli talk about Murujuga, they talk about Land and Sea Country, which consists of a narrow peninsula of land extending approximately 22 kilometres from the mainland, a group of 42 islands, islets and

¹⁷ <https://whc.unesco.org/en/tentativelists/6445/>

rocks and the surrounding sea up to 40 kilometres from the port of Dampier (Murujuga Aboriginal Corporation 2016). With more than one million images in an area of more than 37,000 hectares, Murujuga is home to one of the most significant and diverse collections of petroglyphs in the world which documents the transition of an arid maritime cultural landscape through time (McDonald 2015, Mulvaney 2015, McDonald et al. 2018). Murujuga has the densest known concentration of hunter-gatherer petroglyphs anywhere in the world (Jo McDonald Cultural Heritage Management 2011, Australian Heritage Council 2012, Mulvaney 2015).

For the Aboriginal people of the Pilbara region, including the Ngurra-ra Ngarli, the petroglyphs are the work of the Marrga, the ancestral creator beings. They are a permanent reminder of Traditional Lore and retain their spiritual power. On Murujuga, the petroglyphs are an inherited and ongoing responsibility of the Ngurra-ra Ngarli (Jo McDonald Cultural Heritage Management 2011). The songs and mythologies for many of the images, such as Minyuburru (Seven Sisters), the fruit bat and Archaic Face, have important meaning across the whole of the Pilbara region and are central to Ngurra-ra Ngarli culture.

Archaic Faces have a widespread distribution throughout the arid zone of Australia and include a locally developed form on Murujuga (McDonald 2005, Mulvaney 2010, Veth et al. 2011). The Archaic Faces of Murujuga are a permanent reminder of how Traditional Lore should be followed. The presence of the Archaic Faces across the Pilbara region and into the Western Desert demonstrates the importance of the deep time shared cultural practices, including through the transfer of songs and mythologies between different language groups over thousands of kilometres.

“Some of these carvings are our Lore and Culture. The Lore, it goes from here, right to Uluru, from Uluru into the desert and back again to the West. That’s including the Kimberley and Northern Territory area. It’s still going strong”.

Source: Jakari Togo (Geoffrey Togo), Senior Cultural Ranger (deceased) 2013. Murujuga Cultural Heritage Management Plan (Murujuga Aboriginal Corporation 2016)

There is evidence that suggests that the Ngurra-ra Ngarli first started living and using this part of the Pilbara coastal plain around 50,000 years ago, when the coastline was understood to be about 100 kilometres away. At that time Murujuga is understood to have been wetter and warmer than it is now. The archaeological record of the coastal plain at this time reveals a faunal assemblage no longer found in this part of Australia, such as nail-tailed wallabies and crocodiles. Murujuga’s artists recorded this group of animals in the engraving assemblage. During the last ice age (between 30,000 and 18,000 years ago), when the coastline was understood to be 160 kilometres away, Ngurra-ra Ngarli are understood to have lived in the Murujuga Ranges (McDonald et al. 2018) as well as other desert refugia. Evidence of Ngurra-ra Ngarli living in this landscape is seen in a number of petroglyphs of animals that are now extinct, such as thylacines (Tasmanian Tiger) and a fat-tailed species of kangaroo (Brown 2018; Mulvaney 2013) which are distributed widely across the Pilbara region and into the sandy deserts. More recent petroglyphs depict fish, turtles, dugong and small marsupials that now live on the islands (McDonald 2015). The variations in petroglyphs and archaeological evidence demonstrate how Ngurra-ra Ngarli are understood to have adapted to the changing environments wrought by sea level rise (McDonald and Berry 2016).

The estimated more than one million petroglyphs of Murujuga demonstrate an extraordinary diversity of style, theme, mode of production and aesthetic repertoire. This art province is an inscribed landscape complete with other archaeological components, such as stone structures, middens and quarries, and provides a social context and means for interpreting the complexity of the petroglyphs (McDonald and Veth 2009).

The many stone features of Murujuga include standing stones, fish traps, stone arrangements, hunting hides and domestic structures. Some standing stones are thalu sites, places where ceremonies are carried out to increase and manage the social and economic benefits of natural resources (Daniel 1990). On Murujuga, stone feature sites range from single monoliths through to

extensive alignments comprising at least three or four hundred standing stones (Vinnicombe 2002). Thalu sites are permanent reminders of the Traditional Lore.

Murujuga is sacred to Ngurra-ra Ngarli, it is a place where everything is connected, through the Ancestral Beings – the land, the sky, the sea, the plants, the animals, the Lore and the spiritual world. This is the belief system that underlies life on Murujuga today (Murujuga Aboriginal Corporation 2016).

National Heritage Place – Dampier Archipelago

The Dampier Archipelago, including Murujuga, was included in the National Heritage List in 2007. Values listed against National Heritage criteria in the gazettal notice include:

- Engravings of a wide range of terrestrial, avian and marine fauna. These provide an “outstanding visual record of the course of Australia’s cultural history through the Aboriginal responses to the rise of sea levels at the end of the last Ice Age”
- Engraved “archaic faces” which demonstrate the long contact between Aboriginal societies on the Dampier Archipelago and inland arid Australia
- Diversity in representation of the human form in engravings, including depictions of groups of people “engaged in both mundane and sacred activities”
- Standing stones, stone pits and circular stone arrangements associated with various uses
- Ability to link research on archaeological remains (middens, grinding patches, quarries) and associated rock engravings to “contribute to an understanding of the cultural and economic meaning”

Further detail of these values can be found in the publicly available Gazettal¹⁸.

Murujuga National Park Management Plan

Parts of the Burrup Peninsula (4,913 hectares which is approximately 44% of the Burrup Peninsula) are owned by the Murujuga Aboriginal Corporation, leased back to the Western Australian Government and is jointly managed with DBCA as a National Park¹⁹ (DBCA, 2024). The Park and some adjacent areas is managed under the Murujuga National Park management plan 78 (2013, as amended 2023)). The Management Plan created by Ngarda-Ngarli and their joint management partners seeks to ensure the protection of the area and to revive Ngarda-Ngarli knowledge, associations and responsibility. Table 4-24: Murujuga National Park Management Plan objectives and applicability to Woodside. Table 4-24 lists the Plans main objectives and how these are applicable to Woodside, as well as the mechanisms under which Woodside implements requirements of the Plan.

The Plan acknowledges the coexistence of Woodside production facilities and the Park, identifying its objective ‘To promote effective, integrated and cooperative management between Murujuga National Park and adjacent land managers’ (DBCA, 2013, and amendment DBCA & MAC 2023).

In 2007, the Australian Government signed a Conservation Agreement with Woodside Energy Ltd to protect and research the National Heritage values of the Dampier Archipelago. In July 2017, Woodside signed the ‘Ngajarli (Deep Gorge) Joint Statement’ reaffirming the cooperative commitments made under each of the Conservation Agreements.

It is under the Conservation Agreement that Woodside provides ongoing funding to continue to support research into, and monitoring of the National heritage values of the Park so that activities are carried out in a manner that is consistent with the Murujuga National Park Management Plan 78 (2013). Further protections and management practices have been integrated into Woodside’s Cultural Heritage Management Plans and

¹⁹ <https://www.dbca.wa.gov.au/management/plans/murujuga-national-park>

engagement protocols. Outcomes of funded programmes include processes to identify sites with National Heritage values, present and transmit information about the National Heritage values, and manage the National Heritage values so that they are conserved for future generations.

Table 4-24: Murujuga National Park Management Plan objectives and applicability to Woodside

Murujuga National Park Management Plan Objectives	Applicability to Woodside	Demonstration of meeting objectives
Murujuga National Park will be managed to the highest standards that meet the expectations of the Australian community for protection of cultural, heritage and natural values.	Not Applicable	NA
Cultural, heritage and natural values will be conserved, protected and promoted.	Applicable	<ul style="list-style-type: none"> • Conservation Agreement • Deep Gorge Joint Statement
Ngarda-ngarli will meet their obligations to country and satisfy their people's aspirations for benefits from land ownership.	Not Applicable	NA
Members of MPC will together make shared, informed, consistent, transparent and accountable decisions.	Not Applicable	NA

World Heritage Nomination

The United Nations Educational, Scientific and Cultural Organisation (UNESCO) “seeks to encourage the identification, protection and preservation of cultural and natural heritage around the world considered to be of outstanding value to humanity” via the World Heritage List, established under the World Heritage Convention 1972 (UNESCO 2024). The Murujuga Cultural Landscape was nominated to the UNESCO Tentative World Heritage List by the Federal Department of the Environment and Energy in 2020. Inscription on the World Heritage List means that Murujuga’s unique cultural, spiritual and archaeological values would be internationally recognised at the highest level.

As stated by the State Department of Biodiversity, Conservation and Attractions, “World Heritage Listing also brings a commitment at local, state and national levels to protect and manage the property for present and future generations.” World Heritage listing and industry can occur in parallel, as long as there are no significant impacts on World Heritage values.

As required under the World Heritage framework, the tentative World Heritage Listing of the Murujuga Cultural Landscape submission justifies its Outstanding Universal Values by meeting two of the possible ten selection criteria:

- *To represent a masterpiece of human creative genius*, with “more than one million images in an area of more than 27,000 hectares, the Murujuga Cultural Landscape has one of the densest known concentration of petroglyphs anywhere in the world,” and for the content, age and significance of the petroglyphs
- *To bear a unique or at least exceptional testimony to a cultural tradition or to a civilisation which is living or which has disappeared*, through the unbroken connection of the Ngarda-Ngarli people to Murujuga “since the world was soft and Ancestral Beings moved over the earth,” reflecting both deep-time history and ongoing critical cultural significance.

Further submissions on how the Murujuga Cultural Landscape meets World Heritage criteria can be found on the publicly available UNESCO World Heritage Tentative Listing²⁰.

Current Condition of Murujuga Cultural Landscape

The current condition of the Murujuga Cultural Landscape has been assessed from a number of publicly available sources.

The World Heritage Tentative List Submission for Murujuga Cultural Landscape (MAC, DBCA, DEE 2020) notes, with regards to the Statements of Integrity and/or Authenticity:

“Aboriginal cultural landscapes are living landscapes that change as time progresses, where oral tradition is the canon of proof and where changing practices of embodied experience with landscapes grow from generation to generation (Andrews and Buggey 2008).

In the context of Aboriginal cultural landscapes, any test of authenticity, must recognise, expect, and endorse changes (Andrews and Buggey 2008). The archaeological and anthropological evidence for Murujuga is well preserved, with a high degree of authenticity. The exceptionally well-preserved cultural values of Murujuga can be found across an area of more than 37,000 hectares, comprising the majority of the Burrup Peninsula, as well as the surrounding islands of the Dampier Archipelago...

The petroglyphs of Murujuga have been made on the exceptionally hard, dark volcanic rock using stone tool technology. Methods of production included pecking, abrasion, incision and bas-relief. When first produced the very pale grey petroglyphs would have contrasted starkly with the dark red-brown cortex of the rock. With subsequent patination and weathering, this contrast gradually reduces...

Murujuga has a high level of integrity and received enhanced protection and management following its National Heritage listing in 2007. A detailed land-use impact study of Murujuga documented that all 40 islands included in the Dampier Archipelago (including Burrup Peninsula) National Heritage place and approximately 85 per cent of the Burrup Peninsula, retain extremely high integrity (McDonald and Veth 2006a), and contain all the attributes that constitute the potential Outstanding Universal Value of the place...

Within the National Heritage listed area, the petroglyphs are whole and intact (Jo McDonald Cultural Heritage Management 2009, 2011). Although the entirety of Murujuga has not been surveyed and recorded, there are thousands of known sites which demonstrate the potential Outstanding Universal Value of the Murujuga Cultural Landscape...

While industrial development visually compromises some areas of the southern section of the Burrup Peninsula, the topography, with its deeply dissected gorges, valleys and scree slopes, means that a large portion of Murujuga, including the vast majority of its islands retain high visual integrity (Jo McDonald Cultural Heritage Management 2011, Australian Heritage Council 2012). In summary, the Murujuga Cultural Landscape is an intact and representative example of one of the most significant concentrations of human artistic creativity in the world, which survives through the continuity of Ngurra-ra Ngarli cultural and social practices and active management.”

The Report “The Potential Outstanding Universal Value of the Dampier Archipelago Site and Threats to that Site - A report by the Australian Heritage Council to the Minister for Sustainability, Environment, Water, Population and Communities” (Australian Heritage Council 2012) found that:

“It is clear that the undisturbed area within the boundaries of the National Heritage Listed place is complete and whole, notwithstanding the proximity of industry”

²⁰ <https://whc.unesco.org/en/tentativelists/6445/>

The Australian Heritage Database listing for the Nationally Heritage Listed Damper Archipelago (including Burrup Peninsula) states:

“Condition: Parts of the area, particularly the Burrup Peninsula, East Intercourse Island and Mid East Intercourse Island, have been subject to industrial development and other impacts such as the construction of towns and work camps. A land use impact assessment, undertaken using aerial photographs from August 2004, estimates that high levels of impact have occurred on 1,643 hectares (or 16.4 square kilometres) on the Burrup Peninsula (McDonald and Veth 2006). A high level of impact in these areas on the Burrup Peninsula has resulted in the destruction of archaeological material and in some cases the relocation of engravings and other stone features. Despite this, the natural and cultural heritage in Dampier Archipelago and its surrounding waters is in good condition” (DCCEEW 2007).

Research to date on the impacts of industrial emissions on rock art has not been conclusive and is summarised in section 4.9.6.

4.9.6 Summary of Existing Research on Onshore Industrial Emissions

The presence of industry on the Burrup Peninsula has been the subject of topics and issues raised by some Relevant Persons during consultation. The topics and issues have centred around emissions associated with industrial activity leading to an accelerated weathering of rocks on which rock art is present which may reduce the visibility or destroy the rock art. This is based on a hypothesis that deposition of compounds such as NO_x, SO_x and ammonia (NH₃) from anthropogenic industrial sources have the potential to increase the acidity of the rock surface through chemical and/or biological processes and that acidic conditions may then accelerate the weathering of rock patina, eroding or affecting the contrast of the rock art. There have been several independent studies and rock art monitoring initiatives since the mid-2000s, none of which have conclusively demonstrated a causal link between degradation of rock art and industrial activity. There are therefore also no applicable environmental air quality standards or guidelines available that can be applied to engraved rock art (Government of Western Australia, 2023).

Nevertheless, Relevant Persons have raised through consultation (Appendix F: Consultation) the possibility that emissions from the processing of LNG onshore at Murujuga may have an impact on the preservation of rock art. While these onshore emissions are not within the scope of the PAP, they are assessed in this EP as potential indirect impacts (Section 6.7.7). Research to date on the impacts of industrial emissions on rock art has not been conclusive, and is summarised in this section.

Further research is being undertaken by the Murujuga Rock Art Monitoring Program (MRAMP), run by the Murujuga Aboriginal Corporation and Western Australian Department of Water and Environmental Regulation (DWER). MRAMP is described as “A best practice monitoring and analysis program” by the Western Australian Government which “will provide reliable information on changes and trends in the condition of the rock art and whether the rock art is showing signs of accelerated change... The results from these studies will guide management and protection of the rock art” (Government of Western Australia, 2023). MRAMP will provide the necessary certainty to guide management and protection of the rock art.

In the absence of scientific certainty on the level of emissions which theoretically may affect rock art, Pluto LNG Plant (PLP) where the majority of Scarborough’s gas is planned to be processed is applying best available practicable and efficient technologies to minimise and monitor air emissions from the plant.

It is a condition of the existing approvals for PLP (MS 757) that the proponent of PLP produce a “Front End Engineering Design Report demonstrating that the proposed works adopt best practice pollution control measures to minimise emissions from the plant”. An update of the Best Practice Air Emissions Report was prepared for the operation of a second LNG train at PLP and was submitted in July 2019 to the EPA for assessment (Woodside, 2019).

PLP's publicly available Air Quality Management Plan has been reviewed and approved by the Western Australian Environment Protection Authority as meeting the requirement for best available practicable and efficient technologies to be used to minimise and monitor air emissions from the plant (Woodside, 2019a). This included independent peer review assessment which concluded that the design of Pluto Train 2 is consistent with best practice in the context of air emissions control for LNG plants and the minimisation of greenhouse gas emissions (Woodside 2019a).

4.9.6.1 Research, Monitoring and Publications

In 2002, Bednarik speculated the existence of several possible pathways for industrial emissions to impact rock art, including acidification of rain and promotion of microbial activity. Bednarik suggested there was colour change in the rock surfaces. Bednarik's speculation led to further studies detailed in this section.

In 2002, the Western Australian Government established the Burrup Rock Art Monitoring Management Committee (BRAMMC) to assess the impacts of industrial emissions on the rock art of Murujuga. Research conducted by the BRAMMC included measurements of colour change as well as air quality, microclimate, dust deposition, mineral spectrometry, microbiological analyses, air dispersion modelling, and laboratory simulations of chemical impacts at contemporary, predicted and 10-times predicted pollutant estimates.

During the course of the BRAMMC studies, several further publications were produced including:

- MacLeod 2005, which found that acidity of rockfaces on Murujuga is higher than samples kept in museum conditions. The paper does not demonstrate that the museum samples, which have been subject to decades of museum preservation conditions, are representative of the natural pH of Murujuga's rocks nor does it draw any conclusions on the impacts of acidity on rock art preservation.
- Bednarik 2006 and 2007a were editorials, which did not include any original research.
- Bednarik 2007b argued that industrial emissions were impacting rock art but provided no evidence beyond analogy to bird droppings and expert advice that the absence of rock patina near trees was not the result of any known process caused by plants. The data provided by Bednarik is not sufficient to demonstrate that industrial emissions have negative impacts on the rock art but did warrant further study (which was already underway at that time).

In 2009, the BRAMMC reviewed the results of studies conducted under their program and concluded that "there is no scientific evidence to indicate that there is any measurable impact of emissions on the rate of deterioration of the Aboriginal rock art in the Burrup" and recommended that a technical working group be established to continue long-term monitoring.

In 2010, the Burrup Rock Art Technical Working Group (BRATWG) was established. Under the BRATWG the CSIRO continued to monitor potential colour change on the rock art (Markley et al 2015). In 2016, an unpublished paper by Black and Diffey concluded, contrary to CSIRO analysis at the time, that colour change was detected in the CSIRO data but that "a cause for the colour changes cannot be properly determined" and "the colour changes at the southern [non-control] sites are not readily explained by the concentrations of NO_x and SO_x compounds in the air."

These criticisms of the statistical methods used by CSIRO prompted the Department of Environment Regulation to commission Data Analysis Australia (DAA) to review the CSIRO research. The DAA report found that "Superficially our analyses and those of Black and Diffey suggest that some changes may have taken place, but... we have substantial doubts about the reliability of the data and hence any conclusions drawn" and, in relation to the conclusions of Black and Diffey "it would not be appropriate for the Draft paper to be published in its current form – the findings are based on highly doubtful data rendering any discussion of statistical significance moot." The final CSIRO report includes a reassessment using more robust methods informed by the DAA report. The result of this analysis was "not fully conclusive" (Duffey et al 2017).

In 2016, the BRATWG commissioned an extreme condition weathering study to investigate the effects of different concentrations of acids on weathered rock surfaces. This study found that the dissolution of chemicals began at lower pH levels than previously estimated (pH 3 for aluminium, manganese and iron), but was recognised as a preliminary study and did not provide definitive results (Ramanaidou et al 2017). These results cannot be relied on as a meaningful threshold for determining whether rock art is being impacted by emissions.

Since the 2016, BRATWG extreme weathering study, several additional papers have been produced, including:

- Black et al 2017a provides a review of the conclusions of earlier studies into emissions impacts by the CSIRO, specifically those undertaken with regards to the fumigation of rock samples with acid gasses, emersion of iron-rich rocks in acids, air pollution modelling and colour change. This review concluded that a number of errors and inaccuracies prevent any meaningful conclusion being drawn from the CSIRO data. This review did not demonstrate impacts to rock art from industrial emissions.
- Black et al 2017b provides a theoretical evaluation of MacLeod 2005 research. It provides no data that links industrial air emissions or subsequent deposition to changes in pH on Murujuga rock surfaces. There are practical limitations that prevent the MacLeod data from being adapted to the paper's purpose, including variation in sample dilution and the arbitrary exclusion of data.
- Black et al 2018 speculates the existence of several possible impact pathways, including acidification of rain and promotion of microbial activity. The paper recognises, however, that "There is no proof yet that the patina on Murujuga rocks is dissolving" and asserts that "there has not been credible research to determine" whether rock art is being degraded. In drawing conclusions regarding changes in acidity this paper assumes, without evidence, that geological samples which have been subject to decades of preservation in a museum are representative of the natural pH of Murujuga's rocks. The key conclusions of this paper are that further, more robust research is required, and that the precautionary principle should be applied in the interim.
- Gleeson et al 2018 primarily discusses microbial organisms that may be responsible for the formation of rock varnish. The paper briefly speculates on the possible impacts of industrial emissions but does not purport to provide any evidence of impacts to Murujuga's rock art.
- In 2019 the Department of Water and Environmental Regulation (DWER) produced the Murujuga Rock Art Strategy (MRAS), which built on the research to that date, and according to DWER will establish a world's best practice program to monitor, evaluate and report on factors that could affect the condition of rock art. This will be undertaken in consultation with a team of national and international experts in relevant disciplines and funded by industry including from Woodside. Research by this program is led by MAC and DWER so that results are independent from industry influence.
- CBG Solutions 2020 repurposes previous pH records from 2003 and 2004 (as a baseline) and data collected between 2017 and 2019 to assess changes in acidity on rock surfaces. The report repurposes historical and inconsistent pH data and acknowledges a number of resulting statistical issues which "makes determination of long-term pH changes problematic." The report states that "There appears to be no detrimental (acidification) impact that can be statistically supported regarding proximity to either the NW Gas plant or to the Pluto plant" and "Owing to the many variables that determine the surface pH of the Burrup rocks and the significant impact of periodic cyclonic heavy rain and the lack of historic data on all the tested sites, it is not possible to claim that there is sufficient evidence for the statement that there is a continuing increase in acidity across Murujuga since measurements commenced in 2003."
- Dorn 2020 discusses competing theories of desert varnish growth and how chemical changes to desert varnish result from human sources, such as lead concentration following the addition of lead to petrol. The chapter predominantly focusses on North America, but

uncritically restates the conclusions of Black et al 2017b. Only one other example in the paper, regarding an apparent change in varnish texture from near Los Angeles, appears to have even tangential relevance to industry on Murujuga. Acid fog is proposed as one *possible* cause, but this suggestion is not supported by any provided data and is based on examinations from an area with significantly higher acid gas concentration than Murujuga experiences.

- MacLeod 2020 provided results of a study commissioned by Yara Pilbara Nitrates. This report observes a variability of the relationship between colour difference and pH, with colour difference diminishing with increasing pH at some points, and diminishing with decreasing pH at other points although the final sentence of the report claims “There is unequivocal evidence that the changes in colour contrast are affected by the changes in the mean and in the minimum pH observed on the rock art sites at the reference positions.” At several points this report notes that rainfall events—particularly cyclonic events—appear to substantially reduce the acidity. The executive summary states that “There is a clear link between the minimum pH and the amount of sulphate on the rock surfaces, *which indicates some of the sulphate comes from anthropogenic sources*” (emphasis added) though the report does not articulate how a link between pH and sulphate contributes to an understanding of sulphate origin. MacLeod (2020) comments in relation to the two sites that are closest to Pluto LNG Plant and Karratha Gas Plant that the observed low sulphate concentrations “strongly supports that these exhaust sources are not resulting in any significant SO_x deposition on the rock surfaces.”
- MacLeod 2021 provides an update to this previous work which found that pH had increased during the study period but pH changes were affected by microclimate at each site including seasonal variations, microbial activity, and localised rainfall events. Any relationship between anthropogenic NO_x and SO_x emissions and acidity was not established and “Just as the mechanisms of adsorption of NO_x and SO_x onto the moistened rock surfaces are yet to be unequivocally established, the presence of a direct relationship between the concentration of sulphate in the wash solutions with the underlying acidity can be regarded as a de-facto correlation.” Once again, the report states that “There is unequivocal evidence that the changes in colour contrast are affected by the changes in the mean and in the minimum pH observed on the rock art sites at the reference positions.”
- Also in 2021, MacLeod and Fish (2021) published results of the studies commissioned by Yara Pilbara Nitrates, including that “there is presently no adverse impact on the rock engravings from industrial pollution owing to a lower NO_x level than when the studies commenced 14 years ago”. This conclusion was critiqued by Smith et al 2022a, who correctly noted that this conclusion is based on limited data and makes a number of key assumptions without adequate peer-reviewed research.
- Gagan et al 2022 is an investigation of anthropogenic air-borne sulphur on rock art on limestone substrate in Sulawesi, Indonesia. This is not comparable to the Murujuga petroglyphs as the Murujuga petroglyphs are not on a limestone substrate. The research notes that “the bulk of the damage was present before 1950 CE” for example due to biomass burning ~3,500 years ago; current threats include “vandalism and sulphur emissions from diesel-powered traffic and cement-based infrastructure”; and that “the rate of rock art loss may be on the decline.”
- Smith et al 2022a is a review of the Fish and McLeod report; the review does not contain original research and therefore does not further the existing scientific understanding of the subject. Claims that Smith et al 2022a demonstrate that emissions from industry are impacting rock art are incorrect.
- Smith et al 2022b does provide evidence of impacts to rock art and attributes these to three sources: mechanical removal and damage, chemical emissions and unsympathetic human presence. Evidence of the first and third of these is apparent and easily demonstrated from the photographic record, yet the paper itself notes that the use of photographic records to

assess chemical impacts through colour change are subject to considerable errors including distortion and degradation of early photographs, variable lighting conditions and other factors. The researchers do note that several petroglyphs (numbered 2, 5, 6, 9, 16, 17, 21, 22 and 24) appear to have lightened over time in line with a hypothesis that emissions have played a role in this, while one petroglyph (1) appears to have darkened and at least 13 do not demonstrate any change, including several in close proximity to industry. The paper appropriately notes that further research is required to determine the causes of these perceived changes.

- Neumann et al 2022 is an important proof-of-concept for analytical techniques, but is clear in its conclusion that:

Although our data clearly demonstrate that acidic rain has measurable effects on the varnish surface, including its colour and increased dissolution of Fe and Mn compounds, it should be stressed here that this does not necessarily mean that natural weathering of the petroglyphs is accelerated by anthropogenic pollution.

- Ruffolo et al 2023 review the formation of “black crusts”, accumulation of materials on the surface of stone buildings, in highly polluted urban environments, and intervention strategies to mitigate damage to built heritage from black crusts. The study notes “the research outcomes have established some correlations between black crusts and the surrounding air pollution, leading to them being considered as a “record” and also a “passive sampler” of past pollution patterns. However, in this case, there is not yet a well-defined procedure to obtain accurate and unambiguous information.” This paper does not provide new science applicable to the Murujuga petroglyphs due to its focus on built heritage and urban pollution.

In 2019, DWER released the Murujuga Rock Art Strategy (MRAS), “A monitoring, analysis and decision-making framework to protect Aboriginal rock art located on Murujuga (the Dampier Archipelago and Burrup Peninsula)” (DWER, 2019). The MRAS notes “This strategy builds on the previous work on Murujuga to deliver a scientifically rigorous approach to monitoring, analysis and management that will provide an appropriate level of protection to the rock art. It describes a risk-based approach for the management of impacts to the rock art that is consistent with the State Government’s responsibilities under the Environmental Protection Act 1986 (EP Act) and provides the monitoring and analysis to determine whether accelerated change is occurring to the petroglyphs” (DWER 2019).

In regards to previous scientific studies and monitoring, the MRAS states “In 2002, the Western Australian Government established the Burrup Rock Art Monitoring Management Committee (BRAMMC) in response to concerns about possible adverse impacts on the rock art from industrial air emissions...In 2009, after reviewing the information from these studies and the comments from the international peer reviewers, BRAMMC concluded there was no scientific evidence of any measurable impact of industrial emissions on the rate of deterioration of the Burrup rock art. BRAMMC recommended that no environmental management measures specifically to protect the rock art from air pollution were necessary at that time. BRAMMC recommended that colour contrast and spectral mineralogy monitoring be continued on an annual basis for 10 years and be reviewed after five years; and that a technical working group be established to consider the results of monitoring and other studies. BRAMMC also recommended that the monitoring of ambient air quality and rock microbiology be suspended and only recommenced if warranted by a major increase in emissions or if evidence became available indicating further monitoring was required.

The Burrup Rock Art Technical Working Group (BRATWG) was established to oversee the colour contrast and spectral mineralogy monitoring program and other studies between September 2010 and June 2016. The then Department of Environment Regulation (DER) managed the monitoring program from the expiry of BRATWG’s tenure in June 2016 until the formation of DWER on 1 July 2017” (DWER 2019).

Outcomes of both the BRAMMC and the BRATWG have been discussed above.

The MRAS states that “The successful implementation of the management framework to protect the rock art from anthropogenic emissions will require...a monitoring program that is appropriately designed and implemented to take the necessary measurements, to analyse the data and to report on the integrity or condition of the rock art and change in that condition” (DWER 2019). As described in the MRAS “The Western Australian Government in partnership with MAC and in consultation with international and national experts in relevant disciplines and the Murujuga Rock Art Stakeholder Reference Group, will develop and implement a revised long-term Murujuga Rock Art Monitoring Program” (DWER 2019).

In December 2023, the first interim report of MRAMP was published. An accompanying summary report notes that “Data collected in the first year of observation do not permit any firm conclusions to be drawn about trends in rock surface condition and any relationship to air quality over time” (Government of Western Australia 2023). However, several techniques were considered promising for future analysis, including spectral measurement of rock art condition, geological studies and mineralogical studies. Though requiring more data to draw any conclusions, the report and summary both note that the correlation observed between acid-producing emissions and pH were the *inverse* of predictions if these gases were causing acidification of rock surfaces (that is, higher concentrations of these gases were associated with *less* acidic rock surfaces). Woodside does not consider these results to be definitive and recognises that further work by MRAMP is required. Final results by MRAMP are scheduled for December 2025, just prior to the earliest commencement date for the Petroleum Activities Program (Section 3.4), with interim Environmental Quality Criteria anticipated to be published in the preceding years. This will provide the necessary certainty to guide management and protection of the rock art for industry on Murujuga.

Produced subsequent to these interim results, Smith 2024 provides the results of laboratory studies on Murujuga rock samples. The methodology for these experiments is not provided. The reported results are that particles of weathering rind begin to detach from the rock samples when the pH of rocks reach 6 or lower—significantly higher than, for example, suggested in Ramanaidou et al 2017. This report also reinterprets results from the MRAMP program (although excluding results from the first campaign of this work from consideration). This reinterpretation requires cautious consideration, noting the MRAMP interim report’s caveats that the available data is insufficient for drawing meaningful conclusions. The conclusions of Smith 2024 state that “The rock surfaces of Murujuga have become increasingly acidic *due to the nitric and sulphuric dusts emitted by industry in the area.*” (emphasis added). This causal link is not supported in the report by reference to any other study, and as the report does not provide a clearly stated methodology it is unclear that this is supported by the laboratory work performed. A correlation may, perhaps, be implied by reference to historic trends reported in reports discussed elsewhere in this section, which have noted methodological issues. Smith 2024 also fails to address, in its reinterpretation of MRAMP data, the preliminary observation that higher levels of acid-producing emissions were found to correlate with less acidic rock surfaces.

Woodside is also aware of a draft paper, Black 2024, which reiterates previous conclusions drawn by Mr Black but does not provide new science regarding Murujuga’s rock art. The paper summarises some of the scientific literature addressing rock art on Murujuga and other locations around the world described above.

On 1 July 2024, a Statutory Declaration by Mr Nigel Carney, formerly employed by Murujuga Aboriginal Corporation as Coordinator of the Murujuga Rock Art Strategy and the Monitoring Program (MRAMP) was tabled in the Australian Senate by Senator Lidia Thorpe which alleges that:

- Calibre Ventures Pty Ltd, a third-party private contractor “was in effect managing the MRAMP” (paragraph 10), and
- the partnership between MAC and DWER (as it stood in 2023) required “significant changes in the existing management structure, due largely to conflict of interest and related issues”, (paragraph 11) and

- people in leadership positions at MAC have attempted to unduly influence the outcome of MRAMP (paragraphs 4-5, 24-25 and 34).

Mr Carney also claimed to record “multiple scientific flaws” (paragraph 13) and “numerous deficiencies” (paragraph 17) with MRAMP, though the nature of these issues is not provided. No such errors are apparent from the MRAMP first interim report, which has been subject to independent peer review (Government of Western Australia 2024).

The CEO of MAC provided comments to media in response to the tabled documents, stating “The claims made in the tabled documents do not stand up to scrutiny,..The Murujuga rock art monitoring program is a strong, best-practice program that has been designed with international experts to examine the impact of industrial emissions on Murujuga’s petroglyphs” (WA Today, 6 June 2024, article entitled “Leaked letter reveals internal concerns about science on Australia’s next world heritage site by Hamish Hastie and Peter Milne, 2024)

The Government of Western Australia maintains that the MRAMP is a “best practice monitoring and analysis program” which “will provide reliable information on changes and trends in the condition of the rock art and whether the rock art is showing signs of accelerated change” (Government of Western Australia 2024). As a basic principle of managing First Nations cultural heritage, and as reflected in Woodside’s First Nations Communities Policy (Woodside, 2022), the involvement of MAC as representatives of Traditional Custodians in this project is also important to ensuring that the broader values of Murujuga are appropriately managed. Further results from the MRAMP are expected periodically until its conclusion in 2025, and relevant findings will be managed through Woodside’s Management of Change process.

4.9.7 Historic Sites of Significance

There are no known sites of historic heritage of significance within the PAA. Appendix D: Aboriginal Cultural Heritage Inquiry System Searches describes cultural heritage sites within the EMBA.

4.9.8 Underwater Heritage

A search of the Australasian Underwater Cultural Heritage Database, which records all known Maritime Cultural Heritage (shipwrecks, aircraft, relics and other underwater cultural heritage) in Australian waters revealed 14 shipwrecks located within the EMBA (Figure 4-18). The Curlew, Marietta, Vianen, Wild Wave, and Trial wrecks are classified as a historic shipwrecks under the

Underwater Cultural Heritage Act 2018 and a Protected Place under the EPBC Act and listed in Table 4-25: Recorded shipwrecks within EMBA

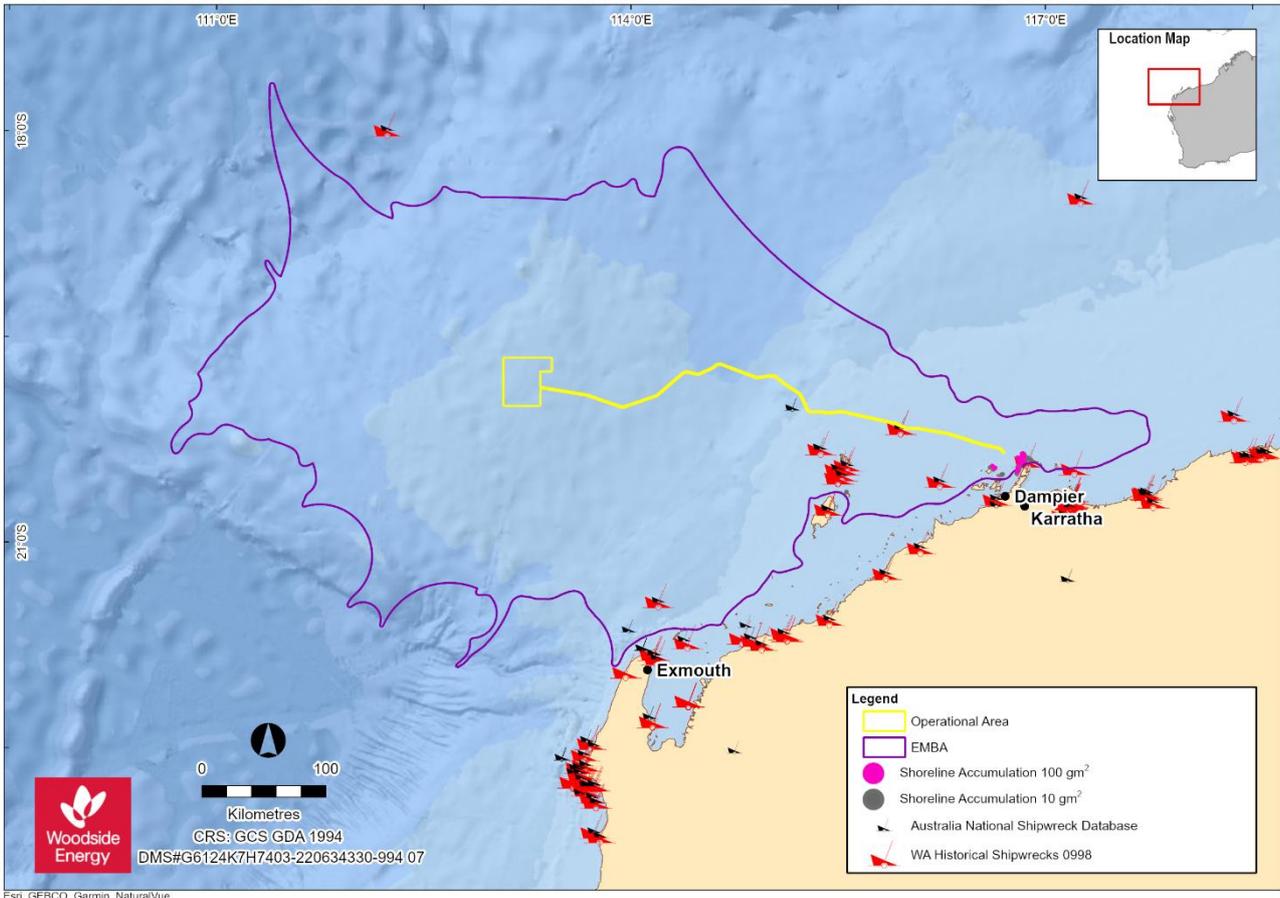

Figure 4-18: Petroleum Activities Area and environment that may be affected in relation to State and Commonwealth shipwrecks

Table 4-25: Recorded shipwrecks within EMBA

Vessel Name	Year Wrecked	Wreck Location	Latitude	Longitude	Distance from PAA
Curlew	1911	At Onslow, Montebellos Group	20.0°S	115.17°E	8 km south of Trunkline Operational Area
Zelma	1990	Dampier Archipelago	20.38 ° S	116.87° E	18 km east of Trunkline Operational Area (State Waters end)
Tanami	N/A	WA - North West (Montebellos Area)	20.28 ° S	115.37° E	24 km south of Trunkline Operational Area
Trial	1622	WA - North West (Montebellos Area)	20.29 ° S	115.38° E	24 km south of Trunkline Operational Area
Dampier	N/A	Enderby Island, Dampier Archipelago	20.52 ° S	116.23° E	34 km south of Trunkline Operational Area (State Waters end)
Plym HMS	1952	WA - North West (Montebellos Area)	20.40 ° S	115.57° E	36 km south of Trunkline Operational Area
Tropic Queen	1975	WA - North West (Montebellos Area)	20.43 ° S	115.51° E	41 km south of Trunkline Operational Area
Parks Lugger	N/A	WA - North West (Montebellos Area)	20.48 ° S	115.53° E	45 km south of Trunkline Operational Area
Lady Ann	1982	WA - North West (NW Cape)	20.40 ° S	114.20° E	154 km south of Trunkline Operational Area (FPU end)

4.9.9 World, National and Commonwealth Heritage Listed Places

No listed world, national or commonwealth heritage places overlap the PAA. World, National and Commonwealth heritage places within the EMBA are identified in Table 4-26. Section 11 of the Appendix L: Woodside Master Existing Environment outline the natural values and sensitivities of protected places and other sensitive areas in the PAA and EMBA.

Table 4-26: World Heritage Properties and National/Commonwealth Heritage Listed Places within the environment that may be affected

Listed Place	Distance and Direction from Listed Place to PAA (km)
World Heritage Properties	
Ningaloo Coast	178 km south of Trunkline Operational Area (FPU end)
Murujuga Cultural Landscape (tentative list)	8km south of Trunkline Operational Area
National Heritage Places	
Ningaloo Coast (natural)	178 km south of Trunkline Operational Area (FPU end)
Barrow Island and the Montebello-Barrow Islands Marine Conservation Reserves	25 km south-east of Trunkline Operational Area (State Waters)
Dampier Archipelago (including Burrup Peninsula)	8 km south of Trunkline Operational Area
Commonwealth Heritage Places	
Ningaloo Marine Area – Commonwealth Waters	181 km south of Trunkline Operational Area (FPU end)

4.10 Socio-economic Environment

4.10.1 Commercial Fisheries

A number of Commonwealth and State fishery management areas are located within the PAA and EMBA. The Annual Fishery Status Reports published by the Australian Bureau of Agricultural and Resource Economics and Sciences (ABARES) were used to identify whether Commonwealth managed fisheries have fished within the PAA and EMBA in the last five years. FishCube data were also requested from the WA Department of Primary Industries and Regional Development (DPIRD) for the most recently available five-year period of fishery catch and effort data (2018-2022) to analyse the potential for interaction of fisheries with the PAA. Data was reviewed from the last 5 years as a subset of past fishing effort. This was deemed an appropriate period to represent potential future fishing effort for a period of approximately five years following acceptance of this EP. In addition, any impacts to fish are expected to be temporary in nature (See Section 6.7 and Section 6.7.13) and therefore not extending beyond the life of the EP.

Table 4-27 provides an assessment of the potential interaction and provides further detail on the fisheries that have been identified through desktop assessment and consultation (Section 5). Two Commonwealth managed, and twelve State managed fisheries (in addition to charter operators) were identified as having a potential to interact with the Petroleum Activities Program, within the PAA (see Table 4-27, Figure 4-19 to Figure 4-22).

Table 4-27: Commonwealth and State commercial fisheries overlapping the Petroleum Activities Area and environment that may be affected, and the potential for interaction during the Petroleum Activities Program

Fishery	Potential for interaction		
	PAA ²¹	EMBA ¹³	Description ²²
Commonwealth Managed Fisheries			
North West Slope Trawl Fishery	✓	✓	The North West Slope Trawl Fishery management area overlaps the PAA and the EMBA. The fishery is predominantly a scampi fishery using demersal trawl gear in water depths > 200 m. While targeting scampi, finfish and squid are also retained. The number of vessels active in the fishery since 2005-06 ranges between one and six. Fishing effort in 60 NM graticular reporting blocks overlapping the EMBA and PAA (trunkline operational area) has been recorded within the last five years. Accordingly, Woodside considers it a possibility that interactions with the fishery may occur in the PAA and EMBA.
Southern Bluefin Tuna Fishery	✘	✘	The Southern Bluefin Tuna Fishery management area overlaps the PAA and the EMBA. The Southern Bluefin Tuna Fishery spans the Australian Fishing Zone, however since 1992, the majority of Australian catch has concentrated in south-eastern Australia. No activity within the fishery has occurred in the PAA or EMBA within the last five years. Accordingly, Woodside considers there to be no potential for interaction with this fishery and the Petroleum Activities Program.
Western Deepwater Trawl Fishery	✓	✓	The Western Deepwater Trawl Fishery management area overlaps the PAA and the EMBA. The fishery targets finfish and deepwater bugs using demersal trawl gear. Effort is concentrated between Shark Bay and Cape Range. Fishing effort in 60 NM graticular reporting blocks overlapping the PAA (trunkline operational area) and EMBA has been recorded within the last five years. Accordingly, Woodside considers it a possibility that interactions with the fishery may occur in the PAA and EMBA.
Western Skipjack Fishery	✘	✘	The Western Skipjack Fishery management area overlaps the PAA and the EMBA. The Western Skipjack Tuna Fishery encompasses the entire Australian Exclusive Economic Zone (EEZ). Collectively with the Eastern Skipjack Tuna Fishery (which targets the east coast stock of skipjack tuna) these fisheries form the Skipjack Tuna Fishery. The fishery targets western skipjack tuna (<i>Katsuwonus pelamis</i>) and primarily employs Purse seine fishing methods (about 98%), with some minor pole-and-line fishing.

²¹ Green highlights in these columns denotes overlap between the PAA with the fishery management area. Ticks or crosses indicate the potential for interaction.

²² All descriptions derived from Patterson et al., (2023), Newman et al. (2023), and catch data available from DPIRD and the Australian Bureau of Agricultural and Resource Economics and Sciences unless otherwise cited.

			The Fishery is not currently active and no fishing has been recorded since the 2008–2009 fishing season as a result of the natural variability of skipjack tuna stocks in Australian waters and low unit price for this species. Accordingly, Woodside considers there to be no potential for interaction with this fishery and the Petroleum Activities Program.
Western Tuna and Billfish Fishery	x	x	The Western Tuna and Billfish Fishery management area spans the Australian Fishing Zone west of Victoria and the Torres Strait and overlaps the PAA and the EMBA. The fishery targets marlin, swordfish, and tuna (<i>Thunnus</i> spp.) using pelagic longlines. Effort in recent years is concentrated off the west and south coasts of Western Australia, between Geraldton and Albany. No activity within the fishery has been recorded within the EMBA within the last five years. Accordingly, Woodside considers there to be no potential for interaction with this fishery and the Petroleum Activities Program.
State Managed Fisheries			
Abalone Managed Fishery	x	x	The Abalone Managed Fishery management area overlaps the PAA and EMBA. The fishery is diver-based and targets greenlip, blacklip, and Roe's abalone in relatively shallow coastal waters (< 30 m). The species targeted by the fishery are temperate or subtropical. No activity within the fishery has been recorded within the EMBA within the last five years. Accordingly, Woodside considers there to be no potential for interaction with this fishery and the Petroleum Activities Program.
Exmouth Gulf Prawn Managed Fishery	x	✓	The Exmouth Gulf Prawn Managed Fishery management area overlaps the EMBA. The fishery uses demersal trawl gear to target several prawn species within Exmouth Gulf. Fishing effort in 10 NM graticular reporting blocks overlapping the EMBA (but not the PAA) has been recorded within the last five years. Accordingly, Woodside considers there to be potential for interaction with this fishery within the EMBA.
Hermit Crab Managed Fishery	x	x	The Land Hermit Crab Managed Fishery management area overlaps the EMBA where shoreline contact is predicted. FishCube reported no fishing effort within the EMBA where shoreline contact has been modelled. Woodside considers there to be no potential for interaction with this fishery and the Petroleum Activities Program.
Mackerel Managed Fishery	✓	✓	The Mackerel Managed Fishery management area overlaps the PAA and the EMBA. The fishery is managed within three areas - Kimberley (Area 1), Pilbara (Area 2), and Gascoyne and West Coast (Area 3). The fishery targets mackerel (primarily Spanish mackerel) using surface trolled gear. Most landings are in the Kimberley (Area 1), beyond the EMBA. Fishing effort in 10 NM graticular reporting blocks overlapping PAA (trunkline operational area) and EMBA has been recorded within the last five years. Accordingly, Woodside considers it a possibility that interactions with the fishery may occur within the PAA and the EMBA.

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

Marine Aquarium Fish Managed Fishery	✓	✓	The Marine Aquarium Fish Managed Fishery management area overlaps the PAA and EMBA. The fishery occurs state-wide and is primarily diver-based in shallow coastal waters (< 30 m). The fishery targets species for the aquarium trade. Fishing effort in 10 NM graticular reporting blocks overlapping the PAA (trunkline operational area) and EMBA has been recorded within the last five years. Accordingly, Woodside considers it a possibility that interactions with the fishery may occur within the PAA and the EMBA.
Nickol Bay Prawn Managed Fishery ²³	x	✓	The Nickol Bay Prawn Managed Fishery management area overlaps the PAA and EMBA. The fishery uses demersal trawl gear to target several prawn species in Nickol Bay. Fishing effort in 10 NM graticular reporting blocks overlapping the EMBA (but not the PAA) has been recorded within the last five years. Accordingly, Woodside considers it a possibility that interactions with the fishery may occur within the EMBA.
North Coast Shark Fishery	x	x	The WA North Coast Shark Fishery management boundary includes waters between 114°06'E (approximately Onslow) to 123°45'E (Eighty Mile Beach) and extends to approximately the 200 m isobath. In 2008, the WA North Coast Shark Fishery's Wildlife Trade Operation approval under the EPBC Act was revoked because a formal management plan had not been finalised (Patterson et al., 2019). Therefore, no vessels are active in the fishery. While there is an overlap with the WA North Coast Shark Fishery management area, Woodside considers there to be no potential for interaction with fishers within the Operational Area.
Onslow Prawn Managed Fishery	x	✓	The Onslow Prawn Managed Fishery overlaps the PAA and EMBA. The fishery uses demersal trawl gear to target several prawn species in coastal waters off Onslow. Fishing effort in 10 NM graticular reporting blocks overlapping the EMBA (but not the PAA) has been recorded within the last five years. Accordingly, Woodside considers it a possibility that interactions with the fishery may occur in the EMBA.
Pearl Oyster Managed Fishery	x	x	The Pearl Oyster Managed Fishery management area overlaps the PAA and EMBA (specifically Zone 1 of the fishery). The fishery is diver-based and typically restricted to relatively shallow coastal waters (< 30 m). Most fishing effort occurs off the Kimberley coast around Broome. No fishing activity has occurred within the EMBA within the last five years. Accordingly, Woodside considers there to be no potential for interaction with this fishery and the Petroleum Activities Program.
Pilbara Crab Managed Fishery	✓	✓	The Pilbara Crab Managed Fishery management area overlaps the PAA and the EMBA. The fishery targets blue swimmer crabs in coastal waters using baited pots. Fishing effort in 10 NM graticular reporting blocks overlapping the EMBA and PAA (trunkline operational area) has been recorded within the last five years.

²³ Nickol Bay Prawn Managed Fishery has a 10nm CAES block showing fishing effort from up to 3 vessels in the 2017-18 season overlapping the PAA. However, as the fishery management area does not overlap the PAA, it is inferred that fishing activities may occur adjacent but not within the PAA boundary.

			Accordingly, Woodside considers it a possibility that interaction with the fishery may occur in the PAA and EMBA.
Pilbara Fish Trawl (Interim) Managed Fishery	✓	✓	The Pilbara Fish Trawl (Interim) Managed Fishery management area overlaps the PAA and the EMBA. The fishery uses demersal trawl gear to target finfish in continental shelf waters (typically < 150 m). Fishing effort in 60 NM graticular reporting blocks overlapping the EMBA and PAA (trunkline operational area) has been recorded within the last five years. Accordingly, Woodside considers it a possibility that interactions with the fishery may occur within the PAA and EMBA.
Pilbara Line Fishery	✓	✓	The Pilbara Line Fishery management area overlaps the PAA and EMBA. The fishery uses baited lines to target finfish in continental shelf waters (typically < 150 m). Fishing effort in 60 NM graticular reporting blocks overlapping the EMBA and PAA (trunkline operational area) has been recorded within the last five years. Accordingly, Woodside considers it a possibility that interactions with the fishery may occur within the PAA and the EMBA.
Pilbara Trap Managed Fishery	✓	✓	The Pilbara Trap Managed Fishery management area overlaps the PAA and the EMBA. The fishery uses baited traps to target finfish in continental shelf waters (typically < 150 m). Fishing effort in 60 NM graticular reporting blocks overlapping the EMBA and PAA (trunkline operational area) has been recorded within the last five years. Accordingly, Woodside considers it a possibility that interactions with the fishery may occur within the PAA and the EMBA.
South West Coast Salmon Managed Fishery	x	x	The South West Coast Salmon Fishery management area overlaps the PAA and EMBA. No fishing effort has been recorded in the PAA or EMBA in the last five years. The target species is temperate and does not occur within the EMBA. Accordingly, Woodside considers there to be no potential for interaction with this fishery and the Petroleum Activities Program.
Specimen Shell Managed Fishery	✓	✓	The Specimen Shell Managed Fishery management area overlaps the PAA and the EMBA. The fishery occurs state-wide and is primarily diver-based in shallow coastal waters (< 30 m). Fishing effort in 10 NM graticular reporting blocks overlapping the EMBA and PAA (trunkline operational area) has been recorded within the last five years. Accordingly, Woodside considers it a possibility that interactions with the fishery may occur within the PAA and the EMBA.
West Coast Deep Sea Crustacean Managed Fishery	✓	✓	The West Coast Deep Sea Crustacean Managed Fishery management area overlaps the PAA and EMBA. The fishery targets several species of crab using baited pots, with fishing effort concentrated between 500 m and 800 m water depth. Effort is concentrated off the Shark Bay coast. Fishing effort in 10 NM graticular reporting blocks overlapping the EMBA (but not the PAA) has been recorded within the last five years. Accordingly, Woodside considers it a possibility that interactions with the fishery may occur in the EMBA.

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

West Coast Rock Lobster Fishery	x	x	<p>The Western Rock Lobster Fishery management area overlaps the EMBA, but not the PAA. The fishery uses baited pots to target western rock lobster in continental shelf waters. No fishing effort has been recorded within the EMBA or PAA in the last five years.</p> <p>Accordingly, Woodside considers there to be no potential for interaction with this fishery and the Petroleum Activities Program.</p>
Western Australian Sea Cucumber Fishery	x	✓	<p>The Western Australian Sea Cucumber Fishery is permitted to fish throughout WA waters. The fishery is diver- and wader-based and typically restricted to shallow coastal waters (< 30 m). Fishing effort in 10 NM graticular reporting blocks overlapping the EMBA (but not the PAA) has been recorded within the last five years.</p> <p>Accordingly, Woodside considers it a possibility that interactions with the fishery may occur within the EMBA.</p>
Charter based commercial operators			
Tour Operators	✓	✓	<p>Fishing Tour Operators are permitted to operate across WA state waters and are required to report monthly logbook records of client fish catches. FishCube data reports fishing effort within 10 NM graticular reporting blocks the EMBA and PAA (trunkline operational area).</p> <p>Accordingly, Woodside considers it a possibility that interactions with tour operators will occur in both the PAA and EMBA.</p>

4.10.2 Traditional Fisheries

There are no traditional or customary fisheries within the PAA, as these are typically restricted to shallow coastal waters and/or areas with structures such as reefs. However, it is recognised that the Dampier Archipelago, Barrow Island, Montebello Islands, Exmouth, Ningaloo Reef and the adjacent foreshores have a known history of fishing when areas were occupied (as from historical records).

Areas that are covered by registered native title claims are likely to practice Aboriginal fishing techniques at various sections of the WA coastline (see Section 4.9.3).

4.10.3 Tourism and Recreation

The Offshore Operational Area is located far from most tourism activities in the NWMR. However, the Trunkline Operational Area is in the vicinity of the Dampier Archipelago where tourism activities occur. Recreational fishing in the North West Shelf Province is mainly concentrated around the coastal waters and islands (including Ningaloo Marine Park, North West Cape area, the Montebello Islands, and other islands and reefs in the region) (DoF, 2011). It has grown substantially with the expanding regional centres and increasing residential and fly in/fly out work force, particularly in the Pilbara region. Occasional recreational fishing occurs at Rankin Bank and Glomar Shoals (located about 114 km north-west and 84 km north of the Trunkline Operational Area, respectively). The Montebello Islands (approximately 32 km from the Trunkline Operational Area) are the next closest location for tourism, with some charter boat operators taking visitors to these remote islands. Charter based commercial operators are active within the PAA and EMBA, as shown in Table 4-27.

Dolphin and turtle watching tours may occur near the Dampier Archipelago within the EMBA. Cruise ships operate within the EMBA. Dive sites are located in a number of locations within the EMBA including Montebello Islands, and Rowley Shoals.

It is acknowledged that there are growing tourism and recreational sectors in WA. These sectors have expanded in area over the last couple of decades. Potential for growth and further expansion in tourism and recreational activities in the Pilbara and Gascoyne regions is recognised, particularly with the development of regional centres and a workforce associated with the resources sector (Gascoyne Development Commission, 2012).

4.10.4 Commercial Shipping

The Australian Maritime Safety Authority (AMSA) has introduced a network of marine fairways across the NWMR off WA to reduce the risk of vessel collisions with offshore infrastructure. Whilst none of these fairways intercept the Offshore Operations Area, a number of the fairways intersect with the Trunkline Operational Area (Figure 4-23).

Commercial shipping traffic is high within the NWMR, with vessel activities including commercial fisheries, tourism such as cruises, international shipping and oil and gas operations. There are 12 ports adjacent to the NWMR, including the major ports of Dampier, Port Hedland and Broome, which are operated by their respective port authorities. The State waters adjacent to the easternmost point of the Trunkline Operational Area falls within the boundaries of the Pilbara Ports Authority, within which the ports of Dampier and Port Hedland lie. Vessel tracking data suggest shipping is concentrated to the east of the Trunkline Operational Area where increased vessel traffic will be associated with ports servicing the resource industry at Barrow Island, Onslow and Dampier as detailed in Section 12.5 of Appendix L: Woodside Master Existing Environment.

The Port of Dampier overlaps the EMBA through the Dampier Archipelago and is a major industrial port in the north-west of WA. It is currently one of the world's largest bulk export ports by tonnage and services the petrochemical, salt, iron ore and natural gas export industries. It is also the departure point for day cruises through the Dampier Archipelago.

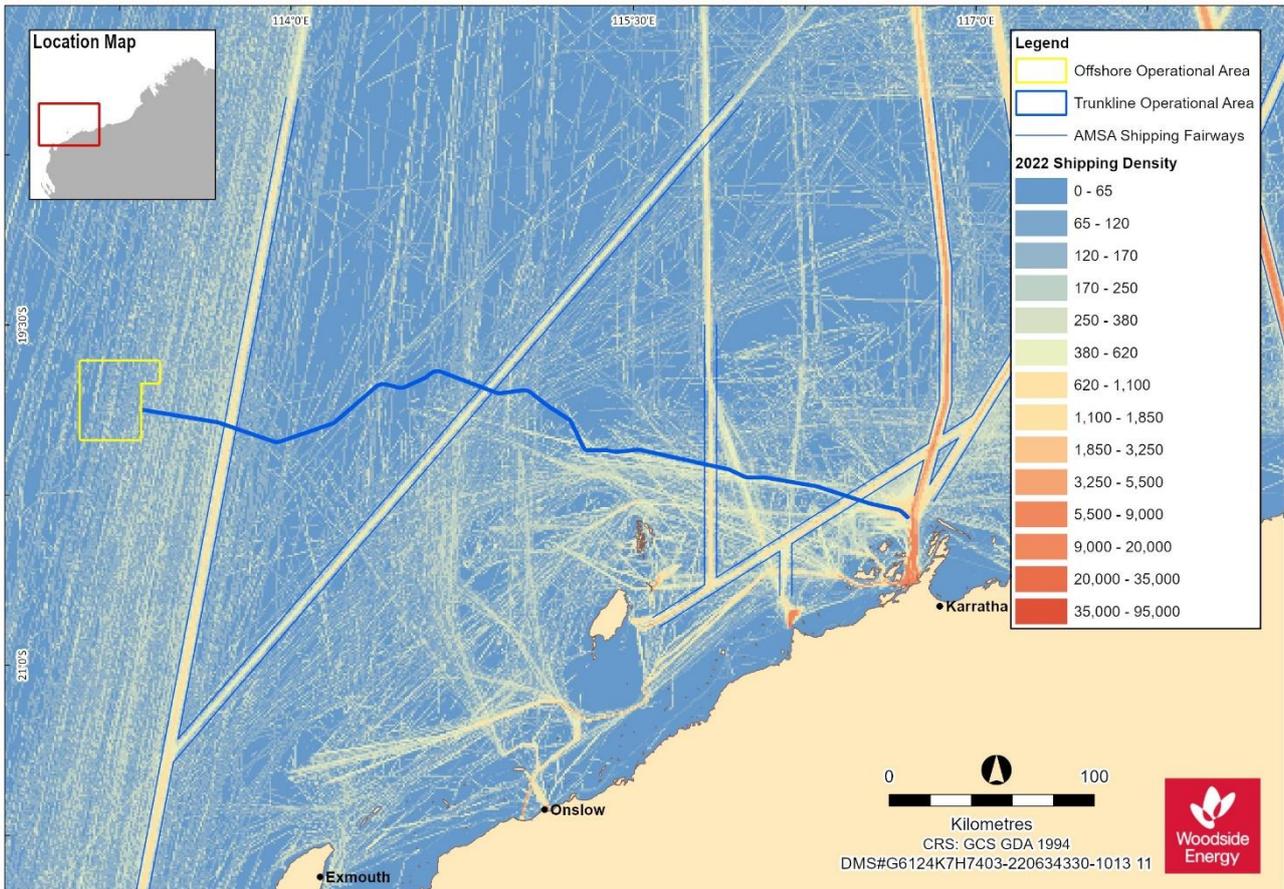

Figure 4-23: Vessel density map for the Petroleum Activities Area, derived from Australian Maritime Safety Authority satellite tracking system data

Note: Vessels include cargo, LNG tanker, passenger vessels, support vessels, and others/unnamed vessels

4.10.5 Oil and Gas

The PAA is located in the Exmouth Plateau area of the Northern Carnarvon Basin. The Trunkline Operational Area intersects several existing oil and gas export trunklines and several facilities are located within 50 km of the Trunkline Operational Area (Table 4-28 and Figure 4-24).

Table 4-28: Other oil and gas facilities located within 50 km of the Petroleum Activities Area

Facility Name and Operator	Distance and direction from PAA to facility
Pluto Platform – Woodside	2 km north
Wheatstone Platform – Chevron	10 km north
Stag Platform – Jadestone	5 km south
Reindeer Platform – Santos	15 km north
Goodwyn Platform – Woodside	48 km north
Campbell Platform and Sinbad platform (Varanus hub) – Santos	50 km south
Reindeer Trunkline – Santos	Crosses at KP75
Wheatstone Trunkline – Chevron	Crosses at KP191
Julimar-Brunello Flowlines and Umbilical	Crosses at KP192
Pluto Flowlines and Umbilical	Crosses at KP194
Pyxis Flowline and Umbilical	Crosses at KP212

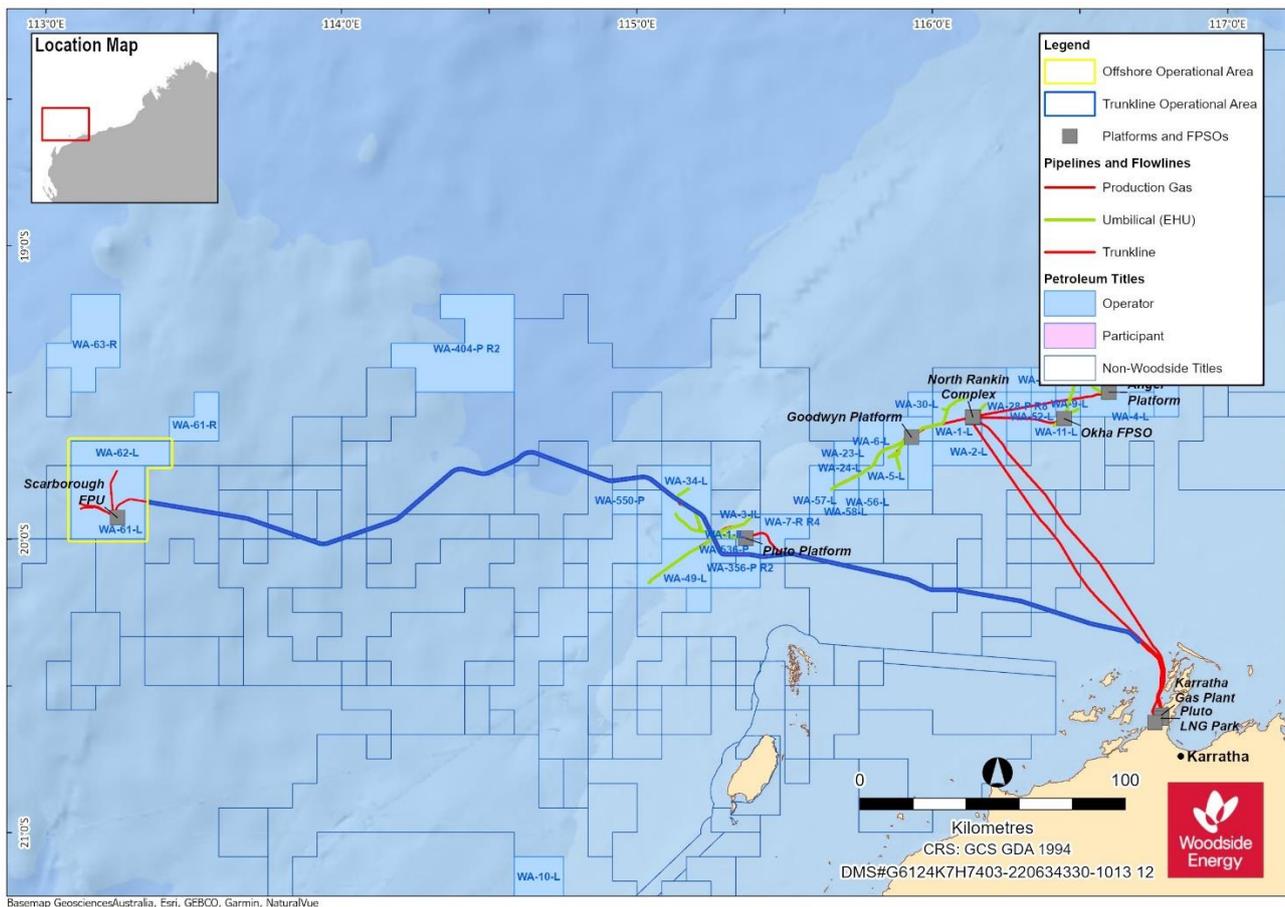

Figure 4-24: Oil and gas titles and infrastructure relative to the Petroleum Activities Area

4.10.6 Submarine Communications Infrastructure

The PAA overlaps a variety of communication infrastructure, or submarine cables (Table 4-29).

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

Table 4-29: Communications Infrastructure located within 50 km of the Petroleum Activities Area

Communications Infrastructure (submarine cables)	Distance and direction from PAA to facility
Darwin Jakarta Singapore Cable (DJSC)	Overlaps Offshore Operational Area
Scarborough Fibre Optic Cable	Overlaps Offshore Operational Area
Chevron Fibre Optic Cable Route	Overlaps Trunkline Operational Area
Woodside Fibre Optic Cable Route	46.5 km North East

Source: submarine cable locations sourced from Vocus and Telstra.

The Darwin Jakarta Singapore Cable (DJSC) System is a 1,000 km fibre optic cable that connects the Australia Singapore Cable to the North West Cable System. The DJSC System is owned and operated by Vocus Communications. The DJSC overlaps the Offshore Operational Area (specifically in WA-62-L Permit Area). An extension (Scarborough Fibre Optic Cable) of the cable has been installed to connect the SCA FPU with the existing DJSC System. The extension will be installed prior to commencement of the Scarborough Offshore Facility and trunkline activities detailed in Section 3. Therefore, potential interaction and impacts to cable installation are not considered or assessed further in the EP.

4.10.7 Defence

There are designated Department of Defence practice areas in the offshore marine waters off Ningaloo Reef and the North West Cape in the EMBA. The PAA lies within the northern tip of one of these defence training areas, the North West Exercise Area (NWXA) accessed by Royal Australian Air Force (RAAF) Base Learmonth (Figure 4-25). The Learmonth Air Weapons Range (AWR) practice area is located approximately 70 km south of the Offshore Operational Area. The Trunkline Operational Area (from KP 120) overlaps the Defence Training Area associated with the Learmonth RAAF base. The closest site where unexploded ordinance is known to occur is east of Montebello Islands, approximately 28 km south of the Trunkline Operational Area and within the EMBA. The closest site to the Offshore Operational Area is Anchor Island, located approximately 195 km south-east of the Offshore Operational Area, within the EMBA. Defence areas overlapping the PAA are presented in Figure 4-25.

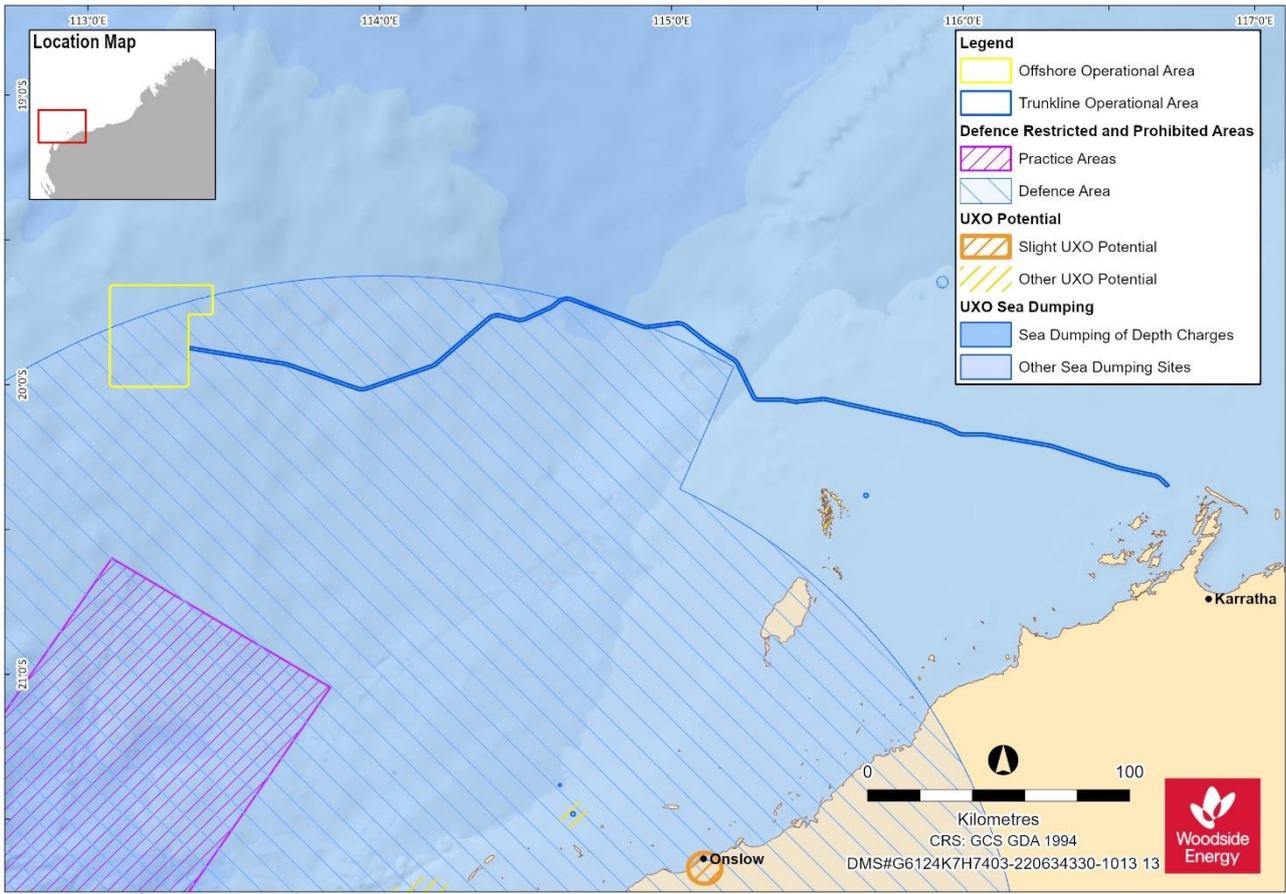

Figure 4-25: Defence Restricted and Prohibited areas relative to the Petroleum Activities Area

5 CONSULTATION

5.1 Summary

Woodside consults relevant persons in the course of preparing an Environment Plan (EP) in accordance with regulation 25 of the Environment Regulations. (In this Section, references to 'regulations' are to regulations of the Environment Regulations, unless otherwise stated).

The consultation process is designed to identify relevant persons and give them with sufficient information and a reasonable period to allow them to make an informed assessment of the possible consequences of the proposed activity on their functions, interests or activities. This enables Woodside to assess the merits of objections or claims about the adverse impact of each activity to which the EP relates that are received from relevant persons and for Woodside to adopt appropriate measures (if any) in response to those objections or claims so that the activity is carried out in a manner by which the environmental impacts and risks of the activity will be reduced to as low as reasonably practicable (ALARP) and will be of an acceptable level.

Consultation is informed by both the Environment Regulations and the findings of relevant Courts, including the Full Federal Court in the *Santos NA Barossa Pty Ltd v Tipakalippa* [2022] FCAFC 193 (Tipakalippa Appeal) (see Section 5.2 and 5.5.1) and *Munkara v Santos NA Barossa Pty Ltd (No 3)* [2024] FCA 9 (Munkara Case).

For this EP, Woodside has considered both the Operational Areas and the broader EMBA in undertaking consultation (see further discussion in Section 5.2). The broadest extent of the EMBA has been determined by reference to the highly unlikely event of a hydrocarbon release resulting from activities in the Operational Area (see Section 4). Consultation beyond the defined EMBA is too remote, would mean persons with interests are not reasonably capable of ascertainment and would mean consultation is not workable (*Tipakalippa* para [88]). Woodside has also, where relevant, considered, assessed and proactively responded to historical feedback received from stakeholders on the Scarborough OPP and prior Scarborough EPs, as that feedback relates to Scarborough operations.

Woodside's consultation methodology is divided into two parts:

- The first section (Section 5.2 to 5.5) provides an overview of Woodside's consultation methodology for its EPs, including how we apply regulation 25(1) to identify relevant persons.
- The second section (Section 5.6 to 5.7) details Woodside's approach to accepting feedback and assessment of the merits of each objection or claim about the adverse impact of each activity to which the EP relates, and engaging in ongoing consultation for this EP.

Woodside undertook a tiered consultation approach for this EP, building on the existing consultation approach with further measures due to the nature and scale of the activity outlined in the EP. The approach is proactive, extended, has enabled self-identification, and has raised broad awareness of Woodside's activities related to this EP and the Scarborough Project (see Appendix F: Consultation).

Woodside's consultation record is at Appendix F: Consultation and includes a summary of the:

- assessment and identification of relevant persons
- consultation information provided to relevant persons, feedback received, Woodside's assessment of the merits of objections or claims about the adverse impact of each activity to which this EP relates and Woodside's response to relevant persons and other stakeholders Woodside chose to consult
- engagement with persons or organisations that Woodside chose to contact who are not relevant persons for the purposes of regulation 25(1) (see Section 5.3.7)
- opportunities provided to persons or organisations to participate in consultation.

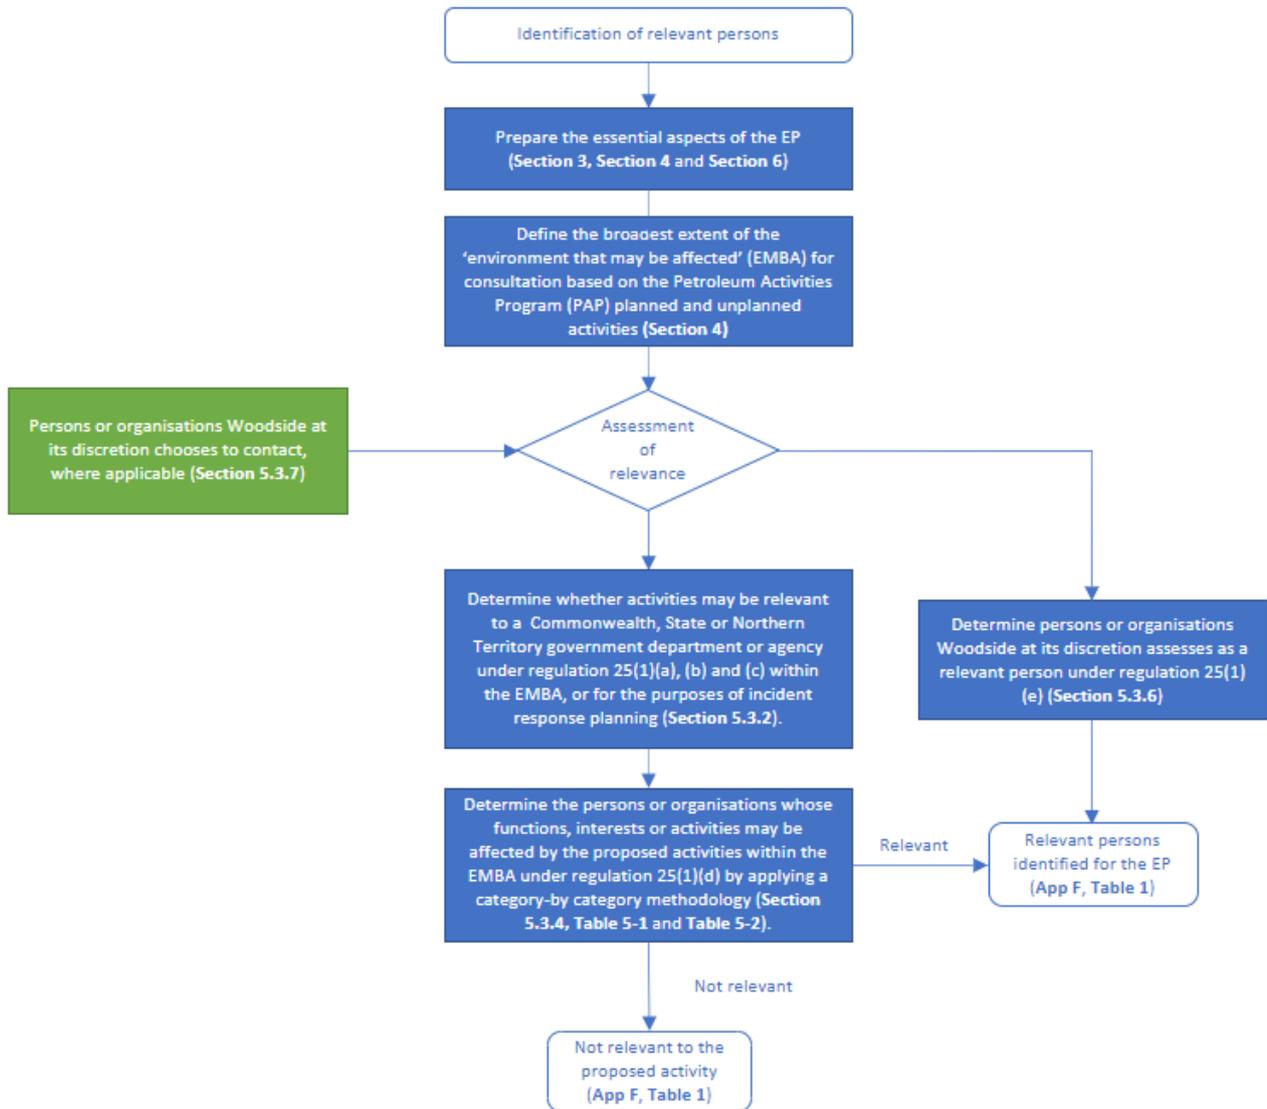

Figure 5-1: Overview of Woodside’s methodology to identify relevant persons

5.2 Consultation – General Context

Woodside has a portfolio of quality oil and gas assets and more than 30 years of operating experience. We have a strong history of working with local communities, the relevant regulators and a broad range of persons and organisations, to better understand the potential risks and impacts associated with our proposed activities and to develop appropriate measures to manage them.

The length of time that we have operated in Commonwealth and State waters, and the history of continued engagement with a wide range of persons and organisations, enables Woodside to develop an extensive consultation list to inform its consultation process. This consultation list is not used as a definitive list of persons to consult but, rather, assists Woodside as an input to its understanding of relevant persons with whom to consult on a Petroleum Activities Program. The information in the consultation list has been captured from years of experience: it contains insights relating to the type of information particular persons or organisations want to receive during consultation, the appropriate method of consultation for relevant persons and includes appropriate contact details, which are reviewed and updated periodically.

Woodside acknowledges NOPSEMA's *Guideline on Consultation in the course of preparing an environment plan* (12 May 2023) as well as judicial guidance in the *Tipakalippa Appeal* on the intent of consultation, as follows:

- At paragraph 54 of the appeal decision: ... *provide a basis for NOPSEMA's considerations of the measures, if any, that a titleholder proposes to take or has taken to lessen or avoid the deleterious effect of its proposed activity on the environment, as expansively defined.*
- At paragraph 89 of the appeal decision: ... *its purpose is to ensure that the titleholder has ascertained, understood and addressed all the environmental impacts and risks that might arise from its proposed activity. Consultation facilitates this outcome because it gives the titleholder an opportunity to receive information that it might not otherwise have received from others affected by its proposed activity. Consultation enables the titleholder to better understand how others with an objective stake in the environment in which it proposes to pursue the activity perceive those environmental impacts and risks. As the Regulations expressly contemplate, it enables the titleholder to refine or change the measures it proposes to address those impacts and risks by taking into account the information acquired through the consultations. Objectively, the scheme intends that this is likely to improve the minimisation of environmental impacts and risks from the activity.*

The *Tipakalippa Appeal* and *Munkara Case* have also been further considered in the context of specific methods for consultation with First Nations' relevant persons (Section 5.5.1).

To undertake consultation, Woodside has developed a methodology for identifying relevant persons in accordance with regulation 25(1) (Section 5.3). This methodology is consistent with NOPSEMA's *Guideline* and demonstrates that, to meet the requirements of regulation 34 (criteria for EP acceptance) when preparing the EP, Woodside understands:

- our planned activities in the Operational Area, being the area in which our planned activities are proposed to occur (see Section 3.3)
- the geographical extent to which the environment may be affected (EMBA) by risks and impacts from our activities (unplanned) (identified in Section 4.1 and assessed in Section 6.7.13).

Woodside has undertaken consultation in the course of preparing this EP in compliance with regulation 25, which requires a titleholder to:

- consult with each of the following (a **relevant person**) in the course of preparing an EP:
 - each Commonwealth, State or Northern Territory agency or authority to which the activities to be carried out under the EP may be relevant
 - if the plan relates to activities in the offshore area of a State – the Department of the responsible State Minister
 - if the plan relates to activities in the Principal Northern Territory offshore area – the Department of the responsible Northern Territory Minister
 - a person or organisation whose functions, interests or activities may be affected by the activities to be carried out under the EP
 - any other person or organisation that the titleholder considers relevant (regulation 25(1))
- give each relevant person sufficient information to allow the relevant person to make an informed assessment of the possible consequences of the activity on their functions, interests or activities (regulation 25(2))
- allow a relevant person a reasonable period for the consultation (regulation 25(3))
- tell each relevant person that the titleholder consults with, that the relevant person may request that particular information it provides in the consultation not be published and any information subject to such a request is not to be published (regulation 25(4)).

Further, Woodside seeks to carry out consultation in a manner that:

- is consistent with the principles of ecologically sustainable development (ESD) set out in section 3A of the EPBC Act – see Section 2
- is intended to reduce the environmental impacts and risks from the activity to ALARP and an acceptable level (regulation 4)
- is intended to minimise harm to the relevant person and the environment from the proposed petroleum activities and to enable Woodside to consider measures that may be taken to mitigate the potential adverse environmental impacts from the petroleum activity
- provides opportunities for relevant persons to provide feedback throughout the life of the EP through its ongoing consultation process (refer to Section 5.7 and Section 7.10.5)
- is collaborative; Woodside respects that, for a relevant person, consultation is voluntary. Where the relevant person seeks to engage, Woodside engages with the relevant person with the aim of seeking genuine and meaningful two-way dialogue.

An overview of Woodside's consultation approach is outlined at Figure 5-2.

5.3 Identification of Relevant Persons for Consultation

5.3.1 Regulations 25(1)(a), (b) and (c)

The relevant inquiry for determining relevant persons under regulations 25(1)(a) and (b) is whether the activities to be carried out under the EP may be relevant to one of the government departments or agencies in those regulations. The government departments and agencies relevant to the EP are listed in Appendix F, Table 1. In accordance with Regulation 25(1)(b), Woodside consults with the Department of the relevant State Minister.

5.3.2 Identification of Relevant Persons under Regulations 25(1)(a), (b) and (c)

Woodside's methodology for identifying relevant persons under regulations 25(1)(a), (b) and (c) is as follows:

- Woodside considers the defined responsibilities of each of the departments and agencies to which the activities to be carried out in the EMBA under the EP may be relevant. This list of relevant departments and agencies is formulated by reference to the responsibilities of the government departments, as set out on their websites, in NOPSEMA's *GL1887 – Consultation with Commonwealth agencies with responsibilities in the marine area guideline* (January 2024), which describes where the Department is a relevant agency under the Environment Regulations, as well as experience and knowledge that Woodside has gained from years of operating. This list is revised from time to time, for example, for the purposes of accommodating government restructures, renaming of departments, shifting portfolios and/or to account for new agencies that might arise.
- Woodside has categorised government department or agency groups as:

Government departments / agencies – marine	Agencies with legislated responsibilities for use of the marine environment.
Government departments / agencies – environment	Agencies with legislated responsibilities for the protection of the marine environment.
Government departments / agencies – industry	The legislated Department of the responsible Commonwealth, State or Northern Territory Minister for Industry.

- Woodside considers each of the responsibilities of the departments and agencies, determining whether those responsibilities overlap with potential risks and impacts specific to the PAP in the EMBA. The assessment is both activity and location based.
- Woodside acknowledges the roles and responsibilities of government departments and agencies acting on behalf of various industry participants. For example, AMSA – Marine Safety is responsible for the safety of vessels and the seafarers who are operating in the domestic commercial shipping industry; and AHO is responsible for maritime safety and Notices to Mariners. To undertake activities in the Operational Area in a manner that prevents a substantially adverse effect on the potential displacement of marine users, Woodside therefore consults AMSA – Marine Safety and AHO on its proposed activities. Woodside considers each of the responsibilities of the departments and agencies and determines those that would either be involved in the incident response itself or in relation to the regulatory or decision-making capacity with respect to planning for the unlikely event of a worst-case hydrocarbon release incident response specific to the Operational Area. Feedback received, if any, is assessed in accordance with the intended outcome of consultation.
- The list of government departments and agencies assessed as relevant is set out in Appendix F: Consultation, Table 1.

- Feedback received, if any, is assessed in accordance with the intended outcome of consultation and summarised at Appendix F, Table 2 and Table 3 as appropriate to the relevance assessment.

Woodside does not consult with departments or agencies with interests that do not overlap with risks and impacts specific to the proposed petroleum activity in the EMBA or would not be involved in incident response planning.

5.3.3 Regulation 25(1)(d)

To identify a relevant person for the purposes of regulation 25(1)(d), the meaning of “functions, interests or activities” needs to be understood. In regulation 25(1)(d), the phrase “functions, interests or activities” should be construed broadly and consistently with the objects of the Environment Regulations (regulation 4) and the objects of the EPBC Act (section 3A).

In developing its methodology for consultation, Woodside acknowledges the guidance below from NOPSEMA’s GL2086 – *Consultation in the course of preparing an environment plan guideline (May 2023)*:

Functions	Refers to a power or duty to do something.
Interests	Conforms to the accepted concept of ‘interest’ in other areas of public administrative law and includes any interest possessed by an individual whether or not the interest amounts to a legal right or is a proprietary or financial interest or relates to reputation.
Activities	Broader than the definition of ‘activity’ in regulation 5 of the Environment Regulations and is likely be directed to what the relevant person is already doing.

Woodside’s methodology for determining ‘relevant persons’ for the purpose of regulation 25(1)(d) includes consideration of:

- whether a person or organisation has functions interests or activities that overlap with the Operational Area and EMBA
- whether a person or organisation’s functions, interests or activities may be affected by Woodside’s proposed planned or unplanned activities.

5.3.4 Identification of Relevant Persons under Regulation 25(1)(d)

Relevant persons under regulation 25(1)(d) are defined as a person or organisation whose functions, interests or activities may be affected by the activities to be carried out under the EP. In identifying relevant persons, Woodside considers:

- the planned activities to be carried out under the EP (described in Section 3)
- the EMBA by unplanned activities (identified in Section 4 and assessed in Section 6.7.13).

To identify relevant persons who fall within regulation 25(1)(d), Woodside adopts the following methodology, and then undertakes consultation with relevant persons.

As a general proposition, Woodside assesses whether a person or organisation is a relevant person having regard to:

- whether a person or organisation has functions, interests or activities that overlap with the Operational Area and EMBA
- whether a person or organisation's functions, interests or activities may be affected by Woodside’s proposed planned or unplanned activities to be carried out under the EP.

This assessment will include applying judgement, knowledge and considering available, relevant literature.

To assist in identifying the full range of relevant persons, Woodside considers the impacts and risks associated with its proposed activities and considers the broad categories of relevant persons who may be affected by the activities to be carried out under the EP. The broad categories are identified in Table 5-1 and identification methodology applied as set out in Table 5-2.

For this EP, Woodside also considered feedback from relevant persons on other Scarborough Energy Project EPs, and if that feedback relates to this EP.

The list of those persons or organisations assessed as relevant persons or organisations Woodside separately chose to contact is set out in Appendix F: Consultation, Table 1.

Feedback received, if any, is assessed in accordance with the intended outcome of consultation and applying the categories of relevant persons methodology outlined in Table 5-2, as appropriate.

Feedback from relevant persons is summarised at Appendix F: Consultation, Table 2. Feedback from persons assessed as “not relevant” but whom Woodside chose to contact, or self-identified and Woodside assessed as “not relevant”, are summarised at Appendix F: Consultation (Table 3).

Table 5-1: Categories of relevant persons

Category	Explanation
Commercial fisheries (Commonwealth and State) and peak representative bodies	Commonwealth or State Commercial Fishery with a fishery management plan recognised under the <i>Commonwealth Fisheries Management Act 1991 (Cth)</i> and the <i>Western Australian Fish Resources Management Act 1994 (WA)</i> , which may be amended from time to time. Commonwealth peak fishery representative bodies are identified by AFMA. WAFIC is the peak representative body for state fishers in Western Australia.
Recreational marine users and peak representative bodies	Charter boat, tourism and dive operators identified by DPIRD specific to the location of the proposed activity. Representative bodies are the recognised peak organisation(s) for recreational marine users.
Titleholders and Operators	Registered holder of an offshore petroleum title or GHG title under the <i>OPGGGS Act</i> and associated regulations.
Peak industry representative bodies	Recognised peak organisation(s) for the oil and gas sector.
Traditional Custodians (individuals and/or groups/entity)	Traditional Custodians are First Nations Australians with cultural rights and interests or cultural functions or who perform cultural activities over particular lands and waters. Where a First Nations person, group or entity self-identifies and asserts cultural rights, functions, interests or activities they will be considered under the definition of Traditional Custodian for the purpose of this EP (as appropriate).
Nominated Representative Corporations	Nominated representative corporations are Traditional Custodians' nominated representative institutions such as Prescribed Bodies Corporate (PBC). PBCs are established under the <i>Native Title Act 1993 (Cth)</i> by Traditional Custodians to represent their entire Traditional Custodian group (defined broadly by reference to descents from an ancestor set who were known to be the Traditional Custodians at the time of European colonisation) and their interests including, among other things, management and protection of cultural values.
Native Title Representative Bodies	A Representative Aboriginal/Torres Strait Islander Bodies (RATSIB) is a regional organisation appointed under the <i>Native Title Act 1993 (Cth)</i> with prescribed functions, set out in Part 11 of the <i>Native Title Act 1993 (Cth)</i> , which relate to: facilitation and assistance; certification; dispute resolution; notifications; agreement making. They are also known, and referred to here, as Native Title Representative Bodies.
Historical heritage groups or organisations	Legislated or government enlisted groups or organisations responsible for the management of marine heritage.

Category	Explanation
Local government and elected Parliamentary representatives and recognised local community reference/liaison groups or organisations	Local government body formed under the <i>Local Government Act 1995</i> (WA) and elected Parliamentary representatives which are responsible for representing the local community. Recognised local community reference or liaison group or organisation in relation to oil and gas matters.
Other non-government groups, organisations or individuals	Non-government organisation with public website material targeting the proposed activity. Individual who demonstrates the proposed activity could potentially impact their interests, functions or activities. Non-government organisation or individual who has provided feedback relevant to this EP on the OPP, and other Scarborough Energy Project EPs.
Research institutes and local conservation groups or organisations	Research institutes are government or private institutions that conduct marine or terrestrial research. Local conservation groups are local non-government organisation that regularly conduct conservation activities focused on the local environment or wildlife.

Table 5-2: Methodology for identifying relevant persons within the environment that may be affected undertaken under regulation 25(1)(d) – by category

Category	Relevant person identification methodology
Commercial fisheries (Commonwealth and State) and peak representative bodies	<p>Woodside assesses relevance for commercial fisheries (Commonwealth and State) and their representative bodies using the following next steps in its methodology:</p> <ul style="list-style-type: none"> Defining the parameters having regard to timing, location and duration of the proposed petroleum activity. Confirming whether the EMBA overlaps with the fisheries management area (i.e., the spatial area the fishery is legally permitted to fish in) (see Section 4.10.1). Woodside acknowledges WAFIC’s consultation guidance²⁴, that Titleholders develop separate consultation strategies for significant unplanned events (for example an oil spill) where titleholders can demonstrate the likelihood of such events occurring is extremely low. WAFIC’s guidance is that consultation on unplanned events resulting in an emergency scenario should only be undertaken if an incident occurs (see Appendix I: Oil Pollution First Strike Plan) For Commonwealth and State commercial fisheries, Woodside assesses the potential spatial and temporal extent for interaction with the fishery by reviewing AFMA, ABARES and DPIRD FishCube data within the Operational Area and EMBA (see Section 4.10.1). <p>Assessment of relevance:</p> <ul style="list-style-type: none"> State commercial fisheries that have been assessed as having a potential for interaction within the Operational Area or EMBA (see Section 4.10.1) are assessed as relevant to the proposed activity. However, to avoid over consulting and as requested in WAFIC’s guidance, Woodside only consults individual licence holders based on WAFIC’s advice. Woodside also utilises WAFIC’s consultation service whereby WAFIC: <ul style="list-style-type: none"> directly consults fishery licence holders that are assessed as having a potential for interaction in the Operational Area

24 Consultation Approach for Unplanned Events - WAFIC

Category	Relevant person identification methodology
	<ul style="list-style-type: none"> ○ consults fisheries that are assessed as having a potential for interaction in the EMBA only in the event of an unplanned emergency scenario. • Commonwealth commercial fisheries that have been assessed as having a potential for interaction within the Operational Area or EMBA (see Section 4.10.1) are assessed as relevant to the proposed activity. • If Woodside has identified that a Commonwealth or State fishery is a relevant person, then Woodside also consults the fisheries relevant representative body. For example, WAFIC represents the interests of State fisheries in Western Australia. If a State fishery is identified as relevant, Woodside would also identify WAFIC as relevant. Recognised Commonwealth fishery representative bodies are identified by AFMA via its website. WAFIC is the only recognised State fishery representative body.
<p>Recreational marine users and peak representative bodies</p>	<p>Woodside assesses relevance for recreational marine users and peak representative bodies using the following next steps in its methodology:</p> <ul style="list-style-type: none"> • Using Woodside knowledge and operating experience, applying knowledge of recreational marine users in the area. This assessment is both activity and location based. • Defining the parameters having regard to timing, location and duration of the proposed petroleum activity. • Assessing the potential spatial and temporal extent for interaction with recreational marine users by reviewing DPIRD FishCube data to assess whether there has been activity within the EMBA in the past 5 years. <p>Assessment of relevance:</p> <ul style="list-style-type: none"> • Recreational marine users that have been active in the past 5 years within the EMBA are assessed as relevant to the proposed activity. Woodside is provided with the contact details of charter, boat tourism and dive operators specific to the region of the EMBA by DPIRD to consult with the relevant persons. • If Woodside has identified recreational marine users as relevant persons, then Woodside also consults identified peak recreational marine user representative bodies. For example, Recfishwest represents the interests of recreational fishers. These representative bodies are identified via Woodside's existing consultation list, which is updated as appropriate via advice from known groups and DPIRD.
<p>Titleholders and Operators</p>	<p>Woodside assesses relevance for other Titleholders and operators using the following steps in its methodology:</p> <ul style="list-style-type: none"> • Using GPInfo to determine overlap with other Titleholders' or Operators' permit areas within the EMBA. • Using Woodside knowledge and operating experience, applying knowledge of other operators in the area. • Woodside produces a map showing the outcome of this assessment. <p>Assessment of relevance:</p> <ul style="list-style-type: none"> • Titleholders and Operators whose permit areas are identified as having an overlap within the EMBA are assessed as relevant.
<p>Peak industry representative bodies</p>	<p>Woodside assesses relevance for peak industry representative bodies using the following steps in its methodology:</p> <ul style="list-style-type: none"> • Review of peak industry representative bodies responsibilities that Woodside actively participates in, with consideration of overlap between industry focus area and Woodside's proposed activities within the EMBA. • Review of Woodside's existing consultation list.

Category	Relevant person identification methodology
	<ul style="list-style-type: none"> Website search to identify whether any additional peak industry representative bodies have been created whose responsibilities may overlap with Woodside's proposed activities within the EMBA. <p>Assessment of relevance:</p> <ul style="list-style-type: none"> Peak industry representative bodies whose responsibilities are identified as having an overlap with Woodside's proposed activities within the EMBA are assessed as relevant.
<p>Traditional Custodians (individuals and/or groups/entity) and Nominated Representative Corporations</p>	<p>Consistent with its understanding of the matters discussed in Section 4.9, to identify Traditional Custodian groups or individuals, Woodside:</p> <ul style="list-style-type: none"> uses existing systems of recognition to identify First Nations groups who overlap or are coastally adjacent to the EMBA (for example, recognition provided under native title or cultural heritage legislation, or marine park management plans, or identification by other First Nations groups or entities) notifies and invites consultation with First Nations people through their nominated representative corporation (for example PBCs); or, in the case of native title and where appropriate, the Native Title Representative Body requests the nominated representative body to forward the notifications and invitations to consult to their members (members are individual communal rights holders; requests advice as to other First Nations groups or individuals that should be consulted advertises widely so as to invite self-identification and consultation by First Nations groups and individuals. <p>Further detail to Woodsides methodology is as follows.</p> <p>Woodside uses the databases of the National Native Title Tribunal:</p> <ul style="list-style-type: none"> to understand whether there are any Native Title Claims (historical or current) or determinations overlapping or coastally adjacent to the EMBA to understand whether there are any relevant Indigenous Land Use Agreements (ILUA), registered with the National Native Title Tribunal that overlap or are adjacent to the EMBA that may identify Traditional Custodians or representative bodies to contact regarding potential cultural values. <p>Where there is a positive determination of native title, contacting the PBC or, where their representative is a Native Title Representative Body, contacting the Native Title Representative Body.</p> <p>Where appropriate, contacting the relevant Native Title Representative Body to request a list of any First Nations groups asserting Traditional Custodianship over an area of coastline adjacent to the EMBA.</p> <p>Review of Commonwealth and State Marine Park Management Plans that overlap the EMBA which may identify Traditional Custodians or representative bodies to contact regarding potential cultural values.</p> <p>First Nations groups or individuals identified by a Traditional Custodian, nominated representative corporation, Native Title Representative Body.</p> <p>Request to the PBC to distribute Woodside consultation materials through its membership. Woodside is unable to contact this membership through any other means.</p> <p>Woodside has a number of public notification and information sharing processes by which individual Traditional Custodians can become aware of the proposed activity, its risks and impacts, and self-identify.</p> <p>Individuals that consider their functions, interests or activities may be affected by a proposed activity are provided an opportunity to self-identify for each EP. Woodside does not presume that self-identification for an activity, covered by another EP, automatically means that an individual/s functions, interests and activities may be affected by other activities where EMBAs overlap. This decision is for the individual to make. The public notification,</p>

Category	Relevant person identification methodology
	<p>information sharing, and consultation processes Woodside puts in place enables Traditional Custodians to become aware of proposed activities, assess risks and impacts to their values, and enable individuals to self-identify.</p> <p>Assessment of relevance:</p> <ul style="list-style-type: none"> Traditional Custodian groups, entities or individuals and Nominated Representative Corporations who are identified through the above methodology and overlap or are coastally adjacent to the EMBA are assessed as relevant.
Native Title Representative Bodies	<p>Woodside assesses relevance for Native Title Representative Bodies using the following steps in its methodology:</p> <ul style="list-style-type: none"> A Representative Aboriginal/Torres Strait Islander Body (RATSIB) is a regional organisation appointed under the <i>Native Title Act 1993</i> (Cth) with prescribed functions set out in Part 11 of the <i>Native Title Act 1993</i> (Cth), which relate to: facilitation and assistance; certification; dispute resolution; notifications; agreement making. They are also known, and referred to here, as Native Title Representative Bodies. Review of National Native Title Tribunal RATSIB areas that overlap or are coastally adjacent to the EMBA. <p>Assessment of relevance:</p> <ul style="list-style-type: none"> Where the area for which a Native Title Representative Body is recognised under the <i>Native Title Act 1993</i> (Cth), overlaps with the EMBA or is coastally adjacent to the EMBA, Woodside will assess the Native Title Representative Body as relevant.
Historical heritage groups or organisations	<p>Woodside assesses relevance for groups or organisations whose responsibilities are focused on historical heritage using the following steps in its methodology:</p> <ul style="list-style-type: none"> Using the Australasian Underwater Cultural Heritage Database to assess known records Maritime Cultural Heritage sites (shipwrecks, aircraft and relics) within the EMBA (see Section 4.9) <p>Assessment of relevance:</p> <ul style="list-style-type: none"> Where there is a known underwater heritage site (shipwrecks, aircraft and relics) within the EMBA, the relevant group or organisation that manages the site will be assessed as relevant.
Local government and elected Parliamentary representatives and recognised local community reference/liaison groups or organisations	<p>Woodside assesses relevance for local government and elected Parliamentary representatives and recognised local community reference/liaison groups or organisations using the following steps in its methodology:</p> <ul style="list-style-type: none"> Review Woodside maps (developed based on data from the WA Local Government, Sport and Cultural Industries 'My Council' database and WA Local Government Association (WALGA) Local Government Directory maps) to assess overlap between the local government's defined area of responsibility and the EMBA. Woodside hosts regular community reference/liaison group meetings. Members represent a cross-section of the community and local towns interests. Representatives are from community and industry and generally include, Woodside, State Government (for instance relevant Regional Development Commissions), Local Government, Indigenous Groups, Industry representative bodies, community and industry organisations. Woodside considers these reference/liaison groups to be the appropriate recognised representatives of the local community for the oil and gas sector. Woodside reviews the community reference/liaison group's terms of reference to determine its area of responsibility and overlap with the EMBA. For example, the Exmouth Community

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

Category	Relevant person identification methodology
	<p>Liaison Group's area of responsibility in relation to Woodside's operational, development and planning activities, is defined in the terms of reference as the Exmouth sub-basin. Comparatively, the Karratha Community Liaison Group's area of responsibility is the Pilbara region (i.e., onshore).</p> <ul style="list-style-type: none"> • Commonwealth and State elected politicians. <p>Assessment of relevance:</p> <ul style="list-style-type: none"> • The local government and elected Parliamentary representative/s whose defined area of responsibility overlaps the EMBA is assessed as relevant. • The community reference/liaison group whose defined area of responsibility overlaps the EMBA is assessed as relevant and consulted collectively via the relevant reference/liaison group.
<p>Other non-government groups, organisations or individuals</p>	<p>Woodside assesses relevance for other non-government groups, organisations or individuals using the following steps in its methodology:</p> <ul style="list-style-type: none"> • Review Woodside's existing consultation list. • Search websites of registered non-government groups or organisations (i.e., registered with an Australian Business Number (ABN) and publicly available contact information) that may have public website material specific to the proposed activity at the time of development of the EP. • Organisation has a publicly available mission statement (or purpose) that clearly describes their collective functions, interests or activities. • Review current website material to identify targeted information which demonstrates functions, interests or activities relevant to the potential risks and impacts associated with planned activities. • Review an individual's feedback to consider whether their functions, interests or activities could be impacted. <p>Assessment of relevance:</p> <ul style="list-style-type: none"> • Registered non-government groups or organisations with current targeted public website material specific to the proposed activity at the time of developing the EP and who have demonstrated functions, interests or activities relevant to the potential risks and impacts associated with planned activities in accordance with the intended outcome of consultation will be assessed as relevant. • Individual demonstrates their functions, interests or activities could be impacted will be assessed as relevant.
<p>Research institutes and local conservation groups or organisations</p>	<p>Woodside assesses relevance for research institutes and local conservation groups or organisations using the following steps in its methodology:</p> <ul style="list-style-type: none"> • Review Woodside's existing consultation list. • Search websites for research institutes that may operate within the EMBA. This assessment is both activity and location based. • Search websites for local conservation groups or organisations that regularly conduct conservation activities within the EMBA. <p>Assessment of relevance:</p> <ul style="list-style-type: none"> • Where there is known research being undertaken by a research institute within the EMBA, the research institute that is conducting the research will be assessed as relevant. • Local environmental conservation groups who regularly conduct conservation activities or have demonstrated conservation functions, interests or activities within the EMBA are assessed as relevant. This assessment is both activity and location based.

5.3.5 Regulation 25(1)(e)

In addition to assessing relevance under regulation 25(1)(d), Woodside has discretion to categorise any other person or organisation as a relevant person under regulation 25(1)(e).

5.3.6 Identification of Relevant Persons under Regulation 25(1)(e)

Woodside adopts a case-by-case approach for each EP to assess relevance under regulation 25(1)(e).

5.3.7 Persons or Organisations Woodside Chooses to Contact

In addition to undertaking consultation with relevant persons under regulation 25(1), from time to time there are persons or organisations that Woodside chooses to contact in relation to a proposed activity. For example, these are persons or organisations:

- that are 'not relevant' pursuant to regulation 25(1) but that Woodside has chosen to seek additional guidance from, for example, to inform the correct contact person that Woodside should consult, or engage with
- that are 'not relevant' pursuant to regulation 25(1) but have been contacted as a result of consultation requirements changing, updated guidance from the Regulator, or has provided historical feedback on the OPP or previous Scarborough EPs.
- where it is unclear what their functions, interests or activities are, or whether their functions, interests or activities may be affected. In this circumstance, engagement is used to inform relevance under Woodside's methodology. Woodside follows the same methodology for assessing a person or organisation's relevance as it does during its initial assessment (as described in Figure 5-1 and Section 5.3). The result of Woodside's assessment of relevance during the development of the EP is outlined at Appendix F, Table 1.

5.3.8 Assessment of Relevant Persons for the Proposed Activity

The result of Woodside's assessment of relevant persons in accordance with regulation 25(1) is outlined at Appendix F: Consultation, Table 1 and Table 2.

Persons or organisations that Woodside assessed as not relevant but chose to contact at its discretion in accordance with Section 5.3.4, or self-identified and Woodside assessed as not relevant, are summarised at Appendix F: Consultation (Table 1 and Table 3).

5.4 Consultation Material and Timing

Regulation 25(2) provides that a titleholder must give each relevant person sufficient information to allow the relevant person to make an informed assessment of the possible consequences of the activity on the functions, interests or activities of the relevant person. Regulation 25(3) provides that the titleholder must allow a relevant person a reasonable period for the consultation.

As set out in Section 5.2, Woodside notifies relevant persons of the proposed activities, respecting that consultation is voluntary, and collaborates on a consultation approach where further engagement is sought by the relevant person. The consultation process aims to be appropriate for the category of relevant persons and not all persons or organisations will require the same level of engagement. In circumstances where there is an ongoing relationship or previous consultation on other EPs, Woodside follows the method of consultation that was historically engaged in and was accepted by the person being consulted. Respecting historic engagement is also important because it means that topics have often been assessed and discussed previously and it also assists to manage consultation fatigue where relevant persons are frequently consulted. Woodside recognises that the level of engagement is dependent on the nature and scale of the Operational Area. Woodside acknowledges published guidance for good practice consultation, relevant to different

sectors and disciplines. Woodside's methodology for providing relevant persons with sufficient information as well as a reasonable period of time to provide feedback is set out in this section.

5.4.1 Sufficient Information

Woodside produces a Consultation Information Sheet for each EP. This is provided to relevant persons and organisations and is also available on Woodside's website for interested parties to access and to provide feedback on. The Consultation Information Sheet typically includes:

- a description of the proposed petroleum activity
- the Operational Area or PAA, dependant on the EP
- where the activity will take place
- the timing and duration of the activity
- a location map of the Operational Area or PAA and EMBA²⁵
- a description of the EMBA
- relevant exclusion zones
- a summary of relevant risks and mitigation and management control measures relevant to the PAP.

It also sets out contact details to provide feedback to Woodside.

The level of information necessary to assist a person or organisation to understand the impacts of the proposed activity on their functions, interests or activities may vary and may depend on the degree to which a relevant person may be affected and also may depend on historic consultation engagements. For example, Woodside considers that relevant persons who may be affected by planned activities in the Operational Area, as a result of temporary displacement due to exclusion zones, may require more targeted information relevant to their functions, interests or activities. Relevant persons who have been consulted on other EPs relevant to the Project may previously have been provided with information relevant to their topics of interest and may not need to receive this again in order to make an informed assessment of the possible consequences of the activity on their functions, interests or activities. Further, sufficient information may have been provided to a relevant person even where all documents requested by a relevant person have not been provided. Woodside also acknowledges NOPSEMA's brochure entitled *Consultation on offshore petroleum environment plans information for the community*, which advises persons being consulted that they may inform titleholders that they only want to be consulted in the very unlikely event of an oil spill.

Woodside places advertisements in selected local, state and national newspapers. This typically includes:

- the name of the EP Woodside is seeking feedback on
- an overview of the activity
- the consultation feedback date
- the ways in which a person or organisation can provide feedback.

Advertising in the local paper in the area of the activity is also consistent with the public notification process under section 66 of the *Native Title Act 1993* (Cth) for native title applications. Woodside typically aligns advertisement feedback timeframes with the timing described below. Feedback received is assessed in accordance with Section 5.3 to determine relevance and evidenced in Appendix F: Consultation, Table 1 as appropriate.

²⁵ Following issue of the consultation information sheet the EMBA modelling was re-run to incorporate recent advancements in the model developed by the specialist modelling consultant. Therefore the EMBA described in this EP is different to that used for consultation.

Woodside utilises a range of tools to provide sufficient information to relevant persons, which may include one or more of:

- Consultation Information Sheet available on Woodside’s website and shared directly with relevant persons
- Summary Consultation Information Sheet, presentations or summaries specific to a particular relevant person group
- project information on Woodside’s website
- a subscribe function available on Woodside’s website to receive notification of new Consultation Information Sheets for Woodside EPs and to receive Woodside’s consultation newsletter ‘Let’s Talk’
- emails
- letters
- phone calls
- face-to-face meetings (virtual or in person) with presentation slides or handouts as appropriate
- Let’s Talk newsletter – digital copy and hard copy
- maps outlining a person or organisation’s defined area of responsibility in relation to the proposed activity, for example a fisheries management area or defence training area
- community meetings, as appropriate
- attendance at on-the-ground community events or planned regional roadshows
- broader awareness campaigns on the how to be involved in the EP consultation process
- broad proactive communication activities were undertaken with the public to raise awareness of Woodside’s activities related to this EP and the Scarborough Energy Project more generally.

Woodside recognises that information may be provided to relevant persons in an iterative manner during the consultation process. Woodside considers that genuine two-way engagement may, in certain instances, be demonstrated via information on incorporation of controls, where applicable, being provided to the relevant person so that the relevant persons understand how their input has been considered in the development of the EP.

Woodside communicates with relevant persons in different ways. Woodside recognises that, as part of genuine two-way dialogue, these forms of communication may evolve including, for example due to changes to organisation representation, as relationships are further established, or a preference for an alternative form of communication is expressed by a person or organisation. There might also be limitations in how Woodside can consult with relevant persons.

Typical forms of communications for categories of relevant persons are set out in Table 5-3.

Table 5-3: Typical forms of communication

Category of relevant person	Typically accepted form of communication
Government departments/agencies – marine	Woodside applies NOPSEMA’s guideline for engagement with Commonwealth government departments or agencies GL1887 – Consultation with Commonwealth agencies with responsibilities in the marine area – January 2023_by using email for its consultation unless another form of communication_is requested. Other forms of communication, such as phone calls, meetings and/or presentation briefings are used on request.
Government departments/agencies – environment	
Government departments/agencies – industry	

Category of relevant person	Typically accepted form of communication
Commercial fisheries and peak representative bodies	Commonwealth commercial fisheries: Email is used as the primary form of communication with Commonwealth commercial fisheries in the ordinary course of business. Other forms of communication, such as phone calls, and meetings and/or presentation briefings are used on request.
Recreational marine users and peak representative bodies	State commercial fisheries and recreational marine users: The Western Australian Department of Primary Industries and Regional Development (DPIRD) has responsibility for managing the <i>Fish Resources Management Act 1994 (WA)</i> and <i>Aquatic Resources Management Act 2016 (WA)</i> , which limits the provision of contact details from the register to the name and business address of licence holders. Alternative forms of communication are at the licence holder’s discretion. Other forms of communication, such as phone calls, and meetings and/or presentation briefings are used on request. Peak representative bodies: Email is used as the primary form of communication with commercial fishery and recreational marine user peak representative bodies in the ordinary course of business. Other forms of communication, such as phone calls, and meetings and/or presentation briefings are used on request.
Titleholders and Operators	Email is used as the primary form of communication between titleholders and operators in the ordinary course of business. Other forms of communication, such as phone calls, and meetings and/or presentation briefings are used on request.
Peak industry representative bodies	Email is used as the primary form of communication with peak representative bodies in the ordinary course of business. Other forms of communication, such as phone calls, and meetings and/or presentation briefings are used on request.
Traditional Custodians and nominated representative corporations	There are many forms of communication that Woodside uses on a case-by-case basis and as appropriate to or requested by the specific group, such as email, phone calls, meetings and community forums. Other forms of communication are used on request.
Native Title Representative Bodies	There are many forms of communication that Woodside uses on a case-by-case basis and as appropriate to or requested by the specific group, such as email, phone calls, meetings and community forums. Other forms of communication are used on request.
Historical heritage groups or organisations	NOPSEMA’s guideline (GL1887 – Consultation with Commonwealth agencies with responsibilities in the marine area – January 2023) for engagement with government departments or agencies is used as a reference for Woodside’s approach for communicating with historical heritage groups or organisations. Other forms of communication, such as phone calls, and meetings and/or presentation briefings are used on request.
Local government and elected Parliamentary representatives and recognised local community reference/liaison groups or organisations	Local government: NOPSEMA’s guideline (GL1887 – Consultation with Commonwealth agencies with responsibilities in the marine area – January 2023) for engagement with local government is used as a reference for Woodside’s approach for communicating with historical heritage groups or organisations. Community reference/liaison groups and chambers of commerce: Email and presentations are used as the primary form of communication with local community reference/liaison groups or organisations in the ordinary course of business. Other forms of communication, such as phone calls, and meetings and/or presentation briefings are used on request.
Other non-government groups or organisations or individuals	Email is used as the primary form of communication with Other non-government groups or organisations. Other forms of communication, such as phone calls, and meetings and/or presentation briefings are used on request.
Research Institutes and Local conservation groups or organisations	Email is used as the primary form of communication with research institutes and local conservation groups or organisations. Other forms of communication, such as phone calls, and meetings and/or presentation briefings are used on request.

Information which is provided to relevant persons for the purposes of consultation on this EP is summarised at Appendix F: Consultation, Table 2.

Appendix F: Consultation, Table 3 sets out the information which is provided to persons or organisations that are not relevant for the purposes of regulation 25 but which Woodside has chosen to contact.

When engaging in consultation, Woodside notifies relevant persons that, in accordance with regulation 25(4), the relevant person may request that the titleholder notifies NOPSEMA that particular information the person or organisation provides in the consultation not be published, and that information subject to that request will not be published under the Environment Regulations.

5.4.2 Reasonable Period for Consultation

Woodside seeks to consult in order to support preparation of its EP. Woodside acknowledges that what constitutes allowing a reasonable period for consultation should be considered on a case-by-case basis, with reference to the nature, scale and complexity of the activity.

For this EP, relevant persons were allowed a reasonable consultation period (in some instances 30 days and in some instances around 4.5 months) to enable an informed assessment of possible consequences of the activity on their functions, interests or activities. The consultation timeframe was also extended at the request of some relevant and non-relevant persons.

The consultation period under this EP is consistent with benchmark periods under other relevant legislative processes:

- Regulation 30 sets out a public consultation period of 30 days.
- The Department of Mines, Energy and Petroleum (DEMIRS) “Guidelines for Consultation with Indigenous People by Mineral Explorers” directs a period of 21 to 30 days of consultation with traditional owners.
- While repealed, guidance taken from the *Aboriginal Cultural Heritage Act 2021—Consultation Guidelines* (Government of Western Australia, 2023) suggests that up to 12 weeks may be a reasonable period to allow identification, contact and response from First Nations peoples (subject to any alternative timeframe being agreed through co-design of consultation).

Woodside allowed relevant persons either 30 days or an approximately 4.5-month period of consultation demonstrating that Woodside has provided a “reasonable period” for relevant persons to consult in accordance with regulation 25(3). Commentary in the *Tipakalippa Appeal* judgment limits consultation to a process that must be capable of being discharged within a reasonable time:

“it must be taken to be the regulatory intention that the consultation requirement cannot be one that is incapable of being complied with within a reasonable time...”²⁶

Woodside seeks feedback in order to support preparation of its EP. What is considered to be a titleholder allowing a relevant person a reasonable period for consultation is considered on a case-by-case basis, with reference to the person being consulted and the nature, scale and complexity of the activity.

Woodside's typical approach to allowing a relevant person a reasonable period for consultation is:

- advertising in selected local, state and national newspapers to give persons or organisations the opportunity to understand the activity and make an informed assessment of the possible consequences of the activity on their functions, interests or activities. Woodside also undertook advertised, regional consultation roadshows and facilitated consultation at regional community events for this EP.
- providing consultation materials directly to relevant persons as well as persons who are not relevant but Woodside chose to contact and providing a target date for feedback. Woodside acknowledges that feedback may be received from relevant persons following the target date

²⁶ Santos NA Barossa Pty Ltd v Tipakalippa [2022] FCAFC 193 at paragraph [136].

- acknowledging that the way in which Woodside provides consultation information may vary depending on the relevant person or organisation and, may depend on the degree to which a relevant person or organisation is affected. Different consultation processes may be required for relevant persons and organisations
- following up with relevant persons prior to EP submission. Where possible, if no response has been received, Woodside will endeavour to use an alternative method of communication to contact the relevant person. Woodside also reviewed, assessed, and proactively wrote to numerous relevant and non-relevant persons based on their historical feedback on and topics of interest relating to the OPP or previous Scarborough Energy Project EPs.
- engaging in two-way dialogue with relevant persons or organisations where feedback is received.

Appendix F: Consultation Table 2 and Table 3 sets out a history of ongoing consultation and demonstrates that a reasonable period of consultation has been provided.

Woodside considers and has communicated that consultation for this EP has closed.

As detailed in Section 5.6, if comments and feedback are received after the EP has been submitted, Woodside will consider those comments and update controls as appropriate and at all stages of the life of the EP as per Woodside's ongoing consultation approach described in Section 5.7.

5.4.3 Discharge of Regulation 25

The Full Federal Court made clear in the *Tipakalippa Appeal* that consultation should be approached in a “reasonable”, “pragmatic” and “not so literal” way, so that consultation obligations were capable of being met by titleholders (Section 5.5.1).²⁷ Consultation is a “real world activity” and must be capable of reasonable discharge.²⁸ The Full Federal Court referred to Native Title cases as an illustration that reasonable limits should be applied to consultation efforts to ensure the process is workable.²⁹

When the titleholder demonstrates that it has given a relevant person sufficient information and allowed a relevant person a reasonable period for consultation, then regulation 25 consultation requirements are met.³⁰ Meeting these obligations requires evaluative judgement to determine reasonable satisfaction of the consultation obligation and whether these criteria are met. The nature of the person being consulted and their function, interest and activity that may be affected, will inform the manner of consultation and the reasonable period to be allowed for consultation.³¹

While a titleholder is required to provide an opportunity to consult showing that the consultation is appropriate and adapted to the interests of the relevant person, there are limits. For example, the titleholder is not required to obtain consent from a person being consulted, or confirmation from a person being consulted, that consultation is complete. The Federal Court has commented that a “reasonable opportunity” for consultation must be afforded to relevant persons.³² A reasonable opportunity does not mean every opportunity requested and is limited to reasonable opportunities to consult.

²⁷ *Santos NA Barossa Pty Ltd v Tipakalippa* [2022] FCAFC 193 [89], [98], [103]-[104] and [109].

²⁸ *Santos NA Barossa Pty Ltd v Tipakalippa* [2022] FCAFC 193 at [89].

²⁹ *Santos NA Barossa Pty Ltd v Tipakalippa* [2022] FCAFC 193 at [96] and [103].

³⁰ Explanatory Statement, Offshore Petroleum and Greenhouse Gas Storage (Environment) Regulations 2023, page 29.

³¹ Explanatory Statement, Offshore Petroleum and Greenhouse Gas Storage (Environment) Regulations 2023, page 30 and *Santos NA Barossa Pty Ltd v Tipakalippa* [2022] FCAFC 193 at [153].

³² *Cooper v National Offshore Petroleum Safety and Environmental Management Authority (No 2)* [2023] FCA 1158 at paragraph [11]; *Santos NA Barossa Pty Ltd v Tipakalippa* [2022] FCAFC 193 at [153].

Woodside has discharged its consultation obligations. Woodside has given relevant persons sufficient information to enable relevant persons to make an informed assessment of the possible consequences of the activity on their functions, interests or activities. Woodside has also allowed relevant persons a sufficient period to provide relevant feedback for Woodside to assess objections or claims about the adverse impact of the activity to which this EP relates. Woodside has also provided a reasonable opportunity in that consultation is appropriate and adapted to the interests of the relevant person, including that there has been genuine two-way dialogue on a relevant person's claims or objections about the adverse impact of the activity to which this EP relates.

Woodside has discharged its duty under regulation 25. Consultation for this EP is complete.

Appendix F: Consultation (Table 2 and Table 3) of this EP sets out the history of consultation under regulation 25. To the extent a relevant person says that they have further information to share or claims that consultation under regulation 25 has not been completed, Appendix F: Consultation (Table 2 and Table 3) provide reasons why Woodside considers consultation under regulation 25 has been met, in relation to that relevant person.

5.5 Context of Consultation Approach with First Nations

To comply with regulation 25, Woodside identifies and consults Traditional Custodians whose functions, interests or activities may be affected by the activities under an EP.

5.5.1 Approach to Methodology – Woodside's Interpretation of *Tipakalippa Appeal*

Woodside has implemented a consultation methodology consistent with regulation 25 and guidance provided in the *Tipakalippa Appeal* and *Munkara* case (Section 5.2). Woodside's consultation methodology allows for a sufficiently broad capture of Traditional Custodian relevant persons, provides for informed consultation, follows cultural protocols and allows a reasonable opportunity for consultation with Traditional Custodians whose functions, interests or activities may be affected by the activity described in this EP (Section 5.5.2.1 to 5.5.2.5).

Woodside notes the Full Federal Court discussed several *Native Title Act 1993 (Cth)* cases in response to a submission made in that case that a requirement under regulation 25 to consult "each and every" relevant person would be "unworkable". The reference to native title cases dealt with how decision-making processes under the NTA requiring "all" members of a group to be contacted for communal approval are interpreted by courts in a "reasonable", "pragmatic" and "not so literal" way,³³ and how obligations to consult "each and every" person under regulation 25 should be interpreted in a similarly pragmatic way, so that consultation is workable. The reference to NTA authorities was made by analogy:

*"It can be seen that the terms of [the native title legislation] are somewhat absolute – "all". However, [the native title legislation] has consistently been construed in a way that is not so literal ... The cases concerning [the native title legislation] ... have reiterated ... that [the native title legislation] does not require that "all" of the members of the relevant claim group be involved in the decision. The key question will be whether a reasonable opportunity to participate in the decision-making process has been afforded by the notice for a relevant meeting."*³⁴

*"We consider the authorities in relation to processes under the NTA to be illustrative of how a seemingly rigid statutory obligation to consult persons holding a communal interest may operate in a workable manner"*³⁵ (emphasis added).

33 Santos NA Barossa Pty Ltd v Tipakalippa [2022] FCAFC 193 at paragraph [95], [98], [103]-[104] and [109].

34 Santos NA Barossa Pty Ltd v Tipakalippa [2022] FCAFC 193 at paragraph [98].

35 Santos NA Barossa Pty Ltd v Tipakalippa [2022] FCAFC 193 at paragraph [96].

“[T]here is no definition of what constitutes “consultation for the purpose of Reg11A [now regulation 25] ... A titleholder will need to “demonstrate” to NOPSEMA that what it did constituted consultation appropriate and adapted to the nature of the interests of the relevant persons”³⁶ (emphasis added).

The Judgment in the *Tipakalippa Appeal* makes it clear that a titleholder will have some decisional choice in identifying which person(s) are to be approached, how the information will be given to allow the "relevant person" to assess the possible consequence of the proposed activities on their functions, interests or activities, and how consultation is undertaken.³⁷ Consultation is not fixed to a rigid process and will be adapted so that it is informed by the relevant person or group. Woodside has met its regulation 25 requirements through its consultation methodology (Section 5.2).

Consistent with the *Tipakalippa Appeal*, Woodside considers NTA-style “full group” meetings are not required for there to be compliance with regulation 25. Nominated representative corporations (such as PBCs established under the NTA) have a designated role of representing the views of their member Traditional Custodians. They have established methods for engaging with their own members. Woodside will not undermine the purpose and authority of nominated representative corporations by requiring full group meetings where the nominated representative corporations have not requested engagement of members via full group meetings. It is not appropriate for titleholders to direct or challenge the nominated representative corporations on how to engage with their members.

Woodside's approach described below demonstrates that sufficient information and a reasonable opportunity is provided to individual Traditional Custodians to provide feedback on Woodside activities beyond the opportunity provided to nominated representative corporations.

5.5.2 Consultation Method

Woodside's First Nations team has experience in engaging and working with First Nations organisations and individuals, including within the Commonwealth native title and cultural heritage systems, and state and territory cultural heritage and land rights systems. The team understands the complexities of making information accessible to groups and individuals and engaging in accordance with First Nations groups' established channels of communication and methods of consultation. The First Nations team exercises its professional judgement and is respectful of long-standing relationships (where in place) when considering consultation with First Nations groups. The First Nations team's approach is also informed by the established systems of recognition for First Nations groups and their nominated representative corporations within particular jurisdictions. For example, the methodology for engaging with First Nations groups in the Northern Territory (not relevant for this EP) tends to centre around engagement through Aboriginal land councils (under the *Aboriginal Land Rights (Northern Territory) Act 1976 (Cth)*) as well as community meetings that target clan groups where they do not have PBCs or other nominated representative corporations to represent them.

By contrast, recognition for First Nations groups and their nominated representative corporations in Western Australia falls under the *Native Title Act 1993 (Cth)* because the vast majority of the Western Australian coastline is settled under the native title regime. This means that the methodology and process for consultation in Western Australia places greater emphasis on, but is not limited to, Native Title Representative Bodies and PBCs.

Native title determinations provide certainty about the appropriate Traditional Custodian groups that have the cultural authority to speak for country and help Woodside to identify Traditional Custodian persons and groups asserting Traditional Custodianship. The Judgment in the *Tipakalippa Appeal*

36 Santos NA Barossa Pty Ltd v Tipakalippa [2022] FCAFC 193 at paragraph [104].

37 Santos NA Barossa Pty Ltd v Tipakalippa [2022] FCAFC 193 at paragraph [47] and [48].

endorses methods of consultation with groups of relevant persons that are appropriate and adapted to the characteristics of groups.³⁸ Woodside's consultation methodology is adapted and appropriate to the recognised systems of communal interests in Western Australia.

In Western Australia (relevant for this EP), Woodside has sought to follow the established, effective and respectful means of communication used by Native Title Representative Bodies and nominated representative corporations (including PBCs) with their respective First Nations communities. Woodside follows these processes for the appropriate broad capture of individuals' awareness of our activities, to self-identify (Section 5.5.2.2), and to provide feedback to inform the management of environmental impacts and risks.

Using these processes, Woodside communicates information about EPs in the following ways:

- Woodside advertises in relevant newspapers, which encourages self-identification, by advertising proposed activities widely through newspapers that have national and intra-state circulation, i.e. Koori Mail, National Indigenous Times, The West Australian.
- Woodside creates carefully considered Consultation Summary Sheets with information developed by an Indigenous member of the First Nations Team to remove jargon and provide relevant information for people to have informed understandings about the activities.
- Woodside makes direct contact through nominated representative corporations.
- Woodside uses social media (i.e. Facebook/Instagram), texts and emails. These mediums are the preferred communication methods used by Traditional Custodians throughout Western Australia and, on that basis, used by Native Title Representative Bodies and other government agencies and industry, to engage with Traditional Custodians or call meetings. First Nations woman, Professor Bronwyn Castle, through 10 years of research found "*Social media is an intrinsic part of daily life. The use of Facebook is around 20 per cent higher [among First Nations people] than the national average across all geographical locations*" (Social media mob: being Indigenous online, Professor Bronwyn Carlson (2018)).
- For ongoing consultation post regulation 25 consultation, Woodside has a Program of Ongoing Engagement with Traditional Custodians which sets out Woodside's commitment to ongoing engagement and support to care for and manage country, including Sea Country. The program was developed in response to Traditional Custodian feedback.
- Woodside has members of its First Nations team who are based in Karratha and Roebourne and who serve as on-Country points of contact for First Nations organisations and individuals. These team members have broad local knowledge and established, on-the-ground relationships within communities. This helps contribute to positive outcomes including encouraging First Nations attendance and involvement at Woodside's information sessions and Community roadshows. Team members on the ground engage in a great deal of preparatory work including by distributing information and providing notice to the community to support First Nations attendance at information sessions and Community roadshows.
- From the commencement of engagement with Traditional Custodians, Woodside seeks direction on how they prefer to be consulted and has consulted accordingly. Consultation processes that are informed by Traditional Custodians and co-designed on a case-by-case basis and includes, where appropriate, direction from Traditional Custodians as to cultural protocols, structure of consultation and who to appropriately consult with (such as elders).
- Woodside holds meetings on Country at a place and time agreed with Traditional Custodians and offers and provides financial support for meeting expenses to enable consultation (as appropriate).

³⁸ Santos NA Barossa Pty Ltd v Tipakalippa [2022] FCAFC 193 at paragraphs [95], [104], [153].

- Woodside provides information specifically designed to be easily understood, to reach relevant people, and give a reasonable period of time for those people to make an informed assessment of the possible consequences of the proposed activity on them.

The First Nations team's approach to consultation is also consistent with the Federal Court's decision in the *Munkara Case*. The *Munkara Case* notes that the word "culture" (and hence the word "cultural") has a communal aspect to it. To establish cultural features, it is necessary that the beliefs and values are held by the relevant people *as a people*. For values, features or beliefs that are expressed by an individual to be "cultural" they cannot simply be an individual's belief – the belief must have a communal aspect too, and demonstrate that the "individual beliefs are broadly representative of the beliefs of other members of the group"³⁹. The phrase "cultural features", when applied to "people" as constituent parts of an ecosystem, is not directed to idiosyncratic views or beliefs of an individual⁴⁰. When the First Nations team is told that a particular value is cultural by an individual Traditional Owner, that information is taken back to the relevant cultural authority to test its broad acceptance. In the case of gender sensitive information, that information would be restricted to the specific gender within the community.

5.5.2.1 Identification of Relevant Persons

To undertake consultation, Woodside has developed a methodology for identifying relevant persons, in accordance with regulation 25(1) (Section 5.2 and 5.3).

Woodside's approach for identifying relevant Traditional Custodians is consistent with Woodside's First Nations Communities Policy (Woodside, 2022) and consultation is guided by Traditional Custodians by directing consultations through their nominated representative corporation. This has been implemented by Woodside through consultation with a nominated representative corporation, where that corporation has advised Woodside that it acts as the representative body for a Traditional Custodian group and has requested that Woodside engage with it as the representative body for that Traditional Custodian group.

Woodside has an approach designed to facilitate broad capture for consultation. It asks nominated representative corporations (such as PBCs) and Native Title Representative Bodies to identify individuals that should be consulted, and also enables individuals to self-identify in response to national and local advertising, social media and community engagement opportunities (Section 5.5.2.2). Where there is a nominated representative corporation for an area, unless directed by the nominated representative corporation, Woodside does not directly approach individuals for consultation, because this has the potential to undermine the role of the nominated representative corporation. Approaching individuals directly is a practice that is no longer considered acceptable because of divisions it has been shown to cause in communities. In addition to asking for the identification of individuals, Woodside also asks nominated representative corporations to distribute consultation information to whomever the nominated representative corporations deem appropriate, including members of the nominated representative corporations who are communal rights holders.

Having said this, as set out in further detail in Section 5.5.2.2, individuals are also given the opportunity to self-identify, consult and provide their own feedback on the proposed activity. When approached in this way, Woodside will engage individuals as relevant persons and will also (subject to any confidentiality or cultural restrictions) advise the nominated representative body of the consultation with individuals where it relates to cultural values. These methods of consultation are consistent with requirements for notification under the *Native Title Act 1993 (Cth)*, such as under the future act provisions (section 29), which requires notification of the Native Title Representative Body, the PBC (or nominated representative) and notification through newspapers. The notification process has been selected as a respectful, practical and pragmatic analogue for consultation with

³⁹ *Munkara v Santos NA Barossa Pty Ltd* (No 3) [2024] FCA 9 at [205]

⁴⁰ *Munkara v Santos NA Barossa Pty Ltd* (No 3) [2024] FCA 9 at [205]

First Nations peoples, rather than requiring members to be notified via a formal authorisation process which seeks, from members, authorisation of agreements and native title/compensation claims under the *Native Title Act 1993 (Cth)*⁴¹.

In this consultation, Woodside requested nominated representative corporations to identify any potential individual relevant persons for consultation. Woodside requests nominated representative corporations to distribute consultation materials to their members. However, Woodside recognises that the process is voluntary and that it cannot compel nominated representative corporations (such as PBCs) to do so. Woodside also recognises that it would not be appropriate to seek to audit the nominated representative corporations for compliance with any member consultation request.

5.5.2.2 Opportunity to Self-identify and Identifying Other Individuals

Woodside requests nominated representative corporations and Native Title Representative Bodies to identify other individuals to consult with or individuals who may seek to self-identify for a proposed activity. Woodside also advertises broadly through Indigenous, national and local advertising, social media and community engagement opportunities to provide individuals with an opportunity to consult. Woodside does not directly approach individuals for consultation, as this undermines the role of the nominated representative corporations (Section 5.5.2.1). Woodside's approach to providing individual Traditional Custodians the opportunity to self-identify and consult for an EP is as follows:

- Woodside applies the principles of self-determination when consulting with Traditional Custodians by consulting through the Traditional Owners' authorised representative entities.
- Recognising the function of nominated representative corporations (such as PBCs) and Native Title Representative Bodies to represent communal interests and manage cultural values, Woodside requests that the information provided to representative entities is provided to their members but Woodside recognises the process is voluntary and Woodside cannot compel them to do so, nor seek to audit the representative entities for compliance with any request.
- Representative entities cannot provide membership details to Woodside due to individual confidentiality requirements.
- Woodside requests advice as to who else Woodside should be consulting but recognises the process is voluntary and cannot compel nominated representative corporations to provide this information.
- Modern Indigenous engagement practises focus on the building and maintaining of respectful relationships. To date, most nominated representative corporations have requested the building of a relationship of that kind, where one is not already in place.
- Woodside has, in some instances, been required to approach individuals, directors and Elders outside of this process due to requirements imposed in EP consultation. However, this approach is considered inappropriate by modern Indigenous engagement standards as it fundamentally undermines the authority of the authorised representative entity and can be detrimental to the relationship.

For this proposed activity, Woodside requested nominated representative corporations (including PBCs) and Native Title Representative Bodies to identify any potential individual relevant persons for consultation, and to distribute consultation materials to their member base. However, Woodside recognises the process is voluntary and it cannot compel them to do so nor seek to audit the representative entities for compliance with any request. Woodside has not been directed to engage individual Traditional Custodians by nominated representative corporations for this proposed activity. Woodside has nevertheless provided reasonable opportunity for individual Traditional Custodians to

⁴¹ Santos NA Barossa Pty Ltd v Tipakalippa [2022] FCAFC 193, at [104]

engage in consultation through appropriate and adapted consultation methods. Woodside has also consulted specific individuals where there has been previous consultation with them and has confirmed this consultation with relevant representative corporations.

5.5.2.3 Sufficient Information

Woodside gives relevant persons information that is sufficient to allow a person or organisation to make an informed assessment of the possible consequences of the proposed activity on their functions, interests or activities. This information sets out an overview of the activity, the location of the activity, timing of the activity and a summary of risks and impacts of the activity. It also includes maps showing the location of the activity and EMBA, diagrams and details on consultation and providing feedback. It is acknowledged that some relevant persons may seek additional information and the information that is sufficient may depend on the degree to which a relevant person is potentially affected.

Woodside produces Consultation Information Sheets for each EP which are provided to relevant persons and organisations for the purpose of seeking feedback on the activity (Section 5.4.1). In response to feedback from Traditional Custodians, Woodside has tailored consultation methods for its activities, specifically for Traditional Custodians, so that information is provided in a form that is readily accessible and appropriate. The Summary Information Sheet is developed and reviewed by Woodside's First Nations Team so that content is appropriate to the intended recipients, which is then provided to relevant Traditional Custodian groups. In instances where consultation has not occurred before, phone calls are often made following provision of the Summary Information Sheet so as to provide context to the consultation.

Where face-to-face consultation meetings are requested, Woodside coordinates engagement at the Traditional Custodians location of choice (where practicable) and with their nominated attendees. Key project personnel, environmental and First Nations relations experts are typically present to enable effective communication, provide explanatory information or background and provide prompt responses to questions. Materials for these sessions include visual aids such as photos, maps and videos, and plain language suitable for people with a non-technical background.

During consultation, Woodside provides relevant persons with additional information as appropriate in response to requests. There is no requirement to provide relevant persons with all information or documents requested and a titleholder will have provided sufficient information even where it has not provided all information or documents requested.

Woodside has sought to provide sufficient information to individual members of nominated representative corporations (such as PBCs) by providing information to representative bodies and requesting dissemination with members. However, Woodside recognises consultation is voluntary and it cannot compel them to do so, nor would it be appropriate to seek to audit the representative entities for compliance with any request.

Woodside also notes that, in an effort to simplify, support and enable consultation, Woodside has offered to enter into consultation framework agreements with Traditional Owners. The framework agreements ask Traditional Owners to provide their input on a number of factors including how the Traditional Owners would like to be consulted, what amount of information is sufficient for them, what period of time is reasonable, how best to capture their feedback and how they would like their information included in EPs. Woodside has also offered to provide for reasonable sitting fees and other costs to support and enable Traditional Owners to engage in consultation. Despite offering consultation agreements to numerous Traditional Owners, in a number of instances Woodside has observed a low priority or a significant degree of negotiation from groups to progress the agreements. Woodside has engaged in continuing negotiations on the framework agreements and has nevertheless continued consultation on this EP in parallel with those negotiations. Woodside has also confirmed that payment of reasonable sitting fees and other reasonable costs to support and enable consultation, must accord with Woodside's internal policies and procedures.

5.5.2.4 Reasonable Period for Consultation

Woodside seeks to consult in order to support preparation of its EP. Under Woodside's methodology, Woodside allows relevant persons at least 30 days for consultation in preparation of the EP. For many relevant persons, that period is a reasonable period for them to engage in consultation. In some instances, that period is extended, especially where there is a reasonable request from a relevant person for more time. Woodside also recognises that what constitutes a reasonable period for consultation may also take into account the nature, scale and complexity of the activity (Section 5.4.2).

5.5.2.5 Discharge of Regulation 25

Woodside's consideration and approach to discharging regulation 25 for relevant persons is discussed in Section 5.4.3 and Appendix F: Consultation. In addition to this, Woodside has considered the application of regulation 25 specific to First Nations based on the Tipakalippa Appeal and Munkara case.

In relation to Traditional Custodian relevant persons (and all relevant persons), Woodside has discharged its duty under regulation 25 of the Environment Regulations. Consultation under regulation 25 is complete (Section 5.4.3).

5.6 Providing Feedback and Assessment of Merit of Objections or Claims

There are a number of ways in which feedback can be provided to Woodside during consultation. Feedback can be provided through the Woodside feedback email or via the Woodside feedback toll free phone line as outlined in the Consultation Information Sheet and the Woodside website. Where appropriate, consultation may also be supported by phone calls or meetings. An EP feedback form is also available on Woodside's website enabling anyone to provide feedback on proposed activities, or to request additional information.

Woodside consults widely on its EPs and notes that feedback is received in various forms and with varying tones and objectives. Feedback that is considered inappropriate or that puts the environment, health, safety or wellbeing of Woodside employees or operations at risk will not be tolerated. Woodside respects people's rights to protest peacefully and lawfully but actions that put the environment, health, safety or wellbeing of Woodside employees or operations at risk go beyond those boundaries.

Woodside accepts feedback and engages in consultation in order to achieve the aims set out in Section 5.2. Woodside recognises that there are persons and organisations that take a view that Woodside's activities, operations and/or growth projects should be stopped or at least delayed as far as possible. Whilst Woodside assesses the merits of objections or claims about the adverse impact of the activity that Woodside receives, it acknowledges NOPSEMA's guidance in its brochure entitled *Consultation on offshore petroleum environment plans information for the community*, which states that relevant persons are free to respond on any matter and raise any concern, however this may not be able to be considered if it is outside the scope or purpose of the EP and approval process, for example, statements of fundamental objection to offshore petroleum activities or information containing personal threats or profanities.

Woodside notes that the regulations require Woodside to determine the sufficient information to give a relevant person and the reasonable period of time to allow a person to consult. There is no requirement for a relevant person to agree or confirm they have been provided sufficient information or a reasonable period of time. There is also no requirement for a relevant person to agree or confirm that they have been adequately consulted by Woodside or that consultation is closed.

Feedback, objections or claims about the adverse impact of the activity under the EP received from relevant persons are reviewed and an assessment of the merits of objections or claims is made. This might, for instance, be done through a review of data and literature and for relevance to the nature and scale of the activity outlined in the EP. Consistent with the aim of consultation in Section 5.2,

Woodside will consider information received when reviewing and designing appropriate measures to put in place to manage impacts and risks of the activity to ALARP and acceptable levels.

Woodside considers feedback during consultation from relevant persons and other persons Woodside chose to contact (see Section 5.3.4). Woodside has also considered topics raised and relevant to this EP from prior consultation on the OPP and other Scarborough Energy project EPs. This information is summarised in Appendix F: Consultation (Table 1 and Table 2) of the EP and includes a summary of Woodside's response, or proposed response, if any, to each objection and claim.

In accordance with the purpose of consultation, where Woodside receives information during consultation that enables Woodside to better understand the environment and to refine or change the measures it proposes to address risks and impact, that information is included in the EP. Cultural information relevant to the environment is incorporated in Chapter 4 "Existing Environment" of this EP.

In accordance with regulation 26(8), sensitive information (if any) in an EP, and the full text of any response by a relevant person to consultation under regulation 25, must be contained in the sensitive information part of the plan and not anywhere else in the plan.

5.7 Ongoing Consultation

In addition to consultation in the course of preparing EP, consultation can continue to occur during the life of an EP, including after an EP has been accepted by NOPSEMA.

As per Woodside's ongoing consultation approach (refer to Section 7.10.5), feedback and comments received from relevant persons continue to be assessed and responded to (as appropriate) throughout the life of an EP, including during its assessment and once accepted, in accordance with the intended outcome of consultation.

Should consultation feedback be received following the acceptance of an EP that identifies a measure or control that Woodside considers requires implementation or updates to meet the intended outcome of consultation, Woodside will apply its Management of Change and Review process as appropriate (see Section 7.2.7).

6 ENVIRONMENTAL RISK ASSESSMENT, PERFORMANCE OUTCOMES, STANDARDS AND MEASUREMENT CRITERIA

6.1 Overview

This section presents the impact and risk analysis, evaluation and Environment Performance Outcomes (EPOs), Environmental Performance Standards (EPS) and Measurement Criteria (MC) for the Petroleum Activities Program, using the methodology described in Section 2 of this EP.

6.2 Impact and Risk Analysis and Evaluation

As required by Regulations 21(5) and 21(6) of the Environment Regulations, the following analysis and evaluation demonstrates that the identified impacts and risks associated with the Petroleum Activities Program are reduced to ALARP and are of an acceptable level, and considers all operations of the activity, including potential emergency conditions.

Impacts and risks identified during the ENVID workshops (including decision type, current risk level, acceptability of impacts and risks, and tools used to demonstrate acceptability and ALARP) have been divided into two broad categories:

- planned (routine and non-routine) activities
- unplanned events (accidents, incidents or emergency situations).

Within these categories, impact and risk assessment groupings are based on environmental aspect (e.g. emissions, physical presence etc). For all hazardous events considered, the worst-case risk was assumed.

The ENVID identified 12 impacts and 11 risks associated with the Petroleum Activities Program. Planned activities and unplanned events are summarised in Table 6-1 and Table 6-2. The assigned risk ratings were determined with controls in place as described in Section 2.3.4.

The analysis and evaluation for the Petroleum Activities Program indicates that current environmental risks and impacts associated with the activity are reduced to ALARP and are of an acceptable level, as discussed further in Sections 6.7 and Section 6.7.13.

The environmental impacts and risks for all aspects are summarised in Table 6-1.

Table 6-1: Environmental risk analysis and summary

Aspect	EP Section	Risk Rating				Acceptability
		Impact/Consequence	Potential Impact/Consequence Level	Likelihood	Current Risk Rating	
Planned Activities (Routine and Non-routine)						
Physical Presence – Interaction with other marine users	6.7.1	E	Slight, short-term impact (<1 year) to a community or area/item of cultural significance.	-	-	Broadly Acceptable Has been shown to meet requirements listed in Section 2.3.6
Physical Presence – Seabed Disturbance	6.7.2	E	Environment – Slight, short-term impact (<1 year) on species, habitat (but not affecting ecosystems function), physical or biological attributes.	-	-	Broadly Acceptable Has been shown to meet requirements listed in Sections 2.3.5 and 2.3.6
Routine Light Emissions: FPU and Vessels	6.7.3	E	Environment – Slight, short-term impact (<1 year) on species, habitat (but not affecting ecosystems function), physical or biological attributes.	-	-	Broadly Acceptable Has been shown to meet requirements listed in Section 2.3.6
Routine Acoustic Emissions: FPU Hook-up and Commissioning	6.7.4	E	Environment – Slight, short-term impact (<1year) on species, habitat (but not affecting ecosystems function), physical or biological attributes.	-	-	Broadly Acceptable Has been shown to meet requirements listed in Section 2.3.6
Routine Acoustic Emissions: Routine Operations	6.7.5	E	Environment – Slight, short-term impact (<1year) on species, habitat (but not affecting ecosystems function), physical or biological attributes.	-	-	Broadly Acceptable Has been shown to meet requirements listed in Section 2.3.6
Routine Greenhouse Gas Emissions	6.7.6	F	Environment – No lasting effect on net global atmospheric GHG concentrations.	-	-	Broadly Acceptable Has been shown to meet requirements listed in Section 2.3.6

Aspect	EP Section	Risk Rating			Acceptability	
		Impact/Consequence	Potential Impact/Consequence Level	Likelihood		Current Risk Rating
Routine Atmospheric Emissions: Offshore, and Indirect Emissions from gas processing onshore	6.7.7	F	Environment – No lasting effect (<1 month); localised impact not significant to environmental receptors.			Broadly Acceptable Has been shown to meet requirements listed in Section 2.3.6
Physical Presence: Interactions between diurnal migratory/foraging seabirds and shorebirds and the FPU	6.7.8	E	Environment – Slight, short-term impact (<1 year) on species, habitat (but not affecting ecosystems function), physical or biological attributes.	-	-	Broadly Acceptable Has been shown to meet requirements listed in Section 2.3.6
Routine and Non-Routine Discharges: Vessels	6.7.9	E	Environment – Slight, short-term impact (<1 year) on species, habitat (but not affecting ecosystems function), physical or biological attributes.	-	-	Broadly Acceptable Has been shown to meet requirements listed in Section 2.3.6
Routine and Non-Routine Discharges: FPU Operations (Wastewater streams)	6.7.10	E	Environment – Slight, short-term impact (<1 year) on species, habitat (but not affecting ecosystems function), physical or biological attributes.	-	-	Broadly Acceptable Has been shown to meet requirements listed in Section 2.3.6
Routine and Non-routine Discharges: FPU Operations (Commingled PW/Seawater Return Stream stream)	6.7.11	E	Environment – Slight, short-term impact (<1 year) on species, habitat (but not affecting ecosystems function), physical or biological attributes.	-	-	Broadly Acceptable Has been shown to meet requirements listed in Section 2.3.6
Routine and Non-routine Discharges: Subsea Operations, Activities and Contingent Trunkline Dewatering	6.7.12	E	Environment – Slight, short-term impact (<1 year) on species, habitat (but not affecting ecosystems function), physical or biological attributes.	-	-	Broadly Acceptable Has been shown to meet requirements listed in Section 2.3.6

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

Aspect	EP Section	Risk Rating				Acceptability
		Impact/Consequence	Potential Impact/Consequence Level	Likelihood	Current Risk Rating	
Routine and Non-Routine Discharges: FPU and Subsea Commissioning and Initial Start-up	6.7.13	E	Environment – Slight, short-term impact (<1 year) on species, habitat (but not affecting ecosystems function), physical or biological attributes.	-	-	Broadly Acceptable Has been shown to meet requirements listed in Section 2.3.6
Unplanned Activities (Accidents, Incidents, Emergency Situations)						
Unplanned Diesel Release: Vessel Collision	6.8.2	C	Environment - Moderate, medium-term impact (2-10 years) on ecosystems, species, habitat or physical or biological attributes	1	M	Acceptable if ALARP
Unplanned Diesel Release: Loss of FPU/ASV Structural Integrity/Stability	6.8.3	D	Environment – Minor, short-term impact (1–2 years) on species, habitat (but not affecting ecosystem function), physical or biological attribute.	1	M	Broadly Acceptable Has been shown to meet requirements listed in Section 2.3.6
Unplanned Gas Release: Loss of Well Containment	6.8.4	E	Environment – Slight, short-term impact (<1 year) on species, habitat (but not affecting ecosystems function), physical or biological attributes.	1	L	Broadly Acceptable Has been shown to meet requirements listed in Section 2.3.6
Unplanned Gas Release: Subsea Equipment and Trunkline Loss of Containment	6.8.5	E	Environment – Slight, short-term impact (<1 year) on species, habitat (but not affecting ecosystems function), physical or biological attributes.	1	L	Broadly Acceptable Has been shown to meet requirements listed in Section 2.3.6
Unplanned Diesel Release: FPU Topsides Loss of Containment including bunkering/refuelling	6.8.6	E	Environment – Minor short-term impact (1–2 years) on species, habitat (but not affecting ecosystem function), physical or biological attributes.	2	M	Acceptable if ALARP

6.2.1 Concurrent Operations and Cumulative Impacts

The Scarborough OPP (Section 8) assesses the potential cumulative impacts of the Scarborough Project and other activities/developments. In addition, Woodside has considered other Scarborough activities that could result in overlapping temporal and spatial extents.

Concurrent operations may occur between activities included in this Petroleum Activities Program and Scarborough activities covered by future EPs (e.g. drilling and completions, subsea installation or seismic survey). Cumulative impacts associated with these activities will be assessed in future EPs, as required.

Drilling operations covered under the current approved Scarborough Drilling & Completions Environment Plan may occur concurrently with activities covered under this Environment Plan. As such, cumulative impact assessment has been carried out for routine acoustic emissions and physical presence (unplanned): interactions with marine fauna, within this Environment Plan.

Other facilities located in proximity to the PAA were identified within Section 4.10.5. While there is spatial overlap with a number of pipelines and cables, it is highly unlikely that concurrent activities with other operations would occur, due to required communications between operators and the inherent risk reduction in avoiding such situations. Therefore, no cumulative risks or impacts will credibly occur.

6.3 Environmental Performance Outcomes, Standards and Measurement Criteria

Regulation 21(7) of the Environment Regulations requires that an EP includes Environmental Performance Outcomes (EPOs), Environmental Performance Standards (EPSs) and Measurement Criteria (MC) that address legislative and other controls to manage the environmental risks of the activity to ALARP and an acceptable level.

As defined in Regulation 5 of the Environment Regulations, an EPO “for an activity, means a measurable level of performance required for the management of environmental aspects of the activity to ensure that environmental impacts and risks of the activity will be of an acceptable level”.

The EPOs, EPSs and MC specified are consistent with legislative requirements and Woodside’s standards and procedures. They have been developed based on the Codes and Standards, Good Industry Practices and Professional Judgement outlined in Sections 2.3.2 and 2.3.3 as part of the acceptability and ALARP justification process.

The EPOs, EPSs and MC are presented throughout this section and in Appendix H: Oil Spill Preparedness and Response Mitigation Assessment (Oil Spill Preparedness and Response). A breach of these EPOs or standards constitutes a 'Recordable Incident' under the Environment Regulations (refer to Section 7.12.4).

The Scarborough OPP identified the impacts and risks associated with the proposed development and defined suitable EPOs. The OPP EPOs have been cascaded to the relevant project activities under this EP or new EPOs created which are commensurate with the OPP EPOs and enable the same or greater level of protection. The relationship between OPP EPOs and those developed in this EP is summarised in Table 6-2.

For the physical and biological receptors within the EMBA, Woodside has set EPOs that are consistent with the Matters of National Environmental Significance – Significant impact guidelines 1.1 (DoE, 2013). EPOs are set so that they are consistent with the principles of ESD as defined in the Section 3A of the EPBC Act and this is demonstrated through the acceptability process (described in Section 2.3.6), which is applied to the aspects / receptors in Section 6. The EPOs for planned activities have been set at a level of environmental performance that considers the planned activities and associated level of environmental impact. This means that it can be demonstrated that

changes which do not trigger EP resubmission as per MOC process (refer to Section 7.2.7) are able to be managed to the Acceptable level.

For social receptors, including fishing and other commercial activities, the EPOs that have been set reflect the requirements in the section 280(2) of the OPGGS Act, in that the activities undertaken as a part of the development of Scarborough should not interfere with other marine users, to a greater extent than is necessary for the exercise of right conferred by the titles granted.

The EPOs for all environmental impacts/risks are identified and summarised in Table 6-2.

Table 6-2: Comparison of Environment Plan Environmental Performance Outcomes to the relevant Offshore Project Proposal Environmental Performance Outcomes

Aspect	EPOs in this EP	Relevant EPOs from the Scarborough OPP	Comparison
Planned Activities			
Section 6.7.1 Physical Presence – Interactions with other Marine Users	EPO 1 Impacts to relevant stakeholders from the Petroleum Activities Program planned activities will be limited through the provision of appropriate information / notification.	EPO 5.1 & EPO 5.2	EPOs 5.1 and 5.2 from the Scarborough OPP require undertaking the Scarborough development in a manner that prevents substantial adverse effect on commercial fishing, and in a manner that does not interfere with other marine users to a greater extent than is necessary to exercise rights under the Title. This EP EPO 1, to limit impacts to planned activities through provision of appropriate information, is aligned with preventing substantial adverse effect, and not interfering with other users beyond the extent necessary to exercise rights conferred by the Title(s) granted.
Section 6.7.2 Physical Presence – Seabed Disturbance	EPO 2 Seabed disturbance to be limited to planned activities and impacts described as part of the Petroleum Activities Program and will not occur outside the Operational Area. EPO 4 No adverse impact to unexpected finds of Underwater Cultural Heritage without a permit ⁴² .	EPO 6.1, 6.4 and 6.8	EPOs 6.1, 6.4 and 6.8 from the Scarborough OPP require the prevention of substantial change, adverse impact on a range of receptors including biodiversity, ecological integrity, social amenity, human health and KEFs. The EP EPOs align with the OPP by limiting seabed disturbance to the ALARP and Acceptable level described in the Section 6.7.2 impact assessment, which takes into consideration impact potential for relevant receptors and alignment with impact significance levels for individual receptors from the OPP, conservation management plans, requirements for protected places and other sensitivities or values raised through consultation.

⁴² Permit for Entry into a Protected Zone or to Impact Underwater Cultural Heritage would be acquired under the UCH Act.

Aspect	EPOs in this EP	Relevant EPOs from the Scarborough OPP	Comparison
<p>Section 6.7.3 Routine Light Emissions from FPU and Vessels</p>	<p>EPO 6 No impacts to marine fauna greater than that caused by minimum required light emissions for safe work / navigation.</p> <p>EPO 7 No displacement of marine turtles from habitat critical during nesting and interesting periods and marine turtles' biologically important behaviour can continue in biologically important areas.</p>	<p>EPO 1.1 - EPO 1.4</p>	<p>OPP EPO's 1.1 through to 1.4 require protection of habitat such that no adverse impact occurs on the marine ecosystem, as well as no substantial adverse effect on a population of seabirds / shorebirds, or migratory species.</p> <p>The EP EPO 6 aligns with these protection requirements in that lighting impacts will be limited to the ALARP and Acceptable level discussed in the Section 6.7.3 Risk Assessment, taking into consideration the National Light Pollution Guidelines.</p> <p>An additional EPO 7 has been included for marine turtles.</p>
<p>Section 6.7.4 Routine Acoustic Emissions: FPU Hook-up and Commissioning</p> <p>Section 6.7.5 Routine Acoustic Emissions: Routine Operations</p>	<p>EPO 8 No injury of, or mortality to, EPBC Act 1999 and WA Biodiversity Conservation Act 2016 listed marine fauna as a result of noise generated by the Petroleum Activities Program.</p> <p>EPO 9 No displacement of marine turtles or pygmy blue whales from habitat critical during nesting/breeding (inc. interesting periods for turtles) and ensure biologically important behaviour can continue in biologically important areas.</p>	<p>EPO 4.1 – EPO 4.3</p>	<p>OPP EPOs 4.1 through to 4.3 relating to underwater noise impact potential require protection of habitat such that no adverse impact occurs on the marine ecosystem, no substantial adverse effect on fish, marine mammals, marine reptiles or spatial distribution of a population. The OPP EPO's also require no serious disruption to lifecycle of an ecologically significant proportion of the population of a migratory species.</p> <p>The EP EPO's provide a higher level of protection than the OPP EPO's due to requirement to protect against injury or mortality to individual marine fauna, rather than the population level set in the OPP.</p> <p>EP EPO 9 aligns with OPP EPO 4.3 and offers a greater level of protection through no displacement of marine turtles and pygmy blue whales as opposed to the level of serious disruption established in the OPP.</p>
<p>Section 6.7.6 Routine and Non-Routine Atmospheric</p>	<p>EPO 3 Minimise GHG emissions from vessels through efficient fuel usage and consideration of fuel types utilised.</p>	<p>EPO 3.1 and EPO 3.2</p>	<p>OPP EPO's 3.1 and 3.2 require optimisation of air emissions, reduction in direct GHG emissions and active support for the global transition to a lower carbon future.</p>

Aspect	EPOs in this EP	Relevant EPOs from the Scarborough OPP	Comparison
and Greenhouse Gas Emissions	EPO 10 Net FPU GHG emissions shall achieve GHG reductions under reformed Safeguard Mechanism (inclusive of legislated net zero emissions by 2050).		EP EPO's have been rewritten to be more measurable, align with Regulatory regimes whilst still meeting the intent of the OPP EPO's to drive reduction in Woodside direct emissions and support customers in reducing their own emissions.
	EPO 11 Woodside will support customers to reduce their GHG emissions		
	EPO 12 Net GHG emissions associated with onshore processing will be subject to reduction requirements under the reformed Safeguard Mechanism (inclusive of legislated net zero emissions by 2050)		
	EPO 29 Estimated GHG emissions associated with third party transport, regasification, distribution and end use shall remain below 162 MtCO ₂ -e over 5 year operational span of this EP revision		
Section 6.7.7 Routine Atmospheric Emissions –Offshore, and Indirect emissions from gas processing onshore	EPO 13 Impacts of routine offshore atmospheric emissions will be limited to planned activities and impacts described as part of the Petroleum Activities Program.	EPO 2.1	OPP EPO 2.1 requires no substantial change to air quality which may adversely impact on biodiversity, ecological integrity, social amenity or human health. The EP EPOs align with the OPP protection requirements through limiting impacts to those that have been assessed as ALARP and Acceptable in the Section 6.7.8 risk assessment. The risk assessment takes into consideration the context of community interest and concern and existing studies such as the Murujuga Rock Art Monitoring Program (MRAMP).
	EPO 14 Prevent accelerated weathering of Murujuga rock art or impact to human health from air emissions that result from onshore processing of Scarborough gas.

Aspect	EPOs in this EP	Relevant EPOs from the Scarborough OPP	Comparison
Section 6.8.3 Unplanned Diesel Release: Loss of FPU / ASV Structural Integrity/Stability	EPO 21 No release of hydrocarbons to the marine environment due to structural integrity failure or loss of stability of the FPU/ASV.	EPO 19.1	There is no EPO in the OPP which relates directly to this risk, however EPO 19.1, which requires there to be no release of hydrocarbons to the marine environment (due to a vessel collision) associated with the Scarborough development, is the closest comparable. EPO 21 is the same as EPO 19.1 in that no release of hydrocarbons to the marine environment is permitted.
Section 6.8.4 Unplanned Gas Release: Loss of Well Containment	EPO 22 No release of hydrocarbons to the marine environment due to well loss of containment.	EPO 19.1	There is no EPO in the OPP which relates directly to this risk, however EPO 19.1, which requires there to be no release of hydrocarbons to the marine environment (due to a vessel collision) associated with the Scarborough development, is the closest comparable. EPO 22 is the same as EPO 19.1 in that no release of hydrocarbons to the marine environment is permitted.
Section 6.8.5 Unplanned Gas Release: Subsea Equipment and Trunkline Loss of Containment	EPO 23 No release of hydrocarbons to the marine environment from subsea equipment and the Scarborough Trunkline.	EPO 19.1	There is no EPO in the OPP which relates directly to this risk, however EPO 19.1, which requires there to be no release of hydrocarbons to the marine environment (due to a vessel collision) associated with the Scarborough development, is the closest comparable. EPO 23 is the same as EPO 19.1 in that no release of hydrocarbons to the marine environment is permitted.
Section 6.8.6 Unplanned Diesel Release: FPU Topsides Loss of Containment including Bunkering/Refuelling	EPO 24 No release of hydrocarbons or chemicals to the marine environment from FPU Topsides or bunkering activities.	EPO 19.1 and EPO 14.1	EPO 19.1 from the Scarborough OPP requires there to be no release of hydrocarbons to the marine environment (due to a vessel collision) associated with the Scarborough development while OPP EPO 14.1 requires no unplanned release of chemicals to the marine environment resulting in a substantial change in water quality which may adversely impact on biodiversity, ecological integrity, social amenity or human health.
Section 6.8.7 Unplanned Discharge: Chemical Release during Transfer, Storage and Use	EPO 24 No release of hydrocarbons or chemicals to the marine environment from FPU Topsides or bunkering activities.

Summary of Assessment Outcomes				
Receptor	Impact	Receptor Sensitivity Level	Magnitude	Impact Significance Level/Risk Consequence
<p>Overall Impact Significance Level/Risk consequence: Roll up to Impact/consequence rating (in impact/risk evaluation summary at top of this table) but need to look at individual receptors as being equal to or less than level of acceptability in the OPP.</p>				

Demonstration of ALARP				
Control Considered	Control Feasibility (F) and Cost/Sacrifice (CS)	Benefit in Impact/Risk Reduction	Proportionality	Control Adopted
ALARP Tool Used – Section 2.3.5				
Summary of control considered to ensure the impacts and risks are continuously reduced to ALARP. Regulation 21(5)(c).	Technical/logistical feasibility of the control. Cost/sacrifice required to implement the control (qualitative measure).	Quantum of impact/risk that could be averted (measured in terms of reduction of likelihood, consequence and current risk rating) if the cost/sacrifice is made and the control is adopted.	Proportionality of cost/sacrifice vs environmental benefit. If proportionate (benefits outweigh costs) the control will be adopted. If disproportionate (costs outweigh benefits) the control will not be adopted.	If control is adopted: Reference to Control # provided.
<p>ALARP Statement: Made on the basis of the environmental risk assessment outcomes, use of the relevant tools appropriate to the decision type (Section 2.3.3 and Figure 2-2) and a proportionality assessment. Regulation 34(b).</p>				

Demonstration of Acceptability
Acceptability Criteria and Assessment
Impact Significance Level/Risk Consequence levels for receptors are within acceptable bounds of the OPP: Adoption of relevant OPP EPOs and controls: Internal/external context and other requirements specific to this EP Petroleum Activities Program:
<p>Acceptability Statement: Outcomes of the impact assessment in comparison to OPP and ALARP demonstration.</p>

<p>controls via the measurement criteria.</p> <p>A: Achievability/feasibility of the outcome demonstrated via discussion of feasibility of controls in ALARP demonstration. Controls are directly linked to the outcome.</p> <p>R: The outcome will be relevant to the source of risk and the potentially impacted environmental value.</p> <p>T: The outcome will state the timeframe during which the outcome will apply or by which it will be achieved.</p>			

6.5 Potential Environment Risks Not Included Within the Scope of this Environment Plan

The ENVID identified environmental risks that were assessed as not being applicable within or outside the PAA as a result of the Petroleum Activities Program and, therefore, were determined to not form part of this EP. These are described in the next sections for information only.

6.5.1 Shallow/Near-shore Activities

The Petroleum Activities Program is located in water depths greater than 30 m and more than 5 km from nearest landfall (Dampier Archipelago). Consequently, risks associated with shallow/nearshore activities such as vessel anchoring, and risks of grounding were assessed as not credible.

6.5.2 Loss of Containment of Existing or Third-party Subsea Infrastructure

As described in Section 4.10.5, the Trunkline Operational Area intersects several existing oil and gas export trunklines. A subsea loss of containment from a rupture of one of these export trunklines within the Trunkline Operational Area could occur in the event of a dropped object during IMMR activities. While credible, the risk has been eliminated through the adoption of lifting controls, detailed in the controls of Section 6.8.9.

Worst-case credible hydrocarbon release scenarios have been defined in relevant EPs including:

- Start-Up and Operations EP for the Wheatstone Project
- Reindeer Wellhead Platform and Offshore Pipeline Operations EP
- Julimar Operations EP
- Pluto Facility Operations EP.

These EPs include subsea loss of containment resulting from a rupture of the export trunkline/flowline where relevant. The existing EPs provide a description and assessment of impacts and risks as well as management controls and response capabilities for an export trunkline/flowline rupture.

While it is credible for activities within the Petroleum Activities Program to cause damage to third party infrastructure, so that assessments can be made, at the point of environmental consequence occurring, the event falls in the scope of the relevant third-party Environment Plan described above.

6.6 Indirect Impacts

For the proposed Petroleum Activities Program, potential 'indirect' environmental impacts and risks are those associated with waste brought onshore, mobilisation/demobilisation of vessels to the PAA, wet-tow of the FPU to the operational area, and emissions associated with the extraction of Scarborough gas for onshore processing and third party transport, regassification, distribution and use. Due to the nature and scale of these potential indirect environmental impacts and risks, and the regulatory frameworks in place to manage them, Woodside considers the potential indirect impacts and risks from these activities to be inherently managed to ALARP and acceptable in its current state.

However, recognising stakeholder interest with the processing of Scarborough gas onshore and the potential indirect impacts from atmospheric emissions; and indirect GHG emissions from third party use, further information and evaluation has been provided for in Section 6.7.6 and Section 6.7.7.

Description of Source of Impact/Risk

(approximately 0.79 km²). The FPU is highly visible under most conditions and is lit to meet operational requirements and navigational codes and regulations. The nature of the facility (large steel structure) ensures a clear radar return to alert ships fitted with anti-collision radars.

Routine vessel activities associated with the Petroleum Activities Program will be concentrated within the FPU PSZ (e.g. activities performed by Support Vessels at the FPU). Support Vessels, LCVs, or Uncrewed Surface Vessels (USV) may undertake activities (e.g. IMMR activities, gravimetry surveys, removing redundant equipment) within the PAA at any time, including within parts of the PAA which are beyond the PSZ. The duration and location of these activities will vary depending on the activity being undertaken (**Section 3.4**).

Subsea infrastructure associated with the Petroleum Activities Program such as wells, risers, flowlines, support structures and mooring piles and chains may also impact other marine users.

A number of oil and gas facilities are located in the vicinity of the Operational Areas, including existing pipelines and fibre optic cables (**Section 4.10.5** and **Section 4.10.6**).

Detailed Impact Assessment

Assessment of Potential Impacts

Exclusion and Displacement of Other Users

Interaction with other marine users due to the physical presence of the Petroleum Activities Program may result in localised changes to the functions, interests or activities of other users. The duration of change will be for the period of the Petroleum Activities Program.

Commercial Fisheries – FPU Installation and Mooring Hook-up, Commissioning and Start-up

Potential impacts to commercial fisheries from FPU installation and mooring hook-up, commissioning, and start-up include the loss of commercial catch due to displacement from fishing grounds and potential damage to fishing gear. Fishing activities will be excluded from the PSZ around the FPU and SEZs around applicable vessels.

The Offshore Operational Area is in relatively deep water ~216km from the closest landfall. Very few fisheries routinely operate in similar depths and distances from shore in the region; only the North West Slope Trawl Fishery and Western Deep Water Trawl Fishery operate in similar depths and neither fishery recorded landings in graticular blocks overlapping the Offshore Operational Area in the last five years.

While the presence of the FPU in the field will be ongoing, the presence of vessels and temporary SEZ's outside the FPU PSZ will be intermittent. The potential impact to commercial fishers is considered to be limited to a minor displacement of fishing effort (i.e. navigational hazard).

Commercial Fisheries – Operations

Fishing activities will be excluded from the PSZ around the FPU and from vessel temporary SEZs during IMMR or gravimetry activities. Potential impacts to commercial fisheries include loss of commercial catch due to displacement from fishing grounds and potential damage to fishing gear.

The PAA overlaps four Commonwealth and sixteen State managed commercial fisheries management areas (**Section 4.10**). Of these fisheries, eight have recorded landings from graticular reporting blocks overlapping the PAA. None of these fisheries have recorded landings in graticular reporting blocks overlapping the Offshore Operational Area in the last five years, with landings only recorded in graticular blocks overlapping the Trunkline Operational Area by the following fisheries:

- North West Slope Trawl Fishery
- Western Deep Water Trawl Fishery
- Mackerel Managed Fishery
- Marine Aquarium Fishery
- Pilbara Crab Managed Fishery
- Pilbara Line Managed Fishery
- Pilbara Trap Managed Fishery
- Specimen Shell Fishery.

Fisheries using divers, lines, traps, and pots have little or no potential to interact with subsea infrastructure, hence impacts to such fisheries will be limited to localised displacement from the PSZ and temporary SEZs associated with vessels undertaking work in the PAA. The presence of the trunkline may provide relatively complex habitat that aggregates commercially targeted demersal fish species. This may result in increased fishing effort along the trunkline by line- and trap-based fisheries.

The presence of subsea infrastructure over the field life could present a hazard to bottom trawl fisheries due to the risk of equipment entanglement and subsequent equipment damage/loss. Fisheries using bottom trawl gear with landings

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

in the PAA in the last five years are the North West Slope Trawl Fishery and the Western Deep Water Trawl Fishery. The majority of the activity in both fisheries occurs beyond the PAA. The Pilbara Trawl Fishery, the most active trawl fishery in the region, has not recorded landings in the PAA in the last five years, and current management arrangements prohibit this fishery from trawling in the PAA. The PSZ precludes trawl fishing around the FPU, however trawl fishing is permitted along the trunkline.

The design of the trunkline has an inherently low risk of snagging trawled gear, as there are no projections that may present a snag risk. Development of free spans may pose a risk to snagging otter boards of trawled fishing gear. Based on Woodside's operational experience, the development of free spans that pose a risk to snagging trawled gear is infrequent. The consequence of snagging trawled gear is expected to be limited to damage to or loss of trawled gear. Impacts, such as loss of a vessel, are not credible based on operational experience and studies of trawl fishing interactions with subsea infrastructure in Australia. Given the very low levels of trawl fishing in the PAA, the presence of infrastructure on nautical charts, and Woodside's consultation to date, interactions between trawled gear and subsea infrastructure will not credibly occur.

Consequently, impacts to commercial fisheries will be limited to a localised displacement of fishing effort to avoid subsea infrastructure, the PSZ, and vessels undertaking the petroleum activity.

Tourism and Recreation

Tourism and recreation within the PAA are expected to be limited by the distance offshore and water depths. Some tourism may occur in the nearshore waters of the Trunkline Operational Area, particularly in proximity to the Montebello Islands (refer to Section 4.10.3). However, impacts are expected to be limited by the short duration and intermittent nature of vessel activities at this location, and the distance from these islands. Recfishwest has stated that given the location of the activities it is unlikely they will have a high impact on recreational fishing therefore Recfishwest has no concerns. Given the location, and the temporary nature of activities within the Trunkline Operational Area, potential impacts to tourism and recreational activities would likely be a minor interference (i.e. navigational hazard) and temporary, localised displacement/avoidance.

Shipping

Impact to commercial shipping is limited to the temporary presence of vessels throughout the Petroleum Activities Program. It is noted that a number of AMSA marine fairways intersect with the Trunkline Operational Area (refer to Section 4.10.4). The closest major shipping channel is approximately 35 km from the Offshore Operational Area and shipping activity is therefore expected to be low. Vessel traffic data shows that the majority of vessel movements occur to the south-east of the Offshore Operational Area.

Given the temporary nature of vessel activities in the Trunkline Operational Area and the low level of shipping activity within the Offshore Operational Area, impacts to shipping are considered slight with no lasting effect.

The NWS is an area of active oil and gas exploration and production. There are no oil and gas platforms owned or operated by other petroleum titleholders located within 50 km of the Offshore Operational Area (FPU). Displacement of, or interference with, other oil and gas activities are not expected within the Offshore Operational Area.

Defence

The PAA lies within the northern tip of one of these defence training areas, the North West Exercise Area (NWXA) accessed by Royal Australian Air Force (RAAF) Base Learmonth (Section 4.10.6). Defence stakeholders were notified and feedback addressed as per Section 5. Any potential interaction is expected to be negligible and consistent with other facilities within the northwest region.

Industry

A number of oil and gas facilities are located in proximity to the Offshore and Trunkline Operational Area, including a number of existing platforms, export trunklines and fibre optic cables (Section 4.10.5 and Section 4.10.6). The operational area (**Section 3.3**) also includes overlap with adjacent petroleum titles (WA-67-R, WA-89-R and WA-518-P), which are held by other oil and gas operators. There is potential that gravimetry vessel (surface activity) may occur temporarily within the adjacent titles to allow for vessel manoeuvrability and only for the period of time required to undertake the gravimetry activity. Where titleholders are undertaking activities within adjacent titles at the same time, there is sufficient flexibility in the gravimetry survey schedule (e.g. gravimetry to be undertaken at concrete pads away from adjacent title boundaries), that there will be limited to no interference or impacts to other oil and gas operator activities. The nearest oil and gas platform is Pluto. Pluto is operated by a Woodside entity; impacts from the Petroleum Activities Program to Pluto do not affect third parties. The nearest facilities not operated by Woodside are the Jadestone-operated Stag platform and Chevron operated Wheatstone platform 5 km and 10 km respectively outside of the PAA. Activities associated with the occasional physical presence of vessels conducting IMMR activities along the export trunkline route may result in localised, short-term interference to industry vessels requiring minor course alteration or readjustment in asset management while the Petroleum Activities Program is active in the area. However, impacts are not expected to have lasting effect.

Summary of Assessment Outcomes				
Receptor	Impact	Receptor Sensitivity Level	Magnitude	Impact Significance Level
Commonwealth Managed Fisheries	Changes to the function interests or activities of others	High value marine user	No Lasting Effect	Slight (E)
State Managed Fisheries		High value marine user	No Lasting Effect	Slight (E)
Tourism and Recreation		High value marine user	No Lasting Effect	Slight (E)
Commercial shipping		High value marine user	No Lasting Effect	Slight (E)
Industry		Medium value marine user	No Lasting Effect	Negligible (F)
Defence		High value marine user	No Lasting Effect	Slight (E)
Overall Impact Significance Level: The overall impact significance level for Interaction with other marine users is Slight (E) based on no lasting effect to high value socio-economic receptors. The impact significance levels for individual receptors are consistent with the levels in the OPP, noting that defence, tourism and recreation were not identified receptors for this risk in the Scarborough OPP.				

Demonstration of ALARP				
Control Considered	Control Feasibility (F) and Cost/Sacrifice (CS)	Benefit in Impact/Risk Reduction	Proportionality	Control Adopted
Legislation, Codes and Standards				
Vessels to adhere to the navigation safety requirements including the <i>Navigation Act 2012</i> and any subsequent Marine Orders.	F: Yes. CS: Minimal cost. Standard practice.	The act regulates ship related activities and invokes certain requirements of MARPOL. Vessels (relevant to class) will adhere to requirements.	Control based on legislative requirement – must be adopted.	Yes C 1.1
Implementation of a 500 m PSZ around FPU.	F: Yes. CS: Minimal cost. Standard practice.	The PSZ is a requirement under Australian regulations and reduces the likelihood of interactions with third parties and the FPU.	Control based on legislative requirement – must be adopted.	Yes C 1.2
Establishment of temporary SEZ by applicable vessels and communicated to marine users.	F: Yes. CS: Minimal cost. Standard practice.	Establishment of temporary SEZ around applicable vessels reduces the likelihood of interaction with other marine users.	Benefits outweigh cost/sacrifice.	Yes C 1.3
Good Practice				
Notify Australian Hydrographic Service (AHO) of activities and movements, where vessels will be in	F: Yes. CS: Minimal cost. Standard practice.	Notification of AHO will enable them to update maritime charts thereby reducing the likelihood of	Benefits outweigh cost/sacrifice.	Yes C 1.5

Demonstration of ALARP				
Control Considered	Control Feasibility (F) and Cost/ Sacrifice (CS)	Benefit in Impact/Risk Reduction	Proportionality	Control Adopted
prior to the commencement of activities.		undertaken in close proximity or within adjacent title areas ensures they are informed and aware, thereby reducing the likelihood of potential impact		
Professional Judgement – Eliminate				
Limit activities to avoid peak shipping and commercial fishing activities.	F: No. Shipping occurs year-round and cannot be avoided. SIMOPS with fishing seasons cannot be eliminated as exact timings for all activities are not confirmed. CS: Not considered – control not feasible,	Not considered – control not feasible.	Not considered – control not feasible.	No
Reducing the PSZ.	F: No. PSZ is mandated by the OPGGS Act and is an SCE; it cannot be reduced. CS: Not assessed, control not feasible.	Not assessed, control not feasible.	Not assessed, control not feasible.	No
Professional Judgement – Substitute				
No additional controls identified.				
Professional Judgement – Engineered Solution				
FPU's collision prevention system is implemented during Operations to alert marine vessels of the facility location, which reduces the likelihood of adverse interaction with other marine users.	F: Yes. CS: Minimal cost. Standard practice.	Collision prevention system equipment has the ability to alert marine vessels of the facility location, which reduces the likelihood of adverse interaction with other marine users.	Control is SCE requirement – must be adopted during Operations.	Yes C 1.10
Over-trawl protection on subsea infrastructure.	F: Yes. Over-trawl protection on subsea infrastructure could be fitted to subsea infrastructure. CS: Significant additional cost associated with designing and installing trawl protection on subsea infrastructure.	Over-trawl protection on subsea infrastructure could mitigate the potential for commercial fishing trawl gear to damage infrastructure or result in gear loss.	Given the PAA only overlaps a small portion of the fisheries management area open to trawl fishing, the cost of installing over-trawl protection is considered grossly disproportionate to the environmental benefit.	No

Demonstration of ALARP				
Control Considered	Control Feasibility (F) and Cost/ Sacrifice (CS)	Benefit in Impact/Risk Reduction	Proportionality	Control Adopted
<p>ALARP Statement:</p> <p>On the basis of the environmental impact assessment outcomes and use of the relevant tools appropriate to the decision type (i.e. Decision Type A; Section 2.3.3), Woodside considers the adopted controls appropriate to manage the impacts of the physical presence of the Petroleum Activities Program on other users.</p> <p>As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts are considered ALARP.</p>				

Demonstration of Acceptability
<p>Acceptability Criteria and Assessment</p> <p>Demonstration of acceptability for the sources of aspect and associated impacts assessed in this section are provided in Section 7.1 of the Scarborough OPP. The Petroleum Activities Program meets the acceptability criteria (Section 2.3.5):</p> <ul style="list-style-type: none"> • Overall impact significance levels for individual receptors are less than the significant impact level defined in the OPP. • EPOs in this EP are aligned with EPOs in the OPP (refer to Table 6-2) • Controls in the OPP that are relevant to this EP Section have been adopted. • There are no changes to internal/external context specific to this risk from the OPP, including issues raised during consultation.
<p>Acceptability Statement:</p> <p>The impact assessment has determined that, given the adopted controls, physical presence of the Petroleum Activities Program is unlikely to result in an impact significance level greater than Slight.</p> <p>The adopted controls are considered good oil-field practice/industry best practice and meet requirements of Australian Marine Orders, AMSA, DPIRD, DOD and AHO identified during impact assessment and consultation with relevant persons.</p> <p>The potential impacts are considered broadly acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to, manage the impacts from the physical presence of the Petroleum Activities Program to a level that is broadly acceptable; and demonstrates the EPOs are met.</p>

Placement and retrieval of seabed transponders (DP vessels)		✓	✓		✓				F					

Description of Source of Impact
<p>FPU Mooring Line Retrieval and Connection Operations</p> <p>The transport of the FPU and its subsequent mooring is proposed to be undertaken by tugs as described in Section 3.9.7. While the FPU is held in position by the tugs, two mooring hook-up Anchor Handling Tugs (AHTs) will recover the pre-laid mooring chains from the seabed for attachment. During the recovery of the wet-stored mooring chains, some additional minor seabed disturbance cumulative to the pre-lay footprint (0.008 km² within a 11 km² area) is expected due to the metocean conditions and vessel heave experienced during the activity.</p>

Description of Source of Impact

Once the 20 mooring chains are securely connected, the FPU will be connected (hooked-up) to the wet stored subsea system consisting of six risers and one dynamic umbilical. Pick-up rigging left attached to the pre-laid subsea systems will be used by AHT's to pull-in and hang-off the risers/umbilical from the FPU in order to facilitate installation. Similar to the mooring hook-up, some additional seabed disturbance is expected to occur during this activity.

Gravimetry Surveys

Gravimetry surveys will be conducted at routine intervals and each survey will take approximately 55 days to complete (subject to weather constraints). The surveys involve the measurement of gravity and water pressure by the temporary placement of a passive gravity meter and water pressure sensor, sequentially on each concrete pad (224 installed previously under the *WA-61-L and WA-62-L Subsea Infrastructure Installation EP*) by ROV, and temporary deployment of tide gauges on the seabed. The ROV will stand off during the measurements and is planned to be landed on the seabed. Approximately 39 tide gauges will be deployed at 13 locations, the seabed disturbance footprint at each of the 13 locations will be approximately 1 m² resulting in very minor localised seabed disturbance. The tide gauges will be recovered after each survey is complete.

ROV Operations

ROVs may be used during activities including observation during IMMR activities; physical installation assistance; condition surveys; and removal of debris or marine growth. The use of an ROV may result in temporary seabed disturbance and suspension of sediment as a result of working close to, or occasionally on, the seabed. ROV use close to or on the seabed is limited to that required for effective and safe subsea activities. The footprint of a typical ROV is about 2.5 m × 1.7 m (4.25 m²). Disturbance is expected to be limited to within the immediate vicinity of subsea infrastructure.

Underwater Acoustic Positioning

Accurate positioning for DP systems may be required, and therefore long base line (LBL) and/or ultra short baseline (USBL) acoustic positioning may be required in some instances (**see** Section 3.9.17.11). **LBL** transponders may be moored to the seabed by a clump weight or stands (approximate footprint of <1 m²), which are recovered by means of a hydrostatic release. If clump weights or stands are used, they will be recovered where practicable.

Operations

The facility and associated subsea infrastructure provide hard substrate habitat; extending from the sea surface through the water column to the seabed (e.g., risers), as well as along the seabed (e.g., pipelines, flowlines, etc). The presence of subsea infrastructure may result in localised scouring around the infrastructure due to currents, subsurface waves and seabed sediment fluid dynamics. Scour around subsea infrastructure may necessitate IMMR activities as part of integrity management practices.

Flowline and/or trunkline movement may occur as per design and within integrity margins along the flowline and trunkline corridors. Normal flowline/trunkline operational movement occurs due to factors such as buckling, walking and varying metocean conditions. Lateral movement can occur within the flowline and trunkline corridors. Management of flowline/trunkline buckling and walking may necessitate IMMR activities. Refer to Unplanned Hydrocarbon Release Subsea Equipment Loss of Containment in **Section 6.8.5**, which includes controls to limit scour and flowline movement within integrity requirements.

To maintain the integrity of subsea infrastructure, Woodside may be required to undertake routine subsea IMMR activities, as described in Section 3.9.17. These may impact the benthic environment in the immediate vicinity of the activity. IMMR activities identified as impacting the benthic environment may include but are not limited to:

- inspections – localised sediment resuspension by ROV
- marine growth removal – localised resuspension of sediment; removal of marine biota from subsea infrastructure
- sediment relocation – localised modification of benthic habitat and sediment resuspension
- span rectification, trunkline protection and stabilisation – minor, localised modification of benthic habitat within footprint of area subject to rectification/protection/stabilisation
- jumper and umbilical replacement – minor, localised modification of benthic habitat in the vicinity of the jumper/umbilical
- spool repair/replacement – minor, localised modification of benthic habitat in the vicinity of the spool
- temporary placement of tools on the seabed, e.g. baskets – minor localised modification of the benthic habitat in the vicinity of the items
- temporary pig launcher/receiver installation and retrieval - minor, localised modification of benthic habitat and sediment resuspension in the vicinity of the receiver.

The area of benthic habitat predicted to be impacted varies depending on the nature and scale of the IMMR activity. Span rectification is the IMMR activity with the greatest potential to modify benthic habitats, due to the alteration of the existing soft sediment habitat to hard substrate. Woodside's prior operational experience on the North West Shelf

Description of Source of Impact

indicates these activities are typically restricted to relatively short (tens of metres) linear sections of pipeline, with areas of up to approximately 100 m² impacted.

Contingency Activities

Equipment, materials or tools may need to be wet stored on the seabed in the Operational Area during infrastructure installation. This could include, but not be limited to, work baskets for ROV tools, pig launcher/receiver prior/after connection, damaged risers or flowlines etc.

Detailed Impact Assessment

Assessment of Potential Impacts

Seabed disturbance can be categorised into two potential impacts, direct seabed disturbance (physical alteration to seabed such as placement of tide gauges), or indirect disturbance (activities that cause sediment movement such as ROV operations).

Water and Sediment Quality

Seabed disturbance may include localised and temporary decline in water quality due to increased suspended sediment concentrations and increased sediment deposition caused by the activities described above. However, sediment loads are not expected to be significant due to the relatively small footprint and duration for each activity. Elevations in turbidity will be intermittent and temporary in nature depending on the activity (e.g. IMMR activities, and/or ROV use etc.). Further, the sediment dispersed during these activities is naturally occurring and will settle under existing hydrodynamic conditions. Similarly, removal of marine growth during IMMR activities on an as-required basis would cause localised temporary decrease in water quality and suspended sediment from water jetting activities.

Epifauna and Infauna

The Offshore Operational Area is located in water depths of approximately 900–1000 m and the Trunkline Operational Area in water depths ranging from ~30 - 1400 m (refer to Section 3.2). **Marine** life, such as benthic epifauna and infauna (living on and in the sediment dominated habitat), may be impacted from operational activities that result in disturbance to the seabed.

Disturbance to the seabed can alter the physical seabed habitat conditions, resulting in epifauna and infauna community changes (Newell et al., 1998). The seabed of the Offshore Operational Area is characterised by sparse marine life dominated by mobile organisms (ERM, 2013). The benthic biota are predominantly deposit feeders such as epifauna (living on the seabed): shrimp (crustaceans) and sea cucumbers (echinoderms), and infauna (living within the surface sediments) small, burrowing worms (polychaetes) and crustaceans (ERM, 2013).

No threatened or migratory species, or ecological communities (as defined under the EPBC Act), were identified in the benthic communities during studies completed in the PAA (e.g. ERM, 2013). The epifauna and infauna benthic communities known to exist in the PAA are likely to be well represented elsewhere in the region, with impacts restricted to a highly localised proportion of benthic communities.

The seabed sediments of the PAA contain low levels of contaminants such as metals and no hydrocarbons (Section 4.4) so no toxicological impacts to benthic biota from disturbed sediments is predicted. The scale and magnitude of potential impacts will be limited to the offshore seabed infrastructure and trunkline physical footprint area, representing a relatively small proportion of the total area of deep water habitat and associated benthic communities of the PAA, that are known to be present in the wider region.

Offshore Operational Area

Temporary disturbance to the seabed will occur in the Offshore Operational Area from infrastructure and equipment associated with FPU hook-up. Impacts will be highly localised and equipment (e.g., ROV associated equipment and transponders) will be removed upon completion of the activity. Permanent infrastructure will be present for the duration of field life including gravimetry pads; flowlines, umbilicals and associated structures (including mud mats); RBM and foundation and FPU mooring legs. Habitat modification will be highly localised as a result of scouring around subsea infrastructure or disturbance to the seabed during IMMR activities.

Trunkline Operational Area

The export trunkline up to approximately KP 33 is buried and ongoing disturbance to benthic communities is not expected. Between KP 50 and KP 109, the seabed is generally featureless with occasional areas where the underlying calcarenite is intermittently exposed that may support patches of benthic filter feeder communities. The calcarenite outcrops generally run perpendicular to the export trunkline and are spread widely over the North West Shelf (Wilson, 2013). Any intersections of the isolated calcarenite outcropping identified from the geophysical data represent a very small area (<0.01km²). From KP 109 to KP 192 the export trunkline intersects the Montebello AMP, with potential impacts to the values of the AMP assessed below. From KP 192 to the continental slope and deep waters of the PLET, the seabed has been observed to be generally featureless, with epifauna more abundant on the continental shelf compared to the slope. Soft sediment benthic communities are dominated by infauna (including molluscs, crustaceans and worms) and isolated larger fauna (free swimming cnidarian, demersal fish and benthic crustaceans).

Detailed Impact Assessment

Direct seabed disturbance, including permanent modification of benthic communities, may result as a consequence of IMMR activities such as span rectification, export trunkline protection and stabilisation. These activities may disturb a small area (typically < 100 m²) of soft sediment habitat, which is broadly represented in the PAA and wider region. Benthic communities may be reduced or altered, leading to a highly localised impact to any epifauna and infauna benthic communities present. Potential impacts include; burial or smothering of benthic biota from localised sediment deposition, particularly to sessile epifauna such as sea pens and infauna (polychaetes), and sediment coating resulting from elevated turbidity/TSS potentially causing clogging or damage to the physiological functioning of certain biota (sea pens, polychaetes) reliant on external respiratory and feeding structures.

The estimated overall extent of direct and indirect seabed disturbance is extremely small in relation to the extent of the soft sediment habitats which are broadly represented within the PAA. As such, impacts are expected to be slight (E) and short term.

Artificial Habitat

The presence of the FPU, subsea infrastructure and trunkline (including concrete mattresses and rock armour) provides hard substrate for the settlement of marine organisms; the availability of hard substrate is often a limiting factor in benthic communities. As such, the ongoing presence of these structures will lead to the development of ecological communities which would not have existed otherwise. For example, export trunkline infrastructures has been shown to support more diverse fish assemblages and benthic biota (McLean et al. 2017). These communities are relatively diverse compared to the open water and soft sediment habitats in the broader PAA.

The provision of artificial habitat associated with the FPU, subsea infrastructure and export trunkline will either have no adverse environmental impact or a low level of positive environmental impact through increasing biological diversity.

KEFs

The Exmouth Plateau, Continental Slope Demersal Fish Communities and Ancient Coastline at 125 m depth contour KEFs overlap the PAA and seabed disturbance may lead to a highly localised change in habitat and water quality (Table 6-3). Impact to habitats from localised scour or seabed disturbance in the proximity of infrastructure represents a small area relative to the large extent of the KEFs and disturbance will be short-term, associated with the temporal extent of the operational activities described above (e.g. FPU mooring hook-up, gravimetry surveys and IMMR activities). These potential impacts are unlikely to impact the ecological value of the KEFs (as described in Section 4.7). Physical habitat modification is not listed as a potential concern for Exmouth Plateau KEF or Ancient Coastline at 125 m Depth Contour KEF and therefore impacts to the values of these KEFs are not anticipated. Physical habitat modification is listed as a potential concern for the Continental Slope Demersal Fish Communities KEF; however, the total impact area is small, and impacts will be highly localised to the Trunkline Operational Area.

Table 6-3: Potential Petroleum Activities Program within key ecological features and disturbance

KEF	Activities which may occur within KEF	Disturbance within KEF (%) based on 30 m disturbance
Exmouth Plateau KEF	FPU hook-up and subsea/trunkline IMMR activities (including span rectification)	<0.0035
Ancient Coastline at 125 m Depth Contour KEF	Trunkline IMMR activities (including span rectification)	<0.0004
Continental Slope Demersal Fish Communities KEF	Trunkline IMMR activities (including span rectification)	<0.0007

AMPs

The Trunkline Operational Area intersects the Montebello AMP (Multiple Use Zone (VI)) between KP 109 to KP191. This equates to an approximate 2.48 km² overlap (allowing for a 30 m disturbance area for the export trunkline during IMMR activities), which is equivalent to 0.07% of the AMP, including the area intersecting the Ancient Coastline KEF. Potential scour around the export trunkline will be highly localised. IMMR activities along the export trunkline such as span rectification will also result in short-term temporary disturbance within the 30 m disturbance corridor. No mooring of vessels during IMMR activities will be required.

A description of the epifaunal communities in the Montebello Islands AMP is provided in Section 4.8. The trunkline intersects an area of sparse epifauna in the South-eastern section of the AMP and intersects areas of slightly more abundant and diverse epifauna in the North-western section of the AMP (Advisian 2019a and 2019b, Keesing 2019). However, these areas are typical of the benthos found both within the AMP and regionally. Benthic organisms (including sponges and soft corals) generally occur as single or low density aggregations of individuals with isolated denser areas of sponges in areas identified from the bathymetry as having a more complex seabed structure (Advisian, 2019b). In the long term, the trunkline and crossing materials will provide hard substrate to the marine environment for the duration of the activity, which may support epifaunal communities (McLean et al. 2020; McLean et al. 2018; Bond et al. 2018; McLean et al. 2017).

Detailed Impact Assessment				
Potential impacts to foraging habitat for marine fauna, such as turtles (listed as part of the natural values of the Montebello AMP), are not expected due to the highly localised and short-term nature of seabed disturbance within the AMP during operational activities. Furthermore, the relatively deep offshore waters where the export trunkline overlaps the northern extent of the Montebello AMP (46 m to 214 m) do not represent important internersting habitat for flatback turtles.				
Summary of Assessment Outcomes				
Receptor	Impact	Receptor Sensitivity Level	Magnitude	Impact Significance Level
Water quality	Change in water quality	Low value	Slight	Negligible (F)
Sediment quality	Change in sediment quality	Low value	Slight	Negligible (F)
Epifauna and infauna	Injury/mortality	Low value	Slight	Negligible (F)
KEFs	Change in habitat Change in water quality	High value	No lasting effect	Slight (E)
AMPs	Change in habitat Change in water quality	High value	No lasting effect	Slight (E)
Overall Impact Significance Level: The overall impact significance level for disturbance to benthic habitat from subsea infrastructure installation activities is E based on a Slight impact to the high value receptors (KEFs and AMPs). The impact significance levels for individual receptors are consistent with the level in the OPP.				

Demonstration of ALARP				
Control Considered	Control Feasibility (F) and Cost/ Sacrifice (CS)	Benefit in Impact/Risk Reduction	Proportionality	Control Adopted
Legislation, Codes and Standards				
Maintain log of equipment on the seabed to confirm all temporary equipment is removed and wet stored equipment is tracked and recorded.	F: Yes CS: Minimal cost ROV as left survey is standard practice	In accordance with OPGGS Act Section 572 all equipment is removed when neither used nor to be used in connection with the operations	Legislative requirement	Yes C 2.1
Good Practice				
Unexpected finds of potential Underwater Cultural Heritage sites/features, including first nations UCH are managed in accordance with an Unexpected Finds Procedure set out in Section 7.7	F: Yes CS: Costs of implementation	Allows management of new finds in accordance with legislative requirements (including Underwater Cultural Heritage Guidance for Offshore Developments and the Assessing and Managing Impacts to Underwater Cultural Heritage in Australian Waters – Guidance on the application of the <i>Underwater Cultural Heritage Act 2018</i>), expert advice and community expectations.	Benefits outweigh cost/sacrifice.	Yes C 2.2

Demonstration of ALARP				
Control Considered	Control Feasibility (F) and Cost/ Sacrifice (CS)	Benefit in Impact/Risk Reduction	Proportionality	Control Adopted
Professional Judgement – Engineered Solution				
Monitoring and maintenance of subsea infrastructure to manage scour and flowline movement to within integrity envelope.	F: Yes, subsea inspection maintenance and integrity monitoring is undertaken which inherently controls extent of scour and flowline movement. CS: Minimal cost. Standard practice.	Monitoring and maintenance of subsea infrastructure confirms benthic seabed disturbance is limited to design flowline corridor.	Control is WMS requirement – must be adopted.	Yes C 2.6 Refer also Section 6.8.5
Monitoring and maintenance of subsea infrastructure to manage scour and flowline movement to within integrity envelope.	F: Yes. ROV footage collected as part of subsea integrity surveys could be reviewed to observe and detect changed in benthic habitats. CS: Costs associated with the review of collected footage.	Limited environmental benefit (information) gained from monitoring benthic habitats.	Given the sparsely populated infauna habitat and low sensitivity of the environment surrounding the FPU and associated subsea infrastructure, any environmental benefit gained is outweighed by costs associated with implementing control.	No

ALARP Statement:

On the basis of the environmental impact assessment outcomes and use of the relevant tools appropriate to the decision type (i.e. Decision Type A, **Section 2.3.3**), Woodside considers the adopted controls appropriate to manage the impacts of seabed disturbance from activities associated with the Petroleum Activities Program. As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts are considered ALARP.

Demonstration of Acceptability

Acceptability Criteria and Assessment

Demonstration of acceptability for the sources of aspect and associated impacts assessed in this section are provided in Section 6.3 of the Scarborough OPP. The Petroleum Activities Program meets the acceptability criteria (Section 2.3.5):

- Overall impact significance levels for individual receptors are consistent with the levels rated in the OPP.
- EPOs in this EP are aligned with EPOs in the OPP
- Controls in the OPP that are relevant to this EP Section have been adopted.
- There are no changes to internal/external context specific to this risk from the OPP, including issues raised during consultation. Following consultations with DNP on the potential risks to AMPs, the DNP noted it has no objections and claims at this time.

Acceptability Statement:

The impact assessment has determined that, given the adopted controls, the Petroleum Activities Program is unlikely to result in an impact significance level greater than Slight. Further opportunities to reduce the impacts have been investigated above. The adopted controls are considered consistent with industry good practice and meet the requirements of Woodside relevant systems and procedures.

The potential impacts are considered broadly acceptable if the adopted controls are implemented. The inclusion of C2.1 and C2.6 will confirm the activity is undertaken as described. Activities do not have a significant impact on MNES (**Section 2.4.2**). Therefore, Woodside considers the adopted controls appropriate to manage the impacts of disturbance to benthic habitat to a level that is broadly acceptable; and demonstrate the EPOs are met.

Vessel Operations

Project vessels will have external lighting, which includes navigation lights and work area lighting (i.e., bright white lights on deck areas or the exterior of accommodation areas) typically commensurate with the size of the vessel. Navigation lighting is required for the safe operation of all vessels and cannot be eliminated. Crewed vessels require the use of exterior lighting to enable a safe working environment for personnel on the back deck or in accommodation areas and cannot reasonably be eliminated. Vessels will be lit to maintain operational safety on a 24-hour basis. Uncrewed surface vessels do not require the use of exterior lighting except for the purposes of navigation, and therefore emit less light into the surrounding environment than typical crewed vessels.

During IMMR activities, underwater lighting is generated over short periods of time while ROVs are in use, as well as from deck lighting on crewed vessels. Given the typical intensity of ROV lights and the attenuation of light in seawater, light from ROVs will be localised to the vicinity of the ROV and vessels. The extent of this potential impact for the Petroleum Activities Program is restricted to the line of sight for each activity emitting light, which based on previous work undertaken by Woodside is about 30 km from vessels (Woodside, 2014). As described above, light monitoring of navigational lighting on a MODU measured light density to attenuate below 1.00 Lux and 0.03 Lux at distances of 300 m and 1.4 km, respectively. Since vessels have lower deck height than MODUs, navigational lighting from vessels is expected to be below 1.00 Lux within 300 m from the source (Woodside, 2014).

Offshore Operational Area

Cumulative light scenarios are likely with light emissions from the FPU, an ASV and additional vessels during FPU hook-up and commissioning, potentially concurrent with MODU conducting D&C activities, Support Vessels, LCVs and uncrewed surface vessels conducting gravimetry surveys and/or IMMR activities. Light emissions from the FPU will be a persistent source under normal operations, while emissions from Support Vessel activities will be temporary, only lasting for the time required to undertake the activity alongside the FPU. The location of concurrent activities in permit areas WA-61-L and WA-62-L and the existing environment with low presence of light sensitive receptors, means that cumulative impact from light on sensitive receptors, as a result of concurrent operations, is not considered credible.

Trunkline Operational Area

Vessels may temporarily be present in the Trunkline Operational Area for IMMR activities. Once activities are completed and vessels depart the area, there will be no further light emissions from activities within the Trunkline Operational Area. Light emissions in any one area are governed by the transient nature of the works along the export trunkline route. Activities will be completed sequentially which limits cumulative impacts from multiple light sources in a single area.

Detailed Impact Assessment

Assessment of Potential Impacts

Ambient Light

Lighting from the FPU and vessels may appear from direct unshielded light sources or through skyglow. Where direct light falls upon the ocean, this area of light is referred to as light spill. Skyglow is the diffuse glow caused by light that is screened from view, but through reflection and refraction creates a glow in the atmosphere. The distance at which direct light and skyglow may be visible from the source is dependent on the lighting on the FPU/vessel and environmental conditions.

Receptors that have important habitat present within a 20 km buffer of the PAA were considered as having potential for interaction, based on recommendations of the *National Light Pollution Guidelines for Wildlife Including Marine Turtles, Seabirds and Migratory Shorebirds* (NLPG). The 20 km threshold provides a precautionary limit based on observed effects of sky glow on marine turtle hatchlings (15 to 18 km) and fledgling seabirds grounded in response to artificial light 15 km away (Commonwealth of Australia, 2020).

Light emissions can affect fauna in two main ways:

- **Behaviour:** many organisms are adapted to natural levels of lighting and the natural changes associated with the day and night cycle as well as the phase of the moon. Artificial lighting has the potential to create a constant level of light at night that can override these natural levels and cycles.
- **Orientation:** organisms such as marine turtles and birds may use lighting from natural sources to orient themselves in a certain direction at night. In instances where an artificial light source is brighter than a natural source, the artificial light may act to override natural cues, leading to disorientation.

Offshore Operational Area

The marine fauna within the Offshore Operational Area are predominantly pelagic fish and zooplankton, with a low abundance of species such as turtles, whale sharks and large whales transiting through the area. Of these identified species, those with known impact pathways related to artificial light include marine turtles and a variety of seabirds and migratory shorebirds (PENV, 2023). Additionally, there is no known critical habitat within the Offshore Operational Area for EPBC listed species or BIAs listed in **Section 4.6** that overlap the Offshore Operational Area. Of the operational areas specified in the PAA, the Offshore Operational Area will have the greatest and most protracted light emissions, with concurrent activities relating to the FPU and associated vessels together with IMMR activities and gravimetry surveys, at times, all occurring within a small, localised area. Once the FPU has started up and normal operations have

Detailed Impact Assessment

Assessment of Potential Impacts

commenced, a constant source of light from the FPU external lighting and flare tower, along with external lighting from the associated vessels, will persist until the end of the Petroleum Activities Program timeline. The impact of emissions will be dampened by the remoteness of the Offshore Operational Area (~ 210 km from nearest shoreline) relative to light sensitive receptors.

Trunkline Operational Area

Due to its extensive geographic coverage from east to west, the Trunkline Operational Area overlaps a whale shark foraging BIA, various marine turtle Habitat Critical areas and BIAs, pygmy blue whale and humpback whale migration BIAs, and several seabird breeding BIAs including wedge-tailed shearwater, roseate terns, and fairy terns. Light emissions will be infrequent and transient, with occasional IMMR works and span rectification activities occurring along specified parts of the Trunkline Operational Area, typically over short timelines.

Existing light sources at the eastern end of the Trunkline Operational Area (within 20 km of land) include heavy vessel traffic within the Pilbara Port Authority (PPA) Management area and 26 designated anchorages for vessels such as bulk carriers, petroleum and gas tankers and drilling rigs. These anchorages are located between Rosemary Island and the Trunkline Operational Area. Existing light pollution in this area is expected to be high (Commonwealth of Australia, 2017).

Seabirds

High levels of marine lighting can attract and disorient seabird species resulting in species behavioural changes (e.g. circling light sources or disrupted foraging), injury or mortality near the light source (e.g. Longcore and Rich, 2004; Gaston et al., 2014; Rich and Longcore, 2006). All seabird species active at night are vulnerable to artificial light as it can disrupt their ability to orient towards the sea (Commonwealth of Australia, 2020). The potential for bird interactions is dependent upon their ability to perceive the dominant wavelengths in the spectral composition of a light source (PENV, 2023). Species with a nocturnal component to their behaviour and life history, such as procellariiforms (including wedge-tailed shearwaters), are at greater risk of negative impacts from artificial light sources at night. The bulk of the literature concerning impacts of lighting upon procellariiforms relates to the synchronised mass exodus of fledgling seabirds from their nesting sites (Deppe et al., 2017; Raine et al., 2007; Rodriguez et al., 2017a; Rodriguez et al., 2017b), with fewer investigating the impacts of light at sea. Diurnal seabird species, such as terns, noddies and boobies, in contrast to procellariiforms, are less vulnerable to impacts resulting from nocturnal behaviours. However, the presence of lit facilities can result in localised alteration of foraging behaviours such as extended foraging durations. When Seabirds and shorebirds interact with bright light sources which could alter migratory pathways and/or nocturnal roosting behaviours when artificial light spill occurs over the habitat (PENV, 2023).

Offshore Operational Area

A variety of avian species may occur within a 20 km radius from the FPU, including terns, petrels, tropicbirds, noddies and shorebirds utilising the East Asian-Australasian Flyway (Dunlop et al., 1988, Bamford et al., 2008). Artificial light at night can alter foraging and migratory behaviours of avian species and lead to disorientation, grounding or death. As the Offshore Operational Area is offshore and away from islands or other emergent features, including a 105 km separation from a breeding BIA for the wedge-tailed shearwater, any presence of seabirds or shorebirds is considered likely to be of a transient nature only. Minimal disruption to seabird foraging or migratory behaviours is therefore expected. The isolated and remote location of the FPU and related vessels in the Offshore Operational Area relative to sensitive receptors will reduce light impacts to 'no lasting effect'.

Trunkline Operational Area

The Trunkline Operational Area is in proximity to and overlaps breeding and foraging habitat for a number of seabird species. Key Biodiversity Areas (KBAs) are sites contributing significantly to the global persistence to biodiversity. The nearest KBA for migratory shorebirds is located at the Dampier Saltworks. Onshore nesting habitat, including for the wedge-tailed shearwater, roseate, caspian and Australian fairy tern, is reported for the Dampier Archipelago and other offshore islands groups such as the Montebellos and Lowendals. Adults utilising these breeding habitats (see BIAs in Table 4-14) will forage in nearshore waters (e.g., the Australian fairy tern) or offshore waters (e.g., wedge-tailed shearwater, caspian and roseate terns, refer to Section 4.6.4). The Trunkline Operational Area represents a relatively small portion of the seabird BIAs and while seabird presence may occur, it is considered likely to be of a transient nature only.

There is a small overlap between the Trunkline Operational Area and a breeding BIA for roseate terns between KP 32 to ~KP 58. Breeding populations of this tern species occur throughout the NWMR on fringing islands of the Burrup Peninsula, Montebello Islands, North Turtle Island, Airlie Island, the Ningaloo coast and Bernier Island. There is small overlap of the fairy tern breeding BIA with the State Waters end of the Trunkline Operational Area. The fairy tern mainly occurs on sheltered coasts and is rarely out of sight of land. In the North-west Marine Region they breed on islands of the North West coast, including the Dampier Archipelago. They feed in inshore waters around island archipelagos, foraging mainly for fish in shallow water.

There is also an overlap between the Trunkline Operational Area and a breeding/foraging BIA for wedge-tailed shearwaters between KP 32 to ~KP 220. Wedge-tailed shearwaters occur throughout the NWMR across fringing islands

Detailed Impact Assessment

Assessment of Potential Impacts

of the Dampier Archipelago to Cape Range and to Barrow Island. Given the broad breeding distribution it may be assumed that wedge-tailed shearwaters may breed on any of the vegetated, unoccupied islands of the Dampier Archipelago.

Adult shearwaters are vulnerable to artificial lighting in the breeding cycle, when returning to and leaving the nesting colony to maintain nesting sites or forage. Foraging wedge-tailed shearwaters may be attracted to sources of light emissions to feed on fish drawn to the light, however the species reportedly feeds predominately during the day (Catty et al. 2009). Artificial light can also impact behaviour and adult nest attendance, or confuse shearwater species, resulting in injury or mortality as a result of birds colliding with structures (Cianchetti-Benedetti et al. 2018; Rodriguez et al. 2017a and b). Fledglings of burrow-nesting seabirds, and to a lesser extent adults, are attracted to and then grounded (i.e., forced to land) by lights when they fly at night with the most affected seabirds being petrels and shearwaters (Procellariiformes) (Rodriguez et al. 2017). Shearwater fledglings are predominately impacted by onshore lighting sources, which can override sea finding cues and attract fledglings further inland, preventing them from reaching the sea (Mitkus et al. 2016; Telfer et al., 1987). Fledglings leave the nesting colony for the sea at night and the main fledgling period for shearwaters in Western Australia is reportedly April (Advisian, 2022). Reported mass groundings and mortalities are associated with formerly uninhabited islands and the risk of light pollution from tourism and urban sprawl, and generally occur during adverse weather conditions. This is probably because of the potential for clouds, mist and rain to increase light pollution levels (Kyba et al., 2011), however recent research is revealing added complexity including moon phase, wind strength and direction (see Commonwealth of Australia, 2020b for review).

Potential for overlap of IMMR activities, near the State waters boundary, with the wedge-tailed shearwater fledgling exodus from islands of the Dampier Archipelago in April is possible. Wedge-tail shearwater rookeries have been confirmed at Goodwyn Island and Malus Island (Pendoley Environmental, 2022) and Malus Satellite, Lady Nora and northeast Enderby Island have had rookeries detected post survey by MAC (Pendoley Environmental, 2022). However, given the localised vessel light emissions predicted and existing light sources in the marine waters of the area, vessels are expected to move at varying speeds and the expected, generally benign weather conditions in this region, the potential for wedged-tailed shearwater fledglings leaving burrows at night to collide, ground or become disoriented are considered unlikely. Artificial light from the Petroleum Activities Program is not predicted to disrupt critical breeding behaviours within important nesting habitat or displace seabirds from nesting habitat.

The magnitude of impact to seabirds and migratory shorebirds in the Trunkline Operational Area from artificial light emissions will be 'no lasting effect' given the localised and temporary nature of any effects as described above, plus the incremental increase of vessel lighting in a region that already experiences considerable vessel traffic. For all the PAA, the receptor sensitivity is high and thus the impact significance level has therefore been identified as slight (E).

Marine Reptiles

Exposure of marine turtles to artificial light can result in changes to their natural behaviour. Witherington and Martin (2003) state that light pollution on nesting beaches is detrimental to marine turtles because it alters critical nocturnal behaviours, namely, how turtles choose nesting sites, how they return to the sea after nesting, and how hatchlings find the sea after emerging from their nests.

Offshore Operational Area

There are no sensitive marine turtle habitats near the Offshore Operations Area. Loggerhead, Green, Leatherback, Hawksbill and Flatback turtles all may occur within the 20 km radius from the FPU. The closest known turtle nesting beaches are at the North West Cape and Montebello Islands; the flatback turtle BIA located approximately 165 km from the Offshore Operational Area. Marine turtles generally have a pelagic life stage as juveniles, before returning to nearshore coastal habitats as adults to forage and breed. Marine turtles are not expected to commonly occur within the Offshore Operational Area due to the deep waters (>900 m). Leatherback turtles are an oceanic, pelagic species known to regularly forage within continental shelf waters. While leatherback turtles may occur in the Offshore Operational Area in small numbers, their distribution is widespread in Australia and their presence is unlikely. No turtles were observed during the winter or summer offshore marine surveys in the PAA (ERM, 2013). Artificial lighting may be visible up to 46.6 km away from the FPU (during flaring). The light intensity will be low during normal operations, reaching a maximum intensity during an infrequent blowdown event, which typically last between 1 to 2 hours. Light from flaring will not be visible within the nearest flatback turtle BIA, approximately 165 km away. Although individuals undertaking behaviours such as migration or foraging (adults and pelagic juveniles) may occur within the Offshore Operations Area, marine turtles do not use light cues to guide these behaviours (PENV, 2020). There are no known impact pathways for foraging or migrating marine turtles associated with light emissions (PENV, 2023). As such, it could be inferred light emissions from the FPU and vessels are unlikely to result in displacement of, or behavioural changes to individuals in these life stages (PENV, 2020).

PENV's (2023) line of sight analysis, identified a maximum distance of 46.6 km from which routine flare operations would be visible from the source. Thus, lighting from the FPU would not be visible in sensitive nesting areas such as the Montebellos and the North West Cape, or from the nearest BIA (165 km away). Due to the distance from any identified nesting habitat for marine turtles, impacts associated with hatchlings are considered to be unlikely (PENV, 2023). For

Detailed Impact Assessment

Assessment of Potential Impacts

any isolated individual potentially attracted to light spill from the FPU, following sunrise, any effect of these light sources on hatchlings will be eliminated allowing dispersal behaviour to resume.

Trunkline Operational Area

The Trunkline Operational Area overlaps habitat critical to the survival for turtles and overlaps various BIAs for flatback, green, hawksbill and loggerhead turtles. Adult female turtles will spend several months in the shallow coastal marine environment in proximity to nesting beaches. Pendoley (2005b) provides details of tracking data for green and hawksbill turtles nesting on Rosemary Island. Results suggested that nesting female hawksbill turtles remained within 1 km of nesting beaches on Rosemary Island (Pendoley, 2005b). Female green turtles travelled greater distances, up to 5 km, but typically remained within shallow, nearshore waters between 0 and 10 m deep (Pendoley, 2005b). The 60 km interesting buffer for flatback turtles in the Recovery Plan for Marine Turtles in Australia (DoEE, 2017) is based primarily on the movements of tagged interesting flatback turtles along the North West Shelf from a 2014 study, which found that flatback turtles may demonstrate interesting displacement distances up to 62 km from nesting beaches (Whitlock et al., 2014). However, these movements were confined to longshore movements in nearshore coastal waters or travel between island rookeries and the adjacent mainland (Whitlock et al., 2014). The flatback turtle interesting habitat along the North West Shelf has since been defined more precisely using satellite tracking of 47 turtles, combined with a range of environmental variables (Whitlock et al., 2016). Suitable interesting habitats were identified at water depths of 0-16 m, within 5-10 km of the coastline.

Seasonality of nesting differs between flatback, green and hawksbill turtle species. Whiting (2018) provides defined seasonality specific nesting data for Rosemary Island and found that hawksbill turtles have a much earlier peak (October/November) compared to flatback turtles (December/January peak). Seasonality for green turtles was not well defined from the available data (Whiting, 2018). Fossette et al. (2021) reported a peak in nesting for green turtles for the period November and December (refer to Table 4-15).

The peak hatchling emergence time for the three turtle species nesting within Dampier Archipelago differs between species, with hawksbill turtles earliest (December to January peak), flatback turtle peak from January to February and green turtle peak from January to March (PENV, 2022) (refer to Table 4-15). Given IMMR activities may occur at any time during the year there is potential for vessels to be operating in the Trunkline Operational Area during these nesting and hatchling seasons.

For measuring the impact of Artificial Light At Night (ALAN) on marine turtles, PENV has developed an approach based on the visibility of the full moon. PENV's (2020, 2022) studies on light impacts from vessels within the Trunkline Operational Area were based on a suite of construction vessels used throughout the seabed intervention and trunkline installation scope (refer to *Scarborough Seabed Intervention and Trunkline Installation EP*) of the Scarborough Project. A single smaller vessel is planned for IMMR activities related to this EP's scope, which would emit far less light than the suite and type of vessels previously studied. For comparison purposes, the least impactful vessel for light from the study (i.e., Trailing Suction Hopper Dredge (TSHD)) will be used whilst still remaining conservative for impacts from Scarborough operations. The distance between turtle nesting beaches and the Trunkline Operational Area at the closest point (6.6 km to Legendre Island and >10 km to closest nesting beach on Legendre Island and 14 km to Rosemary Island) are all greater than the zone where behavioural impacts from vessel lighting are possible: 1.5 km from the TSHD. Therefore, impacts to nesting female turtles, including discouraging females from nesting, or affecting nest site selection and sea-finding behaviour, are not predicted, and females are not expected to be displaced from nesting habitat (PENV, 2022).

Disturbance to transient adult turtles in offshore waters along the Trunkline Operational Area from artificial light is not expected given light emissions are unlikely to result in behavioural change for key life cycle stages such as interesting and nesting.

Impacts to hatchling emergence, including hatchling mis- or dis-orientation, are not predicted and highly unlikely. Impacts to hatchling dispersal resulting from vessel lighting are possible but will be limited as:

- The distance between turtle nesting beaches and the Trunkline Operational Area at the closest point (6.6 km to Legendre Island and >10 km to closest nesting beach on Legendre Island and 14 km to Rosemary Island).
- Nearshore currents would need to carry hatchlings into the zone where behavioural impacts from vessel lighting are possible (1.5 km for the TSHD).
- The density of hatchlings will decrease with distance from the nesting beach as individuals disperse in open ocean.
- Nearshore currents in the region must be weaker than hatchling swimming speed in order for hatchlings to override wave cues and successfully swim toward light sources.
- The potential for attraction to vessel lighting is expected to be overridden by the radiance of the moon during full moon periods.

Detailed Impact Assessment

Assessment of Potential Impacts

- Vessels within 20 km of nesting beaches will be in the area temporarily (hours to days) during the Petroleum Activities Program, light emissions will not be ongoing.
- Vessels within the Trunkline Operational Area will be continuously moving at varying speeds
- Attraction to light sources will not occur during daylight and hatchling dispersal will resume upon sunrise.

Attraction to artificial lighting may have consequences at the individual level (e.g. energy depletion and increased predation risk), however, the number of marine turtles that could be impacted is likely to be low and undetectable against normal population fluctuations. The desktop lighting assessments by PENV (2020, 2022) concluded that the light emissions from vessel activities in the Trunkline Operational Area would not have significant impact on marine turtles across the whole life cycle. This assessment is highly conservative for the current Petroleum Activities Program as it is based on significantly larger vessels.

Impacts are not expected to be contrary to the priority actions or measures of success criteria outlined in the Recovery Plan for Marine Turtles (Commonwealth of Australia, 2017a) for the relevant marine turtle stocks or management of artificial light.

The magnitude of impact to marine turtles from artificial light emissions will be 'no lasting effect' given the localised and temporary nature of any effects as described for the Trunkline Operational Area, whilst the distance offshore to the FPU and vessels of the Offshore Operational Area will nullify light impacts on the distant turtle nesting and interesting areas. Receptor sensitivity is high. The impact significance level of has therefore been identified as slight (E).

Fish, Sharks and Rays

Experiments using light traps have found that some fish and zooplankton species are attracted to light sources (Meekan et al., 2001), and therefore, lighting from the FPU and vessels may result in localised aggregations of fish around these structures. Krill or plankton may also aggregate around the source of light. The concentration of organisms attracted to light may result in an increase in food source for predatory species and marine predators may subsequently aggregate in these areas (Shaw et al., 2002). The Trunkline Operational Area overlaps with a whale shark foraging BIA, however, potential light disturbance is restricted to infrequent and transient vessels partaking in IMMR activities and span rectification. Presence of other threatened fish species within the PAA is expected to be of a transient nature only. Vessels undertaking IMMR activities and span rectification will be present for short periods only and are not expected to seriously disrupt the lifecycle of an ecologically significant proportion of whale sharks. The more persistent light sources emitted from the external lighting and flare tower of the FPU, in-concert with the vessels of the Offshore Operational Area, will have the greatest light emission footprint, however they are distant from whale shark BIAs (approximately 165 km) and the more densely populated corals reefs and nearshore habitats of the coast and islands, hence will only impart a very localised impact to the fish communities of the open ocean. It is conceivable, that the rare whale shark individual foraging widely outside of their usual area, may display altered behaviour due to increased plankton biomasses around the FPU. These behaviours would be limited to night-time hours and the individual would likely move on during daytime hours as plankton aggregations diminished.

The magnitude of impact to fish from artificial light emissions will be 'no lasting effect' and receptor sensitivity is medium. The impact significance level of has therefore been identified as Negligible (F).

AMPs

The Trunkline Operational Area overlaps the Montebello AMP between KP 108.4 – KP 191.6. The North-west Marine Parks Network Management Plan (DNP, 2018a) lists the natural values of the Montebello AMP as including a range of threatened, migratory, marine or cetacean species listed under the EPBC Act, as well as BIAs that include seasonal breeding habitat for seabirds, internesting habitat for marine turtles and a migratory pathway for humpback whales. The Montebello AMP also includes foraging, mating, and nesting habitat for marine turtles and foraging habitat for whale sharks. The Montebello AMP is overlapped by Habitat Critical to the survival of flatback, green and hawksbill turtles. As described above, there is no evidence, published or anecdotal, to suggest that internesting, mating, foraging or migrating turtles are impacted by light from offshore vessels and the distant FPU at approximately 200 km from the marine park will not be visible, even during emergency flaring events. Although individuals undertaking internesting, migration, mating (adults) or foraging (adults and pelagic juveniles) may occur within the PAA, marine turtles do not use light cues to guide these behaviours, and therefore light emissions from the vessels are unlikely to result in displacement of, or behavioural changes to individuals during these life stages. Hence, light emissions from vessels in the areas where the Trunkline Operational Area overlaps these AMPs will not result in any impacts to internesting female turtles.

The wedge-tailed shearwater, which has a breeding and foraging BIA overlapping the Trunkline Operational Area, occupies offshore islands including the Montebello Islands. For activities occurring within the Montebello AMP, the short-term and transient nature of activities associated with light emissions will not be inconsistent with the objectives of the management plan for the North-west Marine Park Network (DNP, 2018a).

The values identified for both these marine parks including BIAs for marine turtles, seabirds and migratory shorebirds will not be impacted given the significant distance from sensitive locations. Therefore, no impacts are expected to the cultural values of the AMP as those are intrinsically linked to the natural values described above.

Detailed Impact Assessment				
Assessment of Potential Impacts				
The magnitude of impact to AMPs from artificial light emissions will be 'no lasting effect' given the localised and temporary nature of any effects as described above. Receptor sensitivity is high based on important habitat for marine turtles and seabirds that are sensitive to lighting impacts. The impact significance level has therefore been identified as slight (E).				
Summary of Assessment Outcomes				
Receptor	Impact	Receptor Sensitivity Level	Magnitude	Impact Significance Level
Ambient light	Change in ambient light	Low value (open water)	Slight	Negligible (F)
Seabirds and migratory shorebirds	Change in fauna behaviour	High value species (e.g. wedge-tailed shearwater)	No lasting effect	Slight (E)
Marine reptiles		High value species (e.g. flatback turtle)	No lasting effect	Slight (E)
Fish, sharks and rays		High value species (e.g. Whaleshark)	No lasting effect	Negligible (F)
AMP		High value species (e.g. flatback turtle)	No lasting effect	Slight (E)
Overall Impact Significance Level: The overall impact significance level for routine light emissions is E based on no lasting effect to the high value receptors (seabirds, migratory shorebirds and marine turtles). The impact significance levels for individual receptors are consistent with the level in the OPP.				

Demonstration of ALARP				
Control Considered	Control Feasibility (F) and Cost/Sacrifice (CS)	Benefit in Impact/Risk Reduction	Proportionality	Control Adopted
Legislation, Codes and Standards				
No additional controls identified.				
Good Practice				
Minimise vessel/FPU lighting to that required for navigational, safety and operational requirements, with the exception of emergency events.	F: Yes. Lighting is typically appropriate for navigation and safety.	Given the potential impacts to turtles during this activity is insignificant, implementation of this control would not result in a reduction in consequence.	While the control does not result in significant reduction of impacts, it is good practice and not at significant cost.	Yes C 3.1
Lighting modifications (shielding, directional lighting) to minimise over water light spill and light emissions during peak turtle hatchling season (Dec to Mar) for vessels operating in the Trunkline Operational Area.	F: Yes, lighting is able to be modified on the IMMR vessel. CS: Financial cost of changes and time associated with implementing these.	Reducing light spill over water and overall light glow from a vessel can reduce the likelihood that hatchling behaviour will be influenced. Previous light modelling undertaken by Woodside of a Pipelay Vessel and	The cost/sacrifice outweighs benefit gained.	No

Demonstration of ALARP				
Control Considered	Control Feasibility (F) and Cost/Sacrifice (CS)	Benefit in Impact/Risk Reduction	Proportionality	Control Adopted
Professional Judgement – Eliminate				
Substitute external lighting with “marine fauna” light sources (reduced emissions in turtle visible spectrum) for all vessels working in close proximity to sensitive habitats.	F: Yes. Replacement of external lighting with marine fauna friendly lighting is technically feasible, although is not considered to be practicable. CS: Significant cost sacrifice. The retrofitting of external lighting on the vessels, etc., would result in considerable cost and time expenditure. Considerable logistical effort to source sufficient inventory of the range of light types onboard the vessels.	Given the potential impacts to marine fauna during this activity is insignificant, implementation of this control would not result in a reduction in consequence.	Grossly disproportionate. Implementation of the control requires considerable cost sacrifice and provides minimal environmental benefit. The costs/sacrifices outweigh the benefit gained.	No
Variation of the timing of the Petroleum Activities Program to avoid IMMR activities on the export trunkline overlapping peak turtle interesting periods (December to January).	F: Yes. It is possible to avoid peak turtle hatchling emergence periods, through scheduling. CS: Significant cost and schedule impacts due to delays in securing vessels for specific timeframes.	Implementation of this control would not result in a reduction in consequence due to the distance of the Trunkline Operational Area from turtle nesting beaches and the small area impacted by vessel light glow.	The cost/sacrifice outweighs benefit gained.	No
Crew transfers which require direction of floodlights outside the vessel will preferentially occur during daylight hours, when vessels within 20 km of islands between December and April ⁴⁵	F: Yes CS: Cost implication and delay of crew transfers.	Reducing light spill onto the water can reduce hatchling attraction to the vessel. Given the distance of the Trunkline Operational Area from known turtle nesting beaches, a reduction in consequence from implementation of this control is not expected.	Implementation would be disproportionate to the risk reduction. While the control may reduce light spill, any crew change activity is expected to be short in duration and infrequent during Trunkline IMMR only.	No
Professional Judgement – Substitute				
Substitute external lighting with “turtle friendly” light sources, (e.g. lights containing short	F: Yes. Replacement of some/all external lighting with turtle friendly lighting is technically feasible.	Substituting external lighting will reduce light emissions in turtles visible	The cost/sacrifice outweighs benefit gained.	No

⁴⁵ Peak turtle hatchling emergence period is December to March, with the wedge-tailed shearwater fledglings emergence in April.

Impacts to hatching dispersal resulting from vessel lighting are possible but will be limited by the distance of the PAA from the turtle nesting beaches and the temporary nature of vessel activities associated with the Petroleum Activities Program. Implementation of this control would not result in a reduction in consequence.</p>		
Professional Judgement – Engineered Solution				
None identified.				
ALARP Statement:				
<p>On the basis of the environmental impact assessment outcomes and use of the relevant tools appropriate to the decision type (i.e. Decision Type A, Section 2.3.3), Woodside considers the potential impacts from routine light emissions from the vessels to be ALARP. As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts are considered ALARP.</p>				
Demonstration of Acceptability				
Acceptability Criteria and Assessment				
<p>Demonstration of acceptability for the sources of aspect and associated impacts assessed in this section are provided in Section 7.1.1.3 of the Scarborough OPP. The Petroleum Activities Program meets the EP acceptability criteria (Section 2.3.5):</p> <ul style="list-style-type: none"> • Overall impact significance levels for individual receptors are less than the significant impact level defined in the OPP. • EPOs in this EP are aligned with EPOs in the OPP (refer to Table 6 2) • Controls in the OPP that are relevant to this EP Section have been adopted. • There are no changes to internal/external context specific to this risk from the OPP, including issues raised during consultation. 				
Acceptability Statement:				
<p>The impact assessment has determined that, given the adopted controls, routine light emissions from external lighting from the FPU and vessels is unlikely to result in an impact significance level greater than slight. BIAs for ten EPBC Act listed Threatened or Migratory species overlap or are adjacent to the PAA. Regard has been given to relevant conservation advice and wildlife conservation plans during the assessment of potential impacts and the NLPG were taken into consideration during the impact evaluation. The Petroleum Activities Program is not considered to be inconsistent with the overall recovery objectives and actions of these recovery plans and conservation advice (Section 6.9.3).</p> <p>The potential impacts are considered broadly acceptable if the adopted controls are implemented. Activities do not have a significant impact on MNES (Section 4.3). Therefore, Woodside considers the adopted controls appropriate to, manage the impacts of light emissions to a level that is broadly acceptable; and demonstrate the EPOs are met.</p>

Description of Source of Impact/Risk
<p>During FPU hook-up and commissioning, sound will be generated from a variety of vessels involved with this phase. Acoustic emissions during routine operations (including IMMR activities) are assessed in Section 6.7.5.</p> <p>Sound will fluctuate based on concurrent vessel activities, with various vessel arrangements specific to the hook-up, commissioning and start-up phases occurring. These acoustic sources will contribute to and have the potential to exceed ambient noise levels in the region. Mean ambient sound levels have been measured as 109 dB re 1 µPa sound pressure level (SPL) and 115 dB re 1 µPa SPL at locations near the Offshore Operational Area (Warren, 2022).</p> <p>Key acoustic sources associated with FPU hook-up and commissioning are described below. Table 6-5 presents likely concurrent activities contributing to cumulative underwater noise levels during FPU hook-up and commissioning. This has been used to inform the worst-case credible sound propagation scenarios for modelling as well as cumulative impact assessment as a result of concurrent operations, discussed below.</p> <p>Vessels and Operation of DP</p> <p>Vessels will generate noise both in the air and underwater, due to the operation of thrusters, engines, propeller cavitation, etc. Vessels may use dynamic positioning (DP) where propellers and thrusters are used to hold position, rather than anchoring.</p> <p>The sound levels and frequencies generated by vessels varies with the size of the vessel, speed, engine type and the activity being undertaken. Larger or more powerful vessels typically produce higher sound levels at lower frequencies than small vessels, although significant variation may be found among vessels within the same group (Jiménez-Arranz et al., 2020). Sound levels tend to be greatest when engaging the throttle or thrusters, such as use of DP or when</p>

Description of Source of Impact/Risk

vessels are operating under load, compared with slow moving or idling vessels (Salgado Kent et al. 2016). The greatest sound levels are likely to be associated with vessels using DP thrusters to maintain position on station.

Vessels produce low frequency sound (i.e. below 1 kHz) from the operation of machinery, hydrodynamic flow sound around the hull and from propeller cavitation, which is typically the dominant source of sound (Ross, 1987, 1993).

Examples of vessels proposed to be used for FPU hook-up and commissioning activities are detailed in **Section 3.11**. These include:

- Light Construction Vessel (LCV)
- Support Vessels
- Accommodation Support Vessel (ASV)
- Anchor Handling Tugs (AHTs).

Source levels for representative vessels that will be used for FPU hook-up and commissioning are described in **Table 6-4**.

Table 6-4: Modelled energy source level spectra (in deci-decade frequency-band) for sound sources associated with proposed Scarborough vessels during floating production unit hook-up and commissioning

Vessel type and operation mode	Energy source level	Basis for source level estimation and source depth
AHTs under DP	194.1 dB re 1 $\mu\text{Pa}^2\text{m}^2.\text{s}$	Representative vessel (Siem AHTS VS491 CD) (McPherson et al. 2021)
Tug vessel under DP (high thruster power)	192.2 dB re 1 $\mu\text{Pa}^2\text{m}^2.\text{s}$	Representative vessel (FAR Statesman) estimated using the spectra of the publicly available Siem Sapphire (McPherson et al. 2021). The overall broadband level of the Siem Sapphire has been scaled down based on maximum installed thruster power.
Tug vessel under DP	187.6 dB re 1 $\mu\text{Pa}^2\text{m}^2.\text{s}$	Representative vessel (FAR Statesman). Based on lower thruster powers associated with DP in comparison to high thruster power, the broadband (10 Hz to 25 kHz) source level has been chosen to match the OSV under DP with the spectral shape of the Siem Sapphire (McPherson et al. 2021) scaled to that level
Tug under transit	171.3 dB re 1 $\mu\text{Pa}^2\text{m}^2.\text{s}$	Representative vessel (FAR Statesman) represented via scaling the spectra of the Siem Sapphire under slow transit (McPherson et al. 2021)
Support Vessel under transit	177.8 dB re 1 $\mu\text{Pa}^2\text{m}^2.\text{s}$	Representative Vessel (Fugro Etime) operating at 20% capacity
FPU	173.9 dB re 1 $\mu\text{Pa}^2\text{m}^2.\text{s}$	Representative surrogate vessel derived from the average of measured levels of two Floating Production Storage Offload (FPSO) vessels, Ngujima and Nganhurra (Erbe et al. 2013).
LCV under DP	180.9 dB re 1 $\mu\text{Pa}^2\text{m}^2.\text{s}$	Representative vessel (Deep Orient) (Quijano and McPherson, 2021)
Support Vessel under DP	187.6 dB re 1 $\mu\text{Pa}^2\text{m}^2.\text{s}$	Representative Vessel (Fugro Etime) at 50% capacity
ASV	183.6 dB re 1 $\mu\text{Pa}^2\text{m}^2.\text{s}$	Floatel Triumph based on median noise measurements from a similarly sized but higher powered semi-submersible vessels previously measured by JASCO whilst under DP (Austin et al. 2023), which were scaled down based on maximum installed thruster power

Positioning Equipment

An array of long baseline (LBL) and/or ultra-short baseline (USBL) transponders may be used for underwater positioning. Transponders typically emit pulses (impulsive noise) of medium frequency sound, generally within the range 21 to 31 kHz. The estimated SPL would be 180 to 206 dB re 1 μPa at 1 m (Jiménez-Arranz et al., 2017). Transmissions are not continuous but consist of short ‘chirps’ with a duration that ranges from 3 to 40 milliseconds. Transponders will not emit any sound when on standby. The operating frequency range is above the auditory range of low frequency

Detailed Impact Assessment

The area over which sound may adversely impact marine species depends upon multiple factors including the extent of sound propagation relative to the location of receptors, and the sensitivity and range of spectral hearing of different species (Slabbekoorn et al., 2010; Popper and Hawkins, 2012).

Sound Propagation

Increasing the distance from the noise source results in the level of noise reducing, due primarily to the spreading of the sound energy with distance. The way that the noise spreads (geometrical divergence) will depend upon several factors such as water column depth, pressure, temperature gradients, and salinity, as well as surface and bottom conditions.

Acoustic Modelling

To assess the potential magnitude and extent of impacts from underwater noise produced during the Petroleum Activities Program, Woodside commissioned JASCO Applied Sciences (JASCO) to model sound propagation for a range of concurrent operations and vessel scenarios. The modelling study (Stephen et al., 2023) considered specific components of the Petroleum Activities Program for representative scenarios within the PAA.

The modelled scenarios presented in Table 6-6, include several permutations of concurrent activities that may occur during FPU installation and hook-up, commissioning and operations. Scenarios 5 to 7 are discussed in the context of routine operations (i.e. long-term acoustic emissions from FPU operations) in Section 6.7.5.

Table 6-6: Summary of modelled scenarios for floating production unit hook-up and commissioning

Scenario Group	Scenario Number	Description
FPU Installation and hook-up (base case)	1	1x AHTs under DP (24hrs)
	2	Silent FPU, 2x AHTs under DP, 1x OSV on standby (24hrs)
FPU Installation and hook-up (worst case)	3	1x tow tug heavy thrusting, under DP (24hrs)
	4	Silent FPU, 2x tow tug heavy thrusting DP, 2x tow tug DP, 2x AHTS, 1x tow tug standby, 1x OSV standby (24hrs) <i>This scenario was remodelled using sound exposure thresholds updated in October 2024 – results presented below</i>
FPU Commissioning	5	FPU operating and anchored (24hrs)
	6	FPU operating and anchored (24hrs), resupply OSV under DP (8hrs)
	7	FPU operating and anchored, ASV under DP (24hrs), LCV under DP (8hr) <i>This scenario was remodelled using sound exposure thresholds updated in October 2024 – results presented below</i>

The modelling study specifically assessed distances from operations where underwater sound levels were predicted to reach thresholds corresponding to potential behavioural response, TTS and PTS. The animals considered here included low-frequency (LF), high-frequency (HF) cetaceans, turtles, and fish including fish larvae and eggs.

The modelling methodology considered the source levels of the individual thrusters for the vessels, as well as environmental properties that effect sound propagation. Estimated underwater acoustic levels are presented as SPL, and accumulated sound exposure levels (SEL) as appropriate for non-impulsive (continuous) noise sources. In this study, the duration of the SEL accumulation was defined as integrated over a 24-hour period (SEL_{24h}).

The SEL_{24h} is a cumulative metric that reflects the dosimetric impact of noise levels within 24 hours based on the assumption that an animal is consistently exposed to such noise levels at a fixed position. The corresponding SEL_{24h} radii represent an unlikely worst-case scenario. More realistically, marine mammals (as well as pelagic fish and turtles) would not stay in the same location for 24 hours. Therefore, a reported radius for SEL_{24h} criteria does not mean that marine fauna travelling within this radius of the source will be impacted, but rather that an animal could be exposed to the sound level associated with impact (TTS or PTS) if it remained in that location for 24 hours. Overall, the impact significance level for ambient noise has been identified as Negligible (F).

Updated acoustic modelling to account for new sound exposure thresholds

In October 2024, the U.S National Oceanic and Atmospheric Administration (NOAA) issued Technical Memorandum NMFS-OPR-71 which was a 2024 update to *Technical Guidance for Assessing the Effects of Anthropogenic Sound on Marine Mammal Hearing (V 3.0)*. The memo contains updated underwater and in-air criteria for onset of auditory injury and temporary threshold shifts, and relevant to the noise modelling originally conducted for this EP (Stephen et al., 2023) means that thresholds for LF and HF cetaceans changed as shown in Table 6-7.

To better understand the impacts of the change in these sound exposure thresholds, Woodside commissioned Jasco to re-model two of the conservative scenarios (4 and 7) with the new criteria. Scenario 4 was chosen to represent the

Detailed Impact Assessment

credible worst-case noise scenario for FPU hookup and installation while Scenario 7 was chosen to represent worst-case noise during commissioning. A decision was made to only remodel these two conservative scenarios (instead of remodelling all the scenarios), because they represent the worst case credible noise propagation (as shown by original modelling results in Table 6-8 and reducing impacts based on these noise emissions to ALARP and Acceptable levels means that the other scenarios producing lower noise levels will also be ALARP and Acceptable. The changes to the thresholds are not considered significant enough to warrant remodelling all scenarios, and investigation of the worst case noise scenarios was considered adequate to understand impact of the threshold change.

The new thresholds relate to PTS and TTS onset, with behavioural response thresholds remaining the same for continuous noise. Results for Scenario 4 and 7 using the new thresholds are discussed below, however impact assessment relating to behavioural response remains unchanged.

Sound Frequency and Hearing Sensitivity

Different animals are sensitive to different sound frequencies, which are measured in hertz (Hz) and kilohertz (kHz). For example, some large baleen whales are sensitive to very low frequency sounds (7 Hz to 35 kHz), while other toothed whales and dolphin species are considered more sensitive to mid-high frequency sounds (150 Hz to 160 kHz) with their peak hearing frequency somewhere between these frequency ranges (National Marine Fisheries Service, 2018).

In some cases, a sound level is specified relative to a given frequency range or is weighted according to the auditory sensitivity of an animal (e.g. low-frequency, medium-frequency and high-frequency groups of cetaceans). This has the advantage of placing the sound into a more biologically relevant context for that animal. If a frequency range or weighting is not specified, the frequency of the sound is generally referred to as “broadband” sound i.e. the sound level accounts for sound across all frequencies, noting again that a particular animal may not be able to detect all of the sound frequencies and associated energy that are emitted. Therefore, the frequency of a sound and how sensitive different animals are to sound can make a considerable difference to how loud the sound is perceived to be and any resultant impact.

Marine Mammals/Cetaceans

Eight cetacean species may be present within the PAA, including LF cetaceans such as pygmy blue whales, and HF cetaceans such as sperm whales and orcas (Section 4.6.3). There are no BIAs overlapping the Offshore Operational Area.

Species Sensitivity and Sound Exposure Thresholds

Marine mammals and especially cetaceans rely on sound for important life functions including individual recognition, socialising, detecting predators and prey, navigation and reproduction (Weilgart, 2007; Erbe et al., 2015; Erbe et al., 2018). Underwater noise can affect marine mammals in various ways including interfering with communication (masking), behavioural changes, a shift in the hearing threshold (PTS and TTS), physical damage and stress (Erbe, 2012; Rolland et al., 2012). There is little information available regarding call masking in whales (Richardson et al., 1995), although it has been suggested that an observed lengthening of calls in response to low-frequency noise in humpback whales and orcas may be a response to auditory masking (Fristrup et al., 2003; Foote et al., 2004).

The thresholds that could result in a behavioural response, TTS and PTS for cetaceans as a result of noise sources are presented in Table 6-7. These thresholds have been adopted by the United States National Oceanic and Atmospheric Administration (NOAA) (National Marine Fisheries Service [NMFS], 2014, 2018; Southall et al., 2019; NOAA, 2019), and were updated in October 2024 (NMFS, 2024). The adopted thresholds are based on best data available and published in peer-reviewed literature and represent conservative internationally accepted and applied impact evaluation thresholds for impulsive and continuous (non-impulsive sound sources).

Table 6-7: Thresholds for permanent and temporary threshold shift and behavioural response onset for low-frequency and high-frequency cetaceans for impulsive and continuous noise

Hearing group	Impulsive			Continuous		
	PTS onset thresholds: SEL _{24h} (dB re 1 μPa ² .s)	TTS onset thresholds: SEL _{24h} (dB re 1 μPa ² .s)	Behavioural response (dB re 1 μPa)	PTS onset thresholds: SEL _{24h} (dB re 1 μPa ² .s)	TTS onset thresholds: SEL _{24h} (dB re 1 μPa ² .s)	Behavioural response (dB re 1 μPa)
LF cetaceans	183	168	160	199	179	120
Updated Threshold*	No change	No change		197	177	
HF cetaceans	185	170		198	178	
Updated Threshold*	193	178		201	181

Detailed Impact Assessment

* Source Updated Thresholds: NMFS 2024

Results – Acoustic Modelling

Modelling of cumulative sound propagation from a range of vessel scenarios is presented in (Table 6-8). These results relate to the outputs from the original modelling report (Stephen et al., 2023) which were based on thresholds in Southall et al. (2019). Updated permanent and temporary threshold shift and behavioural response thresholds in cetaceans for Scenarios 4 and 7 are presented separately below. Modelling of sound propagation loss under the worst-case scenario during FPU hook-up and installation within the Offshore Operational Area, predicted that noise levels would drop below 120 dB re 1 µPa (behavioural response threshold for continuous noise sources) within 43.4 km (Scenario 4). Considering the NMFS (2018) SEL_{24h} TTS threshold criteria for LF cetaceans (179 dB re 1 µPa².s), TTS onset could occur within 7.4 km under the same scenario (Stephen et al., 2023). For LF cetaceans, the maximum distance to the PTS onset threshold was 210 m for Scenario 4.

For HF cetaceans, TTS onset could occur at a distance of up to 90 m for the various scenarios, and the PTS threshold for HF cetaceans was not reached within the limits of the modelled resolution (20 m) for any scenario modelled.

The SEL_{24h} criterion used for calculating the potential for TTS and PTS impacts is a cumulative metric that reflects the dosimetric impact of sound energy accumulated over a 24-hour period and assumes that an animal is consistently exposed to such noise levels at a fixed location. The radii that correspond to SEL_{24h} therefore represent an unlikely worst-case scenario for SEL-based exposure since, more realistically, marine fauna would not stay in the same location or at the same range for 24-hours (Stroot et al., 2023). It is highly unlikely that PTS and TTS thresholds would be exceeded and furthermore it is highly unlikely given the known movement behaviour of cetaceans including key migrating LF whale species such as the PBW transiting through the PAA.

Table 6-8: Maximum predicted horizontal distances (R_{max}) to permanent and temporary threshold shift and behavioural response thresholds in cetaceans

Hearing group	Sound exposure threshold	Scenario 1 (AHTS)	Scenario 2 (2x AHTS, OSV)	Scenario 3 (tow tug)	Scenario 4 (2x AHTS, 5x tow tug, OSV)	Scenario 5 (FPU)	Scenario 6 (FPU, OSV)	Scenario 7 (FPU, ASV, LCV)
		R _{max} (km)	R _{max} (km)	R _{max} (km)	R _{max} (km)	R _{max} (km)	R _{max} (km)	R _{max} (km)
PTS								
LF cetaceans	199 dB re 1 µPa ² .s (SEL _{24h})	0.17	0.17	0.15	0.21	-	0.06	0.05
HF cetaceans	198 dB re 1 µPa ² .s (SEL _{24h})	-	-	-	-	-	-	-
TTS								
LF cetaceans	179 dB re 1 µPa ² .s (SEL _{24h})	1.75	4.52	1.36	7.4	0.1	0.49	0.74
HF cetaceans	178 dB re 1 µPa ² .s (SEL _{24h})	0.09	0.09	0.08	0.09	-	0.06	0.02

LF/HF cetaceans	120 dB re 1 µPa (SPL)	17.0	25.7	13.3	43.4	0.68	4.91	5.02

A dash indicates the level was not reached within the limits of the modelled resolution (20 m).

Results – Updated Acoustic Modelling for Scenarios 4 and 7

Modelling of cumulative sound propagation for Scenarios 4 and 7 is presented in Table 6 9. The results show that the radius from the activity at which a LF cetacean could be exposed to temporary threshold shift after 24 hours continuous exposure increased from 7.4 km under previous thresholds, to 11.7 km using the new threshold value. The new

Detailed Impact Assessment

thresholds predict TTS onset at 177 dB re 1 $\mu\text{Pa}^2\cdot\text{s}$, previously this value was 179 dB re 1 $\mu\text{Pa}^2\cdot\text{s}$. This means that there is a greater area over which LF cetaceans could be exposed to PTS/TTS associated with FPU installation and hookup. However, it continues to remain unlikely that cetaceans will spend 24hrs in close proximity to noise generating activities within this PAP, as any cetacean activity in the operational area would be migratory in nature. The offshore Operational Area is not associated with any cetacean BIAs (with the PBW migration corridor being ~35km to the East).

Modelling results showed that this increase of 37% for distance to LF cetacean TTS for Scenario 4 is similar in magnitude to the increase in distance for Scenario 7, which increased from 740m to 940m (or 27%). With the revision of PTS threshold for LF cetaceans from 199 dB re 1 $\mu\text{Pa}^2\cdot\text{s}$ to 197 dB re 1 $\mu\text{Pa}^2\cdot\text{s}$, the maximum horizontal distance at which PTS exposure could occur increased for both Scenario 4 and Scenario 7; from 210m to 590m for Scenario 4 (2.8 times greater) and from 50m to 70m for Scenario 7.

While the threshold changes have resulted in increases to PTS and TTS maximum horizontal distances for both Scenario 4 and Scenario 7, due to the location of the Offshore Operational Area and nature of cetacean use of the area; the conclusion of the impact assessment conducted based on results of the original modelling remain valid for all scenarios.

Table 6-9: Maximum predicted horizontal distances (Rmax) to updated permanent and temporary threshold shift and behavioural response thresholds in cetaceans for Scenarios 4 and 7:

Hearing group	Sound exposure threshold	Scenario 4 (2x AHTS, 5x tow tug, OSV)	Scenario 7 (FPU, ASV, LCV)
		<i>R_{max}</i> (km)	<i>R_{max}</i> (km)
PTS			
LF cetaceans	197 dB re 1 $\mu\text{Pa}^2\cdot\text{s}$ (SEL _{24h})	0.59	0.07
HF cetaceans	201 dB re 1 $\mu\text{Pa}^2\cdot\text{s}$ (SEL _{24h})	0.04	-
TTS			
LF cetaceans	177 dB re 1 $\mu\text{Pa}^2\cdot\text{s}$ (SEL _{24h})	11.7	0.94
HF cetaceans	181 dB re 1 $\mu\text{Pa}^2\cdot\text{s}$ (SEL _{24h})	1.09	0.17
Behavioural response			
LF/HF cetaceans	120 dB re 1 μPa (SPL)	43.4	5.02

A dash indicates the level was not reached within the limits of the modelled resolution (20 m).

Impact Assessment – Vessel Activities

The Blue Whale Conservation Management Plan (Action Area 2) states that anthropogenic noise in BIAs should be managed such that any blue whale continues to utilise the area without injury (Commonwealth of Australia, 2015a). Although TTS in cetaceans has previously been regarded as hearing impairment, not injury, advice issued by DCCEEW is that TTS should be considered a form of injury to PBW and this should be prevented within the BIAs (DAWE 2021).

As described in Section 4.6.3, the PBW migration BIA represents the area of core migratory routes for pygmy blue whales. The migration BIA is about 35 km from the Offshore Operational Area. There is no potential for PTS or TTS impacts from FPU hook-up and commissioning activities from the Offshore Operational Area in the PBW migration BIA as demonstrated by the modelling presented, given the maximum distance to TTS impact is 11.7 km (using the updated sound exposure thresholds) for the worst case scenario (Scenario 4).

As demonstrated by the acoustic modelling, it is reasonable to expect that cetaceans may demonstrate avoidance or attraction behaviour to the noise generated by the Petroleum Activities Program (behavioural response). With respect to the western extent of the pygmy blue whale distribution range that overlaps the Offshore Operational Area, as described in Section 4.6.3, the likelihood of encountering migrating or foraging PBWs is considered low. There is likely to be occasional individual or small groups transiting through the distribution range during the northbound or southbound migration seasons. The worst-case cumulative vessel scenarios modelled (e.g. Scenario 4) predict potential behavioural disturbance beyond 40 km from the source; however, these only represent short-term activities. Further, the Offshore Operational Area is surrounded by open water, with no restrictions (e.g. shallow waters, embayments) to an animal's ability to avoid the activities. Consequently, any PBWs transiting through the area, may deviate slightly from their

Detailed Impact Assessment

migration route, but can continue on their migration pathway without any likely biologically significant impacts. Potential behavioural disturbance to PBWs within the distribution range is most likely to occur during migratory periods, with the highest likelihood of impacts occurring during the peak northbound (April to July [peak: May and June]) and southbound (October to January [peak: November]) migratory seasons.

To account for the potential presence of blue pygmy whales within the distribution range (and possibly west of the migratory BIA) in the peak northbound migratory season, adaptive management procedures will be implemented during FPU hook-up and commissioning to manage potential impacts to pygmy blue whales (refer to ALARP table below) and to ensure the activity is not inconsistent with the CMP (Action Area 2 and 3 see **Section 6.9.3**). Other marine mammals may be periodically present in the Offshore Operational Area during FPU hook-up and commissioning activities. As described above, PTS and TTS impacts are highly unlikely for individuals passing through the area. Avoidance behaviours may be expected resulting in deviation around the activities. However, hook-up and commissioning activities are short-term and given the deep, open water location of the FPU, impacts are expected to be minor.

The National Recovery Plan for the Southern Right Whale (DCCEEW, 2024b) also identified anthropogenic noise as a threat, however the BIAs and habitat critical to the survival are over 190km away, well outside the area where behavioural responses are expected to extend from the Operational Area and as such, there is not expected to be any anthropogenic noise from the PAA that could displace or interfere with life cycle activities within, or near, the reproduction or migration BIAs and habitat critical to the survival.

Impact Assessment – Non-vessel Activities

Positioning transponders (USBL, LBL) produce mid to high frequency sound, which may only be audible to dolphins and other mid-frequency cetaceans. The USBL has lower source levels than the other instruments proposed for geophysical surveys and is not expected to result in any injury or hearing impairment. Some localised behavioural effects may occur in close proximity to the USBL, but the extent of any effect is expected to be smaller than that of other survey instruments and so the effects are considered to be negligible. Based on empirical spreading loss estimates measured by Warner and McCrodan (2011), received levels from USBL transponders are expected to exceed the cetacean behavioural response threshold for impulsive sources out to about 42 m. Given the short-duration chirps and the mid frequencies used by positioning equipment, the acoustic noise from a single transponder is unlikely to have any substantial effect on the behavioural patterns of marine fauna. Therefore, potential impacts from transponder noise are likely to be restricted to temporary and localised avoidance behaviour of individuals transiting through the PAA, and therefore are considered localised with no lasting effect. Overall, the impact significance level for marine mammals has been identified as Slight (E).

Marine Reptiles

Five species of marine turtle may occur in the PAA: flatback, green, hawksbill, loggerhead and leatherback turtles. However, marine turtle presence within the Offshore Operational Area is expected to be infrequent as described above.

Species Sensitivity and Thresholds

There is a paucity of data regarding responses of marine turtles to underwater noise. However, turtles have been shown to respond to low frequency sound, with indications that they have the highest hearing sensitivity in the frequency range 100–700 Hz (Bartol and Musick, 2003). Lenhardt (1994) observed marine turtles avoiding low-frequency sound.

McCauley et al. (2000) observed the behavioural response of caged sea turtles—green (*Chelonia mydas*) and loggerhead (*Caretta caretta*)—to an approaching seismic airgun. For received levels above 166 dB re 1 µPa (SPL), the turtles increased their swimming activity and above 175 dB re 1 µPa (SPL) they began to behave erratically, which was interpreted as an agitated state. No numerical thresholds have been developed for impacts of continuous sources (e.g., vessel noise) on marine turtles. A Popper et al. (2014) review assessed thresholds for marine turtles and found qualitative results that the risk of behavioural disturbance was high for near field exposure, moderate for intermediate exposure and low for far field exposure (refer to Table 6-10).

Sound exposure thresholds and criteria for continuous sound sources (e.g. vessel noise) and impulsive sources (e.g. transponders) applicable to marine turtles are summarised in Table 6-10. There was no change to sea turtle thresholds for permanent and temporary threshold shift in the updated NMFS-OPR-71.

Table 6-10: Thresholds for permanent and temporary threshold shift and behavioural response onset in marine turtles for impulsive and continuous noise

Hearing group	Impulsive			Continuous		
	PTS onset thresholds: SEL _{24h} (dB re 1 µPa ² .s)	TTS onset thresholds: SEL _{24h} (dB re 1 µPa ² .s)	Behavioural response (dB re 1 µPa)	PTS onset thresholds: SEL _{24h} (dB re 1 µPa ² .s)	TTS onset thresholds: SEL _{24h} (dB re 1 µPa ² .s)	Behavioural response (dB re 1 µPa)
Marine turtles	204	189	166* 175+	220	200	(N) High (I) Moderate (F) Low [#]

Detailed Impact Assessment

Source: PTS and TTS thresholds (Finneran et al., 2017), * behavioural response threshold (impulsive) (NSF 2011), + behavioural disturbance threshold (impulsive) (McCauley et al. 2000), # behavioural response threshold (continuous) (Popper et al. 2014),

Note: The sound units provided in the table above for continuous noise include: relative risk (high, medium and low) is given for marine turtles at three distances from the source defined in relative terms as near (N – tens of metres), intermediate (I – hundreds of metres) and far (F – thousands of metres) (after Popper et al. 2014).

Results – Acoustic Modelling

As described in the acoustic modelling for cumulative vessel noise, based on the application of the multiple SEL_{24h} thresholds (Finneran et al., 2017), PTS for turtles was not predicted to occur within the modelling resolution (20 m), and turtles could potentially experience TTS within 140 m in the worst case scenario (Scenario 4) (Table 6-11). However, marine turtles within the Offshore Operational Area are expected to be transient, and unlikely to remain with 140 m of the vessels for 24-hours, and therefore PTS and TTS thresholds are not expected to be reached. Behavioural impacts to marine turtles from continuous noise sources generated by the Petroleum Activities Program are expected to be short-term and localised as described below.

Table 6-11: Maximum predicted horizontal distances (R_{max}) to permanent and temporary threshold shifts in marine turtles

Hearing group	Sound exposure threshold	Scenario 1 (AHTs)	Scenario 2 (2x AHTs)	Scenario 3 (tow tug)	Scenario 4 (2x AHTs, 5x tow tug, OSV)	Scenario 5 (FPU)	Scenario 6 (FPU, OSV)	Scenario 7 (FPU, ASV, LCV)
		R _{max} (km)	R _{max} (km)	R _{max} (km)	R _{max} (km)	R _{max} (km)	R _{max} (km)	R _{max} (km)
PTS								
Marine Turtles	220 dB re 1 μPa ² .s (SEL _{24h})	-	-	-	-	-	-	-
TTS								
Marine Turtles	200 dB re 1 μPa ² .s (SEL _{24h})	0.13	0.13	0.11	0.14	-	0.06	0.05

N.B. A dash indicates the threshold was not reached within the limits of the modelling resolution (20 m).

Impact Assessment

The Recovery Plan for Marine Turtles (Commonwealth of Australia, 2017) notes there is limited information available on the impact of noise on marine turtles and that the impact of noise on turtle stocks may vary depending on whether exposure is short (acute) or long-term (chronic). However, given the thresholds outlined in Table 6-10, it is reasonable to expect that marine turtles may demonstrate avoidance or attraction behaviour to the noise generated by the Petroleum Activities Program.

There are no marine turtle BIAs or Habitat Critical within 160 km of the Offshore Operational Area, and given the water depths and distance from shore, this area does not represent suitable foraging or interning habitat. Marine turtle presence the Offshore Operational Area is therefore expected to be infrequent, and potential impacts from predicted noise levels from the vessels during FPU hook-up and commissioning activities are not considered to be ecologically significant at a population level. Overall, the impact significance level for marine reptiles has been identified as Slight (E).

Fish, Sharks and Rays

A number of demersal and pelagic fish species will be present within the PAA. However, given species richness has been shown to correlate with habitat complexity (Gratwicke and Speight, 2005), it is unlikely that the sand/silt sediments that comprise the largest proportion of the PAA will support a wide diversity of species. Migratory species such as whale sharks may be present, however, it should be noted the BIA for foraging is a distant 194 km south of the Offshore Operational Area where the hook-up and commissioning activities will be occurring.

Species Sensitivity and Thresholds

Detailed Impact Assessment

The majority of fish species detect sounds from <50 Hz up to 500-1500 Hz (Popper and Hawkins, 2019). A smaller number of species can detect sounds over 3 kHz, while very few species can detect ultrasound over 100 kHz (Ladich and Fay, 2013). The critical issue for understanding whether an anthropogenic sound will affect the hearing of a fish is whether it is within the hearing frequency range of the fish and loud enough to be detectable above background ambient noise.

Fish perceive sound through the ears and the lateral line, which are sensitive to vibration. Some species of teleost or bony fish (e.g. herring) have a structure linking the gas-filled swim bladder and ear, and these species usually have increased hearing sensitivity. These species are considered to be more sensitive to anthropogenic underwater noise sources than species such as cod (*Gadus sp.*), which do not possess a structure linking the swim bladder and inner ear. Fish species that either do not have a swim bladder (e.g. elasmobranchs (sharks and rays) and scombrid fish (mackerel and tunas)) or have a much-reduced swim bladder (e.g. flat fish) tend to have a relatively low auditory sensitivity.

Considering these differences in fish physiology, Popper et al. (2014) developed sound exposure guidelines for fish; these are presented in Table 6-12 and are considered appropriate to assess continuous acoustic discharges to fish from the Petroleum Activities Program.

Table 6-12: Impact thresholds to fish, sharks and rays for continuous noise

Hearing group	Impulsive			Continuous		
	PTS onset thresholds: SEL _{24h} (dB re 1 µPa ² .s)	TTS onset thresholds: SEL _{24h} (dB re 1 µPa ² .s)	Behavioural response (dB re 1 µPa)	PTS onset thresholds: SEL _{24h} (dB re 1 µPa ² .s)	TTS onset thresholds: SEL _{24h} (dB re 1 µPa ² .s)	Behavioural response (dB re 1 µPa)
Fish: no swim bladder	216	186	(N) High (I) Moderate (F) Low	(N) Low (I) Low (F) Low	(N) Moderate (I) Low (F) Low	(N) Moderate (I) Moderate (F) Low
Fish: swim bladder not involved in hearing	203	186	(N) High (I) Moderate (F) Low	(N) Low (I) Low (F) Low	(N) Moderate (I) Low (F) Low	(N) Moderate (I) Moderate (F) Low
Fish: swim bladder involving hearing	203	186	(N) High (I) High (F) Moderate	170 dB rms SPL for 48-hours	158 dB rms SPL for 12-hours	(N) High (I) Moderate (F) Low

Impulsive noise: All criteria are presented as sound pressure, even for fish without swim bladders, since no data for particle motion exist.

Continuous noise: rms SPL: root mean square of time-series pressure level, useful for quantifying continuous noise sources.

Relative risk (high, moderate, or low) is given for animals at three distances from the source defined in relative terms as near (N), intermediate (I), and far (F).

Source: Popper et al. (2014).

Impact Assessment

The acoustic modelling of cumulative vessel noise in the Offshore Operational Area did not find any scenarios with the potential to cause injury to fish species with a swim bladder involved in hearing. TTS effects could occur within 70 m of the vessels if the fish remained within this distance for 12-hours in the worst-case scenario, however this is highly unlikely given the mobility of fish species and known behaviours that would reduce long exposure periods required to cause TTS.

The potential for injury or TTS effects to fish resulting from single impulse PK or accumulated exposures to SBP, MBES and SSS sound is limited to within 1–2 m beneath or to the side of the sound source (Zykov, 2013; McPherson and Wood 2017). Single impulse exposures at this range are highly unlikely to occur and accumulated exposures over several hours at this range are not credible.

Potential impacts to demersal and pelagic fish and sharks/rays are expected to be limited to a behavioural response. Behavioural responses are expected to be short-lived, with duration of effect less than or equal to the duration of exposure. While fish may initially be startled and move away from the sound source, once the source moves on fish would be expected to move back into the area. Potential impacts from predicted noise levels from the vessels and transponders are not considered to be ecologically significant at a population level.

Detailed Impact Assessment

Commercial Fish Spawning

Depth ranges and key spawning periods for six key indicator commercial fish on the NWS are as follows:

- red emperor – depth range 10–180 m, spawns Sept–June (bimodal peaks Sept–Nov and Jan–Mar)
- rankin cod – depth range 10–150 m, spawns June–Dec and Mar (peak Aug–Oct)
- goldband snapper – depth range 50–200 m, spawns Oct–May
- bluespotted emperor – depth range 5–110 m, spawns Jul–Mar
- ruby snapper – depth range 150–480 m, spawns Dec–Apr (peak Jan–Mar)
- Spanish mackerel – depth range 1 m to at least 50 m, spawns Sept–Jan.

It is understood that all of these species undergo group spawning throughout their range, rather than aggregating at specific locations. The PAA overlaps the depth ranges for these key indicator commercial fish species. However, as described above, the potential impact of acoustic emissions on demersal and pelagic fishes is expected to be limited to a short-lived behavioural response confined to a few hundred metres from the vessels. As such, the potential for the Petroleum Activities Program to impact spawning of key indicator commercial fish species is assessed as being extremely low.

Potential impacts from acoustic emissions on fish, sharks and rays are likely to be restricted to localised and temporary avoidance behaviour while transiting through the PAA, and individuals impacted are unlikely to represent a significant proportion of the population with the PAA and the NWS region overall. As such, the impact significance level for Fish, Sharks and Rays has been identified as Slight (E).

Cumulative impacts

Cumulative impacts for activities within the scope of this Petroleum Activities Program have been assessed above.

As described in Section 6.2.1, there is potential for drilling operations conducted in accordance with the Scarborough Drilling and Completions EP to occur within the Offshore Operational Area. The MODU plus a support vessel (from Scarborough D&C activities) are conservatively estimated to have a maximum combined broadband source level of 192 dB re 1 $\mu\text{Pa}^2\text{m}^2\text{s}$. Within the Scarborough WA-61-L and WA-62-L Subsea Infrastructure Installation Environment Plan, modelling of cumulative effects of a MODU operating concurrently with a sequence of subsea installation activities had a maximum radius to 120db SPL of less than 29.6 km. This simulation has been used to inform this cumulative impact assessment.

In a worst-case scenario, D&C activities may occur simultaneously with FPU hook up activities (as per Scenario 4 in Table 6-6) for a period of up to 30 days (as per Table 6-5). Modelling outlined above predicts noise from the hook up scenario attenuating to less than 120db (the lowest impact threshold for any species) at a distance of 43.4 km. Underwater noise is not additive and noise propagation from a conservative worst case cumulative activity scenario is estimated to result in underwater noise that attenuates to below 120 db at no more than 50% more than the relevant activities occurring in isolation, or approximately 65km away. In the more likely, but still temporary activity where commissioning relies on the use of a smaller number of vessels (as per Scenario 2 in Table 6-6), noise would attenuate to below the 120db threshold at no more than 25% further than that modelled for the highest noise activity (D&C) which was modelled at the same location as resulting in noise attenuating to below 120db by 30km from the source – resulting in attenuation to below the 120 db threshold at no more than 45km from the source.

The pygmy blue whale migration BIA is about 35 km from the Offshore Operational Area. There is no potential for PTS or TTS impacts from FPU hook-up and commissioning activities occurring at the same time as D&C activities due to the maximum distance to TTS impact for each of the activities being <10 km for D&C and 11.7km for the worst-case FPU hook-up scenario (Scenario 4).

As demonstrated by the acoustic modelling, it is reasonable to expect that cetaceans may demonstrate avoidance or attraction behaviour to the noise generated by these activities occurring concurrently. With respect to the western extent of the pygmy blue whale distribution range that overlaps the Offshore Operational Area, as described in Section 4.6.3, the likelihood of encountering migrating or foraging PBWs is considered low. There is likely to be occasional individual or small groups transiting through the distribution range during the northbound or southbound migration seasons.

The concurrent activity scenario (D&C and FPU hookup occurring at the same time) predicts potential behavioural disturbance beyond 40 km from the source (45km – 65km away); however, these only represent short-term activities. Further, the Offshore Operational Area is surrounded by open water, with no restrictions (e.g. shallow waters, embayments) to impede an animal's ability to avoid the activities. Consequently, any PBWs transiting through the area, may deviate slightly from their migration route, but can continue on their migration pathway without any likely biologically significant impacts. Potential behavioural disturbance to PBWs within the distribution range is most likely to occur during migratory periods, with the highest likelihood of impacts occurring during the peak northbound (April to July [peak: May and June]) and southbound (October to January [peak: November]) migratory seasons.

Detailed Impact Assessment				
Summary of Assessment Outcomes				
Receptor	Impact	Receptor Sensitivity Level	Magnitude	Impact Significance Level
Ambient noise	Change in ambient noise	Low value (open water)	No lasting effect	Negligible (F)
Marine mammals	Change in fauna behaviour	High value species (i.e. pygmy blue whale)	No lasting effect	Slight (E)
Marine reptiles	Change in fauna behaviour	High value species (i.e. flatback, green, hawksbill or loggerhead turtles)	No lasting effect	Slight (E)
Fish, Sharks and Rays	Change in fauna behaviour Hearing impairment to fauna	High value species	No lasting effect	Slight (E)

Overall Impact Significance Level: The overall impact significance level for routine acoustic emissions is Slight (E) based on no lasting effect to the high value receptors (marine mammals, reptiles and fish). The impact significance levels for individual receptors are consistent with the level in the OPP.

Based on the assessment above, the implementation of controls and the absence of any TTS effects within the pygmy blue whale migration BIA, and no impact to the foraging BIA, the potential impacts of noise emissions from the activity on cetaceans are considered to be slight and short-term. Impacts to cetaceans are likely to be restricted to temporary behavioural changes (avoidance) in individuals moving through the PAA, with predicted noise not considered likely to cause injury effects. This is not inconsistent with the Blue Whale Conservation Management Plan (Section 6.9.3).

Demonstration of ALARP				
Control Considered	Control Feasibility (F) and Cost/ Sacrifice (CS)	Benefit in Impact/Risk Reduction	Proportionality	Control Adopted
Professional Judgement – Substitute				
Management of vessel noise by varying the timing of the Petroleum Activities Program to avoid migration periods.	<p>F: Yes. It is possible to vary the timing of the Petroleum Activities Program to avoid migration periods, however the risk of potential impacts from routine acoustic emissions is considered to be low and limited to a behavioural response.</p> <p>CS: Significant cost and schedule impacts due to delays in securing vessels for specific timeframes. A variation in timing to avoid migration periods would result in significant delays to the project. Ideal (calm) sea states for subsea installation occur over the summer months.</p>	<p>Given the potential impacts to migrating fauna during this activity is low, implementation of this control would not result in a reduction in consequence.</p> <p>Additionally operating outside of migration periods does not guarantee the absence of individuals in the PAA and therefore doesn't eliminate possibility of impacts all together.</p>	<p>Grossly disproportionate. Implementation of the control requires considerable cost with minimal environmental benefit.</p> <p>While activities may result in a behavioural disturbance to PBWs, this is likely to affect a small portion of individuals travelling outside of the Migration and Foraging BIAs and will not have a population level impact on the species.</p> <p>The cost/sacrifice outweigh the benefit gained.</p>	No
Professional Judgement – Engineered Solution				
Reduce vessel speed in the Operational Area to reduce vessel noise propagation.	<p>F: Yes.</p> <p>CS: Increased vessel transit times, potential schedule delays and impact to subsequent activities.</p>	<p>The Offshore Operational Area does not overlap with any cetacean BIAs or critical habitat and the presence of marine fauna is likely to be limited to infrequent occurrences of individuals or small groups. Therefore, there is no further risk reduction from the application of this control.</p>	<p>Given the slow speeds at which vessels operate, the likely presence of marine fauna in the Operational Area and the controls currently in place the adoption of this control offers no further reduction in risk.</p>	No
Passive Acoustic Monitoring (PAM).	<p>F: No. PAM has limited ability to detect calls from baleen whales such as the pygmy blue whale, particularly with added background noise from vessel activities and known reliability and practicality limitations of the technology.</p> <p>CS: Costs associated with PAM technology acquisition and implementation.</p>	<p>Not considered – control not feasible.</p>	<p>Not considered – control not feasible.</p>	No

Demonstration of ALARP				
Control Considered	Control Feasibility (F) and Cost/ Sacrifice (CS)	Benefit in Impact/Risk Reduction	Proportionality	Control Adopted
Use of thermal imaging equipment at night or periods of low visibility to identify cetacean presence.	F: Yes. Some technology may be feasible to install on vessels such as automated vessel mounted camera systems that employ machine learning algorithms to detect cetaceans. Other technology such as hand-held thermal imaging binoculars are not feasible for use due to limitations in ability to be used open ocean sea states. CS: Costs associated with acquisition and implementation of vessel mounted camera systems are significant.	Some thermal imaging equipment if effective, can increase likelihood of identifying cetacean presence - however limitations on detection distance/depth, interpretation of data (identification of cetacean type for example) and practicality exist. The open ocean sea states and conditions (i.e., high winds and rough seas) of the PAA may decrease the rate of marine mammal detection. This is in addition to the already low numbers, cryptic nature, and often solitary and distribution of PBW.	Cost/sacrifice outweighs benefit. Lack of proven application in detection of cetaceans in deep water environment and limitations of the technology reduce potential benefit gained when compared with low likelihood of expected cetacean activity and low likelihood of vessel movement at night.	No
Use of Autonomous Underwater Vehicle (AUV) to monitor for presence of pygmy blue whales using detection of their vocalisations.	F: Yes. Could be deployed from Support Vessel. CS: Costs associated with obtaining and operating the technology. Schedule delays while data is collected and interpreted (not real time monitoring).	Limited benefit as the technology relies on pygmy blue whale vocalisation, which is currently not well understood, particularly during foraging activities. Technology and applications still under development and not widely tested in field. Application limited due to lack of real time capability.	Cost/sacrifice outweighs benefit. Due to distance of PAA from pygmy blue whale migration and foraging BIAs, presence of PBWs carrying out opportunistic foraging activities in the area is expected to be low. It is not expected that an AUV would add significantly more value than opportunistic observations, to warrant deployment.	No
Manage vessel speed in the humpback and PBW whale BIAs in migration seasons within the Trunkline Operational Area.	F: Yes. It is possible to carry out for vessels transiting within the Operational Area CS: will impact with longer transit times for vessels.	There is mounting evidence that reduction of vessel speeds can reduce vessel underwater noise emissions and increase the likelihood that fauna will be seen by vessels (and have more time to react) thereby	Benefits outweigh cost/sacrifice	C 4.8

Demonstration of ALARP				
Control Considered	Control Feasibility (F) and Cost/ Sacrifice (CS)	Benefit in Impact/Risk Reduction	Proportionality	Control Adopted
		reducing possibility of vessel strike. Where this control prevents impacts to humpback and pygmy blue whales at a population level, it maintains a culturally significant resource to a level that results in no observable change to coastal communities (migratory pathways maintained).		

ALARP Statement:

On the basis of the environmental impact assessment outcomes and use of the relevant tools appropriate to the decision type (i.e. Decision Type A, Section 2.3.1), Woodside considers the adopted controls appropriate to manage the potential impacts from noise emissions. As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts are considered ALARP.

Demonstration of Acceptability

Acceptability Criteria and Assessment

Demonstration of acceptability for the sources of aspect and associated impacts assessed in this section are provided in Section 7.1.4.3 of the Scarborough OPP. The Petroleum Activities Program meets the acceptability criteria (Section 2.3.5):

- Overall impact significance levels for individual receptors are less than the significant impact level defined in the OPP.
- EPOs in this EP are aligned with EPOs in the OPP (refer to Table 6 2)
- Controls in the OPP that are relevant to this EP Section have been adopted.
- Additional guidance on key terms within the CMP was issued in September 2021 and these were considered in the assessment against relevant actions in the CMP. The Petroleum Activities Program is not considered to be inconsistent with the relevant actions of this plan.
- There are no additional changes to internal/external context specific to this risk from the OPP, including issues raised during consultation.

Acceptability Statement:

The impact assessment has determined that the generation of noise from Project Vessels and positioning equipment is unlikely to result in an impact significance level greater than slight. EPBC Act requirements (principles of ESD; MNES significant impact guidelines; recovery plans, conservation advice and marine park management plans) have been considered during the impact assessment. The Petroleum Activities Program is not considered to be inconsistent with any relevant EPBC Act requirements, including the objectives, overall recovery objectives and actions of relevant recovery plans, conservation advice and management plans (Section 6.8.11).

The potential impacts are considered broadly acceptable if the adopted controls are implemented and EPO 10 has been applied to demonstrate the activities are not inconsistent with the Blue Whale Conservation Management Plan. Activities do not have a significant impact on MNES (Section 2.4.2). Therefore, Woodside considers the adopted controls appropriate to, manage the impacts of acoustic emissions to a level that is broadly acceptable; and demonstrate the EPOs are met.

Description of Source of Impact/Risk
<p>Routine operation of the FPU will comprise a number of different acoustic emissions sources, primarily associated with infield vessel operations and support activities, such as geophysical surveys and other IMMR activities. Sound will also be associated with the operation phase of the FPU and subsea facilities. Acoustic emissions during FPU hook-up and commissioning are assessed in Section 6.7.4.</p> <p>Sound levels will fluctuate over the course of the Petroleum Activities Program; this will largely depend upon concurrent vessel activities. Generally, sound associated with steady state operations will be limited, with periodic and short-term increases in sound associated with IMMR, supply operations or gravimetry surveys.</p> <p>These acoustic sources will contribute to and have the potential to exceed ambient noise levels in the region. Mean ambient sound levels have been measured as 109 dB re 1 µPa sound pressure level (SPL) and 115 dB re 1 µPa SPL at locations near the Offshore Operational Area and at the continental shelf edge along the Trunkline Operational Area, respectively (Warren, 2022).</p>

Description of Source of Impact/Risk

Key acoustic sources associated with the Petroleum Activities Program are described below. Table 6-14 presents likely concurrent activities contributing to cumulative underwater noise levels. This has been used to inform the worst-case credible sound propagation scenarios for modelling as well as cumulative impact assessment as a result of concurrent operations, discussed below.

Continuous (Non-Impulsive) Sources

Support Vessels and Operation of DP

The Support Vessels will generate noise both in the air and underwater, due to the operation of thrusters, engines, propeller movement, etc (as described in Section 6.7.4).

Examples of vessels proposed to be used during routine operations are detailed in Section 3.11 Table 6-13. Those involved with FPU Operations, IMMR and Gravimetry Surveys include the FPU, support vessels, USV, and LCV.

Source levels for representative vessels are described in Table 6-13.

Table 6-13: Modelled broadband sound source levels for PAP during routine operations.

Vessel type and operation mode	Energy source level	Basis for source level estimation and source depth
Support Vessel under transit	177.8 dB re 1 $\mu\text{Pa}^2\text{m}^2.\text{s}$	Representative Vessel (Fugro Etive) operating at 20% capacity
FPU	173.9 dB re 1 $\mu\text{Pa}^2\text{m}^2.\text{s}$	Representative surrogate vessel derived from the average of measured levels of two Floating Production Storage Offload (FPSO) vessels, Ngujima and Nganhurra (Erbe et al. 2013).
LCV under DP	180.9 dB re 1 $\mu\text{Pa}^2\text{m}^2.\text{s}$	Representative vessel (Deep Orient) (Quijano and McPherson, 2021)
Support Vessel or USV under DP	187.6 dB re 1 $\mu\text{Pa}^2\text{m}^2.\text{s}$	Representative Vessel (Fugro Etive) at 50% capacity

Operating FPU

The FPU will have machinery mounted on the decks raised above sea level. Machinery noise may be radiated into the underwater environment via the hull, with noise emitted to the air having limited input to underwater noise levels due to impedance at the sea surface (air/water boundary). Underwater source levels for the FPU were derived from the average of measured levels of two moored Floating Production Storage Offload (FPSO) vessels, Ngujima and Nganhurra, when thrusters and offtake activities were absent (Table 6-13).

The HP and LP flare system generate noise from combustion. Noise from flaring is emitted at the top of the flare tower, which is approximately 150 m above sea level. Noise from the tip of the flare is not constrained and spreads in all directions. Received levels from airborne propagation modelling were used to ascertain the underwater received levels during flaring activities for a drilling and subsea installation activity (Woodside, 2019b). Only a very small fraction of the acoustic energy produced from flaring will transmit through the air/water boundary due to the surface of water acting as a reflective plane and a significant component of acoustic energy reflecting back into the air. While underwater received sound pressure level during flaring is estimated to be 136 dB re 1 μPa at 1m below the sea surface it is estimated to attenuate to ambient levels within a very short distance (e.g. metres) and therefore is not considered further in the impact assessment.

Operating Wellheads, Export Trunkline and Subsea Infrastructure

The noise produced by an operational wellhead was measured by McCauley (2002). The broadband noise level was very low, 113 dB re 1 μPa , which is comparable to ambient noise levels. For a number of nearby wellheads, the sources would have to be in very close proximity (< 50 m apart) before their signals summed to increase the total noise field (with two adjacent sources only increasing the total noise field by three dB). Hence for multiple wellheads in an area, the broadband noise level in the vicinity of the wellheads would be expected to be of the order of 113 dB re 1 μPa and this would drop very quickly to ambient conditions on moving away from the wellhead, falling to background levels within 200 m from the wellhead.

Based on the measurements of wellhead noise discussed in McCauley (2002), which included flow noise in pipelines, noise produced along the trunkline may be expected to be similar to that described for wellheads, with the radiated noise field falling to ambient levels within 200 m of the trunkline.

Woodside has undertaken acoustic measurements on the noise generated by the operation of choke valves associated with the Angel facility on the North West Shelf (JASCO, 2015). These measurements indicated choke valve noise is continuous, and the frequency and intensity of noise emitted is dependent on the rate of production from the well. Noise intensity at low production rates (16% and 30% choke positions) were approximately 154-155 dB re 1 μPa , with higher production rates (85% and 74% choke positions) resulting in lower noise levels (141-144 dB re 1 μPa). Noise from

Description of Source of Impact/Risk

choke valve operation was broadband in nature, with the majority of noise energy concentrated above 1 kHz. Noise from choke valve operation was considered minor compared to noise generated by vessels using thrusters in the area. Given the low levels of noise emitted by subsea infrastructure such as wellheads, choke valves and pipelines, no significant impacts to marine fauna from these noise sources are expected. Measurements of noise generated by choke valves indicated it is relatively high frequency (>1 kHz), and hence it attenuates over relatively short distances in the water column; significant impacts to marine fauna are not considered credible and therefore not considered further in the impact assessment.

Helicopter Transfers

Helicopter activities will occur in the PAA, including landing and take-off on the FPU or vessel helidecks. Sound emitted from helicopter operations is typically below 500 Hz (Richardson et al., 1995). The peak received level diminishes with increasing helicopter altitude, but the duration of audibility often increases with increasing altitude. Richardson et al. (1995) reports that helicopter sound is audible in air for four minutes before it passed over underwater hydrophones, but detectable underwater for only 38 seconds at 3 m depth and 11 seconds at 18 m depth. Noise levels reported for a Bell 212 helicopter during fly-over was reported at 162 dB re 1 µPa and for Sikorsky-61 is 108 dB re 1 µPa at 305 m (Simmonds et al. 2004). Water has a very high acoustic impedance contrast compared to air, and the sea surface is a strong reflector of noise energy (i.e. very little noise energy generated above the sea surface crosses into and propagates below the sea surface (and vice versa) – the majority of the noise energy is reflected). The angle at which the sound path meets the surface influences the transmission of noise energy from the atmosphere through the sea surface, angles >13° from vertical being almost entirely reflected (Richardson et al., 1995). Given this, and the typical characteristics of helicopter flights within the PAA (duration, frequency, altitude and air speed), the opportunity for underwater noise levels to exceed the behavioural thresholds is not considered credible and is not assessed further in the impact assessment.

Non-routine Impulsive Noise Sources

Geophysical Surveys During IMMR Activities

The noise emitted during IMMR survey activities is generated by a combination of the survey equipment and the Support vessel. Geophysical survey activities may occur within the PAA during commissioning and routine operations. A range of geophysical sources can emit pulses (impulsive noise) with frequency outputs ranging from 10 Hz (low end of refraction system) to 900 kHz (side scan sonar). The survey methods may include multibeam echo sounders (MBES), side scan sonar (SSS) and sub-bottom profiler (SBP).

Most commercial SBPs are small, low-powered, high-resolution and shallow-penetrating systems, producing electrical pulses across a range of frequencies (Salgado Kent et al., 2016; Jiménez-Arranz et al., 2017). The instruments that could be used for the survey are expected to produce pulses of sound between approximately 50 Hz and 30 kHz with source levels between approximately 192 and 220 dB re 1µPa SPL at 1 m.

MBES and SSS are very high-frequency and high-resolution systems, producing short micro-pulses of sound at frequencies in the tens or hundreds of kilohertz. The high-frequency pulses of sound produced by MBES are focused within multiple highly directional and narrow beams, which form a fan shape directed at the seabed (Salgado Kent et al., 2016; Jiménez-Arranz et al., 2017). SSS also produces sound in a focussed swath directed at the seabed. The pulses of sound produced by these instruments are of such high frequency that they rapidly attenuate outside of the beam (Zykov, 2013).

An array of long baseline (LBL) and/or ultra-short baseline (USBL) transponders may be used for underwater positioning. Transponders typically emit pulses (impulsive noise) of medium frequency sound, generally within the range 21 to 31 kHz. The estimated SPL would be 180 to 206 dB re 1 µPa at 1 m (Jiménez-Arranz et al., 2017). Transmissions are not continuous but consist of short ‘chirps’ with a duration that ranges from 3 to 40 milliseconds. Transponders will not emit any sound when on standby. The operating frequency range is above the auditory range of low frequency cetaceans (peak hearing at 0.2-19 kHz; NMFS 2018), marine turtles and the majority of fish species (<1 kHz; Ladich, 2000; Popper et al., 2014), however dolphins have the capacity to hear the sound produced from LBL/USBL.

Cumulative Noise Sources

Concurrent activities contributing to cumulative underwater noise from vessel activities during routine operations are outlined in Table 6-14. The FPU will be supported by an offshore Support Vessel on an ongoing basis (Scenario 1), with the addition of an LCV during IMMR activities (Scenario 2). Other activities utilising single vessels (i.e. gravimetry survey) are not expected to contribute significantly to the cumulative noise footprint, due to their relatively small size, short activity duration and separation distances from other activities.

Table 6-14: Concurrent activities contributing to cumulative underwater vessel noise

Planned Concurrent Activities	Approximate Timing & Duration	Vessels/sources

Approximate campaign length of 2 weeks at the FPU location (500 m radius) Maintenance: Intervention for repair or replacement must be carried out when equipment fails in service Repairs: From 105 to over 548 days Flowline pigging: Duration ~1 week per flowline; start date ~ 1 year after start-up Export trunkline pigging: Duration ~ 2 weeks; start date approximately ~ 1 year after start-up Gravimetry ~55 days per survey; approximately; 18-24 months post RFSU, and subsequently every 2-3 years	FPU Offshore Support Vessel Light Construction Vessel (LCV) Uncrewed Surface Vessel (USV)

Detailed Impact Assessment
Assessment of Potential Impacts
<p>Receptors</p> <p>The PAA comprises the Offshore Operational Area and the Trunkline Operational Area. The Offshore Operational Area is located in water depths of approximately 900–1000 m (refer to Section 3.3). The fauna associated with this area will be predominantly pelagic species of fish, with migratory species such as cetaceans and marine turtles potentially occurring in the area seasonally (Section 4.6). Fauna associated with the Trunkline Operational Area includes both pelagic and demersal species of fish. Noise interference is a key threat to a number of migratory and threatened cetaceans and marine turtles identified as potentially occurring within the Offshore Operational Area, including the pygmy blue whale (PBW). The Trunkline Operational Area extends from the Offshore Operational Area, across Commonwealth Waters to the boundary with WA State Waters. The fauna associated with the Trunkline Operational Area includes both pelagic and demersal species of fish. Additional migratory species associated with the Trunkline Operational Area include migrating humpback whales, and marine turtle aggregation areas near to State waters and the coastline (Section 4.6). Relevant actions included in recovery plans for these species are outlined in Section 6.9.3. The key BIAs within the PAA include:</p> <ul style="list-style-type: none"> • PBW migration BIA (overlapping the Trunkline Operational Area; 35 km east of the Offshore Operational Area) • Humpback whale migration BIA (overlapping the Trunkline Operational Area; 156 km south-east of the Offshore Operational Area) • a number of marine turtle interesting BIAs and Habitat Critical areas (overlapping the Trunkline Operational Area; greater than 165 km east of the Offshore Operational Area). <p>Potential effects of sound on marine fauna, including hearing sensitivity are described in Section 6.7.4.</p> <p>Acoustic Modelling</p> <p>As described in Section 6.7.4, to assess the potential magnitude and extent of impacts from underwater noise produced during routine operations, Woodside commissioned JASCO Applied Sciences (JASCO) to model sound propagation for a range of concurrent operations and vessel scenarios. The modelling study (Stephen et al., 2023) considered specific components of the Petroleum Activities Program for representative scenarios within the PAA. The modelled scenarios presented in Table 6-6 (Section 6.7.4), include several permutations of concurrent activities that may occur during routine operations (Scenarios 5 to 7) as follows:</p> <ul style="list-style-type: none"> • Scenario 5: FPU operating and anchored (24 hrs) • Scenario 6: FPU operating and anchored (24hrs), resupply OSV under DP (8hrs) • Scenario 7: FPU operating and anchored, ASV under DP (24hrs), LCV under DP (8hrs). <p>The modelling study specifically assessed distances from operations where underwater sound levels were predicted to reach thresholds corresponding to potential behavioural response, TTS and PTS. The animals considered here included low-frequency (LF), high-frequency (HF) cetaceans, turtles, and fish including fish larvae and eggs. Further details on the modelling methodology are provided in Section 6.7.4.</p>

Detailed Impact Assessment

Marine Mammals/Cetaceans

Eight cetacean species may be present within the PAA, including LF cetaceans such as pygmy blue whales, and HF cetaceans such as sperm whales and orcas (Section 4.6.3).

Species with BIAs (Section 4.6.3) that intercept the Trunkline Operational Area are:

- pygmy blue whale – migration BIA occurs in deeper waters of the Trunkline Operational Area
- humpback whale – migration BIA occurs in the nearshore waters of Trunkline Operational Area.

Species Sensitivity and Sound Exposure Thresholds

Thresholds that could result in a behavioural response, TTS and PTS for cetaceans as a result of continuous and impulsive noise sources are presented in Table 6-7 in Section 6.7.4.

Results – Acoustic Modelling

Modelling of cumulative sound propagation from all modelled scenarios are presented in Section 6.7.4. Results for Scenarios 5 to 7 of relevance to routine operations are also presented below for ease of reference (Table 6-15). As described in Section 6.7.4., in October 2024, the U.S National Oceanic and Atmospheric Administration (NOAA) issued Technical Memorandum NMFS-OPR-71 which was a 2024 update to *Technical Guidance for Assessing the Effects of Anthropogenic Sound on Marine Mammal Hearing (V 3.0)*. The memo contains updated underwater and in-air criteria for onset of auditory injury and temporary threshold shifts, and relevant to the noise modelling originally conducted for this EP (Stephen et al., 2023) means that thresholds for LF and HF cetaceans changed as shown in Table 6-7.

To better understand the impacts of the change in these sound exposure thresholds, Woodside commissioned Jasco to re-model two of the conservative scenarios (4 and 7) with the new criteria. Scenario 4 was chosen to represent the credible worst-case noise scenario for FPU hookup and installation while Scenario 7 was chosen to represent worst-case noise during commissioning and is also a scenario that may be realised during operations.

A decision was made to only remodel these two conservative scenarios (instead of remodelling all the scenarios), because they represent the worst case credible noise propagation (as shown by original modelling results in Table 6-8 and reducing impacts based on these noise emissions to ALARP and Acceptable levels means that the other scenarios producing lower noise levels will also be ALARP and Acceptable. The changes to the thresholds are not significant enough to warrant remodelling all scenarios, and investigation of the worst case noise scenarios was considered adequate to understand impact of the threshold change.

The new thresholds relate to PTS and TTS onset, with behavioural response thresholds remaining the same for continuous noise. Results for Scenario 7 using the new thresholds are discussed below, however impact assessment relating to behavioural response remains unchanged.

The results from the remodelled scenarios are presented in Table 6-9: Maximum predicted horizontal distances (Rmax) to updated permanent and temporary threshold shift and behavioural response thresholds in cetaceans for Scenarios 4 and 7:

Scenarios 5 and 6 are representative of normal operations, with Scenario 7 representative of IMMR activities in proximity to the FPU. The three scenarios recorded a maximum distance to behavioural disturbance onset of 680 m, 4.91 km and 5.02 km respectively for LF and HF cetaceans. For LF cetaceans the modelling predicted a TTS onset distance of 100 m, 490 m and 740 m respectively for Scenarios 5, 6 and 7 and a PTS onset distance of 60 m and 50 m respectively for Scenarios 6 and 7 only.

Remodelling of Scenario 7 using the new thresholds for PTS and TTS onset showed that distance to LF cetacean TTS for Scenario 7 increased from 740m to 940m (or 27%). With the reduction in PTS threshold for LF cetaceans from 199 dB re 1 $\mu\text{Pa}^2\cdot\text{s}$ to 197 dB re 1 $\mu\text{Pa}^2\cdot\text{s}$, the maximum horizontal distance to threshold increased for Scenario 7 from 50m to 70m (a 40% increase).

While the threshold changes have resulted in increases to PTS and TTS maximum horizontal distances, due to the location of the Offshore Operational Area and nature of cetacean use of the area; impact assessment carried out for results from the original modelling is still valid (described below). Scenario 7 is still representative of the worst case credible scenario for noise propagation during normal operations.

For HF cetaceans, TTS onset could occur at a distance of up to 60 m for Scenario 6.. The PTS threshold for HF cetaceans was not reached within the limits of the modelled resolution (20 m) for any scenario modelled.

The SEL_{24h} criterion used for calculating the potential for TTS and PTS impacts is a cumulative metric that reflects the dosimetric impact of sound energy accumulated over a 24-hour period and assumes that an animal is consistently exposed to such noise levels at a fixed location. The radii that correspond to SEL_{24h} therefore represent an unlikely worst-case scenario for SEL-based exposure since, more realistically, marine fauna would not stay in the same location or at the same range for 24-hours (Stroot et al., 2023). It is highly unlikely that PTS and TTS thresholds would be exceeded and furthermore it is highly unlikely given the known movement behaviour of cetaceans including key migrating LF whale species such as the PBW transiting through the PAA.

A dash indicates the level was not reached within the limits of the modelled resolution (20 m).

Impact Assessment – Vessel Noise Impacts

Pygmy Blue Whale BIAs

The Blue Whale Conservation Management Plan (Action Area 2) states that anthropogenic noise in BIAs should be managed such that any blue whale continues to utilise the area without injury (Commonwealth of Australia, 2015a). Although TTS in cetaceans has previously been regarded as hearing impairment, not injury, advice from DCCEW (DAWE 2021) is that TTS should be considered a form of injury to PBW and this should be prevented within the BIAs.

As described in **Section 4.6.3**, the PBW migration BIA represents the area of core migratory routes for pygmy blue whales. The migration BIA is about 35 km from the Offshore Operational Area where ongoing operational noise from the FPU will occur. There is no potential for PTS or TTS impacts from FPU noise in the migration BIA as demonstrated by the modelling presented above, given the maximum distance to TTS impact is 940 m for the worst-case scenario (Scenario 7), using updated TTS thresholds.

As demonstrated by the acoustic modelling, it is reasonable to expect that cetaceans may demonstrate avoidance or attraction behaviour to the noise generated by the Petroleum Activities Program. With respect to the western extent of the pygmy blue whale distribution range that overlaps the Offshore Operational Area, as described in **Section 4.6.3**, the likelihood of encountering migrating or foraging PBWs is considered low. There is likely to be occasional individual or small groups transiting through the distribution range during the northbound or southbound migration seasons. The worst-case cumulative vessel scenarios modelled for FPU operations (e.g. Scenario’s 5 to 7) predict potential behavioural disturbance up to 5 km from the source. The Offshore Operational Area is surrounded by open water, with no restrictions (e.g. shallow waters, embayments) to an animal’s ability to avoid the activities. Consequently, any PBWs transiting through the area, may deviate slightly from their migration route, but can continue on their migration pathway without any likely biologically significant impacts. Potential behavioural disturbance to PBWs within the distribution range is most likely to occur during migratory periods, with the highest likelihood of impacts occurring during the peak northbound (April to July [peak: May and June]) and southbound (October to January [peak: November]) migratory seasons.

Impact Assessment – IMMR Activities

Acoustic modelling of sub-bottom profilers by Zykov (2013), MacGillivray et al. (2013) and McPherson and Wood (2017), indicates limited horizontal sound propagation outside of the main directional beams of sound. The modelling studies also indicate that PK and SEL_{24h} thresholds for PTS are not exceeded. The potential for TTS resulting from single pulse PK pressure exposure is not predicted to occur, while the potential for TTS resulting from SEL_{24h} exposures is limited

Detailed Impact Assessment

to a few metres from the moving sound source (Zykov, 2013; McPherson and Wood 2017), which is not considered to be a credible exposure for mobile marine fauna. Exceedance of the 160 dB re 1 μ Pa SPL behavioural response threshold for impulsive sound is limited to within a few tens of metres in most instances, or up to a maximum of 150 m depending upon which instrument is used, water depth and the seabed sediment characteristics (Zykov, 2013; McPherson and Wood 2017).

The very high-frequency micro-pulses of sound produced by MBES and SSS during seabed surveys rapidly attenuate outside of the beam (MacGillivray et al., 2013; Zykov, 2013). The high operating frequencies of these instruments also places the majority of sound frequencies above the principal auditory range of most marine fauna species. Dolphins and other mid-frequency cetaceans, which have peak hearing sensitivity up to 110 kHz, with potential for some limited hearing ability up to approximately 160 kHz (NMFS 2018), may be able to detect a small amount of the sound energy from some survey instruments in the lower operating frequency ranges (MacGillivray et al., 2013; Zykov, 2013). The propagation of the high frequency sound from MBES and SSS has been undertaken by Zykov (2013) and MacGillivray et al. (2013). The modelling results indicate that the sound emissions outside of the main beams are below the threshold levels for potential injury, PTS or TTS. Sound levels that may result in behavioural effects are likely limited to within tens of metres, but potentially up to a few hundreds of metres from the sound source for some mid-frequency cetaceans such as dolphins (Zykov, 2013; MacGillivray et al., 2013). Varghese et al. (2020) recently studied the foraging behaviours and vocalisations of beaked whales (mid-frequency cetaceans) to 12 kHz MBES surveys and concluded there was not a consistent change in foraging behaviour during the MBES surveys that would suggest a clear response. The animals did not leave the area nor stop foraging during MBES activity. Geophysical and other survey activities using this technology or similar are therefore expected to result in temporary behavioural effects to marine mammals within tens or hundreds of metres from the survey activities. Such localised effects are smaller than those expected from the vessels and are not expected to be biologically significant.

Positioning transponders (USBL, LBL) also produce mid to high frequency sound, which may only be audible to dolphins and other mid-frequency cetaceans. The USBL has lower source levels than the other instruments proposed for geophysical surveys and is not expected to result in any injury or hearing impairment. Some localised behavioural effects may occur in close proximity to the USBL, but the extent of any effect is expected to be smaller than that of other survey instruments and so the effects are considered to be negligible. Based on empirical spreading loss estimates measured by Warner and McCrodan (2011), received levels from USBL transponders are expected to exceed the cetacean behavioural response threshold for impulsive sources out to about 42 m. Given the short-duration chirps and the mid frequencies used by positioning equipment, the acoustic noise from a single transponder is unlikely to have any substantial effect on the behavioural patterns of marine fauna. Therefore, potential impacts from transponder noise are likely to be restricted to temporary and localised avoidance behaviour of individuals transiting through the PAA, and therefore are considered localised with no lasting effect.

Pygmy Blue Whale BIAs

The Trunkline Operational Area intersects the PBW migration BIA (from KP200 to KP375), and also overlaps with the broader pygmy blue whale distribution range. Considering the overlap with the Trunkline Operational Area, as well as the recorded presence and satellite tracking of both north and south bound tagged individuals in the area (Thums et al. (2022), it is likely that transient individuals or small groups are occasionally in and around the Trunkline Operational Area during migratory north and south seasons (April to July and October to January, respectively) (McCauley, 2011; Gavrilov et al., 2018; Thums et al., 2022). Significant numbers of pygmy blue whales are not expected to be encountered, particularly outside peak periods for northbound or southbound migrations (Figure 4 10).

While the Trunkline Project Area overlaps part of the PBW migration BIA, there is no overlap with known or possible foraging areas for the species, as defined in the Blue Whale Conservation Management Plan (CMP). In September 2021, the Department of Agriculture, Water and the Environment (DAWE) (now known as DCCEEW) published guidance on key terms within the CMP, which provided a definition of 'a foraging area' and noted the potential for opportunistic foraging and feeding to occur outside these designated foraging areas. PBW's may engage in opportunistic foraging during both northbound and southbound migrations, so there is the potential for this activity to occur in the Trunkline Project area, particularly where it overlaps the migration BIA.

While a PTS or TTS impact is possible in close proximity to a single IMMR vessel operating within the PBW migration BIA within the Trunkline Operational Area, PTS and TTS criteria exceedances are based upon exposure for 24-hours by a stationary receptor, which is not a realistic scenario. As described above, the SEL_{24h} criterion is a cumulative metric that reflects the dosimetric impact of sound energy accumulated over a 24-hour period and assumes that an animal is consistently exposed to such noise levels at a fixed location. The radii that correspond to SEL_{24h} therefore represent an unlikely worst-case scenario for SEL-based exposure since, more realistically, marine fauna would not stay in the same location or at the same range for 24-hours (Stroot et al., 2023). PTS and TTS thresholds are therefore unlikely to be exceeded for cetaceans transiting through the PAA. This aligns with The Blue Whale Conservation Management Plan (Action Area 2), which states that anthropogenic noise in BIAs should be managed such that any blue whale continues to utilise the area without injury (Commonwealth of Australia, 2015a).

Behavioural disturbance from an IMMR vessel operating along the trunkline may also result in some behavioural disturbance resulting in slight deviation of individuals. However, effects are expected to be minimal based on a single vessel operating for a short period in any given area along the trunkline route.

Detailed Impact Assessment

Humpback Whale BIA

Humpback whales are expected to be encountered during IMMR activities along the trunkline, particularly should these activities occur during annual migrations (July [northbound] and late August/September [southbound]). PTS and TTS impacts are not considered credible, as discussed above for PBWs. Behavioural response may result in a deviation in course during migration, which is expected to be insignificant in the context of the long distances over which individuals migrate (thousands of kilometres). Marine mammals that are frequently exposed to sounds such as vessel noise may also habituate and adapt to this noise (Richardson et al. 1995; NRCC, 2003). This may be the case for the humpback whale population that regularly passes through areas of significant shipping traffic during their migrations. Overall, the impact significance level for Marine mammals/Cetaceans has been identified as Slight (E).

Marine Reptiles

Five species of marine turtle may occur in the PAA: flatback, green, hawksbill, loggerhead and leatherback turtles. The Trunkline Operational Area overlaps interinteresting Habitat Critical and interinteresting buffer BIAs for the flatback, green and hawksbill turtle around the Dampier Archipelago and Montebello Islands (Section 4.6.2).

Species Sensitivity and Thresholds

As discussed in Section 6.7.4, turtles have been shown to respond to low frequency sound, with indications that they have the highest hearing sensitivity in the frequency range 100–700 Hz (Bartol and Musick, 2003). Lenhardt (1994) observed marine turtles avoiding low-frequency sound.

Sound exposure thresholds and criteria for continuous sound sources (e.g. vessel noise) and impulsive sources (e.g. transponders) applicable to marine turtles are summarised in Table 6-10 of Section 6.7.4.

Results – Acoustic Modelling

Modelling of cumulative sound propagation from all modelled scenarios are presented in Section 6.7.4. Results for Scenarios 5 to 7 of relevance to routine operations are also presented below for ease of reference (Table 6-16).

As described in the acoustic modelling for cumulative vessel noise, based on the application of the multiple SEL_{24h} thresholds (Finneran et al., 2017), PTS for turtles was not predicted to occur within the modelling resolution (20 m), and turtles could potentially experience TTS within 60 m in the worst case scenario (Scenario 6) which is limited to the Offshore Operational Area (Table 6-16). However, marine turtles within the Offshore Operational Area are expected to be transient, and unlikely to remain with 60 m of the vessels for 24-hours, and therefore PTS and TTS thresholds are not expected to be reached. Behavioural impacts to marine turtles from continuous noise sources generated by the Petroleum Activities Program are expected to be short-term and localised as described below.

Table 6-16: Maximum predicted horizontal distances (R_{max}) to permanent and temporary threshold shifts in marine turtles

Hearing group	Sound exposure threshold	Scenario 5 (FPU)	Scenario 6 (FPU, OSV)	Scenario 7 (FPU, ASV, LCV)
		R _{max} (km)	R _{max} (km)	R _{max} (km)
PTS				
Marine Turtles	220 dB re 1 μPa ² .s (SEL _{24h})	-	-	-
TTS				
Marine Turtles	200 dB re 1 μPa ² .s (SEL _{24h})	-	0.06	0.05

N.B. A dash indicates the threshold was not reached within the limits of the modelling resolution (20 m).

Impact Assessment – Vessel Noise Impacts

The Recovery Plan for Marine Turtles (Commonwealth of Australia, 2017) notes there is limited information available on the impact of noise on marine turtles and that the impact of noise on turtle stocks may vary depending on whether exposure is short (acute) or long-term (chronic). However, given the thresholds outlined in Table 6-16, it is reasonable to expect that marine turtles may demonstrate avoidance or attraction behaviour to the noise generated by the Petroleum Activities Program.

There are no marine turtle BIAs or Habitat Critical within 160 km of the Offshore Operational Area, and given the water depths and distance from shore, this area does not represent suitable foraging or interinteresting habitat. Marine turtle presence the Offshore Operational Area is therefore expected to be infrequent, and potential impacts from predicted noise levels from the Vessels and transponders are not considered to be ecologically significant at a population level.

Helicopter noise when on the sea surface may impact turtles (e.g. when basking or breathing). Typical startle responses occur at relatively short ranges (tens of metres) (Hazel et al., 2007) and as such, startle responses during typical

Detailed Impact Assessment

helicopter flight profiles are considered to be remote. In the event of a behavioural response to the presence of a helicopter, turtles are expected to exhibit diving behaviour, which is of no lasting effect.

Potential impacts from routine acoustic emissions on marine turtles are expected to be limited to behavioural impacts within a localised area around the FPU and Vessels, with no lasting effect.

Impact Assessment – IMMR Activities

Turtles may occasionally be present in deeper waters of the Trunkline Operational Area but are more likely to be encountered closer to the Dampier Archipelago where they may be present foraging year-round. Increased numbers of marine turtles may be present, albeit still in low numbers within the Trunkline Operational Area, during interesting periods. Vessel activities within the Trunkline Operational Area are limited to IMMR (**Section 3**), which typically does not involve cumulative noise sources and are performed infrequently with a limited duration (e.g. weeks) reducing the potential for impacts at the individual and population level.

The islands of Dampier Archipelago provide nesting beaches for flatback, green, hawksbill and loggerhead turtles, with Rosemary Island being a major rookery for hawksbill turtles in WA. A study of interesting movements of individuals nesting on the Dampier Archipelago has not been conducted, however, tracking studies at other islands (Barrow and Thevenard) suggest interesting flatback turtles remain in shallow water, close (< 3 km) to nesting beaches (Whitlock et al., 2014). The Trunkline Operational Area overlaps interesting Habitat Critical to the survival of flatback turtles, which is also designated a BIA. However, it is noted that the defined BIA and Habitat Critical are considered very conservative as they are based on the maximum range of interesting females and many marine turtles are more likely to remain near their nesting beaches. There is no evidence to date to indicate flatback turtles swim out into deep offshore waters during the interesting period.

PTS and TTS impacts are not considered credible as a result of vessel IMMR activities in the Trunkline Operational Area as turtles are expected to be transient and unlikely to remain in close proximity to a vessel for long periods. Behavioural impacts to marine turtles from continuous noise sources generated by the Petroleum Activities Program are expected to be short-term and localised.

Sound levels that are likely to be produced by various different SBP instruments are predicted to fall below the 166 dB re 1 µPa SPL threshold within a few metres or tens of metres (Zykov, 2013; McPherson and Wood 2017). The high-frequency sounds produced by the MBES, SSS and USBL are expected to be above the auditory range of marine turtles and so behavioural impacts are not expected to occur.

Potential impacts from predicted noise levels from IMMR Support Vessels and activities are not considered to be ecologically significant at a population level. Overall, the impact significance level for Marine reptiles has been identified as Slight (E).

Fish, Sharks and Rays

A number of demersal and pelagic fish species will be present within the PAA. However, given species richness has been shown to correlate with habitat complexity (Gratwicke and Speight, 2005), it is unlikely that the sand/silt sediments that comprise the largest proportion of the PAA will support a wide diversity of species. Migratory species such as whale sharks may be present, particularly given a BIA for foraging overlaps the Trunkline Operational Area (~KP 72 to KP 199).

Species Sensitivity and Thresholds

A detailed description of fish acoustic sensitivity and thresholds is presented in Section 6.7.4. As fish physiology is closely correlated with acoustic sensitivities, Popper et al. (2014) has developed sound exposure guidelines for fish; these are presented Table 6-12 in Section 6.7.4 and are considered appropriate to assess continuous acoustic discharges to fish from the Petroleum Activities Program.

Impact Assessment – Vessel Noise Impacts

The acoustic modelling of cumulative vessel noise in the Offshore Operational Area did not find any scenarios with the potential to cause injury to fish species with a swim bladder involved in hearing. TTS effects could occur within 70 m of the vessels if the fish remained within this distance for 12-hours in the worst-case scenario, however this is highly unlikely given the mobility of fish species and known behaviours that would reduce long exposure periods required to cause TTS.

Potential impacts to demersal and pelagic fish and sharks/rays are expected to be limited to a behavioural response. Behavioural responses are expected to be short-lived, with duration of effect less than or equal to the duration of exposure. While fish may initially be startled and move away from the sound source, once the source moves on fish would be expected to move back into the area. Potential impacts from predicted noise levels from the Vessels and FPU Operations are not considered to be ecologically significant at a population level.

Impact Assessment – IMMR Activities

The potential for injury or TTS effects to fish resulting from single impulse PK or accumulated exposures to SBP, MBES and SSS sound is limited to within 1–2 m beneath or to the side of the sound source (Zykov, 2013; McPherson and Wood 2017). Single impulse exposures at this range are highly unlikely to occur and accumulated exposures over several hours at this range are not credible.

Detailed Impact Assessment

Transponders used for positioning during IMMR activities typical operate at frequencies of 21 to 31 kHz which is well outside the hearing frequency range of fish. Therefore, no impacts are considered credible.

The Trunkline Operational Area overlaps a small proportion of the foraging BIA for whale sharks between about KP 72 and KP 199 and therefore they may be seasonally present between March and November (with the annual peak aggregation at Ningaloo Reef between April and May), as demonstrated by acoustic detections of tagged whale sharks at the North Rankin A and Goodwyn A platforms during two periods—June to July and October to January (Thomson et al. 2021). This overlap represents a very small proportion of the overall area of the BIA (0.22%), and the Trunkline Operational Area is located at least 215 km from the whale shark foraging (high density prey) BIA adjacent to Ningaloo Reef. Behavioural disturbance to whale sharks as a result of vessel or survey noise from IMMR activities along the export trunkline may result in a temporary deviation on their migration route, which covers a wide area and is not spatially restricted.

Commercial Fish Spawning

Key spawning periods for key indicator commercial fish on the NWS are described in Section 6.7.4. The potential impact of acoustic emissions on demersal and pelagic fishes is expected to be limited to a short-lived behavioural response confined to a few hundred metres from the Vessels. As such, the potential for the Petroleum Activities Program to impact spawning of key indicator commercial fish species is assessed as being extremely low.

Potential impacts from acoustic emissions on fish, sharks and rays are likely to be restricted to localised and temporary avoidance behaviour while transiting through the PAA, and individuals impacted are unlikely to represent a significant proportion of the population with the PAA and the NWS region overall. As such, the impact significance level for Fish, Sharks and Rays has been identified as Slight (E).

AMPs

The North-west Marine Parks Network Management Plan (DNP, 2018a) lists the natural values of the Montebello AMP as including a range of threatened, migratory, marine or cetacean species listed under the EPBC Act, as well as BIAs that include seasonal breeding habitat for seabirds, internesting habitat for marine turtles, a migratory pathway for humpback whales and foraging habitat for whale sharks. The Montebello AMP also includes foraging, mating, and nesting habitat for marine turtles.

For IMMR activities occurring along the export trunkline within the Montebello Marine Park the short-term and transient nature of activities associated with acoustic emissions will not be inconsistent with the objective of the Multiple Use Zone (VI) to provide for ecologically sustainable use and the conservation of ecosystems, habitats and native species, or for the Habitat Protection Zone (IV) to provide for the conservation of ecosystems, habitats and native species in as natural a state as possible, while allowing activities that do not harm or cause destruction to seafloor habitats. The values identified for the Montebello AMP, including BIAs, for marine turtles will not be impacted given the significant distance from sensitive locations. Additionally, the approved conservation advice for whale sharks (TSSC 2015) does not list acoustic emissions as a potential threat to whale sharks. Therefore, no impacts are expected to the cultural values of the AMP as those are intrinsically linked to the natural values described above. Impacts from acoustic emissions are therefore not inconsistent with the objectives of the North-west Marine Parks Network Management Plan or the zoning of the Montebello AMP (DNP, 2018a). As such, the impact significance level for Fish, Sharks and Rays has been identified as Slight (e).

Cumulative impacts

Cumulative impacts for activities within the scope of this Petroleum Activities Program have been assessed above.

As described in Section 6.2.1, there is potential for drilling operations related to the Scarborough Drilling and Completions EP to occur at the same time as routine FPU operations, within the Offshore Operational Area.

As described in Section 6.7.5, underwater noise from a MODU and any supporting vessels associated with the Scarborough D&C activities are expected to have an overall combined source level of 192 dB re μ Pa (rms SPL). When considered cumulatively with activities planned to occur as part of routine operations (e.g., FPU, support vessel and Gravimetry or IMMR vessel under DP), no cumulative noise scenario was assessed as having the potential to result in impacts greater than those described as part of the FPU Hook up and Commissioning Noise, assessed in Section 6.7.5. Refer to this assessment for worst-case credible cumulative noise impact from concurrent operations.

Any cumulative impacts will be limited to the temporary duration of the D&C activities.

Summary of Assessment Outcomes

<i>Receptor</i>	<i>Impact</i>	<i>Receptor Sensitivity Level</i>	<i>Magnitude</i>	<i>Impact Significance Level</i>
Ambient noise	Change in ambient noise	Low value (open water)	No lasting effect	Negligible (F)

Have a dedicated experienced and trained Marine Fauna Observer (MFO) onboard vessels to undertake marine fauna observations.	F: Yes CS: Cost of MFO hire and occupancy of bed-space on vessel(s) which may be limited or displace required crew.	Use of a dedicated MFO may detect fauna in the area, however, benefit of increased sightings is limited by follow-on controls to be carried out by vessel.	Limited benefit due to no adaptive management or sightings-based vessel action.	No
Professional Judgement – Eliminate				
Stop DP operations if a PBW is sighted.	F: This may be possible for vessels transiting between activity locations, but when undertaking activities, the generation of noise from these sources cannot be eliminated due to operating requirements. Note that vessels operating on DP may be a safety critical requirement. CS: Time/Cost associated with interrupting construction activities.	Ceasing vessel DP operations will reduce the potential for TTS effects to occur if a PBW stays within range of vessels for an extended period.	Grossly disproportionate. Implementation of the control requires considerable cost with minimal environmental benefit, given that PTS and TTS are not credible. Evidence suggests that the likelihood of encountering a migrating or foraging PBW within the Operational Area is considered low, and it is highly unlikely that PBW would spend sufficient time within range of vessel operations to encounter PTS or TTS.	No

Demonstration of ALARP				
Control Considered	Control Feasibility (F) and Cost/Sacrifice (CS)	Benefit in Impact/Risk Reduction	Proportionality	Control Adopted
			The cost/sacrifice outweigh the benefit gained.	
Professional Judgement – Substitute				
None identified				
Professional Judgement – Engineered Solution				
Reduce vessel speed in the Operational Area to reduce vessel noise propagation.	F: Yes. CS: Increased vessel transit times, potential schedule delays and impact to subsequent activities.	During operations, vessels undertaking IMMR or supply activities will already be subject to operational speed restrictions when within proximity of the FPU for safety reasons. Additionally, whilst vessels are operating in the trunkline operational area vessels will operate on DP or at low speeds for safety. During transit to and from the operational area, vessels will often transit by the shortest and most efficient direct route from which is outside of the operational area and is therefore outside the scope of this EP. There is no further risk reduction from the application of this control.	Given the slow speeds at which vessels operate, the likely presence of marine fauna in the Operational Area and the controls currently in place the adoption of this control offers no further reduction in risk.	No
Manage vessel speed in the humpback and PBW whale BIAs in migration seasons within the Trunkline Operational Area.	F: Yes. It is possible to carry out for vessels transiting within the Operational Area CS: will impact with longer transit times for vessels.	There is mounting evidence that reduction of vessel speeds can reduce vessel underwater noise emissions and increase the likelihood that fauna will be seen by vessels (and have more time to react) thereby reducing possibility of vessel strike. Where this control prevents impacts to humpback and pygmy blue whales at a population level, it maintains a culturally significant resource to a level that results in no observable change to coastal communities (migratory pathways maintained).	Benefits outweigh cost/sacrifice	C 4.8

ALARP Statement:

On the basis of the environmental impact assessment outcomes and use of the relevant tools appropriate to the decision type (i.e. Decision Type A, **Section 2.3.3**), Woodside considers the adopted controls appropriate to manage

the potential impacts from noise emissions. As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts are considered ALARP.				
Demonstration of Acceptability				
Acceptability Criteria and Assessment				
<p>Demonstration of acceptability for the sources of aspect and associated impacts assessed in this section are provided in Section 7.1.4.3 of the Scarborough OPP. The Petroleum Activities Program meets the acceptability criteria (Section 2.3.5):</p> <ul style="list-style-type: none"> • Overall impact significance levels for individual receptors are less than the significant impact level defined in the OPP. • EPOs in this EP are aligned with EPOs in the OPP (refer to Table 6 2) • Controls in the OPP that are relevant to this EP Section have been adopted. • Additional guidance on key terms within the CMP was issued in September 2021 and these were considered in the assessment against relevant actions in the CMP. The Petroleum Activities Program is not considered to be inconsistent with the relevant actions of this plan. • There are no additional changes to internal/external context specific to this risk from the OPP, including issues raised during consultation. 				
<p>Acceptability Statement:</p> <p>The impact assessment has determined that the generation of noise from Vessels and positioning equipment is unlikely to result in an impact significance level greater than slight. EPBC Act requirements (principles of ESD; MNES significant impact guidelines; recovery plans, conservation advice and marine park management plans) have been considered during the impact assessment. The Petroleum Activities Program is not considered to be inconsistent with any relevant EPBC Act requirements, including the objectives, overall recovery objectives and actions of relevant recovery plans, conservation advice and management plans (Section 6.9.3).</p> <p>The potential impacts are considered broadly acceptable if the adopted controls are implemented and EPO 10 has been applied to demonstrate the activities are not inconsistent with the Blue Whale Conservation Management Plan. Activities do not have a significant impact on MNES (Section 2.4.2). Therefore, Woodside considers the adopted controls appropriate to manage the impacts of acoustic emissions to a level that is broadly acceptable and demonstrate the EPOs are met.</p>

Description of Source																
<p>Climate change is caused by the net global concentration of greenhouse gases in the atmosphere. Greenhouse gas (GHG) refers to those gases within the atmosphere that absorb long-wave radiation, and thus trap heat reflected from the Earth's surface. The main gases responsible for this effect include carbon dioxide (CO₂), methane (CH₄) and nitrous oxide (N₂O). Other greenhouse gases include perfluorocarbons (PFCs), hydrofluorocarbons (HFCs) and sulphur hexafluoride (SF₆).</p> <p>Human-caused climate change is a consequence of more than a century of net GHG emissions from energy use, land use change, lifestyle patterns of consumption, and production (IPCC 2023). The IPCC has stated that observed increases in GHG concentrations since 1750 leading to climate change are unequivocally caused by human activities and that there's a near linear relationship between cumulative anthropogenic CO₂ emissions and the global warming they cause (IPCC 2023).</p> <p>In this Section greenhouse gas emissions are estimated using the <i>National Greenhouse and Energy Reporting (NGER) Measurement Determination 2008 (Cth)</i> (as amended including the 100-year Global Warming Potential). The following Section has been separated into Direct Emissions (Scope 1) and Indirect Emissions (Scope 3), aligned with the definitions of the GHG Protocol Corporate Standard (GHG Protocol 2015) and NGERs. The emission sources described in this Section are consistent with the sources described in the Scarborough OPP.</p>																

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

The main sources of GHG emissions associated with the PAP are shown in Table 6-17. GHG emissions sources that are not part of the PAP (e.g. GHG emissions from the onshore processing of Scarborough gas) are included for completeness. In the context of this EP, GHG emissions are classified as Direct and Indirect Emissions.

Table 6-17: Direct and indirect greenhouse gas emissions from the Scarborough facility floating production unit and supply chain

Emission type	Emissions source	Location	Jurisdiction	Process
Direct	Scarborough FPU operations	Offshore	Commonwealth	GHG emissions from fuel, flares and fugitives
Indirect	Support vessels and helicopters	Offshore	Commonwealth	GHG emissions from engines on vessels and helicopters under control of contractors
	Onshore processing*	Onshore	State	GHG emissions from venting reservoir CO ₂ , combustion of gas as fuel, flares and fugitives associated with processing gas to LNG and domestic gas
	Transport, regasification, distribution and combustion by third party users	Transit and Market	Subject to consumer location	GHG emissions from transport of products to market, including regasification and distribution of LNG, combustion of products as part of power generation and other energy solutions within the final market

*The GHG Protocol defines indirect GHG emissions as *emissions that are a consequence of the activities of the reporting entity but occur at sources owned or controlled by another entity*. For the purposes of this EP the “reporting entity” is the Scarborough facility and therefore, onshore processing and support vessel/helicopter operations are considered indirect emissions sources.

Direct GHG Emissions – Scarborough FPU

Fuel Use Emissions

On the Scarborough FPU, both fuel gas and diesel are used. Fuel gas consumption for export compression and power generation are the largest sources of combustion emissions from the FPU. Diesel is used for Main Power Generators when fuel gas is not available during commissioning, start-up and shutdowns, and for firewater pumps, emergency generators and other temporary equipment.

Diesel usage is expected to be highest during the period from FPU installation through to operations due to the availability and reliability of the fuel gas system being established during commissioning and start-up. Diesel usage during the first year of operations will also be higher than average due to the establishment of steady operations and increased facility testing. Consumption will remain relatively stable throughout operations after this period. Diesel consumption is estimated at 14,800 m³ total during installation through to operations, 1900 m³ during the first year of operations and 600 m³ per year thereafter. These figures were calculated based on predicted equipment usage and their associated diesel consumption rates.

The greenhouse gases CO₂, CH₄, N₂O, expressed as CO₂e, were estimated using the *National Greenhouse and Energy Reporting Measurement Determination 2008 (Cth)* (NGER Determination). These are derived from the National Greenhouse Accounts Factors.

Table 6-18: Estimated direct annual GHG emissions from fuel combustion during commissioning and start-up, and under steady state operations (excluding support vessels)

Component	Estimated annual emissions from fuel gas combustion during operations (tonnes) ¹	Estimated annual emissions from diesel combustion, during commissioning and start up (tonnes)	Estimated annual emissions from diesel combustion during operations (tonnes) ²
Fuel quantity (m ³)	272,145,000	14,800	600
CO ₂	549,738	39,932	1,619
CH ₄	1,070	57	2
N ₂ O	321	114	5

Total CO ₂ eq	551,129	40,104	1,626
--------------------------	---------	--------	-------

¹ Based on estimated annual operational emissions within this EP period. Variance within the period may occur.

² Based on the estimated annual diesel use within this EP period. Variance within the period may occur. Specifically, the first year of operations post-start-up is estimated to result in 1,900 m³ of fuel used due to increased facility testing.

Key Assumptions – Fuel Consumption

Fuel Gas

The FPU will utilise fuel gas to power the compressor turbines and power generator turbines during normal operations. Fuel Gas usage for compressor turbines is calculated based on the available compressor power, modelled in chemical process simulation software (HYSYS). In early field life this is based on operating three compressors. In mid field life the turbines may be upgraded for increased available output power, pending technical and financial evaluation of installing the new technology, which will result in higher fuel gas usage (and is factored into the emissions estimates). Timing of this potential upgrade is currently uncertain, due to unknown reservoir decline rates and other production variables. Based on the most current information available, this upgrade may take place around the year 2039. In later field life as the field declines further, operation with two compressors is possible resulting in a lower fuel gas usage assumed. The export gas compressor turbines (model PGT25+G4) have an ISO rated output power 34MW and the maximum turbine output power is approximately 30 MW, though actual output will vary based on reservoir pressure and onshore demand/availability. The potential future turbine upgrade would be to PGT25+G5 (ISO rated output power 38MW), with turbine output power limited to 34MW to remain within the original package design limits.

Fuel Gas usage for power generator turbines has been estimated assuming two 4.6 MW turbines. Individual fuel rate has been assumed from measured data from the factory testing.

Diesel

Diesel is planned to be used intermittently on the FPU during normal operations for the main power generators, emergency generator, black start generator, firewater pump generators, fast rescue craft and temporary equipment. During commissioning and start-up, diesel will be required to run generators prior to the fuel gas system being made available. As such, diesel use has been calculated based on the following:

- Equipment fuel use rates:
 - Main Power Generators – 8 m3/hr
 - Black Start Generator – 0.55 m3/hr
 - Emergency Power Gen – 0.55 m3/hr
 - Firewater Pump – 0.55 m3/hr.
- For commissioning and start-up: estimates for duration of days of Commissioning from Takeover to RFSU has been assumed as 6 months using 1 generator, and Days of Commissioning from RFSU to Fuel Gas Introduction has been assumed as 2 months using 2 generators.
- For normal operations:
 - 10% yearly shutdown requiring Main Power Gen (year 1 only).
 - 3.41% yearly shutdown requiring Main Power Gen (year 2 onwards)
 - 18 hours usage per year for Black Start Generator and Emergency Power Gen
 - 8 hours per year usage for Firewater Pumps
 - 2 full tanks per year for the Fast Rescue Craft.

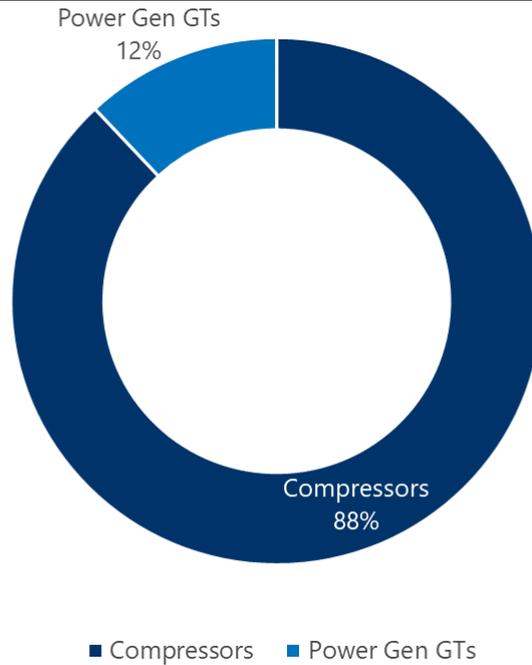

Figure 6-1: Fuel gas greenhouse gas emissions by source during normal operations

Flaring

The release of hydrocarbon gas to atmosphere by flaring is an essential practice to meet safety requirements. The FPU has been designed to have no continuous operational flaring, consistent with Woodside’s implementation of the World Bank Zero Routine Flaring Initiative. In line with Woodside’s implementation of the World Bank Zero Routine Flaring Initiative (ZRFI), definitions for sources exempt from “routine flaring” are as follows:

- non-routine flaring is considered flaring for intermittent and short duration non-routine activities (e.g. start-up) and rectification of unplanned issues (e.g. equipment failure).
- safety flaring is gas flared to ensure the safe operation of the facility, including flaring for immediate and short term purposes to make the facility safe (e.g. blowdown/PSV), as well as minimum flare purge and pilot gas.
- small source flaring is flaring from an individual source that contributes less than 1kt per annum.
- poor quality source flaring is flaring from an individual source that has a high degree of non-hydrocarbon contamination, and therefore cannot be recovered back into the process.

When flaring is required, hydrocarbon gas is flared via the HP and LP flare systems (**Section 3.9.8**). Gas flaring emits GHG to atmosphere and consumes natural gas, a non-renewable resource. Emissions and combustion products include water vapour, CO₂, NO_x, methane, particulates, and VOCs. Incomplete combustion under certain scenarios may also generate dark smoke.

Flaring is expected to occur during start-up, maintenance, process upsets and emergencies, when it is required to protect the integrity of the facility and to prevent harm to personnel, environment and equipment. These are considered non-routine activities, and include:

- pressure relief and emergency blowdown, including planned and unplanned shutdowns – to protect the integrity of the facility and prevent loss of containment
- manual blowdown – to safely depressurise equipment before maintenance activities
- process upset – i.e. an unplanned event, such as gas exceeding the necessary dewpoint specification for export, requiring it to be flared to protect the integrity of the SCAETL
- pigging – to inspect the flowlines/trunkline
- process start-up – to get gas to the correct specifications for processing. Refer to Section 3.7.3 for further detail.

Non-routine flaring events are minimised through facility design (with equipment sparing/redundancy to maintain production during unplanned outages), operating procedures developed to minimise flaring upon facility restart, equipment maintenance for reliability, and adaptive processes to addresses cases of non-routine flaring found to emerge during operations (GHG Emissions and Energy Management Procedure (Section 7.2.4.1) and the Production Optimisation and Opportunity Management Procedure (POOMP) (Section 7.2.4.2). Flaring during the initial start-up phase is describes below.

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

The start-up program will continually aim to minimise flaring where practicable. During the initial start-up phase, flaring is required until operation of several systems has been fully established. Flaring is planned during activities such as well clean up and multi-rate testing, when wells are flowing but the gas is not yet fully utilised as fuel gas or exported to the trunkline. Once the first compressor has been started-up flaring will be largely reduced, as gas will be directed to the trunkline instead of partially to the flare. Flare pilots will remain on propane until the fuel gas system is commissioned and a stable fuel gas supply has been established. Likewise, topsides systems will be run off diesel until a stable fuel gas supply has been established.

In operations, some smaller volume, low-pressure sources of hydrocarbons are continuously routed to the flare. These sources are not practicable to capture and route back into the process, due to low pressure, low quality or negligible volume, and flaring provides a better alternative than venting. This approach is consistent with the World Bank Zero Routine Flaring Initiative for oil projects, which states that “some flare gas sources... are so small and at such low pressure that it is environmentally more beneficial to utilize resources to reduce other flaring sources and other types of emission.” Such sources of flaring (<1ktpa) on the FPU include instrument tubing, level gauges, sample points, LP MEG flash vessel, closed drains waste drum, riser annulus vent, export gas compressor seal gas primary vent.

The annual atmospheric emissions from flaring were estimated using the NPI EET and GHG estimates using NGER Determination and summarised in Table 6-19.

Table 6-19: Estimated emissions from flaring at the facility

Component	Estimated annual routine flaring emissions during normal operations (tonnes)	Estimated annual non-routine flaring emissions during normal operations (tonnes) ¹	Estimated flaring emissions from Scarborough commissioning and initial start up (tonnes)
Flared gas quantity	1,100	4,400	83,600
CO ₂	2,970	11,880	225,720
CH ₄	146	585	11,119
N ₂ O	29	114	2,174
Total CO _{2eq}	3,145	12,580	239,012

¹ Based on estimated annual operational emissions within this EP period. Variance within the period may occur. Specifically, the first year of operations post-start-up is estimated to result in ~8,600t of non-routine flared gas due to increased facility testing.

Emissions as a result of flaring have been calculated from the inputs of:

- pilot and purge gas
- facility trips and restarts
- smaller volume, low-pressure sources of hydrocarbons routine flaring
- facility commissioning and start up, including well clean up

Non-routine Venting of Process Hydrocarbons via Flare System

In the unlikely event the flares are extinguished (for example during a tropical cyclone) or unavailable (such as after a major shutdown prior to system start-up), the hydrocarbon gas discharged via the flare system may initially not be combusted during the period required to purge the flare and re-establish flare ignition. This may result in the short term (hours) low-rate release of methane to atmosphere, at a rate of approximately 125 kg/h (rate of routine flaring). The measures described below have been implemented to reduce the risk of such an occurrence to ALARP.

Flare gas ignition is maintained by continuously burning pilot flames. Three pilots are provided for HP flare tip and two pilots are provided for LP flare tip. Fuel gas is used for pilot burning gas with permanent backup of propane. The propane skid is suitable for cylinders required for 12 hours of HP and LP flare pilot burning. The pilot ignition is with high energy spark ignition (primary) with back-up (secondary) of Flame Front Generator. Both the ignition systems can be used automatically and remotely, and minimise the risk of venting uncombusted hydrocarbons.

Monitoring of the flare pilot flames to assure effective operation will be achieved using dual thermocouples monitoring temperature on the individual pilot heads (Primary). Secondary monitoring will be available with a dedicated thermal (spectral analysis) camera system that will allow control room operators to confirm the status of the pilot flames and alert them if a pilot flameout occurs. This redundancy built into the flare ignition and monitoring systems minimises time spent cold venting, should a flame-out occur.

Before the ignition of the flare, the LP and HP flare headers will be purged to ensure no oxygen is present in the system. This purging operation will be carried out with a nitrogen and fuel gas mix for HP flare and with the fuel gas or nitrogen (as a back-up) for LP flare during the start-up.

Intermittent venting from the facility is expected to represent a minor source of atmospheric emissions and is not considered to pose a risk beyond the routine air emissions described in this Section.

Non-routine Venting from Scarborough Trunkline via Flare System

During the initial start-up of the Scarborough system, following connection of the Scarborough Trunkline to Onshore, the trunkline will contain nitrogen (~95% nitrogen and ~5% oxygen) at atmospheric pressure. The introduction of hydrocarbons into the trunkline from onshore will push the nitrogen offshore where it may be directed to the FPU HP flare. This would occur post-RFSU and the HP flare pilots will be ignited during the venting of the nitrogen. Once the nitrogen is removed, hydrocarbons will arrive at the flare tip with the visible change in flare indicating that the nitrogen has been removed and flaring can be stopped. The total mass of nitrogen in the trunkline to be vented/flared at the FPU is estimated to be around 270 tonnes.

Fugitive Emissions

Fugitive emissions can occur from pressurised equipment, and are inherent in design, emitted by infrequent operational activities, or can be caused by unintentional equipment leaks. Sources can include valves, flanges, pump seals, relief valves, vents, sampling connections, process drains, open-ended lines, casing, tanks and other potential leak sources from pressurised equipment. Fugitive emissions are, by their nature, difficult to quantify and are estimated by application of methods from the NGER Determination.

As much of the safe operation of the facility relies on the effective containment of hydrocarbons, the volume of routine and non-routine fugitive emissions negligible in comparison to GHG emissions from other sources (refer to Section 6.8.4 for potential atmospheric unplanned hydrocarbon releases associated with accidents, incidents and emergency situations).

According to the National Greenhouse and Energy Reporting (Measurement) Determination 2008 (Cth), estimates of fugitive emissions from deep water offshore platforms (e.g. Scarborough FPU) are:

Table 6-20: Fugitive emissions

Component	Estimated annual fugitive emissions (tonnes) ¹
CO ₂	2
CH ₄	21,105
N ₂ O	0
Total CO ₂ eq	21,107

¹ Variance within the period for this EP may occur.

Fugitive emissions are calculated using NGER Determination factors:

- For offshore platforms (Subdivision 3.3.6B.1): [Number of platforms x factor] * [share of gas type (by volume)/default share of gas type] for CO₂ and CH₄. This component makes up 21,038 tCO₂-e per year.
- For Produced formation water component (Subdivision 3.73NB): used an assumed factor of 2 tCO₂-e/m³, and a Produced Water discharge rate of 4.08 m³/h. 2 tCO₂-e/m³. This component makes up 69 tCO₂-e per year.

The NGER framework provides a consistent and accurate methodology to estimate annualised methane emissions. It permits a variety of methods to report methane emissions with varying uncertainty and complexity. Method 1 factors are based on industry averages linked to facility type which is how Woodside reports fugitive emissions compliantly within the framework.

Discrete relatively small volumes of packed gases and charged systems, including non-ozone depleting refrigerant gases, are used across the facility and vessels which have potential for small volume leaks (typically less than 100 kg per isolatable inventory). Such gases are used in the HVAC and refrigerant systems on the facility and vessels.

The facility is fitted with portable and wheeled fire extinguishing units utilising CO₂. Fire suppression systems utilise water mist or NOVEC1230. NOVEC 1230 has zero ozone depleting potential and a low global warming potential; it is used to protect the electrical rooms and requires manual activation for release.

There are no sources of continues process (hydrocarbon) venting on the facility. Some venting may occur in order to depressurise systems for safety purposes, e.g. fuel gas pockets in equipment piping vented on shutdown. These sources are unable to be routed to the flare, due to technical constraints associated with flare back pressure. The total volume of vented hydrocarbon gas is considered to be negligible.

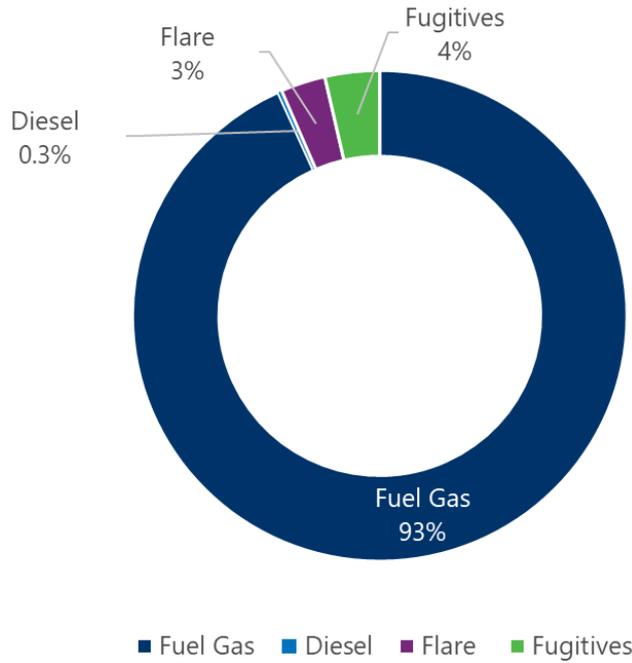

Figure 6-2: Direct greenhouse gas emissions by source during normal operations

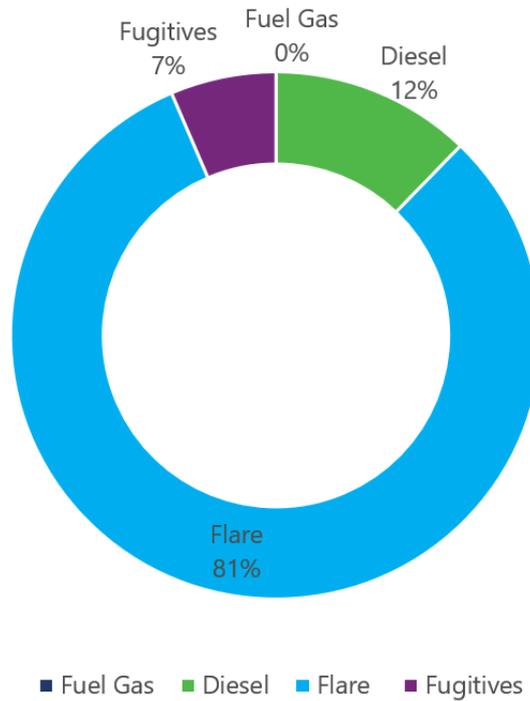

Figure 6-3: Direct greenhouse gas emissions by source during hook-up and commissioning

Indirect Emissions

Indirect emissions associated with the PAP result from offshore vessel and helicopter use, hydrocarbon processing (onshore), third party transport of products, regasification, distribution and combustion by end users.

Vessels and Helicopters during HUC and Start-up

A number of vessels and vessel types will perform activities in the PAA during the Installation, Hook-up, Commissioning and Start-up phase of the Petroleum Activities Program. Vessels are described in Section 3.11 and activity durations in Section 3.4.

Vessels are powered via the use of on-board generators (diesel-powered and/or LNG). Vessel operations require the use of marine diesel to undertake daily activities functions such as dynamic positioning, crane movements, desalination, sewage treatment, etc. Atmospheric emissions will be generated by the vessels from internal combustion engines (including all equipment and generators) and incineration activities (including onboard incinerators).

GHG will be emitted from vessels involved in the activity consuming marine diesel fuel, and by helicopters transferring personnel. Using vessel fuel consumption rates estimated by contractors, internal helicopter fuel consumption data and emission factors from the National Greenhouse and Energy Reporting Scheme, GHG emissions have been estimated and are presented in Table 6-22.

These figures are estimates only. The actual consumption of fuel varies based on factors such as the nature of activity being undertaken by vessels, metocean conditions etc. While Woodside may influence via contracting approaches, in-field day to day operations including fuel consumption is under the control of vessel masters.

Support Vessels and Helicopters during Operations

GHG emissions will be generated by vessels supporting the FPU during steady state operations, undertaking gravimetry, performing IMMR activities and by helicopters being used for crew and other transport needs. Vessel emissions include those from internal combustion engines and fugitives. Atmospheric and GHG emissions from support vessels vary depending on the nature of activities being undertaken; for example, travelling or “steaming” to a destination at low speed uses less fuel and generates lower atmospheric and GHG emissions than high speed steaming. Emissions generated during safety related vessel standby activities, holding station using DP during loading and unloading of materials to the facility or undertaking IMMR work also vary. Vessel Masters control day to day operations that determine Support Vessel emissions. Woodside has the potential to influence fleet level approach to Support Vessel emissions through contracting activities. Refrigerant gases are used onboard supply vessels in small quantities.

Expected annual GHG emissions for vessel and helicopter activities during steady state operations have been estimated and are presented in Table 6-22.

Indirect emissions from these sources are expected to be relatively constant throughout the EP period and until EOFL.

Onshore Processing

Onshore processing GHG emissions will principally be generated by:

- processing: fuel combustion, flaring and fugitives
- venting of reservoir CO₂.

GHG emissions associated with processing of gas at onshore facilities will be subject to regulation under State and Commonwealth legislation. GHG emissions associated with onshore processing of Scarborough gas (fuel, flare and fugitive emissions) have been estimated by using emission factors appropriate to the likely processing facility, Pluto LNG. A smaller volume of Scarborough gas may also be processed at Karratha Gas Plant.

The Emission Factor used to estimate onshore processing GHG emissions is 0.33 tCO₂-e/tLNG. This factor includes reservoir CO₂ emissions. Reference for this factor can be found in the publicly available *Pluto Greenhouse Gas Abatement Program Rev 3a* (Woodside 2021), approved by the Western Australian Minister for Environment in August 2021. It also aligns with the LNG processing intensity of Karratha Gas Plant as defined in the publicly available *NWS Project Extension Greenhouse Gas Management Plan Rev 1* (Woodside 2019a), which excludes emissions of reservoir CO₂. To account for the different approach taken regarding reservoir emissions between these factors, the Scarborough reservoir emissions have been calculated based on reservoir composition and separately added to the gross emissions estimate associated with onshore processing, which is a conservative approach.

It is acknowledged that factors used to estimate emissions intensity in the Pluto GGAP and NWS Project Extension GHGMP are subject to change, for example via updates to the NGER Determination. Assumptions for onshore processing emissions will be verified when production commences, and the EP change management process (section 7.2.7) applied.

An assessment of the total quantity of reservoir CO₂ likely to be emitted over the life of the activities has been completed, based on the expected CO₂ composition of the Scarborough reservoir and assuming that all reservoir CO₂ must be removed prior to liquefaction of the gas at the relevant onshore facility.

CO₂ content in the hydrocarbon reservoir is a naturally occurring geological phenomenon that is typically treated as a waste product during LNG liquefaction.

A number of contemporary large operating and proposed developments off the west coast of Australia have levels of CO₂ in the reservoir which are comparatively higher (at an average of 10–20 mol%) compared to Scarborough. Examples of approximate reservoir CO₂ concentrations for recent developments are given below:

- Barossa Development (under construction): 16–20 mol%
- Gorgon LNG Development (operating): <1-14 mol%
- Ichthys Project (operating): 8-17 mol%
- Prelude FLNG (operating): 9 mol%
- Pluto Project (operating): 2 mol%.
- Scarborough, Thebe and Jupiter: 0.1 mol%.

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

The negligible expected CO₂ concentration in greater Scarborough reservoirs (Scarborough, North Scarborough, Thebe and Jupiter gas fields) means that the emissions associated with venting of reservoir CO₂ will be small in comparison with these other projects and not considered to be a major source of GHG emissions for Scarborough. The expected annual emissions from reservoir CO₂ venting during onshore processing is 0.1 MtCO_{2e} per annum throughout the EP period. Variance within the period may occur.

Emissions from the combustion of fuel and flaring as part of onshore processing have been estimated based on apportioning GHG emissions associated with the processing of Scarborough feed gas. For Pluto LNG, emissions were initially described in the Pluto LNG Development Public Environment Review (Pluto PER). The Pluto LNG Facility was approved under Ministerial Statement 757 and Commonwealth Approval Decision EPBC 2006/2968. The Pluto PER is available for review on the WA EPA website⁵⁰.

The total GHG emissions described in the PER were 4.1 MtCO_{2e}/yr. The Pluto LNG Facility currently emits approximately 2 MtCO_{2e}/yr (Woodside 2021). The proportion of gas from the Scarborough reservoirs and Pluto, Xena or other reservoirs processed at the Pluto LNG Facility will vary over time, but are subject to relevant approvals and regulatory frameworks. Similarly, any potential volumes of Scarborough gas processed at the Karratha Gas Plant will be subject to the limits set by the relevant approvals for the Karratha Gas Plant.

An annual production of 8.55 t LNG and 1.35 t Domgas is assumed as input for both Onshore hydrocarbon processing and third-party transport of products, regasification, distribution and end use GHG emissions estimates. These figures are estimates only and reflect expected maximum production rates. Variance within the period may occur.

Third Party Consumption

Indirect GHG emissions associated with the PAP have been estimated in Table 6-22. Key influences impacting indirect GHG emissions from Scarborough include:

- Total production – indirect GHG emissions are proportional to total production, which varies with shutdown activity, well performance and reservoir performance.
- Split of saleable products from Pluto LNG– the proportion of hydrocarbons from Scarborough sold as LNG and domestic gas varies. Each product requires differing amounts of energy to process to the point of sale and varies based on reservoir composition, field contribution and commercial reasons.
- Efficiency of end user – sold product may be used in a variety of ways by the customer, with the energy efficiency of their transport and processing contributing to the GHG emissions released.

For the consumption of LNG anticipated to be produced from Scarborough, which is expected to predominately occur internationally, an emissions factor has been sourced from the Ecoinvent v3.5 database (Table 6-21). This emissions factor considers the transport, regasification, distribution and final combustion of LNG. The factor used in the Pluto PER is also presented for comparison. The difference between these factors is primarily due to the PER factor not considering emissions associated with regasification and distribution.

For the consumption of domestic gas anticipated to be produced from Scarborough, an emissions factor has been developed based on NGRS. This emissions factor considers the distribution in a pipeline system in Western Australia and final combustion of natural gas. Emissions related to other potential uses, e.g. chemical feedstock, have been estimated based on Perdaman Environment Management Plan Greenhouse Gas Emissions (2021), and are lower than the estimates presented here. Therefore, they are not discussed further.

For each source, the estimate of CO₂-e emissions is based on the quantity of product, multiplied by the respective emissions factor. The same annual production rate is assumed for estimating emissions associated with third party consumption as for onshore processing

Table 6-21: Emissions factors for Scarborough gas customer use and transport emissions

Source	Units	Value	Reference
Third Party – LNG (1a)	kgCO ₂ -e/kg product	2.78	Pluto PER Factor includes transport and combustion. – Reference only, not used in final GHG emissions estimates.
Third Party – LNG (1b)	kgCO ₂ -e/kg product	3.32	Ecoinvent 3.5⁵¹ Factor includes transport, regasification, distribution and combustion. Factor has been updated from 3.13 kgCO ₂ -e/kg product in the OPP to account for updated assumptions used in emissions estimates. Refer to Appendix J Concordance Table for further detail.

⁵⁰ http://www.epa.wa.gov.au/sites/default/files/PER_documentation/1632-PER-PLUTO%20LNG%20PER.pdf

⁵¹ EcoInvent v3.5 represents a large collection of inventory data. It has been recognised as emission factor source for the European Union Renewable Energy Directive greenhouse gas methodology and is aligned to the principles of the NGRs methodology.

Third Party – Domgas	kgCO ₂ -e/GJ	58.06	NGER Determination Factor includes distribution and combustion. This factor is equivalent to the factor included in OPP 2.99 kgCO ₂ /kg product, expressed in different units.

Summary of GHG Emissions

For the first five years of operations, direct GHG emissions from the FPU are estimated to follow the profile shown in Figure 6-4.

Direct GHG Emissions by source

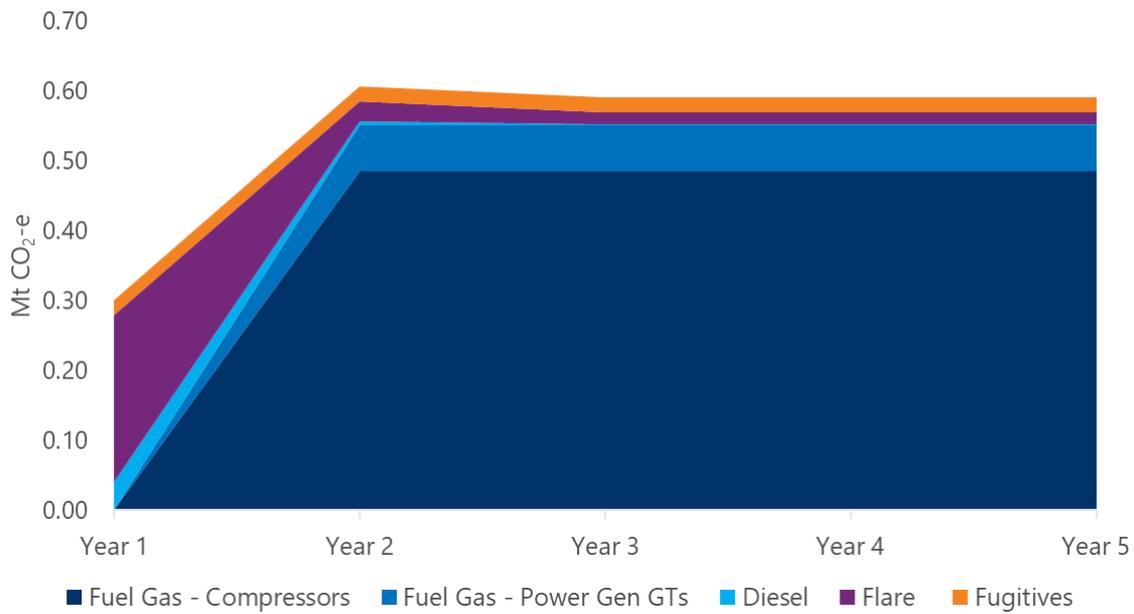

Figure 6-4: Direct greenhouse gas emissions by source during the period of this Environmental Plan

The split of indirect GHG Emissions is shown in Figure 6-5. *Third-Party Transport, Regasification, Distribution and End Use* of both LNG and Domgas is the major contributor. Note: Emissions from vessel & helicopters, including the ASV, are negligible in comparison to other sources (<1%).

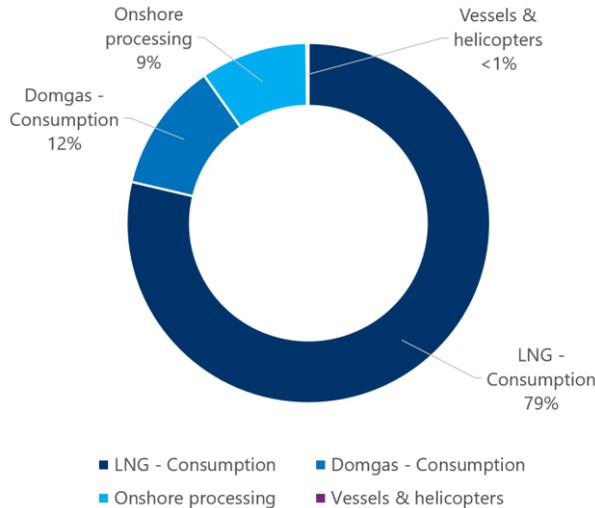

Figure 6-5: Indirect greenhouse gas emissions by source over the life of this Environment Plan

Based on the estimates provided above, the total GHG emissions for the EP period are provided in **Table 6-21**. The Annual estimated emissions column represents the year with highest GHG emissions in the duration of this EP (5 years). All estimates are sensitive to production rate, which is subject to uncertainty associated with reservoir and process performance and will change over the life of the facility. Relatively high initial “plateau” production rates are expected to extend beyond the duration of this EP, however will eventually decrease as reservoir/s are depleted, and emissions associated with onshore processing and third party consumption which are highly sensitive to produced volumes are expected to decline accordingly over field life. Estimates over Development Life are inclusive of potential future fields which may be tied back to the Scarborough offshore infrastructure, subject to future approvals.

Differences between the estimates presented in Table 6-22 and the Scarborough Offshore Project Proposal are explored in Appendix J, Concordance Table.

Table 6-22: Indirect and direct greenhouse gas emissions associated with Scarborough production

Source	Annual estimated emissions (MtCO ₂ e)	Total 5 years of EP (MtCO ₂ -e)	Development life (MtCO ₂ -e)
Direct Emissions			
Offshore processing (fuel, flaring and fugitives)	0.61	3	12
Net direct emissions	0.1	0.5	2.6
Indirect Emissions			
Project vessels and helicopters during Installation, Hook-up and Commissioning	0.04	0.04	0.04
Vessels and helicopters during Operations	0.005	0.02	0.14
Onshore hydrocarbon processing	2.90	14.5	88
Third party transport of products, regasification, distribution and end use	32	162	778
Totals	36	179	878

Emissions estimates will be tracked/reviewed monthly to monitor progress against energy use and flare targets and prepare for annual NGERs reporting. Any material deviations will be managed under the MOC process as required (Section 7.2.7). Material deviations from the emissions estimates presented in the EP would be any deviation that is beyond the basis of the risk assessment. Material deviations may be caused by, for example, significant inefficient fuel consumption or equipment failure causing unplanned flaring. Such deviations are managed through technical MOC and POOMP processes, which includes analysis of environmental impact and consideration by the environment team of whether it puts at risk exceedance of emissions targets and basis of the EP risk assessment.

GHG emissions associated with onshore hydrocarbon processing are regulated under both Commonwealth and State legislation. The National Greenhouse and Energy Reporting (Safeguard Mechanism) Rule 2015 is the primary mechanism for the management of GHG emissions from facilities with direct emissions over 100,000 tonnes CO₂e,

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

including the Pluto LNG Facility (Pluto) and North West Shelf Karratha Gas Plant (KGP). The Safeguard Mechanism imposes a declining baseline (limit) on these facilities, consistent with achieving Australia's emission reduction targets of 43% below 2005 levels by 2030 and net zero by 2050.

The Western Australian Environmental Protection Authority (EPA) also assesses GHG emissions under the Environmental Protection Act 1986, with GHG conditions for Pluto and KGP outlined in Ministerial Statements 1208 and 1233 respectively.

GHG emissions data made publicly available, for example from regulatory reporting requirements outlined above, will be used to verify the onshore hydrocarbon processing emission estimates for Scarborough gas.

Net direct emissions are provided above based on the current requirements of the Federal Safeguard Mechanism. These are described in the Management and Abatement section below.

Management and Abatement

Management and Abatement for Scarborough (Direct) GHG Emissions

In accordance with Woodside's decarbonisation strategy as relevant to Scope 1 GHG emissions, a scope of work has been ongoing through multiple project phases to design and operate out direct GHG emissions. This commenced in the Concept Definition phase with application of Woodside engineering standards and drafting of the project Basis of Design and setting expectations for EPC contractors. These considerations included:

- specifying no normal or routine operational flaring
- specifying waste heat recovery
- requiring rotating equipment (eg turbines) and auxiliaries to be selected and designed to be efficient and minimise emissions
- requiring the principal design contractor to undertake studies focused on energy efficiency and emissions minimisation.

As design work on the facility was ongoing, Woodside held a multi-disciplinary Energy Efficiency Workshop in Q1 2019, in early FEED phase. This workshop was facilitated by a specialist third party consultant with access to early design documents and information. Through a process of considering expected energy use and GHG emissions generation on a system-by-system level, a total of 37 emissions abatement/energy efficiency opportunities were identified.

These identified opportunities formed the basis of the Scarborough Carbon Opportunity Register, which has been added to through multiple other opportunity identification workshops and processes. The most recent workshop was held in Q3 2023 and focused specifically on the start-up and operate phase, and identified 10 new opportunities for the team to consider and screen. This register remains a live document for the project design, execute and start-up phases. Opportunities identified for future implementation will be carried into the facility Decarbonisation Plan, and ongoing opportunity identification will occur via the POOMP. In total 79 opportunities to reduce direct GHG emissions or reduce direct emissions intensity have been identified and screened to date, 30 are implemented via design and/or operational planning, and 20 remain under investigation. An estimated 13% reduction of emissions compared to reference case design has been achieved through design phase, and Woodside aims to continue reducing operate phase emissions by minor design changes and embedding GHG emissions reductions through operations readiness and planning.

The most significant opportunities which have been implemented are described below.

Avoid

Complete avoidance of GHG emissions from gas from the Scarborough project is not considered practicable. As described above, direct GHG emissions will result from various sources during the PAA. As a readily accessible energy source at the offshore processing location, gas will be used to power the facility in the form of fuel gas and will be flared when required (non-routine) to maintain safe operations. The measures to reduce direct GHG emissions from the PAP are described below.

Reduce

Design and Operations Planning Phase

Following an extensive opportunity identification and screening process as described above, a number of energy efficiency and GHG abatement measures have been incorporated in project design. Examples of these measures, categorised by emissions source is provided in Table 6-23. Estimates are based on engineering calculations and provided as indicative values only. Not all measures listed have benefit calculated, and in most cases, verification of the actual abatement benefit of opportunities is not possible:

Table 6-23: Emissions reduction measures incorporated into FPU and Scarborough Project design.

Source:	Measures:
Fuel Gas	Waste heat recovery, which draws heat for process requirements from turbine exhaust in heat exchangers rather than gas fired heating in boilers. This is expected to reduce fuel gas use on the facility and reduce total direct GHG emissions by approximately 5%.

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

	<p>An internally flow coated trunkline to reduce pressure loss associated with transporting gas to shore through the Scarborough Trunkline. This reduces requirements for gas compression on the facility and could reduce total direct GHG emissions by approximately 3%.</p> <p>Since the majority of direct GHG emissions are a result of fuel gas combustion, ongoing process optimisation from base case throughout the detailed design phase of the project has resulted in material GHG emissions abatement. Examples achieving a combined estimated reduction of 2% include:</p> <ul style="list-style-type: none"> • compressor efficiency optimisation to improve design efficiency in context of updated early/mid field life arrival conditions. This aligns with the engineering design requirement to consider thermal efficiency of turbines. • removal of continuous bypass around gas/gas exchanger, increasing efficiency of gas pre-cooling. • gas/gas exchanger <p>Inclusion of a battery energy storage system, which removes the requirement to run an additional power generation turbine (powered by fuel gas) in “spinning reserve” while not powering anything, in case one of the duty generators trips. As such, there will be two operational turbines and one offline (cold standby). Operating the BESS could reduce total direct GHG emissions by approximately 2%. The BESS is sized for 4.6 MW for 2 minutes and 2.8MW for 30 minutes.</p> <p>Reliability/availability of the BESS has been factored into the reliability, availability, maintainability (RAM) for the facility, which constitutes part of the emissions estimates. Specifically, the BESS works in unison with the black start generator and the GTG, so the RAM model assesses the intersection of critical events to register an RAU (reliability, availability, utilisation) impact.</p> <p>The BESS is designed for high reliability with parallel inverters and batteries to provide redundancy. This means that even if one set of inverter/battery groups and associated controls are out of service, the BESS will still meet its power requirements. Common components such as the transformer and master Programmable Logic Controller (PLC) are considered high reliability and are not expected to significantly impact BESS reliability or availability. The parallel design also allows most maintenance to be performed without taking the BESS offline. It can be expected that the BESS will always be available in the event of a GTG trip.</p> <p>Precooling of incoming gas stream using a gas-gas heat exchanger with export gas to increase liquid removal efficiency.</p> <p>Selection of aeroderivative gas turbines, which are more efficient than industrial type equivalents. This aligns with the engineering design requirement to consider thermal efficiency of turbines. The export gas compressor (model BCL455/B) has a measured polytropic efficiency of 83.4% at the guaranteed condition. The export gas compressor turbines (model PT25+G4) are a high efficiency aero-derivative gas turbine with a thermal efficiency of about 41.3%. The main power generation turbines (model Taurus 60) are a light industrial gas turbine with a thermal efficiency of about 31.6%.</p> <p>Enabling common export gas compressor mode operation, allowing number of compressors in operation to be optimised where arrival conditions and export requirements are conducive, such as late field life.</p> <p>Use of electric cranes rather than diesel, approximately 50% more efficient.</p>
Flaring	<p>Implementation of the World Bank Zero Routine Flaring initiative in design. The facility design has been verified to have no continuous operational flaring (exemptions listed above).</p> <p>Maximising use of nitrogen in flare purge rather than fuel gas, reducing amount of hydrocarbon gas sent to flare. Flare purge is required to keep a positive pressure in the flare system, avoiding oxygen ingress which could potentially cause a flammable atmosphere inside the flare system.</p> <p>Blanketing MEG tank with nitrogen instead of fuel gas, which would then need to be sent to flare or vented.</p>
Fugitives	<p>Selection of minimally attended concept which reduces living quarters requirements and drives process simplification.</p> <p>Adoption of the Methane Guiding Principles Best Practice Guide – Engineering Design and Construction. An internal review of design against this standard was undertaken, and initiatives such as increasing valve tightness and reducing number of connections were supported by Woodside’s alignment with MGP.</p>
Venting	<p>Directing riser annulus gas to flare rather than venting direct to atmosphere, reducing methane emissions. This is a very low rate of gas which passes through the flexible riser carcass into the surrounding annulus space.</p>

Initial Start-Up Phase

During the initial start-up phase, flaring is required until operation of several systems has been fully established. Flaring is planned during activities such as well clean up and performance testing, when wells are flowing but the gas is not yet fully utilised as fuel gas or exported to the trunkline. Once the first compressor has been started-up flaring will be largely reduced, as gas will be directed to the trunkline instead of partially to the flare. Flare pilots will be fuelled by propane until the fuel gas system is commissioned and a stable fuel gas supply has been established. Likewise, topsides systems will be run off diesel until a stable fuel gas supply has been established.

In planning for start-up of the Scarborough facility, a Start-Up Strategy has been developed to consider schedule, risks, opportunities and environmental parameters, including the minimisation of flaring and fuel use. Multiple opportunities have been implemented to achieve this, including:

- Prioritisation of fuel gas system start-up to reduce facility diesel use
- Alignment of activity sequencing (**Section 3.8**) to maximise utilisation of gas for equipment start-up and trunkline pressurisation, instead of directing to flare
- Pressurising the trunkline to the minimum pressure required for compressor start-up, in order to expedite the process the redirection of gas from flare to the trunkline via the compressor
- Well clean up via the FPU, rather than via the MODU, which reduces the volume of gas required to be flared and the emissions associated with MODU presence in-field
- Sparing of major equipment in facility design, to allow switching if issues are encountered (e.g. the common suction and discharge headers of the EGCs allow switching between the 3 units, should significant issues/delays occur during the first EGC commissioning)
- Alignment of FPU initial startup activities with onshore readiness to receive gas

Additional fuel and flare minimisation opportunities will continue to be considered as part of start-up planning and will be implemented if feasible from environmental, safety and technical perspectives. These are documented and tracked in the Carbon Opportunity Register.

If target exceedances are foreseen based on daily tracking or variations to the proposed start-up process, measures will be implemented to manage the risk of exceedance via the fuel and flare target setting procedure (detailed in Section 7.2.4.4).

Notably, the onshore plant is expected to be ready to receive the FPU export gas upon start-up. However, if this is not the case, the CSU of the FPU will continue until the trunkline is filled to its maximum capacity. At that point, a decision will be made on turning wells down or off, depending on the expected time to achieve onshore readiness, with considerations and process as per Section 7.2.4.4.

If any of the receiving onshore users reduces gas intake (e.g. due to a train trip), gas export from the FPU can continue for a number of hours (i.e. 4-5 hours at full export rate, or longer with a reduced export rate), increasing the pressure in the trunkline, before action at the FPU is required (e.g. well turn down or flaring). With the trunkline providing this large buffer volume, any offshore flaring is not expected for the majority of onshore trip scenarios, as this provides time to shut down the FPU without the need to flare from the FPU.

If extension of the initial start-up phase beyond indicated timelines (Table 3-3) is foreseen, the EP Management of Change Process will be enacted (Section 7.2.7), including consideration of additional control measures to limit flaring to ALARP and prevent further unplanned flaring (as per Figure 7-4). Commissioning and initial start-up phase controls (including fuel and flare target setting) will continue to apply until facility final acceptance, after which they will be replaced by operational phase controls. Fuel and flare targets are aligned with the estimates set out in this EP, hence deemed to be ALARP and acceptable.

Upset cases have been considered in the estimates of flared emissions during initial start-up, and will be subject to the flare target process.

No additional allowance is provided in Federal Safeguarding Mechanism (SGM) Baseline for the emissions associated with initial start-up of the facility. This means that emissions associated with this phase will be aligned with “international best practice” for operation of the facility. The SGM and Scarborough’s compliance are further described in the ‘Offset’ section below.

Operate Phase

Woodside’s requirements for GHG emissions in the operate phase will be applied to continue the identification and evaluation of emission reduction opportunities. This includes implementation of the following Woodside protocols, described in Section 7:

- The GHG Emissions and Energy Management Procedure
- The Production Optimisation and Opportunity Management Procedure (POOMP)
- The facility Decarbonisation Plan
- The Flare Management Framework
- The Greenhouse Gas, Energy and Flare Target Setting Guideline

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

- The methane management strategy
- Environmental Performance Procedure

These protocols enable continued reduction of direct GHG emissions to ALARP, including systems of continual review and improvement of key emissions sources from Scarborough FPU and downstream processing, and ongoing identification, screening and implementation of opportunities to reduce emissions.

Opportunities identified for implementation in design will continue to be applied and maintained in operations for ALARP purposes, for example via inclusion in operating procedures and maintenance planning.

Offset

The Federal Safeguarding Mechanism (SGM)⁵² requires Australia's highest greenhouse gas emitting facilities to reduce or limit their emissions in line with Australia's emission reduction targets of 43% below 2005 levels by 2030 and net zero by 2050. Direct GHG emissions from the Scarborough project, indirect emissions associated with onshore processing of gas from the Scarborough project as well as indirect emissions associated with the transportation and end use of gas within Australian safeguard facilities are subject to the SGM, and net emissions from these sources must be kept below a specified limit or baseline.

The SGM baseline parameters set for new facilities such as the Scarborough FPU are based on "international best practice" emissions intensity values. The baseline gives no allowance for reservoir CO₂ emissions from processing Scarborough gas associated with arrangements for new gas fields supplying LNG facilities. Additionally, an annual decline rate of 4.9% has been set to 2030. Post 2030 decline rates are intended to be set in predictable five-year blocks, after updates to Australia's Nationally Determined Contribution (NDC) under the Paris Agreement. This means that net direct emissions from the Scarborough FPU will be lower than current international best practice from start-up, and decline thereafter. If a baseline is calculated to be less than 100 ktCO₂-e per annum, a minimum baseline rule takes effect and the annual compliance baseline is rounded up to 100 ktCO₂-e (CER 2024).

The SGM baseline related to onshore processing of Scarborough gas is expected to be based on facility specific and industry-average emissions intensities transitioning to be based on industry-average values only in 2030. These baselines will also be subject to the same requirements noted above. The Scarborough net direct GHG emissions considering these requirements are summarised in Table 6-22.

Safeguard facilities that exceed their baseline must manage their excess emissions, such as by surrendering Australian Carbon Credit Units (ACCU) or Safeguard Mechanism Credits (SMCs), which are representative of one tonne of CO₂-e per credit, so that net emissions are brought in line with the baseline. So that sufficient credits are available and that there is a means to comply, safeguard facilities that exceed their baseline are able to buy Government-held ACCU from the Clean Energy Regulator via the Cost Containment Measure implemented as part of recent reforms.

Safeguard Mechanism (SGM) obligations for the Scarborough facility will be met by emissions abatement via operational controls as first preference (described above for both operations phase and initial start-up). Options to manage residual net emissions in excess of baseline include surrendering ACCU or SMCs, applying to become a trade-exposed baseline-adjusted facility, applying to borrow baseline from the following year or applying for a multi-year monitoring period. Surrendered carbon credits may be generated from Woodside projects, purchased from the market or purchased from the Government through the Cost-Containment Mechanism.

Carbon Management – Business Context

Woodside established a Carbon Business in 2018 in order to develop a portfolio of carbon credits and skills and expertise in managing carbon credit integrity. Total expenditure to date has been split between approximately one-third on origination of new Woodside projects, and the remainder on purchase of credits. In the future, focus is expected to shift towards project origination.

Woodside recognises that assessing integrity of carbon credits and managing a diverse portfolio of credits is important. In addition to regulatory requirements associated with the SGM, management of carbon credits is informed by current and emerging external frameworks such as the Integrity Council for the Voluntary Carbon Market's Core Carbon Principles, the Investor Group on Climate Change's guidance, and the Oxford Principles for Net Zero Aligned Offsetting. More information on Woodside's approach and management of carbon credits can be found in section 3.4 of the 2024 Climate Transition Action Plan.

Woodside Climate Targets

Woodside is targeting a reduction of net equity Scope 1 and 2 GHG emissions of 15% by 2025 and 30% by 2030, with an aspiration of net zero by 2050 or sooner. The net equity Scope 1 and 2 emissions reduction targets are relative to a starting base of 6.32 MtCO₂-e which is representative of the gross annual average equity Scope 1 and 2 GHG emissions over 2016-2020. This starting base may be adjusted (up or down) for potential equity changes in producing or sanctioned assets with a final investment decision prior to 2021. Net equity emissions include the utilisation of carbon credits as offsets.

⁵² Further information about the SGM and SGM Baselines can be found at the Clean Energy Regulator website: <https://cer.gov.au/schemes/safeguard-mechanism> and <https://cer.gov.au/schemes/safeguard-mechanism/safeguard-baselines>

The targets mean that total portfolio net equity Scope 1 and 2 emissions for the 12 month period ending December 2025 are targeted to be 15% lower than the starting base, and that net equity Scope 1 and 2 emissions for the 12 months period ending 31 December 2030 are targeted to be 30% lower than the starting base.

There is no direct mapping of these corporate level Scope 1 targets to Scarborough operations. The Scarborough Project was not operational in 2016-2020 during which the starting baseline was established; and therefore estimated GHG emissions from the operation of Scarborough were not included in the baseline, but will nonetheless be part of Woodside's total global GHG emissions, which the targets apply to. Abatement of these emissions may come from other facilities with more cost-effective or impactful abatement opportunities, or from offsets. Meeting these targets may mean additional net voluntary abatement beyond that required by the SGM described above.

Management and Abatement for Onshore Processing (Indirect) GHG Emissions

As described above, indirect GHG emissions will be generated by the onshore processing of gas from the Scarborough project. Onshore processing facilities are also subject to GHG emissions management frameworks and relevant regulatory approvals. As outlined above, the National Greenhouse and Energy Reporting (Safeguard Mechanism) Rule 2015 is the primary regulation mechanism for the management of GHG emissions from facilities with direct emissions over 100,000 tonnes CO₂e. Both Pluto and KGP are subject to the requirements of the Safeguard Mechanism and net emissions from these sources must be kept below a specified limit or baseline.

The Western Australian EPA have also assessed GHG emissions from Pluto and KGP under the Environmental Protection Act 1986. Ministerial Statement 757 for Pluto required the development of a Greenhouse Gas Abatement Program (Pluto GGAP), prior to the commencement of construction, in order to:

- ensure that the plant is designed and operated in a manner which achieves reductions in GHG emissions as far as practicable
- provide for onshore GHG emissions reductions over time
- ensure that, through the use of best practice measures, the total net GHG emissions and/or GHG emissions per unit of product from the project are minimised.

The Pluto GGAP for the initial Pluto train 1 development was updated to incorporate Pluto train 2 and included interim and long-term emission reduction targets approved by the Minister for Environment in August 2021. Ministerial Statement 1208, issued in August 2023, updates the Greenhouse Gas Abatement conditions from Ministerial Statement 757 and includes net GHG emission limits reflected in the approved Pluto GGAP targets in addition to ongoing review and reporting of GHG emissions and updates to the Pluto GGAP. The Pluto GGAP Revision 3A is currently applicable and in-force under MS1208 and is subject to annual compliance reporting provided to the WA EPA and published on the Woodside website.

Following EPA assessment of the North West Shelf Project Extension Proposal, which allows for continued operation of the NWS Project and processing of third party gas (such as from Scarborough via the Interconnector pipeline) at KGP, Ministerial Statement 1233 was issued in December 2024, approving the proposal with conditions relating to the management of GHG emissions (Condition 2-1 to 2-5). The GHG conditions require:

- notifying the relevant state government department if implementation of the proposal will not be or is not expected to be regulated under Safeguard legislation and of the implications of any changes to Federal Safeguard Legislation including obligations to reduce net Scope 1 GHG emissions.
- within 12 months of publication of the Ministerial Statement, and thereafter at five yearly intervals, to carry out a review of best practice design and operational measures that could be implemented to reduce GHG emissions, and provide to the relevant state government department a report which:
 - identifies practicable and reasonable options to reduce GHG emissions from the proposal
 - explains the assessment of both technical and economic feasibility of these options, and identifies which are considered feasible
 - includes an independent peer-review report of this options analysis
 - considers reasonably practicable options for reductions in scope 3 emissions

On 15 October 2024, the WA State Government released its updated greenhouse gas emissions policy for major projects (State policy) assessed by the EPA. Recognizing reforms that strengthened the Commonwealth SGM in 2023, the State policy describes that conditions to reduce net greenhouse gas emissions will no longer be applied to major proposals assessed under Part IV of the Environmental Protection Act 1986 where the proposals are subjected to alternative regulatory measures such as the current SGM.

In November 2024, the EPA updated its Environmental Factor Guideline: Greenhouse Gas Emissions with consideration of 'rapidly evolving' climate science and policy and the updated State Policy. In its updated guideline, the EPA states that 'emission reductions required under the SGM are now likely to represent an "as far as practicable" reduction of, and in most cases meet its factor expectation for, covered emissions.'

The WA Minister for Environment has recently requested the EPA to inquire into and report on the matter of changing the implementation conditions relating to the management of GHG emissions at Pluto. It is anticipated that Ministerial Statement 1208 will be amended to align with conditions of other major projects, recognizing the SGM declining baseline, and other conditions such as those outlined for Ministerial Statement 1233 (summarised above), to achieve the EPA's objective to minimise the risk of environmental harm associated with climate change by reducing GHG

emissions as far as practicable. For Pluto, the trajectory of net GHG emission limits under the SGM is substantially lower than the net GHG limits currently specified in Ministerial Statement 1208.

These regulatory frameworks, which are designed so that GHG emissions from onshore processing of Scarborough gas are managed consistent with Australia's emission reduction targets, routinely publicly reported and emission reduction opportunities periodically reviewed, ensure that GHG emissions associated with the onshore processing of Scarborough gas are ALARP and Acceptable.

Management and Abatement for Third Party Consumption (inc. Transport, Regasification, Distribution, Combustion) (Indirect)

Woodside continues to pursue a range of management and abatement measures relevant to GHG emissions associated with third party consumption of gas from the Scarborough project. These are appropriate and practicable given that Woodside does not have operational control over third party GHG emissions. Examples of initiatives we are involved with are given below, involvement may change over time.

Reduce

Methane Guiding Principles: Woodside joined the Methane Guiding Principles in 2018. The MGP focuses on priority areas for action to reduce methane emissions across the natural gas supply chain.

Completed activities under the MGP include:

- led the "Global Midstream initiative" which encourages MGP members to engage and collaborate with supply chain and share best practises for methane reduction
- sponsored the first technical workshop of the Australian Energy Producers methane taskforce
- presented and participated in panels at the Global Methane Summit and International Gas Union conference

ASEAN Methane Leadership Programme: Woodside joined in 2023 and initiated an Australian methane programme through the Australian Climate Leaders Coalition. These programmes allow Woodside to share expertise with other companies in the natural gas value chain to help them reduce emissions of methane to near-zero⁵³

IPIECA Scope 3 Emissions Taskforce: Providing members the opportunity to convene and disseminate knowledge and good practice in the area of Scope 3 emissions, including categorisation, value chain emission analysis, Scope 3 measurement and reporting and engagement along the value chain.

OGMP 2.0: Woodside joined OGMP 2.0 in 2024. The OGMP 2.0 is the United Nations Environment Programme's flagship oil and gas reporting and abatement programme. OGMP 2.0 is the only comprehensive, measurement-based reporting framework for the oil and gas industry that improves the accuracy and transparency of methane emissions reporting. This is key to prioritising methane abatement actions in the sector.

Woodside shares examples of emissions reduction initiatives being implemented on its assets with the Operator of non-operated assets at governance forums and joint venture technical committee meetings. Examples have included sharing knowledge about methane measurement (such as drone observation surveys), reduction opportunities such as thermal oxidisers at the Wheatstone asset, and approach to workforce engagement on decarbonisation and identification of opportunities.

Woodside also supports customers⁵⁴ to reduce their emissions via the investment in new energy products and lower carbon services, including the progression of corporate Scope 3 targets that apply across Woodside's portfolio including:

- Scope 3 Investment Target⁵⁵: Woodside has a Scope 3 investment target aiming to invest \$5 billion in new energy products and lower carbon services by 2030⁵⁶
- Scope 3 Emissions Abatement Target⁵⁵: Woodside has a Scope 3 emissions abatement target, to indicate the potential abatement impact of these products and services upon customer Scope 1 or 2 emissions. This target

⁵³ OGMP, 2023. "Implementation Plan Guidance", p. 2 https://ogmpartnership.com/wp-content/uploads/2023/02/OGMP-2.0-Implementation-Plan-Guidance_2.pdf. OGMP provides the OGCI collective average target for upstream operations as an example of 'near zero' emissions intensity

⁵⁴ The customers for these products and services may be the same as the customers of our oil and gas business, directly substituting their energy for new products or directly abating the associated emissions. There may also be customers of the new products and services, without also being customers of oil and gas

⁵⁵ Scope 3 targets are subject to commercial arrangements, commercial feasibility, regulatory and Joint Venture approvals, and third party activities (which may or may not proceed). Individual investment decisions are subject to Woodside's investment targets. Not guidance. Potentially includes both organic and inorganic investment. Timing refers to financial investment decision, not start-up/operations.

⁵⁶ Includes pre-RFSU spend on new energy products and lower carbon services that can help our customers decarbonise by using these products and services. It is not used to fund reductions of Woodside's net equity Scope 1 and 2 emissions which are managed separately through asset decarbonisation plans.

it to take final investment decisions on new energy products and lower carbon services by 2030, with total abatement capacity of 5 Mtpa CO₂-e⁵⁷

Substitute

Promoting and marketing the role of LNG in displacing higher carbon intensity fuels (IEA, 2019): Woodside continues to advocate LNG as a means for customers to reduce their Scope 1 and 2 emissions, in accordance with the customer nations' NDCs (see section below). Evidence of the effectiveness of this strategy is the recent buy into the Scarborough project by Japan LNG (10% – 8 August 2023) and JERA (15.1% – 23 February 2024) with associated potential LNG offtake and collaboration on opportunities in new energy.

Advocate

Advocacy for stable policy frameworks that reduce carbon emissions: Woodside aligns its advocacy to support the goals of the Paris Agreement. A list of speeches and submissions to international and domestic audiences which contain climate related content or positions in 2023 is presented in the Woodside Climate Transition Action Plan, section 6.1.

Monitor and Report

Monitor and report on the global energy outlook: This will be achieved via the release of Woodside's annual disclosures.

Verification

Verification of assumptions used to estimate third party emissions (transport, regasification, distribution and end use) will be undertaken as far as reasonably practicable based on data available. This may include:

- Information on LNG cargo destinations, for example from sales contracts
- Domestic gas volumes
- Updates to relevant estimation factors
- Data published by third parties involved in the value chain

If assumptions used in calculation of third party emissions are found to have varied or are no longer valid, Woodside will undertake review and re-estimate third party emissions, applying change management process as described in Section 7.2.7.

Reporting

NGERS requires Woodside to report on GHG emissions and energy use from activities which are under its operational control. Woodside will report GHG emissions and energy use from offshore facilities, including the FPU, in accordance with its requirements under the NGERS Act.

Data on broader GHG emissions, such as Scope 3 emissions and progress against corporate targets and commitments, will be published as part of Woodside's annual disclosures.

Detailed Impact/Risk Assessment

Assessment of Potential Climate Change Impacts

Climate change is caused by the net global concentration of greenhouse gases in the atmosphere. Human-caused climate change is a consequence of more than a century of net GHG emissions from energy use, land use change, lifestyle patterns of consumption, and production (IPCC 2023). The IPCC has stated that observed increases in GHG concentrations since 1750 leading to climate change are unequivocally caused by human activities and that there's a near linear relationship between cumulative anthropogenic CO₂ emissions and the global warming they cause (IPCC 2023). This relationship implies that reaching net zero anthropogenic CO₂ emissions is a requirement to stabilize human-induced global temperature increase at any level, but that limiting global temperature increase to a specific level would imply limiting cumulative CO₂ emissions to within a carbon budget (IPCC 2023)

As stated by the IPCC, "it is unequivocal that human influence has warmed the atmosphere, ocean and land. Widespread and rapid changes in the atmosphere, ocean, cryosphere and biosphere have occurred". These impacts are summarised in the below section *Climate Change – Global and Australian Context*.

The Paris Agreement

The Paris Agreement is an international treaty on climate change, signed in 2016. It includes the goal to hold "the increase in the global average temperature to well below 2°C above pre-industrial levels and to pursue efforts to limit the temperature increase to 1.5°C."

Carbon budgets "refer to the total net amount of carbon dioxide that can still be emitted by human activities while limiting global warming to a specified level" (IPCC 2023). A number of factors influence the calculation of remaining carbon

⁵⁷ Includes binding and non-binding opportunities in the portfolio, subject to commercial arrangements, commercial feasibility, regulatory and Joint Venture approvals, and third party activities (which may or may not proceed). Individual investment decisions are subject to Woodside's investment targets. Not guidance.

Detailed Impact/Risk Assessment

budgets, such as the level of global warming chosen, probability, contribution of other greenhouse gases, how much global warming has already occurred due to historical emissions. The remaining carbon budget to limit global warming to 1.5°C and 2°C was 500 GtCO₂ and 1350 GtCO₂ respectively, as calculated from 2020 (IPCC 2023).

Since 2020, a portion of this global carbon budget has been consumed by ongoing global CO₂ emissions. The Global Carbon Budget, an initiative of the Global Carbon Project of the University of Exeter “tracks the trends in global carbon emissions and sinks and is a key measure of progress towards the goals of the Paris Agreement.” It is recognised by being presented at the UNFCCC’s Conference of Parties (COP) sessions. The last Global Carbon Budget in 2024 estimated that the remaining carbon budget for cumulative global GHG emissions to limit global warming to 1.5°C, and 2°C were 235 GtCO₂, and 1110 GtCO₂ respectively (50% likelihood).

Federally, the Australian domestic policy response to its Paris Agreement commitments is contained in multiple pieces of Commonwealth legislation (for example, *Australian Registry of Emissions Units Act 2011* (Cth); *Carbon Credits (Carbon Farming Initiative) Act 2011* (Cth); *Climate Change Act 2022* (Cth); *National Greenhouse and Energy Reporting Act 2007* (Cth); *National Greenhouse and Energy Reporting (Safeguard Mechanism) Rule 2015* (Cth); *Offshore Electricity Infrastructure Act 2011* (Cth); *Renewable Energy (Electricity) Act 2000* (Cth)). There are also climate change policies at State level. Policies and mechanisms of this kind will serve as Woodside’s primary means of managing GHG. As recent Court decisions have noted, current domestic environmental protection and assessment mechanisms are ill-suited for considering climate change impacts.

The Federal Safeguard Mechanism (SGM) described in the Management and Abatement section above is the key piece of legislation that implements the Australian Government’s policy for reducing emissions at Australia’s largest industrial facilities. The SGM sets legislated limits, known as baselines, on the net greenhouse gas emissions of these facilities. These emissions limits will decline, predictably and gradually. Through these limits, the Australian Government aims to help achieve Australia’s emission reduction targets, as committed in Australia’s Nationally Determined Contribution (NDC) to the Paris Agreement of 43% below 2005 levels by 2030 and net zero by 2050.

Climate Related Scenarios

The use of fossil fuels for energy currently accounts for around three quarters of anthropogenic GHG emissions (IEA 2021). This means that efforts to meet climate change goals must include changes to the way that the world produces and consumes energy. These changes are referred to as the “energy transition”.

The precise shape and pace of the energy transition is uncertain. It is expected to vary in different countries because they have different starting points, development requirements, resources and capabilities. However, the scale of the transition is clearer. It will take many trillions of dollars, invested over decades. The International Renewable Energy Agency estimates it will require \$115 trillion of cumulative investment by 2050 (IRENA 2022).

During 2022, the world experienced what the IEA has called the “first truly global energy crisis” (UNFCCC 2022). This crisis has seen higher energy prices and in some cases constraints on access to energy supply, impacting both businesses and households. The energy crisis has led to a renewed focus on energy security and has reconfirmed that the energy transition needs to be carefully managed if it is to be fair, inclusive and ultimately successful.

Gas from the Scarborough project is understood to have an ongoing role in supporting customers’ plans to secure their energy needs, while they reduce their emissions. Current uses of gas include power generation⁵⁸, heating and chemical feedstock.

In 2021, the IEA published its Net Zero by 2050: A Roadmap for the Global Energy Sector report (the NZE Scenario) (IEA 2021). The report is clear that “the route mapped out here is a path, not necessarily the path”, and Woodside recognises that this is one scenario out of many. A range of pathways are considered by the IPCC.

Even in the NZE Scenario, investment in oil and gas development does not cease. The IEA estimates the need for an average \$365 billion of upstream oil and gas investment every year until 2030, and \$171 billion every year thereafter to 2050 is required in the NZE Scenario. The IEA cautions that “The fact that no new oil and natural gas fields are required in the NZE does not mean that limiting investment in new fields will lead to the energy transition outcomes in the NZE. If demand remains at higher levels, reduced investment would result in a shortfall in supply in the years ahead, and this would lead to higher and more volatile prices.

A range of climate pathways which limit global warming to either 1.5°C or 2°C have been published in addition to the NZE Scenario. Figure 6-6 shows the range of potential global gas consumption in these scenarios, along with forecast supply with and without new investment.

⁵⁸ Electricity generation fueled with natural gas typically releases about half the lifecycle amount of greenhouse gases compared to electricity generation fueled with coal (IEA 2019). Additionally, natural gas fired electricity generation offers a flexible means of providing support to batteries and help stabilize the power grid during periods of reduced renewable energy production (e.g. at night, and when the wind is calm)

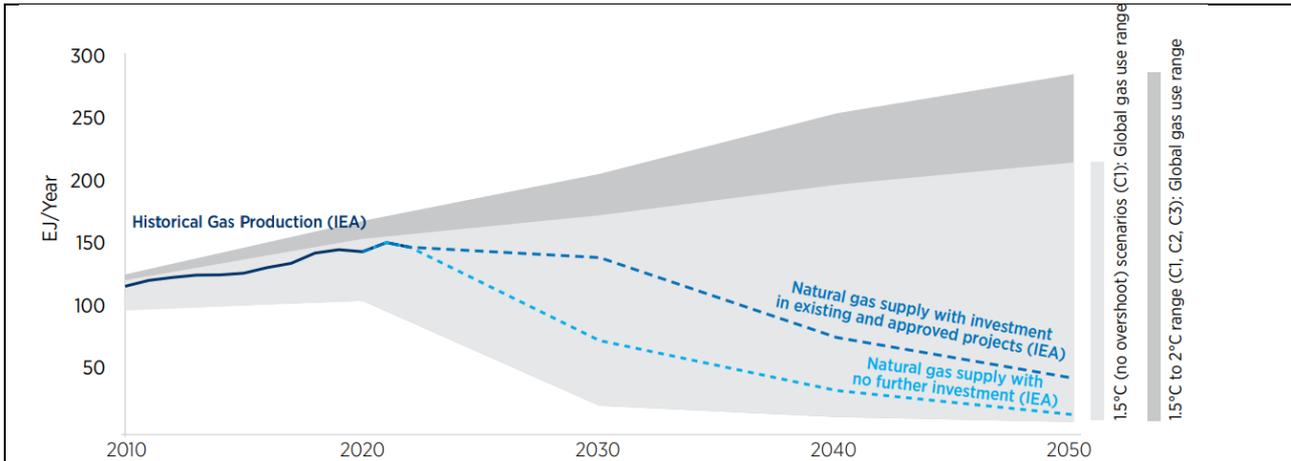

Figure 6-6: Forecast global gas use in climate pathways that limit warming to 1.5°C and 2°C, with expected supply

Woodside notes that the IEA has published two special reports, Emissions from Oil and Gas Operations in Net Zero Transitions and The Oil and Gas Industry in Net Zero Transitions (IEA 2023). Combined, these reports note that oil and gas operations currently account for around 15% of total energy related emissions globally, identify and advocate for opportunities for oil and gas producers to abate these emissions, and analyse broader implications for the sector through the energy transition which includes the need for increased investment in clean energy. This EP demonstrates that management and abatement measures applied reduce GHG emissions associated with the project to acceptable and ALARP levels. Through meeting requirements of the Federal SGM, direct GHG emissions and those created by onshore processing of Scarborough gas are aligned with Australia’s emission reduction targets under the Paris Agreement. Further, Woodside’s Scope 3 targets demonstrate how Woodside’s products and services can help our customers avoid or reduce their Scope 1 or 2 emissions and therefore reduce life cycle (Scopes 1, 2 and 3) emissions intensity of Woodside’s portfolio.

Woodside notes that the IEA makes the following statements in their World Energy Outlook 2024 on LNG demand in their Stated Policies Scenario (STEPS), Announced Pledges Scenario (APS) and Net Zero Emissions by 2050 Scenario (NZE):

- In the STEPS, LNG demand increases by more than 2.5% per year over the 2023-2035 period, which is faster than overall natural gas demand but far less rapid than the average 6% per year LNG growth rate between 2013 and 2022. Around 270 bcm of new LNG supply is currently under construction, and this will lead to a near-doubling of capacity in the United States and Qatar, which are set to dominate supply in 2035, together accounting for around 50% of global LNG trade in the STEPS by this date. This increased supply concentration is likely to put a spotlight on possible security of supply risks that might arise from extreme weather in the Gulf of Mexico and from disruption in the Middle East.
- Due to an upward adjustment to projected natural gas demand growth to 2030, LNG demand growth in the STEPS is higher than in the WEO-2023, reaching more than 700 bcm by 2035. However, this pace of growth does not keep pace with export capacity additions. As a result, a 130 bcm surplus emerges by 2030, bringing prices down in key importing regions like the European Union, China and Japan to a range between USD 6.5- 8.5 per million British thermal units (MBtu). This makes it difficult for some exporters to fully recover their long-run marginal cost of supply during this period.
- This LNG surplus narrows in subsequent years as LNG demand growth continues in the 2030s, and a supply gap emerges in 2040. By 2050, around 175 bcm of additional LNG export capacity is required in the STEPS to cover both demand growth and retiring capacity. This additional supply mainly comes from the Middle East, East Africa and North America. In the APS, projects currently under construction are sufficient to meet LNG demand: this peaks at 650 bcm in 2030, and no supply gap emerges. In the NZE Scenario, demand can be met in aggregate from projects existing today, without any need for additional LNG from projects currently under construction: this has a profound effect on gas prices in importing regions, which fall to around USD 5/MBtu by 2030.

Japan and Korea have significant energy- and carbon-intensive industry sectors which account for approximately 30% of GDP for each. Most energy used in industry is imported, which creates a priority for energy security during energy transitions. In the APS, energy supplies in Japan and Korea are underpinned by a variety of sources over the next decade as they pivot to increased use of clean energy sources – including renewables, nuclear and low emissions fuels – to reduce emissions and secure supply. Although the share of fossil fuels in power generation decreases through to 2035 and beyond, natural gas continues to provide stable and flexible power for both countries in light of limited domestic supply options or interconnections with neighbouring countries. Natural gas is projected to remain an important energy

Detailed Impact/Risk Assessment

source, accounting for nearly 12% of the power mix in 2035 in the APS, though gas-fired power drops to just 3% by 2050.

It is acknowledged that information related to climate related scenarios and the energy transition are subject to change, through mechanisms such as ongoing work by the IPCC and other agencies. Woodside will stay abreast of such changes and apply change management processes as described in section 7.2.7.

Gas's Role in the Energy System

The IEA identifies that there are strong macroeconomic drivers for growth in natural gas consumption in emerging markets and developing economies in Asia over the next decade, at least partially driven by coal to gas switching which "helps countries with net-zero emissions targets accelerate the transition away from coal, even if renewables are the major source of emissions reductions" (IEA 2023).

In the 2019 report *The Role of Gas in Today's Energy Transition*, the IEA indicates that electricity generation fuelled with natural gas typically releases about half the lifecycle amount of greenhouse gases compared to electricity generation fuelled with coal (IEA 2019). Additionally, natural gas-fired electricity generation offers a flexible means of providing support to batteries and helps stabilise the power grid during periods of decreased renewable energy production (e.g. at night or when the wind is calm).

The same IEA report states that "beating coal on environmental grounds sets a low bar for natural gas, given there are lower emissions and lower cost alternatives to both fuels". However, as shown in Figure 6-6 there is ongoing demand for gas in Paris aligned scenarios regardless of the presence or trajectory of renewable energy development.

It is noted that a recent paper published in the Energy Science & Engineering Journal comments on the greenhouse gas footprint of LNG exported from the United States (Howarth 2024). This paper is not an appropriate assessment of emissions associated with the Scarborough PAP because it:

- overestimates methane emissions associated with gas production and processing in the US (the paper uses a methane emissions intensity rate over three times higher than the International Energy Agency (IEA) Global Methane Tracker¹ uses for US gas production)
- the Howarth 2024 study assumes a leak rate of 2.8% methane during the upstream gas process (does not include liquefaction). The industry has a target of 0.2% (Oil and Gas Climate Initiative 2025 target) and in the 2024 CTAP, Woodside reported methane emissions around 0.1% of production by volume, which is supported by surveys, aerial and point source measurements at existing operational facilities. This value can also be assumed to apply for Scarborough, since it is subject to similar methane management approach as other Woodside operations.
- is based on LNG exported from the USA and not relevant to Australian projects including Scarborough (the IEA finds that the methane emissions intensity of Australian gas production and processing is around half that of the US (IEA,2024)
- underestimates the emissions from coal use in Asia.
 - The IEA Methane Tracker Documentation estimates that methane emissions from India and China coal production are 34% and 56% higher respectively than US domestic coal production, which was used as the basis for comparison in the Howarth paper (IEA, 2024)

Additionally, as mentioned above, the IEA indicates that electricity generation fuelled with natural gas typically releases about half the lifecycle amount of greenhouse gases compared to electricity generation fuelled with coal (IEA 2019). Woodside considers the IEA a more authoritative source than Howarth.

The IPCC has noted Carbon intensity (from fossil fuel combustion and industrial processes) decreased, with large regional variations, over 2010-2019 "mainly due to fuel switching from coal to gas, reduced expansion of coal capacity, and increased use of renewables" (IPCC 2023).

Global energy demand is expected to increase. Since the availability of gas can support the reduction of more carbon-intensive firming fuel sources such as coal, rather than displacing renewable energy, it cannot be assumed that emissions associated with customer consumption of Scarborough gas would be entirely additive to global atmospheric emissions.

While the US market is not expected to be customers for Scarborough gas, it serves as a relevant example. In an article titled *Natural gas is now stronger than ever in the United States power sector*, the IEA states "the switch from coal to gas and uptake of renewables has lowered emissions in the US power sector... In this period, gas-fired generation more than doubled while coal-fired generation was cut by half" (IEA 2023).

Woodside will reassess, on an annual basis, the role of gas in the energy transition and its potential to contribute to the net displacement of more carbon intensive energy sources. The assessment may include relevant literature reviews, participating or commissioning studies, assessing carbon intensities of the electricity mix of customer nations (relative to LNG), or by using other data available. Adaptive measures will be designed and implemented if Woodside concludes the assessments are showing gas is not displacing more carbon intensive fuels or contributing to the global energy transition, either directly (gas displacing more carbon intensive energy sources, such as coal) or indirectly (gas enabling build out of further renewables by providing the base-load/firming needed for grid stability). Asia has more than half of

Detailed Impact/Risk Assessment

the world's people and is growing. Across Asia many countries are still heavily reliant on coal which accounts for approximately 50% of the total energy supply in the Asia Pacific (IEA 2020).

Gas also provides important input to industry, with industrial uses of gas including:

- A feedstock for ammonia and methanol production, which are used for fertiliser and consumer goods manufacturing, among other processes that fuel economic growth and an increasing population
- A source of hydrogen production for the refining and chemical industries
- A source of heat for high-temperature industrial processes, such as producing aluminium, ceramics, cement, glass and steel. Due to its high energy density and controllable combustion characteristics, gas is particularly suitable for generating high temperature heat which may not be achievable through direct electrification (International Gas Union 2023).

Woodside currently expects that natural gas will continue to have a role in the energy transition.

Consideration of likely customer markets and associated energy mixes is important to understand the context of emissions from third party consumption of Scarborough gas. Offtake is not fully contracted for the life of the project, however a reasonable assumption is that gas from the Scarborough project will be part of the regional, commoditised LNG market. Recent sale of equity and associated gas sales agreement to customers including LNG Japan and JERA demonstrates a strong demand for Scarborough product (Woodside 2023). Scarborough is geographically positioned to provide LNG to Asian markets which also enables lower shipping emissions. The strong demand for Scarborough gas, including from customer nations who have publicly stated that they intend to use LNG as part of their approach to meeting their Paris commitments (see the next section below), some of which have already secured sales agreements or purchased stakes in the Scarborough Project, indicate that it is possible for Scarborough Gas to have a role in reducing global emissions.

The International Energy Agency (IEA) forecasts suggest that most future gas demand in Asia is China, India, Japan, Korea and other developing regions. These regions are therefore considered as likely customer markets for the purpose of evaluating the role of gas from the Scarborough project in existing energy mixes. This does not preclude the sale of gas from the Scarborough project to other customers.

Customer Markets' Nationally Determined Contributions (NDCs)/commitments

The emissions associated with the consumption of Scarborough gas along with other feed sources in customer markets will be considered under domestic and international emissions control frameworks. Anticipated customers of gas from the Scarborough Project are in countries that are parties to the Paris Agreement. Under the Paris Agreement and global GHG accounting conventions, each country is responsible for accounting for, reporting and reducing emissions that physically occur in its jurisdiction. As described in the *Management and Abatement* section above, Woodside will seek to minimise these emissions associated with Scarborough gas as appropriate to our level of control.

The Paris Agreement requires countries to publish Nationally Determined Contributions to the goals of the Agreement. GHG emissions associated with customer use in countries that have ratified the Paris Agreement are considered under relevant national plans, summarised along with other policies below:

- **Japan:** "Japan aims to reduce its greenhouse gas emissions by 46 percent in fiscal year 2030 from its fiscal year 2013 levels, setting an ambitious target which is aligned with the long-term goal of achieving net zero by 2050." Japan also published an "Outline of Strategic Energy Plan" in October 2021. This plan assumes that LNG, while reducing from 37% in 2019, still makes up 20% of Japan's electricity generation mix in 2030.
- **The People's Republic of China:** "China would scale up its NDCs by adopting more vigorous policies and measures, and aims to have CO₂ emissions peak before 2030 and achieve carbon neutrality before 2060." It goes on to state that "energy storage and gas-powered electricity will be stepped up rapidly"
- **Republic of Korea:** "The Republic of Korea is seeking to dramatically phase down coal-fired power generation while ramping up renewable power. Aged coal power plants will be shut down or shift their fuels from coal to Liquefied Natural Gas (LNG)."

Woodside's analysis of the NDCs and key policy documents of key customer nations is that LNG has an important role in supporting their decarbonisation plans under the Paris Agreement. If the introduction of Scarborough LNG into the global energy market serves to reduce GHG emissions elsewhere, then in Woodside's view the full volume of GHG emissions associated with the project are not expected to be additive to global GHG concentrations.

Gas' Role in Australia's Energy Market

Domestic users of Scarborough gas are expected to be subject to Australia's GHG framework which reflect Australia's NDCs, such as the Federal SGM which applies to Australia's largest industrial facilities.

The primary product from the Scarborough project will be LNG. However, under Western Australia's domestic gas reservation policy, gas from the Scarborough project will also contribute to domestic use in WA.

The emissions intensity of gas-fuelled electricity generation can be compared to other fuels data published by the Clean Energy Regulator (CER 2024). This includes data for designated generation facilities only, which according to the CER are facilities "where the principal activity is electricity production."

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

Table 6-24: Comparative emissions intensity of different energy sources in Western Australia, 2022 2023 financial year

Primary Fuel	Total Generation (million MWh)	Scope 1 and 2 Emissions (MtCO ₂ e)	Emissions Intensity (tCO ₂ e/MWh)
Natural Gas	13.89	7.95	0.57
Coal	6.23	5.33	0.86
Oil, Diesel	0.10	0.06	0.65
Solar, Wind, Hydro	3.79	0.00	0.00
Other	0.10	0.01	0.08
Total	24.10	13.35	0.55

Table 6-24 shows that the GHG emissions intensity of gas-fuelled electricity generation in WA is approximately 30% lower than coal-fuelled electricity generation, and comparable to that of the total aggregated electricity generation. This may continue to change, for example as the portion of electricity generated from zero-carbon sources increases.

As stated by the Australian Energy market Operator,

[the 2023 data shows] strong growth in electricity demand, driven by electrification, electric vehicle uptake, and new energy-intensive industries including green hydrogen production. Several of these trends lead to reduced gas consumption. However, increases in expected electricity consumption, coupled with the phased closure of state-owned coal power stations has a corresponding impact on modelled use of gas-powered generation to support the transition to a majority-renewables power system

And

Pressures associated with future coal supply and the planned retirements of coal-fired generation, are expected to increase the reliance of the South West Integrated System gas powered generation (GPG) fleet, and GPG is expected to play an important role, along with renewables, storage and supporting transmissions infrastructure, in ensuring the reliability in the SWIS as the energy transition continues. (AEMO 2023)

The Scarborough Energy Project will deliver more gas to the WA market, at a time when WA is predicted to face supply shortages. According to 2022 WA Gas Statement of Opportunities report by Australian Energy Market Operator (AEMO) it is forecast there will be insufficient gas supply to meet WA demand. The start-up of Scarborough will help to address the anticipated forecast supply gap in the WA domestic gas market.

Scarborough Contribution to Global Greenhouse Gas Concentrations

The Scarborough project will create Scope 1 GHG emissions from the PAP and there will be Scope 3 emissions associated with onshore processing of Scarborough gas. There will also be Scope 3 GHG emissions from customer use associated with the project. These are estimated in the *Description of Source* section above.

The remaining carbon budget to limit global warming to 1.5°C and 2°C was 500 GtCO₂ and 1350 GtCO₂ respectively, as calculated from 2020 (IPCC 2023).

Since 2020, a portion of this global carbon budget has been consumed by ongoing global CO₂ emissions. The Global Carbon Budget, an initiative of the Global Carbon Project of the University of Exeter “tracks the trends in global carbon emissions and sinks and is a key measure of progress towards the goals of the Paris Agreement.” The University of Exeter presented at the UNFCC’s Conference of Parties (COP) sessions. The last Global Carbon Budget in 2024 estimated that the remaining carbon budget for cumulative global GHG emissions to limit global warming to 1.5°C, and 2°C were 235 GtCO₂, and 1110 GtCO₂ respectively at January 2025 (50% likelihood).

As described above, LNG can have a role in displacing higher carbon intensity fuels and lowering carbon intensity of existing energy mixes, and key customer nations have stated that LNG has an important role in supporting their decarbonisation plans under the Paris Agreement. If the introduction of Scarborough LNG into the global energy market serves to reduce GHG emissions elsewhere, then the full volume of GHG emissions associated with the project may not be additive to global GHG concentrations.

To facilitate a comparison against carbon budgets, a hypothetical scenario where GHG emissions associated with the Scarborough project are treated as entirely additive is considered. This scenario is not expected to eventuate due to the reasons described above. The estimated Scarborough GHG emissions over the expected life of the development are compared with remaining carbon budgets expected to achieve the goals of the Paris Agreement below. Additionally, no allowance is given for future abatement of GHG emissions associated with the project (such as through future abatement opportunities or future policy requirements), or changes to the carbon budgets which are known to be estimates only. As described above, the carbon budgets are developed based on CO₂ only however the comparison below conservatively considers all GHG emissions from the project normalised as CO₂-e, the vast majority of which are CO₂.

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

Detailed Impact/Risk Assessment

Emissions associated with onshore processing of Scarborough gas will also be subject to GHG frameworks which are expected to reduce the estimate from the gross figure used, such as the Federal SGM.

Table 6-25: Comparison of expected lifecycle GHG emissions associated with the project to global carbon budgets, assuming they are additive

Source	Estimated GHG Emissions over Development Life (MtCO ₂ -e)	Proportion of remaining global carbon budget – achieving 1.5°C (235 GtCO ₂)	Proportion of remaining global carbon budget – achieving 2°C (1110 GtCO ₂)
Direct + Vessels and Helicopters	12	0.005%	0.001%
Onshore hydrocarbon processing	88	0.04%	0.008%
Third party transport of products, regasification, distribution and end use	778	0.33%	0.07%
Total	878	0.37%	0.08%

Assuming the scenario in which all GHG emissions associated with the Scarborough project are additive to global GHG gas concentrations, which they may not be, the project’s contribution to the global carbon budget required to meet the goals of the Paris Agreement is de minimis.

Greenhouse gas emissions associated with Scarborough are estimated to be up to 878 Mt CO₂-e till EOFL, of which approximately 100 Mt CO₂-e may originate from extraction and processing in Australia. Projected annual extraction and processing GHG emissions of approximately 3.5 Mt CO₂-e would represent ~0.8% of national Australian emissions, relative to FY2024 (440.6 Mt CO₂-e for the year until June 2024) (DCCEEW, 2024c).

Based on Australia’s GHG emission reduction commitments and NDC, an Australian carbon budget of 4,377 MtCO₂-e for the years 2021-2030 has been estimated (DCCEEW 2024c), GHG emissions associated with the Scarborough project until 2030 occurring in Australia, conservatively assuming 5 full years of operation and emissions from consumption of domestic gas, are estimated to be 38 MtCO₂-e, representing 0.9% of Australia’s carbon budget for this period. Net emissions associated with Scarborough in Australia are set to be lower than these totals - with ongoing abatement via implementation of the NGERs Safeguard Mechanism which sets out an abatement trajectory consistent with achieving Australia’s emission reduction targets.

These emissions represent a de minimis contribution to either Australia’s GHG emissions or global GHG emissions.

Climate Change – Global and Australian Context

Climate change is caused by the net global concentration of greenhouse gases in the atmosphere. Noting that human-caused climate change is a consequence of more than a century of net GHG emissions from energy use, land use change, lifestyle patterns of consumption, and production (IPCC 2023), the following contextual evaluation of Climate Change impacts is provided.

Climate science is a rapidly evolving field in which new observations continue to deepen understanding of the current and potential impacts of global warming, and the possible pathways for mitigation and adaptation.

The CSIRO State of the Climate 2024 Report (CSIRO, 2024) draws on the latest national and international climate research, encompassing observations, analyses and future projections to describe year-to-year variability and longer-term changes in Australia’s climate. Key points from this report on measured warming trends and forecast trajectories include the following:

- Australia’s climate has warmed by an average of 1.51 ± 0.23 °C since national records began in 1910.
- Sea surface temperatures have increased by an average of 1.08 °C since 1900.
- The warming has led to an increase in the frequency of extreme heat events over land and in the oceans.
- Mass coral bleaching is a stress response of corals occurring primarily due to elevated ocean temperature, with five bleaching events associated with marine heatwaves occurring on the Great Barrier Reef over the past 10 years: in 2016, 2017, 2020, 2022 and 2024. In 2016, bleaching was associated with then record high sea surface temperatures, which in turn led to the largest recorded mass bleaching to date on the Great Barrier Reef.
- The 2022 event was the first time that mass bleaching occurred on the Reef during a La Niña year. Accumulated thermal stress during the 2024 event was higher than in 2016, although the full impact in terms of bleaching is still being assessed.

Detailed Impact/Risk Assessment

- In 2022 bleaching was also observed on some reefs on Australia’s west coast, including Ningaloo Reef. This was due to warm ocean temperatures, driven by the 2021–2022 La Niña. The region’s previous severe marine heatwave was driven by the 2010–2011 La Niña, which resulted in bleaching being recorded for the first time on Ningaloo and the closure of several Western Australian fisheries.
- In the south-west of Australia there has been a decrease of around 16% in April to October rainfall since 1970. Across the same region, May to July rainfall has seen the largest reduction, by around 20% since 1970.
- In the south-east of Australia, there has been a decrease of around 9% in April to October rainfall since 1994.
- Heavy short-term rainfall events are becoming more intense.
- There has been a decrease in streamflow at most gauges across Australia since 1970.
- There has been an increase in rainfall and streamflow across parts of northern Australia since the 1970s.
- There has been an increase in extreme fire weather, and a longer fire season, across large parts of the country since the 1950s.
- There has been a decrease in the number of tropical cyclones observed in the Australian region since at least 1982.
- Snow depth, snow cover and number of snow days have decreased in alpine regions since the late 1950s.
- Oceans around Australia are becoming more acidic, with changes happening faster in recent decades.
- Sea levels are rising around Australia, including more frequent extreme high levels that increase the risk of inundation and damage to coastal infrastructure and communities.

The CSIRO report states that in the coming decades, Australia will experience ongoing changes to its weather and climate which are projected to include:

- Continued increase in air temperatures, with more heat extremes and fewer cold extremes.
- Continued decrease, on average, in cool season rainfall across many regions of southern and eastern Australia, which will likely lead to more time in drought.
- More intense short-duration heavy rainfall events even in regions where the average rainfall decreases or stays the same.
- Continued increase in the number of dangerous fire weather days and a longer fire season for much of southern and eastern Australia.
- Further sea level rise and continued warming and acidification of the oceans around Australia.
- Increased and longer-lasting marine heatwaves that will affect marine environments such as kelp forests and increase the likelihood of more frequent and severe bleaching events in coral reefs around Australia, including the Great Barrier Reef and Ningaloo Reef.
- Fewer tropical cyclones, but with higher intensity on average, and greater impacts when they occur through higher rain rates and higher sea level.
- Reduced average snow depth in alpine regions, but with variations from year to year.

The IPCC is the United Nations body for assessing the science related to climate change, and finalised the Sixth Assessment Report (AR6) in 2023. This consists of three Working Group contributions and a Synthesis Report. A summary of outcomes of the working group’s contributions comprises a range of matters, which amongst others include:

- The AR6 Working Group I (AR6-WG1) report stated that it is unequivocal that there is human-induced warming. It also stated that increased atmospheric carbon dioxide (CO2) levels, generated by human activity, are the largest driver of warming over the longer term, and that there are a range of factors, including emissions of methane, which increase warming in the short-term.
- The AR6 Working Group II (AR6-WG2) report stated that human-induced climate change, including more frequent and intense extreme events, has caused widespread adverse impacts and related losses and damages to nature and people, beyond natural climate variability. It stated that global warming, reaching 1.5°C in the near-term, would cause unavoidable increases in multiple climate hazards and present multiple risks to ecosystems and humans. The report noted that societal choices and actions implemented in the next decade will determine the extent to which medium- and long-term pathways will deliver climate resilient development.
- The AR6 Working Group III (AR6-WG3) report provided an updated global assessment of climate change mitigation progress and pledges and examined the sources of global emissions. It explained developments in emissions reduction and mitigation efforts and assessed the impact of national climate pledges in relation to long-term emissions goals. More than 2000 quantitative emissions pathways were submitted to the IPCC, of which 1202 scenarios included sufficient information for assessing the associated warming. The report found that there are many pathways in the literature that likely limit global warming to 2°C with no overshoot, or to 1.5°C with limited overshoot. These variations occur because, while climate science is able to calculate a ‘carbon budget’ of net emissions before any particular temperature outcome is reached, the allocation of this

Detailed Impact/Risk Assessment

budget between different human activities requires additional judgements about for example technology, economics, consumer preferences and policy choices.

- The AR6 Working Group I (AR6-WGI) report states “[c]limate change is a global phenomenon, but manifests differently in different regions” (IPCC 2021). IPCC projections for climate change in Australia from the AR6 Working Group II (AR6-WGII) report include:
 - further climate change is inevitable, with the rate and magnitude largely dependent on the emission pathway (*very high confidence*)⁵⁹
 - ongoing warming is projected, with more hot days and fewer cold days (*very high confidence*)
 - further sea level rise, ocean warming, and ocean acidification are projected (*very high confidence*)
 - less winter and spring rainfall is projected in southern Australia, with more winter rainfall in Tasmania, less autumn rainfall in southwestern Victoria and less summer rainfall in western Tasmania (*medium confidence*), with uncertain rainfall changes in northern Australia
 - more extreme fire weather is projected in southern and eastern Australia (*high confidence*)
 - increased drought frequency is projected for southern and eastern Australia (*medium confidence*)
 - increased heavy rainfall intensity is projected, with fewer tropical cyclones and a greater proportion of severe cyclones (*medium confidence*) (Lawrence et al., 2022).
- The AR6-WGII also contains information about projected impacts to health and well-being for the Australasian region including, amongst others:
 - detrimental effects on human health due to heat stress, changing rainfall patterns including floods and drought climate-sensitive air pollution (including that caused by wildfires) (*high confidence*) and vector-borne diseases (*medium confidence*)
 - vulnerability to detrimental effects of climate change will vary with socioeconomic conditions (*high confidence*) (Lawrence et al. 2022).

For further information related to Woodside’s approach to climate change, please see Section 5.3 ‘Managing Physical Risk’ and Section 6.3 ‘A Just Transition’ of Woodside’s Climate Transition Action Plan and 2023 Progress Report.

The AR6-WGII report identified nine key climate risks for the Australasian region:

- loss and degradation of coral reefs and associated biodiversity and ecosystem service values in Australia due to ocean warming and marine heatwaves (*very high confidence*)
- loss of alpine biodiversity in Australia due to less snow (*high confidence*)
- transition or collapse of alpine ash, snowgum woodland, pencil pine and northern jarrah forests in southern Australia due to hotter and drier conditions with more fires (*high confidence*)
- loss of kelp forests in southern Australia due to ocean warming, marine heatwaves, and overgrazing by climate-driven range extensions of herbivore fish and urchins (*high confidence*)
- loss of natural and human systems in low-lying coastal areas due to sea level rise (*high confidence*)
- disruption and decline in agricultural production and increased stress in rural communities in south-western, southern and eastern mainland Australia due to hotter and drier conditions (*high confidence*)
- increase in heat-related mortality and morbidity for people and wildlife in Australia due to heatwaves (*high confidence*)
- cascading, compounding and aggregate impacts on cities, settlements, infrastructure, supply-chains and services due to wildfires, floods, droughts, heatwaves, storms and sea level rise (*high confidence*)
- inability of institutions and governance systems to manage climate risks (*high confidence*) (Lawrence et al., 2022).

An earlier report by Australia’s Biodiversity and Climate Change Advisory Group summarised the potential impacts of climate change to marine and terrestrial species, habitats and ecosystems across Australia (Steffen et al., 2009). The 2009 report identified examples of observed changes in Australia’s biota that were considered consistent with the emerging climate change ‘signal’, as genetic constitution, geographic ranges, lifecycles, populations, ecotonal boundaries, ecosystems, and disturbance regimes (Steffen et al., 2009). The report also stated:

- “Biodiversity is one of the most vulnerable sectors to climate change”.

⁵⁹ A level of confidence is expressed using five qualifiers: very low, low, medium, high, and very high. For a given evidence and agreement statement, different confidence levels can be assigned, but increasing levels of evidence and degrees of agreement are correlated with increasing confidence (Lawrence et al., 2022).

Detailed Impact/Risk Assessment

- “Australia’s biodiversity is not distributed evenly over the continent but is clustered in a small number of hotspots with exceptionally rich biodiversity”, and that these “include the Great Barrier Reef, south-west Western Australia, the Australian Alps, the Queensland Wet Tropics and the Kakadu wetlands”.

Further, it was stated that “many of the most important impacts of climate change on biodiversity will be the indirect ones at the community and ecosystem levels, together with the interactive effects with existing stressors (Steffen et al., 2009). Future climate change (e.g., increased temperature and decreased, but more variable, rainfall) has the potential to have a range of impacts on ecological factors and threaten biodiversity in the Australian Mediterranean ecosystem (CSIRO, 2017).

Extensive modelling and monitoring studies over the last twenty years provide considerable evidence that global climate change is already affecting and will continue to affect species (Hoegh-Guldberg et al., 2018); however, these impacts are likely to be highly species-dependent and spatially variable. The most frequently observed and cited ecological responses to climate change include species distributions shifting towards the poles, upwards in elevation and shifts in phenology (earlier and later autumn life-history events) (M. Dunlop et al., 2012). Climate change may not only change species distribution patterns but also life-history traits such as migration patterns, reproductive seasonality and sex ratios (Steffen et al., 2009).

Impacts of climate change such as altering temperature, rainfall patterns and fire regimes, are likely to lead to changes in vegetation structure across all terrestrial ecosystems within Australia (M. Dunlop et al., 2012; Steffen et al., 2009). Increases in fire regimes will impact Australian ecosystems altering composition structure, habitat heterogeneity and ecosystem processes. Changes in climate variability, as well as averages, could also be important drivers of altered species interactions, both endemic and invasive species (M. Dunlop et al., 2012). Climate change could result in significant ecosystem shifts, as well as alterations to species ranges and abundances within those ecosystems (Hoegh-Guldberg et al., 2018).

The ‘loss of climatic habitat caused by anthropogenic emissions of greenhouse gases’ has been listed as a key threatening process under the EPBC Act (DCCEEW, 2021). The threatening process consists of reductions in the bioclimatic range within which a given species or ecological community exists due to emissions induced by human activities of greenhouse gases (DCCEEW, 2021). The process is considered to have a continental distribution, including both terrestrial and marine areas. Ecosystems in which the process occurs include: alpine habitats, coral reefs, wetlands and coastal ecosystems, polar communities, tropical forests, temperate forests, and arid and semi-arid environments (DCCEEW, 2021).

Coral reefs were recognised by both IPCC and the Australian Government as being at risk of climate change (Lawrence et al., 2022; DCCEEW, 2021). Protected coral reef areas in Australia include those within World Heritage listed sites, such as Ningaloo Coast, Shark Bay, or the Great Barrier Reef. Climate change has been identified as a threat for each of these World Heritage areas, with potential risks to coral reef as well as other environmental values (such as marine fauna) within these ecosystems (IUCN, 2020b, 2020c, 2020a).

Climate variability and change has been identified as a threat to some EPBC Act protected species, including marine turtles, whales, seabirds and migratory shorebirds:

- The Recovery Plan for Marine Turtles in Australia (CoA 2017) states that “[c]limate change is of particular concern to marine turtles because it is likely to have impacts across their entire range and at all life stages. Climate change is expected to cause changes in dispersal patterns, food webs, species range, primary sex ratios, habitat availability, reproductive success and survivorship”.
- The Conservation Management Plan for the Blue Whale (CoA 2015a) states: “[c]limate change is expected to cause changes in migratory timing and destinations, population range, breeding schedule, reproductive success and survival of baleen whales, including blue whale species and subspecies”.
- The Wildlife Conservation Plan for Seabirds (CoA 2022) states that “[c]onsequences to seabirds could include negative impacts from an increase in extreme weather events, reduced or changed prey abundance and distribution, and decrease in nesting habitat”.
- The Wildlife Conservation Plan for Migratory Shorebirds (CoA 2015) states that “[s]uch changes have the potential to affect migratory shorebirds and their habitats by reducing the extent of coastal and inland wetlands or through a poleward shift in the range of many species”.

The Recovery Plan for the Southern Right Whale (DCCEEW, 2024b) states that ‘modelling the links between krill and whale population dynamics with climate change, including changes in ocean temperature, primary productivity, and sea ice, suggests future ocean conditions are likely to have a negative impact on krill populations and in association the baleen whale species that feed on them.’ The North-west Marine Parks Network Management Plan 2018 (DNP, 2018) identifies climate change as a pressure that may impact marine park values. The management plan states that “[t]he impacts of climate change on the marine environment are complex and may include changes in sea temperature, sea level, ocean acidification, sea currents, increased storm frequency and intensity, species range extensions or local extinctions, all of which have the potential to impact on marine park values” (DNP, 2018).

Detailed Impact/Risk Assessment				
Within the Marine Bioregional Plan for the NWMR (DSEWPaC, 2012), pressures related to climate change are assessed as 'of potential concern' for species of marine turtle, inshore dolphins, sawfish, sea snakes, whale shark, dugong, and seabird and shorebird, as well as the KEFs and shipwrecks known to occur in the NWMR.				
Summary of Assessment Outcomes				
Receptor	Impact	Receptor Sensitivity Level	Magnitude	Impact Significance Level
Global atmospheric GHG concentration	Reduction of global carbon budgets estimated to meet goals of Paris Agreement	Low ⁶⁰	No lasting effect ⁶¹	Negligible (F)
<p>Overall Impact Significance Level:</p> <p>Climate change impacts cannot be attributed to any one activity as they are instead the result of global GHG emissions, minus global GHG sinks, that have accumulated in the atmosphere since the industrial revolution started. They do not take into account the net impact of each project or activity. Even discounting the role gas can play towards customer commitments and plans to decarbonise through the energy transition, emissions associated with the project are expected to have a de minimis impact to global carbon budgets estimated to meet goals of the Paris Agreement.</p> <p>Scarborough and downstream processing facilities will also comply with the Federal Safeguarding Mechanism Baseline, aligning with Australia's carbon management framework and implementation of the Paris Agreement</p>				

Demonstration of ALARP				
Control Considered	Control Feasibility (F) and Cost/Sacrifice (CS)	Benefit in Impact/Risk Reduction	Proportionality	Control Adopted
Legislation, Codes and Standards				
Vessels will comply with Marine Order 97 (Marine pollution prevention – Air pollution).	F: Yes. CS: Minimal cost. Standard practice	Legislative requirements to be followed may slightly reduce the likelihood of air pollution.	Control based on legislative requirements – must be adopted.	Yes C 6.1
Additional controls related to emissions associated with helicopter travel	F: No. Helicopter travel is already highly optimised due to fuel payload and safety considerations CS: Not assessed, not feasible	Minimal potential benefit. Emissions associated with helicopter travel are ~0.002% of annual emissions, considered ALARP and Acceptable	Not assessed, control not feasible	No
Reporting GHG emissions associated with the project in accordance with National Greenhouse and Energy Reporting Scheme (NGERS), National Pollutant Inventory (NPI) and other legislative requirements	F: Yes. CS: Minimal cost. Standard practice for Woodside activities.	Control based on legislative requirements to provide the national reporting framework for the reporting and dissemination of information related to emissions, hazardous wastes, greenhouse gas emissions, greenhouse gas projects, energy consumption and energy	Control based on legislative requirements – must be adopted	Yes C 6.2

⁶⁰ As described in sections above, global atmospheric GHG concentrations have been subject to anthropogenic trends since the industrial revolution and has low sensitivity to contributions on the scale of the project.

⁶¹ Based on assumption that GHG emissions associated with the project are additive to global concentrations, the contribution to carbon budgets expected to meet the goals of the Paris Agreement is de minimis

Control Considered	Control Feasibility (F) and Cost/Sacrifice (CS)	Benefit in Impact/Risk Reduction	Proportionality	Control Adopted
Forecast, measure and or estimate facility fuel and flare GHG emissions from the FPU (in accordance with NGERs/NPI) to inform optimisation management practices and minimise environmental impact of direct Scarborough emissions.	F: Yes CS: Minimal cost. Standard practice.	Minimises environmental impact of emissions through planning, ongoing review, governance and optimisation. It combines with good operating practice to maximise production and reduce flaring and fuel emissions at Scarborough and onshore processing to manage cost, which improves energy intensity (e.g., cleaner production), optimising emissions. Fuel and flared gas are potential product streams, as such, Woodside applies routine short and long term optimisation and opportunity management framework to identify and prioritise enhancement opportunities. Annual fuel and flare target setting and monthly review of performance will be completed for Scarborough, and also at onshore processing facilities for indirect emissions.	Control is WMS requirement – must be adopted.	Yes C 6.5
Develop and implement asset specific Methane Action Plan, which shall detail: <ul style="list-style-type: none"> planned measurement activities; inventory of methane sources; suitable methane mitigation/minimisation projects. 	F: Yes CS: Some cost associated with implementation of commitments. Can be managed by proving technology application and process at onshore facilities and applying, where appropriate, to Scarborough.	Implementing asset specific Methane Action Plan enables achievement of Woodside corporate objectives as described in Section 7.2.4.5 as well as global methane reduction initiatives.	Control has been committed by Woodside as part of corporate objectives – must be adopted	Yes C 6.6
Contracting strategy and evaluation for hire of support vessels includes consideration of vessel emissions parameters and low carbon/alternative fuels.	F: Yes. CS: Fuel cost over the five year contract is considered in the evaluation of responses, allowing for competitive consideration of low carbon alternatives.	Minimises costs and emissions through eco-efficiency approach recognising cost of fuel and carbon emissions over the contract term.	Control effectively allocates a cost to emissions to recognise that higher emitting fuel sources with other lower operating costs do not represent overall best value.	Yes C 6.7
Track and review GHG emissions from vessel	F: Yes	Minimal potential benefit related to emissions	Implementation of control is not	No

activity during the Petroleum Activities Program with the objective to identify further opportunities to improve efficiencies if possible	CS: Cost of implementation tracking process and costs of implementing additional opportunities	reduction.Vessels during Installation, Hook-up and Commissioning will undertake activities for a short period and are estimated to contribute 0.04MtCO ₂ e. Vessels during operations phase including for support, IMMR and gravimetry activities will be short and intermittent in nature and are estimated to contribute 0.005 MtCO ₂ e annually. Woodside's engages vessels through an integrated approach across its portfolio and assesses emissions reduction as part of the contracting process (C 6.7). Woodsides previous experience across its contracted vessels, suggests that opportunities to reduce vessel emissions are limited, and often already implemented if practicable. E.g. newer vessels with higher efficiency engines and reduction in fuel use through efficient planning leads to simultaneous cost and emissions reduction. Vessel emissions in operations are reduced to ALARP with the implementation of C 6.7.	proportionate to the benefit gained.	
Vessel contractors undertaking hook up and commissioning activities will be engaged during activity planning to identify additional GHG opportunities where feasible.	F: Yes CS: Time and resources in implementing process to identify GHG reduction opportunities.	Engaging contractors during planning for the activity may allow for additional emissions opportunities to be identified, reducing overall emissions.	Benefit does not outweigh cost/sacrifice. GHG emissions from vessels involved in hook up and commissioning activities are not significant due to short duration of activities. Fuel usage in vessels is intrinsically ALARP due to reduced fuel usage being associated with	No

Demonstration of ALARP				
Control Considered	Control Feasibility (F) and Cost/Sacrifice (CS)	Benefit in Impact/Risk Reduction	Proportionality	Control Adopted
Eliminate flaring by reinjecting un-combusted hydrocarbons	F: No. Routine hydrocarbon reinjection, as opposed to transport to onshore facilities, would not be consistent with the approved Scarborough Field Development Plan (FGP) which seeks to optimize hydrocarbon recovery whilst fulfilling Scarborough gas supply commitments. As such, gas reinjection would not meet concept screening criteria to warrant option evaluation. CS: not assessed, control not feasible.	Not assessed, control not feasible	Not assessed, control not feasible. Implementation of Zero Routine Flaring Initiative largely meets the same goal.	No
Eliminate emissions related to offshore power generation at the Scarborough FPU by powering it from an onshore renewable power source	F: Yes CS: Significant costs associated with acquiring a significant amount of renewable energy such as solar and, construction and maintenance of an offshore power cable is disproportionate to the benefit.	Power generation at the FPU creates emissions related to the burning of fuel (gas or diesel) to run the power turbines. Displacing these fuel sources with onshore sources has the potential to reduce emissions generated at the FPU. Given the significant costs and proportionately low emissions produced at the FPU and temporary impact to the local air shed	Grossly disproportionate. Implementation of this control requires considerable cost with minimal environmental benefit.	No
Do not combust fuel.	F: No. If the facility was powered with electricity from shore or local low carbon source, backup power generation still required for safety during outages. CS: Not considered – control not feasible.	Not considered – control not feasible.	Not considered – control not feasible.	No
Professional Judgement – Engineered Solution				
The facility has been designed to reduce direct GHG emissions to ALARP, by implementing a number of GHG abatement opportunities in design and	F: Yes CS: Varies, considered commensurate	An estimated 13% reduction of emissions compared to reference case design has been achieved through design phase	Potential benefit outweighs cost/sacrifice	Yes C 6.15

Demonstration of ALARP				
Control Considered	Control Feasibility (F) and Cost/Sacrifice (CS)	Benefit in Impact/Risk Reduction	Proportionality	Control Adopted
operational planning. These are described in Table 6-23				
Maintaining flare ignition and monitoring mechanisms, to maximise efficiency of combustion and minimise venting, incomplete combustion waste products.	F: Yes. CS: Minimal cost. Standard practice.	Flare tip integrity and ignition and monitoring system functionality minimises potential for venting, incomplete combustion waste products and smoke emissions.	Benefits outweigh cost/sacrifice	Yes C 6.11
Free flow to shore rather than having an offshore facility, or to further minimise offshore processing requirement	F: No, precluded by slugging issues caused by liquids in long trunkline and distance for MEG circuit. Would significantly impact ability to recover reserves without compression CS: Not considered, control not feasible	Removal of offshore facility may reduce direct GHG emissions, however would increase associated onshore emissions	Not considered, control not feasible	No
Dewpoint control using a turbo-expander rather than Joule-Thompson valve (to capture power from gas expansion)	F: Yes CS: Additional cost associated with more complex equipment selection, operation and maintenance requirements for rotating equipment	Turboexpander can generate lower temperature gas more efficiently than a JT valve, and recover power from gas expansion. This could marginally improve facility efficiency	Not proportional. Minor efficiency benefit outweighed by introduction of complex equipment (rotating equipment) with operational and maintenance requirement not aligned with minimally attended concept.	No
Use of printed circuit (PCHE) rather than shell and tube for gas-gas heat exchanger	F: Yes CS: Minor cost of more complex equipment, however fouling risk of PCHE increases maintenance requirements	Minor benefit to heat transfer in gas/gas exchanger could marginally improve facility efficiency	Not proportional. Fouling risk associated with PCHEs in "dirty" service introduces unacceptable reliability issues/maintenance requirement.	No
Deep seawater intake to reach cooler water and reduce system flow/pumping requirements	F: No, due to deep thermocline at location would need to be >250m deep to reach significantly cooler water CS: Not considered, control not feasible	Potential reduction in power requirement for seawater cooling lift and pumping	Not considered, control not feasible	No

Demonstration of ALARP				
Control Considered	Control Feasibility (F) and Cost/Sacrifice (CS)	Benefit in Impact/Risk Reduction	Proportionality	Control Adopted
Combined cycle gas turbines ⁶⁶	F: Yes CS: Additional cost associated with more complex equipment selection, operation and maintenance requirements. Additional weight, footprint and support requirements	Combined cycle gas turbines could use heat from turbine exhaust to produce steam, which then powers separate additional turbines to generate electricity. This could reduce emissions associated with power generation. However, the electrical load on the topsides is relatively small	Not proportional. Additional complex equipment on topsides with weight, support, operational and maintenance requirements outweighs potential benefit. Adoption of CCHT would also introduce dependency between power generation and export turbine operation	No
Carbon Capture and Storage ⁶⁷	F: No, requires an amenable reservoir to inject GHG emissions to, and significant infrastructure to capture GHG emissions not feasible for an offshore floating facility CS: Not considered, control not feasible	Reducing direct emissions from the FPU by capturing and sequestering some of the GHG emissions	Not considered, control not feasible	No
Electrification of compressor drive (e-drive compressors) ⁶⁸	F: Yes CS: Cost associated with alternative equipment selection	Implementation of electric compressor drives instead of gas turbine drives could reduce an emission source associated with fuel gas combustion. However, the distance offshore means that the large electrical power requirements would be generated onboard by other turbines burning fuel gas and creating emissions. Supply of power from shore would similarly come from existing gas-driven sources	Not proportional	No
Unloading of wells to the FPU rather than the MODU	F: Yes CS: Minor cost	Reduction in GHG emissions from volume of gas flared during the unloading process and fuel	Potential benefit outweighs cost/sacrifice.	Yes C 6.12

Demonstration of Acceptability

- indirect GHG emissions associated with Scarborough will be managed to ALARP and an acceptable level through the implementation of the controls detailed below.
- Feedback, objections and claims from Relevant Persons were considered, see Appendix F
- **Precautionary Principle**
 - there is some scientific uncertainty associated with the projection of climate change trends, the predicted and observed environmental effects of climate change, and the changing regulatory and social requirements and/or expectations
 - Woodside has committed to management and mitigation measures for GHG emissions to ensure that Scarborough continues to manage GHG emissions to an ALARP and acceptable level
- **Intergenerational Principle**
 - continue to provide LNG as a source of fuel for global markets and pursue the development of new energy products and lower carbon services with reference to the UN Sustainable Development Goal 7, Affordable and Clean Energy
 - gas having the potential to contribute to an incremental reduction in global GHG emissions by displacing more carbon intensive power generation (e.g., coal), firming up renewables, or in hard-to-abate sectors
 - Woodside considers that this development is aligned with its goals for supporting the energy transition and is compatible with the Paris Agreement goal to hold “the increase in the global average temperature to well below 2°C above pre-industrial levels and to pursue efforts to limit the temperature increase to 1.5°C.”
- **Biodiversity Principle**
 - the existing environment (Section 7) identifies and describes relevant MNES, as defined in regulation 7(3) of the Environment Regulations; any relevant values and sensitivities are included in the contextual evaluation of climate change.
 - As described above the estimated GHG emissions associated with the Scarborough Project will have a de minimis contribution the net atmospheric global GHG concentrations and therefore are not expected to affect biodiversity.

Woodside looks after the communities and environments where we operate. Risks are inherent in petroleum activities; however, through sound management, systematic application of policies, standards, procedures and processes

Internal Context

The Petroleum Activities Program is consistent with Woodside corporate policies, culture, processes, standards, structure and systems as outlined in the Demonstration of ALARP and Environmental Performance Outcomes, including:

- Woodside Environment and Biodiversity Policy (Appendix A: Woodside Policies)
- Woodside Risk Management Policy (Appendix A: Woodside Policies)
- Woodside Climate Policy (Appendix A: Woodside Policies)
- Woodside being a signatory to the Aiming for Zero Methane Emissions Initiative, the Oil and Gas Methane Partnership 2.0 and the World Bank’s Zero Routine Flaring by 2030 Initiative for oil projects.
- WMS requirements such as the GHG emissions and Energy Management Procedure and Production Optimisation and Opportunity Management Procedure, which require continuous improvement and demonstration of ALARP in the context of the asset. This is achieved by implementing tools to identify, evaluate, implement and review emissions reductions projects and develop, govern and report on plans to reduce methane fugitive emissions.
- Equipment has been designed to meet engineering design requirements where applicable. Any deviations to standards are supported by appropriate technical input and verification, ensuring design intent remains uncompromised

External Context

GHG emissions are a global concern, and as such Woodside has undertaken an impact assessment of GHG associated with the Scarborough facility and identified key measures to manage GHG emissions to an acceptable level.

The global consensus on climate change led to the implementation of the Paris Agreement. The aim of the Paris Agreement, as stated in the Article 2.1(a), is to hold the increase in global average temperature to well below 2°C above pre-industrial levels. The Agreement also aims to pursue efforts to limit the temperature increase to 1.5°C above pre-industrial levels, recognising that this would significantly reduce the risks and impacts of climate change.

Paris Agreement text extract⁶⁹:

“Article 2

1. This Agreement, in enhancing the implementation of the Convention, including its objective, aims to strengthen the global response to the threat of climate change, in the context of sustainable development and efforts to eradicate poverty, including by:

(a) Holding the increase in the global average temperature to well below 2 °C above pre-industrial levels and pursuing efforts to limit the temperature increase to 1.5 °C above pre-industrial levels, recognizing that this would significantly reduce the risks and impacts of climate change;”

This was reaffirmed in December 2023 in the COP28 decision text on the First global stocktake.⁷⁰ The text further recognised that the transition away from fossil fuels in energy systems is to be done in a just, orderly and equitable manner accelerating action in this critical decade, so as to achieve net zero by 2050 in keeping with the science.⁷¹ It also recognises that transitional fuels can play a role in facilitating the energy transition while ensuring energy security⁷². The Paris Agreement establishes a framework where countries make Nationally Determined Contributions (NDCs) to manage and reduce their own emissions.

Australia has ratified the Paris Agreement and has set a target to reduce emissions by 43% below 2005 levels by 2030 and to reach net-zero emissions by 2050. Australia’s emissions projections under a ‘with additional measures’ scenario is projected to be 42.6% below 2005 levels by 2030, the next waypoint to net zero emissions by 2050 (DCCEEW 2024c) Climate science has drawn a link between cumulative emissions of GHG and global temperature levels. The link between cumulative emissions and temperature levels allows a carbon budget to be calculated. This is the remaining amount of net emissions (i.e. all global sources of emissions minus all global sinks of emissions) that can occur before today’s concentration of greenhouse gases increases to the concentration associated with potential temperature outcomes.

Assuming the scenario in which all GHG emissions associated with the Scarborough project are additive to global GHG gas concentrations, which they may not be, the project’s contribution to the carbon budget required to meet the goals of the Paris Agreement is de minimis.

However, the distribution of this carbon budget across different human activities requires additional judgements about a wider range of social, economic and technological factors and consumer and policy choices. Strategies to achieve emissions reductions include transitioning from fossil fuels without CCS to very low-or zero-carbon energy sources, such as renewables or fossil fuels with CCS, demand side measures and improving efficiency, reducing non-CO2 emissions, and deploying carbon dioxide removal (CDR) methods to counterbalance residual greenhouse gas emissions. Pathways to limit warming therefore show different combinations of sectoral mitigation strategies consistent with a given warming level.

As a result the demand for oil and gas in climate-related scenarios that could limit global warming to 1.5°C or 2°C is uncertain. For example in the AR6-WG3 report, the IPCC stated that in pathways that limit warming to 1.5°C (with a greater than 50% probability and with no or limited overshoot) the potential global use of gas in 2050 ranges from 30% above 2019 levels to 85% below them with a median 45% decline.

Woodside considers our role in providing energy as core to our contribution to a just energy transition. UNSD Goal 7 is to “ensure access to affordable, reliable, sustainable and modern energy for all”. The FPU, will provide an incremental volume of hydrocarbons to Australian and international markets during its estimated field life (approximately 30 years). Woodside considers that this development is aligned with goals for supporting the energy transition and is compatible with the Paris Agreement goal.

Woodside is a signatory to several global initiatives which are complementary to our corporate approach to methane emissions management, which include OGMP 2.0 (2024), Oil and Gas Climate Initiative Aiming for Zero Methane Emissions (OGCI Near-Zero) and the Methane Guiding Principles (MGP, 2022), which are voluntary, international multi-stakeholder partnerships between industry and non-industry organisations. Woodside is actioning these commitments at the Scarborough facility in line with the control measures (C.6.6), detailed in Section 7.2.4.5.

External context – stakeholder expectations and feedback

GHG emissions associated with the project, and the impacts of climate change, were noted as a material issue for relevant persons consulted in the course of preparing this EP. All feedback, claims or objections from Relevant Persons has been appropriately responded to and addressed (see Appendix F), and controls proposed have been assessed in the EP.

Other Requirements (Includes Laws, Polices, Standards and Conventions)

Legislation and other requirements considered relevant for this aspect, and a demonstration of how these requirements are met, are described in Table 6-26

Table 6-26 Legislation and other requirements relevant to greenhouse gas emissions

Requirement	Demonstration
Marine Order 97 Gives effect to Annex VI of MARPOL 73/78	The requirements of Marine Order 97 are incorporated into the key control measures.

Demonstration of Acceptability

As per Section 2.3.6, decision type B, GHG emissions are acceptable if “ALARP” is demonstrated using good industry practice and risk-based analysis, if legislative requirements are met and societal concerns are accounted for and the alternative control measures are grossly disproportionate to the benefit gained. In addition, acceptability is assessed against the above criteria. Further opportunities to reduce GHG emissions have been investigated (refer ALARP demonstration discussion). The potential impacts are considered acceptable if ALARP is demonstrated.

Indirect GHG emissions associated with Scarborough are managed to an acceptable level by meeting (where they exist) legislative requirements, industry codes and standards, applicable company requirements, and industry guidelines, and these have been adopted as key controls.

Even discounting the role gas can play towards customer commitments and plans to decarbonise through the energy transition, emissions associated with the project are negligible in the context of existing and future predicted global GHG emissions. As described above, even in the hypothetical scenario when taken to be wholly additive, the GHG emissions created by and associated with the project represent a de minimis contribution to the carbon budgets estimated to achieve the goals of the Paris Agreement. Further, the Project will comply with the relevant Australian carbon management framework, for example the Federal SGM. The impact on national and international emission reduction targets is therefore negligible and acceptable.

Routine Atmospheric Emissions – Offshore, and indirect emissions from gas processing onshore
Description of Source of Impact/Risk
<p>Background</p> <p>Offshore activities, and the processing of gas from the Scarborough project at onshore facilities will result in the release of atmospheric emissions. Atmospheric emissions are the gases and particulates released into the atmosphere from an activity, which may have an adverse effect on human health or the environment. The main emissions responsible for these effects include carbon monoxide (CO), oxides of nitrogen (NOx), sulphur dioxide (SO2), particulate matter less than 10 microns (PM10), non-methane volatile organic compounds (VOCs) and BTEX (benzene, toluene, ethylbenzene and xylenes), which are specific VOCs of interest.</p> <p>Sources of atmospheric emissions from offshore activities and processing of Scarborough gas onshore include:</p> <ul style="list-style-type: none"> • combustion • flaring • venting.

Gas from the Scarborough project transported to shore through the trunkline is planned to be processed at the Pluto LNG Facility. A small volume of gas from the Scarborough project may also be processed at Karratha Gas Plant. It will then be sold as LNG and delivered to customers via ship or road, or distributed to customers via pipeline for domestic consumption for purposes such as heating, electricity generation or industrial processes such as the production of LNG, ammonia, urea or hydrogen.

This section relates to atmospheric emissions that arise from processing of gas exported from the FPU to onshore facilities. While the operation and scope of these onshore processing facilities are outside the scope of this Environment Plan, the atmospheric emissions associated with processing Scarborough gas at these facilities is addressed in this section. The processing facilities addressed in this section are the Pluto LNG facility and Karratha Gas Plant. Further, given its proximity to Murujuga and that it will use Scarborough gas, this section also addresses emissions associated with the use of Scarborough gas at the Perdaman Urea facility.

Potential indirect impacts considered in this section include potential impacts to human health and the potential contribution to accelerated weathering of rock art on the Burrup Peninsula and within the Dampier Archipelago (i.e. Murujuga), which has been raised by stakeholders and Regulator to be assessed in this EP.

This section provides contextual evaluation of consideration for any potential indirect impacts, particularly consideration of the potential for air emissions (attributable to the PAA) to cause a reduction in ambient air quality impacting human health. This section also addresses whether any potential impacts to air quality (attributable to the PAA) have potential to contribute to accelerated weathering of rock art on the Burrup Peninsula and within the Dampier Archipelago (i.e. Murujuga). Neither of these potential indirect impacts can be considered in isolation, as they are the result of cumulative airshed conditions.

No other indirect impacts or risks from the release of atmospheric emissions are considered within this Environment Plan.

Murujuga Rock Art Strategy

The WA State Government (DWER) have established a Murujuga Rock Art Strategy (MRAS) in partnership with MAC as the Traditional Owners and custodians of Murujuga.

DWER has primary responsibility for the day-to-day implementation of the strategy in partnership with MAC. This includes working with MAC to oversee the development and implementation of a world’s best practice monitoring and analysis program that will determine whether the rock art on Murujuga is subject to accelerated change (for further information see Murujuga Rock Art | Western Australian Government (www.wa.gov.au)).

The results from studies underway will guide management and protection of Murujuga rock art, with State environmental protection and heritage legislation in place as the applicable regulatory framework.

MRAS states that:

“The data currently available from previous monitoring projects does not allow for a conclusive answer on whether anthropogenic emissions are impacting Murujuga’s rock art. The Murujuga Rock Art Strategy is therefore essential to fill these gaps in knowledge.

Although it is not known whether the rock art is being impacted currently, there are feasible impact pathways by which emissions from industrial activities and other local sources could cause accelerated weathering of the rock art. The strategy is examining these potential pathways and the condition of the rock art to understand whether change is occurring, and whether there is a need to set a future limit on emissions to ensure accelerated weathering does not occur.”

Therefore, as a causal link between industrial air emissions and anthropogenic-induced change to rock art on Murujuga has not been established, nor sources and potential pathways defined – it is not appropriate to attribute potential impact to the Scarborough PAP. This section acknowledges uncertainty in this topic, and provides context with regard to emissions related to the onshore processing of Scarborough gas, and provides a summary of adaptive and precautionary management frameworks in place by way of the MRAS/MRAMP together with the State Environmental Protection (EP) Act 1986 (WA), regulatory framework and administration.

The MRAS and MRAMP follow a history of studies and monitoring under previous bodies such as the BRATWG and BRAMMC, as described in section 4.9.6.

Source of Direct Emissions

National Pollutant Inventory (NPI) Emission Estimation Techniques were applied to estimate annual atmospheric pollutants (non-GHG emissions) (NOx, SOx and CO) from fuel combustion (diesel and fuel gas) and flaring on the FPU.

Table 6-27: Estimated direct annual atmospheric emissions from fuel combustion and flaring during commissions and start-up, and under steady state operations (excluding support vessels)

Component	Estimated annual emissions from fuel gas combustion during operations (tonnes)	Estimated annual emissions from diesel combustion, during commissioning and start up (tonnes)	Estimated annual emissions from diesel combustion during operations (tonnes)

NO _x	9	141
CO	53	817

Based on estimated annual emissions within this EP period. Variance within the period may occur.

Reference for NOx and CO components: NPI EET Manual for Oil and Gas v2.0 2013, Table 8.

Source of Atmospheric Emissions from Onshore Processing

The principal source of atmospheric emissions associated with onshore processing will be from the combustion of gas in fuel turbine generators and compressors as well as gas conditioning process vents at onshore facilities. Gas processing and liquefaction can also result in flaring of some gas and incidental venting of un-combusted gas. The most significant by-products of gas combustion, flaring and venting of gas from the Scarborough project will include oxides of nitrogen (NOx), carbon monoxide (CO), methane and non-methane volatile organic compounds (VOCs) including BTEX (benzene, toluene, ethylbenzene and xylenes).

Ozone is not emitted typically directly from gas consumption or processing, but is formed through anthropogenic sources via chemical reactions between oxides of nitrogen and other emissions such as VOCs and CO in the presence of ultraviolet light. There may also be traces of particulate matter (PM) and sulphur dioxide (SO₂) but such emissions are generally considered negligible from the onshore processing of Scarborough gas, due to fact it has a very low sulphur content and absence of products that are precursors to the formation of particulate pollution. Emissions of PM from the consumption of gas from the Scarborough project is negligible in comparison to background and other industrial sources.

Sources of Emissions within the Murujuga Airshed

Potential indirect impacts from processing of gas from Scarborough could arise via a contribution to the cumulative effect of all emissions in the airshed. The Murujuga airshed encompasses the entire Burrup Peninsula and includes the population centres of Dampier and Karratha and surrounding areas. Industrial facilities that currently release or have approval to emit into the Murujuga airshed include⁷⁹ :

- Woodside Operated North West Shelf Venture’s Karratha Gas Plant (KGP)
- Woodside Operated Pluto LNG Facility
- Yara Pilbara Fertilisers Pty Ltd Ammonia Plant
- Yara Pilbara Nitrates Pty Ltd Technical Ammonium Nitrate Production Facility (TANPF)
- Perdaman Urea Project
- Pilbara Iron Yurralyi Maya Power Station
- Santos Devil Creek Power Station
- ATCO Karratha Power Station
- EDL West Kimberley Power Plant (Maitland LNG Plant).

Atmospheric Emissions into the Murujuga Airshed from Onshore Processing of Gas from the Scarborough Project

Emissions associated with onshore processing of Scarborough gas are combined with similar emissions from natural sources and other industrial activities in proximity of the Murujuga region. Assessment of potential impacts considers cumulative impacts within the airshed rather than estimating emissions influence associated with processing gas from Scarborough in isolation. Further, estimating ground level concentrations of atmospheric constituents as related to

⁷⁹https://www.epa.wa.gov.au/sites/default/files/EPA_Report/EPA%20Report%201727%20-%20North%20West%20Shelf%20Extension%20Project%20-%20assessment%20report.pdf

human health and deposition relies on complex non-linear photochemical modelling, underpinned by biochemical and physical forcing systems such as regional meteorological forcing model.

Therefore, impact assessment is based on a cumulative airshed modelling inclusive of contribution from onshore processing of Scarborough gas, and other material sources.

In 2021, DWER commissioned Ramboll Australia Pty Ltd to undertake a *Study of the Cumulative Impacts of Air Emissions in the Murujuga Airshed*⁸⁰ (Ramboll 2022) considered a “complete emission inventory” including air emissions from existing and proposed future industries, shipping, and aggregated sources in the Pilbara region. The study used the CAMx atmospheric emission model, which includes atmospheric photochemistry to evaluate concentrations of a range of pollutants including NOx, ozone, Sox, CO, VOCs, and particulates across two domains. The detailed 1.33 km grid encompasses the Dampier Archipelago, as far East as Wickham and as far West as 40 Mile Beach. Predicted ground level concentrations were evaluated at Karratha, Dampier, Hearson Cove and Ngajarli (Deep Gorge) and compared with relevant criteria in the National Environment Protection Measure (NEPM) air quality standards. Deposition rates were also predicted.

Emission estimates in the Ramboll 2022 study were based on a range of sources, including, publicly available datasets, engineering design estimates (maximum and averages) and facility level monitoring data which match the selected year’s meteorological data. The scenarios investigated as part of this study included:

- A baseline scenario reflecting 2014 sources, including all industrial, mobile, domestic and commercial as well as natural sources. This covers onshore gas processing at steady state operational capacity at Pluto Train 1 and KGP Gas Plants. The year 2014 was selected due to typical meteorology (Ramboll 2022). A comparison of modelled data with real-world air quality monitoring data was undertaken, which “indicated reasonable agreement with the measurements at Burrup Road, Dampier, and Karratha”
- A future scenario that considered the above scenario as a basis, but included proposed future additional industrial emissions sources in 2030. This scenario included operation of Pluto Train 1, Pluto Train 2, KGP and Perdaman onshore processing facilities at capacity which includes the processing of Scarborough gas, and other future projects.

Assumptions regarding non-industrial emissions considered in these scenarios were based on a range of sources (Ramboll 2022):

- Mobile sources:
 - Commercial shipping and boating, with data sourced from the maritime automatic identification system (AIS) which also identifies vessel type, enabling application of USEPA default specifications for engines. Recreational boating
 - vehicles, which included data from an ABS survey of motor vehicle use scaled down the region, vehicle registration information and traffic and road network data from Main Roads WA
 - aircraft, which applied techniques from NPI to data supplied by airports and public sources such as aircraft operator website and tracking tools
 - railways, based on public data on fuel consumption per tonne of minerals delivered and minesite production rates. All rail lines in the region are operated by mining companies
- Domestic and commercial sources:
 - estimates of population (with growth for future scenario),
 - other sources such as solvent and aerosol use (per capita data), bitumen road construction (materials usage), service stations (applying population data to service station locations), domestic fuel burning (from previous surveys) and others
- Natural sources such as vegetation, dust, bushfires and oceanic sources which came from other models

Specific assumptions for individual emission sources were provided by all regional parties in confidence to DWER or were otherwise estimated by Ramboll based on sources such as NPI for operating facilities, and as such are not published in the report. Woodside provided inputs to the Ramboll 2022 study in response to DWER’s data request, and these are aligned with scenario descriptions and assumptions described in North West Shelf Project Extension Environmental Review Document Appendix E Air Quality Impact Assessment⁸¹ (Jacobs 2019), Section 4, Scenarios 3 and 4 which included (amongst others):

- Airshed baseline
- NWS Extension Project with NOx improvement opportunities
- Expansion of Pluto (Train 2, fed by Scarborough gas)

⁸⁰ Study of the Cumulative Impacts of Air Emissions in the Murujuga Airshed: <https://www.wa.gov.au/system/files/2023-03/Study-of-the-cumulative-impacts-of-air-emissions-in-the-Murujuga-airshed.pdf>

⁸¹ NWS Extension Environment Review Document Appendices: <https://www.woodside.com/docs/default-source/current-consultation-activities/australian-activities/north-west-shelf-project-extension---appendices.pdf>

- Perdaman Urea project
- Methanol facility proposal

Ramboll used tools such as the EPA’s Proposal Search Tool and related assessment documentation (such as Environment Document Review or Works Approvals) to provide data on future proposed developments. The model performance was validated at a number of locations using real-world air quality monitoring data provided by DWER and industrial operators in the region. This indicated that NO₂ concentrations predicted by the model were “similar ranges at Karratha, but the model is biased high at Burrup Road and Dampier” which indicates that modelled outcomes at these locations on Murujuga are conservative. It also indicates that assumptions for model inputs are appropriate.

The Jacobs 2019 assumptions were developed with “reasonable and conservative emission estimates” for the purposes of completing a robust risk and impact assessment of industrial sources, such as elevated flare rates (Jacobs 2019). This is the “Future Burrup Strategic Industrial Area state (existing, approved and referred) with proposed emission reductions in place” referred to in Table 6-5 of the NWS Project Extension ERD⁸². The Jacobs 2019 report drew on an earlier aggregated air emissions inventory for the Pilbara region developed by SKM (2003) for sources such as biogenic emissions, vegetation sources and other natural sources, and other previous modelling studies. The Jacobs 2019 model outputs were compared with real-world air quality monitoring results from multiple locations, which indicated that the model was “performing well in terms of being able to accurately predict a variety of statistical results for NO₂. as measured by Woodside at the Burrup, Dampier and Karratha monitoring stations.” In addition to validating model performance, this also demonstrates that the assumptions used for existing emissions sources were appropriate.

Ramboll 2022 estimated that NO_x loads to the Murujuga airshed (1.33 km grid encompassing Dampier Archipelago, Murujuga, Karratha and Roebourne) from industrial sources were estimated to be 13,937 tonnes per year in 2014, representing the baseline scenario, and are forecast to decrease to 12,052 tonnes per year by 2030, within this reference frame. A significant contribution to this reduction is associated with commitments by the NWSJV to reduce NO_x emissions from the Karratha Gas Plant by 40% by 2030. The Ramboll study did not predict NO_x air concentrations in excess of current air quality standards in any modelled scenario.

The assumptions for Murujuga airshed NO_x emissions underpinning Ramboll 2022 are suitably conservative for reviewing contribution of KGP and Pluto for the onshore processing of Scarborough gas using information provided by the respective facilities, as described below:

Table 6-29: Comparison of modelled NO_x emission assumptions with recent reported information

	Pluto		KGP	
	<i>NO_x emission rate annual avg (g/s)</i>	<i>Source/comment</i>	<i>NO_x emission rate annual avg (g/s)</i>	<i>Source/comment</i>
Baseline Scenario (2014)	34.1 g/s (Train 1)	Jacobs 2019	281.1	Jacobs 2019
Current	29.1 g/s (Train 1 - 15% below modelled baseline)	Reported NPI data, 2022/23 period	248.7 (12% below modelled baseline)	Reported NPI data, 2022/23 period
Future emissions scenario assumptions	35.6 (Train 1) + 33.59 g/s (Train 2)	Train 2 estimates – Jacobs 2019	149.2 g/s (40% reduction commitment)	NWS Extension ERD commitment (Table 6-9, p 106)

The current trajectory of aggregated emissions in the Murujuga airshed indicates that the future emissions scenario assumptions considered by Ramboll 2022 were conservative because:

- Assumptions for Pluto Train 1 and Train 2 include conservatism as set out in the Jacobs report. Assumptions for Train 2 equipment are based on vendor specified performance, which is a conservative basis for emission estimation. This performance will be measured and validated in accordance with Condition 38 of the Pluto Train 2 Works Approval⁸³ which will include a summary of the environmental performance of equipment against design specifications and the Pluto AQMP (which is consistent with Jacobs 2019). Validation is also covered in section 5 of the Pluto AQMP

⁸² https://www.woodside.com/docs/default-source/current-consultation-activities/australian-activities/north-west-shelf-project-extension---environmental-review-document.pdf?sfvrsn=a8b10277_4

⁸³ https://www.der.wa.gov.au/our-work/licences-and-works-approvals/lwa-available-for-public-appeal/item/download/12092_8dfe908804d6cc7505eb20a79d09f08f

- KGP has commenced the NO_x reduction committed in the NWS Extension ERD⁸⁴ (see Table 6-9 on pg 106) with one LNG train planned to be taken offline between late 2024 and mid 2025 (Woodside 2024)
- Emissions estimates for the Perdaman urea project in Jacobs 2019 are 8.93 g/s. It is acknowledged that the current Perdaman Urea Project Air Quality Management Plan (2021) references an Air Quality Impact Assessment (Jacobs 2020) which estimates ‘based on engineering and other data’ total NO_x emissions for the plant of 11.7 g/s. This increase is 0.7% of the Ramboll future scenario and therefore negligible in context of the broader airshed
- It is Woodside’s understanding that the proposed Methanol plant is no longer proceeding⁸⁵, which for context was expected to contribute 28.05 g/s

Woodside is not aware of any reason why the future emissions scenario assumptions for contribution to the Murujuga airshed from non-Woodside sources are not appropriate. Any potential future development not considered in this scenario would be required to undergo its own assessment process under regulatory frameworks (described below). Further, the MRAS/MRAMP is expected to identify any ongoing or future trends in air quality which could potentially impact rock art.

The Ramboll 2022 study found that “SO₂, NO₂, PM_{2.5}, PM₁₀, CO and NH₃ peak ground level concentrations are centered at industrial facilities near or on the Burrup Peninsula, showing that industrial sources and shipping contribute to emissions in the area, but with total air concentrations for these compounds remaining below current air quality standards except for PM_{2.5} and PM₁₀.” The report also noted that the governing driver for particulate matter concentrations was dust, rather than industrial emissions. As stated in the report “There are no accepted or commonly applied standards for assessing deposition of acidic air pollutants on land surfaces or on sensitive receptors such as the Burrup Peninsula rock art. While this assessment report provides results for acidic deposition, no assessment, or commentary is provided about the potential impacts on areas of sensitivity such as the rock art.”

Some recommendations are provided in the Ramboll 2022 report related to potential improvements in accuracy regarding terrain datasets, modelling approach for dust and treatment of plumes in the model grid, and uncertainty related to emissions estimates including NPI data. However, “significant effort was made to obtain the most accurate information available with particular focus on sources located near or on the Burrup peninsula” and the comparison of modelled emissions with latest data shown in Table 6-29 indicates that conservatism exists in assumptions. The NWS Project Extension ERD Air Quality Impact Assessment compared measured ground level concentrations of NO₂ from 2009-2015 with NEPM criteria and found no exceedances. The report states that there was “no currently accepted or commonly applied standards for assessing deposition of air pollutants on land surfaces, such as Burrup Peninsula rock art” and the report does not provide any assessment or commentary on potential impacts to rock art.

Applying expected NO_x emission rates from Table 6-28, whilst assuming no production downtime, annual NO_x emissions associated with processing of Scarborough gas through Pluto are conservatively estimated to average approximately 1,800 t/yr over an assumed 30 year field life. It is estimated that this would account for approximately 15% of the total estimated industrial 2030 NO_x load in the Murujuga airshed. Application of this estimate over the expected life of the development results in a total NO_x emission estimate of approximately 54,000 t. This estimate is considered conservative because it carries conservatisms described above, and doesn’t fully account for likely equipment turndown (reduced power demand) as production rate naturally declines over field life.

It is noted that the 2 Mtpa Perdaman urea proposal estimates 11.7 g/s NO_x emissions representing up to 370 tpa. If gas from the Scarborough project is processed at the Karratha Gas Plant, it would displace another source of gas processed at this facility and therefore not result in a net increase in total NO_x emissions to the airshed. Therefore, the Pluto estimate above is considered conservative.

Processing of gas from the Scarborough project is therefore not predicted to increase NO_x within the Murujuga airshed beyond historic maximum levels, which as described in section 4.9.6 has resulted in no scientifically conclusive evidence for anthropogenic change to rock art on Murujuga. The reduction in future NO_x load within the Murujuga air-shed presented in the Ramboll study is reflective of commitments made by third party proponents that are publicly disclosed either in Ministerial Statements or Air Quality Management Plans.

Existing Regulatory Framework

Facilities associated with the onshore processing of LNG are not subject to the Offshore Petroleum and Greenhouse Gas Storage (Environment) Regulations 2023 (Cth). Assessment and management of these emissions is required pursuant to various State and Commonwealth legislative frameworks. Impacts associated with atmospheric emissions are subject to an appropriate level of independent assessment by regulatory agencies and management measures are in place which are sufficient to ensure the environment performance outcome of this PAP can be achieved.

⁸⁴ https://www.woodside.com/docs/default-source/current-consultation-activities/australian-activities/north-west-shelf-project-extension---environmental-review-document.pdf?sfvrsn=a8b10277_4

⁸⁵ <https://www.parliament.wa.gov.au/pq/qsearch.nsf/5ba5221642b0ed73482569d60026c3a7/504273a549cd5b5148256df2007b9bbc?OpenDocument>

A summary of the relevant legislation, approvals and governance measures in place to manage atmospheric emissions from onshore processing facilities (Pluto LNG facility, NWS Karratha Gas Plant and Perdaman Urea facility) are outlined below.

Environmental Protection (EP) Act 1986 (WA)

The EP Act is the principal legislation in WA that provides for “the prevention, control and abatement of pollution and environmental harm” and for “the conservation, preservation, protection, enhancement and management of the environment”.

The object of the EP Act is to protect the environment of Western Australia, having regard to a number of principles, including:

- the precautionary principle, which holds that where there are threats of serious or irreversible damage, lack of full scientific certainty should not be used as a reason for postponing measures to prevent environmental degradation. In the application of the precautionary principle, decisions are to be guided by:
 - careful evaluation to avoid, where practicable, serious or irreversible damage to the environment
 - an assessment of the risk-weighted consequences of various options
- the principle of intergenerational equity, which holds that the present generation should ensure that the health, diversity and productivity of the environment is maintained or enhanced for the benefit of future generations
- the principle of waste minimisation, which holds that all reasonable and practicable measures should be taken to minimise the generation of waste and its discharge into the environment
- principles relating to improved valuation, pricing and incentive mechanisms, which include the ‘polluter pays principle’ whereby those who generate pollution and waste should bear the costs of containment, avoidance or abatement.

Assessment of Proposals under Pt IV of the EP Act

In Western Australia, it is the role of the independent Environment Protection Authority (EPA) to assess proposals against the requirements of the EP Act and EPA objectives.

Section 15 of the Act establishes the objectives of the EPA (Authority): It is the objective of the Authority to use its best endeavours to protect the environment; and to prevent, control and abate pollution and environmental harm. The object and principles guide the overall application of the powers of the Act. The principles are matters to which the EPA is required to have regard as a condition of the valid exercise of its powers to assess and report on proposals and schemes under the Act. The EPA only recommends that the Minister approve a proposal if it can be demonstrated the proposal is aligned with the Act including any relevant objectives.

Under the EPA’s Air Quality Environmental Factor Guideline, the EPA has an objective to *maintain air quality and minimise emissions so that environmental values are protected*⁸⁶ (Air Quality Objective). The Air Quality Environmental Factor Guideline identifies that this objective recognises the fundamental link between good air quality and the environmental values it supports. It also recognises the principle of waste minimisation as set out in the EP Act. In the context of this factor and objective, the EPA recognises that maintaining good air quality and minimising emissions protects human health and amenity, as well as the broader environment. When considering the significance of potential impacts to air quality, the EPA may have regard to the various matters outlined in Section 5 of the Statement of Environmental Principles, Factors and Objectives⁸⁷, including the Air Quality Objective.

Applicable assessments by the EPA and subsequent decisions by the Minister for Environment under Part IV of the EP Act include Ministerial Statement (MS) 757 for the Pluto LNG Facility, MS 1180 for the Perdaman Urea Project, and MS 536 for LNG trains 4 and 5 at the Karratha Gas Plant (KGP). MS 1233 was also recently issued for the North West Shelf (NWS) Project Extension, published in December 2024, which allows for continued operation of the NWS Project and processing of third party gas at KGP. Further information regarding conditions of implementation is detailed in sections below.

Environment Protection and Biodiversity Conservation Act 1999 (Cth)

The EPBC Act is the Australian Government’s key piece of environmental legislation providing for the protection of the environment and the conservation of biodiversity. The EPBC Act requires approval for activities with a significant impact on a number of matters of national environmental significance including for example, National Heritage places and listed threatened species or endangered communities.

The NWS Project Extension (a proposal to extend operation of the NWS Project beyond 2030) has been assessed under the EPBC Act by the WA EPA under an accredited process (Refer EPA Report 1727). The controlling provision for the proposed action is ‘National heritage places’, and the Project is subject to assessment by accredited assessment

86 EFG - Air Quality - 03.04.2020.pdf (epa.wa.gov.au)

87 Statement of environmental principles, factors, objectives and aims of EIA (epa.wa.gov.au)

under Part IV of the EP Act at the level of Public Environment Review. The Commonwealth Minister for the Environment will make an approval decision once the State process has completed.

Aboriginal Heritage

Aboriginal sites are of cultural heritage importance to both the Aboriginal and wider community. The Aboriginal Heritage Act 1972 (AH Act) is the principal legislation providing for the preservation of Aboriginal sites and objects in WA. All Aboriginal heritage sites or places to which s.5 of the AH Act applies are protected, whether or not they are registered with the Department of Planning, Lands and Heritage (DPLH). It is an offence under the AH Act to excavate, destroy, damage, conceal or in any way alter any Aboriginal site unless the consent of the Registrar or the Minister for Aboriginal Affairs is first obtained.

Approvals under Pt V of the EP Act

DWER regulates certain premises through a works approval and licensing process to prevent, control, abate and mitigate pollution and environmental harm, under Part V of the EP Act.

Woodside currently holds the following licences for facilities operated on the Burrup Peninsula:

- Pluto Liquefied Natural Gas (LNG) Project (L8752/2013/2)⁸⁸
- Woodside Onshore Gas Treatment Plant (KGP) (L5491/1984/18)⁸⁹

The abovementioned licences specify air emission limits for individual emission points. NO_x concentration in Pluto turbine exhausts is limited to 100 mg/m³ over a stack test average period not less than 30 minutes; and at KGP 350 mg/m³ for trains 1, 2 and 3 and 100 mg/m³ for trains 4 and 5. Monitoring of emissions points is required at the facilities annually and quarterly (respectively). Woodside is required under these licences to submit an Annual Audit Compliance Report identifying compliance with the conditions of the licences ensuring emissions remain within acceptable levels. Copies of the Annual Audit Compliance Reports are available on the DWER's website.

Other Regulatory Measures in Place for Management of Atmospheric Emissions

National Environmental Protection (Ambient Air Quality) Measure (Cth)

The National Environment Protection Council (NEPC), comprising Commonwealth, State, and Territory Ministers, finalised the NEPM (Ambient Air Quality), on 26 June 1998. The National Environment Protection Council Act 1994 (Cth) allows the National Environment Protection Council to make National Environment Protection Measures (NEPMs). NEPMs are a special set of national objectives designed to assist in protecting or managing particular aspects of the environment. The NEPM [Ambient Air Quality] outlines ambient air quality monitoring protocol that allows for the adequate protection of human health and well-being.

National Environment Protection (National Pollutant Inventory) Measure 1998 (Cth)

The National Pollutant Inventory (NPI) is a public database that provides information on 93 selected air pollutants and their emissions, produced as a result of industry, transport, commercial premise, and household activities, and emitted to air, land, and water in Australia. The NPI is a Commonwealth Government initiative and each state and territory is responsible for implementing the program. The objective of the NPI is to inform the community about emissions to water, air, and land and acceptable emissions levels. It also provides information for policy and decision making, environmental planning and management, and minimising waste.

The Woodside operated facilities on the Burrup Peninsula have been reporting emission data to the NPI from the NWS Project since the 1998/1999 reporting period and Pluto since the commencement of operations in 2012. Other facilities located on the Burrup Peninsula including Yara Pilbara Fertilisers Pty Ltd have reported since 2005.'

Other Relevant Frameworks and Programs

Murujuga National Park Management Plan

As outlined in Section 4.9.5, Murujuga National Park management plan objectives are achieved through measures which include Conservation Agreements, funding and support, and Cultural Heritage Management Plans (Section 6.10). It is under the Conservation Agreement that Woodside continues to support research into, and monitoring of, the National Heritage values of the Park, and conducts its activities in a manner not inconsistent with the Murujuga National Park management plan.

Program: Murujuga Rock Art (Western Australian Government)

The Western Australian Government publish on their Aboriginal heritage conservation website a summary of their Murujuga Rock Art Program, the partnership with Murujuga Aboriginal Corporation, and the Murujuga Rock Art Strategy. A description of the program is provided in Appendix K, courtesy of Govt of Western Australia Website: <https://www.wa.gov.au/service/aboriginal-affairs/aboriginal-heritage-conservation/program-murujuga-rock-art>

Murujuga Rock Art Monitoring Program

⁸⁸ https://www.der.wa.gov.au/component/k2/item/download/4517_d69d5c4f5e6e32e9687a81cd206801d1

⁸⁹ https://www.der.wa.gov.au/component/k2/item/download/6862_f7458bf91f1480d35d8f604ed3b129e0

In recognising the high level of stakeholder concern and scientific uncertainty regarding the links between anthropogenic emissions and risks to rock art (see Appendix F), in 2019 the Department of Water and Environmental Regulation (DWER) produced the Murujuga Rock Art Strategy⁹⁰ (MRAS), which builds on the research to date, and according to DWER will establish a world's best practice program to monitor, evaluate and report on factors that could affect the condition of Murujuga rock art. This is being undertaken in consultation with the Murujuga Aboriginal Corporation, a team of national and international experts in relevant disciplines and is funded by industry, including Woodside. The MRAS describes a risk-based approach for the management of impacts to the rock art that is consistent with the State Government's responsibilities under the EP Act.

A program being executed as part of the MRAS is the Murujuga Rock Art Monitoring Program (MRAMP) which will monitor, evaluate, and report on changes and trends in the integrity of the rock art, specifically to determine whether anthropogenic emissions are accelerating the natural weathering, alteration, or degradation of the rock art. This will enable timely and appropriate management responses by the Western Australian Government, industry and other stakeholders to emerging issues and risks. The following extract from the WA Government website MRAS website outlines this. (Courtesy of Govt of Western Australia (December 2023) <https://www.wa.gov.au/service/aboriginal-affairs/aboriginal-heritage-conservation/program-murujuga-rock-art#frequently-asked-questions>):

How will the Murujuga Rock Art Strategy provide protection for the rock art?

The initial studies will allow the scientific team to determine the levels of various air emissions that may cause accelerated weathering of the rock art. These levels will not necessarily be identified during the field studies on Murujuga Country, in which case they will be informed by laboratory tests.

The research will inform an environmental quality management framework. Specifically, the levels of air emissions at which accelerated weathering is deemed to occur will be used to inform environmental quality criteria. The ongoing monitoring program, administered by MAC and the department, will gather data and ensure that emissions do not exceed the criteria. Industry will also be regulated to ensure their emissions will not cause the criteria to be exceeded.

There are two types of environmental quality criteria under the framework: environmental quality standards and environmental quality guidelines. Guidelines provide early warning of potential environmental effects, while standards indicate where the level of risk is no longer acceptable, triggering a management response to prevent environmental harm. In the case of the rock art, an exceedance of the standard means there is a high risk of permanent loss or damage to the rock art.

While environmental quality criteria have been used successfully in other contexts, it is important to remember that there are no environmental quality standards or guidelines values currently available anywhere in the world that can be applied to engraved rock art.

What is the connection with World Heritage listing?

The World Heritage nomination for Murujuga includes a comprehensive and effective management framework that outlines how the potential 'Outstanding Universal Value' of the area will be protected, conserved and monitored. As part of this framework, the State Government and MAC will demonstrate how they are working closely together to protect the rock art through the Murujuga Rock Art Strategy and the Murujuga Rock Art Monitoring Program.

The DBCA website has more information on the [World Heritage nomination](#)

In recent EPA assessment reports for industrial facilities on the Burrup Peninsula, the EPA has recommended a condition mandating relevant facilities to comply with air quality standards such as those derived from the MRAMP.

In the EPA's North West Shelf Project Extension Assessment Report 1727 (EPA Report 1727), the EPA recommends the 'Air Quality Outcome' for recommended condition 3 be 'to ensure that no air emissions from the proposal have an adverse impact accelerating the weathering of rock art within Murujuga beyond natural rates.'

Recommended condition 3-3 states that if the Minister notifies the proponent in writing of one or more air quality standards to be met (including standards derived from the results of the Murujuga Rock Art Monitoring Program) and the proponent complies with all those standards, and any amendments to the standards the proponent is taken to have achieved the Air Quality Outcome.

EPA Report 1727⁹¹ specifies that the proponent is to achieve compliance with any detailed air quality standards to ensure that there are no adverse impacts accelerating the weathering of rock art within Murujuga beyond natural rates. The EPA expects that this will include environmental quality objectives and environmental quality standards derived from the results of the MRAMP.

Ministerial Statement 1233 was subsequently issued for the North West Shelf Project Extension, published in December 2024, adopting the above mentioned EPA recommended conditions relating to air quality.

⁹⁰ <https://www.wa.gov.au/system/files/2020-07/DWER-Murujuga-rock-art-strategy.pdf>

⁹¹ North West Shelf Project Extension Proposal (epa.wa.gov.au)

The Ministerial Statement for the Perdaman Urea Project (MS 1180) includes the same air quality outcome condition that is proposed in EPA Report 1727 and MS 1233.

The Pluto LNG Facility has a Cultural Heritage Management Plan and Air Quality Management Plan (AQMP) (required under Ministerial Statement 757). Statements and commitments made by Woodside within the North West Shelf Air Quality Management Plan and the Pluto LNG Facility Air Quality Management Plan commit to manage potential impacts to Aboriginal rock art on the Burrup Peninsula in accordance with the MRAS and as a member of the Murujuga Rock Art Stakeholder Reference Group. Woodside actively supports the implementation of the Murujuga Rock Art Strategy through membership of the Murujuga Rock Art Reference Group and provides funding associated with the Murujuga Rock Art Monitoring Program. Woodside also supports the coordinated approach for an atmospheric deposition monitoring program to be established under the Strategy, and currently provides data to the program from the Woodside Atmospheric and Ambient Air Quality Monitoring Programs

Onshore Facility Air Emission Design Mitigations

Under the regulatory Conditions and Part IV Air Quality Management Plans of onshore processing facilities on the Burrup, operators are required to implement a number of controls and risk management practices related to air emissions, including the demonstration of best practice design, and monitoring and abatement programs.

It is noted that there is currently no arrangement in place to treat Scarborough gas at KGP, however this may be pursued as an opportunity in future. The interconnector which may transport gas from Pluto to KGP is connected to the newer LNG processing trains at KGP (Trains 4 and 5). The NWS Extension Environment Review Document⁹² details how the most recent LNG trains (Trains 4 and 5) constructed at the existing North West Shelf Project, which are those which may process Scarborough gas, are already equipped with lower NOx technology for gas turbines. KGP's Ministerial Statement 536⁹³ (February 2000) applicable for the construction and operation of Train 4 and Train 5 included the requirement to install low-NOx burners on new gas equipment.

Condition 11-1 of Ministerial Statement 757⁹⁴ required the development of an Assessment of Best Practice for Minimising Emissions to Air from Major Plant (Best Practice Report) for the Pluto LNG Facility and condition 11-2 required the development of the Pluto LNG Facility Air Quality Management Plan to demonstrate that best available practicable and efficient technologies are used to minimise and monitor air emissions from the plant. This demonstration was required to meet the requirements of the Minister for the Environment on advice of the Environmental Protection Authority prior to Woodside applying for and obtaining a Works Approval to construct the Pluto LNG facility. In 2019, these reports were updated to include Pluto Train 2 and subject to an independent peer review commissioned by the EPA, before being approved by the Minister for Environment in 2020 on advice of the EPA.

Best practice technologies to minimise air emissions implemented in Pluto LNG design and operation include:

- Dry Low NOx emissions control systems on gas turbines
- Specification of activated methyldiethanolamine (aMDEA) in the acid gas removal system to reduce co-absorption of benzene, toluene and xylene (BTX) and other hydrocarbons.
- installation of a regenerative thermal oxidiser on the acid gas removal unit
- flare design integrated smokeless flaring technologies implemented for the storage and loading flare system, cold dry flare, warm wet flare and common spare flare.

Best practice technologies to minimise air emissions implemented in Pluto LNG (Train 2) design and operation include:

- Dry Low Nox emissions control systems on gas turbines
- specification of aMDEA in the acid gas removal system to reduce co-absorption of BTX and other hydrocarbons.

The Pluto Ministerial Statement 757 requires the Pluto Air Quality Management Plan to include:

- targets and standards
- an emissions monitoring programme to cover specified pollutant compounds
- an ambient air monitoring programme and a nitrogen deposition monitoring programme
- provisions for annual reporting

Annual compliance reporting against these requirements is provided to the WA EPA, and published on the Woodside website – Pluto LNG Environmental Compliance Reporting⁹⁵.

⁹² https://www.epa.wa.gov.au/sites/default/files/PER_documentation2/NWS%20Project%20Extension%20-%20Environmental%20Review%20Document.pdf

⁹³ <https://www.epa.wa.gov.au/sites/default/files/1MINSTAT/Ministerial%20Statement%20536.pdf>

⁹⁴ https://www.epa.wa.gov.au/sites/default/files/1MINSTAT/Ministerial%20Statement%20757_0.pdf

⁹⁵ <https://www.woodside.com/what-we-do/operations/pluto-lng/pluto-lng-environmental-compliance-reporting>

Ministerial Statement 1233 (MS 1233⁹⁶) for the North West Shelf Project Extension, published December 2024, requires that:

...no air emissions from the proposal have an adverse impact accelerating the weathering of rock art within Murujuga beyond natural rates.

MS 1233 contains a number of conditions related to air quality and NOx emissions, including but not limited to:

- Within 12 months of issue of MS 1233, the Air Quality Management Plan must be revised in consultation with Murujuga Key Stakeholders
- Compliance with all air quality objectives and standards, including, if applicable, those derived from the results of the MRAMP
- At a minimum, reduce NOx emissions to 3065 tpa by 31 December 2030, corresponding to a 60% reduction
- Include provisions for adoption of continuous or predictive emission monitoring technologies on each stack of LNG processing trains by 30 June 2030
- Identification of best practice design and operational measures and efficient technologies implemented or to be implemented:
 - Specifying when each measure will be implemented
 - Methodology for determination of effectiveness of the measure in minimising air emissions
 - Independent Peer Review Report assessing these measures against international and Australian industry best practice

Monitoring data and compliance reporting is required to be provided to the WA EPA and made public.

The existing NWS Air Quality Management Plan includes the following management actions:

- MA4: Adopt practicable and efficient technologies to reduce air emissions. The AQMP states that Woodside has identified and evaluated credible opportunities to achieve a long term reduction in air emissions, and commits to a 40% [updated to 60% in MS1233 Condition] reduction in NOx emissions from a baseline set between 2013 and 2018. Measures which the NWS has or is considering include implementation of technology such as water injection, dry-low NOx, ultra dry-low NOx, selective catalytic reduction (SCR) systems on turbines, or ceasing operation of older non-DLN equipment with proportionally higher NOx emissions.
- MA5: Implement an adaptive management plan addressing the potential impact to rock art from industrial emissions. This is described in the AQMP, stating that since it is difficult to set appropriate management actions given the current lack of scientific understanding of the impacts of air emissions on petroglyphs, actions will be monitored, reviewed, evaluated and updated considering a range of factors including outcomes from MRAS.

Should credible scientific evidence emerge that industrial emissions are causing accelerated weathering of Murujuga rock art as an outcome of MRAMP, the impact profile of onshore atmospheric emissions may change. In this scenario, sufficient provisions exist in the relevant onshore regulatory frameworks as described above to ensure that onshore atmospheric emissions are limited to acceptable levels, which may require review of controls currently in place at onshore processing facilities to manage potential impacts (for example under condition 3 of MS1233 for NWS, or section 10 of the Pluto AQMP). In such a case whereby impact is attributed to the onshore processing of Scarborough gas, the EP change management process would apply (Section 7.2.7) as required by Regulation 39. Until the report is published, it is not feasible to pre-emptively lay out a planned response to such an outcome because there is a broad range of potential findings, severity of change, mechanism timeframes, attribution considerations, and outcomes from stakeholder engagement. However, potential options are available to reduce NOx emissions in this context and to achieve the 60% reduction in NOx emissions at NWS required under MS1233, which may include:

- Retrofitting NOx reduction technology such as DLN (or other technologies as noted above under description of NWS AQMP MA4) on, or ceasing operation of older non-DLN equipment at KGP which emits proportionally higher NOx concentration, noting that Scarborough gas will not be processed through these older trains in any case

Implementation of further NOx reduction measures or technologies which may no longer be considered disproportionate in context of a proven impact pathway, such as water injection, dry-low NOx, ultra dry-low NOx.

Both Pluto LNG Facility and NWS Karratha Gas Plant are also subject to cultural heritage management obligations detailed in MS757 and MS1233 respectively – further described in Section 6.10.

⁹⁶https://www.epa.wa.gov.au/sites/default/files/1MINSTAT/1727%20Statement%201233%20for%20publishing%20North%20West%20Shelf_0.pdf

Detailed Impact Assessment

Offshore Atmospheric Emissions

Air Quality

Facility and vessel emissions, predominantly flaring, have the potential to result in localised, temporary reduction in air quality, and generation of dark smoke. Potential impacts of emissions depend on the nature of the emissions, as well as the location and nature of the receiving environment.

Facility design (including the rapidly dispersive characteristics of the gas turbine exhausts, flare and other emissions), the estimated level of pollutants in the emissions, and the absence of elevated background ambient levels have been considered in estimating the potential for interaction with human and environmental sensitivities. The PAA is in a remote offshore location, with no expected adverse interaction with populated areas or sensitive environmental receptors associated with air emissions.

Birds (including migratory birds) are known to opportunistically roost on offshore facilities. Given the highly dispersed nature of facility air emissions, no adverse impacts to birds are anticipated due to air emissions.

Potential impacts are expected to be temporary, localised air quality changes, limited to the airshed local to the FPU. Air emission impacts are not expected to have direct or cumulative impacts on sensitive environmental receptors, or above National Environmental Protection (Ambient Air Quality) measures and are expected to disperse well before the nearest populated area (Exmouth).

The flare and potential black smoke resulting from emissions may impact visual amenity. The offshore location of the Petroleum Activities Program is not directly visible from the nearest landfall (Exmouth, ~230 km from the PAA where these emissions may occur). Hence, no impacts to visual amenity for residential communities are expected. Visual amenity impairment to tourism activities is not expected.

Indirect Emissions from Gas Processing Onshore – Assessment of Potential Impacts

Contribution to Accelerated Weathering of Murujuga Rock Art

The Dampier Archipelago, including the Burrup Peninsula and surrounds, traditionally referred to as Murujuga (which means ‘Hip Bone Sticking Out’ in the Ngarluma-Yaburara language) is located in the Pilbara region of WA. With more than one million images, Murujuga is home to one of the largest, densest and most diverse collections of rock art in the world⁹⁷.

The presence of industry on the Burrup Peninsula has generated concerns from some stakeholders that these emissions may lead to an accelerated weathering of rocks on which rock art is present which may reduce the visibility or destroy the rock art. Research to date on the impacts of emissions on rock art has not been conclusive, and there are currently no set air quality thresholds for the protection of rock art.

As outlined in Section 4.9.6, industrial emissions on the Burrup Peninsula are subject to extensive scientific studies to understand any potential pathway to impact on rock art, including wet and dry deposition which may alter the pH of rocks as well as the supply of nutrients which may promote microbial activity, the metabolic by-products of which may interact with rock surfaces.

The history of research on this subject, set out in more detail in Section 4.9.6 may be broadly divided into four periods. The earliest period, from 2002 to 2009, aligns with the studies conducted by the Burrup Rock Art Monitoring Management Committee (BRAMMC) but also includes work conducted by others, primarily Bednarik who identified potential impact pathways through acid formation and microbial impacts. During this period MacLeod (2005) also took some comparative pH samples between in-situ rocks and museum samples. None of this parallel work established that industrial emissions were impacting rock art, or the levels of emissions at which impacts may be expected to occur. This period concluded with the 2009 BRAMMC report which stated that “there is no scientific evidence to indicate that there is any measurable impact of emissions on the rate of deterioration of the Aboriginal rock art in the Burrup” (BRAMMC 2009) but recommended the establishment of the Burrup Rock Art Technical Working Group (BRATWG) to conduct ongoing monitoring.

The second period of research aligns with this monitoring from 2010 to 2017. A significant component of this monitoring involved the monitoring of rock art colour. In 2016 Black and Diffey produced an unpublished paper critiquing the statistical methods applied by the CSIRO, which led to a review by Data Analysis Australia (DAA) which also raised “substantial doubts about the reliability of the data”. A final report from the CSIRO adapted its statistical methods to respond where possible to the conclusions from DAA but the results were described as “not fully conclusive”. Also during this period the BRATWG also commissioned an extreme condition weathering study which found that the dissolution of chemicals began at lower pH levels than previously estimated, however this work was only preliminary and should not be relied upon in setting thresholds for potential impacts.

The third research period, although overlapping with the conclusion of the BRATWG and initial years of the MRAS and MRAMP, is marked by the absence of any results from a coordinated, well-resourced research program and instead

⁹⁷ <https://www.wa.gov.au/system/files/2020-07/DWER-Murujuga-rock-art-strategy.pdf>

comprises a number of independent studies between 2017 and 2023. As a result, it is difficult to characterise these studies consistently. Some (Black et al 2017a, Dorn 2020; Smith 2022a) critiqued or re-stated conclusions of previous studies. Black et al 2017b repurposes historic pH data and concludes that “theoretical evaluation using electrochemical equilibrium principles” indicates impacts to rock art will result from an decreased pH since pre-industrial times; CGB Solutions 2020’s analysis of historic pH and contemporary measurements found that pH was not decreasing and that any correlation between acidity and LNG production sites could not be statistically supported. Both studies suffer from significant issues with the available data.

Other studies (Black et al 2018; Gleeson et al 2018) discuss possible impact pathways but stop short of drawing conclusions on whether impacts to rock art are resulting from industrial emissions. Smith et al (2022b) does hypothesise that industrial emissions may be responsible for some reported impacts but acknowledges that the methodologies applied are subject to considerable errors that prevent a definitive conclusion being drawn. A series of studies by MacLeod (2020, 2021, MacLeod and Fish 2021) report on the results of monitoring conducted for Yara Pilbara Nitrates. The outcomes of these reports are inconsistent. Solo reports by MacLeod (2020, 2021) both state that “There is unequivocal evidence that the changes in colour contrast are affected by the changes in the mean and in the minimum pH observed on the rock art sites at the reference positions” though the results include increased acidity correlating in some places with increased contrast and elsewhere with decreased contrast. MacLeod and Fish (2021) then state that “there is presently no adverse impact on the rock engravings from industrial pollution owing to a lower NO_x level than when the studies commenced 14 years ago”. This conclusion is critiqued by Smith et al (2022a).

As noted in the MRAMP conceptual model, “*while many of these studies form useful datasets to include in subsequent analyses, in general these studies have been inconclusive or failed to show any significant impact of anthropogenic impact on the rock art or chemical/biological species composition and abundance (Commonwealth of Australia, 2018). Nor have they produced any definitive relationships to inform a conceptual impact model, which is instead reliant on fundamental scientific studies in other regions to inform the likely processes occurring at Murujuga (e.g. Dorn, 2020⁹⁸).*”

In December 2023, the first interim report of MRAMP⁹⁹ was published (refer to Section 4.9.6), marking the start of a fourth period of research. The report states that results remain inconclusive with regards to whether industrial air emissions are resulting in anthropogenic change to rock art and recommends that further scientific studies are required. The MRAMP report noted that while some spatial trends in electrochemical parameters (such as pH) and rock surface elemental composition have been found, more work is required to determine causal relationships for these trends (as relationships were not as expected). Spatial trends were also identified as appearing for several measured air pollutants such as Nitrogen Dioxide that are generally consistent with earlier air quality modelling by Ramboll (Ramboll 2022).

The MRAMP monitoring report outlined that similar trends exist for the pH measurements taken in March–April 2022 and the measured NO₂ levels generally. This relationship was the reverse of what would be expected to confirm the acid deposition hypothesis in previous literature as MRAMP found pH values in March–April 2022 were highest where NO₂ concentrations are highest; whereas with acid deposition, pH is expected to be lower where NO₂ is higher, as NO₂ is often a precursor to the formation of nitric acid, which has a low pH. Neutral pH is around 7, with low pH indicating potentially acidic conditions. The results in the MRAMP monitoring report have been reinterpreted by Smith (2024) in addition to original research but fails to address this unexpected correlation. Smith (2024) claims that “the damaging impact of acidic emissions on the rock surfaces is not in doubt” but does not provide adequate detail on the original research to allow its reliability to be considered, nor does it provide reason to question the conclusions of the MRAMP report, which stress that the available data is insufficient to draft any meaningful conclusions.

Throughout this ongoing period of research, new information will continue to be considered and responded to. However, the resourcing, scope and expertise available to MRAMP make it by far the most significant source of research on the cultural impacts of industrial emissions on Murujuga. MRAMP is also co-managed by MAC and emphasises Indigenous decision making and management, aligned with international guidance and standards, including the United Nations Declaration on the Rights of Indigenous Peoples and ICOMOS Charter for the Protection and Management of the Archaeological Heritage. For these reasons, the results of the MRAMP are prioritised in understanding the potential for emission to impact Murujuga’s rock art.

The contribution of emissions from processing of Scarborough gas to the Murujuga airshed is relatively small. Further, there is inconclusive evidence for any causal link between industrial air emissions and anthropogenic change to rock art on Murujuga. Given this, and that downstream facilities are subject to separate regulatory assessment outcomes, the risk of processing of Scarborough gas at onshore facilities adversely impacting rock art on Murujuga is considered to be low and no impact significance has been evaluated.

Potential Impacts to Human Health

It is recognised that gaseous emissions causing a reduction in ambient air quality have the potential to impact human health as regulated by the NEPM. Both the Pluto LNG Facility and NWS Project Air Quality Management Plans have modelled and assessed the potential impacts of industrial emissions on human health in accordance with the requirements of Western Australian regulatory requirements and international standards (e.g. World Health

Organisation). Ambient air quality monitoring programs are in place which demonstrate that current air pollution levels were well below standards set to protect human health and well-being¹⁰⁰. The magnitude of emissions from processing Scarborough Gas are insufficient to lead to the exceedance of any relevant health criteria on the Burrup Peninsula or surrounding region.

Both Pluto LNG facility and the NWS Project have committed to maintaining an ongoing air quality monitoring program that is in place to monitor the ambient ground-level concentrations of relevant gases on the Burrup Peninsula, with comparisons being made against the NEPM standards and reported to DWER.

Ambient air quality monitoring results from Pluto and NWS Project will be summarised in the relevant facilities Annual Environment Report, including any observed exceedances of ambient air quality standards.

As part of the NWS Extension proposal, the EPA assessed the residual impact to human health and amenity from the proposal's nitrogen dioxide (NO₂), SO₂, NH₃, ozone (O₃), and particulate (as PM₁₀ and PM_{2.5}) emissions at sensitive receptors both in isolation and in a cumulative context with other existing and future emission sources. Predicted ground level concentrations (GLCs) at Dampier, Karratha, Hearson Cove, and Deep Gorge (Ngajarli) remain below applicable current and future proposed air quality criteria at 'standard operating conditions' and 'worst case' cumulative impact scenarios, with the exception of annual PM₁₀ and PM_{2.5} GLCs at Hearson Cove and Deep Gorge (Ngajarli), which slightly exceed the applicable criteria due to high levels of natural background dust. Subject to recommended conditions, the impact of the proposal was considered as being consistent with the EPA's objective for air quality in respect of human health.

Noting the absence of any current impacts to human health from industrial activity on Murujuga and presence of a comprehensive regulatory regime including monitoring program, the risk of processing of Scarborough gas to human health is assessed as Negligible.

Summary of Assessment Outcomes

<i>Receptor</i>	<i>Impact</i>	<i>Receptor Sensitivity Level</i>	<i>Magnitude</i>	<i>Impact Significance Level</i>
Air quality	Change in air quality	Low value	Slight	Negligible (F)
Socio-economic	Accelerated weathering of rock art	No consequence assigned ¹⁰¹		

Overall Impact Significance Level:

The overall impact significance level for routine and non-routine atmospheric emissions is negligible (F) based on a slight effect on air quality. The impact significance levels for individual receptors are consistent with the levels rated in the Scarborough OPP.

Noting the relatively small contribution of emissions from processing of Scarborough gas to the Murujuga airshed, outcomes of regulatory assessments of downstream facilities and the inconclusive evidence for any causal link between industrial air emissions and anthropogenic change to rock art on Murujuga, the risk of processing of Scarborough gas at onshore facilities adversely impacting rock art on Murujuga is assessed as low and no impact significance has been evaluated.

Demonstration of ALARP

ALARP Statement:

On the basis of the environmental risk assessment outcomes and the use of the relevant tools appropriate to decision type A for offshore activities, and B for indirect emissions from gas processing onshore, Woodside considers the adopted controls appropriate to manage the risk.

Air emissions from onshore processing at Pluto LNG Facility are managed under Ministerial Statement 757.

Air emissions from onshore processing at the NWS Project have been assessed and approved in accordance with Ministerial Statement 536 (and others). Air emissions from onshore processing at the NWS Project Extension (i.e. an extension of the life the NWSV beyond 2030) have been assessed by the EPA under Assessment Report 1727 and approved by Ministerial Statement 1233. Both facilities are subject to the provisions of Commonwealth and State legislation to ensure unacceptable environmental impacts are avoided.

The assessment in this section reflects the current status of controls related to routine atmospheric emissions, in the context that there is currently no scientific consensus that anthropogenic emissions are accelerating weathering of Murujuga rock art. These current controls are considered to appropriately implement a risk-weighted precautionary principle.

As described above, established programs and frameworks such as MRAS/MRAMP are designed to investigate theorised impact pathways and determine whether impact is occurring. Should credible scientific evidence emerge that anthropogenic emissions associated with processing of Scarborough gas are causing accelerated weathering of Murujuga rock art as an outcome of MRAMP, the impact profile of onshore atmospheric emissions may change. In this eventuality, sufficient provisions exist in the relevant onshore regulatory frameworks to ensure that onshore atmospheric emissions are limited to acceptable levels, which may require review of controls currently in place at onshore processing facilities to manage potential impacts.

As no reasonable additional/alternative controls were identified that would further reduce the impacts without being grossly disproportionate the impacts and risks are considered ALARP.

Societal Values

Consultation was undertaken for this program to identify the views and concerns of relevant stakeholders, as described in Section 5 and Appendix F: Consultation. Industrial air emissions on the Burrup Peninsula are being managed by the EPA as part of the EP Act Part IV assessment process and DWER as part of their EP Act Part V process and via the MRAS. It is important to note that operators of the Pluto LNG Facility and Northwest Shelf Karratha Gas Plant have both made public commitments to supporting the outcomes of MRAS.

Atmospheric emissions associated with onshore processing of Scarborough gas and potential for impact of those emissions on rock art was noted as a material issue for relevant persons consulted in the course of preparing this EP. All feedback, claims or objections from relevant persons has been appropriately responded to, addressed and assessed (see Appendix F: Consultation), and controls proposed have been assessed in the EP.

Summary of ALARP Statement:

On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type (i.e. Decision type B for indirect emissions), the adopted controls are appropriate to manage the indirect impacts of air emissions related with processing Scarborough gas onshore. The adopted controls meet NEPM, EP Act Part IV and Part V legislative requirements and include application of precautionary measures to protect environmental cultural heritage values. As no reasonable additional/alternative controls were identified that would further reduce the impacts without being grossly disproportionate sacrifice, the impacts and risks are considered ALARP.

Demonstration of Acceptability
Acceptability Criteria and Assessment
<p>Acceptability Statement: Offshore Activities Atmospheric Emissions</p> <p>Given the adopted controls, atmospheric emissions represent a negligible impact that is unlikely to result in greater than isolated impacts with close proximity of the facility, in an unpopulated area approximately 230 km from the nearest community receptor. The adopted controls are considered good oil-field practice/industry best practice and meet requirements of Australia Marine Orders and National Pollutant Inventory reporting.</p> <p>The potential impacts and risks are considered broadly acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the impacts and risks of atmospheric emissions to a level that is broadly acceptable.</p> <p>Acceptability Statement: Indirect Atmospheric Emissions</p> <p>The impact assessment concludes that indirect atmospheric emissions from the onshore processing of Scarborough gas contribute only a minor portion to the overall industrial emission airshed load on the Burrup Peninsula. Atmospheric emissions within the Murujuga airshed from both Pluto LNG, NWS Project Extension and Perdaman Urea have undergone independent assessment by the WA and agencies and have been considered acceptable, and are subject to management conditions. Woodside supports the ongoing management of heritage values under listings; Murujuga Cultural Landscape, Murujuga National Park and Dampier Archipelago (Including Burrup Peninsula) National Heritage Place. Planned activities under the PAP are not inconsistent with relevant heritage legislation, management plans and agreements under which these values are protected.</p> <p>Based on the implemented controls and the inconclusive evidence for any causal link between industrial air emissions and anthropogenic change to rock art, uncertainty and precaution are addressed by the existing State regulatory processes including the MRAS, which can apply adaptive management and mitigation measures as further scientific knowledge of potential pathways and indirect links to rock art are established. NOx emissions to the Murujuga airshed are regulated under the EP Act and Ministerial Conditions. Therefore, based on application of a risk-weighted precautionary principle and existing regulatory frameworks, impacts from indirect air emissions as a result of onshore processing of Scarborough gas are considered Acceptable.</p>

Migratory / foraging seabirds and shorebirds interacting with the FPU for roosting and or nesting.					✓	✓		A	F	-	-	LCS GP P ₂	Broadly Acceptable	EPO 5
Description of Source of Impact														
<p>The long term, physical presence of the FPU introduces a new emergent feature in the ocean that may provide a temporary refuge for migratory / foraging seabirds and possibly shorebirds; or a more permanent refuge if behaviours such as nesting are displayed. Unlike nocturnal seabirds, which can be impacted by facility lighting through attraction or disorientation (refer to Section 6.7.3), diurnal seabirds and shorebirds are attracted to the offshore facility because of its presence and refuge potential.</p> <p>The potential presence of marine birds on the FPU introduces the safety and environmental risk of bird strike during helicopter operations (addressed in Section 6.8.10). In addition, the build-up of large volumes of guano can impact maintenance of a safe working environment, leading to increased risk of potential slips/trips/falls and potential biological waste hazards for workers.</p> <p>Given the absence of other permanent facilities within the offshore marine environment of the Exmouth Plateau, the potential for the FPU to be used by seabirds and/or shorebirds for this purpose is unconfirmed, including the species assemblage, number of individuals or the specific location of potential refuge on the FPU.</p>														
Detailed Impact Assessment														
Assessment of Potential Impacts														
<p>The NWMR provides a variety of habitats, including BIAs, for numerous threatened and migratory marine bird species. The spatial and temporal distribution of species within the NWMR can vary seasonally, depending upon the resource requirements of different behaviours and/or life stages of the bird species present. The FPU Operational Area is located 375 km west-north-west of Dampier and the nearest offshore island (Barrow Island) is ~238km away; the nearest anthropogenic emergent feature is ~190km (Santos Spar-2 Facility). Seabirds utilising the waters within and surrounding the FPU Operational Area are expected to comprise migrating and foraging pelagic seabirds. Nearshore seabirds and shorebirds coastal distributions largely exclude their presence in and around the location of the FPU with the exception of possible migration pathways. Given the distance from shore, including nearest offshore islands, the numbers of</p>

individual such birds traversing the FPU Operational Area are expected to be low compared to areas of the NWMR closer to shore.

The PMST report determined that 16 species of threatened or migratory seabird / shorebird species may occur within the Petroleum Activities Area (Table 4-13). Not all of these are truly pelagic marine bird species however or are likely to utilise waters of the FPU Operational Area. Table 6-30 lists the species which are likely or possible to interact with the FPU, noting only two of the five identified are EPBC Act listed, threatened or migratory species (Common noddy, Roseate tern).

While there are reports of migratory shorebirds utilising ships as resting stopovers (e.g. Sara et al. 2023), reports of this behaviour within Australian waters are absent, reflecting either a lack of reporting or few such events. Occurrences of migratory shorebirds utilising offshore platforms of the NWMR would most likely be associated with a low number of individuals being blown off course during inclement weather events, rather than birds utilising facilities as a strategy to conserve energy during migration by large numbers of individuals.

Of the pelagic seabirds, wedge-tailed shearwaters are known to use offshore waters for foraging during the breeding season (Cannell et al. 2019). Like other species of the Procellariiform order, shearwaters do not rest or roost on emergent features, coming to land only to breed, incubate eggs and provision chicks. Roosting and resting behaviours are undertaken on the water surface in offshore environments. Interaction of Procellariiforms with offshore platforms are typically due to attraction of individuals to artificial light owing to their nocturnal life history traits. The risk of lighting impacts on nocturnal seabirds is assessed in Section 6.7.3. The focus of this assessment and resulting controls relate to the risks posed to diurnal seabirds and shorebirds due to the physical presence of the FPU.

Considering behaviour and reports of seabird use of offshore platforms, species considered likely and possible to utilise the FPU for resting and/or roosting are summarised in Table 6-30. It is noted that the two pelagic seabird species listed as likely, have wide-ranging distributions but their designated BIAs do not overlap with the FPU location. The species considered possible to utilise the FPU are not typically found at such distances offshore as the FPU Operation Area and there is no overlap of designated BIAs, however some of these species have been reported utilising not-normally-crewed offshore platforms on NWS.

The use of the FPU may lead to a positive impact on these species by providing resting/roosting habitat and potentially increased foraging efficiency should fish and other prey species aggregate around the subsea structures associated with the FPU. However, the increased presence of species may result in injury or death if individuals become entangled or trapped in topside infrastructure or as a result of collision with helicopters (Ronconi et al. 2015) – these unplanned impacts are considered in Section 6.8.10. Other safety risks include hazards associated with fouling caused by guano deposits, which could cause health and safety issues for workers accessing the facility.

Other Woodside facilities located closer to shore and the islands of the Dampier Archipelago such as Pluto (designed to be operated not-normally-attended or minimally attended) and Angel, have experienced bird roosting activities. These facilities are located 160km and 123km respectively north-west of the Karratha Gas Plant, on the Burrup Peninsula, with Pluto being 75km north of Barrow Island. On Angel platform, the installation of temporary bird proofing exclusion devices has been carried out, to enable the maintenance of a safe working environment for personnel and reduce risks to common noddys (from helicopter strike and other potential harm from processes on the facility).

The potential impacts of the FPU presence on seabird species considered likely to rest or roost on the FPU are considered negligible given that use of the FPU by seabirds is not expected to alter population size, habitat use or distribution at the NWMR level and will most likely result in a temporary behavioural change

Table 6-30: Seabird species most likely to interact with the FPU.

Species Common Name	Seasonality	Type of Interaction	Source/Example
Likely

Control Considered	Control Feasibility (F) and Cost/ Sacrifice (CS)	Benefit in Impact/Risk Reduction	Proportionality	Control Adopted
Demonstration of Acceptability				
Acceptability Criteria and Assessment				
<p>Demonstration of acceptability for the sources of aspect and associated impacts assessed in this section are provided in Section 6.3 of the Scarborough OPP. The Petroleum Activities Program meets the acceptability criteria (Section 2.3.5):</p> <ul style="list-style-type: none"> • Overall impact significance levels for individual receptors are consistent with the levels rated in the OPP. • EPOs and controls in the OPP that are relevant to disturbance to pelagic seabirds have been adopted. • There are no changes to internal/external context specific to this risk from the OPP, including issues raised during consultation. 				
<p>Acceptability Statement:</p> <p>The impact assessment has determined that, given the adopted controls, the Petroleum Activities Program is unlikely to result in an impact significance level greater than Slight. Further opportunities to reduce the impacts have been investigated above. The adopted controls are considered consistent with industry good practice and meet the requirements of Woodside relevant systems and procedures.</p> <p>The potential impacts are considered broadly acceptable if the adopted controls are implemented. Activities do not have a significant impact on MNES (Section 2.4.2). Therefore, Woodside considers the adopted controls appropriate to manage the impacts of disturbance to seabirds to a level that is broadly acceptable; and demonstrate the EPOs are met.</p>

- vessels – up to 75 m³/day (based on 200 POB the largest vessel) per vessel
- ASV – up to 188 m³/day (Based on 500 POB).

Note that wastes may also be stored and transported to shore for disposal.

Discharge of Deck, Bilge and Drain Water from Vessels (including ASV)

Vessels and the ASV will routinely generate and discharge relatively small volumes of bilge water. Bilge tanks receive fluids from many parts of the vessel, including machinery spaces. Bilge water can contain water, oil, detergents, solvents, chemicals, particles and other liquids, solids or chemicals. There is also variable discharge of drainage water from decks directly overboard or via deck drainage systems. Deck drainage may contain traces of chemicals. Potential sources could include rainfall events and/or from deck activities such as cleaning/wash-down of equipment/decks.

Discharge of Cooling Water and Brine (from Reverse Osmosis) from Vessels (including ASV)

Seawater is pumped on board and used as a heat exchange medium for the cooling of machinery engines on vessels. It is subsequently discharged to the sea surface at a potentially higher temperature. Cooling water is often treated with additives including scale inhibitors and biocide to avoid fouling of pipework. Scale inhibitors and biocide are usually used at low dosages, and are typically consumed in the inhibition process, so there is little or no residual chemical concentration remaining upon discharge. Seawater used for cooling purposes will be routinely discharged at a temperature expected to be less than 70°C and rates ~50 m³/d.

Potable water, primarily for accommodation and associated domestic areas, may be generated on vessels and the ASV using a reverse osmosis (RO) plant. This process will produce brine, which is diluted and discharged at the sea surface. Discharged brine is typically 20 to 50 percent higher in salinity than the intake seawater (depending on the desalination process used) and may contain low concentrations of scale inhibitors and biocides, which are used to avoid fouling of pipework (Woodside, 2014).

Detailed Impact Assessment

Assessment of Potential Impacts

Water Quality

Monitoring of vessel sewage discharges has demonstrated that a 10 m³ sewage discharge over 24 hours from a stationary source in shallow water reduced to about 1% of its original concentration within 50 m of the discharge location (Woodside, 2008). Monitoring stations confirmed that discharges were rapidly diluted or nutrients rapidly metabolised and no elevations in water quality parameters (e.g. total nitrogen, total phosphorous and selected metals) were recorded above background levels at any station.

Discharge of food waste has the potential to change the local water quality for a short period through the addition of a temporary nutrient source, however this nutrient loading would rapidly return to background conditions following dispersion in the water.

Drainage and treated bilge water discharges may contain a range of chemicals, oil, grease and solid material; however these discharges are expected to rapidly dilute in the water column (Shell, 2010). In addition, vessels are typically moving during discharges of treated bilge water, which promotes mixing and dilution.

The key physicochemical stressors that are associated with reject brine and cooling water discharge include salinity, pH, temperature and chemical toxicity. Water quality of the surrounding environment may be altered through the addition of chemicals and an increase in salinity. Scale inhibitors and biocides are commonly used within the systems described above to prevent fouling. Scale inhibitors are typically low molecular weight phosphorous compounds that are water-soluble, and only have acute toxicity to marine organisms about two orders of magnitude higher than typically used in the water phase (Black et al., 1994). The biocides typically used in the industry are highly reactive and degrade rapidly (Black et al., 1994).

The potential impacts on water quality due to cooling water discharge include chlorine toxicity and increased water temperatures. Discharges will disperse and dilute rapidly, with impacts to water quality localised to the discharge point.

Reject brine water is typically 20–50% higher in salinity to the surrounding water and based on models developed by the US EPA (Frick et al., 2001), discharges of brine water will sink through the water column where it will be rapidly mixed with receiving waters and dispersed by ocean currents, decreasing in salinity rapidly as distance from source increases.

Generally, reject brine and cooling water containing chemical additives are inherently safe at the low dosages used. They are usually consumed in the inhibition process, so there is little or no residual chemical concentration remaining upon discharge.

Impacts from routine and non-routine discharges from vessels on water quality will have no lasting effect due to the transient nature of discharges, which will occur in a localised mixing zone, with a high level of dilution into the open water marine environment of the PAA. As such, the impact significance level for water quality has been identified as Negligible (F).

Marine Fauna

A change in water quality from the discharge of sewage and greywater could result in injury or mortality to marine fauna. This could be the result of oxygen depletion in the waters due to nutrient enrichment, or due to toxins and chemicals present in the discharged wastes. Open marine waters are typically influenced by regional wind and large-scale current patterns resulting in the rapid mixing of surface and near surface waters where sewage discharges may occur. This means nutrients from the discharge of sewage will not accumulate or lead to eutrophication due to the highly dispersive environment. Therefore, the receptors with the greatest potential to be impacted are those in the immediate vicinity of the discharge (NERA, 2017). Given that sewage discharges are at or near the surface, and remain buoyant, the receptors with the potential to be impacted are also those within or on surface waters; i.e. plankton, fish and other marine fauna.

Discharge of food waste into the marine environment has the potential to attract some opportunistic marine fauna including fish and seabirds to the area in response to the increased food availability or, indirectly because of attraction of prey species. However, given the small quantities of food waste to be disposed, any attraction is likely to be minor, temporary and localised.

As a result of a change in water quality, further impacts to receptors may occur, which include injury or mortality to marine fauna resulting from exposure to toxins in drainage and treated bilge water discharges. The discharges, which may include non-organic contaminants, will rapidly dilute. Such discharges are expected to be intermittent and in very small quantities and concentrations as to not pose any significant risk to any relevant receptors.

Increased salinity and other toxins from chemical additives in brine and cooling water discharges could potentially harm marine fauna. Due to the relatively inert properties and low concentrations of scale inhibitors and biocides within the brine and cooling water discharge, the high level of dilution and mixing within the receiving offshore environment and the limited area of impact, impacts (if any) to pelagic species are expected to be highly localised.

As discharges will be sporadic (i.e. no continuous flow), there is no potential for fluids to accumulate in the water column.

It is possible that marine fauna transiting the localised area may come into contact with the discharges outlined above (e.g. marine turtles, whales, whale sharks; Section 4.6) as they traverse the PAA. While the likely presence of marine fauna varies at different times of the year depending on migration, foraging and breeding patterns in the region, the potential for impact remains low due to the localised nature of discharges and rapid dilution. No BIAs for marine fauna overlap the Offshore Operational Area; and activities in the Trunkline Operational Area will be limited to a Support Vessel. As such, the impact significance level for Marine fauna has been identified as slight (E).

Plankton

Routine and non-routine discharges may affect the ecophysiology of marine organisms as a result in changes of salinity. Studies indicate that effects from increased salinity on planktonic communities in areas of high mixing and dispersion are generally limited to the point of discharge only (Azis et al., 2003). Research has demonstrated that zooplankton are not affected in areas of sewerage or greywater discharge for transient vessels (Mearns et al., 2003; Ytreberg et al., 2020). Plankton communities are expected to rapidly recover from short term, localised impacts due to their naturally high mortality, and rapid replacement rates (UNEP, 1985).

Planktonic productivity in the NWMR is low. No significant impacts from the planned routine discharges are expected, because of the minor quantities involved, the expected localised mixing zone and high level of dilution into the open water marine environment of the PAA. Impacts to plankton from routine and non-routine discharges are not expected. As such, the impact significance level for Plankton has been identified as Negligible (F).

AMPs

The Trunkline Operational Area overlaps the Montebello AMP. The North-west Marine Parks Network Management Plan (DNP, 2018a) lists the natural values of the Montebello AMP as including a range of threatened, migratory, marine or cetacean species listed under the EPBC Act and cultural values which are intrinsically linked to those natural values. For activities occurring within the Montebello Marine Park, the short-term and localised impacts of routine and non-routine discharges in open waters will not be inconsistent with the natural and cultural values and objective of the Multiple Use Zone (VI) to provide for ecologically sustainable use and the conservation of ecosystems, habitats and native species, or for the Habitat Protection Zone (IV) to provide for the conservation of ecosystems, habitats and native species in as natural a state as possible, while allowing activities that do not harm or cause destruction to seafloor habitats. Impacts are therefore not inconsistent with the objectives of the North-west Marine Parks Network Management Plan or the zoning of the Montebello AMP (DNP, 2018a). As such, the impact significance level for AMPs has been identified as slight (E).

Summary of Assessment Outcomes				
Receptor	Impact	Receptor Sensitivity Level	Magnitude	Impact Significance Level/Risk Consequence
Water quality	Change in water quality	Low value (open water)	No lasting effect	Negligible (F)
Migratory shorebirds and seabirds	Injury/mortality or behavioural changes to marine fauna	High value species	No lasting effect	Slight (E)
Fish, sharks and rays		High value species	No lasting effect	Slight (E)
Marine mammals		High value species	No lasting effect	Slight (E)
Marine reptiles		High value species	No lasting effect	Slight (E)
Plankton		Low value (open water)	No lasting effect	Negligible (F)
AMPs		High value	No lasting effect	Slight (E)
<p>Overall Impact Significance Level/Risk Consequence: The overall impact significance level for routine and non-routine discharges of sewage, putrescible waste, grey water, bilge water, drain water, cooling water and brine is E based on no lasting effect to marine fauna. The impact significance level for water quality is consistent with the level rated in the Scarborough OPP. Potential impacts to marine fauna and AMPs have been additionally assessed in this EP. There is no change in magnitude of impact (no lasting effect); however, the impact significance level is slightly higher due to the higher receptor sensitivity level.</p>

ALARP Statement:				
On the basis of the environmental impact assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts of routine and non-routine discharges from the vessels. As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.				

Demonstration of Acceptability
Acceptability Statement:
The impact assessment has determined that, given the adopted controls, routine and non-routine discharges from the vessels are not expected to result in potential impacts greater than localised contamination not significantly above background levels outside a localised mixing zone. Further opportunities to reduce the impacts have been investigated above. The adopted controls are considered good oil-field practice/industry best practice and meet legislative requirements under Marine Orders 91, 95 and 96. The potential impacts and risks are considered broadly acceptable if the adopted controls are implemented. Activities do not have a significant impact on MNES (Section 2.4.2) including those with an First Nations connection or with traditional use in nearshore areas as defined in Section 4.9). Therefore, Woodside considers the adopted controls appropriate to manage the impacts and risks of these discharges to a level that is broadly acceptable and demonstrate the EPOs are met.

meter. The system is designed to achieve OIW concentration discharge below 15 mg/L, and process is monitored by a hydrocarbon/water interface level meter. Hydrocarbons collected from the open drains tank are directed to the waste drums for onshore disposal.

Drains from machinery spaces and diesel containing systems are directed towards the machinery open drains tank to capture and contain liquids before sending onshore for disposal. The machinery open drains are protected from rain ingress by being undercover or in enclosures.

The helideck area has a free-draining system to direct rainwater, fuel spillage and/or firefighting substances away from the helideck surface to overboard at safe locations. The helideck refuelling system is contained and connected to the non-hazardous open drain system. During routine operations the helideck fire deluge system will be tested for safety purposes and will involve the use and subsequent release of approximately 50L of water and fluorine free foam at the manufacturers recommended concentration.

Chemical storage areas have dedicated spill containment facilities, with segregation appropriate to prevent hazardous reactions from chemical mixing. Chemical spills can be directed to the open drains tank or direct to waste drums.

It is noted that cooling water and brine from the FPU will be co-mingled with produced water and are assessed as a combined discharge in Section 6.7.11.

Detailed Impact Assessment

Water Quality

Discharge of sewage, grey water and putrescible waste from the FPU has the potential to change the local water quality, with the addition of a temporary nutrient source. As discussed above (Section 6.7.9) a 10 m³ sewage discharge over 24 hours from a stationary source in shallow water, is reduced to about 1% of its original concentration within 50 m of the discharge location (Woodside, 2008). Monitoring stations confirmed that discharges were rapidly diluted or nutrients rapidly metabolised and no elevations in water quality parameters (e.g. total nitrogen, total phosphorous and selected metals) were recorded above background levels. Discharge of sewage (7 m³ to 28 m³) from the FPU may therefore be expected to disperse rapidly within a localised area around the FPU. Discharge of unmacerated sewage for limited time periods is not expected to increase potential impacts. This is supported by infield monitoring undertaken around the GWA platform, which indicated there was no detectable decrease in oxygen saturation, nutrients or increase in oxygen demand and that a 10 m³ discharge of sewage reduces to approximately 1% of its original concentration within 50 m of the discharge location (Woodside 2008).

Additionally, treated drainage water discharges from the FPU may contain a range of chemicals, oil, grease and solid material. Water quality of the surrounding environment may be altered through the addition of these contaminants; however, these discharges are expected to rapidly dilute in the water column given the deep, open water location of the FPU (Shell, 2010).

Impacts from routine and non-routine discharges from the FPU on water quality will have a slight effect on water quality around the FPU due to the nature of discharges, which will occur in an approved mixing zone, with a high level of dilution into the open water marine environment of the PAA. As such, the impact significance level for water quality has been identified as Negligible (F).

Marine Fauna

Discharge of sewage and greywater to the marine environment has the potential to result in injury or mortality to marine fauna. This could be the result of oxygen depletion in the waters due to nutrient enrichment, or due to toxins and chemicals present in the discharged wastes. Key factors influencing large open marine environments include large-scale current patterns and regional wind patterns, which lead to rapid mixing of surface and near surface waters where sewage and greywater discharges may occur. It is likely nutrients from the discharge of sewage will not accumulate or lead to eutrophication due to the highly dispersive environment. Due to the localised nature of discharge, receptors with the largest potential to be impacted are those in the immediate vicinity of the discharge area (NERA, 2017). Given that sewage discharges are at or near the surface, and remain buoyant, the receptors with the potential to be impacted are also those within or on surface waters; i.e. plankton, fish and other marine fauna.

Due to changes in water quality, receptors may be impacted further, with injury or mortality to marine fauna possible, resulting from exposure to toxins in drainage and treated bilge water discharges. The discharges, which could include non-organic contaminants, will rapidly dilute, with distance from the source. These kinds of discharges are anticipated to be in small quantities, small concentrations and intermittent in nature, as such are not likely to pose a significant risk to any receptors.

There is potential for marine fauna transiting the localised area (close to the FPU) to come into contact with the discharges discussed above, such marine fauna could include marine turtles, whales and whale sharks; Section 4.6. Although presence depends on time of the year and migration and foraging preferences, the potential for impact remains low due to the localised nature of discharges and rapid dilution. As discharges will be sporadic (i.e. no continuous flow), there is no potential for fluids to accumulate in the water column. There are no BIAs for marine fauna overlapping the Offshore Operational Area. As such, the impact significance level for Marine fauna has been identified as Slight (E).

Plankton

Routine and non-routine discharges may affect the ecophysiology of marine organisms as a result in changes in water quality. Research has demonstrated that zooplankton are not affected in areas of sewerage or greywater discharge for transient vessels (Mearns et al., 2003; Ytreberg et al., 2020). Although the FPU is stationery and discharges will occur at a fixed location, discharges will be sporadic (i.e. no continuous flow) and there is no potential for fluids to accumulate in the water column. Plankton communities are expected to rapidly recover from localised impacts due to their naturally high mortality, and rapid replacement rates (UNEP, 1985).

Planktonic productivity in the NWMR is low. No significant impacts from the planned routine discharges are expected, because of the minor quantities involved, the expected approved mixing zone and high level of dilution into the open water marine environment of the Offshore Operational Area. Impacts to plankton from routine and non-routine discharges are not expected. As such, the impact significance level for water quality has been identified as Negligible (F).

Summary of Assessment Outcomes

<i>Receptor</i>	<i>Impact</i>	<i>Receptor Sensitivity Level</i>	<i>Magnitude</i>	<i>Impact Significance Level/Risk Consequence</i>
Water quality	Change in water quality	Low value (open water)	No lasting effect	Negligible (F)
Migratory shorebirds and seabirds	Injury/mortality or behavioural changes to marine fauna	High value species	No lasting effect	Slight (E)
Fish		High value species	No lasting effect	Slight (E)
Marine mammals		High value species	No lasting effect	Slight (E)
Marine reptiles		High value species	No lasting effect	Slight (E)
Plankton		Low value (open water)	No lasting effect	Negligible (F)

Overall Impact Significance Level/Risk Consequence: The overall impact significance level for routine and non-routine discharges of sewage, putrescible waste, grey water, bilge water and drain water is E based on no lasting effect to marine fauna. The impact significance level for water quality is consistent with the level rated in the Scarborough OPP. Potential impacts to marine fauna have been additionally assessed in this EP. There is no change in magnitude of impact (no lasting effect); however, the impact significance level is slightly higher due to the higher receptor sensitivity level.

ALARP Statement:

On the basis of the environmental impact assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts of routine and non-routine discharges from the FPU. As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.

Demonstration of Acceptability

Acceptability Statement:

The impact assessment has determined that, given the adopted controls, routine and non-routine discharges from the FPU are not expected to result in potential impacts greater than localised contamination not significantly above background levels outside an approved mixing zone. Further opportunities to reduce the impacts have been investigated above. The adopted controls are considered good oil-field practice/industry best practice and meet legislative requirements under Marine Orders 91, 95 and 96. The potential impacts and risks are considered broadly acceptable if the adopted controls are implemented. Activities do not have a significant impact on MNES (Section 2.4.2). Therefore, Woodside considers the adopted controls appropriate to manage the impacts and risks of these discharges to a level that is broadly acceptable and demonstrates the EPOS are met.

Produced Water (PW) is condensed water (water vapour present within gas that condenses when brought to the surface) or formation water (derived from a water reservoir below the hydrocarbon formation), or a combination of both, which dissolves into the rich MEG stream that returns from subsea to the FPU. PW on the FPU (in both salt-free or salt modes) is a byproduct of MEG regeneration. A description of the MRU and PWTP has been provided in Section 3.9.9 and Section 3.9.10, respectively.

The two operating modes of the PWTP include:

- Salt-free mode - condensed water from production gas. PW rate approximately 50 m³/d
- Salt mode - condensed water + formation water (and dissolved salts). PW rate up to approximately 76 m³/d.

A short-term peak produced water rate of up to 100 m³/day (the integrity limit of the system is 108 m³/day) may occur during coincident maximum formation water production and an increased MEG processing rate, to re-establish normal storage tank levels. The condensed water and produced formation water are distilled in the MRU, and may contain naturally occurring contaminants including dispersed oil, dissolved organic compounds (aliphatic and aromatic hydrocarbons, organic acids and phenols), inorganic compounds (e.g., soluble inorganic chemicals or dissolved metals) and residual process chemicals (including MEG).

Condensed water is expected for the majority of field life (no formation water) and therefore the MRU and PWTP will usually operate in salt-free mode, within the order of 50 m³/d PW rate. Wells are not expected to produce formation water within the first 5 years of operations until they begin to water out toward the end of well life, however the scenario is included in this EP in case it unexpectedly occurs due to reservoir uncertainty. Once wells start to water out this may result in produced water rates of up to 76 m³/day for approximately 1-2 years, or at lower rates for up to 5 years. Table 6-31 shows the maximum discharge volumes for all Woodside facilities and relative water depths for context.

Table 6-31:PW discharge volumes and water depths at other Woodside offshore facilities.

Facility	Maximum discharge volume (m3 /day)	Approximate Water depth (m)	Commenced PW discharge
Okha	18,000	80	2011
Pyrenees	9,000	198	2010
GWA	7,500	130	1995
Angel	4,800	80	2008
PLA	3,500	85	N/A
NRC	1,900	125	1984
Scarborough	100	950	N/A

Formation water has a different composition to condensed water, most significantly in that it contains salts from the reservoir. When formation water is produced, the MRU is operated in salt mode which means that the MEG solids handling system is in operation. This removes salts/particles from the MEG slurry that has precipitated in the MEG flash separator and recycle loop. The salts removed from the MEG are then re-dissolved (small amount remains undissolved) by a side stream of produced water which is then re-combined to be discharged with the comingled PW and seawater stream.

Produced Water Treatment

Following removal from the MEG process stream by distillation, produced water (in both operating modes) is directed to the produced water treatment system. A best-practice interchangeable adsorption media bed arrangement is used to remove hydrocarbons and mercury. This permanent tertiary treatment option is facilitated by the relatively low PW rates expected on the FPU

Seawater Discharge Stream

The FPU facilities have an indirect cooling water system where seawater is pumped up to the facility, treated with hypochlorite and passed through the heat exchangers where it cools a closed circuit cooling medium system, prior to discharge back overboard.

The hypochlorite system will inject chlorine to protect the seawater cooling system from biofouling. Seawater (containing residual chlorine) will be discharged overboard as part of the cooling water discharge stream. Residual free chlorine concentration in this discharged water is expected to be approximately 0.2 mg/L during normal operations.

Seawater used for cooling purposes, comingled with treated produced water and salts removed from the MEG stream (when MRU is in salt mode) will be routinely discharged overboard at a temperature less than 60°C and rates of up to 3,971 m³/h.

Monitoring and Management Framework

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

This section describes the monitoring and management framework which Woodside has developed to support the monitoring of PW discharges from offshore assets. The monitoring and management framework comprises of:

- operational monitoring
- baseline monitoring
- Initial monitoring during the first 12 months of steady-state
- Initial salt mode monitoring after initiation of salt mode
- routine monitoring

Further details are provided in Section 7.2.5 which described Woodside's Offshore Marine Discharge Adaptive Management Plan (OMDAMP). The monitoring and management here will be implemented in accordance the OMDAMP.

Operational Monitoring

Oil in Water

OIW is monitored at the outlet of the PWTP (prior to comingling with seawater return) during routine operations via online analysers. Online analyser information is sent via transmitter and reported to the Scarborough distributed control system (DCS) and is also captured within the process historian database (PHD). The DCS facilitates visibility in the control room, for manual or automated process control changes to be made, and/or alarms enunciated (e.g. high OIW specification). PHD information is available onshore for analysis and trending.

During attended operation, manual samples of PW are taken weekly for OIW analysis with results compared with online analyser readings. During unattended operation, manual sampling is undertaken during each intervention visit (~every 28 days) and sent onshore via helicopter at the start of the visit for analyser QC checks at the onshore lab. The results are sent back to the operator to allow calibration of both analysers during the visit. As detailed in the **Section 3.9.10**, two analysers are installed on the facility. If one analyser is faulty or breaks down, any anomalies that are identified are investigated to determine the cause and may be addressed by corrective maintenance during the next attended period. In the event of high OIW readings, management measures are implemented to reduce OIW to below thresholds as described in *High OIW Management* below.

Analysers were selected from a range of technology solutions in the specific context of the facility and the range of possible flow rates and stream characteristics expected. A key consideration was ability detect and measure dissolved hydrocarbons, since dispersed/entrained hydrocarbon concentration is expected to be negligible. Dispersed hydrocarbons will be effectively measured in laboratory analysis.

High OIW Management

Increasing OIW concentration in the outlet of the PWTP may indicate approaching media bed saturation, triggering remote switching to the spare bed in accordance with operational procedures. If risk of OIW exceedance (24-hour rolling average) is anticipated, the off-spec water will be directed back inboard to the rich MEG tank while results are verified and the cause of the exceedance is investigated. The capacity of rich MEG tank to hold PW is limited to ~1170 m³. A Standard Operating Procedure for high OIW management is in place, with decision criteria to allow clear interpretation and facilitation of compliance with OIW standards.

Loss of Signal Management

During unattended operation, if there is a loss of signal from both OIW analysers, operators attempt to reset analysers remotely and monitor process stability for changes with the potential to result in an increase in the OIW concentration. If one of the analyser readings cannot be restored, the facility will apply the following remote response:

- Inboard PW water to Rich MEG tank (instead of discharge).
- Cut back water producing wells, if necessary.
- Prepare for a response visit to facility pending rich MEG tank ullage and timing with next facility planned intervention visit.
- Once re-attended, troubleshoot analysers and use manual sampling to monitor OIW discharges.

If there is a loss of signal from both OIW analysers during attended operation, Operators will take manual samples to monitor OIW concentrations using (4 times per day).

A Standard Operating Procedure for loss of signal is in place, with decision criteria to allow clear interpretation and facilitation of compliance with OIW standards.

Mercury

During attended operation, manual samples of PW are taken weekly for mercury analysis onshore. Attended operation is planned for the first ~2 years of facility operation (Section 3.9.6), providing sufficient operating experience to understand bed saturation trends and timeframes and achieve reliable operations, ahead of transitioning to unattended operation. Two media beds are onboard providing 100 % redundancy, with a third bed present in the FPU laydown or onshore being regenerated. During unattended operation, sampling is undertaken during each attended period (as described in Section 3.9.6) and sent onshore via helicopter at the start of the visit. The results are communicated to operators to allow for filter change out during the visit if required

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

High Mercury Management

Increasing mercury concentration in the outlet of the PWTP may indicate approaching media bed saturation, triggering the vessel to be replaced with a non-saturated bed in accordance with the operating procedure.

If there is a risk that mercury levels may exceed the end of pipe trigger the off-spec water will be directed back inboard to the rich MEG tank while results are verified and the cause of the exceedance is investigated. The capacity of rich MEG tank to hold PW is limited to ~1170 m³. A Standard Operating Procedure for high mercury management is in place, with decision criteria to allow clear interpretation and facilitation of compliance with mercury standards.

Baseline Monitoring

A baseline monitoring program has been conducted at the Scarborough field location (ERM 2013). The study was completed in two parts, in wet season 2012 and dry season 2013. The objectives of the study was to characterise the benthic communities, seasonal water quality, sediment quality, plankton communities and seasonal primary productivity of the location in context of the broader region.

The study indicated that biophysical characteristics are generally typical of the North West Marine Bioregion tropical deepwater environments, including:

- No hydrocarbons were detected in the water and sediment samples.
- Metal concentrations were below ANZG guideline trigger values, with exception of mean concentrations for cobalt, copper and zinc in water samples and nickel in sediment samples. These concentrations are considered to likely represent natural conditions at the location.
- Nutrient concentrations were low.

Initial Monitoring

Post start-up, a period is required to optimise the PW treatment system and to understand how it operates and reacts to changes in the process (pressures, chemical concentrations, flow rates). It is expected that this will take approximately 4 months, in-line with the expected initial start-up duration. Once the facility achieves steady state operations, the PW stream is sampled to characterise the discharge stream. The system is considered to be in “steady state” once routine discharge commences, and contaminant concentrations (OIW and mercury measurements) are seen to remain steady. PW samples should represent normal operations, so sampling should only be undertaken during periods of normal production for the facility. Sampling should, as far as reasonably practicable, provide a representative sample with consideration of chemicals that may be present in the discharge stream.

PW samples should represent normal operations, so sampling should only be undertaken during periods of normal production for the facility. Sampling should, as far as reasonably practicable, provide a representative sample with consideration of chemicals that may be present in the discharge stream. Monitoring includes the following:

- Chemical characterisation to identify if toxicants with the potential to bioaccumulate exceed the 80% species protection guideline value at end of pipe (after comingling). If toxicants with the potential to bioaccumulate are predicted to exceed guideline values at end of pipe, further investigations are required as described in the Offshore Marine Discharges Management Plan (OMDAMP).
- WET testing will be conducted in parallel with chemical characterisation to verify 99% species protection safe dilutions for comparison with the approved mixing zone. If 99% safe dilutions are not predicted to be achieved at the boundary of the mixing zone, further investigations are required as described in the OMDAMP.
- Settling velocity and particle size distribution analysis will be conducted to ascertain the potential for contaminants to flocculate and settle out of solution and impact sediment quality. The results of these studies will inform requirements for non-routine sediment sampling.

Descriptions of monitoring techniques are provided under routine monitoring. Initial monitoring will then cover a 12-month period. The initial monitoring will be reviewed to confirm assumptions (chemical composition, particle size, toxicity etc) and used to determine potential for impact.

Salt-Mode Initial Monitoring

Due to uncertainty related to composition of salts removed from the MEG and comingled with the PW discharge stream, the initial suite of sampling and testing conducted following start-up (chemical characterisation, WET testing, settling velocity and particle size distribution) will also be carried out in reaction to commencement of formation water being produced from the reservoir and the MRU operation entering salt mode.

Routine Monitoring

Routine monitoring applicable to the facility, is undertaken to compare against trigger values (described in Table 6-32). Changes in discharge composition can be detected early and can indicate the potential for an impact to water quality prior to it occurring. Woodside analyses the PW sample as a uniform whole via WET testing, which includes all constituents along with their potential interactions. WET testing confirms if there is a potential for impact on biota. Chemical characterisation is undertaken to understand toxicants that may be driving toxicity in the WET test and to assess whether the discharge has changed significantly from the last WET test. It is not appropriate to monitor for changes in species composition, diversity, etc., as there are limited receptors in the direct impact zone (a surface buoyant plume), and such changes may be detected after an impact occurs, and therefore are not considered appropriate for early detection.

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

Routine monitoring assesses the following

- Chemical characterisation to identify if toxicants with the potential to bioaccumulate exceed the 80% species protection guideline value at end of pipe (after comingling).
- WET testing to verify 99% species protection safe dilutions for comparison with the approved mixing zone is conducted in parallel with chemical characterisation to identify drivers of ecotoxicity

WET tests are undertaken on a broad range of taxa of ecological relevance. A minimum of eight toxicity tests are carried out with each PW sample during WET testing. Specific toxicity tests are listed in the OMDAMP which include a range of mainly tropical, Australian marine species and are selected based on their ecological relevance, known sensitivity to contaminants, availability of robust test protocols and known reproducibility and sensitivity as test species for assessing PW in marine environments. Tests can be exchanged over time if tests are not available, or become obsolete, however, preference would be for tests that mimic the receiving environment as closely as possible (i.e. for most facilities this would be tropical, marine water tests) (Warne et al. 2018). The dilutions required to protect 99% and 95% of species is calculated using the ANZG (2018) statistical distribution methodology on the results of direct toxicity assessment using sub-lethal chronic endpoints. The protection of 99% of species maintains a high level of ecological protection at the boundary of the approved mixing zone and is considered appropriate to account for the uncertainty in composition. The approved mixing zone boundary is 400 m.

Woodside previously sampled sediment at other Woodside operated facilities every six years and no benthic impacts from PW were detected. Therefore, based on this, maximum PW discharge being less than 5 years, the water depth (over 900 m) and the predicted plume behaviour no routine sediment sampling is included. Settling velocity and particle size distribution analysis is proposed as part of the initial monitoring of representative discharge to confirm potential for sediment impacts in addition to quarterly chemical characterisation end of pipe. Results of these studies will inform if non-routine sediment sampling is required.

Results of chemical characterisation and WET testing will be compared against OMDAMP trigger values (Table 6-32). Exceedances of trigger values require further investigation, including multiple lines of evidence. If further investigations confirm the trigger value has been exceeded, a review of single species testing is conducted¹⁰⁵, plus additional WET testing if required. Monitoring will be conducted in accordance with the OMDAMP and where appropriate routine monitoring triggers, methodologies and standards applied (e.g. requirements for WET testing) to ensure consistency and comparability of data.

Table 6-32 Trigger values and frequency of monitoring

Monitoring	Trigger Value	Frequency
Initial Monitoring (including once MRU operation enters salt mode)		
Review of continuous operational monitoring results	Increases in the average monthly OIW concentration by 5 mg/L total over six consecutive months or by 10 mg/L total over two consecutive months	Monthly
Chemical characterisation end of pipe sample – physio-chemical and toxicants	Results that are predicted to be higher than the 99% species protection guideline value at approved mixing zone boundary and above the value recorded during last WET test or above the last WET test where no guideline is available.	Quarterly (over a 12-month period)
	Toxicants with the potential to bioaccumulate are predicted to be higher than the 80% species protection guideline value at end of pipe	Quarterly (over a 12-month period)
WET testing	The 99% species protection safe dilutions derived from the WET testing species sensitivity distributions are not predicted to be achieved at the boundary of the approved mixing zone	Annually (with first chemical characterisation sampling event)
Sedimentation and settling studies	Particles >40 µm with the potential to settle are identified.	Annually (with first chemical characterisation sampling event)
Standard routine monitoring		

¹⁰⁵ Single species testing is conducted in parallel to chemical characterisation to support further investigations (See Section 7.2.4)

Review of continuous operational monitoring results	Increases in the average monthly OIW concentration by 5 mg/L total over six consecutive months or by 10 mg/L total over two consecutive months	Monthly
Chemical characterisation end of pipe sample – physio-chemical and toxicants	Results that are predicted to be higher than the 99% species protection guideline value at approved mixing zone boundary or above the value recorded during last WET test where no guideline value is available.	Annual
	Mercury with the potential to bioaccumulate is predicted to be higher than the 99% species protection guideline value at end of pipe.	Annual
WET testing	The 99% species protection safe dilutions derived from the WET testing species sensitivity distributions are not predicted to be achieved at the boundary of the approved mixing zone	Three yearly (calendar year), Conducted in parallel with annual chemical characterisation.
Discharge volume	Monthly mean discharge volume is equal to or above level required to meet the approved mixing zone boundary based on WET testing.	Monthly review

Detailed Impact Assessment

Potential impacts of PW discharge include:

- changes to water quality
- toxicity to biota
- changes to sediment quality.
- changes to Key Ecological Features (KEFs).

The maximum expected discharge rate is 100 m³/day. The average daily PW discharge rate is expected to be significantly less than the maximum rate as demonstrated on other Woodside facilities. However, as the total volume of PW is expected to increase as the field ages, environmental impacts have been assessed against maximum expected discharge rates.

Water Quality

Potential impacts to water quality are to be assessed through chemical characterisation of discharge and monitoring of ongoing discharge volumes. Variability is managed via the Monitoring and Management Framework.

Although formation water and gas samples are available from a number of wells, these are not deemed to be representative of PW characteristics at the FPU. There is significant difference between the natural compositions of PW associated with the reservoir compared to water condensed from the gas during processing. Condensed water has low levels of dissolved salts while PW from the reservoir typically contains high levels of salts. The presence of residual process chemicals further complicates any comparisons between formation water and offshore PW. Given the difference, reservoir samples are deemed to not be representative however they can provide an indication of the potential presence of contaminants. It is not possible to collect a sample of PW that is representative of the discharge prior to treatment facilities operating.

The discharge stream is expected to comprise primarily of condensed water and cooling water comingled prior to discharge. Woodside has successfully managed impacts from PW from six facilities via the OMDAMP and intends to implement this Monitoring and Management Framework to manage variability in PW at this facility.

Chemical Characterisation of PW (Physio-chemical and Toxicants in Water)

During appraisal drilling for the Scarborough project, samples of gas and water were obtained from three wells at various locations and depths within the reservoir with trace elements measured from each well in order to establish a basis for the process design (Table 6-33). The reported concentrations were based on the highest levels measured from any of the three wells sampled. The concentrations of mercury measured within gas samples within the three wells were highly variable ranging from 2 and 182 ug/m³. Given the low reservoir temperatures and expected reservoir fluid, mercury is expected to be <25 ug/Sm³ however to ensure the initial design and possible future expansions were robust to high mercury a design limit of 200 ug/Sm³ was adopted (Woodside, 2019c). Mercury process modelling was undertaken to understand the potential for mercury to partition from gas to the produced water stream. This modelling considered two scenarios; a worst case 200 ug/Sm³ and expected 20 ug/Sm³. The worst case modelling predicted that concentrations in produced water could be up to 95 ug/L prior to entering the produced water treatment system (Woodside, 2019d). After treatment mercury is expected to be 0.03 ug/L during operations and 0.11 ug/L during startup. Three and 11 dilutions are required to meet 99% species protection guideline values during operations and start up respectively.

Table 6-33 Development Basis of Design Reservoir Metal Characteristic Concentrations.

Contaminant	Maximum measured concentration
Mercury	200 ug/Sm3
Arsenic	< 0.005 mg/Sm3
Sodium	12,153 mg/L
Potassium	1,186 mg/L
Calcium	285 mg/L
Magnesium	118 mg/L
Barium	12 mg/L
Strontium	30 mg/L
Chloride	20,617 mg/L
Sulphate	13 mg/L

The composition of PW is complex and may consist of additional components such as volatile aromatic compounds Benzene, Toluene, Ethylbenzene, Xylenes (BTEX) and Polycyclic Aromatic Hydrocarbons (PAHs), concentrations of which vary throughout the field life. The composition of PW will be verified by the initial and subsequent monitoring and that toxicants with the potential to bioaccumulate are below 80% species protection at end of pipe.

Based on the potential for the discharge of these contaminants there is potential for slight, localised decrease in water quality at the discharge location and within the mixing zone with potential adverse effects on marine biota.

Residual Process Chemicals

Residual process chemicals may be present in the PW stream. Process chemicals are subject to Woodside’s chemical selection and approval process. The largest chemical by volume, MEG is rated OCNS Group E (lowest hazard) and is considered PLONOR. In addition, scale inhibitors are typically low molecular weight phosphorous compounds that are water-soluble, and only have acute toxicity to marine organisms about two orders of magnitude higher than typically used in the water phase (Black et al., 1994). The biocides typically used in the industry are highly reactive and degrade rapidly (Black et al., 1994).

Chemicals will decrease the water quality in the immediate area of the release (i.e. surface waters at the release location); however, the effect is expected to be temporary and localised due to dilution with the combined stream and the open ocean mixing environment, distance from sensitive receptors and relatively low volumes.

Sodium hypochlorite functions as a biocide in the cooling water system and is expected to readily dissociate and break down once discharged. Modelling was undertaken of assuming a residual concentration of 0.2 mg/L (normal operations) as described below.

Potential impacts to water quality are expected to be localised to the immediate vicinity of the FPU. Impacts from routine and non-routine discharges of comingled PW and cooling water will have a Negligible (F) effect on water quality.

Potential Impacts to Biological Indicators

Upon achieving steady state operations PW processing, initial monitoring of the PW will be completed in order to establish actual toxicity and to verify the approved mixing zone.

WET Testing

Most treated PW has low to moderate toxicity (Neff et al. 2011), with actual toxicity of discharge dependant on the chemical constituents of the PW and any added process chemicals, the level of treatment and dilution with condensed water prior to release, and the dilution of the discharge as it mixes with sea water. Most hydrocarbons in PW are considered non-specific narcotic toxins with additive toxicities; therefore, the toxicity of a PW will, in part, depend on the total concentration and range of bioavailable hydrocarbons (Neff, 2002).

WET testing is undertaken to allow for interactions between toxicants and take into account toxicants that cannot readily be measured or are not known to be present in the sample. A formation water sample from the Scarborough reservoir was unable to be obtained during exploration for WET testing (noting that actual 99% and 95% species protection safe dilutions will be provided from initial monitoring WET testing).

Woodside has extensive operational experience with PW characterisation from gas condensate facilities on the North West Shelf of Western Australia. WET testing data (Table 6-34) from existing operating facilities were reviewed to determine an analogue for Scarborough in order to define an approved mixing zone.

The dilutions from the onshore Pluto LNG MEG effluent were selected as the best analogue for this assessment. Given Pluto effluent is generated from a MEG reclamation process conceptually similar to that implemented on the Scarborough FPU. Required dilutions are also comparatively high and likely to be conservative given the sample

location used was prior to water treatment. Following initial monitoring the WET testing results will be used to review and clarify the approved mixing zone boundary.

Table 6-34: Whole effluent toxicity testing data (highest recorded value)

Facility	Dilutions required (PC99)	Year
GWA	1 in 1,388	2023
Angel	1 in 417	2022
NRC	1 in 3130	2017
Okha	1 in 157	2023
Pluto Onshore MEG effluent	1 in 1,282	2022

Determination of Mixing Zone

The principal aim of the dispersion modelling was to quantify the likely extents of the near-field and far-field mixing zones and therefore the potential impact of the combined PW and cooling water discharge to the marine environment. Site specific modelling was undertaken from the Scarborough FPU discharge. Modelling methods were integrated to simulate the potential dispersion, a near-field discharge model (CORMIX), and a far-field advection and dispersion model (CHEMMAP) (RPS, 2023c). Ocean current data, from the Scarborough FPU location, was sourced from a ten-year hindcast data set of combined large-scale ocean (HYCOM) and tidal currents (Hydromap). The dispersion of contaminants will depend, initially, on the geometry and hydrodynamics of the discharge itself, where the induced momentum and buoyancy effects dominate over background processes. This region is generally referred to as the near-field zone and is characterised by variations over short time and space scales. As the discharge mixes with the ambient waters, the momentum and buoyancy signatures are eroded, and the background, or ambient, processes become dominant. The far-field modelling expands on the near-field work by allowing the time-varying nature of currents to be included, and the potential for recirculation of the plume back to the discharge location to be assessed. The near-field simulations consider steady-state unidirectional currents, while the far-field simulations account for currents that vary in speed and direction over time and space, far field modelling represents minimum dilutions achieved 95% of the time. Validation of tidal predictions was performed using the model output and independent predictions of tides at the Scarborough FPU location. All comparisons show that the model produces a very good match to the known tidal behaviour for a wide range of tidal amplitudes and clearly represents the varying diurnal and semi-diurnal nature of the tidal signal.

Modelling was conducted to quantify the likely extents of the near-field and far-field mixing zones based on the required dilution levels for contaminant levels in the co-mingled cooling water and PW discharge.

As described above, the comingled discharge comprises:

- PW from the processing of hydrocarbons
- seawater discharge stream (SW) including seawater return from three systems:
 - Seawater Cooling Medium Exchangers (largest flowrate)
 - Brine from RO Water Maker Package
 - Hypochlorite Generator Package.

Two scenarios were modelled, scenario 1 (normal operations) and scenario 2 (start-up). Each scenario was modelled with and without chlorine degradation applied. The main distinction between the two scenarios, normal operations and start-up, are the flow rates of the commingled discharges, influenced entirely by the SW flow rate. The dilution modelling results are based on the maximum design flow rates of 100 m³/day for PW representing the worst-case load to the environment. At lower actual discharge rates, dilutions levels are expected to be achieved closer to the discharge point than those predicted by the modelling due to reduced loading to the environment.

The potential area that may be influenced was assessed for three distinct seasons: (i) summer (December to February); (ii) the transitional periods (March and September to November); and (iii) winter (April to August). An annualised aggregation of outcomes was also assembled. Current strengths of weak, medium and strong were also considered.

Table 6-35: Summary of the combined discharge characteristics

Parameter	Scenario 1 Normal Operations	Scenario 2 Start-up
Flow rate (m3/hr)	3,971 (PW: 4.1; CW: 3,967)	1,988 (PW: 4.1; CW: 1,984)
Number of outlet ports	1	
Outlet port internal diameter (m)	1.092	
Outlet port orientation	Vertical Downward	

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

Depth of ports below sea surface (m)	8
Hypochlorite degradation rate (hr-1)	0.395

Prior to discharge PW will be diluted 968 times in scenario 1 and 484 times in scenario 2 by comingling with cooling water. Further information on near field and far field modelling is described below.

Near field modelling

The near-field modelling of the comingled cooling water discharge indicates the following general outcomes (results by operational scenario are shown in Table 6-36:

- A turbulent mixing zone is created in the immediate vicinity of the discharge point by the momentum of the discharge. This turbulent zone emerges at a depth of 8 meters below the water surface and reaches depths of up to 23 m below the sea surface.
- Medium and strong currents are shown to increase the extent of the turbulent mixing zone. Following this initial mixing, the positively buoyant plume is predicted to rise in the water column.
- For all combinations of discharge case and season, the primary factor influencing dilution of the plume is the strength of the ambient current. Weak currents allow the plume to reach the trapping depth (surface) closer to the discharge point, which slows the rate of dilution.

Table 6-36: Summary of near-field modelling results

Scenario 1 (Normal operations)	Scenario 2 (Start-up)
<ul style="list-style-type: none"> • Maximum horizontal distance: 76 m • Maximum plume diameter: 10 m • Annualised minimum dilution at trapping depth under medium currents: 1:24 • Annualised average dilution at trapping depth under medium currents: 1:40 	<ul style="list-style-type: none"> • Maximum horizontal distance: 88 m • Maximum plume diameter: 6 m • Annualised minimum dilution at trapping depth under medium currents: 1:18 • Annualised average dilution at trapping depth under medium currents: 1:30

The results for the Scenario 1 (normal operation) and 2 (start-up) discharges indicate that OIW, mercury and MEG were either already below threshold concentration at discharge or reached below threshold concentration in the nearfield. The modelling indicates a turbulent mixing zone in the immediate vicinity of the discharge point, induced by the momentum of the discharge. Before the buoyant plume is predicted to rise in the water column.

Far-field modelling

For the far- field model, a CHEMMAP model simulated the discharge into a time-varying current field with the initial dilution set by the near-field results. Both comingled water discharge operational scenarios were modelled as a continuous discharge using 50 simulations for each season. Once the simulations were complete, they were reported on a seasonal and annualised basis.

The model predicted higher dilutions (lower concentrations) are predicted during periods of increased current speed, whereas patches of lower dilutions (higher concentrations) tend to accumulate during the turning of the tide or during periods of weak drift currents. During prolonged periods of lowered current speed, the plume has a more continuous appearance, with higher-concentration patches, moving as a unified group. These findings agree with the research of King & McAllister (1997, 1998) who noted that concentrations within effluent plumes generated by an offshore platform were patchy and likely to peak around the reversal of the tides.

Applying the 972 or 484 dilutions achieved prior to discharge (comingling with seawater return prior to discharge), leaving a remaining 227 or 798 dilutions required after discharge to reach PC99. Based on modelling described above, the minimum distance required to achieve 1,282 dilutions is 400 m. In-situ measurement and analysis of PW plume dilution and mixing characteristics will be conducted. This study will focus on:

- obtaining background measurements of surface and sub surface temperature and salinity levels surrounding the FPU including the PW near-field mixing zone under different current conditions
- tracking the plume to quantify the horizontal and vertical plume dilutions achieved under different current conditions
- verifying no environmental impact at the approved mixing zone boundary

The purpose of these oceanographic field measurements will be to verify the plume dispersion model (RPS, 2018) used as the basis for assessing safe dilution levels of PW discharges.

A threshold concentration of 0.002 mg/L has been derived (Batley & Simpson 2020)., assuming a source concentration of 0.2 mg/L (normal operations) and 2.0 mg/L (start-up) and a decay constant (0.395 hr⁻¹), the discharge reaches the threshold at 100 m and 300 m respectively.

Bioaccumulation

Bioaccumulation refers to the amount of a substance taken up by an organism through all routes of exposure (water, diet, inhalation, epidermal). The Bioaccumulation Factor is the ratio of the steady-state tissue concentration and the steady-state environmental concentration (assuming uptake is from food and water). The test developed to measure the ability of a substance to bioaccumulate, namely, the octanol-water partition (Pow), is based on the preferential partitioning of lipophilic organic compounds into the octanol phase. Partitioning into octanol can be correlated with the attraction for such compounds to the fatty tissue (lipid) of organisms.

Bioaccumulation of BTEX compounds has been observed to occur in the laboratory, only at concentrations far in excess of that discharged from facilities (for example refer to Berry, 1980); hence it is unlikely that BTEX would bioaccumulate at the exposure concentrations that may be experienced by biota around the FPU. Baseline characterisation of the PW discharge will verify BTEX levels in the PW from the FPU.

In contrast to BTEX compounds, PAH compounds have high Pow values indicative of the potential for bioaccumulation (Vik et al, 1996). Neff and Sauer (1996) based on available literature for laboratory and field studies investigating the bioaccumulation of PAHs. The bioaccumulation values for PAHs in marine organisms collected near PW discharges in the Gulf of Mexico reported by Neff and Sauer (1996) indicate that the highest bioaccumulation factor was in the tissues of bivalve molluscs and the lowest in the muscle tissue of fish.

The most comprehensive field study assessing bioaccumulation of hydrocarbons and metals from PW discharged into offshore waters is that by Neff et al (2011). At the request of the United States Environmental Protection Agency (USEPA), the Gulf of Mexico Offshore Operators Committee sponsored a study of bioconcentration of selected PW chemicals by marine invertebrates and fish around several offshore production facilities discharging more than 731 m³ per day of PW to outer continental shelf waters of the western Gulf of Mexico (by comparison discharges will be up to 100 m³/day). The target chemicals identified by USEPA included five metals (As, Cd, Hg, 226Ra and 228Ra), three volatile Monocyclic Aromatic Hydrocarbons (MAH), benzene, toluene, and ethylbenzene, and four semi-volatile organic chemicals, phenol, fluorene, benzo(a)pyrene, and di (2-ethylhexyl) phthalate. Additional MAH (m-, p-, and o-xylenes) and a full suite of 40 parent and alkyl-PAH and dibenzothiophenes were also analysed by Neff et al (2011) in PW, ambient water, and tissues at some platforms.

Concentrations of MAH, PAH, and phenol as determined by Neff et al (2011) were orders of magnitude higher in PW than in ambient seawater. There was no evidence of MAH or phenol being bioconcentrated. All MAH and phenol were either not detected (> 95% of tissue samples) or were present at trace concentrations in all invertebrate and fish tissue samples. Concentrations of several petrogenic PAHs, including alkyl naphthalene's and alkyl dibenzothiophenes, were slightly, but significantly higher in some bivalve molluscs, but not fish, from discharging than from non-discharging platforms. These PAH could have been derived from PW discharges or from tar balls or small fuel spills. Concentrations of individual and total PAH in mollusc, crab, and fish tissues were well below concentrations that might be harmful to the marine animals or to humans who might collect them for food at offshore platforms (Neff et. al., 2011). It is expected that bioaccumulation is unlikely to result in increased levels of BTEX or PAH in biota surrounding the FPU.

Mercury in the marine environment exists mainly as complexes of mercury (II) and as organomercurials (Hart 1982). Of particular concern is inorganic forms of mercury (of relatively low toxicity and availability to bioconcentrate) that may be converted by bacteria in situ into organomercury complexes (particularly methylmercury), which are more toxic and tend to bioaccumulate. Neff et al (2011) attempted to measure bioaccumulation of four metals (arsenic, barium, cadmium, and mercury), by two species of bivalve molluscs from platform legs and five species of fish collected within 100 m of produced water discharging and non-discharging platforms in the Gulf of Mexico. The study found no difference in metal concentrations between impact and control sites.

For bioaccumulating substances such as mercury, the ANZG 80% guideline value is expected to be met end of pipe prior to discharge and the 99% guideline value is anticipated to be met within 400 m. Potential impacts to biota from heavy metals would be localised to the immediate vicinity of the FPU. Therefore based on outcomes from studies (Neff et al 2011) and given the size of the mixing zone and the wide distribution of most species potential impacts would be limited to individuals and not impact on populations.

The potential environmental impact associated with bioaccumulation of PW constituents in the water column is considered to be a localised effect in waters immediately surrounding the FPU. The potential risk to fisheries is further reduced to ALARP as a result of negligible exposure given the PSZ prohibits fishing from or near the FPU. Given the nature of the PW discharge from the FPU, the potential for bioaccumulation of PW contaminants (in particular mercury) is considered to be restricted to sessile organisms growing on the FPU.

Marine Fauna

Given that PW will be managed to achieve 99% species protection at the approved mixing zone boundary potential for impacts to marine fauna are limited to a localised area in proximity to the FPU (within 400 m). In addition, toxicants are expected rapidly dilute and are not considered to cause acute toxicity. Therefore, impacts would be limited to fish communities associated with the FPU exposed to water quality changes. While transiting cetaceans, whale sharks or turtles (noting that there are no BIAs or critical habitats within the mixing zone) may pass through the plume they are not anticipated to spend long durations within the mixing zone and no impacts are expected. As such, the magnitude for fish, whale sharks, rays, cetaceans and marine reptiles has been identified as no lasting effect (F).

Plankton

A change in water quality as a result of comingled PW and cooling water discharges has the potential to result in the injury or death of planktonic species within the water column through toxicity effects. Early life stages of fish (embryos, larvae) and other plankton would be the most susceptible organisms to exposure from hydrocarbons and chemicals in the discharges, as they have limited mobility and are therefore likely to be exposed to the plume, if present. Impacts are predicted to be limited to within 400 m of the discharge location and impacts are expected to be slight. These types of organisms are known to have high levels of natural mortality and a rapid replacement rate (UNEP, 1985). Plankton is generally abundant in the upper layers of the water column and is the basis of the marine food web, so localised impacts in any one location are unlikely to have long-lasting impacts on plankton populations at a regional level. Reproduction by survivors or migration from unaffected areas is likely to rapidly replenish losses (Volkman et al., 2004).

Primary productivity appears to be enhanced along the northern and southern boundaries of the Exmouth Plateau, and along the adjacent shelf edge to the east of the plateau (Brewer et al., 2007). As described by Falkner et al. (2009), the centre of the plateau is characterised by moderate seafloor temperatures and low primary productivity. Given the total area of plankton and, significant distance (>150 km) from the periphery of the plateau that has been identified as having increased productivity (Brewer et al., 2007; Falkner et al., 2009) it is not anticipated that this discharge will impact the primary productivity of the KEF. As such, the impact magnitude for plankton has been identified as slight (E).

Key Ecological Features

The Offshore Operational Area occurs within the Exmouth Plateau KEF. The Exmouth Plateau is defined as a KEF as it is a unique seafloor feature with ecological properties of regional significance, which apply to both the benthic and pelagic habitats within the feature. Therefore as a result of a change in sediment and/or water quality potential impacts to the KEF may occur. Potential for impacts to sediment quality are not expected (see below). Therefore values of the Exmouth Plateau to be affected by PW discharges are limited to impacts to water quality. Modelling predicts the discharge will form a buoyant plume extending less than 400 m from the discharge point, therefore, impacts to values associated with the KEF are expected outside the approved mixing zone are anticipated.

Given the small amount of representative habitat within the KEF that overlaps the Offshore Operational Area (approximately 2.4% of the Exmouth Plateau KEF), noting that mixing zone would be an even smaller area, and predicted impact limited to slight change in water quality no impacts to marine ecosystem functioning or integrity of the KEF is expected.

Impacts from routine and non-routine comingled PW and cooling water discharges will have no lasting effect on KEFs.

Sediment Quality

Accumulation of PW contaminants in sediments depends primarily on the volume/concentration of particulates in PW discharges or constituents that sorb onto seawater particulates the area over which those particulates could settle onto the seabed (dominated by current speeds and water depths) and re-suspension, bioturbation and microbial decay of those particulates in the water column and on the seabed.

The benthic habitat at the FPU location is predominantly soft sediment with sparsely associated epifauna, (Section 4.5.1). Benthic communities of deposit feeders such as epifauna (living on the seabed): shrimp (crustaceans) and sea cucumbers (echinoderms), and infauna (living within the surface sediments) small, burrowing worms (polychaetes) and crustaceans (ERM, 2013).

The discharge plume is predicted to be buoyant, due to lower salinity and/or higher temperature than surrounding seawater. Therefore, potential contaminants in the PW discharge could only be introduced into sediments around the FPU through precipitations of soluble contaminants and flocculation and sedimentation of the particles in the PW plume. Studies into potential sediment accumulation from PW discharge have been undertaken by Woodside (Jacobs 2016). The study found that the PW at all facilities had very small amounts of solid material, with very little potential of settling or flocculation due to small particle sizes. Initial monitoring (described above) includes settling velocity and particle size distribution to confirm potential for precipitation and flocculation.

Dr Graeme Hubbert categorised particulate behaviour based on oceanographic experience and mathematical calculations using settling rates and resuspension velocities for various particle sizes. He determined that particles of a size 1 to 5 µm would never permanently settle out of the water column, and that particles of a size 5 to 40 µm would not permanently settle out of the water column, unless they were in very deep water (> 5000 m) or in areas where hydrodynamic conditions were very weak and did not continuously resuspend the particles.

The plume is not predicted to contact the seafloor and contaminants will be diluted well below ANZG 99% guideline values at 950 m water depth. It is not expected that PW will not impact sediment quality. Settling velocity and particle size distribution analysis is proposed as part of the initial monitoring of representative discharge to confirm potential for sediment impacts. Results will be considered and managed by the OMDAMP (See Section 7.2.4)

Summary of Assessment Outcomes

	to a significantly lower limit.		proportionate to the impact reduction offered.	
Implement Monitoring and Management Framework for PW discharges including: <ul style="list-style-type: none"> • Initial monitoring. • monitoring of PW discharge volume • chemical characterisation (including BTEX, PAH's Organic Acids, metals and glycol) • WET testing timing of annual / triennial sampling to be representative aiming to detect change, • Sampling of MEG salts when initially operating in salt mode to verify assumptions and implement management measures if required. 	F: Yes. CS: Monitoring costs. Standard practice.	The OMDAMP manages changes to PW discharge characteristics (i.e. volumes, OIW concentration, chemical dosage, etc.) that may increase the impact or risk to the marine environment. The initial monitoring (including when operating in salt mode) will characterise the discharge stream, verifying assumptions and inform the understanding of risk and management. Monitoring is designed to detect if 99% species protection dilutions (WET) are achieved at the approved mixing zone boundary therefore confirming that the EPO has been met. Through the implementation of the OMDAMP, potential risks to the environment are reduced.	Woodside has developed the OMDAMP based on operational experience from other operating assets. The OMDAMP considers risk-based adaptive management measures.	Yes C 10.2
Online monitoring and/or procedural controls in place to monitor and control PW discharge volume and OIW concentrations and prevent discharge of PW with high OIW concentrations through OIW analyser, or off spec/outage procedures.	F: Yes. CS: Minimal cost. Standard practice.	The OIW analysers and flow meter provides optimal process control and safeguarding to monitor, control and prevent discharge of PW with high OIW concentration to the environment.	Online monitoring control is WMS requirement – must be adopted. Minor additional cost to resource manual sampling is proportionate to the environmental benefit during start-up of the Scarborough wells.	Yes C 10.3
The online analyser is calibrated with a	F: Yes.	Calibration of equipment to maintain quality control.	Calibrations undertaken at appropriate	Yes C 10.5

Demonstration of ALARP				
Control Considered	Control Feasibility (F) and Cost/Sacrifice (CS)	Benefit in Impact/Risk Reduction	Proportionality	Control Adopted
manual sample in accordance with Offshore Laboratory Determination of Oil in Water Standard Operating Procedure.	CS: Monitoring and implementation costs. Standard practice		frequency to maintain quality control and in line with procedures.	
Procedural controls in place to monitor mercury concentration and prevent discharge of PW with high mercury concentrations. <ul style="list-style-type: none"> switching mercury adsorption beds off-spec water directed inboard to the rich MEG tank 	F: Yes. CS: Monitoring and implementation costs. Standard practice	Manual sampling during commissioning and intervention visits provides process control and safeguarding to monitor, control and prevent discharge of PW with high mercury concentration to the marine environment.	Minor additional cost to resource manual sampling is proportionate to the environmental benefit during start-up and operation of the Scarborough wells.	Yes C 10.6
Inboard off-specification PW to maintain OIW concentrations, within limits of tank capacity.	F: Yes. However, tank capacity is limited to 1170 m ³ . CS: Monitoring and implementation costs.	In-boarding of PW is a contingency measure to ensure that rolling 24-hour period limits are not exceeded, even if a temporary spike in OIW concentration occurs. Limiting OIW concentrations within PW reduces impacts to the environment.	If the facility exceeds OIW limit for a short period, which places the rolling 24-hour period limit at risk, the facility is able to inboard PW in the MEG storage tank to prevent a breach of the OIW limit does not occur. This control allows the adaptive management of OIW to achieve the 24 hour rolling average limit.	Yes Embedded in C 10.1 as individual Performance Standard
<i>In situ</i> plume measurement and analysis of plume dilution and mixing characteristics (including water quality monitoring of potential PW indicators at approved mixing boundary).	F: Yes. CS: Monitoring and implementation costs.	<i>In situ</i> plume studies confirm the validity of the predicted mixing zone and dilutions from the model. This provides confidence in the ongoing application of the model outputs to understand dilutions of the PW. By using the measured WET testing and chemical characterisation results and applying the verified model dilutions as well as water quality monitoring at the approved mixing zone boundary confirms that the EPO has been met.	Additional cost is proportionate to the environmental benefit.	Yes C 10.8

Demonstration of ALARP				
Control Considered	Control Feasibility (F) and Cost/Sacrifice (CS)	Benefit in Impact/Risk Reduction	Proportionality	Control Adopted
Limit mercury to less than 0.1 µg/L end of pipe (after comingling with cooling water but prior to discharge).	F: Yes. CS: Monitoring and implementation costs. The 0.1 µg/L limit aligns with current ANZG 2018 recommendation for inorganic mercury by adopting the 99% guideline value end of pipe due to potential for bioaccumulation.	Monitoring does not reduce impact but allows for detection of potential impacts and management measure to be implemented to reduce impact to the environment.	Additional cost is proportionate to the environmental benefit.	Yes C 10.9
Professional Judgement – Eliminate				
Reinjecting PW into reservoirs.	F: Yes. CS: Significant expense. Requires drilling an additional well, additional topsides and subsea infrastructure, potential impact to reservoir performance. ~\$300M.	Minor benefit – PW rates are low and not expected to exceed ecological thresholds.	Disproportionate. In addition to the significant expense, additional environment and safety risks associated with drilling an additional well such as acoustic emissions, seabed disturbance, discharges of cuttings and drilling fluids, emissions and unplanned releases. Not considered proportionate to the impact reduction offered.	No
Onshore MEG salt disposal.	F: Potentially feasible. Requires complex salt drying and handling facilities with onerous operational and maintenance requirements not aligned with minimally attended/unattended philosophy. No other offshore facilities were identified with this infrastructure. CS: Engineering, procurement and lifetime operations/maintenance costs.	Minor reduction. Salts are inert and naturally occurring from the reservoir. Proportion of time in which the facility will operate with formation water (MRU in salt-mode) is low, and comingling of salts with PW and seawater return stream effectively reduces toxicity.	Disproportionate. Processing and handling MEG salts for transport to shore requires complex equipment and introduces material safety concerns with handling. This is not considered proportionate to the impact reduction offered.	No

Demonstration of ALARP				
Control Considered	Control Feasibility (F) and Cost/Sacrifice (CS)	Benefit in Impact/Risk Reduction	Proportionality	Control Adopted
Professional Judgement – Substitute				
None identified.				
Professional Judgement – Engineered Solution				
Adoption of a permanent tertiary treatment stage to reduce OIW and mercury concentrations.	F: Yes. Relatively low PW rate makes this technology feasible. CS: Engineering, procurement and lifetime operations/maintenance costs.	Best practice removal of contaminants from PW stream via media adsorption.	Proportional. The relatively low PW rate, expected composition of the PW stream and operations/maintenance philosophy make adoption of a plug and play adsorption media beds to remove TPH and mercury from the PW stream an effective and practicable option.	Yes Adopted in design
Adoption of technology to further remove MEG contamination from PW stream.	F: Potentially feasible. MEG removal technology based on bio-treatment requires large deck space and weight allowance and has significant operational and maintenance requirements. CS: Cost associated with engineering, procurement and ongoing operations/maintenance.	Minor benefit. MEG concentration in PW already expected to be significantly below ecological thresholds.	Not proportional. MRU is already designed to maximise MEG recovery (minimising concentration in PW). Addition of large, heavy bio treatment package with onerous operational and maintenance requirements to reduce already low MEG concentration in PW not justified.	No
Online monitoring of mercury concentration in PW discharge.	F: No. Technology review did not identify any online analysers capable of reliably monitoring mercury at the expected concentrations and in all expected operational modes.	Negligible benefit. The mercury adsorption beds are in lead/guard arrangement and sampling between beds is sufficient to detect lead bed approaching saturation while the guard bed retains capacity to remove mercury from the PW stream.	Not feasible.	No
Online monitoring of MEG concentration in PW discharge.	F: No. Technology review did not identify any online analysers capable of reliably monitoring MEG at the expected concentrations.	Negligible benefit. MEG is considered PLONAR, and process monitoring with in the MRU and manual sampling are sufficient to identify process upsets.	Not feasible.	No

Demonstration of ALARP				
Control Considered	Control Feasibility (F) and Cost/Sacrifice (CS)	Benefit in Impact/Risk Reduction	Proportionality	Control Adopted
Professional Judgement – Procedures and Administration				
Routine in-situ ambient environmental monitoring beyond the requirements of Woodside’s OMDAMP.	F: Yes. CS: Increasing the frequency of field based monitoring would result in additional offshore demand on resources, safety hazards and costs associated with an offshore environmental monitoring program, such as vessel activities, logistics, manual labour, analytical laboratory and service provider costs.	In-situ monitoring following release is not an effective control to manage the nature of PW discharges and results in no impact reduction. Increases to in-situ monitoring beyond the adaptive management approach outlined in the OMDAMP does not follow good application of the hierarchy of controls and results in disproportionate sacrifice with regard to execution risks and costs for limited gain.	Long term monitoring of water and sediment (at other Woodside facilities as listed in Table 6-31) characteristics indicate the PW discharge is not detectable beyond the approved mixing zone. This also supports the appropriateness of non field based monitoring outlined in the OMDAMP as effective controls. Given the volume of discharge is an order of magnitude smaller (and therefore relatively small contaminant load) as well as increased water depth compared to other facilities, routine monitoring of water and sediment is not proposed. If initial monitoring indicates an increased risk to sediment that is likely to be detectable by <i>insitu</i> monitoring (elevated contaminant loads, increased particles size) non-routine monitoring may be undertaken. PW separation process design, optimisation, monitoring and surveillance offer the primary controls, with discharge OIW analysis in place to detect performance variations. Further, Woodside maintains a routine OIW monitoring program for the PW stream (including adaptive management via the OMDAMP, which assesses the need for in-situ monitoring). The initial monitoring and increased frequency of	No

Demonstration of ALARP				
Control Considered	Control Feasibility (F) and Cost/Sacrifice (CS)	Benefit in Impact/Risk Reduction	Proportionality	Control Adopted
			<p>end of pipe sampling are proposed to verify assumptions and demonstrate compliance at end of pipe. If triggers are not met end of pipe non routine <i>insitu</i> monitoring would be considered.</p> <p>The work undertaken to date provides Woodside with a sound understanding of the nature and scale of the environmental impacts from PW discharge, which would not be further improved by increasing the frequency of in-situ monitoring. The execution risks and cost of implementing this control is grossly disproportionate to the environmental benefit.</p>	
On an annual basis review routine monitoring results and determine if non routine sediment quality monitoring should be undertaken as per OMDAMP	F: Yes. CS: Monitoring and implementation costs. Standard practice.	Reviewing the monitoring results to determine if additional monitoring is required does not reduce environmental impact but does provide assurance impact is being appropriately defined.	Additional monitoring on a risk-based basis is proportional to the additional cost of implementation and part of the OMDAMP.	Yes C 10.4
Prior to next 5 year EP revision, review if OIW limit can be reduced further.	F: Yes. CS: Minimal cost.	Following commissioning and start-up and operating in steady state data will be available to support whether a reduction in the OIW limit is feasible. Reducing the OIW may result in a small reduction in environmental impact to water quality in the immediate vicinity of the FPU.	Although the reduction in environmental impact may be small a review of the limit once operating does not incur any large cost and demonstrates continual improvement and ALARP. It should be noted that regardless of the limit the system will be operated to the lowest practicable OIW concentration that can be achieved based on system design and functionality.	Yes C 10.7

Demonstration of ALARP				
Control Considered	Control Feasibility (F) and Cost/Sacrifice (CS)	Benefit in Impact/Risk Reduction	Proportionality	Control Adopted
<p><u>Risk Based Analysis</u></p> <p>Application of Woodside’s Risk Management Procedures and implementation of the OMDAMP ensures the routine assessment of PW impacts, identification of changes to discharges, systematic assessment of risks and ongoing assessment/monitoring of discharge streams to reduce risk to ALARP, that includes:</p> <ul style="list-style-type: none"> • ongoing hazard identification, risk assessment and the identification of control measures • ongoing PW discharge monitoring. <p><u>Company Values</u></p> <p>Corporate values require all personnel at Woodside to comply with appropriate policies, standards, procedures and processes while being accountable for their actions and holding others to account in line with the Woodside Compass. As detailed above, the Petroleum Activities Program is undertaken in line with these policies, standards and procedures that include suitable controls to manage PW discharge.</p> <p><u>Societal Values</u></p> <p>Due to the Petroleum Activities Program’s proximity to sensitive receptors (e.g. Exmouth Plateau), the PW discharge consequence rating presents a Decision Type B in accordance with the decision support framework described in Section 2.3.3. Consultation was undertaken for this program to identify the views and concerns of relevant persons, as described in Section 5.</p> <p>ALARP Statement:</p> <p>On the basis of the environmental impact and risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts of PW discharge. Woodside has undertaken risk-based analysis (PW discharge modelling) to inform the evaluation and assessment of environmental impacts and risks. Woodside also implements a risk-based adaptive OMDAMP. The outcomes of both the modelling studies and long-term monitoring have been considered in determining the ALARP position.</p> <p>As no reasonable additional/alternative controls are currently identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts are considered ALARP.</p>				

Demonstration of Acceptability
<p>To assess and determine the acceptable limits of impacts from PW discharges, Woodside has considered the following criteria, appropriate guidelines, principles of Ecologically Sustainable Development, Company Values and Societal Values.</p> <p>Other Requirements (includes Laws, Polices, Standards and Conventions)</p> <p>The adopted controls and acceptability assessment has considered regulatory guidance, in particular WA EPA (2016) Technical Guidance: Protecting the Quality of Western Australia’s Marine Environment and the ANZG (2018) guidelines. Both sources of Regulatory Guidance provide that environmental values should be identified and levels of ecological protection should then be set. To ensure ecosystem health is maintained overall, the cumulative size of the areas where lower levels of ecological protection apply should be proportionally small compared to the areas designated high and maximum.</p> <p>The Monitoring and Management Framework aligns to the levels of protection described by both WA EPA (2016) and the ANZG (2018) guidelines through the acceptable limits of change.</p> <p>The level of ecological protection provided to sensitive receptors is consistent with the North-west Network Management Plan (2018). By monitoring and managing to the 99% species protection safe dilutions at 400 m, there can be high confidence that potential impacts can be detected and managed via the OMDAMP in accordance with an appropriate representative mixing zone.</p> <p>The Minamata Convention 2013 (ratified by Australia in 2021) requires measures to be in place to control releases containing mercury or mercury compounds. Each of these measures, with information on how each measure is met for discharges of PW from the FPU is provided below:</p> <ul style="list-style-type: none"> • <i>Release limit values to control, and where feasible, reduce releases.</i> Trigger values related to mercury are in place and described above. • <i>The use of best available techniques and best environmental practices to control releases.</i> The implementation of permanent tertiary treatment in the form of mercury adsorbent beds on the FPU is considered best practice.

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

- *A multi pollutant control strategy for mercury releases.* The monitoring framework implemented includes full chemical characterisation and WET testing of discharge stream, which allows understanding of holistic toxicity of the effluent considering all contaminants and potential additive effects.

Principles of Ecologically Sustainable Development

Woodside has established several research projects to understand the marine environments in which we operate, notably in the Exmouth Region and the Kimberley Region, including Rankin Bank, Glomar Shoal, Enfield Canyon and Scott Reef. Woodside's corporate values require that we consider the environment and communities in which we operate when making decisions. These principles of ESD were considered for this aspect:

- **Integration Principle**
 - the existing environment (Section 4) has been described consistent with the definition within regulation 5 of the Environment Regulations (i.e. includes ecological, socioeconomic, and cultural features), and any relevant values and sensitivities have been included within this impact analysis; therefore, the impact assessment process inherently includes economic, environmental and social considerations
 - Feedback, objections and claims from Relevant Persons were considered, see Appendix F
- **Precautionary Principle**
 - the impact consequence rating for this aspect is slight (E), therefore, potential for serious or irreversible environmental damage is not expected
 - although serious or irreversible environmental damage is not predicted to occur, there is some scientific uncertainty associated with the produced water composition however it is not expected to change the consequence level and PW will be monitored and managed as per the adopted control measures.
- **Intergenerational Principle**
 - the acceptable levels were developed consistent with the principles of ESD, including that the environmental impacts and risks of the offshore project will not forego the health, diversity, or productivity of the environment for future generations
 - as described above, the predicted environmental impact spatially limited to an area around the FPU, which is not considered as having the potential to affect ecological integrity. By maintaining ecological integrity the discharge of PW is not considered to have the potential affect intergenerational equity
- **Biodiversity Principle**
 - the existing environment (Section 7) identifies and describes relevant MNES, as defined in regulation 7(3) of the Environment Regulations; any relevant values and sensitivities are included within this (Section 9.1.12) impact analysis
 - as described above, the predicted environmental impact are spatially limited to an area around the FPU, which is not considered as having the potential to affect ecological integrity. By maintaining ecological integrity the discharge of PW is not considered to have the potential affect biological diversity.

Woodside looks after the communities and environments where we operate. Risks are inherent in petroleum activities; however, through sound management, systematic application of policies, standards, procedures and processes, Woodside considers that the predicted impact from PW discharge is acceptable.

Internal Context

The Petroleum Activities Program is consistent with Woodside corporate policies, standards, procedures, and processes as outlined in the Demonstration of ALARP and Environmental Performance Outcomes, including:

- Woodside Environment and Biodiversity Policy (Appendix A: Woodside Policies)
- Woodside Risk Management Policy (Appendix A: Woodside Policies)
- Woodside Environmental Performance Procedure (that specifies maximum mixing zones and minimum sampling requirements).

Woodside corporate values include working sustainably, with respect to the environment and communities in which we operate, listening to internal and external stakeholders (below) and considering HSE when making decisions.

External Context

Woodside recognises that its licence to operate from a regulator and societal perspective is based on historical performance, complying with appropriate policies, standards and procedures, and understanding the expectations of external stakeholders. External consultation was undertaken with relevant persons (**Section 5**), prior to the Petroleum Activities Program and feedback was incorporated into this EP where appropriate. Interest in discharges from the FPU was noted from one stakeholder, which was provided appropriate information in response.

By providing PW monitoring and control measures that are commensurate with the risk rating, location and sensitivity of the receiving environment (including social and aesthetic values), Woodside believes this addresses broad societal concerns to an acceptable level.

Acceptability Statement

Routine and non-routine discharges of PW have been evaluated as representing potential slight, localised, short-term impacts to water quality, marine sediment, marine fauna and ecosystem/habitat. As per Section 2.3.3, Woodside considers 'high order impacts' (Decision Type B impacts such as PW discharge) as acceptable if ALARP is demonstrated using good industry practice, consideration of company and societal values and risk based analysis, if legislative requirements are met and societal concerns are accounted for, and the alternative control measures are grossly disproportionate to the benefit gained. In addition, acceptability is assessed against the above criteria.

The adopted controls are considered good oil-field practice/industry best practice, are consistent with WA EPA (2016), ANZG (2018) and Woodside's internal requirements. Further opportunities to reduce the impacts have been investigated (refer ALARP demonstration) and considered to be grossly disproportionate to the benefit gained. Therefore Woodside considers the adopted controls appropriate to manage the impacts of PW discharge to an acceptable level and demonstrates the EPOs are met.

Environmental Performance Outcomes, Standards and Measurement Criteria			
Environmental Performance Outcomes	Controls	Environmental Performance Standards	Measurement Criteria
EPO 17 No impact to the environment outside of the Approved Mixing Zone from planned discharge of comingled produced water / cooling water and brine.	C 8.4 Chemicals will be selected with the lowest practicable environmental impacts and risks subject to technical constraints.	PS 8.4.1 Refer to Section 6.7.9	MC 8.4.1 Refer to Section 6.7.9

Discharge of cement, grout and sand		✓	✓		✓			A	E	-	-			
Discharge of treated seawater from Trunkline during FCGT or dewatering activities			✓					A	E	-	-			

Description of Source of Impact/Risk
<p>Hydrocarbons and chemicals may be discharged as a result of planned routine and non-routine operations and activities as described below. Planned chemical discharges may occur during a range of subsea system operation and IMMR activities. However, these are either small volumes, or discharged intermittently. Operational chemicals to be used in the subsea infrastructure are selected and assessed using Woodside’s chemical selection and assessment guideline, as detailed in Section 3.9.16.5.</p> <p>Operational discharges include:</p>

Description of Source of Impact/Risk

- discharge of subsea control fluids – subsea control fluid is used to control valves remotely; it is an open-loop system, designed to release control fluid from the control system during valve operations (e.g. up to about 20 L from a single XT sweep)
- potential non-routine hydraulic fluid discharge associated with umbilical system losses/weeps
- discharge of minor fugitive hydrocarbon from wells and subsea equipment (e.g. weeps/seeps/bubbles)
- IMMR activities (nominal discharges described in Section 3.9.17) including:
- discharge of residual hydrocarbons in subsea lines and equipment associated with isolation testing and breaking containment
- discharge of residual chemicals in subsea lines and equipment associated with isolation testing and breaking containment
- during span rectification works, possible cement discharges from overflow while filling/filtering cement through cement bags for span rectification, line washout (down line cleaning); or cement until washout from on board vessel
- discharge of sand from stabilisation bags
- discharge of chemicals used to remove marine growth (e.g. sulphamic acid or equivalent).

As described in Section 3.9.17 environmental discharges during subsea IMMR activities are expected to be minor (e.g. during pressure/leak testing or flushing). Where practicable, flushing is performed before a subsea component is disconnected to reduce residual hydrocarbon or chemical releases to the environment upon disconnection. Where possible, flushed fluids will return to the platform.

Trunkline repair and Flooding, Cleaning, Gauging and Testing (FCGT) – Contingent Activities

If there is an emergency situation during Trunkline operations (i.e., dragged anchor or dropped object over/on the Trunkline), or the Trunkline fails to meet testing integrity requirements during IMMR, there may be a need for Trunkline repairs. Repairs may involve the removal of a damaged section of the Trunkline and the remaining good section of Trunkline being dewatered. It is necessary to carry out dewatering and repairs as soon as possible to minimize damage (corrosion) to the Trunkline internal lining, as described in Section 3.13.1.

If FCGT is used, the trunkline will be filled with treated seawater, hydrotested and dewatered, and potentially dried and inerted. Depending on where the damage in the Trunkline occurs, discharge volumes may vary. As a worst case, the whole Trunkline length may need to be dewatered should it become flooded with raw seawater during incident / from damage and require flushing to remove debris and desalinate. The activity will be conducted in several phases and may include pre-flooding to ensure control of flow as pigs move down the slope crossing.

In the event the Trunkline breaks and is flooded with seawater, the raw seawater ingress will be pushed out of the trunkline with treated water, which is used to prevent corrosion and maintain the integrity of the trunkline. The Trunkline would be dewatered from shore to offshore. The discharge could occur at any point along the Trunkline, with the location dependent on where the Trunkline was cut to remove the damaged section. Discharge volume and chemical concentrations are dependent on the dewatering option selected. These include:

- Pre-flooding of the trunkline with treated seawater: this involves first flooding the length of the trunkline with treated seawater. The discharge volume will increase the further along the Trunkline damage occurs, due to the greater volume of flushing required to reduce salt contamination in the Trunkline. Damage around KP 32 for example could result in a discharge of chemically treated seawater around 19,080 m³ while damage around KP432 (i.e. at the end of the trunkline) could result in a discharge of treated seawater approximately 243,256 m³. Discharge along the Trunkline route between these two points would have a volume around ~210,000 m³ (KP 190).
- Pre-flooding the trunkline with untreated seawater followed by treated freshwater slugs: this involves using a pig train separated by chemically treated fresh water (desalination) slugs to dewater the trunkline. The volumes of treated water would be up to approximately 1200 m³ of freshwater treated with chemicals up to 700 ppm.

Table 6-37: Estimated contingent Trunkline discharges

	Full Trunkline	Partial volume along Trunkline route
Discharge location	Commonwealth waters	Commonwealth waters
	Pipeline End Termination Assembly (Approx. KP 433)	Approx KP33
Ave Water depth (m MSL)	941	39.3
Discharge depth (m MSL)	938	39

Discharge duration	~22.5 days	~1.39 days

Water treatment chemicals

Chemicals used in water treatment for FCGT and trunkline dewatering activities ensure the integrity of the Trunkline is not compromised by internal corrosion development. These chemicals are typically comprised of an oxygen scavenger, biocide and corrosion inhibitor. These chemicals will be Hazard Quotient Colour Band ‘Gold’ (or OCNS Grouping E) with no substitution or product warnings.

Quantitative Risk Assessment

In order to understand the potential impacts and risks associated with contingent discharges of hydrotest fluids from the Trunkline, Woodside commissioned RPS to model the fate and transport of two representative discharge scenarios, one at the PLET and another in Commonwealth waters near the State waters boundary (RPS, 2021). To determine the fate, transport and dilution of the hydrotest discharge, both near-field and far-field modelling was undertaken as these are used to describe different processes and scales of effect. The modelled scenarios included:

- The full trunkline FCGT comprised of:
 - Pre-flooding / cleaning water of 254,300 m3
 - Hydrotest / squeeze water of 245,511 m3
- Nearshore damage:
 - Cleaning water of 29,000 m3

Stochastic modelling was conducted for this study, which compiled data from 150 hypothetical releases under different environmental conditions and seasons to determine the largest extent of plume dispersion. A three-dimensional, spatially-varying current data set surrounding the discharge locations for a ten-year (2006-2015) hindcast period were used, with summer, winter and transitional seasons modelled. The data set included the combined influence of drift and tidal currents and was suitably long as to be indicative of interannual variability in ocean currents. The current data set was validated against metocean data collected in the Scarborough Project Area.

Results of the replicate simulations were then statistically analysed and mapped to define contours of predicted dilutions.

Development of thresholds for impact assessment

Due to the proposed chemical additives with the hydrotest fluid (i.e., biocides, corrosion inhibitors, oxygen scavenger, fluorescent dyes), the discharges have the potential to impact sensitive receptors within the discharge area of influence, primarily through toxicological effects ranging from the inhibition of key biological processes (e.g., reproduction) to mortality. The outputs of the quantitative modelling are used to assess the environmental risk by delineating which areas of the marine environment could be exposed to chemicals exceeding toxicological threshold concentrations, and the expected time taken for concentrations to reduce to below thresholds.

The 99% species protection level concentration is suggested by the Australian and New Zealand Guidelines for Fresh and Marine Water Quality (ANZG, 2018) for the development of environmental criteria for high conservation ecosystems or chemicals that have a tendency to bioaccumulate. Due to the unknown nature of chemicals to be used and lack of availability of whole effluent toxicity data for similar chemicals used previously for this activity; species protection level

Description of Source of Impact/Risk

concentrations cannot be derived. Therefore, the 99% species protection value derived for Hydrosure 0-37670R was used as an analogue to interrogate the outputs of the model for the purpose of the impact assessment. Noting that Hydrosure 0-3670R will not be used as it does not meet the required performance standard, with regard to its OCNS rating.

Chevron Australia Pty Ltd (2015) conducted whole effluent toxicity (WET) testing on Hydrosure 0-3670R (Champion Chemicals Pty Ltd), diluted in seawater. WET testing was undertaken on five locally relevant species, for the NWMR, from four different taxonomic groups based on ANZECC & ARMCANZ (2000). Since Hydrosure 0-3670R is a mixture containing both the biocide and oxygen scavenger for chemical treatment, only one assay in each test species was necessary to evaluate the toxicity of the product. The results of the WET testing are described in Table 6-38. As expected, simpler life forms (e.g. algae and larvae) had a higher sensitivity to the chemical compared to be more complex life forms such as fish. From these results Chevron (2015) developed species sensitivity distribution curves to determine species protection concentrations (Table 6-39).

Table 6-38: Ecotoxicological test results for Hydrosure 0-3670R

Species	Duration (hrs)	NOEC (mg/L)
<i>Nitzschia Closterium</i> (Algae)	72	1.30
<i>Saccostrea echinate</i> (Mollusc)	48	0.250
<i>Heliocidaris tuberculata</i> (Echinoderm)	72	1.25
<i>Melita plumulosa</i> (Crustacean)	96	0.13
<i>Lates calcifer</i> (Fish) [#]	96	12.5

[#]toxicity test is defined as an acute test

Table 6-39: Species protection concentrations for Hydrosure 0-3670R

	PC 99% (mg/L)	PC 95% (mg/L)	PC 90% (mg/L)
Hydrosure (based on NOEC)	0.06	0.10	0.15

The results from this study established a 99% species protection value of 0.06 mg/L, which was applied in the modelling over a 48-hr rolling median (Chevron Australia Pty Ltd, 2015). The duration was a conservative approach to account for the fact that the hydrodynamics of the marine environment result in dilution of the chemical concentration after discharge therefore it is unlikely that concentrations would remain elevated for long durations. Therefore, the duration was based on the minimum test duration of 48 hours.

Based on the expected initial concentration of 350 mg/L for pre-flooding and cleaning water and damaged trunkline discharges; 5,833 dilutions are required. While for an initial concentration of 550 mg/L for hydrotesting, 9,167 dilutions are required to meet threshold concentration at the 99% species protection. Though this likely over represents the residual toxicity of the fluid following discharge as it was assumed that the residual discharge concentration of the chemicals within the fluid is the same as the initial dosing concentration with no degradation or decay during residence within the pipeline.

FCGT – trunkline modelling results

Nearfield modelling results for discharge at the offshore PLET location indicates that a turbulent mixing zone will be created at the seabed, for a horizontal distance of ~90 to 115 m, with a vertical distribution up to 40 m. Outside of this turbulent zone, a positively buoyant plume is expected to rise in the water column, which may reach a horizontal distance of up to ~425 m from the PLET prior to reaching trapping depth.

Farfield modelling for this discharge indicates that dilutions required to reach the threshold concentration (0.06 mg/L) at the 95th percentile (applied as a 48-hour rolling median) for the pre-flooding and cleaning water (additive concentration 350 mg/L) is achieved at a maximum distance of ~6,100 m from the PLET, however on average it is much less and was reached at 600 m (Table 6-40). Similarly, the maximum distance to achieve threshold concentration at 95th percentile (applied as a 48 hr rolling median) for the hydrotest discharges ranges from ~1,400 m (additive concentration 550 mg/L) to ~900 m (additive concentration 350 mg/l) from the PLET. Again, on average, the distances to achieve the threshold concentration were less and ranged from 500 to 600 m. The significantly greater spatial rate of dilution for hydrotest discharge when compared with pre-flood/cleaning is attributed to the lower rate of discharge. Noting that the discharge rate for the pre-flooding and cleaning water is 1000 m³/ hr whereas on average the discharge rate for the hydrotest discharge was ~430 m³/hr.

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

Table 6-40: Average and maximum distances to achieve the threshold concentration at the 99% and 95% species protection

Scenarios	99% Species Protection		95% Species Protection	
	Average distance	Maximum distance	Average distance	Maximum distance
	Dosage concentration 350 ppb (5833 dilutions)		Dosage concentration 350 ppb (3500 dilutions)	
Pre-flooding / cleaning water of 254,300 m ³ (at 1000 m ³ /hr)	600 m	6.1 km	500 m	4.2 km
Hydrotest / squeeze water of 245,511 m ³ (at average of ~430 m ³ /hr)	500 m	900 m	300 m	500 m
	Dosage concentration 550 ppb (9167 dilutions)		Dosage concentration 550 ppb (5500 dilutions)	
Hydrotest / squeeze water of 245,511 m ³ (at average of ~430 m ³ /hr)	800 m	1.4 km	400 m	800 m

The maximum time for concentrations to fall below threshold concentration under weak current conditions (resulting in low mixing and low dilution) was 2.77 days. Therefore a minimum time period of 3 days will be applied between pre-flooding/cleaning and hydrotest discharges for the full trunkline FCGT.

Trunkline damage along route – State waters boundary worst case example

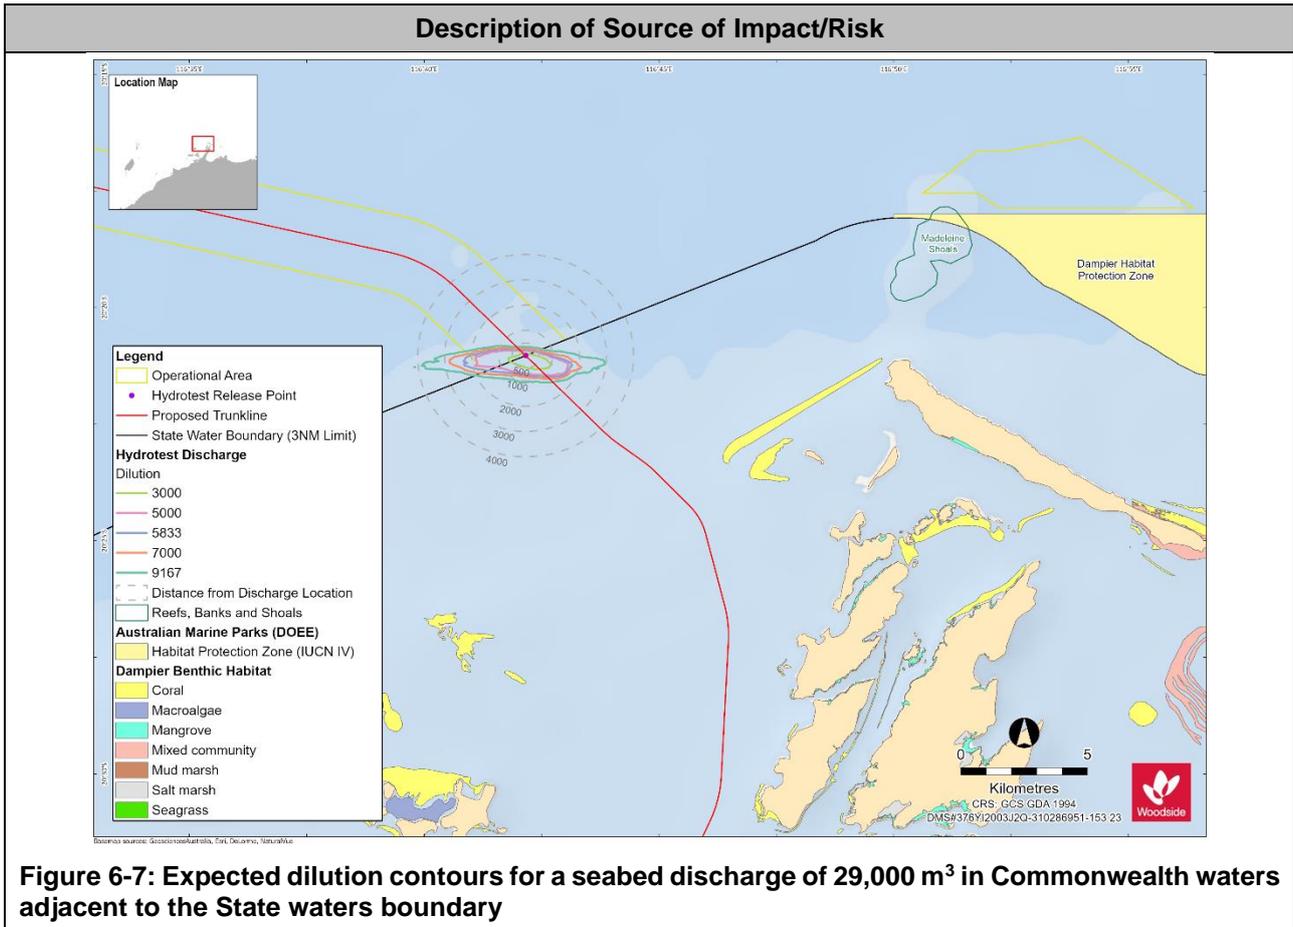

Nearfield modelling results for nearshore component discharge adjacent to the State waters boundary indicates that a turbulent mixing zone will be created at the seabed, for a horizontal distance of ~40 m, with vertical distribution around 10 m. Outside of this turbulent zone, a positively buoyant plume is expected to rise in the water column, which may reach a horizontal distance of up to ~60 m from the discharge location prior to reaching trapping depth.

Farfield modelling for this discharge indicates that dilutions required to reach the threshold concentration (0.06 mg/L) at the 95th percentile (applied as a 48-hour rolling median) for the pre-flooding and cleaning water (additive concentration 350 mg/L) is achieved at a maximum distance of ~2100 m from the release location however on average it is much less and was reached at 400 m. This was based on a discharge rate of 1000 m³/hr.

Table 6-41: Average and maximum distances to achieve the threshold concentration at the 99% and 95% species protection

Scenarios	99% Species Protection		95% Species Protection	
	Average distance	Maximum distance	Average distance	Maximum distance
	Dosage concentration 350 ppb (5833 dilutions)		Dosage concentration 350 ppb (3500 dilutions)	
Cleaning water of 29,000 m ³ (at 1000 m ³ /hr)	500 m	2.1 km	200 m	900 m

Dilution contours, representing 150 simulations, for this discharge in context of nearby receptors are shown in **Figure 6-7**.

Detailed Impact Assessment
Assessment of Potential Impacts
<p>There is potential for localised impacts to water and sediment quality, and impacts to marine biota as a result of planned routine and non-routine hydrocarbon and chemical discharges. However, planned discharges of hydrocarbons and chemicals are minor and are minimised as far as practicable via flushing of the lines back to the FPU. Discharge locations are either the PW stream, subsea valves (subsea control fluid), at disconnection points in subsea infrastructure, including during installation of PLRs, or via the export trunkline to onshore process.</p> <p>Water Quality</p> <p>Subsea control fluids are discharged in relatively small volumes during valve actuations and IMMR activities at or near the seabed. On release the subsea control fluids are expected to mix rapidly and dilute in the water column. Pigging activities are infrequent and result in relatively small releases of hydrocarbon (indicative discharge volumes associated with pigging the export trunkline are provided in Table 3-9. The small quantities of hydrocarbons that may be released as fugitives or during IMMR activities that break containment of isolated subsea infrastructure are buoyant and will float upwards towards the surface. Given the water depth, pressure, and the small volumes released, these hydrocarbons are not expected to reach the sea surface. Rather, the release will disperse and dissolve within the water column. Chemicals may be discharged intermittently and in small volumes, with similar dispersion influenced by buoyancy and water currents.</p> <p>There is potential for slight, localised decrease in water quality at planned discharge locations and potential impacts on marine biota. Impacts to pelagic fish are expected to be limited to avoidance of the localised area of the discharge and short-term, localised decline in planktonic organisms in the immediate vicinity of the discharge.</p> <p>Cement discharges may occur during span rectification works, from overflow, and can result in an increase in turbidity in the water column. Reduction in water quality will be temporary (limited to the cement operation discharges) and due to small volumes, are likely to rapidly disperse and dilute in prevailing currents. As such, the impact significance level for Water Quality has been identified as Slight (E).</p> <p>Sediment Quality</p>

Detailed Impact Assessment

Accumulation of contaminants in sediments depends primarily on the volume/concentration of particulates in discharges or constituents that adsorb onto seawater particulates, the area over which those particulates could settle onto the seabed (dominated by current speeds and water depths), and the resuspension, bioturbation and microbial decay of those particulates in the water column and on the seabed. Valve actuation discharges are frequent but low in volume (typically <6 L). Given the frequency and volumes of chemical releases, accumulation in sediments is not considered likely.

Cement discharges at the seabed are likely to be minimal and once cement has hardened, chemical additives are locked into the cement (Terrens et al., 1998) and are not expected to pose any toxicological risk to benthic biota from leaching or direct contact. The physical sediment properties of the area directly adjacent to the discharge location will be permanently altered however it will be highly localised physical footprint and is not expected to affect the overall diversity or ecosystem function of the benthic communities in the area.

The potential impacts to benthic communities caused by smothering from a surface release of cement are expected to be minimal due to small volumes, intermittent nature of these discharges, and high potential for dispersal by ocean currents. This impact on soft sediment communities is not expected to affect the diversity or ecosystem function in the area, and is considered to be a localised impact. As such, the impact significance level for Sediment Quality has been identified as Negligible (F).

Water and Sediment Quality – Contingent Trunkline FCGT and dewatering discharges

Stochastic and deterministic modelling of the FCGT discharge scenarios indicates that chemical concentrations are expected to be below the 99% species protection level within 6,100 m (based on the minimum dilutions) of the PLET, with changes in water quality predicted to return below the threshold value within approximately three days of completing the discharges. A smaller distance may be expected to achieve the required dilutions, in the event of discharging smaller volumes (not full Trunkline length) due to the lower discharge rate (~570 m³/hr). Depending on the location of Trunkline damage along the trunkline route, chemical concentrations can be expected to drop below the 99% species protection level within ~1-2 kilometres. This is based on the ~900 m and 2,100 m distances where chemical concentrations are expected to be below the 99% species protection level at the PLET (for hydrotest discharges) and at the state boundary release locations respectively.

The presence of chemical additives in discharged hydrotest fluids are expected to degrade, decay, dilute and disperse once released through both dynamic mixing in the nearfield and by prevailing currents in the farfield, due to the open oceanic waters of the Project Area. The discharge is expected to remain close to the seabed which means the temporary change in water quality will be restricted to deep waters at the PLET location and predominantly near seabed at the release location near the State waters boundary. As such, the discharge is expected to result in a temporary decline in water quality around the discharge locations, with no lasting effect on water quality is predicted.

As the discharge plume is expected to remain close to the seabed, a temporary change in sediment quality may occur. However, as demonstrated by the modelling, due to rapid dispersion of the treated seawater, the chemical additives will degrade and dilute rapidly following discharge with no predicted accumulation within seabed sediments and as such no lasting effect on sediment quality is predicted.

There are no variations in seasonal sensitivity in relation to water and sediment quality that would influence the effect of the discharge. Receptor sensitivity is low (low value, open water), and therefore Impact Significant Level of discharges on water quality and sediment quality is negligible.

Plankton

A change in water quality has the potential to result in the injury or mortality of planktonic species in the water column due to toxicity. Ichthyoplankton (eggs, larvae) are the most susceptible organisms to chemical exposure, as they have limited mobility and thus likely to be exposed to the plume if present. These organisms however, have a high natural mortality and rapid replacement rate and are therefore likely to recover after activity ceases.

Plankton populations may be affected by discharges around the FPU and along the trunkline route in the shallower waters of the continental Shelf within a limited area (~1-2 km) of the discharge location. However, given the expected rapid dispersion and dilution of any discharges plume by prevailing currents and the temporary nature of the discharge, impacts to plankton are likely to only occur in the immediate area of the discharge plume, over a period of days to weeks. Given the fast population turnover of open water plankton populations (ITOPF, 2011), the potential impacts are expected to be localised and temporary. For discharges from installed infrastructure in greater water depths, no lasting effect on plankton is expected, given phytoplankton and zooplankton are generally limited to near-surface waters (i.e., the photic and meso-photic zones).

Plankton – Contingent Trunkline FCGT and dewatering discharges

Stochastic and deterministic modelling of the FCGT discharge scenarios indicates that chemical additive concentrations are expected to be below the 99% species protection level within 6,100 m with changes in water quality predicted to return below the threshold value within approximately three days of completing the discharges. As described above, chemical concentrations resulting from a smaller Trunkline volume discharge can be expected to drop below the 99% species protection level within a ~1-2 kilometres of the discharge location.

Treated seawater discharge in the unlikely event of full Trunkline FCGT or Trunkline damage in deeper waters will occur close to the seafloor in water depths of about ~940 m at the PLET location. Given phytoplankton and zooplankton are

Detailed Impact Assessment

generally limited to near-surface waters (i.e., the photic and meso-photoc zones) no lasting effect on plankton is expected.

Plankton populations may be affected by FCGT / dewatering along the trunkline route in the shallower waters of the continental Shelf within a limited area (~1-2 km) of the discharge location. However, given the expected rapid dispersion and dilution of the plume by prevailing currents and the temporary nature of the discharge, impacts to plankton are likely to only occur in the immediate area of the discharge plume, over a period of days to weeks. Given the fast population turnover of open water plankton populations (ITOPF, 2011), the potential impacts are expected to be localised and temporary.

FCGT / dewatering discharges will be restricted to a small area around the discharge point and will disperse rapidly in the environment. Impacts from contingent treated seawater discharges will have no lasting effect on plankton.

Epifauna and Infauna

The seabed in the PAA is dominated by soft sediments (as described in Section 4.4), with filter feeders such as sponges, ascidians, soft corals and gorgonians associated with areas of hard substrate. The only areas of hard substrate expected in the vicinity are artificial habitat associated with subsea infrastructure. Subsea control fluid is non-toxic and does not have the potential to bioaccumulate. Impacts to ecosystems are not expected due to the localised nature of discharges and limited potential for sediment quality impacts. Given the nature and scale of planned discharges, potential impacts are considered to be slight and short term (expected to recover once routine discharges cease). As such, the impact significance level for Epifauna and Infauna has been identified as Negligible (F).

Epifauna and Infauna – Contingent Trunkline FCGT and dewatering discharges

As a result of a change in sediment or water quality, impacts to benthic habitat receptors may occur. This may include sub-lethal effects or mortality to benthic epifauna and infauna resulting from the increased (water) or accumulation of (sediment) potential contaminants and toxins. Epifauna and infauna sensitivity to dewatering discharges is expected to be similar to pelagic invertebrate species such as plankton.

Discharges during pipeline repairs will be restricted to a relatively small area around the discharge point and will disperse rapidly in the environment. The extent of seabed exposure at levels where impacts could occur will be small, and potential impacts are expected to be localised, temporary and negligible. Impacts from contingent treated seawater discharges will have no lasting effect on epifauna and infauna. Receptor sensitivity of epifauna and infauna is considered low at the PLET discharge location. The Impact Significance Level of an FCGT/hydrotest discharge on epifauna and infauna has therefore been identified as Negligible (F). There are no variations in seasonal sensitivity in relation to epifauna and infauna that would influence the effect of the discharges.

Stochastic and deterministic modelling of a treated seawater discharge near the State waters boundary indicates that chemical additive concentrations are expected to be below the 95% species protection within 900 m and below the 99% species protection threshold within 2.1 km of the discharge location. Therefore, there is potential for a small, localised area of epifauna to be exposed to lethal and sub-lethal concentrations near the release location. Due to rapid dispersion of the treated seawater, uptake and bioaccumulation of contaminants is not expected to occur in sediments or benthic organisms beyond the point of release.

In the event of damage along the trunkline route, and discharge of a smaller Trunkline volume, chemical concentrations resulting from discharge of treated seawater can be expected to drop below the 99% species protection level between ~1-2 km as described above, depending on the location of the discharge. Section 4.4.2 describes benthic habitats and communities along the trunkline. The seabed along the trunkline route is generally featureless with occasional areas of hard substrate that may support patches of benthic filter feeder communities. Within the Montebello AMP (KP 109 and KP 192) soft sediment habitats predominate, with calcarenite outcrops supporting sponges, whips and gorgonians. Denser areas of filter feeders also occur in areas with more complex seabed structure. These areas of filter feeding benthos (sponges, soft corals, gorgonians, hydroids, sea pens, crinoids) are widely representative of benthos found both within the AMP (Advisian, 2019a) and regionally (potential impacts to the values of the AMP are evaluated further in the AMP section below). Rock pinnacles have been observed approximately 360 m south of the trunkline at KP 206. The pinnacles are isolated forms restricted to an area about 100 m long x 75 m wide, and do not constitute continuous reef. The structures provide habitat for a diverse range of epifaunal and demersal species that commonly occur across the NWMR, including a very low percentage cover of soft coral growing on top of the pinnacles. It is not possible to predict where Trunkline damage and repair may occur - in the unlikely event repair is required along the trunkline route in proximity to the more complex benthic habitats described (e.g. within the Montebello AMP or near the rock pinnacles), the extent of seabed exposure at levels where impacts could occur will be small and likely limited to within hundreds of metres of the discharge location. Potential impacts will be localised and temporary as the one-off discharge disperses rapidly within the water column. While a diverse range of epifaunal and demersal species are reported to be associated with these habitats, they commonly occur across the NWMR. Receptor sensitivity of epifauna and infauna is considered low to medium along the trunkline route. The Impact Significance Level of a FCGT/dewatering discharge on epifauna and infauna has therefore been identified as Slight (E). There are no variations in seasonal sensitivity in relation to epifauna and infauna that would influence the effect of the discharges.

Marine fauna

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

Detailed Impact Assessment

Given the temporary nature of the discharges, impacts to protected species are not expected. Potential impacts to pelagic or demersal fish species from discharged fluids are expected to be confined to the vicinity of discharge point. Marine fauna are likely to be transient within the receiving environment adjacent to the discharge location, and as such are unlikely to be exposed to sufficient concentrations or durations of the discharge constituents to elicit a response. Furthermore, marine fauna have the capacity to adapt their behaviour in response to changes in environmental conditions and can be expected to move away from the discharge if exposed. Given the low likelihood of pelagic species being exposed to the discharge; and the ability of fauna to move away from the discharge plume, the potential for toxic impacts to occur from the temporary and small volumes of discharged fluids are considered to be localised, short-term and no lasting effect at the population or bioregional scale.

Marine fauna – Contingent Trunkline FCGT and dewatering discharges

Marine fauna could pass through the discharge plume however exposure would be at low concentrations and short duration. The 99% species protection threshold and the subsequent mixing zone have been determined through the application of chronic exposure ecotoxicological tests on sensitive life stage marine fauna. The toxicity of the water treatment chemicals is less on larger life forms as demonstrated by the WET testing (Table 6-38) which determined that the NOEC for a fish species was 12.5 mg/L. Modelling predicted that this would occur out to a maximum of 30 m from the release location. In addition, marine fauna are transient and as such are unlikely to be exposed to sufficient concentrations or durations of the discharge constituents to elicit a response.

The location of the FCGT discharge at the PLET does not overlap any BIAs for protected marine fauna and given the water depth (about ~940 m), toxicity and temporary nature of the discharge, impacts to protected species are not expected. The deep water and predominantly featureless, flat soft sediment seabed at the PLET discharge location is of low complexity and low productivity (see Section 4.5) and reduces the species diversity and richness of pelagic and demersal fish assemblages. Although sporadic upwelling events and increased primary productivity along the northern and southern boundaries of the Exmouth Plateau KEF may temporarily increase fish diversity, overall, fish fauna is not expected to be abundant at the FCGT discharge location, which is located >50 km from the periphery of the plateau. Continental slope fish communities off the west coast of Australia (including the Exmouth Plateau) have a low overall density, which appears to be linked to the low biological productivity of the overlying waters (Williams et al., 2001). Based on the low likelihood of pelagic species being exposed to the discharge; the ability of fish to move away from the discharge plume and the potential for toxic impacts to occur from contingent treated seawater discharge potential impacts are considered to be localised and short-term with no lasting effect at the population or bioregional scale.

Fish are perhaps most susceptible in their early life stages, particularly during egg and planktonic larval stages. Six key indicator commercial fish, and spawning depth ranges / seasonality, on the NWS are as follows:

- red emperor – depth range 10–180 m, spawns Sept–June (bimodal peaks Sept–Nov and Jan–Mar);
- Rankin cod – depth range 10–150 m, spawns June–Dec and Mar (peak Aug–Oct);
- goldband snapper – depth range 50–200 m, spawns Oct–May;
- bluespotted emperor – depth range 5–110 m, spawns Jul–Mar;
- ruby snapper – depth range 150–480 m, spawns Dec–Apr (peak Jan–Mar); and
- Spanish mackerel – depth range 1 m to at least 50 m, spawns Sept–Jan.

The Operational Area overlaps the depth ranges for these key indicator commercial fish species, and the timing of activities means that there would be overlap with peak spawning periods for a number of these species. However, it is believed that all of these species undergo group spawning throughout their range, rather than aggregating at specific locations. Therefore, that treated seawater is discharged impacts to fish spawn would be limited to a localised area around the discharge location and not expected to have a substantial adverse effect on the population.

In the event of Trunkline repairs along the trunkline route, discharge volumes of treated seawater will be limited to the length of pipeline requiring dewatering and will similarly result in a temporary reduction in water quality with negligible effect to protected fauna. In the unlikely event of a discharge located in the humpback whale migration BIA, pygmy blue whale migration BIA or interesting BIAs and Habitat Critical for a number of marine turtle species, during the migration / nesting season, potential impacts to protected marine fauna are highly unlikely given the potential toxicity, temporary nature of the discharge and transient nature of marine fauna.

Stochastic and deterministic modelling indicates that potential impacts to protected marine fauna, as well as pelagic or demersal fish species from Trunkline repair discharges are expected to be confined to the vicinity of discharge point.

KEFs

The Exmouth Plateau, Continental Slope Demersal Fish Communities and Ancient coastline at 125 m depth contour KEFs overlap the PAA. Discharge locations for hydrocarbons and chemicals are either at the subsea valves (subsea control fluid) or at dis/connection points in subsea infrastructure and therefore limited to the Offshore Operational Area, which overlaps the Exmouth Plateau KEF. There is potential for cement discharges associated with span rectification of the export trunkline within the three KEFs. There is potential for slight, short-term decrease in water quality and adverse effects on marine biota as a result of planned routine and non-routine hydrocarbon, chemical and cement discharges within the KEFs. However, these potential impacts will be highly localised and are unlikely to impact the

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

Detailed Impact Assessment

ecological value of the KEFs (as described in Section 4.7). As such, the impact significance level for KEFs has been identified as Slight (E).

KEFs – Contingent Trunkline FCGT and dewatering discharges

The FCGT discharge location at the PLET occurs within the Exmouth Plateau KEF. The Exmouth Plateau is defined as a KEF as it is a unique seafloor feature with ecological properties of regional significance, which apply to both the benthic and pelagic habitats within the feature. Therefore, as a result of a change in sediment quality and/or water quality, potential impacts to this KEF may occur. Values of the Exmouth Plateau with the potential to be affected by dewatering is limited to impacts to benthic environments containing low habitat heterogeneity within the plume. There is no solids component in the discharge, and therefore no smothering or alteration of the seabed is expected to occur.

The seafloor composition within the area of the dewatering discharge is expected to primarily be mud and clay material. Survey of the plume area identified the seafloor to contain sparse marine life dominated by motile taxa typical of deep-water soft substrates (ERM, 2013; DEWHA, 2008).

The Trunkline Project Area has a minor overlap with the Continental Slope Demersal Fish Communities KEF at ~KP 200 for about 9 km (<0.05% overlap), and with the Ancient Coastline at 125 m depth contour KEF at ~KP190 for about 3 km (0.03% overlap). The Ancient Coastline KEF includes areas of hard substrate, and higher diversity and species richness relative to surrounding areas of predominantly soft sediment. The submerged coastline may facilitate mixing of the water column enhancing productivity. Combined with greater diversity of sessile benthic organisms, this may increase abundance of pelagic species such as fishes and cetaceans, impacts to which are discussed above. The Continental Slope Demersal Fish Communities KEF represents high levels of endemism of demersal fish species. Based on the assessment above, in the unlikely event of Trunkline repair discharges within a KEF - potential impacts to the values of the KEF would be highly localised to the Trunkline Project Area and temporary in nature as the treated seawater disperses within the water column.

Impacts from contingent discharges of treated seawater will have no lasting effect on KEFs.

Australian Marine Parks

The Trunkline Operational Area intersects the Montebello AMP (Multiple Use Zone (VI)) between KP 109 to KP191. There is potential for minor cement discharges associated with span rectification of the export trunkline (if required) within the AMP, which may result in a short-term decrease in water quality and localised adverse effects on marine biota. However, these potential impacts will be highly localised and are unlikely to impact the ecological value of the AMP (as described in Section 4.8). As such, the impact significance level for AMPs has been identified as Slight (E).

AMPs – Contingent Trunkline FCGT and dewatering discharges

There is potential for contingent FCGT / dewatering discharges to occur within the Montebello Marine Park, should Trunkline damage occur at this location. The maximum discharge volume would be ~210,000 m³ based on the trunkline length at KP 190. As described above, chemical concentrations resulting from a discharge can be expected to drop below the 99% species protection level within ~1-2 km of the discharge location. The North-west Marine Parks Network Management Plan (DNP, 2018a) lists the natural values of the Montebello AMP as including a range of threatened, migratory, marine or cetacean species listed under the EPBC Act. Potential impacts to benthic communities and marine fauna are assessed above. Impacts are predicted to have no lasting effect due to the one-off nature of the discharge and rapid dispersion of the treated seawater. Even if more than one discharge was to occur in the AMP there is no potential for cumulative impact given the chemical additives will degrade and dilute rapidly following discharge, with no predicted accumulation within seabed sediments. Potential impacts to the natural values of the AMP are a magnitude of 'no lasting effect'.

Changes to the functions, interests or activities of other users – Contingent Trunkline FCGT and dewatering discharges

The NWSTF is the only Commonwealth-managed fishery expected to be active within the PLET discharge location. Given the water depth of the full Trunkline discharge location (about 1400 m) and the temporary nature and rapid dilution of the discharge, impacts from the discharge of treated seawater such as changes to the functions, interest or activities of Commonwealth are unlikely.

Similarly, FCGT / dewatering discharges near the State waters boundary overlaps the State-managed fisheries, however given the rapid dilution of the discharge and hence duration of exposure, impacts are considered unlikely. In the event of trunkline repairs along the trunkline route, the presence of dewatering fluids will be temporary and disperse rapidly in the water column.

In general, given the oceanic locations and the localised and temporary nature of the contingent treated seawater discharges, exposure to fisheries is considered negligible.

Summary of Assessment Outcomes

Discharge of fluids during subsea infrastructure commissioning and initial start-up activities to the marine environment		✓	✓		✓	✓		A	E	-	-			
Description of Source of Impact/Risk														
<p>Routine and non-routine discharges will occur during commissioning and initial start-up of the subsea production/export systems and FPU. Discharges will be limited to the Offshore Operational Area. Discharges during this phase will, at times, include those as per normal operations, which are described and assessed in Section 6.7.10, Section 6.7.11, Section 6.7.12 and Section 6.7.12. This section is applicable to activities prior to steady-state operation of the produced water system. The system is considered to be in “steady-state” once routine discharge commences, and contaminant concentrations and discharge volumes are seen to remain steady. Post start-up, a period is required to optimise the PW treatment system and to understand how it operates and reacts to changes in the process (pressures, chemical concentrations, flow rates). It is expected that this will take approximately 6 months, in-line with the expected initial start-up duration.</p> <p>Subsea Commissioning</p> <p>Subsea infrastructure will be pre-installed (under a separate EP) and left flooded with treated seawater/freshwater, with chemical additives including corrosion inhibitor, biocide, oxygen scavenger and dye. The volumes and concentrations of the injected chemicals will be monitored and total chemical use measured. Following the connection of all mooring lines to the FPU, the subsea infrastructure will be pulled-in, hooked-up to the FPU and dewatered. Dewatering of the production and export systems will be performed from FPU end of the risers using a Nitrogen dewatering spread. Dewatering of risers, manifold and spool will result in multiple discharges subsea, including:</p> <ul style="list-style-type: none"> dewatering of production flowlines and risers: 6500 m³ (filtered and treated seawater; 600 ppm preservation fluid; split across multiple discharges) dewatering of export risers and spool: 1,100 m³ (filtered and treated seawater; 600 ppm preservation fluid; split across multiple discharges), 0.1 m³ (MEG from jumper hose) pigs for dewatering: 250 m³ filtered and treated freshwater, 40 m³ MEG, and glycol-based gel HP cap installation: 10 m³ filtered and treated seawater, 300 m³ MEG. 														

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

Additional volumes of filtered and treated seawater/freshwater, MEG or glycol-based gel may be discharged if additional flushing is required due to damage or contamination during installation or hook-up (e.g. approximately 2,200 m³ filtered and treated seawater, 80 m³ filtered and treated freshwater, and 15 m³ MEG if a full flowline replacement was required).

Cold commissioning of the subsea infrastructure will involve testing of subsea controls communications from the FPU to the subsea control modules, in order to confirm system readiness for hydrocarbon introduction. It is an open-loop system, designed to release control fluid from the control system during valve operations (up to about 20 L per XT sweep).

FPU Commissioning

The FPU commissioning process involves activities to confirm the integrity of the interconnected facility, so it is RFSU with the introduction of reservoir hydrocarbons. Treated water may be discharged during planned commissioning activities (~200 m³ total). Unplanned discharges may eventuate from scenarios such as contamination, ineffective equipment preservation or unplanned maintenance. Fluids suitable for discharge will be over boarded or routed through the produced water treatment system, while fluids not suitable for discharge (e.g. waste oil) will be captured in a tank and transported onshore.

Facility Initial Start-up

After the FPU achieves RFSU and before a steady state of production can be achieved, an initial start-up period is required to allow clean-up of the wells and to introduce hydrocarbons to the topsides equipment and pressurise the export trunkline. Discharges during the initial start-up will occur via the same process as described in Section 6.7.11. PWT contaminant removal is expected to be at full efficiency during the start-up period and therefore contaminant concentrations at the outlet of the PWTP will be aligned to those in operations (see Section 6.7.11), although there may be short term peaks in contaminant values as equipment is brought online for the first time, but this is not expected, based on the system design (see Section 6.7.11 for discharge modelling).

During the well clean-up process, rich MEG coming onto the FPU from the online flowline will be contaminated with residual drilling and completions fluids. All dirty MEG will be held in a rich MEG tank and then either reclaimed (processed) onboard or send onshore. Criteria for reclamation will be based on whether the MEG is contaminated enough to impact the MRU. If the MEG is reclaimed onboard, the standard MEG reclamation process will be applied and subsequent PW discharges may contain additional contaminants from the drilling and completions process. These substances have been assessed in accordance with Woodside’s chemical assessment and selection framework under the Scarborough Drilling and Completions EP.

In the unlikely scenario where a well produces formation water during clean up, the formation water and well clean up liquids will be sent to a dedicated tank (base case for all well clean up liquids). If a well is identified to be producing formation water, it is expected that it will be immediately shut-in. In the unlikely event that a water-producing well was kept online for an extended period, the formation water would either be segregated with the other well clean up liquids (for disposal onshore) or alternatively, be sent to a rich MEG tank for processing and discharge as per the usual process. The formation water would only be discharged if it was on spec with the alternative being to re-direct it inboard to the rich MEG tanks if off-spec.

As the initial start-up progresses, the MRU will be brought online and uncontaminated MEG from cleaned-up wells will be directed to the MRU for treatment as per normal operations. It is expected that normal operation discharge limits will be achieved.

Monitoring and Management

During initial start-up, a laboratory technician and temporary laboratory will be located on the facility in order to manually calibrate and measure OIW levels. Samples of PW will be analysed for OIW and MEG content daily which can be performed onboard. Due to the more specialised equipment required, mercury analysis is performed onshore weekly. High OIW, MEG and mercury readings will be managed as per Section 6.7.11.

Discharge of Treated Ballast Water from the FPU

On first arrival and following hook-up, ballast water may be discharged from the FPU to the marine environment. This water will be a combination of:

- fresh or treated water taken onboard in China prior to sail down
- seawater taken onboard in high seas, which is filtered and dosed with hypochlorite to 2 mg/L on intake
- local seawater taken onboard in/around Scarborough field location, also filtered and dosed with hypochlorite to 2 mg/L on intake.

Discharges to the Marine Environment May Include Hypochlorite and Particles

During operations, ballast water may infrequently need to be taken onboard from the surrounding marine environment and eventually discharged to maintain FPU stability. This local water will be dosed with hypochlorite at a rate of 2 mg/L, which will degrade over time.

Detailed Impact Assessment

Assessment of Potential Impacts

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

Detailed Impact Assessment

Impacts assessed in this section relate to commissioning/start-up specific discharges only. Discharges during these phases that align with normal Operations are assessed in Section 6.7.11.

Water and Sediment Quality

The presence of chemical additives in discharged fluids are expected to degrade, decay, dilute and disperse once released due to the open oceanic waters of the Offshore Operational Area. The discharges for subsea infrastructure are expected to remain close to the seabed which means the temporary change in water quality will be restricted to deep waters, while the discharges from topsides are expected to remain close to the surface (RPS, 2023) which means the temporary change in water quality will be restricted to surface waters. As such, the discharges are expected to result in a temporary decline in water quality around the discharge locations, with no lasting effect on water quality predicted.

As the discharge plumes from subsea infrastructure are expected to remain close to the seabed, a temporary change in sediment quality may occur. However, due to rapid dispersion of the discharge fluids, the chemical additives will degrade and dilute rapidly following discharge with no predicted accumulation within seabed sediments, as such no lasting effect on sediment quality is predicted. The modelling suggests that discharges from topsides will not reach the seabed due to the water depth at which the FPU operates (952 m), and the dispersive nature of PW discharges in a high energy offshore marine environment such as the Offshore Operational Area. The maximum depth of the plume is predicted to be approximately 23 m (RPS, 2023). Overall, the impact significance level for water and sediment quality has been identified as Negligible (F).

The release of treated ballast water during FPU installation may result in an increase in the turbidity of the receiving waters close to the point of discharge. Ballast water discharges will include low residual hypochlorite concentration which is expected to rapidly disperse and degrade locally when discharged. The addition of these substances into the marine environment could alter ambient water quality; however, these discharges will dilute rapidly, with concentrations significantly dropping with distance from the discharge point. Impacts from non-routine discharges from ballast water on water quality will have a slight effect on water quality around the FPU due to the nature of discharges, which will occur in an approved mixing zone, with a high level of dilution into the open water marine environment of the PAA. As such, the impact significance level for water quality has been identified as Negligible (F).

Plankton

A change in water quality has the potential to result in localised injury or mortality of planktonic species in the water column due to toxicity. Ichthyoplankton (eggs, larvae) are the most susceptible organisms to chemical exposure, as they have limited mobility and thus likely to be exposed to discharge plumes if present. These organisms however, have a high natural mortality and rapid replacement rate and are therefore likely to recover after the discharge ceases.

Some discharges during FPU commissioning and initial start-up activities will occur close to the seafloor in water depths of 900 to 1000 m. Given phytoplankton and zooplankton are generally limited to near-surface waters (i.e., the photic and meso-photoc zones) no lasting effect on plankton is expected from these sources. In terms of topsides discharges, as described by Falkner et al. (2009), the centre of the Exmouth plateau is characterised by moderate seafloor temperatures and low primary productivity. Therefore, while the discharge is to occur within the Exmouth Plateau KEF, this is at a significant distance (>150 km) from the periphery of the plateau that has been identified as having increased productivity (Brewer et al., 2007; Falkner et al., 2009). Consequently, it is not anticipated that this discharge will result in impacts to the ecological integrity of the KEF. As such, the impact significance level for plankton has been identified as Negligible (F).

Epifauna and infauna

As a result of a change in sediment or water quality, localised impacts to benthic habitat receptors may occur. This may include sub-lethal effects or mortality to benthic epifauna and infauna resulting from the increased (water) or accumulation of (sediment) potential contaminants and toxins. Epifauna and infauna sensitivity to discharged fluids is expected to be similar to pelagic invertebrate species such as plankton. Benthic infauna and epifauna communities in the Offshore Operational Area are primarily soft sediment communities featuring burrowing organisms. No primary producer communities (hard corals, seagrass, macroalgae) are present due to the lack of light.

There is potential for a localised area of epifauna to be exposed to lethal and sub-lethal concentrations in the immediate vicinity of release locations. However, due to rapid dispersion of the discharged fluids, uptake and bioaccumulation of contaminants is not expected to occur in sediments or benthic organisms beyond the point of release. The extent of seabed exposure at levels where impacts could occur will be very small, and potential impacts are expected to be localised, temporary and negligible. Impacts from discharged fluids will have no lasting effect on epifauna and infauna. There are no variations in seasonal sensitivity in relation to epifauna and infauna that would influence the effect of the discharges. As such, the impact significance level for Epifauna and Infauna has been identified as Negligible (F).

Marine Fauna

The Offshore Operational Area does not overlap any BIAs for protected marine fauna and given the temporary nature of the discharges, impacts to protected species are not expected. The deep water and predominantly featureless, flat soft sediment seabed in the Offshore Operational Area is of low complexity and low productivity (see Section 4.5) and reduces the species diversity and richness of pelagic and demersal fish assemblages. Potential impacts to pelagic or demersal fish species from discharged fluids are expected to be confined to the vicinity of discharge point. Fish are likely to be transient within the receiving environment adjacent to the discharge location, and as such are unlikely to be

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

Detailed Impact Assessment				
<p>exposed to sufficient concentrations or durations of the discharge constituents to elicit a response. Furthermore, fish and other marine fauna have the capacity to adapt their behaviour in response to changes in environmental conditions and can be expected to move away from the discharge if exposed. Given the low likelihood of pelagic species being exposed to the discharge; and the ability of fish to move away from the discharge plume, the potential for toxic impacts to occur from the temporary and small volumes of discharged fluids are considered to be localised, short-term and no lasting effect at the population or bioregional scale. Overall, the impact significance level for Marine Fauna has been identified as Slight (E).</p> <p>KEFs</p> <p>The Offshore Operational Area is located within the Exmouth Plateau KEF. The Exmouth Plateau is defined as a KEF as it is a unique seafloor feature with ecological properties of regional significance, which apply to both the benthic and pelagic habitats within the feature. Values of the Exmouth Plateau with the potential to be affected by discharged fluids is limited to localised impacts to benthic environments containing low habitat heterogeneity. There is no solids component in the discharges, and therefore no smothering or alteration of the seabed is expected to occur. A temporary change in sediment quality may occur as a result of discharges made close to the seabed.</p> <p>The seafloor composition within the area of discharge is expected to primarily be mud and clay material. Impacts from the temporary and small volumes of discharged fluids will have no lasting effect on the KEF. As such, the impact significance level for KEFs has been identified as Slight (E).</p>				
Summary of Assessment Outcomes				
Receptor	Impact	Receptor Sensitivity Level	Magnitude	Impact Significance Level
Water quality	Change in water quality	Low value (open water)	No lasting effect	Negligible (F)
Sediment quality	Change in sediment quality	Low value	No lasting effect	Negligible (F)
Plankton	Injury/mortality to fauna	Low value (open water)	No lasting effect	Negligible (F)
Epifauna and infauna	Injury/mortality to fauna	Low value (open water)	No lasting effect	Negligible (F)
Fish, sharks and rays	Injury or behavioural changes to marine fauna	High value species	No lasting effect	Slight (E)
Marine mammals		High value species	No lasting effect	Slight (E)
Marine Reptiles		High value species	No lasting effect	Slight (E)
KEFs	Change in habitat	High value habitat	No lasting effect	Slight (E)
<p>Overall Impact Significance Level: The overall impact significance level for routine and non-routine discharges during FPU start-up and commissioning activities is E based on slight effect to high value receptors (marine fauna and KEFs). The impact significance level for water quality is consistent with the level rated in the Scarborough OPP. Potential impacts to marine fauna have been additionally assessed in this EP. There is no change in magnitude of impact (no lasting effect).</p>

Standard practice	Manual sampling during commissioning and intervention visits provides process control and safeguarding to monitor, control and prevent discharge of PW with high mercury concentration to the marine environment.	Minor additional cost to resource manual sampling is proportionate to the environmental benefit during start-up and operation of the Scarborough wells.	Yes C 10.6
Online monitoring and/or procedural controls in place to monitor and control PW discharge volume and OIW concentrations and prevent discharge of PW with high OIW concentrations through OIW analyser, or off spec/outage procedures.	F: Yes. CS: Minimal cost. Standard practice.	The OIW analysers and flow meter provides optimal process control and safeguarding to monitor, control and prevent discharge of PW with high OIW concentration to the environment.	Online monitoring control is WMS requirement – must be adopted. Minor additional cost to resource manual sampling is proportionate to the environmental benefit during start-up of the Scarborough wells.	Yes C 10.3
Professional Judgement – Eliminate				
No subsea discharges to be released to the marine environment	F: Not feasible. Commissioning discharges are required to ensure verification of structural integrity is achieved. CS: Not considered, control not feasible.	Not considered – control not feasible.	Not considered – control not feasible	No
Professional Judgement – Substitute				
No additional controls identified.				
Professional Judgement – Engineered Solution				
No additional controls identified.				
ALARP Statement: On the basis of the environmental impact assessment outcomes and use of the relevant tools appropriate to the decision type (i.e. Decision Type A, Section 2.3.3), Woodside considers the adopted controls appropriate to manage the impacts of planned routine and non-routine discharges during FPU start-up and commissioning activities. As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.

Demonstration of Acceptability

Acceptability Criteria and Assessment

The Petroleum Activities Program meets the acceptability criteria (Section 2.3.5):

- Overall impact significance level for water quality is consistent with the level rated in the Scarborough OPP. As discussed above, potential impacts to marine fauna have been additionally assessed in this EP. There is no change in magnitude of impact (no lasting effect); however, the impact significance level is slightly higher due to the higher receptor sensitivity level. This is not considered a significant change to the overall environmental impact and risk assessed in the Scarborough OPP.
- EPOs and controls in the Scarborough OPP that are relevant to routine discharges have been adopted.
- There are no changes to internal/external context specific to this risk from the Scarborough OPP, including issues raised during consultation.

Acceptability Statement:

The impact assessment has determined that, given the adopted controls, routine and non-routine discharges during FPU start-up and commissioning activities are unlikely to result in an impact significance level greater than Slight. No BIAs for EPBC Act listed Threatened or Migratory species overlap the Offshore Operational Area (refer to Section 4.6). The adopted controls are considered consistent with industry legislation, codes and standards, and professional judgement.

The potential impacts are considered broadly acceptable if the adopted controls are implemented. Activities do not have a significant impact on MNES (**Section 2.4.2**). Therefore, Woodside considers the adopted controls appropriate to, manage the impacts of these discharges to a level that is broadly acceptable; and demonstrate the EPOs are met.

6.8 Unplanned Activities (Accidents, Incidents, Emergency Situations)

6.8.1 Quantitative Spill Risk Assessment Methodology and Floating Production Unit Significant Environment Event Overview

6.8.1.1 Quantitative Hydrocarbon Spill Modelling

Quantitative hydrocarbon spill modelling was performed by RPS, on behalf of Woodside, using a three-dimensional hydrocarbon spill trajectory and weathering model, SIMAP (Spill Impact Mapping and Analysis Program). The model is designed to simulate the transport, spreading and weathering of specific hydrocarbon types under different environmental conditions (both meteorological and oceanographic). Near-field subsurface discharge modelling was performed using OILMAP, which predicts the droplet sizes that are generated by the turbulence of the discharge as well as the centreline velocity, buoyancy, width and trapping depth (if any) of the rising gas and oil plumes. The OILMAP output parameters were used as input into SIMAP.

The algorithms in the SIMAP model are based on the best available scientific knowledge and are updated when necessary in response to significant advances in knowledge. Recent improvements have been implemented to the entrainment algorithm, which have been adjusted to implement the findings of published data based on field research performed during the Macondo spill event in the Gulf of Mexico (Spaulding et al., 2017; Li et al., 2017; French McCay et al., 2018).

Stochastic modelling was conducted for this study, which compiled data from 200 hypothetical spills under different environmental conditions to determine the widest extent of possible oil dispersion. The environmental conditions for each of the hypothetical spills were selected randomly from an historic time-series of wind and current data representative of the study area. Results of the replicate simulations were then statistically analysed and mapped to define contours of percentage probability of contact at identified thresholds around the hydrocarbon release point. The simulations that show something unusual or unexpected make an important contribution to the overall outcomes and fate of the hydrocarbon.

The model simulates surface releases and uses the unique physical and chemical properties of a representative hydrocarbon type to calculate rates of evaporation and viscosity change, including the tendency to form oil-in-water emulsions. Moreover, the unique transport and dispersion of surface slicks and in-water components (entrained and dissolved) are modelled separately. Thus, the model can be used to understand the wider potential consequences of a spill, including direct contact of hydrocarbons due to surface slicks (floating hydrocarbon) and exposure of organisms to entrained and dissolved aromatic hydrocarbons in the water column. The model also calculates the accumulation of hydrocarbon mass that arrives on each section of shoreline over time, taking into account any mass that is lost to evaporation and/or subsequent removal by current and wind forces.

All hydrocarbons spill modelling assessments performed by RPS undergo initial sensitivity modelling to determine appropriate time to add to the simulation after the cessation of the spill. The amount of time following the spill is based on the time required for the modelled concentrations to practically drop below threshold concentrations anywhere in the model domain in the test cases.

Worst-case Scenario

In assessing the potential impacts of an unplanned hydrocarbon release, representative worst-case scenarios (in terms of volume and location) were assessed. A summary of the credible hydrocarbon spill scenarios that could occur during the Petroleum Activities Program are provided in Table 6-42.

Table 6-42: Credible hydrocarbon spill scenarios

Scenario	Hydrocarbon type	Maximum credible volume	Location
Loss of FPU structural integrity/stability	MDO	467 m ³	FPU, Offshore Operational Area
Vessel collision resulting in rupture of a tank	MDO	400 m ³	Offshore Operational Area
Vessel collision resulting in rupture of a tank	MDO	250 m ³	Trunkline Operational Area
Loss of well integrity	Dry gas	No or negligible liquid hydrocarbon	Well locations, Offshore Operational Area
Pipeline and riser loss of containment	Dry gas	No or negligible liquid hydrocarbon	Offshore Operational Area Trunkline Operational Area
Topsides loss of containment	MDO	220 m ³	FPU, Offshore Operational Area
Loss of containment during bunkering	MDO	50 m ³	Offshore Operational Area Trunkline Operational Area
ASV loss of structural integrity	MDO	Slow leak*	Offshore Operational Area

*Leaking of MDO would occur at a very slow rate and be rapidly diluted in the nearfield water column, resulting in impacts well within those expected from larger instantaneous releases.

For the Petroleum Activities Program, the worst-case spill scenarios were identified to be:

- an instantaneous surface release of 470 m³ of marine diesel, representing loss of the full inventory stored on the FPU as a result of loss of structural integrity within the Offshore Operational Area
- an instantaneous surface release of 250 m³, representing loss of the largest vessel fuel tank integrity (support vessel) following a collision within the Trunkline Operational Area.

The assessment of impacts for the worst-case scenarios will also address the potential impacts of other credible releases with lesser volumes.

To inform the impact assessment, quantitative hydrocarbon spill modelling was undertaken for the worst-case hydrocarbon release scenarios (RPS, 2024).

It is not practicable for spill modelling to be undertaken at every potential release location within the PAA. Release locations were selected by considering locations that would:

- have the greatest potential environmental consequence to the receiving environment (closest to sensitive receptors), and/or
- be considered at greater risk of a spill event occurring.

Accordingly, a release of marine diesel was modelled at three representative locations; one in the Offshore Operational Area (Location 1) and two in the Trunkline Operational Area (Locations 2 and 3) at sensitive locations (Table 6-43). The EMBA has been defined using a combination of modelling from all three locations, as described below.

Table 6-43: Spill locations for marine diesel instantaneous release

Location	Coordinates	Water Depth	Credible Spill Volume	Modelled Spill Volume
Location 1: FPU Location	19° 53' 54.72" S, 113° 14' 19.56" E	953 m	467 m ³	470 m ³
Location 2: Outside Mermaid Sound (State and Commonwealth waters boundary)	20° 21' 3.28" S, 116° 42' 5.58" E	31 m	250 m ³	250 m ³
Location 3: Within the Montebello Australian Marine Park	20° 03' 1.44" S, 115° 31' 35.04" E	74 m	250 m ³	250 m ³

6.8.1.2 Environment that May Be Affected and Hydrocarbon Contact Thresholds

The outputs of the quantitative hydrocarbon spill modelling are used to assess the environmental risk, if a credible hydrocarbon spill scenario occurred, by delineating which areas of the marine environment could be exposed to hydrocarbon levels exceeding hydrocarbon threshold concentrations (outlined in Table 6-44). The summary of all the locations where hydrocarbon thresholds could be exceeded by any of the simulations modelled is defined as the 'environment that may be affected' (EMBA).

As the weathering of different fates of hydrocarbons (surface, entrained and dissolved) differs due to the influence of the metocean mechanism of transportation, the EMBA combines the potential spatial extent of the different fates. Note, no shoreline accumulation of hydrocarbons above threshold concentrations resulted from the modelled worst-case credible spill.

The EMBA covers a larger area than the area that is likely to be affected during any single spill event, as the model was run for a variety of weather and metocean conditions. The EMBA therefore represents the total extent of all the locations where hydrocarbon thresholds could be exceeded from all modelling runs for each of the three modelled locations. Given the EMBA comprises the results of many individual simulations, the total area covered at the thresholds has been smoothed to create a continuous boundary for the purpose of describing the environment within it (Figure 4-2).

Surface and accumulated shoreline hydrocarbon concentrations are expressed as grams per square metre (g/m²), with entrained and dissolved aromatic hydrocarbon concentrations expressed as parts per billion (ppb). A conservative approach adopting accepted contact thresholds that are documented to impact the marine environment are used to define the EMBA. These hydrocarbon thresholds are described in the following subsections.

Woodside recognises that hydrocarbons may be present beyond the ecological impact EMBA at low concentrations that may be visible but are not expected to cause ecological impacts. The threshold for visible surface oil (1 g/m²) has therefore been used to define an additional boundary within which socio-cultural impacts to the visual amenity of the marine environment may occur. This area is referred to as the socio-cultural EMBA. Any ecological impacts from dissolved and entrained hydrocarbons above prescribed thresholds, as in (Table 6-44), may also result in socio-cultural impacts. Potential impacts to socio-cultural values assessed within these EMBA's include:

- protected areas
- national and Commonwealth Heritage Listed places
- tourism and recreation
- fisheries.

Table 6-44: Summary of environmental impact thresholds applied to the quantitative hydrocarbon spill risk modelling results

Hydrocarbon Type	EMBA				Socio-cultural EMBA
	Surface hydrocarbon (g/m ²)	Dissolved hydrocarbon (ppb)	Entrained hydrocarbon (ppb)	Accumulated hydrocarbon (g/m ²)	Surface hydrocarbon (g/m ²)
Marine Diesel	10	50	100	100	1

6.8.1.3 Surface Hydrocarbon Threshold Concentrations

The spill modelling outputs defined the EMBA for surface hydrocarbons resulting from a spill (contact on surface waters) using a threshold of ≥ 10 g/m² for marine diesel. This threshold is used to define an area within which ecological impacts to the marine environment may occur from surface hydrocarbons. It represents the minimum oil thickness (0.01 mm) at which ecological impacts (e.g. to birds and marine mammals) are expected to occur.

Thresholds for registering biological impacts resulting from contact of surface slicks have been estimated by different researchers at about 10–25 g/m² (French et al., 1999; Koops et al., 2004; National Oceanic and Atmospheric Administration, 1996). Potential impacts of surface slick concentrations in this range for floating hydrocarbons may include harm to seabirds through ingestion from preening of contaminated feathers, or the loss of the thermal protection of their feathers. The 10 g/m² threshold is the reported level of oiling to instigate impacts to seabirds and is also applied to other wildlife, though it is recognised that ‘unfurred’ animals, where hydrocarbon adherence is less, may be less vulnerable. ‘Oiling’ at this threshold is taken to be of a magnitude that can cause a response from the most vulnerable wildlife such as seabirds. Due to weathering processes, surface hydrocarbons will have a lower toxicity due to change in their composition over time. Potential impacts to shoreline sensitive receptors may be markedly reduced in instances where there is extended duration until shoreline contact.

A surface threshold of 10 g/m² represents a ‘dull metallic colour’ (Bonn Agreement, 2015). A lower concentration of 1 g/m² is used to define an area within which social-cultural impacts to the visual amenity of the marine environment may occur. The surface threshold of ≥ 1 g/m² is based on the relationship between film thickness and appearance (Bonn Agreement oil appearance code, 2015), and represents a ‘rainbow sheen’ appearance. This threshold is considered below levels which would cause ecological impacts, and instead represents potential for visual amenity impacts. This threshold area is referred to as the ‘socio-cultural EMBA’.

Table 6-45: The Bonn Agreement oil appearance code

Appearance (following Bonn visibility descriptors)	Mass per area (g/m ²)	Thickness (µm)	Volume per area (L/km ²)
Discontinuous true oil colours	50 to 200	50 to 200	50,000 to 200,000
Dull metallic colours	5 to 50	5 to 50	5000 to 50,000
Rainbow sheen	0.30 to 5.00	0.30 to 5.00	300 to 5000
Silver sheen	0.04 to 0.30	0.04 to 0.30	40 to 300

6.8.1.4 Accumulated Hydrocarbon Threshold Concentrations

Owens et al (1994) define accumulated hydrocarbon < 100 g/m² to have an appearance of a stain on shorelines. French-McCay (2009) defines accumulated hydrocarbons ≥ 100 g/m² to be the threshold that could impact the survival and reproductive capacity of benthic epifaunal invertebrates living in intertidal habitat. A threshold of ≥ 100 g/m² has been adopted as the threshold for shoreline

accumulation and has been included in the EMBA. Further, any ecological impacts at the shoreline accumulation threshold may also result in socio-cultural impacts.

6.8.1.5 Dissolved Aromatic Hydrocarbon Threshold Concentrations

Dissolved hydrocarbons present a narcotic effect resulting from uptake into the tissues of marine organisms. This effect is additive, increasing with exposure concentration or with time of exposure (French-McCay, 2002; National Resource Council, 2005). The dissolved aromatic threshold of 50 ppb has been selected as a medium level threshold to approximate the potential toxic effects, particularly sublethal effects to sensitive species, as consistent with the NOPSEMA Oil Spill Modelling Guidance Bulletin (NOPSEMA, 2019).

6.8.1.6 Entrained Hydrocarbon Threshold Concentrations

This threshold is used to define an area within which ecological impacts to the marine environment may occur from entrained hydrocarbons. Therefore, it may also be associated with socio-cultural impacts.

Entrained hydrocarbons present a number of possible mechanisms for toxic exposure to marine organisms. The entrained hydrocarbon droplets may contain soluble compounds, hence have the potential for generating elevated concentrations of dissolved aromatic hydrocarbons (e.g. if mixed by breaking waves against a shoreline). Physical and chemical effects of the entrained hydrocarbon droplets have also been demonstrated through direct contact with organisms; for example, through physical coating of gills and body surfaces, and accidental ingestion (National Research Council, 2005).

The entrained threshold has been selected to be consistent with the NOPSEMA Oil Spill Modelling Guidance Bulletin (NOPSEMA, 2019). An entrained threshold of 100 ppb is considered to be appropriate given the oil characteristics for informing potential impacts to receptors.

6.8.1.7 Scientific Monitoring

A planning area for scientific monitoring is also described in Section 5.8 of Appendix H: Oil Spill Preparedness and Response Mitigation Assessment. This planning area has been set with reference to the low exposure entrained value of 10 ppb detailed in NOPSEMA Bulletin #1 Oil Spill Modelling (2019). This low exposure threshold is based on the potential for exceeding water quality triggers.

A scientific monitoring program would be activated following a Level 2 or 3 unplanned hydrocarbon release, or any release event with the potential to contact sensitive environmental receptors. This would consider receptors at risk (ecological and socio-economic) for the entire predicted EMBA and in particular, any identified Pre-emptive Baseline Areas (PBAs) for the worst-case credible spill scenario or other identified unplanned hydrocarbon releases associated with the operational activities.

6.8.1.8 Classification and Analysis of Significant Environment (Process Safety) Events

For Woodside's production facilities, a further level of analysis is undertaken to identify, classify and analyse unplanned events deemed significant environmental (process safety) events (such as those with potential Major consequence, termed MEEs). This extra level of rigour is applied to ensure sufficient controls are in place for risks with potential Level B and above consequences. In the health and safety area, Major Accident Events (MAEs) are identified using a similar process, which supports consistency in managing key risks within Woodside in accordance with Process Safety Risk Management Procedures. Process safety events are defined around the production process equipment to apply good design principles, engineering, operating and maintenance practices. It deals with the prevention and control of events that have the potential to release hazardous materials and energy.

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

Woodside defines an MEE as an event with potential environment, reputation (pertaining to environment events), social or cultural consequences of level B or higher as per Woodside's Risk Matrix (Figure 2-3). MEEs are evaluated against credible worst-case scenarios that may occur when all controls are absent or have failed. Some high consequence/low probability significant environment (process safety) events which do not meet the MEE consequence threshold may still undergo additional consequence and probability assessment where they could have a high adverse impact on the Woodside's reputation or relationships with relevant persons, which also supports demonstration of ALARP and acceptable risk levels following application of controls. No MEEs have been identified for Scarborough operations, primarily due the inherently lower risk presented due to Scarborough process fluids being predominantly 'dry' hydrocarbon gas (meaning limited inventories of liquid hydrocarbons in production systems). Nevertheless, Scarborough's assessment and representation of ALARP and Environment Plan controls (EPS) selection is applied for the key significant environment (process safety) events of:

- Vessel Collision
- Loss of FPU/ASV Structural Integrity/Stability
- Loss of Well Containment
- Subsea Equipment and Trunkline Loss of Containment
- FPU Topsides Loss of Containment including Bunkering / Refuelling

These are broadly consistent with assessing and representing MEEs for other Woodside production facilities.

Scenario and risk evaluation includes the potential for interaction and escalation events which could cause one or more significant LOC scenarios.

These risk events are subject to more detailed analysis focussing on understanding cause-outcome pathways for each risk and identifies controls in place to prevent the 'top event' or mitigate the consequences (outcomes). Tables are presented to support ALARP demonstration; illustrating the outcomes of safety in design philosophies applied during project development, such as hierarchy of engineering controls applied, and key integrity, maintenance and operational practices in place during operations to manage risk and includes emergency response in case of unplanned events occurring.

Key integrity controls owned and operated by Woodside are identified as critical technical barriers known as Safety and Environment Critical Elements (SCEs) – further discussed in Section 7.2.8. Each group of safety critical controls is listed under technical or management system Performance Standards with consistent naming conventions used across Woodside's process safety management processes (e.g. pipeline integrity SCEs are captured as P09 – Pipeline / Trunkline Systems). Management system specific measures (such as key standards or procedures) are listed which enables verification of and linking to the relevant sections of Woodside's Management System that supports key barriers. Potential common causes that contribute to significant environment events, or that can result in failure or degradation of the controls in place to protect against these events, include some generic mechanisms of SCE failure.

Critical controls and management system specific measures are set out which support the management of these potential common causes.

ALARP is demonstrated through controls and barriers being analysed for selection based on their independence, prioritised in accordance with the Hierarchy of Controls where controls further up the hierarchy take precedence over controls further down, and further analysed to consider the type of effect the control provides. ALARP controls presented for process safety related unplanned hydrocarbon LOC risks are labelled in accordance with Type of Effect classifications presented in Table 6-46.

Woodside has developed a tailored ALARP position for hydrocarbon spill response, including EPOs, EPSs and MC for preparedness and response. The response arrangements are a mitigative control that applies to all MEEs where a liquid hydrocarbon release may credibly occur. The hydrocarbon spill response arrangements are described in Appendix H: Oil Spill Preparedness and Response Mitigation Assessment.

Table 6-46: Barrier hierarchy and type of effect

Type of Effect	Description
Elimination (Technical)	Elimination controls form the 'first line of defence'. They eliminate the underlying hazard and therefore are the most effective category of control measure. If practicable, they should be selected in preference to any other type, as their existence removes the need for any other controls (e.g. a corrosion-resistant metal could replace the original material of construction).
Elimination (Administration)	
Prevention (Technical)	Prevention controls are intended to remove certain causes of incidents or reduce their likelihood. The corresponding hazard remains, but the frequency of incidents involving the hazard is lowered (e.g. introduction of regular maintenance programs can prevent the development of events involving the hazard). Where hazards and causes could not be 'eliminated', controls are required to prevent them from leading to unwanted events and consequences.
Prevention (Administration)	
Detection (Technical)	Detection controls are those that identify a potentially hazardous scenario (e.g. a change in operating parameters), allowing initiation of procedures or systems to prevent the cause occurring. Controls that detect the occurrence of events are often critical to being able to respond with other control measures that reduce the propagation of the events. Detection controls themselves often provide no actual control other than the awareness of the need to respond.
Detection (Administration)	
Reduction/Control (Technical)	Reduction controls are intended to limit the scale and consequence of incidents. They include systems that detect incidents and take some action (e.g. to reduce the rate of leakage of a toxic gas) and also aspects such as inter-unit separation that prevent escalation of fire and explosion incidents. As there is always potential for controls to fail, additional measures are required to limit the scale and severity of any unwanted event or outcome that may arise, by providing the ability to intervene and limit the propagation of the events.
Reduction/Control (Administration)	
Mitigation (Technical)	Mitigation controls take effect in response to an incident. They include controls that lessen the significance or damage caused by an unwanted event. Such controls only take effect after the hazardous event and outcomes occur. Mitigation controls are generally those designed to protect personnel against the consequences of a hazard or to aid in recovering from the effects of the hazard.
Mitigation (Administration)	

6.8.1.9 Safety and Environment Critical Elements and Technical Performance Standards

Woodside identifies and manages SCEs technical and management system performance standards in accordance with Process Safety Management Procedures, Risk Management Procedures and Change Management Procedures (further described in the implementation strategy in Section 7). SCEs are identified for MAEs and MEEs and significant environment events. An SCE is a hardware control, the failure of which could cause or contribute substantially to, or the purpose of which is to prevent or limit the effect of a MAE, MEE or significant environment event. In addition, Woodside defines Safety and Environment Critical Component (SCC) as an item of equipment or structure forming part of a hardware SCE that supports the SCE in achieving the safety function.

Once an SCE is identified as an MEE barrier for the operated facility, technical performance requirements are developed for the facility SCE in accordance with the Global SCE Performance Standards and process described in the SCE Management Procedure and form the SCE Facility Performance Standard. Each SCE Performance Standard represents a statement of the performance required of an SCE (e.g. functionality, availability, reliability, survivability). SCE Performance Standard requirements are used to establish agreed assurance tasks for each SCE, support the management of operations within acceptable safety and/or environment risk levels, and

ensure continuous management of risk to ALARP. An assurance task is an activity carried out by the operator to confirm that the SCE meets, or will meet, its SCE Performance Standard. Examples of assurance tasks include inspection routines, maintenance activities, test routines, instrumentation calibration, and reliability monitoring.

SCE Facility Performance Standards do not always align directly with EPSs. They are used in conjunction with the WMS to identify and treat potential step-outs from expected controls performance or integrity envelopes and ensure SCE performance can be optimised. Woodside's HSE Event Reporting Guideline describes the process for identifying 'Failure to meet Facility Performance Standard', which is when the SCE does not meet the goal as stated in the relevant Performance Standard. (see Section 7.2.8). Situations where SCEs fail to meet Facility Performance Standards represent a potential increase in risk that, if not addressed immediately, have the potential to result in a significant environment event, or worsen the consequences of one. Recording SCE Failure to Meet Performance Standard Events into the Event Reporting Database is important to highlight risk, investigate causes, ensure risks are managed and meet potentially applicable external reporting requirements. For applicable SCEs, 'Failure to meet Facility Performance Standard' represent scenarios that may fail to achieve an EPS presented in this EP. Failures that continue to pose an increased risk above baseline (e.g. functional objective not able to be remediated in a timely manner) are considered for Recordable reporting. More detail on the SCE and Performance Standards process, and the interrelationships to other parts of the SCE Management Procedures, is described in Section 7.2.8. Safety-critical Management System specific measures are also identified. These are management system components (generally WMS processes) that are key barriers to, or measures for, managing significant environment events.

6.8.2 Unplanned Diesel Release: Vessel Collision

Loss of hydrocarbons to marine environment in the Offshore Operational Area due to a vessel collision (with Project Vessels or third party vessels, including vessel collision with FPU or ASV)			✓		✓	✓	✓	A	D	1	M	LCS GP PJ RBA		

Description of Source of Impact/Risk
<p>Background</p> <p>A loss of marine vessel separation between a vessel and the facility / ASV or other vessels may result in a loss of hydrocarbon containment from the release of fuel from the vessel. Marine Diesel Oil (MDO) fuel storage presents the highest potential hydrocarbon volumes for this risk event.</p> <p>Vessel collisions can arise from:</p> <ul style="list-style-type: none"> vessel to vessel collision between project/operational vessels visiting vessel collisions associated with project/operational vessels (such as ASV, and support vessels) – ships which are visiting the facility can accidentally collide with the FPU during approach or manoeuvring

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

Description of Source of Impact/Risk

- Vessel operations during adverse weather
- errant passing vessel collision – ships which are not visiting the platform (i.e. passing vessels) moving off-course and colliding with the facility

The different collision hazards involve significantly different sized vessels and collision speeds, hence, differing impact energies and consequences, and have been assessed.

Fuel storage onboard the FPU and ASV are not deemed credible to be lost by potential vessel impacts due to the facility design and layout of fuel storage. Fuel storage tanks on ASV *Floatel Triumph* (for example) are positioned in protected positions, on the inboard side of pontoons behind ballast water tanks and below the water line. FPU fuel storage is elevated above the waterline, in crane pedestal tanks.

Visiting Vessels

Visiting vessels are defined as those which are used to service the facility. Operating procedures will dictate how vessels are operated, loaded and unloaded, but it will generally occur so that the prevailing winds move the vessel away from the facility. The primary causes of visiting vessel collisions are failure to follow safe procedures and communication errors between the marine vessels and platform operations. These errors could be worsened by the following:

- vessel station keeping failures, or
- vessel operations in adverse weather conditions.

Errant Passing Vessels

Errant passing vessels are defined as third-party vessels that enter the riser platform’s 500 m PSZ, but do not call at the FPU facility or other installations (i.e. not facility or Support Vessels). The collision can be powered or drifting. Either has the potential to cause significant damage to project or operations marine vessels.

The causes of errant passing vessel collisions include:

- failure of propulsion or steering systems
- adverse weather conditions resulting in poor visibility
- rough seas
- human error.

Woodside implements a range of preventative control measures to mitigate the risk of errant vessel collision reasonably within its control. Powered collisions from large passing vessels or tankers could have sufficient impact energy to breach one or more skins of the third party vessel to the extent that there is a loss of containment of cargo or fuel oil with the potential for significant loss of inventory and consequent environmental impact. This is not within the control of Woodside, and is regulated under Australian marine and shipping legislation so is not assessed further.

Industry Experience

Registered vessels or foreign flag vessels in Australian waters are required to report events to the Australian Transport Safety Bureau (ATSB), AMSA or Australian Search and Rescue (AusSAR). From a review of the ATSB marine safety and investigation reports, one vessel collision occurred in 2011/12 that resulted in a spill of 25–30 L of oil into the marine environment as a result of a collision between a tug and support vessel off Barrow Island. Two other vessel collisions occurred in 2010, one in the port of Dampier, where a Support Vessel collided with a barge being towed. Minor damage was reported and no significant injury to personnel or pollution occurred. The second 2010 vessel collision involved a vessel under pilot control in port connecting with a vessel alongside a wharf, causing it to sink. No reported pollution resulting from the sunken vessel. These incidents demonstrate the likelihood of only minor volumes of hydrocarbons being released during the highly unlikely event of a vessel collision.

From 2010 to 2011, the ATSB’s annual publication defines the individual safety action factors identified in marine accidents and incidents: 42% related to navigation action (2011). Of those, 15% related to poor communication and 42% related to poor monitoring, checking and documentation (ATSB, 2011). The majority of these also related to grounding instances.

Credible Spill Scenario

For marine vessels, maximum credible spill volume is taken as the volume of the largest single fuel tank in line with AMSA guidelines (AMSA 2015).

The vessels with the largest single fuel tank capacity that will be operating in the Offshore Operational Area are a tow tug and AHT which have capacity typically between 350 to 400 m³. The largest Vessel that will be operating in the Trunkline Operational Area is a support vessel, with a maximum single fuel tank capacity of 250 m³. The single largest tank onboard the ASV *Floatel Triumph* is 359 m³.

For the purposes of this assessment, a worst-case credible risk scenarios was identified for each Operational Area:

- Offshore Operational Area: a collision of a Project Vessel with a third-party vessel or between Project Vessels. The largest tank of a Project vessel is unlikely to exceed 400 m³ within this area.

Description of Source of Impact/Risk

- Trunkline Operational Area: a collision of a Project Vessel along the Trunkline route with a third-party vessel or between Project Vessels. The largest tank of a project/operational vessel is unlikely to exceed 250 m³ within this area.

A worst-case loss of up to 400 m³ of MDO is considered an appropriate conservative worst case for rupture of a single fuel tank in the Offshore Operational Area. This is representative of the largest fuel tank on the AHTs, LCV and ASV that will be used for FPU Mooring and Hook-up, IMMR and commissioning activities.

Loss of containment of up to 250 m³ of MDO from collision with a vessel engaged in IMMR activities in the Trunkline Operational Area closer to sensitive receptors in the Montebello Marine Park and Dampier Archipelago is also considered credible. Given the offshore location of the PAA, vessel grounding is not considered a credible risk.

Likelihood

For a vessel collision to result in the worst-case scenario of a hydrocarbon spill potentially impacting an environmental receptor, several factors must align as follows:

- The identified causes of vessel interaction must result in a collision.
- The collision must have enough force to penetrate the vessel hull.
- The collision must be in the location of the fuel tank.
- The fuel tank must be full, or at least have a volume which is higher than the point of penetration.

The probability of the chain of events described above aligning, to result in a breach of fuel tanks resulting in a spill that could potentially affect the marine environment is considered credible in some circumstances, however deemed Highly Unlikely.

The environmental risk analysis and evaluation identified and assessed a range of potential scenarios that could result in a loss of vessel structural integrity, resulting in damage to fuel storage tank(s) and a loss of marine diesel to the marine environment. The likelihood of a collision resulting in a hydrocarbon spill from a storage tank was assessed as being highly unlikely, given standard vessel operations and equipment in place to prevent collision at sea, the construction and placement of storage tanks and the number of times such an incident has occurred in the oil and gas industry and within Woodside.

Quantitative Hydrocarbon Risk Assessment

Modelling of a 250 m³ surface release of marine diesel was undertaken for two locations within the Trunkline Operational Area (RPS, 2024) (Table 6-43). A conservative representation of worst-case (400 m³) spill associated with loss of marine vessel separation is represented by a 470 m³ surface release scenario modelled within the Offshore Operational Area. This 470m³ scenario also represents release of marine diesel storage on FPU topsides, as a result of loss of structural integrity of the FPU (ref. Section 6.8.3).

The modelling assessed the extent of a marine diesel spill for all seasons, using historic samples of wind and current data for the region (2006-2015, inclusive). A total of 200 simulations were modelled over an annual period, with each simulation tracked for 42-days. The coordinates of the modelled spill locations are detailed in (Table 6-43).

Hydrocarbon Characteristics

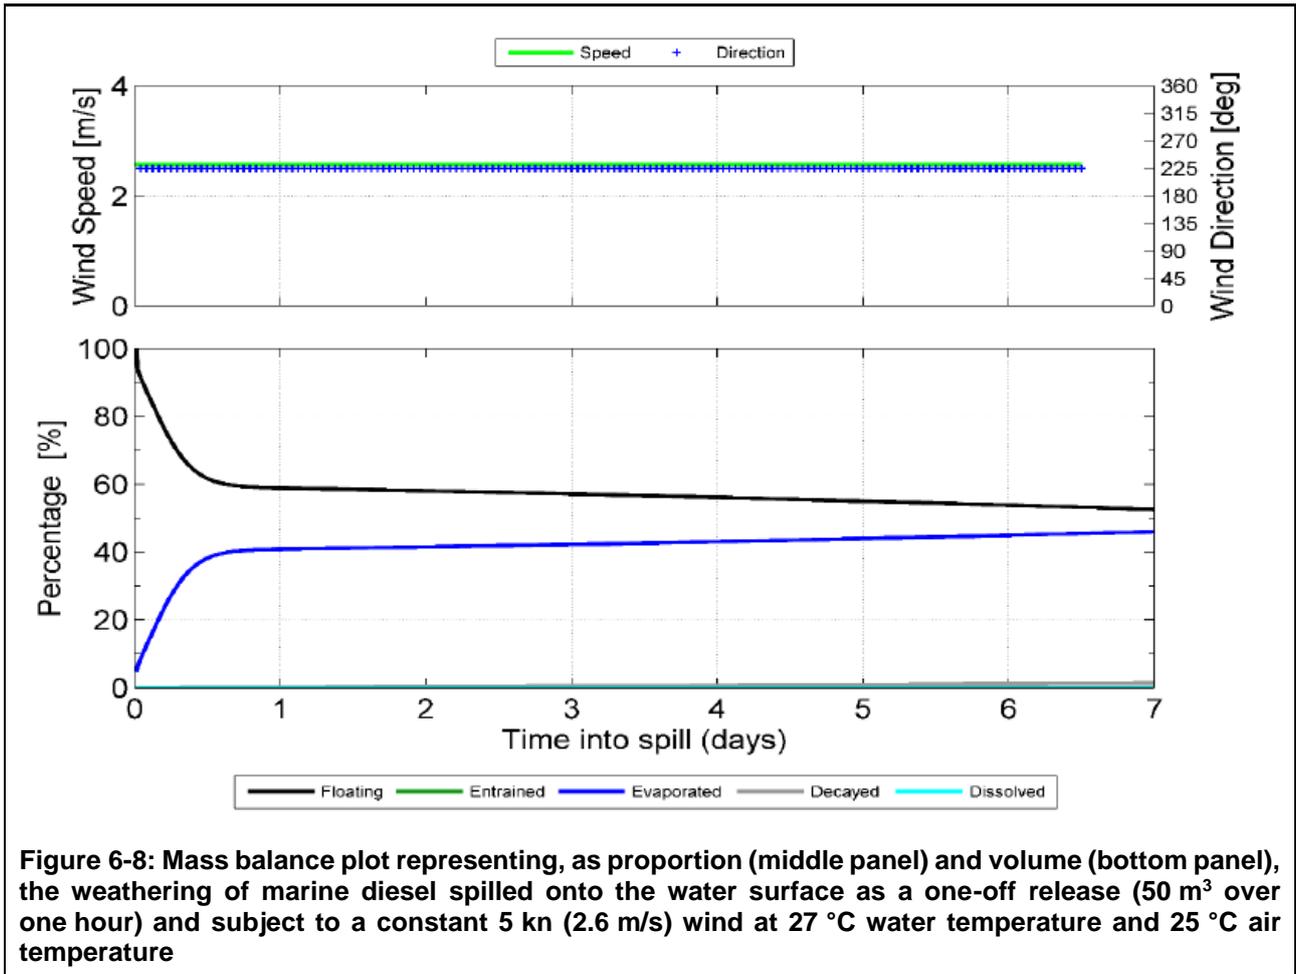

MDO is a non-persistent fuel oil and contains a small proportion of heavy components (or low volatile components) that tend to physically entrain into the upper water column in the presence of moderate winds (i.e. >12 knots) and breaking waves but may re-float to the surface if these conditions abate. In the event of a substantial spill, the heavier components can remain entrained or remain on the sea surface for an extended period. The characteristics of the marine diesel are given in Table 6-47.

Marine diesel is a mixture of both volatile and persistent hydrocarbons. Predicted weathering of marine diesel, based on typical conditions in the region, indicates that about 24% of the oil mass should evaporate within the first 24 hours. (Figure 6-8) (RPS, 2024). After this time the majority of the remaining hydrocarbon is entrained into the upper water column. Given the environmental conditions experienced in the PAA, marine diesel is expected to undergo rapid spreading and this, together with evaporative loss, is likely to result in a rapid dissipation of the spill. Marine diesel distillates tend not to form emulsions at the temperatures found in the region.

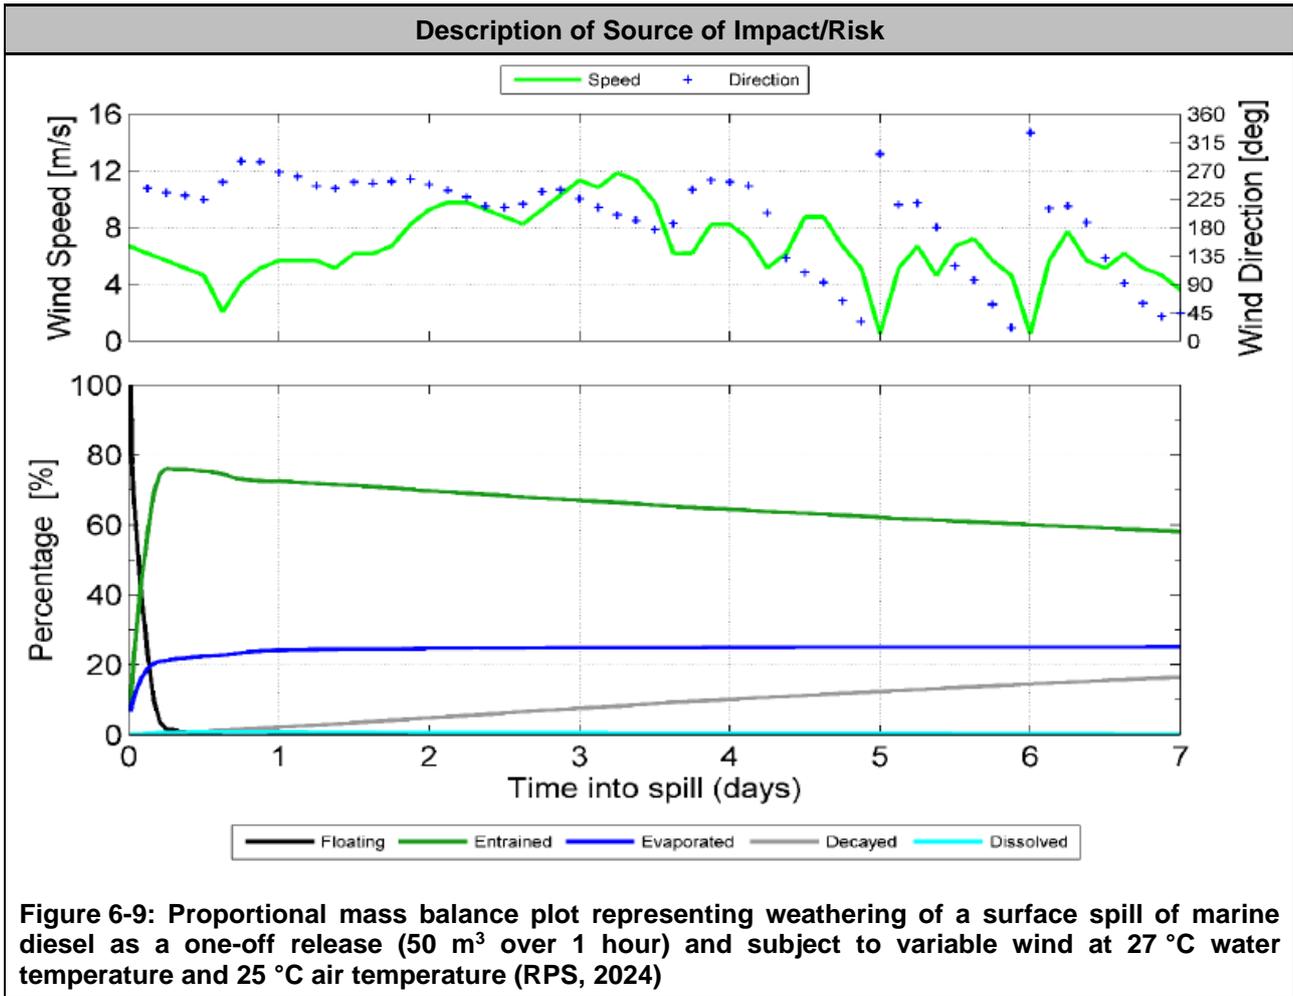

Table 6-47: Characteristics of the marine diesel

Hydrocarbon type	Initial density (g/cm ³) at 25 °C	Viscosity (cP @ 25 °C)	Component BP (°C)	Volatiles %<180	Semi volatiles % 180–265	Low volatility (%) 265-380	Residual (%) >380
				Non-Persistent			Persistent
Marine diesel	0.829	4.0	% of total	6	34.6	54.4	5
			% of aromatics	1.8	1.0	0.2	-

Detailed Impact Assessment

Assessment of Potential Impacts

Environment that May Be Affected

The overall EMBA for the Petroleum Activities Program is based on stochastic modelling, which compiles data from 200 hypothetical worst-case spills under a variety of weather and metocean conditions (as described in **Section 6.8.1**). The EMBA therefore covers a larger area than the area that would be affected during any one single spill event, and therefore represents the total extent of all the locations where hydrocarbon thresholds could be exceeded from all modelling runs. The trajectory of a single spill would have a considerably smaller footprint.

As described in **Section 6.8.1**, three hydrocarbon spill locations were modelled in order to represent the range of locations of where vessel collision could occur within the PAA. The EMBA has been defined using a combination of all three locations, the largest extent of the Hydrocarbon EMBA is based on the entrained threshold from the modelled locations and therefore includes the results from 600 modelling runs. In the event of a spill the EMBA would be much smaller and is intermittent e.g. a plume travels away from the release location based on prevailing currents and winds directions. Therefore one area is not exposed to hydrocarbons above thresholds for the entire simulation.

Spill modelling was undertaken based on an instantaneous surface release at the following locations:

- Location 1: Trunkline Operational Area, outside Mermaid Sound (250 m³)
- Location 2: Trunkline Operational Area, within Montebello AMP (250 m³)
- Location 3: Offshore Operational Area, FPU location (470 m³) (assessed in Section 6.8.3).

As the weathering of different fates of hydrocarbons (surface, entrained and dissolved) differs due to the influence of the metocean transport mechanism, a different EMBA is discussed for each fate.

Surface Hydrocarbons: The modelling indicates that for a spill at Location 1 (Mermaid Sound) there is a low probability (2%) of the Dampier Archipelago encountering surface hydrocarbons of 10 g/m². A number of other receptors are predicted to have a low probability of encountering surface hydrocarbons at the 10 g/m² threshold,

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

Detailed Impact Assessment

including Dampier Archipelago (2% probability) Cape Bruguieres (3.5% probability and Legendre Island (1% probability). A socio-cultural EMBA for surface hydrocarbons includes the threshold for visible surface hydrocarbons of 1 g/m² and there is a low probability of encountering surface hydrocarbons of 1 g/m² at the following locations additional locations: Dampier Marine Park (2.5%), Hammersley Shoal (3.5%), Madeleine Shoals (2.5%), Rosemary Island (1%) and Cohen Island (2%).

For a spill at Location 2 (Montebello AMP), the modelling indicates there is a 100% probability of Montebello AMP encountering hydrocarbons of 10 g/m² and 1 g/m². Rankin Bank is also predicted to have a low probability of contact at 10 g/m² and 1 g/m² (1%).

A summary of all receptors predicted to be contacted by surface hydrocarbons is provided in Table 6-48.

Entrained Hydrocarbons: For a vessel collision spill at Location 1, the receptors predicted to be contacted by entrained oil concentrations at the 100 ppb threshold are: Dampier AMP (39.5% probability), Dampier Archipelago (31.5% probability), Cohen Island (12% probability), Keast Island (9.5% probability), Legendre Island (22% probability), Rosemary Island (8% probability), Hammersley Shoal (12.5% probability), Madeleine Shoals (37.5% probability) and a number of other locations with a probability of 5% or less (Table 6-48).

For a spill at Location 2 the Montebello AMP is predicted to be contacted by entrained oil concentrations at the 100 ppb threshold (49% probability) and a number of other locations are predicted to be contacted with a probability of 1% or less (Table 6-48).

Dissolved Hydrocarbons: For a vessel collision spill at Location 1, the receptors predicted to be contacted by dissolved oil concentrations at the 50 ppb threshold are: Dampier AMP (7% probability), Dampier Archipelago (3% probability), Legendre Island (2.5% probability), Madeleine Shoals (6% probability) and a number of other locations with a probability of 1% or less (Table 6-48).

For a spill at Location 2, the receptors predicted to be contacted by dissolved oil concentrations at the 50 ppb threshold are: Montebello AMP (16% probability) and a number of other locations with a probability of 1% or less (Table 6-48).

Accumulated Hydrocarbons: Accumulated hydrocarbons above threshold concentrations (≥ 100 g/m²) were predicted by the modelling to occur at several locations with a low probability: Cape Bruguieres (2%), Dampier Archipelago (2%), Cohen Island (2%), Gidley Island (0.5%), Keast Island (2%), Rosemary Island (1%) and Legendre Island (2%).

There is no predicted contact with shoreline locations above threshold concentrations from a spill at Location 2.

Impact Assessment

Water Quality

An unplanned release of marine diesel, would result in a change in water quality, affecting the ambient water quality within the EMBA as follows:

The highly-mixed, open water location and characteristics of hydrocarbons released will result in rapid evaporation and dispersion. However, MDO contains a small proportion of heavy components (or low-volatile components) that tend to physically entrain into the upper water column in the presence of moderate winds (i.e. >12 knots) and breaking waves but may resurface if these conditions abate. If a substantial spill occurred, the heavier components could remain entrained or remain on the sea surface for an extended period and travel significant distances from the source, albeit at low concentrations.

As described above, predicted weathering of marine diesel, based on typical conditions in the region, indicates that about 24% of the oil mass should evaporate within the first 24 hours (Figure 6-9) (RPS, 2024). After this time the majority of the remaining hydrocarbon is entrained into the upper water column.

Water quality would be reduced and is predicted to be at or above biological effect concentrations for the surrounding marine waters over the Montebello Marine Park. The submerged Tryal Rocks (30-40 m depth) within the Montebello Marine Park has the potential to be exposed to entrained hydrocarbons at or greater than 100 ppb. The waters surrounding this submerged habitat would show a reduction in quality due to hydrocarbon contamination above background and/or national/international quality standards.

Exposure to significant habitats will be at low levels such that no significant habitats or ecosystem function or integrity will be impacted (as discussed in the receptor sections). Given the short time periods of exposure and the nature of MDO to evaporate and spread quickly, the magnitude of a potential impact to water quality associated with a release of hydrocarbons is assessed as Slight (E).

Plankton

Injury/mortality to planktonic species may occur due to a change in water quality following an unplanned hydrocarbon release.

Primary production by plankton (supported by sporadic upwelling events in the offshore waters of the NWS) is an important component of the primary marine food web. Planktonic communities are generally mixed, including phytoplankton (cyanobacteria and other microalgae) and secondary consuming zooplankton, such as crustaceans (e.g. copepods), and the eggs and larvae of fish and invertebrates (meroplankton).

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

Detailed Impact Assessment

Exposure to hydrocarbons in the water column (entrained or dissolved) can change species composition, with declines or increases in one or more species or taxonomic groups (Batten et al., 1998). Phytoplankton may also experience decreased rates of photosynthesis (Tomajka, 1985). For zooplankton, such as fish, coral and invertebrate eggs and larvae, direct effects of contamination may include toxicity, suffocation, changes in behaviour, or environmental changes that make them more susceptible to predation. Impacts on plankton communities are likely to occur in areas where entrained or dissolved aromatic hydrocarbon threshold concentrations are exceeded, but communities are expected to recover relatively quickly (within weeks or months). This is due to high population turnover, with copious production within short generation times that also buffers the potential for long-term (i.e. years) population declines (International Tanker Owners Pollution Federation, 2011a).

When first released, MDO has a higher toxicity due to the presence of the volatile components. Plankton making contact close to the spill source at the time of the spill may be impacted, however, due to low planktonic productivity within the NWMR it is unlikely that large populations of plankton will be affected at the sea surface above thresholds as this is only predicted for the first few days after the spill.

Given hydrocarbon characteristics, expected rapid weathering and then degradation of the entrained component to below impact thresholds, and relatively quick recovery times of plankton, a vessel spill is not expected to have a substantial adverse effect on plankton life cycle and spatial distribution.

There are no Management Plans, Recovery Plans or Conservation Advice related to plankton.

Based on the detailed risk evaluation, the magnitude of potential impact to plankton from unplanned release of MDO is assessed as Negligible (F).

Fish, Sharks and Rays

Injury/mortality to fish species may occur due to a change in water quality following an unplanned hydrocarbon release. Any surface and subsurface hydrocarbon release could impact fish, as they are widely dispersed throughout the water column.

Impacts to sharks and rays may occur through direct contact with hydrocarbons and contaminate the tissues and internal organs, either through direct contact or via the food chain (consumption of prey). As gill breathing organisms, sharks and rays may be vulnerable to toxic effects of dissolved hydrocarbons (entering the body via the gills) and entrained hydrocarbons (coating of the gills inhibiting gas exchange). In the offshore environment, it is probable that pelagic shark species are able to detect and avoid hydrocarbons by swimming into deeper water or away from the affected areas.

Fish mortalities are rarely observed to occur as a result of hydrocarbon spills (International Tanker Owners Pollution Federation, 2011b). This has generally been attributed to the possibility that pelagic fish are able to detect and avoid surface waters underneath hydrocarbon spills by swimming into deeper water or away from the affected areas. Fish that have been exposed to dissolved aromatic hydrocarbons are capable of eliminating the toxicants once placed in clean water; hence, individuals exposed to a spill are likely to recover (King et al., 1996). Where fish mortalities have been recorded, the spills (resulting from the groundings of the tankers Amoco Cadiz (E)n 1978 and the Florida in 1969) have occurred in sheltered bays.

Laboratory studies have shown that adult fish can detect hydrocarbons in water at very low concentrations, and large numbers of dead fish have rarely been reported after hydrocarbon spills (Hjermann et al., 2007). This suggests that juvenile and adult fish can avoid water contaminated with high concentrations of hydrocarbons.

The effects of exposure to oil on the metabolism of fish appear to vary according to the organs involved, exposure concentrations and route of exposure (waterborne or food intake). Oil reduces the aerobic capacity of fish exposed to aromatics in the water, and to a lesser extent affects fish consuming contaminated food (Cohen et al., 2005). The liver, a major detoxification organ, appears to be where anaerobic activity is most impacted, probably increasing anaerobic activity to help eliminate ingested oil from the fish (Cohen et al., 2005).

Fish are perhaps most susceptible to the effects of spilled oil in their early life stages, particularly during egg and planktonic larval stages, which can become entrained in spilled oil. Contact with oil droplets can mechanically damage feeding and breathing apparatus of embryos and larvae (Fodrie and Heck, 2011). The toxic hydrocarbons in water can result in genetic damage, physical deformities and altered developmental timing for larvae and eggs exposed to even low concentrations over prolonged timeframes (days to weeks) (Fodrie and Heck, 2011). Subtler, chronic effects on the life history of fish because of exposure in early life stages to hydrocarbons include disruption to complex behaviour such as predator avoidance, reproductive and social behaviour (Hjermann et al., 2007). Prolonged exposure of eggs and larvae to weathered concentrations of hydrocarbons in water has also been shown to cause immunosuppression and allows expression of viral diseases (Hjermann et al., 2007).

Adult fish exposed to low hydrocarbon concentrations are likely to metabolise the hydrocarbons and excrete the derivatives, with studies showing that fish can metabolise petroleum hydrocarbons and that accumulated hydrocarbons are released from tissues when the fish is returned to hydrocarbon-free sea water. Several fish communities in these areas are demersal (i.e. living closer to the seabed) where concentrations of entrained hydrocarbons will be lower; any impacts are expected to be highly localised.

When first released, MDO has a higher toxicity due to the presence of the volatile components. Individual fish making contact close to the spill source at the time of the spill may be impacted. Fish presence is generally concentrated in

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

Detailed Impact Assessment

waters closer to shore. Although fish presence may occur throughout the entire PAA and defined EMBA, it is unlikely that a large number of fish will be affected at the sea surface above thresholds. Mobile transient fauna are not expected to remain within entrained hydrocarbon plumes for an extended time. Therefore, no acute impacts or risks associated with entrained exposures from an unplanned MDO release are expected. Any impacts from this exposure are expected to result in localised short-term effects to limited small numbers of juvenile fish and prey species (larvae and planktonic organisms), which are not expected to affect population viability and recruitment of fish. Consequently, diverse fish assemblages are not expected to be significantly impacted.

A BIA for whale shark foraging overlaps the Trunkline Operational Area between KP 72 and KP 199, as well as the EMBA. Whale sharks may transit offshore open waters when migrating to and from Ningaloo Reef, where they aggregate for feeding from March to July. Whale sharks are versatile feeders, filtering large amounts of water over their gills, catching planktonic and nektonic organisms (Jarman and Wilson, 2004). It is therefore possible that surface and/or entrained hydrocarbon and/or dissolved aromatic hydrocarbon could come in contact with, or be ingested by whale sharks migrating or aggregating in the area at the time of release.

Although potential impacts could include mortality or sub-lethal injury/illness of pelagic fish, this would be expected to comprise a small proportion of the resident and transitory population. Given hydrocarbon characteristics, expected rapid weathering to below impact thresholds and degradation of entrained fractions, and the mobile transient nature of fish, unplanned releases of MDO are not expected to have a substantial adverse effect on the population or spatial distribution of fish; or substantially modify, destroy or isolate an area of important habitat for migratory species. Additionally, unplanned releases will not seriously disrupt the lifecycle of an ecologically significant proportion of any migratory fish species.

There are specific conservation advices for some fish species which identify habitat degradation/modification as a key threat. While for some species there are specific requirements (e.g. sawfish), no specific requirements have been identified for relevant species (i.e. species identified as having potential to occur in the EMBA).

The magnitude of a potential impact to fish associated with a release of hydrocarbons is minor (D). Although potential impacts could include mortality or sub-lethal injury/illness of pelagic fish, this would be expected to comprise a small proportion of the resident and transitory population. Given hydrocarbon characteristics, expected rapid weathering to below impact thresholds and degradation of entrained fractions, and the mobile transient nature of fish, unplanned release is not expected to have a substantial adverse effect on the population, or spatial distribution of fish/sharks/rays.

Marine Mammals

A change in marine fauna behaviour or injury/mortality to marine mammals may occur due to a change in water quality after an unplanned hydrocarbon release.

Air-breathing fauna such as marine mammals are most at risk from surface exposures due to the high volatile components. Marine mammals that have direct physical contact with surface, entrained or dissolved aromatic hydrocarbons may suffer surface fouling, ingest hydrocarbons and inhale toxic vapours. This may result in the irritation of sensitive membranes such as the eyes, mouth, digestive and respiratory tracts and organs, impairment of the immune system or neurological damage (Helm et al., 2015). If prey (fish and plankton) are contaminated, this can result in the absorption of toxic components of the hydrocarbons (PAHs).

In a review of cetacean observations in relation to a number of large-scale hydrocarbon spills, Geraci (1988) found little evidence of mortality associated with hydrocarbon spills. However, behavioural disturbance (i.e. avoiding spilled hydrocarbons) was observed in some instances for several species of cetaceans. This suggests that cetaceans are able to detect and avoid surface slicks. While this reduces the potential for physiological impacts from contact with hydrocarbons, active avoidance of an area may disrupt behaviours such as migration, or displace individuals from important habitat, such as foraging, resting or breeding.

When first released, MDO has a higher toxicity due to the presence of the volatile components. Individual cetaceans making contact close to the spill source at the time of the spill may be impacted.

A range of marine mammal species were identified as potentially occurring within the Operational Area and EMBA (**Section 4.6.3**). BIAs of marine mammals listed as MNES overlap the Trunkline Project Area, including humpback whales (migration and resting BIAs) and pygmy blue whales (northbound and southbound migrations). BIAs of MNES listed marine mammals also overlap the EMBA (**Section 4.6.3**), including humpback whales (migration and resting BIAs), dugongs (foraging and breeding, nursing, calving BIAs) and pygmy blue whales (northbound and southbound migrations, distribution and foraging BIAs).

There is a low probability (0.5%) of a small overlap of the southern right whale migration and reproduction BIAs in proximity to the North West Cape with entrained oil exceeding thresholds, however no floating oil is present in this area and no hydrocarbons are predicted to enter the Exmouth Gulf, which is used as a resting area by humpback whales during the southern migration and a reproduction area by the Southern Right Whale

Humpback and/or pygmy blue whale populations may be impacted if the hydrocarbon release occurs during the seasonal migration periods. Such disruption could include behavioural impacts (e.g. avoidance of impacted areas), sub-lethal biological effects (e.g. skin irritation, irritation from ingestion or inhalation, reproductive failure) and, in rare circumstances, death.

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

Detailed Impact Assessment

Dugongs may be indirectly impacted via habitat loss due to reduction in seagrass due to contact with entrained hydrocarbons. Direct impacts to dugongs could occur through foraging or ingesting seagrass coated with hydrocarbon. Although potential impacts could include mortality or sub-lethal injury/illness of marine mammals, this would be expected to comprise a small proportion of the resident and transitory population. Given hydrocarbon characteristics, expected rapid weathering of surface oil to below impact thresholds, and the mobile transient nature of marine mammals and potential avoidance behaviour, unplanned releases of MDO are not expected to have a substantial adverse effect on the population or spatial distribution of marine mammals; or substantially modify, destroy or isolate an area of important habitat for migratory species. Additionally, unplanned releases will not seriously disrupt the lifecycle of an ecologically significant proportion of any migratory species.

There are specific conservation advices for some species which identify key threats. While hydrocarbon spills are not explicitly identified as a threat, the sei whale conservation advice does include the management of physical disturbance and development activities. No explicit management actions are identified relevant to hydrocarbon spills.

The magnitude of a potential impact to marine mammals associated with a release of hydrocarbons is Minor(D). Although potential impacts could include mortality or sub-lethal injury/illness of marine mammals, this is expected to comprise a small proportion of the resident and transitory population. Given hydrocarbon characteristics, expected rapid weathering of surface oil to below impact thresholds, and the mobile transient nature of marine mammals and potential avoidance behaviour, unplanned releases of marine diesel are not expected to have a substantial adverse effect on the population, or spatial distribution of marine mammals; or substantially modify, destroy or isolate an area of important habitat for migratory species.

Marine Reptiles

A change in marine fauna behaviour or injury/mortality to marine reptiles may occur due to a change in water or sediment quality following an unplanned hydrocarbon release.

Marine reptiles can be impacted by surface exposure when they surface to breathe, and by shoreline accumulation of hydrocarbons when breeding and nesting.

Hydrocarbons in surface waters may impact turtles when they surface to breathe and inhale toxic vapours. Their breathing pattern, involving large 'tidal' volumes and rapid inhalation before diving, results in direct exposure to petroleum vapours which are the most toxic component of the hydrocarbon spill (Milton and Lutz, 2003). This can lead to lung damage and congestion, interstitial emphysema, inhalant pneumonia and neurological impairment (National Oceanic and Atmospheric Administration, 2010). Contact with entrained hydrocarbons can result in hydrocarbon adherence to body surfaces, irritating mucous membranes in the nose, throat and eyes, leading to inflammation and infection (Gagnon and Rawson, 2010).

Adult sea turtles exhibit no avoidance behaviour when they encounter hydrocarbon spills (National Oceanic and Atmospheric Administration, 2010). Oiling can also irritate and injure skin, which is most evident on pliable areas such as the neck and flippers (Lutcavage et al., 1995). A stress response associated with this exposure pathway includes an increase in the production of white blood cells, and even a short exposure to hydrocarbons may affect the functioning of their salt gland (Lutcavage et al., 1995).

When first released, MDO has a higher toxicity due to the presence of the volatile components. Individual turtles making contact close to the spill source at the time of the spill may be impacted. Flatback, green, loggerhead and hawksbill turtle interesting BIA's overlap the Trunkline Project Area and EMBA (**Section 4.6.2**). Flatback, green and hawksbill turtles also have interesting habitat critical overlapping with the Trunkline Project Area, particularly, for the Dampier Archipelago. Accumulated hydrocarbons on shorelines could impact marine fauna that utilise beaches including marine turtles, dependent upon the timing of a release. However volumes of accumulated hydrocarbons are low.

Impacts to turtles from unplanned hydrocarbon releases are to be managed in accordance with the Recovery Plan for marine turtles in Australia (Commonwealth of Australia, 2017). The Recovery Plan identifies ensuring spill risk strategies and response programs include management for turtles and their habitats. In addition, there is in place approved Conservation Advice for the short-nosed sea snake (DSEWPac, 2011), which includes ensuring there is no anthropogenic disturbance in areas where the species occurs, excluding necessary actions to manage the conservation of the species.

Impacts to sea snakes from direct contact with hydrocarbons are likely to result in similar physical effects to those recorded for marine turtles.

The magnitude of potential impacts to marine reptiles from unplanned hydrocarbon releases is assessed as Slight (E)(from change in fauna behaviour) and Minor (D)(from injury/mortality to fauna). Although potential impacts could include mortality or sub-lethal injury/illness of marine reptiles, this is expected to comprise a small proportion of the resident and transitory population. Given hydrocarbon characteristics, expected rapid weathering to below impact thresholds, and the mobile transient nature of individuals, unplanned hydrocarbon releases are not expected to substantially modify, destroy or isolate an area of important habitat for migratory species.

Seabirds and Migratory Shorebirds

A change in marine fauna behaviour or injury/mortality to seabirds and migratory shorebirds may occur due to a change in water or sediment quality following an unplanned hydrocarbon release.

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

Detailed Impact Assessment

Seabirds and migratory birds are particularly vulnerable to contact with floating hydrocarbons, which may mat feathers. This may lead to hypothermia from loss of insulation and ingestion of hydrocarbons when preening to remove hydrocarbons. Both impacts may result in mortality (Hassan and Javed, 2011). Pathways of biological exposure that can result in impact may occur through ingesting contaminated fish (nearshore waters) or invertebrates (intertidal foraging grounds such as beaches, mudflats and reefs). Ingestion can also lead to internal injury to sensitive membranes and organs (International Petroleum Industry Environmental Conservation Association, 2004). Whether the toxicity of ingested hydrocarbons is lethal or sub-lethal will depend on the weathering stage and its inherent toxicity. Exposure to hydrocarbons may have longer term effects, with impacts to population numbers due to decline in reproductive performance and malformed eggs and chicks, affecting survivorship and losing adult birds.

When first released, MDO has a higher toxicity due to the presence of the volatile components. Individual birds making contact close to the spill source at the time of the spill may be impacted. Bird presence within the NWMR is more concentrated in waters closer to shore with the potential for individual migratory birds within the PAA.

There are specific conservation advices for some species which identify habitat degradation as the key threat, but generally no explicit management actions are identified relating to hydrocarbon spills.

The magnitude of a potential impact to seabirds and migratory shorebirds associated with a release of hydrocarbons is Slight (E)(from change in fauna behaviour) and Minor (D) (from injury/mortality to fauna). Although potential impacts could include mortality or sub-lethal injury/illness of birds, this is expected to comprise a small proportion of the resident and transitory population. Given hydrocarbon characteristics, expected rapid weathering to below impact thresholds, and the mobile transient nature of individuals, unplanned hydrocarbon releases are not expected to substantially modify, destroy or isolate an area of important habitat for migratory species.

Coral

Significant areas of coral are known to occur fringing the Dampier Archipelago (such the outer islands of Legendre etc), Montebello Islands, Rankin Bank, Barrow Island, Lowendal Islands, the Ningaloo Coast, all within the EMBA with low probability of contact with hydrocarbons.

Exposure to entrained hydrocarbons (≥ 100 ppb) has the potential to result in lethal or sub-lethal toxic effects to corals and other sensitive sessile benthos within the upper water column, including upper reef slopes (subtidal corals) and reef flat (intertidal corals). Sub-lethal effects to corals may include polyp retraction, changes in feeding, bleaching (loss of zooxanthellae), increased mucous production resulting in reduced growth rates and impaired reproduction (Negri and Heyward, 2000).

Should a hydrocarbon release occur at the time of coral spawning (at potentially affected coral locations), there is the potential for a significant reduction in successful fertilisation and coral larval survival, due to the sensitivity of coral in early life stages to hydrocarbons (Negri and Heyward, 2000).

Due to the short duration of a vessel spill (i.e. instantaneous release, and short exposure time), the confined spatial extent and the tendency of MDO to remain on the sea surface, significant exposure over a large scale is limited. An unplanned vessel spill is not expected to modify, destroy, fragment, isolate or disturb an important or substantial area of habitat, such that an adverse impact on marine ecosystem functioning or integrity results. Based on the assessment, the magnitude of a potential impact to coral associated with a release of hydrocarbons is Moderate (E) (i.e. medium-term impacts to ecosystem/habitat service on a far-field scale).

Seagrass and Macroalgae

Seagrass and macroalgae communities are found in shallow waters surrounding islands of the Dampier Archipelago and other shorelines predicted to be contacted by hydrocarbons. Modelling predicts that both Dampier and Montebello marine parks are predicted to be intersected with entrained hydrocarbons over the exposure thresholds (RPS, 2024). In particular, the Montebello Marine Park has a 100% probability, with high concentrations of entrained hydrocarbons. This is to be expected, as the release location modelled is within the marine park boundaries.

Exposure to entrained hydrocarbons may result in mortality of seagrass and macroalgae, depending on actual entrained aromatic hydrocarbon concentrations received and duration of exposure. Physical contact with entrained hydrocarbon droplets could cause sub lethal stress, causing reduced growth rates and reduced tolerance to other stress factors.

Seagrass and macroalgal beds in the intertidal and subtidal zone may be susceptible to impacts from entrained hydrocarbons. Toxicity effects can also occur due to absorption of soluble fractions of hydrocarbons into tissues.

While areas where seagrass and macroalgae can occur may be exposed, given the hydrocarbon characteristics, expected rapid weathering to below impact thresholds, any exposure would be to a limited area and short-term, and as such an unplanned hydrocarbon release is not expected to result in a level of exposure to seagrass and macroalgae that would cause an adverse impact on marine ecosystem functioning or integrity results. Based on the assessment, the magnitude of a potential impact to seagrass and macroalgae associated with a release of hydrocarbons is Slight (E).

Mangroves

Modelling predicts that there is 2% probability of shorelines being contacted over the exposure threshold for any release location at WA Coastline and Dampier Archipelago, with the maximum local volume predicted to accumulate of 55 m³. Both shorelines include some areas of mangroves (RPS, 2024).

Mangroves are considered to have a high sensitivity to hydrocarbon exposure. Mangroves can be impacted by heavy or viscous oil, or emulsification, that covers the trees breathing pores thereby asphyxiating the subsurface roots, which depend on the pores for oxygen (IPIECA, 1993). Hydrocarbons deposited on the aerial roots can block the pores used to breathe, or interfere with the trees salt balance, resulting in sub-lethal and potentially lethal effects. Acute impacts to mangroves can be observed within weeks of exposure, whereas chronic impacts may take months to years to detect.

Given hydrocarbon characteristics and rapid weathering, an unplanned release is not expected to have a substantial adverse impact on marine ecosystem functioning or integrity. Based on the assessment, the magnitude of a potential impact to mangroves associated with a release of hydrocarbons is Slight (E).

Shoreline Habitats

Hydrocarbons that contact sandy shores may be incorporated into fine sediments through mixing in the surface layers from wave energy, penetration down worm burrows and root pores. Hydrocarbon in the intertidal zone can adhere to sand particles however high tide may remove some or most of the hydrocarbon from the sediments. Accumulated hydrocarbons ≥ 100 g/m² could impact the survival and reproductive capacity of benthic epifaunal invertebrates living in intertidal habitat (French-McCay, 2009). Coastal habitats that occur on the coastline within the EMBA include saltmarshes and mangroves around the Dampier Archipelago.

Given hydrocarbon characteristics and rapid weathering, an unplanned release is not expected to have a substantial adverse impact on marine ecosystem functioning or integrity at exposed shorelines. Based on the assessment, the magnitude of a potential impact to shoreline habitats associated with a release of hydrocarbons is assessed as Negligible (F).

Saltmarshes

Areas of saltmarshes are known to occur within the Dampier Archipelago and WA Coastline, with both areas potentially receiving shoreline accumulation above 100 g/m². Hydrocarbons can enter saltmarsh systems during the tidal cycles, if the estuary/inlet is open to the ocean. Similar to mangroves, this can lead to a patchy distribution of the oil and its effects, due to different areas within the inlets at different tidal heights. Hydrocarbons can adhere to the marshes, coating the stems from tidal height to sediment surface.

Given hydrocarbon characteristics and rapid weathering an unplanned release is not expected to have a substantial adverse impact on marine ecosystem functioning or integrity at exposed shorelines. Based on the assessment, the magnitude of a potential impact to saltmarsh associated with a release of hydrocarbons is assessed as Slight(E).

Key Ecological Features

A change in habitat may occur due to a change in water or sediment quality that could impact KEFs.

The location of the KEFS within the EMBA are presented in Section 4.7. As marine diesel typically remains in the top 10 m of the water column and rapidly weathers, in-water hydrocarbons are only likely to intersect with seafloor and demersal values in shallower waters. The water depths and potential impacts to the six relevant KEFs are summarised as follows:

Exmouth Plateau KEF (intersects the Operational Area and EMBA): Values and sensitivities are related to seafloor features. Receptors on the seafloor are not expected to be impacted by a surface release of hydrocarbons, given the water depths (~930 m). However, these seafloor features may promote enhanced upwelling; potential impacts to plankton and fishes are discussed above.

Ancient coastline KEF (intersects the Operational Area and EMBA): The KEF includes areas of hard substrate and higher diversity and species richness relative to surrounding areas of predominantly soft sediment. Given the minimum water depth in this KEF is 115 m, seafloor receptors are unlikely to be impacted by a surface hydrocarbon release. However, the submerged coastline may facilitate mixing of the water column enhancing productivity. Combined with greater diversity of sessile benthic organisms, this may increase abundance of pelagic species such as fishes and cetaceans, impacts to which are discussed above.

Continental Slope Demersal Fish Communities KEF (intersects the Operational Area and EMBA): The KEF represents high levels of endemism of demersal fish species. Considering the minimum water depths of this KEF are 220–500 m and 750–1,000 m, impacts to demersal fishes are unlikely to occur. However, the values of the KEF may support higher order consumers, such as pelagic fish and shark species, impacts to which are discussed above.

Canyons linking the Cuvier Abyssal Plain and the Cape Range Peninsula KEF (intersects the EMBA): Aggregations of whale sharks, manta rays, humpback whales, sea snakes, sharks, predatory fishes and seabirds are known to occur in the KEF due to its enhanced productivity, impacts to which are discussed above.

Commonwealth Waters Adjacent to Ningaloo KEF (intersects the EMBA): The spatial boundary of this KEF, as defined in the National Conservation Values Atlas, is the waters contained in the existing Ningaloo AMP and is described below.

Glomar Shoal KEF (intersects the EMBA on the Rowley shelf at depths of 33 m to 77 m): The values of the KEF are high productivity and aggregations of marine life, impacts to which are discussed above.

Detailed Impact Assessment

Based on the assessment, the magnitude of a potential impact to KEFs associated with a release of hydrocarbons is Slight.

AMPs

The quantitative spill risk assessment results indicate that the open water environment protected within the Dampier and Montebello AMPs may be affected by the released hydrocarbons.

A vessel spill in the PAA is unlikely to result in significant impacts to AMPs based on the nature of the spilled hydrocarbons. Natural values for the AMPs include:

- marine turtle BIAs for Dampier and Montebello Marine Parks
- humpback whale migration BIAs for Montebello and Dampier Marine Park
- pygmy blue whale possible foraging area and migration BIA for Montebello Marine Park
- diverse fish communities for the Dampier, and Montebello Marine Parks
- whale shark foraging habitat BIAs for Montebello Marine Park
- seabird breeding habitat BIAs for Montebello and Dampier Marine Parks
- seabird foraging habitat BIAs for Dampier and Montebello, Marine Parks.

While this results in exposure to hydrocarbons for some of the natural values of the marine parks, the impacts will be temporary as the MDO evaporates and degrades and moves with ocean currents. The evaluation of impacts to specific receptors are detailed in the individual receptor assessments above and below. Based on the assessment, the magnitude of a potential impact to AMPs associated with a release of hydrocarbons is Minor (D).

Commonwealth and State Managed Fisheries

A change in marine fauna behaviour or injury or mortality to marine fauna – in particular to commercially targeted species, or their prey species (e.g. plankton) – can impact fisheries.

Fish exposure to hydrocarbon can result in ‘tainting’ of their tissues. Even very low levels of hydrocarbons can impart a taint or ‘off’ flavour or smell in seafood. Tainting is reversible through the process of depuration which removes hydrocarbons from tissues by metabolic processes, although it depends on the magnitude of the contamination. Fish have a high capacity to metabolise these hydrocarbons while crustaceans (such as prawns) have a reduced ability (Yender et al., 2002). Seafood safety is a major concern associated with spill incidents. Therefore, actual or potential contamination of seafood can affect commercial and recreational fishing and can impact seafood markets long after any actual risk to seafood from a spill has subsided (Yender et al., 2002).

A major spill could result in the establishment of an exclusion zone around the spill affected area. There would be a temporary prohibition on fishing activities for a period and subsequent potential for economic impacts to affected commercial fishing operators. Additionally, hydrocarbon can foul fishing equipment such as traps and trawl nets, requiring cleaning or replacement.

MDO presence in the water would be restricted to the surface and upper water column only. Dissolved aromatics (i.e. the form that is bioavailable) are in such small concentrations in MDO that their effect in the marine environment is negligible (F); i.e. tainting from an MDO exposure is not considered likely to occur. Any exclusion zone established would be limited to the immediate vicinity of the release point, and due to the rapid weathering of MDO would only be in place days after release, therefore physical displacement to vessels is unlikely to be a significant impact.

A number of Commonwealth and State fishery management areas are located within the PAA and EMBA. FishCube data was requested to analyse the potential for interaction of fisheries with the PAA, which was used to determine consultation with State Fisheries who may be impacted by proposed petroleum activities (Department of Primary Industries and Regional Development [DPIRD], 2021). Table 4-27 provides an assessment of the potential interaction provides further detail on the fisheries that have been identified through desk-based assessment and consultation (**Section 5**).

In the highly unlikely event of a release of marine diesel to the environment as a result of vessel collision there may be the presence of hydrocarbons in areas used by the fisheries that overlap the EMBA (Table 4-27).

Although potential impacts from a worst case spill could include mortality or sub-lethal injury/illness of pelagic fish (described in the specific receptor evaluation), this would be expected to comprise a small proportion of the resident and transitory population. Given the hydrocarbon characteristics, expected rapid weathering to below impact thresholds and low fishing effort, an unplanned hydrocarbon spill from the Petroleum Activities Program is not expected to have an adverse effect on the sustainability of commercial fishing; or to interfere with other marine users.

Based on the detailed risk evaluation, the magnitude of potential impacts to Commonwealth and State managed fisheries from an unplanned hydrocarbon release is assessed as Slight (E).

Tourism and Recreation

Change in marine fauna behaviour, injury or mortality to marine fauna, change in aesthetic value and change to the functions, interests or activities of other users would impact tourism and recreation following an unplanned hydrocarbon release. Charter fishing, diving, snorkelling, marine fauna (whale, marine turtle and dolphin) watching and cruises are the main commercial tourism activities in and adjacent to the NWMR. With the exception of offshore charter fishing,

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

Detailed Impact Assessment

most marine tourism activities occur in State waters (DEWHA, 2008). Any impacts to receptors that provide nature-based tourism features (e.g. whales) may cause a subsequent negative impact to recreation and tourism activities. There is also potential for impacts to the wider service industry (hotels, restaurants and their supply chain) and local communities in terms of economic loss as a result of spill impacts to tourism.

Given hydrocarbon characteristics, expected rapid weathering to below impact thresholds, small volumes predicted ashore an unplanned release is not expected to interfere with other marine users to a greater extent than necessary. Based on the assessment, the magnitude of a potential impact to tourism and recreation associated with a release of hydrocarbons is Slight (E).

Shipping

In the event of a spill, an exclusion zone may be established around the spill affected area. This could result in exclusion of other users such as shipping vessels or vessels used by the mining and petroleum industries. Any exclusion zone established would be limited to the immediate vicinity of the release point, and due to the rapid weathering of MDO would only be in place for days after release, therefore physical displacement to vessels is unlikely to be a significant impact.

Given hydrocarbon characteristics, expected rapid weathering to below impact thresholds, short duration of displacement, and the offshore location of the PAA, unplanned releases of MDO are not expected to interfere with shipping to a greater extent than necessary.

Based on the assessment, the magnitude of a potential impact to shipping associated with an unplanned release of hydrocarbons is Slight (E).

Industry

A change in water quality and change to the functions, interests or activities of other users may impact industry following an unplanned hydrocarbon release. In the event of a major hydrocarbon spill, an exclusion zone may be established around the spill affected area. This could result in exclusion of other users such as vessels used by the mining and petroleum industries.

Defence

A change to the functions, interests or activities of other users may impact Defence following an unplanned hydrocarbon release. In the event of a major hydrocarbon spill, an exclusion zone may be established around the spill affected area. This could impact Defence by restricting areas where training or exercises can be conducted, for a designated period of time.

Any exclusion zone established would be limited to the immediate vicinity of the release point, and due to the rapid weathering of marine diesel would only be in place for days after release, therefore physical displacement to vessels is highly unlikely to be an impact of Negligible (F).

Table 6-48: Key receptor locations and sensitivities potentially contacted above impact thresholds by the vessel collision scenario with summary hydrocarbon spill contact for a 250 m³ instantaneous marine diesel spill at two release locations in the Trunkline Project

--	---	---	--	---

ALARP Statement:

On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type (i.e. Decision type A, Section 2.3.1), Woodside considers the adopted controls appropriate to manage the risks of an unplanned hydrocarbon release as a result of vessel collision. As no reasonable additional/alternative controls were identified for vessel activities that would further reduce the risks and consequences without grossly disproportionate sacrifice, the risks and consequences are considered ALARP.

If hydrocarbon loss of containment occurs, mitigation measures and emergency response protocols are in place to minimise the consequence.

Controls have been selected following hierarchy of control principles and consider independence of each barrier and their type of effect in controlling the hazardous event. Qualitative hazard analysis and spill risk assessment considers potential for causal events and their consequences. Based on the environmental risk assessment outcomes (Highly Unlikely likelihood and Moderate consequence) and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the potential impacts, risks and potential escalation events.

The controls in place for prevention and mitigation of significant process safety release events are specified and assured through implementing Woodside risk management procedures.

- Given the controls in place to prevent vessel collision and loss of separation events, and mitigate their consequences, it is considered that the risk is managed to ALARP.

Demonstration of Acceptability

Acceptability Criteria and Assessment

Demonstration of acceptability for the sources of risk and associated impacts assessed in this section are provided in Section 7.2.6.4 of the Scarborough OPP. The Petroleum Activities Program meets the acceptability criteria (Section 2.3.5):

- Overall risk consequence/risk ratings for individual receptors are less than the significant impact level defined in the OPP.
- EPOs and controls in the OPP that are relevant to an unplanned hydrocarbon release from a vessel collision have been adopted.
- There are no changes to internal/external context specific to this risk from the OPP, including issues raised during consultation.

Acceptability Statement:

The impact assessment has determined that an accidental hydrocarbon release as a result of a vessel collision represents a moderate current risk rating and is unlikely to result in a consequence greater than Moderate. Relevant recovery plans and conservation advice have been considered during the impact assessment, and the Petroleum Activities Program is not considered to be inconsistent with the overall recovery objectives and actions of these recovery plans and conservation advice. The adopted controls are considered consistent with industry legislation, codes and standards, good practice and professional judgement and meet the requirements and expectations of Australian Marine Orders, AMSA and AHO identified during impact assessment and consultation. The potential risks and consequences are considered acceptable if the adopted controls are implemented. Activities do not have a significant impact on MNES (Section 2.4.2) including those with an Indigenous connection with, or traditional use in nearshore areas as defined in Section 4.9).

Therefore, Woodside considers the adopted controls appropriate to manage the risks and consequences of a loss of vessel structural integrity to a level that is broadly acceptable; and demonstrates the EPO is met.

- external corrosion
- fatigue
- extreme environmental weather conditions (cyclone, high waves)
- operation outside of design
- fire/explosion event (escalation from LOC event)
- dropped object
- subsea equipment hydrocarbon loss of containment (fire/explosion) (Section 6.8.5)
- loss of marine vessel separation with FPU
- topsides loss of containment (fire/explosion) or loss of control of suspended load from facility lifting operations (Section 6.8.6).

Vessel collision with FPU causing structural damage with potential for ignition and escalation are also managed under the Scarborough Safety Case (MAE-05, and MAE-04) – see C17.8.

The Scarborough FPU's hull/substructure, topsides structures, mooring and ballast systems are designed to provide and maintain structural integrity under all expected operational and environmental conditions through service life.

Substructures, Moorings and Ballast systems

The FPU's substructure (e.g. hull structure, hull mating posts, mooring and riser/caisson supports, protection frames and fire/blast partition supports) is designed to provide and maintain structural integrity under all expected operational and environmental conditions through service life, and to provide sufficient robustness to maintain availability of critical systems. The FPU hull design includes key features such as no hydrocarbon storage in the hull, no external hull penetrations above the waterline, with design to maintain stability with two compartments flooding. The mooring arrangement consists of 20 mooring lines, with 5 lines per column in a 4 by 5 pattern, connected via wire and chain to anchor piles ensuring appropriate redundancy.

The FPU substructure (hull) and mooring is designed to;

- consider a range of dynamic fatigue factors through the design life
- consider impacts of potential dropped objects and swung loads
- withstand potential impacts by the largest vessel class from Woodside's integrated marine fleet
- suitably withstand extreme and abnormal environmental loading (100-year and 10,000 year cyclonic return periods respectively).

The FPU ballast system consists of equipment including pumps, piping, valves, fittings, instrumentation and controls necessary to ballast and de-ballast the FPU hull's ballast tanks and void compartments for all pre-service (including float over and integration) and operating conditions. The facility is designed such that stability is maintained in all design conditions without the use of the ballast system. However, the ballast system is capable of adjusting ballast weight to correct inclination in case of an accidental flooding event. The ballast system can be operable from local or remote control rooms.

The ASV complies with Class requirements. It maintains a ballast and bilge management system with alarms, and a watertight integrity system with tank design which prevents down-flooding.

Topside Structures

The design and integrity of topside primary steel structures (such as main trusses, deck framing, flare boom, deck posts, crane pedestals, blast and fire walls, and various secondary structures) are key to preventing structural failures which could lead to a loss of containment of hydrocarbon containing equipment, loss of flare system and other critical systems integrity which could lead to progressive collapse of the FPU's topside structure and loss of containment of stored hydrocarbons to the environment.

The topsides structures are designed to have adequate structural capacity to support its self-weight, all facilities (including allowance for future installed facilities), and all operating and environmental loads during in-service conditions to ensure its integrity for the facility life.

The design has considered in-service loads and accident limit state loads including:

- permanent and variable (live action) structural loads
- environmental loads, including hull motion induced loads
- Lower Deck's Bottom of Steel (BOS) is designed to clear the wave crest associated with the 10,000-year storm
- seismic loads (for subsea and mooring structures)
- fatigue inducing loads (hull motions, Vortex Induced Vibration (VIV), transportation induced loads)
- dropped and swung loads
- potential fire and explosion loads.

A ship collision study assessed the risks associated with loss of marine vessel separation through consideration of collision between the FPU and errant vessels (powered or drifting) and in-field vessels, including Support Vessels. The frequency of collision has been established for passing vessels within the area, based on data obtained from AMSA and are presented in the Scarborough FPU Safety Case. The conclusions of the study are summarised as follows:

- Attendant vessels present the most frequent threat to the FPU, however with drive-off impact energies considered within the capacity of the FPU hull structure.
- The subsea system risers are protected from Support Vessel drive-off by their location outside the Support Vessel operating area and are provided with impact protection within robust I-tubes. The frequency of riser damage to support vessel collision is thus considered negligible (F).
- FPU mooring lines are not vulnerable to support vessel collision, as the chains are supported from chain stoppers 20m below water level.
- The energy associated with errant vessels adrift or under power is expected to be high and could lead to catastrophic damage to the FPU hull integrity (Section 6.8.3).

Based on the vessel traffic density in the area the expected collision frequency that may cause significant damage to the FPU is considered Highly Unlikely in the order of 8×10^{-5} per annum.

FPU Loss of Structural Integrity – Credible Scenario

Loss of structural integrity of the FPU resulting in foundering or a full capsized could result in the worst-case loss of the full diesel inventory stored on the FPU (crane pedestals, fire water pump, black start and emergency diesel storage tanks). In such an instance, the maximum total volume of marine diesel stored on the FPU is 470 m^3 . Loss of full diesel inventory concurrently from both crane pedestal tanks and smaller tanks is selected as a conservative scenario for environmental consequence assessment, suitably governing other potential smaller or lower rate discharges from stored hydrocarbons such as distributed topsides lube oil storage systems, process system drain and waste drums.

ASV Loss of Structural Integrity – Credible Scenario

Damage to the ASV could cause capsizing, foundering or sinking. In accordance with AMSA guidance, the maximum credible scenario for loss of vessel is the volume of the largest fuel tank, 359 m^3 of diesel at the surface. Further loss could occur at the seabed, however at a slower rate and the instantaneous surface release is considered conservative. The potential impact of this scenario is within that of the FPU loss of structural integrity scenario.

Quantitative Spill Risk Assessment

Modelling of a 470 m^3 surface release of marine diesel was undertaken at the FPU location (RPS, 2024) (Table 6-43). The modelling assessed the extent of a marine diesel spill for all seasons, using historic samples of wind and current data for the region (2006-2015, inclusive). A total of 200 simulations were modelled over an annual period, with each simulation tracked for 42-days. The coordinates of the modelled spill locations are detailed in Table 6-43.

A description of the characteristics of MDO, including predicted weathering is presented in Section 6.8.2, and QSRA outcomes further described in Detailed Impact Assessment section below.

Escalation events

Loss of structural integrity/stability has the potential to cause unplanned hydrocarbon release from subsea equipment due to over-stress of subsea risers. Process safety management measures are described in this structural integrity section (preventative and mitigative barriers), with subsea system escalation consequence presented in (Section 6.8.5).

Localised topsides structural integrity failures and dropped objects have the potential to cause unplanned hydrocarbon release to the environment associated with Topsides Loss of Containment hazards, with causes and controls discussed in Section 6.8.6 and Safety Case MAE-02.

Outcome Mitigation

Potential hydrocarbon release environmental consequences associated with loss of structural integrity/stability are mitigated at facility by detection and alarm, ballasting system response, emergency shutdown (for isolation of reservoir, topsides and pipeline/trunkline inventories), SSIVs and trunkline non-return valves (NRV), critical communications systems and emergency preparedness (including facility ERP, spill response arrangements). Ignition control, emergency power, safety critical buildings and fire/explosion escalation controls (such as depressurisation blowdown systems and firewalls) are part of the FPU design as described in the Scarborough Safety Case for Major Accident mitigation, thus contributing to management of associated potential environmental consequences of MAEs.

Likelihood Assessment

The frequency of structural failure attributed to weather is drawn from industry published data based upon data within the World Offshore Accident Databook as described in the Scarborough FPU Safety Case. The adopted data is based on that for all units worldwide (fixed and mobile, excluding towing) is 1.3×10^{-5} per annum.

The structural degradation (corrosion and fatigue) design target reliability level for structural integrity of the FPU is 3×10^{-5} per annum, and is taken as a conservative value for potential loss of FPU topsides hydrocarbons to sea. This gives a likelihood level of 1 “Highly Unlikely” on the Woodside Risk Matrix.

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

With respect to seismic induced failures, as a floating installation, seismic events would not be capable of impacting the FPU directly, however the mooring system could be impacted. Due to the relatively low seismic activity within the area and design consideration, seismic events are not considered a credible threat.

A worse-case catastrophic loss of structural integrity/stability event could occur during severe loading conditions such as in a storm exceeding abnormal environmental loading design criteria (1:10,000 year cyclonic return period). Potential hydrocarbon release in such conditions however would not be anticipated to exhibit worst-case environmental consequences, given high energy sea surface mixing and extreme cyclonic weathering effects.

Detailed Impact Assessment

Assessment of Potential Impacts

Environment that May Be Affected

The overall EMBA for the Petroleum Activities Program is based on stochastic modelling, which compiles data from 200 hypothetical worst-case spills under a variety of weather and metocean conditions (as described in **Section 6.8.1**). The EMBA therefore covers a larger area than the area that would be affected during any one single spill event, and therefore represents the total extent of all the locations where hydrocarbon thresholds could be exceeded from all modelling runs. The trajectory of a single spill would have a considerably smaller footprint.

As described in Section 6.8.1, three hydrocarbon spill locations were modelled in order to represent the range of locations of where vessel collision could occur within the PAA. The EMBA has been defined using a combination of all three locations, as shown in Figure 4-2. The largest extent of the Hydrocarbon EMBA is based on the entrained threshold from the modelled locations and therefore includes the results from 600 modelling runs. In the event of a spill the EMBA would be much smaller and is intermittent e.g. a plume travels away from the release location based on prevailing currents and winds directions. Therefore one area is not exposed to hydrocarbons above thresholds for the entire simulation.

Location 3 presents the worst credible loss of containment event applicable to loss of structural integrity, at the Offshore Operational Area, FPU location (470 m³ MDO instantaneous surface release). As the weathering of different fates of hydrocarbons (surface, entrained and dissolved) differs due to the influence of the metocean transport mechanism, a different EMBA is discussed for each fate, with modelling results presented below.

Surface Hydrocarbons: Modelling of surface hydrocarbons from the loss of FPU structural integrity scenario shows a surface hydrocarbon slick would form down-current of the release location, with the trajectory dependent on prevailing wind and current conditions at the time. The modelling indicates that the EMBA from this spill scenario would be confined to open water, with surface hydrocarbons extending up to about 105 km from the release location at or above the 10 g/m² impact threshold, with the direction of maximum travel to the northeast. A socio-cultural EMBA for surface hydrocarbons which includes the threshold for visible surface hydrocarbons of 1 g/m² may extend up to about 115 km from the release site, with the direction of maximum travel being to the southwest. No emergent receptor locations are predicted to be contacted by floating hydrocarbons.

Entrained Hydrocarbons: The modelling indicates that locations exposed to entrained hydrocarbons at or above the threshold concentration of 100 ppb are predicted to be limited to offshore areas up to 287 km from the release site, with the direction of maximum travel being to the northwest. Concentrations above 100 ppb are not expected to exceed depths of approximately 30 m below MSL. The only sensitive receptor location predicted to be contacted by entrained oil concentrations at the 100 ppb threshold is the Gascoyne AMP (2.5% probability).

Dissolved Hydrocarbons: Dissolved aromatic hydrocarbons at concentrations equal to or greater than the 50 ppb threshold are predicted to be found up to 314 km from the spill site at Location 3, with the direction of maximum travel to the northwest. Concentrations above 50 ppb are not expected to exceed depths of approximately 40 m BMSL. The modelling predicted a 1.5% probability of dissolved oil concentrations at ≥50 ppb contacting the Gascoyne AMP; no other key receptors areas were predicted to be contacted at or above the dissolved oil threshold.

Accumulated Hydrocarbons: Accumulated hydrocarbons above threshold concentrations (≥100 g/m²) were not predicted by the modelling to occur at any location. Floating oil at concentrations equal to or greater than 1 g/m² are not predicted to contact any shoreline receptors.

Impact Assessment

An unplanned hydrocarbon release as a result of loss of structural integrity of the FPU has the potential to result in the following impacts:

- change in water quality
- impacts to marine fauna
- impacts to other marine users.

Modelling of the potential extent of a worst-case spill resulting from a loss of structural integrity demonstrates that impacts would be limited to offshore, open waters, with no shoreline contact predicted.

In the unlikely event of this scenario occurring there will be potential impacts to megafauna, plankton and fish populations (surface and water column biota) that are within the spill affected area.

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

The potential biological and ecological impacts associated with a large-scale marine diesel spill in open waters (i.e. vessel collision) are described in detail in Section 6.8.2 and include impacts to plankton, seabirds, fish, marine mammals and marine reptiles. In the event of a spill from a loss of structural integrity of the FPU, potential impacts are considered Moderate.

Water Quality

The highly-mixed, open water location and characteristics of hydrocarbons released will result in rapid evaporation and dispersion. However, MDO contains a small proportion of heavy components (or low-volatile components) that tend to physically entrain into the upper water column in the presence of moderate winds (i.e. >12 knots) and breaking waves but may resurface if these conditions abate. If a substantial spill occurred, the heavier components could remain entrained or remain on the sea surface for an extended period and travel significant distances from the source, albeit at low concentrations.

Predicted weathering of marine diesel, based on typical conditions in the region, indicates that about 24% of the oil mass should evaporate within the first 24 hours (Figure 6-9) (RPS, 2024). After this time the majority of the remaining hydrocarbon is entrained into the upper water column.

The magnitude of potential impact of a change in water quality from unplanned release of MDO is assessed as slight. Receptor sensitivity of water quality is low (low value, open ocean), and therefore the consequence of a release of hydrocarbons on water quality is Negligible (F).

Marine Sediment

In the event of loss of structural integrity, there is the remote potential for full loss of the FPU to occur leading to an incremental increase of the FPU's footprint on the seabed. The potential area that would be affected can conservatively be defined as the existing FPU footprint plus 100 m in all directions; that is, approximately 237 m by 267 m (0.063 km²). The benthic habitats are dominated by soft bottom habitat and characterised by sparse marine life dominated by motile organisms. The benthic habitats surrounding the FPU have been subject to some disturbance (e.g. subsea infrastructure and FPU installation). Subsequently, the physical disturbance to the seabed resulting from the collapse of the FPU would be localised but may result in long-term disturbance to benthic communities.

The FPU could also act as a source of environmental contaminants due to material on board the platform (e.g. chemical/hydrocarbon inventories, corrosion of structural materials, debris, etc.). The potential for contamination would diminish over time, as the structure degrades. Depending on the nature of the loss of structural integrity, complete or partial salvage of the FPU may not be feasible. These structures are expected to be colonised by marine organisms, and a deepwater subsea habitat would develop over time on the structures. As such, the magnitude of a potential impact to water quality associated with loss of structural integrity is assessed as Negligible (F).

KEFs

The Exmouth Plateau KEF overlaps the Offshore Operational Area and seabed disturbance as a result of loss of structural integrity of the FPU may lead to a highly localised change in habitat and water quality. Impact to habitats would represent a small area relative to the large extent of the KEF. Physical habitat modification is not listed as a potential concern for the Exmouth Plateau KEF and potential impacts are unlikely to impact the ecological value of the KEF (as described in **Section 4.7**). As such, the magnitude of a potential impact to water quality associated with a loss of structural integrity is assessed as Slight (E).

AMPs

The quantitative spill risk assessment results indicate that the open water environment protected within the Gascoyne AMP may be affected by the released hydrocarbons.

A spill from the FPU in the PAA is unlikely to result in significant impacts to the AMPs based on the nature of the spilled hydrocarbons. Natural values for the AMPs include:

- marine turtle BIAs for Gascoyne Marine Park
- humpback whale migration BIA for Gascoyne Marine Park
- pygmy blue whale possible foraging area and migration BIAs for Gascoyne Marine Park
- diverse fish communities for Gascoyne Marine Park
- seabird breeding habitat BIAs for Gascoyne Marine Park.

While this results in exposure to hydrocarbons for some of the natural values of the marine parks, the impacts will be temporary as the MDO evaporates and degrades and moves with ocean currents. The evaluation of impacts to specific receptors are detailed in the individual receptor assessments above and below. Based on the assessment, the magnitude of a potential impact to AMPs associated with a release of hydrocarbons is Minor (D).

Marine Mammals

A change in marine fauna behaviour or injury/mortality to marine mammals may occur due to a change in water quality after an unplanned hydrocarbon release.

Air-breathing fauna such as marine mammals are most at risk from surface exposures due to the high volatile components. Marine mammals that have direct physical contact with surface, entrained or dissolved aromatic hydrocarbons may suffer surface fouling, ingest hydrocarbons and inhale toxic vapours. This may result in the irritation

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

of sensitive membranes such as the eyes, mouth, digestive and respiratory tracts and organs, impairment of the immune system or neurological damage (Helm et al., 2015). If prey (fish and plankton) are contaminated, this can result in the absorption of toxic components of the hydrocarbons (PAHs).

In a review of cetacean observations in relation to a number of large-scale hydrocarbon spills, Geraci (1988) found little evidence of mortality associated with hydrocarbon spills. However, behavioural disturbance (i.e. avoiding spilled hydrocarbons) was observed in some instances for several species of cetaceans. This suggests that cetaceans are able to detect and avoid surface slicks. While this reduces the potential for physiological impacts from contact with hydrocarbons, active avoidance of an area may disrupt behaviours such as migration, or displace individuals from important habitat, such as foraging, resting or breeding.

When first released, MDO has a higher toxicity due to the presence of the volatile components. Individual cetaceans making contact close to the spill source at the time of the spill may be impacted. Cetacean presence is generally more concentrated in waters closer to shore with the exception of false killer whales. Although cetacean presence may occur throughout the PAA and defined EMBA, it is unlikely that a large number of cetaceans will be affected at the sea surface above thresholds, as only the Gascoyne AMP will be contacted with surface oil and this is highly unlikely to occur (1% probability of 1 g/m²).

Although potential impacts could include mortality or sub-lethal injury/illness of marine mammals, this would be expected to comprise a small proportion of the resident and transitory population. Given hydrocarbon characteristics, expected rapid weathering of surface oil to below impact thresholds, and the mobile transient nature of marine mammals and potential avoidance behaviour, unplanned releases of MDO are not expected to have a substantial adverse effect on the population or spatial distribution of marine mammals; or substantially modify, destroy or isolate an area of important habitat for migratory species. Additionally, unplanned releases will not seriously disrupt the lifecycle of an ecologically significant proportion of any migratory species.

There are specific conservation advices for some species which identify noise interference and vessel disturbance as key threats. While hydrocarbon spills are not explicitly identified as a threat, the sei whale conservation advice does include the management of physical disturbance and development activities. No explicit management actions are identified relevant to hydrocarbon spills.

Potential impacts are unlikely to lead to mortality or sub-lethal injury/illness of an EPBC listed protected species. Based on the detailed risk evaluation, the magnitude of potential impacts to marine mammals (focused on changes in behaviour) from unplanned MDO releases is assessed as slight. Receptor sensitivity of marine mammals is high (high value fauna), and therefore the consequence of a release of hydrocarbons on marine mammals is Minor (D).

Fish, Sharks and Rays

Injury/mortality to fish species may occur due to a change in water quality following an unplanned hydrocarbon release. Any surface and subsurface hydrocarbon release could impact fish, as they are widely dispersed throughout the water column.

Impacts to sharks and rays may occur through direct contact with hydrocarbons and contaminate the tissues and internal organs, either through direct contact or via the food chain (consumption of prey). As gill breathing organisms, sharks and rays may be vulnerable to toxic effects of dissolved hydrocarbons (entering the body via the gills) and entrained hydrocarbons (coating of the gills inhibiting gas exchange). In the offshore environment, it is probable that pelagic shark species are able to detect and avoid hydrocarbons by swimming into deeper water or away from the affected areas.

Fish mortalities are rarely observed to occur as a result of hydrocarbon spills (International Tanker Owners Pollution Federation, 2011b). This has generally been attributed to the possibility that pelagic fish are able to detect and avoid surface waters underneath hydrocarbon spills by swimming into deeper water or away from the affected areas. Fish that have been exposed to dissolved aromatic hydrocarbons are capable of eliminating the toxicants once placed in clean water; hence, individuals exposed to a spill are likely to recover (King et al., 1996). Where fish mortalities have been recorded, the spills (resulting from the groundings of the tankers Amoco Cadiz in 1978 and the Florida in 1969) have occurred in sheltered bays.

Laboratory studies have shown that adult fish can detect hydrocarbons in water at very low concentrations, and large numbers of dead fish have rarely been reported after hydrocarbon spills (Hjermann et al., 2007). This suggests that juvenile and adult fish can avoid water contaminated with high concentrations of hydrocarbons.

The effects of exposure to oil on the metabolism of fish appear to vary according to the organs involved, exposure concentrations and route of exposure (waterborne or food intake). Oil reduces the aerobic capacity of fish exposed to aromatics in the water, and to a lesser extent affects fish consuming contaminated food (Cohen et al., 2005). The liver, a major detoxification organ, appears to be where anaerobic activity is most impacted, probably increasing anaerobic activity to help eliminate ingested oil from the fish (Cohen et al., 2005).

Fish are perhaps most susceptible to the effects of spilled oil in their early life stages, particularly during egg and planktonic larval stages, which can become entrained in spilled oil. Contact with oil droplets can mechanically damage feeding and breathing apparatus of embryos and larvae (Fodrie and Heck, 2011). The toxic hydrocarbons in water can result in genetic damage, physical deformities and altered developmental timing for larvae and eggs exposed to even low concentrations over prolonged timeframes (days to weeks) (Fodrie and Heck, 2011). Subtler, chronic effects on the life history of fish because of exposure in early life stages to hydrocarbons include disruption to complex behaviour such

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

as predator avoidance, reproductive and social behaviour (Hjermann et al., 2007). Prolonged exposure of eggs and larvae to weathered concentrations of hydrocarbons in water has also been shown to cause immunosuppression and allows expression of viral diseases (Hjermann et al., 2007).

Adult fish exposed to low hydrocarbon concentrations are likely to metabolise the hydrocarbons and excrete the derivatives, with studies showing that fish can metabolise petroleum hydrocarbons and that accumulated hydrocarbons are released from tissues when the fish is returned to hydrocarbon-free sea water. Several fish communities in these areas are demersal (i.e. living closer to the seabed) where concentrations of entrained hydrocarbons will be lower; any impacts are expected to be highly localised.

When first released, MDO has a higher toxicity due to the presence of the volatile components. Individual fish making contact close to the spill source at the time of the spill may be impacted. Fish presence is generally concentrated in waters closer to shore. Although fish presence may occur throughout the entire PAA and defined EMBA, it is unlikely that a large number of fish will be affected at the sea surface above thresholds. Mobile transient fauna are not expected to remain within entrained hydrocarbon plumes for an extended time. Therefore, no acute impacts or risks associated with entrained exposures from an unplanned MDO release are expected. Any impacts from this exposure are expected to result in localised short-term effects to limited small numbers of juvenile fish and prey species (larvae and planktonic organisms), which are not expected to affect population viability and recruitment of fish. Consequently, diverse fish assemblages are not expected to be significantly impacted.

Although potential impacts could include mortality or sub-lethal injury/illness of pelagic fish, this would be expected to comprise a small proportion of the resident and transitory population. Given hydrocarbon characteristics, expected rapid weathering to below impact thresholds and degradation of entrained fractions, and the mobile transient nature of fish, unplanned releases of MDO are not expected to have a substantial adverse effect on the population or spatial distribution of fish; or substantially modify, destroy or isolate an area of important habitat for migratory species. Additionally, unplanned releases will not seriously disrupt the lifecycle of an ecologically significant proportion of any migratory fish species.

There are specific conservation advices for some fish species which identify habitat degradation/modification as a key threat. While for some species there are specific requirements (e.g. sawfish), no specific requirements have been identified for relevant species (i.e. species identified as having potential to occur in the EMBA).

The magnitude of a potential impact to fish associated with a release of hydrocarbons is minor (D). Although potential impacts could include mortality or sub-lethal injury/illness of pelagic fish, this would be expected to comprise a small proportion of the resident and transitory population. Given hydrocarbon characteristics, expected rapid weathering to below impact thresholds and degradation of entrained fractions, and the mobile transient nature of fish, unplanned release is not expected to have a substantial adverse effect on the population, or spatial distribution of fish/sharks/rays.

Marine Reptiles

A change in marine fauna behaviour or injury/mortality to marine reptiles may occur due to a change in water or sediment quality following an unplanned hydrocarbon release.

Marine reptiles can be impacted by surface exposure when they surface to breathe, and by shoreline accumulation of hydrocarbons when breeding and nesting.

Hydrocarbons in surface waters may impact turtles when they surface to breathe and inhale toxic vapours. Their breathing pattern, involving large 'tidal' volumes and rapid inhalation before diving, results in direct exposure to petroleum vapours which are the most toxic component of the hydrocarbon spill (Milton and Lutz, 2003). This can lead to lung damage and congestion, interstitial emphysema, inhalant pneumonia and neurological impairment (National Oceanic and Atmospheric Administration, 2010). Contact with entrained hydrocarbons can result in hydrocarbon adherence to body surfaces, irritating mucous membranes in the nose, throat and eyes, leading to inflammation and infection (Gagnon and Rawson, 2010).

Adult sea turtles exhibit no avoidance behaviour when they encounter hydrocarbon spills (National Oceanic and Atmospheric Administration, 2010). Oiling can also irritate and injure skin, which is most evident on pliable areas such as the neck and flippers (Lutcavage et al., 1995). A stress response associated with this exposure pathway includes an increase in the production of white blood cells, and even a short exposure to hydrocarbons may affect the functioning of their salt gland (Lutcavage et al., 1995).

When first released, MDO has a higher toxicity due to the presence of the volatile components. Individual turtles making contact close to the spill source at the time of the spill may be impacted. Turtle presence is generally more concentrated in waters closer to shore, with infrequent presence of turtles as far offshore as the PAA. Although turtle presence may occur throughout the PAA and defined EMBA, it is unlikely that a large number of turtles will be affected. With no shoreline accumulation, there is negligible potential for impacts to turtle nesting beaches.

Impacts to sea snakes from direct contact with hydrocarbons are likely to result in similar physical effects to those recorded for marine turtles.

Potential impacts are unlikely to lead to mortality or sub-lethal injury/illness of an EPBC listed protected species. Given hydrocarbon characteristics, expected rapid weathering to below impact thresholds, and the mobile transient nature of individuals, an unplanned release from a vessel collision is not expected to substantially modify, destroy or isolate an area of important habitat for migratory species. It is not expected that unplanned releases will have a substantial adverse

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

effect on the population, or spatial distribution of marine reptiles; or seriously disrupt the lifecycle of an ecologically significant proportion of any migratory species.

Impacts to turtles from unplanned hydrocarbon releases are to be managed in accordance with the Recovery Plan for marine turtles in Australia (Commonwealth of Australia, 2017). The Recovery Plan identifies ensuring spill risk strategies and response programs include management for turtles and their habitats. In addition, there is in place approved Conservation Advice for the short-nosed sea snake (DSEWPaC, 2011), which includes ensuring there is no anthropogenic disturbance in areas where the species occurs, excluding necessary actions to manage the conservation of the species.

Based on the detailed risk evaluation, the magnitude of potential impacts to marine reptiles from unplanned hydrocarbon releases is assessed as no lasting effects (from change in fauna behaviour) and slight (from injury/mortality to fauna). Receptor sensitivity of marine reptiles is high (high value fauna), and therefore the overall consequence of a release of hydrocarbons on marine reptiles is Minor (D).

Seabirds and Migratory Shorebirds

A change in marine fauna behaviour or injury/mortality to seabirds and migratory shorebirds may occur due to a change in water or sediment quality following an unplanned hydrocarbon release.

Seabirds and migratory birds are particularly vulnerable to contact with floating hydrocarbons, which may mat feathers. This may lead to hypothermia from loss of insulation and ingestion of hydrocarbons when preening to remove hydrocarbons. Both impacts may result in mortality (Hassan and Javed, 2011). Pathways of biological exposure that can result in impact may occur through ingesting contaminated fish (nearshore waters) or invertebrates (intertidal foraging grounds such as beaches, mudflats and reefs). Ingestion can also lead to internal injury to sensitive membranes and organs (International Petroleum Industry Environmental Conservation Association, 2004). Whether the toxicity of ingested hydrocarbons is lethal or sub-lethal will depend on the weathering stage and its inherent toxicity. Exposure to hydrocarbons may have longer term effects, with impacts to population numbers due to decline in reproductive performance and malformed eggs and chicks, affecting survivorship and losing adult birds.

When first released, MDO has a higher toxicity due to the presence of the volatile components. Individual birds making contact close to the spill source at the time of the spill may be impacted. Bird presence within the NWMR is more concentrated in waters closer to shore with the potential for individual migratory birds within the PAA.

There are specific conservation advices for some species which identify habitat degradation as the key threat, but generally no explicit management actions are identified relating to hydrocarbon spills.

The magnitude of a potential impact to seabirds and migratory shorebirds associated with a release of hydrocarbons is Slight (E) (from change in fauna behaviour) and Minor (D) (from injury/mortality to fauna). Although potential impacts could include mortality or sub-lethal injury/illness of birds, this is expected to comprise a small proportion of the resident and transitory population. Given hydrocarbon characteristics, expected rapid weathering to below impact thresholds, and the mobile transient nature of individuals, unplanned hydrocarbon releases are not expected to substantially modify, destroy or isolate an area of important habitat for migratory species.

Commonwealth and State Managed Fisheries

A change in marine fauna behaviour or injury or mortality to marine fauna – in particular to commercially targeted species, or their prey species (e.g. plankton) – can impact fisheries.

Fish exposure to hydrocarbon can result in 'tainting' of their tissues. Even very low levels of hydrocarbons can impart a taint or 'off' flavour or smell in seafood. Tainting is reversible through the process of depuration which removes hydrocarbons from tissues by metabolic processes, although it depends on the magnitude of the contamination. Fish have a high capacity to metabolise these hydrocarbons while crustaceans (such as prawns) have a reduced ability (Yender et al., 2002). Seafood safety is a major concern associated with spill incidents. Therefore, actual or potential contamination of seafood can affect commercial and recreational fishing and can impact seafood markets long after any actual risk to seafood from a spill has subsided (Yender et al., 2002).

A major spill could result in the establishment of an exclusion zone around the spill affected area. There would be a temporary prohibition on fishing activities for a period and subsequent potential for economic impacts to affected commercial fishing operators. Additionally, hydrocarbon can foul fishing equipment such as traps and trawl nets, requiring cleaning or replacement.

MDO presence in the water would be restricted to the surface and upper water column only. Dissolved aromatics (i.e. the form that is bioavailable) are in such small concentrations in MDO that their effect in the marine environment is negligible (F); i.e. tainting from an MDO exposure is not considered likely to occur. Any exclusion zone established would be limited to the immediate vicinity of the release point, and due to the rapid weathering of MDO would only be in place days after release, therefore physical displacement to vessels is unlikely to be a significant impact.

A number of Commonwealth and State fishery management areas are located within the PAA and EMBA. FishCube data was requested to analyse the potential for interaction of fisheries with the PAA, which was used to determine consultation with State Fisheries who may be impacted by proposed petroleum activities (Department of Primary Industries and Regional Development [DPIRD], 2021). Table 4-27 provides an assessment of the potential interaction and provides further detail on the fisheries that have been identified through desk-based assessment and consultation (**Section 5**).

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

In the highly unlikely event of a release of marine diesel to the environment as a result of vessel collision there may be the presence of hydrocarbons in areas used by the fisheries that overlap the EMBA (Table 4-27).

Although potential impacts from a worst case spill could include mortality or sub-lethal injury/illness of pelagic fish (described in the specific receptor evaluation), this would be expected to comprise a small proportion of the resident and transitory population. Given the hydrocarbon characteristics, expected rapid weathering to below impact thresholds and low fishing effort, an unplanned hydrocarbon spill from the Petroleum Activities Program is not expected to have an adverse effect on the sustainability of commercial fishing; or to interfere with other marine users.

Based on the detailed risk evaluation, the magnitude of potential impacts to Commonwealth and State managed fisheries from an unplanned hydrocarbon release is assessed as Slight (E).

Shipping

In the event of a spill, an exclusion zone may be established around the spill affected area. This could result in exclusion of other users such as shipping vessels or vessels used by the mining and petroleum industries. Any exclusion zone established would be limited to the immediate vicinity of the release point, and due to the rapid weathering of MDO would only be in place for days after release, therefore physical displacement to vessels is unlikely to be a significant impact.

Given hydrocarbon characteristics, expected rapid weathering to below impact thresholds, short duration of displacement, and the offshore location of the PAA, unplanned releases of MDO are not expected to interfere with shipping to a greater extent than necessary.

Based on the assessment, the magnitude of a potential impact to shipping associated with an unplanned release of hydrocarbons is Slight (E).

Summary of Assessment Outcomes

Receptor	Impact	Receptor Sensitivity Level	Risk Consequence	Likelihood	Risk Rating
Water quality	Change in water quality	Low value (open water)	Negligible (F)	Highly unlikely	Low
Marine sediment	Change in sediment quality	Low value	Negligible (F)	Highly unlikely	Low
Plankton	Injury/mortality to fauna	Low value (open water)	Negligible (F)	Highly unlikely	Low
Marine mammals	Change in fauna behaviour	High value species	Minor (D)	Highly unlikely	Moderate
	Injury/mortality to fauna	High value species	Minor (D)	Highly unlikely	Moderate
Fish, sharks and rays	Change in fauna behaviour	High value species	Minor (D)	Highly unlikely	Moderate
	Injury/mortality to fauna	High value species	Minor (D)	Highly unlikely	Moderate
Marine reptiles	Change in fauna behaviour	High value species	Slight (E)	Highly unlikely	Low
	Injury/mortality to fauna	High value species	Minor (D)	Highly unlikely	Moderate
Seabirds and migratory shorebirds	Change in fauna behaviour	High value species	Slight (E)	Highly unlikely	Low
	Injury/mortality to fauna	High value species	Minor (D)	Highly unlikely	Moderate
AMPs	Change in habitat	High value	Minor (D)	Highly unlikely	Moderate
KEFs	Change in habitat	High value	Slight (E)	Highly unlikely	Low
Commonwealth and State managed fisheries	Changes to the functions, interests or activities of other users	High value marine use	Slight (E)	Highly unlikely	Low
Shipping	Changes to the functions, interests or activities of other users	Medium value	Slight (E)	Highly unlikely	Low

ALARP Statement:

On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type (i.e. Decision type B, Section 2.3.1), Woodside considers the adopted controls appropriate to manage the risks of an unplanned hydrocarbon release as a result of loss of FPU/ASV loss of structural integrity/stability.

The principle of inherent safety and environmental protection is based on the prevention of a significant environmental event through design of the Scarborough FPU facility, ensuring the equipment is operated within the design envelope through operating practices and assurance through maintenance and inspection. If a loss of structural integrity occurs, mitigation measures are in place to minimise the consequence by limiting the inventory which can be released and implementing remediation.

Controls have been selected following hierarchy of control principles and consider independence of each barrier and their type of effect in controlling the hazardous event. Qualitative hazard analysis and spill risk assessment considers potential for causal events and their consequences. Based on the environmental risk assessment outcomes (Highly Unlikely likelihood and Moderate consequence) and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the potential impacts, risks and potential escalation events.

The application of Woodside Risk Management Procedures, and implementation of the Scarborough FPU Safety Case ensures the continuous identification of hazards, systematic assessment of risks and ongoing assessment of alternative control measures to reduce risk to ALARP, which includes:

- ongoing hazard identification, risk assessment and the identification of control measures
- ongoing integrity management of hardware control measures, assured in accordance with the technical performance standards which define requirements to be suitably maintained, such that they retain effectiveness, functionality, availability and survivability
- engineering codes and standards
- MSPS for Safety Critical Management System Controls.

Given the controls in place to prevent FPU loss of structural integrity events, and mitigate their consequences, it is considered that the risk is managed to ALARP.

Demonstration of Acceptability
<p>Acceptability Criteria and Assessment</p> <p>Demonstration of acceptability for the sources of risk and associated impacts assessed in this section are provided in Section 7.2.6.4 of the Scarborough OPP. The Petroleum Activities Program meets the acceptability criteria (Section 2.3.5):</p> <ul style="list-style-type: none"> • Overall risk consequence/risk ratings for individual receptors are less than the significant impact level defined in the OPP. • EPOs and controls in the OPP that are relevant to loss of structural integrity have been adopted. • There are no changes to internal/external context specific to this risk from the OPP, including issues raised during consultation.
<p>Acceptability Statement:</p> <p>The impact assessment has determined that a loss of structural integrity represents a Moderate current risk rating and is highly unlikely to result in a risk consequence greater than Minor. Relevant recovery plans and conservation advice have been considered during the impact assessment, and the Petroleum Activities Program is not considered to be inconsistent with the overall recovery objectives and actions of these recovery plans and conservation advice. The adopted controls are considered consistent with industry legislation, codes and standards, good practice and professional judgement (supported by hierarchy of controls and risk based analysis). The FPU is designed to satisfy AMSA regulatory requirements including applicable Marine Orders, and is supported by verification via a Recognised Organisation, DNV. The ASV meets industry standard Class requirements. No additional requirements were identified during impact assessment and consultation. The potential risks and consequences are considered acceptable if the adopted controls are implemented. Activities do not have a significant impact on MNES (Section 2.4.2) including those with an First Nations connection or with traditional use in nearshore areas as defined in Section 4.9.</p> <p>Therefore, Woodside considers the adopted controls appropriate to, manage the risks of FPU loss of structural integrity/stability to a level that is broadly acceptable; and demonstrates the EPO is met.</p>

Detailed Impact Assessment

Assessment of Potential Impacts

Water Quality

A well loss of containment may temporarily decrease the water quality in the immediate vicinity of the release.

The Scarborough reservoir properties are dry gas, primarily methane (approximately 95%) and nitrogen (approximately 4%), with some ethane, CO2 content and limited heavier hydrocarbon components. Understanding of the Scarborough gas composition was supported by information collected from reservoir samples and well tests obtained from the Scarborough-4 and Scarborough-5 appraisal wells, and compositional analysis undertaken in 2018 and 2019. Analysis of worst case (“heaviest”) reservoir composition indicates that no liquid hydrocarbons will exist at any pressure or temperature conditions that will be experienced in the environment. Liquid hydrocarbons are only expected at sub-zero temperatures which are not present in the marine environment at the location.

In the event of a well loss of containment during the production phase, the well may release gas at up to a worst-case discharge rate of 423 MMscf/d assumed over 65 days. Hydrocarbons will be released from the well until intervention, either:

- capping stack, or
- a relief well is drilled with successful well kill.

In the event of a release of gaseous hydrocarbons from a well loss of containment, the pressurised discharge will emit a jet of small gas bubbles with high momentum into the water column. The initial momentum of the jet would rapidly dissipate, and following the initial jet phase as the bubbles expand due to pressure reduction their buoyancy becomes the driving force for an upward plume of gas bubbles and entrained water.

As the gas travels upwards through the water column, dissolution will occur. The majority of the methane gas released would immediately dissolve into the water column, form hydrates, with a small proportion potentially reaching the sea surface. Studies show methane oxidation in deep water, and water column characteristics like pycnoclines (stratification of the water column due to differences in density) and thermoclines (stratification of the water column due to differences in water temperature), limit the amount of methane that is transported upwards to the sea surface. Even in relatively shallow water depths (less than 100 m water depths) only minor amounts of methane are actually released to the atmosphere (Deimling et al., 2015; Gentz et al., 2014; Schmale et al., 2010).

Because of the deep water location, it is expected that any transfer of methane to warmer surface waters would be restricted and, therefore, air-sea exchange would be limited (Gentz et al., 2014). Gentz et al. (2014) found approximately 80% of methane dissolution occurs below the water column stratification, such as with a pycnocline, and that methane levels return to background concentrations rapidly above the pycnocline. Methane dissolved in the water column is also subject to microbial oxidation, which further restricts transfer of methane into the upper surface water layer and the atmosphere (Gentz et al., 2014; Valentine et al., 2001). When methane is oxidised it forms water and carbon dioxide. Dissolved methane and carbon dioxide exist naturally in water and pose no risk to the marine environment.

Following the 2012 gas leak from the Elgin platform in the North Sea, monitoring of water and sediment (Webster et al., 2012a,b) and fish health (Webster et al., 2012b,c) found no evidence of hydrocarbon contamination above background levels. Although the sea temperatures were colder than those in the Offshore Operational Area, natural processes such as microbial oxidation would be expected to occur in the Offshore Operational Area which would greatly reduce any dry gas release to the atmosphere or impacts to the marine environment. Given this, changes in the chemistry of the water column or sediment from a gas release are expected to be localised and there is no pathway for impacts to habitat or ecosystem function or integrity.

Based on the risk evaluation, the magnitude of potential impact of a change in water quality from a well loss of containment is assessed as Slight short-term impact. Receptor sensitivity of water quality is Low (open ocean), and the consequence of a release of hydrocarbons on water quality is assessed as Slight (E).

Air Quality

A hydrocarbon release during a loss of well containment has the potential to result in localised, temporary reduction in air quality and contribution of greenhouse gases to the global concentration of these gases in the atmosphere. Potential impacts from reduced air quality are expected to be Slight (E), short-term and predominantly localised.. The ambient concentrations of methane and VOCs released from diffuse sources is difficult to accurately quantify, although the behaviour and fate is predictable in open offshore environments as it is dispersed rapidly by meteorological factors such as wind and temperature. Methane and VOC emissions from a hydrocarbon release in such environments are rapidly degraded in the atmosphere by reaction with photo chemically-produced hydroxyl radicals.

Outcome Mitigation

From an environmental management perspective, a hydrocarbon release caused by a well loss of containment is mitigated at the connected facility by detection and alarm; emergency shutdown (for isolation of inventories and the reservoir, critical communications systems and emergency preparedness (including facility ERP, spill response and drilling a relief well, if required).

Likelihood Assessment

Woodside has a history of implementing industry standard practice in well design and construction. In Woodside’s 60-year history, it has not experienced any well integrity events that have resulted in significant releases or significant environmental impacts.

The blowout likelihood was evaluated using Blowout and Well release Frequencies based on SINTEF offshore blowout database as analysed in the IOGP, 2019 Study *Risk Assessment Data Directory Blowout Frequencies – Report 434-02* (September 2019). This uses data from 1980-2014 to determine likelihood for well blowouts and releases. For a gas well, the IOGP study calculated gas blowout frequency during production as 7.20×10^{-5} per year per well.

Given consideration for 8 and 13 subsea gas wells and using SINTEF/IOGP database, blowout during production occurs with a frequency of 5.8×10^{-4} to 9.4×10^{-4} per year which gives a likelihood level of 2 “Unlikely” on the Woodside Risk Matrix. An order of magnitude reduction has been taken to reduce the likelihood of significant environmental impacts to Level 1 “Highly Unlikely”, for the following reasons:

SINTEF and Lloyds data presented in the IOGP 2019 Blowout Frequencies study considers Production well integrity events between 1980 and 2011, with some additional data from the North Sea between 2011 and 2014. Frequencies are informed by incidents which occurred in Gulf of Mexico, which occurred prior to standards improvement following the Macondo event. Similarly, improvements in standards have been achieved in the North Sea compared to the pre-Macondo era. External causes are excluded for subsea production wells, as causes discussed appears to only be relevant to dry-tree/platform wells.

For the international blowout incidents analysed, these are expected to have resulted in varied release outcomes with varied flow and environmental consequence outcomes – not all are aligned with a worst case unconstrained full-bore blowout, from the highest flowing well, nor necessarily required a relief well to remediate (which is the basis for this risk assessment)

Woodside has adopted international best practice – the Offshore Energies UK (OEUK) Well Lifecycle Integrity Guidelines (post-Macondo industry improvements). Woodside continue to apply a rigorous well integrity management program (refer WOMP) as required under WMS and Australian regulations, including verification, and testing of key barriers including SSSVs.

Additionally, when considering likelihood from an ‘Experience’ perspective, and considering the significant environmental consequence likelihood as the outcome of a blowout event; historical blowouts resulting in significant impact to the environment have not occurred “many times in industry”. Hence, alignment with Highly Unlikely likelihood classification is deemed appropriate.

Summary of Assessment Outcomes

Receptor	Impact	Receptor Sensitivity Level	Risk Consequence	Likelihood	Risk Rating
Water quality	Change in water quality	Low value (open water)	Slight (E)	Highly unlikely	Low
Air quality	Change in air quality	Low value (offshore airshed)	Slight (E)	Highly unlikely	Low

Overall Risk Consequence: The risk rating for an unplanned discharge from a loss of well control is Low based on a slight consequence to a low value receptor (open water/offshore airshed) and a highly unlikely likelihood. The risk consequence/risk rating for individual receptors are consistent with the levels rated in the OPP.

ALARP Statement:

On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type (i.e. Decision type A, Section 2.3.1), Woodside considers the adopted controls appropriate to manage the risks and consequences of an unlikely unplanned hydrocarbon release as a result of a well loss of containment.

Controls have been selected following hierarchy of control principles and consider independence of each barrier and their type of effect in controlling the hazardous event. A qualitative spill risk assessment considers studies of gas release behaviour and fate through a deep water-column when considering potential for environmental impact. Based on the environmental risk assessment outcomes (highly unlikely likelihood and slight consequence) and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the potential impacts and risks.

The principle of inherent safety and environmental protection is based on the prevention of the significant environmental events through design of well integrity and ensuring the wells are operated within their design envelope through operating practices and assurance through maintenance and inspection. If hydrocarbon loss of containment occurs, mitigation measures are in place to minimise the consequence by limiting the inventory which can be released and implementing remediation.

The controls in place for prevention and mitigation of significant process safety release events are specified and assured through implementing the WOMP, SCE management procedures including performance standards for SCEs, and MSPS for Safety Critical Management System Controls.

The application of Woodside Risk Management Procedures, and implementation of the WOMP ensures the continuous identification of hazards, systematic assessment of risks and ongoing assessment of alternative control measures to reduce risk to ALARP, which includes:

- ongoing hazard identification, risk assessment and the identification of control measures
- ongoing integrity management of hardware control measures in accordance with the technical performance standards which define requirements to be suitably maintained, such that they retain effectiveness, functionality, availability and survivability.

Wells Integrity Codes and Standards

Given the controls in place to prevent and control loss of containment events and mitigate their consequences, alongside procedural control of well intervention activities, it is considered that the risk associated with Well Loss of Containment for Scarborough subsea wells is managed to ALARP.

Demonstration of Acceptability

Acceptability Criteria and Assessment

Demonstration of acceptability for the sources of aspect and associated impacts assessed in this section are provided in Section 7.2.6.4 of the Scarborough OPP. The Petroleum Activities Program meets the acceptability criteria (**Section 2.3.5**):

- Overall risk consequence/risk ratings for individual receptors are less than the significant impact level defined in the OPP.
- EPOs and controls in the OPP that are relevant to a loss of well control have been adopted.
- There are no changes to internal context specific to this risk from the OPP.
- Potential impacts from an unplanned hydrocarbon release, from well loss of containment, was raised during consultation (Section 5). Further information was provided to relevant persons as requested (App F) and this feedback was considered in the finalisation of the EP.

Acceptability Statement:

The impact assessment has determined that an unplanned hydrocarbon release resulting from a well loss of containment represents a Low current risk rating and is highly unlikely to result in a consequence greater than Slight. A gas release is expected to result in a temporary change to water quality with no pathway for impacts to habitat or ecosystem function or integrity. Relevant recovery plans and conservation advice have been considered during the impact assessment, and the Petroleum Activities Program is not considered to be inconsistent with the overall recovery objectives and actions of these recovery plans and conservation advice. The adopted controls are considered consistent with industry legislation, codes and standards, and industry good practice. Opportunities to reduce risk have been adopted during the well integrity and protective system design.

The potential risks and consequences are considered acceptable if the adopted controls are implemented. Activities do not have a significant impact on MNES (Section 2.4.2) including those with an First Nations connection or with traditional use in nearshore areas as defined in Section 4.9. Therefore, Woodside considers the adopted controls appropriate to

manage the risks and consequences of a loss of well control to a level that is broadly acceptable and demonstrates the EPO is met.

Description of Source of Impact/Risk														
<p>During operations, hydrocarbons extracted from the reservoir will flow from the wellheads via the Xmas trees and manifolds daisy-chained along three 16" rigid production flowlines 13 km, 14 km and 18 km long to the FPU, connected via three 14" risers. On the FPU, the gas is separated from the MEG and dehydrated further prior to export. Export of dry gas is via three 14" export risers to a Riser Base Manifold (RBM) featuring three Non-Return Valves before connecting into the 32" header line. From there, the Scarborough Trunkline to shore is approximately 430 km in length, and of dual diameter: 32" diameter from the FPU location, increased to a nominal 36" diameter at ~KP200 through to the onshore LNG facility.</p> <p>The subsea systems include hydrocarbon containing components between the well isolations through to the riser emergency shutdown valves at the FPU where flowline-risers terminate, and export risers/trunkline originates and runs to the onshore LNG facility. Across the subsea equipment, there is potential for a loss of containment of gas from the trunkline, flowlines, jumpers, risers and supporting subsea infrastructure (such as FLETs/ILTs, Pig Laucher/receiver, RBFLETs, Manifolds)</p> <p>The potential hazard sources that could instigate a loss of containment of inventory from the trunkline or subsea flowlines and risers are:</p> <ul style="list-style-type: none"> • internal corrosion • external corrosion • erosion (for flowlines) • over/under pressure • low temperature

- equipment fatigue (risers and structural supports)
- overstress (pipeline stability, scour and freespan)
- FLIP (flowline induced pulsation).
- Loss of control of suspended load from visiting vessel and FPU
- external impacts such as anchor impact/dragging
- extreme weather/environmental events that exceed design limits of subsea pipelines/flowlines
- critical equipment failures
- human error.

Escalation from other significant environment events interacting with the FPU can cause subsea equipment loss of containment:

- Loss of Structural Integrity/Stability (including FPU position keeping/mooring failure) (**Section 6.8.3**)
- Loss of Marine Vessel Separation with FPU (**Section 6.8.2**).

Credible Scenario – Subsea Equipment and Trunkline Loss of Containment

The worst-case credible hydrocarbon release caused by subsea loss of containment is a release from the Scarborough Export Trunkline (SCATL). The SCATL is estimated to typically contain approximately 28,000 tonnes of hydrocarbon gas. Catastrophic failure could potentially release hydrocarbons (primarily methane) to the water column, and evolve gas to the sea surface in waters less than approximately 700m deep. No appreciable surface expression of gas would be expected from the subsea and flowline system upstream of the FPU, and deep trunkline sections.

For potential shallow water loss of containment events, there may be potential for localised, temporary reduction in air quality, and escape of GHG to the atmosphere.

A subsea loss of containment from subsea riser infrastructure (above the seabed) may escalate to major accident events. An ignited gas release adjacent to the FPU could cause large scale fire and explosion with significant equipment damage. Potential escalation from subsea loss of containment with potential for spill to the environment is considered a cause for FPU Loss of Structural Integrity/Stability (**Section 6.8.3**).

Detailed Impact Assessment

Assessment of Potential Impacts

Water Quality

A loss of containment from the subsea equipment (such as worst-case export trunkline) may temporarily decrease the water quality in the immediate vicinity of the release. As described in Section 6.8.4, the Scarborough reservoir properties are dry gas, primarily methane (approximately 95%) and nitrogen (approximately 4%), with some ethane, CO₂ content and limited heavier hydrocarbon components. Given that hydrocarbons of the Scarborough reservoir contain no measurable liquid fraction, in the event of a subsea riser equipment loss of containment there is expected to be no or negligible liquid component. As such, quantitative spill modelling has not been undertaken.

If a worst case subsea loss of containment event occurred from the export trunkline in deep-water, the majority of the methane gas released would dissolve into the water column (methane is highly soluble in water), with a small proportion expected to reach the sea surface and 'flash off' on exposure to the atmosphere. The proportion reaching the surface will be greater in shallower waters whilst reducing the depth and duration of water-column interaction.

As discussed in Section 6.8.4, changes in the chemistry of the water column or sediment from a gas release are expected to be localised and there is no expected pathway for impacts to habitat or ecosystem function or integrity. Based on the risk evaluation, the magnitude of potential impact of a change in water quality from a loss of containment is assessed as Slight short-term impact. Receptor sensitivity of water quality is Low (open ocean), and the consequence of an unplanned release of hydrocarbons on water quality is assessed as Slight (E).

Air Quality

For potential shallow water loss of containment events, there may be potential for localised, temporary reduction in air quality, and contribution of greenhouse gases to the global concentration of these gases in the atmosphere. Potential impacts from reduced air quality are expected to be Slight (E), short-term and predominantly localised. There is potential for human health effects for workers in the immediate vicinity of atmospheric emissions. The ambient concentrations of methane and VOCs released from diffuse sources is difficult to accurately quantify, although the behaviour and fate is predictable in open offshore environments as it is dispersed rapidly by meteorological factors such as wind and temperature. Methane and VOC emissions from a hydrocarbon release in such environments are rapidly degraded in the atmosphere by reaction with photo chemically-produced hydroxyl radicals.

Escalation Events

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

Subsea loss of containment releases from the production and export risers or full-bore releases from the Export RBM 32" piping sections adjacent to the FPU 500m safety zone are considered credible to cause a flammable gas environment at the sea-surface. Significant release events with ignition present possible causes for unplanned hydrocarbon release due to FPU Loss Structural Integrity/Stability Section 6.8.3. Process safety management measures described in this Subsea Loss of Containment section are applicable to subsea system controls (preventative and mitigative barriers), with escalation consequence and risk presented in Section 6.8.3. Significant subsea loss of containment events adjacent to the FPU with potential for ignition and escalation are also managed under the Scarborough Safety Case (MAE01, and MAE-04), with worst-case associated liquid hydrocarbon release to environment considered Highly Unlikely.

Outcome Mitigation

From an environmental management perspective, a hydrocarbon release caused by a subsea loss of containment is mitigated at the connected facility by detection and alarm; emergency shutdown (for isolation of reservoir, topsides and pipeline/trunkline inventories), SSIVs and trunkline non-return valves (NRV), critical communications systems and emergency preparedness (including facility ERP, spill response).

Quantitative Risk Assessment

The Scarborough Export Trunkline Detailed Design Quantitative Risk Assessment (QRA) studies were applied to inform and review trunkline route selection and protection design. The detailed design QRA summarises the following potential key hazards to the residual unprotected export trunkline sections:

Shipping/Vessel Activity/Dropped Objects

Shipping activity along the export trunkline in Commonwealth waters is relatively low, with some activity in KP32-58 and along four shipping fairway crossings. Credible shipping impact scenarios included sinking and dropped/dragged anchor scenarios. Design risk based analysis indicates that impacts from small vessels such as tugs, fishing vessels and pleasure craft would result in minor damage only.

The separation distance between the FPU cranes and subsea risers established in design means that potential dropped objects do not pose a material threat to subsea risers, pipelines or umbilicals, with management system measures in place to manage lifting in restricted areas.

Impacts to the trunkline from larger vessels (such as OSV's and larger) could result in major damage (e.g. significant displacement) and in some instances, loss of containment. Export trunkline protection design measures has been incorporated in specific segments of the export pipeline to reduce the safety and environmental risk from the shipping impacts to a level that is considered ALARP. Risk-based analysis considering implementation of these pipeline protection measures, indicated a significant proportion of residual major damage frequencies between the State Waters boundary and KP58 would be caused by OSV's and other vessels of similar size. In these instances, results suggested significant lateral displacement of the export trunkline may be caused by a dragged anchor, however the risk of loss of containment is negligible. The remaining damage frequencies are from large vessels such as bulk carriers and tankers, and have potential to cause a loss of containment event, albeit at a very low likelihood of occurrence.

Commercial Fishing

Trawl activity is low throughout the SCATL route, and the route avoids the Pilbara Trawl Managed Fishery. The export trunkline was checked for fishing interference loads and found to withstand the loads associated with credible trawl board impact/fishing vessel pull-over and hooking without loss of containment.

Maintenance of subsea infrastructure structural protection frames are included in mechanical integrity controls set out for export trunkline integrity performance standard P09 – Pipeline / Trunkline Systems.

Summary of Assessment Outcomes

Receptor	Impact	Receptor Sensitivity Level	Risk: Consequence	Risk: Likelihood	Risk Rating
Water quality	Change in water quality	Low value (open water)	Slight (E)	Highly unlikely	Low
Air quality	Change in air quality	Low value (offshore airshed)	Slight (E)	Highly unlikely	Low

Overall Risk Rating: The risk rating for an unplanned hydrocarbon release from a worst-case subsea / Trunkline loss of containment is Low based on a Slight consequence to a low value receptor (open water/offshore airshed) and a Highly Unlikely likelihood. The risk rating for individual receptors are consistent with the levels rated in the OPP.

ALARP Statement:

On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type (i.e. Decision Type A, Section 2.3.3), Woodside considers the adopted controls appropriate to manage the risks of an unplanned hydrocarbon release as a result of subsea loss of containment.

The principle of inherent safety and environmental protection is based on the design of the subsea equipment, flowlines, export trunkline and risers. The system is design in accordance with recognised subsea design standards and subject to third-party independent verification. Woodside practices mean that the system is operated within their design envelope through operating practices, and assurance through maintenance and inspection. If hydrocarbon loss of containment occurs, mitigation measures and emergency response protocols are in place to minimise the consequence.

Controls have been selected following hierarchy of control principles and consider independence of each barrier and their type of effect in controlling the hazardous event. Qualitative spill risk assessment considers studies of gas release behaviour and fate through a deep water-column when considering potential for environmental impact and escalation potential. Based on the environmental risk assessment outcomes (Highly Unlikely likelihood and Slight consequence) and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the potential impacts and risks.

The controls in place for prevention and mitigation of significant process safety release events are specified and assured through implementing the Scarborough FPU and Export Trunkline Safety Cases, SCE management procedures including performance standards for SCEs, and MSPS for Safety Critical Management System Controls.

The application of Woodside Risk Management Procedures, and implementation of the Safety Cases involves the continuous identification of hazards, systematic assessment of risks and ongoing assessment of alternative control measures to reduce risk to ALARP, which includes:

- ongoing hazard identification, risk assessment and the identification of control measures
- ongoing integrity management of hardware control measures in accordance with the technical performance standards which define requirements to be suitably maintained, such that they retain effectiveness, functionality, availability and survivability
- subsea system, pipeline and riser codes and standards.

Given the controls in place to prevent subsea equipment or Trunkline loss of containment events and mitigate their consequences, alongside controls of subsea IMMR activities, it is considered that the risk associated with Subsea Loss of Containment is managed to ALARP.

Demonstration of Acceptability

Acceptability Criteria and Assessment

Demonstration of acceptability for the sources of aspect and associated impacts assessed in this section are provided in **Section 7.2.6.4** of the Scarborough OPP. The Petroleum Activities Program meets the acceptability criteria (**Section 2.3.5**):

- Overall risk consequence/risk ratings for individual receptors are less than the significant impact level defined in the OPP.
- EPOs and controls in the OPP that are relevant to a loss of containment have been adopted.
- There are no changes to internal context specific to this risk from the OPP.
- No potential impacts from an unplanned hydrocarbon release from subsea equipment loss of containment was raised during consultation (**Section 5**).

Acceptability Statement:

The impact assessment has determined that an unplanned hydrocarbon release resulting from a subsea loss of containment represents a low current risk rating and is unlikely to result in a risk consequence greater than Slight. A gas release is expected to only result in a temporary change to water and air quality with no pathway for impacts to habitat or ecosystem function or integrity. Relevant recovery plans and conservation advice have been considered during the impact assessment, and the Petroleum Activities Program is not considered to be inconsistent with the overall recovery objectives and actions of these. The adopted controls are considered consistent with industry legislation, codes and standards, and industry good practice. Risk and impact reduction measures have been identified and implemented through design, with subsea system operations aligned with Woodside’s proven operational management system.

The potential risks and consequences are considered acceptable if the adopted controls are implemented. Activities do not have a significant impact on MNES (Section 2.4.2 including those with an First Nations connection with, or traditional use in, nearshore areas as defined in Section 4.9). Therefore, Woodside considers the adopted controls appropriate to manage the risks and consequences of a subsea loss of containment to a level that is broadly acceptable and demonstrates the EPO is met.

- critical equipment failures
- human/management error.

Escalation from other significant environment events interacting with the FPU can cause topsides loss of containment:

- Loss of Structural Integrity/Stability (including FPU position keeping/mooring failure) (Section 6.8.3)
- Loss of Marine Vessel Separation with FPU (Section 6.8.2).

Diesel LOC from Bunkering

Bunkering of marine diesel can occur vessels to vessel (including to the ASV) and the vessel to FPU. It is likely refuelling of vessels (and other equipment) will take place primarily within the Offshore Operational Area (comparatively there is a low likelihood for refuelling within the Trunkline Operational Area due to the nature of vessel activities primarily transiting this area).

The FPU and ASV have a dedicated diesel bunkering station which supports pumping of diesel from Support Vessel to FPU diesel storage systems. Onboard transfer of diesel is also undertaken.

LOC from Diesel System

FPU diesel storage tanks (2 x 219 m³) are housed within the East and West crane pedestals and are integral into the structure which supports the crane. As such the tank structures have a low probability of failure.

Both Storage Tanks will be in operation simultaneously and are lined up to the Diesel Circulation Pumps continuously.

During design development, Main Power Generators maximum consumption and day tanks filling rate have been reduced to eliminate potential uncontained overflow of the machinery open drain tank. The Diesel system supplies diesel to a number of users via day tanks such as the emergency power generator and the fire water pumps generator. Diesel will be supplied to day tanks via diesel distribution network (normally there will be no flow to the day tanks).

The Machinery Open Drain (MOD) system collects liquid with potential lube oil/diesel content both from hazardous and non-hazardous areas. The collected hydrocarbon drains will be pumped to the Open Drain Waste Drum for onshore disposal.

The Control Room Operator is alerted to an increasing level of liquids in the MOD tank that would signify an upstream leakage or spill that would need to be investigated.

Topsides Loss of Containment – Credible Scenarios

Worst case Topsides loss of containment scenarios that could occur are:

- A loss of containment and subsequent hydrocarbon release to the marine environment due to diesel storage tank or distribution system failure. The largest total single tank diesel inventory in crane pedestals is 220 m³ per tank, which are the largest liquid hydrocarbon storage tanks on the facility.
- A loss of containment and subsequent hydrocarbon release to the marine environment due to Lube Oil tank leaks and overflow onto Hazardous Open Drains.

Bunkering Loss of Containment – Credible Scenarios

Two credible scenarios for the loss of containment of marine diesel during bunkering operations have been identified:

Scenario 1 – Partial or total failure of a bulk transfer hose or fittings during bunkering, due to operational stress or other integrity issues could spill marine diesel to the deck and/or into the marine environment. This would be in the order of less than 0.2 m³ (200 L), based on the likely volume of a bulk transfer hose (assuming a failure of the dry break and complete loss of hose volume).

Scenario 2 – Partial or total failure of a bulk transfer hose or fittings during bunkering, combined with a delay to shutoff fuel pumps, for a period of up to fifteen minutes, resulting in approximately 50 m³ (50,000 L) marine diesel lost to the deck and/or into the marine environment.

Given the limited volume of the potential release and offshore location, no modelling has been undertaken as potential diesel releases are less than the 470 m³ of MDO modelled and assessed in Section 6.8.3 for the Offshore Operational Area, and 250 m³ modelled and assessed in Section 6.8.2 for the Trunkline Operational Area

Woodside spill records indicate that while there have been smaller releases (<30 L) associated with bunkering, there have been no recorded partial or total failures of bulk transfer hose or fittings during bunkering, combined with a failure in procedure to shut off fuel pumps for a period of up to fifteen minutes. Thus the scenario of an 50 m³ loss of diesel is a conservative worst-case.

International Tanker Owners Pollution Federation Limited (IOTPF) (2020) data reports that for tanker operations during 1970-2017, 7% of small (<7 tonnes) spills occurred during bunkering and 2% of medium (7-700 tonnes) spills. While this data is from the oil tanker industry it has been used as an indicator of potential for spills associated with bunkering activities. A risk assessment by AMSA of oil spills in Australian ports and waters (Det Norske Veritas, 2011) identifies transfer spills as a risk.

Detailed Impact Assessment

Water Quality

The highly-mixed, open water location and characteristics of hydrocarbons released will result in rapid evaporation and dispersion. However, MDO contains a small proportion of heavy components (or low-volatile components) that tend to physically entrain into the upper water column in the presence of moderate winds (i.e. >12 knots) and breaking waves but may resurface if these conditions abate. If a substantial spill occurred, the heavier components could remain entrained or remain on the sea surface for an extended period and travel significant distances from the source, albeit at low concentrations.

Predicted weathering of marine diesel, based on typical conditions in the region, indicates that about 24% of the oil mass should evaporate within the first 24 hours (Figure 6-9) (RPS, 2024). After this time the majority of the remaining hydrocarbon is entrained into the upper water column.

The magnitude of potential impact of a change in water quality from unplanned release of MDO is assessed as slight. Receptor sensitivity of water quality is low (low value, open ocean), and therefore the consequence of a release of hydrocarbons on water quality is Negligible (F).

Plankton

MDO may cause acute toxic effects to planktonic organisms that come into contact close to the spill source at the time of the spill however. Given the short generation times and high productivity of planktonic communities, this impact would be localised and have a Negligible (F) on planktonic species populations.

Marine Fauna

A range of marine species may be present around the FPU / ASV or vessels being refuelled, such as cetaceans, marine turtles, whale sharks, fishes and birds. These species are widely distributed relative to the potential EMBA that would result from a topsides loss of containment or bunkering release (due to the smaller volume of hydrocarbons compared to the scenario considered in Section 6.8.3). Many large marine fauna in the region are migratory and are seasonally present in the PAA, which reduces the potential for exposure depending on the timing of a spill. Marine fauna at or near the sea surface may be contacted by liquid-phase hydrocarbons, resulting in oiling. This may lead to impacts such as irritation of sensitive mucous membranes (e.g. eyes, mouth and digestive tract), matting of feathers (leading to inability to fly and loss of insulation) or clogging of filtering structures (e.g. gills). Pelagic and site attached fish (i.e. those resident around risers and jackets) may be exposed to spilled hydrocarbons, but are expected to avoid areas of high concentrations. Depending on the degree of exposure and the sensitivity of the receptor, these impacts may lead to injury or death. Mortality of larger fauna is not expected to occur. No impacts to ecosystem function are expected. Given the volatile nature of the hydrocarbons, the potential for these impacts is largely constrained to the initial 12 hours immediately after the release. Hence, the highest potential impacts to species would be Minor (D).

Escalation Events

Significant FPU topsides loss of containment or bunkering loss with ignition or dropped object events, present possible causes for FPU Loss Structural Integrity/Stability Section 6.8.3. Process safety management measures described in this FPU Topsides Loss of Containment section are applicable to topsides controls (preventative and mitigative barriers), with escalation consequence and risk presented in Section 6.8.3. Significant FPU topsides loss of containment events with potential for ignition and escalation are also managed under the Scarborough Safety Case, with worst-case associated liquid hydrocarbon release to environment considered Highly Unlikely.

Outcome Mitigation

Potential hydrocarbon release environmental consequences associated with topsides and bunkering loss of containment are mitigated at the FPU by detection and alarm, emergency shutdown (for isolation of equipment such as diesel circulation pumps, plus reservoir, topsides and pipeline/trunkline inventories), facility drain systems, critical communications systems and emergency preparedness (including facility ERP, spill response arrangements). Ignition control, emergency power, safety critical buildings and fire/explosion escalation controls (such as depressurisation blowdown systems and firewalls) are part of the FPU design as described in the Scarborough Safety Case for Major Accident mitigation, thus contributing to management of associated potential environmental consequences of MAEs.

The likelihood of worst-case credible hydrocarbon release from topsides equipment and spill during bunkering has been assessed as Unlikely.

Quantitative Risk Assessment

An MDO spill from a topsides or bunkering loss of containment is expected to be confined to within several kilometres of the release site, and well within the affected area assessed in Section 6.8.3. Once released to the open offshore marine environment a spill of MDO is expected to weather rapidly. As a consequence, the potential for impacts to environmental receptors is limited to those in the immediate vicinity. MDO weathering modelling indicates approximately 24% of the mass should evaporate within the first 24 hours (Section 6.8.1.8).

Commonwealth and State Managed Fisheries

A change in marine fauna behaviour or injury or mortality to marine fauna – in particular to commercially targeted species, or their prey species (e.g. plankton) – can impact fisheries.

Fish exposure to hydrocarbon can result in ‘tainting’ of their tissues. Even very low levels of hydrocarbons can impart a taint or ‘off’ flavour or smell in seafood. Tainting is reversible through the process of depuration which removes hydrocarbons from tissues by metabolic processes, although it depends on the magnitude of the contamination. Fish have a high capacity to metabolise these hydrocarbons while crustaceans (such as prawns) have a reduced ability (Yender et al., 2002). Seafood safety is a major concern associated with spill incidents. Therefore, actual or potential contamination of seafood can affect commercial and recreational fishing and can impact seafood markets long after any actual risk to seafood from a spill has subsided (Yender et al., 2002).

A major spill could result in the establishment of an exclusion zone around the spill affected area. There would be a temporary prohibition on fishing activities for a period and subsequent potential for economic impacts to affected commercial fishing operators. Additionally, hydrocarbon can foul fishing equipment such as traps and trawl nets, requiring cleaning or replacement.

MDO presence in the water would be restricted to the surface and upper water column only. Dissolved aromatics (i.e. the form that is bioavailable) are in such small concentrations in MDO that their effect in the marine environment is negligible (F); i.e. tainting from an MDO exposure is not considered likely to occur. Any exclusion zone established would be limited to the immediate vicinity of the release point, and due to the rapid weathering of MDO would only be in place days after release, therefore physical displacement to vessels is unlikely to be a significant impact.

A number of Commonwealth and State fishery management areas are located within the PAA and EMBA. FishCube data was requested to analyse the potential for interaction of fisheries with the PAA, which was used to determine consultation with State Fisheries who may be impacted by proposed petroleum activities (Department of Primary Industries and Regional Development [DPIRD], 2021). Table 4-27 provides an assessment of the potential interaction and provides further detail on the fisheries that have been identified through desk-based assessment and consultation (Section 5).

In the highly unlikely event of a release of marine diesel to the environment there may be the presence of hydrocarbons in areas used by the fisheries that overlap the EMBA (Table 4-27).

Although potential impacts from a worst case spill could include mortality or sub-lethal injury/illness of pelagic fish (described in the specific receptor evaluation), this would be expected to comprise a small proportion of the resident and transitory population. Given the hydrocarbon characteristics, expected rapid weathering to below impact thresholds and low fishing effort, an unplanned hydrocarbon spill from the Petroleum Activities Program is not expected to have an adverse effect on the sustainability of commercial fishing; or to interfere with other marine users.

Based on the detailed risk evaluation, the magnitude of potential impacts to Commonwealth and State managed fisheries from an unplanned hydrocarbon release is assessed as Slight (E).

Shipping

In the event of a spill, an exclusion zone may be established around the spill affected area. This could result in exclusion of other users such as shipping vessels or vessels used by the mining and petroleum industries. Any exclusion zone established would be limited to the immediate vicinity of the release point, and due to the rapid weathering of MDO would only be in place for days after release, therefore physical displacement to vessels is unlikely to be a significant impact.

Given hydrocarbon characteristics, expected rapid weathering to below impact thresholds, short duration of displacement, and the offshore location of the PAA, unplanned releases of MDO are not expected to interfere with shipping to a great extent.

Based on the assessment, the magnitude of a potential impact to shipping associated with an unplanned release of hydrocarbons is Slight (E).

Summary of Assessment Outcomes

Receptor	Impact	Receptor Sensitivity Level	Risk Consequence	Likelihood	Risk Rating
Water quality	Change in water quality	Low value (open water)	Slight (E)	Unlikely	Moderate
Plankton	Injury/mortality to fauna	Low value (open water)	Negligible (F)	Unlikely	Low
Marine mammals	Change in fauna behaviour	High value species	Negligible (F)	Unlikely	Low
	Injury/mortality to fauna	High value species	Negligible (F)	Unlikely	Low
Fish	Change in fauna behaviour	High value species	Slight (E)	Unlikely	Moderate

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

	Injury/mortality to fauna	High value species	Slight (E)	Unlikely	Moderate
Marine reptiles	Change in fauna behaviour	High value species	Slight (E)	Unlikely	Moderate
	Injury to fauna	High value species	Slight (E)	Unlikely	Moderate
Seabirds and migratory shorebirds	Change in fauna behaviour	High value species	Slight (E)	Unlikely	Moderate
	Injury to fauna	High value species	Slight (E)	Unlikely	Moderate
Commonwealth and State managed fisheries	Changes to the functions, interests or activities of other users	High value marine use	Slight (E)	Highly unlikely	Low
Shipping	Changes to the functions, interests or activities of other users	Medium value	Slight (E)	Highly unlikely	Low

Overall Risk Consequence: The risk rating for an unplanned worst-case discharge from FPU topsides including bunkering loss of containment is Moderate based on a Slight consequence to the high value receptors (seabirds and migratory shorebirds and marine reptiles), an unlikely likelihood. The risk consequence/risk rating for individual receptors are consistent with the levels rated in the OPP.

Therefore, no overall benefit.	Disproportionate . The cost/sacrifice outweighs the benefit gained.	No

ALARP Statement:

On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type (i.e. Decision type A, Section 2.3.3), Woodside considers the adopted controls appropriate to manage the risks and consequences of an unlikely unplanned hydrocarbon release as a result of a topside loss of containment or bunkering/refuelling.

The principle of inherent safety and environmental protection is based on the design of the FPU equipment. The system is design in accordance with recognised design standards and subject to third-party independent verification. Woodside practices ensure the system is operated within their design envelope through operating practices, and assurance through maintenance and inspection. If hydrocarbon loss of containment occurs, mitigation measures and emergency response protocols are in place to minimise the consequence.

Based on the environmental risk assessment outcomes (Unlikely likelihood and Moderate consequence) and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the potential impacts and risks.

The controls in place for prevention and mitigation of significant process safety release events are specified and assured through implementing the Scarborough FPU Safety Case, SCE management procedures including performance standards for SCEs, and MSPS for Safety Critical Management System Controls.

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

The application of Woodside Risk Management Procedures, and implementation of the Safety Case ensures the continuous identification of hazards, systematic assessment of risks and ongoing assessment of alternative control measures to reduce risk to ALARP, which includes:

- ongoing hazard identification, risk assessment and the identification of control measures
- ongoing integrity management of hardware control measures in accordance with the technical performance standards which define requirements to be suitably maintained, such that they retain effectiveness, functionality, availability and survivability
- engineering codes and standards.

Given the controls in place to prevent loss of containment events and mitigate their consequences, alongside administrative and management system measures, it is considered that the risk associated with Topsides Loss of Containment is managed to ALARP.

Demonstration of Acceptability

Acceptability Criteria and Assessment

Demonstration of acceptability for the sources of aspect and associated impacts assessed in this section are provided in Section 7.2.6.4 and 7.2.1.3 of the Scarborough OPP. The Petroleum Activities Program meets the acceptability criteria (Section 2.3.5):

- Overall risk consequence/risk ratings for individual receptors are less than the significant impact level defined in the OPP.
- EPOs and controls in the OPP that are relevant to a topsides loss of containment have been adopted.
- There are no changes to internal context specific to this risk from the OPP.
- Potential impacts from an unplanned hydrocarbon release, from the topsides loss of containment, was raised during consultation (Section 5) and this feedback was considered in the finalisation of the EP.

Acceptability Statement:

The impact assessment has determined that, given the adopted controls, a topsides loss of containment or accidental discharge of hydrocarbons as a result of bunkering failure represents a moderate risk rating that is unlikely to result in a consequence greater than minor that is localised to the release location. Further opportunities to reduce the risks have been investigated above. The adopted controls are considered good practice and meet requirements of the facility Safety Case.

The potential risks are considered broadly acceptable if the adopted controls are implemented. Activities do not have a significant impact on MNES (Section 2.4.2). Therefore, Woodside considers the adopted controls appropriate to, manage the risks of a topsides loss of containment to a level that is acceptable; and demonstrate the EPO is met.

Chemical storage areas are typically set up in cabinets or drained/bunded storage areas to contain releases to deck from transportable containers (e.g. bulk containers, barrels, drums, pails, etc.). Releases from equipment are predominantly from the failure of hydraulic hoses or minor leaks from process components, or spills during refuelling of equipment, which can either be located within bunded/drained areas or outside of bunded/drained areas (e.g. over grating on cranes).

The FPU and Support Vessels/ASV also store other non-process chemicals and hydrocarbons, in various volumes (Section 3.9.16.2 and Section 3.9.16.1). Operational non-process chemicals and maintenance chemicals present on the facility and support vessels/ASV are generally held in low quantities (usually less than 50 L isolatable volumes).

Detailed Impact Assessment

Assessment of Potential Impacts

Water Quality

Unplanned discharges of non-process chemicals and hydrocarbons may decrease the water quality in the immediate vicinity of the release. Only small volumes are anticipated, resulting in very short-term impacts to water quality, and limited to the immediate release location.

MEG is miscible in water, non-hazardous and biodegradable. It is rated OCNS Group E and is considered PLONOR. A maximum credible spill of MEG is expected to mix with the receiving environment with no lasting environmental impact.

Accidental releases of chemicals (including corrosion inhibitor) or non-process hydrocarbons will decrease the water quality in the immediate area of the release. The consequence is expected to be a Negligible (F) given the open ocean mixing environment, distance from sensitive receptors and relatively low credible release volumes.

Marine Fauna

Depending on the chemical released, the toxicity and/or potential to bioaccumulate may potentially result in localised impacts to pelagic fish or other marine species in the vicinity of the discharge. Given that surface discharges are rapidly dispersed, and subsea discharges (from ROVs) would be of very small volumes, potential impacts would be highly localised and temporary. Potential impacts to plankton from an accidental chemical spill may include acute toxicity, resulting in mortality of planktonic organisms. Given the rapid turnover of plankton communities and nature and scale of the credible releases, these impacts would be short-lived (hours to days). Impacts to fish are expected to be of no lasting effect, as fish species are mobile and expected to avoid the area affected by an accidental chemical spill. Impacts to air-breathing fauna such as cetaceans, birds and marine turtles are expected to be restricted to irritation of sensitive membranes, such as the eyes, mouth and digestive system. As such, potential impacts are considered Slight (E).

Summary of Assessment Outcomes

Receptor	Impact	Receptor Sensitivity	Risk Consequence	Likelihood	Risk Rating
Water quality	Change in water quality	Low value (open water)	Negligible (F)	Possible	Moderate
Migratory shorebirds and seabirds	Injury/mortality to fauna	High value species	Slight (E)	Highly unlikely	Low
Fish, sharks and rays		High value species	Slight (E)	Highly unlikely	Low
Marine mammals		High value species	Slight (E)	Highly unlikely	Low
Marine reptiles		High value species	Slight (E)	Highly unlikely	Low

Overall Risk Consequence: The overall risk consequence/risk rating for an unplanned deck and subsea spills is Moderate based on negligible consequence to the low value receptors (Water Quality) and a possible likelihood. The risk consequence/risk ratings for water quality is consistent with the levels rated in the Scarborough OPP. Potential impacts to marine fauna have been additionally assessed in this EP; there is no change in risk rating (low); however, the risk consequence is slightly higher due to the higher receptor sensitivity level.

Demonstration of ALARP				
Control Considered	Control Feasibility (F) and Cost/ Sacrifice (CS)	Benefit in Impact/Risk Reduction	Proportionality	Control Adopted
Legislation, Codes and Standards				
Liquid chemical and fuel storage areas are banded or secondarily contained when they are not being handled/moved temporarily.	F: Yes. CS: Minimal cost. Standard practice.	Implementation of procedures for chemical storage and handling on the vessels will reduce the consequence of impacts resulting from unplanned discharges to the marine environment by ensuring chemicals have been assessed for environmental acceptability.	Controls based on legislative requirements – must be adopted.	Yes C 19.1
Good Practice				
Chemicals will be selected with the lowest practicable environmental impacts and risks subject to technical constraints.	F: Yes. CS: Minimal cost. Standard practice.	Environmental assessment of chemicals in discharges will reduce the consequence of impacts resulting from discharges to the marine environment by ensuring chemicals have been assessed for environmental acceptability. Planned discharges are required for the safe execution of activities and therefore no reduction in likelihood can occur.	Benefits outweigh cost/sacrifice.	Yes C 8.4
Spill kits positioned in high-risk locations around the FPU/crewed vessels, excluding the USV (near potential spill points such as transfer stations).	F: Yes. CS: Minimal cost. Standard practice.	Spill kits would reduce the likelihood of a deck spill from entering the marine environment. The consequence is unchanged.	Benefits outweigh cost/sacrifice.	Yes C 17.7
Implementation of waste management procedures which provide for safe handling and transportation, segregation and storage and appropriate classification of all waste generated.	F: Yes. Demonstration of ALARP				
Control Considered	Control Feasibility (F) and Cost/Sacrifice (CS)	Benefit in Impact/Risk Reduction	Proportionality	Control Adopted
A reduction in the volumes of chemicals and hydrocarbons stored onboard vessels.	F: Yes. Increases the risks associated with transportation and lifting operations. CS: Project delays if required chemicals not on board. Increases the risks associated with transportation and lifting operations.	No reduction in likelihood or consequence since chemicals will still be required to enable operational activities to occur.	Disproportionate. The cost/sacrifice outweighs the benefit gained.	No

ALARP Statement:

On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type (i.e. Decision Type A, Section 2.3.3), Woodside considers the adopted controls appropriate to manage the risks and consequences of an unplanned release of chemicals. As no reasonable additional/alternative controls were identified that would further reduce the risks and consequences without grossly disproportionate sacrifice, the risks and consequences are considered ALARP.

Demonstration of Acceptability

Acceptability Criteria and Assessment

Demonstration of acceptability for the sources of aspect and associated impacts assessed in this section are provided in Section 7.2.1 of the Scarborough OPP. The Petroleum Activities Program meets the acceptability criteria (Section 2.3.5):

- Overall risk consequence for individual receptors are less than the significant impact level defined in the OPP.
- EPOs and controls in the OPP that are relevant to an unplanned chemical and minor hydrocarbon spill have been adopted.
- There are no changes to internal/external context specific to this risk from the OPP, including issues raised during consultation.

Acceptability Statement:

The impact assessment has determined that unplanned chemical and minor hydrocarbon spills represents a Moderate current risk rating and is unlikely to result in a risk consequence greater than Slight. Relevant recovery plans and conservation advice have been considered during the impact assessment, and the Petroleum Activities Program is not considered to be inconsistent with the overall recovery objectives and actions of these recovery plans and conservation advice. The adopted controls are considered consistent with industry legislation, codes and standards, good practice and professional judgement and meet the requirements and expectations of Australian Marine Orders identified during impact assessment.

Further opportunities to reduce the impacts have been investigated above. The potential risks and consequences are considered acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the risks and consequences of an unplanned discharge of chemicals/hydrocarbons to a level that is broadly acceptable and demonstrates the EPO is met.

Description of Source of Impact/Risk
<p>Normal operations on the FPU and Vessels will generate a variety of hazardous and non-hazardous wastes. These materials could potentially impact the marine environment, if incorrectly disposed of, lost overboard or discharged in significant quantities.</p> <p>Non-hazardous wastes include domestic and industrial wastes such as paper and cardboard, aluminium cans, bottles, polystyrene, organics and scrap steel. Hazardous wastes include recovered solvents, excess or spent chemicals, oil contaminated materials (e.g. sorbents, filters and rags), batteries, used lubricating oils and potentially material containing Naturally Occurring Radioactive Material (NORMs). Sand and sludges containing a variety of contaminants (e.g. mercury, NORMS) may be periodically generated during well clean up, process and vessel maintenance.</p> <p>Equipment (small hand-held tools) and Personal Protective Equipment (PPE) may also be accidentally lost overboard. Equipment that has been recorded as being lost on other similar facilities and vessels has primarily been windblown or dropped overboard and has included things such as hardhats, gloves, safety glasses and small tools or materials. Equipment (small hand-held tools) and PPE are not classified as waste as per the Woodside <i>Offshore Facilities Waste Management Plan</i> and are not included any further in this risk assessment. Equipment (small hand-held tools) and PPE lost overboard are recorded, investigated and corrective actions tracked as per requirements in Section 7.10.3 and Section 7.12.3. Loss of hazardous and non-hazardous wastes have occurred during backloading activities, periods of adverse weather and incorrect waste storage.</p> <p>All waste materials not suitable for discharge to the environment, including hazardous wastes (i.e. liquid and solid wastes), generated during the Petroleum Activities Program are transported to shore for disposal or recycling by Woodside’s licenced waste contractor.</p>

Detailed Impact Assessment

Assessment of Potential Impacts

The potential impacts of hazardous or non-hazardous solid waste accidentally discharged to the marine environment include contamination of the environment as well as secondary impacts relating to potential contact of marine fauna with wastes. This could result in entanglement or ingestion and lead to injury and death of individual animals and changes to aesthetic values. The temporary or permanent loss of waste materials into the marine environment is not likely to have a significant environmental impact, based on the location of the PAA, the types, size and frequency of wastes that could occur, and species present.

Water and Sediment Quality

Hazardous solid wastes such as paint cans, oily rags, etc., can cause localised contamination of the water and sediment through a release of toxins and chemicals. Given likely small volumes of any unplanned solid waste discharge, and the occasional nature of the event, these would result in temporary and highly localised changes to the water quality and has been assessed as negligible (F)

Seabirds and Migratory Shorebirds, Fish, Marine Reptiles and Marine Mammals

Marine fauna, including fish, seabirds and shorebirds, marine mammals and marine reptiles may be impacted through ingestion or entanglement of waste or through exposure to toxic chemicals. Ingestion or entanglement of marine fauna has the potential for physical harm which may limit feeding/foraging behaviours potentially resulting in mortalities. Injury and fatality to vertebrate marine life caused by ingestion of, or entanglement in, harmful marine debris was listed as a key threatening process under the EPBC Act in August 2003 (DoEE, 2018). The Threat Abatement Plan for the impacts of marine debris on the vertebrate wildlife of Australia’s coasts and oceans (DoEE, 2018) identifies EPBC Act-listed species for which there are scientifically documented adverse impacts resulting from marine debris. Marine turtles and seabirds in particular may be at risk from plastics which may cause entanglement or be mistaken for food (e.g. DoEE, 2018; Commonwealth of Australia, 2017) and ingested causing damage to internal tissues and potentially preventing feeding activities. In the worst instance this could have a lethal affect to an individual. Marine debris has been identified as threat in the Recovery Plan for Marine Turtles in Australia (2017–2027).

Impacts to species including fish, birds, marine mammals and marine reptiles from the unplanned discharge of solid waste is unlikely given low occurrence of unplanned discharges and the location of the activities at significant distance from sensitive habitats. Significant impacts are unlikely to occur at an individual level and will not occur at a population level, nor result in the decrease of the quality of the habitat such that the extent of these species is likely to decline.

While the threat abatement plan for impacts of marine debris on vertebrate marine life does not list explicit management actions for non-related industries (DEWHA, 2009b), management controls will reduce the risk of unplanned discharge of solid waste.

The temporary or permanent loss of waste materials into the marine environment is not likely to have a significant environmental impact, based on the nature and scale of activities that may generate wastes, the types, size and frequency of wastes that could occur. As such, potential impacts are considered Slight (E).

Summary of Assessment Outcomes

<i>Receptor</i>	<i>Impact</i>	<i>Receptor Sensitivity</i>	<i>Risk Consequence</i>	<i>Likelihood</i>	<i>Risk Rating</i>
Water quality	Change in water quality	Low value (open water)	Negligible (F)	Unlikely	Low
Sediment quality	Change in water quality	Low value (open water)	Negligible (F)	Unlikely	Low
Seabirds and migratory shorebirds	Injury/mortality to fauna	High value species	Slight (E)	Unlikely	Moderate
Fish, sharks and rays		High value species	Slight (E)	Unlikely	Moderate
Marine mammals		High value species	Slight (E)	Unlikely	Moderate
Marine reptiles		High value species	Slight (E)	Unlikely	Moderate

Overall Risk Consequence: The overall risk rating for unplanned discharge of hazardous and non-hazardous solid waste is Moderate based on a Slight consequence, to the high value receptors (marine fauna), and unlikely likelihood. The risk consequence levels/risk ratings for individual receptors are consistent with the levels rated in the OPP.

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

which provide safe handling and transportation, segregation and storage and appropriate classification of all waste generated.	CS: Minimal cost. Standard practice.	unplanned release. The consequence is unchanged.		C 20.3
<p>Vessel ROV or crane may be used to attempt recovery of solid wastes lost overboard.</p> <p>Where safe and practicable for this activity will consider:</p> <ul style="list-style-type: none"> risk to personnel to retrieve object whether the location of the object is in recoverable water depths object's proximity to subsea infrastructure ability to recover the object (i.e. nature of object, lifting equipment or, ROV availability and suitable weather). <p>Any material dropped objects/waste that remain in the title will undergo an impact assessment and be added to the inventory.</p>	<p>F: May not always be possible. Assessed case by case.</p> <p>CS: Potentially significant cost. Standard practice.</p>	Occurs after an unplanned release of solid waste and therefore no change to the likelihood. Since the waste objects may be recovered, a reduction in consequence is possible.	Benefit outweighs cost sacrifice.	Yes C 20.5

Professional Judgement – Eliminate

No additional controls identified.

Professional Judgement – Substitute

No additional controls identified.

Professional Judgement – Engineered Solution

No additional controls identified.

ALARP Statement:

On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type (i.e. Decision Type A, Section 2.3.3), Woodside considers the adopted controls appropriate to manage the risks and consequences of accidental loss of hazardous or non-hazardous solid wastes/equipment to the marine environment. As no reasonable additional/alternative controls were identified that would further reduce the risks and consequences without grossly disproportionate sacrifice, the risks and consequences are considered ALARP.

Demonstration of Acceptability

Acceptability Criteria and Assessment

Demonstration of acceptability for the sources of aspect and associated impacts assessed in this section are provided in **Section 7.2.2.3** of the Scarborough OPP. The Petroleum Activities Program meets the acceptability criteria (**Section 2.3.5**):

- Overall risk consequence/risk ratings for individual receptors are less than the significant impact level defined in the OPP.

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

Demonstration of Acceptability
<ul style="list-style-type: none"> EPOs and controls in the OPP that are relevant to an unplanned release of hazardous and non-hazardous wastes have been adopted. There are no changes to internal/external context specific to this risk from the OPP, including issues raised during consultation.
<p>Acceptability Statement:</p> <p>The impact assessment has determined that unplanned discharges from a release of solid hazardous and non-hazardous wastes represents a low current risk rating and is unlikely to result in a risk consequence greater than slight. Relevant recovery plans and conservation advice have been considered during the impact assessment, and the Petroleum Activities Program is not considered to be inconsistent with the overall recovery objectives and actions of these recovery plans and conservation advice. The adopted controls are considered consistent with industry legislation, codes and standards, good practice and professional judgement and meet the requirements of Australian Marine Orders identified during impact assessment.</p> <p>The potential risks and consequences are considered acceptable if the adopted controls are implemented. Activities do not have a significant impact on MNES (Section 2.4.2) including those with an First Nations connection or with traditional use in nearshore areas as defined in Section 4.9). Therefore, Woodside considers the adopted controls appropriate to manage the impacts and risks of accidental discharge of non-hazardous and hazardous waste to a level that is broadly acceptable; and demonstrates the EPO is met.</p>

- Crane operator error; dropped anchor/object from Support Vessel
- adverse weather conditions.

Detailed Impact Assessment

Assessment of Potential Impacts

In the unlikely event of an object being dropped into the marine environment, potential environmental effects would be limited to localised physical impacts on benthic communities. In most cases, objects will be able to be recovered and therefore these impacts will also be temporary in nature. However, there may be instances where objects are unable to be recovered due to health and safety, operational constraints or other factors such as the difficulty of recovering dropped objects at depth. When dropped objects are unable to be recovered, the impact will continue to be localised but would also be long-term.

Epifauna and Infauna

As a result of a change in water quality and change in habitat, localised injury or mortality to marine fauna resulting from an increase in turbidity may occur. Given a change to water quality is highly unlikely, the only receptors that would potentially be at risk of unplanned seabed disturbance are bottom dwelling species including epifauna and infauna. Benthic communities, including epifauna and infauna may be impacted by the dropped objects on the seabed. If not recovered, dropped objects may result in the permanent loss of a small area under the object.

Given the generally sparse benthic communities in the PAA and that no threatened or migratory species or ecological communities were identified, and those epifauna and infauna communities observed are likely to be well represented elsewhere in the region; impacts are expected to be restricted to a localised proportion of epifauna and infauna communities.

Epifauna and benthic habitats are likely to be sparse, comprising of ascidians, sponges, invertebrate communities and octocorals representative of the wider region, as well as larger motile organisms (demersal fish, shrimp, sea cucumbers etc.) and infauna (i.e. polychaetes). These communities are well represented through the region, and any impacts are likely to be at a localised proportion of communities (Keesing, 2019; Advisian, 2019a). The proposed export trunkline route avoids areas of potentially high diversity, relative to the surrounding area such as rock pinnacles.

The magnitude of potential impacts to epifauna and infauna from unplanned seabed disturbance during activities associated with the PAP is evaluated to be Slight. Sensitivity for epifauna and infauna is low, leading to a Negligible (F) risk consequence.

KEFs

The temporary or permanent loss of dropped objects into the marine environment during operational activities (as described above) is likely to result in a localised impact only, as the benthic communities associated with the PAA are of low sensitivity and are broadly represented throughout the NWMR. As described in Section 4.7, the Exmouth Plateau KEF overlaps the Offshore Operational Area and deeper waters of the Trunkline Operational Area. Benthic communities in these areas of the PAA are representative of the Exmouth Plateau and of deep water soft sediment habitats reported in the wider region (e.g. BHP Billiton, 2004; Woodside, 2005; Woodside, 2006; Brewer et al., 2007; RPS, 2011; Woodside, 2013; Apache, 2013).

Two additional KEFs overlap the Trunkline Operational Area: the Continental Slope Demersal Fish Communities and Ancient Coastline at 125 m Depth Contour KEFs. The Continental Slope Demersal Fish Community is recognised as a KEF because of its biodiversity values, including high levels of endemism (DAWE, 2020). The Trunkline Operational Area intersects a small portion of the KEF (Figure 4-13), across one of its thinnest points throughout its distribution. The Ancient Coastline at 125 m Depth KEF overlaps the Trunkline Operational Area, located about 360 km offshore (Figure 4-13), north-north-west of the Montebello Islands. External inspections of the export trunkline will be non-routine, and conducted where required, such as after a large cyclone event. The window where potential dropped objects may occur from Support Vessels will be extremely small and temporary, with any impact to the KEFs from unplanned habitat disturbance restricted to the footprint of a dropped object and will be highly localised.

Given the nature and scale of risks and consequences from dropped objects, no lasting effect is expected to seabed sensitivities within the PAA. Further, considering the types, size and frequency of dropped objects that could occur, it is highly unlikely that a dropped object would have a significant impact on any benthic community. Any unplanned seabed disturbance within the KEFs would be highly localised and relatively small compared to the size of the KEFs. There will be no substantial adverse effect on the KEFs or the communities within them. On this basis, the magnitude of potential impacts to KEFs from unplanned seabed disturbance during activities is Slight. Receptor sensitivity for KEFs is high, resulting in a Minor (D) risk consequence.

AMPs

The Trunkline Operational Area intersects the Montebello Marine Park between KP 109 to KP191. Dominant benthic organisms recorded within the section of the Trunkline Operational Area intersecting the AMP have included a wide

Detailed Impact Assessment					
<p>variety of sponges and soft corals including whips and gorgonians, hydroids, seapens and crinoids (Advisian, 2019a), however these are typical of the benthos found both within the AMP (Advisian, 2019a) and regionally (Keesing, 2019). Due to the infrequent and short duration of any IMMR activities that may occur within this region of the Trunkline Operational Area and the small footprint of any objects that potentially may be dropped, it is highly unlikely there would be notable changes to filter feeder sponge habitats or indirect effects to benthic communities from increases in suspended sediments, however, due to the high sensitivity of the receptor, the risk consequence is Slight (E).</p>					
Summary of Assessment Outcomes					
<i>Receptor</i>	<i>Impact</i>	<i>Receptor sensitivity</i>	<i>Risk Consequence</i>	<i>Likelihood</i>	<i>Risk Rating</i>
Epifauna and infauna	Change in habitat Injury/mortality to fauna	Low value	Negligible (F)	Unlikely	Low
KEFs	Change in habitat	High Value	Slight (E)	Unlikely	Moderate
AMPs	Change in habitat	High Value	Slight (E)	Unlikely	Moderate
<p>Overall Risk Consequence: The overall risk rating for disturbance to benthic habitat from unplanned seabed disturbance is Moderate based on minor consequence to the high value receptors (KEFs and Montebello AMP) and a highly unlikely likelihood. The risk consequence/risk ratings for individual receptors are consistent with the levels rated in the OPP.</p>

<p>ALARP Statement: On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type (i.e. Decision Type A, Section 2.3.3), Woodside considers the adopted controls appropriate to manage the risks and consequences of unplanned seabed disturbance. As no reasonable additional/alternative controls were identified that would further reduce the risks and consequences without grossly disproportionate sacrifice, the risks and consequences are considered ALARP.</p>				

Demonstration of Acceptability
Acceptability Criteria and Assessment
<p>Demonstration of acceptability for the sources of aspect and associated impacts assessed in this section are provided in Section 7.2.3.3 of the Scarborough OPP. The Petroleum Activities Program meets the acceptability criteria (Section 2.3.5):</p> <ul style="list-style-type: none"> • Overall risk consequence/risk ratings for individual receptors are less than the significant impact level defined in the OPP. • EPOs and controls in the OPP that are relevant to an unplanned seabed disturbance have been adopted. • There are no changes to internal/external context specific to this risk from the OPP, including issues raised during consultation.
<p>Acceptability Statement: The impact assessment has determined that disturbance to seabed from dropped objects represents a moderate current risk rating and is unlikely to result in a risk consequence greater than Slight. The adopted controls are considered industry good practice. Further opportunities to reduce the impacts have been investigated above. The potential risks and consequences are considered broadly acceptable if the adopted controls are implemented. Activities do not have a significant impact on MNES (Section 2.4.2) including those with an First Nations connection or with traditional use in nearshore areas as defined in Section 4.9. Therefore, Woodside considers the adopted controls appropriate to, manage the risks and consequences of unplanned seabed disturbance to a level that is broadly acceptable; and demonstrate the EPO is met.</p>

Description of Source of Impact/Risk														
<p>Activities associated with the Petroleum Activities Program will require vessels for FPU installation, hook-up, commissioning, start-up, support operations, IMMR and gravimetry. The type and number of vessels in the PAA at any one time, and the duration of presence, will differ depending on the activities being undertaken.</p> <p>Vessel presence will be greater during FPU installation, hook-up and commissioning, compared with ongoing normal operations.</p> <p>A number of vessels may be operating concurrently during the Petroleum Activities Program, as described in Section 6.7.4. The largest number of vessels will be present during FPU installation and hook-up, including AHTs, an LCV and Support Vessel. This activity will be of short duration (~30 days).</p> <p>Vessels operating within the PAA may present a potential hazard to marine mammals and other protected marine fauna such as whale sharks and marine reptiles. Vessel movements can result in collisions between the vessel (hull and propellers) and marine fauna, potentially resulting in superficial or serious injury that may affect life functions (e.g. movement and reproduction) or cause mortality. The frequency and severity of impacts due to collisions vary greatly due to vessel type, vessel operation (specific activity, speed), physical environment (e.g. water depth), the type of marine fauna present and their behaviours.</p> <p>Vessels within the PAA are likely to be travelling <8 knots (and will often be stationary), unless operating in an emergency. At times, vessels will be transiting within the PAA or to and from a supply base where speed could be up to a maximum of about 15 knots.</p>														

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

Seasonally, seabirds may rest and roost on the FPU facility. This presence may result in accidental bird strike incidents associated with helicopter use, and bird interactions with the FPU facility / infrastructure.

Detailed Consequence Assessment

Assessment of Potential Consequences

The likelihood of vessel/fauna collision being lethal is influenced by vessel speed, the greater the speed at impact, the greater the risk of mortality (Jensen and Silber, 2004; Laist et al., 2001). Vanderlaan and Taggart (2007) found that the chance of lethal injury to a large whale as a result of a vessel strike increases from about 20% at 8.6 knots to 80% at 15 knots. According to the data of Vanderlaan and Taggart (2007), it is estimated that the risk is less than 10% at a speed of four knots. Vessel-whale collisions at this speed are uncommon and, based on reported data contained in the US NOAA database (Jensen and Silber, 2004), there only two known instances of collisions when the vessel was travelling at less than six knots. Both of these were from whale watching vessels that were deliberately placed among whales.

Vessels undertaking the Petroleum Activities Program within the PPA are likely to be travelling less than eight knots (and will often be stationary). Therefore, the risk of a vessel collision with protected species resulting in death is inherently low. The risk of marine life getting caught in operating thrusters is highly unlikely, given the low presence of individuals, combined with the avoidance behaviour commonly displayed during dynamic positioning operations.

Unplanned interaction with marine fauna has the potential to occur within the PAA. There are a number of EPBC listed species with the potential to occur within the PAA (Section 4.6). It is recognised that there is both spatial and temporal variation in the potential for interaction with marine fauna. For example, the Trunkline Operational Area traverses a number of BIAs for marine species protected under the EPBC Act that may be seasonally present, including migration BIAs for humpback whales and pygmy blue whales, a foraging BIA for whale sharks and breeding and nesting BIAs for marine turtles. The Trunkline Operational Area also traverses the Montebello Marine Park between KP 109 and KP 192. The North-west Marine Parks Network Management Plan (DNP, 2018a) lists the natural values of the Montebello AMP as including a range of threatened, migratory, marine or cetacean species listed under the EPBC Act, including overlapping BIAs.

Marine Mammals

As described above, vessel speed influences the probability of a vessel collision with a cetacean and also whether a collision may result in lethal injury (Vanderlaan and Taggart, 2007). Additionally, behaviour of individuals may also influence the likelihood of a collision occurring. Although large cetaceans are expected to show localised avoidance in response to vessel noise, studies have reported limited behavioural response to approaching ships (McKenna et al., 2015) and individuals engaging in behaviours such as feeding, mating or nursing may be less aware of their surroundings and more susceptible to collision (Laist et al., 2001).

No known key aggregation areas for marine mammals (resting, breeding or feeding) are located within or immediately adjacent to the Offshore Operational Area. However, individuals may occasionally be present, including pygmy blue whales during seasonal migrations (Section 4.6.5). Pygmy blue whale may occasionally transit through the Offshore Operational Area as individuals and/or small groups during the northbound (April to July) and southbound (October to January) migratory seasons. However, the migration BIA is about 35 km to the west of the Offshore Operational Area and the likelihood of encountering pygmy blue whales is low. The nearest BIAs and HCTS for the southern right whale under the National Recovery Plan (DCCEE, 2024b) are over 190 km from the Operational Areas therefore it is not expected that there is a risk of vessel interaction.

The Trunkline Operational Area traverses migration BIAs for humpback whales and pygmy blue whales. The risk of vessel collision with marine mammals is present year-round but is seasonally elevated for humpback whales and pygmy blue whales during times of migration. Peak migration periods for humpback whales are June to August (northbound) and September to November (southbound). Pygmy blue whale migration periods are as described above for the Offshore Operational Area. Although there is increased likelihood of marine mammal presence within the Trunkline Operational Area, vessel presence will be significantly reduced, and will be transiting the area for short periods of time.

The Conservation Management Plan for the blue whale identifies vessel disturbance and strike as a threat to the EPBC listed species (Commonwealth of Australia, 2015a; TSSC, 2015b). The humpback whale is not a listed threatened species under the EPBC Act, but is a listed migratory species. Accordingly, there is no recovery plan in place for humpback whales, and no specific requirements with respect to potential impacts within BIAs.

Smaller cetaceans, such as dolphins, comprise a lower proportion of vessel collision records (DoEE, 2016), though it is difficult to determine if this is due to a lower collision rate or lower detection rate of incidents. Dolphins often engage in bow riding which may make them more vulnerable to entanglement with propellers or thrusters compared to larger cetaceans. As such, potential impacts are considered Slight (E).

Marine Reptiles

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

Detailed Consequence Assessment

The Recovery Plan for Marine Turtles in Australia recognises turtles are at risk from vessel strikes, particularly in shallow coastal foraging habitats and interesting areas where there are high numbers of recreational and commercial vessels (Commonwealth of Australia, 2017).

The effect of vessel speed on turtle flee response can be significant. A study by Hazel et al. (2007) found that 60% of green turtles fled from vessels travelling at 2.2 knots (4 km/h) while only 4% fled from vessels travelling at 10.2 knots (19 km/h). When fleeing 75% of turtles moved away from the vessel's track, 8% swam along the vessel track and 18% crossed in front of the vessel. The study concluded that most turtles would be unlikely to avoid vessels travelling at speeds greater than around 2.2 knots (Hazel et al., 2007; Commonwealth of Australia, 2017a). Furthermore, the relatively small size of turtles and the significant time spent below the surface makes their observation by vessel operators extremely difficult or impossible. Green turtles observed by Hazel et al. (2009) generally only exposed the dorsal-anterior part of the head above the surface of the water and not for longer than two seconds.

The Trunkline Operational Area overlaps with an interesting buffer BIA and Habitat Critical to the survival of flatback, green, hawksbill and loggerhead turtles. There is no overlap with the Offshore Operational Area. An increased number of turtles may be encountered seasonally during the Petroleum Activities Program within the vicinity of offshore islands/archipelagos during interesting/nesting seasons. It is expected that individuals will respond to vessel presence by avoiding the immediate vicinity of the vessels, and combined with low vessel speed, will reduce the likelihood of a vessel-turtle collision. In addition, vessel movements within sensitive turtle areas (BIAs and Habitat Critical to survival) will be limited to occasional and temporary IMMR activities, further reducing the potential for impact at the individual and population level. As such, potential impacts are considered Slight (E).

Fish, Sharks and Rays

Boat strike is recognised by the Approved Conservation Advice for *Rhincodon typus* (whale shark) (TSSC, 2015a) as one of the threats to their recovery. Whale sharks are at risk from vessel strikes when feeding at the surface or in shallow waters (where there is limited option to dive). Whale sharks may traverse offshore NWS waters including the PAA during their migrations to and from Ningaloo Reef, as demonstrated by acoustic detections of tagged whale sharks at the North Rankin A and Goodwyn A platforms during two periods—June to July and October to January (Thomson et al. 2021) The PAA is located at least 215 km from the whale shark foraging (high density prey) BIA adjacent to Ningaloo Reef. The Trunkline Operational Area overlaps a small proportion of the foraging BIA for whale sharks between about KP 72 and KP 199, and they may be seasonally present between March and November (with the annual peak aggregation at Ningaloo Reef between April and May). The risk of vessel strike may be elevated during this period. However, this overlap represents only 0.15% of the overall area of the whale shark foraging BIA.

Smaller fish may also be at risk of injury or mortality from vessels through being caught in thrusters during station keeping operations (i.e. during DP). However, this is unlikely given the low presence of individuals, combined with the avoidance behaviour commonly displayed during station keeping operations. As such, potential impacts are considered Slight (E).

Seabirds and Migratory shorebirds

The injury or mortality of seabirds due to accidental collision with helicopters or interactions with the FPU facility / infrastructure is expected to be restricted to a low number (i.e. individuals) with negligible impacts at the population level. Because seabirds and migratory shorebirds are a high value species, potential impacts are considered Slight (E).

Cumulative Impacts

There is potential for cumulative impacts to marine fauna to occur as a result of overlap of PAP vessel activities. The FPU and ASV may be operational at the same time, as well as additional vessels during FPU hook-up and commissioning and other Scarborough activities being carried out under existing Environment Plans such as drilling and completions. During the operations phase of the FPU, concurrent vessel activities may occur between the FPU support vessel(s), IMMR and gravimetry. Given the offshore waters and deep water depths (approx. 900-1000 m), interaction with marine fauna is likely to be limited to individuals and/or small groups of transient cetaceans, with potential impacts expected to result in a behavioural disturbance, i.e. avoidance of the vessels, with a potential risk consequence of Slight (E) due to high value species.

Summary of Assessment Outcomes

Receptor	Impact	Receptor Sensitivity	Risk Consequence	Likelihood	Risk Rating
Marine mammals	Injury to/mortality of fauna	High value species	Slight (E)	Highly unlikely	Low
Marine reptiles		High value species	Slight (E)	Highly unlikely	Low
Fish, sharks and rays		High value species	Slight (E)	Highly unlikely	Low

Demonstration of ALARP				
Control Considered	Control Feasibility (F) and Cost/ Sacrifice (CS)	Benefit in Impact/ Risk Reduction	Proportionality	Control Adopted
	cetacean observation training. CS: Additional cost of MFOs			
Manage vessel speed in the humpback and PBW whale BIAs in migration seasons within the Trunkline Operational Area.	F: Yes. It is possible to carry out for vessels transiting within the Operational Area CS: will impact with longer transit times for vessels.	There is mounting evidence that reduction of vessel speeds can reduce vessel underwater noise emissions and increase the likelihood that fauna will be seen by vessels (and have more time to react) thereby reducing possibility of vessel strike. Where this control prevents impacts to humpback and pygmy blue whales at a population level, it maintains a culturally significant resource to a level that results in no observable change to coastal communities (migratory pathways maintained).	Benefits outweigh cost/sacrifice	Yes C 4.8

ALARP Statement:

On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type (i.e. Decision Type A, **Section 2.3.3**), Woodside considers the adopted controls appropriate to manage the risks and consequences of potential interactions with fauna. As no reasonable additional/alternative controls were identified that would further reduce the risks and consequences without grossly disproportionate sacrifice, the risks and consequences are considered ALARP.

Demonstration of Acceptability

Acceptability Criteria and Assessment

Demonstration of acceptability for the sources of aspect and associated impacts assessed in this section are provided in Section 7.2.5.3 of the Scarborough OPP. The Petroleum Activities Program meets the acceptability criteria (**Section 2.3.5**):

- Overall risk consequence/risk ratings for individual receptors are less than the significant impact level defined in the OPP.
- EPOs and controls in the OPP that are relevant to the risk of interactions with fauna have been adopted.
- There are no changes to internal/external context specific to this risk from the OPP, including issues raised during consultation.

Acceptability Statement:

The impact assessment has determined that, given the adopted controls, interactions with fauna represents a low current risk rating that is unlikely to result in a risk consequence greater than Slight. Relevant recovery plans and conservation advice have been considered during the impact assessment, and the Petroleum Activities Program is not considered to be inconsistent with the overall recovery objectives and actions of these recovery plans and conservation advice (Section 6.9.3). The adopted controls are considered consistent with industry good practice and professional judgement and meet the requirements of Part 8 (Division 8.1) of the EPBC Regulations 2000.

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

Demonstration of Acceptability

Further opportunities to reduce the impacts have been investigated above. The potential risks and consequences are considered broadly acceptable if the adopted controls are implemented. Activities do not have a significant impact on MNES (Section 2.4.2) including those with an First Nations connection or with traditional use in nearshore areas as defined in Section 4.9). Therefore, Woodside considers the adopted controls appropriate to manage the risks of interaction with marine fauna to a level that is broadly acceptable.

	Soil and Groundwater	Marine Sediment	Water Quality	Air Quality (inc. odour)	Ecosystems/Habitat	Species	Socio-economic	Decision Type	Impact/Consequence	Likelihood	Current Risk Rating	ALARP Tools	Acceptability	Outcome
Introduction and establishment of invasive marine species (IMS) within the PAA.					✓	✓	✓	A	F	0	L	LCS	Broadly Acceptable	EPO 28
Description of Source of Impact/Risk														
<p>There are several pathways for the potential introduction and spread of Invasive Species, associated with the PAP, including the mobilisation of FPU (including topsides) and vessels from international waters. Vessels (including the FPU) shall obtain required biosecurity clearances/approvals per the <i>Biosecurity Act (2015)</i> prior to entering Australian waters. This process and risk management are handled by the Department of Agriculture, Fisheries and Forestry (DAFF) and focuses on risks associated with all pest species including both aquatic and terrestrial. The EP includes an impact and risk assessments from biofouling pathways for the introduction of Invasive Marine Species (IMS) during vessel operations (including immersible equipment) and the FPU within the Operational Area. This is aligned to the “Reducing marine pest biosecurity risks through good practice biofouling management” NOPSEMA Information paper (N-04750-IP899 A715054) specifically section 2 – Nationally accepted approach to biofouling management. Section 2 highlights that “Offshore industry biosecurity risk assessment processes that do not adequately account for biofouling risk factors can lead to unreliable or false ‘low’ risk assessment outcomes.” And therefore requiring additional assessment under this EP for biofouling risks.</p> <p>Vessel Operations</p> <p>During the Petroleum Activities Program, vessels will be transiting to and from the PAA and may mobilise from an Australian port or directly from international waters. Vessels include AHTs, LCV, ASV and other general Support Vessels (Section 3.11).</p> <p>Vessel activities in the Offshore Operational Area include FPU installation, hook-up commissioning, support of ongoing operations (including IMMR activities), and gravimetry surveys as discussed in Section 3. Vessel movements in the Trunkline Operational Area include IMMR activities during ongoing operations. Vessel presence, type and frequency will vary depending on the activities being undertaken and vessel numbers will be greater during FPU installation, hook-up and commissioning, compared with ongoing normal operations.</p> <p>All vessels are subject to some level of marine fouling whereby organisms attach to the vessel hull. This could particularly occur in areas where organisms can find a good attachment surface (e.g. seams, strainers and unpainted surfaces) or where turbulence is lowest (e.g. niches, sea chests, etc.), although commercial vessels typically maintain</p>

anti-fouling coatings to reduce the build-up of fouling organisms. Biofouling increases the risk of IMS presence on vessels. IMS could also be present as biofouling on immersible equipment (survey equipment, ROV etc.).

IMS could be translocated to the Offshore Operational Area and Trunkline Operational Area and either transferred directly to the seafloor or subsea structures where they could establish. IMS that transfer and establish on these structures, such as the FPU hull, could translocate to vessels that undertake operations in close proximity and subsequently transfer IMS to other locations such as ports. Organisms can also be drawn into ballast tanks during onboarding of ballast water as cargo is loaded or to balance vessels under load.

Cross contamination between vessels can also occur (e.g. IMS translocated between Vessels) during times when vessels need to be alongside each other.

FPU

The FPU will be wet-towed from international waters directly to the Offshore Operational Area prior to hook up for the life of the field. Prior to FPU sail-away from the construction yard in China, there is potential for the FPU to become exposed to, and therefore potentially become contaminated with IMS during stationary periods in the shipyard or during stopovers at international ports during the transit. IMS could then potentially be translocated between the FPU and Vessels during periods of proximity including during hook-up, commissioning, IMMR, support and supply operations.

Ballast water will be used in the FPU hull to maintain stability and may be exchanged upon arrival to the Scarborough field and during operations once moored. Ballast water if left unmanaged may act as a potential pathway through discharge of high-risk ballast water potentially containing IMS into the vicinity of the FPU and potentially submerged nearby vessel hulls. Where IMS settles on a vessel hull or is taken up into the ballast tanks of a nearby vessel, this can act as pathway where a vessel may unknowingly later discharge ballast water containing IMS into sensitive, unaffected environments.

Detailed Impact Assessment

Assessment of Potential Impacts

IMS are a subset of Non-indigenous Marine Species (NIMS) that have been introduced into a region beyond their natural biogeographic range resulting in impacts to social/cultural, human health, economic and/or environmental values. NIMS are species that have the ability to survive, reproduce and establish founder populations. However, not all NIMS introduced into an area will thrive or cause demonstrable impacts; the majority of NIMS around the world are relatively benign and few have spread widely beyond sheltered ports and harbours. NIMS are only considered IMS when they result in impacts to environmental values and/or have social/cultural, economic and/or human health impacts.

Once introduced, IMS may prey on local species (which had previously not been subject to this kind of predation and therefore not have evolved protective measures against the attack), they may outcompete indigenous species for food, space or light and can also interbreed with local species, creating hybrids such that the endemic species is lost. These changes to the local marine environment result in changes to the natural ecosystem.

IMS have also proven economically damaging to areas where they have been introduced and established. Such impacts include direct damage to assets (fouling of vessel hulls and infrastructure) and depletion of commercially harvested marine life (e.g. shellfish stocks). IMS have proven particularly difficult to eradicate from areas once established. If the introduction is detected early, eradication may be effective but is likely to be expensive, disruptive and, depending on the method of eradication, harmful to other local marine life.

Potential IMS have historically been introduced and translocated around Australia by a variety of natural and human means, including marine fouling and ballast water. Potential IMS vary from one region to another depending on various environmental factors such as water temperature, salinity, nutrient levels and habitat type, which dictate their survival and invasive capabilities. IMS typically require hard substrate in the photic zone; therefore, requiring shallow waters to become established. Highly disturbed, shallow-water environments such as shallow coastal waters, ports and marinas are more susceptible to IMS colonisation, whereas IMS are generally unable to successfully establish in deep-water ecosystems and open-water environments where the rate of dilution and the degree of dispersal are high (Williamson and Fitter, 1996; Paulay et al., 2002; Geiling, 2014).

Epifauna and Infauna

Epifauna and infauna are susceptible to impacts from IMS due to the risk of changes to the ecosystem dynamics such as competition for resources and predation.

Benthic productivity on the outer continental shelf and slope region of the PAA is low, and is a function of water depth, low nutrient availability, and the absence of hard substrates. Studies completed within the region indicate that benthic composition in deep-water habitats is generally lower in abundance than shallow water habitats of the region (DEWHA, 2008a; Brewer et al., 2007). The seafloor in the Offshore Operational Area is characterised by sparse marine life dominated by motile organisms (ERM, 2013). Such motile organisms included shrimp, sea cucumbers, demersal fish and small, burrowing worms and crustaceans. This soft bottom habitat also supports patchy distributions of mobile epibenthos, such as sea cucumbers, ophiuroids, echinoderms, polychaetes and sea-pens (DEWHA, 2008a). The dominant types of epifauna were arthropods and echinoderms (especially shrimp and sea cucumbers, respectively),

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

Detailed Impact Assessment

while the dominant infauna groups were crustaceans and polychaetes (ERM, 2013). Benthic communities in the Offshore Operational Area are representative of the Exmouth Plateau and of deep-water soft sediment habitats reported in the region.

While Vessels have the potential to introduce IMS into the Offshore Operational Area, the deep offshore open waters (approximately 900–1000 m) are not conducive to the settlement and establishment of IMS. Furthermore, the Offshore Operational Area is away from shorelines and/or critical habitat. The likelihood of IMS being introduced and establishing viable populations on the seabed within the Offshore Operational Area or immediate surrounds is considered not credible.

The Trunkline Operational Area in shallower waters (30-40 m) presents a slightly increased risk of IMS establishment. The trunkline has the potential to act as suitable substrate for IMS establishment in these water depths if exposed, however given the short nature of typical activities undertaken in proximity to the trunkline in these water depths, it is considered the potential of IMS colonisation is low. Additionally given the isolation of the trunkline from other hard substrates such as islands or shoals, the risk of establishment, whilst credible, is remote. In addition, shallower waters represent a very small area of the overall PAA.

Accordingly, impact to epifauna/infauna in the PAA is considered remote. Receptor sensitivity for epifauna and infauna is low, leading to a Negligible (F) risk consequence.

Industry, Shipping, Defence

The establishment of IMS has the potential to cause changes to the functions, interests or activities of other users through indirect impact such as changes to fisheries target species resulting in economic and social implications, or due to compromised reputation to the oil and gas industry. IMS have proven particularly difficult to eradicate from areas once established. If the introduction is detected early, eradication may be effective but is likely to be expensive, disruptive and, depending on the method of eradication, harmful to other local marine life. Given the low likelihood of IMS translocation to, and colonisation of environments within the PAA, project activities will not result in establishment of IMS, and as such not adversely affect other marine user activities in the region.

FPU

The FPU poses a potential risk as a pathway for introduction of IMS through both settlement on the hull and in ballast water. Prior to being moored and operated in the Scarborough field, the FPU will originate from the construction yard located in the Yantai region of China and will be towed directly from China to the offshore operational area. The FPU will not enter Australian nearshore waters (within 12nm of Australian land) prior to hook-up to the pre-laid mooring lines.

A review of the potential risk associated with the establishment of IMS on the FPU prior to arrival in the Scarborough field, undertaken by an independent IMS expert (Biofouling Solutions), found that there is potential for IMS to be present in the waters in construction yard in China and subsequent risks associated with potential for these species to settle on the hull of the FPU. This included that up to 8 species of IMS known to occur in China which could survive the stresses of the tow to the Scarborough Offshore Operational Area.

To reduce likelihood of colonisation of biofouling (and potential associated IMS) on the hull of the FPU prior to sail-away to the Scarborough field, the hull has been coated with an antifouling coating (AFC) system which was selected based on tests conducted over an 8 month period in the waters of the construction yard in China. These trials included testing a range of market available antifouling coating paints on representative metal surfaces at representative depths. Additionally, niche areas and areas not able to be painted such as anodes, have a number of additional controls which will be implemented such as temporary covers and sealing of crevices to reduce seawater interactions with these niches to reduce the likelihood of IMS survival.

To reduce the likelihood of colonisation of biofouling (and potential associated IMS) from FPU ballast water uptake, the Scarborough FPU IMS Management Plan (FPU IMSMP) details key processes to reduce risk including:

- Prior to the FPU departing China for transit to Australia, ballasting will be undertaken using freshwater to maintain D2 requirements per IMO guidelines and ensure minimum keel draft during any movements within China.
- To commence the tow of the FPU to Australia, the FPU will need to ballast down in preparation for the wet tow to Australia. The Location of the ballast water (seawater origin) uptake will be in a low risk location and in compliance with Scarborough FPU IMSMP.
- During the wet tow to Australia, emergency scenarios may arise such as cyclones or poor weather conditions which may require the FPU to be ballasted to protect the structure, improve seakeeping and tow arrangement safety. Where practicable and per the Scarborough FPU IMSMP, the Scarborough FPU will be towed in > 50 m water depth such that any contingency ballast water taken in is of low risk. Once the cyclone conditions have passed, depending on distance remaining to transit, the FPU will again be de-ballasted to 19m draft to continue its journey to sail down to the Operational Area.

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

Detailed Impact Assessment

During sail down to the Scarborough field the FPU will be towed by tugs. During the transit it will be constantly under tow at a speed of approximately 4 knots. The tow route will be designed to avoid shallow waters and areas of high risk of harbouring IMS. There is provision for the FPU to require stopover during the sail down if any issues are identified. If stopover is required management of IMS risk would be considered based on time at stationary speed and considering water depth to ensure that low risk status is maintained.

It is not considered credible that IMS could establish viable populations at the depth of the Offshore Operational Area, but there is potential that IMS may viably transfer between the FPU and vessels either through either direct transfer between the hull or by transfer through ballast water exchange. The ASV may be within close proximity to the FPU for up to a 6-month period. During this time, any potential IMS established on the FPU have the potential to transfer from the hull of the FPU to the hull of the ASV. Additionally, Project Vessels may operate within close proximity to the FPU during installation activities. However, this will only be for short and temporary periods of time during hook-up and commissioning of the FPU, therefore it is considered highly unlikely that IMS transfer could occur during these activities.

When examining the potential impacts from translocation of marine pests to the Scarborough facility itself during normal operations, interactions with the facility and any Support Vessels (most likely Australian sourced) are limited, with time within the 500 m Petroleum Safety Zone around the facility limited to Support Vessel transfers/bunkering. However, the risk of this occurring is considered manageable, given the ballast water and biofouling controls which are implemented during and prior to the Petroleum Activities Program.

Summary

In support of Woodside’s assessment of the risks and consequences of IMS introduction associated with the Petroleum Activities Program, Woodside conducted a risk and impact evaluation of the different aspects of a marine pest translocation. The results of this assessment are presented in Table 6-49.

Table 6-49: Credibility, consequence and likelihood of introducing invasive marine species

IMS Introduction Location	Credibility of Introduction	Consequence of Introduction	Likelihood
Introduced to Offshore Operational Area and establishment on the seafloor or subsea structures	Not Credible The deep offshore open waters of the PPA, away from shorelines and/or critical habitat, more than 50 km from a shoreline and in waters more than 100 m deep are not conducive to the settlement and establishment of IMS.		
Introduced to the FPU from Vessels	Credible There is potential that IMS could transfer between project or support vessels and the FPU or mooring lines. The most credible risk of establishment would be during hook-up and commissioning activities when the ASV and the highest number of Vessels will be in proximity to the FPU. However, given the controls implemented to manage IMS for Vessels, the likelihood is considered remote given that IMS must first be present and then be able to transfer through the water column to the FPU.		
Introduced to Trunkline Operational Area and establishment on the seafloor or subsea structures	Credible There is potential for IMS to be introduced and established in the shallower waters of the Trunkline Operational Area. The Trunkline Operational Area in shallower waters (30 – 40 m) present a slightly increased risk of IMS establishment, however, IMS require hard substrate/features on the seabed to attach to, none of which is present, except for the trunkline itself. Therefore, the risk of establishment, whilst credible, is remote given vessels must first have IMS present and then transfer IMS to the trunkline.		
Transfer between Vessels and from Vessels to other marine environments beyond the PAA.	Credible This risk is considered credible but remote. Vessels that spend significant time in close proximity such as the ASV and FPU have the potential to transfer IMS if present, however this is considered remote given the controls implemented for the purposes of the Petroleum Activities Program. For a marine pest to then establish into a mature spawning population on the new Project Vessel (which would have been managed through Woodside’s IMS process) and then transfer to another environment is credible but remote given these controls.		

Summary of Assessment Outcomes

Receptor	Impact	Receptor Sensitivity	Risk Consequence	Likelihood	Risk Rating

Demonstration of ALARP				
Control Considered	Control Feasibility (F) and Cost/Sacrifice (CS)	Benefit in Impact/Risk Reduction	Proportionality	Control Adopted
	<p>surveys is significant based on Woodside's experience with other facilities. Costs including vessel hire, ROV to support survey and divers to check niche areas are significant.</p> <p>HS: Exposure of personnel while conducting survey is four days of two–three people (based on subsea ROV surveys of similar size).</p>		<p>verification of EPO 28.</p> <p>Consequently, any additional benefit gained by implementing this control is considered disproportionate, given the controls already adopted (and noting already incurred cost through implementation of IMSMP (i.e. inspections and cleaning where risk warrants)) and the unlikely likelihood of a translocation event.</p>	
Professional Judgement – Eliminate				
No discharge of ballast water during the Petroleum Activities Program.	<p>F: No. Ballast water discharges are critical for maintaining vessel stability. Given the nature of the Petroleum Activities Program, the use of ballast (including the potential discharge of ballast water) is considered to be a safety critical requirement.</p> <p>CS: Not assessed, control not feasible.</p>	Not assessed, control not feasible.	Not assessed, control not feasible.	No
Eliminate use of vessels.	<p>F: No. Given that vessels must be used to implement project, there is no feasible means to eliminate the source of risk.</p> <p>CS: Loss of the project.</p>	Not assessed, control not feasible.	Not assessed, control not feasible.	No
Professional Judgement – Substitute				
Source Vessels based in Australia only.	<p>F: Potentially. Limiting activities to only use local Vessels could potentially pose a significant risk in terms of time and duration of sourcing a vessel, as well as the ability of the local vessels to perform the required tasks. For example, there are limited installation</p>	Sourcing vessels from within Australian will reduce the likelihood of IMS from outside Australian waters, however, it does not reduce the likelihood of introduction of species native to Australia but alien to the PAA and NWMR, or of IMS that have established	Disproportionate. Sourcing vessels from Australian waters may result in a reduction in the likelihood of IMS introduction to the PAA; however, the potential cost of implementing this control is grossly disproportionate to	No

Demonstration of ALARP				
Control Considered	Control Feasibility (F) and Cost/Sacrifice (CS)	Benefit in Impact/Risk Reduction	Proportionality	Control Adopted
	vessels based in Australian waters. While the project will attempt to source Vessels locally it is not always possible. Availability cannot always be guaranteed when considered competing Oil and Gas activities in the region. In addition, sourcing Australian based vessels only will cause increases in cost due to pressures of vessel availability. CS: Significant cost and schedule impacts due to restrictions of vessel hire opportunities.	elsewhere in Australia. The consequence is unchanged.	the minor environmental gain (or reducing an already remote likelihood of IMS introduction) potentially achieved by using only Australian based vessels, consequently this risk is considered not reasonably practicable.	
IMS inspection of all vessels.	F: Yes. Approach to inspect vessels could be a feasible option. CS: Significant cost and schedule impacts. In addition, Woodside's IMS risk assessment process (C 13.2) is seen to be more cost effective as this control allows Woodside to manage the introduction of marine pests through biofouling, while targeting its efforts to and resources to areas of greatest concern.	Inspection of all vessels for IMS would reduce the likelihood of IMS being introduced to the PAA. However, this reduction is unlikely to be significant given the other control measures implemented. No change in consequence would occur.	Disproportionate. The cost/sacrifice outweighs the benefit gained, as other controls to be implement achieve an ALARP position.	No
Professional Judgement – Engineered Solution				
None identified.				
ALARP Statement: On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the risks and consequences of IMS introduction. As no reasonable additional/alternative controls were identified that would further reduce the risks and consequences without grossly disproportionate sacrifice, the risks and consequences are considered ALARP.

Demonstration of Acceptability
Acceptability Criteria and Assessment
<p>Demonstration of acceptability for the sources of aspect and associated impacts assessed in this section are provided in Section 7.2.4.3 of the Scarborough OPP. The Petroleum Activities Program meets the acceptability criteria (Section 2.3.5):</p> <ul style="list-style-type: none"> • Overall risk consequence for individual receptors are less than the significant impact level defined in the OPP. • EPOs and controls in the OPP that are relevant to an unplanned introduction of IMS have been adopted. • There are no changes to internal/external context specific to this risk from the OPP, including issues raised during consultation. <p>Acceptability Statement:</p> <p>The impact assessment has determined that the accidental introduction and establishment of IMS represents a low current risk rating and is unlikely to result in a risk consequence greater than Slight. The adopted controls are considered consistent with industry legislation, codes and standards. Further opportunities to reduce the impacts have been investigated above. The potential risks and consequences are considered broadly acceptable if the adopted controls are implemented. Activities do not have a significant impact on MNES (Section 2.4.2) including those with an First Nations connection or with traditional use in nearshore areas as defined in Section 4.9. Therefore, Woodside considers the adopted controls appropriate to, manage the risks of invasive marine species to an acceptable level.</p>

Environmental Performance Outcomes, Standards and Measurement Criteria			
EPO	Adopted Control(s)	EPS	MC
<p>EPO 28 No introduction and establishment of invasive marine species into the Operational Area(s) as a result of the Petroleum Activities Program.</p>	<p>C 23.1 Vessels (including foreign vessels not party to the International Convention for the Control and Management of Ships' Ballast Water and Sediments 2004 (BWM Convention)) will manage their ballast water using one of the approved ballast water management options, as specified in the Australian Ballast Water Management Requirements. This applies to all Vessels that will enter the Operational Area, including those carrying out activities outside of Australian Territorial Seas (>12nm).</p>	<p>PS 23.1.1 Prevent the translocation of IMS within the vessel's ballast water from high risk locations to the PAA.</p>	<p>MC 23.1.1 Ballast Water Records System maintained by vessels which verifies compliance against Australian Ballast Water Management Requirements.</p>
	<p>C 23.2 Internationally sourced Vessels will manage their biosecurity risk associated with biofouling as specified in the Australian Biofouling Management Requirements.</p>	<p>PS 23.2.1 Compliance with Australian Biofouling Management Requirements.</p>	<p>MC 23.2.1 Records of implementation of biofouling management measures and pre-arrival reporting</p>

Ballast water uptake per plan requirements 	<p>PS 23.5.1 Implementation of the Scarborough Floating Production Unit IMS Management Plan.</p>	<p>MC 23.5.1 Records confirm FPU IMSMP was implemented (AFC certificate, IMS Inspection report, Ballast water records).</p>

¹¹⁰ Low risk of introducing IMS of concern is defined as either no additional management measures required or, management measures have been applied to reduce the risk.

6.9 Environment Protection and Biodiversity Conservation Act Assessment

6.9.1 Matters of National Environmental Significance Significant Impact Guidelines

As part of the evaluation of potential impacts and risks from planned and unplanned activities (Section 6.7 and 6.7.13) an assessment was undertaken to determine if any relevant significant impact criteria for EPBC Act listed Endangered or Vulnerable species were met.

The activity will not result in any population level effects on any populations of listed Endangered or Vulnerable species, nor will it “modify, destroy, remove, isolate or decrease the availability or quality of habitat to the extent that the species is likely to decline”. Therefore, the Petroleum Activities Program will not have a significant impact on any MNES.

6.9.2 Principles of Ecologically Sustainable Development

For all impacts and risks assessed in Section 6, an assessment was conducted to determine if the Petroleum Activities Program was consistent with relevant principles of ESD, as described in Section 2.3.

This assessment determined that the activity is consistent with the principles of ESD as set out in sections 3A(a), (b), (c) and (d) of the EPBC Act. The principle set out in section 3A(E) of the EPBC Act (‘improved valuation, pricing and incentive mechanisms should be promoted’) is not relevant to the Petroleum Activities Program.

6.9.3 Recovery Plan and Threat Abatement Plan Assessment

As described in Section 2.4, an EP must not be inconsistent with a recovery plan or threat abatement plan for a listed threatened species or ecological community. This section describes the assessment that Woodside has undertaken to demonstrate that the Petroleum Activities Program is not inconsistent with any relevant recovery plans or threat abatement plans. For the purposes of this assessment, the relevant Part 13 statutory instruments (recovery plans and threat abatement plans are:

- Recovery Plan for Marine Turtles in Australia 2017–2027 (Commonwealth of Australia, 2017).
- Conservation Management Plan for the Blue Whale – A Recovery Plan under the Environment Protection and Biodiversity Conservation Act 1999 2015-2025 (Commonwealth of Australia, 2015a).
- National Recovery Plan for the Southern Right Whale (DCCEEW, 2024b)
- Recovery Plan for the Grey Nurse Shark (*Carcharias taurus*) 2014 (Commonwealth of Australia, 2014b).
- Sawfishes and River Sharks Multispecies Recovery Plan (Commonwealth of Australia, 2015c).
- Threat Abatement Plan for the impacts of marine debris on the vertebrate wildlife of Australia’s coasts and oceans 2018 (DoEE, 2018).

Table 6-50 lists the objectives and (where relevant) the action areas of these plans, and also describes whether these objectives/action areas are applicable to government, the Titleholder and/or the Petroleum Activities Program. For those objectives/action areas applicable to the Petroleum Activities Program, the relevant actions of each plan have been identified, and an evaluation has been conducted as to whether impacts and risks resulting from the activity are clearly inconsistent with that action or not. The results of this assessment against relevant actions are presented in Table 6-51 to Table 6-56.

The assessment of potential impacts and risks to pygmy blue whales from underwater noise emissions in Section 6.7.4 has taken into account the definitions of terminology in the CMP, as

described in the DAWE and NOPSEMA guidance released in September 2021. Similarly, the assessment against relevant actions in the CMP has been undertaken in the context of the definitions included in the guidance note.

Table 6-50: Identification of applicability of recovery plan and threat abatement plan objectives and action areas

EPBC Act Part 13 Statutory Instrument	Applicable to:		
	Government	Licence/ Titleholder	Petroleum Activities Program
Marine Turtle Recovery Plan			
Long-term Recovery Objective: Minimise anthropogenic threats to allow for the conservation status of marine turtles to improve so they can be removed from the EPBC Act threatened species list	Y	Y	Y
Interim Recovery Objectives			
Current levels of legal and management protection for marine turtle species are maintained or improved, both domestically and throughout the migratory range of Australia's marine turtles	Y		
The management of marine turtles is supported	Y		
Anthropogenic threats are demonstrably minimised	Y	Y	Y
Trends in nesting numbers at index beaches and population demographics at important foraging grounds are described	Y	Y	
Action Areas			
A. Assessing and addressing threats			
A1. Maintain and improve efficacy of legal and management protection	Y		
A2. Adaptively manage turtle stocks to reduce risk and build resilience to climate change and variability	Y	Y	Y
A3. Reduce the impacts of marine debris	Y	Y	Y
A4. Minimise chemical and terrestrial discharge	Y	Y	Y
A5. Address international take within and outside Australia's jurisdiction	Y		
A6. Reduce impacts from terrestrial predation	Y		
A7. Reduce international and domestic fisheries bycatch	Y		
A8. Minimise light pollution	Y	Y	Y
A9. Address the impacts of coastal development/infrastructure and dredging and trawling	Y	Y	
A10. Maintain and improve sustainable Indigenous management of marine turtles	Y		
B. Enabling and measuring recovery			
B1. Determine trends in index beaches	Y	Y	Y
B2. Understand population demographics at key foraging grounds	Y		
B3. Address information gaps to better facilitate the recovery of marine turtle stocks	Y	Y	Y
Blue Whale Conservation Management Plan			
Long-term recovery objective: Minimise anthropogenic threats to allow for their conservation status to improve so that they can be removed from the EPBC Act threatened species list	Y	Y	Y

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

EPBC Act Part 13 Statutory Instrument	Applicable to:		
	Government	Licence/ Titleholder	Petroleum Activities Program
Interim Recovery Objectives			
The conservation status of blue whale populations is assessed using efficient and robust methodology	Y		
The spatial and temporal distribution, identification of BIAs, and population structure of blue whales in Australian waters is described	Y	Y	Y
Current levels of legal and management protection for blue whales are maintained or improved and an appropriate adaptive management regime is in place	Y		
Anthropogenic threats are demonstrably minimised	Y	Y	Y
Action Areas			
A. Assessing and addressing threats			
A.1: Maintain and improve existing legal and management protection	Y		
A.2: Assessing and addressing anthropogenic noise	Y	Y	Y
A.3: Understanding impacts of climate variability and change	Y	Y	Y
A.4: Minimising vessel collisions	Y	Y	Y
B. Enabling and Measuring Recovery			
B.1: Measuring and monitoring population recovery	Y		
B.2: Investigating population structure	Y		
B.3: Describing spatial and temporal distribution and defining biologically important habitat	Y	Y	Y
Southern Right Whale Recovery Plan			
Long-term vision: increase population to a level that the conservation status has improved and the species no longer qualifies for listing as threatened under any of the EPBC Act listing criteria.	Y	Y	Y
Interim Recovery Objectives			
Current levels of Commonwealth and State legislative and management protection for southern right whales are implemented, maintained, or improved, so threats continue to be managed and reduced over the life of the plan	Y		
Anthropogenic threats are managed consistent with ecologically sustainable principles to facilitate recovery of southern right whales	Y	Y	Y
Population dynamics, including demographics, distribution, residency, and coastal movement across the species range are monitored and quantified using robust, standardised, best-practice methodology to assess population recovery	Y		
The population structure in Australian waters is clearly characterised to evaluate the degree to which the western and eastern populations are separate populations and inform the degree of connectivity with other southern right whale populations	Y		
Capability of First Nation Australians, research, citizen science, and general community groups is improved to assist in addressing recovery actions of southern right whales in Australia.	Y		
Action Areas

EPBC Act Part 13 Statutory Instrument	Applicable to:		
	Government	Licence/ Titleholder	Petroleum Activities Program
A. Assessing and addressing threats			
A1: Maintain, implement and improve efficacy of current legislative and management protection for southern right whales.	Y		
A2: Address habitat degradation impacts from coastal and offshore marine infrastructure developments within the species' range.	Y	Y	Y
A3: Understand impacts of climate variability and anthropogenic climate change on the species biology and population recovery.	Y	Y	Y
A4: Manage and mitigate the threat of entanglements from commercial active or discarded fishing gear throughout the species' range in Australian waters.	Y		
A5: Assess, manage, and mitigate impacts from anthropogenic underwater noise.	Y	Y	Y
A6: Manage, minimise and mitigate the threat of vessel strike.	Y	Y	Y
B. Enabling and Measuring Recovery			
B1: Measure and monitor population demographic and recovery	Y		
B2: Characterise population structure	Y		
B3: Determine migratory paths and offshore distribution	Y		
B4: Improve capability of First Nation Australians, research, citizen science and general community groups to assist management of southern right whales	Y		
Grey Nurse Shark Recovery Plan			
Overarching Objective			
To assist the recovery of the grey nurse shark in the wild, throughout its range in Australian waters, with a view to: <ul style="list-style-type: none"> improving the population status, leading to future removal of the grey nurse shark from the threatened species list of the EPBC Act ensuring that anthropogenic activities do not hinder the recovery of the grey nurse shark in the near future, or impact on the conservation status of the species in the future. 	Y	Y	Y
Specific Objectives			
Develop and apply quantitative monitoring of the population status (distribution and abundance) and potential recovery of the grey nurse shark in Australian waters	Y		
Quantify and reduce the impact of commercial fishing on the grey nurse shark through incidental (accidental and/or illegal) take, throughout its range.	Y		
Quantify and reduce the impact of recreational fishing on the grey nurse shark through incidental (accidental and/or illegal) take, throughout its range	Y		
Where practicable, minimise the impact of shark control activities on the grey nurse shark	Y		
Investigate and manage the impact of ecotourism on the grey nurse shark	Y		
Manage the impact of aquarium collection on the grey nurse shark	Y

EPBC Act Part 13 Statutory Instrument	Applicable to:		
	Government	Licence/ Titleholder	Petroleum Activities Program
Improve understanding of the threat of pollution and disease to the grey nurse shark	Y	Y	Y
Continue to identify and protect habitat critical to the survival of the grey nurse shark and reduce the impact of threatening processes within these areas	Y	Y	
Continue to develop and implement research programs to support the conservation of the grey nurse shark	Y	Y	
Promote community education and awareness in relation to grey nurse shark conservation and management	Y		
Sawfish and River Sharks Recovery Plan			
Primary Objective			
To assist the recovery of sawfish and river sharks in Australian waters with a view to: <ul style="list-style-type: none"> improving the population status leading to the removal of the sawfish and river shark species from the threatened species list of the EPBC Act ensuring that anthropogenic activities do not hinder recovery in the near future, or impact on the conservation status of the species in the future. 	Y	Y	
Specific Objectives			
Reduce and where possible, eliminate adverse impacts of commercial fishing on sawfish and river shark species.	Y		
Reduce and, where possible, eliminate adverse impacts of recreational fishing on sawfish and river shark species.	Y		
Reduce and, where possible, eliminate adverse impacts of Indigenous fishing on sawfish and river shark species.	Y		
Reduce and, where possible, eliminate the impacts of illegal, unregulated and unreported fishing (IUU) on sawfish and river shark species.	Y		
Reduce and, where possible, eliminate adverse impacts on habitat degradation and modification on sawfish and river shark species.	Y	Y	Y
Reduce and, where possible, eliminate any adverse impacts of marine debris on sawfish and river shark species noting the linkages with the Threat Abatement Plan for the Impact of Marine Debris on Vertebrate Marine Life.	Y	Y	Y
Reduce and, where possible, eliminate any adverse impacts of collection for marine aquaria on sawfish and river shark species.	Y		
Improve the information base to allow the development of a quantitative framework to assess the recovery of, and inform management options for, sawfish and river shark species.	Y		
Develop research programs to assist conservation of sawfish and river shark species.	Y	Y	
Improve community understanding and awareness in relation to sawfish and river shark conservation and management.	Y

6.10 Cultural Features and Heritage Values Assessment

As described in Section 4, the identification of cultural features and heritage values of the environment as well as the social, economic and cultural features important to First Nations' people is integral to understanding the environment and any potential impacts and risks to the environment.

In line with Woodside's First Nations Communities Policy (Woodside 2022), Woodside seeks to avoid damage or disturbance to cultural heritage (including intangible heritage) and, if avoidance is not possible, minimise and mitigate the impacts, in consultation with First Nation communities and Traditional Custodians. Please note that the First Nations Communities Policy is reviewed regularly and is updated as required. The First Nations Communities Policy is made available on our website, along with the other Board policies: <https://www.woodside.com/who-we-are/corporate-governance-and-policies>. Mitigation can include any measure or control aimed at ensuring the viability of the intangible cultural heritage and its intergenerational transmission. This can include reducing impacts and risks to environmental features that are associated with intangible cultural heritage (UNESCO 2003; ICOMOS 2013).

It is important to note that not all topics raised by First Nations groups/individuals through consultation are considered values for the purpose of the cultural features and heritage values impact assessment below. Topics were raised in the context of a general interest in environmental management and ecosystem health (i.e., natural environment interest), where the group/individual was seeking further information about potential impacts and risks from the Petroleum Activities Program on a receptor. As these interests relate to the maintenance of the natural environment, these are adequately addressed through impact and risk assessments described in Sections 6.7 and 6.7.13 respectively and not further assessed below.

Aspect	Cultural Features and Heritage Values
Description of source impact/risk (key aspects)	<p>Physical presence of vessels</p> <p>Several vessel types will be required to complete the activities associated with the Petroleum Activities Program (refer to Section 3.11). The physical presence and movement of vessels within the Operational Area has the potential to displace other marine users.</p> <p>Vessel physical presence and movement closer to the Dampier Archipelago and the Pilbara Port Authority Management Area is limited to activities along the export trunkline route. These activities will be conducted intermittently as described in Section 6.7.1. Temporary exclusion zones will be established around operating vessels. Refer to Section 6.7.1 for more details.</p> <p>Light emission from vessels</p> <p>Vessels will have external lighting to support safe operations at night, as well as to communicate the presence and activities of Vessels to other marine users (i.e. navigational lights). This lighting typically consists of bright white (i.e. metal halide, halogen, fluorescent) lights, and is not dissimilar to lighting used for other offshore activities, including fishing and shipping. Lighting is required for the safe operation of the Vessels and cannot reasonably be eliminated.</p> <p>Vessel light emissions in any one area will be limited by the transient nature of the works along the export trunkline route. Refer to Section 6.7.3 for more details.</p> <p>Acoustic emissions from vessels</p> <p>There are various sources of underwater acoustic emissions during the Petroleum Activities Program primarily associated with infield vessel operations and support activities, such as geophysical surveys and other IMMR activities, with some sound will also be associated with the start-up and operation phase of the FPU and subsea facilities. Generally, sound associated with steady state operations will be limited, with periodic and short-term increases in sound associated with activities such as FPU installation, commissioning and start-up, and IMMR.</p> <p>The sound levels and frequencies generated by vessels varies with the size of the vessel, speed, engine type and the activity being undertaken. Large vessels typically produce higher sound levels at lower frequencies than small vessels, although significant variation may be found among vessels within the same group. Sound levels tend to be greatest when engaging the throttle or thrusters, such as use of DP or when vessels are operating under load, compared with slow moving or idling vessels.</p> <p>The greatest sound levels are likely to be associated with vessels using DP thrusters to maintain position on station. Refer to Sections 6.7.4 and 6.7.5 for more details.</p>

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

	<p>Seabed disturbance</p> <p>Subsea infrastructure will be present on the seabed throughout the PAA over the operating life of the Scarborough field permanently altering the seabed for the duration of its presence. Gravimetry surveys, IMMR activities, ROV operations will be conducted at routine intervals, underwater acoustic positioning may be required and, flowline and/or export trunkline movement may occur, all resulting in seabed disturbance. Refer to Section 6.7.2 for more details.</p> <p>Unplanned hydrocarbon release from vessel (basis of EMBA)</p> <p>The temporary presence of the Vessels in the Operational Area may result in a navigational hazard for commercial shipping within the immediate area. This navigational hazard could result in a third-party vessel colliding with the Vessels which could result in a loss of containment. Vessels typically have multiple isolated tanks and the largest volume of a single tank for these types of vessels is in the order of 250 m³ (for survey and Support Vessels to 467 m³ (loss of FPU structural integrity).</p> <p>The EMBA is the largest spatial extent where unplanned events could have an environmental consequence on the surrounding environment. For this EP, the EMBA is the potential spatial extent of surface and in-water hydrocarbons at concentrations above ecological impact thresholds, in the highly unlikely event of the worst-case credible spill (467 m³) modelled at the FPU location and 250 m³ at two key locations. The EMBA therefore covers a larger area than the area that would be affected during any one single spill event. In the event of a spill the EMBA would be much smaller and is intermittent e.g., plume travels away from the release location based on prevailing currents and winds directions.</p> <p>The EMBA is driven by the distribution of entrained hydrocarbon above ecological thresholds and hence although Islands such as Barrow and Montebello Islands are within the EMBA, these are not expected to be affected unless there is shoreline contact above thresholds. No shoreline contact was predicted (Sections 6.8.2 and 6.8.3).</p> <p>Indirect impacts to rock art from downstream processing of LNG</p> <p>The presence of industry on the Burrup Peninsula has been the subject of topics and issues raised by some Relevant Persons during consultation. The topics and issues have centred around emissions associated with industrial activity leading to an accelerated weathering of rocks on which rock art is present which may reduce the visibility or destroy the rock art. This is based on a hypothesis that deposition of compounds such as NO_x, SO_x and ammonia (NH₃) from anthropogenic industrial sources have the potential to increase the acidity of the rock surface through chemical and/or biological processes and that acidic conditions may then accelerate the weathering of rock patina, eroding or affecting the contrast of the rock art. There have been several independent studies and rock art monitoring initiatives since the mid-2000s, which have not conclusively demonstrated a causal link between degradation of rock art and industrial activity. Refer to Section 6.7.7 for more details.</p>
<p>Receptor sensitivity</p>	<p>Cultural features and heritage values: High value</p> <p>Marine mammals: High value species</p> <p>Marine reptiles: High value species</p> <p>Fish: High value species</p> <p>Seabirds: High value species</p> <p>Coral: High value habitat</p> <p>Seagrass: High value habitat</p> <p>Mangroves: High value habitat</p>
<p>Planned Activity Aspect</p>	<p><i>The potential environmental impact from the Petroleum Activities Program to species that have a cultural feature or heritage value have been summarised below to provide the context related cumulative impact on the cultural feature or heritage value.</i></p>

Aspect	Impact Significance Level

6.8.11 Physical Presence (Unplanned): Introduction and Establishment of Invasive Marine Species	N/A						
---	-----	-----	-----	-----	-----	-----	-----

** No consequence has been assigned because there is no conclusive evidence of a causal link between industrial air emissions and potential anthropogenic change to rock art on Murujuga (as described in Section 6.7.7 and Section 4.9.6). Woodside will continue to monitor the outcomes of MRAMP (as per C 7.1), apply a precautionary approach through implementation of Controls listed in Section 6.7.7, and update or change manage the EP accordingly (Section 7.2.7)

Impact and Risk Assessment

The Petroleum Activities Program has the potential impact cultural features and heritage values through the following ways:

Archaeological heritage:

Places that are identified in the literature for their value as archaeological sites can be assumed to be impacted where there is an impact to the archaeological or scientific values of its tangible elements. This could include damage or disturbance of archaeological material or to the archaeological context.

Intangible cultural heritage:

Songlines: Songlines can become lost, fragmented, or broken when there is a loss of Country or forced removal from Country (Neale and Kelly 2020:30). Physical sites that have been identified as comprising a component of a songline are important to protect to prevent the fragmenting or breaking apart of songlines and loss of sacred cultural knowledge. It is noted that oil and gas infrastructure exists in many areas of the North West Shelf, and that songlines are still acknowledged and recognised. It is inferred that if there were to be any impacts to surviving songlines these would be significantly more likely to be described as qualitative (i.e. “weaken” a songline) rather than binary or absolute (i.e. destroy a songline).

Creation/dreaming sites; sacred sites; ancestral beings: Activities that physically alter landscape features may be assumed to potentially impact values of creation/dreaming sites, sacred sites or ancestral beings.

Ceremonial sites: Activities that prevent the performance of ceremony at these sites will directly impact its values.

Cultural obligations to care for Country: Environmental impacts may be assumed to impact rights and obligations to care for Sea Country. Exclusion of Traditional Custodians from Sea Country (e.g., by restricting access) or decision-making processes (e.g., by not conducting ongoing consultation) are other potential sources of impact.

Knowledge of Country/customary law and transfer of knowledge: Direct impact to communities practicing these skills will inherently occur when relevant aspects of the environment disappear, are displaced or suffer a reduction in population. Therefore, the transmission of these skills is expected to be impacted where there are impacts at the species/population level. Limitations on access to sites or disruption/relocation of First Nations communities may have implications for the preservation of First Nations knowledge.

Connection to Country: Where people are displaced or disrupted (e.g., during colonisation) or where there is a loss of technical skills or environmental knowledge this may damage connection to Country (McDonald and Phillips, 2021).

Access to Country: Impacts to access to Country may be classified as temporary (e.g. where exclusion zones exist around activities for safety reasons) or permanent (e.g. where infrastructure obstructs access or navigation). Impacts to access to Country can only occur in areas that were traditionally accessed by Traditional Custodians. As described in Section 4.9.4.5 this is anticipated to be focussed on areas adjacent to the coast.

Kinship systems and totemic species: It is assumed that marine species may have kinship/totemic relationships to Traditional Custodians, but it is understood that these relationships do not prohibit people outside of that “skin group” from hunting or eating that same species (Juluwarlu 2004). It is therefore inferred that the management of totemic or kinship species applies at the species/population level and not to individual plants and animals.

Resource collection: Direct impact to communities using these resources will inherently occur when the resource disappears, is displaced or suffers a reduction in population. Therefore, marine species (as resources) will be impacted where there is an impact at the species/population level.

Marine ecosystems and species:

Marine ecosystems may hold both cultural and environmental value (see **Section 4.9**), with cultural and environmental values intrinsically linked (DCCEEW 2024a, MAC 2022 as cited in Woodside 2023a). It necessarily follows that an impact to marine ecosystems has the potential to impact cultural features where the impact is detectable within sea country—the seascape which Traditional Custodians view, interact with or hold knowledge of.

Archaeological Heritage

Onshore/intertidal archaeological sites

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

No coastal areas or islands exist within the Operational Area. A review of the DPLH's Aboriginal Heritage Inquiry System identified 58 Registered Aboriginal Sites and 5 lodged Heritage Places in the EMBA. These were mainly comprised of sites at Barrow Island, Dampier Archipelago and the Ningaloo coast. These locations do exist within the EMBA boundary, however given the EMBA is driven by an unplanned marine diesel spill there is no anticipated impact pathway from this activity to onshore archaeological sites above highest astronomical tide (HAT).

Archaeological sites may exist in intertidal landscapes within the EMBA and may be exposed to marine diesel from an unplanned spill, however there is no anticipated impact pathway from the presence of marine diesel on archaeological values, as this is not expected to impact the fabric or context of sites on an exposed shoreline site. Impacts to the heritage value of fish traps from marine diesel in an unplanned spill may occur indirectly through impacts to fish. However, it is expected that continued use of fish traps beyond their archaeological value will be preserved where fish species and distribution are maintained at a population level. With regard to fish, refer to species specific assessment below for further information, in addition to the impact and risk assessment in Sections 6.7 and 6.7.13 respectively.

Onshore processing of LNG from the Petroleum Activities Program will occur onshore on Murujuga, which has a high concentration of rock art sites (estimated to exceed a million examples (DBCA & MAC 2024)) with significant local cultural and spiritual values in addition to their inclusion on Australia's National Heritage List and Tentative World Heritage List. PLP's publicly available Air Quality Management Plan has been reviewed and approved by the Western Australian Environment Protection Authority as meeting the requirement for best available practicable and efficient technologies to be used to minimise and monitor air emissions from the plant as described in Section 6.7.7.

Woodside onshore operations at Pluto LNG facility and KGP are managed via Cultural Heritage Management Plans as implementation conditions required by EPA Act (Pt IV) Ministerial Conditions.

- Ministerial Statement 757 – for the Pluto LNG Development includes Condition 10 for Indigenous Heritage management to develop and implement a CHMP prepared in liaison with the Department of Indigenous Affairs. The Pluto LNG Aboriginal Cultural Heritage Management Plan - Commissioning and Operations Phase (2012) is implemented at the facility.
- Ministerial Statement 1233 (North West Shelf Project Extension Proposal) Conditions section 4 set out Cultural Heritage Outcomes and Objectives to be achieved:
 - allowing traditional owner and custodian access to enable traditional activities and connection to culturally significant heritage areas within the development envelopes
 - avoid where possible, and otherwise minimise direct impacts to social, cultural, heritage and archaeological values within the development envelopes

Conditions require implementation of the North West Shelf Project Extension Cultural Heritage Management Plan (2021), including further revision in consultation with Murujuga Key Stakeholders. The plan is required to include elements (not limited to); a framework for ongoing consultation, and operational environmental management activities, monitoring, targets, management actions and reporting relevant to cultural heritage. Related air quality management conditions in MS1233 are outlined in Section 6.7.7.

These conditions support the management and recognition of Murujuga Cultural Values related to the NWS Operations. The NWS CHMP (2021) provides management provisions and actions including provide access for Traditional Owners to Aboriginal cultural heritage sites within the Proposal development envelope when requested [MA2], the adoption of technologies to prevent impacts to terrestrial and nearshore vegetation of heritage and conservation value [MA4] and support the implementation of, and participate in, the DWER Murujuga Rock Art Strategy [MA6] (see Section 6.7.7).

Submerged archaeological sites

No archaeological sites have been identified beyond terrestrial or intertidal areas, with the exception of two sites at Murujuga in Cape Bruguieres channel and Flying Foam Passage (Benjamin et al. 2020; Benjamin et al 2023), which are outside of the EMBA. Nevertheless, there is the potential for submerged archaeological sites on the Ancient Landscape. Assessments of the Operational Area, detailed in Section 4.9, have not identified any archaeological sites on the Ancient Landscape. Additionally, volcanic rock which may contain petroglyphs do not occur within the Operational Area.

Submerged archaeological sites (locations undefined) may exist on the Ancient Landscape within the broader EMBA. However, given the EMBA is driven by an unplanned marine diesel spill, it is not expected to impact the seabed or archaeological material on or within it. Therefore, there is no anticipated impact pathway to submerged archaeological sites in the broader EMBA from the Petroleum Activities Program.

Rivers, waterholes, tidal channels and seeps

Assessments detailed in Section 4.9.4.2 have not identified any active or former freshwater sources within the Operational Area. There are no known significant freshwater systems within the EMBA. Oceanographic studies indicate that both the open ocean and coastal zone off Western Australia are well-mixed and saline. Submerged former water sources (e.g. river beds) may exist within the EMBA which are archaeologically prospective or culturally significant.

It has been asserted that locations where saltwater and freshwater meet “are where the biggest energy lines are”. Energy lines are understood by Woodside to be the same as songlines which are addressed below. The EMBA is driven by an unplanned marine diesel spill, which is not expected to impact the seabed or features on it. As such, there is no

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

anticipated impact pathway from this activity to submerged water sources in the broader EMBA. In the highly unlikely and unmitigated worst case, unplanned marine diesel release may contact shorelines and receptors such as mangroves, and shoreline habitats. These habitats may contain brackish or fresh water due to runoff from land. Given hydrocarbon characteristics, rapid weathering, the low predicted volume ashore (Section 6.8.2), an unplanned release is expected to have no lasting effect on any freshwater sources along the shoreline.

Submerged calcarenite ridges/paleo beach barrier systems

Calcarenite ridges have been identified within the Operational Area, as detailed in Section 4.9.4.2. These features on the “mid shelf” identified in UWA (2021) are considered to predate human occupation of the Australian continent and therefore are not expected to contain archaeological material within it. Features on the “outer shelf” may contain archaeological material, but it was determined that “landforms and features that were identified on the seabed as having a higher probability of hosting indigenous UCH [underwater cultural heritage] ... have not been identified within the proposed export trunkline route.” There is also no planned dredging or large-scale seabed disturbance of calcarenite features that may expose archaeological material within the Operational Area. Further there is no anticipated impact pathway to calcarenite ridges in the broader EMBA from the Petroleum Activities Program.

Submerged hills

Assessments detailed in Section 4.9.4.2 have not identified submerged hills within the Operational Area, however submerged hills have been identified in the broader EMBA. These features on the “mid shelf” identified in UWA (2021) may be archaeologically prospective or culturally significant. The EMBA is driven by an unplanned marine diesel spill, which is not expected to impact the seabed or features on it. There is no anticipated impact pathway to submerged hills in the broader EMBA from the Petroleum Activities Program.

Madeleine Shoals

Madeleine Shoals is a potentially archaeologically prospective location found outside the Operational Area. While Madeleine Shoals is within the EMBA, this is driven by an unplanned marine diesel spill, and as such is not expected to impact the seabed or archaeological features on it. Therefore, there is no anticipated impact pathway to potentially archaeologically prospective sites at Madeleine Shoals from the Petroleum Activities Program.

Karst depressions/ravines and valleys between submerged ridges

Assessments detailed in Section 4.9.4.2 have not identified Karst depressions or other “catch points” within the Operational Area. Catch points have the potential to contain artefacts displaced by erosion during inundation which may be impacted by seabed disturbance. No planned seabed disturbance will occur outside the Operational Area.

General Intangible Values

Songlines

Management of intangible cultural heritage can include reducing impacts and risks to environmental features that are associated with intangible cultural heritage (UNESCO 2003). Impacts to marine plants, animals and other cultural features associated with songlines might impact the intergenerational transmission of knowledge of songlines when individuals can no longer witness or interact with the cultural features tied to songlines on Country. Therefore, managing songlines may require environmental controls protecting species at a population level, including migratory routes. Refer to species specific assessment below for further information, in addition to the impact and risk assessment in **Section 6.7** and **6.7.13** respectively.

Physical features comprising a component of a songline are important to protect to prevent the fragmenting or breaking apart of songlines and loss of sacred cultural knowledge. Songlines can become lost, fragmented, or broken when there is a loss of Country or impact to culturally important physical features (Neale and Kelly 2020:30). No specific details of songlines within the EMBA have been provided by relevant persons during consultation for this Activity, and no landforms typical of songlines (e.g. mountains, rivers, caves and hills (Higgins 2021)) are anticipated to be impacted by the Activity.

In publicly available literature, Murujuga is acknowledged as a starting point for songlines, including the flying fox songline (MAC 2023a). Precise location of this songline, and features of this songline that might be impacted, are not clearly articulated in the reviewed sources, but it is stated that “the sea is a source of creation for flying foxes” (DEC 2013). Although this does not provide the specificity required to determine the location of the flying fox songline or associated sites, Murujuga is located outside of the EMBA. Ethnographic survey (Section 4.9.4.2) also noted that “Dreamtime narratives... that commence at Murujuga and may also arrive from the sea including the... Bat (Flying Fox)” (McDonald and Phillips 2021). The ethnographic survey did not identify any sites within the EMBA related to songlines or make recommendations that any mitigations were required to manage songlines. Consultation with MAC and other Traditional custodians has not identified the flying fox songline as overlapping the EMBA, and flying foxes do not occur within the EMBA.

An ethnographic survey also noted “Dreamtime narratives... that commence at Murujuga and may also arrive from the sea including the *Marlu* (Plains Kangaroo)” (McDonald and Phillips 2021). Kearney et al (2023) notes a connection between the Kangaroo songline and a pair of submerged waterholes identified through seabed mapping by the Deep History of Sea Country project, which later found submerged artefacts in Flying Foam passage. Assessments detailed in Section 4.9.4.2 have not identified any active or former freshwater sources within the Operational Area that may connect to the Kangaroo or other songlines. Other terrestrial species with narratives originating or potentially originating from the sea at Murujuga noted by McDonald and Phillips (2021) include *Tarnguna* (Emu) and *Jugurru* (Dingo). The

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

ethnographic survey did not identify any sites within the EMBA related to any songlines, or make recommendations that any mitigations were required to manage songlines. Consultation with MAC and other Traditional custodians has not identified these songlines as overlapping the EMBA, and these species do not occur within the EMBA.

In publicly available literature, Murujuga is acknowledged as the starting point for the seven sisters songline (Bainger 2021). Precise location of this songline, and features of this songline that might be impacted, are not clearly articulated in the reviewed sources, however Murujuga is located outside of the EMBA. Ethnographic survey (Section 4.9.4.2) also noted that “a number of Dreamtime narratives... extend from the waters around Murujuga on to country, including the KurriKurri (Seven Sisters)” (McDonald and Phillips 2021). The seven sisters story is associated with Whitnell [sic] Bay, Murujuga, Depuch Island and Port Hedland, all being outside of the EMBA (McDonald and Phillips 2021). The ethnographic survey did not identify any sites within the EMBA related to songlines or make recommendations that any mitigations were required to manage songlines. Consultation with MAC and other Traditional custodians has not identified the seven sisters songline as overlapping the EMBA.

The existence of a whale songline potentially intersecting the EMBA has also been asserted by members of Save Our Songlines. Consultation with this group and associated individuals has not provided detail on the presence, features or route of this songline. It is assumed (from information provided by this group) that whales as an environmental receptor are a feature of this songline; the environmental impacts and risk on whales are assessed in Sections 6.7 and 6.7.13. The most detailed description available to Woodside is asserted in the Concise Statement and Affidavit filed by Raelene Cooper in the context of Scarborough seismic activities. Specifically, “whales carry important songlines, the whale dreaming, and connection between land and sea.” Specific details regarding the whale dreaming story are provided in Table 4-22. In summary, the whale dreaming story relates to transmission of knowledge and connection between environment and people, the women’s lore and connection to whales through their heart centre and obligation to care for country. It is stated that “because each animal uses songlines for migration, breeding and feeding, the disruption or distortion to the songlines causes the animals to become disoriented, confused or lost.” Further, that the whale’s songline creates a path for other fauna to follow.

It is therefore expected that the whale songline has the potential to be affected by the Petroleum Activities Program where there are impacts to whales at a population level, including disruption of migration routes, permanent displacement of whales and population decline, that result in discontinuation of story/transmission of knowledge, interruption of caring for Country activities, interruption of whale caretaker/midwife behaviour and interruption to performance of song/ceremony onshore. Given potential impacts to whales are limited to behavioural disturbance to transient individuals, which are not considered to be ecologically significant at a population level, the whale songline and associated whale dreaming story is not anticipated to be affected by the Petroleum Activities Program. Note further assessment of intangible values and marine mammals are provided below, in addition to the impact and risk assessment in Section 6.7 and 6.7.13 respectively.

Creation/dreaming sites; sacred sites; ancestral beings

Woodside has undertaken all reasonable steps to identify creation and dreaming sites, and places associated with ancestral beings within the EMBA. No such sites have been identified. A review of relevant literature has been undertaken which has identified creation, dreaming and ancestral narratives related to the sea more broadly without confirming where (if anywhere) these overlap the EMBA. These references are of a general nature, and do not identify any features or values requiring specific protection or management from the proposed activities.

Sea serpents or water serpents are common in Aboriginal creation narratives, and several references were identified in the reviewed literature. The majority of these refer to serpents residing within inland rivers or pools outside of the EMBA (Barber and Jackson 2011, Dury v Western Australia [2018] FCA 1849, Hayes v Western Australia [2008] FCA 1487, Juluwarlu 2004, Kalbarri Visitor Centre (2024) Water Corporation 2019). In some versions, the serpent originates from the sea or coast and creates the rivers as it heads inland. Barber and Jackson (2011) also recount a story where a freshwater serpent pushes a sea serpent back into the ocean where it presumably continues to reside. This does not provide the specificity required to determine the location of sea serpents within the sea, and it is possible that the ocean as a whole (out to and beyond other continents) should be viewed generally as housing the sea serpent(s). Consultation with Traditional Custodians and ethnographic surveys have not identified activities of this Petroleum Activities Program as having an impact on sea serpents. However, by analogy to other water serpent narratives across Australia, possible impact pathways may include interruption of its path by blocking or reducing flows of water, damaging sacred sites such as thalu or rock art sites or depleting water sources.

No impacts to water flows (either tidal movement or ocean currents) or depletion of water sources are anticipated from this Petroleum Activities Program. Features of the landscape with the potential for connection to creation/dreaming stories and ancestral beings were noted within the EMBA—notably nearshore submerged waterways and hills in the “mid shelf” identified by UWA (2021). However, there are no anticipated impact pathways to submerged landscape features within the broader EMBA from the Petroleum Activities Program.

Ceremonial sites

All mentions of active ceremonial sites were confined to onshore locations and no direct impacts to onshore ceremonial sites are anticipated from the Petroleum Activities Program. However, indirect impacts may occur where ceremonies cannot be performed due to limitations on access, loss of knowledge or impacts to the environment, which are further described below.

Cultural obligations to care for Country

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

Caring for Country collectively refers to the cultural obligations of individuals and groups, as well as rituals and ceremonies required for the physical and spiritual health of the environment. Lack of access to coastally located cultural sites that carry songlines or remain ceremonially important can impact First Nations people's livelihoods and impact their ability to carry out cultural obligations on Country. While there is potential for shoreline accumulation of hydrocarbons within the EMBA, relevant cultural authorities will be engaged in the event of a spill that may affect them, as specified in Appendix I: Oil Pollution First Strike Plan, Table 1-1.

Knowledge of Country/customary law and transfer of knowledge

Cultural knowledge about Sea Country/customary law and the intergenerational transmission of knowledge are important values identified through consultation, assessments and the literature review.

Transfer of knowledge includes continuing traditional practices to pass on practical skills. No traditional practices conducted within the EMBA have been identified.

Direct impact to communities practicing these skills will inherently occur when relevant aspects of the environment disappear, are displaced or suffer a reduction in population—for example traditional fishing methods require the survival of traditional fish resources. Therefore, ensuring the transmission of cultural knowledge may require environmental controls protecting species and migratory pathways at a population level. Refer to species specific assessment below for further information, in addition to the impact and risk assessment in **Section 6.7** and **6.7.13** respectively.

Connection to Country

Connection to Country describes the multi-faceted relationship between First Nations people and the landscape, which is envisioned as having personhood and spirit. Connection to Country may be damaged where people are displaced or disrupted (e.g. during colonisation) or where there is a loss of technical skills or environmental knowledge (McDonald and Phillips, 2021). No impacts of this nature are considered to arise from this Petroleum Activities Program. Access to Country is discussed below.

Access to Country

Access to Country, including Sea Country, is necessary for the continuation of other values including caring for Country and the transfer of traditional knowledge. Access is also a value in its own right, as a continuation of traditional Sea Country access and use.

Access to areas within the Operational Area may be limited where exclusion zones are established around vessels for safety purposes. Exclusion zones around IMMR activities are temporary, and the presence of subsea infrastructure are not anticipated to affect navigation, particularly given the water depth within the Operational Area. Access to country within the EMBA would be limited to temporary exclusion in areas where there are hydrocarbons present, including shoreline accumulation. However relevant cultural authorities will be engaged in the event of a spill that may affect them, as specified in Appendix I: Oil Pollution First Strike Plan, Table 1-1.

Kinship systems and totemic species

Individuals may have kinship to specific species (Smyth 2008, Juluwarlu 2004) and/or a responsibility to care for species (Muller 2008). These relationships are understood to impose obligations on Traditional Custodians. It is understood that these obligations do not impose restrictions on other people generally, but it is considered that impacts to species at a population level may inhibit Traditional Custodians with kinship relationships' ability to perform their obligations where this results in reduced or displaced populations. It is therefore considered that the management of totemic or kinship species applies at the species/population level and not to individual plants and animals. As such, impacts to individual marine fauna is not expected to impact on the totemic or kinship cultural connection.

Totemic species identified during consultation include whales, fish, stingrays and octopuses. Refer to species specific assessment below for further information, in addition to the impact and risk assessment in Sections 6.7 and 6.7.13 respectively. In the highly unlikely event of a marine diesel spill relevant cultural authorities will be engaged in the event of a spill that may affect them, as specified in Appendix I: Oil Pollution First Strike Plan, Table 1-1.

Resource collection

A suite of marine species have been identified through consultation and literature as important resources, particularly as food sources. For example, Sea Country resources of noted relevance to Thalanyji people which may be present in the vicinity of the Montebello Islands include dugongs, majun (marine turtles), turtle eggs, fish and shellfish. Other resource species include marine mammals, fish, shellfish, crustaceans, seabirds, gastropods, sea urchins and mangrove seeds.

In addition to their immediate value as sustenance, the gathering and preparation of these resources are informed by cultural knowledge, and an inability to use these resources may result in a loss of ability to transfer that knowledge to future generations. Direct impact to communities using these resources will inherently occur when the resource disappears, is displaced or suffers a reduction in population. Therefore, these communities may be impacted where there is an impact at the species/population level.

As assessed in Section 6.7, impacts from planned activities on the marine environment, including resources important to First Nations people, is expected to be limited to negligible or slight and therefore impacts that result in population effects (e.g., population decline, changes in migration routes, etc) are not expected. Impacts to potential resources within the EMBA, in the highly unlikely event of marine diesel spill, are described and risk assessed in Section 6.8.2 and are not expected to result in species/population level impacts. There may be potential impacts to resource collection

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

along the coastlines where there is shoreline contact with the marine diesel oil. In the highly unlikely event of a marine diesel spill relevant cultural authorities will be engaged in the event of a spill that may affect them, as specified in Appendix I: Oil Pollution First Strike Plan, Table 1-1.

Marine Species

Marine mammals (whale, dolphins, dugongs)

There are increase ceremonies/rituals for species of animals and plants important to First Nations, to enhance or maintain populations. Thalu are places where these increase ceremonies are performed. All mentions of active ceremonial sites in the reviewed literature were confined to onshore locations, though the values may extend offshore where, for example, the thalu relates to marine species populations. As thalu ceremonies are performed to maintain and increase populations of marine species, it is inferred that management applies at the species/population level and not to individuals—for example the thalu site on Murujuga which “brings in whales to beach” will continue to serve its purpose so long as whales continue to migrate through Mermaid Sound. Reviewed literature (DBCA 2020) also includes information that is marked as information that cannot be copied, reproduced or used without consent. The values described in the literature are environmental in nature, apply to marine mammal behaviours at a population level and are managed through existing environmental controls in Sections 6.7 and 6.7.13.

Related intangible cultural heritage may include the transmission of cultural knowledge about whales and whale behaviour, including birthing areas, whale communication and migratory patterns. Such cultural knowledge may be associated with various cultural functions and activities that support the social and economic life of a community (Fijn 2021). Whale symbology expressed through stories, music, and dance can reflect a group’s connections with the sea, as well as marine fauna, which then comprise a group’s cultural values (Ardler 2021; Bursill et al. 2007; Cressey 1998). Whales also speak to a broader connection that exists between First Nation people and their surrounding environment. Beyond mythology and symbolism, whales can be connected with various economic and social functions associated with everyday life. Cultural knowledge of whales, whale migration, behaviour and the related marine environment may all be important in ensuring the continuation of these socio-economic functions and other related activities that remain valuable to First Nations people (Fijn 2021). No impacts to communities’ ability to perform or transmit stories, music or dance are anticipated from the Petroleum Activities Program. Where timing or performance is linked to sighting or engaging with these species, impacts may occur where numbers or migration behaviours are impacted at a population level.

First Nations groups have expressed interest about whale migratory routes and studies. Inter-generational transmission of cultural knowledge (including songlines) relating to marine mammals may be impacted where changes to population or behaviour at a population level results in reduced sightings (e.g. through population decline, changes to migration routes or changes to migration seasonality). This transfer of knowledge may be integral to managing a group’s intangible cultural heritage (UNESCO 2003).

As described in the relevant environmental impact and risk assessments in Sections 6.7 and 6.7.13 respectively, potential impacts to cetaceans from planned activities are limited to behavioural impact, which may include temporary and localised deviations from migratory pathways for cetaceans. However, no permanent impacts preventing cetaceans from entering or occupying the areas have been identified. These impacts and risks are not considered to be ecologically significant at a population level, and hence are not expected to impact the value of marine mammals, including the transmission of cultural knowledge. As such, cultural values and intangible cultural heritage associated with these species are expected to be maintained.

Marine reptiles (turtles, sea snakes)

Turtles and their eggs have been identified through consultation and existing literature as an important resource, particularly as food sources. Direct impact to communities using these resources will inherently occur when the resource disappears, is displaced or suffers a reduction in population. Therefore, these species (as resources) will be impacted where there is an impact at the species/population level.

Intangible cultural heritage may also include the transmission of cultural knowledge about marine reptiles, such as nesting areas, hunting areas and migratory patterns. Cultural knowledge may also be conveyed through stories, such as the turtle being trapped in the sea as a result of its greed for berries as recounted by Capewell (2020). Such cultural knowledge may be associated with various cultural functions and activities that support the social and economic life of a community (Fijn 2021). First Nations groups have expressed an interest regarding turtle monitoring programs and migration patterns. Activities that impact turtle populations and their marine environment may have an indirect impact on some Aboriginal communities as this can limit access to cultural sites or deplete hunting areas that would threaten local food security (Delisle et al. 2018:251). Inter-generational transmission of cultural knowledge (including songlines) relating to marine reptiles may be impacted where changes to population or behaviour results in reduced sightings (e.g. through population decline, changes to migration routes or changes to migration seasonality). This transfer of knowledge may be integral to managing a group’s intangible cultural heritage (UNESCO 2003).

As described in the relevant environmental impact and risk assessments in Sections 6.7 and 6.7.13 respectively, potential impacts to marine reptiles are likely to be restricted to temporary behavioural changes, which are not considered to be ecologically significant at a population level, and hence not expected to impact the value of marine reptiles, including the transmission of cultural knowledge or use as a resource. Further, impacts to turtle foraging habitat from dredging activities in Commonwealth waters will be limited to direct removal of sparse epifauna habitat, as modelling of the suspended sediment plumes from dredging is predicted to cause a detectable change to water quality

with no impact to benthic communities and habitats. As such, cultural values and intangible cultural heritage associated with these species are expected to be maintained.

Fish and Cephalopods

Fish and squid have been identified through consultation and existing literature as an important resource, particularly as food sources. Direct impact to communities using these resources will inherently occur when the resource disappears, is displaced or suffers a reduction in population. Therefore these species (as resources) will be impacted where there is an impact at the species/population level.

Through consultation, fish were identified as important agents in the management of the broader ecosystem. It may be assumed that inter-generational transmission of cultural knowledge relating to fish may be impacted where changes to population or behaviour results in reduced sightings (e.g. through population decline). This transfer of knowledge may be integral to managing a group's intangible cultural heritage (UNESCO 2003). Intangible cultural heritage associated with fish, including inter-generational knowledge regarding fishing techniques and migratory patterns, can be managed by reducing impacts to fish in nearshore marine environments to which this cultural knowledge is intrinsically connected.

The octopus is an important totem to Ngarla People and features in the creation story of Solitary Island. There are increase ceremonies/rituals for species of squid and octopus to enhance or maintain populations. Thalu are places where these increase ceremonies are performed. All mentions of active ceremonial sites in the reviewed literature were confined to onshore locations, though the values may extend offshore where, for example, the thalu relates to marine species populations. As thalu ceremonies are performed to maintain and increase populations of marine species, it is inferred that management applies at the species/population level and not to individuals.

As described in the relevant environmental impact and risk assessments in Sections 6.7 and 6.7.13 respectively, the potential impacts from the Petroleum Activities Program on fish¹¹³ are considered to be localised and with slight, short-term (<1-year) impact potential on species (or lower), but not affecting ecosystem function, physical or biological attributes. Impact potential is not considered to be ecologically significant at a population level. As such, cultural values and intangible cultural heritage associated with these species are expected to be maintained.

Seabirds

Seabirds, specifically shags, have been identified through literature as a culturally significant species (Malgana Aboriginal Corporation 2021), as well as a resource (seabird eggs; Smyth 2007). Direct impact to communities using these resources will inherently occur when the resource disappears, is displaced or suffers a reduction in population. Therefore, these species (as resources) will be impacted where there is an impact at the species/population level. Intangible cultural heritage may also include the transmission of cultural knowledge about seabirds, such as nesting areas, hunting areas and migratory patterns. Such cultural knowledge may be associated with various cultural functions and activities that support the social and economic life of a community (Fijn 2021) Inter-generational transmission of cultural knowledge relating to seabirds may be impacted where changes to population or behaviour results in reduced sightings (e.g. through population decline, changes to migration routes or changes to migration seasonality). This transfer of knowledge may be integral to managing a group's intangible cultural heritage (UNESCO 2003).

As described in the relevant environmental impact assessments in Sections 6.7 and 6.7.13 the potential impacts from the Petroleum Activities Program on seabirds is assessed to be Negligible (F). The potential for temporary behavioural disturbance localised around vessels from light is not expected to result in a substantial adverse effect on species' population, and light emissions will not seriously disrupt the lifecycle of an ecologically significant proportion any migratory bird species. In terms of risk, as described in Section 6.8.2, a change in marine fauna behaviour or injury/mortality to seabirds and migratory shorebirds may occur due to a change in water or sediment quality following an unplanned hydrocarbon release. Given hydrocarbon characteristics, expected rapid weathering to below impact thresholds, and the mobile transient nature of individuals, unplanned hydrocarbon releases are not expected to substantially modify, destroy or isolate an area of important habitat for migratory species. As such, cultural values and intangible cultural heritage associated with these species are expected to be maintained.

Benthic habitats (coral, seagrass)

Through consultation, First Nations groups identified benthic habitats as valuable for their ecological values, including corals attracting fish and seagrass providing shelters for fauna, as well as an important habitat for dugongs. Additionally, coral is valued by Murujuga Aboriginal Corporation (MAC) for its aesthetic values.

In terms of risk, as described in Section 6.8.2, a change in habitat may occur due to a change in water or sediment quality following an unplanned hydrocarbon release. Given hydrocarbon characteristics, rapid weathering, short-term exposure, as well as the response strategies planned to be deployed, an unplanned release is not expected to result in a level of exposure to coral and seagrass that would cause an adverse impact on marine ecosystem functioning or integrity results. As such, cultural values and intangible cultural heritage associated with benthic habitats are expected to be maintained.

Shoreline habitats (mangroves)

¹¹³ Squid and octopus are considered to be impacted through similar impact pathways as fish, and hence the conclusion represented here are considered appropriate for cephalopods.

Through consultation, First Nations groups identified shoreline habitats as valuable for their ecological values, including mangroves for providing shelter to marine invertebrates, which are identified resources, and potential nursery for turtles. Literature also notes that mangroves are also valued for the flora and fauna they are associated with and support (Commonwealth of Australia 2002) and Smyth (2007) reports that mangrove seeds are used as a resource by Ngarda-Ngarli (the collective term for the Traditional Custodians who look after Murujuga Country).

There is no overlap between the Operational Area and mangrove habitat, and no planned impacts to mangroves from the Petroleum Activities Program. In terms of risk, as described in Section 6.8.2, a change in habitat may occur due to a change in water or sediment quality following an unplanned hydrocarbon release however no shoreline accumulation is expected. As such, cultural values and intangible cultural heritage associated with shoreline habitats are expected to be maintained.

Conclusion

The impact and risk assessment for cultural features and heritage values has determined that the planned activities are unlikely to result in an impact greater than negligible (F) and unplanned activities are assessed to have a residual risk rating of moderate (or lower). Woodside will continue to consider new heritage information as it becomes available (See C 24.1).

Demonstration of ALARP

As marine ecosystems may hold both cultural and environmental value (see Section 4.9), with cultural and environmental values intrinsically linked, in addition to the specific controls for cultural features and heritage values, the controls and performance standards in **section 6.7** and **6.7.13** will reduce impacts to cultural features and heritage values, including marine species and habitats.

Control Considered	Feasibility (F) & Cost/Sacrifice (CS)	Benefit in Impact/Risk Reduction	Proportionality	Adopted
Apply a 'living heritage' ¹¹⁴ management approach. Woodside seeks advice and incorporates Traditional Custodian cultural knowledges across our activities. Cultural safety considerations are factored for our workforce and the Traditional Custodian community.	F: Yes CS: Minimal	Implementation of the 'living heritage' approach pays acknowledgement and respect to Traditional Custodian communities. It supports the transfer of cultural knowledges and is an effective strategy to manage intangible cultural values.	Benefits outweigh cost/sacrifice.	Yes C 24.1
The environmental impacts and risks of the activity will continue to be managed to as low as reasonably practicable and an acceptable level for cultural features and heritage values.	F: Yes CS: Substantial costs	Implementation of activities and associated controls to ALARP and acceptable levels supports the maintenance of cultural features and heritage values	Benefits outweigh cost/sacrifice	Yes C 24.2
Use of cultural heritage monitors on vessels to oversee implementation of controls protecting cultural values	F: No CS: Not feasible	Primary Installation Vessels are POB constrained with no ability to facilitate additional personnel	Not considered – control not feasible.	No

¹¹⁴ Living heritage supports community and individual identity. Intangible cultural heritage is 'living heritage' that is inherited from ancestors and passed on to their descendants. It is comprised of many influences, including oral traditions, art, social practices, rituals and ceremonies, cultural knowledge and practices. It is transmitted from generation to generation and evolves in response to the environment. Woodside applies a 'living heritage' approach to its cultural heritage management. This includes ensuring that Traditional Custodians are given voice to identify interests, transmit information and express concerns. Woodside works with Traditional Custodians to support and follow appropriate cultural protocols, including calling to Country, conducting smoking ceremonies (in areas where this custom is appropriate) and undertaking cultural awareness. Woodside will collaborate and provide relevant information it holds to groups such as Heritage Management Committees where they are established.

Demonstration of ALARP				
Project inductions to all relevant marine crew, prior to the individual commencing the activity, will include information on cultural features and heritage values, including tangible and intangible cultural heritage.	F: Yes CS: Minimal	Ensures workforce is suitably aware of cultural features and heritage values in the area they are operating.	Benefits outweigh cost/sacrifice.	Yes C 24.3
New information from further archaeological or ethnographic studies relevant to MAC will be forwarded to MAC for their consideration and feedback.	F: Yes CS: Sitting fees of Traditional Custodians and additional costs of independent experts	Allows effective response to new heritage information, ensuring appropriate management and prioritising Traditional Custodian input, including through MAC Circle of Elders or relevant experts when identified as necessary by MAC.	Benefits outweigh cost/sacrifice.	Yes C 24.5
Activities under the Petroleum Activities Program will be carried out in accordance with any protection declarations relevant to the Operational Area, under Sections 9,10,12 of the ATSIHP Act	F: Yes CS: Costs associated with the implementation	Implementation of the control ensures any impacts to significant Aboriginal areas and significant Aboriginal objects protected by Ministerial declaration, are acceptable under the standards of the ATSIHP Act.	Control based on legislative requirements – must be adopted.	Yes C 24.6
Unexpected finds of potential Underwater Cultural Heritage ¹¹⁵ sites/features, including first nations UCH are managed in accordance with the Unexpected Finds Procedure set out in Section 7.87.7	F: Yes CS: Costs of implementation	Allows management of new finds in accordance with legislative requirements, expert advice and community expectations.	Benefits outweigh cost/sacrifice.	Yes C 2.2
Report any potential UCH finds to relevant stakeholders and authorities in accordance with the Unexpected Finds Procedure, Underwater Cultural Heritage Act 2018 and the ATSIHP Act.	F: Yes CS: Minimal	Meets legislative requirements and community expectations.	Benefits outweigh cost/sacrifice.	Yes C 2.4
Manage vessel speed in the humpback and PBW whale BIAs in migration seasons within the Trunkline Operational Area.	F: Yes. It is possible to carry out for vessels transiting within the Operational Area CS: will impact with longer transit times for vessels.	There is mounting evidence that reduction of vessel speeds can reduce vessel underwater noise emissions and increase the likelihood that fauna will be seen by vessels (and have more time to react) thereby	Benefits outweigh cost/sacrifice	Yes C 4.8

¹¹⁵ Underwater Cultural Heritage is defined as any trace of human existence that has a cultural, historical or archaeological character and is located under water, in accordance with the UCH Act.

Demonstration of ALARP				
		<p>reducing possibility of vessel strike.</p> <p>The Pilbara Port boundaries have been excluded As the Pilbara Port Authority sets speed limits for within the Port boundaries.</p> <p>Where this control prevents impacts to humpback and pygmy blue whales at a population level, it maintains a culturally significant resource to a level that results in no observable change to coastal communities (migratory pathways maintained).</p>		
Should it be identified that relevant cultural authorities may be affected in the unlikely event of a spill, Woodside will engage with those parties as appropriate and in alignment with the FSP.	F: Yes CS: Minimal	Engaging with relevant cultural authorities that may be impacted by a spill will allow the Traditional Custodians to identify areas of concern.	Benefits outweigh cost/sacrifice	Yes Adopted, see Appendix I: Oil Pollution First Strike Plan (Notifications Table 1-1)
The Murujuga Rock Art Strategy and Monitoring Program (MRAS/MRAMP), run by DWER and MAC, is in place to protect the Aboriginal rock art by providing a long-term framework that builds on previous work to deliver an improved approach to monitoring, analysis and management. Woodside will maintain its support of the MRAS/MRAMP, and monitor the outcomes as part of the implementation strategy of this EP	F: Yes CS: Minimal	<p>Benefit as defined in sections detailed in Section 6.7.7</p> <ul style="list-style-type: none"> • -Program: Murujuga Rock Art (Western Australian Government) • -Murujuga Rock Art Monitoring Program <p>Further studies by DWER/Murujuga Aboriginal Corporation are required to provide scientific certainty and allay stakeholder concerns.</p>	Benefits outweigh cost/sacrifice	Yes C 7.1
Onshore processing facilities (i.e. Pluto LNG, NWS Karratha Gas Plant and Perdaman Urea) are subject to regulatory assessment and compliance under the Environmental Protection Act 1986 (WA) This includes implementation of potential EQMF developed as an outcome of MRAS; and measures such as NOx concentration limits at emissions point sources under EP Act Part V licenses,	F: Yes CS: Minimal	<p>Ensures application of precautionary principle to potential emissions risks relating to rock art.</p> <p>Ensures technical solutions to emissions management are considered and employed to keep potential impacts ALARP.</p> <p>Ensures adaptive management to evolving scientific evidence and that downstream emissions are maintained at a level that is acceptable with regards to</p>	Benefits outweigh cost/sacrifice	Yes C 7.2

Demonstration of ALARP				
and implementation of Part IV conditions Further detail on this control is described in Section 6.7.7.		the management of cultural heritage values.		
Implement the PAP in a manner that is not inconsistent with the objectives of the Murujuga National Park Management Plan 78, through execution of the Conservation Agreement and Deep Gorge Joint Statement.	F: Yes CS: Significant potential cost. Legal requirement.	Legal requirement to carry out activities not inconsistent with the Murujuga National Park Management Plan.	Control based on legislative requirements – must be adopted.	Yes. C 7.3
<p>ALARP Statement:</p> <p>On the basis of the impact and risk assessment outcomes and use of the relevant tools appropriate to the decision type (i.e. Decision Type A, Section 2.3.3), Woodside considers the adopted controls appropriate to manage the potential impacts and risks to cultural features and heritage values. As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts are considered ALARP.</p>				

Demonstration of Acceptability
<p>The impact and risk assessment has determined that, given the adopted controls, planned activities are unlikely to result in an impact greater than negligible (F)¹¹⁶ and unplanned activities are assessed to have a residual risk rating of moderate (or lower).</p> <p>The Petroleum Activities Program and the EMBA are not expected to have a significant impact (e.g. changes in population levels) on MNES including marine fauna with a First Nations connection with, or traditional use in nearshore areas as defined in Section 4.9. While the activity will occur on the Ancient Landscape Woodside has:</p> <ul style="list-style-type: none"> • Consulted with MAC to identify any concerns associated with activities of this EP in Commonwealth waters. To address relevant concerns (see Appendix F: Consultation, Table 2) additional controls (C 24.4) have been included in the EP. • Undertaken desktop assessments by qualified professionals, using remote sensing techniques, to identify known or potential underwater cultural heritage (refer to Section 4.9) and an unexpected finds procedure will be implemented (C 2.2). Therefore, the activity is not inconsistent with Underwater Cultural Heritage Guidance for Offshore Developments (DoEE 2019b) and the Assessing and Managing Impacts to Underwater Cultural Heritage in Australian Waters Guidelines on the application of the <i>Underwater Cultural Heritage Act 2018</i> (DCCEE 2024a). <p>In addition, Woodside has engaged with Traditional Custodians adjacent to the EMBA to understand the cultural features and heritage values that may occur and potential impacts from the activity.</p> <p>Appendix G: Program of Ongoing Engagement with Traditional Custodians and the 'living heritage' management approach (C 24.1) have been developed to enable Woodside to manage cultural values which may be identified at any time during Woodside's activities via ongoing dialogue with Traditional Custodians.</p> <p>Woodside supports the ongoing management of heritage values under listings; Murujuga Cultural Landscape, Murujuga National Park and Dampier Archipelago (Including Burrup Peninsula) National Heritage Place. Planned activities under the PAP are not inconsistent with relevant heritage legislation, management plans and agreements under which these values are protected.</p> <p>Further opportunities to reduce the impacts have been investigated above. The potential impacts and risks are considered acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the impacts and risks to cultural features and heritage values to a level that is acceptable, if ALARP.</p>

¹¹⁶ Noting that as the receptor sensitivity is high the impact significance level is Slight (E).

Key Environmental Performance Outcomes, Standards and Measurement Criteria related to Cultural Features and Heritage Values¹¹⁷			
EPO	Adopted Control(s)	EPS	MC
<p>EPO 4 No adverse impact to unexpected finds of Underwater Cultural Heritage without a permit¹¹⁸.</p> <p>EPO 5 Prevent injury or mortality to seabirds as a result of the Petroleum Activities Program.</p> <p>EPO 6 No impacts to marine fauna greater than that caused by minimum required light emissions for safe work / navigation.</p> <p>EPO 7 No displacement of marine turtles from habitat critical during nesting and internesting periods and marine turtles' biologically important behaviour can continue in biologically important areas.</p> <p>EPO 8 No injury of, or mortality to, EPBC Act 1999 and WA Biodiversity Conservation Act 2016 listed marine fauna as a result of noise generated by the Petroleum Activities Program.</p> <p>EPO 9</p>	<p>C 24.1 Apply a 'living heritage' management approach. Woodside seeks advice and incorporates Traditional Custodian cultural knowledge across our activities. Cultural safety considerations are factored for our workforce and the Traditional Custodian community.</p>	<p>PS 24.1.1 Woodside will continue to give voice to Traditional Custodians to identify interests, transmit information and express concern through ongoing consultation as identified in Section 7.10.5.</p>	<p>MC 24.1.1 Records demonstrate Change Management and Management of Knowledge processes have been followed where new controls or management measures identified</p>
		<p>PS 24.1.2 Woodside will assess and where deemed practicable implement appropriate cultural protocols where requested by Traditional Custodians</p>	<p>MC 24.1.2 Records demonstrate Woodside implemented cultural protocols as requested</p>
	<p>C 24.2 The environmental impacts and risks of the activity will continue to be managed to as low as reasonably practicable and an acceptable level for cultural features and heritage values.</p>	<p>PS 24.2.1 Consideration of cultural values/new information, through the life of the EP, and the development of avoidance or mitigation strategies in collaboration with Traditional Custodians if impacts to cultural values are identified. Where avoidance is not possible, impact minimisation will be prioritised and demonstrated through a written options analysis/ALARP to ensure an acceptable level of impact. This will be documented through Woodside's Management of Change and Management of Knowledge processes.</p>	<p>MC 24.2.1 Records demonstrate Change Management and Management of Knowledge processes have been followed where new controls or management measures identified</p>
	<p>C 24.3 Project inductions to all relevant marine crew, prior to the individual commencing the activity, will include information on cultural features and heritage values, including tangible and intangible cultural heritage.</p>	<p>PS 24.3.1 All relevant marine crew have completed Project inductions that include information on cultural values, including tangible and intangible cultural heritage for awareness</p>	<p>MC 24.3.1 Records demonstrate all relevant marine crew have completed inductions that include cultural material</p>
	<p>C 24.5</p>	<p>PS 24.5.1</p>	<p>MC 24.5.1</p>

¹¹⁷ As marine ecosystems may hold both cultural and environmental value (see Section 4.9.1), with cultural and environmental values intrinsically linked, in addition to the specific controls for cultural features and heritage values, the controls and performance standards in section 6.7 and 6.8 will reduce impacts to cultural features and heritage values including marine species and habitats.

¹¹⁸ Permit for Entry into a Protected Zone or to Impact Underwater Cultural Heritage would be acquired under the UCH Act.

Key Environmental Performance Outcomes, Standards and Measurement Criteria related to Cultural Features and Heritage Values¹¹⁷			
EPO	Adopted Control(s)	EPS	MC
<p>No displacement of marine turtles or pygmy blue whales from habitat critical during nesting/breeding (inc. interesting periods for turtles) and ensure biologically important behaviour can continue in biologically important areas.</p> <p>EPO 14 Prevent accelerated weathering of Murujuga rock art or impact to human health from air emissions that result from onshore processing of Scarborough gas.</p>	<p>New information from further archaeological or ethnographic studies relevant to MAC will be forwarded to MAC for their consideration.</p>	<p>Any new information from archaeological or ethnographic studies relevant to MAC is forwarded to MAC for their consideration.</p>	<p>Evidence that any new information from archaeological or ethnographic studies relevant to MAC has been forwarded to MAC.</p>
	<p>C 24.6 Activities under the Petroleum Activities Program will be carried out in accordance with any protection declarations relevant to the Operational Area, under Sections 9,10,12 of the ATSIHP Act</p>	<p>PS 24.6.1 Where an object or Significant Aboriginal Area is protected by a declaration under Section 12 or Sections 9/10 respectively of the ATSIHP Act, no work inconsistent with that declaration will be conducted for the duration of that declaration.</p>	<p>MC 24.6.1 No non-compliances with any protection declarations relevant to the Operational Area, under Sections 9,10,12 of the ATSIHP Act</p>

7 IMPLEMENTATION STRATEGY

7.1 Overview

Regulation 22 of the Environment Regulations requires an EP to contain an implementation strategy for the activity. The implementation strategy for the Petroleum Activities Program confirms fit for purpose systems, practices and procedures are in place to direct, review and manage the activities so environmental risks and impacts are continually being reduced to ALARP and are acceptable, and that EPOs and EPSs outlined in this EP are achieved.

Woodside, as Operator, is responsible for ensuring the Petroleum Activities Program is managed in accordance with this Implementation Strategy and the WMS (see Section 1.9).

7.2 Systems, Practice and Procedures

All operational activities are planned and carried out in accordance with relevant legislation and internal environment standards, management measures (i.e. controls) identified in this EP and internal environment standards and procedures (Section 6).

The systems, practices and procedures that will be implemented are listed in the Performance Standards (PS) contained in this EP. Document names and reference numbers may be subject to change during the statutory duration of this EP and is managed through a Change Register and update process.

7.2.1 Woodside Management System Operate Processes

Under the WMS Operate Activity (see Section 1.9 for an overview of the WMS), there are four overarching processes; those directly relevant to the implementation of this EP and environmental management during the Petroleum Activities Program are described below (Operate Plant Process and the Maintain Assets Process). These processes apply only to the Operations phase (i.e. after Initial Start-up), and do not apply to one off activities such as Hook-up and Commissioning.

7.2.1.1 Operate Plant

The objective of the Operate Plant Process is to ensure production is carried out in a safe, efficient, reliable and economic manner, and that all required process variables are within allowable limits. This ensures the potential for unplanned (accident/incident) events that may impact the environment are minimised.

The Operate Plant Process develops key activities to support ongoing production activities to ensure the facility is operated within the Basis of Design. The process also identifies required production routines, routine execution, recording of data gathered and formulation of remedial activities. The Operate Plant Process includes the Integrated Safe System of Work (ISSoW) system (described below).

In addition, the Operating Practice MSPS (M02) is in place to assure operating practices are in place, such that:

- integrity critical operating procedures are available, accurate, up to date, understood and used
- safe operating and technical integrity limits are defined, understood and the process is managed within these limits.

7.2.1.2 Integrated Safe System of Work

The ISSoW Procedure outlines the key activities required to achieve effective management of permit-controlled work on the facility. The ISSoW process is a management system for all work and

is a key element in ensuring the safety of personnel, protection of the environment and technical integrity of the facility.

Work within the facility 500 m PSZ and operations within the vicinity of the connected flowlines is controlled in accordance with ISSoW.

The ISSoW system takes a risk-based approach to activities, thus tasks with higher levels of risk are subjected to greater scrutiny and control. The ISSoW system also allows for low-risk routine tasks to be carried out with adequate but minimal administration. The prime objective of ISSoW is to ensure work other than normal operations is properly planned, risk assessed, controlled, coordinated, and safely executed. It provides a methodical approach to identifying hazards, assessing risks, and creating and supporting permits to work and associated certificates.

In keeping with ALARP principles, this system is critical to ensuring the appropriate level of hazard identification and risk assessment is carried out for activities performed on the facility.

In addition, the Safe Work Control MSPS (M04) is in place to assure effective safe work control, permit to work and task risk management arrangements are in place and followed to control the risks arising from work activities.

7.2.1.3 Maintain Assets

The Maintain Assets Process aims to improve the reliability and availability of plant and equipment (which includes that required for safe operation) through well managed and planned execution of maintenance that promotes a proactive maintenance culture.

Maintenance, inspection and testing systems and procedures are in place to safeguard the integrity of the facility. The maintenance strategy for the facility is based on optimising safety, minimising environmental impact and maximising production. Maintenance practices used to establish well managed maintenances strategies, planned execution and improvement are described in the Maintenance of Assets Procedure.

A risk-based approach is used as the basis for establishing and prioritising inspection, maintenance and testing requirements at the facility. Equipment is assessed to establish equipment criticality with respect to the consequences and likelihood of equipment failure. This informs determination of appropriate maintenance and inspection activities. Maintenance activities are allocated risk rankings according to the criticality of equipment, to ensure high risk maintenance work orders are completed as a priority.

A computerised maintenance management system provides a database called SAP-PM that contains facility registers, equipment details, spare parts data and associated planned maintenance tasks. This system is used to plan, monitor and record maintenance activities. The system provides a variety of reports that enable monitoring and assessment of maintenance activities.

SCE Technical Performance Standards identify SCEs and associated assurance activities. These activities are identified in the CMMS and given the appropriate priority. Refer to Sections 6.8.1.9 and 7.2.8 for more detail on SCE Technical Performance Standards and how they differ from EPSs required by the Environment Regulations. SCE Technical Performance Standards form a key component in the processes and systems implemented by Woodside to maintain safety and environment critical plant and equipment.

In addition, the Maintenance and Inspection MSPS (M03) is in place to assure that the necessary inspection and maintenance requirements are identified and carried out to maintain the integrity of SCEs and SCCs.

7.2.2 Process Safety Management

To ensure that Woodside protects the safety, security and health of its employees, contractors, the environment and assets, Woodside has adopted the Energy Institute's Process Safety Management

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

Controlled Ref No: SA0006AF0000022

(PSM) framework within its Process Safety Management Procedure which sets out a disciplined framework for managing the integrity of systems and processes that handle hazardous substances over the production (and exploration) lifecycle. It deals with the prevention and control of events that have potential to release hazardous materials and energy.

PSM consists of four main focus areas. Each focus area contains a number of PSM requirements that define key aspects required to ensure that PSM is integrated through the organisation. There are 20 PSM requirements. The focus areas and requirements are shown in Figure 7-1.

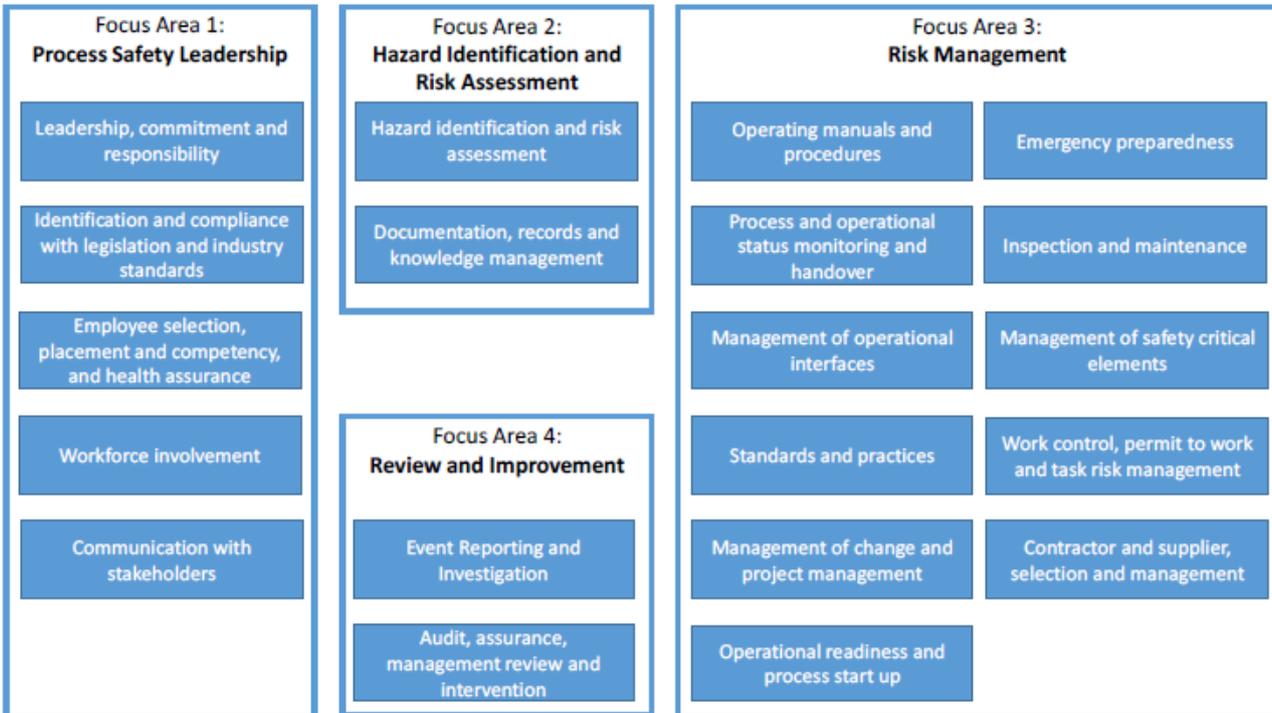

Figure 7-1: Process safety management focus area

7.2.2.1 Woodside Safety Culture Framework

Woodside's 'Our Safety Culture' framework (shown in Figure 7-2) promotes a strong HSE culture and is a key enabler for effective process safety management. This framework outlines the expected behaviours for everyone including supervisors and managers/executives, and is openly discussed as part of inductions, training and development.

Theme	Everyone	Supervisors	Managers/Executives
Standards	Follow rules	Ensure compliance	Set high standards
Communication	Speak up	Encourage the team	Communicate openly
Risk management	Be mindful	Promote risk awareness	Confront risk
Involvement	Get involved	Involve the team	Involve the workforce

Figure 7-2: Woodside ‘Our Safety Culture’ framework

7.2.3 Risk Management

Risk management processes and practices are applied on an ongoing basis to design, production and maintenance activities at the FPU to manage risks to personnel, assets and the environment.

Potential environmental consequences and impacts from the FPU are risk assessed and controlled in accordance with the Woodside risk management processes described in Section 2 of this EP (Environmental Risk Management Methodology).

The results of the Scarborough Operations ENVID are described in Section 6 and in the Operations Environmental Impacts and Risk Register. This register, in conjunction with the EP, provides a demonstration that environmental risks have been identified, and that appropriate controls are in place to manage those risks to a level that is acceptable and ALARP throughout the life of the facility.

A number of other risk management tools and techniques are used to manage environmental and other risks on a routine basis during operational, maintenance and inspection tasks. Examples include:

- the processes outlined in Section 2.2
- risk management tools including: ISSoW tools, e.g. Hazard Identification and Risk Assessments, Level 2 Risk Assessments, Operational Risk Assessments, the technical Management of Change (MoC) system (Section 7.2.7), and Step back 5 x 5
- integrity review studies, HAZIDs and Hazard Operability studies.

These tools, risk and integrity management practices are described further in the Scarborough Safety Case, WOMP, and the Control of Operational Risk Procedure.

In addition, other risk sub-processes and practices are also applied within Woodside on an ongoing basis to manage different types of risk. A summary of those relevant to the Petroleum Activities Program is provided below. Woodside’s risk management processes (refer to Section 2.2), along with the supporting risk sub-processes and practices discussed in this section, ensure the environmental impacts and risks of the activity continue to be identified and reduced to a level that is ALARP.

7.2.3.1 Management of Risks – Contracting and Procurement (Operations)

Suppliers and contractors play a significant role in meeting the resource needs of Woodside’s operations, including the facility operations. Effective management of environmental risks in contracts is achieved by setting clear expectations and managing environmental risks throughout

the duration of the contract. Environmental risks in contracts are managed under the Contracting and Procurement Procedure supported by the Health, Safety and Environment in Contracting Guideline. The guideline provides a risk-based approach to contractor selection and management and is aligned with 'HSE Management – Guidelines for Working Together in a Contract Environment' (International Association of Oil and Gas Producers, Report No. 423).

The Engineering Standard: Quality Requirements for Supply of Products and Services defines specific quality requirements for engineering contracts and purchase orders. The specified quality control requirements in the Standard are required to be complied with as applicable to the scope of supply.

7.2.3.2 Management of Risks – Subsea Activities (Operations)

Subsea activities are managed in line with the Subsea and Pipelines Integrity Management Procedure which defines the practices and technical requirements that must be applied to deliver and safeguard integrity of the subsea equipment and pipelines during the facility lifecycle. It provides the relationship between the PSM Framework (including management of change) and Subsea and Pipelines Group services processes.

IMMR activities are managed under the Manage IMMR Work Procedure. Risk assessments are conducted as required under this procedure.

These requirements are supported by implementation of the Subsea Construction and Inspection, Maintenance and Repair Environment Screening Questionnaire tool. The screening questionnaire is used to understand the scope of the activity, potential environmental impact and if additional regulatory approvals are required. To achieve this, the questionnaire captures key project information such as seabed disturbance, chemical use and waste. This information is used by an environment focal point to determine if further assessment is required. For projects that have the potential for environmental impact, an assessment is undertaken against this EP and other Woodside environmental requirements. If determined by the Subsea and Pipeline Environment Screening Questionnaire process, an EP MoC review (as per Section 7.2.7.2) is undertaken to confirm if the level of environmental risk warrants revision and resubmission of an EP. Environmental questionnaires are maintained in the Subsea and Pipeline (SSPL) Environment Project Register.

Key environmental requirements and regulatory commitments are communicated to project teams and incorporated into key project documentation where applicable and required (i.e. not addressed via existing Woodside practices).

7.2.3.3 Management of Risks – Major Projects

Major projects are required to follow the Appraise and Develop Management Procedure and the Opportunity Management Framework. This procedure defines the requirements to deliver a commercially valuable production facility or modify to an existing facility. The process workflow requires integration of work from various functions utilising their people and processes, including Environment, for example HSE philosophy and regulatory approval requirements.

These requirements are supported by implementation of the Brownfields Environment Screening Questionnaire tool. The screening tool is used to determine if a project has the potential for environmental impact or requires additional regulatory approvals. For projects that have the potential for environmental impact, an environmental focal point is assigned, and the risks and impacts assessed against the facility EP and other Woodside environmental requirements.

Key environmental requirements and regulatory commitments are communicated to project teams and incorporated into key project documentation where applicable and required (i.e. not addressed via existing Woodside practices). Where it is identified that the project scope has the potential to result in modification or change to the facility description provided in the EP, or where potential new environmental risks or impacts or increases in an existing environmental risk or impact are identified,

an EP MoC review (as per Section 7.2.7) is undertaken to confirm if the level of environmental risk warrants revision and resubmission of an EP.

7.2.3.4 Management of Risks – Well Integrity

Wells are managed throughout their lifecycle in line with the Well Lifecycle Management Procedure. This procedure provides the basis for ensuring well integrity in accordance with the Process Safety Management Procedure.

In addition, wells are required to have a regulator accepted Well Operations Management Plan to demonstrate that well integrity risks are managed to ALARP levels. Wells tied back to the facility are managed under a WOMP.

7.2.3.5 Management of Risks – Marine Services

Woodside's Marine Services provides a platform for the conduct of safe and efficient Marine Operations across Woodside through the Marine Services Management. A set of procedures that Support Vessel assurance and management (including HSE and quality (HSEQ) management) are in place to ensure marine operations are conducted in a safe and efficient manner, and in accordance with regulatory requirements.

More details on vessel assurance and the communication of environment requirements to vessels are provided in **Section 7.9**.

Vessel masters are required to request clearance from the facility OIM delegate prior to entering the 500 m PSZ around the FPU.

7.2.3.6 Management of Human Factor Related Risks

The term 'human factors' is used to describe the consideration of people as part of complex systems. Woodside defines 'human factors' as follows: 'human factors uses what we know about people, organisation and work design to influence performance'.

Human factors can contribute to unplanned events or result in failure or degradation of the controls in place to protect against unplanned events. The WMS includes a number of procedures designed to manage human factors related risks and prevent incident causation, which includes:

- information management
- integrity limits defined and communicated
- standardised operational work management practices
- Our Safety Culture framework and Golden Safety Rules
- competency management frameworks, organisation change management
- Safe Work Controls (permit systems)
- Step Back 5x5
- HSE, medical, fatigue management and alcohol and other drugs procedures
- HSE Event reporting and investigation.

7.2.4 Emissions and Energy Management

Emissions generation and energy use are managed consistently with the Energy Management System elements of ISO 50001. Table 7-1 sets out the EP sections which correspond to key ISO elements of Scarborough Facility's Energy Management Plan.

Table 7-1: Scarborough Facility Energy Management Plan

ISO 50001 Energy Management System element		Scarborough alignment
Leadership	Top management shall demonstrate commitment to continual improvement in energy performance and effectiveness of the Energy Management System, establish an energy policy, and ensure that the responsibilities for relevant roles are assigned and communicated within the organisation.	7.6 - Organisation Structure Appendix A: Woodside Policies- (Climate Policy) 7.2.4.1 - GHG Emissions and Energy Management Procedure 7.2.4.2 - Production Optimisation and Opportunity Management
Planning	The organisation shall establish objectives and energy targets, and plan actions to address risks and opportunities. The organisation shall conduct energy reviews to analyse energy use and consumption; key characteristics of its operations affecting energy performance shall be identified, measured, monitored and analysed at planned intervals; energy performance indicators shall be tracked to measure and monitor performance, and an energy baseline shall be established based on energy reviews.	7.2.4.1 - GHG Emissions and Energy Management Procedure (including facility Decarbonisation Plan) 7.2.4.2 - Production Optimisation and Opportunity Management 7.2.4.3 - Greenhouse Gas, Energy and Flare Target Setting - Operations 7.2.4.5 Methane Management
Support	The organisation shall provide the resources needed for the establishment, implementation, maintenance and continual improvement of energy performance and the Energy Management System, including competency of personnel, communications, and required documentation.	7.6 - Organisation Structure 7.2.4.2 - Production Optimisation and Opportunity Management
Operation	The organisation shall plan, implement and control the processes related to its significant energy uses, needed to meet its requirements. The organisation shall consider energy performance improvement opportunities in the design of new, modified and renovated facilities, equipment, systems and processes that can have a significant impact on its energy performance.	7.2.4.1 - GHG Emissions and Energy Management Procedure (including Environmental Performance Procedure) 7.2.4.2 - Production Optimisation and Opportunity Management 7.2.4.3 - Greenhouse Gas, Energy and Flare Target Setting - Operations 7.2.4.5 Methane Management
Performance evaluation	The organisation shall implement appropriate monitoring, measurement, analysis and evaluation of energy performance, conduct internal audits and management reviews of the Energy Management System to understand its implementation and effectiveness.	7.2.4.2 - Production Optimisation and Opportunity Management 7.2.4.3 - Greenhouse Gas, Energy and Flare Target Setting - Operations 7.2.4.5 Methane Management 7.10 - Monitoring, Auditing, Management of Non-conformance and Review 6.7.6 – Controls C 6.5 & C 6.6
Improvement	Nonconformities shall be responded to with appropriate corrective actions, and the organisation shall continually improve the suitability, adequacy and effectiveness of its Energy Management System, and demonstrate continual energy performance improvement.	7.2.4.2 - Production Optimisation and Opportunity Management 7.2.4.3 - Greenhouse Gas, Energy and Flare Target Setting - Operations 7.10 - Monitoring, Auditing, Management of Non-conformance and Review 6.7.6 – Control C 6.5

7.2.4.1 GHG Emissions and Energy Management Procedure

Emissions generation and energy use is managed in line with the GHG Emissions and Energy Management Procedure which defines the minimum mandatory requirements to manage and deliver continuous improvement in energy efficiency and reduction in GHG emissions. The procedure

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

supports the implementation of the Climate Policy and aligns with the requirements of the Environmental Performance Procedure, applicable to assets in Operate phase. It supports the “operate out” component of limiting net emissions, as shown in the Woodside Climate Policy.

Implementation of the GHG Emissions and Energy Management Procedure assists in meeting external expectations, such as Woodside’s net equity Scope 1 and 2 greenhouse gas emissions reduction targets of 15% by 2025 and 30% by 2030, and our aspiration for net zero equity Scope 1 and 2 greenhouse gas emissions by 2050 or sooner¹¹⁹. (See Section 7.5). These targets apply across Woodside’s portfolio and progress against targets are reported in annual corporate disclosures. No specific reduction targets are set for individual assets as part of the corporate target. It also maintains consistency with the principles of current corporate initiatives, such as the Zero Routine Flaring Initiative for oil assets, the OGMP 2.0, OGI Near-Zero, and Methane Guiding Principles. These initiatives aim to improve methane emissions inventorisation, methane materiality assessments, evaluation, reduction implementation and increased transparency through reporting. The Woodside Flare Framework is an optional WMS tool that seeks to improve awareness of flaring-related issues and influence for reduced flaring.

The GHG Emissions and Energy Management Procedure links to the annual review of opportunities to improve energy performance through identification and evaluation as described in the Production Optimisation and Opportunity Management Procedure. It also requires measurement, analysis and communication of energy performance across the Operations Division and consideration of actual or potential impacts to energy efficiency in Woodside decision making, such as management of change, operational decisions, issue resolution options analysis and facility optimisation plans.

The facility Decarbonisation Plan supports implementation of the GHG Emissions and Energy Management Procedure. This is used for prioritising facility-specific emissions reduction opportunities consistent with company and facility targets, requirements and strategies, combining information from operations and design/execute phases, via various processes including the POOMP (Section 7.2.4.2) and Methane Action Plan (7.2.4.5). It articulates the emissions forecast and how GHG emissions are intended to reduce through design and operational opportunities.

The Environmental Performance Procedure requires that assets measure, monitor or estimate direct air and GHG emissions, and that such emissions and energy intensities are minimised to ALARP in design. The requirement to set, measure and track emissions targets for assets, help to manage the emissions to meet the EPS requirements in Section 6.7.6.

7.2.4.2 Production Optimisation and Opportunity Management

Woodside’s Production Optimisation and Opportunity Management Procedure (POOMP) outlines the process for identification, prioritisation and management of production opportunities that reduce emissions intensity across Woodside operated assets. Opportunities are identified throughout the year in various forums and teams, including individual recommendations, development planning, well reviews and production optimisation meetings. This organic approach encourages continual improvement by all roles across the assets, and formal workshops are held occasionally to supplement this. Opportunities are prioritised and managed according to the workflow shown in Figure 7-3.

¹¹⁹ Targets and aspiration are for net equity Scope 1 and 2 greenhouse gas emissions relative to a starting base of 6.32 Mt CO₂-e which is representative of the gross annual average equity Scope 1 and 2 greenhouse gas emissions over 2016-2020 and which may be adjusted (up or down) for potential equity changes in producing or sanctioned assets with a final investment decision prior to 2021. Net equity emissions include the utilisation of carbon credits as offsets.

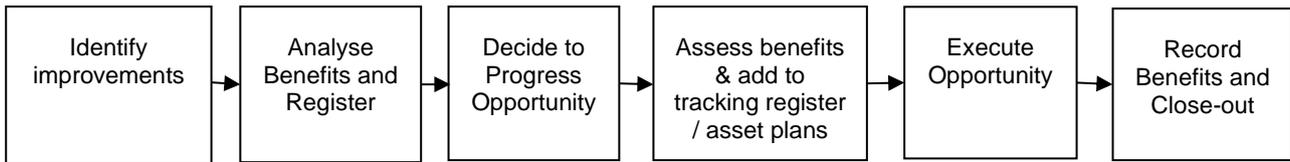

Figure 7-3: Opportunity Management Workflow

Opportunities are added to a formal tracking register where they are evaluated, prioritised within the constraints of technical feasibility, cost, resource availability and other factors. Roles and responsibilities are flexible within the POOMP process, but are broadly defined as follows:

- Everyone (e.g. operators, engineers, optimisation lead, managers): Opportunity identification, add to a formal tracking register.
- Optimisation lead/team: Opportunity analysis, prioritisation and tracking, update and maintain tracking register oversight.
- Engineering team: relevant engineering analysis and execution planning in consultation with planning team, update tracking register.
- Planning team: Incorporation of opportunity into relevant asset plans.
- Asset execute team: execute delivery of opportunity (team varies depending on opportunity).
- Asset managers/leaders: Decision maker on opportunities requiring significant budget, downtime, resources, etc. (as required).

Following delivery, opportunities are validated prior to closeout. Close out timeframes vary on a case-by-case basis, as opportunities are prioritised based on the above constraints. The POOMP process varies between assets, based on organisational structure, production lifecycle and age of technology, decarbonisation plans and general ways of working. For Scarborough, opportunities identified via the Carbon Opportunity register in Design/Execute phases, which remain applicable during Operations phase, will be captured in POOMP processes. Additionally, a post-start-up workshop will be held within the first 18 months of Scarborough facility operations (marked by Final Acceptance) for formal opportunity identification, once the facility is well understood and areas for long-term emissions intensity improvement become evident.

7.2.4.3 Greenhouse Gas, Energy and Flare Target Setting - Operations

In demonstrating the risks and impacts relating to flaring have been reduced to ALARP, flare and energy efficiency targets for the facility are set annually, concurrent with annual forecasting practices, in accordance with Woodside’s *Greenhouse Gas, Energy and Flare Target Setting Guideline*. Targets are estimated based on operating experience and forecast activities, e.g. shutdowns. Consideration is also given to the estimates contained within this EP.

The flare target is tracked against flare performance through the year. If achieving a flare target is projected to be at risk in question, an internal flare target deviation is developed, which requires an ALARP justification. A flare target deviation considers EP flare estimates. If estimate is likely to be exceeded, an EP management of change assessment (see Section 7.2.7) is undertaken to determine if a revision and resubmission is required.

A baseline facility “energy efficiency” will be established after the first year of operation and will be reset annually. Efficiency improvements will be targeted through a continuous feedback loop during operations (via the POOMP, see Section 7.2.4.2).

Fuel use can vary diurnally and seasonally depending on operational power requirements, and is also dependent on facility production and activity plans, reservoir outcomes, availability, utilisation and reliability across systems. Monthly emissions tracking of flare and efficiency metrics via asset governance reports is reviewed in this context to support identification of potential excursions and opportunities.

Values are finalised for financial-year annual regulatory reporting (such as NGERS and NPI submissions), and calendar year tracking.

7.2.4.4 Fuel and Flare Target Setting - Initial Start-Up

Fuel and flare targets are developed for flaring during initial start-up of the facility, in accordance with Woodside's Greenhouse Gas, Energy and Flare Target Setting Guideline. The targets are based on the planned Start-Up Strategy and sequence, prioritising the reduction of flaring to ALARP through opportunities identified in the Carbon Opportunity Register.

Progress against the targets will be monitored throughout the initial start-up phase, with appropriate oversight from key environment and start-up managers. Management of initial start-up fuel use/flaring is a key factor within the start-up process, and is identified as a control in overarching start-up MOC. See Section 7.2.4.4 for the process for fuel and flare target setting, tracking and management. If exceedances are foreseen, based on daily tracking or changes to the start-up strategy, measures will be proactively implemented to minimise the risk of exceedance via the MOC process (Section 7.2.7). This daily "tracking" considers activities undertaken and their actual flaring/fuel use, against planned activities/flaring/fuel use, in order to provide a forecast for potential future target exceedances. The following factors and management measures will be considered when managing potential fuel/flare exceedances:

- Minimising flared volumes
- Net benefit of using diesel vs fuel gas
- Turndown of flow from wells to minimum or below, considering flow assurance implications
- Maintaining stability of subsea and topsides process systems
- Maintaining well and completions integrity
- Good safety outcomes
- Implementation timeframes

The targets are aligned with the estimates risk assessed in Section 6.7.6, hence deemed to be ALARP and acceptable. As per the Guideline, targets are based on planned activities and expected flaring rates, and are set to drive positive environmental decision making to remain below them.

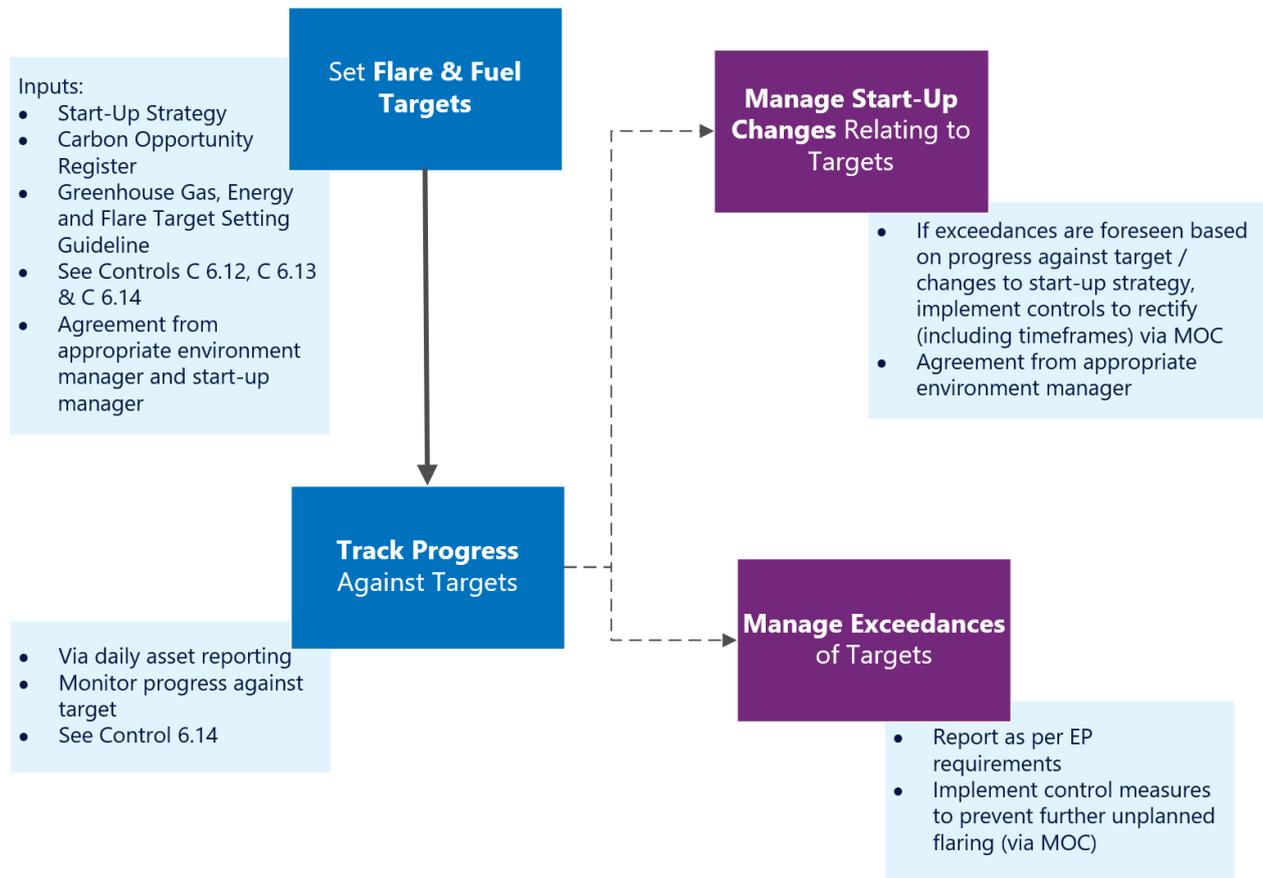

Figure 7-4: Fuel and flare target management during initial start-up

7.2.4.5 Methane Management

Woodside’s methane management strategy aligns with the principles of OGMP 2.0 and Oil and Gas Climate Initiative Aiming for Zero Methane Emissions (OGCI Near-Zero), in order to:

- Deliver appropriate and proportional identification and reduction efforts of methane based on facility nature and scale;
- Align with recommended reporting framework levels and timelines;
- Achieve corporate targets for methane emissions intensity; and
- Assess the suitability of best practice proven techniques, technologies, and operational practices.

The methane management strategy is implemented via execution of asset specific Methane Action Plans. Scarborough’s Methane Action Plan details the discreet activities to be conducted at the facility, encompassing:

- Measurement activities;
- Maintenance of an inventory of methane sources;
- Identification and implementation of suitable methane mitigation projects;
- Minimisation of unmitigated sources with reasonable controls (appropriate to nature and scale).

See Section 6.7.6 for facility-specific activities. Implementation of methane mitigation opportunities is prioritised based on size of source and relative cost, managed via the POOMP process (Section 7.2.4.2). Screening of methane projects is prioritised through use of the 20-year Global Warming

Potential (GWP) of 84 and a carbon price of US\$80/tCO₂-e (i.e. \$6720/tCO₂-e). Sources that are not mitigated through this process will be minimised via controls consistent with OGCI.

As per OGMP 2.0, companies are encouraged to measure at least 70% of their methane emissions, with a target of reaching 90%. These targets are considered when planning facility measurement activities and maintaining the facility's inventory of methane sources, i.e. priority focus is given to the largest sources, with potential to have the biggest impact in mitigation. For example, re-measurement and estimate of methane emissions from the flare (via drone) may only be triggered if the baseline measurement and ongoing visual verification suggested that flare performance was a potentially significant methane source.

As per OGCI's Initiative, companies are to put in place all reasonable means to avoid methane venting and flaring, and to repair detected leaks, while preserving the safety of people and the integrity of operations. In practice, for example, this could mean delaying the repair of a leak until a planned shutdown, rather than creating additional emissions from an extra shutdown, only to repair the leak. In other words, leaks will be rectified as soon as practicable.

Methane measurement technologies are continually advancing, and Woodside has tested and deployed a variety of these across its facilities (see Woodside's 2024 Climate Transition Action Plan (CTAP)). Such activities are ongoing and will be utilised where practicable to aid in achieving the aims of the methane management strategy.

Methane emissions will be reported through the National Greenhouse and Energy Reporting (NGER) system, in accordance with the Safeguard Mechanism rule (starting FY24). This rule mandates the transparent disclosure of emissions by species at the asset level, ensuring greater accountability and clarity in environmental reporting.

Woodside's methane targets are planned to be set in 2025 as part of OGMP 2.0 implementation. In 2024, Woodside reported methane emissions around 0.1% of production by volume (CTAP), which is below the industry benchmark of 0.2% from the Oil and Gas Climate Initiative for 2025.

Further detail on Woodside's participation in global methane reduction initiatives (Methane Guiding Principles, ASEAN Methane Leadership Programme, and OGMP 2.0) and industry collaboration can be seen in Section 6.7.6 under subheading *Reduce*. Additionally, this methane management strategy is aligned with the Future Gas Strategy's action to reduce emissions associated with gas supply (including venting, flaring and methane leak mitigation).

7.2.5 Offshore Marine Discharge Adaptive Management Plan

7.2.5.1 Overview

The Offshore Marine Discharges Adaptive Management Plan (OMDAMP) has been developed to manage routine discharges to the marine environment from applicable offshore production facilities.

The objectives of the OMDAMP are to:

- Manage marine discharges in a way that reduces the environmental risks and potential environmental impacts to As Low As Reasonably Practicable (ALARP) and of an acceptable level.
- Define monitoring measures to determine whether routine marine discharges comply with regulatory requirements and Woodside's Environmental Performance Procedure.
- Detail verification assessment and non-routine monitoring to be undertaken when routine monitoring identifies a change in discharge characteristics which have the potential to alter existing compliance with the Environmental Performance Procedure or relevant facility Operations Environment Plans (EPs).

The OMDAMP defines a process and rational for management of routine discharges such as produced water (PW), cooling water, and brine to the marine environment. The OMDAMP considers

applicable technical guidance (including the Commonwealth ANZG for fresh and marine water quality, National Water Quality Management Strategy and Technical Guidance: Protecting the quality of Western Australia's marine environment (EPA, 2016)) as well as relevant internal procedures and asset specific EP commitments. In addition, the OMDAMP is based on Woodside's experience managing PW at multiple northwest shelf offshore facilities and considers monitoring data collected over 20-30 years (Table 6-31); allowing the application of appropriate controls and any lessons learnt to ensure impacts are acceptable and reduced to ALARP.

7.2.5.2 Routine Monitoring and Management

Monitoring changes in water quality as well as investigating potential toxicity via whole effluent toxicity (WET) testing and implementing management to maintain acceptable levels of changes is standard industry practice in Commonwealth and State waters. By limiting the changes to water quality and therefore pathway to impact sediment quality and biota there is high confidence no environmental impact has occurred outside the approved mixing zone boundary.

The OMDAMP details trigger values, routine monitoring assessment against trigger values, analytical methods and actions when a trigger value is exceeded. The trigger values are applied through a risk-based approach that is intended to capture uncertainty around the level of impact by staging monitoring and management responses according to the degree of risk of environmental impact. This approach provides a level of confidence that management responses are not triggered too early (i.e. when there is no actual impact) or too late after significant or irreversible damage to the surrounding ecosystem (EPA 2016). Changes in discharge contaminants and PW toxicity can be detected early and can indicate the potential for an impact prior to an impact occurring allowing for timely management. WET testing confirms if there is a potential for impact.

PW samples should be representative of normal operations, hence timing of sampling coincides with a period of normal operating circumstances for a facility, as well as also considering when wells have begun to cut water, which formation water producing wells are online and chemicals that may be present in the discharge stream. Ensuring samples are representative of normal operations may require deferring sampling within the calendar year if required. Samples are analysed by a NATA accredited laboratory (where applicable) for key physio-chemical parameters and chemical analytes.

WET tests are undertaken on a broad range of taxa of ecological relevance for which accepted standard test protocols are well established. WET tests mainly focus on the early life stages of test organisms, when organisms are typically most sensitive to contaminants; the tests are designed to represent local trophic level receptors. For WET testing, a range of tropical and temperate Australian marine species were selected based on their ecological relevance, known sensitivity to contaminants, availability of robust test protocols, and known reproducibility and sensitivity as test species. The dilutions required to protect 99% and 95% of species are calculated using the Warne et al. (2018) methodology. If a trigger value is not met, it indicates uncertainty around whether the environmental value is being protected and further investigation is required (Figure 7-5).

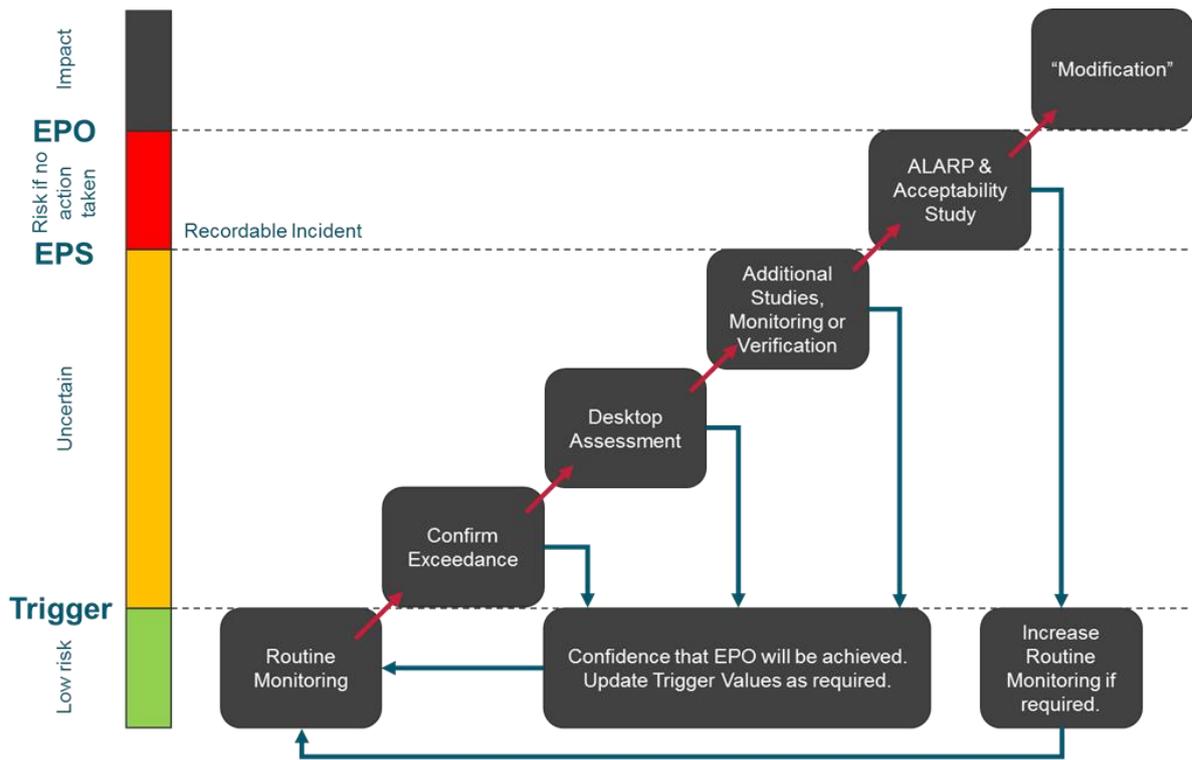

Figure 7-5: Routine monitoring and adaptive management framework for produced water

7.2.5.3 Further Investigations

Detectable exceedances in trigger values may occur without impacting the environment. To provide confidence that environmental impact has not occurred outside the approved mixing zone boundary, further investigation would be required (Figure 7-5) in the form of a desktop study to initially assess the exceedance in context of available data and confirm if there is potential for impact to the environment. A desktop assessment is necessary before undertaking additional in-field monitoring. This ensures monitoring programs are designed and implemented to provide robust findings based on good survey design.

A range of methods can be used to detect trigger value exceedances (e.g. relative percentage difference, control charts, multivariate analysis, etc.) depending on the dataset available. An appropriate method is selected as described in the OMDAMP due to the variable nature of environmental data. If critical data are not available, the desktop study identifies potential data gaps and may recommend additional non-routine studies and/or monitoring to ensure the assessment is appropriately undertaken. The purpose of the ‘further investigations’ step is to provide certainty that the EPO has been achieved, if a trigger value has been exceeded. The key investigation steps are described below:

- **Confirm the trigger value has been exceeded** – Review quality assurance and quality control, methodology and possible sources of contamination to determine if the results are reliable, or if any factors have occurred that may compromise the integrity of the monitoring or data. If necessary repeat monitoring.
- **Desktop assessment to understand whether the EPO is at risk** – If a trigger value is confirmed to be exceeded, multiple lines of evidence are considered including historical and current data from routine and non-routine monitoring and studies. This assessment shall consider whether there is adequate evidence to demonstrate that acceptability criteria have been met and (EPO not breached). If the desktop assessment determines that the existing body of evidence is insufficient, it shall outline what additional monitoring or studies are required. Potential additional monitoring/studies may include but is not limited to:

This document is protected by copyright. No part of this document may be reproduced, adapted, transmitted, or stored in any form by any process (electronic or otherwise) without the specific written consent of Woodside. All rights are reserved.

- single species test (collected annually in parallel with routine chemical characterisation should further investigation be required)
- dilution modelling and or studies
- flocculation, sedimentation, settling velocity and/or dispersion analysis
- metal bioavailability
- scanning electron microscopy and particle size distribution analyses
- in-situ monitoring (water quality and/or sediments).

Routine monitoring activities may be required ahead of schedule and additional monitoring not listed may be undertaken as appropriate. Field monitoring is undertaken in accordance with a plan that details timing, locations and objectives of monitoring.

- Conduct additional studies to confirm the EPO is not at risk – Monitoring results provide additional lines of evidence to determine whether there is a risk of environmental impact at the mixing zone boundary due to unacceptable changes in water quality resulting in changes to sediment, or biological indicators. Given the significant health, safety and technical risks, logistics and planning required, monitoring of the receiving environment is typically only considered when all other sources of evidence are insufficient to demonstrate that the EPO is not at risk. The OMDAMP provides detailed guidance on the steps and actions required to be undertaken if a trigger value is exceeded and this may include additional non-routine monitoring to verify that environmental impacts have not occurred outside the boundary of the mixing zone.

If triggers are being exceeded but no impact to the environment is predicted to occur the desktop assessment may consider development of site-specific trigger values in line with ANZG. For example, if chemical characterisation identified copper as exceeding trigger - ANZG 99% DGV but further investigations concluded levels observed were consistent with baseline and naturally occurring in the region. If potential impacts to environment are identified, an ALARP/Acceptability Study is required to determine what additional controls can be implemented to ensure the impacts are not realised.

7.2.5.4 ALARP/Acceptability Study

An ALARP/Acceptability study is conducted once it has been determined, as a result of further investigations, that there is potential for an impact that exceeds the acceptable limits of change. The ALARP/Acceptability study shall be conducted in accordance with the ALARP Demonstration Procedure, to determine additional controls that may be necessary to reduce the potential impacts. Additional management measures (controls) may include technology, process upgrades or reservoir management. Woodside will implement the additional controls identified in the ALARP/Acceptability study that are required to give confidence that the acceptable limits of impact can be achieved.

In the event sampling of MEG salts indicates that there is a potentially significant pathway for mercury to enter the marine environment, the study would need to consider as a minimum volumes, duration, source, speciation and potential for settlement. The ALARP study may implement measures such as:

- well management,
- inboarding,
- collection of MEG salts for onshore disposal,
- increased non routine monitoring,
- insitu monitoring,
- remediation,
- technology or process upgrades.

In the event WET testing identifies a higher-than-expected effluent toxicity the study would need to consider discharge volumes, duration, well line up, potential drivers of toxicity. The ALARP study may recommend the following:

- non routine WET testing,
- operational discharge limits,
- change out of process chemicals if appropriate or reduce dosing rates, implement
- well management,
- inboarding,
- insitu monitoring,
- technology or process upgrades.

In the event in-situ plume measurement and analysis of plume dilution indicates that the EPO may not be met the study would need to consider discharge volumes, discharge toxicity, well line up, process chemicals and baseline data. The ALARP study may recommend:

- implement discharge limits,
- well management
- insitu monitoring,
- technology or process upgrades
- inboarding,
- change out of process chemicals if appropriate or reduce dosing rates

7.2.5.5 Review and revision

This OMDAMP is typically reviewed annually to incorporate the following:

- Completion of the annual OMDAMP compliance review – incorporating any recommendations for further assessment and/or updates to the monitoring framework
- Recently accepted EPs - incorporating any new/amended monitoring commitments/triggers
- Regulatory inspections – incorporating any relevant findings or recommendations
- Updates to key guidelines, guideline values or changes to recommended sampling/ methodologies.

7.2.6 Woodside Invasive Marine Species Risk Assessment Process

7.2.6.1 Objective and Scope

To minimise the risk of introducing IMS as a result of the Petroleum Activities Program, all applicable vessels and immersible equipment will be subject to Woodside's IMS risk assessment process (unless exempt as outlined below).

The objective of the risk assessment process is to identify the level of threat a contracted vessel, or immersible equipment poses if no additional risk reduction management measures are implemented. This allows Woodside (and its contractors) to apply management options that are commensurate to the identified level of risk.

In context of the activities specified in Section 3, the IMS risk assessment process does not apply to:

- vessels or immersible equipment that do not plan to enter the IMS Management Area (IMSMA)¹²⁰ or operational areas defined in environmental approvals
- ‘new build’ vessels launched less than 14 days prior to mobilisation
- vessels or immersible equipment which have been inspected by a suitably qualified IMS inspector who has classified the vessels or immersible equipment as acceptably low risk no more than 14 days prior to mobilisation
- locally sourced vessels or immersible equipment from within the Pilbara locally sourced zone¹²¹. Vessels, or immersible equipment are defined as Locally Sourced when the same supply facilities/port have been used since their last IMS inspection, full hull clean in dry dock or application of antifouling coating (AFC)¹²².

The FPU will be subject to a separate IMS risk management under a specific FPU IMS Management Plan prior to entering the offshore operational area.

7.2.6.2 Risk Assessment Process

Woodside’s IMS risk assessment process was developed with regard to the national biofouling management guidelines for the petroleum production and exploration industry and guidelines for the control and management of a ships’ biofouling to minimise the transfer of invasive aquatic species (IMO Guidelines, 2011).

In order to effectively evaluate the potential for vessels and immersible equipment to introduce IMS, a risk assessment process has been developed to score and evaluate the risk posed by each Vessel, or immersible equipment planning to undertake activities within the IMSMA/Operational Area. The risk assessment process considers a range of factors, as listed in Table 7-2 and Table 7-3.

The IMS risk assessments will be undertaken by a trained environment adviser who has completed relevant Woodside IMS training or by a qualified and experienced IMS inspector. A QA/QC process is implemented for all Woodside conducted IMS risk assessments where a secondary trained environment adviser verifies the assessment to minimise the risk of misapplication and errors within the risk assessment process.

Table 7-2: Key factors considered as a part of the risk assessment process for vessels

Factors	Details
Vessel type	The risk of IMS infection varies depending on the type of vessel undertaking the activity. A higher risk rating is applied for more complex, slow-moving vessels (e.g., dredges) in comparison to simple vessels (e.g., crew transfer vessel).
Recent IMS inspection and cleaning history, including for internal niches	In the case of biofouling on external hull niches, different risk ratings are applied dependant on whether out-of-water or in-water IMS inspections by qualified IMS inspectors and cleaning (if required) have been undertaken prior to contract commencement. If an IMS inspection (and clean if required) has not been undertaken in the past six months (from the time of

¹²⁰ IMSMA is based on current legal framework and includes all nearshore waters around Australia, extending from the lowest astronomical tide mark to 12 nm from land (including Australian territorial islands). The IMSMA also includes all waters within 12 nm from the 50-metre depth contour outside of the 12 nm boundary (i.e. Submerged reefs and atolls).

¹²¹ The Pilbara Locally Sourced Zone includes Port, nearshore and offshore movements between Exmouth and Port Headland (excluding high environmental value areas, World Heritage Areas, Commonwealth Marine Reserve Sanctuary Zones and State Marine Management Areas and Marine Parks).

¹²² Vessels and immersible equipment can still be classified as locally sourced even if the AFC application occurred in a different port provided the amount of time between AFC application and departure to the locally sourced area (i.e. period of time in waters <12nm/50m water depth) did not exceed consecutive 7 days or the period of time the vessel or immersible equipment has spent within the locally sourced zone exceeds 1 year (i.e. the risk of introducing a species from a different location has already passed).

Factors	Details
	contract commencement), the highest risk factor is applied. The risk factor then lessens for vessels as the time between inspection and mobilisation reduces.
Out-of-water period before mobilisation	A risk reduction factor can be applied for vessels that are hauled out and then mobilised as deck cargo or by road during mobilisation, therefore becoming air dried over an extended period. Risk reduction factor increases with exposure time out of water.
Age and suitability of AFC at mobilisation date	AFC manufacturers provide a range of coatings, each designed to avoid premature coating failure if it is correctly applied and matched to the vessel's normal speeds and activity profile (i.e., proportion of time spent stationary or below three knots), and its main operational region (i.e., tropical, sub-tropical temperate). If the AFC type is deemed to be unknown, unsuited or absent, the highest risk value is applied. If the AFC type is suitable the risk factor applied reduces with age since application.
Internal treatment systems	A risk reduction factor applied if the vessel has an internal biological fouling control system in place at the time of assessment, or evidence of manual dosing.
Vessel origin and proposed area of operation	Differing risk ratings are assigned in relation to the climatic relationship between the vessel's origin and the proposed climatic region of the proposed area of operation. Highest risk rating is applied to similar climatic regions.
Number of stationary/slow speed periods >7 days	A risk factor is calculated based on the number of 7 day periods that the vessel has operated at stationary or at low speed (less than three knots) in port or coastal waters which is any waters less than 50 metres deep outside 12 nautical miles from land or any waters within 12 nautical miles of land. The greater the number of periods the higher the risk factor applied.
Region of stationary or slow periods	A further multiplier is applied depending on the location of the stationary/slow speed periods. The highest risk rating applied if the stationary or slow speed periods occurred within ports or coastal waters of the same climatic region,
Type of activity – contact with seafloor.	The potential for the introduction of IMS varies on the planned vessel activity taking place. Those activities that come in contact with sediments and thus have the potential to accumulate and harbour IMS in areas such as hoppers (dredges) and spud cans (drilling rigs) are considered to have a greater risk of infection.

Table 7-3: Key factors considered as a part of the risk assessment process for immersible equipment

Factors	Details
Region of deployment since last thorough clean, particularly coastal locations	Climatic region of use since last overhaul, thorough cleaning or prolonged period out of water (>28 day). Highest risk rating is applied to similar climatic regions. Activities occurring in nearshore areas (less than 50 meters deep and/or within 12 nautical miles from land) are given the highest risk rating.
Duration of deployments	Maximum duration of deployment (maximum time in water) since last overhaul or thorough cleaning. The longer the period of immersion the higher the risk rating applied.
Duration of time out of water since last deployment	A further risk reduction factor can be applied for immersible equipment that has been out of the water for an extended period.
Transport conditions during mobilisation	If the equipment is stored in damp conditions, then a high-risk factor is applied, while if equipment is stored in dry and well ventilated (low humidity) conditions then a low risk factor is applied.
Post-retrieval maintenance regime.	A risk reduction factor is applied if the equipment/item of interest is routinely washed, cleaned, checked and/or disassembled between project sites. While a higher risk rating is applied where no routine cleaning occurs.

Following implementation of the risk assessment process, vessels and/or immersible equipment are classified as one of three risk categories:

- 'Low'– Low risk of introducing IMS of concern and hence no additional management required, or management options have been applied to reduce the risk.
- 'Uncertain'– Risk of introducing IMS is not apparent and as such the precautionary approach is adopted, and additional management options may be required.

- ‘High’– High risk of introducing IMS means additional management options are required prior to this vessel mobilising to the Operational Area.

Following the allocation of a ‘low’ risk rating for a vessel or immersible equipment, the information provided by the vessel operator for the purposes of risk assessment must be confirmed prior to mobilisation. For vessels or equipment classified as posing an ‘uncertain’ or ‘high’ theoretical risk, a range of management options are presented to reduce this theoretical risk to acceptable levels and achieve a low-risk status. These management options have been developed with the intention of reducing IMS risk to levels that are as low as reasonably practicable (i.e., ALARP). It is a flexible approach that allows for a range of management actions to be tailored for a specific vessel movement. These will be assessed on a case-by-case basis and may include, but not limited to, the following:

- Inspection (desktop, in-water or dry dock) by a suitably qualified and experienced IMS inspector to verify risk status. Where practicable, the inspection shall occur within seven days (but not more than 14 days) prior to final departure to the Operational Area.
- In-water or dry dock cleaning of the hull and other niche areas. This is typically applied where the risk assessment outcome is High risk driven by the age of the AFC on the vessel and its time spent in similar climatic region ports.
- Treatment of vessels internal seawater systems. This is typically applied in isolation for vessels with AFC applied to their hull within the last twelve months and where subsequent assessment through the process achieves a low-risk rating.
- Limiting the duration that the vessel spends within the IMSMA to a maximum of 48 hours (cumulative entries). This is applicable for Uncertain risk vessels only.
- Reject the vessel.

Vessels and immersible equipment are required to be a low risk of introducing IMS prior to entering the Operational Area.

7.2.6.3 Scarborough FPU Invasive Marine Species Management Plan

A separate IMS Management Plan has been written for the FPU, to minimise/reduce the likelihood of IMS being introduced into Australian waters. This plan compliments the core Woodside IMS Management Plan, with long term management strategies to ensure risk reduction through FPU construction, float-over, ballast intake and transport to the project area.

The FPU IMS Management Plan covers:

- Understanding of National, State and Company requirements;
- Understanding IMS pathways;
- Understanding IMS Likelihood;
- Selection of appropriate Anti Fouling Coatings (AFC) to prevent IMS recruitment;
- Proactive measures considered for vulnerable areas of FPU e.g. risers, sacrificial anodes.
- Final cleaning and inspections by qualified IMS Inspector.

Compliance with the FPU IMS Management Plan will be tracked as per C 23.5 (refer to 6.8.11).

7.2.7 Change Management

Woodside’s Change Management Procedure describes Woodside’s requirements for change management at Woodside owned or controlled operations/sites.

Change management is used where there is no existing approved business baseline, such as a process, procedure or accepted practice, or where conformance with an approved baseline is not possible or intended; for example, due to equipment fault or failure or a recently discovered issue

which will take time to rectify. Change management is also used when the baseline is changed (e.g. the process is modified). It applies to management of temporary, permanent, planned or unplanned change encompassing one or more of the following:

- plant (equipment, plant, technology, facilities, operations or materials)
- projects (budget, schedule)
- people (organisation structure, performance, roles)
- process (WMS content, processes, procedures, standards, legislation, information).

Woodside’s change management process hierarchy is depicted in Figure 7-6. The hierarchy has been developed with sub-processes to address the different types of change performed at Woodside.

Figure 7-6: Change management hierarchy

To help manage the day-to-day operation of the facility, Woodside has developed a Golden Safety Rules Booklet, which provides a summary of mandatory requirements for safety in the workplace and includes guidance for managing changes that have a Health, Safety, Integrity and/or Environment impact.

7.2.7.1 Technical Change Management

Technical changes within the Operations Division are managed using the Management of Change – Assets Procedure. The objective of the procedure is to ensure HSE risks associated with both realised and potential changes. Assessed changes must be recommended, agreed and decided upon based on the assessed current level of risk, as defined by Woodside’s Technical Decision Authority matrices.

Changes as a result of abnormal conditions, e.g. failure to meet the facility SCE Technical Performance Standards, are identified, assessed and reduced to ALARP through the Operational Risk Assessment (ORA) Procedure Section 7.2.8 provides further information on management of SCE Technical Performance Standards.

The management of change requirements contained in the Process Safety Management Procedure and Management System Performance Standard M05 Management of Change are considered when conducting any changes with the potential to impact process safety.

The Engineering Management Procedure specifies key requirements of engineering related changes, and requires that engineering Technical Decisions are agreed, recommended and decided at the appropriate engineering authority level according to the risk. Change management and risk assessment include consideration of applicable legislation/regulation.

Change is also managed under management system requirements set out as part of major projects (Brownfields), wells integrity, subsea and pipelines integrity management and marine management system. Change management includes consideration of regulatory requirements, managed in accordance with the Regulatory Compliance Management Procedure.

In addition, the Management of Change MSPS (M05) is in place to assure process safety risks arising from change (temporary and permanent) are systematically identified, assessed and managed.

7.2.7.2 Environment Plan Management of Change and Revision

Management of changes relevant to this EP concerning the scope of the activity description (Section 3) will be managed in accordance with Regulations 38 and 39 of the Environment Regulations, including the following changes:

- review of advances in technology at stages where new equipment may be selected such as vessel contracting
- changes in understanding of the environment, DAWE EPBC Act listed threatened and migratory species status, Part 13 statutory instruments (recovery plans, threat abatement plans, conservation advice, wildlife conservation plans) and current requirements for AMPs
- potential new advice from external stakeholders (Section 5).
- changes in assumptions or estimation techniques leading to a material change in indirect emissions (GHG or atmospheric) estimates

Risk will be assessed in accordance with the environmental risk management methodology (Section 2.3) to determine the significance of any potential new environmental impacts or risks not provided for in this EP. Risk assessment outcomes are reviewed in compliance with Regulations 38 and 39 of the Environment Regulations.

Minor changes where a review of the activity and the environmental risks and impacts of the activity do not trigger a requirement for a formal revision under Regulations 38 and 39 of the Environment Regulations, will be considered a 'minor revision'. Minor administrative changes to this EP, where an assessment of the environmental risks and impacts is not required (e.g. document references, phone numbers, etc.) will also be considered a 'minor revision'. Minor revisions as defined above will be made to this EP using Woodside's document control process. Minor revisions will be tracked in an MOC Register to ensure visibility of cumulative risk changes, as well as enable internal EP updates/reissuing as required. This document will be made available to NOPSEMA during regulator environment inspections.

7.2.7.3 Oil Pollution Emergency Plan Management of Change

Relevant documents from the OPEP will be reviewed in the following circumstances:

- implementation of improved preparedness measures
- a change in the availability of equipment stockpiles
- a change in the availability of personnel that reduces or improves preparedness and the capacity to respond
- the introduction of a new or improved technology that may be considered in a response for this activity
- to incorporate, where relevant, lessons learned from exercises or events
- if national or state response frameworks and Woodside's integration with these frameworks changes.

Where changes are required to the OPEP, based on the outcomes of the reviews described above, they will be assessed against Regulations 38 and 39 of the Environment Regulations to determine if resubmission of the EP, including OPEP, is required (see Section 7.2.7.2). Changes with potential to influence minor or technical changes to the OPEP are tracked in management of change records, project records and incorporated during internal updates of the OPEP or revisions to the EP.

7.2.8 Management of Safety and Environment Critical Element Technical Performance Standards and Management System Performance Standards (Operations)

7.2.8.1 Management System Performance Standards

Woodside applies Management System Performance Standards (MSPS) to confirm that safety critical management processes function as required. MSPS are developed and owned at non-facility specific level (i.e. across Woodside) and include assurance checks for the key requirements of the applicable management system.

Individual facilities demonstrate conformance against the MSPS through the conduct of reviews. Non-conformances against an MSPS are internally managed in accordance with the Woodside Management System.

7.2.8.2 Safety and Environment Critical Element Technical Performance Standards

An SCE is defined by Woodside as a hardware barrier, the failure of which could cause or contribute substantially to, or the purpose of which is to prevent or limit the effect of, a MAE/MEE or process safety event.

Woodside identifies/develops, implements, monitors/assures and verifies/optimises SCEs by applying SCE technical Performance Standards as described in the Safety and Environment Critical Element (SCE) Management Procedure. Key elements of the procedure are summarised in Table 7-4.

Table 7-4: Safety and Environment Critical Element Management Procedure summary

Identify/Develop	<p>Identify SCE – SCEs must be identified from the facilities PSRAs (e.g. Formal Safety Assessments) (Section 2.2). The identification of SCEs for which Performance Standards are required are part of the formal safety and environmental risk assessment processes. Woodside’s Global Performance Standards (based on industry and Woodside Standards) should be used for preliminary selection of SCEs.</p> <p>Complete Engineering Design Studies – Engineering design studies must be completed to demonstrate that SCE Performance Criteria specified in the global Performance Standard and/or determined by PSRA will be met by the facility design, allowing for normal SCE degradation in operation. The studies must establish the testing and inspection tasks required to assess performance against the criteria. The scope and frequency of SCE Assurance Tasks are guided by the Global Performance Standard and may require designated Engineering Design Studies. Studies should include Reliability Centred Maintenance, Risk Based Inspection and Safety Instrumented Function studies to determine the Assurance Task scope and frequencies, RBI plans, and classification and implementation requirements for instrumented safeguarding.</p> <p>Develop Performance Standards – Facilities must develop Performance Standards for all SCEs by:</p> <ul style="list-style-type: none"> • selecting the applicable Global Performance Standard (including Assurance Tasks) • considering facility specific requirements and applicable regulatory requirements • adding the specific data from the facility Engineering Design Studies and PSRA to compile scope and frequency of SCE assurance activities.
Implement	<p>Identify SCE in Asset Register – SCEs must be uniquely identified on the asset register and assigned Performance Standard flags.</p> <p>Develop Testing, Inspection and Maintenance Programs – SCE assurance tasks are developed into maintenance procedures.</p> <p>Implement Testing, Inspection and Maintenance Programs – SCE testing, inspection and maintenance requirements must be implemented in the CMMS (Section 7.2.1.3).</p>
