WRSSV	Wireline Retrievable Subsurface Safety Valve

Executive Summary

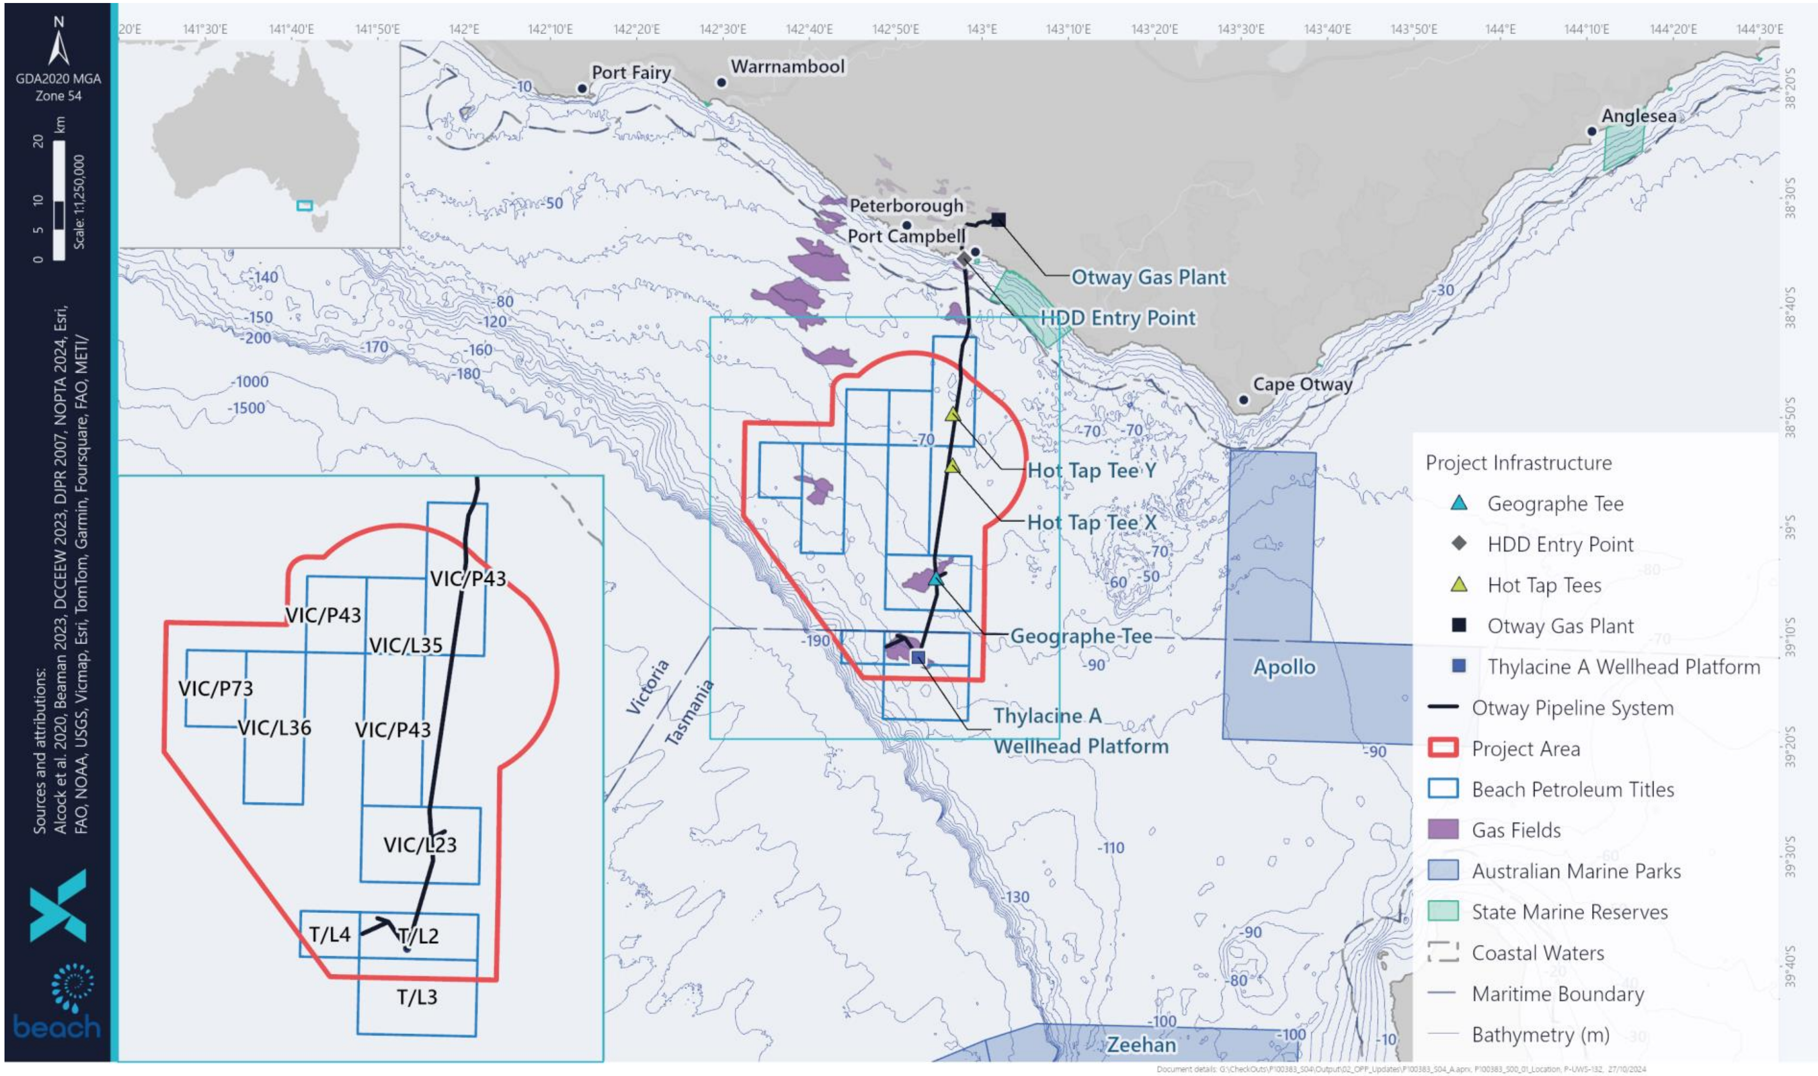
ES1 Introduction

The Otway Offshore Gas Victoria (OGV) Project (the Project) is designed to explore and develop new gas discoveries in the offshore Otway Basin. The Project provides an opportunity to develop currently stranded gas reserves and future resources in the offshore Otway Basin through integrated subsea drilling and installation campaigns and by utilising Beach's existing offshore infrastructure.

The development concept selected for the Project is a subsea tie-back to existing facilities. The stages of the Project will include an initial drilling campaign operated by a semi-submersible MODU. Successful wells will be tied back to existing Otway Gas Production Pipeline (OGPP) and/or Thylacine A platform via installation of new subsea flowlines and facilities. Recovered gas will be transported through the OGPP to the onshore OGP located onshore near Port Campbell, Victoria. The OGP supplies gas to the domestic market in south-east Australia.

The Project focuses on exploration, appraisal and development of existing and future gas discoveries in Beach's exploration permits (VIC/P43 and VIC/P73). On 30 September 2024, the Artisan field (1 block within VIC/P43) was converted to production licence, VIC/L35 and the La Bella field (2 blocks within VIC/P73) was converted to production licence, VIC/L36. For the purpose of the OPP, all references to VIC/P43 are defined as VIC/P43 and VIC/L35 and all reference to VIC/P73 are defined as VIC/P73 and VIC/L36.

The Project covers an area that is located approximately 17 km south of the Victorian mainland and 80 km north-west of Tasmania (King Island) at its closest points (ES Figure 0-1). The Project is adjacent to Beach's current production operations at the Geographe and Thylacine gas fields in the offshore Otway Basin.



ES Figure 0-1: Project Location

The petroleum activities planned for the Project include full lifecycle of petroleum operations summarised in the below ES Table 0-1.

ES Table 0-1: Project Summary

Project Stage	Key Activities
Surveys	Geotechnical and geophysical surveys will occur over a maximum of 200 days and are undertaken to assess the suitability of the seabed for drilling and infrastructure placement.
Drilling and Completions	• Drilling campaign(s) for up to 8 wells to include: ◦ Campaign commencing 2025 for up to 3 wells (plus options to drill 5 additional wells) ◦ Future drilling campaign(s) may be carried out in the OPP Project Area • Completions (in success case) of up to 9 wells (including up to 8 wells from above drilling campaign and Artisan 1 re-entry and completion): ◦ Campaign commencing 2025-2026 for well completions and subsea tree installations ◦ Future well completion campaign(s) may be carried out in the OPP Project Area • Drilling operations will be succeeded by: ◦ Permanent plug and abandon, or, ◦ Temporary suspension.
Facilities Installation and Commissioning	• Installation of subsea infrastructure to connect gas discoveries Artisan, La Bella and any successful exploration or appraisal wells from the initial drilling campaign to the OGPP including wellheads, flowlines, umbilicals, manifolds and skids • Commissioning and testing of new equipment including flowlines • Unload of drilling and completion fluid from the well is planned through new and existing subsea infrastructure to the onshore Otway Gas Plant (OGP). Well unload and testing to the MODU is a contingent option. • Future tie backs of successful exploration or appraisal wells comprising similar subsea infrastructure to the initial development may be undertaken in the Project Area during the life of the Project. • There is the potential for future tie-ins in the vicinity of the Project Area by other operators comprising similar subsea infrastructure to the initial development.
Operations and Maintenance	• Production from Artisan, La Bella and future prospects is expected to have an operation life of up to 20 years with end of field life estimated as 2045. • However, subject to future investment and developments in surrounding fields, operations and infrastructure life may be extended. • Further well and installation campaigns required to support future developments within the Project Area may be undertaken during the operations stage. • Operations stage may include well intervention and inspection, maintenance and repair of wells and subsea infrastructure as required.
Decommissioning	• Well plug and abandonment • Decommissioning of subsea infrastructure

Proponent

Beach Energy (Operations) Limited (Beach) is the proponent for the Project and is the operator and titleholder (60% participating interest) of the petroleum titles. Beach also owns and operates existing production assets and infrastructure in the Otway Basin at Thylacine and Geographe fields, Thylacine A platform and Offshore Otway Gas Pipeline.

Offshore Project Proposal

This Offshore Project Proposal (OPP) has been prepared in accordance with the Offshore Petroleum and Greenhouse Gas Storage (Environment) Regulations 2023 (OPGGS (Environment) Regulations) and associated guidelines, which require an OPP to be submitted for all offshore projects. The OPP is an early-stage project assessment which, subject to acceptance by the National Offshore Petroleum Safety and Environmental Management Authority (NOPSEMA), will form the basis for future activity-specific Environment Plans.

For completeness, this OPP includes description of exploration and appraisal drilling activity which is an activity that does not require an accepted OPP as part of the environmental permitting framework.

This OPP also described existing petroleum infrastructure for Thylacine and Geographe which was approved under the *Environment Protection and Biodiversity Conservation Act 1999*.

ES2 Environmental Legislation and Other Requirements

The OGV Project is located entirely in Commonwealth waters. The key legislation and regulations for petroleum activities are:

- *Offshore Petroleum Greenhouse Gas Storage Act 2006* - provides a legal framework for the exploration and recovery of petroleum (and greenhouse gas activities) in Commonwealth waters. The OPGGS Act establishes the National Offshore Petroleum Safety and Environmental Management Authority (NOPSEMA) as the independent regulator for environmental management, health and safety, and well integrity and for all offshore petroleum (and greenhouse gas storage) activities in Commonwealth waters

- *Environment Protection and Biodiversity Conservation Act 1999 (EPBC Act)* - provides a legal framework to protect and manage important flora, fauna, ecological communities and heritage places defined in the EPBC Act as matters of national environmental significance. Specific to petroleum activities in Commonwealth waters:

    - In February 2014, a Program was endorsed under the EBPC Act to provide for NOPSEMA to assess and make approval decisions for new offshore petroleum development projects and shorter-term activities. NOPSEMA’s environmental assessment processes consider all project and activity specific environmental impacts and risks, including but not limited to those relevant to matters protected under Part 3 of the EPBC Act. Decision-making under the Program ensures that environmental impacts and risks, including to matters protected under Part 3 of the EPBC Act, will be of an acceptable level and reduced to as low as reasonably practicable (ALARP).

    - Offshore Petroleum Greenhouse Gas Storage (Environment) Regulations 2023 - provide for the regulation of environmental management of petroleum (and greenhouse gas storage) activities in Commonwealth waters, and aim to ensure that petroleum activities in these areas are carried out in a manner that is consistent with ecologically sustainable development and consistent with the objective that environmental impacts and risks are of an acceptable level and reduced to ALARP

ES3 Description of the Project

Key characteristics of the Project are described in ES Table 0-2.

ES Table 0-2: Key Project Areas

Project Characteristics	Description
Project Area	The Project Area is defined in ES1 Introduction
Key Project Stages	• Surveys (geotechnical and geophysical) • Drilling and completions • Facilities installation and commissioning • Operations and maintenance • Decommissioning
Proposed Wells	Eight wells are anticipated to be drilled and completed (in a success case) and one re-entered and completed as part of the initial drilling campaign: • Re-entry and completion of Artisan 1 • Drilling and completion of La Bella 2 • Maximum 5 wells drilled and completed (in success case) in VIC/P43 (defined as VIC/P43 and VIC/L35 - see section 1.1). Maximum 2 wells drilled and completed (in a success case) in VIC/P73 (defined as VIC/P73 and VIC/L36 – see section 1.1).
Subsea Infrastructure	Installation of subsea infrastructure to connect gas discoveries (Artisan 1, La Bella 2) and future connections of successful wells (from above drilling and completion campaigns) to the OGPP or Thylacine Platform including: • Wellheads, flowlines, umbilicals, manifolds and skids.

Project Areas

The Project will be carried out in the defined Project Area shown in above ES Figure 0-1. The Project Area includes the Artisan and La Bella gas discoveries, future exploration prospects located in VIC/P43 and VIC/P73. The Project Area also includes the proposed locations of subsea flowlines and facilities (with buffer areas) for future subsea tie-back to the OGPP or the Thylacine platform.

Project Stages and Schedule

Beach is planning an initial drilling campaign commencing in 2025, installation of new subsea facilities commencing in 2026 with the earliest achievable date for commissioning and first gas in 2026 subject to corporate, joint venture and regulatory approvals. See ES Table 0-3 for an indicative project schedule.

ES Table 0-3: Indicative Project Schedule

Project Stage	Indicative Timing
Execution Decision Gate	Q3 2024
Initial Exploration & Appraisal Drilling Campaign	Commencing Q2 2025
Installation of Subsea Infrastructure	Earliest commencement Q1-2 2028

Commissioning & RFSU	Earliest commencement Q2-3 2028
Future Drilling and Tie-backs	Within operating life of the Project
End of Field Life	2045
Decommissioning (Wells and Subsea Infrastructure)	Decommissioning will be managed in compliance with Sections 572(3) and 270 of the OPGGS Act (unless alternative arrangements are accepted)

ES4 Description of the Environment

The OPP describes the physical, ecological, and socio-economic environment that may be affected (Planning Area) from planned and unplanned events associated with the Project, including MNES protected under the EPBC Act. This description informs the assessment of environmental impacts and risks.

The outer boundary of the Planning Area is the worst-case and largest spatial extent where unplanned hydrocarbon releases from Project activities could have an environmental consequence. All planned activities will occur within the Project Area (ES Figure 0-1).

Physical Environment

The dominant seabed character is medium to coarse carbonate sands with areas of low relief exposed limestone. There are no known bathymetric features such as reefs, shoals or banks within the Project Area. The continental shelf slope is in close proximity to the Project Area and has been designed to not include the deeper waters off the continental shelf.

Otway is a high-energy environment exposed to frequent storms and significant wave heights. Winds in the area generally exceed 13 knots (23.4 km/h) for more than 50% of the time contributing to the moderate to high wave-energy environment.

The region is oceanographically complex, with subtropical influences from the north and subpolar influences from the south. The Leeuwin Current transports warm, subtropical water southward along the Western Australian coast and then eastward into the Great Australian Bight where it mixes with the cool waters from the Zeehan Current running along the west coast of Tasmania. These currents are stronger in winter than in summer.

Water and sediment quality within the Project Area is high, with little evidence of contamination.

The climate in the Otway is typical of a cool temperate region with cold, wet winters and warm dry summers. In winter, when the subtropical ridge moves northwards over the Australian continent, cold fronts generally create sustained west to south-westerly winds and frequent rainfall in the region. In summer, frontal systems are often shallower and occur between two ridges of high pressure, bringing more variable winds and rainfall.

Ecological Environment

The benthic habitat is similar across the Project Area, consisting of carbonate rich coarse to medium sands with areas of exposed limestone substrate. This type of seabed is highly mobile making it difficult for filter feeders and soft body invertebrates to survive and establish in significant populations. Epifauna is dominated by low density, patchy assemblages of branching bryozoans, gorgonian cnidarians and sponges.

No benthic species or ecological communities listed as threatened under the Environmental Protection and Biodiversity Conservation Act 1999 (the EPBC Act) were identified.

No benthic species or ecological communities listed as threatened under the Environmental Protection and Biodiversity Conservation Act 1999 (the EPBC Act) were identified.

A range of other communities and habitats occur within the Planning Area beyond the Project Area, including:

- benthic habitats such as bare substrate, seagrasses, and macroalgae.
- coastal habitats such as mangroves and saltmarsh.

A number of listed threatened, migratory, marine or cetacean species protected under the EPBC Act were identified within the Project Area and Planning Area, including:

- 12 fishes (including sharks) (9 within the Project Area and another 3 within the Planning Area beyond the Project Area)
- 111 birds (33 within the Project Area and another 78 within the Planning Area beyond the Project Area)
- 34 marine mammals (29 within the Project Area and another 5 within the Planning Area beyond the Project Area)
- 3 marine reptiles (within both the Project Area and Planning Area beyond the Project Area)

Socio-Economic Environment

No protected areas overlap the Project Area, although a number occur within the Planning Area beyond the Project Area, including:

- 2 Commonwealth Australian Marine Parks (AMPs)
- 12 Victorian marine protected areas
- 13 Victorian terrestrial protected areas
- 13 Tasmanian terrestrial protected areas
- 1 wetland of international importance (Ramsar wetland)

Eight Commonwealth commercial fisheries have jurisdictions to fish within the Planning Area.

There are 8 Victorian state-managed commercial fisheries that overlap the Planning Area. Of these, catch effort was identified within the Project Area for the Giant Crab Fishery, Rock Lobster Fishery and Wrasse (Ocean) Fishery.

There are 8 Tasmanian state-managed commercial fisheries that may overlap the Planning Area. No fishing effort for Tasmanian fisheries has been identified within the Project Area.

There are 5 South Australian-state managed commercial fisheries that may overlap the Planning Area. No fishing effort for South Australian fisheries has been identified within the Project Area.

No World, Commonwealth or National Heritage properties occur within the Project Area. Only 3 National Heritage Places occur within the Planning Area beyond the Project Area.

Within the Planning Area there is a 130 km stretch of coastline known as the 'Shipwreck Coast' because of the large number of shipwrecks present, with most wrecked during the late nineteenth century. The strong waves, rocky reefs and cliffs of the region contributed to the loss of these ships.

First Nations people groups inhabited the south-west Victorian coast as is evident from the terrestrial sites of Aboriginal archaeological significance throughout the area. During recent ice age periods (the last ending approximately 12,000-14,000 years ago), sea levels were significantly lower, and the coastline was a significant distance seaward of its present location, enabling occupation and travel across land that is now submerged.

The Eastern Maar are Traditional Owners of south-west Victoria, and currently occupy a registered Native Title claim on the land adjacent to the Project Area and Planning Area and 100 m out to sea. Their land extends as far north as Ararat and encompasses Warrnambool, Port Fairy, and other areas along the Great Ocean Road, it also stretches 100 m out to sea from low tide and therefore includes the iconic Twelve Apostles (EMAC 2020). According to EMAC (2020), one of the services provided by the Eastern Maar group is the involvement/consultation and conducting of fieldwork with Cultural Heritage Management Plans in conjunction with a Heritage Advisor, with this collaboration reflecting the notion of "Working on Country together" (EMAC 2020).

Coastal Aboriginal heritage sites include mostly shell middens, some stone artefacts, a few staircases cut into the coastal cliffs, and at least one burial site. The various shell middens within the Port Campbell National Park and Bay of Islands Costal Park are close to coastal access points that are, in some cases, now visitor access points (Parks Victoria 1998). The Aboriginal Heritage Register (AHR) lists over 13,000 sites; however, there is no searchable database to identify any sites in the Planning Area.

The south-east marine region is one of the busiest shipping regions in Australia and Bass Strait is one of Australia's busiest shipping routes. Commercial vessels use the route when transiting between ports on the east, south and west coasts of Australia, and there are regular passenger and cargo services between mainland Australia and Tasmania.

Ongoing consultation with Department of Defence has identified that the Project Area is located within restricted airspace, but no other defence areas were identified. The Department of Defence also advised that unexploded ordnance (UXO) may be present on and in the sea floor.

ES5 Environment Impacts and Risks Assessment Methodology

Beach has undertaken environmental impact and risk assessments for the Project in accordance with the Beach OEMS Risk Management Standard.

The impact or risk for each activity and associated hazards was assessed following the application of controls. For planned events, only the consequence of the impact was assessed. Likelihood was not assessed, as the occurrence of planned events is effectively certain. The consequence for planned events was based on all controls functioning effectively. For unplanned events, the environmental residual risk of the event was determined based on the likelihood and consequence of the events.

The likelihood of an unplanned event occurring was based on all controls functioning effectively. The consequence was based on a worst-case event occurring with all controls having failed. This provides a conservative approach to assessing consequence, as the likelihood of a worst-case event with the failure of all controls is remote.

The resulting consequence (planned events) or residual risk (unplanned events) was then compared to Beach acceptable levels of impact and risk, including receptor-specific acceptable levels of impact. If the impact or residual risk was determined to not be acceptable, additional controls were applied and the impact or risk was assessed again. This process was repeated until each impact or residual risk was reduced to an acceptable level.

In addition to assessing each aspect and its associated hazards independently, Beach has also undertaken a cumulative impact assessment (Section 8). This cumulative impact assessment considered potential synergistic impacts on environmental values and sensitivities from all aspects of the Project and third-party activities. The cumulative impact assessment was only undertaken for planned events. No consideration of cumulative impacts from unplanned events was made, as these events are not expected to occur during the Project activities.

ES6 Environmental Performance Outcomes and Control Measures

The specific EPOs and control measures of the Project relevant for each impact and risk are provided in Sections 6 and 7.

Each EPO for the Project is listed below with the control measures for planned activities provided in ES Table 0-4 and provided for unplanned events in ES Table 0-5.

- EPO1: Implement CM05 and CM06 for the establishment and maintenance of petroleum safety zones, temporary exclusion zones and cautionary zones.
- EPO2: Decommissioning of Project facilities in compliance with Section 572 (3) of the *Offshore Petroleum and Greenhouse Gas Storage Act 2006* (Cth).
- EPO3: Implement CM08 Project Execution Plans and CM09 MODU and Vessel Anchoring Plan to ensure placement of infrastructure and anchors will avoid unique seafloor habitats in the Project Area.
- EPO4: Implement CM 10 Seabed assessments to identify seabed composition, benthic habitats and communities and ensure areas of unique seafloor habitats, maritime archaeology, UXOs, submerged cultural heritage and landscapes are avoided where practicable within technical and safety constraints.
- EPO5: No impact on underwater cultural heritage.
- EPO6: Implement CM11 Cultural heritage assessments to identify any maritime archaeological and submerged cultural heritage and landscapes to inform protection priorities, and develop and implement management measures and reporting requirements, where required, to prevent potential impacts.

- EPO7: No death or injury[1] to listed threatened or migratory species from Project activities.
- EPO8: Biologically important behaviours[2] can continue while Project Activities are being undertaken.
- EPO9: Implement CM13 Lighting Management Procedure as per the National Light Pollution Guidelines (DCCEEW 2023a) to ensure artificial light in biologically important areas will be managed such that biologically important behaviours within or outside a BIA can continue while Project activities are being undertaken.
- EPO10: Anthropogenic noise in biologically important areas and habitat critical to the survival of a species will be managed such that:
  - Any blue whale continues to utilise biologically important areas without injury[1], and is not displaced from a foraging area.
  - It does not prevent any southern right whale from utilising biologically important areas or habitat critical to the survival of a species or cause auditory impairment (TTS and PTS).
- EPO11: Implement CM15, CM16, CM17, CM18 Whale Management Procedures to ensure impacts and risks to whales from underwater sound are managed in accordance with relevant recovery plans.
- EPO12: Implement CM19 Noise Assessments to ensure impacts and risks to whales from underwater sound evaluated in relevant activity specific Environment Plans are based on the latest available scientific research on noise effect criteria.
- EPO13: Manage atmospheric emissions from the combustion of fuel during vessel and MODU operations in accordance with MARPOL Annex VI (Prevention of Air Pollution from Ships) enacted in the *Navigation Act 2012*.

---

[1] Injury to cetaceans as defined as auditory impairment from the onset of TTS and PTS, where DAWE (2021a) defines 'injury to blue whales' as: For the purpose of interpreting and applying Action Area A.2 of the Blue Whale CMP, injury is both permanent and temporary hearing impairment (Permanent Threshold Shift and Temporary Threshold Shift) and any other form of physical harm arising from anthropogenic sources of underwater noise

[2] Biologically important behaviours such as reproduction, feeding, migration and resting (DCCEEW, 2023j).

- EPO14: Implement CM22 Emissions Abatement Opportunities Register to maintain a register of opportunities for emissions reduction across its asset portfolio to reduce emissions.
- EPO15: GHG emissions related to the Project, including (scope 1 [Inside Project Boundary, scope 1* [Outside Project Boundary] and scope 3) emissions are consistent with Australia's international GHG emissions commitments, as outlined in the Climate Change Act 2022. Emissions are to be determined based on the NGER scheme and managed by the Safeguard Mechanism.
- EPO16: Implement CM28 Well design to ensure all wells to be drilled with WBDF, with SBDF only to be used where technical requirements preclude the use of WBDF.
- EPO17: Implement CM29 Chemical selection process to ensure chemicals used are environmentally acceptable whilst also meeting technical requirements.
- EPO18: Implement CM30 Drilling fluid inventory to reduce or avoid discharge of bulk materials including excess powders, brines, and drilling fluids.
- EPO19: Implement CM31 Solids control equipment to recover and reduce residual SBDF content prior to overboard discharge, if SBDF is used.
- EPO20: Implement CM32 Minamata convention to ensure drilling fluids will have concentrations of mercury and cadmium less than 1 mg/kg and 3 mg/kg respectively in stock barite (WBM and SBM).
- EPO21: Defined well locations and immediate surrounds (<2 km from well location) within the Project Area will not contain unique seafloor habitats.
- EPO 22: Implement CM33 Cementing program to reduce or avoid discharge of cement to the marine environment, including the reduction and avoidance of excess cement discharge upon completion of the drilling program.
- EPO 23: Implement CM34 Hydrotest assessment to detail the hydrotesting requirements including the definition of discharge characteristics (i.e. chemical additives and concentrations), discharge locations and volumes, methodology and species impact thresholds.
- EPO24: Implement CM35 Marine orders to manage routine discharges of operational wastes from vessels in accordance with Marine Orders 91 and 95.
- EPO25: No introduction of a known or potential invasive marine species.
- EPO26: No unplanned discharge of materials or waste to the marine environment.
- EPO27: No unplanned loss of containment of hydrocarbons or chemicals to the marine environment during Project activities.
- EPO28: In event of an unplanned release of chemicals or hydrocarbons, spill response control measures will be implemented in accordance with accepted EP, OPEP and OSMP (CM48 EP, OPEP and OSMP).

ES Table 0-4: Aspect Specific Control Measures for Planned Activities

Aspect	Residual Impact		Control Measures
Physical Presence - Interaction with Other Users	Minor	CM01 Navigation safety	Beach Marine Assurance System ensures that the MODU and vessels meet relevant maritime laws and includes pre-commencement MODU and vessel inspections of class certification requirements under the *Navigation Act 2012* and associated Marine Orders. All vessels operating within the project area will adhere to the navigation safety requirements including: • International Regulations for Preventing Collisions at Sea 1972 • Chapter 5 of International Convention for the Safety of Life at Sea 1974 • International Convention on Standards of Training, Certification and Watchkeeping for Seafarers 1978 *Navigation Act 2012* and any subsequent Marine Orders that specify standards for crew training and competency, navigation, communication, and safety measures
		CM02 Notifications	The Australian Hydrographic Office will be notified of the Project activities and installed subsea infrastructure prior to commencement to facilitate the issuing of Notice to Mariners and maintain nautical charts. Relevant stakeholders are notified prior to the activity so that third party marine users are aware of vessel location and timing
		CM03: Fair Ocean Access Procedure	Beach's Fair Ocean Access Procedure was developed with input from commercial fishing industry organisations. The procedure details the process whereby a commercial fisher can claim compensation for an economic loss associated with Beach's offshore activities where impacts cannot be avoided
		CM04 Stakeholder consultation	Beach will undertake consultation with relevant persons for all petroleum activities in accordance with the OPGGS (Environment) Regulations and detailed in Section 10 of this OPP. Observation, incidents, and opportunities for improvement regarding the interaction with other users will be reported to other petroleum titleholders.
		CM05 Petroleum safety zones	The Project will comply with OPGGS Act 2006 – Section 616(2) petroleum safety zones, which includes establishment and maintenance of petroleum

			safety zones around wells, offshore structures or equipment which prohibits vessels entering without written consent
		CM06 Temporary exclusion/cautionary zones	500m temporary exclusion and 2 km cautionary zones will be established and maintained around drilling and installation activities
		CM07 Decommissioning	Decommissioning of subsea wells and infrastructure in compliance with Section 572 of the OPGGS Act.
Physical Presence – Seabed disturbance	Minor	CM08 Project Execution Plans	Infrastructure will be positioned on the seabed within design footprint to reduce seabed disturbance and avoid unique seafloor habitats in the Project Area.
		CM09 MODU and vessel anchoring plan	A MODU and vessel anchoring plan will identify suitable areas for anchors to be placed within the Project Area to avoid unique seafloor habitats.
		CM10 Seabed assessments	Seabed assessments undertaken of each well location and tie-back route prior to final selection to identify seabed composition, benthic habitats and communities and ensure areas of high relief outcrops, reefs, sponge beds, maritime archaeology, UXOs, submerged cultural heritage and landscapes are avoided where practicable within technical and safety constraints. Seabed assessment data will be provided to the following appropriately qualified specialists to identify sensitive benthic receptors: • Marine benthic ecologist to identify seabed habitat types including areas of high relief outcrops, reefs or sponge beds that are likely to be associated with site-attached fish. • Underwater archaeologist to identify shipwrecks and other maritime archaeological heritage. • Geophysical data analyst to identify location of unexploded ordinances. • Underwater archaeologist to identify submerged cultural heritage and landscapes. Reports from each specialist evaluation of seabed assessment data will be provided to Beach. Beach will assess the reports and identify any areas of overlap, potential risks from Project activities, and determine any exclusion areas that may be required.

		CM11 Cultural heritage assessments	Imagery and data from seabed surveys and assessments will be provided to appropriately qualified underwater archaeologists to identify any maritime archaeological and submerged cultural heritage and landscapes and inform protection priorities, management measures and reporting requirements. Should any maritime archaeological and submerged cultural heritage and landscapes be identified, Beach will report the findings in accordance with the *Underwater Cultural Heritage Act 2018*, and will consult with the relevant First Nations groups and determine any exclusion areas or further cultural heritage management procedures that may be required.
		CM07 Decommissioning	Refer above - Physical Presence - Interaction with Other Users.
Light emissions	Minor	CM01 Navigational safety	Refer above - Physical Presence - Interaction with Other Users.
		CM02 Notifications	Refer above - Physical Presence - Interaction with Other Users.
		CM12 MODU and vessel lighting	MODU and vessel lighting will be limited to the minimum required for navigational and safety requirements, with the exception of emergency events.
		CM13 Light Management Procedure	Beach will contract appropriately qualified lighting practitioners, together with an appropriately qualified marine biologist or ecologist to develop and support the implementation of a Light Management Procedure as per the National Light Pollution Guidelines for Wildlife (CoA 2023). MODU and vessels will implement a Light Management Procedure as per the National Light Pollution Guidelines (DCCEEW 2023a) for Project activities. The Light Management Procedure will detail additional adaptive mitigations to manage light based on the information in the Seabird Light Mitigation Toolbox and Beach Energy’s Vessel Light Management Procedure Guidance (CDN/ID 19012450). Specifically, the Light Management Plan for vessels and rigs is required to cover: • Requirements to minimise non-essential lights and outward facing lights ensuring safety navigational lighting and safe work condition requirements are met. • Program for managing grounded birds. • Reporting and recording requirements.

			Prior to commencement of an initial flaring event at each well, the area extending from the tip of the flare will be visually confirmed to be clear of birds [**PC249**]. Adaptive management will be detailed the light management procedure to be included in future EPs under this OPP when scheduling of the activity is known in greater detail.
Underwater sounds emissions	Moderate	CM14 EPBC Regulations 2000 – Part 8 Division 8.1 interacting with cetaceans	Vessels will adhere to EPBC Regulations 2000 – Part 8 Division 8.1 interacting with cetaceans in relation to distances to cetaceans. Helicopters will adhere to EPBC Regulations 2000 – Part 8 Division 8.1 interacting with cetaceans in relation to distances to cetaceans
		CM15 Geophysical Survey Whale Management Procedure	Development and implementation of a whale management procedure which outlines specific measures to minimise anthropogenic noise threats to relevant species, including the implementation of safe operating distances between vessels and whales, night-time and low visibility controls and pre-activity surveys for geophysical surveys using a boomer or SBP. This procedure provides a framework for minimising noise impacts to whales and details specific measures to be implemented that will ensure impacts and risks meet or are better than acceptable levels 1, 2 and 3. By meeting these acceptable levels, impacts will be consistent with Conservation Management Plan for the Blue Whale 2015-2025 (CoA, 2015b) and National Recovery Plan for the Southern Right Whale Eubalaena australis (DCCEEW 2024o). Specific measures in the procedure will include the following: • pre-start-up visual observations. Visual observations for the presence of whales carried out at least 30 minutes out to a distance of at least 300m from the source before startup of the boomer or SBP. • If during the prestart visual observation period, a whale is sighted within 300m of the vessel the equipment activation will be delayed until the whale has moved outside of the 300m zone or 30 minutes has lapsed since the last whale sighting within 300m. • SBP equipment will not be started at night if there have been three or more delays to the start-up of the equipment due to whales in the previous 24 hours.

		Use of suitably trained Marine Mammal Observers Once the survey has commenced CM14 applies where the vessel is required to maintain a 300m distance to all whales. Adaptive management will be detailed the procedure to be included in future EPs under this OPP when scheduling of the activity is known in greater detail.
	CM16 VSP Whale Management Procedure	Development and implementation of a whale management procedure which outlines specific measures to minimise anthropogenic noise threats to relevant species, including the implementation of safe operating distances, night-time and low visibility controls and pre-activity surveys for VSP activities that complies with 'Standard Management Procedures' set out in EPBC Act Policy Statement 2.1 – Interaction between Offshore Seismic Exploration and Whales: Industry Guidelines (DEWHA 2008c) (or the contemporary requirements at the time of the activity). This procedure provides a framework for minimising noise impacts to whales and details specific measures to be implemented that will ensure impacts and risks meet or are better than acceptable levels 1, 2 and 3. By meeting these acceptable levels, impacts will be consistent with Conservation Management Plan for the Blue Whale 2015-2025 (CoA, 2015b) and National Recovery Plan for the Southern Right Whale Eubalaena australis (DCCEEW 2024o). Specific measures in the procedure will include the following: • pre-start-up visual observations. • start-up and normal operating procedures, including a process for delayed start-up/recommencement, should whales be sighted. • night time and low visibility procedures • use of suitably trained Marine Mammal Observers • Adaptive management will be detailed the procedure to be included in future EPs under this OPP when scheduling of the activity is known in greater detail.
	CM17 Drilling Whale Management Procedure	Development and implementation of a whale management procedure which outlines specific measures to minimise anthropogenic noise threats to relevant species, including the implementation of safe operating distances between vessels and whales, pre-activity surveys for specific activities, night-time and low visibility controls and establishment of safe points for operational activities in accordance with the Safety Case and Well Integrity requirements for drilling activities. This procedure provides a framework for minimising noise impacts to

		whales and details specific measures to be implemented that will ensure impacts and risks meet or are better than acceptable levels 1, 2 and 3. By meeting these acceptable levels, impacts will be consistent with Conservation Management Plan for the Blue Whale 2015-2025 (CoA, 2015b) and National Recovery Plan for the Southern Right Whale Eubalaena australis (DCCEEW 2024o). Specific measures in the procedure will include the following: • pre-start-up visual observations. • start-up and normal operating procedures, including a process for delayed start-up/recommencement, should whales be sighted. • night time and low visibility procedures • use of suitably trained Marine Mammal Observers • weekly aerial surveys to detect and report the presence of whales within 20 km for anchor pre-lay, rig mooring and resupply activities in the shelf edge locations • Adaptive management will be detailed the procedure to be included in future EPs under this OPP when scheduling of the activity is known in greater detail.
	CM18 Vessel Whale Management Procedure	Development and implementation of a whale management procedure which outlines specific measures to minimise anthropogenic noise threats to relevant species, including the implementation of safe operating distances between vessels and whales, night-time and low visibility controls and pre-activity surveys for installation, IMR and vessel transit/resupply activities. This procedure provides a framework for minimising noise impacts to whales and details specific measures to be implemented that will ensure impacts and risks meet or are better than acceptable levels 1, 2 and 3. By meeting these acceptable levels, impacts will be consistent with Conservation Management Plan for the Blue Whale 2015-2025 (CoA, 2015b) and National Recovery Plan for the Southern Right Whale Eubalaena australis (DCCEEW 2024o). Specific measures in the procedure will include the following: • pre-start-up visual observations. • start-up and normal operating procedures, including a process for delayed start-up/recommencement, should whales be sighted. • night-time and low visibility proceduresuse of suitably trained Marine Mammal Observers

			• Adaptive management will be detailed the procedure to be included in future EPs under this OPP when scheduling of the activity is known in greater detail.
		CM19 Noise Assessments	Acoustic noise assessments of significant noise generating activities associated with the Project will be detailed in relevant activity specific Environment Plans prior to activities commencing. The EPs will detail the sound levels and distances to noise effect criteria, with the mitigations required to ensure the acceptable levels and Environmental Performance Outcomes of this OPP are met and ensure consistency against Conservation Management Plan for the Blue Whale 2015-2025 (CoA, 2015b) and National Recovery Plan for the Southern Right Whale Eubalaena australis (DCCEEW 2024o).
Atmospheric emissions	Minor	CM20 MARPOL Annex VI (Prevention of Air Pollution from Ships)	Vessels and MODU will comply with MARPOL Annex VI (Prevention of Air Pollution from Ships), the Navigation Act 2012, the Protection of the Sea (Prevention of Pollution from Ships) Act 1983 and Marine Orders – Part 97: Marine Pollution Prevention – Air Pollution (appropriate to vessel class) for emissions from combustion of fuel including: • valid International Air Pollution Prevention (IAPP) certificate and a current international energy efficiency certificate • have a Ship Energy Efficiency Management Plan (SEEMP) as per MARPOL 73/78 Annex VI • engine NOx emission levels will comply with Regulation 13 of MARPOL 73/78 Annex VI • use low sulphur content fuel oil/diesel (≤0.5% m/m S) or an approved measure that achieves an equivalent air quality outcome
		CM21 Emissions Monitoring	Measure, monitor or estimate facility fuel and flare emissions (in accordance with the National Pollutant Inventory) to inform and optimise management practices and minimise environmental impact of emissions
		CM22 Emission Abatement Opportunities Register	Per the requirements of the OEMS Sustainability Standard, Beach will maintain a register of opportunities for emissions reduction across its asset portfolio to reduce emissions.

Greenhouse gas emissions	Minor	CM22 Emission Abatement Opportunities Register	Refer above – atmospheric emissions. Refer above – atmospheric emissions.
		CM23 GHG Management Plan	The intent of this plan is to guide activities needed to manage Beach Scope 1 and Scope 1* GHG emissions, including the Project, in line with relevant policy and legislative requirements such as the Safeguard Mechanism and NGER. Implementation of Beach GHG Emissions Management Plan incorporates: • the framework and specific techniques used to ensure that GHG emission related EPOs will be met over the life of the facility • emissions monitoring • emissions forecasting • an adaptive management approach to facilitate a continuous cycle of monitoring, evaluating and implementing improvements to minimise GHG emissions to ALARP and acceptable levels over the life of the Project
		CM24 GHG Emissions Monitoring	Beach reports scope 1 and scope 2 emissions under the *National Greenhouse and Energy Reporting Act 2007* (NGER). This includes annual, mandatory reporting of emissions by 31 October for the prior financial year. We track our progress against emissions reduction targets according to the methods defined by NGER. Beach calculates scope 3 emissions based on the Greenhouse Gas Protocol's Corporate Value Chain (scope 3) Accounting and Reporting Standard and scope 3 guidance documents. Scope 3 emissions derived from the use of product will be reviewed against forecasts, with this focus reflecting the proportional contribution of final product use to overall Otway asset Scope 3 emissions. GHG emissions forecasts are prepared periodically using data such as production forecasts. This data informs the disclosures in our Sustainability Report and Climate Transition Action Plan [**PC206**].
		CM25 Fugitive Leak Detection and Repair Program	Beach undertakes periodic leak detection and repair (LDAR) fugitive emissions surveys at the Otway Gas Plant and Thylacine Platform. The scope, methodology, frequency, and repair guidance is detailed in the GHG Management Plan

		CM26 Preventative Maintenance System	Combustion equipment is inspected and maintained in accordance with the preventative maintenance system to ensure efficient operations
		CM27 Logistics Planning	Operations planning is undertaken for supply vessel and helicopter movements, thereby minimising unnecessary travel and minimising fuel combustion
Planned Discharge – Drill Cuttings and Fluids	Minor	CM10 Seabed assessments	Refer above – physical presence seabed disturbance
		CM11 Cultural heritage assessments	Refer above – physical presence seabed disturbance
		CM28 Well design	All wells to be drilled with WBDF, with SBDF only to be used where technical requirements preclude the use of WBDF
		CM29 Chemical selection process	A process for chemical selection will be implemented to ensure chemicals used are environmentally acceptable whilst also meeting technical requirements
		CM30 Drilling fluid inventory	Drilling fluids inventory will be developed and tracked to reduce or avoid discharge of bulk materials including excess powders, brines, and drilling fluids
		CM31 Solids control equipment	If SBDF is used, drill cuttings will be processed on the MODU to recover and reduce residual SBDF content prior to overboard discharge
		CM32 Minamata convention	Drilling fluids will have concentrations of mercury and cadmium less than 1 mg/kg and 3 mg/kg respectively in stock barite (WBM and SBM)
Planned Discharge – Cement	Minor	CM10 Seabed assessments	Refer above – physical presence seabed disturbance
		CM11 Cultural heritage assessments	Refer above – physical presence seabed disturbance
		CM33 Cementing program	Cementing programs shall be developed to reduce or avoid discharge of cement to the marine environment, including the reduction and avoidance of excess cement discharge upon completion of the drilling program.
		CM29 Chemical selection process	Refer above – planned discharge drill cuttings and fluids.
Planned Discharge – Commissioning and Operational Fluids	Minor	CM29 Chemical selection process	Refer above – planned discharge drill cuttings and fluids.
		CM34 Hydrotest assessment	Hydrotest assessments will be detailed in the relevant activity specific EPs developed during the detailed engineering and design studies of the Project. The EPs will detail the hydrotesting requirements including the definition of

			discharge characteristics (i.e. chemical additives and concentrations), discharge locations and volumes, methodology and species impact thresholds
Planned Discharge – Routine Operational Wastes from MODU and Vessels	Minor	CM29 Chemical selection process	Refer above – planned discharge drill cuttings and fluids.
		CM35 Marine Orders	All wastewater discharges will comply with relevant MARPOL 73/78, Navigation Act 2012, Protection of the Sea (Prevention of Pollution) Act 1983 and subsequent Marine Order requirements (as appropriate for vessel classification): • Marine Order 91 (Marine Pollution Prevention – Oil), which implements Annex I of MARPOL 73/78, including (as required by vessel class): ◦ Machinery space bilge/oily water shall have IMO-approved oil filtering equipment (oil/water separator) with an on-line OIW monitoring device ◦ OIW content to be less than 15 ppm prior to discharge. ◦ A deck drainage system capable of controlling the content of discharges for areas of high risk of fuel/oil/grease or hazardous chemical contamination. ◦ Valid International Oil Pollution Prevention Certificate. • Marine Order 95 (Marine Pollution Prevention – Garbage), which implements Annex V of MARPOL 73/78, including: ◦ Garbage management plan in place. ◦ Garbage record book maintained onboard. • Marine Order 96 (Marine Pollution Prevention – Sewage), which implements Annex IV of MARPOL 73/78, including (as required by vessel class): ◦ a valid International Sewage Pollution Prevention Certificate, ◦ an IMO-approved sewage treatment plant, ◦ a sewage comminuting and disinfecting system, a sewage holding tank sized appropriately to contain all generated waste (sewage and grey water) ◦ discharge of sewage will occur at a moderate rate while vessel is proceeding (more than 4 knots)

Cumulative Impacts with other reasonably foreseeable projects	Minor	CM51 Cumulative Impact Review	Each future EP resulting from the OGV OPP will undertake a review for additional or significantly revised reasonably foreseeable projects. Additional or significantly revised projects will be assessed as per CIA methodology (Section 8.2). Any cumulative impacts from new, significantly revised or currently unknown activities that results in an unacceptable level of impact to receptors, will be subject to new or revised control measures within the appropriate EP to reduce cumulative impacts to ALARP

ES Table 0-5: Aspect Specific Control Measures for Unplanned Activities

Aspect	Residual Impact		Control Measures
Invasive Marine Species	Low	CM36 IMS Management Plan	Implementation of Beach IMS Management Plan which includes the following minimum requirements: • compliance with relevant Australian legislation and current regulatory guidance • outline of when an IMS risk assessment is required and the associated inspection, cleaning and certification requirements • implementation of management measures commensurate with the level of risk based on outcomes if the IMS risk assessment, such as inspections, cleaning and movement restrictions anti-fouling prevention measures, including vessels (of appropriate class) having a valid International Anti Fouling Systems (IAFS) Certificate
		CM37 Australian Ballast Water Management Requirements	The MODU and vessels fulfil the requirements of the Australian Ballast Water Management Requirements (DAWR, 2020, v8). This includes requirements to: • Carry a valid Ballast Water Management Plan (BWMP). • Submit a Ballast Water Report (BWR) through the Maritime Arrivals Reporting System (MARS). • If intending to discharge internationally sourced ballast water, submit BWR through MARS at least 12 hours prior to arrival. • If intending to discharge Australian sourced ballast water, seek a low-risk exemption through MARS. • Hold a Ballast Water Management Certificate (BWMC). • Ensure all ballast water exchange operations are recorded in a Ballast Water Record System (BWRS)
Physical Presence – Interaction with Marine Fauna	Low	CM14 EPBC Regulations 2000 – Part 8 Division 8.1 interacting with cetaceans	Refer above – underwater sound emissions
	Low	CM10 Seabed assessments	Refer above – physical presence seabed disturbance

Accidental Discharge - Hazardous and Non-Hazardous Materials		CM11 Cultural heritage assessments	Refer above – physical presence seabed disturbance
		CM35 Marine orders	Refer above – planned discharge routine operational wastes from MODU and vessels
		CM38 Waste Management Plan	Beach Waste Management Plan implemented that includes details of: • Classification and segregation of wastes • Appropriate storage of wastes • Transportation and disposal of wastes to licensed treatment and disposal facilities onshore
		CM39 Lifting	Crane and lifting operations will comply with the following: • Lifting equipment will be inspected and certified • Preventative maintenance will be carried out • Lifting operators will be competent and qualified
Loss of Containment - Hydrocarbons and Chemicals	Medium (MDO) Low (Condensate)	CM01 Navigation safety	Refer above - Physical Presence - Interaction with Other Users
		CM02 Notifications	Refer above - Physical Presence - Interaction with Other Users
		CM03: Fair Ocean Access Procedure	Refer above - Physical Presence - Interaction with Other Users
		CM05 Petroleum safety zones	Refer above - Physical Presence - Interaction with Other Users
		CM06 Temporary exclusion/cautionary zones	Refer above - Physical Presence - Interaction with Other Users
		CM40 WOMP	The Well Operations Management Plan (WOMP) is a regulatory requirement under the Offshore Petroleum and Greenhouse Gas Storage Act 2006 and the associated Offshore Petroleum and Greenhouse Gas Storage (Resource Management and Administration) Regulations 2011. It is the primary approval document for ensuring a high standard of well integrity and details the risk assessment, critical procedures and safety mechanisms to be implemented throughout the duration of the relevant petroleum activity
		CM41 MODU Safety Case	The Safety Case for the MODU is a regulatory requirement under the OPGGS Act and the associated Offshore Petroleum and Greenhouse Gas Storage (Resource Management and Administration) Regulations 2011 The Safety Case identifies hazards and risks specific to drilling wells, describes how the risks are controlled and describes the safety management system in

	place to ensure the controls are effectively and consistently applied. This includes the subsea control system configured for all wells to fail-safe in the event of loss of communication and/or hydraulics. Prevention of loss of well control and subsequent release of hydrocarbons is a key focus as this is the source of major accident events
CM42 Well Engineering and Construction Management System (WECS)	Beach Well Engineering and Construction Management System (WECS) that ensures well activities are fit for purpose with operational risks managed to a level that is as low as reasonably practicable. It also ensures that changes are made in a controlled manner, that appropriate standards are adhered to, and that a sufficiently resourced and competent organisation is in place. The Beach Operations Excellence Management System consists of Well Integrity Standard and WECS.
CM43 Workforce capability	Beach Workforce Capability Requirements Matrix to ensure Operations personnel are qualified, trained and certified as competent to operate and maintain Beach facilities
CM44 Crisis and Emergency Management	Beach's Crisis and Emergency Management Standard requires Beach to have plans, procedures and resources in place to effectively respond to crisis and emergency situations, including hydrocarbon spills
CM45 Preventative maintenance	Computerised Maintenance Management System to ensure all wells and subsea infrastructure is maintained to schedule
CM46: SMPEP or SOPEP (appropriate to class)	In accordance with MARPOL Annex I and AMSA's MO 91 [Marine Pollution Prevention – oil], a SMPEP or SOPEP (according to class) is required to be developed based upon the Guidelines for the Development of Shipboard Oil Pollution Emergency Plans, adopted by IMO as Resolution MEPC.54(32) and approved by AMSA. To prepare for a spill event, the SMPEP/SOPEP details: • response equipment available to control a spill event; • review cycle to ensure that the SMPEP/SOPEP is kept up to date; and • testing requirements, including the frequency and nature of these tests. In the event of a spill, the SMPEP/SOPEP details: • reporting requirements and a list of authorities to be contacted; • activities to be undertaken to control the discharge of hydrocarbon; and • procedures for coordinating with local officials.

		Specifically, the SMPEP/SOPEP contains procedures to stop or reduce the flow of hydrocarbons to be considered in the event of tank rupture.
	CM47 Bunkering procedure	Bunkering procedures to manage fuel transfers that include: • Weather limits on bunkering operations • Bunkering equipment specifications and inspection • Visual observations during transfers • Emergency shutdowns
	CM48 EP, OPEP and OSMP	Accepted Environment Plans (EP) Oil Pollution Emergency Plans (OPEP) and Operational and Scientific Monitoring Plans (OSMP) in place for all relevant Project activities and oil spills responded to in accordance with the plans
	CM49 Oil spill modelling	Oil spill modelling and environmental risk assessments for the Project EPs and OPEPs will consider the full range of worst-case scenario LOWC consequences
	CM50 Source control	Source Control Emergency Response Plans in place for all drilling activities

ES7 Environmental Management Implementation Approach

The Operations Excellence Management System (OEMS) is Beach's framework which provides the basis by which it defines, aligns, standardises and implements company processes to manage risks and ensure successful outcomes in its operations.

The OEMS defines the minimum standards, expectations and behaviours that ensure the company operates successfully in all core business processes including Health & Safety, Environmental Management, Production & Reliability, Financial & Stakeholder Management and Project Delivery. The OEMS applies to all personnel performing work within the company's jurisdiction.

The OEMS defines Beach's key elements and standards and how the proponent will deliver the OGV Project.

ES Figure 0-2: Operational Excellence Management System

ES8 Stakeholder Consultation

To complement the NOPSEMA assessment process for OPPs and provide stakeholders with sufficient time to consider the project, Beach will adopt a phased consultation approach for this OPP:

- Phase 1: Consultation on the Project prior to OPP public comment period
- Phase 2: Formal consultation via the OPP public comment period
- Phase 3: Ongoing consultation for development activities.

Beach will consider all feedback provided by stakeholders and, where relevant, incorporate information provided by stakeholders into the environmental management of the Project.

1 Introduction

1.1 Project Overview

The Otway Offshore Gas Victoria (OGV) Project (the Project) is designed to explore and develop new gas discoveries in the offshore Otway Basin. The Project covers an area that is located approximately 17 km south of the Victorian mainland and 80 km north-west of Tasmania (King Island) at its closest points.

Beach Energy (Operations) Limited (Beach) is the proponent for the Project and also owns and operates existing production assets and infrastructure in the Otway Basin including the Thylacine A production platform, Thylacine platform wells and subsea wells, flowlines and facilities, Geographe subsea wells flowlines and facilities, and Otway Gas Production Pipeline (OGPP) which transports gas and liquid hydrocarbons to the onshore Otway Gas Plant (OGP) located near Port Campbell (Figure 1-1). The OGP supplies gas to the domestic market in south-east Australia.

The Project provides the opportunity to develop currently stranded gas reserves and future resources using Beach's existing offshore infrastructure through exploration, appraisal and development activities in Beach's exploration permits, VIC/P43 and VIC/P73. On 30 September 2024, the Artisan field (1 block within VIC/P43) was converted to production licence, VIC/L35 and the La Bella field (2 blocks within VIC/P73) was converted to production licence, VIC/L36. For the purpose of the OPP, all references to VIC/P43 are defined as VIC/P43 and VIC/L35 and all reference to VIC/P73 are defined as VIC/P73 and VIC/L36.

The Artisan and La Bella gas discoveries, are in close proximity to Beach's existing production assets. The development of Artisan and La Bella gas discoveries will involve the drilling and completion of subsea wells, and the tie-back of these wells to the existing OGPP through which it will be transported to the OGP.

The development of undrilled future prospects will involve the same subsea development concept as Artisan and La Bella and will be tied back to existing infrastructure either directly to the OGPP or via the Thylacine platform.

The petroleum exploration, appraisal and development activities planned for the Project will commence in 2025 with an initial multi-well drilling campaign. Installation of new subsea facilities is anticipated to commence in 2028 with the earliest achievable date for commissioning and first gas also in 2028 subject to corporate, joint venture and regulatory approvals.

Additional subsea developments from new exploration success in future drilling campaigns may also be carried out and are in the scope of this OPP.

Figure 1-1: Project Location

1.2 Proponent

The Project proponent is Beach Energy (Operations) Limited (Beach) which is a wholly owned subsidiary of Beach Energy Limited.

Beach is the operator of the Otway Joint Venture which includes Thylacine (production licences T/L2, T/L3, T/L4), Geographe, Artisan and La Bella (production licences VIC/L23, VIC/L36 and VIC/L35), and exploration permits VIC/P43 and VIC/P73. The participating interests in the Otway Joint Venture are Beach, 60% interest and OGOG (Otway) Pty Ltd, 40% interest.

The contact details for Beach are provided in the below Table 1-1.

Table 1-1: Proponent Details

Details	
Business Address	Level 8 80 Flinders Street Adelaide South Australia 5000
Contact Details	Brad Muir Project Manager T: (08) 8338 2833 F: (08) 8338 2336 E: info@beachenergy.com.au

Beach Energy Limited is an ASX listed, oil and gas exploration and production company headquartered in Adelaide, South Australia. It has operated and non-operated, onshore and offshore, oil and gas production from five producing basins across Australia and New Zealand and is a key supplier to the Australian east coast gas market.

Beach Energy Limited’s asset portfolio includes ownership interests in strategic oil and gas infrastructure, as well as a suite of high potential exploration prospects. Beach Energy Limited’s gas exploration and production portfolio includes acreage in the Otway, Bass, Cooper/Eromanga and Perth basins in Australia, and the Taranaki Basin in New Zealand.

1.3 Project Scope

The Project aims to develop stranded gas reserves and future resources in the Otway Basin through utilisation of the existing offshore infrastructure and creating further efficiencies through consolidated drilling and installation campaigns.

A summary of the key elements and activities for the Project is presented in Table 1-2. The development concept is consistent for all Beach’s nearby gas fields in the Otway Basin and involves subsea wells, flowlines and facilities to be tied back to the existing OGPP or Thylacine platform. The scope covers multiple small fields that may be developed in stages.

All activities will be carried out within the Project Area defined in Section 3.8.

Table 1-2: Project Summary

Project Stage	Key Activities
Surveys	Geotechnical and geophysical surveys undertaken to assess the suitability of the seabed for drilling and infrastructure placement
Drilling and Completions	Drilling & Completion campaign(s)
Facilities Installation and Commissioning	• Installation of subsea infrastructure to connect gas discoveries Artisan, La Bella and any successful exploration or appraisal wells from the initial drilling campaign to the OGPP including; wellheads, flowlines, umbilicals, manifolds and skids • Commissioning and testing of new equipment including flowlines, • Unload of drilling and completion fluid from the well is planned through new and existing subsea infrastructure to the onshore Otway Gas Plant (OGP). Well unload and testing to the MODU is a contingent option. • Future tie backs of successful exploration or appraisal wells comprising similar subsea infrastructure to the initial development may be undertaken in the Project Area during the life of the Project: • There is the potential for future tie-ins in the vicinity of the Project Area by other operators comprising similar subsea infrastructure to the initial development.
Operations and Maintenance	• Production from Artisan, La Bella and future prospects is expected to have an operational life of up to 20 years with EOFL estimated as 2045. • However, subject to future investment and developments in surrounding fields, operations and infrastructure life may be extended. • Operations stage may include well intervention and inspection, maintenance and repair of wells and subsea infrastructure as required
Decommissioning	• Well abandonment • Decommissioning of subsea infrastructure

1.4 **Project Location**

The Project Area is located in the Otway Basin in offshore Commonwealth waters, approximately 17 km south of the Victorian mainland and 80 km north-west of Tasmania (King Island) (Figure 1-1). The Project location is further defined in Section 3.4.

The Project Area is defined in Section 3.5.

1.5 **OPP Purpose and Scope**

1.5.1 OPP Purpose

This Offshore Project Proposal (OPP) has been prepared by Beach, as the proponent of the Project, in accordance with the requirements of the Offshore Petroleum and Greenhouse Gas Storage (Environment) Regulations 2023 (OPGGS (Environment) Regulations), and associated guidelines.

The purpose of the OPP process is to allow assessment and decision-making at the whole-of project level for offshore projects in Commonwealth waters. This, together with the assessment of activity specific Environment Plans, are part of the broader environmental management authorisations process for offshore petroleum activities. These processes aim to ensure that activities in the offshore area are carried out in a manner consistent with the principles of ecologically sustainable development (ESD), and that the environmental impacts and risks of the activities will be of an acceptable level.

The OPP is an early-stage project assessment which, subject to acceptance by the National Offshore Petroleum Safety and Environmental Management Authority (NOPSEMA), will form the basis for future activity-specific Environment Plans (EPs). An OPP must be accepted by NOPSEMA before the proponent can submit EPs for activities that make up an offshore project. This pre-requisite does not apply to exploration and appraisal activities such as seismic surveys and exploratory drilling, however Section 15 of the OPGGS (Environment) Regulations allows for the use of the OPP arrangements for exploration and appraisal activities if a proponent choses to do so.

More information can be found on the OPP process on NOPSEMA's website.

1.5.2 Out of Scope Activities not covered by this OPP

The Project Area (defined in Section 3.5) also includes the location of existing Otway Development at Thylacine and Geographe which was approved by the Environment Minister under Part 9 of the *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act) (EPBC No 2002/621).

In March 2010, Origin Energy Resources Ltd (Origin) commenced operatorship of the development (later changing its name to Lattice Energy Limited (Lattice)). In February 2018, Beach acquired Lattice, which included the Otway Development. The EIS covered development activities at the Geographe and Thylacine fields which make up the existing Otway Development. As these development activities have been approved under Part 9 of the EPBC Act they are not required to be covered by this OPP.

The transit of vessels to and from the offshore locations is excluded from this OPP as this is outside the scope of the OPGGS Act and is regulated by maritime legislation, including the *Commonwealth Navigation Act 2012*.

1.5.3 Scope of Activities covered by this OPP

The scope of activities covered by the OPP is defined by the Project summary provided in Section 1.3 and the description of the Project provided in Section 3.

1.6 Document Structure

The structure of this OPP is detailed in Table 1-3. This structure is concordant with the requirements of the OPGGS (Environment) Regulations and NOPSEMA's Offshore Project Proposal Content Requirements Guidance Note (N-04790-GN-1663, 10.8.2020) and Offshore Project Proposal Assessment Policy (N-04790-PL-1650, 11.8.2020) as set out in in Table 1-4.

Table 1-3: Structure of this Document

Section		Content
1	Introduction	Development overview, location, proponent details and outlines the purpose and structure of the OPP.
2	Environmental Legislation and Other Requirements	Legislation, other regulatory requirements, relevant standards and guidelines.
3	Description of the Project and Alternatives Analysis	A description of all activities associated with the project and an analysis of alternatives
4	Description of the Environment	A description of the existing environment highlighting significant physical, ecological and socioeconomic values.

5	Environmental Impact and Risk Assessment Methodology	The methodology for identifying and evaluating environmental impacts and risks.
6	Environmental Impact Evaluation - Planned Activities	Results and justification of environmental impact assessments.
7	Environmental Risk Evaluation – Unplanned Events	Results and justification of environmental risk assessments.
8	Cumulative Impact Assessment	Provides an assessment of cumulative impacts for the Project.
9	Implementation Strategy	Details how environmental performance outcomes stated within this OPP will be implemented.
10	Stakeholder Consultation	A summary of Beach's stakeholder consultation methods which includes the process of stakeholder identification and consultation history and future consultation requirements.
11	References	A summary of documents referred to within this OPP.

Table 1-4: Concordance of this Document with the OPGGS (Environment) Regulations

OPGGS (Environment) Regulations	**Requirements**	**Relevant section of the OPP**
Section 7 – Contents of Offshore Project Proposal		
7(2) (a)	The proponent's name and contact details.	Section 1
7(2) (b)	A summary of the Project, including the following: • a description of each activity that is part of the Project • the location or locations of each activity • a proposed timetable for carrying out the Project • a description of the facilities that are proposed to be used to undertake each activity • a description of the actions proposed to be taken, following completion of the project, in relation to those facilities.	Section 2.2.2
7(2) (c)	A description of the existing environment that may be affected by the project.	Section 4
7(2) (d)	Details of the relevant values and sensitivities (if any) of that environment.	Section 4.2
7(2) (e)	The environmental performance outcomes for the Project.	Section 6 and 7
7(2) (f)	A description of any feasible alternative to the Project, or an activity that is part of the Project, including: • a comparison of the environmental impacts and risks arising from the Project or activity and the alternative. • an explanation, in adequate detail, of why the alternative was not preferred.	Section 2.2.2
7(3)	Requirement to address relevant values and sensitivities (as defined in the EPBC Act).	Section 2
7(4)	The proposal must describe:	Section 2 and 0

	• the requirements, including legislative requirements, that apply to the Project and are relevant to the environmental management of the project, and • how those requirements will be met.	
7(5)	The proposal must include: • details of the environmental impacts and risks of the activities that are part of the Project, and • an evaluation of all the impacts and risks, appropriate to the nature and scale of each impact or risk.	Section 6 and 7

2 Environmental Legislation and Other Requirements

The Project is located in Commonwealth waters and is governed by Commonwealth legislation and regulations for petroleum, environment, health and safety and maritime activities which are set out in the below sections.

2.1 **Offshore Petroleum and Greenhouse Gas Storage Act 2006 (OPGGS Act)**

The *Offshore Petroleum and Greenhouse Gas Storage Act 2006* (OPGGS Act) provides a legal framework for the exploration and development of petroleum in Commonwealth waters (beyond the 3 nm), including licensing, health, safety, environment and royalties. Subordinate regulations include:

- Offshore Petroleum and Greenhouse Gas Storage (Environment) Regulations 2023 (OPGGS (Environment) Regulations)
- Offshore Petroleum and Greenhouse Gas Storage (Safety) Regulations 2009
- Offshore Petroleum and Greenhouse Gas Storage (Resource Management and Administration) Regulations 2011

The OPGGS Act establishes the National Offshore Petroleum Safety and Environmental Management Authority (NOPSEMA) as the independent regulator for environmental management, health and safety, and well integrity and for all offshore petroleum (and greenhouse gas storage) activities in Commonwealth waters.

2.2 **Offshore Petroleum Greenhouse Gas Storage (Environment) Regulations 2023**

The OPGGS (Environment) Regulations provide for the regulation of environmental management of petroleum (and greenhouse gas storage) activities in Commonwealth waters, and aim to ensure that petroleum activities in these areas are:

- Carried out in a manner that is consistent with ecologically sustainable development (ESD) and
- Consistent with the objective that environmental impacts and risks are of an acceptable level.

The OPGGS (Environment) Regulations also set out the requirements for an OPP and Environment Plans (EP) as described in the below sections.

2.2.1 Offshore Project Proposal Requirements

The OPGGS (Environment) Regulations defines an offshore project as one or more activities that are '*undertaken for the purpose of the recovery of petroleum, other than on an appraisal basis, including any conveyance of recovered petroleum by pipeline*'.

The OPGGS (Environment) Regulations (Section 6(1)) requires that "before commencing an offshore project, a person must submit an offshore project proposal for the Project to NOPSEMA". However, section 6(2) states that section 6(1) does not apply if the Environment Minister:

- has made a decision under section 75 of the EPBC Act that an action that is equivalent to or includes the Project is not a controlled action; or
- has made a component decision under section 77A of the EPBC Act that a particular provision of Part 3 of that Act is not a controlling provision for an action that is equivalent to or includes the Project, because the Environment Minister believes the action will be taken in a particular manner; or
- has approved, under Part 9 of the EPBC Act, the taking of an action that is equivalent to or includes the Project.

2.2.2 Environment Plans

The OPGGS (Environment) Regulations require a titleholder to have an accepted EP in place for a petroleum (or greenhouse gas) activity. EPs for activities that form part of the OPP can only be submitted to NOPSEMA once the OPP has been accepted.

The exploration and appraisal activities, specifically the initial and future drilling campaigns, are included in this OPP under section 15 of the OPGGS (Environment) Regulations. In including the exploration and appraisal activities in the OPP, the proponent notes that acceptance of an OPP prior to submission of a related EP does not apply to exploration and appraisal activities. The proponent submitted an Environment Plan for the drilling campaign for assessment by NOPSEMA in February 2024.

Under the OPGGS (Environment) Regulations, an EP must be appropriate for the nature and scale of the activity and describe the activity, the existing environment, details of environmental impacts and risks and the control measures for the activity. In addition, the EP must include an implementation strategy to demonstrate that the impacts and risks can be managed to as low as reasonably practicable (ALARP) and an acceptable level and to describe how appropriate environmental performance outcomes (EPOs), environmental performance standards (EPS) and measurement criteria detailed in the EP will be met. The EP must also provide a summary of all consultation undertaken with relevant persons. The EPs required in support of the Project will address activities related to:

- drilling and completion of development wells for production
- installation, commissioning and operation of wells and subsea infrastructure
- progressive decommissioning activities

2.2.3 Other Petroleum Activity Approvals

In addition to environmental approvals, the OPGGS (Safety) Regulations 2009 require that a Safety Case and the OPGGS (Resource Management and Administration) Regulations 2011 require a Well Operations Management Plan (WOMP), be assessed and accepted by NOPSEMA for petroleum facilities, along with any relevant licences to support pipelines, infrastructure and production. Beach will prepare and submit the required licence and permit applications, Safety Cases and WOMPs to NOPSEMA as the Project is progressed.

2.3 Environmental Protection and Biodiversity Conservation Act 1999 (EPBC Act)

The EPBC Act is the Commonwealth Government’s primary environmental legislation administered by the Department of Climate Change, Energy, the Environment and Water (DCCEEW)) (formerly the Department of Agriculture, Water and Environment, DAWE). The EPBC Act provides a legal framework to protect and manage important flora, fauna, ecological communities and heritage places defined in the EPBC Act as Matters of National Environmental Significance (MNES) listed under Part 3 of the EPBC Act. Under the EPBC Act, any action that is likely to have a significant impact on the MNES must not be undertaken without the approval of the Minister. Actions with the potential to impact on the MNES trigger the Commonwealth environmental assessment and approval process.

From 28 February 2014, following streamlining of regulatory processes under the OPGGS Act (Section 2.1) and s146 EPBC Act, certain offshore petroleum activities can be authorised under the OPGGS Act without requiring a separate authorisation process under the EPBC Act.

These changes took effect following the approval by the Minister for the Environment under section 146B of the EPBC Act, for the taking of actions in accordance with an endorsed “Program” The ‘Program’ is described in ”Program Report – Strategic Assessment of the environmental management authorisation process for petroleum and greenhouse gas storage activities administered by the National Offshore Petroleum Safety and Environmental Management Authority under the Offshore Petroleum and Greenhouse Gas Storage Act 2016”. The Program outlined the environmental management authorisation process for offshore petroleum and greenhouse gas activities under the OPGGS Act to be administered by NOPSEMA. The objective of the Program Report was to demonstrate how the Program will ensure activities are conducted in a manner consistent with the principles of ecologically sustainable development and will not result in unacceptable impacts to matters protected under Part 3 of the EPBC Act. Specifically, the report outlined the commitments and undertakings of NOPSEMA to ensure adequate protection of EPBC Act Part 3 protected matters (MNES).

The streamlined approach enabled by the approved ‘Program’ excludes actions which are petroleum and greenhouse gas activities that:

- have, will have or are likely to have a significant impact on the environment on Commonwealth land
- are taken in any area of sea or seabed that is declared to be a part of the Great Barrier Reef Marine park under the Great Barrier Reef Marine Park Act 1975 (Cth)
- have, will have or are likely to have a significant impact on the work heritage values of the Great Barrier Reef National Heritage place

- are taken in the Antarctic
- are injection and/or storage of greenhouse gas

Additionally, actions taken in state or territory waters are also noted to not be covered by the approved class of actions. The scope of this OPP does not include any of the excluded actions.

To support the streamlining, several changes to the OPGGS (Environment) Regulations were made to environmental approvals processes for offshore petroleum activities. In addition to changes to the existing EP assessment processes, the changes included the introduction of the OPP authorisation process for offshore projects to allow for public comment on a project early in the Project lifecycle. The OPP process reflects the level of transparency and opportunity for public comment that is provided for as part of the 'Environmental Impact Statement/Public Environmental Review' assessment process under the EPBC Act.

Unlike the EPBC Act assessment process previously applicable to offshore petroleum activities, the OPP and EP assessment process under the OPGGS Act apply to all offshore petroleum activities regardless of the potential level of impact or risk to the environment that the proposal may present.

2.3.1 Listed Threatened Species Management / Recovery Plans and Conservation Advice

Under Part 13 of the EPBC Act, species can be listed as one, or a combination, of the following protection designations:

- Threatened (further divided into categories; extinct, extinct in the wild, critically endangered, endangered, vulnerable, conservation dependent)
- Migratory
- Whales and other cetaceans
- Marine

Threatened species are managed through management plans, recovery plans and / or conservation advice. These plans provide advice on relevant impacts and threats and set requirements for management and protection.

Species management plans, recovery plans and conservation advice have been considered during the development of this OPP to identify the appropriate management of the Project activities. These have been considered in the assessment of impacts and risks, the assessment of acceptability, and the development of EPOs. Table 2-1 outlines the management plans, recovery plans and conservation advice and associated key threats and conservation actions relevant to the Project. Threatened species of state and local significance relevant to the Project are also considered and are included in appropriate state management or recovery plans.

In addition to species specific management plans, recovery plans and conservation advice, the following plans have also been taken into consideration:

- The Action Plan for Australian Cetaceans (Bannister et al. 1996)

- National Recovery Plan for Ten Species of Seabirds (DEH 2005a)
- King Island Biodiversity Management Plan (DPIPWE 2012)

Table 2-1: Summary of EPBC Management / Recovery Plans and Conservation Advice Relevant to the Project

Relevant Plan/Advice	**Description**	**Applicable Threats and Conservation Actions**
South-east Marine Parks Network Draft Management Plan 2024	Draft management plan developed for the South-east Marine Parks Network. Outlines management of the parks to protect biodiversity and other natural, social and cultural values and allow for ecologically sustainable use.	*Climate change* *Invasive species (including marine pests)* *Marine pollution (emission of noise or light, marine debris and discharge of oil, noxious substances (including chemicals and heavy metals) or sewage waste).* No explicit management actions relevant to climate change, invasive species or marine pollution.
South-east Marine Parks Network Management Plan 2013-2023 (DNP 2013)	Outlines management of the parks to protect biodiversity and other natural, social and cultural values and allow for ecologically sustainable use.	*Noise pollution* *Oil pollution* *Invasive species* *Light pollution* No explicit management actions relevant to noise/ light/ oil pollution or invasive species.
Threat abatement plan for the impacts of marine debris on the vertebrate wildlife of Australia's coasts and oceans (CoA 2018a)	Threat abatement plan for the impacts of marine debris on vertebrate marine life	*Marine debris* Evaluate risk of marine debris (including risk of entanglement and/or ingestion) and, if required, appropriate mitigation measures are implemented.
The National Strategic Plan for Marine Pest Biosecurity (2018-2023) (DAWR 2018)	Australia's national strategic plan for marine pest biosecurity.	*Invasive Marine Species* There are five objectives in the plan: 1. Minimise the risk of marine pest introductions, establishment and spread 2. Strengthen the national marine pest surveillance system 3. Australia's preparedness and response capability for marine pest introductions 4. Support marine pest biosecurity research and development 5. Engage stakeholders to better manage marine pest biosecurity.
National Marine Pest Surveillance Work Plan (DAWE, 2022)	Guideline for implementation of the National Marine Pest Surveillance Strategy (2021-2026). Identifies suggested projects and stakeholders to achieve surveillance strategy activities.	*Invasive Marine Species* Identifies gas and oil industry as key stakeholder for the following activities: 1. Relevant authorities to identify priority surveillance locations for marine pests

		2. Provide advice on use of surveillance techniques such that methods used across and between jurisdictions are quantifiable 3. Review and provide guidance on pest distribution modelling techniques that may be used in surveillance programs 4. Review marine pest surveillance activities and data sets relevant to Australia 5. Identify and engage stakeholder groups (including government) and educate on the importance of marine pest surveillance
Wildlife Conservation Plan for Seabirds (CoA, 2020a)	Outlines national activities to support seabird conservation initiatives and provides a strategic framework to ensure these activities plus future research and management actions are integrated and remain focused on the long-term survival of seabird populations and their habitats.	*Anthropogenic disturbance* Ensure all areas of important habitat for seabirds are considered in the development assessment process. Manage the effects of anthropogenic disturbance to seabird breeding and roosting areas. *Pollution (marine debris, light, water)* Enhance contingency plans to prevent and/or respond to environmental emergencies that have an impact on seabirds and their habitats. *Invasive species* Ensure seabirds are protected from the adverse effects of invasive species. *Climate Change* *Habitat loss and degradation from pollution* No explicit management actions relevant to climate change or habitat loss and degradation form pollution.
Wildlife Conservation Plan for Migratory Shorebirds (CoA, 2015a)	Sets out the research and management actions necessary to support survival of one or more migratory, marine, conservation dependant or cetacean species listed under the Environment Protection and Biodiversity Conservation Act 1999 (the EPBC Act).	*Habitat loss* *Habitat modification (chronic and acute pollution, invasive marine species)* *Anthropogenic disturbance (aircraft over-flights, industrial operations and construction, artificial lighting)* Investigate the significance of cumulative impacts on migratory shorebird habitat and populations in Australia. Ensure all areas important to migratory shorebirds in Australia continue to be considered in development assessment processes (specifically for coastal developments). *Climate variability and change* Investigate the impacts of climate change on migratory shorebird habitat and populations in Australia.
National Light Pollution Guideline for Wildlife including Marine Turtles, Seabirds and	Guideline to raise awareness of the potential impacts of artificial light on wildlife and provide a framework for assessment and managing	*Light Emissions* Evaluate risk of artificial light on wildlife and, if required, appropriate mitigation measures are implemented.

Migratory Shorebirds (DCCEEW 2023a)	these impacts around susceptible listed wildlife.	
National Recovery Plan for Albatrosses and Petrels 2022 (CoA 2022)	The recovery plan is a co-ordinated conservation strategy for albatrosses and giant petrels listed as threatened.	*Marine pollution* Evaluate risk of oil spill impact to nest locations and, if required, appropriate mitigation measures are implemented. *Marine debris* Evaluate risk of marine debris (including risk of entanglement and/or ingestion) and, if required, appropriate mitigation measures are implemented. *Climate change* Appropriate monitoring strategies are implemented to fill information gaps; and Mitigation actions are identified and adopted where feasible and appropriate.
Approved Conservation Advice for *Pterodroma mollis* (soft-plumaged petrel) (TSSC 2015a)	Conservation advice provides management actions that can be undertaken to ensure the conservation of the soft-plumaged petrel.	None identified.
Approved Conservation Advice for *Sternula nereis nereis* (Australian Fairy Tern) (TSSC 2011a)	Conservation advice provides management actions that can be undertaken to ensure the conservation of the fairy tern.	*Marine pollution* Ensure appropriate oil-spill contingency plans are in place for the subspecies' breeding sites which are vulnerable to oil spills, such as the breeding colonies in Victoria
National Recovery Plan for the Australian Fairy Tern (*Sternula nereis nereis*) (CoA 2020)	National recovery plan for actions so species no longer qualifies for listing as threatened under any of the EPBC Act listing criteria.	*Habitat degradation and loss of breeding habitat / Pollution / Climate variability* No explicit relevant management actions
Conservation Advice for *Numenius madagascariensis* (Far Eastern Curlew) (DCCEEW, 2023)	Conservation advice provides management actions that can be undertaken to ensure the conservation of the eastern curlew.	*Habitat loss / Pollution* No explicit relevant management actions
Conservation Advice for *Limosa lapponica baueri* (Bar-tailed Godwit (Western Alaskan)) (DCCEEW 2024e)	Conservation advice provides management actions that can be undertaken to ensure the conservation of the bar-tailed godwit (Western Alaskan).	*Habitat loss, degradation and fragmentation* No explicit relevant management actions
Conservation Advice for *Limosa limosa* (black-tailed godwit) (DCCEEW 2024f)	Conservation advice provides management actions that can be undertaken to ensure the conservation of the black-tailed godwit (Western Alaskan).	*Habitat loss, degradation and fragmentation* Ensure that future development projects avoid any activities that disproportionately affect the upper-tidal flats and/or areas providing major foraging opportunities as identified by species experts, local studies and site managers. *Acute Pollution* *Climate Change*

		No explicit relevant management actions for climate change or acute pollution.
Conservation Advice for *Arenaria interpres* (ruddy turnstone) (DCCEEW 2024d)	Conservation advice provides management actions that can be undertaken to ensure the conservation of the ruddy turnstone.	*Habitat loss, degradation and fragmentation* Ensure that future development projects avoid any activities that disproportionately affect the upper-tidal flats and/or areas providing major foraging opportunities as identified by species experts, local studies and site managers. *Acute Pollution* *Climate Change* No explicit relevant management actions for climate change or acute pollution.
Approved Conservation Advice for *Calidris acuminata* (sharp-tailed sandpiper) (DCCEEW 2024g)	Conservation advice provides management actions that can be undertaken to ensure the conservation of the sharp-tailed sandpiper.	*Habitat loss, degradation and fragmentation* Ensure that future development projects avoid any activities that disproportionately affect the upper-tidal flats and/or areas providing major foraging opportunities as identified by species experts, local studies and site managers. *Acute Pollution* *Climate Change* No explicit relevant management actions for climate change or acute pollution.
Conservation Advice for *Calidris tenuirostris* (great knot) (DCCEEW 2024l)	Conservation advice provides management actions that can be undertaken to ensure the conservation of the great knot.	*Habitat loss, degradation and fragmentation* Ensure that future development projects avoid any activities that disproportionately affect the upper-tidal flats and/or areas providing major foraging opportunities as identified by species experts, local studies and site managers. *Acute Pollution* *Climate Change* No explicit relevant management actions for climate change or acute pollution.
Conservation Advice for *Ardenna grisea* (sooty shearwater (DCCEEW 2023d)	Conservation advice provides management actions that can be undertaken to ensure the conservation of the sooty shearwater.	*Climate Change* No explicit management actions relevant to climate change.
Conservation Advice for *Aphelocephala leucopsis* (southern whiteface) (DCCEEW 2023g)	Conservation advice provides management actions that can be undertaken to ensure the conservation of the southern whiteface.	*Climate Change* No explicit management actions relevant to climate change.
Conservation Advice for *Gallinago hardwickii* (Latham's snipe) (DCCEEW 2024j)	Conservation advice provides management actions that can be undertaken to ensure the conservation of the Latham's snipe.	*Climate Change* No explicit management actions relevant to climate change.
Conservation Advice for *Neophema chrysostoma* (blue-	Conservation advice provides management actions that can be undertaken to ensure the	*Climate Change* No explicit management actions relevant to climate change.

winged parrot) (DCCEEW 2024h).	conservation of the blue-winged parrot.	
Approved Conservation Advice for *Pluvialis squatarola* (grey plover) (DCCEEW 2024k)	Conservation advice provides management actions that can be undertaken to ensure the conservation of the grey plover.	*Habitat loss, degradation and fragmentation* Ensure that future development projects avoid any activities that disproportionately affect the upper-tidal flats and/or areas providing major foraging opportunities as identified by species experts, local studies and site managers. *Acute Pollution* *Climate Change* No explicit relevant management actions for climate change or acute pollution.
Conservation Advice for *Stagonopleura guttata* (diamond firetail) (DCCEEW 2023e)	Conservation advice provides management actions that can be undertaken to ensure the conservation of the diamond firetail.	*Climate Change* No explicit management actions relevant to climate change.
Approved Conservation Advice for *Xenus cinereus* (Terek sandpiper) (DCCEEW 2024i)	Conservation advice provides management actions that can be undertaken to ensure the conservation of the Terek sandpiper.	*Habitat loss, degradation and fragmentation* Ensure that future development projects avoid any activities that disproportionately affect the upper-tidal flats and/or areas providing major foraging opportunities as identified by species experts, local studies and site managers. *Acute Pollution* *Climate Change* No explicit relevant management actions for climate change or acute pollution.
Approved Conservation Advice for *Pachyptila subantarctica* (Fairy prion (Southern)) (TSSC 2015b)	Conservation advice provides management actions that can be undertaken to ensure the conservation of the Fairy Prion (Southern).	None identified.
Approved Conservation Advice for *Rostratula australis* (Australian Painted Snipe) (DSEWPaC 2013a)	Conservation advice provides management actions that can be undertaken to ensure the conservation of the Australian Painted Snipe.	None identified.
National Recovery Plan for *Rostratula australis* (Australian Painted Snipe) (CoA 2022a)	National recovery plan for actions so species no longer qualifies for listing as threatened under any of the EPBC Act listing criteria.	*Deterioration of water quality / human disturbance* No explicit relevant management actions
Conservation Advice for *Charadrius leschenaultia* (Greater Sand Plover) (TSSC 2016b)	Conservation advice provides management actions that can be undertaken to ensure the conservation of the Greater Sand Plover.	*Habitat degradation/ loss (oil pollution)* No explicit relevant management actions
Conservation Advice *Calidris ferruginea*	Conservation advice provides management actions that can	*Habitat degradation/ loss (oil pollution)*

(Curlew Sandpiper) (DCCEEW 2023f)	be undertaken to ensure the conservation of the Curlew Sandpiper.	No explicit relevant management actions
Approved Conservation Advice for *Calidris canutus* (Red Knot) (DCCEEW 2024m)	Conservation advice provides management actions that can be undertaken to ensure the conservation of the Red Knot.	*Habitat degradation/ loss* No explicit relevant management actions; oil pollutions recognised as a threat. *Climate change* No explicit relevant management actions
National Recovery Plan for the Australasian Bittern (*Botaurus poiciloptilus*) (DCCEEW 2023h).	The recovery plan provides management actions that can be undertaken to ensure the conservation of the Australasian Bittern.	*Reduced water quality as a result of increasing salinity, siltation and pollution* *Climate change* No explicit relevant management actions.
Approved Conservation Advice for *Botaurus poiciloptilus* (Australasian Bittern) (TSSC 2019)	Conservation advice provides management actions that can be undertaken to ensure the conservation of the Australasian Bittern.	Habitat degradation/ loss (pollution) No explicit relevant management actions. Climate change No explicit relevant management actions
National Recovery Plan for Gould's Petrel (*Pterodroma leucoptera leucoptera*) (DEC NSW 2006)	The recovery plan provides management actions that can be undertaken to ensure the conservation of the Gould's Petrel.	None identified.
National Recovery Plan for the Orange-bellied Parrot (*Neophema chrysogaster*) (DELWP 2016)	The recovery plan is a co-ordinated conservation strategy for the Orange-bellied Parrot.	*Barriers to migration and movement* Illuminated boats and structures: Evaluate risk of lighting on vessels and offshore structures. *Climate change* Minimise the impacts of climate change by reducing greenhouse gas concentrations
Conservation advice *Lathamus discolor* Swift Parrot (TSSC 2015f)	Conservation advice provides management actions that can be undertaken to ensure the conservation of the Swift Parrot	None identified.
National Recovery Plan for the Swift Parrot (*Lathamus discolor*) (DCCEEW 2024n)	The recovery plan is a co-ordinated conservation strategy for the Swift parrot.	*Climate change* No explicit relevant management actions
Approved Conservation Advice for the Blue Petrel (*Halobaena caerulea*) (TSSC 2015c)	Conservation advice provides management actions that can be undertaken to ensure the conservation of the Blue petrel	*Habitat loss, disturbance and modification* Continue to manage Macquarie Island and its surrounds in such a way that human disturbance is minimised.
National Recovery Plan for the Australian Grayling (*Prototroctes*	The recovery plan is a co-ordinated conservation strategy for the Australian Grayling.	*Climate Change* No specific management actions in relation to climate change. *Poor water quality*

maraena) (Backhouse et al. 2008)		Manage water quality where Australian Grayling occurs to maintain waters free of significant levels of nutrient, sediment, pesticide and other pollutants, consistent with the ANZECC guidelines for water quality.
Conservation Advice *Prototroctes maraena* Australian Grayling (TSSC 2021)	Conservation advice provides management actions that can be undertaken to ensure the conservation of the Australian Grayling.	*Climate change* No explicit management actions relevant to habitat modification or climate change.
Recovery Plan for the White Shark (*Carcharodon carcharias*) (DSEWPaC 2013c)	The recovery plan is a co-ordinated conservation strategy for the White Shark.	*Habitat modification* *Climate change* No explicit management actions relevant to habitat modification or climate change.
Recovery Plan for Marine Turtles in Australia, 2017-2027 (CoA 2017)	The long-term recovery plan objective for marine turtles is to minimise anthropogenic threats to allow for the conservation status of marine turtles	*Climate change and variability* No specific management actions in relation to climate prescribed in the plan relevant to industry. *Marine debris* Support the implementation of the EPBC Act Threat Abatement Plan for the impacts of marine debris on vertebrate marine life *Chemical and terrestrial discharge* Ensure spill risk strategies and response programs adequately include management for marine turtles and their habitats, particularly in reference to 'slow to recover habitats', e.g. nesting habitat, seagrass meadows or coral reefs *Light pollution* Artificial light within or adjacent to habitat critical to the survival of marine turtles will be managed such that marine turtles are not displaced from these habitats; Identify the cumulative impact on turtles from multiple sources of onshore and offshore light pollution. *Habitat modification* No explicit relevant management actions *Vessel disturbance* No explicit relevant management actions *Noise interference* No explicit relevant management actions
Approved Conservation Advice for *Dermochelys coriacea* (Leatherback Turtle) (DEWHA 2008)	See above for Recovery Plan for Marine Turtles in Australia, 2017-2027.	
Conservation Management Plan for	The long-term recovery plan objective for blue whales is to minimise anthropogenic	*Noise interference* Assess and address anthropogenic noise.

the Blue Whale, 2015-2025 (CoA 2015b)	threats to allow for their conservation status to improve	Anthropogenic noise in biologically important areas will be managed such that any blue whale continues to utilise the area without injury, and is not displaced from a foraging area. *Vessel disturbance* Ensure all vessel strike incidents are reported in the National Ship Strike Database. Ensure the risk of vessel strikes on blue whales is considered when assessing actions that increase vessel traffic in areas where blue whales occur and, if required, appropriate mitigation measures are implemented. *Habitat degradation* (Includes Acute and chronic chemical discharge (Marine pollution)). Maintain and improve existing legal and management protection. *Climate variability and change* Continue to meet Australia's international commitments to reduce greenhouse gas emissions and regulate the krill fishery in Antarctica.
Approved Conservation Advice for *Balaenoptera borealis* (Sei Whale) (TSSC 2015e)	Conservation advice provides threat abatement activities that can be undertaken to ensure the conservation of the sei whale.	*Noise interference* Evaluate risk of noise impacts to cetaceans and, if required, appropriate mitigation measures are implemented. *Vessel disturbance* Minimise vessel collision. Ensure all vessel strike incidents are reported in the National Vessel Strike Database. *Climate variability and change* Continue to meet Australia's international commitments to reduce greenhouse gas emissions and regulate the krill fishery in Antarctica. *Pollution (persistent toxic pollutants)* No explicit relevant management actions; pollution identified as a threat.
Listing Advice *Megaptera novaeangliae* (Humpback Whale) (TSSC 2022)	Listing advice provides threats in the context of the Humpback Whale which has been recovering strongly for at least five decades following intense exploitation during the period of commercial whaling.	*Noise interference* Assess and address anthropogenic noise. *Vessel disturbance and strike* Ensure the risk of vessel strike on humpback whales is considered when assessing actions that increase vessel traffic in areas where humpback whales occur and, if required appropriate mitigation measures are implemented to reduce the risk of vessel strike. Maximise the likelihood that all vessel strike incidents are reported in the National Ship Strike Database. *Climate and oceanographic variability and change*

		Continue to meet Australia's international commitments to reduce greenhouse gas emissions and regulate the krill fishery in Antarctica.
National Recovery Plan for the Southern Right Whale *Eubalaena australis* (DCCEEW 2024o)	The recovery plan is a co-ordinated conservation strategy for the Southern Right Whale.	*Anthropogenic underwater noise* Assess, manage and mitigate impacts from anthropogenic noise *Vessel collision* Manage, minimise and mitigate the threat of vessel strike *Habitat degradation from coastal and offshore development* Address habitat degradation impacts from coastal and offshore marine infrastructure developments
Approved Conservation Advice for *Balaenoptera physalus* (Fin Whale) (TSSC 2015d)	Conservation advice provides threat abatement activities that can be undertaken to ensure the conservation of the fin whale.	*Noise interference* Evaluate risk of noise impacts to cetaceans and, if required, appropriate mitigation measures are implemented. *Vessel disturbance* Minimise vessel collision. Ensure all vessel strike incidents are reported in the National Vessel Strike Database. *Climate variability and change* Continue to meet Australia's international commitments to reduce greenhouse gas emissions and regulate the krill fishery in Antarctica. *Pollution (persistent toxic pollutants)* No explicit relevant management actions; pollution identified as a threat.
Conservation Advice *Neophoca cinerea* Australian sea lion (TSSC 2020x)	Conservation advice provides threat abatement activities that can be undertaken to ensure the conservation of the Australian Sea Lion	*Habitat degradation and pollution – Oil spills* Require all vessels to have oil spill mitigation measures in place, and implement jurisdictional oil spill response strategies as required *Human disturbance – Noise* Monitor and mitigate impacts (including cumulative impacts) of human interactions on Australian Sea Lion colonies
Recovery Plan for the Australian sea lion (*Neophoca cinerea*) (DSEWPaC 2013d)	The plan considers the conservation requirements of the species across its range and identifies the actions to be taken to ensure its long-term viability in nature and the parties that will undertake those actions.	*Habitat degradation* No explicit relevant management actions *Vessel strike* Collect data on direct killings and confirmed vessel strikes *Pollution (oil spills, toxins)* implement jurisdictional oil spill response strategies as required *Climate change* No explicit relevant management actions

2.3.2 Biologically Important Areas

Biologically important areas (BIAs) are spatially defined areas where aggregations of individuals of a species are known to display biologically important behaviour such as breeding, foraging, resting or migration. They are designed to assist decision-making under the EPBC Act.

BIAs have been identified using expert scientific knowledge about species' distribution, abundance and behaviour in the region. The presence of the observed behaviour is assumed to indicate that the habitat required for the behaviour is also present. The selection of species for which BIAs have been identified was informed by the availability of scientific information, the conservation status of listed species and the importance of the region for the species.

The level of certainty attached to a BIA has two dimensions:

- the certainty of the species' occurrence
- the certainty of the behaviour occurring

BIAs that overlap the Project Area are detailed in Section 4.4.9.2.

2.3.3 Australian Marine Parks Management Principles

Under the EPBC Act, Australian Marine Parks (AMPs) are recognised for the purpose of conserving marine habitats and species that live and rely on these habitats. AMPs which are relevant to the Project are detailed in Section 4.2.2. These AMPs are currently managed as per the South-East Commonwealth Marine Reserves Network Management Plan 2013 – 2023 (DNP 2013) and Transitional management arrangements (DNP 2023). The South-east Marine Parks Network Draft Management Plan (DNP 2024) under development and while not currently in force (as of February 2025), has been considered within the assessment.

2.3.4 Other Protected Area Management Plans

The following protected area management plans have been considered during the preparation of this OPP to identify the appropriate management of the activities; in particular these have been considered in the assessment of impacts and risks, the assessment of acceptability, and the development of EPOs:

- South-east Commonwealth Marine Reserves Network Management Plan 2013-2023 (DNP 2013)
- Management Plan for Twelve Apostles Marine National Park and The Arches Marine Sanctuary (Parks Victoria 2006d)
- Management Plan for Point Addis Marine National Park, Point Danger Marine Sanctuary and Eagle Rock Marine Sanctuary (Parks Victoria 2005b)
- Barwon Bluff Marine Sanctuary Management Plan (Parks Victoria 2007b)
- Bunurong Marine National Park Management Plan (Parks Victoria 2006b)
- Cape Liptrap Coastal Park Management Plan (Parks Victoria 2003)
- Great Otway National Park and Otway Forest Park Management Plan (Parks Victoria and DSE 2009)

- Lavinia Ramsar Site Ecological Character Description. Lloyd Environmental (DSEWPaC 2012c)
- Marengo Reefs Marine Sanctuary Management Plan (Parks Victoria 2007a)
- Mornington Peninsula National Park and Arthurs Seat State Park Management Plan (Parks Victoria 2013)
- Mushroom Reef Marine Sanctuary Management Plan (Parks Victoria 2007d)
- Ngootyoong Gunditj Ngootyoong Mara South West Management Plan (Parks Victoria 2015)
- Port Phillip Heads Marine National Park Management Plan (Parks Victoria 2006c)
- Port Campbell National Park and Bay of Islands Coastal Park (Parks Victoria 1998)
- Western Port Ramsar Site Management Plan (DELWP 2017a)
- Western Port Ramsar Wetland Ecological Character Description. (Kellogg et al. 2010 for DSEWPaC)
- Wilsons Promontory Marine National Park and Wilsons Promontory Marine Park Management Plan May 2006 (Parks Victoria 2006a)

2.4 **Commonwealth Legislation**

The Commonwealth Government legislation and international conventions that are relevant to the Project are summarised in Table 2-2.

Of particular relevance to this proposal, specific consideration is given to the:

- Matters of National Environmental Significance - Significant Impact Guidelines 1.1 published by the DoEE (DoE 2013a). These have been used to inform the definition of acceptability of impacts, and are described in further detail in Section 5, and carried into the subsequent evaluation of impacts and risks in Section 6 and 7.

- EPBC Act Policy Statement 'Indirect consequences' of an action: Section 527E of the EPBC Act (Department of Sustainability, Environment, Water, Population and Communities ((DSEWPaC) 2013a). This has been consideration in the specific context of indirect consequences of a proposal with regard to GHG emissions.

2.5 **State Legislation**

Although offshore petroleum activities within the scope of this OPP are located entirely in Commonwealth waters, Victorian and Tasmanian legislation relevant to offshore petroleum activities are described in Table 2-3 and Table 2-4 on the basis that modelling indicates a worst-case credible oil spill Section has the potential to intersect Victorian or Tasmanian waters. Although the worst-case credible oil spill does not extend into South Australian state waters there is still potential for South Australian fisheries to be impact (see Section 4.5.13 and Table 2-5).

2.6 **International Agreements**

Relevant international agreements and conventions that Australia is signatory to are summarised in Table 2-7. These are typically implemented by Commonwealth legislation.

Table 2-2: Relevant Commonwealth Legislation

Legislation/Regulation	Scope	Related International Conventions	Administering Authority
Air Navigation Act 1920 Air Navigation Regulations 1947 Air Navigation (Aircraft Engine Emissions) Regulations 1995 Air Navigation (Aircraft Noise) Regulations 1984	This Act and associated regulations relate to the management of air navigation. **Relevance to Project**: Applies to helicopter activities undertaken during all stages. The requirements under this Act are related to safety, and therefore not relevant to the environmental management of the Project.	Chicago Convention 1947	Department of Infrastructure, Transport, Regional Development, Communications and the Arts
Australian Maritime Safety Authority Act 1990	This Act facilitates international cooperation and mutual assistance in preparing and responding to a major oil spill incident and encourages countries to develop and maintain an adequate capability to deal with oil pollution emergencies. Requirements are affected through Australian Maritime Safety Authority (AMSA) who administers the National Plan for Maritime Environmental Emergencies (NatPlan). **Relevance to Project** AMSA is the designated Control Agency for oil spills from vessels in Commonwealth waters. These arrangements will be detailed in the OPEP associated with the relevant EPs for petroleum activities.	International Convention on Oil Pollution Preparedness, Response and Cooperation 1990 Protocol on Preparedness, Response and Co-operation to Pollution Incidents by Hazardous and Noxious Substances, 2000 International Convention Relating to Intervention on the High Seas in Cases of Oil Pollution Casualties 1969 Articles 198 and 221 of the United Nations Convention on the Law of the Sea 1982	AMSA
Biosecurity Act 2015 Biosecurity Regulations 2016	This Act and associated regulations replaced the Quarantine Act 1908 in 2015 and is the primary legislation for the management of the risk of diseases and pests that may cause harm to human, animal or plant health, the environment and the economy. The objects of this Act are to provide for: (a) managing biosecurity risks; human disease; risks related to ballast water; biosecurity emergencies and human biosecurity emergencies	International Convention for the Control and Management of Ships' Ballast Water and Sediments (adopted in principle in 2004 and in force on 8 September 2017)	Department of Agriculture, Fisheries and Forestry (DAFF)

	(b) to give effect to Australia's international rights and obligations, including under the International Health Regulations, the Sanitary and Phytosanitary Agreement and the Biodiversity Convention **Relevance to Project**: The Biosecurity Act and regulations apply to 'Australian territory' which is the airspace over and the coastal seas out to 12 nm from the coastline. The Act regulates vessels entering Australian territory regarding ballast water and hull fouling. Biosecurity risks associated with the activity are detailed in Section 7.1.		
Environment Protection and Biodiversity Conservation Act 1999 (EPBC Act)	This Act applies to actions that have, will have or are likely to have a significant impact on matters of national environmental or cultural significance. The Act protects matters of national environmental significance (MNES) and provides for a Commonwealth environmental assessment and approval process for actions. There are eight MNES, these being: • World heritage properties • Ramsar wetlands • Listed threatened species and communities • Listed migratory species • Protection of the environment from nuclear actions • Marine environment (Commonwealth) • Great Barrier Reef Marine Park • Protection of water resources from coal seam gas developments and large coal mining developments **Relevance to Project**: Petroleum activities are excluded from within the boundaries of a World Heritage Area (Sub regulation 10A(f)). The Project is not within a World Heritage Area. The OPP must describe matters protected under Part 3 of the EPBC Act and assess any impacts and risks to these.	1992 Convention on Biological Diversity and 1992 Agenda 21 Convention on International Trade in Endangered Species of Wild Fauna and Flora 1973 Agreement between the Government and Australia and the Government of Japan for the Protection of Migratory Birds and Birds in Danger of Extinction and their Environment 1974 Agreement between the Government and Australia and the Government of the People's Republic of China for the Protection of Migratory Birds and their Environment 1986 Agreement between the Government of Australia and the Government of the Republic of Korea on The Protection of Migratory Birds 2006 Convention on Wetlands of International Importance especially as Waterfowl Habitat 1971 (Ramsar)	DCCEEW

	The OPP must assess any actual or potential impacts or risks to MNES from the activity. Section 6 provides an assessment of the impacts and risks from the activity to matters protected under Part 3 of the EPBC Act.	International Convention for the Regulation of Whaling 1946 Convention on the Conservation of Migratory Species of Wild Animals (Bonn Convention) 1979	
Environment Protection (Sea Dumping) Act 1981 Environment Protection (Sea Dumping) Regulations 1983	This Act and associated regulations provide for the protection of the environment by regulating dumping matter into the sea, incineration of waste at sea and placement of artificial reefs. **Relevance to Project**: The Project plans decommissioning to include complete removal of plant and property as a base case, however, in the event equipment cannot be removed or retrieved and remains on the seabed, activities will be undertaken in accordance with the Act.	London Protocol	DCCEEW
Fisheries Management Act 1991	This Act and associated regulations protect Australia's fishery resources and establish responsibilities in ecologically sustainable development. **Relevance to Project**: The Project overlaps several Commonwealth-managed fisheries, described in Section 4.5.10. Impacts and risks to Commonwealth-managed fisheries are assessed in Section 6.1	United Nations Convention on the Law of the Sea (UNCLOS) (1982) Unite Nations Fish Stocks Agreements (UNFSA) (1995) Code of Conduct for Responsible Fisheries (1995)	AFMA DAFF
National Environment Protection Measures (Implementation) Act 1998 National Environment Protection Measures (Implementation) Regulations 1999	This Act and associated regulations provide for the implementation of National Environment Protection Measures (NEPMs) to protect, restore and enhance the quality of the environment in Australia and ensure that the community has access to relevant and meaningful information about pollution. The National Environment Protection Council has made NEPMs relating to ambient air quality, the movement of controlled waste between states and territories, the national pollutant inventory, and used packaging materials. **Relevance to Project**: Activities associated with the Project will meet any relevant requirements of the Act including energy and greenhouse gas reporting.	-	DCCEEW

National Greenhouse and Energy Reporting Act 2007 (NGER Act)	The Act provides for the reporting and dissemination of information related to greenhouse gas emissions (GHG), greenhouse gas projects, energy production and energy consumption, and for other purposes. **Relevance to Project**: GHG emissions and energy use from offshore facilities, vessels and mobile offshore drilling unit (MODU) will be reported in accordance with the requirements of the NGER Act. Applicable requirements are specified as controls to relevant impacts and risks.	-	Clean Energy Regulator
Navigation Act 2012	This Act regulates ship-related activities and invokes certain requirements of the International Convention for the Prevention of Pollution from Ships (MARPOL 73/78) relating to equipment and construction of ships. Several Marine Orders (MO) are enacted under this Act relating to offshore petroleum activities, including: • MO 27: Safety of navigation and radio equipment • MO 30: Prevention of collisions • MO 31: Safety of Life at Sea (SOLAS) and non-SOLAS certification **Relevance to Project**: Vessels (according to class) will adhere to the relevant Marine Orders with regard to navigation and preventing collisions in Commonwealth waters.	Certain sections of MARPOL International Convention for the SOLAS 1974 COLREG 1972	AMSA
Offshore Petroleum and Greenhouse Gas Storage Act 2006 (OPGGS Act)	The OPGGS Act sets out the requirements for maintenance and removal of all property. Under subsection 572(2) of the OPGGS Act, a titleholder must must maintain in good condition and repair all structure, property and equipment within a title area. Under subsection 572(3) of the OPGGS Act, a titleholder must remove from the title area all structures that are, and all equipment and other property that is neither used nor to be used in connection with the operations. Under subsection 270 of the OPGGS Act, before title surrender, all property brought into the surrender area must be removed to the satisfaction of NOPSEMA, or arrangements that are		NOPSEMA / NOPTA

	satisfactory to NOPSEMA must be made relating to the property. **Relevance to Project**: Proponent must comply with maintenance and decommissioning of all property in accordance with the OPPGS Act		
Ozone Protection and Synthetic Greenhouse Gas Management Act 1989 Ozone Protection and Synthetic Greenhouse Gas Management Regulations 1995	This Act and associated regulations provide for measures to protect ozone in the atmosphere by controlling and ultimately reducing the manufacture, import and export of ozone depleting substances (ODS) and synthetic greenhouse gases, and replacing them with suitable alternatives. **Relevance to Project**: The Act will only apply to Beach if it manufactures, imports or exports ODS. Activities undertaken as a part of this project will adhere to the requirements of this Act including restrictions on import and use of ODS (in refrigeration and air conditioning equipment) through control measures in procurement. Applicable requirements are specified as controls to relevant impacts and risks.	Vienna Convention for the Protection of the Ozone Layer, the Montreal Protocol on Substances that Deplete the Ozone Layer, and the United Nations Framework Convention on Climate Change and its Kyoto Protocol	DCCEEW
Protection of the Sea (Harmful Antifouling Systems) Act 2006	Under this Act, it is an offence for a person to engage in negligent conduct that results in a harmful anti-fouling compound being applied to or present on a ship. The Act also provides that Australian ships must hold 'anti-fouling certificates', provided they meet certain criteria. **Relevance to Project**: Vessels will comply with anti-fouling system requirements in accordance with this Act. MO 98: Marine Pollution Prevention – Anti-fouling Systems is enacted under this Act.	International Convention on the Control of Harmful Anti-fouling Systems on Ships 2001	AMSA
Protection of the Sea (Prevention of Pollution from Ships) Act 1983 Protection of the Sea (Prevention of Pollution from Ships) (Orders) Regulations 1994	This Act and associated regulations regulate Australian regulated vessels with respect to ship-related operational activities and invokes certain requirements of the MARPOL Convention relating to discharge of noxious liquid substances, sewage, garbage, air pollution etc. **Relevance to Project**: Vessels are required to abide to the requirements under this Act.	Various parts of MARPOL	AMSA

	Several MOs are enacted under this Act relating to the Project activities, including: • MO 91: Marine Pollution Prevention – Oil • MO 93: Marine Pollution Prevention – Noxious Liquid Substances • MO 94: Marine Pollution Prevention – Packaged Harmful Substances • MO 95: Marine Pollution Prevention – Garbage • MO 96: Marine Pollution Prevention – Sewage • MO 97: Marine Pollution Prevention – Air Pollution		
Underwater Cultural Heritage Act 2018	This Act protects the heritage values of shipwrecks, sunken aircraft and relics (older than 75 years) including submerged Aboriginal archaeological sites [**PC321**] in Australian Territorial waters from the low water mark to the outer edge of the continental shelf (excluding the State's internal waterways). The Act allows for protection through the designation of protection zones. Activities / conduct prohibited within each zone will be specified. **Relevance to Project**: In the event of removal, damage or interference to shipwrecks, sunken aircraft or relics declared to be historic under the legislation, activity is proposed with declared protection zones, or there is the discovery of shipwrecks or relics. Section 4.2.5 identifies no known shipwrecks or sunken aircrafts in the Project Area.	Agreement between the Netherlands and Australia concerning old Dutch Shipwrecks 1972	DCCEEW

Table 2-3: Relevant Victorian Legislation

Legislation/Regulation	**Scope**	**Application to Activity**	**Administering Authority**
Environment Protection Act 2017 (& Environmental Protection Regulations 2021)	This is the key Victorian legislation which controls discharges and emissions (air, water) to the environment within Victoria (including state and territorial waters). It gives the Environment Protection Authority (EPA) powers to licence	Oil pollution management in Victorian State waters	Environment Protection Authority (EPA)

	premises discharges to the marine environment, control marine discharges and to undertake prosecutions. Provides for the maintenance and, where necessary, restoration of appropriate environmental quality.		
	The State Environment Protection Policy (Waters of Victoria) designates: • Spill response responsibilities by Victorian Authorities to be undertaken in the event of spills (DJPR) with EPA enforcement consistent with the *Environment Protection Act 2017* and the *Pollution of Waters by Oil & Noxious Substances Act 1986*. • Requires vessels not to discharge to surface waters sewage, oil, garbage, sediment, litter or other wastes which pose an environmental risk to surface water beneficial uses. To protect Victorian State waters from marine pests introduced via domestic ballast water, ballast water management arrangements applying to all ships in State and territorial waters must be observed as per the Environment Protection (Ships' Ballast Water) Regulations 2006, Waste Management Policy (Ships' Ballast Water) and the Protocol for Environmental Management. High risk domestic ballast water (ballast water which leachates from an Australian port or within the territorial sea of Australia (to 12 nm)), regardless of the source, must not be discharged into Victorian State waters. Ship masters must undertake a ballast water risk assessment on a voyage by voyage basis to assess risk level, provide accurate and comprehensive information to the EPA on the status and risk of ballast water contained on their ships (i.e. domestic/international), and to manage domestic ballast water discharges with EPA written approval.	Discharge of domestic ballast water from emergency response vessels into Victorian State waters must comply with these requirements.	
Emergency Management Act 2013	Provides for the establishment of governance arrangements for emergency management in Victoria, including the Office of the Emergency Management Commissioner and an Inspector-General for Emergency Management.	Emergency response structure for managing emergency incidents within Victorian State waters. Emergency management structure will be	Department of Justice and Community Safety (Inspector General for Emergency Management)

	Provides for integrated and comprehensive prevention, response and recovery planning, involving preparedness, operational co-ordination and community participation, in relation to all hazards. These arrangements are outlined in the Emergency Management Manual Victoria.	triggered in the event of a spill impacting or potentially impacting State waters.	
Fisheries Act 1995 (& Regulations 2019)	The purpose of this Act is to provide legislative framework for the regulation, management and conservation of Victorian fisheries including aquatic habitats.	The Project overlaps Victorian commercial fisheries and may overlap areas where recreational fishing occurs, as described in Section 4.5.11. Impacts and risks to fishing are assessed in Section 6.1.	Victorian Fisheries Authority (VFA)
Flora and Fauna Guarantee Act 1988 (FFG Act) (& Regulations 2020)	The purpose of this Act is to protect rare and threatened species; and enable and promote the conservation of Victoria's native flora and fauna and to provide for a choice of procedures that can be used for the conservation, management or control of flora and fauna and the management of potentially threatening processes. Where a species has been listed as threatened an Action statement is prepared setting out the actions that have or need to be taken to conserve and manage the species and community.	Action Statement controls for threatened species present in the zone of potential impact as adopted (as relevant) within this OPP. Triggered if an incident results in the injury or death of an FFG Act listed species (e.g. collision with a whale).	Victoria Department of Energy, Environment and Climate Action (DEECA)
Heritage Act 2017	The purpose of the Act is to provide for the protection and conservation of historic places, objects, shipwrecks and archaeological sites in state areas and waters (complementary legislation to Commonwealth legislation). Part 4 Underwater cultural heritage of the Act is focused on historic shipwrecks, which are defined as the remains of all ships that have been situated in Victorian State waters for 75 years or more. The Act addresses, among other things, the registration of wrecks, establishment of protected zones, and the prohibition of certain activities in relation to historic shipwrecks.	May be triggered in the event of impacts to a known or previously un-located shipwreck in Victorian State waters whilst undertaking emergency response activities.	Heritage Victoria Department of Transport and Planning

Marine Safety Act 2010 (& Regulations 2023)	Act provides for safe marine operations in Victoria, including imposing safety duties on owners, managers and designers of vessels, marine infrastructure and marine safety equipment; marine safety workers, masters and passengers on vessels; regulation and management of vessel use and navigation in Victorian State waters; and enforcement provisions of Police Officers and the Victorian Director of Transport Safety. This Act reflects the requirements of international conventions - Convention on the International Regulations for Preventing Collisions at Sea & International Convention for the Safety of Life at Sea. The Act also defines marine incidents and the reporting of such incidents to the Victorian Director of Transport Safety.	Applies to vessel masters, owners, crew operating vessels in Victorian State waters.	Maritime Safety Victoria
National Parks Act 1975	Established a number of different types of reserve areas onshore and offshore, including Marine National Parks and Marine Sanctuaries. A lease, licence or permit under the OPGGS Act 2010 that is either wholly or partly over land in a marine national park or marine sanctuary is subject to the *National Parks Act 1975* and activities within these areas require Ministerial consent before activities are carried out.	Applies where there are activities within marine reserve areas.	DEECA
Pollution of Waters by Oil and Noxious Substances Act 1986 (POWBONS) (& Regulations 2022)	The purpose of the Pollution of Waters by Oils and Noxious Substances Act 1986 (POWBONS) is to protect the sea and other waters from pollution by oil and noxious substances. This Act also implements the MARPOL Convention (the International Convention for the Prevention of Pollution from Ships 1973) in Victorian State waters. Requires mandatory Reporting of marine pollution incidents. Act restricts within Victorian State waters the discharge of treated oily bilge water according to vessel classification (>400 tonnes); discharge of cargo substances or mixtures; prohibition of garbage disposal and packaged harmful substances; restrictions on the discharge of sewage; regulator reporting requirements for incidents; ship construction certificates and survey requirements. Restriction on discharges within Victorian State waters incorporated into EP.	Triggered in the event of a spill impacting or potentially impacting State waters.	Jointly administered by DECCA and EPA

Wildlife Act 1975 (& Regulations 2024)	The purpose of this Act is to promote the protection and conservation of wildlife. Prevents wildlife from becoming extinct and prohibits and regulates persons authorised to engage in activities relating to wildlife (including incidents). The Wildlife (Marine Mammal) Regulations 2019 prescribe minimum distances to whales and seals/seal colonies, restrictions on feeding/touching and restriction of noise within a caution zone of a marine mammal (dolphins (150m), whales (300m) and seals (50m).	Applies where vessels are within State waters responding to a spill event. Prescribed minimum proximity distances to whales, dolphins and seals will be maintained. Triggered if an incident results in the injury or death of whales, dolphins or seals.	DECCA
Aboriginal Heritage Act 2006 [**PC320**]	The primary purpose of the Act is to provide for the protection of Aboriginal cultural heritage in Victoria.	Applies to underwater cultural heritage in Victorian State waters	First Peoples – State Relations (Department of Premier and Cabinet)

Table 2-4: Relevant Tasmanian Legislation

Legislation/Regulation	Scope	Application to Activity	Administering Authority
Environmental Management and Pollution Control Act 1994 (EMPCA) (& Regulations)	EMPCA is the primary environment protection and pollution control legislation in Tasmania. It is a performance-based style of legislation, with the fundamental basis being the prevention, reduction and remediation of environmental harm. The clear focus of the Act is on preventing environmental harm from pollution and waste. Relevant regulations under the EMPCA include: • Environmental Management and Pollution Control (General) Regulations 2017 • Environmental Management and Pollution Control (Waste Management) Regulations 2010 The EPA Division Compliance Policy provides the Director of the Environment Protection Authority (EPA) powers of compliance.	Defines the EPA's jurisdiction during a spill event. Prescribes the fee structure to waste events and environmental protection notices. Regulates the management and control of controlled wastes.	EPA Tasmania - Department of Natural Resources and Environment (NRE)
Living Marine Resources Management Act 1995 (& Regulations)	The Act promotes the sustainable management of living marine resources to provide for management plans relating to fish resources and protect marine habitats.	The Project overlaps Tasmanian commercial fisheries and may overlap areas where recreational fishing occurs, as described in Section 4.5.12. Impacts and risks to fishing are assessed in Section 6.1.	NRE (Tasmania) Wild Fisheries Management Branch – Fishing Tasmania
Marine-related Incidents (MARPOL Implementation) Act 2020	Pollution of the sea in Tasmanian State waters may be regulated by general pollution laws such as the EMPCA (see above), but the deals specifically with discharges of oil and other pollutants from ships. It gives effect in Tasmania to the MARPOL international convention on marine pollution	Gives effect to MARPOL in Tasmanian waters.	NRE (Tasmania)
Threatened Species Protection Act 1995	Provide for the protection and management of threatened native flora and fauna and to enable and promote the conservation of native flora and fauna.	Identification of species that are also protected under Tasmanian legislation.	NRE (Tasmania)
Aboriginal Heritage Act 1975 (Tas) [**PC168, PC169**]	The Act defines Aboriginal heritage and how that heritage must be managed and protected	Applies to underwater cultural heritage in Tasmanian State waters	Department of Premier and Cabinet

Table 2-5: Relevant South Australian Legislation

Legislation/Regulation	Scope	Application to Activity	Administering Authority
Fisheries Management Act 2007 *(& Regulations)*	The Act provides for the conservation and management of the aquatic resources of the State, the management of fisheries and aquatic reserves, the regulation of fishing and the processing of aquatic resources and the control of exotic aquatic organisms and disease in aquatic resources, and for other purposes.	The Project overlaps South Australian commercial fisheries areas, as described in Section 4.5.13. Impacts and risks to fishing are assessed in Section 6.1.	Department of Primary Industries and Regions (South Australia)

Table 2-6: Relevant New South Wales Legislation

Legislation/Regulation	Scope	Application to Activity	Administering Authority
Aboriginal Land Rights Act 1983	An Act to make provisions with respect to the land rights of Aboriginal persons, including provisions for or with respect to the constitution of Aboriginal Land Councils, the vesting of land in those Councils, the acquisition of land by or for those Councils and the allocations of funds to and by those Councils; to amend certain other Acts; and to make provisions for certain other purposes.	There is the potential for aboriginal heritage and Registered Aboriginal Land Councils within the Planning Areas.	
Heritage Act 1977	Act provides for the identification, registration and interim protection of items of State heritage significance (including shipwrecks within state waters) in NSW.	Applies where an oil spill or oil spill response activities may pose a risk to items of State heritage significance.	Heritage Council of NSW
Marine Estate Management Act 2014	To provide for the management of the marine estate of New South Wales consistent with the principles of ecologically sustainable development	Applies where an oil spill or oil spill response activities may pose a risk to NSW marine parks.	NSW Department of Primary Industries
Marine Pollution Act 2012	This Act is the NSW state legislation giving effect to the requirements of MARPOL 73/78 within state waters. The Act provides the power to respond to oil and chemicals listed within MARPOL.	Applies to oil spill response in NSW waters. Provides the portfolio Minister with powers of intervention in regard to the detention or direction of commercial and trading vessels and for preventing, combating, and cleaning up of oil and chemical spills in State waters.	Transport for NSW
National Parks and Wildlife Act 1974	This Act provides for the care, control and management of all national parks, historic sites, nature reserves, conservation reserves, Aboriginal areas and game reserves, and the protection and care of native flora and fauna, and Aboriginal places and objects.	Applies where oil spill poses a risk to NSW National parks, historic sites, nature reserves, conservation reserves, Aboriginal areas and game reserves, and the protection and care of native flora and fauna protected under the Act.	NSW National Parks and Wildlife Service (NPWS)
Protection of the Environment Operations Act 1997	The object of the Act is to achieve the protection, restoration, and enhancement of the quality of the NSW environment.	Applies where oil spill poses a risk to NSW waters or lands.	NSW Environmental Protection Authority

Table 2-7: Relevant International Agreements and Conventions

Agreement / Convention	Summary	Relevance to the Project
Convention on the Conservation of Migratory Species of Wild Animals 1979 (the Bonn Convention)	This convention aims to conserve migratory fauna species throughout their ranges, particularly where their range crosses international jurisdictional boundaries. It is implemented in Commonwealth law by the EPBC Act, which makes provision for species listed under the Bonn Convention to be listed as migratory under the EPBC Act. Species listed as migratory under the EPBC Act are MNES.	Several species listed as migratory under the EPBC Act were identified as potentially being impacted by the petroleum activities considered in this OPP. Refer to Section 4.4.9.
The Agreement on the Conservation of Albatrosses and Petrels (ACAP)	ACAP through its 13 Parties strives to conserve albatrosses and petrels by coordinating international activities to mitigate threats to their populations.	Several albatross and petrel species were identified as potentially being impacted by the petroleum activities considered in this OPP. Section Refer to Section 4.4.9.
Agreement between the Government of Australia and the Government of Japan for the Protection of Migratory Birds in Danger of Extinction and their Environment 1974 (JAMBA)	This agreement aims to conserve migratory bird species that travel between Japan and Australia. This includes many species of shorebirds that use the East Asian - Australasian Flyway. It is implemented in Commonwealth law by the EPBC Act, which makes provision for species listed under JAMBA to be listed as migratory under the EPBC Act. Species listed as migratory under the EPBC Act are MNES.	Several birds listed as migratory under the EPBC Act were identified as potentially being impacted by the petroleum activities considered in this OPP. Section Refer to Section 4.4.9.
Agreement between the Government of Australia and the Government of the People's Republic of China for the Protection of Migratory Birds and their Environment 1986 (CAMBA)	This agreement aims to conserve migratory bird species that travel between China and Australia. This includes many species of shorebirds that use the East Asian - Australasian Flyway. It is implemented in Commonwealth law by the EPBC Act, which makes provision for species listed under CAMBA to be listed as migratory under the EPBC Act. Species listed as migratory under the EPBC Act are MNES.	Several birds listed as migratory under the EPBC Act were identified as potentially being impacted by the petroleum activities considered in this OPP. Refer to Section 4.4.9.
Agreement between the Government of Australia and the Government of the Republic of Korea for the Protection of Migratory Birds and their Environment 2007 (ROKAMBA)	This agreement aims to conserve migratory bird species that travel between the Republic of Korea and Australia. This includes many species of shorebirds that use the East Asian - Australasian Flyway. It is implemented in Commonwealth law by the EPBC Act, which makes provision for species listed under ROKAMBA to be listed as migratory under the EPBC Act. Species listed as migratory under the EPBC Act are MNES.	Several birds listed as migratory under the EPBC Act were identified as potentially being impacted by the petroleum activities considered in this OPP. Refer to Section Refer to Section 4.4.9.
International Convention on Wetlands of International Importance 1975 (Ramsar)	This convention aims to conserve and promote the sustainable human use of wetlands. Many wetlands have been identified as important habitat for migratory bird species, and Ramsar wetlands are of importance in	The Lavinia Ramsar wetland was identified as potentially being impacted in the event of an unplanned release of large volumes of

	conserving many species of migratory shorebirds and waders. Ramsar wetlands are protected under the EPBC Act and are MNES.	hydrocarbons (e.g. loss of well control). Refer to Section 7.4.4.
London Convention on the Prevention of Marine Pollution by Dumping of Wastes and Other Matter 1972 (London Convention)	This convention is an agreement to control pollution of the sea by intentional disposal at sea of potentially harmful materials. It is implemented under Commonwealth law by the *Environment Protection (Sea Dumping) Act 1981*.	Chemical inventories onboard vessels and MODUs may potentially breach this convention if unpermitted via this OPP and deliberately discharged to the sea.
Minamata Convention on Mercury 2017	This convention is an agreement to protect human and environmental health from the effects of releases of mercury and mercury-containing compounds to the environment. The convention is not yet ratified by Australia, and hence is not currently implemented in Commonwealth law. Australia has signed the convention and is currently undertaking an assessment process prior to ratification.	Drilling activities may result in mercury compounds being produced from wells as a by-product. Mercury may pose a risk to the environment if not managed appropriately.
International Convention for the Prevention of Pollution from Ships, 1973 as modified by the Protocol of 1978 (commonly known as MARPOL 73/78)	This convention is an agreement to minimise the pollution of the marine environment by ships. The convention provides a standardised approach to the environmental management of international and domestic shipping. The convention is implemented in Commonwealth law by the *Protection of the Sea (Prevention of Pollution from Ships) Act 1983* and a series of Marine Orders made under this Act.	All marine support vessels are required to comply with MARPOL.
International Convention on Standards of Training, Certification and Watch keeping for Seafarers 1978 (STCW)	This convention provides a standardised approach to the qualifications and competencies of masters, officers and watch personnel. It is implemented in Commonwealth law by the *Navigation Act 2012* and a series of Marine Orders made under this Act.	All project vessels and crew are required to comply with STCW.
International Convention for the Safety of Life at Sea 1974 (SOLAS)	This convention provides internationally agreed minimum standards for the construction, equipment and operation of vessels. It is implemented in Commonwealth law by the *Navigation Act 2012* and a series of Marine Orders made under this Act.	All project vessels are required to comply with SOLAS.
International Regulations for Preventing Collisions at Sea 1972 (COLREGS)	These regulations provide internationally agreed rules for the navigation of vessels, which are intended to reduce the likelihood of vessel collisions. COLREGS are implemented in Commonwealth law by the *Navigation Act 2012* and a series of Marine Orders made under this Act.	All project vessels are required to comply with COLREGS.
Paris Agreement on Climate Change (2015)	The Paris Agreement is an instrument made under the UNFCCC, with the central aim of strengthening the global response to the threat of climate change by keeping the global temperature rise this century well below 2 degrees Celsius above pre-industrial levels and to pursue efforts to limit	The Paris Agreement provides the international framework and context around Australia's NDC, which is important to

	the temperature increase even further to 1.5 degrees Celsius in order to prevent dangerous human caused interference with the climate system. It deals with GHG emissions mitigation, adaptation, and finance. The agreement's language was negotiated by representatives of 196 state parties, including Australia, and adopted by consensus on 12 December 2015, before entering in to force in late 2016. Australia has since ratified the Paris Agreement. The Paris Agreement requires each party to: volunteer its own Nationally Determined Contributions (NDCs), to report against them annually, and improve them if it is determined that the collective commitment to NDCs is considered ineffective or insufficient to keep global temperature increases to less than 2ºC below pre-industrial levels. This allows for variation in emissions reduction performance according to the development status of the country; and determine, plan, and regularly report on the contribution that it undertakes to mitigate global warming. No mechanism forces a country to set a specific emissions target by a specific date, but each target should go beyond previously set targets. The Intergovernmental Panel on Climate Change (IPCC) released a report in October 2018 on the 1.5 degrees Celsius target; it concluded that global emissions need to reach net zero around mid-century to give a reasonable chance of limiting warming to 1.5 degrees Celsius.	establishing the defined acceptable level of GHG emissions from the Otway Project.

3 Description of the Project and Alternatives Analysis

3.1 Overview

The purpose of this section is to provide a description of the key project stages and the Project activities for the development of new discoveries at Artisan and La Bella and development of future discoveries in surrounding petroleum permits identified by initial and future drilling campaigns.

3.2 Project Concept and Design

A key feature of the Project is the use of existing production assets to develop surrounding gas discoveries. The development of the Thylacine and Geographe gas fields was approved under Part 9 of the Environment Protection and Biodiversity Act (EPBC Decision No. 2002/621). Development of the gas fields commenced in 2004 by Woodside Petroleum Ltd under a joint venture arrangement, with first production in mid-2007. Since this date, additional wells have been drilled at the Geographe location (VIC/L23) and the Thylacine location (T/L2) to maintain supply. A further exploration well was drilled in 2021 at the Artisan location (VIC/P43), which was cased and suspended as a potential future producer.

Natural gas is produced from Thylacine gas fields via a combination of subsea wells and Thylacine offshore production platform, while Geographe field is produced via subsea wells and infrastructure. Gas from Geographe and Thylacine fields is transport by the OGPP to the OGP. Currently, production from these fields is in natural decline with end of field life expected by 2038.

The current project provides an opportunity for Artisan, La Bella and surrounding fields to be developed through existing infrastructure. The concept therefore relies on existing pipeline and production operations at Thylacine platform with the following concepts:

- Suspending successful wells with two verified barriers and installation of completions and Christmas Tree (Tree)
- Subsea tie-back of wells to existing OGPP via hot tap tee assembly, Geographe tee or via the connection point at the base of the Thylacine platform
- Control of all new wells via extension of the existing electro-hydraulic (EH) control system linked to the Thylacine Platform and the OGP.

Beach is undertaking concept engineering to support the subsea developments. The subsea development will be optimised for recovery of gas from potentially multiple fields via new subsea installation and tie-back to existing OGPP (via hot tap tee assemblies and Geographe tee) or Thylacine A platform. The development concepts may require some brownfield modifications to existing production infrastructure at the hot tap tee (HTT) assembly, Geographe tee, Thylacine platform and the OGP.

The Project is designed to accommodate future tie back opportunities identified via future drilling campaigns, with the infrastructure to support these developments is likely to be similar to that required for the initial development. Any future development will be undertaken in accordance with the environmental legislative requirements in force at that time.

As described in this section, an objective of the OGV Project is to development new gas fields in VIC/P43 and VIC/P73 via existing Otway infrastructure, with production volumes therefore considered backfill to the existing production and ullage at OGP.

Production from existing fields (Thylacine, Geographe, Halladale-Black Watch–Speculant (HBWS), and Enterprise Fields) is processed at OGP, with the maximum production rate 205 TJ/day (i.e. nameplate capacity of the plant).

Forecast production from existing fields is naturally declining and expected end of economic field life (2P) is currently forecast for 2037. In an exploration success scenario, the combined production from development and exploration projects is forecast to reach facility nameplate capacity of 205 TJ/d and extend the end of field life from 2037 to 2045.

Production volumes are published in Beach's annual reserves report (June 2024) and are represented by 2P reserves of 357 PJ and 2C resources (La Bella and Artisan) of 92 PJ (Gross). As the drilling campaign includes exploration targets, the estimate of prospective resources has not been unpublished at the time of the OPP assessment.

The key characteristics of the Project are summarised inTable 3-1.

Table 3-1: Key Project Activities

	Description
Project Area	The Project Area is defined in Section 3.5
Key Project Stages	• Surveys (geotechnical and geophysical) • Drilling and completions • Installation and Commissioning • Operations and maintenance • Decommissioning
Proposed Wells	Up to 8 wells are anticipated to be drilled and completed (in success case) and one re-entered and completed as part of the initial drilling campaign. In summary: In summary, activities covered in this OPP include: • Re-entry and completion of Artisan 1 (VIC/P43) • Drilling and completion of La Bella 2 (VIC/P73) • Maximum of 5 additional wells in VIC/P43 expected to be within approximately 10 km of Artisan or hot tap tee locations Maximum of 2 additional wells in VIC/P73 expected to be within approximately 10 km of La Bella or HTT locations.
Subsea infrastructure	Installation of subsea infrastructure to connect gas discoveries (Artisan 1 and La Bella 2) and future connections of successful wells (from above drilling & completion campaigns) to the OGPP, Thylacine platform or including wellheads, flowlines, umbilicals, manifolds and skids

3.3 **Project Schedule**

Beach is planning an exploration and appraisal drilling and completions campaign commencing in 2025, installation of new subsea facilities commencing in 2028 with the earliest achievable date for commissioning and first gas in 2028 subject to corporate, joint venture and regulatory approvals. An indicative early project schedule is provided in **Error! Reference source not found.**.

Table 3-2: Project Schedule Summary

Project Stage	Indicative Timing (as of October 2024)
Exploration & Appraisal Drilling Campaign	Commencing Q2 2025
Well completion & Subsea Tree installation	Commencing Q4 2025
Installation of Subsea Infrastructure	Earliest commencement Q1-Q2 2028
Commissioning & RFSU	Earliest commencement Q2-Q3 2028
Future drilling and tie-backs	Within operating life of the Project
End of Field Life	2045
Decommissioning (wells and subsea infrastructure)	Decommissioning will be managed in compliance with Sections 572(3) and 270(3) of the OPGGS Act: (unless alternative arrangements are accepted)

3.3.1 Drilling and Completions Campaign

An OPP is needed for most new offshore petroleum development projects in Commonwealth waters. An 'offshore project' is defined in the OPGGS (Environment) Regulations as 'one or more activities that are undertaken for the purpose of the recovery of petroleum…".

As described in section 1.5.1 of the OPP, section 15 of Environment Regulations allows a proponent to use the OPP arrangements for exploration and appraisal activities. While an OPP must be accepted by NOPSEMA before the proponent can submit EPs for activities that make up an offshore project, this pre-requisite does not apply to exploration and appraisal activities such as exploratory drilling. As such, Beach has submitted an EP to NOPSEMA for the exploration and appraisal drilling activities.

The initial exploration and appraisal drilling campaign described in this OPP is part of the OGV Drilling and P&A Activities EP. Activities in the EP include exploration drilling and depending on well results, either P&A or temporary well suspensions **[PC302, PC309, PC194]**.

For the exploration and appraisal drilling and completion campaign, Beach is part of a consortium with other operators who are planning drilling and completions activities in the Otway Basin using a semi-submersible mobile offshore drilling unit (MODU). The commencement of the campaign is dependent upon the release of the MODU by another operator in north-west Australia and the and the sequencing of activities agreed by all the operators within the consortium. At this stage, the drilling campaign is likely to commence in Q2 of 2025 and well completions campaign is likely to commence in Q4 of 2025 to Q1 of 2026.

It is Beach's intention to undertake drilling activities at the beginning of the campaign and complete successful wells near the end of the campaign. This approach is consistent with Beach's "drill-to-keep" exploration and development strategy. thereby reducing the environmental impact associated with multiple MODU campaigns to develop individual offshore gas fields.

A decision to P&A or suspend an exploration or appraisal well will be made and carried out before the MODU is released from the well. Where the well is suspended, a subsequent decision to P&A or complete the well will be made and carried out as a follow-up activity before the MODU is released from the consortium. The MODU contract provides sufficient flexibility to achieve this objective.

In the event that the MODU is unable to undertake the follow up activity before being released from the consortium (or if the MODU becomes otherwise unavailable for any reason), and subsequent to that, the well becomes redundant, Beach commits to the timeframes for decommissioning of redundant wells as set out in NOPSEMA's Decommissioning Compliance Strategy 2024-2029. The design concept for the Project relies on existing Otway production assets to develop surrounding gas discoveries (refer section 3.2), therefore wells and infrastructure are considered part of the Otway production system categorised in NOPSEMA's Decommissioning Compliance Strategy 2024-2029. Redundant wells within a producing asset or production system must be P&A as soon as practicable:

- If a rig is contracted to undertake infill drilling or workovers within a field, it is NOPSEMA's expectation that suspended wells within the field are abandoned.
- Wells that have been suspended within a larger active production system, must be abandoned no later than 10 years from when it was suspended.

3.3.2 Development Activities

For the purpose of this OPP, the completion of exploration or appraisal wells with a subsea tree for future production is an activity which is undertaken for the purpose of the recovery of petroleum. Other activities that are planned for the purpose of the recovery of petroleum in this OPP include installation, operation and maintenance of subsea wells, flowlines and infrastructure [**PC302, PC309].**

Following acceptance of the OPP (expected in early 2025), Beach plans to submit EPs for the development activities, including well completions and suspension with a subsea tree, installation of subsea flowlines and infrastructure and operating of the subsea production.

The schedule for the Project (Table 3-2) assumes an approximate two-to-three-year period between well completions and subsea tree installation, and the subsequent construction of tie-ins and gas production. The preference for construction of subsea infrastructure (flowlines, umbilicals, manifolds, etc) is during summer months corresponding with Q1 to Q2 of 2028.

In the interim, wells will be regularly inspected in line with Beach's Well Integrity Standard and the accepted Well Lifecycle Management Plan (Corporate Management Systems, CDN/ID 19060820) documenting Beach's OEMS Standards for well life cycle management.

Further, as set out in Beach's accepted Well Lifecycle Management Plan (CDN/ID 19060820), if a decision is made to not proceed with development of a suspended or completed well (i.e. – connection for future production), such that the well becomes redundant, Beach will comply with section 270 of the OPGGSA for the permanent plug and abandonment of wells and acknowledges and commits to the timeframes for well decommissioning as set out in NOPSEMA's Decommissioning Compliance Strategy 2024-2029, specifically, redundant wells within Beach's Otway production asset well be P&A as soon as practicable:

- If a rig is contracted to undertake infill drilling or workovers within a field, it is NOPSEMA's expectation that suspended wells within the field are abandoned.

- Wells that have been suspended within a larger active production system, must be abandoned no later than 10 years from when it was suspended.

3.3.3 Future Drilling and Tie-backs

Future drilling programs and related tie backs to existing infrastructure will be developed based on the outcomes of the current exploration program.

3.3.4 Decommissioning

Decommissioning of wells and infrastructure installed as part of this Project will occur when it is no longer used (unless alternative arrangements are accepted) in accordance with sections 572(3) and 270 of the OPGGS Act.

3.3.5 Concurrent Activities

The Project is currently in the planning stage where there is uncertainty with regards to scheduling details for specific Project activities including the potential for concurrent and sequential activities. Activities such as the exploration and appraisal drilling and well completion are planned to commence in 2025 and subsea tree installation is likely to commence in 2028 (see Table 3-2). At this stage, activities are likely to be sequential, however, for the purpose of this OPP and credible concurrent activities, the installation of subsea infrastructure stage, and the future drilling and tie-backs stage may occur concurrently. The concurrent activities scenario from these stages is pipelay or diving/tie-in activities (10 to 20 days) may occur concurrently during MODU positioning (9 to 13 days) activities (which may be propulsion system or towed by vessels – see section 3.8.2). This scenario has the potential for up to five vessels operating in the Project Area at any one time. This scenario is considered the worst-case credible concurrent activities. Concurrent activities will be kept to a minimum and are unlikely to occur for more than 13 days.

Decommissioning of wells is expected to be performed progressively sequentially depending on existing well design and integrity, casing cement quality, and well condition and production status. The final P&A program for each well will be included in the WOMP which must be accepted by NOPSEMA prior to commencement of activity.

3.4 **Project Location**

The Project Area is located in the Otway Basin in offshore Commonwealth waters, approximately 17 km south of the Victorian mainland and 86 km west of Tasmania (King island) at its closest points in water depths ranging from 63 m to 160 m. The nearest regional centre of Geelong is approximately 140 km to the north east.

The Project Area is described in Section 3.5.

The locations of key existing and proposed initial development infrastructure are presented in Figure 1-1 and Figure 3-1.

3.5 **Project Area**

The Project Area (Figure 1-1and Figure 3-1) is within Commonwealth waters and is where all infrastructure and activities associated with the Project will be undertaken.

The Project Area is defined as a single combined area extending north and south of the existing Thylacine platform.

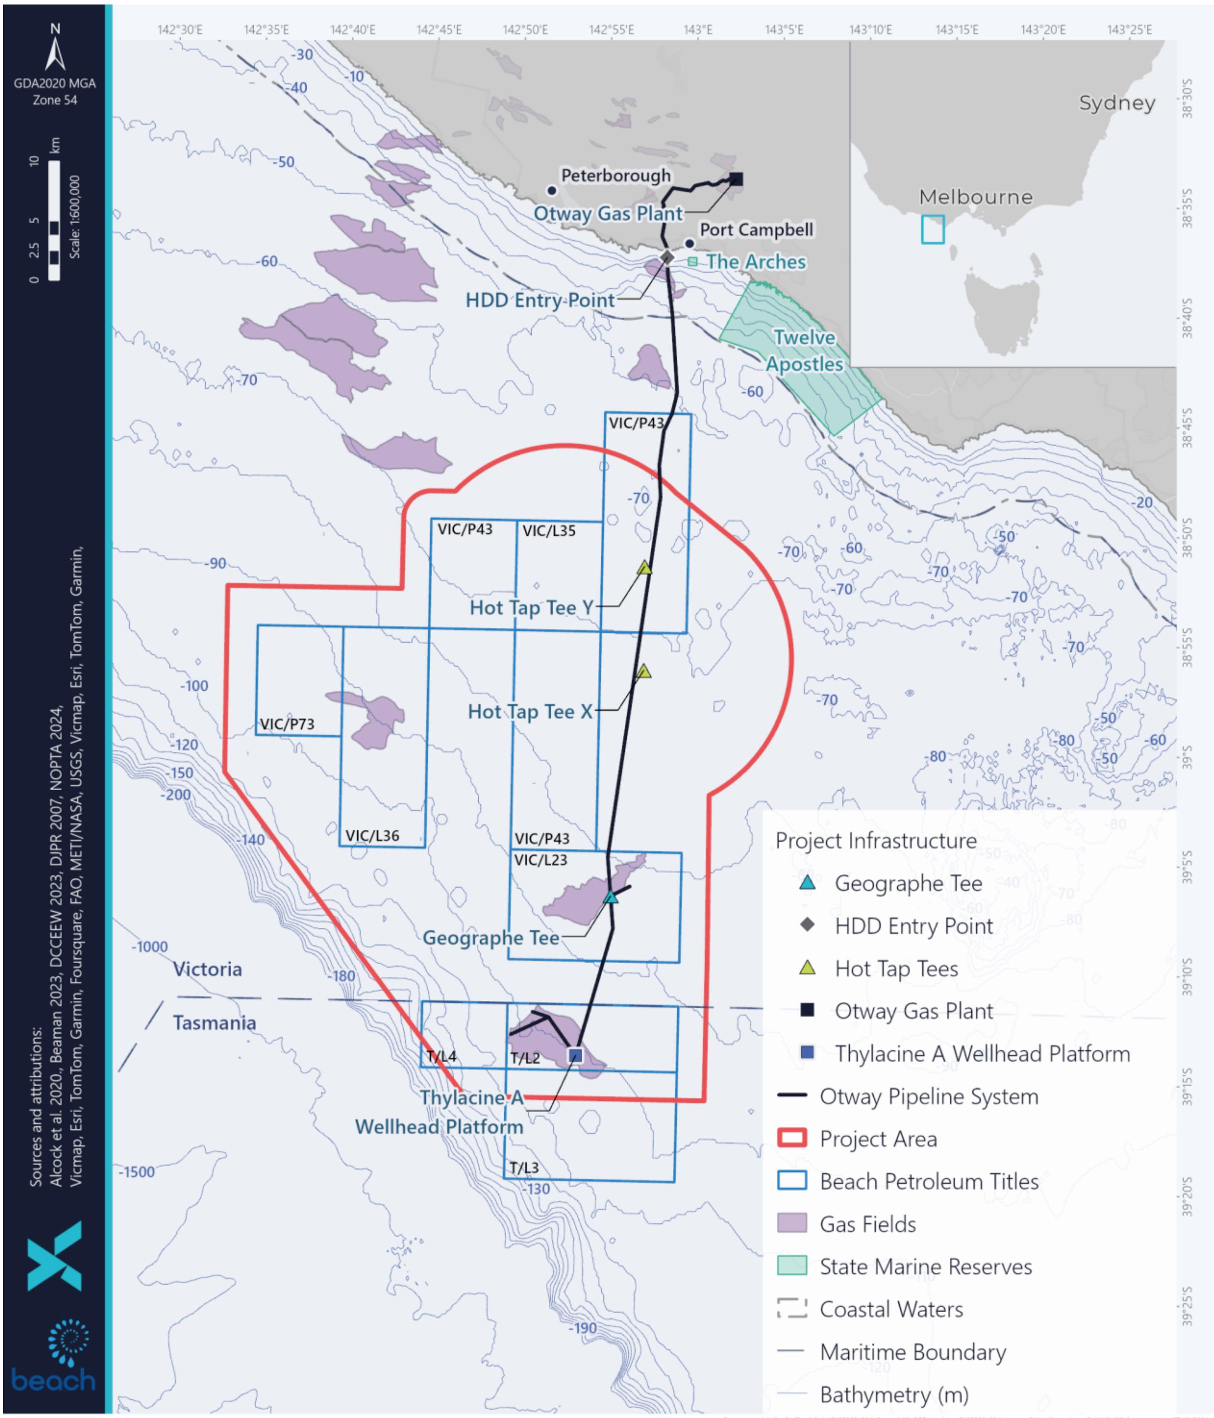
The Project Area located north of the Thylacine A platform includes the locations of gas discoveries (Artisan and La Bella) and exploration prospects within approximately 10 km of these discoveries and pipeline tie in points with the likely corridors (with buffer) for subsea connections.

Beach has taken a conservative approach and defined a Project Area (Figure 3-1) with buffer extents applied to inform the basis of the impact and risk assessment and provide flexibility to account for the early design phase and potential future developments.

The Project Area has been designed to not include the deeper waters off the continental shelf. In addition, since the Project has been refined it does not overlap any environmentally important features with the closest being the West Tasmanian Canyons Key Ecological Feature (KEF) situated approximately 9 km away.

The Project Area will accommodate a MODU for drilling and well completion activities and movement of all vessels around the offshore facilities during installation, commissioning, decommissioning and operations. Transit of vessels to and from the offshore locations is excluded from this OPP as this is outside the scope of the OPGGS Act and is regulated by maritime legislation, including the Commonwealth *Navigation Act 2012*.

Onshore support facilities required during construction, commissioning and operation will be located in existing ports. It is expected that the Project will utilise the onshore supply base facilities (Geelong and Portland) that are currently used to service Beach's existing Otway Basin operations.



Document details: G:\CheckOuts\P100383_S04\Output\02_OPP_Updates\P100383_S04_A.aprx, 01_WellLocations, P-UWS-132, brenna.waite, 27/10/2024

Figure 3-1: Project Area

3.6 **Hydrocarbon Composition**

The reservoir targets are gas within the Turonian Waarre Formation. Liquid condensate will form within the gas stream as temperature and pressure decrease when the gas is brought to the surface. The initial condensate gas ratio is expected to be up to 16 barrels per million standard cubic feet of gas.

Compositions for Thylacine, Artisan and La Bella gas are provided in Table 3-3 and Figure 3-2. Thylacine and La Bella are similar compositions, with Artisan having lower CO_2, higher methane and fewer heavy ends (lower condensate yield). These gas compositions are considered suitable analogues for all potential new fields within the Project Area.

Section 7.4.3.2 describes in further detail why Thylacine condensate is used as a suitable analogue for quantitative spill modelling.

Table 3-3: Gas Composition

Composition (mol%)	**Thylacine**	**Artisan**	**La Bella**
H_2S	0.00	0.00	0.00
CO_2	9.29	1.63	13.30
N_2	1.38	1.63	2.90

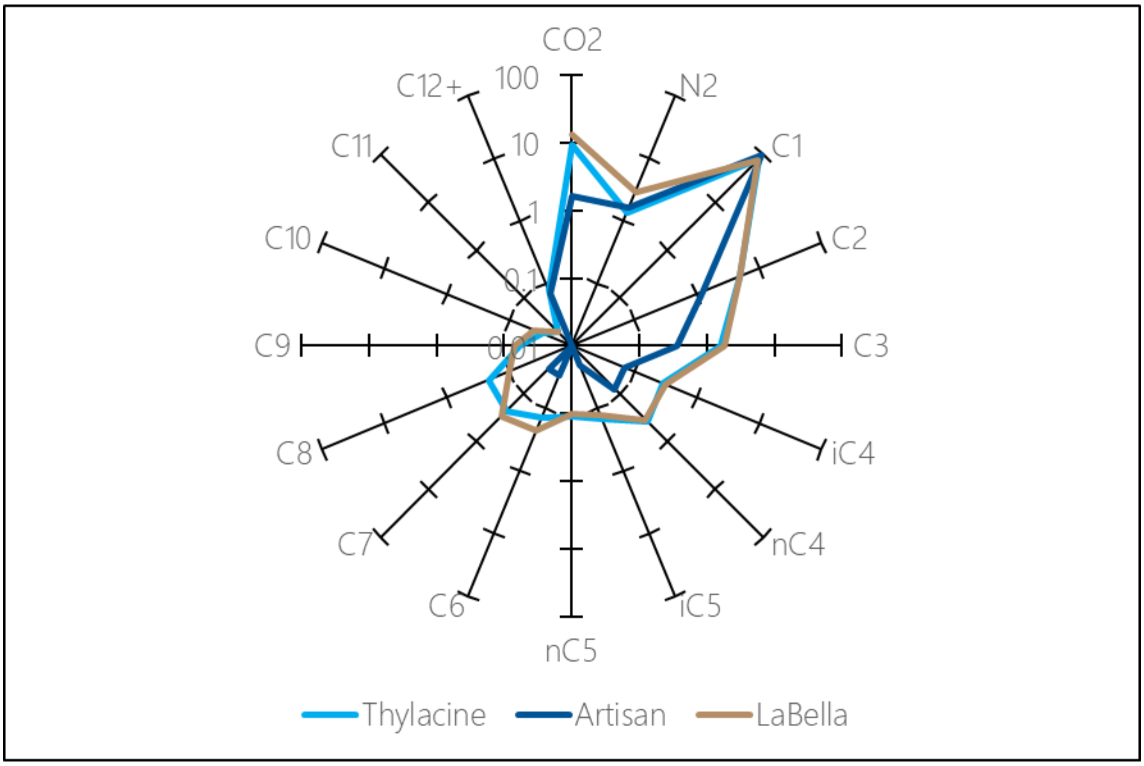

Figure 3-2: Gas Composition

3.7 **Project Infrastructure**

3.7.1 Existing Infrastructure

A key feature of the Project is the use of existing infrastructure to develop surrounding gas discoveries. A schematic of the key existing Otway Development infrastructure shown in Figure 3-3 and includes:

- Thylacine A Platform - a normally unmanned installation wellhead platform with four production wells
- Four subsea Thylacine wells, flowlines and infrastructure tied back to Thylacine A platform
- Geographe subsea facilities – subsea wells connected by flexible flowline directly into the OGPP with control and services provided via an umbilical from Thylacine A Platform and Monoethylene glycol (MEG) supplied directly from the MEG Service Line via an in-field umbilical.
- OGPP system:
  - Offshore section of DN500 raw gas pipeline from Thylacine A Platform (Platform) to the onshore OGP and a DN100 MEG Service Line supplying MEG and chemicals from the OGP for injection into the OGPP and Thylacine subsea flowlines.
  - The OGPP design for the Thylacine Otway development included two pre-installed hot tap tee (HTT) assemblies (HTT 'X' and HTT 'Y') to allow for future development of additional fields in the Otway Basin. There is also the potential to extend the Geographe infrastructure, which has additional capacity in relation to tie-in to the Subsea Valve Structure (SVS) and Tee, which sits adjacent to the OGPP.

Figure 3-3: Schematic Diagram of Existing Otway Infrastructure

3.7.2 Planned Infrastructure

The key infrastructure components of the Project are subsea and include wells, trees, flowlines, umbilicals, manifolds and skid structures.

3.7.2.1 Wells

Up to 8 wells are anticipated to be drilled and completed (in success case) and one re-entered and completed as part of the initial campaign. In summary the initial campaign includes:

- Re-entry and completion of Artisan 1 (VIC/P43)
- Drilling and completion of La Bella 2 (VIC/P73)
- Maximum of 5 additional wells in VIC/P43 (expected to be within approximately 10 km of Artisan or HTT locations)
- Maximum of 2 additional wells in VIC/P73 (expected to be within approximately 10 km of La Bella or HTT locations

Successful wells will have a wellhead, which provides means for hanging the production well casing and installing the subsea Christmas tree (or 'tree') and well control facilities. The tree enables reservoir fluids to flow from the well to the flowlines. It is also used to manage chemical injection and control production. The tree consists of a series of hydraulically operated valves, spools and instrumentation that are used to control and manage the production flow from a well and provide well shut-off mechanism. The tree includes a subsea control module (SCM). The SCM receives hydraulic and electrical signals from the topside facility and communicates this to a specific tree function. The hydraulic system operates with low pressure (LP), high pressure (HP) and chemical injection capabilities.

Trees are typically designed with open loop hydraulic systems with actuation fluid which will vent to sea via the SCM. Included in the system are accumulators which are mounted on the tree frame which are used to supply and open actuators fitted to each hydraulic valve (fail safe closed type). The hydraulic fluid used to fill the actuator open side (to compress a spring) will be vented to sea when it is closed.

3.7.2.2 Subsea System

The Artisan and La Bella gas discoveries and any successful wells from the initial and future drilling campaigns will be connected to the existing infrastructure by flowlines, umbilicals, manifolds and skid structures.

Beach is undertaking concept engineering to support the subsea developments and a base case and alternatives have been identified. Several options exist to tie-back new gas fields to the existing Thylacine and Geographe infrastructure including HTT X and Y on the OGPP, Geographe Tee and at the base of the Thylacine A platform.

A schematic of the base case for the subsea infrastructure of the Artisan tie-back is shown in Figure 3-4 and is representative of the La Bella and potential future tie-backs north of the Thylacine platform in the area of permits VIC/P43 and VIC/P73. The Artisan and La Bella flowline and umbilical routes are still in the early design stage with final routes to be confirmed within future EPs.

Flowlines will transport production fluids (gas and condensate) from the wellheads and manifolds to the pipeline or platform. This includes flowline end terminations to connect the flowline to other infrastructure.

Umbilicals will transfer power, electric and communication signals, hydraulic fluids and chemicals (such as MEG) to the wellheads. The umbilicals will connect to other infrastructure via umbilical termination assemblies.

Flowlines or umbilicals will not be trenched and may either be rigid or flexible. Localised placement of stabilisation material may be required to assure stability, primarily adjacent to well and structure tie-in locations.

Additional in-field subsea structures such as manifolds, skids, and distribution units will connect flowlines and umbilicals together and to the pipeline or platform tie-in points.

The total extent of seabed footprint required for the installation of seabed infrastructure for the initial development is estimated at approximately 74.95 km^2. This includes stabilisation support at tie in points if required. This total area is subject to refinement during the design process and drilling campaign outcomes however it represents a conservative approach of each potential exploration and appraisal well being tied back.

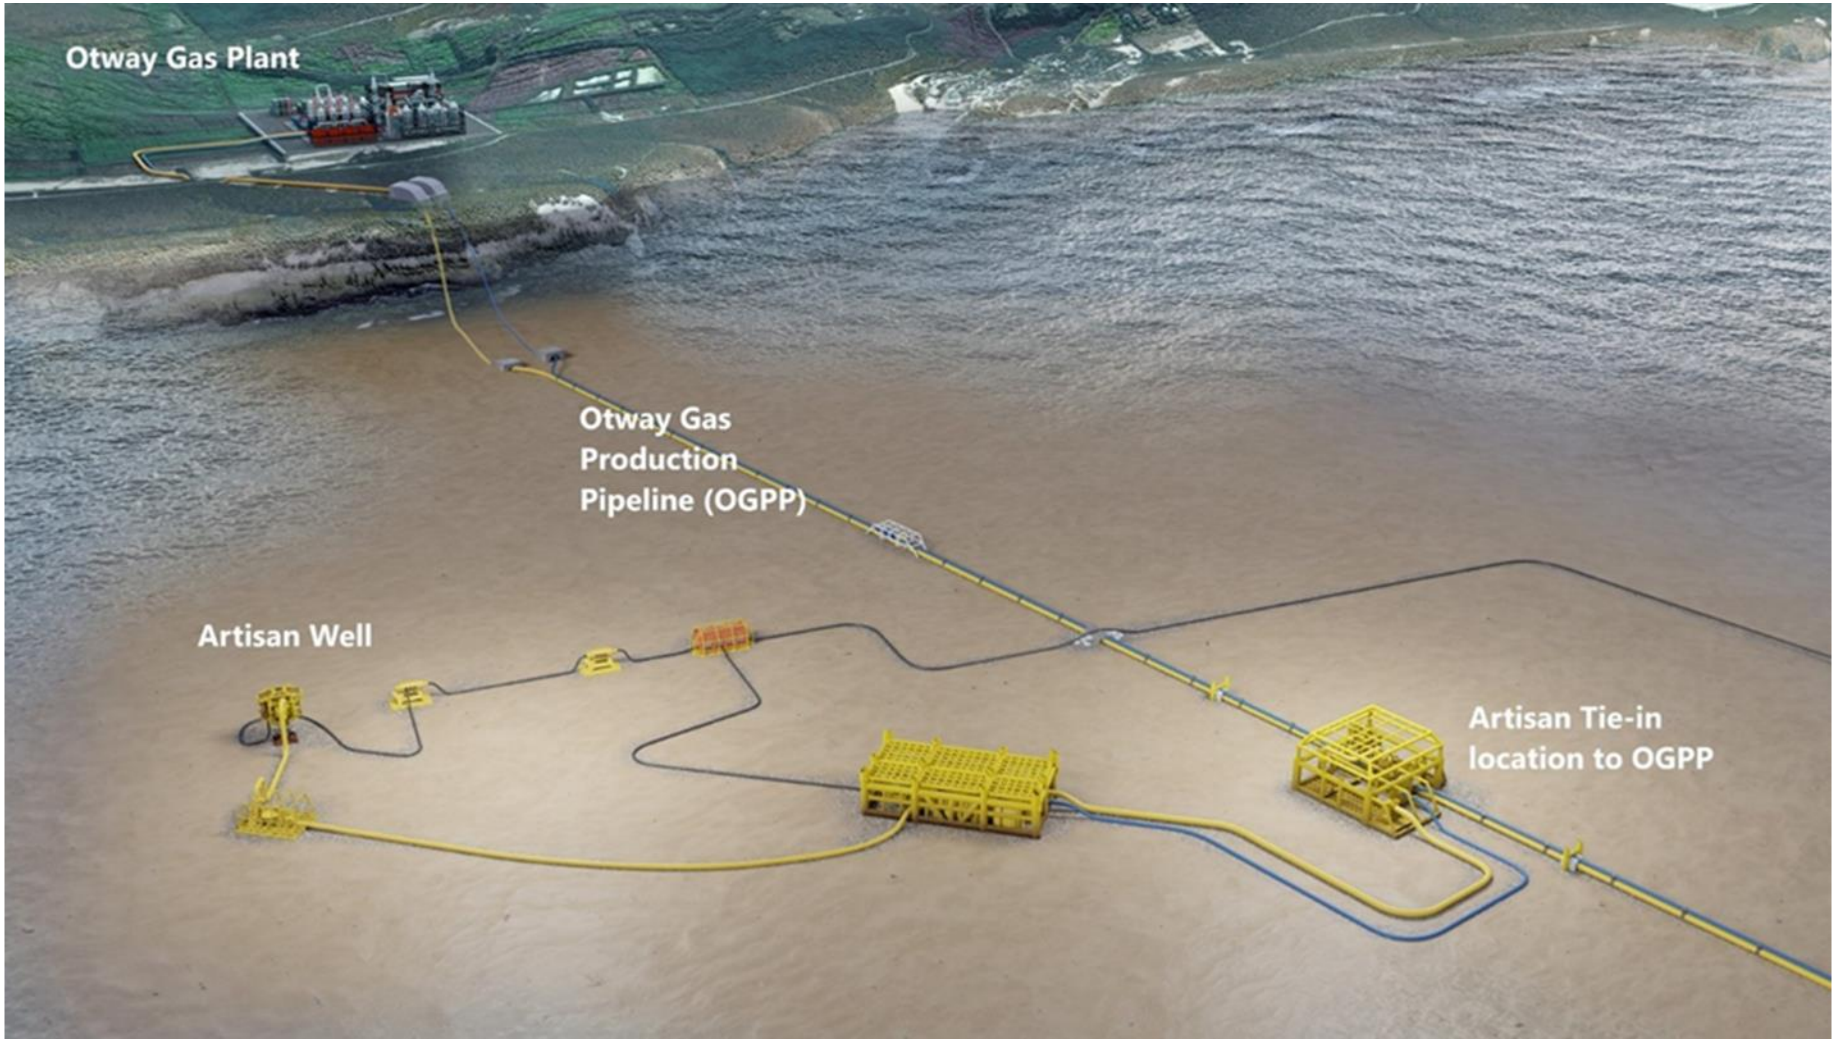

Figure 3-4: Schematic Diagram of Proposed Artisan Tie-back

3.8 **Description of Activities**

Activities associated with the Project are summarised in the sections below and are considered a base case of activities.

3.8.1 Surveys

Geotechnical and geophysical surveys may be required to assess the suitability of the seabed for drilling, infrastructure installation (including along the length of proposed flowline) and umbilical routes.

As detailed in the approved OGV Geophysical and Geotechnical Seabed Survey Environment Plan (Document Reference: V-1000-P1-MP-0011), surveys may be conducted over a total of approximately 200 days.

3.8.1.1 Geotechnical Survey

Geotechnical surveys may include techniques that involve using high-frequency sonar to provide high-resolution bathymetry and geophysical data, such as side-scan sonar, sub bottom profiler or multibeam echo sounder. Sonar generates high-frequency acoustic emissions that attenuate rapidly in the underwater environment. These geophysical surveys would be expected to take 10-20 days [PC236] to complete, depending on the length of the subsea system flowline routes.

Geotechnical surveys typically involve in-situ testing and piston/push sampling and coring. Following sampling, all equipment is withdrawn from the seabed. A small hole (<1 m^2) will remain, which will eventually collapse and infill with the movement of surface sediments in ocean current.

3.8.1.2 Geophysical Survey

Specific noise modelling from geophysical survey equipment was carried out to inform the risk assessment. The acoustic emissions will decrease rapidly due to the relatively high frequency of the acoustic emissions, with received sound levels estimated to be reduced to 160 dB re 1 µPa within 150 m.

3.8.2 MODU Positioning

A MODU will either mobilise to the required Project Area with its own propulsion system or be towed by vessels and anchored or connected to pre-laid anchors prior to commencing activities. Anchors may be pre-laid on the sea floor typically 1 month prior to the MODU arriving at the location.

The MODU will be moored with 8 or 12 anchors, with weight ranging from 15 to 30 MT each, resulting in an individual footprint of up to approximately 60 m^2 . A mooring analysis will be undertaken to determine specific mooring requirements for each well location. The mooring analysis will incorporate the results from the geophysical and geotechnical survey obtained prior to MODU mobilisation and which is subject to a separate EP (Offshore Gas Victoria Geophysical and Geotechnical Seabed Survey Environment Plan CDN/ID V-1000-P1-MP-0011).

Anchors are attached to the MODU by a chain or chain / wire system. The anchors will be positioned at approximately 2 km (ranging from 1.5 km – 2.1 km) from the MODU. The MODU is equipped with a thruster assisted mooring system to mitigate mooring fatigue in heavy sea states / poor weather conditions.

Transponders may be required to inform anchor positioning. The transponders for mooring are called ADAPS (Anchor Distance and Positioning) – they can be acoustically interrogated for GPS position and anchor orientation. They are affixed to the anchor so are deployed and recovered in the same timeframes as the anchor installation.

Each pre-laid anchor consists of:

- Anchor covering an area ~60 m^2
- Anchor chain including swivels and shackles. Typically, the anchor chain consists of 84–120 mm links. Approximately 1,000-1,200 m of chain is laid on the seabed with a pennant wire in the water column attached to a surface buoy. This equates to approximately 360 m^2 footprint per anchor based on the chain being approximately 300 mm wide.
- Surface buoy with a navigation light.

The pre-lay of anchors at the well locations is likely to take 9 to 13 days.

The total footprint for each anchor and chain will be less than 200 m^2. However, co-located wells sharing a common drill centre may use the same anchors with the MODU moving across to the new well location.

An array of long baseline and/or ultra-short baseline transponders for metrology and positioning may be installed on the seabed, within a radius of 500 m from the well locations. This positioning system is only expected to be used on selected wells and only if required.

Transponders, if used, will be moored to the seabed by a clump weight. Clump weights are typically made of cement or steel with a footprint of ~0.2 m^2. On completion of the positioning operation, transponders and associated equipment will be removed.

3.8.3 Drilling Method

The initial drilling campaign wells are planned to be drilled vertically. The wells will be drilled to depths of approximately between 2,000 m and 3,500 m beneath the seabed to intersect the reservoirs. Drilling is expected to be in the order of approximately 30 to 40 days duration for each well.

While not currently planned, where there is high inclination wells or wells with extended reach requirements in the future, these wells may require directional drilling to depths of up to approximately 4,500 m beneath the seabed. Drilling of these wells is expected to be in the order of approximately 30 to 40 days duration for each well.

The drilling process will use standard offshore drilling methods with the wells drilled in sections which decrease in diameter at increasing depths until the target reservoir is reached. Protective steel casing, supported by the wellhead, is inserted into the wells and cemented into place to isolate each section from subsequent sections and provide structural support and stability to the well.

In the process of drilling, drilling fluids (also known as drilling muds) will be used to lubricate and cool the drill bit, maintain well bore stability, and remove drill cuttings (rock fragments) from the well sections as they are drilled.

It is envisaged that water-based drilling fluid (WBDF) will be appropriate to drill and complete the wells within the Project Area, and that up to approximately 1,500 m^3 of WBDF per well will be discharged to the marine environment.

Synthetic based drilling fluids (SBDF) may be required in the future for high inclination wells or wells with extended reach requirements. In the unlikely scenario that SBDF is required, the potential discharge volumes will be minimised and be up to approximately 100 m^3. There will be no bulk discharge, with all SBDF remaining at the end of the well either being reused on the next well, passed onto the next operator or returned to the vendor for reprocessing or appropriate disposal. Management of SBDF if required will be detailed in the relevant activity specific Environment Plans.

Table 3-4 presents the types of drilling fluids and their typical components proposed to be used for the different sections of each well.

Drilling fluids and cuttings will be discharged at the seabed during drilling of the upper well sections as is standard industry practice due to the wellhead not yet being installed. The drilling fluids and cuttings from the lower sections will be circulated to the MODU, with fluids separated for recycling and cuttings discharged overboard. It is expected that up to approximately 600 m^3 of drill cuttings per well will be discharged.

Cementing of the casing may result in the release of small amounts of cement (up to approximately 50 m^3 per well) when the cement mixture is circulated to the seabed during grouting or when surplus fluids require disposal after cementing operations.

Table 3-4: Drilling Fluid Types and Typical Components (Indicative Based on Standard Otway Basin Well Design)

Well Selection Diameter (inches)	Drilling Fluid Type and Typical Main Components
36	Seawater and prehydrated gel sweeps (i.e. seawater to which high viscosity prehydrated bentonite has been added).
26	
17.5	WBFD - drilling fluids in which seawater is the major component of the liquid phase and to which bentonite clay, barite, brine and/or gellants (such as guar gum or xanthum gum) have been added
12.25	
8.5	
Future wells depending on well profile (intermediate and/or production hole sections)	SBDF - drilling fluids in which synthetic oil is the base fluid with bentonite clay, barite, fluid-loss control agents, lime, aqueous chloride, bridging agents and emulsifiers added

3.8.3.1 Blow-out Preventor Installation and Function Testing

After completion of the top-hole sections, a blow out preventer (BOP) is installed onto the wellhead. The BOP consists of a series of hydraulically operated valves and sealing mechanisms (annular preventers, ram preventers and blind shear rams) that are used to close in the well should a loss of well control situation arise. The annular preventers and ram preventers are used to shut in around various tubulars and regaining hydrostatic overbalance using the MODU's high pressure circulating system. The blind shear rams are designed to shear the pipe and seal the well.

Once the BOP is installed, function and pressure tests are undertaken in accordance with industry standards and the drilling contractor's maintenance system. Function testing involves activating the hydraulic control system aboard the MODU and is generally undertaken every seven days. Pressure testing is undertaken to verify seals on the BOP stack and is undertaken every 21-days. The tests discharges approximately 2 m^3 of control fluid to the marine environment. This fluid is water-soluble and readily disperses in the receiving waters after discharge from the BOP.

3.8.3.2 Formation Evaluation

During drilling, the formation may be evaluated to determine the presence and quantity of hydrocarbon within the target reservoir. This information is gathered real-time from 'logging while drilling' techniques or by running wireline tools into the well.

'Logging while drilling' and wireline logging involve the use of downhole instruments such as sonic and resistivity sensors, low-level radioactive sources, magnetic resonance imaging, coring, and formation pressure/sampling tools.

There are no planned emissions or discharges during formation evaluation. All instruments are deployed directly down hole with no exposure to the marine environment.

3.8.3.3 Vertical Seismic Profiling

While vertical seismic profiling (VSP) is not expected to be required for the initial drilling campaign, VSP may be performed at some stage in the Project, such as during future drilling campaigns within the in-field development area. VSP may also be performed on a targeted basis during operations. The use of VSP in these instances will be through deployment of a single small sound source from the MODU or vessel in the water column while receivers are positioned at specific depths downhole within the well.

VSP provides a seismic image of the geology in the immediate vicinity of the well, and typically takes approximately eight to 24 hours per well. Beach Energy expects a maximum of 2 VSP events.

VSP noise is not continuous. Each discharge of the seismic source generates a short, discrete, low frequency sound impulse. Seismic impulses during VSP are typically much lower than those generated during typical marine seismic surveys .

3.8.4 Completions

Well completion is the process of preparing a drilled well for production, either immediately following drilling or via re-entry into an existing suspended well. It involves:

- Installation of the sand face completion, typically a production liner or sand screen across the producing reservoir interval
- Wellbore cleanup where the drilling fluid is displaced from the well and replaced with a filtered completion fluid, typically brine
- Evaluation of the cement bond for barrier and/or zonal isolation confirmation
- Perforation of cemented production casing or liner with explosive charges to create communication from the reservoir into the wellbore

- Installation of the upper completion consisting of the production tubing, tubing hanger, surface-controlled subsurface safety valve (SSSV) and production packer, and may also include installation of downhole monitoring capability and flow control equipment
- Installation of a production tree (an assembly of valves, spools, and fittings used to regulate hydrocarbon flow within a well) on the existing wellhead.

In the case of a new well the completion would be performed by the MODU immediately after drilling operations have concluded. A well re-entry operation would require the mobilisation of MODU to the existing well and removal of downhole barriers prior to commencing completion operations.

A re-entry operation may also entail a drilling element to either deepen or sidetrack the well to access undamaged or alternative reservoir targets or increase the reservoir interval available to production.

Well completion is expected to take in the order of approximately 30 to 40 days duration for each well.

Discharge of completion fluids may occur as part of wellbore clean-up during completions. During the clean-up process, the completion fluids (consisting of completion brine and any formation water or condensate present in the wellbore) are circulated back to the MODU for treatment prior to discharge. Discharge may also include any excess completion brine remaining in the MODU tank system discharged to sea as per standard operating procedures.

If there is the potential for hydrocarbons to be present, the completion fluids will be tested and discharged only if the oil in water content is below 30 ppm. Any fluid not meeting this criterion will be stored in tanks onboard the MODU for later onshore disposal.

Well cleanup is performed after the well has been completed and is the process of removing well construction fluid from the well and bringing reservoir fluid (oil, condensate and/or gas) to surface. The objective of this activity is to remove well construction fluid from the well, and if necessary, undertake production testing to evaluate the reservoir potential and understand reservoir fluid properties.

The well construction fluid is typically a mixture of completion fluid (completion brine and any formation water or condensate present in the wellbore) and underbalance/low density fluid (base oil, diesel or nitrogen), remnants of drilling mud and loss-circulation materials. Depending on the formation and well construction process there could also be solids such as formation and perforating debris. As the well construction fluid exits the well, reservoir fluid becomes more prominent in the flow stream consisting of hydrocarbons and native groundwater present in the formation.

In the case of well unloading being undertaken on the MODU, the various flow stream mediums are separated (gas, oil, water) with the flammable components sent to the flare and burnt off. The non-flammable components, including any produced formation water or completion brine, will be discharged to the marine environment via the well test water filtration treatment package or stored in tanks and disposed onshore.

Unloading of well construction fluid to the MODU would be performed up to ~65 MMscf of gas per day being flared for up to 48 hours depending on the well geometry and objectives of the unload and testing. Gas is flowed to the flare via a dedicated gas line whilst high efficiency burners will be used that minimise the risk of fallout to ocean and enhance smokeless combustion of liquids.

In the case of a rig-based unloading operation undertaken on the MODU, the various flow stream mediums are separated (gas, oil, water) and either burnt off via a flare boom or stored in tanks for treatment prior to disposal overboard or onshore. Well testing may be undertaken for up to 48 hours depending on the well geometry, the objectives of the clean-up and the test operation.

Unloading a well of well construction fluid to the MODU would be performed at up to approximately 65MMscf of gas per day being flared for between one and two days per well. Gas is flowed to flare via a dedicated gas line whilst high efficiency burners will be used that minimise the risk of fallout to ocean and enhance smokeless combustion of liquids.

The majority of fluids returned from the wellbore and formation are flammable and will be sent to the flare and burnt off. Non-flammable fluids, including any produced formation water or completion brine initially present in the wellbore, will be discharged to the marine environment via the well test water filtration treatment package.

In some operations, there may be applications it is necessary to bleed off formation fluids (gas) direct to atmosphere. This can be performed by the MODU degasser (mud gas separator) or in some situations a dedicated “bleed off package” may be required. In such instances, gas is cold vented rather than flared. This may be required during abandonment and intervention operations when gas which is present in the wellbore needs to be removed, such as when performing a leak off test on a downhole device (barrier) or when displacing gas to fluid to perform a well re-entry, intervention or abandonment operation. Cold venting is considered an appropriate method of reservoir gas emission in instances when the gas volume and the rate of emission is typically significantly lower than which would be burnt at flare during a well unload and test.

Total discharge volume of completion fluids from well completion, unloading and testing will be up to approximately 300 m^3. Approximately 100 bbls (16 m^3) of produced water may be generated and discharged per well as part of this total volume, which will be treated to reduce the oil in water content to below 30 ppm oil in water content prior to overboard discharge. Fluid not meeting this criterion will be stored in tanks for later onshore disposal. This low volume of 16 m^3 is due to the low formation water content in formation gas.

3.8.4.1 Disposal of Bulk Powders

Beach participates in the bulk transfer working group appointed by the Drilling Industry Steering Committee (DISC) to assess the options for removing excess dry bulk products from the MODU at the end activities. Beach is committed to continuing to explore safe, feasible options that result in overall environmental benefit to manage the excess bulk including bringing the excess bentonite, barite, and cement that is not used at the end of the campaign back to shore for disposal. Beach will follow Australian industry practice at the time the bulk needs to be managed, with environmental assessment to be performed to supplement the decision.

3.8.5 Facilities Installation and Commissioning

3.8.5.1 Installation

Subsea infrastructure will be transported to site and installed by Installation Support Vessels (ISVs) equipped with remotely operated vehicles (ROVs). A dedicated pipelay vessel or multipurpose service vessel may be required for long flowlines or umbilicals.

Diving may be required for limited activities such as tie-in to the existing OGPP hot tap tee assemblies, which are equipped with diver connections only. Such activities will be undertaken from a dive support vessel using saturation diving.

Flowlines and umbilicals will be laid directly onto the seabed within defined corridors, with no trenching required, and will be designed to be inherently stable. Localised placement of stabilisation mattresses, gravity weights, or small rock anchor structures may be required to assure stability adjacent to well and structure tie-in locations. Generally, stabilisation mattress are used for the flowlines, while gravity weights or anchor piles are used for OGPP and the hot tap tee locations to mitigate the lateral movement of these structures. Stabilisation mattresses and gravity weights are lowered over the flowline from a vessel and typically cover an area of 18 m^2. Rock anchor structures are generally installed by divers using a small installation frame. Once installed, the rock anchor sits above the flowline and has minimal impact on the seafloor. The combined footprint is included in the total disturbance footprint of 74.95 km^2.

Depending on the scope and length of the flowlines and umbilicals, the installation could take in the order of approximately between 10 to 20 days duration per well tieback.

3.8.5.2 Commissioning

It is anticipated that the majority of the commissioning activities will take place onshore, with only limited commissioning activities occurring within the Project Area.

Once installation is complete, subsea infrastructure will be integrity tested by hydrotesting from the vessel to verify system leak integrity before the vessel leaves the field. Flowlines are filled with hydrotest fluid (including MEG) and subjected to test pressures that will meet design code requirements, typically significantly above any pressures likely during operation.

The hydrotest fluid will comprise filtered seawater with MEG, corrosion inhibitor, oxygen scavenger and biocide additives. The chemical additives are required to avoid metal corrosion, prevent bacterial growth and the accumulation of scale on internal surfaces. The hydrotest fluid volume is typically 120% of the flowline volume, with the longest flowline for the Artisan and La Bella tie back base case being ~23 km. These fluids will either be flowed back to the Otway Gas Plant for processing through existing facilities or discharged to the marine environment.

3.8.6 Operations

Activities associated with production operations include:

- Hydrocarbon extraction and export;
- Inspection, maintenance and repair; and
- Well intervention.

3.8.6.1 Hydrocarbon Extraction and Export

Reservoir fluids will flow via the subsea infrastructure to the existing OGPP for export to OGP. Control of the subsea system is via the umbilical(s) which transport electrical power, hydraulic fluids and chemicals to the required subsea locations.

The hydraulic fluid used is typically glycol-based (distinct from MEG used as a hydrate inhibitor) and used to actuate subsea valves. The system is open so there will be a small volume released each time the valve is actuated. Based on the existing Otway Development, it is estimated about 4 m^3 per year will be discharged to the marine environment.

Chemicals used for injection into the wells include hydrate inhibitor (likely MEG or methanol) and scale inhibitor. These fluids operate in a closed loop system, with no planned discharges to the marine environment.

3.8.6.2 Inspection, Maintenance and Repair

Inspection, maintenance and repair activities are ongoing activities to ensure the reliability and performance of equipment. An as-built survey will be undertaken on completion of infrastructure installation with further inspections on a risk-based frequency. Depending on the scope, each campaign could take in the order of approximately 30 days.

Inspections are undertaken by a ROV from a vessel and may include but are not limited to:

- Tree valve and equipment assessments
- Cathodic protection surveys and anode replacement
- Fluid leak detection
- General visual inspections for damage and missing items, fishing and anchoring interactions
- Marine growth and fouling
- Seabed scouring and flowline/structure freespans
- Wall thickness measurements

Maintenance and repair activities are typically part of regular inspection activities but may also be required in response to inspection results. These activities are undertaken by ROV or divers from an appropriate vessel. Typical maintenance and repairs undertaken which may have an environmental impact include:

- Tree control module and/or choke replacement
- Wet gas flowmeter replacement
- Acoustic sand detector replacement
- Anode replacement
- Cathodic protection system maintenance
- Flowline and umbilical repairs
- Flowline and umbilical stabilisation

- General subsea infrastructure servicing including leak testing
- Marine growth removal
- Removal of fishing nets or other marine debris

3.8.6.3 Well Intervention and Workovers

If required, well interventions will be conducted from either a MODU or a light well intervention vessel. Well interventions may be required to:

- Evaluate well condition or performance
- Undertake well servicing operations such as to function or remediate downhole valves, remove obstructions, stimulate the well and shut-off or access producing zones
- Restore well integrity
- Suspend or prepare the well for abandonment

Intervention operations include activities such as:

- Slickline / wireline / coil-tubing operations
- Well testing and flowback
- Well stimulation (acidizing, hydraulic fracturing)
- Subsea tree replacement

The most likely requirement for well intervention for the Project would be slickline and/or wireline operations.

Subsea well intervention and servicing occurs by accessing the wellbore via the tree. This would be managed either by utilising a MODU BOP and marine riser, an Emergency Disconnect Package (EDP) / Lower Marine Riser Package (LMRP) system, or a light well intervention system.

An intervention takes place within the upper well completion and can often involve access to the sand face completion. Specific types of tools can be deployed down the well, conveyed by slickline, wireline or coil tubing to achieve the operation objectives.

A workover typically refers to the replacement of the well upper completion. Workovers may be required to:

- Restore well integrity not possible via other intervention methods
- Restore production and/or flow control functionality not possible via other intervention methods
- Isolate and/or access alternative reservoir targets not possible via other intervention methods
- Replace a subsea tree

Workovers are not anticipated to be required for the Project, If required they would result from an unplanned event.

The frequency of well intervention and workover activities depends on well performance, objective criticality, MODU/vessel availability and regulatory requirements with an anticipated frequency for the Project of up to one well worked over every seven years. The duration for workovers is up to ~30 days.

Note there may be a potential requirement to cold vent formation gas during intervention and workover operations.

3.8.7 Decommissioning

Beach acknowledges that planning for decommissioning should commence at the earliest stage of project development. This section provides information on the decommissioning of property that will require removal once it is of no further use.

Once production has ceased, wells will be shut-in and monitored as part of the IMR program. P&A of wells and removal of subsea infrastructure described within this OPP will occur as either a standalone campaign or as part of a wider decommissioning campaign. Decommissioning of subsea infrastructure is expected to take up to approximately 30 days per tie-back, with P&A of wells estimated at up to approximately 30 days per well.

The base case for decommissioning will involve the complete removal of all infrastructure and includes:

- Displacement of hydrocarbons in manifolds, flowlines and umbilicals with a displacement fluid such as treated seawater to the existing infrastructure or a support vessel, followed by depressurisation. This fluid will be treated to remove hydrocarbons and discharged to the marine environment, with volumes in the order of those estimated for commissioning and detailed in activity specific EPs.
- Disconnection and removal of production manifolds and subsea structures
- Disconnection and removal of umbilicals
- Disconnection and removal of flowlines
- Retrieval of any flowline stabilisation equipment such as mattresses where possible
- Cutting of rock anchors or piles level with seabed
- Plugging and abandonment of wells

Well P&A procedures are designed to isolate the well and prevent the release of well fluids to the marine environment. During abandonment, cement and/or mechanical plugs may be set within the well to install a permanent reservoir and surface barrier. P&A includes activities such as:

- Installation of a temporary isolation plug in wellbore
- Removal of tree

- Installation of BOP
- Isolation of all reservoir and production zones with cement plugs
- Setting of permanent cement plug just below the mudline
- Removal of BOP stack
- Cutting of conductor below the mudline and recovery to MODU

Discharges to the marine environment will be limited to cement dust, cement contaminated water, excess dry cement (due to cement job for P&A operations) and annulus fluid released during conductor cutting, and those associated with MODU and vessel operations (Sections 3.8.8.1 and 3.8.8.2). There may be a potential requirement to cold vent formation gas during P&A operations (refer to Section 3.8.6.3).

Further information on decommissioning and how Beach will demonstrate compliance with the requirements of the OPPGS Act are provided in Section 9 of the OPP.

3.8.8 Support Operations

Support operations associated with the Project will include the use of MODUs, vessels, helicopters and ROVs with requirements varying depending on the Project stage (Table 3-5).

Table 3-5: Support Operations for each Project Stage

Support Type	**Drilling and Completions**	**Installation and Commissioning**	**Operations**	**Decommissioning**
MODU	✓		✓	✓
Helicopter	✓	✓	✓	✓
ROV	✓	✓	✓	✓
Anchor Handling Tug Support	✓		✓	✓
Supply / Support Vessel	✓	✓	✓	✓
Pipelay/Multipurpose service		✓		✓
Installation support		✓		✓
Inspection, Maintenance, Repair Vessel			✓	
Dive Support Vessel		✓	✓	✓

3.8.8.1 MODU Operations

The semi-submersible MODU most likely to be used for drilling, well intervention and workover, and plug and abandonment operations. The MODU is expected to accommodate ~170 workers and will be equipped with marine–standard catering and ablution facilities. Capacity for fuel oil is expected to be up to ~3500 m^3 and it will use ~15 m^3 of diesel per day.

Environmental aspects include:

- Bunkering / bulk transfer of fuel, chemicals, and supplies
- Transfer of waste to supply vessels
- Bilge water discharge
- Sewage, greywater and food waste discharge
- Cooling water, bilge and reverse osmosis (RO) brine discharge

The MODU will likely be mobilised from the previous operator’s location to the Project Area using one or two vessels with a third vessel providing support. Essential personnel will remain on the MODU during mobilisation, with the remainder to transit to the vessel by helicopter once moored on location.

While on location, a temporary exclusion zone will be gazetted in accordance with the OPGGS Act (500 m radius around the drill rig). The purpose of the exclusion zone is to maintain a safe distance between the drilling campaign areas and fishing boats and other vessels that may operate in the area.

A representative semi-submersible MODUs is shown in Figure 3-5.

Figure 3-5: Representative Semi-submersible MODU

3.8.8.2 Vessel Operations

Table 3-6 summarises the expected vessel types, numbers and specifications for each stage of the Project. Examples of vessel types are shown in Figure 3-6 to Figure 3-10. Vessels will use dynamic positioning (DP) to maintain position while undertaken activities. No vessel anchoring will take place unless in an emergency situation.

Typically, three vessels would operate in the Project Area at any one time, however, this could increase to five if, for example, pipelay and diving/tie-ins are undertaken at the same time as MODU positioning. Simultaneous operations will be kept to a minimum and are unlikely to occur for more than 13 days.

Table 3-6: Summary of Typical Support Vessel Requirements

Vessel Type	**Duration**	**Purpose**	**Typical POB per vessel**
Anchor Handling Tug Support Vessel (Figure 3-6)	9-13 days per well location	Up to three vessels could be used to lay anchors and tow the MODU into position.	15
Supply/Support vessel (Figure 3-7)	As required for all stages of the Project	Throughout all stages, support vessels will transport fuel, stores, waste and specialist supplies such as cement and drilling fluids to the MODU / vessels operating in the Project area. Whilst drilling one support vessel will always be with the MODU.	30
Pipelay and multipurpose service vessel (Figure 3-8)	~10-20 days per tie-in for Installation and Commissioning stages and the same for Decommissioning	Installation and decommissioning of the flowlines and umbilicals	120-160
Installation Support Vessel and/or Dive Support Vessel (Figure 3-9)	~10-20 days per tie-in for Installation and Commissioning stages and the same for Decommissioning	Installation and commissioning of subsea infrastructure and decommissioning activities	120
Inspection Maintenance and Repair vessel (Figure 3-10)	Approximately 1 month per IMR activity	Inspections, maintenance and repair campaigns are expected to be conducted annually for the life of the field.	30

Figure 3-6: Example of an Anchor Handling Tug

Figure 3-7: Example of a Supply Vessel

Figure 3-8: Example of a Pipelay/Multipurpose Service Vessel

Figure 3-9: Example of an Installation Support Vessel/Dive Support Vessel

Figure 3-10: Example of an Inspection, Maintenance, Repair Vessel

3.8.8.3 Helicopters

Helicopters are the primary form of transport for personnel to be transported to and from the MODU and may be used for installation and construction vessel transfers. It is also the quickest and preferred method to evacuate personnel in an emergency.

During drilling activities it is expected that there will be 5-8 round trips per week from the mainland to the MODU for crew changes and urgent supply needs. Helicopters will not be required during the operations stage.

Refuelling of helicopters does not usually take place offshore.

3.8.8.4 Remotely Operated Vehicles (ROV) and Autonomous Underwater Vehicles (AUV)

ROV and AUV operations may be conducted throughout all Project stages. ROVs and AUVs may also be used in an unplanned event such as a loss of well control.

ROVs and AUVs are not likely to be required to park or moor on the seabed during planned / routine activities.

3.8.8.5 Diving

Saturation and air diving operations may be conducted as part of installation, commissioning, operations (inspections, maintenance and repair), and decommissioning. Diving may also be used in an unplanned event such as a loss of containment from a flowline.

There are no emissions or discharges expected from diving activities other than those generated by the vessel.

3.9 **Assessment of Alternatives**

3.9.1 Overview

The OPGGS (Environment) Regulations (7(2)(f)) require that the OPP describe any feasible alternatives to the Project or to an activity that is part of the Project, including:

- A comparison of the environmental impacts and risks arising from the Project or activity and the alternative; and
- An explanation as to why the alternative was not preferred.

This section of the OPP presents feasible alternatives which have been considered for the Project concept and design. It provides an overview of the advantages and disadvantages of each feasible alternative with an emphasis on environmental impacts and risks.

For the purposes of the OGV OPP, a feasible alternative is one that is available and reasonably capable of being carried out after taking into consideration cost, existing technology and logistics in light of overall project purposes. As per NOPSEMA's *Offshore Project Proposal Content Requirements* (NOPSEMA 2024) the selection of the preferred Project concept also considers economic, social and engineering factors as part of the selection process.

3.9.2 Methodology

Feasible alternative design concepts were identified by Beach and summarised in Section 3.9.3.

Initial concepts were reviewed with those not carried through for alternative analysis assessment detailed in Section 3.9.4.

Concepts carried through for alternative assessment are detailed in Section 3.9.5 along with a high-level comparison of activities associated with each.

The alternative assessment for each concept is undertaken by focusing on the following two steps:

- Undertake a comparative assessment of the alternative concepts against environmental criteria to identify the concept with the least environmental impact.
- Further assess each alternative concept against the other focus areas (lifecycle, environmental impacts, economics, health & safety, technical feasibility) to justify the final selected concept.

Each of the above focus areas were assessed against criteria, as detailed in Table 3-7, in a workshop attended by subject matter experts for potential concepts that were considered to be technically and commercially feasible.

A decision matrix was used to rate each criteria based on a predetermined quality Likert scale (Table 3-8). Due to the potential large variation between options a 5-point scale was considered appropriate. The matrix was used to assess the environmental, social and economic impacts and risks of each concept with the range consisting of 1 (very good) through to 5 (very poor).

Where there was no material difference between all the provided options, each criteria was given a score of 3 (neutral). If criteria were not considered relevant, they were given a score of N/A (not applicable).

A total score has been provided for environmental criteria which represents all potential project drivers (Table 3-11). The option with the lowest score is considered the preferred environmental option. A total score for other focus areas has also been calculated (Table 3-11). Unless engineer or economic factors negate it, the concept with the combined lowest score has been carried through for impact and risk evaluation.Following the selection of the preferred design concept the above procedure was repeated for design and activity options (Section 3.9.6) for the Project which include:

- MODU type
- Completion fluids unloading
- Hydrotest discharge

Table 3-7: Assessment Criteria used in Alternatives Analysis

Aspect		Criteria
Environment	Physical presence	Interaction with other users
		Seabed Disturbance
		Interaction with marine fauna
	Emissions	Light
		Underwater noise emissions
		Atmospheric/ GHG emissions
	Discharges	Planned discharges: • Drill cutting and fluids • Cement • Commissioning and operational fluids • Routine operational wastes from vessels • Bulk powders including cement, bentonite and barite
		Unplanned discharges: • Hazardous and non-hazardous materials • Hydrocarbons and chemicals
	Introduction of invasive marine species	Invasive marine species (IMS)
Other Focus Area	Lifecycle environmental impacts	Consideration of relative life-of-field impact spanning infrastructure construction and presence, production operations and abandonment legacy impacts
	Economics	Economic viability
	Health & Safety	Health & safety standards and legislation
	Technical	Technical feasibility plus ability to operate and maintain infrastructure

Table 3-8: Quality Scale for Alternative Concepts / Options

Score	Description
1	Very good
2	Good
3	Neutral
4	Poor
5	Very poor

3.9.3 Identification of Concept Alternatives

Beach initially considered 4 different concepts during the alternative analysis comparative assessment process (Table 3-9). This assessment identified the benefits, impacts and potential risks that corresponded with each development concept. A summary of each concept is provided in Table 3-9.

Concept 4 – No development, was reviewed during early screening and was determined not to be commercially or economically viable as detailed in Section 3.9.4.

Table 3-9: Summary of Concept Alternatives

Development Concepts	**Summary**
Concept 1 - Subsea tie-back to existing facilities	Subsea tie-back to existing facilities via the shortest suitable routes between fields and tie-ins, featuring either hub and spoke or daisy chain subsea architecture arrangement for initial development with well tiebacks direct to pipeline tie in points.
Concept 2 - Well-head platform with dry trees	Unmanned fixed offshore platform / well head platform (WHP), with dry tree wells (surface well heads), to enable treatment of reservoir fluids for export via existing sub-sea infrastructure and OGPP to onshore OGP.
Concept 3 - Floating production facility	Subsea wells feeding into a manned offshore floating production facility (either floating production storage and offloading (FPSO) or floating liquefied natural gas (FLNG)) with appropriate anchor layout over the fields with the offloading of processed gas via shuttle tankers.
Concept 4 - No development	No development.

3.9.4 Concepts not carried through for assessment (Concept 4 – No Development)

Not undertaking the Project was an alternative considered by Beach during early screening and was discounted as if the Project does not go-ahead, then gas production from Beach's Otway assets will decline and the gas pools will become stranded with considerable commercial and economic impacts for Beach and the broader community.

The Project is being undertaken to replace existing production at the OGP from the Otway Basin and ultimately to deliver natural gas to the east coast gas market. Importantly, this gas will help arrest a predicted gas shortfall in Victoria and is therefore critical to ensure Victoria's energy security.

In March 2024 the Australian Energy Market Operator (AEMO) published the Victorian Gas Planning Report update (AEMO 2024) which found that Victorian production continues to decline, with large forecast reductions from 2024 to 2026. The total available gas supply is forecast to reduce by 48% over the outlook period, from 297 petajoules (PJ) in 2024 to 154 PJ in 2028. This will impact negatively on the reliability of the gas supply system and ability to meet daily peak supplies.

The Victorian economy is heavily reliant on gas. It is utilised for electricity generation, and for manufacturing, construction, agricultural and chemical industries with Victorian households having the highest natural gas usage in Australia. Victoria accounts for ~50% of gas demand in south-eastern Australia. It is vitally important to the viability of Victorian industries and residents that gas supplies are adequate and price volatility is suppressed. The ongoing supply from the Project will contribute not only to individual and community well-being but will support businesses and industry to maintain a competitive economy.

Demand is expected to continue in Victoria and the south-eastern states particularly because of the decline in coal consumption with the closure of coal-fired power stations with peak gas demand records being broken and will likely increase.

Existing southern gas reserves are in decline, and more development is required in the southern states from 2024 to ensure that all demand is met. AEMO has forecast that if Victoria wishes to accelerate the closure of its coal-fired power stations, more peaking gas-powered generation (gas needed during periods of high demand) will be needed to ensure the reliability of supply. As Australia transitions to a low emissions economy underpinned by renewable energy, natural gas will play a critical role by efficiently supporting the intermittency of solar and wind energy and future renewable technologies whilst assisting in the continued development of an internationally competitive economy. The role of gas is illustrated in Figure 3-11.

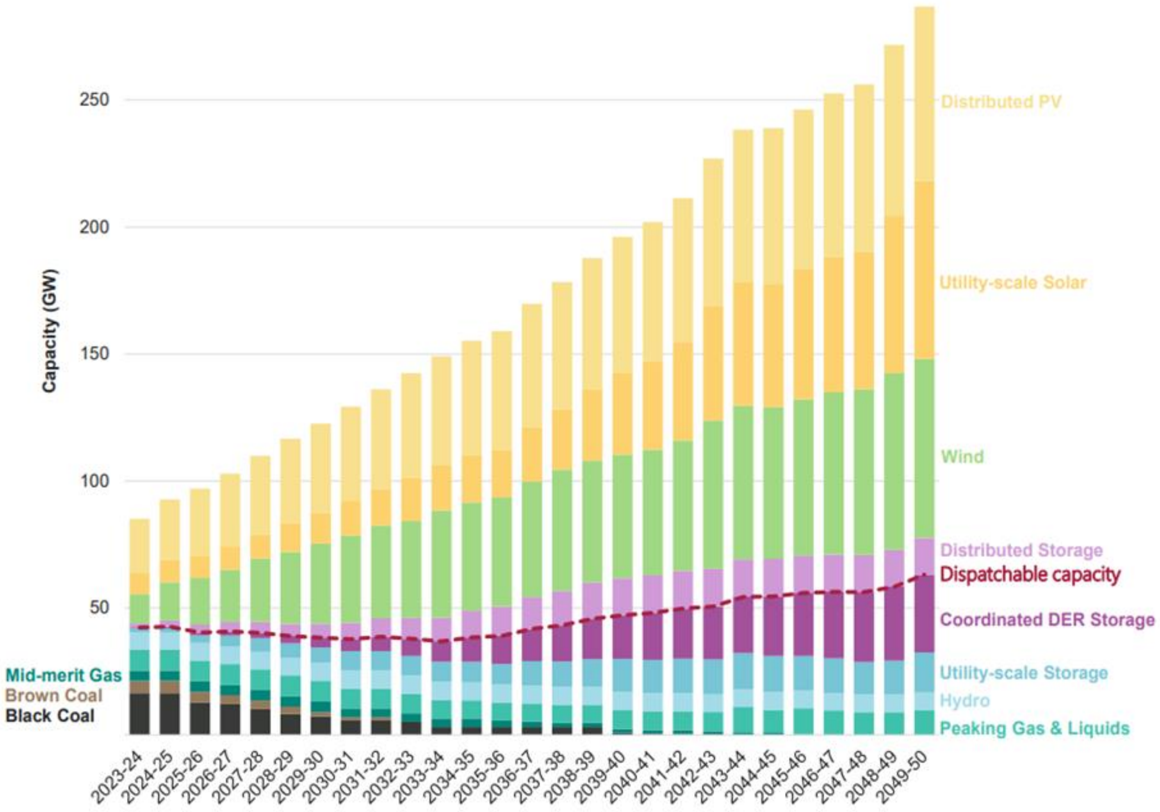

Figure 3-11: Forecast National Energy Market capacity to 2050, Step Change scenario (AEMO 2022 Integrated System Plan)

The *Victorian Climate Change Act 2017* establishes a long-term emissions reduction target for Victoria of Net Zero by 2050. The legislation requires 5-year interim targets to track the state's progress. From 2021, Adaptation Action Plans are required for key Victorian systems that may be vulnerable to climate change impacts. The legislation also requires periodic reporting to ensure transparency and accountability to the community.

The role of new gas investments within this geopolitical context is part of the transition toward lower emissions technologies and energy sources. Otway gas will play a role in reducing Victoria and Australia's emissions footprint. The development of more natural gas supplies is seen as critical in reducing Australia's emissions footprint. The Integrated System Plan (ISP), which models electricity generation up to 2050 in the National Electricity Market (NEM), was updated in June 2024 by AEMO. In the ISP most aggressive 'Step Change' scenario, it forecasts 15 GW of gas-powered generation to ensure the NEM remains resilient under a range of power system and extreme weather events. The ISP states that "electricity from gas-powered generation is forecast to continue its important role in the

NEM. After coal-fired generators retire, gas will be needed to support energy supply during periods of renewable drought and of extreme peak demand (AEMO, Integrated System Plan June 2024).

3.9.5 Concepts carried through for assessment

Beach has previously assessed the facility type and functionality for the nearby proposed Trefoil Project in Bass Strait. These learnings on technically and commercially feasible options were applied to the screening of development options for this Project in addition to factors specific to the Otway Development. Particularly considering the presence of existing subsea infrastructure and the relatively small number of additional potential wells.

The three alternative development concepts (as described in Table 3-9) carried forward for assessment were:

- Subsea tie-back to existing facilities (Concept 1);
- Well-head platform with dry trees (Concept 2); and
- Floating production facility (FPSO or FLNG) (Concept 3).

Table 3-10 provides a high-level comparison of activities associated with each concept used to identify potential risks and impacts of each concept.

Using the assessment criteria, as detailed in Section 3.9.2, Table 3-11 provides a high level summary of the impacts and risks (or lack of) for each of the three concepts carried forward for assessment. It also provides a summary of scores assigned to each criteria. Environmental, other focus areas, and total scores are summarised detailing which concept or option is carried forward for full detailed assessment within the OGV OPP.

Table 3-10: Comparison of Activities Associated with Proposed Concepts

	Concept 1 – Subsea tie-back to existing facilities	**Concept 2** – Wellhead platform with dry trees	**Concept 3** – Floating production facility
Infrastructure	Subsea wells and infrastructure connected to existing OGPP.	Dry tree wells and WHP connected to existing OGPP.	Subsea wells and infrastructure connect with floating production facility (either FPSO or FLNG)
Activities			
Surveys	Required for MODU anchor locations plus well and subsea infrastructure locations.	Required for MODU anchor locations plus subsea infrastructure and WHP locations.	Required for MODU anchor locations plus wells, subsea infrastructure, and floating production facility anchor locations.
Drilling and Completions	Anchored MODU to drill and complete wells at well locations.	Anchored MODU to drill and complete wells at well locations.	Anchored MODU to drill and complete wells at well locations.
Installation and Commissioning	Use of ISV to install and connect wells to existing OGPP.	Use of ISV to install and connect wells to existing OGPP.	Use of ISV to install and connect wells to floating production facility.

	Subsea infrastructure integrity tested with hydrotest water discharged to marine environment.	Subsea infrastructure integrity tested with hydrotest water discharged to marine environment.	Subsea infrastructure integrity tested with hydrotest water discharged to marine environment.
Operations	IMR undertaken by vessel for subsea wells and infrastructure. Well interventions conducted from either a MODU or a well intervention vessel.	IMR undertaken by vessel for subsea wells and infrastructure. Operation and maintenance of WHP. Well interventions conducted from a MODU or well intervention vessel.	IMR undertaken by vessel of subsea wells and infrastructure. Operation and maintenance of floating production facility (either FPSO of FLNG) Shuttle tankers required for offload of processed gas. Well interventions conducted from either a MODU or a well intervention vessel.
Decommissioning	MODU required for well P&A. Vessel to remove subsea infrastructure.	MODU required for well P&A. Vessel to remove subsea infrastructure. Decommissioning of WHP and removal via heavy-lift vessel, floating cranes, barges	MODU required for well P&A. Vessels to remove subsea infrastructure and floating production facility including anchor array. Floating production facility ceases operations and sails to new location or to shipyard for decommissioning.

Table 3-11: Comparative Assessment of Development Concepts

Focus Area		**Criteria**	**Concept 1** - Subsea tie-back to existing facilities	**Score**	**Concept 2** - Wellhead platform with dry trees	**Score**	**Concept 3** - Floating production storage offloading facility	**Score**	**Summary**
Environmental	Physical Presence	Interaction with other users	Potential interaction with marine stakeholders restricted to construction, interventions, IMR & decommissioning. No permanent surface facilities, therefore, no risk of surface collision during operations. Petroleum Safety Zone (PSZ) around wells and subsea infrastructure restricting access to area.	**1**	Potential interaction with marine stakeholders during construction, interventions, IMR & decommissioning. WHP is a permanent structure with associated PSZ, close to existing shipping lanes therefore increased risk of interactions / collision with other vessels. Increased IMR and decommissioning activities with associated vessels required compared to Concept 1.	**4**	Potential interaction with marine stakeholders during construction, interventions, IMR & decommissioning. FPSO / FLNG is a permanent floating structure with associated PSZ, including subsea wells and anchor spread. FPSO / FLNG close to existing shipping lanes therefore increased risk of interactions / collision with other vessels. Increase in vessel traffic from shuttle tanker movements. Increased IMR and decommissioning activities with associated vessels required compared to Concept 1 and 2.	**5**	Concept 1 score is lowest in relation to the interaction with other users due to the lack of permanent surface structures, reducing the impact and risk to other marine traffic. Both concepts 2 and 3 have permanent surface installations. Concept 3 may have a significantly larger PSZ, excluding other marine users for the duration of the project, due to the extent of the permanent anchor spread required for the floating facilities. Concept 3 will also result in additional vessel traffic than from shuttle tankers increasing risk of interactions with other marine users.
		Seabed disturbance	Footprint of subsea wells and flowlines used for tie-in to existing OGPP minimal. Anchor placement for MODU during installation and decommissioning is temporary.	**1**	Footprint of dry trees and flowlines used for tie-in to WHP and existing OGPP minimal. Anchor placement for MODU during installation and decommissioning is temporary. WHP permanently positioned on seabed for duration of the Project.	**4**	Footprint of subsea wells and flowlines used for tie-in to the floating facility minimal. Anchor placement for MODU during installation and decommissioning is temporary. Permanent anchor spread for floating facility for duration of the Project.	**5**	Concept 1 score is lowest in relation to seabed disturbance. All concepts would have minimal disturbance from subsea wells and flowlines. Both concepts 2 and 3 would have the potential for greater, longer-term seabed disturbance from the installation and decommissioning of a WHP and for the floating facility anchor spread, (which scores highest) which would be present throughout the duration of the Project.
		Interaction with marine fauna	Potential for vessel interaction with marine fauna restricted to construction, interventions, IMR & decommissioning. No permanent surface facilities.	**1**	Potential for vessel interaction with marine fauna restricted to construction, interventions, IMR & decommissioning. Potential impact (displacement and noise) to marine fauna from WHP for the duration of the Project.	**4**	Potential for vessel interaction with marine fauna during construction, interventions, IMR, decommissioning plus shuttle tanker movements for the duration of the Project. Potential impact (displacement and noise) of marine fauna from permanent floating facility, including anchor spread, for the duration of the Project.	**5**	Concept 1 score is lowest in relation to interaction with marine fauna due to the lack of surface facilities. Concept 2 and 3 score higher due to the physical presence of surface facilities. Concept 3 scores the highest due to the increase in vessel traffic as a result of regular shuttle tankers required to offload processed gas.
	Emissions	Light emissions	Temporary light emissions restricted to construction, interventions, IMR & decommissioning activities. No permanent surface facilities.	**1**	Temporary light emissions during construction, interventions, IMR & significant WHP decommissioning activities. Light emissions from permanent surface facilities (unmanned) for the duration of the Project.	**4**	Temporary light emissions during construction, interventions, IMR & significant decommissioning activities. Light emissions from permanent surface facilities (manned) for the duration of the Project.	**5**	Concept 1 scores lowest in relation to light emissions due to the lack of surface facilities during the operational phase of the Project. Concept 3 scores higher than Concept 2 as the FPSO / FLNG would be a manned surface facility which would likely be larger and require a greater degree of safety / working lights than an unmanned WHP.
		Underwater noise emissions	Potential for underwater noise emissions largely restricted to construction, interventions, IMR & decommissioning activities. No permanent surface facilities with minimal noise associated with subsea well operations.	**1**	Potential for underwater noise emissions from construction (including WHP installation), interventions, IMR & significant decommissioning activities. WHP is an unmanned permanent structure for the duration of the Project with associated onboard noise.	**4**	Potential for underwater noise emissions from construction (including floating facility anchor installation), interventions, IMR & significant decommissioning activities. Floating facility is a manned permanent facility with associated onboard noise. Increased underwater noise due to a MODU and associated support vessels being required for well interventions.	**5**	Concept 1 scores lowest in relation to underwater noise emissions due to the lack of surface facilities during the operational phase of the Project. Concept 3 scores higher than Concept 2 as the FPSO / FLNG would be a manned surface facility which would likely require increased operational noise in comparison to an unmanned WHP.

		Atmospheric / GHG emissions	Atmospheric emissions during construction, interventions, IMR & decommissioning phases.	1	Atmospheric emissions during construction, interventions, IMR & decommissioning phases. Unmanned WHP present for the duration of the operational phase will result in continuous long-term atmospheric emissions from power generation and processing.	4	Atmospheric emissions during construction, interventions, IMR & decommissioning phases. Manned floating facility present for the duration of the operational phase will result in continuous long-term atmospheric emissions from power generation and processing. Additional atmospheric emissions from shuttle tankers for the duration of the Project required to offload processed gas.	5	Concept 1 scores the lowest in relation to atmospheric / GHG emissions due to the lack of surface facilities during the operational phase of the Project. Concept 2 and 3 score higher due to the presence of surface facilities which produce continuous emissions throughout the operational phase. Concept 3 scores higher as it is a manned surface facility which results in increased operational emissions plus the increase in vessel traffic from shuttle tankers required to offload processed gas.
	Discharges	Planned discharges	Planned discharges during construction, interventions, IMR & decommissioning from support vessels and MODU. Control fluid, IMR and hydrotest discharges from subsea infrastructure during operations.	1	Planned discharges during construction, interventions, IMR & decommissioning from support vessels and MODU. Control fluid, IMR and hydrotest discharges from subsea infrastructure during operations. Possible cooling water and produced formation water from unmanned WHP which is present for the duration of the operational phase of the Project.	4	Planned discharges during construction, interventions, IMR & decommissioning from support vessels and MODU. Control fluid, IMR and hydrotest discharges from subsea infrastructure during operations. Moderate planned emissions/discharges associated with normally manned floating production facility operations. Potential planned emissions from shuttle tankers required for the duration of the operational phase of the Project required to offload processed gas.	5	Concept 1 scores lowest in relation to planned discharges due to the lack of surface facilities during the operational phase of the Project. Concept 2 and 3 score higher due to the presence of surface facilities and their associated discharges throughout the operational phase. Concept 3 scores higher due to the presence of a manned surface facility plus shuttle tankers which results in increased planned discharges during the operational phase.
		Unplanned discharges	Potential for unplanned discharges during construction, interventions, IMR & decommissioning from support vessels and MODU. Low risk of loss of containment from subsea infrastructure (wells and/or flowlines).	1	Potential for unplanned discharges during construction, interventions, IMR & decommissioning from support vessels and MODU. Low risk of loss of containment from subsea infrastructure (wells and/or flowlines). Small liquid hydrocarbon volumes planned to be maintained/stored on WHP for the duration of the Project.	4	Potential for unplanned discharges during construction, interventions, IMR & decommissioning from support vessels and MODU. Large liquid hydrocarbon volumes maintained/stored on floating facility with low risk of unplanned discharges. Risk of spills during offloading to shuttle tankers for duration of operational phase of the Project. Increased risk of spills from greater vessel presence (shuttle tankers) during the operational phase of the Project.	5	Concept 1 scores lowest in relation to unplanned discharges due to the lack of surface facilities during the operational phase of the Project. Concept 2 and 3 score higher due to the presence of surface facilities which store hydrocarbons. Concept 3 scores higher as it has a larger storage capacity plus increased risks resulting from offloading of processed gas to shuttle tankers.
	Introduction of invasive marine species	Invasive marine species (IMS)	IMS risk associated with vessels used during construction, interventions, IMR & decommissioning activities only.	1	IMS risk associated with vessels used during construction, interventions, IMR & decommissioning activities. Increased risk of introduction of IMS from WHP due to overseas manufacture. Presence of WHP structure suitable for colonisation.	4	IMS risk associated with vessels used during construction, interventions, IMR & decommissioning activities. Increased risk of introduction of IMS from floating facility due to overseas manufacture. Presence of floating facility and anchor spread suitable for colonisation. Increased risk of introduction of IMS from visiting shuttle tankers from overseas locations.	5	Concept 1 scores lowest in relation to IMS due to the lack of surface facilities and possible colonisation surfaces during the operational phase of the Project. Concept 2 and 3 score higher due to the presence of surface facilities which provide a surface for possible colonisation. Concept 3 is scored higher due to the anchor spread plus increased risks resulting from offloading of processed gas to shuttle tankers transiting from oversea locations.
Other Focus	Lifecycle environmental impacts	Consideration of relative life-of-field impact	Concept footprint is minimal, localised and benefits from utilising existing subsea infrastructure, with limited new subsea infrastructure required for tie-in.	1	Concept footprint is moderate, localised and includes installation of new WHP and associated infrastructure.	4	Concept footprint is minimal, localised and includes anchor mooring spread for floating facility.	5	Concept 1 scores lowest in relation to the lifecycle environmental impacts due to the lack of surface facilities and limited planned discharges.

				Minimal planned discharges associated with unmanned WHP for the duration of the operational phase of the Project. Atmospheric emissions associated with this concept are significant.		Moderate planned emissions/discharges associated with normally manned floating production facility for the duration of the operational phase of the Project. Atmospheric emissions associated with this concept are significant.		Concept 2 and 3 score higher due to the presence of surface facilities which result in additional emissions/discharges. Concept 3 is scored higher due to the increased vessel movements as a result of offloading processed gas to shuttle tankers.
Economics	Economic viability	Costs associated with development include tie-in to an existing facility and utilise existing infrastructure.	**1**	Costs associated with installation, IMR and decommissioning of unmanned WHP. Costs associated with tie-in to WHP.	**4**	Cost associated with installation, IMR and decommissioning of manned floating production facility. Costs associated with operations of shuttle tankers for the duration of the operational Phase of the Project. Costs associated with tie-in to floating facility.	**5**	Concept 1 scores low in relation to the economics of the project due to the lack of surface facilities and associated costs for construction and installation. Concept 3 scores high due to the construction and maintenance costs associated with a manned surface facility and costs associated with shuttle tankers required to offload processed gas.
Health & Safety	Health & safety standards and legislation	Risks associated with support vessels and MODU during construction, interventions, IMR & decommissioning. No manned offshore facilities. Minimal IMR for subsea infrastructure.	**1**	Risks associated with support vessels and MODU during drilling and IMR plus major offshore construction and decommissioning of WHP. WHP will require periodic maintenance. As no accommodation on WHP frequent helicopter transfers required. Systems on the topsides therefore are likely to require more frequent IMR than a manned installation. Risk of vessel collision due to presence of WHP during the operational phase of the Project. Risk to personnel whilst temporarily manned during maintenance.	**4**	Risks associated with support vessels and MODU during drilling and IMR plus major offshore construction and decommissioning of floating facility anchor spread. Normally manned floating facility will require frequent vessel resupply transfers. Higher risk of vessel collision due to presence of a floating facility. Risk to personnel as permanently manned during all phases of operation.	**5**	Concept 1 scores lowest in relation to health and safety. The risks and considered significantly smaller than those associated with the surface facilities for concepts 2 and 3. Concept 3 scores high due to the presence of a manned floating facility and associated risks, plus considerably increase vessel operations resulting from shuttle tanker movements.
Technical	Technical feasibility	All processing via existing Otway Gas Plant. Subsea completions may be completed by either a MODU or the use of a light well intervention vessel.	**1**	Subsea completions may be completed by either a MODU or the use of a light well intervention vessel. Crews to visit the platform for periodic maintenance and inspections via helicopter. Significant construction associated with WHP. Increased IMR associated with the WHP compared with Concept 1.	**4**	Subsea completions may be completed by either a MODU or the use of a light well intervention vessel. Normally manned floating facility requires continuous IMR by onboard personnel. Significant construction associated with floating facility.	**5**	Concept 1 score lowest in relation to technical feasibility with the relatively simpler concept of the tie-in to existing infrastructure and lack of surface facilities. Concept 2 and 3 scores high due to the construction requirements for surface facilities which result in additional technical complexities. Concept 3 scores higher due to the major construction requirements of a floating facility and logistics involved with operating shuttle tankers throughout the operational phase of the Project.
Environmental Score			**9**		**36**		**45**	**Concept 1** is the simplest possible option, utilising existing infrastructure and subsea wellheads, with the shortest suitable routes between fields and tie-ins and therefore has the lowest environmental and social footprint when considered over the life of the development. Furthermore, it is the most economical, safe and feasible option and as such is the preferred choice. In comparison, Concepts 2 and 3 add complexity and cost in addition to potential increased environmental impact and risk.
Other Focus Areas			**4**		**16**		**20**	
Total Score			**13**		**52**		**65**	

3.9.6 Analysis of Preferred Concept Design / Activity Alternatives

Following the selection of the preferred concept (Concept 1 – Subsea tie-back to existing subsea facilities), alternative options were considered for the design and activities associated with this concept. The design was evaluated against planned and unplanned activities for elements requiring further assessment (Table 3-12). This section describes the key alternative elements that were considered and compared for Concept 1.

Design and activity elements for the Project include:

- MODU type
- Completion fluids unloading
- Hydrotest discharge

Within the following subsections each element and their associated alternatives are compared.

Table 3-12: Scoping for Design Alternatives for Concept 1 - Subsea Tie-back to Existing Facilities

Focus Area		**Criteria**	**Concept 1** - Subsea tie-back to existing facilities	**Design/Activity Alternative Analysis Required**
Environmental	Physical Presence	Interaction with other users	Potential interaction with other marine users restricted to when MODU and vessels undertaking activities. Type of vessel selected does not impact on the risk of interaction with other marine users. Type of MODU selected could impact on the risk of interaction with other marine users as some MODU types require less support vessels.	Yes – MODU type.
		Seabed disturbance	Subsea infrastructure seabed disturbance is as low as feasibly possible with limited new subsea infrastructure required for tie-in. Type of MODU selected could impact drilling and intervention seabed disturbance area.	Yes – MODU type.
		Interaction with marine fauna	Potential interaction with marine fauna restricted to when MODU and vessels undertaking activities. Type of vessel selected does not impact on the risk of interaction with marine fauna.	Yes – MODU type.
	Emissions	Light emissions	Light emissions restricted to when MODU and vessels undertaking activities. MODU and vessel types will have similar light emissions. Well unload and testing could impact light emissions.	Yes – MODU type.
		Underwater noise emissions	Minimal noise associated with subsea well operations. Underwater noise emissions restricted when MODU and vessels undertaking activities. All vessels will be DP as water depths are to deep for anchoring. Type of MODU selected could impact drilling and intervention underwater noise emissions.	Yes – MODU type.
		Atmospheric / GHG emissions	Atmospheric emissions restricted to when MODU and vessels undertaking activities. Type of MODU selected could impact atmospheric emissions. Well unload and testing could impact atmospheric emissions.	Yes – MODU type.

	Discharges	Planned discharges	Domestic liquid/solids waste discharges restricted to when MODU and vessels undertaking activities. Type of MODU selected could impact on domestic liquid/solids wastes discharges as some MODU types require less support vessels. BOP, drilling and completion fluid discharges are the same for all MODU types. Discharge of completion fluids options (MODU or OGP) could impact planned liquid discharges. Unloading and testing the well to the OGP is not intended, however, is provided for as a contingency in the event it is required for technical and feasibility reasons. Discharge of hydrotest fluids options (discharge to marine environment or OGP) could impact planned liquid discharges.	Yes – MODU type. Yes – Completion fluids discharge. Yes – Hydrotest discharge.
		Unplanned discharges	Low risk of loss of containment from subsea infrastructure (wells and/or flowlines). Vessels have similar risk of loss of containment. Type of MODU selected could impact on the risk of loss of containment.	Yes – MODU type.
	Introduction of invasive marine species	Invasive marine species (IMS)	IMS risk restricted to when MODU and vessels undertaking activities. Vessels have similar IMS risk. Type of MODU selected could impact IMS risk.	Yes – MODU type.

3.9.6.1 MODU Type

For Project activities where a MODU is required three options were considered as detailed within Table 3-13.

- Option 1 – Anchored MODU (or DP assist Anchored MODU). The MODU is towed into position and moored to the seabed with anchors. Approximately 8-12 anchors are required, which are tethered to the MODU with mooring lines.
- Option 2 – Dynamic Positioned (DP) MODU. The MODU uses DP to hold itself in position.
- Option 3 – Jack up MODU. The MODU is towed into position with its legs lowered to the seabed raising the MODU hull above sea level.

Table 3-13 details the environmental, social and economic impacts and risks of each option using the 5-point scale (Table 3-8) as per previous methodology.

Table 3-13: Comparative Assessment of Criteria for MODU Options

Focus Area		Criteria	**Option 1** – Anchored MODU (or DP assist Anchored MODU	Score	**Option 2** – DP MODU	Score	**Option 3** – Jack-up MODU	Score	Summary
Environmental	Physical presence	Interaction with other users	Temporary MODU presence and associated exclusion zone close to existing fishing and shipping lanes.	3	Temporary MODU presence MODU and associated exclusion zone close to existing fishing and shipping lanes.	3	Temporary MODU presence MODU and associated exclusion zone close to existing fishing and shipping lanes.	3	Whilst the anchor spread of Option 1 would impact a greater area, all 3 options will have a similar exclusion zone whilst the MODU is on site and operational. Therefore, it is considered that there are no material differences between options.
		Seabed disturbance	Seabed disturbance associated with temporary anchor spread used for MODU mooring. Flowlines and well sites present for the duration of the Project	2	Flowlines and well sites present for the duration of the Project	1	Seabed disturbance associated with jack-up legs lowered onto seabed. Risk of leg "punch-throughs" previously seen in similar operations in the Bass Strait. Flowlines and well sites present for the duration of the Project	5	Option 2 scores lowest in relation to seabed disturbance. Seabed disturbance will be limited to wells and flowlines only. Option 3 is scores high due to the risk of "punch-throughs".
		Interaction with marine fauna	Risk of marine fauna interaction associated with presence of MODU and support vessels	3	Risk of marine fauna interaction associated with presence of MODU and support vessels.	3	Risk of marine fauna interaction associated with presence of MODU and support vessels.	3	Whilst the anchor spread of Option 1 covers a slightly greater area the additional risk of interaction with marine fauna it is considered negligible with all 3 options considered to have similar risks.
	Emissions	Light emissions	Temporary presence of MODU on site during drilling and decommissioning phases with support vessels required.	3	Temporary presence of MODU on site during drilling and decommissioning phases with support vessels required.	3	Temporary presence of MODU on site during drilling and decommissioning phases with support vessels required.	3	Each MODU will spend a similar time on site during drilling and decommissioning phases.
		Underwater noise emissions	Minor noise emissions associated with occasional use of dynamic positioning thruster system to assist positioning during extreme weather events. Onboard machinery noise. Noise emissions associated with support vessels."	2	Significant noise emissions associated with continuous use of dynamic positioning thruster system to hold location. Onboard machinery noise. Noise emissions associated with support vessels.	5	Noise emissions associated with jack-up and jack-down operations. Onboard machinery noise. Noise emissions associated with support vessels.	1	Option 3 scores lowest in relation to underwater noise emissions. Whilst all options will have similar noise levels resulting from onboard machinery and support vessels there is no associated noise from DP. DP is known to generate increased underwater noise levels. Option 2 scores high due to the continuous use of DP for the duration of the time that the MODU would be on site.
		Atmospheric / GHG emissions	Emissions associated with MODU operations and power generation. Emissions associated with occasional use of dynamic positioning thruster system to assist with holding position in extreme weather events. Atmospheric emissions associated with support vessels.	2	Emissions associated with MODU operations and power generation. Emissions associated with continuous use of dynamic positioning thruster system to hold location. Atmospheric emissions associated with support vessels.	5	Emissions associated with MODU operations and power generation. Atmospheric emissions associated with support vessels.	1	Option 1 scores low in relation to atmospheric / GHG emissions. Whilst options 1 and 3 will have similar emission levels, it is expected that whilst on station Option 1 will require the occasional use of DP to hold position in extreme weather events. Option 2 scores high due to the continuous use of DP for the duration of the time that the MODU would be on site.
	Discharges	Planned discharges	Typical waste as expected from temporary drilling, commissioning and routine operations.	3	Typical waste as expected from temporary drilling, commissioning and routine operations.	3	Typical waste as expected from temporary drilling, commissioning and routine operations.	3	Similar planned discharges are expected from all options whilst the MODU is on site and operational.
		Unplanned discharges	Typical risks associated with drilling, commissioning and routine operations including accidental discharge of hazardous and non-hazardous material plus loss of containment.	3	Typical risks associated with drilling, commissioning and routine operations including accidental discharge of hazardous and non-hazardous material plus loss of containment.	3	Typical risks associated with drilling, commissioning and routine operations including accidental discharge of hazardous and non-hazardous material plus loss of containment.	3	Similar planned discharges are expected from all options whilst the MODU is on site and operational.

	Introduction of invasive marine species	Invasive marine species (IMS)	Risk of IMS introduction related to MODU travelling from overseas, anchor spread and seabed contact.	**4**	Risk of IMS introduction related to MODU travelling from overseas.	**2**	Risk of IMS introduction related to MODU travelling from overseas and seabed contact.	**5**	Option 2 scores lowest in relation to the risk of the introduction of invasive marine species. Options 1 will have no seabed contact limiting the possibility of an IMS being able to establish itself. Whilst both option 1 and 2 will have seabed contact anchor spreads are usually transported in dry conditions making it difficult for an IMS to establish. The legs of a jack-up MODU can remain wet whilst travelling between locations increasing the possibility of transporting an IMS.
	Lifecycle environmental impacts	Consideration of relative life-of-field impact	Temporary presence on site.	**N/A**	Temporary presence on site.	**N/A**	Temporary presence on site.	**N/A**	As MODU presence on site will be temporary, lifecycle environmental impacts are not considered applicable for this assessment.
Other Focus Areas	Economics	Economic viability	Moderate design. Generally, more expensive to contract than Option 3 but less than Option 2.	**4**	More expensive to contract Options 1 and 3 due to technical capabilities of DP.	**5**	Simple design. Generally, less expensive to contract than Option 1 or Option 2	**1**	Option 1 scores lowest in relation to economics. Jack-up rigs are of a relatively simpler design than anchored or DP MODUs. Option 2 scores high due to the technical capabilities of DP.
	Health & Safety	Health & safety standards and legislation	Success of historical operations in region.	3	No anchor handling risk. Risk of station keeping	**3**	Based on feasibility studies, safety risk exacerbated by inherent risk for rapid leg penetration (punch-through) as seen in similar operations in the Bass Strait.	**5**	Options 2 and 3 are considered to have no material difference between options considering health and safety, with operations for both MODU types well understood with standard industry practises. Option 3 scores high due to the risk of rapid leg penetration of the seabed (punch-through).
	Technical	Technical feasibility	Success of historical operations in region	1	MODU generally suitable for deeper water depths than those present in the Project Area.	**4**	Risk for rapid leg penetration (punch-through) as seen in similar operations in the Bass Strait. Water depths and metocean conditions may not be suitable	**5**	Option 1 scores lowest in relation to technical feasibility due the success of historical operations utilising this type of MODU in the region. Option 3 scores high due to the risk of rapid leg penetration of the seabed (punch-through).
Environmental Score				**25**		**28**		**27**	**Option 1** is the most suitable option for drilling operations for the Project. It has the lowest environmental and other focus score when considered against options 2 and 3. Methods for Option 1 are commonly used in the Otway region with impacts and risks well understood. Technically both the full DP and jack-up MODU are generally not suitable for the Otway region due to water depths, metocean conditions and the risk of punch through.
Other Focus Areas				**8**		**12**		**11**	
Total Score				**33**		**40**		**38**	

3.9.6.2 Completion Fluids Unloading Qualitative Assessment of Alternatives

Beach may utilise completion fluids as part of wellbore clean-up during completions. This fluid is placed in the well to facilitate final operations prior to initiation of production.

Two options were considered for the disposal of completion fluids for the Project which are:

- Option 1 - Wells cleaned up to MODU (Clean up to rig/MODU - CUTR)
- Option 2 - Wells cleaned up to plant (OGP) (Clean up to Plant – CUTP)

With Option 1, the completion fluids (consisting of completion brine and any formation water or condensate present in the wellbore) are circulated back to the MODU for treatment prior to discharge. The discharge may also include any excess completion brine remaining in the MODU tank system discharged to sea as per standard operating procedures. These discharges may result in a temporary decrease in water quality in the water column, however, the risks can be managed to an acceptable level.

If there is the potential for oil to be present, the completion fluids will be tested and discharged only if the oil-in-water content is below 30ppm. Fluid not meeting this criterion will be stored in tanks onboard the MODU for later onshore disposal.

With Option 2, the completion fluids are circulated back to the OGP via the OGPP for treatment prior to disposal, with this activity occurring post-installation and tie-in of subsea infrastructure.

Table 3-14 provides a comparison of criteria for each option as per previous methodology.

Table 3-14: Completions Fluids Unloading Qualitative Assessment of Alternatives

Focus Area		**Criteria**	**Option 1** – Wells cleaned up to rig/MODU (CUTR)	**Score**	**Option 2** – Wells cleaned up to the plant (CUTP)	**Score**	**Summary**
Environmental	Physical presence	Interaction with other users	No additional risk other than those identified for MODU Option 1.	3	No additional risk other than those identified for MODU Option 1.	3	No material difference between options
		Seabed disturbance	No additional risk other than those identified for MODU Option 1.	3	No additional risk other than those identified for MODU Option 1.	3	No material difference between options
		Interaction with marine fauna	No additional risk other than those identified for MODU Option 1.	3	No additional risk other than those identified for MODU Option 1.	3	No material difference between options
	Emissions	Light emissions	Short term flaring	4	No additional risk other than those identified for MODU Option 1.	1	Option 2 scores lowest in relation to light emissions as no flaring. Option 1 involves short-term flaring and increased light emissions.
		Underwater noise emissions	Temporary flaring noise.	4	Perforations runs.	1	Option 2 scores lowest in relation to underwater noise emissions as none expected. Option 1 involves short-term flaring and increased surface noise emissions with minimal in water impacts.
		Atmospheric / GHG emissions	No additional risk other than those identified for MODU Option 1.	3	No additional risk other than those identified for MODU Option 1.	3	No material difference between options
	Discharges	Planned discharges	Temporary and localised changes to water quality	4	No additional risk other than those identified for MODU Option 1.	1	Option 2 scores lowest in relation to planned discharges as there will be no discharges to the marine environment with this option.
		Unplanned discharges	No additional risk other than those identified for MODU Option 1.	3	No additional risk other than those identified for MODU Option 1.	3	No material difference between options
	Introduction of invasive marine species	Invasive marine species (IMS)	No additional risk other than those identified for MODU Option 1.	3	No additional risk other than those identified for MODU Option 1.	3	No material difference between options
	Lifecycle environmental impacts	Consideration of relative life-of-field impact	Temporary activity	**N/A**	Temporary activity	**N/A**	Temporary activity, therefore, lifecycle environmental impacts are not considered applicable for this assessment.
Other Focus Areas	Economics	Economic viability	Comparative low cost.	1	Comparative high cost.	5	Option 1 scores lowest in relation to economics. CUTR is the most viable economical viable option as: • costs can be shared between other operators. • cost associated with rig time and significantly less • reduced critical path rig time • elimination of deferred production risk from offshore production wells tied to subsea flowline whilst testing the new wells through the OGP.
	Health & Safety	Health & safety standards and legislation	Risk includes bringing HC to surface on the MODU and handling through a temporary processing facility	4	Common industry practice. Hydrocarbons will be flowed back to the OGP for processing through existing facilities.	2	Option 2 scores lowest in relation to health and safety as hydrocarbons will be flowed back to existing facilities. However, Option 1 is common industry practice.
	Technical	Technical feasibility	Common industry practice. Reduced technical risk by eliminating the requirement for coil hose, nitrogen pumping and additional wireline activities required for perforating.	1	Technically feasible but increased technical risk due to requirement for coil hose, nitrogen pumping and additional wireline activities required for perforating.	5	Option 1 scores lowest in relation to technical feasibility as is common industry practice and has a reduced technical risk.
Environmental Score				**30**		**21**	Whilst Option 2 scores slightly lower for combined environmental and social footprints, Option 1, is a commonly used method in the Otway region with impacts and risks well understood. The significant difference between the technical and economics of Option 1 compared with that of Option 2, offsets the differences between environmental criteria of the 2 options.
Other Focus Areas				**6**		**12**	
Total Score				**36**		**33**	

3.9.6.3 Hydrotest Fluid Discharge Qualitative Assessment of Alternatives

Beach will complete hydrostatic testing to determine the integrity of subsea infrastructure. Flowlines will be filled with inhibited seawater and subjected to test pressures that will meet design code requirements, typically significantly above any pressures seen during operation.

Two options were considered for the disposal of hydrotest discharges for the Project which are:

- Option 1 - Discharge to the marine environment
- Option 2 - Discharge to plant via OGPP

Table 3-15 provides a comparison of criteria for each option as per previous methodology.

Table 3-15: Hydrotest Fluid Discharge Qualitative Assessment of Alternatives

Focus Area		**Criteria**	**Option 1** – Discharge to marine environment	**Score**	**Option 2** – Discharge to plant via OGPP	**Score**	**Summary**
Environmental	Physical presence	Interaction with other users	No impact identified.	**3**	No impact identified.	**3**	No material difference between options
		Seabed disturbance	No impact identified.	**3**	No impact identified.	**3**	No material difference between options
		Interaction with marine fauna	No impact identified.	**3**	No impact identified.	**3**	No material difference between options
	Emissions	Light emissions	No impact identified.	**3**	No impact identified.	**3**	No material difference between options
		Underwater noise emissions	No impact identified.	**3**	No impact identified.	**3**	No material difference between options
		Atmospheric / GHG emissions	No impact identified.	**3**	No impact identified.	**3**	No material difference between options
	Discharges	Planned discharges	Temporary and localised changes to water quality	**4**	No impact identified.	**1**	Option 2 scores lowest in relation to planned discharges as there will be no discharges to the marine environment with this option.
		Unplanned discharges	Similar risk of unplanned discharge	**3**	Similar risk of unplanned discharge	**3**	No material difference between options
	Introduction of invasive marine species	Invasive marine species (IMS)	No impact identified.	**3**	No impact identified.	**3**	No material difference between options
	Lifecycle environmental impacts	Consideration of relative life-of-field impact	Temporary activity	**N/A**	Temporary activity	**N/A**	Temporary activity, therefore, lifecycle environmental impacts are not considered applicable for this assessment.
Other Focus Areas	Economics	Economic viability	No additional cost.	**1**	Potentially requires existing production from existing Thylacine/Geographe Fields to be taken offline. Added economic risk should production stay offline longer than planned.	**5**	Option 1 scores lowest in relation to economics as Option 2 would require existing facilities to pause production.
	Health & Safety	Health & safety standards and legislation	Common industry practice,	**4**	Common industry practice. Fluids will be flowed back to the Otway Gas Plant for processing through existing facilities.	**2**	Option 2 scores lowest in relation to health and safety as hydrocarbons will be flowed back to existing facilities. However, Option 1 is common industry practice.
	Technical	Technical feasibility	Technically feasible, common industry practice.	**3**	Technically feasible, common industry practice.	**3**	No material difference between options
Environmental Score				**28**		**25**	The qualitative assessment of each concept shows similar results with Option 2 – Discharge to plant having, having a very slightly lower environmental footprint. Similarly, Option 1 – Discharge to the marine environment has a slightly lower score for other focus areas. Both are commonly used methods in the Otway region with impacts and risks well understood. Therefore, for the purposes of this OPP, Beach Energy will carry both options through for assessment
Other Focus Areas				**8**		**10**	
Total Score				**36**		**35**	

4 Description of the Environment

The physical, biological, and socio-economic environment that may be affected by the Project is described in this section, together with the details of the particular relevant values and sensitivities of that environment.

The existing environment that may be affected by the Project is defined as the area where a change to ambient environmental conditions may potentially occur as a result of planned activities or unplanned events. It is noted that a change does not always imply that an adverse impact will occur; for example, a change may be required over a particular exposure value or over a consistent period of time for an adverse impact to occur.

Table 4-1 and Figure 4-1 detail the areas associated with the Project that are used to describe the environmental that may be affected. In addition to those zones, aspect-specific EMBAs are defined in the environmental impact evaluation sections (Section 5), including light EMBAs and noise EMBAs. Where relevant, these EMBAs are shown spatially within this chapter.

Table 4-1: Description of the Areas Used to Define the Existing Environment

Zones	Description
Project Area	The Project Area is within Commonwealth waters and is where all infrastructure and activities associated with the Project will be undertaken as detailed in Section3.5 The EPBC Protected Matters Search Tool (PMST) Report for the Project Area is provided in Appendix A.
Planning Area	The Planning Area is within Commonwealth, Victorian and Tasmanian waters and reaches Victorian and Tasmanian (King Island) shorelines (Figure 4-1). The Planning Area is based on a combination of the MDO (Diesel) Planning Area and Condensate Planning Area based on the spill modelling to the low thresholds as detailed in Section 7.4. for two separate release locations for conservatism. The PMST Report for the Planning Area is in Appendix B.

4.1 Regional context

The Project Area and Planning Area are within the South-east Marine Region, with the Project Area within the Western Bass Strait Shelf Transition and West Tasmania Transition Provincial bioregions (Figure 4-1). The bioregions are based on the Integrated Marine and Coastal Regionalisation of Australia (IMCRA v4.0) which is a spatial framework for classifying Australia’s marine environment into bioregions that make sense ecologically and are at a scale useful for regional planning (CoA 2005).

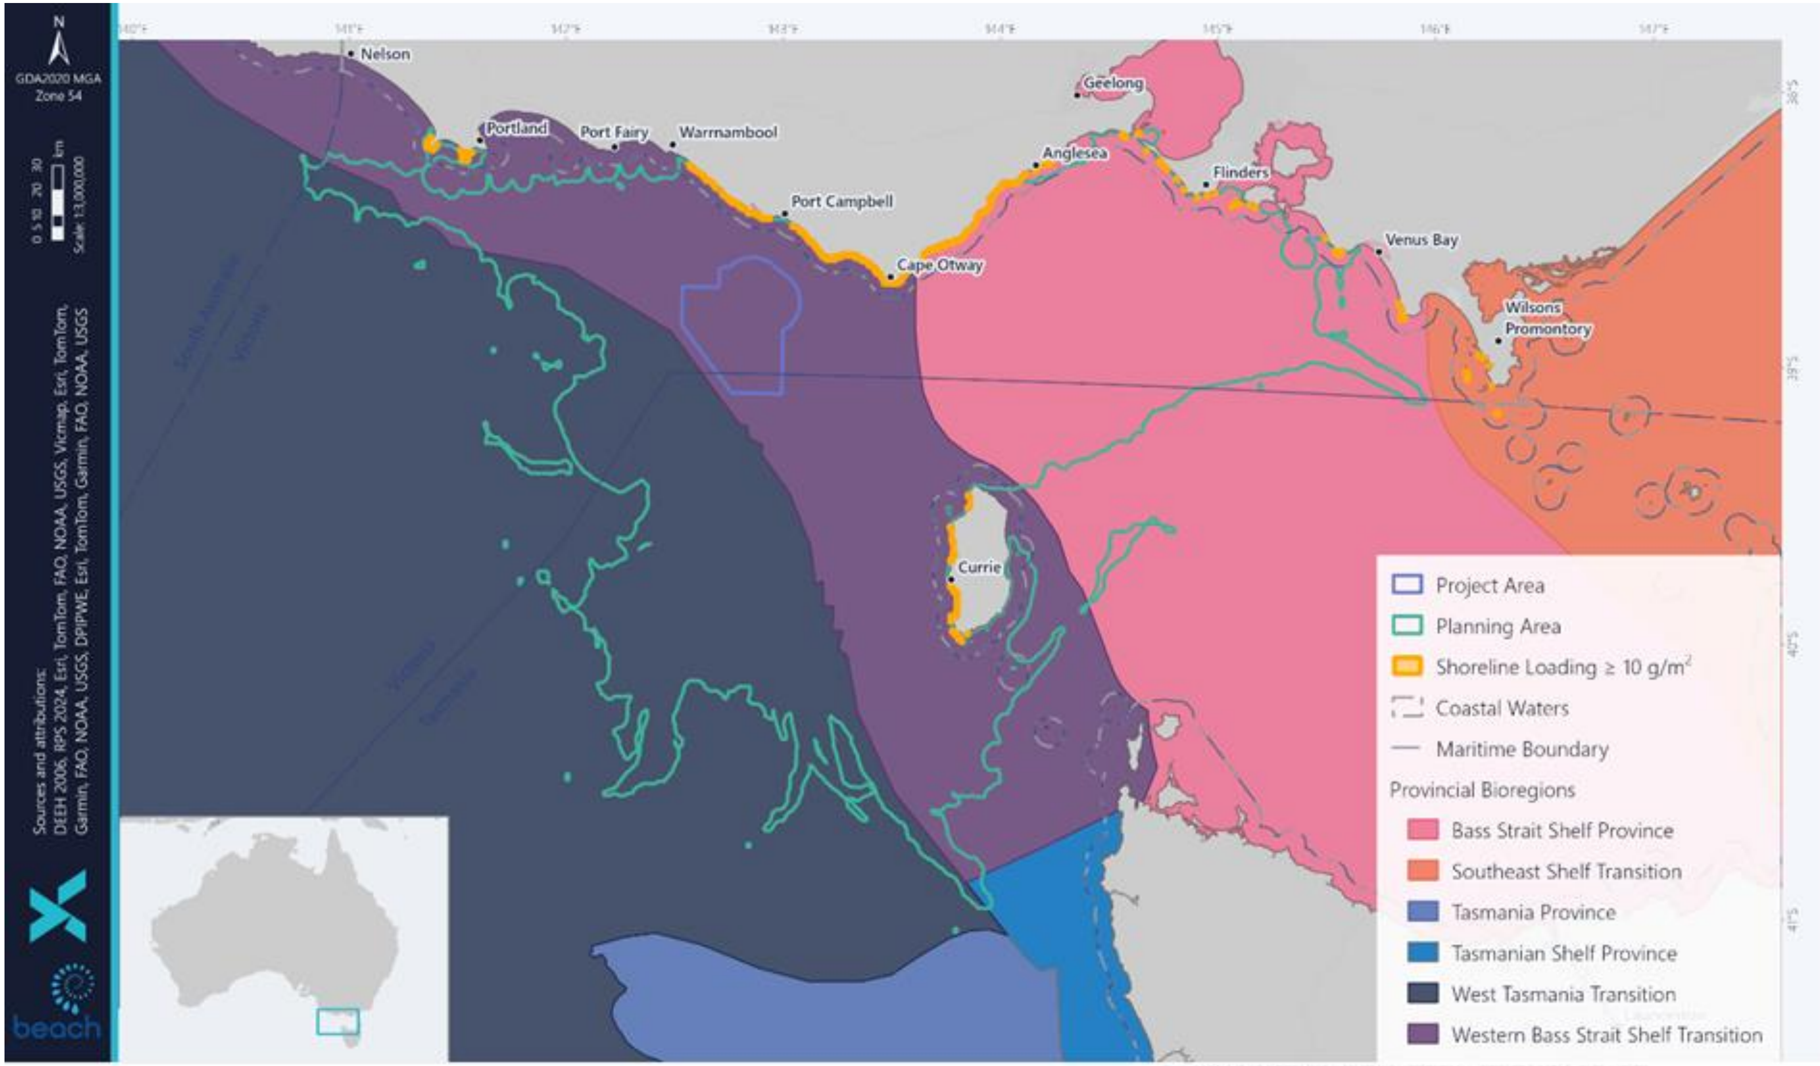

Figure 4-1: Provincial Bioregions within the Project Area and Planning Area

4.2 **Conservation Values and Sensitivities**

The following section details the conservation values and sensitivities identified within the Project Area and Planning Area identified from PMST Reports (Appendix A; Appendix B), reputable, peer-reviewed literature and relevant person consultation.

4.2.1 World Heritage Properties

No World Heritage Properties were identified within the Project or Planning Areas (Appendix A; Appendix B).

4.2.2 Australian Marine Parks

No Australian Marine Parks were identified within the Project Area (Figure 4-2).

Australian Marine Parks identified within the Planning Area (Appendix B) are presented in Table 4-2 and Figure 4-2. Australian Marine Parks identified in the PMST Reports due to the size of the grids used in the PMST but not actually intersecting the Planning Area are listed in the table with 'X'. Australian Marine Parks which intersect the Planning Area are discussed in the subsections below.

Table 4-2: Australian Marine Parks Identified within the Project and Planning Areas

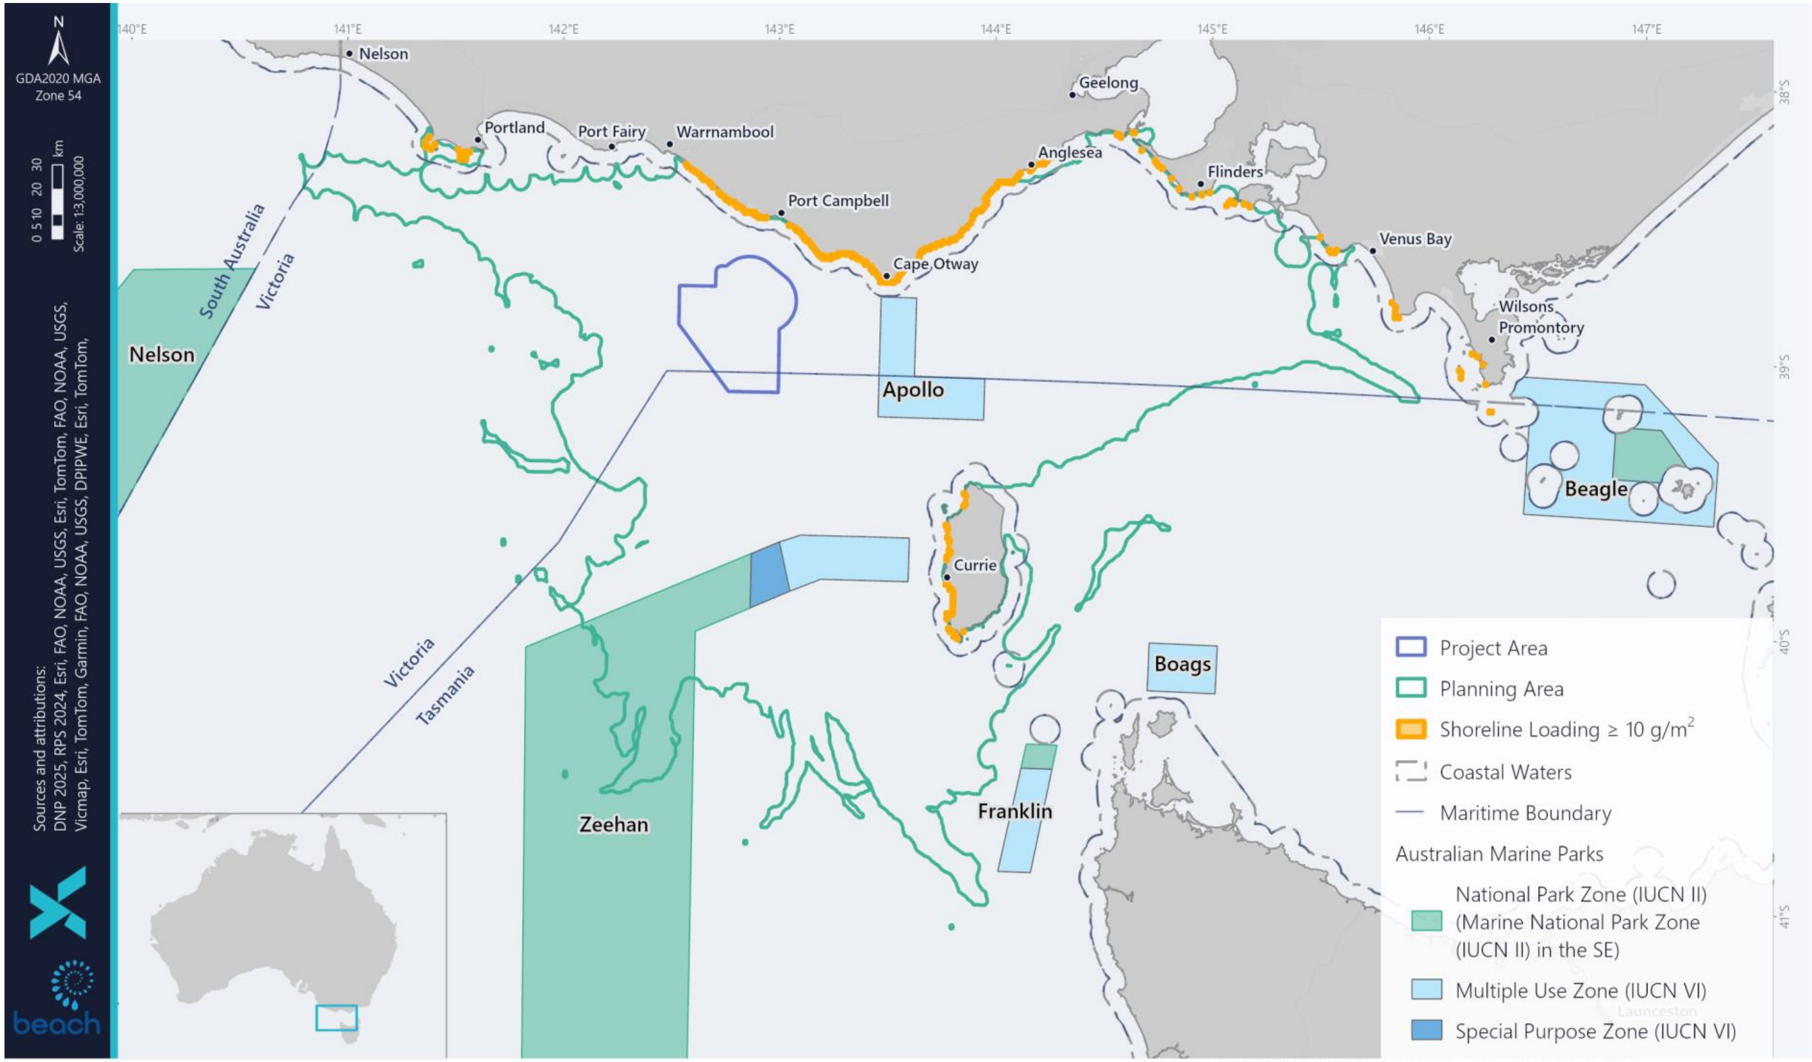
Australian Marine Park	Zone & IUCN Categories	Project Area	Planning Area
Apollo	Multiple Use Zone (IUCN VI)	-	✓
Franklin	Multiple Use Zone (IUCN VI) National Park Zone (IUCN II)	-	X
Zeehan	Multiple Use Zone (IUCN VI)	-	✓
	Special Purpose Zone (IUCN VI)	-	✓
	National Park Zone (IUCN II)	-	✓

The majority of AMPs within the Planning Area are classified as International Union for Conservation of Nature (IUCN) VI – Multiple Use Zone, in which a wide range of sustainable activities are allowed if they do not significantly impact on benthic (seafloor) habitats or have an unacceptable impact on the values of the area. Allowable activities include commercial fishing, general use, recreational fishing, defence, and emergency response. Some forms of commercial fishing, excluding demersal trawl, Danish seine, gill netting (below 183 m) and scallop dredging, are allowed, provided that the operator has approval from the Director of National Parks and abides by the conditions of that approval.

A section of Zeehan AMP within the Planning Area is classified as IUCN VI - Special Purpose Zone, which allows for limited mining and low-level extraction of natural resources. Permitted activities are similar to Multiple Use Zones; however, commercial fishing is not permitted.

Further, a section of the Zeehan AMP within the Planning Area is classified as IUCN II – National Park Zone, which provide for the protection and conservation of ecosystems, habitats and native species in as natural a state as possible. Unauthorised activities include mining, offshore wind energy, CCS, commercial fishing, etc.

The South-east Marine Reserves are managed under the South-east Marine Parks Network Management Plan (DNP 2025).



Document details: G:\CheckOuts\P100383_S04\Output\02_OPP_Updates\P100383_S04_A.aprx, P100383_S00_04_MPAs, XWS-PER003, 24/02/2025

Figure 4-2: Australian Marine Parks within the Planning Area

4.2.2.1 Apollo AMP

The Apollo AMP is located off Apollo Bay on Victoria's west coast in waters 80 m to 120 m deep on the continental shelf. The reserve covers 1,184 km^2 of Commonwealth ocean territory (DNP 2013). The AMP encompasses the continental shelf ecosystem of the major biological zone that extends from South Australia to the west of Tasmania. The area includes the Otway Depression, an undersea valley that joins the Bass Basin to the open ocean. Apollo AMP is a relatively shallow reserve with big waves and strong tidal flows; the rough seas provide habitats for fur seals and school sharks (DNP 2013).

The major conservation values of the Apollo AMP (DNP 2013) are:

- ecosystems, habitats, and communities associated with the Western Bass Strait Shelf Transition and the Bass Strait Shelf Province and associated with the seafloor features: deep/hole/valley and shelf.
- important migration area for blue, fin, sei and humpback whales.
- important foraging area for black-browed and shy albatross, Australasian gannet, short-tailed shearwater and crested tern.
- cultural and heritage site - wreck of the MV City of Rayville.

4.2.2.2 Zeehan AMP

The Zeehan AMP covers an area of 19,897 km^2 to the west and south-west of King Island in Commonwealth waters surrounding north-western Tasmania (DNP 2013). It covers a broad depth range from the shallow continental shelf depth of 50 m to the abyssal plain which is over 3,000 m deep. The AMP spans the continental shelf, continental slope and deeper water ecosystems of the major biological zone that extends from South Australia to the west of Tasmania. Four submarine canyons incise the continental slope, extending from the shelf edge to the abyssal plains. A rich community made up of large sponges and other permanently attached or fixed invertebrates is present on the continental shelf, including giant crab (*Pseudocarcinus gigas*). Concentrations of larval blue wahoo (*Seriolella brama*) and ocean perch (*Helicolenus* spp.) demonstrate the role of the area as a nursery ground.

Rocky limestone banks provide important seabed habitats for a variety of commercial fish and crustacean species including the giant crab. The area is also a foraging area for a variety of seabirds such as fairy prion, shy albatross, silver gull, and short-tailed shearwater (DNP 2013).

The major conservation values for the Zeehan AMP (DNP 2013) are:

- examples of ecosystems, habitats and communities associated with the Tasmania Province, the West Tasmania Transition and the Western Bass Strait Shelf Transition and associated with the seafloor features: abyssal plain/deep ocean floor, canyon, deep/hole/valley, knoll/abyssal hill, shelf, and slope.
- important migration area for blue and humpback whales.
- important foraging habitat for black-browed, wandering and shy albatrosses, and great-winged and cape petrels.

4.2.3 National Heritage Places

No National Heritage Places were identified within the Project Area (Figure 4-3 ; Appendix A).

National Heritage Places identified within the Planning Area (Appendix B) are presented in Table 4-3 and Figure 4-3. National Heritage Places which overlap the Planning Area are described in the subsections below.

Table 4-3: National Heritage Places Identified within the Project Area and Planning Area

National Heritage Places	Class	Status	Coastal Component	Project Area	Planning Area
Great Ocean Road and Scenic Environs	Historic	Listed place	✓	-	✓
Point Nepean Defence Sites and Quarantine Station Area	Historic	Listed place	✓	-	✓
Quarantine Station and Surrounds (within Point Nepean Site)	Historic	Within listed place	✓	-	✓

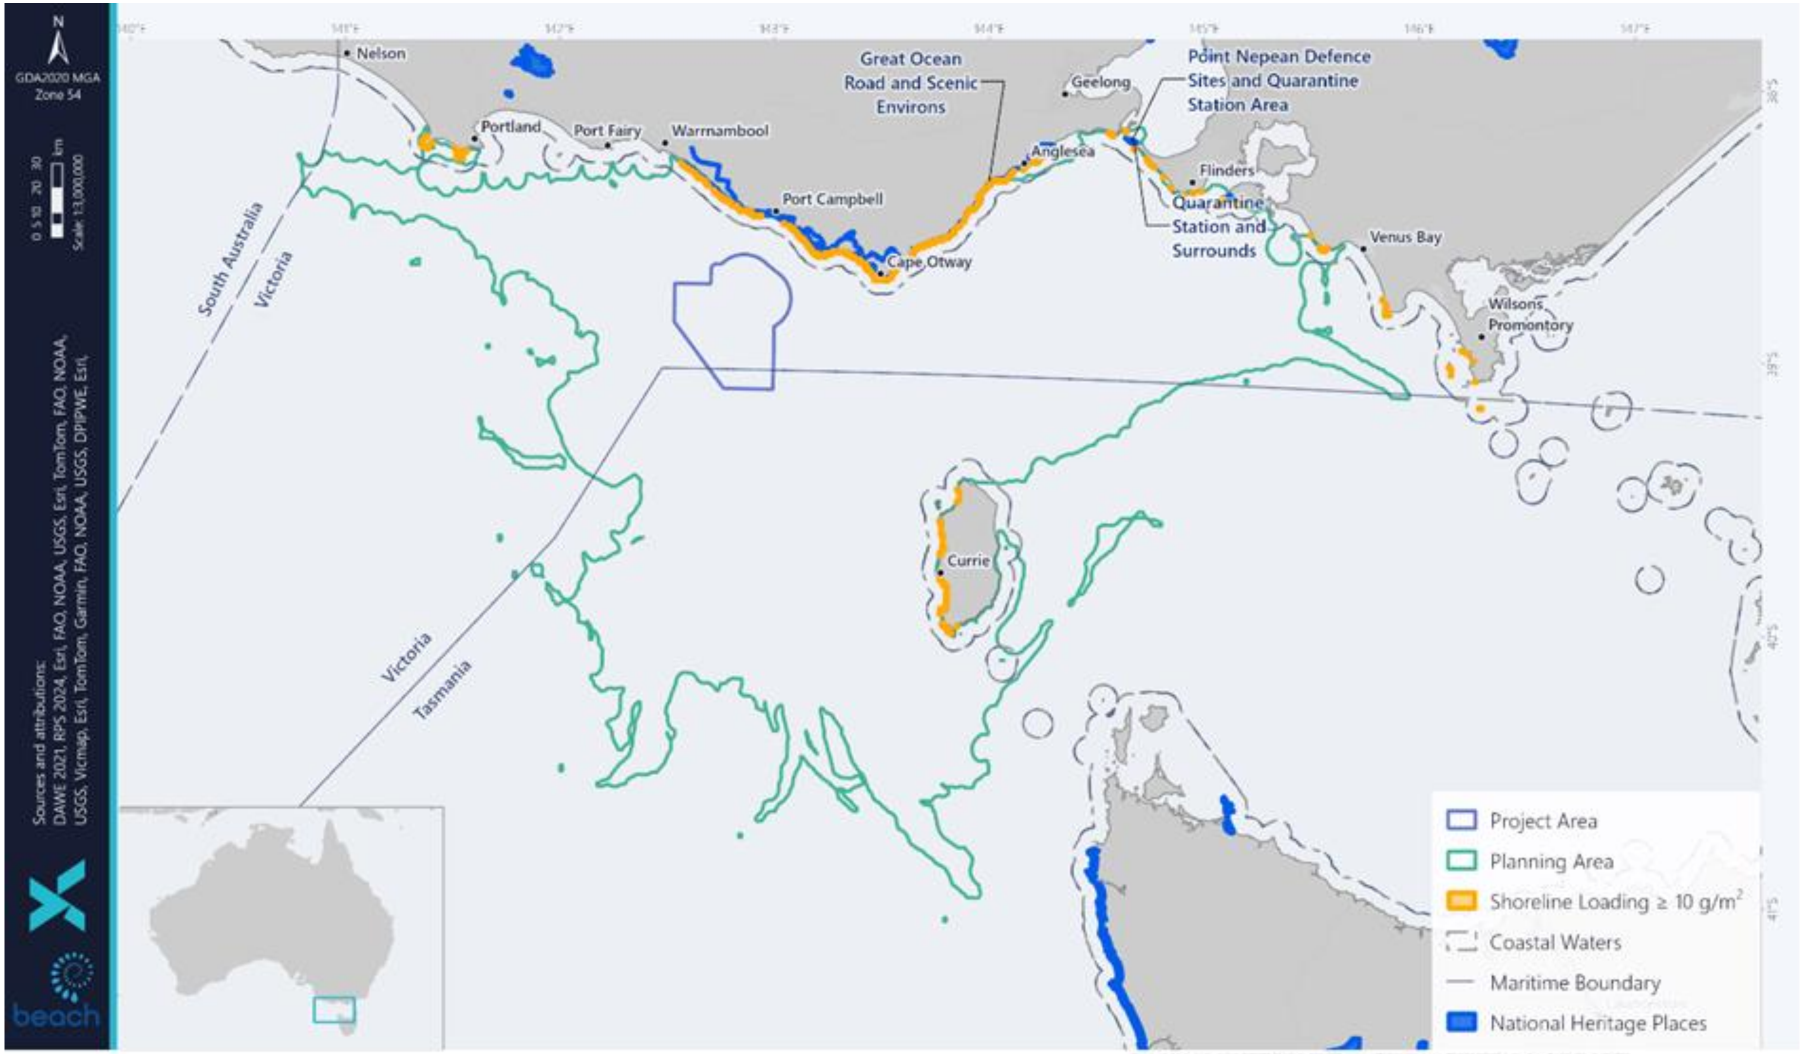


Figure 4-3: National Heritage Places within the Planning Area

4.2.3.1 Great Ocean Road and Scenic Environs

The Australian Heritage Council found the Great Ocean Road and its scenic environs road from Torquay to Allansford, a journey of 242 km, as a place of outstanding national heritage significance. Constructed by workers, including more than 3,000 returned servicemen, as a memorial to First World War servicemen, the Great Ocean Road is a significant reminder of the participation of Australian servicemen in the First World War, the Australian community's appreciation of their service, and the support provided for the welfare of servicemen and women upon returning to Australia.

The scenic environs include all views from the Great Ocean Road and Great Ocean Walk, including the Twelve Apostles, the Bay of Islands and Bay of Martyrs. The coastline from Lorne to Kennett River is among the world's most dramatic cliff and ocean scenery able to be viewed from a vehicle.

Along the length of the Great Ocean Road, the pullover points, and lookouts beside or nearby the road provide travellers with spectacular views of the coastline, hinterland, and Bass Strait seascape, framed only by cliffs, lighthouses and unencumbered by intrusive built structures. The place is also listed for its; outstanding rocky coastline, dinosaur fossil sites, geomorphological monitoring sites, its association with the pioneering landscape architect Edna Walling, and for the significance of Bells Beach to surfing.

4.2.3.2 Point Nepean Defence Sites and Quarantine Station Area including Quarantine Station and Surrounds

Point Nepean comprises approximately 520 ha at the western end of the Mornington Peninsula, along the southern coast of Port Phillip Bay. The coastline at Point Nepean is rocky with cliffs as well as Pleistocene and Holocene dunes. Ninety species of birds have been recorded at the site.

Point Nepean demonstrates the primary importance of coastal defence as well as Victorian and national quarantine processes. It contains the oldest surviving quarantine accommodation buildings in Australia which was established in 1852 after the discovery of gold which saw 100,000 migrants arriving to the region by sea.

4.2.4 Commonwealth Heritage Places

No Commonwealth Heritage Places were identified within the Project Area (Appendix A). One natural Commonwealth Heritage Place, Swan Island and Naval Waters, was identified in the Planning Area (Appendix B) however this is due to the size of the grids used in the PMST and does not actually overlap the Planning Area.

4.2.5 Maritime Archaeological Heritage

Shipwrecks over 75 years old are protected within Commonwealth waters under the *Underwater Cultural Heritage Act 2018* (Cth), in Victorian State waters under the *Heritage Act 1995* (Vic) and in Tasmanian waters under the *Historic Cultural Heritage Act 1995* (Tas). Some historic shipwrecks lie within protected zones of up to 800 m radius, typically when the shipwreck is considered fragile or at particular risk of interference. The primary purpose of the *Heritage Act 1995* (Vic) is to provide for the protection and conservation of the cultural heritage of the State and is administered by Heritage Victoria **[PC322].** In Tasmania, the Historic Heritage Section of the Parks and Wildlife Service is the government authority responsible for the management of the State's historic shipwrecks and other maritime heritage sites.

Within the Planning Area there is a 130 km stretch of coastline known as the 'Shipwreck Coast' because of the large number of shipwrecks present, with most wrecked during the late nineteenth century. The strong waves, rocky reefs and cliffs of the region contributed to the loss of these ships. More than 180 shipwrecks are believed to lie along the Shipwreck Coast (DELWP 2016a) and well-known wrecks include Loch Ard (1878), Thistle (1837), Children (1839), John Scott (1858) and Schomberg (1855).

The wrecks represent significant archaeological, educational, and recreational (i.e. diving) opportunities for locals, students and tourists (Flagstaff Hill 2015). There are 188 documented historic wrecks in the Planning Area, one of which (S.S. Alert) has a protection zone (Figure 4-4). The S.S. Selje, a Norwegian cargo ship, wrecked in 1929 is 688 m from the Project Area (Figure 4-4).

Beach commissioned a seabed site assessment for the Otway Basin Environmental Survey (Ramboll 2020; Appendix C). As part of the seabed site assessment a sub-bottom profiler was used to identify any buried objects. The penetration of the sub-bottom profiler was limited to a maximum of approximately 100 cm, with the average thickness of the sand patches being approximately 20-30 cm precluding burial of a shipwreck.

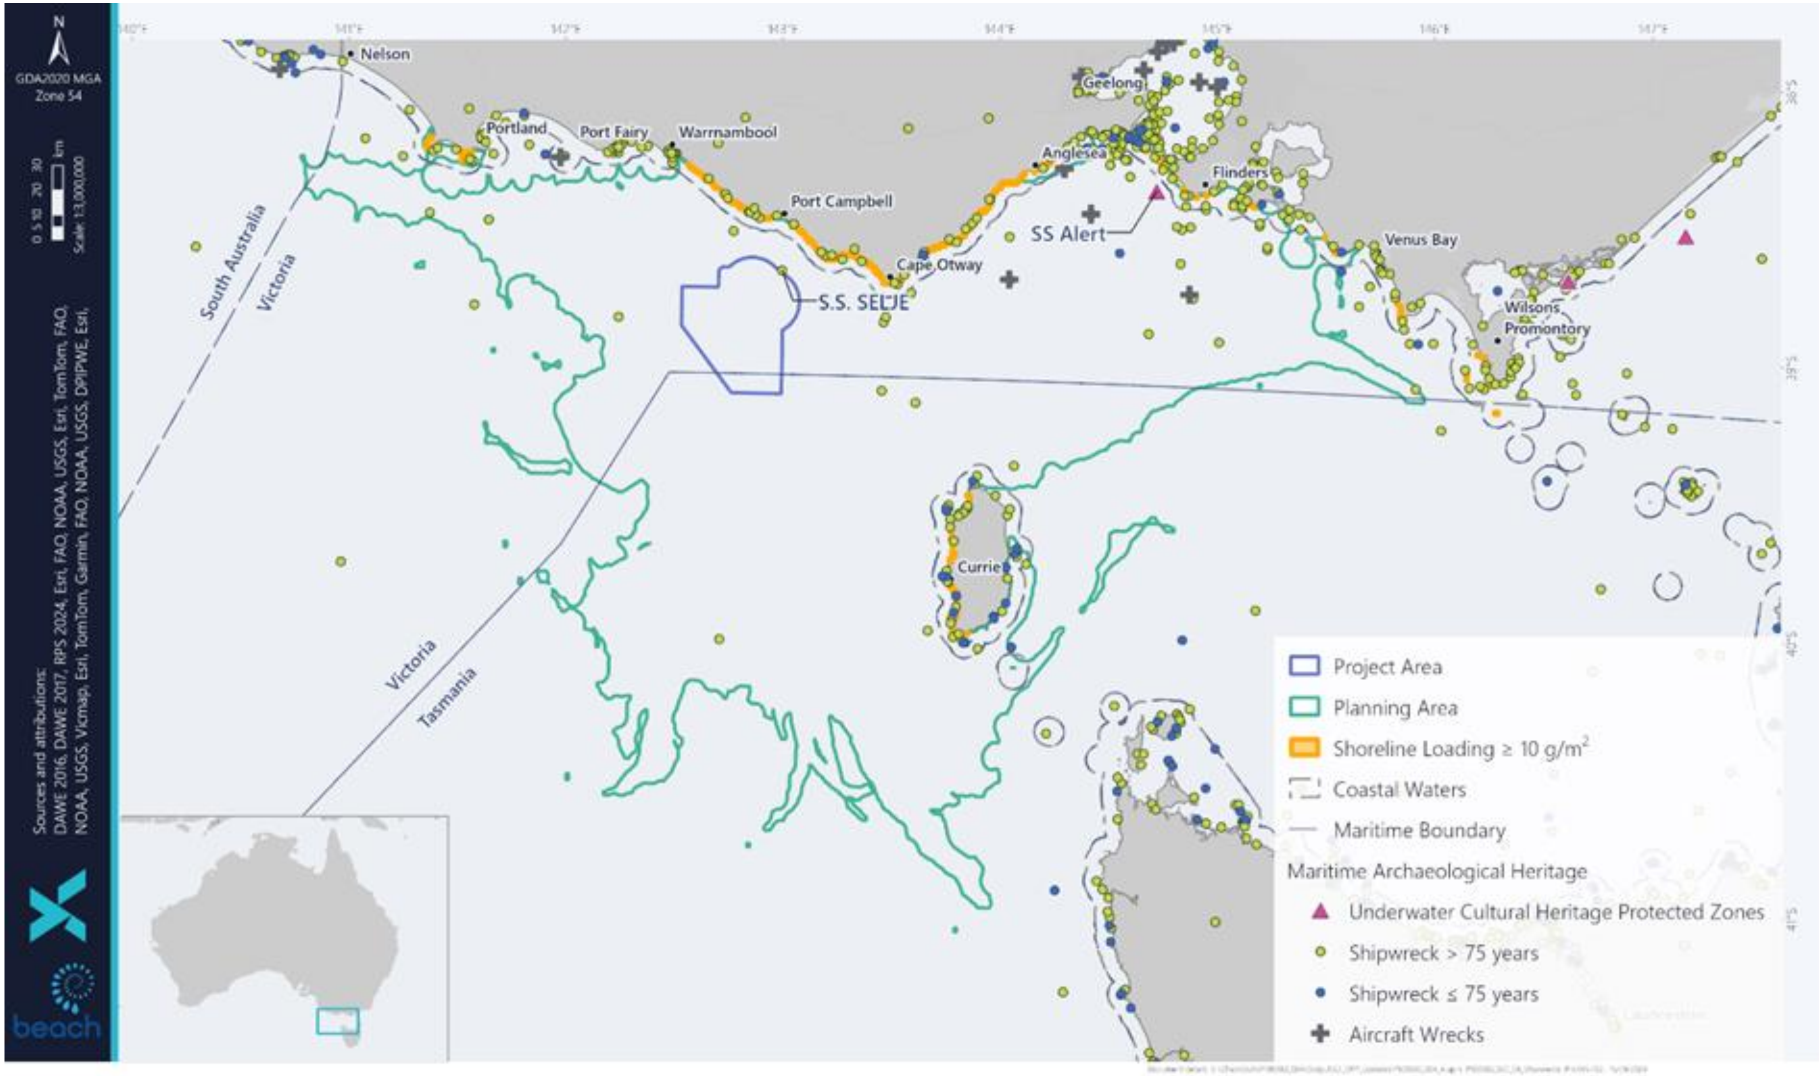

Figure 4-4: Maritime Archaeological Heritage within the Project and Planning Areas

4.2.6 Wetlands of International Importance

No Wetlands of International Importance were identified in the Project Area (Appendix A).

Wetlands of International Importance (Ramsar-listed wetlands) identified within the Planning Area (Appendix B) are presented in Table 4-4 and Figure 4-5. Wetlands identified in the PMST Report due to the size of the grids used in the PMST but not actually intersecting the Planning Area are listed in the table with 'X'. Wetlands of International Importance which intersect the Planning Area and have a coastal component which may be exposed to hydrocarbons from a spill event are described in the subsections below.

As defined in the OPGGS(E)R, particular relevant values and sensitivities include: the ecological character of a declared Ramsar wetland within the meaning of that Act. The ecological character and values of the overlapping Ramsar sites are described below and are from the Australian Wetlands Database (DCCEEW 2024b).

Table 4-4: Wetlands of International Importance within the Planning Area

Wetland of International Importance	Coastal Component	Project Area	Planning Area
Glenelg Estuary and Discovery Bay Wetlands	✓	-	X
Lavinia	✓	-	✓
Port Phillip Bay (Western Shoreline) and Bellarine Peninsula	✓	-	X
Western Port	✓	-	X

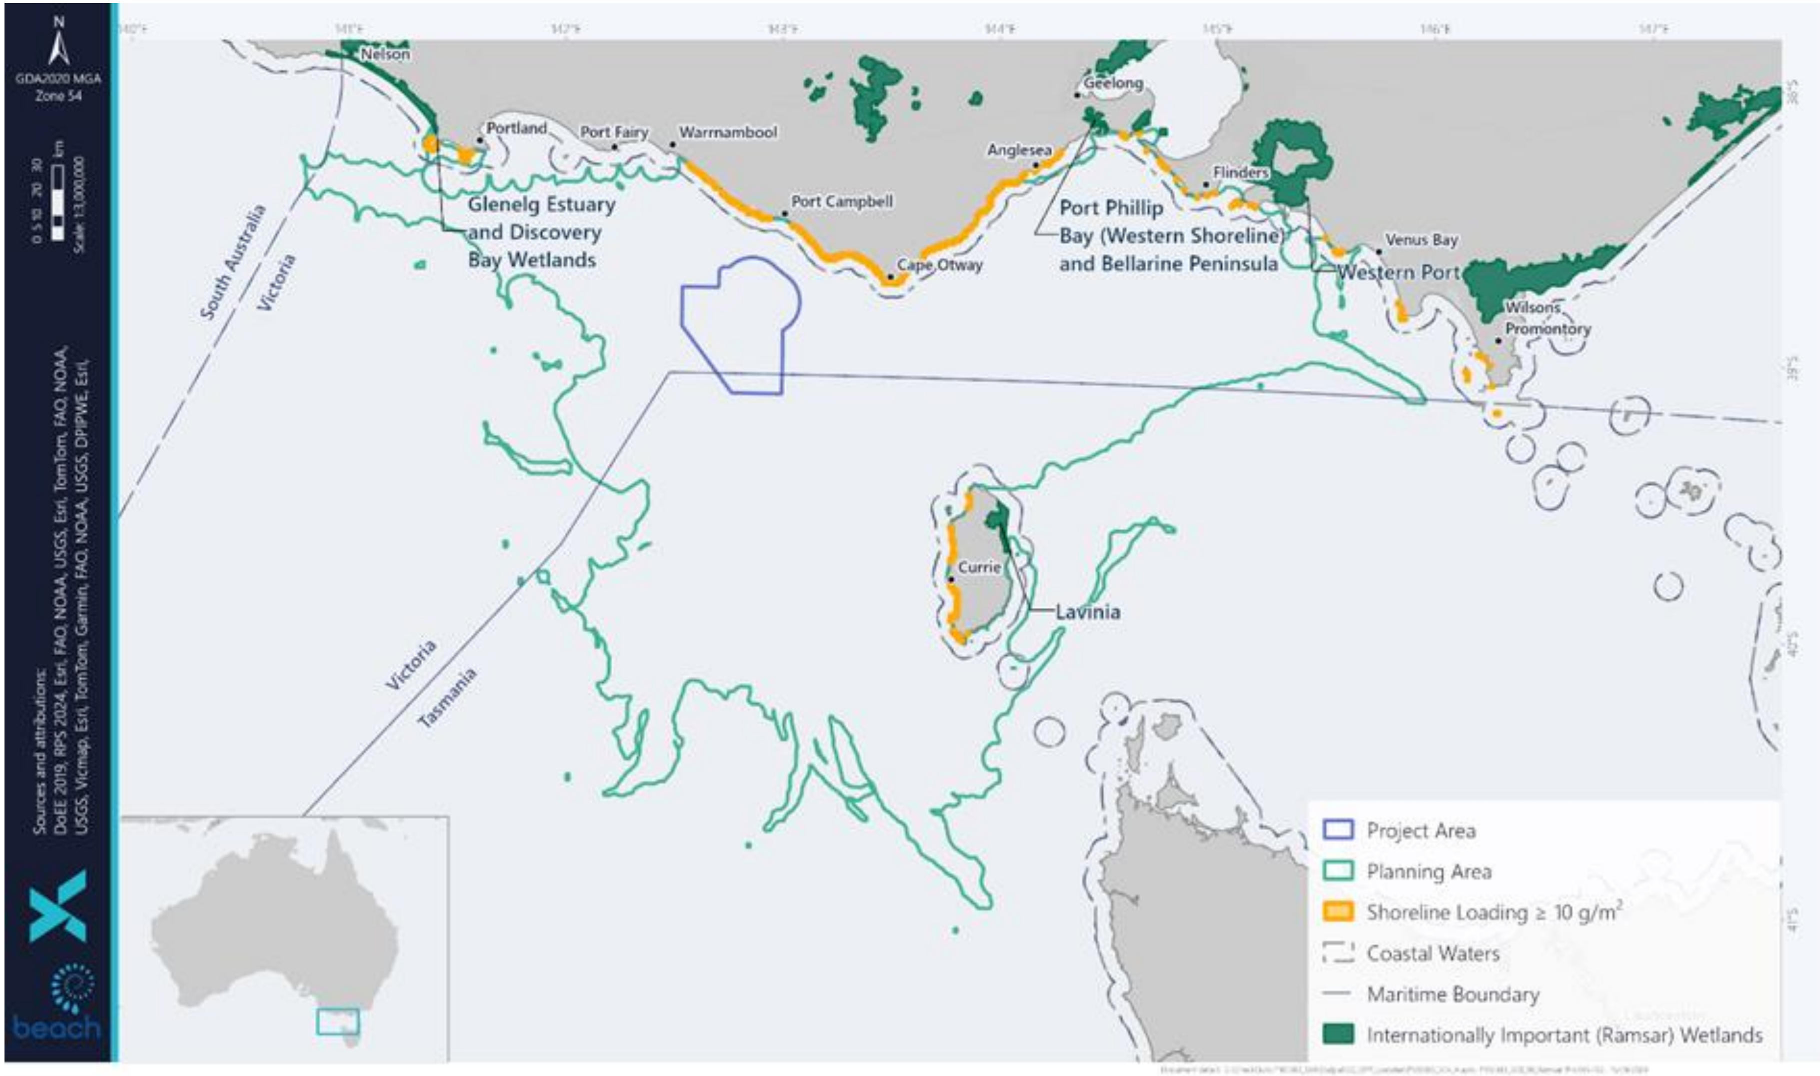

Figure 4-5: Wetlands of International Importance (Ramsar) within the Planning Area

4.2.6.1 Lavinia

The Lavinia Ramsar site is located on the north-east coast of King Island, Tasmania. The boundary of the site forms the Lavinia State Reserve, with major wetlands in the reserve including the Sea Elephant River estuary area, Lake Martha Lavinia, Penny's Lagoon, and the Nook Swamps. It is subject to the Lavinia Nature Reserve Management Plan (2000) (in draft).

The shifting sands of the Sea Elephant River's mouth have caused a large back-up of brackish water in the Ramsar site, creating the saltmarsh which extends up to 5 km inland. The present landscape is the result of several distinct periods of dune formation. The extensive Nook Swamps, which run roughly parallel to the coast, occupy a flat depression between the newer parallel dunes to the east of the site and the older dunes further inland. Water flows into the wetlands from the catchment through surface channels and groundwater and leaves mainly from the bar at the mouth of the Sea Elephant River and seepage through the young dune systems emerging as beach springs.

The Lavinia State Reserve is one of the few largely unaltered areas of the island and contains much of the remaining native vegetation on King Island. The vegetation communities include Succulent Saline Herbland, Coastal Grass and Herbfield, Coastal Scrub and King Island Eucalyptus globulus Woodland. The freshwater areas of the Nook Swamps are dominated by swamp forest. Nook Swamps and the surrounding wetlands contain extensive peatlands.

The site is an important refuge for a collection of regional and nationally threatened species, including the nationally endangered, Orange-bellied Parrot. This parrot is heavily dependent upon the samphire plant, which occurs in the saltmarsh, for food during migration. They also roost at night in the trees and scrub surrounding the Sea Elephant River estuary.

Several species of birds which use the reserve are rarely observed on the Tasmanian mainland, including the Dusky Moorhen, Nankeen Kestrel, Rufous Night Heron and the Golden-headed Cisticola.

The site is currently used for conservation and recreation, including boating, fishing, camping and off-road driving. There are artefacts of Indigenous Australian occupation on King Island that date back to the last ice age when the island was connected to Tasmania and mainland Australia via the Bassian Plain.

There are ten critical components and processes identified in the Ramsar site: wetland vegetation communities, regional and national rare plant species, regionally rare bird species, Kind Island scrubtit, Orange-bellied Parrot, water and sea birds, migratory birds, striped marsh frog and the green and gold frog. Elements essential to the site are the marine west coast climate, mild temperatures along with wind direction and speed. Sandy deposits dominant the site, inland sand sheets cover majority of the western area of the site (PWS 2000). Between these sand sheets and the eastern coast there is an important geoconservation feature, several sand dunes. The dunes impede drainage from inland causing extensive swamps, lakes and river reflections. Terrestrial vegetation communities are important in providing the overall structure by buffering and supporting habitat (PWS 2000). Wetland vegetation in the Ramsar site include swamp forest and forested peatlands are rare and vulnerable in the region. Along with other types the vegetation, the wetland provides support and provides habitat for rare flora and fauna highlighting the significance of the wetlands. Six wetland associated species have been recorded within the site. Rare bird and frog species are dependent on the wetland habitat along with ten migratory birds and other water and sea birds. Benefits provided by the Lavinia Ramsar site include aquaculture (oyster farming), tourism, education, and scientific value.

There has been considerable damage caused to the saltmarsh community by vehicle disturbance in the Sea Elephant Estuary and the coastal strip (PWS 2000). Vegetation clearance in parts of the catchment upstream as contributed to altered water balance due to less evapotranspiration of rainfall and build-up of the groundwater. There are threats to flora and fauna by invasive weeds and fungus. Although aquaculture plays a role in the Lavinia benefits risk from inputs of nutrients from feeding and occasional opening of the barred estuary for tidal flushing although with farm vehicles disturbance can impact the site.

4.2.7 Nationally Important Wetlands

No Nationally Important Wetlands were identified in the Project Area (Appendix A).

Nationally Important Wetlands identified within the Planning Area (Appendix B) are presented in Table 4-5 and Figure 4-6. Wetlands identified in the PMST Report due to the size of the grids used in the PMST but not actually intersecting the Planning Area are listed in the Table with 'X'. Nationally Important Wetlands which intersect the Planning Area and have a coastal component which may be exposed to hydrocarbons from a spill event are discussed in the subsections below. Information provided on these wetlands is from the DCCEEW Directory of Important Wetlands in Australia.

Table 4-5: Nationally Important Wetlands Identified within the Planning Area

Nationally Important Wetland	State	Coastal component	Project Area	Planning Area
Aire River	VIC	-	-	X
Bungaree Lagoon	TAS	-	-	X
Lake Connewarre State Wildlife Reserve	VIC	✓	-	X
Lake Flannigan	TAS	-	-	X
Lavinia Nature Reserve	TAS	✓	-	X

Figure 4-6: Nationally Important Wetlands within the Planning Area

4.2.7.1 Western Port

Western Port is a large bay with extensive intertidal flats, mangroves, saltmarsh, seagrass beds, several small islands and two large islands.

Western Port is a high value wetland for its ecological, recreational, tourist, scientific, educational, cultural, and scenic features. It is a very good example of a saltmarsh-mangrove-seagrass wetland system.

Western Port is of high value for its avifauna and flora. The bays seagrass flats are nursery grounds for King George Whiting and other species of fish and many birds depend on these areas. Many sites in Western Port are of special significance as breeding, roosting, or feeding sites for waterbirds, including migratory waders.

4.2.8 Victorian Protected Areas – Marine

Victoria has a representative system of marine protected areas consisting of 13 Marine National Parks and 11 Marine Sanctuaries established under the *National Parks Act 1975* (Vic).

No Victorian marine protected areas were identified within the Project Area (Appendix A).

Victorian marine protected areas identified in the Planning Area (Appendix B) are presented in Table 4-6 and Figure 4-7. Some Victorian marine protected areas are identified in the PMST Report due to the size of the grids used in the PMST but do not actually intersect the Planning Area. These are denoted in the table below with 'X'. Victorian marine protected areas which intersect the Planning Area are described in the subsections below.

Figure 4-7: State Marine Protected Areas within the Planning Area

4.2.8.1 Barwon Bluff Marine Sanctuary

Barwon Bluff Marine Sanctuary is managed through the Barwon Bluff Marine Sanctuary Management Plan (Parks Victoria 2007b). The marine sanctuary protects 17 ha of reef and marine environment near the mouth of the Barwon River. The management plan identifies the key values of the sanctuary as:

- Intertidal reef platforms with a high diversity of invertebrate fauna and flora.
- Subtidal reefs that support diverse and abundant flora, including kelps, other brown algae, and green and red algae.
- Calcarenite and basalt reefs extending from The Bluff that are of regional geological significance.
- Intertidal habitats that support resident and migratory shorebirds, including threatened species.
- Subtidal habitats that support sedentary fish and are also used by migratory fish and marine mammals.
- Marine habitats and species that are of scientific interest and valuable for marine education.
- An important landmark and area for gathering fish and shellfish for the Wathaurong people.
- A strong historic and ongoing connection with marine education.
- Remnants from the Earl of Charlemont, a heritage-listed shipwreck.

4.2.8.2 Bunurong Marine National Park

The Bunurong Marine National Park is classified as IUCN II (National Parks) and the Bunurong Marine Park as IUCN IV (Habitat/species management area).

The Bunurong Marine National Park and Bunurong Marine Park are managed through the Bunurong Marine National Park Management Plan (Parks Victoria 2006b). The Plan identifies the key values of the Parks as:

- Extensive intertidal rock platforms and subtidal rocky reefs with a geology and form that is uncommon along the Victorian coast.
- Abundant and diverse marine flora and fauna including over 22 species of marine flora and fauna recorded, or presumed to be, at their eastern or western distributional limits (Plummer et al. 2003).
- Highest diversity of intertidal and shallow subtidal invertebrate fauna recorded in Victoria on sandstone (ECC 2000).
- High proportion of the common invertebrates occurring along the Victorian coast.
- High diversity of vegetation communities, many of which are considered rare, depleted or endangered within the region (WGCMA 2003; Carr 2003).
- Important coastal habitat for several threatened species.

- Spectacular coastal scenery, featuring rugged sandstone cliffs, rocky headlands, intertidal rock platforms and sandy cove.
- Eagles Nest, a prominent rock stack, recognised as a site of national geological and geomorphological significance (Buckley 1993).
- One of the richest Mesozoic fossil areas in Victoria.
- Landscape and seascape of cultural significance to Indigenous people.
- Numerous places and objects of significance to Indigenous people.
- European history rich in diversity, including sites associated with shipping, coal mining, holidaying and living on the coast.
- Two historical shipwrecks listed on the Victorian Heritage Register (Heritage Victoria 2004).
- Opportunities for cultural values investigation in an area protected from human disturbance.
- Extensive subtidal reefs with magnificent underwater seascapes, offering numerous opportunities for diving and snorkelling.
- Highly accessible intertidal rock platforms offering opportunities for rock-pooling, marine education, and interpretation.
- Spectacular coastal drive, with numerous lookouts and panoramic views of the coast and surrounding waters.
- Coastline offering opportunities for swimming, surfing, boating, fishing, and rock-pooling in a natural setting.

4.2.8.3 Discovery Bay Marine National Park

Discovery Bay Marine National Park protects 2,770 ha within the Southern Ocean and experiences some of the highest wave energy environments in Victoria. It is managed under the Ngootyoong Gunditj Ngootyoong Mara South West Management Plan (Parks Victoria 2015). It is part of Koonang Mirring (Sea Country) with the coast of Discovery Bay filled with Aboriginal artefacts that are evidence of earlier ages of plenty and integral to the cultural heritage of the Gunditjmara people.

The Bonney Coast, which extends from Robe in South Australia to Discovery Bay, is a productive area because of a nutrient rich cold water upwelling, known as the Bonney Upwelling, which provides a nutrient-rich environment for fish, whales, seals, penguins, and invertebrates (Parks Victoria 2015).

Conservation Action Planning for marine protected areas across Victoria identified two key focal ecosystems in the park (Parks Victoria 2015):

- Subtidal Reefs with six key natural assets – Brown macroalgae dominated beds, large mobile fish including sharks and rays, motile macroinvertebrates, Giant Kelp Forest communities, sessile invertebrate dominated communities such as thick growths of sponges, ascidians, bryozoans and gorgonians, and mixed red algae sessile invertebrate dominated communities.

- Water Column with key assets including planktonic and other species, baleen whales and seabirds.

4.2.8.4 Marengo Reefs Marine Sanctuary

The Marengo Reefs Marine Sanctuary (12 ha) is in Victorian State waters near Marengo and Apollo Bay, which are on the Great Ocean Road, approximately 220 km south-west of Melbourne. The sanctuary protects two small reefs and a wide variety of microhabitats. Protected conditions on the leeward side of the reefs are unusual on this high wave energy coastline and allow for dense growths of bull kelps and other seaweed. There is an abundance of soft corals, sponges, and other marine invertebrates, and over 56 species of fish have been recorded in and around the sanctuary. Seals rest on the outer island of the reef and there are two shipwrecks (the Grange and Woolamai) in the sanctuary (Parks Victoria 2007a).

The Marengo Reefs Marine Sanctuary Management Plan (Parks Victoria 2007a) identifies the environmental, cultural, and social values as:

- Subtidal soft sediments, subtidal rocky reefs, and intertidal reefs.
- High diversity of algal, invertebrate and fish species.
- Australian Fur-seal haul out area.
- Evidence of a long history of Indigenous use, including many Indigenous places and objects nearby.
- Wrecks of coastal and international trade vessels in the vicinity of the sanctuary.
- Spectacular underwater scenery for snorkelling and scuba diving.
- Intertidal areas for exploring rock pools.
- Opportunities for a range of aquatic recreational activities including seal watching.

4.2.8.5 Mushroom Reef Marine Sanctuary

Mushroom Reef Marine Sanctuary covers 80 ha along the southern Mornington Peninsula and protects a system of ancient basalt platforms and reefs. The sanctuary is adjacent to Mornington Peninsula National Park, extending from the high water mark to approximately 1 km offshore. The Mushroom Reef Marine Sanctuary Management Plan (Parks Victoria 2007d) identifies the following important natural values:

- Among the most diverse intertidal and rocky reef communities in Victoria.
- Numerous subtidal pools and boulders in the intertidal area that provide a high complexity of intertidal basalt substrates and a rich variety of microhabitats.
- Subtidal reefs that support diverse and abundant flora including kelps, other brown algae, and green and red algae.
- Sandy bottom habitats that support large beds of *Amphibolis* seagrass and patches of green algae.

- Diverse habitats that support sedentary and migratory fish species.
- A range of reef habitats that support invertebrates including gorgonian fans, seastars, anemones, ascidians, barnacles and soft corals.
- A distinctive basalt causeway that provides habitat for numerous crab, seastar and gastropod species.
- Intertidal habitat that support resident and migratory shorebird species including threatened species.

The Burinyung-Bulluk, one of the six clans that made up the Boonwurrung people, inhabited the coastal area from Point Nepean to Hastings, which incorporates the sanctuary area. The reefs and waters of this coast provided excellent sites for gathering shellfish and hunting fish and seals and were among the most important sources of food for Boonwurrung people (Parks Victoria 2007d).

4.2.8.6 Point Addis Marine National Park

Point Addis Marine National Park lies east of Anglesea and covers 4,600 ha. This park protects representative samples of subtidal soft sediments, subtidal rocky reef, rhodolith beds and intertidal rocky reef habitats. The park also provides habitat for a range of invertebrates, fish, algae, birds and wildlife. The world-famous surfing destination of Bells Beach is within Point Addis Marine National Park.

It is managed under the Management Plan for Point Addis Marine National Park, Point Danger Marine Sanctuary and Eagle Rock Marine Sanctuary (Parks Victoria 2005b) and is classified as IUCN II. The plan identifies the following environmental, cultural, and social values for the parks and sanctuaries:

- Sandy beaches, subtidal soft sediments, subtidal rocky reefs, rhodolith beds and intertidal reefs.
- High diversity of algal, invertebrate and fish species.
- High diversity of sea slugs (opisthobranchs) and other invertebrate communities within Point Danger Marine Sanctuary.
- Evidence of a long history of Indigenous use, including many Indigenous places and objects adjacent to the park and sanctuaries near dunes, headlands, estuaries, and creeks.
- Surf breaks, including those at Bells Beach, which are culturally important to many people associated with surfing.
- Coastal seascapes of significance for many who live in the area or visit.
- Recreational and tourism values.
- Spectacular underwater scenery for snorkelling and scuba diving.
- Intertidal areas for exploring rock pools.
- Opportunities for a range of recreational activities.

- Spectacular seascape complementing well-known visitor experiences on the Great Ocean Road.

4.2.8.7 Port Phillip Heads Marine National Park

Port Phillip Heads Marine National Park protects 3,850 ha across six sections including Swan Bay, Mud Islands, Point Lonsdale, Point Nepean, Popes Eye and Portsea Hole. The Port Phillip Heads Marine National Park is managed under the Port Phillip Heads Marine National Park Management Plan (Parks Victoria 2006c). The plan identifies the key values of the park as:

- Incised entrance to Bay (the Rip) and the 'Heads' at Point Nepean and Point Lonsdale.
- Spectacular dive sites such as the Lonsdale and Nepean Walls and popular recreational dive locations.
- Intertidal rock platforms at Cheviot Beach and Point Lonsdale the coastal landscape of Point Nepean in Point Nepean National Park.
- Bottlenose dolphin populations sites listed under the Ramsar Convention for their importance for migratory wading birds (Swan Bay, Mud Islands).
- Distinctive bird-dominated island ecosystem of Mud Islands.
- Sheltered environments such as the seagrass meadows of Swan Bay.

Indigenous tradition indicates that the Mornington Peninsula side of the park, including Mud Islands is part of Country of the Boonwurrung and that the Bellarine Peninsula side of the park is part of Country of the Wathaurong (Parks Victoria 2006c).

4.2.8.8 The Arches Marine Sanctuary

The Arches Marine Sanctuary protects 45 ha of ocean directly south of Port Campbell. It is managed in conjunction with the Twelve Apostles Marine Park under the Management Plan for Twelve Apostles Marine National Park and The Arches Marine Sanctuary (Parks Victoria 2006d).

It has a spectacular dive site of limestone formations, rocky arches, and canyons. The sanctuary is also ecologically significant, supporting habitats such as kelp forests and a diverse range of sessile invertebrates on the arches and canyons. These habitats support schools of reef fish, seals, and a range of invertebrates such as lobster, abalone, and sea urchins.

It is also important to indigenous culture based on spiritual connection to Sea Country.

4.2.8.9 Twelve Apostles Marine National Park

The Twelve Apostles Marine National Park (75 km^2) is located 7 km east of Port Campbell and covers 16 km of coastline from east of Broken Head to Pebble Point and extends offshore to 5.5 km (Plummer et al. 2003).

The area is representative of the Otway Bioregion and is characterised by a submarine network of towering canyons, caves, arches, and walls with a large variety of seaweed and sponge gardens plus resident schools of reef fish. The park contains areas of calcarenite reef supporting the highest diversity of intertidal and sub-tidal invertebrates found on that rock type in Victoria (DSE 2012).

The park includes large sandy sub-tidal areas consisting of predominantly fine sand with some medium to coarse sand and shell fragment (Plummer et al. 2003). Benthic sampling undertaken within the park in soft sediment habitats at 10 m, 20 m and 40 m water depths identified 31, 29 and 32 species respectively based upon a sample area of $0.1m^2$. These species were predominantly polychaetes, crustaceans, and nematodes with the mean number of individuals decreasing with water depth (Heisler and Parry 2007). No visible macroalgae species were present within these soft sediment areas (Plummer et al. 2003; Holmes et al. 2007). These sandy expanses support high abundances of smaller animals such as worms, small molluscs, and crustaceans; larger animals are less common.

The Twelve Apostles Marine Park is managed in conjunction with the Arches Marine Sanctuary under the Management Plan for Twelve Apostles Marine National Park and The Arches Marine Sanctuary (Parks Victoria 2006d) and is classified as IUCN II. The Plan describes the key environmental, cultural, and social values as:

- Unique limestone rock formations, including the Twelve Apostles.
- Range of marine habitats representative of the Otway marine bioregion.
- Indigenous culture based on spiritual connection to Sea Country and a history of marine resource use.
- Wreck of the Loch Ard (shipwreck).
- Underwater limestone formations of arches and canyons.
- Diverse range of encrusting invertebrates.
- Spectacular dive site.

4.2.8.10 Wilsons Promontory Marine National Park

The Wilsons Promontory Marine National Park protects 15,500 ha and is located approximately 220 km south-east of Melbourne on Victoria’s southernmost tip (Parks Victoria 2006a). Adjacent to Wilsons Promontory Marine National Park are the marine park (overlapped by the Planning Area) and marine reserve (not overlapped by the Planning Area).

Wilsons Promontory Marine National Park is located in the Flinders marine bioregion, as identified by the Interim Marine and Coastal Regionalisation for Australia (IMCRA). The Flinders marine bioregion extends across Bass Strait and is characterised by cool wet winters and warm summers, predominately granite and unconsolidated clastic sediments with rocky headlands and promontories interspersed by long sandy beaches, highly variable wave exposure, and high fish and plant species richness (Parks Victoria 2006a).

The Wilsons Promontory Marine National Park is managed under the Wilsons Promontory Marine National Park Management Plan (Parks Victoria 2006a). The plan identifies the key values of the park as:

- biological communities with distinct biogeographic patterns, including shallow subtidal reefs, deep subtidal reefs, intertidal rocky shores, sandy beaches, seagrass and subtidal soft substrates.

- Important habitat for several threatened shorebird species, including species listed under international migratory bird agreements.
- Important breeding sites for a significant colony of Australian fur seals
- Indigenous cultural lore and interest maintained by the Gunai / Kurnai and Boonwurrung people. Also is part of a past land link to Tasmania occupied and used by Indigenous people.
- magnificent underwater seascapes for diving and snorkelling.

4.2.9 Victorian Protected Areas – Terrestrial

No Victorian terrestrial protected areas were identified within the Project Area (Appendix A).

Victorian terrestrial protected areas identified in the Planning Area (Appendix B) are presented in Table 4-7 and Figure 4-8. Some Victorian terrestrial protected areas were identified in the PMST Report due to the size of the grids used in the PMST but do not actually intersect the Planning Area. These are denoted in Table 4-7 with 'X'. Victorian terrestrial protected areas which intersect the Planning Area and have a coastal component which may be exposed to hydrocarbons from a spill event are discussed in the subsections below where information is available.

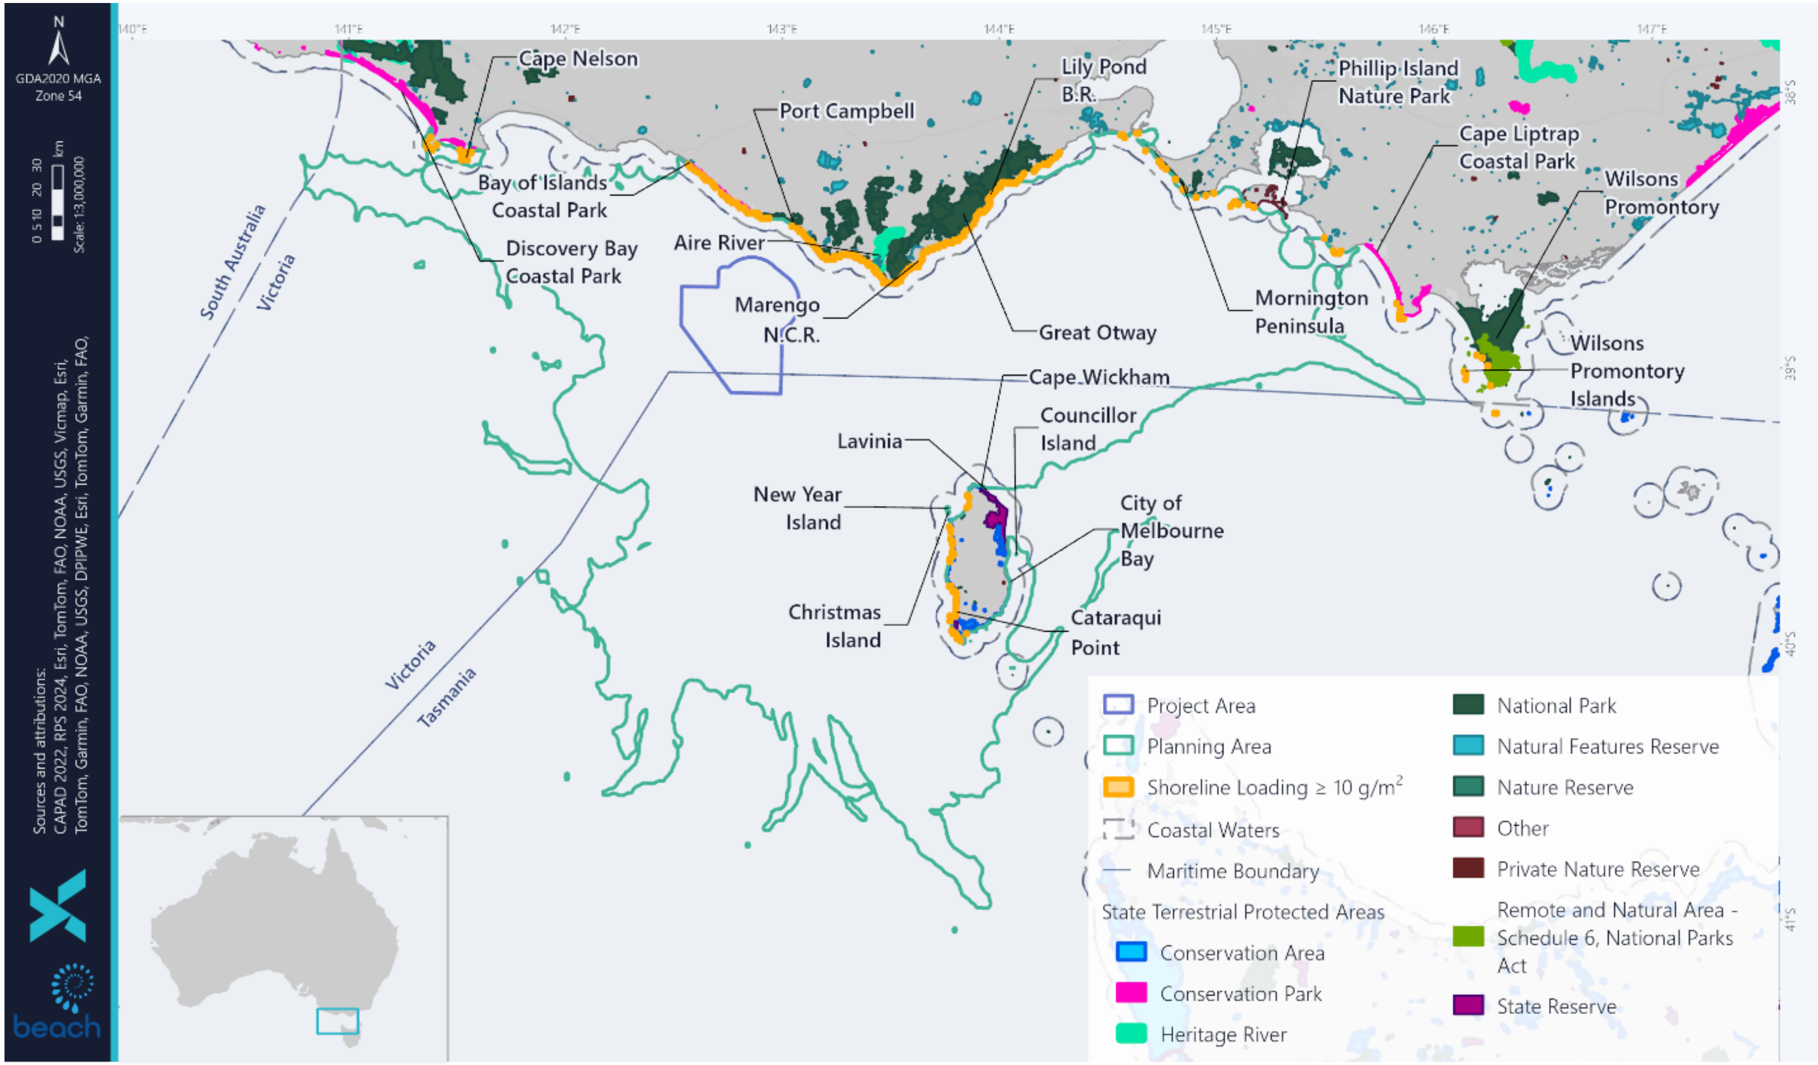

Figure 4-8: State Terrestrial Protected Areas within the Planning Area

4.2.9.1 Aire River Heritage River

The Aire River is a perennial river of the Corangamite catchment, located in the Otway region. The river generally flows west by south then south through the Great Otway National Park, joined by three minor tributaries, before reaching its mouth and emptying into Bass Strait west of Cape Otway. It is a popular fishing and camping area.

4.2.9.2 Bay of Islands Conservation Park

This coastal park has outstanding ocean views and geological features and covers an extensive area of the coastline (~32 km in length and 950 ha), stretching east from Warrnambool to Peterborough. Sheer cliffs and rock stacks dominate the bays, and the heathlands contain wildflowers. Beaches are accessible at some points (Parks Victoria 1998).

This park protects the terrestrial environment above the low water mark of this coastline. This Coastal Park is protected under the Port Campbell National Park and Bay of Islands Coastal Park Management Plan (Parks Victoria 1998).

4.2.9.3 Cape Nelson State Park

Cape Nelson State Park comprises 210 ha and is located near Portland, 377 km south-west of Melbourne. The park is a popular destination for hikers as it is positioned along the Great South West Walk as well as several other popular day walks. The park is managed under the Ngootyoong Gunditj Ngootyoong Mara South West Management Plan (DELWP 2015). Cape Nelson contains rocky platforms which provide habitat for the Australian Fur-seal and New Zealand Fur-seal.

4.2.9.4 Discovery Bay Coastal Park

Discovery Bay Coastal Park comprises 10,460 ha and extends along the coast of Discovery Bay from Cape Nelson north-westwards for 50 kilometres to the border with South Australia. The park is managed under the Ngootyoong Gunditj Ngootyoong Mara South West Management Plan (DELWP 2015). The Cape Bridgewater fur seal colony is located within the park.

4.2.9.5 Great Otway National Park

The Great Otway National Park (103,185 ha) is located near Cape Otway and stretches from the low water mark inland on an intermittent basis from Princetown to Apollo Bay (approximately 100 km).

Landscapes within the park are characterised by tall forests and hilly terrain extending to the sea with cliffs, steep and rocky coasts, coastal terraces, landslips, dunes and bluffs, beaches, and river mouths. There is a concentration of archaeological sites along the coast, coastal rivers, and reefs. The park contains many sites of international and national geological and geomorphological significance including Dinosaur Cove (internationally significant dinosaur fossil site), Lion Headland and Moonlight Head to Milanesia Beach (internationally significant coastal geology and fossils).

The park provides habitats for the conservation of the Rufous Bristlebird, Hooded Plover, White-Bellied Sea Eagle, Fairy Tern, Caspian Tern and Lewin's Rail and native fish such as the Australian Grayling.

The park contains significant Aboriginal cultural sites adjacent to rivers, streams and the coastline including over 100 registered archaeological sites, particularly shell middens along the coast, as well as non-physical aspects such as massacre sites, song lines, family links and stories. The park also contains four sites listed on the Victorian Heritage Register including the Cape Otway Light Station and several shipwreck features along the coast (i.e. anchors) (Parks Victoria and DSE 2009).

This park protects the terrestrial environment above the low water mark of this coastline. The Park is protected under the Great Otway National Park and Otway Forest Park Management Plan (Parks Victoria and DSE 2009) and relevant values are:

- a large area of essentially unmodified coastline, linking the land to marine ecosystems and marine national parks.
- a diverse range of lifestyle and recreation opportunities for communities adjacent to the parks – for local permanent residents and holiday homeowners Regionally, nationally, and internationally.
- significant tourist attractions, close to access routes and accommodation, such as spectacular coastal scenery along the Great Ocean Road, access to beautiful beaches, clifftop lookouts, picnic areas, historic sites, waterfalls and walking tracks such as the Great Ocean Walk.
- the basis for continued growth of nature-based tourism associated with the parks and the region, providing economic opportunities for accommodation providers, food and services providers, and recreation, tourism, and education operators.

4.2.9.6 Lake Connewarre Wilderness Reserve

Lake Connewarre Wilderness Reserve is within the Port Phillip Bay (Western Shoreline) and Bellarine Peninsula Ramsar site.

4.2.9.7 Mornington Peninsula National Park

Mornington Peninsula National Park protects 2,686 ha of land along the coast approximately 70 km south of Melbourne, often described as ‘Melbourne’s Playground’ due to its popularity for recreation. Mornington Peninsula National Park is the most visited park in Victoria.

The park is managed under the Mornington Peninsula National Park and Arthurs Seat State Park Management Plan (Parks Victoria 1998a) which identifies the following natural values:

- largest and most significant remaining areas of native vegetation on the Mornington Peninsula.
- numerous sites and features of geomorphic significance, particularly along the coast (cliffed calcarenite coast, sandy forelands and basalt shore platforms).
- only representation in the Victorian conservation reserve system of four particular land systems formed within the Southern Victorian Coastal Plains and the Southern Victorian Uplands.
- many significant native plants and vegetation communities.
- highly scenic landscape values along the ocean coast and at Port Phillip heads and prominent feature of Arthurs Seat.
- many significant fauna species, including populations of the nationally significant Hooded Plover, over 30 species of State significance and many species of regional significance.

- high quality marine and intertidal habitats, with some pristine areas within Point Nepean.

4.2.9.8 Phillip Island Nature Park

Phillip Island is east of Melbourne and forms a natural breakwater for the shallow waters of Western Port. Phillip Island is Biologically Important Area (BIA) for the Little Penguin, with breeding and foraging sites present. There is no management plan for Phillip Island Nature Park.

4.2.9.9 Point Nepean National Park

Point Nepean National Park protects 560 ha of land at the tip of Mornington Peninsula, surrounded by Port Phillip Heads Marine National Park (see Section 4.2.8.7). The park is of great cultural significance as a sacred place to Traditional Owners for over 35,000 years, a landmark and natural resource to European settlers, as well as a line of defence for Victoria and Australia (Parks Victoria 2017). Restricted access has allowed the park to maintain the largest and most intact area of remnant coastal vegetation on the Port Phillip coast and Victoria's largest remnant area of coastal alkaline scrub. Intertidal rock platforms support a diverse marine ecosystem while dune habitats provide roosting and feeding opportunities for resident and migratory seabirds.

4.2.9.10 Port Campbell National Park

Port Campbell National Park is slightly west of Twelve Apostles Marine National Park and 10 km east of Warrnambool. The park is 1,750 ha that presents an extraordinary collection of wave-sculptured rock formations. Port Campbell National Park is home to various fauna such as the Little Penguin, Short-tailed Shearwater and various whale species (Parks Victoria 2019).

4.2.10 Tasmanian Protected Areas – Marine

No Tasmanian marine protected areas were identified within the Project or Planning Areas (Appendix A; Appendix B).

4.2.11 Tasmanian Protected Areas – Terrestrial

No Tasmanian terrestrial protected areas were identified within the Project Area (Appendix A).)

Tasmanian terrestrial protected areas identified in the Planning Area (Appendix B) are presented in Table 4-8 and Figure 4-8. Areas identified in the PMST Report due to the size of the grids used in the PMST but not actually intersecting the Planning Area are listed in the table with 'X'. Tasmanian terrestrial protected areas which intersect the Planning Area and have a coastal component which may be exposed to hydrocarbons from a spill event are described in the subsections below, where information is available.

4.2.11.1Badger Box Creek Nature Reserve

Badger Box Creek Nature Reserve covers an area of 23.51 ha on King Island. It is designated as IUCN Category V which is a protected landscape/seascape. There is no management plan for the Badger Box Creek Nature Reserve.

4.2.11.2Cape Wickham Conservation Area

The Cape Wickham Conservation Area on the northern tip of King Island and contains Cape Wickham lighthouse and the gravesites of the crew of Loch Leven, a ship that was wrecked nearby. It is designated as IUCN Category V which is a protected landscape/seascape. There is no management plan for the Cape Wickham Conservation Area.

4.2.11.3 Cataraqui Point Conservation Area

Cataraqui Point Conservation Area is located on the west coast of King Island covering an area of 3.05 km^2 and extending from the coast to 100-200 m inland. The conservation area is designated as IUCN Category V and there is no management plan in place.

4.2.11.4 Christmas Island Nature Reserve

Christmas Island Nature Reserve covers 84.24 ha surrounding the granite island to the north-west of King Island. The reserve is part of the King Island Important Bird Area recognised by BirdLife Australia for providing important habitat for the Orange-bellied Parrot during its migration as well as significant numbers of Short-tailed Shearwater, Black-faced Cormorant, Fairy Tern, Hooded Plover and Pacific Gull (BirdLife Australia 2023c).

4.2.11.5 City of Melbourne Bay Conservation Area

City of Melbourne Bay Conservation Area covers 201.03 ha on King Island. The conservation area is designated as IUCN Category V and there is no management plan in place.

4.2.11.6 Colliers Swamp Conservation Area

Colliers Swamp Conservation Area covers 1,089.8 ha on King Island. The conservation area is designated as IUCN Category VI and there is no management plan in place.

4.2.11.7 Councillor Island Nature Reserve

Councillor Island Nature Reserve covers 17.58 ha of the granite island within the New Year Group. The reserve is part of the King Island Important Bird Area recognised by BirdLife Australia for providing important habitat for the Orange-bellied Parrot during its migration as well as significant numbers of Short-tailed Shearwater, Black-faced Cormorant, Fairy Tern, Hooded Plover and Pacific Gull (BirdLife Australia 2023d). The conservation area is designated as IUCN Category Ia and there is no management plan in place.

4.2.11.8 Lavinia State Reserve

Lavinia State Reserve covers 7,860.4 ha on King Island at the Lavinia Ramsar Site. See Section 4.2.6.1.

4.2.11.9 New Year Island Game Reserve

New Year Island Game Reserve covers 118.22 ha to the north-west of King Island. The reserve is part of the King Island Important Bird Area recognised by BirdLife Australia for providing important habitat for the Orange-bellied Parrot during its migration as well as significant numbers of Short-tailed Shearwater, Black-faced Cormorant, Fairy Tern, Hooded Plover and Pacific Gull (BirdLife Australia 2023f).

4.2.11.10 Porky Beach Conservation Area

Porky Beach Conservation Area is located on the west coast of King Island covering an area of 4.55 km^2 and extending from the coast to 100-200 m inland. The conservation area is designated as IUCN Category V and there is no management plan in place.

4.2.11.11 Red Hut Point Conservation Area

Red Hut Point Conservation Area covers an area of 159.84 ha on King Island. The conservation area is designated as IUCN Category V and there is no management plan in place.

4.2.11.12 Reid Rocks Nature Reserve

Reid Rocks Nature Reserve covers 6.62 ha in the New Year Island Group. It is the only breeding site in Tasmania for Australian Fur-seals (PWS 2000).

4.2.11.13 Sea Elephant Conservation Area

Sea Elephant Conservation Area covers 722.06 ha on King Island, approximately 25 km north-east of Currie. The conservation area is designated as IUCN Category VI and there is no management plan in place.

4.2.11.14 Seal Rocks State Reserve

Seal Rocks State Reserve is a 5.84 km^2 area on the south-western coast of King Island. The state reserve is an IUCN category III and there is no management plan in place. Images produced by google maps and google earth, show the coastal sections of the reserve consist primarily of large rocks and rocky cliffs.

4.2.11.15 Stokes Point Conservation Area

Stokes Conservation Area is a 2.44 km^2 area on the south-western coast of King Island. The state reserve is an IUCN category V and there is no management plan in place.

4.2.12 Key Ecological Features

Key Ecological Features (KEFs) are elements of the marine environment, based on current scientific understanding, and are considered to be of regional importance for either the region's biodiversity or ecosystem function and integrity of a Commonwealth Marine Area.

No KEFs were identified within the Project Area. Areas identified in the PMST Report (Appendix A) due to the size of the grids used in the PMST but not actually intersecting the Project Area are listed in the table with 'X'

KEFs identified in the Planning Area (Appendix B) are presented in Table 4-9 and Figure 4-9 and described in the subsections below.

Table 4-9: Key Ecological Features within the Planning Area

Key Ecological Feature	Project Area	Planning Area
Bonney Coast Upwelling	-	✓
West Tasmania Canyons	X	✓

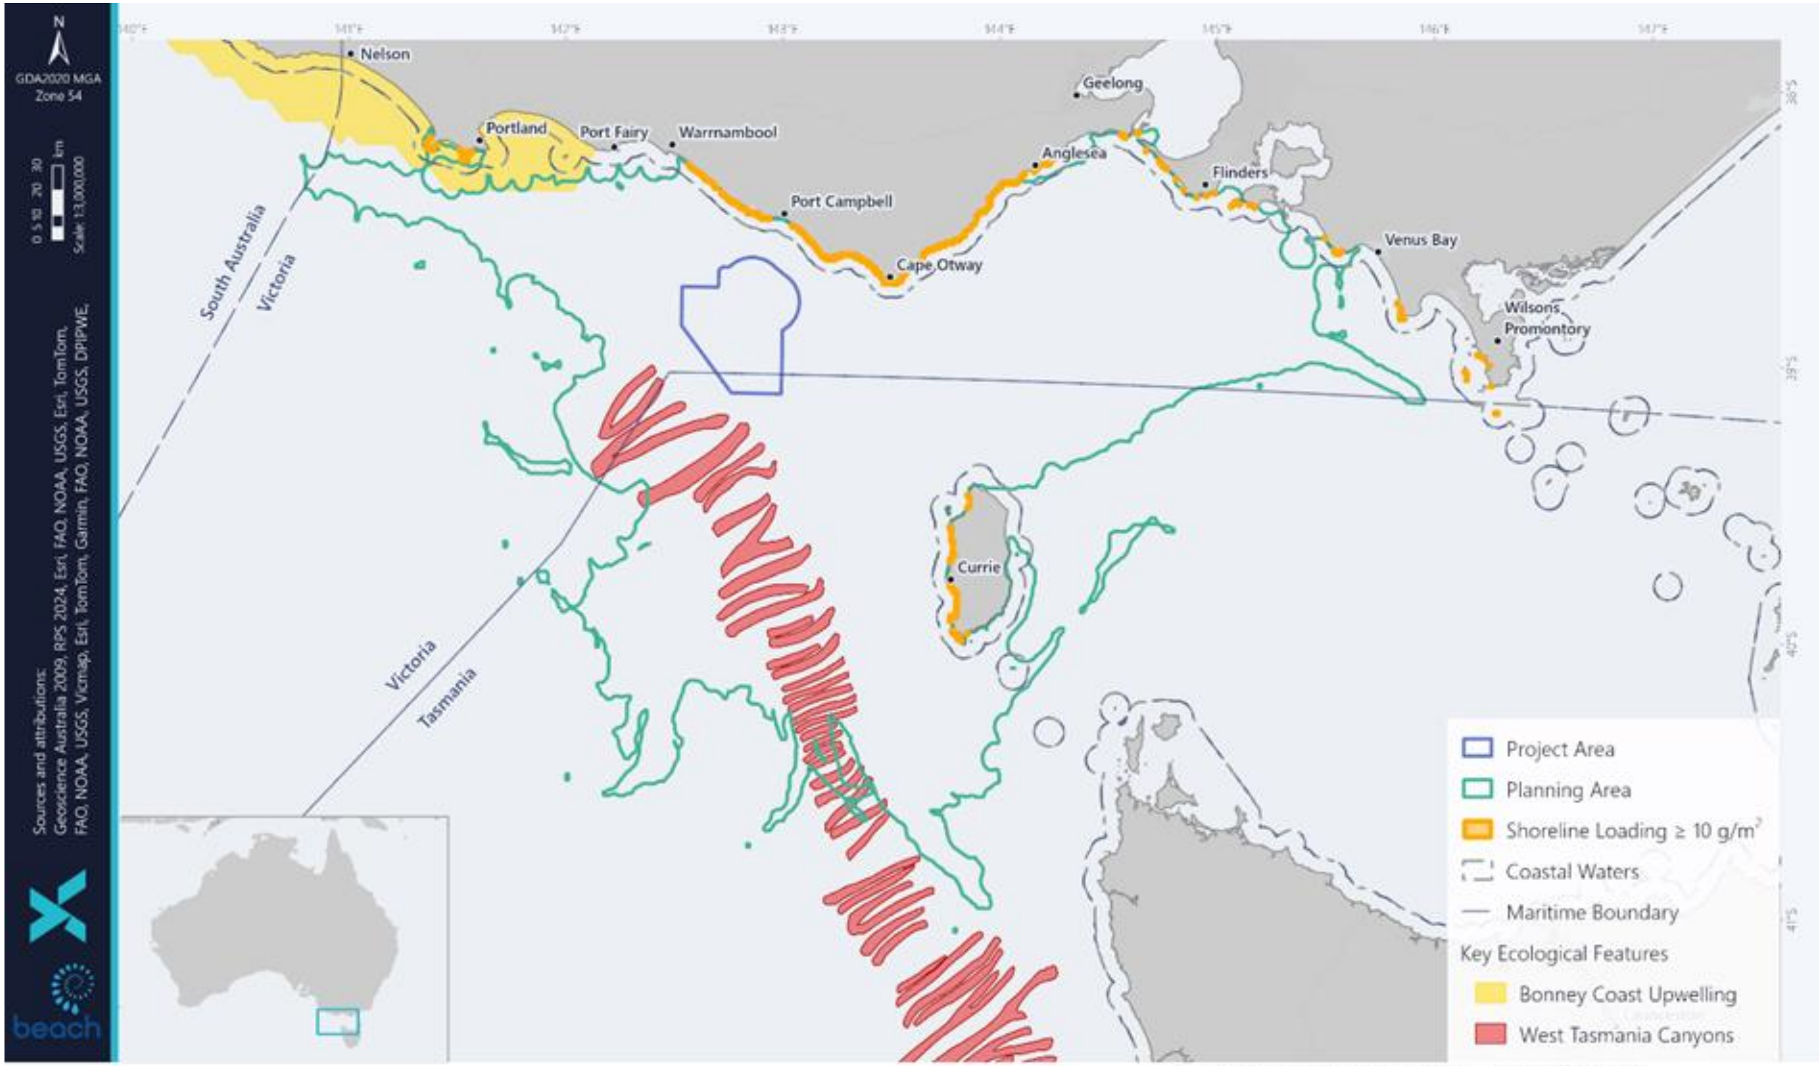

Figure 4-9: Key Ecological features within the Planning Area

4.2.12.1 Bonney Coast Upwelling

The Bonney Coast upwelling is a predictable, seasonal upwelling bringing cold nutrient rich water to the sea surface and supporting regionally high productivity and high species diversity in an area where such sites are relatively rare and mostly of smaller scale (CoA 2015). The Bonney Coast upwelling is defined as a key ecological feature as it is an area of enhanced pelagic productivity and has high aggregations of marine life (DCCEEW 2023b). In addition to whales, many endangered and listed species frequent the area, possibly also relying on the abundance of krill that provide a food source to many seabirds and fish. The high productivity of the Bonney coast upwelling is also capitalised on by other higher predator species such as little penguins and Australian Fur-seals feeding on baitfish (CoA 2015).

The Bonney Coast Upwelling KEF lies on the continental shelf situated approximately 120 km north-west of Cape Jaffa, South Australia to Portland, Victoria (Figure 4-9). The location of the Bonney Coast Upwelling KEF was originally derived through a review of enhanced chlorophyll occurrence for summer seasonal data between the years of 1998 and 2010 (Research Data Australia 2013).

4.2.12.2 West Tasmanian Canyons

The West Tasmanian Canyons are located on the relatively narrow and steep continental slope west of Tasmania. This location has the greatest density of canyons within Australian waters where 72 submarine canyons have incised a 500 km-long section of slope (Heap and Harris 2008). The canyons in the Zeehan AMP are relatively small on a regional basis, each less than 2.5 km wide and with an average area of 34 km^2 shallower than 1,500 m (Williams et al. 2009). The Zeehan canyons are typically gently sloping and mud-filled with less exposed rocky bottoms compared with other canyons in the south-east marine region (e.g. Big Horseshoe Canyon).

Submarine canyons modify local circulation patterns by interrupting, accelerating, or redirecting current flows that are generally parallel with depth contours. Their size, complexity and configuration of features determine the degree to which the currents are modified and therefore their influences on local nutrients, prey, dispersal of eggs, larvae and juveniles and benthic diversity with subsequent effects which extend up the food chain.

Eight submarine canyons surveyed in Tasmania, Australia, by Williams et al. (2009) displayed depth-related patterns with regard to benthic fauna, in which the percentage occurrence of faunal coverage visible in underwater video peaked at 200-300 m water depth, with averages of over 40% faunal coverage. Coverage was reduced to less than 10% below 40 m depth. Species present consisted of low-relief bryozoan thicket and diverse sponge communities containing rare but small species in 150 to 300 m water depth.

Sponges are concentrated near the canyon heads, with the greatest diversity between 200 m and 350 m depth. Sponges are associated with abundance of fishes and the canyons support a diversity of sponges comparable to that of seamounts. Based upon this enhanced productivity, the West Tasmanian canyon system includes fish nurseries (Blue Wahoo and Ocean Perch), foraging seabirds (albatross and petrels), White Shark and foraging Blue and Humpback Whales (TSSC 2022).

4.3 Physical Environment

4.3.1 Climate

The climate in the Otway Basin is typical of a cool temperate region with cold, wet winters and warm dry summers. It is located on the northern edge of the westerly wind belt known as the Roaring Forties. In winter, when the subtropical ridge moves northwards over the Australian continent, cold fronts generally create sustained west to south-westerly winds and frequent rainfall in the region (McInnes and Hubbert 2003). In summer, frontal systems are often shallower and occur between two ridges of high pressure, bringing more variable winds and rainfall.

4.3.2 Oceanography

4.3.2.1 Winds

The Otway Basin is a high-energy environment exposed to frequent storms and significant wave heights. Winds in the area generally exceed 13 knots (23.4 km/h) for more than 50% of the time contributing to the moderate to high wave-energy environment. Strongest winds are associated with eastward-moving low pressure and frontal systems that cross the site every 4 to 6 days in winter. Directions are predominantly south-westerly veering north-westerly. September is the windiest month, with average wind speeds of 29 km/h.

4.3.2.2 Waves

The Otway Basin has a predominantly south-westerly aspect and is highly exposed to swell from the Southern Ocean. Wave heights generally range from 1.5 m to 2 m. Waves up to 10 m can occur during winter storm events.

4.3.2.3 Tides

Tides are semi-diurnal with a diurnal inequality (Jones and Padman 1983). The maximum tidal range in western Bass Strait is 1.2 m. Currents are directed along a north-east/south-west axis, with maximum speeds of 0.3 m/s (Fandry 1983).

4.3.2.4 Ocean Currents

The South-east Marine Region is oceanographically complex, with subtropical influences from the north and subpolar influences from the south. The Leeuwin Current transports warm, subtropical water southward along the Western Australian coast and then eastward into the Great Australian Bight where it mixes with the cool waters from the Zeehan Current running along the west coast of Tasmania. These currents are stronger in winter than in summer (Figure 4-10).

The eastern parts of the Region are strongly influenced by the East Australian Current (EAC) that flows southward adjacent to the east coast of New South Wales, Victoria, and Tasmania, carrying warm equatorial waters. The EAC is up to 500m deep and 100 km wide and is strongest in summer when it can flow at up to 5 knots. In winter it flows at 2–3 knots as the oceanographic and climatic drivers in the Coral Sea diminish.

The EAC tends to form ocean eddies that rotate around warm, central cores that can be up to 200 km across and may persist for months. The eddies can cross the continental shelf, and when mixing with shelf break waters, create upwellings that form isolated areas of enhanced productivity 200–300 km in diameter. Eddies form more frequently off the south coast of New South Wales than other areas but are also common along the east coast of Tasmania. The EAC affects sea surface temperatures on the eastern Tasmanian shelf, which can vary substantially among years depending on the relative influence of subtropical waters.

During winter, the South Australian current moves dense, salty warmer water eastward from the Great Australian Bight into the western margin of the Bass Straight. In winter and spring, waters within the straight are well mixed with no obvious stratification, while during summer the central regions of the straight become stratified.

4.3.2.5 Sea Temperature

Surface seawater temperatures in the Otway Basin typically range from 14°C in winter to 21°C in summer. However, upwelling of cooler nutrient-rich water occur along the seafloor during mid to late summer. This upwelling is an extension of the regional Bonney coast upwelling system, which affects southern Australia because of south-east winds forcing surface water offshore thus triggering a compensatory subduction along the bottom. If the wind is strong enough the water sometimes shoals against the coast. The water originates from a subsurface water flow called the Flinders current and has the characteristics of reheated Antarctic Intermediate Water (Levings and Gill 2011).

During winter and spring onshore winds cycling from the south-west to north-west mound the surface layer against the land and cause a south-easterly flow along the coast that fills the shelf from the shore outwards to a depth of 500 m deep. Shelf water temperatures at these times range from between 18°C to 14°C with seafloor temperatures warmer in winter than in summer.

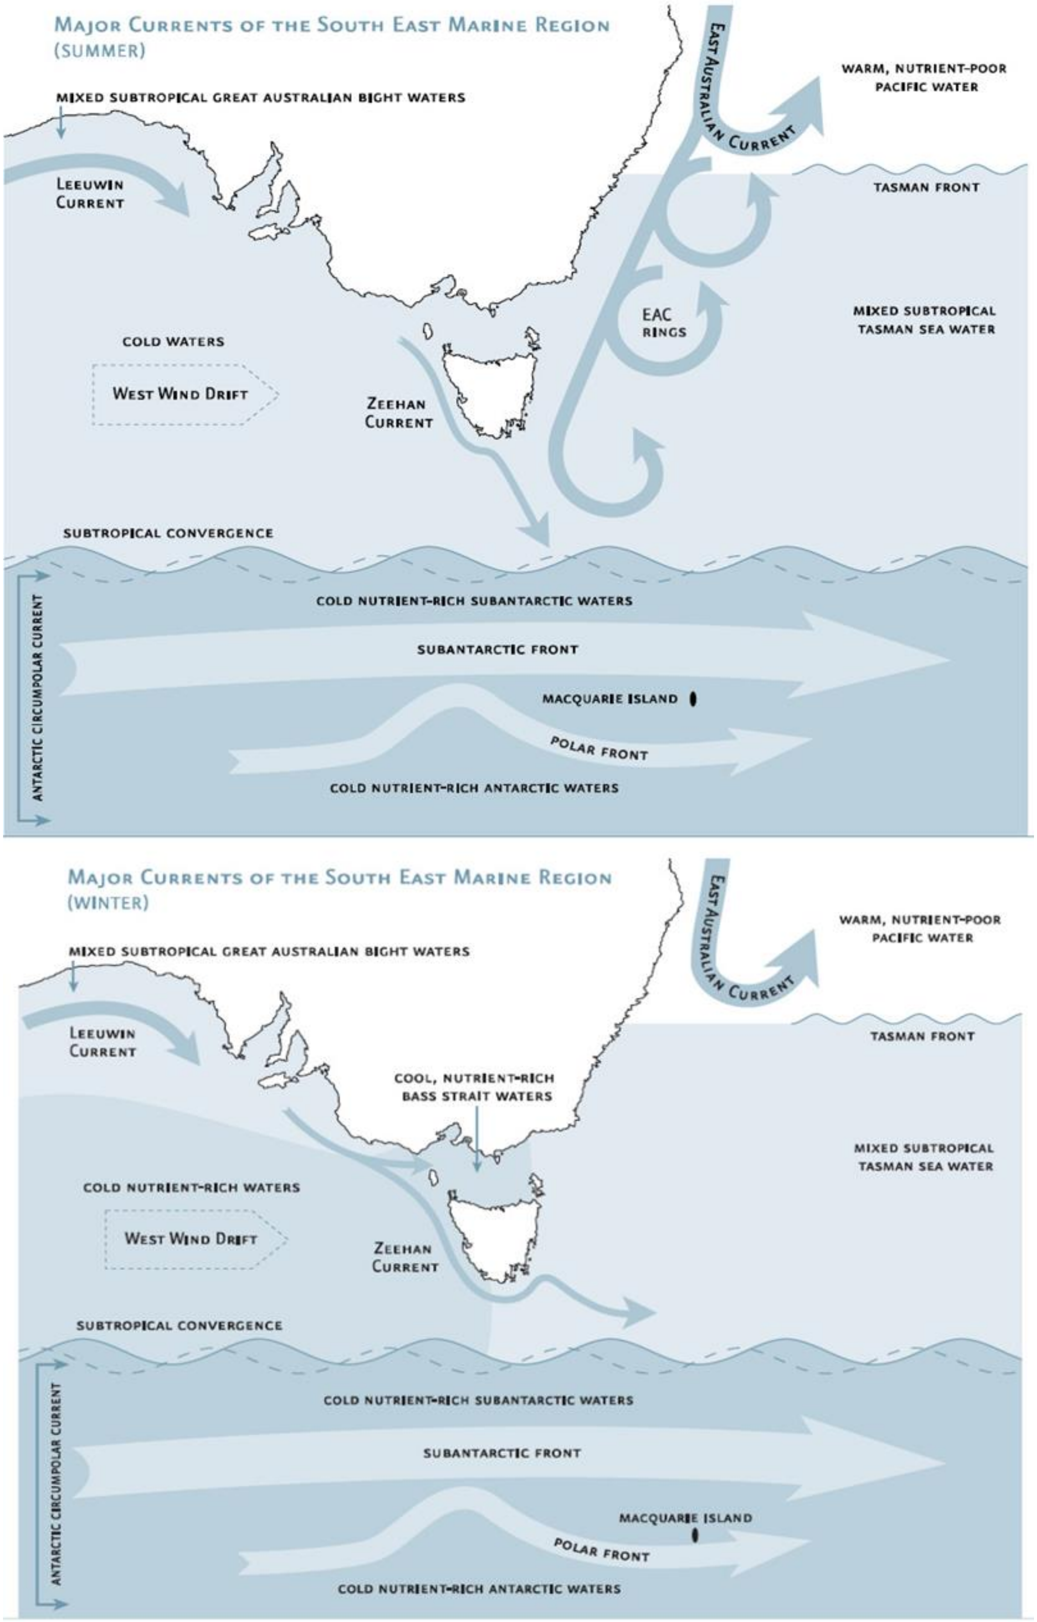

Figure 4-10: Ocean Currents in South-eastern Australian Waters during Summer (top) and Winter (bottom) (Source: CoA 2015)

4.3.3 Geomorphology

The south-eastern section of Australia's continental margin comprises the Otway Shelf and the Bonney Coast, Bass Strait, and the western shelf of Tasmania. The 400 km long Otway Shelf lies between 37° and 43.5°S and 139.5°E (Cape Jaffa) and 143.5°E (Cape Otway). The narrowest point is off Portland, where the shelf is less than 20 km wide. It broadens progressively westward, to 60 km off Robe, SA, and eastward to 80 km off Warrnambool. The Otway shelf is comprised of Miocene limestone below a thin veneer of younger sediments.

Boreen et al. (1993) examined 259 sediment samples collected over the Otway Basin and the Sorell Basin of the west Tasmanian margin. Based on assessment of the sampled sediments the authors concluded the Otway continental margin is a swell-dominated, open, cool-water, carbonate platform. A conceptual model was developed which divided the Otway continental margin into five depth-related zones – shallow shelf, middle shelf, deep shelf, shelf edge and upper slope (Figure 4-11).

In the shallow shelf are exhumed limestone substrates that host dense encrusting mollusc, sponge, bryozoan, and red algae assemblages. The middle shelf is a zone of swell-wave shoaling and production of mega-rippled bryozoan sands. The deep shelf is described as having accumulations of intensely bioturbated, fine, bioclastic sands. At the shelf edge and top of slope, nutrient-rich upwelling currents support extensive, aphotic bryozoan/sponge/coral communities. The upper slope sediments are a bioturbated mixture of periplatform bioclastic debris and pelleted foraminiferal/nano-fossil mud. The lower slope is described as crosscut by gullies with low accumulation rates, and finally, at the base of the slope the sediments consist of shelf-derived, coarse-grain turbidites and pelagic ooze.

The Project Area is primarily located within the shallow, middle and deep shelf zones with the south-western portions extending beyond the shelf edge to the upper slope.

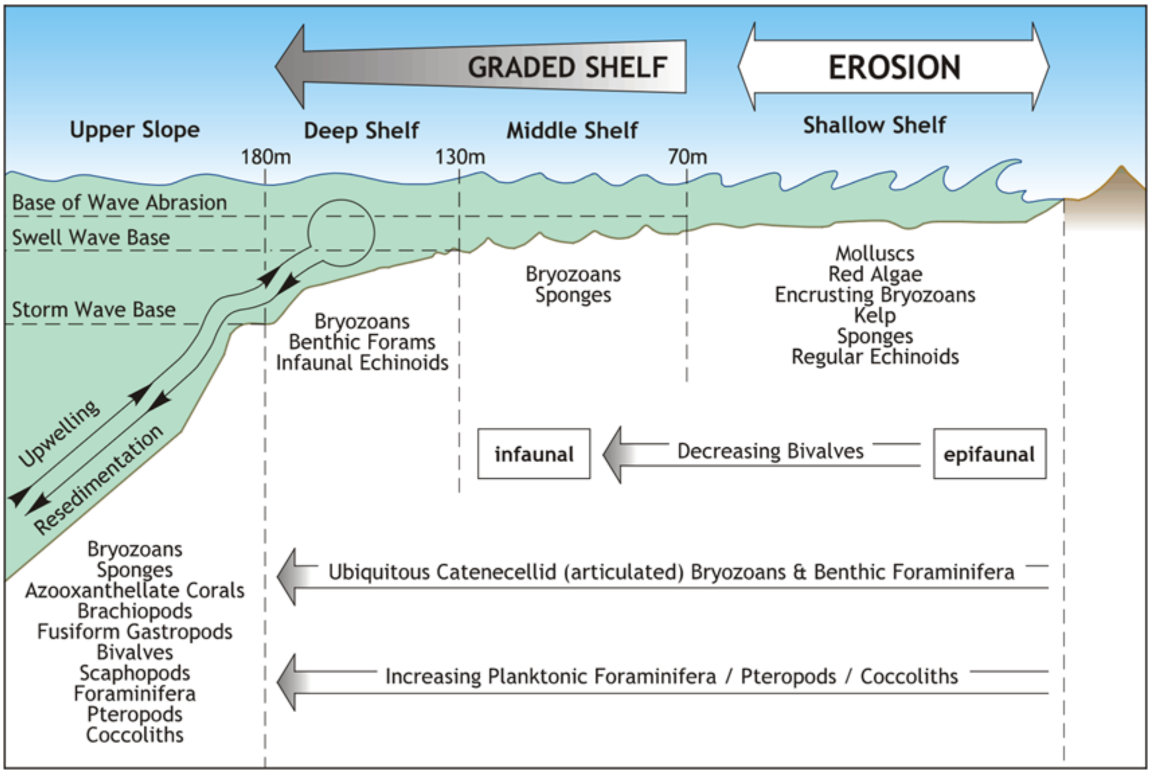

Figure 4-11: Model of the Geomorphology of the Otway Shelf (Boreen et al. 1993)

Previous surveys of the shallow shelf and middle shelf zones where existing Beach infrastructure is located are provided in detail in Section 4.4.1. A video survey of the seabed at selected sites along proposed offshore pipeline routes for the Otway Gas Development (BBG 2003) found that the substrate in water depths between 82 and 66m were predominantly low-profile limestone with an incomplete sand veneer that supported a low to medium density, sponge dominated filter feeding community. Fish and other motile organisms were uncommon.

In shallower depths of between 63 and 30 m, the video surveys showed a rippled, sand or sand/pebble substrate with minor sponge dominated benthic communities. The epibenthic organisms were generally attached to outcropping or sub-outcropping limestone pavements. Only in waters shallower than approximately 20 m, was an area of significant, high profile reef and associated high density macroalgae dominated epibenthos encountered.

Prior to activities in the deep shelf and upper slope, further studies will be undertaken to understand the geomorphology of areas where infrastructure will be installed. Section 4.4.1 provides further detail on studies to be undertaken.

4.3.4 Sediment Quality

Sediments were sampled during the Otway Basin Environmental Survey (Ramboll 2020; Appendix C). Sediment samples were collected at two of the gas fields, Artisan and Thylacine. For sample locations see Appendix C. The Artisan field would be representative of the sediments closer to shore, while the Thylacine field which is further offshore would be representative of the sediments in the deeper waters of the Project Area. Further studies are planned to understand the sediment quality of the deepest portion of the Project Area, located on the deep shelf (refer to Section 4.4.1).

The sediment within all samples was predominantly sand with a range of 95-97% as a proportion of each sample. There was very little silt and a maximum of 4.7% for the clay fraction. There were no discernible trends based on the location of sample collection.

The oxidation reduction potential (ORP) of sediments within the samples was measured and the anoxic layer with low ORP was not detected in any of the sediments analysed and the range of measurements indicated that these sediments maintain a well oxygenated, unmodified environment.

There was a notable degree of variability in the nutrient samples collected in the Thylacine field, however the small number of samples means that a trend or pattern was not discernible. Nitrate-nitrite was not detected in any samples. Total organic content and detectable nitrogen concentrations were slightly higher in the Artisan samples compared to the Thylacine samples. Generally, the concentrations of nutrients in the marine sediments were to be expected for this environment and type of sediment.

Of the inorganic compounds tested, Cd, Cu, Pb, Hg, Ni and Sn were below the limit of reporting in all sediment samples. The concentration of Cr in sediments was low, and well below the default guideline values which indicate the concentrations below which there is a low risk of unacceptable effects occurring within the recommended sediment quality guidelines set out in the Australian and New Zealand Guidelines for Fresh and Marine Water Quality (2018). The concentration of Cr was slightly higher in the samples from Artisan than those from Thylacine. Zn was detected in two of the six samples (one sample from each field) and was well below the default guideline values set out within the Sediment Quality Guidelines.

BTEXs, PAHs, PCBs and TRHs were either below the LOR or at levels of no concern.

In summary, sediments had a high ORP and low or undetectable levels of toxicants indicating an unmodified seabed environment. It is expected that sediment quality within the Project Area and Planning Area will be typical of the offshore marine environment of the Otway Basin.

4.3.5 Water Quality

Water quality was sampled during the Otway Basin Environmental Survey (Ramboll 2020; Appendix C). For sample locations see Appendix C. Water samples were collected at two of the gas fields, Artisan and Thylacine. The Artisan field would be representative of the water quality closer to shore, while the Thylacine field which is further offshore would be representative of the water quality in the deeper waters of the Project Area.

In situ measurements were taken for dissolved oxygen (DO), pH and ORP and DO and pH were assessed against the default trigger values for physical and chemical stressors for south-east Australia for slightly disturbed ecosystems set out in the Australian and New Zealand Guidelines for Fresh and Marine Water Quality (ANZG 2018). Trigger values are used to assess risk of adverse effects due to nutrients, biodegradable organic matter, and pH in various ecosystem types.

DO was between the lower and upper limits of 90 and 110% saturation for marine waters in all samples. Likewise, pH was between the lower and upper limits of 8.0 and 8.4 for all samples. The range of ORP measurements indicated a well oxygenated, ecologically healthy environment.

Laboratory analyses for a suite of analytes were undertaken and has been compared to the Australian and New Zealand Guidelines for Fresh and Marine Water Quality (2018) default guideline values for physical and chemical stressors for nutrient analytes and the trigger values for toxicants at alternative levels of protection for all other analytes.

The concentration of ammonia, nitrite and reactive phosphorus was at or below the level of reporting (LOR) for all samples. Only one sample contained a concentration of nitrate-nitrite, NO_3, Total Kjeldahl Nitrogen and Total Nitrogen above the LOR. This same sample site (Thylacine_1_3) slightly exceeded ANZG (2018) default guideline values for Total Nitrogen. Concentrations of Total Phosphorus were recorded in all samples, but all measurements were below ANZG (2018) default guideline values. Total Suspended Solids was typically within the range expected for unmodified marine waters.

The concentrations of Cd, Cr, Co, Pb, Hg, and Ni were at or below LOR in all samples. The concentration of Cu was below, at or very close to the LOR for all samples. The concentration of all contaminants (Cd, Cr, Co, Pb, Hg, Zn, Ni and Cu) against the Australian and New Zealand Guidelines for Fresh and Marine Water Quality (2018) were all below the default guideline values in all samples. This is consistent with a slightly disturbed marine system which is described in (ANZG 2018) as an ecosystem in which biodiversity may have been affected to small degree by human activity.

BTEXs and PAHs were below the detection limit in all water samples. Very low traces of Total Recoverable Hydrocarbon (TRHs) were detected in a Thylacine water sample but were at levels of no concern. TRHs were below detection limits in all other samples. The level of chlorophyll a in filtered samples was below the detection level.

In summary, the water quality at the Thylacine and Artisan survey areas indicated an undisturbed mid-depth environment.

It is expected that water quality within the Project Area and Planning Area will be typical of the offshore marine environment of the Otway Basin, which is characterised by high water quality with low background concentrations of trace metals and organic chemicals.

4.3.6 Ambient Light

Ambient light is defined as the light that is already present within an environment. Ambient light is predominantly from solar/lunar luminescence. There are minor anthropogenic sources from townships and nearby shipping lanes within the vicinity of the light EMBAs (Figure 4-12). Within the Otway Basin artificial light emissions can be expected from both permanent (e.g. onshore/ offshore developments) and temporary (e.g. vessel) activities. Lighting from the existing Thylacine- A Wellhead Platform is required for navigational and safety purposes and complies with Sections 2.1 and 2.2 of the Recommendation O-139 on *The Marking of Man-Made Offshore Structures* (IALA, Ed 2, 2013). Moderate levels of commercial vessel traffic are expected within the Planning Area (Section 4.5.6) and light EMBAs with navigation and working lighting complying with Australian Maritime Safety Authority (AMSA) Marine Orders Part 30 (Prevention of Collisions). Closer to shore, particularly in coastal communities, natural light is considered to be a community value. Major population centres and areas associated with popular tourist attractions and their potential presence within the light EMBAs are detailed in Table 4-10. Artificial light may attract light sensitive species such as shorebirds, seabirds, and turtles (Section 6.3.3).

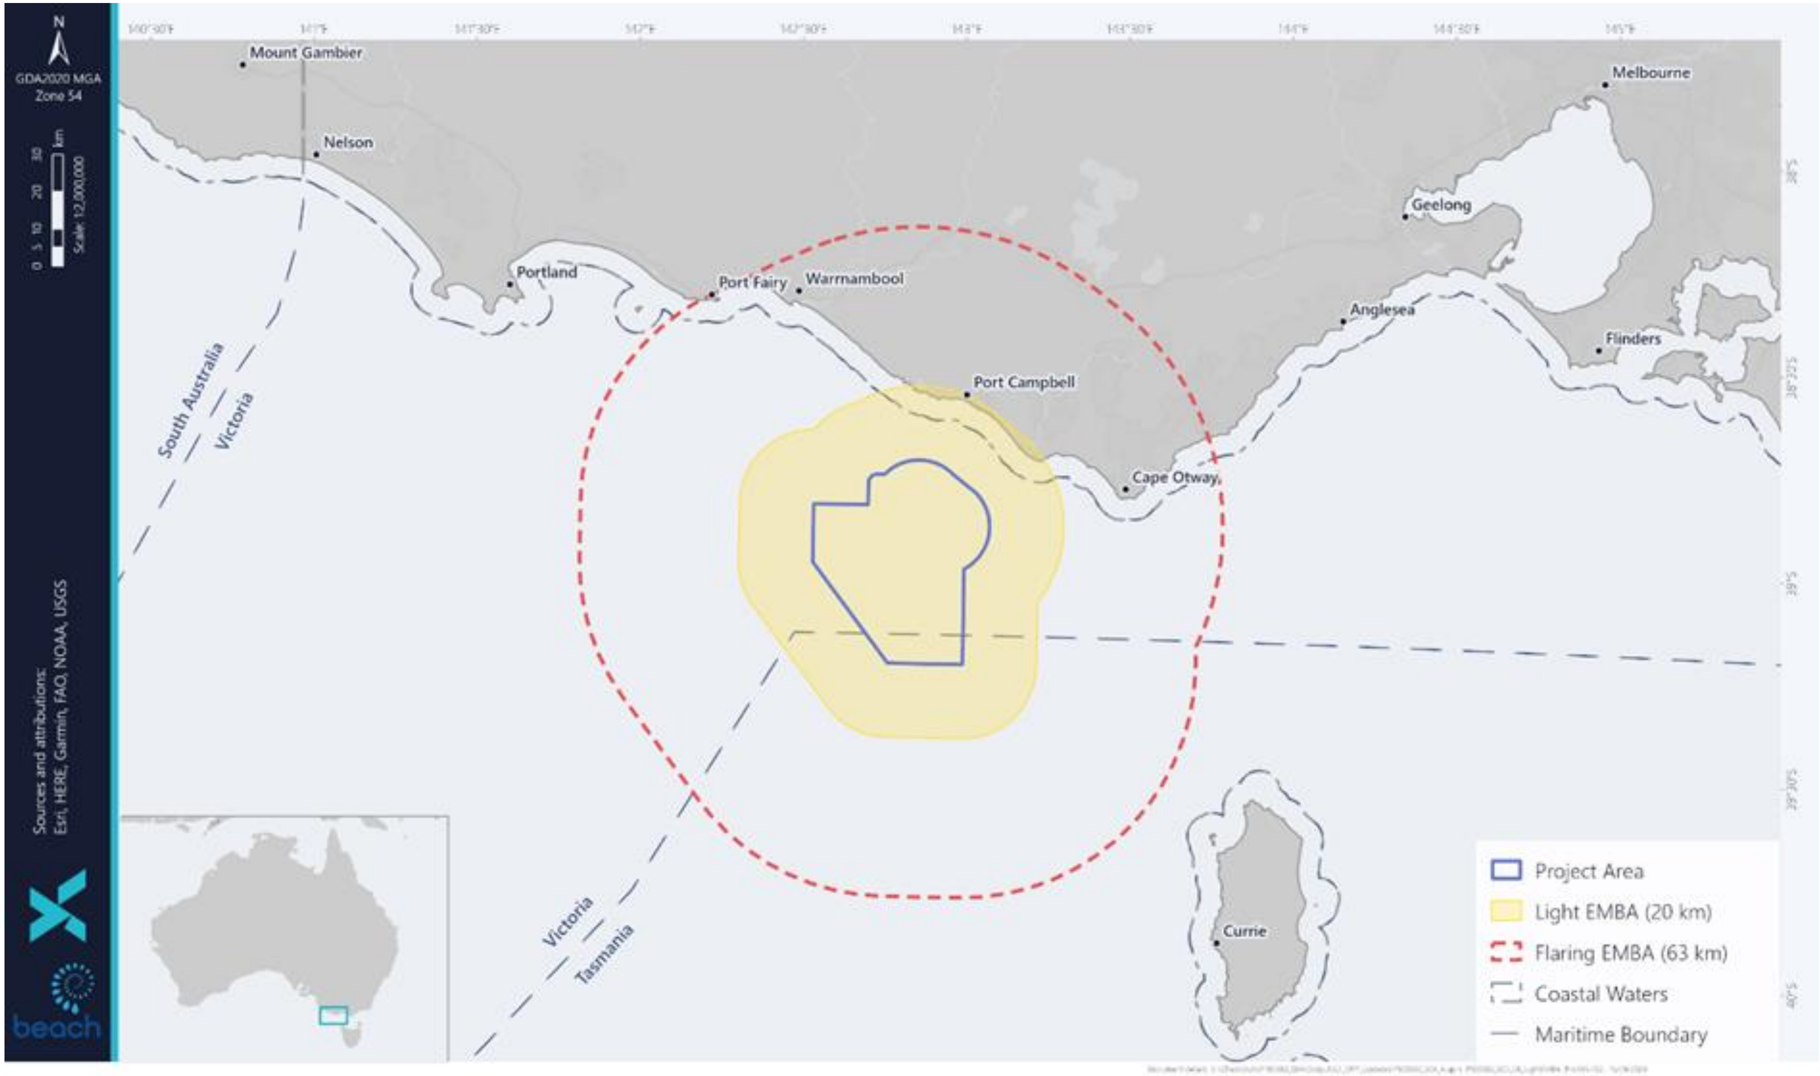

Figure 4-12: Light EMBAs

Peterborough Population: 322	✓	✓
Port Campbell Population: 440	✓	✓
Princetown Population: 236	-	✓
Thylacine A Platform	✓	✓
Shipping	✓	✓

4.3.7 Ambient Sound

McCauley and Duncan (2001) undertook a desktop review of natural and man-made sea sound sources likely to be encountered in the Otway Basin. They concluded that natural sea sound sources are dominated by wind noise, but also include rain noise, biological noise and the sporadic noise of earthquakes. Man-made underwater sound sources in the region comprise shipping and small vessel traffic, petroleum production and exploration drilling activities and sporadic petroleum seismic surveys.

Between 2009 and 2016 the Integrated Marine Observing System (IMOS) recorded underwater sound south of Portland, Victoria (38°32.5' S, 115°0.1'E). Prominent sound sources identified in recordings include Blue and Fin Whales at frequencies below 100 Hz, ship noise at 20 to 200Hz and fish at 1 to 2 kHz (Erbe et al. 2016). In the broader region, primary contributors to background sound levels were wind, rain and currents-and waves associated sound at low frequencies under 2kHz (Przeslawski et al. 2016). Biological sound sources including dolphin vocalisations were also recorded (Przeslawski et al. 2016).

During April-May 2001 two underwater noise loggers were placed (5.1 km and 2.9 km south-west of an exploration petroleum drilling vessel at the Thylacine site) to measure underwater noise before, during and after drilling activity. A further logger was placed in the shipping lane approximately 60 km due south of Port Fairy to measure ambient noise produced by physical, manmade and biological sources between late November 2001 and early March 2002 (Woodside 2003). Baseline broadband underwater noise for the period was in the order of 93 to 97 dB re 1 µPa with shipping raising the averaged noise level above 105 dB re 1 µPa for 6% of the deployment time.

An acoustic monitoring program was also undertaken during exploratory drilling of the Casino-3 well. A sound logger located 28.03 km from the drill site did not detect drilling noise and recorded ambient noise that ranged between 90 and 110 dB re 1 µPa (McCauley 2004). Passive acoustic monitoring commissioned by Origin from April 2012 to January 2013, 5 km offshore from the coastline east of

Warrnambool, identified that ambient underwater noise in coastal areas is generally higher than further offshore, with a mean of 110 dB re 1 µPa and maximum of 161 dB re 1 µPa (Duncan et al. 2013).

More recently JASCO Applied Sciences (Australia) (JASCO) completed a monitoring study for Beach in relation to exploration drilling activities at the Artisan 1 well with the aim of completing an acoustic characterisation of the drilling and associated vessel activity within the Otway Basin. McPherson et al. (2021) details the monitoring program and results. Four recorders were deployed in February and retrieved in early April 2021 with Stations 1 through 4 deployed at distances of 0.336, 1.13, 5.11, and 25 km from the Ocean Onyx drill rig.

The results for Station 4, the furthest from the drill rig, were a median broadband ambient noise of 104.5 dB re 1 µPa, a mean of 118.3 dB re 1 µPa, a minimum of 86.6 dB re 1 µPa, and a maximum of 153.6 dB re 1 µPa. This is both quieter and louder than those for Casino 3. The mean levels at Station 4 are 8.3 dB higher than those recorded 5 km offshore of Warrnambool, while the maximum recorded at Station 4 is lower by 7.4 dB. For Station 4 contributors to the soundscape were weather, shipping, and marine mammals. Local variations in ambient noise and received levels can depend upon water depth and the proximity to contributors. In this case, the shipping lanes and the frequency and proximity of vessel passes are strong drivers of the ambient noise at Station 4. The quieter levels reported at Thylacine in Lattice Energy (2017) are likely due to the placement of the monitoring station at a distance from the shipping lanes, which limited their contributions to the data set and thus resulted in a lower reported range of received sound levels.

4.3.8 Bonney Coast Upwelling

The Bonney coast upwelling is mainly driven by the frequent south-easterly winds during the austral summer (Lewis 1981, Middleton and Bye 2007, Nieblas et al. 2009, Schahinger 1987). The frequent south-easterly winds are the result of southern migration of the subtropical ridge (Nieblas et al. 2009, Schahinger 1987). The upwelling occurs via Ean dynamics, where the ocean surface experiences a steady wind stress which results in a net transport of water at right angles to the left of the wind direction which brings cold, nutrient rich water to the sea surface.

Huang and Wang (2019) developed an image processing technique to map upwelling areas along the south-eastern coast of Australia. This study used monthly Moderate Resolution Imaging Spectroradiometer (MODIS) sea surface temperature (SST) composites between July 2002 and December 2016, which were generated from daily SST images with a spatial resolution of ~1 km. As upwelling in winter is unlikely to occur images during this period were not analysed. Upwelling reaching the surface often displays a colder SST signature than the adjacent area (e.g., Dabuleviciene et al. 2018, Gill et al. 2011, Kampf et al. 2004, McClatchie et al. 2006, Oke and Griffin 2011, Oke and Middleton 2001, Roughan and Middleton 2004, Willis and Hobday 2007). This negative SST anomaly is the foundation of upwelling mapping using SST data (Huang and Wang 2019).

The spatial patterns of the mapped Bonney coast upwelling have been shown to follow a clear temporal pattern. When the upwelling season starts during late spring and early summer (November and December), the influence of the Bonney coast upwelling was found to be often restricted to the coast. During the mid-summer and early autumn (January to March) when the upwelling is the strongest, the upwelling influence often extended to the shelf break before retreating in April (Huang and Wang 2019).

Gill et al (2011) states that the Bonney coast upwelling generally starts in the eastern part of the Great Australian Bight and spreads eastwards to the Otway Basin. At the height of the Bonney coast upwelling during February and March, the upwelling's area of influence often exceeds 12,000 km^2, its SST anomaly often exceeds 1°C, and its chlorophyll-a concentrations are often >1.5 times of its adjacent areas (Huang and Wang 2019).

Figure 4-13: Bonney Coast Upwelling Frequency within the Project and Planning Areas (Source: Huang and Wang 2019, Geoscience Australia 2020)

4.3.8.1 Variability

While the general characteristics of the Bonney coast upwelling are broadly understood virtually nothing is known of the longer-term variability of the phenomenon. Alongshore wind is the predominant mechanism in the upwelling, which is, therefore, directly impacted by any changes to the strength or frequency of these winds. However, not all favourable upwelling winds lead to an upwelling event. Huang and Wang (2019) state that each year for the period of 14 years (Sept 2002 to May 2016) of their study there was large variability in the distribution of the upwelling influence areas, month to month, season to season and year to year.

The El Niño – Southern Oscillation (ENSO) has been identified by some authors as a potential driver of upwelling strength along the south Australian coast. The ENSO is the dominant global mode of inter-annual climate variability, is a major contributor to Australia's climate and influences Australia's marine waters to varying degrees around the coast. The two phases of ENSO, El Niño and La Niña, produce distinct and different changes to the climate.

Middleton et al. (2007) examined meteorological and oceanographic data and output from a global ocean model. The authors concluded that El Niño events lead to enhanced upwelling along Australia's southern shelves. However, it has been found that relationships between ENSO events and upwelling and production indices off southern Australia are weak due to the high interannual and inter-seasonal variability in these indices.

Huang and Wang (2019) results indicate that the ENSO events are likely to have a low-to-moderate impact on the upwelling intensity although the El Nino events tend to strengthen upwelling intensity along the south-east coast of Australia with La Nina events tending to weaken upwelling intensity. Previous studies (Middleton and Bye 2007; Middleton et al. 2007) indicated that the El Nino events would raise the thermocline (along the Australian margin) which effectively forms a colder and nutrient-rich pool at shallower depths. This is likely to enhance upwelling intensity, with higher SST and chlorophyll-a anomalies and a larger area of influence.

4.3.8.2 Ecological Importance

The primary ecological importance of the Bonney coast upwelling is as a feeding area for the Blue Whale (Balaenoptera musculus). The upwelled nutrient-rich re-heated Antarctic intermediate water promotes blooms of coastal krill, *Nyctiphanes australis*, which in turn attracts Blue Whales to the region to feed.

The Bonney coast upwelling is one of only two identified seasonal feeding areas for Blue Whales in Australian coastal waters and is one of 12 known Blue Whale feeding aggregation areas globally. Sightings of the sei whale in the upwelling indicate this is potentially an important feeding ground for the species (Gill et al. 2015). There have also been sightings of the fin whale, which indicate this could potentially be an important feeding ground (Morrice et al. 2004)

The high productivity of the Bonney coast upwelling also leads to other attributes such as algal diversity and its productivity as a fishery. This productivity is also capitalised on by other higher predator species such as Little Penguins and Fur-seals feeding on baitfish. Robinson et al. (2008) postulated that upwelling waters may bring fish prey of Australian Fur-seals to surface waters, which are then flushed into Bass Strait within foraging range of seals.

4.3.8.3 Linkages between Climate, Upwelling Strength, and Blue Whale Abundance

The complex interaction between climatic conditions, upwelling strength and seasonal Blue Whale distribution and abundance within the Bonney coast upwelling is currently poorly understood other than at a general level. Factors to be resolved to enable a more detailed understanding include observations that not all strong upwelling-favourable winds necessarily lead to strong upwelling events (Griffin et al. 1997) and that increased upwelling does not necessarily equate to increased productivity as conditions may be less optimal for plankton growth. Huang and Wang (2019) found a generally weak and unclear correlation between chlorophyll-a and SST. This weak correlation may be due to chlorophyll-a concentrations (a remote measure of plankton population) are also influenced by other complex oceanographic and biological mechanisms such as grazing, seasonality and transportation.

Further an increase in plankton biomass does not necessarily coincide with the presence of the Blue Whales. Review of pygmy Blue Whale aerial observation data from Gill et al. (2011) from the 2001-02 to 2006-07 seasons, and additional surveys in the Otway Basin commissioned by Origin during February 2011 and November -December 2012 did not find a significant positive correlation between El Niño conditions and pygmy Blue Whale abundance. Such a positive correlation could be expected if El Niño conditions caused stronger upwelling, stronger upwelling led to increased planktonic productivity and Blue Whales were more likely to be present when productivity is higher.

Two of the six seasons subject to aerial surveys in the eastern section of the Otway Basin (Gill et al. 2011) were determined by the Bureau of Meteorology to demonstrate weak to moderate El Nino conditions. The remainder of the years were assessed to be neutral. The two El Nino seasons (2002-03 and 2006-07) corresponded with the lowest observation frequencies (sightings/1,000 km) for pygmy Blue Whales of all the yearly surveys.

Aerial surveys commissioned by Origin undertaken during February 2011 and November-December 2012 were undertaken during La Nina events classified by the Bureau of Meteorology as very strong and strong respectively. Although observation frequencies are not available, the absolute numbers of pygmy Blue Whales observed was substantially higher than during the 2001-01 to 2006-07 surveys. Also, of note is that pygmy Blue Whales observed during February 2011 were congregated along the seaward edge of a plume of terrestrial runoff, potentially suggesting use of this plume as a feeding resource, which has no relationship to upwelling.

As such, the interactions between climate and ecology for this upwelling system are complex and no definitive linkages between climatic events, upwelling strength and Blue Whale abundance have yet been described.

4.3.8.4 Operational Setting

Mapping of the Bonney coast upwelling frequency by Huang and Wang (2019) identified that the occurrence of an upwelling event between 2002 and 2016 (measured by remote sensing of a combination of SST anomaly and chlorophyll-a) within the Project Area was unlikely with an upwelling frequency for this area of <10%. The closest areas of increased frequency of upwelling events to the Project Area (10-30% occasional/semi-seasonal) were small, isolated areas situated in coastal areas to the north and north-east (Gill et al (2011) states that the Bonney coast upwelling generally starts in the eastern part of the Great Australian Bight and spreads eastwards to the Otway Basin. At the height of the Bonney coast upwelling during February and March, the upwelling's area of influence often exceeds 12,000 km^2, its SST anomaly often exceeds 1°C, and its chlorophyll-a concentrations are often >1.5 times of its adjacent areas (Huang and Wang 2019). Areas of further increased frequencies of Bonney coast upwellings (30-50% seasonal) were found over 198 km to the west of the Project Area (Figure 4-13).

4.4 **Ecological Environment**

To characterise the ecological environment, a literature search and online resources and databases were reviewed to identify and assess species that may be present or potentially present in the Project and Planning Areas. The following information sources were used:

- Online government databases, publications, and interactive mapping tools, such as the SPRAT database and National Conservation Values Atlas.
- Protected Matters Search Tool (PMST) for Matters of National Environmental Significance (MNES) protected under the EPBC Act.
- Species conservation advice and recovery plans.
- In field survey data for the Otway area.
- Published observations, data, and statistics on marine mammals.
- Reports from scientific experts and institutions, marine biologist and experts in Blue Whale and Southern Right Whale populations in the Otway area.
- Relevant listings under the *Victorian FFG Act 1988*
- Relevant listings under the *Tasmanian Threatened Species Conservation Act (1995)*
- Relevant environmental guidelines and publicly available scientific literature on individual species.

4.4.1 Benthic Habitats and Communities

As discussed in Section 4.3.3, a number of studies (Boreen et al. 1993, BBG 2003, CEE Consultants Pty Ltd 2003 and Ramboll 2020) have been undertaken within the Project Area within the shallow and middle shelf zones. These studies have identified the seabed is similar across these areas, consisting of carbonate rich coarse to medium sands with areas of exposed limestone substrate. This type of seabed is highly mobile making it difficult for filter feeders and soft body invertebrates to survive and establish in significant populations. Epifauna is dominated by low density, patchy assemblages of branching bryozoans, gorgonian cnidarians and sponges. A summary of these studies is provided below.

The existing studies focus on the shallow and middle shelf zones of up to approximately 130 m water depth (refer to Section 4.3.3). Further seabed assessments will be undertaken of the deep shelf zone (from approximately 130m to 160m water depth) located predominantly in the southern and western portions of the Project Area. These assessments will enable the seabed composition, benthic habitats and communities to be identified for locations where seabed disturbance activities such as drilling and infrastructure installation may take place and will include:

- geophysical surveys consisting of multibeam bathymetry, side scan sonar, magnetometer, and sub-bottom profiling

- geotechnical sampling consisting of cone penetration tests and coring
- biological sampling consisting of sediment and water samples, and use of seabed imagery to identify benthic habitats at representative locations.

4.4.1.1 Existing Studies

In 2002, 2003 and 2004, Fugro undertook a number of bathymetric surveys of the two proposed pipeline rights of way: one constructed for the Thylacine Geographe pipeline and one extending from the completed Geographe A well to Flaxman's Hill.

A review of the available geotechnical data was carried out in March 2011 for the Geographe location (Advanced Geomechanics 2011). Overall, the seabed in the Otway area surveyed slopes to the south at a gentle average gradient of less than 1 degree. However, the local topography is predominantly irregular in nature, varying from gently undulating and locally smooth in areas of increased sediment deposition, to areas of outcropping cemented calcrete features that are from smooth to jagged relief. These areas are covered in marine growth. ROV video survey confirmed the presence of a shallow hard underlying substrate at a depth of 50 mm below the sediment in areas of marine growth (JP Kenny 2012).

The Flaxman's Hill alignment traverses the Thistle drilling area and the Thylacine Geographe pipeline runs parallel and north east of this area. During 2003, bathymetric data was collected, and the right of way was assessed and recorded using an underwater video camera (CEE Consultants Pty Ltd 2003). The Flaxman's Hill pipeline route travels approximately 68 km from the Geographe gas field to the shoreline. Visual assessment of the sea floor was undertaken from a water depth of 99 m to 16 m terminating at Flaxman's Hill.

A summary of the seabed morphology and benthic assemblages is provided in Table 4-11 to Table 4-15.

Table 4-11: Otway Margin Geomorphology (Boreen et al. 1993)

Zone	Depth (m)	Width (m/km)	Gradient	Features
Shallow Shelf	30 - 70	4 – 28	1.5 – 10	Drops rapidly from strandline to depths of 30 m, characterised by rugged but subdued topography
Middle Shelf	70 - 130	7 – 65	1 - 8.5	Generally smooth topography with occasional rock out crops

Table 4-12: Thylacine to Geographe Seabed Morphology and Benthic Assemblages (CEE Consultants Pty Ltd 2003)

Depth (m)	Seabed morphology	Benthic assemblage
92	High profile reef stone with deep sand gutters.	Diverse, high density sessile: sponge, coral dominated crinoids common and mobile species
88	Low profile with areas of high profile limestone ridges; incomplete sand veneer.	Diverse, high density sessile: sponge, dominated and mobile species

Table 4-13: Geographe to Flaxman's Hill Seabed Morphology and Benthic Assemblages (CEE Consultants Pty Ltd 2003)

Depth (m)	Seabed morphology	Benthic assemblage
82	Low profile with areas of high profile limestone ridges; incomplete sand veneer	Medium density sessile: sponge, dominated low density mobile species. (small shark)
82	Equal % of exposed low profile limestone and sand. Two reef outcrops. Low profile with areas of high profile limestone ridges; incomplete sand veneer.	Medium density, sessile: sponge, dominated
78	Low profile with areas of high profile limestone ridges; incomplete sand veneer	Medium density, sessile: sponge, dominated Motile: sea urchins dominated
76		Medium density, sessile: sponge, dominated
76		Low - Medium density, sessile: sponge, dominated
70		Diverse, med density sessile, sponge dominated
68		Medium density, sessile: sponge, dominated
65		Diverse, med density sessile, sponge dominated
60		Medium density, sessile: sponge, dominated

Table 4-14: Geographe to Rifle Range Seabed Morphology and Benthic Assemblages (CEE Consultants Pty Ltd 2003)

Depth (m)	Seabed morphology	Benthic assemblage
82	Low profile with areas of high profile limestone ridges; incomplete sand veneer	Very low density sessile; large sponge.
79		Diverse, low – high density sessile
75	Low profile with areas of high profile limestone ridges; incomplete sand veneer	Medium density, sessile: sponge, dominated. Motile: sea urchins dominated
74		Medium density, sessile: sponge, dominated
70		Low - Medium density, sessile: sponge, dominated
67		Diverse, med density sessile, sponge dominated
66	Low profile limestone with sand gutters	Medium density, sessile: sponge, dominated
66	Low profile with areas of high profile limestone ridges; incomplete sand veneer	Diverse, med density sessile, sponge dominated
70	(Pock marks) Data not documented.	Medium density, sessile: sponge, dominated
63	Corse gravel to fine sand	High density sessile: micro algae dominated

Table 4-15: Nearshore Seabed Morphology and Benthic Assemblages (CEE Consultants Pty Ltd 2003)

Depth (m)	Seabed morphology	Benthic assemblage
53	Sand	None observed
45		Only sea pens noted
16-30	Very high profile l/stone reef to sand	High density, sessile: sponge, macroalgae (Bull Kelp common)

A video survey of the seabed at selected sites along proposed offshore pipeline routes for the Otway Gas Development was undertaken by BBG during 2003 (Figure 4-14). BBG (2003) found that the substrate in water depths between 82 and 66 m were predominantly low- profile limestone with an incomplete sand veneer that supported a low to medium density, sponge dominated filter feeding community. Fish and other motile organisms were uncommon.

In shallower depths of between 63 and 30 m, the video surveys showed a rippled, sand or sand/pebble substrate with minor sponge dominated benthic communities. The epibenthic organisms were generally attached to outcropping or sub-outcropping limestone pavements. Only in waters shallower than approximately 20 m, was an area of significant, high profile reef and associated high density macroalgae dominated epibenthos encountered. Details of the seabed and benthic epifaunal assemblage are provided in Table 4-16.

Table 4-16: Nearshore Seabed Morphology and Benthic Assemblages (CEE Consultants Pty Ltd 2003)

Site No.	Depth (m)	Seabed type	Benthic Assemblage
3097	99	Bare rippled sand; minor limestone outcrops	Low density sessile; small sponge dominated
3118	99	Low profile limestone reef with sand veneer. isolated areas of raised l/stone	Low density sessile; sponge dominated
3084	99	Low profile limestone reef with incomplete sand veneer	Low density sessile; sponge dominated
3072	99	Low profile limestone reef with incomplete sand veneer	Low density sessile; sponge dominated
3054	98	Mix of low and high profile l/stone; shallow and deep sand	Low density sessile on low l/stone; high density sessile on high l/stone plus fish; sponge dominated
3185	95	Low profile limestone reef with incomplete sand veneer	Low density sessile; sponge dominated
3196	94	Low profile limestone reef with incomplete sand veneer	Low density sessile; sponge dominated
3232	92	High profile reef stone with deep sand gutters.	Diverse, high density sessile: sponge, coral dominated crinoids common and mobile species
3267	88	Low profile with areas of high profile limestone ridges; incomplete sand veneer.	Diverse, high density sessile: sponge, dominated and mobile species
2801	82	Low profile with areas of high profile limestone ridges; incomplete sand veneer	Very low density sessile; large sponge.

Site No.	Depth (m)	Seabed type	Benthic Assemblage
2720	79		Diverse, low – high density sessile
2590	75	Low profile with areas of high profile limestone ridges; incomplete sand veneer	Medium density, sessile: sponge, dominated. Motile: sea urchins dominated
2490	74		Medium density, sessile: sponge, dominated
2339	70		Low - Medium density, sessile: sponge, dominated
2291	67		Diverse, med density sessile, sponge dominated
2191	66	Low profile limestone with sand gutters	Medium density, sessile: sponge, dominated
2181	66	Low profile with areas of high profile limestone ridges; incomplete sand veneer	Diverse, med density sessile, sponge dominated
1191	63	Coarse gravel to find sand	High density sessile: micro algae dominated
1668	53	Sand	None observed

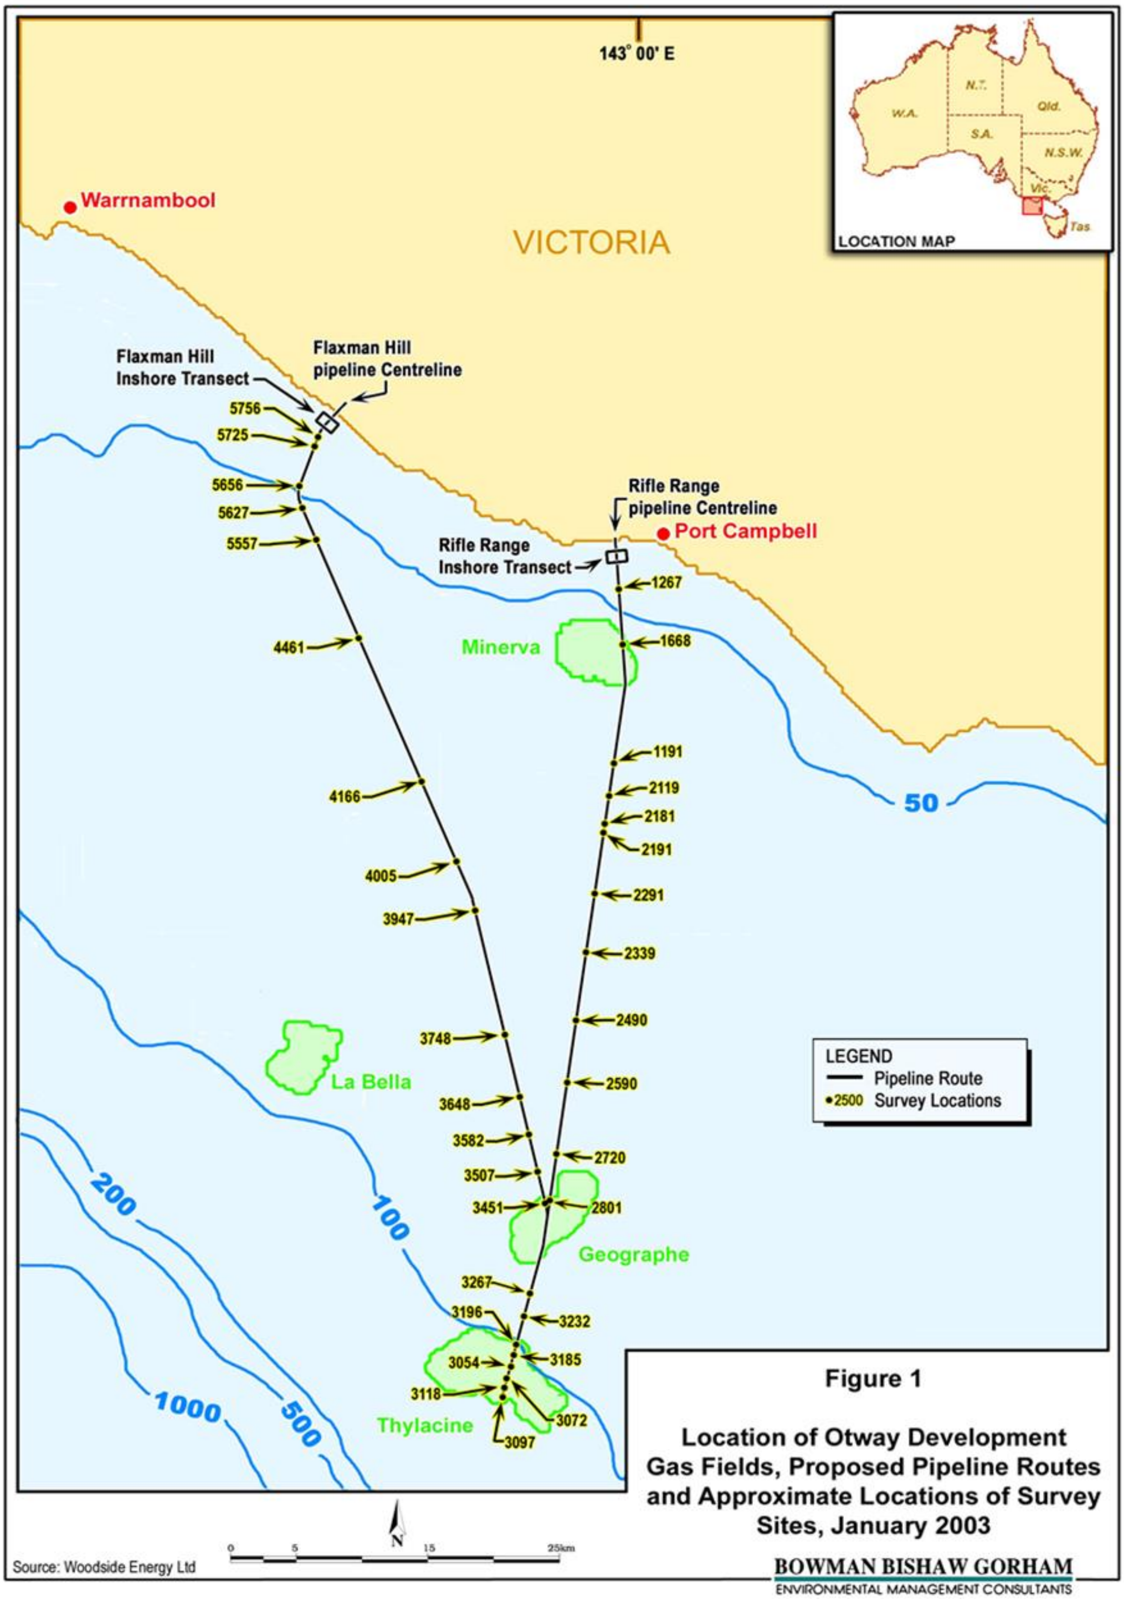

Figure 4-14: Seabed Sites Assessed by Video Survey During 2003 (BBG 2003)

Beach commissioned a seabed site assessment of the preferred infrastructure routes for the Otway Gas Development which was undertaken during the Otway Basin Environmental Survey from November

2019 to January 2020 and ranged in water depths from 70 to 104 m (Ramboll, 2020. Appendix C). details the survey area and sample locations.

The objective of the seabed site assessment was to determine suitable locations for anchoring and MODU placement for drilling operations and the installation of infrastructure to connect new production wells to the existing infrastructure. Several different investigation techniques were used to examine and describe the seabed and benthic habitats, as well as identify possible hazards from manmade, natural, and geological features including benthic habitats

The survey comprised of multibeam bathymetry, side scan sonar, magnetometer, and sub-bottom profiling, cone penetration tests and seabed samples. In addition, sediment samples for infauna were collected and the composition and percent coverage of epifauna was assessed from photographs of the seafloor taken with a drop camera. Drop camera images at various locations are shown in Figure 4-16 to Figure 4-23 and survey results are summarised in Table 4-17.

Sediment samples for infauna were collected at two of the gas fields, Artisan and Thylacine. It was considered that the Artisan field would be representative of the infauna closer to shore (such as along the pipeline route), while the Thylacine field which is further offshore would represent the Geographe field.

The benthic infauna identified and counted from samples collected at the Thylacine and Artisan sites were relatively depauperate in both abundance and diversity. A total of 22 morpho-species were identified, from a total of 45 organisms collected from the grab samples, most of which were polychaete worms or crustaceans. These results are reflective of the sedimentary environment at the Thylacine and Artisan fields. All sites were dominated by sand, which typically have a lower abundance and diversity of infauna given that this abrasive type of substrate tends to be more easily subjected to laminar flows that move the sediment more dynamically than muddy substrates. The consequence of this is a physical environment that is not favourable for filter feeding and burrowing infauna species to inhabit. The types of species that were present in the samples were all those which can be expected to tolerate this somewhat dynamic environment. There were no discernible spatial trends in the distribution of sediment particle size. Likewise, there were no clear trends in the abundance, diversity, or composition of benthic infauna.

The composition and percent coverage of epifauna was assessed from photographs of the seafloor taken with a drop camera system. Percent cover ranged from 0 to 80% of the sample photograph for all samples but on average the percent cover was typically no more than 37%. The seabed at Hot Tap X had the greatest average coverage of epibiota (Figure 4-21) while the lowest coverage of epibiota was recorded along the route between Artisan and Hot Tap Y (Figure 4-16). Of the gas field sites, Artisan and Hercules had a slightly greater coverage of epifauna, while the routes between gas fields and Hot Tap Y have the least coverage of epifauna. Of the individual epibenthic organisms, *Gastropoda* sp. 2 (a cone shell) and crionids (featherstars) were the most abundant.

Further analysis of epifauna from grab samples at Artisan showed that much of the epifauna is comprised of branching bryozoans, feather-like gorgonian cnidarians and sponges. This complex of encrusting/branching fauna provides refuge for macrofauna such as amphipods, isopods, polychaete worms and molluscs.

Based on the assessment of epifauna using seabed photographs, the general impression of the seafloor is of an unmodified marine environment that supports a patchy complex of branching epibiota (i.e., bryozoans, gorgonian cnidarians, and sponges). This complex was highly patchy, covering 0.25 m^2 on average but could be found in patches of at least 0.4 m^2. A microscopic examination of a qualitative sample of this epibiota indicated that this complex of fauna provide microhabitat for a range of macrofauna such as amphipods, isopods, polychaete worms and molluscs. Such epifaunal habitats are known to provide refuge and other resources for benthic species (Jones 2006). By comparison, there was a low abundance and diversity of infauna living within the sediment which reflects the coarse nature of the substrate. This type of substrate is highly mobile making it difficult for filter feeders and soft bodies invertebrates to survive and establish significant populations.

Ramboll (2020) summarise that the epibiota on the seabed in the vicinity of the Thylacine and Artisan gas fields is representative of what is expected at depths around 70-100 m. The infauna was of relatively low abundance and diversity as expected for coarse sand substrates. No benthic species or ecological communities listed as threatened under the Environmental Protection and Biodiversity Conservation Act 1999 (the EPBC Act) were identified.

The findings from Ramboll (2020) align with findings from the Otway Gas Development studies (CEE Consultants Pty Ltd 2003; BBG 2003) and Boreen et al. (1993) concerning the subsea features and biological communities likely to dominate the middle shelf zones of the Project Area. In summary the seabed of the Project Area can be characterised as a carbonate mid shelf and deeper sections (60 – 70 m) of the shallow shelf with surficial sediments of carbonate rich coarse to medium sands with areas of exposed limestone substrate. The epifauna is dominated by low density, sessile sponge assemblages.

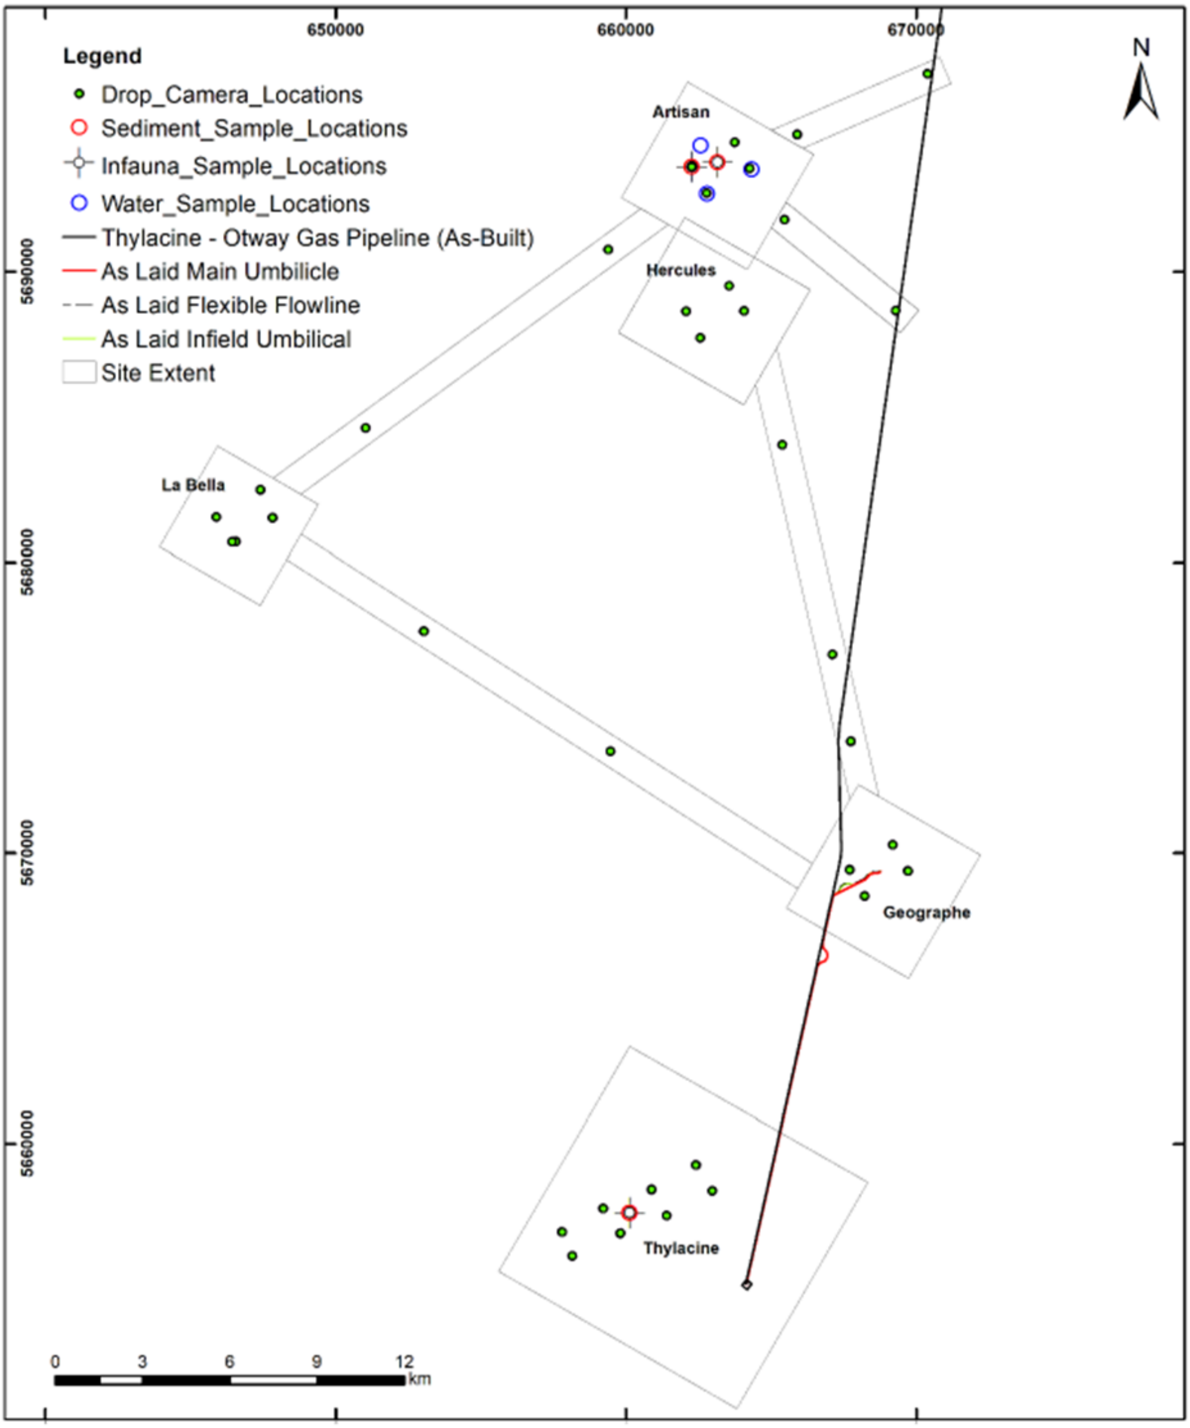

Figure 4-15: Seabed Sites Assessed during the Otway Gas Development Phase 4 Seabed Survey (Fugro, 2019; Ramboll, 2020)

Table 4-17: Results of the Otway Gas Development Phase 4 Seabed Survey (Fugro, 2019; Ramboll, 2020)

Survey Location	Results
Artisan (Figure 4-16)	Very little bathymetric variation across the survey area with water depths ranging from 68 to 74m. Seabed topography dominated by exposed rock on the seabed. Small patches of very thin transgressive coarse sand are present across the survey area. Megaripples were seen in some areas, with a wavelength of 1.5 to 2m and a height of 0.3 to 0.5m. Survey area characterised by low to moderate reflectivity characteristic of rock outcrop. A series of elevated mounds were noted in the north-west of the Artisan survey area 0.5 -1.0m above ambient seabed. Seabed showed a scattered sessile biota on a sandy seafloor.
Thylacine (Figure 4-17)	Seabed depths vary ranging from 92 to 115m, with an overall south-western slope. Seabed topography compromises of rocky outcrops of the regionally dipping Port Campbell limestones. Sands are coarse (siliceous) calcareous medium sand. A local relief of up to 3m is identified on the rocky scarp surfaces, which are separated by shallow depressions often with a transgressive sandy infill. Percentage epifauna cover from the eight drop camera sites ranged from zero to 65% with an average percentage cover of 14%. Predominantly hard seabed with coarse sand substrates that supports a patchy complex of branching epibiota (i.e., bryozoans, gorgonian cnidarians and sponges). Epibiota on the seabed in the vicinity of the Thylacine gas fields is representative of what is expected at depths around 70 – 100m. Infauna was of relatively low abundance and diversity as expected for coarse sand substrates.
Geographe (Figure 4-18)	Very little bathymetric variation across the survey area with water depths ranging from 80 to 91m. Rocky outcrops of the Port Campbell Limestone show some variable relief up to 2m. Sand is clean washed and well sorted and comprising predominantly of angular broken shells and bryozoans. Percentage cover from the four drop camera sites ranged from zero to 55% with an average percentage cover of 13%. Predominantly hard seabed with coarse sand substrates that supports a patchy complex of branching epibiota (i.e., bryozoans, gorgonian cnidarians, and sponges).
La Bella (Figure 4-19)	Water depth varies from 89 to 104m, with an overall south-western slope. Seabed characterised by rocky outcrops interspersed with low-lying areas of shallow uncemented sediment. Seabed topography is typical of an eroded platform, with inferred calcarenite lithology. Side scan sonar results also provide flat seabed and megarippled sands and rock outcrop features. At rock exposures, seabed photographs appear to show biogenic growth.

Survey Location	Results
Hercules (Figure 4-20)	Very little bathymetric variation across the survey area with water depths ranging from 71 to 77m. Seabed characterised by rocky outcrops interspersed with low-lying areas of shallow uncemented sediment. Port Campbell limestone cap rock is covered in places by mobile sediments of 1m thickness. Hercules site is a southern extension of the Artisan site, and therefore the seabed features bear strong similarities to those seen at Artisan site. Seabed features are typical of an eroded platform, including parallel asymmetric ridges with intermittent depressions.
OGPP and Umbilical Routes (Figure 4-21 Figure 4-22 Figure 4-23)	Seabed terrain is largely comprised of outcropping calcarenites, incised with erosional features and interspersed with (relatively) low-lying areas where shallow uncemented sands occur. Sands are generally less than 1m thick. Side scan sonar results also provide flat seabed and megarippled sands and rock outcrop features. At rock exposures, seabed photographs appear to show biogenic growth.

4.4.2 Seagrass

Seagrasses are marine flowering plants, with around 30 species found in Australian waters (Huisman 2000). While seagrass meadows are present throughout southern and eastern Australia, the proportion of seagrass habitat within the south-eastern sector is not high compared to the rest of Australia (in particular with parts of South Australia and Western Australia) (Kirkham 1997).

Seagrass generally grows in soft sediments within intertidal and shallow subtidal waters where there is sufficient light and are common in sheltered coastal areas such as bays, lees of islands and fringing coastal reefs (McClatchie et al. 2006, McLeay et al. 2003). Seagrass meadows are important in stabilising seabed sediments, and providing nursery grounds for fish and crustaceans, and a protective habitat for the juvenile fish and invertebrates species (Huisman 2000, Kirkham 1997).

Known seagrass meadows within the Planning Area are present along the Victorian coastline (Figure 4-24). No seagrass meadows were identified within the Project Area.

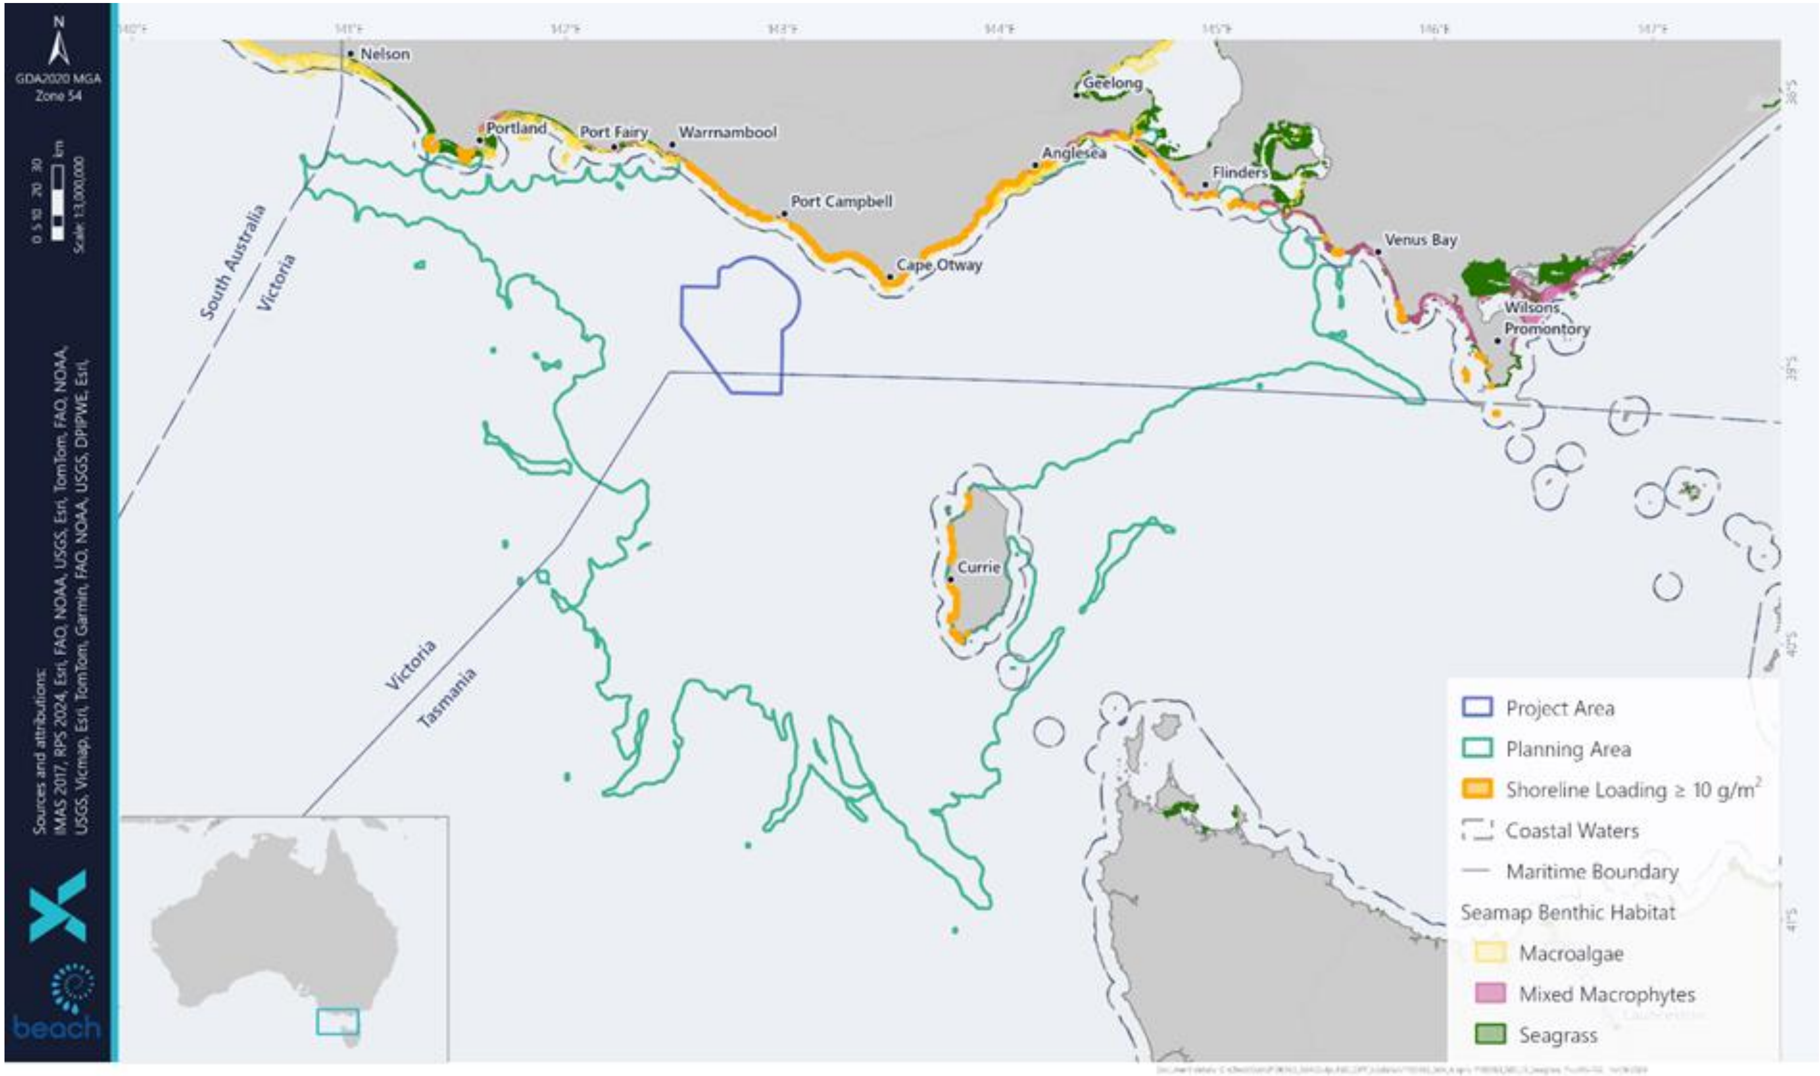

Figure 4-24: Presence of Seagrass (and mixed macrophyte) Habitat within the Planning Area

4.4.3 Algae

Benthic microalgae are present in areas where sunlight reaches the sediment surface. Benthic microalgae are important in assisting with the exchange of nutrients across the sediment-water interface; and in sediment stabilisation due to the secretion of extracellular polymetric substances (Ansell et al. 1999). Benthic microalgae can also provide a food source to grazers such as gastropods and amphipods (Ansell et al. 1999).

Macroalgae communities occur throughout the Australian coast and are generally found on intertidal and shallow subtidal rocky substrates. Macroalgal systems are an important source of food and shelter for many ocean species; including in their unattached drift or wrack forms (McClatchie et al. 2006). Macroalgae are divided into three groups: *Phaeophyceae* (Brown Algae), *Rhodophyta* (Red Algae), and *Chlorophyta* (Green Algae). Brown Algae are typically the most visually dominant and form canopy layers (McClatchie et al. 2006). The presence and growth of macroalgae are affected by the principal physical factors of temperature, nutrients, water motion, light, salinity, substratum, sedimentation, and pollution (Sanderson 1997). Macroalgae assemblages vary, but *Ecklonia radiata* and *Sargassum* sp. are typically common in deeper areas.

Within the Planning Area, macroalgae are present along the Victorian coastline (Figure 4-25). No macroalgae have been mapped within Project Area.

Kelp are a special group of large brown algae that attach themselves to solid structures to form forests. They extend their leaf-like fronds into the waters above them reaching towards the sunlight. These larger algae in turn create a habitat for smaller algae, invertebrates, and fish (VFA 2023). On Victoria's coast kelp forests grow on most rocky reefs in waters to a depth of around 30 m, although most are found in shallower waters (VFA 2023).

Bull Kelp or Southern Bull Kelp (Durvillaea potatorum) is a fast-growing brown macroalgae (seaweed) with large dark brown and leathery strap-like blades. It consists of a body, called the thallus, with a stipe connecting the blades to the holdfast (a structure adhering the Bull Kelp to the seafloor.

Offshore Victoria and Tasmania there are two main species of *Durvillaea*, these are *D. potatorum* and *D. amatheiae*. The approximate distribution of the species is shown in Figure 4-25.

Durvillaea spp. are a significant habitat. The holdfast can be inhabited by a diverse array of epifauna and infauna invertebrates. These burrow into the holdfast creating holes that can be used by a wide variety of animals. In addition, *Durvillaea* spp. grow in large groups or forests that can become important nursery areas and sanctuary areas for fish, crustaceans, and other fauna.

Thurstan et al. (2018) gathered historical data on the use of Bull Kelp by First Nations. Bull Kelp has a long history of use by First Nations people in Australia, New Zealand, and Chile. In Australia this reportedly dates back 65,000 years (Thurstan et al. 2018). First Nations people in Tasmania used dried bull kelp to transport water and food. The species name came from this use: '*potatorum*' means 'to drink' in Latin (Govt of SA 2023).

Thurstan et al. (2018) details a number of First Nations historical references for Bull Kelp including:

- Cultural activities and cultural history –mythology and sacred songs.

- Ceremonial activities –being burned or being used during smoking ceremonies.
- Medicinal use –bandages and medicinal poultice.
- Clothing – cloaks and shoes.
- Diet – raw, jelly, dried and roasted (preserving for several months).
- Fishing – ropes and fishing nets / traps, traps for short-finned eels, also used to assist during diving for crayfish.
- Shelter – waterproofing, wind proofing and carpeting.

Bulk Kelp is also collected by the seaweed industry as described in Section 4.5.14.

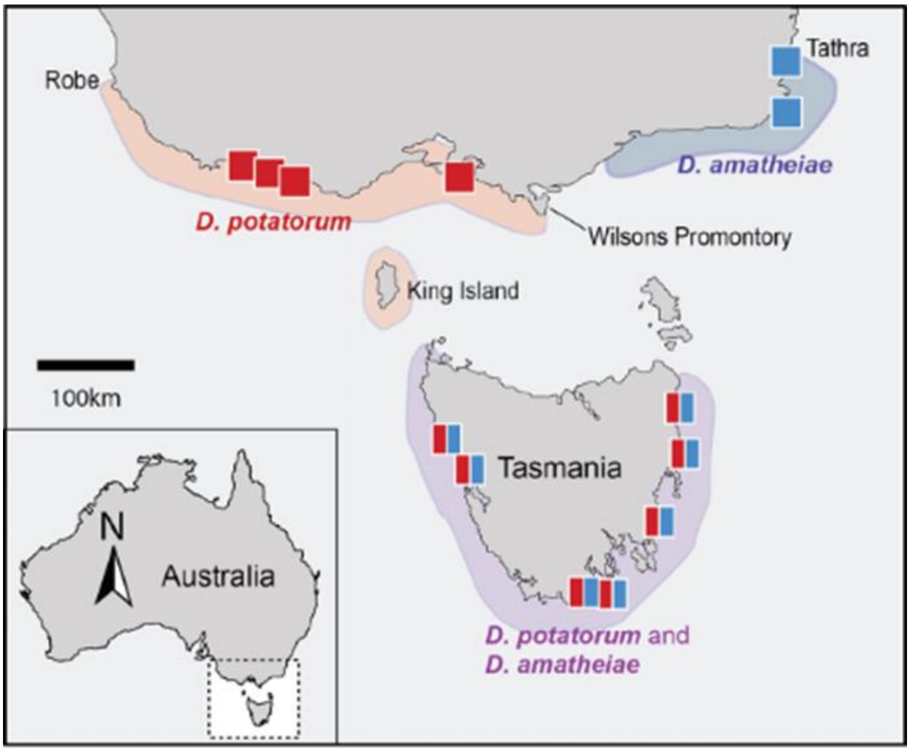

Figure 4-25: Distribution of Bull Kelp off Victoria and Tasmania (Velasquez et al. 2019)

4.4.4 Mangrove

Mangroves grow in intertidal mud and sand, with specially adapted aerial roots (pneumatophores) that provide for gas exchange during low tide (McClatchie et al. 2006). Mangrove forests are important in helping stabilise coastal sediments, providing a nursery ground for many species of fish and crustacean, and providing shelter or nesting areas for seabirds (McClatchie et al. 2006).

The mangroves in Victoria are the most southerly extent of mangroves found in the world and are located mostly along sheltered sections of the coast within inlets or bays (MESA 2015). There is only one species of mangrove found in Victoria, the white or grey mangrove (*Avicennia marina*), which is known to occur at Western Port and Corner Inlet. Small patches of mangroves have been mapped within the Planning Area at the Erskine River (Figure 4-26).

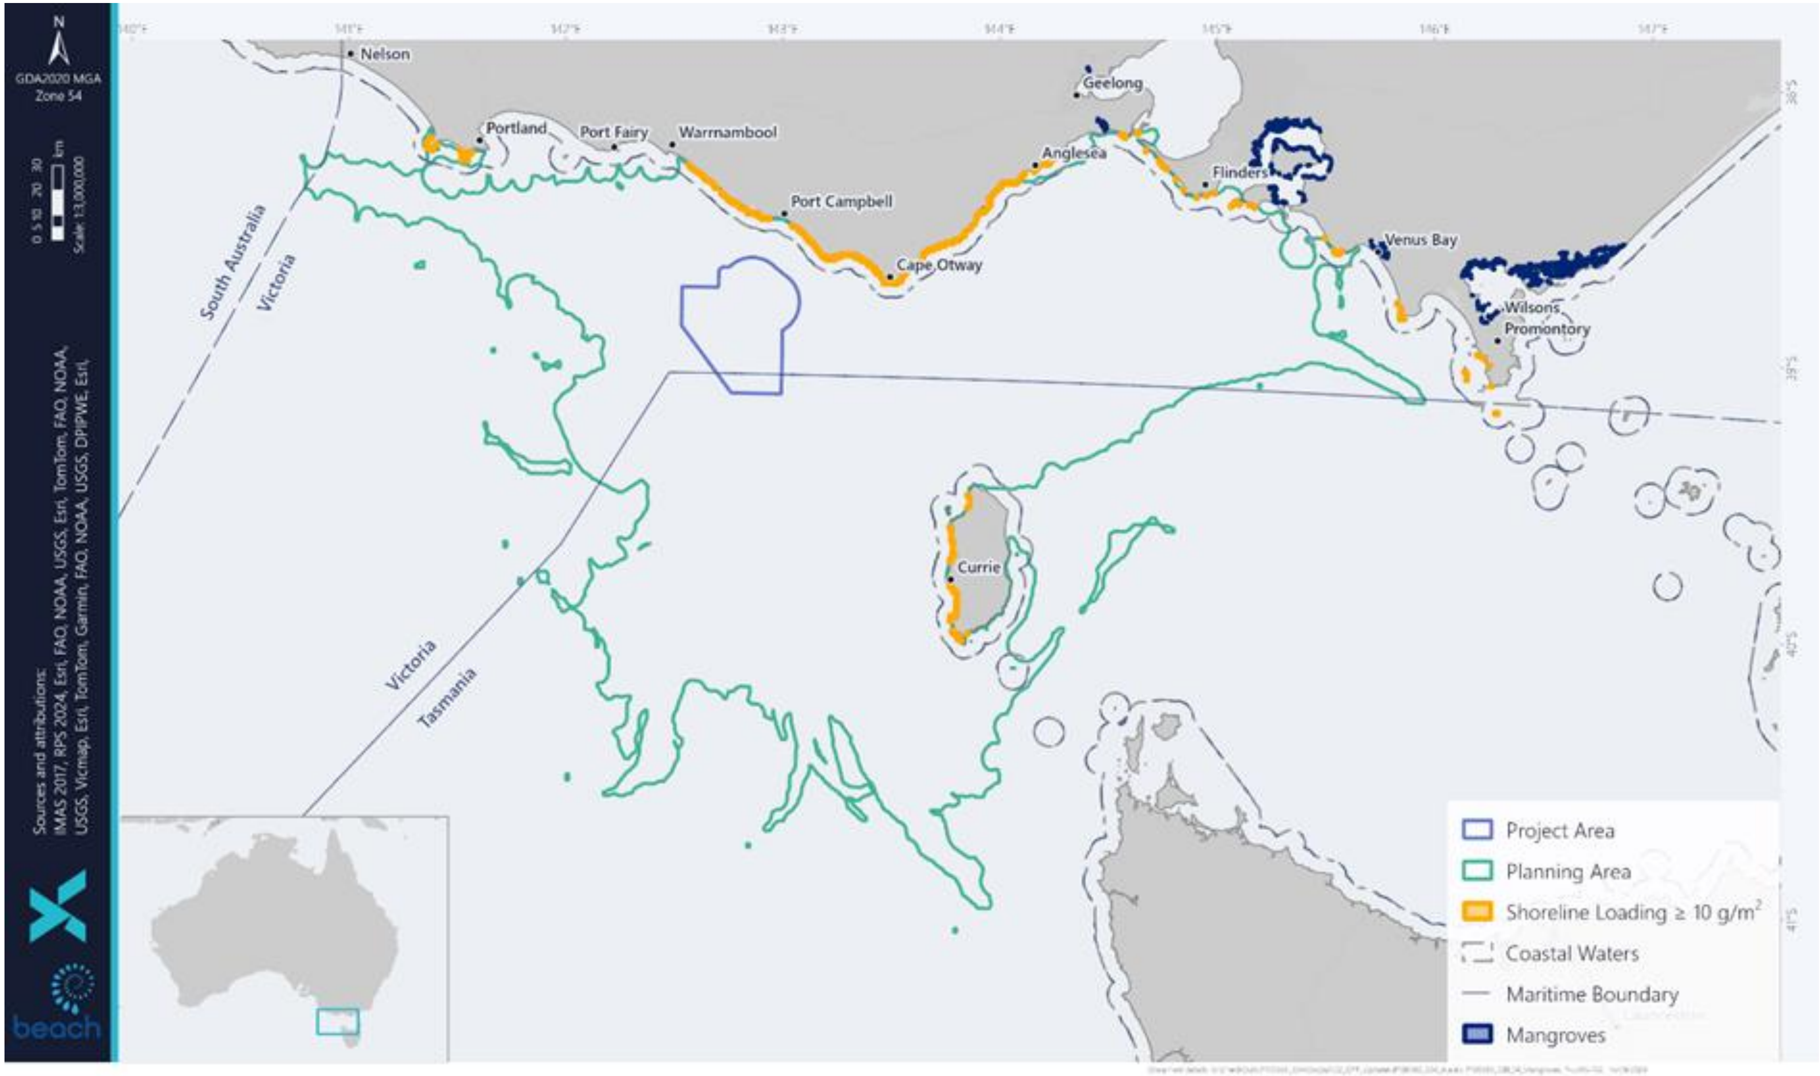

Figure 4-26: Presence of Mangrove Habitat within the Planning Area

4.4.5 Saltmarsh

Saltmarshes are terrestrial halophytic (salt-adapted) ecosystems that mostly occur in the upper-intertidal zone and are widespread along the coast. Saltmarshes are typically dominated by dense stands of halophytic plants such as herbs, grasses, and low shrubs. In contrast to mangroves, the diversity of saltmarsh plant species increases with increasing latitude. The vegetation in these environments is essential to the stability of the saltmarsh, as they trap and bind sediments. The sediments are generally sandy silts and clays and can often have high organic material content. Saltmarshes provide a habitat for a wide range of both marine and terrestrial fauna, including infauna and epifaunal invertebrates, fish, and birds.

Saltmarsh is found along many parts of the Victorian coast, although is most extensive in western Port Phillip Bay, northern Western Port, within the Corner Inlet-Nooramunga complex, and behind the sand dunes of Ninety Mile Beach in Gippsland (Boon et al. 2011). Within the Planning Area, saltmarsh habitat has been mapped along the Victorian coastline including Kennett River (Figure 4-27).

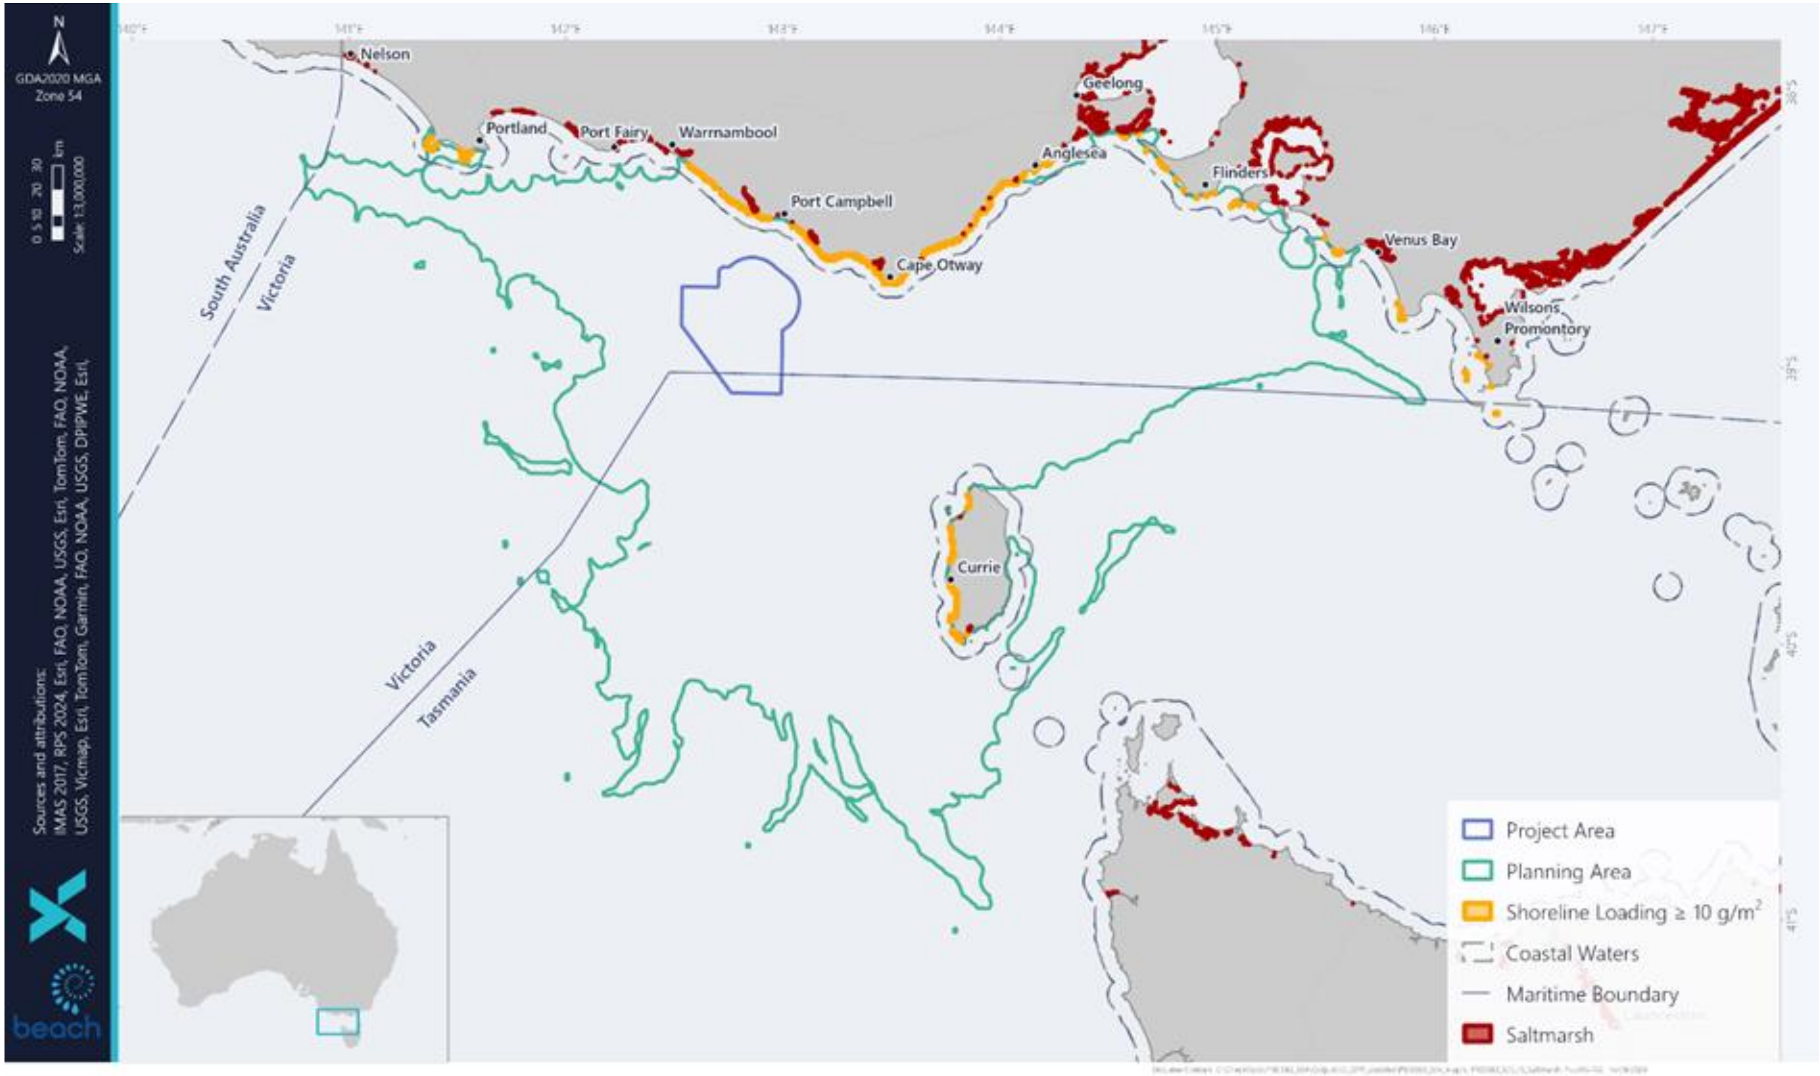

Figure 4-27: Presence of Saltmarsh Habitat within the Planning Area

4.4.6 Plankton

Plankton are small animals and plants that float or drift on the surface or within the water column. Some forms have limited swimming ability but are still dispersed mainly by water currents. Plankton are a very important part of the ecosystem for several reasons:

- Primary production of the phytoplankton is considerable.
- Much of the plankton consists of eggs and juvenile stages of organisms which are not planktonic as adults. It is thus an important contributor to the maintenance of population and diversity in other habitats.
- Plankton is an important food resource for many larger organisms, including fish.

Plankton are abundant and widely distributed in the South East Marine Region. In the Otway Basin, they have patchy distributions linked to localised and seasonal productivity that produces sporadic bursts in populations (CoA 2015). Distribution in the Project Area is expected to be highly variable both spatially and temporally and are likely to comprise characteristics of tropical, Southern Australian, central Bass Strait and Tasman Sea distributions.

Plankton are not protected under the EPBC Act.

4.4.7 Invertebrates

There is a very large number of marine invertebrates in deep waters around Australia. Knowledge of the species in different habitats is extremely patchy; the number of deep-water benthic fauna is large but almost unknown. Throughout the region, a variety of seabed habitats support a range of animal communities such as sparse sponges to extensive ‘thickets” of lace corals and sponges, polychaete worms and filter feeders (DNP 2013).

Characteristics of large species of crustacea, such as lobster, prawn and crab, which are significant commercial species in southern Australia, are well known. Mollusc species, such as oysters, scallops and abalone are also commercially fished, and their biology and abundance are well known. Major fisheries for the blacklip and to a lesser extent, greenlip abalone and scallops have been founded. The cooler waters of southern Australia also support the Maori Octopus commercial fishery, which is one of the largest octopuses in Australia (with arm spans longer than 3 m and weighing more than 10 kg). Other molluscs are abundant in southern Australia and Tasmania such as the sea-slug with more than 500 species. Volutes and cowries represent a relic fauna in southern Australia, with several species being very rare and can be highly sought after by collectors.

Echinoderms, such as sea stars, sea urchins and sea cucumbers are also an important fauna species of the southern Australian and Tasmanian waters, with several species at risk of extinction (DPIPWE 2016).

Studies by the Museum of Victoria found that invertebrate diversity was high in southern Australian waters although the distribution of species was patchy, with little evidence of any distinct biogeographic regions (Wilson and Poore 1987). Results of sampling in shallower inshore sediments reported high diversity and patchy distribution (Parry et al. 1990). In these areas, crustaceans, polychaetes, and molluscs were dominant.

4.4.7.1 Commercially Important Invertebrate Species

1. Abalone

Blacklip abalone (*Haliotis rubra rubra*) and greenlip abalone (*Haliotis laevigata*) are commercially important reef-dwelling species widely distributed across tropical and temperate coastal areas. Abalone are single shelled with a fleshy body and muscular foot which they use to attach to hard substrate, typically in water depths of 5-10 m however they can be found in depths up to 40 m (DPI 2024). A distinguishing feature of this genus is their rows of small holes or ‘pores’ along the edge of their shells where the organism will expel water that has passed through its gills (DPIRD 2016). Females produce and release millions of eggs each year into the water column, where they are fertilised by sperm released by males. Fertilised eggs hatch into larvae and after about a week the larvae develop into small juveniles which settle onto rocks (DPIRD 2016). After settlement, juvenile abalone hide under rocks during the day only emerging in the night to feed. Once abalone reach sexual maturity (approximately 5-8 years old) most animals no longer engage in this behaviour and become sedentary, rarely moving more than a few hundred metres from their natal site (DNRET 2022a). Evidence confirms that the greenlip abalone comprises numerous independent biological stocks at a spatially broad scale, even larger than the biological stock structure of the blacklip abalone (Mayfield et al. 2021).

Stock status records show the blacklip abalone to be sustainable in 2 of 3 South Australian stocks and in 3 of 4 Tasmanian stocks. Of the remaining 5 stocks, 4 are determined to be depleted (SA, TAS, VIC) and the last is undefined (NSW). Stock status records show the greenlip abalone to be depleted in 3 stocks (SA, TAS) and undefined in 3 stocks (VIC, SA). Figure 4-28 and Figure 4-29 show the distribution of reported commercial catch of both species in south-eastern Australia (Mundy et al. 2021; Mayfield et al. 2021) which indicates that they are likely to be present in the Planning Area. Although neither abalone species have EPBC status or an associated recovery or management plans, there are a range of anthropogenic threats that have the potential to affect them including:

- Commercial and recreational fishing, and
- Climate change (i.e. ocean acidification).

During consultation it was identified that Victorian stocks are at risk of a herpes-like virus that is believed to reappear when abalone are under stress.

Figure 4-28: Distribution of Reported Commercial Catch of Blacklip Abalone (Mundy et al. 2021)

Figure 4-29: Distribution of Reported Commercial Catch of Greenlip Abalone (Mayfield et al. 2021)

2. Commercial Scallop

Commercial scallops (*Pecten fumatus*) are a commercially important species that can be distinguished from other scallops by their equal-sized circular shaped shells. This species is distributed throughout southern Australia, from mid NSW to mid-WA including Tasmania in depths between 1-120 m. Scallops are typically sedentary benthic organisms that aggregate into beds and can be found buried in soft sediment (mud and sand). Spawning is known to only occur after a two-year development period and is thought to be triggered by an increase in temperature. Commercial scallops can release up to one million eggs into the water column during spawning.

There are four commercial scallop stocks in Australia: Bass Strait Central Zone Scallop Fishery, Port Phillip Bay Dive Scallop Fishery, Tasmanian Scallop Fishery and Victoria's Ocean Scallop Fishery. Stock status records show the species to be sustainable through the Commonwealth and Port Phillip Bay jurisdictions, while stocks are considered depleted in the Tasmanian and Victorian Fisheries jurisdictions (Semmens and Woodhams 2021). However, since being closed in 2015 due to low stock the Tasmanian Scallop Fishery was approved to reopen in September of 2021 and has continued on with the 2022 season. Figure 4-30 shows the distribution of reported commercial catch of commercial scallop in south-eastern Australia (Semmens and Woodhams 2021) which indicates it is likely to be present in the Planning Area. Although, the commercial scallop does not have EPBC status or an associated recovery or management plan, there are a range of anthropogenic threats that have the potential to affect commercial scallops including:

- Commercial and recreational fishing, and
- Climate change (i.e. ocean acidification).

Figure 4-30: Distribution of Reported Commercial Catch of Commercial Scallops (Semmens and Woodhams 2021)

3. Giant Crab

The giant crab (*Pseudocarcinus gigas*) is a commercially important species in the region that is endemic to the waters of southern Australia (DoE 2014b) (Figure 4-31). This species resides on muddy or rocky bottoms in waters of the Southern Ocean at depths from 18 to 600 m depth (Gardner and Welsford 2003, Poore 2004, Heeren and Mitchell 1997). Most commonly this species is found in the shelf break habitat associated with bryozoan substrates between 140 m and 270 m (Poor 2004, Leon et al. 2017). The habitat of early juveniles has yet to be established, however there is some evidence that smaller individuals occur in deeper water (Williams et al 2009; Leon unpublished data). Additionally, bryozoan communities are rich in prey items suitable for juvenile crabs, suggesting that this particular habitat is likely to be important for the settlement and growth of giant crab (Levings 2001). Williams et al. (2009) notes that giant crabs observed during surveys along the continental slope were using ledges and sponges for shelter. Given its habitat preferences and mapped fishing activity (edge of the continental slope), giant crabs are known to be present in the shelf slope of the Planning Area and may be present in the Project Area.

Giant carb feeds on carrion and slow-moving benthic species including gastropods, crustaceans and starfish. They breed in June and July, and the females carry up to two million eggs for approximately four months. As hatching approaches (October to November), females are thought to migrate to the shelf-break (Currie and Ward 2009). Upon hatching, the larval duration is around 50 days with larvae release occurring at the edge of the continental shelf (FRDC 2017). There is a strong capacity for larval dispersal over large spatial scales prior to settlement (PIRSA 2002). Recruitment is not distributed evenly, with some areas having higher juvenile abundance than others, which is not a function of habitat but larval drift and ocean current movements (FRDC 2018a). Oceanographic modelling has demonstrated the species is of a single biological stock with larval dispersal occurring along the edge of the continental shelf and drifting with plankton for a 50-day period.

Female moulting peaks strongly in winter (June and July). Males moult in summer (November and December). Intermoult period estimates varied from 3 to 4 years for juvenile males and females, with rapid lengthening in time between moulting events to approximately 7 years for females and 4.5 years for males. Gardner (1998) reports that females appear to mate while soft-shelled with stored sperm remaining viable for at least 4 years; broods are produced annually although females occasionally skip a reproductive season, which may be associated with moulting, and several broods may be produced between moults although fecundity declines with successive broods.

The species key biological features (e.g., long-lived, slow growing) have the potential to leave the population vulnerable to decline (FRDC 2018a). While there is little scientific data on the population, stock status records show the species to be sustainable throughout WA, SA and Victoria but depleted in Tasmania (Hartmann et al. 2021). The giant crab does not have EPBC status or an associated recovery or management plan. There are a range of anthropogenic threats that affect giant crabs including:

- Commercial and recreational fishing, and
- Ecosystem effects as a result of habitat modification and climate change.

Figure 4-31: Distribution of Reported Commercial Catch of Giant Crab (Hartmann et al. 2021)

4. Octopus

The pale octopus (*Octopus pallidus*) is a commercially important species found across the Great Australian Bight around Tasmania and towards southern NSW. They can be found inhabiting sand and mud substrates, often in association with sponge gardens or beds of large solitary sea squirts in depths up to 600 m (Atlas of Australia 2022a). This species hides during the day and feeds at night primarily on bivalves, which are pulled apart or drilled. The pale octopus lays large eggs that are attached to hard substrates and foraging begins immediately after hatching. Evidence suggests that there are a number of subpopulations within the Bass Strait due to limited species dispersal and isolation due to distance (Krueck et al. 2021).

Stock status records show the species to be depleting in the Tasmanian jurisdiction, undefined in the Victorian jurisdiction and negligible in both SA and NSW due to historically low catch rates. Figure 4-32 shows the distribution of reported commercial catch of pale octopus in south-eastern Australia (Krueck et al. 2021) which indicates it is likely that they will be present within the Project and Planning Areas. Although, the pale octopus does not have EPBC status or an associated recovery or management plan, there are a range of anthropogenic threats that have the potential to affect them. Key threats identified include:

- Commercial and recreational fishing, and
- Climate change.

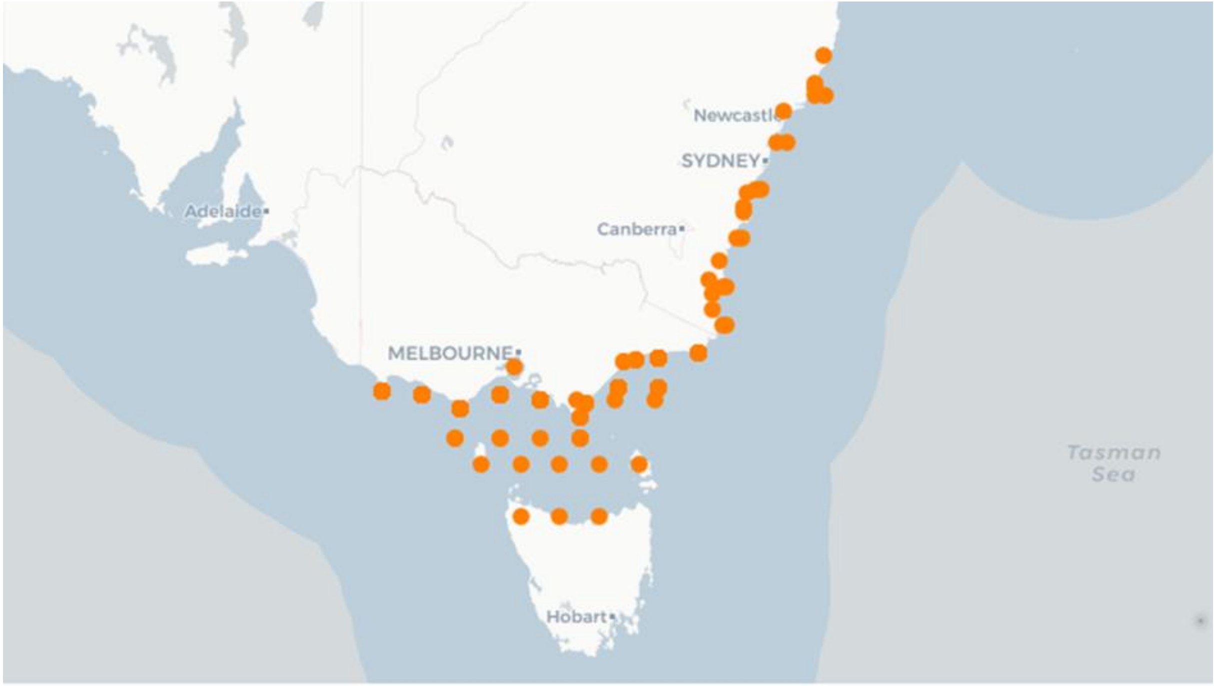

Figure 4-32: Distribution of Reported Commercial Catch of Pale Octopus (Krueck et al. 2021)

5. Pipi

Pipi (*Donax deltoides*) are a commercially important species found on sandy beaches between southern QLD and the Murray River in SA and have been a culturally important species to First Nations people for thousands of years. Life expectancy for this species is between 4-5 years and like most bivalves this species filter feeds by extracting microscopic matter from the water column (Ferguson and Johnson 2021). Typically, pipi reach sexual maturity towards the end of their first year and are then able to spawn year-round. East Australian and South Australian currents act as key drivers of gene flow on the east and south coasts of Australia which has resulted in high genetic variation between populations on either side of Bass Strait (Ferguson and Johnson 2021).

Stock status records show the species to be sustainable through the NSW and SA jurisdiction while the Victorian jurisdiction is undefined. Figure 4-33 shows the distribution of reported commercial catch of pipi in south-eastern Australia (Ferguson and Johnson 2021) which indicates it is likely that they will be present in the Planning Area. Although, pipi does not have EPBC status or an associated recovery or management plan, there are a range of anthropogenic threats that have the potential to affect them. Key threats identified include:

- Commercial and recreational fishing, and
- Climate change.

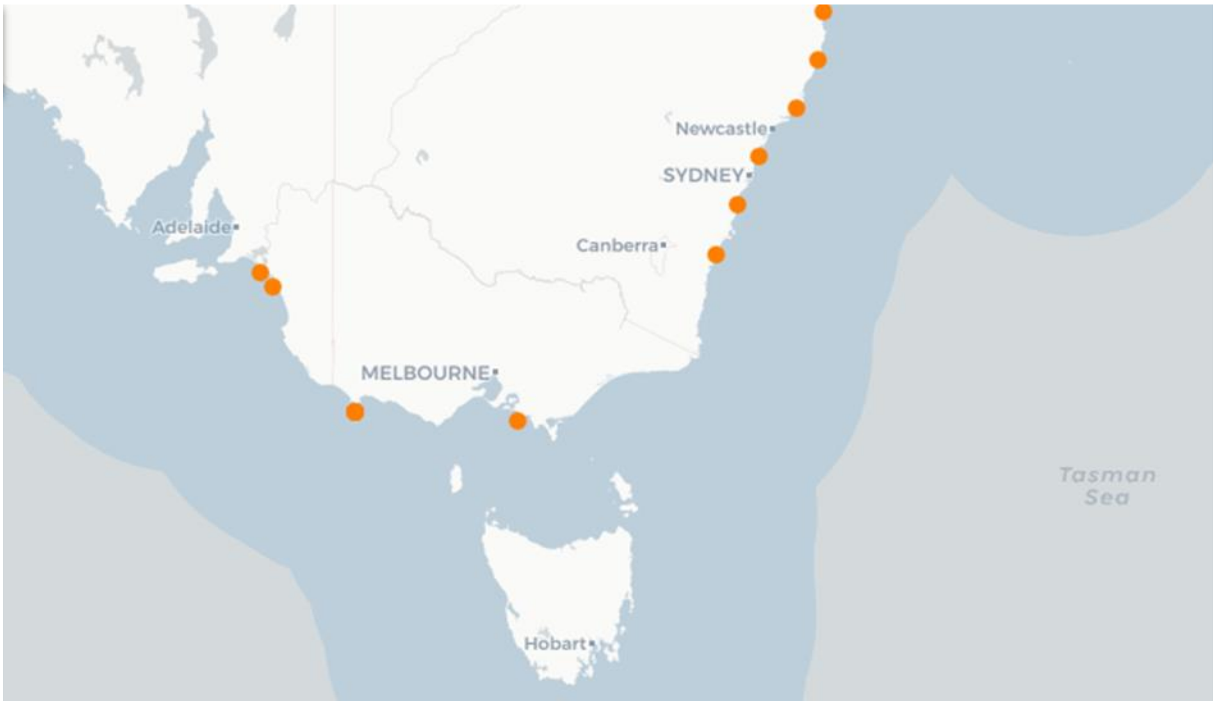

Figure 4-33: Distribution of Reported Commercial Catch of Pipi (Ferguson and Johnson 2011)

6. Southern Rock Lobster

The southern rock lobster (SRL) (*Jasus edwardsii*) is a commercially important species that is found on coastal reefs from the south-west coast of WA to the south coast of NSW, including Tasmania and the New Zealand coastline (Figure 4-34). SRL are found in depths up to 150 m (DPI 2009). In Victoria, the abundance of SRL decreases from west to east reflecting a decreasing area of suitable rocky reef habitat (DPI 2009).

Most adult SRL remain within the same region (moving less than 1 km), though some tagged SRL have moved more than 80 km between inshore and offshore reefs (SRL 2021). More broadly in the region, SRL habitat occurs as patchy, discontinuous low-profile reef running parallel to the coast. Bathymetry mapping, including recent shelf mapping of the Zeehan Multiple Use Zone funded by Parks Australia found the existence of multiple marine canyons in the area as well as areas of deep reef extending across the shelf from the shelf-break. The outer shelf region is limestone reef pavement that becomes significantly more fractured with notable long step-features which were rarely undercut limiting habitat available for crevice-dwelling species such as the SRL (Barrett et al. 2023). Preliminary research in the area has found that while multibeam sonar mapping has identified areas of suitable reef, 300 camera drops identified no lobsters which is likely due to the absence of suitable crevice-like habitat (Barrett et al. 2023). Therefore, the Zeehan Multiple Use Zone is likely low-quality habitat (Barrett et al. 2023) for the SRL at ecologically or commercially important levels. In any case, it is assumed that where rocky reef is located within the Planning Area, SRL are likely to be present.

Adult SRL are carnivorous and feed mostly at night on a variety of bottom dwelling invertebrates such as molluscs, crustaceans and echinoderms. The main predators of SRL are octopus, sharks and reef fish such as wrasse and ling (SRL 2021).

The life cycle of the SRL is complex. After mating between April and July (SRL 2021), fertilised eggs (up to 1,000,000 per female) are carried under the tail of the female for approximately 4-6 months before being released, typically between September and November. Larval release occurs across the southern continental shelf, which is a high-current area, facilitating dispersal. Oceanographic modelling has also indicated that SRL dispersal occurs over large spatial scales, indicating that there is a single biological stock (Bruce et al. 2007). Genetic analyses also indicate that it is a single stock (Ovenden et al. 1992). This suggests that SRL in the Otway Bioregion is present as a connected stock with recruitment into the permit area from upstream subpopulations.

Once released, SRL larvae, or phyllosoma, undergo 11 developmental stages over a period of 12 and 24 months (Hartmann et al. 2013; SRL 2021) while being carried by ocean currents up to 200 km offshore far beyond the continental shelf. At the end of this developmental phase, phyllosoma larvae moult and metamorphose into a puerulus larvae (a transparent miniature version of the adult), still living in the water column but not feeding (SRL 2021). Successful metamorphosis from the final-stage phyllosoma to puerulus stage occurs far offshore sometimes even beyond the continental shelf (SRL 2021). The puerulus swim inshore at night to settle onto reef habitat in depths from 50 m to the intertidal zone (Booth et al. 1991) where they moult into pigmented juvenile lobsters (SRL 2021). Bruce et al. 2007 reported data for state-maintained puerulus collector sites, which indicates that most puerulus settlement in NW Tasmania occurs June through August, tapering off in September.

SRL grow by moulting or shedding their exoskeleton. Juvenile lobsters moult approximately 5 times per year, declining to once a year for mature adults. Research on temporal moulting patterns in adult SRL in Tasmanian waters including King Island (Gardner and Mills 2013), which tracked over 4,000 tagged individuals, found females mainly moult between February and May while males moult mainly in August and September with the greater majority moulting in August. The Tasmanian Seafood Industry Council (TSIC) advised that moulting for adult males occurs in September and October. Males grow faster and larger than females, reaching 160 mm in carapace length after ten years. Females generally reach 120 mm in the same period. Growth rates also vary spatially, with growth faster in the east than in the west (DPI 2009). It can take between 3 and 10 years for SRL to reach commercial fishing size (SRL 2021).

Although rock lobsters have no formal protection under Australian law, Hayes et al. (2021) identified SRL as a key natural value for the South-East marine park network. The key natural values were identified by subject matter experts using a set of criteria developed from the criteria used to identify equivalent or similar concepts in other national and international contexts. Each key natural value is allocated to an ecosystem within the common language and thereby mapped.

The SRL does not have an EPBC status or associated recovery or management plan. While there is little scientific data on the population, stock status records indicate that the southern Australian stock is sustainable (Linnane et al. 2021). However, the stock status is only marginally above the limit reference point for egg production. The populations of SRL in the north-west of Tasmania are characterised by larger individuals and faster growth than much of the rest of the state. The Tasmanian stock assessment area that incorporates King Island and part of the AMP has the second lowest biomass in Tasmania, as well as the lowest egg production in the state (Hartmann 2022).

Surveys of commercial fishers operating in and around the ZMP, as well as analysing commercial rock lobster catch data in the region, identified that most of the fishing reported occurred in waters closer to King Island than the marine park offshore (UTAS 2023). Surveys also identified that the aggregate catches recorded in fishery reporting blocks overlapping the ZMP were low relative to other areas, implying an overall low population density within the park. A review of catch data showed that catch in tonnes appears to have remained steady since 2008 for both the Tasmanian and Victorian fishing blocks.

Pressures on SRL populations include fishing, climate change, with respect to declining individual performance with warming, potential future competition with conspecific lobsters, and future interactions with the range-extending destructive sea urchin (UTAS 2023).

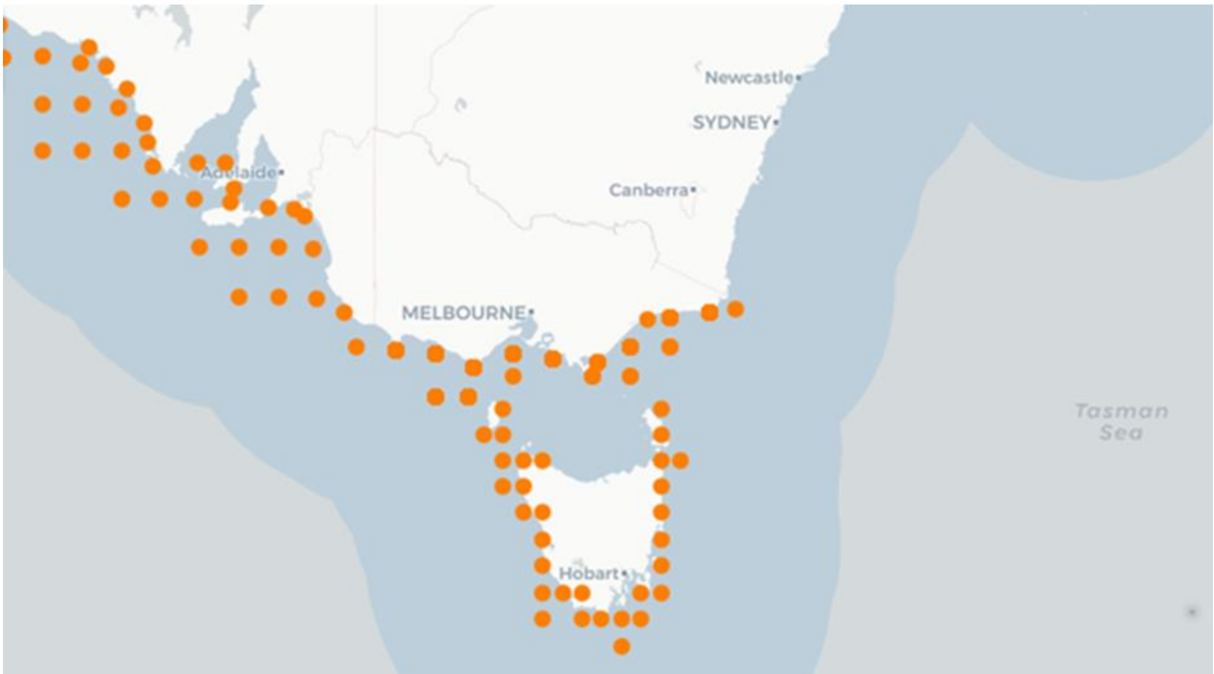

Figure 4-34: Distribution of Reported Commercial Catch of Southern Rock Lobster (Linnane et al. 2021)

7. Squid

Gould's squid (*Nototodarus gouldi*) are a commercially important species typically found at depths from 50 – 200 m off the subtropical and temperate coasts of Australia (Atlas of Living Australia 2022b). Gould's squid feed on crustaceans, fish and cephalopods at night and in turn are prey for birds, large fish, sharks and marine mammals (O'Sullivan and Cullen 1983). Gould's squid are short lived (less than one year), spawn multiple times during their life cycle, and display highly variable growth rates, size and age at maturity (Jackson and McGrath-Steer 2003).

Noriega et al (2021) highlights characteristics of the Gould's squid's lifecycle which lend itself to rapid increases in biomass during favourable environmental conditions, making it less susceptible to becoming overfished than longer-lived species. The species is commercially harvested and the population size in Bass Strait varies from year to year. This is primarily due to its short life cycle, the 'boom and bust' nature of its population dynamics and life history characteristics. Figure 4-35shows the distribution of reported commercial catch of Gould's squid in south-eastern Australia (Noriega et al. 2021) which indicates it is likely that Gould's squid will be present in the Planning Area.

There is no formal stock assessment available for the population, however stock status records show the species in south-eastern Australia to be of a sustainable level (Noriega et al. 2021). However, there are a range of anthropogenic threats that affect the population including:

- Commercial and recreational fishing, and

- Ecosystem effects as a result of habitat modification and climate change.

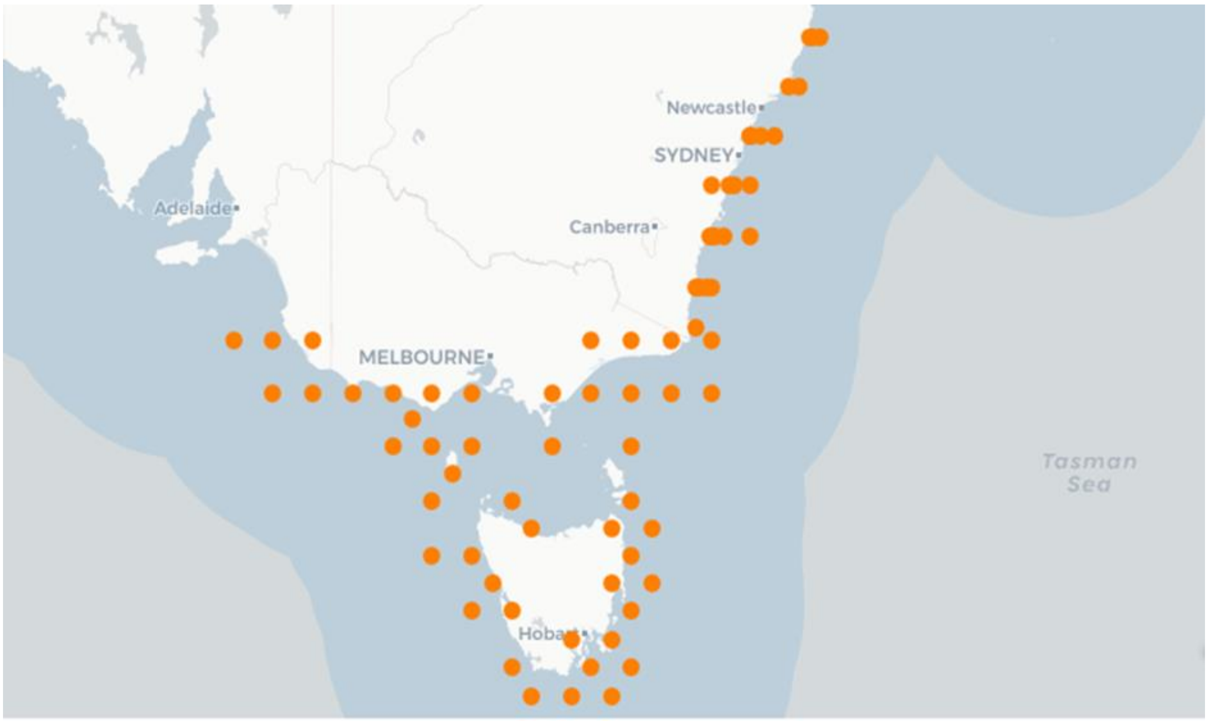

Figure 4-35: Distribution of Reported Commercial Catch of Gould's Squid (Noriega et al. 2021)

4.4.8 Threatened Ecological Communities

Threatened Ecological Communities (TECs) provide wildlife corridors or refugia for many plant and animal species, and listing a TEC provides a form of landscape or systems-level conservation (including threatened species).

No TECs were identified within the Project Area. TECs identified in the PMST Report (Appendix B) as occurring in the Planning Area are presented in Figure 4-36 and Table 4-18. TECs identified in the PMST Report due to the size of the grids used in the PMST but not actually intersecting the Planning Area are listed in the Table with 'X'. TECs which intersect a Planning Area and have a coastal component which may be exposed to hydrocarbons from a spill event are discussed in the subsections below.

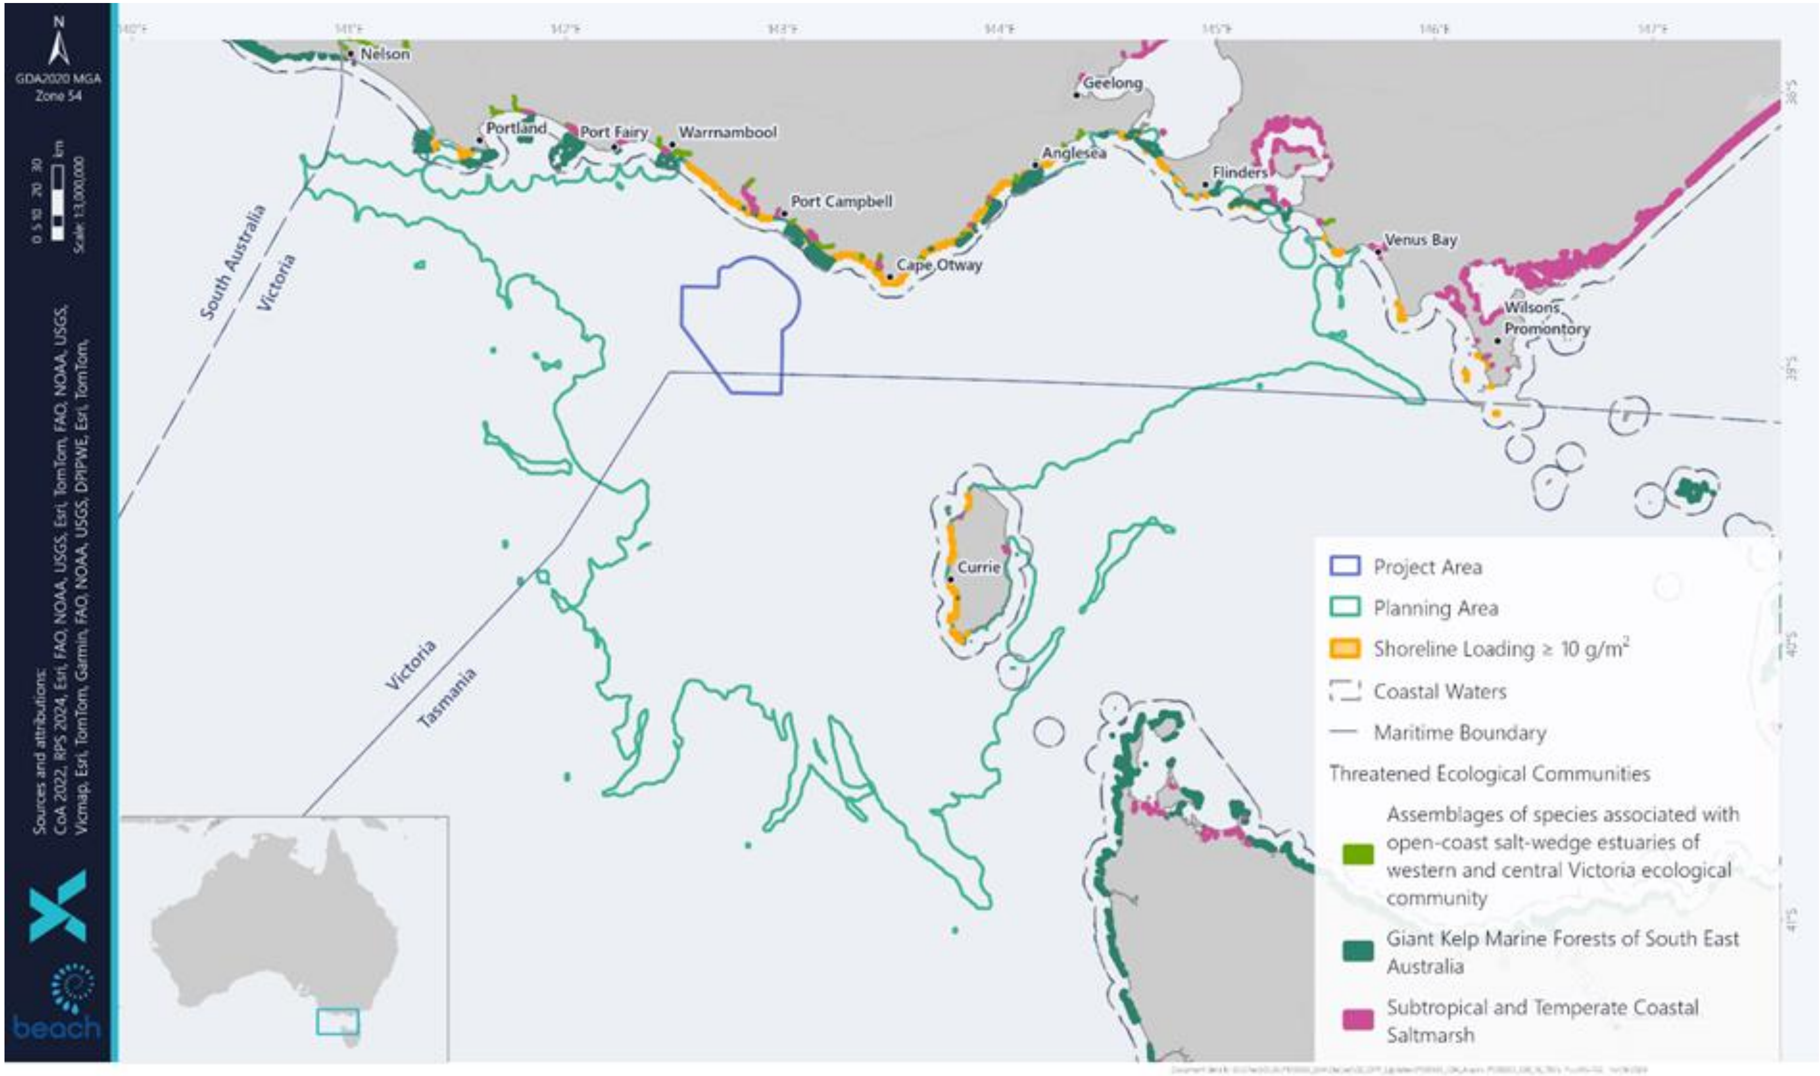

Figure 4-36: Threatened Ecological Communities within the Planning Area

Table 4-18: Threatened Ecological Communities within the Planning Area

Threatened Ecological Community	Threatened Category	Coastal Component	Project Area	Planning Area
Assemblages of species associated with open-coast salt-wedge estuaries of western and central Victoria ecological community	Endangered	✓	-	✓
Giant Kelp Marine Forests of South East Australia	Endangered	✓	-	✓
Grassy Eucalypt Woodland of the Victorian Volcanic Plain	Critically Endangered	-	-	X
Karst springs and associated alkaline fens of the Naracoorte Coastal Plain Bioregion	Endangered	-	-	X
King Island Scrub Complex	Endangered	-	-	X

White Box-Yellow Box-Blakely's Red Gum Grassy Woodland and Derived Native Grassland	Critically Endangered	-	-	X

4.4.8.1 Assemblages of Species associated with Open-coast Salt-wedge Estuaries of Western and Central Victoria Ecological Community

This TEC is the assemblage of native plants, animals and micro-organisms associated with the dynamic salt-wedge estuary systems that occur within the temperate climate, microtidal regime (<2 m), high wave energy coastline of western and central Victoria. The TEC currently encompasses 25 estuaries in the region defined by the border between South Australia and Victoria and the most southerly point of Wilsons Promontory (TSSC 2018).

Salt-wedge estuaries are usually highly stratified, with saline bottom waters forming a 'salt-wedge' below the inflowing freshwater layer of riverine waters. The dynamic nature of salt-wedge estuaries has important implications for their inherent physical and chemical parameters, and ultimately for their biological structure and ecological functioning. Some assemblages of biota are dependent on the dynamics of these salt-wedge estuaries for their existence, refuge, increased productivity, and reproductive success. The TEC is characterised by a core component of obligate estuarine taxa, with associated components of coastal, estuarine, brackish, and freshwater taxa that may reside in the estuary for periods of time and/or utilise the estuary for specific purposes such as reproduction, feeding, refuge, migration (TSSC 2018).

4.4.8.2 Giant Kelp Marine Forests of South East Australia

Giant kelp (*Macrocystis pyrifera*) is a large brown algae that grows on rocky reefs in cold temperate waters off south east Australia. The kelp grows up from the sea floor 8 m below the sea surface and deeper, vertically toward the water surface. It is the foundation species of this TEC in shallow coastal marine ecological communities. The kelp species itself is not protected, rather, it is communities of closed or semi-closed Giant Kelp canopy at or below the sea surface that are protected (DSEWPaC 2012b).

Giant Kelp is the largest and fastest growing marine plant. Their presence on a rocky reef adds vertical structure to the marine environment that creates significant habitat for marine fauna, increasing local marine biodiversity. Species known to shelter within the kelp forests include weedy sea dragons (*Phyllopteryx taeniolatus*), six-spined leather jacket (*Mesuchenia freycineti*), brittle stars (ophiuroids), sea urchins, sponges, blacklip abalone (*Tosia* spp.) and southern rock lobsters (*Jasus edwardsii*). The large biomass and productivity of the Giant Kelp plants also provides a range of ecosystem services to the coastal environment.

Giant Kelp requires clear, shallow water no deeper than approximately 35 m deep (Edyvane 2003; Shepherd and Edgar 2012; cited in TSSC 2012). They are photo-autotrophic organisms that depend on photosynthetic capacity to supply the necessary organic materials and energy for growth. O'Hara (in Andrew 1999) reported that Giant Kelp communities in Tasmanian coastal waters occur at depths of 5-25 m.

Figure 4-36 shows that the largest extent of Giant Kelp marine forests are along the SA coastline with patches around the Victorian coastline.

James et al (2013) undertook extensive surveys of macroalgal communities along the Otway Shelf from Warrnambool to Portland in south-west Victoria. Sites were adjacent to shore or on offshore rocky reefs covering a depth range of 0 to 36 meters water depth. These surveys did not locate Giant Kelp at any site but identified that other brown algae species (*Durvillaea, Ecklonia, Phyllospora, Cystophora*, and *Sargassum*) are prolific to around 20 m water depth. Brown algae tend to be replaced by red algae in deeper waters.

Surveys of the Arches Marine Sanctuary (Edmunds et al. 2010) and Twelve Apostles Marine National Park (Holmes et al. 2007 cited in Barton et al. 2012) have not located Giant Kelp. The species has been recorded in Discovery Bay National Park forming part of a mixed brown algae community (Ball and Blake 2007) (not part of the TEC), on basalt rocky reefs. An assemblage dominated by the species has been recorded from Merri Marine Sanctuary occupying a very small area (0.2ha) of rocky reef (Barton et al. 2012).

4.4.8.3 Subtropical and Temperate Coastal Saltmarsh

This TEC occurs in a relatively narrow strip along the Australian coast, within the boundary along 23°37′ latitude along the east coast and south from Shark Bay on the west coast (DSEWPaC 2013b). The TEC is found in coastal areas which have an intermittent or regular tidal influence. Figure 4-36 shows that from Corner Inlet to Marlo there is a substantial amount of subtropical and temperate coastal saltmarsh along the Victorian coastline.

The TEC community consists mainly of salt-tolerant vegetation including grasses, herbs, sedges, rushes, and shrubs. Succulent herbs, shrubs and grasses generally dominate, and vegetation is generally less than 0.5 m in height (Adam 1990). In Australia, the vascular saltmarsh flora may include many species, but is dominated by relatively few families, with a high level of endism at the species level.

The TEC is inhabited by a wide range of infaunal and epifaunal invertebrates and low and high tide visitors such as fish, birds, and prawns (Adam 1990). It is often important nursery habitat for fish and prawn species. Insects are also abundance and an important food source for other fauna. The dominant marine residents are benthic invertebrates, including molluscs and crabs (Ross et al. 2009).

The TEC provides extensive ecosystem services such as the filtering of surface water, coastal productivity and the provision of food and nutrients for a wide range of adjacent marine and estuarine communities and stabilising the coastline and providing a buffer from waves and storms. Most importantly, saltmarshes are one of the most efficient ecosystems globally in sequestering carbon, due to the biogeochemical conditions in the tidal wetlands being conducive to long-term carbon retention. A concern with the loss of saltmarsh habitat is that it could release the huge pool of stored carbon to the atmosphere.

4.4.9 Threatened and Migratory Species

PMST Reports (Appendix A, Appendix B) were generated for the Project Area and Planning Area, and were used in combination with reputable peer-reviewed literature to identify the listed Threatened and Migratory species that may be present.

4.4.9.1 Marine Fauna of Conservation Significance

Under Part 13 of the EPBC Act, species can be listed as one, or a combination, of the following protection designations:

- Threatened (further divided into categories; extinct, extinct in the wild, critically endangered, endangered, vulnerable, conservation-dependent)
- Migratory
- Whale or other cetaceans
- Marine

Details of listed fauna and their likely presence in the Project or Planning Areas are provided in the following sections.

For the purpose of the OPP, species listed as threatened or migratory under the EPBC Act and are known or likely to occur in the Project or Planning Areas and/or have an intercepting BIA with the Project or Planning Areas are discussed in more detail. Known and likely occurrence was determined from the PMST report and reputable peer-reviewed literature or through designation of important habitat (e.g. BIA).

4.4.9.2 Biologically Important Areas and Habitat Critical to the Survival of the Species

DCCEEW (2023b) detail that biologically important areas (BIAs) are spatially defined areas where aggregations of individuals of a species are known to display biologically important behaviour such as breeding, foraging, resting or migration. Their designation is based on expert scientific knowledge about species' distribution, abundance, and behaviour. The presence of the observed behaviour is assumed to indicate that the habitat required for the behaviour is also present.

CoA (2013) details that habitat critical to the survival of a species or ecological community' refers to areas that are necessary:

- for activities such as foraging, breeding, roosting, or dispersal.
- for the long-term maintenance of the species or ecological community (including the maintenance of species essential to the survival of the species or ecological community, such as pollinators)
- to maintain genetic diversity and long-term evolutionary development, or
- for the reintroduction of populations or recovery of the species or ecological community.

Such habitat may be but is not limited to: habitat identified in a recovery plan for the species or ecological community as habitat critical for that species or ecological community; and/or habitat listed on the Register of Critical Habitat maintained by the minister under the EPBC Act.

BIAs and habitat critical to the survival of a species within the Project Area and Planning Area are detailed in Table 4-19 with further details in the relevant species sections. Seasonality of important behaviours within BIAs is summarised in Table 4-20. No habitat critical to the survival of species was identified within the Project Area.

Table 4-19: Proximity of BIAs and Habitat Critical to the Survival of a Species to the Project and Planning Areas

Receptor	Project Area	Planning Area	Type of BIA	Habitat Critical to the Survival of a Species
Birds				
Antipodean Albatross	Overlap	Overlap	Foraging	-

4.4.9.3 Fish

Fish species present in the Project or Planning Areas are either pelagic (living in the water column), or demersal (benthic). Fish species inhabiting the region are largely cool temperate species, common within the South-east Marine Region. Table 4-21 details the listed fish species identified in the PMST Reports (Appendix A, Appendix B) as occurring in the Project and/or Planning Areas.

Two fish species identified in the PMST Reports are freshwater species, Dwarf Galaxias and Yarra Pygmy Perch as they will be outside of the areas potentially affected by the Project they are not discussed further.

Threatened or migratory species that are likely or known to occur or have an intercepting BIA with the Project or Planning Areas are discussed in more detail.

Five species of fish are listed as Conservation Dependent which do not receive special protection, as they are not considered MNES under the EPBC Act. These species are targeted by commercial fisheries as detailed in Sections 4.5.10 to 0.

Information on eels is also provided as Beach's consultation with the Eastern Maar Aboriginal Corporation for the previous Otway Project activities identified that they have interests regarding eels, and they are possibly present within the Planning Area during migration and spawning seasons.

Table 4-21: Listed Fish Species or Species Habitat identified in the Project and/or Planning Areas

Common Name	Scientific Name	Threatened Category	Migratory Status	Migratory Category	Marine Status	Biologically Important Area (BIAs)	Presence in Planning Area	Presence in Project Area
Fish								
Australian Grayling	*Prototroctes maraena*	Vulnerable					Species or species habitat known to occur within area	Species or species habitat may occur within area

1. Australian Grayling

The Australian grayling (*Prototroctes maraena*) is a dark brown to olive-green fish attaining 19 cm in length. The species typically inhabits the coastal streams of New South Wales, Victoria, and Tasmania, migrating between streams and the ocean. Spawning occurs in freshwater, with timing dependant on many variables including latitude and temperature regimes (Backhouse et al. 2008). Most of its life is spent in fresh water, with parts of the larval or juvenile stages spent in coastal marine waters (Backhouse et al. 2008), though its precise marine habitat requirements remain unknown (Backhouse et al. 2008). They are a short-lived species, usually dying after their second year soon after spawning (a small proportion may reach four or five years) (DSE 2008).

Australian Grayling has been recorded from the Gellibrand River (DSE 2008) making it likely that it occurs in coastal waters. As marine waters are not part of the species' spawning grounds, the Planning Area is not likely to represent critical habitat for the species.

2. Eels

a. Ecology and Biology

The shortfin eel (*Anguilla australis australis*) and the longfin eel (*A. reinhardtii*) both occur naturally within Victoria and are the target species of the Victorian Eel Fishery. The eels have differing but overlapping distributions east and south of the Great Dividing Range in estuarine and freshwater catchments (VFA 2022b) (Figure 4-37).

The shortfin eel is widespread across the southern parts of Victoria and occurring occasionally in northern streams draining into the Murray River, while the longfin eel is found within south-east parts of Victoria only (VFA 2022a). Both species spend the majority of their life cycle in fresh water or estuaries before travelling to the ocean to spawn once before dying (VFA 2022a). Shortfin eels are listed as 'near threatened' on the IUCN red list, with barriers to riverine movement and freshwater habitat loss being key threats. Additionally, changes in ocean currents, primary production, and thermal regimes may also affect eel migration, spawning success, and recruitment (Koster et al. 2021). The longfin eel is listed as 'least concern' by the IUCN. Neither species are listed as threatened under the EPBC Act.

Both species of eel are primarily carnivorous, however, they will both opportunistically eat plant material (VFA 2022a; 2022c). The shortfin eel is known to eat various types of fish, worms, insects, small crustaceans, molluscs, and water plants and can grow up to 1.1 m long and weigh up to 6.8 kg (VFA 2022a). The longfin eel consumes primarily fish and insects. The longfin eel is larger in size compared to the shortfin eel, reported to grow up to 2 m and weigh up to 16 kg, however, they are usually much smaller and often reach 1 m in length (VFA 2022c). Both species are believed to follow a seasonal feeding pattern, with the most intense feeding window being at night during summer and spring (VFA 2022a; 2022c). Both species sexes are determined by influences such as salinity, temperature, diet, and population density (more females as the population density decreases) (VFA 2017).

b. Migration and Spawning

Both species of eel have a remarkable lifecycle that is not entirely understood, remaining a natural phenomenon. They spend most of their life cycle in freshwater or estuaries before undergoing a mass migration into the ocean, travelling in excess of 3,000 km to spawn once (VFA 2022b). Spawning location is believed to be in the Coral Sea near New Caledonia although no precise spawning location for either species has been identified (VFA 2022a). Both species migrate to the ocean once matured;

male shortfin eels generally mature at 8 to 12 years of age, whilst females mature at 10 to 20 years and long-finned eels can take double this time to mature. Migration occurs during late summer to autumn, and after a period of insatiable feeding and significant growth, the eels undergo a series of physical changes to prepare for their migration (VFA 2022a).

Once the eels are prepared for spawning, they move out of their freshwater environments into the ocean in total darkness and swim north against the current to reach the Coral Sea. By the time they arrive, they have used up all their energy resources then they spawn and die, and their young commence the cycle over again. Their life begins at unknown spawning sites at a depth of 200 m as larvae. The pelagic larvae are then carried southwards by the ocean currents that parallel the east coast of Australia such as the EAC and swing east past Tasmania and then north to New Zealand. Along the way, they feed on microscopic organisms and develop into transparent, leaf-shaped larvae and eventually metamorphose into 'glass eels' which are eel-shaped, but extremely small and still transparent. At this stage, they move closer to land and commence migrating towards estuaries. Most glass shortfin eels migrate in the winter and spring, while glass longfin eels migrate during summer and autumn (VFA 2022a), although glass eels of both species may continue to arrive anytime throughout the year (VFA 2017).

Koster et al. (2021) tracked the shortfin eel spawning migration for the first time in Australia. Sixteen eels were collected and tagged from the Hopkins and Fitzroy River estuaries as they migrated from the river mouths outwards to the Southern Ocean over a sandbar in 2019. They were then released at either Warrnambool Harbour, Hopkins's mouth beach or Killarney beach. Twelve of the 16 tags returned data. The results showed that the shortfin eels exhibit diel vertical migration, meaning they travel in the top layers of water during the night and travel further down in the water column during the day (Koster et al. 2021). Of the small number of eels that made the entire journey to the spawning location, their last movements were recorded in the Coral Sea. Many of the eels (about 30%) migrations were cut short due to predation, suspected by sharks, tuna, or other marine mammals. The conclusion of the study talks about the need for further research to determine the eel's exact spawning locations and timing and how the information can be used to support conservation management, particularly when looking at anthropogenic impacts on the species. Koster et al. (2021) listed construction and operation of energy developments as having potential to interact with eel migration.

c. Victorian Eel Fishery

Both the longfin and shortfin eel are the target species for the Victorian Eel Fishery. The first commercial catches of eel were recorded in 1914, and up until 1950 eel was primarily fished for bait. Export of frozen shortfin eel to Europe began in the 1960s (VFA 2022a). Eel are harvested in Victorian coastal river basins south of the Great Dividing Range using fyke nets, with a maximum of 18 licences allowed in Victoria. Certain waterways are closed to fishing to allow for eels to escape and spawn (VFA 2022a). Shortfin eels are the most abundant and the most keenly targeted eel species in Victoria, productivity from the fishery is highly susceptible to short and long term and seasonal environmental variations, particularly drought (VFA 2017).

The eel fishery comprises both a wild catch sector and a culture (stock enhanced) sector. The culture sector has developed strategies for growth consistent with the species life cycle by translocating juvenile eels from other parts of Victoria into lakes and impoundments (culture waters) in western inland Victoria where they continue to grow (VFA 2017). Fishing for glass eels has been of limited success due to the highly variable abundance in Victoria. Most of Victoria's eel catch is taken by commercial fishers and is comprised of adult eels during different stages of their migration.

d. First Nations Connection to Eels

Eels were, and continue to be, an important resource for certain First Nations communities. Their use for communal gatherings and for barter and trade was extensive in pre-colonial times. Today, eel remains a popular food for community events (VFA 2017). Shortfin eels in particular hold a cultural significance to First Nations people. For example, the Gunditjmara People of south-western Victoria built and used sophisticated aquaculture systems throughout the Budj Bim cultural landscape to exploit eel migrations at least 7,000 years ago. These systems and their eel catches have since provided a lasting and sustainable economic and social base for the Gunditjmara society (Koster et al. 2021). The Budj Bim cultural landscape is outside of the Planning Area.

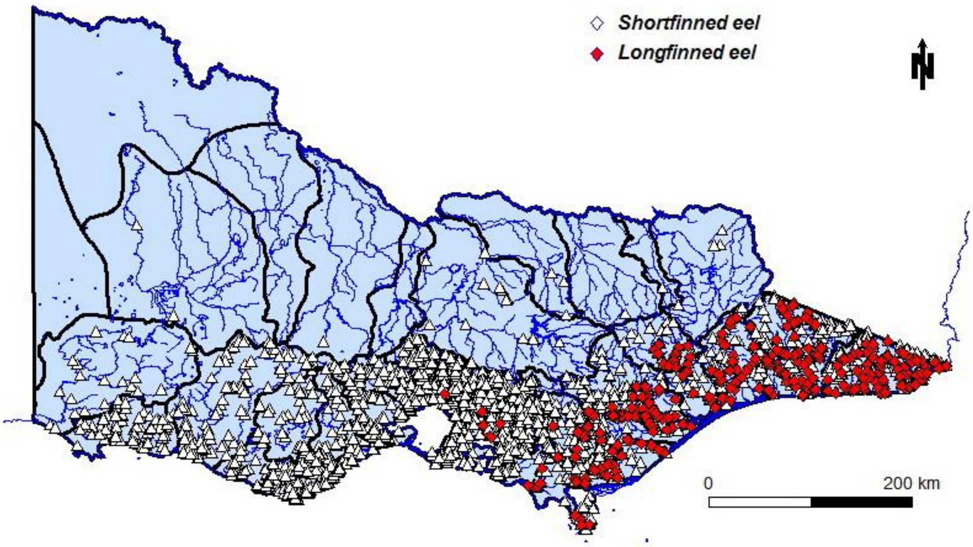

Figure 4-37: Distribution of Longfinned and Shortfinned Eels in Victoria (VFA 2017)

3. Porbeagle Shark

The porbeagle shark (*Lamna nasus*) is widely distributed in the southern waters of Australia including Victorian and Tasmanian waters. The species preys on bony fishes and cephalopods and is an opportunistic hunter that regularly moves up and down in the water column, catching prey in mid-water as well as at the seafloor. It is most commonly found over food-rich banks on the outer continental shelf, but does make occasional forays close to shore or into the open ocean, down to depths of approximately 1,300 m. It also conducts long-distance seasonal migrations, generally shifting between shallower and deeper water (Pade et al. 2009). The porbeagle shark is likely to be present in the Project and Planning Areas in low numbers.

4. Shortfin Mako Shark

The shortfin mako shark (*Isurus oxyrinchus*) is a pelagic species with a circum-global oceanic distribution in tropical and temperate seas (Mollet et al. 2000). It is widespread in Australian waters, commonly found in water with temperatures greater than 16°C. Populations of the shortfin mako shark are considered to have undergone a substantial decline globally. These sharks are a common by-catch species of commercial fisheries (Mollet et al. 2000).

The use of dorsal satellite tags on 10 juvenile shortfin mako sharks captured in the Great Australian Bight between 2008 and 2011 investigated habitat and migration patterns. It revealed the Great

Australian Bight and south east of Kangaroo Island near the norther extent of the Bonney Upwelling Region, to be areas of highest fidelity and indicating critical habitats for juvenile shortfin mako Ssarks (Rogers 2011). The tagged sharks also showed migration to south west Western Australia, Victoria, Bass Strait and south-west of Tasmania. Stomachs of shortfin mako shark were also analysed from specimens collected by game fishing competitors in Port MacDonnell, South Australia and Portland, Victoria from 2008 and 2010 which found they specialise in larger prey including pelagic teleosts and cephalopods (Rogers 2011). Due to their widespread distribution in Australian waters, shortfin mako sharks are likely to be present in the Project Area and Planning Area in low numbers.

5. Syngnathids

Syngnathids identified in the EPBC PMST Reports (Appendix A, Appendix B) as potentially occurring in the Project and Planning Areas include seahorses and their relatives (sea dragon, pipehorse and pipefish). The majority of these species are associated with seagrass meadows, macroalgal seabed habitats, rocky reefs and sponge gardens located in shallow, inshore waters (e.g. protected coastal bays, harbours, and jetties) less than 50 m deep (Fishes of Australia 2015). They are sometimes recorded in deeper offshore waters, where they depend on the protection of sponges and rafts of floating seaweed such as Sargassum.

Of the 29 species of Syngnathids identified in the EPBC PMST Report, only the big-belly seahorse (*Hippocampus abdominalis*) has a documented species profile and threats profile, indicating how little published information exists in general regarding Syngnathids.

The PMST report species profile and threats profiles indicate that the Syngnathids species identified in the Project Area and Planning Area are widely distributed throughout southern, south-eastern and south-western Australian waters. It is unlikely that these species will be present within the Project Area as water depths are greater than 50 m, however they may be present within the Planning Area.

6. White Shark

The white shark (*Carcharodon carcharias*) is widely distributed and located throughout temperate and sub-tropical waters with their known range in Australian waters from the Northwest Cape, Western Australia, through southern waters to the central coast of Queensland (Last and Stevens 2009; DoE 2023d). Studies of white sharks indicate that they are largely transient, with several discrete populations (Pardini et al. 2000; Gubili et al. 2012). In the Australasian region, white sharks differ genetically from other populations and data suggest there is an eastern and a western population in southern Australia, divided by the Bass Strait (Blower et al. 2012). A recent long-term electronic tagging study of juvenile white sharks off eastern Australia, indicated complex movement patterns over thousands of kilometres, including annual fidelity to spatially restricted nursery areas, directed seasonal coastal movements, intermittent areas of temporary nearshore residency and offshore movement into the Tasman Sea (Bruce et al. 2019). This study also supported the two-population model for the species in Australian waters with restricted east to west movements through Bass Strait. Bruce et al. (2019) observed seasonal movements of juvenile White Sharks being in the northern region during winter and spring (June through November) and southern region during summer and autumn (December through May).

Observations of adult sharks are more frequent around fur seal and sea lion colonies, including Wilsons Promontory and the Skerries. Juveniles are known to congregate in certain key areas including the Ninety Mile Beach area (including Corner Inlet and Lakes Entrance) in eastern Victoria and the Portland area of western Victoria).

The distribution BIA for the white shark intersects the Project Area. The foraging BIA is 38 km, and the breeding BIA is 295 km from the Project Area (Figure 4-38). The known distribution is on the coastal shelf/upper slope waters out to 1000 m and the broader area where they are likely to occur extends from Barrow Island in WA to Yeppoon in NSW. They are more likely to be found between the 60 to 120 m depth contours than in the deeper waters. There is a known nursery area at Corner Inlet, and they are known to forage in waters off pinniped colonies throughout the SEMR. It is likely that White Sharks will be present in the Project and Planning Areas.

7. Commercially Important Fish Species

a. Blue Warehou

The blue warehou (*Seriolella brama*) is a bentho-pelagic species that inhabits continental slope waters at depth from 50-300 m (AFMA 2024a). The blue warehou is a targeted species within the Southern and Eastern Scalefish and Shark Fishery (SESSF) Commonwealth Trawl and Scalefish Hook sectors. There are two separate stocks of the blue warehou (east and west). The eastern stock extends offshore from southern New South Wales to southern Tasmania and the western stock extends offshore from western Tasmania northward to western Victoria (Bessell-Browne et al. 2021). Both the western and eastern stock of the blue warehou is classified as overfished and was actively avoided in 2022-23 (Butler et al., 2023).

b. Eastern Gemfish

The eastern gemfish (*Rexea solandri*) is a bottom-dwelling species that inhabits temperate waters of Australian and New Zealand and typically found in large schools at water depths of 100-800 m (AFMA 2024b). The species typically preys on bentho-pelagic fish such as grenadier, as well as squid and crustaceans (AFMA 2024b). Female eastern gemfish reach reproductive maturity at 4-6 years and males at 3-5 years, with spawning occurring in northern and central New South Wales during winter (AFMA 2024b). The species is incidentally caught in the SESSF Commonwealth Trawl sector and the Gillnet Hook and trap sector. The eastern Gemfish has been classified as overfished since 1992 and a rebuilding strategy established the eastern gemfish as an incidental catch-only species, which was implemented in 2008 (Butler et al. 2023)

c. Gummy Shark

Gummy sharks (*Mustelus antarcticus*) are a demersal species that inhabits the continental shelf at depths of 80-350 m (AFMA 2024c). The species typically remains on or near the surface feeding on cephalopods, crustaceans and occasionally fish. Newborn and juvenile sharks aggregate across southern Australia, with adults more widely distributed. Gummy sharks reach reproductive maturity at 4-5 years of age, with males maturing at a smaller size. The females are ovoviviparous producing litters of about 14-57 pups during the summer months after an 11–12-month gestation period (AFMA 2024c).

The gummy shark is a key targeted species within the SESSF Gillnet Hook and Trap sector, and incidentally caught in the Commonwealth Trawl Sector (Butler et al. 2024). The species is mainly caught in southern Australia, extending from Bunbury in Western Australia to Jervis Bay in New South Wales (White and Last 2008). As of 2023, the gummy shark is classified as not overfished (Butler et al. 2023).

d. Orange Roughy

Orange roughy (*Hoplostethus atlanticus*) is listed as Conservation Dependent under the EPBC Act. The orange roughy is a deep-water species that inhabits waters over steep continental slopes and ocean ridges at water depths between 700-1400 m (AFMA 2024d). The species usually aggregate 5-10 m above the seabed, with some extending over 50 m from the seafloor, and are associated with submerged hills or pinnacles (AFMA 2024d). At these depths, orange roughy prey on benthopelagic and meso-pelagic fish such as viperfish, lanternfish, whiptails, squid, crustaceans, amphipods and mysids (AFMA 2024d). The orange roughy reach reproductive maturity at 27-32 years of age, with spawning aggregations occurring between mid-July and late August.

The orange roughy is targeted within the SESSF south-East Trawl Sector and incidentally caught within the Great Australian Bight Trawl (Butler et al. 2023). The species has been historically targeted in aggregations around seamounts, mainly at depths from 600 m to about 1,300 m (Butler et al. 2023). However, no commercial catch of orange roughy was landed in 2022-23 (Butler et al. 2023). The species is considered overfished and no documented evidence of recovery (Butler et al. 2023).

e. School Shark

The school shark (*Galeorhinus galeus*) is a temperate demersal species found on the continental shelf and slop at depths of 550 m (AFMA 2024e). The species undertakes long migrations of up to 1,400 km along the southern coast of Australia, which may be associated with mating and pupping grounds (AFMA 2024e). The school shark reaches reproductive maturity at 8-15 years of age, with the females producing litters of 15-42 pups every 2-3 years (AFMA 2024e). Birth occurs in early summer after 12 months gestation period. The pups and juveniles tend to aggregate in shallower waters during the spring and summer.

School sharks were historically the primary target species within the SESSF shark gillnet and shark hook sector. Assessments for the school shark indicate that the stock has been overfished since approximately 1990 (Butler et al. 2023). Although overfished, the school shark remains the second most economically important stock in the fishery (Butler et al. 2023).

f. Southern Bluefin Tuna

The southern bluefin tuna (*Thunnus maccoyii*) is a highly migratory, pelagic species and is distributed throughout the Atlantic, Pacific and Indian Oceans. The species inhabits water depths of 500 m, feeding on fish, cephalopods, crustaceans and salps (AFMA 2024f). In Australia, the southern bluefin tuna and mainly found in the Great Australian Bight and typically caught between December to April (AFMA 2024f). The species reaches reproductive maturity at 11-12 years of age, with spawning occurring in tropical waters during spring and summer (AFMA 2024f). Only one spawning ground has been identified and is located in the north-eastern Indian Ocean, south of Java (AFMA 2024f). The juveniles are generally associated with coastal and continental shelf waters **[PC227]**.

The southern bluefin tuna is a key targeted species within the Southern Bluefin Tuna Fishery and Eastern Tuna and Billfish Fishery. The species is not considered to be overfished (Butler et al. 2023).

4.4.9.4 Seabirds and Shorebirds

A diverse array of seabirds and shorebirds birds utilise the Otway region and potentially forage within or fly over the Project and Planning Areas. Figure 4-39 through Figure 4-42 show the seabird BIAs that overlap the Project and Planning Areas. No shorebird BIAs were identified within the Project and Planning Areas.

Table 4-22 details the listed bird species identified as likely or known to occur in the Project and Planning Areas PMST Reports (Appendix A, Appendix B).

Threatened or migratory species that are likely or known to occur or have an intercepting BIA with the Project or Planning Areas are discussed in more detail.

No habitats critical to the survival of a bird species were identified in the Project Area or Planning Area.

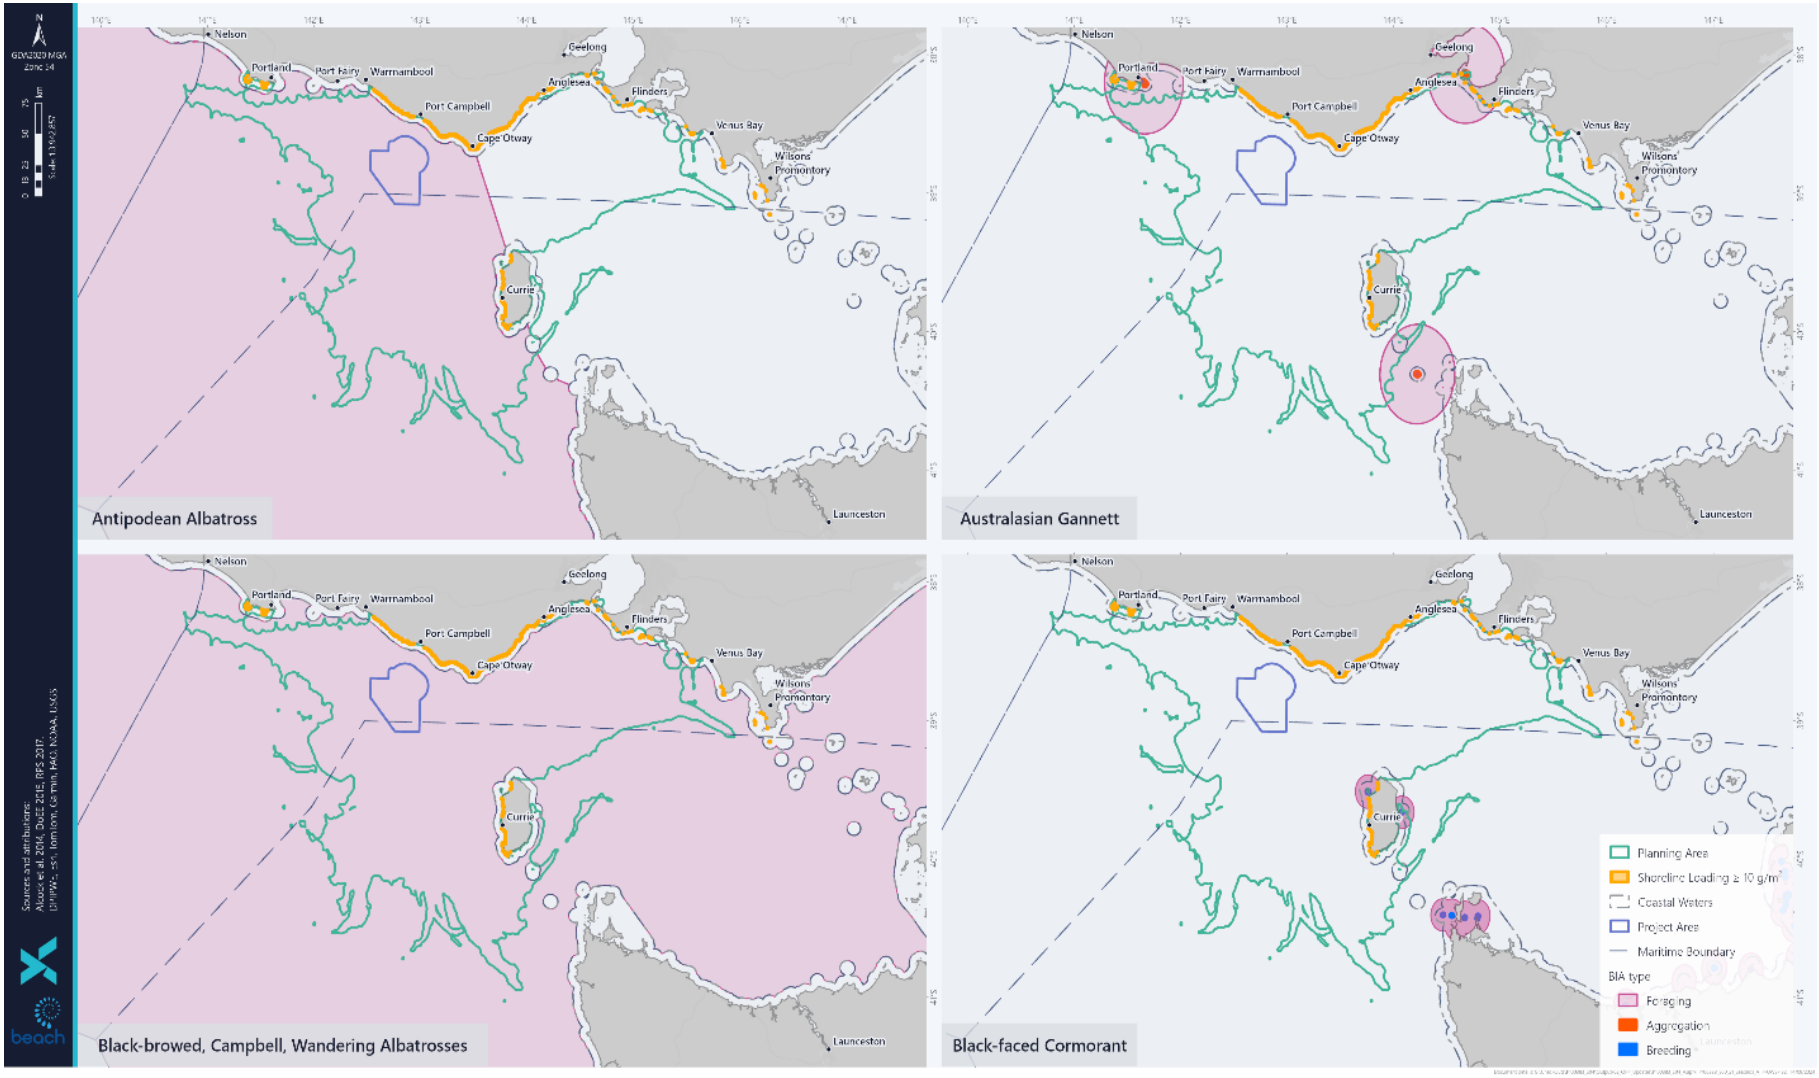

Figure 4-39: BIAs for Antipodean Albatross, Australasian Gannett, Black-browed/Campbell/Wandering Albatross and Black-faced Cormorant within the Project and Planning Areas

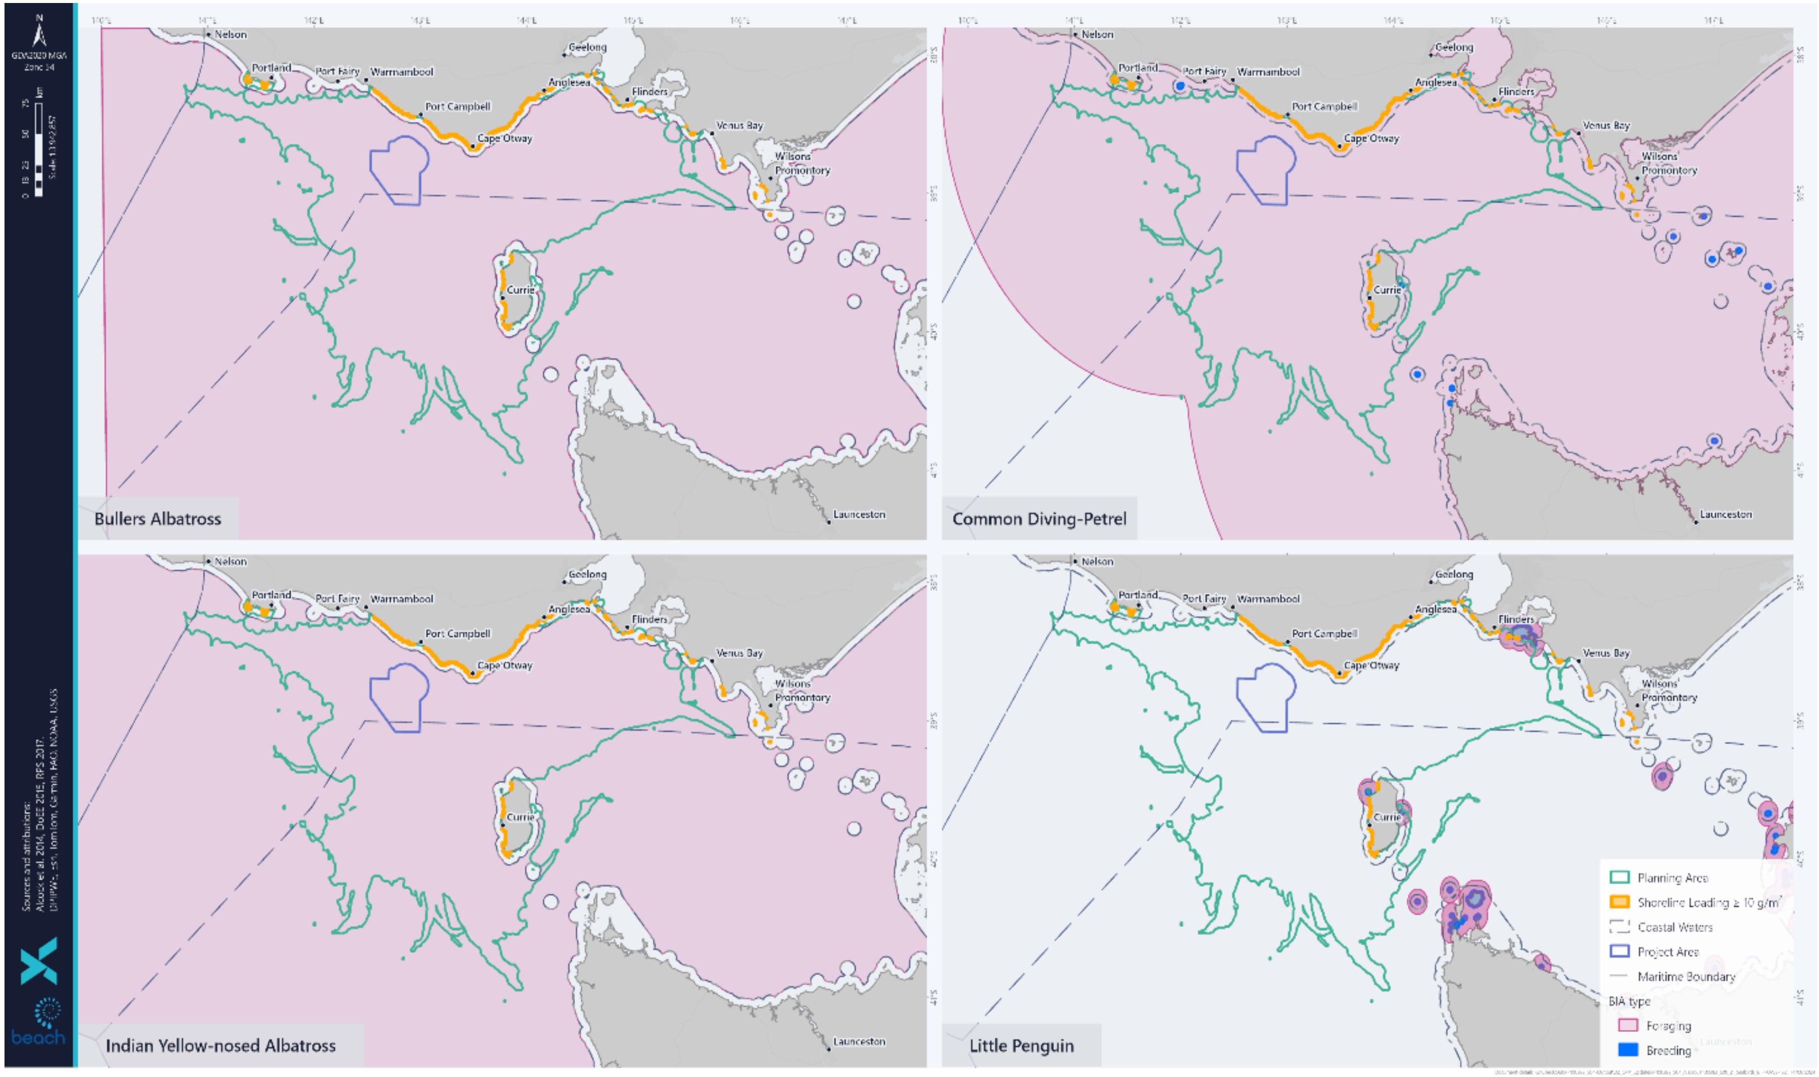

Figure 4-40: BIAs for Bullers Albatross, Common Diving-petrel, Indian Yellow-nosed Albatross and Little Penguin within the Project and Planning Areas

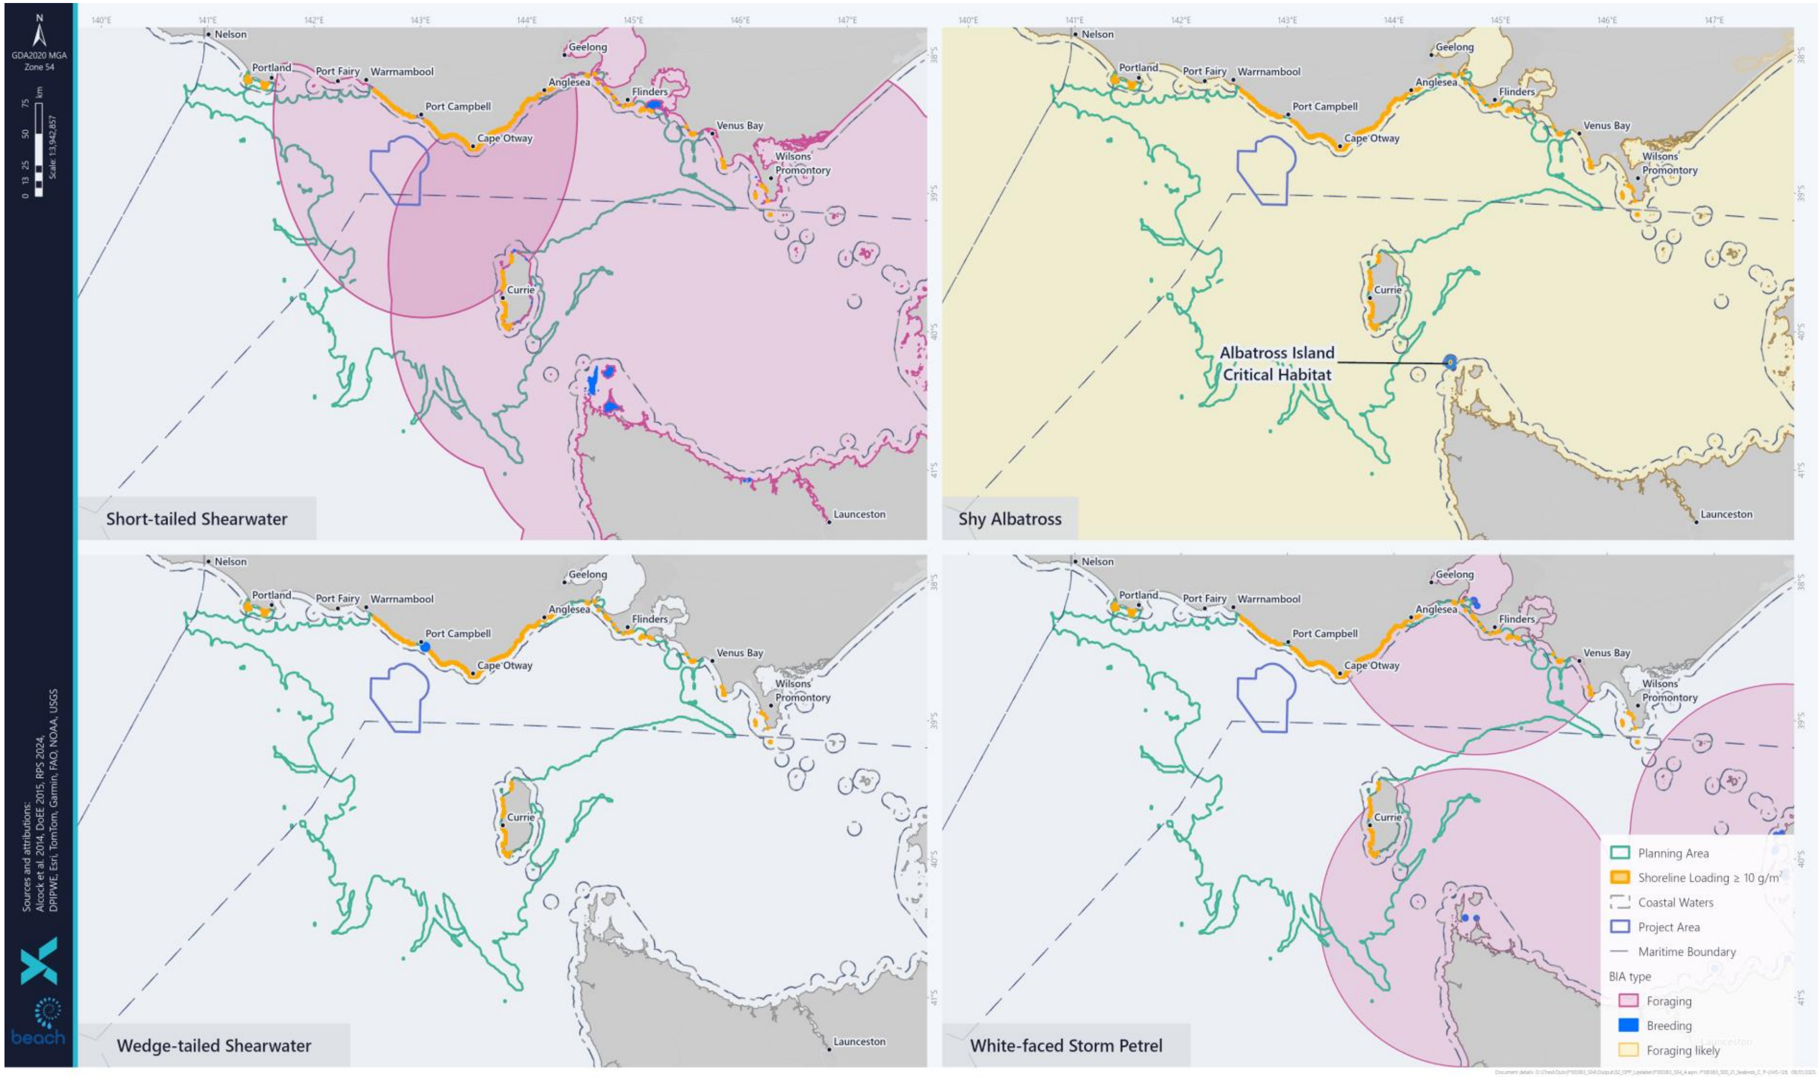

Figure 4-41: BIAs for Short-tailed Shearwater, Shy Albatross, Wedge-tailed Shearwater and White-faced Storm Petrel within the Project and Planning Areas

1. Albatross and Petrels

Albatross and giant-petrels are among the most dispersive and oceanic of all birds, spending more than 95% of their time foraging at sea in search of prey and usually only returning to land (remote islands) to breed (CoA 2022). Only seven species of Albatross and the Southern and Northern Giant Petrel are known to breed within Australia, which are protected under The National Recovery Plan for Albatross and Petrels (CoA 2022). Breeding within Australian territory occurs on the isolated islands of Antarctica (Giganteus Island, Hawker Island and Frazier islands) and the Southern Ocean (Heard Island, McDonald Island, Macquarie Island, Bishop and Clerk Islands), as well as islands off the south coast of Tasmania and Albatross Island off the north-west coast of Tasmania in Bass Strait (CoA 2022). There are no islands with colonies of threatened marine seabirds within the Project Area. Albatross Island, defined as habitat critical to the survival of the Shy Albatross (*Thallassarche cauta*), supports a breeding population of approximately 5,000 pairs and is 184 km south-east of the Project Area outside of the Planning Area. No habitats critical to the survival of threatened albatross or petrel species occur within the Project Area or Planning Area, this includes known nesting or migrating sites.

A critical life phase for birds is termed “fledging”. Fledging occurs when juvenile birds begin taking their first flights. Unlike albatross species which forage most actively during daylight and are less active at night because their ability to see and capture prey from the air is reduced (Phalan et al. 2007), many petrels are known to be nocturnal at their breeding places, increasing the species susceptibility to light emissions, particularly during fledging (Chevillion et al. 2022). Survival rates during the first few weeks as a fledging are the lowest as there is no parental care and young petrels will need to learn how to fly, forage, and maintain plumage alone (Menkhorst 2010). Fledging typically occurs within the first two hours after sunset during the fledging period (Chevillion et al. 2022). Therefore this biologically sensitive period can be impacted by light at night and result in groundings or fallout events, sometimes leading to mortality (Atchoi et al. 2024). Impacts to fledglings from light emissions are assessed in Section 6.3.3.2.

Albatross and Giant Petrel species exhibit a broad range of diets and foraging behaviours; hence their at-sea distributions are diverse. Combined with their ability to cover vast oceanic distances, all waters within Australian jurisdiction can be considered foraging habitat, however the most critical foraging habitat is those waters south of 25° where most species spend most of their foraging time (CoA 2022). Therefore, albatross and petrel species are likely to fly through and forage sporadically within the Project Area and Planning Area year-round.

The Antipodean Albatross, Black-browed Albatross, Campbell Albatross, Wandering Albatross, Buller’s Albatross, Indian yellow-nosed Albatross and Shy Albatross have BIAs for foraging that overlap the Project Area and Planning Area (Figure 4-39; Figure 4-40; Figure 4-41).

Both the Common Diving-petrel and the White-faced Storm Petrel are not listed as threatened species under the EPBC Act, and have large populations within Australia, accounting for 5% and 25% respectively of the global population (CoA 2015). The Common Diving-petrel breeds on islands off south-east Australia and Tasmania; there are 30 sites with significant breeding colonies (defined as more than 1,000 breeding pairs) known in Tasmania, and 12 sites in Victoria (including Seal Island, Wilson’s Promontory and Lady Julia Percy Island) (DCCEEW 2023a). Common diving-petrels are thought to be fairly sedentary, remaining more or less in the area of their breeding colony year-round, however, there are instances where individuals have been recorded venturing into the open ocean to forage outside of the breeding season and may migrate to more tropical climates (Brooke 2004). Within the Bass Strait the common diving-petrels has shown high foraging efforts compared to other populations (with foraging trips averaging 71 ± 3 km). This is believed to potentially be due to the sparse distribution of prey such as krill (Formant et al. 2021). There are 15 sites with significant breeding colonies for the White-faced Storm Petrel in Tasmania and 3 sites within Victoria (CoA 2015). The Project Area and Planning Area overlap a foraging BIA for the Common Diving-petrel which is expected to be utilised year-round by the species (Figure 4-40). While the closest breeding BIA for the Common Diving-petrel is located 70 km from the Project Area, within the Planning Area (Table 4-19).

Southern Royal Albatross forage from 36° to 63°. They range over the waters off southern Australia at all times of the year but especially from July to October (CoA 2022). The Northern Royal Albatross is regularly recorded throughout the year around Tasmania and South Australia at the continental shelf edge and feeds frequently in these waters. Despite breeding colonies in New Zealand, the White Capped and the Chatham Albatross are common off the coast of south-east Australia throughout the year (CoA 2022). During the non-breeding season, the Salvin's Albatross occur over continental shelves around continents with a small number of non-breeding adults flying regularly across the Tasman Sea to south-east Australian waters (CoA 2022). Sooty Albatrosses although rare are likely regular migrants to Australian waters mostly in the autumn to winter months and have been observed foraging in southern Australia (Thiele 1977; Pizzey and Knight 1999). The Pacific Albatross (equivalent to the Northern Buller's Albatross) is a non-breeding visitor to Australian waters mostly limited to the Tasman Sea and Pacific Ocean, occurring over inshore, offshore, and pelagic waters and off the east-coast of Tasmania (CoA 2022). Gibson's Albatross has breeding colonies in New Zealand but has been known to forage in the Tasman Sea and South Pacific Ocean with individuals occurring offshore from Coffs Harbour in the north to Wilson's Promontory in the south (CoA 2022; Marchant and Higgins 1990). Therefore, it is likely that these species along with the Tasmanian Shy Albatross will be present throughout the year and forage within the Project Area and Planning Area.

The White-bellied Storm Petrel breed on small offshore islets and rocks in Lord Howe Island and has been recorded over near-shore waters off Tasmania (Baker et al. 2002). The Great-winged Petrel breeds in the Southern Hemisphere between 30° and 50° south, outside of the breeding season they are widely dispersed.

2. Terns and Shearwaters

Four species of shearwater (flesh-footed shearwater (*Ardenna carneipes*), short-tailed shearwater (*Ardenna tenuirostris*), sooty shearwater (*Ardenna grisea*), wedge-tailed shearwater (*Ardenna pacifica*)) may occur within the Planning Area. All of the shearwater species listed are managed under the Wildlife Conservation Plan for Seabirds (CoA 2020a). There are a range of anthropogenic threats that affect the shearwater family which may vary based on species, stocks and life history stage.

Like petrels, shearwaters are also considered to be primarily nocturnal at their breeding places making them susceptible to light emissions when they commute from breeding colonies to forage out at sea (Chevillion et al. 2022). Therefore, like petrels, the fledging phase, a biologically sensitive period, can be impacted by light at night and result in groundings or fallout events, sometimes leading to mortality (Atchoi et al. 2024). The fledging season may vary between species; however it is known to occur over a short period of time with the first flight typically occurring within the first two hours after sunset (Chevillion et al. 2022). The wedge-tailed shearwater, for example, has a very synchronized breeding regime with all fledglings leaving nests within a very short period of time (less than one lunar cycle) (Chevillion et al. 2022). While the fledging period of the short-tailed shearwater is believed to occur between the third week of April and the first week of May each year (Skira 1991; Rodriguez et al. 2014; Price 2022). The short-tailed shearwater fledglings in particular, appear to have an increased sensitivity to artificial light although fewer than 1% of fledglings produced annually are thought to be affected by mortality (DCCEEW 2020). Impacts to fledglings from light emissions are assessed in Section 6.3.3.2.

Flesh-footed shearwater may forage in the Project Area and Planning Area. The species is a trans-equatorial migrant widely distributed across the south-western Pacific during breeding season (early September to early May) and is a common visitor to the waters of the continental shelf/slope and occasionally inshore waters (DoE 2023b). The species breeds in burrows on sloping ground in coastal forest, scrubland, or grassland. Thirty-nine of the 41 islands on which the species breeds lie off the coast of southern Western Australia, with the remaining two islands being Smith Island (SA) and Lord Howe Island (DoE 2023b), all of which are located outside of the Project Area and Planning Area. The flesh-footed shearwater feeds on small fish, cephalopod molluscs (squid, cuttlefish, nautilus and argonauts), crustaceans (barnacles and shrimp), other soft-bodied invertebrates (such as *Velella*) and offal (DoE 2023b). The species forages almost entirely at sea and very rarely on land. It obtains most of its food by surface plunging or pursuit plunging. It also regularly forages by settling on the surface of the ocean and snatching prey from the surface ('surface seizing'), momentarily submerging onto prey beneath the surface ('surface diving') or diving and pursuing prey beneath the surface by swimming ('pursuit diving'). Birds have also been observed flying low over the ocean and pattering the water with their feet while picking food items from the surface (termed 'pattering') (DoE 2023b). This species is likely to visit and forage within the Project and Planning Areas outside of the breeding season.

The Short-tailed Shearwater has a foraging BIA (September to May) within the Project Area and breeding BIAs that overlap the Planning Area (Figure 4-41). The short-tailed shearwater migrates to the Northern hemisphere for the austral winter and is generally only present in Australian waters from September to May. Huge numbers arrive along the south and south-east coast of Australia from wintering grounds in the North Pacific and are observed in large numbers foraging the surrounding coastal and offshore waters (Marchant and Higgins 1990). They are common in the South-east Marine Region and largely found on numerous islands off Victoria and Tasmania during the breeding season (Baker and Hamilton 2013, Skira et al. 1996). Though not designated as BIAs, breeding has been recorded at additional locations such as Middle Island and Griffiths Island which are located over 50 km from the Project Area within the Planning Area (Baker and Hamilton 2013). During breeding the short-tailed shearwater conducts a bimodal feeding strategy, alternating short foraging trips to local waters with long foraging trips (up to 17 days) to the Polar Frontal Zone (Berlincourt and Arnould. 2015). Short trips allow greater chick provisioning at the sacrifice of body condition, which is then recovered in richer subantarctic waters. Diet includes fish (particularly myctophids), crustaceans and squid (Weimerskirch and Cherel 1998). Short-tailed shearwaters have been identified as a conservation value in the temperate east and south-west marine areas. Therefore, considering the presence of breeding islands within proximity of the Project the short-tailed shearwater is likely to be present in the Project Area and Planning Area between September and May each year.

The Sooty Shearwater may occur within the Project Area. The Sooty shearwater is migratory and breeds in summer around southern Australia in New South Wales and Tasmania. The Australian breeding population is estimated to be 6,500 pairs (DCCEEW 2023d). In Australian territory, the sooty shearwater breeds on offshore islands off New South Wales and Tasmania. Breeding populations within Tasmania are known on Tasman Island, Hippolyte Rock, Maatsuyker Island and Courts Island, all of which occur outside of the Project Area and Planning Area. The species forages mainly in subtropical (open ocean), sub-Antarctic and Antarctic waters. No BIAs have been identified to overlap with the Project Area or Planning Area. It has been recorded in areas with sea surface temperature of 8.7-22.0 ^{0}C (Reid et al. 2002). The species takes most food by pursuit-plunging and other methods and feeding concentrations are often observed over thermal fronts at edges of upwellings at boundaries of cool and warm water-masses. Although this species may occur and forage opportunistically within the Project and Planning Areas the absence of defined BIAs and the distance to breeding colonies reduce the chance of interaction.

The Wedge-tailed Shearwater has a breeding BIA 18 km north of the Project Area (Figure 4-41). A review of the DCCEEW Species Profile and Threats Database (SPRAT), Atlas of Living Australia and South-east Marine Region Profile did not provide any information on the Victorian Muttonbird Island Wedge-tailed Shearwater colony. The DCCEEW SPRAT profile does not show any locations for the Wedge-tailed Shearwater in Victoria and Beaver (2022) details Montague Island in NSW was the southernmost known colony, however, in 2017 breeding individuals of Wedge-tail Shearwaters were discovered a couple of hundred kilometres further south on Gabo Island Lighthouse Reserve, Victoria near the NSW border. Movement patterns of the wedge-tailed shearwater are poorly known but populations at the northern and southern extremities of the known range are migratory, departing nests in early April to early May and spending the non-breeding season in the tropics (DoE 2025). The species have been recorded to predominantly forage during the day and form large aggregations referred to as "rafts" just offshore from their breeding colony just on dusk and enter and leave the colony at night to avoid predators (Warham 1996). Although this species may occur and forage opportunistically within the Project and Planning Areas during the breeding season (November to April) the absence of defined BIAs and the distance to known breeding colonies reduce the chance of interaction.

The Australian Fairy Tern occurs along the coastline of Victoria, South Australia, Western Australia and Tasmania. Breeding habitat for the Caspian, Little Tern and Australian Fairy Tern vary from terrestrial wetlands, rocky islets or banks, low islands, beaches, cays and spits. Nests are present in the open sparse vegetation such as tussocks and other sand binding plants to sometimes near bushes and driftwood. Their diet also consists primarily of fish along with aquatic invertebrates, insects, and eggs and the young of other birds (Higgins and Davis 1996; Taylor and Roe 2004; Van de Kam et al. 2004).

The Caspian Tern is the largest tern in Australia, they inhabit both coastal and inland regions and breeding occurs widespread throughout Australia. In Victoria breeding sites are mostly along coastal regions with three significant regular breeding colonies at Corner Inlet, Mud Island and Mallacoota (Minton and Deleyev 2001). Breeding occurs between September to December are resident and occur throughout the year at breeding sites (Minton and Deleyev 2001).

The Little Tern species is also widespread in Australia with three major sub populations, the northern population that breeds from Broome to Northern Territory. The eastern subpopulation breeds on the eastern and south-eastern coast extending as far as western Victoria and the south-eastern parts of South Australia, to the northern and eastern coast of Tasmania. The third population migrate from breeding grounds in Asia to spend the spring and summer in Australia. The Little Tern has a naturally high rate of breeding failure due to the ground nets being exposed to adverse weather conditions, and native predators.

The Sooty Tern has a much larger foraging range, encompassing open shelf waters, shelf edge and deep water (DSEWPaC 2012c). Main breeding colonies occur off Australia's west and east coast. Like the Crested Tern where distribution is widespread in Australia, but breeding occurs off islands in large colonies off Queensland and NSW (Higgins and Davis 1996). Foraging diet consists of pelagic fish, cephalopods, crustaceans and insects. Sooty Terns were observed amongst mixed flocks of seabirds (such as Albatross and Shearwaters) during drilling activities within the Project Area in April 2021.

3. Osprey and white bellied sea eagle

No BIAs were identified for Osprey or white bellied sea eagles (*Haliaeetus leucogaster*) within the Project or Planning Areas. The White-bellied Sea Eagle is a large raptor generally seen singly or in pairs, distributed along the coastline of mainland Australia and Tasmania (Threatened Species Section 2023). Breeding records are patchily distributed mainly along the coastline especially the eastern coast extending from Victoria and Tasmania to Queensland. There are recorded breeding sites as far inland as the Murray, Murrumbidgee and Lachlan River in norther Victoria (Marchant and Higgins 1993). There is no quantitative data available on area of occupancy, but it is believed that there could be a decline due to increased development of coastal areas. Estimations of 500 or more pairs in Australia account for 10-20% of the global population (Marchant and Higgins 1993). Recorded decline in numbers have been recorded across Australia, with a decline in Victoria's Gippsland Lakes, Phillip Island and the Sunraysia district (Bilney and Emison 1983; Quinn 1969). White-bellied sea eagle feed on a variety of fish, birds, reptiles, mammals and crustaceans. They hunt from a perch and while in flight (circling slowly). Described as a breeding resident throughout much of its range in Australia, breeding is generally sedentary, and the home range can be up to 100 km^2 (Marchant and Higgins 1993). White-bellied sea eagle are sensitive to disturbance particularly in the early stages of nesting, human activity may cause nests and young to be abandoned (Debus et al. 2014).

The Osprey (*Pandion haliaetus)* is a medium sized raptor extending around the northern coast of Australia from Albany, Western Australia to Lake Macquarie in NSW with an isolated breeding population on the coast of South Australia. Listed as migratory under the EPBC Act they are resident around breeding territories. They are found along coastal habitats and terrestrial wetlands and require open fresh or saltwater for foraging (Marchant and Higgins 1993). Osprey feed mainly on fish, occasionally molluscs, crustaceans, mammals, birds, reptiles, and insects. Generally, they search or prey by soaring, circling, and quartering above water and dive directly into the water at their target prey (Clancy 2005). This species is likely to be an uncommon visitor to the Project and Planning Areas.

4. Orange-bellied Parrot

The Orange-bellied parrot (*Neophema chrysogaster*) (listed as critically endangered under the EPBC Act) breeds in south-west Tasmania during summer (November to March), migrates north across Bass Strait in autumn and spends winters (April to October) on the coast of south-east mainland Australia (DELWP 2016). The migration route includes the west coast of Tasmania and King Island (Figure 4-42). Birds depart the mainland for Tasmania from September to November (Green 1969). The southward migration is rapid (Stephenson 1991), so there are few migration records. The northward migration across western Bass Strait is more prolonged (Higgins and Davies 1996); but typically occurs late-February to early-April (Australian Museum 2020). Migration activities are known to occur within the Planning Area based on PMST Report and reputable peer-review literature (Appendix B). The Orange-bellied parrot is protected under the National Recovery Plan for the Orange-bellied parrot (DELWP 2016). The parrot's breeding habitat is restricted to south-west Tasmania, where breeding occurs from November to mid-January mainly within 30 km of the coast.

The species forage on the ground or in low vegetation (Loyn et al. 1986). During winter, on mainland Australia, Orange-bellied Parrots are found mostly within 3 km of the coast. In Victoria, they mostly occur in sheltered coastal habitats, such as bays, lagoons and estuaries. They are also found in low samphire herbland dominated by beaded glasswort (*Sarcocornia quinqueflora*), Sea Heath (*Frankenia pauciflora*) or Sea-Blite (*Suaeda australis*), and in taller shrubland dominated by Shrubby Glasswort (*Sclerostegia arbuscula*). There are also non-breeding Orange-bellied Parrots on mainland Australia, between Goolwa in Australia and Corner Inlet in Victoria. The west coast of King Island and coastal Victoria has been identified as resting and feeding areas, however, parrots rarely land or forage out at sea.

The Orange bellied Parrot may overfly the Project Area on its migrations to and from breeding grounds between March and April and October and November each year. The Project Area overlaps a small portion of the probable migration route and where the species is likely to occur. The Planning Area overlaps the migration route in the Bass Strait as well as habitat on the coast of King Island (Figure 4-42).

5. Little Penguin

The little penguin is recognised as a conservation value in the South-east Marine Region (CoA 2015). It is the smallest species of penguin in the world and are permanent residents on a number of inshore and offshore islands. The Australian population is large but not thought to exceed one million birds (CoA 2015). Despite the colony of little penguins at Manly, Sydney Harbour, being protected as an endangered population, the Australian population is considered stable (Birdlife Australia 2025). Bass Strait has the largest proportion (approximately 60%) of the known breeding colonies in Australia. Individuals exhibit strong site fidelity, returning to the same breeding colony each year to breed in the winter and spring months (Gillanders et al. 2013). Breeding typically occurs from September to February. The diet of a little penguin includes small school fish, squid and krill. Prey is typically caught with rapid jabs of the beak and swallowed whole. Little penguins are also an important component of the Australian and New Zealand fur-seals' diet (Parliament of South Australia 2011). The species is known to exhibit a wide foraging range, with individuals able to spend weeks away at sea foraging (McCutcheon et al. 2011). The closest foraging BIA to the Project area is surrounding Christmas Island located off of nearby King Island, approximately 74 km from the Project Area (see Figure 4-40).

The closest breeding BIA to the Project Area correlates with the foraging BIA at Christmas Island, approximately 83 km from the Project Area (see Figure 4-40). However, additional breeding sites which are not designated BIAs have been recorded at Middle Island, the Twelve Apostles and Port Campbell (Norman et al. 2017). Therefore, considering the occurrence of a number of breeding sites within the region it is considered that the little penguin is likely to transit and forage within the Project and Planning Areas.

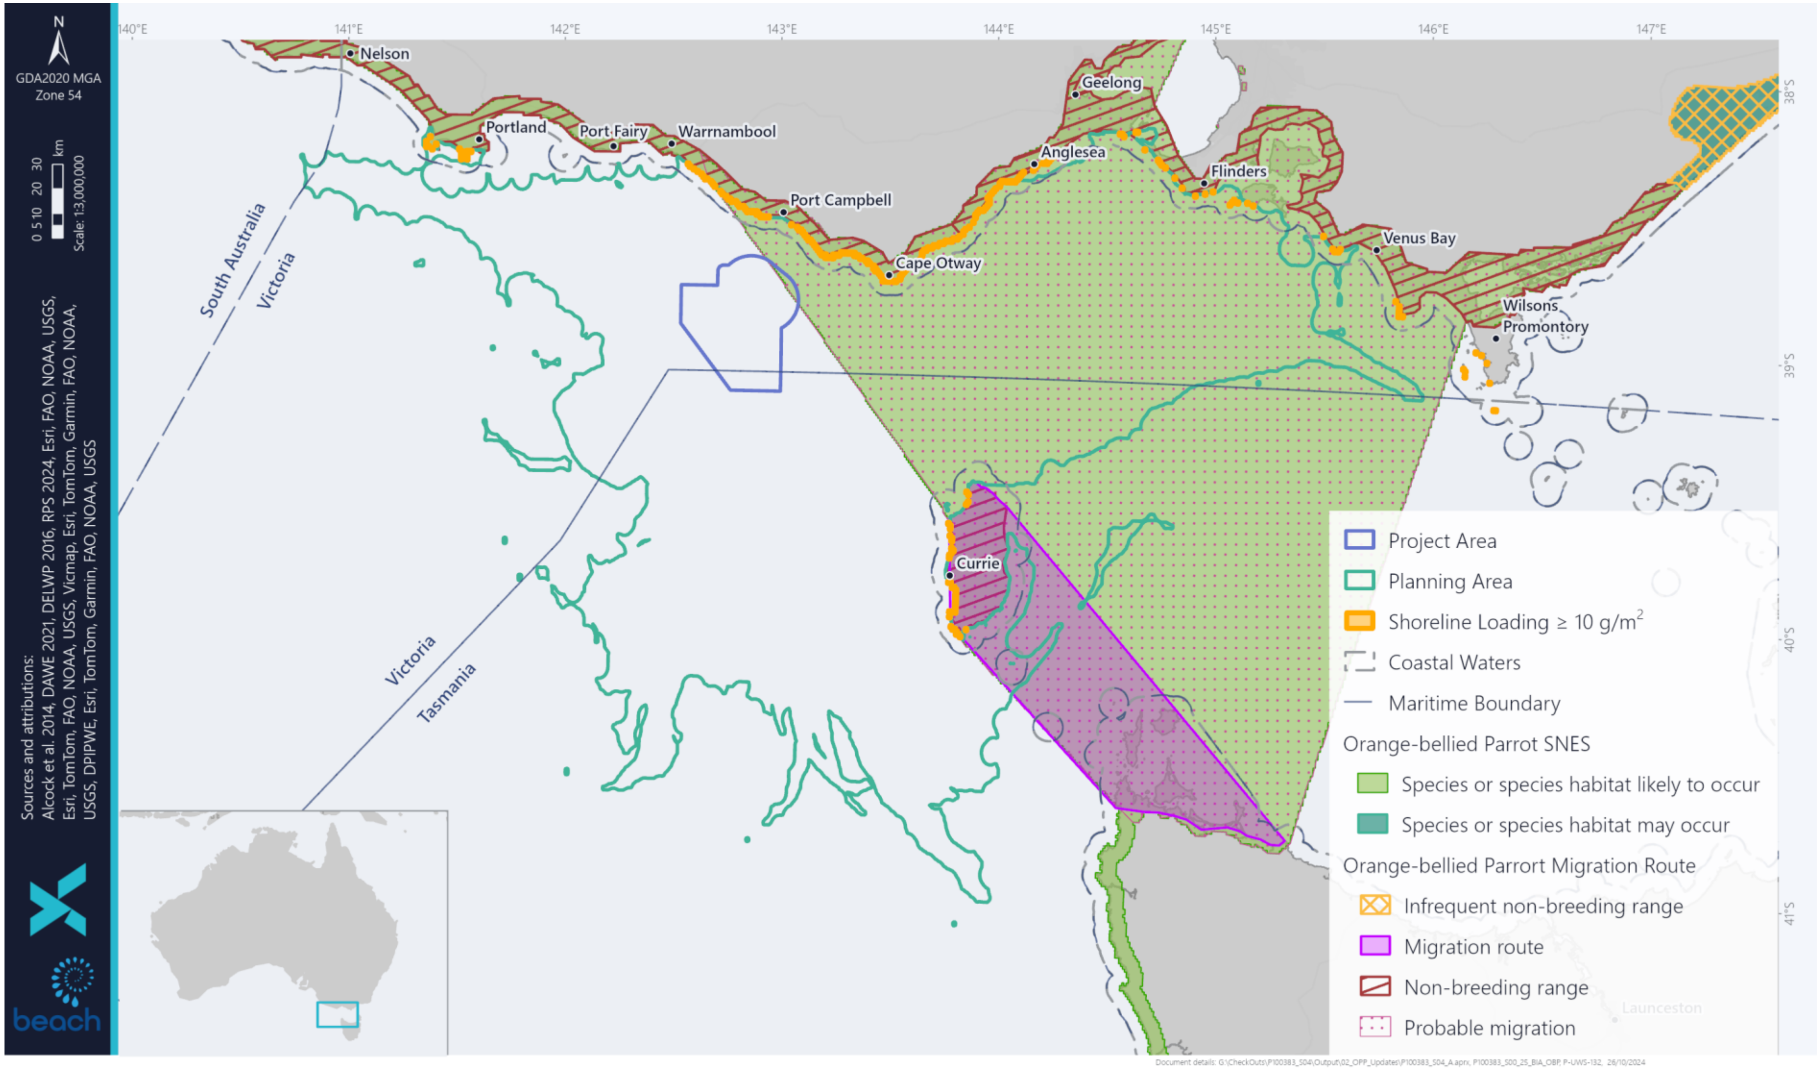

Figure 4-42: Distribution of the Orange-bellied Parrot within the Project and Planning Areas

6. Other Shorebirds

A number of species listed in Table 4-22 use coastal shoreline habitats such as Australasian Gannet, Fairy Prion, Red Knot, Pectoral Sandpiper, Fork-tailed Swift, Sharp-tailed Sandpiper, Curlew Sandpiper, Eastern Curlew, Little Curlew, Yellow Wagtail, and species of plover. These species are commonly found on coastal shores including beaches and rocky shores and either feed at low tide on worms, crustaceans and molluscs or fish species or feed on aquatic biota (Parks Victoria 2016). These species are unlikely to be present in the Project Area due to the distance offshore but are likely to be present in the Planning Area.

Many sandpipers including the Broad-billed, Common, Marsh and Terek are widespread through Australia's coastline inhabiting saltwater and freshwater ecosystems. They migrate from the Northern Hemisphere in non-breeding months, favouring estuaries, saltmarshes, intertidal mudflats, swamps, and lagoons and foraging on worms, molluscs, crustaceans, insects, seeds and occasionally rootlets and other vegetation (Marchant and Higgins 1993; Higgins and Davies 1996).

The Australian Painted Snipe is a stocky wading bird most commonly in eastern Australian wetlands. Feeding on vegetation, insects, worms, molluscs, crustaceans, and other invertebrates. Latham's, Swinhoe's and Pin-tailed Snipe is a non-breeding visitor to Australia occurring at the edges of wetlands, shallow swamps, ponds, and lakes (Marchant and Higgins 1993). The Grey-tailed Tattler migrate from the Northern hemisphere and inhabit rocky coasts with reefs and platforms, offshore islands, and intertidal mudflats. Foraging on polychaete worms, molluscs and crustaceans and roosting on branches of mangroves and rocks and boulders close to water. The Bar-tailed Godwit and Black-tailed Godwit are large waders, migrating from the Northern hemisphere in the noon-breeding months to coastal habitat in Australia. The large waders are commonly found in sheltered bays, estuaries, intertidal mudflats, and occasionally on rocky coasts (Higgins and Davies 1996).

Hooded and Eastern Hooded Plovers are small beach nesting birds. They predominantly occur on wide beaches and are easily disturbed by human activity. The Lesser Sand and Greater Sand Plover are migratory and inhabits intertidal sand and mudflats, forage on invertebrates and breed in areas characterised by high elevation. Breeding occurs outside Australia, but roosting occurs near foraging areas on beaches, banks, spits and banks (Pegler 1983). The Pacific Golden and Grey Plover are widespread in coastal regions foraging on sandy beaches, spits, rocky points, exposed reef and occasional low saltmarsh and mangroves. Roosting usually occurs near foraging areas while breeding occurs in dry tundra areas away from the coast (Bransbury 1985; Pegler 1983; Marchant and Higgins 1993). The Double-banded Plover is found in both coastal and inland areas with greatest numbers in Tasmania and Victoria. It breeds only in New Zealand and migrates to Australia.

Other waders including Common Noddy, Ruddy Turnstone, Sanderling, Red-necked Stint, Whimbrel, Common Greenshank, Pied Stilt, White-throated Needletail, Red-necked Phalarope, Ruff, Red-necked Avocet, Rufous Fantail and Black-faced Cormorant are common along Australia's coastline. Many are migratory travelling from the Northern Hemisphere in non-breeding months. Most inhabit intertidal mudflats, rocky islets, sand beaches, mangroves, rocky coastline, and coral reefs. Roosting occurs in similar habitats and species are found feeding on fish, crustaceans, aquatic insects, as well as plants and seeds (Higgins and Davies 1996). These species are unlikely to be present in the Project Area due to the distance offshore. The Plains Wanderer is a unique bird that lives predominantly in grasslands in Victoria, South Australia, New South Wales, and Queensland. The Swift Parrot is a small parrot breeding in colonies in Tasmania. The entire population migrates to the mainland during winter. The Great Knot is listed as vulnerable and migratory, arriving in large numbers in Australia occurring in sheltered coastal habitats with large intertidal mudflats. Typically, they roost in large open areas at the water's edge to in shallow water close to foraging grounds (Higgins and Davies 1996). These species are critically endangered and may occur within the Planning Area.

4.4.9.5 Marine Reptiles

The PMST reports identified three marine turtle species with potential to occur in the Project Area and/or Planning Area (Table 4-23). All three species of marine turtles are protected by the Recovery Plan for Marine Turtles in Australia (CoA 2017a). Foraging, feeding or related behaviours are known to occur within the Planning Area for two of the identified marine turtle species. No BIAs or habitat critical to the survival of marine turtles overlap the Project Area or Planning Area.

1. Green turtle

Green Turtles (*Chelonia mydas*) nest, forage and migrate across tropical northern Australia. They usually occur between the 20°C isotherms, although individuals can stray into temperate waters as vagrant visitors. Green turtles spend their first 5 to 10 years drifting on ocean currents. During this pelagic (ocean-going) phase, they are often found in association with drift lines and floating rafts of Sargassum. Green Turtles are predominantly found in Australian waters off the Northern Territory, Queensland, and Western Australian coastlines, with limited numbers in New South Wales, Victoria, and South Australia. There are no known nesting or foraging grounds for Green Turtles offshore Victoria; they occur only rarely in these waters (DoE 2023m) therefore it is expected they would only be occasional visitors in the Project Area and Planning Area.

2. Leatherback turtle

The Leatherback Turtle (*Dermochelys coriacea*) is a pelagic feeder found in tropical, sub-tropical and temperate waters throughout the world. Unlike other marine turtles, the leatherback turtle utilises cold water foraging areas, with the species most commonly reported foraging in coastal waters between southern Queensland and central NSW, south-east Australia (Tasmania, Victoria, and eastern SA), and southern WA (CoA 2017a). This species is an occasional visitor to the Otway shelf and has been sighted on a number of occasions during aerial surveys undertaken by the Blue Whale Study Group (Gill 2020), particularly to the south-west of Cape Otway. It is mostly a pelagic species, and away from its feeding grounds is rarely found inshore (CoA 2017a). Adults feed mainly on soft-bodied organisms such as jellyfish, which occur in concentrations at the surface in areas of convergence and upwelling (Bone 1998; Cogger 1992). Bass Strait is one of three of the largest concentrations of feeding Leatherback Turtles (DoE 2023n).

No major nesting has been recorded in Australia, with isolated nesting recorded in Queensland and the Northern Territory. The Leatherback turtle is expected to be only an occasional visitor in the Project Area and Planning Area.

3. Loggerhead turtle

The Loggerhead Turtle (*Caretta caretta*) is globally distributed in tropical, sub-tropical and temperate waters. The loggerhead is a carnivorous turtle, feeding primarily on benthic invertebrates in habitat ranging from nearshore to 55 m depth (Plotkin et al. 1993).

The main Australian breeding areas for Loggerhead Turtles are generally confined to southern Queensland and Western Australia (Cogger et al. 1993). Loggerhead Turtles will migrate over distances in excess of 1,000 km but show a strong fidelity to their feeding and breeding areas (Limpus 2008).

Loggerhead Turtles forage in all coastal states and the Northern Territory, but are uncommon in South Australia, Victoria, and Tasmania (CoA 2017a). Due to water depths, it is unlikely Loggerhead Turtles would be present in the Project Area but may be occasional visitors to the Planning Area.

Table 4-23: Listed Turtle Species or Species Habitat identified in the Project and/or Planning Areas

Common Name	Scientific Name	Threatened Category	Migratory Status	Migratory Category	Marine Status	Biologically Important Areas	Present in Planning Area	Present in Project Area
Green Turtle	*Chelonia mydas*	Vulnerable	Migratory	Migratory Marine Species	Listed		Species or species habitat may occur within area	Species or species habitat may occur within area
Leatherback Turtle, Leathery Turtle	*Dermochelys coriacea*	Endangered	Migratory	Migratory Marine Species	Listed		Foraging, feeding or related behaviour known to occur within area	Species or species habitat likely to occur within area
		Approved Conservation Advice for *Dermochelys coriacea* (leatherback turtle) (DEWHA 2008). Threats identified relevant to the Project are as per the recovery plan.						
Loggerhead Turtle	*Caretta caretta*	Endangered	Migratory	Migratory Marine Species	Listed		Foraging, feeding or related behaviour known to occur within area	Species or species habitat likely to occur within area

4.4.9.6 Marine Mammals – Pinnipeds

The PMST Report and reputable peer-reviewed literature identified three pinniped species with potential to occur in the Planning Area (Table 4-24). Two of these were also identified within the Project Area. The Project and Planning Areas do not overlap any BIAs for pinnipeds. Breeding and haul-out sites for Australian fur seals and New Zealand fur seals are displayed in Figure 4-43.

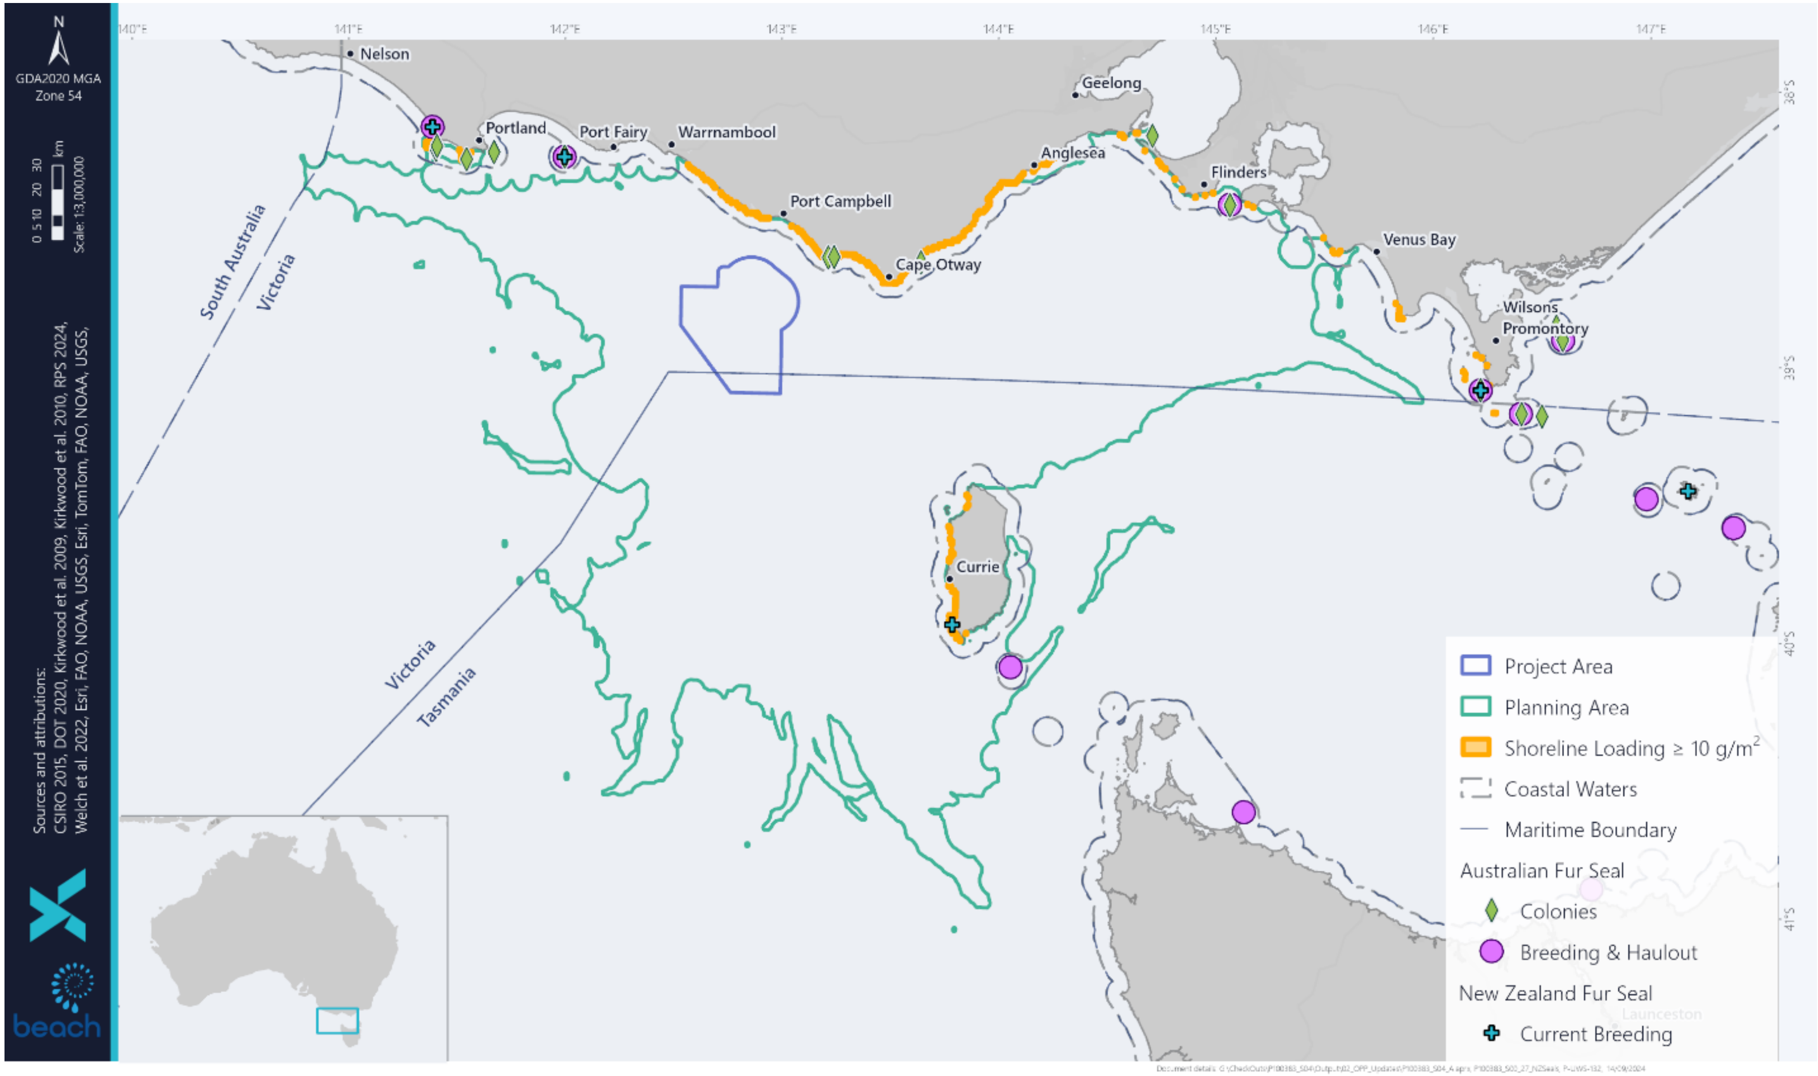

Figure 4-43: Australian Fur-seal and New Zealand Fur-seal Breeding and Haul-out Sites within the Planning Area (Kirkwood et al. 2010)

Table 4-24: Listed Pinniped Species or Species Habitat identified in the Project and/or Planning Areas

Common Name	Scientific Name	Threatened Category	Migratory Status	Migratory Category	Marine Status	Biologically Important Areas	Presence in Planning Area	Presence in Project Area
Australian Fur-seal, Australo-African Fur-seal	*Arctocephalus pusillus*				Listed		Breeding known to occur within area	Species or species habitat may occur within area
Australian Sea-lion, Australian Sea Lion	*Neophoca cinerea*	Endangered			Listed		Species or species habitat may occur within area	–
		Conservation advice *Neophoca cinerea* Australian sea lion (TSSC 2020x). Threats relevant to the Project are: • Habitat degradation and pollution – Oil spills • Require all vessels to have oil spill mitigation measures in place, and implement jurisdictional oil spill response strategies as required • Human disturbance – Noise • Monitor and mitigate impacts (including cumulative impacts) of human interactions on Australian Sea Lion colonies Recovery Plan for the Australian sea-lion (*Neophoca cinerea*) (DSEWPaC, 2013d). Threats relevant to the Project are: • Habitat degradation - No explicit relevant management actions • Vessel strike - Collect data on direct killings and confirmed vessel strikes • Pollution (oil spills, toxins) - implement jurisdictional oil spill response strategies as required Climate change - No explicit relevant management actions						
Long-nosed Fur-seal, New Zealand Fur-seal	*Arctocephalus forsteri*				Listed		Species or species habitat may occur within area	Species or species habitat may occur within area

1. Australian Fur-seal

Australian Fur-seals (*A. pusillus*) breed on islands of the Bass Strait but range throughout waters off the coasts of South Australia, Tasmania, Victoria, and NSW. Numbers of this species are believed to be increasing as the population recovers from historic hunting (Hofmeyr et al. 2008). The species is endemic to south-eastern Australian waters.

Australian Fur-seals are present in the region all year, with breeding taking place during November and December. In Victorian State waters they breed on offshore islands, including Lady Julia Percy Island, Seal Rocks in Westernport Bay, Kanowna, and Rag Islands off the coast of Wilson's Promontory and The Skerries off Wingan Inlet in Gippsland. Within the Planning Area, there are breeding colonies at Cape Bridgewater, Cape Volney, Judgement Rocks, Kanowna Island, Lady Julia Percy Island, Rag Island, Reid Rocks, Seal Rocks and West Moncoeur Island (Figure 4-43). There are important breeding sites on Lady Julia Percy Island and Seal Rocks, with 25% of the population occurring at each of these islands. Their preferred breeding habitat is a rocky island with boulder or pebble beaches and gradually sloping rocky ledges.

Haul-out sites with occasional pup births are located at Cape Bridgewater, at Moonlight Head, on various small islands off Wilsons Promontory and Marengo Reef near Apollo Bay. Within the Planning Area, haul-out sites include Maatsuyker Island and Walker Island (Figure 4-43).

Research being undertaken at Lady Julia Percy Island indicates that adult females feed extensively in the waters between Portland and Cape Otway, out to the 200 m bathymetric contour. Seal numbers on the island reach a maximum during the breeding season in late October to late December. By early December, large numbers of lactating females are leaving for short feeding trips at sea and in late December there is an exodus of adult males. Thereafter, lactating females continue to alternate between feeding trips at sea and periods ashore to suckle their pups. Even after pups begin to venture to sea, the island remains a focus, and at any time during the year groups may be seen ashore resting (Robinson et al. 2008; Hume et al. 2004; Arnould and Kirkwood 2007).

During the summer months, Australian Fur-seals travel between northern Bass Strait islands and southern Tasmania waters following the Tasmanian east coast, however, lactating female fur-seals and some territorial males are restricted to foraging ranges within Bass Strait waters. Lactating female Australian Fur-seals forage primarily within the shallow continental shelf of Bass Strait and Otway on the benthos at depths of between 60 to 80 m and generally within 100 to 200 km of the breeding colony for up to five days at a time.

Male Australian Fur-seals are bound to colonies during the breeding season from late October to late December, and outside of this they time forage further afield (up to several hundred kilometres) and are away for long periods, even up to 9 days (Kirkwood et al. 2009; Hume et al. 2004).

Within the Planning Area, a breeding colony is located at Cape Bridgewater and haul out sites identified at Marengo Reefs and New Chinaman's Hat. Additional colonies were identified at Reid Rocks and Seal Rocks (Figure 4-43). As there are colonies, breeding and haul out sites within the Planning Area it is expected that Australian Fur-seals would be present in the Planning Area. During Beach's Otway drilling campaign in 2021, 394 Australian Fur-seal detections were made, spread across the year.

Australian Sea Lion

The Australian Sea Lion is the only endemic, and least abundant, pinniped that breeds in Australia (DoE 2013b). All current breeding populations are outside of the Planning Area and are located from the Abrolhos Islands (Western Australia) to the Pages Islands (South Australia). The Australian Sea Lion uses a variety of shoreline types but prefer the more sheltered side of islands and typically avoid rocky exposed coasts (Shaughnessy 1999). The nearest BIA is for male foraging off the South Australian coast, 100 km to the west of the Planning Area and over 250 km west of the Project Area.

The Australian Sea Lion is a specialised benthic forager, i.e. it feeds primarily on the sea floor (DSEWPaC 2013d). The Australian Sea Lion feeds on the continental shelf, most commonly in depths of 20–100 m, with adult males foraging further and into deeper waters (DSEWPaC 2013d). They typically feed on a range of prey including fish, cephalopods (squid, cuttlefish and octopus), sharks, rays, rock lobster and penguins (DSEWPaC 2013d) They typically forage up to 60 km from their colony but can travel up to 190 km when over shelf waters (Shaughnessy 1999).

2. New Zealand Fur-seal

New Zealand Fur-seal (*Arctocephalus forsteri*) are found in the coastal waters and offshore islands of South Australia, Western Australia, Victoria, NSW and New Zealand. Population studies for New Zealand Fur-seal in Australia carried out in 1990 estimated an increasing population of about 35,000. The species breeds in southern Australia at the Pages Islands and Kangaroo Island, which produces about 75% of the total pups in Australia. Small populations are established in Victorian coastal waters including at Cape Bridgewater near Portland, Lady Julia Percy Island near Port Fairy, Kanowna Island (near Wilsons Promontory) and The Skerries in eastern Victoria.

Figure 4-43 shows the current and historic distribution of New Zealand Fur-seal colonies (Kirkwood et al. 2009). These colonies are typically found in rocky habitat with jumbled boulders. Colonies are typically occupied year-round, with greater activity during breeding seasons. Pups are born from mid-November to January, with most pups born in December (Goldsworthy 2008). No known breeding sites or colonies for the New Zealand Fur-seal were identified within the Planning Area (Figure 4-43).

4.4.9.7 Marine Mammals - Cetaceans

The PMST Reports and reputable peer-reviewed literature identified several cetaceans with potential to occur in the Project and Planning Areas (Table 4-25). Threatened or migratory species that are likely or known to occur or have a BIA that overlaps the Project and/or Planning Areas are discussed in more detail in the following sections.

The Bass Strait and the Otway Basin are considered an important migratory path for Humpback, Blue, Southern Right, and to some extent the Fin and Sei Whales. The whales use the Otway region to migrate to and from the north-eastern Australian coast and the sub-Antarctic. Of environmental importance in the Otway Basin is the Bonney coast upwelling, the eastward flow of cool nutrient rich water across the continental shelf of the southern coast of Australia that promotes blooms of krill and attracts baleen whales during the summer months.

Table 4-25: Listed Cetacean Species or Species Habitat Identified in the Project and/or Planning Areas

Common Name	Scientific Name	Threatened Category	Migratory Status	Migratory Category	Marine Status	Biologically Important Areas	Presence in Planning Area	Presence in Project Area
Andrew's Beaked Whale	*Mesoplodon bowdoini*						Species or species habitat may occur within area	Species or species habitat may occur within area
Antarctic Minke Whale, Dark-shoulder Minke Whale	*Balaenoptera bonaerensis*		Migratory	Migratory Marine Species			Species or species habitat likely to occur within area	Species or species habitat likely to occur within area
Arnoux's Beaked Whale	*Berardius arnuxii*						Species or species habitat may occur within area	Species or species habitat may occur within area
Blainville's Beaked Whale, Dense-beaked Whale	*Mesoplodon densirostris*						Species or species habitat may occur within area	Species or species habitat may occur within area
Blue Whale	*Balaenoptera musculus*	Endangered	Migratory	Migratory Marine Species		Foraging, Distribution,	Foraging, feeding or related behaviour known to occur within area	Foraging, feeding or related behaviour known to occur within area
	Conservation Management Plan for the Blue Whale (CoA 2015b). The long-term recovery plan objective for Blue Whales is to minimise anthropogenic threats to allow for their conservation status to improve. Threats relevant to the Project are: • Noise interference -Evaluate risk of noise impacts and, if required, appropriate mitigation measures are implemented • Vessel disturbance - Evaluate risk of vessel strikes and, if required, appropriate mitigation measures are implemented.							
Bottlenose Dolphin	*Tursiops truncatus* s. str.						Species or species habitat may occur within area	Species or species habitat may occur within area

Common Dolphin, Short-beaked Common Dolphin	*Delphinus delphis*				Species or species habitat may occur within area	Species or species habitat may occur within area
Cuvier's Beaked Whale, Goose-beaked Whale	*Ziphius cavirostris*				Species or species habitat may occur within area	Species or species habitat may occur within area
Dusky Dolphin	*Lagenorhynchus obscurus*		Migratory	Migratory Marine Species	Species or species habitat likely to occur within area	Species or species habitat likely to occur within area
Dwarf Sperm Whale	*Kogia sima*				Species or species habitat may occur within area	Species or species habitat may occur within area
False Killer Whale	*Pseudorca crassidens*				Species or species habitat likely occur within area	Species or species habitat likely to occur within area
Fin Whale	*Balaenoptera physalus*	Vulnerable	Migratory	Migratory Marine Species	Foraging, feeding or related behaviour known to occur within area	Foraging, feeding or related behaviour likely to occur within area
		Approved Conservation Advice for *Balaenoptera physalus* (Fin Whale) (TSSC 2015d). Threats relevant to the Project are: • Noise interference - Evaluate risk of noise impacts to cetaceans and, if required, appropriate mitigation measures are implemented. • Vessel disturbance - Evaluate risk of vessel strikes and, if required, appropriate mitigation measures are implemented.				
Gray's Beaked Whale, Scamperdown Whale	*Mesoplodon grayi*				Species or species habitat may occur within area	_
Hector's Beaked Whale	*Mesoplodon hectori*				Species or species habitat may occur within area	Species or species habitat may occur within area
Humpback Whale	*Megaptera novaeangliae*		Migratory	Migratory Marine Species	Species or species habitat known to occur within area	Species or species habitat likely to occur within area

		Approved Listing Advice for *Megaptera novaeangliae* (Humpback Whale) (TSSC 2022). Listing advice details that the humpback is no longer listed as vulnerable and has been removed from the threatened species list. It will remain a matter of national environmental significance under the EPBC Act as a listed Migratory Species. Threats identified relevant to the Project: • Marine debris • Noise interference • Pollution • Vessel disturbance and strike • No explicit relevant management actions.				
Indian Ocean Bottlenose Dolphin, Spotted Bottlenose Dolphin	*Tursiops aduncus*				Species or species habitat likely to_ occur within area	
Killer Whale, Orca	*Orcinus orca*		Migratory	Migratory Marine Species	Species or species habitat likely to occur within area	Species or species habitat likely to occur within area
Long-finned Pilot Whale	*Globicephala melas*				Species or species habitat may occur within area	Species or species habitat may occur within area
Minke Whale	*Balaenoptera acutorostrata*				Species or species habitat may occur within area	Species or species habitat may occur within area
Pygmy Right Whale	*Caperea marginata*		Migratory	Migratory Marine Species	Foraging, feeding or related behaviour likely to occur within area	Foraging, feeding or related behaviour may occur within area
Pygmy Sperm Whale	*Kogia breviceps*				Species or species habitat may occur within area	Species or species habitat may occur within area
Risso's Dolphin, Grampus	*Grampus griseus*				Species or species habitat may occur within area	Species or species habitat may occur within area

Sei Whale	*Balaenoptera borealis*	Vulnerable	Migratory	Migratory Marine Species		Foraging, feeding or related behaviour known to occur within area	Foraging, feeding or related behaviour likely to occur within area
		Approved Conservation Advice for *Balaenoptera borealis* (Sei Whale) (TSSC 2015e). Threats identified relevant to the Project: • Noise interference -Evaluate risk of noise impacts to cetaceans and, if required, appropriate mitigation measures are implemented. • Vessel disturbance -Evaluate risk of vessel strikes and, if required, appropriate mitigation measures are implemented.					
Shepherd's Beaked Whale, Tasman Beaked Whale	*Tasmacetus shepherdi*					Species or species habitat may occur within area	_
Short-finned Pilot Whale	*Globicephala macrorhynchus*					Species or species habitat may occur within area	Species or species habitat may occur within area
Southern Bottlenose Whale	*Hyperoodon planifrons*					Species or species habitat may occur within area	_
Southern Right Whale	*Eubalaena australis*	Endangered	Migratory (as *Balaena glacialis australis*)	Migratory Marine Species	Migration Reproduction	Breeding known to occur within area	Species or species habitat known to occur within area
		National Recovery Plan for the Southern Right Whale *Eubalaena australis* (DCCEEW 2024o). Threats identified relevant to the Project: • Habitat degradation from coastal and offshore development • Anthropogenic underwater noise • Vessel collision • Actions identified relevant to the Project: • Address habitat degradation impacts from coastal and offshore marine infrastructure developments • Assess, manage and mitigate impacts from anthropogenic noise • Manage, minimise and mitigate the threat of vessel strike					

Southern Right Whale Dolphin	*Lissodelphis peronii*			Species or species habitat may occur within area	Species or species habitat may occur within area
Sperm Whale	*Physeter macrocephalus*	Migratory	Migratory Marine Species	Species or species habitat may occur within area	Species or species habitat may occur within area
Strap-toothed Beaked Whale, Strap-toothed Whale, Layard's Beaked Whale	*Mesoplodon layardii*			Species or species habitat may occur within area	Species or species habitat may occur within area
True's Beaked Whale	*Mesoplodon mirus*			Species or species habitat may occur within area	Species or species habitat may occur within area

1. Cultural significance

First Nation’s people around Australia have long had a strong connection to whales, which has significance as totemic ancestors to some groups. The arrival of whales along Australia's coastline marked the arrival of the "elders of the sea", which follows a songline or ancient memory code, that traces the journeys of ancestral spirits as they created the land, animals, and lore.

Indigenous Australians have a long tradition of utilising beached (or stranded) whales as a food source and whale stranding’s were occasions for feasting (Clarke 2001). For example, Ngarrindjeri had gathered to harvest the bodies of stranded whales well before Kringkari (pink-skinned men) arrived in their lands. Runners were sent inland telling others of the arrival of Kondoli, which was a time for ceremony and trade (Paterson and Wilson 2019).

a. Otway Whale Surveys

Gill et al. (2015) summarised cetacean sightings from 123 systematic aerial surveys undertaken over western Bass Strait and the eastern Great Australian Bight between 2002 and 2013. This paper does not include sighting data for Blue Whales, which has previously been reported in Gill et al. (2011).

These surveys recorded 133 sightings of 15 identified cetacean species consisting of seven mysticetes (baleen) whale species, eight odontocete (toothed) species and 384 sightings of dolphins (Table 4-26 and Table 4-27). Survey effort was biased toward coverage of upwelling seasons, corresponding with Pygmy Blue Whales’ seasonal occurrence (November to April; 103 of 123 surveys), and relatively little survey effort occurred during 2008–2011. Cetacean species sighted within the region are described in the following sections.

Gill et al. (2015) encountered Southern Right and Humpback Whales most often from May to September, despite low survey effort in those months. Southern Right Whales were not recorded between October and May. Fin, Sei, and Pilot whales were sighted only from November to May (upwelling season), although this may be an artefact of their relative scarcity overall and low survey effort at other times of year. Dolphins were sighted most consistently across years. The authors caution that few conclusions about temporal occurrence can be drawn because of unequal effort distribution across seasons and the rarity of most species.

Species of cetacean sighted in the period 31 October to 19 December 2010 during the Speculant 3D Transitions Zone Seismic Survey (3DTZSS) undertaken by Origin Energy, recorded species of Common Dolphin (*Delphinus* spp.), Bottlenose Dolphin (*Tursiops* spp.), unidentified small cetaceans and fur-seals.

Origin conducted a survey for cetaceans focused on Origin operations and permits in the Otway basin from June 2012 through to March of 2013. Table 4-28 lists the species present in the area Origin surveyed.

As part of Beach’s Otway drilling campaign, marine fauna observations occurred through most of 2021 (2 February to 31 December 2021) from the MODU and support vessels at the Artisan 1, Geographe 4, Geographe 5 and Thylacine North 1 drilling locations. Table 4-26 provides this cetacean sighting data. For whales, the highest number of detections was for Blue Whales (198), while for dolphins, it was the Common Dolphin (519).

Table 4-26: Cetacean Species Recorded during Aerial Surveys 2002–2013 in Southern Australia

SRW = Southern Right Whales; ROR = rorquals; ODO = other odontocetes; DOL = dolphins

b. Antarctic Minke Whale

The Antarctic Minke Whale (*Balaenoptera bonaerensis*) has been found in all Australian states except the Northern Territory and occupies cold temperate to Antarctic offshore and pelagic habitats between 21°S and 65°S (Bannister et al. 1996). In summer the species is found in pelagic waters from 55°S to the Antarctic ice edge. During winter the species retreat to breeding grounds between 10-30°S, occupying oceanic waters exceeding 600 m depth and beyond the continental shelf break (DoE 2023f). They have been observed as far north as 21°S along the east coast of Australia and are presumed to follow the same migration pattern on Australia's west coast (Bannister et al. 1996). Mating occurs from June through December, with a peak in August and September and calving occurs during late May and early June in warmer waters north of the Antarctic Convergence (DoE 2023f). The species primarily feeds in the Antarctic on Antarctic krill during summer and does not appear to feed much while in the breeding grounds of lower latitudes (DoE 2023f).

The Antarctic Minke Whale has been observed within the region, however, there are no BIAs in the Project Area or Planning Area.

c. Blue Whale

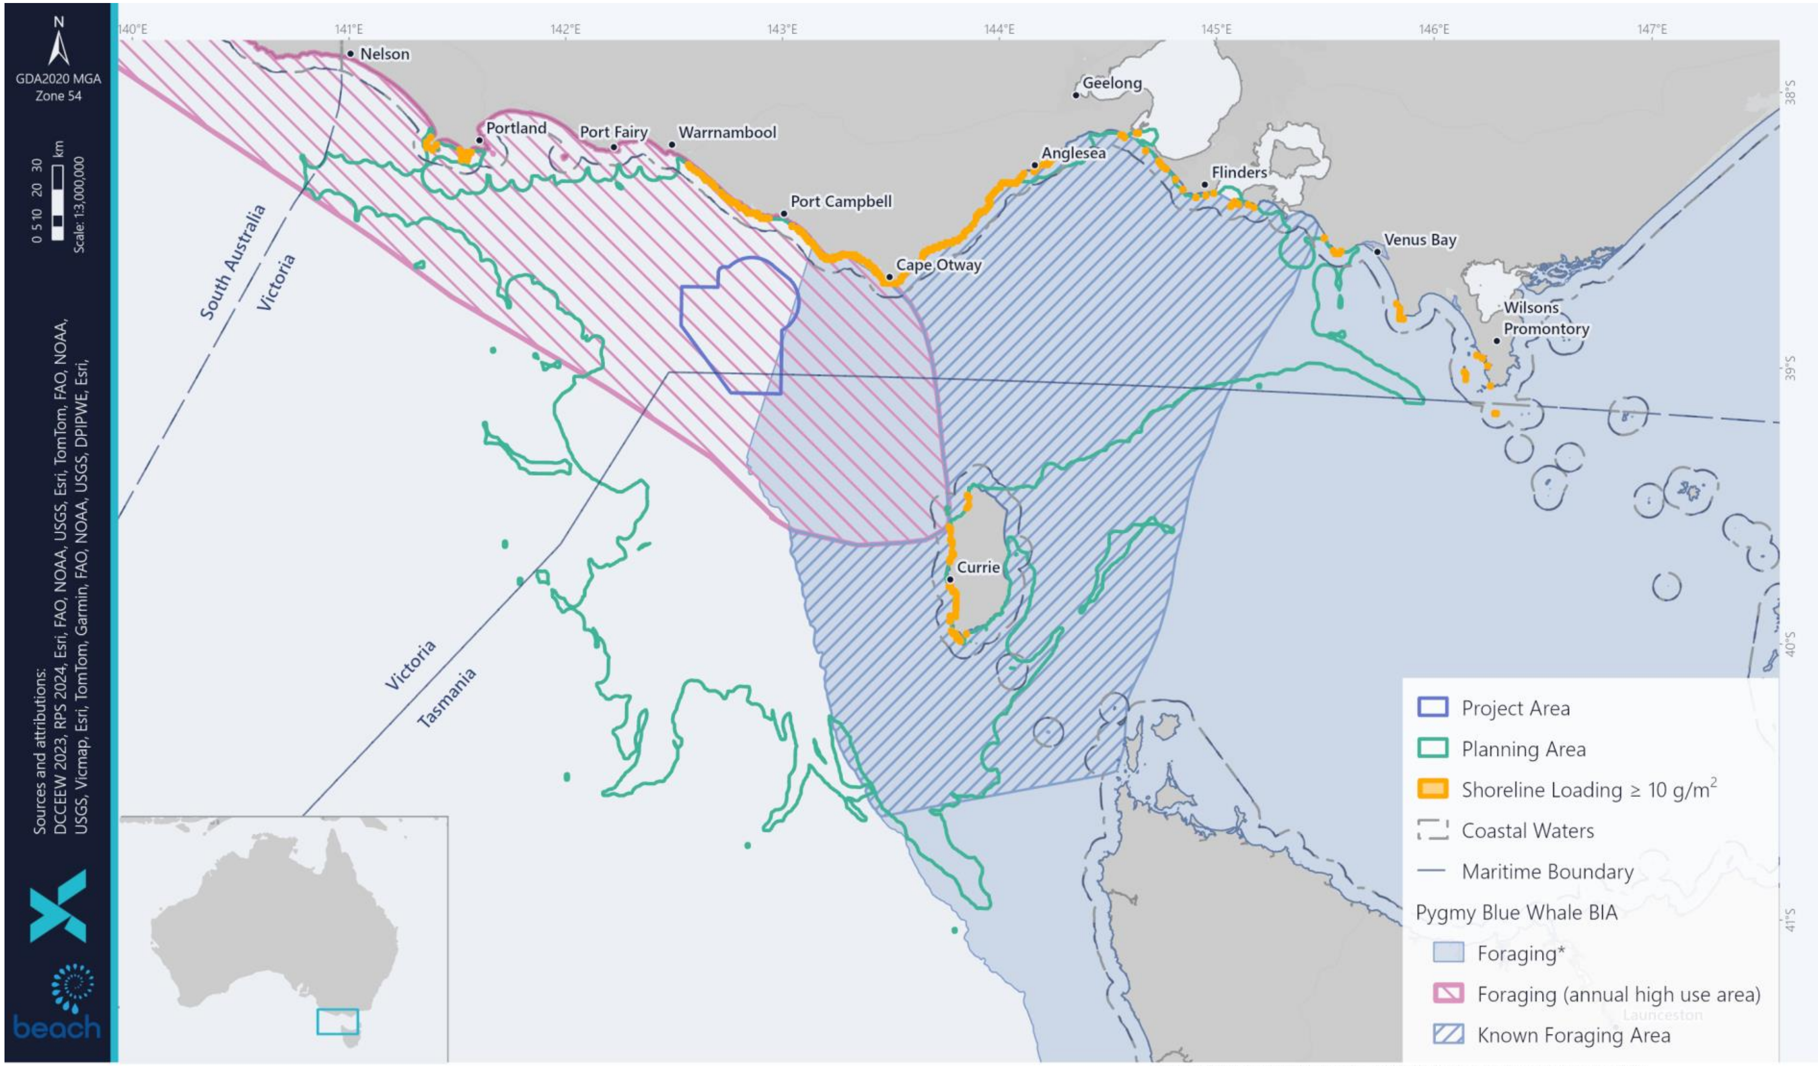
The Pygmy Blue Whale has a foraging (annual high use area) BIA within the Project and Planning Areas (Figure 4-44).

Data, as detailed in this section, suggests that Blue Whales are most likely to first appear during December/January and reach peak number during February/March. The likelihood and extent of the interaction is dependent on broad scale environmental factors affecting the abundance and distribution of Blue Whale feeding resources.

(i) Status

The Blue Whale (*Balaenoptera musculus*) is listed as an endangered species under the EPBC Act (1999) and the IUCN Red List. There are two subspecies of Blue Whales that use Australian waters (including Australian Antarctic waters), the Pygmy Blue Whale (*B. m. brevicauda*) and the Antarctic Blue Whale (*B.*

m. intermedia). Reference to Blue Whale unless otherwise specified is generally synonymous to both species. The Conservation Management Plan for the Blue Whale (CoA 2015b) identifies threats and establishes actions for assisting the recovery of Blue Whale populations using Australian waters (CoA 2015b).



Document details: G:\CheckOuts\P100383_S04\Output\02_OPP_Updates\P100383_S04_A.aprx, P100383_S00_22_BIA_PBW, P-UWS-132, 14/09/2024

Figure 4-44: Pygmy Blue Whale BIAs within the Project and Planning Areas

(ii) Population

The Antarctic Blue Whale was extremely abundant until the early 20th century when they were hunted to near extinction. Approximately 341,830 Blue Whale takes were recorded by commercial whaling in the Antarctic and sub-Antarctic in the 20th century, of which 12,618 were identified as Pygmy Blue Whales (Branch et al. 2004). The current global population of Blue Whales is uncertain but is plausibly in the range of 10,000 to 25,000, corresponding to about 3-11% of the 1911 estimated population size (Reilly et al. 2008). The Antarctic Blue Whale subspecies remains severely depleted from historic whaling and its numbers are recovering slowly. The Antarctic Blue Whale population is growing at an estimated rate of 7.3% per year, but it was hunted to such a low level that it remains at a tiny fraction of pre-whaling numbers (Branch et al. 2004). Recent studies suggest an updated rate of increase in population growth of 12.6 %, consistent with growth rates in waters off the south of Australia (McCauley et al. 2018). The updated abundance estimate uses acoustic chorus squared pressure levels to estimate growth rate off Portland (McCauley et al. 2018). This growth rate considers the number of whales calling assuming the range distribution of whales, source levels, sound propagation and calling behaviour were all similar between years.

Genetic analysis has shown that Pygmy Blue Whales which feed off the Perth Canyon and the Bonney Upwelling constitute the same population (Attard et al. 2010, in Commonwealth of Australia 2015b). Photo identification and genomic studies suggest population exchange between the two feeding grounds of the Bonney coast upwelling and the Perth Canyon (Attard et al. 2018). A Pygmy Blue Whale was tagged in 2014 north of the Perth Canyon and travelled a total distance of 506.3 km in 7.6 days, indicating the vast distances that the large marine mammals can travel in a short amount of time (Owen et al. 2016). While migrating the whale made dives at depths just below the surface which likely reduces energy expenditure but also increases the risk of ship strike greatly for longer periods than previously thought.

Global Pygmy Blue Whale abundance estimates range from 2,000 to 5,000 individuals (Reilly et al. 2018). Abundance estimates based on photo-identification mark-recapture from 1999/2000 to 2004/2005 for Blue Whales in the Perth Canyon were between 532 and 1,754 individuals, which generally agree with acoustic abundance estimates of 662 to 1,559 calling Blue Whales migrating south in 2004 past Exmouth in Western Australia and a 1992/1993 season cruise which estimated 671 (95% interval 289–1,557) individuals offshore of southern Western Australia (35–45^0 South, 115–125^0 East) (CoA 2015b).

(iii) Distribution

The Blue Whale is a cosmopolitan species, found in all oceans except the Arctic, but absent from some regional seas such as the Mediterranean, Okhotsk and Bering seas. Little is known about mating behaviour or breeding grounds. The Pygmy Blue Whale is mostly found north of 55°S, while Antarctic Blue Whales are mainly sighted south of 60°S in Antarctic waters. The presence of Antarctic Blue Whales in the area is considered rare (Gavrilov 2012), however acoustic detection of Antarctic Blue Whales indicates that they occur along the entire southern coastline of Australia (McCauley et al. 2018).

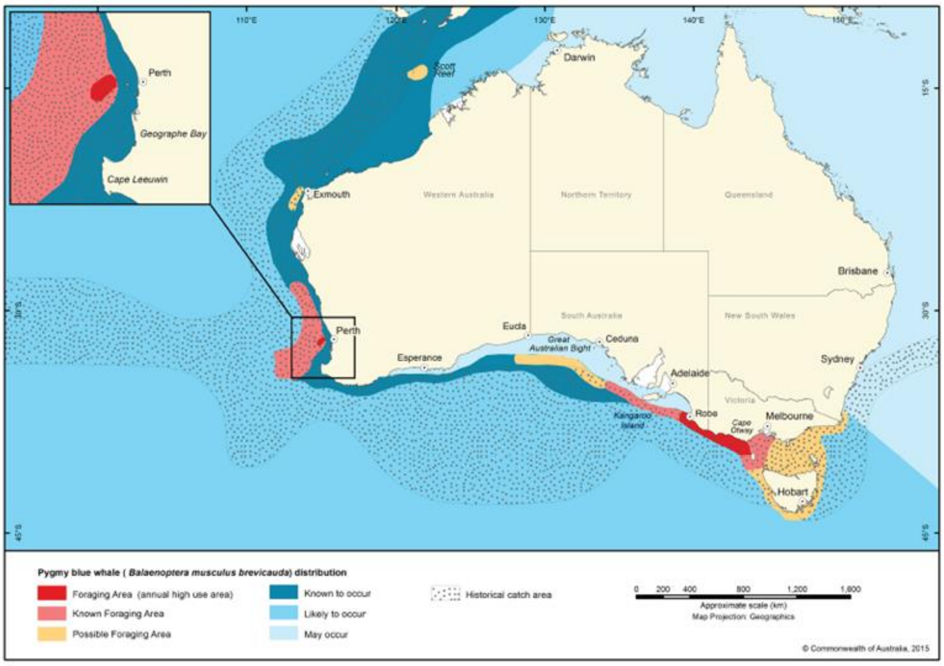
Pygmy Blue Whales are most abundant in the southern Indian Ocean on the Madagascar plateau, and off South Australia and Western Australia, where they form part of a more or less continuous distribution from Tasmania to Indonesia.

Blue Whales are rapid long-distance travellers, and pygmy Blue Whales spend the winter breeding in Indonesian waters, returning to cool temperate waters around November each year, interchanging between these waters and remoter waters of the Southern Ocean during the upwelling 'season' (Gill 2020). Pygmy Blue Whales have three migratory stages around Australia; the "southbound migration stage" is predominantly between October to December (sometimes into January) where whales travel from Indonesian waters down to the WA coast. The "southern Australian stage" between January and June is where whales spread across the southern Australian waters. The "northbound migration stage" is where whales travel back up to Indonesia between April and August. The "southern stage" involves animals searching for feeding sites, feeding and then marking their way north towards June (McCauley et al. 2018).

The distribution of Blue Whales in the Australian region is shown in Figure 4-44. There are two known seasonal feeding aggregations areas in Australia, the Bonney Coast Upwelling KEF and adjacent waters off South Australia and Victoria and the Perth Canyon KEF and adjacent waters in Western Australia. The Otway Offshore Project is located within a Blue Whale BIA – Foraging Area (annual high use area).

McCauley et al. (2018) suggests that acoustic detection of Pygmy Blue Whales indicate they predominantly occur west of Bass Strait. Acoustic detections of Pygmy Blue Whales off Portland Victoria correlated with upwelling indicators in the Bonney coast upwelling in late summer to autumn (February to April) (McCauley et al. 2018). The two Pygmy Blue Whale call types and the Antarctic Blue Whale call have been detected in central Bass Strait. On one occasion all three types were detected between April and June with more commonly two calls present over this period during other years.

The Otway Shelf is squarely within the productive, and to a certain extent predictable, Great Southern Australian Upwelling System. It has been shown to be an important, consistently used Blue Whale foraging area over many years (Gill et al. 2011).



Foraging Area (Annual high use area)	Blue whales are regularly observed feeding on a seasonal basis
Known Foraging Area	Known foraging occurs in these areas but is highly variable both between and within seasons
Possible Foraging Area	Evidence for feeding is based on limited direct observations or through indirect evidence, such as occurrence of krill in close proximity of whales, or satellite tagged whales showing circling tracks. Blue whales travel through on a seasonal basis, possibly as part of their migratory route

Known to occur	Blue whales are known to occur based on direct observations, satellite tagged whales or based on acoustic detections
Likely to occur	Blue whales are likely to occur based on occasional observations in the area and nearby areas
May occur	Evidence for the presence of blue whales through strandings or rare observations
Historical catch area	Blue whales were caught during the whaling period based on whaling data

Figure 4-45: Pygmy Blue Whale Distribution Areas around Australia (CoA 2015b)

(iv) Foraging Ecology

Krill are the key to understanding the ecology and behaviour of Blue Whales. Krill is sensitive to temperature and migrates vertically and horizontally to maintain optimal positioning with respect to nutrients, often being found along thermal fronts and thermoclines. Krill abundance in a given season may be linked to oceanographic conditions of the previous year. Unlike most krill species, *Nyctiphanes australis* frequently swarm at or near the surface, making it easily available to foraging Blue Whales. However, it is often found at depth, when Blue Whales must dive to search for and consume it. Foraging is energetically expensive for these giant mammals, which must regularly find sufficient food to balance their enormous energy requirements (Gill 2020). Blue Whales typically feed during daylight hours when krill is visible to them (Gill 2020).

Between the months of November and April, south-east winds drive upwelling of nutrient-rich water drawn from the continental slope, onto the continental shelf. An upwelling regime known as the Great Southern Australian Upwelling System extends along the shelf from the eastern Great Australian Bight to western Tasmania. Prominent surface upwelling commonly occurs west of Portland where the shelf is narrow (the Bonney Upwelling); whereas on the broader shelf between Portland and King Island, upwelling is usually subsurface, with cooler upwelled water beneath a warmer surface layer (Gill 2020).

Important foraging grounds for Blue Whales include the Great Australian Bight, South Australia and off Portland, Victoria where Blue Whales visit between December and June to forage on the inshore shelf break (Figure 4-45). The time and location of the appearance of Blue Whales in the east generally coincides with the upwelling of cold water in summer and autumn along this coast (the Bonney

Upwelling, see Section 4.3.8) and the associated aggregations of krill that they feed on (Gill and Morrice 2003). The Bonney Upwelling generally starts in the eastern part of the Great Australian Bight in November or December and spreads eastwards to the Otway Basin around February as southward migration of the subtropical high-pressure cell creates upwelling favourable winds. Sighting data indicates that Blue Whales are seasonally distributed (Gill et al. 2011; McCauley et al. 2018).

Diving behaviour of Blue Whales associated with feeding at depth was observed by Gill and Morris (2003) in the Otway region, who note that Blue Whales dived steeply, submerging for 1 to 4 minutes, then returned to the surface. Tagging of a Pygmy Blue Whale at the Perth Canyon identified 1,677 dives over the tag duration (7.6 days) (Owen et al. 2016). The duration of dives was:

- Feeding - mean of 7.6 minutes, maximum of 17.5 minutes;
- Migratory – mean of 5.2 minutes, maximum of 26.7 minutes; and
- Exploratory – mean of 8.6 minutes, maximum of 22.05 minutes.
- Tagging of 13 Pygmy Blue Whales (five of which had tags that monitored dive depth and duration) in the Bonney Upwelling identified (Möller et al. 2015):
- Whales predominantly carried out area-restricted search (presumably foraging) with generally shallow and short dives. However, dives were generally deeper at night compared to during the day.
- Whales performed mostly square shaped dives that were shallow in depth and short in duration.
- Dives recorded to a maximum of 492 m (mean = 59.5 m ± 94.3), and for a maximum duration of 112 minutes (mean = 6.1 minutes ± 5.2).

The seasonal distribution and abundance of Blue Whales is variable across years and influenced by climate variables. The time and location of the appearance of Blue Whales in the Otway region generally coincides with the upwelling of cold water between November and April along the Bonney coast and the associated aggregations of krill that they feed on (Gill and Morrice 2003). The Bonney Upwelling generally starts in the eastern part of the Great Australian Bight in November or December and spreads eastwards to the Otway Basin around February as southward migration of the subtropical high-pressure cell creates upwelling favourable winds. Sighting data indicates that Blue Whales are seasonally distributed (Gill et al. 2011; McCauley et al. 2018).

Foraging of Pygmy Blue Whales is known to occur in Bass Strait and the west coast of Tasmania where they have been recorded diving at depth presumably feeding (DoE 2023a). Blue Whales are known as ‘constant foragers’; their ecology in feeding grounds consists of constantly searching for patchily distributed krill resources, preferably those that reward the effort involved in consuming them (Torres et al. 2020). They are physically well-adapted for rapid movement between widely separated foraging areas (Woodward et al. 2006), but when they enter areas where krill may occur, they carry out zigzagging ‘area-restricted searches’ (ARS) patterns until either they find prey, or exhaust local possibilities, and move on to another possible foraging ground based on past experience (Abrahms et al. 2019). Based on this it is assumed that once blue whales have finished feeding, they will move from the feeding area to commence searching for another area.

(v) The Otway Region

Aerial Surveys (2001-02 to 2006-07)

Seasonal (November to April) aerial surveys between Cape Jaffa and Cape Otway (eastern distribution) over six seasons found that the general pattern of seasonal movement of Blue Whales is from west to east, with whales foraging between the Great Australian Bight and Cape Nelson in November and spreading further east into the Otway Shelf between Portland and Cape Otway around December. Whales were typically widely distributed throughout Otway shelf waters from January through to April (Gill et al. 2011) (Figure 4-46 and Figure 4-47).

The sighting and effort data presented in Figure 4-46and Figure 4-47 was used to calculate an ‘encounter rate’ (NB: key in upper right corner of the November, January and April figures). Dots represent Blue Whale sightings while squares are aerial survey effort (10 km by 10 km squares) represented as minutes flown per grid square. The data was pooled for all seasons. Thick solid lines represent 50% and 95% probability contours for Blue Whale distribution from density kernel analysis. Dashed lines are central and eastern boundaries (Gill et al. 2011). During 2002-11, Blue Whales were twice more likely to be found west of Portland than to its east (Gill et al. 2011).

The Project Area is on the outer edge of the eastern distribution.

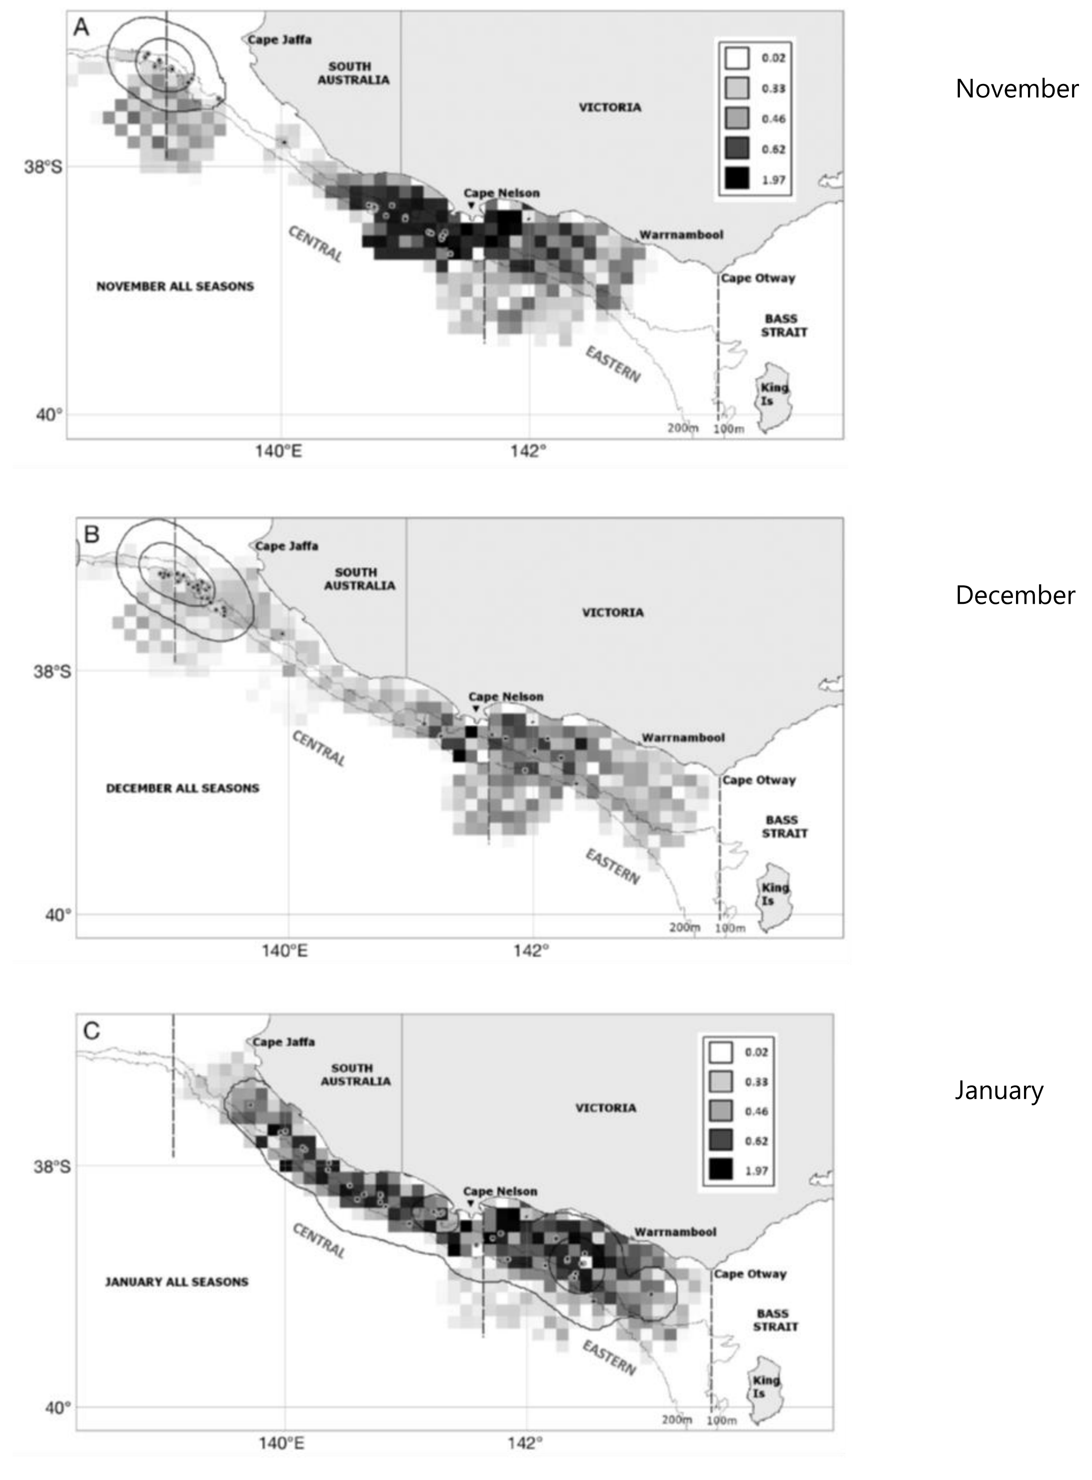


Figure 4-46: Blue Whale Sightings in the Otway Basin (Nov, Dec, Jan) (Gill et al. 2011)

Note: Dots represent Blue Whale sightings while squares are aerial survey effort (10 km by 10 km squares) represented as minutes flown per grid square (key, upper right corner of the November and January figures).

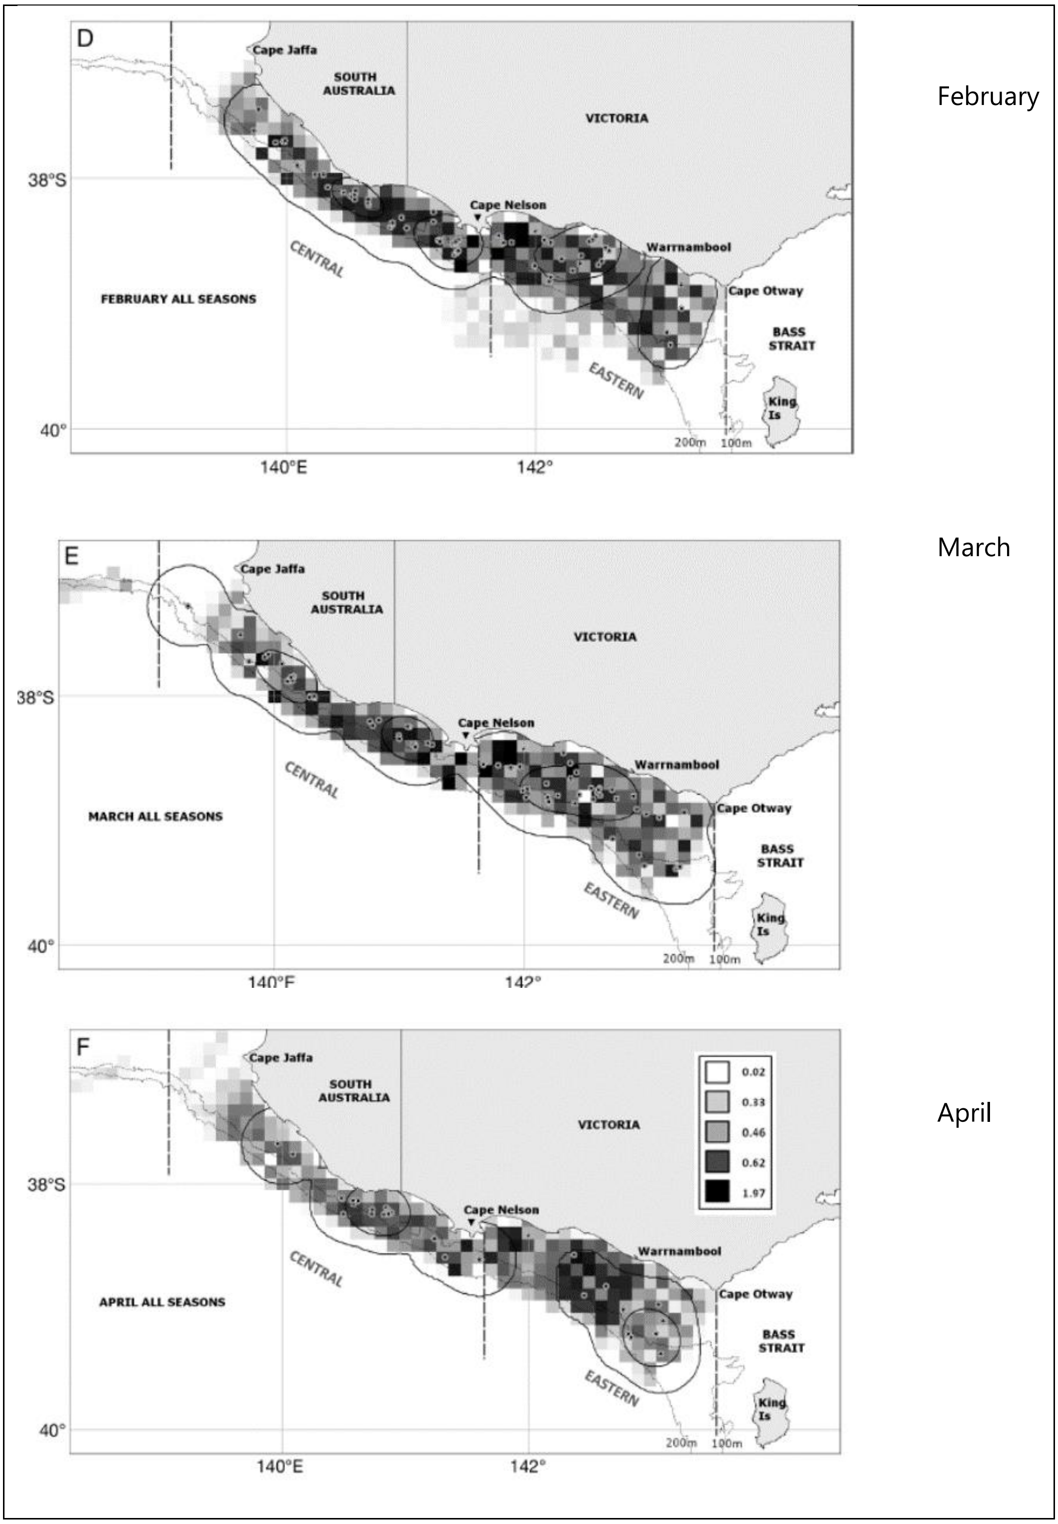

Figure 4-47: Blue Whale sightings in the Otway Basin (Feb, Mar, Apr) (Gill et al. 2011)

Note: Dots represent Blue Whale sightings while squares are aerial survey effort (10 km by 10 km squares) represented as minutes flown per grid square (key, upper right corner of the April figure).

Monthly Blue Whale encounter rates between 2001 and 2007 in the central and eastern study area (Cape Nelson to Cape Otway) are shown in Figure 4-48The encounter rates increased from 1.6 whales per 1,000 km in December, to 9.8 whales per 1,000 km in February, decreased slightly to 8.8 whales per

1,000 km in March, then declined sharply to a single sighting for May (0.4 whales per 1,000 km) (Gill et al. 2011). A mean Blue Whale group size of 1.3±0.6 was observed per sighting with cow-calf pairs observed in 2.5% of the sightings. Gill et al. (2011) also identified that 80% of Blue Whale sightings are encountered in water depths between 50 and 150 m; 93% of sightings occurred in water depths <200 m and 10% of sightings occurred within 5 km of the 200 m isobath in the eastern and central zones (Gill et al. 2011).

Gill et al. (2011) found that across the eastern zone (Cape Nelson to Cape Otway), there were no Blue Whale sightings in November (2001-2007) despite significant effort (Figure 4-48).

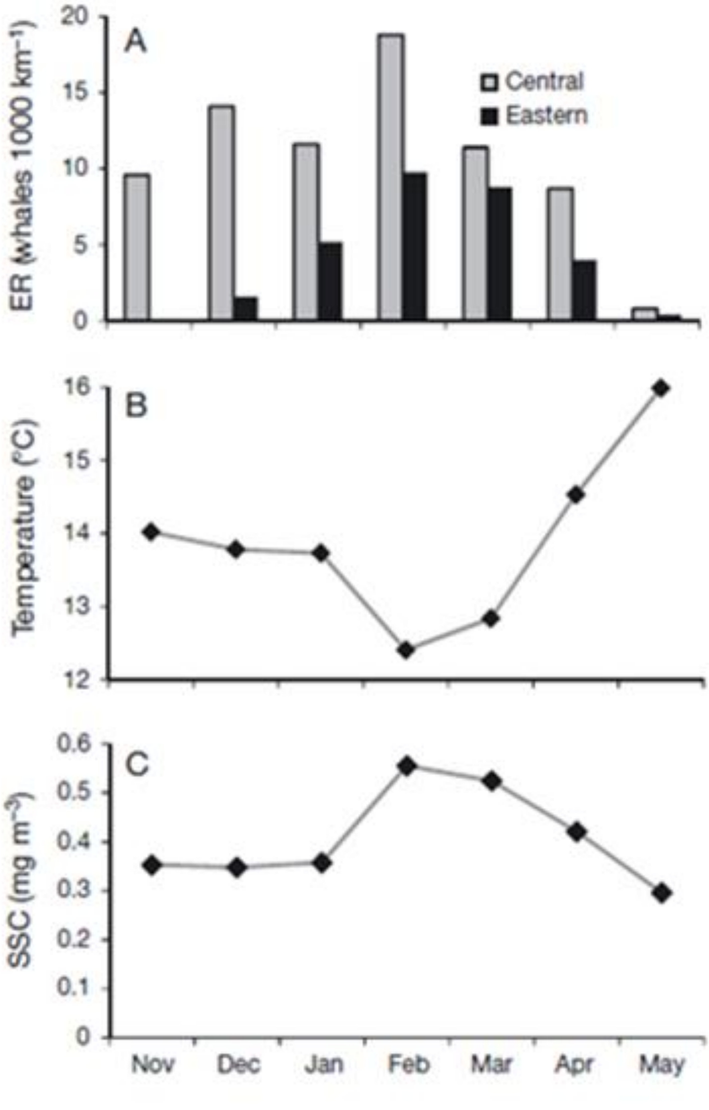

Figure 4-48: Blue Whale Encounter Rates in the Central and Eastern Study (Cape Nelson to Cape Otway) Area by Month (Gill et al. 2011)

- Blue Whales are typically widely distributed throughout central and eastern areas shelf waters from January through to April.
- Blue Whale numbers are significantly lower in November, December and January in the eastern area compared to the central area.

- No Blue Whales were sighted in the eastern area (Cape Nelson to Cape Otway) during November for any season despite significant effort.
- Encounter rates in central and eastern zones peaked in February, coinciding with peak upwelling intensity and primary productivity.

Origin Energy Surveys (2010-2014)

There were no confirmed sightings of Blue Whales during Origin's Speculant 3D Transition Zone marine seismic survey in November and December 2010, the Astrolabe 3D seismic survey undertaken in early November 2013 (RPS 2014) or during the Enterprise 3D seismic survey undertaken in late October and early November 2014 (RPS 2014).

From February to October 2011 Origin located an array of marine loggers east of the Thylacine platform to document nearby ambient marine noise, detect cetaceans and measure acoustics associated with the Origin 3D Bellerive Marine Seismic Survey. Pygmy and Antarctic Blue Whales were acoustically detected in the monitored area (east of the Thylacine A wellhead platform). Pygmy Blue Whales were observed from early February to early June being abundant from March to mid-May. Rare calls from Antarctic Blue Whales were observed in June.

Aerial surveys were commissioned by Origin and undertaken during 2011 and 2012 by the Blue Whale Study (Gill 2020). During five aerial surveys between 8 and 25 February 2011, 56 Blue Whales were sighted. Most of the sightings were at inshore areas between Moonlight Head to Port Fairy with whales apparently aggregating along and offshore of the boundary between the runoff plume from major flooding prevalent at the time and adjacent seawater. Figure 4-49 shows sightings from 14 February 2011 (Gill 2020).

The 2012 aerial surveys found that Blue Whales were common in the eastern upwelling zone during November and December 2012 (Figure 4-50). In November, an estimated 21 individual Blue Whales were sighted, with most sightings near the 100 m isobath or deeper. December 2012 surveys identified 70 Blue Whales foraging along the edge of the continental shelf west of King Island. This was the largest recorded aggregation of Blue Whales during any aerial surveys of the Bonney coast upwelling since 1999 (Gill 2020).

The large numbers of whales found in this area during November and December indicated high productivity, although the krill was too deep to be seen from the air. Subsequent surveys in the same area for Origin Energy in early 2013 resulted in 17 Blue Whales sighted in January, eight in February, and two (a cow and calf) in March 2013, despite the extremely warm surface conditions. The high productivity of this area seen in November to December 2012 evidently tailed off during the next few months (Gill 2020).

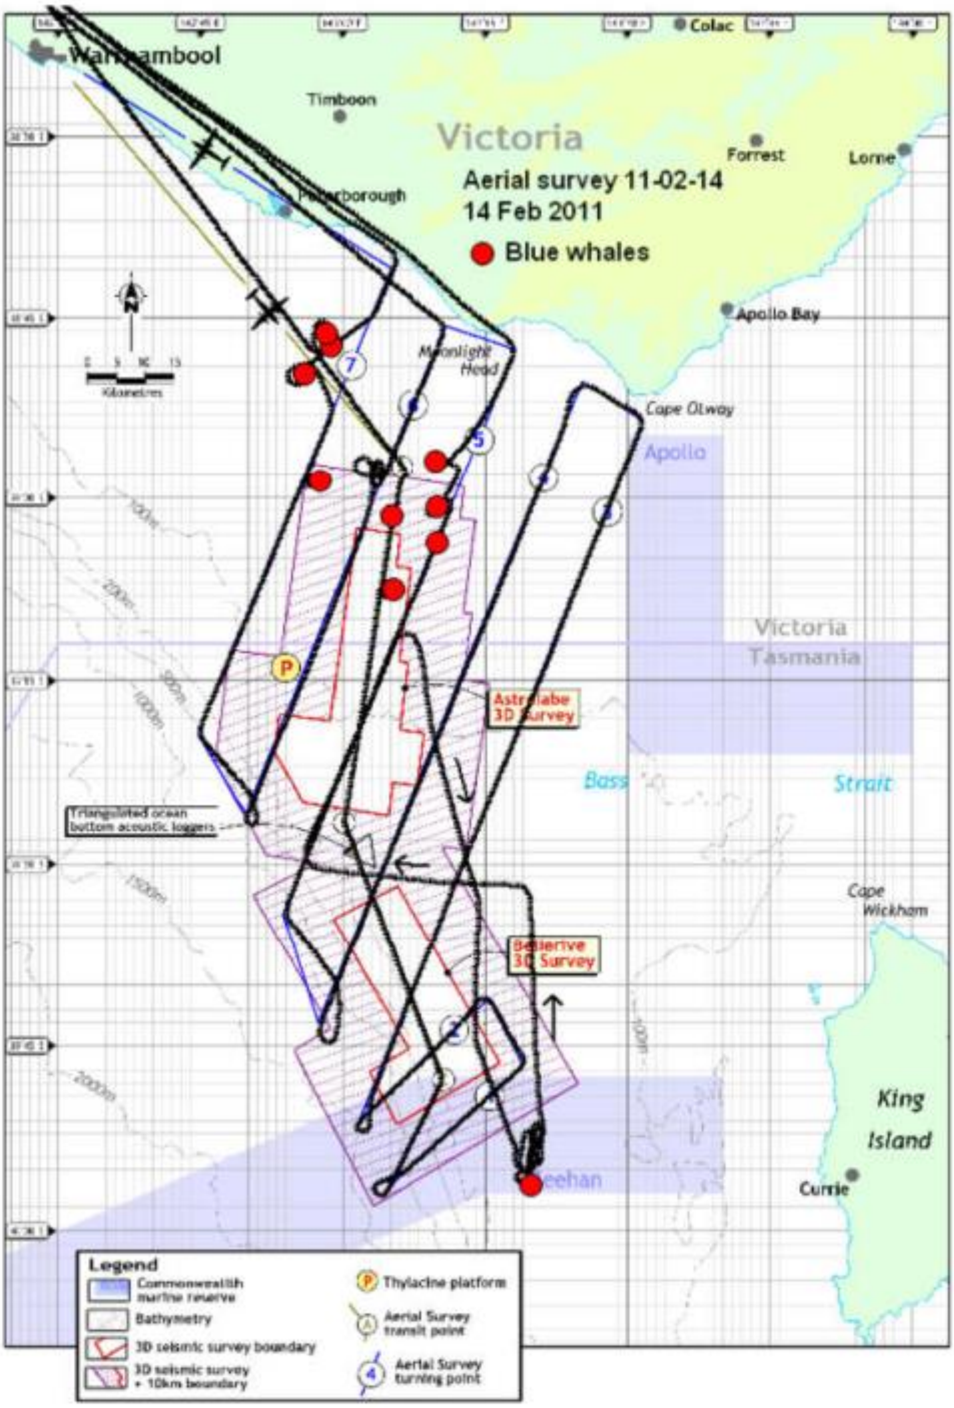

Figure 4-49: Blue Whale Sightings During an Aerial Survey for Origin Energy in February 2011 (Gill 2020)

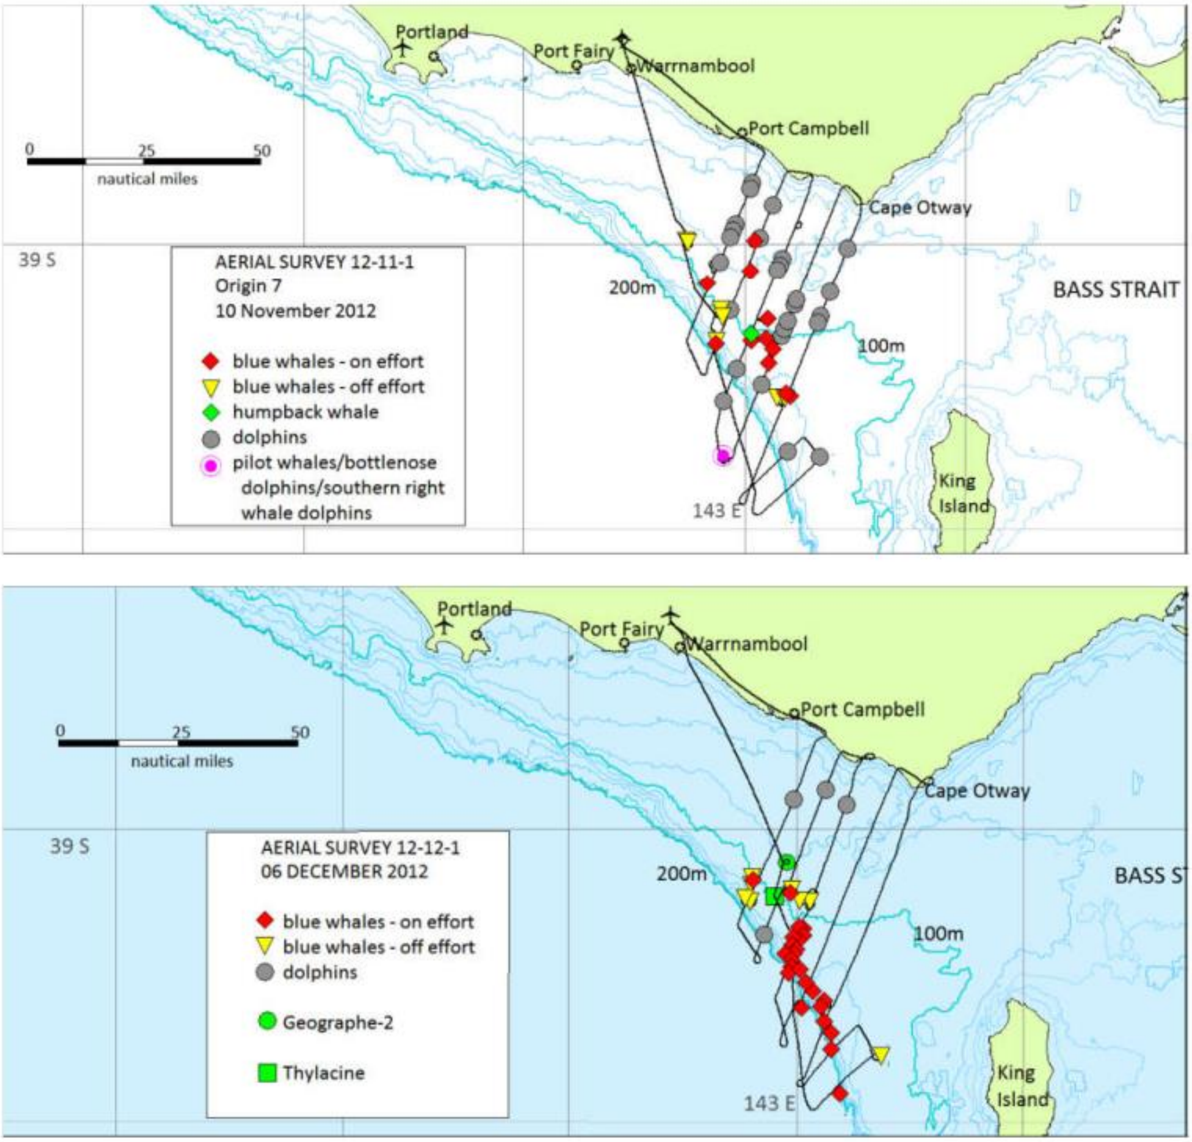

Figure 4-50: Blue Whale Sightings During an Aerial Survey for Origin Energy in November and December 2012 (Gill 2020).

Tagging Study (2015-2016)

Möller et al. (2020) analysed data from 13 Pygmy Blue Whales tagged in the Bonney Upwelling region in January 2015 with tags transmitting up to March 2016 (Figure 4-51). In summary:

- the whales' movements in the Great Southern Australian Coastal Upwelling System (GSACUS) ranged mostly from eastern South Australia, over the continental shelf south of Kangaroo Island, to between mainland Australia and Tasmania), with a few whales performing some movements to the continental slope and the deep-sea.
- in the GSACUS, most tagged whales remained over the continental shelf, utilising this region from at least January to July. This was the area of highest occupancy by the whales, with one whale returning to the Bonney Upwelling in January the year after and remaining there for at least three

months. This timing coincides with the upwelling season, which generally occurs from November to March each year.

- a low probability of area restricted search (ARS) behaviour (i.e. high probability of transiting behaviour) was mainly observed between April and June, and then between November and December, suggesting that the Pygmy Blue Whales were mainly migrating during those times.
- seascape correlates of ARS behaviour for these whales suggested the importance of sea surface temperature, sea surface height anomaly, wind speed and chlorophyll a concentration as proxies of upwelling productivity and presence of krill patches.

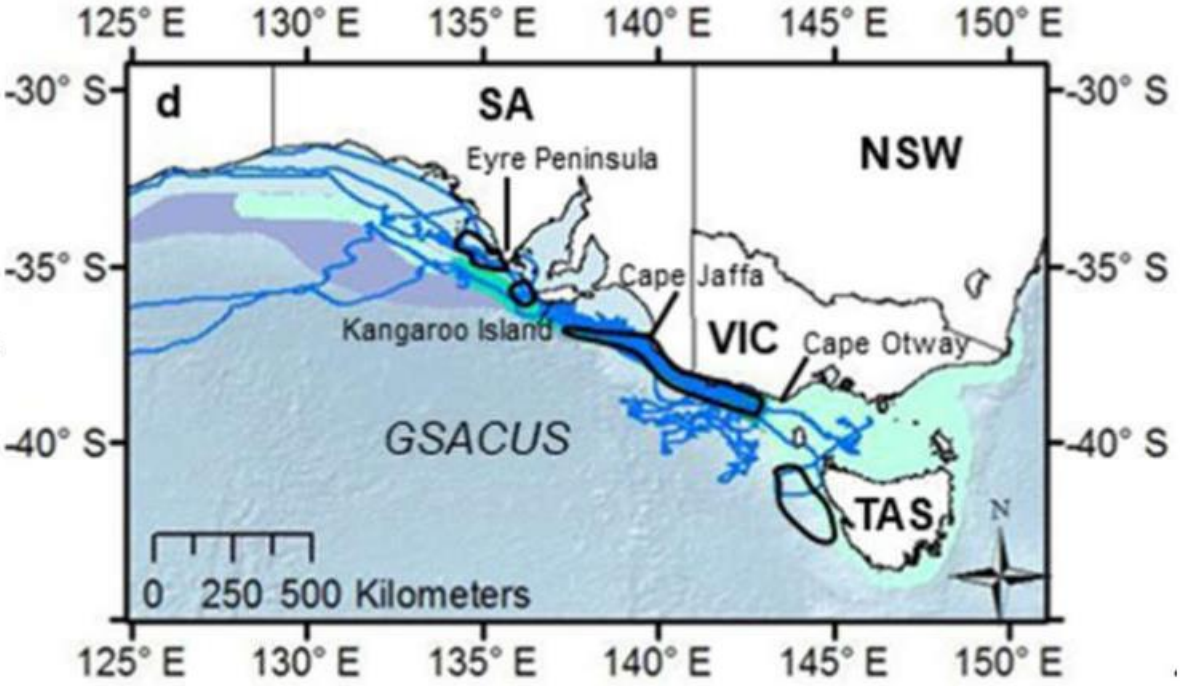

Figure 4-51: Tracks of 13 Pygmy Blue Whales in the GSACUS (Möller et al. 2020)

Passive Acoustic Recorders (2009-2017)

Between 2009 and 2016 the Integrated Marine Observing System (IMOS) recorded underwater sound south of Portland. McCauley et al. (2018) analysed the data from to look at Blue Whale presence, distribution, and population parameters.

Antarctic Blue Whale calls were received via deep sound channel propagation south of Portland and the maximum chorus levels occurred from late February to late June with yearly increases in chorus levels (McCauley et al. 2018).

In 2009 and 2011, Pygmy Blue Whales arrived in November or December whereas in other years, calls were not detected until January or February (Figure 4-52). There was substantial variation in presence within a season, with some whales remaining in the Portland detection area until mid-June each year with no consistent trend other than a peak in presence somewhere over February to June.

McCauley et al. (2018) noted it is difficult to predict numbers within a season but when correlated across seasons, the strength and persistence of the Bonney Coast Upwelling, given by time integrated water temperature, significantly correlates with time integrated number of individual whales calling from the same site (Figure 4-52). The upwelling index explains 83% of the variability in Blue Whale calling presence across seasons when using seasonal whale counts (not corrected for population growth). When a growth rate of 4.3% is applied a correlation of 90% of the variance in seasonal occurrence is predicted by the upwelling index. McCauley et al. (2018) also noted that the number of Pygmy Blue Whales calling in Portland could be expected in increase yearly with whale population growth.

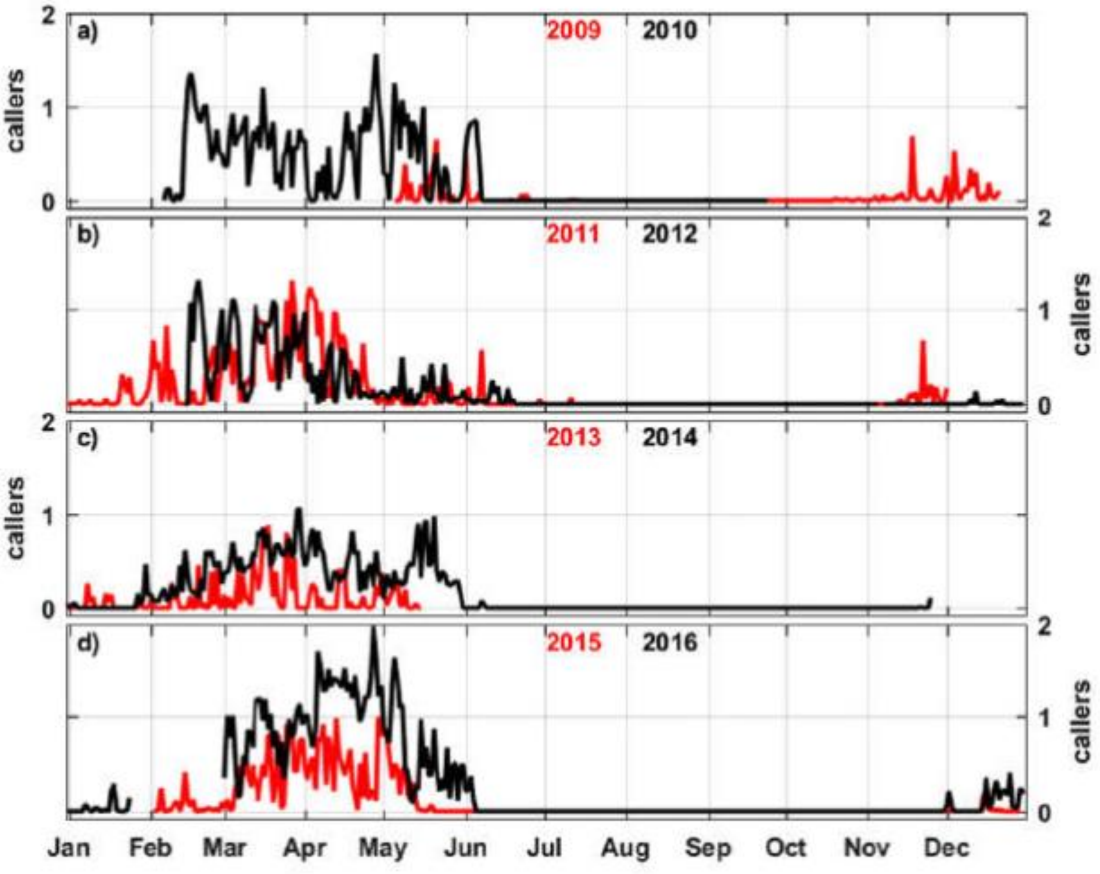

Figure 4-52: Mean Number of Individual Pygmy Blue Whales Calling (McCauley et al. 2018)

<u>Beach Surveys (2019-2022)</u>

During the Beach Otway Development Seabed Survey there were 4 sightings of Blue Whales within 3.5 km of the Thylacine Platform in November 2019 and one sighting in January 2020 about 1 km from the Artisan well location. The whales were identified as swimming.

JASCO completed a monitoring study for Beach in relation to exploration drilling activities at the Artisan 1 well from the 1 February to 6 April 2021 (McPherson et al. 2021). Songs of Pygmy Blue Whales were detected sporadically through February and the first half of March. By the end of March, the signals were present in almost every hour of recording. This pattern of occurrence was reflected across all recording stations. The data were too sparse to confirm anything about animal movements.

Beach commenced its Otway drilling program in February 2021 in the Project Area, including:

- Exploration drilling at the Artisan 1 location (2 February 2021 – 27 March 2021)
- Development drilling, well abandonment, subsea installation, and commissioning activities in the Geographe field (27 March 2021 – 13 November 2021)
- Development drilling of the Thylacine North 1 well (16 November 2021 – 11 January 2022)
- Development drilling of the Thylacine West wells (23 January 2022 – 30 April 2022)

Drilling was undertaken by a mobile offshore drilling unit (MODU), the Ocean Onyx. The Blue Whale Study (Gill 2020) was engaged to undertaken aerial surveys from February to May 2021 to identify Blue Whale and krill surface swarms within the Project Area and outside of this area. A preliminary data summary provided to Beach detailed:

- Nine aerial surveys were undertaken from 25 February to 21 May 2021
- There were 34 Blue Whale sightings consisting of 43 individuals
- The highest number of Blue Whale sightings was on 7 April 2021, with 19 Blue Whales sighted
- The first Blue Whale was sighted 25 February 2021and the final Blue Whale was sighted 7 April 2021
- Blue Whales and krill surface swarms were distributed throughout the area surveyed

Throughout the drilling campaign, Marine Fauna Observers (MFOs) were employed (January 2021 to April 2022) to ensure activities complied with Beach's Whale Management Standard Operating Procedure (WMSOP) (Document No.: S4000AF726092). The data collected includes the numbers of Blue Whales observed at varying distances from the MODU, based on the WMSOP management zones, during different MODU activities, along with information on whether the whale was observed to be approaching the MODU or moving away from it. They also collect additional data whilst in transit, or at distances outside of the zones specified in the WMSOP. Observations are based on distances of:

- 0 – 500 m
- 501 – 1,500 m
- 1,501 – 2,000 m
- 2,001 – 3,000 m
- 3,000 m

The total number of Blue Whales sighted by the aerial surveys and by MFOs was 324 individuals (Figure 4-53), with a peak of 102 whales in March 2021 (note that the period February – May 2021 includes aerial survey data). Over this period, whales were observed in most months apart from July, August, and October.

Figure 4-54 shows all whale sightings by MFOs between 2 February 2021 and 31 March 2022 across all well location. Figure 4-55 shows Blue Whale sightings within the Thylacine field between 16 November 2021 and 31 March 2022. Note that many observations were made whilst in transit.

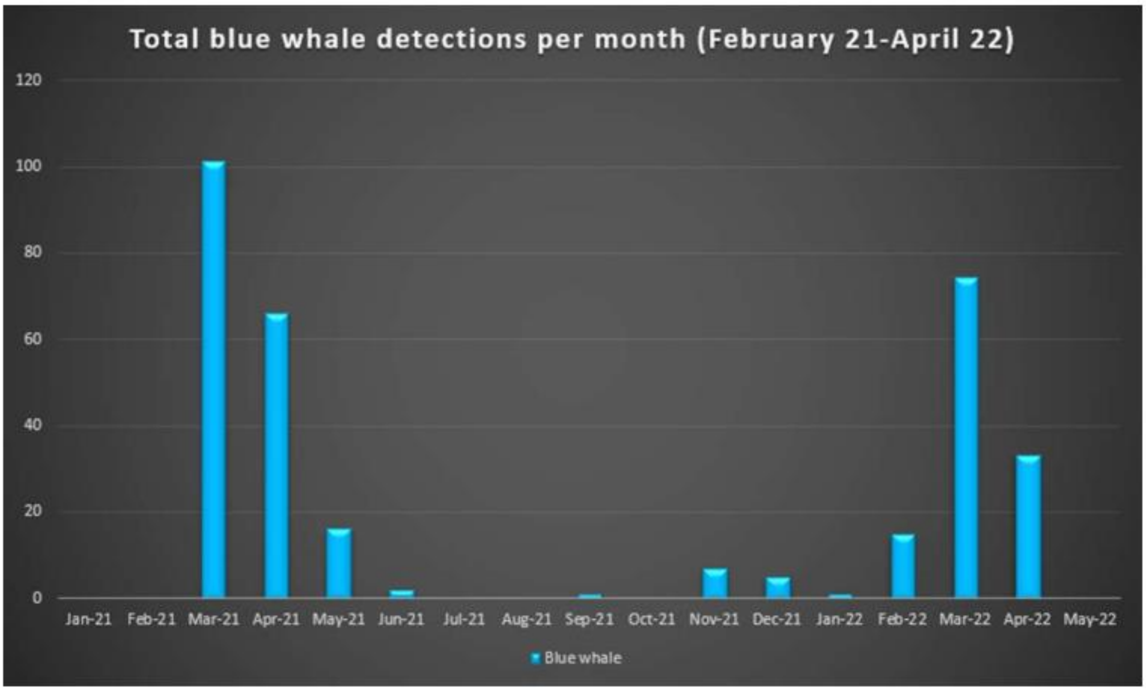

Figure 4-53: Blue Whale Observations during the Otway Offshore Drilling Campaign

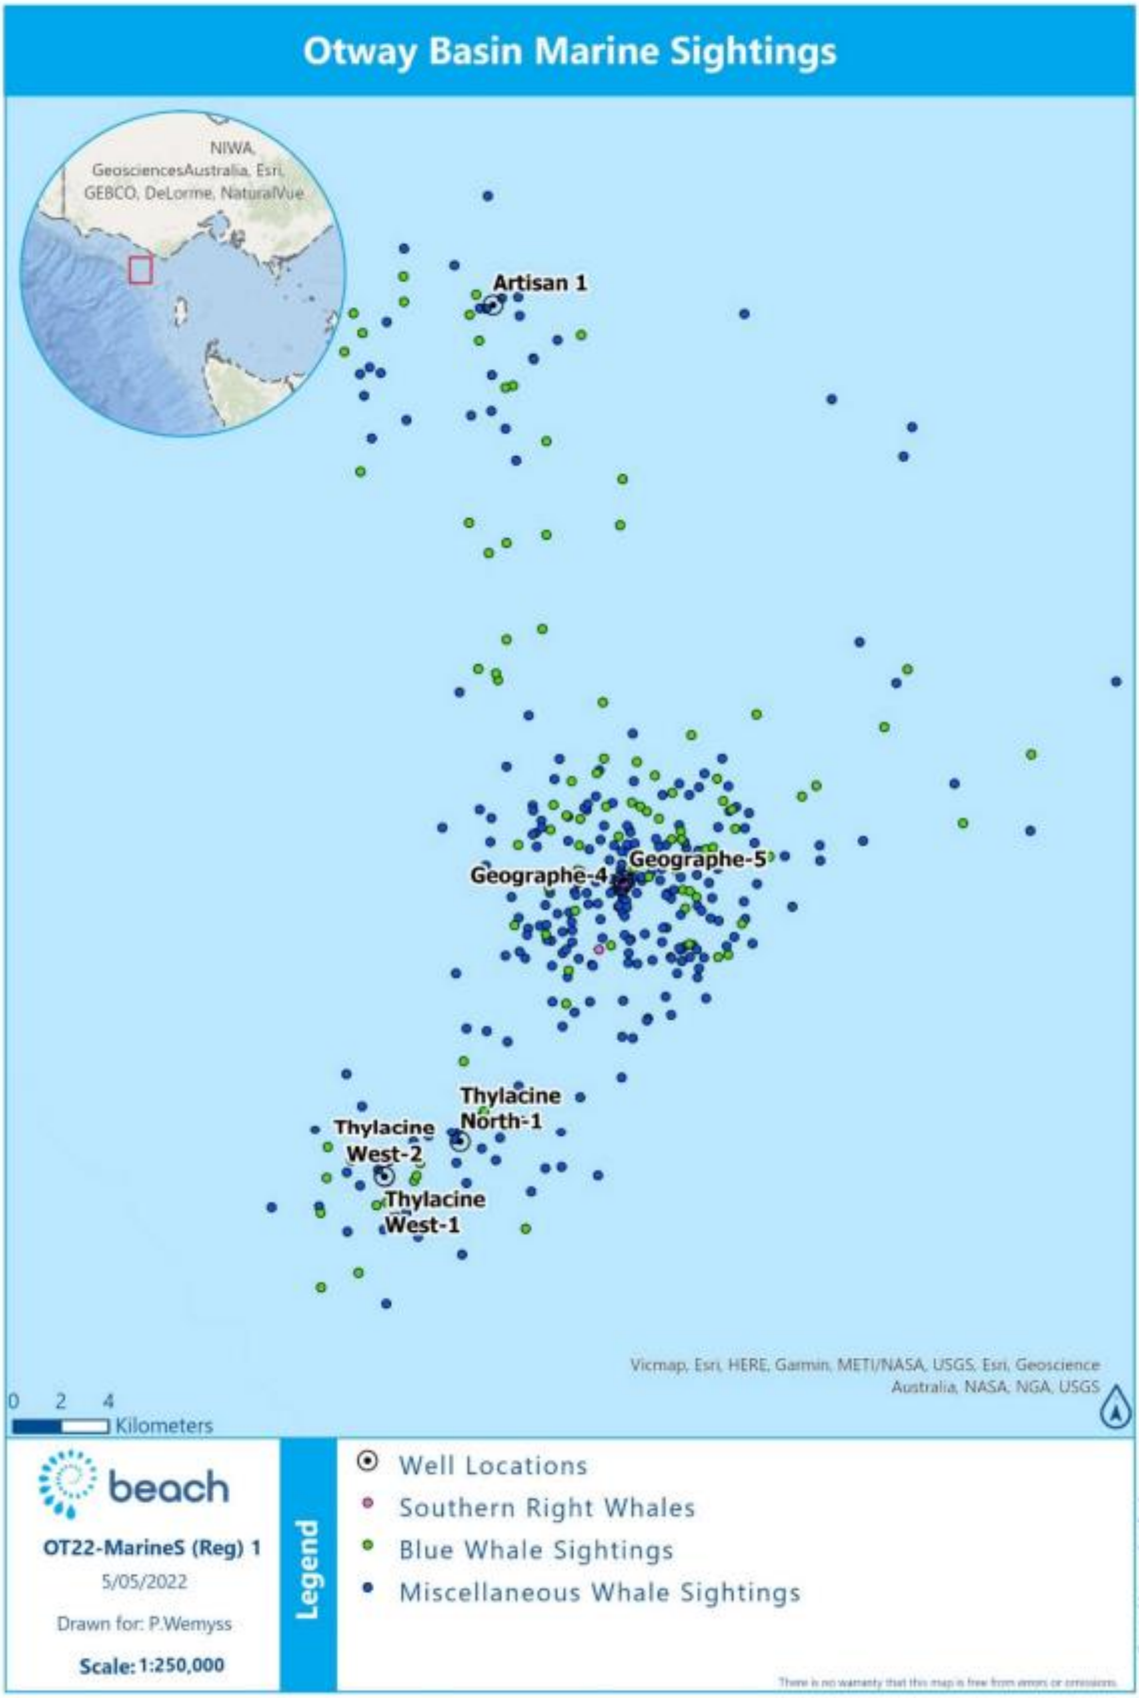

4-54: Whale Sightings between 2 February 21 – 31 March 22.

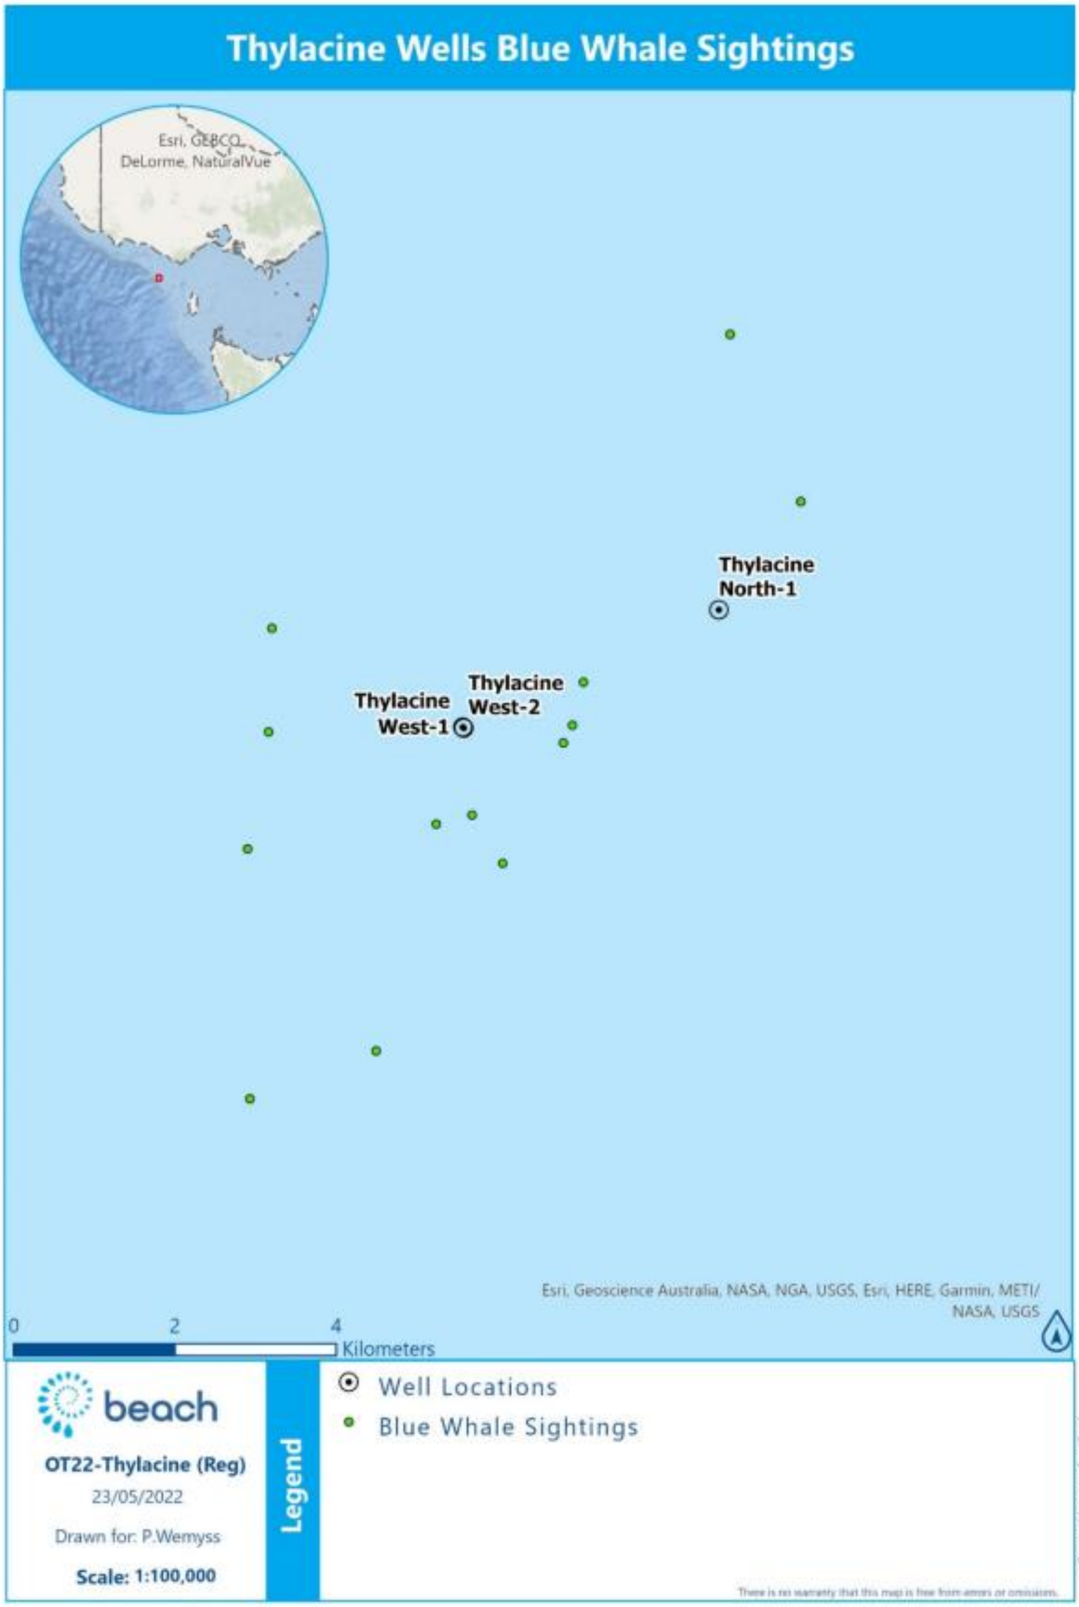

Figure 4-55: Blue Whale Sightings in the Thylacine field TN-1 (16 Nov 21 – 11 Jan 22); TW (23 Jan 22 – 31 Mar 22)

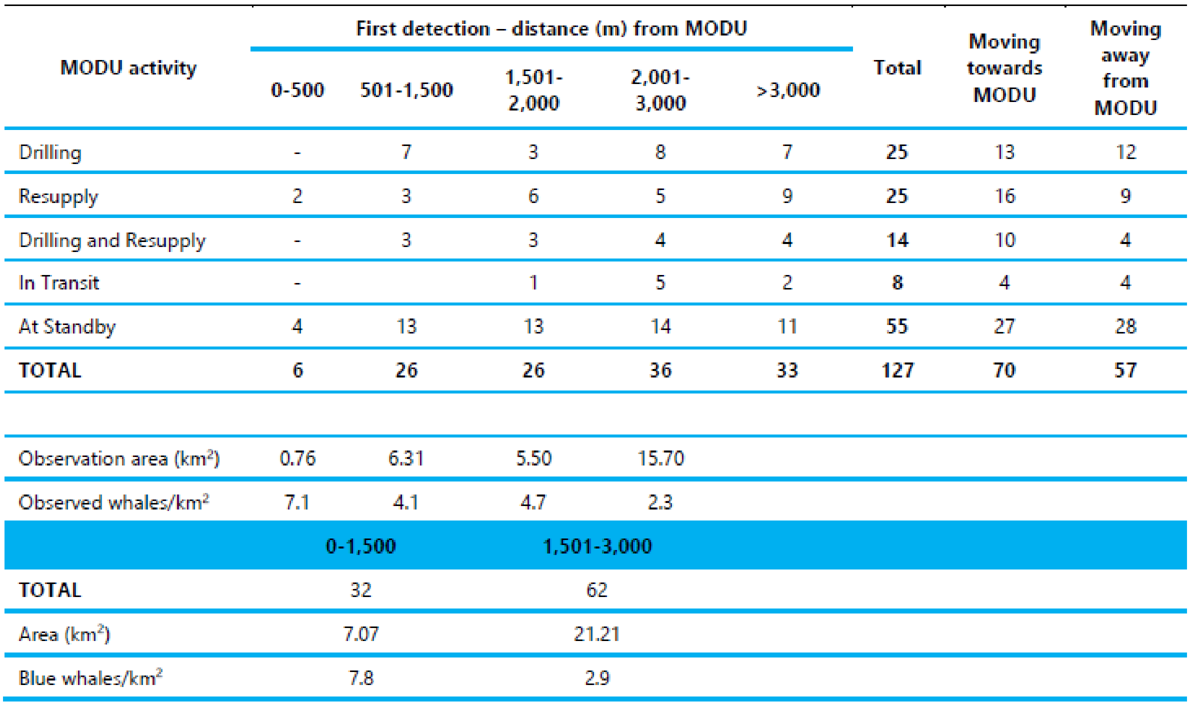
The Lead MFO provided summary data collected under the WMSOP for the period between 2 February 2021 and 31 March 2022. This was reviewed and a brief analysis undertaken.

During this period, 127 blue whales were observed within 3 km of the MODU (Table 4-30). Thirty-two whales were first detected within 1,500 m of the MODU. Sixty-two were first detected at 1,501 to 3,000 m. Thirty-three were first observed to be further than 3 km from the MODU before moving towards it. The total number of blue whales observed to move towards the MODU (following first detection) was 70 (55%); 57 were observed to move away from the MODU (45%).

Of the 94 whales first detected within 3,000 m of the MODU, 32 were observed within 1,500 m and 62 observed between 1,501 and 3,000 m. The number of blue whales/km^2 observed was 2.7x higher in the 0-1,500 m zone (7.8 whales/km^2) than in the 1,501 to 3,000 m zone (2.9 whales/km^2) (Table 4-30).

It would be expected that the number of blue whales/km^2 would be the same in all zones if underwater noise was not displacing blue whales from the area. Alternatively, if whales are being displaced then it would be expected that the number of blue whales/km^2 would increase with increasing distance from the MODU. The apparent increased density of whales within 1,500 m of the MODU in Table 4-30 can be explained by the fact that it is harder to detect whales at greater distances (i.e., the probability of detection is inversely related to distance). To correct for this a detection function is needed. The data collection methods employed by the MFOs were not designed to enable detection functions to be generated so surrogate detection functions were applied.

Table 4-30: Blue Whale Observations within 3,000 m of the MODU (2 February 2021 and 31 March 2022)



MODU activity	First detection – distance (m) from MODU					Total	Moving towards MODU	Moving away from MODU
	0-500	501-1,500	1,501-2,000	2,001-3,000	>3,000			
Drilling	-	7	3	8	7	**25**	13	12
Resupply	2	3	6	5	9	**25**	16	9
Drilling and Resupply	-	3	3	4	4	**14**	10	4

TOTAL	**6**	**26**	**26**	**36**	**33**	**127**	**70**	**57**
Observation area (km^2)	0.76	6.31	5.50	15.70				
Observed whales/km^2	7.1	4.1	4.7	2.3				
	0-1,500		**1,501-3,000**					
TOTAL	32		62					
Area (km^2)	7.07		21.21					
Blue whales/km^2	7.8		2.9					

Williams et al. (2016) collected 3,262 vessel-based observations from 2008 to 2015 of humpback whales in and near Glacier Bay National Park, Alaska, which is a site of a regionally important feeding aggregation of humpback whales. They analysed this data (85% truncated at 4,565 m) to generate detection functions to understand the probability of whale detection and how it varies with distance under different environmental and biological characteristics. Figure 4-56 shows the detection function for all data; Figure 4-57 shows the detection functions under different visibility conditions; Figure 4-58 shows the detection functions for different group sizes. Shaded areas show 95% confidence intervals. Arrows identify detection probability at 1,000 m reference distance.

Detection probability of surfacing whales decreased markedly with increasing distance from the ship. They found visibility and group size to be the most important variables influencing detection. The worst visibility conditions reduced detection probability to near 0 at 1000 m. Compared to detecting a single whale, a group of 2 or 3 whales almost doubled detection probability at 1000 m. Surface active behaviour increased detection compared to spouting while showing no flukes. In south-eastern Alaska, single whales that spouted during excellent visibility conditions were most commonly encountered and had a detection probability of 0.569 at 1000 m (Williams et al. 2016).

The Lead MFO for the Otway drilling program advised that they were only able to detect whales further than 3 km on 25% of occasions. The detection function from Williams et al. (2016) which best matches the MFOs advice was the curve showing '4+ group size' in Figure 4-58. Detection probabilities for this case, along with those for 'excellent visibility' conditions (Figure 4-57) and 'all' data (Figure 4-56) were extracted to provide probabilities in 500 m increments (Table 4-31). To allow these probabilities to be applied to the management zones shown in Table 4-30, the average probability for each management zone was calculated and expected numbers and densities calculated for the three scenarios (Table 4-32).

The total expected number of blue whales is 158.6 for the '4+ group size' scenario, 437.9 for the 'excellent visibility' scenario and 530.7 for the 'all data' scenario. The total observed blue whales was 127.

The expected densities for each management zone for the three scenarios are shown in Figure 4-59. The data shows that for the '4+ group size' there is no significant difference in expected blue whale densities between any of the four management zones, with highest expected densities in the 0–500 m zone. The 'excellent visibility' and 'all data' scenarios show significant expected differences between the 0 to 1,500 m and 1,501 to 3, 000 m management zones, however no significant differences between the 0–500 and 501 –1,500 m zones.

All the scenarios presented show similar expected densities for the 0 to 1,500 m zone. All three scenarios show that there is no increase in expected densities between the 0–500 and 501–1,500 m zones which implies that blue whales are not being displaced within 1,500 m. The '4+ group size' scenario (which most closely matches the Lead MFOs advice) implies that there is no displacement of blue whales within 3,000 m.

The '4+ group size' scenario has a mean expected density of 6.21 blue whales/km^2 across all zones, which (if correct) should apply to the wider area beyond observations. If whales are being displaced beyond 1,500 m as implied by the 'excellent visibility' and 'all data' scenarios, then the minimum mean expected densities for the wider area should be calculated using the observations between 1,501 and 3,000 m. These expected minimum mean densities are 18.70 blue whales/km^2 and 22.91 blue whales/km^2 for the 'excellent visibility' and 'all data' scenarios, respectively.

All data	8.14	7.31	23.64	22.19

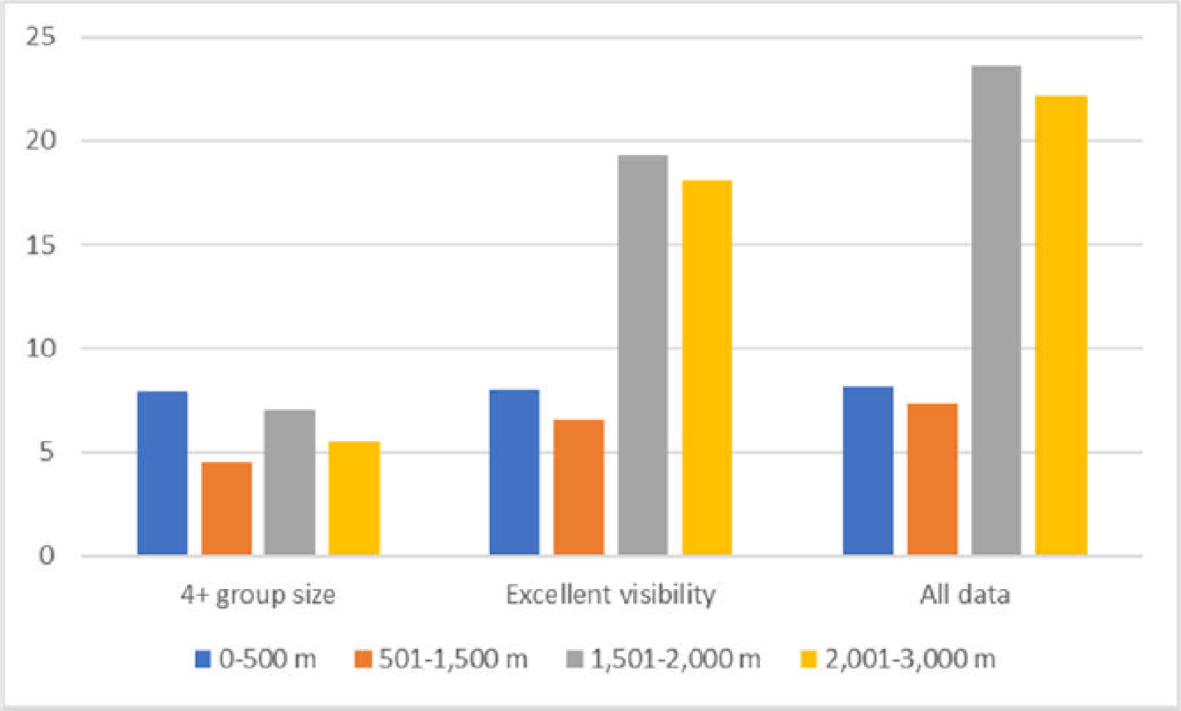

Figure 4-59: Expected Density (blue whales/km^2) for each Management Zone

d. Fin Whale

Fin Whales are listed as Vulnerable and Migratory under the EPBC Act considered a cosmopolitan species and occur from polar to tropical waters and are rarely in inshore waters. They show well defined migratory movements between polar, temperate, and tropical waters. Migratory movements are essentially north–south with little longitudinal dispersion. Fin Whales regularly enter polar waters. Unlike Blue Whales and Minke Whales, Fin Whales are rarely seen close to ice, although recent sightings have occurred near the ice edge of Antarctica.

There are stranding records of this species from most Australian states, but they are considered rare in Australian waters (Bannister et al. 1996). The fin whale has been infrequently recorded between November and February during aerial surveys in the region (Gill et al. 2015). Fin Whales have been sighted inshore in the proximity of the Bonney Upwelling, Victoria, along the continental shelf in summer and autumn months (Gill 2002). Fin Whales in the Bonney Upwelling are sometimes seen in the vicinity of Blue Whales and Sei Whales.

Fin Whales were sighted, and feeding was observed between November-May (upwelling season) during aerial surveys conducted between 2002 and 2013 in South Australia (Gill et al. 2015). This is one of the first documented records these whales feeding in Australian waters, suggesting that the region may be used for opportunistic baleen whale feeding (Gill et al. 2015). Fin Whales have also been acoustically detected south of Portland, Victoria (Erbe et al. 2016). Aulich et al. (2019) recorded infrequent presence of Fin Whales in Portland between 2009 to 2016. This suggests that the area may not be a define migratory route however, calls recorded in July may be from whales migrating northward towards the east coast of NSW. Calls detected in late August and September may be indication of the presence of whales on their migration route back to Antarctica waters.

The sighting of a cow and calf in the Bonney Upwelling in April 2000 and the stranding of two Fin Whale calves in South Australia suggest that this area may be important to the species' reproduction, perhaps as a provisioning area for cows with calves (Morrice et al. 2004). However, there are no defined mating or calving areas in Australia waters.

e. Humpback Whale

Humpback Whales (*Megaptera novaeangliae*) are listed as Vulnerable and Migratory under the EPBC Act and are present around the Australian coast in winter and spring. Humpbacks undertake an annual migration between the summer feeding grounds in Antarctica to their winter breeding and calving grounds in northern tropical waters (DoE 2023i). Along the south-east coast of Australia, the northern migration starts in April and May while the southern migration peaks around November and December (DoE 2023i). A discrete population of humpback whales have been observed to migrate along the west coast of Tasmania and through Bass Strait, and these animals may pass through the Project Area and Planning Area. The exact timing of the migration period varies between years in accordance with variations in water temperature, extent of sea ice, abundance of prey, and location of feeding grounds (DoE 2023i). Feeding occurs where there is a high krill density, and during the migration this primarily occurs in Southern Ocean waters south of 55°S (DoE 2023i).

Humpback Whales satellite-tagged off Australia's east coast were tracked during three austral summers in 2008/2009, 2009/2010 and 2010/2011 (Andrews-Goff et al. 2018). Of the 30 tagged Humpbacks, 21 migrated south along the coastline across into Bass Strait during October. In November the whales then migrated along the east coast (12 whales) and west coast (1 whale) of Tasmania to Antarctic feeding grounds. The state space model used shows both search and transit behaviour revealing new temperate feeding grounds in Bass Strait, the east coast of Tasmania and in the eastern Tasman Sea.

There is no known feeding, resting or calving grounds for Humpback Whales in the Project Area or Planning Area, although feeding may occur opportunistically where sufficient krill density is present DoE 2023i). The nearest BIA which is important habitat for migrating humpback whales is Twofold Bay, a resting area off the NSW coast (DCCEEW 2024).

During Origin's Enterprise 3D seismic survey undertaken during early November 2014, 16 Humpback Whales were sighted (RPS 2014).

The recovery of Humpback Whale populations following whaling has been rapid. The Australian east coast Humpback Whale population, which was hunted to near-extinction in the 1950s and early 1960s, had increased to 7,090±660 (95% CI) whales by 2004 with an annual rate of increase of 10.6±0.5% (95% CI) between 1987–2004 (Noad et al. 2011). The available estimates for the global population total more than 60,000 animals, and global population is categorised on the IUCN Red List as Least Concern.

f. Killer Whale

Killer Whales (*Orcinus orca*) are listed as Migratory under the EPBC Act and thought to be the most cosmopolitan of all cetaceans and appear to be more common in cold, deep waters; however, they have often been observed along the continental slope and shelf particularly near seal colonies (Bannister et al. 1996). The killer whale is widely distributed from polar to equatorial regions and has been recorded in all Australian waters with concentrations around Tasmania. The only recognised key locality in Australia is Macquarie Island and Heard Island in the Southern Ocean (Bannister et al. 1996).

The habitat of Killer Whales includes oceanic, pelagic and neritic (relatively shallow waters over the continental shelf) regions, in both warm and cold waters (DoE 2023l).

Killer Whales are top-level carnivores. Their diet varies seasonally and regionally. The specific diet of Australian Killer Whales is not known, but there are reports of attacks on dolphins, young Humpback Whales, Blue Whales, Sperm Whales, dugongs and Australian sea-lions (Bannister et al. 1996). In Victoria, sightings peak in June/July, where they have been observed feeding on sharks, sunfish, and Australian Fur-seals (Morrice et al. 2004; Mustoe 2008).

The breeding season is variable, and the species moves seasonally to areas of food supply (Bannister et al. 1996; Morrice et al. 2004). Killer Whales are frequently present in Victorian waters with sightings recorded along most of Victoria's coastline. Mustoe (2008) describes between 2002 and 2008 web-based casual sightings had an average of 13 Killer Whales sighted per year in Victoria and NSW, more than half in Victorian waters. This combined with the Atlas of Victorian Wildlife indicates a peak in killer whale sightings in June to July and September to November (Mustoe 2008).

The Killer Whale has been observed within the region however there are no BIAs in the Project Area and Planning Area.

g. Pygmy Right Whale

The Pygmy Right Whale (*Caperea marginata*) is a little-studied baleen whale species that is found in temperate and sub-Antarctic waters in oceanic and inshore locations and listed as migratory under the EPBC Act. The species, which has never been hunted commercially, is thought to have a circumpolar distribution in the Southern Hemisphere between about 30°S and 55°S. Distribution appears limited by the surface water temperature as they are almost always found in waters with temperatures ranging from 5° to 20°C (Baker 1985) and staying north of the Antarctic Convergence. There are few confirmed sightings of Pygmy Right Whales at sea (Reilly et al. 2008). The largest reported group was sighted (100+) just south-west of Portland in June 2007 (Gill et al. 2008).

Species distribution in Australia is found close to coastal upwellings and further offshore it appears that the Subtropical Convergence may be important for regulating distribution (Bannister et al. 1996). Key locations include south-east Tasmania, and Kangaroo Island and southern Eyre Peninsula in South Austalia close to upwelling habitats rich in marine life and zooplankton upon which it feeds (Bannister et al. 1996).

The Pygmy Right Whale has been observed in surveys in the region, however, Origin did not observe it during the 2010 Speculant MSS and 2014 Enterprise MSS. There are no BIAs identified in the Project Area or Planning Area.

h. Sei Whale

Sei Whales (*Balaenoptera borealis*) are listed as Vulnerable and Migratory under the EPBC Act, and are considered a cosmopolitan species, ranging from polar to tropical waters, but tend to be found more offshore than other species of large whales. They show well defined migratory movements between polar, temperate, and tropical waters. Migratory movements are essentially north-south with little longitudinal dispersion. Sei Whales do not penetrate the polar waters as far as the Blue, Fin, Humpback and Minke Whales (Horwood 1987), although they have been observed very close to the Antarctic continent.

Sei Whales move between Australian waters and Antarctic feeding areas; sub-Antarctic feeding areas (e.g. Subtropical Front); and tropical and subtropical breeding areas. The proportion of the global population in Australian waters is unknown as there are no estimates for Sei Whales in Australian waters.

Sei Whales feed intensively between the Antarctic and subtropical convergences and mature animals may also feed in higher latitudes. Sei Whales feed on planktonic crustaceans, in particular copepods and amphipods. Below the Antarctic convergence Sei Whales feed exclusively upon Antarctic krill (*Euphausia superba*).

In the Australian region, Sei Whales occur within Australian Antarctic Territory waters and Commonwealth waters, and have been infrequently recorded off Tasmania, NSW, Queensland, the Great Australian Bight, Northern Territory and Western Australia (Parker 1978; Bannister et al. 1996; Chatto and Warneke 2000; Bannister 2008).

Sightings of Sei Whales within Australian waters includes areas such as the Bonney Coast Upwelling off South Australia (Miller et al. 2012), where opportunistic feeding has been observed between November and May (Gill et al. 2015).

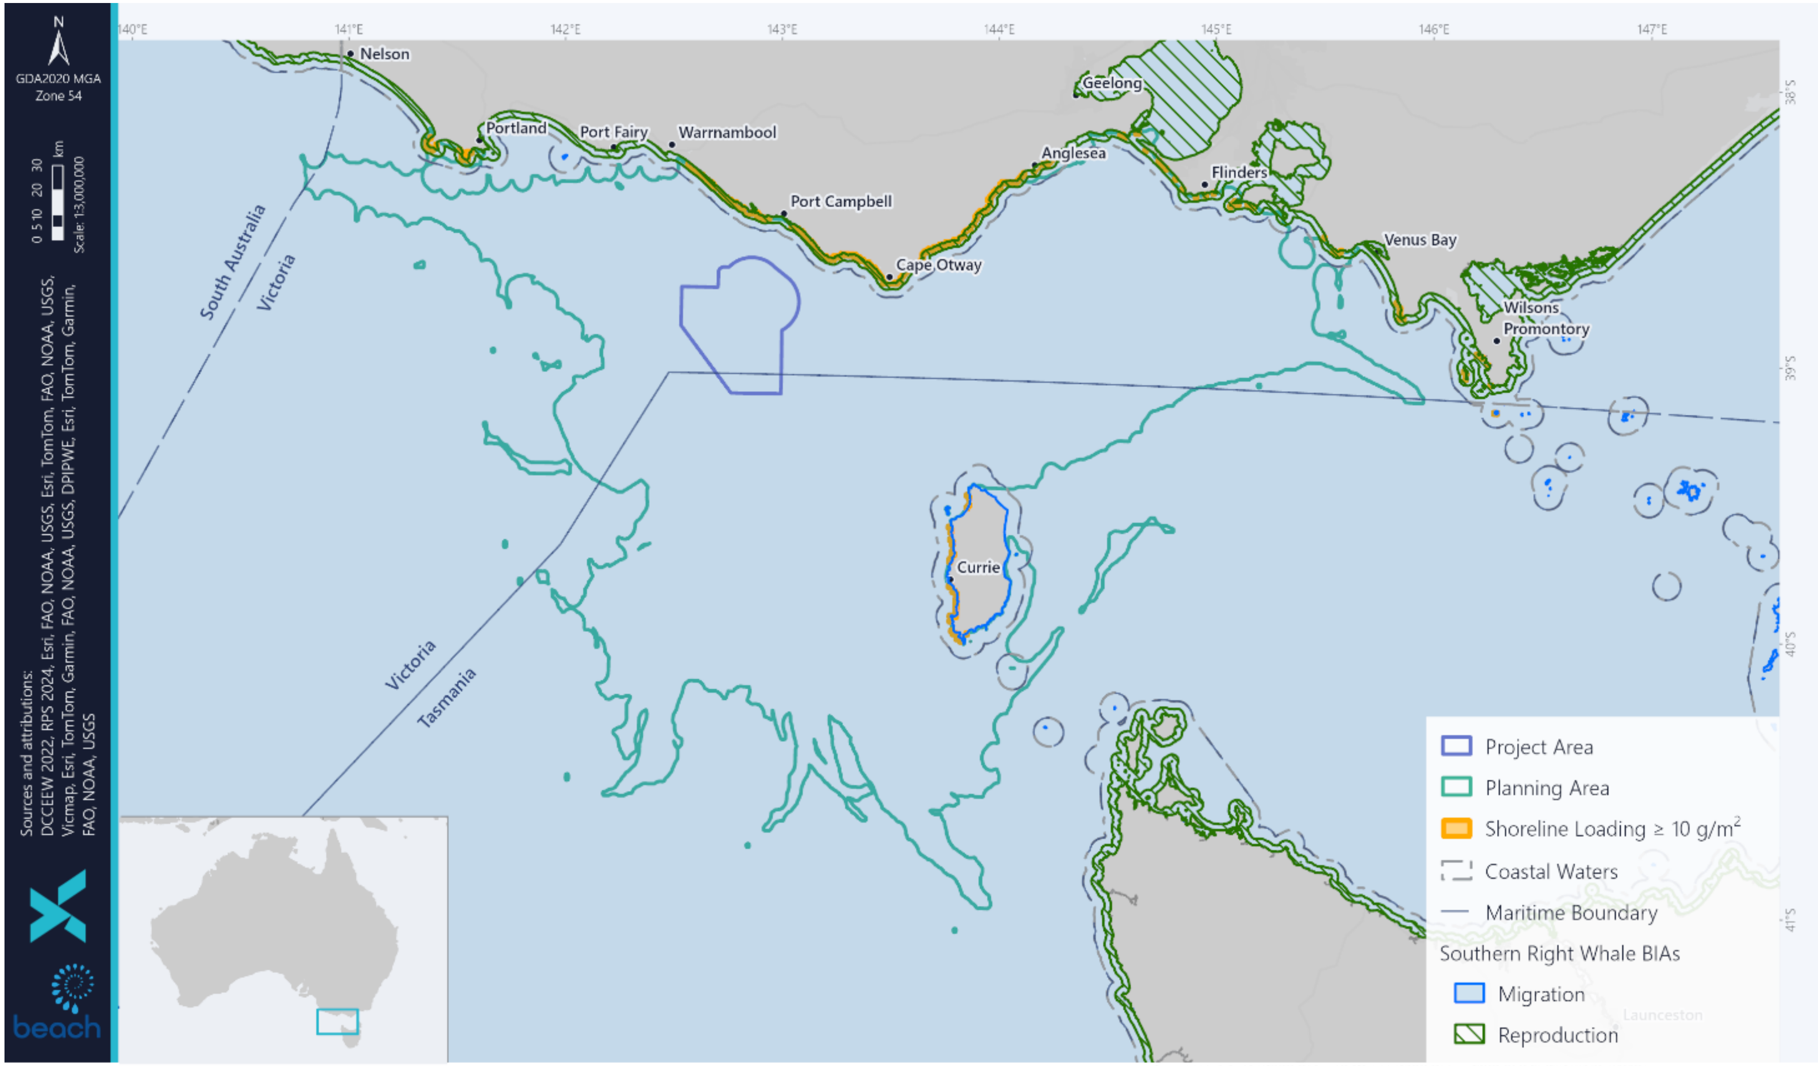
There are no known mating or calving areas in Australian waters.

i. Southern Right Whale

The southern right whale (*Eubalaena australis*) is listed as Endangered under the EPBC Act in Australia and as Endangered on the Victorian Threatened Species Advisory List.

The National Recovery Plan for the Southern Right Whale (DCCEEW 2024o) contains Biologically Important Areas, as displayed in Figure 4-60 (DCCEEW 2024).

The Project Area overlaps the southern right whale migration BIA and the Planning Area overlap the southern right whale reproduction and migration BIAs (Figure 4-60).



Sources and attributions: DCCEEW 2022, RPS 2024, Esri, FAO, NOAA, USGS, Esri, TomTom, FAO, NOAA, USGS, Vicmap, Esri, TomTom, Garmin, FAO, NOAA, USGS, DPIPWE, Esri, TomTom, Garmin, FAO, NOAA, USGS

Figure 4-60: Project and Planning Areas and Southern Right Whale BIAs

(vi) Population

Southern right whales were depleted to less than 300 individuals globally due to commercial whaling in the 19th and 20th centuries (Tormosov et al. 1998). They were protected from whaling in 1935 however, due to illegal whaling in the 1970s and because southern right whales have a slow rate of increase compared to other marine mammals, their numbers remain low (IWC 2013). Global abundance estimates are 13,000 for the species, across key wintering grounds in South Africa, Argentina, Australia, and New Zealand.

The Australian population of southern right whales is divided into two sub-populations due to genetic diversity (Carroll et al. 2011; Baker et al. 1999) and different rates of increase (DCCEEW 2024o; DSEWPaC 2012a). The western sub-population occurs predominantly between Cape Leeuwin, Western Australia (WA) and Ceduna, South Australia (SA) This sub-population comprises most of the Australian population and is estimated at 3,200 individuals increasing at an annual rate of approximately 6% p.a. (Smith et al. 2019). The eastern sub-population can be found along the south-eastern coast, including the region from Tasmania to Sydney, with key aggregation areas in Portland and Warrnambool in Victoria. The eastern sub-population is estimated at less than 300 individuals and is showing no signs of increase (Bannister, 2017). A rate of around 7% p.a. is considered the maximum biological rate of increase for southern right whales (IWC 2013). Connectivity between the two populations is unknown however, some limited movement between the two areas has been recorded (Burnell 2001, Charlton 2017, Pirzl et al. 2009).

(vii) Distribution

Southern right whales are distributed in the Southern Hemisphere with a circumpolar distribution between latitudes of 16°S and at least 65°S. They migrate from southern feeding grounds in sub-Antarctic waters to Australia in between May and November to calve, mate and rest (Bannister et al. 1996; DCCEEW 2024o). They are distributed across thirteen primary aggregation areas along the southern coast of Australia (Figure 4-61) (DCCEEW 2024o; DSEWPaC 2012a). In Australian coastal waters, they occur along the southern coastline of the mainland and Tasmania and generally extend as far north as Sydney on the east coast and Perth on the west coast (DCCEEW 2024o; DSEWPaC 2012a). There are occasional sightings further north, with the extremities of their range recorded at Hervey Bay and Exmouth (DCCEEW 2024o; DSEWPaC 2012a).

The largest established calving areas in Australia include Head of Bight in SA, and Doubtful Island Bay and Israelite Bay in WA. Smaller but established aggregation areas regularly occupied by southern right whales include Yokinup Bay in WA, Fowlers Bay in SA and the Warrnambool and Portland in Victoria. Emerging aggregation areas include Flinders Bay, Hassell Beach, Cheyne/Wray Bays, and Twilight Cove in WA, and sporadically occupied areas include Encounter Bay in SA (DCCEEW 2024o; DSEWPaC 2012a) Southern right whales generally occupy shallow sheltered bays within 2 km of shore and within water depths of less than 20 m (Charlton et al. 2019). A number of additional areas for southern right whales are emerging that might be of importance, particularly to the south-eastern population. In these areas, small but growing numbers of non-calving whales regularly aggregate for short periods of time. These areas include coastal waters off Peterborough, Port Campbell, Port Fairy, and Portland in Victoria (DCCEEW 2024o; DSEWPaC 2012a) (Figure 65).

There is variation in annual abundance on the coast of Australia due to the 3-year calving cycles (Charlton 2017). Female and calf pairs generally stay within the calving ground for 2–3 months (Burnell 2001). Peak periods for mating in Australian coastal waters are from mid-July through August

(DCCEEW 2024o; DSEWPaC 2012a). Pregnant females generally arrive during late May/early June and calving/nursery grounds are generally occupied until October (occasionally as early as April and as late as December) (Charlton et al. 2019). A study conducted by Stamation et al. (2020) shows that despite an increase in breeding females sighted in south-eastern Australian between 1985 and 2017, there is no evidence of an increase in annual numbers of mother-calf pairs.

As a highly mobile migratory species, southern right whales travel thousands of kilometres between habitats used for essential life functions. Movements along the Australian coast are reasonably well understood, but little is known of migration travel, non-coastal movements and offshore habitat use. Exactly where southern right whales approach and leave the Australian coast from, and to, offshore areas remain unknown (DCCEEW 2024o; DSEWPaC 2012a). The Victorian and Tasmania coastal waters are known to include migrating habitat and southern right whales are known to arrive at the south eastern Australian coastline and travel west to established aggregation areas in South Australia such as the Head of the Great Australian Bight (Watson et al. 2021). There is one established calving ground for female and calf pairs in south-eastern Australian at Logans Beach, Warrnambool, Victoria (Watson et al. 2021). A predominance of westward movements amongst long-range photo-identification re-sightings may indicate a seasonal westward movement in coastal habitat (Burnell 2001). Direct approaches and departures to the coast have also been recorded through satellite telemetry studies (Mackay et al. 2015).

Aerial surveys of western Bass Strait and eastern Great Australian Bight undertaken by Gill et al. (2015) detected southern right whales between May and September. A survey in early November 2010 did not observe any whales in the Warrnambool area and it was assumed that cows and calves had already left the calving and aggregation areas (M. Watson pers. comm. 2010). No southern right whales were encountered during Origin's Enterprise 3D seismic survey undertaken during November 2014 (RPS 2014), or during spotter flights of the coastline undertaken prior to the survey in late October 2014. Aerial surveys between Ceduna, SA and Sydney NSW (and included Tasmania) were undertaken in August of 2013 and 2014 and recorded a total of 34 southern right whale individuals (17 breeding females) in 2013 and 39 (11 breeding females) in 2014, respectively (Watson et al. 2015).

Marine mammal observer data from January 2021 to April 2022 for the drilling program in the Otway Development Area identified three southern right whales consisting of a single individual in June and August., and two in July (Figure 4-62).

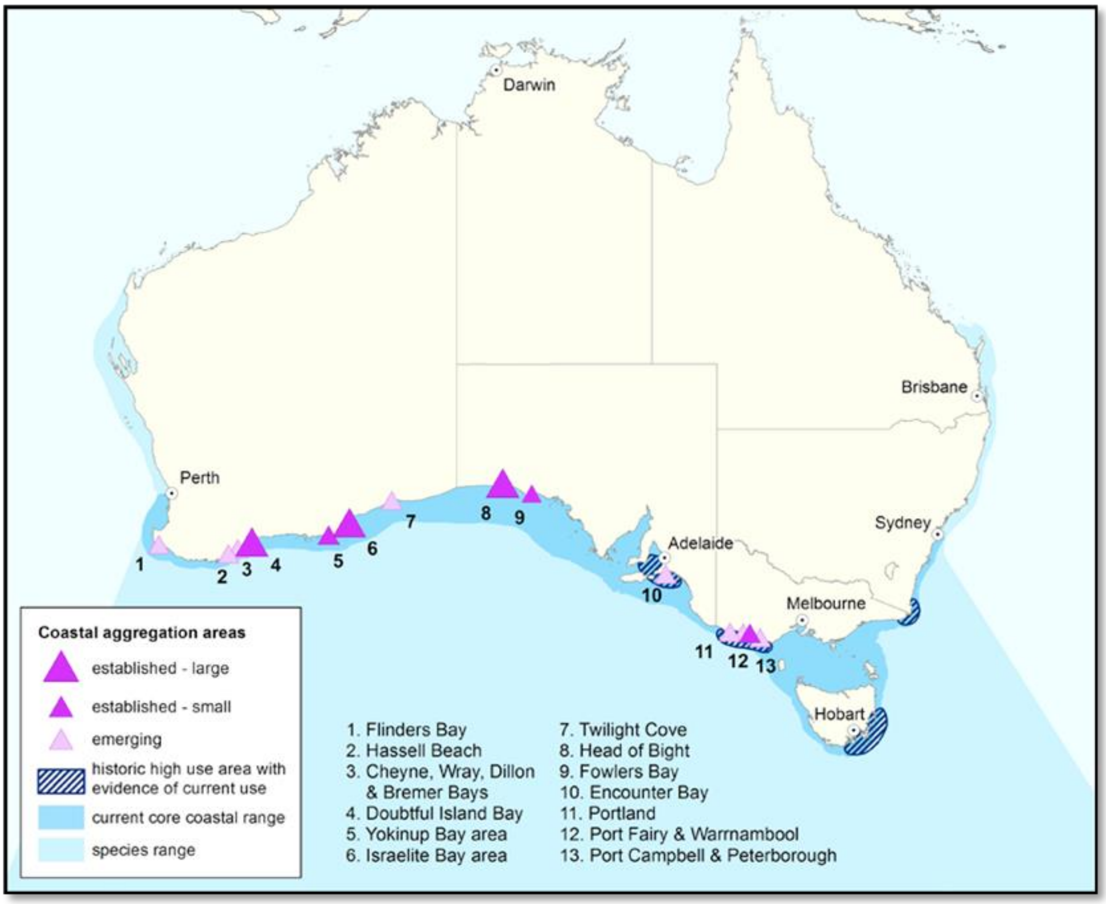
The National Recovery Plan for the Southern Right Whale (DCCEEW 2024) reports that known and potential threats that may have individual or population level impacts to southern right whales include entanglement in fishing gear, habitat degradation from coastal and offshore developments, anthropogenic underwater noise, vessel interactions and disturbance, whaling, prey depletion and pollution as well as cumulative impacts from these threats.

(viii) Cultural significance

The National Recovery Plan for the Southern Right Whale (DCCEEW 2024o) provides information on the cultural significance of southern right whales to Indigenous Australians. The plan details:

At the Great Australian Bight in South Australia, the Mirning People are whale people, and the white whale Jeedara is their totem and part of the Dreaming, which tells how the Mirning and southern right whales are connected (Burgoyne 2000). Mirning Country is the sacred place of the Mirning People, and the Yinyila Nation of Mirning clans forms a huge yerrambai, or rainbow arch, spanning the length of the coastal area of the Great Australian Bight from Point Culver in Western Australia to near Streaky Bay in South Australia (Burgoyne 2000). The Far West Coast Aboriginal Corporation (FWCAC) manages the Far West Coast Land, which belongs to the Far West Coast Aboriginal Peoples. FWCAC represents six distinct cultural groups of Aboriginal people: Mirning Peoples, the descendants of Edward Roberts, Wirangu Peoples, Yalata Peoples, Kokatha Peoples and Maralinga Tjaratja (Oak Valley) Peoples.

In Victoria, Koontapool (southern right whales) occur along the coastlines of south-west Victoria in Gunditjmara Sea Country to feed and birth. These Koontapool Woorrkngan Yakeen (Whale Birthing Dreaming Sites), are in coastal bay areas from Port Campbell to Portland, including Warrnambool. These places on Gunditjmara Country are known resting and feeding sites for mothers and calves and are directly related to Gunditjmara Neeyn (midwives), explaining why Gunditjmara is a Matrilineal Nation.



▪

Figure 4-61: Aggregation Areas for Southern Right Whales (DSEWPaC 2012a)

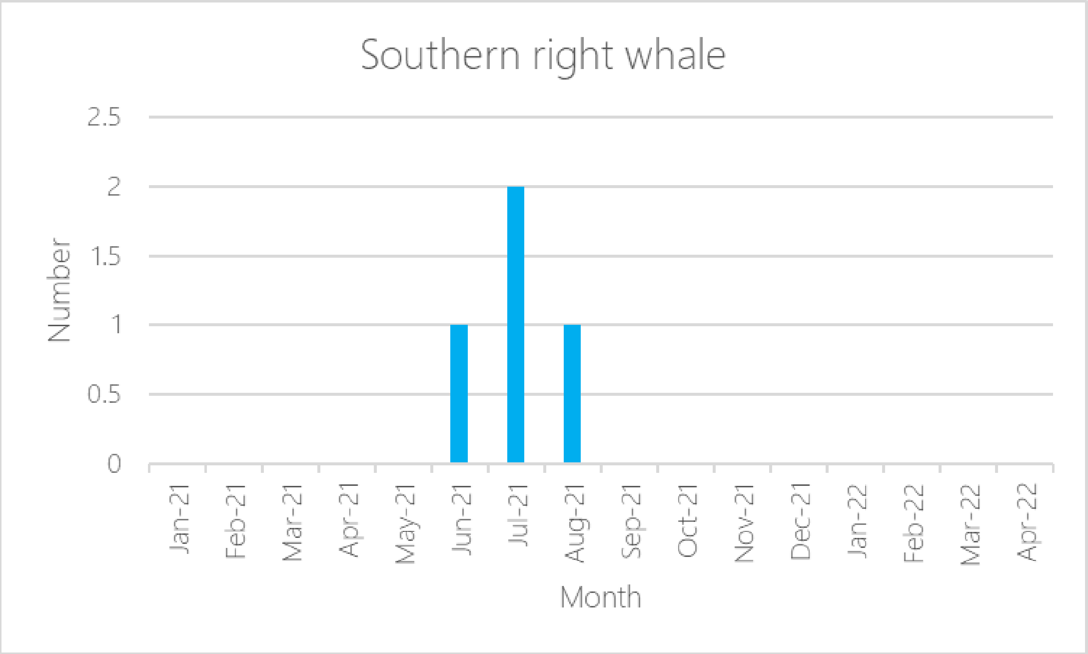


Figure 4-62: Southern Right Whale Sightings for the Otway Drilling Campaign

j. Sperm Whale

The Sperm Whale (*Physeter macrocephalus*) is listed as migratory under the EPBC Act and has a worldwide distribution, having been recorded in all Australian states. Sperm Whales tend to inhabit offshore areas with a water depth of 600 m or greater and are uncommon in waters less than 300 m deep (DoE 2023j). Key locations for the species include the area between Cape Leeuwin to Esperance (WA); south-west of Kangaroo Island (SA), deep waters of the Tasmanian west and south coasts, areas off southern NSW (e.g., Wollongong) and Stradbroke Island (Qld) (DoE 2023j). Concentrations of Sperm Whales are generally found where seabed rise steeply from a great depth (i.e., submarine canyons at the edge of the continental shelf) associated with concentrations of food such as cephalopods (DoE 2023j).

Females and young males are restricted to warmer waters (i.e., north of 45°S) and are likely to be resident in tropical and sub-tropical waters year-round (DoE 2023j). Adult males are found in colder waters and to the edge of the Antarctic pack ice. In southern Western Australian waters Sperm Whales move westward during the year. In oceanic waters, there is a more generalised movement of Sperm Whales' southwards in summer and northwards in winter (DoE 2023j).

Sperm Whales are prolonged and deep divers often diving for over 60 minutes (Bannister et al. 1996) however studies have observed Sperm Whales do rest at, or just below, surface for extended periods (>1 hr) (Gannier et al. 2002). In addition, female and juvenile Sperm Whales in temperate waters have been observed to spend several hours a day at surface resting or socialising (Hastie et al. 2003).

The Sperm Whale has been observed in the region, however the closest recognised BIA for foraging is further west near Kangaroo Island in South Australia (DCCEEW 2024a). Therefore, it is likely they would be uncommon visitors in the Project Area and Planning Area.

k. Dusky Dolphin

The Dusky Dolphin (*Lagenorhynchus obscurus)* is listed as migratory under the EPBC Act and is rarely sighted in Australian waters, with most records across southern Australia from Western Australia to Tasmania with a handful of confirmed sightings near Kangaroo Island and off Tasmania (DoE 2023k). Only 13 reports of the Dusky Dolphin have been made in Australia since 1828, and key locations are yet to be identified (Bannister et al. 1996). Therefore, it is likely that they would be uncommon visitors in the Project Area and Planning Area. The species is primarily found from approximately 55°S to 26°S, though sometimes further north associated with cold currents. They are considered to be primarily an inshore species but can also be oceanic when cold currents are present (DoE 2023k). No Dusky Dolphins were detected during Beach's Otway drilling campaign.

4.5 **Socio-economic Values**

Potential socio-economic receptors occurring within the Project Area and Planning Area are detailed in the following sections.

4.5.1 Coastal Settlements

There are no coastal settlements or Local Government Areas (LGAs) within the Project Area. The nearest settlement to the Project Area is Port Campbell. The Planning Area and potential shoreline contact are within the following LGAs (Figure 4-63):

- Bass Coast Shire

- Colac Otway Shire
- Corangamite Shire
- Flinders Council
- Glenelg Shire
- Greater Geelong City
- King Island Council
- Mornington Peninsula Shire
- Moyne Shire
- Queenscliffe Borough
- South Gippsland Shire
- Surf Coast Shire

The larger Victorian coastal settlements within the Planning Area are described below based on ABS (2021) census data:

- Anglesea has a population of 3,208 people and a median age of 54. Of those in the labour force, 54.9% work full-time and 39.9% work part-time. Professionals and managers are the most popular occupations, comprising 48.5% of the workforce.
- Apollo Bay has a population of 1,790 people and a median age of 52. Of those in the labour force, 40.05% work full-time and 44.2% work part-time. Labourers and managers are the highest occupation making up 33.9% of the workforce. Accommodation and supermarket and grocery stores are the biggest industries, making up 21.1% of employment.
- Portland has a population of 9,712 people and a median age of 45. Of those in the labour force, 50.3% work full-time and 35% work part-time. Professionals, managers and clerical workers are the most popular occupations, comprising 50.1% of the workforce. Aluminium smelting is the biggest industry, making up 8.1% of employment.
- Warrnambool, which is adjacent to the Planning Area,has a population of 35,406 and a median age of 42. Of those in the labour force, 53.3% work full-time and 36.6% work part-time. Hospitals employ 6.6% of the workforce followed by cheese and other dairy product manufacturing, aged care residential services, other social assistance services and supermarket and grocery stores. Professionals, technicians and trade workers and labourers comprise 47.7% of occupations.

The largest Tasmanian coastal settlement within the Planning Area is described below based on ABS (2021) census data:

- Currie (King Island) has a population of 659 and a median age of 49. Of those in the labour force, 63.0% work fulltime and 33.3% work part-time. Dairy and beef cattle farming comprise 34.6% of occupations.

Document details: G:\CheckOuts\P100383_S04\Output\02_OPP_Updates\P100383_S04_A.aprx, P100383_S00_03_LGAs, P-UWS-132, 29/09/2024

Figure 4-63 Local Government Areas within the Planning Area

4.5.2 Offshore Petroleum Industry

Petroleum exploration has been undertaken within the Otway Basin since the early 1960s. Gas reserves of approximately 2 trillion cubic feet (tcf) have been discovered in the offshore Otway Basin since 1995, with production from five gas fields using 700 km of offshore and onshore pipeline. Up to 2015, the DEDJTR reports that 23 PJ of liquid hydrocarbons (primarily condensate) has been produced from its onshore and offshore basins, with 65 PJ remaining, while 85 PJ of gas has been produced (Victoria and South Australia), with 1,292 PJ remaining.

There is no non-Beach oil and gas infrastructure within the Project Area. The Cooper Energy Casino gas field and Casino-Henry pipeline and the Minerva gas field and pipeline are within the Planning Area to the north of the Project Area.

4.5.3 Offshore Renewable Energy Industry

In 2021 Australia introduced the Offshore Electricity Infrastructure Bill 2021 (Cth) (OEI Act) and in August 2022 the Federal Government announced 6 proposed areas in Australian Commonwealth waters for offshore renewable energy Projects. The Southern Ocean Region declared offshore wind area is situated off Warrnambool and Port Fairy in western Victoria and was declared by the Australian Government on 6 March 2024, which overlaps the Planning Area (Figure 4-64). The Project Area does not overlap any declared or proposed offshore wind areas. The Southern Ocean declared area is 15.2 km north-west of the Project Area.

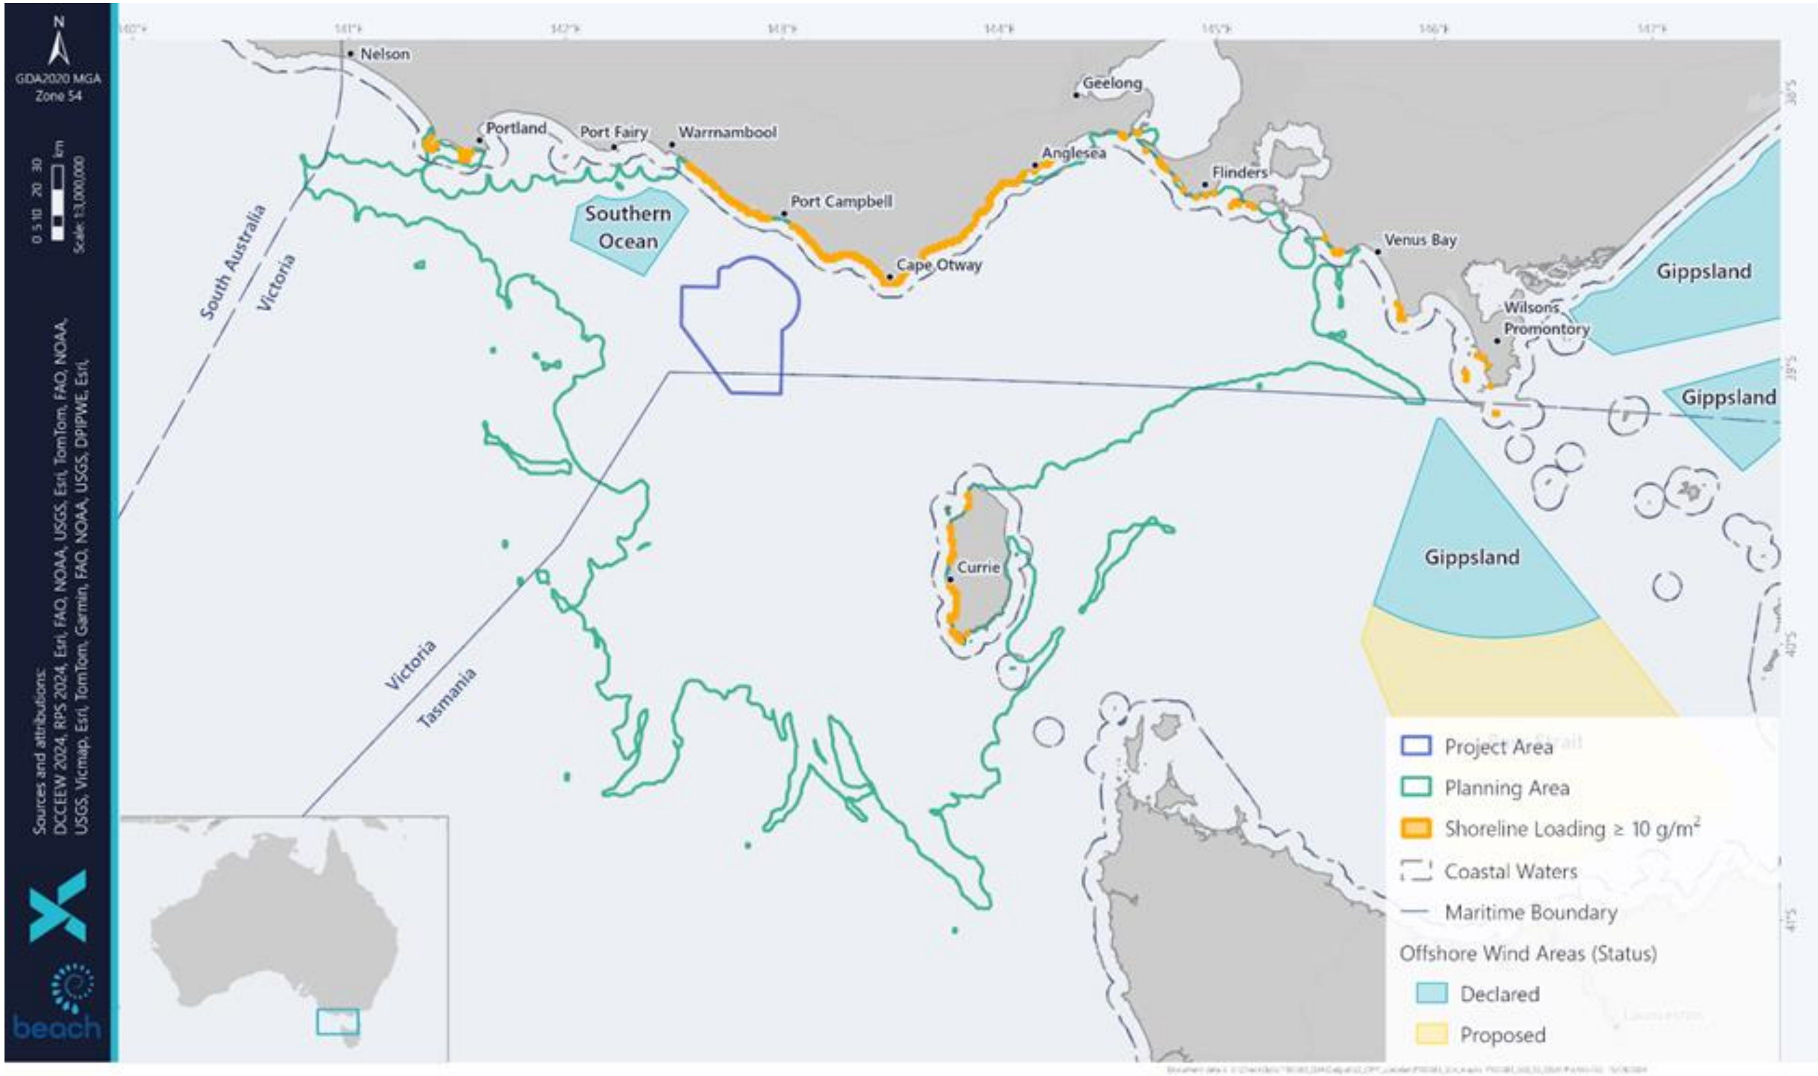

Figure 4-64: Offshore Wind Areas within the Planning Area

4.5.4 Other Infrastructure

The Victorian Desalination Plant is located at Wonthaggi, 5 km north of the Planning Area. Operation of the plant commenced in December 2012. The seawater intake and outlet structures are connected to the onshore plant via a 1.2 km and 1.5 km underground tunnel, respectively. The two intake structures are 8 m high, 13 m in diameter, situated 50 m apart and located in a water depth of 20 m. They draw in water at very low speeds (the suction effect is not strong enough to draw fish in).

The Indigo Central telecommunications cable, which connects Perth and Sydney through southern Australia, intersects the Planning Area north of King Island. There are two Telstra telecommunications cables located in central Bass Strait; Bass Strait-1, and Bass Strait-2, which intersect the east of the Planning Area (Figure 4-65).

Three new cables are planned to be installed in the next 5 years that may be within the Planning Area:

- East Coast Cable System between Melbourne, Sydney and Brisbane is being developed by Vocus.
- Hawaiki Nui – Hawaiki Submarine Cable between Melbourne and Sydney.
- Marinus Link undersea electricity and data cable that will connect Tasmania and Victoria. Construction is likely to commence in early 2025. Based on current spatial data, the cable will be 3.5 km east of the Planning Area (Figure 4-65).

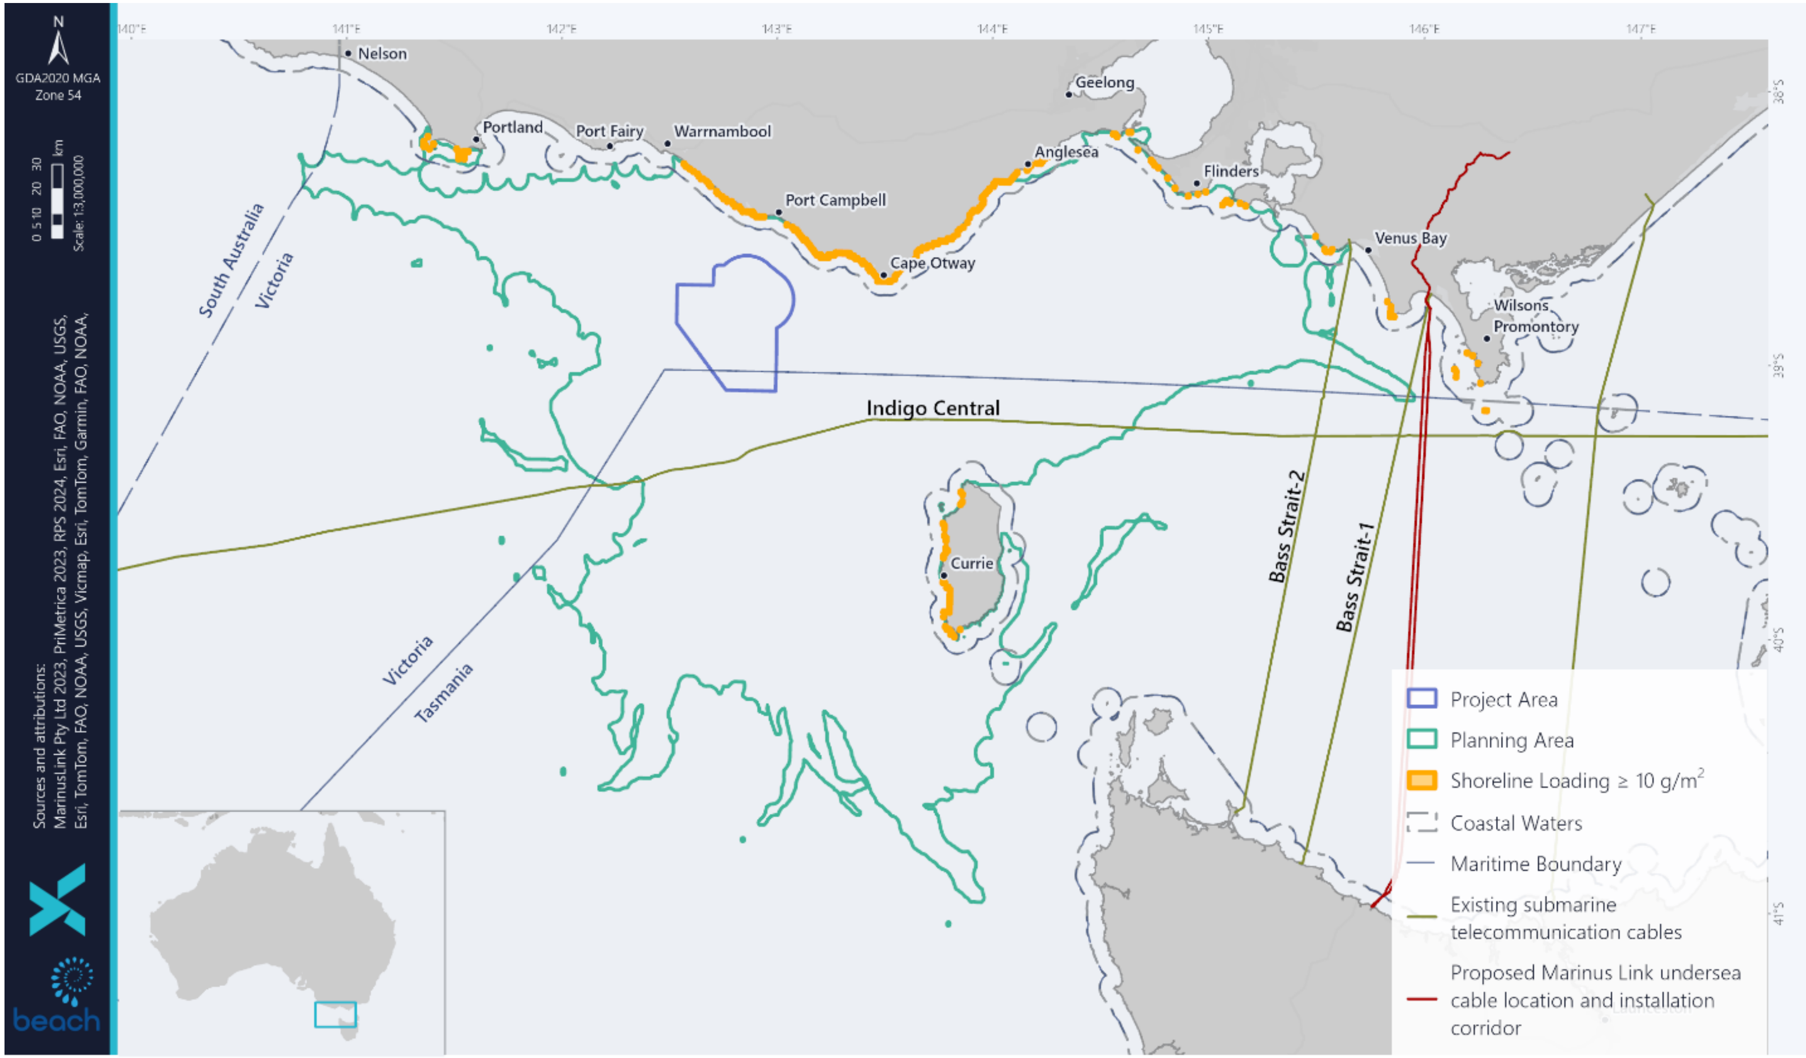

Figure 4-65: Existing Submarine Telecommunication Cables within the Project and Planning Areas

4.5.5 Defence Activities

Ongoing consultation with Department of Defence has identified that the Project Area is located within restricted airspace, but no other defence areas were identified. The Department of Defence also advised that unexploded ordnance (UXO) may be present on and in the sea floor.

UXO is a by-product of past training activities undertaken by the Australian Defence Force or foreign defence forces.

The interactive Department of Defence database (DoD 2023) indicates that the Project Area is located within a UXO Zone 1052 King Island (Figure 4-66), which is within the 'slight potential' category', meaning there is confirmed history of military activities that may have resulted in numerous residual hazardous munitions, components, or constituents, but where confirmed UXO affected areas cannot be defined (DoD 2022). The site was used during 1954 as an Air-to-Air Firing Range (DoD 2022).

Beach will undertake site surveys ahead of any seabed disturbing activities to confirm the absence of UXO within the Project Area.

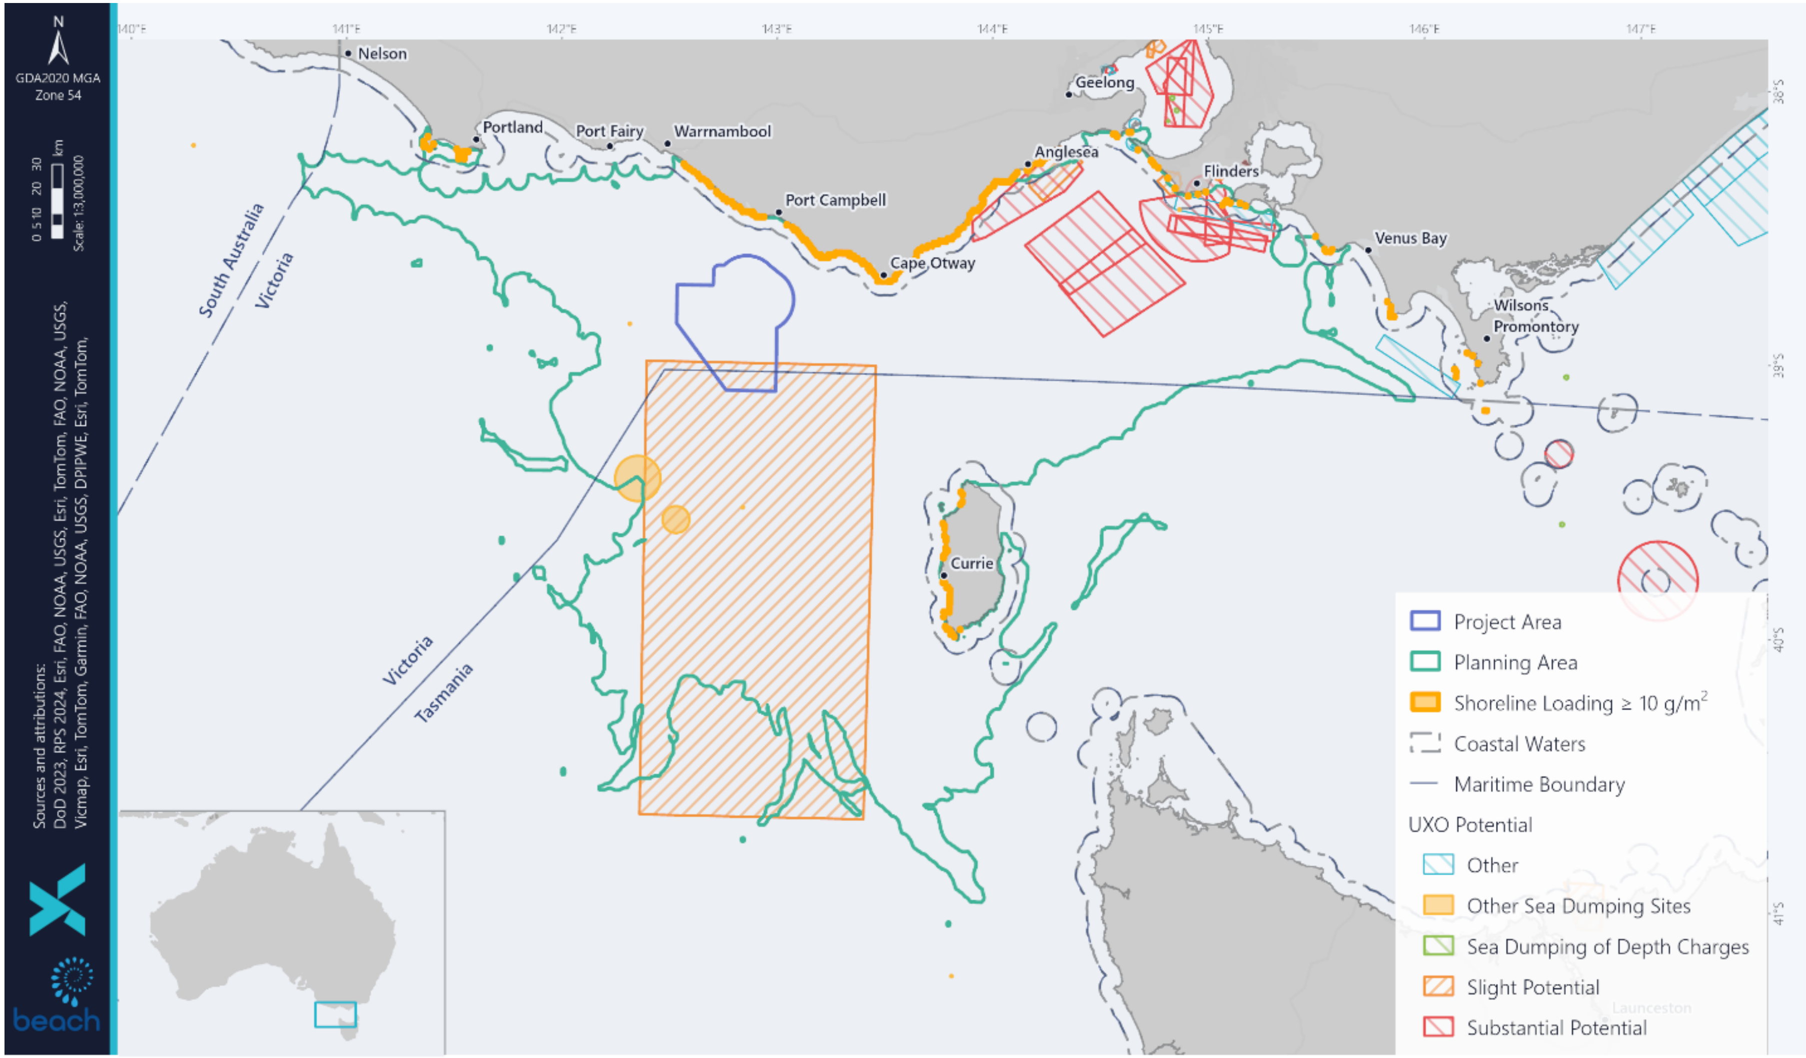

Figure 4-66: UXO within Project and Planning Areas

4.5.6 Shipping

The south-east marine region is one of the busiest shipping regions in Australia and Bass Strait is one of Australia's busiest shipping routes (Figure 4-67). Commercial vessels use the route when transiting between ports on the east, south and west coasts of Australia, and there are regular passenger and cargo services between mainland Australia and Tasmania. Automated Identification System (AIS) data from the Australian Maritime Safety Authority (AMSA 2024) provides a summary of vessels overlapping the Project Area for the period January to December 2022 (Table 4-33).

Ports Australia (2022) provide statistics for port operations throughout Australia's main commercial ports. Based on the latest information (2021) the majority of commercial shipping traffic transiting to and from Victorian ports were container (3,682), general cargo (2,663), bulk liquid carriers (2,019), dry bulk (1,715), car carrier (1,342), bulk gas (220), other cargo (47) and livestock (9).

Table 4-33: Summary of Shipping Traffic within the Project Area (AMSA 2022)

Vessel Type	**Shipping activity within Project Area**	
	Number of Vessels*	**Average Speed (kts)**
Cargo Ship	2,105	11.8
Tanker	453	11.1
Passenger	29	10.5
Other	433	2.6
Tug	196	2.0
Fishing	31	6.7
Sailing	27	4.7
Total	3,274	10
Average vessels per day	9	

*Calculated as individual vessels within Project Area each day

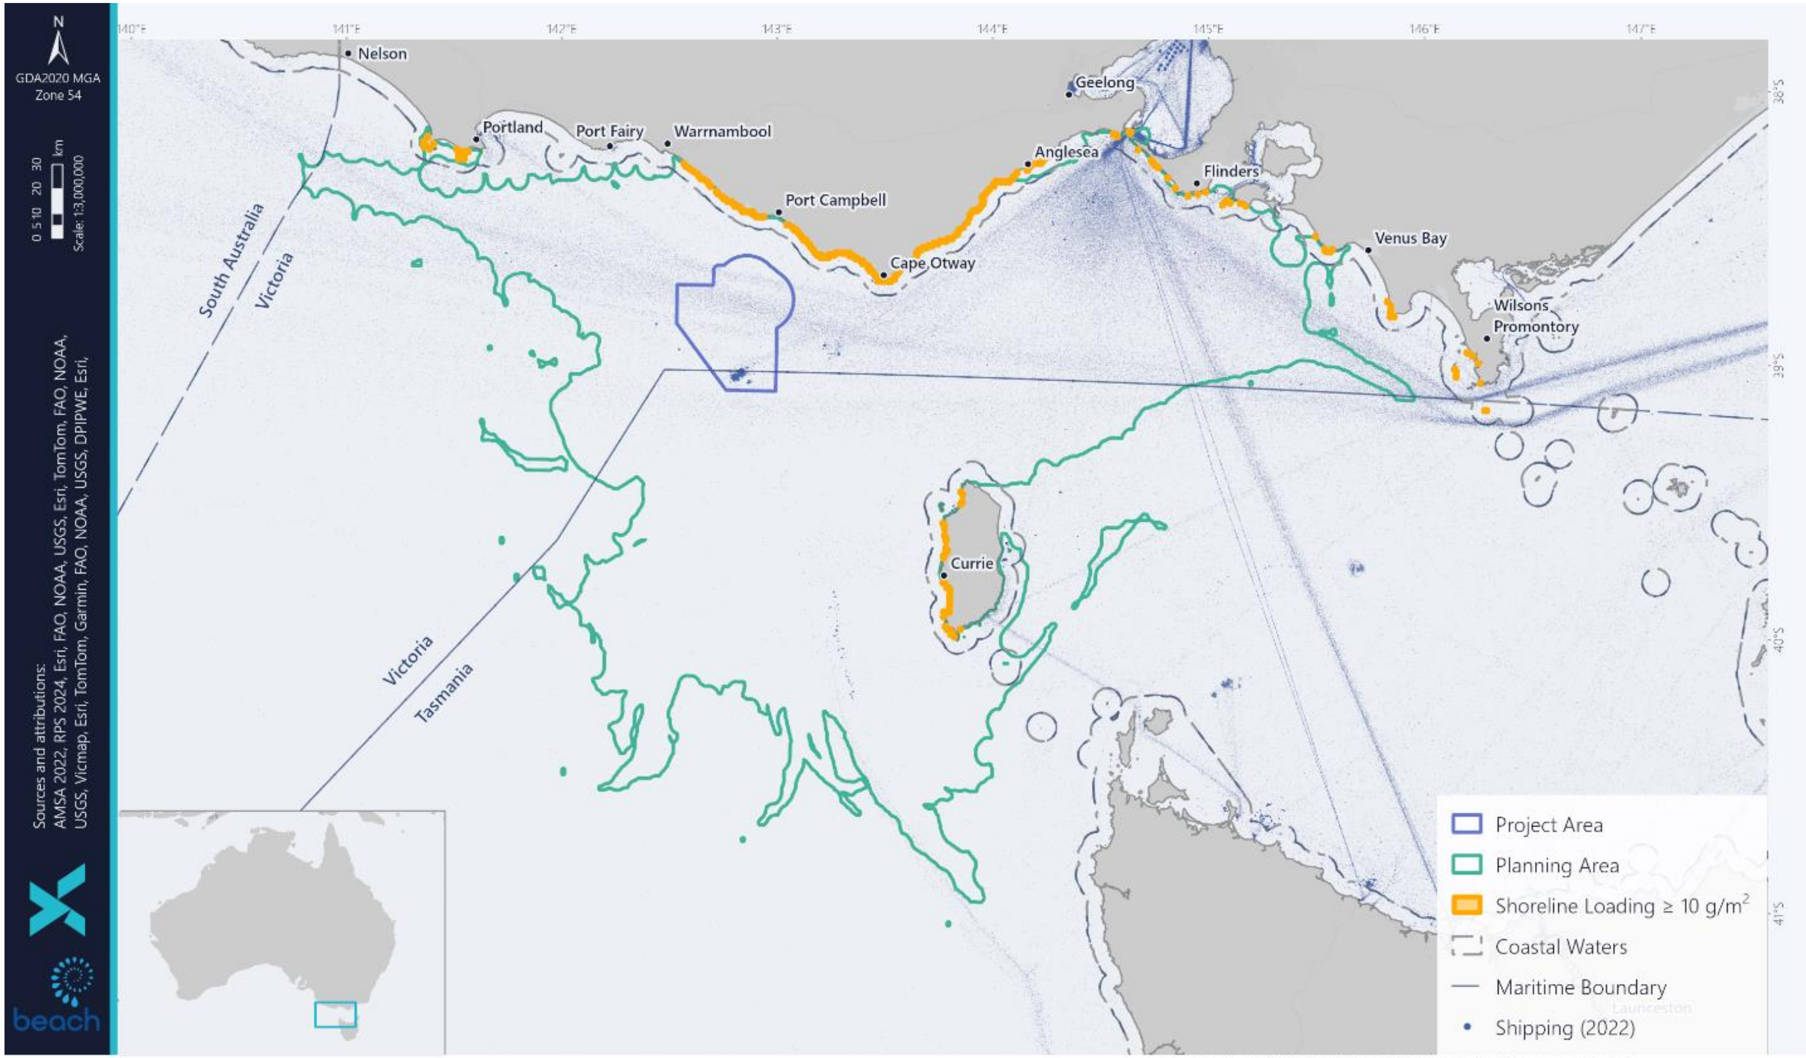

Figure 4-67: Shipping Traffic within the Project and Planning Areas

4.5.7 Tourism

Consultation has identified that the key areas of tourism in the region include land-based sightseeing from the Great Ocean Road and lookouts along that road, helicopter sightseeing, private and chartered vessels touring into the Twelve Apostles Marine Park, diving and fishing. Land-based tourism in the region peaks over holiday periods and in 2011, Tourism Victoria reported a total of approximately 8 million visitors to the Great Ocean Road region.

Local vessels accessing the area generally launch from Boat Bay in the Bay of Islands or from Port Campbell. Given the available boat launching facilities in the area (Peterborough and Port Campbell), and the prevailing sea-state of the area, vessel-based tourism is limited.

4.5.8 Recreational Diving

Recreational diving occurs along the Victorian coastline. Popular diving sites near Peterborough include a number of shipwrecks such as the Newfield, which lies in 6 m of water and the Schomberg in 8 m of water. Peterborough provides a number of good shore dives at Wild Dog Cove, Massacre Bay, Crofts Bay and the Bay of Islands. In addition, there is the wreck of the Falls of Halladale (4 to 11 m of water) which can be accessed from shore or via boat. King Island is also known for several wreck sites and the Waterwitch Reef. A number of operators in the region offer dive charters in the waters of King Island.

Consultation with local vessel charterers and providers of SCUBA tank fills has confirmed that diving activity is generally concentrated around The Arches Marine Sanctuary and the wreck sites of the Loch Ard and sometimes at the Newfield and Schomberg shipwrecks. Diving activity peaks during the Rock Lobster season with the bulk of recreational boats accessing the area launching from Boat Bay at the Bay of Islands or Port Campbell.

4.5.9 Recreational Fishing

Recreational fishing is popular in Victoria and is largely centred within Port Phillip Bay and Western Port, although beach and boat-based fishing occurs along much of the Victorian coastline.

Recreational fishing also occurs in Tasmania in coastal and offshore waters, primarily within 3 nm of the shore.

Recreational fisheries that may occur within the Planning Area are:

- Rock lobster
- Finfish (multiple species are targeted, including sharks)
- Abalone
- Scallops
- Squid
- Pipi

Of these, active recreational fishing for rock lobster, abalone, finfish, and sharks is likely to occur within the Planning Area. Recreational scallop and squid fishing primarily occurs within Port Phillip Bay and Western Port and as such fishing for these species is possible within the Planning Area. Pipi harvesting occurs in Venus Bay, adjacent to the Planning Area, but due to high levels of toxins in pipis at that location the public is currently advised that they are unsafe for human consumption.

There is the potential for low levels of recreational fishing to occur within the areas of the Project Area which are nearest to shore.

Due to the distance offshore (approximately 20 km) and the lack of emergent features, recreational fishing and tourism in the Project Area is unlikely.

4.5.10 Commonwealth Managed Fisheries

Commonwealth fisheries are managed by the Australian Fisheries Management Authority (AFMA) under the Fisheries Management Act 1991 (Cth). AFMA jurisdiction covers the area of ocean from 3 nm from the coast out to the 200 nm limit (the Australian Fishing Zone (AFZ)). Commonwealth commercial fisheries with jurisdictions to fish within the Planning Area are:

- Bass Strait Central Zone Scallop Fishery (BSCZSF)
- Eastern Tuna and Billfish Fishery (ETBF)
- Skipjack Tuna Fishery
- Small Pelagic Fishery (SPF)
- Southern Bluefin Tuna Fishery (SBTF)
- Southern and Eastern Scalefish and Shark Fishery (SESSF)
- Southern Squid Jig Fishery (SSJF)
- Western Tuna and Billfish Fishery (WBTF).

Table 4-34 details fisheries with catch and effort occurring within the Project and Planning Areas using data obtained from Fisheries Status Reports published by the Australian Bureau of Agricultural and Resource Economics and Sciences (ABARES) (Butler et al. 2024; ABARES 2024). The Skipjack Fishery is not currently active and management arrangements for the fishery are under review.

Information relating to the target species, fishing locations, landed catch, value and other relevant aspects of each fishery are taken from current and previous Commonwealth Fishery Status Reports (Butler et al. 2024; Butler et al. 2023; Patterson et al. 2022), unless indicated, is summarised in Table 4-34.

Figures of fishing intensity for 2016 – 2023 are provided where there is an overlap with fishing intensity and the Project Area and/or Planning Area. Relative fishing intensity shows areas where 5 or more fishing vessels operated with the relative effort expended or the catch displayed. Reporting grids show the total area where fishing occurred at a resolution of one degree (approximately 111 x 111 km). Intensity data may not be displayed where less than or equal to 5 vessels operated (policy requirement to protect commercial confidentiality of data). As this data is confidential, due to the limited number of vessels, fishing activity may have occurred anywhere within the reporting grid and not intersect with the Project Area.

Beach also commissioned the South East Trawl Fishing Industry Association (SETFIA) to provide a report on trawl and gillnet fishing activity in Otway Gas Development Phase 4 Project Area (October 2019). The report concluded the following:

- Trawl fishing in the SESSF CTS board trawl sub-sector does not occur in the Otway Gas Development Phase 4 Project area proposed footprint. It does occur to the south-east of the Project Area. The grounds around the Otway Gas Development Phase 4 Project area appear too rough for trawl fishing in its current form. For unknown reasons gillnet fishing in the SESSF GHaT gillnet sub-sector does not seem to occur within the Otway Gas Development Phase 4 Project Area. However, there is some activity from this sub-sector nearby to the east. Gillnet fishing cannot occur deeper than 183 m (100 fathoms).

There is no SESSF CTS Danish seine sub-sector fishing in the Otway Gas Development Phase 4 Project Area.

Table 4-34: Commonwealth Managed Fisheries within the Project Area and Planning Area

Fishery	Target species	Description	Fishing Effort Project Area	Fishing Effort Planning Area
Bass Strait Central Zone Scallop Fishery	Scallop (*Pecten fumatus*)	The Bass Strait Central Zone Scallop Fishery operates in the Bass Strait between Victorian and Tasmanian and starts at 20 nm from their respective coastlines. In 2023, fishing was permitted throughout the management area, except in 4 scallop beds that were closed to fishing under the harvest strategy. Fishing in 2023 was primarily concentrated in the western Bass Strait. Additional information for the 2023 season includes: Active boats – 9 (using towed dredges) (2022 season – 10) Fishing season – 8 July to 31 December. Major landing ports – Apollo Bay and Queenscliff. Actual catch – 2,063 tonnes (2022 season – 495 tonnes; 2021 season – 2,344 tonnes). Total fishery value – A$1.4 million (2022 season – A$1.3 million; 2021 season – A$4.4 million). Sensitivities – Target species can be prone to die-off events (e.g. in 2010 and 2011) and disease (paralytic shellfish toxin in 2014). Target species is not listed under the EPBC Act. Existing pressures – Target species within the Bass Strait (between Victoria and Tasmania) are classified as not overfished and not subject to overfishing. Activity trends – Fishing intensity data between 2016 and 2023 (ABARES 2024) shows no significant shift in the location of either low, medium or high intensity fishing activity within the Bass Strait Central Zone Scallop Fishery. No fishing intensity data between 2016 and 2023 overlaps the Project Area (Figure 4-68). However, the Project Area is overlapped by reporting grids which contain confidential data due to less than 5 vessels operating. The Planning Area overlaps areas of low to high relative fishing intensity which is concentrated to the east of King Island (Figure 4-68).	Yes*	Yes
Eastern Tuna and Billfish Fishery	Albacore Tuna (*Thunnus alulunga*) Bigeye Tuna (*T. obesus*) Yellowfin Tuna (*T. albacares*) Broadbill Swordfish (*Xiphias gladius*)	The Eastern Tuna Billfish Fishery is a longline and minor-line fishery that operates in water depths >200 m from Cape York to Victoria. Fishing effort is typically concentrated along the NSW coast and southern Queensland coast. No Victorian ports are used. Fishing in 2023 was primarily concentrated off the east coast of Australia from Queensland to New South Wales. Additional information for the 2023 season includes: Active boats – 34 longline, 12 minor line (2022 season – 36 longline, 6 minor line) Fishing season – 1 January – 31 December Major landing ports – Bermagui, Cairns, Coffs Harbour, Mooloolaba, Southport, Ulladulla	Yes	Yes

	Striped Marlin (*Tetrapturus audux*)	Actual catch — 4,040 tonnes (2022 season – 4,032 tonnes) Total fishery value — A$40.1 million (2022 season – A$34.7 million). Existing pressures – Striped Marlin overfished. Activity trends – Fishing intensity data between 2016 and 2023 (ABARES 2024) shows no significant shift in the location of either medium or high intensity fishing within the Eastern Tuna and Billfish Fishery. A small increase in low intensity fishing was noted near Flinders outside of the Project Area. No fishing intensity data between 2016 and 2023 overlaps the Project Area. The Planning Area overlaps an area of low relative intensity near Flinders (Figure 4-69). The Project Area and Planning Area overlap reporting grids which contain confidential data due to less than 5 vessels operating (Figure 4-69).		
Skipjack Tuna Fishery (Eastern and Western)	Skipjack Tuna (*Katsuwonus pelamis*)	The Skipjack Tuna Fishery is not currently active and the management arrangements for this fishery are under review. There has been no catch effort in this fishery since the 2008 -2009 season.	No	No
Small Pelagic Fishery (Western sub-area)	Australian Sardine (*Sardinops sagax*) Blue Mackerel (*Scomber australasicus*) Jack Mackerel (*Trachurus declivis*) Redbait (*Emmelichthys nitidus*)	The Small Pelagic Fishery extends from the southern Queensland to southern Western Australia. Fishers use midwater trawls and purse seine nets. Fishing in 2023 was primarily concentrated along the southern coast of New South Wales into Gippsland and the eastern coast of South Australia. Activity trends – Fishing intensity data between 2016 and 2023 is not available. However there is no significant shift in the location of reporting grids showing fishing activity (containing confidential data due to less than 5 vessels operating) within the Small Pelagic Fishery (Western sub-area). There has been no fishing effort reported in the Project Area or Planning Area between 2016 and 2023.	No	No
Southern and Eastern Scalefish and Shark Fishery (SESSF) Commonwealth Trawl Sector (CTS) Danish-seine	Blue-eye trevalla (*Hyperoglyphe antarctica*) Blue grenadier (*Macruronus novaezelandiae*) Blue warehou (*Seriolella brama*) Deepwater sharks (up to 18 spp.) Eastern school whiting (*Sillago flindersi*)	The Commonwealth Trawl Sector (CTS) is part of the SESSF and extends from Barrenjoey Point in northern New South Wales to Kangaroo Island in South Australia. Management of the CTS is separated into demersal otter-board trawl and Danish-seine fishing methods. Danish-seine fishing in 2023 was generally concentrated along the 200 m bathymetric contour from the east coast of Tasmania to the Gippsland coast. Additional information for the 2023 season includes: Active boats – 18 (2022 season – 18) Fishing season – 1 May – 30 April Major landing ports – Eden, Hobart, Lakes Entrance, Portland, Sydney, Ulladulla Actual catch — 10,854 tonnes (combined with otter-board trawl) (2022 season – 11,257 tonnes)	Yes	Yes

	Flathead (*Neoplatycephalus richardsoni*) Orange roughy (*Hoplostethus atlanticus*) Pink ling (*Genypterus blacodes*)	Total fishery value — A$65.9 million (2022 - entire CTS including otter-board trawl and scalefish hook). 2023 financials not published. Existing pressures – Some species overfished or subject to overfishing. Activity trends – Fishing intensity data between 2016 and 2023 (ABARES 2024) shows no significant shift in the location of fishing intensity within the Danish-seine sector of the Commonwealth Trawl Sector (CTS) Fishery. No fishing intensity has been identified within the Project Area during 2016-2023. The Project Area overlaps reporting grids which contain confidential data due to less than 5 vessels operating. The Planning Area overlaps low to medium fishing intensity near Phillip Island (Figure 4-70).		
Southern and Eastern Scalefish and Shark Fishery (SESSF) Commonwealth Trawl Sector (CTS): Otter-board trawl	Blue-eye trevalla (*Hyperoglyphe antarctica*) Blue grenadier (*Macruronus novaezelandiae*) Blue warehou (*Seriolella brama*) Deepwater sharks (up to 18 spp.) Eastern school whiting (*Sillago flindersi*) Flathead (*Neoplatycephalus richardsoni*) Orange roughy (*Hoplostethus atlanticus*) Pink ling (*Genypterus blacodes*)	The Commonwealth Trawl Sector (CTS) is part of the SESSF and extends from Barrenjoey Point in northern New South Wales to Kangaroo Island in South Australia. Management of the CTS is separated into demersal otter-board trawl and Danish-seine fishing methods. Otter-board trawl fishing in 2023 was generally concentrated along the 200 m bathymetric contour from Adelaide to Ulladulla. Additional information for the 2023 season includes: Active boats – 24 (2022 season – 31) Fishing season – 1 May – 30 April Major landing ports – Eden, Hobart, Lakes Entrance, Portland, Sydney, Ulladulla Actual catch — 10,854 tonnes (combined with Danish-seine) (2022 season – 11,257 tonnes) Total fishery value — A$65.9 million (2022 - entire CTS including Danish-seine and scalefish hook). 2023 financials not published. Existing pressures – Some species overfished or subject to overfishing. Activity trends – Fishing intensity data between 2016 and 2023 (ABARES 2024) shows no significant shift in the location of fishing intensity within the otter-board trawl sector of the Commonwealth Trawl Sector (CTS) Fishery. The Project Area and Planning Area overlap a band of relative fishing intensity from 2016-2023 which follows the 200 m bathymetry contour (Figure 4-71). Only low relative intensity overlaps the Project Area.	Yes	Yes
Southern and Eastern Scalefish and Shark Fishery (SESSF)	Blue-eye trevalla (*Hyperoglyphe antarctica*) Blue grenadier (*Macruronus novaezelandiae*)	The Scalefish Hook Sector (SHS) is primarily in the south-east of Australia with most fishing intensity occurring off the coast of Tasmania. The SHS is managed under the Gillnet, Hook and Trap Sector (GHTS) of the SESSF. The broader SESSF stretches south from Fraser Island in southern Queensland, around Tasmania, to Cape Leeuwin in southern Western Australia. The SHS shares target species with the CTS. Scalefish hook fishing in 2023 was generally concentrated along the 200 m bathymetric contour. Additional information for the 2023 season includes:	Yes	Yes

Gillnet, Hook and Trap Sector (GHTS) Scalefish Hook Sector (SHS)	Blue warehou (*Seriolella brama*) Deepwater sharks (up to 18 spp.) Eastern school whiting (*Sillago flindersi*) Flathead (*Neoplatycephalus richardsoni*) Orange roughy (*Hoplostethus atlanticus*) Pink ling (*Genypterus blacodes*)	Active boats – 13 (2022 season – 12) Fishing season – 1 May – 30 April Major landing ports – Eden, Hobart, Lakes Entrance, Portland, Sydney, Ulladulla Actual catch — 719 tonnes (2022 season – 715 tonnes) Total fishery value — A$65.9 million (2022 - entire CTS including otter-board trawl and Danish-seine). 2023 financials not published. Existing pressures – Some species overfished or subject to overfishing. Activity trends – Fishing intensity data between 2016 and 2023 shows no significant shift in the location of reporting grids within the SHS Fishery. Relative fishing intensity data is not published for the SHS fishery and spatial data for the 2023 fishing season is not yet available but is mapped in the fishery status report (ABARES 2024). The Project Area and Planning Area overlap reporting grids for the SHS which contain confidential data due to less than 5 vessels operating (Figure 4-72).		
Southern and Eastern Scalefish and Shark Fishery (SESSF) Gillnet, Hook and Trap Sector (GHTS) Shark Gillnet and Shark Hook Sectors (SGSHS) Shark Gillnet subsector	Elephantfish (*Callorhinchus milii*) Gummy Shark (*Mustelus antarcticus*) Sawsharks (*Pristiophorus cirratus, P. nudipinnis*) School Shark (*Galeaorhinus galeus*)	The Shark Gillnet and Shark Hook Sectors (SGSHS) are part of the Gillnet, Hook and Trap Sector (GHTS) of the Southern and Eastern Scalefish and Shark Fishery (SESSF). Most fishing in the SGSHS using nets occurs in the Bass Strait while most fishing using hooks occurs off South Australia. Shark gillnet fishing in 2023 was concentrated in the waters between Victoria and Tasmania, with the highest intensity occurring off the Gippsland coast and Flinders Island. Additional information for the 2023 season includes: Active boats – 31 (2022 season – 30) Fishing season – 1 May – 30 April Major landing ports – Adelaide, Devonport, Hobart, Lakes Entrance, Port Lincoln, Port Welshpool, Robe, San Remo Actual catch – 1,700 tonnes (combined with Shark Hook sector) (2022 season – 1,661 tonnes) Total fishery value – A$21.6 million (2022 – including Shark Hook sector). 2023 financials not published. Existing pressures – Elephantfish has no reliable indicators of fishing mortality or biomass; Schoolshark overfished Activity trends – Fishing intensity data between 2016 and 2023 (ABARES 2024) shows a slight shift to the east of the Project Area in the location of low, medium and high intensity fishing within the Shark Gillnet Fishery. There has been fishing intensity in the Project Area and Planning Area from 2016-2023 (Figure 4-73Figure 4-73). The northern-most portion of the Project Area overlaps an area of low to medium relative fishing intensity. Areas of low to high fishing intensity occur within the Planning Area throughout the Bass Strait and along the Victorian coast.	Yes	Yes

Southern and Eastern Scalefish and Shark Fishery (SESSF) Gillnet, Hook and Trap Sector (GHTS) Shark Gillnet and Shark Hook Sectors (SGSHS) Shark Hook subsector	Elephantfish (*Callorhinchus milii*) Gummy Shark (*Mustelus antarcticus*) Sawsharks (*Pristiophorus cirratus, P. nudipinnis*) School Shark (*Galeaorhinus galeus*)	The Shark Gillnet and Shark Hook Sectors (SGSHS) are part of the Gillnet, Hook and Trap Sector (GHTS) of the Southern and Eastern Scalefish and Shark Fishery (SESSF). Most fishing in the SGSHS using nets occurs in the Bass Strait while most fishing using hooks occurs off South Australia. Shark hook fishing in 2023 was concentrated along the coast of South Australia, Victoria and Tasmania, with the highest intensity occurring off Cape Jaffa in South Australia. Additional information for the 2023 season includes: Active boats – 68 (2022 season – 57) Fishing season – 1 May – 30 April Major landing ports – Adelaide, Devonport, Hobart, Lakes Entrance, Port Lincoln, Port Welshpool, Robe, San Remo Actual catch – 1,700 tonnes (combined with Shark Gillnet sector) (2021 season – 1,661 tonnes) Total fishery value – A$21.6 million (2022 – including Shark Gillnet sector). 2023 financials not published. Existing pressures – Elephantfish has no reliable indicators of fishing mortality or biomass; School shark overfished Activity trends – Fishing intensity data between 2016 and 2023 (ABARES 2024) shows an increase in activity in South Australian water for 2019 and 2020, decreasing thereafter but with no significant shift in the location of the fishing intensity within the Shark Hook subsector. A small increase in relative intensity also occurred in 2023 near Hunter Island and Three Hummock Island in the north east of Tasmania outside of the Planning Area. The Project Area and Planning Area overlap reporting grids which contain confidential data due to less than 5 vessels operating (Figure 4-74).	Yes	Yes
Southern Bluefin Tuna Fishery	Southern Bluefin Tuna (*Thunnus maccoyii*)	The Southern Bluefin Tuna Fishery covers the entire sea area around Australia, out to 200 nm from the coast. The majority of catch since 1992 has been taken in the Great Australian Bight via purse seine. Longline fishing effort is more common along the east coast. Fishing effort in 2022 was concentrated off the coasts of South Australia and southern New South Wales. Data is not yet published for the 2023 season. Additional information for the 2022 season includes: Active vessels – 24 longline, 6 purse seine (2021 – 22 longline, 8 purse seine) Fishing season – 1 December to 30 November Major landing ports – Port Lincoln Actual catch – 6,034 tonnes (2021 – 5,972 tonnes) Total fishery value – A$32.6 million (2021 – A$35.5 million) Existing pressures – Not overfished or subject to overfishing. Activity trends – Fishing intensity data between 2016 and 2023 (ABARES 2024) shows no significant shift in the location of either low, medium or high intensity fishing within the Southern Bluefin Tuna Fishery. The Project Area and Planning Area overlap reporting grids which contain confidential data due to less than 5 vessels operating (Figure 4-75).	Yes	Yes

Southern Squid Jig Fishery	Gould's Squid (Arrow Squid) (*Nototodarus gouldi*)	The Southern Squid Jig Fishery is a single species fishery that operates year-round. Portland and Queenscliff are the major Victorian landing ports. Jigging typically occurs midwater at depths between 50 and 100 m at night using large lights that illuminate the waters around a boat. Fishing effort for the Southern Squid Jig Fishery in 2023 was concentrated off Victoria and north-eastern Tasmanian coasts, with the highest intensity occurring near Portland and off the east coast of Tasmania. Fishing effort for the CTS squid catch in 2023 followed the 200 m bathymetry contour from New South Wales to the east coast of Tasmania and between Cape Otway and Robe. Additional information for the 2023 season includes: Active vessels – 6 (2021 – 8) Fishing season – 1 January – 31 December Major landing ports – Apollo Bay, Lakes Entrance, Portland, Queenscliff, Triabunna Actual catch – 394 tonnes (2021 – 982 tonnes) Total fishery value – A$1.86 million (2021 – A$3.30 million) Existing pressures – Not overfished or subject to overfishing. Activity trends – Fishing effort in 2023 increased to 4,509 jig-hours from 8 vessels from 1,320 jig-hours from 6 vessels in 2022. Fishing mortality: Not subject to overfishing. Biomass: Not overfished. The Project Area overlaps an area of low relative fishing intensity as well as reporting grids which contain confidential data due to less than 5 vessels operating. The Planning Area overlaps areas of low to high intensity north of King Island and off the coast of Warrnambool (Figure 4-76).	Yes	Yes
Western Tuna and Billfish Fishery	Albacore (*Thunnus alalunga*) Bigeye Tuna (*T. obesus*) Striped Marlin (*Kajikia audax*) Swordfish (*Xiphias gladius*) Yellowfin Tuna (*Thunnus albacares*)	The Western Tuna and Billfish Fishery primarily uses pelagic longline gear with low levels of minor-line fishing. The management area extends west from the eastern border of South Australia to Cape York, including Cocos Keeling Islands and Christmas Island. Fishing effort in 2023 was mostly concentrated in south-west Western Australia. Additional information for the 2023 season includes: Active vessels – 2 longline, 1 minor line (2022 – 2 longline, 3 minor line) Fishing season – 1 July – 30 June Major landing ports – Fremantle, Geraldton Actual catch – 208 tonnes (2022 – 146 tonnes) Total fishery value – confidential	No	Yes

	Existing pressures – Striped marlin overfished; Bigeye Tuna and Yellowfin Tuna subject to overfishing. Activity trends – Fishing intensity data between 2016 and 2023 is not available. However, there is no significant shift in the location of reporting grids showing fishing activity (containing confidential data due to <5 vessels operating) within the Western Tuna and Billfish Fishery. The Planning Area overlaps a reporting grid which contains confidential data due to less than 5 vessels operating (Figure 4-77). There has been no fishing effort identified in the Project Area.

* *Planning Area overlapped by an area designated as a reporting grid at a resolution of one degree (approximately 111 x 111 km).*

4.5.11 Victorian Managed Fisheries

There are eight Victorian state-managed commercial fisheries that overlap the Planning Area:

- Abalone Fishery
- Giant Crab Fishery
- Multispecies Ocean Fisheries (Inshore Trawl and Ocean General)
- Octopus Fishery
- Pipi Fishery
- Rock Lobster Fishery
- Scallop (Ocean) Fishery
- Wrasse (Ocean) Fishery

Of these, three Victorian state-managed commercial fisheries were identified to be active within the Project Area in recent years:

- Giant Crab Fishery
- Rock Lobster Fishery
- Wrasse (Ocean) Fishery

Information relating to the target species, fishing locations, landed catch, value and other relevant aspects of each fishery is provided in Table 4-35. Maps are also provided displaying the number of vessels reported in a VFA grid between 2013–2023 in relation to the Project and/or Planning Areas. Fishing effort data is confidential if a grid has less than 5 active vessels. No data on the Abalone Fishery locations was available from VFA due to the confidential nature of the data.

Data sources are from the Victorian Fisheries Authority Commercial Fish Production Information Bulletin July 2020 to June 2021 (VFA 2021) and VFA website (VFA 2024) unless indicated.

Table 4-35: Victorian Managed Fisheries within the Project Area and Planning Area

Fishery	Target species	Description	Fishing Effort Project Area	Fishing Effort Planning Area
Abalone Fishery (central, eastern and western zones)	Blacklip Abalone Greenlip Abalone	The Victorian Abalone Fishery is a highly valuable fishery (A$16.8 million in 2020-21) that operates along most of the Victorian shoreline, generally to 30 m depth. Abalone are harvested by divers. Total allowable commercial catch (TACC) limits of Blacklip Abalone for the western zone are considerably less than the central and eastern zone (for 2019-20 season, 73.2 tonnes compared with 262.5 and 345.5 tonnes, respectively). There are 14 licences in the western zone, 23 in the eastern zone and 34 in the central zone. The water depths where abalone are fished are close to shore and therefore abalone fishing is likely to occur within the Planning Area. No abalone fishing is expected within the Project Area due to minimum water depth being 64 m.	No	Yes
Giant Crab Fishery	Giant Crab	The Giant Crab Fishery is a small fishery operating in western Victoria and closely linked with the Rock Lobster Fishery. Most vessels are used primarily for Rock Lobster fishing with Giant Crab taken as by-product. Fishing effort is concentrated on the continental shelf edge (~200 m). Giant Crabs inhabit the continental slope at approximately 200 m depth and are most abundant along the narrow band of the shelf edge. Closed seasons operate for male (15 Sept to 15 Nov) and female (1 June to 15 Nov) Giant Crabs. Total landed catch in 2015-16 was 10 tonnes. Data for 2020/21 is confidential due to less than 5 vessels reporting fishing effort. The Project Area is within the western management zone of the fishery (Figure 4-78). Figure 4-78 shows overlap of Giant Crab management areas and fishing effort from 2013-2023 with the Project Area and Planning Area (VFA 2024). The Project Area and Planning Area overlap reporting grids with up to 15 active vessels.	Yes	Yes
Multispecies Ocean Fisheries – Inshore Trawl and Ocean General	Australian Salmon Eastern King Prawn Gummy Shark Lobster/Balmain Bug School Shark School Prawn Shovelnose	The Multispecies Ocean Inshore Trawl fishery operates along the entire Victorian coastline, excluding marine reserves, bays and inlets. Most operators are based at Lakes Entrance. The Inshore Trawl fishery uses otter-board trawls with no more than a maximum head- line length of 33 m, or single mesh nets. The Wrasse, Inshore Trawl, Southern Rock Lobster and Giant Crab Fisheries are able to catch Gummy Shark and School Sharks as part of their fishery. The Multispecies Ocean Ocean General fishery uses lines, nets and haul seine to catch snapper. Over 90% of the catch is from Port Phillip Bay, and around 5% from coastal waters. In 2020-21, 45 tonnes were landed but a values could not be provided as there is insufficient data to report because there are less than five licence holders (policy requirement to protect commercial confidentiality of data).	No	Yes

	Snapper Minor bycatch of School Whiting and Flathead	Figure 4-79 shows the Planning Area overlaps areas with up to 78 active vessels for the Multispecies Ocean Fisheries. No fishing effort was identified within the Project Area. Catch effort data is considered confidential if there are less than 5 vessels active.		
Octopus Fishery	Pale Octopus Maori Octopus Gloomy Octopus	The Octopus Fishery (Eastern Zone) is a new fishery harvesting mainly Pale Octopus (*Octopus pallidus*) in East Gippsland. The fishery may also catch Maori Octopus (*Macroctopus maorum*) and Gloomy Octopus (*Octopus tetricus*). Octopus are caught using purpose-built unbaited traps. The fishery commenced on 1st August 2020. Three fishery locations have been established for this new fishery; Eastern, Central and Western octopus zones. The Eastern zone is where the majority of commercial octopus takes place with the Central and Western zones are less established but are being managed by VFA through exploratory, temporary permits. Figure 4-80 shows the Planning Area overlaps reporting grids with up to 14 active vessels between 2013-2023. No fishing effort was identified within the Project Area. Catch effort data is considered confidential if there are less than 5 vessels active.	No	Yes
Pipi Fishery	Pipi	The Pipi Fishery is a newly managed fishery with its first management plan declared in 2018. The fishery is now utilising an ongoing quota management regime with access licences issued for Discovery Bay and Venus Bay management zones, each with their own TACC. Pipi harvested commercially are sold for bait or for human consumption. The main commercial harvesting area for the Victorian Pipi Fishery is Discovery Bay with limited activity in Venus Bay. Pipis are harvested in the high impact beach zone using traditional dip nets. Figure 4-81 shows the Planning Area overlaps a small area fished between 2013-2023. Intensity data for the Pipi Fishery is confidential. the Project Area does not overlap the Victorian Pipi Fishery.	No	Yes
Rock Lobster Fishery (western zone)	Southern Rock Lobster	The Rock Lobster Fishery is Victoria's second most valuable fishery with a production value of A$13.6 million in 2020/21. Since 2009-10, annual quotas have been set at between 230 and 260 tonnes and have been fully caught each year. In the western zone, most catch is landed through Portland, Port Fairy, Warrnambool, Port Campbell and Apollo Bay. Closed seasons operate for male (15 Sept to 15 Nov) and female (1 June to 15 Nov) lobsters. Southern Rock Lobsters are found to depths of up to 150 m, with most of the catch coming from inshore waters less than 100 m. Figure 4-82 shows the Project Area and Planning Area overlap the Southern Rock Lobster Fishery. The Project Area overlaps reporting grids with up to 24 active vessels while the Planning Area overlaps areas with as many as 101 active vessels between 2013-2023.	Yes	Yes

Scallop (Ocean) Fishery	Commercial Scallop	The Scallop Fishery extends the length of the Victorian coastline from high tide mark to 20 nm offshore. Fishers use a scallop dredge. Doughboy Scallops are taken as by-product but are not harvested in commercial quantities. Temporary closures occur when stocks are low to allow scallop beds to recover. TACC for 2015-16 was set at 135 tonnes, with results from the 2017/18 abundance survey indicating that TACC should remain at the same level. Scallops are mostly fished from Lakes Entrance and Welshpool. The Project and Planning Areas do not overlap Victorian Scallop Fishery effort.	No	No
Wrasse (Ocean) Fishery	Bluethroat Wrasse Purple Wrasse Small catches of Rosy Wrasse, Senator Wrasse and Southern Maori Wrasse	The Victorian Wrasse (Ocean) Fishery extends the length of the Victorian coastline from high tide mark to 20 nm offshore. Fishers mostly use hook and line. There is limited entry to the fishery with 22 current licences. Total annual catches in 2019-20 was approximately 21.5 tonnes. Figure 4-83 shows the Project Area overlaps the wrasse fishery management area as well as a small corner of a reporting grid (1.85 km^2) with less than 5 active vessels between 2013-2023 (VFA 2024). The Planning Area overlaps reporting grids along the coast with up to 35 active vessels.	Yes	Yes

4.5.12 Tasmanian Managed Fisheries

Fishing Tasmania manages Tasmania's commercial fisheries under the *Living Marine Resources Management Act 1995*.

All fisheries except for the Giant Crab Fishery and the Rock Lobster Fishery operate within Tasmanian waters. The Giant Crab Fishery and the Rock Lobster Fishery also operate in Commonwealth waters under an Offshore Constitutional Settlement (OCS) between the Australian Government and the Government of Tasmania.

There are eight Tasmanian state-managed commercial fisheries that may overlap the Planning Area:

- Abalone Fishery
- Commercial Dive Fishery
- Giant Crab Fishery
- Marine Plant Fishery
- Rock Lobster Fishery
- Scalefish Fishery
- Scallop Fishery
- Shellfish Fishery

No fishing effort has been identified within the Project Area. Project information relating to the target species, fishing locations, landed catch, value and other relevant aspects of each fishery is detailed in Table 4-36. Data and information sources are Department of Natural Resources and Environment Tasmania (DNRET 2022) and Australian fisheries and aquaculture statistics 2014-15 (Patterson et al. 2022).

Maps are also provided showing where the number of vessels reported in a Tasmanian Fishery grid between 2011 – 2021 in relation to the Project Area and/or Planning Area and for the Rock Lobster Fishery and Giant Crab Fishery for which data from Fishing Tasmania is available.

Table 4-36: Tasmanian Managed fisheries within the Project Area and Planning Area

Fishery	**Target species**	**Description**	**Fishing Effort Project Area**	**Fishing Effort Planning Area**
Abalone Fishery (Northern, Western and Bass Strait Zones)	Blacklip Abalone Greenlip Abalone	The Tasmanian Abalone Fishery is the largest wild abalone fishery in the world (providing ~25% of global production) and a major contributor to the local economy. Abalone are hand-captured by divers in depths between 5-30 m. Blacklip Abalone are collected around on rocky substrate around the Tasmanian shoreline and are the primary target of the fishery. Greenlip Abalone are distributed along the north coast and around the Bass Strait islands and usually account for around 5% of the total wild harvest. In 2020/21, the gross value of production of the fishery was around A$50 million from a total catch of approximately 1,000 tonnes. The jurisdictional area of the Abalone Fishery is Tasmanian State waters. The Project Area does not overlap the Abalone Fishery. The Planning Area overlaps the Northern Zone (waters around King Island) of the Abalone Fishery (Figure 4-84).	No	Yes
Commercial Dive Fishery (Northern and Western Zones)	Longspined Sea Urchin Shortspined Sea Urchin Wavy Periwinkle	The Tasmanian Commercial Dive Fishery is a capture fishery that targets several different species; the main species collected being sea urchins and periwinkles. In 2020-2021 approximately 180 t of sea urchins and 2.07 t of periwinkles were harvested. Sea urchins and periwinkles accounted for 63% and 37% of the total respectively. Jurisdiction encompasses all Tasmanian State waters (excluding protected and research areas), although licence holders largely operate out of small vessels (<10 m) and effort is concentrated on the south and east costs of Tasmania around ports. The Project Area does not overlap the Commercial Dive Fishery. The Planning Area overlaps the Northern Zone of the Commercial Dive Fishery at King Island (Figure 4-84).	No	Yes
Giant Crab Fishery	Giant crab	The Giant Crab Fishery is a comparatively small fishery with the annual harvest set at 20.7 tonnes but with a high landed value of around A$2 million. The fishery has been commercially targeted since the early 1990s, moving from open access to limited entry. The area of the fishery includes waters surrounding the state of Tasmania generally south of 39º12 out to 200 nm. Within the area of the fishery, most effort takes place on the edge of the continental slope in water depths between 140 m and 270 m. CPUE has declined continually since the inception of the fishery in the early 1990s indicating that it has been overfished. The TAC has been reduced to 20.7 t for 2019/120 and 2021/2022 to address the issue.	No	Yes

		Figure 4-85 shows the Planning Area overlaps areas with up to 11 active vessels. No fishing effort was identified within the Project Area. Catch effort data is considered confidential if there are less than 6 vessels active.		
Marine Plant Fishery	Bull kelp Japanese kelp	Marine plants include kelp, seaweed, seagrasses, and algae which are food and habitat for other marine species. To protect Tasmanian marine ecosystems, no marine plants may be harvested directly from the water, except in the Undaria fishery. The majority of cast bull kelp is collected from King Island. The right to harvest and process kelp on King Island was granted exclusively to Kelp Industries Pty Ltd in the mid-1970s. About 80 to 100 individuals collect cast bull kelp and transport it to the Kelp Industries plant in Currie. An average annual harvest above 3,000 t (dried weight) has been produced in recent years, accounting for about 5% of the world production of alginates (i.e. the end product of dried bull kelp). The cast bull kelp harvesting on King Island generates about A$2 million annually. Comparatively minor cast bull kelp collection also occurs at two centres of operation on Tasmania's West Coast: around Bluff Hill Point and at Granville Harbour. Japanese kelp is harvested by divers only along Tasmania's east coast where it is already well established. The Planning Area overlaps the area where bull kelp is potentially collected from King Island.	No	Yes
Rock Lobster Fishery	Southern rock lobster	The Rock Lobster Fishery is the other major wild-caught Tasmanian fishery. For 2022-23 the Total Allowable Catch remains at 1,050.7 t. Southern rock lobsters are found to depths of 150 m with most of the catch coming from inshore waters less than 100 m throughout state waters. The fishery is a limited entry with 312 licences. Figure 4-86 shows the Planning Area overlaps areas with up to 152 active vessels from 2011-2021. The Project Area does not overlap recent fishing effort for the Tasmanian Rock Lobster Fishery.	No	Yes
Scalefish Fishery (north-west coast)	Multi-species and multi-gear fishery	The Scalefish Fishery is a complex multi-species fishery harvesting a range of scalefish, shark and cephalopod species. Fourteen different fishing methods are used. The highest commercial catches in 2019/20 were reported for southern calamari (85.8 t), wrasse (52.4 t), and eastern school whiting (43.7 t). Due to the fishery being under caught by 26.7% in the previous season 2020/21, the TAC for the 2021/22 season has increased to 30 kg quota unit. The Planning Area overlaps the Scalefish Fishery management area (Figure 4-87).	No	Yes
Scallop Fishery	Commercial Scallop	The Scallop Fishery uses a benthic scallop dredge to target one of three species of scallop naturally occurring in Tasmania, the Commercial Scallop (*Pecten fumatus*). The fishery extends 200 nm from the eastern, western and southern coasts of Tasmania. In the Bass Strait, the fishery extends 3-20 nm offshore along the north coast from King Island to Flinders Island.	No	Yes

		The Planning Area overlaps the Scallop Fishery Management Area.		
Shellfish Fishery	Katelysia Cockles Venerupis Clam Native Oyster Pacific Oyster	The Shellfish Fishery comprises specific shellfish species hand captured by divers in defined locations on the east coast of Tasmania, namely Angasi oysters in Georges Bay, Venerupis clams in Georges Bay and Katelysia cockles in Ansons Bay. The taking of Pacific oysters, an invasive species, is also managed as part of the fishery but no zones apply. Pacific oysters can be collected throughout all State waters (which includes areas within the Planning Area), as the aim of harvesting these animals is to deplete the wild population. The estimated total value of the shellfish fishery based on landings from 2001-2005 was A$345,538. The Planning Area could potentially overlap areas where Pacific oysters are collected.	No	Yes

4.5.13 South Australian Managed Fisheries

The *Fisheries Management Act 2007* and its regulations provide the legislative framework, objectives, and guiding principles for the management of fisheries in South Australia. Management rules for commercial fisheries are provided in fisheries regulations under the Act.

The Department of Primary Industries and Regions (DPIR) is responsible for the ecologically sustainable development of South Australia's aquatic resources and the administration of the *Fisheries Management Act 2007*.

The Project Area does not overlap any South Australian Fisheries.

Data from DPIR identified that the Planning Area overlaps the following fisheries:

- Abalone Fishery
- Charter Boat Fishery
- Giant Crab Fishery
- Marine Scalefish Fishery
- Rock Lobster Fishery

Information relating to the target species, fishing locations, landed catch, value and other relevant aspects of each fishery is included in Table 4-37. Data sources are from DPIR fishing data from 2012 to 2021 for fishing block 58 which the Planning Area overlaps, and PIRSA (2022), unless otherwise noted.

Table 4-37: South Australian Managed Fisheries within the Project Area and/or Planning Area

Fishery	Target species	Description	Fishing Effort Project Area	Fishing Effort Planning Area
Abalone Fishery	Blacklip Abalone Greenlip Abalone	The South Australian commercial abalone fishery takes Greenlip and Blacklip Abalone that inhabit subtidal reefs out to approximately 30 m. Commercial abalone divers mostly operate from large, trailered boats. Divers use surface supplied air from the boat and may use motorised cages to mitigate physical interactions with White Sharks. The Planning Area overlaps the Southern Zone of the fishery however the minimum depth of the Planning Area in South Australian waters is 300 m, so abalone fishing is not expected. The Southern Zone of the Abalone Fishery records six active licences from 2021 to 2022. Hours dived range from 921 to 1,496 per year with annual catch between 101,133 to 153,491 kg.	No	No
Charter Boat Fishery	Various	The Charter Boat Fishery is a limited entry fishery with 82 licence holders of which 47 were active in 2020/2021. Fishing in inshore regions where water depths are <50 m is the most frequent activity. Peak periods are between December and April (summer) and October. Seventy-eight species of fish, shark, mollusc, cephalopods, and crustacean are targeted with King George Whiting, snapper and Bight Redfish are the highest catches. The above information is from Durante et al. (2022). The Planning Area overlaps the fishery reporting grid where there have been 1,104 charter fishing trips from 2012 to 2021 (Figure 4-88).	No	Yes
Giant Crab Fishery	Giant Crab	Information from in this section is from McLeay (2022). Giant Crab (*Pseudocarcinus gigas*), also known as King Crab, is endemic to southern Australian waters and distributed from southern Western Australia to central New South Wales. While they occur at depths ranging from 20 to 600 m, the highest population densities are found at the edge of the continental shelf at depths of approximately 140 to 270 m. Fishers use a maximum of 100 steel-framed pots that must comply with pot dimension specifications. Commercial access to the Giant Crab resource is limited to licence holders in the Miscellaneous Fishery and Rock Lobster Fishery. Total allowable catch in the fishery is 22.1 t per year, consisting of	No	Yes

		13.4 t in the Northern Zone and 8.7 t in the Southern Zone, with total catch ranging from 15.4 t in 202/21 to 18.4 t in 2017/218. The Giant Crab fishing season in between 1 October 31 May, with the fishing season in the Southern Zone between 1 October and 30 April, and in the Northern Zone between 1 November and 31 May. The Planning Area overlaps the southern zone of the fishery. DPIR could not provide data specific to the area that the Environmental Planning Area overlaps as all data for the Giant Crab Fishery is confidential.		
Marine Scalefish Fishery	King George Whiting Southern Garfish Southern Calamari	Information in this section is from Smart et al. (2022). The Marine Scalefish Fishery is a multi-species and multi-gear fishery. Commercial fishing can be undertaken for more than 60 species of scalefish using a range of gear types. The Sardine Fishery is a part of the Marine Scalefish Fishery The Marine Scalefish Fishery operates in all coastal waters of South Australia between the Western Australian and Victorian border. For some species the Offshore Constitutional Settlement extends the fishery area out 200 nm to the Australian Exclusive Economic Zone miles. The fishing area includes gulfs, bays and estuaries, excluding the Coorong. The main species taken are: • King George Whiting • Southern Garfish • Southern Calamari. • Those 4 species comprise: • 60% of the total fishery production weight • 70% of the total fishery value. Not all species taken by this fishery are scalefish. Other species include squid, worms, sharks. In 2020 there were more than 300 licences in the fishery. Total annual catches of primary species decline from 2,089 t in 2001 to 807 tonnes in 2020. The Planning Area overlaps the fishery where there have been 15 active licences in 2012/13 to less than 5 in 2021/22 (Figure 4-86).	No	Yes

Rock Lobster Fishery	Southern Rock Lobster	The information in the section below is from Linnane et al. (2022). The Rock Lobster Fishery is based on the capture of Southern Rock Lobster (*Jasus edwardsii*). Other species are permitted to be landed and sold, including Giant Crabs and octopus. Rock lobsters are commercially harvested with pots that are set overnight. Rock lobster licence holders may also harvest marine scalefish as endorsed on their licence. The Planning Area is within the fishery Southern Zone which is closed from 31 May to 1 October (Figure 4-90). The total reported 2020 logbook catch was 1,275.5 tonnes (99% of TACC). The annual catch within the Planning Area ranged from 331-420 tonnes from 2012 to 2022. During this period the number of licence holders ranged from 43 to 71.	No	Yes

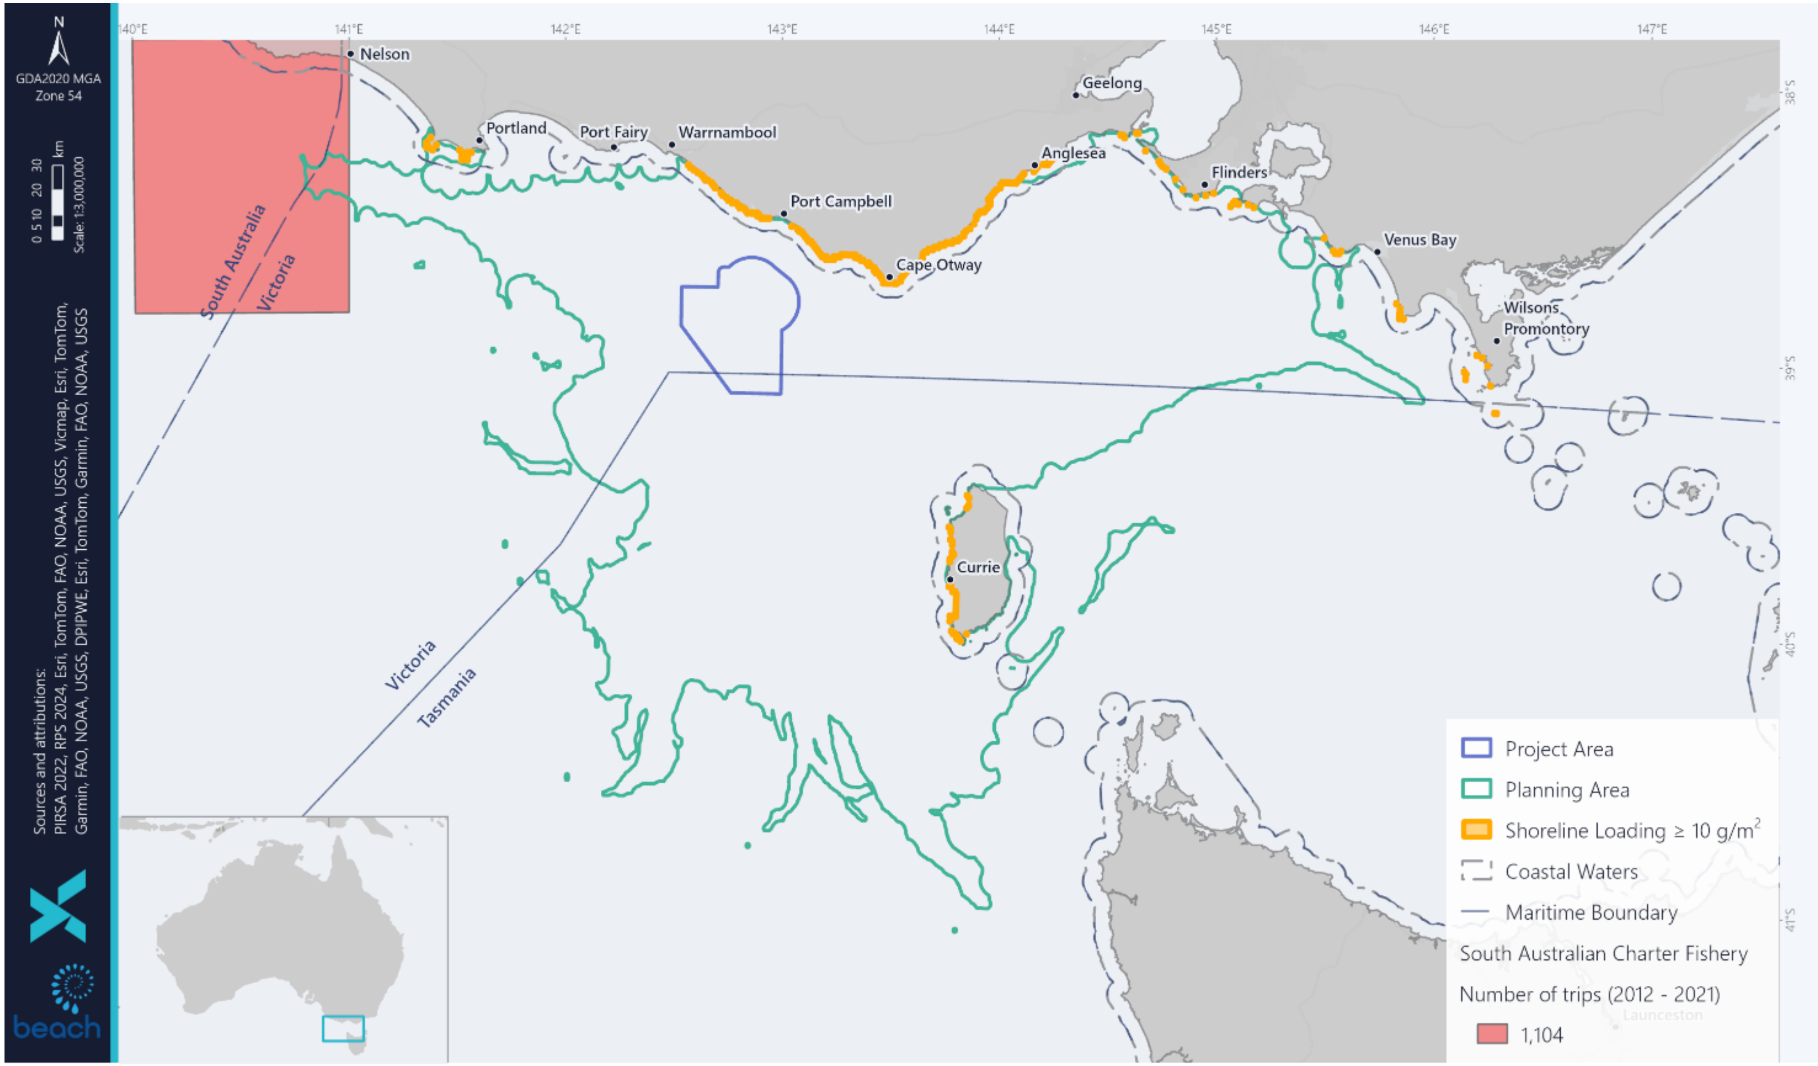

Figure 4-88: South Australian Charter Fishery Number of Trips from 2011-2021. Data obtained from PIRSA 2022.

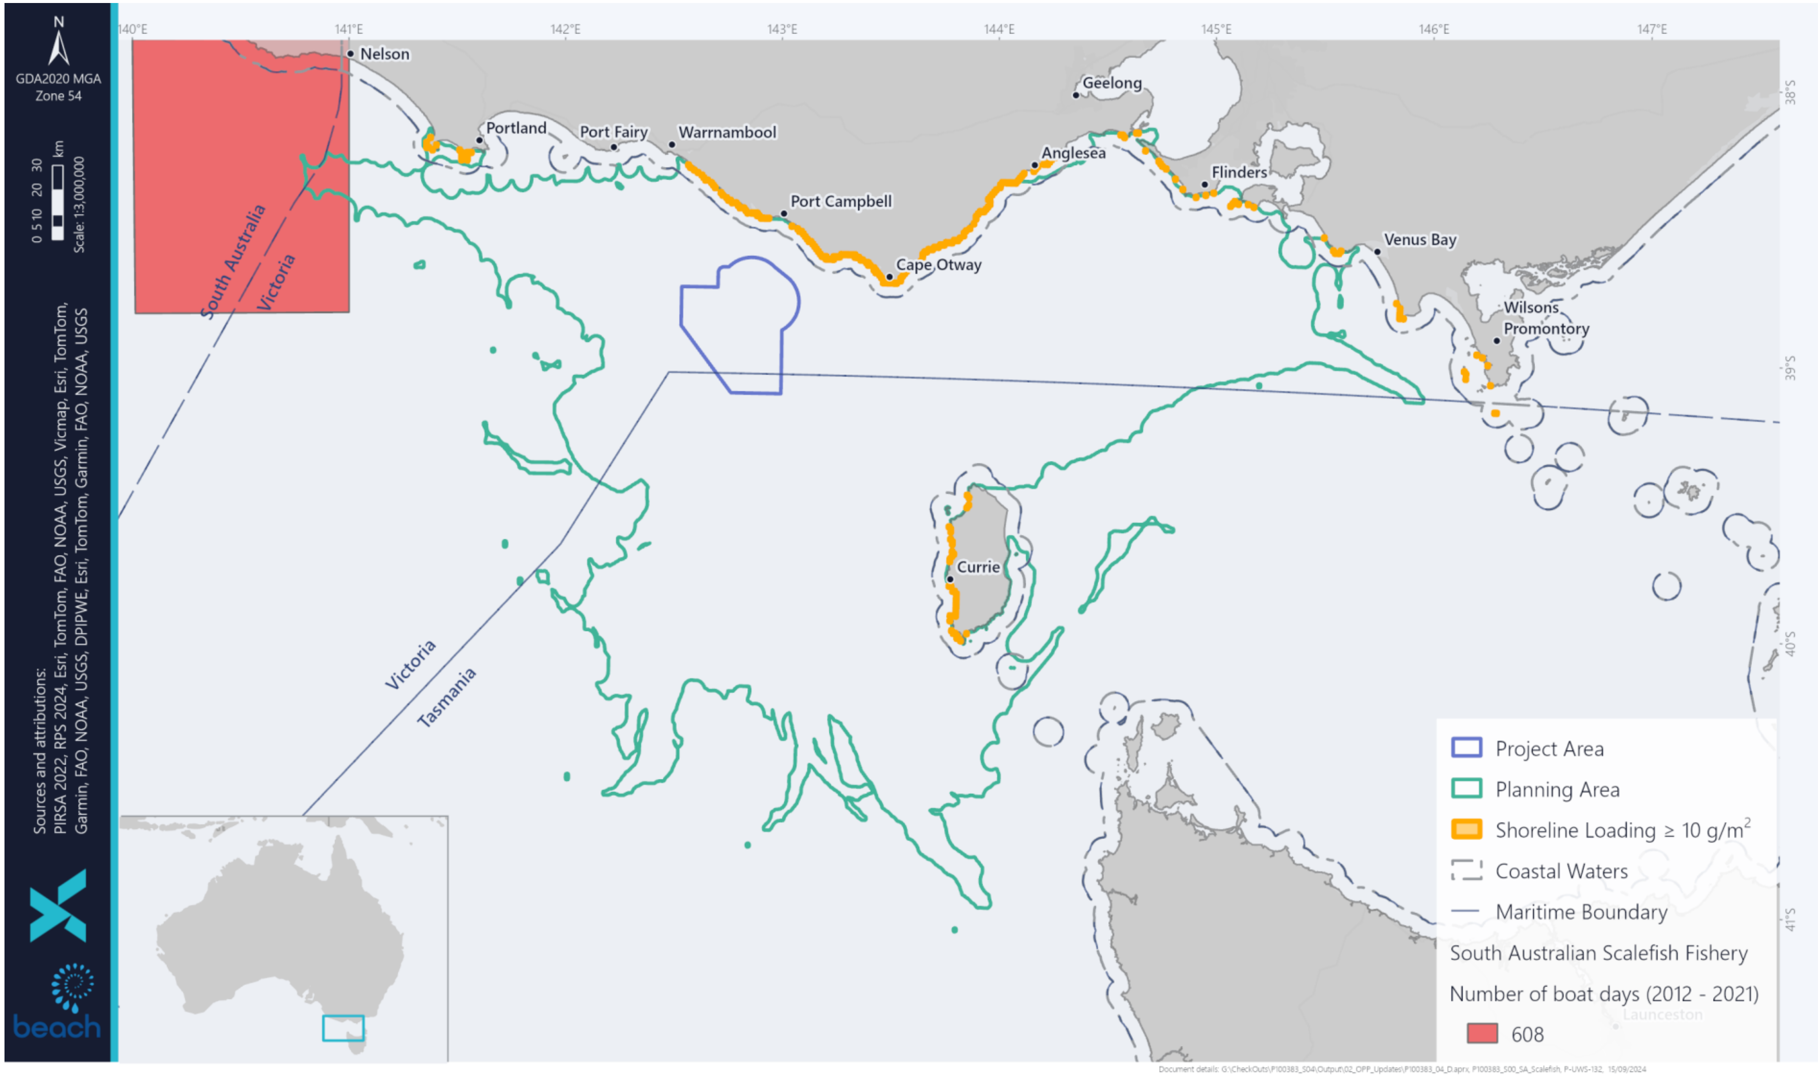

Figure 4-89: South Australian Scalefish Fishery Number of Boat Days from 2012-2021. Data obtained from PIRSA 2022.

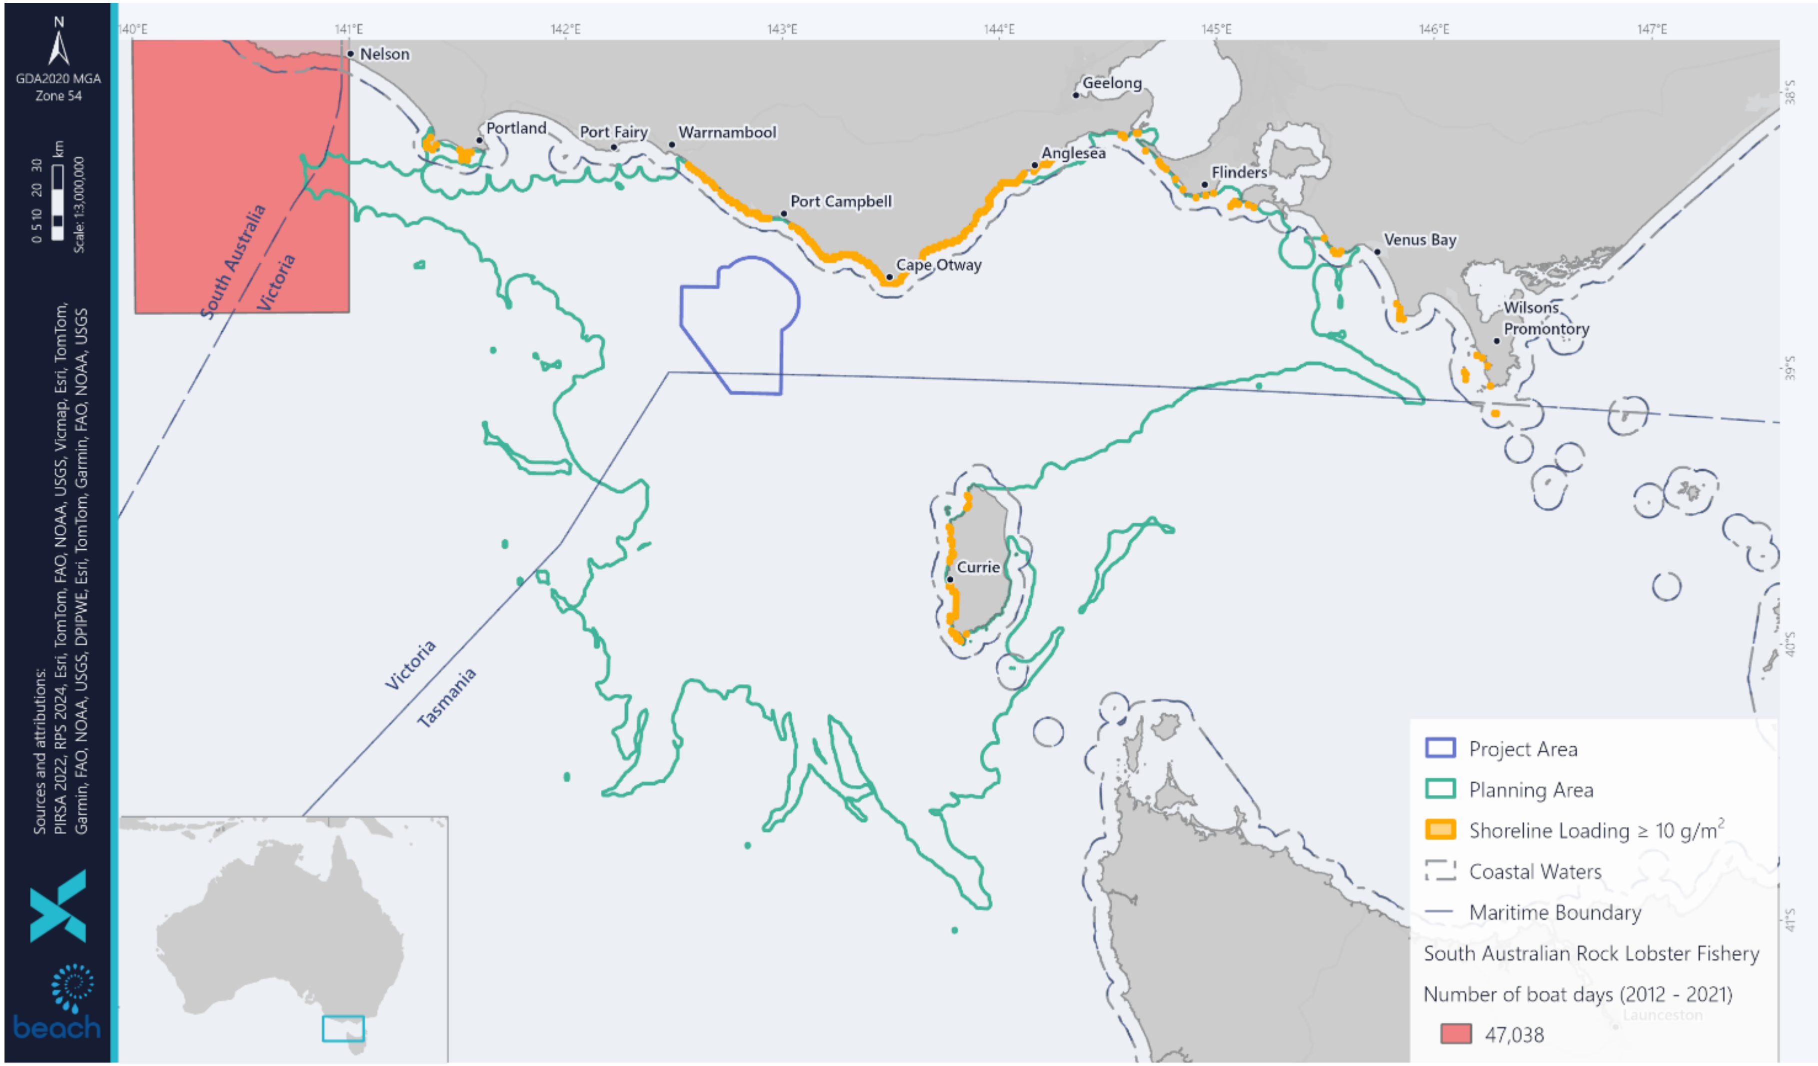

Figure 4-90: South Australian Southern Rock Lobster Fishery Number of Boat Days from 2012-2021. Data obtained from PIRSA 2022.

4.5.14 Seaweed Industry

The Australian seaweed industry is small: currently valued at an estimated GVP of AUD $3 million. Of this, the majority is from one company, Kelp Industries Pty Ltd on King Island in Tasmania, who hand collect plants cast bull kelp (*Durvillea pototorum*) on the beaches from predominantly the west coast of the island, predominantly for export to a large alginate manufacturer and for use in biofertiliser products (Australian Seaweed Institute 2023). Australia Bureau of Statistics (ABS) data shows seaweed exports from Australia are valued at $1.5 million for non-human consumption and it is assumed that this is almost entirely from Kelp Industries exports.

Besides Kelp Industries, other seaweed collectors in Tasmania include Kelpomix and TasKelp. There are also licenses for wild harvest of the invasive species of Undaria in Tasmania (KaiHo Ocean Treasure) and some in Victoria (Australian Seaweed Institute 2023).

The harvesting of native seaweed in Victorian marine waters is prohibited without a permit (s. 112(2) Fisheries Act 1995) and licences enabling seaweed aquaculture are not currently available in Victoria (VFA 2023a).

While there are numerous research projects taking place or being planned, currently there are two projects in Tasmania (Australian Seaweed Institute 2023). The first, is a CRC-P project involving collaboration with Tassal, Spring Bay Seafoods and University of Tasmania (UTAS). This project aims to demonstrate the benefits of Kelps as part of an integrated multitrophic aquaculture approach. The second is a research collaboration between UTAS and Huon Aquaculture in Storm Bay that will also yield its first harvest in late 2020. A Giant Kelp Marine Forest Restoration Plan is sponsored by the Tasmania Smart Seafood Partnership [PC184].

4.6 **First Nations**

4.6.1 Methodology to Identify Cultural Values and Sensitivities

The definition of environment in the OPGGS(E)R includes the people and communities, heritage value of places, and their social, economic, and cultural features. Specifically for First Nations peoples, this includes cultural heritage and sea country values which, in accordance with Indigenous tradition, may be a spiritual and cultural connection that may be affected by the Project.

Beach recognises First Nations Groups and their deep spiritual and cultural connection to the environment. The cultural values and features within the Project and Planning Areas are addressed in this section.

The description of the environment for cultural features and values was developed through:

- Consultation with First Nations Groups with connection to Sea Country in the Project and Planning Areas
- Review of available publications by First Nations Groups relating to Sea Country.
- Engagement of Extent Heritage Pty Ltd (Extent), a specialist archaeological consulting firm, to undertake a literature review and review of Beach's assessment.

Through these processes, and in particular, consultation with First Nations Groups, Beach is confident that the cultural heritage values, and cultural features and sensitivities of First Nations groups within the Project and Planning Areas have been identified.

4.6.2 Recognition of First Nations Groups

First Nation Groups and Traditional Owners and connection to Country is recognised through contemporary laws such as the Commonwealth *Native Title Act (1993)*, as well as various State laws and agreement making (e.g. *Traditional Owner Settlement Act 2010* (Vic) and Aboriginal Heritage Acts).

While connection to Country for some First Nations Groups has been formally recognised through native title, other First Nations Groups and their connection and rights to land and sea is recognised through relevant State legislation.

A review of the statutory laws, rights and recognition conferred to First Nations Peoples within the Planning Area is summarised in the below sections.

4.6.2.1 Native Title

The Commonwealth *Native Title Act 1993* is an Australia-wide native title scheme with the following key objectives:

- Providing for the recognition and protection of native title.
- Establishing a mechanism for determining claims to native title.
- Establishing ways in which future dealings affecting native title (future acts) may proceed.

Native title is the formal recognition that Aboriginal and Torres Strait Islander people have rights and interests to land and waters according to their traditional law and customs.

A key principle for native title determination is for First Nation's people to establish and prove that Indigenous people have an unbroken and current connection to their lands and waters and in practicing their culture from the time of European settlement.

Native title can be granted with non-exclusive or exclusive rights to lands and waters. Non-exclusive native title can include, for example, the right to live and camp on an area, and hunt and fish, and can co-exist with the rights of other land users. In sea areas, only non-exclusive native title can be recognised as exclusive native title is considered inconsistent with other common law rights regarding marine access and navigation (Native title 2010).

The Federal Court of Australia first recognised native title over the sea for the Traditional Owners of Croker Island in Arnhem Land in 1998 (Tribunal File No. DCD 1998/001). Since the Croker Islands Seas native title determination, (non-exclusive) native title in sea country has been recognised along Australia's coastline through numerous claims and determinations under the Native Title Act 1993.

A search of the National Native Title Tribunal (the Tribunal) database identified the following native title claims and consent determinations within the Planning Area.

1. Victoria
    a. Eastern Maar People

The Eastern Maar People made application to the Federal Court of Australia for a native title claim which was accepted and registered on 20 March 2013 (Tribunal File No. VC2012/001). A consent determination by the Federal Court of Australia recognising the native title rights for the Eastern Maar Peoples was registered on 28 March 2023 (Tribunal File No. VCD2023/001). The native title area is located in south-western Victoria near Port Fairy along the Great Ocean Road, up to Ararat in the north, and to Colac in the East and extends seaward 100 m from the mean low-water mark of the coastline (Figure 4-91; NNTT 2016).

The determination recognises Eastern Maar's non-exclusive right to access, use, and protect public land in accordance with their traditional law and custom. The Eastern Maar First Nations Corporation (EMAC) is the registered native title body corporate under the *Corporations (First Nations and Torres Strait Islander) Act 2006* and manages the native title rights for the Eastern Maar Peoples.

    b. Gunditjmara - Part A

A consent determination recognising the native title rights of the Gunditjmara People was registered on 30 March 2007 (Tribunal File No. VCD2007/001) over 140,000 hectares in South-west Victoria (Figure 4-91). The determination recognises Gunditjmara People's native title rights and interests in traditional lands and waters and provides non-exclusive rights to access, use, and protect public land in accordance with their traditional law and custom. The Gunditj Mirring Traditional Owners Aboriginal Corporation (GMTOAC) is the registered native title body corporate under the *Corporations (First Nations and Torres Strait Islander) Act 2006* and manages the native title rights for the Gunditjmara Peoples.

    c. Gunditjmara and Eastern Maar

On 27 July 2011, the Federal Court of Australia determined (Tribunal File No. VCD2011/001) that both the Traditional Owners represented by GMTOAC and the EMAC are the native title holders for the land and waters between the Shaw and Eumeralla Rivers from Deen Maar (including Yambuk) to Lake Linlithgow (Figure 4-91). The native title includes Deen Maar (Lady Julia Percy Island) which holds deep and significant cultural association for Traditional Owners.

    d. Wadawurrung People

A native title claim application was registered for the Wadawurrung People on 24 July 2023 (Tribunal File No. VC2022/002). The claim area covers land and waters covering about 12,510 km^2 on the southern coast of Victoria (Figure 4-91). The application area is located south-east of Ararat and extends towards the coast around Sugarloaf, Geelong, and Port Phillip Bay.

    e. Gunaikurnai People.

A determination by the Federal Court of Australia recognising the native title rights of the Gunaikurnai People over parts of the determination area was registered on 22 October 2010 (Tribunal File No. VCD2010/001). This determination area exists outside but adjacent to the Planning Area.

The area covers the land and waters, including sea country, from Wilsons Promontory to Newmerella, and includes the culturally significant Nooramunga Marine & Coastal Park and Lakes Entrance and connected wetlands (Figure 4-91). The Gunaikurnai Land & Waters Aboriginal Corporation is the registered native title body corporate under the *Corporations (Aboriginal and Torres Strait Islander) Act 2006* and manages the native title rights for the Gunaikurnai People.

2. Tasmania

There are no native title areas in Tasmania.

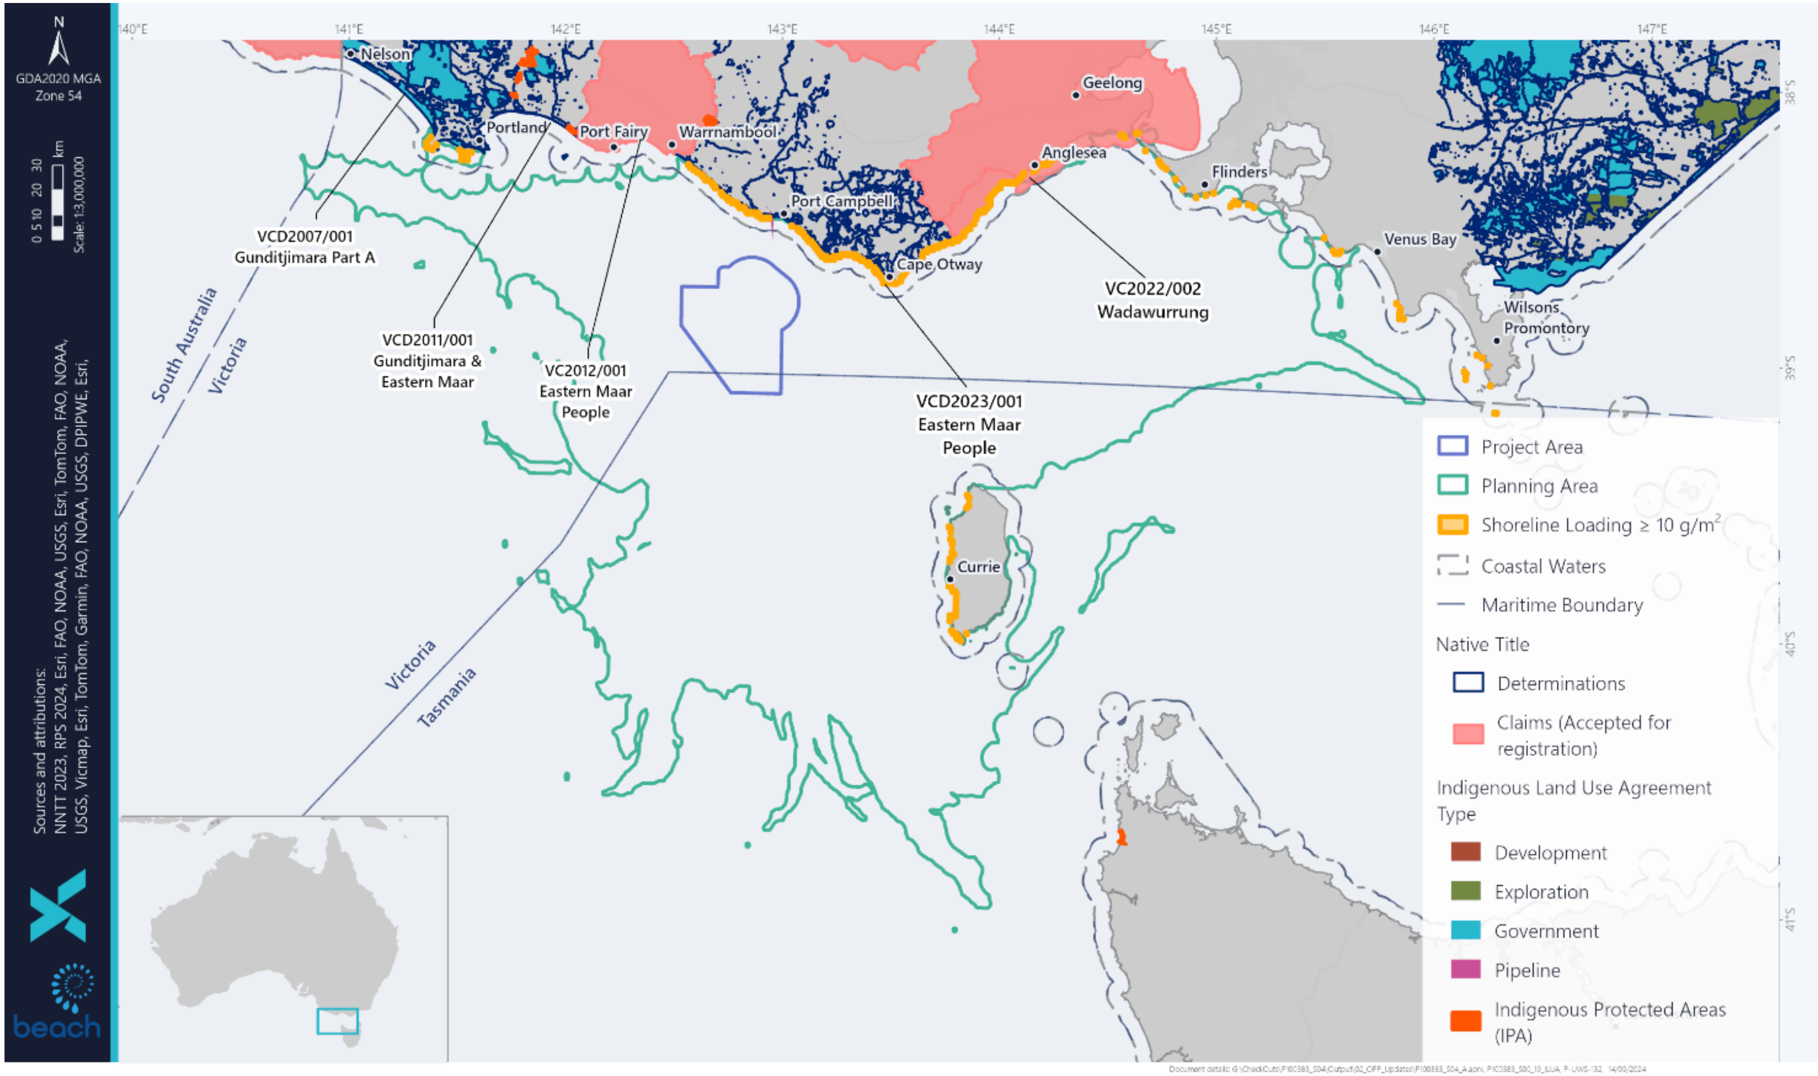

Figure 4-91: Native Title, Indigenous Protected Areas, and Indigenous Land Use Agreements relevant to the Project

4.6.2.2 Registered Aboriginal Parties

As an operator in Victoria, Beach is also cognisant of the *Aboriginal Heritage Act 2006* (Vic) (AHA 2006 VIC) that recognises a Registered Aboriginal Party (RAP) as the Traditional Owner Corporation to manage and protect First Nations cultural heritage over their Country including coastal and onshore waters. The AHA 2006 VIC recognises RAPs as the primary guardians, keepers and knowledge holders of First Nations cultural heritage and the primary source of advice and knowledge on matters relating to First Nations places or objects in the appointed RAP region.

The following groups are recognised RAPs within the Planning Area described in this OPP:

- Bunurong Land Council Aboriginal Corporation
- Eastern Maar Aboriginal Corporation
- Gunaikurnai Land and Waters Aboriginal Corporation
- Gunditj Mirring Traditional Owners Aboriginal Corporation
- Wadawurrung Traditional Owners Aboriginal Corporation

Figure 4-92 details the location of these Registered Aboriginal Parties.

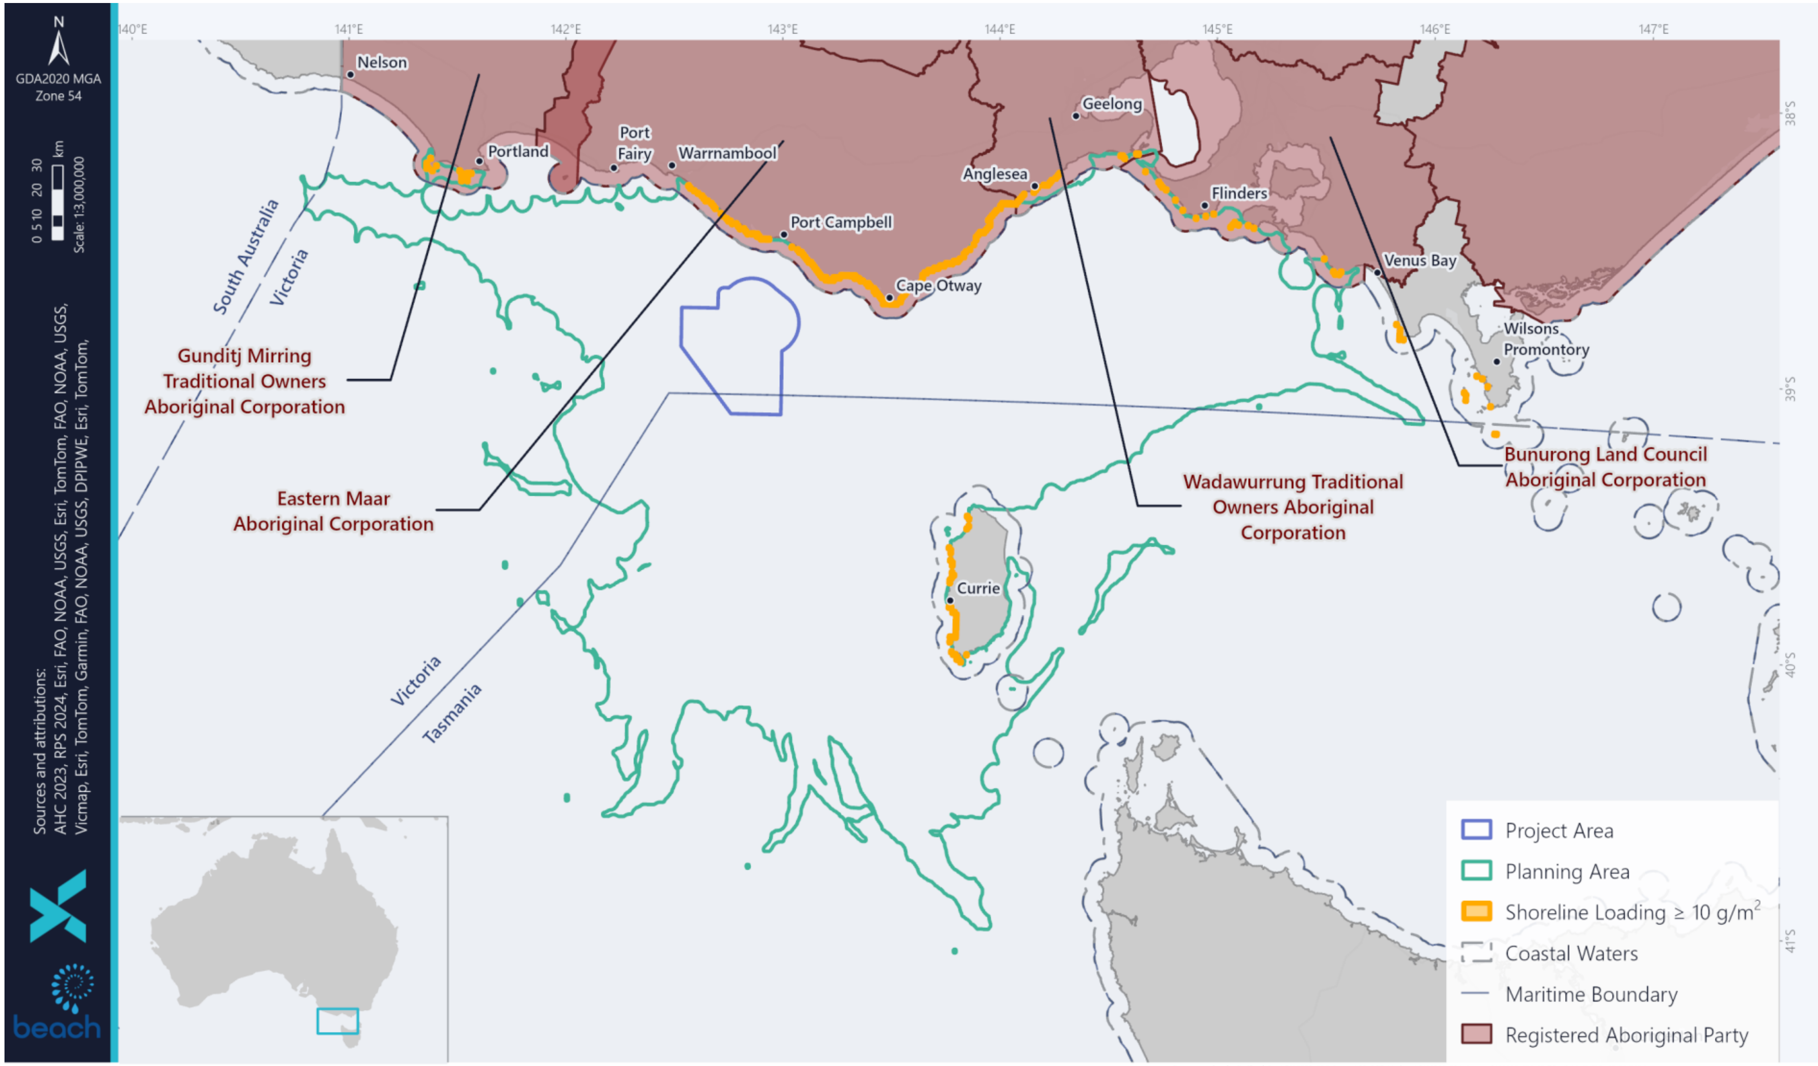

Figure 4-92: Registered Aboriginal Parties relevant to the Project

4.6.2.3 Indigenous Land Use Agreements

An Indigenous land use agreement (ILUAs) is a voluntary agreement between a native title group and other parties on the use and management of land and waters. ILUAs are established by the *Native Title Act 1993*.

No registered ILUAs were identified within the Project Area. The following ILUAs have been identified in the Planning Area:

- VI2006/004: Gunditj Mirring and State of Victoria.
- VI2010/001: Gunditj Mirring Non-Extinguishment Principle ILUA.
- VI2015/002: Gunditjmara – SEAGAS Port Campbell VIC to Torrens Island SA Pipeline ILUA.
- VIA1999/001: BHPP – Minerva.
- VIA2000/004: Blairgowrie.

ILUA locations are shown in Figure 4-91.

4.6.2.4 Land Rights

Most states and territories have legislation which sets out land rights arrangements with First Nations peoples within their jurisdiction. In most cases the statutory land rights legislation does not extend to marine areas. An exception is under the *Traditional Owner Settlement Act 2010* (Vic) which provides the possibility of agreements to extend to marine areas.

1. Victoria

In Victoria, the *Traditional Owner Settlement Act 2010* (Vic) was developed as an alternative approach to the native title process that recognises traditional owners' relationship to land and provides certain rights on Crown land.

The Gunaikurnai People entered into an agreement with the State of Victoria under the *Traditional Owner Settlement Act 2010* (Vic). An agreement to commence negotiate a recognition and settlement agreement between the Eastern Maar and the Victorian Government under the Traditional Owner Settlement Act 2010 was announced in 2017 (Justice and Community Safety (Vic) 2023).

In Victoria, the *Aboriginal Nations Heritage Act 2006* (Vic) recognises a Registered Aboriginal Party as the Traditional Owner to manage and protect First Nations cultural heritage over their Country including coastal and onshore waters.

2. South Australia

In South Australia, the *Aboriginal Land Trust Act 2013* (SA) is land rights legislation that provides for land to be acquired, held, and managed by the Aboriginal Lands Trust. No land rights have been granted or agreed under the relevant SA legislation within the Project or Planning Areas.

3. Tasmania

Tasmania does not have a First Nations land rights legislative regime. Rather, under the *Aboriginal Lands Act 1995* (Tas), grants of land parcels of historic or cultural significance 'to promote reconciliation with the Tasmanian Aboriginal community' may be made and vested in the Aboriginal Land Council of Tasmania. Some islands in the Bass Strait and adjacent to the Planning Area, such as Badger Island and Clarke Island, were returned to the Tasmanian First Nations community under the *Aboriginal Lands Act 1995*.

4.6.2.5 Indigenous Protected Areas

Indigenous Protected Areas (IPAs) are areas of land and sea managed by First Nations groups through their custodianship and stewardship obligations for Country. IPAs deliver biodiversity conservation outcomes for the benefit of all Australians, through voluntary agreements the Traditional Owners of land or sea and the Australian Government. The IPA program has a dual purpose of achieving conservation obligations and providing sustainable uses to deliver social, cultural, and economic benefits for local Indigenous communities. Indigenous People are active participants in the management of IPAs through land and sea ranger programs and other custodian and management activities.

No IPAs were identified in the Project Area or Planning Area (Figure 4-91). One future sea country IPA is likely to overlap with the Planning Area which is described below.

1. Future Sea Country IPAs

The Australian Government, through DCCEEW, is expanding the IPA program. In 2021-22 the Australian Government announced a program to expand the IPA network to include coastal and marine areas (the Sea Country IPA Program). Through the Sea Country IPA Program, the Australian Government is seeking to strengthen the conservation and protection of the marine and coastal environments, while creating employment and economic opportunities for Indigenous People (DCCEEW 2024c).

Of the ten future Sea Country IPA consultation projects announced in 2022, one is located within the Planning Area (DCCEEW 2024c). No spatial data is available for the Sea Country IPAs at the time of writing.

a. Gunditjmara Sea Country IPA, Victoria (Gunditj Mirring Traditional Owners First Nations Corporation with Eastern Maar First Nations Corporation)

The IPA consultation area is located in south-west Victoria from the Convincing Ground north-east of Portland to Yambuk Lakes in the east. The area includes volcanic plains, rivers, coast, estuaries, and coastal wetlands, and is an important breeding place and nursery for fish, eels, and birds, including nationally listed species. The area's waters encompass sites of national geological and geomorphological importance, and habitat for threatened marine animal species. The area also incorporates important cultural sites such as Deen Maar Island, which has a central role in the creation story of Gunditjmara Country. Whilst Budj Bim is located outside of the Project and Planning Areas, the Sea Country IPA Program will allow Traditional Owners to further protect the Budj Bim Cultural Landscape with activities including implementation of on land/sea management activities; community employment and capacity building; sharing and documentation of traditional knowledge; and the development and enhancement of regional partnerships.

4.6.3 Cultural Values and Sensitivities

4.6.3.1 Country and Sea Country Overview

Country is a cultural landscape, it includes the tangible (cultural heritage) and intangible (song, creation stories and cultural practices). First Nations cultural concepts are firmly intertwined with the nature of the environment, of Country. Country describes all aspects of place, environment, spirituality, law, and identity. Part of Country that extends into the oceans is known as Sea Country. Values of Country differ between First Nations groups, and not all First Nations groups and communities in Australia hold the same belief systems as formational pillars of their community or spirituality. Differences can be due to aspects of post-colonialism, such as dispossession, genocide, and cultural practice restrictions.

Due to the varied culture and history of First Nations groups, and in particular owing to various degrees of dispossession and removal from country, loss of connection, and continuation of culture, the responses of First Nations communities to caring for and talking about Country are different throughout Australia. These individualised but community-based beliefs and values contribute to the need for a varied and responsive approach to managing cultural (tangible and intangible) values.

A cultural landscape is about both pre-colonial and contemporary interactions between humans and the physical environment including non-human animals, plants, physical structures, ancestors, song lines, trade routes and other significant cultural connections to Country. Cultural landscapes are reflections of how First Nations people engaged with Country, as they see that landscape features are not just physical features, their understanding is that the landscape intrinsically connects the past and the present to people, stories, and history.

Smyth and Isherwood (2016) describe Sea Country as all estuaries, beaches, bays, and marine areas collectively, within a traditional estate. Sea Country contains evidence of the ancient mystical events by which all geographic features, animals, plants, and people were created. Sea Country contains sacred sites and contains tracks (or song lines) along which mythological beings travelled during the creation period (Smyth and Isherwood 2016). The sea, like the land, is integral to the identity of First Nations groups. Connection to Sea Country is accompanied by a complexity of cultural rights and responsibilities. Formal recognition of Sea Country rights lags considerably compared to land rights; this could be for a range of reasons including conflicting perspectives and opinions on traditional custodianship of land and how far it extends (Smyth and Isherwood 2016).

Coastal areas were amongst the most densely populated areas, due to abundance of resources. Sea Country, as it does on land, has been found to contain evidence of the ancient Dreamtime events by which all geographic features, animals, plants, and people were created. Sea Country may contain sacred sites, which may be related to these creation events, and it contains tracks (or Songlines) along which ancestral beings travelled during the creation period. Sea Country has a continuing cultural value because of the connection to creation and dreaming stories, ceremonial sites, and places of occupation.

Country is the term often used by First Nations people to describe the lands, waterways, and seas to which they are connected. The term contains complex ideas about law, place, custom, language, spiritual belief, cultural practice, material sustenance, family, and identity (AIATSIS 2022). Sea Country also known as Saltwater Country extends into the Project and Planning Areas.

4.6.3.2 Sea Country within the Project and Planning Areas

There are First Nations groups with Native Title recognition in areas adjacent the Project and Planning Areas. However, it is important to also acknowledge and respect the intangible cultural values and sensitivities that exist for other First Nations groups described in this section that are not directly adjacent to the Project Area, due to the interconnectedness of marine ecosystems and existences of various marine fauna and flora and intangible cultural values.

The land adjacent the Project and Planning Areas is the traditional land of the Eastern Maar Peoples legally represented by the EMAC. EMAC is both a Registered Aboriginal Party and a Recognised Native Title Prescribed Body Corporate. Eastern Maar land extends north to Ararat and encompasses Port Fairy, Warrnambool, Port Campbell, and other areas along the Great Ocean Road. It also extends 100 m out to sea from low tide and therefore includes the iconic Twelve Apostles (EMAC 2024). Based on consultation, Eastern Maar have always had a close connection with Sea Country which has nourished and supported their ancestors for thousands of years. Sea Country for Eastern Maar holds significant Dreaming stories, telling the story of their ancestors movement across Country. Harvesting of eel, or “Kooyang”, is incredibly important to the Eastern Maar today and remains a cultural practice handed down from their ancestors.

The land adjacent the Planning Area includes the traditional lands of the Wadawurrung people. Sea Country, or “Warre” for Wadawurrung extends from Painkalac Creek at Aireys Inlet, east into Port Phillip Bay and to the Werribee River and to the north as far as Mt Emu and Fiery Creeks (Clark 1990). Based on consultation, for the Wadawurrung peoples, Warre, holds the stories and footprints of their ancestors, with Warre being a place to meet, trade, share meals and practice ceremony. Eel, or Beniyak, have cultural significance to the Wadawurrung peoples.

The Wadawurrung native title claim and registration decision (Tribunal File No. VC2022/002) state that the claimants see Wadawurrung country and its waters as an anatomical being, with its head to the south, spine to the east, feet to the north and the arms lying along the Otway coast. This posture and orientation is replicated in traditional burial practices. Names of places in Wadawurrung language also follow the same theme and are named after body parts, like spine, head, tongue, or elbow. The Wadawurrung ‘see our Dja land and Warre sea Country as all one’ (WTOAC 2020).

Also adjacent to the Planning Area is the lands and Sea Country of the Gunditjmara. Gunditjmara recognise four types of landscape across their Country Sea Country, as one of the four, “Koonang Mirring” is defined by the meeting of salt and fresh water. Abundant in shellfish, fish, and birds, it also has a history of conflict and violence between the Gunditjmara and colonial settlers. Koonang Mirring includes the submerged landscape and the place where the spirits of Gunditjmara ancestors cross the sea to Deen Maar (CoA 2017b). The Gunditjmara published their Sea Country Plan, Gunditjmara Nyamat Mirring Plan 2023-2033, on 13 March 2024 (GMTOAC 2023). This plan details Gunditjmara’s values and species of cultural significance in the Sea Country [PC196, etc].

The Bunurong First Nations peoples are the Traditional Owners of the Victorian land adjacent to the Planning Area. They are represented by the Bunurong Land Council Aboriginal Corporation (BLCAC). Bunurong Country extends from the Werribee river to Wilsons Promontory includes some of the submerged land bridge to Tasmania. Through consultation with Beach, BLCAC advised that Sea Country is very significant for cultural practices and ceremony. Eels hold special cultural significance for the Bunurong people.

The Project and Planning Areas are also adjacent to lutruwita (Tasmania) The palawa (Tasmanian First Nations) are the Traditional Owners of lutruwita (Tasmania). Palawa people have inhabited Tasmania for at least 35,000 years. At the end of the last ice age the sea level rose, and Tasmania became isolated from the mainland of Australia. They survived in the changing landscape partly due to their ability to harvest aquatic resources, such as seals and shellfish. Following conflict between the European colonists and the Tasmanian First Nation peoples, many were relocated to missions on Bruny Island, Flinders Island, and other sites, and finally to Oyster Cove. Through consultation with Department of Premier and Cabinet and Department of Aboriginal Affairs Tasmania, Beach understands that kelp, whales, and mutton birds hold special cultural significance for First Nations peoples on mainland Tasmania, King Island and Flinders Island.

4.6.3.3 Sea Country Values

The Planning Area overlaps the South-east Marine Region. Indigenous uses and values within the South-east Marine Region are described in Sea Country - an Indigenous Perspective (NOO 2002). Specifically, Indigenous activities described in the South-east Marine Region Profile (CoA 2015) state:

Most parts of coastal Australia are of continuing cultural and spiritual significance to Indigenous people, many of whom engage in subsistence hunting, fishing and gathering and depend directly on marine resources for food. Through their involvement in commercial activities, many Indigenous people also depend on marine resources for their income.

Fishing is an important part of Indigenous culture, and a variety of methods and equipment are used, including hand gathering, lines, rods and reels, nets, traps and spears. Indigenous fishing targets a range of species of fish, shellfish, crabs and worms that are used for food, medicine or bait. Abalone, crab and lobster harvesting are important Indigenous fisheries. Indigenous people in south-eastern Australia engage in fishing and shellfish collecting on a regular basis and are involved in commercial fishing activities.

Indigenous people in the South-east Marine Region have articulated particular aspirations in terms of access rights and traditional use of marine resources, participation in management processes, and participation in the fishing sector.

First Nations people’s interests in the South-east Marine Region, are diverse and complex. Indigenous people live around the region in major cities, regional centres, small towns and on First Nations land. Coastal areas of south-east Australia were amongst the most densely populated regions of pre-colonial Australia. These highly populated areas provided an abundance of marine and other resources. However, we know that many have been displaced from the coastal areas (NOO 2002).

It is recognised that spiritual corridors extend from terrestrial areas into nearshore and offshore waters, that a number of marine animals are totems for Indigenous people, and that songlines pass through marine parks.

4.6.3.4 Sea Country Values - Resources

1. Adornment and Function

Frequently, tangible resources, such as food items, animal and plant species, and other resources, such as stone, bone and wood, are also tied strongly to intangible elements of First Nations culture. First Nations people of Tasmania, the palawa, were noted for creating durable and waterproof containers of sea-kelp threaded and dried to shape on wooden handles. In addition, shells were collected and worn as adornment. Throughout south-eastern Australia, reports of seaweed use include for cultural and ceremonial activity, medicine, clothing, food, fishing, and domestic/shelter uses (Thurstan et. al 2017). The Wadawurrung, for example, used "pink seaweed" as a poultice for jellyfish stings (Lane 1980).

Other fish and shellfish species have been noted by community during consultation, including abalone, cockles, and rock lobster (crayfish). The Eastern Maar have noted the migration routes of crustaceans as of notable significance. The Wadawurrung mention that crayfish, mussels, oysters, pipis, and fish provided important bush tucker, medicines, and other resources. Fish were caught using hooks, nets, and traps (WTOAC 2020). Other species were specifically not eaten or associated with other custom, for example, the Stingray (Baalangurk) was not eaten by the Kurnai (Howitt n.d.). Swans were hunted with boomerangs and spears, whilst other birds were caught in nets woven from plant fibres (WTOAC 2020).

2. Eels

It has been well documented that the Gunditjmara employed complex systems of aquaculture, comprising channels, weirs, and dams, to harvest kooyang (eels) on their Country (CoA 2017b). The migration of juvenile eels from freshwater to the ocean to mature and breed is integral to the survival of the species, and their physical health is inherently tied to the spiritually of the Gunditjmara. The aquaculture system is an economic and social base for Gunditjmara society (CoA 2017b). Eels and their migration are also held in social and cultural significance by the Eastern Maar, as neighbours to the Gunditjmara sharing many similar beliefs of their significance. Other coastal and river groups, including the Wadawurrung (buniya) and Bunurung, also utilised eels as an important resource and seek to protect their migration along rivers, creeks, and into the oceans. Section 4.4.9.3 provides more details on eels.

The Kulin and Kurnai Dreaming Story of Lo-an includes Lo-an and his wife Lo-an-tuka surviving mostly on eels cooked in a marin-a-thung (earth oven) on the Yarra flats. After finding a feather on his chest, Lo-an with Lo-an-tuka proceeded to follow the breeze to find the swans that the feather had come from and walked to the shores of Western Port. They camped for a long time feeding on swans and continued following the coastline to Corner Inlet. The Kulin believe they became the stars Sirius and Canopis. The Kurnai believe Lo-an is upon his mountain and looks out towards to sea, watching over the people (Massola 1968).

3. Whales

Through consultation, whales and whale migration have been noted as of significance by coastal groups in Victoria. Eastern Maar have noted the migration routes of the southern right and blue whale as of social and cultural importance. The same whale species are similarly noted by the Gunditjmara and Wadawurrung.

First Nations communities in the south-east of Australia often saw whales as spirits that transformed when they entered the water, creating a respectful relationship between whales and First Nations communities.

Kartnubul (whales) have featured in dreaming stories, ceremony, song and dance of Gunditjmara people for millennia. Gunditjmara maintain a strong spiritual connection to all species of whales that travel through Gunditjmara country (GMTOAC RNTBC 2023). Karntabul yarkeen (whale dreaming) stories connect Aboriginal groups all along the coasts of Australia, neighbouring groups in Victoria, including Gunditjmara, still gather today to strengthen the connection of groups to whales and their stories. The arrival of Karntabul in Gunditjmara waters also signifies the beginning of the 'big wet' season (May-Oct), 1 of 6 Gunditjmara seasons. Whales are also a food source, in traditional times, tribes would send up smoke signals and gather when whales got beached. Protection of whales is paramount to Gunditjmara spiritual, physical wellbeing (GMTOAC RNTBC 2023). [PC230]

Whale hunts took place from small, shore-based vessels, and targeted smaller animals (Eldridge 2015). First Nations methods of hunting may have included using fire and smoke to lure the whales to the coast and bays (Eldridge 2015), and the opportunistic utilisation of beached whales also occurred, which may have prompted periods of intense gathering of people and ceremony like those observed by early settlers such as Henty (Eldridge 2015). In Howitt's notes on the Kurnai, whales are called Ganda - 'Dead whales thrown up by the sea were supposed to have been killed by the Mrarts [ghost or spirit] and birds called Yauruk [or Yara-wuk] and sent ashore. The Mrarts then communicated to the Biraaks who told the Kurnai where to go and find the Ganda. (Howitt n.d.).

The Gunaikurnai have noted bottlenose dolphin at Lakes Entrance, and the significance of dolphins is echoed by the Wadawurrung. Wesson (2001) notes that 'the souls of prominent community leaders [were] reincarnated as dolphins and orcas'.

4.6.3.5 Sea Country Intangible Values

Landforms and landscape features in and surrounding watery places are known to hold particular significance for First Nations coastal communities. Islands off the Southern Ocean coastline have cultural importance to First Nations people as Islands of the Dead and are frequently connected to the shore by journey-after-death stories (Draper 2015).

For example, the Gunditjmara of Western Victoria seasonally occupied the caves and escarpments in the coastal limestone karst formation. These caves at Cape Bridgewater are associated with Bunjil who descended from the caves where he resided to walk along the shoreline (Bonwick 1858). The Gunditjmara believe that 'Bunjil, their creator and eagle and his brother Pallian ascended to the sky from Deen Maar in a sheet of flame after creating the land and sea and all living things' (Draper 2015). Mathews (1904) noted that the Gunditjmara buried their dead on the mainland with their heads pointed to Deen Maar island where their souls would be transported to await reincarnation. Dawson (1881) records that a haunted cave, Tarn wirring 'road of the spirits', is believed to form a passage between the mainland and the island, and the good spirit 'Put put cheptech' conveys the spirit from the island to the clouds. Other Islands in south-eastern Australia, such as Kangaroo Island (Karta), hold similar stories.

Contact and post-contact places are also noted to be in or adjacent to Sea Country, and these include sites of massacre and dispossession. The site of the Convincing Ground massacre (1833/34), where a group of whalers murdered Gunditjmara over ownership of a stranded whale, is located north of Allestree on the Portland coast. This place continues to be a place of great sorrow for the community. Other coastal massacre sites include on the Aire River Estuary at Cape Otway (1846), Eurmerella (1842), Freshwater Creek (1843) Twofold Bay (1806), and Cape Grimm (1828) (Newcastle University 2024). Missionary activity and forced removal of First Nations people in Tasmania resulted in detainment of First Nations people on Flinders Island (at Wybalenna). Other First Nations groups were taken to Swan Island and Gun Carriage Island. This detainment resulted in significant loss of life, and a loss of culture, language, and connection.

1. Law, Spirituality and Songlines

Intangible heritage refers to the cultural assets, cultural knowledge and intellectual property collectively held by First Nations and may involve practices, oral traditions, ancestral narratives, performing arts, local knowledges and practices concerning nature, the environment, and the universe. Intangible cultural heritage performs an important function of safeguarding to recognise and protect knowledge and skills that are transmitted through it from one generation to the next.

Songlines are described as short songs pertaining to the travels and exploits of ancestral beings during the Dreamtime. These songs are usually sung in association with a ritual activity, particularly dancing (Tonkinson 1972). Songlines are stories ancestral beings which includes creation stories, they are multipurpose the stories educate and uphold traditional lore, they are also communication and trade routes. (Fuller & Busill 2021).

Understanding First Nations songlines and stories also means understanding the Dreaming. Often described as the 'Dreamtime', or 'deep time', recognising the existence of Dreamtime beyond the Western concept of past, present, and future.

First Nation's people around Australia have long had a strong connection to whales, which has significance as totemic ancestors to some groups. The arrival of whales along Australia's coastline marked the arrival of the "elders of the sea", which follows a songline or ancient memory code, that traces the journeys of ancestral spirits as they created the land, animals, and lore.

In Victoria, Koontapool (southern right whales) occur along the coastlines of south-west Victoria in Gunditjmara Sea Country to feed and birth. These Koontapool Woorrkngan Yakeen (Whale Birthing Dreaming Sites), are in coastal bay areas from Port Campbell to Portland, including Warrnambool. These places on Gunditjmara Country are known resting and feeding sites for mothers and calves and are directly related to Gunditjmara Neeyn (midwives), explaining why Gunditjmara is a Matrilineal Nation. (DCCEEW 2024o).

A Kulin Dreaming story includes Angel Cave (between Port Philip and Western Port) where "One Day Bunjil, the All Father, was walking upon the sea, when suddenly there rose a great storm. Bunjil walked to the rocky shore and spoke to it, and immediately the shore rose up into a cliff and the cave was made before his eyes. Bunjil stepped into it and sheltered there till the storm was over' (Massola 1968).

A Kurnai Dreaming story of Port Albert includes the sick frog, Tide-lek, who drank all the water from the land. He didn't feel sick anymore, but he felt bad for leaving the people with nothing to drink. He walked across Port Albert one day and everyone tried to make him laugh to regurgitate the water, but they all failed until No-yang (the eel) danced on his tail and Tide-lek laughed and the land flooded. Many people died or were marooned, forming the islands. The pelican saved people with a large canoe. As part of this Dreaming Story, the pelican also formed the white pipe-clay used for ceremony at White Rock, the southernmost Island of the Seal Group east of Wilsons Promontory (Massola 1968).

As part of the Kurnai creation stories the first man and woman were Borun the pelican, and Tuk the musk duck (VACL 2014). Totemic Species are spiritually important and can be bestowed in a number of ways – through family relations or through ceremony. Randall Mumbler, from the Eurobodalla region, for example, discusses that '… Fish are more likely to be ceremonial totems; it is not common to have a fish as a totem… I have certain species that I can't fish for or eat. These rules have been placed upon me through ceremony and so I stay away from them. There are certain fish that my brother and I never eat. That is also like a conservation thing…it keeps that species alive…" Randal Mumbler (in Donaldson 2012).

The Eastern Maar discuss their connection to Sea Country noting that the sea was 'central to our culture, economy, and survival. The coastline is home to sites that are important for our Dreaming - Three Sisters Rocks and Deen Maar (Lady Julia Percy Island) where our Ancestors leave the earth. Our connection with our Sea Country extends well beyond the current shoreline to the edge of the continental shelf. While this area is under the sea today, we occupied it for thousands of years and rising sea levels have not washed away the history, physical evidence or our connection (EMAC 2015).

4.6.3.6 Submerged Cultural Heritage and Landscapes

First Nations peoples in Victoria have occupied, used, and managed sea country for thousands of years, including areas now submerged by sea level rise since time immemorial. An understanding of submerged landscapes and sea level changes may be evident from stories from First Nations groups, "Indigenous peoples still relate to land that was inundated by sea during the last ice age and regard it as their own" (NOO 2002b).

The lava flows of the World Heritage listed Budj Bim Cultural Landscape (which is outside of the Project and Planning Areas) have recently, through ocean scanning methods, been revealed to extend into the sea. The mapping of this geological formation allows the Gunditjmara to connect to Sea Country in new ways assisted by modern technology, as a supplement to their traditional knowledge and ancient connection to the sea. There is potential that early cultural deposits relating to aquaculture systems have been preserved in association with this formation, and as stated above evidence of this kind is highly significant to Gunditjmara.

4.6.3.7 Conservation and Contemporary Cultural Values

It is frequently raised by First Nations communities that ecological protection and sustainability is integral to First Nations cultural and contemporary values. Sea Country Plans, such as those completed by the Gunaikurnai (GLAWAC 2015), Wadawurrung (WTOAC. 2020), and Eastern Maar (EMAC 2015), highlight the importance of approaches that protect and enhance the environment, including biodiversity, coastal erosion, management of sea level rise and addressing climate change impacts. Goals include managing impacts to whale migration, bird and bat nesting and migration (such as the microbat, bent-wing bat, and orange-bellied parrot), protection of environmentally fragile resources such as seagrass and kelp fields, as well as securing habitat for threatened species such as the leafy seadragon.

'Increased pollution from coastal communities, agricultural and industrial run off is changing the sea hydrology and choking our sea life with plastics. Our Warre is being overused and heating up with climate changes. We are seeing the loss of our kelp forests and dramatic changes in sea life which we all depend upon' (WTOAC 2020).

'Our coastal dunes are layered with living places and hearths from the many generations of our ancestors living, harvesting, sharing meals, trading in these living places, and practicing ceremony here. We have the largest stretch of registered cultural sites in Australia along our coastline. Our fish traps, which were used to catch the abundant fish, have survived the storms and sea level changes. Ochre pits of different colours are dotted along our sandstone and limestone cliffs and headlands. Our sandy beaches, rock pools, rocky platforms and reefs were and continue to be places of abundance for harvesting food and resources like crustaceans, shellfish, and kelp' (WTOAC 2020).

Seals, or Bithaui or Gurnun in Kurnai (Howitt n.d.), are noted by the Gunaikurnai as a significant species, and habitat for fur seals at Wilsons Promontory Marine National Park is identified as an important resource to be protected, particularly due to the reliance of species on both the land and sea for different life cycle stages. It is therefore considered important that programs for environmental management consider both land and marine environments, as they are interconnected and must be managed as a whole to ensure success (GLAWAC 2015).

Through the processes identified above, and in particular, consultation with First Nations Groups, Beach is confident we have identified the cultural heritage values, and cultural features and sensitivities of First Nations groups identified within the Project and Planning Areas.

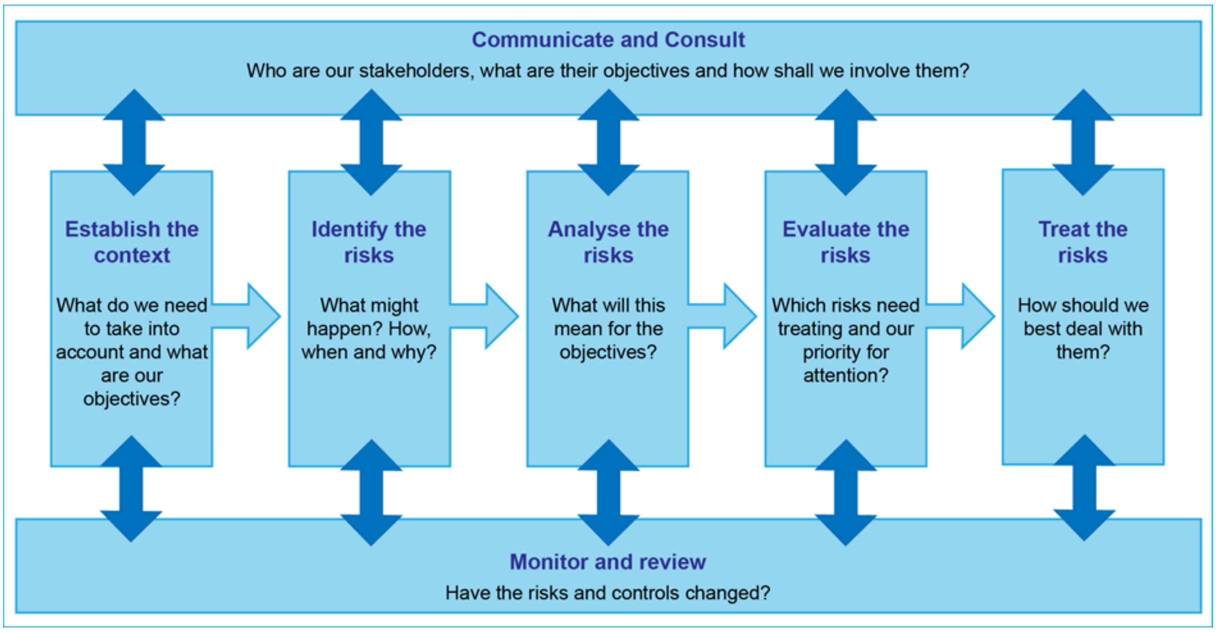
4.6.4 Assessment of Potential Impacts and Risks to Cultural Values and Sensitivities

Sections 6 and 7 evaluate the environmental impacts and risks of the Project and identifies where First Nations cultural values and sensitivities may be potentially affected. Where a potential impact to First Nations cultural values and sensitivities has been identified, details of the control measures, if required, to reduce impacts and risks from the Project are of an acceptable level and as low as reasonably practicable are provided.

5 Environmental Impact and Risk Assessment Methodology

5.1 Overview

This section outlines the environmental impact and risk assessment methodology used for the assessment of Project activities in this OPP. The methodology is consistent with the Australian and New Zealand Standard for Risk Management (AS/NZS ISO 31000:2018, Risk Management – Principles and Guidelines). Figure 5-1 outlines this risk assessment process.



Communicate and Consult

Who are our stakeholders, what are their objectives and how shall we involve them?

Establish the context

What do we need to take into account and what are our objectives?

Identify the risks

What might happen? How, when and why?

Analyse the risks

What will this mean for the objectives?

Evaluate the risks

Which risks need treating and our priority for attention?

Treat the risks

How should we best deal with them?

Monitor and review

Have the risks and controls changed?

Figure 5-1: Risk Assessment Process

5.2 Definitions

Definitions of the term used in the risk assessment process are detailed in Table 5-1.

Table 5-1: Definition of Terms for Risk Assessment

Term	Definition
Activity	Refers to a 'petroleum activity' as defined under the OPGGS(E)R as: petroleum activity means operations or works in an offshore area undertaken for the purpose of: • exercising a right conferred on a petroleum titleholder under the Act by a petroleum title; or, • discharging an obligation imposed on a petroleum titleholder by the Act or a legislative instrument under the Act.
Consequence	The consequence of an environmental impact is the potential outcome of the event on affected receptors (particular values and sensitivities). Consequence can be positive or negative
Control measure	Defined under the OPGGS(E)R as a system, an item of equipment, a person or a procedure, that is used as a basis for managing environmental impacts and risks
Emergency condition	An unplanned event that has the potential to cause significant environmental damage or harm to MNES. An environmental emergency condition may, or may not, correspond with a safety incident considered to be a Major Accident Event
Environmental aspect	An element or characteristic of an operation, product, or service that interacts or can interact with the environment. Environmental aspects can cause environmental impacts
Environmental impact	Defined under the OPGGS(E)R as any change to the environment, whether adverse or beneficial, that wholly or partially results from an activity
Environmental performance outcome	Defined under the OPGGS(E)R as a measurable level of performance required for the management of environmental aspects of an activity to ensure that environmental impacts and risks will be of an acceptable level.
Environmental performance standard	Defined under the OPGGS(E)R as a statement of the performance required of a control measure
Environmental risk	An unplanned environmental impact has the potential to occur, due either directly or indirectly from undertaking the activity
Likelihood	The chance of an environmental risk occurring
Measurement criteria	A verifiable mechanism for determining control measures are performing as required
Residual risk	The risk remaining after control measures have been applied (i.e. after risk treatment).

5.3 **Communicate and Consult**

Beach has been operating in the Otway Basin for numerous years and has undertaken extensive consultation with relevant person(s) (stakeholders) to obtain information about their functions, activities and interests and to assess how the Project and associated activities may impact on these. This information has been used to inform the impact and risk assessment in the OPP.

The stakeholder consultation process is described in detail in Section 10.

5.4 **Establish the Context**

The first step in the risk assessment process (outlined in Figure 5-1) is to establish the context. This involves:

- Understanding the regulatory framework in which the activity takes place (described in the in Section 2 – Environmental Legislation and Other Requirements)
- Defining the activities that will cause impacts and create risks (outlined in Section 3 – Description of the Project)
- Understanding concerns of stakeholders and incorporating those concerns into the design of the activity where appropriate (outlined in Section 10 - Stakeholder Consultation)
- Describing the environment in which the activity takes place (described in Section 4 – Description of the Environment)

Once the context has been established, the hazards of the activity can be identified, along with the impacts and risks of these hazards. This process is described in the following sections.

5.5 **Identify the Impacts and Risks**

This step seeks to identify the impacts and risks to be managed. It involves considering the objectives and the uncertainties of the internal and external context and identifying what might happen, when and where it might happen and why and how it can happen. In general, the process for identifying risks involves identifying the following:

- Sources of impact or risk
- Areas of impact
- Events and other uncertainties and their causes
- Potential consequences

Impacts and risks are differentiated as follows:

Impacts result from planned events – there will be consequences (known or unknown) associated with the event occurring and there is little or no uncertainty. Impacts are an inherent part of the activity. For example, sound and light will be generated during the activity and this will have consequences for marine life.

For impacts, only a consequence is assigned (likelihood is irrelevant given that the event does occur).

Risks result from unplanned events – there may be consequences if an unplanned event occurs. Risks are not an inherent part of the activity. For example, a hydrocarbon spill may occur if the activity vessel collides with another vessel, but this is not a certainty. The risk of this event is determined by considering the consequence of the impact (using factors such as the type and volume of hydrocarbons and the nature of the receiving environment) and the likelihood of this event happening (which may be determined objectively or subjectively, qualitatively or quantitatively).

5.6 **Analyse the Impacts and Risks**

Risk analysis involves developing an understanding of the impacts or risks. Risk analysis provides an input to risk evaluation and to decisions on whether risks need to be treated, and on the most appropriate risk treatment strategies and methods. Risk analysis can also provide an input into making decisions where choices must be made, and the options involve different types and levels of risk.

Beach's risk analysis process is described below:

- Establish criteria for an acceptable level of impact or risk
- Determine the maximum credible consequence arising from the impact or risk without introducing additional controls. This determination is provided in the risk assessment tables throughout Section 6 and 7
- Adopt controls for each impact or risk
- Undertake an assessment of the consequence of the impact or risk, corresponding to the maximum credible impact across the consequence categories (Figure 5-2) considering the controls identified and their effectiveness
- Identify the likelihood of occurrence of those consequences ('remote' through to 'almost certain'), considering the controls identified and their effectiveness, as outlined in Figure 5-2.
- For risks, use the consequence and likelihood to determine the overall risk level using the Beach Risk Matrix.

5.7 **Evaluate and Treat the Potential Impacts and Risks**

The following steps are undertaken using the Beach Risk Matrix (Figure 5-2) to evaluate the potential impacts and risks:

- Identify the consequences of each potential environmental impact, corresponding to the maximum credible impact.
- For unplanned events, identify the likelihood (probability) of unplanned environmental impacts occurring.
- For unplanned events, assign a level of risk to each potential environmental impact using the risk matrix.
- Identify control measures to manage potential impacts and risks to an acceptable level
- Establish environmental performance standards for each of the identified control measures.
- Environmental performance outcomes (EPO) (or objectives) are developed to provide a measurable level of performance for each environmental hazard

CDN 14740489 Beach Risk Matrix

Risk Matrix

CONSEQUENCE	CONSEQUENCE CATEGORY					LIKELIHOOD						
	PEOPLE	**ENVIRONMENT**	**REPUTATION**	**FINANCIAL[1]**	**LEGAL**	**A. Remote**	**B. Highly Unlikely**	**C. Unlikely**	**D. Possible**	**E. Likely**	**F. Almost Certain**	
	Impact to Beach or contracting personnel	Natural environment	Community safety, reputation/social licence. media, items of cultural significance.	Financial impact (e.g. due to loss of revenue, business interruption, asset loss etc.)	Breach of law, prosecution, civil action	<1% chance of occurring within the next year. Requires exceptional circumstances, unlikely event in the long-term future. Only occur as a 100-year event.	>1% chance of occurring within the next year. May occur but not anticipated. Could occur years to decades.	>5% chance of occurring within the next year. May occur but not for a while. Could occur within a few years.	>10% chance of occurring within the next year. May occur shortly but a distinct probability it won't. Could occur within months to years.	>50% chance of occurring within the next year. Balance of probability will occur. Could occur within weeks to months.	99% chance of occurring within the next year. Impact is occurring now. Could occur within days to weeks.	
6 Catastrophic	Multiple fatalities >4 or severe irreversible disability to large group of people (>10)	Catastrophic offsite or onsite release or spill; long-term destruction of highly significant ecosystems; significant effects on endangered species or habitats; irreversible or very long-term impact	Multiple community fatalities; complete loss of social licence; prolonged negative national media; complete loss of items of cultural significance	>$500m	Prolonged and complex civil and/or regulatory litigation; potential jail terms and/or very high fines and/or damages claim	HIGH	HIGH	VERY HIGH	VERY HIGH	VERY HIGH	VERY HIGH	6 Catastrophic
5 Critical	1-3 fatalities or serious irreversible disability (>30%) to multiple persons (<10)	Significant offsite or onsite release or spill; eradication or impairment of the ecosystem; significant impact on highly valued species or habitats; widespread long-term impact	Community fatality; significant loss of social licence; negative national media for 2 or more days; significant damage to items of cultural significance	$100m-$500m	Civil and/or regulatory litigation; potential significant fines and/or damages claim	MEDIUM	MEDIUM	HIGH	HIGH	VERY HIGH	VERY HIGH	5 Critical
4 Major	Serious permanent injury/ illness or moderate irreversible disability (<30%) to one or more persons	Major offsite or onsite release or spill; very serious environmental effects, such as displacement of species and partial impairment of ecosystem; major impact on highly valued species or habitats; widespread medium and some long-term impact	Serious permanent injury to community member; major damage to social licence; negative national media; major damage to items of cultural significance	$10m-$100m	Civil and/or regulatory litigation; potential major fine and damages claim	MEDIUM	MEDIUM	MEDIUM	HIGH	HIGH	VERY HIGH	4 Major
3 Serious	Serious reversible/ temporary injury/illness; Lost Time Injury >5 days or Alternate/Restricted Duties >1 month	Minor offsite or onsite release or spill; serious short-term effect to ecosystem functions; serious impact on valued species or habitats; moderate effects on biological or physical environment	Serious reversible injury to community member; serious damage to social licence; negative state media; serious damage to items of cultural significance	$1m-$10m	Serious potential breach of law; report and investigation by regulator; possible prosecution or regulatory notice (e.g. improvement notice or equivalent), or possible civil litigation and serious damages claim	LOW	MEDIUM	MEDIUM	MEDIUM	HIGH	HIGH	3 Serious
2 Moderate	Reversible temporary injury/ illness requiring Medical Treatment; Lost Time Injury ≤5 days or Alternate/Restricted Duties for ≤1 month	Event contained within site; short-term effects but not affecting ecosystem functions; some impact on valued species or habitats; minor short-term damage to biological and/or physical environment	Moderate injury to community member; moderate impact to social licence; negative local media; moderate damage to items of cultural significance	$100k-$1m	Potential breach of law or non-compliance; inquiry by a regulator leading to Low-level legal issues; possible civil litigation and moderate damages claim	LOW	LOW	MEDIUM	MEDIUM	MEDIUM	HIGH	2 Moderate
1 Minor	First Aid Injury/illness	Spill limited to release location; minor effects but not affecting ecosystem functions; no impact on valued species or habitats; low-level impacts on biological and physical environment	Minor injury to community member, public concern restricted to local complaints, minor damage to items of cultural significance	≤$100k	Minor potential breach of law; not reportable to a regulator; on the spot fine or technical non-compliance	LOW	LOW	LOW	MEDIUM	MEDIUM	MEDIUM	1 Minor

Figure 5-2: Beach Risk Matrix

5.7.1 Impact and Risk Level

The Beach Risk Matrix (Figure 5-2) provides a six-level scale for assessing both consequence and likelihood which leads to an overall risk level which can be Low, Medium, High or Very High. Consequence and likelihood levels are defined in Figure 5-2, whereas the risk levels can be understood as follows:

- Low: risks can be considered broadly acceptable and are required to be reviewed annually by the risk owner. Compliance with 'good industry practice' is generally sufficient for these risks to be considered acceptable by the Site Activity Manager. No further controls are required for risks at this level.

- Medium: risks can be considered broadly acceptable and are required to be reviewed annually by the risk owner. In addition to ‘good industry practice’, further controls may be considered for risks at this level to be reduced to a level deemed acceptable by the Asset/Project/Site Manager.

- High: Beach considers High risks to be material risks which require regular quarterly reviews to ensure they are being managed effectively. Further controls will be considered for risks at this level to be reduced to a level deemed acceptable

- Very High: Beach considers Very High risks to bematerial risks which require regular monthly reviews to ensure they are being managed effectively. Further controls and high level oversight is maintained for risks at this level

5.7.1.1 Low Order Environmental Impacts and Risks

NOPSEMA defines lower-order environmental impacts and risks as those where the environment or receptor is not formally managed, less vulnerable, widely distributed, not protected and/or threatened and there is confidence in the effectiveness of adopted control measures.

Impacts and risks are considered lower-order and are generally acceptable when, using the Beach risk matrix (Figure 5-2), the impact consequence is rated as ‘minor’ or ‘moderate’ or risks are rated as ‘low’ or ‘medium’. In these cases, applying ‘good industry practice’ is sufficient to manage the impact or risk to an acceptable level as defined in Table 5-4. To ensure lower-order impacts and risks are acceptable, an evaluation of lower-order risks are undertaken against a range of factors to demonstrate the acceptability of these impacts and risks (refer to Section 5.8).

5.7.1.2 Higher Order Environmental Impacts and Risks

NOPSEMA defines higher-order environmental impacts and risks as those that are not lower order risks or impacts (i.e., where the environment or receptor is formally managed, vulnerable, restricted in distribution, protected or threatened and there is little confidence in the effectiveness of adopted control measures).

Impacts and risks are considered higher-order when, using the Beach risk matrix (Figure 5-2) the impact consequence is rated as ‘serious’, ‘major’, ‘critical’ or ‘catastrophic’, or when the risk is rated as ’ high’ or ‘very high’. In these cases, further controls and control plans must be considered to reduce impacts and risks to levels deemed acceptable by the Risk, Corporate Governance and Sustainability Committee. To ensure higher-order impacts and risks are acceptable, an evaluation of higher-order risks are undertaken against a range of factors to demonstrate the acceptability of these impacts and risks (refer to Section 5.8).

5.8 **Demonstration of Acceptability**

A key outcome of the OPP process is to inform a conclusion as to whether the impacts and risks will be of an 'acceptable' or 'unacceptable' level. Beach considers a range of factors to demonstrate the acceptability of the environmental impacts and risks, including:

- The principles of ecologically sustainable development (ESD)
- Other requirements (e.g. laws, policies, standards, conventions etc.), including significant impacts to MNES
- Internal context
- External context
- Comparison of predicted impact or risk against the defined acceptable level.

5.8.1 Principles of Ecologically Sustainable Development

Based on Australia's National Strategy for Ecologically Sustainable Development (Council of Australian Governments, 1992), Section 3A of the EPBC Act defines ecologically sustainable development as:

Using, conserving and enhancing the community's resources so that ecological processes, on which life depends, are maintained and the total quality of life, now and in the future, can be increased.

The principles of ecologically sustainable development as defined under the EPBC Act and in alignment with NOPSEMA's OPP Decision Making Guideline (NOPSEMA 2024) are provided in Table 5-2. Table 5-2 describes how this OPP aligns with these principles and the relevance of each principle in the development of acceptable levels of impact.

Table 5-2: Assessment of Ecologically Sustainable Development Principles

Principle	Definition	OPP Demonstration
A 'Integration principle'	Decision-making processes should effectively integrate both long-term and short-term economic, environmental, social and equitable considerations.	Assessment confirming identification and evaluation of environmental impacts and risks and defining acceptable levels (against conservation values and sensitivities, physical environment, ecological environment, socio-economic values, and First Nations values and sensitivities described in Section 4.6), incorporates consultation feedback, and demonstrates that the potential impacts and risks are manageable to an acceptable level. Consideration of the integration principle of ESD is provided against each defined acceptable level in Table 5-4 and all impact and risk acceptability demonstration evaluations in Sections 6 and 7.
B 'Precautionary principle'	If there are threats of serious or irreversible environmental damage, lack of full scientific certainty	Serious or irreversible environmental damage equates to higher-order environmental impacts and risks. Impacts and risks are considered higher-order when, using the Beach risk matrix (Figure 5-2) the impact consequence is rated as 'serious', 'major', 'critical' or 'catastrophic', or when the risk is rated as 'severe' or 'extreme'.

	should not be used as a reason for postponing measures to prevent environmental degradation.	Review of potential impacts and risks identified threats of serious or irreversible environmental damage to be limited to the unplanned events of • introduction of IMS • loss of containment of hydrocarbons and chemicals. However, as a conservative approach, an evaluation of scientific uncertainty is conducted for all impacts and risks. This includes assessing how uncertainty is addressed in adopted controls for managing residual uncertainty throughout the project. Consideration of the precautionary principle of ESD is provided for all impact and risk acceptability demonstration and environmental performance evaluations in Sections 6 and 7.
C 'Intergenerational principle'	The present generation should ensure that the health, diversity and productivity of the environment is maintained or enhanced for the benefit of future generations.	Evaluation that the predicted impacts and risks will be managed to an acceptable level that will ensure the health, diversity, or productivity of the environment for current and future generations. Consideration of the intergenerational principle of ESD is provided against each defined acceptable level in Table 5-4 and all impact and risk acceptability demonstration evaluations in Sections 6 and 7.
D 'Biodiversity principle'	The conservation of biodiversity and ecological integrity should be a fundamental consideration in decision making.	Evaluation that the predicted impacts and risks (including impacts and risks to MNES identified within regulation 7(3) of the Environment Regulations) will be managed to an acceptable level that will not affect the conservation of biological diversity and ecological integrity. Consideration of the biodiversity principle of ESD is provided against each defined acceptable level in Table 5-4 and all impact and risk acceptability demonstration evaluations in Sections 6 and 7.
E 'Valuation principle'	Improved valuation, pricing and incentive mechanisms should be promoted.	Consideration of the valuation principle of ESD is factored into the maintenance of project financial assurances to prove Beach's capacity to meet costs, expenses and liabilities associated with the Project. As part Project financial assurances, Beach will bear the cost of environmental management for the whole of project life to ensure that the environmental impacts and risks are managed to an acceptable level. Financial assurance obligations includes consideration of costs associated with: • The polluter pays principle: eliminating or controlling the escape of petroleum, cleaning up the escaped petroleum and remediating any resulting damage to the environment and carrying out environmental monitoring of the impact of the escape on the environment. • Maintenance and removal of property: Section 572 of the OPGGS Act places requirements on titleholders in relation to the maintenance and removal of structures, equipment and other property brought into a title area. • Safeguard mechanism: Scope 1 emissions associated with gas production from the Project would be reported at the individual facility (NGER) level and are forecast to be below the Safeguard Mechanism threshold. Beach have engaged with the Clean Energy Regulator to discuss the Safeguard Mechanism boundary. Beach

	will continue these discussions with the Clean Energy Regulator as the Project progresses. In accordance with the OPGGS Act, Beach will demonstrate compliance with the financial assurance obligations under the OPGGS Act to NOPSEMA prior to acceptance of an EP under this OPP. No further consideration of the valuation principle of ESD has been provided in this OPP.

5.8.2 Other Requirements

Other requirements includes compliance with relevant legislation, government policies and guidelines, international agreements and industry best practice.

Given this OPP forms the basis for NOPSEMA’s assessment of matters protected under Part 3 of the EPBC Act in Commonwealth waters, particular attention is paid to MNES (Section 2.3) with acceptability demonstrated if:

- Significant impact criteria (Table 5-3) are not exceeded; and
- Impacts and risk are not inconsistent with published guidance material from DAWE, including species management plans, recovery plans and conservation advice (Section 2.3.1).

Table 5-3: MNES Significant Impact Criteria Defined in the Significant Impact Guidelines Published by the DoEE (DoE 2013a)

Category	**Significant Impact Criteria**
Listed Critically Endangered and Endangered species	An action is likely to have a significant impact on critically endangered or endangered species if there is likelihood that it will: • Lead to a long-term decrease in the size of a population • Reduce the area of occupancy of the species • Fragment an existing population • Adversely affect habitat critical to the survival of a species • Disrupt the breeding cycle of a population • Modify, destroy, remove, isolate or decrease the availability or quality of habitat to the extent that the species is likely to decline • Result in invasive species that are harmful to a critically endangered or endangered species becoming established in the endangered or critically endangered species' habitat • Introduce disease that may cause the species to decline, or • Interfere with the recovery of the species.
Listed Vulnerable Species	An action is likely to have a significant impact on vulnerable species if there is a likelihood that it will: • Lead to a long-term decrease in the size of an important population • Reduce the area of occupancy of an important population • Fragment an existing important population into two or more populations • Adversely affect habitat critical to the survival of a species • Disrupt the breeding cycle of a population • Modify, destroy, remove, isolate or decrease the availability or quality of habitat to the extent that the species is likely to decline

Category	Significant Impact Criteria
	• Result in invasive species that are harmful to a vulnerable species becoming established in the vulnerable species' habitat • Introduce disease that may cause the species to decline, or • Interfere substantially with the recovery of the species.
Listed Migratory Species	An action is likely to have a significant impact on migratory species if there is likelihood that it will: • Substantially modify, destroy or isolate an area of important habitat for a migratory species • Result in an invasive species that is harmful to the migratory species becoming established in an area of important habitat for the migratory species, or • Seriously disrupt the lifecycle of an ecologically significant proportion of the population of a migratory species.
Wetlands of International Importance	An action is likely to have a significant impact on a wetland of international importance if there is likelihood that it will result in: • Areas of wetland being destroyed or substantially modified • A substantial and measurable change in the hydrological regime of the wetland • The habitat or lifecycle of native species dependent upon the wetland being seriously affected • A substantial and measurable change in the water quality of the wetland which may adversely impact on the biodiversity, ecological integrity, social amenity or human health, or • An invasive species that is harmful to the ecological character of the wetland being established in the wetland.
Commonwealth Marine Area	An action is likely to have a significant impact on the environment in a Commonwealth Marine Area if there is likelihood that it will: • Result in a known or potential pest species becoming established in the Commonwealth marine area • Modify, destroy, fragment, isolate or disturb an important or substantial area of habitat such that an adverse impact on marine ecosystem functioning or integrity on a Commonwealth marine area results • Have a substantial adverse effect on a population of a marine species or cetacean including its life cycle and spatial distribution • Result in a substantial change in air quality or water quality which may adversely impact on biodiversity, ecological integrity, social amenity or human health

Category	Significant Impact Criteria
	• Result in persistent organic chemicals, heavy metals, or other potentially harmful chemicals accumulating in the marine environment such that biodiversity, ecological integrity[3], social amenity or human health may be adversely affected, or • Have a substantial adverse impact on heritage values of the Commonwealth marine area, including damage or destruction of an historic shipwreck.

5.8.3 Internal Context

The internal context relates to alignment with Beach's policies, objectives, environmental risk management framework, internal standards, procedures, technical guidance and opinions of internal stakeholders.

5.8.4 External Context

The external context relates to consultation undertaken with Relevant Persons (Section 10) both during historic activities and in the process of preparing this OPP. Impacts and risks will be acceptable if merits of claims or objections raised by Relevant Persons are adequately assessed and where relevant additional controls are adopted to manage concerns.

5.8.5 Acceptable Levels of Impact and Risk

The acceptable levels of impacts and risks to environmental receptors that are applied in the impact and risk assessments to determine and demonstrate acceptability are summarised in Table 5-4 and are based on the following:

- **Principles of ESD**, specifically:
    - Integration principle (decision-making processes should effectively integrate both long-term and short-term economic, environmental, social and equitable considerations)
    - Precautionary principle (if there are threats of serious or irreversible environmental damage, lack of full scientific certainty should not be used as a reason for postponing measures to prevent environmental degradation)

---

[3] In the context of the activities covered by this OPP, a change to ecological integrity is considered to take into account broadscale, long term impacts to the ecosystem. With regards to the Commonwealth marine environment, the Project Area is located in open offshore waters and the seabed is generally characterised by soft sediments. These characteristics are typical of the offshore Otway Basin."

  - Intergenerational principle (environment is maintained or enhanced for the benefit of future generations)
  - Biodiversity principle (conservation of biodiversity and ecological integrity should be a fundamental consideration in decision making)
- **Other requirements**: including legislative requirements (relevant requirements of the EPBC Act and the endorsed NOPSEMA Program), policy frameworks, scientific literature, standards, guidelines, plans of management (for protected matters under the EPBC Act), MNES Significant impact criteria (defined in Matters of National Environmental Significance -Significant impact guidelines 1.1. EPBC Act (Department of the Environment 2013))
- **Internal context:** Beach processes and procedures
- **External context:** stakeholder advice.

In alignment with NOPSEMA's OPP Decision Making Guideline (NOPSEMA 2024), the predicted level of impact and risk (Sections 5.9) will be compared against the acceptable level(s) to determine if they can be met, or if additional adopted controls are required to further reduce the impact or risk so that they do not exceed the acceptable level(s).

Table 5-4 outlines acceptable levels of impact and risk for receptors potentially affected by Project activities, as assessed in Sections 6 and 7. Receptors not credibly impacted by the Project will not have defined acceptable levels of impact and risk.

Table 5-4: Summary of Acceptable Levels of Impact for Environmental Receptors that may be Affected by the Activities Considered in this OPP

Receptor sub-category	Project aspect interactions	Acceptable level of impact and risk to the receptor sub-category	Sources used to define acceptable level	How the sources define the acceptable level
Conservation values and sensitivities				
Key ecological features	**Emissions light (Section 6.3)** **Invasive marine species (Section 7.1)** **Loss of containment – hydrocarbons and chemicals (Section 7.4)**	**Acceptable level 1:** No interference with the recovery of EPBC Act listed threatened species. **Acceptable level 2:** No modification, isolation or decrease in the availability or quality of habitat to the extent that EPBC Act listed threatened, migratory or cetacean species are likely to decline.	EPBC Act	The objects of the EPBC Act are to provide for the protection of the environment and to promote the conservation of biodiversity. KEFs are elements of the Commonwealth marine environment that are of regional importance for either a region's biodiversity or its ecosystem function and integrity. Project aspects (light, IMS and loss of containment – hydrocarbons and chemicals) may interact with values of the Bonney Coast Upwelling and West Tasmanian Canyon KEFs. These KEFs seasonally support high productivity and aggregations of marine life due to increased food availability. Light emissions may impact aggregations of seabirds supported by the Bonney Coast Upwelling KEF and fish aggregations supported by the West Tasmanian Canyon KEF. To address potential impacts to these marine fauna, acceptable levels 1, 2 and 3 have been defined to incorporate the protection of listed EPBC Act marine fauna species. The unplanned establishment of IMS may change the ecosystem dynamics of the Bonney Coast Upwelling and West Tasmanian Canyon KEFs. Also, unplanned loss of containment – hydrocarbons and chemicals events have the potential to impact on marine fauna aggregations of both Bonney Coast Upwelling and West Tasmanian Canyon KEFs. Acceptable levels 4 and 5 were defined on the premise that the absence of these unplanned events would result in no impact to the KEFs, and therefore, Project activities are acceptable if these unplanned events do not occur.
		Acceptable level 3: Impacts will not be inconsistent with conservation advice, recovery plans and threat abatement plans for EPBC Act listed threatened, migratory or cetacean species.	Principles of ESD (integration principle)	The public, including relevant stakeholders, have had the opportunity to provide feedback on potential impacts to KEFs including acceptability demonstration for aspects with the potential to impact KEFs. External context gained from the public consultation period allowed Beach to update the OPP. Acceptable levels 1, 2, 3, 4 and 5 have been defined based on the updated impact and risk evaluations and acceptability demonstrations which included consideration of external context. The inclusion of external context to define these acceptable levels ensures consistency with the integration principle of ESD.
		Acceptable level 4: Unplanned establishment of invasive marine species is unacceptable**.**	Principles of ESD (intergenerational principle)	Acceptable levels 1, 2, 3, 4 and 5 are consistent with the intergenerational principle of ESD by aligning with the EPBC Act, to provide for the protection of KEF values that have the potential to be impacted by the Project. Potential impacts equivalent to or better than this acceptable level will ensure Project activities will not significantly impact aggregations of listed EPBC Act marine fauna species that may forego the health, diversity and productivity of the environment for current and future generations.
		Acceptable level 5: Unplanned loss of containment – hydrocarbons and chemicals is unacceptable	Principles of ESD (biodiversity principle)	Acceptable levels 1, 2, 3, 4 and 5 are consistent with the biodiversity principle of ESD given that in meeting these levels the objects of the EPBC Act, which considers protection, and promotion of biological diversity, are also met. Potential impacts equivalent to or better than these acceptable levels will prevent significant impacts on aggregating marine fauna in KEFs, which in turn ensures the conservation of biodiversity and ecological integrity of KEF values unique to the south-east marine region.
Threatened ecological communities	**Invasive marine species (Section 7.1)** **Loss of containment – hydrocarbons and chemicals (Section 7.4)**	**Acceptable level 4:** Unplanned establishment of invasive marine species is unacceptable**.** **Acceptable level 5:** Unplanned loss of containment – hydrocarbons and chemicals is unacceptable	EPBC Act	The objects of the EPBC Act are to provide for the protection of the environment and to promote the conservation of biodiversity. Listed threatened ecological communities are matters of national environmental significance (protected matters) under the EPBC Act. TECs provide wildlife corridors or refugia for many plant and animal species (including threatened species). Unplanned project aspects (IMS and loss of containment – hydrocarbons and chemicals) have the potential to impact listed threatened species within TECs. The unplanned establishment of IMS may change the ecosystem dynamics of TECs. Also, unplanned loss of containment – hydrocarbons and chemicals events have the potential to impact on listed threatened species within TECs. Acceptable levels 4 and 5 were defined on the premise that the absence of these unplanned events would result in no impact to the TECs, and therefore, Project activities are acceptable if these unplanned events do not occur.
			Principles of ESD (integration principle)	The public, including relevant stakeholders, have had the opportunity to provide feedback on potential impacts to TECs including acceptability demonstration for aspects with the potential to impact TECs. External context gained from the public consultation period allowed Beach to update the OPP. Acceptable levels 4 and 5 have been defined based on the updated impact and risk evaluations and acceptability demonstrations which included consideration of external context. The inclusion of external context to define these acceptable levels ensures consistency with the integration principle of ESD.
			Principles of ESD (intergenerational principle)	Acceptable levels 4 and 5 are consistent with the intergenerational principle of ESD by aligning with the EPBC Act, to provide for the protection of TECs from unplanned events of IMS establishment and loss of containment scenarios. Potential impacts equivalent to or better than this acceptable level will ensure Project activities will not impact TECs and therefore will protect the health, diversity and productivity of the environment for current and future generations.
			Principles of ESD (biodiversity principle).	Acceptable levels 4 and 5 are consistent with the biodiversity principle of ESD given that in meeting these levels the objects of the EPBC Act, which considers protection, and promotion of biological diversity, are also met. Potential impacts equivalent to or better than these acceptable levels will prevent impacts on TECs, which in turn ensures the conservation of biodiversity and ecological integrity of TECs.

Receptor sub-category	Project aspect interactions	Acceptable level of impact and risk to the receptor sub-category	Sources used to define acceptable level	How the sources define the acceptable level
AMPs	**Emissions light (Section 6.3)** **Invasive marine species (Section 7.1)** **Loss of containment – hydrocarbons and chemicals (Section 7.4)**	**Acceptable level 1:** No interference with the recovery of EPBC Act listed threatened species. **Acceptable level 2:** No modification, isolation or decrease in the availability or quality of habitat to the extent that EPBC Act listed threatened, migratory or cetacean species are likely to decline. **Acceptable level 3:** Impacts will not be inconsistent with conservation advice, recovery plans and threat abatement plans for EPBC Act listed threatened, migratory or cetaceans species. **Acceptable level 4:** Unplanned establishment of invasive marine species is unacceptable**.** **Acceptable level 5:** Unplanned loss of containment – hydrocarbons and chemicals is unacceptable	EPBC Act	The objects of the EPBC Act are to provide for the protection of the environment and to promote the conservation of biodiversity. AMPs are established by proclamation under the EPBC Act for the purpose of protecting and maintaining biological diversity in the parks. Project aspects (light, IMS and loss of containment – hydrocarbons and chemicals) may interact with values for the Apollo and Zeehan AMPs i.e., habitat for EPBC Act listed bird and mammal species. Light emissions have the potential to impact on EPBC Act listed bird and mammal species and their habitats within the Apollo and Zeehan AMPs. To address potential impacts to both EPBC Act listed species and their habitats in AMPs, acceptable levels 1, 2 and 3 have been defined to incorporate the protection of listed EPBC Act marine fauna species. Acceptable level 2 specifically refers to the protection of habitats for EPBC Act listed species. The unplanned establishment of IMS may change the ecosystem dynamics of Apollo and Zeehan AMPs. Also, unplanned loss of containment – hydrocarbons and chemicals events have the potential to expose bird and mammal species and their habitats within the Apollo and Zeehan AMPs to hydrocarbons and chemicals. Acceptable levels 4 and 5 were defined on the premise that the absence of these unplanned events would result in no impact to the AMPs, and therefore, Project activities are acceptable if these unplanned events do not occur.
			South-east Marine Parks Network Management Plan (DNP, 2025)	The objectives of the South-east Network are to provide for: • the protection and conservation of biodiversity and other natural, cultural and heritage values of marine parks in the south-east network • ecologically sustainable use and enjoyment of the natural resources within marine parks in the south-east network, where this is consistent with the objective above. These objectives are broadly applied across all Australian Marine Parks. Potential impacts that meet or are better than acceptable levels 1, 2, 3, 4 and 5 will ensure the protection of the values of the Apollo and Zeehan AMPs and therefore objectives of the South-east Marine Parks Network Management Plan South-east Marine Park Network draft management plan (DNP, 2025) are inherently met.
			Principles of ESD (integration principle)	The public, including relevant stakeholders, have had the opportunity to provide feedback on potential impacts to AMPs including acceptability demonstration for aspects with the potential to impact AMPs. External context gained from the public consultation period allowed Beach to update the OPP. Acceptable levels 1, 2, 3, 4 and 5 have been defined based on the updated impact and risk evaluations and acceptability demonstrations which included consideration of external context. The inclusion of external context to define these acceptable levels ensures consistency with the integration principle of ESD.
			Principles of ESD (intergenerational principle)	Acceptable levels 1, 2, 3, 4 and 5 are consistent with the intergenerational principle of ESD by aligning with the EPBC Act, to provide for the protection of AMP values that have the potential to be impacted by the Project. Potential impacts equivalent to or better than this acceptable level will ensure the protection of listed EPBC Act marine fauna species and habitats to conserve the health, diversity and productivity of the environment for current and future generations.
			Principles of ESD (biodiversity principle).	Acceptable levels 1, 2, 3, 4 and 5 are consistent with the biodiversity principle of ESD given that in meeting these levels the objects of the EPBC Act, which considers protection, and promotion of biological diversity, are also met. Potential impacts equivalent to or better than these acceptable levels will prevent significant impacts on EPBC Act listed marine fauna in AMPs and their habitats, which in turn ensures the conservation of biodiversity and ecological integrity of AMP values unique to the south-east marine region.
National Heritage Places	**Loss of containment – hydrocarbons and chemicals (Section 7.4)**	**Acceptable level 5:** Unplanned loss of containment – hydrocarbons and chemicals is unacceptable	EPBC Act	The objects of the EPBC Act are to provide for the protection of the environment and to promote the conservation of biodiversity. The EPBC Act is Australia's primary legislation to protect and manage national heritage places located in Australia's near and offshore environment (DCCEEW 2024). Unplanned events of loss of containment – hydrocarbons and chemicals have the potential to impact National Heritage Places through hydrocarbon and chemical exposure. National heritage places with the potential to be impacted from these unplanned events include Great Ocean Road and Scenic Environs and Point Nepean which contain natural values associated with rocky cliffs and dunes. Acceptable level 5 was defined on the premise that the absence of these unplanned events would result in no impact to the National Heritage Places, and therefore, Project activities are acceptable if these unplanned events do not occur.
			Principles of ESD (integration principle)	The public, including relevant stakeholders, have had the opportunity to provide feedback on potential impacts to National Heritage Places including the acceptability demonstration for loss of containment – hydrocarbons and chemicals. External context gained from the public consultation period allowed Beach to update the OPP. Acceptable level 5 was defined based on the updated impact and risk evaluations and acceptability demonstration which included consideration of external context. The inclusion of external context to define this acceptable level ensures consistency with the integration principle of ESD.
			Principles of ESD (intergenerational principle)	Acceptable level 5 is consistent with the intergenerational principle of ESD by aligning with the EPBC Act, to provide for the protection of National Heritage Places from unplanned events loss of containment – hydrocarbons and chemicals. For the acceptable level to be met, unplanned events of loss of containment – hydrocarbons and chemicals will be prevented to ensure Project activities will not impact National Heritage Places and therefore will protect the natural values of the environment for current and future generations.

Receptor sub-category	Project aspect interactions	Acceptable level of impact and risk to the receptor sub-category	Sources used to define acceptable level	How the sources define the acceptable level
			Principles of ESD (biodiversity principle).	Acceptable level 5 is consistent with the biodiversity principle of ESD given that in preventing unplanned events of loss of containment – hydrocarbons and chemicals the objects of the EPBC Act, which considers protection, and promotion of ecological integrity, are also met. Great Ocean Road and Scenic Environs and Point Nepean National Heritage Places contain natural values associated with rocky cliffs, and dunes. Potential impacts equivalent to or better than acceptable level 5 will prevent impacts on the natural values of these National Heritage Places, which in turn ensures the ecological integrity of these places.
Nationally Important Wetlands	**Loss of containment – hydrocarbons and chemicals (Section 7.4)**	**Acceptable level 5:** Unplanned loss of containment – hydrocarbons and chemicals is unacceptable	EPBC Act	The objects of the EPBC Act are to provide for the protection of the environment and to promote the conservation of biodiversity. The EPBC Act is Australia's primary legislation to protect and manage Ramsar wetlands and migratory species that may be dependent on Nationally Important Wetlands (DCCEEW 2024). Unplanned events of loss of containment – hydrocarbons and chemicals have the potential to impact Nationally Important Wetlands through hydrocarbon and chemical exposure. Acceptable level 5 was defined on the premise that the absence of these unplanned events would result in no impact to the Nationally Important Wetlands, and therefore, Project activities are acceptable if these unplanned events do not occur.
			Principles of ESD (integration principle)	The public, including relevant stakeholders, have had the opportunity to provide feedback on potential impacts to Nationally Important Wetlands including the acceptability demonstration for loss of containment – hydrocarbons and chemicals. External context gained from the public consultation period allowed Beach to update the OPP. Acceptable level 5 was defined based on the updated impact and risk evaluations and acceptability demonstration which included consideration of external context. The inclusion of external context to define this acceptable level ensures consistency with the integration principle of ESD.
			Principles of ESD (intergenerational principle)	Acceptable level 5 is consistent with the intergenerational principle of ESD by aligning with the EPBC Act, to provide for the protection of Nationally Important Wetlands from unplanned events loss of containment – hydrocarbons and chemicals. For the acceptable level to be met, unplanned events of loss of containment – hydrocarbons and chemicals will be prevented to ensure Project activities will not impact Nationally Important Wetlands and therefore will protect the natural values of the environment for current and future generations.
			Principles of ESD (biodiversity principle).	Acceptable level 5 is consistent with the biodiversity principle of ESD given that in preventing unplanned events of loss of containment – hydrocarbons and chemicals the objects of the EPBC Act, which considers protection, and promotion of ecological integrity, are also met. Potential impacts equivalent to or better than acceptable level 5 will prevent impacts on the Nationally Important Wetlands, which in turn ensures the ecological integrity of these places.
State Protected Areas (Terrestrial and Marin)	**Loss of containment – hydrocarbons and chemicals (Section 7.4)**	**Acceptable level 5:** Unplanned loss of containment – hydrocarbons and chemicals is unacceptable	*National Parks Act 1975* (Vic)	The objects of the *National Parks Act 1975* are for the preservation and protection of the natural environment in national parks, state parks, marine national parks, and marine sanctuaries. These areas aim to ensure conservation and enable recreation in areas of environmental and cultural significance. Unplanned events of loss of containment – hydrocarbons and chemicals have the potential to impact State Protected Areas through hydrocarbon and chemical exposure. Acceptable level 5 was defined on the premise that the absence of these unplanned events would result in no impact to the State Protected Areas, and therefore, Project activities are acceptable if these unplanned events do not occur.
			Principles of ESD (integration principle)	The public, including relevant stakeholders, have had the opportunity to provide feedback on potential impacts to State Protected Areas including the acceptability demonstration for loss of containment – hydrocarbons and chemicals. External context gained from the public consultation period allowed Beach to update the OPP. Acceptable level 5 was defined based on the updated impact and risk evaluations and acceptability demonstration which included consideration of external context. The inclusion of external context to define this acceptable level ensures consistency with the integration principle of ESD.
			Principles of ESD (intergenerational principle)	Acceptable level 5 is consistent with the intergenerational principle of ESD by aligning with the EPBC Act, to provide for the protection of State Protected Areas from unplanned events loss of containment – hydrocarbons and chemicals. For the acceptable level to be met, unplanned events of loss of containment – hydrocarbons and chemicals will be prevented to ensure Project activities will not impact State Protected Areas and therefore will protect the natural values of the environment for current and future generations.
			Principles of ESD (biodiversity principle).	Acceptable level 5 is consistent with the biodiversity principle of ESD given that in preventing unplanned events of loss of containment – hydrocarbons and chemicals the objects of the EPBC Act, which considers protection, and promotion of ecological integrity, are also met. Potential impacts equivalent to or better than acceptable level 5 will prevent impacts on the State Protected Areas, which in turn ensures the ecological integrity of these places.

Receptor sub-category	Project aspect interactions	Acceptable level of impact and risk to the receptor sub-category	Sources used to define acceptable level	How the sources define the acceptable level
Physical environment				
Water quality	**Planned discharge – drill cuttings and fluids (Section 6.7)** **Planned discharge – cement (Section 6.8)** **Planned discharge – commissioning and operational fluids (Section 6.9)** **Planned discharge – routine operational wastes from vessels (Section 6.10)**	**Acceptable level 6:** Localised change in water quality (<2 km from discharge point located in the Project Area[1]) which will return to baseline conditions following completion of planned discharges (as defined in the OPP) is acceptable. These discharges will contain chemical additives subject to Beach's chemical selection process.	EPBC Act	The objects of the EPBC Act are to provide for the protection of the environment and to promote the conservation of biodiversity. It is an offence under the EPBC Act if an action results or will result in a significant impact on the environment. The significant impact guidelines for MNES defines an action is likely to have a significant impact on the environment in a Commonwealth marine area if there is a real chance or possibility that the action will result in a substantial change in water quality which may adversely impact on biodiversity, ecological integrity, social amenity, or human health. Acceptable level 6 defines a localised extent (2 km from the discharge point localised in the Project Area) of impact to water quality which will return to baseline conditions following completion of planned discharges (as defined in the OPP) to ensure there is no real chance Project activities will result in a substantial change in water quality.
			Australian and New Zealand Guidelines for Fresh and Marine Water Quality (ANZG, 2018)	The Australian and New Zealand Guidelines for Fresh and Marine Water Quality (ANZG) establishes standards for marine water quality protection (ANZG, 2018). The key objective of these guidelines is maintenance of biological diversity and advise a precautionary approach for assessment (ANZG, 2018). Acceptable level 6 is consistent with the ANZG given it prevents substantial change in water quality which will ensure biological diversity is maintained by defining a localised extent (2 km from the discharge point localised in the Project Area) of impact to water quality which will return to baseline conditions following completion of planned discharges (as defined in the OPP).
			Principles of ESD (integration principle)	The public, including relevant stakeholders, have had the opportunity to provide feedback on potential impacts to water quality including acceptability demonstration for aspects with the potential to impact water quality. External context gained from the public consultation period allowed Beach to update the OPP (PC265, PC266, PC267). Acceptable level 6 was defined based on the updated impact and risk evaluations and acceptability demonstrations which included consideration of external context. The inclusion of external context to define this acceptable level ensures consistency with the integration principle of ESD.
			Principles of ESD (intergenerational principle)	Acceptable level 6 is consistent with the intergenerational principle of ESD by aligning with the EPBC Act, to prevent a substantial change in water quality which may adversely impact on biodiversity, ecological integrity, social amenity, or human health. Potential impacts equivalent to or better than this acceptable level will ensure the protection of water quality in the Commonwealth marine area to conserve the health, diversity and productivity of the environment for current and future generations.
			Principles of ESD (biodiversity principle).	Acceptable level 6 is consistent with the biodiversity principle of ESD given that in meeting this level the objects of the EPBC Act, which considers protection, and promotion of biological diversity, are also met. Potential impacts equivalent to or better than this acceptable level will prevent a substantial change in water quality which may adversely impact on biodiversity, ecological integrity, social amenity, or human health.
Sediment quality	**Planned discharge – drill cuttings and fluids (Section 6.7)** **Planned discharge – cement (Section 6.8)**	**Acceptable level 7:** Localised change in sediment quality (between 1 km and 2 km from the discharge point located in the Project Area[1]) for sediments highly represented throughout the region from planned discharges (as defined in the OPP) is acceptable. These discharges will contain chemical additives subject to Beach's chemical selection process.	EPBC Act	The objects of the EPBC Act are to provide for the protection of the environment and to promote the conservation of biodiversity. It is an offence under the EPBC Act if an action results or will result in a significant impact on the environment. The significant impact guidelines for MNES defines an action is likely to have a significant impact on the environment in a Commonwealth marine area if there is a real chance or possibility that the action will result in adversely affecting biodiversity, ecological integrity, social amenity, or human health. Acceptable level 7 ensures the protection of biodiversity by defining a localised extent of impact (between 1 km and 2 km from the discharge point located in the Project Area[1]) within an area that contains sediments highly represented throughout the region. These limitations will ensure biological diversity is maintained and therefore aligns with the objects of the EPBC Act.
			Australian and New Zealand Guidelines for Fresh and Marine Water Quality (ANZG, 2018)	The ANZG establishes sediment quality guideline values to help ensure physical and chemical stressors do not exceed harmful levels (ANZG, 2018). The key objective of the ANZG is maintenance of biological diversity and advise a precautionary approach for assessment (ANZG, 2018). Acceptable level 7 states that chemical additives contained in planned discharges will be subject to Beach's chemical selection process to ensure chemicals used are environmentally acceptable whilst also meeting technical requirements. The use of Beach's chemical selection process considers aquatic toxicity, bioaccumulation, and persistence data for each chemical, along with the discharge concentration, duration, frequency, rate, and volume to assess chemicals that may or will be discharged to the marine environment. This approach aligns with international industry best practice for chemical assessment and will ensure that discharges to the marine environment are aligned with the key objective of ANZG.
			Principles of ESD (integration principle)	The public, including relevant stakeholders, have had the opportunity to provide feedback on potential impacts to sediment quality including acceptability demonstration for aspects with the potential to impact sediment quality. External context gained from the public consultation period allowed Beach to update the OPP. Acceptable level 7 was defined based on the updated impact and risk evaluations and acceptability demonstrations which included consideration of external context. The inclusion of external context to define this acceptable level ensures consistency with the integration principle of ESD.

[1] The 2 km localised extent from the discharge point is derived from a conservative 2 km exposure radius, which accounts for the potential benthic deposition of drill cuttings and fluids transported through the water column.

Receptor sub-category	Project aspect interactions	Acceptable level of impact and risk to the receptor sub-category	Sources used to define acceptable level	How the sources define the acceptable level
		[1] Seabed disturbance from upper well section drilling fluids and cuttings discharges is expected to be within 1 km of the well location (RPS 2023). This area of disturbance is included in the total project seabed disturbance footprint (Table 6 5) as long-term seabed disturbance, where relevant acceptable levels and EPOs for seabed disturbance are defined in Section 6.2.6.	Principles of ESD (intergenerational principle)	Acceptable level 7 is consistent with the intergenerational principle of ESD by aligning with the EPBC Act, by defining limitations in the spatial extent and location of impacts to sediment quality to prevent adverse impacts on biodiversity, ecological integrity, social amenity, or human health. Potential impacts equivalent to or better than this acceptable level will ensure the protection of sediment quality in the Commonwealth marine area to conserve the health, diversity and productivity of the environment for current and future generations.
			Principles of ESD (biodiversity principle).	Acceptable level 7 is consistent with the biodiversity principle of ESD given that in meeting this level the objects of the EPBC Act, which considers protection, and promotion of biological diversity, are also met. Potential impacts equivalent to or better than this acceptable level will prevent a substantial change in sediment quality which may adversely impact on biodiversity, ecological integrity, social amenity, or human health.
Air quality	**Emissions – atmospheric emissions (Section 6.5)**	**Acceptable level 8:** Temporary change in air quality from atmospheric pollutants emitted during Project activities (as defined in the OPP) will comply with MARPOL Annex VI (Prevention of Air Pollution from Ships) enacted in the *Navigation Act 2012*.	*Navigation Act 2012*	This Act regulates ship-related activities and invokes certain requirements of the International Convention for the Prevention of Pollution from Ships (MARPOL 73/78) including MARPOL Annex VI (Prevention of Air Pollution from Ships). Acceptable level 8 is based on the compliance of atmospheric pollutants emitted during Project activities in accordance with MARPOL Annex VI (Prevention of Air Pollution from Ships) enacted in the *Navigation Act 2012.* The direct reference to MARPOL Annex VI and this Act in the acceptable level ensures OPP vessel related activities (including emissions) meet these requirements.
			National Environment Protection Measures (Implementation) Act 1998	This Act and associated regulations provide for the implementation of National Environment Protection Measures (NEPMs) to protect, restore and enhance the quality of the environment in Australia and ensure that the community has access to relevant and meaningful information about pollution. The National Environment Protection Council has made NEPMs relating to ambient air quality standards. Acceptable level 8 ensures temporary change in air quality is achievable through compliance with MARPOL Annex VI (Prevention of Air Pollution from Ships). By complying with MARPOL Annex VI, ambient air quality for personnel on vessels will be protected in accordance with NEPM ambient air quality standards for the adequate protection of human health and well-being.
			Principles of ESD (integration principle)	The public, including relevant stakeholders, have had the opportunity to provide feedback on potential impacts to air quality including the acceptability demonstration for atmospheric emissions. External context gained from the public consultation period allowed Beach to update the OPP. Acceptable level 8 was defined based on the updated impact and risk evaluations and acceptability demonstrations which included consideration of external context. The inclusion of external context to define this acceptable level ensures consistency with the integration principle of ESD.
			Principles of ESD (intergenerational principle)	Acceptable level 8 is consistent with the intergenerational principle of ESD by ensuring temporary change in air quality from atmospheric emissions is compliant with MARPOL Annex VI and inherently NEPM ambient air quality standards to the protection of human health and well-being. Potential impacts equivalent to or better than this acceptable level will ensure the protection of air quality in the Commonwealth marine area to conserve the health, diversity and productivity of the environment for current and future generations.
			Principles of ESD (biodiversity principle).	Acceptable level 8 is consistent with the biodiversity principle of ESD through compliance with MARPOL Annex VI. The prevention of unnecessary air pollution from Project vessels, ensures changes to air quality can be reduced. This in turn protects offshore air quality which is a component of the Commonwealth marine area which is a MNES under the EPBC Act. Potential impacts equivalent to or better than this acceptable level will prevent long-term change in air quality which may adversely impact on biodiversity, social amenity, or human health.
GHG emissions	**Emissions – greenhouse gases (Section 6.6)**	**Acceptable level 9:** Project activities will not interfere with Australia's GHG commitments under the Paris Agreement and enacted in the *Climate Change Act 2022* and managed by the safeguard mechanism.	Paris Agreement	Australia, as a signatory to the Paris Agreement, is committed to its goals. These goals include limiting global warming to well below 2°C above pre-industrial levels, with efforts to limit the increase to 1.5°C. The Agreement emphasises the importance of protecting ecosystems, including oceans, and safeguarding biodiversity in addressing climate change. It also acknowledges the critical need to ensure food security, given the vulnerability of food production systems to climate change impacts. As a signatory, Australia is obligated to contribute to achieving these global climate goals through Australia's GHG commitments as per the *Climate Change Act 2022*. Acceptable level 9 ensures Australia's GHG commitments as per the *Climate Change Act 2022* will not be interfered with to meet the goals of the Paris Agreement.
			Climate Change Act 2022	The key legislative instrument that enacts Australia's commitments under the Paris Agreement is the *Climate Change Act 2022*. Under the *Climate Change Act 2022*, Australia's Nationally Determined Contributions (NDC) was updated in 2022, committing Australia to a target of net zero emissions by 2050 and reduce Greenhouse gas emissions by 43% from 2005 levels. Acceptable level 9 ensures Australia's GHG commitments as per the *Climate Change Act 2022* will not be interfered with to meet Australia's NDC.
			Safeguard Mechanism	The Safeguard Mechanism was developed to ensure that Australia's largest GHG emitters keep their net emissions below an emissions limit (a baseline) and stays within the 2030 emissions budget established by the 2030 NDC. The Safeguard Mechanism applies to facilities that emit more than 0.1 Mt CO_2-e per annum. The Safeguard Mechanism is the Government's primary legislation for achieving industrial emissions reduction in line with Australia's NDC.

Receptor sub-category	Project aspect interactions	Acceptable level of impact and risk to the receptor sub-category	Sources used to define acceptable level	How the sources define the acceptable level
			Principles of ESD (integration principle)	The public, including relevant stakeholders, have had the opportunity to provide feedback on GHG emissions. External context gained from the public consultation period allowed Beach to update the OPP (PC326, PC218). Acceptable level 9 was defined based on the updated impact and risk evaluations and acceptability demonstrations which included consideration of external context. The inclusion of external context to define this acceptable level ensures consistency with the integration principle of ESD.
			Principles of ESD (intergenerational principle)	Acceptable Level 9 aligns with the intergenerational principle of ESD by supporting Australia's commitments under the *Climate Change Act 2022*, which are in line with the Paris Agreement. Both the intergenerational principle of ESD and the Paris Agreement prioritise protecting the environment for future generations by addressing climate change. By ensuring that Project activities do not interfere with Australia's GHG commitments, Acceptable Level 9 contributes to maintaining a healthy environment for current and future generations, the objective of the intergenerational principle of ESD.
			Principles of ESD (biodiversity principle).	Acceptable level 9 is consistent with the biodiversity principle of ESD by supporting Australia's commitments under the *Climate Change Act 2022*, which are in line with the Paris Agreement. The Agreement emphasises the importance of protecting ecosystems, including oceans, and safeguarding biodiversity in addressing climate change. By ensuring that Project activities do not interfere with Australia's GHG commitments, Acceptable Level 9 contributes to safeguarding biodiversity.
Ecological environment				
Benthic habitats and communities	**Physical presence – seabed disturbance (Section 6.2)** **Planned discharge – drill cuttings and fluids (Section 6.7)** **Planned discharge – cement (Section 6.8)**	**Acceptable level 10**: No impacts on unique seafloor habitats[2] to the south-east region, including deep-sea reefs, continental shelf habitats, seamounts canyons and kelp forests. **Acceptable level 11**: Impacts on benthic habitats and communities within the Project Area that are highly represented throughout the region and are not unique seafloor habitats is acceptable.	EPBC Act	The objects of the EPBC Act are to provide for the protection of the environment and to promote the conservation of biodiversity. It is an offence under the EPBC Act if an action results or will result in a significant impact on the environment. The significant impact guidelines for MNES defines an action is likely to have a significant impact on the environment in a Commonwealth marine area if there is a real chance or possibility that the action will modify an important or substantial area of habitat such that an adverse impact on marine ecosystem functioning or integrity in a Commonwealth marine area results. Acceptable levels 10 and 11 ensures no impacts on unique seafloor habitats of the south-east region for the protection of important areas of habitat. Acceptable level 11 also specifically highlights that only benthic habitats and communities that are to be impacted will be highly represented throughout the region. These limitations will ensure biological diversity is maintained and therefore aligns with the objects of the EPBC Act.
			South-east Marine Parks Network Management Plan (DNP, 2025)	The objectives of the South-east Marine Parks Network Management Plan (DNP, 2025)are: • the protection and conservation of biodiversity and other natural, cultural and heritage values of marine parks in the south-east network • ecologically sustainable use and enjoyment of the natural resources within marine parks in the south-east network (where this is consistent with first objective). Acceptable levels 10 and 11 ensures the protection of unique seafloor habitats which are values of marine parks in the south-east network. The prevention of impacts on unique seafloor habitats ensures consistency with the objectives of the South-east Marine Parks Network Management Plan for the protection of natural values of marine parks in the south-east network.
			Principles of ESD (integration principle)	The public, including relevant stakeholders, have had the opportunity to provide feedback on potential impacts to benthic habitats and communities including acceptability demonstration for aspects with the potential to impact this receptor. External context gained from the public consultation period allowed Beach to update the OPP. Acceptable levels 10 and 11 were defined based on the updated impact and risk evaluations and acceptability demonstrations which included consideration of external context. The inclusion of external context to define this acceptable level ensures consistency with the integration principle of ESD.
			Principles of ESD (intergenerational principle)	Acceptable levels 10 and 11 are consistent with the intergenerational principle of ESD by aligning with the EPBC Act, by preventing impacts on unique seafloor habitats of the south-east region which in turn preserves biodiversity and ecological integrity for current and future generations. Potential impacts equivalent to or better than this acceptable level will ensure the protection of benthic habitats and communities in the Commonwealth marine area to conserve the health, diversity and productivity of the environment for current and future generations.
			Principles of ESD (biodiversity principle).	Acceptable levels 10 and 11 are consistent with the biodiversity principle of ESD given that in meeting this level the objects of the EPBC Act, which considers protection, and promotion of biological diversity, are also met. Potential impacts equivalent to or better than this acceptable level will prevent impacts to unique seafloor habitats which may adversely impact on biodiversity, ecological integrity, social amenity, or human health.
Intertidal and subtidal habitats (including seagrass, algae,	**Loss of containment – hydrocarbons and chemicals (Section 7.4)**	**Acceptable level 5:** Unplanned loss of containment – hydrocarbons and chemicals is unacceptable	EPBC Act	The objects of the EPBC Act are to provide for the protection of the environment and to promote the conservation of biodiversity. It is an offence under the EPBC Act if an action results or will result in a significant impact on the environment. The significant impact guidelines for MNES defines an action is likely to have a significant impact on the environment in a Commonwealth marine area if there is a real chance or possibility that the action will modify an important or substantial area of habitat such that an adverse impact on marine ecosystem functioning or integrity in a Commonwealth marine area results. Acceptable level 5 was defined on the premise that the absence of these unplanned events would result in no impact to intertidal and subtidal habitats, and therefore, Project activities are acceptable if these unplanned events do not occur.

---

[2] Unique seafloor habitats of the south-east region including deep-sea reefs, continental shelf habitats, seamounts canyons and kelp forests (DNP, 2025).

Receptor sub-category	Project aspect interactions	Acceptable level of impact and risk to the receptor sub-category	Sources used to define acceptable level	How the sources define the acceptable level
mangrove, saltmarsh)			Principles of ESD (integration principle)	The public, including relevant stakeholders, have had the opportunity to provide feedback on potential impacts to intertidal and subtidal habitats including the acceptability demonstration for loss of containment – hydrocarbons and chemicals. External context gained from the public consultation period allowed Beach to update the OPP. Acceptable level 5 was defined based on the updated impact and risk evaluations and acceptability demonstration which included consideration of external context. The inclusion of external context to define this acceptable level ensures consistency with the integration principle of ESD.
			Principles of ESD (intergenerational principle)	Acceptable level 5 is consistent with the intergenerational principle of ESD by aligning with the EPBC Act, to provide for the protection of intertidal and subtidal habitats from unplanned events loss of containment – hydrocarbons and chemicals. For the acceptable level to be met, unplanned events of loss of containment – hydrocarbons and chemicals will be prevented to ensure Project activities will not impact intertidal and subtidal habitats and therefore will protect the natural values of the environment for current and future generations.
			Principles of ESD (biodiversity principle).	Acceptable level 5 is consistent with the biodiversity principle of ESD given that in preventing unplanned events of loss of containment – hydrocarbons and chemicals the objects of the EPBC Act, which considers protection, and promotion of ecological integrity, are also met. Potential impacts equivalent to or better than acceptable level 5 will prevent impacts on the intertidal and subtidal habitats, which in turn ensures the ecological integrity of these places.
Marine fauna (including plankton, invertebrates, and threatened and migratory species)	**Emissions – light (Section 6.3)** **Underwater sound (Section 6.4)** **Physical presence – interaction with marine fauna (Section 7.2)** **Accidental discharge – hazardous and non-hazardous materials (Section 7.3)** **Loss of containment – hydrocarbons and chemicals (Section 7.4)**	**Acceptable level 1:** No interference with the recovery of EPBC Act listed threatened species. **Acceptable level 2:** No modification, isolation or decrease in the availability or quality of habitat to the extent that EPBC Act listed threatened, migratory or cetacean species are likely to decline. **Acceptable level 3:** Impacts will not be inconsistent with conservation advice, recovery plans and threat abatement plans for EPBC Act listed threatened, migratory or cetacean species. **Acceptable level 12:** Death or injury to listed threatened, migratory or cetacean species from unplanned interactions with marine fauna is unacceptable. **Acceptable level 13:** Unplanned accidental discharge of hazardous and non-hazardous materials is unacceptable. **Acceptable level 5:** Unplanned loss of containment – hydrocarbons and chemicals is unacceptable	EPBC Act	The objects of the EPBC Act are to provide for the protection of the environment and to promote the conservation of biodiversity. The EPBC Act protects listed threatened species to assist its recovery and identify actions required for conservation and recovery of the threatened species. Migratory species listed under international agreements to which Australia is a party are protected under the EPBC Act. It is an offence under the EPBC Act if an action results or will result in a significant impact on the environment. The significant impact guidelines for MNES defines an action is likely to have a significant impact on a threatened species if there is a real chance or possibility that it will: • Interfere with the recovery of the species • modify, destroy, remove, isolate or decrease the availability or quality of habitat to the extent that the species is likely to decline • adversely affect habitat critical to the survival of a species. The significant impact guidelines for MNES defines an action is likely to have a significant impact on a migratory species if there is a real chance or possibility that it will: • seriously disrupt the lifecycle (breeding, feeding, migration or resting behaviour) of an ecologically significant proportion of the population of a migratory species • substantially modify (including by fragmenting, altering fire regimes, altering nutrient cycles or altering hydrological cycles), destroy or isolate an area of important habitat for a migratory species. To address potential impacts to marine fauna, acceptable levels 1, 2 and 3 have been defined to incorporate the protection of listed EPBC Act marine fauna species in accordance with the objectives of conservation advice, recovery plans and threat abatement plans for EPBC Act listed threatened, migratory or cetacean species; and definitions of significant impacts on EPBC Act listed threatened and migratory marine fauna. The unplanned interaction with marine fauna, accidental discharge of hazardous and non-hazardous materials and loss of containment – hydrocarbons and chemical events have the potential to impact on marine fauna. Acceptable levels 12, 13 and 5 were defined on the premise that the absence of these unplanned events would result in no impacts to marine fauna, and therefore Project activities are acceptable if these unplanned events to not occur.
			Threatened species recovery plans or conservative advice	Recovery plans and conservation advice are adopted for species listed under the EPBC Act. The objectives of recovery plans and conservation advice for species which may be impacted are incorporated into these acceptable levels. Primary or long-term objectives of species recovery plans include: • Minimise anthropogenic threats to improve the population status of species, leading to the removal of the species from the threatened species list of the EPBC Act • Ensuring that anthropogenic activities do not hinder recovery in the near future, or impact on the conservation status of the species in the future. Relevant objectives of conservation advice include: • Minimise further loss of habitat critical to the survival of species throughout Australia (including habitat predicted to become habitat critical in the future because of climate change). Acceptable level 3 ensures impacts from the Project will not be inconsistent with conservation advice, recovery plans and threat abatement plans for EPBC Act listed threatened, migratory or cetacean species, therefore will meet the objectives of these plans.
			Principles of ESD (integration principle)	The public, including relevant stakeholders, have had the opportunity to provide feedback on potential impacts to marine fauna including acceptability demonstration for aspects with the potential to impact marine fauna. External context gained from the public consultation period allowed Beach to update the OPP. Acceptable levels 1, 2, 3, 5, 12 and 13 have been defined based on the updated impact and risk evaluations and

Receptor sub-category	Project aspect interactions	Acceptable level of impact and risk to the receptor sub-category	Sources used to define acceptable level	How the sources define the acceptable level
				acceptability demonstrations which included consideration of external context. The inclusion of external context to define these acceptable levels ensures consistency with the integration principle of ESD.
			Principles of ESD (intergenerational principle)	Acceptable levels 1, 2, 3, 5, 12 and 13 are consistent with the intergenerational principle of ESD by aligning with the EPBC Act, to provide for the protection of marine fauna that have the potential to be impacted by the Project. Potential impacts equivalent to or better than this acceptable level will ensure Project activities will not significantly impact EPBC Act listed marine fauna species which may forego the health, diversity and productivity of the environment for current and future generations.
			Principles of ESD (biodiversity principle).	Acceptable levels 1, 2, 3, 5, 12 and 13 are consistent with the biodiversity principle of ESD given that in meeting these levels the objects of the EPBC Act, which considers protection, and promotion of biological diversity, are also met. Potential impacts equivalent to or better than these acceptable levels will prevent significant impacts on marine fauna, which in turn ensures the conservation and biodiversity of Australian marine fauna.
Socio-economic values				
Other marine users (including offshore petroleum industry, offshore renewable industry, defence activities, shipping, commercial fisheries, tourism and recreation)	**Physical presence – interaction with other users (socio-economic) (Section 6.1)**	**Acceptable level 14:** No interference with other marine users to a greater extent than is necessary for the reasonable exercise of the rights and performance of duties as conferred by the titles granted to Beach.	OPGGS Act	Section 280(2)(a) and (b) of the OPGGS Act outlines that a person (the first person) carrying on activities in an offshore area under the permit, lease, licence, authority or consent must carry on those activities in a manner that does not interfere with a range of other marine activities including navigation or fishing, to a greater extent than is necessary for the reasonable exercise of the rights and performance of the duties of the first person. Acceptable level 14 incorporates this requirement stating no interference with other marine users to a greater extent than is necessary to meet the rights and performance of the duties as conferred by the titles granted to Beach.
			Principles of ESD (integration principle)	The public, including relevant stakeholders, have had the opportunity to provide feedback on potential impacts to other marine users including the acceptability demonstration for physical presence – interaction with other users. External context gained from the public consultation period allowed Beach to update the OPP. Acceptable level 14 was defined based on the updated impact and risk evaluations and acceptability demonstration which included consideration of external context. The inclusion of external context to define this acceptable level ensures consistency with the integration principle of ESD.
			Principles of ESD (intergenerational principle)	Acceptable level 14 is consistent with the intergenerational principle of ESD by preventing unnecessary interference with other marine users. By only allowing interference that is essential for the project, the rights of current and future marine users are protected.
			Principles of ESD (biodiversity principle).	The biodiversity principle of ESD is not considered relevant to other marine users, given the rights of other marine users is focused on human activities, rather than the ecological integrity of the biological environment.
Cultural values and sensitivities				
Maritime archaeological heritage First Nations	**Physical presence – seabed disturbance (Section 6.2)** **Planned discharge – drill cuttings and fluids (Section 6.7)** **Planned discharge – cement (Section 6.8)**	**Acceptable level 15**: No impacts on underwater cultural heritage with values as conferred by the *Underwater Cultural Heritage Act 2018* (Cth).	*Underwater Cultural Heritage Act 2018*	The objective of the UCH Act is to provide for the identification, protection and conservation of Australia's underwater cultural heritage. The Act protects archaeological remains of vessels and aircraft (including Aboriginal and Torres Strait Islander traditional watercraft) that have been wholly or partially submerged in Australian waters for 75 years or longer. Other types of underwater cultural heritage, including First Nations archaeological heritage associated with dry-land habitation on the submerged Pleistocene landscapes on the Australian continental shelf and remains of shipwrecks or aircraft younger than 75 years (DCCEEW, 2024). No maritime or First Nations archaeological heritage is known to exist within the Project Area (Section 4.2.5 and 4.6.3.6). Acceptable level 15 incorporates the UCH Act objective by preventing impacts on underwater cultural heritage and thereby ensuring the protection and conservation of underwater cultural heritage.
			Principles of ESD (integration principle)	The public, including relevant stakeholders, have had the opportunity to provide feedback on potential impacts to underwater cultural heritage including the acceptability demonstration for aspects with the potential to impact this receptor. External context gained from the public consultation period allowed Beach to update the OPP. Acceptable level 15 was defined based on the updated impact and risk evaluations and acceptability demonstration which included consideration of external context. The inclusion of external context to define this acceptable level ensures consistency with the integration principle of ESD.
			Principles of ESD (intergenerational principle)	Acceptable level 15 is consistent with the intergenerational principle of ESD by aligning with the UCH Act, to provide for the protection of underwater cultural heritage for current and future generations.
			Principles of ESD (biodiversity principle).	The biodiversity principle of ESD is not considered relevant to maritime archaeological heritage and underwater cultural heritage, as these heritage values primarily focus on the preservation and understanding of human-made artifacts and historical contexts, rather than the ecological integrity of the biological environment.

Receptor sub-category	Project aspect interactions	Acceptable level of impact and risk to the receptor sub-category	Sources used to define acceptable level	How the sources define the acceptable level
First Nations values and sensitivities	**Physical presence – seabed disturbance (Section 6.2)** **Planned discharge – drill cuttings and fluids (Section 6.7)** **Planned discharge – cement (Section 6.8)** **Loss of containment – hydrocarbons and chemicals (Section 7.4)**	**Acceptable level 16**: No impacts on declared areas or objects of particular significance with values as conferred by the *Aboriginal and Torres Strait Islander Heritage Protection Act 1984* (Cth).	*Aboriginal and Torres Strait Islander Heritage Protection Act 1984* (ATSHIP Act)	The ATSHIP Act provides protection to places and objects of particular significance from injury or desecration (DCCEEW, 2023). The ATSIHP Act states that an area will be taken to be injured or desecrated if: • it is used or treated in a manner inconsistent with Aboriginal tradition • by reason of anything done in, on or near the area, the use or significance of the area in accordance with Aboriginal tradition is adversely affected, or • passage through or over, or entry upon, the area by any person occurs in a manner inconsistent with Aboriginal tradition. An object will be taken to be injured or desecrated if it is used or treated in a manner inconsistent with Aboriginal tradition. Acceptable level 16 incorporates the ATSHIP Act objective by stating Project activities will not impact Aboriginal areas and objects defined under the ATSHIP Act.
			Principles of ESD (integration principle)	The public, including relevant stakeholders, have had the opportunity to provide feedback on potential impacts to First Nations values and sensitivities including the acceptability demonstration for aspects with the potential to impact this receptor. External context gained from the public consultation period allowed Beach to update the OPP. Acceptable level 16 was defined based on the updated impact and risk evaluations and acceptability demonstration which included consideration of external context. The inclusion of external context to define this acceptable level ensures consistency with the integration principle of ESD.
			Principles of ESD (intergenerational principle)	Acceptable level 16 is consistent with the intergenerational principle of ESD. This consistency is achieved by aligning with the objective of the ATSHIP Act, which considers the protection of significant Aboriginal areas and objects. By setting the acceptable level as having no impacts on declared areas or objects of particular significance as conferred under the ATSHIP Act, this level will provide for the protection of Aboriginal areas and objects defined under the ATSHIP Act for current and future generations.
			Principles of ESD (biodiversity principle).	Acceptable level 16 aligns with the biodiversity principle of ESD by safeguarding significant Aboriginal areas and objects whose values are inherently connected to biodiversity. Meeting Acceptable level 16 ensures that this connection, as recognised under the ATSHIP Act, remains unbroken.

5.9 **Environmental Performance Outcomes**

Environmental Performance Outcomes (EPOs) are measurable performance levels designed to manage environmental aspects of an activity, ensuring impacts and risks remain within acceptable levels (NOPSEMA 2024).

Beach has developed EPOs for the project in accordance with NOPSEMA's OPP Decision Making Guideline (NOPSEMA 2024). These EPOs are aligned with ESD principles and relevant to identified environmental impacts and risks and establish environmental performance levels equal to or exceeding defined acceptable levels.

EPOs are based on the evaluated predicted levels of impact and risk in the OPP. The basis of EPO environmental performance levels ensures levels of impacts or risks will not exceed the upper range of predicted levels of environmental impact or risk in the OPP (Figure 5-3).

The Project's EPOs are consistent with ESD principles as they incorporate ESD considerations into acceptable levels (Section 5.8.5), the demonstration of acceptability process (Section 5.8), and are equal to or better than the defined acceptable levels (NOPSEMA 2024).

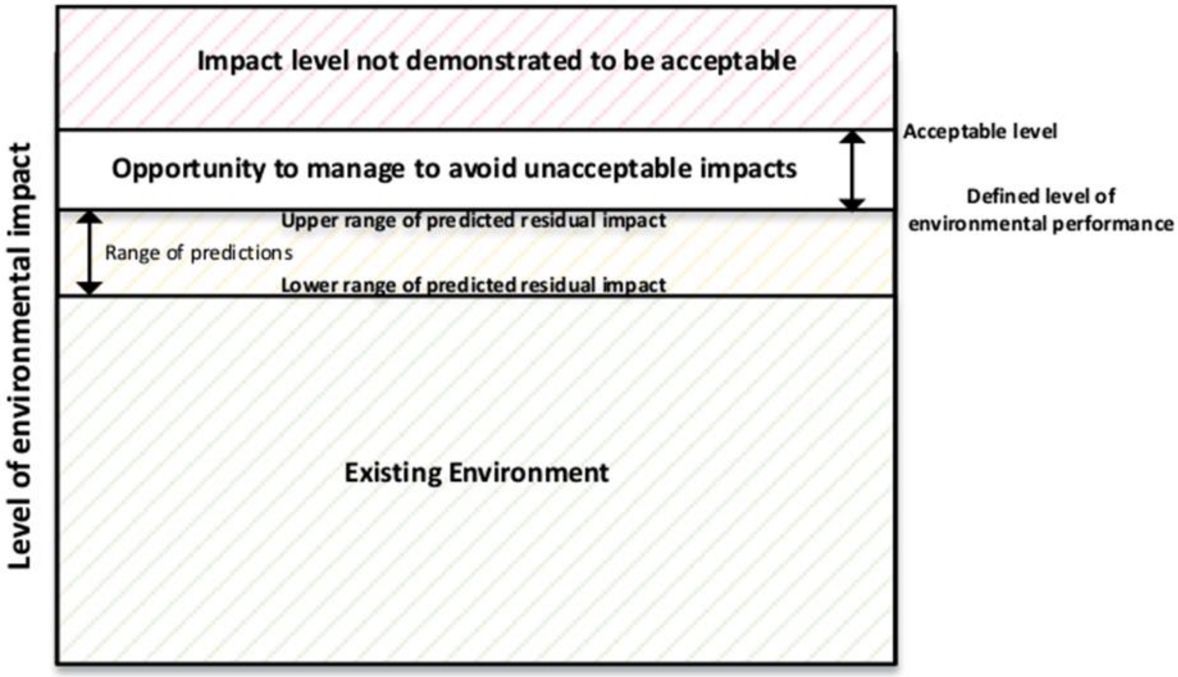


Figure 5-3: Framework for the Acceptable Level of Impact and Associated Levels of Environmental Performance (NOPSEMA 2024)

6 Environmental Impact Evaluation – Planned Activities

6.1 **Physical Presence – Interaction with Other Users (Socio-economic)**

6.1.1 Hazard Identification

The presence of vessels and infrastructure within the Project Area has the potential to interact with other marine users. Relevant stages and associated activities that relate to physical presence of vessels and infrastructure with the potential to interact with other users are defined below in Table 6-1 and described in Section 6.1.2.

Table 6-1: Activities Undertaken During the Project which may Interact with other users

Stage	Activity
Operations	Hydrocarbon extraction and export
Support Operations (all stages)	MODU operations; vessel operations

It is noted that MODU and vessel operations within the Project Area are considered part of a petroleum activity. MODU and vessel operations outside of the Project Area are excluded from the scope of this OPP, as these operations are fall under maritime legislation such as the *Navigation Act 2012*.

6.1.2 Hazard Description

6.1.2.1 Operations

Infrastructure required for hydrocarbon extraction and export operations includes the proposed wells, and subsea systems. The physical presence of this infrastructure is expected to be present for at least 20 years in the Project Area (based on the estimated end of field life in 2045). To avoid direct interactions between infrastructure and other users, safety zones can be administered by NOPSEMA prohibiting other user vessels to enter or be present in the safety zones.

The following safety zones will be gazetted for the life of the Project:

- 500 m around the OGPP tie in locations; and
- 500 m around wells (up to 9 wellheads across VIC/P43 and VIC/P73).

Gazetted safety zones for proposed wells, and OGPP tie in locations in the Project Area restricts other users from accessing these future specified areas. Restriction of access from these specified areas will displace other users for approximately 20 years from safety zones in the Project Area.

6.1.2.2 Support Operations

Short-term support operations are associated with all stages of the Project. The type and number of vessels in the Project Area at any one time, and the duration of presence, will differ depending on the project stage. For a single activity, there will be no more than three vessels operating simultaneously. The longest duration for a single activity requiring support vessel operations is 40 days to drill a single well utilising a MODU and two support vessels. In the event of concurrent activities, five vessels may operate simultaneously for a period of up to 20 days during concurrent drilling and installation activities. In this case, a MODU with two support vessels and an installation vessel with a support vessel could be undertaking concurrent drilling and installation activities.

MODU anchors could be prelaid and may be in place for up to three months prior to the MODU entering the field. Surface buoys associated with the anchors will be in place until the MODU is anchored on location. These can be up to 2 km from the well location and will have a navigation light.

MODU operations are required during drilling, well intervention and workovers and plug and abandonment activities. The MODU will be stationary whilst undertaking these activities. To avoid direct interactions between the MODU and other marine users, cautionary and exclusion zones will be applied during MODU operations in the Project Area:

- 2 km cautionary zone around MODU, anchors, mooring chains, and surface buoys during the drilling stage
- 500 m petroleum safety zone (PSZ) or exclusion zone around the MODU and each well during drilling, operation and decommissioning stages.

Vessel operations are required during all stages of the Project. Vessel operations in the Project Area will require temporary exclusion or cautionary zones for third party vessels whilst undertaking Project activities:

- 500 m Safe Navigation Area (SNA) around vessel(s), and any towed equipment during the seabed survey.

6.1.3 Impact Analysis and Evaluation

Socioeconomic receptors identified as susceptible to changes to functions, interests, or activities from the physical presence of the MODU, vessels, and subsea systems are:

- Commonwealth & state managed fisheries
- Industry
- Tourism and recreation
- Cultural values and sensitivities

6.1.3.1 Commonwealth and State Managed Fisheries

Beach has studied Commonwealth catch effort data (ABARES 2024) and consulted extensively with fishers as part of its ongoing operations in the Planning Area. Five Commonwealth Fisheries with effort intensity data or reporting grids for seasons between 2016 and 2023 overlap the Project Area, including:

- Bass Strait Central Zone Scallop Fishery (BSCZSF)
- Eastern Tuna and Billfish Fishery (ETBF)
- Southern and Eastern Scalefish and Shark Fishery (SESSF) includes the following subsections:
    - Commonwealth Trawl Sector (SESSF – CTS) (Danish-seine)
    - Commonwealth Trawl Sector (SESSF – CTS) (otter-board trawl)
    - Gillnet Hook Trap Sector Shark Gillnet sub-sector (SESSF – GHTS: SGSHS)
    - Gillnet Hook Trap Sector Shark Hook sub-sector (SESSF – GHTS: SGSHS)

  - Gillnet Hook Trap Sector Scalefish Hook sub-sector (SESSF – GHTS: SHS)
  - Southern Bluefin Tuna Fishery (SBTF)
  - Southern Squid Jig Fishery (SSJF)

In addition, three State Managed Fisheries with catch effort overlap the Project Area:

- Victorian Rock Lobster Fishery
- Victorian Giant Crab Fishery
- Victorian Wrasse (Ocean) Fishery

The interference to the above receptors has the potential to result in changes to the functions, interests, or activities of other users.

Bass Strait Central Zone Scallop Fishery (BSCZSF)

No fishing intensity data available from 2016 through 2023 fishing seasons overlaps the Project Area. However, the Project Area is partially overlapped by 1 reporting grid since 2016 (0.9% overlap) reported during the 2019 fishing season. Little or no fishing activity from the Bass Strait Central Zone Scallop Fishery is expected within the Project Area with the majority of fishing intensity data occurring to the east of King Island (Figure 4-68). Therefore, activities from the Project are unlikely to have an impact to fishers within the fishery.

Eastern Tuna and Billfish Fishery (ETBF)

No fishing intensity data available from 2016 through 2023 fishing seasons overlaps the Project Area. However, the Project Area is partially overlapped by 3 reporting grids, ranging between 1.5% and 9.2% overlap. Each grid is overlapped during only one fishing season since 2016, two of which during the 2017 season (7.7 and 9.2% overlap) and the other during the 2023 season (1.5% overlap). Little fishing activity from the Eastern Tuna and Billfish Fishery is expected within the Project Area with significant fishing intensity data shown to occur in off NSW and Queensland (Butler et al. 2024). Therefore, activities from the Project are unlikely to have an impact to fishers within the fishery.

Southern and Eastern Scalefish and Shark Fishery – Commonwealth Trawl Sector (SESSF – CTS)

No fishing intensity data available from 2016 through 2023 fishing seasons overlaps the Project Area for the Danish-seine method of the Commonwealth Trawl Sector (CTS). However, the Project Area is overlapped by reporting grids from available data since 2016. In 2020, the Project Area is partially overlapped by 4 grids ranging from 0.9 to 9.1% overlap. In 2018 and 2019 the Project Area is overlapped by only 2 grids (1.4% and 0.9% overlap) with only one grid overlapping in years 2016, 2017, 2021, 2022 and 2023 (1.5% overlap). Beach commissioned a report from SETFIA on Trawl and Gillnet fishing activity (SEFTIA 2019) which confirmed no Danish seine sub-sector fishing in the project area. The majority of fishing intensity data occurs in the Gippsland area and to the east of Tasmania (

Figure 4-70). Therefore, activities from the Project are unlikely to have an impact to fishers within the fishery.

The Project Area overlaps an area designated as low intensity fishing (<0.5 hours/km^2) for combined data (2016 through 2023) for the otter-board trawl method of the CTS by 0.8%. The Project Area does not overlap moderate or high intensity fishing areas. Little or no fishing activity from the otter-board trawl segment of the CTS is expected within the Project Area. Fishing activity is primarily along the continental shelf spanning from South Australian offshore waters to NSW offshore waters plus the west and east coasts of Tasmania (Figure 4-71). SEFTIA (2019) states that trawl fishing in the SESSF Commonwealth Trawl Sector (CTS) otter-board trawl sub-sector does not occur in the Project Area as the grounds are too rough. Therefore, activities from the Project are unlikely to have an impact to fishers within the fishery.

Southern and Eastern Scalefish and Shark Fishery – Gillnet Hook Trap Sector Shark Gillnet sub-sector (SESSF – GHTS SGSHS)

The Project Area overlaps an area designated as low intensity fishing (net length <300 m/km^2) and moderate intensity (net length 600-1200 m/km^2) for combined data (2016 to 2023) for the Gillnet Hook Trap Sector Shark Gillnet sub-sector by 0.7% and 0.4% respectively. The Project Area does not overlap high intensity fishing areas. Low activity from the Gillnet Hook Trap Sector Shark Gillnet sub-sector is expected in the vicinity of the Project Area with the majority of high intensity effort in the eastern Bass Strait (Figure 4-73). Therefore, activities from the Project are unlikely to have an impact to fishers within the fishery.

Southern and Eastern Scalefish and Shark Fishery – Gillnet Hook Trap Sector Shark Hook sub-sector (SESSF – GHTS SGSHS)

No available fishing intensity data available from 2016 through 2023 fishing seasons overlaps the Project Area. However, the Project Area is partially overlapped by 4 reporting grids (between 0.9 and 9.2% overlap) since 2016. Little fishing activity from the Gillnet Hook Trap Sector Shark Hook sub-sector is expected within the Project Area with significant fishing intensity data shown to occur in South Australia and north-eastern Tasmania (Figure 4-74). Therefore, activities from the Project are unlikely to have an impact to fishers within the fishery.

Southern and Eastern Scalefish and Shark Fishery – Scalefish Hook Sector (SESSF – GHTS SHS)

No fishing intensity data available from 2016 through 2023 fishing seasons overlaps the Project Area. However, the Project Area is partially overlapped by 3 reporting grids (between 0.9% and 9.2% overlap) from 2015 to 2023. Little fishing activity from the Scalefish Hook Sector is expected within the Project Area with significant fishing intensity data shown to occur off the Gippsland coast (Butler et al. 2024). Therefore, activities from the Project are unlikely to have an impact to fishers within the fishery.

Southern Bluefin Tuna Fishery (SBTF)

No fishing intensity data available for the SBTF longline or purse-seine methods from 2016 through 2023 fishing seasons overlap the Project Area. However, the Project Area is partially overlapped by 3 reporting grids for the SBTF longline method from available data, two from the 2016 fishing season (7.7 and 9.2% overlap) and one from the 2022 fishing season (1.5% overlap). No reporting grids for the SBTF purse seine method overlap the Project Area since 2016 based on available data. Little or no fishing activity from the Southern Bluefin Tuna Fishery is expected within the Project Area with the majority of fishing intensity occurring in New South Wales and South Australia (Butler et al. 2024). Therefore, activities from the Project are unlikely to have an impact to fishers within the fishery.

Southern Squid Jig Fishery (SSJF)

The Project Area overlaps an area designated as low intensity fishing (<0.5 hours/km^2) for combined data (2016 through 2023 fishing seasons) for the Southern Squid Jig Fishery by 3.0%. The Project Area does not overlap moderate or high intensity fishing areas. Low activity from the Southern Squid Jig Fishery is expected in the vicinity of the Project Area with the majority of high intensity to both the west and east of the Project Area (

Figure 4-76). Therefore, activities from the Project are unlikely to have an impact to fishers within the fishery.

Victorian Rock Lobster Fishery

The greatest numbers of vessels within Victorian Rock Lobster fishery are adjacent to the coastline, primarily west of Wilsons Promontory. Reporting grids overlapping the Project Area show low levels of activity (up to 17 vessels per grid between 2013 and 2023) (Figure 4-82). Therefore, activities from the Project are expected to have a minimal impact to fishers within the fishery.

Victorian Wrasse (Ocean) Fishery

VFA (2024) data shows the highest level of fishing activity in the Victorian Wrasse (Ocean) Fishery between 2013-2023 occurred off Port Fairy and Flinders Island. The Project Area overlaps one reporting grid for the fishery which has 1 day fished between 2013-2023. The Project Area overlaps only 1.8 km^2 of this reporting grid. Therefore, activities from the Project are unlikely to have an impact on fishers within the fishery.

Victorian Giant Crab Fishery

There have been less than 5 dedicated fishers active in the fishery and up to 20 fishers annually reporting Giant Crab catch as by-product from Rock Lobster fishing (VFA 2021a). The Project Area overlaps 8 reporting grids with fishing effort between 2013-2023 which show low levels of activity (up to 15 vessels per grid) (Figure 4-74). However, the greatest fishing intensity for the Giant Crab fishery occurs south of the Project Area along the continental shelf at depths between approximately 150 to 300 m (SETFIA and Fishwell Consulting 2020 in ConocoPhillips 2024) (Figure 4-74).

As the Project Area is located in water depths ranging from 63 m to 159 m, the overlap of Project activities with giant crab fishing is likely to be minimal. Therefore, activities from the Project are unlikely to have an impact to fishers within the fishery.

Summary of potential impacts to Commonwealth and State Managed Fisheries

Beach will continue consultation and, as with all activities, will provide stakeholders prior notification of operations and their timings. We will also request the formal issue of Notice to Mariners prior to activities commencing.

The application of safety zones around wells and OGPP tie in locations; cautionary and exclusion zones around the MODU; and SNAs around vessels undertaking Project activities in the Project Area; will prevent the risk of snagging and damaging fishing equipment as commercial fishing vessels will be excluded from these areas. The location of the flowline and umbilicals outside these areas will be clearly marked on marine charts and fishers will be made aware of their positions to enable avoidance.

Beach's Fair Ocean Access Procedure was developed with input from commercial fishing industry organisations (including Bass Strait Scallop Industry Association, Scallop Fisherman's Association of Tasmania, South East Trawl Fishing Industry Association and Tasmanian Seafood Industry Council). The procedure details the process whereby a commercial fisher can claim compensation for an economic loss associated with Beach's offshore activities where impacts cannot be avoided.

The application of safety zones, cautionary and exclusion zones, and SNAs in the Project area will ensure potential interactions with other users are limited to restricted access to these localised areas. As detailed above, Commercial and state managed fisheries have only recorded low levels of fishing effort within the Project Area. The Project Area does not overlap high relative intensity fishing areas and overlaps medium relative intensity only in one fishery, the Gillnet Hook Trap Sector Shark Gillnet sub-sector (0.4% overlap of the entire medium intensity areas for the fishery). As a result, low levels of commercial fishing activity have the potential to be prevented from the localised restriction of access of Commonwealth and state managed fisheries to specified areas in the Project Area. Localised restriction of potential low commercial fishing effort in the Project Area is considered to result in minor changes to the functions, interests, or activities of Commonwealth and state managed fisheries. These minor changes are evaluated as Minor (1) consequences that are considered lower-order impacts that is acceptable with the application of good industry practice.

6.1.3.2 Defence Activities

The Department of Defence have identified that the Project Area overlaps restricted airspace. Helicopter operations within the Project Area, to transfer personnel from the mainland to the MODU or vessels, may interact with Defence operations that restricts airspace within the Project Area. Helicopters currently access the Thylacine platform approximately once per week and to date there have been no negative interactions. Beach will ensure specified permissions for aircraft movement in restricted airspace will be attained from Air Traffic Control, if helicopter operations are required for the transfer of personnel to the MODU located in the Project Area overlapping restricted airspace. With specified permissions in place, helicopter operations will have negligible impacts to Defence operations.

6.1.3.3 Shipping

The Project Area includes major shipping routes (Section 4.5.6). The application of safety zones, cautionary and exclusion zones, and SNAs in the Project Area will prevent commercial vessels from entering localised areas within the Project Area. Commercial vessels are expected to avoid these localised areas with minor shipping route deviations. Any required deviations are expected to have negligible impact on travel times or fuel use of commercial vessels. All infrastructure will be identified on navigational charts and through Notice to Mariners advice. Vessel and MODU activities associated with the existing Otway Gas Development have been ongoing for over 10 years and to date there has been no interactions or incidents.

Minor shipping route deviations to commercial shipping vessels may occur during the Project. However prior notification through stakeholder consultation and the issuing of a notice to mariners will inform other users of safety zones around wells and OGPP tie in locations; cautionary and exclusion zones around the MODU; and SNAs around vessels undertaking Project activities in the

Project Area. Minor shipping route deviations to avoid localised safety, cautionary and exclusion zones and SNAs within the Project Area will have negligible or minor changes to the functions, interests, or activities of commercial vessels. These minor changes are evaluated as Minor (1) consequences that are considered lower-order impacts that is acceptable with the application of good industry practice.

6.1.3.4 Tourism and Recreational Diving and Fishing

Interaction with tourism and recreational diving and fishing is considered unlikely due to the offshore location of the Project Area, the lack of emergent features and water depths outside of recreational diving depths. The Project Area is approximately 17 km from the coast at its closest point and is situated in water depths of approximately 63 m to 160 m. Vessel based tourism and recreation activities occurs along the Victorian coastline in water depths approximately less than 11 m (Section 4.5.8). Consultation with local vessel charterers and providers of SCUBA tank fills has confirmed that diving activity is generally concentrated around The Arches Marine Sanctuary (17 km from the Project Area) and the wreck sites of the Loch Ard (18 km from the Project Area) and sometimes at the Newfield and Schomberg shipwrecks (16 and 17 km from the Project Area, respectively). The Project Area does not overlap these areas and as a result interaction with tourism and recreational diving and fishing is not expected to occur within the Project Area,

6.1.3.5 Cultural Values and Sensitivities

No First Nations people’s cultural activities have been identified to occur within the Project Area via stakeholder consultation or during Beach’s current Otway or Bass Operations.

Notices to Mariners will be issued for the Drilling Program and First Nation’s people or groups are consulted in relation to the Project activities as detailed in Section 10 of this OPP.

For potential interaction with First Nations people’s cultural values and sensitivities refer to Section 7.4

6.1.4 Impact Evaluation Summary

The impact evaluation for the potential for interaction with other users, is summarised in Table 6-2.

Table 6-2: Impact Evaluation Summary for Interaction with Other Users

Summary	
Summary of impact	The potential impacts to other users from the physical presence of the MODU, vessels, wells and subsea systems is expected to result in minor consequences of temporary and localised restricted access to specified safety zones within the Project Area.
Extent and duration of impact	For the life of the project, there will be mandatory 500 m petroleum safety zones gazetted around wells and OGPP tie in locations, from which third-party users will be prohibited entry. During drilling and installation activities there will be a temporary 500 m exclusion zone around the MODU and construction vessel from which third-party users will be prohibited entry) for campaigns of up to in the order of 30 to 40 days duration. In addition, there will be a 2 km cautionary zone around the MODU plus a 500 m Safe Navigation Area (SNA) around vessel(s) and any towed equipment during the seabed survey.
Level of certainty	At the time of writing this OPP, there is uncertainty with regards to the specific locations for wells and subsea systems. However, it is certain the locations for wells and subsea systems will be within the Project Area. The impact evaluation considers

Summary	
	any potential interaction with other users for the entire Project Area. This approach ensures all potential hazards and impacts have been evaluated for interaction with other users with potential activities in the Project Area. Further certainty on the location of wells and subsea systems will be known during the development of future EPs under this OPP. As a result, future EPs under this OPP will assess the potential interaction with other users based on well and subsea system locations that have greater certainty. Beach has a high level of certainty about the potential impacts to other users in the Project Area and has long-term experience in the area on the application of good industry practice to ensure impacts associated with interaction with other users are acceptable. Beach will continue stakeholder consultation and request issue of Notice to Mariners prior to activities commencing. These will inform other users and stakeholders of Project activities within the Project Area and minimise impacts on other users' activities.
Is the impact considered lower-order or higher-order?	Impacts from interaction with other users have been evaluated to result in Minor (1) consequences. Minor (1) consequences are considered lower-order impacts that are acceptable with the application of good industry practice.
Impact consequence	
Minor	

6.1.5 Demonstration of Acceptability

Table 6-3 demonstrates how and why predicted environmental impacts from physical presence – interaction with other marine users meets the defined acceptable levels (Table 5-4).

Table 6-3: Demonstration of Acceptability – Physical Presence – Interaction with Other Users

Demonstration of Acceptability		
Impact and risk comparison with relevant defined acceptable levels	The acceptable level relevant to the physical presence – interaction with other marine users includes acceptable level 14 (as detailed in Table 5-4). A Minor (1) consequence level was assigned for this aspect based on the impact analysis and evaluation. Minor (1) consequences resulting from interactions with other users: • will not result in interference with other marine users to a greater extent than is necessary for the reasonable exercise of the rights and performance of duties as conferred by the titles granted to Beach. As a result, the predicted environmental impact for other marine users is better than the defined acceptable level 14.	
Principles of ESD	Integration principle	Section 6.1.3 identifies and evaluates environmental impacts associated with the physical presence – interaction with other users. As part identifying the potential impacts; conservation values and sensitivities, physical environment, ecological environment, socio-economic values, and First Nations values and sensitivities (described in Section 4 were reviewed to determine potential interactions of the aspect against each of these receptors they may result in environmental impact. As a result, consideration of economic, environmental, social and equitable receptors was conducted as part of identifying the impacts and risks.

Demonstration of Acceptability		
		For Phase 1: Initial Project Consultation (Section 10.2.3), Beach consulted with relevant stakeholders on the Project and associated activities. No objections or claims were raised against this aspect during Phase 1: Initial Project Consultation (Section 10.2.3). The public, including relevant stakeholders, had the opportunity to provide further advice and responses for this OPP during the public consultation period (18/3/2024 – 20/5/2024). External context gained from the public consultation period allowed Beach to update the OPP. No public comment relating to this aspect was provided during the public consultation period. As a result, the impact assessment is considered acceptable to the public and therefore is of an acceptable level. The potential environmental impact against this aspect was assessed as having a Minor (1) impact consequence level which is considered a lower-order environmental impact. Lower-order environmental impacts are considered 'broadly acceptable' and considered managed to an acceptable level by meeting relevant requirements (adopted controls as listed below).
	Precautionary principle	The potential environmental impacts against this aspect were assessed as having a Minor (1) consequence level which is considered a lower-order environmental impact and below the defined acceptable level 14. Lower-order environmental impacts cannot result in serious or irreversible environmental damage. Despite uncertainty in the locations for wells and subsea systems, potential impacts were evaluated for any interactions within the Project Area. With significant experience operating in the Otway and Bass based on their existing offshore developments and associated activities including the Beach Otway Drilling Campaign in 2021/2022, Beach has high confidence in the potential environmental impacts and effectiveness of controls against this aspect.
	Intergenerational principle	The defined acceptable levels were developed to meet the principles of ESD (Section 5.8.5). Given predicted environmental impacts for interaction with other marine users is better than the defined acceptable level 14; the health, diversity, or productivity of the environment for future generations is expected to be maintained.
	Biodiversity principle	The potential environmental impacts against this aspect were assessed as having a Minor (1) consequence level which is considered a lower-order environmental impact and below the defined acceptable level 14. Lower-order environmental impacts cannot result in effects to biological diversity or ecological integrity.
Internal context	Beach Policy compliance	The defined acceptable levels, EPOs and controls proposed for this aspect are consistent with Beach Environmental Policy objectives. As a result, potential environmental impacts and risks from Project can be managed to align with Beach Environmental Policy objectives.
External context	Stakeholder engagement is being carried out as part of this OPP process.	

<table>
<tr><th colspan="2">Demonstration of Acceptability</th></tr>
<tr><td></td><td>Beach operates the existing Otway project and has established good relations with both onshore and offshore stakeholders. Engagement with stakeholders will continue throughout all aspects of the Project to build and maintain trust with stakeholders and the local community and minimise community and stakeholders concern and impacts where practicable.
During Phase 1: Initial Project Consultation (Section 10.2.3), no objections or claims were raised against this aspect.
During the public consultation period (18/3/2024 – 20/5/2024) (Section 10.2.4), comments were raised against this aspect. The assessment of merit for comments against this aspect found the responses provided in the public comment report to be sufficient to address the comments against this aspect. Given the thorough assessment and responses outlined in the public comment report, the impact evaluation for this aspect remains acceptable as is, demonstrating that public comments have been adequately addressed.</td></tr>
<tr><td>Other requirements</td><td>Other requirements associated with this aspect includes compliance with Australian legislative requirements.
Management of this aspect is aligned with the legislative requirements below.
<table>
<tr><th>Requirement</th><th>Demonstration</th></tr>
<tr><td>Navigation Act 2012 (Cth)
Notice to mariners
Several Marine Orders (MO) are enacted under this Act which relate to offshore petroleum activities, including:
• MO 21: Safety and emergency arrangements
• MO 30: Prevention of collisions
• MO 31: SOLAS and non-SOLAS certification</td><td>These requirements are addressed through the adoption of the following control measures:
CM01 Navigation safety
Beach Marine Assurance System ensures that the MODU and vessels meet relevant maritime laws and includes pre-commencement MODU and vessel inspections of class certification requirements under the <i>Navigation Act 2012</i> and associated Marine Orders.
All vessels operating within the project area will adhere to the navigation safety requirements including:
• International Regulations for Preventing Collisions at Sea 1972
• Chapter 5 of International Convention for the Safety of Life at Sea 1974
• International Convention on Standards of Training, Certification and Watchkeeping for Seafarers 1978
• <i>Navigation Act 2012</i> and any subsequent Marine Orders that specify standards for crew training and competency, navigation, communication, and safety measures
CM02 Notifications
The Australian Hydrographic Office will be notified of the Project activities and installed subsea infrastructure prior to commencement to facilitate the issuing of Notice to Mariners and maintain nautical charts.
Relevant stakeholders are notified prior to the activity so that third party marine users are aware of vessel location and timing.</td></tr>
</table></td></tr>
</table>

Demonstration of Acceptability		
	OPGGS Act 2006 (Cth) Section 280 – requires that a person carrying out activities in an offshore area under the permit, lease, licence, authority or consent must carry out those activities in a manner that does not interfere with navigation or fishing (among others). Section 616(2) – requires establishment and maintenance of petroleum safety zones	This requirement is addressed through the adoption of the following control measures: **CM03 Fair Ocean Access Procedure** Beach's Fair Ocean Access Procedure was developed with input from commercial fishing industry organisations. The procedure details the process whereby a commercial fisher can claim compensation for an economic loss associated with Beach's offshore activities where impacts cannot be avoided. An information sheet on the procedure is available in Appendix D. **CM04 Stakeholder consultation** Beach will undertake consultation with relevant persons for all petroleum activities in accordance with the OPGGS (Environment) Regulations and detailed in Section 10 of this OPP. Observation, incidents, and opportunities for improvement regarding the interaction with other users will be reported to other petroleum titleholders. **CM05 Petroleum safety zones** The Project will comply with OPGGS Act 2006 – Section 616(2) petroleum safety zones, which includes establishment and maintenance of petroleum safety zones around wells, offshore structures or equipment which prohibits vessels entering without written consent. **CM06 Temporary exclusion/cautionary zones** 500m temporary exclusion and 2 km cautionary zones will be established and maintained around drilling and installation activities.
	Environmental Protection (Sea Dumping) Act 1981 (Cth) Sea dumping permits	This requirement is addressed through the adoption of the following control measures: **CM07 Decommissioning** Decommissioning of subsea wells and infrastructure in compliance with Section 572 of the OPGGS Act.

6.1.6 Environmental Performance

In accordance with NOPSEMA's OPP Decision Making Guideline (NOPSEMA 2024), the EPO for this aspect (Table 6-4) has been developed to be relevant to identified environmental impacts and risks, consistent with the principles of ESD and equivalent to or better than the defined acceptable level of impact. Control measures listed in Table 6-3 provides detail on how each control measure will be implemented for the Project to ensure the acceptable levels and EPOs, defined in Table 6-4 are met.

Table 6-4: Environmental Performance Outcomes: Physical Presence – Interaction with Other Users

Defined Acceptable Level	Environmental Performance Outcomes	
Acceptable level 14: No interference with other marine users to a greater extent than is necessary for the reasonable exercise of the rights and performance of duties as conferred by the titles granted to Beach.	EPO1:	Implement CM5 and CM6 for the establishment and maintenance of petroleum safety zones, temporary exclusion zones and cautionary zones.
	EPO2:	Decommissioning of Project facilities in compliance with Section 572 (3) of the *Offshore Petroleum and Greenhouse Gas Storage Act 2006* (Cth).

6.2 **Physical Presence – Seabed Disturbance**

6.2.1 Hazard Identification

During all stages of the Project, seabed disturbance is an outcome resulting from activities which interact with the seabed. Stages and associated activities which will interact with the seabed are defined below in Table 6-5 and described in Section 6.2.2.

Table 6-5: Activities Undertaken During the Project which may Result in Seabed Disturbance

Stage	Activity
Surveys	Geotechnical survey
Drilling and completions	MODU Positioning Drilling Method
Installation and commissioning	Installation
Operations	Inspection, maintenance and repair Well intervention and workovers
Decommissioning	Removal of subsea infrastructure Well plugging and abandonment
Support operations	Vessel operations ROV operations

6.2.2 Hazard Description

6.2.2.1 Surveys

Geotechnical surveys may be required to collect data to inform installation activities, in order to confirm the seabed sediments. Depending on the area surveyed, geotechnical surveys may take up to 10 to 20 days. Seabed disturbance can result from placing survey equipment on the seafloor, or when collecting seabed samples.

Geotechnical surveys typically involve in-situ testing and piston/push sampling. Following sampling, all equipment is withdrawn from the seabed creating short-term seabed disturbance. A small hole (<1 m^2) may temporarily remain, which will rapidly collapse and infill with the movement of surface sediments in ocean current given the highly mobile seabed of the region. Approximately 74 samples are expected during a single campaign under the Project, resulting in a total area of 74 m^2 of seabed disturbance during a single campaign.

6.2.2.2 Drilling

1. MODU Positioning

Drilling operations will be undertaken using a semi-submersible MODU. The MODU will use a mooring system to remain in position that will result in short-term seabed disturbance.

Each mooring will consist of:

- 8 to 12 anchors, each covering an area of approximately 30 – 60 m^2.
- 8 to 12 x 2500 m lengths chain (Chain width of ~0.3 m). Approximately 1000 to 1,200 m of the chain length is grounded chain, resulting in total disturbance area of 4,320 m^2 per well.

Thus, the total area of short-term seabed disturbance per well is up to approximately 5,040 m^2 (0.0050 km^2)

2. Drilling Method

Drilling of the wells will result in short-term seabed disturbance from the discharge of drilling fluids and cuttings to the seabed during drilling of the upper well sections. The upper well sections of each well will be drilled riserless (with seawater scuffs) with drilling fluids and cuttings discharged in the near vicinity of the hole. Seabed disturbance from upper well section drilling fluids and cuttings discharges is expected to be within 1 km of the well location (RPS 2023).

Drill cuttings from the bottom hole sections will be discharged at the sea surface from the MODU after being processed and will disperse further and settle on to the seabed. These impacts have been evaluated as part of Section 6.7 Planned Discharge – Drill Cuttings and Fluids.

6.2.2.3 Installation and Commissioning

Subsea systems infrastructure, including umbilicals, flowlines and subsea structures (wellheads, manifolds, skids), will be placed on the seabed resulting in long-term seabed disturbance. Localised placement of stabilisation material may be required to assure stability adjacent to well and structure tie-in locations.

As a conservative estimate, based on the maximum 9 wells anticipated for the Project, the total seabed disturbance footprint from 9 subsea systems including wells, flowlines and stabilisation support is ~4.1 km^2.

6.2.2.4 Operations

1. Inspection, Maintenance and Repair (IMR)

IMR activities may result in small areas of disturbance to the seabed due to placement of stabilisation mattresses and disturbance to sediments around the infrastructure. This will result in highly localised and short-term seabed disturbance.

2. Well Intervention and Workovers

Well intervention and workover operations may necessitate actions such as well servicing, temporary suspension, plugging, or permanent abandonment. These activities can disturb the seabed and their frequency depends on the well's performance. Seabed disturbance footprint for well intervention and workovers is anticipated to be the same as for drilling (refer to Section 6.2.2.2).

6.2.2.5 Decommissioning

A MODU or lightweight intervention vessel will be used to remove subsea infrastructure including flowlines, umbilicals, subsea structures and plug and abandonment of wells. Decommissioning of subsea infrastructure is expected to take up to approximately 30 days per tie-back, with P&A of wells estimated at up to approximately 30 days per well.

The seabed disturbance footprint for decommissioning will be similar to the footprints for drilling (Section 6.2.2.2) and installation (Section 6.2.2.3). Following well plugging and abandonment, wellheads will be cut below seabed and removed to eliminate seabed disturbance from scouring.

6.2.2.6 Support Operations

Vessel anchoring in deeper waters for support vessels is unlikely. Occasions where support vessels may anchor include during an emergency, or while working on the flowline routes to conserve fuel. Should support vessel anchoring be required, the level of seabed disturbance is dependent on the anchoring, however, use of a single anchor could result in a total disturbance area of up to 1300 m^2 (NERA, 2018).

The use of an ROV or AUV during may result in temporary seabed disturbance when temporarily parked on the seabed. In the event a ROV is required to temporarily park on the seabed, the short-term seabed disturbance footprint is estimated to be 2.5 m × 1.7 m (4.25 m^2).

6.2.2.7 Total Project Seabed Disturbance Footprint

The total area of seabed disturbance from Project activities identified in Table 6-5 is summarised below in Table 6-6. The impact assessment for seabed disturbance considers the total Project seabed disturbance footprint. As a result, concurrent or sequential activities are considered assessed given the entire Project seabed disturbance footprint is evaluated for potential impacts.

Table 6-6: Total area of Seabed Disturbance from Each Stage and Activity

Stage	Activity	Description of pathway	Predicted impact for footprint	Footprint area
Short-term seabed disturbance				

Stage	Activity	Description of pathway	Predicted impact for footprint	Footprint area
Surveys	Geotechnical survey	Seabed disturbance will occur during geotechnical survey from the physical footprint of taking a CPT, core, or sediment sample.	Geotechnical samples for wells, and anchor locations • ~74 locations x 1 m^2 ◦ Subtotal = 74 m^2 Proposed flowline route 10 samples along route • 10 x 30 m^2 ◦ Subtotal = 300 m^2	0.37 km^2
Drilling	MODU positioning	Anchors will be used to maintain position of the MODU during normal operations.	Maximum of 12 anchors and chains. Footprint of up to: • 420 m^2 per anchor and chain. • 45,360 m^2 (9 x 12 x 420) for Drilling Program. Based on 9 wells (including 8 new wells and re-entry/completion at Artisan 1)	45.36 km^2
Operations	Inspection, maintenance and repair	Emergency anchoring or temporary wet parking of equipment or an ROV will take place within the area where long-term seabed disturbance is expected.	N/A	N/A
			Total short-term footprint	**~45.73 km^2**
Long-term seabed disturbance				
Installation and Commissioning	Installation	New subsea infrastructure	Estimated as a 0.1 km corridor along ~41 km of flowline route. All subsea infrastructure included in corridor. • 41 km x 0.1 km ◦ Subtotal = 4.1 km^2	4.1 km^2
Drilling	Drilling	New wells - drilling of the upper hole section including initial penetration of the seabed	Per well: ~0.67 m^2 footprint (8 new wells)	0.005 km^2
		Drilling discharges (i.e. cement and drill	Per well: ~3.14 km footprint (8 new wells)	25.12 km^2

Stage	Activity	Description of pathway	Predicted impact for footprint	Footprint area
		cuttings) may be present up to 1 km from the well and are described and assessed in Section 6.7.		
Support operations	Vessel anchoring	Emergency anchoring or temporary wet parking of equipment or an ROV will take place within the area where long-term seabed disturbance is expected.	N/A	N/A
			Long-term footprint	**29.22 km^2**
Total seabed disturbance footprint for Project				**74.95 km^2**

6.2.3 Impact Analysis and Evaluation

Seabed disturbance from the Project can result in impacts to:

- Water quality, resulting in:
    - Change in water quality
- Benthic habitats and communities resulting in:
    - Injury/mortality to fauna.
    - Change in habitat.

Seabed disturbance from the Project also has the potential to result in indirect changes to the functions, interests, or activities of the following receptors:

- Commonwealth and state commercial fisheries
- Subsea infrastructure including UXO.
- Cultural values and sensitivities.

6.2.3.1 Water Quality

Seabed disturbances during the Project (refer to Table 6-6) has the potential to suspend seabed sediments into the water column which will temporarily change the water quality, increasing turbidity levels, until suspended sediments settle back on the seabed. Each Project activity described in Table 6-6, is expected to generate a temporary plume of suspended sediment within areas of soft sand habitats. Given the hydrodynamics in open ocean areas such as the Project Area, suspended sediments are expected to quickly disperse and settle out of the water column within tens of metres of the seabed disturbance area. Change in water from increase in turbidity is expected to be localised and temporary, as suspended sediment loads will be limited to the small footprint for each Project activity

(Table 6-6). The potential change in water quality is expected to be similar to those caused by natural factors, such as strong water currents (NERA, 2018).

Localised and temporary changes to water quality from seabed disturbance during the Project at levels considered similar to natural changes to water quality from water currents has been evaluated as a Minor (1) consequence. Minor (1) consequences are considered lower-order impacts that are acceptable with the application of good industry practice.

6.2.3.2 Benthic Habitats and Communities

Benthic habitats and communities within the Project Area may temporarily change during short-term seabed disturbance activities or will be subject to long-term changes from the physical presence of seabed systems infrastructure during the Project. Benthic habitats expected to be found within the Project Area include carbonate sands, low relief exposed limestone, sponge beds and unconsolidated sediment (IMAS 2017). Benthic communities in the Project Area are expected to consist of numerous marine invertebrates, sessile epifauna and bryozoans. It is unlikely that extensive areas of rocky reefs or outcrops (where sponges, coral and more diverse fauna may be present) occur within the Project Area. Prior to the commencement of the seabed disturbance activities, a seabed survey will be conducted to obtain further information on the benthic habitat and species in the Project Area. It is expected that benthic habitats and communities within the Project Area are highly represented throughout the region (see Section 4.4.1 for further details).

The footprint for short-term changes in habitat is estimated to be ~45.73 km^2, whereas the footprint for long-term changes in habitat is estimated to be 4,17 km^2. The extent of short-term and long-term changes in habitat is considered small in relation to the highly represented benthic habitats found in the Project Area and the Otway Basin.

Injury or mortality to benthic fauna communities may occur from the short-term or long-term changes in habitat, specifically sessile taxa. Ecological receptors likely to be present within the Project Area that may be impacted by seabed disturbance include:

- Benthic and filter-feeding epifauna (e.g. sponges, macroalgae, coral, bryozoans, molluscs, ascidians)
- Crustaceans (e.g. giant crabs, rock lobster, shrimp, krill)
- Echinoderms (e.g. urchins, sea cucumbers), and
- Annelids (e.g. polychaete worms).

The physical presence of seabed system infrastructure may also lead to the emigration of resident mobile biota and colonisation of sessile benthic biota such as sponges and gorgonians on the hard surfaces of seabed infrastructure (Dernie et al. 2003). The biological impacts to benthic habitats and communities depends upon the equipment, footprint, seabed substrate, the frequency and the ecosystem's resilience (Watson et al. 2022). Furthermore, the recovery timeframe following seabed disturbance also varies on several factors, including the species and seabed substrate disturbed (Hiddink et al. 2017), the time of year, larval recruitment, and the local hydrodynamics (Dernie et al. 2003). There is limited information on the recovery of benthic habitats after the removal of anchors and other equipment.

A study on the recovery of seabed following bottom trawling activities identified faster recovery times for coarse-sediment (sand) compared to fine-sediment regions (Hiddink et al. 2017). Dernie et al. (2003) identified that benthic community recovery time following physical disturbance in soft sediment habitats varied from 64 days for low intensity disturbances, up to 208 days following higher intensity disturbance. For Project activities, it is expected that following short-term seabed disturbances and decommissioning (refer to Table 6-6), disturbed areas will recolonise quickly as impacted areas for each activity are small and the benthic habitat is consistent with the low intensity disturbances recovery period, as identified by Hiddink et al. 2017 and Dernie et al. 2003. Impacts are not expected to cause long-lasting changes to population characteristics.

The extent of the impact is predicted to be ~74.95 km^2 (including subsea infrastructure) for the Project. Given the above, change in habitat from seabed disturbance is likely to result in Minor (1) consequences. The impact from Minor (1) consequences is therefore acceptable based on:

- The area of impact is predicted to be small per well location (including typical subsea infrastructure) compared to the extent of the distribution of the benthic habitats and communities found within the Project Area.
- The PMST Report did not identify any marine protected areas, KEFs, threatened benthic species or ecological communities, critical habitats or BIAs relevant to the benthic environment within the Project Area.
- Impacts are localised, with the impacted area of seabed predicted to return to pre-impacted state with no long-term effects to habitat, population characteristics or productivity.
- Studies on benthic habitat and assemblages within the Project Area did not identify the area as unique, with similar benthic habitats found elsewhere in the region.
- Seabed surveys will be undertaken to allow for the consideration of seabed habitat type in the final selection of well locations to avoid area of high relief outcrops, reefs or sponge beds.
- Seabed disturbance associated with the Project is not predicted to impact marine ecosystem integrity or functioning.

6.2.3.3 Commonwealth and State Commercial Fisheries

Seabed disturbance has the potential to result in a change to benthic habitat and, subsequently, to associated commercially valued benthic species. Potential changes to commercially valued benthic species in the Project Area may result in indirect changes to the functions, interests, or activities of Commonwealth and state commercial fisheries. There are two commercially fished marine benthic invertebrate species which are present within the Project Area which could be indirectly susceptible to seabed disturbance: the giant crab, and the southern rock lobster (Section 4.4.7.1).

Southern rock lobster live in rocky reefs (VFA 2023b) a habitat unlikely to be disturbed by Project activities as rocky reefs are not an appropriate substrate for anchoring or drilling of a well. Giant crab have recorded movements up and down the continental shelf depending on food availability (Levings et al. 2001), with seabed disturbance in potential giant crab habitats in the Project Area potentially leading to emigration of the mobile biota to other areas along the continental shelf.

The extent of the impact is predicted to be ~74.95 km^2 (including subsea infrastructure) for the Project. Given the above, the impact from seabed disturbance is likely to result in Minor (I) consequences. to the functions, interests, or activities of Commonwealth and state commercial fisheries The impact from Minor (1) consequences is therefore acceptable based on:

- Giant crab and southern rock lobster are mobile species and are generally less vulnerable than sessile taxa to sedimentation, as they are able to move to areas with less sediment accumulation or by more efficiently physically removing particles (Fraser et al. 2017).
- The Project Area intersects the following giant crab and southern rock lobster fisheries areas:
  - Southern rock lobster
    - 14 of the 200 Victorian southern rock lobster reporting blocks (up to 20 active vessels – Figure 4-78).
    - The Project Area does not overlap the Tasmanian southern rock lobster reporting blocks.
  - Giant crab
    - 9 of the 48 Victorian giant crab reporting blocks (up to 13 active vessels – Figure 4-74).
    - 1 of the 386 Tasmanian giant crab reporting blocks (confidential fishing effort due to less than 5 vessels being active within the fishery – Figure 4-81).
- The southern rock lobster fishery has a stock status listed as sustainable for Victoria, Tasmania and South Australia (FRDC 2020). The giant crab fishery has a stock status listed as sustainable for Victoria and South Australia and depleted for Tasmania (FRDC 2020; 2020a). The depleted stock status for the Tasmanian giant crab fishery is based on data obtain from 2013-2014, and there has been insufficient data for the fishery since 2013 to determine if the stock is recovering (FRDC 2020a).
- Due to the spatial area of seabed which may be disturbed within the wider extent of available fishing grounds and the short duration of Project activities which would interact with the seabed, impacts to benthic species of commercial importance are predicted to be localised and insignificant at a population level.
- As rock lobster live in rocky reefs (VFA 2023b) it is unlikely that their habitat would be disturbed as rocky reefs are not an appropriate substrate for anchoring or drilling of a well.
- Seabed surveys will be undertaken to allow for the consideration of seabed habitat type in the final selection of well locations to avoid area of high relief outcrops, reefs or sponge beds.
- The area of impact is predicted to be small compared to the extent of available and utilised commercial fishing areas for both the Victorian and Tasmanian giant crab and southern rock lobster fisheries.

6.2.3.4 Unexploded ordnance (UXO)

As detailed in Section 4.5.5 the Project Area overlaps UXO Zone 1052 King Island which is within the 'slight potential' category, meaning there is confirmed history of military activities that may have resulted in numerous residual hazardous munitions, components, or constituents, but where confirmed UXO affected areas cannot be defined (DoD 2022).

The extent of the impact is predicted to be ~74.95 km^2 (including subsea infrastructure) for the Project. Given the above, the impact from seabed disturbance is likely to result in Minor (1) consequences. The impact from Minor (1) consequences is therefore acceptable based on:

- For parts of the Project Area, Beach undertook site surveys ahead of the Otway Drilling Campaign in 2021/2022, with no UXO identified.
- A seabed survey will be undertaken to identify any UXO with any known locations included in the Drill Rig Mooring Plan (CM06) and Drilling Program (CM09).

6.2.3.5 Cultural values and sensitivities

As detailed in Section 4.6 no First Nations underwater cultural heritage has been identified in the Project Area. However, First Nations people specifically Eastern Maar highlights that although the edge of the continental shelf is under sea, it was occupied for thousands of years and rising sea levels have not washed away the history, physical evidence, or connection to that part of Sea Country (Section 4.6.3.5). At present, oil and gas infrastructure exists across the Otway Basin and memories and songlines relating to the historical occupation of the present-day seabed are still acknowledged and recognised (Biosis 2023).

Management of intangible cultural heritage can include reducing impacts and risks to environmental features that are associated with intangible cultural heritage (Australia ICOMOS Burra Charter, 2013). As per the draft Guidelines for Working in the Near and Offshore Environment to Protect Underwater Cultural Heritage (DCCEEW 2023) Beach has consulted with First Nations groups and relevant underwater culture heritage researchers and organisations to understand what data could be obtained from the seabed survey that will be undertaken prior to the seabed disturbing activities (refer to Table 6-6) to identify First Nations submerged cultural heritage and submerged cultural landscapes. Data from seabed surveys will be provided to an appropriately qualified underwater archaeologist to identify submerged cultural heritage. Should any submerged cultural heritage be identified, Beach will consult with the relevant First Nations groups (see Section 4.6.2) and determine any exclusion areas or further cultural heritage management procedures that may be required. Thus, impacts to First Nations underwater cultural heritage are not predicted.

6.2.4 Impact Evaluation Summary

The impact evaluation for seabed disturbance is summarised in Table 6-7.

Table 6-7: Impact evaluation summary for seabed disturbance

Summary	
Summary of impact	The potential localised seabed disturbance impacts in the Project Area are expected to result in minor consequences to water quality, benthic habitats, Commonwealth and State commercial fisheries, and UXO.

	Benthic habitats and communities in the Project Area include carbonate sands, low relief exposed limestone, sponge beds and unconsolidated sediment supporting bryozoans, which are highly represented throughout the planning area and Otway Basin region. There are no marine protected areas, KEFs, threatened benthic species or ecological communities, critical habitats, or BIAs relevant to the benthic environment within the Project Area. The total seabed disturbance footprint is ~74.95 km^2 over the duration of the Project. Minor consequences to water quality, benthic habitats, Commonwealth and State commercial fisheries, UXO and cultural values and sensitivities are based on the following conclusions: • Localised and brief increase in turbidity in an area where suspended sediments occur naturally from strong water currents • Seabed disturbance footprint is small compared to the extent of the distribution of the benthic habitats and communities found within the Project Area • Following short-term seabed disturbances and decommissioning (refer to Table 6-6), disturbed areas will recolonise quickly as impacted areas for each activity are small • Impacts to benthic species of commercial importance are predicted to be localised and insignificant at a population level considering the wider extent of available fishing grounds and species habitat • Beach is committed to undertake seabed surveys to identify any UXO to avoid UXO impacts • Beach is committed to undertake seabed surveys, commission an appropriately qualified underwater archaeologist to identify submerged cultural heritage and where appropriate engage with First Nations groups to avoid impacts to cultural values and sensitivities. The Minor (1) consequences to water quality, benthic habitats, Commonwealth and State commercial fisheries, UXO and cultural values and sensitivities from seabed disturbance is considered acceptable, given controls are in place to ensure potential impacts are better than the defined acceptable levels 1, 6, 14, 15 and 16.
Extent and duration of impact	Localised – the seabed disturbance footprint is small compared to the extent of the distribution of the benthic habitats and communities found within the Project Area. Short-term seabed disturbance is less than 2.5% of the Project Area and long-term seabed disturbance is less than 1.5% of the Project Area. Temporary – Following short-term seabed disturbances and decommissioning (refer to Table 6 2), disturbed areas will recolonise quickly as impacted areas for each activity are small.
Level of certainty	At the time of writing this OPP, there is uncertainty with regards to the locations of unidentified UXOs and cultural heritage values and sensitivities. The uncertainty of these unidentified objects in the Project Area will be managed through the implementation of the following controls: • Beach is committed to undertake seabed surveys to identify any UXO to avoid UXO impacts • Beach is committed to undertake seabed surveys and commission an appropriately qualified underwater archaeologist to identify submerged cultural heritage and where appropriate engage with First Nations groups to avoid impacts to cultural values and sensitivities.to avoid impacts to cultural values and sensitivities. These controls adhere with industry standards and the *Cultural Heritage Act 2018* and Guidelines on the application of the Underwater Cultural Heritage Act 2018 (DCCEEW 2023).

	Beach has a high level of certainty about the potential impacts from seabed disturbance and how to address uncertainty with regards to unidentified UXOs and submerged cultural heritage. Beach has long-term experience in the area on the application of good industry practice to ensure impacts associated with seabed disturbance are acceptable.
Is the impact considered lower-order or higher-order?	Potential impacts from seabed disturbance have been evaluated to result in Minor (1) consequences. Minor consequences are considered lower-order impacts that is acceptable with the application of good industry practice.
Impact consequence	
Minor	

6.2.5 Demonstration of Acceptability

Table 6-8 demonstrates how and why predicted environmental impacts from physical presence – seabed disturbance meets the defined acceptable levels (Table 5-4).

Table 6-8: Demonstration of Acceptability – Physical Presence – Seabed Disturbance

Demonstration of Acceptability		
Impact and risk comparison with relevant defined acceptable levels	The acceptable level relevant to the physical presence – seabed disturbance includes acceptable levels 10, 11, 15 and 16 (as detailed in Table 5-4). A Minor (1) impact consequence level was assigned for this aspect based on the impact analysis and evaluation. Minor (1) consequences resulting from seabed disturbance: • will not impacts on unique seafloor habitats to the south-east region, including deep-sea reefs, continental shelf habitats, seamounts canyons and kelp forests. • will only impact on benthic habitats and communities within the Project Area that are highly represented throughout the region and are not unique seafloor habitats • will not impact on underwater cultural heritage with values as conferred by the *Underwater Cultural Heritage Act 2018* (Cth) • will not impact on declared areas or objects of particular significance with values as conferred by the *Aboriginal and Torres Strait Islander Heritage Protection Act 1984* (Cth). As a result, the predicted environmental impact for the seabed is better than the defined acceptable levels 10, 11, 15 and 16.	
Principles of ESD	Integration principle	Section 6.2.3 identifies and evaluates environmental impacts associated with the physical presence – seabed disturbance. As part identifying the potential impacts; conservation values and sensitivities, physical environment, ecological environment, socio-economic values, and First Nations values and sensitivities (described in Section 4) were reviewed to determine potential interactions of the aspect against each of these receptors they may result in environmental impact. As a result, consideration of economic, environmental, social and equitable receptors was conducted as part of identifying the impacts and risks. During Phase 1: Initial Project Consultation (Section 10.2.3), Beach consulted with relevant stakeholders for feedback in relation to the Project, the planning area, environmental impact and risk evaluations, and the acceptability evaluation.

		No objections or claims were raised against this aspect during Phase 1: Initial Project Consultation (Section 10.2.4). The public, including relevant stakeholders, had the opportunity to provide further advice and responses for this OPP during the public consultation period (18/3/2024 – 20/5/2024). External context gained from the public consultation period allowed Beach to update the OPP. No public comment relating to this aspect was provided during the public consultation period. As a result, the impact assessment is considered acceptable to the public and therefore is of an acceptable level. The potential environmental impact against this aspect was assessed as having a Minor (1) impact consequence level which is considered a lower-order environmental impact. Lower-order environmental impacts are considered 'broadly acceptable' and considered managed to an acceptable level by meeting relevant requirements (adopted controls as listed below).
	Precautionary principle	The potential environmental impacts against this aspect were assessed as having a Minor (1) impact consequence level which is considered a lower-order environmental impact and below the defined acceptable levels 10, 11, 15 and 16. Lower-order environmental impacts cannot result in serious or irreversible environmental damage. Despite uncertainty on the presence of unidentified UXO and cultural heritage in the Project Area, Beach is confident that seabed surveys and commissioning an appropriately qualified underwater archaeologist to identify UXOs and submerged cultural heritage will prevent impacts to underwater cultural heritage. With significant experience operating in the Otway and Bass based on their existing offshore developments and associated activities including the Beach Otway Drilling Campaign in 2021/2022, Beach has high confidence in the potential environmental impacts and effectiveness of controls against this aspect.
	Intergenerational principle	The defined acceptable levels were developed to meet the principles of ESD (Section 5.8.5). Given predicted environmental impacts from seabed disturbance is a lower-order environmental impact and below the defined acceptable levels 10, 11, 15 and 16 ; the health, diversity, or productivity of the environment for future generations is expected to be maintained.
	Biodiversity principle	Section 6.2.3 identifies and evaluates environmental impacts associated with the physical presence – seabed disturbance. As part of identifying the potential impacts; conservation values and sensitivities including MNES in Section 4 were reviewed. The potential environmental impacts against this aspect were assessed as having a Minor (1) impact consequence level which is considered a lower-order environmental impact and below the defined acceptable levels 10, 11, 15 and 16 . Lower-order environmental impacts cannot result in affects to biological diversity or ecological integrity.
Internal context	Beach Policy compliance	The defined acceptable levels, EPOs and controls proposed for this aspect are consistent with Beach Environmental Policy objectives. As a result, potential environmental impacts and risks

<table>
<tr><td></td><td></td><td>from Project can be managed to align with Beach Environmental Policy objectives.</td></tr>
<tr><td>External context</td><td colspan="2">Stakeholder engagement is being carried out as part of this OPP process.
Beach operates the existing Otway project and has established good relations with both onshore and offshore stakeholders. Engagement with stakeholders will continue throughout all aspects of the Project to build and maintain trust with stakeholders and the local community and minimise community and stakeholders concern and impacts where practicable.
During Phase 1: Initial Project Consultation (Section 10.2.3), no objections or claims were raised against this aspect.
During the public consultation period (18/3/2024 – 20/5/2024) (Section 10.2.4), comments were raised against this aspect. The assessment of merit for comments against this aspect found the responses provided in the public comment report to be sufficient to address the comments against this aspect. Given the thorough assessment and responses outlined in the public comment report, the impact evaluation for this aspect remains acceptable as is, demonstrating that public comments have been adequately addressed.</td></tr>
<tr><td>Other requirements</td><td colspan="2">Other requirements associated with this aspect includes compliance with Australian legislative requirements.
Management of this aspect is aligned with the legislative requirements below.
<table>
<tr><th>Requirement</th><th>Demonstration</th></tr>
<tr><td>OPGGS Act 2006 (Cth):
Section 460(2) – a person carrying on activities in an offshore area under the permit must carry out those activities in a manner that does not interfere with…the conservation of the resources of the sea and seabed to a greater extent than is necessary for the reasonable exercise of the rights and performance of the duties of the first person.</td><td>This requirement is addressed through the adoption of the following control measures:
CM07 Decommissioning
Decommissioning of subsea wells and infrastructure in compliance with Section 572 of the OPGGS Act.
CM08 Project Execution Plans
Infrastructure will be positioned on the seabed within design footprint to reduce seabed disturbance and avoid unique seafloor habitats in the Project Area.
CM09 MODU and Vessel Anchoring Plan
A MODU and vessel anchoring plan will identify suitable areas for anchors to be placed within the Project Area to avoid unique seafloor habitats.</td></tr>
<tr><td>Underwater Cultural Heritage Act 2018 (Cth) and Assessing and Managing Impacts to Underwater Cultural Heritage in Australian Waters – Guidelines on the application of the Underwater Cultural Heritage Act 2018 (DCCEEW 2023)
All actions involving seabed contact…have potential to cause adverse impact to located or unlocated UCH… proponent is responsible for</td><td>CM10 Seabed assessments
Seabed assessments undertaken of each well location and tie-back route prior to final selection to identify seabed composition, benthic habitats and communities and ensure areas of high relief outcrops, reefs, sponge beds, maritime archaeology, UXOs, submerged cultural heritage and landscapes are avoided where practicable within technical and safety constraints.
Seabed assessment data will be provided to the following appropriately qualified specialists to identify sensitive benthic receptors:
• Marine benthic ecologist to identify seabed habitat types including areas of high relief</td></tr>
</table>
</td></tr>
</table>

	meeting the protection requirements of the UCH Act.' Requirements include: • No adverse impact to UCH without a permit; • Notify the discovery of all suspected UCH exposed through the proposed action within 21 days of discovery. An adequate process of UCH assessment, impact mitigation and management is to be undertaken ahead of (and in certain cases concurrent with and/or following) any proposed actions in the near and offshore environment	outcrops, reefs or sponge beds that are likely to be associated with site-attached fish. • Underwater archaeologist to identify shipwrecks and other maritime archaeological heritage. • Geophysical data analyst to identify location of unexploded ordinances. • Underwater archaeologist to identify submerged cultural heritage and landscapes. Reports from each specialist evaluation of seabed assessment data will be provided to Beach. Beach will assess the reports and identify any areas of overlap, potential risks from Project activities, and determine any exclusion areas that may be required. **CM11 Cultural heritage assessments** Imagery and data from seabed surveys and assessments will be provided to appropriately qualified underwater archaeologists to identify any maritime archaeological and submerged cultural heritage and landscapes and inform protection priorities, management measures and reporting requirements. Should any maritime archaeological and submerged cultural heritage and landscapes be identified, Beach will report the findings in accordance with the *Underwater Cultural Heritage Act 2018*, and will consult with the relevant First Nations groups and determine any exclusion areas or further cultural heritage management procedures that may be required.

6.2.6 Environmental Performance

In accordance with NOPSEMA's OPP Decision Making Guideline (NOPSEMA 2024), the EPO for this aspect (Table 6-9) has been developed to be relevant to identified environmental impacts and risks, consistent with the principles of ESD and equivalent to or better than the defined acceptable level of impact. Control measures listed in Table 6-8 provides detail on how each control measure will be implemented for the Project to ensure the acceptable levels and EPOs, defined in Table 6-9 are met.

Table 6-9: Environmental Performance Outcomes: Physical Presence – Seabed Disturbance

Defined Acceptable Level	**Environmental Performance Outcomes**	
Acceptable level 10: No impacts on unique seafloor habitats[1] to the south-east region, including deep-sea reefs, continental shelf habitats, seamounts canyons and kelp forests. **Acceptable level 11**: Impacts on benthic habitats and communities within the Project Area that are highly represented throughout the region and are not unique seafloor habitats is acceptable.	EPO3:	Implement CM08 Project Execution Plans and CM09 MODU and Vessel Anchoring Plan to ensure placement of infrastructure and anchors will avoid unique seafloor habitats in the Project Area.
	EPO2:	Decommissioning of Project facilities in compliance with Section 572 (3) of the Offshore Petroleum and Greenhouse Gas Storage (OPGGS) Act 2006 (Cth)

	EPO4:	Implement CM 10 Seabed assessments to identify seabed composition, benthic habitats and communities and ensure areas of unique seafloor habitats, maritime archaeology, UXOs, submerged cultural heritage and landscapes are avoided where practicable within technical and safety constraints.
Acceptable level 15: No impacts on underwater cultural heritage with values as conferred by the *Underwater Cultural Heritage Act 2018* (Cth). **Acceptable level 16**: No impacts on declared areas or objects of particular significance with values as conferred by the *Aboriginal and Torres Strait Islander Heritage Protection Act 1984* (Cth).	EPO5:	No impact on underwater cultural heritage.
	EPO6:	Implement CM11 Cultural heritage assessments to identify any maritime archaeological and submerged cultural heritage and landscapes to inform protection priorities, and develop and implement management measures and reporting requirements, where required, to prevent potential impacts.

[1] Unique seafloor habitats of the south-east region including deep-sea reefs, continental shelf habitats, seamounts canyons and kelp forests (DNP, 2025).

6.3 **Emissions – Light**

6.3.1 Hazard Identification

During the Drilling and Completions and Support operations phases of the Project, localised and temporary light emissions will change ambient light levels. There will be no permanent lighting associated with the Project. Temporary light emissions from flaring during drilling and completions and navigational lighting for support operations to comply with navigational and safety requirements, will be emitted during the Project when the MODU or vessels are on location in the Project Area [**PC244, PC245**]. Stages and associated activities which will produce light emissions are defined below in Table 6-10 and described in Section 6.3.2.

Table 6-10: Activities Undertaken During the Project Which Will Result in Light Emissions

Stage	**Activity**	
Drilling and completions	Drilling and completions	Well Completion, Unload and Test
Support operations (all stages)	Support operations (all stages)	MODU operations; vessel operations

6.3.2 Hazard Description

6.3.2.1 Drilling and Completion

1. Well Completion, Unload and Test

Well unloading and testing may introduce localised and temporary light emissions if flaring is required.

Flaring associated with well flowback during the potential testing of the wells via the MODU may occur in the initial or future drilling campaigns if the base case of unloading the wells to the OGP is not feasible.

The duration of flaring for unloading a well of well construction fluid to the MODU is in the order of one to two days per well and up to approximately 65 MMscf per day being flared.

6.3.2.2 Support Operations

Vessel and MODU operations will introduce localised and intermittent light emissions from navigational and safety lighting while active in the Project Area.

Vessel and MODU operations may be undertaken 24 hours a day with lighting required at night for navigation and to ensure safe operations in working areas. Halogens, fluorescent and metal halide lights are generally used offshore. These emit white light and would be similar to lighting used in other offshore activities (i.e. shipping and fishing).

The MODU will be present in the Project Area during several Project phases including drilling and completions, operations (well intervention and workovers) and decommissioning. The longest duration the MODU is expected to be in position is approximately 40 days.

The type and number of vessels in the Project Area at any one time, and the duration of presence, will differ depending on the project stage. For a single activity, there will be no more than three vessels operating simultaneously. The longest duration for a single activity requiring support vessel operations is 40 days to drill a single well utilising a MODU and two support vessels.

For concurrent activities, five vessels could operate in the Project Area at any one time, for example, pipelay or diving/tie-in activities may occur concurrently during MODU positioning. Concurrent operations will be kept to a minimum and are unlikely to occur for more than 13 days.

6.3.2.3 Light Modelling

The spatial extent of Project light emissions was determined using light modelling conducted for the Project (Appendix O) as well as the National Light Pollution Guidelines for Wildlife (the Guidelines) (DCCEEW 2023a). Based on these sources, 2 light EMBAs were deemed relevant to the Project which are detailed in Table 6-11.

Table 6-11: Light EMBAs Relevant to the Project

Distance	Source	Light emitting scenarios included
20 km	National Light Pollution Guidelines for Wildlife (DCCEEW 2023a)	Routine light emissions from both MODU and vessels Precautionary threshold for light impacts to wildlife
63 km	Appendix O (Xodus 2024)	Light emissions from flaring during drilling and completions from any location in the Project Area (65 MMscf per day)

The 20 km EMBA for routine light emissions is based on the National Light Pollution Guidelines for Wildlife (the Guidelines) (DCCEEW 2023a). The guidelines recommend undertaking a light impact assessment where important habitat for list species sensitive to light are located within 20 km of the light source. The 20 km threshold provides a precautionary limit based on observed effects of sky glow on marine turtle hatchlings demonstrated to occur at 15-18 km and fledgling seabirds grounded in response to artificial light 15 km away (DCCEEW 2023a). Seabird grounding, as described in Rodriguez et al (2014), relates to impacts of onshore fixed light sources such as streetlights and buildings and the effect this can have on young fledgling birds making their first flight from their nests to the open ocean.

This 20 km light EMBA is considered to be highly conservative based on the following studies. These studies used a MODU as the basis for assessing routine light emissions from MODU and vessels given the MODU would be the largest and tallest piece of infrastructure used:

- Beach commissioned Xodus to conduct a light assessment study for the Project (Appendix O). The study predicted that the area of potential impact from routine facility lighting would be up to 10 km from the MODU as there was no measurable changes to ambient light intensity levels beyond this distance.
- A light assessment study was undertaken for the Browse FLNG development (Woodside 2014) to assess the likely light density levels from a MODU. This study predicted light density levels at representative of background levels beyond 12.6 km from the MODU.

The 63 km EMBA for flaring light emissions is based on the light assessment study conducted for the Project (Appendix O). The threshold for this distance corresponding to ambient light levels is an illuminance of 0.001 lux, the equivalent of a new moon (Appendix O). The 63 km EMBA threshold distance was calculated based on a horizontal boom at a height of 49 m extending horizontally approximately 14 m from the MODU deck with a peak flare rate of 65 MMscf per day. This calculation is considered conservative as it does not account for atmospheric or topographic interactions such as shadowing, absorption or scattering which would naturally occur to some degree. It is therefore likely to overestimate the illuminance distance.

6.3.3 Impact Analysis and Evaluation

Light emissions from the Project can cause a change in ambient light resulting in direct impacts to:

- Change in fauna behaviour of:
  - Fish and plankton
  - Seabirds and shorebirds
  - Marine reptiles
- Changes in aesthetic and conservation values for:
  - Coastal communities
  - Conservation values and sensitivities
- Changes to cultural values and sensitivities

- Changes to the functions, interests, or activities of other users for:
    - Commonwealth and state commercial fisheries

Socio-economic impacts to commercial fisheries have not been evaluated further as there are no expected impacts to commercially fished species at a population level (See Section 6.3.3.1)

The process outlined in The National Light Pollution Guidelines for Wildlife (DCCEEW 2023a) is used to assess potential impacts, including:

- The guidelines identify marine turtles, seabirds and migratory shorebirds as potentially being impacted by artificial light to a level significant enough to require assessment. In addition to this, impacts on fish/plankton and coastal communities are assessed.
- The guidelines detail that important habitats are those areas necessary for an ecologically significant proportion of a listed species to undertake important activities such as foraging, breeding, roosting or dispersal. For this assessment the two light EMBAs were used to identify any areas where turtles, shorebirds and seabirds may be foraging, breeding, roosting, or migrating. The EPBC Protected Matters Report for these EMBAs are in Appendix E.

For the purposes of this OPP, species listed as Threatened under the EPBC Act, coastal communities, conservation values and sensitivities, and cultural values and sensitivities that are likely to occur in the light EMBAs were considered to have conservation significance warranting impact evaluation. Relevant receptors were determined by the PMST Reports, reputable peer-reviewed literature, susceptibility to light, and from comments received during Phase 2: Project OPP Public Comment Period [**PC229**].

6.3.3.1 Fish and Plankton

Intermittent light emissions during the Project have the potential to cause temporary behavioural changes to fish and plankton within localised artificial light halos surrounding the MODU and vessels. Behavioural changes to fish and plankton are expected to be limited to temporary and localised avoidance or aggregation behaviours (DCCEEW 2022).

Avoidance of fish and plankton from offshore light emissions from vessels—including fishing boats, cargo vessels, recreational watercraft, jetties and oil and gas platforms—have been observed where zooplankton and their vertebrate predators descend away from the surface; these effects occurred at depths of up to 200 m, and up to 200 m horizontally from the light source (Berge et al. 2020). Since most zooplankton need to ascend to forage on phytoplankton near the water's surface, light pollution may lead to an overall reduction in zooplankton, with cascading effects on their predators, and so on up the food chain (DCCEEW 2022).

Temporary and localised avoidance behaviours from short-finned eels are also expected from Project light emissions. Koster et al. (2021) tracked Australasian short-finned eels off Victoria and found mean night-time swimming depth of all eels showed diel vertical migration in time with the phase of the moon, with the mean depth increasing with increasing moon irradiation. As anguillid eels do not feed during their spawning migration, it has been suggested that the function of the vertical migrations relates to predator avoidance, swimming efficiency, thermal regulation, and control of maturation. Thus, short-finned eels are expected to avoid rather than be attracted to light emissions when migrating as part of inherent predator avoidance behaviours.

Fish and plankton may be directly or indirectly attracted to offshore light emissions. Experiments using light traps have found that some fish and zooplankton species are attracted to light sources (Meekan et al. 2001), with traps drawing catches from up to 90 m (Milicich et al. 1992). Lindquist et al (2005) concluded from a study of larval fish populations around an oil and gas platform in the Gulf of Mexico that an enhanced abundance of clupeids (herring and sardines) and engraulids (anchovies), both of which are highly photopositive, was caused by the platforms' light fields. The concentration of organisms attracted to light results in an increase in food source for predatory species and marine predators are known to aggregate at the edges of artificial light halos. Shaw et al (2002), in a similar light trap study, noted that juvenile tunas (Scombridae) and jacks (Carangidae), which are highly predatory, may have been preying upon concentrations of zooplankton attracted to the light field of the platforms. This could potentially lead to temporary increased predation rates compared to unlit areas.

The potential impacts to fish and plankton from light emissions are expected to be limited to temporary attraction or avoidance behaviours within localised artificial light halos. These temporary and localised behavioural changes to fish and plankton from light emissions associated with the Project will have no change in critical behaviours of these species, such as breeding or migration, or population persistence of prey species.

As a result, the change in fauna behaviour to fish and plankton from intermittent light emissions generated during the Project are evaluated as Minor (1) consequences based on:

- The localised extent of the impacts to fish, plankton and invertebrates is predicted to be limited to 200 m from the light source.
- Light emissions from the Project Area will be temporary based on the intermittent operations of MODU and vessels in the Project Area.
- Lighting on the MODU and support vessels will be limited to regulatory requirements for navigation and safety purposes.

6.3.3.2 Seabirds and Shorebirds

Intermittent light emissions during the Project have the potential to cause temporary behavioural changes to seabirds and shorebirds within the light glow generated by navigational lighting and flaring activities. Bright lighting (including from navigational lighting and flaring) can disorientate birds, Behavioural disorientation in seabirds and shorebirds from light emissions may result in entrapment, stranding, grounding, and interference with navigation (CoA 2023). These behavioural changes increase the likelihood of seabird and shorebird injury or mortality through collision with the vessel, or mortality from starvation due to disrupted migration or foraging at sea (Wiese et al. 2001). Seabirds and shorebirds that are active at night while undertaking critical behaviours such as migrating, foraging, or returning to colonies are most at risk from light emissions (CoA 2023).

Behavioural disorientation is also more likely to occur to young birds (fledglings). In general, fledglings are even more vulnerable to behavioural disorientation from light emissions than adults. Fledglings have been observed being affected by lights up to 15 km away, with counts of fledgling mortalities from grounding shown to be largely underreported (Rodriguez et al. 2014). Artificial lights are thought to override the natural cues from the moon and star light on the horizon, which has the potential to attract fledging seabirds back onshore after reaching the sea (Warham 1996), or to prevent fledging's from imprinting the location of their natal colony prior to migration (DCCEEW 2023a). Furthermore, fledglings may not undertake their first flight if their nesting habitat never becomes dark (DCCEEW 2023a). The impacts of artificial light upon the viability of breeding seabird populations are largely unknown (Griesemer and Holmes 2011).

Seabird and shorebirds species most vulnerable to behavioural disorientation from light emissions are species with critical behaviours that are conducted nocturnally. Review of the EPBC Act PMST species of birds that may undertake critical behaviours nocturnally within the routine light and/or flaring EMBAs (Appendix E) include:

- Albatrosses are known to nocturnally forage at sea, however forage most actively during daylight and are less active at night (Phalan et al. 2007).
- Petrels have been observed foraging at night, however forage primarily during the day in nearshore areas (Brooke 2004).
- Shearwaters are known to actively forage at night in proximity to breeding colonies, however in Australian waters are observed to typically forage during daylight, returning to colonies after feeding (AAD 2020).
- Little penguins are known to exhibit a wide foraging range, with individuals able to spend weeks away at sea foraging (McCutcheon et al. 2011).
- Orange-bellied parrots are thought to mostly travel at night when migrating between mainland Australia and Tasmania (Nicholls 2022).

These seabird and shorebird species are considered susceptible to impacts from light emissions from the Project and are listed in Table 6-12 including details of biologically important behaviours for each of these species within the light and flaring EMBAs. Figure 6-1 through to Figure 6-4 illustrates the overlap between BIAs for susceptible seabird and shorebird species and the light and flaring EMBAs.

Table 6-12: Seabirds and Shorebirds with BIAs or Undertaking a Biologically Important Behaviour within the Light EMBAs

1. Albatrosses

The PMST Reports for the light EMBAs (Appendix E) identified 14 albatross species which have a presence within the light EMBAs. Twelve of these species have foraging BIAs or foraging behaviours identified within the light EMBAs (Table 6-12). Though the National Recovery Plan for Albatrosses and Petrels (CoA 2022) identifies light emissions as a threat, it classifies marine infrastructure interactions including those associated with artificial light as having no risk category priority and affecting 'Nil' species in Australian jurisdiction. In addition, no actions are identified.

All albatross species are migratory with widespread distributions throughout the Southern hemisphere and have been shown to travel large distances when foraging. For example, the wandering albatross has been shown to cover distance between 3,600 and 15,000 km in a single foraging trip during the breeding season on subantarctic islands (Jouventin and Weimerskirch 1990). The recognised foraging BIAs for albatross species generally cover large areas. For example, the entire South-east Marine Region is recognised as a foraging BIA for the Indian yellow-nosed, Campbell and black-browed albatross species. Albatrosses forage most actively during daylight and are less active at night because their ability to see and capture prey from the air is reduced (Phalan et al. 2007).

The potential for light emissions to cause behavioural disorientation to albatrosses foraging at night is expected to be limited to individuals. Due to the expansive distribution of albatross foraging BIAs in southern Australian waters, the absence of breeding BIAs and colonies in the light and flaring EMBAs, and albatross foraging behaviours occurring primarily during daylight hours; the potential of behavioural disorientation from temporary Project light emissions are expected to be limited to individuals and therefore no impacts to albatrosses will occur at a population level.

2. Petrels

The PMST reports for the light EMBAs (Appendix E) identified 7 petrel species which have a presence or BIA within the light EMBAs. Four of these species have foraging BIAs and/or foraging behaviours identified within the light EMBAs (Table 6-12). Though the National Recovery Plan for Albatrosses and Petrels (CoA 2022) identifies light emissions as a threat, it classifies marine infrastructure interactions including those associated with artificial light as having no risk category priority and affecting 'Nil' species in Australian jurisdiction. In addition, no actions are identified.

Petrel species have a widespread distribution throughout the Southern hemisphere, with wide, recognised foraging areas.

The common diving-petrel is listed as marine and does not have a recovery plan or conservation advice. Brooke (2004) details that common diving-petrels spend the night in burrows during the breeding season and seem to forage in nearshore areas primarily during the day, although they also have been observed foraging at night on vertically migrating plankton. They are thought to be fairly sedentary, remaining more or less in the area of their breeding colony year-round, although they may venture into the open ocean to forage outside of the breeding season and migrate to more tropical climates (Brooke 2004). In general, they undertake a unimodal foraging trip duration strategy (consistent short daily foraging trips) during both incubation and chick-rearing periods, unlike other small seabirds within their family (Fromant et al. 2021). However, studies on common diving-petrels within the Bass Strait have shown higher foraging efforts compared to other populations (with foraging trips averaging 71 ± 3 km), potentially due to the sparse distribution of prey (mostly coastal krill) (Formant et al. 2021). There is potential for light emissions from the activity to overlap with the occasional foraging times of the common diving-petrel. The common diving-petrel's foraging BIA is overlapped by the light EMBAs with the largest light footprint (63 km around the Project Area during flaring) overlapping <2% of the species' foraging BIA (Figure 6-2).

The northern giant-petrel was identified in the light and flaring EMBA PMST reports as likely to be foraging within the light EMBAs (Table 6-12). It is thought to be a predominantly diurnal forager, feeding its chicks during both day and night, however individuals provisioning young typically forage inshore and near nesting areas (DCCEEW 2023a). Breeding occurs on Macquarie Island between New Zealand and Antarctica, over 2,000 km from the Project and light EMBAs.

The southern giant-petrel was identified in the light and flaring EMBA PMST reports as foraging likely within the flaring EMBA (Table 6-12). Light is not identified as a key threatening process for the southern giant-petrel (CoA 2022). Like the northern giant-petrel, this species also feeds its chicks during both day and night and breeds exclusively on Antarctic and sub-Antarctic islands, the closest of which being Macquarie Island, still over 2,000 km from the Project and light EMBAs (DCCEEW 2024p).

The white-faced storm petrel is widely distributed throughout Australia, with the Australian population estimated to be about 25% of the global population (CoA 2020a). The species is migratory, moving from their temperate breeding grounds to tropical and subtropical locations in late March (Underwood and Bunce 2004). A foraging BIA for the white-faced storm petrel was identified within the flaring EMBA (Figure 6-3). The white-faced storm-petrel is a listed marine species. Light has not been identified as threatening process for this species (DCCEEW 2023a).

The potential for light emissions to cause behavioural disorientation to petrels foraging at night is expected to be limited to individuals. Due to the expansive distribution of petrel foraging BIAs in southern Australian waters, the absence of breeding BIAs and colonies in the light and flaring EMBAs, and petrel foraging behaviours occurring primarily in nearshore areas during the day; the potential of behavioural disorientation from temporary Project light emissions are expected to be limited to individuals and therefore no impacts to petrels will occur at a population level.

3. Shearwaters

The PMST Reports for the light EMBAs (Appendix E) identified 4 shearwater species which have a presence or BIA within the light EMBAs. Three of these species (flesh-footed shearwater, short-tailed shearwater, and wedge-tailed shearwater) have BIAs and/or biologically important behaviours identified within the light EMBAs (Table 6-12).The flesh-footed shearwater was identified in the flaring EMBA PMST report as foraging likely within the flaring EMBA, no BIAs exist for this species within the light and flaring EMBAs. The flesh-footed shearwater routinely attends fishing vessels to feed on baited hooks, discarded scraps and prey attracted to the surface by such vessels (DoE 2023b). However, incidental deaths from fishing activities typically involve ingesting baited hooks or hooks embedded in scraps, which won't be a factor in the Project. While flesh-footed shearwaters may be attracted to the localised artificial light halos created by vessel or flaring activities, they are primarily active at night near their breeding colonies, which are far from the Project Area (including Lord Howe Island, Saint Paul Island, Western Australia, Smith Island, and New Zealand) (TSSC 2014). As a result, the flesh-footed shearwater has been observed to be accustomed to vessel navigational lighting. Therefore, the addition of light emissions from the Project is not expected to change existing behaviours of the flesh-footed shearwater being attracted to vessels for opportunistic feeding. Potential impacts to flesh-footed shearwaters are expected to be limited to the attraction of foraging individuals and no impacts will occur at a population level given the absence of breeding BIAs in the light and flaring EMBAs.

The light and flaring EMBAs overlap the short-tailed shearwater foraging BIA (Figure 6-2). The light and flaring EMBA PMST reports identified breeding behaviours are known to occur for the short-tailed shearwater, but as detailed in Figure 6-2 the light EMBAs do not overlap any sites declared as a breeding BIA for the short-tailed shearwater. This species is listed as marine and migratory and does not have a recovery plan or conservation advice. When present in Australian waters (September to May) the species are known to typically forage during daylight, returning to the colonies after feeding (AAD 2020). Though not designated as BIAs, breeding has been recorded at additional locations such as Middle Island and Griffiths Island (Baker and Hamilton 2013) which are within the flaring EMBA but more than 50 km from the Project Area. Because these breeding locations are not considered BIAs, behavioural changes to short-tailed shearwaters at these breeding sites are not expected to result in population impacts. According to the light emissions modelling conducted for the Project (Appendix O), during short-term flaring activities Middle Island (along the coast of Warrnambool) may be exposed to a maximum of 0.0014 lux, which is approximately equivalent illuminance to a moonless clear night sky (0.001 lux). During routine facility lighting, illuminance from the Project may only reach less than 0.0001 lux at Middle Island, which equates to less light than a moonless overcast night sky. This change in ambient light levels at these locations is therefore not expected to be discernible from other artificial light sources and will be intermittent and temporary (up to 2 days per well). Potential impacts to short-tailed shearwaters as a result of Project light emissions are expected to be limited to foraging individuals and therefore no impacts to short-tailed shearwater will occur at a population level.

The light EMBA overlaps the wedge-tailed shearwater breeding BIA at Muttonbird Island, Victoria (

Figure 6-3). The species have been recorded to predominantly forage during the day and form large aggregations referred to as "rafts" just offshore from their breeding colony just on dusk and enter and leave the colony at night to avoid predators (Warham 1996). This species is listed as marine and migratory and does not have a recovery plan or conservation advice. Light has not been identified as a threat to this species (DCCEEW 2023a). The breeding BIA at Muttonbird Island is 18 km from the Project Area within Port Campbell National Park, which is predicted to be exposed to a maximum of 0.011 lux during flaring activities, approximately equivalent illuminance to that of a quarter moon (Appendix O). This change in ambient light levels is not expected to be discernible from other light sources in the area and will be of intermittent and temporary duration (up to 2 days per well). By comparison, Phillip Island Important Bird Area receives a maximum light pollution level of 5.3 nW/sr*cm^2 and reports between 0.39% and 0.70% of shearwater fledglings affected by grounding events (Rodriguez et al. 2014). This is equivalent to 0.035 lux and therefore more than triple the maximum illuminance subjected to the Muttonbird Island breeding BIA from Project activities. Consequently, given wedge-tailed shearwaters predominantly forage during the day and would be exposed only to a temporary change in ambient light levels within the flaring EMBA, the potential of behavioural disorientation from temporary Project light emissions are expected to be limited to individuals and therefore no impacts to wedge-tailed shearwaters will occur at a population level.

4. Little Penguin

The little penguin (*Eudyptula minor*) is known to breed within the flaring and light EMBAs according to the PMST reports (Appendix E) despite not overlapping breeding or foraging BIAs (Figure 6-2). Despite the colony of little penguins at Manly, Sydney Harbour, being protected as an endangered population, the Australian population is considered stable at approximately one million birds (Birdlife Australia 2025). The species is known to exhibit a wide foraging range, with individuals able to spend weeks away at sea foraging (McCutcheon et al. 2011). The closest breeding BIA to the Project exists at Christmas Island located of off nearby King Island, approximately 80 km from the Project Area (see Figure 6-2). However, additional breeding sites which are not designated BIAs have been recorded within the flaring EMBA at Middle Island in Warrnambool and within the light EMBA at Twelve Apostles and Port Campbell (Norman et al. 2017). Breeding typically occurs from September to February. Studies suggest that penguins were habituated to artificial lights and were unaffected by a 15 lux increase in artificial illumination (Rodriguez et al. 2016). According to the light modelling report (Appendix O), Port Campbell and Warrnambool would be subjected to 0.011 lux and 0.001 lux illuminance, respectively, during flaring activities. As such, Port Campbell would be subjected to the highest illuminance, 0.011 lux, during flaring activities which is equivalent to that of a quarter moon (Appendix O). This change in ambient light levels is not expected to be discernible from other artificial light sources and due to its intermittent and temporary duration (up to 2 days per well) it is not expected to cause impact at a population level. Therefore, as the little penguin is exposed only to a change in ambient light levels within the flaring EMBA, behavioural changes to the little penguin are unlikely.

5. Orange-bellied Parrot

The likely distribution and probable migration route identified for the Critically Endangered orange-bellied parrot (*Neophema chrysogaster*) overlap the light and flaring EMBAs. The flaring EMBA (63 km around the Project Area during flaring) overlaps the likely distribution range by ~7.4%, the probable migration route by ~8.6% and the non-breeding range by ~7.3% (Figure 6-4). No BIAs or areas deemed as habitat critical to the survival of the species were identified within the light or flaring EMBAs.

The orange-bellied parrot is a ground feeding parrot which breeds in south-west Tasmanian. They migrate from Tasmania to Victoria between late February and early April (Australian Museum 2022b). In Victoria, the orange-bellied parrot mostly occurs in sheltered coastal habitats, such as bays, lagoons and estuaries, or, rarely, saltworks. The parrot's breeding habitat is restricted to south-west Tasmania, where breeding occurs from November to mid-January mainly within 30 km of the coast (Brown and Wilson 1980). During winter, on mainland Australia, orange-bellied parrots are found mostly within 3 km of the coast (DELWP 2016).

The 2023-24 breeding season showed a record number of 92 orange-bellied parrots return to breeding grounds breaking last years census of 82 birds. Of these 64 orange-bellied parrots were wild-born, with the remaining 28 captive-bred released (NRE Tasmania 2024). Thirty-seven birds were female and the remaining 55 males. As of December 2024, a total of 25 nestlings and one fledgling were counted (NRE Tasmania 2024).

The National Recovery Plan for the orange-bellied parrot (DELWP 2016) identifies that the behaviour of this species may be modified by the presence of barriers such illuminated structure and boats, with the impacts of barriers greatest where they occur on migration routes, though there is little more than anecdotal evidence to support this (Holdsworth 2006). Intermittent Project light emissions do not present the same risk as that associated with long-term or permanent illuminated structures or illuminated commercial vessels which are positioned within the migration route, year-round. In addition, in the 15 years of operating the Thylacine A Wellhead Platform, Beach has not recorded any orange-bellied parrots being present. During the Otway Drilling Campaign in 2021/2022, no birds were identified to be attracted or grounded due to MODU or vessel lighting or flaring. Despite light emissions generated from support vessels servicing the Thylacine A Wellhead Platform and the Otway Drilling Campaign in 2021/2022, the 2021 orange-bellied parrot breeding season still showed a record number (at that time) of 70 orange-bellied parrots return to breeding grounds (NRE Tasmania 2023). Light emissions from the support vessels servicing the Thylacine A Wellhead Platform and the Otway Drilling Campaign in 2021/2022 are considered equivalent to the light emissions associated with the Project. Given the observed increase in orange-bellied parrot migration during periods of light emissions from the Thylacine A Wellhead Platform and the Otway Drilling Campaign in 2021/2022, it is anticipated that the Project's light emissions will not adversely impact migration numbers. The light and flaring EMBA overlaps the probable migration route of the orange-bellied parrot by 2.2% and 8.6%, respectively. Whereas the flaring EMBA overlaps the non-breeding range from Port Fairy east to Cape Otway, overall a 7.3% overlap of total non-breeding range area, not including the infrequent non-breeding range on the entire NSW coast. Changes in ambient light in the non-breeding range associated with short-term flaring (up to 2 days per well) in these areas are predicted to result in an increase in light intensity between 0.001 lux (Warrnambool) and 0.011 lux (Port Campbell National Park) (Appendix O). These values represent an approximately equivalent of illuminance from a moonless clear night sky (0.001 lux) to a quarter moon night sky (0.01 lux).

In summary, significant behavioural changes to the orange-bellied parrot while on migration or within the non-breeding range are not predicted based on:

- the intermittent and temporary duration of flaring activities that could change ambient light levels within the probable migration range
- no records of orange-bellied parrots during previous offshore activities involving routine lighting and flaring
- the observed increase in orange-bellied parrot migration during periods of light emissions from the Thylacine A Wellhead Platform and the Otway Drilling Campaign in 2021/2022, it is anticipated that the Project's light emissions will also not adversely impact migration numbers
- a Light Management Plan will be in place to minimise external light emissions as required by the National Light Pollution Guidelines
- light emissions from the Project will result in a localised and short-term change in ambient light with levels returning to existing ambient levels following the completion of the activities.

6. Seabirds and Shorebirds Consequence Evaluation

The potential impacts to seabirds and shorebirds from intermittent Project light emissions are limited to potential behavioural disorientation of individuals not resulting in population effects. As a result, the change in fauna behaviour to seabirds and shorebirds from intermittent light emissions generated during the Project was evaluated as Minor (1) consequences based on:

- Lighting on survey vessels, the MODU and support vessels will be limited to that which is required for navigational and safety purposes and of a temporary nature (30 to 40 days for a single activity).
- Due to the expansive distribution of albatross foraging BIAs in southern Australian waters, the absence of breeding BIAs and colonies in the light and flaring EMBAs, and albatross foraging

behaviours occurring primarily during daylight hours; the potential of behavioural disorientation from temporary Project light emissions are expected to be limited to individuals and therefore no impacts to albatrosses will occur at a population level.

- Due to the expansive distribution of petrel foraging BIAs in southern Australian waters, the absence of breeding BIAs and colonies in the light and flaring EMBAs, and petrel foraging behaviours occurring primarily in nearshore areas during the day; the potential of behavioural disorientation from temporary Project light emissions are expected to be limited to individuals and therefore no impacts to petrels will occur at a population level.

- The addition of light emissions from the Project is not expected to change existing behaviours of the flesh-footed shearwater being attracted to vessels for opportunistic feeding. As a result, potential impacts to flesh-footed shearwaters are expected to be limited to the attraction of foraging individuals and no impacts will occur at a population level given the absence of breeding BIAs in the light and flaring EMBAs.

- The addition of light emissions from the Project is not expected to change existing behaviours of the short-tailed shearwater being attracted to vessels for opportunistic feeding. Breeding locations will be exposed only to a change in ambient light levels within the flaring EMBA. As a result, potential impacts to short-tailed shearwaters are expected to be limited to foraging individuals and therefore no impacts to short-tailed shearwaters will occur at a population level.

- For wedge-tailed shearwaters, the breeding BIA at Muttonbird Island is subject to temporary and intermittent light emissions equivalent to that of a quarter moon. Compared to the Phillip Island Bird Area which has a baseline maximum light pollution more than three times greater than this, Given this species predominantly forages during the day, the potential of behavioural disorientation from temporary Project light emissions are expected to be limited to individuals and therefore no impacts to wedge-tailed shearwaters will occur at a population level.

- The little penguin is exposed only to a change in ambient light levels within the flaring EMBA, therefore behavioural changes to the little penguin are unlikely.

- Based on the observed increase in orange-bellied parrot migration during periods of light emissions from the Thylacine A Wellhead Platform and the Otway Drilling Campaign in 2021/2022, it is anticipated that the Project's light emissions will also not adversely impact migration numbers.

- Light emissions are identified as a threat in the National Recovery Plan for albatrosses and petrels (2022) (CoA 2022) but classifies marine infrastructure interactions including those associated with artificial light as having no risk category priority and affecting ‘Nil’ species in Australian jurisdiction

- Light pollution is listed as a threat to seabirds in the Wildlife Conservation Plan for Seabirds (CoA 2020a), with potential for consequences affecting individuals but not whole populations. Light emissions will be managed in a manner to not contravene the objectives of this plan.

- Light emissions will be managed in a manner to not impact on the recovery of the orange-bellied parrot as per the recovery plan (DELWP 2016):

Illuminated structures and illuminated boats have been identified as a potential barrier to migration and movement for the orange-bellied parrot (DELWP 2016). The light and flaring EMBAs overlap only

2.2% and 8.6% of the probable migration route, respectively. Therefore, the temporary activities of the MODU and vessels when undertaking the petroleum activity do not present the same risk as that associated with long-term or permanent illuminated structures or illuminated commercial vessels which are positioned within the migration route year-round. This critically endangered species may migrate over a portion of the Project Area and light EMBAs from February-April and when returning in November. Impacts associated with flaring, which may change ambient light in the area, will be temporary and of short duration and are not expected to result in in impacts to migration numbers.

6.3.3.3 Marine Reptiles

Artificial light can disrupt turtle nesting and hatching behaviours and is listed as a key threat in the Recovery Plan for Marine Turtles in Australia (CoA 2017). Offshore light emissions can attract hatchlings and disrupt dispersal behaviours of marine turtles at night by interfering with natural lighting and silhouettes (DCCEEW 2023a; CoA 2017).

Behaviours critical to marine turtle survival are generally contained within the areas defined by marine turtle BIAs and habitat critical to the survival of marine turtle species. The Project Area and light EMBAs do not overlap marine turtle BIAs or habitat critical to the survival of marine turtle species and there are no documented nesting activities along Victorian coastlines. However, the PMST report identified the loggerhead turtle with a presence of 'breeding likely to occur' within the light EMBAs. However, the main Australian breeding areas are generally confined to southern Queensland and Western Australia (Cogger et al. 1993). Loggerhead turtles show a strong fidelity to their breeding areas (Limpus 2008). They forage in all coastal states, though are uncommon in Victoria and hence are expected to be occasional visitors in the light EMBAs (CoA 2017a). Species or habitat is 'known to occur' for the leatherback turtle and 'may occur' for the green turtle within the light EMBAs (Appendix E). Consequently, population level impacts to marine turtles from routine light and flaring emissions are not predicted to occur. Potential impacts due to light emissions from the Project would be limited to temporary behavioural changes to individual marine turtles transiting through the light EMBAs at night, within 20 km of the MODU and vessels during routine operations and within 63 km of flaring sources within the Project Area during flaring activities. [**PC229**]. The potential impacts to marine reptiles from light emissions are expected to be limited to temporary and localised attraction of occasional visiting individuals at night. As a result, the change in fauna behaviour to marine reptiles from intermittent Project light emissions are evaluated as Minor (1) consequences based on:

- Lighting on the MODU and support vessels will be limited to that which is required for navigational and safety purposes.
- Artificial light is listed as a key threat in the Recovery Plan for Marine Turtles in Australia (CoA 2017), however, no BIAs or habitat critical to survival for marine turtles were identified within the light EMBAs.
- All turtle species are expected to be occasional visitors to the light EMBAs. [**PC229**]

6.3.3.4 Coastal Communities

Light emissions from the Project have the potential to impact coastal communities.

Light emissions as a result of routine operations are expected to have a minor impact on coastal communities and will be indistinguishable from other marine traffic within the area and given the temporary nature of the light emissions associated with the Project. Given the maximum predicted duration for drilling at each location is 30-40 days, the low levels of ambient light changes from the routine light will be short-term and fully recoverable. According to the light emissions modelling conducted for the Project (Appendix O), the coastal receptor which may be exposed to the highest level of illuminance from routine facility lighting is Port Campbell National Park at 0.0002 lux, which equates to less light than a new moon (0.001 lux). Warrnambool, the largest settlement within the light EMBAs, may be exposed to <0.0001 lux from routine facility lighting, equating to less than a moonless overcast night sky (0.0001 lux).

There are several coastal communities and areas conducive to tourism located on the Victorian coast which are within the flaring EMBA (Figure 4-12). Light emissions as a result of short-term flaring (up to 2 days per well) are expected to have a negligible impact on coastal communities due to the low levels of illuminance. According to the light emissions modelling conducted for the Project (Appendix O), the coastal receptor which would be exposed to the highest level of illuminance from short-term flaring is Port Campbell National Park at 0.0111 lux, which is approximately the same as a quarter moon (0.01 lux). Warrnambool, the largest settlement within the flaring EMBA, may be exposed to 0.0014 lux, or approximately the same illuminance as a new moon (0.001 lux).

Given the above, the impact from light emissions is likely to result in Minor (1) consequences to coastal communities based on:

- Illuminance from flaring at the closest possible locations to the coast would be comparable to natural ambient light levels of less than a quarter moon (0.01 lux).
- The MODU and vessel will have a Lighting Management Plan to minimise external light emissions as required by the National Light Pollution Guidelines.
- Visibility of routine lighting and the flare when flaring would be reduced by the prevailing weather conditions within the region, and would be comparable to ongoing shipping traffic and historical drilling and flaring activities and within the region.

6.3.3.5 Conservation Values and Sensitivities

Light emissions from the Project have the potential to impact conservation values and sensitivities as well as National Heritage. Relevant receptors identified within the light EMBAs are presented below in Table 6-13.

Table 6-13: Marine Protected Areas, National Parks and National Heritage Places within Light and Flaring EMBAs

Receptor	**Marine Protected Area**	**Intersection with flaring EMBA**	**Intersection with light EMBA**
Australian Marine Park	Apollo Multiple Use Zone	✓	-
	Zeehan Multiple Use Zone	✓	-
	Zeehan Special Purpose Zone	✓	-
State Marine Reserve	Twelve Apostles Marine National Park	✓	✓
	Marengo Reefs Marine Sanctuary	✓	-
	Merri Marine Sanctuary	✓	-
	The Arches Marine Sanctuary	✓	✓
State Terrestrial Reserve	Great Otway National Park	✓	✓
	Port Campbell National Park	✓	✓
Key Ecological Feature	Bonney Coast Upwelling	✓	-
	West Tasmanian Canyons	✓	✓
National Heritage Place	Great Ocean Road and scenic environs	✓	✓

Light pollution associated with offshore mining operations (including oil and gas) and other offshore activities is listed as a pressure on the conservation values of the South-east Marine Region (DNP 2013). As described in Section 4.2.2.2, conservation values for the Apollo and Zeehan AMPs include seafloor features and habitat for conservation significant bird and mammal species (DNP 2013). Evaluation of light-sensitive fauna including seabirds is conducted in Section 6.3.3.2.

Light emissions are not identified as a key management objective for conservation of natural values associated with the Twelve Apostles Marine National Park (Parks Victoria 2006d), Marengo Reefs Marine Sanctuary (Parks Victoria 2007a), Merri Marine Sanctuary (Parks Victoria 2007c) or The Arches Marine Sanctuary (Parks Victoria 2006d). Conservation values for marine protected areas are detailed in Section 4.2.8. According to the management plans, light-sensitive receptors relevant to the values of the Twelve Apostles Marine National Park and Marengo Reefs, Merri and The Arches Marine Sanctuaries include invertebrates and fish. Based on the evaluation of light-sensitive fauna in Section 6.3.3.1, impacts to invertebrates and fish within the marine reserves are not predicted based on impacts to invertebrates and fish from light only being predicted up to 200 m from the light source. The Project Area where MODU and vessel lighting will occur is ~18 km from the nearest reserve, Twelve Apostles Marine National Park.

The light EMBA overlaps 2 KEFs, the Bonney Coast Upwelling and West Tasmanian Canyons. The values associated with KEFs are described in Section 4.2.12 Light-sensitive receptors in the Bonney Coast Upwelling KEF include fish and invertebrates as well as seabirds, which may be present in the KEF due to increased food availability. Light-sensitive receptors in the West Tasmanian Canyons KEF include fish associated with sponges near canyon heads. Potential impacts to seabirds and shorebirds from intermittent light emissions generated during the Project was evaluated as Minor (1) consequences (Section 6.3.3.2). Impacts to fish within the West Tasmanian Canyons KEF are expected to also be of Minor (1) consequences based on the greatest diversity being between 200 m and 350 m depth (CoA 2015) and, as detailed in Section 6.3.3.2, impacts to fish from light are not predicted in water depths greater than 200 m.

Terrestrial receptors including The Great Ocean Road and Scenic Environs National Heritage Place, and Great Otway and Port Campbell National Parks are within the light EMBAs (Table 6-13; Appendix E). Light emissions as a result of routine facility lighting and short-term flaring (up to 2 days per well) are expected to have a negligible impact on these receptors due to the low levels of illuminance reaching the coast. According to the light emissions modelling conducted for the Project (Appendix O), during short-term flaring activities Port Campbell National Park may be exposed to 0.011 lux, which is approximately the same as a quarter moon (0.01 lux). During routine facility lighting, illuminance from the Project may only reach 0.0002 lux, which equates to less light than a new moon (0.001 lux). Cape Otway Light Station Lookout is modelled to be exposed to even less illuminance than this at 0.0029 lux when flaring and less than 0.0001 lux from routine facility lighting (less than a moonless overcast night sky; Appendix O). The Great Ocean Road and Scenic Environs National Heritage Place overlaps the boundaries of the National Parks and therefore subject to the same level of illuminance.

Given the above, the impact from light emissions is likely to result in Minor (1) consequences to conservation values and sensitivities. The impact from Minor (1) consequences is therefore acceptable based on:

- Lighting on the MODU and support vessels will be limited to that which is required for navigational and safety purposes.

- Visibility of routine lighting and the flare when flaring would be reduced by the prevailing weather conditions within the region, and would be comparable to ongoing shipping traffic and historical drilling and flaring activities and within the region.
- Illuminance from flaring at the closest possible locations to the coast would be comparable to natural ambient light levels of less than a quarter moon (0.01 lux).
- The Project will not affect the national heritage management objectives to protect, conserve, present and transmit to all generations the National Heritage Values, with no long-term or irreversible impacts on the principle or aesthetic characteristics or social and tourism values.
- Impacts to the principal and aesthetic characteristics of the Great Ocean Road and Scenic Environs are predicted to be limited to intermittent visibility of navigation and operational lighting and short-duration flaring from some locations along the Great Ocean Road and Great Ocean Walk at night.
- Impacts to invertebrates and fish associated with the Twelve Apostles Marine National Park, Marengo Marine Sanctuary, Merri Marine Sanctuary, The Arches Marine Sanctuary and West Tasmanian Canyons KEF are not predicted based on light impacts to invertebrates and fish occurring within a distance of 200 m.
- The National Recovery Plan for Albatrosses and Petrels 2022 (CoA 2022) identifies light emissions as a threat, it classifies marine infrastructure interactions including those associated with artificial light as having no risk category priority and affecting 'Nil' species in Australian jurisdiction. In addition, no actions are identified.
- Albatross forage most actively during daylight and are less active at night because their ability to see and capture prey from the air is reduced (Phalan et al. 2007).
- As the light EMBAs overlaps a number of seabird foraging and breeding BIAs, the migratory route for the critically endangered orange-bellied parrot and areas where birds are likely or known to be foraging, breeding, or roosting, the MODU and vessel will have a Lighting Management Plan to minimise external light emissions as required by the National Light Pollution Guidelines.
- Light pollution is listed as a threat to seabirds in the Wildlife Conservation Plan for Seabirds (CoA 2020a), with potential for consequences affecting individuals but not whole populations.

6.3.3.6 Cultural Values and Sensitivities

Based on Section 4.6, the following First Nations cultural values and sensitivities have been identified as potentially affected by light emissions:

- Birds including orange-bellied parrot and short-tailed shearwater (muttonbird)
- Fish (including eels)

The marine fauna listed above are connected to places associated with songlines or connected to individuals through ceremony (Section 4.6.3.5). The connection of marine fauna to places or individuals are considered cultural intangible values.

Light emissions have the potential to impact marine fauna that have songlines, or spiritual connection to First Nations people. It is considered that impacts to species at a population level may prevent First Nations people's obligations to maintain spiritual connections and care for culturally significant species and their habitats. As evaluated in Section 6.3.3.2, potential impacts to birds including the orange-bellied parrot, short-tailed shearwater and fish including eels from light emissions will not impact these species at a population level. Minor behavioural changes to birds and fish are expected from the intermittent light emissions generated during the Project.

As described in detailed in Section 6.3.3.2, light emissions will be managed in a manner to not impact on the recovery of the orange-bellied parrot to ensure the proposed activity is not inconsistent with the Recovery Plan for this species. The recovery plan was developed in consultation with First Nations peoples to ensure all activities will respect the cultural knowledge and traditions of Indigenous people throughout the species range. Section 6.3.3.2 assesses the potential impacts to these receptors and concluded that light emissions will not result in impacts at a population level to birds and fish including eels. As such, light emissions from the Project are likely to result in Minor (1) consequences to cultural values and sensitivities based on:

- Lighting on the MODU and support vessels will be limited to that which is required for navigational and safety purposes.
- Based on the observed increase in orange-bellied parrot migration during periods of light emissions from the Thylacine A Wellhead Platform and the Otway Drilling Campaign in 2021/2022, it is anticipated that the Project's light emissions will also not adversely impact migration numbers.
- For short-tailed shearwaters, the behavioural response threshold range for fledgling shearwaters against flaring light emissions excludes the additional breeding locations (Middle Island and Griffiths Island) from the area that may cause behavioural changes to fledgling shearwaters. As a result, potential impacts to short-tailed shearwaters are expected to be limited to foraging individuals and therefore no impacts to short-tailed shearwater will occur at a population level.
- Short-finned eels are expected to avoid rather than be attracted to Project light emissions when migrating as part of inherent predator avoidance behaviours. This change in behaviour will prevent increase predation in short-finned eels and is considered Minor (1) consequence affecting individuals but not whole populations.
- The National Recovery Plan for Albatrosses and Petrels 2022 (CoA 2022) identifies light emissions as a threat, it classifies marine infrastructure interactions including those associated with artificial light as having no risk category priority and affecting 'Nil' species in Australian jurisdiction. In addition, no actions are identified.
- As the light EMBA overlaps a number of seabird foraging and breeding BIAs, the migratory route for the critically endangered orange-bellied parrot and areas where birds, including muttonbirds, are likely or known to be foraging, breeding, or roosting, the MODU and vessel will have a Lighting Management Plan to minimise external light emissions as required by the National Light Pollution Guidelines.
- No BIAs or spawning areas are identified within the light EMBA for fish or invertebrates and the area (200 m) where invertebrates may be attracted to light is small and temporary.

6.3.4 Impact Evaluation Summary

The impact evaluation for light emissions from the Project is summarised in Table 6-14.

Table 6-14: Impact Evaluation Summary for Emissions - Light

Summary	
Summary of impacts	Potential impacts from light emissions will result in Minor (1) consequences of behavioural change to marine fauna including temporary and localised avoidance or attraction affecting individuals but not whole populations. This in turns prevents impacts to conservation, and cultural values and sensitivities. The potential impact of light emissions to coastal communities is also expected to result in Minor (1) consequences given Project light emissions will be comparable to ongoing shipping traffic and historical flaring activities within the region.
Extent of impacts	The extent of the area potentially impacted by light emissions from the Project has been assessed as up to 63 km for flaring and 20 km for routine light. Flaring will only occur on a temporary basis of up to two days per well. Navigational lighting from MODU and vessel operations will generate intermittent light emissions from the Project Area and is limited to the drilling & completions and support operations stages of the Project when the MODU and vessels, which will require lighting to comply with navigational and safety requirements, when on location **[PC244, PC245].** During MODU and vessel operations lighting levels will be reduced to acceptable levels through implementation of controls and limiting of light to only that required for navigational, safety and emergency requirements.
Duration of impacts	Light impacts are temporary only lasting for the duration of each activity (1-2 days per well for flaring; and the longest duration for a single activity requiring support vessel operations is 40 days to drill a single well utilising a MODU and two support vessels)
Level of certainty	At the time of writing this OPP, there is uncertainty with regards to the specific locations for wells and subsea systems and therefore the location of MODU and vessel operations within the Project Area resulting in light emissions. To ensure all potential impacts were considered, the light and flaring EMBA was based on ranges (defined by project specific light modelling (Appendix O) from the perimeter of the Project Area to consider the greatest range/extent for the potential change in ambient light. This approach ensures all potential receptors have been evaluated for potential impacts from light emissions. Further certainty on the location of wells and subsea systems will be known during the development of future EPs under this OPP. As a result, future EPs under this OPP will assess a much more precise and accurate range of potential impact from light emissions. Beach has a high level of certainty about the potential impacts from light emissions in the light and flaring EMBAs and has long-term experience in the area on the application of good industry practice to ensure impacts associated with light emissions are acceptable.
Is the impact considered lower-order or higher-order?	Impacts from light emissions have been evaluated to result in Minor (1) consequences. Minor (1) consequences are considered lower-order impacts that are acceptable with the application of good industry practice.
Impact Consequence	
Minor	

6.3.5 Demonstration of Acceptability

Table 6-15 demonstrates how and why predicted environmental impacts from light emissions meets the defined acceptable levels (Table 5-5).

Table 6-15: Demonstration of Acceptability – Emissions – Light

Demonstration of Acceptability		
Impact and risk comparison with relevant defined acceptable levels	Acceptable levels relevant to light emissions include acceptable levels 1, 2, and 3 (as detailed in Table 5-4). A **Minor** impact consequence level was assigned for this aspect based on the impact analysis and evaluation. Minor impact consequences due to light emissions will not result in: • interference with the recovery of EPBC Act listed threatened species • modification, isolation or decrease in the availability or quality of habitat to the extent that EPBC Act listed threatened, migratory or cetacean species are likely to decline • inconsistencies with conservation advice, recovery plans and threat abatement plans for EPBC Act listed threatened, migratory or cetacean species. As a result, the predicted environmental impact for light emissions is better than the defined acceptable levels 1, 2, and 3.	
Principles of ESD	Integration principle	Section 6.3.3 identifies and evaluates environmental impacts associated with light emissions. As part of identifying the potential impacts, conservation values and sensitivities, coastal communities, ecological environment, and cultural values and sensitivities described in Section 4 were reviewed to determine potential interactions of the aspect against each of these receptors they may result in environmental impact. As a result, consideration of economic, environmental, social and equitable receptors was conducted as part of identifying the impacts and risks. For Phase 1: Initial Project Consultation (Section 10.2.3), Beach consulted with relevant stakeholders on the Project and associated activities. No objections or claims were raised against this aspect during Phase 1: Initial Project Consultation. For Phase 2: Project OPP Public Comment Period (Section 10.2.4), the public had the opportunity to provide further comment to this OPP during the period (18/3/2024 – 20/5/2024). Beach prepared the public comment report summarising all comments, an assessment of the merits of each comment, a statement of the response to each comment, and an outline of any changes made to the OPP as a result of the comment (Appendix P). The impact assessment for this aspect has been updated to reflect the merit provided by public comment reference numbers PC229, PC190, PC244, PC245 and PC249. As a result, the impact assessment now integrates responses to public comments of merit and therefore is of an acceptable level. The potential environmental impact against this aspect was assessed as having a Minor (1) impact consequence level which is considered a lower-order environmental impact. Lower-order environmental impacts are considered 'broadly acceptable' and considered managed to an acceptable level by meeting relevant requirements (adopted controls as listed below).
	Precautionary principle	The potential environmental impacts against this aspect were assessed as having a Minor (1) impact consequence level which is considered a lower-order environmental impact. Lower-order environmental impacts cannot result in serious or irreversible environmental damage. Control measures meet the requirements of the National Light Pollution Guidelines for Wildlife (DCCEEW 2023a). To account for uncertainty in the locations for wells and subsea systems, the light and flaring EMBAs were based on ranges defined by project specific light modelling (Appendix O) for the perimeter of the Project

Demonstration of Acceptability		
		Area. This method ensures there is high confidence in the impact assessment and effectiveness of controls for this aspect given the use of project specific light modelling (Appendix O) and the National Light Pollution Guidelines for Wildlife (DCCEEW 2023a). As a result, there is no uncertainty associated with this aspect.
	Intergenerational principle	The defined acceptable levels were developed to meet the principles of ESD (Section 5.8.5). Given predicted environmental impacts from light emissions is lower than the defined acceptable levels 1, 2, and 3; the health, diversity, or productivity of the environment for future generations is expected to be maintained.
	Biodiversity principle	Section 6.3.3 identifies and evaluates environmental impacts associated with light emissions. Environmental values and sensitivities including MNES as described in Section 4 were assessed. Given predicted environmental impacts from light emissions are lower than the defined acceptable levels 1, 2, and 3; there is no potential to affect biological diversity or ecological integrity.
Internal context	Policy compliance	The defined acceptable levels, EPOs and controls proposed for this aspect are consistent with Beach Environmental Policy objectives. As a result, potential environmental impacts from the Project can be managed to align with Beach Environmental Policy objectives.
External context	Stakeholder engagement is being carried out as part of this OPP process Beach operates the existing Otway project and has established good relations with both onshore and offshore stakeholders. Engagement with stakeholders will continue throughout all aspects of the Project to build and maintain trust with stakeholders and the local community and minimise community and stakeholders concern and impacts where practicable. During Phase 1: Initial Project Consultation (Section 10.2.3), no objections or claims were raised against this aspect. During Phase 2: Project OPP Public Comment Period (Section 10.2.4), comments were raised against this aspect. The assessment of merit for these comments found this aspect to require updates. Changes to the OPP to address PC229, PC190, PC244, PC245 and PC249 have been integrated into the impact evaluation for this aspect. The science of artificial light impacts is continually evolving. Any new guidance or advice will be assessed and incorporated into the impact evaluation and controls prepared for activity specific EPs under this OPP.	
Other requirements	**Requirement**	**Demonstration**
	Navigation Act 2012 (Cth) Several Marine Orders (MO) are enacted under this Act which relate to offshore petroleum activities, including: • MO 21: Safety and emergency arrangements • MO 27: Safety of Navigation and Radio Equipment • MO 30: Prevention of collisions	These requirements are addressed through the adoption of the following control measures: **CM01 Navigation safety** Beach Marine Assurance System ensures that the MODU and vessels meet relevant maritime laws and includes pre-commencement MODU and vessel inspections of class certification requirements under the *Navigation Act 2012* and associated Marine Orders. All vessels operating within the project area will adhere to the navigation safety requirements including:

Demonstration of Acceptability		
		• International Regulations for Preventing Collisions at Sea 1972 • Chapter 5 of International Convention for the Safety of Life at Sea 1974 • International Convention on Standards of Training, Certification and Watchkeeping for Seafarers 1978 Navigation Act 2012 and any subsequent Marine Orders that specify standards for crew training and competency, navigation, communication, and safety measures **CM02 Notifications** The Australian Hydrographic Office will be notified of the Project activities and installed subsea infrastructure prior to commencement to facilitate the issuing of Notice to Mariners and maintain nautical charts. Relevant stakeholders are notified prior to the activity so that third party marine users are aware of vessel location and timing.
	National Light Pollution Guidelines for Wildlife (DCCEEW 2023a) Aim of the guidelines is that artificial light will be managed so wildlife is: 1) not disrupted within, or displaced from, important habitat 2) able to undertake critical behaviours such as foraging, reproduction and dispersal. Outlines the following management principles to reduce light pollution: 1) Start with natural darkness and only add light for specific purposes. 2) Use adaptive light controls to manage light timing, intensity and colour. 3) Light only the object or area intended – keep lights close to the ground, directed, and shielded to avoid light spill. 4) Use the lowest intensity lighting appropriate for the task. 5) Use non-reflective, dark-coloured surfaces. 6) Use lights with reduced or filtered blue, violet and ultraviolet wavelengths	**CM12 MODU and vessel lighting** MODU and vessel lighting will be limited to the minimum required for navigational and safety requirements, with the exception of emergency events. **CM13 Lighting Management Procedure** Beach will contract appropriately qualified lighting practitioners, together with an appropriately qualified marine biologist or ecologist to develop and support the implementation of a Light Management Procedure as per the National Light Pollution Guidelines for Wildlife (CoA 2023). MODU and vessels will implement a Light Management Procedure as per the National Light Pollution Guidelines (DCCEEW 2023a) for Project activities. The Light Management Procedure will detail additional adaptive mitigations to manage light based on the information in the Seabird Light Mitigation Toolbox and Beach Energy's Vessel Light Management Procedure Guidance (CDN/ID 19012450). Specifically, the Light Management Plan for vessels and rigs is required to cover: • Requirements to minimise non-essential lights and outward facing lights ensuring safety navigational lighting and safe work condition requirements are met.

Demonstration of Acceptability		
	The following conservation advice or management plans identify artificial light as a threat: • National Recovery Plan for Albatrosses and Petrels (CoA, 2022) • Wildlife Conservation Plan for Seabirds (CoA, 2020a) • Wildlife Conservation Plan for Migratory Shorebirds (CoA, 2015a) • National Recovery Plan for the Orange-bellied Parrot (DELWP, 2016) • Recovery Plan for Marine Turtles in Australia, 2017-2027 (CoA, 2017) • Approved Conservation Advice for *Dermochelys coriacea* (Leatherback Turtle) (DEWHA, 2008) • South-east Marine Region Profile (CoA, 2015c) South-east Marine Parks Network Management Plan (DNP, 2025)	• Program for managing grounded birds. • Reporting and recording requirements. Prior to commencement of an initial flaring event at each well, the area extending from the tip of the flare will be visually confirmed to be clear of birds [**PC249**]. Adaptive management will be detailed the light management procedure to be included in future EPs under this OPP when scheduling of the activity is known in greater detail.

6.3.6 Environmental Performance

In accordance with NOPSEMA's OPP Decision Making Guideline (NOPSEMA 2024), the EPO for this aspect (Table 6-) has been developed to be relevant to identified environmental impacts and risks, consistent with the principles of ESD and equivalent to or better than the defined acceptable level of impact. Control measures listed in Table 6-15 provides detail on how each control measure will be implemented for the Project to ensure the acceptable levels and EPOs, defined in Table 6- are met.

Table 6-16: Environmental Performance Outcomes: Emissions – Light

Defined Acceptable Level	Environmental Performance Outcomes	
Acceptable level 1: No interference with the recovery of EPBC Act listed threatened species.	EPO7:	No death or injury to listed threatened or migratory species from Project activities.
Acceptable level 2: No modification, isolation or decrease in the availability or quality of habitat to the extent that EPBC Act listed threatened, migratory or cetacean species are likely to decline.	EPO8:	Biologically important behaviours can continue while Project Activities are being undertaken.
Acceptable level 3: Impacts will not be inconsistent with conservation advice, recovery plans and threat abatement plans for EPBC Act listed threatened, migratory or cetacean species.	EPO9:	Implement CM13 Lighting Management Procedure as per the National Light Pollution Guidelines (DCCEEW 2023a) to ensure artificial light in biologically important areas will be managed such that biologically important behaviours within or outside a BIA can continue while Project activities are being undertaken.

6.4 **Underwater Sound**

6.4.1 Hazard Identification

Underwater sound emissions will be generated by various stages of the Project. The Project will generate both continuous and impulsive sound emissions, with different metrics used to describe the sound levels in decibels:

- continuous – continuous noise is a continual non-pulsed sound that can be transient (short duration) but without the rapid rise-time (pulse) (Southall et al. 2007), examples are vessel and drilling operations; and
- impulsive – impulsive noise is a series of pulsed sound events that are brief, broadband, atonal and transient, an example is acoustic emissions from geophysical equipment and discharges of air guns during vertical seismic profiling.

Stages and associated activities which will produce either continuous or impulsive sound emissions are defined in Table 6-17 and further described in Section 6.4.2.

Table 6-17: Activities Undertaken During the Project which will Generate Underwater Sound Emissions

Stage	**Activity**
Surveys	Geophysical survey
Drilling and Completions	MODU Positioning Drilling Method
Installation and Commissioning	Installation
Operations	Inspection, maintenance, and repair
Decommissioning	Removal of subsea infrastructure Well plugging and abandonment
Support Operations	MODU Operations Vessel Operations Helicopters ROV Operations

6.4.2 Hazard Description

6.4.2.1 Sound Metric Terminology

Sound travels as a wave with the amplitude of the wave related to the amount of acoustic energy it carries, or how loud the sound will appear to be. Figure 6-5 shows a representative sound wave and the sound measures used in this assessment. Table 6-18 provides definitions of the sound measures and other sound related terms used in this assessment.

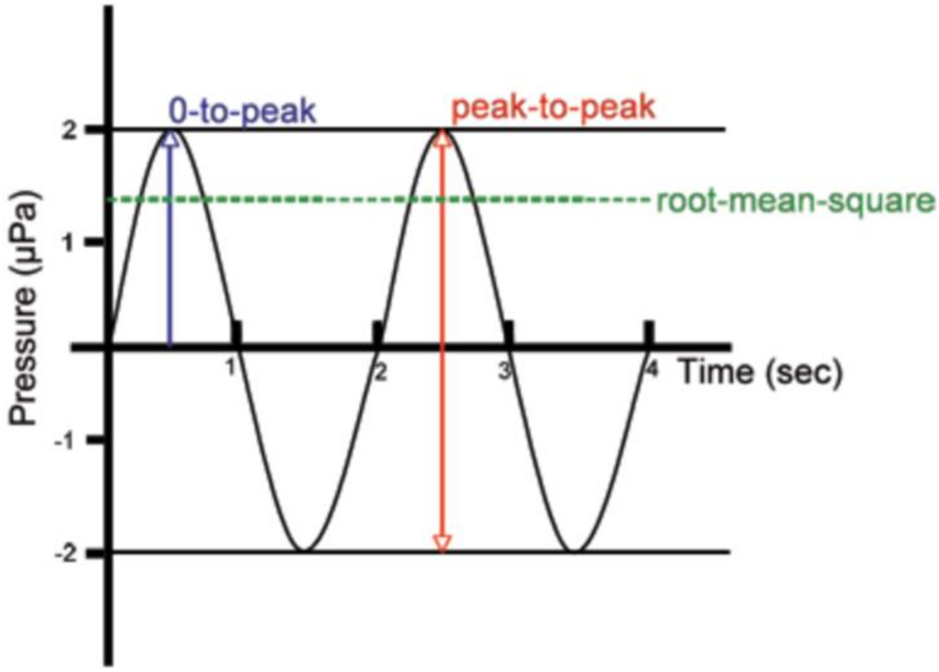

Figure 6-5: Representative Sound Wave and Sound Measures

Table 6-18: Sound Terminology

Term	Definition
0-to-peak or Peak sound pressure level (PK)	The peak pressure, also called the 0-to-peak pressure, is the range in pressure between zero and the greatest pressure of the signal. It is represented by PK and the unit dB re 1 µPa and summarised as dB PK.
Peak-to-peak sound pressure level (PK-PK)	The peak-to-peak pressure is the range in pressure between the most negative pressure and the most positive pressure of the signal. It is represented by PK-PK and the unit dB re 1 µPa or dB re 1 µPa2m2 and summarised as dB PK-PK.
Permanent threshold shift (PTS)	Permanent loss of hearing sensitivity caused by excessive noise exposure.
Received sound levels	The sound level measured at a receiver.
Root mean square sound pressure level (SPL)	The root-mean-square pressure is the square root of the average of the square of the pressure of the sound signal over a given duration. It is represented by sound pressure level (SPL) and the unit dB re 1 µPa and summarised as dB SPL.
Sound exposure level (SEL)	A measure of the sound energy that considers both received level and duration of exposure. SEL is specified in terms of either single pulse (SEL) or a defined accumulation period (SELcum). For this assessment 24hrs has been used for the accumulation period and is shown as SEL24h. Units are dB re 1 µPa2·s or dB re 1 µPa2m2s.
Source sound level	The sound pressure level or sound exposure level measured 1 metre from a theoretical point source that radiates the same total sound power as the actual source.
Temporary threshold shift (TTS)	Temporary loss of hearing sensitivity caused by excessive noise exposure.

6.4.2.2 Impulsive Sound

1. Surveys

Geophysical equipment will introduce impulsive sound into the marine environment. The geophysical surveys will typically use techniques such as MBES, SSS, SBP, USBL, and SVP, which produce acoustics, generating short, pulsed underwater sound. Depending on the area surveyed, geotechnical surveys may take up to 10 to 20 days to complete.

Table 6-19 summarises the expected sound levels and frequency ranges anticipated for the different techniques used in the geophysical surveys.

Table 6-19: Survey Equipment Source Levels, Frequency Ranges, and Relevant Literature Sources

Sound source	Frequency range	Source Levels	Literature
SBES: Single-beam echo sounder	120-710 kHz	SPL: 200-235 dB re 1µPa@ 1 m	Seiche 2020
MBES: Multi-beam echo sounder	200-500 kHz	SPL: 210-247 dB re 1µPa@ 1 m	Seiche 2020
SSS: Side-scan Sonar	70-400 kHz	SPL: 200-234 dB re 1 µPa @ 1 m	Seiche 2020
SBP: Sub-bottom profiler (with CHIRP)	2-16 kHz	SEL: 171.4 dB re 1 µPa2·s @ 1 m SPL: 191.7 dB re 1 µPa @ 1 m PK: 197.6 dB re 1 µPa @ 1 m PK-PK: 204.7 dB re 1 µPa @ 1 m	Martin et al., 2012
SBP: Sub-bottom profiler (with boomers)	200 Hz -16 kHz	SEL: 180 dB re 1 1µPa2·s @ 1 m SPL: 200.5 dB re 1 µPa @ 1 m PK: 210.8 dB re 1 µPa @ 1 m PK-PK: 227.7 dB re 1 µPa @ 1 m	Martin et al., 2012

2. Drilling and Completions

   a. MODU Positioning

The MODU will either mobilise to the Project Area with its own propulsion system or be towed by vessels and anchored or connected to pre-laid anchors prior to commencing activities. MODU positioning will require a maximum of 2 x support vessels on DP to tow and position the MODU into place within the Project Area. The continuous sound emissions produced by the support vessels and MODU are described in Section 6.4.2.3.

Transponders may be required to inform the anchor positioning. Transponders emit short ‘chirps’ sound transmissions with a duration that ranges from 3 to 40 milliseconds. Transponders will not emit any sound when on standby and may emit acoustic signals for about six hours per well if used. When required for general positioning, they will emit one chirp every five seconds (estimated to be required for four hours at a time). When required for precise positioning, they will emit one chirp every second (estimated to be required for two hours at a time).

The source levels of typical transponders are provided in Table 6-20.

Table 6-20: Transponder Source Levels, Frequency Range and Relevant Literature Source

Sound source	Frequency range	Source Levels	Literature
Transponders	21-31 kHz	SPL: 180-106 dB re 1µPa	Jiménez-Arranz et al. 2017

b. Vertical Seismic Profiling

VSP is a standard well logging technique that is routinely used to collect geophysical measurements within well bores. VSP is not expected to be used in relation to the OGV drilling campaign but may be used on future wells. VSP typically involves the use of a seismic energy source (e.g. a single air gun or a small air gun array) suspended in the water column and a receiver (e.g. hydrophone or geophone) suspended within the well bore. The seismic source may be suspended directly below the drilling MODU or may be offset (e.g. suspended behind a vessel). Vertical seismic profiling typically generates noise emissions between 8 hours and 24 hours per well.

Table 6-21 outlines the typical source levels for VSP (450 in^3 array at a centroid depth of 6 m).

Table 6-21: Vertical Seismic Profiling Source Level, Frequency Range, and Relevant Literature Source

Sound source	Frequency range	Source Levels	Literature
VSP: Vertical Seismic Profiling	10-25000 Hz	SEL: 170-220 dB re 1 µPa2·s @ 1 m PK: 237.8 dB re 1 µPa @ 1 m	McPherson and Wood 2017

6.4.2.3 Continuous Sound

1. Drilling and Completions

a. MODU Positioning

MODU positioning will require a maximum of 2 x support vessels on DP to tow and position the MODU into place within the Project Area. This process will take 9 to13 days to complete depending on constraints and weather restrictions. Table 6-23 outlines the expected source levels for support vessels for the Project.

b. Drilling Method

Drilling operations will introduce short-term, low-intensity continuous sound into the marine environment. Underwater sound levels produced from jack-up and semi-submersible MODUs during routine drilling operations (i.e. excluding vertical seismic profiling) are typically considerably lower than the sound emissions produced from the support vessels. Drilling is expected to take approximately 30 to 40 days per well.

As part of Beach's Drilling Campaign in 2021/2022, in the Otway Basin, JASCO undertook underwater sound monitoring to determine the source levels of the Ocean Onyx semi-submersible drill MODU over different drilling depths (McPherson et al. 2021). These sound levels have been considered representative of the drilling activities associated with the Project, as discussed in Section 6.4.2.3, and have been used for the assessment. The source levels are provided in

Table 6-22.

2. Decommissioning

Sound emissions may be generated by the removal of subsea infrastructure and well P&A methods such as mechanical cutting and wellhead cutting. The sound generated from these decommissioning activities are anticipated to be comparable. Decommissioning of subsea infrastructure is expected to take approximately 30 days per tie-back, and P&A of wells expected to take 30 days.

Pangerc et al. (2016) described the underwater sound measurement data during an underwater diamond wire cutting of a 32″ conductor (10 m above seabed in ~80 m depth) and found that at lower frequencies, the operation was generally indistinguishable above the background noise of the vessel. This is confirmed via acoustic modelling undertaken by JASCO (Koessler and McPherson 2021) who modelled a stationary vessel at Thylacine North 1 on DP (operating at 20% MCR) plus a stationary vessel on DP (operating at 20% MCR) using a ROV cutting tool at Geographe 4. This showed an increase of ~30 m for the behaviour exposure criteria compared to an installation vessel on DP and ~6 m for the TTS 24 h exposure criteria.

As the wellhead cutting will not be distinguishable from the drilling underwater sound emissions, it is considered inherently part of the assessment of drilling sound emissions and has not been discussed further.

3. Support Operations

Underwater sound emissions will be generated from the MODU, support vessels, helicopters and ROV operations. Support operations are associated with all stages of the Project and will introduce localised and short-term continuous sound into the marine environment.

a. MODU Operations

The MODU will generate sound from onboard equipment vibrations (e.g. pumps, generators, and machinery), and a smaller portion transmitted directly via the drill bit during drilling.

As part of Beach's Drilling Campaign in 2021/2022, in the Otway Basin, JASCO undertook underwater sound monitoring to determine the source levels of the Ocean Onyx semi-submersible drill rig and support vessels, and further validate their propagation models (McPherson et al. 2021). The mean monopole source levels for the MODU and support vessels measured in-field during Beach's Drilling Campaign in 2021/2022 (McPherson et al. 2021) were used to inform the MODU and vessel source levels in the JASCO underwater acoustic modelling studies used for this impact assessment (Koessler and McPherson 2021; Connell and Koessler 2023).

Table 6-22 describes the expected source levels for the MODU whilst anchored and whilst drilling and Table 6-23 outlines the expected source levels for support vessels in transit and under DP for the Project.

The MODU will have a thruster assisted capability to assist in reducing fatigue on the mooring system and to assist the MODU during transit. This system generates variable non-impulsive sound during infrequent operation up to six thrusters in response to feedback from the mooring system. A review of 33 months of historical operational data from the North Sea indicates thrusters are typically not active (>96% of the time) and utilisation is otherwise limited low loads across a small number of thrusters for short periods, (typically hours) in response to metocean conditions. Therefore, the MODU under DP has not been considered further.

Table 6-22: Drilling Source Levels, Frequency Ranges, and Relevant Literature Source

Sound source	Frequency range	Source Levels	Literature
MODU anchored		178.7 dB re 1µPa	McPherson et al. 2021
MODU while anchored and drilling	0.01-30 kHz	SPL: 162-180 dB re 1µPa	McPherson et al. 2021

b. Vessel Operations

The type and number of vessels in the Project Area at any one time, and the duration of presence, will differ depending on the project stage. For a single activity, there will be no more than three vessels operating simultaneously. The longest duration for a single activity requiring support vessel operations is 40 days to drill a single well utilising a MODU and two support vessels. For concurrent activities, five vessels could operate in the Project Area at any one time, for example, pipelay or diving/tie-in activities may occur concurrently during MODU positioning. Concurrent operations will be kept to a minimum and are unlikely to occur for more than 13 days.

Vessels generate sound emissions mainly by propeller and thruster cavitation, with a smaller fraction of noise produced by sound transmitted through the hull, such as by engines, gearing, and other mechanical systems. Acoustic emissions from thrusters when the vessel is keeping station under dynamic positioning have the greatest potential for impact due to relatively loud source levels.

Acoustic broadband source levels typically increase with increasing vessel size, with smaller vessels (<50 m) having source levels 160-175 dB (re 1µPa), medium size vessel (50-100 m) 165-180 dB (re 1µPa) and large vessels (>100 m) 180-190 dB (re 1µPa) (OSPAR 2009, Richardson, et al. 1995).

Table 6-23 outlines the expected source levels for support vessels in transit and under DP for the Project.

Table 6-23: Support Vessel Sound Sources, Frequency Ranges and Relevant Literature Sources

Sound source	Frequency range	Source Levels	Literature
OSV: Offshore Supply Vessels – slow transit	0.01-30 kHz	SEL: 173.1 dB re 1 µPa2m2s SPL: 183 dB re 1 µPa	Connell et al. 2023 McPherson et al. 2021
OSV: Offshore Supply Vessel - under DP	0.01-30 kHz	SEL: 194.1 dB re 1 µPa2m2s SPL: 186.6-193.9 dB re 1 µPa	Connell et al. 2023 McPherson et al. 2021

c. Helicopters

Helicopters will enter the project area for short periods of time to undertake crew change or other personnel transfer activities. On approach to the drill rig the helicopter will descend to the helideck where there is greatest potential to ensonify the water column. The level of underwater sound from helicopters is affected by helicopter altitude, aspect and strength of noise emitted, and the receiver depth, water depth and other variables (Richardson et al. 1995). Sound pressure will be greatest at the sea surface and rapidly diminish with increasing depth.

Helicopter engine sound is emitted at a range of frequencies generally below 500Hz (Richardson et al. 1995). Richardson et al. (1995) reported helicopter sound (for a Bell 214 helicopter) as being audible in air for 4 minutes before it passed over underwater hydrophones, but detectable underwater for only 38 seconds at 3 m depth and 11 seconds at 18 m depth. The maximum received level was 109 dB re 1µPa2.s. Due to their short duration and near surface impacts only, helicopter noise emissions are not considered to be a credible source of noise impact and will not be evaluated further.

6.4.2.4 Underwater Sound Modelling

1. Impulsive Sound

Beach commissioned JASCO Applied Sciences (JASCO) to undertake acoustic modelling to assist in understanding the potential acoustic impact of geophysical survey equipment and VSP on key regional receptors in the Project Area.

Based on a review of the geophysical equipment used for the seabed survey it was identified that the boomer and SBP were most relevant to the assessment of potential impacts to receptors, due to their operating frequencies and source sound levels. The modelling approach accounted for the acoustic emission characteristics of a representative boomer (AP3000) and SBP (Edgetech X-star system).

The modelling study was undertaken at six locations within the Project Area including the Artisan, Geographe and Thylacine fields at water depths ranging from ~71 m to 130 m (McPherson and Wood 2017 Appendix I). Further modelling was undertaken at four of the sites to obtain maximum ranges to updated impact thresholds for cetaceans and pinnipeds (Wood and McPherson 2019, Appendix J). The locations and water depths are considered representative of the Project Area.

The sound levels at shelf edge locations for geophysical sources can be reasonably inferred from the additional modelling study of drilling and vessel noise that was undertaken at the shelf edge within 156 m water depth to enable adequate representation of deeper shelf edge locations (deep shelf geomorphic zone) between 130 m and 180m water depth (Ryan and Koessler 2023, Appendix G). The results for drilling sources at the shelf edge location indicates that the distances to noise thresholds are up to a maximum of 150% greater than the distances to thresholds for locations on the shelf. Therefore, this has been applied to the geophysical sources to conservatively represent shelf edge locations.

2. Continuous Sound

JASCO Applied Sciences (JASCO) undertook an acoustic modelling study of underwater sound levels associated with drilling, installation, IMR and vessel transit activities at two locations within the Project Area, Artisan and Thylacine fields, at water depths ranging from 71m to 102m (Koessler and McPherson 2021 Appendix F). This modelling was a revision of previous modelling conducted by McPherson et al. (2021) (Appendix H). Table 6-24 details the activities and locations within Project Area applicable to each of the studies and scenarios modelled.

The modelling for drilling was based on the Ocean Onyx semi-submersible MODU drilling in the Otway Basin which is representative of the drilling associated with the Project. The modelled scenario for drilling was resupply with an OSV on DP during MODU drilling operations as this is expected to be the highest noise level produced during drilling.

The modelling for a large pipelay/construction vessel undertaking installation as well as IMR activities was based on the Skandi Singapore and would be a representative sized vessel to undertake these activities. The approach used to estimate sound levels under dynamic positioning (DP) is based upon vessels under transit and is an approximation based on the Maximum Continuous Rating (MCR). The scenario selected to represent installation and IMR activities was the combined sound levels of two pipelay vessels on DP approximately 10 km distant from each other within the Project area. One vessel located at Thylacine North 1 laying pipe and another vessel at Geographe 1 operating a subsea cutting tool. This is considered to be representative of any simultaneous operations associated with Project installation or IMR activities.

The Thylacine Field location in 102m water depth was selected to estimate sound levels that would be representative of potential activity locations within the Project Area that are on the shelf given that this depth encompasses the middle shelf geomorphic zone of the Otway region between 70 and 130m (refer Section 4.3.3) and resulted in higher sound levels and when compared to the results from Artisan Field.

An additional modelling study (Ryan and Koessler 2023, Appendix G) was undertaken for both drilling and vessel activities at the most southerly identified potential well location at 156 m water depth to enable adequate representation of deeper shelf edge (deep shelf geomorphic zone) locations at between 130 m and 180 m water depth (refer Section 4.3.3).

From this additional study, the Installation and IMR sound levels at shelf edge locations can be reasonably inferred. The results for drilling and vessel sources at the shelf edge location indicates that the distances to noise thresholds can be up to a maximum150% greater than the distances to thresholds for locations on the shelf.

Based on this the results for Installation & IMR at the shelf location of Thylacine have been conservatively increased by 150% to represent shelf edge locations. Where modelling at shelf locations did not predict the noise effect criteria being reached, it is considered unlikely that the criteria would be reached for shelf edge locations. If this did occur, it would be at small distances that are encompassed by the larger defined sound EMBAs for continuous sound sources of the Project.

Table 6-24: Modelling Study Scenarios Selected for the Impact Assessment of Continuous Sources

Activity	**Location**	**Relevant Modelling Scenario**	**Relevant Modelling Report**
Drilling + Resupply	Thylacine North 1	Scenario A5: MODU Drilling + 4hr OSV Resupply for shelf locations (70-130m)	Beach Otway Project: Additional and Revised Modelling Study (Koessler and McPherson, 2021)
Drilling + Resupply – shelf edge	Well Location South	Scenario 3: MODU Drilling + 4hr OSV Resupply Ops for shelf edge locations (130-180m)	Beach Otway Project: Additional Modelling at Well Location South (Connell and Koessler, 2023)
Installation and IMR	Thylacine North 1 + Geographe 4	Scenario 15: Vessel stationary, operating on DP (Thylacine North 1) + Vessel stationary, operating on DP + ROV cutting tool (Geographe 4) (June) - shelf locations (70-130m)	Beach Otway Project: Additional and Revised Modelling Study (Koessler and McPherson, 2021)

Activity	Location	Relevant Modelling Scenario	Relevant Modelling Report
Installation and IMR – shelf edge	Well Location South	N/A: Vessel stationary, operating on DP (Thylacine North 1) + Vessel stationary, operating on DP + ROV cutting tool (Geographe 4) (June) – shelf edge locations (130-180m).	Inferred from the highest increase in distances to noise effect criteria from shelf to shelf edge locations (150%)
Vessel standby/ transit	Thylacine North 1	Scenario A3: OSV vessel on standby for 24 hrs – shelf locations (70-130m)	Beach Otway Project: Additional and Revised Modelling Study (Koessler and McPherson, 2021)
Vessel standby/ transit – shelf edge	Well Location South	Scenario 3: OSV vessel on standby for 24 hrs – shelf edge locations (130-180m)	Beach Otway Project: Additional Modelling at Well Location South (Connell and Koessler, 2023)

3. Justification

The three major environmental parameters in acoustic modelling are: (1) a bathymetric grid of the modelled area, (2) underwater sound speed as a function of depth, and (3) a geoacoustic profile based on the overall stratified composition of the seafloor.

As the modelling studies mentioned above were conducted within the Otway Basin (the Project Area), in the noise impact assessment, the following basis were used, corresponding to the three major environmental properties:

(1) The bathymetry varied little in the intermediate vicinity of the modelling site, with the majority shallower than 200 m.

(2) The sound speed profile used in these studies were derived from temperature and salinity profiles from the US GDEM model from the literature (Teague et al., 1990, Carnes 2009). A September Yearly average was selected for the impulsive acoustic modelling studies and June sound speed profile for the continuous modelling studies, which were conservatively selected as part of the approach. Therefore, the previous and current modelling studies conducted for various locations in the Otway Basin used the same sound speed profiles which are considered appropriate to represent the current condition/area for similar operational activities.

(3) The approach used to model the propagation loss in the previous studies was already corrected/updated based on the results of a measurement study conducted (McPherson et al. 2021). Therefore, it is considered an appropriate representation of Beach activities on the continental shelf of the Otway Basin.

As a continuation for Point (3) above, for the shelf edge with water depths 130-180 m, Beach had conducted additional acoustic modelling in the southern and western portions of the Project Area, for the scenario 'Drilling + Resupply' and 'Vessel standby', at 156 m water depth, to be representative of deeper shelf edge locations between 130 m and 180 m water depth. The shelf edge acoustic modelling during Installation and IMR was then inferred from the new study ('Drilling + Resupply - shelf edge') (Connell and Koessler, 2023).

Overall, the impact evaluation was conducted on the basis that the broadband level predictions/propagation loss as a very similar type of seabed environment is expected within the continental shelf portion of the Otway Basin (Project Area) because it is supported by measurements of very similar operational activities (McPherson et al. 2021).

The acoustic modelling studies have considered water depths covering continental shelf and shelf edge locations, and with an appropriate geoacoustic profile representative of the Project Area, and conservatively selected sound speed profiles and mean drilling sound levels. Beach also commits to undertaking further seabed assessments of the deep shelf and upper slope zones (~130 m to 180 m water depth, as well as 130 m to 200 m water depth) (Page 372). These assessments will then enable more accurate acoustic modelling to be conducted/updated (from the measurement study in 2021).

6.4.3 Impact Analysis and Evaluation

Underwater sound emissions from the Project can result in direct impacts to:

- Marine fauna, resulting in:
    - Change in behaviour, including:
    - Disturbance leading to behavioural changes or displacement of fauna. Masking or interfering with other biologically important sounds (including vocal communication, echolocation, signals and sounds produced by predators or prey).
    - Injury/mortality to fauna, including:
        - Recoverable injury
        - Mortality of potential mortal injuries - immediate or delayed death either due to injury or substantially reduced fitness.
        - Temporary threshold shift (TTS) – temporary reduction in the ability to perceive sound.
        - Permanent threshold shift (PTS) – permanent reduction in the ability to perceive sound.

6.4.3.1 Impulsive Sound

Receptors that may be impacted by impulsive sound include:

- Plankton
- Marine Invertebrates
- Fish
- Marine Mammals
- Marine reptiles
- Socio-economic receptors (i.e., commercial fisheries)
- Cultural values and sensitivities

Acoustic modelling was used to assess potential impacts to receptors from underwater acoustic emissions associated with the geophysical survey and VSP activities as identified in Section 6.4.2.2. The modelled received sound levels were compared to defined noise effect criteria detailed in Table 6-25, as determined by scientific research and academic papers. In lieu of any noise criteria specific to geophysical surveys, criteria that is applied to seismic surveys have been used.

1. Plankton

There is no data or studies that indicate geophysical survey and VSP equipment acoustic emissions impact plankton. In lieu of any data the noise effect criteria from the American National Standards Institute (ANSI) accredited report of sound exposure guidelines for fishes and sea turtles (Popper et al. 2014) is used.

Table 6-25 details the noise effect criteria from Popper et al. (2014) and the distances at which modelling estimated they could be reached for plankton. In summary:

- The noise effect criteria for injury to plankton for the boomer is predicted at a maximum distance of 4 m and 0.8 m for the SBP for the peak sound pressure level (PK) while the noise effect criteria based on the sound exposure level (SEL) is not reached.
- Neither noise effect criteria were reached for the VSP.

Based on these distances the mortality or mortal injury impacts to plankton (including fish eggs and larvae) will be well below natural mortality rates, which are very high, as report by Tang et al. (2014) of daily mortality rates of 11.6% (average minimum) to 59.8% (average maximum). In a review of mortality estimates (Houde and Zastrow 1993) the mean mortality rate for marine fish larvae was equivalent to a loss of 21.3% per day. In the experiment undertaken by McCauley et al. (2017) zooplankton mortality rate background levels were 19%.

Richardson et al (2017) notes that for seismic surveys, which would also apply to geophysical surveys and VSP operations, zooplankton communities can begin to recover in number during a survey, such that a continuous decline in zooplankton throughout the survey is unlikely and parts of the survey area would be replenished with zooplankton as the survey progresses. Impacts to phytoplankton, the food source for zooplankton, are not predicted and such they are still available for zooplankton to graze on.

Predicted impacts to plankton do not remove them from the food web and as such the nutrients and energy they contain are retained within the ecosystem. Even after plankton die, their carcasses remain in the water column for several days where they are scavenged before any remaining carcasses sink to the seafloor to be consumed by opportunistic benthic organisms (Kirillin et al. 2012, Tang et al. 2014, Dubovskaya et al. 2015). Thus, impacts to primary production and ecosystem function are not predicted.

The area of predicted impact overlaps the pygmy blue whale high density, known and possible foraging BIAs. Foraging is associated with the timing of the Bonney Coast Upwelling and the presence of the krill. Mortality or mortal injury effects to krill does not impact on pygmy blue whales being able to feed on them as the krill will still be available within the water column. If zooplankton are impacted, they may remain in the water column for several days and are likely scavenged or otherwise sink to the seafloor to be consumed by benthic organisms (Krillin et. al. 2012, Tang et al. 2014, Dubovskaya et al. 2015) [**PC232**]. In addition, any impacts to krill are likely to be within natural mortalities rates thus not effecting the availability of krill available for foraging.

Impacts to the Bonney Coast Upwelling and its role it plays in ecosystem function and productivity is not predicted as:

- Impacts to phytoplankton are not predicted,
- Mortality or mortal injury effects to zooplankton are within natural mortality rates and zooplankton communities can begin to recover during the geophysical survey such that a continuous decline in zooplankton throughout the duration of the survey is not anticipated and parts of the survey area would be replenished as the survey progressed, and
- Mortality or mortal injury effects to zooplankton, including krill, does not impact on marine fauna being able to feed on them as they will still be available within the water column.

2. Marine Invertebrates

There has been a number of comprehensive reviews of seismic noise impacts to invertebrates such as Carroll et al. (2017) and Edmonds et al. (2016). Available literature suggests particle motion, rather than sound pressure, is a more important factor for crustacean and bivalve hearing. There are currently no defined noise effect criteria for invertebrates and hence the results from the Day et al. (2016) study on acoustic impacts from seismic exposure on southern rock lobsters (*Jasus edwardsii*) are typically used. The study found that sub-lethal effects, relating to impairment of reflexes, damage to the statocysts and reduction in numbers of haemocytes (possibly indicative of decreased immune response function), were observed after exposure to measured received sound levels of:

- Single-pulse SEL: 186–190 dB re 1 µPa2.s
- Accumulated SEL: 192–199 dB re 1 µPa2.s
- Peak-peak pressure: 209–212 dB re 1 µPa

Payne et al (2007) found no effects to the American lobster (Homarus americanus) in righting time or haemolymph biochemistry but a possible reduction in calcium after exposure to received noise levels of 202 dB re 1 µPa (PK-PK). Thus, the Payne et al (2007) level is applied as a no effect criteria. This assessment also used the no effect level proposed by McCauley and Duncan (2016) for rock lobsters of accumulated SEL 183 dB re 1 µPa2.s.

Table 6-25 details that the sound levels from the representative boomer and SBP do not reach any of the effect or no effect criteria for invertebrates at the seafloor. The VSP sound levels reached the no effect criteria within 470m of the source.

The VSP source is short term, being in the order of up to 24 hours duration per well. The drilling is not being undertaken in any relevant commercial fishery areas or sensitive habitats for invertebrates or benthic communities.

McCauley et al. (2000) assessed the effects of air gun noise on caged squid (*Sepioteuthis australis*). No sub-lethal injury or mortality as a result of exposures in this study was observed. Several squid showed alarm responses to the start-up of an airgun by firing their ink sacs and/or jetting away from the source, but this was not observed for similar or greater levels if the signal was ramped up. General habituation was observed with a decrease in alarm responses with subsequent exposures. During the trial the squid showed avoidance to the airgun by keeping close to the water surface at the end of the cage furthest from the airgun (within the sound shadow). McCauley suggests a threshold of 166 SPL would give an indication of the extent of disruption of a seismic survey by significant alteration in swimming patterns.

Table 6-25 details that the noise effect criteria at which a behavioural alteration of swimming patterns may occur is predicted within 3.9 km of the VSP, 90m of the boomer and not reached for the SBP.

This potential squid behavioural impact extent of 3.9 km for the VSP is short term, being in the order of up to 24 hours duration per well. The drilling is not being undertaken in any relevant commercial fishery areas or sensitive habitats for invertebrates or benthic communities.

Based on this, no mortality or injury effects to invertebrates including commercial squid, rock lobster and giant crab species are predicted with potential impacts limited to short term and localised behavioural affects with a Minor (1) consequence ranking assigned.

3. Fish

Noise effect criteria for fish are based on the presence of a swim bladder. Typically, site-attached, and demersal fish have a swim bladder, whereas pelagic fish do not. As noise effect criteria for sharks does not currently exist, they are assessed as fish without swim bladders. Noise effect criteria used in this assessment for fish are from the American National Standards Institute (ANSI) accredited report of sound exposure guidelines for fishes and sea turtles (Popper et al. 2014). These guidelines defined quantitative effect criteria for three types of immediate effects:

- Mortality, including injury leading to death
- Recoverable injury, including injuries unlikely to result in mortality, such as hair cell damage and minor haematoma
- TTS

Table 6-25 details the noise effect criteria from Popper et al. (2014) and the distances at which modelling estimated they could be reached for fish with and without a swim bladder. In summary:

- The noise effect criteria for mortality/potential mortal injury from the boomer is predicted for fish with a swim bladder at a maximum distance of 4m and for fish without a swim bladder at 1.5m
- The noise effect criteria for recoverable injury is predicted for fish with a swim bladder and without a swim bladder at a maximum distance of 1.5m from the boomer
- The noise effect criteria for TTS for fish with and without a swim bladder was not reached
- No noise effect criteria for fish with or without a swim bladder was predicted to be reached from the VSP

Studies to date have not shown mortality in relation to potential impact to fish from impulsive noise, though prolonged or extreme exposure to high-intensity, low-frequency sound, may lead to physical damage such as threshold shifts in hearing or barotraumatic ruptures (Carroll et al. 2017). Based on the modelling and the fact that the geophysical surveys and VSP will not result in prolonged or extreme exposure to fish it is unlikely that injury impacts to fish would occur with a Minor (1) consequence ranking assigned.

Eels that have important cultural value to First Nations may also migrate through the Project or Planning Areas (Section 4.4.9.3). Eels that may migrate through the Otway shelf to deeper waters are not predicted to be impacted as a study by Koster et al. 2021 which tracked 16 short-finned eels found that the average speed was 30.8 ± 7.3 km/day while eels were on the continental shelf and 29.7 ± 11.1 km/day while in deep water. Thus, migrating eels are unlikely to be impacted based on the small distances to the sound exposure criteria (4 m) and the distance eels travel while migrating.

4. Marine Turtles

Noise effect criteria used in this assessment for injury to turtles are from the ANSI accredited report of sound exposure guidelines for fishes and sea turtles (Popper et al. 2014). Table 6-25 details the noise effect criteria from Popper et al. 2014 and the distances at which modelling estimated they could be reached. In summary:

- The noise effect criteria for injury to turtles was reached within only 4 m for the boomer and 0.8 m for the SBP for the peak sound pressure level (PK) and the noise effect criteria based on the sound exposure level (SEL) is not reached.
- There were no potential injury effects from the VSP.

Based on limited data regarding noise levels that illicit a behavioural response in turtles, the United States National Marine Fisheries Service criterion of 166 dB re 1 µPa (SPL) is typically applied (NFS 2011) and is detailed in the Recovery Plan for Marine Turtles in Australia (CoA 2017b).

This behavioural noise effect criteria is predicted at a maximum distance of 3.9 km from the VSP, 90m from the boomer but was not reached for the SBP.

Three marine turtle species are ‘known’ or ‘likely’ to occur within the Project Area based on the PMST search, however no BIAs or habitat critical to the survival of the species are present. The PMST presence for the Loggerhead Turtle is classified as ‘breeding likely to occur’. The presence of turtles in the Project Area and surrounds is considered unlikely, based on the following information provided in Section 4.4.9.5 [**PC229**]:

- Green Turtles are predominantly found in Australian waters off the Northern Territory, Queensland, and Western Australian coastlines, with limited numbers in New South Wales, Victoria, and South Australia. There are no known nesting or foraging grounds for Green Turtles offshore Victoria; they occur only rarely in these waters (DoE 2023m) (Section 4.4.9.5).
- This species (Leatherback Turtle) is an occasional visitor to the Otway shelf and has been sighted on a number of occasions during aerial surveys undertaken by the Blue Whale Study Group, particularly to the south-west of Cape Otway (Section 4.4.9.5).
- Loggerhead Turtles forage in all coastal states and the Northern Territory, but are uncommon in South Australia, Victoria, and Tasmania (CoA 2017a). Due to water depths, it is unlikely Loggerhead Turtle would be present in the Project Area but may be occasional visitors to the Planning Area (Section 4.4.9.5).’

Impacts to turtles are likely to be restricted to short term and highly localised behavioural avoidance from the VSP source. VSP is short term, being in the order of up to 24 hours duration per well, and this extent is within that of the potential for seabed disturbance around the MODU due to anchor footprint (2 km). Behavioural impacts to turtles would be temporary and unlikely to have a significant impact on individuals or at a population level with a Minor (1) consequence ranking assigned.

5. Marine Mammals

Noise effect criteria used in this assessment for impacts to marine mammals from impulsive noise activities are based on the following:

- The National Oceanic and Atmospheric Administration (NOAA 2019) acoustic threshold for behavioural effects in marine mammals of 160 dB re 1 µPa (SPL). Whilst the newly published Southall et al. (2021) provides recommendations and discusses the nuances of assessing behavioural response, the authors do not recommend new numerical thresholds for onset of behavioural responses for marine mammals.
- Southall et al. (2019) for the onset of PTS and TTS. These criteria are based on dual acoustic criteria for impulsive sounds that included peak pressure level thresholds and SEL_{24h} thresholds, where the subscripted 24h refers to the accumulation period for calculating SEL.
- Secondary effects in marine mammals, such as masking, are poorly understood. Threshold levels cannot yet be applied in the same way as they can for direct sound effects, therefore a qualitative approach must be taken (Erbe et al. 2016). For the purpose of this evaluation, behavioural effect thresholds (as per NOAA 2019) are adopted as a conservative threshold for secondary effects i.e. masking (Hawkins and Popper 2017).

Table 6-25 details the noise effect criteria and the distances at which modelling estimated they could be reached.

a. Low Frequency Cetaceans

Several low frequency cetaceans may occur within the Project Area. Foraging behaviours were identified for the blue, fin, pygmy right and sei whales; no other important behaviours were identified. The following impulsive noise source EMBAs intersect the foraging BIAs for the pygmy blue whale (Figure 6-6) and the migration BIA for the southern right whale (Figure 6-7):

- Geophysical Sound Behaviour (360 m)
- VSP Sound Behaviour (2.6 km)
- VSP Sound Behaviour – shelf edge (6.5 km)

The reproduction BIA for the southern right whale does not overlap the Project area.

These EMBAs are based on the greatest distances from the activity where noise effect criteria are reached for impulsive noise sources, being for marine mammal behaviour (Table 6-25).

For low-frequency cetaceans the results showed the following:

- For low-frequency cetaceans the noise effect criteria for PTS is not reached and for TTS is only reached at 25 m for the 24-hour cumulative SEL.
- The acoustic threshold for behavioural effects is predicted at a maximum of 2 m from the SBP, 360 m from the boomer, 2.56 km for VSP operations and 6.5 km for VSP operations in shelf edge locations.

It is not feasible that a low-frequency cetacean, even if foraging, resting, or migrating would be within 25 m of a moving geophysical survey vessel for 24 hours.

Predicted impacts would, therefore, be limited to short term and localised behavioural responses such as avoidance of the area while the geophysical survey (360 m) or VSP (2.56 km on shelf and 6.5 km on shelf edge) is undertaken.

The consequence is assessed as Minor (1) for fin, pygmy right and sei whales as there are no biologically important behaviours or BIAs identified within the predicted ensonified area.

The fin and sei whale's conservation advice (TSSC 2015d, TSSC 2015e) has a consequence rating for anthropogenic noise and acoustic disturbance as minor with the extent over which the threat may operate as moderate-large. The pygmy right whale Species Profile and Threats Database (DotEE 2020a) in lieu of no conservation advice, does not identify anthropogenic noise and acoustic disturbance as a threat.

The consequence is assessed as Moderate (2) for southern right and pygmy blue whales as the activity area overlaps BIAs for these species.

Further detailed impact evaluation on Blue whales and Southern right whales, including the interaction with Conservation Management Plans relevant to both the impulsive and continuous noise sources of the Project, is addressed in Section 6.4.3.2.

b. High Frequency Cetaceans

High frequency cetaceans such as dolphins, sperm whales and beaked whales may occur in the Project Area, but no BIAs or biologically important behaviours were identified.

- The noise effect criteria for TTS and PTS for these species was not reached.
- The extent of the area of where high frequency cetaceans may be impacted behaviourally by noise is predicted to be 360 m for surveys and 2.56 km for VSP operations in shelf locations and 6.5 km on shelf edge locations.

Impacts to high-frequency cetaceans are likely to be limited to avoidance behavioural where they may move away from the vessel as it is undertaking the geophysical survey or MODU while undertaking VSP.

The area of impact is not within a BIA or habitat critical to the survival of a high frequency cetacean species and thus impacts are unlikely to have a significant impact on individuals or at a population level.

Based on this, the consequence ranking of potential impacts of impulsive noise to high frequency cetaceans is considered Minor (1).

c. Very High Frequency Cetaceans

Very high frequency cetaceans, such as pygmy and dwarf sperm whales, may occur in the Project Area but no BIAs or biologically important behaviours were identified.

- The maximum distance for the PTS noise effect criteria is 4.5 m and 22 m for TTS.
- The extent of the area of where very high frequency cetaceans may be impacted behaviourally by noise is predicted to be 360m for surveys and 2.56 km for VSP operations in shelf locations and 6.5 km for shelf edge locations.

Impacts to very high frequency cetaceans are likely to be limited to avoidance behavioural where they may move away from the vessel as it is undertaking the geophysical survey or VSP operations.

The area of impact is not within a BIA or habitat critical to the survival of a very high frequency cetacean species and thus impacts are unlikely to have a significant impact on individuals or at a population level.

Based on this, the consequence ranking of potential impacts of impulsive noise to very high frequency cetaceans is considered Minor (1).

d. Pinnipeds

The Australian and New Zealand fur-seals may occur in the Project Area but no BIAs or haul out areas were identified.

- The noise effect criteria for TTS and PTS for these species was not reached
- The extent of the area of where pinnipeds may be impacted behaviourally by noise is predicted to be 360m for surveys and 2.56 km for VSP operations in shelf locations and 6.5 km for shelf edge locations.

Impacts are likely to be limited to avoidance behavioural where they may move away from the vessel as it is undertaking the geophysical survey or VSP operations.

The area of impact is not within a BIA or habitat critical to the survival of pinniped species and thus impacts are unlikely to have a significant impact on individuals or at a population level.

Based on this, the consequence ranking of potential impacts of impulsive noise to pinnipeds is considered Minor (1).

6. Socio-economic Values

Where the functions, interests or activities of other marine users involve marine fauna, any effect to fauna presence or abundance may indirectly impact these users. The potential impact may occur for the duration of the sound emission; however, following cessation of the activity, long term changes in fauna abundance or distribution are not expected. Given the location of the Project Area and short-term nature of the more significant sound generating activities, changes to the functions, interests or activities of other users, such as commercial fisheries, from acoustic emissions are not expected.

7. Cultural Values and Sensitivities

The following First Nations values and sensitivities from Section 4.6.3 have been identified as potentially affected by sound and the potential impacts have been assessed within this section:

- Eels
- Fish
- Dolphins
- Blue whales
- Southern right whales
- Seals

The marine fauna listed above are connected to places associated with songlines or connected to individuals through ceremony (Section 4.6.3.5). The connection of marine fauna to places or individuals are considered cultural intangible values.

Underwater sound has the potential to impact marine fauna that have songlines, or spiritual connection to First Nations people. It is considered that impacts to species at a population level may prevent First Nations people’s obligations to maintain spiritual connections and care for culturally significant species and their habitats. As evaluated in Section 6.4.3.1, potential impacts to eels, fish, and marine mammals will not impact these species at a population level. Minor behavioural changes are expected from intermittent underwater sound emissions generated during the Project. As a result, underwater sound emissions from the Project are likely to result in Minor (1) consequences to cultural values and sensitivities.

Table 6-25: Noise Effect Criteria and Maximum Received Sound Levels for Impulsive Sources

Receptor	Noise Effect Criteria	Boomer Maximum Distance (m)	Boomer Maximum Distance – shelf edge (m)	SBP Maximum Distance (m)	SBP Maximum Distance – shelf edge (m)	VSP Maximum Distance (m)	VSP Maximum Distance – shelf edge (m)	Noise Effect Criteria Reference
Plankton: mortality/potential mortal injury	>207 dB PK or 210 dB SEL$_{24h}$	1.6 NR	4 NR	0.3 NR	0.8 NR	NR NR	NR NR	Popper et al. 2014

Figure 6-6: Impulsive Sound Behaviour EMBAs and Pygmy Blue Whale BIAs

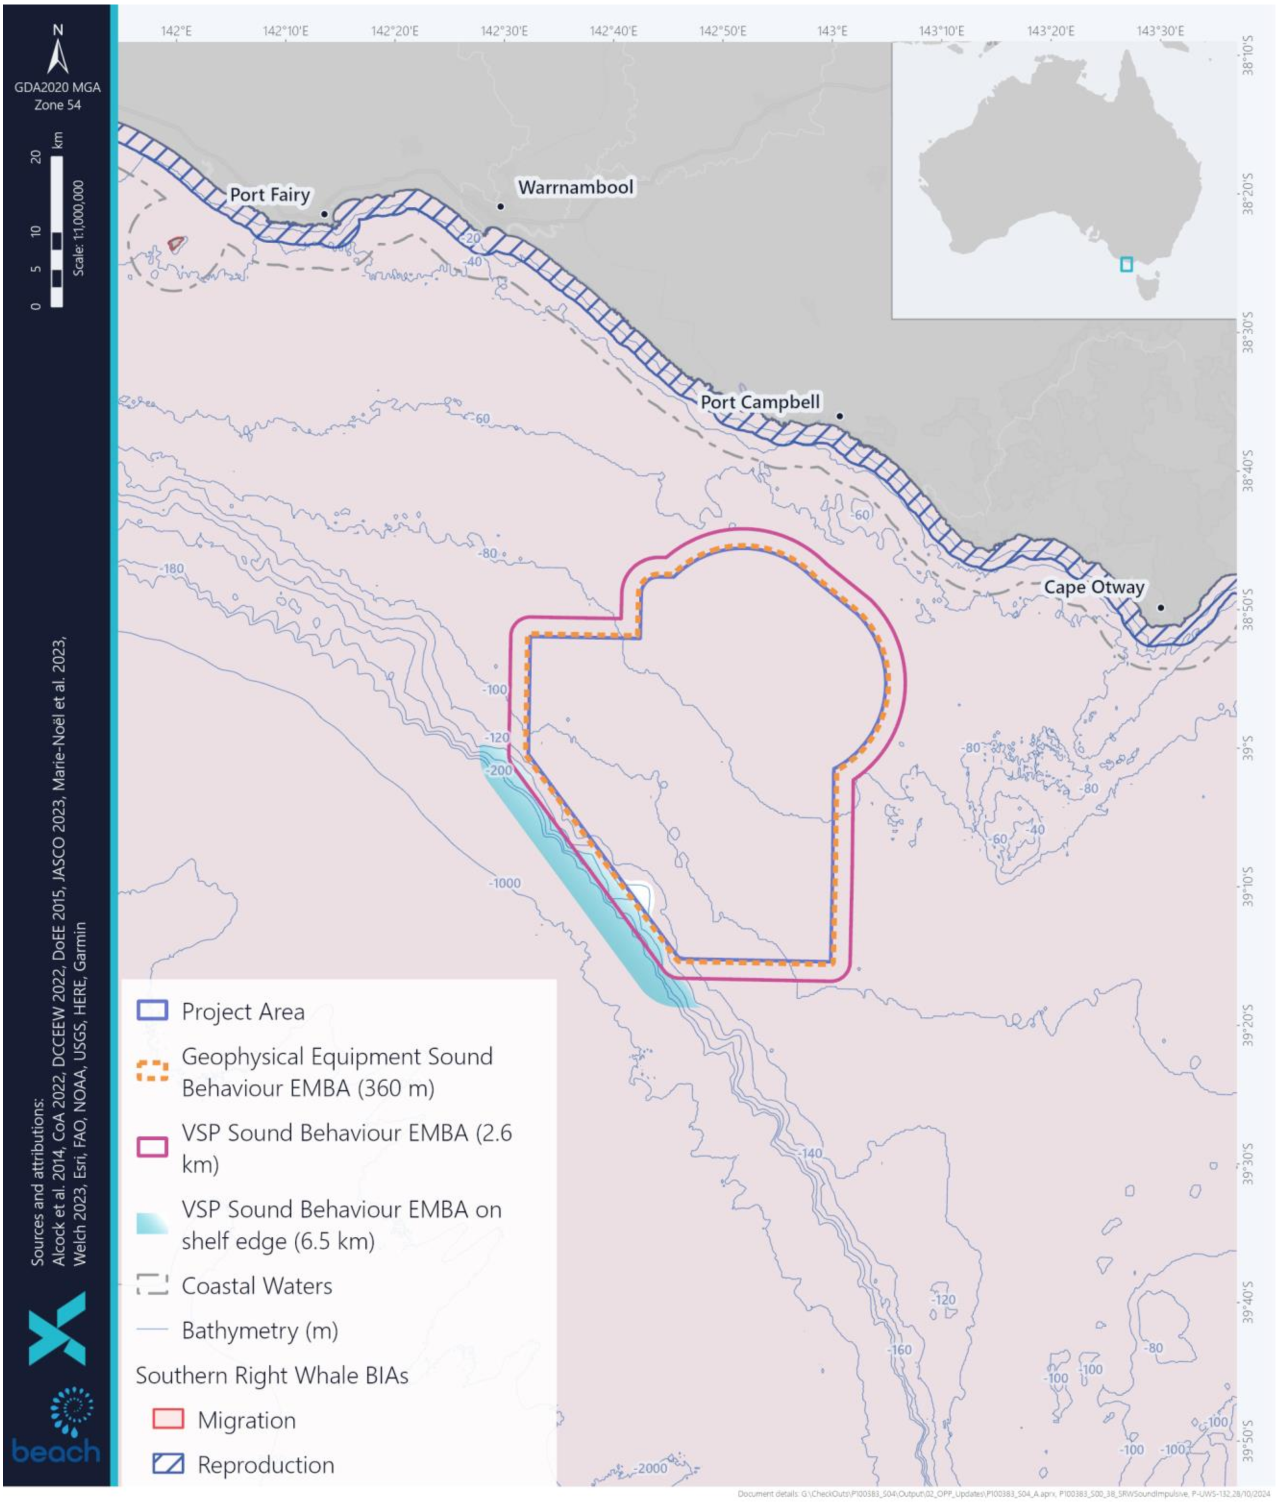

Figure 6-7: Impulsive Sound Behaviour EMBAs and Southern Right Whale BIAs

6.4.3.2 Continuous Sound

Receptors that may be impacted by continuous sound include:

- Fish
- Marine reptiles
- Marine Mammals
- Socio-economic receptors (i.e., commercial fisheries)
- Cultural values and sensitivities

The modelling studies assessed distances from activities where underwater sound levels reached exposure criteria corresponding to various levels of potential impact to marine fauna. The marine fauna considered was based on a review of receptors that may be impacted by continuous sound, these were marine mammals, turtles, and fish.

To assess the potential impacts to receptors from underwater continuous sound from the Project, acoustic modelling was used to identify the furthest underwater sound level to reach the defined noise effect exposure criteria for each receptor. The exposure criteria selected for the modelling and the impact assessment were selected as they have been accepted by regulatory agencies and because they represent current best available science (Koessler et al. 2020, Matthews et al. 2020).

The modelled received sound levels were compared to defined noise effect criteria detailed in Table 6-25 to Table 6-28 as determined by scientific research and academic papers.

1. Fish

Popper et al. (2014) details that there is no direct evidence of mortality or potential mortal injury to fish from ship sound emissions. Popper et al. (2014) details that risks of mortality and potential mortal injury, and recoverable injury impacts to fish with no swim bladder (sharks) or where the swim bladder is not involved in hearing is low and that TTS in hearing may be a moderate risk near (tens of metres) the vessel. For fish with a swim bladder involved in hearing risks of mortality and potential mortal injury impacts is low. However, some evidence suggests that fish sensitive to acoustic pressure show a recoverable loss in hearing sensitivity, or injury when exposed to high levels of sound and Popper et al. (2014) details SPL criteria for fish with a swim bladder involved in hearing.

Table 6-26 details the criteria and modelled distances to the effect criteria for fish as follows:

- The 48 hr recoverable injury threshold was reached within 50 m for drilling and not reached for the other activities
- The 12 hr TTS criteria was reached within 150 m for drilling, 40 m for Installation and IMR, and not reached for vessel resupply activities.

Surveys within the Project Area (Ramboll 2020, Appendix C) concluded that the seafloor in the surveyed area is unmodified marine sediment which supports a patchy complex of branchy epibiota and is typical of what is expected at shallow and middle shelf zones. Fauna associated with this type of habitat included amphipods, isopods, polychaete worms and molluscs. The survey also identified areas of rock outcrops. Based on available data, the presence of habitat which support site-attached fish within the Project Area cannot be ruled out.

The existing studies focus on the shallow and middle shelf zones of up to approximately 130m water depth. Beach commits to undertaking further seabed assessments of the deep shelf and upper slope zones (from approximately 130m to 180m water depth) located predominantly in the southern and western portions of the Project Area. These assessments will enable the seabed composition, benthic habitats and communities to be identified for locations where seabed disturbance activities such as drilling may take place, allowing final well location selection to avoid areas of high relief outcrops, reefs and sponge beds (CM#10).Based on this commitment, it is unlikely that fish species would be present within these distances from the activities for periods of over 12 or 48 hours and therefore injury and TTS impacts are not predicted.

Further seabed assessments will be undertaken of the deep shelf and upper slope zones (from approximately 130m to 200m water depth) located predominantly in the southern and western portions of the Project Area. These assessments will enable the seabed composition, benthic habitats and communities to be identified for locations where seabed disturbance activities such as drilling and infrastructure installation may take place

The West Tasmanian Canyons, where there are fish nurseries and the potential for site-attached fish was identified as being within the Project Area to a minor extent. The KEF is located on the continental slope where Project activities are not planned and is not within the potential area of impact for continuous noise.

Behavioural impacts are more likely such as moving away from the MODU or vessel. There are no habitats or features within the Project Area that would restrict fish and sharks from moving away from the activities.

The white shark is known to occur within the Project Area but there are no BIAs or critical habitats. The Recovery Plan for the White Shark (DSEWPaC 2013c) does not identify underwater acoustic emissions as a threat.

Impacts to fish, including sharks, would be limited to behavioural impacts such as startle response or avoidance behaviour near the MODU or vessel. Thus, behavioural impacts to fish would be temporary and unlikely to have a significant impact on individuals or at a population level.

Temporary avoidance behaviour may occur near the vessel for commercial fish species; however, recovery would occur once the activities have ceased after up to between 30-40 days each. Based on the small area of impact and that displaced fish would still be available to be caught, impacts to commercial fishing are not predicted.

Based on this, the consequence ranking of potential impacts to fish is considered Minor (1).

Eels that have important cultural value to First Nations may also migrate through the Project or Planning Areas (Section 4.4.9.3.2). Eels that may migrate through the Otway shelf to deeper waters are not predicted to be impacted as a study by Koster et al. 2021 tracked 16 short-finned eels found that the average speed was 30.8 ± 7.3 km/day while eels were on the continental shelf and 29.7 ± 11.1

km/day while in deep water. Thus, migrating eels are unlikely to be impacted based on the small distances to the sound exposure criteria (up to 150 m) and the distance eels travel while migrating.

2. Marine Turtles

The Recovery Plan for Marine Turtles in Australia (CoA 2017b) identifies noise interference as a threat to turtles. It details that exposure to chronic (continuous) loud noise in the marine environment may lead to avoidance of important habitat.

Popper et al. (2014) details that there is no direct evidence of mortality or potential mortal injury to sea turtles from ship sound emissions.

Popper et al. (2014) found that there was insufficient data available to propose a quantitative exposure guideline or criteria for marine turtles for continuous sound such as those generated by vessels and instead suggested general distances to assess potential impacts. Using semi-quantitative analysis, Popper et al. (2014) suggests that there is a low risk to marine turtles from shipping and continuous sound except for TTS near (10s of metres) to the sound source, and masking at near, intermediate (hundreds of metres) and far (thousands of metres) distances and behaviour at near and intermediate distances from the sound source.

Finneran et al. (2017) presented revised thresholds for turtle PTS and TTS for continuous sound. Table 59 details the criteria and modelled distances to them (Koessler and McPherson 2021. Appendix F) as follows:

- The 24hr PTS criteria was reached within 50m of drilling, 20m of installation and IMR, and not reached for OSV transit
- The 24hr TTS criteria was reached within 160m of drilling, 80m of installation and IMR, and 30m for OSV transit

Three marine turtle species may occur within the Project Area although no BIAs or habitat critical to the survival of the species were identified.

The Recovery Plan for Marine Turtles in Australia (CoA 2017b) details that exposure to chronic (continuous) loud noise in the marine environment may lead to avoidance of important habitat and no marine turtle important habits are located within the area that maybe impacted.

Low numbers of marine turtles are predicted in the Project Area and therefore impacts would be limited to a small number of individuals and over a temporary period of up to between 30-40 days for each activity and at a localised extent (160m).

Based on this, the consequence ranking of potential impacts to marine turtles is considered Minor (1).

3. Marine Mammals

Noise effect criteria used in this assessment for impacts to marine mammals are based on:

- NOAA (2019) acoustic threshold for behavioural effects in marine mammals of 120 dB re 1 µPa (SPL). Whilst the newly published Southall et al. (2021) provides recommendations and discusses the nuances of assessing behavioural response, the authors do not recommend new numerical thresholds for onset of behavioural responses for marine mammals

- NMFS (2018) exposure criterion for the onset of temporary hearing TTS and PTS for marine mammals based on their frequency hearing range. NMFS (2018) details that after sound exposure ceases or between successive sound exposures, the potential for recovery from hearing loss exists, with PTS resulting in incomplete recovery and TTS resulting in complete recovery. The NMFS (2018) exposure criteria are based on a cumulative SELs over a period of 24 hours
- Secondary effects in marine mammals, such as masking, are poorly understood. Threshold levels cannot yet be applied in the same way as they can for direct sound effects, therefore a qualitative approach must be taken (Erbe et al. 2016). For the purpose of this evaluation, behavioural effect thresholds (as per NOAA 2019) are adopted as a conservative threshold for secondary effects i.e. masking (Hawkins and Popper 2017).

Table 6-27 details the furthest modelled distance of each activity to the criteria for each marine mammal hearing group.

a. Low Frequency Cetaceans

Several low frequency cetaceans may occur within the Project Area. Foraging behaviours were identified for the blue, fin, pygmy right and sei whales; no other important behaviours were identified. The continuous noise source sound behaviour EMBAs for marine mammals of 7.98 km and for marine mammals on shelf edge of 19.6 km intersect the foraging BIAs for the pygmy blue whale (Figure 6-8) and the migration BIA for the southern right whale (Figure 6-9). These EMBAs are based on the greatest distances from the activity where noise effect criteria are reached for continuous noise sources.

For low-frequency cetaceans the modelling results showed the following:

- The 24hr PTS criteria is reached within 180m from drilling and 100m from drilling on shelf edge, 60m from installation/IMR and 150m for installation/IMR on shelf edge, and not reached for OSV standby/transit.
- The 24hr TTS criteria is reached within 1.31 km from drilling and 1.48 km from drilling on shelf edge, 660m from installation/IMR and 1.65 km for installation/IMR on shelf edge, not reached for OSV standby/transit and 10m for OSV standby/transit on shelf edge.
- The behavioural criteria is reached within 7.89 km from drilling and 19.6 km from drilling on shelf edge, 2.98 km from installation/IMR and 6.5 km from installation/IMR on shelf edge, 380m for OSV standby/transit and 410m from OSV standby/transit on shelf edge.

The consequence is assessed as Minor for fin, pygmy right and sei whales as there are no biologically important behaviours or BIAs identified within the sound EMBAs.

The fin and sei whale's conservation advice (TSSC 2015d, TSSC 2015e) has a consequence rating for anthropogenic noise and acoustic disturbance as minor with the extent over which the threat may operate as moderate-large. The pygmy right whale Species Profile and Threats Database (DotEE 2020a) in lieu of no conservation advice, does not identify anthropogenic noise and acoustic disturbance as a threat.

The consequence is assessed as Moderate (2) for southern right and pygmy blue whales as the activity area overlaps BIAs for these species.

Blue whales

Foraging behaviour for blue whales has been identified in the area where the PTS, TTS and behavioural criteria is reached for Project activities. On the advice of Gill (2020), all blue whales are assumed to be foraging.

The Conservation Management Plan for the Blue Whale (Commonwealth of Australia, 2015c) requires that 'anthropogenic noise in BIAs will be managed such that any blue whale continues to utilise the area without injury and is not displaced from a foraging area'. The Guidance on Key Terms within the Blue Whale Conservation Management Plan (Commonwealth of Australia, 2021) defines the requirements of this action as "to ensure that any blue whale can continue to forage with a high degree of certainty in a Foraging Area, and that any blue whale is not displaced from a Foraging Area".

The Guidance on Key Terms within the Blue Whale Conservation Management Plan (Commonwealth of Australia, 2021) suggests a whale could be displaced from a foraging area if stopped or prevented from foraging, caused to move on when foraging, or stopped or prevented from entering a foraging area. A whale is considered to be displaced from a foraging area if foraging behaviour is disrupted, regardless of whether the whale can continue to forage elsewhere within that foraging area (Commonwealth of Australia, 2021).

A precautionary approach has been taken in the assessment of possible displacement from a foraging area BIA by using conservative assumptions so as to ensure that control measures will be implemented. The potential impacts of continuous underwater sound on blue whales is assessed as Moderate (2) consequence because:

- An assessment of Beach's MFO data collected between February 2021 and March 2022 for the ongoing drilling and installation campaign was undertaken (Section 4.4.9.7). Activities included drilling and construction at the Artisan well location and activities in the Geographe and Thylacine fields A summary of findings include:

- Of the 127 blue whales that were observed to enter the 3,000 m management zone, 70 (55%) were observed to move towards the MODU (following first detection) and 57 (45%) were observed to move away from the MODU. This indicates that blue whales are not being displaced.

- Published detection functions (Williams et al. 2016) and conservative assumptions were used to estimate blue whale densities in the management zones applied (0-500, 501-1,500, 1,501-2,000, 2,001-3,000, >3,000 m). If underwater noise was displacing blue whales, it would be expected less whales would be observed in the zones closest to the underwater noise. The expected densities of blue whales based on the detection function most closely matching the Lead MFOs advice indicated there was no difference in expected densities between any of the management zones (mean of 6.21 blue whales/ km^2).

- The expected densities of blue whales based on the conservative detection functions showed similar results for the 0-500 and 501-1,500 m zones (means of 7.27 and 7.73 blue whales/ km^2). However, they showed mean expected densities of 18.70 blue whales/ km2 and 22.91 blue whales/ km^2 for the 1,501-2,000 and 2,001-3,000 m zones. Even if the conservative functions are used there is still no detectable difference in expected densities of blue whales in the 0-500 and 501-1,500 m zones, which conservatively means that blue whales are not displaced within 1,500 m of the noise source.

- The Conservation Management Plan for the Blue Whale (Commonwealth of Australia, 2015c) details that shipping and industrial noise are classed as a ‘minor’ consequence (defined as: individuals are affected but no affect at a population level).
- The activities will be of a short duration (up to 30-40 days per campaign)
- The area within the largest behavioural distance EMBA represents less than 4% of the BIA.
- Adopted controls for Project noise sources will prevent possible PTS, TTS and displacement impacts to pygmy blue whale that may be foraging.
- The largest sound EMBA is ~50 km from the Bonney coast upwelling KEF, which is a known feeding aggregation area (Gill et al. 2011; McCauley et al. 2018). The sound EMBAs are within an area where the occurrence of an upwelling event between 2002 and 2016 was assessed as very unlikely with an upwelling frequency of <10% (Huang and Wang 2019). Thus, blue whale foraging is likely to be opportunistic within the sound EMBAs
- Aerial surveys in the Otway region (2001 – 2007) recorded mean blue whale group size of 1.3±0.6 per sighting (Gill et al., 2011), meaning that pods do not have high numbers.
- Attard et al. (2017) showed that pygmy blue whales travel widely between the two known foraging areas (Bonney coast upwelling and Perth Canyon) and that records suggest that this population of blue whales may visit diverse, widespread areas for feeding during the austral summer, including perhaps the southern Indian Ocean and sub-Antarctic region, and travel to winter breeding grounds in the Indonesian region where they may also feed.
- The Commonwealth of Australia (2021) guidance regarding the definition of ’displaced from a foraging area’ states that mitigation measures must be implemented to reduce the risk of displacement occurring during operations where modelling indicates that behavioural disturbance within a foraging area may occur. The implementation of the control measures, including Whale Management Plans for each relevant Project activity, means that blue whale displacement from a foraging area is unlikely to occur. As such, the activity will be managed in a manner that is not inconsistent with the Conservation Management Plan for the Blue Whale (Commonwealth of Australia, 2015c), specifically Action Area A.2.

Southern right whales

Migration behaviour for southern right whales has been identified in the area where the PTS, TTS and behavioural criteria is reached for Project activities.

The potential impacts from continuous underwater sound to southern right whales is assessed as Moderate (2) consequence due to the following:

- The activities will be of a short duration (up to 40 days per campaign).
- The area within the behavioural distance EMBA represents less than 1% of the BIA.

- The noise effect criteria thresholds are not reached at the southern right whale reproduction BIA and are ~10 km away at the closest point

- The activity is not being undertaken within the coastline areas of south-west Victoria in Gunditjmara Sea Country where southern right whale feed and birth or the Whale Birthing Dreaming Sites in coastal bay areas from Port Campbell to Portland, including Warrnambool (DCCEEW 2024o). Noise impacts to southern right whales in these sites are not predicted.

- Low numbers of SRW are predicted in and around the activity area based on aerial surveys in the Otway region (2002 – 2013), which recorded 12 groups of SRW consisting of 52 individuals (Gill et al., 2015). None were observed away from the coast, which Gill et al (2015) noted is consistent with winter habitat preferences.

- SRW are a highly mobile migratory species that travel thousands of kilometres between habitats used for essential life functions (DCCEEW 2024o; DSEWPaC 2012a). Along the Australian coast, individual SRW use widely separated coastal areas (200–1,500 km apart) within a season, indicating substantial coast-wide movement. The longest movements are undertaken by non-calving whales, though calving whales have also been recorded at locations up to 700 km apart within a single season (DCCEEW 2024o; DSEWPaC 2012a).

- The National Recovery Plan for the Southern Right Whale (DCCEEW 2024o) identifies industrial noise as a Moderate consequence and vessel noise as Minor consequence.

- Anthropogenic noise will be managed such that SRW are not deterred from calving nor displaced from the emerging aggregation area. The EPOs and control measures, including Whale Management Plans for each relevant Project activity, ensure that SRW will continue to utilise the emerging aggregation area; and movements are not deterred in and out of the migration area. The activity will be managed in a manner that is not inconsistent with National Recovery Plan for the Southern Right Whale (DCCEEW 2024o).

- The activity can be managed to ensure that it will not be inconsistent with the National Recovery Plan for the Southern Right Whale (DCCEEW 2024o) that details that actions within and adjacent to southern right whale BIAs and habitat critical to the survival of the species, should demonstrate that it does not prevent any southern right whale from utilising the area or cause injury (TTS and PTS) and/or disturbance. Adopted controls will prevent possible PTS, TTS and displacement impacts to southern right whales.

b. High Frequency Cetaceans

High frequency cetaceans such as dolphins, sperm whales and beaked whales may occur in the Sound behaviour EMBAs for continuous noise sources of 7.98 km and 19.6 km for shelf edge locations, but no BIAs or biologically important behaviours were identified.

For high frequency cetaceans the modelling results showed the following:

- The 24hr PTS criteria is reached within 50m from drilling and drilling on shelf edge, 20m for installation/IMR and 50m from installation/IMR on shelf edge, and not reached for OSV standby/transit

- The 24hr TTS criteria is reached within 160m from drilling and 80m from drilling on shelf edge, 90m for installation/IMR and 225m from installation/IMR on shelf edge, and not reached for OSV standby/transit
- The behavioural criteria is reached within 7.89 km from drilling and 19.6 km from drilling on shelf edge, 2.98 km from installation/IMR and 6.5 km from installation/IMR on shelf edge, 380m for OSV standby/transit and 410m from OSV standby/transit on shelf edge.

It is unlikely that a high frequency cetacean would be within the PTS and TTS extent distances of a MODU or vessel for in excess of 24 hours.

Predicted impacts would be limited to behavioural response such as avoidance of the area for a small number of individuals, not population level, while the activities are being undertaken for a temporary period of up to between 30-40 days.

Based on this, the consequence ranking of potential impacts of continuous noise to high frequency cetaceans is considered Minor (1).

c. Very High Frequency Cetaceans

Very high frequency cetaceans, such as pygmy and dwarf sperm whales, may occur in the Sound behaviour EMBAs for continuous noise sources of 7.98 km and 19.6 km for shelf edge locations, but no BIAs or biologically important behaviours were identified.

For very high frequency cetaceans the modelling results showed the following:

- The 24hr PTS criteria is reached within 260m from drilling and 170m from drilling on shelf edge, 120m for installation/IMR and 300m for installation/IMR from shelf edge, and not reached for OSV transit
- The 24hr TTS criteria is reached within 1.16 km from drilling and 1.53 km from drilling on shelf edge, 870m for installation/IMR and 2.18 km from installation/IMR on shelf edge, not reached for OSV transit and 10m from OSV standby/transit.
- The behavioural criteria is reached within 7.89 km from drilling and 19.6 km from drilling on shelf edge, 2.98 km from installation/IMR and 6.5 km from installation/IMR on shelf edge, 380m for OSV standby/transit and 410m from OSV standby/transit on shelf edge.

It is unlikely that a very high frequency cetacean would be within the PTS and TTS extent distances of a MODU or vessel for in excess of 24 hours.

Predicted impacts would be limited to behavioural response such as avoidance of the area for a small number of individuals, not population level, while the activities are being undertaken for a temporary period of up to between 30-40 days.

Based on this, the consequence ranking of potential impacts of continuous noise to very high frequency cetaceans is considered Minor (1).

d. Otariid Seals

Otariid seals, such as the Australian sea lion and Australian and New Zealand fur seals may occur within the Sound behaviour EMBAs for continuous noise sources of 7.98 km and 19.6 km for shelf edge locations, but no BIAs or biologically important behaviours were identified.

For otariid seals the modelling results showed the following:

- The 24hr PTS criteria is reached within 50m from drilling and 30m from drilling on shelf edge, 10m for installation/IMR and 25m from installation/IMR on shelf edge, and not reached for OSV transit
- The 24hr TTS criteria is reached within 90m from drilling and 50m from drilling on shelf edge, 20m for installation/IMR and 50m for installation/IMR on shelf edge, and not reached for OSV transit
- The behavioural criteria is reached within 7.89 km from drilling and 19.6 km from drilling on shelf edge, 2.98 km from installation/IMR and 6.5 km from installation/IMR on shelf edge, 380m for OSV standby/transit and 410m from OSV standby/transit on shelf edge.

It is unlikely that an otariid seal would be within the PTS and TTS extent distances of a MODU or vessel in excess of 24 hours.

Predicted impacts would be limited to behavioural response such as avoidance of the area for a small number of individuals, not population level, while the activities are being undertaken for a temporary period of up to between 30-40 days.

Based on this, the consequence ranking of potential impacts of continuous noise to otariid seals is considered Minor (1).

4. Socio-economic Values

Where the functions, interests or activities of other marine users involve marine fauna, any effect to fauna presence or abundance may indirectly impact these users. The potential impact may occur for the duration of the sound emission; however, following cessation of the activity, long term changes in fauna abundance or distribution are not expected. Given the location of the Project Area and short-term nature of the more significant sound generating activities, changes to the functions, interests or activities of other users, such as commercial fisheries, from acoustic emissions are not expected.

5. Cultural Values and Sensitivities

The following cultural values and sensitivities from Section 4.6.3 have been identified as potentially affected by sound and the potential impacts have been assessed within this Section 6.4.3:

- Eels
- Fish
- Dolphins
- Blue whales
- Southern right whales

- Seals

The marine fauna listed above are connected to places associated with songlines or connected to individuals through ceremony (Section 4.6.3.5). The connection of marine fauna to places or individuals are considered cultural intangible values.

Underwater sound has the potential to impact marine fauna that have songlines, or spiritual connection to First Nations people. It is considered that impacts to species at a population level may prevent First Nations people's obligations to maintain spiritual connections and care for culturally significant species and their habitats. As evaluated in Sections 6.4.3.2, potential impacts to eels, fish, and marine mammals will not impact these species at a population level. However, there is potential for possible injury to blue whales and southern right whales resulting in Moderate (2) consequences from continuous underwater sound emissions. As a result, continuous underwater sound emissions from the Project are likely to result in Moderate (2) consequences to cultural values and sensitivities. Underwater sound has not been identified as an impact to submerged cultural heritage.

Table 6-26: Noise Effect Criteria and Modelled Distances to the Criteria for Fish

Figure 6-9: Southern Right Whale BIAs and Continuous Sound Behaviour EMBAs

6.4.4 Impact Evaluation Summary

The impact evaluation for underwater noise emissions is summarised in Table 6-29.

Table 6-29: Impact Evaluation Summary for Underwater Noise Emissions

Summary	
Summary of impact	Potential impacts from underwater noise emissions are expected to cause Minor (1) consequences of short term and highly localised changes in behaviour to marine fauna including fish, marine turtles, and most marine mammals. Injury and mortality is expected to be limited to plankton at rates well below natural mortality rates, however this is also considered a Minor (1) consequence. The potential for continuous underwater sound emissions to cause PTS, TTS and displacement impacts to blue whales and southern right whales results in a Moderate (2) consequence for these receptors. As a result, potential impacts to cultural values and sensitivities are also considered to be Moderate (2) consequences. With the adoption of controls to prevent the onset of injury and displacement to blue whales and southern right whales, these impacts will not have significant impacts on individuals or at impacts to population levels. With no potential impacts to the abundance or distribution of marine fauna including species of commercial value, impacts to socio-economic values are not expected.
Extent of impacts	Underwater noise that could potentially impact marine fauna will be generated during impulsive source activities (geophysical surveys, VSP operations) with a predicted maximum extent of impact (behavioural disturbance threshold for whales) of up to 2.56 km. Underwater noise that could potentially impact marine fauna will be generated during continuous source activities (drilling, installation and IMR and vessel transit) with a predicted maximum extent of impact (behavioural disturbance threshold for whales) of up to 7.89 km.
Duration of impacts	Continuous underwater sound emissions will be intermittent for the duration of Project activities based on the presence of vessels in the Project Area. Impulsive underwater sound emissions will be based on short-term activities including VSP operations (up to 24hrs per well), and geophysical surveys (up to 30-40 days per campaign).
Level of certainty of impacts	At the time of writing this OPP and at this preliminary stage of the Project, MODU and vessels contractors for the Project have not been confirmed. As a result, there is uncertainty with regards to specific sound source values for impulsive and continuous underwater sound. To ensure an acceptable level of certainty with regards to potential impacts from this aspect, analogue sound source values and acoustic modelling studies conducted for previous and relevant Beach operations in the region was used to inform the spatial extent of potential impact. This approach is considered appropriate to evaluate potential impacts from underwater sound until MODU and vessel contractors have been assigned for the Project. Previous underwater sound modelling studies commissioned by Beach for impulsive and continuous sound sources are considered suitable and representative analogues to define the spatial extent of the impact. The acoustic modelling studies have considered water depths covering continental shelf and shelf edge locations, and with an appropriate geoacoustic profile representative of the Project Area, and conservatively selected sound speed profiles and mean drilling sound levels. Overall, the impact evaluation was conducted on the basis that the broadband level predictions/propagation loss as a very similar type of seabed environment is expected within the continental shelf portion of the Otway Basin (Project Area) because it is supported by measurements of very similar operational activities (McPherson et al. 2021). MODU and vessel contractors are expected to be known during the development of future EPs under this OPP. As a result, future EPs under this OPP will use Project specific modelling if the analogue studies are not considered conservative, suitable and representative predictions.

Summary	
	Beach has a high level of certainty about the potential impacts from underwater sound emissions and has long-term experience in the area on the application of good industry practice to ensure impacts associated with underwater sound are acceptable.
Is the impact considered lower-order or higher-order?	Impacts from underwater sound emissions have been evaluated to result in consequences up to the Moderate (2) level. Moderate (2) consequences are considered lower-order impacts that are acceptable with the application of good industry practice.
Impact Consequence	
Moderate	

6.4.5 Demonstration of Acceptability

Table 6-30 demonstrates how and why predicted environmental impacts from sound emissions meets the defined acceptable levels (Table 5-4).

Table 6-30: Demonstration of Acceptability – Sound Emissions

Demonstration of Acceptability		
Impact and risk comparison with relevant defined acceptable levels	Acceptable levels relevant to sound emissions include acceptable levels 1, 2, and 3 (as detailed in Table 5-4). A **Moderate** impact consequence level was assigned for this aspect based on the impact analysis and evaluation. Moderate impact consequences from sound emissions will not result in: • interference with the recovery of EPBC Act listed threatened species • modification, isolation or decrease in the availability or quality of habitat to the extent that EPBC Act listed threatened, migratory or cetacean species are likely to decline • inconsistencies with conservation advice, recovery plans and threat abatement plans for EPBC Act listed threatened, migratory or cetacean species As a result, the predicted environmental impact for sound emissions is better than the defined acceptable levels 1, 2, and 3.	
Principles of ESD	Integration principle	Section 6.4.3 identifies and evaluates environmental impacts associated with underwater sound emissions. As part of identifying the potential impacts, conservation values and sensitivities, physical environment, ecological environment, socio-economic values, and First Nations values and sensitivities described in Section 4 were reviewed to determine potential interactions of the aspect against each of these receptors they may result in environmental impact. As a result, consideration of economic, environmental, social and equitable receptors was conducted as part of identifying the impacts and risks. For Phase 1: Initial Project Consultation (Section 10.2.3), Beach consulted with relevant stakeholders on the Project and associated activities. No objections or claims were raised in Phase 1: Initial Project Consultation. For Phase 2: Project OPP Public Comment Period (Section 10.2.4), the public had the opportunity to provide further comment to this OPP during the period (18/3/2024 – 20/5/2024). Beach prepared the public comment report summarising all comments, an assessment of the merits of each comment, a statement of the response to each comment, and an outline of any changes made to the OPP as a result of the comment

Demonstration of Acceptability		
		(Appendix P). The impact assessment for this aspect has been updated to reflect the merit provided by public comment reference numbers PC190, PC229 and PC232. As a result, the impact assessment now integrates responses to public comments of merit and therefore is of an acceptable level. The potential environmental impact against this aspect was assessed as having a Moderate (2) impact consequence level which is considered a lower-order environmental impact. Lower-order environmental impacts are considered managed to an acceptable level by meeting relevant requirements (adopted controls as listed below).
	Precautionary principle	The potential environmental impacts against this aspect were assessed as having a Moderate (2) impact consequence level which is considered a lower-order environmental impact. Lower-order environmental impacts cannot result in serious or irreversible environmental damage. There is high confidence in the impact assessment and effectiveness of controls against this aspect given the use of suitable analogue modelling, scientific literature and noise effect criteria. Beach has significant experience operating in the Otway and Bass based on their existing offshore developments and associated activities including the Beach Otway Drilling Campaign in 2021/2022.
	Intergenerational principle	The defined acceptable levels were developed to meet the principles of ESD (Section 5.8.5). Given predicted environmental impacts from underwater sound emissions is lower than the defined acceptable levels 1, 2, and 3, the health, diversity, and/ or productivity of the environment for future generations is expected to be maintained.
	Biodiversity principle	Section 6.4.3 identifies and evaluates environmental impacts associated with sound emissions. As part of identifying the potential impacts, conservation values and sensitivities including MNES in Section 4 were reviewed. Given predicted environmental impacts from sound emissions are lower than the defined acceptable levels 1, 2, and 3, there is no potential to affect biological diversity or ecological integrity is expected.
Internal context	Policy compliance	Beach Environmental Policy objectives are met through this environmental impact assessment.
	Management system compliance	Section 9 describes the implementation strategy employed for this activity.
External context	Stakeholder engagement is being carried out as part of this OPP process. Beach operates the existing Otway project and has established good relations with both onshore and offshore stakeholders. Engagement with stakeholders will continue throughout all aspects of the Project to build and maintain trust with stakeholders and the local community and minimise community and stakeholders concern and impacts where practicable. During Phase 1: Initial Project Consultation (Section 10.2.3), no objections or claims were raised against this aspect. During Phase 2: Project OPP Public Comment Period (Section 10.2.4), comments were raised against this aspect. The assessment of merit for these comments found this aspect to require updates. Changes to the OPP to address PC190, PC229 and PC232 have been integrated into the impact evaluation for this aspect. The science of underwater sound is continually evolving. Any new guidance or advice will be assessed and incorporated into adaptive management plans prepared for activity specific EPs.	

Demonstration of Acceptability		
Other requirements	**Requirement**	**Demonstration**
	Conservation Management Plan for the Blue Whale 2015-2025 (CoA, 2015b) Relevant management actions: • Assess and address anthropogenic noise. Anthropogenic noise in biologically important areas will be managed such that any blue whale continues to utilise the area without injury, and is not displaced from a foraging area. **National Recovery Plan for the Southern Right *Whale Eubalaena australis* (DCCEEW 2024o)** Relevant management actions: Assess, manage and mitigate impacts from anthropogenic noise **The following conservation advice or management plans identify underwater sound as a threat:** • Approved Conservation Advice for *Balaenoptera borealis* (Sei Whale) (TSSC, 2015e) • Approved Conservation Advice for *Balaenoptera physalus* (Fin Whale) (TSSC, 2015d) • Listing Advice *Megaptera novaeangliae* (Humpback Whale) (TSSC, 2022) • Recovery Plan for Marine Turtles in Australia, 2017-2027 (CoA, 2017) • Approved Conservation Advice for *Dermochelys coriacea* (Leatherback Turtle) (DEWHA, 2008) • Conservation Listing Advice for the *Neophoca cinerea* (Australian sea lion) (TSSC, 2020) South-east Marine Region Profile (CoA, 2015c)	**CM14 EPBC Regulations 2000 – Part 8 Division 8.1 interacting with cetaceans** All vessels will adhere to EPBC Regulations 2000 – Part 8 Division 8.1 interacting with cetaceans in relation to distances to cetaceans. Helicopters will adhere to EPBC Regulations 2000 – Part 8 Division 8.1 interacting with cetaceans in relation to distances to cetaceans **CM15 Geophysical Survey Whale Management Procedure** Development and implementation of a whale management procedure which outlines specific measures to minimise anthropogenic noise threats to relevant species, including the implementation of safe operating distances between vessels and whales, night-time and low visibility controls and pre-activity surveys for geophysical surveys using a boomer or SBP. This procedure provides a framework for minimising noise impacts to whales and details specific measures to be implemented that will ensure impacts and risks meet or are better than acceptable levels 1, 2 and 3. By meeting these acceptable levels, impacts will be consistent with Conservation Management Plan for the Blue Whale 2015-2025 (CoA, 2015b) and National Recovery Plan for the Southern Right Whale Eubalaena australis (DCCEEW 2024o). Specific measures in the procedure will include the following: • pre-start-up visual observations. Visual observations for the presence of whales carried out at least 30 minutes out to a distance of at least 300m from the source before startup of the boomer or SBP. • if during the prestart visual observation period, a whale is sighted within 300 m of the vessel the equipment activation will be delayed until the whale has moved outside of the 300 m zone or 30 minutes has lapsed since the last whale sighting within 300 m. • SBP equipment will not be started at night if there have been three or more delays to the start-up of the equipment due to whales in the previous 24 hours. • use of suitably trained Marine Mammal Observers (MMO) • once the survey has commenced CM#14 applies where the vessel is required to maintain a 300 m distance to all whales.

Demonstration of Acceptability

Adaptive management will be detailed the procedure to be included in future EPs under this OPP when scheduling of the activity is known in greater detail.

CM16 VSP Whale Management Procedure

Development and implementation of a whale management procedure which outlines specific measures to minimise anthropogenic noise threats to relevant species, including the implementation of safe operating distances, night-time and low visibility controls and pre-activity surveys for VSP activities that complies with 'Standard Management Procedures' set out in EPBC Act Policy Statement 2.1 – Interaction between Offshore Seismic Exploration and Whales: Industry Guidelines (DEWHA 2008c) (or the contemporary requirements at the time of the activity). This procedure provides a framework for minimising noise impacts to whales and details specific measures to be implemented that will ensure impacts and risks meet or are better than acceptable levels 1, 2 and 3. By meeting these acceptable levels, impacts will be consistent with Conservation Management Plan for the Blue Whale 2015-2025 (CoA, 2015b) and National Recovery Plan for the Southern Right Whale Eubalaena australis (DCCEEW 2024o). Specific measures in the procedure will include the following:

- pre-start-up visual observations.
- start-up and normal operating procedures, including a process for delayed start-up/recommencement, should whales be sighted.
- night time and low visibility procedures
- use of suitably trained Marine Mammal Observers (MMO)

Adaptive management will be detailed the procedure to be included in future EPs under this OPP when scheduling of the activity is known in greater detail.

CM17 Drilling Whale Management Procedure

Development and implementation of a whale management procedure which outlines specific measures to minimise anthropogenic noise threats to relevant species, including the implementation of safe operating distances between vessels and whales, pre-activity surveys for specific activities, night-time and low visibility controls and establishment of safe points for operational activities in accordance with the Safety Case and Well Integrity requirements for drilling activities. This procedure provides a framework for minimising noise impacts to whales and details specific measures to be implemented that will ensure impacts and risks meet or are better than acceptable levels 1, 2 and 3. By meeting these acceptable levels, impacts will be consistent with

Demonstration of Acceptability

Conservation Management Plan for the Blue Whale 2015-2025 (CoA, 2015b) and National Recovery Plan for the Southern Right Whale Eubalaena australis (DCCEEW 2024o). Specific measures in the procedure will include the following:

- pre-start-up visual observations.
- start-up and normal operating procedures, including a process for delayed start-up/recommencement, should whales be sighted.
- night time and low visibility procedures
- use of suitably trained Marine Mammal Observers (MMO)
- weekly aerial surveys to detect and report the presence of whales within 20 km for anchor pre-lay, rig mooring and resupply activities in the shelf edge locations

Adaptive management will be detailed the procedure to be included in future EPs under this OPP when scheduling of the activity is known in greater detail.

CM18 Vessel Whale Management Procedure

Development and implementation of a whale management procedure which outlines specific measures to minimise anthropogenic noise threats to relevant species, including the implementation of safe operating distances between vessels and whales, night-time and low visibility controls and pre-activity surveys for installation, IMR and vessel transit/resupply activities. This procedure provides a framework for minimising noise impacts to whales and details specific measures to be implemented that will ensure impacts and risks meet or are better than acceptable levels 1, 2 and 3. By meeting these acceptable levels, impacts will be consistent with Conservation Management Plan for the Blue Whale 2015-2025 (CoA, 2015b) and National Recovery Plan for the Southern Right Whale Eubalaena australis (DCCEEW 2024o). Specific measures in the procedure will include the following:

- pre-start-up visual observations.
- start-up and normal operating procedures, including a process for delayed start-up/recommencement, should whales be sighted.
- night time and low visibility procedures
- use of suitably trained Marine Mammal Observers (MMO)

Adaptive management will be detailed the procedure to be included in future EPs under this OPP when scheduling of the activity is known in greater detail.

CM19 Noise Assessments

Acoustic noise assessments of significant noise generating activities associated with the Project will

Demonstration of Acceptability		
		be detailed in relevant activity specific Environment Plans prior to activities commencing. The EPs will detail the sound levels and distances to noise effect criteria, with the mitigations required to ensure the acceptable levels and Environmental Performance Outcomes of this OPP are met and ensure consistency against Conservation Management Plan for the Blue Whale 2015-2025 (CoA, 2015b) and National Recovery Plan for the Southern Right Whale Eubalaena australis (DCCEEW 2024o).

6.4.6 Environmental Performance

In accordance with NOPSEMA's OPP Decision Making Guideline (NOPSEMA 2024), the EPO for this aspect (Table 6-31) has been developed to be relevant to identified environmental impacts and risks, consistent with the principles of ESD and equivalent to or better than the defined acceptable level of impact. Control measures listed in Table 6-30 provides detail on how each control measure will be implemented for the Project to ensure the acceptable levels and EPOs, defined in Table 6-31 are met.

Table 6-31: Environmental Performance Outcomes – Emissions – Underwater Sound

Defined Acceptable Level	Environmental Performance Outcomes	
Acceptable level 1: No interference with the recovery of EPBC Act listed threatened species. **Acceptable level 2:** No modification, isolation or decrease in the availability or quality of habitat to the extent that EPBC Act listed threatened, migratory or cetacean species are likely to decline. **Acceptable level 3:** Impacts will not be inconsistent with conservation advice, recovery plans and threat abatement plans for EPBC Act listed threatened, migratory or cetaceans species.	EPO7:	No death or injury[1] to listed threatened or migratory species from Project activities.
	EPO8:	Biologically important behaviours[2] can continue while Project Activities are being undertaken.
	EPO10:	Anthropogenic noise in biologically important areas and habitat critical to the survival of a species will be managed such that: - Any blue whale continues to utilise biologically important areas without injury[1], and is not displaced from a foraging area. It does not prevent any southern right whale from utilising biologically important areas or habitat critical to the survival of a species or cause auditory impairment (TTS and PTS).
	EPO11:	Implement CM15, CM16, CM17, CM18 Whale Management Procedures to ensure impacts and risks to whales from underwater sound are managed in accordance with relevant recovery plans.

Defined Acceptable Level	Environmental Performance Outcomes	
	EPO12:	Implement CM19 Noise Assessments to ensure impacts and risks to whales from underwater sound evaluated in relevant activity specific Environment Plans are based on the latest available scientific research on noise effect criteria.

---

[1] Injury to cetaceans as defined as auditory impairment from the onset of TTS and PTS, where DAWE (2021a) defines 'injury to blue whales' as:

> *For the purpose of interpreting and applying Action Area A.2 of the Blue Whale CMP, injury is both permanent and temporary hearing impairment (Permanent Threshold Shift and Temporary Threshold Shift) and any other form of physical harm arising from anthropogenic sources of underwater noise.*

[2] Biologically important behaviours such as reproduction, feeding, migration and resting (DCCEEW, 2023j).

6.5 **Emissions – Atmospheric Emissions**

6.5.1 Hazard Identification

Atmospheric emissions can be divided into greenhouse gas (GHG), and non-GHG emissions – also known as atmospheric pollutants. This section will only evaluate non-GHG emissions (atmospheric pollutants). GHG emissions are assessed in Section 6.6.

Atmospheric emissions refer to the release of atmospheric pollutants including gases, particles, and other substances into the air. These emissions have the potential to impact on air quality and human health. Atmospheric pollutants considered in this section include: Carbon monoxide (CO), Particulate Matter (PM) (i.e. dust in the air), typical pollutants for nitrogen oxides (NO_x), sulphur oxides (SO_x), and non-methane volatile organic compounds (NMVOCs), which includes aromatic (BTEX – benzene, toluene, ethylbenzene and xylene) and aliphatic (propane and long organic compound containing carbon and hydrogen joined together in straight chain).

Atmospheric emissions will be generated in the Project Area during the Project stages and associated activities identified in Table 6-32.

Table 6-32: Activities Undertaken During the Project that will Generate Atmospheric Emissions

Stage	Activity
Drilling and completions	Well Completion, Unload and Test
Support operations	MODU operations Vessel operations Helicopter operations

6.5.2 Hazard Description

6.5.2.1 Drilling and Completions

Well unloading and testing may generate atmospheric emissions if flaring is required.

Flaring associated with well flowback during the potential testing of the wells via the drilling rig may occur in the initial or future drilling campaigns if the base case of unloading the wells to the OGP is not feasible.

The duration of flaring for unloading a well of well construction fluid to the rig is in the order of one to two days per well and up to approximately 65 MMscf per day being flared.

During a well unload and test, when the gas volume and the rate of emission is typically significantly lower than which would be burnt at flare, it is necessary to bleed off formation fluids (gas) direct to atmosphere such that gas is cold vented rather than flared.

6.5.2.2 Support Operations

Atmospheric emissions will be generated from MODU, vessel and helicopter operations via the use of fuel for onboard generators and engine operation to generate power. Fuel will be marine diesel oil (MDO) or marine gas oil (MGO). Pollutants such as PM, CO, NO_x, SO2 and NMVOCs are released to the atmosphere during the combustion of these fuels.

Helicopters will be used during well construction and installation activities, primarily for crew change and medevac, and occasionally equipment and material transfers. Helicopter flights are expected to occur of 8 times a week during drilling and completions, installation, IMR, well intervention, and decommissioning, dependent on the progress of the drilling program, subsea installation, and logistical constraints. Helicopters use aviation fuel.

6.5.3 Impact Analysis and Evaluation

Atmospheric emissions have the potential to result in the following impact:

- change in air quality.

Atmospheric emissions generated during the Project are unlikely to impact on human health or amenity due to the remote location and rapid dispersion and dilution offshore. NO_2 is the main emission that poses a threat to receptor health. NO_2 emissions from routine MODU power generation for an offshore project was previously modelled by BP (BP, 2013). The model demonstrated that atmospheric emissions generated by MODU operations may increase ambient NO_2 concentrations by 1 $\mu g/m^3$ (0.001 ppm) within 10 km of the source. The predicted change in NO_2 concentrations within 10 km, is well below the WHO air quality guideline for NO_2 of 40 $\mu g/m^3$ annual mean. Given the change in NO_2 concentrations is limited to offshore environment and does not overlap coastal settlements, adverse impact on local or regional biodiversity, ecological integrity, social amenity, or human health is not predicted.

The Project Area overlaps foraging BIAs for albatross, petrel, and shearwater species. No habitat critical to the survival of birds occur within the Project Area. As it is unlikely that seabirds would remain close to the emission source for an extended period interaction between change in air quality and marine fauna are not predicted. Rapid dispersion and dilution will also ensure that seabirds and other fauna are not chronically exposed to concentrated plumes from vessel exhaust points. The impact associated with atmospheric emissions is therefore limited to change in air quality.

6.5.3.1 Air Quality

Intermittent atmospheric emissions during the Project from fuel combustion, flaring or venting will temporarily change the air quality within the immediate surrounds of the discharge location.

Air quality within the project area is expected to be high and typical to that of an unpolluted offshore environment. Emissions generated during activities will be similar to that generated during other activities undertaken in the region and result in a localised decrease in air quality at the point of release. The open ocean environment and prevailing winds of the Otway means that atmospheric emissions will rapidly disperse to background levels close to the emission source.. Concentrations of air emissions are not expected to be above the National Environment Protection (Ambient Air Quality) Measure levels at any point throughout the Project.

Atmospheric emissions from flaring and venting are not predicted to result in a substantial change to air quality within the local air shed given the dry gas is expected to readily combust via the flare package high-efficiency burner head or rapidly disperse in the wind.

Given the limited duration and intermittent nature of support operations, flaring and venting activities during the Project, and the rapid dispersion of atmospheric emissions close to the source, no substantial or cumulative impacts to air quality within the local airshed are predicted.

Temporary and localised changes to air quality from atmospheric emissions have been evaluated as a Minor (1) consequence.

6.5.4 Impact Evaluation Summary

The impact evaluation for atmospheric emissions is summarised in Table 6-33.

Table 6-33: Impact Evaluation Summary for Atmospheric Emissions

Summary	
Summary of impact	Atmospheric emissions generated during fuel combustion, flaring or venting operations in the Project Area are expected to temporarily change the air quality within the immediate surrounds of the discharge location. The Minor (I) consequences to air quality from atmospheric emissions is considered acceptable, given the controls are in place to ensure potential impacts are better than the defined acceptable level 1.
Extent and duration of impact	Localised - the open ocean environment and prevailing winds of the Otway Basin will rapidly disperse atmospheric emissions generated by the Project. Rapid dispersion allows for air quality to return to background levels within the immediate surrounds of the discharge location. Temporary - the intermittent short-term nature of support operations, flaring and venting activities prevents on-going generation of atmospheric emissions, as a result change to air quality will be infrequent and temporary.

Level of certainty	Impacts from atmospheric emissions are well understood and there is nothing new or unusual. Good practice is defined through the implementation of the following controls which ensures uncertainty is minimal: • Beach is committed to MARPOL Annex VI prevention of air pollution from ships • Beach is committed to measure, monitor or estimate facility fuel and flare emissions (in accordance with the National Pollutant Inventory) Beach has long-term experience in the area on the application of good industry practice to ensure impacts associated with atmospheric emissions are acceptable.
Is the impact considered lower-order or higher-order?	Potential impacts from atmospheric emissions have been evaluated to result in Minor (I) consequences. Minor consequences are considered lower-order impacts that is acceptable with the application of good industry practice.
Impact consequence	
Minor	

6.5.5 Demonstration of Acceptability

Table 6-34 demonstrates how and why predicted environmental impacts from atmospheric emissions meet the defined acceptable levels (Table 5-4).

Table 6-34: Demonstration of Acceptability – Atmospheric Emissions

Demonstration of Acceptability		
Impact and risk comparison with relevant defined acceptable levels	Potential localised impacts from atmospheric emissions in the Project Area is expected to result in minor consequences to air quality. The acceptable level relevant to atmospheric emissions is acceptable level 8 (as detailed in Table 5-4). A Minor (1) impact consequence level was assigned for this aspect based on the impact analysis and evaluation. Minor (1) consequences from atmospheric emissions: • will ensure temporary change in air quality from atmospheric pollutants emitted during Project activities (as defined in the OPP) will comply with MARPOL Annex VI (Prevention of Air Pollution from Ships) enacted in the *Navigation Act 2012*. As a result, the predicted environmental impact for atmospheric emissions is below the defined acceptable level 9.	
Principles of ESD	Integration principle	Section 6.5.3 identifies and evaluates environmental impacts associated with atmospheric emissions. Conservation values and sensitivities, physical environment, ecological environment, socio-economic values, and First Nations values and sensitivities described in Section 4 were reviewed to determine potential interactions of the aspect against each of these receptors they may result in environmental impact. As a result, consideration of economic, environmental, social and equitable receptors was conducted as part of identifying the impacts and risks. For Phase 1: Initial Project Consultation (Section 10.2.3), Beach consulted with relevant stakeholders on the Project

Demonstration of Acceptability		
		and associated activities. No objections or claims were raised in Phase 1: Initial Project Consultation. For Phase 2: Project OPP Public Comment Period (Section 10.2.4), the public had the opportunity to provide further comment to this OPP during the period (18/3/2024 – 20/5/2024). Beach prepared the public comment report summarising all comments, an assessment of the merits of each comment, a statement of the response to each comment, and an outline of any changes made to the OPP as a result of the comment (Appendix P). The assessment of merit for comments against this aspect found the response provided in the public comment report to be sufficient to address the comments against this aspect. Therefore, no further updates were required for this aspect. Given the thorough assessment and responses outlined in the public comment report, the impact evaluation for this aspect remains acceptable as is, demonstrating that public comments have been adequately addressed. The potential environmental impact against this aspect was assessed as having a Minor (1) impact consequence level which is considered a lower-order environmental impact. Lower-order environmental impacts are considered 'broadly acceptable' and considered managed to an acceptable level by meeting relevant requirements (adopted controls as listed below).
	Precautionary principle	The potential environmental impacts against this aspect were assessed as having a Minor (1) impact consequence level which is considered a lower-order environmental impact and below the defined acceptable level 8. Lower-order environmental impacts cannot result in serious or irreversible environmental damage. There is high confidence in the potential environmental impacts and effectiveness of controls against this aspect. Beach has significant experience operating in the Otway and Bass based on their existing offshore developments and associated activities including the Beach Otway Drilling Campaign in 2021/2022.
	Intergenerational principle	The defined acceptable levels were developed to meet the principles of ESD (Section 5.8.5). Given predicted environmental impacts for atmospheric emissions is lower than the defined acceptable level 8; the health, diversity, or productivity of the environment for future generations is expected to be maintained.
	Biodiversity principle	Section 6.5.3 identifies and evaluates environmental impacts associated with atmospheric emissions. Air quality is a component of the Commonwealth Marine Area, which is a MNES. Given predicted environmental impacts from atmospheric emissions are lower than the defined acceptable level 8; there is no potential to affect biological diversity or ecological integrity.

	Demonstration of Acceptability	
	protection of human health and well-being.	Measure, monitor or estimate facility fuel and flare emissions (in accordance with the National Pollutant Inventory) to inform and optimise management practices and minimise environmental impact of emissions. **CM22 Emission Abatement Opportunities Register** Per the requirements of the OEMS Sustainability Standard, Beach will maintain a register of opportunities for emissions reduction across its asset portfolio to reduce emissions.

6.5.6 Environmental Performance

In accordance with NOPSEMA's OPP Decision Making Guideline (NOPSEMA 2024), the EPO for this aspect (Table 6-) has been developed to be relevant to identified environmental impacts and risks, consistent with the principles of ESD and equivalent to or better than the defined acceptable level of impact. Control measures listed in Table 6-34 provides detail on how each control measure will be implemented for the Project to ensure the acceptable levels and EPOs, defined in Table 6- are met.

Table 6-35: Environmental Performance Outcomes – Atmospheric Emissions

Defined Acceptable Level	Environmental Performance Outcomes	
Acceptable level 8: Temporary change in air quality from atmospheric pollutants emitted during Project activities (as defined in the OPP) will comply with MARPOL Annex VI (Prevention of Air Pollution from Ships) enacted in the *Navigation Act 2012*.	EPO13:	Manage atmospheric emissions from the combustion of fuel during vessel and MODU operations in accordance with MARPOL Annex VI (Prevention of Air Pollution from Ships) enacted in the *Navigation Act 2012*.
	EPO14:	Implement CM22 Emissions Abatement Opportunities Register to maintain a register of opportunities for emissions reduction across its asset portfolio to reduce emissions.

6.6 Emissions – Greenhouse Gases

6.6.1 Hazard Identification

Greenhouse gas (GHG) emissions are associated with global warming and climate change. GHGs include carbon dioxide (CO_2), methane (CH_4), nitrous oxide (N_2O), sulphur hexafluoride (SF_6) and specified types of hydrofluorocarbons and perfluorocarbons. GHGs trap heat in the Earth's atmosphere, leading to an increase in the planet's average temperature. This can lead to a variety of negative effects, including more extreme weather events, sea level rise, ocean acidification and changes in the distribution of plant and animal species. These changes can cause harm to human populations and ecosystems and could potentially have severe economic and social consequences.

6.6.2 Hazard Description

The activities listed in Table 6-36 may generate GHG emissions.

Table 6-36: Activities Undertaken During the Project which will Generate GHG Emissions

Stage	Activity
Drilling and completion	Well unload and production testing (flaring)
Production	Gas processing (fuel use, reservoir CO_2, fugitive emissions) Well intervention
Support Activities (all stages)	MODU operations, Vessel operations
Decommissioning	Plug and abandonment of wells

6.6.2.1 Drilling and Completions

Drilling will be carried out using a MODU. During well unload and production testing activities, the well is flowed to remove contaminants, including drilling or completions fluids and debris from the formation. These contaminants are flowed back via the OGPP to the onshore production separator, and the reservoir gas is flared. Unloading and production testing the well to the MODU for the Project is not intended, however, is provided for in this OPP as a contingency in the event it is required for technical and feasibility reasons. This may result in up to approximately 65MMscf of gas per day being flared for between one and two days per well.

During drilling fugitive emissions will result from releases from process vents, system upsets and accidents.

6.6.2.2 Production

During production, reservoir fluids will be extracted, transported via the OGPP to the OGP for processing. The OGP supplies gas to the domestic market in south-east Australia. GHG emissions will be produced during processing, transport and end use of sold products.

Well intervention and workovers may be required during Production. Flaring may be required as part of well intervention, similar to drilling. If well intervention is required, it will be infrequent, and if flaring is required, the estimated duration is one to two days per well. During well intervention, unloading and testing the well to the MODU is not intended however is provided for in this OPP as a contingency in the event it is required for technical and feasibility reasons. This may result in up to approximately 65MMscf of gas per day being flared for between one and two days per well. During well intervention, small volumes of gas may need to be transferred back to the OGP. The frequency of well intervention and workover activities depends on well performance, objective criticality, MODU/vessel availability and regulatory requirements with one well every 7 years being estimated based on historical interventions.

During production, fugitive emissions may occur from Project and existing infrastructure.

GHG emissions will also be generated from the processing of Project hydrocarbons, and from the transportation and use of sold products.

6.6.2.3 Support Activities

GHG emissions will be produced from combustion of fuel for power generation and propulsion on the MODU and support vessels during all phases.

6.6.2.4 Decommissioning

During well P&A, GHG emissions may occur due to unloading the well to the MODU is not intended however is provided for in this OPP as a contingency in the event it is required for technical and feasibility reasons. This may result in up to approximately 65 MMscf of gas per day being flared for between one and two days per well.

6.6.3 Impact Analysis and Evaluation

6.6.3.1 Greenhouse Gas Emissions Assessment

Beach commissioned Xodus to undertake a Greenhouse Gas emissions quantification assessment for the Project (Xodus 2025, Appendix K).

All emissions factors and energy content figures used to predict emissions were sourced from the NGER (Measurement) Determination 2008 and the API Compendium of GHG Emissions Methodologies (API 2009).

Emissions estimates are based on current Project definition and assumptions, current control measures, with inputs from the nature of the feed gas, and the efficiency and processes of the existing facilities.

Emissions are categorised based on the type of emissions:

- Scope 1 greenhouse gas emissions are emissions released into the atmosphere as a direct result of the activities at an organisation's facility. To align with the boundary of this OPP Scope 1 has been further categorised as:
  - Emitted within Project Boundary. Scope of OPP
  - Emitted outside Project Boundary (denoted Scope 1*)
- Scope 2 emissions for a facility represent the emissions that were released outside of an organisation's facility boundary to produce the electricity that is imported into the facility and used.
- Scope 3 emissions are indirect emissions other than scope 2 emissions. They occur outside of the boundary of an organisation as a result of the organisation's actions.

The activities and sources that emit GHG emissions over the lifecycle of the Project are outlined Table 6-36.

Table 6-37: Activities and Sources that Contribute to GHG Emissions from the Project

GHG Scope	Phase	Sub-Category	Source / Activities
1 (Emitted within Project Boundary. Scope of OPP)	Drilling and Completions; Production	Flaring & Venting	Well unload, well testing. Well intervention
	Production	Fugitive Emissions	Fugitive emissions from wells and flowlines
1* (Emitted outside Project Boundary)	Production	Reservoir CO_2	Reservoir CO_2 from Artisan, La Bella and future prospects emitted at OGP.
	Production	Onshore gas processing	Estimated fuel use apportioned to the processing of well fluids from Artisan, La Bella and prospects.
	Production	Onshore gas processing (fugitive emissions)	Fugitive emissions from OGP apportioned to throughput from Artisan, La Bella and prospects.
3	Support Activities (all stages)	Vessels	Variations of fleet including MODU and support vessels and helicopters required for: • Drilling • Installation • Inspection, Maintenance and Repair (IMR) • Well workover, • Decommissioning
	Production	Transmission and distribution losses	Transmission and distribution losses related to sales gas, assuming all sales gas are sold into the Victorian market.
		Sales Product	Use of sales gas, condensate from Artisan, La Bella and future prospects.
	Drilling and Completions, Installation, Decommissioning	Materials	Wells, flowlines, subsea equipment, cement, drilling mud.
	Production	Onshore gas processing	Estimated fuel use apportioned to the processing of well fluids from Artisan, La Bella and future prospects at OGP, including fugitive emissions.

GHG Scope	Phase	Sub-Category	Source / Activities

There are no scope 2 emissions from the Project.

The key inputs for the inventory assessment cover the full scope of the Project, including potential future development, as follows:

- Drilling of up to 8 wells between 2025 and 2026 (Note Artisan has been drilled, making a total of 9 wells in scope of the Project).
- Completions of up to 9 wells in 2027.
- Installation of associated infrastructure and flowlines for up to 9 wells in 2028.
- Production from existing wells and new wells from the Project to year 2045. The wells from the Project is forecasted to produce hydrocarbons from 2028 to 2038.
- Operations, and decommissioning of up to 9 wells and associated infrastructure from the Project by 2049.

The characteristics of the hydrocarbons, including CO_2 content, from the La Bella and Artisan fields are based on samples from these fields. Compositions from nearby fields targeting similar geological formations (Artisan and Thylacine) were used as conservative and representative proxies for the future prospects for this inventory assessment (refer to Section 3.6).

The input values used in the emissions estimates are considered “credible high” values, this accounts for a range of uncertainties including extended contingencies beyond a typical schedule of an activity. Up to 9 wells, with associated infrastructure, were considered in the emissions estimates, including at Artisan, La Bella, and future prospects.

The emissions created as a result of the Project at OGP have been determined. For fuel gas usage/processing feed gas and fugitive emissions, the emissions were calculated by determining the proportion of feed gas to be supplied by the Project to OGP compared to existing supply sources, on an annual basis. This annual proportion was used to apportion the fuel gas usage at OGP (based on historical data) required to process the Project feed gas, which was in turn used to calculate the predicted emissions. The calculated annual proportion of feed gas was also used to apportion the fugitive emissions at OGP (based on historical data) to the Project. Reservoir CO_2 venting at OGP was determined based on the flow rate of Project feed gas and the percentage of reservoir CO_2 in the Project feed gas.

Additional details related to the methodology and assumptions used in the emissions estimates are provided in Appendix K.

Table 6-38 provides a summary of the emissions inventory results. The emissions a forecasted based on scope 1 (Inside Project Boundary), and scope 1* (Outside Project Boundary) and scope 3, which comprises reservoir CO_2, embodied carbon, onshore processing at OGP and sale products.

Table 6-38: Emissions related to the Project Summary

Emissions t CO_2-e	**Scope 1 (Inside Project Boundary)**			**Scope 1* (Outside Project Boundary)**			**Scope 3**					**Total**
	Flaring	Venting	Fugitive (wells)	Processing	Fugitives (processing)	Reservoir CO2	Vessels	Helios	Embodied Carbon	Transmission and Distribution Losses	Product	
	103,505	1,507	14,560	751,162	20,235	318,645	393,296	1,287	124,322	366,203	10,954,872	13,049,595

Annualised emissions related to the Project are provided in Section 3.3 of Appendix K.

The emissions estimates do not account for ongoing emissions reduction that may be realised at OGP or by users of sold products.

The Project equates to a very small fraction of global emissions. In isolation, they will have no discernible impact on GHG concentrations in the atmosphere. Project gas is backfill for, and a replacement for, the depleting Thylacine and Geographe fields – the sales gas production is constrained by the existing facility, and no modifications to the gas plant is made. Thus, the emissions would be consistent on a per annum basis at the same sales gas production rate.

The United Nations International Panel on Climate Change in its Sixth Assessment Report forecast the remaining carbon budgets (from 1 January 2020) for a 50% likelihood to limit global warming to a specified range of temperature increase based on pre-industrialised levels (i.e. since 1850-1900) (IPCC, 2021). These carbon budgets and the percentage of carbon budget used due to the Project are shown in Table 6-39.

Table 6-39: Comparison of emissions related to the Project to the Global Carbon Budget

Global surface temperature change	**Estimated carbon budgets (50th percentile)**	**Percentage of Global Carbon Budget used due to the Project** **(Scope 1 (Inside Project Boundary), scope 1* (Outside Project Boundary) and scope 3)**
1.5°C	500 $GtCO_2$	0.0025%
2.0°C	1350 $GtCO_2$	0.0009%

In 2022, Australia revised its National Determined Contribution (NDC) under the Paris Agreement to reduce GHG emissions to 43% below 2005 levels by 2030 and reaffirmed the net zero emissions by 2050 target. These targets are legislated under the Commonwealth *Climate Change Act 2022*.

The Commonwealth Government has modelled a range of annual carbon reduction scenarios. The scenario modelled that is most relevant to this assessment is the ‘with additional measures’, which includes policies and measures in place at the time of publication. The ‘with additional measures’ scenario includes the 82% renewable energy target in Australia’s electricity grid by 2030 and further measures under the National Electric Vehicle Strategy (DCCEEW 2024r). Noting that the Safeguard Mechanism imposes a binding requirement on large emitters to net emissions reduction and net zero by 2050, consistent with Australia’s NDC under the Paris Agreement) [**PC218**].

An Australian carbon budget over the period of the Project (2025 to 2049) was calculated by:

- Using the DCCEEW Emissions Projections 2024 under the ‘with additional measures’ scenario to determine the Australian annual emissions (DCCEEW 2024r). Summing these annual projected emissions for the years where the Project activities and the DCCEEW forecast overlap (2025 to 2040). This provides a carbon budget for this period, and:

- for the period of 2041 to 2049, assuming a linear decline from the 2035 budget to zero emissions by 2050. The annual emissions budgets were summed to create an annual budget for this period.
- Both of these carbon budgets are summed together.

This creates an Australian carbon budget of 6729 Mt CO_2-e. The total scope 1 (Inside Project Boundary), scope 1* (Outside Project Boundary) and scope 3 GHG emissions from the Project are estimated to be approximately 0.19% of the Australian carbon budget [**PC218, PC326**].

6.6.3.2 Potential Impact

GHG emissions generated during the Project can contribute to the overall concentration of GHG emissions in the Earth's atmosphere. This consequence evaluation considers the contribution of emissions attributed to the Project (i.e. scope 1 [Inside Project Boundary], scope 1* [Outside Project Boundary] and scope 3) to global emissions and the potential impacts of climate change on sensitive receptors, including MNES within Australian jurisdictions.

It is important to acknowledge that climate change impacts cannot be directly attributed to any one activity, as they are the result of global GHG emissions, minus global GHG sinks, that have accumulated in the atmosphere since the industrial revolution began. Therefore, there is no direct link between GHG emissions from the Project and climate change impacts to specific ecological receptors.

Changes to production capacity, reservoir composition or process design are managed under Beach's Management of Change and Project Management Systems (depending on the complexity), both of which require an assessment of the change in safety, environment and financial risk profile brought about by the proposed change, and if material, each require revisions to the relevant EP, Safety Case and/or WOMP as a necessary step to achieve completion.

1. Climate Systems

The Intergovernmental Panel on Climate Change (IPCC) Sixth Assessment Report (AR6) Working Group I was released in August 2021. The IPCC states with high confidence that many extreme heat events and global surface temperature rise would not have occurred without human influence and could be irreversible for several decades to millennia (IPCC 2021).

This is reiterated in the AR6 Synthesis Report released in March 2023, "Human activities, principally through emissions of greenhouse gases, have unequivocally caused global warming, with global surface temperature reaching 1.1°C above 1850-1900 in 2011-2020. Global greenhouse gas emissions have continued to increase over 2010-2019, with unequal historical and ongoing contributions arising from unsustainable energy use, land use and land-use change, lifestyles and patterns of consumption and production across regions, between and within countries, and between individuals (high confidence). Human-caused climate change is already affecting many weather and climate extremes in every region across the globe" (IPCC 2023).

According the AR6 Synthesis Report, heat extremes (including heatwaves) have become more frequent and more intense across most land regions since the 1950s while cold extremes have become less frequent and less severe. Marine heatwaves have approximately doubled in frequency since the 1980s. The frequency and intensity of heavy precipitation events have increased since the 1950s over most land areas for which observational data are sufficient for trend analysis. It is likely that the global proportion of major (Category 3–5) tropical cyclone occurrence has increased over the last four decades (IPCC 2023).

The State of the Climate 2024 (BoM and CSIRO 2024) reported that:

- Australia's climate has warmed by an average of 1.51 ± 0.23 °C since national records began in 1910.
- Sea surface temperatures have increased by an average of 1.08 °C since 1900.

Considering scope 1 (Inside Project Boundary), scope 1* (Outside Project Boundary) and scope 3 from the Project, the contribution to national and global carbon budgets over the duration of the Project will be:

- 0.19% of the Australian carbon budget
- 0.0025% of the global carbon budget under a modelled 1.5°C temperature increase scenario
- 0.0009% of the global carbon budget under a modelled 2°C temperature increase scenario.

2. Ecosystems

Ecosystems that are particularly susceptible to adverse effects of climate change include alpine habitats, coral reefs, wetlands and coastal ecosystems, polar communities, tropical forests, temperate forests and arid and semi-arid environments (DoEE 2019). In Australia, this includes coral reefs, alpine regions, rainforests, arid and semi-arid environments, mangroves, grasslands, temperate forests and sclerophyll forests. Future climate change (increased temperature and decreased, but more variable, rainfall) has the potential to have a range of impacts on ecological factors and threaten biodiversity in the Australian Mediterranean ecosystem (CSIRO 2017a).

Redistribution and reorganisation of natural systems, driven by climate-change, is a major threat to biodiversity (Chapman et al. 2020). A report by Australia's Biodiversity and Climate Change Advisory Group summarises the potential impacts of climate change to marine and terrestrial species, habitats, and ecosystems across Australia (Steffen et al. 2009). The impacts to taxa are outlined in Table 6-40 and the impacts to ecosystems in Table 6-41.

Extensive modelling and monitoring studies over the last twenty years provide considerable evidence that global climate change is already affecting and will continue to affect species (Hoegh-Guldberg et al. 2018) however, these impacts are likely to be highly species-dependent and spatially variable. The most frequently observed and cited ecological responses to climate-change include species distributions shifting towards the poles, upwards in elevation and shifts in phenology (earlier and later autumn life history events) (Dunlop et al. 2012). Climate change may not only change species distribution patterns but also life-history traits such as migration patterns, reproductive seasonality, and sex-ratios.

Impacts of climate change such as altering temperature, rainfall patterns and fire regimes, are likely to lead to changes in vegetation structure across terrestrial ecosystems within Australia (Table 6-41, Dunlop et al. 2012). Increases in fire regimes will impact Australian ecosystems altering composition structure, habitat heterogeneity and ecosystem processes. It has been found that is already been an increase in extreme fire weather in Australia, with a longer fire season, across large parts of the country since the 1950s (BoM and CSIRO 2024). Changes in climate variability, as well as averages, could also be important drivers of altered species interactions, both native and invasive species (Dunlop et al. 2012). Climate change could result in significant ecosystem shifts, as well as alterations to species ranges and abundances within those ecosystems (Hoegh-Guldberg et al. 2018).

The IPCC Special Report describes impacts of warming above pre-industrial levels to key receptor groups including terrestrial ecosystems, mangroves, warm-water corals, unique and threatened systems, and arctic regions (Hoegh-Guldberg et. al. 2018). These receptor groups show varying sensitivity to warming conditions, with a range of responses shown at 1°C warming; from corals suffering moderate impacts, to mangroves not showing any impacts that are detectable and attributable to climate change (Hoegh-Guldberg et al. 2018). As warming reaches 1.5°C, which has already experienced in Australia (BoM and CSIRO 2024), all receptor groups show impacts attributable to climate change with severity ranging from moderate impacts that are detectable and attributable to climate change (mangroves), to impacts that are severe and widespread (warm-water corals) (Hoegh-Guldberg et al. 2018). At the point where global temperature rise, due to climate change, reaches 2°C, increasing numbers of receptor groups suffer impacts which are high to very high, and likely to be irreversible (terrestrial ecosystems, warm-water corals, unique and threatened systems, and arctic regions) (Hoegh-Guldberg et al. 2018).

The State of the Environment (SoE) report is produced every five years by the Australian Government as a comprehensive review on the state of the Australian environment. The most recent report was released in July 2022. The SoE concluded that climate change and extreme weather events was impacting the Australian environment and especially impacting various taxa (DCCEEW 2021). In many cases, the impacts of climate change on biodiversity are exacerbated by other pressures such as land clearing and invasive species, but in some cases impacts can be unequivocally attributed to climate change. A summary of the SoE impacts from climate change is provided in Table 6-43.

3. Terrestrial Ecosystems

All terrestrial ecosystems are likely to be impacted by a changing climate (Table 6-41, Steffen et al 2009, Hughes 2011, Dunlop et al. 2012, Hoegh-Guldberg et. al. 2018). The predicted impact of climate change on these ecosystems is highly variable, both between ecosystems and within individual ecosystems (Dunlop et al. 2012). Below is a summary of potential climate change impacts to two key terrestrial ecosystems – tropical rainforests and alpine/montane areas, other terrestrial ecosystems are summarised in Table 6-41.

a. Tropical Rainforests

Projections of future climate changes in the wet tropics of Australia under different scenarios are outlined by McInnes (2015). It is likely that temperatures in the wet tropics will become hotter and potentially fires and cyclones will be more intense. Consequently, there is an increased probability of fires penetrating into rainforest vegetation resulting in a shift from fire-sensitive vegetation to communities dominated by fire-tolerant species; and changing rainforest disturbance regime as cyclones become more intense) (Hughes 2011, Steffen et al. 2009). Changes in the timing of seasons (e.g., extended summer) could cause change in the seasonal response of plants, and alterations to species ranges and abundances (Hoegh-Guldberg et al. 2018).

b. Alpine/Montane Areas

Alpine systems are generally considered to be among the most vulnerable to future climate change (Hughes 2003). The extent of true alpine habitat in Australia is very small (0.15% of the Australian land surface) with limited high-altitude refuge (Hughes 2003). Australian alpine regions are home to a variety of alpine vertebrates who rely on snow cover for their survival. Maximum snow depth, snow cover and number of snow days have all decreased in Australian alpine regions since the late 1950s (BoM and CSIRO 2024). There is evidence of a reduction in populations of dusky antechinus, broad-toothed rats, and the mountain pygmy possum. The first two species are active under the snow throughout winter and are therefore subject to increased predation by foxes when snow is reduced (Hughes 2003). The pygmy possum depends upon snow cover for stable, low temperatures during hibernation (Hughes 2003).

4. Marine Ecosystems

Average sea surface temperature in the Australian region has warmed by 1.08°C since 1900, with nine of the 10 warmest years on record occurring since 2010 (BoM and CSIRO 2024). A warming ocean affects the global ocean and atmospheric circulation, the cryosphere, global and regional sea levels, and causes losses in dissolved oxygen, impacts on marine ecosystems (BoM and CSIRO 2024), including changes to species abundance, community structure and increased frequency and intensity of thermally induced coral bleaching events (CSIRO 2017a).

Oceanic warming has also served to alter ocean currents around Australia. In response to both ocean warming and stratospheric ozone depletion, the East Australian Current has increased in strength by about 20% between 1978 and 2005 (Cai and Cowan 2006) and extended further south, creating an area of more rapid warming in the Tasman Sea, where the warming rate is now twice the global average (BoM and CSIRO 2024). Sea-surface temperatures are projected to continue to increase, with estimates of warming in the Southern Tasman Sea of between 0.6 to 0.9°C and between 0.3 to 0.6°C elsewhere along the Australian coast by 2030 (Church et al. 2006).

Global mean sea level increased by 0.22 m since 1900 (BoM and CSIRO 2024). Global mean sea level rise is accelerating. Tide gauge and satellite altimetry observations show that the rate of global mean sea level rise increased from 1.5 cm (± 0.2 cm) per decade from 1901 to 2000, and is now approaching 4 cm (± 0.4 cm) per decade from 1993 to 2023. The dominant cause of global mean sea level rise since 1970 is anthropogenic climate change (BoM and CSIRO 2024).

Global mean sea level is predicted to rise between 0.308 m and 0.448 m by 2050, and between 0.438 m and 1.168 m by 2100, relative to 1900 levels (IPCC 2023). This global mean sea level rise is primarily caused by thermal expansion and mass loss from glaciers and ice sheets, with minor contributions from changes in land-water storage. Global mean sea level will continue to increase for centuries to millennia due to continuing deep ocean warming and ice sheet melt, and sea levels will remain elevated for thousands of years, at rates dependent on future emissions (IPCC 2023). This will lead to some coastal inundation affecting mangroves, salt marshes and coastal freshwater wetlands. Furthermore, as CO_2 is gradually absorbed by oceans and fresh water, the water becomes more acidic, which increases the solubility of calcium carbonate, the principal component of the skeletal material in aquatic organisms (Steffen et al. 2009).

Below is a summary of potential climate change impacts to two key marine ecosystems - mangroves and coral reefs, other marine ecosystems are summarised in Table 6-41.

a. Mangroves

Mangrove ecosystems in Australia will face higher temperatures, increased evaporation rates and warmer oceans (McInnes 2015) as well as an associated sea-level rise (Hoegh-Guldberg et al. 2018). Modelling indicates an increased likelihood of future severe and extended droughts across parts of Northern Australia (Dai 2013). Consequently, mangrove ecosystems may increase their southern range as a result of warmer temperatures. However, higher temperatures and evaporation rates, and extended droughts could lead to die-offs in northern Australia and a change in mangrove distribution and abundance (Duke et al. 2017). Mangrove systems should cope with rising sea-level by accumulating more peat or mud which will give them the opportunity to adjust to a rising sea level (Field 1995).

b. Coral Reefs

Climate change has emerged as a threat to coral reefs, with temperatures of just 1°C above the long-term summer maximum for an area over 4–6 weeks being enough to cause mass coral bleaching and mortality (Baker et al. 2008, Hoegh-Guldberg 1999, Hughes et al. 2017, Spalding and Brown 2015). Coral mortality or die off following coral bleaching events can stretch across thousands of square kilometres of ocean (Gilmour et al. 2016, Hoegh-Guldberg 1999, Hughes et al. 2017). The impacts associated with a warming ocean, coupled with increasing acidification (which is occurring faster than in recent decades [BoM and CSIRO 2024], are expected to undermine the ability of tropical coral reefs to provide habitat for fish and invertebrates, which together provide a range of ecosystem services (e.g., food, livelihoods, coastal protection) (Hoegh-Guldberg et al. 2018). Coral reefs are projected to decline by 70–90% as a result of 1.5°C of global warming (IPCC 2023).

Table 6-40: Potential Climate Change Impacts to Taxa

Taxa	Potential Vulnerability
Mammals	Narrow-ranged endemics susceptible to rapid climate change in-situ; changes in competition between grazing macropods in tropical savannas mediated by changes in fire regimes and water availability; herbivores affected by decreasing nutritional quality of foliage as a result of CO_2 fertilisation.
Birds	Changes in phenology of migration and egg-laying; increased competition of resident species; breeding of waterbirds susceptible to reduction; top predators vulnerable to changes in food supply; rising sea levels affecting birds that nest on sandy and muddy shores, saltmarshes, intertidal zones, coastal wetlands, and low-lying islands; saltwater intrusion into freshwater wetlands affecting breeding habitat.
Reptiles	Warming temperatures may alter sex ratios of species with environmental sex determination to cope with warming in-situ.
Amphibians	Frogs may be the most at-risk terrestrial taxa. Amphibians may experience altered interactions between; pathogens, predators, and fires.
Fish	Freshwater species vulnerable to reduction in water flows and water quality; limited capacity for freshwater species to migrate to new waterways; all species susceptible to flow-on effects of warming on the phytoplankton base of food webs. Significant decreases in streamflow are concentrated in southern Australia, while the increases are almost all in the north (BoM and CSIRO 2024).
Invertebrates	Expected to be more responsive than vertebrates due to short generation times, high reproduction rates and sensitivity to climatic variables.

Taxa	Potential Vulnerability
	No invertebrate species including limpets are listed as threatened under the EPBC Act or under the Victorian Flora and Fauna Guarantee Act 1988 Threatened List [**PC205**].
Plants	Climate change may impact various functional dynamics of plants due to changes in; increasing CO_2, fires, plant phenology and specific environmental characteristics.

Table 6-41: Potential Climate Change Impacts to Ecosystems

Key Component of Environmental Change	Projected Impacts on Ecosystems
Coral reef	
CO_2 increases leading to increased ocean acidity	Reduction in ability of calcifying organisms, such as corals, to build and maintain skeletons.
Sea surface temperature increases, leading to coral bleaching	If frequency of bleaching events exceeds recovery time, reefs will be maintained in an early successional state or be replaced by communities dominated by microalgae.
Oceanic systems (including planktonic systems, fisheries, sea mounts and offshore islands)	
Ocean warming	Many marine organisms are highly sensitive to small changes in average temperature (1-2 degrees), leading to effects on growth rates, survival, dispersal, reproduction, and susceptibility to disease.
Changed circulation patterns, including increase in temperature stratification and decrease in mixing depth and strengthening of the East Australian Current	Distribution and productivity of marine ecosystems is heavily influenced by the timing and location of ocean currents; currents transfer the reproductive phase of many organisms. Climate change may suppress upwelling in some areas and increase it in others, leading to shifts in location and extent of productivity zones.
Changes in ocean chemistry	Increasing CO_2 in the atmosphere is leading to increased ocean acidity and a concomitant decrease in the availability of carbonate ions.
Estuaries and coastal fringe (including benthic, mangrove, saltmarsh, rocky shore, and seagrass communities)	
Sea level rise	Landward movement of some species as inundation provides suitable habitat, changes to upstream freshwater habitats will have flow-on effects to species.
Increase in water temperature	Impacts on phytoplankton production will affect secondary production in benthic communities.
Savannas and grasslands	
Elevated CO_2	Shifts in competitive relationships between woody and grass species due to differential responses.
Increased rainfall in north and north-west regions	Increased plant growth will lead to higher fuel loads, in turn leading to fires that are more intense, frequent and occur over large areas.
Tropical rainforests	
Warming and changes in rainfall patterns	Increased probability of fires penetrating into rainforest vegetation resulting in shift from fire-sensitive vegetation to communities dominated by fire-tolerant species.
Changes in length of dry seasons	Altered patterns of flowering, fruiting and leaf flush will affect resources for animals.

Key Component of Environmental Change	Projected Impacts on Ecosystems
Rising atmospheric CO_2	Differential response of different growth forms to enhanced CO_2 may alter structure vegetation
Temperate forests	
Potential increases in frequency and intensity of fires	Changes in structure and species composition of communities with obligate seeders may be disadvantaged compared with vegetative resprouters.
Warming and changes in rainfall patterns	Potential increases in productivity in areas where rainfall is not limiting; reduced forest cover associated with soil drying projected for some Australian forests.
Inland waterways and wetlands	
Reductions in precipitation, increased frequency and intensity of drought	Reduced river flows and changes in seasonality of flows.
Changes in water quality, including changes in nutrient flows, sediment, oxygen and CO_2 concentration	May affect eutrophication levels, incidence of blue-green algal outbreaks.
Sea level rise	Saltwater intrusion into low-lying floodplains, freshwater swamps and groundwater; replacement of existing riparian vegetation by mangroves.
Arid and semi-arid regions	
Increasing CO_2 coupled with drying in some regions	Interaction between CO_2 and water supply critical, as 90% of the variance in primary production can be accounted for by annual precipitation.
Shifts in seasonality or intensity of rainfall events	Any enhanced runoff redistribution will intensify vegetation patterning and erosion cell mosaic structure in degraded areas. Changes in rainfall variability and amount will also impacts on fire frequency. Dryland salinity could be affected by changes in the timing and intensity of rainfall.
Warming and drying, leading to increased frequency and intensity of fires	Reduction in patches of fire-sensitive mulga in spinifex grasslands potentially leading to landscape-wide dominance of spinifex.
Alpine/Montane areas	
Reduction in snow cover depth and duration	Potential loss of species dependent on adequate snow cover for hibernation and protection from predators; increased establishment of plant species at higher elevations as snowpack is reduced.

Table 6-42: Potential Climate Change Impacts on BIAs

Receptor	Biologically Important Behaviour
Mammals	Terrestrial mammals are subject to ongoing population declines due to climate change and changes within habitats.
Birds	There is strong evidence of population declines in threatened bird species, waterbirds and migratory birds. Various extensive and persistent impacts contribute to declines, including climate change (particularly drought) and extreme events, habitat degradation, and invasive predators.

Reptiles	Reptile species in all areas of Australia have an increasing risk of extinction. Risk of extinction was recognised as primarily related to ongoing pressure from invasive predators, but compounded by pressure from habitat modification, climate change (particularly drought) and disease.
	Half of Australian freshwater turtle species are in drastic population decline due to climate change.
Amphibians	Droughts and fires are increasing pressures within habitats that impact amphibian species.
	The number of known threatened amphibian species, including those that are Critically Endangered in Australia, is increasing. Drought and fire are recognised as increasing pressures contributing to this decline.
Fish	Freshwater fish throughout Australia have more than a 50% risk of extinction in the next 20 years due to climate change and changes within freshwater habitats.
Invertebrates	Most threatened invertebrates are suffering from largescale habitat degradation and loss of biodiversity. Changes in regional temperature, humidity and rainfall impact their distribution, development and reproduction.
Plants	Habitat destruction is the leading cause of vulnerability within plant species. However, changes in temperature, rainfall and fire regimes are contributing threats to plant species.
	Alpine ecosystems and biodiversity in Australia are particularly vulnerable to climate change that affects snow depth and the spatial and temporal extent of snow, which have all declined since the late 1950s.

5. Socio-economic Values

Changes to climate can result in impact to social receptors that have values which include the ecological receptors previously discussed. This includes KEFs and AMPs.

Climate change also impacts on the functions, interests or activities of other users which rely on ecological values, including commercial and recreational fisheries and tourism. A temperature change of between 0.9°C to 2.0°C is forecast to reduce fisheries yield as the maximum catch potential around Australia by between 3% and 10% (IPCC 2023).

Rising sea levels pose a significant threat to coastal communities by amplifying the risks of coastal inundation, storm surge, erosion and saltwater intrusion into groundwater systems. Coastal communities in Australia are already experiencing some of these changes (BoM and CSIRO 2024).

6. Cultural Values and Sensitivities

Impacts to cultural heritage sites and places of spiritual importance in coastal locations may also be experienced due to rising sea levels. Global mean sea level is predicted to rise between 0.308 m and 0.448 m by 2050, and between 0.438 m and 1.168 m by 2100, relative to 1900 levels (IPCC 2023).

6.6.3.3 National and International Agreements and Frameworks Relevant to GHG Management

This section describes the relevant key national and international agreements and frameworks relevant to GHG management, including how these environmental requirements are relevant to the activity.

1. Paris Agreement **[PC211]**

The Paris Agreement is a global pact to respond to the challenge of climate change, signed by 196 countries. It is a landmark agreement that aims to strengthen the global response to the threat of climate change. Alignment with the intent of the Paris Agreement is considered a yardstick measure for climate ambition.

Article 2 of the Paris Agreement states that the global response to the threat of climate change, in the context of sustainable development and efforts to eradicate poverty, includes "Holding the increase in the global average temperature to well below 2°C above pre-industrial levels and pursuing efforts to limit the temperature increase to 1.5°C above pre-industrial levels, recognizing that this would significantly reduce the risks and impacts of climate change".

Australia's commitment to the Paris Agreement is reflected in the *Climate Change Act 2022*, which among other functions, sets out Australia's greenhouse gas emission reduction targets, which "contribute to the global goals of:

- (i) holding the increase in the global average temperature to well below 2°C above pre-industrial levels; and
- (ii) pursuing efforts to limit the temperature increase to 1.5°C above pre-industrial levels;"

This is consistent with the Paris Agreement.

Beach reports our Australian scope 1 and scope 2 emissions under the *National Greenhouse and Energy Reporting Act 2007* (NGER). This includes the *National Greenhouse and Energy Reporting (Safeguard Mechanism) Rule 2015* made under section 22XS of the Act. The Safeguard Mechanism is an instrument used by the Australian Government to ensure that operators of large facilities manage their emissions in line with Government commitments to the global community, as described in Australia's Nationally Determined Contribution (NDC), and in alignment with the *Climate Change Act 2022*.

As part of the commitment to the Paris Agreement, Australia has an emissions budget for the 2021-2030 decade of 4353 $MtCO_2e$. The emissions related to the Project (including all scopes) during this period is ~ 0.1% of this carbon budget.

Safeguard Mechanism covered facilities ("safeguard facilities") are responsible for ~28% of Australia's greenhouse gas emissions; they have legislated emissions caps to ensure that Australia meets its emissions targets and stays within the 2030 emissions budget.

Three different emissions caps are set out in the Safeguard Mechanism rules and described in the *Safeguard Mechanism (Crediting) Amendment Act 2023*.

- Net emissions cap, drawn from the proportionate coverage of the safeguard facilities of ~28% of Australian emissions, sets a carbon budget of 1233 $MtCO_{2}$-e between 2020 and 2030.
- Net emissions from safeguard facilities must be no more than 100 $MtCO_{2}$-e in 2030, and net zero in 2050, reflecting the Australian government emissions targets.
- A limit on gross emissions, so that from 2025 5-year rolling average emissions must go down.

After the Australian Government sets the Nationally Determined Contribution (NDC) targets for 2035 and beyond, adjustments to the emissions budget will likely flow through the Safeguard Mechanism.

2. National Greenhouse and Energy Reporting (Safeguard Mechanism) Rule 2015

One of the key statutory instruments for regulating Australia's GHG emissions in line with Australia's NDCs under the Paris Agreement, is the National Greenhouse and Energy Reporting (Safeguard Mechanism) Rule 2015 (Cth) (the Safeguard Mechanism) made under the NGERS Act and administered by the Clean Energy Regulator. The Safeguard Mechanism was developed to ensure that Australia's largest greenhouse gas emitters keep their net emissions below an emissions limit (a baseline). The Safeguard Mechanism currently applies to facilities that emit more than 0.1 $MtCO_2$-e per annum and requires annual emissions to be reported against a designated emissions 'baseline'.

Key elements of the mechanism include:

- Safeguard facilities must meet the reporting and record-keeping requirements of the NGER Act, including the Clean Energy Regulator's requirements for audits prior to baseline setting or to check compliance management.
- If a safeguard facility is likely to exceed its baseline, the responsible emitter must act, including by purchasing and/or surrendering Australian carbon credit units, to offset excess emissions.
- Penalties for non-compliance.

The Safeguard Mechanism is the Government's primary legislation for achieving industrial emissions reduction in line with Australia's Nationally Determined Contribution (NDC). The OGP is an existing covered facility regulated under the Safeguard Mechanism and will receive a production adjusted, emissions intensity baseline that will decline by 4.9% per annum, in line with the 2030 emissions reduction target. OGP currently receives unprocessed natural gas from three pipelines: one offshore from the combined Thylacine and Geographe facilities and two onshore pipelines from the Halladale, Black Watch & Speculant (HBWS) and Enterprise well sites. The Thylacine, Geographe, HBWS and Enterprise sites are individual NGER facilities which do not meet the legislated safeguard threshold of 100,000 tonnes per annum of CO_2-e to be covered by the Safeguard Mechanism. However, scope 1 emissions produced within the OGP facility that are created in support of the Thylacine and Geographe, HBWS and Enterprise facilities such as venting of reservoir CO_2 are reported under the OGP facility.

Scope 1 emissions associated with gas production from the Otway Offshore Project would be reported at the individual facility (NGER) level and are forecast to be below the Safeguard Mechanism threshold. However, emissions associated with processing the gas from the Otway Offshore Project (including reservoir CO_2) would be reported as part of the OGP facility. If the Otway Offshore Project was to increase the emissions intensity of the OGP, the facility baseline would ensure emissions are reduced in accordance with Australia's emissions targets and budgets.

Beach Energy have engaged with the Clean Energy Regulator to discuss the Safeguard Mechanism boundary. Beach will continue these discussions with the Clean Energy Regulator as the Project progresses.

Gas and condensate from OGP is supplied into the domestic Australian market. The scope 3 emissions associated with the transmission/transport and end use of the gas and condensation will occur within Australian Commonwealth jurisdiction. Therefore the scope 3 emissions will be managed in accordance with Australia's regulatory regime including NGER and the Safeguard Mechanism, which is designed "to deliver emissions reductions consistent with Australia's [NDC] under the Paris Agreement" (DCCEEW, 2023i) and the *Climate Change Act 2022*.

3. National Greenhouse and Energy Reporting Scheme

The NGER Scheme is a single national framework for reporting company information about GHG emissions, energy production, and energy consumption. Key NGER Scheme legislation includes the *National Greenhouse and Energy Reporting Act 2007*, the National Greenhouse and Energy Reporting Regulations 2008, and the National Greenhouse and Energy Reporting (Measurement) Determination 2008.

The NGER Act provides a single, national framework for the reporting and distribution of information related to GHG emissions, energy production, and energy consumption. Beach reports scope 1 (Inside Project Boundary), scope 1* (Outside Project Boundary) emissions associated with the Otway Offshore Operations and Otway Gas Plant under the NGER Act.

4. Intergovernmental Panel on Climate Change (IPCC) 6th Report

The IPCC released its sixth assessment consisting of four reports,

- Climate Change 2021: The Physical Science Basis, released in August 2021 (IPCC 2021)
- Climate Change 2022: Impacts, Adaptation and Vulnerability, released in February 2022 (IPCC 2022a)
- Climate Change 2022: Mitigation of Climate Change, released in April 2022 (IPCC 2022b)
- Climate Change 2023: Synthesis Report, released in March 2023 (IPCC 2023)

The four releases of the report relate climate change and anthropogenic influence as well as deduce the impact that climate change has had on ecosystems, biodiversity, humans, and cities, and inform the 2023 Global Stocktake under the United Nations Framework Convention on Climate Change. The Physical Science Basis IPCC Report, released in August 2021, was the first to unequivocally relate climate change to human influences and the use of hydrocarbon fuels. Surface temperatures have increased at a rapid rate since 1970 compared to any other 50-year period in the last 2,000 years. The rapid changes that have occurred since the industrial revolution are unprecedented, even with the research on ice boreholes and the subsequent calculations of historical CO_2 concentrations. The IPCC states with high confidence that in 2019, atmospheric CO_2 concentrations were higher than anytime in at least 2 million years, along with very high confidence that concentrations of CH_4 and N_2O far exceeding intensities from at least 800,000 years (IPCC 2021).

The sixth assessment report presents a number of scenarios to understand climate response to a range of GHG emissions levels. The best-case scenario, scenarios with very low and low GHG emissions and CO_2 emissions decreases to net zero around or after 2050 (IPCC 2021), aligns with Beach's aspiration to achieve net zero Scope 1 and Scope 2 GHG emissions by 2050 and its interim target to reduce Beach GHG emissions intensity.

The IPCC found that natural gas may remain part of energy systems through mid-century, both for electricity generation and use in industry and buildings, even if warming is limited to 2°C or lower (IPCC 2023b). The decline in natural gas use from 2020 to 2050 is forecast to be between 21–62% of 2020 levels (interquartile range) in scenarios limiting warming to 1.5°C (>50%) with no or limited overshoot. Natural gas use is forecast to decline by between 14% to 36% by 2050 from 2020 levels (interquartile range) in scenarios limiting warming to 2°C (>67%). Scenarios indicate that gas use in electricity will likely peak around 2035 and 2050 if warming is limited to 1.5°C (>50%) with limited or no overshoot or to 2°C (>67%) with action starting in 2020, respectively (IPCC 2023b). The development of the Project, which does not increase the rate of gas supply, is not inconsistent with these modelled scenarios.

5. International Energy Agency World Energy Outlook **[PC211]**

The International Energy Agency (IEA) World Energy Outlook considers three main scenarios which are possible pathways for the energy sector to 2050. They are not forecasts, but a tool to be used to inform robust strategic planning.

The World Energy Outlook is published annually, using the most recent available energy market and cost data; recent editions have included three scenarios:

- Stated Policies Scenario (STEPS).
- Announced Pledges Scenario (APS)
- Net Zero Emissions by 2050 (NZE) Scenario

As described by the IEA, "each scenario responds in different ways to the fundamental economic and demographic drivers of rising demand for energy services. These differences largely reflect the various policy choices assumed to be made by governments, which, in turn, shape investment decisions and the ways in which households and companies satisfy their energy needs".

The Net Zero Emissions by 2050 scenario prepared by the IEA is consistent with the goals of the Paris Agreement.

In April 2024, Beach released their inaugural Climate Transition Action Plan (CTAP). This plan outlines the important role that we expect to play as a provider of critical energy products, as the world addresses the significant challenge of climate change. It describes the processes we have in place to consider and respond to climate-related risks and opportunities, and the targets that we have set to guide our progress. Emissions reduction is at the heart of our CTAP. We are actively pursuing reductions in our Scope 1 and 2 emissions and improvements in measuring and reporting our scope 3 emissions.

Beach uses scenario analysis to test the resilience of our portfolio under different climate scenarios, as we consider the risks and opportunities associated with climate change and the energy transition. We use the three IEA scenarios as the basis for this analysis.

In the most recent World Energy Outlook 2024, the IEA outlined the uncertainty of global natural gas demand (IEA 2024). The IEA assessed natural gas demand within the APAC region by specifically considering 'Japan and Korea' and 'Developing Asia' across the STEPS and APS scenarios. Whilst APS shows an increase in demand in Developing Asia from 2023-2025, demand decreases in Japan and Korea over the same period, both regions see a decrease in demand during 2035-2050. Under the STEPS scenario, Japan and Korea see demand reductions from 2023-2050, where Developing Asia is indicates an increase in demand over the same period. No gas demand for the NZE scenario was presented in the World Energy Outlook. Australia was not modelled in the results presented (IEA 2024).

AEMO has conducted detailed analysis of the natural gas demand in Australia across a range of future scenarios. The 2024 Gas Statement of Opportunities forecasts the adequacy of gas supplies in central and eastern Australia, based on information from gas industry participants, to meet the changing energy needs of households and businesses from now to 2043 (AEMO 2024). To meet this demand, AEMO outlines a range of options the market is considering to address the forecast supply challenges. The options include additional southern supply such as from the Otway Basin, where the Project is located. This analysis indicates that the development of the Project is consistent with required supply in the East Coast Gas Market and the Project is unlikely to result in a stranded asset.

Production of gas from the Beach Otway Gas Plant is critical in ensuring Victoria's energy security as demand for gas is expected to continue in Victoria and the south-eastern states particularly as a result of the decline in consumption of more emission intensive coal associated with the closure of coal-fired power stations. As a result of its lower emissions intensity, coal-to-gas switching has avoided more than 500 $MtCO_2$-e emissions over the 2011-2018 period, or around 750 $MtCO_2$-e by 2020 (IEA 2019). It is estimated that approximately 1.2 Gt CO_2 could be avoided by switching from coal to existing gas-fired plants, assuming a supportive relative pricing and government policies (IEA 2019).

6. Beach Environmental Management System Relevant to GHG Emissions

Beach's climate change framework sits within their Operations Excellence Management System (OEMS). Table 6-43 provides a summary of the Beach OEMS components relevant to the management of GHG emissions.

Table 6-43: Summary of the Beach OEMS Components Relevant to the Management of GHG emissions

Beach OEMS Component	**Description**	**Contribution to Managing Climate Change**
Corporate Policies		
Beach Climate Change Policy	Beach's climate change policy commitments include: Measuring and reporting carbon emissions as required by regulatory requirements. Integration of climate risks into project decision-making. Evaluating investment decisions to potential changes in global climate policy and changes in climate. Setting targets to encourage innovation and drive reductions in our carbon.	This public published policy specifies that Beach's top management is expected to demonstrate leadership, commitment to, and accountability for climate change adaptation. It identifies that the Board Risk, Corporate Governance and Sustainability Committee is responsible for overseeing the effectiveness of the policy. It formally expresses specific commitments related to climate change mitigation and adaptation.

Beach OEMS Component	Description	Contribution to Managing Climate Change
		All Beach policies are approved by the Board.
Environmental Policy	The relevant commitments/aspects within Beach's Environment Policy are: Establish environmental objectives and targets and implement programs to achieve them that will support continuous improvement. Identify, assess, and control environmental impacts of our operations by proactive management of activities and mitigation of impacts. Efficiently use natural resources and energy and engage with stakeholders on environmental issues. Publicly report on our environmental performance.	Specifies that all environmental impacts will be proactively identified, assessed, and managed; and publicly reported against. All applicable legal and other requirements will be complied with and managed via Beach's OEMS. Commits to setting environmental objectives and targets, and a program of continuous improvement.
Sustainability Policy	The relevant commitments/aspects within Beach's Sustainability Policy are: Ensuring an appropriate governance system is in place to maintain a sustainable business. Assessing and addressing material social, environmental, climate and economic risks and the impact of our operations, and integrating these considerations into business planning. Conducting business activities in an ethical and transparent manner. Setting clearly defined targets, measuring, monitoring and reporting sustainability performance to support continuous improvement. Complying with relevant legislation, standards and procedures. Providing information and training, as required, and encouraging the adoption of sustainable principles and practices.	Specifies that Beach's top management is expected to demonstrate leadership, commitment to, and accountability for climate change adaptation; and formally expresses specific commitments related to climate change mitigation and adaptation. It identifies Beach Executives and managers are responsible for leading the adoption of this policy and the integration of sustainability practices.
Climate Transition Action Plan (CTAP) [**PC172, etc**]	The CTAP considers the physical and transition risks of climate change, and the potential impacts to Beach under different climate scenarios. It describes how climate change risk is governed at Beach, and targets that we are pursuing as we work within the changing context of the energy transition. Emissions reduction is at the heart of our CTAP, and we support the pursuit of Paris-aligned emissions reduction targets. We are actively pursuing reductions in our scope 1 and 2 emissions and improvements in measuring and reporting our scope 3 emissions. This is reflected in our short-term (annual) and medium-term (2030) equity emission reduction targets. We also have a long-term (2050) net zero ambition.	The CTAP is a publicly disclosed plan which is available on the company website. It describes the important role that we expect to play as a provider of critical energy products, as the world addresses the significant challenge of climate change.
OEMS – Key Relevant Standards		

Beach OEMS Component	Description	Contribution to Managing Climate Change
8.1 Risk Management Standard	Standard 8.1 defines Beach's requirements to mitigate and manage risk at all levels within the business. It defines the Risk Management Framework for identifying, understanding, managing and reporting risks. The framework defines the documents, training, tools and templates to be used, and the accountabilities to be applied in support of effective risk management. Risks to people, the environment, Beach's reputation, financial position and any legal risks are assessed through the framework. The methodology is consistent with the Australian and New Zealand Standard for Risk Management (AS/NZS ISO 31000:2018, Risk Management – Principles and Guidelines).	The potential impact of GHG emissions is assessed using Standard 8.1 and the risk assessment process described in Section 6 of this OPP.
10.1 Environment Management Standard	Beach has an Environmental Management Standard (EMS) that was issued for use in December 2020 with a review frequency of 3 years. The standard requirements that are included within the EMS include: General rules Land Disturbance, Reinstatement and Rehabilitation Biodiversity Contaminated Land Management Water Management Air Quality and Emissions Noise and Vibration Amenity (Dust, Odour, Visual, Lighting); and Waste	Within Beach's EMS, there are management standards that will directly manage climate change. Most notably under the standards for Biodiversity and Air Quality and Emissions. Where Beach can manage emissions and protection to biodiversity, they will ensure that as much as they can. Notable standards for mitigating climate change include: 10.1.3.5 – Decisions to proceed with exploration, development, operation and closure activities must consider the presence of, and impact on, legally designated protected areas and be recorded. 10.1.6.3 – When assessing and selecting new plant and equipment, low emissions technology must be prioritised. 10.1.6.6 – An inventory of sources of air emissions including point, fugitive and mobile related emissions must be developed and maintained.
11.1 – Sustainability Standard	Standard 11.1 operationalises the requirements established by the Company's Sustainability Policy and other associated Beach policies. The Standard includes the following requirements: Responsibility for steering the company's response on sustainability. Completion of a Sustainability Report. Monitoring market and societal trends and Beach's response to them. Risk assessments to consider social, environmental, governance and economic risks.	Beach's senior management is expected to demonstrate leadership, commitment to, and accountability for climate change adaptation. The Sustainability Report allows Beach to publicly report the impacts of their activities in a transparent structured way that is transparent to stakeholders and other interested parties, incorporating recommendations from the Task Force on Climate Related Disclosures.

Beach OEMS Component	Description	Contribution to Managing Climate Change
	Preparation of sustainability targets and initiatives. Linkage to Project and Risk Management Systems.	Monitoring of trends interfaces closely with risk management and setting of targets and initiatives. In alignment with BTSD 8.1 (Risk Management Standard), operational and project level risk assessments ensures the Company continues to pursue sustainable activities and projects. The Project Management System ensures that Sustainability in Design is considered during the design phase of a project life cycle.
Leadership and Accountability		
Risk, Corporate Governance and Sustainability Committee Sustainability Steering Committee	The Beach Energy Board has the Risk, Corporate Governance and Sustainability Committee (RiskCo) which provides oversight on sustainability at Beach. The Sustainability Steering Committee sits under this. It is made up of all company executives as well as the Chief Executive Officer; and oversees the management and execution of sustainability performance and risks in the business. Both committees meet on a quarterly basis to discuss sustainability risks, opportunities, projects as well as performance against the targets set out in the sustainability reports. In respect to climate change, RiskCo's purpose is to assist the Board in the following: Regularly reviewing material risks (including through detailed reviews, or deep dives) and management actions and consider that the residual risk is appropriate. Monitoring and reviewing the company's policies and performance in relation to health, safety, environment, community, climate change and other sustainability matters. Developing annual sustainability reporting, including public disclosures regarding material climate change risks. Ensuring the effectiveness of the Climate Change Policy.	Provides management review of the system and changing circumstances in order to inform decisions on actions needed for improvement.
Commitment to Emissions Reduction		
Net zero Scope 1 and 2 operated emissions	Beach has an aspiration to achieve net zero Scope 1 and 2 emissions by 2050. This aspiration was announced in Beach's Financial Year report 2021, the Full Year Results ASX release, as well as being stated on the company's website under "reducing emissions".	Beach is working towards this aspiration via the processes described in this document. Estimated actual operated FY22 emissions were 12% lower than FY18.

Beach OEMS Component	Description	Contribution to Managing Climate Change
Corporate emissions reduction target	Beach has a stated, publicly available, objective to reduce company net equity emissions intensity by 35 per cent by FY30 against FY18 levels/ targets https://www.beachenergy.com.au/reducing-emissions/.	Initiatives include: LDAR surveys completed at all assets remedial actions being taken through the maintenance management system. Equity stake in Moomba CCS Project. Multiple emission reduction projects completed at operated facilities.

6.6.4 Impact Evaluation Summary

The impact evaluation for GHG emissions is summarised in Table 6-44.

Table 6-44: Impact Evaluation Summary for GHG Emissions

Summary	
Summary of Impacts	Emissions related to the Project scope 1 [Inside Project Boundary, scope 1* [Outside Project Boundary] and scope 3) will be a minor contributor to global GHG emissions and climate change.
Extent of impacts	Impact solely from the emissions related to the Project will be minor.
Duration of impacts	Not applicable for the emissions related to the Project in isolation.
Level of certainty of impact	Beach has a high level of certainty about the impacts of GHG emissions from the Project.
Impact decision framework context	C – the precautionary approach has been applied for assessment and mitigation of impacts.
Impact Consequence	
Minor	

6.6.5 Demonstration of Acceptability

Table 6-45 demonstrates how and why predicted environmental impacts from GHG emissions meet the defined acceptable levels (Table 5-4).

Table 6-45: Demonstration of Acceptability – GHG Emissions

Demonstration of Acceptability	
Impact and risk comparison with relevant defined acceptable levels	Acceptable level 9 is relevant to GHG emissions (as detailed in Table 5-4). A Minor (1) impact consequence level was assigned for this aspect based on the impact analysis and evaluation. Minor (1) consequences due to GHG emissions will not: • interfere with Australia's GHG commitments under the Paris Agreement and enacted in the *Climate Change Act 2022* and managed by the safeguard mechanism As a result, the predicted environmental impact for GHG emissions is lower than the defined acceptable level 10.

		Demonstration of Acceptability
ESD principles	Integration principle	Section 6.6.3 identifies and evaluates environmental impacts associated with GHG emissions. As part of identifying the potential impacts; conservation values and sensitivities, physical environment, ecological environment, socio-economic values, and First Nations values and sensitivities described in Section 4 were reviewed to determine potential interactions of the aspect against each of these receptors they may result in environmental impact. As a result, consideration of economic, environmental, social and equitable receptors was conducted as part of identifying the impacts and risks. For Phase 1: Initial Project Consultation (Section 10.2.3), Beach consulted with relevant stakeholders on the Project and associated activities. No objections or claims were raised against this aspect during Phase 1: Initial Project Consultation. For Phase 2: Project OPP Public Comment Period (Section 10.2.4), the public had the opportunity to provide further comment to this OPP during the period (18/3/2024 – 20/5/2024). Beach prepared the public comment report summarising all comments, an assessment of the merits of each comment, a statement of the response to each comment, and an outline of any changes made to the OPP as a result of the comment (Appendix P). The impact assessment for this aspect has been updated to reflect the merit provided by public comment reference numbers PC172, PC205, PC206, PC211, PC218 and PC326. As a result, the impact assessment now integrates responses to public comments of merit and therefore is of an acceptable level. The potential environmental impact against this aspect was assessed as having a Minor (1) impact consequence level which is considered a lower-order environmental impact. Lower-order environmental impacts are considered ‘broadly acceptable’ and considered managed to an acceptable level by meeting relevant requirements (adopted controls as listed below).
	Precautionary principle	The potential environmental impacts against this aspect were assessed as having a Minor (1) impact consequence level which is considered a lower-order environmental impact. Lower-order environmental impacts cannot result in serious or irreversible environmental damage. There is high confidence in the potential environmental impacts and effectiveness of controls against this aspect. Beach commissioned a Greenhouse Gas emissions quantification assessment, with all emissions factors and energy content figures used to predict emissions sourced from the NGER (Measurement) Determination 2008 and the API Compendium of GHG Emissions Methodologies (API 2009). The Project is in line with the Australia’s commitments under the Paris Agreement and Climate Change Act 2022. As such there is no uncertainty associated with this aspect.
	Intergenerational principle	The defined acceptable levels were developed to meet the principles of ESD (Section 5.8.5). Given predicted environmental impacts from GHG emissions is lower than the defined acceptable level 9; the health, diversity, or productivity of the environment for future generations is expected to be maintained. Gas and condensate from OGP is supplied into the domestic Australian market. The scope 3 emissions associated with the transmission/transport and end use of the gas and condensation will occur within Australian Commonwealth jurisdiction. Therefore the scope

Demonstration of Acceptability		
		3 emissions will be managed in accordance with Australia's regulatory regime including NGER and the Safeguard Mechanism, which is designed "to deliver emissions reductions consistent with Australia's [NDC] under the Paris Agreement" (DCCEEW, 2023i) and the *Climate Change Act 2022*.
	Biodiversity principle	Section 6.6.3 identifies and evaluates environmental impacts associated with GHG emissions. As part of identifying the potential impacts; conservation values and sensitivities including MNES in Section 4 were reviewed. Given predicted environmental impacts from GHG emissions are lower than the defined acceptable level 9; no potential to affect biological diversity or ecological integrity is expected.
Internal context	Policy compliance	Beach Climate Change, Sustainability and Environmental Policy objectives are met through this environmental impact assessment with further detail provided in future environment plans.
	Beach GHG Emission Management Plan	Requirements in the Beach Corporate GHG Emission Management Plan are applicable to the Otway Project.
	Management system compliance	The OEMS system has been, and will be, applied to management of GHG emissions. For example: • The Standard 8.1 and the Risk Matrix framework has been used to assess the potential impact of GHG emissions. • The Environmental Management Standard (10.1) requires low emissions technology to be prioritised when assessing and selecting new plant and equipment and an inventory of sources of air emissions including point, fugitive and mobile related emissions be developed and maintained
External context	Stakeholder engagement is being carried out as part of this OPP process. Beach operates the existing Otway project and has established good relations with both onshore and offshore stakeholders. Engagement with stakeholders will continue throughout all aspects of the Project to build and maintain trust with stakeholders and the local community and minimise community and stakeholders concern and impacts where practicable. During Phase 1: Initial Project Consultation (Section 10.2.3), no objections or claims were raised against this aspect. During Phase 2: Project OPP Public Comment Period (Section 10.2.4), comments were raised against this aspect. The assessment of merit for these comments found this aspect to require updates. Changes to the OPP to address PC172, PC205, PC206, PC211, PC218 and PC326 have been integrated into the impact evaluation for this aspect. The science of impacts of greenhouse gas emissions is continually evolving. Any new guidance or advice will be assessed and incorporated into adaptive management plans prepared for activity specific EPs.	
Other requirements	**Requirement**	**Demonstration**
	Climate Change Act 2022 (Cwth) Sets Australia's GHG emissions reduction targets consistent with the Paris Agreement.	**CM22 Emission Abatement Opportunities Register** Per the requirements of the OEMS Sustainability Standard, Beach will maintain a register of opportunities for emissions reduction across its asset portfolio to reduce emissions.

Demonstration of Acceptability		
	Climate Change Act 2017 (Vic) Victorian legislation to manage climate change risks. Establishes a long-term emissions reduction target of net-zero by 2050 with 5 yearly interim targets.	**CM23 GHG Management Plan** The intent of this plan is to guide activities needed to manage Beach Scope 1 and Scope 1* GHG emissions, including the Project, in line with relevant policy and legislative requirements such as the Safeguard Mechanism and NGER. Implementation of Beach GHG Emissions Management Plan incorporates: • the framework and specific techniques used to ensure that GHG emission related EPOs will be met over the life of the facility • emissions monitoring • emissions forecasting • an adaptive management approach to facilitate a continuous cycle of monitoring, evaluating and implementing improvements to minimise GHG emissions to ALARP and acceptable levels over the life of the Project. **CM24 GHG Emissions Monitoring** Beach reports scope 1 and scope 2 emissions under the National Greenhouse and Energy Reporting Act 2007 (NGER). This includes annual, mandatory reporting of emissions by 31 October for the prior financial year. We track our progress against emissions reduction targets according to the methods defined by NGER. Beach calculates scope 3 emissions based on the Greenhouse Gas Protocol's Corporate Value Chain (scope 3) Accounting and Reporting Standard and scope 3 guidance documents. Scope 3 emissions derived from the use of product will be reviewed against forecasts, with this focus reflecting the proportional contribution of final product use to overall Otway asset Scope 3 emissions. GHG emissions forecasts are prepared periodically using data such as production forecasts. This data informs the disclosures in our Sustainability Report and Climate Transition Action Plan [PC206]. **CM25 Fugitive Leak Detection and Repair Program** Beach undertakes periodic leak detection and repair (LDAR) fugitive emissions surveys at the Otway Gas Plant and Thylacine Platform. The scope, methodology, frequency, and repair guidance is detailed in the GHG Management Plan. **CM26 Preventative Maintenance System** Combustion equipment is inspected and maintained in accordance with the preventative maintenance system to ensure efficient operations. **CM27 Logistics Planning** Operations planning is undertaken for supply vessel and helicopter movements, thereby minimising unnecessary travel and minimising fuel combustion.

6.6.6 Environmental Performance

In accordance with NOPSEMA’s OPP Decision Making Guideline (NOPSEMA 2024), the EPO for this aspect (Table 6-) has been developed to be relevant to identified environmental impacts and risks, consistent with the principles of ESD and equivalent to or better than the defined acceptable level of impact. Control measures listed in Table 6-45 provides detail on how each control measure will be implemented for the Project to ensure the acceptable levels and EPOs, defined in Table 6- are met.

Table 6-46: Environmental Performance Outcomes – GHG Emissions

Defined Acceptable Level	Environmental Performance Outcomes	
Acceptable level 9: Project activities will not interfere with Australia's GHG commitments under the Paris Agreement and enacted in the *Climate Change Act 2022* and managed by the safeguard mechanism.	EPO15:	GHG emissions related to the Project, including (scope 1 [Inside Project Boundary], scope 1* [Outside Project Boundary] and scope 3) emissions are consistent with Australia's international GHG emissions commitments, as outlined in the *Climate Change Act 2022*. Emissions are to be determined based on the NGER scheme and managed by the Safeguard Mechanism.

6.7 **Planned Discharge – Drill Cuttings and Fluids**

6.7.1 Hazard Identification

Planned discharges including drill cuttings, fluids (such as completion, wellbore cleanout, well annular and suspension fluids) and swarf, herein termed 'drill cuttings and fluids', are to be discharged to the marine environment during the Project. Relevant stages and associated activities that results in planned discharges of drill cuttings and fluids are defined below in Table 6-47 and described in Section 6.7.2.

Table 6-47: Activities Undertaken During the Project Resulting in Planned Discharges - Drill Cuttings and Fluids

Stage	Activity
Drilling and completions	Drilling method Well completion, unload and test Well unload and testing
Operations	Well intervention and workover
Decommissioning	Plug and abandonment of wells

6.7.2 Hazard Description

6.7.2.1 Drilling and Completions

The Project plans to drill 8 wells across VIC/P43 and, VIC/P73 within the scope of this OPP. A MODU will be used to drill the wells. To drill a single well, the MODU will be present at the well location for 40 days. During drilling of the upper well sections, cuttings and drilling fluids will be released directly to the seabed in the vicinity of the well site (subsea). Following the installation of the riser within which the remainder of the well sections will be drilled through, the cuttings and associated drill fluids will be routed back to the MODU.

Cuttings are then processed within the solids control equipment (SCE), with drilling fluids separated from the cuttings and recirculated back for further use. Cuttings are processed further through shale shakers and centrifuges to remove course and fine material. Processed cuttings, coated in drilling fluids, are discharged overboard.

A description for each planned discharge is detailed as follows:

- **Drill cuttings:** are the rock and sediment brought to the surface during the process of drilling in offshore environments. These cuttings can include a mixture of clay, silt, sand, and rock, and can also contain small amounts of oil and other drilling fluids.

- **Drilling fluids:** also known as drilling mud, are used to lubricate the drill bit, cool the drill, maintain the stability of the well, transport the cuttings out of the hole and control the pressure in the well. Water Based Drilling Fluid (WBDF) with the use of Synthetic Based Drilling Fluid (SBDF) as a contingency will be used to drill and complete the wells associated with the Project. WBDF use seawater with pre-hydrated bentonite gel sweeps and will be discharged directly to the seabed with cuttings. The seawater may be treated with caustic soda (NaOH) and/or soda ash (Na2CO3) to increase pH and alkalinity. If required, SBDF will be used once the riser is installed and returned to the topsides of the MODU, treated through the mud systems and reused. SBDF has increased lubricity, greater cleaning abilities with less viscosity than water-based fluids plus can withstand greater heat without breaking down. Base fluid is typically a hydrocarbon, ether, ester, or acetal as a base. Additives include organophilic clays, barite, lime, aqueous chloride, rheology modifiers fluid loss control agents, and emulsifiers. Excess seawater with pre-hydrated bentonite gel sweeps and water-based fluids will be discharged to the marine environment, however no whole SBDF will be discharged into the marine environment. SBDF that is recovered from drill cuttings for re-use will be recycled or disposed of at a land-based facility or used in future drilling activities.

- **Completion fluids:** Completion fluids are usually brines (i.e. a mixture of seawater or formation water) with additives that can include chlorides (often sodium, potassium or calcium), bromides, hydrate inhibitor (MEG), biocide, oxygen scavenger, viscosifiers and surfactants. They are designed to have the proper density and flow characteristics to be compatible with the reservoir formation. Completion fluids are used to run well completions, and during wellbore clean-up, unloading and testing during drilling.

- **Wellbore cleanout fluid:** Wellbore and casing clean-up are required at various stages of the drilling operations to ensure the contents of the well are free of contaminants before the next stage of drilling. A chemical wellbore cleanout fluid train may be used to remove residual fluids (including SBDF, if used) from the wellbore. The wellbore cleanout fluid is usually brine (similar to completion fluid) that can include several chemicals, such as biocide and surfactant. During the clean-up process, fluids are circulated back to the MODU, and analysed before they are discharged overboard.

The expected volumes for the above drill cuttings and fluids to be discharged for each well is detailed in Table 6-48. Concurrent drilling campaigns are not a credible scenario given only one MODU will be used for the Project.

6.7.2.2 Operations

Well intervention activities may be undertaken, consisting of well workovers, wireline, logging, testing and flowback. Discharges from these activities may include:

- **Completion fluids:** associated with well testing, as detailed above in Section 6.7.2.1, where the total discharge volume of completion fluids would be up to approximately 300 m^3 per well, containing up to 16 m^3 of formation water, and

- **Well annular fluids:** fluids that remain in the wellbore, or annular spaces between the casing and typically of any remaining drill fluids and may include small amounts of hydrocarbon may be discharged from the seabed up to a volume of 10 m^3.

6.7.2.3 Decommissioning

During well P&A, discharge of suspension fluids may occur during the operation. Suspension fluids are fluids suspended in wells that are estimated to consist of corrosion inhibitor (soluble oil) and of suspension fluid (treated with dilute oxygen scavenger, preservative (Glutaraldehyde) and caustic soda) for each well. It is expected that up to approximately 100 m^3 of well suspension fluid per well will be discharged during the wellhead removal operation

Section milling may be required to re-establish permanent wellbore barriers, which would generate swarf. This is lifted to surface via a circulated water-based fluid system and separated for onshore disposal.

Following P&A the wellhead is cut with the use of either a mechanical cutting tool or an abrasive cutter using water and inert abrasives and removed below the mudline (~2 m). Should a mechanical cutting tool be used, the process produces <0.002 m^3 per well of metal shavings (swarf) which will remain on the seabed.

WBDF used during riserless drilling and well annular fluids will be released to the marine environment when the well head is removed during abandonment. Upon wellhead removal, small volumes (up to 10 m^3) of fluid exchange between the annular spaces and the ocean may occur. The exchange will not be instantaneous as the annular spaces are small and the fluids are typically heavier than seawater. The non-instantaneous nature of the release of the well annular fluids is expected to result in rapid dilution within meters of the release.

6.7.2.4 Volumes of Planned Discharges – Drill Cuttings and Fluids

Table 6-48 summarises the expected volumes of drill cuttings and fluids to be discharged for each well. This is conservatively based on a directional well up to approximately 4,500 m deep that is not currently planned but may be required for future wells. The Project plans to drill 8 wells vertically to depths of approximately between 2,000 m and 3,500 m. As a result, the planned wells will have lower associated cuttings and fluids discharge volumes.

Table 6-48: Total Expected Volumes of Planned Discharges – Drill Cutting and Fluids

Project Stage	**Discharge type**	**Discharge location**	**Indicative volume (per well)**
Drilling	Drill cuttings	Seabed	400 m^3
		Surface	200 m^3
	Drilling fluids *Seawater & pre-hydrated gel sweeps*	Seabed	2,500 m^3
	WBDF	Surface	1,500 m^3
	SBDF (contingency)	Surface	100 m^3

	Wellbore cleanout fluids	Surface	100 m^3
	Completion fluids	Surface	300 m^3 *(including 16 m^3 of formation water)*
Operations (well workovers and interventions)	Completion fluids	Surface	300 m^3 *(including 16 m^3 of formation water)*
	Well annular fluid	Seabed	10 m^3
Decommissioning	Suspension fluids	Seabed	100 m^3
	Metal shavings (swarf)	Seabed	<0.002 m^3

6.7.3 Impact Analysis and Evaluation

Planned discharges of drill cuttings and fluids to the marine environment have the potential to result in the following impacts:

- change in water quality
- change in sediment quality
- change in habitats and communities.

As a result of a change in water and sediment quality, further impacts may occur, which include:

- injury/mortality to fauna.

The potential impacts of injury/mortality to fauna will be limited to the Project Area, as such receptors potentially affected are:

- plankton
- fish, marine mammals, and marine reptiles.

Changes to benthic habitats and communities also has the potential to result in indirect changes to the functions, interests, or activities of the following receptors:

- Commonwealth and state commercial fisheries
- cultural values and sensitivities.

6.7.3.1 Water Quality

Periodic discharges of drill cuttings and fluids will temporarily change the water quality within the immediate surrounds of the discharge location. Changes in water quality include increased turbidity within the water column. Discharge of drill cuttings and fluids to sea have been well-studied, where in-field observations and predictive studies have all found these discharges to cause temporary water quality changes, mainly due to increased turbidity that dissipates quickly (Sanzone et al., 2016).

Drilling fluids will be discharged intermittently in batches ranging from around 1 m^3 to 400 m^3 and, depending on volume, may be discharged over a matter of minutes or over several hours.

During drilling of the top-hole section, discharges of drill cuttings and fluids will occur at the seabed, resulting in a localised increase in turbidity immediately around the well. The drill cuttings and fluids will settle rapidly within proximity to the wellhead, with finer particles (approx. 10% of the discharge volume) dispersing further within ocean currents (Hinwood et al. 1994).

For drill cuttings and fluids discharged below the sea surface, Hinwood et al. (1994) indicates that larger particles of cuttings and adhered muds (90-95%) discharged from the surface fall to the seabed within close proximity to the release point. Larger particles, representing approximately 90% of the mass of mud solids discharged to the marine environment will form a plume which settles swiftly on the seafloor (or until the plume entrains enough seawater to reach neutral buoyancy). The remaining 10% of the mass forms another plume in the upper water column which drifts with prevailing currents away from the source and is diluted rapidly in the water column (Neff 2005, 2010). In well-mixed oceans, drilling cuttings and fluid plume is diluted by more than 100-fold within 10 m of the discharge (Neff 2005), with drilling fluid concentration falling to below acute toxicity threshold of 10,000 ppm within 100 m of the discharge source (Neff 2010).

Dispersion of the cuttings plume is influenced by two factors: fluid type (i.e. particle size) and ocean current speed. The case studies described in Neff (2005) used WBMs and uses lower surface current speeds as a conservative estimate of 0.15–0.3 m/s. The Project will also use WBMs to drill the wells in ocean currents in excess of 1 m/s (Section 4.3.2.4), as a result, the dispersion extents and dilution rates in Neff (2005) are considered highly conservative.

WBDF is a water-based drilling fluid where water or brine is the primary liquid component. The potential use of oil-based Synthetic Based Drilling Fluids (SBDF) is considered as a contingency activity for the Project. SBDFs, though generally less toxic than traditional oil-based muds, can introduce low concentrations of hydrocarbons to the marine environment. The potential use of SBDF would be subject to Beach's chemical selection process to ensure chemicals used are environmentally acceptable whilst also meeting technical requirements. WBM includes additives that are either:

- Inert in marine environments
- Naturally occurring, benign minerals
- Readily biodegradable organic polymers
- Low-concentration substances with minimal environmental impact.

Bentonite sweeps or barite, commonly used as weighting agents, are classified internationally as posing little or no risk to the environment (PLONOR). Ambient water quality in the Project Area is expected to be high and typical of the offshore marine environment. In the high-energy shelf waters, any changes in water quality will be quickly dispersed where dilution rates are expected to be more than 100-fold within 10 m of the discharge (Neff 2005). The increase in turbidity is expected to be intermittent and temporary where drill cuttings and fluids will settle rapidly within proximity to the wellhead resulting in localised impacts to water quality. Planned discharges of drill cuttings and fluids will occur at both the surface and seabed, but will occur in short periods, with no long-term or continuous discharges planned. This will allow water quality to quickly recover, with no long-term changes to ambient water quality expected. Temporary and localised changes to water quality have been evaluated as a Minor (1) consequence.

6.7.3.2 Sediment Quality

Periodic discharges of drill cuttings and fluids will temporarily change sediment quality within the immediate surrounds of the discharge location. Changes in sediment quality includes the introduction and accumulation of contaminants and change in physical characteristics of seafloor sediments from both subsea and surface discharges of drill cuttings and fluids. Contaminants may accumulate within benthic sediment because of chemical additives within drilling fluids. Increased sedimentation because of cuttings material deposition may alter the physical characteristics of the seabed sediment profile through changes in minerology, sediment structure, particle distribution, particle flow and chemical composition. The area of thickness for seabed deposition is dependent on a range of factors including:

- fluid type adhered to cuttings (WBDF or SBDF)
- amount of fluid retained on cuttings
- particle size distribution of cuttings
- water depth
- current speed and direction at varying depths

Drill cuttings and fluids discharged during drilling operations are expected to result in the greatest change in sediment quality, as cuttings tend to clump together and settle rapidly, with thicker cuttings piles generally located downstream from the discharge. This is especially evident for SBDF. Deposition of sediments is expected to be highly localised around the well site (Neff 2005).

Field studies summarised by International Association of Oil & Gas Producers (IAOGP) (2016), found that cuttings and adhered WBDF could be detected either visually or through increases in barium concentrations within 10 – 150 m of the source. Maximum height of the cuttings pile was usually <50 cm. When cuttings were discharged from the rig (i.e. at the surface), the increased depth allows small particles to disperse over greater distances, leaving thinner layers of cuttings near the well site – for example, WBDF cuttings discharged from a single well in >300 m water may disperse so widely they may not be detectable in sediments at any distance from the well.

Metals present in drilling fluids generally resemble that of marine sediments, albeit with concentrations of some metals higher than clean marine sediments (Neff 2005). Metals associated with WBDF drill cuttings have been shown to have a low bioavailability as they tend to remain in a non-ionic form, remaining bound to other compounds, presenting a low toxicity risk to marine fauna (Neff 2005). Other metals present in drilling wastes, mainly as salts, may originate from formation cuttings or from impurities in barite and other mud components. Barite used during the Drilling and P&A activities will have very low concentrations of mercury (Hg) and cadmium (Cd) (less than 1 mg/kg and 3 mg/kg respectively). A study investigating barite solubility and the release of trace metal compounds recorded that <1% of the mercury and 15% of the cadmium dissolved from the barite after one-week exposure to the marine environment (Crecelius et al. 2007). Further, these do not contribute to sediment toxicity due to their low bioavailability (Schaanning et al. 2002). The field studies summarised by IAOGP at three continental slope drilling locations in water depths between 37 and 119 m found that within a year, concentrations of barium and chemicals from WBDF and SBDF discharges reduced by 2.4 to 80% for barium and 65 to 99% for chemicals within 100 m of the discharge source (IAOGP 2016). The IAOGP studies (IAOGP 2016) also found the following regarding the extent of cuttings deposition and potential impact:

Cuttings and adhered fluids typically disperse slower and cover a wider area when WBDF are used rather than SBDF.

Surface discharges of SBDF are generally deposited within approximately 100–200 m downstream of the discharge source for shallower water (<400 m) and up to a maximum of 1 km downstream for deeper waters with concentrations decreasing with distance from the discharge site

WBDF cuttings discharged near to the sea surface tend to accumulate on the seafloor down current from the discharge at distances of about 100m to up to a maximum of 1.4 km.

The Minerva exploration well study in the Bass Strait identified that cuttings were visually detected to 100 m from wellhead at 1 week post-drilling and no cuttings detected 11 months post drilling.

For both SBDF and WBDF discharges at the seafloor; cuttings could be detected visually, or as elevated barium concentrations in benthic sediments within 10 – 150 m of the discharge, with a greater spread down-current.

Based on these studies, a conservative exposure radius of up to 2 km is assumed for drill cuttings and fluids on the seabed to result in change to sediment quality for up to 11 months before returning to pre-drilling conditions.

In summary, change in sediment quality is expected to localised and temporary such that changes are limited to 2 km from the discharge location for each well and pre-drilling conditions will return within 11 months of the discharge. Temporary and localised changes to sediment quality have been evaluated as Minor (1) consequence.

6.7.3.3 Benthic Habitats and Communities

Periodic drill cuttings and fluid discharges will alter benthic habitats and communities within the immediate surrounds of the discharge location. Drill cuttings are expected to physically smother seabed habitats and communities, whereas fluid adhered to cuttings discharges will expose localised benthic habitats and communities to bio accumulative chemicals such as hydrocarbons and metals such as lead and zinc..

As discussed in Section 4.3.3, several studies (Boreen et al. 1993, BBG 2003, CEE Consultants Pty Ltd 2003 and Ramboll 2020) have been undertaken within the Project Area within the shallow and middle shelf zones. These studies have identified the seabed is similar across these areas, consisting of carbonate rich coarse to medium sands with areas of exposed limestone substrate. This type of seabed is highly mobile making it difficult for filter feeders and soft body invertebrates to survive and establish in significant populations. Epifauna is dominated by low density, patchy assemblages of branching bryozoans, gorgonian cnidarians and sponges.

Seabed discharges of drill cuttings and fluids will create a cuttings pile surrounding the well location. The size of the cuttings pile generally extends tens of metres from the well location. The cuttings pile will directly bury and smother the benthic habitats and communities surrounding the immediate well location, resulting in the localised loss of low density sessile benthic fauna and alteration of carbonate rich coarse to medium sand habitats. The presence of the hydrocarbon component in the cuttings pile is SBDF is used will prevent recolonisation of benthic communities in the area. Recolonisation of the cuttings pile (SBDF mud-cuttings piles in cold-water marine environments) is expected within one to two years of ceasing discharges once the hydrocarbon component of the cutting piles biodegraded (Neff 2010). As a result, the localised loss of benthic habitats and communities is expected to be temporary.

Surface water discharges of drill cuttings and fluids will generally deposit on the seabed up to a maximum of 1 km from the discharge site. However, effects to benthic habitats and communities from surface discharges is expected to be within 200 m of the discharge location given cuttings concentrations decreases with distance from the discharge site (Terrens et al. 1998; Jones et al. 2021). The loss of low density sessile benthic fauna and alteration of carbonate rich coarse to medium sand habitats is expected within 200 m of the well location based on smothering effects of drill cuttings and fluid discharges. Impacts to mobile benthic fauna (e.g. crabs, shrimps, demersal fish) are not expected given their ability to avoid effected areas (IOGP, 2016).

In a contingency event where SBDF is used for lower well sections, the discharge of SBDF adhered to cuttings will deposit of the seabed resulting in an increase in SBDF in benthic sediments that may lead to depletion of oxygen in surface layers and cause a change in or decrease in diversity of the benthic community (IOGP, 2016). SBDF also contains hydrocarbons that may bioaccumulate. However, Melton et al. (2000) suggests that given the ability for organisms to oxidise and expel aromatics, hydrocarbons are not expected to bioconcentrate given the reactivity and biodegradation rate of drilling materials in high energy environments.

A study on the impacts of drilling in Bass Strait, where the Drilling and P&A activities will be conducted, by Terrens et al. (1998) observed biological effects within 100 m of the drilling site shortly after drilling; recovery of seabed communities across the area were reported within four months. This study found that after 11 months SBDF was not detectable in sediments, indicating that recovery of the seabed is through a combination of dispersion and biodegradation. Neff (2010) found that recolonisation of SBDF mud-cuttings piles in cold-water marine environments began within one to two years of ceasing discharges once the hydrocarbon component of the cutting piles biodegraded. Thus, for WBDF recolonisation would be faster as there is no hydrocarbon component.

A recent study on the Northwest Shelf (Jones et al. 2021), where in-situ surveys were undertaken during a drilling campaign, suggest a zone of high impact surrounding the drill centre up to 50–75 m in all directions which would have been caused by cuttings and fluid discharges from the drill rig. Outside this zone was an area of medium impact up to approximately 200 m where there were clear losses of epifauna, but nevertheless sponges and soft corals were still observed. Pre- and post-drilling ROV surveys which documented physical smothering effects from WBDF cuttings within 100 m of the well were compared and found that outside the area of smothering, fine sediment was visible on the seabed up to 250 m from the well (Jones et al. 2006, 2021). After three years, there was significant removal of cuttings particularly in the areas with relatively low initial deposition (Jones et al. 2021). The area impacted by complete cuttings cover had reduced from 90 m to 40 m from the drilling location, and faunal density within 100 m of the well had increased considerably and was no longer significantly different from conditions further away.

Marine fauna that are exposed in the laboratory or field to cuttings in sediments do not bioaccumulate significant quantities of metals (Hartley et al. 2003). There is some evidence of a limited bioavailability of a few metals, such as lead and zinc, which are present in cuttings piles; however, doubt remains that metal bioaccumulation in marine fauna from cuttings piles is sufficient to cause harmful effects in marine fauna living on or near cuttings piles (OSPAR 2019). Neff (2010) concludes that, due to a lack of toxicity and low bioaccumulation potential of drilling fluids, the effects of drilling discharges are highly localised and are not expected to spread through the food web.

Hinwood et al. (1994) explain that the main environmental disturbance from discharging drilling cuttings and fluids is associated with the smothering and burial of sessile benthic and epibenthic fauna. Many studies have shown that the effects on seabed fauna and flora from the discharge of drilling cuttings with water-based muds are minimal (e.g. Cranmer 1988, Neff et al. 1989, Hyland et al. 1994, Daan & Mulder 1996, Currie and Isaacs 2005, OSPAR 2009, Bakke et al. 2013).

The above-mentioned studies have concluded that impacts to benthic habitats and communities from drill cuttings and fluid discharges are limited to localised burial and smothering of low density sessile benthic fauna and carbonate rich coarse to medium sand habitats. Impacts are expected to be within 200 m of the well location, where recovery of benthic habitats is expected to be within 11 months and recolonisation of cuttings piles is expected to be within one to two years of ceasing discharges. The biodegradation rate of drilling materials in high energy environments ensures low bioaccumulation potential to benthic fauna communities.

The localised and temporary change in benthic habitats and communities from periodic planned discharges of drill cuttings and fluids is expected from direct burial and smothering. Given that epifaunal communities are likely well represented in the region and that the footprint of the potential impact of drilling 8 wells is small in comparison with the spatial extent of these communities in the region, there is a high level of confidence that drill cuttings and fluids will not destroy, fragment or isolate these communities nor modify or disturb substantial areas of habitat. Temporary and localised changes to benthic habitats and communities highly represented in the region have been evaluated as a Minor (1) consequence.

6.7.3.4 Plankton

A reduction in water quality through increased turbidity and increased toxicity, caused by the discharge of drill cuttings and fluids within the Project Area, will have a negligible effect on plankton populations at a measurable level. Jenkins and McKinnon (2006) identified suspended sediment concentrations greater than 500 mg/L will likely result in a measurable impact to larvae species of most fish species, with concentrations of 100 mg/L effecting larvae species of most fish if exposed to for longer than 96 hours. Previous studies (Neff, 2010) showed discharges of cuttings and fluids could reach 100 mg/L within 100 m of the MODU within approximately 16 minutes, assuming a conservative 0.1 m/s current speed. Changes in water quality associated with increased turbidity are therefore restricted to within proximity of the discharge source.

Plankton have a patchy distribution linked to localised and seasonal productivity that produces sporadic bursts in populations (CoA, 2015c). Plankton distribution in the project area is expected to be highly variable both spatially and temporally and are likely to comprise characteristics of tropical, southern Australian, central Bass Strait and Tasman Sea distributions. A change in water quality at levels that may illicit acute toxicity to plankton as a result of drill cuttings and fluids is likely to be limited to within 100 m of the MODU (limited to within the project area) and therefore unlikely to lead to injury or mortality of plankton at a measurable level and will not result in a change in the viability of the population or ecosystem dynamics during regional upwelling events or otherwise. Therefore, no impacts to plankton populations from drill cuttings or fluids discharges are expected. Not all zooplankton are alive in the natural environment, non-consumptive mortality of zooplankton in marine habitats have been recorded from naturally occurring changes to oxygen layers, thermoclines, upwelling, and salinity gradients (Daase & Soreide 2021). As a result, zooplankton carcasses may play an important role in marine food webs as they may serve as nutritious food for benthic organisms (Daase & Soreide 2021). Consequently, the temporary and localised loss of plankton from planned discharge of drilling cuttings and fluids will not significantly contribute to existing non-consumptive mortality of zooplankton naturally occurring in the marine habitats and therefore has been evaluated as a Minor (1) consequence.

6.7.3.5 Fish, Marine Mammals and Marine Reptiles

A reduction in water quality through increased turbidity and increased toxicity, caused by the discharge of drill cuttings and fluids in the Project Area, will have negligible effects on fish, marine mammals, and marine reptiles. Neff et al. (2000) states that drill cuttings are of little risk to water column biota due to Water Based Drilling Fluid having low toxicity levels and will be rapidly diluted near the source. Based on the low toxicity levels and short duration of the drill cuttings and fluids plume in the Project Area, there is no potential for acute or chronic exposure of fish, marine mammals, and marine reptiles from the low toxicity levels contained within a highly temporary drill cuttings and fluids plume. With no potential for acute or chronic exposure, the potential for injury or mortality to occur to these species is not credible.

Marine fauna found in the water column, such as fish, marine mammals and marine reptiles, are expected to actively avoid discharge plumes and associated turbidity within the water column. If marine fauna does not actively avoid the discharge plume, exposure to low toxicity levels in the plume is expected to be temporary given the Project Area is habitat to transient fish, marine mammals, and marine reptiles based on the absence of site attached habitats for these species.

The intermittent and temporary drill cuttings and fluids plumes are expected to be restricted within the Project Area (Section 6.7.3.1) and therefore will only overlap fish, marine mammal, and marine reptile BIAs relating to distribution (white shark), foraging (blue whale), and migration (southern right whale). These BIAs and the open offshore waters of the Project Area does not foster site fidelity or attachment for these species.

The Project Area overlaps the BIA distribution area for the white shark. No habitat critical to the survival of the white shark or behaviours were identified. The Recovery Plan for the White Shark (*Carcharodon carcharias*) (DSEWPaC, 2013c) does not identify waste discharges as a threat. As a result, the white shark is expected to be a highly mobile and transient species within the Project Area. The temporary exposure of low toxicity levels from the drill cuttings and fluids plume in the Project Area prevents acute or chronic exposure to transient white sharks, therefore, no injury or mortality is expected.

Three species of marine mammal listed as Vulnerable (sei whale, fin whale, humpback whale) and two species listed as Endangered (blue whale, southern right whale) are known or likely occur within the Project Area. The Project Area overlaps foraging and distribution BIAs for the pygmy blue whale and migration BIA for the southern right whale. The Conservation Management Plans for the Blue Whale (CoA, 2015b) and Southern Right Whale (DSEWPaC, 2012a) identifies acute and chronic chemical discharges as a threat mainly in relation to hydrocarbon spills and bioaccumulation of pollutants. Pollution (persistent toxic pollutions) is identified as a minor threat for the sei whale (Approved Conservation Advice for Balaenoptera borealis (Sei Whale) (TSSC, 2015e) and fin whale (Approved Conservation Advice for Balaenoptera physalus (Fin Whale) (TSSC, 2015d). Based on the low toxicity levels contained within highly temporary and intermittent drill cuttings and fluids plumes in the Project Area, , there is no potential for acute or chronic exposure of pollutants to marine mammals and therefore no injury or mortality is expected. There are three marine turtle species with potential to be present, however no BIAs or habitat critical to the survival of the marine turtle species occur within the Project Area. The Recovery Plan for Marine Turtles in Australia, (CoA, 2017) identifies chemical and terrestrial discharge as a threat, although this is mostly in relation to pollution from agricultural, terrestrial industrial and domestic sources. Based on the low toxicity levels contained within highly temporary and intermittent drill cuttings and fluids plumes in the Project Area, there is no potential for acute or chronic exposure of pollutants to marine reptiles and therefore no injury or mortality is expected.

6.7.3.6 Commonwealth and State Commercial Fisheries

a Discharges of drill cuttings and fluids has the potential to result in a change to benthic habitats and communities. This change is indirectly associated with commercially valued benthic species. Potential changes to commercially valued benthic species in the Project Area may then result in indirect changes to the functions, interests, or activities of Commonwealth and state commercial fisheries. There are two commercially fished marine benthic invertebrate species which are present within the Project Area which could be indirectly susceptible to discharges of drill cuttings and fluids: the giant crab and the southern rock lobster (Section 4.4.7.1).

Southern rock lobster live in rocky reefs (VFA 2023b) a habitat unlikely to be disturbed by Project activities as rocky reefs are not an appropriate substrate for anchoring or drilling of a well. Giant crab have recorded movements up and down the continental shelf depending on food availability (Levings et al. 2001), where change to benthic habitats and communities in potential giant crab habitats in the Project Area potentially leading to emigration of the mobile biota to other areas along the continental shelf.

The extent of the impact is expected to be within 200 m of the discharge location and recovery from change in benthic habitats and communities is anticipated to be within 11 months (Section 6.7.3.3). Therefore, the impact from discharges of drill cuttings and fluids is likely to result in Minor (I) consequences to the functions, interests, or activities of Commonwealth and State commercial fisheries based on:

- Giant crab and southern rock lobster are mobile species and are generally less vulnerable than sessile taxa to sedimentation, as they are able to move to areas with less sediment accumulation or by more efficiently physically removing particles (Fraser et al. 2017).
- The Project Area intersects the following giant crab and southern rock lobster fisheries areas:
    - Southern rock lobster
        - 14 of the 200 Victorian southern rock lobster reporting blocks (up to 20 active vessels – Figure 4-82).

        - The Project Area does not overlap the Tasmanian southern rock lobster reporting blocks.
    - Giant crab
        - 9 of the 48 Victorian giant crab reporting blocks (up to 13 active vessels – Figure 4-78).
        - 1 of the 386 Tasmanian giant crab reporting blocks (confidential fishing effort due to less than 5 vessels being active within the fishery – Figure 4-85).

- The southern rock lobster fishery has a stock status listed as sustainable for Victoria, Tasmania and South Australia (FRDC 2020). The giant crab fishery has a stock status listed as sustainable for Victoria and South Australia and depleted for Tasmania (FRDC 2020; 2020a). The depleted stock status for the Tasmanian giant crab fishery is based on data obtain from 2013-2014, and there has been insufficient data for the fishery since 2013 to determine if the stock is recovering (FRDC 2020a).
- Based on the localised change in benthic habitats and communities (within 200 m of the discharge location) and recovery of benthic habitats is expected to be within 11 months, the disturbance footprint is considered negligible compared with the wider extent of available fishing grounds and the intermittent nature of drilling discharges, impacts to benthic species of commercial importance are predicted to be localised and insignificant at a population level.
- As rock lobster live in rocky reefs (VFA 2023b) it is unlikely that their habitat would be disturbed as rocky reefs are not an appropriate substrate for anchoring or drilling of a well.
- Seabed surveys will be undertaken to allow for the consideration of seabed habitat type in the final selection of well locations to avoid area of high relief outcrops, reefs or sponge beds.
- The area of impact is predicted to be small compared to the extent of available and utilised commercial fishing areas for both the Victorian and Tasmanian giant crab and southern rock lobster fisheries.

6.7.3.7 Cultural Values and Sensitivities

As detailed in Section 4.6 no First Nations underwater cultural heritage has been identified in the Project Area. However, First Nations people specifically Eastern Maar highlights that although the edge of the continental shelf is under sea, it was occupied for thousands of years and rising sea levels have not washed away the history, physical evidence, or connection to that part of Sea Country (Section 4.6.3.5). At present, oil and gas infrastructure exists across the Otway Basin and memories and songlines relating to the historical occupation of the present-day seabed are still acknowledged and recognised (Biosis 2023).

Periodic discharges of drill cuttings and fluids will result in localised and temporary change in benthic habitats and communities which may interact with unknown First Nations submerged cultural heritage and landscapes. To prevent potential interaction with First Nations submerged cultural heritage and landscapes in the Project Area, Beach has consulted with First Nations groups to define the management approach of intangible cultural heritage to prevent impacts and risks to environmental features that are associated with intangible cultural heritage (Australia ICOMOS Burra Charter, 2013). As per the draft Guidelines for Working in the Near and Offshore Environment to Protect Underwater

Cultural Heritage (DCCEEW 2023) Beach has consulted with First Nations groups and relevant underwater culture heritage researchers and organisations to understand what data could be obtained from the seabed survey that will be undertaken prior to planned drilling discharges and other seabed disturbing activities to identify First Nations submerged cultural heritage and submerged cultural landscapes. Data from seabed surveys will be provided to an appropriately qualified underwater archaeologist to identify submerged cultural heritage. Should any submerged cultural heritage be identified, Beach will consult with the relevant First Nations groups (see Section 4.6.2) and determine any exclusion areas or further cultural heritage management procedures that may be required. Thus, impacts to First Nations underwater cultural heritage are not predicted.

6.7.4 Impact Evaluation Summary

The impact evaluation for planned discharge of drill cuttings and fluids is summarised in Table 6-49.

Table 6-49: Impact Evaluation Summary for Planned Discharges of Drill Cuttings and Fluid

Summary	
Summary of impact	Intermittent discharges of drill cuttings and fluids in surface waters and at the seabed is expected to result in temporary and localised changes to water quality, sediment quality, and benthic habitats and communities. These changes act as impact pathways to the localised injury and mortality of plankton, emigration of commercially valued species from the Project Area and the potential interaction with First Nations submerged cultural heritage and landscapes in the Project Area. Data from seabed surveys will be provided to an appropriately qualified underwater archaeologist to identify submerged cultural heritage. Should any submerged cultural heritage be identified, Beach will consult with the relevant First Nations groups (see Section 4.6.2) and determine any exclusion areas or further cultural heritage management procedures that may be required to prevent interactions with First Nations submerged cultural heritage and landscapes. Together these impacts from intermittent discharges of drill cuttings and fluids will result in Minor (1) consequences with the application of adopted controls. The Minor (1) consequences are considered acceptable, given controls are in place to ensure potential impacts are better than the defined acceptable levels 1, 6, 14, 15, and 16.
Extent of impacts	The greatest extent of impact is from change in sediment quality where localised changes are limited to within 2 km from the discharge location.
Duration of impacts	The longest impact duration is from change in benthic habitats and communities where habitat recovery is expected within 11 months of the discharge and recolonisation of communities is expected within one to two years of ceasing discharges.
Level of certainty of impacts	Impacts from planned discharges of drill cuttings and fluids are well understood and there is nothing new or unusual. There is high level of certainty on the predicted impacts from drill cuttings and fluids, including: • Impact and fate in the environment • Toxicity of individual components within the drilling fluids • likely distribution of cuttings on the seabed. Good practice is defined through the implementation of the following controls which ensures uncertainty is minimal: • Beach is committed to undertake seabed surveys and commission an appropriately qualified underwater archaeologist to identify submerged cultural heritage to avoid impacts to cultural values and sensitivities. Beach has long-term experience in the area on the application of good industry practice to ensure impacts associated with planned discharge of drill cuttings and fluids are acceptable.

Is the impact considered lower-order or higher-order?	Potential impacts from planned discharges of drill cuttings and fluids have been evaluated to result in Minor (I) consequences. Minor consequences are considered lower-order impacts that is acceptable with the application of good industry practice.

Impact Consequence
Minor

6.7.5 Demonstration of Acceptability

Table 6-50 demonstrates how and why predicted environmental impacts from planned discharges of drill cuttings and fluids meet the defined acceptable levels (Table 5-4).

Table 6-50: Demonstration of Acceptability – Planned Discharge – Drill Cuttings and Fluids

Demonstration of Acceptability		
Impact and risk comparison with relevant defined acceptable levels	The acceptable level relevant to the planned discharge – drill cuttings and fluids includes acceptable levels 6, 7, 10, 11, 15, and 16 (as detailed in Table 5-4). A **Minor** impact consequence level was assigned for this aspect based on the impact analysis and evaluation. Minor (1) consequences resulting from planned discharge – drill cuttings and fluids: • will contain chemical additives subject to Beach’s chemical selection process • will result in a localised change in water quality (<2 km from discharge point located in the Project Area) which will return to baseline conditions following completion of planned discharges • will result in localised change in sediment quality (<2 km from the discharge point located in the Project Area) for sediments highly represented throughout the region from planned discharges • will not impact on unique seafloor habitats[2] to the south-east region, including deep-sea reefs, continental shelf habitats, seamounts canyons and kelp forests • will only impact on benthic habitats and communities within the Project Area that are highly represented throughout the region and are not unique seafloor habitats • will not impact on underwater cultural heritage with values as conferred by the *Underwater Cultural Heritage Act 2018* (Cth) • will not impact on declared areas or objects of particular significance with values as conferred by the *Aboriginal and Torres Strait Islander Heritage Protection Act 1984* (Cth). As a result, the predicted environmental impact from planned discharge – drill cuttings and fluids is better than the defined acceptable levels 6, 7, 10, 11, 15, and 16.	
ESD principles	Integration principle	Section 6.7.3 identifies and evaluates environmental impacts associated with the discharge of drill cuttings and fluids. Conservation values and sensitivities, physical environment, ecological environment, socio-economic values, and First Nations values and sensitivities described in Section 4 were reviewed to determine potential interactions of the aspect against each of these receptors they may result in environmental impact. As a result, consideration of economic, environmental, social and equitable receptors was conducted as part of identifying the impacts and risks. For Phase 1: Initial Project Consultation (Section 10.2.3), Beach consulted with relevant stakeholders on the Project and associated activities. No objections or claims were raised against this aspect during Phase 1: Initial Project Consultation. For Phase 2: Project OPP Public Comment Period (Section 10.2.4), the public had the opportunity to provide further comment to this OPP during the period (18/3/2024 – 20/5/2024). Beach prepared the public comment report

		summarising all comments, an assessment of the merits of each comment, a statement of the response to each comment, and an outline of any changes made to the OPP as a result of the comment (Appendix P). The assessment of merit for comments against this aspect found the response provided in the public comment report to be sufficient to address the comments against this aspect. Therefore, no further updates were required for this aspect. Given the thorough assessment and responses outlined in the public comment report, the impact evaluation for this aspect remains acceptable as is, demonstrating that public comments have been adequately addressed. The potential environmental impacts against this aspect was assessed as having Minor (1) consequences which is considered a lower-order environmental impact. Lower-order environmental impacts are considered 'broadly acceptable' and considered managed to an acceptable level by meeting relevant requirements (adopted controls as listed below).
	Precautionary principle	The potential environmental impacts against this aspect were assessed as having Minor (1) consequences which is considered a lower-order environmental impact and below defined acceptable levels 6, 7, 10, 11, 15, and 16 . Lower-order environmental impacts cannot result in serious or irreversible environmental damage. There is high confidence in the potential environmental impacts and effectiveness of controls against this aspect. Beach has significant experience operating in the Otway and Bass based on their existing offshore developments and associated activities including the Beach Otway Drilling Campaign in 2021/2022.
	Intergenerational principle	The defined acceptable levels were developed to meet the principles of ESD (Section 5.8.5). Given predicted environmental impacts due to the discharge of drill cuttings and fluids is lower than the defined acceptable levels 6, 7, 10, 11, 15, and 16 ; the health, diversity, or productivity of the environment for future generations is expected to be maintained.
	Biodiversity principle	Section 6.7.3 identifies and evaluates environmental impacts associated with the discharge of drill cuttings and fluids. As part of identifying the potential impacts; conservation values and sensitivities including MNES in Section 4 were reviewed. Given predicted environmental impacts due to the discharge of cement is lower than the defined acceptable levels 6, 7, 10, 11, 15, and 16; no potential to affect biological diversity or ecological integrity is expected.
Internal context	Beach Policy compliance	The defined acceptable levels, EPOs and controls proposed for this aspect are consistent with Beach Environmental Policy objectives. As a result, potential environmental impacts and risks from Project can be managed to align with Beach Environmental Policy objectives.
External context	Stakeholder engagement is being carried out as part of this OPP process. Beach operates the existing Otway project and has established good relations with both onshore and offshore stakeholders. Engagement with stakeholders will continue throughout all aspects of the Project to build and maintain trust with stakeholders and the local community and minimise community and stakeholders concern and impacts where practicable. During Phase 1: Initial Project Consultation (Section 10.2.3), no objections or claims were raised against this aspect. During Phase 2: Project OPP Public Comment Period (Section 10.2.4), comments were raised against this aspect. The assessment of merit for comments against this aspect found the responses provided in the public comment report to be sufficient to address the comments against this aspect. Given the thorough assessment and responses outlined in the public comment	

	report, the impact evaluation for this aspect remains acceptable as is, demonstrating that public comments have been adequately addressed.
Other requirements	Other requirements associated with this aspect includes compliance with Australian legislative requirements. Management of this aspect is aligned with the legislative requirements below.

Requirement	Demonstration
OPGGS Act 2006 (Cth) Section 460(2) - a person carrying on activities in an offshore area under the permit must carry out those activities in a manner that does not interfere with the conservation of the resources of the sea and seabed to a greater extent than is necessary for the reasonable exercise of the rights and performance of the duties of the first person.	This requirement is addressed through the adoption of the following control measures: **CM10 Seabed assessments** Seabed assessments undertaken of each well location and tie-back route prior to final selection to identify seabed composition, benthic habitats and communities and ensure areas of high relief outcrops, reefs, sponge beds, maritime archaeology, submerged cultural heritage and landscapes are avoided where practicable within technical and safety constraints. Seabed assessment data will be provided to the following appropriately qualified specialists to identify sensitive benthic receptors: • Marine benthic ecologist to identify seabed habitat types including areas of high relief outcrops, reefs or sponge beds that are likely to be associated with site-attached fish. • Underwater archaeologist to identify shipwrecks and other maritime archaeological heritage. • Geophysical data analyst to identify location of unexploded ordinances. • Underwater archaeologist to identify submerged cultural heritage and landscapes. Reports from each specialist evaluation of seabed assessment data will be provided to Beach. Beach will assess the reports and identify any areas of overlap, potential risks from Project activities, and determine any exclusion areas that may be required. **CM11 Cultural heritage assessments** Imagery and data from seabed surveys and assessments will be provided to appropriately qualified underwater archaeologists to identify any maritime archaeological and submerged cultural heritage and landscapes and inform protection priorities, management measures and reporting requirements. Should any maritime archaeological and submerged cultural heritage and landscapes be identified, Beach will report the findings in accordance with the *Underwater Cultural Heritage Act 2018*, and will consult with the relevant First Nations groups and determine any exclusion areas
The Minimata Convention Countries that have ratified the Convention are bound by international law to put controls in place to manage emissions, releases and disposal of mercury and mercury compounds. At present there are no specific guidelines regarding acceptable levels of mercury waste in drilling fluids.	
The following management plans or conservation advice identify pollution, habitat degradation or discharges as a threat: • Recovery Plan for Marine Turtles in Australia, 2017-2027 (CoA, 2017) • Approved Conservation Advice for *Dermochelys coriacea* (Leatherback Turtle) (DEWHA, 2008) • Conservation Management Plan for the Blue Whale, 2015-2025 (CoA, 2015b) • National Recovery Plan for the Southern Right Whale *Eubalaena australis* (DCCEEW, 2024o) • Approved Conservation Advice for *Balaenoptera borealis* (Sei Whale) (TSSC, 2015e) • Approved Conservation Advice for *Balaenoptera physalus* (Fin Whale) (TSSC, 2015d)	

		or further cultural heritage management procedures that may be required. **CM28 Well design** All wells to be drilled with WBDF, with SBDF only to be used where technical requirements preclude the use of WBDF **CM29 Chemical selection process** A process for chemical selection will be implemented to ensure chemicals used are environmentally acceptable whilst also meeting technical requirements **CM30 Drilling fluid inventory** Drilling fluids inventory will be developed and tracked to reduce or avoid discharge of bulk materials including excess powders, brines, and drilling fluids **CM31 Solids control equipment** If SBDF is used, drill cuttings will be processed on the MODU to recover and reduce residual SBDF content prior to overboard discharge **CM32 Minamata convention** Drilling fluids will have concentrations of mercury and cadmium less than 1 mg/kg and 3 mg/kg respectively in stock barite (WBM and SBM)

6.7.6 Environmental Performance

In accordance with NOPSEMA's OPP Decision Making Guideline (NOPSEMA 2024), the EPO for this aspect (Table 6-) has been developed to be relevant to identified environmental impacts and risks, consistent with the principles of ESD and equivalent to or better than the defined acceptable level of impact. Control measures listed in Table 6-50 provides detail on how each control measure will be implemented for the Project to ensure the acceptable levels and EPOs, defined in Table 6- are met.

Table 6-51: Environmental Performance Outcomes – Planned Discharge – Drill Cuttings and Fluids

Defined Acceptable Level	Environmental Performance Outcomes	
Acceptable level 7: Localised change in water quality (<2 km from discharge point located in the Project Area) which will return to baseline conditions following completion of planned discharges (as defined in the OPP) containing chemical additives subject to Beach's chemical selection process is acceptable. **Acceptable level 8:** Localised change in sediment quality (between 1 km and 2 km from the discharge point located in the Project Area[1]) where physical characteristics of seafloor sediments will return to pre-drilling conditions within a year following completion of planned discharges (as defined in the OPP) containing chemical additives subject to Beach's chemical selection process is acceptable.	EPO16:	Implement CM28 Well design to ensure all wells to be drilled with WBDF, with SBDF only to be used where technical requirements preclude the use of WBDF.
	EPO17:	Implement CM29 Chemical selection process to ensure chemicals used are environmentally acceptable whilst also meeting technical requirements
	EPO18:	Implement CM30 Drilling fluid inventory to reduce or avoid discharge of bulk materials including excess powders, brines, and drilling fluids.
	EPO19:	Implement CM31 Solids control equipment to recover and reduce residual SBDF

Defined Acceptable Level	Environmental Performance Outcomes	
		content prior to overboard discharge, if SBDF is used.
	EPO20:	Implement CM32 Minamata convention to ensure drilling fluids will have concentrations of mercury and cadmium less than 1 mg/kg and 3 mg/kg respectively in stock barite (WBM and SBM)
Acceptable level 11: No impacts on unique seafloor habitats[2] to the south-east region, including deep-sea reefs, continental shelf habitats, seamounts canyons and kelp forests. **Acceptable level 12**: Impacts on benthic habitats and communities within the Project Area that are highly represented throughout the region and are not unique seafloor habitats is acceptable.	EPO21:	Defined well locations and immediate surrounds (<2 km from well location) within the Project Area will not contain unique seafloor habitats[2].
	EPO4:	Implement CM 10 Seabed assessments to identify seabed composition, benthic habitats and communities and ensure areas of unique seafloor habitats[2], maritime archaeology, UXOs, submerged cultural heritage and landscapes are avoided where practicable within technical and safety constraints.
Acceptable level 16: No impacts on underwater cultural heritage with values as conferred by the *Underwater Cultural Heritage Act 2018* (Cth). **Acceptable level 17**: No impacts on declared areas or objects of particular significance with values as conferred by the *Aboriginal and Torres Strait Islander Heritage Protection Act 1984* (Cth).	EPO5	No impact on underwater cultural heritage.
	EPO6:	Implement CM11 Cultural heritage assessments to identify any maritime archaeological and submerged cultural heritage and landscapes to inform protection priorities, and develop and implement management measures and reporting requirements, where required, to prevent potential impacts.

---

[1] Seabed disturbance from upper well section drilling fluids and cuttings discharges is expected to be within 1 km of the well location (RPS 2023). This area of disturbance is included in the total project seabed disturbance footprint (Table 6-5) as long-term seabed disturbance, where relevant acceptable levels and EPOs for seabed disturbance are defined in Section 6.2.6.

[2] Unique seafloor habitats of the south-east region including deep-sea reefs, continental shelf habitats, seamounts canyons and kelp forests (DNP, 2025).

6.8 **Planned Discharge – Cement**

6.8.1 Hazard Identification

Planned discharges including cement are to be discharged into the marine environment during the Project. The cement used in offshore drilling is typically a blend of Portland cement, water, and various additives that are designed to improve its performance under the high pressures and temperatures.

Relevant stages and associated activities that results in planned discharges of cement are defined below in Table 6-52and described in Section 6.8.2.

Table 6-52: Activities Undertaken During the Project Resulting in Planned Discharges - Cement

Stage	Activity
Drilling and completions	Drilling method
Operations	Well intervention and workovers
Decommissioning	Well plugging and abandonment

6.8.2 Hazard Description

6.8.2.1 Drilling and Completions

The Project plans to drill and develop 9 wells across VIC/P43 and, VIC/P73 within the scope of this OPP. These wells are planned to be drilled as exploration wells, and subject to success, will undergo completions to become development wells. Cementing fluids will be discharged during drilling of the 9 wells. Cement is used to form permanent barriers and fix casings in place during drilling operations. Cementing of the casings may result in the release of small amounts of cement (up to approximately 50 m^3 per well) to the seabed when the cement mixture is circulated to the seabed during grouting or when surplus fluids require disposal after cementing operations. During liner cement jobs, some excess cementing fluids will be circulated back to the surface and discharged to the sea. Cement discharged at the sea surface is expected to be a combination of cement slurry and wash water and will be a maximum of 70 m^3 per well, and an additional 25 m^3 at the final well location.

6.8.2.2 Operations

Well intervention and workovers may require the use of cement. If well intervention and workovers are required, cement discharges are not expected to exceed the volumes estimated for the drilling stage.

6.8.2.3 Decommissioning

During well plug and abandonment, cement and/or mechanical plugs may be set within the well to install a permanent reservoir and surface barrier.

During well plug and abandonment activities, cement discharges are not expected to exceed the volumes estimated for the drilling stage.

6.8.3 Impact Analysis and Evaluation

Planned discharges of cement to the marine environment have the potential to result in the following impacts:

- change in water quality
- change in sediment quality
- change in habitats and communities.

As a result of a change in water and sediment quality, further impacts may occur, which include:

- injury/mortality to fauna.

The potential impact of injury/mortality to fauna will be limited to the Project Area, as such receptors potentially affected are:

- plankton
- fish, marine mammals, and marine reptiles.

Changes to benthic habitats and communities also has the potential to result in indirect changes to the functions, interests, or activities of the following receptors:

- Commonwealth and state commercial fisheries
- cultural values and sensitivities.

6.8.3.1 Water quality

The surface discharge of cement can cause increased turbidity in the water column and result in a temporary change in surface water quality. However, cement particles are expected to disperse under the action of metocean conditions and eventually settle out of the water column. Cement slurry discharge from the rig is not expected to result in excessive turbidity as it will stick together and deposit rapidly to the seabed. BP (2013) modelled a large cement discharge of ~78m^3 over a one-hour period and found that, within two hours of discharge, suspended solid concentrations within the plume, which was 150 m horizontal and 10 m vertical, ranged between 5–50 mg/L. Four hours after discharge concentrations were <5 mg/L. The volume modelled is slightly greater than the maximum surface discharge volume predicted for the Drilling activities, therefore it is predicted that the concentration of suspended sediments would be lower within a localised area surrounding the discharge location.

The chief chemical components of Portland cement are calcium, silica, alumina and iron. Calcium is derived from limestone, marl or chalk, while silica, alumina and iron come from the sands, clays and iron ore sources. Other raw materials may include shale, shells and industrial by products such as mill scale. All these products are inert and will, therefore, pose little or no risk to the environment. Similarly, chemical additives used will be selected to ensure low risk to the environment.

Planned discharges of cement will occur at both the surface and seabed, but will occur in short periods, with no long-term or continuous discharges planned. This will allow water quality to quickly recover, with no long-term changes to ambient water quality expected. Temporary and localised changes to water quality have been evaluated as a Minor (1) consequence.

6.8.3.2 Sediment quality

Intermittent cement discharges will temporarily change sediment quality within the immediate surrounds of the discharge location. Changes in sediment quality includes the introduction and accumulation of contaminants and change in physical characteristics of seafloor sediments from subsea discharges of cement. Contaminants may accumulate within benthic sediment because of chemical additives within cement. However, cement is typically inert and is considered to pose little or no risk to the environment. CIN (2005) states that once cement has set it is essentially inert and not likely to have chronic toxicity effects.

The area of thickness for seabed deposition is dependent on a range of factors including:

- particle size distribution of cement

- water depth
- current speed and direction at varying depths

The environmental survey undertaken for the Otway Gas Development (Ramboll, 2020) concluded that sediments in the project area had a high ORP (oxidation-reduction potential) and low or undetectable levels of toxicants indicating an unmodified seabed environment. Cement discharged during the Project is expected to result in the greatest change in sediment quality. Deposition of sediments is expected to be highly localised around the well site (Neff 2005).

6.8.3.3 Benthic Habitats and Communities

It is estimated that approximately 50 m^3 of cement will be discharged to seabed per well which has the potential to smother and alter the benthic habitats and communities.

Cement discharged at the seabed is not expected to disperse as it is designed to set in a marine environment and will therefore set in-situ. BP (2013) modelled a 200 t (~83 m^3) cement discharge at the seabed and found changes to the benthic environment were limited to 10 m. Chevron (2018) indicated that planned cement discharges from overflow during drilling operations may affect the seabed around the well to a radius of ~10 – 50 m. This is an area of 0.007 km^2 for an individual well. For cement discharged in surface waters, modelling undertaken by de Campos et al. (2017) showed average deposition of 0.05 mg/m^2 of cement material on the seabed from a release of 18 m^3 of cement wash water. It is expected that benthic habitats and communities within 50 m of the discharge location has the potential to be smothered by deposition of cement from both surface and seabed cement discharges. Benthic habitats and communities within the Project Area are highly represented throughout the region. No species or ecological communities listed as threatened under the EPBC Act were observed. Therefore, the loss of 0.007 km^2 per well within the Project Area of benthic habitats and communities highly represented throughout the region is considered area very localised area of disturbance.

Given the change in benthic habitats and communities from cement discharges results in a very localised area of disturbance (within 50m of the well) in non-threatened benthic habitats highly represented throughout the region, the impact has been evaluated as a Minor (1) consequence.

6.8.3.4 Plankton

A reduction in water quality from increased turbidity caused by the discharge of cement slurry from surface waters within the Project Area will have a negligible effect on plankton populations at a measurable level.

Plankton have a patchy distribution linked to localised and seasonal productivity that produces sporadic bursts in populations (CoA, 2015c). Plankton distribution in the project area is expected to be highly variable both spatially and temporally and are likely to comprise characteristics of tropical, southern Australian, central Bass Strait and Tasman Sea distributions.

Jenkins and McKinnon (2006) reported that levels of suspended sediments greater than 500 mg/l are likely to produce a measurable impact upon zooplankton (larvae of most fish species and marine invertebrates) and levels of 100 mg/l where exposure occurs for greater than 96 hours may also affect the larvae of some species. Jenkins and McKinnon (2006) further indicate that levels of 100 mg/l may affect the larvae of several marine invertebrate species. It is understood that the zooplankton (such as egg and larval stages) are more vulnerable to suspended particles than other life stages. Modelling conducted by BP (2013) detailed that particulate concentrations within the cement discharge plume 2 hours after the start of discharge were in the 5-50 mg/l and 4 hours after the start of the discharge, the modelling indicates that the plume will have completely dispersed to particulate concentrations of less than 5 mg/l. Thus, impacts to plankton are not predicted.

A change in water quality as a result of cement discharges is unlikely to lead to injury or mortality of plankton at a measurable level and will not result in a change in the viability of the population or ecosystem dynamics during regional upwelling events or otherwise. Consequently, the temporary and localised loss of plankton, with no effects on plankton populations at a measurable level, from cement discharges has been evaluated as a Minor (1) consequence.

6.8.3.5 Fish, Marine Mammals and Marine Reptiles

A reduction in water quality through increased turbidity, caused by the cement discharges in the Project Area, will have negligible effects on fish, marine mammals, and marine reptiles. Cement is typically inert and is considered to pose little or no risk to the environment, and the cement plume from surface water discharge is expected to deposit rapidly to the seabed within four hours of discharge (BP 2013). Based on the low toxicity levels and short duration of the cement plume in the Project Area, there is no potential for acute or chronic exposure of fish, marine mammals, and marine reptiles from the low toxicity levels contained within a highly temporary cement plume. With no potential for acute or chronic exposure, the potential for injury or mortality to occur to these species is not credible.

6.8.3.6 Commonwealth and State Commercial Fisheries

Seabed discharges of cement have the potential to result in a change to benthic habitats and communities. This change is indirectly associated with commercially valued benthic species. Potential changes to commercially valued benthic species in the Project Area may then result in indirect changes to the functions, interests, or activities of Commonwealth and state commercial fisheries. There are two commercially fished marine benthic invertebrate species which are present within the Project Area which could be indirectly susceptible to discharges of cement: the giant crab, and the southern rock lobster (Section 4.5.11).

Southern rock lobster live in rocky reefs (VFA 2023b) a habitat unlikely to be disturbed by Project activities as rocky reefs are not an appropriate substrate for anchoring or drilling of a well. Giant crab have recorded movements up and down the continental shelf depending on food availability (Levings et al. 2001), where change to benthic habitats and communities in potential giant crab habitats in the Project Area potentially leading to emigration of the mobile biota to other areas along the continental shelf.

The extent of the impact is expected to be within 50 m of the discharge location (Section 6.8.3.3). Therefore, the impact from discharges of cement is likely to result in Minor (I) consequences to the functions, interests, or activities of Commonwealth and state commercial fisheries based on:

- Giant crab and southern rock lobster are mobile species and are generally less vulnerable than sessile taxa to sedimentation, as they are able to move to away from impacted benthic areas (Fraser et al. 2017).
- The Project Area intersects the following giant crab and southern rock lobster fisheries areas:

- Southern rock lobster
    - 14 of the 200 Victorian southern rock lobster reporting blocks (up to 20 active vessels – Figure 4-82).
    - The Project Area does not overlap the Tasmanian southern rock lobster reporting blocks.
- Giant crab
    - 9 of the 48 Victorian giant crab reporting blocks (up to 13 active vessels – Figure 4-78).
    - 1 of the 386 Tasmanian giant crab reporting blocks (confidential fishing effort due to less than 5 vessels being active within the fishery – Figure 4-85).

The southern rock lobster fishery has a stock status listed as sustainable for Victoria, Tasmania and South Australia (FRDC 2020). The giant crab fishery has a stock status listed as sustainable for Victoria and South Australia and depleted for Tasmania (FRDC 2020; 2020a). The depleted stock status for the Tasmanian giant crab fishery is based on data obtain from 2013-2014, and there has been insufficient data for the fishery since 2013 to determine if the stock is recovering (FRDC 2020a).

Based on the localised change in benthic habitats and communities (within 50 m of the discharge location), the disturbance footprint is considered negligible compared with the wider extent of available fishing grounds and the intermittent nature of drilling discharges, impacts to benthic species of commercial importance are predicted to be localised and insignificant at a population level.

As rock lobster live in rocky reefs (VFA 2023b) it is unlikely that their habitat would be disturbed as rocky reefs are not an appropriate substrate for anchoring or drilling of a well.

Seabed surveys will be undertaken to allow for the consideration of seabed habitat type in the final selection of well locations to avoid area of high relief outcrops, reefs or sponge beds.

The area of impact is predicted to be small compared to the extent of available and utilised commercial fishing areas for both the Victorian and Tasmanian giant crab and southern rock lobster fisheries.

6.8.3.7 Cultural values and Sensitivities

Impacts to First Nations values and sensitivities such as intangible spiritual connection or responsibility to whales, dolphins, seals, fish, and eels are not predicted as cement is inert and considered to pose little or no risk to the environment (OSPAR 2021) and the turbidity plume is temporary and suspended sediments are below levels where measurable impact upon plankton (larvae of most fish species) which are likely to be more sensitive than eels and whales, dolphins and seals may be present.

As detailed in Section 4.6, no First Nations underwater cultural heritage has been identified in the Project Area. However, First Nations people specifically Eastern Maar highlights that although the edge of the continental shelf is under sea, it was occupied for thousands of years and rising sea levels have not washed away the history, physical evidence, or connection to that part of Sea Country (Section 4.6.3.5). At present, oil and gas infrastructure exists across the Otway Basin and memories and songlines relating to the historical occupation of the present-day seabed are still acknowledged and recognised (Biosis 2023).

Intermittent cement discharges will result in localised change in benthic habitats and communities which may interact with unknown First Nations submerged cultural heritage and landscapes. To prevent potential interaction with First Nations submerged cultural heritage and landscapes in the Project Area, Beach has consulted with First Nations groups to define the management approach of intangible cultural heritage to prevent impacts and risks to environmental features that are associated with intangible cultural heritage (Australia ICOMOS Burra Charter, 2013). As per the draft Guidelines for Working in the Near and Offshore Environment to Protect Underwater Cultural Heritage (DCCEEW 2023) Beach has consulted with First Nations groups and relevant underwater culture heritage researchers and organisations to understand what data could be obtained from the seabed survey that will be undertaken prior to planned cement discharges and other seabed disturbing activities to identify First Nations submerged cultural heritage and submerged cultural landscapes. Data from seabed surveys will be provided to an appropriately qualified underwater archaeologist to identify submerged cultural heritage. Should any submerged cultural heritage be identified, Beach will consult with the relevant First Nations groups (see Section 4.6.2) and determine any exclusion areas or further cultural heritage management procedures that may be required. Thus, impacts to First Nations underwater cultural heritage are not predicted.

6.8.4 Impact Evaluation Summary

The impact evaluation for planned discharges of cement is summarised in Table 6-53.

Table 6-53: Impact Evaluation Summary for Planned Discharges - Cement

Summary	
Summary of impacts	Intermittent planned discharges of cement in surface waters and at the seabed is expected to result in temporary and localised changes to water quality, sediment quality, and benthic habitats and communities. These changes act as impact pathways to the localised injury and mortality of plankton and the potential interaction with First Nations submerged cultural heritage and landscapes in the Project Area. Data from seabed surveys will be provided to an appropriately qualified underwater archaeologist to identify submerged cultural heritage. Should any submerged cultural heritage be identified, Beach will consult with the relevant First Nations groups (see Section 4.6.2) and determine any exclusion areas or further cultural heritage management procedures that may be required to prevent interactions with First Nations submerged cultural heritage and landscapes. Together these impacts from intermittent discharges of cement will result in Minor (1) consequences with the application of adopted controls. The Minor (1) consequences are considered acceptable, given controls are in place to ensure potential impacts are better than the defined acceptable levels 1, 15, and 16.
Extent of impact	Localised – The greatest extent of impact is from change in sediment quality where localised changes are limited to within 50 m from the discharge location.
Duration of impact	Temporary - the longest impact duration is from change in benthic habitats and communities where the presence of the cement overflow is expected to exist until decommissioning.
Level of certainty	Impacts from planned discharges of cement are well understood and there is nothing new or unusual. There is high level of certainty on the predicted impacts from cement discharges, including: • Cement dispersion;

Summary	
	• toxicity of individual components within the cement; and • likely distribution of overspill on the seabed. Good practice is defined through the implementation of the following controls which ensures uncertainty is minimal: • Beach is committed to undertake seabed surveys and commission an appropriately qualified underwater archaeologist to identify submerged cultural heritage to avoid impacts to cultural values and sensitivities. Beach has long-term experience in the area on the application of good industry practice to ensure impacts associated with planned discharge of cement are acceptable.
Is the impact considered lower-order or higher-order?	Impacts from planned discharges of cement has been evaluated to result in Minor (1) consequences. Minor (1) consequences are considered lower-order impacts that is acceptable with the application of good industry practice.
Impact Consequence	
Minor	

6.8.5 Demonstration of Acceptability

Table 6-54 demonstrates how and why predicted environmental impacts from planned discharges of cement meets the defined acceptable levels (Table 5-4).

Table 6-54: Demonstration of Acceptability – Discharge of Cement

Demonstration of Acceptability		
Impact and risk comparison with relevant defined acceptable levels	Acceptable levels relevant to cement discharge includes acceptable levels 6, 7, 10, 11, 15, and 16 (as detailed in Table 5-4). A Minor (1) impact consequence level was assigned for this aspect based on the impact analysis and evaluation. Minor (1) consequences resulting from planned discharge – cement: • will contain chemical additives subject to Beach's chemical selection process • will result in a localised change in water quality (<2 km from discharge point located in the Project Area) which will return to baseline conditions following completion of planned discharges • will result in localised change in sediment quality (<2 km from the discharge point located in the Project Area) for sediments highly represented throughout the region from planned discharges • will not impact on unique seafloor habitats[2] to the south-east region, including deep-sea reefs, continental shelf habitats, seamounts canyons and kelp forests • will only impact on benthic habitats and communities within the Project Area that are highly represented throughout the region and are not unique seafloor habitats • will not impact on underwater cultural heritage with values as conferred by the *Underwater Cultural Heritage Act 2018* (Cth) • will not impact on declared areas or objects of particular significance with values as conferred by the *Aboriginal and Torres Strait Islander Heritage Protection Act 1984* (Cth). As a result, the predicted environmental impact for cement discharge is lower than the defined acceptable levels 6, 7, 10, 11, 15, and 16.	
ESD Principles	Integration principle	Section 6.8.3 identifies and evaluates environmental impacts associated with the discharge of cement. Conservation values and sensitivities, physical environment, ecological environment, socio-

Demonstration of Acceptability		
		economic values, and First Nations values and sensitivities described in Section 4 were reviewed to determine potential interactions of the aspect against each of these receptors they may result in environmental impact. As a result, consideration of economic, environmental, social and equitable receptors was conducted as part of identifying the impacts and risks. For Phase 1: Initial Project Consultation (Section 10.2.3), Beach consulted with relevant stakeholders on the Project and associated activities. No objections or claims were raised against this aspect during Phase 1: Initial Project Consultation. For Phase 2: Project OPP Public Comment Period (Section 10.2.4), the public had the opportunity to provide further comment to this OPP during the period (18/3/2024 – 20/5/2024). Beach prepared the public comment report summarising all comments, an assessment of the merits of each comment, a statement of the response to each comment, and an outline of any changes made to the OPP as a result of the comment (Appendix P). The assessment of merit for comments against this aspect found the response provided in the public comment report to be sufficient to address the comments against this aspect. Therefore, no further updates were required for this aspect. Given the thorough assessment and responses outlined in the public comment report, the impact evaluation for this aspect remains acceptable as is, demonstrating that public comments have been adequately addressed. The potential environmental impact against this aspect was assessed as having a Minor (1) consequences which is considered a lower-order environmental impact. Lower-order environmental impacts are considered 'broadly acceptable' and considered managed to an acceptable level by meeting relevant requirements (adopted controls as listed below).
	Precautionary principle	The potential environmental impacts against this aspect were assessed as having a Minor (1) consequences which is considered a lower-order environmental impact and below defined acceptable levels 6, 7, 10, 11, 15, and 16. Lower-order environmental impacts cannot result in serious or irreversible environmental damage. There is high confidence in the potential environmental impacts and effectiveness of controls against this aspect. Beach has significant experience operating in the Otway and Bass based on their existing offshore developments and associated activities including the Beach Otway Drilling Campaign in 2021/2022.
	Intergenerational principle	The defined acceptable levels were developed to meet the principles of ESD (Section 5.8.5). Given predicted environmental impacts due to the discharge of cement is lower than the acceptable levels 6, 7, 10, 11, 15, and 16; the health, diversity, or productivity of the environment for future generations is expected to be maintained.
	Biodiversity principle	Section 6.8.3 identifies and evaluates environmental impacts associated with the discharge of cement. As part of identifying the potential impacts, conservation values and sensitivities including MNES in Section 4 were reviewed.

Reports from each specialist evaluation of seabed assessment data will be provided to Beach. Beach will assess the reports and identify any areas of overlap, potential risks from Project activities, and determine any exclusion areas that may be required. **CM11 Cultural heritage assessments** Imagery and data from seabed surveys and assessments will be provided to appropriately qualified underwater archaeologists to identify any maritime archaeological and submerged cultural heritage and landscapes and inform protection priorities, management measures and reporting requirements. Should any maritime archaeological and submerged cultural heritage and landscapes be identified, Beach will report the findings in accordance with the *Underwater Cultural Heritage Act 2018*, and will consult with the relevant First Nations groups and determine any exclusion areas or further cultural heritage management procedures that may be required. **CM29 Chemical selection process** A process for chemical selection will be implemented to ensure chemicals used are environmentally acceptable whilst also meeting technical requirements. **CM33 Cementing program** Cementing programs shall be developed to reduce or avoid discharge of cement to the marine environment, including the reduction and avoidance of excess cement discharge upon completion of the drilling program.

6.8.6 Environmental Performance

In accordance with NOPSEMA's OPP Decision Making Guideline (NOPSEMA 2024), the EPO for this aspect (Table 6-) has been developed to be relevant to identified environmental impacts and risks, consistent with the principles of ESD and equivalent to or better than the defined acceptable level of impact. Control measures listed in Table 6-54 provides detail on how each control measure will be implemented for the Project to ensure the acceptable levels and EPOs, defined in Table 6- are met

Table 6-55: Environmental Performance Outcomes – Planned Discharge – Cement

Defined Acceptable Level	Environmental Performance Outcomes	
Acceptable level 7: Localised change in water quality (<2 km from discharge point located in the Project Area) which will return to baseline conditions following completion of planned discharges (as defined in the	EPO17:	Implement CM29 Chemical selection process to ensure chemicals used are environmentally acceptable whilst also meeting technical requirements

Defined Acceptable Level	Environmental Performance Outcomes	
OPP) containing chemical additives subject to Beach's chemical selection process is acceptable. **Acceptable level 8:** Localised change in sediment quality (between 1 km and 2 km from the discharge point located in the Project Area[1]) where physical characteristics of seafloor sediments will return to pre-drilling conditions within a year following completion of planned discharges (as defined in the OPP) containing chemical additives subject to Beach's chemical selection process is acceptable.	EPO22:	Implement CM33 Cementing program to reduce or avoid discharge of cement to the marine environment, including the reduction and avoidance of excess cement discharge upon completion of the drilling program.
Acceptable level 11: No impacts on unique seafloor habitats[2] to the south-east region, including deep-sea reefs, continental shelf habitats, seamounts canyons and kelp forests. **Acceptable level 12**: Impacts on benthic habitats and communities within the Project Area that are highly represented throughout the region and are not unique seafloor habitats is acceptable.	EPO21:	Defined well locations and immediate surrounds (<2 km from well location) within the Project Area will not contain unique seafloor habitats[2].
	EPO4:	Implement CM 10 Seabed assessments to identify seabed composition, benthic habitats and communities and ensure areas of unique seafloor habitats[2], maritime archaeology, UXOs, submerged cultural heritage and landscapes are avoided where practicable within technical and safety constraints.
Acceptable level 16: No impacts on underwater cultural heritage with values as conferred by the *Underwater Cultural Heritage Act 2018* (Cth). **Acceptable level 17**: No impacts on declared areas or objects of particular significance with values as conferred by the *Aboriginal and Torres Strait Islander Heritage Protection Act 1984* (Cth).	EPO5	No impact on underwater cultural heritage.
	EPO6:	Implement CM11 Cultural heritage assessments to identify any maritime archaeological and submerged cultural heritage and landscapes to inform protection priorities, and develop and implement management measures and reporting requirements, where required, to prevent potential impacts.

---

[1] Seabed disturbance from upper well section drilling fluids and cuttings discharges is expected to be within 1 km of the well location (RPS 2023). This area of disturbance is included in the total project seabed disturbance footprint (Table 6-5) as long-term seabed disturbance, where relevant acceptable levels and EPOs for seabed disturbance are defined in Section 6.2.6.

[2] Unique seafloor habitats of the south-east region including deep-sea reefs, continental shelf habitats, seamounts canyons and kelp forests (DNP, 2025).

6.9 **Planned Discharge – Commissioning and Operational Fluids**

6.9.1 Hazard Identification

Commissioning and operational fluids associated with drilling, commissioning, operations and decommissioning activities will be released to the marine environment. All planned discharges from commissioning and operational fluids will occur in the Project area.

Planned discharges from drilling activities including drilling muds and cements are discussed in Section 6.7 and Section 6.8 respectively. Operational waste discharges are discussed in Section 6.10.

Table summarises activities within the relevant activities that can result in commissioning and operational fluid discharges.

Table : Activities Undertaken During the Project which will Result in the Discharge of Subsea Equipment Discharges

Stage	Activity
Drilling	Blow-out preventer installation and function testing
Installation	Commissioning and Hydrotest
Operations	Valve actuation
Decommissioning	Plug and abandonment of wells

6.9.2 Hazard Description

6.9.2.1 Drilling and Decommissioning

During drilling (and well P&A), hydraulic control fluids will be released during BOP functioning and pressure testing. Function tests are generally undertaken every 7 days and will release ~ 2,200 L of potable water with 1 – 3% water-soluble control fluid. Pressure tests are generally undertaken every 21 days and may release small volumes of water-soluble fluids. In addition to this, BOP fluids are released whenever the riser is unlatched resulting in an additional release of fluids to the environment.

Hydraulic control fluids are water-based, low toxicity and readily biodegradable. On discharge they dilute rapidly in the open water environment to concentrations below which could possibly cause environmental harm. This means that their discharge into the marine environment will inherently have a minor impact to receptors, as any exposure will be short-lived and non-toxic, and chemicals will disperse quickly in the marine environment meaning that the potential timeframe for exposure will be short [**PC265**]. The extent of the impact is predicted to be within tens of metres from the MODU with a duration of hours whilst the BOP is being tested. The severity is assessed as less than Minor (1) and not discussed further, based on:

- BOP hydraulic fluid is of low toxicity, readily biodegradable and low potential for bioaccumulation.
- discharges will rapidly disperse in the marine environment.
- no sensitive resident receptors were identified within the area that may be affected.

6.9.2.2 Installation

Flowlines are filled with inhibited seawater and subjected to test pressures that will meet design code requirements, typically above any pressures seen during operation. Hydrotesting activities of flowlines will result in the release of treated seawater being released to the marine environment. Based conservatively on the maximum flowline diameter (12 inches), this would result in a discharge of approximately 5,700 m^3 of hydrotest fluid.

The chemicals added to the treated seawater will result in the discharge of residual chemicals to the marine environment. These chemicals may include biocides, dyes, corrosion inhibitors and scale inhibitors; these residual chemicals may result in a temporary decrease in water quality in the water column affected by the discharge. This decrease in water quality may result in impacts to marine biota, benthic habitats and sediments.

6.9.2.3 Operations

During the operations stage planned discharges from the actuation of subsea valves or maintenance and repair of hydraulic leads will result in the discharge of hydraulic fluid (~2 L). Based on the existing Otway Development it is estimate that the volume discharged from the additional Development valves would be ~ 4 m^3 per year. These fluids are typically low toxicity and biodegradable and would dissipate rapidly within the water column. Thus, impacts to water quality will be negligible and have not been discussed further.

6.9.2.4 Hydrotest discharge modelling

Beach commissioned a modelling study (RPS, 2023a) to better understand the potential fate of discharged hydrotest water in the environment; the report is provided as Appendix L. The modelling considered a 6,000 m^3 discharge of treated seawater over a period of 42.9 hours (140 m^3/hr), from a discharge outfall 2 m above the seafloor. The modelling study conservatively assumed a discharge volume of 120% of the longest potential flowline of 65 km between the prospect in the southern portion of the T/30P permit and Thylacine platform, being in the order of 6,000 m^3.

The discharge location was selected as the prospect in the southern portion of the T/30P permit as it is considered “worst-case” due to the higher sensitivity of the receiving environment, including the proximity to the Zeehan AMP. T/30P has since been removed from the scope of this OPP, however fate predictions of this modelling study are still considered a suitable and representative analogue for hydrotest discharges within the Project Area based on the conservative estimate provided by the parameters of the modelled location and the larger discharge volume.

The biocide concentration was the parameter modelled, as this component of the treated seawater has the greatest potential for environmental impacts. The modelling was based on the concentration of biocide at the time of discharge assumed to be 550 ppm; this is a conservative assumption as the actual concentration is expected to be significantly lower than this. The modelling also assumed the biocide is not consumed in the environment (i.e. it does not get consumed as it reacts with material); which is an additional conservative assumption upon which the modelling results are based.

An impact threshold of 1 ppm of biocide was defined; it was assumed that concentrations below this threshold would not result in significant environmental impacts. This threshold is consistent with published acute toxicity test data for aquatic species for typical biocides that may be used. For example, the Wheatstone Project Offshore Facilities and Produced Formation Water Discharge Management Plan: Stage 1 (Chevron, 2015) identified an acute toxicity threshold of 1 ppm for Hydrosure, a representative biocide product. The Safety Data Sheet for Hydrosure O-3670R states the 96-hour LC50 as 3.09 mg/L (3.09 ppm) for fish in marine waters, with a 48-hour EC5028 of 5.66 mg/L (5.66 ppm) for aquatic invertebrates (Champion Technologies, 2013). Sano et al (2005) assessed the potential toxicity effects of glutaraldehyde, another representative biocide, and reported a 24-hour LC50 of 4.7 mg/L (4.7 ppm) for the aquatic invertebrate *Ceriodaphnia dubia*. Note that ecotoxicological studies are typically undertaken using constant doses for periods ranging from 24 to 96 hours under controlled conditions. This approach is in contrast to the natural environment, where the concentration and exposure durations can vary widely. For the purpose of this assessment, selection of an impact threshold of 1 ppm provides a conservative basis to evaluate the potential effects of biocide in the receiving environment.

The near-field modelling results showed that treated seawater would initially project upward at a 45-degree angle due to diffuser orientation and high exit velocity. Once the plume lost momentum, the plume descended slightly till it was neutrally buoyant with the ambient water and then mixed laterally due to ambient currents. Given the negligible difference in the density of the hydrotest water and the ambient waters, the discharge plume remained above the seabed for all modelled scenarios. The far-field modelling results indicate that for the 99th and 100th-percentile analysis (i.e. 99% and 100% of the time), the maximum distances from the release location to the predicted dilutions of 1:550 (i.e. 1 mg/L which represents the impact threshold concentration/trigger value) contour were 20 m and 156 m, respectively (Figure 6-10). Based on the 95th percentile analysis (or 95% of the time), the 1:550 dilution was achieved very close to the release location (<20 m). The treated seawater will have the same water temperature and salinity as the surrounding seawater.

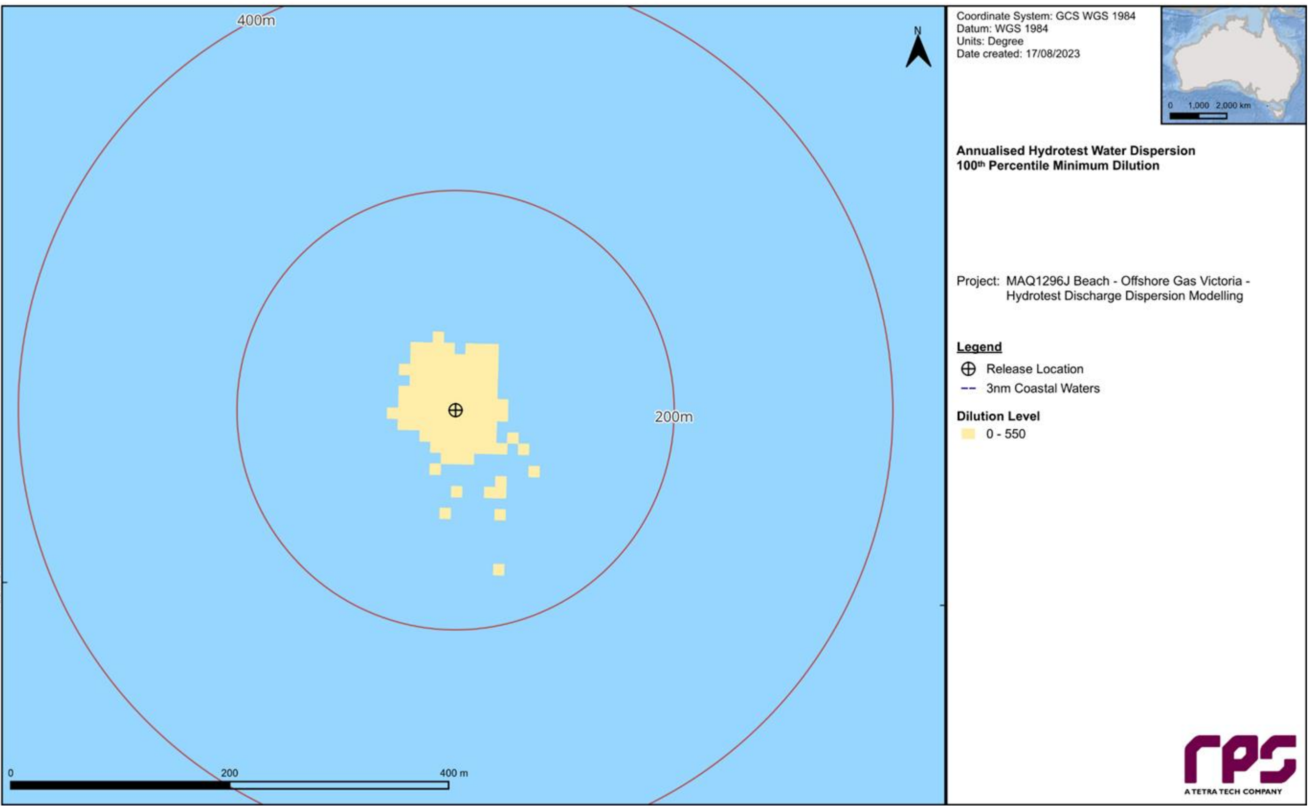

Figure 6-10: Predicted 100th-percentile Concentrations of the Hydrotest Discharge up until 550 Dilutions (1 ppm)

6.9.3 Impact Analysis and Evaluation

Planned discharges from commissioning and operational fluids to the marine environment have the potential to result in:

- change in water quality.

As a result of a change in water quality, further impacts may occur, including:

- injury/mortality to fauna.

The potential impact of injury/mortality to fauna will be limited to the Project Area, as such receptors potentially affected are:

- plankton
- fish, turtles, and marine mammals.

Hydrotest dispersion modelling (RPS, 2023a) indicates the dispersion plume (released 2 m from the seafloor) is neutrally buoyant with ambient sea water, driven upwards by discharge velocities. Given the similar densities of the hydrotest water to the surrounding water, the discharge plume remained predominately above the seabed for all modelled scenarios (RPS, 2023a). Due to there being no discernible impacts to water quality at or above the seabed, impacts to sediment quality and benthic habitats and communities have not been evaluated further.

Impacts to cultural and socio-economic receptors from commissioning and operational fluid discharges are not predicted, and have not been evaluated further, due to:

The discharge plume being restricted to the water column, without contacting surface or seabed features or commercially valued benthic species; and

The temporary nature of the plume and rapid dispersion by the open ocean environment.

6.9.3.1 Water Quality

Commissioning and operations discharges will include hydrotest and hydraulic fluids. These discharges are intermittent, non-continuous, and of short duration and may result in localised and temporary reduction in water quality during installation and commissioning, operations, and decommissioning phases of the Project. Based on operational experience, it is anticipated approximately 4 m^3 of hydraulic fluid will be released per year, from valve testing activities.

The hydrotest discharges from flowline commissioning activities, presents the worst-case for potential impacts to the marine environment. This discharge will result in localised and temporary reduction in water quality around the release location. As discussed in Section 6.9.2.4, the hydrotest modelling predicted the discharge plume will become neutrally buoyant in the water column and then mixed laterally with ambient currents. The plume is predicted to reach a maximum distance of 156 m from the release location to the 1 ppm threshold before dissipating in the water column to concentrations below the threshold.

Given the conservative volume modelled, high biodegradable rates of the chemical additives, and the high dispersion in the open, offshore environment, any reduction in water quality from the discharges is expected to be localised and short-term. Localised and short-term change to water quality from intermittent discharges of commissioning and operational fluids has been evaluated as a Minor (1) consequence.

6.9.3.2 Plankton

Intermittent planned discharges of commissioning and operational fluids have the potential to cause injury/mortality to plankton entrained within the discharge plume. Commissioning and operational fluids including hydrotest fluids contain residual chemicals, such as biocides, which have the potential to be acutely toxic to plankton. The acute toxicity threshold for Hydrosure (representative biocide) was defined as 1 ppm (Section 6.9.2.4). Hydrotest modelling predicted the resulting discharge plume to exceed the acute toxicity threshold at a maximum distance of 156 m from the release location before dissipating in the water column to concentrations below the threshold. It is anticipated that in the event sporadic distribution of plankton is present within the Project Area, non-consumptive mortality of plankton may occur if plankton is entrained within the discharge plume and exposed to acute toxicity levels of biocide. However, dilution of the plume is rapid and the concentration that the organism is exposed to will continually reduce with dispersion.

Plankton are widely distributed throughout the region, and, in the context of their lifecycle, impacts will be short term and negligible. Not all zooplankton are alive in the natural environment, non-consumptive mortality of zooplankton in marine habitats have been recorded from naturally occurring changes to oxygen layers, thermoclines, upwelling, and salinity gradients (Daase & Soreide 2021). As a result, zooplankton carcasses may play an important role in marine food webs as they may serve as nutritious food for benthic organisms (Daase & Soreide 2021). Consequently, the temporary and localised loss of plankton from planned discharge of commissioning and operational fluids will not significantly contribute to existing non-consumptive mortality of zooplankton naturally occurring in the marine habitats and therefore has been evaluated as a Minor (1) consequence.

6.9.3.3 Fish, Marine mammals, and Marine reptiles

A reduction in water quality through increased toxicity caused by the intermittent discharge of commissioning and operational fluids in the Project Area, will have negligible effects on fish, marine mammals, and marine reptiles.

Hydrotest fluids contain biocides at concentrations which are acutely toxic to smaller biota (such as plankton and algae) however are not acutely toxic to larger highly mobile marine fauna such as fish, marine mammals, and marine reptiles. Higher concentrations of biocide are required to elicit an effect on these larger species. For example, the Safety Data Sheet for Hydrosure O-3670R states the 96-hour LC50 for fish in marine waters as 3.09 mg/L (3.09 ppm). Therefore, for fish to receive a lethal concentration of biocide, individuals will need to remain within proximity to the discharge location for 96 hours for a 50% chance of mortality.

Based on the temporary and localised presence of the hydrotest discharge plume in the Project Area (Section 6.9.2.4), and the absence of habitats that encourages site fidelity and attachment for fish, marine mammals, and marine reptiles, there is no potential for acute or chronic exposure of these species to biocide concentrations contained within the discharge plume. With no potential for acute or chronic exposure, the potential for injury or mortality to occur to these species is not credible.

The discharge plumes are expected to be restricted within the Project Area (Section 6.9.2.4) and therefore will only overlap fish, marine mammal, and marine reptile BIAs relating to distribution (white shark), foraging (blue whale), and migration (southern right whale). These BIAs and the open offshore waters of the Project Area does not foster site fidelity or attachment for these species.

The Project Area overlaps the BIA distribution area for the white shark. No habitat critical to the survival of the white shark or behaviours were identified. The Recovery Plan for the White Shark (*Carcharodon carcharias*) (DSEWPaC, 2013c) does not identify waste discharges as a threat. As a result, the white shark is expected to be a highly mobile and transient species within the Project Area. The temporary exposure of toxicity levels from the hydrotest plume in the Project Area prevents acute or chronic exposure to transient white sharks, therefore, no injury or mortality is expected.

Three species of marine mammal listed as Vulnerable (sei whale, fin whale, humpback whale) and two species listed as Endangered (blue whale, southern right whale) are known or likely occur within the Project Area. The Project Area overlaps foraging and distribution BIAs for the pygmy blue whale and migration BIA for the southern right whale. The Conservation Management Plans for the Blue Whale (CoA, 2015b) and Southern Right Whale (DSEWPaC, 2012a) identifies acute and chronic chemical discharges as a threat mainly in relation to hydrocarbon spills and bioaccumulation of pollutants. Pollution (persistent toxic pollutions) is identified as a minor threat for the sei whale (Approved Conservation Advice for Balaenoptera borealis (Sei Whale) (TSSC, 2015e) and fin whale (Approved Conservation Advice for Balaenoptera physalus (Fin Whale) (TSSC, 2015d). Based on the low chance of bioaccumulation from exposure to the temporary hydrotest plumes in the Project Area, there is no potential for acute or chronic exposure of pollutants to marine mammals and therefore no injury or mortality is expected.

There are three marine turtle species with potential to be present, however no BIAs or habitat critical to the survival of the marine turtle species occur within the Project Area. The Recovery Plan for Marine Turtles in Australia, (CoA, 2017) identifies chemical and terrestrial discharge as a threat, although this is mostly in relation to pollution from agricultural, terrestrial industrial and domestic sources. The temporary exposure of toxicity levels from the hydrotest plume in the Project Area prevents acute or chronic exposure to transient marine reptiles, therefore, no injury or mortality is expected.

6.9.4 Impact Evaluation Summary

The impact evaluation for planned discharges of commissioning and operational fluids is summarised in Table 6-56.

Table 6-56: Impact Evaluations Summary for Planned Discharges – Commissioning and Operational Fluids

Summary	
Summary of impacts	Intermittent planned discharges of commissioning and operational fluids are expected to result in temporary and localised changes to water quality. This change acts as an impact pathway to the localised mortality of plankton if present within the Project Area. High dilution rates will reduce biocide concentrations to levels below thresholds required to elicit acute or chronic toxic effects to fish, marine mammals, and marine reptiles. The temporary and localised change to water quality and localised mortality of plankton will result in Minor (1) consequences that are considered acceptable, given controls are in place to ensure potential impacts are better than the defined acceptable level 1.
Extent of impacts	Localised – Hydrotest modelling predicted the resulting discharge plume to exceed the acute toxicity threshold at a maximum distance of 156 m from the release location before dissipating in the water column to concentrations below the threshold.
Duration of impacts	Temporary – the hydrotest plume is expected to dissipate rapidly in the water column from exposure to ambient water currents.

Summary	
Level of certainty	Impacts from planned discharges of commissioning and operational fluids are well understood and there is nothing new or unusual. There is high level of certainty on the predicted impacts from drill cuttings and fluids, including: Impact and fate in the environment based on Project specific modelling Toxicity of biocide within fluids Dilutions rates. Beach has long-term experience in the area on the application of good industry practice to ensure impacts associated with planned discharge of commissioning and operational fluids are acceptable.
Is the impact considered lower-order or higher-order?	Potential impacts from planned discharges of commissioning and operational fluids have been evaluated to result in Minor (I) consequences. Minor consequences are considered lower-order impacts that is acceptable with the application of good industry practice.
Impact Consequence	
Minor	

6.9.5 Demonstration of Acceptability

Table 6-57 demonstrates how and why predicted environmental impacts from planned discharges of commissioning and operational fluids meets the defined acceptable levels (Table 5-4).

Table 6-57: Demonstration of Acceptability – Planned Discharge – Commissioning and Operational Fluids

Demonstration of Acceptability		
Impact and risk comparison with relevant defined acceptable levels	The acceptable level relevant to planned commissioning and operational discharges is acceptable level 6 (as detailed in Table 5-4). A Minor (1) impact consequence level was assigned for this aspect based on the impact analysis and evaluation. Minor (1) consequences resulting from planned discharge – commissioning and operational fluids: • will contain chemical additives subject to Beach's chemical selection process • will result in a localised change in water quality (<2 km from discharge point located in the Project Area) which will return to baseline conditions following completion of planned discharges As a result, the predicted environmental impact for planned discharge – commissioning and operational fluids is lower than defined acceptable level 6.	
ESD Principles	Integration principle	Section 6.9.3 identifies and evaluates environmental impacts associated with planned commissioning and operational discharges. Conservation values and sensitivities, physical environment, ecological environment, socio-economic values, and First Nations values and sensitivities described in Section 4 were reviewed to determine potential interactions of the aspect against each of these receptors they may result in environmental impact. As a result, consideration of economic, environmental, social and equitable receptors was conducted as part of identifying the impacts and risks. For Phase 1: Initial Project Consultation (Section 10.2.3), Beach consulted with relevant stakeholders on the Project and associated activities. No objections or claims were raised against this aspect during Phase 1: Initial Project Consultation.

Demonstration of Acceptability		
		For Phase 2: Project OPP Public Comment Period (Section 10.2.4), the public had the opportunity to provide further comment to this OPP during the period (18/3/2024 – 20/5/2024). Beach prepared the public comment report summarising all comments, an assessment of the merits of each comment, a statement of the response to each comment, and an outline of any changes made to the OPP as a result of the comment (Appendix P). The impact assessment for this aspect has been updated to reflect the merit provided by public comment reference numbers PC265. As a result, the impact assessment now integrates responses to public comments of merit and therefore is of an acceptable level. The potential environmental impact against this aspect was assessed as having a Minor (1) consequences which is considered a lower-order environmental impact. Lower-order environmental impacts are considered 'broadly acceptable' and considered managed to an acceptable level by meeting relevant requirements (adopted controls as listed below).
	Precautionary principle	The potential environmental impacts against this aspect were assessed as having Minor (1) consequences which is considered a lower-order environmental impact and below defined acceptable level 6. Lower-order environmental impacts cannot result in serious or irreversible environmental damage. There is high confidence in the potential environmental impacts and effectiveness of controls against this aspect. Beach has significant experience operating in the Otway and Bass based on their existing offshore developments and associated activities including the Beach Otway Drilling Campaign in 2021/2022.
	Intergenerational principle	The defined acceptable levels were developed to meet the principles of ESD (Section 5.8.5). Given predicted environmental impacts due to planned commissioning and operational discharges is lower than the defined acceptable level 6; the health, diversity, or productivity of the environment for future generations is expected to be maintained.
	Biodiversity principle	Section 6.9.3 identifies and evaluates environmental impacts associated with planned commissioning and operational discharges. As part of identifying the potential impacts, conservation values and sensitivities including MNES in Section 4 were reviewed. Given predicted environmental impacts due to planned commissioning and operational discharges is lower than the defined acceptable level 6; no potential to affect biological diversity or ecological integrity is expected.
Internal context	Beach Policy compliance	The defined acceptable levels, EPOs and controls proposed for this aspect are consistent with Beach Environmental Policy objectives. As a result, potential environmental impacts and risks from Project can be managed to align with Beach Environmental Policy objectives.
External context	Stakeholder engagement is being carried out as part of this OPP process. Beach operates the existing Otway project and has established good relations with both onshore and offshore stakeholders. Engagement with stakeholders will continue throughout all aspects of the Project to build and maintain trust with stakeholders and the local community and minimise community and stakeholders concern and impacts where practicable. Planned discharges of commissioning and operational fluids are not predicted to impact stakeholders. During Phase 1: Initial Project Consultation (Section 10.2.3), no objections or claims were raised against this aspect.	

<table>
<tr><th colspan="2">Demonstration of Acceptability</th></tr>
<tr><td></td><td>During Phase 2: Project OPP Public Comment Period (Section 10.2.4), comments were raised against this aspect. The assessment of merit for these comments found this aspect to require updates. Changes to the OPP to address PC265 have been integrated into the impact evaluation for this aspect.
Any new guidance or advice in relation to this aspect will be assessed and incorporated into adaptive management plans prepared for activity specific EPs.</td></tr>
<tr><td>Other requirements</td><td>Other requirements associated with this aspect includes compliance with Australian legislative requirements.
Management of this aspect is aligned with the legislative requirements below.
<table>
<tr><th>Requirement</th><th>Demonstration</th></tr>
<tr><td>OPGGS Act 2006 (Cth)
Section 460(2) - a person carrying on activities in an offshore area under the permit must carry out those activities in a manner that does not interfere with the conservation of the resources of the sea and seabed to a greater extent than is necessary for the reasonable exercise of the rights and performance of the duties of the first person.</td><td rowspan="2">This requirement is addressed through the adoption of the following control measures:
CM29 Chemical selection process
A process for chemical selection will be implemented to ensure chemicals used are environmentally acceptable whilst also meeting technical requirements.
CM34 Hydrotest assessment
Hydrotest assessments will be detailed in the relevant activity specific EPs developed during the detailed engineering and design studies of the Project. The EPs will detail the hydrotesting requirements including the definition of discharge characteristics (i.e. chemical additives and concentrations), discharge locations and volumes, methodology and species impact thresholds</td></tr>
<tr><td>The following management plans or conservation advice identify pollution, habitat degradation or discharges as a threat:
• Recovery Plan for Marine Turtles in Australia, 2017-2027 (CoA, 2017)
• Approved Conservation Advice for <i>Dermochelys coriacea</i> (Leatherback Turtle) (DEWHA, 2008)
• Conservation Management Plan for the Blue Whale, 2015-2025 (CoA, 2015b)
• National Recovery Plan for the Southern Right Whale <i>Eubalaena australis</i> (DCCEEW, 2024o)
• Approved Conservation Advice for <i>Balaenoptera borealis</i> (Sei Whale) (TSSC, 2015d)
• Approved Conservation Advice for <i>Balaenoptera physalus</i> (Fin Whale) (TSSC, 2015e)</td></tr>
</table>
</td></tr>
</table>

6.9.6 Environmental Performance

In accordance with NOPSEMA’s OPP Decision Making Guideline (NOPSEMA 2024), the EPO for this aspect (Table 6-58) has been developed to be relevant to identified environmental impacts and risks, consistent with the principles of ESD and equivalent to or better than the defined acceptable level of impact. Control measures listed in Table 6-57 provides detail on how each control measure will be implemented for the Project to ensure the acceptable levels and EPOs, defined in Table 6-58 are met

Table 6-58: Environmental Performance Outcomes – Planned Discharge – Commissioning and Operational Fluids

Defined Acceptable Level	Environmental Performance Outcomes	
Acceptable level 6: Localised change in water quality (<2 km from discharge point located in the Project Area) which will return to baseline conditions following completion of planned discharges (as defined in the OPP) containing chemical additives subject to Beach's chemical selection process is acceptable.	EPO17:	Implement CM29 Chemical selection process to ensure chemicals used are environmentally acceptable whilst also meeting technical requirements
	EPO23:	Implement CM34 Hydrotest assessment to detail the hydrotesting requirements including the definition of discharge characteristics (i.e. chemical additives and concentrations), discharge locations and volumes, methodology and species impact thresholds.

6.10 **Planned Discharge – Routine Operational Wastes from Vessels**

6.10.1 Hazard Identification

MODU and vessel operations will generate routine operational waste that will be discharged to surface waters. Routine operational wastes include discharges of cooling water, brine, deck drainage, bilge water, sewage, grey water, and putrescible waste, into the sea. This is a standard practice in the maritime industry and commonly undertaken in Australian offshore waters. While routine vessel operations will necessitate the discharge of routine operational waste, these discharges are subject to IMO regulations so most will undergo treatment prior to discharge.

Relevant stages and associated activities that have the potential for routine operational wastes from vessels are defined below in Table 6-59 and described in Section 6.10.2.

Table 6-59: Activities Undertaken During the Project which will Discharge Routine Operational Waste from Vessels

Stage	Activity
Support activities	Vessel operations MODU operations

6.10.2 Hazard Description

6.10.2.1Support operations

The type and number of vessels in the Project Area at any one time, and the duration of presence, will differ depending on the project stage. For a single activity, there will be no more than three vessels operating simultaneously. The longest duration for a single activity requiring support vessel operations is 40 days to drill a single well utilising a MODU and two support vessels. For concurrent activities, five vessels could operate in the Project Area at any one time, for example, pipelay or diving/tie-in activities may occur concurrently during MODU positioning. Concurrent operations will be kept to a minimum and are unlikely to occur for more than 13 days.

MODU and vessels operating in the Project Area will generate and discharge routine operational waste. MODU and vessels operations undertaken for the Project will adhere to the Navigation Act 2012, MARPOL and the various Marine Orders (as appropriate to vessel class) enacted under this Act.

Table 6-60 provides volume estimates for routine operational wastes calculated based on the number of people on board (POB), with the exception of bilge. The volume of bilge discharge from the MODU and vessel can vary depending on operational activities, maintenance and cleaning practices, and weather and sea conditions. Australian regulations, specifically the *Marine Pollution Control Act 1973*, impose strict limits on the discharge of oily bilge water. The maximum allowable oil content in discharged bilge water is 15 parts per million (ppm). Though the specific volume of bilge discharge cannot be definitively determined, the MODU and vessel will employ best practices and adhere to rigorous regulatory standards to minimise the environmental impact of these operations.

Table 6-60: Estimated MODU and Vessel Routine Operational Waste Discharge Volumes

Discharge Type	**Quantity MODU (approximate) 140 POB**	**Quantity Vessel (approximate) 15 POB**
Cooling Water	4,800 m^3/d combined (Rig + single vessel)	
RO Brine	170 m^3/day combined (Rig + single vessel)	
Sewage & Grey water	63 m^3 / day (0.45 m^3 pp/day)	7 m^3 / day (0.45 m^3 pp/day)
Putrescible waste	280 kg / day (1-2 kg pp/day)	30 kg / day (1-2 kg pp/day)

1. A description of each of the routine operational waste streams are provided as follows:Cooling Water and Brine (Desalination Unit Waste)

Cooling water is seawater used for non-contact, once through cooling of various machinery on the vessels and MODU. Seawater is extracted through intakes and circulated through heat exchanges and then discharged at elevated temperatures back to the sea. Desalination unit waste is residual high-concentration brine, associated with the process of creating freshwater from seawater. The concentrate is similar to sea water in chemical composition, however, anion and cation concentrations are higher. Brine discharges are typically 20 to 50% higher in salinity than the intake seawater (depending on the desalination process used).

Both discharges may contain low concentrations of chemical additives such as scale inhibitors and biocides (typically chlorine) used to mitigate biofouling on condenser tubes and intake and discharge conduits. These chemicals are usually consumed during the inhibition process resulting in little or no residual chemicals remaining upon discharge.

2. Deck Drainage

Deck drainage refers to any wastewater generated from deck washing, spillage, rainwater, and runoff from drains, including drip pans and wash areas. When this water contacts oil-coated surfaces, the water becomes contaminated. Oil and grease are the primary pollutants identified in the deck drainage waste stream (USEPA 1993). In addition to oil, various other chemicals used in drilling operations might be present in deck drainage. Such chemicals could include drilling fluids, ethylene glycol, lubricants, fuels, biocides, surfactants, detergents, corrosion inhibitors, cleaners, solvents, paint cleaners, bleach, dispersants, coagulants, and any other chemical used in the daily operations of the facility (Dalton, Dalton, and Newport 1985).

Contaminated waters will drain to a bilge/slops tank for treatment prior to discharge. Chemical selection procedures will be used to control the use of deck washdown detergents.

3. Treated Bilge

Bilge water is a collective term for fluid which comes from machinery and storage areas. The bilge system is designed to safely collect, contain and dispose of oily water from hazardous areas so that discharge of hydrocarbons to the marine environment is avoided. These fluids may contain contaminants such as oil, detergents, solvents, chemicals and solid waste, typically at low levels.

Bilge water will be processed via an oil-in-water separator (OWS), before being discharged into the sea, to reduce any oily residue to below 15 ppm. Residual oil will be retained onboard for onshore disposal.

4. Sewage, Greywater and Putrescible Waste

Sewage is waste discharged from toilets and urinals and treated with a marine sanitation device. The discharge is subject to secondary treatment and consists of chlorinated effluent. Greywater is waste from sinks, showers, laundries, safety showers, eyewash stations, and galleys. This can include kitchen solids, detergents, cleansers, oil and grease. Putrescible waste refers to solid food waste.

Sewage, grey water and putrescible waste generated onboard the vessels and MODU are commonly discharged to the marine environment. Volumes will vary, however, based on activities it is estimated that between 5 – 15 m^3 of sewage and greywater and up to 1 m^3 of putrescible waste could be generated per day. This waste will be treated prior to discharge to the environment as per guidelines under the MARPOL 73/78 Annex IV and Protection of the Sea (Prevention of Pollution from Ships) Act 1983.

6.10.3 Impact Analysis and Evaluation

Planned discharges of routine operational wastes from vessels to the marine environment have the potential to result in:

- change in water quality.

As a result of a change in water quality, further impacts may occur, including:

- behavioural changes
- injury/mortality to fauna.

The potential impact of injury/mortality to fauna will be limited to the Project Area, as such receptors potentially affected are:

- plankton
- fish, turtles, and marine mammals.

Impacts to cultural and socio-economic receptors from planned discharges of routine operational wastes from vessels are not predicted, and have not been evaluated further, due to:

- The discharge plume being restricted to the water column, without contacting seabed features or commercially valued benthic species; and

The temporary nature of the plume and rapid dispersion by the open ocean environment.

6.10.3.1Water quality

Routine operational discharges from vessels into the marine environment will result in localised and temporary changes in water quality within the Project Area. These contaminants have the potential to impact waters surrounding the discharge point by:

- Elevated water temperature from cooling water discharges, predicted to be less than 11°C above ambient within 100 m (horizontally) of the discharge point, and 10 m vertically (Woodside 2014). Cooling water will be less dense than the ambient water and will tend to remain at the surface. In contrast brine water density is greater and will tend to sink through the water column. Discharge rates are relatively low and temperature and salinity differentials will breakdown rapidly in the receiving environment.

- Intermittently elevated nutrient levels from sewage, putrescible waste, and grey water discharges, limited to 500 m from the rig and vessels based on discharges from a conservative 400 POB fixed facility (NERA 2017). As the volume estimated to be discharged per day from the vessels and MODU are below this discharge level the use of 500 m as the extent of impact is reasonable and likely to be conservative.

- Elevated salinity levels and chemical additives from brine discharges, modelled by the US EPA as diluted 40-fold within 4 m with no ocean current (Woodside 2014).

- Intermittently elevated hydrocarbon levels within 100 m of bilge water discharge (Shell 2009), from deck drainage, engine oil, lubricants, fuel residues and other petroleum-based substances that may have leaked or spilled into the bilge. The concentration of any bilge or deck drainage discharge will rapidly fall below levels which could impact the marine environment.

Discharges from routine operational wastes from vessels are intermittent, low volume, low toxicity and on release to the environment will rapidly dilute by prevailing waves and currents to below no effect levels, resulting in only localised and temporary impacts to water quality. The maximum extent of potential impact to water quality is conservatively predicted to be within 500 m of the MODU or vessels resulting in a Minor (1) consequence. [**PC266**] The consequence is assessed as Minor (1) based on:

- Discharges will be of low toxicity with controls such as treatment and chemical assessment in place.

- Discharges will be intermittent and of a low volume and as the discharges are discharged into an open oceanic environment, they are predicted to mix rapidly with the surrounding waters returning to a pre-impacted state without any long-term impacts to water quality.

- Cumulative impacts from planned routine operational discharges from vessels may occur for short periods when support vessels are within 500 m of the rig, i.e. during resupply activities. The small quantities involved, and intermittent nature of the discharges are not predicted to increase the impact extent beyond 500 m based on discharges from a conservative 400 POB fixed facility (NERA 2017).

6.10.3.2Plankton

Changes to water quality as a result of routine operational discharges from vessels could result in behavioural change or injury / mortality of plankton within 500 m of the rig and vessels.

Without controls, these discharges can contain contaminants such as oil, heavy metals, and bacteria that can degrade water quality and therefore result in the loss of plankton from acute or chronic exposure to contaminants. However, these discharges are subject to IMO regulations so most will undergo treatment prior to discharge (Section 6.10.2.1). The maximum extent of potential impact to water quality is conservatively predicted to be within 500 m of the MODU or vessels. On release to the environment, they will rapidly dilute resulting in only localised and temporary impacts to water quality [**PC267**]. The change in water quality from these discharges can result in possible changes in behaviour, if plankton are attracted and habituate to elevated nutrient levels from sewage, putrescible waste, and grey water discharges as a food source. Change in water quality from these discharges can also result in injury/mortality, if plankton are acutely or chronically exposed to elevated temperatures, salinity, chemical additives and hydrocarbon levels.

Plankton, including early life stages of fish (embryos, larvae), would be most susceptible to toxic exposure from chemicals in routine operational discharges from vessels, as they are less mobile and therefore can become entrained and exposed in the discharge plume. However, negligible effects are expected given previous studies on wastewater discharges which show no elevation in contaminant levels above background concentrations in proximity to the discharge point (Woodside 2008; 2014; Shell 2009). Not all zooplankton are alive in the natural environment, non-consumptive mortality of zooplankton in marine habitats have been recorded from naturally occurring changes to oxygen layers, thermoclines, upwelling, and salinity gradients (Daase & Soreide 2021). As a result, zooplankton carcasses may play an important role in marine food webs as they may serve as nutritious food for benthic organisms (Daase & Soreide 2021). Consequently, the temporary and localised loss of plankton from routine operational discharges from vessels will not significantly contribute to existing non-consumptive mortality of zooplankton naturally occurring in the marine habitats.

Change in water quality as a result of routine operational discharges from vessels is unlikely to lead to injury or mortality of plankton at a measurable level and will not result in a change in the viability of the population or ecosystem dynamics during regional upwelling events or otherwise. Impacts are likely to be limited to:

- localised non-consumptive mortality of plankton from exposure to elevated temperatures, salinity, chemical additives and hydrocarbon levels

- temporary attraction of plankton to elevated nutrient levels from sewage, putrescible waste, and grey water discharges as a food source.

Consequently, the temporary and localised attraction and loss of plankton, with no effects on plankton populations at a measurable level, from routine operational discharges from vessels has been evaluated as a Minor (1) consequence.

6.10.3.3 Fish, Marine Mammals, and Marine Reptiles

Changes to water quality as a result of routine operational discharges from vessels could result in behavioural change or injury / mortality of fish, marine mammals, and marine reptiles within 500 m of the rig and vessels.

Without controls, these discharges can contain contaminants such as oil, heavy metals, and bacteria that can degrade water quality and therefore harm marine life. However, these discharges are subject to IMO regulations so most will undergo treatment prior to discharge (Section 6.10.2.1). The maximum extent of potential impact to water quality is conservatively predicted to be within 500 m of the MODU or vessels. On release to the environment, they will rapidly dilute resulting in only localised and temporary impacts to water quality [**PC267**]. The change in water quality from these discharges can result in possible changes in behaviour, if fish, marine mammals, and marine reptiles are attracted and habituate to elevated nutrient levels from sewage, putrescible waste, and grey water discharges as a food source. Change in water quality from these discharges can also result in injury/mortality, if fish, marine mammals, and marine reptiles are acutely or chronically exposed to elevated temperatures, salinity, chemical additives and hydrocarbon levels.

- The temporary and localised presence of the discharge plume in the marine environment will prevent acute and chronic exposure and therefore injury/mortality to fish, marine mammals, and marine reptiles is not predicted, based on:
- A distribution BIA for the white shark has been identified within the Project Area. Routine operational discharges from vessels are not identified as a threat in the Recovery Plan for the white shark (*Carcharodon carcharias*) (DSEWPaC 2013c). Sharks will be transient through the Project Area thus impacts are not predicted due to the low toxicity of discharges and rapid dilution as a result of oceanic conditions.
- No BIAs or protected habitat were identified for other fish species within the Project Area. Although a variety of fish species, including commercial species, maybe be present in the area, impacts are not predicted due to the low toxicity of discharges and rapid dilution as a result of oceanic conditions. In addition, the sporadic discharge of macerated food scraps over short durations and are not predicted to result in habituation to this food source.
- No BIAs or critical habitat were identified for marine turtles within the Project Area although some species may occur. Chemical and terrestrial discharge are identified as a threat in the Recovery Plan for Marine Turtles in Australia (CoA 2017b). However, due to the low toxicity of planned discharges and their rapid dilution as a result of oceanic conditions, along with the transient nature of these species within the area, impacts are not predicted to occur.
- The Project Area also overlaps foraging BIAs for albatross, petrel, and shearwater species. As impacts to plankton and fish species are not predicted due to the low toxicity of planned discharges and their rapid dilution as a result of oceanic conditions, impacts to foraging seabirds are not predicted. In addition, the sporadic discharge of macerated food scraps over short durations and are not predicted to result in habituation to this food source.

- The Project Area overlaps the pygmy blue whale foraging and distribution BIAs. Routine operational discharges from vessels are not identified as a threat to the recovery of pygmy blue whales within the Conservation Management Plan for the Blue Whale (DoE 2015). Marine pollution by acute and chronic chemical discharge is identified as a threat that has minor consequences to the population by only affecting individuals (DoE 2015). Due to the low toxicity of planned discharges and their rapid dilution as a result of oceanic conditions, impacts are not predicted to occur to foraging blue whales or krill that they forage on.

- The Project Area is within the southern right whale migration BIA. Routine operational discharges from vessels are not identified as a threat to the National Recovery Plan for the Southern Right Whale *Eubalaena australis* (DCCEEW 2024o). Marine pollution by acute and chronic chemical discharge is identified as a threat that has minor consequences to the population by only affecting individuals (DCCEEW 2024o). Chemical pollution from sewage and other discharges is identified as a threat to the species, particularly within coastal BIAs where regular exposure may occur. However, due to the low toxicity of planned discharges and their rapid dilution as a result of oceanic conditions, along with the transient nature of these species within the area, impacts are not predicted to occur.

Potential impacts are expected to be limited to temporary and localised behavioural changes of attraction to food sources to fish, marine mammals, and marine reptiles within 500 m of the discharge source. Consequently, the temporary and localised attraction of fish, marine mammals, and marine reptiles to routine operational discharges from vessels has been evaluated as a Minor (1) consequence.

6.10.4 Impact Evaluation Summary

The impact evaluation for planned discharges of routine operational wastes from vessels is summarised in Table 6-61.

Table 6-61: Impact Evaluations Summary for Planned discharges – Routine Operational Wastes from Vessels

Summary	
Summary of impacts	Routine operational wastes from vessels into the marine environment will result localised and temporary changes in water quality. Change in water quality can result in possible changes in behaviour, where elevated nutrient levels from sewage, putrescible waste, and grey water discharges act as a food source and temporarily attracts plankton, fish, marine mammals, and marine reptiles. Change in water quality from these discharges can also result in injury/mortality to plankton exposed to elevated temperatures, salinity, chemical additives and hydrocarbon levels. High dilution rates will reduce elevated temperatures, salinity, chemical additives, and hydrocarbon levels to levels below thresholds required to elicit injury/mortality from acute or chronic toxic effects to fish, marine mammals, and marine reptiles. The temporary and localised change to water quality; temporary behavioural changes to plankton, fish, marine mammals, and marine reptiles attracted to food sources; and localised mortality of plankton will result in Minor (1) consequences that are considered acceptable, given controls are in place to ensure potential impacts are better than the defined acceptable level 1.
Extent of impacts	Localised - The extent of discharge of routine operational wastes from vessels is expected to be within 500 m of the discharge point from the MODU and support vessels.

Summary	
Duration of impacts	Temporary - intermittent routine operational wastes from vessels is expected to dissipate rapidly in the water column from exposure to ambient water currents.
Level of certainty	Impacts from planned discharges of routine operational wastes from vessels are well understood and there is nothing new or unusual. There is high level of certainty on the predicted impacts from routine operational wastes from vessels, including: Impact and fate in the environment High biodegradable rates of the chemical additives Dilutions rates. Beach has long-term experience in the area on the application of good industry practice to ensure impacts associated with planned discharge of routine operational wastes from vessels are acceptable.
Is the impact considered lower-order or higher-order?	Impacts from routine operational wastes from vessels has been evaluated to result in Minor consequences. Minor consequences are considered lower-order impacts that is acceptable with the application of good industry practice.
Impact Consequence	
Minor	

6.10.5 Demonstration of Acceptability

Table 6-62 demonstrates how and why predicted environmental impacts from planned discharges of routine operational wastes from vessels meets the defined acceptable levels (Table 5-4).

Table 6-62: Demonstration of Acceptability – Planned Discharge – Routine Operational Wastes form Vessels

Demonstration of Acceptability		
Impact and risk comparison with relevant defined acceptable levels	The acceptable level relevant to planned discharges of routine operational wastes from vessels is acceptable level 6 (as detailed in Table 5-4). A Minor (1) impact consequence level was assigned for this aspect based on the impact analysis and evaluation. Minor (1) consequences resulting from planned discharge – routine operational wastes from vessels: • will contain chemical additives subject to Beach's chemical selection process • will result in a localised change in water quality (<2 km from discharge point located in the Project Area) which will return to baseline conditions following completion of planned discharges As a result, the predicted environmental impact for planned discharge – routine operational wastes from vessels is lower than defined acceptable level 6.	
Principles of ESD	Integration principle	Section 6.10.3 identifies and evaluates environmental impacts associated with wastewater and putrescible discharges. As part of identifying the potential impacts; conservation values and sensitivities, physical environment, ecological environment, socio-economic values, and First Nations values and sensitivities described in Section 4 were reviewed to determine potential interactions of the aspect against each of these receptors they may result in environmental impact. As a result, consideration of economic, environmental, social and

Demonstration of Acceptability		
		equitable receptors was conducted as part of identifying the impacts and risks. For Phase 1: Initial Project Consultation (Section 10.2.3), Beach consulted with relevant stakeholders on the Project and associated activities. No objections or claims were raised in Phase 1: Initial Project Consultation. For Phase 2: Project OPP Public Comment Period (Section 10.2.4), the public had the opportunity to provide further comment to this OPP during the period (18/3/2024 – 20/5/2024). Beach prepared the public comment report summarising all comments, an assessment of the merits of each comment, a statement of the response to each comment, and an outline of any changes made to the OPP as a result of the comment (Appendix P). The impact assessment for this aspect has been updated to reflect the merit provided by public comment reference numbers PC266 and PC267. As a result, the impact assessment now integrates responses to public comments of merit and therefore is of an acceptable level. The potential environmental impact against this aspect was assessed as having a Minor (1) consequences which is considered a lower-order environmental impact. Lower-order environmental impacts are considered 'broadly acceptable' and considered managed to an acceptable level by meeting relevant requirements (adopted controls as listed below).
	Precautionary principle	The potential environmental impacts against this aspect were assessed as having a Minor (1) impact consequence level which is considered a lower-order environmental impact and below defined acceptable level 6. Lower-order environmental impacts cannot result in serious or irreversible environmental damage. There is high confidence in the potential environmental impacts and effectiveness of controls against this aspect. Beach has significant experience operating in the Otway and Bass based on their existing offshore developments and associated activities including the Beach Otway Drilling Campaign in 2021/2022.
	Intergenerational principle	The defined acceptable levels were developed to meet the principles of ESD (Section 5.8.5). Given predicted environmental impacts due to wastewater and putrescible discharges is lower than the defined acceptable level 6; the health, diversity, or productivity of the environment for future generations is expected to be maintained.
	Biodiversity principle	Section 6.10.3 identifies and evaluates environmental impacts associated with wastewater and putrescible discharges. As part of identifying the potential impacts, conservation values and sensitivities including MNES in Section 4 were reviewed. Given predicted environmental impacts due to wastewater and putrescible discharges is lower than the defined

<table>
<tr><th colspan="3">Demonstration of Acceptability</th></tr>
<tr><td></td><td></td><td>acceptable level 6; no potential to affect biological diversity or ecological integrity is expected.</td></tr>
<tr><td>Internal context</td><td>Beach Policy compliance</td><td>The defined acceptable levels, EPOs and controls proposed for this aspect are consistent with Beach Environmental Policy objectives. As a result, potential environmental impacts and risks from Project can be managed to align with Beach Environmental Policy objectives.</td></tr>
<tr><td>External context</td><td colspan="2">Stakeholder engagement is being carried out as part of this OPP process.
Beach operates the existing Otway project and has established good relations with both onshore and offshore stakeholders. Engagement with stakeholders will continue throughout all aspects of the Project to build and maintain trust with stakeholders and the local community and minimise community and stakeholders concern and impacts where practicable.
Wastewater and putrescible discharges are not expected to result in impacts to stakeholders.
During Phase 1: Initial Project Consultation (Section 10.2.3), no objections or claims were raised against this aspect.
During Phase 2: Project OPP Public Comment Period (Section 10.2.4), comments were raised against this aspect. The assessment of merit for these comments found this aspect to require updates. Changes to the OPP to address PC266 and PC267 have been integrated into the impact evaluation for this aspect.
Any new guidance or advice in relation to this aspect will be assessed and incorporated into adaptive management plans prepared for activity specific EPs.</td></tr>
<tr><td>Other requirements</td><td colspan="2">Other requirements associated with this aspect includes compliance with Australian legislative requirements.
Management of this aspect is aligned with the legislative requirements below.
<table>
<tr><th>Requirement</th><th>Demonstration</th></tr>
<tr><td>Navigation Act 2012 (Cth)
Several Marine Orders (MO) are enacted under this Act which relate to offshore petroleum activities, including:
• MO 91: Marine pollution prevention – oil
• MO 95: Marine pollution prevention – garbage</td><td rowspan="3">This requirement is addressed through the adoption of the following control measures:
CM29 Chemical selection process
A process for chemical selection will be implemented to ensure chemicals used are environmentally acceptable whilst also meeting technical requirements.
CM35 Marine orders
All wastewater discharges will comply with relevant MARPOL 73/78, Navigation Act 2012, Protection of the Sea (Prevention of Pollution) Act 1983 and subsequent Marine Order requirements (as appropriate for vessel classification):
Marine Order 91 (Marine Pollution Prevention – Oil), which implements Annex I of MARPOL 73/78, including (as required by vessel class):
• Machinery space bilge/oily water shall have IMO-approved oil filtering equipment (oil/water separator) with an on-line OIW monitoring device</td></tr>

</table>

Demonstration of Acceptability		
	• Recovery Plan for Marine Turtles in Australia, 2017-2027 (CoA, 2017) • Approved Conservation Advice for *Dermochelys coriacea* (Leatherback Turtle) (DEWHA, 2008) • Conservation Management Plan for the Blue Whale, 2015-2025 (CoA, 2015b) • National Recovery Plan for the Southern Right Whale *Eubalaena australis* (DCCEEW, 2024o) • Approved Conservation Advice for *Balaenoptera borealis* (Sei Whale) (TSSC, 2015d) • Approved Conservation Advice for *Balaenoptera physalus* (Fin Whale) (TSSC, 2015e)	• OIW content to be less than 15 ppm prior to discharge. • A deck drainage system capable of controlling the content of discharges for areas of high risk of fuel/oil/grease or hazardous chemical contamination. • Valid International Oil Pollution Prevention Certificate. Marine Order 95 (Marine Pollution Prevention – Garbage), which implements Annex V of MARPOL 73/78, including: • Garbage management plan in place. • Garbage record book maintained onboard. Marine Order 96 (Marine Pollution Prevention – Sewage), which implements Annex IV of MARPOL 73/78, including (as required by vessel class): • a valid International Sewage Pollution Prevention Certificate, • an IMO-approved sewage treatment plant, • a sewage comminuting and disinfecting system, a sewage holding tank sized appropriately to contain all generated waste (sewage and grey water), • discharge of sewage will occur at a moderate rate while vessel is proceeding (more than 4 knots).

6.10.6 Environmental Performance

In accordance with NOPSEMA's OPP Decision Making Guideline (NOPSEMA 2024), the EPO for this aspect (Table 6-63) has been developed to be relevant to identified environmental impacts and risks, consistent with the principles of ESD and equivalent to or better than the defined acceptable level of impact. Control measures listed in Table 6-62 provides detail on how each control measure will be implemented for the Project to ensure the acceptable levels and EPOs, defined in Table 6-63 are met

Table 6-63: Environmental Performance Outcomes – Planned Discharge – Routine Operational Wastes from Vessels

Defined Acceptable Level	Environmental Performance Outcomes	
Acceptable level 6: Localised change in water quality (<2 km from discharge point located in the Project Area) which will return to baseline conditions following completion of planned discharges (as defined in the OPP) containing chemical additives subject to Beach's chemical selection process is acceptable.	EPO17:	Implement CM29 Chemical selection process to ensure chemicals used are environmentally acceptable whilst also meeting technical requirements

Defined Acceptable Level	Environmental Performance Outcomes	
	EPO24:	Implement CM35 Marine orders to manage routine discharges of operational wastes from vessels in accordance with Marine Orders 91 and 95.

7 Environmental Risk Evaluation – Unplanned Events

7.1 **Invasive Marine Species**

7.1.1 Hazard Identification

Invasive marine species (IMS) are non-native plants, animals and microorganisms that have been introduced, either intentionally or unintentionally, to a new marine environment and can establish and spread, causing harm to the local ecosystem, economy, and human well-being. Within Australia, over 250 exotic marine species have been introduced with most having little impact, but some species have become aggressive pests in certain locations (DoA 2019b). Typical habitats of the ten species currently listed on the Marine Pest website (DoA 2019b) are shallow marine water areas. Highly disturbed environments (such as marinas) are more susceptible to colonisation than open-water environments (Paulay et al. 2002).

Introductory pathways for IMS include:

- ship ballast water
- biofouling on vessel hulls' niche areas such as anchor lockers, bilges, sea chests or internal seawater systems (DAFF 2003)

All Project stages involving MODU and vessel operations therefore have the potential to introduce IMS. Vessels may be required to adjust their ballast during installation, loading and offloading operations to maintain stability, balance and trim. During the uptake of ballast water from the surrounding environment in an international or domestic location, it is possible for a vessel to take in water that contains planktonic biota, including holoplankton, gametes, spores and larvae. This biota may then be discharged at the vessel's new location during ballast water exchange. Activities associated with the Project that could result in the introduction, establishment and spread of IMS are identified in Table 7-1 and described in the subsections below.

Table 7-1: Activities Undertaken During the Project which could cause Unplanned Introduction, Establishment and Spread of IMS

Stage	Activity
Operations	Inspection, maintenance and repair
Decommissioning	Removal of subsea infrastructure Well plugging and abandonment
Support operations	MODU operations

	Vessel operations ROV operations

7.1.2 Hazard Description

7.1.2.1 IMS already established in the region

In the South-east Marine Region, 115 marine pest species have been introduced and an additional 84 have been identified as possible introductions, or 'cryptogenic' species (NOO 2002a). Several introduced species have become pests either by displacing native species, dominating habitats, or causing algal blooms.

IMS known to occur were identified from 'www.marinepests.gov.au' (DAFF 2024) in ports where the rig and support vessels may mobilise from are detailed in Table 7-2.

Table 7-2: Marine Pests known to occur in Ports Relevant to the Project

Marine Pest	Description	Portland	Melbourne
Asian date mussel (*Musculista senhousia*)	Prefers soft sediments in waters up to 20 m deep, forming mats and altering food availability for marine fauna.	✓	✓
Asian shore crab (*Hemigrapsus sanguineus*)	Established in Victoria. Asian shore crabs were detected in Port Phillip Bay in 2020. Generally found hard substrates in intertidal areas, under rocks, shells, debris, or artificial structures. Likely habitats include burrowed up to 30cm deep, hard, and soft surfaces, shallow waters, up to 30m deep.	-	✓
European fan worm (*Sabella spallanzanii*)	Can form dense colonies and consume vast amounts of food to the detriment of native species. It fouls infrastructure and can increase operating costs for industry. Likely habitats include burrowed up to 30cm deep, hard, and soft surfaces, shallow waters, up to 30m deep.	✓	✓
European shore crab (*Carcinus maenas*)	Prefers intertidal areas, bays, estuaries, mudflats, and subtidal seagrass beds, but occurs in waters up to 60 m deep. It is widespread across Victorian intertidal reef and common in Western Port.	-	✓
Japanese kelp (*Undaria pinnatifida*)	Occupies cold temperate oceanic waters up to 20 m deep, growing on rock, reef, stones, and artificial structures. It rapidly forms dense forests and overgrows native species. It first established in Port Phillip Bay in the 1980s (Parks Victoria 2020).	-	✓
Northern pacific seastar (*Asterias amurensis*)	Prefer soft sediment habitat, but also use artificial structures and rocky reefs, living in water depths usually less than 25 m (but up to 200 m water depths). It is thought to have been introduced through ballast water from Japan.	-	✓

7.1.2.2 Operations

Marine growth removal from subsea infrastructure may be required during inspection, maintenance and repair activities which are undertaken by ROV or divers from an appropriate vessel.

7.1.2.3 Decommissioning

Marine growth may be dislodged during the removal of subsea infrastructure including flowlines, umbilicals and subsea equipment.

7.1.2.4 Support operations

Support operations including MODU, ROV and support vessel operations have the potential to introduce IMS from the discharge of ballast water or biofouling. MODU operations are relevant to drilling and completions activities, well intervention and workovers and well plugging and abandonment. ROV operations may be conducted through all Project stages including inspection, maintenance and repair. Support vessels are relevant to all stages of the Project for purposes such as transporting fuel, waste and supplies, MODU towing, flowline and umbilical installation and decommissioning, and inspections, maintenance and repairs.

MODU, ROV and support vessels have the potential to host IMS and may be sourced internationally or domestically. During Project activities, support vessels will transit between the Project Area and domestic ports.

7.1.3 Risk Analysis and Evaluation

Successful IMS colonisation requires the following three stages (Marine Pest Sectoral Committee 2018):

- colonisation and establishment of the marine pest on a vector (vessel, equipment or structure) in a donor region (a home port, harbour or coastal project site where a marine pest is established)
- survival of the settled marine pests on the vector during the voyage from the donor to the recipient region
- colonisation (for example, by reproduction or dislodgement) of the recipient region by the marine pest, followed by successful establishment of a viable new local population.

The potential risk of an IMS being able to successfully establish itself will depend on depth, distance from the coast, water movement and latitude. The probability of successful IMS settlement and recruitment will decrease in well mixed, deep ocean waters away from coastal habitats (Geiling 2014). An IMS travelling through several latitudes will also have to survive significant temperature and salinity changes.

Establishment of IMS could result in the following risk events:

- Change in ecosystem dynamics which may include
    - reduction in native marine species diversity and abundance
    - displacement of native marine species

Potential changes in ecosystem dynamics may result in the following secondary risks:

- Socio-economic impacts on commercial fisheries

- Changes to conservation values of protected areas
- Changes to First Nations cultural values and sensitivities

7.1.3.1 Change in Ecosystem Dynamics

The introduction of IMS may result in the colonisation of IMS in the Project Area. If this event is realised this could result in a change in ecosystem dynamics which may include a reduction in native marine species diversity and abundance, displacement of native marine species. The change in ecosystem dynamics also has the potential to result in secondary effects such as socio-economic impacts on commercial fisheries, changes to conservation values of protected areas and First Nations cultural values and sensitivities. The consequence of a successful IMS colonisation event are considered to be Serious (3).

More than 250 marine species have been introduced into Australian waters from around the world. Many of these species remain inconspicuous, but a few have established large populations and become pests. It is estimated that one in each six to 10 introduced marine species will become a pest (DCCEEW 2024q). Typical habitats of the species currently listed on the Marine Pest website (DAFF 2024) are shallow marine water areas for example Portland and Port Phillip Bay.

The likelihood of a successful translocation and establishment of IMS event into a new environment depends on several factors. Water currents, upwellings, habitat type, water depth, wave exposure, water temperature, salinity and the distance from the coast are all natural dispersion barriers which have been shown to limit the successful establishment and reproduction of IMS populations (Forrest et al. 2009). Based on these factors, the probability of successful IMS settlement and recruitment decreases in well-mixed, deep ocean waters away from coastal habitats. IMS colonisation also requires a suitable habitat in which to establish itself, such as rocky and hard substrates or subsea infrastructure.

The Project Area contains natural dispersion barriers to prevent IMS colonisation such as water depths greater than 50 m, strong ocean currents and an open-water environment. The probability of successful IMS settlement and recruitment will decrease in well mixed, deep ocean waters away from coastal habitats (Geiling 2014) such as the Project Area. It has been found that highly disturbed environments (such as marinas) are more susceptible to colonisation than open-water environments, where the number of dilutions and the degree of dispersal are high (Paulay et al. 2002). Based on the requirements for successful IMS establishment, the Project Area does not present an environment that is typically favourable to IMS survival. The Project Area is in an open-water offshore environment influenced by strong ocean currents associated with the East Australian Current. Ocean currents in the Project Area are expected to flow up to 5 knots in summer and 2-3 knots in winter, with the area therefore considered a well-mixed high energy offshore environment. The Australian Government Bureau of Resource Sciences (BRS) established that the relative risk of an IMS becoming established around Australia decreases with distance from the coast. Modelling conducted by BRS (BRS 2007) estimates: 33% chance of colonisation at 3 nm, 8% chance at 12 nm, and 2% chance at 24 nm. There Project Area is approximately ~11 nm from the Victorian coast and therefore the risk of IMS colonisation is anticipated to be 8%. .The likelihood of IMS colonisation in the Project Area is expected to be Remote (A) given the Project Area contains natural dispersion barriers to prevent IMS colonisation.

Established marine pest species can deplete fishing grounds and aquaculture stock, with between 10% and 40% of Australia's fishing industry being potentially vulnerable to marine pest incursion. The Project Area presents unfavourable conditions for IMS colonisation, therefore the potential for secondary impacts such as socio-economic impacts on commercial fisheries, changes to conservation values of protected areas and changes to First Nations cultural values and sensitivities from IMS colonisation is also considered to be Remote (A).

Given the impact of a successful IMS colonisation event can significantly impact local species and thus change local epifauna and infauna populations permanently, which could also impact State and Commonwealth fisheries and alter conservation values and First Nations cultural values and sensitivities, the consequences have been evaluated as Serious (3). However, it is considered that the likelihood of such an event is Remote (A) due to the unfavourable conditions within the Project Area required for colonisation and the implementation of the Beach Domestic IMS Biofouling Risk Assessment Process in accordance with regulatory requirements to manage the introduction of IMS. In addition, there has been no IMS introductions from Beach's previous Otway Drilling Campaign and ongoing activities in the area.

7.1.4 Risk Evaluation Summary

The risk evaluation for the introduction of IMS is summarised in Table 7-3.

Table 7-3: Risk Evaluation Summary for Introduction of IMS

Summary	
Summary of risks	The introduction of IMS in the Project Area has a Low risk of IMS colonisation resulting in change in ecosystem dynamics and therefore also a Low risk of secondary effects to commercial fisheries, values of protected areas and First Nations cultural values and sensitivities. The consequence and likelihood levels to determine the Low risk is defined as follows. The consequences of a successful IMS colonisation event are considered to be Serious (3) such that it may result in the reduction in native marine species diversity and abundance, displacement of native marine species, socio-economic impacts on commercial fisheries and changes to conservation values of protected areas and First Nations cultural values and sensitivities. The likelihood of such an event occurring is Remote (A) given the Project Area contains natural dispersion barriers to prevent IMS colonisation, such that the area is primarily in water depths greater than 50 m, exposed to strong ocean currents and in an open-water environment located away from coastal habitats. Based on the potential Serious (3) consequences and Remote (A) likelihood, the risk of introduction and establishment of IMS is Low.
Extent and duration of risk	Localised (isolated locations if there is no spread) to widespread (if colonisation and spread occurs).
Level of certainty	Beach has a high level of certainty about the risk of IMS introduction. The threat posed by invasive marine species is well known and strict regulatory requirements are in place to control the risk. With these regulatory controls in place, we have a high level of certainty that project activities will not introduce invasive marine species.
Is the impact considered lower-order or higher-order?	Risks from IMS has been evaluated to be Low risk. Low risks are considered lower-order risks that is acceptable with the application of good industry practice.
Risk Assessment	

Consequence	Likelihood	Risk rating
Serious	**Remote**	**Low**

7.1.5 Demonstration of Acceptability

Table 7-4 demonstrates how and why the risk of the introduction of IMS meets the defined acceptable levels (Table 5-4).

Table 7-4: Demonstration of Acceptability – Introduction of IMS

Demonstration of Acceptability		
Impact and risk comparison with relevant defined acceptable levels	Acceptable level 4 is relevant to the introduction of IMS (as detailed in Table 5-4). A **Low** risk rating was assigned for this aspect based on the combination of Serious (3) potential consequence and Remote (A) event likelihood. By implementing control measures that satisfy legislative and other requirements, the occurrence of an unplanned establishment of IMS event will be prevented, thereby ensuring Acceptable level 4 is met and achieved. Refer below to list of control measures to be implemented to prevent such an event from occurring.	
Principles of ESD	Integration principle	Section 7.1.3 identifies and evaluates environmental hazards associated with the introduction of IMS. As part of identifying the potential risks; conservation values and sensitivities, physical environment, ecological environment, socio-economic values, and First Nations values and sensitivities described in Section 4 were reviewed to determine potential interactions of the aspect against each of these receptors they may result in environmental risk. As a result, consideration of economic, environmental, social and equitable receptors was conducted as part of identifying the impacts and risks. During Phase 1: Initial Project Consultation (Section 10.2.3) Beach consulted with relevant stakeholders for feedback in relation to the Otway project, the Project Area, environmental impact and risk evaluations, and the acceptability evaluation. No objections or claims were raised against this aspect during Phase 1: Initial Project Consultation (Section 10.2.4). The public, including relevant stakeholders, had the opportunity to provide further advice and responses for this OPP during the public consultation period (18/3/2024 – 20/5/2024). External context gained from the public consultation period allowed Beach to update the OPP. No public comment relating to this aspect was provided during the public consultation period. As a result, the risk assessment is considered acceptable to the public and therefore is of an acceptable level. The potential environmental impact against this aspect was assessed as having a Low risk which is considered a lower-order environmental risk. Lower-order environmental risks are considered 'broadly acceptable' and considered managed to an acceptable level by meeting relevant requirements (adopted controls as listed below).
	Precautionary principle	The potential environmental risks against this aspect were assessed as having a Low risk which is considered a lower-order environmental risk and below the defined acceptable level 4 . As a lower-order environmental risk there is confidence in the effectiveness of adopted

<table>
<tr><td></td><td></td><td colspan="2">control measures to prevent serious or irreversible environmental damage.
There is high confidence in the effectiveness of controls against this aspect. Beach has significant experience operating in the Otway and Bass based on their existing offshore developments and associated activities including the Beach Otway Drilling Campaign in 2021/2022.</td></tr>
<tr><td></td><td>Intergenerational principle</td><td colspan="2">The defined acceptable levels were developed to meet the principles of ESD (Section 5.8.5). This includes requirements to: - Carry a valid Ballast Water Management Plan (BWMP). - Submit a Ballast Water Report (BWR) through the Maritime Arrivals Reporting System (MARS). - If intending to discharge internationally sourced ballast water, submit BWR through MARS at least 12 hours prior to arrival. - If intending to discharge Australian sourced ballast water, seek a low-risk exemption through MARS. - Hold a Ballast Water Management Certificate (BWMC). - Ensure all ballast water exchange operations are recorded in a Ballast Water Record System (BWRS)
	OPGGS Act 2006 (Cth) Section 280 – requires that a person carrying on activities in an offshore area under the permit, lease, licence, authority or consent must carry out those activities in a manner that does not interfere with navigation or fishing (among others)	

7.1.6 Environmental Performance

In accordance with NOPSEMA's OPP Decision Making Guideline (NOPSEMA 2024), the EPO for this aspect (Table 7-) has been developed to be relevant to identified environmental impacts and risks, consistent with the principles of ESD and equivalent to or better than the defined acceptable level of impact. Control measures listed in Table 7-4 provides detail on how each control measure will be implemented for the Project to ensure the acceptable levels and EPOs, defined in Table 7- are met.

Table 7-5: Environmental Performance Outcomes: Introduction of IMS

Defined Acceptable Level	Environmental Performance Outcomes	
Acceptable level 4: Unplanned establishment of invasive marine species is unacceptable**.**	EPO25:	No introduction of a known or potential invasive marine species.

7.2 **Physical Presence – Interaction with Marine Fauna**

7.2.1 Hazard Identification

MODU, vessel and helicopter movements within the Project Area may result in unplanned interactions with marine fauna via MODU/vessel strike (collision with moving vessel or MODU and marine fauna) or bird strike (collision with helicopter and avifauna).

Activities undertaken during the Project which have the potential to result in unplanned interactions with marine fauna are identified in Table 7-6.

Table 7-6: Activities Undertaken During the Project with the Potential to Result in Unplanned Interactions with Marine Fauna

Stage	Activity
Drilling and Completions	MODU positioning

Stage	Activity
Support operations	Vessel operations Helicopter operations

7.2.2 Hazard Description

7.2.2.1 Drilling and Completions

1. MODU Positioning

A MODU will either mobilise to the Project Area with its own propulsion system or be towed into place by vessels and will only be present in the Project Area during drilling, well intervention and for decommissioning activities. MODU positioning will require a maximum of 2 support vessels on DP to tow and position the MODU into place within the Project Area. This process will take 9 to 13 days to complete depending on constraints and weather restrictions

Once the MODU is positioned within the Project Area it will primarily be stationary resulting in no potential for collision with marine fauna. The MODU will be present at each well location for 40 days before moving to the next well (maximum 9).

7.2.2.2 Support Operations

Vessel and helicopter operations will occur within the Project Area throughout the life of the Project.

The type and number of vessels in the Project Area at any one time, and the duration of presence, will differ depending on the project stage. For a single activity, there will be no more than three vessels operating simultaneously. The longest duration for a single activity requiring support vessel operations is 40 days to drill a single well utilising a MODU and two support vessels. For concurrent activities, five vessels could operate in the Project Area at any one time, for example, pipelay or diving/tie-in activities may occur concurrently during MODU positioning. Concurrent operations will be kept to a minimum and are unlikely to occur for more than 13 days.

Vessels undertaking petroleum activities described in this project will typically be holding station or travelling at speeds slower than typical shipping traffic, and therefore exhibit a lower risk of interactions with marine fauna.

Helicopters will be utilised as required, throughout the life of the project, primarily for crew change and medical evacuation. Helicopter operations are expected to be the greatest during drilling activities where 5-8 round trips per week are anticipated. No helicopter operations will be required for operational activities.

7.2.3 Risk Analysis and Evaluation

MODU, vessel and helicopter movements within the Project Area have the potential to result in:

- Injury / mortality to marine fauna.

The potential risk of injury/mortality to marine fauna will be limited to large marine fauna and birds within the Project Area, as such receptors potentially affected are:

- marine reptiles

- marine mammals
- seabirds and shorebirds.

The potential risk of injury/mortality to marine fauna also has the potential to result in indirect changes to the functions, interests, or activities of the following receptors:

- cultural values and sensitivities.

7.2.3.1 Marine Mammals

Five marine mammals were identified with biologically important areas and/or biologically important behaviours within the Project Area (Table 7-7). Two fur-seal species may occur within the Project Area according to the PMST (Appendix A)

Table 7-7: Marine Mammals with Biologically Important Behaviours within the Project Area

Species	Biologically Important Behaviour
Blue whale	Foraging, feeding or related behaviour known to occur within area.
	Foraging BIAs: foraging, known foraging area and annual high use area.
Fin whale	Foraging, feeding or related behaviour likely to occur within area.
	No BIAs
Pygmy right whale	Foraging, feeding or related behaviour may occur within area.
	No BIAs
Sei whale	Foraging, feeding or related behaviour likely to occur within area.
	No BIAs
Southern right whale	Migration BIA

Vessel collisions have the potential to result in injury/mortality to marine mammals, such as cetaceans and pinnipeds. Cetaceans and pinnipeds are naturally inquisitive species which are often attracted to offshore vessels, for example dolphins are commonly reported to 'bow ride'. The reaction of cetaceans to an approaching vessel is variable and unpredictable. Often species remain motionless whilst in the vicinity of a vessel, whereas others have been known to be curious, often approaching ships which have stopped or are slow moving. In general, they do not approach, and sometimes actively avoid, faster moving vessels (Richardson et al. 1995). For example, humpback whales have been shown to frequently change course to avoid a vessel after detection (WDCS 2006).

Vessel collisions with cetaceans occur more frequently in areas where high vessel traffic and cetacean habitat coincide (WDCS 2006). Peel et al. (2016) analysed the number of vessel collisions with cetaceans within Australian waters, stating at least 109 vessel collisions have been reported since 1840. However, the paper emphasises a lack of reporting as an issue in confirming exact numbers. Recorded instances of cetacean deaths due to vessel strikes indicate that they are much more likely to be associated with container ships and fast ferries (WDCS 2006). When vessels are stationary or slow moving, the risk of collision with cetaceans is extremely low, as the vessel's size and underwater noise 'footprint' will alert cetaceans to its presence and thus elicit avoidance.

The extent of the area of risk of interaction with marine mammals is within the Project Area and the risk could occur while Project activities are undertaken. The consequence is assessed as Minor (1) and likelihood as highly unlikely, and the resulting risk is Low based on:

- Minimising vessel collision is ranked as a high priority action within the Conservation Management Plans for the blue whale and southern right whale, and within the Conservation Advice for fin and sei whales.
- The foraging BIAs for the pygmy blue whale intersects with the Project Area. The Conservation Management Plan for the Blue Whale (CoA 2015b) details that vessel collisions will impede the recovery of blue whale populations if a sufficient number of individuals in the population lose reproductive fitness or are killed. A vessel strike to a whale is considered highly unlikely as it has not happened to date in 15 years of Beach's activities within the Otway Basin. It is further reduced by there being an appropriately qualified marine mammal observer on each support vessel to detect the presence of marine fauna and provide instruction to avoid collisions where feasible. (CM15, CM17, CM18: Whale Management Procedures).
- The Project Area is within a migration BIA of the southern right whale. The National Recovery Plan for the Southern Right Whale (DCCEEW 2024o) lists vessel strike collisions as a high-risk threat. The plan identifies managing, minimising and mitigating the threat of vessel strike as an action and notes that reducing ship strike mortality can be most easily done either by reducing vessel speed or by separating vessels and whales. As both these controls will be implemented, with the MODU and vessels being either stationary or operating at slow speeds (≤ 10 knots as per CM02: Vessel and MODU Operating Procedures) and vessels when transiting maintaining a distance of 300 m from a whale (CM15, CM17, CM18: Whale Management Procedures), reducing the likelihood of a strike. An appropriately qualified marine mammal observer will be present on each support vessel to detect the presence of marine fauna and provide instruction to avoid collisions where feasible (CM15, CM17, CM18: Whale Management Procedures).
- The Listing Advice for the Humpback Whale (DAWE 2022a) details that the species is no longer listed as Vulnerable and identifies vessel strike as a current impact not threatening or preventing population growth.
- The Recovery Plan for the Australian Sea-lion (DSEWPaC 2013d) identifies the need to investigate and mitigate other potential threats including vessel strike, to ensure that anthropogenic activities do not hinder the recovery of the species. An appropriately qualified marine mammal observer will be present on each support vessel to detect the presence of marine fauna and provide instruction to avoid collisions where feasible (CM15, CM17, CM18: Whale Management Procedures).
- Peel et al. (2016) reviewed vessel strike data (2000-2015) for marine species in Australian waters and identified that there were no vessel interaction reports during the period for Australia sea-lions, Australian or New Zealand fur- seals. There have been incidents of seals being injured by boat propellers, however all indications are rather than 'boat strike' these can be attributed to the seal interacting/playing with a boat, with a number of experts indicating the incidence of boat strike for seals is very low.
- A vessel strike to a marine mammal is considered highly unlikely as it has not happened to date in 15 years of Beach's activities within the Otway Basin.

- Rig and vessel movements in the Project Area will be low (≤ 10 knots as per CM02: Vessel and MODU Operating Procedures) which affords protection to fauna as the most severe injuries have been identified to be caused by vessels travelling faster than 14 knots (Jensen and Silber 2004, Laist et al. 2001).

- An appropriately qualified marine mammal observer will be present on each support vessel to detect the presence of marine fauna and provide instruction to avoid collisions where feasible as per CM15, CM17, CM18: Whale Management Procedures.

- Given the expected low likelihood of vessel strike, and if it did occur it will not affect the long-term recovery of marine mammal species in accordance with relevant conservation plans and advice.

7.2.3.2 Marine Reptiles

Three marine turtle species are likely or may occur within the Project Area, however, no BIAs or habitat critical to the survival of the species were identified according to the PMST (Appendix A).

Vessel strikes have been identified as a threat to marine turtles within the Recovery Plan for Marine Turtles in Australia (CoA 2017b). However, there is a limited amount of available data regarding vessel strike to fauna such as marine turtles; potentially due to a lack of vessel collisions being noticed, and a lack of reporting (Peel et al. 2016).

Marine turtles are most vulnerable to vessel collisions when they are either resting or returning to the surface to breathe. Studies have demonstrated that marine turtles spend limited time at the sea surface, approximately 3% to 6%, with dive times recorded from 15 to 60 minutes (Milton and Lutz 2003). A study on green turtles by Hazel (2009) found that individuals only exposed the dorsal-anterior part of the head above the water surface, and for never longer than two seconds.

Turtles can detect sound in water and will generally move from anthropogenic noise-generating sources, such as vessels, within their detection range (Popper et al. 2014). Studies have shown that the ability of turtles to respond and avoid vessels greatly depends on the speed of the vessel. In general, marine turtles are not able to avoid vessels when they are travelling faster than 4 km/h (2.2 knots) (Hazel 2009). The propagation characteristics of sound within the marine environment make it difficult for marine turtles to identify the direction of the source of vessel noise. Furthermore, individual noise from a vessel may be masked within areas of high vessel and other noise -generating activities use, which is likely to limit the ability of marine turtles to identify and avoid approaching vessels (Hazel 2009).

The extent of the area of risk of interaction with marine turtles is within the Project Area and the risk could occur while Project activities is undertaken. The consequence is assessed as Minor (1) and likelihood as highly unlikely, and the resulting risk is Low based on:

- The Recovery Plan for Marine Turtles in Australia (CoA 2017b) identifies vessel disturbance as a key threat but details that although the outcome can be fatal for individual turtles, boat strike (as a standalone threat) has not been shown to cause stock level declines.

- Three marine turtle species may occur within the Project Area, though no BIAs or habitat critical to the survival of the species were identified, and the presence of turtle species is expected to be of a transitory nature only.

- The presence of turtles in the Project Area and surrounds is considered unlikely, based on the following information provided in Section 4.4.9.5 [**PC229**]:
    - Green Turtles are predominantly found in Australian waters off the Northern Territory, Queensland, and Western Australian coastlines, with limited numbers in New South Wales, Victoria, and South Australia. There are no known nesting or foraging grounds for Green Turtles offshore Victoria; they occur only rarely in these waters (DoE 2023m) (Section 4.4.9.5.1).
    - This species (Leatherback Turtle) is an occasional visitor to the Otway shelf and has been sighted on a number of occasions during aerial surveys undertaken by the Blue Whale Study Group, particularly to the south-west of Cape Otway (CoA 2017a). (Section 4.4.9.5.2).
    - Loggerhead Turtles forage in all coastal states and the Northern Territory, but are uncommon in South Australia, Victoria, and Tasmania (CoA 2017a). Due to water depths, it is unlikely Loggerhead Turtle would be present in the Project Area but may be occasional visitors to the Planning Area (Section 4.4.9.5.3 Loggerhead Turtle).'
- A vessel strike to a turtle is considered highly unlikely as it has not happened to date in 15 years of Beach's activities within the Otway.
- An appropriately qualified marine mammal observer will be present on each support vessel to detect the presence of marine fauna and provide instruction to avoid collisions where feasible as per activity specific Whale Management Procedure.

The consequence of a strike on a single animal is not predicted to affect the overall population or recovery of marine turtles.

7.2.3.3 Seabirds and Shorebirds

A number of seabirds and shorebirds utilise the Otway region and may forage within or fly over the Project Area. BIAs for 10 species of seabirds overlap the Project Area and no habitats critical to the survival of a bird species were identified in the Project Area (refer to Section 4.4.9.4). However, considering the offshore location of the Project Area and the absence of roosting or nesting habitat individuals at potentially vulnerable life stages are not expected. Viola (2023) identified the following species that landed on a support vessel for the Beach Otway Drilling Campaign from March until 5 April 2022 and from 29 April until 31 May 2022:

- Australasian Pipit
- Brush bronzewing
- Galah
- Grey fantail
- Nankeen kestrel
- Rock dove

- Satin flycatcher
- Silvereye

No species were recorded as injured and all left the vessel within<24 h after arrival (Viola 2023).

Helicopters arriving to, or departing from, the Project Area have the potential to collide with birds, potentially result in injury/mortality. The risk of bird collision with helicopter operations is a safety consideration for flights to and from the MODU. The consequence of a helicopter bird strike varies and is influenced by the individual's seasonal distribution, body mass, flocking and flight behaviour, while the probability of a strike is related to the abundances of different bird species on or near the MODU.

The Wildlife Conservation Plan for Seabirds (CoA 2020a) recognises that seabirds are known to aggregate around oil and gas platforms in above average numbers due to night lighting, flaring, food concentrations and other visual cues (Wiese et al. 2001). While most interactions are harmless, some can be detrimental and may cause injury or death e.g. from collision or indirectly from depleted body reserves (Ronconi et al. 2015). Bird mortality has been documented due to collision with structures, and interactions with flaring activities (Wiese et al. 2021).

The extent of the area of risk of interaction with birds is within the Project Area and the risk could occur while the Project activities is undertaken. The consequence is assessed as Minor (1) and likelihood as possible, and the resulting risk is Low based on:

- The National Recovery Plan for Albatrosses and Petrels (2022) (CoA 2022) classifies marine infrastructure interactions including those associated with artificial light as having no risk category priority and affecting 'Nil' species in Australian jurisdiction.
- The National Recovery Plan for the Orange-bellied Parrot (DELWP 2016) identified as Critically Endangered, lists illuminated structures, and illuminated boats as potential barriers to migration and movement as a main threat. In 15 years of Beach's activities within the Otway and Bass an Orange-bellied parrot has not been reported on a vessel, rig, or platform.
- Albatross, petrels, shearwaters, and terns were identified to have foraging BIAs or foraging behaviour likely within the Project Area. In 15 years of Beach's activities within the Otway and Bass an albatross, shearwater or petrel has not been reported on a vessel, MODU or platform.
- The consequence of a strike on a single bird is not predicted to affect the overall population.

7.2.3.4 Cultural Values and Sensitivities

The following cultural values and sensitivities have been identified as potentially at risk from unplanned interaction with MODU, vessel and/or helicopters movements:

- Marine mammals
- Marine reptiles
- Seabirds and shorebirds

Noting that eels and fish are not identified at risk from MODU or vessel movements.

The marine fauna listed above are connected to places associated with songlines or connected to individuals through ceremony (Section 4.6). The connection of marine fauna to places or individuals are considered cultural intangible values.

MODU, vessel and/or helicopters movements have the potential unplanned interactions with marine fauna that have songlines, or spiritual connection to First Nations people. It is considered that risks to species at a population level may prevent First Nations people's obligations to maintain spiritual connections and care for culturally significant species and their habitat. As evaluated in Sections 7.2.3.1 to 7.2.3.3, potential risks to marine mammals, marine reptiles, and shorebirds and seabirds from unplanned interaction will not impact these species at a population level, any interactions would be expected to be individuals only.

Based on the potential risk of unplanned interaction to individual species of cultural value, the consequence is assessed as Minor (1) and likelihood as possible, and the resulting risk is Low.

7.2.4 Risk Evaluation Summary

The risk evaluation for interaction with marine fauna is summarised in Table 7-9.

Table 7-8: Risk Evaluation Summary for Physical Presence – Interaction with Marine Fauna

Summary		
Risk summary	An unplanned interaction with marine fauna event, resulting in injury or mortality to an individual marine mammal, marine reptiles or seabird or shorebird, has been evaluated as a Low risk. The consequence and likelihood levels to determine the Low risk is defined as follows. The consequence of injury or mortality to an individual marine mammal, marine reptile or seabirds or shorebird is assessed as Minor (1), given the loss of a single animal is not predicted to affect the overall population or recovery of the species. The likelihood of such an event occurring is Highly Unlikely as it has not happened to date in the 15 years of Beach's activities within the Otway Basin.	
Extent and duration of risk	Localised – limited to individuals interacting with vessel or helicopter operations. Temporary – Vessels and helicopters may periodically be present in the Project Area, creating a temporary risk.	
Level of certainty	Beach has a high level of certainty about the risks of unplanned interaction with marine fauna. The threat posed by vessel and helicopter collision is well known and strict regulatory requirements are in place to control the risk. With these regulatory controls in place, Beach has a high level of certainty that Project activities will not result in the injury or death of an individual marine mammal, marine reptile or seabird or shorebird from vessel or helicopter collision.	
Is the risk considered lower-order or higher-order	The risk of an unplanned interaction with marine fauna event has been evaluated to be Low. Low risks are considered lower-order risks that is acceptable with the application of good industry practice.	
Risk Assessment		
Consequence	Likelihood	Risk rating
Minor	**Highly unlikely**	**Low**

7.2.5 Demonstration of Acceptability

Table 7-9 demonstrates how and why the risk of interaction with marine fauna meets the defined acceptable levels (Table 5-4).

Table 7-9: Demonstration of Acceptability – Physical Presence – Interaction with Marine Fauna

Demonstration of Acceptability		
Impact and risk comparison with relevant and defined acceptable levels	Acceptable level 12 is relevant to the unplanned interaction with marine fauna (as detailed in Table 5-4). A **Low** risk rating was assigned for this aspect based on the combination of Minor (1) potential consequence and Highly Unlikely event likelihood. By implementing control measures that satisfy legislative and other requirements, the occurrence of an unplanned interaction with marine fauna event will be prevented, thereby ensuring that Acceptable level 12 is met and achieved. Refer below to list of control measures to be implemented to prevent such an event from occurring.	
Principles of ESD	Integration principle	Section 7.2.4 identifies and evaluates environmental risks associated with interaction with marine fauna. As part of identifying the potential risks; conservation values and sensitivities, physical environment, ecological environment, socio-economic values, and First Nations values and sensitivities described in Section 4 were reviewed to determine potential interactions of the aspect against each of these receptors they may result in environmental risk. As a result, consideration of economic, environmental, social and equitable receptors was conducted as part of identifying the impacts and risks. For Phase 1: Initial Project Consultation (Section 10.2.3), Beach consulted with relevant stakeholders on the Project and associated activities. No objections or claims were raised in Phase 1: Initial Project Consultation. For Phase 2: Project OPP Public Comment Period (Section 10.2.4), the public had the opportunity to provide further comment to this OPP during the period (18/3/2024 – 20/5/2024). Beach prepared the public comment report summarising all comments, an assessment of the merits of each comment, a statement of the response to each comment, and an outline of any changes made to the OPP as a result of the comment (Appendix P). The impact assessment for this aspect has been updated to reflect the merit provided by public comment reference number PC229, PC301 and PC314. As a result, the impact assessment now integrates responses to public comments of merit and therefore is of an acceptable level. The potential environmental risk against this aspect was assessed as having a Low risk level which is considered a lower-order environmental risk. Lower-order environmental risks are considered 'broadly acceptable' and considered managed to an acceptable level by meeting relevant requirements (adopted controls as listed below).
	Precautionary principle	The potential environmental risks against this aspect were assessed as having a Low risk level which is considered a lower-order environmental risk and below the defined acceptable level 12. Lower-order environmental risks cannot result in serious or irreversible environmental damage. There is high confidence in the potential environmental impacts and risks and effectiveness of controls against this aspect. Beach has significant experience operating in the Otway and Bass based on their existing offshore developments and associated activities including the Beach Otway Drilling Campaign in 2021/2022.

<table>
<tr><td></td><td>Intergenerational principle</td><td>The defined acceptable levels were developed to meet the principles of ESD (Section 5.8.5). Given predicted environmental impacts due to interaction with marine fauna is lower than the defined acceptable level 12; the health, diversity, or productivity of the environment for future generations is expected to be maintained.</td></tr>
<tr><td></td><td>Biodiversity principle</td><td>Section 7.2.4 identifies and evaluates environmental risks associated with interaction with marine fauna. As part of identifying the potential impacts and risks; conservation values and sensitivities including MNES in Section 4 were reviewed.
The potential risks against this aspect were assessed as having a Low risk ranking which is considered a lower-order environmental risk and can be managed to meet the defined acceptable level 12. Lower-order environmental risks cannot result in affects to biological diversity or ecological integrity.</td></tr>
<tr><td>Internal context</td><td>Policy compliance</td><td>The defined acceptable levels, EPOs and controls proposed for this aspect are consistent with Beach Environmental Policy objectives. As a result, potential environmental impacts and risks from Project can be managed to align with Beach Environmental Policy objectives.</td></tr>
<tr><td>External context</td><td colspan="2">Stakeholder engagement is being carried out as part of this OPP process.
Beach operates the existing Otway project and has established good relations with both onshore and offshore stakeholders. Engagement with stakeholders will continue throughout all aspects of the Project to build and maintain trust with stakeholders and the local community and minimise community and stakeholders concern and impacts where practicable.
During Phase 1: Initial Project Consultation (Section 10.2.3), no objections or claims were raised against this aspect.
During Phase 2: Project OPP Public Comment Period (Section 10.2.4), comments were raised against this aspect. The assessment of merit for these comments found this aspect to require updates. Changes to the OPP to address PC229, PC301 and PC314 have been integrated into the impact evaluation for this aspect.
Any new guidance or advice in relation to this aspect will be assessed and incorporated into adaptive management plans prepared for activity specific EPs.</td></tr>
<tr><td rowspan="4">Other requirements</td><td colspan="2">Other requirements associated with this aspect includes compliance with Australian legislative requirements.
Management of this aspect is aligned with the legislative requirements below.</td></tr>
<tr><td>Requirement</td><td>Demonstration</td></tr>
<tr><td>**National Strategy for Reducing Vessel Strikes on Cetaceans and other Marine Megafauna (DoEE, 2017c).**
Vessel movements will be aligned to ‘Objective 3: Mitigation’ of the Strategy by:
• maintaining separation of vessels and whales
• maintaining slow vessel speeds
• avoidance manoeuvres</td><td rowspan="2">This requirement is addressed through the adoption of the following control measures:
CM14 EPBC Regulations 2000 – Part 8 Division 8.1 interacting with cetaceans
• Vessels will adhere to EPBC Regulations 2000 – Part 8 Division 8.1 interacting with cetaceans in relation to distances to cetaceans.
• Helicopters will adhere to EPBC Regulations 2000 – Part 8 Division 8.1 interacting with cetaceans in relation to distances to cetaceans</td></tr>
<tr><td>**OPGGS Act 2006 (Cth)**
Section 460(2) - a person carrying on activities in an offshore area under the permit must carry out those activities in a manner that does not interfere with the conservation of the resources of the sea and seabed to a greater extent than is necessary</td></tr>
</table>

	for the reasonable exercise of the rights and performance of the duties of the first person.	
	The following management plans or conservation advice identify vessel or aircraft strike as a threat: • Wildlife Conservation Plan for Migratory Shorebirds (CoA, 2015a) • National Recovery Plan for Albatrosses and Petrels 2022 (CoA, 2022) • Recovery Plan for Marine Turtles in Australia, 2017-2027 (CoA, 2017) • Approved Conservation Advice for *Dermochelys coriacea* (Leatherback Turtle) (DEWHA, 2008) • Conservation Management Plan for the Blue Whale, 2015-2025 (CoA, 2015b) • Approved Conservation Advice for *Balaenoptera borealis* (Sei Whale) (TSSC, 2015e) • Approved Listing Advice *Megaptera novaeangliae* (Humpback Whale) (TSSC, 2022) • National Recovery Plan for the Southern Right Whale *Eubalaena australis* (DCCEEW, 2024o) • Approved Conservation Advice for *Balaenoptera physalus* (Fin Whale) (TSSC, 2015d) • Recovery Plan for the Australian sea -lion (*Neophoca cinerea*) (DSEWPaC, 2013d)	

7.2.6 Environmental Performance

In accordance with NOPSEMA's OPP Decision Making Guideline (NOPSEMA 2024), the EPO for this aspect (Table 7-) has been developed to be relevant to identified environmental impacts and risks, consistent with the principles of ESD and equivalent to or better than the defined acceptable level of impact. Control measures listed in Table 7-9 provides detail on how each control measure will be implemented for the Project to ensure the acceptable levels and EPOs, defined in Table 7- are met

Table 7-10: Environmental Performance Outcomes – Physical Presence – Interaction with Marine Fauna

Defined Acceptable Level	Environmental Performance Outcomes	
Acceptable level 12: Death or injury to listed threatened, migratory or cetacean species from unplanned interactions with marine fauna is unacceptable.	EPO7:	No death or injury to listed threatened or migratory species from Project activities.

7.3 **Accidental Discharge – Hazardous and Non-Hazardous Materials**

7.3.1 Hazard Identification

Small quantities of hazardous and non-hazardous materials are used during routine vessel and MODU operations, and consequently result in waste generation which requires handling and storage on vessels and the MODU. Non-hazardous materials could be accidentally dropped or blown overboard due to overfull bins, crane incidents or improper storage or handling throughout Project phases. Hazardous waste may also be accidentally dropped or lost overboard as a result of leaks, overfilling of tanks or emergency disconnection of hoses.

Table 7-11 summarises activities within the Project stages that could result in the accidental release of hazardous and non-hazardous materials.

Table 7-11 Activities Undertaken During the Project which may Result in the Accidental Release of Hazardous and Non-hazardous Materials

Stage	Activity
Drilling and completions	Blow-out Preventer Installation and Function testing
Installation and commissioning	Installation
Operations	Inspection, maintenance and repair
Decommissioning	Decommissioning
Support operations	MODU operations Vessel operations ROV and AUV operations

7.3.2 Hazard Description

7.3.2.1 Drilling and Completions

Subsea infrastructure (non-hazardous), such as the BOP, have the potential to be accidentally dropped from support vessels or the MODU during drilling.

7.3.2.2 Installation and Commissioning

Subsea infrastructure (non-hazardous) including trees, manifolds, spools, jumpers and stabilisation materials will be installed under the scope of the OPP. These objects have the potential to be accidentally dropped from support vessels during installation.

7.3.2.3 Operations

1. Inspection, Maintenance and Repair

Objects (non-hazardous) such as small tools have the potential to be accidentally dropped from support vessels during IMR activities.

7.3.2.4 Decommissioning

Removal of subsea infrastructure (non-hazardous) such as trees, manifolds and spools, is the base case for decommissioning. These objects, or parts of, have the potential to be accidentally dropped during recovery.

7.3.2.5 Support Operations

An accidental LOC of hydrocarbons, chemicals or non-hazardous waste during support operations may occur due to:

- deck spills and a loss of primary containment.
- equipment failure including rupture, line failure, bunding and lifting equipment.
- dropped objects from supply cranes.
- bulk transfer failure between supply vessels and the MODU or project vessels.

Deck spills from vessels or the MODU may occur from mishandling or human error, poor handling processes, mechanical integrity failures and inadequate hazard analysis. Typical deck spills will be captured by onboard drainage systems, where liquids are diverted to a bilge tank (or similar), where it can be treated or transported onshore for proper disposal.

7.3.3 Risk Analysis and Evaluation

In the event of a loss of material or waste overboard, injury/mortality to fauna could occur.

In the event hazardous decommissioning waste is incorrectly disposed of onshore, contamination of air, soil and water at onshore facilities could occur.

Loss of material or waste overboard could occur within the Project Area potentially impacting:

- Sharks, seabirds, marine reptiles, and marine mammals.

These marine fauna species are values of the following within the Project Area:

- Conservation values and sensitivities
- Cultural values and sensitivities

Incorrect disposal of hazardous decommissioning waste onshore results in indirect contamination of air, soil, and water at the disposal site/facility. No impacts on valued species or habitats within the Project Area is expected.

In the event of a loss of material or waste overboard, potential risks are limited to within the Project Area.

7.3.4 Marine Fauna

The Threat Abatement Plan for the Impacts of Marine Debris on Vertebrate Wildlife of Australia’s Coasts and Ocean (CoA 2018) details harmful marine debris impacts on a range of marine life, including protected species of birds, sharks, turtles, and marine mammals. Harmful marine debris refers to all plastics and other types of debris from domestic or international sources that may cause harm to vertebrate marine wildlife. This includes land sourced plastic garbage (e.g. bags, bottles, ropes, fibreglass, piping, insulation, paints, and adhesives), derelict fishing gear from recreational and commercial fishing activities and ship-sourced, solid non-biodegradable floating materials lost or disposed of at sea.

Solids accidently released to the marine environment may lead to injury or death to individual marine fauna through ingestion or entanglement. Impacts will be restricted in exposure and quantity and will be limited to individual fauna.

A distribution BIA for the white shark has been identified within the Project Area. The Recovery Plan for the White Shark (DSEWPaC 2013c) does not identify waste or marine debris as a threat. White shark presence within the Project Area is expected to be transitory in nature.

Three marine turtle species (or species habitat) may occur within the Project Area though no BIAs or critical habitat to the survival of the species were identified. The Recovery Plan for Marine Turtles in Australia (CoA 2017b) identified marine debris as a threat.

The Project Area also overlaps foraging BIAs for albatross, petrel, and shearwater species. Marine debris is identified as a threat in the National Recovery Plan for Albatrosses and Petrels 2022 (CoA 2022).

Five marine mammals were identified with biologically important areas and/or biologically important behaviours within the Project Area according to the PMST (Appendix A). Foraging behaviours were identified for some species (blue, fin, pygmy right and sei whales); no other important behaviours that potentially lead to the ingestion of materials were identified. The Project Area intersects foraging BIAs for the pygmy blue whale and migration BIA for the southern right whale.

The Conservation Management Plan for the blue whale (CoA 2015b) and Conservation Advice for the sei whale (TSSC 2015e) and fin whale (TSSC 2015d) do not identify marine debris as threat. The National Recovery Plan for the Southern Right Whale (DCCEEW 2024o) identifies marine debris as a threat, specifically vessel-sourced, solid, non-biodegradable floating materials disposed of or lost at sea. It details that ingestion of marine debris, however, is thought to be unlikely for southern right whales in Australian coastal waters given whales are less likely to be feeding. No actions from the recovery plan were identified specific to vessel debris.

According to the PMST (Appendix A), the Project Area does not contain any threatened marine invertebrate species or benthic habitats.

The extent of the area of impact is adjacent to the MODU or support vessels within the Project Area. The consequence to ecological receptors is assessed as Minor (1) and likelihood as Unlikely, and the resulting risk is Low based on:

- MODU and vessel management systems addressing dropped object, waste storage and chemical handling and storage are well practiced, well understood.
- An unplanned release of waste will be of a very low volume if an incident occurred, and impacts would be restricted to individual fauna and would not impede the recovery of a protected species.

- Where possible material lost overboard would be recovered.
- The Threat Abatement Plan for the Impacts of Marine Debris on Vertebrate Wildlife of Australia's Coasts and Ocean (CoA 2018) suggests that most marine plastic debris are associated to shipping and fishing activities (fishing gear, balloons and plastic bags).
- Waste will be handled in accordance with AMSA Discharge Standards and respective MODU and vessel Garbage Management Plans. Given this, any waste lost overboard would be in minimal quantities.
- Hazardous decommissioning waste will be disposed on in accordance with *Hazardous Waste (Regulation of Exports and Imports) Act 1989* to prevent the likelihood of incorrect disposal of infrastructure.
- The likelihood of losing waste or other materials overboard is unlikely with the MODU and vessels management systems in place. The consequence of a loss of material or waste overboard would be limited to individuals and not affect an entire population.

7.3.5 Socio-economic Receptors

In the event a buoyant object is accidentally released and cannot be recovered by a vessel, the buoyant object may present a navigation or entanglement hazard to commercial fishers and other marine users. Further the buoyant object may become non-buoyant overtime and sink to the seabed, where it may present a snagging hazard on the seafloor for commercial trawling activities.

The extent of the area of impact is adjacent to the MODU or vessels within the Project Area. The consequence to socio-economic receptors is assessed as Minor (1) and likelihood as Unlikely, and the resulting risk is Low based on:

- MODU and vessel management systems addressing dropped object, waste storage and chemical handling and storage are well practiced and well understood.
- An unplanned release of waste will be of a very low volume if an incident occurred, and impacts would be restricted to individual marine users or individual fishers.
- Where possible material lost overboard would be recovered.
- Waste will be handled in accordance with AMSA Discharge Standards and respective MODU and vessel Garbage Management Plans. Given this, any waste lost overboard would be in minimal quantities.
- Disposal of hazardous decommissioning waste to be compliant with *Hazardous Waste (Regulation of Exports and Imports) Act 1989* to prevent the likelihood of incorrect disposal of infrastructure.
- The likelihood of losing waste or other materials overboard is unlikely with the MODU and vessels management systems in place. The consequence of a loss of material or waste overboard would be restricted to impacts to individual marine users or individual fishers.

7.3.6 Risk Evaluation Summary

The risk evaluation for the accidental discharge of hazardous and non-hazardous materials is summarised in Table 7-12.

Table 7-12: Risk Evaluation Summary for Accidental Discharge – Hazardous and Non-hazardous Materials

Summary		
Risk summary	An unplanned accidental discharge event, resulting in injury or mortality to a single animal or present a navigation or entanglement hazard to other marine users, has been evaluated as a Low risk. The consequence and likelihood levels to determine the Low risk is defined as follows. The consequence of injury or mortality to single animal is assessed as Minor (1), given the loss of a single animal is not predicted to affect the overall population or recovery of the species. The consequence of a navigation or entanglement hazard to other marine users is assessed as Minor (1), given impacts would be restricted to individual marine users or individual fishers. The likelihood of such an event occurring is Unlikely given the controls in place to prevent such an event from occurring.	
Extent and duration of risk	Localised – risks are limited to an individual animal or marine user or commercial fisher. Temporary – Vessels may periodically be present in the Project Area, creating a temporary risk of an event occurring.	
Level of certainty	Beach has a high level of certainty about the risks of unplanned accidental discharge of hazardous and non-hazardous materials. The threat posed by dropped objects is well known and strict regulatory requirements are in place to control the risk. With these regulatory controls in place, Beach has a high level of certainty that Project activities will not result in the injury or death of an individual animal or pose a navigation or entanglement hazard to other marine users or commercial fishers.	
Is the risk considered lower-order or higher-order?	The risk of an unplanned interaction with marine fauna event has been evaluated to be Low. Low risks are considered lower-order risks that is acceptable with the application of good industry practice.	
Risk Assessment		
Consequence	**Likelihood**	**Risk rating**
Minor	**Unlikely**	**Low**

7.3.7 Demonstration of Acceptability

Table 7-13 demonstrates how and why environmental risks from the accidental discharge of hazardous and non-hazardous materials meets the defined acceptable levels (Table 5-4).

Table 7-13: Demonstration of Acceptability – Accidental Discharge of Hazardous and Non-hazardous Materials

Demonstration of Acceptability	
Impact and risk comparison with relevant defined acceptable levels	Acceptable level13 is relevant to accidental discharge of hazardous and non-hazardous materials (as detailed in Table 5-4). A **Low** risk rating was assigned for this aspect based on the combination of Minor (1) potential consequence and Unlikely event likelihood. By implementing control measures that satisfy

	legislative and other requirements, the occurrence of an accidental discharge – hazardous and non-hazardous materials event will be prevented, thereby ensuring that Acceptable level 13 is met and achieved. Refer below to list of control measures to be implemented to prevent such an event from occurring	
Principles of ESD	Integration principle	Section 7.1.3 identifies and evaluates environmental risks associated with the accidental discharge of hazardous and non-hazardous materials. As part of identifying the potential risks; conservation values and sensitivities, physical environment, ecological environment, socio-economic values, and First Nations values and sensitivities described in Section 4 were reviewed to determine potential interactions of the aspect against each of these receptors they may result in environmental risk. As a result, consideration of economic, environmental, social and equitable receptors was conducted as part of identifying the impacts and risks. For Phase 1: Initial Project Consultation (Section 10.2.3), Beach consulted with relevant stakeholders on the Project and associated activities. No objections or claims were raised in Phase 1: Initial Project Consultation.. For Phase 2: Project OPP Public Comment Period (Section 10.2.4), the public had the opportunity to provide further comment to this OPP during the period (18/3/2024 – 20/5/2024). Beach prepared the public comment report summarising all comments, an assessment of the merits of each comment, a statement of the response to each comment, and an outline of any changes made to the OPP as a result of the comment (Appendix P). The assessment of merit for comments against this aspect found the response provided in the public comment report to be sufficient to address the comments against this aspect. Therefore, no further updates were required for this aspect. Given the thorough assessment and responses outlined in the public comment report, the impact evaluation for this aspect remains acceptable as is, demonstrating that public comments have been adequately addressed. The potential environmental risk against this aspect was assessed as having a Low risk rating which is considered a lower-order environmental risk. Lower-order environmental risks are considered 'broadly acceptable' and considered managed to an acceptable level by meeting relevant requirements (adopted controls as listed below).
	Precautionary principle	The potential environmental risks against this aspect were assessed as having a Low risk rating which is considered a lower-order environmental risk and below defined acceptable level 13 (as detailed in Table 7-14). Lower-order environmental risks cannot result in serious or irreversible environmental damage. There is high confidence in the potential environmental impacts and risks and effectiveness of controls against this aspect. Beach has significant experience operating in the Otway and Bass based on their existing offshore developments and associated activities including the Beach Otway Drilling Campaign in 2021/2022.
	Intergenerational principle	The defined acceptable levels were developed to meet the principles of ESD (Section 5.8.5). Given predicted environmental impacts due to the accidental discharge of hazardous and non-hazardous materials is lower than the defined acceptable level 13; the health, diversity, or productivity of the environment for future generations is expected to be maintained.
	Biodiversity principle	Section 7.3.3 identifies and evaluates environmental risks associated with the accidental discharge of hazardous and non-hazardous materials. As part of identifying the potential impacts and risks; conservation values and sensitivities including MNES in Section 4 were reviewed.

		The potential risks against this aspect were assessed as having a Low risk ranking which is considered a lower-order environmental risk and can be managed to meet the defined acceptable level 13 detailed in Table 5-4. Lower-order environmental risks cannot result in affects to biological diversity or ecological integrity.
Internal context	Policy compliance	The defined acceptable levels, EPOs and controls proposed for this aspect are consistent with Beach Environmental Policy objectives. As a result, potential environmental impacts and risks from Project can be managed to align with Beach Environmental Policy objectives.
External context	Stakeholder engagement is being carried out as part of this OPP process. Beach operates the existing Otway project and has established good relations with both onshore and offshore stakeholders. Engagement with stakeholders will continue throughout all aspects of the Project to build and maintain trust with stakeholders and the local community and minimise community and stakeholders concern and impacts where practicable. During Phase 1: Initial Project Consultation (Section 10.2.3), no objections or claims were raised against this aspect. During Phase 2: Project OPP Public Comment Period (Section 10.2.4), comments were raised against this aspect. The assessment of merit for comments against this aspect found the responses provided in the public comment report to be sufficient to address the comments against this aspect. Given the thorough assessment and responses outlined in the public comment report, the impact evaluation for this aspect remains acceptable as is, demonstrating that public comments have been adequately addressed.	
Other requirements	**Requirement**	**Demonstration**
	Navigation Act 2012 (Cth) Section 4 – Prevention of pollution MO 47 MO 94: Marine pollution prevention – packaged harmful substances MO 95: Marine pollution prevention - garbage	**CM10 Seabed assessments** Seabed assessments undertaken of each well location and tie-back route prior to final selection to identify seabed composition, benthic habitats and communities and ensure areas of high relief outcrops, reefs, sponge beds, maritime archaeology, submerged cultural heritage and landscapes are avoided where practicable within technical and safety constraints. Seabed assessment data will be provided to the following appropriately qualified specialists to identify sensitive benthic receptors: • Marine benthic ecologist to identify seabed habitat types including areas of high relief outcrops, reefs or sponge beds that are likely to be associated with site-attached fish. • Underwater archaeologist to identify shipwrecks and other maritime archaeological heritage. • Geophysical data analyst to identify location of unexploded ordinances. • Underwater archaeologist to identify submerged cultural heritage and landscapes. Reports from each specialist evaluation of seabed assessment data will be provided to Beach. Beach will assess the reports and identify any areas of
	Protection of the Sea (Prevention of Pollution by Ships) Act 1983 (Cth) Part III – Prevention of pollution by noxious substances Part IIIA – Prevention of pollution by packaged harmful substances Part IIIC – Prevention of pollution by garbage	
	OPGGS Act 2006 (Cth) Section 460(2) - a person carrying on activities in an offshore area under the permit must carry out those activities in a manner that does not interfere with the conservation of the resources of the sea and seabed to a greater extent than is necessary for the reasonable exercise of the rights and performance of the duties of the first person.	

	The following management plans or conservation advice identify marine debris as a threat: • Threat abatement plan for the impacts of marine debris on the vertebrate wildlife of Australia’s coasts and oceans (CoA, 2018a) • Wildlife Conservation Plan for Seabirds (CoA, 2020a) • National Recovery Plan for Albatrosses and Petrels 2022 (CoA, 2022) • Conservation Management Plan for the Blue Whale, 2015-2025 (CoA, 2015b) • Recovery Plan for Marine Turtles in Australia, 2017-2027 (CoA, 2017) • Approved Conservation Advice for *Dermochelys coriacea* (Leatherback Turtle) (DEWHA, 2008)	overlap, potential risks from Project activities, and determine any exclusion areas that may be required. **CM11 Cultural heritage assessments** Imagery and data from seabed surveys and assessments will be provided to appropriately qualified underwater archaeologists to identify any maritime archaeological and submerged cultural heritage and landscapes and inform protection priorities, management measures and reporting requirements. Should any maritime archaeological and submerged cultural heritage and landscapes be identified, Beach will report the findings in accordance with the *Underwater Cultural Heritage Act 2018*, and will consult with the relevant First Nations groups and determine any exclusion areas or further cultural heritage management procedures that may be required. **CM35 Marine orders** All wastewater discharges will comply with relevant MARPOL 73/78, Navigation Act 2012, Protection of the Sea (Prevention of Pollution) Act 1983 and subsequent Marine Order requirements (as appropriate for vessel classification): • Marine Order 91 (Marine Pollution Prevention – Oil), which implements Annex I of MARPOL 73/78, including (as required by vessel class): ◦ Machinery space bilge/oily water shall have IMO-approved oil filtering equipment (oil/water separator) with an on-line OIW monitoring device ◦ OIW content to be less than 15 ppm prior to discharge. ◦ A deck drainage system capable of controlling the content of discharges for areas of high risk of fuel/oil/grease or hazardous chemical contamination. ◦ Valid International Oil Pollution Prevention Certificate. • Marine Order 95 (Marine Pollution Prevention – Garbage), which implements Annex V of MARPOL 73/78, including: ◦ Garbage management plan in place. ◦ Garbage record book maintained onboard. • Marine Order 96 (Marine Pollution Prevention – Sewage), which implements Annex IV of MARPOL 73/78, including (as required by vessel class): ◦ a valid International Sewage Pollution Prevention Certificate, ◦ an IMO-approved sewage treatment plant,

		◦ a sewage comminuting and disinfecting system, a sewage holding tank sized appropriately to contain all generated waste (sewage and grey water) discharge of sewage will occur at a moderate rate while vessel is proceeding (more than 4 knots)**CM38 Waste Management Plan** Beach Waste Management Plan implemented that includes details of: • Classification and segregation of wastes • Appropriate storage of wastes • Transportation and disposal of wastes to licensed treatment and disposal facilities onshore **CM39 Lifting** Crane and lifting operations will comply with the following: • Lifting equipment will be inspected and certified • Preventative maintenance will be carried out • Lifting operators will be competent and qualified

7.3.8 Environmental Performance

In accordance with NOPSEMA's OPP Decision Making Guideline (NOPSEMA 2024), the EPO for this aspect (Table 7-) has been developed to be relevant to identified environmental impacts and risks, consistent with the principles of ESD and equivalent to or better than the defined acceptable level of impact. Control measures listed in Table 7-13 provides detail on how each control measure will be implemented for the Project to ensure the acceptable levels and EPOs, defined in Table 7- are met

Table 7-14: Environmental Performance Outcomes – Accidental Discharge of Hazardous and Non-hazardous Materials

Defined Acceptable Level	Environmental Performance Outcomes	
Acceptable level 13: Unplanned accidental discharge of hazardous and non-hazardous materials is unacceptable.	EPO26:	No unplanned discharge of materials or waste to the marine environment.
	EPO7:	No death or injury to listed threatened or migratory species from Project activities.

7.4 Loss of Containment – Hydrocarbons and Chemicals

7.4.1 Hazard Identification

Hydrocarbons and chemicals may be accidentally released from vessels, subsea equipment or the MODU over the life of the Project (see Table 7-15).

The risk of an unplanned release of minor volumes of hazardous chemicals and hydrocarbons for the Project is assessed in Section 7.3.

Stages and associated activities which may result in an unplanned loss of hydrocarbons or chemicals are defined in Table 7-15 and further described in Section 7.4.4.

Table 7-15: Activities Undertaken During the Project Resulting in the Unplanned Release of Hydrocarbons and Chemicals

Stage	Activity
Drilling and completions	Drilling method Completions
Installation and commissioning	Commissioning
Operations	Hydrocarbon extraction and export Well intervention and workovers
Support operations (all stages)	MODU operations Vessel operations
Decommissioning	Well plugging and abandonment

It is noted that MODU and vessel operations within the Project Area are considered part of a petroleum activity. MODU and vessel operations outside of the Project Area are excluded from the scope of this OPP, as these operations are fall under maritime legislation such as the *Navigation Act 2012*.

7.4.2 Hazard Description

Marine Diesel Oil (MDO) will be the fuel type used by the vessels and MODU commissioned by the Project. An accidental release of MDO may occur as a result of a collision between the MODU and a project vessel, between project vessels or between a project vessel and a third-party vessel within the Project Area. During support activities, there is the potential for a loss of containment of hazardous substances, from handling, use and transfer activities.

Further, an accidental release of gas and condensate may result from a loss of well containment (LOWC) or integrity failure during Project activities. Credible spill scenarios are provided in Table 7-16.

Activities associated with the Project have the potential to result in an accidental release of hydrocarbons or chemicals to the marine environment as follows:

7.4.2.1 Drilling and Completions

Drilling Method

Drilling of subsea wells introduces the potential for unplanned release of gas and condensate. Up to eight exploration wells are anticipated to be drilled within permits VIC/P43 and VIC/P73, with each well taking approximately 30-40 days per well (Section 3.1). Wells will be drilled by a MODU using standard offshore drilling methods with the wells drilled in sections which decrease in diameter at increasing depths until the target reservoir is reached. A LOWC event is a credible risk during drilling and may be caused by:

- dropped objects, collision, mooring lines and anchor drag;
- a loss of well integrity resulting from the failure of multiple well control barriers; and
- a prolonged and uncontrolled influx of formation fluid into the well bore (a well kick).

The Project is in offshore Commonwealth waters in the Otway Basin, approximately 17 km (south) and 80 km (west) of Victoria and King Island (Tas) respectively.

7.4.2.2 Installation and Commissioning

Commissioning

During commissioning activities subsea infrastructure will be tested and flushed prior to the introduction of hydrocarbons. A loss of containment of MEG stored in flowlines may occur from subsea facilities as a result of erosion, corrosion, or external forces (e.g. dropped object; fishing vessel interactions). The maximum credible MEG spill volume from subsea infrastructure loss of containment during commissioning is in the order of up to 400 m^3, assuming 50% loss of contents (80% MEG and 20% treated water used to displace existing fluid in the flowline) from 30km of 8-inch flowline, prior to pressure equilibrium being reached.

7.4.2.3 Operations

Hydrocarbon Extraction and Export

An accidental loss of containment of condensate may occur from the OGPP during the operations phase, as a result from a loss of integrity from an inadvertent third-party interaction or corrosion defects. Reservoir fluids, from Project wells will flow via flowlines to the existing OGPP for export to the Otway Gas Plant.

Loss of flowline containment from the subsea facilities may result from erosion, corrosion, or external forces (e.g. dropped object; fishing vessel interactions). The greatest length of infield flowlines transporting condensate from potential wells to the OGPP is approximately 23 km length (Section 3.8.5). Condensate fluids from the Project will be commingled with fluids in the existing OGPP.

A loss of containment from flowlines may also result in the discharge of gas and condensate from the OGPP pipeline as the current design does not include actuated valves at the flowline. Further, if the flowline is connected to a producing well, additional hydrocarbons may be introduced to the flowline if the well cannot be shut in quickly (e.g. – if the hydraulic umbilical has been damaged). However, as the subsea control system is configured for all wells to fail-safe in the event of loss of communication and/or hydraulics as a core design philosophy, this is not considered a credible scenario.

In a flowline rupture scenario, combined loss of condensate from a flowline (141m, see Table 7-16) and loss of condensate from the OGPP (up to 320 – 560m^3 modelled in the Otway Offshore Operations EP CDN/ID 3977021), is estimated at up to 701m^3, a substantially smaller volume that the worst-case scenario for loss of containment from a well (69,188m^3 at northern location and 16,308m^3 at the southern location). As a result, LOWC is used as the worst-case scenario to evaluate the risks for loss of containment for wells and for flowline/pipeline rupture.

Table 7-16 details the worst-case loss of containment for this scenario.

Well Intervention and Workovers

Wells may require maintenance and completion activities, also known as a workover or downhole intervention. These activities involve re-entering the well bore and carry the risk of a loss of hydrocarbon containment. Re-entry activities are planned during the initial drilling campaign for the Artisan 1 well. Following this, it is anticipated up to one well may require intervention or workover activities every seven years, for the duration of the Project. The duration for workovers is up to 30 days.

The potential loss of condensate volumes, resulting from well intervention and workovers would be similar to those discussed in drilling activities.

7.4.2.4 Support Operations

MODU Operations; Vessel Operations

A loss of MDO may result from an unplanned collision between the project vessels, including a project vessel and the MODU, or a project vessel and a third-party passing vessel within the project area. Vessel grounding has not been considered as a credible risk, as there are no shallow areas or emergent features in the project area.

The various project vessels will be required for specific purposes, depending on the project phase, and are listed in Table 3-5. The MODU and support vessels will be present in the project area during drilling, operations, and decommissioning stages, for approximately 40 days per well. Vessels used for support operations will vary in size and duration and are detailed in Table 3-6.

To support the impact analysis and evaluation, Beach assessed the worst-case credible spill scenario that could result from a vessel collision. Considering AMSA's guideline for indicative maximum credible spill volumes for other, non-oil tanker, vessel collision (AMSA, 2015), the worst-case scenario for a vessel loss of containment (MDO) scenario was an instantaneous release of MDO due to a vessel collision rupturing a vessel fuel tank (~603.7 m^3 of MDO over 6 hours). This was based on a collision between an installation, resupply or IMR vessel and third-party vessel. Based on the types of vessel used for installation, IMR and resupply activities the loss of the largest tank volume of 603.7 m^3 is considered appropriate.

Vessels and MODU used throughout the Project will contain hazardous substances stored on board. The transfer and handling of these chemicals could result in the potential loss of containment to the marine environment and are outlined further in Table 7-16.

7.4.2.5 Decommissioning

Well Plugging and Abandonment

Plugging and abandoning a well can lead to a LOC of gas and condensate. These activities will be carried out from a MODU and are projected to take up to 30 days per well (Section 3.8.7). Abandonment activities involve setting a series of mechanical and cement plugs within the wellbore, to isolate the reservoir and prevent any further flow from the well.

Well abandonment activities can similarly lead to the loss of well control (LOWC) as drilling activities. At the time when decommissioning activities are commenced, the pressures and volumes of hydrocarbon reservoirs are expected to be lower, than those during drilling, as gas reservoirs will likely have been depleted over time by production.

7.4.3 Hydrocarbon Spill Modelling

Guidance on the identification of worst-case credible spill scenarios is given in AMSA's Technical Guidelines for Preparing Contingency Plans for Marine and Coastal Facilities (AMSA 2015) and Technical Report on Calculation of Worst-Case Discharge (SPE 2016). These documents were used to identify the potential significant and credible loss of containment scenarios associated with the Project as detailed in Table 7-16.

Historical LOWC incidents listed in the IOGP Risk Assessment Data Directory (2019) found blowout events during development drilling for a gas well to be at a frequency of 4.2×10^{-5} per drilled well; for development drilling operations on deep, normal wells of North Sea standard (IOGP, 2019). This frequency is based on two blowout incidents occurring in the UK between 1980 and 2014 during development drilling (IOGP, 2019); and represents the frequency of the cause (i.e. LOWC) that results in the worst-case consequence.

Review of Australian Transport Safety Bureau vessel collision type marine investigations in Victorian waters between found only two vessel collision incidents both between container ship and fishing vessel (ATSB 2024). Both collisions did not result in loss of hydrocarbons.

To date no incidents relating to LOWC or vessel collision events have occurred during Beach operations in Australia including in the Otway basin. Future spills from LOWC or vessel collision events are considered remote and highly unlikely events based on history of no known MDO or condensate spills in southern Australia from LOWC or vessel collision events. [**PC275**].

Table 7-16: Risk Assessment Summary for the Accidental Release of Hydrocarbons and Chemicals

Scenario	Description	Worst-case release volume and rate
Loss of Containment – hazardous substances stored on drill MODU and vessels	Routine operation of the MODU and vessels includes handling, use and transfer of hydrocarbons and chemicals with the following were identified as potentially leading to a loss of containment event: Use, handling and transfer of hydrocarbons and chemicals on board. Hydraulic line failure from equipment.	Hydraulic line failure and use of hazardous materials onboard are associated with small volume spill events – with the maximum volume based upon the loss of an intermediate bulk container ~1 m^3.
Vessel Collision -Marine Diesel Oil (MDO) spill	Collision between an installation, resupply or IMR vessel and third-party vessel.	Based on the types of vessel used for installation, IMR and resupply activities the loss of the largest tank volume of 603.7 m^3 is considered appropriate.
Flowline and/or pipeline loss of containment – gas and condensate	Loss of containment from a flowline and/or pipeline from the subsea facilities as a result of erosion, corrosion, or external forces (e.g. dropped object; fishing vessel interactions).	Maximum credible condensate spill volume from the longest proposed flowline is a loss of containment up to a maximum of 141 m^3 depending on production rates and the production wells online. This may also include up to 320 to 560m^3 additional condensate release volume should the OGPP pipeline be

Scenario	Description	Worst-case release volume and rate
		ruptured, for a total of up to 701 m^3 condensate.
Umbilical or flowline loss of containment – MEG	Loss of containment from an umbilical from the subsea facilities as a result of erosion, corrosion, or external forces (e.g. dropped object; fishing vessel interactions) or from a flowline during installation and commissioning	Maximum credible MEG spill volume from subsea infrastructure loss of containment is in the order of up to 400 m^3.
Loss of well containment - gas and condensate	Loss of containment as a result of well integrity failure during drilling, completions, operations or well workover.	Worst case release volumes for all currently identified exploration prospects within the Project Area were calculated. The highest potential discharge volume for wells in the northern fields of the Project Area (Vic/P43) are: 69,118 m^3 over 86 days The highest potential discharge volume for wells in the southern fields of the Project Area at TW1 (T/L2) are: 16,308 m^3 over 86 days

7.4.3.1 Project Quantitative Spill Modelling

Beach commissioned RPS Group (RPS) to conduct quantitative spill modelling for the vessel collision and loss of well control spill scenarios as the worst case for both hydrocarbon types (RPS, 2024) with the report available as Appendix M. Due to changes in the Project Area – these scenarios were remodelled by RPS (2024). The worst-case scenario, hydrocarbon types and volumes remained the same, only the location changed.

The flowline and/or pipeline loss of containment scenario (including loss of containment from OGPP) was not modelled due to the potential condensate volume of up to 701 m^3 being less than the volume of the loss of well containment scenario; which is considered the worst case scenario for a condensate spill.

The umbilical or flowline loss of containment scenario was not modelled due to the relatively small volume (up to 400 m^3) and MEG being a category ‘E’ OCNS chemical, with no substitution warning, readily biodegradable with a low potential for bioaccumulation and a Minor potential impact consequence ranking.Beach acknowledge that despite the very low aquatic toxicity of MEG there is potential for the chemical to contribute to hypoxic conditions within the water column (ANZG 2018). However, due to the metocean conditions within the Otway region, which facilitate the rapid dispersion of the discharge throughout the marine environment, it is not anticipated that there would be a noticeable change in dissolved oxygen concentrations to an extent that would result impacts to marine fauna [**PC285**].

Modelling of MDO and condensate spill scenarios, from within the Project Area were selected to ensure a conservative assessment, and are detailed in Table 7-17 and presented in Figure 7-1.

Thylacine fluid composition was used as a conservative analogue for the LOWC scenarios. The release duration represents the time estimated to implement a full dynamic well kill through the drilling of a relief well. This is considered the worst-case scenario for potential gas condensate releases and therefore yields the largest spatial extent that could possibly occur from the Project.

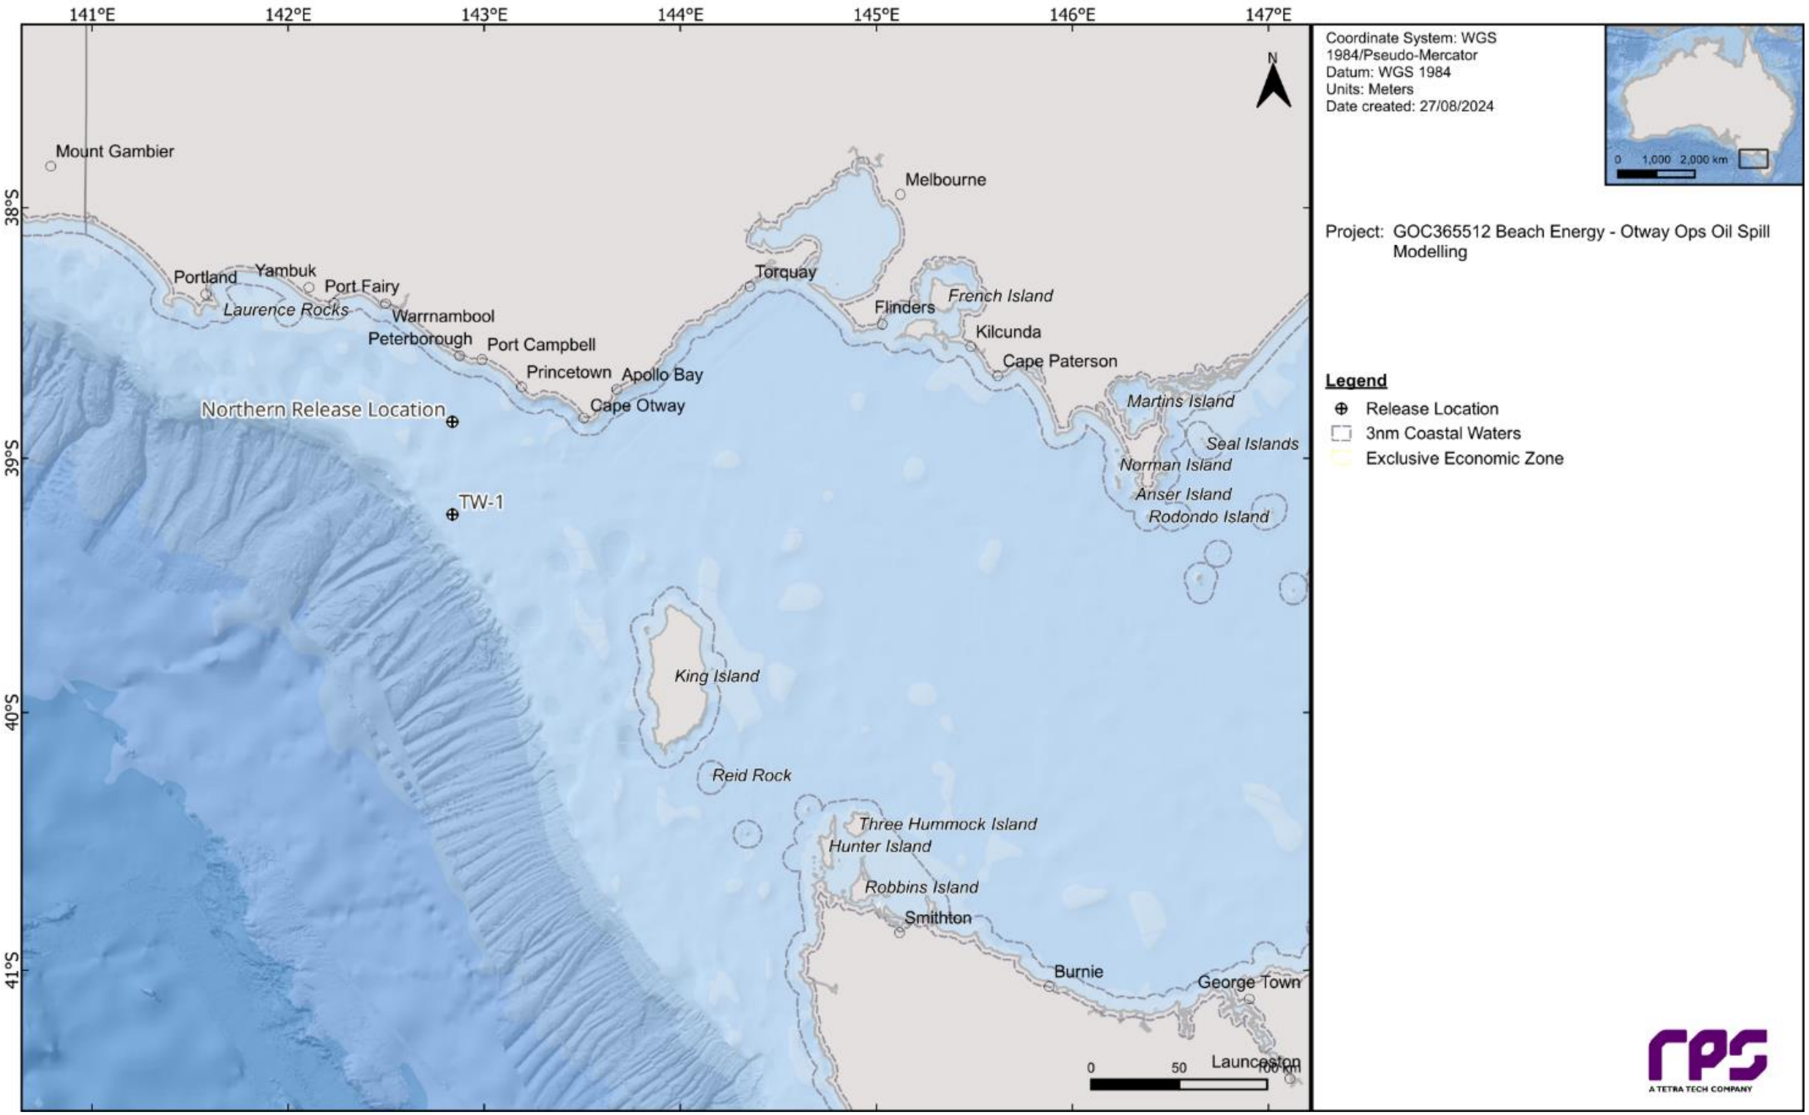

Figure 7-1: Assessed Hydrocarbon Release Locations

Table 7-17: Worst-case Credible Hydrocarbon Scenarios Modelled

Location	Latitude	Longitude	Water depth (m)	Hydrocarbon Type	Volume (m^3)	Release Duration	Reasoning	Report
Loss of well containment – gas and condensate								
Northern Release Location	38.8552° S	142.8381° E	71.5	Condensate	69,118	86 days	Furthermost north proposed well location. Largest flow rate for Vic/P43 and Vic/P73 wells. Worse case for impacts to Victoria.	RPS 2024
TW1	39.2223° S	142.8386° E	105	Condensate	16,308	86 days	Furthest southern proposed well location. Largest flow rate for T/L2 wells. Worse case for impacts to Tasmania and King Island.	RPS 2024
Vessel Collision -Marine Diesel Oil (MDO) spill								
Northern Release Location	38.8552° S	142.8381° E	N/A	MDO	603.7	6 hours	Furthest northern proposed well location. Largest flow rate for Vic/P43 and Vic/P73 wells. Worse case for impacts to Victoria.	RPS 2024
TW1	39.2223° S	142.8386° E	N/A	MDO	603.7	6 hours	Furthest southern proposed well location. Largest flow rate for T/L2 wells. Worse case for impacts to Tasmania and King Island.	RPS 2024

GCS: WGS84

7.4.3.2 Hydrocarbon Characteristics

Beach produces gas from the Thylacine field in the Otway Basin and has comprehensive data on its hydrocarbon characteristics. The hydrocarbon characteristics used for the quantitative spill modelling conducted by RPS are detailed in Table 7-18.

All offshore fields in the greater Shipwreck Trough area of the Otway Basin belong to the Austral 2 Petroleum System (Mehin and Link 1994; Foster and Hodgson 1995; Luxton et al 1995; Boreham et al. 2004), consisting of Thylacine Member, Flaxman Formation, and Waarre Formation reservoirs charged by the regionally extensive marine shales, organic-rich mudstones and coals of the underlying Eumeralla Formation source rock (Edwards et al. 1999; Boreham et al. 2004; O'Brien et al. 2009). Based on burial history modelling and geochemical data, this source rock is interpreted as gas/condensate-prone, also evidenced in multiple discoveries across the Otway Basin. As a consequence of all fields in the region being charged from the same source, significant variations in condensate properties are not expected.

An assessment of offset field data from the currently producing Thylacine and Geographe Fields (operated by Beach, with first production in 2007) was made to inform input parameters for spill modelling. Thylacine Field condensate properties are used as the primary analogue, with the exception of the Condensate Gas Ratio (CGR) which is taken from the Geographe Field. The Geographe Field CGR, which features the highest CGR of the Otway wells (16 bbl/MMscf), is used for modelling as it represents the largest potential condensate discharge and therefore worst-case scenario. In addition to the assessment of offset field data from the producing Thylacine and Geographe Fields, well data from Artisan 1 (drilled 2021) and La Bella 1 (drilled 1993) was also assessed to inform hydrocarbon spill modelling. As Artisan 1 and La Bella 1 have not been connected and produced to date, relevant geotechnical data that may be used to inform spill modelling is restricted to downhole MDT sampling undertaken at the time of drilling. As these downhole samples are typically small in volume (further reduced by the low CGR observed in the wells), condensate assay analysis was not undertaken, with compositional information only sufficient to indicate that upon production the CGR in Artisan 1 and La Bella 1 will be lower than that observed in the Thylacine and Geographe Fields. Therefore, the hydrocarbon characteristics for spill modelling are best represented by Thylacine condensate properties with Geographe CGR.

The Thylacine condensate hydrocarbon characteristics are used for the quantitative spill modelling. Beach commissioned RPS to conduct quantitative spill modelling for the vessel collision and loss of well control spill scenarios (RPS 2024).

Thylacine condensate has an API of 44.3 and a density of 804.6 kg/m^3 (at 15ºC) with a viscosity value (0.875cP) classifying it as a Group I (not-persistent) oil according to the International Tankers Owners Pollution Federation (ITOPF 2020) and US EPA/USCG classifications.

The condensate is a mixture of volatile and persistent hydrocarbons with high proportions of volatile and semi- to low-volatile components. In favourable evaporation conditions, 64.0% of the oil mass should evaporate within the first 12 hours (BP < 180°C), a further 19.0% is expected to evaporate within the first 24 hours (180°C < BP < 265°C) and a further 16.0% should evaporate over several days (265°C < BP < 380°C). Approximately 1.0% of the condensate is shown to be persistent.

MDO has an API of 37.6 and a density of 829.1 kg/m^3 (at 25ºC) with a viscosity value (4.0 cP) classifying it as a Group II (light-persistent) oil according to the International Tankers Owners Pollution Federation (ITOPF 2014) and US EPA/USCG classifications.

The MDO is a mixture of volatile and persistent hydrocarbons with high proportions of volatile and semi- to low-volatile components. In favourable evaporation conditions, about 6.0% of the oil mass should evaporate within the first 12 hours (BP < 180°C); a further 34.6% should evaporate within the first 24 hours (180°C < BP < 265°C); and a further 54.4% should evaporate over several days (265°C < BP < 380°C). Approximately 5.0% of the oil is shown to be persistent.

Table 7-18: Hydrocarbon Characteristics of the Hydrocarbons Modelled for the Project

Hydrocarbon Type	**API**	**Density (kg/m^3)**	**Viscosity (cP)**	**Pour Point (°C)**	**Wax Content (%)**
Thylacine Condensate	44.3	804.6 at 15ºC	0.875 at 15ºC	-50	<1%
Geographe Condensate	56.9	751 at 15ºC	0.50 at 25ºC	-50	<1%
Marine Diesel Oil	37.6	829.1 at 15ºC	4.0 at 25ºC	-14	1

7.4.3.3 Hydrocarbon Exposure thresholds

In the event of an oil spill incident, the environment may be affected in several ways, depending on the concentration and duration of exposure of the environment to hydrocarbons. The hydrocarbon exposure thresholds used for the spill modelling are based on the NOPSEMA Bulletin: Oil Spill Modelling (NOPSEMA 2019) and are detailed in Table 7-19.

These thresholds have been used to:

- Predict potential hydrocarbon exposure at conservative (low exposure) concentrations to inform the description of the environment (Section 4)
- Inform the oil spill impact and risk evaluation (Section 7.4.4)
- Inform oil spill response planning based on the actionable thresholds of:
    - Surface moderate exposure (10 g/m^2)
    - Shoreline moderate exposure (100 g/m^2)
    - Inform oil spill monitoring planning based on the low exposure thresholds.

Table 7-19: Hydrocarbon Exposure Thresholds

	Threshold	Description
Surface		
Low exposure	1 g/m^2	Approximates range of socioeconomic effects and establishes planning area for scientific monitoring.
Moderate exposure	10 g/m^2	Approximates lower limit for harmful exposures to birds and marine mammals.
High exposure	50 g/m^2	Approximates surface oil slick and informs response plan.
Shoreline		
Low exposure	10 g/m^2	Predicts potential for some socio-economic impact.
Moderate exposure	100 g/m^2	Loading predicts area likely to require clean-up effort.
High exposure	1000 g/m^2	Loading predicts area likely to require intensive clean-up effort.
Dissolved*		
Low exposure	10 ppb	Establishes planning area for scientific monitoring based on potential for exceedance of water quality triggers.
Moderate exposure	50 ppb	Approximates potential toxic effects, particularly sublethal effects to sensitive species.
High exposure	400 ppb	Approximates toxic effects including lethal effects to sensitive species
Entrained*		
Low exposure	10 ppb	Establishes planning area for scientific monitoring based on potential for exceedance of water quality triggers.
High	100 ppb	As appropriate given oil characteristics for informing risk evaluation.

7.4.3.4 Summary of Modelling Results

The potential environmental impacts to receptors from are discussed in Table 7-20 to Table 7-22 (MDO spill) and Table 7-23 to Table 7-25 (Condensate LOWC) and are based on the spill modelling areas of exposure from the two release locations, detailed in Appendix M and summarised below.

7.4.3.5 Extent of Hydrocarbon Exposure - Marine Diesel

1. Northern Release Location

- The maximum distance from the release location to the low (1–10 g/m^2), moderate (10–50 g/m^2) and high (>50 g/m^2) surface exposure thresholds was 32.65 km (ESE), 19.85 km (SE) and 10.53 km (SE), recorded during winter months.

- No State waters were predicted to be exposed to surface hydrocarbons at any threshold.

- No conservation values or sensitivities (Section 4.2) were identified to be exposed to surface hydrocarbons at any threshold.

- The probability of accumulation to any shoreline at, or above, the low level (10 g/m^2) threshold was 31% during summer conditions and 27% during winter conditions.

- The minimum time before shoreline accumulation above the low threshold was 4 days (summer) ,and 2 days (winter), predicted for Cape Otway West.
- The maximum volume ashore for a single spill trajectory during the summer and winter conditions was 30.86 m^3 and 58.33 m^3, respectively, whilst the maximum length of shoreline accumulation at the low threshold was 29.23 km and 43.19 km, respectively.
- Only the receptors that the Northern Release Location resides within were contacted by dissolved hydrocarbon at the low threshold.
- At the depths of 0-10 m the maximum dissolved hydrocarbon concentration was 101.35 ppb and 65.67 ppb during summer and winter respectively.
- At the depths of 0-10 m, during summer and winter, the maximum entrained concentration at any given receptor was predicted to be 11,343.38 ppb and 11,396.24 ppb, respectively.
- Outside of the receptors that the release location resides within, the maximum entrained hydrocarbon exposure predicted during summer and winter was 745.77 ppb and 1,391.43 ppb, respectively.

a. TW1 Location

- The maximum distance from the release location to the low (1–10 g/m^2), moderate (10–50 g/m^2) and high (>50 g/m^2) surface exposure thresholds was 64.97 km (SE), 49 km (SE) and 10.08 km (SSE), recorded during winter months.
- No State waters were predicted to be exposed to surface hydrocarbons at any threshold.
- No conservation values or sensitivities (Section 4.2) were identified to be exposed to surface hydrocarbons at any threshold.
- The probability of accumulation to any shoreline at, or above, the low level (10 g/m^2) threshold was 9% during winter conditions. No shoreline accumulation was predicted during summer conditions at any threshold.
- The minimum time before shoreline accumulation above the low threshold was 15.02 days, predicted for King Island Council.
- The maximum volume ashore for a single spill trajectory during winter conditions was 9.67 m^3, whilst the maximum length of shoreline accumulation at the low threshold was 17.67 km.
- At the depths of 0-10 m, during the summer and winter conditions the maximum dissolved hydrocarbon concentration was 67.28ppb and 73.23 ppb during summer and winter, respectively. Outside of the receptors that the release location resides within, the maximum dissolved hydrocarbon exposure during summer and winter was 23.94 ppb and 23.23 ppb, respectively.
- At the depths of 0-10 m, during summer and winter, the maximum entrained concentration at any given receptor was predicted to be 7,505.14 ppb and 7,419.26 ppb, respectively. Outside of the receptors that the release location resides within, the maximum entrained hydrocarbon exposure during summer and winter was 2,776.45 ppb and 1,760.94 ppb, respectively.

7.4.3.6 Extent of Hydrocarbon Exposure – Condensate

1. Northern Release Location

- The maximum distance from the low (1–10 g/m^2) and moderate (10–50 g/m^2) surface exposure zones was 54.03 km (E) and 5.83 km (ESE), recorded during winter months. No contact was predicted for the high threshold (>50 g/m^2).

- Victorian State waters were predicted to be exposed to surface hydrocarbons at low surface exposure thresholds at a low probability of 3% only during winter conditions.

- No conservation values or sensitivities (Section 4.2) were identified to be exposed to surface hydrocarbons at any threshold.

- The probability of accumulation to any shoreline at, or above, the low level (10 g/m^2) threshold was 99% during summer conditions and 96% during winter conditions. The minimum time before shoreline accumulation at or above the low threshold was 5.7 days (summer) and 3.7 days (winter), predicted for Cape Otway West.

- The maximum volume ashore for a single spill trajectory during the summer and winter conditions was 67.91 m^3 and 87.54 m^3, respectively, whilst the maximum length of shoreline accumulation at the low threshold was 104.17 km and 114.39 km, respectively.

- At the depths of 0-10 m, during the summer and winter conditions the maximum dissolved hydrocarbon concentration was 742.67 ppb and 1,332.51 ppb during summer and winter, respectively. Outside of the receptors that the release location resides within, the maximum dissolved hydrocarbon exposure during summer and winter was 570.15 ppb and 620.89 ppb, respectively.

- At the depths of 0-10 m, during summer and winter, the maximum entrained concentration at any given receptor was predicted to be 3,246.16 ppb and 3,192.69 ppb, respectively. Outside of the receptors that the release location resides within, the maximum entrained hydrocarbon exposure during summer and winter was 358.93 ppb and 527.26 ppb, respectively.

   a. TW1 Location

- The maximum distance from the low threshold (1–10 g/m^2) surface exposure zones was 24.49 km (SE) and 18.35 km (S) during summer and winter conditions, respectively. No contact was predicted for the moderate (10–50 g/m^2) or high thresholds (>50 g/m^2).

- No State waters were predicted to be exposed to surface oil.

- No conservation values or sensitivities (Section 4.2) were identified to be exposed to surface oil at the low threshold or above.

- The probability of accumulation to any shoreline at, or above, the low level (10 g/m^2) threshold was 32% during summer conditions and 57% during winter conditions. The minimum time before shoreline accumulation at or above the low threshold was 25.38 days (summer) ,and 21.93 days (winter), predicted for King Island Council.

- The maximum volume ashore for a single spill trajectory during the summer and winter conditions was 6.15 m^3 and 8.36 m^3, respectively, whilst the maximum length of shoreline accumulation at the low threshold was 12.62 km and 13.90 km, respectively.
- At the depths of 0-10 m, during the summer and winter conditions the maximum dissolved hydrocarbon concentration was 770.64 ppb and 1,280.79 ppb during summer and winter, respectively. Outside of the receptors that the release location resides within, the maximum dissolved hydrocarbon exposure during summer and winter was 553.15 ppb and 528.54 ppb, respectively.
- At the depths of 0-10 m, during summer and winter, the maximum entrained concentration at any given receptor was predicted to be 1,111.04 ppb and 1,179.85 ppb, respectively. Outside of the receptors that the release location resides within, the maximum entrained hydrocarbon exposure during summer and winter was 338.67 ppb and 328.89 ppb, respectively.

7.4.4 Risk Analysis and Evaluation

The potential impacts on environmental receptors from hydrocarbon spills (MDO and/or Condensate) may result from a change in water quality.

As a result of a change in water quality, further impacts may occur, which include:

- Injury / mortality to fauna.
- Change in fauna behaviour.
- Change in ecosystem dynamics.
- Changes to the conservation, socio-economic and cultural values and sensitivities.

The potential environmental impacts to receptors from hydrocarbon exposure from a loss of containment of condensate and MDO are discussed in the following sections.

7.4.4.1 Marine Diesel Oil Exposure

Sea Surface Exposure

Table 7-20: Environmental Impact Summary from Floating Oil Exposure (MDO Spill)

Receptor Group	Receptor Type	Impact	Exposure Evaluation	Consequence Evaluation
Marine fauna	Seabirds	Change in fauna behaviour Injury / mortality to fauna	Several listed Threatened, Migratory and/or listed marine species have the potential to be rafting, resting, diving and feeding within predicted worst-case extent of exposure to moderate levels of surface hydrocarbons, 19.85 km of the northern release location and 49 km of the TW1 release location. Foraging BIAs for several albatross species, common diving-petrel and	When first released, MDO has higher toxicity due to the presence of volatile components. Individual birds making contact close to the spill source at the time of the spill (i.e. areas of moderate concentrations >10 g/m^2 out to 19.85 km of the northern release location and 49 km of the TW1 release location) may be impacted; however, it is unlikely that many birds will be affected as the majority of volatile

Receptor Group	Receptor Type	Impact	Exposure Evaluation	Consequence Evaluation
			short-tailed shearwater are present in the areas with potential to be exposed to moderate levels of surface hydrocarbons. Foraging and breeding BIAs for little penguins are within the planning area, but not within the predicted area of surface exposure at moderate levels. Colonies of little penguins, without defined BIAs, are known to be present along parts of Port Campbell Bay area; therefore, it is possible that little penguins may be present in the area exposed to surface hydrocarbon at moderate levels.	surface hydrocarbons are expected to evaporate or entrain over 24 hours. Seabirds rafting, resting, diving or feeding at sea have the potential to encounter areas where hydrocarbons concentrations are greater than 10 g/m^2 and due to physical oiling may experience lethal surface concentrations. As such, acute or chronic toxicity impacts (death or long-term poor health) to birds are possible but unlikely for an MDO spill because of the limited period of exposure above 10 g/m^2. Due to the hydrocarbon characteristics of MDO, majority of the surface oil is expected to either evaporate or entrain within the first 24 hours under variable-wind conditions. Surface oil is only predicted to remain after 24 hours in calm conditions (RPS, 2024). Therefore, potential impact would likely be limited to individuals, however, impacts to aggregations may occur. There is the potential for serious impact on valued species or habitats with a consequence considered to be Serious (3).
	Marine reptiles	Change in fauna behaviour Injury / mortality to fauna	There may be marine turtles in the area predicted to be exposed to surface oil. However, there are no BIAs or habitat critical to the survival of a marine turtle species within this area.	Marine turtles are vulnerable to the effects of oil at all life stages. Marine turtles can be exposed to surface oil externally (i.e. swimming through oil slicks) or internally (i.e. swallowing the oil). Ingested oil can harm internal organs and digestive function. Oil on their bodies can cause skin irritation and affect breathing. The number of marine turtles that may be exposed to surface MDO is expected to be low as there are no BIAs or habitat critical to the survival of the species present; however, turtles may be transient within the area of exposure. Due to the hydrocarbon characteristics of MDO, majority of the surface oil is expected to either evaporate or entrain within the first 24 hours under variable-wind conditions. Surface oil is only predicted to remain after 24 hours in calm conditions (RPS, 2024). Therefore, potential impact would likely be

Receptor Group	Receptor Type	Impact	Exposure Evaluation	Consequence Evaluation
				limited to individuals, with population impacts not anticipated. There could be expected to be minor short-term impacts and some impact on valued species or habitats with a potential consequence considered to be Moderate (2)
	Pinnipeds (seals and sea lions)	Change in fauna behaviour Injury / mortality to fauna	The Australian and New Zealand fur-seals may occur within the area predicted to be exposed to moderate surface hydrocarbons >10 g/m^2. No BIAs, breeding colonies or haul outs areas are within the area of exposure.	Seals are vulnerable to sea surface exposures given they spend much of their time on or near the surface of the water, as they need to surface every few minutes to breathe. Exposure to surface oil can result in skin and eye irritations and disruptions to thermal regulation. Fur seals are particularly vulnerable to hypothermia from oiling of their fur. The number of seals that may be exposed to surface MDO at >10 g/m^2 is expected to be low as there are no BIAs or habitat critical to the survival of the species present; however, seals may be transient in low numbers within areas of potential surface exposure at >10 g/m^2. Due to the hydrocarbon characteristics of MDO, majority of the surface oil is expected to either evaporate or entrain within the first 24 hours under variable-wind conditions. Surface oil is only predicted to remain after 24 hours in calm conditions (RPS, 2024). Therefore, potential impact would be limited to individuals, with population impacts not anticipated. There could be expected to be minor short-term impacts and some impact on valued species or habitats with a potential consequence considered to be Moderate (2)
	Cetaceans (whales)	Change in fauna behaviour Injury / mortality to fauna	Several threatened, migratory and/or listed marine species have the potential to be within the area predicted to be exposed to moderate surface hydrocarbons of >10 g/m^2. Foraging and distribution BIAs for pygmy blue whales and the migration BIA for southern right whales are within the area predicted to be exposed to surface hydrocarbons >10 g/m^2.	Geraci (1988) found little evidence of cetacean mortality from hydrocarbon spills; however, some behaviour disturbance (including avoidance of the area) may occur. However, observations during spills have recorded whales and dolphins traveling through and feeding in oil slicks. During the Deepwater Horizon spill cetaceans were routinely seen swimming in surface slicks offshore (and nearshore) (Aichinger Dias et al.

Receptor Group	Receptor Type	Impact	Exposure Evaluation	Consequence Evaluation
				2017). Cetaceans observed during the spill response for the Montara oil spill included oceanic species such as false killer whales, bottlenose dolphins, spotted dolphins and spinner dolphins (Watson et al. 2009). [**PC282**] Cetaceans exposed to surface hydrocarbons above moderate exposure thresholds may suffer external oiling, ingestion of oil and inhalation of toxic vapours (Deepwater Horizon Natural Resource Damage Assessment Trustees 2016). [**PC282**] In addition, active avoidance of an area may displace individuals from important habitat, such as foraging. If whales are foraging at the time of the spill, a greater number of individuals may be present in the area where sea surface oil is present. However, due to the hydrocarbon characteristics of MDO, majority of the surface oil is expected to either evaporate or entrain within the first 24 hours under variable-wind conditions. Surface oil is only predicted to remain after 24 hours in calm conditions (RPS, 2024). Also, the area exposed by moderate levels of surface hydrocarbons (19.85 km from the northern release location and 49 km from the TW1 release location) is relatively small compared to the overall distribution area of cetaceans. Given this is a relatively small area of the total distribution and foraging BIAs for pygmy blue whales and migration BIA for southern right whales, the risk of displacement to whales is considered low. Project activities could occur at any time of year. Therefore, there is potential for interaction with southern right whales given the activity has the potential to overlap with the northern migration period of May-June, the peak breeding (July-August) and southern migration period (September-November). The activity timing may overlap with the blue whale season for migration and foraging in the impact area. Visual and acoustic surveys suggest that blue

Receptor Group	Receptor Type	Impact	Exposure Evaluation	Consequence Evaluation
				whales are present in the Otway region between November to June, peaking in February and March. It is expected that foraging whales would be present in the area. As such in the event of a spill potential hydrocarbon exposure could possibly affect aggregations of blue or other foraging whale species. There is the potential for serious impact on valued species or habitats with a consequence considered to be Serious (3).
	Cetaceans (dolphins)	Change in fauna behaviour Injury / mortality to fauna	Several dolphin species have the potential to be within the area predicted to be exposed to moderate surface hydrocarbons of >10 g/m^2. However, there are no BIAs or habitat critical to the survival of a dolphin species.	Dolphins surface to breathe air and may inhale hydrocarbon vapours or be directly exposed to dermal contact with surface hydrocarbons. Direct contact with oil can result in direct impacts to the animal, due to toxic effects if ingested, damage to lungs when inhaled at the surface, and damage to the skin and associated functions such as thermoregulation (AMSA 2010). Dolphins are highly mobile and are considered to have some ability to detect and avoid oil slicks (Geraci and St. Aubin, 1988; Smith et al, 1983). Direct surface hydrocarbon contact may pose little problem to dolphins due to their extraordinarily thick epidermal layer which is effective as a barrier to the substances found in hydrocarbons (Geraci and St. Aubin, 1990; Volkman et al., 1994). The number of dolphins exposed is expected to be low. If dolphins are foraging at the time of the spill, a greater number of individuals may be present in the area where sea surface oil is present, however due to the short duration of the surface exposure above the impact threshold (approximately 24 hrs dependent on the weather conditions), this is not likely. There could be expected to be minor short-term impacts and some impact on valued species or habitats with a potential consequence considered to be Moderate (2)

Receptor Group	Receptor Type	Impact	Exposure Evaluation	Consequence Evaluation
Socio-economic	Petroleum Exploration and Production	Displacement of other marine users	There are no oil and gas operations or activities within the area predicted to be exposed to surface hydrocarbons >10 g/m^2 (19.85 km from the northern release location and 49 km from the TW1 release location).	No impact predicted as there are no non-Beach oil and gas platforms located within the area predicted to be exposed to surface hydrocarbons.
	Shipping	Displacement of other marine users	Shipping occurs within the area predicted to be exposed to surface hydrocarbons >10 g/m^2 (19.85 km from the northern release location and 49 km from the TW1 release location).	Vessels may be present in the area where sea surface oil is present, however, due to the short duration of the surface exposure (approximately 24 hrs depending on weather conditions) deviation of shipping traffic would be unlikely.
	Tourism and recreation (including recreational diving and recreational fisheries)	Change in aesthetic value Changes to the functions, interests or activities of other users	Marine pollution can result in reduced visual aesthetic. The modelling predicts visible surface sheen at the low threshold up to 32.65 km from the northern release location or 64.97 km from the TW1 release location. This oil may be visible as a rainbow sheen on the sea surface during calm conditions.	Visible surface hydrocarbons (i.e. a rainbow sheen) have the potential to reduce the visual amenity of the area for tourism and discourage recreational activities. Due to the expecting weathering of the surface oil, there may be short-term and localised consequences, which are ranked as Moderate (2). Refer also to ecological receptors above.
	Commercial fisheries	Change in aesthetic value Changes to the functions, interests or activities of other users	Commercial fishing occurs within the area predicted to be exposed to surface hydrocarbons >10 g/m^2 (19.85 km from the northern release location and 49 km from the TW1 release location).	Commercial fishing vessels may be present in the area where sea surface oil is present, however, due to the short duration of the surface exposure (approximately 24 hrs depending on weather conditions) deviation of vessels would be unlikely. Impacts to commercial fish and invertebrate species are not predicted from surface oil. A short-term fishing exclusion zone may be implemented. However, given the temporary nature of any surface oil and the low intensity in the area of exposure, there are unlikely to be any significant impact on fisheries in terms of lost catches (and associated income). There may be short-term and localised consequences, which are ranked as Moderate (2)
First Nations	Sea Country	Change in aesthetic value Changes to the functions,	Marine pollution can result in reduced visual aesthetic. The modelling predicts visible surface sheen at the low threshold up to 32.65 km from the northern release	Beach understands that First nations people are linked to the marine environment and may be affected by a change in the environment. Due to the hydrocarbon characteristics of MDO,

Receptor Group	Receptor Type	Impact	Exposure Evaluation	Consequence Evaluation
		interests or activities of other users	location or 64.97 km from the TW1 release location. This oil may be visible as a rainbow sheen on the sea surface during calm conditions.	majority of the surface oil is expected to either evaporate or entrain within the first 24 hours under variable-wind conditions. Surface oil is only predicted to remain after 24 hours in calm conditions (RPS, 2024). Therefore, although no long term or permanent changes to marine environment are expected it is considered that the visual presence of floating oil may impact Sea Country at a spiritual level (i.e. rituals, songlines, culturally important species) and could affect culturally important activities such as mutton birding or affect culturally important species including whales. There may be short-term and localised consequences, which are ranked as Moderate (2). [**PC274**] Refer also to: cetaceans (whales) exposure and consequence evaluation

Shoreline Exposure

Table 7-21: Environmental Impact Summary form Shoreline Oil Exposure (MDO Spill)

Receptor Group	Receptor Type	Impact	Exposure Evaluation	Consequence Evaluation
Threatened and Migratory species	Birds [**PC270**]	Injury/Mortality to fauna Change in fauna behaviour	The modelling predicts potential shoreline exposure at the moderate threshold at Cape Otway West and Moonlight Head from MDO release at the north release location. The moderate threshold is not predicted to be reached based on MDO release at the TW1 release location. Several listed threatened, migratory and/or listed marine seabird and shorebird species have the potential to be foraging at these locations. Shorelines at the Otway coast with the potential to be exposed to moderate hydrocarbon thresholds overlap a foraging BIA and a breeding BIA and therefore may expose birds to shoreline	Shorebird species foraging for invertebrates in intertidal feeding habitats, such as exposed sand and mud flats at lower tides, will be at potential risk of both direct impacts through contamination of individual birds (ingestion or soiling of feathers) and indirect impacts through the contamination of foraging areas that may result in a reduction in available prey items (Clarke 2010). Any direct impact of oil on terrestrial habitats has the potential to contaminate seabirds present at the breeding sites (Clarke 2010). Bird eggs may also be damaged if an oiled adult sits on the nest. Fresh crude was shown to be more toxic than weathered crude, which had a medial lethal dose of 21.3 mg/egg (Clarke 2010). Studies of contamination of duck eggs by small quantities of crude oil, mimicking the effect of oil transfer by parent birds, have been shown to result in mortality of developing embryos (French-McCay 2009).

Receptor Group	Receptor Type	Impact	Exposure Evaluation	Consequence Evaluation
			hydrocarbons for the short-tailed and wedge-tailed shearwater at Muttonbird Island.	Shoreline accumulation will be concentrated along the high tide mark while the lower/upper parts are often untouched (IPIECA 1995). As breeding activities of shorebirds and seabirds generally occurs above the high tide mark, exposure to hydrocarbons is considered unlikely to occur. However, oiled bird species may track oil into their nests, which may then have subsequent impacts on any eggs present. The little penguin would be the highest-risk species, as they have to traverse through the intertidal area to reach nesting sites. Based on the worst-case scenario, the modelling predicted the maximum probability of shoreline accumulation at, or above, the moderate (100 g/m^2) threshold from MDO release at the northern release location to occur at Cape Otway West (6% probability) with the minimum time for shoreline contact predicted as 6.8 days with a peak volume ashore of 4.46 m^3 and Moonlight Head (2% probability) with the minimum time for shoreline contact predicted as 7.7 days with a peak volume ashore of 2.45 m^3 (RPS 2024). Acute or chronic toxicity impacts (death or long-term poor health) to seabirds and shorebirds is possible, however, with the minimum time for shoreline contact predicted as 6-7 days, potential contamination of nests and eggs from oiled parent bird species is limited to weathered MDO. The Otway coast, including Cape Otway West and Moonlight Head, is exposed to substantial wave action that would further break down any shoreline hydrocarbons. The limited exposure to shoreline hydrocarbons will prevent potential death or long-term poor health to seabirds and shorebirds over multiple breeding seasons, therefore it is expected that shoreline hydrocarbons will only impact a single breeding season at most. Consequently, the potential consequence to seabirds and shorebirds is considered to be Serious (3), as there is potential for serious impact on valued species or habitats.

Receptor Group	Receptor Type	Impact	Exposure Evaluation	Consequence Evaluation
Socio-economic	Coastal settlements Recreation and tourism (including recreational fisheries)	Change in aesthetic value Changes to the functions, interests or activities of other users	Marine pollution can result in reduced visual aesthetic. The modelling predicts shoreline exposure at the low threshold along the Otway coast, including Bay of Islands (1%), Cape Otway West (24%), Cape Patton (10%), Childers Cove (1%), Moonlight Head (9%), Point Hicks (1%), Port Campbell (2%), around to Lorne (3%), Apollo Bay (8%), and Anglesea (1%). There is a low probably of shoreline exposure at the low threshold on King Island (9% from TW1 and 1% from the northern release location).	Shoreline oil had potential for exposure on along the Victorian coast including the Otway coast, Port Campbell and Anglesea. The minimum time for shoreline accumulation ranged from 2.03 days at Cape Otway West, 3.18 days at Moonlight Head, 15.05 days at King Island, up to 26.11 days at Anglesea. Visible shoreline hydrocarbons have the potential to reduce the visual amenity of the area for tourism and discourage recreational activities. Given the minimum time to shoreline accumulation ranged from 2-26 days it is likely that majority of the oil will have dissipated. Both the Otway coast and the west side of King Island are exposed to substantial wave action that would further breakdown any shoreline hydrocarbons. There may be minor short-term consequences, which are ranked as Moderate (2).
	Seaweed industry	Change in ecosystem dynamics Changes to the functions, interests or activities of other users	The modelling predicts a low probability of shoreline exposure at the low threshold at King Island (1% from the northern release location and 9% from TW1 release location) where bull kelp may be collected.	Experiments verified the susceptibility of *Nereocystis luetkeana* (bull kelp – North America) tissue to the direct exposure to several petroleum types. Antrim et al (1995) showed that petroleum treatments resulted in visible tissue damage, with a distinct bleached line being the most visible indication of plant contact with the petroleum. Moderate to heavy colour loss, which was generally followed by rapid decay of tissue, was most pronounced in 24 h exposures to unweathered and weathered MDO. As bull kelp is collected from the shoreline there is a potential for some plants to be affected and not be suitable for collection and processing. However, given the low levels of shoreline oil predicted (peak volume of 1.38 m^3) it is unlikely to be a significant impact on seaweed collection and associated income. There may be minor short-term consequences, which are ranked as Moderate (2).

Receptor Group	Receptor Type	Impact	Exposure Evaluation	Consequence Evaluation
First Nations	Sea Country Native Title	Change in aesthetic value Changes to the functions, interests or activities of other users	Marine pollution can result in reduced visual aesthetic. The modelling predicts shoreline exposure at the low and moderate threshold along the Otway coast (Eastern Maar native title claim) and further east at Anglesea (Wadawurrung native title claim).	Beach understands that First nations people are linked to the marine environment and may be affected by a change in the environment. Although no long term or permanent changes to marine environment are expected it is considered that the visual presence of shoreline oil may impact Sea Country at a spiritual level (i.e. rituals, songlines) and could affect culturally important activities such as mutton birding. The predicted minimum time for oil to reach a shoreline means it is likely to have dissipated during that time. The Otway coast is exposed to substantial wave action that would further breakdown any shoreline hydrocarbons. [**PC274**] The relatively low volume means there may be short-term and localised consequences, which are ranked as Moderate (2)

In Water Exposure

Table 7-22: Environmental Impact Summary from In water Oil Exposure (MDO Spill)

Receptor Group	Receptor Type	Impact	Exposure Evaluation	Consequence Evaluation
Conservation Values and Sensitivities	Australian Marine Parks	Change in values Changes to the functions, interests or activities of other users	Apollo AMP may be exposed to entrained hydrocarbons at the moderate threshold within the upper 0 -10 m of the water column for up to 11 hours (RPS 2024). Zeehan AMP may be exposed to entrained hydrocarbons at the moderate threshold within the upper 0 -10 m of the water column for up to 7.25 hours (RPS 2024). No AMPs were predicted to be exposed to dissolved hydrocarbons at any threshold.	The Apollo AMP is located in waters 80 m to 120 m deep and thus conservation values such as ecosystems, habitats and communities associated with the Western Bass Strait Shelf Transition and the Bass Strait Shelf Province and associated with the seafloor features and the wreck of the MV City of Rayville are not predicted to be impacted. The conservation value of important migration area for blue, fin, sei and humpback whales is unlikely to be impacted as these whales would be moving through the area and thus unlikely to be exposed to in water hydrocarbons within 0 -10 m of the water column for a substantial period to elicit a toxic effect. The Apollo AMP is an important foraging area for black-browed and shy albatross, Australasian gannet, short-tailed shearwater and crested tern. These seabirds forage over an

Receptor Group	Receptor Type	Impact	Exposure Evaluation	Consequence Evaluation
				extensive area and are distributed over a wide geographic range. The area of entrained hydrocarbon predicted to meet the high threshold is relatively small compared to the Bass Strait and Otway region. It is these small areas where sub-lethal and toxic effects to birds may occur. There is a low probability that seabirds would be feeding exclusively or predominantly on fish found in these areas of higher hydrocarbon thresholds, meaning there is low probability of seabirds themselves experiencing sub-lethal or toxic impacts as a result of consuming hydrocarbon-tainted fish. The Zeehan AMP is located in waters 50 m to 3,000 m deep and thus conservation values such as ecosystems, habitats and communities associated with the Tasmania Province, the West Tasmania Transition and the Western Bass Strait Shelf Transition and associated with the seafloor features are not predicted to be impacted. The conservation value of important migration area for blue and humpback whales is unlikely to be impacted as these whales would be moving through the area and thus unlikely to be exposed to in water hydrocarbons within 0 -10 m of the water column for a substantial period to elicit a toxic effect. The Zeehan AMP is also an important foraging habitat for black-browed, wandering and shy albatrosses, and great-winged and cape petrels. These seabirds forage over an extensive area and are distributed over a wide geographic range. The areas of dissolved hydrocarbon predicted to meet the moderate threshold and entrained hydrocarbon predicted to meet the high threshold are relatively small compared to the Bass Strait and Otway region. It is these small areas where sub-lethal and toxic effects to birds may occur. There is a low probability that seabirds would be feeding exclusively or predominantly

Receptor Group	Receptor Type	Impact	Exposure Evaluation	Consequence Evaluation
				on fish found in these areas of higher hydrocarbon thresholds, meaning there is low probability of seabirds themselves experiencing sub-lethal or toxic impacts as a result of consuming hydrocarbon-tainted fish. Consequently, the potential consequence to these AMPs are considered to be Moderate (2), as they could be expected to result in minor short-term impacts to an area of recognised conservation value.
	State Marine Protected Areas	Change in values Changes to the functions, interests or activities of other users	The Twelve Apostles Marine National Park has a 1% probability of being exposed to entrained hydrocarbons at the moderate threshold within the upper 0 -10 m of the water column for up to 6.75 hours. The Arches and Mushroom Reef Marine Sanctuaries may be exposed to entrained hydrocarbons at the low threshold within the upper 0-10 m of the water column for up to 35.5 hours (2% probability) and 8 hours (1 % probability), respectively.	As impacts are only predicted within 0 – 10 m of the water column values such as the wreck of the Loch Ard, underwater limestone formations of arches and canyons, diverse range of encrusting invertebrates and dive sites are not predicted to be impacted. The unique limestone rock formations, including the Twelve Apostles, marine habitats representative of the Otway marine bioregion and indigenous culture based on spiritual connection to sea country and a history of marine resource use are unlikely to be impacted by entrained hydrocarbons at the low threshold. Consequently, the potential consequence to the Twelve Apostles Marine National Park and The Arches and Mushroom Reef Marine Sanctuaries is considered to be Moderate (2), as they could be expected to result in minor short-term impacts to an area of recognised conservation value.
	Key Ecological Features	Change in ecosystem dynamics	The West Tasmanian Canyons KEF may be exposed to entrained hydrocarbons at the low threshold within the upper 0 -10 m of the water column for up to 59.25 hours. The Bonney Coast Upwelling KEF may be exposed to entrained hydrocarbons at low threshold within the upper 0-10 m of the water column for up to 67 hours.	The West Tasmanian Canyons KEF is in water depths > 70 m and thus impacts from in-water hydrocarbons are not predicted. No impacts from the low threshold of in-water hydrocarbons are predicted to the Bonney Coast Upwelling KEF.

Receptor Group	Receptor Type	Impact	Exposure Evaluation	Consequence Evaluation
			No KEF was predicted to be contacted by dissolved hydrocarbons.	
Benthic Habitat	Algae	Change in habitat	Video surveys confirmed the presence of high density macroalgae dominated epibenthos in waters shallower than 20 m, however, communities are typically limited to intertidal and shallow subtidal rocky substrates (Section 4.4.3). In-water exposure (dissolved and entrained hydrocarbons) is only predicted to occur within the 0 -10 m of the water column. Dissolved hydrocarbons in the upper 0–10 m of the water column at the moderate threshold could impact algae found within Victorian waters where waters may be shallower than 10 m. Entrained hydrocarbons in the upper 0–10 m of the water column at the moderate threshold could impact algae found within Victorian waters to the west of Cape Otway where waters may be shallower than 10 m.	Reported toxic responses to oils have included a variety of physiological changes to enzyme systems, photosynthesis, respiration, and nucleic acid synthesis (Lewis & Pryor 2013). A review of field studies conducted after spill events by Connell et al (1981) indicated a high degree of variability in the level of impact, but in all instances, the algae appeared to be able to recover rapidly from even very heavy oiling. Given the restricted range of exposure (shallow nearshore and intertidal waters only) and only the predicted moderate threshold concentrations of dissolved hydrocarbons predicted in shallow waters, any impact to algae is not expected to result in long-term or irreversible damage. Consequently, the potential consequence to algae are considered to be Minor (1), as they could be expected to result in localised low-level impacts.
	Soft Coral	Change in habitat	Corals do not occur as a dominant habitat type within the Planning Area. However, their presence has been recorded around areas such as Twelve Apostles Marine Park and Cape Otway where low threshold concentrations of entrained hydrocarbons are predicted to be reached.	Exposure of entrained hydrocarbons to shallow subtidal corals has the potential to result in lethal or sublethal toxic effects, resulting in acute impacts or death at moderate to high exposure thresholds (Shigenaka 2001). Contact with corals may lead to reduced growth rates, tissue decomposition, and poor resistance and mortality of sections of reef (NOAA 2010). However, given the lack of coral reef formations, and the sporadic cover of hard or soft corals in mixed nearshore reef communities along the Otway coast, such impacts are considered to be limited to isolated corals. Consequently, the potential consequence to soft corals are considered to be Minor (1), as they

Receptor Group	Receptor Type	Impact	Exposure Evaluation	Consequence Evaluation
				could be expected to result in localised low-level impacts.
	Seagrass	Change in habitat	Seagrass may be present within the area predicted to be exposed to in-water hydrocarbons as seagrass is known to occur within Twelve Apostles Marine Park which has the potential to be exposure to entrained hydrocarbons at the moderate threshold.	There is the potential that entrained in-water hydrocarbon exposure could result in sub-lethal impacts from smothering, more so than lethal impacts, possibly because much of seagrasses' biomass is underground in their rhizomes (Zieman et al., 1984). Potential impacts are considered to be Moderate (2), as they could be expected to result in minor short-term impacts to an area of recognised conservation value.
Marine fauna	Plankton	Injury/ Mortality to fauna	Plankton are likely to be exposed to in-water hydrocarbons. Effects will be greatest in the upper 10 m of the water column and areas close to the spill source where hydrocarbon concentrations are likely to be highest.	Relatively low concentrations of hydrocarbon are toxic to both plankton including zooplankton and ichthyoplankton (fish eggs and larvae). Plankton risk exposure through ingestion, inhalation and dermal contact. Impacts would predominantly result from exposure to dissolved fractions, as larval fish and plankton are pelagic, and are moved by seawater currents. Potential impacts would largely be restricted to planktonic communities, which would be expected to recover rapidly following a hydrocarbon spill. Plankton are numerous and widespread but do act as the basis for the marine food web, meaning that an oil spill in any one location is unlikely to have long-lasting impacts on plankton populations at a regional level. Once background water quality conditions have re-established, the plankton community may take weeks to months to recover (ITOPF, 2011a), allowing for seasonal influences on the assemblage characteristics. Additionally, with the elevated nutrient loading expected during seasonal upwelling events within the Otway region (November to April), plankton are likely to recover more rapidly than when upwelling of nutrient-rich waters is less prevalent. the potential consequence to plankton are considered to be Minor (1), as they could be expected to

Receptor Group	Receptor Type	Impact	Exposure Evaluation	Consequence Evaluation
				result in low-level short-term and recoverable impacts.
	Marine invertebrates	Injury/ Mortality to fauna	In-water invertebrates of value have been identified to include squid, crustaceans (rock lobster, crabs) and molluscs (scallops, abalone). Impact by direct contact of in-water hydrocarbons to benthic species in the deeper areas of potential exposure are not predicted. Species located in shallow nearshore or intertidal waters may be exposed to in-water hydrocarbons low thresholds. Several commercial fisheries for marine invertebrates are within the area predicted to be exposed to moderate levels of entrained in-water hydrocarbons.	Acute or chronic exposure through contact and/or ingestion can result in toxicological risks. Larval or juvenile forms of invertebrates may be more prone to impacts (Suchanek, 1993). Localised impacts to larval stages may occur which could impact on population recruitment that year. Tainting of recreation or commercial species is considered unlikely to occur given exposure is limited to entrained hydrocarbons, however if it did it is expected to be localised and low level with recovery expected. Consequently, the potential consequence to invertebrates, including commercially fished invertebrates are considered to be Moderate (2), as they could be expected to result in localised and minor short-term impacts to species of value.
	Fish (including eels) [**PC294**]	Injury/ Mortality to fauna	Entrained hydrocarbon droplets can physically affect fish exposed for an extended duration (weeks to months). Effects will be greatest in the upper 10 m of the water column and areas close to the spill source where hydrocarbon concentrations are likely to be highest. Several fish communities in these areas are demersal and therefore more prevalent towards the seabed, which is not likely to be exposed). Therefore, any impacts are expected to be highly localised. The Australian grayling spends most of its life in fresh water, with parts of the larval or juvenile stages spent in coastal marine waters, therefore it is not expected to be present in offshore waters in large numbers. There is a known distribution and foraging BIA for the white	Pelagic free-swimming fish and sharks are unlikely to suffer long-term damage from oil spill exposure because dissolved/entrained hydrocarbons in water are not expected to be sufficient to cause harm (ITOPF, 2011a). Subsurface hydrocarbons could potentially result in acute exposure to marine biota such as juvenile fish, larvae, and planktonic organisms, although impacts are not expected cause population-level impacts. Environmental monitoring of pelagic and demersal fishes immediately following the Montara oil spill indicated that fish were exposed to hydrocarbons, although no adverse effects were detected (Gagnon and Rawson 2012, 2011). Further sampling and testing over time indicated that fish captured in close proximity to the Montara wellhead were comparable to those collected from reference sites (Gagnon and Rawson 2012, 2011). [**PC282**] Consequently, the potential consequence to fish, including those

Receptor Group	Receptor Type	Impact	Exposure Evaluation	Consequence Evaluation
			shark in the area of exposure, however, it is not expected that this species spends a large amount of time close to the surface where thresholds may be highest.	commercially fished, are considered to be Moderate, as they could be expected to result in localised low-level short-term impacts to species of value. Impacts on fish eggs and larvae entrained in the upper water column are not expected to be significant given the temporary nature of the resulting change in water quality. As egg/larvae dispersal is widely distributed in the upper layers of the water column it is expected that current induced drift will rapidly replace any oil affected populations. Consequently, the potential consequence to eggs/larva are considered to be Minor (1), as they could be expected to result in localised low-level short-term impacts.
	Pinnipeds (seals and sea lions)	Injury/ Mortality to fauna Change in fauna behaviour	Australian and New Zealand fur-seals may occur within the area of exposure There are no identified BIAs for seals or sea lions within the area of exposure. No known breeding colonies of Australian or New Zealand fur-seals are exposed to moderate dissolved or high entrained exposure thresholds. Given the mobility of pinnipeds, there may be small numbers of seals in the areas predicted to be temporarily exposed to moderate dissolved or high entrained exposure thresholds in the water column, noting that in-water exposure (dissolved or entrained) is only predicted to occur within the upper 0 - 10 m of the water column.	Exposure to moderate dissolved or high entrained exposure thresholds in the water column or consumption of prey affected by the oil may cause sub-lethal impacts to pinnipeds. Due to the temporary and localised nature of the spill, pinnipeds widespread nature, the low-level exposure zones and rapid loss of the volatile components of MDO in choppy and windy seas (such as that of the area exposed), the potential consequence to pinnipeds are considered to be Moderate (2), as they could be expected to result in localised and minor short-term impacts to species of recognised conservation value.
	Cetaceans (whales and dolphins)	Injury/ Mortality to fauna Change in fauna behaviour	Several threatened, migratory and/or listed marine cetacean species have the potential to be migrating or foraging within the area predicted to be exposed to in-water hydrocarbons.	Cetacean exposure to entrained hydrocarbons can result in physical coating as well as ingestion (Geraci and St Aubin, 1988; Deepwater Horizon Natural Resource Damage Assessment Trustees 2016). Such impacts are associated with 'fresh'

Receptor Group	Receptor Type	Impact	Exposure Evaluation	Consequence Evaluation
			BIAs for foraging for pygmy blue whales and the migration BIA for southern right whales are within the area predicted to be exposed to moderate dissolved or high entrained exposure thresholds in the water column, noting that in-water exposure (dissolved or entrained) is only predicted to occur within the upper 0-10 m of the water column.	hydrocarbon; the risk of impact declines rapidly as the MDO weathers. The potential for impacts to cetaceans and dolphins would be limited to a relatively short period following the release and would need to coincide with seasonal foraging or aggregation event to result in exposure to a large number of individuals, as may be the case during seasonal upwelling events within the Otway region. However, such exposure is not anticipated to result in long-term population viability effects. A proportion of the foraging or distributed population of whales could be affected in the relatively localised area and water depth of the total foraging BIA for pygmy blue whales and migration BIA for southern right whales. There is the potential for serious impact on valued species or habitats with a consequence considered to be Serious (3).
	Birds [**PC284**]	Injury/ Mortality to fauna Change in fauna behaviour	The extent of in-water hydrocarbons at the moderate threshold from a MDO release overlaps foraging BIAs for several seabird species, including various albatross species (i.e. antipodean, black-browed, Bullers, Campbell, Indian-yellow-nosed, shy and wandering), petrels (common-diving and white-faced storm) and shearwaters (short-tailed and wedge-tailed).	Seabirds could be impacted by in-water hydrocarbon exposure directly (i.e., whilst diving through the water column foraging) or indirectly (i.e. by consuming hydrocarbon-tainted fish, resulting in sub-lethal or toxic impacts). As seabirds are top order predators, any impact on other marine life (e.g., pelagic fish) from hydrocarbon exposure may disrupt and limit food supply both for the maintenance of adults and the provisioning of young. Furthermore, the foraging BIAs are typically over relatively extensive areas, therefore, impacts are not anticipated at a population level due to the localised and temporary exposure of moderate levels of surface hydrocarbons. Acute or chronic toxicity impacts (death or long-term poor health) to seabirds is possible, however, the presence of birds within areas exposed to moderate threshold levels is expected to be limited, due to the transitory nature of foraging

Receptor Group	Receptor Type	Impact	Exposure Evaluation	Consequence Evaluation
				individuals, and given the absence of offshore aggregation areas in the area. However, due to the anticipated hydrocarbon weathering and fate of the MDO, the majority is expected to have either evaporated or entrained during that time. Modelling predicted between approximately 40% of the volume to evaporate and up to approximately 60% to entrain within the first 24 hours, depending on the wind conditions (RPS 2023). Furthermore, tidal and wave action within the area is anticipated to breakdown any shoreline hydrocarbons. Consequently, the potential consequence to seabirds and shorebirds is considered to be Moderate (2), as they could be expected to result in minor, short-term impact to species of recognised conservation value.
Socio-economic	Commercial and recreational fisheries	Change in ecosystem dynamics Changes to the functions, interests or activities of other users	In-water exposure to hydrocarbons may result in a reduction in commercially targeted marine species, resulting in impacts to commercial fishing and aquaculture. Actual or potential contamination of seafood can affect commercial and recreational fishing and can impact seafood markets long after any actual risk to seafood from a spill has subsided (NOAA, 2002) which can have economic impacts to the industry. Several commercial fisheries operate in the planning area and overlap the spatial extent of the water column hydrocarbon predictions	Any acute impacts are expected to be limited to small numbers of juvenile fish, larvae, and planktonic organisms, which are not expected to affect population viability or recruitment. Impacts from entrained exposure are unlikely to manifest at a fish population viability level. Any exclusion zone established would be limited to the immediate vicinity of the release point, and due to the rapid weathering of MDO would only be in place 1-3 days after release, therefore physical displacement to vessels is unlikely to be a significant impact. Consequently, the potential consequence to commercial and recreational fisheries are considered to be Moderate (2), as they could be expected to result in localised minor short-term impacts.
	Recreation and tourism	Change in ecosystem dynamics Changes to the functions, interests or activities of other users	Tourism and recreation are also linked to the presence of marine fauna (e.g. whales), particular habitats and locations for recreational fishing. The area between	Any impact to receptors that provide nature-based tourism features (e.g. whales) may cause a subsequent negative impact to recreation and tourism activities.

Receptor Group	Receptor Type	Impact	Exposure Evaluation	Consequence Evaluation
			Cape Otway and Port Campbell is frequented by tourists. It is a remote stretch of coastline dominated by cliffs with remote beaches subject to the high energy wave action. Access to the entire coastline is via a 7 to 8-day walking track from Apollo Bay ending at the Twelve Apostles. Recreation is also linked to the presence of marine fauna and direct impacts to marine fauna such as whales, birds, and pinnipeds can result in indirect impacts to recreational values. It is important to note that the impact from a public perception perspective may be even more conservative. This may deter tourists and locals from undertaking recreational activities. If this occurs, the attraction is temporarily closed, economic losses to the business are likely to eventuate. The extent of these losses would be dependent on how long the attraction remains closed.	Any impact to receptors that provide nature-based tourism features (e.g. fish and cetaceans) may cause a subsequent negative impact to recreation and tourism activities. However, impacts would be localised and for a relatively short duration. Consequently, the potential consequence to recreation and tourism are considered to be Moderate (2), as they could be expected to result in localised minor short-term impacts.
	Seaweed Industry	Change in ecosystem dynamics Changes to the functions, interests or activities of other users	In-water exposure to entrained MDO may result in a reduction in commercially targeted seaweed species. Areas along the west side of King Island where bull kelp is collected may be exposed to entrained hydrocarbons at the moderate threshold within the upper 0 -10 m of the water column.	Experiments verified the susceptibility of *Nereocystis luetkeana* (bull kelp – North America) tissue to the direct exposure to several petroleum types. Antrim et al (1995) showed that petroleum treatments resulted in visible tissue damage, with a distinct bleached line being the most visible indication of plant contact with the petroleum. Moderate to heavy colour loss, which was generally followed by rapid decay of tissue, was most pronounced in 24-hour exposures to unweathered and weathered MDO. The study did not look at how this would affect the productivity of bull kelp. However, given the low levels of entrained hydrocarbons predicted it is unlikely to be a significant impact on seaweed collection and associated

Receptor Group	Receptor Type	Impact	Exposure Evaluation	Consequence Evaluation
				income. The relatively low volume means there may be short-term localised consequences, which are ranked as Moderate (2).
First Nations	Sea Country Native Title Indigenous Protected Area	Change in aesthetic value Changes to the functions, interests or activities of other users	In-water exposure to hydrocarbons is predicted along the Victorian and Tasmanian coastal waters within the planning area which is Sea Country for a number of First Nations groups and is adjacent to the Eastern Maar Native Title claim.	Section 4 details the connection First Nations people have to Sea Country which could be potentially impacted by in-water exposure to hydrocarbons. The relatively low volume means there may be short-term and localised consequences. Although no long-term or permanent changes to marine environment are expected the short-term contamination of Sea Country may result in impacts associated at a spiritual level (i.e. rituals, songlines, culturally important species) and could affect culturally important activities such as mutton birding or affect culturally important species including eels and whales. The potential short-term and localised consequences are ranked as Moderate (2). [**PC274**] Refer also to: fish (including eels) and cetaceans (whales) exposure and consequence evaluations above.

7.4.4.2 Condensate Exposure

Sea Surface Exposure

Table 7-23: Environmental Impact Summary from Floating Oil Exposure (Condensate Spill)

Receptor Group	Receptor Type	Impacts	Exposure Evaluation	Consequence Evaluation
Marine fauna	Seabirds	Injury / mortality to fauna Change in fauna behaviour	Several listed Threatened, Migratory and/or Listed Marine species have the potential to be rafting, resting, diving or feeding within predicted worst-case extent of exposure to moderate levels of surface hydrocarbons, up to 5.83 km from the northern release location. Surface hydrocarbons are not predicted to reach moderate threshold levels from a loss of well control at the TW1 release location.	When first released, gas condensate has higher toxicity due to the presence of volatile components. Individual birds making contact close to the spill source at the time of the spill (i.e. areas of concentrations >10 g/m^2 up to between 5.83 km from the northern release location) may be impacted however it is unlikely that a large number of birds will be affected. Seabirds exposed to surface hydrocarbons at moderate exposure levels may experience

Receptor Group	Receptor Type	Impacts	Exposure Evaluation	Consequence Evaluation
			No exposure at the high threshold is predicted from either to extend only 1 km from the release location. Foraging BIAs for several albatross species, the short-tailed shearwater, and common diving-petrel overlap the area predicted to be exposed to moderate thresholds of surface oil from the northern release location. The release location resides within the boundaries of all of these BIAs.	acute or chronic toxicity impacts, however the area of contact is relatively localised and the presence of birds is expected to be limited to foraging individuals of a transitory nature, given the absence of offshore aggregation areas and the large foraging BIAs. Consequently, the potential consequence is considered to be Serious (3), as they could be expected to result in serious impact on valued species or habitat.
	Marine reptiles	Injury / mortality to fauna Change in fauna behaviour	There may be transiting marine turtles within up to 5.83 km of the northern release locations predicted to be exposed to moderate levels of surface hydrocarbons. However, there are no BIAs or habitat critical to the survival of the species within the area predicted to be exposed to moderate thresholds of surface oil. No exposure at the high threshold is predicted from either release location.	Marine turtles are vulnerable to the effects of oil at all life stages. Marine turtles can be exposed to surface oil externally (i.e. swimming through oil slicks) or internally (i.e. swallowing the oil). Ingested oil can harm internal organs and digestive function. Oil on their bodies can cause skin irritation and affect breathing. The number of marine turtles that may be exposed to surface condensate is expected to be low as there are no BIAs or habitat critical to the survival of the species present and the localised (up to 5.83 km from the northern release location) extent of exposure above the 10 g/m^2 threshold; however, turtles may be transient within the area. Therefore, potential impact would be limited to individuals, with population impacts not anticipated. Consequently, the potential consequence is considered to be Moderate (2), as they could be expected to result in localised and minor short-term impacts to species of value.
	Pinnipeds (seals and sea-lions)	Injury / mortality to fauna Change in fauna behaviour	The Australian and New Zealand fur-seals may occur within 5.83 km of the northern release location predicted to be exposed to moderate levels of surface hydrocarbons. No BIAs, breading colonies or haul outs	Exposure to surface oil can result in skin and eye irritations and disruptions to thermal regulation. Fur seals are particularly vulnerable to hypothermia from oiling of their fur – however the characteristics of Thylacine

Receptor Group	Receptor Type	Impacts	Exposure Evaluation	Consequence Evaluation
			areas within the area predicted to be exposed to moderate thresholds of surface oil.	condensate mean this is not likely. The number of pinnipeds exposed is expected to be low, with population impacts not anticipated. The potential consequence is considered to be Moderate (2) as they could be expected to result in short term effects and some impact on valued species or habitat.
	Cetaceans (whales)	Injury / mortality to fauna Change in fauna behaviour	Several threatened, migratory and/or listed cetacean species have the potential to be foraging within 5.83 km of the northern release location predicted to be exposed to moderate levels of surface hydrocarbons. The area of predicted moderate exposure overlaps a foraging BIA for pygmy blue whales and the migration BIA for southern right whale. The release location resides within the boundaries of these BIAs.	Geraci (1988) found little evidence of cetacean mortality from hydrocarbon spills; however, some behaviour disturbance (including avoidance of the area) may occur. However, observations during spills have recorded whales and dolphins traveling through and feeding in oil slicks. During the Deepwater Horizon spill cetaceans were routinely seen swimming in surface slicks offshore (and nearshore) (Aichinger Dias et al. 2017). Cetaceans observed during the spill response for the Montara oil spill included oceanic species such as false killer whales, bottlenose dolphins, spotted dolphins and spinner dolphins (Watson et al. 2009). [**PC282**] Cetaceans exposed to surface hydrocarbons above moderate exposure thresholds may suffer external oiling, ingestion of oil and inhalation of toxic vapours (Deepwater Horizon Natural Resource Damage Assessment Trustees 2016). [**PC282**] In addition, active avoidance of an area may displace individuals or aggregations from important habitat, such as foraging. If whales are foraging at the time of the spill, a greater number of individuals may be present in the plume, however due to the small area of the surface exposure above the impact threshold (5.83 km from release location), this is not likely. Given this is a

Receptor Group	Receptor Type	Impacts	Exposure Evaluation	Consequence Evaluation
				relatively small area of the total foraging BIA for pygmy blue whales and migration BIA for southern right whales, the risk of displacement to whales is considered low. There is potential for interaction with southern right whales given that the activity window may overlap with the northern migration period of May-June, the peak breeding (July-August) and southern migration period (September-November). The activity window timing may also overlap with the blue whale season for migration and foraging. Visual and acoustic surveys suggest that blue whales are present in the Otway region between November to June, peaking in February and March. As such in the event of a spill potential hydrocarbon exposure could possibly affect blue or other foraging whale species. Consequently, the potential consequence is considered to be Serious (3), as they could be expected to result in serious impact on valued species or habitat.
	Cetaceans (dolphins)	Injury / mortality to fauna Change in fauna behaviour	There may be dolphins within 5.83 km of the northern release location predicted to be exposed to moderate levels of surface hydrocarbons However, it is not identified as critical habitat, and there are no spatially defined aggregations within the area predicted to be exposed to moderate thresholds of surface oil.	Dolphins surface to breathe air and may inhale hydrocarbon vapours or be directly exposed to dermal contact with surface hydrocarbons. Direct contact with oil can result in direct impacts to the animal, due to toxic effects if ingested, damage to lungs when inhaled at the surface, and damage to the skin and associated functions such as thermoregulation (AMSA 2010). Dolphins are highly mobile and are considered to have some ability to detect and avoid oil slicks (Geraci and St. Aubin, 1988; Smith et al, 1983). Direct surface hydrocarbon contact may pose little problem to dolphins due to their extraordinarily thick epidermal layer which is effective as a barrier to the substances

Receptor Group	Receptor Type	Impacts	Exposure Evaluation	Consequence Evaluation
				found in hydrocarbons (Geraci and St. Aubin, 1990; Vol kman et al., 1994). The number of dolphins exposed is expected to be low, with population impacts not anticipated. Due to the rapid weathering of condensate, the potential exposure to surface hydrocarbons is relatively short, with the majority of surface condensate evaporating or entraining within 24 hours (RPS, 2024). Consequently, the potential consequence to dolphins are considered to be Moderate (2), as they could be expected to result in localised minor short-term impacts to species of recognised conservation value.
Socio-economic	Petroleum Exploration and Production	Displacement of other marine users	There are no oil and gas platforms, or activities within 5.83 km of the northern release location predicted to be exposed to moderate levels of surface hydrocarbons	No impact predicted as there are no non-Beach oil and gas platforms located within the area predicted to be exposed to surface hydrocarbons.
	Shipping	Displacement of other marine users	Shipping may occur within 5.83 km of the northern release location predicted to be exposed to moderate levels of surface hydrocarbons	Vessels may be present in the area where moderate levels of sea surface oil are predicted, however, due to small area of exposure (5.83 km) no impact is predicted.
	Tourism and recreation (including recreational diving and recreational fisheries)	Change in aesthetic value Changes to the functions, interests or activities of other users	Marine pollution can result in reduced visual aesthetic. The modelling predicts visible surface sheen at the low threshold up to approximately 54 km from the northern release location or 24.5 km from the TW1 release location. This oil may be visible as a rainbow sheen on the sea surface during calm conditions.	Visible surface hydrocarbons (i.e. a rainbow sheen) have the potential to reduce the visual amenity of the area for tourism and discourage recreational activities. However, the distance from shore means there may be minor consequences and some impact, which are ranked as Moderate (2).
	Commercial fisheries	Displacement of other marine users	Commercial fishing may occur within 5.83 km of the release location predicted to be exposed to moderate levels of surface hydrocarbons	Commercial fishing vessels may be present in the area where moderate levels of sea surface oil are predicted, however, due to the timeframes of presence given the LOWC scenarios a Moderate (2) impact is assigned.

Receptor Group	Receptor Type	Impacts	Exposure Evaluation	Consequence Evaluation
First Nations	Sea Country	Change in aesthetic value Changes to the functions, interests or activities of other users	Marine pollution can result in reduced visual aesthetic. The modelling predicts visible surface sheen at the low threshold up to approximately 54 km from the northern release location or 24.5 km from the TW1 release location. This oil may be visible as a rainbow sheen on the sea surface during calm conditions.	Visible surface hydrocarbons (i.e. a rainbow sheen) have the potential to reduce the visual amenity of the areas of Sea Country. The distance from shore means there may be minor consequences and some impact. Beach understands that First Nations people are linked to the marine environment and may be affected by a change in the environment. Although no long term or permanent changes to marine environment are expected it is considered that the visual presence of floating oil may impact Sea Country at a spiritual level (i.e. rituals, songlines, culturally important species) and could affect culturally important activities such as mutton birding or affect culturally important species including whales. There may be short-term and localised consequences, which are ranked as Moderate (2). [**PC274**] Refer also to cetaceans (whales) exposure and consequence evaluation above.

Shoreline Exposure

Table 7-24: Environmental Impact Summary from Shoreline Oil Exposure (Condensate Spill)

Receptor Group	Receptor Type	Impacts	Exposure Evaluation	Consequence Evaluation
Conservation Values and Sensitivities	National Heritage Places	Change in aesthetic value Changes to the functions, interests or activities of other users	Marine pollution can result in reduced visual aesthetic. The modelling predicts potential shoreline exposure at the low and moderate threshold at Great Ocean Road and Scenic Environs.	Visible shoreline hydrocarbons have the potential to reduce the visual amenity of the area for tourism and discourage recreational activities. The predicted minimum time for oil at the low threshold to reach the Otway coast where the Great Ocean Road and Scenic Environs is located was 3.7 days. The condensate will likely be dissipated by that time. The relatively short area of shoreline and low volume means there may be short-term and

Receptor Group	Receptor Type	Impacts	Exposure Evaluation	Consequence Evaluation
				localised consequences, which are ranked as Moderate (2).
	Nationally Important Wetlands	Change in aesthetic value Change in ecosystem dynamics Changes to the functions, interests or activities of other users	Marine pollution can result in reduced visual aesthetic. The modelling predicts potential shoreline exposure at the low threshold at Aire River/Lower Aire River and Princetown Wetlands (Section 4.2.7).	Visible shoreline hydrocarbons have the potential to reduce the visual amenity of the area for tourism and discourage recreational activities within protected areas. The predicted minimum time for oil to reach the shoreline adjacent to the River/Lower Aire River and Princetown Wetlands is 3.7 days and it is likely to have dissipated during that time. Cape Otway is exposed to substantial wave action that would further breakdown any shoreline hydrocarbons. The Aire River/Lower Aire River Wetlands consist of three shallow freshwater lakes, brackish to saline marshes and an estuary on the Aire River floodplain. Depending on where the shoreline contact occurs there is a potential for shoreline oil to move into the estuary and wetlands at low concentrations which are not predicted to impact the aesthetic and ecological value of the wetlands. The Princetown Wetlands and upstream of the Gellibrand River mouth at Princetown Beach. Depending on where the shoreline contact occurs there is a potential for shoreline oil to move into the estuary and wetlands at low concentrations which are not predicted to impact the aesthetic and ecological value of the wetlands. The relatively short duration and low volume means there may be short-term and localised consequences, which are ranked as Moderate (2).
	State Terrestrial Protected Area	Change in aesthetic value Change in ecosystem dynamics	Marine pollution can result in reduced visual aesthetic. The modelling predicts potential shoreline exposure at the low and moderate thresholds at	Visible shoreline hydrocarbons have the potential to reduce the visual amenity of the area for tourism and discourage recreational activities within

Receptor Group	Receptor Type	Impacts	Exposure Evaluation	Consequence Evaluation
		Changes to the functions, interests or activities of other users	Great Otway National Park, Port Campbell Southern Wilsons Promontory, Wilsons Promontory and Wilson Promontory Islands National Parks, and the following on the west side of King Island; Cape Wickham Conservation Area, Cataraqui Point Conservation Area, Porky Beach Conservation Area, Seal Rocks State Reserve, Stokes Point Conservations Area and West Point State Reserve.	protected areas. Seal Rocks on King Island is also a New Zealand fur-seal breeding colony. The predicted minimum time for oil to reach a shoreline is 3.7 days for the Victorian coast. The condensate is likely to have dissipated during that time due to substantial wave action that would further breakdown any shoreline hydrocarbons. The predicted minimum time for oil to reach King Island was 22 days. As above, the condensate it is likely to have dissipated during that time due to substantial wave action that would further breakdown any shoreline hydrocarbons. Consequently, the potential consequence is considered to be Serious (3), as they could be expected to result in serious impact on valued species or habitat.
	Threatened Ecological Communities Saltmarsh	Change in habitat Change in ecosystem dynamics	The modelling predicts potential shoreline exposure at the low , and some isolated moderate, thresholds where saltmarsh communities and the Assemblages of species associated with open-coast salt-wedge estuaries of western and central Victoria ecological community and Subtropical and Temperate Coastal Saltmarsh Threatened Ecological Communities may be present.	Saltmarshes are considered to have a high sensitivity to hydrocarbon exposure. Saltmarsh vegetation offers a large surface area for oil absorption and tends to trap oil. Evidence from case histories and experiments shows that the damage resulting from oiling, and recovery times of oiled marsh vegetation, are very variable. In areas of light to moderate oiling where oil is mainly on perennial vegetation with little penetration of sediment, the shoots of the plants may be killed but recovery can take place from the underground systems. Good recovery commonly occurs within one to two years (IPIECA, 1994). Consequently, the potential consequences to saltmarsh exposed to shoreline hydrocarbons is considered to be Moderate (2), as they could be

Receptor Group	Receptor Type	Impacts	Exposure Evaluation	Consequence Evaluation
				expected to short-term and localised.
Marine fauna	Pinnipeds (seals and sea lions)	Injury/Mortality to fauna Change in fauna behaviour	The modelling predicts potential shoreline exposure at the low threshold at Seal Rocks on King Island which is a New Zealand fur-seal breeding colony.	Breeding colonies (used to birth and nurse until pups are weaned) are particularly sensitive to hydrocarbon spills (Higgins & Gass, 1993) and have shown to be impacted by oil at the moderate and high thresholds. The predicted minimum time for oil to reach the King Island coastline (such as Seal Rocks) was 22 days for the low threshold. No contact at King Island was predicted for the moderate or high thresholds. This is ranked as Moderate (2) consequence.
	Birds [**PC270**]	Injury/Mortality to fauna Change in fauna behaviour	The modelling predicts potential shoreline exposure at or above the moderate threshold only along the Otway coast from LOWC condensate release at the northern location. No shoreline exposure at, or above, the moderate threshold was predicted for the southern release locations. Several listed Threatened, Migratory and/or listed marine bird species have the potential to be foraging or nesting at these locations. Shorelines exposed at or above moderate hydrocarbon thresholds include a breeding BIA for the wedge-tailed shearwater as well as breeding BIAs and surrounding foraging BIAs for the black-faced cormorant, common diving-petrel, little penguin and short-tailed shearwater.	Shorebird species foraging for invertebrates in intertidal feeding habitats, such as exposed sand and mud flats at lower tides, will be at potential risk of both direct impacts through contamination of individual birds (ingestion or soiling of feathers) and indirect impacts through the contamination of foraging areas that may result in a reduction in available prey items (Clarke 2010). Any direct impact of oil on terrestrial habitats has the potential to contaminate seabirds present at the breeding sites (Clarke 2010). Bird eggs may also be damaged if an oiled adult sits on the nest. Fresh crude was shown to be more toxic than weathered crude, which had a medial lethal dose of 21.3 mg/egg (Clarke 2010). Studies of contamination of duck eggs by small quantities of crude oil, mimicking the effect of oil transfer by parent birds, have been shown to result in mortality of developing embryos (French-McCay 2009). Shoreline accumulation will be concentrated along the high tide mark while the lower/upper parts

Receptor Group	Receptor Type	Impacts	Exposure Evaluation	Consequence Evaluation
				are often untouched (IPIECA 1995). As breeding activities of shorebirds and seabirds generally occurs above the high tide mark, exposure to hydrocarbons is considered unlikely to occur. However, oiled bird species may track oil into their nests, which may then have subsequent impacts on any eggs present. The little penguin would be the highest-risk species, as they have to traverse through the intertidal area to reach nesting sites. Based on the worst-case scenario, the modelling predicted the maximum probability of shoreline accumulation at, or above, the moderate (100 g/m^2) threshold from a LOWC condensate release at the Northern location at Cape Otway West (34%), followed by Moonlight Head (11%), Point Hicks (10%) and Port Campbell (1%). The minimum time to shore was at Cape Otway West (9 days), followed by Moonlight Head and Port Campbell (both 18 days), then Point Hicks (46 days). Cape Otway West had the maximum peak volume ashore predicted (6.6 m^3), followed by Point Hicks (5.56 m^3), Moonlight Head (4.39 m^3), and Port Campbell (1.76 m^3). The modelling predicted no shoreline accumulation at, or above, the moderate (100 g/m^2) threshold to occur from the southern spill release location. Acute or chronic toxicity impacts (death or long-term poor health) to seabirds and shorebirds is possible, however, with the minimum time for shoreline contact predicted as 9-46 days, potential contamination of nests and eggs from oiled parent bird species is limited to weathered condensate. Also, given the predicted minimum time for oil to reach shorelines within

Receptor Group	Receptor Type	Impacts	Exposure Evaluation	Consequence Evaluation
				breeding BIAs is 9-46 days. The majority of condensate at sea is likely to have dissipated during that time. The Cape Otway coast is exposed to wave and tidal action that would further breakdown any shoreline hydrocarbons. The limited exposure to shoreline hydrocarbons will prevent potential death or long-term poor health to seabirds and shorebirds over multiple breeding seasons, therefore it is expected that shoreline hydrocarbons will only impact a single breeding season at most. Consequently, the potential consequence is considered to be Serious (3), as they could be expected to result in serious impact on valued species or habitat.
Socio-economic	Coastal settlements Recreation and tourism (including recreational fisheries)	Change in aesthetic value Changes to the functions, interests or activities of other users	Marine pollution can result in reduced visual aesthetic. The modelling predicts shoreline exposure at the low and moderate threshold several local government areas (LGA)	Visible shoreline hydrocarbons have the potential to reduce the visual amenity of the area for tourism and discourage recreational activities. The predicted minimum time for oil at low thresholds to reach any shoreline was 3.7 days (Colac Otway) up to 89 days (Cape Nelson), Majority of the oil is likely to have dissipated during that time due to substantial wave action that would breakdown any shoreline hydrocarbons. The relatively short duration and low volume means there may be short-term and localised consequences, which are ranked as Moderate (2).
	Seaweed industry	Change in ecosystem dynamics Changes to the functions, interests or activities of other users	The modelling predicts potential shoreline exposure at the low threshold in areas along the west side of King Island where bull kelp is collected. No shoreline accumulation at, or above, the moderate threshold was predicted for King Island from either spill release location.	Experiments verified the susceptibility of *Nereocystis luetkeana* (bull kelp – North America) tissue to the direct exposure to several petroleum types. Antrim et al (1995) showed that petroleum treatments resulted in visible tissue damage, with a distinct bleached line being the most visible indication of plant contact with the

Receptor Group	Receptor Type	Impacts	Exposure Evaluation	Consequence Evaluation
				petroleum. Moderate to heavy colour loss, which was generally followed by rapid decay of tissue, was most pronounced in 24 h exposures to unweathered and weathered MDO. As bull kelp is collected from the shoreline there is a potential for some plants to be affected and not be suitable for collection and processing. However, given the low levels of shoreline oil predicted it is unlikely to be a significant impact on seaweed collection and associated income. The relatively low volume and absence of contact at the moderate threshold indicates that any impact will be short-term and localised consequences to a valued species or habitats, which have been ranked as Serious (3).
First Nations	Sea Country Native Title	Change in aesthetic value Changes to the functions, interests or activities of other users	Marine pollution can result in reduced visual aesthetic. The modelling predicts shoreline exposure at the low threshold within Victorian Traditional Owner areas of Eastern Maar Native Title determination (Tribunal File No. VCD2023/001), Gunditjmara Native Title determination (Tribunal File No. VCD2007/001) and Bunurong Land Council Aboriginal Corporation. [**PC269**] The modelling predicts shoreline exposure at the low threshold on the western side of King Island..	Visible shoreline hydrocarbons have the potential to reduce the visual amenity of Sea Country. The predicted minimum time for oil to reach a shoreline is 3.7 days for the Victorian coast, and 22 days for King Island. Condensate is likely to have dissipated during that time due to substantial wave action that would breakdown any shoreline hydrocarbons. Although no long term or permanent changes to marine environment are expected it is considered that the visual presence of shoreline oil may impact Sea Country at a spiritual level (i.e. rituals, songlines) and could affect culturally important activities such as mutton birding. [**PC274**] The relatively localised extent and low volume means there may be short-term and localised consequences, which are ranked as Moderate (2).

In-Water Exposure

Table 7-25: Environmental Impact Summary from In-Water Oil Exposure (Condensate Spill)

Receptor Group	Receptor Type	Impacts	Exposure Evaluation	Consequence Evaluation
Conservation Values and Sensitivities	Australian Marine Parks	Change in values Changes to the functions, interests or activities of other users	Apollo and Zeehan AMPs may be exposed to dissolved in water hydrocarbons at, or above, the low threshold within the upper 0 -10 m of the water column. Apollo and Zeehan AMPs were predicted to be exposed to in water entrained hydrocarbons at, or above, the low threshold within the upper 0 -10 m of the water column.	The Apollo AMP is located in waters 80 m to 120 m deep and thus conservation values such as ecosystems, habitats and communities associated with the Western Bass Strait Shelf Transition and the Bass Strait Shelf Province and associated with the seafloor features and the wreck of the MV City of Rayville are not predicted to be impacted. The conservation value of important migration area for blue, fin, sei and humpback whales is unlikely to be impacted as these whales would be moving through the area and thus unlikely to be exposed to in water hydrocarbons within 0 -10 m of the water column for a substantial period to elicit a toxic effect. The Apollo AMP is an important foraging area for black-browed and shy albatross, Australasian gannet, short-tailed shearwater and crested tern. These seabirds forage over an extensive area and are distributed over a wide geographic range. The areas of dissolved hydrocarbon predicted to meet the moderate or high threshold and entrained hydrocarbon predicted to meet the moderate threshold are relatively small compared to the Bass Strait and Otway region. It is these small areas where sub-lethal and toxic effects to birds may occur. There is a low probability that seabirds would be feeding exclusively or predominantly on fish found in the hydrocarbon exposed area, thus there is low probability of seabirds themselves experiencing sub-lethal or toxic impacts as a result of consuming hydrocarbon-tainted fish. The Zeehan AMP is located in waters 50 m to 3,000 m deep and thus conservation values such as ecosystems, habitats and communities associated with the Tasmania Province, the West Tasmania Transition and the Western Bass Strait Shelf Transition and associated with the seafloor features are not predicted to be impacted. The conservation value of important migration area for blue and humpback

Receptor Group	Receptor Type	Impacts	Exposure Evaluation	Consequence Evaluation
				whales is unlikely to be impacted as these whales would be moving through the area and thus unlikely to be exposed to in water hydrocarbons within 0 -10 m of the water column for a substantial period to elicit a toxic effect. The Zeehan AMP is also an important foraging habitat for black-browed, wandering and shy albatrosses, and great-winged and cape petrels. These seabirds forage over an extensive area and are distributed over a wide geographic range. The areas of dissolved hydrocarbon predicted to meet the moderate or high threshold and entrained hydrocarbon predicted to meet the moderate threshold are relatively small compared to the Bass Strait and Otway region. It is these small areas where sub-lethal and toxic effects to birds may occur. There is a low probability that seabirds would be feeding exclusively or predominantly on fish found in these areas of hydrocarbon exposure, thus there is low probability of seabirds themselves experiencing sub-lethal or toxic impacts as a result of consuming hydrocarbon-tainted fish. Consequently, the potential consequence is considered to be Serious (3), as they could be expected to result in serious impact on valued species or habitat.
	State Marine Protected Areas	Change in values Changes to the functions, interests or activities of other users	Bunurong and Point Addis were predicted to be exposed to in-water entrained hydrocarbons at high thresholds. Twelve Apostles was predicted to be exposed to in-water dissolved hydrocarbons at high thresholds. Discovery Bay has potential for being impacted at the moderate threshold of in water entrained hydrocarbons. The Arches MS has potential for being impacted at the moderate threshold of in-water dissolved hydrocarbons. Twelve Apostles and , Port Phillip Heads MNPs and Mushroom Reef MS were predicted to be exposed	Impacts to Bunurong Marine National Park values, such as abundant and diverse marine flora and fauna, important coastal habitat for threatened species, recreational activities, cultural places and objects of high traditional significance to indigenous people, and important maritime and heritage values, may be impacted by high threshold levels of entrained hydrocarbons. Point Addis Marine National Park values, such as the diverse invertebrates, underwater scenery, intertidal reefs, recreational activities, and potential traditional use of the area by indigenous people, may be impacted by high thresholds of in-water entrained hydrocarbons. The Twelve Apostles Marine National Park values, such as the wreck of the Loch Ard, underwater limestone formations of arches and canyons, diverse range of

Receptor Group	Receptor Type	Impacts	Exposure Evaluation	Consequence Evaluation
			above the low threshold of in water entrained and/or dissolved hydrocarbons..	encrusting invertebrates and dive sites are not predicted to be impacted by high thresholds of dissolved hydrocarbons, given impacts are only predicted within 0 – 10 m of the water column. The unique limestone rock formations, including the Twelve Apostles, marine habitats representative of the Otway marine bioregion and indigenous culture based on spiritual connection to sea country and a history of marine resource use, may be impacted by in water hydrocarbons at the high threshold. Consequently, the potential consequence to these State Marine Protected Areas is considered to be Serious (3) as they could be expected to result in localised minor short-term impacts to an area of recognised conservation value.
	Key Ecological Features	Change in ecosystem dynamics	The West Tasmanian Canyons KEF may be exposed to dissolved hydrocarbons at high thresholds and entrained hydrocarbons at the moderate threshold within the upper 0 - 10 m of the water column. Bonney Coast Upwelling KEF may be exposed to entrained hydrocarbons at low thresholds within the upper 0-10m of the water column and entrained hydrocarbons at low thresholds. Upwelling East of Eden was predicted to be exposed to low entrained threshold of in water hydrocarbons.	The West Tasmanian Canyons KEF is in water depths > 70 m and thus impacts from in-water hydrocarbons are not predicted. No impacts from the low threshold of in water hydrocarbons are predicted to the KEFs.
	Threatened Ecological Communities	Change in ecosystem dynamics	The following Threatened Ecological Communities may be exposed to dissolved and entrained hydrocarbons at the low threshold within the upper 0 -10 m of the water column. Assemblages of species associated with open-coast salt-wedge estuaries of western and central Victoria ecological community. Giant Kelp Marine Forests of South East Australia.	Entrained hydrocarbons at the low threshold are not predicted to impact on the ecological function of the Threatened Ecological Communities.

Receptor Group	Receptor Type	Impacts	Exposure Evaluation	Consequence Evaluation
			Subtropical and Temperate Coastal Saltmarsh.	
Benthic Habitat	Algae	Change in habitat	Video surveys confirmed the presence of high density macroalgae dominated epibenthos in waters shallower than 20 m, however, communities are typically limited to intertidal and shallow subtidal rocky substrates (Section 4.4.3). Dissolved hydrocarbons in the upper 0 – 10 m of the water column at the moderate threshold that could impact algae found within Victorian waters where waters may be shallower than 10 m. Entrained hydrocarbons in the upper 0 – 10 m of the water column at the high threshold that could impact algae are not predicted in Tasmanian waters or Victorian waters where waters may be shallower than 10 m.	Reported toxic responses to oils have included a variety of physiological changes to enzyme systems, photosynthesis, respiration, and nucleic acid synthesis (Lewis & Pryor 2013). A review of field studies conducted after spill events by Connell et al (1981) indicated a high degree of variability in the level of impact, but in all instances, the algae appeared to be able to recover rapidly from even very heavy oiling. Given the restricted range of exposure (shallow nearshore and intertidal waters only) and only the predicted moderate threshold concentrations of dissolved hydrocarbons predicted in shallow waters, any impact to algae is not expected to result in long-term or irreversible damage. Consequently, the potential consequence to algae are considered to be Minor (1), as they could be expected to result in localised low-level impacts.
	Soft Coral	Change in habitat	Corals do not occur as a dominant habitat type within the planning area, however their presence has been recorded around areas such as Wilsons Promontory National Park and Cape Otway where low threshold concentrations of dissolved or entrained hydrocarbons are predicted.	Exposure of entrained hydrocarbons to shallow subtidal corals has the potential to result in lethal or sublethal toxic effects, resulting in acute impacts or death at moderate to high exposure thresholds (Shigenaka, 2001). Contact with corals may lead to reduced growth rates, tissue decomposition, and poor resistance and mortality of sections of reef (NOAA, 2010). However, given the lack of coral reef formations, and the sporadic cover of hard or soft corals in mixed nearshore reef communities along the Otway coast, such impacts are considered to be limited to isolated corals. Also, only low exposure thresholds are predicted at known coral habitat sites. Consequently, the potential consequence to algae are considered to be Minor (1), as they could be expected to result in localised low-level impacts.

Receptor Group	Receptor Type	Impacts	Exposure Evaluation	Consequence Evaluation
	Seagrass	Change in habitat	In-water exposure (dissolved or entrained) is only predicted to occur within the upper 0 – 10 m of the water column; therefore, benthic habitat within intertidal or shallow nearshore waters has the potential to be exposed. Note that the greater wave action and water column mixing within the nearshore environment will also result in rapid weathering of the condensate. Seagrass may be present within the area predicted to be exposed to in-water hydrocarbons (e.g. seagrass is known to occur within Twelve Apostles Marine Park, and areas around Warrnambool) Exposure in nearshore and intertidal areas is predicted to only be at a low threshold for dissolved and entrained hydrocarbons.	There is the potential that exposure could result in sub-lethal impacts, more so than lethal impacts, possibly because much of seagrasses' biomass is underground in their rhizomes (Zieman et al., 1984). Exposure also can take place via uptake of hydrocarbons through plant membranes and seeds may be affected by contact with oil contained within sediments (NRDA 2012). When seagrass leaves are exposed to petroleum oil, sub-lethal quantities of the soluble fraction can be incorporated into the tissue, causing a reduction in tolerance to other stress factors (Zieman et al. 1984). The toxic components of petroleum oils are thought to be the PAH, which are lipophilic and therefore able to pass through lipid membranes and tend to accumulate in the thylakoid membranes of chloroplasts (Ren et al. 1994). Susceptibility of seagrasses to hydrocarbon spills will depend largely on distribution, with deeper communities protected from oiling under all but the most extreme weather conditions. Shallow seagrasses are more likely to be affected by dispersed oil droplets. Given the restricted range of exposure (shallow nearshore and intertidal waters only) and the predicted low concentrations of hydrocarbons predicted in these waters, any impact to seagrass is not expected to result in long-term or irreversible damage. Consequently, the potential consequence to seagrass are considered to be Moderate (2), as they could be expected to result in localised minor short-term impacts to habitat of recognised conservation value.
Marine fauna	Plankton	Injury / mortality to fauna	Plankton are likely to be exposed to in-water hydrocarbons within the upper 0 – 10 m of the water column. Effects will be greatest in the area close to the spill source where hydrocarbon concentrations are likely to be highest.	Relatively low concentrations of hydrocarbon are toxic to both plankton including zooplankton and ichthyoplankton (fish eggs and larvae). Plankton risk exposure through ingestion, inhalation, and dermal contact. Impacts would predominantly result from exposure to dissolved fractions, as larval fish and plankton are pelagic, and are moved by seawater currents. Potential impacts would largely be restricted to planktonic communities, which would be

Receptor Group	Receptor Type	Impacts	Exposure Evaluation	Consequence Evaluation
				expected to recover rapidly following a hydrocarbon spill. Plankton are numerous and widespread but do act as the basis for the marine food web, meaning that an oil spill in any one location is unlikely to have long-lasting impacts on plankton populations at a regional level. Once background water quality conditions have re-established, the plankton community may take weeks to months to recover (ITOPF, 2011a), allowing for seasonal influences on the assemblage characteristics. Additionally, with the elevated nutrient loading expected during seasonal upwelling events within the Otway region (November to April), plankton are likely to recover more rapidly than when upwelling of nutrient-rich waters is less prevalent. Consequently, given the limited area exposed by moderate levels of dissolved hydrocarbons, the potential consequence to plankton are considered to be Minor (1), as they could be expected to result in localised low-level short-term and recoverable impacts.
	Marine invertebrates	Injury / mortality to fauna	In-water invertebrates of value have been identified to include squid, crustaceans (rock lobster, crabs) and molluscs (scallops, abalone). Impact by direct contact of in-water hydrocarbons to benthic species in the deeper areas of potential exposure are not predicted as in-water exposure (dissolved or entrained) is only predicted to occur in the upper 0 – 10 m of the water column. Species located in shallow nearshore or intertidal waters may be exposed to in-water hydrocarbons low thresholds. Several commercial fisheries for marine invertebrates are within the area predicted to be exposed to moderate levels of entrained in-water hydrocarbons.	Acute or chronic exposure through contact and/or ingestion can result in toxicological risks. Larval or juvenile forms of invertebrates may be more prone to impacts (Suchanek, 1993). Localised impacts to larval stages may occur which could impact on population recruitment that year. Tainting of recreation or commercial species is considered unlikely to occur given exposure is limited to entrained hydrocarbons, however if it did it is expected to be localised and low level with recovery expected. Consequently, the potential consequence to invertebrates, including commercially fished invertebrates are considered to be Moderate (2) as they could be expected to result in localised short-term impacts to species of value.

Receptor Group	Receptor Type	Impacts	Exposure Evaluation	Consequence Evaluation
	Fish (including eels) [**PC294**]	Injury / mortality to fauna	In-water exposure (dissolved or entrained) is only predicted to occur in the upper 0 – 10 m of the water column the surface layers of the water column. Several fish communities in these areas are demersal and therefore more prevalent towards the seabed, as such, exposure to these species is not expected to occur. Any fish or shark species within the surface layers of the water column, may come into contact with the area of predicted exposure for in-water hydrocarbons. The Australian grayling spends most of its life in fresh water, with parts of the larval or juvenile stages spent in coastal marine waters, therefore it is not expected to be present in offshore waters in large numbers. There is distribution and foraging BIAs for the white shark are predicted to be overlapped by the hydrocarbon exposure, however, it is not expected that this species spends a large amount of time close to the surface where thresholds may be highest.	Pelagic free-swimming fish and sharks are unlikely to suffer long-term damage from oil spill exposure because dissolved/entrained hydrocarbons in water are not expected to be sufficient to cause harm (ITOPF, 2010). Subsurface hydrocarbons could potentially result in acute exposure to marine biota such as juvenile fish, larvae, and planktonic organisms, although impacts are not expected cause population-level impacts. Environmental monitoring of pelagic and demersal fishes immediately following the Montara oil spill indicated that fish were exposed to hydrocarbons, although no adverse effects were detected (Gagnon and Rawson 2012, 2011). Further sampling and testing over time indicated that fish captured in close proximity to the Montara wellhead were comparable to those collected from reference sites (Gagnon and Rawson 2012, 2011). [**PC282**] Consequently, the potential consequence to fish, including those commercially fished, are considered to be Moderate, as they could be expected to result in localised low-level short-term impacts to species of value. Impacts on eggs and larvae entrained in the upper water column are not expected to be significant given the temporary period of water quality impairment, and the limited geographical extent of the spill. As egg/larvae dispersal is extensive in the upper layers of the water column and it is expected that current induced drift will rapidly replace any oil affected populations. Impacts are assessed as temporary and localised, and therefore considered to be Moderate (2)
	Pinnipeds (seals and sea-lions)	Injury / mortality to fauna Change in fauna behaviour	Australian and New Zealand fur-seals may occur within the area of exposure. There are no identified BIAs for seals or sea lions within the area of exposure. No known breeding colonies of Australian or New Zealand fur-seals are exposed to moderate dissolved or high entrained exposure thresholds.	Exposure to moderate dissolved or high entrained exposure thresholds in the water column or consumption of prey affected by the oil may cause sub-lethal impacts to pinnipeds. Due to the temporary and localised nature of the spill, pinnipeds widespread nature, the low-level exposure zones and rapid loss of the volatile components of MDO in choppy and windy seas (such as that of the area exposed), the potential consequence to pinnipeds are considered

Receptor Group	Receptor Type	Impacts	Exposure Evaluation	Consequence Evaluation
			Given the mobility of pinnipeds, there may be small numbers of seals in the areas predicted to be temporarily exposed to moderate dissolved or high entrained exposure thresholds in the water column, noting that in-water exposure (dissolved or entrained) is only predicted to occur within the upper 0 - 10 m of the water column.	to be Moderate (2), as they could be expected to result in localised minor short-term impacts to species of recognised conservation value.
	Cetaceans (whales and dolphins)	Injury / mortality to fauna Change in fauna behaviour	Several threatened, migratory and/or listed marine cetacean species have the potential to be migrating, resting or foraging within the area predicted to be exposed to in-water hydrocarbons. BIAs for foraging for pygmy blue whales and the migration BIA for southern right whales are within the area predicted to be exposed to moderate or high exposure thresholds in the water column, noting that in-water exposure (dissolved or entrained) is only predicted to occur within the upper 0 - 10 m of the water column.	Cetacean exposure to entrained hydrocarbons can result in physical coating as well as ingestion (Geraci and St Aubin, 1988; Deepwater Horizon Natural Resource Damage Assessment Trustees 2016). Such impacts are associated with 'fresh' hydrocarbon; the risk of impact declines rapidly as the oil weathers. The potential for impacts to cetaceans and dolphins would be limited to a relatively short period following the release and would need to coincide with seasonal foraging or aggregation event to result in exposure to a large number of individuals, as may be the case during seasonal upwelling events within the Otway region. However, such exposure is not anticipated to result in long-term population viability effects. A proportion of the foraging or distributed population of whales could be affected in the relatively localised area and water depth of the total foraging BIA for pygmy blue whales and migration BIA for southern right whales. Consequently, the potential consequence is considered to be Serious (3), as they could be expected to result in serious impact on valued species or habitat.
	Birds [**PC284**]	Injury / mortality to fauna Change in fauna behaviour	The extent of in-water hydrocarbons at the moderate threshold from a LOWC overlaps foraging BIAs for several seabird species, including various albatross species (i.e. antipodean, black-browed, Bullers, Campbell, Indian-yellow-nosed, shy and wandering), petrels (common-diving), shearwaters (short-	Seabirds could be impacted by in-water hydrocarbon exposure directly (i.e., whilst diving through the water column foraging) or indirectly (i.e. by consuming hydrocarbon-tainted fish, resulting in sub-lethal or toxic impacts). Penguins may be especially vulnerable to oil because they spend a high portion of their time in the water and readily lose insulation and buoyancy if their feathers are oiled. The Iron Baron vessel spill, of

Receptor Group	Receptor Type	Impacts	Exposure Evaluation	Consequence Evaluation
			tailed and wedge-tailed), Australasian gannet, black-faced cormorant and little penguin.	325 tonnes of bunker fuel in Tasmania in 1995, is estimated to have resulted in the death of up to 20,000 penguins (Hook et al. 2016).
			In-water hydrocarbons at low threshold were predicted to overlap the breeding BIA for the little penguin (at Phillip Island and the buffer around Christmas Island).	As seabirds are top order predators, any impact on other marine life (e.g., pelagic fish) from hydrocarbon exposure may disrupt and limit food supply both for the maintenance of adults and the provisioning of young. Furthermore, the foraging BIAs are typical over relatively extensive areas, therefore, impacts are not anticipated at a population level due to the localised and temporary exposure of moderate levels of surface hydrocarbons. Breeding little penguins oiled by in-water hydrocarbons during foraging may contaminate nests and eggs from oil transfer by parent birds (Clarke 2010). Bird eggs may become damaged from oil contamination if an oiled adult sits on the nest. Fresh crude was found to be more toxic than weathered crude, which had a median lethal dose of 21.3 mg/egg (Clarke 2010). Studies of contamination of duck eggs by small quantities of crude oil, mimicking the effect of oil transfer by parent birds, have been shown to result in mortality of developing embryos (French-McCay 2009). Acute or chronic toxicity impacts (death or long-term poor health) to seabirds is possible, however, the presence of birds within areas exposed to moderate threshold levels is expected to be limited, due to the transitory nature of foraging individuals, and temporary presence of in-water hydrocarbons in waters surrounding breeding BIAs.. However, due to the anticipated hydrocarbon weathering and fate of the condensate, the majority is expected to have either evaporated or entrained during that time. Modelling predicted between approximately 69.4% to 82.5% of the volume to evaporate and up to approximately 22.1% to entrain within the first 24 hours, depending on the wind conditions (RPS 2024). Furthermore, tidal and wave action within the area is anticipated to breakdown any shoreline hydrocarbons.

Receptor Group	Receptor Type	Impacts	Exposure Evaluation	Consequence Evaluation
				Consequently, the potential consequence to seabirds and shorebirds is considered to be Moderate (2), as they could be expected to result in minor, short-term impact to species of recognised conservation value.
Socio-economic	Commercial and recreational fisheries	Change in ecosystem dynamics Changes to the functions, interests or activities of other users	In-water exposure to hydrocarbons may result in a reduction in commercially targeted marine species, resulting in impacts to commercial fishing and aquaculture. Actual or potential contamination of seafood can affect commercial and recreational fishing and can impact seafood markets long after any actual risk to seafood from a spill has subsided (NOAA, 2002) which can have economic impacts to the industry. Several commercial fisheries operate in the planning area and overlap the spatial extent of the water column hydrocarbon predictions	Any acute impacts are expected to be limited to small numbers of juvenile fish, larvae, and planktonic organisms, which are not expected to affect population viability or recruitment. Impacts from entrained exposure are unlikely to manifest at a fish population viability level. Any exclusion zone established would be limited to the safety exclusion zone around the vicinity of the release point, and due to the rapid weathering of hydrocarbons would only be in place whilst well-control activities are enacted, therefore physical displacement to vessels is unlikely to be a significant impact. Consequently, the potential consequence to commercial and recreational fisheries are considered to be Moderate (2), as they could be expected to result in localised low-level short-term impacts.
	Recreation and tourism	Changes to the functions, interests or activities of other users Change in aesthetic value	Tourism and recreation are linked to the presence of marine fauna (e.g. whales), particular habitats and locations for recreational fishing. The area between Cape Otway and Port Campbell is frequented by tourists. It is a remote stretch of coastline dominated by cliffs with remote beaches subject to the high energy wave action. Access to the entire coastline is via a 7 to 8-day walking track from Apollo Bay ending at the Twelve Apostles. Recreation is also linked to the presence of marine fauna and direct impacts to marine fauna such as whales, birds, and pinnipeds can result in indirect impacts to recreational values. It is important to note that the	Any impact to receptors that provide nature-based tourism features (e.g. whales) may cause a subsequent negative impact to recreation and tourism activities. Any impact to receptors that provide nature-based tourism features (e.g. fish and cetaceans) may cause a subsequent negative impact to recreation and tourism activities. However, the relatively short duration, and distance from shore means there may be short-term and localised consequences, which are ranked as Moderate (2).

Receptor Group	Receptor Type	Impacts	Exposure Evaluation	Consequence Evaluation
			impact from a public perception perspective may be even more conservative. This may deter tourists and locals from undertaking recreational activities. If this occurs, the attraction is temporarily closed, economic losses to the business are likely to eventuate. The extent of these losses would be dependent on how long the attraction remains closed.	
	Seaweed Industry	Change in ecosystem dynamics Changes to the functions, interests or activities of other users	In-water exposure to hydrocarbons may result in a reduction in commercially targeted seaweed species. Areas along the west side of King Island where bull kelp is collected may be exposed to dissolved and entrained hydrocarbons at the low threshold within the upper 0 - 10 m of the water column.	Experiments verified the susceptibility of *Nereocystis luetkeana* (bull kelp – North America) tissue to the direct exposure to several petroleum types. Antrim et al (1995) showed that petroleum treatments resulted in visible tissue damage, with a distinct bleached line being the most visible indication of plant contact with the petroleum. Moderate to heavy colour loss, which was generally followed by rapid decay of tissue, was most pronounced in 24 h exposures to unweathered and weathered MDO. The study did not look at how this would affect the productivity of bull kelp. Consequently, the potential consequence is considered to be Serious (3), as they could be expected to result in serious impact on valued species or habitat.
First Nations	Sea Country Native Title Indigenous Protected Area	Change in aesthetic value Changes to the functions, interests or activities of other users	In-water exposure to hydrocarbons is predicted along coastal First Nations Sea Country including Victorian coastal waters stretching from Discovery Bay to the west to Hopkins River mouth/ Warnambool in the east. Sea Country predicted to be exposed to in-water exposure to hydrocarbons is adjacent to the Eastern Maar Native Title determination (Tribunal File No. VCD2023/001), Gunditjmara Native Title determination (Tribunal File No. VCD2007/001) and Preminghana Indigenous Protected Area. [**PC269**]	Section 4 details the connection First Nations people have to Sea Country which could be potentially impacted by in-water exposure to hydrocarbons. Although no long term or permanent changes to marine environment are expected the short-term contamination of Sea Country may result in impacts associated at a spiritual level (i.e. rituals, songlines, culturally important species) and could affect culturally important activities such as mutton birding or affect culturally important species including eels and whales. The potential short-term and localised consequences are ranked as Moderate (2). Refer also to fish (including eels) and cetaceans (whales) exposure and consequence evaluations above. [**PC274**].

7.4.4.3 Credible Scenario Risk Evaluation

Table 7-26 provides likelihood, consequence, and risk evaluations for each credible scenario for loss of containment – hydrocarbons and chemicals, supported by consequence evaluations detailed in Sections 7.4.4.1, 7.4.4.2 and 6.9 from exposure to MDO, condensate and MEG, respectively.

Table 7-26: Risk Evaluation for Each Credible Scenario for Loss of Containment – Hydrocarbons and Chemicals

Credible Scenario (Stage)		**Risk Evaluation**
Loss of well containment - gas and condensate (drilling and completions /decommissioning)	Consequence	An unplanned LOWC event has the potential for widespread exposure of hydrocarbons in the marine environment. Section 7.4.4.2 provides detailed consequence evaluations on receptors with the potential for sea surface, in-water and shoreline condensate exposure based on hydrocarbon spill modelling of a LOWC event (Section 7.4.3). This evaluation found the highest consequence ranking to be Serious (3) for the following receptors: • Seabirds • Cetaceans • State terrestrial protected areas • Seaweed industry • Australian Marine Parks • State marine protected areas. To encapsulate all potential consequences to the environment, the highest consequence ranking of Serious (3) has been assigned as the overall consequence level for unplanned LOWC event.
	Likelihood	The likelihood of a LOWC event occurring is Highly Unlikely. To date no incidents relating to LOWC events have occurred during Beach operations in Australia including in the Otway basin. Future spills from LOWC events are considered remote events based on history of no known condensate spills in southern Australia from LOWC events.
	Risk Rating	**Medium**
Umbilical or flowline loss of containment – MEG (installation and commissioning)	Consequence	An unplanned umbilical or flowline loss of containment – MEG has the potential for to result in temporary and localised changes to water quality, and plankton. This scenario was not modelled due to the relatively small volume (up to 400 m^3) and MEG being a category 'E' OCNS chemical, with no substitution warning, readily biodegradable with a low potential for bioaccumulation and a Minor potential impact consequence ranking. To encapsulate all potential consequences to the environment, the highest consequence ranking of Minor (1) has been assigned as the overall consequence level for unplanned umbilical or flowline loss of containment – MEG.
	Likelihood	The likelihood of an unplanned umbilical or flowline loss of containment – MEG event occurring is considered Unlikely. Marine pollution from offshore developments has occurred previously in the Australian oil and gas industry. An unplanned umbilical or flowline loss of containment – MEG may occur but is not anticipated.
	Risk Rating	**Low**
Flowline and/or pipeline loss of containment – gas and condensate (operations)	Consequence	An unplanned flowline and/or pipeline loss of containment – gas and condensate event has the potential for widespread exposure of hydrocarbons in the marine environment. Section 7.4.4.2 provides detailed consequence evaluations on receptors with the potential for sea surface, in-water and shoreline condensate exposure based on hydrocarbon spill modelling of a LOWC event (Section 7.4.3). This evaluation found the

Credible Scenario (Stage)		**Risk Evaluation**
		highest consequence ranking to be Serious (3). The use of LOWC consequence evaluations for a flowline and/or pipeline loss of containment event is considered a highly conservative but suitably representative estimate. However, to encapsulate all potential consequences to the environment, the highest consequence ranking of Serious (3) has been assigned as the overall consequence level for unplanned flowline and/or pipeline loss of containment – gas and condensate event.
	Likelihood	The likelihood of a flowline and/or pipeline loss of containment event occurring is Highly Unlikely. To date no incidents relating to flowline and/or pipeline loss of containment event have occurred during Beach operations in Australia including in the Otway basin. Future spills from a flowline and/or pipeline loss of containment event are considered remote events based on history of no known condensate spills in southern Australia from LOWC events.
	Risk Rating	**Medium**
Vessel Collision - Marine Diesel Oil (MDO) spill (support operations)	Consequence	An unplanned vessel collision event has the potential for receptors in the marine environment to be exposed to hydrocarbons. Section 7.4.4.1 provides detailed consequence evaluations on receptors with the potential for sea surface, in-water and shoreline MDO exposure based on hydrocarbon spill modelling of a vessel collision event (Section 7.4.3). This evaluation found the highest consequence ranking to be Serious (3) for seabirds and cetaceans. To encapsulate all potential consequences to the environment, the highest consequence ranking of Serious (3) has been assigned as the overall consequence level for unplanned vessel collision event.
	Likelihood	The likelihood of a vessel event occurring is Unlikely. Industry data (2005-2012) shows vessel collisions are rare (3% of marine incidents in Australian waters), and these incidents typically involve smaller, often double-lined forward tanks.
	Risk Rating	**Medium**
Loss of Containment – hazardous substances stored on drill MODU and vessels (support operations)	Consequence	An unplanned loss of containment – hazardous substances stored on drill MODU and vessels event has the potential for receptors in the marine environment to be exposed to hydrocarbons and chemicals of up to 1 m^3. Section 7.4.4.1 provides detailed consequence evaluations on receptors with the potential for sea surface, in-water and shoreline MDO exposure based on hydrocarbon spill modelling of a vessel collision event (Section 7.4.3). This evaluation found the highest consequence ranking to be Serious (3). The use of vessel collision consequence evaluations for loss of containment – hazardous substances stored on drill MODU and vessels event is considered a highly conservative but suitably representative estimate. However, to encapsulate all potential consequences to the environment, the highest consequence ranking of Serious (3) has been assigned as the overall consequence level for unplanned loss of containment – hazardous substances stored on drill MODU and vessels event.
	Likelihood	The likelihood of an unplanned loss of containment – hazardous substances stored on drill MODU and vessels event occurring is considered Unlikely. Marine pollution from offshore developments has occurred previously in the Australian oil and gas industry. An unplanned loss of containment – hazardous substances stored on drill MODU and vessels event may occur but is not anticipated.
	Risk Rating	**Medium**

7.4.5 Risk Evaluation Summary

The risk evaluation for the loss of containment of hydrocarbons and chemicals is summarised in Table 7-27.

Table 7-27: Risk Evaluation Summary for the Loss of Containment of Hydrocarbons and Chemicals

Summary		
Risk summary	Risk evaluations of potential unplanned loss of containment events identified the potential for Low to Medium risks to the environment. The consequence and likelihood levels to determine the Low to Medium risks are defined in Table 7-26. The highest consequence level for the loss of containment scenarios is Serious (3) as a result of potential hydrocarbon exposure to the following receptors: • Seabirds • Cetaceans • State terrestrial protected areas • Seaweed industry • Australian Marine Parks • State marine protected areas The likelihood unplanned loss of containment events occurring ranges from Unlikely to Highly Unlikely based on the frequency of these events occurring in the Australian oil and gas industry or during Beach operations in Australia including in the Otway basin. Future spills from LOWC or vessel collision events are considered remote and highly unlikely events based on history of no known MDO or condensate spills in southern Australia from LOWC or vessel collision events. [**PC275**]	
Extent of risks	The greatest extent of risks results from the loss of containment of condensate and MDO from a loss of well containment event and vessel collision event, respectively, will result in widespread exposure of hydrocarbon to the environment.	
Duration of risks	The unplanned loss of containment events anticipated to result in the longest duration of risks are from loss of containment of condensate and MDO from a loss of well containment event and vessel collision event, respectively. Condensate and MDO are non-persistent hydrocarbons. Worst case spills are not considered to result in long-term or irreversible environmental damage or affect ecosystem functioning. Due to the volatility of the hydrocarbons released (condensate and MDO), once on the water surface most of the hydrocarbon volume will evaporate within several days of release.	
Level of certainty	Beach has a high level of certainty about the risks of the unplanned loss of containment events. The threats posed by loss of containment events including loss of well control and vessel collision are well known and strict regulatory requirements are in place to control the risk. With these regulatory controls in place, Beach have a high level of certainty that Project activities will not result in a loss of containment event.	
Is the impact considered lower-order or higher-order?	The highest risk ratings for unplanned loss of containment events are Medium risks (Table 7-26). Medium risks are considered lower-order risks that are acceptable with the application of good industry practice.	
Risk Assessment		
Loss of well containment - gas and condensate		
Consequence	**Likelihood**	**Risk rating**

7.4.6 Demonstration of Acceptability

Table 7-28 demonstrates how and why environmental risks from loss of containment of hydrocarbons and chemicals meets the defined acceptable levels (Table 5-4).

Table 7-28: Demonstration of Acceptability – Loss of Containment – Hydrocarbons and Chemicals

Demonstration of Acceptability		
Impact and risk comparison with relevant defined acceptable levels	Acceptable level 5 addresses the risks of unplanned loss of containment – hydrocarbons and chemicals, as outlined in Table 5-4. These risks were evaluated, resulting in Low to Medium risk ratings based on the combination of Minor (1) to Serious (3) potential consequences and Unlikely to Highly Unlikely event likelihoods. By implementing control measures that satisfy legislative and other requirements, the occurrence of a loss of containment – hydrocarbons and chemicals event will be prevented, thereby ensuring that Acceptable level 5 is met and achieved. Refer below to list of control measures to be implemented to prevent such an event from occurring.	
ESD Principles	Integration principle	Section 7.4.4 identifies and evaluates environmental risks associated with the loss of containment of hydrocarbons and chemicals. As part of identifying the potential risks; conservation values and sensitivities, physical environment, ecological environment, socio-economic values, and First Nations values and sensitivities described in Section 4 were reviewed to determine potential interactions of the aspect against each of these receptors they may result in environmental risk. As a result, consideration of economic, environmental, social and equitable receptors was conducted as part of identifying the impacts and risks. For Phase 1: Initial Project Consultation (Section 10.2.3), Beach consulted with relevant stakeholders on the Project and associated activities. No objections or claims were raised in Phase 1: Initial Project Consultation For Phase 2: Project OPP Public Comment Period (Section 10.2.4), the public had the opportunity to provide further comment to this OPP during the period (18/3/2024 – 20/5/2024). Beach prepared the public comment report summarising all comments, an assessment of the merits of each comment, a

		statement of the response to each comment, and an outline of any changes made to the OPP as a result of the comment (Appendix P). The impact assessment for this aspect has been updated to reflect the merit provided by public comment reference number PC232, PC269, PC270, PC274, PC275, PC282, PC284, and PC294. As a result, the impact assessment now integrates responses to public comments of merit and therefore is of an acceptable level. The potential environmental risk against this aspect was assessed as having a Medium risk level which is considered a lower-order environmental risk. Lower-order environmental risks are considered 'broadly acceptable' and considered managed to an acceptable level by meeting relevant requirements (adopted controls as listed below).
	Precautionary principle	The potential environmental risks against this aspect were assessed as having a Medium risk level which is considered a lower-order environmental risk and below the defined acceptable levels detailed in Table 5-4, except for acceptable level 5. Lower-order environmental risks cannot result in serious or irreversible environmental damage. There is high confidence in the potential environmental impacts and risks and effectiveness of controls against this aspect. Beach has significant experience operating in the Otway and Bass based on their existing offshore developments and associated activities including the Beach Otway Drilling Campaign in 2021/2022.
	Intergenerational principle	The defined acceptable levels were developed to meet the principles of ESD (Section 5.8.5). Given predicted environmental impacts due to the loss of containment of hydrocarbons and chemicals is lower than the defined acceptable levels detailed in Table 5-4, except for acceptable level 5; the health, diversity, or productivity of the environment for future generations is expected to be maintained.
	Biodiversity principle	Section 7.4.3 identifies and evaluates environmental risks associated with the loss of containment of hydrocarbons and chemicals As part of identifying the potential impacts; conservation values and sensitivities including MNES in Section 4 were reviewed. The potential risks against this aspect were assessed as having Low to Medium risk rankings which are considered lower-order environmental risks that can be management to meet the defined acceptable level 5. Lower-order environmental risks cannot result in affects to biological diversity or ecological integrity.
Internal context	Policy compliance	The defined acceptable levels, EPOs and controls proposed for this aspect are consistent with Beach Environmental Policy objectives. As a result, potential environmental impacts and risks from Project can be managed to align with Beach Environmental Policy objectives.
External context	Stakeholder engagement is being carried out as part of this OPP process. Beach operates the existing Otway project and has established good relations with both onshore and offshore stakeholders. Engagement with stakeholders will continue throughout all aspects of the Project to build and maintain trust with stakeholders and the local community and minimise community and stakeholders concern and impacts where practicable. During Phase 1: Initial Project Consultation (Section 10.2.3), no objections or claims were raised against this aspect. During Phase 2: Project OPP Public Comment Period (Section 10.2.4), comments were raised against this aspect. The assessment of merit for these comments found this aspect to require updates. Changes to the OPP to address PC232, PC269, PC270, PC274, PC275, PC282, PC284, and PC294 have been integrated into the impact evaluation for this aspect.	

	Any new guidance or advice in relation to this aspect will be assessed and incorporated into adaptive management plans prepared for activity specific EPs.	
Other requirements	Requirement	Demonstration
	OPGGS Act 2006 (Cth) A Well Operations Management Plan (WOMP) must be in place for all wells.	**CM 01 Navigation Safety** All vessels operating within the project area will adhere to the navigation safety requirements including: • International Regulations for Preventing Collisions at Sea 1972 • Chapter 5 of International Convention for the Safety of Life at Sea 1974 • International Convention on Standards of Training, Certification and Watchkeeping for Seafarers 1978 • Navigation Act 2012 and any subsequent Marine Orders that specify standards for crew training and competency, navigation, communication, and safety measures. **CM02 Notifications** The Australian Hydrographic Office will be notified of the Project activities and installed subsea infrastructure prior to commencement to facilitate the issuing of Notice to Mariners and maintain nautical charts. Relevant stakeholders are notified prior to the activity so that third party marine users are aware of vessel location and timing **CM03 Fair Ocean Access Procedure** Beach's Fair Ocean Access Procedure was developed with input from commercial fishing industry organisations. The procedure details the process whereby a commercial fishers can claim compensation for an economic loss associated with Beach's offshore activities where impacts cannot be avoided, including in the event of an oil spill. **CM05 Petroleum safety zones** The Project will comply with OPGGS Act – Section 616 (2) petroleum safety zones, which includes establishment and maintenance of petroleum safety zones around wells, offshore structures or equipment which prohibits vessels entering without written consent. **CM06 Temporary exclusion/cautionary zones** 500 m temporary exclusion and 2 km cautionary zones will be established and maintained around drilling and installation activities. **CM40 WOMP** The Well Operations Management Plan (WOMP) is a regulatory requirement under the Offshore Petroleum and Greenhouse Gas Storage Act 2006 and the associated Offshore Petroleum and Greenhouse Gas Storage (Resource Management and Administration) Regulations 2011. It is the primary approval document for ensuring a high standard of well integrity and details the risk assessment, critical procedures and safety mechanisms to be implemented throughout the duration of the relevant petroleum activity.
	OPGGS (Resource Management and Administration) Regulations 2011 A WOMP will be prepared and detail well design and detail safety measures to prevent a spill. This must be accepted by NOPSEMA.	
	OPGGS (Environment) Regulations 2023 Part 3 (Incidents, reports and records).	
	OPGGS Act 2006 (Cth) Section 460(2) - a person carrying on activities in an offshore area under the permit must carry out those activities in a manner that does not interfere with the conservation of the resources of the sea and seabed to a greater extent than is necessary for the reasonable exercise of the rights and performance of the duties of the first person.	
	The following management plans identify loss of containment (pollution, habitat degradation or chemical discharge) as a threat: • South-east Marine Parks Network Management Plan 2025 • Wildlife Conservation Plan for Seabirds (CoA, 2020a) • Wildlife Conservation Plan for Migratory Shorebirds (CoA, 2015a) • National Recovery Plan for Albatrosses and Petrels 2022 (CoA, 2022) • Approved Conservation Advice for *Sternula nereis nereis* (Australian Fairy Tern) (TSSC, 2011) • National Recovery Plan for the Australian Fairy Tern (*Sternula nereis nereis)* (CoA, 2020)	

	• Conservation Advice for *Numenius madagascariensis* (Far Eastern Curlew) (DCCEEW, 2023f) • Conservation Advice for *Limosa lapponica baueri* (Bar-tailed Godwit (Western Alaskan)) (DCCEEW, 2024e) • Conservation Advice for *Limosa limosa* (black-tailed godwit) (DCCEEW, 2024f) • Approved Conservation Advice for *Calidris acuminata* (sharp-tailed sandpiper) (DCCEEW, 2024i) • Conservation Advice for *Calidris tenuirostris* (great knot) (DCCEEW, 2024l) • Approved Conservation Advice for *Pluvialis squatarola* (grey plover) (DCCEEW, 2024k) • Approved Conservation Advice for *Xenus cinereus* (Terek sandpiper) (DCCEEW, 2024i) • National Recovery Plan for *Rostratula australis* (Australian Painted Snipe) (DSEWPaC, 2013a) • Conservation Advice for *Charadrius leschenaultia* (Greater Sand Plover) (TSSC, 2016b) • Conservation Advice *Calidris ferruginea* (Curlew Sandpiper) (DoE, 2015f) • Approved Conservation Advice for *Calidris canutus* (Red Knot) (DCCEEW, 2024m) • National Recovery Plan for the Australiasian Bittern (*Botaurus poiciloptilus*) (DCCEEW, 2022x). • Approved Conservation Advice for *Botaurus poiciloptilus* (Australasian Bittern) (TSSC, 2019) • National Recovery Plan for the Orange-bellied Parrot (*Neophema chrysogaster*) (DELWP, 2016) • Approved Conservation Advice for the Blue Petrel (*Halobaena caerulea*) (TSSC, 2015c) • National Recovery Plan for the Australian Grayling (*Prototroctes	**CM41 MODU Safety Case** The Safety Case for the MODU is a regulatory requirement under the OPGGS Act and the associated Offshore Petroleum and Greenhouse Gas Storage (Resource Management and Administration) Regulations 2011. The Safety Case identifies hazards and risks specific to drilling wells, describes how the risks are controlled and describes the safety management system in place to ensure the controls are effectively and consistently applied. This includes the subsea control system configured for all wells to fail-safe in the event of loss of communication and/or hydraulics. Prevention of loss of well control and subsequent release of hydrocarbons is a key focus as this is the source of major accident events. **CM42 Well Engineering and Construction Management System (WECS)** Beach Well Engineering and Construction Management System (WECS) that ensures well activities are fit for purpose with operational risks managed to a level that is as low as reasonably practicable. It also ensures that changes are made in a controlled manner, that appropriate standards are adhered to, and that a sufficiently resourced and competent organisation is in place. The Beach Operations Excellence Management System consists of Well Integrity Standard and WECS. **CM43 Workforce capability** Beach Workforce Capability Requirements Matrix to ensure Operations personnel are qualified, trained and certified as competent to operate and maintain Beach facilities. **CM44 Crisis and Emergency Management** Beach's Crisis and Emergency Management Standard requires Beach to have plans, procedures and resources in place to effectively respond to crisis and emergency situations, including hydrocarbon spills. **CM45 Preventative maintenance** Computerised Maintenance Management System to ensure all wells and subsea infrastructure is maintained to schedule. **CM46: SMPEP or SOPEP (appropriate to class)** In accordance with MARPOL Annex I and AMSA's MO 91 [Marine Pollution Prevention – oil], a SMPEP or SOPEP (according to class) is required to be developed based upon the Guidelines for the Development of Shipboard Oil Pollution Emergency Plans, adopted by IMO as Resolution MEPC.54(32) and approved by AMSA. To prepare for a spill event, the SMPEP/SOPEP details: • response equipment available to control a spill event; • review cycle to ensure that the SMPEP/SOPEP is kept up to date; and

	maraena) (Backhouse et al., 2008) - Recovery Plan for the White Shark (*Carcharodon carcharias*) (DSEWPaC, 2013c) - Recovery Plan for Marine Turtles in Australia, 2017-2027 (CoA, 2017) - Approved Conservation Advice for *Dermochelys coriacea* (Leatherback Turtle) (DEWHA, 2008) - Conservation Management Plan for the Blue Whale, 2015-2025 (CoA, 2015b) - National Recovery Plan for the Southern Right Whale *Eubalaena australis* (DCCEEW, 2024o) - Approved Conservation Advice for *Balaenoptera borealis* (Sei Whale) (TSSC, 2015e) - Approved Conservation Advice for *Balaenoptera physalus* (Fin Whale) (TSSC, 2015d) - Conservation Advice *Neophoca cinerea* Australian sea lion (TSSC, 2020) - Recovery Plan for the Australian sea lion (*Neophoca cinerea*) (DSEWPaC, 2013d)	- testing requirements, including the frequency and nature of these tests. - reporting requirements and a list of authorities to be contacted; - activities to be undertaken to control the discharge of hydrocarbon; and - procedures for coordinating with local officials. Specifically, the SMPEP/SOPEP contains procedures to stop or reduce the flow of hydrocarbons to be considered in the event of tank rupture. **CM47 Bunkering procedure** Bunkering procedures to manage fuel transfers that include: - Weather limits on bunkering operations - Bunkering equipment specifications and inspection - Visual observations during transfers - Emergency shutdowns **CM48 EP, OPEP and OSMP** Accepted Environment Plans (EP) Oil Pollution Emergency Plans (OPEP) and Operational and Scientific Monitoring Plans (OSMP) in place for all relevant Project activities and oil spills responded to in accordance with the plans **CM49 Oil spill modelling** Oil spill modelling and environmental risk assessments for the Project EPs and OPEPs will consider the full range of worst-case scenario LOWC consequences. **CM50 Source control** Source Control Emergency Response Plans in place for all drilling activities.

7.4.7 Environmental Performance

In accordance with NOPSEMA's OPP Decision Making Guideline (NOPSEMA 2024), the EPO for this aspect (Table 7-29) has been developed to be relevant to identified environmental impacts and risks, consistent with the principles of ESD and equivalent to or better than the defined acceptable level of impact. Control measures listed in Table 7-28 provides detail on how each control measure will be implemented for the Project to ensure the acceptable levels and EPOs, defined in Table 7-29 are met

Table 7-29: Environmental Performance Outcomes – Loss of Containment of Hydrocarbons and Chemicals

Defined Acceptable Level	Environmental Performance Outcomes	
Acceptable level 5: Unplanned loss of containment – hydrocarbons and chemicals is unacceptable	EPO27:	No unplanned loss of containment of hydrocarbons or chemicals to the marine environment during Project activities.
	EPO7:	No death or injury to listed threatened or migratory species from Project activities.

Defined Acceptable Level	Environmental Performance Outcomes	
	EPO28:	In event of an unplanned release of chemicals or hydrocarbons, spill response control measures will be implemented in accordance with accepted EP, OPEP and OSMP (CM48 EP, OPEP and OSMP).

8 Cumulative Impact Assessment

8.1 Overview

Cumulative environmental impacts in the context of offshore petroleum activities are successive, additive, or synergistic impacts of collectively significant activities or projects with material impacts on the environment that have the potential to accumulate over temporal and spatial scales (NOPSEMA Environment Plan Decision Making Guideline, N-04750-GL1721 A524696, Dec 2022).

The effects of past projects and activities, and currently operating projects, are captured when describing the existing condition of and any pressure or threats affecting the environment (see Section 4). This baseline condition and understanding of the capacity of the receiving environment and receptors to accommodate changes, in light of existing pressures and threats, informs the environmental impact and risk assessments conducted in Sections 6 and 7 of this OPP.

The focus of this cumulative impact assessment (CIA) is to further build on these assessments by considering the impacts of the proposed activity on key matters in conjunction with the impacts from other reasonably foreseeable future projects.

The types of activities and projects typically considered in CIA are large in scale and are of relevance in terms of potentially contributing to or compounding material impacts in the relevant project area. While an environmental value is at the centre of the CIA this doesn’t mean that every potential impact of regional concern to that value needs to be addressed. For example, while loss of habitat to a threatened species may be of regional concern, there may be no reason to incorporate those potential impacts into a project-initiated cumulative impact assessment (CIA) if the project under assessment does not contribute to long term habitat reduction (Minerals Council of Australia 2015).

8.2 Methodology

Guidance from the United Kingdom (UK) National Infrastructure Planning Advice Note Seventeen: Cumulative effect assessment relevant to nationally significant infrastructure programs (UK 2019) and the New South Wales (NSW) Cumulative Impact Assessment Guidelines for State Significant Projects (NSW 2022), form the basis of this assessment.

Both the UK and NSW guidelines are intended to apply to large-scale national and state significant projects, respectively, with greater potential for cumulative impacts into the long-term. Consequently, the assessment process applied here has been adapted to the nature and scale of the activities associated with the Project.

8.2.1 Identifying Reasonably Foreseeable Future Projects and Activities CIA Scoping

CIA considers projects and activities that are reasonably foreseeable within the spatial and temporal extent of the assessment. This defines the boundaries of the assessment by including projects and activities that have a realistic likelihood of occurring and could contribute to cumulative impacts.

To identify reasonably foreseeable future projects and activities a search was conducted of the NOPSEMA, DEECA (Vic) Environment Plan and The Offshore Infrastructure Registrar websites to identify any relevant projects and activities. In addition, petroleum titleholders within the Otway Basin have been meeting regularly to discuss environmental management in the region, including processes for improved CIA, focusing on reasonably foreseeable activities. This has provided a more accurate representation of projects and activities and the potential for cumulative impacts, ensuring that relevant impacts are appropriately assessed and managed.

Reasonably foreseeable future projects and activities identified to date, within the life of the Project, are detailed in Table 8-1 and Figure 8-1.

In addition, as the existing Beach Otway Development (Beach's current production operations at the Geographe and Thylacine gas fields) is the baseline condition, a review was undertaken to identify how the impacts associated with existing operations are anticipated to change (cumulative spatial and temporal impacts) as the Project is developed over the life of the Otway operations.

Projects and activities that are not reasonably foreseeable or speculative have been excluded from the assessment scope to maintain practicality and relevance in decision-making processes. The Cumulative Environmental Impact Assessment Industry Guide (Minerals Council of Australia 2015) suggests that speculative projects should not be included which includes projects which have been referred and/or announced but are not under assessment. Despite this, wind farm projects have been considered in brief as a conservative approach.

Information on identified projects and activities are typically accessible once consultation commences and relevant technical supporting information is submitted for public comment or assessment. In addition, information relevant to this CIA has been discussed at the ongoing Otway Basin Petroleum Titleholder meetings. Where project/activity-specific data is not yet available, data from similar projects has been used as a proxy prior to technical information being made available. Given the similarity of impacts, there is a high level of certainty in the prediction of cumulative impacts in most cases.

Some assumptions around specific timings for projects or activities have been made. Whilst there is some level of uncertainty in schedule and timing of approvals to support activities, in general schedules are relatively well known due to titleholders sharing similar resources (i.e. rig consortium utilising a single MODU for all drilling activities).

8.2.1.1 CIA Scoping

Scoping is undertaken to identify the key environmental matters that could be materially affected by the cumulative impacts of the Project and other reasonably foreseeable future projects and require a detailed CIA.

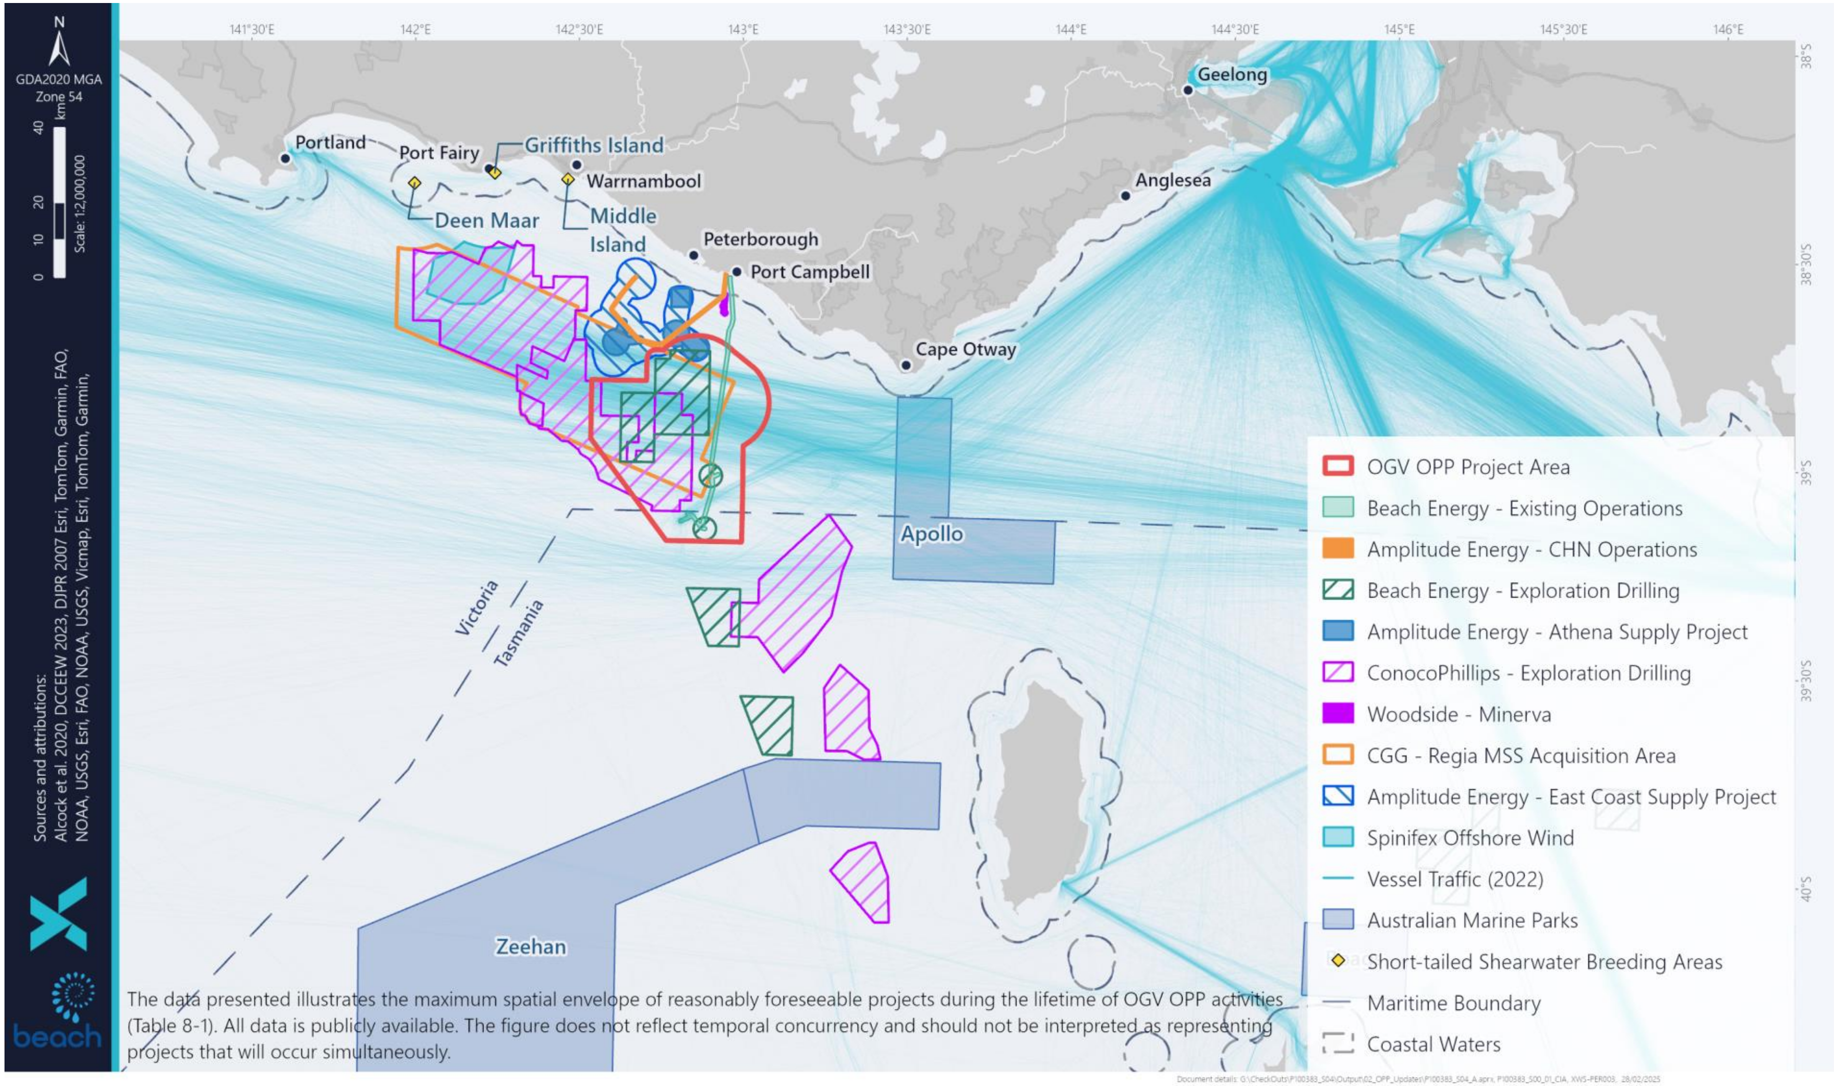
Scoping considerations identified for CIA include:

- **Successive impacts** - those that occur one after the other.
- **Additive impacts** - those where the combined impact is the sum of the separate impacts.
- **Synergistic impacts** - those where the combined impact is greater than the sum of the separate impacts.
- **Key environmental matters** - features of the environment (ecological, socio-economic, and cultural values and sensitivities) that are valued because of their rarity or importance, including the critical role they play in supporting systems which are essential for the environment, people and /

or the economy (NSW 2022), for example, commercial fisheries and threatened species undertaking biologically important behaviours.

- **Material impacts** - impacts of the project and other reasonably foreseeable future projects and activities that may not align with the defined acceptable levels, for example, threats of wide-scale, serious or irreversible damage due to cumulative impacts.
- **Temporal extent** - depends on the key matter and the scale and nature of potential impacts on the matter (NSW 2022) but aligned to reasonably foreseeable timeframes associated with the project and other reasonably foreseeable projects and activities within the Planning Area.
- **Spatial Extent** – depends on the key matter. NSW (2022) recommends that while the area chosen for each key matter must be broad enough to capture all relevant cumulative impacts, it should not be unnecessarily large or include areas where the cumulative impacts are likely to be negligible relative to the baseline condition of the relevant matter.

The scoping steps are detailed below, and the outcomes are in Table 8-2.



The data presented illustrates the maximum spatial envelope of reasonably foreseeable projects during the lifetime of OGV OPP activities (Table 8-1). All data is publicly available. The figure does not reflect temporal concurrency and should not be interpreted as representing projects that will occur simultaneously.

Document details: G:\CheckOuts\P100383_S04\Output\02_OPP_Updates\P100383_S04_A.aprx, P100383_S00_01_CIA, XWS-PER003, 28/02/2025

Figure 8-1: Reasonably Foreseeable Future Projects and Activities in the Offshore Otway Basin

- Step 1: Receptors identified as part of the Risk Evaluation (Section 7) are not subject to the cumulative impact assessment process.
- Step 2: Identify the relevant acceptable levels (as listed in Section 5.8.5) for each receptor. It is noted that the acceptable levels for the Project are derived from legal requirements, management plans and principles of ESD. These acceptable levels reiterate legal mandates to prevent unacceptable impacts to receptors. Reasonably foreseeable future projects and activities and potential of cumulative impacts must also meet these acceptable levels to ensure legal compliance.
- Step 3: Identify whether the Project's spatial extent of impacts overlap with those of other current and reasonably foreseeable projects affecting the same receptor.
- Step 4: Identify whether the Project's temporal extent of impacts overlap with those of other current and reasonably foreseeable projects affecting the same receptor.
- Step 5: If temporal and spatial overlaps are identified (in steps 3 and 4), a scoping assessment is conducted. This assessment determines whether the combined overlaps could cause the acceptable level to be exceeded, resulting in a potential cumulative impact from identified potential cumulative-cause-effect pathways.
- Step 6: Identify the level of certainty of the scoping assessment. The level of certainty of the assessment is deemed to be high if:
    - Impacts are well understood
    - Impacts are relatively easy to predict using standard methods
    - Impacts are capable of being mitigated to comply with relevant standards and to meet the acceptable level as previously detailed Table 5-4.

If one of the points is not met, then there is a moderate level of certainty for the scoping assessment. To ensure thoroughness, a cautious approach is taken. Receptors with scoping assessments of moderate certainty proceed to detailed CIA. However, if a scoping assessment demonstrates a high level of certainty that there are no significant cumulative impact pathways, the receptor is not considered further for detailed CIA.

- Step 7: Confirm if the receptor is considered or not considered for detailed CIA based on potential cumulative-cause-effect pathways and certainty of the scoping assessment.

8.2.2 Detailed CIA

For those receptors and aspects where a potential cumulative cause-effect pathway and material impact was identified in the scoping, a detailed CIA assessment was applied in general alignment with the project-specific methodology described in Section 5. The outcomes of this detailed assessment are detailed in

Table 8-3 to Table 8-5.

The CIA process applied to each aspect and component of the environment are:

- Identification of:
    - Receptor conservation values or values relevant to CIA e.g. EPBC Listed Threatened Species, MNES, commercial or cultural significance.
    - Legislative or other requirements relevant to the assessment.
    - Relevant threatening processes.
    - Relevant spatial extent such as BIAs, and temporal extent when receptor present including any biologically important features such as behaviours or critical life-cycle stages, timings.
    - Relevant actions from legislative or other requirements.
- Detail the baseline existing environment.
- Define the acceptable level to the receptor.
- Identification of other reasonably foreseeable future projects where the aspect overlaps the identified relevant spatial extent.
- Assessment of potential for cumulative impacts:
    - Description of potential cumulative impact.
    - Detail the level of certainty of the assessment.
    - Detail the existing control measures to meet the defined acceptable level. It is noted that Project control measures, developed to meet defined acceptable levels, are directly applicable to reducing the potential consequences of cumulative impacts. These control measures are Beach's primary means of mitigating cumulative impacts. Beach has no direct authority over the planning, implementation, or management of other reasonably foreseeable projects and activities that may potentially contribute to cumulative impacts.
    - Comparison to acceptable level(s), and where required (reiterative process):
    - Identification of additional control measures and demonstration that cumulative impacts are acceptable.
- Detailing any additional actions.

All potential cumulative impacts to the key receptors were evaluated as being Minor (1). No additional controls were identified however Beach will continue to work with other titleholders undertaking activities within the Otway Basin with the aim of identifying and minimising the potential for cumulative impacts, in addition to cooperation on monitoring and management to increase effectiveness.

Table 8-1: Reasonably Foreseeable Future Projects and Activities in the Offshore Otway Basin

Titleholder	Activity	Status	Expected Timing Window	Potential Temporal Overlap with all OGV Project activities (as detailed in Section 3)	Potential Spatial Overlap with relevant OGV Project activities
Beach Energy	Otway Offshore Operations	Existing Operations	Otway Offshore Operations Ongoing, end of field life ~2037	Otway Offshore Operations may involve IMR campaigns and platform resupply for the duration of its operational life. Potential temporal overlap with OGV OPP activities identified as: **Platform Resupply (helicopter) –** ~2 days every 3 months, ~6 hours per day, daylight hours only. **Standby vessel during IMR** - ~2 days every 6 months, ~6 hours per day, daylight hours only. **ROV inspection** - ~30 days every 5 years **Diver inspection** - ~15 days every 10 years **P&A** – not detailed but expected to be 40 to 60 days	Otway Offshore Operations may involve IMR campaigns and platform resupply. Spatial overlap with this OGV OPP activities identified as: **Operational Area** - Otway Offshore Operations OA consists of a 500 m buffer around all subsea infrastructure and wells, including the Otway Pipeline System which is partially overlapped by the OGV OPP Project Area. **Light EMBA** – Light EMBA resulting from Otway Offshore Operations vessels (navigation, safety and working lights) may overlap those of the OGV OPPs Light (20 km) EMBA and Flaring (63 km) EMBA. **Noise EMBA -** Noise EMBA (up to 7.5 km marine mammal behaviour criteria during resupply) resulting from Otway Offshore Operations vessels may overlap those of the OGV OPP (7.97 km non-shelf and 19.6 km shelf areas marine mammal behaviour criteria, drilling phase).
Amplitude Energy (Cooper Energy)	Casino-Henry-Netherby (CHN) Operations	Existing Operations	Ongoing Ongoing, end of filed life ~2030	CHN Operations may involve IMR campaigns for the duration of its operational life. Potential temporal overlap with OGV OPP activities identified as: **Support vessel during IMR** - 2 – 4 weeks at sea for an entire inspection program including mobilisation and demobilisation expected every 2 years. **P&A** – not detailed but expected to be 40 to 60 days	CHN Operations may involve IMR campaigns and platform resupply. Closest distance between projects is ~1 km. Spatial overlap with this OPP activities identified as: **Light EMBA** – 20 km Light EMBA resulting from CHN Operation vessels (navigation, safety and working lights) may overlap with this OPPs Light (20 km) and Flaring (63 km) EMBA. **Noise EMBA** - Noise EMBAs (5.97 km marine mammal behaviour criteria during resupply) resulting from CHN Operation vessels may overlap with those of this OPP (7.97 km non-shelf and 19.6 km shelf areas marine mammal behaviour criteria, drilling phase).
Beach Energy	Offshore Gas Victoria Drilling Program (Drilling, Decommissioning (P&A))	Proposed	2025-2027 Up to 5 new wells (~30-40 days per well), up to 5 wells P&A (~ 15-20 days per well Surveys per well ~7 days Anchor handling per well ~4-6 days	Activities for all 3 projects may involve geophysical and geotechnical surveys, exploration drilling with P&A activities. Potential temporal overlap with this OPP activities identified as: **Survey and support vessels** - ~7 days per survey and ~4 to 6 days anchor handing days per well. 3 hours per resupply. **Drilling Activities –** range of approximately 30 to 60 days per well **P&A** - ~15-20 days per well Note, titleholders in the region are part of a rig consortium which has signed an agreement with Transocean to bring a semi-submersible MODU to the offshore Otway Basin in 2025 and beyond. Due to the financial and logistical implications of operating a semi-submersible MODU, the presence of multiple rigs in the area for future operations (i.e. planned P&A activities), is not considered a credible scenario. Therefore, concurrent drilling and P&A activities are not considered.	Activities for all 3 projects may involve geophysical and geotechnical surveys plus support, drilling and P&A activities. Spatial overlap with this OPP activities identified as (noting simultaneous drilling activities are not possible): **Operational Area:** 3 x projects overlap OGV OPP Project area. **Light EMBA** – Light EMBA (20 km) resulting from 3 listed project's vessels (navigation, safety and working lights) may overlap the OGV OPP's Light (20 km) and Flaring (63 km) EMBA during the OGV drilling phase. **Noise EMBA (non-drilling phases)#** - Noise EMBAs (up to 0.5 km non-shelf marine mammal behaviour criteria, prelay (ConocoPhillips); up to 0.44 km marine mammal behaviour criteria AHTS prelay activity, Amplitude Energy); up to 2.98 km non-shelf and 6.5 km shelf areas marine mammal behaviour criteria, IMR (Beach Energy) resulting from 3 x listed projects vessels may overlap with those of OGV OPP (7.97 km non-shelf and 19.6 km shelf areas marine mammal behaviour criteria, drilling phase). **Noise EMBA (3 x project's drilling phases)#** - Noise EMBAs for marine mammal behaviour criteria up to 12.6/22.8 km non-shelf/shelf (ConocoPhillips); up to 2.72/5.97 km, Amplitude Energy); up to 6.23/19.6 km (Beach Energy) resulting from 3 x listed projects vessels may overlap with those of OGV OPP (2.9 km non-shelf and 6.5 km shelf areas marine mammal behaviour criteria, non-drilling phase. #As concurrent drilling not possible, noise EMBAs for both drilling and non-drilling phases for all projects are detailed (i.e. OGV drilling phase may occur during non-drilling phases of other projects and vice versa).
Amplitude Energy (Cooper Energy)	Athena Supply Project (Exploration Drilling)	Proposed	2024-2026 (~60 days per well, max 3 wells)		
ConocoPhillips	Otway Exploration Drilling Program (Exploration Drilling)	Proposed	2024-2026 (~30-40 days per well, max 6 wells)		
Woodside Energy	Minerva P&A and decommissioning	Proposed	2024-2025 (< 2 months) Equipment removal activities restricted to between September and April inclusive.	Decommission activities may involve MODU plus support and survey vessel activities. Potential temporal overlap with Beach OPP activities identified as: **Survey and support vessels** – 44 to 160 days P&A scope, 45 – 60 days decommission scope. **P&A** - ~44 - 160 days **Decommissioning** – 46 to 60 days Note, Woodside are part of a rig consortium which has signed an agreement with Transocean to bring a semi-submersible MODU to the offshore Otway Basin in 2025. Therefore, additive or synergistic	Decommission activities may involve MODU plus support and survey vessel activities. Closest distance between projects is ~6 km. Spatial overlap with this OPP activities identified as: **Light EMBA** – Light EMBA (20 km) resulting from Minerva project's vessels (navigation, safety and working lights) may overlap with this OPPs Light (20 km) and Flaring (63 km) EMBA. **Noise EMBA** - Noise EMBAs (up to 2.4 km marine mammal behaviour criteria, MPSV Subsea infrastructure removal) resulting from Minerva vessels and ~10.2 km drilling phase) may overlap with those of the OGV OPP (7.97 km non-shelf and 19.6 km shelf areas marine mammal behaviour criteria, drilling phase).

				impacts with other planned drilling or P&A activities are not are not considered credible.	
CGG Services Australia	Regia Marine Seismic Survey (MSS) (Seismic Survey)	Proposed	2024-2028 60 days acquisition 90 days in field One survey between November – May or Two separate surveys April – June, and or September – November.	Regia MSS may involve support vessel and survey activities. Potential temporal overlap with Beach OPP activities identified as: **Survey and support vessels** - up to a maximum of 90 days.	Spatial overlap with this OPP activities and identified as: **Operational Area** – Regia MSS OA overlays the entire Project Area of this OPP. **Light EMBA** – Light EMBA resulting from Regia MSS vessel's (navigation, safety and working lights) may overlap with this OPPs Light (20 km) and Flaring (63 km) EMBA. **Noise EMBA -** Noise EMBA[α] (44 km) resulting from the Regia MSS survey and vessels overlap those of the OGV OPP (7.97 km non-shelf and 19.6 km shelf areas marine mammal behaviour criteria). [α] ~44 km marine mammal behaviour criteria PTS and TTS per pulse effect criteria reached between 410 – 820 m PTS 24hr cumulative effect criteria is reached within 70 m and the TTS 24hr cumulative effect criteria is reached within 190-350 m. Note - not feasible that a cetacean would be within that distance of the moving vessel for 24 hrs, thus impacts are not predicted
Amplitude Energy (Cooper Energy)	East Coast Supply Project (Development and operation of subsea wells)	Proposed	Surveys – 7 to 21 days per campaign Up to 15 wells drilled, ~60 days per well, 30 to 60 days subsea installation per well. Operations, end of field life ~2045 Decommissioning expected ~2050	East Coast Supply Project activities may involve geophysical and geotechnical surveys, drilling, completions, operations and decommissioning activities. Potential temporal overlap with OGV OPP activities identified as: **Survey and support vessels** - ~7 days to 21 days per campaign **Subsea installation vessels** – 30 – 60 days per well. **Drilling Activities** – range of approximately 30 to 60 days per well **Completions** - ~30 to 60 days per well **P&A** - ~15-20 days per well Note, titleholders in the region are part of a rig consortium which has signed an agreement with Transocean to bring a semi-submersible MODU to the offshore Otway Basin in 2025 and beyond. Due to the financial and logistical implications of operating a semi-submersible MODU, the presence of multiple rigs in the area for future operations (i.e. planned P&A activities), is not considered a credible scenario. Therefore, concurrent drilling and P&A activities are not considered.	East Coast Supply Project activities may involve geophysical and geotechnical surveys, drilling, completions, operations and decommissioning activities. Spatial overlap with the OGV OPP activities identified as: **Operational Area**: East Coast Supply Project Area overlaps OGV OPP Project area. **Light EMBA** – Light EMBA (20 km) resulting from East Coast Supply Project's vessels (navigation, safety and working lights) may overlap with this OPPs Light (20 km) and Flaring (63 km) EMBA. **Noise EMBA** - Noise EMBAs (2.72 to 5.97 km marine mammal behaviour criteria, up to 410 m km PTS and) resulting from support phases from the East Coast Supply Project and 7.87 km from drilling phase, may overlap with those of the OGV OPP (7.97 km non-shelf and 19.6 km shelf areas marine mammal behaviour criteria).
Alinta Energy and JERA Nex (Spinifex Offshore Wind)	Spinifex Offshore Wind (Offshore wind installation)	Announced	Surveys – ~2025 - 2028 Turbine Installation – ~2031 Operations, ~2032 to 2057* Decommissioning, ~2058*	Spinifex Offshore Wind Project activities may involve geophysical and geotechnical surveys, piling, installation, IMR and operations and decommissioning activities. The project is in the pre-planning phase and as such no specific details are currently publicly available for the Spinifex Offshore Wind Installation. However, from limited available data, a potential temporal overlap with this OPP activities are identified as: **Survey vessels** – various fauna, geotechnical and geophysical surveys are required to support approval documentation expected to be conducted between 2025 to 2028. Likely to consist of single vessels for short term surveys (up to 3 weeks). **Installation activities** – turbine Installation not expected to begin until ~2031	The Spinifex Offshore Wind Project proposed project area is located ~34 km from the OGV OPP Project Area. Spatial overlap with the OGV OPP activities identified as: **Light EMBA** – Light EMBA (20 km) resulting from Spinifex Offshore Wind Project's vessels (navigation, safety and working lights) may overlap with this OPPs Light (20 km) and Flaring (63 km) EMBA. **Noise EMBA** - Noise EMBA (~20 km‡ marine mammal behaviour criteria during construction and IMR) resulting from the Spinifex Offshore Wind Project's vessels may overlap with those of the OGV OPP (7.97 km non-shelf and 19.6 km shelf areas marine mammal behaviour criteria).
N/A	Shipping / vessel traffic	Existing	All year round	Shipping activities in the area involve vessels (e.g., cargo and tankers) travelling between major Australian and foreign ports. The south-east marine region and Bass Strait is one of Australia's busiest shipping routes, where shipping/vessel traffic operate all year-round. For the life of the Project, shipping/vessel traffic will be excluded within 500 m Safe Navigation Areas, 500 m exclusion zones, 2 km cautionary zones and 500 m petroleum safety zones during Project activities.	Shipping/vessel traffic operations will be excluded within of 500 m Safe Navigation Areas, 500 m exclusion zones, 2 km cautionary zones and 500 m petroleum safety zones during Project activities. This will ensure no spatial overlap of shipping/vessel traffic operations and Project vessel activities within these safety areas/zones. Shipping/vessel traffic transiting outside of Project safety areas/zones will generate light and sound emissions to extents dependant on the type of vessel. Shipping/vessel traffic transiting close to Project safety areas/zones will have moving sound/light EMBAs that may temporarily overlap with Project sound/light EMBAs.

	Temporal overlap of shipping/vessel traffic with the Project will be restricted to those transiting outside of these safety areas/zones. There will be no temporal overlap of shipping/vessel traffic operations within these safety areas/zones.	**Operational Area** – An average of 9 vessels per day may pass through the OGV Project Area. However there will be no spatial overlap of shipping/vessel traffic operations and Project activities because of implemented Project safety areas/zones. **Light EMBA** – Light emissions (navigation, safety and working lights) from transiting shipping outside of Project safety areas/zones may overlap with OGV Project Light (20 km) and Flaring (63 km) EMBAs. An average of 11 and 15 vessels per day may pass through the OGV OPPs Light and Flaring EMBA respectively. **Noise EMBA** – Typical noise emissions (0.38 km marine mammal behaviour criteria (taken from OSV standby/transit modelling) resulting from transiting shipping outside of Project safety areas/zones may overlap with those of the OGV OPP (7.97 km non-shelf and 19.6 km shelf areas marine mammal behaviour criteria). An average of 10.5 vessels per day may pass through the combined shelf and non-shelf OGV OPPs noise EMBA.

*assuming typical 25-year lifespan (DCCEEW 2025a)

‡ Noise modelling for the installation of monopole or jacket design foundation has yet to be completed for this project. Large scale pilling installations within Australian waters are limited, therefore proxy values taken from:

- ConocoPhillips Australia, (2018) Modelling conducted on multiple large diameter piles (similar to monopile installation), however, in depths of ~250 m. Values expected to be highly conservative.
- Norro et al (2013). Details of measurements for both monopile and jacket installations in similar hard substrate as expected in the Otway, but in slightly shower depths (37 m). However, values expected to be comparable..

Table 8-2: CIA Scoping Outcome

Receptors	Planned Environmental Aspects Considered	Acceptable Level	Potential for Cumulative Impact (Spatial Extent)	Potential for Cumulative Impact (Temporal Extent)	Scoping Assessment Outcome	Level of Certainty of Scoping Assessment	Cumulative Cause-effect Pathway
Australian Marine Parks	Emissions – Light	**Acceptable level 1:** No interference with the recovery of EPBC Act listed threatened species. **Acceptable level 2:** No modification, isolation or decrease in the availability or quality of habitat to the extent that EPBC Act listed threatened, migratory or cetacean species are likely to decline. **Acceptable level 3:** Impacts will not be inconsistent with conservation advice, recovery plans and threat abatement plans for EPBC Act listed threatened, migratory or cetacean species. Acceptable level 4: Unplanned establishment of invasive marine species is unacceptable. **Acceptable level 5:** Unplanned loss of containment – hydrocarbons and chemicals is unacceptable	Yes OGV OPP's Flaring EMBA overlaps: • Zeehan AMP • Apollo AMP. OGV OPP's Light EMBA does not overlap any AMPs. Other projects with potential overlap with AMP: • ConocoPhillips	Yes Activities planned to be undertaken during periods of biologically important behaviours for conservation values	The Zeehan Marine Park lists the black-browed (foraging BIA), wandering and shy albatrosses (foraging / foraging likely BIAs) and great-winged and cape petrels as major conservation values. Apollo AMP lists black-browed (foraging BIA) and shy albatross (foraging likely BIA), Australasian gannet (foraging BIA), short-tailed shearwater (foraging BIA) and crested tern as conservation values. Worst case light levels resulting from OGV OPP flaring at the Zeehan and Apollo marine parks are 0.001 and 0.003 Lux respectively (0.01 is equal to a clear moonless night sky). Modelling in Section 6.3 predicted the level of impact from MODU facility lighting to be within 10 km of the MODU. Closest AMP is situated ~35 km from Project Area. Therefore, as detailed in Section 6.3 Impacts from light emissions have been evaluated to result in Minor (1) consequences. OGV OPP flaring EMBA may overlap Light EMBAs of ConocoPhillips activities. As a single MODU is being used for all reasonably foreseeable drilling activities (Table 8-1) additive or synergistic cumulative impacts resulting from flaring is not considered credible. ConocoPhillips proposed support activities in T49P consists of one survey and prelay for one exploration well. The overlap of the OGV Flaring EMBA and those from ConocoPhillips activities with the Apollo and Zeehan marine park and its associated Lux values would be negligible. Lux levels from concurrent actives (as detailed above) would have no impact on light sensitive species. In addition, bird species which are considered values of the AMPs and those that have defined BIAs, are unlikely to have biological important behaviours impacted by the cumulative light emissions resulting from OGV OPP and other reasonably foreseeable future projects as all detailed species are known to forage in daylight. Considering other reasonably foreseeable activities over temporal and spatial scales, the assessment outcomes found there was limited potential for successive, additive or synergistic impacts as the result of light emissions to bird species which are considered values of the Zeehan or Apollo AMPs. However, short-tailed shearwater fledglings are known to be susceptible to light emission. Whilst the fledglings are highly unlikely to be present in the AMP, due to the range from known nesting sites (Figure 8-1), they are considered for further assessment due to their cultural value as detailed in First Nations Cultural Values and Sensitivities section of this table.	High – Light modelling conducted, impacts to sensitive species well understood	Identified for values of the AMPs (short-tailed shearwater), with further assessment required to determine if impacts are material.
Key Ecological Features	Emissions – Underwater Sound	**Acceptable level 1:** No interference with the recovery of EPBC Act listed threatened species. **Acceptable level 2:** No modification, isolation or decrease in the availability or quality of habitat to the extent that EPBC Act listed threatened, migratory or cetacean species are likely to decline. **Acceptable level 3:** Impacts will not be inconsistent with conservation advice, recovery	No OGV OPP's sound EMBAs do not overlap any KEFs.	No No periods of biologically important behaviours for KEF values	Value of the Bonney Coast Upwelling KEF is one of 12 widely recognised and well-known areas worldwide where blue whales are known to feed in relatively high numbers. Values of the West Tasmania Canyons include sponges concentrated near the canyon heads and fish species. Whilst the noise EMBAs do not overlap either KEF, as blue whales are listed as a value of the Bonney Coast Upwelling KEF, they are carried forward for further assessment for reasons as detailed in Section - Marine Mammals of this table.	Moderate - noise modelling conducted, impacts to sensitive species well understood. However, no literature on the cumulative impacts to whale species.	None identified

		plans and threat abatement plans for EPBC Act listed threatened, migratory or cetacean species. **Acceptable level 4:** Unplanned establishment of invasive marine species is unacceptable**.** **Acceptable level 5:** Unplanned loss of containment – hydrocarbons and chemicals is unacceptable.					
Maritime Archaeological Heritage	Physical Presence – Seabed Disturbance Discharges – Drill Cuttings and Cement	**Acceptable level 15**: No impacts on underwater cultural heritage with values as conferred by the *Underwater Cultural Heritage Act 2018* (Cth).	No Limited to individual activity area	Yes Continual presence	The OGV Project Area overlaps only one known shipwreck. OGV OPP activities that could result in the disturbance of maritime archaeological heritage are assessed in Section 6.2 (Seabed Disturbance), Section 6.7 (Planned Discharge – Drill Cuttings and Fluids) and Section 6.8 (Planned Discharges – Cement). Seabed disturbance is limited to individual activity areas and has been assessed as Minor (1). Seabed disturbance for all other reasonably foreseeable projects, detailed in Table 8-1, will also be limited to individual activity areas. Whilst other reasonably foreseeable projects (Table 8 1) may overlap known maritime archaeological heritage and potentially unknown maritime archaeological heritage, cumulative impacts from OGV OPP activities are not considered credible. as impacts are confined to a relatively small area as previously detailed. Impacts to maritime archaeological heritage are not predicted from seismic surveys. All drilling and infrastructure installation activities are required to undertake seabed surveys prior to seabed disturbance however as seabed disturbance and discharges are localised cumulative impacts are not predicted. CM10 (Seabed assessments) and CM11 (Cultural heritage assessments) will provide the opportunity for appropriately qualified persons to identify ecological, maritime, archaeological or submerged cultural heritage, landscapes and inform protection priorities ensuring a high level of certainty prior to drilling and installation activities.	High – OGV activities limited to individual activity areas, impacts well understood with additional control measures in place to detect and avoid sensitive areas.	None identified
Benthic Habitats and Communities	Physical Presence – Seabed Disturbance Discharges – Drill Cuttings and Cement	**Acceptable level 10:** No impacts on unique seafloor habitats[1] to the south-east region, including deep-sea reefs, continental shelf habitats, seamounts canyons and kelp forests. **Acceptable level 11:** Impacts on benthic habitats and communities within the Project Area that are highly represented throughout the region and are not unique seafloor habitats is acceptable.	No Limited to individual activity area	Yes Continual presence	Beach OGV Project area does not impact any areas considered sensitive or communities of value (Key Ecological Features, AMP or threatened ecological communities). Thus, cumulative impacts to these values are not predicted from the Beach OGV Project. OGV OPP activities that could result in the disturbance of benthic habitats and communities are assessed in Section 6.2 (Seabed Disturbance), Section 6.7 (Planned Discharge – Drill Cuttings and Fluids) and Section 6.8 (Planned Discharges – Cement). Seabed disturbance is limited to isolated individual activity areas and has been assessed as Minor (1). No seabed disturbance, inclusive of drill cuttings and cement discharges, will occur within the Beach existing OGV Development or the future development area from other reasonably foreseeable future projects in the Otway Basin based on their location and activities. There is the potential for a cumulative increase in seabed disturbance, inclusive of drill cuttings and cement discharges, from the existing and planned developments within the Otway Basin (Beach, Cooper Energy and Woodside), however, these will be in isolated locations and impacts to areas where benthic habitat and communities are a value (Key Ecological Features, AMPs or threatened ecological communities) are not predicted. In addition, seabed surveys of the shelf area where Cooper Energy, Woodside and Beach's existing development are located have	High – OGV activities limited to individual activity areas with additional control measures in place to detect and avoid sensitive areas.	Identified but impacts not material no further assessment required.

		[1] Unique seafloor habitats of the south-east region including deep-sea reefs, continental shelf habitats, seamounts canyons and kelp forests (DNP, 2025).			identified that the seabed is highly mobile making it difficult for filter feeders and soft body invertebrates to survive and establish in significant populations. CM10 (Seabed assessments) and CM11 (Cultural heritage assessments) will provide the opportunity for appropriately qualified persons to identify ecological, maritime, archaeological or submerged cultural heritage, landscapes and inform protection priorities ensuring a high level of certainty prior to drilling and installation activities.		
Plankton	Emissions – Underwater Sound Discharges – Drill Cuttings and Cement Discharges – Commissioning and Operations Discharges - Vessels	**Acceptable level 2:** No modification, isolation or decrease in the availability or quality of habitat to the extent that EPBC Act listed threatened, migratory or cetacean species are likely to decline.	Yes Limited to individual activity area with exception of seismic operations	Yes Continual presence of plankton	Emissions from underwater sound as a result of OGV OPP activities have been assessed as having a Minor (1) impact on plankton (Section 6.4). Impacts will be localised and well below natural mortality rates. Impacts from other reasonably foreseeable projects are predicted to be similar with no material cumulative impacts. OGV OPP planned discharges that could impact plankton are assessed in Section 6.7 (Planned Discharge – Drill Cuttings and Fluids), Section 6.8 (Planned Discharges – Cement), Section 6.9 (Planned Discharge – Commissioning and Operational Fluids) and Section 6.10 (Planned Discharge – Routine Operational Wastes from Vessels). Impacts where found to be local and temporary with Minor (1) consequences. Discharges to the water column are not predicted to impact water quality at a cumulative scale and therefore will not impact plankton at an ecological integrity level.	High - noise modelling conducted, impacts to sensitive species from discharges well understood	None identified
Invertebrates	Physical Presence – Seabed Disturbance Emissions – Underwater Sound Discharges – Drill Cuttings and Cement	**Acceptable level 2:** No modification, isolation or decrease in the availability or quality of habitat to the extent that EPBC Act listed threatened, migratory or cetacean species are likely to decline.	Yes Limited to individual activity area with exception of seismic operations	Yes Continual presence of invertebrates	Emissions from underwater sound as a result of OGV OPP activities have been assessed as having a Minor (1) impact on invertebrate (Section 6.4). Impacts will be short term and localised as detailed in Section 3. Impacts from other reasonably foreseeable projects are predicted to be similar with no material cumulative impacts identified. Continuous noise from drilling, vessel and installation operations are not predicted to impact invertebrates as per previous impact assessment (Section 6.4) with no cumulative impact pathway identified. Impacts from geophysical surveys to benthic invertebrates are not predicted and impacts from VSP are predicted to result in impacts at very small scale (185 m), this is not predicted to be material to contribute to cumulative impacts. Behavioural impacts to squid are predicted to occur up to 3.9 km of the VSP (up to 24 hrs) and 90 m for seabed surveys, this is not predicted to be material to contribute to cumulative impacts even within areas where squid fishing occurs. Impacts to benthic invertebrates from seabed disturbance including drill cuttings and cement discharge are covered in Benthic Habitats and Communities.	High – noise modelling conducted, impacts to sensitive species from discharges well understood	None identified
Fish and Sharks	Emissions – Underwater Sound	**Acceptable level 1:** No interference with the recovery of EPBC Act listed threatened species. **Acceptable level 2:** No modification, isolation or decrease in the availability or quality of habitat to the extent that EPBC Act listed threatened, migratory or cetacean species are likely to decline. **Acceptable level 3:** Impacts will not be inconsistent with conservation advice, recovery plans and threat abatement plans for EPBC Act listed	Yes Limited to individual activity with exception of seismic operations	Yes Continual presence of fish and sharks likely, however, no periods of biologically important behaviours for sensitive species	Emissions from underwater sound as a result of OGV OPP activities are assessed as having Minor (1) consequences to fish and sharks (Section 6.4). Impacts will be short term and highly localised. Impacts from other reasonably foreseeable drilling and IMR projects are predicted to be similar with no material cumulative impacts identified. CGG's Regia MSS shows a TTS threshold of 8.35 km for a cumulative sound exposure level (SELcum) for fish species (Popper et al. 2014). Popper et al. (2005) reports that fish showing a TTS recovered to normal hearing levels within 18-24 hours. Therefore, any hearing loss and subsequent decrease in fitness would be temporary with recovery taking place in a relatively short timeframe after the seismic source has moved away from the exposed fish. Due to the temporary and isolated nature of noise emissions from OGV OPP activities and other reasonably foreseeable activities plus rapid recovery from any impacts, no cumulative impact pathway was identified.	High - noise modelling conducted, impacts to sensitive species well understood	None identified

		threatened, migratory or cetacean species.					
Birds	Emissions – Light	**Acceptable level 1:** No interference with the recovery of EPBC Act listed threatened species. **Acceptable level 2:** No modification, isolation or decrease in the availability or quality of habitat to the extent that EPBC Act listed threatened, migratory or cetacean species are likely to decline. **Acceptable level 3:** Impacts will not be inconsistent with conservation advice, recovery plans and threat abatement plans for EPBC Act listed threatened, migratory or cetacean species.	Yes BIAs for sensitive species overlapped by light EMBAs from OGV and other foreseeable future activities.	Yes Periods of biologically important behaviours for sensitive species	Light emissions as a result of OGV OPP activities have been assessed as having a Minor (1) impact on birds (Section 6.3.3.2). Considering other reasonable future activities over temporal and spatial scales, the assessment outcomes found there was limited potential for successive, additive or synergistic impacts as the result of light emissions to bird species listed within the light EMBAs. Light emissions from all activities will be temporary. Overlapping light intensity levels are of negligible values which have previously been shown to below those to cause a behavioural response. However due to the sensitivity of certain species, the following are carried forward for further assessment: • orange bellied parrot - listed as Critically Endangered and Marine under the EPBC Act and noted as a species of cultural significance. The National Recovery Plan for the Orange-bellied Parrot lists barriers to migration and movement as a threat. • short-tailed shearwaters - light pollution, including from gas flaring, is listed as a threat to seabirds in the Wildlife Conservation Plan plus one of few Australian native birds that is harvested. • common diving-petrel - listed as a conservation value in the south-east and temperate east plus light emissions are identified as a threat in the National Recovery Plan for Albatrosses and Petrels and the species is known to forage at night where cumulative light emissions could impact foraging behaviour. For other bird species, important biological activities are unlikely to be impacted by light emissions as species known to forage during daylight hours.	High – Light modelling conducted, impacts to sensitive species well understood	Identified for the orange bellied parrot, short-tailed shearwater and the common diving-petrel with further assessment required to determine if impacts are material.
Marine Reptiles	Emissions – Light Emissions – Underwater Sound	**Acceptable level 1:** No interference with the recovery of EPBC Act listed threatened species. **Acceptable level 2:** No modification, isolation or decrease in the availability or quality of habitat to the extent that EPBC Act listed threatened, migratory or cetacean species are likely to decline. **Acceptable level 3:** Impacts will not be inconsistent with conservation advice, recovery plans and threat abatement plans for EPBC Act listed threatened, migratory or cetacean species.	No No BIAs or critical habitat overlapped by noise EMBAs from OGV or other foreseeable future activities.	No No periods of biologically important behaviours for sensitive species	No cumulative effect pathway identified. Individuals in the area are expected to be transient, with no BIAs, critical habitat, or biologically important behaviours within the Otway Basin. Lighting doesn't impact in water navigation or behaviours and impacts from noise will be temporary and recoverable. Although sound impacts are restricted to within typically 20 km around individual activities, activities may be occurring consecutively over a period of time and seismic and drilling at one location have the potential to occur concurrently. However, Section 6.4 (Underwater Sound) found impacts to turtles are likely to be restricted to short term and highly localised behavioural avoidance from the VSP sources with Minor (1) consequences to low numbers present in the Otway region.	High – Light and noise modelling conducted, impacts to sensitive species well understood	None identified
Marine Mammals	Emissions – Underwater Sound	**Acceptable level 1:** No interference with the recovery of EPBC Act listed threatened species. **Acceptable level 2:** No modification, isolation or decrease in the availability or quality of habitat to the extent that EPBC Act listed	Yes BIAs for sensitive species overlapped by noise EMBAs from OGV and other foreseeable future activities.	Yes Periods of biologically important behaviours for sensitive species overlapped by OGV and other foreseeable future activities.	There is potential for cumulative impacts associated with underwater sound depending on location of activities and sensitive receptors, i.e. foraging and migrating endangered species. Although sound impacts are restricted to within typically 10s of kms around individual activities, activities may be occurring consecutively over a period of time and seismic and drilling at one location have the potential to occur concurrently. Marine mammal species considered for further assessment are the:	Moderate - noise modelling conducted, impacts to sensitive species well understood. However, no literature on the cumulative impacts to whale species.	Identified the sensitive marine mammals including the blue, southern right, fin, sei and pygmy right whales for further assessment and to determine if

		threatened, migratory or cetacean species are likely to decline. **Acceptable level 3:** Impacts will not be inconsistent with conservation advice, recovery plans and threat abatement plans for EPBC Act listed threatened, migratory or cetacean species.			• blue whale - listed as Endangered under the EPBC Act with foraging, feeding or related behaviour known to occur within the noise EMBAs with anthropogenic noise interference listed as a threat. • southern right whale - listed as Endangered under the EPBC Act and noted as a species of cultural significance with noise interference listed as a threat. • fin whale - listed as Vulnerable under the EPBC Act, with foraging, feeding or related behaviour likely to occur within the noise EMBAs with anthropogenic noise and acoustic disturbance listed as a minor threat. • sei whale - listed as Vulnerable under the EPBC Act with foraging, feeding or related behaviour likely to occur within the noise EMBAs with anthropogenic noise and acoustic disturbance listed as a minor threat. • pygmy right - listed as foraging may or is likely to occur within the noise EMBAs. Considering other significant activities or projects over temporal and spatial scales, the assessment outcomes found there was limited potential for successive, additive or synergistic impacts other marine mammal species from noise emissions as no BIAs or biologically important behaviour were identified within the noise EMBAs as detailed within Section 6.4 (Underwater Sound).		impacts are material.
Coastal Communities and Onshore Tourism Activities	Emissions – Light	**Acceptable level 14:** No interference with other marine users to a greater extent than is necessary for the reasonable exercise of the rights and performance of duties as conferred by the titles granted to Beach.	No Not predicted to see multiple activities from single vantage point (i.e. King Island, Victorian coast)	Yes May be able to see different activities over time from single vantage point (King Island, Victorian coast)	Section 6.3.3.4 (Emissions – Light) details the highest level of illuminance from short-term flaring is Port Campbell National Park at 0.0111 lux, which is approximately the same as a quarter moon (0.01 lux). As flaring is short term and temporary (as detailed in (Section 3.8 (Description of Activities) impact from light emissions is likely to result in Minor (1) consequences. Cumulative effect pathway identified, associated with visibility of different activities over time, but impacts not material. The likelihood of visibility of multiple activities from a single vantage point is considered low given the distances offshore it is not predicted that a MODU and vessels would be distinguishable from other existing vessel traffic.	High – Light modelling conducted, impacts to sensitive communities well understood	Identified but impacts not material no further assessment required
Offshore Petroleum Activities	Physical Presence - Interaction with Other Users	**Acceptable level 14:** No interference with other marine users to a greater extent than is necessary for the reasonable exercise of the rights and performance of duties as conferred by the titles granted to Beach.	Yes Non-Beach activities restricted to own Project Area outside of OGV OPP project Area. Beach Energy's activities and the Regia MSS overlap.	No Beach's OGV OPP activities and Regia MSS are unlikely to co-occur.	No cumulative impact effect pathway identified. At most, avoidance of a single seismic survey vessel and towed equipment, and a single drilling location at any given time with minimal interaction between activities. All activities are scheduled and or operate within their own exclusion zones/petroleum titles. Notice to mariners will provide advanced warning and opportunity to plan transit route.	High - impacts by offshore petroleum activities well understood	Identified but impacts not material, no further assessment required
Offshore Renewable Energy Activities	Physical Presence - Interaction with Other Users	**Acceptable level 14:** No interference with other marine users to a greater extent than is necessary for the reasonable exercise of the rights and performance of duties as conferred by the titles granted to Beach.	No Non-Beach activities restricted to own Project Area outside of OGV OPP project Area.	Yes IMR activities may overlap with wind farm installation (expected 2031).	No cumulative impact effect pathway identified. Non-Beach activities restricted to own Project Area outside of OGV OPP project Area.	High – displacement by offshore renewable energy activities well understood.	None identified
Defence Activities	Physical Presence - Interaction with Other Users Physical Presence – Seabed Disturbance	**Acceptable level 14:** No interference with other marine users to a greater extent than is necessary for the reasonable exercise of the rights and performance of duties as conferred by the titles granted to Beach.	Yes Potential displacement of military vessels that could be operating in the area as a result of concurrent and consecutive activities	Yes Potential displacement of military vessels that could be operating in the area as a result of concurrent and consecutive activities	Section 6.1.3.2 (Defence Activities) shows that OGV OPP activities will have negligible impacts to Defence operations. Whilst cumulative effect pathway identified from other foreseeably reasonable projects identified, impacts are not considered material. Industry standard controls in place such as notice to mariners will provide advanced warning and opportunity to plan transit route. At most avoiding a single seismic survey vessel and towed equipment, and a single drilling location at any given time with minimal interaction between activities. Impacts to UXO are not predicted from seismic surveys.	High - impacts to defence activities well understood	Identified but impacts not material, no further assessment required

					Drilling and installation activities are required to undertake seabed surveys prior to seabed disturbance which include techniques to identify UXO. Impacts to UXO are not planned event and therefore cumulative impacts not predicted.		
Shipping	Physical Presence - Interaction with Other Users	**Acceptable level 14:** No interference with other marine users to a greater extent than is necessary for the reasonable exercise of the rights and performance of duties as conferred by the titles granted to Beach.	Yes Potential displacement of shipping as a result of concurrent and consecutive activities	Yes Potential displacement of shipping as a result of concurrent and consecutive activities	Section 6.1.3.3 (Shipping) shows that OGV OPP activities will have Minor (1) consequences to existing and future shipping activity. Whilst cumulative effect pathway identified from other foreseeably reasonable projects identified, impacts are not considered material. The area of impact is small compared to the area available for shipping. Industry standard controls in place such as notice to mariners will provide advanced warning and opportunity to plan transit route. At most avoiding a single seismic survey vessel and towed equipment, and a single drilling location at any given time will have minimal interaction between activities.	High - impacts to shipping activities well understood	Identified but impacts not material, no further assessment required
Marine Tourism	Physical Presence - Interaction with Other Users	**Acceptable level 14:** No interference with other marine users to a greater extent than is necessary for the reasonable exercise of the rights and performance of duties as conferred by the titles granted to Beach.	Yes Potential displacement of marine tourists as a result of concurrent and consecutive activities	Yes Potential displacement of marine tourists as a result of concurrent and consecutive activities	Section 6.1.3.4 (Tourism and Recreational Diving and Fishing) shows that OGV OPP activities are unlikely to impact tourism activities. Whilst cumulative effect pathway identified from other foreseeably reasonable projects identified, impacts are not considered material. Diving and recreational fishing are most likely to occur in coastal areas. The area of displacement is small compared to area available for tourism. Industry standard controls in place such as notice to mariners will provide advanced warning and opportunity to plan transit route. At most avoiding a single seismic survey vessel and towed equipment, and a single drilling location at any given time with minimal impact.	High - impacts to marine tourism activities well understood	Identified but impacts not material, no further assessment required
Recreational Fishing	Physical Presence - Interaction with Other Users	**Acceptable level 14:** No interference with other marine users to a greater extent than is necessary for the reasonable exercise of the rights and performance of duties as conferred by the titles granted to Beach.	Yes Potential displacement of recreational fishers as a result of concurrent and consecutive activities	Yes Potential displacement of recreational fishers as a result of concurrent and consecutive activities	Section 6.1.3.4 (Tourism and Recreational Diving and Fishing) shows that OGV OPP activities are unlikely to impact tourism activities. Whilst cumulative effect pathway identified from other foreseeably reasonable projects identified, impacts are not considered material. Diving and recreational fishing are most likely to occur in coastal areas. The area of displacement is small compared to area available for recreational fishing. Industry standard controls in place such as notice to mariners will provide advanced warning and opportunity to plan transit route. At most avoiding a single seismic survey vessel and towed equipment, and a single drilling location at any given time with minimal interaction between activities.	High - impacts to recreational fishing well understood	Identified but impacts not material, no further assessment required
Commercial Fisheries	Physical Presence - Interaction with Other Users Physical Presence – Seabed Disturbance Emissions – Greenhouse Gas Discharges – Drill Cuttings and Cement	**Acceptable level 14:** No interference with other marine users to a greater extent than is necessary for the reasonable exercise of the rights and performance of duties as conferred by the titles granted to Beach.	Yes Potential displacement of commercial fishers as a result of concurrent and consecutive activities	Yes Potential displacement of commercial fishers as a result of concurrent and consecutive activities	Cumulative effect pathway identified. Displacement of fishers operating in fisheries with spatial extent that may be overlapped by a number of offshore activities, i.e. displaced by multiple exclusion zones (MODU and seismic survey) or different exclusion zone over time. Although displacement impacts are restricted to within typically 2-3 kms around individual activities (see Section 6.1.3.1 (Commonwealth and State Managed Fisheries), drilling may be occurring consecutively over a period of time and seismic and drilling at one location have the potential to occur concurrently. Whilst Minor (1) behavioural disturbances are predicted to commercial fish species from underwater sound, cumulative impacts are not predicted.	High – areas of fishing activity known with impacts to commercial fishing well understood	Identified and further assessment required to determine if impacts are material.
First Nations Cultural Values and Sensitivities	Physical Presence – Interaction with Other Users Physical Presence – Seabed Disturbance Emissions – Light Emissions – Underwater Sound	**Acceptable level 16**: No impacts on declared areas or objects of particular significance with values as conferred by the *Aboriginal and Torres Strait Islander Heritage Protection Act 1984* (Cth).	Yes Potential overlap with Sea Country a result of concurrent and consecutive activities	Yes Potential overlap with Sea Country a result of concurrent and consecutive activities	All cultural values and First Nations sensitivities have been reviewed, and cumulative effect pathways for receptors with cultural intangible values have been identified. It is considered that the potential for cumulative impacts to whales (blue and southern right whales) and birds (orange-bellied parrot, short-tailed shearwater) may prevent First Nations people's obligations to maintain spiritual connections and care for culturally significant species. Impacts from the drilling and P&A activities to other cultural values identified such as fish, eels, dolphins, and seals are at a very small scale, which is not predicted to be material to contribute to cumulative impacts.	High - impacts well understood with the addition of control measures to avoid sensitive submerged cultural heritage	Identified for the blue and southern right whale and the orange-bellied parrot and short-tailed shearwater with further assessment required to determine if impacts are material

	Emissions – Greenhouse Gas Discharges – Drill Cuttings and Cement Discharges – Commissioning and Operations Discharges - Vessels	Impacts to submerged cultural heritage are not predicted from the drilling and P&A activities based on a seabed survey will be undertaken to identify any cultural heritage and if identified Beach will consult with the relevant First Nations groups and determine any exclusion areas or further cultural heritage management procedures that may be required.	and results in cumulative impacts at a population level.

Table 8-3: Cumulative Impact Assessment Outcomes for Interaction with Other Users

Aspect	**Interaction with Other Users**
Receptor	**Commercial fishers**
Conservation (or other) value and Status	Socio-economic value to local communities and national economy. The Project Area overlaps where there is fishing intensity for: • Commonwealth Bass Strait Central Zone Scallop Fishery - < 5 vessels • Commonwealth Eastern Tuna and Billfish Fishery - < 5 vessels • Commonwealth Southern and Eastern Scalefish and Shark Fishery (SESSF) ◦ Commonwealth Trawl Sector ▪ Otter-board trawl – Low intensity ▪ Danish-seine – < 5 vessels ◦ Gillnet, Hook and Trap Sector ▪ Scalefish Hook - < 5 vessels ▪ Shark Gillnet – Medium intensity ▪ Shark Hook - < 5 vessels • Commonwealth Southern Bluefin Tuna Fishery - < 5 vessels • Commonwealth Southern Squid Jig Fishery – Low intensity • Victorian Giant Crab – up to 84 days fished • Victorian Rock Lobster Fishery - up to 139 days fished • Victorian Wrasse (Ocean) Fishery – up to 1 day fished
Legislative or Other requirements	*OPGGS Act 2006 (Cth).* Southern and Eastern Scalefish and Shark Fishery (SESSF) Species Summaries (AFMA 2023)
Threatening Processes Relevant to Aspect	None, other than fishing pressure for school shark
Relevant OGV OPP Spatial and Temporal Extent	Fishery Management Areas for the duration of the Project.
Relevant Actions from Legislative or Other Requirements	OPGGS Act 2006 (Cth) Section 280 – requires that a person carrying on activities in an offshore area under the permit, lease, licence, authority, or consent must carry out those activities in a manner that does not interfere with navigation or fishing (among others).
Baseline Environment Condition	Listed fisheries that overlap the Project Area may also interact or be displaced by with: • existing oil and gas activity (Section 4.5.2) • existing shipping (see Section 4.5.6) Current fisheries in the area historically have sustainable stock status (Sections 4.5.10, 4.5.11, 4.5.12).
Acceptable Level	**Acceptable level 14:** No interference with other marine users to a greater extent than is necessary for the reasonable exercise of the rights and performance of duties as conferred by the titles granted to Beach.
Other Reasonably Foreseeable Projects/ Activities Relevant to Aspect	SESSF: Commonwealth Trawl Sector Otter Board, SESSF: Commonwealth Trawl Sector Danish-seine and Southern Squid Jig Fishery potential cumulative impact from exclusion zones associated with reasonably foreseeable projects as detailed in Table 8-1 : • One seismic survey occurring concurrently with drilling/P&A activities and/or Project installation activities. • Consecutive drilling/P&A activities and/or Project installation activities (including those over several seasons / years). • Concurrent drilling and installation activities (including those over several seasons / years). • Project infrastructure / IMR. Victorian Giant Crab and Southern Rock Lobster Fisheries potential cumulative impact from exclusion zones associated with: • One seismic survey occurring concurrently with drilling/P&A activities and/or Project installation activities. • Consecutive drilling/P&A activities and/or Project installation activities (including those over several seasons / years). • Concurrent drilling and installation activities (including those over several seasons / years).

Aspect	Interaction with Other Users
Receptor	**Commercial fishers**
	• Project infrastructure / IMR. Tasmanian Rock Lobster Fishery potential cumulative impact from exclusion zones associated with: • One seismic survey occurring concurrently with drilling/P&A activities and/or Project installation activities. • Consecutive drilling/P&A activities and/or Project installation activities (including those over several seasons / years). • Concurrent drilling and installation activities (including those over several seasons / years). Project infrastructure / IMR.
Description of Cumulative Impact (including spatial/temporal extent)	**Successive impacts -** Commercial fishers may potentially be displaced within relevant Fishery Management Areas in the offshore Otway Basin by the proposed Project and other reasonably foreseeable seismic surveys, drilling, installation, IMR and P&A activities. Drilling, seismic, installation and IMR activity exclusions will only apply while the activity is being undertaken (typically 2 to 3 km) with limited permanent exclusion zones (500 m) to apply to wells and subsea infrastructure present for the duration of production. Drilling, seismic, installation and IMR activities within the OGV OPP (Section 3.3) and other reasonably foreseeable projects (Table 8-1) are conducted over relatively short periods (drilling phases typically 30 to 40 days). **Additive impacts –** as above **Synergistic impacts –** none identified Beach has undertaken previous drilling, installation, IMR and Operations in the area with little displacement to commercial fishers based on the consultation and notification controls implemented that will also be applied to the Project.
Certainty of Assessment	Given the intensity of fishing in the area, and the overlap of fishery management areas with the proposed activities of multiple titleholders, the assessment of cumulative impacts is made with a high level of predictability and certainty.
Existing Control Measures to Meet Acceptable Levels	OGV Project control measures, developed to meet defined acceptable levels, are directly applicable to reducing the potential consequences of cumulative impacts. These control measures are Beach's primary means of mitigating cumulative impacts. Beach has no direct authority over the planning, implementation, or management of other reasonably foreseeable projects and activities that may potentially contribute to cumulative impacts. A single MODU has been contracted to conduct drilling/P&A activities in the region, mitigating the potential for concurrent impacts from these activities. Titleholders overlapping fishery management areas with recorded fishing intensity are required to consult with affect parties and typically have ongoing notifications processes and a compensation protocol in place to ensure fishers are no worse off as a result of their proposed activity. Existing control measures (as listed below) to meet defined acceptable levels are fully detailed in Table 6-2. • CM03 Fair Ocean Access Procedure • CM04 Stakeholder consultation • CM05 Petroleum safety zones • CM06 Temporary exclusion/cautionary zones
Additional Control Measures	Recognising the shared responsibility for managing cumulative impacts, Beach will actively collaborate with other petroleum titleholders, share relevant data and promote coordinated efforts to ensure that all reasonably foreseeable projects and activities adhere to acceptable environmental standards to mitigate cumulative impacts. **Additional Controls:** Observation, incidents, and opportunities for improvement regarding the interaction with other users will be reported to other petroleum titleholders. This additional control has been adopted and included against CM04: Stakeholder consultation, as updated in ES Table 0-4. CM51 Each future EP resulting from the OGV OPP will undertake a review for additional or significantly revised reasonably foreseeable projects. Additional or significantly revised projects will be assessed as per CIA methodology (Section 8.2). Any cumulative impacts from new, significantly revised or currently unknown activities that results in an unacceptable level of impact to receptors, will be subject to new or revised control measures within the appropriate EP to reduce cumulative impacts to ALARP.
Residual Cumulative Consequence	**Minor (1)**
Acceptable Level Achieved	Yes – Following completion of the CIA process, the residual lower order – Minor (1) consequence is considered acceptable because: • The nature and scale of displacement is considered acceptable. • Good practice controls are defined and will be implemented. • The activities will be managed in accordance with relevant company, Commonwealth, international, and Industry standards, guidelines, and requirements.

Table 8-4: Cumulative Impact Assessment Outcomes for Light Sensitive Species

Aspect	**Light Sensitive Species**		
Receptor	Orange-bellied parrot (OBP)	Short-tailed shearwaters (fledglings)	Common diving-petrel
Conservation (or other) value and Status	Listed as Critically Endangered and Marine under the EPBC Act and noted as a species of cultural significance.	Not listed as threatened under the EPBC Act. Listed as Marine and Migratory. Foraging BIAs within flaring EMBA (September to May) The short-tailed shearwater is one of few Australian native birds that is harvested to this day (DNRET 2019).	Not listed as threatened under the EPBC Act. Listed as Marine. Listed as a conservation value in the south-east and temperate east. Does not have a recovery plan or conservation advice.
Legislative or Other requirements	National Recovery Plan for the Orange-bellied Parrot (DoE 2016) National Light Pollution Guidelines for Wildlife (DCCEEW 2023a).	National Recovery Plan for Albatrosses and Petrels (CoA 2022). Wildlife Conservation Plan for Seabirds (CoA 2020). National Light Pollution Guidelines for Wildlife (DCCEEW 2023a).	National Recovery Plan for Albatrosses and Petrels (CoA 2022). Wildlife Conservation Plan for Seabirds (CoA 2020). National Light Pollution Guidelines for Wildlife (DCCEEW 2023a).
Threatening Processes Relevant to Aspect	The National Recovery Plan for the Orange-bellied Parrot lists barriers to migration and movement as a threat. It is suggested that illuminated boats and structures within the migration route could act as a barrier to migration (weak evidence for impact, moderate risk rating). Only barriers within the migration route are considered a threat. Overlap with other light sources (Light and Flaring EMBAs) are not detailed as a threat.	Light pollution, including from gas flaring, is listed as a threat to seabirds in the Wildlife Conservation Plan, with potential for consequences affecting individuals but not whole populations. The recommended management action is to implement measures to reduce the impact of light pollution near breeding colonies. It also states that adult seabirds are less impacted by artificial lighting than fledglings and while vessels may directly affect seabirds through their activities, the Plan only lists those close to colonies or roost sites. The National Recovery Plan for Albatrosses and Petrels also states that light associated with coastal developments at or adjacent to breeding sites represents a moderate threat to short-tailed shearwater.	Light emissions are identified as a threat in the National Recovery Plan for Albatrosses and Petrels but marine infrastructure interactions, including those associated with artificial light, are classified as having no risk category priority and affecting 'Nil' species in Australian jurisdiction. Light pollution, including from gas flaring, is listed as a threat to seabirds in the Wildlife Conservation Plan for Seabirds, with potential for consequences affecting individuals but not whole populations. Potential for light emissions from the activity to overlap with the nocturnal foraging.
Relevant OGV OPP Spatial and Temporal Extent	The probable migration route is detailed in Figure 4-42 and Figure 4-64. OGV Project Area overlaps the OBP probable migration route by ~0.075% Probable Migration Route September-November (Southward); February-mid-March (northwards).	Short-tailed shearwater BIAs are detailed in Figure 4-41 and Figure 6-2. The OGV Light and Flaring EMBA overlap the short-tailed shearwater's foraging BIAs by 0.77% and 2.91% respectively. The OGV Light EMBA does not overlap any short-tailed shearwater Breeding BIAs The OGV Flaring EMBA overlaps the known fledgling areas at Middle and Griffith Islands. Worst case light levels from OGV OPP flaring activities have been calculated as ~0.001 Lux for both sites (illuminance equivalent to ambient light on a moonless clear night sky/new moon). Changes in ambient light at these levels are not known to cause behavioural disturbance as per those described in DCCEEW (2023a). The OGV Flaring EMBA does not overlap the known fledgling area at Deen Maar. Fledging period end of April to beginning of May.	The common-diving petrel are detailed in Figure 4-40 and Figure 6-2. The OGV OPP light and flaring EMBA overlaps the common-diving petrel foraging BIA by ~1.47% and ~4.68% respectively. Present year round. Common diving-petrels are thought to be fairly sedentary, remaining more or less in the area of their breeding colony year-round, however, there are instances where individuals have been recorded venturing into the open ocean to forage outside of the breeding season and may migrate to more tropical climates (Brooke 2004). Within the Bass Strait the common diving-petrels has shown high foraging efforts compared to other populations (with foraging trips averaging 71 ± 3 km). This is believed to potentially be due to the sparse distribution of prey such as krill (Formant et al. 2021).
Relevant Actions from Legislative or Other Requirements	Assess the risk of barriers, being illuminated structures or boats, on the probable migration route. Manage threat if the risk rating warrants action. National Light Pollution Guidelines for Wildlife recommend: 1. Always using Best Practice Lighting Design to reduce light pollution and minimise the effect on wildlife. 2. Undertaking an Environmental Impact Assessment for effects of artificial light on listed species for which artificial light has been demonstrated to affect behaviour, survivorship or reproduction.	Wildlife Conservation Plan for Seabirds: Mitigate against impacts of light pollution around breeding colonies. National Light Pollution Guidelines for Wildlife recommend: 1. Always using Best Practice Lighting Design to reduce light pollution and minimise the effect on wildlife. 2. Undertaking an Environmental Impact Assessment for effects of artificial light on listed species for which artificial light has been demonstrated to affect behaviour, survivorship or reproduction.	Wildlife Conservation Plan for Seabirds: Mitigate against impacts of light pollution around breeding colonies. National Light Pollution Guidelines for Wildlife recommend: 1. Always using Best Practice Lighting Design to reduce light pollution and minimise the effect on wildlife. 2. Undertaking an Environmental Impact Assessment for effects of artificial light on listed species for which artificial light has been demonstrated to affect behaviour, survivorship or reproduction.

Aspect	**Light Sensitive Species**		
Receptor	Orange-bellied parrot (OBP)	Short-tailed shearwaters (fledglings)	Common diving-petrel
Baseline Environment Condition	Ambient light within the Project Area is detailed within Section 4.3.6. The OBP migration route may also be impacted by light sources from: • existing oil and gas activity (Section 4.5.2) • existing shipping (Section 4.5.6). • current commercial fishing effort (Section 4.5.10, 4.5.11, 4.5.12) Note on average ~121 individual vessels pass through the OBP probable migration route area per day.	Ambient light within the Project Area is detailed within Section 4.3.6. The short-tailed shearwater may also be impacted by light sources from: • existing oil and gas activities (Section 4.5.2) • existing shipping (Section 4.5.6) • current commercial fishing effort (Section 4.5.10, 4.5.11, 4.5.12). Note on average ~15 individual vessels pass through the OGV Flaring EMBA per day. On average ~2.5 vessels operate within 20 km of Middle and Griffith Islands plus Deen Maar breeding areas per day. Additional anthropogenic light sources within the vicinity of breeding sites include streetlights, building lights, façade lights, and vehicular. Beach expects that seabirds within the area are highly habituated to light emissions from continuous and long-term exposure to shipping vessels, existing oil and gas activities plus Additional anthropogenic light sources.	Ambient light within the Project Area is detailed within Section 4.3.6. The common-diving petrel may also be impacted by light sources from: • existing oil and gas activities (Section 4.5.2) • existing shipping (Section 4.5.6) • current commercial fishing effort (Section 4.5.10, 4.5.11, 4.5.12). Note on average ~430 individual vessels pass through the common-diving petrel foraging BIA per day. Beach expects that seabirds within the foraging area are highly habituated to light emissions from continuous and long-term exposure to shipping vessels and existing oil and gas activities as per other species (Dunlop and Rippey 2001). Additional anthropogenic light sources within the vicinity of coastal areas include streetlights, building lights, façade lights, vehicular.
Acceptable Level	**Acceptable level 1:** No interference with the recovery of EPBC Act listed threatened species. **Acceptable level 2:** No modification, isolation or decrease in the availability or quality of habitat to the extent that EPBC Act listed threatened, migratory or cetacean species are likely to decline. **Acceptable level 3:** Impacts will not be inconsistent with conservation advice, recovery plans and threat abatement plans for EPBC Act listed threatened, migratory or cetacean species.	**Acceptable level 1:** No interference with the recovery of EPBC Act listed threatened species. **Acceptable level 2:** No modification, isolation or decrease in the availability or quality of habitat to the extent that EPBC Act listed threatened, migratory or cetacean species are likely to decline. **Acceptable level 3:** Impacts will not be inconsistent with conservation advice, recovery plans and threat abatement plans for EPBC Act listed threatened, migratory or cetacean species.	**Acceptable level 1:** No interference with the recovery of EPBC Act listed threatened species. **Acceptable level 2:** No modification, isolation or decrease in the availability or quality of habitat to the extent that EPBC Act listed threatened, migratory or cetacean species are likely to decline. **Acceptable level 3:** Impacts will not be inconsistent with conservation advice, recovery plans and threat abatement plans for EPBC Act listed threatened, migratory or cetacean species.
Other Reasonably Foreseeable Projects/ Activities Relevant to Aspect	Potential scenarios for other reasonably foreseeable projects / activities relevant to have potential cumulative impacts: • One seismic survey occurring concurrently with drilling/P&A activities and/or Project installation activities. • Consecutive drilling/P&A activities and/or Project installation activities (including those over several seasons / years). • Concurrent drilling and installation activities (including those over several seasons / years). • Concurrent project infrastructure / IMR activities (including those over several seasons / years). • Consecutive project infrastructure / IMR activities. (including those over several seasons / years). Drilling, seismic, installation and IMR activities within the OGV OPP (Section 3.3) and other reasonably foreseeable projects (Table 8 1) are conducted over relatively short periods (drilling phases typically 30 to 40 days). Other reasonably foreseeable future projects areas within the OBP probable migration route consist of: • Amplitude Energy CHN operations (~0.025% overlap) • Amplitude Energy East Coast Supply Project (~0.007% overlap)	Potential scenarios for other reasonably foreseeable projects / activities relevant to have potential cumulative impacts: • One seismic survey occurring concurrently with drilling/P&A activities and/or Project installation activities. • Consecutive drilling/P&A activities and/or Project installation activities (including those over several seasons / years). • Concurrent drilling and installation activities (including those over several seasons / years). • Concurrent project infrastructure / IMR activities (including those over several seasons / years). • Consecutive project infrastructure / IMR activities. (including those over several seasons / years). Other reasonably foreseeable future projects areas with light EMBAs that overlap Middle and Griffith Islands plus Deen Maar breeding areas: • Alinta Energy and JERA Nex - Spinifex Offshore Wind. 3 x breeding areas between 20 and 23 km from operational area therefore outside expected vessel light EMBA). • Amplitude Energy - Athena Supply Project (Flaring EMBA (49 km) overlaps Middle Island only). Approximate distance to closest flare site is 41 km which has a calculated light intensity of <0.002 Lux.	Potential scenarios for other reasonably foreseeable projects / activities relevant to have potential cumulative impacts: • One seismic survey occurring concurrently with drilling/P&A activities and/or Project installation activities. • Consecutive drilling/P&A activities and/or Project installation activities (including those over several seasons / years). • Concurrent drilling and installation activities (including those over several seasons / years). • Concurrent project infrastructure / IMR activities (including those over several seasons / years). • Consecutive project infrastructure / IMR activities. (including those over several seasons / years). Other reasonably foreseeable future projects areas within the common-diving petrel foraging BIA consist of: • Alinta Energy and JERA Nex - Spinifex Offshore Wind – light EMBA (~0.07% overlap) • Amplitude Energy - Casino-Henry-Netherby (CHN) Operations – Light EMBA (~0.58% overlap) • Amplitude Energy - Athena Supply Project – Flaring EMBA (~1.78% overlap), light EMBA (~0.64% overlap)

Receptor	Orange-bellied parrot (OBP)	Short-tailed shearwaters (fledglings)	Common diving-petrel
	• CGG Regia MSS (~0.181% operational overlap. No overlap with acquisition or line turn areas) • Woodside Minerva P&A (~0.026% overlap) Temporal: Consecutive and concurrent operations over the lifetime of OGV OPP activities (see Section 3.8) may result in multiple vessels within the probable migration route.	• Amplitude Energy - East Coast Supply Project (Flaring EMBA (49 km) overlaps Middle and Griffiths Island only). Approximate distance to closest flare site is 32 km which has a calculated light intensity of ~0.004 Lux. • CGG Services Australia - Regia Marine Seismic Survey (MSS) – Acquisition Area and line turns are within 20 km of Deen Maar. Nearest line turn is ~1 km to Deen Maar which has a calculated light intensity of <0.001 Lux. • ConocoPhillips - Otway Exploration Drilling Program. 3 x breeding areas between 17 and 20 km from operational area. Calculated light intensity of <0.001 Lux. 3 x breeding areas between 19 and 22 km from closest flare site which has a calculated light intensity of <0.007 Lux. Temporal: Consecutive and concurrent operations over an extended period of time may have vessels within the probable migration route.	• Amplitude Energy - East Coast Supply Project - Flaring EMBA (~2.15% overlap), light EMBA (~0.79% overlap) • Beach Energy - Otway Offshore Operations - light EMBA (~0.83% overlap) • Beach Energy - Offshore Gas Victoria Drilling Program - light EMBA (~3.03% overlap) • CGG Services Australia - Regia Marine Seismic Survey (MSS) - light EMBA (~3.29% overlap) • ConocoPhillips - Otway Exploration Drilling Program Flaring EMBA (~7.5% overlap), light EMBA (~3.7% overlap) • Woodside Energy - Minerva P&A and decommissioning - light EMBA (~0.25% overlap) Temporal: Consecutive drilling operations over an extended period of time may have light EMBAs that overlap the foraging BIA.
Description of Cumulative Impact (including spatial/temporal extent)	With the OGV OPP Project Area minimal overlap (~0.075%) with the OBP probable migration route the likelihood of a vessel or MODU acting as a barrier to the OBP is considered negligible. Potential OGV OPP well sites are situated outside of the OBP probable migration route. Section 6.3.3.2 (Emissions – Light) assessed the impacts to all bird species by OGV OPP activities as having Minor (1) consequences. **Successive and Additive impacts** - Due to the location of potential drilling sites, a MODU (acting as a barrier) will only be present in the OBP probably migration route for activities under Woodside's approved Minerva Decommissioning and Field Management Environment Plan (Woodside 2025). Only activity areas associated with the approved Woodside Minerva decommissioning activities (Woodside 2025) and Amplitudes CHN operations EP (Cooper 2024) overlap the OBP probable migration route. Neither EP identifies any long-term population viability to the OBP or impacts resulting from cumulative impacts. Whilst Regia MSS operational area is within the probable migration route, there is no overlap with acquisition or line turn areas. The likelihood of vessels (barriers) from the Regia MSS being within the OBP probable migration route are considered negligible. With the minimal overlap of all reasonably foreseeable future projects vessels, being within the OBP probable migration route, the likelihood of additional vessels acting as barriers to the OBP are considered negligible. The presence of all vessels will be temporary with no permanent illuminated structures within the OBP probably migration route. In addition, any vessel present will not bisect the probable migration route area restricting migration. Consideration should be given that ~121 vessels are present within the OBP probable migration route each day. Cumulative impacts resulting from the temporary presence of 1 to 3 additional OGV vessels and those from other reasonably foreseeable projects within the small portion of the OBP probable migration route are not of a concern considering the nature and scale of the existing environment. In addition, Beach has been operating in the Otway Basin and undertaking similar activities to the Project activities with no evidence of	Impact assessment of light emissions (Section 6.3.3.2) found that for short-tailed shearwaters, the behavioural response threshold range for fledgling shearwaters against flaring light emissions excludes the breeding locations (Middle Island and Griffiths Island). Due to its distance from OGV OPP activities, fledglings at Deen Maar were not considered. **Successive and Additive impacts** - Potential impacts to short-tailed shearwaters from OGV activities are expected to be limited to foraging individuals and therefore no impacts to short-tailed shearwater fledglings will occur. Short-tailed shearwaters are not known to forage at night therefore the impact from light emissions form OGV operations on foraging short-tailed shearwaters is considered negligible. In addition, modelling by Pendoley (2022) showed that light levels from a large pipelay vessel fell below those know to impact hatchling behaviour at 14.8 km from the vessel. The only project known to have vessels that will be within 14.8 km is CGG's Regia MSS. Approximately 40 km of acquisition lines and run-ins are within 14.8 km of the fledgling sites at Deen Maar. At an estimated 4 knots the equates to a total of 5.5 hours that the CGG vessels may impact fledging sites. Calculated levels for other reasonably foreseeable projects show negligible increases in light intensity levels at the Middle and Griffiths Island and Deen Maar breeding sites which are well below those known to cause behavioural disturbance to short-tailed shearwater fledglings (Section6.3.3.2, DCCEEW 2023a). Existing conditions show that on average ~2.5 vessels not connected with either OGV OPP activities or other reasonably foreseeable activities, operate within 20 km of the breeding sites. The presence of all vessels connected to OGV OPP and other reasonably foreseeable activities will be temporary with no permanent fixed structures. Light intensity from flaring has been shown to be negligible at the breeding sites and are all short-term (1 – 2 days) with possible impacts unlikely during daylight hours. **Synergistic impacts** – none identified with the presence of a MODU and additional vessels.	Section 6.3 (Emission - Light) found that impacts from temporary OGV Project light emissions are expected to be limited to individuals and therefore no impacts to petrels will occur at a population level with Minor (1) consequences. **Successive and Additive impacts** – Light EMBAs for the OGV OPP and other reasonably foreseeable projects have been shown to have limited overlap with the common diving-petrel foraging BIA. Light EMBAs for non-flaring activities are based on conservative thresholds to provides a precautionary limit based on observed effects (20 km) (DCCEEW 2023). Modelling (Appendix O, Pendoley 2022) and observed effects (Rodriguez et al 2017) show area of behavioural impact to be significantly smaller. Therefore, the area of influence, as detailed by percentage overlap of the foraging BIA above, will be negligible considering the nature and scale of the foraging area. In addition, any vessel present will not bisect the BIA restricting critical behaviour .Successive and additive impacts to foraging activities of the common diving-petrel are considered unlikely Light EMBAs for flaring activities are based a change in ambient light levels (0.001 Lux). Behavioural response of bird species at these light intensity levels are not expected which have been calculated to be significantly less (0.18 Lux, adapted from Rodriguez et al 2017). At 63 MMscfd, 0.18 Lux is reached at <10 km from flare source. The successive and additive cumulative impact of light emissions from OGV OPP activities and other reasonably foreseeable projects would be very low in comparison to the light emissions associated with existing shipping and fishing operations within the foraging BIA. The addition of limited vessels to the ~430 vessels already passing through the foraging BIA daily would not significantly increase light intensity levels in the area. With the high level of shipping, the current environment is not considered pristine. The area covered by the foraging BIA is not a habitat that encourages site-fidelity (i.e. seabirds are not

Aspect	Light Sensitive Species		
Receptor	Orange-bellied parrot (OBP)	Short-tailed shearwaters (fledglings)	Common diving-petrel
	OBP presence recorded. Other operators including previous seismic surveys have also not had evidence of OBP presence recorded. OBP numbers continue to increase. **Synergistic impacts** – none identified with the presence of a MODU and additional vessels.		permanently present, are typically transiting whilst opportunistically foraging over wide areas). Beach expects that seabirds within the foraging area are highly habituated to light emissions from continuous and long-term exposure to shipping vessels and existing oil and gas activities. In addition, all vessels connected to OGV OPP and other reasonably foreseeable activities will be temporary with no permanent fixed structures as detailed in Section 3.8 and Table 8-1. Light intensity from flaring is expected to have limited successive cumulative impacts as flaring per project is limited (1-2 days each) with each program expected to take 30 to 60 days. The time between flaring events is expected to be >1 month with the MODU typically 30 to 60 days on site plus the time taken to reposition to the next well site. In addition, not all wells from OGV OPP and other reasonably foreseeable projects will be undertaking flaring activities. Additive or synergistic cumulative impacts from flaring at not possible as a single MODU is being used by operators in the area. **Synergistic impacts** – none identified with the presence of a MODU and additional vessels.
Certainty of Assessment	There is no published information available on the sensitivity of the orange-bellied parrot to light, and only anecdotal evidence exists regarding the impact of barriers to migration (DELWP 2016a). However, light modelling (Appendix O) and impacts on other bird species is well understood (Section 6.3.3.2).	Beach has been operating in the Otway Basin and undertaking similar activities to the Project activities without incident to date of birds being attracted to MODUs or vessels. Other operators including previous seismic surveys have also not had incidents of bird attraction. Light modelling (Appendix O) and impacts on bird species is well understood (Section 6.3.3.2). The assessment of cumulative impacts is made with a high level of predictability and certainty due to the consistent negligible light intensity levels at the breeding sites from OGV activities and other reasonably foreseeable activities.	Beach has been operating in the Otway Basin and undertaking similar activities to the Project activities without incident to date of birds being attracted to MODUs or vessels. Other operators including previous seismic surveys have also not had incidents of bird attraction. Light modelling (Appendix O) and impacts on bird species is well understood (Section 6.3.3.2) as well as modelling conducted for other reasonably foreseeable projects (Table 8-1) and similar offshore construction projects (Pendoley 2022) The assessment of cumulative impacts is made with a high level of predictability and certainty from current modelling.
Existing Control Measures to Meet Acceptable Levels	OGV Project control measures, developed to meet defined acceptable levels, are directly applicable to reducing the potential consequences of cumulative impacts. These control measures are Beach's primary means of mitigating cumulative impacts. Beach has no direct authority over the planning, implementation, or management of other reasonably foreseeable projects and activities that may potentially contribute to cumulative impacts. A single MODU has been contracted to conduct drilling/P&A activities in the region, mitigating the potential for concurrent impacts from these activities. Beach will conduct drilling activities at one location at a time and abide by relevant activity exclusion zones in place for other activities in the offshore Otway Basin, which will minimise the potential for successive and additive cumulative impacts from light emissions. Existing control measures to meet defined acceptable levels (as listed below) are fully detailed in Table 6-3. • CM05 Petroleum safety zones • CM06 Temporary exclusion/cautionary zones	OGV Project control measures, developed to meet defined acceptable levels, are directly applicable to reducing the potential consequences of cumulative impacts. Additional Control Measures	Recognising the shared responsibility for managing cumulative impacts, Beach will actively collaborate with other petroleum titleholders, share relevant data and promote coordinated efforts to ensure that all reasonably foreseeable projects and activities adhere to acceptable environmental standards to mitigate cumulative impacts. **Additional Controls:** Observation, incidents, and opportunities for improvement regarding the interaction with other users will be reported to other petroleum titleholders. This commitment has been adopted and included against CM04: Stakeholder consultation, as updated in ES Table 0-4. CM51 Each future EP resulting from the OGV OPP will undertake a review for additional or significantly revised reasonably foreseeable projects. Additional or significantly revised projects will be assessed as per CIA methodology (Section 8.2). Any cumulative impacts from new, significantly revised or currently unknown activities that results in an unacceptable level of impact to receptors, will be subject to new or revised control measures within the appropriate EP to reduce cumulative impacts to ALARP.	Recognising the shared responsibility for managing cumulative impacts, Beach will actively collaborate with other petroleum titleholders, share relevant data and promote coordinated efforts to ensure that all reasonably foreseeable projects and activities adhere to acceptable environmental standards to mitigate cumulative impacts. **Additional Controls:** Observation, incidents, and opportunities for improvement regarding the interaction with other users will be reported to other petroleum titleholders. Residual Cumulative Consequence	**Minor (1)**	**Minor (1)**	**Minor (1)**
Acceptable Level Achieved	Yes – Following completion of the CIA process, the residual lower order – Minor (1) consequence is considered acceptable because: - Cumulative light emissions will not result in interference with the recovery of EPBC Act listed threatened species - Cumulative light emissions will not result in modification, isolation or decrease in the availability or quality of habitat to the extent that EPBC Act listed threatened, migratory or cetacean species are likely to decline - Cumulative light emissions will not result in inconsistencies with conservation advice, recovery plans and threat abatement plans for EPBC Act listed threatened, migratory or cetacean species. - Light from drilling activities (including flaring) will only occur from a single location within the OBP probable migration route (no concurrent activities due the use of a single MODU between titleholders) and do not represent a permanent illuminated structure (or barrier) within the probable migration route.	Yes – Following completion of the CIA process, the residual lower order – Minor (1) consequence is considered acceptable because: - Cumulative light emissions will not result in interference with the recovery of EPBC Act listed threatened species - Cumulative light emissions will not result in modification, isolation or decrease in the availability or quality of habitat to the extent that EPBC Act listed threatened, migratory or cetacean species are likely to decline - Cumulative light emissions will not result in inconsistencies with conservation advice, recovery plans and threat abatement plans for EPBC Act listed threatened, migratory or cetacean species. - Light from all drilling activities (including flaring) will only occur from a single location with no concurrent flaring activities due the use of a single MODU between titleholders. - Identified breeding areas for the short-tailed shearwater would only be overlapped by the OGV OPP and other reasonably foreseeable flaring EMBAs for short periods while flaring occurred.	Yes – Following completion of the CIA process, the residual lower order – Minor (1) consequence is considered acceptable because: - Cumulative light emissions will not result in interference with the recovery of EPBC Act listed threatened species - Cumulative light emissions will not result in modification, isolation or decrease in the availability or quality of habitat to the extent that EPBC Act listed threatened, migratory or cetacean species are likely to decline - Cumulative light emissions will not result in inconsistencies with conservation advice, recovery plans and threat abatement plans for EPBC Act listed threatened, migratory or cetacean species. - Light from drilling activities (including flaring) will only occur from a single location (no concurrent activities due the use of a single MODU between titleholders), with

Aspect	**Light Sensitive Species**		
Receptor	Orange-bellied parrot (OBP)	Short-tailed shearwaters (fledglings)	Common diving-petrel
	• The presence of vessels / barriers from other reasonably foreseeable projects within the OBP probable migration route are short term and have minimal overlap. They do not bisect the probable migration route of the OBP and will not prevent migration. • Existing environment is not considered pristine in respect of light emissions with multiple vessels (~121 per day) operating within the OBP probable migration route. • Good existing and additional control measures are defined and will be implemented including MODU and vessels requirement to implement a Light Management Plan which will restrict light emissions. • The activities will be managed in accordance with relevant company, Commonwealth, international, and Industry standards, guidelines and requirements. • Due to the minimal cumulative impacts described, seasonal and restricted area controls are not considered necessary.	• OGV Flaring EMBA overlaps the known fledgling areas at Middle and Griffith Islands but with worst case light levels calculated as ~0.001 Lux, below levels known to cause behavioural disturbance in fledglings. • Existing environment is not considered pristine in respect of light emissions with additional anthropogenic light sources within the vicinity of breeding sites include streetlights, building lights, façade lights, and vehicular. • This species is not listed as threatened and periodic changes in ambient light at the predicted levels are unlikely to cause behavioural changes or result in injury/mortality to this species. • The impact of light emissions from other reasonably foreseeable projects overlapping the light emission from a MODU are predicted to result in increases in ambient light that are negligible (short-term, fully recoverable and do not represent permanent illuminated structures or boats within the close vicinity of the breeding sites). • Good existing and additional control measures are defined and will be implemented including MODU and vessels requirement to implement a Light Management Plan which will restrict light emissions. • The activities will be managed in accordance with relevant company, Commonwealth, international, and Industry standards, guidelines and requirements. • Due to the minimal cumulative impacts, seasonal and restricted area controls are not considered necessary.	limited overlap with the foraging BIA and do not represent permanent illuminated structures within the foraging area. • The impact of light emissions from other reasonably foreseeable projects overlapping the light emission from a MODU are predicted to result in increases in ambient light that are negligible (short-term, fully recoverable and do not represent permanent illuminated structures or boats within the foraging BIA). Light emissions do not bisect the foraging BIA and will not prevent critical behaviour. • Limited spatial extent of effect compared to area available for foraging. The National Recovery Plan states that marine infrastructure interactions, including those associated with artificial light, are classified as having no risk category priority and affecting 'Nil' species in Australian jurisdiction. • The common-diving petrel is known to forage over wide areas. • Good existing and additional control measures are defined and will be implemented including MODU and vessels requirement to implement a Light Management Plan which will restrict light emissions. • The activities will be managed in accordance with relevant company, Commonwealth, international, and Industry standards, guidelines and requirements. • Existing environment is not considered pristine in respect of light emissions Light emissions from OGV OPP activities and other reasonably foreseeable projects will be insignificant to the estimated 430 individual vessels that pass through the common-diving petrel foraging BIA per day. Additional anthropogenic light sources within the vicinity of coastal areas include streetlights, building lights, façade lights, vehicular also exist. • Beach expects that seabirds within the foraging area are highly habituated to light emissions from continuous and long-term exposure to shipping vessels and existing oil and gas activities. • Due to the minimal cumulative impacts, seasonal and restricted area controls are not considered necessary.

Table 8-5: Cumulative Impact Assessment Summary for Identified Cetaceans

Aspect	Cetaceans
Receptor	**Blue whale (BW), southern right whale (SRW) and other cetacean species with biologically important behaviours**
Conservation (or other) value and Status	Blue whale listed as Endangered under the EPBC Act Southern right whale listed as Endangered under the EPBC Act and noted as a species of cultural significance in the National Recovery Plan for the Southern Right Whale (DCCEEW 2024o). Fin whale (FW) listed as vulnerable under the EPBC Act Sei whale (SW) listed as vulnerable under the EPBC Act Pygmy right whale (PRW) no Listing Advice for this species
Legislative or Other requirements	Conservation Management Plan for the Blue Whale (DoE 2015) Guidance on key terms within the Blue Whale Conservation Management Plan (DAWE 2021a) National Recovery Plan for the Southern Right Whale (DCCEEW 2024o) Conservation Advice Balaenoptera physalus (fin whale) (TSSC 2015d). Conservation Advice Balaenoptera borealis (sei whale) (TSSC 2015e). No management plan or conservation advice for Caperea marginata (pygmy right whale).
Threatening Processes Relevant to Aspect	Conservation Management Plan for the Blue Whale identifies anthropogenic noise interference as a threat. National Recovery Plan for the Southern Right Whale identify noise interference as a threat. Conservation advice Balaenoptera physalus (fin whale) identifies anthropogenic noise and acoustic disturbance as a minor threat. Conservation advice Balaenoptera borealis (sei whale) identifies anthropogenic noise and acoustic disturbance as a minor threat.
Relevant OGV OPP Activities Spatial and Temporal Extent	BIAs for the BW are detailed in Figure 4-44 and Figure 6-6. BIAs for the SRW are detailed in Figure 4-60 and Figure 6-7. Underwater sound EMBAs for OGV Project Area overlap foraging and annual high use foraging BIAs for the BW (~2.06%), (presence is between November to June, peaking in February and March). Note a typical operational area (3 km radius + 7.98 km Noise EMBA) would overlap foraging and annual high use foraging BIAs by <0.2%. Underwater sound EMBAs for OGV Project Area overlap the migration BIA for the SRW (~0.18%) with SRW migrating through the area between approximately April to October. Note a typical operational area (3 km radius + 7.98 km Noise EMBA) would overlap migration BIA by <0.15%. Note, no OGV OPP underwater sound EMBAs overlap the SRW reproductive BIA. No BIAs or habitat critical to the survival of the FW, SW or PRW identified within the OGV underwater sound EMBAs. PMST report shows presence within EMBAs for FW, SW as listed as foraging, feeding or related behaviour known to occur within area, with PRW foraging, feeding or related behaviour may occur. Whilst there are no defined foraging areas for FW, SW or PRW off the coast of Victoria, it is likely foraging occurs in the same areas identified as the foraging BIAs for BW as they are often recorded foraging in the same areas (Gill et al. 2008; Gill et al. 2015; McCauley et al 2018). FW whale migrations are from higher latitude summer feeding grounds to lower latitude winter breeding grounds. SW seasonal migrations are from subpolar summer feeding grounds to lower latitude winter breeding grounds. Young PRW appear to be restricted to shallower coastal waters (Kemper 2002), possibly moving between areas of coastal upwelling. Weaned juveniles head south of 41° latitude into waters with higher prey abundance (Kemper 2002).
Relevant Actions from Legislative or Other Requirements	Conservation Management Plan for the Blue Whale states that anthropogenic noise in BIAs must be managed so that blue whales can continue to utilise the area without injury and [are] not displaced from a foraging area. DAWE (2021a) details that underwater anthropogenic noise should not: • Stop or prevent any blue whale from foraging • Cause any blue whale to move on when foraging, or • Stop or prevent any blue whale from entering a foraging area The National Recovery Plan for the Southern Right Whale identifies actions within and adjacent to SRW BIAs and habitat critical to the survival of SRWs should demonstrate that it does not prevent any southern right whale from utilising the area or cause auditory impairment and that the risk of behavioural disturbance is minimised. The Conservation Advice for *Balaenoptera physalus* (fin whale) and for *Balaenoptera borealis* (sei whale) identify anthropogenic noise and acoustic disturbance as a minor threat.
Baseline Environment Condition	Ambient sound within the Project Area is detailed within Section 4.3.7. Listed species identified may also be impacted by noise sources from: • existing oil and gas activities (Section 4.5.2) • existing shipping (Section 4.5.6) including current commercial fishing effort (Section 4.5.10, 4.5.11, 4.5.12). On average ~225 vessels operate within the BW combined foraging and foraging (annual high use area) (Otway region) BIAs per day with associated continuous noise emissions. On average ~1663 vessels operate within the SRW migration BIA per day with associated continuous noise emissions.

Aspect	Cetaceans
Receptor	**Blue whale (BW), southern right whale (SRW) and other cetacean species with biologically important behaviours**
Acceptable Level	**Acceptable level 1:** No interference with the recovery of EPBC Act listed threatened species. **Acceptable level 2:** No modification, isolation or decrease in the availability or quality of habitat to the extent that EPBC Act listed threatened, migratory or cetacean species are likely to decline. **Acceptable level 3:** Impacts will not be inconsistent with conservation advice, recovery plans and threat abatement plans for EPBC Act listed threatened, migratory or cetacean species.
Other Reasonably Foreseeable Projects/ Activities Relevant to Aspect	Potential scenarios for other reasonably foreseeable projects / activities relevant to have potential cumulative impacts: • One seismic survey occurring concurrently with drilling/P&A activities and/or Project installation activities. • Consecutive drilling/P&A activities and/or Project installation activities (including those over several seasons / years). • Concurrent drilling and installation activities (including those over several seasons / years). • Concurrent project infrastructure / IMR activities (including those over several seasons / years). • Consecutive project infrastructure / IMR activities. (including those over several seasons / years). Other reasonably foreseeable projects underwater sound EMBAs that overlap the combined BW foraging and annual high use foraging BIAs and the SRW migration and reproductive BIAs are detailed below. Alinta Energy and JERA Nex - Spinifex Offshore Wind: • Estimated underwater sound EMBAs overlap foraging and annual high use foraging BIAs for the BW <1.4%. • Estimated underwater sound EMBAs overlap migration and reproduction BIA for the SRW <0.5% and <0.5% respectively • Project is in the pre-planning phase and as such no specific details are currently publicly available. However, if future underwater sound modelling predicts an overlap with the SRW reproductive BIA, seasonal controls would be likely be based on similar approved developments in the area (Woodside 2025). Amplitude Energy - Casino-Henry-Netherby (CHN) Operations: • Underwater sound EMBAs overlap foraging and annual high use foraging BIAs for the BW <0.5% • Underwater sound EMBAs overlap migration and reproduction BIA for the SRW <0.05% and <0.5% respectively • Approved EP shows no seasonal controls to restrict activities Amplitude Energy - Athena Supply Project: • Underwater sound EMBAs overlap foraging and annual high use foraging BIAs for the BW (<0.5%) • Underwater sound EMBAs overlap migration BIA for the SRW (<0.05%) • No overlap with SRW reproductive BIA • EP under assessment, shows no seasonal controls proposed to restrict activities Amplitude Energy - East Coast Supply Project • Underwater sound EMBAs overlap foraging and annual high use foraging BIAs for the BW (<0.8%) • Underwater sound EMBAs overlap migration and reproduction BIA for the SRW <0.2% and <2% respectively • Under assessment, shows no seasonal controls proposed to restrict activities Beach Energy - Otway Offshore Operations • Underwater sound EMBAs overlap foraging and annual high use foraging BIAs for the BW <1% • Estimated underwater sound EMBAs overlap migration and reproduction BIA for the SRW <0.1% and <0.5% respectively • Approved EP shows no seasonal controls to restrict activities Beach Energy - Offshore Gas Victoria Drilling Program • Underwater sound EMBAs overlap foraging and annual high use foraging BIAs for the BW <3.3% • Underwater sound EMBAs overlap migration BIA for the SRW <0.5% • Approved EP shows no seasonal controls CGG Services Australia - Regia Marine Seismic Survey (MSS) • Underwater sound EMBAs overlap foraging and annual high use foraging BIAs for the BW <8% • Estimated underwater sound EMBAs overlap migration and reproduction BIA for the SRW <1% and <2% respectively • Under assessment showing seasonal controls in place to avoid behavioural disturbance to SRW and BW. ConocoPhillips - Otway Exploration Drilling Program

Aspect	Cetaceans
Receptor	**Blue whale (BW), southern right whale (SRW) and other cetacean species with biologically important behaviours**
	• Underwater sound EMBAs overlap foraging and annual high use foraging BIAs for the BW <6.4% • Underwater sound EMBAs overlap migration BIA for the SRW <1% • No overlap with SRW reproductive BIA • Under assessment with no proposed seasonal controls to restrict activities Woodside Energy - Minerva P&A and decommissioning • Underwater sound EMBAs overlap foraging and annual high use foraging BIAs for the BW <0.05% • Estimated underwater sound EMBAs overlap migration and reproduction BIA for the SRW <0.01% and <0.01% respectively • Approved EP shows seasonal controls to reduce the likelihood of behavioural disturbance to SRW. No BIAs or habitat critical to the survival of the FW, SW or PRW identified within the OGV underwater sound EMBAs. Whilst there are no defined foraging areas for FW, SW or PRW off the coast of Victoria, it is likely foraging occurs in the same areas identified as the foraging BIAs for BW as they are often recorded foraging in the same areas (Gill et al. 2008; Gill et al. 2015; McCauley et al 2018).
Description of Cumulative Impact (including spatial/temporal extent)	The potential impacts from both impulsive and continuous underwater sound to SRW and BW is assessed as having Moderate (2) consequences (Section 6.4). For the FW, SW and PRW consequences were assessed as Minor (1) as there are no BIAs identified within the sound EMBAs. **Successive and Additive impacts –** As a single MODU will be used within the Otway region by multiple titleholders, concurrent drilling activities will not occur. Therefore, additive cumulative impacts by concurrent drilling operations are not possible. Additive impacts are only possible between a single drilling operation, other support or IMR operations, seismic surveys or general shipping. However, these will be limited due to the relatively short time drilling and support activities take compared with the lifetime of the OGV OPP (Section 3) and other reasonably foreseeable projects (Table 8-1, Figure 8-1). Successive impacts are possible throughout the lifetime of the OGV Project (Section 3). However, drilling and support activities are conducted over relatively short durations compared with the lifetime of the OGV OPP and other reasonably foreseeable projects (Table 8-1). In addition, the presence of all vessels connected to OGV OPP and other reasonably foreseeable activities will be temporary (Section 3). The locations of OGV OPP and other reasonably foreseeable activities are isolated and separated such that areas of behavioural impact would not form barriers to the migration of whale species or other biological important behaviours. The spatial extent of underwater sound EMBAs (Behavioural) for the OGV OPP and most other reasonably foreseeable projects have been shown to have very limited overlap with habitat critical to the survival for BW and SRW. Underwater sound EMBAs for projects involved in drilling operations are based on underwater noise modelling associated resupply vessels on DP as well as MODU operations (Table 8-1). These are significantly larger than those associated with support and IMR activities. Therefore, percentage overlaps previously detailed, while minimal are still conservative. The drilling phase of the OGV OPP and other reasonably foreseeable projects is relative short compared to the lifetime of the OGV Project. In addition, successive cumulative impacts resulting in an increase in the likelihood of PTS and TTS for foraging BW, migrating SRW or FW, SW or PRW are not predicted. Distances to the PTS and TTS thresholds are well understood (as detailed in Section 6.4 and Appendices F, G, H, I and J). Due to the isolated nature of OPP OGV and other reasonably foreseeable activities PTS and TTS EMBAs are not expected to overlap (both spatially and temporally) and therefore there acceptable levels will be achieved. Both OGV OPP and other reasonably foreseeable activities have been shown to have a small overlap with underwater sound EMBAs and the BW foraging and annual high use foraging BIAs. Spatial data for the BW BIAs does not identify any areas within the BIA of specific importance for critical behaviour. Therefore, with the isolated and temporary nature of OGV OPP and other reasonably foreseeable activities, no barriers within the BIAs preventing BW migration activities will occur. The Bonney Coast Upwelling KEF (Section 4.2.12.1) is an area where blue whales are known to feed in relatively high numbers. However, this BIA is situated ~60 km from the OGV OPP Project Area with no impacts from underwater noise EMBAs from OGV OPP activities. Behavioural underwater noise EMBAs from ConocoPhillips exploration drilling activities may overlap this KEF but as previously stated, concurrent drilling operation will not occur with successive activities also not expected to cause a cumulative impact. Whilst CGG's Regia MSS underwater noise emissions will overlap the KEF, seasonal controls are proposed to avoid behavioural disturbance to BW. Whilst piling activities from the Spinifex wind farm installation may overlap the BW BIAs and Bonney Coast Upwelling KEF no details are currently available on mitigation measures, but seasonal controls would be expected in line with other operators in the area preventing cumulative impacts from noise emissions. Other reasonably foreseeable projects with underwater sound EMBAs shown to have an overlap with the SRW reproductive area BIA, may have or propose seasonal controls to avoid disturbance to SRW when present. Underwater sound EMBAs from the OGV OPP do not to overlap the SRW reproductive area BIA (Figure 6-7, Figure 6-9). As no underwater sound EMBAs are predicted to overlap the SRW reproductive BIA when the SRW are present, successive or additive cumulative impacts to SRW reproductive activity are not predicted to occur. Major SRW calving areas have been identified in Western Australia and South Australia with females regularly seen in Victoria at Warrnambool. The OGV OPP Project Area is >50 km from this breeding site, which is well beyond any OGV Project underwater sound EMBAs. Only the CGG Regia MSS has noise EMBAs that overlap this breeding site but has seasonal controls to prevent disturbance. Therefore, no successive or additive impacts are predicted for this breeding area when SRW are present. The SRW migration BIA is not intended to reflect entire species occurrence or distribution of the SRW but are areas identified as important by using reliable information on occurrence and behaviour (DCCEEW 2025b). No specific areas of importance of critical behaviour are identified within the SRW migration BIA from spatial data. Therefore, with the isolated and temporary nature of OGV OPP and other reasonably foreseeable activities, no barriers within the BIA preventing SRW migration activities will occur. It is important to note existing conditions show that on average ~225 vessels not connected with either OGV OPP activities or other reasonably foreseeable activities, operate within the BW combined foraging and foraging (annual high use area) (Otway region) BIAs per day with associated continuous noise emissions. In addition, existing conditions show that on average ~1663 vessels not connected with either OGV OPP activities or other reasonably foreseeable activities, operate within the SRW migration BIA per day with associated continuous noise emissions. McPherson et al. (2021) as detailed in Section 4.3.7 (Ambient Sound) showed that shipping traffic in the Otway are strong drivers of the ambient noise. Woodside (2003) details recorded broadband underwater noise levels in the order of 93 to 97 dB re 1 µPa with shipping raising the averaged noise level above 105 dB re 1 µPa. The Otway region should not be considered a pristine environment due to the underwater sound generated by existing shipping. However, despite the presence of existing vessel noise there is a population growth estimate for the BW of 12.6 %, consistent with growth rates in waters off the south of Australia (McCauley et al. 2018). In addition, the eastern Australian SRW population is estimated to have increased at 4.7% p.a. between 1996 and 2017 for all individuals (Stamation et al., 2020). Whilst this increase does not include reproductive females and is lower than seen in some other areas worldwide, the lower rate of increase (recorded at the Head of the Bight) is likely to be reflective of an open population with regular movement of individuals into and out of the area and the expansion

Aspect	**Cetaceans**
Receptor	**Blue whale (BW), southern right whale (SRW) and other cetacean species with biologically important behaviours**
	into former calving grounds (Charlton et al., 2019) suggesting unimpeded migration in the area despite existing vessel movements. Vessel activity from the OGV Project and other reasonably foreseeable projects will present a negligible increase in underwater sound emissions and will not restrict migration. **Synergistic impacts** – none identified with the presence of a MODU and additional vessels.
Certainty of Assessment	There are no studies on the cumulative impacts of underwater noise on marine mammals (pers comm JASCO 2025). However, there is a high level of predictability and certainty in the limited potential for impacts, given the underwater noise modelling data available for the OGV OPP and other reasonably foreseeable projects. In addition, OGV OPP activities and all other reasonably foreseeable projects, as listed in Table 8-1, have controls in place for each activity to prevent / limit impacts.
Existing Control Measures to Meet Acceptable Levels	OGV Project control measures, developed to meet defined acceptable levels, are directly applicable to reducing the potential consequences of cumulative impacts. These control measures are Beach's primary means of mitigating cumulative impacts. Beach has no direct authority over the planning, implementation, or management of other reasonably foreseeable projects and activities that may potentially contribute to cumulative impacts. A single MODU has been contracted to conduct drilling/P&A activities in the region, mitigating the potential for concurrent impacts from these activities. Beach will conduct drilling activities at one location at a time and abide by relevant activity exclusion zones in place for other activities in the offshore Otway Basin, which will minimise the potential for successive and additive cumulative impacts from underwater sound emissions. Existing control measures (as detailed below) to meet defined acceptable levels are fully detailed in Table 6-30. • CM14 EPBC Regulations 2000 – Part 8 Division 8.1 interacting with cetaceans • CM15 Geophysical Survey Whale Management Procedure • CM16 VSP Whale Management Procedure • CM17 Drilling Whale Management Procedure • CM18 Vessel Whale Management Procedure • CM19 Noise Assessments
Additional Control Measures	Recognising the shared responsibility for managing cumulative impacts, Beach will actively collaborate with other petroleum titleholders, share relevant data and promote coordinated efforts to ensure that all reasonably foreseeable projects and activities adhere to acceptable environmental standards to mitigate cumulative impacts. **Additional Controls:** Observation, incidents, and opportunities for improvement regarding the interaction with other users will be reported to other petroleum titleholders. This commitment has been adopted and included against CM04: Stakeholder consultation, as updated in ES Table 0-4. CM51 Each future EP resulting from the OGV OPP will undertake a review for additional or significantly revised reasonably foreseeable projects. Additional or significantly revised projects will be assessed as per CIA methodology (Section 8.2). Any cumulative impacts from new, significantly revised or currently unknown activities that results in an unacceptable level of impact to receptors, will be subject to new or revised control measures within the appropriate EP to reduce cumulative impacts to ALARP.
Residual Cumulative Consequence	**Minor** (1)
Acceptable Level Achieved	Yes – Following completion of the CIA process, the residual lower order – Minor (1) consequence is considered acceptable because: • Underwater sound emissions will not result in interference with the recovery of EPBC Act listed threatened species • Underwater sound emissions will not result in the modification, isolation or decrease in the availability or quality of habitat to the extent that EPBC Act listed threatened, migratory or cetacean species are likely to decline • Underwater sound emissions will not result in inconsistencies with conservation advice, recovery plans and threat abatement plans for EPBC Act listed threatened, migratory or cetacean species • Titleholders are required to undertake their activity in a manner that is not inconsistent with the in-force Conservation Management Plan for the Blue Whale. • Titleholders are required to undertake their activity in a manner that is not inconsistent with the in-force Conservation Management Plan for the Southern Right Whale. • Impact areas from OGV Project activities and those for other reasonably foreseeable projects have been shown to be minimal compared with BIAs or habitat critical to the survival of BW and SRW.Good existing and additional control measures are defined and will be implemented including MODU and vessels requirement to implement a Light Management Plan which will restrict light emissions. • The activities will be managed in accordance with relevant company, Commonwealth, international, and Industry standards, guidelines and requirements. • Elevated ambient underwater noise by existing large volumes of shipping is present within the existing environment. • Seasonal and restricted area controls are not considered necessary as OGV OPP activities nor other reasonably foreseeable projects will individually or cumulatively restrict biologically important behaviour as defined in conservation management plans for the BW and SRW.

9 Environmental Management Implementation Approach

9.1 Implementing Requirements of the OPP in Future EPs

Future Project activities that are within the scope of this OPP will be undertaken in accordance with activity specific EPs that have been accepted by NOPSEMA.

The future EPs within the scope of this OPP will demonstrate environmental impacts and risks will be reduced to ALARP and will be of an acceptable level. The acceptable level defined in future EPs will be equivalent or greater than the acceptable levels defined in this OPP. The future EPs will define EPOs and EPSs, measurement criteria and an implementation strategy based on the implementation approach described in this section to ensure potential environmental impacts and risks are of an acceptable level.

The implementation approach described in this section provides a summary of the systems, practices and procedures used to ensure implementation of activities in accordance with this OPP, and that emergency preparedness and environmental monitoring is applied to manage the Project's risks and impacts. This will ensure the Project's environmental performance outcomes (EPOs) are achieved. Specifically, this section describes Beach's:

- Operations Excellence Management System
- Arrangements for monitoring, review and reporting of environmental performance
- Preparedness for emergencies

9.2 Operations Excellence Management System

Beach's Operations Excellence Management System (OEMS) is the company's framework to define, align, standardise and implement company processes to manage risks and ensure successful outcomes in its operations.

The OEMS defines the minimum standards, expectations and behaviours that ensure the company operates successfully (operations excellence in all core business processes including Health & Safety, Production & Reliability, Financial & Stakeholder Management and Project Delivery). The OEMS applies to all personnel performing work within the company's jurisdiction. The OEMS will be used to implement the Project.

The OEMS provides guidance on how Beach will meet the requirements of its Environmental Policy (Figure 9-1). Beach's OEMS has been developed considering Australian/New Zealand Standard ISO 14001:2016 Environmental Management Systems. The OEMS is an integrated management system and includes all HSE management elements and procedures. The OEMS is aligned with the requirements of recognised international and national standards including:

- ISO 14001 (Environmental Management)
- OHSAS 18001 (Occupational Health and Safety)
- ISO 31000 (Risk Management)
- AS 4801 (Occupational Health and Safety Management Systems)

At the core of the OEMS are 11 elements and associated standards that detail specific performance requirements that incorporate all the requirements for the implementation of the Environment Policy (Figure 9-3) and management of potential HSE impacts and risks (Figure 9-2). The Elements, via the nominated expectations, sponsor 30 Beach OEMS Standards, which provide more granular minimum compliance rule sets under which the company operates.

A core design feature of the OEMS is that every Standard is assigned to a General Manager/Functional Head or Executive with experience in the subject matter and/or accountability to ensure delivery of expected outcomes. OEMS Standard Owners ensure the effectiveness of their respective Standard(s) in addressing applicable risks and facilitate continuous improvement of performance and practices.

In the context of the OPP and the Project, the key Elements of the OEMS are summarised in this Section.

Figure 9-1: Beach Operations Excellence Management Standard (OEMS)

Element		Standard
1	Partners, Leadership and Authority	Leadership Standard
		Technical Authority Standard
		Joint Venture Management Standard
2	Financial Management and Business Planning	Integrated Planning Standard
		Phase Gate Standard
		Hydrocarbon Resource Estimation and Reporting Standard
		Financial Management Standard
3	Information Management and Legal Requirements	Regulatory Compliance Standard
		Document Management Standard
		Information Management Standard
4	People, Capability and Health	Training and Competency Standard
		Health Management Standard
5	Contracts and Procurement	Contracts and Procurement Standard
		Transport and Logistics Standard
6	Asset Management	Asset Management Standard
		Maintenance Management Standard
		Well Integrity Management Standard
		Well Construction Management Standard
		Project Management Standard
7	Operational Control	Operational Integrity Standard
		Process Safety Standard
		Management of Change Standard
8	Risk Management and Hazard Control	Risk Management Standard
		Safe Systems of Work
		Emergency and Security Management Standard

beach

Environment Policy

Objective

Beach is committed to conducting operations in an environmentally responsible and sustainable manner.

Strategy

To achieve this, Beach will:

- Comply with relevant environmental laws, regulations, and the Beach Operations Excellence Management System which is the method by which Beach identifies and manages environmental risk.
- Establish environmental objectives and targets, and implement programs to achieve them that will support continuous improvement;
- Identify, assess and control environmental impacts of our operations by proactive management of activities and mitigation of impacts;
- Ensure that incidents, near misses, concerns and complaints are reported, investigated and lessons learnt are implemented;
- Inform all employees and contractors of their environmental responsibilities including consultation and distribution of appropriate environmental management guidelines, regulations and publications for all relevant activities;
- Efficiently use natural resources and energy, and engage with stakeholders on environmental issues; and
- Publicly report on our environmental performance.

Application

This policy applies to all personnel associated with Beach activities.

Morné Engelbrecht
Chief Executive Officer
April 2023

Figure 9-3: Beach's Environment Policy

9.2.1 Partners, Leadership and Authority – OEMS Element 1

Element 1 focuses on ensuring the organisation is equipped, structured and supported to ensure a healthy, efficient and successful company. A summary of the roles and responsibilities under this OEMS Standard is provided in Table 9-1. Further roles and responsibilities will be provided in future EPs for the relevant activities.

Table 9-1: Key Roles and Responsibilities for the OEMS and OPP Implementation

Role	Responsibilities
OEMS Standard Owner	• Each Standard is assigned to a General Manager/Functional Head or Executive with experience in the subject matter and/or accountability to ensure delivery of expected outcomes. This role is designated as an "OEMS Standard Owner" and is critical to the success of the OEMS. • The Standard Owner has overall accountability for performance of their assigned Standard
OEMS Governance Committee	• The OEMS Governance Committee will ensure periodic assessment of system performance. The Committee will support continuous improvement initiatives and assess the need for system changes, such as, additional standards and new company tools/systems. The Committee will include nominated member(s) of the Company Executive as well as Representatives from Operations and Technical divisions, as a minimum.
Executive Management	• The Chief Executive Officer (CEO) is the designated owner of this standard. The Executive Vice President (EVP) Technical supports the CEO for implementation aspects of the Standard. • All EVPs are responsible for ensuring the understanding and application of this standard within their areas of responsibility, and for managing any deviations and gap closure activities.
General Manager or Equivalent	• Responsible for ensuring resources, including assets, facilities, and teams, under their control have understood the requirements and developed and implemented suitable procedures and tools to satisfy the requirements of this standard
Manager or Superintendent	• Responsible for ensuring their area of the business for which they are accountable, has understood and implemented the requirements of this standard. • Upholding and ensuring suitable discipline with respect to this standard. • Implementing or supporting an annual assurance program to report on compliance to this standard and to identify and address gaps or areas for continuous improvement.
All employees	• Responsible for understanding and following the respective procedure and requirements defined within this standard. • Responsible for escalating areas of non-conformance or areas where local practices do not meet the requirements of this standard the OPP requirements are communicated to the Project team.

9.2.2 Information Management and Legal – OEMS Element 3

Element 3 describes the measures Beach must take to ensure ongoing compliance with regulatory and legal obligations in order to protect the Company's value and reputation, and to maintain Beach's licences to operate. Beach's ability to safely perform its duties in line with its legal obligations relies on robust management of documents and information.

Standard 3.1 (Regulatory Compliance) describes the responsibilities of each stakeholder and the processes for identifying, maintaining, managing and reporting Beach's regulatory compliance obligations. The Standard details the minimum requirements of a system to ensure effective regulatory engagement can be maintained across all its activities including permissions, project execution, operating and reporting.

Section 2 of this OPP details the key environmental requirements applicable to the activity. The acceptability discussion for each aspect is assessed in Sections 6 and 7 and specifically details the environmental requirements pertaining to each aspect.

9.2.3 People, Capability and Health – OEMS Element 4

Element 4 focuses on ensuring the people within the business are fully equipped with the competencies required to perform their assigned duties and are physically and mentally prepared. This element is important in protecting workers' health and is closely aligned with Standard 8.1 (Risk Management) and Standard 8.2 (Safe Systems of Work).

Standard 4.1 (Training and Competency) describes the minimum company requirements to ensure peoples training requirements are identified and meet the tasks they are required to perform, and that verification of competency is carried out where necessary. The Standard defines the responsibilities for ensuring suitable training programmes are available and for ensuring peoples levels of capability are maintained at the required level.

Each employee or contractor with responsibilities pertaining to the implementation of this OPP and subsequent EPs shall have the appropriate competencies to fulfil their designated role.

To ensure that personnel are aware of the environmental requirements for the activity all offshore personnel will complete an induction, as a minimum. Records of completion of the induction will be recorded and maintained. The induction will at a minimum cover:

- Description of the environmental sensitivities and conservation values of the area and surrounding waters.
- Controls to be implemented to ensure impacts and risks are ALARP and of an acceptable level.
- Requirement to follow procedures and use risk assessments/ job hazard assessments to identify environmental impacts and risks and appropriate controls.
- Requirements for interactions with fishers and/or fishing equipment.
- Requirement for responding to and reporting environmental hazards or incidents.
- Overview of emergency response and spill management plans.

- Fauna sighting and vessel interaction procedures.
- Relevant Whale Management Procedure.

In addition to the activity-specific induction, each employee or contractor with specific responsibilities pertaining to the implementation of this OPP and future EPs shall be made aware of their responsibilities, and the specific control measures required to maintain environmental performance and legislative compliance.

9.2.4 Contracts and Procurement – OEMS Element 5

Element 5 addresses the acquiring of external services and materials, and the transportation of those materials. It ensures Beach's business interests are met while maintaining compliance with all legal obligations and retaining HSE performance as the top priority. Element 5 also documents requirements for management of land transport risks.

In accordance with Standard 5.1 (Contracts and Procurement), Beach undertakes a pre-qualification of all contractors in which their HSE systems are reviewed to ensure that the contractor's HSE management system (HSEMS) is adequate for meeting their legal obligations and has identified the significant risks and control measures related to the scope of work being undertaken for Beach. This process includes verifying evidence of HSEMS implementation.

Training and competency of contractor personal engaged to work on the activity shall be managed in accordance with the contractor's HSEMS (or equivalent).

Contractors will be assessed to ensure they have the capabilities and competencies to implement the control measures identified in Sections 6 and 7.

9.2.5 Asset Management – OEMS Element 6

The focus of Element 6 is the design, build and operation of assets. The underpinning standards reflect the importance of inherent safety in design, recognising that hazards and risks are to be reduced to ALARP in the design phase of an asset. The standards define the minimum requirement for the monitoring and assurance processes that support the ongoing safe and reliable management of an asset throughout its lifecycle. Element 6 draws heavily on the principles of process safety and is closely aligned with Elements 7 (Operational Control) and Element 8 (Risk Management).

Equipment that has been identified as a control measure for the purpose of managing potential environmental impacts and risks from activities described in future EPs and have an associated EPS that details the performance required.

9.2.6 Operational Control - Element 7

Element 7 focuses on the definition of parameters, practices and procedures required to ensure adequate controls and safe execution of work at operating assets. It deals with the ongoing management of barrier integrity throughout asset lifecycle, ensuring good process safety practices are consistently deployed, and that facility changes manage holistic risk.

Standard 7.3 (Management of Change) defines the minimum planning and implementation requirements for technical and organisational change at Beach. It details the requirement for holistic assessment of the change, the requirement for consultation with stakeholder's dependent upon the nature of the change, and the need for clear accountability for the change. Risk associated with change is mitigated by ensuring change is appropriately approved, effectively implemented, formally assured and closed out upon completion. Any changes must be classified as either temporary or permanent.

The intent of the Management of Change (MoC) Standard is that all temporary and permanent changes to the organisation, personnel, systems, procedures, equipment, products and materials are identified and managed to ensure HSE risks arising from these changes remain at an acceptable level.

Changes to equipment, systems and documentation are managed in accordance with the MoC Standard to ensure that all proposed changes are adequately defined, implemented, reviewed and documented by suitably competent persons. This process is tracked to provide assurance that all engineering and regulatory requirements have both been considered and met before any change is operational. The MoC process includes not just plant and equipment changes, but also documented procedures where there is an HSE impact, regulatory documents and organisational changes that impact personnel in safety critical roles.

Not all changes require a MoC review. Each change is assessed on a case-by-case basis. The potential environmental impacts and/or risks are reviewed by a member of the Beach Environment Team to determine whether the MoC review process is triggered.

Where risk and hazard review processes nominated in Section 9.2.7 identify a change in impacts, risks or controls (compared to those described and assessed in in future EPs), and triggers a regulatory requirement to revise the EP, the revision shall be defined, endorsed, completed and communicated in accordance with the MoC Standard.

9.2.7 Risk Management and Hazard Control – OEMS Element 8

The identification, assessment and treatment of risk is central to maintaining control of assets. Element 8 defines the means by which Beach manages all types of risk to the business. This element includes general risk management, the Safe Systems of Work by which site activities are controlled and executed, and the emergency and security arrangements in place to protect the Company from unplanned events or the attempts of others to do harm to the business.

9.2.7.1 Standard 8.1 - Risk Management

Standard 8.1 defines Beach’s requirements to mitigate and manage risk at all levels within the business. It defines the Risk Management Framework for identifying, understanding, managing and reporting risks. The framework defines the documents, training, tools and templates to be used, and the accountabilities to be applied in support of effective risk management. Risks to people, the environment, Beach’s reputation, financial position and any legal risks are assessed through the framework. The Standard defines the purpose and use of risk assessments and risk registers. The environmental risk management framework applied to the Development is described in Section 5 and applied to all the aspects assessed in Sections 6 and 7 of this OPP.

Beach will undertake a review of future EPs if required in order to ensure that any changes to the activity, controls, regulatory requirements and information from research, stakeholders, industry bodies or any other sources to inform the future EPs are assessed using the risk management tools nominated. The review will ensure that the environmental impacts and risks of the activity continue to be reduced to ALARP and an acceptable level.

If revision of future EPs is trigged though a change in risk or controls, the revision process shall be managed in accordance with the MoC process.

Additional, or increased, impacts or risks, are identified, outside of the management of change process by the assurance process.

9.2.7.2 Standard 8.3 -Emergency and Security Management

Standard 8.3 defines the minimum performance requirements to effectively manage credible emergency and security events, and to enable an efficient recovery to normal operations following such an event. The Standard defines the prevention, preparedness, response and recovery principles to be applied, the organisational structures to support emergency and security measures, and the training and testing protocols that must be in place to assure Beach maintains a state of readiness.

1. Emergency Response Framework

The Beach Emergency and Security Management Framework consists of a tiered structure whereby the severity of the emergency triggers the activation of emergency management levels. The emergency response framework contains three tiers based on the severity of the potential impact (Emergency Response Team, Emergency Management Team and Crisis Management Team). This framework is described in the Beach Emergency Management Plan (EMP).

2. Beach Emergency Management Plan

The Beach EMP provides the standard mechanism for the Emergency Management Team (EMT) to operate from and includes guidance on effective decision-making for emergency events, identification, assessment and escalation of events and provides training and exercise requirements. The EMP provides information on reporting relationships for command, control and communications, together with interfaces to emergency services specialist response groups, statutory authorities and other external bodies. The roles and responsibilities are detailed for onshore and offshore personnel involved in an emergency, including the response teams, onshore support teams, visitors, contractors and employees. The EMP details the emergency escalation protocol depending on the nature of the emergency.

Associated with the EMP are the Emergency Response Duty Roster and Contact Lists. These documents constitute a suite of emergency response documents that form the basis for Beach's response to an emergency situation.

3. Oil Pollution Emergency Plan

Any future EPs are required to have an accepted Offshore Oil Pollution Emergency Plan (OPEP) as per Section 14(8) of the OPGGS (Environment) Regulations. Regulation 14(8AA) provides a framework for the control measures and arrangements for responding to and monitoring oil pollution. Oil spill response arrangements associated with the Project will be detailed in the relevant OPEP.

4. Operational and Scientific Monitoring Plan

Operational and scientific monitoring arrangement associated with the Project will be detailed within the relevant Operational and Scientific Monitoring Plan (OSMP).

5. Testing of Spill Response Arrangements

The relevant OPEP details the oil spill response testing arrangements.

9.2.8 Incident Management – OEMS Element 9

Element 9 defines how Beach classifies, investigates, reports and learns from incidents. An incident is any unplanned event or change that results in potential or actual adverse effects or consequences to people, the environment, assets, reputation, or the community.

Standard 9.1 (Incident Management) defines the requirement for incident notification, reporting and subsequent investigation requirements. It ensures that incident classification is applied consistently across the company, and that the appropriate level of investigation and approval authority is implemented. The standard describes the requirement for identifying and assigning remedial actions, and for communicating key learnings throughout the business. As such, the standard also defines the requirement for adequate training for those persons involved in performing investigations.

The incident management standard requires that all HSE incidents, including near misses, are reported, investigated and analysed to ensure that preventive actions are taken, and learnings are shared throughout the organisation.

Incident reports and corrective actions are managed using the Beach Incident Management System.

9.2.9 Environment and Community – OEMS Element 10

Element 10 focuses on the measures the organisation must take to ensure that it upholds its reputation as a responsible and ethical company and continues its open and transparent engagements with its communities and stakeholders. Beach operates in environmentally sensitive areas, in close proximity to communities, with potential impacts on stakeholders. Beach has an obligation to ensure that potential impacts from its future activities are clearly identified, minimised to ALARP and mitigated where there is an economic loss to a stakeholder directly impacted by Beach activities.

9.2.9.1 Standard 10.1 - Environmental Management

The purpose of Standard 10.1 is to ensure that all areas of the Company implement appropriate plans and procedures to conduct environmental management of operations in a responsible and sustainable manner.

An assessment of environmental aspects, effects, risks and impacts must be prepared to identify and assess impacts to the environment as a result of the Company's operations and activities. The impact assessment must cover design, development, operation and decommissioning and meet all statutory regulatory compliance requirements. The Standard covers land disturbance, reinstatement and rehabilitation activities, and defines obligations for management of biodiversity, water, air quality and emissions, noise and vibration, amenity and waste.

9.2.9.2 Standard 10.2 - Community Engagement

Standard 10.2 defines the minimum requirements for the conduct of Beach and its staff within the community, and the commitments to plan and execute effective community engagement in the course of its business. Beach staff will conduct themselves as ambassadors for the company and engage positively and respectfully with the community.

The standard describes the obligation of the company to proactively engage with the community at the outset of any activity that may have an impact on that community, and to develop a stakeholder engagement plan to manage that engagement.

Stakeholder consultation specific to the activity is discussed in Section 10 of this OPP.

9.2.9.3 Assurance and Reporting – OEMS Element 11

Element 11 establishes that the company must apply the requirements of relevant policies, and the commitments detailed in the OEMS standards throughout its activities. An assurance process therefore exists to systematically quantify compliance with those commitments, and with the underlying procedures and systems. This Element also documents Beach's approach to sustainability and reporting company performance using established sustainability performance metrics.

9.2.9.4 Standard 11.1 - Sustainability

The purpose of this standard is to operationalise the requirements established by the Company's Sustainability Policy and other associated Beach policies. The standard details how Beach incorporate environmental, social and government requirements into the Board, sustainability reporting, performance monitoring and evaluation, company and project risk assessments and emissions reduction assessments and activities.

9.2.9.5 Standard 11.2 - Assurance

Standard 11.2 describes the "Three Lines of Defence" assurance model employed by Beach to govern its activities and ensure compliance with its commitments and standards. The standard defines Beach's requirements for the establishment and management of risk-based assurance activities at all levels within the company. The assurance process establishes the adequacy and effectiveness of Beach's risk controls and quantifies the status of compliance against our obligations. It ensures that Beach proactively closes any gaps in performance so it can address those issues before harm is manifested. As such, the assurance programme identifies improvement opportunities in business processes and risk controls.

The Standard describes the need to have assurance plans across the business, and for the assurance activities to take place on multiple levels of the organisation. This approach collectively ensures the operational activities Beach perform are compliant with its procedures, standards and ultimately with governing policies and legislative obligations. The holistic results of the assurance programme are reportable to the Board and Committees.

9.2.9.6 Monitoring, review and reporting of environmental performance

An assurance process is undertaken by Beach to ensure that the EPOs provided in this OPP are demonstrated in future EPs (Table 9-2):

- The environmental impacts and risks of the activity continue to be identified and reduced to a level that is ALARP and acceptable.
- Control measures detailed in future EPs are effective in reducing the environmental impacts and risks of the activity to ALARP and an acceptable levels.
- Environmental performance outcomes and standards set out in the future EP are being met

- Emissions and discharges are monitored.

Non-compliances and opportunities for improvements for activities described in future EPs identified via the assurance processes in the following sections are communicated to the appropriate supervisor and/or manager to report and action in a timely manner. Tracking of non-compliances and actions is undertaken using Beach's incident management system which includes assigning a responsible person for ensuring the action is addressed and closed out. Any additional, or increased, impacts or risks identified are managed as per the Management of Change process.

Where an assurance process identifies a breach of an EPO or EPS in future EPs this will be reported as a recordable incident.

Table 9-2: Assurance Processes

Assurance Process
Future EP Assurance Checks covering: • EPOs, EPS and implementation strategy requirements.
Incident reviews and investigations covering: • Review of all incidents to identify any recordable incidents and reportable incidents and any additional, or increased, environmental impacts or risks. • Reporting and investigation of incidents to identify recordable and reportable incidents and any additional, or increased, environmental impacts or risks.
Environmental Impact and Risk Register to ensure impacts and risks continue to be ALARP and an acceptable level and any additional, or increased, environmental impacts or risks identified.
Activity risk review to ensure impacts and risks can be manage to ALARP and an acceptable level and any additional, or increased, environmental impacts or risks identified.
Performance Reporting for activities described in future EPs covering: • Review of EPOs and EPs.
Emissions and discharge records

9.2.9.7 Audits and Inspections

A future EP assurance checklist details the assurance checks required to ensure that for the duration of the EPs:

- EPOs, EPSs and implementation strategy requirements are met.
- Controls measures are effective in reducing the environmental impacts and risks of the activity to ALARP and acceptable levels
- Any additional, or increased, impacts or risks are identified.
- Assurance Checks define the timing of these checks.

Non-compliances and opportunities for improvements identified via assurance checks or any other means are communicated to the appropriate supervisor and/or manager to report and action in a timely manner. Any additional, or increased, impacts or risks identified are managed as per the Management of Change process. Tracking of non-compliances and actions is undertaken using

Beach's incident management system which includes assigning a responsible person for ensuring the action is addressed and closed out.

9.3 Emergency Preparedness and Response

Beach's Crisis and Emergency Management Standard requires Beach to have plans, procedures and resources are in place to effectively respond to crisis and emergency situations, to protect the workforce, the environment, the public and customers, and to preserve the company's assets and reputation.

For activities described in future EPs, Beach will have in place an Emergency Response Plan which identifies emergency events, including hydrocarbon spills, and details the arrangement in place to control, coordinate and respond to those events. To support the Emergency Response Plan, Beach will have an OPEP and an OSMP covering the oil spill response and monitoring arrangements relevant to the hydrocarbon spill risk associated with activities described in future EPs.

9.4 Decommissioning

Requirements for offshore petroleum property are provided in OPGGS Act and reflected in several government policies and guidelines such as:

- NOPSEMA Policy - Section 572 Maintenance and removal of property (09/12/2022)
- Department of Industry, Science and Resources Guideline: Offshore petroleum decommissioning (2 March 2022)
- NOPSEMA Information Paper – Planning for proactive decommissioning (10/01/2024)
- NOPSEMA Policy - Section 270 Consent to surrender title policy (30/06/2022)

Table 9-3 summarises how the proponent intends to comply with decommissioning requirements under the OPPGS Act and relevant policies and guidelines.

Table 9-3: Decommissioning Requirements under the OPPGS Act and Relevant Polices and Guidelines

Decommissioning requirements

Requirement	**Response**
Section 572(2) A titleholder must maintain in good condition and repair all structures that are, and all equipment and other property that is: (a) in the title area; and (b) used in connection with the operations authorised by the permit, lease, licence or authority.	Compliance with section 572(2) will be achieved by Beach's Inspection, Maintenance & Repair for wells and flowlines **Well Maintenance Management** All well integrity inspections, testing and maintenance activities during the Operate Phase are managed per the Beach Well Integrity Management Framework, comprising of the following: • Well Integrity Management Standard (BSTD 6.3) of Beach's Operating Excellence Management System (OEMS) • Well Integrity Technical Standard (WITS) for the Operate & Maintain Phase (CDN/ID 7726350). • Well Integrity Management Plan - Victoria (CDN/ID 19060027) **Subsea infrastructure Inspections** Regular inspections, maintenance and repair of subsea equipment will be undertaken in line with Beach standards: • Maintenance Management Standard BSTD 6.2) of OEMS – based on time and condition-based criteria to assess the potential impacts of equipment failure on safety, production and the environment All maintenance activities are managed via the Computerised Maintenance Management System (CMMS). Use of the CMMS is central to asset integrity management. It provides traceability for the scheduling and completion of critical maintenance tasks. Upon completion, inspection results, maintenance records and the well's integrity status are captured in the WIMS database.
Section 572(3) A titleholder must remove from the title area all structures that are, and all equipment and other property that is, neither used nor to be used in connection with the operations: (a) in the title area; and (b) used in connection with the	Compliance with section 572(3) will be achieved by removal of all property and infrastructure and the plugging and abandonment of wells as the base case. Decommissioning with comply with relevant laws, guidelines and policy (currently the Australian Government Guideline: Offshore petroleum decommissioning) Beach acknowledges targets set in NOPSEMA's Decommissioning Compliance Strategy 2024-2029 for decommissioning planning.

Decommissioning requirements

operations authorised by the permit, lease, licence or authority	Decommissioning is part of Beach's Asset Management Standard (BSTD 6.1) of OEMS and Beach's Decommissioning Guideline which both acknowledges the requirement to comply with legislative and regulatory frameworks for decommissioning. Beach's decommissioning planning lifecycle recognises planning for decommissioning must commence at a suitable timeframe in advance of cessation of production which is achieved via asset lifecycle management processes, asset decommissioning strategy and plan, and restoration cost estimates and financial provisioning.
Section 270(3) The Joint Authority may consent to the surrender sought by the application only if the registered holder of the permit, lease or licence: c) has, to the satisfaction of NOPSEMA, removed or caused to be removed from the surrender area all property brought into the surrender area by any person engaged or concerned in the operations authorised by the permit, lease or licence; or made arrangements that are satisfactory to NOPSEMA in relation to that property d) has, to the satisfaction of NOPSEMA, plugged or closed off all wells made in the surrender area by any person engaged or concerned in the operations authorised by the permit, lease or licence e) has provided, to the satisfaction of NOPSEMA, for the conservation and protection of the natural resources in the surrender area; and f) has, to the satisfaction of NOPSEMA, made good any damage to the seabed or subsoil in the surrender area caused by any person engaged or concerned in the operations authorised by the permit, lease or licence.	Compliance with section 270(3) may be achieved by: • Demonstrated compliance with relevant EPs and principles of ecologically sustainable development ALARP, and acceptable levels for environmental impacts and risks • Monitoring, surveying and reporting in accordance with accepted EPs • Decommissioning EPs to include visual inspections, surveys and sampling. • Demonstrated compliance with relevant WOMPs for P&A activities in accordance with section 569(1) of OPGGS Act c) Decommissioning of wells and subsea infrastructure will be performed in accordance with accepted decommissioning EPs and may include seabed clearance survey will be conducted following decommissioning to confirm all infrastructure on the seabed has been removed, returning the area to original condition as much as possible and practicable d) Relevant decommissioning EPs will include P&A of wells and compliance with section 270(3)(d). Compliance with relevant WOMPs for P&A activities in accordance with section 569(1) of OPGGS Act e) Relevant decommissioning EPs will address section 270(3)(e) by including an assessment of the natural resources to demonstrate conservation and protection of the natural resources f) Relevant decommissioning EPs will address section 270(3)(f) by committing to make good any damage to the seabed or subsoil in the surrender area •

10 Stakeholder Engagement

Beach is committed to open, on-going and effective engagement with the communities in which it operates and providing information that is clear, relevant and easily understandable. Beach welcomes feedback and is continuously endeavouring to learn from experience in order to manage our impacts and risks.

Stakeholder engagement for the Project is a component of Beach's broader engagement in the Otway region. Stakeholder engagement is an integral component of Beach's environmental risk and impact assessment process and has informed the preparation of the OPP (Phase 1) (refer Section 10.2.3). Further, the opportunity for public comment on the OPP was provided through NOPSEMA's publication of the OPP in accordance with the requirements of Regulation 9 of the OPGGS (Environment) Regulations (Phase2) (refer Section 10.2.4). Phase 1 and Phase 2 engagements have informed this OPP resubmitted to NOPSEMA in accordance with Regulation 11.

10.1 Engagement Background

Activities for the existing Otway Development have run over several phases and many years, beginning with seabed assessments, drilling of exploration wells and production wells in the Geographe and Thylacine gas fields, and installation of seabed infrastructure to support tie-in of the wells to the existing Thylacine A Platform and pipeline and finally the commencement of production in late February 2008. Woodside Energy, the titleholder at the time of the initial development, undertook significant consultation with the community, non-government organisations and Government departments. Consultation has been ongoing through the change of titleholders to Origin and then Lattice. In 2017 Lattice commenced consultation in relation to the broader Otway Development. Following its acquisition of Lattice, Beach commenced consultation with stakeholders in early 2019 in relation to Phase 4 of the Otway Development and has continued to do so for more recent developments as described in the following accepted activity specific Environment Plans (EPs):

- Otway Offshore Operations EP (CDN/ID 17275058)
- Artisan Exploration Drilling EP (CDN/ID S4810AH717904)
- Otway Development Drilling and Well Abandonment EP (CDN/ID S4100AH717905)
- Otway Phase 5 Early Dive Installation Campaign EP (CDN/ID S4130AF725242)
- Thylacine Subsea Installation & Commissioning EP (T/L2 and T/L4) (CDN/ID: S4121AF728393)
- OGV Geophysical and Geotechnical Seabed Survey EP (V-1000-P1-MP-0011)

These EPs, along with all Beach's accepted EPs, can be viewed on the NOPSEMA website.

This ongoing engagement has enabled Beach to establish a database of relevant stakeholders and obtain a good understanding of issues and concerns of stakeholders.

10.2 Stakeholder Engagement Approach and Objectives

- Beach is undertaking a phased program of consultation for the Project, including in the preparation of the OPP: Phase 1: Consultation on the Project during the preparation of the OPP to inform the Project impact and risk assessment process (refer Section 10.2.3). This has included the identification or relevant stakeholders (refer Section 10.2.1) and stakeholder mapping to impacts and risks (refer Section 10.2.2).

- Phase 2: Formal consultation via the OPP public comment period (refer Section 10.2.4)
- Phase 3: Ongoing consultation for Project activities (refer Section 10.2.5), including the development of EPs.

The objectives of Beach's stakeholder engagement in preparation of the OPP are to:

- Identify relevant stakeholders to inform the preparation of the OPP.
- Engage with stakeholders in an open, transparent, timely and responsive manner.
- Provide information to stakeholders about the Project including the physical, ecological, socio-economic and cultural environment that may be affected, the potential impacts and risks that may occur and controls proposed to avoid or minimise those impacts.
- Obtain information from stakeholders in relation to if their functions, interests or activities may be affected by the Project.
- Provide additional information to stakeholders who raise any objections or claims.
- Build and maintain trust with stakeholders.

10.2.1 Stakeholder Identification

Relevant stakeholders have been identified by reviewing:

- Social receptors identified in the existing environment section.
- Existing stakeholders within Beach's stakeholder register.
- Consultation records for previous Otway Basin activities undertaken by Beach and Lattice.
- Commonwealth and State fisheries jurisdictions and fishing effort in the region.
- NOPSEMA Guideline Consultation with Commonwealth Agencies with Responsibilities in the Marine Area.

The identification of stakeholders for the purpose of engagement in the preparation of the OPP has been guided by the categorisation of relevant persons as defined in Regulation 25(1) of the of OPGGS (Environment) Regulations. Table 10-1 provides a summary of relevant persons for the Project arranged by category.

Table 10-1: Relevant Persons for the Project

Categories	**Relevant Persons Examples**
Category A	• Australian Border Force – Maritime Border Command • Australian Fisheries Management Authority (AFMA)

Categories	Relevant Persons Examples
Each Department or agency of the Commonwealth to which the activities to be carried out under the environment plan, or the revision of the environment plan, may be relevant	• Australian Maritime Safety Authority (AMSA) • Department of Agriculture, Water and the Environment (DAWE); Fisheries; Biosecurity Marine Pests • Department of Defence - Australian Hydrographic Office (AHO) • Department of Defence - Infrastructure Division, Defence Support & Reform Group • Department of Industry, Science, Energy and Resources (DISER) • Director of National Parks (DNP) • Department of Climate Change, Energy, the Environment and Water – Oceans • Indigenous Land and Sea Corporation • National Native Title Tribunal
Category B Each Department or agency of a State or the Northern Territory to which the activities to be carried out under the environment plan, or the revision of the environment plan, may be relevant	• Department of Energy, Environment and Climate Action (DEECA) - VIC • Department of Infrastructure and Transport - Marine Safety SA • Department for Environment and Water South Australia - Coast Protection Board • Corangamite Catchment Management Authority • Department of Infrastructure and Transport - Marine Safety SA • Department of Natural Resources and Environment Tasmania - Biosecurity • Department of Natural Resources and Environment Tasmania - Conservation • Department of Natural Resources and Environment Tasmania - Marine/Fisheries(Fishing Tasmania) • Department of Natural Resources and Environment Tasmania - Strategic Projects and Policy • Department of Natural Resources and Environment Tasmania - Tasmania Parks and Wildlife Services • Department of Premier and Cabinet - Office of Aboriginal Affairs - (Tasmania) • Department of Primary Industries and Regions South Australia - Commercial Fishing • Department of State Growth - Mineral Resources Tasmania • Department of Transport and Planning: Marine Pollution • Victorian Fisheries Authority • Parks Victoria • Department of Primary Industries, Parks, Water and Environment (DPIPWE) • EPA Tasmania • EPA South Australia • EPA Victoria • First Peoples – State Relations (Victoria) • Marine and Safety Tasmania • Office of the Minister for Environment • Transport Safety Victoria - Maritime Safety Victoria
Category C The Department of the responsible State Minister, or	• Office of the Minister Energy and Resources

Categories	Relevant Persons Examples
the responsible Northern Territory Minister	
Category D A person or organisation whose functions, interests or activities may be affected by the activities to be carried out under the environment plan, or the revision of the environment plan.	• Commercial fishing • Local government authorities • Community • Environmental NGO • Marine based industries • Marine tourism/recreation • Business • Land based tourism • Education & Research organisations • Media • Native Title and Cultural Heritage / Traditional owner groups
Category E Any other person or organisation that the titleholder considers relevant.	• Member of the public or group whose functions, interests or activities are not impacted by Beach Energy activities

10.2.2 Stakeholder Mapping

An initial assessment of stakeholders' functions, interests and activities has been undertaken, based on previous stakeholder consultation and the preliminary impact assessment conducted for the Project. Table 10-2 identifies the receptors and associated potential impacts relevant to each stakeholder group and identifies the planned and unplanned environmental aspects relevant to each stakeholder group. This mapping will be updated as consultation progresses.

Table 10-2: Relevance of Receptor and Environmental Impact to Stakeholder Groups

	Receptor	Potential Impact	Cth Govt	Vic/Tas Govt	Fisheries	Recreation/ Tourism	Industry	Research/ Community Groups
Physical	Ambient light	Change in ambient light	✓	✓		✓		✓
	Ambient noise	Change in ambient noise	✓	✓				
	Water quality	Change in water quality	✓	✓	✓	✓		✓
	Sediment quality	Change in sediment quality	✓	✓	✓			✓
	Air quality	Change in air quality	✓	✓				
	Climate	Change in climate	✓	✓				✓
Ecological	Coastal habitats and communities	Change in habitat	✓	✓				✓
		Change in ecosystem dynamics	✓	✓				✓
	Benthic habitats and communities	Change in habitat	✓	✓				✓
		Change in fauna behaviour	✓	✓	✓			✓
		Injury / mortality to fauna	✓	✓	✓			✓
	Threatened Ecological Communities	Change in habitat	✓	✓				✓
	Plankton	Change in fauna behaviour	✓	✓				✓
		Injury / mortality to fauna	✓	✓		✓		✓
	Seabirds and Shorebirds	Change in fauna behaviour	✓	✓				✓
		Injury / mortality to fauna	✓	✓				✓
	Fish	Change in fauna behaviour	✓	✓		✓		✓
		Injury / mortality to fauna	✓	✓		✓		✓
	Marine mammals	Change in fauna behaviour	✓	✓				✓
		Injury / mortality to fauna	✓	✓				✓

	Receptor	Potential Impact	Cth Govt	Vic/Tas Govt	Fisheries	Recreation/ Tourism	Industry	Research/ Community Groups
	Marine reptiles	Change in fauna behaviour	✓	✓				✓
		Injury / mortality to fauna	✓	✓				✓
Socio-economic	Key Ecological Features	Changes to the functions, interests or activities of other users	✓	✓				✓
		Change in water quality	✓	✓				✓
		Change in habitat	✓	✓				✓
		Injury / mortality to fauna	✓	✓				✓
		Change in fauna behaviour	✓	✓				✓
	Commonwealth Heritage Places	Changes to the functions, interests or activities of other users	✓	✓				✓
	–Australian Marine Parks	Changes to the functions, interests or activities of other users	✓	✓				✓
		Change in water quality	✓	✓				✓
		Change in habitat	✓	✓				✓
		Injury / mortality to fauna	✓	✓				✓
		Change in fauna behaviour						
		Change in aesthetic value						
	State Protected Areas - Marine	Changes to the functions, interests or activities of other users	✓	✓		✓		✓
		Change in water quality	✓	✓				✓
		Change in sediment quality	✓	✓				✓
		Change in habitat	✓	✓				✓
		Injury / mortality to fauna	✓	✓				✓

Receptor	Potential Impact	Cth Govt	Vic/Tas Govt	Fisheries	Recreation/ Tourism	Industry	Research/ Community Groups
	Change in aesthetic value	✓	✓		✓		✓
State Protected Areas - Terrestrial	Changes to the functions, interests or activities of other users	✓	✓		✓		✓
Ramsar Wetlands of International Importance	Change in habitat	✓	✓				✓
Nationally Important Wetlands	Change in habitat	✓	✓				✓
Cth Managed Fisheries	Changes to the functions, interests or activities of other users	✓	✓	✓			✓
State Managed Fisheries	Changes to the functions, interests or activities of other users	✓	✓	✓			✓
Recreation and Tourism	Changes to the functions, interests or activities of other users	✓	✓		✓		✓
	Change in aesthetic value	✓	✓		✓		✓
Industry	Changes to the functions, interests or activities of other users	✓	✓		✓	✓	✓
Heritage and cultural features	Changes to the functions, interests or activities of other users	✓	✓				✓
	Change in water quality	✓	✓		✓		✓
	Change in sediment quality	✓	✓				✓
	Change in habitat	✓	✓				✓
	Injury / mortality to fauna	✓	✓				✓
	Change in fauna behaviour	✓	✓				✓
	Change in aesthetic value	✓	✓		✓		✓

10.2.3 Phase 1: Initial Project Consultation

Whilst consultation requirements for the initial development of the OPP are not prescribed in the OPGGS (Environment) Regulations, Beach has been undertaking consultation for its Offshore Gas Victoria (OGV) Project, including development of EPs, and preliminary advice at the commencement of consultation has included information regarding the development of an OPP. Information provided in relation to the OGV Project and associated activities include:

- Community Information Sessions held in:
    - Port Campbell on 24 July 2023
    - Portland 25 July 2023
    - Warrnambool 26 July 2023
    - Port Fairy 26 July 2023
    - King Island, Burnie, Lakes Entrance and Apollo Bay to follow
- Meetings:
    - Peterborough Residents Association 19 July 2023
    - Corangamite Shire Council 20 July 2023
    - Timboon Action Group 1 August 2023
    - King Island Council 17 August 2023
    - Commercial fishing peak bodies round table 30 August 2023 (Warrnambool)
    - Commercial fishers drop-in 30 August 2023 (Warrnambool)
    - Commercial fishers drop-in scheduled for 12 October 2023 (Lakes Entrance)
    - Moyne Shire Council Meeting scheduled for 17 October 2023
- Provision of information on the Beach website Offshore Gas Victoria | Beach Energy and dedicated online engagement hub, ‘Engage Beach’.
- Provision of the following OGV information sheets (provided in Appendix N) to those stakeholders listed in Table 10-2:
    - Offshore Gas Victoria Project Information sheet
    - OGV Seabed information sheet
    - OGV drilling activities information sheet
    - OGV P&A information sheet

- Ad-hoc requests via phone and email and provision of specific information as requested.
- Public notices published in:
    - Portland Observer
    - Warrnambool Standard
    - Colac Herald
    - Cobden Timboon Coast Times
    - The Advocate (Burnie)
    - South Gippsland Sentinel Times
    - Bairnsdale Advertiser
    - Koori Mail scheduled
    - National Indigenous Times scheduled
- First Nations engagement via a dedicated First Nations Engagement Manager
    - Provision of information sheets
    - Meetings with native title CEOs and board
    - Meetings with key community members
    - Community drop-in sessions to follow
    - Meeting with Heritage Victoria and First Peoples State Relations Victoria

10.2.3.1 Director of National Parks

Beach undertook consultation with the Director of National Parks (DNP) in accordance with the consultation requirements detailed in the NOPSEMA and Parks Australia Petroleum Activities and Australian Marine Parks: A guidance note to support environmental protection and effective consultation (N-04750 -GN1785 A620236 01/06/2023) between September and December 2023.

10.2.4 Phase 2: Project OPP Public Comment Period

On 8 March 2024, NOPSEMA advised that the OPP was suitable for publication for public comment in accordance with Section 9 of the OPGGS (Environment) Regulations 2023. The OPP was published and opened for comment for nine weeks from 18 March 2024 to 20 May 2024.

Beach promoted the public comment process by publishing a public notice in seven different newspapers, emailing the project stakeholder list, and prominently featuring information about the public comment period and links to NOPSEMA's website on Engage Beach, Beach's online consultation hub.

Eleven public submissions were received. Beach acknowledges all those who took time to compile and submit their written comments regarding the OPP. One submission (Submitter 3) provided comments that had no merit and were not relevant to the OPP and was not considered further in the OPP public comment process. One submission (Submitter 4) was made in response to a concurrent public comment process for a separate environmental approval and, by agreement with the submitter, was accepted and managed as part of the public comment process for the environmental approval and excluded from the OPP public comment process.

Beach has prepared a public comment report summarising the comments, an assessment of the merits of each comment, a statement of their response to each comment, and an outline of any changes made to the OPP as a result of the comment. (Appendix P). Where Beach updated the OPP in response to comments, these updates are referenced in the OPP with the corresponding public comment reference number (i.e. [PCXX]).

10.2.5 Phase 3: Ongoing Consultation

Beach will continue to engage with stakeholders on individual activities undertaken for the Project. Consultation will be undertaken as part of developing activity specific EPs as required under the OPGGS (Environment) Regulations. This will be undertaken by:

- Identifying relevant persons that may be potentially affect by the activities.
- Determining the possible consequences of the activities on each stakeholders’ functions, interests or activities from previous knowledge, reviewing any public statements by the stakeholder as to how they want to be engaged by oil and gas companies and/or consulting with stakeholders.
- Providing sufficient information, based on possible consequences and the way they would like to be consulted, for the stakeholder to be able to make an informed assessment of the possible consequences of the activity on their functions, interests or activities.
- Allowing a reasonable period of time for the stakeholder to review and respond to any information provided, typically two to four weeks.
- Providing further information requested by the stakeholder or that becomes available during the consultation period and allowed a reasonable time for the stakeholder to review and respond. Depending on the information provided this was between one to four weeks.
- Ensuring relevant stakeholders are informed about the consultation process and how their feedback, questions and concerns will be considered in the EP.
- Where requested, providing activity notification and specific information such as:
    - type of activity
    - location of activity, coordinates and map
    - timing of activity: expected start and finish date and duration
    - sequencing of locations if applicable

  - vessel/rig details including call sign and contact
  - requested clearance from other vessels
  - Beach contact details

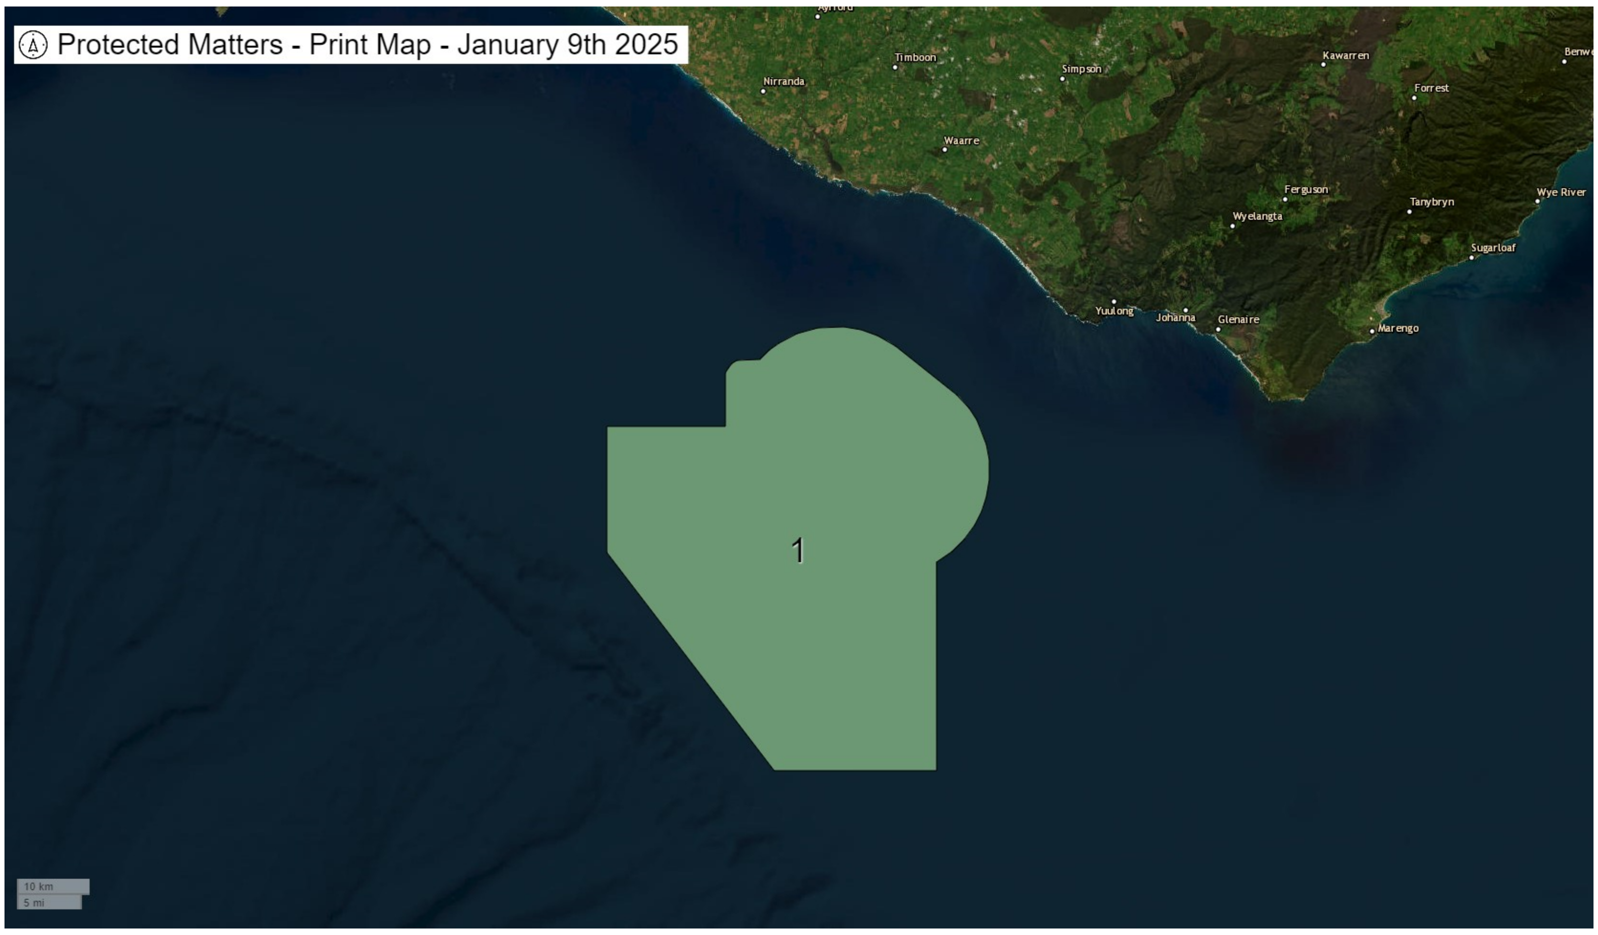
EPBC Act Protected Matters Report

This report provides general guidance on matters of national environmental significance and other matters protected by the EPBC Act in the area you have selected. Please see the caveat for interpretation of information provided here.

Report created: 09-Jan-2025



Summary

Matters of National Environment Significance

This part of the report summarises the matters of national environmental significance that may occur in, or may relate to, the area you nominated. Further information is available in the detail part of the report, which can be accessed by scrolling or following the links below. If you are proposing to undertake an activity that may have a significant impact on one or more matters of national environmental significance then you should consider the Administrative Guidelines on Significance.

World Heritage Properties:	None
National Heritage Places:	None
Wetlands of International Importance (Ramsar	None
Great Barrier Reef Marine Park:	None
Commonwealth Marine Area:	2
Listed Threatened Ecological Communities:	None
Listed Threatened Species:	40
Listed Migratory Species:	40

Other Matters Protected by the EPBC Act

This part of the report summarises other matters protected under the Act that may relate to the area you nominated. Approval may be required for a proposed activity that significantly affects the environment on Commonwealth land, when the action is outside the Commonwealth land, or the environment anywhere when the action is taken on Commonwealth land. Approval may also be required for the Commonwealth or Commonwealth agencies proposing to take an action that is likely to have a significant impact on the environment anywhere.

The EPBC Act protects the environment on Commonwealth land, the environment from the actions taken on Commonwealth land, and the environment from actions taken by Commonwealth agencies. As heritage values of a place are part of the 'environment', these aspects of the EPBC Act protect the Commonwealth Heritage values of a Commonwealth Heritage place. Information on the new heritage laws can be found at https://www.dcceew.gov.au/parks-heritage/heritage

A permit may be required for activities in or on a Commonwealth area that may affect a member of a listed threatened species or ecological community, a member of a listed migratory species, whales and other cetaceans, or a member of a listed marine species.

Commonwealth Lands:	None
Commonwealth Heritage Places:	None
Listed Marine Species:	61
Whales and Other Cetaceans:	27
Critical Habitats:	None
Commonwealth Reserves Terrestrial:	None
Australian Marine Parks:	None
Habitat Critical to the Survival of Marine Turtles:	None

Extra Information

This part of the report provides information that may also be relevant to the area you have

State and Territory Reserves:	None
Regional Forest Agreements:	None
Nationally Important Wetlands:	None
EPBC Act Referrals:	27
Key Ecological Features (Marine):	1
Biologically Important Areas:	12
Bioregional Assessments:	None
Geological and Bioregional Assessments:	None

Details

Matters of National Environmental Significance

Commonwealth Marine Area [Resource Information]

Approval is required for a proposed activity that is located within the Commonwealth Marine Area which has, will have, or is likely to have a significant impact on the environment. Approval may be required for a proposed action taken outside a Commonwealth Marine Area but which has, may have or is likely to have a significant impact on the environment in the Commonwealth Marine Area.

Feature Name
Commonwealth Marine Areas (EPBC Act)
Commonwealth Marine Areas (EPBC Act)

Listed Threatened Species [Resource Information]

Status of Conservation Dependent and Extinct are not MNES under the EPBC Act.
Number is the current name ID.

Scientific Name	Threatened Category	Presence Text
BIRD		
Ardenna grisea Sooty Shearwater [82651]	Vulnerable	Species or species habitat may occur within area
Calidris acuminata Sharp-tailed Sandpiper [874]	Vulnerable	Species or species habitat may occur within area
Calidris canutus Red Knot, Knot [855]	Vulnerable	Species or species habitat may occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area
Diomedea antipodensis Antipodean Albatross [64458]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area

Scientific Name	Threatened Category	Presence Text
Diomedea epomophora Southern Royal Albatross [89221]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea exulans Wandering Albatross [89223]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea sanfordi Northern Royal Albatross [64456]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Halobaena caerulea Blue Petrel [1059]	Vulnerable	Species or species habitat may occur within area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Species or species habitat may occur within area
Macronectes halli Northern Giant Petrel [1061]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Neophema chrysogaster Orange-bellied Parrot [747]	Critically Endangered	Migration route likely to occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat may occur within area
Pachyptila turtur subantarctica Fairy Prion (southern) [64445]	Vulnerable	Species or species habitat may occur within area
Phoebetria fusca Sooty Albatross [1075]	Vulnerable	Species or species habitat likely to occur within area

Scientific Name	Threatened Category	Presence Text
Pterodroma leucoptera leucoptera Gould's Petrel, Australian Gould's Petrel [26033]	Endangered	Species or species habitat may occur within area
Pterodroma mollis Soft-plumaged Petrel [1036]	Vulnerable	Species or species habitat may occur within area
Sternula nereis nereis Australian Fairy Tern [82950]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche bulleri Buller's Albatross, Pacific Albatross [64460]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche bulleri platei Northern Buller's Albatross, Pacific Albatross [82273]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche carteri Indian Yellow-nosed Albatross [64464]	Vulnerable	Species or species habitat likely to occur within area
Thalassarche cauta Shy Albatross [89224]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Thalassarche chrysostoma Grey-headed Albatross [66491]	Endangered	Species or species habitat may occur within area
Thalassarche impavida Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche melanophris Black-browed Albatross [66472]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area

Scientific Name	Threatened Category	Presence Text
Thalassarche salvini Salvin's Albatross [64463]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche steadi White-capped Albatross [64462]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
FISH		
Hoplostethus atlanticus Orange Roughy, Deep-sea Perch, Red Roughy [68455]	Conservation Dependent	Species or species habitat likely to occur within area
Prototroctes maraena Australian Grayling [26179]	Vulnerable	Species or species habitat may occur within area
Seriolella brama Blue Warehou [69374]	Conservation Dependent	Species or species habitat known to occur within area
MAMMAL		
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Foraging, feeding or related behaviour known to occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Eubalaena australis Southern Right Whale [40]	Endangered	Species or species habitat known to occur within area
REPTILE		
Caretta caretta Loggerhead Turtle [1763]	Endangered	Species or species habitat likely to occur within area

Scientific Name	Threatened Category	Presence Text
Chelonia mydas		
Green Turtle [1765]	Vulnerable	Species or species habitat may occur within area
Dermochelys coriacea		
Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Species or species habitat likely to occur within area
SHARK		
Carcharodon carcharias		
White Shark, Great White Shark [64470]	Vulnerable	Migration route known to occur within area
Centrophorus uyato		
Little Gulper Shark [68446]	Conservation Dependent	Species or species habitat likely to occur within area
Galeorhinus galeus		
School Shark, Eastern School Shark, Snapper Shark, Tope, Soupfin Shark [68453]	Conservation Dependent	Species or species habitat may occur within area

Listed Migratory Species

[Resource Information]

Scientific Name	Threatened Category	Presence Text
Migratory Marine Birds		
Ardenna carneipes		
Flesh-footed Shearwater, Fleshy-footed Shearwater [82404]		Foraging, feeding or related behaviour likely to occur within area
Ardenna grisea		
Sooty Shearwater [82651]	Vulnerable	Species or species habitat may occur within area
Diomedea antipodensis		
Antipodean Albatross [64458]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea epomophora		
Southern Royal Albatross [89221]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area

Scientific Name	Threatened Category	Presence Text
Diomedea exulans Wandering Albatross [89223]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea sanfordi Northern Royal Albatross [64456]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Species or species habitat may occur within area
Macronectes halli Northern Giant Petrel [1061]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Phoebetria fusca Sooty Albatross [1075]	Vulnerable	Species or species habitat likely to occur within area
Thalassarche bulleri Buller's Albatross, Pacific Albatross [64460]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche carteri Indian Yellow-nosed Albatross [64464]	Vulnerable	Species or species habitat likely to occur within area
Thalassarche cauta Shy Albatross [89224]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Thalassarche chrysostoma Grey-headed Albatross [66491]	Endangered	Species or species habitat may occur within area
Thalassarche impavida Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area

Scientific Name	Threatened Category	Presence Text
Thalassarche melanophris Black-browed Albatross [66472]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche salvini Salvin's Albatross [64463]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche steadi White-capped Albatross [64462]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Migratory Marine Species		
Balaenoptera bonaerensis Antarctic Minke Whale, Dark-shoulder Minke Whale [67812]		Species or species habitat likely to occur within area
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Foraging, feeding or related behaviour known to occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Caperea marginata Pygmy Right Whale [39]		Foraging, feeding or related behaviour may occur within area
Carcharias taurus Grey Nurse Shark [64469]		Species or species habitat may occur within area
Carcharodon carcharias White Shark, Great White Shark [64470]	Vulnerable	Migration route known to occur within area

Scientific Name	Threatened Category	Presence Text
Caretta caretta Loggerhead Turtle [1763]	Endangered	Species or species habitat likely to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Species or species habitat may occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Species or species habitat likely to occur within area
Eubalaena australis as Balaena glacialis australis Southern Right Whale [40]	Endangered	Species or species habitat known to occur within area
Isurus oxyrinchus Shortfin Mako, Mako Shark [79073]		Species or species habitat likely to occur within area
Lagenorhynchus obscurus Dusky Dolphin [43]		Species or species habitat likely to occur within area
Lamna nasus Porbeagle, Mackerel Shark [83288]		Species or species habitat likely to occur within area
Megaptera novaeangliae Humpback Whale [38]		Species or species habitat likely to occur within area
Orcinus orca Killer Whale, Orca [46]		Species or species habitat likely to occur within area
Physeter macrocephalus Sperm Whale [59]		Species or species habitat may occur within area
Migratory Wetlands Species		
Actitis hypoleucos Common Sandpiper [59309]		Species or species habitat may occur within area

Scientific Name	Threatened Category	Presence Text
Calidris acuminata Sharp-tailed Sandpiper [874]	Vulnerable	Species or species habitat may occur within area
Calidris canutus Red Knot, Knot [855]	Vulnerable	Species or species habitat may occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area
Calidris melanotos Pectoral Sandpiper [858]		Species or species habitat may occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat may occur within area

Other Matters Protected by the EPBC Act

Listed Marine Species

[Resource Information]

Scientific Name	Threatened Category	Presence Text
Bird		
Actitis hypoleucos Common Sandpiper [59309]		Species or species habitat may occur within area
Ardenna carneipes as Puffinus carneipes Flesh-footed Shearwater, Fleshy-footed Shearwater [82404]		Foraging, feeding or related behaviour likely to occur within area
Ardenna grisea as Puffinus griseus Sooty Shearwater [82651]	Vulnerable	Species or species habitat may occur within area
Calidris acuminata Sharp-tailed Sandpiper [874]	Vulnerable	Species or species habitat may occur within area

Scientific Name	Threatened Category	Presence Text
Calidris canutus Red Knot, Knot [855]	Vulnerable	Species or species habitat may occur within area overfly marine area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area overfly marine area
Calidris melanotos Pectoral Sandpiper [858]		Species or species habitat may occur within area overfly marine area
Diomedea antipodensis Antipodean Albatross [64458]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea epomophora Southern Royal Albatross [89221]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea exulans Wandering Albatross [89223]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea sanfordi Northern Royal Albatross [64456]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Halobaena caerulea Blue Petrel [1059]	Vulnerable	Species or species habitat may occur within area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Species or species habitat may occur within area
Macronectes halli Northern Giant Petrel [1061]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area

Scientific Name	Threatened Category	Presence Text
Neophema chrysogaster Orange-bellied Parrot [747]	Critically Endangered	Migration route likely to occur within area overfly marine area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat may occur within area
Pachyptila turtur Fairy Prion [1066]		Species or species habitat may occur within area
Phoebetria fusca Sooty Albatross [1075]	Vulnerable	Species or species habitat likely to occur within area
Pterodroma mollis Soft-plumaged Petrel [1036]	Vulnerable	Species or species habitat may occur within area
Stercorarius antarcticus as Catharacta skua Brown Skua [85039]		Species or species habitat may occur within area
Sterna striata White-fronted Tern [799]		Migration route may occur within area
Thalassarche bulleri Buller's Albatross, Pacific Albatross [64460]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche bulleri platei as Thalassarche sp. nov. Northern Buller's Albatross, Pacific Albatross [82273]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche carteri Indian Yellow-nosed Albatross [64464]	Vulnerable	Species or species habitat likely to occur within area
Thalassarche cauta Shy Albatross [89224]	Endangered	Foraging, feeding or related behaviour likely to occur within area

Scientific Name	Threatened Category	Presence Text
Thalassarche chrysostoma Grey-headed Albatross [66491]	Endangered	Species or species habitat may occur within area
Thalassarche impavida Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche melanophris Black-browed Albatross [66472]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche salvini Salvin's Albatross [64463]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche steadi White-capped Albatross [64462]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Fish		
Heraldia nocturna Upside-down Pipefish, Eastern Upside-down Pipefish, Eastern Upside-down Pipefish [66227]		Species or species habitat may occur within area
Hippocampus abdominalis Big-belly Seahorse, Eastern Potbelly Seahorse, New Zealand Potbelly Seahorse [66233]		Species or species habitat may occur within area
Hippocampus breviceps Short-head Seahorse, Short-snouted Seahorse [66235]		Species or species habitat may occur within area
Histiogamphelus briggsii Crested Pipefish, Briggs' Crested Pipefish, Briggs' Pipefish [66242]		Species or species habitat may occur within area
Histiogamphelus cristatus Rhino Pipefish, Macleay's Crested Pipefish, Ring-back Pipefish [66243]		Species or species habitat may occur within area

Scientific Name	Threatened Category	Presence Text
Hypselognathus rostratus Knifesnout Pipefish, Knife-snouted Pipefish [66245]		Species or species habitat may occur within area
Kaupus costatus Deepbody Pipefish, Deep-bodied Pipefish [66246]		Species or species habitat may occur within area
Leptoichthys fistularius Brushtail Pipefish [66248]		Species or species habitat may occur within area
Lissocampus caudalis Australian Smooth Pipefish, Smooth Pipefish [66249]		Species or species habitat may occur within area
Lissocampus runa Javelin Pipefish [66251]		Species or species habitat may occur within area
Maroubra perserrata Sawtooth Pipefish [66252]		Species or species habitat may occur within area
Mitotichthys semistriatus Halfbanded Pipefish [66261]		Species or species habitat may occur within area
Mitotichthys tuckeri Tucker's Pipefish [66262]		Species or species habitat may occur within area
Notiocampus ruber Red Pipefish [66265]		Species or species habitat may occur within area
Phycodurus eques Leafy Seadragon [66267]		Species or species habitat may occur within area
Phyllopteryx taeniolatus Common Seadragon, Weedy Seadragon [66268]		Species or species habitat may occur within area

Scientific Name	Threatened Category	Presence Text
Pugnaso curtirostris Pugnose Pipefish, Pug-nosed Pipefish [66269]		Species or species habitat may occur within area
Solegnathus robustus Robust Pipehorse, Robust Spiny Pipehorse [66274]		Species or species habitat may occur within area
Solegnathus spinosissimus Spiny Pipehorse, Australian Spiny Pipehorse [66275]		Species or species habitat may occur within area
Stigmatopora argus Spotted Pipefish, Gulf Pipefish, Peacock Pipefish [66276]		Species or species habitat may occur within area
Stigmatopora nigra Widebody Pipefish, Wide-bodied Pipefish, Black Pipefish [66277]		Species or species habitat may occur within area
Stipecampus cristatus Ringback Pipefish, Ring-backed Pipefish [66278]		Species or species habitat may occur within area
Urocampus carinirostris Hairy Pipefish [66282]		Species or species habitat may occur within area
Vanacampus margaritifer Mother-of-pearl Pipefish [66283]		Species or species habitat may occur within area
Vanacampus phillipi Port Phillip Pipefish [66284]		Species or species habitat may occur within area
Vanacampus poecilolaemus Longsnout Pipefish, Australian Long-snout Pipefish, Long-snouted Pipefish [66285]		Species or species habitat may occur within area
Mammal		
Arctocephalus forsteri Long-nosed Fur-seal, New Zealand Fur-seal [20]		Species or species habitat may occur within area

Scientific Name	Threatened Category	Presence Text
Arctocephalus pusillus Australian Fur-seal, Australo-African Fur-seal [21]		Species or species habitat may occur within area
Reptile		
Caretta caretta Loggerhead Turtle [1763]	Endangered	Species or species habitat likely to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Species or species habitat may occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Species or species habitat likely to occur within area

Current Scientific Name	Status	Type of Presence
Mammal		
Balaenoptera acutorostrata Minke Whale [33]		Species or species habitat may occur within area
Balaenoptera bonaerensis Antarctic Minke Whale, Dark-shoulder Minke Whale [67812]		Species or species habitat likely to occur within area
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Foraging, feeding or related behaviour known to occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Berardius arnuxii Arnoux's Beaked Whale [70]		Species or species habitat may occur within area

Current Scientific Name	Status	Type of Presence
Caperea marginata Pygmy Right Whale [39]		Foraging, feeding or related behaviour may occur within area
Delphinus delphis Common Dolphin, Short-beaked Common Dolphin [60]		Species or species habitat may occur within area
Eubalaena australis Southern Right Whale [40]	Endangered	Species or species habitat known to occur within area
Globicephala macrorhynchus Short-finned Pilot Whale [62]		Species or species habitat may occur within area
Globicephala melas Long-finned Pilot Whale [59282]		Species or species habitat may occur within area
Grampus griseus Risso's Dolphin, Grampus [64]		Species or species habitat may occur within area
Kogia breviceps Pygmy Sperm Whale [57]		Species or species habitat may occur within area
Kogia sima Dwarf Sperm Whale [85043]		Species or species habitat may occur within area
Lagenorhynchus obscurus Dusky Dolphin [43]		Species or species habitat likely to occur within area
Lissodelphis peronii Southern Right Whale Dolphin [44]		Species or species habitat may occur within area
Megaptera novaeangliae Humpback Whale [38]		Species or species habitat likely to occur within area

Current Scientific Name	Status	Type of Presence
Mesoplodon bowdoini Andrew's Beaked Whale [73]		Species or species habitat may occur within area
Mesoplodon densirostris Blainville's Beaked Whale, Dense-beaked Whale [74]		Species or species habitat may occur within area
Mesoplodon hectori Hector's Beaked Whale [76]		Species or species habitat may occur within area
Mesoplodon layardii Strap-toothed Beaked Whale, Strap-toothed Whale, Layard's Beaked Whale [25556]		Species or species habitat may occur within area
Mesoplodon mirus True's Beaked Whale [54]		Species or species habitat may occur within area
Orcinus orca Killer Whale, Orca [46]		Species or species habitat likely to occur within area
Physeter macrocephalus Sperm Whale [59]		Species or species habitat may occur within area
Pseudorca crassidens False Killer Whale [48]		Species or species habitat likely to occur within area
Tursiops truncatus s. str. Bottlenose Dolphin [68417]		Species or species habitat may occur within area
Ziphius cavirostris Cuvier's Beaked Whale, Goose-beaked Whale [56]		Species or species habitat may occur within area

Key Ecological Features [Resource Information]

Key Ecological Features are the parts of the marine ecosystem that are considered to be important for the biodiversity or ecosystem functioning and integrity of the Commonwealth Marine Area.

Name	Region
West Tasmania Canyons	South-east

Biologically Important Areas [Resource Information]

Scientific Name	Behaviour	Presence
Seabirds		
Ardenna tenuirostris Short-tailed Shearwater [82652]	Foraging	Known to occur
Ardenna tenuirostris Short-tailed Shearwater [82652]	Foraging	Likely to occur
Diomedea exulans (sensu lato) Wandering Albatross [1073]	Foraging	Known to occur
Diomedea exulans antipodensis Antipodean Albatross [82269]	Foraging	Known to occur
Pelecanoides urinatrix Common Diving-petrel [1018]	Foraging	Known to occur
Thalassarche bulleri Bullers Albatross [64460]	Foraging	Known to occur
Thalassarche cauta cauta Shy Albatross [82345]	Foraging likely	Likely to occur

Scientific Name	Behaviour	Presence
Thalassarche chlororhynchos bassi Indian Yellow-nosed Albatross [85249]	Foraging	Known to occur
Thalassarche melanophris Black-browed Albatross [66472]	Foraging	Known to occur
Thalassarche melanophris impavida Campbell Albatross [82449]	Foraging	Known to occur
Whales		
Balaenoptera musculus brevicauda Pygmy Blue Whale [81317]	Foraging	Likely to be present
Balaenoptera musculus brevicauda Pygmy Blue Whale [81317]	Foraging (annual high use area)	Known to occur

Caveat

1 PURPOSE

This report is designed to assist in identifying the location of matters of national environmental significance (MNES) and other matters protected by the Environment Protection and Biodiversity Conservation Act 1999 (Cth) (EPBC Act) which may be relevant in determining obligations and requirements under the EPBC Act.

The report contains the mapped locations of:

- World and National Heritage properties;
- Wetlands of International and National Importance;
- Commonwealth and State/Territory reserves;
- distribution of listed threatened, migratory and marine species;
- listed threatened ecological communities; and
- other information that may be useful as an indicator of potential habitat value.

2 DISCLAIMER

This report is not intended to be exhaustive and should only be relied upon as a general guide as mapped data is not available for all species or ecological communities listed under the EPBC Act (see below). Persons seeking to use the information contained in this report to inform the referral of a proposed action under the EPBC Act should consider the limitations noted below and whether additional information is required to determine the existence and location of MNES and other protected matters.

Where data is available to inform the mapping of protected species, the presence type (e.g. known, likely or may occur) that can be determined from the data is indicated in general terms. It is the responsibility of any person using or relying on the information in this report to ensure that it is suitable for the circumstances of any proposed use. The Commonwealth cannot accept responsibility for the consequences of any use of the report or any part thereof. To the maximum extent allowed under governing law, the Commonwealth will not be liable for any loss or damage that may be occasioned directly or indirectly through the use of, or reliance on the contents of this report.

3 DATA SOURCES

Threatened ecological communities

For threatened ecological communities where the distribution is well known, maps are generated based on information contained in recovery plans, State vegetation maps and remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

Threatened, migratory and marine species

Threatened, migratory and marine species distributions have been discerned through a variety of methods. Where distributions are well known and if time permits, distributions are inferred from either thematic spatial data (i.e. vegetation, soils, geology, elevation, aspect, terrain, etc.) together with point locations and described habitat; or modelled (MAXENT or BIOCLIM habitat modelling) using point locations and environmental data layers.

Where little information is available for a species or large number of maps are required in a short time-frame, maps are derived either from 0.04 or 0.02 decimal degree cells; by an automated process using polygon capture techniques (static two kilometre grid cells, alpha-hull and convex hull); or captured manually or by using topographic features (national park boundaries, islands, etc.).

In the early stages of the distribution mapping process (1999-early 2000s) distributions were defined by degree blocks, 100K or 250K map sheets to rapidly create distribution maps. More detailed distribution mapping methods are used to update these distributions when time permits.

4 LIMITATIONS

The following species and ecological communities have not been mapped and do not appear in this report:

- threatened species listed as extinct or considered vagrants;
- some recently listed species and ecological communities;
- some listed migratory and listed marine species, which are not listed as threatened species; and
- migratory species that are very widespread, vagrant, or only occur in Australia in small numbers.

The following groups have been mapped, but may not cover the complete distribution of the species:

- listed migratory and/or listed marine seabirds, which are not listed as threatened, have only been mapped for recorded breeding sites; and
- seals which have only been mapped for breeding sites near the Australian continent

The breeding sites may be important for the protection of the Commonwealth Marine environment.

Refer to the metadata for the feature group (using the Resource Information link) for the currency of the information.

Acknowledgements

This database has been compiled from a range of data sources. The department acknowledges the following custodians who have contributed valuable data and advice:

Appendix B EPBC Protected Matters Search Tool Report – Planning Area

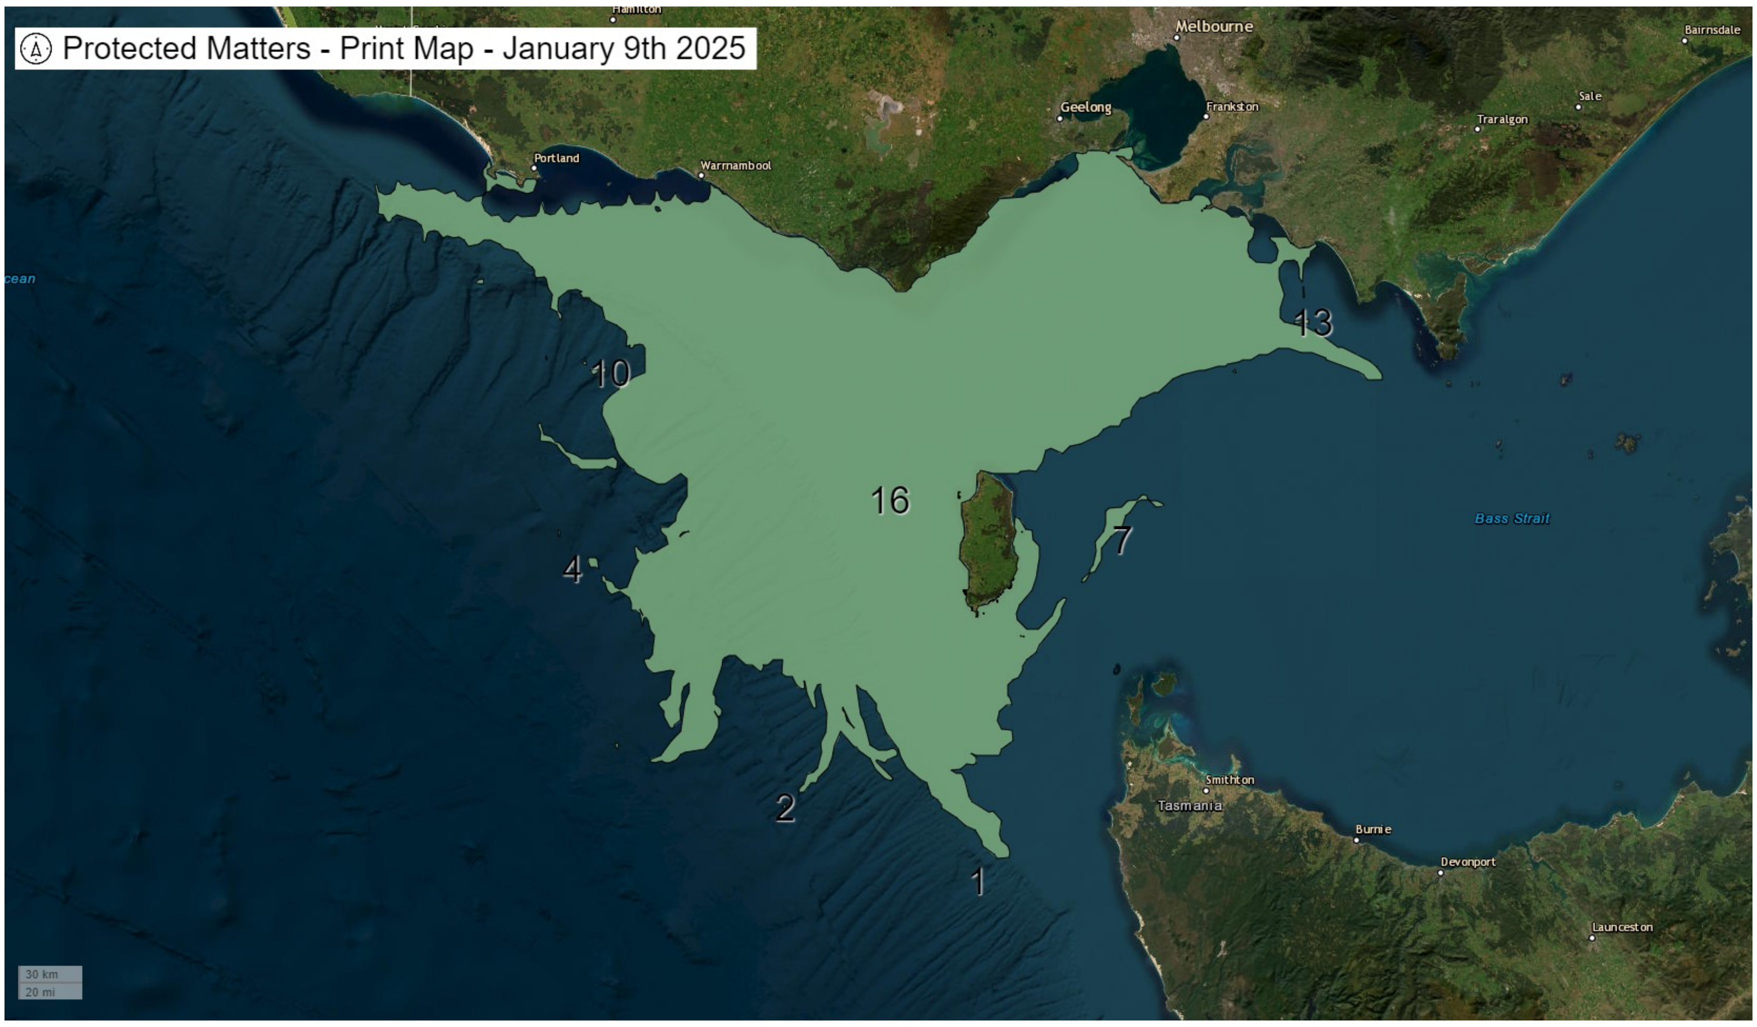
Australian Government

Department of Climate Change, Energy,
the Environment and Water

EPBC Act Protected Matters Report

This report provides general guidance on matters of national environmental significance and other matters protected by the EPBC Act in the area you have selected. Please see the caveat for interpretation of information provided here.

Report created: 09-Jan-2025



Summary

Matters of National Environment Significance

This part of the report summarises the matters of national environmental significance that may occur in, or may relate to, the area you nominated. Further information is available in the detail part of the report, which can be accessed by scrolling or following the links below. If you are proposing to undertake an activity that may have a significant impact on one or more matters of national environmental significance then you should consider the Administrative Guidelines on Significance.

World Heritage Properties:	None
National Heritage Places:	3
Wetlands of International Importance (Ramsar	4
Great Barrier Reef Marine Park:	None
Commonwealth Marine Area:	2
Listed Threatened Ecological Communities:	12
Listed Threatened Species:	130
Listed Migratory Species:	71

Other Matters Protected by the EPBC Act

This part of the report summarises other matters protected under the Act that may relate to the area you nominated. Approval may be required for a proposed activity that significantly affects the environment on Commonwealth land, when the action is outside the Commonwealth land, or the environment anywhere when the action is taken on Commonwealth land. Approval may also be required for the Commonwealth or Commonwealth agencies proposing to take an action that is likely to have a significant impact on the environment anywhere.

The EPBC Act protects the environment on Commonwealth land, the environment from the actions taken on Commonwealth land, and the environment from actions taken by Commonwealth agencies. As heritage values of a place are part of the 'environment', these aspects of the EPBC Act protect the Commonwealth Heritage values of a Commonwealth Heritage place. Information on the new heritage laws can be found at https://www.dcceew.gov.au/parks-heritage/heritage

A permit may be required for activities in or on a Commonwealth area that may affect a member of a listed threatened species or ecological community, a member of a listed migratory species, whales and other cetaceans, or a member of a listed marine species.

Commonwealth Lands:	24
Commonwealth Heritage Places:	5
Listed Marine Species:	123
Whales and Other Cetaceans:	31
Critical Habitats:	None
Commonwealth Reserves Terrestrial:	None
Australian Marine Parks:	4
Habitat Critical to the Survival of Marine Turtles:	None

Extra Information

This part of the report provides information that may also be relevant to the area you have

State and Territory Reserves:	66
Regional Forest Agreements:	2
Nationally Important Wetlands:	14
EPBC Act Referrals:	143
Key Ecological Features (Marine):	2
Biologically Important Areas:	25
Bioregional Assessments:	1
Geological and Bioregional Assessments:	None

Details

Matters of National Environmental Significance

National Heritage Places [Resource Information]

Name	State	Legal Status
Historic		
Great Ocean Road and Scenic Environs	VIC	Listed place
Point Nepean Defence Sites and Quarantine Station Area	VIC	Listed place
Quarantine Station and Surrounds	VIC	Within listed place

Wetlands of International Importance (Ramsar Wetlands) [Resource Information]

Ramsar Site Name	Proximity
Glenelg estuary and discovery bay wetlands	Within Ramsar site
Lavinia	Within Ramsar site
Port phillip bay (western shoreline) and bellarine peninsula	Within Ramsar site
Western port	Within 10km of Ramsar site

Commonwealth Marine Area [Resource Information]

Approval is required for a proposed activity that is located within the Commonwealth Marine Area which has, will have, or is likely to have a significant impact on the environment. Approval may be required for a proposed action taken outside a Commonwealth Marine Area but which has, may have or is likely to have a significant impact on the environment in the Commonwealth Marine Area.

Feature Name
Commonwealth Marine Areas (EPBC Act)
Commonwealth Marine Areas (EPBC Act)

Listed Threatened Ecological Communities [Resource Information]

For threatened ecological communities where the distribution is well known, maps are derived from recovery plans, State vegetation maps, remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.
Status of Vulnerable, Disallowed and Ineligible are not MNES under the EPBC Act.

Community Name	Threatened Category	Presence Text
Assemblages of species associated with open-coast salt-wedge estuaries of western and central Victoria ecological community	Endangered	Community likely to occur within area
Giant Kelp Marine Forests of South East Australia	Endangered	Community may occur within area

Community Name	Threatened Category	Presence Text
Grassy Eucalypt Woodland of the Victorian Volcanic Plain	Critically Endangered	Community likely to occur within area
Karst springs and associated alkaline fens of the Naracoorte Coastal Plain Bioregion	Endangered	Community may occur within area
King Island scrub complex	Endangered	Community may occur within area
Natural Damp Grassland of the Victorian Coastal Plains	Critically Endangered	Community likely to occur within area
Natural Temperate Grassland of the Victorian Volcanic Plain	Critically Endangered	Community likely to occur within area
Seasonal Herbaceous Wetlands (Freshwater) of the Temperate Lowland Plains	Critically Endangered	Community likely to occur within area
Subtropical and Temperate Coastal Saltmarsh	Vulnerable	Community likely to occur within area
Tasmanian Forests and Woodlands dominated by black gum or Brookers gum (Eucalyptus ovata / E. brookeriana)	Critically Endangered	Community likely to occur within area
Tasmanian white gum (Eucalyptus viminalis) wet forest	Critically Endangered	Community may occur within area
White Box-Yellow Box-Blakely's Red Gum Grassy Woodland and Derived Native Grassland	Critically Endangered	Community may occur within area

Listed Threatened Species [Resource Information]

Status of Conservation Dependent and Extinct are not MNES under the EPBC Act.
Number is the current name ID.

Scientific Name	Threatened Category	Presence Text
BIRD		
Acanthiza pusilla magnirostris King Island Brown Thornbill, Brown Thornbill (King Island) [91709]	Endangered	Species or species habitat known to occur within area
Acanthornis magna greeniana King Island Scrubtit, Scrubtit (King Island) [82329]	Critically Endangered	Species or species habitat known to occur within area
Anthochaera phrygia Regent Honeyeater [82338]	Critically Endangered	Foraging, feeding or related behaviour likely to occur within area

Scientific Name	Threatened Category	Presence Text
Aphelocephala leucopsis Southern Whiteface [529]	Vulnerable	Species or species habitat may occur within area
Aquila audax fleayi Tasmanian Wedge-tailed Eagle, Wedge-tailed Eagle (Tasmanian) [64435]	Endangered	Species or species habitat may occur within area
Ardenna grisea Sooty Shearwater [82651]	Vulnerable	Species or species habitat may occur within area
Arenaria interpres Ruddy Turnstone [872]	Vulnerable	Roosting known to occur within area
Botaurus poiciloptilus Australasian Bittern [1001]	Endangered	Species or species habitat known to occur within area
Calidris acuminata Sharp-tailed Sandpiper [874]	Vulnerable	Roosting known to occur within area
Calidris canutus Red Knot, Knot [855]	Vulnerable	Species or species habitat known to occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat known to occur within area
Calidris tenuirostris Great Knot [862]	Vulnerable	Roosting known to occur within area
Callocephalon fimbriatum Gang-gang Cockatoo [768]	Endangered	Species or species habitat known to occur within area
Calyptorhynchus banksii graptogyne South-eastern Red-tailed Black-Cockatoo [25982]	Endangered	Species or species habitat likely to occur within area
Ceyx azureus diemenensis Tasmanian Azure Kingfisher [25977]	Endangered	Species or species habitat known to occur within area

Scientific Name	Threatened Category	Presence Text
Charadrius leschenaultii Greater Sand Plover, Large Sand Plover [877]	Vulnerable	Species or species habitat known to occur within area
Charadrius mongolus Lesser Sand Plover, Mongolian Plover [879]	Endangered	Roosting known to occur within area
Climacteris picumnus victoriae Brown Treecreeper (south-eastern) [67062]	Vulnerable	Species or species habitat may occur within area
Diomedea antipodensis Antipodean Albatross [64458]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea antipodensis gibsoni Gibson's Albatross [82270]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea epomophora Southern Royal Albatross [89221]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea exulans Wandering Albatross [89223]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea sanfordi Northern Royal Albatross [64456]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Falco hypoleucos Grey Falcon [929]	Vulnerable	Species or species habitat likely to occur within area
Fregetta grallaria grallaria White-bellied Storm-Petrel (Tasman Sea), White-bellied Storm-Petrel (Australasian) [64438]	Vulnerable	Species or species habitat likely to occur within area

Scientific Name	Threatened Category	Presence Text
Gallinago hardwickii Latham's Snipe, Japanese Snipe [863]	Vulnerable	Species or species habitat known to occur within area
Grantiella picta Painted Honeyeater [470]	Vulnerable	Species or species habitat may occur within area
Halobaena caerulea Blue Petrel [1059]	Vulnerable	Species or species habitat may occur within area
Hirundapus caudacutus White-throated Needletail [682]	Vulnerable	Species or species habitat known to occur within area
Lathamus discolor Swift Parrot [744]	Critically Endangered	Species or species habitat known to occur within area
Limosa lapponica baueri Nunivak Bar-tailed Godwit, Western Alaskan Bar-tailed Godwit [86380]	Endangered	Species or species habitat known to occur within area
Limosa limosa Black-tailed Godwit [845]	Endangered	Roosting known to occur within area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Macronectes halli Northern Giant Petrel [1061]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Melanodryas cucullata cucullata South-eastern Hooded Robin, Hooded Robin (south-eastern) [67093]	Endangered	Species or species habitat may occur within area
Neophema chrysogaster Orange-bellied Parrot [747]	Critically Endangered	Migration route known to occur within area

Scientific Name	Threatened Category	Presence Text
Neophema chrysostoma Blue-winged Parrot [726]	Vulnerable	Species or species habitat known to occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat known to occur within area
Pachyptila turtur subantarctica Fairy Prion (southern) [64445]	Vulnerable	Species or species habitat known to occur within area
Pedionomus torquatus Plains-wanderer [906]	Critically Endangered	Species or species habitat may occur within area
Phoebetria fusca Sooty Albatross [1075]	Vulnerable	Species or species habitat likely to occur within area
Platycercus caledonicus brownii Green Rosella (King Island) [67041]	Vulnerable	Species or species habitat known to occur within area
Pluvialis squatarola Grey Plover [865]	Vulnerable	Roosting known to occur within area
Pterodroma leucoptera leucoptera Gould's Petrel, Australian Gould's Petrel [26033]	Endangered	Species or species habitat may occur within area
Pterodroma mollis Soft-plumaged Petrel [1036]	Vulnerable	Species or species habitat may occur within area
Pycnoptilus floccosus Pilotbird [525]	Vulnerable	Species or species habitat may occur within area
Rostratula australis Australian Painted Snipe [77037]	Endangered	Species or species habitat known to occur within area

Scientific Name	Threatened Category	Presence Text
Stagonopleura guttata Diamond Firetail [59398]	Vulnerable	Species or species habitat known to occur within area
Sternula nereis nereis Australian Fairy Tern [82950]	Vulnerable	Species or species habitat known to occur within area
Strepera fuliginosa colei Black Currawong (King Island) [67113]	Vulnerable	Breeding likely to occur within area
Thalassarche bulleri Buller's Albatross, Pacific Albatross [64460]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche bulleri platei Northern Buller's Albatross, Pacific Albatross [82273]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche carteri Indian Yellow-nosed Albatross [64464]	Vulnerable	Species or species habitat likely to occur within area
Thalassarche cauta Shy Albatross [89224]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Thalassarche chrysostoma Grey-headed Albatross [66491]	Endangered	Species or species habitat may occur within area
Thalassarche impavida Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche melanophris Black-browed Albatross [66472]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area

Scientific Name	Threatened Category	Presence Text
Thalassarche salvini Salvin's Albatross [64463]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche steadi White-capped Albatross [64462]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Thinornis cucullatus cucullatus Eastern Hooded Plover, Eastern Hooded Plover [90381]	Vulnerable	Species or species habitat known to occur within area
Tringa nebularia Common Greenshank, Greenshank [832]	Endangered	Species or species habitat known to occur within area
Xenus cinereus Terek Sandpiper [59300]	Vulnerable	Roosting known to occur within area
CRUSTACEAN		
Euastacus bispinosus Glenelg Spiny Freshwater Crayfish, Pricklyback [81552]	Endangered	Species or species habitat may occur within area
FISH		
Galaxiella pusilla Eastern Dwarf Galaxias, Dwarf Galaxias [56790]	Endangered	Species or species habitat may occur within area
Hoplostethus atlanticus Orange Roughy, Deep-sea Perch, Red Roughy [68455]	Conservation Dependent	Species or species habitat likely to occur within area
Nannoperca obscura Yarra Pygmy Perch [26177]	Endangered	Species or species habitat known to occur within area
Prototroctes maraena Australian Grayling [26179]	Vulnerable	Species or species habitat known to occur within area
Rexea solandri (eastern Australian population) Eastern Gemfish [76339]	Conservation Dependent	Species or species habitat likely to occur within area

Scientific Name	Threatened Category	Presence Text
Seriolella brama Blue Warehou [69374]	Conservation Dependent	Species or species habitat known to occur within area
FROG		
Litoria raniformis Southern Bell Frog,, Growling Grass Frog, Green and Golden Frog, Warty Swamp Frog, Golden Bell Frog [1828]	Vulnerable	Species or species habitat known to occur within area
INSECT		
Synemon plana Golden Sun Moth [25234]	Vulnerable	Species or species habitat may occur within area
MAMMAL		
Antechinus minimus maritimus Swamp Antechinus (mainland) [83086]	Vulnerable	Species or species habitat known to occur within area
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Foraging, feeding or related behaviour known to occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Dasyurus maculatus maculatus (SE mainland population) Spot-tailed Quoll, Spotted-tail Quoll, Tiger Quoll (southeastern mainland population) [75184]	Endangered	Species or species habitat known to occur within area
Eubalaena australis Southern Right Whale [40]	Endangered	Breeding known to occur within area
Isoodon obesulus obesulus Southern Brown Bandicoot (eastern), Southern Brown Bandicoot (south-eastern) [68050]	Endangered	Species or species habitat known to occur within area

Scientific Name	Threatened Category	Presence Text
Mastacomys fuscus mordicus Broad-toothed Rat (mainland), Tooarrana [87617]	Endangered	Species or species habitat known to occur within area
Miniopterus orianae bassanii Southern Bent-wing Bat [87645]	Critically Endangered	Breeding known to occur within area
Neophoca cinerea Australian Sea-lion, Australian Sea Lion [22]	Endangered	Species or species habitat may occur within area
Perameles gunnii Victorian subspecies Eastern Barred Bandicoot (Mainland) [88020]	Endangered	Translocated population known to occur within area
Petauroides volans Greater Glider (southern and central) [254]	Endangered	Species or species habitat may occur within area
Petaurus australis australis Yellow-bellied Glider (south-eastern) [87600]	Vulnerable	Species or species habitat known to occur within area
Potorous tridactylus trisulcatus Long-nosed Potoroo (southern mainland) [86367]	Vulnerable	Species or species habitat known to occur within area
Pseudomys fumeus Smoky Mouse, Konoom [88]	Endangered	Species or species habitat may occur within area
Pseudomys novaehollandiae New Holland Mouse, Pookila [96]	Vulnerable	Species or species habitat likely to occur within area
Pseudomys shortridgei Heath Mouse, Dayang, Heath Rat [77]	Endangered	Species or species habitat known to occur within area
Pteropus poliocephalus Grey-headed Flying-fox [186]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
PLANT		

Scientific Name	Threatened Category	Presence Text
Amphibromus fluitans River Swamp Wallaby-grass, Floating Swamp Wallaby-grass [19215]	Vulnerable	Species or species habitat likely to occur within area
Caladenia calcicola Limestone Spider-orchid [10065]	Vulnerable	Species or species habitat likely to occur within area
Caladenia colorata Coloured Spider-orchid, Small Western Spider-orchid, Painted Spider-orchid [54999]	Endangered	Species or species habitat likely to occur within area
Caladenia concolor Crimson Spider-orchid, Maroon Spider-orchid [5505]	Vulnerable	Species or species habitat may occur within area
Caladenia hastata Melblom's Spider-orchid [16118]	Endangered	Species or species habitat likely to occur within area
Caladenia orientalis Eastern Spider Orchid [83410]	Endangered	Species or species habitat known to occur within area
Caladenia ornata Ornate Pink Fingers [76213]	Vulnerable	Species or species habitat may occur within area
Caladenia tessellata Thick-lipped Spider-orchid, Daddy Long-legs [2119]	Vulnerable	Species or species habitat known to occur within area
Dodonaea procumbens Trailing Hop-bush [12149]	Vulnerable	Species or species habitat may occur within area
Eucalyptus strzeleckii Strzelecki Gum [55400]	Vulnerable	Species or species habitat known to occur within area
Euphrasia collina subsp. muelleri Purple Eyebright, Mueller's Eyebright [16151]	Endangered	Species or species habitat known to occur within area

Scientific Name	Threatened Category	Presence Text
Glycine latrobeana Clover Glycine, Purple Clover [13910]	Vulnerable	Species or species habitat known to occur within area
Grevillea infecunda Anglesea Grevillea [22026]	Vulnerable	Species or species habitat known to occur within area
Haloragis exalata subsp. exalata Wingless Raspwort, Square Raspwort [24636]	Vulnerable	Species or species habitat known to occur within area
Hiya distans listed as Hypolepis distans Scrambling Ground-fern [92548]	Endangered	Species or species habitat known to occur within area
Ixodia achillaeoides subsp. arenicola Sand Ixodia, Ixodia [21474]	Vulnerable	Species or species habitat known to occur within area
Lachnagrostis adamsonii Adamson's Blown-grass, Adamson's Blowngrass [76211]	Endangered	Species or species habitat may occur within area
Leiocarpa gatesii Wrinkled Buttons [76212]	Vulnerable	Species or species habitat known to occur within area
Lepidium aschersonii Spiny Peppercress [10976]	Vulnerable	Species or species habitat known to occur within area
Lepidium hyssopifolium Basalt Pepper-cress, Peppercress, Rubble Pepper-cress, Pepperweed [16542]	Endangered	Species or species habitat likely to occur within area
Pimelea spinescens subsp. spinescens Plains Rice-flower, Spiny Rice-flower, Prickly Pimelea [21980]	Critically Endangered	Species or species habitat likely to occur within area
Prasophyllum litorale listed as Prasophyllum littorale Coastal Leek Orchid [55234]	Critically Endangered	Species or species habitat known to occur within area

Scientific Name	Threatened Category	Presence Text
Prasophyllum spicatum Dense Leek-orchid [55146]	Vulnerable	Species or species habitat known to occur within area
Prasophyllum suaveolens Fragrant Leek-orchid [64956]	Endangered	Species or species habitat may occur within area
Pterostylis chlorogramma Green-striped Greenhood [56510]	Vulnerable	Species or species habitat known to occur within area
Pterostylis cucullata Leafy Greenhood [15459]	Vulnerable	Species or species habitat known to occur within area
Pterostylis tenuissima Swamp Greenhood, Dainty Swamp Orchid [13139]	Vulnerable	Species or species habitat known to occur within area
Senecio macrocarpus Large-fruit Fireweed, Large-fruit Groundsel [16333]	Vulnerable	Species or species habitat likely to occur within area
Senecio psilocarpus Swamp Fireweed, Smooth-fruited Groundsel [64976]	Vulnerable	Species or species habitat known to occur within area
Thelymitra epipactoides Metallic Sun-orchid [11896]	Endangered	Species or species habitat known to occur within area
Thelymitra matthewsii Spiral Sun-orchid [4168]	Endangered	Species or species habitat known to occur within area
Thelymitra orientalis Hoary Sun-orchid [88011]	Critically Endangered	Species or species habitat may occur within area
Xerochrysum palustre Swamp Everlasting, Swamp Paper Daisy [76215]	Vulnerable	Species or species habitat likely to occur within area
REPTILE		

Scientific Name	Threatened Category	Presence Text
Caretta caretta Loggerhead Turtle [1763]	Endangered	Foraging, feeding or related behaviour known to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Species or species habitat may occur within area
Delma impar Striped Legless Lizard, Striped Snake-lizard [1649]	Vulnerable	Species or species habitat likely to occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Foraging, feeding or related behaviour known to occur within area
Lissolepis coventryi Swamp Skink, Eastern Mourning Skink [84053]	Endangered	Species or species habitat known to occur within area
SHARK		
Carcharodon carcharias White Shark, Great White Shark [64470]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Centrophorus uyato Little Gulper Shark [68446]	Conservation Dependent	Species or species habitat likely to occur within area
Galeorhinus galeus School Shark, Eastern School Shark, Snapper Shark, Tope, Soupfin Shark [68453]	Conservation Dependent	Species or species habitat likely to occur within area

Listed Migratory Species [Resource Information]

Scientific Name	Threatened Category	Presence Text
Migratory Marine Birds		
Anous stolidus Common Noddy [825]		Species or species habitat likely to occur within area
Apus pacificus Fork-tailed Swift [678]		Species or species habitat likely to occur within area

Scientific Name	Threatened Category	Presence Text
Ardenna carneipes Flesh-footed Shearwater, Fleshy-footed Shearwater [82404]		Foraging, feeding or related behaviour likely to occur within area
Ardenna grisea Sooty Shearwater [82651]	Vulnerable	Species or species habitat may occur within area
Ardenna tenuirostris Short-tailed Shearwater [82652]		Breeding known to occur within area
Diomedea antipodensis Antipodean Albatross [64458]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea epomophora Southern Royal Albatross [89221]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea exulans Wandering Albatross [89223]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea sanfordi Northern Royal Albatross [64456]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Hydroprogne caspia Caspian Tern [808]		Breeding known to occur within area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Macronectes halli Northern Giant Petrel [1061]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area

Scientific Name	Threatened Category	Presence Text
Phoebetria fusca Sooty Albatross [1075]	Vulnerable	Species or species habitat likely to occur within area
Sternula albifrons Little Tern [82849]		Breeding known to occur within area
Thalassarche bulleri Buller's Albatross, Pacific Albatross [64460]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche carteri Indian Yellow-nosed Albatross [64464]	Vulnerable	Species or species habitat likely to occur within area
Thalassarche cauta Shy Albatross [89224]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Thalassarche chrysostoma Grey-headed Albatross [66491]	Endangered	Species or species habitat may occur within area
Thalassarche impavida Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche melanophris Black-browed Albatross [66472]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche salvini Salvin's Albatross [64463]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche steadi White-capped Albatross [64462]	Vulnerable	Foraging, feeding or related behaviour known to occur within area

Migratory Marine Species

Scientific Name	Threatened Category	Presence Text
Balaenoptera bonaerensis Antarctic Minke Whale, Dark-shoulder Minke Whale [67812]		Species or species habitat likely to occur within area
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Foraging, feeding or related behaviour known to occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Caperea marginata Pygmy Right Whale [39]		Foraging, feeding or related behaviour likely to occur within area
Carcharias taurus Grey Nurse Shark [64469]		Species or species habitat may occur within area
Carcharodon carcharias White Shark, Great White Shark [64470]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Caretta caretta Loggerhead Turtle [1763]	Endangered	Foraging, feeding or related behaviour known to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Species or species habitat may occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Foraging, feeding or related behaviour known to occur within area

Scientific Name	Threatened Category	Presence Text
Eubalaena australis as Balaena glacialis australis		
Southern Right Whale [40]	Endangered	Breeding known to occur within area
Isurus oxyrinchus		
Shortfin Mako, Mako Shark [79073]		Species or species habitat likely to occur within area
Lagenorhynchus obscurus		
Dusky Dolphin [43]		Species or species habitat likely to occur within area
Lamna nasus		
Porbeagle, Mackerel Shark [83288]		Species or species habitat likely to occur within area
Megaptera novaeangliae		
Humpback Whale [38]		Species or species habitat known to occur within area
Orcinus orca		
Killer Whale, Orca [46]		Species or species habitat likely to occur within area
Physeter macrocephalus		
Sperm Whale [59]		Species or species habitat may occur within area
Migratory Terrestrial Species		
Hirundapus caudacutus		
White-throated Needletail [682]	Vulnerable	Species or species habitat known to occur within area
Motacilla flava		
Yellow Wagtail [644]		Species or species habitat may occur within area
Migratory Wetlands Species		
Actitis hypoleucos		
Common Sandpiper [59309]		Species or species habitat known to occur within area
Arenaria interpres		
Ruddy Turnstone [872]	Vulnerable	Roosting known to occur within area

Scientific Name	Threatened Category	Presence Text
Calidris acuminata Sharp-tailed Sandpiper [874]	Vulnerable	Roosting known to occur within area
Calidris alba Sanderling [875]		Roosting known to occur within area
Calidris canutus Red Knot, Knot [855]	Vulnerable	Species or species habitat known to occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat known to occur within area
Calidris melanotos Pectoral Sandpiper [858]		Species or species habitat known to occur within area
Calidris ruficollis Red-necked Stint [860]		Roosting known to occur within area
Calidris tenuirostris Great Knot [862]	Vulnerable	Roosting known to occur within area
Charadrius bicinctus Double-banded Plover [895]		Roosting known to occur within area
Charadrius leschenaultii Greater Sand Plover, Large Sand Plover [877]	Vulnerable	Species or species habitat known to occur within area
Charadrius mongolus Lesser Sand Plover, Mongolian Plover [879]	Endangered	Roosting known to occur within area
Gallinago hardwickii Latham's Snipe, Japanese Snipe [863]	Vulnerable	Species or species habitat known to occur within area
Gallinago megala Swinhoe's Snipe [864]		Roosting likely to occur within area
Gallinago stenura Pin-tailed Snipe [841]		Roosting likely to occur within area

Scientific Name	Threatened Category	Presence Text
Limicola falcinellus Broad-billed Sandpiper [842]		Roosting known to occur within area
Limosa lapponica Bar-tailed Godwit [844]		Species or species habitat known to occur within area
Limosa limosa Black-tailed Godwit [845]	Endangered	Roosting known to occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat known to occur within area
Numenius minutus Little Curlew, Little Whimbrel [848]		Roosting likely to occur within area
Numenius phaeopus Whimbrel [849]		Roosting known to occur within area
Pandion haliaetus Osprey [952]		Species or species habitat known to occur within area
Phalaropus lobatus Red-necked Phalarope [838]		Roosting known to occur within area
Pluvialis fulva Pacific Golden Plover [25545]		Roosting known to occur within area
Pluvialis squatarola Grey Plover [865]	Vulnerable	Roosting known to occur within area
Thalasseus bergii Greater Crested Tern [83000]		Breeding known to occur within area
Tringa brevipes Grey-tailed Tattler [851]		Roosting known to occur within area
Tringa nebularia Common Greenshank, Greenshank [832]	Endangered	Species or species habitat known to occur within area

Scientific Name	Threatened Category	Presence Text
Tringa stagnatilis Marsh Sandpiper, Little Greenshank [833]		Roosting known to occur within area
Xenus cinereus Terek Sandpiper [59300]	Vulnerable	Roosting known to occur within area

Commonwealth Lands [Resource Information]

The Commonwealth area listed below may indicate the presence of Commonwealth land in this vicinity. Due to the unreliability of the data source, all proposals should be checked as to whether it impacts on a Commonwealth area, before making a definitive decision. Contact the State or Territory government land department for further information.

Listed Marine Species

[Resource Information]

Scientific Name	Threatened Category	Presence Text
Bird		
Actitis hypoleucos Common Sandpiper [59309]		Species or species habitat known to occur within area
Anous stolidus Common Noddy [825]		Species or species habitat likely to occur within area
Anseranas semipalmata Magpie Goose [978]		Species or species habitat may occur within area overfly marine area

Scientific Name	Threatened Category	Presence Text
Apus pacificus Fork-tailed Swift [678]		Species or species habitat likely to occur within area overfly marine area
Ardenna carneipes as Puffinus carneipes Flesh-footed Shearwater, Fleshy-footed Shearwater [82404]		Foraging, feeding or related behaviour likely to occur within area
Ardenna grisea as Puffinus griseus Sooty Shearwater [82651]	Vulnerable	Species or species habitat may occur within area
Ardenna tenuirostris as Puffinus tenuirostris Short-tailed Shearwater [82652]		Breeding known to occur within area
Arenaria interpres Ruddy Turnstone [872]	Vulnerable	Roosting known to occur within area
Bubulcus ibis as Ardea ibis Cattle Egret [66521]		Species or species habitat may occur within area overfly marine area
Calidris acuminata Sharp-tailed Sandpiper [874]	Vulnerable	Roosting known to occur within area
Calidris alba Sanderling [875]		Roosting known to occur within area
Calidris canutus Red Knot, Knot [855]	Vulnerable	Species or species habitat known to occur within area overfly marine area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat known to occur within area overfly marine area
Calidris melanotos Pectoral Sandpiper [858]		Species or species habitat known to occur within area overfly marine area

Scientific Name	Threatened Category	Presence Text
Calidris ruficollis Red-necked Stint [860]		Roosting known to occur within area overfly marine area
Calidris tenuirostris Great Knot [862]	Vulnerable	Roosting known to occur within area overfly marine area
Chalcites osculans as Chrysococcyx osculans Black-eared Cuckoo [83425]		Species or species habitat known to occur within area overfly marine area
Charadrius bicinctus Double-banded Plover [895]		Roosting known to occur within area overfly marine area
Charadrius leschenaultii Greater Sand Plover, Large Sand Plover [877]	Vulnerable	Species or species habitat known to occur within area
Charadrius mongolus Lesser Sand Plover, Mongolian Plover [879]	Endangered	Roosting known to occur within area
Charadrius ruficapillus Red-capped Plover [881]		Roosting known to occur within area overfly marine area
Chroicocephalus novaehollandiae as Larus novaehollandiae Silver Gull [82326]		Breeding known to occur within area
Diomedea antipodensis Antipodean Albatross [64458]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea antipodensis gibsoni as Diomedea gibsoni Gibson's Albatross [82270]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea epomophora Southern Royal Albatross [89221]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area

Scientific Name	Threatened Category	Presence Text
Diomedea exulans Wandering Albatross [89223]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Diomedea sanfordi Northern Royal Albatross [64456]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Eudyptula minor Little Penguin [1085]		Breeding known to occur within area
Gallinago hardwickii Latham's Snipe, Japanese Snipe [863]	Vulnerable	Species or species habitat known to occur within area overfly marine area
Gallinago megala Swinhoe's Snipe [864]		Roosting likely to occur within area overfly marine area
Gallinago stenura Pin-tailed Snipe [841]		Roosting likely to occur within area overfly marine area
Haliaeetus leucogaster White-bellied Sea-Eagle [943]		Breeding known to occur within area
Halobaena caerulea Blue Petrel [1059]	Vulnerable	Species or species habitat may occur within area
Himantopus himantopus Pied Stilt, Black-winged Stilt [870]		Roosting known to occur within area overfly marine area
Hirundapus caudacutus White-throated Needletail [682]	Vulnerable	Species or species habitat known to occur within area overfly marine area
Hydroprogne caspia as Sterna caspia Caspian Tern [808]		Breeding known to occur within area

Scientific Name	Threatened Category	Presence Text
Larus dominicanus Kelp Gull [809]		Breeding known to occur within area
Larus pacificus Pacific Gull [811]		Breeding known to occur within area
Lathamus discolor Swift Parrot [744]	Critically Endangered	Species or species habitat known to occur within area overfly marine area
Limicola falcinellus Broad-billed Sandpiper [842]		Roosting known to occur within area overfly marine area
Limosa lapponica Bar-tailed Godwit [844]		Species or species habitat known to occur within area
Limosa limosa Black-tailed Godwit [845]	Endangered	Roosting known to occur within area overfly marine area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Macronectes halli Northern Giant Petrel [1061]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Merops ornatus Rainbow Bee-eater [670]		Species or species habitat may occur within area overfly marine area
Monarcha melanopsis Black-faced Monarch [609]		Species or species habitat known to occur within area overfly marine area
Morus capensis Cape Gannet [59569]		Breeding known to occur within area

Scientific Name	Threatened Category	Presence Text
Morus serrator Australasian Gannet [1020]		Breeding known to occur within area
Motacilla flava Yellow Wagtail [644]		Species or species habitat may occur within area overfly marine area
Myiagra cyanoleuca Satin Flycatcher [612]		Breeding known to occur within area overfly marine area
Neophema chrysogaster Orange-bellied Parrot [747]	Critically Endangered	Migration route known to occur within area overfly marine area
Neophema chrysostoma Blue-winged Parrot [726]	Vulnerable	Species or species habitat known to occur within area overfly marine area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat known to occur within area
Numenius minutus Little Curlew, Little Whimbrel [848]		Roosting likely to occur within area overfly marine area
Numenius phaeopus Whimbrel [849]		Roosting known to occur within area
Onychoprion fuscatus as Sterna fuscata Sooty Tern [90682]		Breeding known to occur within area
Pachyptila turtur Fairy Prion [1066]		Species or species habitat known to occur within area
Pandion haliaetus Osprey [952]		Species or species habitat known to occur within area

Scientific Name	Threatened Category	Presence Text
Pelagodroma marina White-faced Storm-Petrel [1016]		Breeding known to occur within area
Phalacrocorax fuscescens Black-faced Cormorant [59660]		Breeding known to occur within area
Phalaropus lobatus Red-necked Phalarope [838]		Roosting known to occur within area
Phoebetria fusca Sooty Albatross [1075]	Vulnerable	Species or species habitat likely to occur within area
Pluvialis fulva Pacific Golden Plover [25545]		Roosting known to occur within area
Pluvialis squatarola Grey Plover [865]	Vulnerable	Roosting known to occur within area overfly marine area
Pterodroma mollis Soft-plumaged Petrel [1036]	Vulnerable	Species or species habitat may occur within area
Recurvirostra novaehollandiae Red-necked Avocet [871]		Roosting known to occur within area overfly marine area
Rhipidura rufifrons Rufous Fantail [592]		Species or species habitat known to occur within area overfly marine area
Rostratula australis as Rostratula benghalensis (sensu lato) Australian Painted Snipe [77037]	Endangered	Species or species habitat known to occur within area overfly marine area
Stercorarius antarcticus as Catharacta skua Brown Skua [85039]		Species or species habitat may occur within area

Scientific Name	Threatened Category	Presence Text
Sterna striata White-fronted Tern [799]		Foraging, feeding or related behaviour likely to occur within area
Sternula albifrons as Sterna albifrons Little Tern [82849]		Breeding known to occur within area
Sternula nereis as Sterna nereis Fairy Tern [82949]		Breeding known to occur within area
Thalassarche bulleri Buller's Albatross, Pacific Albatross [64460]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche bulleri platei as Thalassarche sp. nov. Northern Buller's Albatross, Pacific Albatross [82273]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche carteri Indian Yellow-nosed Albatross [64464]	Vulnerable	Species or species habitat likely to occur within area
Thalassarche cauta Shy Albatross [89224]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Thalassarche chrysostoma Grey-headed Albatross [66491]	Endangered	Species or species habitat may occur within area
Thalassarche impavida Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche melanophris Black-browed Albatross [66472]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area

Scientific Name	Threatened Category	Presence Text
Thalassarche salvini Salvin's Albatross [64463]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Thalassarche steadi White-capped Albatross [64462]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Thalasseus bergii as Sterna bergii Greater Crested Tern [83000]		Breeding known to occur within area
Thinornis cucullatus as Thinornis rubricollis Hooded Plover, Hooded Dotterel [87735]		Species or species habitat known to occur within area overfly marine area
Thinornis cucullatus cucullatus as Thinornis rubricollis rubricollis Eastern Hooded Plover, Eastern Hooded Plover [90381]	Vulnerable	Species or species habitat known to occur within area overfly marine area
Tringa brevipes as Heteroscelus brevipes Grey-tailed Tattler [851]		Roosting known to occur within area
Tringa nebularia Common Greenshank, Greenshank [832]	Endangered	Species or species habitat known to occur within area overfly marine area
Tringa stagnatilis Marsh Sandpiper, Little Greenshank [833]		Roosting known to occur within area overfly marine area
Xenus cinereus Terek Sandpiper [59300]	Vulnerable	Roosting known to occur within area overfly marine area
Fish		
Heraldia nocturna Upside-down Pipefish, Eastern Upside-down Pipefish, Eastern Upside-down Pipefish [66227]		Species or species habitat may occur within area

Scientific Name	Threatened Category	Presence Text
Hippocampus abdominalis Big-belly Seahorse, Eastern Potbelly Seahorse, New Zealand Potbelly Seahorse [66233]		Species or species habitat may occur within area
Hippocampus breviceps Short-head Seahorse, Short-snouted Seahorse [66235]		Species or species habitat may occur within area
Hippocampus minotaur Bullneck Seahorse [66705]		Species or species habitat may occur within area
Histiogamphelus briggsii Crested Pipefish, Briggs' Crested Pipefish, Briggs' Pipefish [66242]		Species or species habitat may occur within area
Histiogamphelus cristatus Rhino Pipefish, Macleay's Crested Pipefish, Ring-back Pipefish [66243]		Species or species habitat may occur within area
Hypselognathus rostratus Knifesnout Pipefish, Knife-snouted Pipefish [66245]		Species or species habitat may occur within area
Kaupus costatus Deepbody Pipefish, Deep-bodied Pipefish [66246]		Species or species habitat may occur within area
Kimblaeus bassensis Trawl Pipefish, Bass Strait Pipefish [66247]		Species or species habitat may occur within area
Leptoichthys fistularius Brushtail Pipefish [66248]		Species or species habitat may occur within area
Lissocampus caudalis Australian Smooth Pipefish, Smooth Pipefish [66249]		Species or species habitat may occur within area
Lissocampus runa Javelin Pipefish [66251]		Species or species habitat may occur within area

Scientific Name	Threatened Category	Presence Text
Maroubra perserrata Sawtooth Pipefish [66252]		Species or species habitat may occur within area
Mitotichthys mollisoni Mollison's Pipefish [66260]		Species or species habitat may occur within area
Mitotichthys semistriatus Halfbanded Pipefish [66261]		Species or species habitat may occur within area
Mitotichthys tuckeri Tucker's Pipefish [66262]		Species or species habitat may occur within area
Notiocampus ruber Red Pipefish [66265]		Species or species habitat may occur within area
Phycodurus eques Leafy Seadragon [66267]		Species or species habitat may occur within area
Phyllopteryx taeniolatus Common Seadragon, Weedy Seadragon [66268]		Species or species habitat may occur within area
Pugnaso curtirostris Pugnose Pipefish, Pug-nosed Pipefish [66269]		Species or species habitat may occur within area
Solegnathus robustus Robust Pipehorse, Robust Spiny Pipehorse [66274]		Species or species habitat may occur within area
Solegnathus spinosissimus Spiny Pipehorse, Australian Spiny Pipehorse [66275]		Species or species habitat may occur within area
Stigmatopora argus Spotted Pipefish, Gulf Pipefish, Peacock Pipefish [66276]		Species or species habitat may occur within area

Scientific Name	Threatened Category	Presence Text
Stigmatopora nigra Widebody Pipefish, Wide-bodied Pipefish, Black Pipefish [66277]		Species or species habitat may occur within area
Stipecampus cristatus Ringback Pipefish, Ring-backed Pipefish [66278]		Species or species habitat may occur within area
Urocampus carinirostris Hairy Pipefish [66282]		Species or species habitat may occur within area
Vanacampus margaritifer Mother-of-pearl Pipefish [66283]		Species or species habitat may occur within area
Vanacampus phillipi Port Phillip Pipefish [66284]		Species or species habitat may occur within area
Vanacampus poecilolaemus Longsnout Pipefish, Australian Long-snout Pipefish, Long-snouted Pipefish [66285]		Species or species habitat may occur within area
Mammal		
Arctocephalus forsteri Long-nosed Fur-seal, New Zealand Fur-seal [20]		Species or species habitat may occur within area
Arctocephalus pusillus Australian Fur-seal, Australo-African Fur-seal [21]		Breeding known to occur within area
Neophoca cinerea Australian Sea-lion, Australian Sea Lion [22]	Endangered	Species or species habitat may occur within area
Reptile		
Caretta caretta Loggerhead Turtle [1763]	Endangered	Foraging, feeding or related behaviour known to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Species or species habitat may occur within area

Scientific Name	Threatened Category	Presence Text
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Foraging, feeding or related behaviour known to occur within area

Whales and Other Cetaceans [Resource Information]

Current Scientific Name	Status	Type of Presence
Mammal		
Balaenoptera acutorostrata Minke Whale [33]		Species or species habitat may occur within area
Balaenoptera bonaerensis Antarctic Minke Whale, Dark-shoulder Minke Whale [67812]		Species or species habitat likely to occur within area
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Foraging, feeding or related behaviour known to occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Berardius arnuxii Arnoux's Beaked Whale [70]		Species or species habitat may occur within area
Caperea marginata Pygmy Right Whale [39]		Foraging, feeding or related behaviour likely to occur within area
Delphinus delphis Common Dolphin, Short-beaked Common Dolphin [60]		Species or species habitat may occur within area
Eubalaena australis Southern Right Whale [40]	Endangered	Breeding known to occur within area

Current Scientific Name	Status	Type of Presence
Globicephala macrorhynchus Short-finned Pilot Whale [62]		Species or species habitat may occur within area
Globicephala melas Long-finned Pilot Whale [59282]		Species or species habitat may occur within area
Grampus griseus Risso's Dolphin, Grampus [64]		Species or species habitat may occur within area
Hyperoodon planifrons Southern Bottlenose Whale [71]		Species or species habitat may occur within area
Kogia breviceps Pygmy Sperm Whale [57]		Species or species habitat may occur within area
Kogia sima Dwarf Sperm Whale [85043]		Species or species habitat may occur within area
Lagenorhynchus obscurus Dusky Dolphin [43]		Species or species habitat likely to occur within area
Lissodelphis peronii Southern Right Whale Dolphin [44]		Species or species habitat may occur within area
Megaptera novaeangliae Humpback Whale [38]		Species or species habitat known to occur within area
Mesoplodon bowdoini Andrew's Beaked Whale [73]		Species or species habitat may occur within area
Mesoplodon densirostris Blainville's Beaked Whale, Dense-beaked Whale [74]		Species or species habitat may occur within area

Current Scientific Name	Status	Type of Presence
Mesoplodon grayi Gray's Beaked Whale, Scamperdown Whale [75]		Species or species habitat may occur within area
Mesoplodon hectori Hector's Beaked Whale [76]		Species or species habitat may occur within area
Mesoplodon layardii Strap-toothed Beaked Whale, Strap-toothed Whale, Layard's Beaked Whale [25556]		Species or species habitat may occur within area
Mesoplodon mirus True's Beaked Whale [54]		Species or species habitat may occur within area
Orcinus orca Killer Whale, Orca [46]		Species or species habitat likely to occur within area
Physeter macrocephalus Sperm Whale [59]		Species or species habitat may occur within area
Pseudorca crassidens False Killer Whale [48]		Species or species habitat likely to occur within area
Tasmacetus shepherdi Shepherd's Beaked Whale, Tasman Beaked Whale [55]		Species or species habitat may occur within area
Tursiops aduncus Indian Ocean Bottlenose Dolphin, Spotted Bottlenose Dolphin [68418]		Species or species habitat likely to occur within area
Tursiops truncatus s. str. Bottlenose Dolphin [68417]		Species or species habitat may occur within area
Ziphius cavirostris Cuvier's Beaked Whale, Goose-beaked Whale [56]		Species or species habitat may occur within area

Key Ecological Features [Resource Information]

Key Ecological Features are the parts of the marine ecosystem that are considered to be important for the biodiversity or ecosystem functioning and integrity of the Commonwealth Marine Area.

Name	Region
Bonney Coast Upwelling	South-east
West Tasmania Canyons	South-east

Biologically Important Areas [Resource Information]

Scientific Name	Behaviour	Presence
Seabirds		
Ardenna pacifica Wedge-tailed Shearwater [84292]	Breeding	Known to occur
Ardenna tenuirostris Short-tailed Shearwater [82652]	Breeding	Known to occur
Ardenna tenuirostris Short-tailed Shearwater [82652]	Foraging	Likely to occur
Ardenna tenuirostris Short-tailed Shearwater [82652]	Foraging	Known to occur

Scientific Name	Behaviour	Presence
Diomedea exulans (sensu lato) Wandering Albatross [1073]	Foraging	Known to occur
Diomedea exulans antipodensis Antipodean Albatross [82269]	Foraging	Known to occur
Eudyptula minor Little Penguin [1085]	Breeding	Known to occur
Eudyptula minor Little Penguin [1085]	Foraging	Known to occur
Morus serrator Australasian Gannet [1020]	Aggregation	Known to occur
Morus serrator Australasian Gannet [1020]	Foraging	Known to occur
Pelagodroma marina White-faced Storm-petrel [1016]	Breeding	Known to occur
Pelagodroma marina White-faced Storm-petrel [1016]	Foraging	Known to occur
Pelecanoides urinatrix Common Diving-petrel [1018]	Breeding	Known to occur
Pelecanoides urinatrix Common Diving-petrel [1018]	Foraging	Known to occur
Phalacrocorax fuscescens Black-faced Cormorant [59660]	Breeding	Known to occur
Phalacrocorax fuscescens Black-faced Cormorant [59660]	Foraging	Known to occur
Thalassarche bulleri Bullers Albatross [64460]	Foraging	Known to occur
Thalassarche cauta cauta Shy Albatross [82345]	Foraging likely	Likely to occur

Scientific Name	Behaviour	Presence
Thalassarche chlororhynchos bassi Indian Yellow-nosed Albatross [85249]	Foraging	Known to occur
Thalassarche melanophris Black-browed Albatross [66472]	Foraging	Known to occur
Thalassarche melanophris impavida Campbell Albatross [82449]	Foraging	Known to occur
Sharks		
Carcharodon carcharias White Shark [64470]	Foraging	Known to occur
Whales		
Balaenoptera musculus brevicauda Pygmy Blue Whale [81317]	Foraging	Likely to be present
Balaenoptera musculus brevicauda Pygmy Blue Whale [81317]	Foraging (annual high use area)	Known to occur
Balaenoptera musculus brevicauda Pygmy Blue Whale [81317]	Known Foraging Area	Known to occur

Caveat

1 PURPOSE

This report is designed to assist in identifying the location of matters of national environmental significance (MNES) and other matters protected by the Environment Protection and Biodiversity Conservation Act 1999 (Cth) (EPBC Act) which may be relevant in determining obligations and requirements under the EPBC Act.

The report contains the mapped locations of:

- World and National Heritage properties;
- Wetlands of International and National Importance;
- Commonwealth and State/Territory reserves;
- distribution of listed threatened, migratory and marine species;
- listed threatened ecological communities; and
- other information that may be useful as an indicator of potential habitat value.

2 DISCLAIMER

This report is not intended to be exhaustive and should only be relied upon as a general guide as mapped data is not available for all species or ecological communities listed under the EPBC Act (see below). Persons seeking to use the information contained in this report to inform the referral of a proposed action under the EPBC Act should consider the limitations noted below and whether additional information is required to determine the existence and location of MNES and other protected matters.

Where data is available to inform the mapping of protected species, the presence type (e.g. known, likely or may occur) that can be determined from the data is indicated in general terms. It is the responsibility of any person using or relying on the information in this report to ensure that it is suitable for the circumstances of any proposed use. The Commonwealth cannot accept responsibility for the consequences of any use of the report or any part thereof. To the maximum extent allowed under governing law, the Commonwealth will not be liable for any loss or damage that may be occasioned directly or indirectly through the use of, or reliance on the contents of this report.

3 DATA SOURCES

Threatened ecological communities

For threatened ecological communities where the distribution is well known, maps are generated based on information contained in recovery plans, State vegetation maps and remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

Threatened, migratory and marine species

Threatened, migratory and marine species distributions have been discerned through a variety of methods. Where distributions are well known and if time permits, distributions are inferred from either thematic spatial data (i.e. vegetation, soils, geology, elevation, aspect, terrain, etc.) together with point locations and described habitat; or modelled (MAXENT or BIOCLIM habitat modelling) using point locations and environmental data layers.

Where little information is available for a species or large number of maps are required in a short time-frame, maps are derived either from 0.04 or 0.02 decimal degree cells; by an automated process using polygon capture techniques (static two kilometre grid cells, alpha-hull and convex hull); or captured manually or by using topographic features (national park boundaries, islands, etc.).

In the early stages of the distribution mapping process (1999-early 2000s) distributions were defined by degree blocks, 100K or 250K map sheets to rapidly create distribution maps. More detailed distribution mapping methods are used to update these distributions when time permits.

4 LIMITATIONS

The following species and ecological communities have not been mapped and do not appear in this report:

- threatened species listed as extinct or considered vagrants;
- some recently listed species and ecological communities;
- some listed migratory and listed marine species, which are not listed as threatened species; and
- migratory species that are very widespread, vagrant, or only occur in Australia in small numbers.

The following groups have been mapped, but may not cover the complete distribution of the species:

- listed migratory and/or listed marine seabirds, which are not listed as threatened, have only been mapped for recorded breeding sites; and
- seals which have only been mapped for breeding sites near the Australian continent

The breeding sites may be important for the protection of the Commonwealth Marine environment.

Refer to the metadata for the feature group (using the Resource Information link) for the currency of the information.

Acknowledgements

This database has been compiled from a range of data sources. The department acknowledges the following custodians who have contributed valuable data and advice:

TABLE OF TABLES

1. INTRODUCTION

1.1 Background

This report presents the results of the environmental survey of offshore gas fields in Otway Basin for Beach Energy. Beach Energy is planning further development of the Otway offshore natural gas reserves within existing Commonwealth offshore exploration permits and production licenses. The offshore Otway Basin gas exploration and development program may include drilling up to nine wells using a contracted semi-submersible drill rig, over a 12- to 18-month period. Additional seabed infrastructure would also be installed to tie-in new wells after the drilling phase.

As part of this plan, Fugro Australia Marine Pty Ltd (Fugro) carried out offshore geophysical and geotechnical surveys and Ramboll Australia Pty Ltd (Ramboll) were contracted by Fugro to carry out the environmental survey. These activities were in Commonwealth waters approximately 32 to 80 km from Port Campbell and in water depths ranging from 70 to 104 m.

1.2 Objective

The objective of the seabed site assessments was to determine suitable locations for anchoring and rig placement for drilling operations and the installation of infrastructure to connect new production wells to the existing platform or pipeline. Several different investigation techniques were used to examine and describe the seabed, as well as identify possible hazards from man-made, natural and geological features.

1.3 Report Scope

The scope of the environmental survey carried out in Otway Basin included investigations of:
- Water quality;
- Sediment quality;
- Benthic infauna; and
- Benthic epifauna.

Water quality assessments included laboratory analyses for:
- Suspended solids
- Nutrients
- Chlorophyll *a*
- Metals/metalloids
- Hydrocarbons

Sediment quality assessments included laboratory analyses for:
- Sediment particle size
- Total organic carbon
- Nutrients
- Metals/metalloids

Infauna were microscopically examined to determine taxonomic identification to Family level and morpho-species, and abundance was recorded. The composition and percent cover of epifauna was determined from seabed photographs.

2. SURVEY LOCATIONS

These investigations were based around five survey areas including:

- Thylacine;
- Artisan;
