Pluto Facility Operations Environment Plan

Australian Operations

April 2025

Revision 15

This page has been intentionally left blank

TABLE OF CONTENTS

1. INTRODUCTION 20
1.1 Overview 20
1.2 Purpose of the Environment Plan 21
1.3 Scope of the Environment Plan 21
1.4 Environment Plan Summary 21
1.5 Structure of the Environment Plan 22
1.6 Description of the Titleholder 24
1.7 Details of Titleholder and Nominated Liaison 24
1.7.1 Titleholder 25
1.7.2 Nominated Liaison 25
1.7.3 Arrangements for Notifying Change 25
1.8 Woodside Management System 25
1.8.1 Environment and Biodiversity Policy 27
1.9 Description of Relevant Requirements 27
1.9.1 Offshore Petroleum and Greenhouse Gas Storage Act 2006 28
1.9.2 Environment Protection and Biodiversity Conservation Act 1999 (Cth) 29
1.9.3 Offshore Project Approval 29
1.9.4 Recovery Plans and Threat Abatement Plans 32
1.9.5 Australian Marine Parks 32
1.9.6 World Heritage Properties 34
2. ENVIRONMENT PLAN PROCESS 35
2.1 Overview 35
2.2 Environmental Risk Management Methodology 35
2.2.1 Woodside Risk Management Process 35
2.2.2 Health, Safety and Environment Management Procedure 36
2.2.3 Impact Assessment Procedure 36
2.2.4 Process Safety Management Procedure and Process Safety Risk Assessment Procedure 37
2.3 Environment Plan Development Process 37
2.4 Establish the Context 38
2.4.1 Define the Activity 38
2.4.2 Define the Existing Environment 38
2.4.3 Relevant Requirements 39
2.5 Impact and Risk Identification 39
2.6 Impact and Risk Analysis 40
2.6.1 Decision Support Framework 40
2.6.1.1 Decision Type A 41
2.6.1.2 Decision Type B 41
2.6.1.3 Decision Type C 41
2.6.1.4 Decision Support Framework Tools 42
2.6.1.5 Decision Calibration 42
2.6.2 Control Measures (Hierarchy of Controls) 43

2.6.3 Impact and Risk Classification 43
2.6.4 Risk Rating Process 44
2.6.5 Select the Consequence Level 45
2.6.6 Select the Likelihood Level 45
2.6.7 Calculate the Risk Rating 45
2.7 Classification and Analysis of Major Environment Events (MEEs) 46
2.7.1 Major Environment Event Identification 46
2.7.2 MEE Classification 47
2.7.3 Bowtie Analysis 47
2.7.4 MEE Register 49
2.7.5 Safety and Environment Critical Elements and Technical Performance Standards 49
2.7.6 Safety-critical Management System Barriers 50
2.8 Impact and Risk Evaluation 50
2.8.1 Demonstration of ALARP 50
2.8.2 Demonstration of Acceptability 51
2.9 Recovery Plan and Threat Abatement Plan Assessment 51
2.10 Environmental Performance Outcomes, Environmental Performance Standards, and Measurement Criteria 52
2.11 Implement, Monitor, Review and Reporting 52
2.12 Consultation 52
3. DESCRIPTION OF THE ACTIVITY 53
3.1 Overview 53
3.1.1 Pluto Facility Operations Overview 53
3.1.2 Xena-03 Tie-back Overview 53
3.2 Location 55
3.2.1 Petroleum Activities Area 58
3.2.2 Pluto Operational Area 58
3.2.3 Xena-03 Operational Area 58
3.3 Timing 59
3.3.1 Pluto Operations 59
3.3.2 Xena-03 Tie-back Activities 59
3.4 Facility Layout and Description 59
3.4.1 Pluto Alpha Topsides 59
3.4.2 Wells and Reservoirs 62
3.4.2.1 Pluto Wells 62
3.4.2.2 Xena Wells 62
3.4.2.3 Pyxis Wells 63
3.4.3 Flowline and Riser System 63
3.4.4 Wet Flowline Conversions 64
3.4.5 Pipeline and 6-inch Chemical Supply Line 64
3.4.6 Subsea Infrastructure 66
3.4.6.1 Flowlines Interactions 66
3.4.6.2 Export Pipeline Interactions 67
3.4.7 Field Inventory 69

3.5 Operational Details 70
3.5.1 Production Remote Operations 70
3.5.2 Major Projects 70
3.5.3 Maintenance including Inspection, Monitoring, Maintenance and Repair Subsea Activities 71
3.5.4 Process and Production Description 71
3.5.5 Produced Water System 72
3.5.5.1 Produced Water Treatment System 73
3.5.5.2 Produced Water Discharge Oil in Water Monitoring 73
3.5.5.3 Produced Water Discharge Monitoring 74
3.5.6 Utility Gas and Flare System 74
3.5.7 Drainage Systems 75
3.5.7.1 Closed Drains 75
3.5.7.2 Hazardous Open Drains 75
3.5.7.3 Non-hazardous Open Drains 76
3.6 Utility Systems 76
3.6.1 Platform Lighting 76
3.6.2 Heating, Ventilation and Air Conditioning System 76
3.6.3 Potable Water 76
3.6.4 Monoethylene Glycol System 76
3.6.5 Power Generation 77
3.6.6 Sewage and Putrescible Wastes 77
3.6.7 Sand Management 78
3.6.8 Diesel Fuel System 78
3.6.9 Hydraulic Fluid System 78
3.7 Facility Operations 79
3.7.1 Operational Flaring 79
3.7.2 Normal Operations 79
3.7.3 Intermittent Process Upsets and Activities 79
3.7.3.1 Operational Pigging 79
3.7.3.2 Emergency Blowdown 79
3.7.3.3 Manual Depressurisation 80
3.7.3.4 Subsea Flowline Depressurisation 80
3.7.3.5 Estimated Flare Volumes 80
3.7.4 Greenhouse Gas Emissions 80
3.7.5 Lifting Operations 81
3.7.5.1 Routine Lifting from Platform Support Vessels 81
3.7.5.2 Lifting Around the Facility 81
3.7.5.3 Operational Lifting (Non-crane Based) 81
3.7.6 Safety Features and Emergency Systems 81
3.8 Support Vessel Operations 82
3.8.1 Platform Support Vessels 82
3.8.2 Subsea Support Vessels 83
3.8.3 Accommodation Support Vessel 84
3.8.4 Uncrewed Surface Vessel 84

3.8.5 Remotely Operated Vehicles 85
3.8.6 Helicopter Operations 85
3.9 Hydrocarbon and Chemical Inventories and Selection 85
3.9.1 Hydrocarbons 85
3.9.2 Chemical Usage 86
3.9.3 Operational Chemicals 86
3.9.3.1 Operational Process Chemicals 86
3.9.3.2 Operational Non-Process Chemicals 86
3.9.4 Maintenance Chemicals 86
3.9.5 Indicative Chemical Inventories 87
3.9.6 Environmental Consideration during Selection, Assessment and Approval of Chemicals 87
3.9.7 Environmental Selection Criteria 87
3.9.8 Background Overview of the Offshore Chemical Notification Scheme 88
3.10 Subsea Inspection, Maintenance, Monitoring and Repair Activities 89
3.10.1 Overview 89
3.10.1.1 Inspection 89
3.10.1.2 Monitoring 91
3.10.1.3 Maintenance 91
3.10.1.4 Repair 91
3.10.2 Subsea Chemical Usage 92
3.10.3 Marine Growth Removal 93
3.10.4 Intervention Isolations 93
3.10.5 Pipeline Pigging Operations 93
3.10.6 Sediment Relocation 93
3.10.7 Corrosion Protection 94
3.10.8 Span Rectification, Pipeline Protection and Stabilisation 94
3.10.8.1 Grout Bags 94
3.10.8.2 Mattresses 95
3.10.8.3 Rock Placement 95
3.10.9 Suspension and Preservation of Redundant Equipment 95
3.10.10 Well Management and Maintenance Activities 96
3.10.10.1 Well Unloading and Clean-up 96
3.11 Xena-03 Drilling and Tie-back Activities 96
3.11.1 Drilling Activities 96
3.11.1.1 Cement Unit Test 96
3.11.1.2 Top Hole Section Drilling 96
3.11.1.3 Blowout Preventer and Marine Riser Installation 97
3.11.1.4 Bottom Hole Section Drilling 97
3.11.1.5 Formation Evaluation 97
3.11.1.6 Wellbore Clean Out 98
3.11.1.7 Xmas Tree Installation 98
3.11.1.8 Completions Activities 98
3.11.1.9 Well Unload 98
3.11.2 Drilling Fluid System 99
3.11.2.1 Water-based Mud System 99
3.11.2.2 Mud Pits 99

3.11.2.3 Drill Cuttings 99
3.11.2.4 Cement, Barite and Bentonite Discharge 100
3.11.3 Subsea Installation and Pre-commissioning Activities 100
3.11.3.1 Underwater Acoustic Positioning 100
3.11.3.2 Installation of Structures 101
3.11.3.3 Flexible Flowline Initiation/Initiation Anchor Deployment 101
3.11.3.4 General Flexible Flowline and Flying Leads Installation 101
3.11.3.5 Span/Scouring Rectification and Stabilisation 102
3.11.3.6 Pre-commissioning of the Flexible Flowline 102
3.11.3.7 Tie-in of Flowlines at Pluto Manifold 103
3.11.3.8 Cold Commissioning of Subsea Infrastructure 103
3.11.3.9 Wet Storage of Equipment 103
3.11.3.10 Maintenance of Subsea Infrastructure 104
3.11.3.11 Site Surveys 104
3.11.4 Xena-03 Commissioning (Initial Start-up) Activities 104
3.11.5 Contingent Activities for the Xena-03 Tie-back 104
3.11.5.1 Respud 105
3.11.5.2 Sidetrack 105
3.11.5.3 Workover 105
3.11.5.4 Non-water-based Mud System 105
3.11.5.5 Well Suspension 106
3.11.5.6 Wireline Logging 106
3.11.5.7 Well Intervention 106
3.11.5.8 Well Abandonment 106
3.11.5.9 Wellhead Assembly Left In-situ 107
3.11.5.10 Sediment Mobilisation and Relocation 107
3.11.5.11 Venting 107
3.11.5.12 Emergency Disconnect Sequence 107
3.12 Vessel-based Activities for the Xena-03 Tie-back 107
3.12.1 Mobile Offshore Drilling Unit 108
3.12.2 Installation Vessels 108
3.12.3 Support and Other Vessels 109
3.12.4 Subsea Support Vessel for Light Well Intervention Activities 109
3.12.5 Holding Station: Mooring Installation and Anchor Hold Testing/Soil Analysis 109
3.12.6 Holding Station: Rig Anchor Release Mobile Offshore Drilling Unit 110
3.12.7 Mobile Offshore Drilling Unit and Support Vessel Activities 110
3.12.8 Subsea Installation and Support Vessel Activities 111
3.12.9 Refuelling 111
4. DESCRIPTION OF THE EXISTING ENVIRONMENT 112
4.1 Overview 112
4.2 Regional Context 115
4.3 Matters of National Environmental Significance (EPBC Act) 115
4.4 Physical Environment 116
4.5 Habitats and Biological Communities 119
4.6 Protected Species 122
4.6.1 Fish, Sharks and Rays 123
4.6.2 Marine Reptiles 127

4.6.3 Marine Mammals 136
4.6.4 Seabirds and Migratory Shorebirds 142
4.6.5 Seasonal Sensitivities for Protected Species 149
4.7 Key Ecological Features 151
4.8 Protected Places 153
4.9 Cultural Features and Heritage Values 157
4.9.1 Background 157
4.9.2 First Nations People 157
4.9.3 Coastally Adjacent First Nations Groups 158
4.9.4 Sea Country Values 162
4.9.4.1 Desktop Assessment of Sea Country Values 162
4.9.4.2 Summary of Cultural Features and Heritage Values 182
4.9.5 Murujuga Cultural Landscape 193
4.9.6 Summary of Existing Research on Murujuga Petroglyphs and Anthropogenic Air Emissions 197
4.9.6.1 Research, Monitoring and Publications 199
4.9.7 Historic Sites of Significance 204
4.9.8 Historic Underwater Heritage 204
4.9.9 World, National and Commonwealth Heritage Listed Places 205
4.10 Socio-economic Environment 205
4.10.1 Commercial Fisheries 205
4.10.2 Traditional Fisheries 217
4.10.3 Tourism and Recreation 217
4.10.4 Commercial Shipping 217
4.10.5 Oil and Gas 220
4.10.6 Submarine Communications Infrastructure 222
4.10.7 Defence 222
5. CONSULTATION 224
5.1 Summary 224
5.2 Consultation – General Context 225
5.3 Identification of Relevant Persons for Consultation 228
5.3.1 Regulations 25(1)(a), (b) and (c) 228
5.3.2 Identification of Relevant Persons under Regulations 25(1)(a), (b) and (c) 229
5.3.3 Regulation 25(1)(d) 230
5.3.4 Identification of Relevant Persons under Regulation 25(1)(d) 230
5.3.5 Regulation 25(1)(e) 236
5.3.6 Identification of Relevant Persons under Regulation 25(1)(e) 236
5.3.7 Persons or Organisations Woodside Chooses to Contact 237
5.3.8 Assessment of Relevant Persons for the Proposed Activity 237
5.4 Consultation Material and Timing 237
5.4.1 Sufficient Information 237
5.4.2 Reasonable Period for Consultation 240
5.4.3 Discharge of Regulation 25 241
5.5 Context of Consultation Approach with First Nations 242

5.5.1 Approach to Methodology − Woodside's Interpretation of Tipakalippa Appeal 242
5.5.2 Consultation Method 243
5.5.3 Identification of Relevant Persons 245
5.5.4 Opportunity to Self-identify and Identifying Other Individuals 246
5.5.5 Sufficient Information 247
5.5.6 Reasonable Period for Consultation 247
5.5.7 Discharge of Regulation 25 248
5.6 Providing Feedback and Assessment of Merit of Objections or Claims 248
5.7 Ongoing Consultation 248
6. ENVIRONMENTAL IMPACT AND RISK ASSESSMENT, PERFORMANCE OUTCOMES, STANDARDS AND MEASUREMENT CRITERIA 250
6.1 Overview 250
6.2 Analysis and Evaluation 250
6.2.1 Cumulative Impacts 257
6.3 Environmental Performance Outcomes, Standards and Measurement Criteria 257
6.4 Presentation 257
6.5 Environment Risk/Impacts not Deemed Credible 259
6.5.1 Shallow/Near-shore Activities 260
6.6 Indirect Impacts 260
6.7 Planned Activities 261
6.7.1 Physical Presence: Interaction with Other Marine Users 261
6.7.2 Physical Presence: Disturbance to the Seabed 274
6.7.3 Acoustic Emissions: Generation of Noise for Facility Operations 289
6.7.4 Acoustic Emissions: Generation of Noise During Xena-03 Tie-back Activities 308
6.7.5 Routine and Non-routine Discharges: Discharge of Hydrocarbons and Chemicals 327
6.7.6 Routine and Non-routine Marine Wastewater Discharges: Utility Systems and Drains 340
6.7.7 Routine and Non-routine Discharges: Produced Water 349
6.7.8 Routine and Non-routine Discharges: Drill Cuttings, Drilling Fluids and Well Removal Fluids 378
6.7.9 Routine and Non-routine Discharges: Cement, Cementing Fluids, Subsea Well Fluids, Unused Bulk Product and Subsea Chemicals from Xena-03 Tie-back Activities 396
6.7.10 Routine and Non-routine Atmospheric (Direct) and Greenhouse Gas Emissions (Direct and Indirect) 406
6.7.11 Routine Atmospheric Emissions: Indirect Emissions associated with Gas Processing Onshore 454
6.7.12 Routine Light Emissions: Light Emissions from Facility Operations and Xena-03 Tie-back Activities 479
6.8 Unplanned Activities (Accidents, Incidents, Emergency Situations) – Major Environmental Events 491
6.8.1 Major Environmental Events Overview 491
6.8.2 Quantitative Spill Risk Assessment Methodology 493
6.8.2.1 Hydrocarbon Characteristics 494
6.8.2.2 EMBA and Hydrocarbon Contact Thresholds 501
6.8.3 Unplanned Hydrocarbon Release: Loss of Well Containment from Operating Wells (MEE-01) 504

6.8.4 Unplanned Hydrocarbon Release: Subsea Equipment Loss of Containment (MEE-02) 527
6.8.5 Unplanned Hydrocarbon Release: Loss of Structural Integrity (MEE-03) 551
6.8.6 Unplanned Hydrocarbon Release: Loss of Marine Vessel Separation (MEE-04) 563
6.8.7 Unplanned Hydrocarbon Release: Loss of Control of Suspended Load from Platform (MEE-05) 580
6.8.8 Major Environmental Events Common Cause Event Failure Mechanisms: Safety and Environmental Critical Element Failure CCE-01 and Human Error CCE-02 589
6.9 Unplanned Events (Accidents, Incidents, Emergency Situations)..... 600
6.9.1 Unplanned Hydrocarbon Release: Loss of Well Containment during Drilling of Xena-03 600
6.9.2 Unplanned Hydrocarbon Release: Pluto-A Topsides Loss of Containment 614
6.9.3 Unplanned Hydrocarbon Release: Vessel Collision During Drilling and Tie-back Activities 620
6.9.4 Unplanned Hydrocarbon or Chemical Release: Hydrocarbon Release During Bunkering, Refuelling and Chemical Release during Transfer, Storage and Use, Rupture of Chemical Supply Lines – Pluto Operations 633
6.9.5 Unplanned Hydrocarbon or Chemical Release: Bunkering, Deck and Subsea Spills – Xena-03 Tie-back 643
6.9.6 Unplanned Discharges: Drilling Fluids..... 657
6.9.7 Unplanned Discharges: Hazardous and Non-hazardous Waste Management 666
6.9.8 Physical Presence: Seabed Disturbance from Dropped Objects or Loss of Station Keeping Leading to Anchor Drag 674
6.9.9 Physical Presence: Interactions with Marine Fauna 681
6.9.10 Physical Presence: Introduction of Invasive Marine Species..... 686
6.9.11 Physical Presence (Unplanned): Interaction with Live Infrastructure 697
6.10 Recovery Plan and Threat Abatement Plan Assessment 703
6.11 First Nations Cultural Features and Heritage Values Assessment 720
7. IMPLEMENTATION STRATEGY 738
7.1 Overview..... 738
7.2 Systems, Practice and Procedures 738
7.2.1 Woodside Management System Operate Processes 738
7.2.1.1 Operate Plant 738
7.2.1.2 Maintain Assets 739
7.2.2 Process Safety Management 740
7.2.2.1 Woodside Safety Culture Framework..... 740
7.2.3 Offshore Marine Discharge Adaptive Management Plan 741
7.2.3.1 Overview..... 741
7.2.3.2 Routine Monitoring and Management 741
7.2.3.3 Further Investigations 743
7.2.3.4 ALARP/Acceptability Study..... 744
7.2.3.5 Review and revision..... 744
7.2.4 Woodside Invasive Marine Species Risk Assessment Process..... 744
7.2.4.1 Objective and Scope..... 744
7.2.4.2 Risk Assessment Process 745
7.2.5 Risk Management..... 747
7.2.6 Management of Risks – Contracting and Procurement 748

7.2.7 Management of Risks – Subsea Activities 748
7.2.8 Management of Risks – Major Projects 749
7.2.9 Management of Risks – Well Integrity 749
7.2.10 Management of Risks – Marine Services 749
7.2.11 Management of Risks – Emissions and Energy Management 749
7.2.11.1 Production Optimisation and Opportunity Management 750
7.2.11.2 Flare and Emissions Target Setting 750
7.2.11.3 Methane Management 751
7.2.12 Management of Risks – Indirect Greenhouse Gas Emissions Management 751
7.2.12.1 Annual Review 752
7.2.13 Management of Human Factor Related Risks 753
7.3 Change Management 753
7.3.1 Technical Change Management 753
7.3.2 Environment Plan Management of Change and Revision 754
7.3.3 Oil Pollution Emergency Plan Management of Change 754
7.4 Management of Safety and Critical Element Technical Performance Standards and Management System Performance Standards 755
7.4.1 Management System Performance Standards 755
7.4.2 Safety and Environmental Critical Element Technical Performance Standards 755
7.5 Woodside's Decommissioning Framework 757
7.5.1 Decommissioning in Operations 758
7.5.2 Facility Decommissioning Planning 758
7.5.3 Pluto Decommissioning Strategy 758
7.5.4 Pluto Decommissioning Phasing 759
7.5.4.1 Phase 1: Planning for Decommissioning – Key Activities 761
7.5.4.2 Phase 2: Execute Decommissioning and Plug and Abandonment – Key Activities 761
7.6 Organisation Structure 761
7.7 Roles and Responsibilities 762
7.8 Unexpected Finds Procedure 769
7.9 Training and Competency 769
7.9.1 Inductions and Training 770
7.9.2 Activities Program Specific Environmental Awareness 770
7.9.3 Inductions for Offshore Facility Workers and Visitors 771
7.9.4 Operations Competency Framework Training 771
7.9.5 Permit to Work System Training 772
7.9.6 Emergency and Hydrocarbon Spill Response Training 772
7.9.7 Subsea Inspection, Monitoring, Maintenance and Repair Activity Environmental Awareness 772
7.9.8 Management of Training Requirements 773
7.9.9 Cetacean and Whale Shark Sightings Reporting 773
7.9.10 Marine Fauna Observation Training 773
7.10 Monitoring, Auditing, Management of Non-conformance and Review 774
7.10.1 Monitoring 774
7.10.1.1 Source-based Impacts and Risks 774

7.10.1.2 Internal Auditing and Assurance Program 774
7.10.1.3 Management of Knowledge 776
7.10.1.4 Management of Newly Identified Impacts and Risks 776
7.10.2 Auditing 776
7.10.2.1 Mobile Offshore Drilling Unit Activities 777
7.10.2.2 Project Subsea Scope Activities 777
7.10.2.3 Operations Assurance 778
7.10.2.4 Annual Offshore Inspection/Desktop Review 779
7.10.2.5 Marine Assurance 779
7.10.2.6 Vessel Risk Assessment 780
7.10.3 Management of Non-conformance 781
7.10.4 Review 781
7.10.4.1 Management Review 781
7.10.4.2 Program of Ongoing Engagement with Traditional Custodians 781
7.10.4.3 Learning and Knowledge Sharing 782
7.10.4.4 Continuous Improvement 782
7.11 Record Keeping 782
7.12 Ongoing Consultation 782
7.13 Reporting 785
7.13.1 Overview 785
7.13.2 Routine Reporting (Internal) 785
7.13.2.1 Daily Progress Reports and Meetings 785
7.13.2.2 Regular Health, Safety and Environment Meetings 785
7.13.2.3 Performance Reporting 785
7.13.3 Routine Reporting (External) 785
7.13.3.1 Start and End Notifications of the Petroleum Activities Program 785
7.13.3.2 Cetacean and Whale Shark Sightings Reporting 786
7.13.3.3 Environmental Performance Review and Reporting 786
7.13.3.4 End of the PAP Notification 786
7.13.3.5 End of the Environment Plan 786
7.13.4 Incident Reporting (Internal) 787
7.13.5 Incident Reporting (External) – Reportable and Recordable 787
7.13.5.1 Reportable Incidents 787
7.13.5.2 Recordable Incidents 788
7.13.5.3 Other External Reporting Requirements and Notifications 788
7.14 Emergency Preparedness and Response 790
7.14.1 Overview 790
7.14.2 Emergency Response Training 790
7.14.3 Emergency Response Preparation 791
7.14.4 Emergency Event During Tie-back Activity 792
7.14.5 Initial Response to Facility Incident 792
7.14.6 Oil and Other Hazardous Materials Spill 793
7.14.7 Emergency and Spill Response 793
7.14.7.1 Level 1 Incident 793
7.14.7.2 Level 2 Incident 793
7.14.7.3 Level 3 Incident 793
7.14.8 Source Control Response Capability 793

7.14.8.1 Source Control IMT personnel and resourcing 796
7.14.9 Emergency and Spill Response Drills and Exercises 797
7.14.10 Hydrocarbon Spill Response Testing of Arrangements 798
7.14.10.1 Testing of Arrangements Schedule 799
7.14.10.2 Source Control testing and exercise arrangements 799
7.14.11 Cyclone and Dangerous Weather Preparation 801

1. INTRODUCTION

1.1 Overview

Woodside Burrup Pty. Ltd. (Woodside) is operator of the Pluto offshore facility and export pipeline on behalf of the Pluto Liquefied Natural Gas (LNG) Joint Venture Participants. The Pluto offshore facility (the facility), including the riser platform and subsea hydrocarbon gathering system, has been in production since 2012 and is operated by Woodside under the Petroleum Titles listed in Table 3-1. The facility is located offshore approximately 160 km northwest of Dampier, in WA-1-IL and WA-34-L, while the associated export pipeline and flowlines are within WA-17-PL and WA-16-PL, respectively. The operation of the facility, Xena-03 Drilling and Tie-back activities, and recovery of well fluids from associated fields and subsea infrastructure, is hereafter collectively referred to as the Petroleum Activities Program. Well fluids are recovered from a series of fields via pipelines and subsea infrastructure, which are produced by the facility and exported to the onshore LNG plants for processing. Subsea tiebacks relevant to the facility include:

- Pluto
- Xena-03
- Pyxis.

The Pluto Alpha platform (PLA) combines accommodation, utilities, operation of production facilities and the water treatment module (see Section 3). The platform is designed to be operated in both not-normally crewed and minimally crewed states. The offshore facilities are remotely operated from the Central Control Room (CCR), either from the CCR at Pluto LNG Park (PLP) or Remote CCR in Perth.

This Environment Plan (EP) has been prepared as part of the requirements under the Offshore Petroleum and Greenhouse Gas Storage (Environment) Regulations 2023 (Cth) (referred to as the Environment Regulations), as administered by the National Offshore Petroleum Safety and Environmental Management Authority (NOPSEMA).

In accordance with the requirements of Regulation 41 of the Environment Regulations, Woodside has submitted a revision to the Pluto Facility Operations EP to NOPSEMA at least 14 days prior to the end of the five-year period from the original acceptance under what is now Regulation 35 of the Environment Regulations. At the time of the original acceptance, the relevant provision was Regulation 11 of the Offshore Petroleum and Greenhouse Gas Storage (Environment) Regulations 2009 (Cth).

In accordance with the requirements of Regulation 39 of the Environment Regulations, Woodside has revised the Pluto Facility Operations EP to incorporate a new stage of the activity which is the tie-back, commissioning and operation of the Xena-03 well. Key components of the Xena-03 tie back activity that represent a new stage of the Pluto Facility Operations EP include:

- The activity is a single well; therefore, the Xena-03 well and tieback are proposed to form part of an existing production system.
- The activity would be conducted within the spatial area described in the existing Pluto Facility Operations EP, with a slight temporary expansion to the Operational Area during construction activities.
- The addition of the Xena-03 well forms an orderly continuation of the Pluto project (EPBC 2006/2968) within existing timeframes specified in EPBC approval.
- The operation of proposed Xena-03 well and subsea infrastructure is consistent with the activities already described within this Pluto Facility Operations EP.

- No further increase to the active number of wells producing to the Pluto offshore facility is planned[1].

1.2 Purpose of the Environment Plan

In accordance with the objectives of the Environment Regulations, the purpose of this EP is to demonstrate that:

- The potential environmental impacts and risks (planned (routine and non-routine) and unplanned) that may result from the Petroleum Activities Program (PAP)are identified
- Appropriate management controls are implemented to reduce impacts and risks to a level that is 'as low as reasonably practicable' (ALARP) and acceptable
- The PAP is carried out in a manner consistent with the principles of ecologically sustainable development (ESDev) (as defined in Section 3A of the Environment Protection and Biodiversity Conservation Act 1999 (Cth) (EPBC Act)).

This EP describes the process and resulting outputs of the risk assessment, whereby impacts and risks are managed accordingly.

The EP defines activity-specific environmental performance outcomes, standards, and measurement criteria (MC). These form the basis for monitoring, auditing, and managing the PAP to be undertaken by Woodside and its contractors. The implementation strategy specified in this EP provides Woodside and NOPSEMA with the required level of assurance that impacts and risks associated with the activity are reduced to ALARP and are acceptable.

1.3 Scope of the Environment Plan

The scope of this EP covers the activities that define the Petroleum Activities Program, as described in Section 3, for a period of up to five years. The Petroleum Activities Area (PAA), as defined in Section 3.2.1, defines the spatial boundary of the Petroleum Activities Program.

This EP addresses potential environmental impacts from planned activities and potential unplanned events that originate from within the PAA. Transit to and from the PAA by project vessels, as well as port activities associated with these vessels, are not within the scope of this EP. Vessels supporting the PAP operating outside the PAA (e.g., transiting to and from port) are subject to applicable maritime Regulations and other requirements and are not managed by this EP.

1.4 Environment Plan Summary

Table 1-1 summarises the content of this EP, as required by Regulation 35(7).

[1] Accurate at the time of writing. Should development opportunities be identified during the validity of this EP, Woodside will engage with NOPSEMA to determine the appropriate environmental approval pathway prior to pursuit of the opportunity.

Table 1-1: EP summary

EP Summary Material Requirement	Relevant Section of this EP Containing EP Summary Material
The location of the activity	Section 3.2
A description of the receiving environment	Section 4
A description of the activity	Section 3
Details of the environmental impacts and risks	Section 6
The control measures for the activity	Section 6
The arrangements for ongoing monitoring of the titleholder's environmental performance	Section 7.10
Response arrangements in the oil pollution emergency plan	Section 7.14
Consultation already undertaken and plans for ongoing consultation	Section 5
Details of the titleholder's nominated liaison for the activity	Section 1.7.2

1.5 Structure of the Environment Plan

The EP has been structured to reflect the process and requirements of the Environment Regulations, as outlined in Table 1-2.

Table 1-2: EP process phases, applicable Environment Regulations and relevant section of EP

Criteria for Acceptance	Content Requirements/Relevant Regulations	Elements	Section of EP
Regulation 34(a): is appropriate for the nature and scale of the activity	Regulation 21: Environmental Assessment Regulation 22 Implementation strategy for the environment plan Regulation 24: Other information in the environment plan	The principle of 'nature and scale' applies throughout the EP	Section 2 Section 3 Section 4 Section 5 Section 6 Section 7
Regulation 34(b): demonstrates that the environmental impacts and risks of the activity will be reduced to as low as reasonably practicable	Regulation 21(1)–21(7): 21(1) Description of the activity 21(2)(3) Description of the environment 21(4) Requirements 21(5)(6) Evaluation of environmental impacts and risks 21(7) Environmental performance outcomes and standards Regulation 24(a)–24(c): A statement of the titleholder's corporate environmental policy A report on all consultations between the titleholder and any relevant person	Set the context (activity and existing environment) Define 'acceptable' (the requirements, the corporate policy, relevant persons) Detail the impacts and risks Evaluate the nature and scale Detail the control measures – ALARP and acceptable	Section 1 Section 2 Section 3 Section 4 Section 5 Section 6 Section 7
Regulation 34(c): demonstrates that the environmental impacts and risks of the activity will be of an acceptable level			

Criteria for Acceptance	Content Requirements/Relevant Regulations	Elements	Section of EP
Regulation 34(d): provides for appropriate environmental performance outcomes, EPS and MC	Regulation 21(7): Environmental performance outcomes and standards	Environmental Performance Objectives (EPOs) Environmental Performance Standards (EPSs) Measurement Criteria (MC)	Section 6
Regulation 34(e): includes an appropriate implementation strategy and monitoring, recording, and reporting arrangements	Regulation 22: Implementation strategy for the environment plan	Implementation strategy, including: • Environmental Management System (EMS)Oil Pollution Emergency Plan (OPEP) and scientific monitoring • ongoing consultation.	Section 7 Appendix H
Regulation 34(f): does not involve the activity or part of the activity, other than arrangements for environmental monitoring or for responding to an emergency, being undertaken in any part of a declared World Heritage property within the meaning of the EPBC Act	Regulation 21 (1)–21(3): 21(1) Description of the activity 21(2) Description of the environment 21(3) Without limiting [Regulation 21(2)(b)], relevant values and sensitivities may include any of the following: • (a) the world heritage values of a declared World Heritage property within the meaning of that Act • (b) the national heritage values of a National Heritage place within the meaning of that Act • (c) the ecological character of a declared Ramsar wetland within the meaning of that Act • (c) the presence of a listed threatened species or listed threatened ecological community within the meaning of that Act • (e) the presence of a listed migratory species within the meaning of that Act • (f) any values and sensitivities that exist in, or in relation to, part or all of: • (i) a Commonwealth marine area within the meaning of that Act, or • (ii) Commonwealth land within the meaning of that Act	No activity, or part of the activity, undertaken in any part of a declared World Heritage property	Section 3 Section 4 Section 6

Criteria for Acceptance	Content Requirements/Relevant Regulations	Elements	Section of EP
Regulation 34(g): (i) the titleholder has carried out the consultations required by Regulation 25 (ii) the measures (if any) that the titleholder has adopted, or proposes to adopt, because of the consultations are appropriate	Regulation 25: Consultation with relevant authorities, persons and organisations, etc. Regulation 24(b): A report on all consultations under Regulation 25 of any relevant person by the titleholder, that contains: (i) a summary of each response made by a relevant person, and (ii) an assessment of the merits of any objection or claim about the adverse impact of each activity to which the environment plan relates, and (iii) a statement of the titleholder's response, or proposed response, if any, to each objection or claim, and (iv) a copy of the full text of any response by a relevant person	Consultation in preparation of the EP	Section 5
Regulation 34(h): Complies with the Act, this instrument and any other Regulations made under the Act	Regulation 23: Details of the Titleholder and liaison person Regulation 24(c): Details of all reportable incidents in relation to the proposed activity	All contents of the EP must comply with the Act and the Regulations	Section 1.6 Section 7.12

1.6 Description of the Titleholder

Woodside Burrup Pty Ltd is the operator of the facility and associated infrastructure on behalf of itself and its Pluto LNG joint venture partners, MidOcean Pluto Pty Ltd and Kansai Electric Power Australia Pty Ltd. The Titleholder for this activity is Woodside (refer to Table 3-2 for a list of petroleum titles associated with the Petroleum Activities Program).

Woodside is Australia's leading natural gas producer. Woodside's operations are characterised by strong safety and environmental performance in remote and challenging locations. Wherever Woodside works, it is committed to living its values of one team, we care, innovate every day, results matter and build and maintain trust.

Since 1984, the company has been operating the landmark Australian project, the North West Shelf, which is one of the world's premier liquefied natural gas (LNG) facilities.

Woodside has an excellent track record of efficient and safe production. Woodside strives for excellence in safety and environmental performance and continues to strengthen relationships with customers, partners, co-venturers, governments, and communities. Further information about Woodside can be found at https://www.woodside.com .

1.7 Details of Titleholder and Nominated Liaison

In accordance with Regulation 23 of the Environment Regulations, details of the titleholder and nominated liaison and arrangements for the notification of changes are described below.

1.7.1 Titleholder

Woodside Burrup Ltd

11 Mount Street

Perth, Western Australia

T: 08 9348 4000

ACN: 120 237 416

1.7.2 Nominated Liaison

Andrew Winter

Corporate Affairs Manager

11 Mount Street

Perth, Western Australia

Telephone: 08 9348 4000

Email: feedback@woodside.com

1.7.3 Arrangements for Notifying Change

If the titleholder, titleholder's nominated liaison, or the contact details for either change, then NOPSEMA will be notified in writing within two weeks or as soon as practicable.

1.8 Woodside Management System

The Woodside Management System (WMS) provides a structured framework of documentation to set common expectations governing how all employees and contractors at Woodside will work. Many of the standards presented in Section 6 are drawn from the WMS documentation, which comprises four elements as outlined below (and illustrated in Figure 1-1):

- Our **Values and Policies:** Set the enterprise-wide direction for Woodside by governing our behaviours, actions, and business decisions and ensuring we meet our legal and other external obligations.
- **Expectations**: Set essential activities or deliverables required to achieve the objectives of the Key Business Activities and provide the basis for developing processes and procedures.
- **Processes and Procedures**: Processes identify the set of interrelated or interacting activities that transforms inputs into outputs, to systematically achieve a purpose or specific objective. Procedures specify what steps, by whom, and when required to carry out an activity or a process.
- **Guidelines:** Provide recommended practice and advice on how to perform the steps defined in Procedures, together with supporting information and associated tools. Guidelines provide advice on how activities or tasks may be performed, information that may be taken into consideration, or how to use tools and systems.

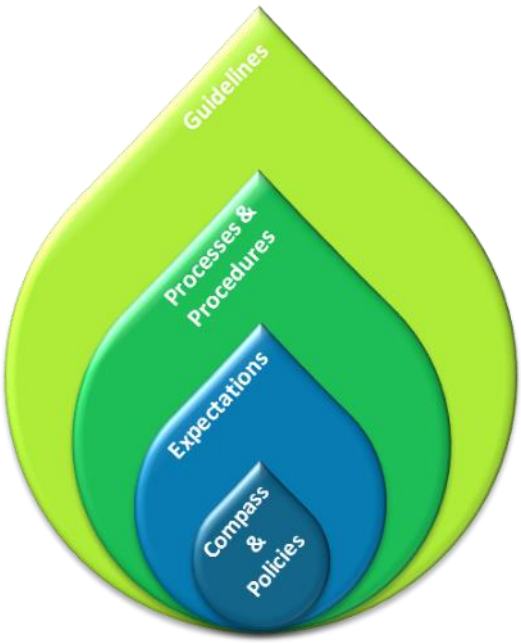

Figure 1-1: The four major elements of the WMS Seed

The WMS is organised within a Business Process Hierarchy based upon Key Business Activities so that the system remains independent of organisation structure, is globally applicable and scalable wherever required. These Key Business Activities are grouped into Management, Support, and Value Stream activities as shown in Figure 1-2. The Value Stream activities capture, generate and deliver value through the exploration and production lifecycle. The Management activities influence all areas of the business, while Support activities may influence one or more value stream activities.

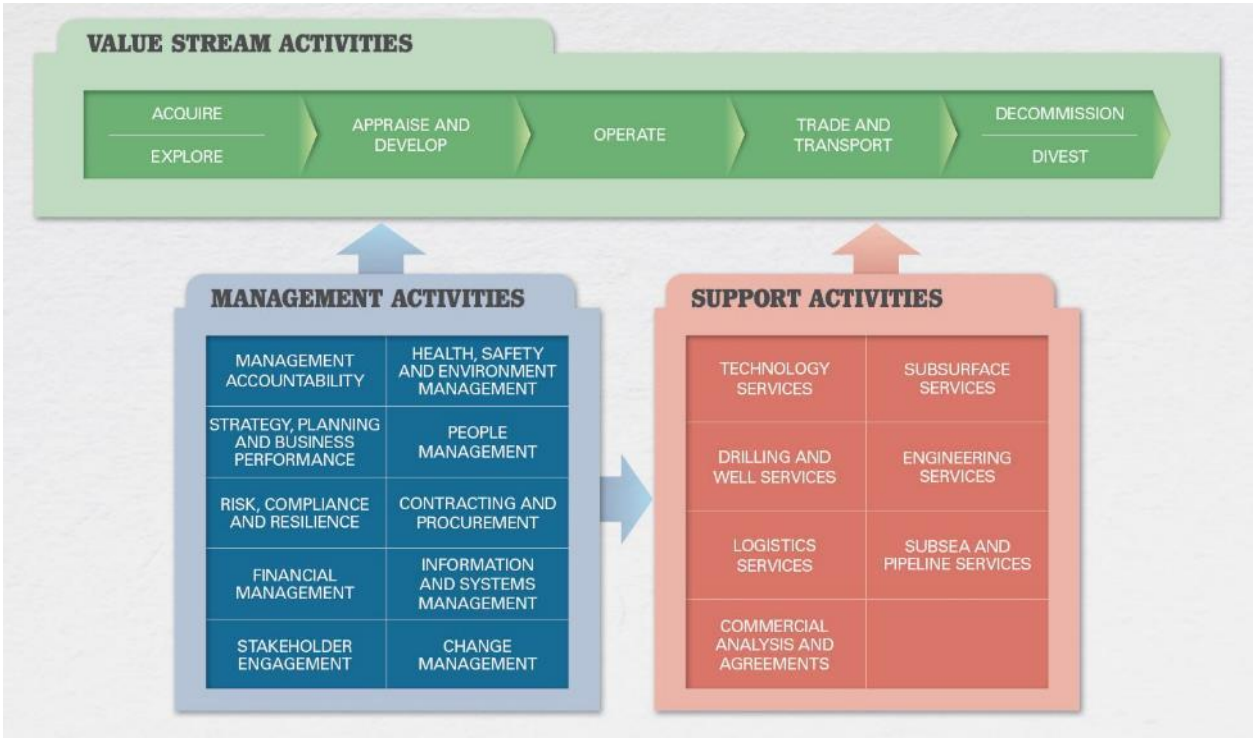

Figure 1-2: The WMS business process hierarchy

1.8.1 Environment and Biodiversity Policy

In accordance with Regulation 24(a) of the Environment Regulations, Woodside's Environment and Biodiversity Policy is provided in Appendix A of this EP.

As the objective of the policy, Woodside recognises the intrinsic value of nature and the importance of conserving biodiversity and ecosystem services to support the sustainable development of our society. We are committed to doing our part. We understand and embrace our responsibility to undertake activities in an environmentally sustainable way.

As part of the policy's principles, Woodside commits to:

- implementing a systematic approach to the management of the impacts and risks of our operating activities on an ongoing basis, including emissions and air quality, discharge and waste management, water management, biodiversity and protected areas
- applying the mitigation hierarchy principle (avoid, minimise, restore) and a continuous improvement approach to ensure we maintain compliance, improve resource use efficiency and reduce our environmental impacts
- embedding environmental and biodiversity management, and opportunities, in our business planning and decision-making processes
- complying with relevant laws and Regulations and applying responsible standards where laws do not exist
- not undertaking new activities[2] within the boundaries of natural sites on the UNESCO World Heritage List[3]
- not undertaking new activities within IUCN Protected Areas [4] unless compatible with management plans in place for the area.
- achieving net zero deforestation[5] for new activities.
- developing Biodiversity Management Plans for all new major projects (CAPEX >USD$2 billion).
- supporting positive biodiversity outcomes in regions and areas in which we undertake activities
- setting targets and publicly reporting on our environmental and biodiversity performance.

The application of the policy is the responsibility of all Woodside employees, contractors and joint venturers engaged in activities under Woodside operational control. Woodside managers are also responsible for promotion of the policy in non-operated joint ventures.

The policy is reviewed regularly and updated as required. The Environment and Biodiversity Policy is made available on our website, along with the other Board policies: https://www.woodside.com/who-we-are/corporate-governance-and-policies .The version applicable to the activity covered in this EP was reviewed in December 2024.

1.9 Description of Relevant Requirements

In accordance with Regulation 21(4) of the Environment Regulations, a description of requirements, including legislative requirements, that apply to the activity and are relevant to the management of

[2] Does not include non-industrial and existing activities that are compatible with maintenance of the listed outstanding universal values
[3] New UNESCO World Heritage Listings that overlap existing activities will be assessed at the time of listing.
[4] New IUCN Protected Areas that overlap existing activities will be assessed at the time of listing.
[5] Definition of Forest: 'native trees higher than 5 metres and a canopy cover of more than 10 percent on the land to be cleared'.

risks and impacts of the PAP are detailed in Appendix B. This EP will not be assessed under the Environment Protection Act 1986 (WA) as the activity does not occur on State land or within State Waters.

1.9.1 Offshore Petroleum and Greenhouse Gas Storage Act 2006

The *Offshore Petroleum and Greenhouse Gas Storage Act 2006* (Cth)(OPGGS Act) provides the regulatory framework for offshore exploration and production activities and greenhouse gas beyond three nautical miles (nm) of the mainland (and islands) to the outer extent of the Australian Exclusive Economic Zone (EEZ) at 200 nm.

The relevant requirements in Section 572 and 270 of the OPGGS Act are detailed in Table 1-3.

Table 1-3: Relevant requirements of Sections 572 and 270 of the OPGGS Act

Section Number	Relevant Requirement	Relevant Section of the EP
Section 270 – Consent to surrender title[6]		
Section 270(c)(i) and Section 270(c)(ii)	The Joint Authority may consent to the surrender sought by the application only if the registered holder of the permit, lease or licence: c) has: (i) to the satisfaction of NOPSEMA, removed or caused to be removed from the surrender area (defined by subsection (7)) all property brought into the surrender area by any person engaged or concerned in the operations authorised by the permit, lease or licence, or (ii) made arrangements that are satisfactory to NOPSEMA in relation to that property, and	Not applicable
Section 572 – Maintenance and removal of property etc. by titleholder		
Section 572(2)	A titleholder must maintain in good condition and repair all structures that are, and all equipment and other property that is: (a) in the title area, and (b) used in connection with the operations authorised by the permit, lease, licence or authority.	Section 7.5
Section 572(3)	A titleholder must remove from the title area all structures that are, and all equipment and other property that is, neither used nor to be used in connection with the operations: (a) in the title area, and (b) used in connection with the operations authorised by the permit, lease, licence or authority.	Sections 3 and 7.5
Section 572(7)	This section has effect subject to: (a) any other provision of this Act, and (b) the Regulations, and (c) a direction given by NOPSEMA or the responsible Commonwealth Minister under: (i) Chapter 3, or (ii) this Chapter (d) any other law	Section 7.5

Under the OPGGS Act, the Environment Regulations apply to petroleum activities in Commonwealth Waters and are administered by NOPSEMA. The objective of the Environment Regulations is to ensure petroleum activities are performed in a manner:

- consistent with the principles of ESDev (as set out in the EPBC Act)

[6] There is no intent to surrender any titles in the scope of this EP.

- by which the environmental impacts and risks of the activity will be reduced to ALARP
- by which the environmental impacts and risks of the activity will be of an acceptable level.

1.9.2 Environment Protection and Biodiversity Conservation Act 1999 (Cth)

One of the objectives EPBC Act is to protect and manage nationally and internationally important flora, fauna, ecological communities and heritage places in Australia. These are defined under Part 3 of the Act as 'matters of national environmental significance' (MNES). The EPBC Act sets a regime which aims to ensure actions taken on (or impacting upon) Commonwealth land or waters are consistent with the principles of ESD. When a person proposes to take an action that they believe may need approval under the EPBC Act, they must refer the proposal to the Commonwealth Minister for Environment.

In relation to offshore petroleum activities in Commonwealth waters, in accordance with the "Streamlining Offshore Petroleum Approvals Program" (the Program), requirements under the Act are now administered by NOPSEMA, commencing February 2014. The Program requires any offshore petroleum activities, authorised by the OPGGS Act to be conducted in accordance with an accepted EP. The definition of 'environment' in the Program covers all matters protected under Part 3 of the EPBC Act.

1.9.3 Offshore Project Approval

The Pluto LNG Project (including both offshore and onshore infrastructure) was referred for assessment under the EPBC Act (EPBC 2006/2968) and the level of assessment was set as Public Environment Report (PER). The action was approved 12 October 2007 with conditions.

It should be noted that a Consolidated Approval Notice for EPBC 2006/2968 dated 14 June 2015 was issued to consolidate the approval conditions, and the approval conditions were subject to variation on the date of the notice. A key element to the variation relates to conditions requiring a plan for managing impacts of the action. The previous conditions required the Minister's approval of such plans, with the variation now automatically deeming the plan to have been approved by the Minister if the measures are included in an environment plan related to the action submitted to NOPSEMA after 27 February 2014 and in force under the Environment Regulations.

Conditions in relation to the EPBC Act approval that are considered relevant to the scope of this EP are provided in Table 1-4.

Table 1-4: Conditions from Pluto Gas condensate field (EPBC 2006/2968) relevant to the PAP

Condition Number	Condition	Relevant Section of EP
1	The person taking the action must submit, for the approval of the Minister, a plan (or plans) for managing the offshore impacts of the action. The plan (or plans) must include measures for: a) drilling operations: (i) drilling fluid type and disposal method. (ii) drill cuttings disposal method. (iii) fuel and chemical handling and transfer procedures. (iv) Cetacean interaction procedures for supply vessels and aircraft that are consistent with Part 8 of the Environment Protection and Biodiversity Conservation Regulations 2000; and (v) Cetacean and Whale shark (*Rhincodon typus*) sightings reporting	The Xena-03 Tie-back project is the only planned construction and installation activity covered under this EP. Relevant sub-conditions are addressed in the following sections: i. Sections 3.11.2 and 6.7.8 ii. Sections 3.11.2.3 and 6.7.8 iii. Section 6.9.5. iv. Sections 6.7.3, 6.7.4 and 6.9.9. v. Sections 6.7.3, 6.7.4 and 6.9.9.

Condition Number	Condition	Relevant Section of EP
	b) construction and installation: (i) design and construction that allow for the decommissioning of all structures and components on the sea floor (ii) impacts and management measures for reuse of any spoil ground material (iii) details of the final selection of wells, anchor type and placements and flowline paths (iv) hydrotest fluid type, handling and risk assessment of disposal impacts (v) interaction procedures for supply vessels and aircraft that are consistent with Part 8 of the Environment Protection and Biodiversity Conservation Regulations 2000 (vi) cetacean and whale shark sightings reporting.	Relevant sub-conditions are addressed in the following sections: i. Sections 3.11 and 7.5 ii. Not relevant iii. Section 3.11 iv. Sections 3.11.4 and 6.7.5 v. Sections 6.7.3, 6.7.4 and 6.9.9 vi. Sections 6.7.3, 6.7.4, 6.9.9 and 7.13.3.2
	c) operations: (i) trading tanker vetting procedures (ii) the monitoring and disposal of produced water (PW), including the analysis of expected PW chemistry, baseline biological and physical information at the PW outfall site, toxic impacts of PW on marine flora and fauna based on ecotoxicological, bioaccumulation and biodegradation studies, industry best practice disposal of PW monitoring and reporting of biological and physical indicators and contingency measures if adverse impacts are indicated (iii) monitoring and management the collection, handling and disposal of naturally occurring radioactive materials (NORMs) (iv) interaction procedures for supply vessels and aircraft that are consistent with Part 8 of the Environment Protection and Biodiversity Conservation Regulations 2000 (v) cetacean and whale shark sightings reporting. Individual offshore activities may not commence until the plan (or plans) for that specific activity has been approved. The approved plan (or plans) must be implemented.	i. Not applicable ii. Sections 3.5.5, 4.4, 4.5 and 6.7.7 iii. Sections 3.6.7 and 6.9.7 iv. Sections 6.7.3, 6.7.4 and 6.9.9 v. Sections 6.7.3, 6.7.4 and 6.9.9.
4	The person taking the action must submit for the Minister's approval an oil spill contingency plan to mitigate the environmental effects of any hydrocarbon spills. The oil spill contingency plan must include: • the types of dispersants, protective booms, clean up gear, and related equipment to be used in the event of an oil spill and the storage arrangements • training of staff in oil spill response measures • identification of sensitive areas, and specific response measures for these areas • details of the insurance arrangements that have been made in respect of the costs associated with repairing any environmental damage arising from potential oil spills • the reporting of oil spill incidents. • Offshore construction may not commence until the plan is approved. The approved plan must be implemented.	Woodside's Emergency Preparedness and Response arrangements (refer to Section 7.14 and associated documents).
8	At least twelve months before the expiry of the period for which this approval has effect, the person taking the action Limited must submit a decommissioning plan for approval by	Decommissioning is beyond the scope of this EP.

Condition Number	Condition	Relevant Section of EP
	the Minister that considers the removal of all structures and components above the sea floor, including subsea wells, manifolds and flowlines and any other associated infrastructure and the disposal and management of any NORMs. Decommissioning may not commence until the plan is approved. The approved plan must be implemented.	
11	If the person taking the action proposes to undertake any subsea tie-in[7] not included in approved plans pursuant to condition 1, the person taking the action must revise such plans or submit a new plan or plans to address the activities associated with, and potential environmental impacts of, the subsea tie-in. Activities associated with subsea tie-ins may not be commenced until each such plan or revised plan has been approved by the Minister. Each plan or revised plan that has been approved by the Minister must be implemented.	The resubmission and subsequent implementation of this EP is considered to meet this Condition (i.e. This EP is submitted as the 'revised plan' to address aspects of condition 1 applicable to the Xena-03 subsea tie-in operation).
12	If the person taking the action wishes to carry out any activity otherwise than in accordance with the plans referred to in conditions 1 ,3, 4, 5, 6 and 8, the person taking the action may submit for the Minister's approval a revised version of any such plan. If the Minister approved a revised plan so submitted the person taking the action must implement that plan instead of the plan as originally approved.	The implementation of this EP is considered to meet this Condition (i.e. This EP is submitted as the 'revised plan' to address aspects of conditions applicable to the Xena-03 subsea tie-in operation).
15	A plan required by condition 1, 4, 8, 11 or 12 is automatically deemed to have been submitted to, and approved by, the Minister if the measures (as specified in the relevant condition) are included in an environment plan (or environment plans) relating to the taking of the action that: • was submitted to NOPSEMA after 27 February 2014, and either: • is in force under the OPGGS Environment Regulations, or • has ended in accordance with Regulation 46 of the OPGGS Environment Regulations.	The implementation of this EP is considered to meet this Condition.
15A	Where a plan required by condition 1, 4, 11 or 12 has been approved by the Minister and the measures (as specified in the relevant condition) are included in an environment plan (or environment plans) that: • was submitted to NOPSEMA after 27 February 2014, and either: • is in force under the OPGGS Environment Regulations, or • has ended in accordance with Regulation 46 of the OPGGS Environment Regulations, the plan approved by the Minister no longer needs to be implemented.	The implementation of this EP is considered to meet this Condition and supersedes previously approved plans.
15B	Where an environment plan, which includes measures specified in the conditions referred to in conditions 15 and 15A above, is in force under the OPGGS Environment Regulations that relates to the taking of the action, the	The implementation of this EP is considered to meet this Condition.

[7] Subsea tie-ins: means the construction and operation of subsea wells, flowlines and other related infrastructure for the purpose of extracting gas from hydrocarbon reserves (other than the Pluto gas reservoir) within that area and conveying that petroleum to the platform located at the site of the Pluto hydrocarbon reservoir.

Condition Number	Condition	Relevant Section of EP
	person taking the action must comply with those measures as specified in that environment plan.	

1.9.4 Recovery Plans and Threat Abatement Plans

Under s139(1)(b) of the EPBC Act, the Environment Minister must not act inconsistently with a recovery plan for a listed threatened species or ecological community or a threat abatement plan for a species or community protected under the Act. Similarly, under s268 of the EPBC Act:

"A Commonwealth agency must not take any action that contravenes a recovery plan or a threat abatement plan."

In relation to offshore petroleum activities in Commonwealth waters, these requirements are now administered by NOPSEMA in accordance with commitments set out in the Programs. Relevant recovery plans or threat abatement plans relevant to the scope of this EP have been identified as described in Section 2.9 and assessed in Section 6.10.

1.9.5 Australian Marine Parks

Under the EPBC Act, Australian Marine Parks (AMPs), formerly known as Commonwealth Marine Reserves, are recognised for conserving marine habitats and the species that live and rely on these habitats. The Director of National Parks (DNP) is responsible for managing AMPs (supported by Parks Australia) and is required to publish management plans for them. Other parts of the Commonwealth Government must not perform functions or exercise powers in relation to these parks that are inconsistent with management plans (s.362 of the EPBC Act). Relevant AMPs are listed in Section 4.8 and in the Master Existing Environment (Appendix K). The North-west Marine Parks Network Management Plan describes the requirements for management.

- Specific zones within the AMPs have been allocated conservation objectives as stated below (International Union for Conservation of Nature [IUCN] Protected Area Category) based on the Australian IUCN reserve management principles outlined in Schedule 8 of the Environment Protection and Biodiversity Conservation Regulations 2000 (Cth) (EPBC Regulations 2000).
- Special Purpose Zone (IUCN category VI) – managed to allow specific activities though special purpose management arrangements while conserving ecosystems, habitats and native species. The zone allows or prohibits specific activities.
- Sanctuary Zone (IUCN category Ia) – managed to conserve ecosystems, habitats and native species in as natural and undisturbed a state as possible. The zone allows only authorised scientific research and monitoring.
- National Park Zone (IUCN category II) – managed to protect and conserve ecosystems, habitats and native species in as natural a state as possible. The zone only allows non-extractive activities unless authorised for research and monitoring.
- Recreational Use Zone (IUCN category IV) – managed to allow recreational use, while conserving ecosystems, habitats and native species in as natural a state as possible. The zone allows for recreational fishing, but not commercial fishing.
- Habitat Protection Zone (IUCN category IV) – managed to allow activities that do not harm or cause destruction to seafloor habitats, while conserving ecosystems, habitats and native species in as natural a state as possible.
- Multiple Use Zone (IUCN category VI) – managed to allow ecologically sustainable use while conserving ecosystems, habitats and native species. The zone allows for a range of

sustainable uses, including commercial fishing and mining where they are consistent with park values.

Two planned activities are proposed within the Montebello Marine Park Multiple Use Zone (IUCN category VI): Subsea Inspection Maintenance, Monitoring and Repair activities along the existing pipeline (Section 3.10) and produced water discharge with associated environmental monitoring (Section 3.5.5). The principles for each zone determine what activities are acceptable within a protected area under the EPBC Act. The Australian IUCN Reserve Management Principles for Multiple Use Zone (IUCN category VI) are considered relevant to the scope of this EP are provided in Table 1-5.

Table 1-5: Australian IUCN Reserve Management Principles relevant to the PAP

Condition Number	Principle
7.01	The reserve or zone should be managed mainly for the sustainable use of natural ecosystems based on the following principles.
7.02	The biological diversity and other natural values of the reserve or zone should be protected and maintained in the long term.
7.03	Management practices should be applied to ensure ecologically sustainable use of the reserve or zone.
7.04	Management of the reserve or zone should contribute to regional and national development to the extent that this is consistent with these principles.

For the North West Marine Parks Network Management Plan (2018), petroleum activities, including transportation of minerals by pipeline, and oil spill response are permittable subject to approval in Multiple Use Zone (IUCN category VI) and Special Purpose Zone Trawl (IUCN category VI). Proposed mining operations conducted under usage rights that existed immediately before the declaration of a marine park do not require approval.

Petroleum Activities (including environmental monitoring in connection with a particular petroleum activity) occurring within these zones are approved by a class approval (Director of National Parks, 2018a). Conditions of the Class Approval that are considered relevant to the scope of this EP are provided in Table 1-6.

Table 1-6: Conditions of Class Approval relevant to the PAP

Condition Number	Condition	Relevant Section of the EP
1	The Approved Actions must be conducted in accordance with: (a) an Environment Plan accepted under the Offshore Petroleum and Greenhouse Gas Storage (Environment) Regulations 2023 (b) the EPBC Act (c) the EPBC Regulations (d) the North-west Network Management Plan (e) any prohibitions, restrictions or determinations made under the EPBC Regulations by the Director of National Parks (f) all other applicable Commonwealth and state laws (to the extent those laws are capable of operating concurrently with the laws and instruments described in paragraphs (a) to (e)).	Conditions 1a, b, c, f are met by the submitted EP (Section 1.2) 1d The impacts on the marine park values have been considered in Sections 6.7.2, 6.7.5 and 6.7.7. 1e Consultation has been undertaken with the Director of National Parks and no prohibitions, restrictions or determinations have been made (Section 5).
2	If requested by the Director of National Parks, an Approved Person must notify the Director prior to conducting Approved Actions within Approved Zones.	Section 5 describes requirements to notify the DNP prior to activities within the Montebello Multiple Use Zone.

3	If requested by the Director of National Parks, an Approved Person must provide the Director with information relating to undertaking the Approved Actions (or gathered while undertaking the Approved Actions), that is relevant to the Director's management of the Approved Zones.	If requested by the Director of National Parks, information relating to undertaking the Approved Actions (or gathered while undertaking the Approved Actions), that is relevant to the Director's management of the Approved Zones will be provided.

1.9.6 World Heritage Properties

Australian World Heritage management principles are prescribed in Schedule 5 of the EPBC Regulations 2000. Management principles that are considered relevant to the scope of this EP are provided in Table 1-7.

Table 1-7: Relevant management principles under Schedule 5 – Australian World Heritage management principles of the EPBC Act

Number	Principle	Relevant Section of the EP
3	Environmental impact assessment and approval 3.01 This principle applies to the assessment of an action that is likely to have a significant impact on the World Heritage values of a property (whether the action is to occur inside the property or not). 3.02 Before the action is taken, the likely impact of the action on the World Heritage values of the property should be assessed under a statutory environmental impact assessment and approval process. 3.03 The assessment process should: – identify the World Heritage values of the property that are likely to be affected by the action, and – examine how the World Heritage values of the property might be affected, and – provide for adequate opportunity for public consultation. 3.04 An action should not be approved if it would be inconsistent with the protection, conservation, presentation or transmission to future generations of the World Heritage values of the property. 3.05 Approval of the action should be subject to conditions that are necessary to ensure protection, conservation, presentation or transmission to future generations of the World Heritage values of the property. 3.06 The action should be monitored by the authority responsible for giving the approval (or another appropriate authority) and, if necessary, enforcement action should be taken to ensure compliance with the conditions of the approval.	3.01 and 3.02: Assessment of significant impact on World Heritage values is included in Section 6. Principles are met by the submitted EP. 3.03 (a) and (b): World Heritage values are identified in Section 4.9.9 and considered in the assessment of impacts and risks for the Petroleum Activity in Section 6. 3.03(c): Relevant persons consultation and feedback received in relation to impacts and risks to the Ningaloo World Heritage Property are outlined in Section 5. 3.04, 3.05 and 3.06: Principles are considered to be met by the acceptance of this EP.

Note that Section 1 – General Principles and Section 2 – Management Planning of Schedule 5 are not considered relevant to the scope of this EP and, therefore, have not been included.

2. ENVIRONMENT PLAN PROCESS

2.1 Overview

This section outlines the process taken by Woodside to prepare this EP, once the activity was defined as a petroleum activity. The process describes the activity, the existing environment, followed by the environmental risk management methodology used to identify, analyse and evaluate risks to meet ALARP levels and acceptability requirements, and develop EPOs and EPSs. This section also describes Woodside's risk management methodologies as applied to implementation strategies for the activity. The EP is revised each 5-year period having regard to material changes to operational processes, amendments to applicable legislation or relevant developments in good industry practice.

Regulation 21(5) of the Environment Regulations requires the EP to include details of the environmental impacts and risks for the Petroleum Activities Program, and an evaluation of all the impacts and risks, appropriate to the nature and scale of each impact and risk. The objective of the risk assessment process described in this section is to identify risks and associated impacts of an activity, so they can be assessed, and appropriate control measures applied to eliminate, control or mitigate the impact/risk to ALARP, and to determine if the impact or risk level is acceptable.

Environmental impacts and risks include those directly and indirectly associated with the Petroleum Activities Program, and include potential emergency and accidental events:

- Planned activities have the inherent potential to cause environmental impacts.
- Environmental risks are unplanned events with the potential for environmental impact (termed risk 'consequence').

In this section, potential impacts from planned activities are termed 'impacts', and 'risks' are associated with unplanned events with the potential for environmental impact (should the risk be realised), with such impacts termed potential 'consequences.

2.2 Environmental Risk Management Methodology

2.2.1 Woodside Risk Management Process

Woodside recognises that risk is inherent to its business and that effective management of risk is vital to delivering on company objectives, success and continued growth. Woodside is committed to managing risk proactively and effectively. The objective of Woodside's risk management system is to provide a consistent process for recognising and managing risks across Woodside's business. Achieving this objective includes ensuring risks consider impacts across these key areas of exposure: health and safety, environment, finance, reputation and brand, legal and compliance, and social and cultural.

The environmental risk management methodology used in this EP is based on Woodside's Risk Management Procedure. This procedure aligns to industry standards, such as international standard ISO 31000. WMS risk management procedures, guidelines and tools provide guidance of specific techniques for managing risk, tailored for particular areas of risk within certain business processes. Procedures applied for environmental risk management include (Sections 2.2.2 to 2.2.4):

- Health, Safety and Environment Management Procedure
- Impact Assessment Procedure
- Process Safety Management Procedure.

The risk management methodology provides a framework to demonstrate that risks and impacts are continually identified, reduced to ALARP and assessed to be at an acceptable level, as required by the Environment Regulations. The key steps of Woodside's Risk Management Process are shown

in Figure 2-1. A description of each step and how it is applied to the scopes of this activity is provided in Sections 2.2 to 2.12.

Figure 2-1: Woodside's risk management process

2.2.2 Health, Safety and Environment Management Procedure

The Health, Safety and Environment Management Procedure provides the structure for managing health, safety and environment (HSE) risks and impacts across Woodside, defines the decision authorities for company-wide HSE management activities and deliverables, and supports continuous improvement in HSE management.

2.2.3 Impact Assessment Procedure

To support effective environmental risk assessment, Woodside's Impact Assessment Procedure (Figure 2-2) provides the steps to meet the required environment, health and social standards by ensuring impact assessments are undertaken appropriate to the nature and scale of the activity, the regulatory context, the receiving environment, interests, concerns and rights of relevant persons, and the applicable framework of standards and practices.

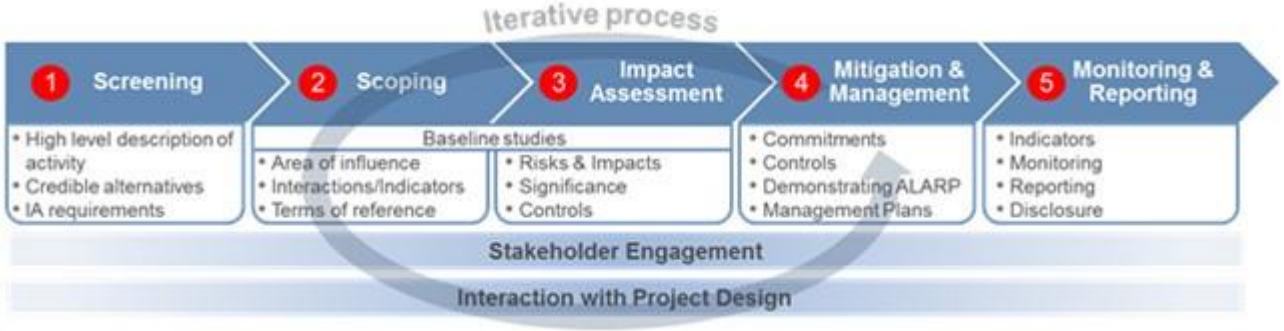

Figure 2-2: Woodside's impact assessment process

2.2.4 Process Safety Management Procedure and Process Safety Risk Assessment Procedure

Due to the nature and scale of petroleum activities, Woodside's Process Safety Management Procedure establishes Woodside's framework for Process Safety Management (Section 7.2.2). This framework includes the Process Safety Risk Assessment Procedure (PSRA). The PSRA is a key part of Woodside's process safety management framework for managing the integrity of systems and processes that handle hazardous substances over the exploration and production lifecycle. The PSRA sets out methods so that process safety risks are understood and controlled, including that all process safety hazards are systematically identified, assessed and treated so that the associated risks are reduced to a level that is tolerable and ALARP.

2.3 Environment Plan Development Process

The EP development process is illustrated in Figure 2-3. Each element of this process is discussed further in Section 2.5 to Section 2.12.

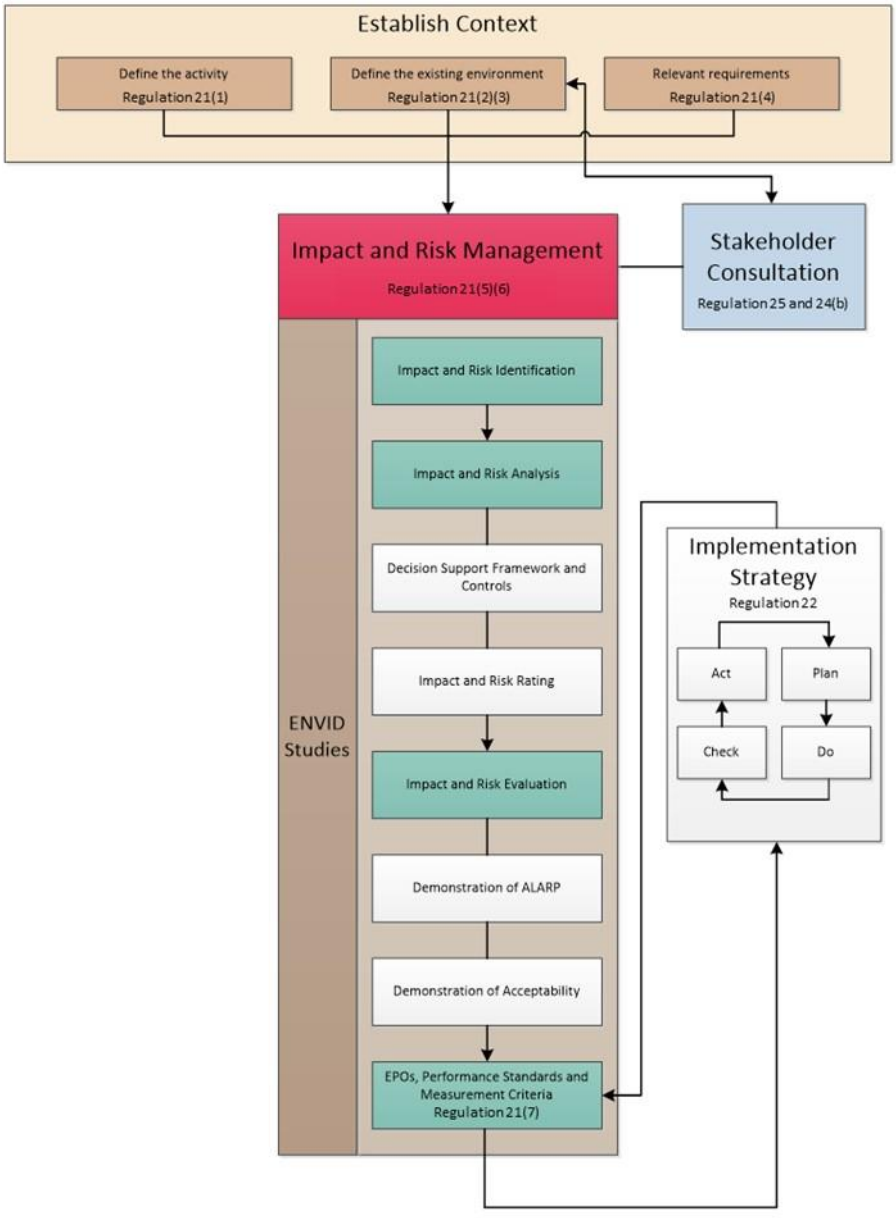

Figure 2-3: EP development process

2.4 Establish the Context

2.4.1 Define the Activity

This first stage involves evaluating whether the activity meets the definition of a 'petroleum activity' as defined in the Environment Regulations. The activity is described in relation to:

- the location
- what is to be undertaken
- how it is planned to be undertaken, including outlining operational details of the activity and proposed timeframes.

The 'what' and 'how' are described in the context of 'environmental aspects'[8] to inform the risk and impact assessment for planned (routine and non-routine) and unplanned (accidents/ incidents/ emergency conditions) activities.

The activity is described in Section 3 and is referred to as the Petroleum Activities Program.

2.4.2 Define the Existing Environment

The context of the existing environment is described and determined by considering the nature and scale of the activity (size, type, timing, duration, complexity, and intensity of the activity), as described in Section 4. The purpose is to describe the existing environment that may be impacted by the activity, directly or indirectly, by planned or unplanned[9] events.

A description of values and sensitivities relevant to Woodside's North West Shelf Operations is contained within the Master Existing Environment (Master EE) document. The Master EE is provided in Appendix K and is revised in accordance with Woodside's Management of Knowledge process when Woodside considers that information contained within the Master EE is superseded or when Woodside assesses relevant new information (Section 7.10.1.3).

The Existing Environment (Section 4) is structured into subsections defining the physical, biological, socio-economic and cultural features and values of the existing environment that may be affected by the activity, in accordance with the definition of environment in Regulation 5 of the Environment Regulations. These subsections make particular reference to:

- The environmental, and social and cultural consequences as defined by Woodside (refer to Table 2-1), which address key physical and biological attributes, as well as social and cultural values of the existing environment. These consequence definitions are applied to the impact and risk analysis (refer Section 2.2) and rated for all planned and unplanned activities. Additional detail is provided for unplanned hydrocarbon spill risk evaluation.
- EPBC Act MNES including listed threatened species and ecological communities and listed Migratory species. Defining the spatial extent of the existing environment is guided by the nature and scale of the PAP (and associated sources of environmental risk). This considers the PAA and wider environment that may be affected (EMBA), as determined by the hydrocarbon spill risk assessments. MNES, as defined under the EPBC Act, are addressed through Woodside's impact and risk assessment (Section 6).

[8] An environmental aspect is an element of the activity that can interact with the environment.

[9] For each source of risk, the credible worst-case scenario in conjunction with impact thresholds is used to determine the spatial extent of the EMBA. The worst-case unplanned event is considered to be an unplanned hydrocarbon release, further defined for each activity through the risk assessment process. Interpretation of stochastic oil spill modelling determines the EMBA for the release, which defines the spatial scale of the environment that may be potentially impacted by the Petroleum Activities Program and in turn provides context to the 'nature and scale' of the existing environment.

- Relevant values and sensitivities, which may include world or national heritage listed areas, listed Threatened species or ecological communities, listed Migratory species, or sensitive values.

By grouping potentially impacted environmental values by aspect (as presented in Table 2-1), the presentation of information about the receiving environment is standardised. This information is then consistently applied to the risk evaluation section to provide a robust approach to the overall environmental risk evaluation and its documentation in the EP.

Table 2-1: Example of the environment values potentially impacted which are assessed within the Environment Plan

Environmental Value Potentially Impacted Regulations 21(2)(3)						
Soil and Groundwater	***Marine Sediment***	***Water Quality***	***Air Quality (incl Odour)***	***Ecosystems/Habitats***	***Species***	***Socio-economic***

2.4.3 Relevant Requirements

The relevant requirements in the context of legislation, other environmental approval requirements, conditions and standards that apply to the PAP are identified and reviewed; and are presented in Appendix B.

The Woodside Risk Management Policy, Climate Policy as well as Environment and Biodiversity Policy are presented in Appendix A.

2.5 Impact and Risk Identification

Relevant environmental aspects and hazards were identified that support the process to define environmental impacts and risks associated with an activity.

The environmental impact and risk assessments presented in this EP has been informed by historic as well as more recent hazard and environmental risk identification studies (e.g. HAZID/ENVID) and consequence modelling studies for high consequence, low probability environmental risks. These studies have been reviewed and revalidated, as required, for the five-year revision of this EP. In preparing the 5-year revision, Woodside also considers environmental performance and compliance information gathered during the implementation phase of the in-force EP. Further, feedback from NOPSEMA to Woodside across Woodside's portfolio of environment plans has been considered and integrated, where relevant.

Impacts, risks and potential consequences were identified based on planned activities and unplanned events (based on the description in Section 3), the existing environment (Section 4) and the outcomes of Woodside's consultation process (Section 5). The environmental outputs of applicable risk and impact workshops and associated studies are referred to as ENVID in this EP.

An environmental impacts and risks identification and assessment workshop was undertaken by multidisciplinary teams comprising relevant operational and environmental personnel with sufficient breadth of knowledge, training and experience to reasonably assure that risks and impacts were identified, and their potential environmental consequences assessed. Impacts and risks were identified, during the workshop, for both planned (routine and non-routine) activities and unplanned (accidents/incidents/emergency conditions) events. During this process, risks identified as not applicable (not credible) were removed from the assessment.

Impacts and risks were evaluated and tabulated for each planned activity and unplanned events respectively. Environmental impacts and risks were recorded in an environmental impacts and risk register. The output of the workshop is used to present the risk assessment and form the basis of performance outcomes, standards, and measurement criteria. This information is presented in Section 6, following the format presented in Table 2-2.

Outside of the ENVID process, other potential risks may be identified through consultation. When this is the case, some of these risks may be included as a Risk Assessment in Section 6, even though no direct impact pathway exists as a result of the PAP (PAP). These risks, which are included to demonstrate impact potential in the context of the PAP (such as accelerated weathering of rock art as a result of onshore emissions from processing of Pluto gas; Section **Error! Reference source not found.**) cannot be assigned a consequence or impact descriptor as per the process outlined in Section 2.6.3 because current literature and evaluation does not identify a credible impact as a result of the PAP.

Table 2-2: Example of layout of identification of risks and impacts in relation to risk sources

Impacts and Risks Evaluation Summary														
Source of Risk	***Environmental Value Potentially Impacted***							***Evaluation***						
	Soil and Groundwater	Marine Sediment	Water Quality	Air Quality (incl Odour)	Ecosystems / Habitat	Species	Socio-economic	Decision Type	Consequence / Impact	Likelihood	Risk Rating	ALARP Tool	Acceptability	Outcome
Summary of source of impact/risk														

2.6 Impact and Risk Analysis

Risk analysis further develops the understanding of a risk by defining the impacts and assessing appropriate controls, as well as considering previous risk assessments for similar activities, relevant studies, past performance, external consultation feedback, and the existing environment.

These key steps were undertaken for each risk identified during the risk assessment:

- Identify the Decision Type in accordance with the decision support framework.
- Identify appropriate control measures (preventive and mitigation) aligned with the Decision Type.
- Assess the risk rating.

2.6.1 Decision Support Framework

To support the risk assessment process and Woodside's determination of acceptability (Section 2.8.2), Woodside's HSE risk management procedures include the use of a decision support framework based on principles set out in the Guidance on Risk Related Decision Making (Oil and Gas UK, 2014). This concept is integrated into the environmental impacts and risks identification and assessment workshop to determine the level of supporting evidence that may be required to draw sound conclusions regarding risk level and whether the risk is acceptable and ALARP (Section 2.8). Application of the decision support framework confirms:

- activities do not pose an unacceptable environmental risk

- appropriate focus is placed on activities where the impact or risk is anticipated to be acceptable and demonstrated to be ALARP
- appropriate effort is applied to manage risks and impacts based on the uncertainty of the risk, the complexity and risk rating (i.e., potential higher order environmental impacts are subject to further evaluation/assessment).

The framework provides appropriate tools, commensurate to the level of uncertainty or novelty associated with the risk/impact (referred to as the Decision Type A, B, or C). The Decision Type is selected based on an informed discussion around the uncertainty of the risk/impact and is documented in impact and risk register worksheets.

This framework enables Woodside to appropriately understand a risk and determine if the risk or impact is acceptable and can be demonstrated to be ALARP.

2.6.1.1 Decision Type A

Decision Type A risks and impacts are well understood and established practice. They are generally recognised as good industry practice and are often embodied in legislation, codes and standards, and use professional judgment.

2.6.1.2 Decision Type B

Decision Type B risks and impacts typically involve greater uncertainty and complexity; and can include potential higher-order impacts/risks. These risks may deviate from established practice or have some lifecycle implications and therefore require further engineering risk assessment to support the decision and so that the risk is ALARP. Engineering risk assessment tools may include:

- risk-based tools such as cost-based analysis or modelling
- consequence modelling
- reliability analysis
- company values.

2.6.1.3 Decision Type C

Decision Type C risks and impacts typically have significant risks related to environmental performance. Such risks typically involve greater complexity and uncertainty therefore requiring the adoption of the precautionary approach. The risks may result in significant environmental impact, significant project risk/exposure, or may elicit negative stakeholder concerns. For these risks or impacts, in addition to Decision Type A and B tools, company and societal values need to be considered by undertaking broader internal and external consultation as part of the risk assessment process.

Figure 2-4: Risk-related Decision-making Framework (Oil and Gas UK, 2014)

2.6.1.4 Decision Support Framework Tools

These framework tools are applied, as appropriate, to help identify control measures based on the Decision Type described above:

- **Legislation, Codes and Standards (LCS)** – identifies the requirements of legislation, codes and standards that are to be complied with for the activity.
- **Good Industry Practice (GP)** – identifies further engineering control standards and guidelines that may be applied by Woodside above that required to meet the LCS.
- **Professional Judgement (PJ)** – uses relevant personnel with the knowledge and experience to identify alternative controls. Woodside applies the hierarchy of control as part of the risk assessment to identify any alternative measures to control the risk.
- **Risk-based Analysis (RBA)** – assesses the results of probabilistic analyses such as modelling, quantitative risk assessment and/or cost–benefit analysis to support the selection of control measures identified during the risk assessment process.
- **Company Values (CV)** – identifies values identified in Woodside's code of conduct, policies and Our Values. Views, concerns and perceptions are to be considered from internal Woodside stakeholders directly affected by the planned impact or potential risk.
- **Societal Values (SV)** – identifies the views, concerns and perceptions of relevant persons and addresses relevant stakeholder views, concerns and perceptions.

2.6.1.5 Decision Calibration

To determine that the alternatives selected, and the control measures applied are suitable, these tools may be used for calibration (i.e., checking) where required:

- LCS/Verification of Predictions – Verification of compliance with applicable LCS and/or good industry practice.
- Peer Review – Independent peer review of PJs, supported by RBA, where appropriate.

- Benchmarking – Where appropriate, benchmarking against a similar facility or activity type or situation that has been deemed to represent acceptable risk.
- Internal Consultation – Consultation undertaken within Woodside to inform the decision and verify company values are met.
- External Consultation – Consultation undertaken to inform the decision and verify societal values are considered.

Where appropriate, additional calibration tools may be selected specific to the Decision Type and the activity.

2.6.2 Control Measures (Hierarchy of Controls)

Risk reduction measures are prioritised and categorised in accordance with the hierarchy of controls, where risk reduction measures at the top of the hierarchy take precedence over risk reduction measures further down:

- Elimination of the risk by removing the hazard.
- Substitution of a hazard with a less hazardous one.
- Engineering Controls include design measures to prevent or reduce the frequency of the risk event, or detect or control the risk event (limiting the magnitude, intensity and duration) such as:
  - prevention: design measures that reduce the likelihood of a hazardous event occurring
  - detection: design measures that facilitate early detection of a hazardous event
  - control: design measures that limit the extent/escalation potential of a hazardous event
  - mitigation: design measures that protect the environment if a hazardous event occurs
  - response equipment: design measures or safeguards that enable clean-up/response after a hazardous event occurs.
- Procedures and Administration includes management systems and work instructions used to prevent or mitigate environmental exposure to hazards.
- Emergency Response and Contingency Planning includes methods to enable recovery from the impact of an event (e.g., protection barriers deployed near the sensitive receptor).

2.6.3 Impact and Risk Classification

Environmental impacts and risks are assessed to determine the potential impact significance/consequence. The impact significance/consequence considers the magnitude of the impact or risk and the sensitivity of the potentially impacted receptor (Figure 2-5).

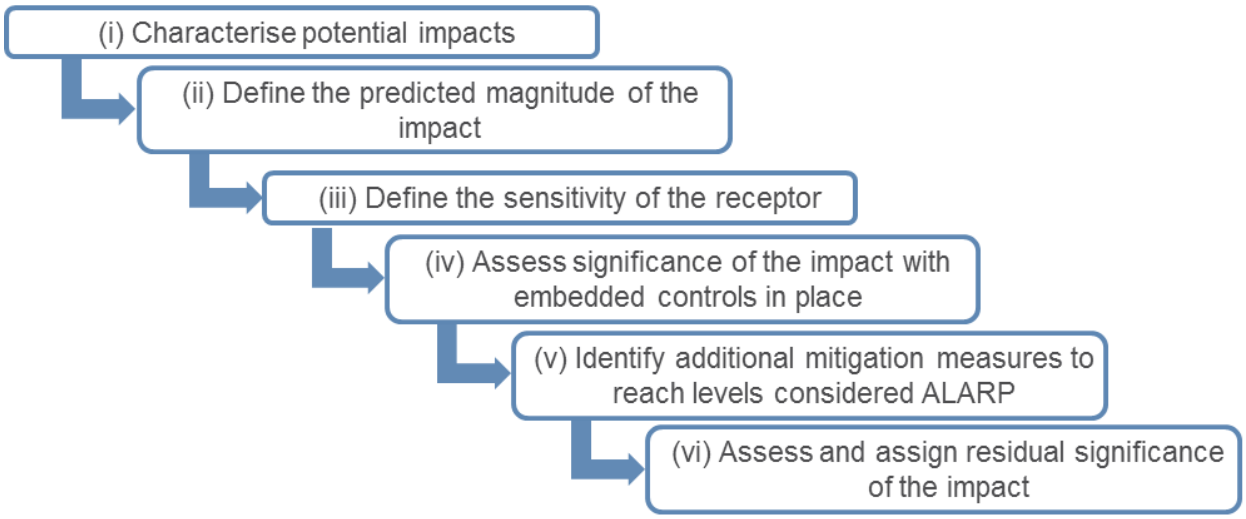

Figure 2-5: Environmental risk and impact analysis

Impacts are classified in accordance with the consequence (Table 2-3) outlined in Woodside's Risk Management Procedure and Risk Matrix (Figure 2-6). Risks are assessed qualitatively and/or quantitatively in terms of both likelihood and consequence in accordance with this matrix.

The impact and risk information, including classification and evaluation information as shown in the example (Table 2-2), are tabulated for each planned activity and unplanned event.

Table 2-3: Woodside Risk Matrix (environment and social and cultural) consequence descriptions

Environment	Social and Cultural	Consequence Level
Catastrophic, long-term impact (>50 years) on highly valued ecosystem, species, habitat or physical or biological attribute.	Catastrophic, long-term impact (>20 years) to a community, social infrastructure or highly valued area/item of international cultural significance.	A
Major, long-term impact (10 to 50 years) on highly valued ecosystem, species, habitat or physical or biological attribute.	Major, long-term impact (5 to 20 years) to a community, social infrastructure or highly valued area/item of national cultural significance.	B
Moderate, medium-term impact (2 to 10 years) on ecosystem, species, habitat or physical or biological attribute.	Moderate, medium-term impact (2 to 5 years) to a community, social infrastructure or highly valued area/item of national cultural significance.	C
Minor, short-term impact (1 to 2 years) on species, habitat (but not affecting ecosystem function), physical or biological attribute.	Minor, short-term impact (1 to 2 years) to a community or highly valued area/item of cultural significance.	D
Slight, short-term impact (<1 year) on species, habitat (but not affecting ecosystem function), physical or biological attribute.	Slight, short-term impact (<1 year) to a community or area/item of cultural significance.	E
No lasting effect (<1 month). Localised impact not significant to environmental receptor.	No lasting effect (<1 month). Localised impact not significant to area/item of cultural significance.	F

2.6.4 Risk Rating Process

The risk rating process assigns a level of risk to each risk event, measured in terms of consequence and likelihood. The assigned risk rating is determined with controls in place, therefore; the risk rating is determined after identifying the Decision Type and appropriate control measures.

The risk rating process considers the potential environmental consequences and, where applicable, the social and cultural consequences of the risk. The risk ratings are assigned using the Woodside Risk Matrix (refer to Figure 2-6).The risk rating process is done using the steps described in the subsections below.

2.6.5 Select the Consequence Level

Determine the worst-case credible consequence (Table 2-3) associated with the selected event, assuming all controls (preventive and mitigative) are absent or have failed. If more than one potential consequence applies, select the highest severity consequence level.

2.6.6 Select the Likelihood Level

Determine the description that best fits the chance of the selected consequence occurring, assuming reasonable effectiveness of the prevention and mitigation controls (Table 2-4).

Table 2-4: Woodside Risk Matrix likelihood levels

Likelihood Description						
Frequency	1 in 100,000 to 1,000,000 years	1 in 10,000 to 100,000 years	1 in 1000 to 10,000 years	1 in 100 to 1000 years	1 in 10 to 100 years	>1 in 10 years
Experience	Remote: Unheard of in the industry	Highly Unlikely: Has occurred once or twice in the industry	Unlikely: Has occurred many times in the industry but not at Woodside	Possible: Has occurred once or twice in Woodside or may possibly occur	Likely: Has occurred frequently at Woodside or is likely to occur	Highly Likely: Has occurred frequently at the location or is expected to occur
Likelihood Level	0	1	2	3	4	5

2.6.7 Calculate the Risk Rating

The risk rating is derived from the consequence and likelihood levels above, in accordance with the Woodside Risk Matrix shown in Figure 2-6. A likelihood and risk rating are only applied to environmental risks, not environmental impacts from planned activities.

This risk rating is used as an input into the risk evaluation process and ultimately for prioritising further risk reduction measures. Once each risk is treated to ALARP, the risk rating articulates the ALARP baseline risk as an output of the ENVID studies.

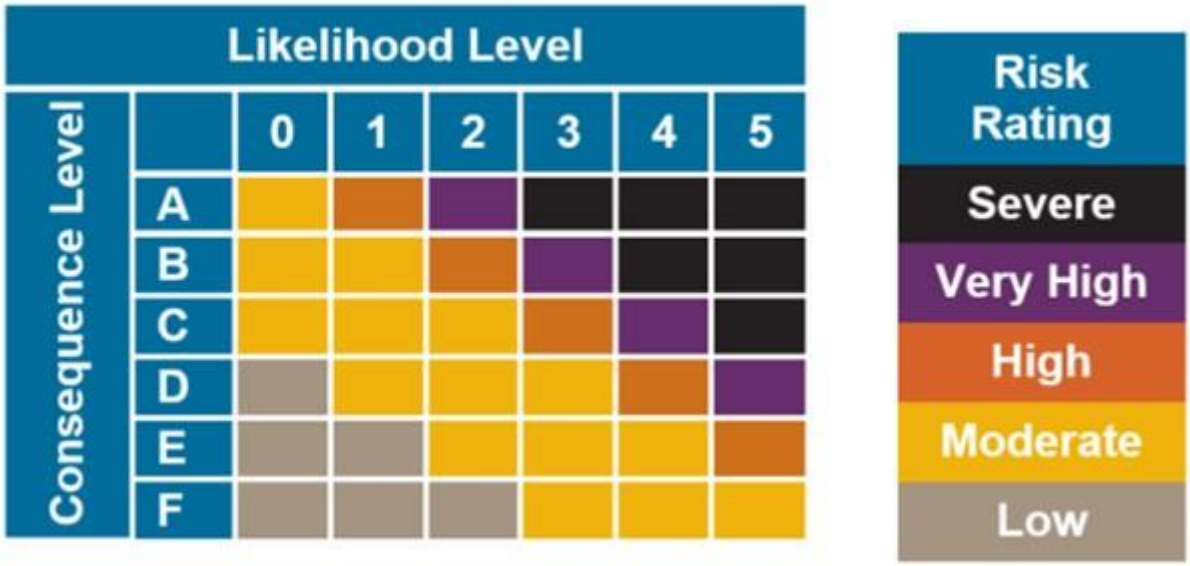

Figure 2-6: Woodside Risk Matrix – risk level

To support ongoing risk management (as a key component of Woodside's Process Safety Management Framework – refer to the implementation strategy in Section 7), Woodside uses the concept of 'current risk' and applies a Current Risk Rating to indicate the current or 'live' level of risk, considering controls that are currently in place and effective on a day-to-day basis. The Current Risk Rating is effective in articulating potential divergence from baseline risk, such as if certain controls fail or could potentially be compromised. Current Risk Ratings aid in communicating and making visible the risk events and for the continual management of risk to ALARP by identifying risk reduction measures and assessing acceptability.

2.7 Classification and Analysis of Major Environment Events (MEEs)

For Woodside's production facilities, a further level of analysis is undertaken to identify, classify and analyse MEEs. This extra level of rigour is applied so that sufficient controls are in place for risks with potential Level B and above consequences. In the health and safety area, major accident events (MAEs) are identified using a similar process, which supports consistency in managing key risks within Woodside in accordance with Process Safety Risk Management Procedures.

Woodside defines a MEE as an event with potential environment, reputation (pertaining to environment events), social or cultural consequences of level B or higher as per Woodside's Risk Matrix (Figure 2-6). MEEs are evaluated against credible worst-case scenarios that may occur when all controls are absent or have failed.

2.7.1 Major Environment Event Identification

The ENVID process identifies numerous sources of risk with differing consequence levels. These risks are screened for those risk events that meet the MEE criteria, and MEE risks are analysed further through detailed consequence modelling and probability/ frequency studies and examined for 'appropriateness' of controls in a bowtie risk assessment.

Risks that do not meet the MEE definition, although screened out of the MEE process, are still evaluated for ALARP and risk acceptability using the methodology described in Section 2.8. Some high consequence/low probability events which do not meet the MEE consequence threshold may still undergo additional consequence and probability assessment where they could have a high adverse impact on the company's reputation or relationships with relevant persons, beyond requirement to demonstrate ALARP and acceptable risk levels following application of controls.

2.7.2 MEE Classification

A standard naming convention has been established for MEEs which is based around ensuring the MEE titles reflect the cause of the event (e.g., 'subsea system loss of containment') rather than the event itself (e.g., significant hydrocarbon spill to the marine environment). The MEEs are assigned a unique identification code (e.g., MEE-01, MEE-02, etc).

2.7.3 Bowtie Analysis

MEEs are subject to more detailed analysis using the bowtie risk assessment technique, which illustrates cause outcome pathways for each MEE and controls in place to prevent the 'top event' or mitigate the consequences (outcomes). The key drivers for adopting the bowtie technique for MEEs are that it:

- identifies the controls (prevention and mitigation barriers) necessary so that the risk is acceptable and ALARP
- supports the process of demonstrating ALARP (described in Section 2.8.1)
- enables verification of and linking to the relevant sections of the WMS that supports barriers
- improves the capacity for lessons learnt and incident prevention by being able to directly relate causes of an incident to those controls that failed
- ensures greater visibility and granularity in the assessment process and enables complex risk scenarios to be presented in an easy to understand format.

The bowtie technique (an example bowtie diagram is shown in Figure 2-7) shows the relationships between the 'Causes' that may lead to a particular unwanted event ('Top Event'), together with the range of potential escalation paths that can lead to a variety of 'Outcomes' (or consequences). A bowtie also shows the preventive barriers that may prevent a Top Event from occurring specific to each Cause, and the mitigation barriers in place to limit the potential effects once the Top Event has been realised, specific to each credible MEE Outcome.

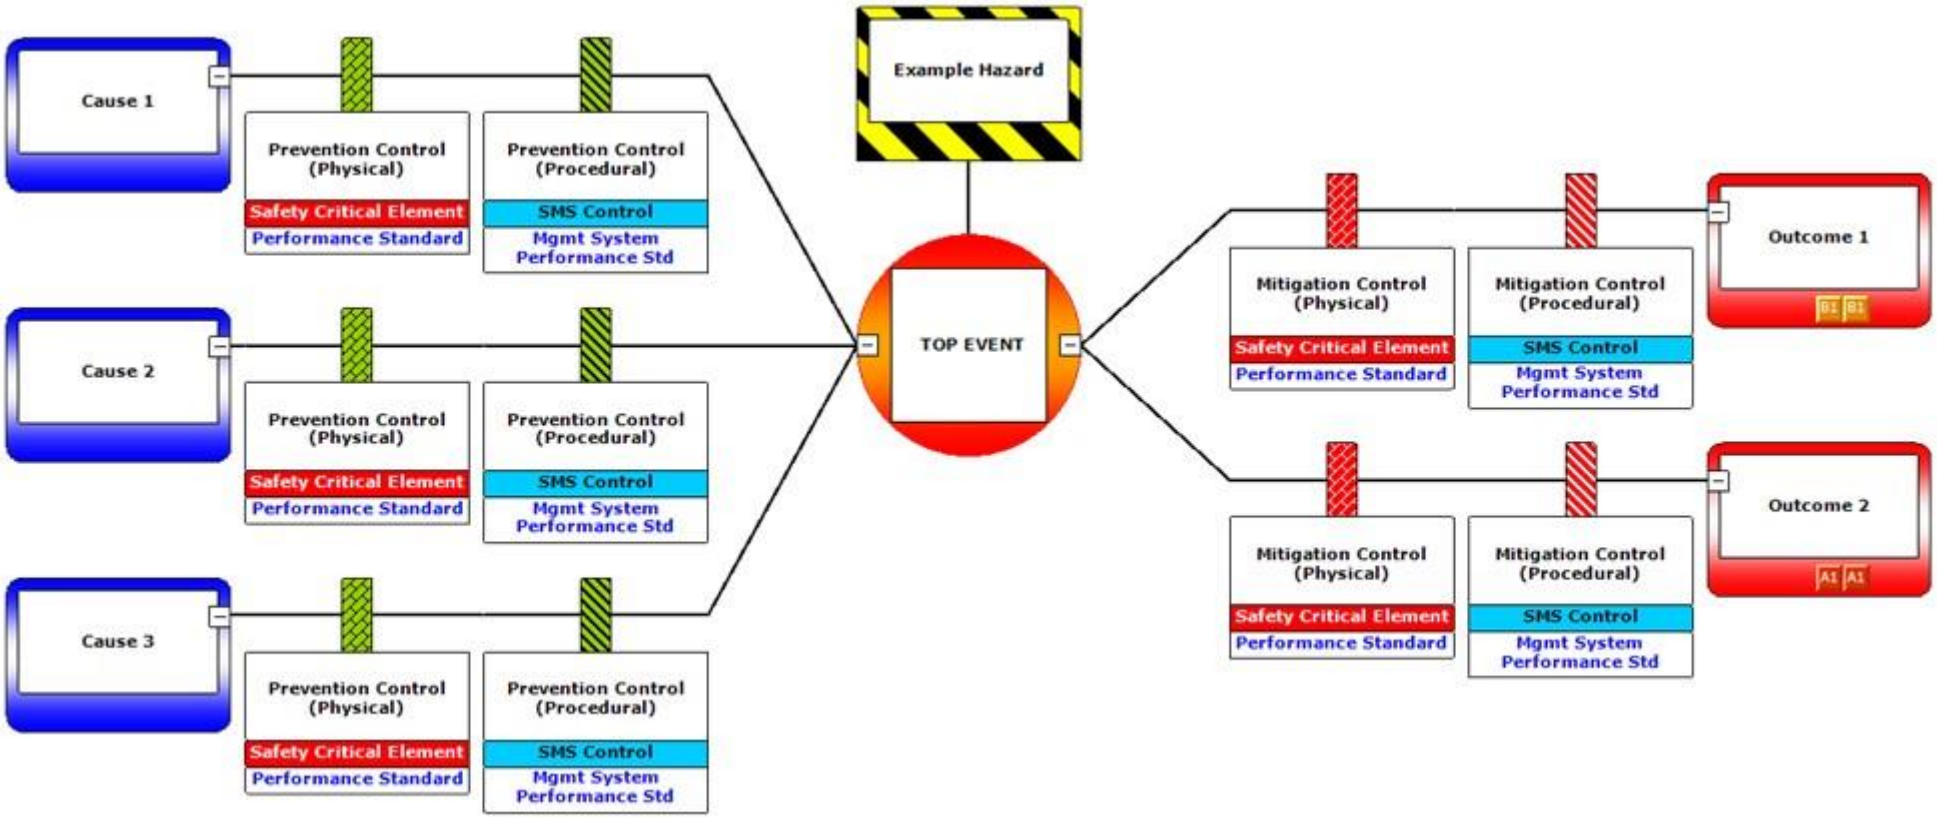

Figure 2-7: Example of bowtie diagram structure

2.7.4 MEE Register

A MEE Register is prepared for each production facility after completing the bowtie diagrams. The purpose of the MEE Register is to record the MEE identification process, groupings, bowtie diagrams and datasheets in a consolidated format. Datasheets are prepared for each MEE, which summarise the hazard description, hazard management, emergency response, ALARP summary and a list of critical barriers identified on the bowties (known as safety and environment critical elements (SCEs)).

Potential common causes that contribute to MAEs/MEEs, or that can result in failure or degradation of the controls in place to protect against MAEs/MEEs, include some generic mechanisms of SCE failure and generic human error. These are represented in bowties applicable to multiple MEEs and identified in the MEEs applicable to this EP.

2.7.5 Safety and Environment Critical Elements and Technical Performance Standards

Woodside identifies and manages SCEs technical and management system performance standards in accordance with Process Safety Management Procedures, Risk Management Procedures and Change Management Procedures (further described in the implementation strategy in Section 7). SCEs are identified for MAEs and MEEs. An SCE is a hardware control, the failure of which could cause or contribute substantially to, or the purpose of which is to prevent or limit the effect of a MAE, MEE or process safety event. In addition, Woodside defines a safety and environment critical component (SCC) as an item of equipment or structure forming part of a hardware SCE that supports the SCE in achieving the safety function.

Once an SCE is identified as an MEE barrier for the operated facility, technical performance requirements are developed for the facility SCE in accordance with the Global SCE Performance Standards and process described in the SCE Management Procedures and form the SCE Facility Performance Standard. Each SCE Performance Standard represents a statement of the performance required of an SCE (e.g., functionality, availability, reliability, survivability). SCE Performance Standard requirements are used to establish agreed assurance tasks for each SCE, support the management of operations within acceptable safety and/or environment risk levels, and for the continuous management of risk to ALARP. An assurance task is an activity carried out by the operator to confirm that the SCE meets, or will meet, its SCE Performance Standard. Examples of assurance tasks include inspection routines, maintenance activities, test routines, instrumentation calibration, and reliability monitoring.

SCE Facility Performance Standards do not always align directly with EPSs. They are used in conjunction with the WMS to identify and treat potential step-outs from expected controls performance or integrity envelopes and so that SCE performance can be optimised. Woodside's HSE Event Reporting Guideline describes the process for identifying 'Failure to meet Facility Performance Standard', which is when the SCE does not meet the goal as stated in the relevant Performance Standard. (see Section 7.4). Situations where SCEs fail to meet Facility Performance Standards represent a potential increase in risk that, if not addressed immediately, have the potential to result in a process safety event, or worsen the consequences of one. Recording SCE Failure to Meet Performance Standard Events into the Event Reporting Database is important to highlight risk, investigate causes, manage risks and meet potentially applicable external reporting requirements. For applicable SCEs, 'Failure to meet Facility Performance Standard' represent scenarios that may fail to achieve an EPS presented in this EP.

The results of the MEE classification and analysis for Pluto Offshore operations are presented in Section 6.8.1 of this EP. More detail on the SCE and Performance Standards process, and the interrelationships to other parts of the SCE Management Procedures, is described in Section 7.4.

2.7.6 Safety-critical Management System Barriers

For each MEE, Safety-critical Management System specific measures are also identified. These are management system components (generally WMS processes) that are key barriers to, or measures for, managing MEEs.

2.8 Impact and Risk Evaluation

Environmental impacts and risks cover a wider range of issues, differing species, persistence, reversibility, resilience, cumulative effects, and variability in severity than safety risks. Determining the degree of environmental risk, and the corresponding threshold for whether a risk/impact has been reduced to ALARP and is acceptable, is evaluated to a level appropriate to the nature and scale of each impact or risk. Evaluation includes considering the:

- decision type
- principles of ESDev – as defined under the EPBC Act
- internal context – ensuring the proposed controls and risk level are consistent with Woodside policies, procedures and standards (Section 7 and Appendix A)
- external context – the environment consequence (Section 6) and stakeholder acceptability (Section 5)
- other requirements – ensuring the proposed controls and risk level are consistent with national and international standards, laws and policies.

In accordance with Regulations 34(a), 34(b), 34(c) and 34(b) and 21(5)(b), Woodside applies the process described in the subsections below to demonstrate ALARP and acceptability for environmental impacts and risks, appropriate to the nature and scale of each impact or risk.

2.8.1 Demonstration of ALARP

The descriptions in Table 2-5 articulate how Woodside demonstrates that different risks, impacts and Decision Types identified within the EP are ALARP.

Table 2-5: Summary of Woodside's criteria for ALARP demonstration

Risk	Impact	Decision Type
Low and Moderate	***Negligible, Slight, or Minor (D, E or F)***	***A***
Woodside demonstrates these risks, impacts and Decision Types are reduced to ALARP if: • identified controls meet legislative requirements, industry codes and standards, applicable company requirements and industry guidelines, or • further effort towards impact/risk reduction (beyond using opportunistic measures) is not reasonably practicable without sacrifices that are grossly disproportionate to the benefit gained.		
High, Very High or Severe	***Moderate and Above (C, B or A)***	***B and C***
Woodside demonstrates these higher order Risks, Impacts and Decision Types are reduced to ALARP (where it can be demonstrated using good industry practice and risk-based analysis) that: • legislative requirements, applicable Woodside requirements and industry codes and standards are met • societal concerns are accounted for • the alternative control measures are grossly disproportionate to the benefit gained.		

2.8.2 Demonstration of Acceptability

The descriptions in Table 2-6 articulate how Woodside demonstrates how different risks, impacts and Decision Types identified within the EP are Acceptable.

Table 2-6: Summary of Woodside's criteria for acceptability

Risk	Impact	Decision Type
Low and Moderate	***Negligible, Slight, or Minor (D, E or F)***	***A***
Woodside demonstrates these risks, impacts and Decision Types are 'Broadly Acceptable' if they meet legislative requirements, industry codes and standards, applicable company requirements and industry guidelines. Further effort towards risk reduction (beyond using opportunistic measures) is not reasonably practicable without sacrifices that are grossly disproportionate to the benefit gained.		
High, Very High or Severe	***Moderate and Above (C, B or A)***	***B and C***
Woodside demonstrates these higher order Risks, Impacts and Decision Types are 'Acceptable if ALARP' if it can be demonstrated using good industry practice and risk-based analysis (RBA), if legislative requirements are met and societal concerns are accounted for, and the alternative control measures are grossly disproportionate to the benefit gained. In undertaking this process for Moderate and High risks, Woodside evaluates: • the principles of ESDev as defined under the EPBC Act • the internal context – the proposed controls and consequence/risk level are consistent with Woodside policies, procedures and standards • the external context – consideration of the environment consequence (Section 6) and stakeholder acceptability (Section 5) are considered • other requirements – the proposed controls and consequence/risk level are consistent with national and international industry standards, laws and policies ad consideration of applicable plans for management and conservation advice, conventions and significant impact guidelines (e.g., MNES). For potential C or above consequence/impact levels where significant uncertainty exists in analysis of the risk or impact (such as, for predicted or potential high risk of significant environmental impacts, significant project risk/exposure, novel activities, lack of consensus on standards, and significant stakeholder concerns; e.g., Decision Type C), acceptability may be required to be conducted separately for key receptors. This is not applicable for risks, given the consequence of an unplanned risk event occurring may not be acceptable and, therefore, acceptability is demonstrated in the context of the residual likelihood of an event occurring and subsequent impacts. Additionally, Very High and Severe risks require 'Escalated Investigation' and mitigation. If after further investigation the risk remains in the Very High or Severe category, the risk requires appropriate business engagement with increasing involvement of senior management in accordance with Woodside's Risk Management Procedure to accept the risk. This includes due consideration of regulatory requirements.		

2.9 Recovery Plan and Threat Abatement Plan Assessment

A separate assessment is undertaken to demonstrate the EP is not inconsistent with any relevant recovery plans or threat abatement plans (refer Section 6.10). An assessment of associated national objectives and action areas contribute to the demonstration of acceptability. The steps in this process are:

- Identify relevant listed threatened species and ecological communities (Section 4).
- Identify relevant recovery plans and threat abatement plans (Section 6.10).
- List all objectives and (where relevant) the action areas of these plans and assess whether these objectives/action areas apply to government, the Titleholder, and the PAP (Section 6.9).
- For those objectives and action areas applicable to the PAP, identify the relevant actions of each plan, and evaluate whether impacts and risks resulting from the activity are clearly not inconsistent with that action (Section 6.10).

2.10 Environmental Performance Outcomes, Environmental Performance Standards, and Measurement Criteria

EPOs, EPSs and MC are defined to address the potential environmental impacts and risks. These are explored in Section 6.

2.11 Implement, Monitor, Review and Reporting

An implementation strategy for the PAP describes the specific measures and arrangements to be implemented for the duration of the program. The strategy is based on the principles of AS/NZS ISO 14001 Environmental Management Systems, and demonstrates:

- control measures are effective in reducing the environmental impacts and risks of the PAP to ALARP and Acceptable levels
- EPOs and EPSs set out in the EP are met through monitoring, recording, auditing, managing non-conformance, and reviewing
- all environmental impacts and risks of the PAP are periodically reviewed in accordance with Woodside's risk management procedures
- roles and responsibilities are clearly defined, and personnel are competent and appropriately trained to implement the requirements set out in this EP, including in emergencies or potential emergencies
- arrangements are in place for oil pollution emergencies, to respond to and monitor impacts
- environmental reporting requirements are met, including 'reportable incidents'
- appropriate consultation is undertaken throughout the activity.

The implementation strategy is presented in Section 7.

2.12 Consultation

Woodside consults relevant persons in the course of preparing an EP in accordance with Regulation 25 of the Environment Regulations. Woodside's consultation methodology is presented in Section 5. Woodside's consultation record is at Appendix F.

3. DESCRIPTION OF THE ACTIVITY

3.1 Overview

This section has been prepared in accordance with Regulation 21(1) of the Environment Regulations and describes the activities to be undertaken as part of the PAP under this EP. It includes the location of the activity, general details of the facility associated infrastructure, the operational details of the activity, and additional information relevant to consideration of environmental risks and impacts.

The Pluto facility currently produces gas and condensate from the Pluto, Pyxis and Xena fields via the Pluto subsea hydrocarbon gathering system (Section 3.4). This EP includes the ongoing operation of the Pluto facility and Xena-03 Drilling and Tie-back activities associated with the Xena-03 well, in the Xena field. An overview of the PAP is provided in Sections 1.1, 3.1.1, 3.1.2 and Table 3-1.

3.1.1 Pluto Facility Operations Overview

The Pluto offshore facility (the facility) and export pipeline is outlined in Figure 3-1. The facility produces wet gas and condensate from the Pluto, Pyxis and Xena fields in Production Licence WA-34-L. The platform is designed to be operated in both not-normally-crewed (NNC) and minimally crewed states. The offshore facilities are remotely operated from the central control room (CCR), either from the central control room at Pluto LNG Park or remote central control room in Perth. Gas and condensate are transported onshore for processing via a 180 km long export pipeline.

A Produced Water Handling Module (PWH) was installed on the riser platform in 2019 and commissioned in 2024 to enable the processing and discharge of produced water at the platform. Wet gas is processed through the PWH, with gas and condensate transported to the onshore LNG Plant for processing. These activities are outlined in Table 3-1.

3.1.2 Xena-03 Tie-back Overview

Woodside plans to drill and complete the Xena-03 infill production well within this EP revision. The work includes drilling one new well in the Xena field, as well as installation of an associated wellhead, xmas tree, and connecting the well to the existing Pyxis Hub subsea infrastructure (Section 3.4). The well will be located at approximately 177 m water depth.

The well will be drilled and completed using a moored or hybrid mobile offshore drilling unit (MODU). Typically, two or three support vessels will support the MODU during drilling activities, with at least one vessel in the vicinity to complete standby duties, if required. Supply vessels from Dampier Port will frequent the MODU at regular intervals throughout drilling operations, as required.

Installation of the subsea infrastructure will be undertaken using an installation vessel. Another installation vessel, similar to vessels used for IMMR activities, may be used to install the xmas tree and for cold commissioning the wells and during start-up (if required). Support vessels associated with subsea installation activities may transit between the PAA and port, however transit activities are not within the scope of this EP.

The scope for this EP covers the tie-back of the Xena-03 well to the existing Pyxis Hub subsea infrastructure (Section 3.4), including drilling, completion, and subsea installation (including minor changes to existing infrastructure) along with pre commissioning, cold commissioning and start-up. These activities are outlined in Table 3-1 and described in detail in Section 3.4.2.3.

Table 3-1: PAP overview

Item	Description
Production/ Infrastructure licences	WA-1-IL, WA-34-L
Pipeline licences	WA-16-PL, WA-17-PL
Platform location	115° 22’ 5.582” E 19° 59’ 46.476’ S
Water depth (lowest astronomical tide (LAT)) at Pluto topsides location	85 m
Key components of the facilities	Fixed platform, processing equipment including PWH, pipelines; subsea infrastructure Pluto, Xena and Pyxis wells, wellheads, manifolds, umbilicals, chemical supply lines, risers, flowlines, flexible jumpers
Key components of pipeline subsea infrastructure	Xmas trees, flowlines/pipelines and umbilicals
Number of wells	11 existing production wells (PLA01, PLA02, PLA03, PLA04, PLA05, PLA06, PLA07, PLA08, XNA01, XNA02, PYA01, and PL-PYA02)) Drilling, completion, and production for 1 new well proposed to be constructed in 2025 (XNA03)
Subsea infrastructure	Existing: • Pluto riser platform • Pluto Export Pipeline • Pluto/Xena-03/Pyxis subsea infrastructure (including umbilicals and flowlines) Xena-03 Proposed (planned installation Q3, 2025): • one subsea xmas tree and wellhead • one flexible flowline • one set of flying leads • one electrohydraulic umbilical (EHU) and associates umbilical termination assemblies (UTAs)
MODU	Moored MODU or hybrid MODU
Vessels	Pluto Operations: • platform support vessels, ASV, subsea support vessels Xena-03 Tie-back: • MODU, MODU support vessels including AHVs, installation vessel/s
Key activities	Pluto Operations: • routine production • routine inspection, maintenance, monitoring and repair of the platform and associated subsea infrastructure. • well unloading and clean-up • non-routine and unplanned activities and incidents associated with the above. Xena-03 Tie-back: • subsea infrastructure stabilisation • mooring installation for the MODU • development drilling and completions activities via MODU • installation of xmas tree

Item	Description
	• site surveys • installation of flowline, flying leads, subsea tree, subsea distribution unit • tie-in to existing subsea infrastructure • pre-commissioning of the new subsea infrastructure • cold commissioning of the well and xmas tree • start-up to the Pluto facility including unload of well to onshore LNG Plant and performance testing • contingent intervention, workover, or re-drill for the new well

3.2 Location

The riser platform is located in Commonwealth waters off WA, in Production Licence Area WA-1-IL approximately 160 km north west of Dampier and 75 km north of Barrow Island (Figure 3-1). Gas and condensate produced from the facility are exported via the 180 km long pipeline and associated 6-inch chemical supply line, to onshore for processing.

Currently, gas is produced from seven Pluto wells, two Pyxis wells and two wells in the Xena field. An additional well in the Pluto field (PLA08) is anticipated to commence production in 2025 and an additional well in the Xena field (Xena-03) is proposed to be tied back in this EP, 11 km from the riser platform.

The riser platform is marked on nautical charts and surrounded by a 500 m petroleum safety zone (PSZ). The riser platform is marked on general aviation maps and categorised as a Danger Area for civil aircraft. The danger-type is listed in the General Pilots Manual as “avoid flight over facility between surface and 1500 feet”. The export pipeline is also marked on nautical charts. The coordinates and permit areas of the facility and associated infrastructure are presented in Table 3-2.

Table 3-2: Approximate location details for the PAP, including all relevant infrastructure

Structure	Water Depth (approx. m LAT)	Latitude	Longitude	Title
Riser platform	85	-19° 54’ 49.24’’	115 ° 7 ‘ 54.47‘’	WA-1-IL

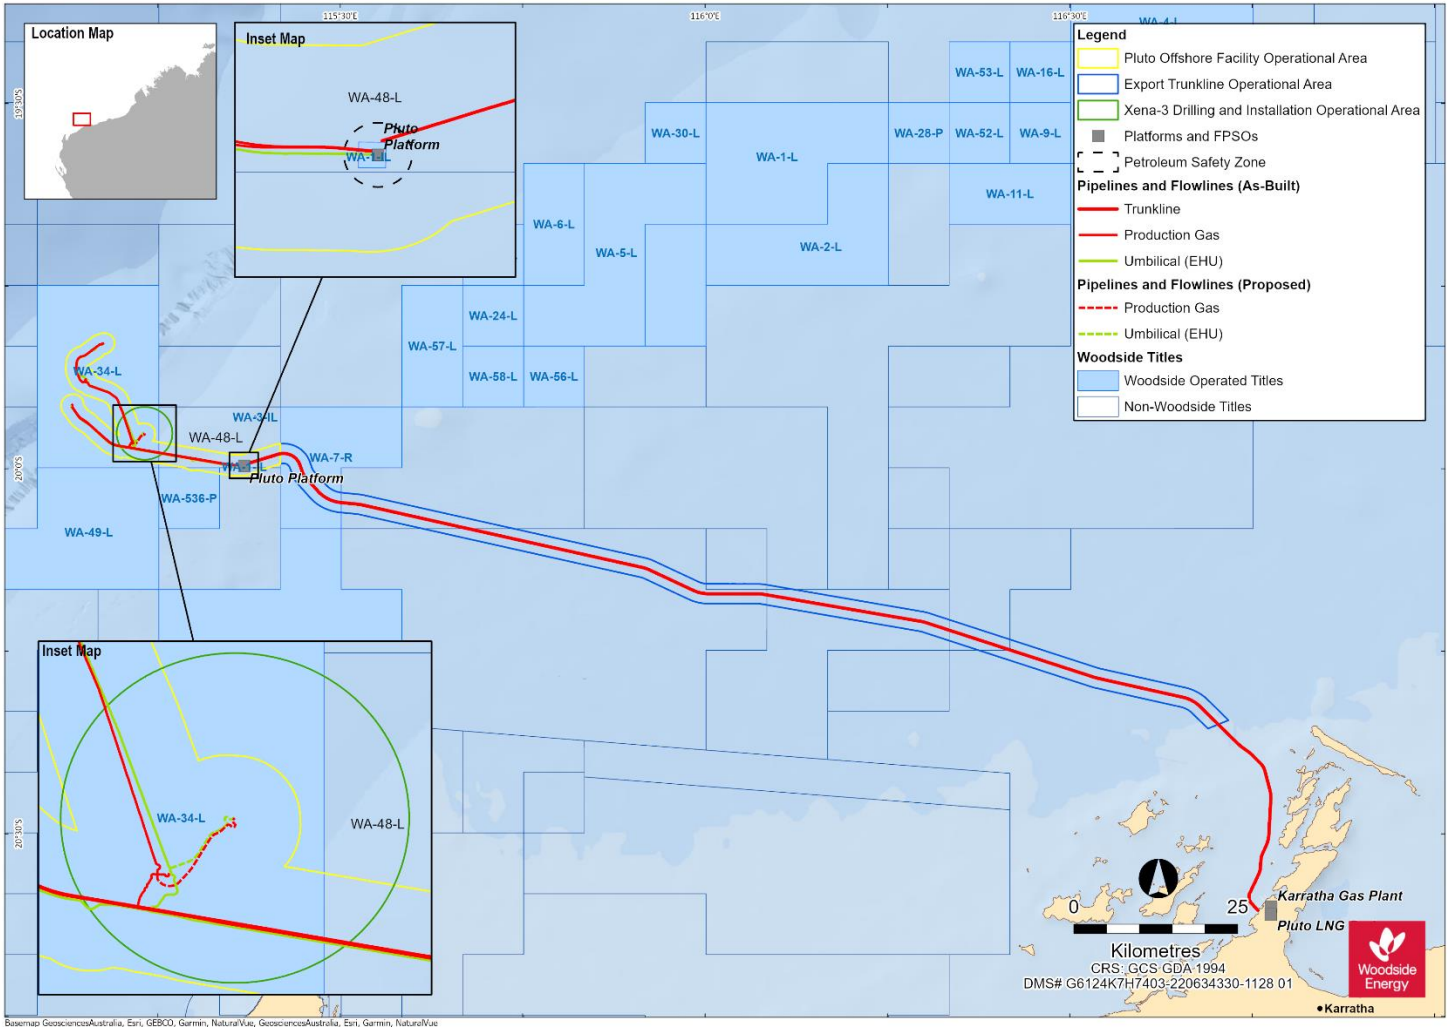

Figure 3-1: Location of the PAP

3.2.1 Petroleum Activities Area

The spatial boundary of the PAP has been described and assessed using three Operational Areas, the Pluto Facility Operational Area, Export Pipeline Operational Area (collectively referred to as the Pluto Operational Area), and the Xena-03 Operational Area. The Operational Areas are collectively referred to as the Petroleum Activity Area (PAA) in this EP, with specific Operational Areas referred to where relevant.

Vessel-related activities within the PAA will comply with this EP. Vessels transiting to the PAA are outside the scope of this EP and are covered by applicable maritime Regulations and other requirements during that time.

3.2.2 Pluto Operational Area

The Pluto Operational Area, risk assessed and managed by this EP, includes vessel-related petroleum activities within the PAA that include:

- the riser platform and the area within a 500 m PSZ around the riser platform
- the export pipeline (P1TL) and associated 6-inch chemical supply line covered by Pipeline Licence WA-17-PL and flowlines in WA-16-PL and an area encompassing 1500 m each side around the subsea pipeline infrastructure
- Pluto, Xena and Pyxis subsea facilities (including wells, production and pigging manifolds, production jumpers, spools, flowlines and flexible jumpers) and an area within 1500 m each side around the subsea infrastructure.

For the purposes of the Description of the Existing Environment (Section 4) and for the Environmental Impact and Risk Assessments (Section 6) the Pluto Operational Area has been divided into two sections where relevant, being:

- the Facility Operational Area (all elements of the Pluto platform and subsea hydrocarbon gathering system (wells, xmas trees, flowlines, spools, jumpers, umbilicals, etc))
- the Export Pipeline Operational Area (pipeline to the boundary between Commonwealth and WA State waters).

3.2.3 Xena-03 Operational Area

The Xena-03 Operational Area has a radius of 4000 m centred on the Xena-03 well location, to allow for MODU mooring operations, drilling of the Xena-03 well, installation of subsea infrastructure (including installation and connection of the Xena-03 flowline), pre-commissioning and related petroleum activities.

The Xena-03 Operational Area allows for MODU mooring operations, including the possible installation of pre-laid moorings and vessel-related petroleum activities. It also includes a 500 m Safety Exclusion Zone (SEZ) around the MODU to manage vessel movements, which will be under the control of the MODU Person in Charge. The primary installation vessel (PIV), operating within the Xena-03 Operational Area, will also be surrounded by a 500 m SEZ when on-location, which will be under the control of the vessel master.

For the purposes of the description of the existing environment (Section 4) and for the environmental impact and risk assessments (Section 6), the Xena-03 Tie-back Operational Area has been referred to where relevant.

3.3 Timing

3.3.1 Pluto Operations

The facility commenced production in 2012. The Pluto facility is designed to operate 24 hours per day, 365 days per year.

Estimated end of life of the Pluto, Xena and Pyxis fields is expected in 2032, subject to reservoir performance Production from PLA08 is expected in Q2 2025. This EP is intended to remain in force in accordance with Regulation 36 of the Environment Regulations.

3.3.2 Xena-03 Tie-back Activities

Drilling of the Xena-03 well is anticipated to commence in Q2 2025 and take around 60 days to complete (Table 3-3). Subsea installation is anticipated to follow in Q3 2025 and to have a cumulative duration of around three weeks (including mobilisation, demobilisation and contingency). Drilling and installation of subsea infrastructure may be performed over multiple campaigns.

Timing and duration of activities is subject to change due to project schedule requirements, MODU/vessel availability, unforeseen circumstances and weather constraints.

When tie-back activities are underway, activities are 24 hours per day, seven days per week. There are no planned concurrent drilling activities under the EP. Simultaneous operations (SIMOPS) activities with subsea installation may occur. Timing and duration of all activities is subject to change due to project schedule requirements, MODU/vessel availability, unforeseen circumstances and weather.

The EP has risk-assessed activities associated with the drilling and tie-back of the Xena-03 well as if they were to occur at any time during the year, this includes drilling activities, subsea infrastructure installation, pre-commissioning activities and intervention, workover, or re-drilling activities. This provides operational flexibility for requirements and schedule changes and vessel/MODU availability. The timeframes are therefore subject to change within the defined calendar years and, as no particular windows have been nominated for avoidance based on environmental and/or stakeholder sensitivities, changes to the above will not be interpreted as ‘new stages’ against Regulation 39(1).

Table 3-3: Summary of timing for tie-back activities

Activity	Approximate Timing (and Cumulative Duration in the Field)
Installation and removal of anchors for MODU	2025 (7–10 days per activity)
Drilling and completions	Q2 2025 (~60 days) 2026 (contingency)
Subsea installation and pre-commissioning/cold commissioning	Q3 2025 (~3 weeks) 2026 (contingency)
Well start-up and performance testing	2025 (~3 weeks) 2026 (contingency)

3.4 Facility Layout and Description

This section provides a high-level overview of the facility and associated infrastructure, as relevant to consideration of the environmental risks and impacts of the Petroleum Activities Program.

3.4.1 Pluto Alpha Topsides

The riser platform topsides comprise five decks separated by two major vertical trusses (Figure 3-2). A pedestal crane is located on the northeast end of the facility. The flare boom is inclined and located

at the northern end of the facility (Figure 3-3). A PWH has been installed on the western side of the riser platform. The helideck is located above the southern corner. Figure 3-3 and Figure 3-4 show the riser platform topsides layout and layout of the PWH respectively.

Other facilities include pig launchers and receivers for the flowlines and export pipeline, vessels for handling pigging fluids, metering for inflow streams, chemical injection facilities (for monoethylene glycol (MEG), water clarifier and corrosion inhibitors), diesel power generators, emergency flare, pedestal crane, temporary waste storage, helideck, bunkering facility, telecommunications, monitoring, control and safety systems and marine navigational aids.

Power generation infrastructure was upgraded during installation of the PWH. This included installation of a gas engine generator as a new main source of power on PLA, commissioning in 2023. Two diesel engine generators are on the platform for backup power generation.

Chemical storage and injection facilities (corrosion inhibitors and water clarifier) are also part of the PWH. Although the riser platform is NNC, permanently installed accommodation facilities are provided on the southern end of the topsides to accommodate personnel required for campaign maintenance, significant modifications and pigging activities. The potential environmental impacts from planned and unplanned activities are discussed in Section 6.

Figure 3-2: Photograph of the Pluto Alpha riser platform

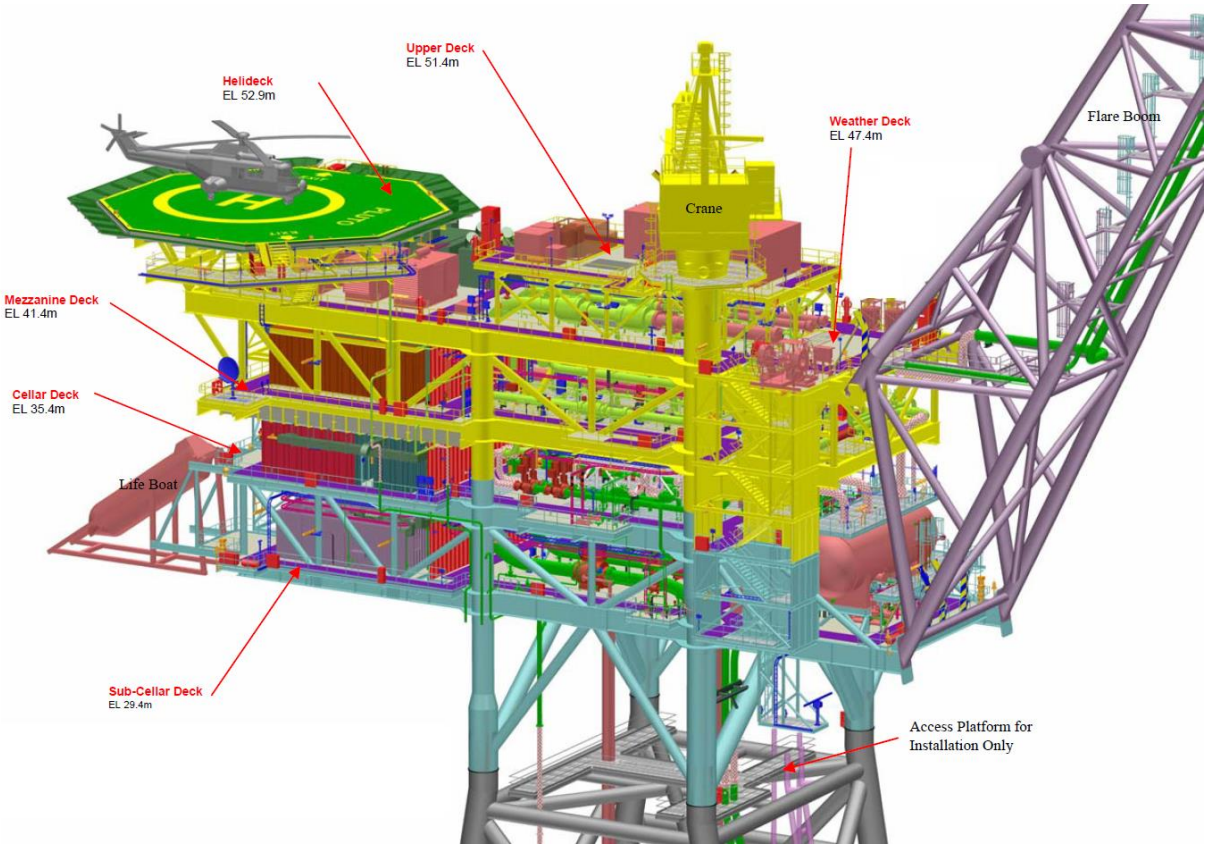

Figure 3-3: Pluto Alpha facility platform layout

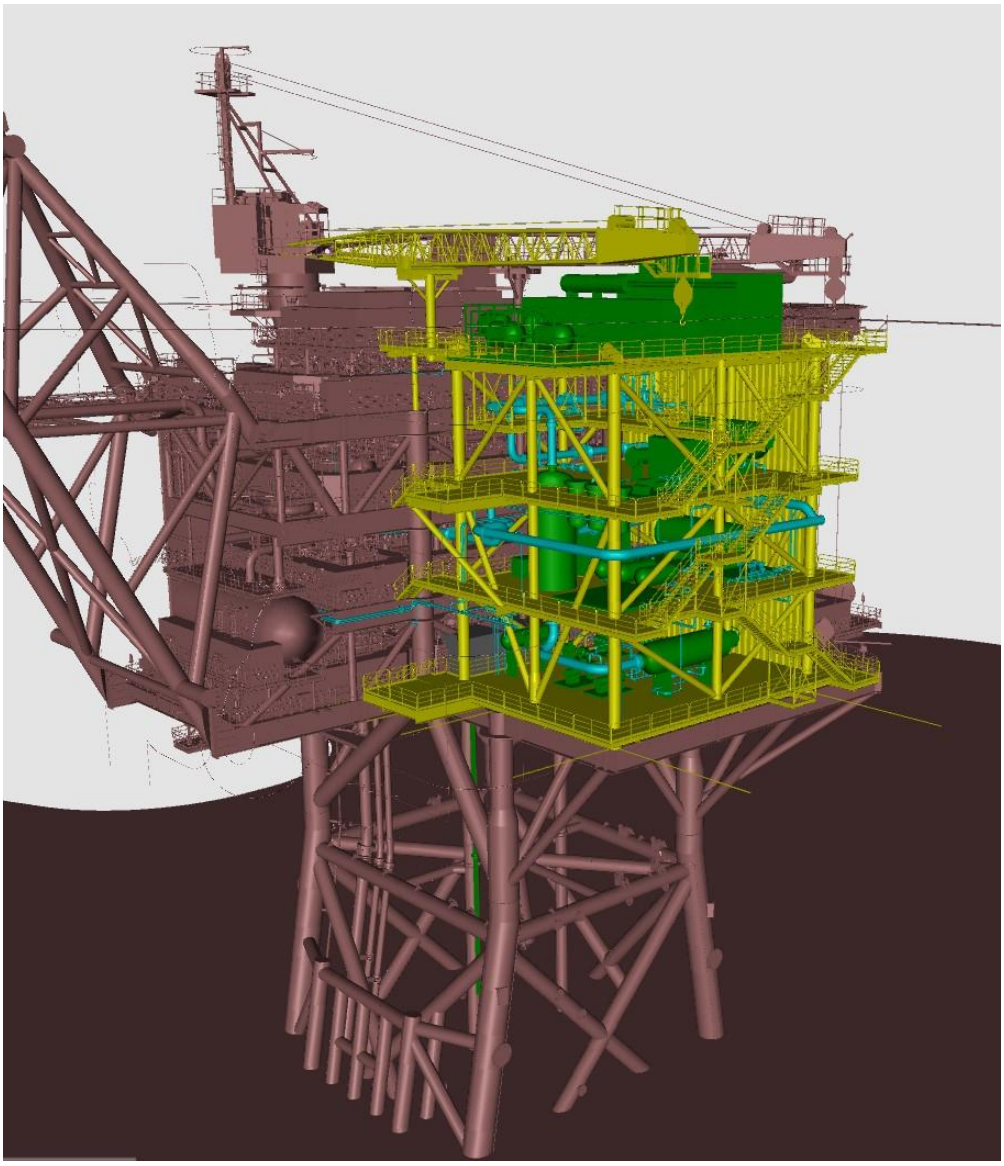

Figure 3-4: Pluto Alpha water handling module layout

3.4.2 Wells and Reservoirs

3.4.2.1 Pluto Wells

Gas and condensate from the Pluto reservoir are currently produced through eight big bore gas production wells (PLA01–07 which are configured in a cluster arrangement around a central manifold at the drill centre (Figure 3-5). PL-PYA02, located separately, also produces from Pluto reservoir (refer Section 3.4.2.3). The primary reservoir isolations are provided by the actuated valves within the tree, and a down-hole surface controlled sub-surface safety valve (SCSSV) is included in the well design as emergency barrier in the event of tree/wellhead catastrophic failure. The wells are completed with a subsea tree system. An additional well (PLA08), is proposed to commence production in Q2 2025.

3.4.2.2 Xena Wells

Condensate and gas from the Xena reservoir are currently produced through two gas production wells (XNA01 and XNA02). The wells are independently isolated and controlled via a spur tie-in to

the existing Pluto electro-hydraulic umbilical, located close to the existing tee locations. MEG and other chemicals as required are distributed to the wells via a dedicated flowline between an existing MEG pipeline end termination (PLET) on the chemical supply line. The existing wells are completed with a subsea tree system, similar to those installed on the Pluto wells. The primary reservoir isolations are provided by the actuated valves within the tree, and a down hole SCSSV is included in the well design as emergency barrier in the event of tree/wellhead catastrophic failure.

An additional infill well from the Xena reservoir (Xena-03) is proposed to be operated during the life of this EP.

3.4.2.3 Pyxis Wells

Condensate and gas from the Pyxis reservoir are produced through one gas production well (PYA01), approximately 25 km north north-east of the existing Pluto A flow line tie-in. PL-PYA02 exploits the Pluto gas field but is considered part of the Pyxis development. Pyxis wells combine in the Pyxis manifold and connect through to the XNA Manifold via a 12-inch flexible flowline.

The wells are independently isolated and controlled via a spur tie-in to the existing Pluto electro-hydraulic umbilical, located close to the existing tee locations (Figure 3-5). MEG and other chemicals are distributed to the well via a new integrated service umbilical supplied from an existing MEG PLET on the chemical supply line. The wells were completed with a subsea tree system, similar to those installed on the Pluto wells. The primary reservoir isolations are provided by the actuated valves within the tree, and a down-hole SCSSV is included in the well design as emergency barrier in the event of tree/wellhead catastrophic failure.

3.4.3 Flowline and Riser System

Two production flowlines connect the subsea production system to the PLA platform. Production from the Pluto wells is selectively directed from the Pluto central manifold into either Flowline A or Flowline B, via Flowline Termination Assemblies and a pigging manifold. The flowlines are routed approximately 27 km through dual 20-inch flowlines with an adjacent chemical supply line, up the continental slope to the riser platform (Figure 3-5).

The wells XNA-02 and proposed Xena-03 connect to production flowlines (currently Flowline A) via the Pyxis hub subsea infrastructure of:

- Well jumpers to the XNA manifold
- flexible production jumper
- mid-line connector system (MLCS-A) to the existing flowline tee

The Pyxis development wells are connected to the production flowlines via the subsea infrastructure of:

- PYX and XNA manifolds and an approximately 25 km connecting flexible flowline up to 12-inch
- Well connection flowlines (8-inch and 10-inch) to PYX manifold
- an 8-inch flexible production jumper from the flowline end terminal to existing MLCS-A and Pluto flowline A in-line tee.

XNA-01 connects to MLCS-B, and tee into Flowline B.

The flowlines are configured as loops to allow round trip pigging of the flowlines from either end, with flowline pig launcher/receivers installed on the topsides. The flowlines and subsea system are sized to match the peak offtake rate required by the onshore LNG plant.

3.4.4 Wet Flowline Conversions

To segregate wet wells for processing through the PWH, Flowline B may need to be converted between dry flowline mode and wet flowline mode. Prior to flowline pigging operations (approximately four-yearly) and in case of infrequent planned/proactive shutdown management, the flowline may be required to be converted between wet and dry flowline modes to treat the flowline with MEG for integrity management and prevent hydrate blockages. Upon restart, the flowline is required to be converted from dry flowline mode back to wet flowline mode. As part of this, up to 52 tonnes of diluted MEG will be displaced from the flowlines and wells, which will enter the water treatment process on the facility and be discharged overboard.

If the wet flowline is shut down, MEG is required to be dosed into in each wet well (~1.6 tonnes) and uninsulated sections of the flowlines subsea (14 tonnes) which will be displaced to the separation and PW treatment process on the facility and discharged overboard.

3.4.5 Pipeline and 6-inch Chemical Supply Line

Gas, condensate and other fluids (process chemicals and produced water) are currently transported from the riser platform to the LNG Plant via a 36-inch pipeline. The pipeline is carbon steel, 36-inch in outside diameter and is corrosion and concrete weight coated. The design and operating parameters for the pipeline and 6-inch chemical supply line are detailed in Table 3-4 and Table 3-5 respectively. Flow assurance is aided by the supply of MEG and other process chemicals in small concentrations (including corrosion inhibitor, biocide, oxygen scavenger, scale inhibitor, etc.) as required to protect the integrity of the pipeline. These chemicals are supplied from onshore storage and MEG regeneration infrastructure and pumped via the 6-inch chemical supply line piggy-backed to the pipeline from onshore to the riser platform. MEG, containing supporting chemicals are then supplied from the riser platform to the wells via a 4-inch chemical supply line.

The offshore gas pipeline and 6-inch chemical supply line route between the shore and the facility is approximately 180 km in length with a shore crossing at Holden Point, just north of the Pluto export jetty. The portion of the pipeline in State waters is not included in the scope of this EP. The offshore pipeline route is shown in Figure 3-1.

Table 3-4: 36-inch Pluto Export Pipeline Design and Operating Parameters

Description	Details
Length	180.94 km (total)
Diameter, external	914 mm from KP -0 KP 180
Wall thickness: Riser Spool pieces and 500m PSZ Pipeline outside of the areas above	 28.6 mm 26.7 mm 24.0 mm
Protective coating specification (Temp <60°C) Pipeline: Riser: Above Water Tie-In and Laydown sections:	 Asphalt Enamel Subsea: System 13B (high build, high solids epoxy) Splash zone: Polychloroprene Top section: System 11A (2 coats of Epoxy Phenolic) FBE (1 joint)
Weight Coating: Material Density Thickness	Concrete (on BE coated sections and at the slope crossing 3040 - 3400 kg/m^3 45 – 120 mm

Pipe steel specifications (pipeline and riser) Material Type: Material Standard: Material Grade:	 Carbon Steel DNV-OS-F101 Grade 450 (X65)
Design pressure and temperature Pressure: Inlet Temperature[11]	 142 barg (@+47m LAT) Max: 60°C / Min: -10°C
Design capacity[12]	1710 MMscfd total wet raw gas equivalent
Minimum Operating Pressure[13]	25 barg at LAT +61m
Cathodic Protection (CP): Pipeline, spool pieces and riser)	 Sacrificial bracelet anodes (Al-Zn-In).
Design Life	35 years
Associated pipeline infrastructure	The pipeline system contains one 36” NRV (swing check valve) and a 36” ROV operated ball valve near the platform location. These valves are installed in an assembly that provides resistance to dropped objects and snag loads and supports the 6” MEG supply line. Pipeline support systems include concrete mattresses and gravity anchors in applicable locations such as pipeline crossings.

Table 3-5: 6-inch Chemical Line Design and Operating Parameters

Description	Details
Length	180.94 km (total)
Diameter, external (all sections)	168.3 mm from KP -0 KP 180
Wall thickness: Riser Spool pieces and 500m PSZ Pipeline outside of the areas above	 14.3 mm 14.3 mm 10.3 to 12.7 mm
Protective coating specification Pipeline: Riser: Above Water Tie-In and Laydown sections:	 3-layer Polypropylene Subsea: System 13B (high build, high solids epoxy) Splash zone: Polychloroprene Top section: System 11A (2 coats of Epoxy Phenolic) FBE (1 joint)
Pipe steel specifications (pipeline and riser) Material Type: Material Standard: Material Grade:	 Carbon Steel ISO 3183-3 (API 5L) L 450 MC (X65)

[11] Maximum operating temperature is at riser inlet. The maximum sustained temperature for corrosion design for the export trunkline is 45°C.
[12] As per Pluto Alpha Facility Safety Case.
[13] For the pipeline, the minimum normal operating pressure will occur when there is full onshore/LNG trains shutdown followed by the onshore plant continuing to draw low rates of fuel gas from the pipeline. The pressure in this condition is equivalent to 25 barg. The minimum internal pressure in the export trunkline under normal operating conditions is 65 barg (i.e. the minimum slug catcher pressure)

Design pressure and temperature Pressure: Inlet Temperature	 34.5 MPag (@+61m LAT) Max: 60°C, Min: 0°C
Design capacity	3,000 bpd lean MEG
Cathodic Protection (CP):	Continuity straps installed on the 6-inch chemical line at all locations where sacrificial bracelets are installed on the pipeline
Design Life	35 years
Associated pipeline infrastructure	On bottom stability achieved using piggyback attachment of 6-inch chemical line onto the trunkline or rock dump.

3.4.6 Subsea Infrastructure

The scope of this EP includes all subsea infrastructure associated with facility. The main components of subsea infrastructure include wells, xmas trees, umbilicals, spools, jumpers, manifolds, flowlines, riser, chemical supply lines and the export pipeline. The layout of existing and proposed subsea infrastructure is shown in Figure 3-5.

The subsea system is remotely operated via satellite links and includes:

- rigid spools transporting hydrocarbons from the wells to the manifold/MLCS where the fluids flow through the 20-inch flowlines to the riser platform for onwards processing at the onshore facility
- jumpers and umbilicals, which provide hydraulic and electric power, communications and chemical supplies
- valves, which control subsea operations and processes
- chokes, which control pressure and flow rates of hydrocarbon
- subsea control module (SCM), which contains sealed and pressure-compensated electro-hydraulic units (typically found on manifold and/or wellheads) and links the surface and subsea controls.

Emergency shutdown (ESD) valves exist at various locations in the offshore facilities, including at the top of each flowline and pipeline risers to the riser platform. A non-return valve (NRV) is also provided on the 36-inch pipeline close to the riser platform as an emergency barrier to reduce the potential for uncontrolled backflow from the pipeline to the riser platform. A number of subsea valves may also be overridden manually from either a remotely operated vehicle (ROV) or by divers.

3.4.6.1 Flowlines Interactions

The following facilities and equipment are near the Pluto flowlines:

- The 44-inch Wheatstone pipeline was installed in 2014 and crosses the Pluto flowlines at approximately KP 19.1. It also crosses the 4-inch MEG line and subsea umbilical.
- The 18-inch Julimar and Brunello flowlines were also installed over the Pluto flowlines, 4-inch MEG line and subsea umbilical crossing at flowline KP21 in 2014.
- The Scarborough 36-inch trunkline (under construction) crosses both Pluto flowlines and MEG/umbilical lines in 152 m water depth, and the Scarborough trunkline 32-inch section crosses the Pyxis flexible flowline in 1007 m water depth.

The design of the crossings ensures the safety and integrity of any new infrastructure can be assured over its design life while not compromising the safety, integrity and operability of the existing facilities.

3.4.6.2 Export Pipeline Interactions

Connected on each side of the Pluto Export Pipeline are the PLA platform and the Pluto LNG Park. The following facilities and equipment are also in the vicinity of the Commonwealth waters section of the Pluto Export Pipeline:

- A 36-inch export pipeline runs adjacent to the 40-inch 1TL within Mermaid Sound (for ~40 km).
- The 36-inch Scarborough Trunkline runs adjacent to the Pluto 36-inch export pipeline from the shore crossing in Mermaid Sound for approximately 161 km.
- The 16-inch Reindeer gas pipeline crosses at KP 75.

3.4.6.2.1 Reindeer Pipeline Crossing

The Santos Reindeer pipeline was installed in late 2010 and crosses the 36-inch pipeline and 6-inch MEG pipeline at KP 75. The design of the Reindeer crossing incorporates sufficient stabilisation of the pipelines, sufficient clearance and was subject to independent validation by DNV.

3.4.6.2.2 Submarine Communications Infrastructure Crossing

The Chevron fibre optic cable to the Wheatstone platform intersects the Export Trunkline Operational Area twice. The fibre optic cable crosses the Pluto trunkline at KP 136 and 150.

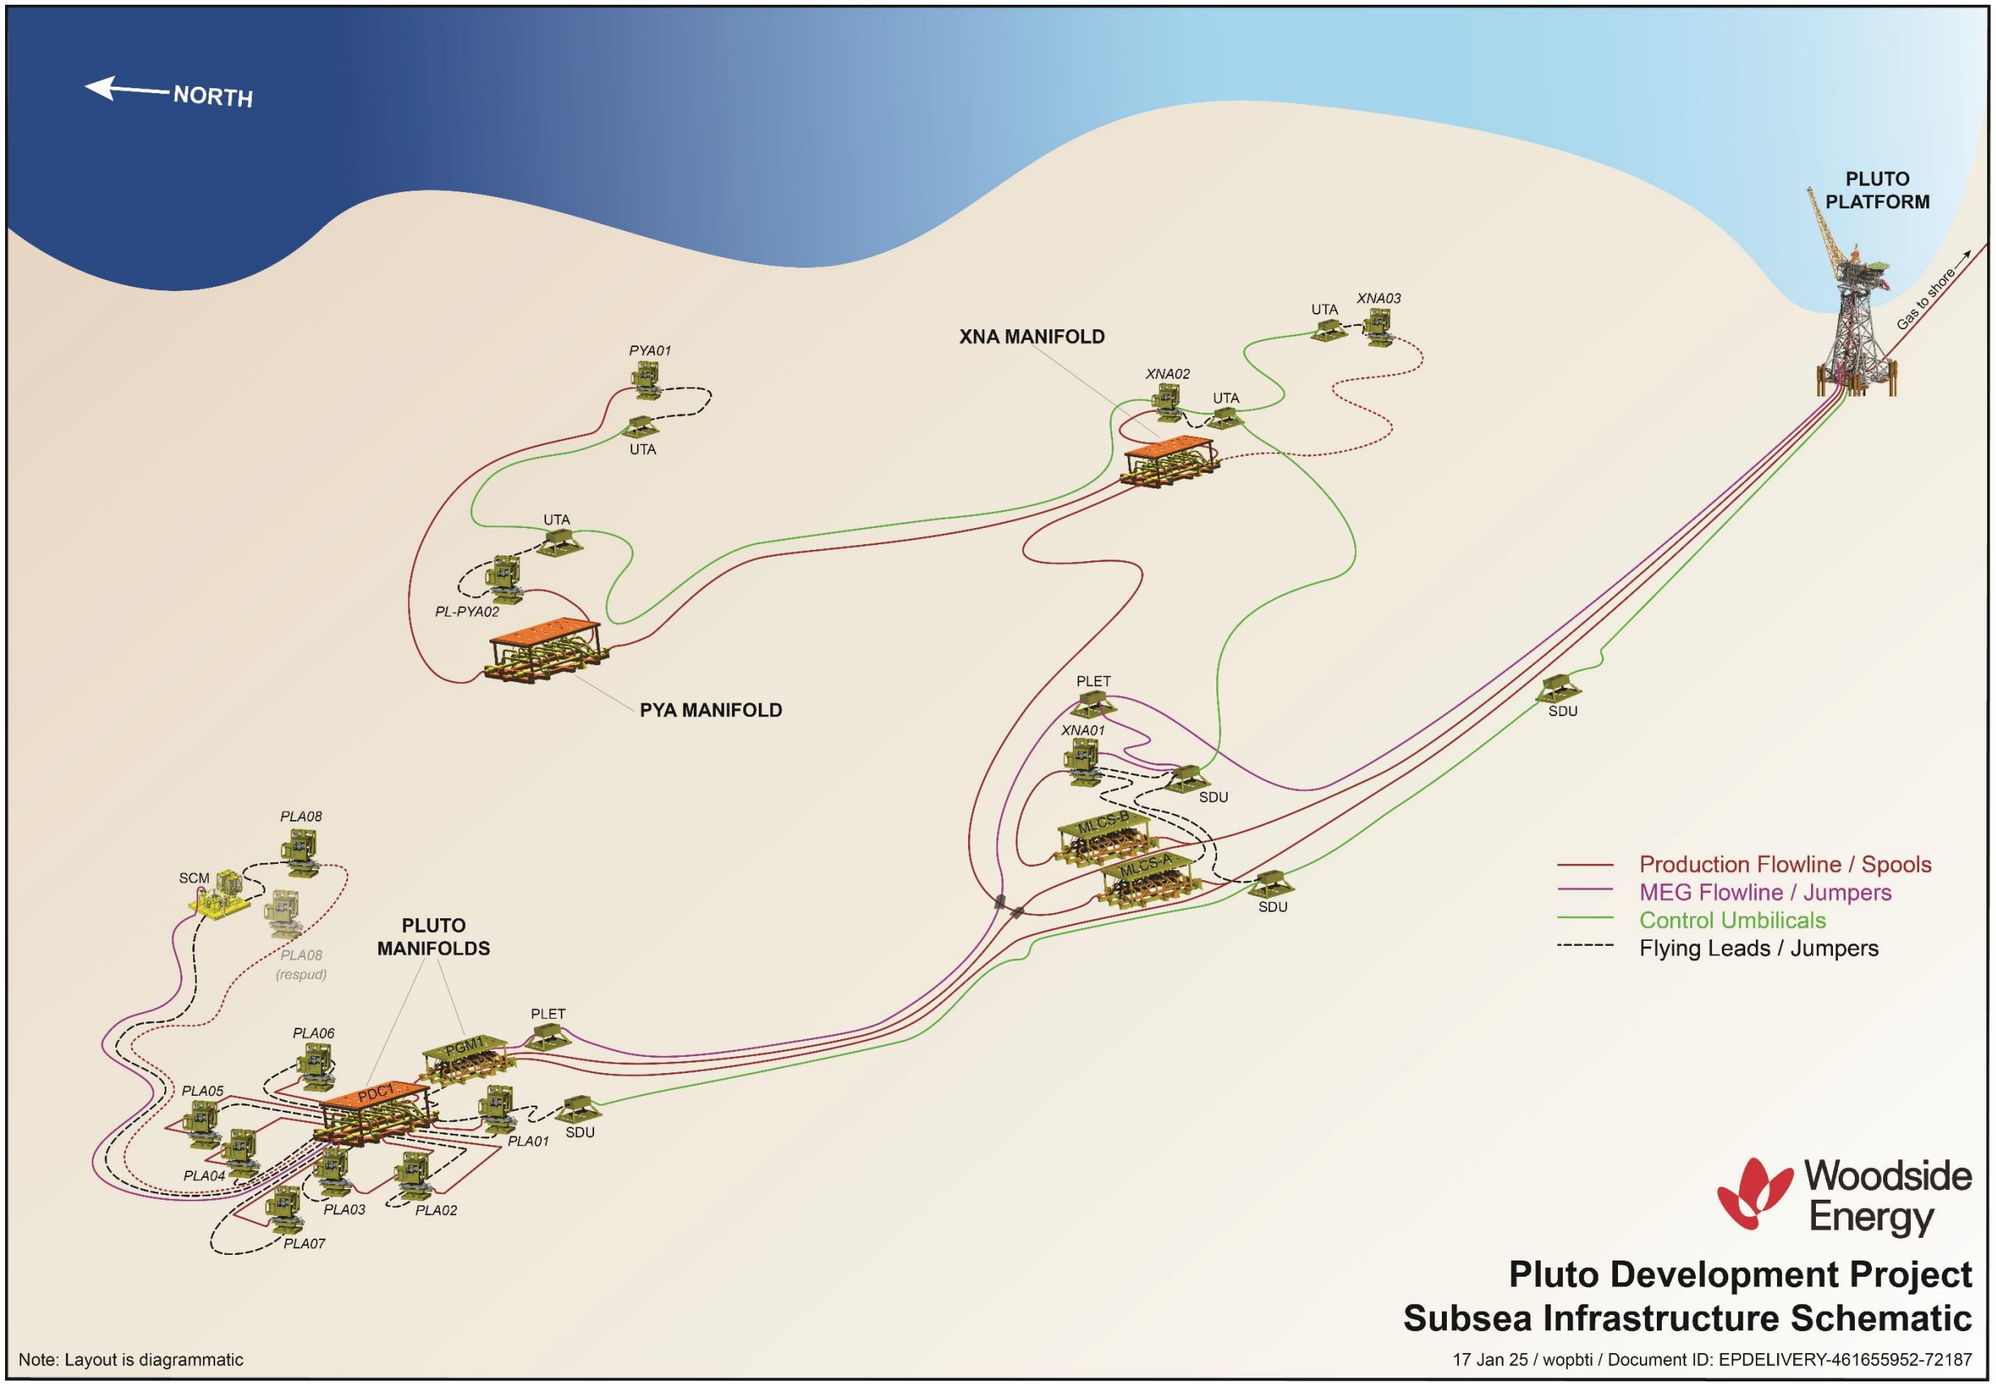

Figure 3-5: Layout of the Pluto facility subsea infrastructure

3.4.7 Field Inventory

The layout of the Pluto subsea infrastructure, including location of the fields, is shown in Figure 3-5 and described in Table 3-6.

Table 3-6: Inventory of subsea wells and key infrastructure, including status

Infrastructure[1]	Status[2]	Decommissioning Planning
Pluto		
7 wells, 2 active pipe support, 2 flowline termination assemblies, 2 manifolds, 7 SDU, 3 PLETs	Maintained for production	Section 7.5
17 rigid spools (2 x 6", 7 x 8", 2 x 14", 4 x 20", 2 x 36"; total length ~2.0 km), 5 flowlines (2 x 4", 1 x 6", 2 x 20"; total length ~263 km), 1 36" trunkline (~181 km)	Maintained for production	
5 umbilicals (total length ~28 km), 25 flying leads, 65 jumpers	Maintained for production	
1 well (PL08), 1 SCM control skid, 2 8" flowlines (total length ~433 m), 10 jumpers	To be commissioned	
Pyxis		
2 wells, 1 manifold, 2 SDU/UTAs	Maintained for production	Section 7.5
3 flowlines (1 x 8", 1 x 10", 1 x 12"; total length ~22 km)	Maintained for production	
2 umbilicals (total length ~21 km), 11 jumpers	Maintained for production	
Xena (existing)		
2 wells, 3 manifolds, 3 SDUs, 1 skid sensor	Maintained for production	Section 7.5
2 8" rigid spools of total length ~800 m, 3 flowlines (2 x 8", 1 x 10"; total length ~1.8 km)	Maintained for production	
1 umbilical (~1.4 km), 29 jumpers	Maintained for production	
1 jumper	Maintained for decommissioning	
Xena-03 (proposed)		
1 well, 2 UTAs	To be installed	Section 7.5
1 10" flowline (~3.0 km)	To be installed	
1 umbilical (~2.2 km), 6 jumpers	To be installed	

[1] Inventory of subsea infrastructure in the title areas or proposed to be installed in the title areas at time of submission of this EP.

[2] Status at time of submission of this EP.

The subsea infrastructure is recorded and tracked using a database. This database is updated as equipment is brought into title, which may include new or replacement equipment. Remotely operated vehicle (ROV) as-found, and as-left surveys are undertaken to identify the location of items placed on the seabed. At the completion of an IMMR campaign, this data is used to update the inventory for the title. Material items dropped to the marine environment and not recovered are added to the inventory for the title.

The subsea system has been designed, fabricated and installed in accordance with best practice and international standards. The pipelines, flowlines and wells are marked on nautical charts. Decommissioning planning is done for infrastructure no longer in use**.**

3.5 Operational Details

This section describes the main operations associated with the facility. It includes key elements in relation to interaction between the activity and the environment, described under the headings of:

- Process Description (Section 3.5.4)
- Utility Systems (Section 3.6)
- Facility Operations (Section 3.7)
- Support Vessel Operations (Section 3.8).

The facility is designed to operate without operator intervention. Normal operations are controlled remotely via satellite links from the Pluto Remote Operations Centre (PROC). Activities that require crewing are:

- engineering projects
- campaign maintenance
- unplanned corrective (breakdown) maintenance
- inspections/audits
- planned facility shutdowns.

Operations fall under any one of the modes of operation of:

- production remote operations
- major projects
- maintenance, including subsea inspection, maintenance, monitoring and repair (IMMR) activities
- well maintenance.

These modes of operation are described below. Production, maintenance and project activities may occur concurrently.

3.5.1 Production Remote Operations

The platform is designed to be operated with minimal/NNC crewing and is remotely operated, monitored, controlled, restarted and diagnosed from the central control room (CCR), either from the central control room at Pluto LNG Park or remote central control room in Perth.

The process control system for the facility provides the monitoring and control functions of:

- basic monitoring of key performance indicators
- adjustment of devices on the facility such as control valves, pumps, and variable speed drives
- alarm signals
- automatic management of duty/standby and lead/lag equipment.

3.5.2 Major Projects

Major projects involve refurbishment, modification or major maintenance on the facility. The Projects function is responsible for undertaking these projects. Potential environmental impacts related to projects are managed through the process outlined in Section 7.2.8.

3.5.3 Maintenance including Inspection, Monitoring, Maintenance and Repair Subsea Activities

Inspection, monitoring, maintenance and repairs, including those undertaken subsea, are intended to maintain safe and sustainable production within the platform.

Maintenance teams routinely visit the facility for:

- planned maintenance campaigns undertaken during routine interventions; campaigns typically last for 15 days, with ten campaigns planned per year
- unplanned corrective (breakdown) maintenance, as required
- shutdown maintenance
- pigging of the pipeline/flowlines for sand and debris removal, liquid management, inline inspection, well clean up and hydrate remediation; the frequency of pigging operations is defined in Pluto Pipeline System Inspection, Monitoring and Maintenance (IMM) Plan
- contingent crewing on the riser platform involving continuous manning for campaign periods to address low probability equipment failures, operational issues or major projects, such as maintenance of the PWH.

The specific team sizes deployed to the facility are based on maintenance requirements, helicopter carrying capacity, availability of accommodation and safety considerations.

When the facility is crewed, primary operation is retained by the PROC, with personnel on the Pluto facility communicating with the PROC. Operational control of equipment is handed to ‘local control’ on the facility on an as-required basis.

3.5.4 Process and Production Description

The riser platform receives well fluids (gas, condensate, associated produced water and other fluids such as process chemicals) from the Pluto, Xena and Pyxis production wells. The facility then exports gas and condensate from the riser platform via the pipeline to the onshore gas plant for processing. With the installation of PWH, the facility has the ability to separate and discharge PW. The riser platform also receives chemicals from the 6-inch chemical supply line, and transports these to the wells via the 4-inch chemical supply flowlines.

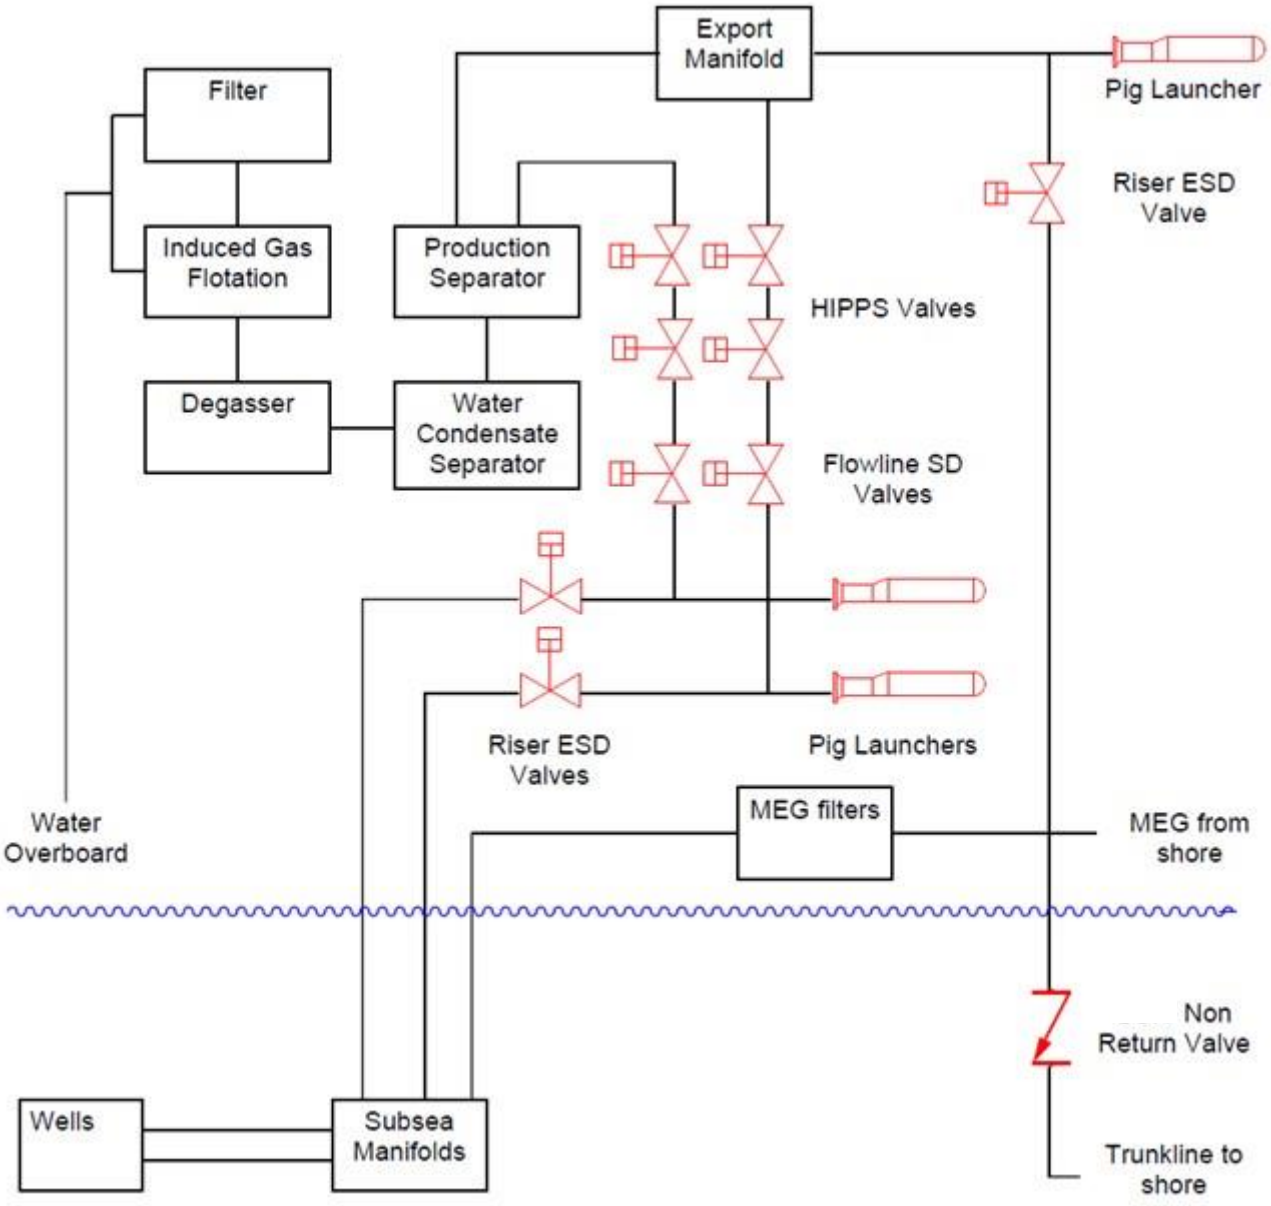

Figure 3-6: High-level Process flow diagram

3.5.5 Produced Water System

Produced water (PW) is brought to the surface from the reservoirs. Each well has a varying amount of PW that is brought to the surface and this changes over time. Due to the expected increase in volumes of PW to be brought to the surface, a PW treatment and disposal system is required on the Pluto facility. Woodside installed a PWH on the riser platform to treat PW. Commissioning of the PWH and associated PW discharge system commenced in 2024, with intermittent operation, and limited produced water rates observed to date (typically <100 m^3/day). The maximum design case for water treatment is 3500 m^3/day. The rate of PW is dependent on the number of wells producing water and their associated flowrate. Prior to reaching elevated discharge rates, there will be initial stages where there will be a no overboard discharge of produced water ('dry mode') as well as periods of low water discharge rates where small volumes of condensed water are continually produced with intervals of short term higher flow produced water. Expected system operating scenarios during production are described as:

- No PW discharge - with production to trunkline system, and PWH module offline or in bypass.
- Low PW flow rates - averaging approximately 100 m^3/d, fluctuating typically between 20 m^3/day – 200 m^3/day. This may increase as wells cut water.
- Elevated PW flow rates established - expected to average approximately 800 m^3/day but may extend up to design capacity 3,500 m^3/day.

The PWH includes a two-phase production separator, water condensate' separator, degasser and a secondary horizontal induced gas floatation (HIGF) vessel, to aid oil in water (OIW) separation. To safeguard from excursions or process upsets, coalescing filters have been installed prior to the end of the process for intermittent use, where OIW concentrations from the HIGF outlet do not meet the required specification for overboard discharge. The filters are in place to manage high OIW without process disruption. They are not suitable for permanent use as the platform is NNC, as described in Section 6.7.7.

3.5.5.1 Produced Water Treatment System

The PWH has a treatment system that directs all wet production fluids through a two-phase production separator and water condensate separator to the PW system, which operates at a low pressure to maximise the removal of dissolved gas. The treatment system consists of a degasser which separates dissolved gas followed by a HIGF unit, which distributes small gas bubbles through the PW in the vessel to enhance OIW separation. In this process, oil and fine solids particles present in the water adhere to the gas bubbles and float to the surface where they are skimmed off as a reject stream to the oily water separator (OWS). PW is then discharged overboard in accordance with OIW monitoring requirements above the water line at +8 m LAT.

If water exiting the HIGF exceeds discharge limits due to excursion or process upset, the water can be routed through a set of coalescing filters for further treatment prior to being discharged overboard. This mitigation stage has been provided to minimise the requirement for reactive platform visits (increased safety risk) in the event of a process upset or excursion of produced water and will allow remote troubleshooting of the process, while maintaining the oil in water specification within operational discharge limits.

The water treatment system includes provision for injection of water clarifier chemical injection if increased efficiency in OIW separation is required. Contingency for demulsifier chemical injection upstream of the inlet separator has also been provided. Use of either is circumstantial based on engineering/operations judgement. In addition, the PW stream can also be routed via coalescing filters, which can be used in upset or non-routine scenarios to reduce OIW concentrations.

Reject streams with residual condensate from the degasser, HIGF and coalescing filters flow to the oily water separator (OWS). Separated condensate is pumped to the pipeline and water is routed back to the main PW stream either upstream of the PW pumps or upstream of the HIGF. The evolved gas from the degasser and HIGF is routed to the flare; the flowrate will be proportional to the PW rate. Water from the OWS can also be comingled with produced water pump discharge (downstream of filters) and discharged overboard. At very low flow rates PW may also be routed back to the trunkline from the PWH.

3.5.5.2 Produced Water Discharge Oil in Water Monitoring

The measurement of OIW in the PW stream is undertaken prior to discharge to the ocean. OIW is measured using online OIW analysers. The analysers are designed specifically for offshore operations and reports total petroleum hydrocarbons (TPH), where TPH is defined as all hydrocarbons that are soluble in the extraction solution and are present in the solvent extract after filtration through Florisil. Two OIW analysers are installed on the module, designed to provide redundancy in case of instrument failure with one analyser at a time selected for process surveillance.

As part of PWH module design, Woodside assessed suitable OIW analyser technologies. Lessons from other Woodside assets were also heeded. The application of the analyser in a low aromatic, gas condensate field like Pluto has been verified with other operators of the selected analyser technology.

Manual sampling and TPH analysis (via offshore-deployed or onshore-laboratory) may be utilised during crewed periods to support produced water system optimisation, calibration activities and in case of equipment outages.

3.5.5.3 Produced Water Discharge Monitoring

PW discharge on the facility is managed in accordance with the Offshore Marine Discharges Adaptive Management Plan (OMDAMP (Section 7.2.3)). This plan has been developed to detail the disposal of routine marine discharges from Woodside's offshore production facilities in accordance with Woodside's Environmental Performance Procedure. Implementation of the plan also verifies the discharges are managed in a way that reduces the potential environmental risks and impacts to ALARP.

In addition to continuous OIW monitoring, PW discharge monitoring includes routine chemical characterisation and ecotoxicity assessments of the PW. This information, combined with dilution modelling is used so that the discharge of PW is in accordance with the required standards outlined in Section 6.7.7. Refer to Section 6.7.7 for a detailed discussion and ALARP justification regarding PW discharge from the Pluto facility.

3.5.6 Utility Gas and Flare System

The riser platform currently has a combined high-pressure flare and utility gas system. A schematic showing the utility gas and flare system is presented in Figure 3-7. With the PWH installed, fuel gas is the primary fuel source for the gas engine. The fuel gas conditioning facilities (filtering and super heating) are part of the module.

Utility gas is required:

- for continuous purging of the flare header to prevent air ingress
- to supply pilot gas for the flare tip pilots
- to supply to the induced gas floatation unit for gas injection to maximise oil in water separation.

The flare system safely collects, contains and disposes relief, blowdown and vent flows from the topsides (pressure safety valves, manual and automatic blowdowns). A flare header collects relieved, entrained or condensed liquids and routes them into a knock-out drum. Liquids in the drum are periodically pumped into the export pipeline. The vapour flows via a riser, mounted on a cantilever boom to the elevated flare tip for burning.

The PWH introduces additional process waste streams directed to the flare including the degasser, induced gas floatation vessel and oily water separation tank.

The flare system is provided with igniters within each of the three wind-shielded flare pilots, each of which can be remotely operated via DCS or manually at the igniter-panel to ensure re-ignition in the unlikely event of flare flame out. Flare flame monitoring is via visual and/or thermal infrared closed circuit TV (CCTV) cameras which are displayed on the main screens within the CCR.

The utility gas system is equipped with a meter that records total utility gas used and a meter that detects the volume of gas purging the flare. Remote operational monitoring of the flare system is in place via:

- flare gas flow metering
- monitoring of the utility gas pressure (with back-up systems activating on low pressure)

- CCTV with thermal infrared view for visual checks

The flare system allows for sustained flaring up to 100 MMscfd, when the flowlines are pigged or in the event depressurisation of the flowlines is necessary.

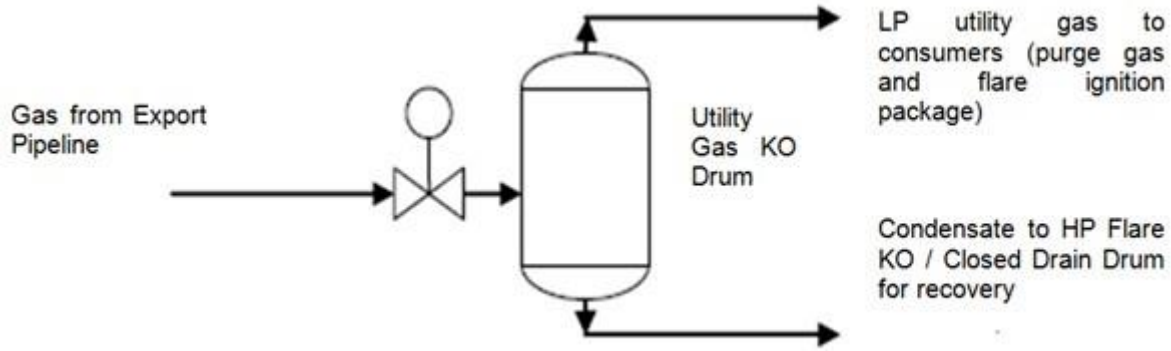

Figure 3-7: Riser platform utility gas system

3.5.7 Drainage Systems

The open and closed drains system consists of both hazardous and non-hazardous open drains. The open drains system is required for disposal of water and hydrocarbons, which are at atmospheric pressure (e.g., deck water). Drains from hazardous areas are totally segregated from drains from non-hazardous areas, to prevent ingress of gases into a non-hazardous area via the drains system.

3.5.7.1 Closed Drains

The closed drain system is designed to safely collect, contain and recycle depressurised hydrocarbons, chemicals and other liquids from normally pressurized and hazardous equipment and is fully contained. The drained liquids are routed to the flare knock-out drum during normal operations and then pumped into the export pipeline for transfer to shore.

3.5.7.2 Hazardous Open Drains

The hazardous open drains system collects non-pressurised spillage, overflows, contaminated deck wash-down and some rainwater from the open drain boxes, tundishes and equipment drip trays in areas designated as hazardous. The PLA hazardous open drains flow to the hazardous open drains collection tank (working volume 11.6 m^3) when the facility is crewed, and work is being undertaken in the area. Areas of the facility have secondary spill protection (bunding) depending on the location, protection and spill risk of each component of the facility to contain and direct flows to the hazardous open drains system.

The hazardous open drains collection tanks are periodically pumped to a waste oil storage tank (capacity 4 m^3) then transported onshore for disposal. The transfer of liquids from the collection tanks to the waste oil storage tank is a manual operation only undertaken while the facility is crewed.

The collection tanks are provided with a submerged centrifugal pump to transfer liquids from the tank at the sub-cellar deck to the waste oil storage tank located in a bunded area on the upper deck.

As part of installation of the PWH to the facility in 2023, an additional open drains collection tank (working volume 10.7 m^3) was added below the sub cellar deck of the module, designed to contain spillage (such as during chemical decant), leakage or washdown during maintenance activities on the module. Pump-out from the module open drain collection tank can be remotely operated to decant to the PLA open drain collection tank, if required, or transferred directly during crewed activities for disposal onshore via the waste oil storage tank.

3.5.7.3 Non-hazardous Open Drains

The non-hazardous area open drains system collects liquids from open drain boxes, tundishes and equipment drip trays in areas designated as non-hazardous. It is segregated from all other drainage systems to eliminate the risk of hydrocarbon vapour transmission from hazardous to non-hazardous areas. Drains from the diesel generator bunds/tanks are part of the non-hazardous area open drains system. Water and any contamination are routed to the non-hazardous area open drains collection tank. This tank is sized for containing in excess of the full volume from a diesel generator day tank and has a working volume of 2 m^3 (with max capacity of 2.6 m^3).

The collected liquids are manually drained to the hazardous area open drains collection tank during every facility campaign maintenance visit (if it contains any liquid) so that the full working volume of the non-hazardous area collection tank is available for spill capture.

3.6 Utility Systems

3.6.1 Platform Lighting

The riser platform has appropriate lighting for there to be a safe working environment during 24-hour operations. Lighting is split between emergency and normal lighting. The emergency light fittings have been located to illuminate the designated escape routes on the facility. Navigational lights are located on the riser platform flare tower and on the booms and towers of the pedestal crane. Helideck lighting is also provided to assist helicopter landing.

Unless required to support over the side activities (such as bunkering and lifting operations), lighting on the facility is directed to the work area when crewed, which limits light spill to the marine environment.

3.6.2 Heating, Ventilation and Air Conditioning System

The heating, ventilation and air conditioning (HVAC) system comprises HVAC equipment, ductwork and associated pipework. It provides independent and interdependent sub-systems with pressurised, conditioned, purge and exhaust air services to all living to various areas including accommodation and various modules which can be operated on an as required basis or continuous basis.

3.6.3 Potable Water

Commercially supplied water from onshore is provided for drinking and domestic use on the riser platform, which is bunkered by support vessels and transferred into a storage tank. The service water passes through a UV disinfection unit to ensure water quality for users.

3.6.4 Monoethylene Glycol System

Lean MEG is filtered onshore, then transferred to the riser platform via the 6-inch subsea chemical supply line. The lean MEG concentration is selected as 90% by weight, which is the optimum concentration to maximise capacity of the distribution system. The topsides arrival pressure of the MEG from the 6-inch chemical supply line is 22 Mpa(g) under normal operations. Once on the riser platform, the MEG is again filtered and distributed to the Pluto/Xena/Pyxis wells via the 4-inch chemical supply line. The MEG flow is controlled by manual adjustments in subsea injection chokes, which are controlled via the PROC.

MEG ensures the water in the flowlines is inhibited against hydrates. Other chemicals, such as corrosion inhibitors, biocides, oxygen scavengers, and scale inhibitors, may be mixed with the MEG to aid in integrity and asset protection. These chemicals are injected into the wells in dilute concentrations as required for technical requirements. Chemicals used on the riser platform are discussed further in Section 3.9.

Injected (rich) MEG normally flows back from the wells with the production fluids in the flowlines to the riser platform, then via the pipeline to the onshore processing facility. It is then separated from the production fluids and stored and regenerated at the onshore processing facility for re-use.

The size and capacity of the MEG supply lines are:

- six-inch chemical supply line (onshore to the riser platform) – 715 m³/day
- four-inch chemical supply line (riser platform to Pluto subsea manifolds) – 354 m³/day.

When MEG is required to be injected into the Wet flowline for hydrate management, this diluted MEG will be processed through the water processing module and discharged overboard via the PW discharge pipe, these volumes are limited and frequency intermittent as detailed in Section 3.5.5. Continuous low-rate MEG discharge to the flowlines and production system and PW discharge may be seen up to 2 m³/day associated with MEG injection bleed into the production system.

If required for intervention purposes, MEG or methanol may also be transferred onto the facility via iso-tanks to a 10 m³ storage vessel.

3.6.5 Power Generation

A gas engine generator provides continuous power during normal operations to systems including the utility gas pre-heater, PWH operations (e.g. pumps), maintaining charge in the uninterruptible power supply (UPS) batteries, and for lighting and navigational aids. Two diesel generators, each with a 240kW capacity, remain on the platform for backup and peak power generation. Peaks in demand also occur during flowline pigging, maintenance activities, and process upset and restart conditions. The generator tanks are located in a bunded area which drains into the non-hazardous open drains system (refer Section 3.5.7).

A grid stability module (GSM) is located on the PWH. The fundamental components of the GSM are a rectifier/inverter and a battery supply. The generators are integrated with a GSM to eliminate the requirement for a hot standby generator and increase fuel efficiency. The gas-fuelled generator is the preferred unit for operation. If fuel gas is not available, or the unit is unavailable, the other diesel units will be started. In the event of a generator trip, the GSM shall maintain the load with no breaks (i.e., seamless) during the transition to an alternate generator supply. When a generator supply is restored, the GSM shall re-commence charging. The generators and GSM are capable of online changeover, synchronisation and load sharing. For operations requiring additional power, one of the standby diesel generators is brought online.

3.6.6 Sewage and Putrescible Wastes

No sewage or putrescible wastes are produced from the riser platform during uncrewed periods. When the facility is crewed, the sanitary drainage system is a combined black and grey water system, with black and grey water discharged to the marine environment as untreated, un-macerated waste. Sewage is disposed via a dedicated overboard caisson. The caisson is a 300 mm carbon steel pipe that discharges at approximately 7.5 m below LAT. A rodding point is also provided at the top of the disposal caisson.

When the facility is crewed, putrescible waste (principally food scraps) is bagged and transported to shore for disposal as domestic waste, in accordance with the requirements of Woodside's Waste Management Plan for Offshore Facilities. During planned maintenance campaigns, shutdown maintenance or major projects additional crew will be present at the Pluto facility. During these times of increased personnel, an accommodation support vessel (ASV) may also be utilised on station to accommodate crew. Sewerage and putrescible discharges associated with the ASV are discussed in Section 3.8.3.

3.6.7 Sand Management

Subsea wells are equipped with downhole sand control (expandable sand screens or open hole gravel pack), acoustic sand detectors and erosion probe located on the subsea xmas trees. The facility basis of design assumes there is a low probability of sand production. Hence, any sand produced in normal operation should not cause any significant erosion or corrosion impact in the flowlines. In the event of sand production and depending on the mode of production (wet or dry), produced sand is expected to accumulate in the onshore facilities (dry mode) or PWH equipment (wet mode). Historical sampling at the facility has not detected any NORM contaminated equipment. Sand and other material (sludge, scale, etc) with the potential to be contaminated with NORMs is tested and disposed of in accordance with Woodside's Waste Management Plan for Offshore Facilities.

3.6.8 Diesel Fuel System

Low sulphur diesel is transferred to the riser platform in bulk from supply vessels via a hose reel located at the dedicated bunker station on the platform. Diesel is bunkered directly into the crane pedestal diesel bulk storage tank which has a maximum storage capacity of 80 m^3. Filters provided on the diesel inlet assist in preventing blockage of the tank level devices. Diesel is metered and distributed to users via a continuously pressurised ring main. Unused diesel is recycled back to the crane pedestal. The tank is equipped with level fall alarms and remote shut-off systems to allow shutdown of the system locally or from the PROC.

Diesel is required for:

- crane tank
- lifeboat tank
- diesel generators (back up to fuel gas).

3.6.9 Hydraulic Fluid System

The riser platform is provided with a hydraulic power unit (HPU) hydraulic fluid storage tank of 4 m^3 capacity. A glycol based hydraulic fluid is supplied to actuate valves on the topsides and subsea facilities including shutdown valves, blowdown valves, high integrity pressure protection system (HIPPS) valves, control valves and subsea xmas tree, surface-controlled sub surface safety valve and choke valves.

Hydraulic fluid is supplied in high- and low-pressure modes with two independent headers. A common production hydraulic power unit is located on the sub-cellar deck to provide both low pressure (LP) and HP hydraulic power for operation of both subsea and topsides valves. The topsides hydraulic system has a supply reservoir and a return reservoir (closed loop), four hydraulic supply pumps and a reservoir pump. Hydraulic fluid supplied to the subsea facilities is in an open-loop configuration, and each actuation of a valve will release a small quantity of the fluid at the SCM vent port. Chemical selection and use are detailed in Section 3.9.All safety critical valves are designed for fail safe operation, in the case of the HPU losing pressure (e.g., in the highly unlikely event of a major platform or umbilical failure).

The PWH has an independent closed loop topsides HPU located on the sub-cellar deck for supplying fluid power to the module actuated on/off valves and control valves with a total system capacity of 2 m^3 in the supply reservoir, with an additional 1 m^3 storage tank permanently connected to the HPU.

Hydraulic power is the only instrument utility available for motive power on the facility. If an activity requires the use of an air powered tool, then portable air compressors will be transported from shore as required. Maintenance of this equipment occurs onshore.

3.7 Facility Operations

3.7.1 Operational Flaring

Flaring is expected to occur during a range of operational circumstances; key operational flaring events are explained in further detail in the following sections. Annual internal facility flare targets are set based on operational activities planned for the year. This target is used to assess facility flare performance.

3.7.2 Normal Operations

A relatively small quantity of gas is required to be continuously flared associated with purge and pilot of the flare system and disposal of waste streams that are not suitable to be recovered to the process.

Continuous flows to the flare (estimated at design PW processing rates) are approximately 4000 tpa. Sources include:

- flare header purges
- flare pilot
- PW degasser
- PW induced gas floatation
- leakage past flare header values such as pressure safety valves (PSVs) and blowdown valves (BDVs)
- oily water separator tank.

3.7.3 Intermittent Process Upsets and Activities

During process upsets or blowdowns, the process control valves on the main process equipment open to relieve topsides system pressure to the flare. The following sources make up intermittent flaring.

3.7.3.1 Operational Pigging

Flaring to facilitate round-trip pigging of the flowlines is an integral part of operation of the facility and occurs as required (approximately once every four years). Produced gas is flared during flowline pigging operations, with liquids exiting the flowlines stored in the flare knock-out drum. Pipeline gas is used to propel the pig in the first half of the flowline loop. Well fluid is used to propel the pig in the second half of the flowline loop, with produced gas and liquids from flowline pigging directed to the pipeline.

The system is sized to flare at a rate of 100 MMscf per day gas during flowline pigging. Additionally, initial depressurisation of the flowlines to flare is required for approximately two hours prior to pig launch to reduce the flowline pressure sufficiently to successfully launch the pigs using pipeline pressure. Each pigging campaign requires three pigging runs each for gauging, cleaning and inspection. The pigging activity typically results in an additional 8,300 tonnes (approx.) in years that flowlines are pigged.

3.7.3.2 Emergency Blowdown

The topsides equipment and piping are divided into isolatable sections, each with a dedicated BDV. During an ESD, each section is separately depressurised to the flare. Each section contains actuated BDVs which allows blowdown of the riser platform inventory. The total volume depressurised is eight tonnes.

3.7.3.3 Manual Depressurisation

Manual depressurisations will result in intermittent flaring of hydrocarbons, triggered by routine equipment maintenance, planned ESD testing and/or depressurisation of equipment and piping to remove the equipment from service. Furthermore, equipment must be depressurised prior to draining as the closed drains system is not intended for high pressure service.

3.7.3.4 Subsea Flowline Depressurisation

The well fluid in the subsea flowlines (which carry hydrocarbons from the subsea wells to the riser platform) may on rare occasions need to be routed to the flare to allow the pressure in the flowlines to be reduced. Reasons the flowlines may require depressurisation are:

- for flowline hydrate management: depressuring must be completed prior to flowlines cooling to seabed temperature when the production system is offline
- over-pressurisation of flowlines above integrity limit
- leak-off testing of well or subsea isolation valves
- production flowline maintenance (if required)
- to facilitate remediation in the event of an unplanned hydrate blockage in the subsea equipment.

3.7.3.5 Estimated Flare Volumes

The amount of gas that may be flared on an annual basis is a dependent of continuous and intermittent process sources, planned activities requiring flaring, and potential unplanned process upsets. The estimated annual amount of gas flared (estimated at design PW processing rates) ranges between approximately 8,500 tpa and 16,800 tpa.

3.7.4 Greenhouse Gas Emissions

The main sources of greenhouse gas (GHG) emissions associated with Pluto production are shown in Table 3-7. GHG sources that are not part of the Pluto facility (e.g., from onshore processing emissions) are included for completeness. In the context of this EP, the emissions are classified as direct and indirect emissions.

Table 3-7: Direct and indirect greenhouse gas emissions sources from the Pluto facility and supply chain

Emission Type	Emissions Source	Location	Jurisdiction	Process
Direct	Pluto facility process	Offshore	Commonwealth	GHG emissions from fuel, flares, fugitives and process vents
Indirect	Support vessels (on charter)	Offshore	Commonwealth	GHG emissions from engines and fugitives on vessels
	Onshore processing*	Onshore	State (WA)	GHG emissions from venting reservoir CO2, combustion of gas as fuel, flares and fugitives associated with processing gas to products such as LNG, LPG, condensate and domestic gas
	Transport	Transit	Subject to consumer location	GHG emissions from transport of products to market, including regassification and distribution of LNG in customer markets
	Regassification, distribution and	Market	Subject to consumer location	GHG emissions from combustion of products as part of power generation and

	combustion by third party user			other energy solutions within the final market

**ISO 19694:2021 defines indirect GHG emissions as GHG emission that is a consequence of an organization's operations and activities, but that arises from GHG sources that are not owned or controlled by the organization. For the purposes of this EP the "organization" is the Pluto facility and therefore onshore processing, and support vessel operations are considered indirect emissions sources.*

3.7.5 Lifting Operations

A pedestal crane is located on the east side of the riser platform at the weather deck, providing the necessary coverage for all on-deck material handling requirements and lifting between the riser platform and supply vessels. The pedestal crane is powered by diesel.

3.7.5.1 Routine Lifting from Platform Support Vessels

Routine lifting operations primarily include transferring stores and equipment from a support vessel to the facility. Support vessels are equipped with dynamic positioning (DP) control for holding station during lifting operations. The types of 'lifted equipment' may vary but generally include containers or skips of various sizes. The stores and equipment required by the facility are secured inside the skip or container. Containers for supply of chemicals are routinely lifted. Equipment is to be appropriately rated for offshore lifting.

After offloading from the supply vessel is complete, the facility then backloads to the supply vessel any items to be returned to shore. These primarily include empty skips or containers or skips containing waste for onshore disposal.

3.7.5.2 Lifting Around the Facility

Once lifted to the lay down area, there may be a need to re-position equipment at various locations throughout the facility for operational purposes. This includes lifting stores or equipment to various landing areas throughout the facility for unloading or use and moving waste bins to required areas.

There may be occasions where a non-routine piece of equipment may need to be lifted. On these occasions, the equipment is packed up in a container or an approved lifting frame.

3.7.5.3 Operational Lifting (Non-crane Based)

There is also a requirement to undertake operational lifting utilising rigging, chain blocks or electric hoists. This lifting is primarily undertaken for maintenance or repairs and involves lifting and removing equipment such as valves, spools and motors.

Maintenance areas are in close proximity to all major equipment. Material handling corridors are provided to allow transportation of materials and equipment.

Once lifted to the lay down area, there may be a need for re-positioning of equipment at various locations throughout the facility for operational purposes. Where required, lifting of material and equipment in/out is achieved via beam clamps. General purpose floor trolleys and skates are used for moving material and equipment to/from laydown areas. Pad-eyes are provided for equipment requiring regular or frequent maintenance, where there is no direct pedestal crane access, or where runway beams are impractical.

3.7.6 Safety Features and Emergency Systems

A range of safety features and emergency systems have been integrated into the design and operation of the offshore facility to manage safety risk. Based on Woodside's Health and Safety Design Premises for Hydrocarbon Facilities, risk management measures have been grouped into the categories of:

- prevention

- detection
- control
- mitigation.

The safety features and emergency measures in place on the facility are listed in Table 3-8. Specific details of these and other safety systems can be found in the Pluto A Operations Safety Case.

Table 3-8: The Pluto facility safety features and emergency systems

Category	Description
Prevention	Inherently safe design (leak minimisation, layout) Dropped object/impact protection (including vessel collision avoidance) Structural design Material selection and corrosion control
Detection	Fire, gas and smoke detection (including manual alarm callpoints)
Control	Process control system Ignition control Depressurisation systems Passive fire protection Heating, ventilation and air conditioning
Mitigation	Escape and evacuation routes Temporary refuge Emergency power and UPS Emergency and escape lighting Critical communications systems Evacuation and rescue facilities and equipment

3.8 Support Vessel Operations

3.8.1 Platform Support Vessels

Platform support vessels are used to transport material and equipment to and from the riser platform when crewed. The specifications of the Mermaid Strait are presented in Table 3-9 as an example and represent typical specifications of a platform support vessel. Vessels supporting the facility may vary depending on vessel schedules and availability. Platform support vessels are typically in operation for the full period that the platform in crewed and may then be further supported by a resupply vessel that visit the platform once or twice in a 15-day period.

While in the field, the vessel(s) also backloads materials and segregated waste for transportation back to the King Bay Supply Facility in Karratha. If a vessel has fast rescue craft (FRC) capability, it can be used to carry out standby duties including during helicopter operations and working over the side activities while in the field. PLA also uses the standby vessel (SBV) located at the nearby Wheatstone platform, which can be called upon to render assistance in the event of a platform emergency and rescue response for helicopter operations.

Figure 3-8: Indicative facility support vessel (Mermaid Strait)

Table 3-9: Indicative platform support vessel specifications (Mermaid Strait)

Particulars	
Type	Diesel Electric, Azimuth, AHT, OSV, DP1
Length overall (LOA)	52.35 metres
Breadth	14.6 metres
Draft	4.9 metres
Dead weight tonnage (DWT)	930 tonnes
Accommodation	Berthing for 24 personnel
Dynamic positioning system	Kongsberg Simrad DP1 with Poscon joystick control
Capacities	
Fuel	592 m^3
Pollution Control	
Spray booms	Nil
Dispersant pump	Nil
Dispersant storage	Woodside issued dispersant kit: tank volume 350 gallons

3.8.2 Subsea Support Vessels

Subsea support vessels, including uncrewed surface vessels (USVs, see Section 3.8.4), are also used for field work such as subsea IMMR activities. Vessels supporting offshore activities may vary depending on operational requirements, vessel schedules, capability and availability.

Subsea activities are typically undertaken from a subsea support vessel or USV and may use an ROV with transponders. For some activities, ROVs (see Section 3.8.5) may also be deployed from the Pluto riser platform. Typical subsea support vessels use a DP system to allow manoeuvrability and avoid anchoring when undertaking works, due to the close proximity of subsea infrastructure. However, vessels are equipped with anchors which may be deployed in an emergency.

The DP system requires the temporary deployment of up to six transponders on the seabed. Transponders are also used for monitoring the location of infrastructure/equipment during a repair. The transponders are attached to small recoverable moorings (metal clump weight or tripod) that are lowered to the seabed and placed in position by ROV. The transponders have a small footprint; less than 0.5 m^2. The transponders and moorings are recovered using ROVs at the end of the activity.

ROV operations often require tool baskets which are temporarily placed on the seabed. These baskets typically have a mesh base with a seabed footprint of approximately 15 m². The baskets are recovered to the vessel at the end of the activity.

3.8.3 Accommodation Support Vessel

An accommodation support vessel (ASV) may be required for short periods to support planned maintenance campaigns, shutdown maintenance or major projects. Typically, these campaigns would last up to 90 days with possible extensions due to unforeseen factors like weather. During the life of this EP, an ASV could be required at any time of the year and would be located next to the facility, inside the PSZ. The use of an ASV may occur once every 3-6 years.

ASV specifications may vary depending on operational requirements, vessel schedules, capability and availability. Typical ASVs use a DP system to allow manoeuvrability and avoid anchoring when in close proximity of the platform. However, vessels are equipped with anchors which may be deployed in an emergency. Indicative ASV specifications are provided in Table 3-10.

Table 3-10: Indicative accommodation supply vessel specifications (Floatel Triumph accommodation support vessel)

Particulars	
Type	Semi-submersible accommodation support vessel
Length overall (LOA)	125 m
Breadth	80 m
Dead weight tonnage (DWT)	27,111 t
Accommodation	500 persons approx.
Dynamic positioning system	DP 3
Capacities	
Fuel	Largest tank 297 m^3 Total capacity 1800 m3

3.8.4 Uncrewed Surface Vessel

A USV may be utilised to complete IMMR activities. The USV will be remotely controlled from an onshore remote operations centre (ROC) in Australia which is staffed 24 hours a day whilst the vessel is in transit or undertaking activities. Key roles in the ROC mirror those on a usual vessel management team and include a Vessel Master, Offshore Manager and ROV Supervisor. The vessels are designed with multiple forms of high speed and reliable communication systems to allow connection to the ROC and provide redundancy in the case of disconnection during operations, including an independent emergency low bandwidth satellite communications system. The vessels are also fitted with 360-degree cameras monitored by the remote vessel master supporting safe navigation. The USV is assessed by Woodside Marine (Section 7.10.2.5) to review compliance with marine laws, flag requirements, vessel class and Woodside's safety and environment requirements. Because there are no facilities to support human occupancy on USVs, emissions and discharges are typically limited to cooling water and combustion of marine diesel. The vessel is equipped with bilge monitoring systems to monitor the bilge tanks for hydrocarbons (such as leaks from engine machinery spaces or from marine diesel tanks), and where detected the bilge pumps will auto disable and the vessel will be required to immediately return to port.

USVs have a maximum speed of 10 knots and may be equipped with a built-in work-class ROV with the ability to deploy and retrieve equipment from the seabed. Key parameters for a typical USV are presented in Table 3-11.

Table 3-11: Indicative USV parameters

Parameter	USV (based on Reach Remote 2)	USV (based on Fugro Maali)
Draft (max)	6 m	2.6 m
Length	23.9 m	12 m
Displacement (Gross Tonnage)	~340 t	14 t
Propulsion System	Diesel-electric hybrid	Diesel-electric hybrid
Total fuel volume	74.1 m^3	3.3 m^3

3.8.5 Remotely Operated Vehicles

The MODU and subsea support vessels may be equipped with an ROV system that is maintained and operated by a specialised contractor aboard the vessel. ROVs may be used during drilling operations and subsea installation, for activities such as:

- anchor holding testing
- connection of mooring systems
- pre-drill seabed and hazard survey
- blowout preventer (BOP) land-out and recovery
- BOP well control contingency
- visual observations at seabed during riserless drilling operation
- pre and post installation survey
- subsea xmas tree control systems hook-up and contingency control
- removal of sediments on or around subsea infrastructure
- installation, testing, pre-commissioning, commissioning and start-up of subsea infrastructure.

An ROV can be fitted with various tools and camera systems that can be used to capture permanent records (both still images and video) of the operations and immediate surrounding environment. Specifically, during installation, the ROV is fitted with hydraulically driven tools to facilitate flowline tie-in. An ROV may also be used in the event of an incident to deploy the Subsea First Response Toolkit.

3.8.6 Helicopter Operations

Helicopters are the primary means of transporting passengers and/or urgent freight to/from the Pluto facility and vessels. They are also the preferred means of evacuating personnel in an emergency. Helicopter operations within the PAA are limited to helicopter take-off and landing on the helideck. Helicopters may be refuelled on the helideck of the MODU. Helicopter support is principally supplied from Karratha Airport, and transports workers from Karratha for planned maintenance.

3.9 Hydrocarbon and Chemical Inventories and Selection

3.9.1 Hydrocarbons

The main hydrocarbon inventories associated with major topside process and non-process equipment are summarised in Table 3-12..

Table 3-12: Hydrocarbon inventories of process and non-process equipment

Material	Storage Means	Capacity/Storage Volume
Hydrocarbons		
Condensate	Knock-out drum	Usual volume 5 to 10 m^3, with capacity 90 m^3
Diesel	Crane pedestal diesel storage tank	80 m^3
	Generator set day tanks	3 × 1.8 m^3
Oily water and chemical waste	Hazardous drain collection tank	14 m^3 (working volume 11.6 m^3)
	Non-hazardous drain collection tank	2.3 m^3
	Waste oil storage tank (transportable ISO container)	4 m^3
	PWH open drains collection tank	14.9 m^3 (working volume 10.7 m^3)
Production separator	Vertical gas/liquid separator	~30 m^3 (normally also incl. PW)
Liquid-liquid separator	Produced water/condensate separator	~40 m^3 (normally also incl. PW)
Degasser	Produced water vessel	40 m^3
Induced gas floatation vessel	Produced water vessel	30 m^3
Oily water separation tank	PW oily water separation tank	~3 m^3

3.9.2 Chemical Usage

Chemicals are utilised for a variety of purposes and can be divided into two broad categories (operational and maintenance), as described below. In addition to the chemicals listed, the riser platform may also maintain small volumes of various facility maintenance chemicals.

3.9.3 Operational Chemicals

3.9.3.1 Operational Process Chemicals

An operational process chemical is the active chemical added to a process or static system, which provides functionality when injected in produced fluid, utility system streams or for pipeline treatment. These chemicals may be present in routine or non-routine discharge streams from the facility. Installation of the PWH, has introduced operational process chemicals corrosion inhibitors (up to 100 ppm dependent on water flow rate due to wet flowline operation) and water clarifiers (up to 50 ppm), some of which will be present in the routine discharge of produced water.

3.9.3.2 Operational Non-Process Chemicals

Operational non-process chemicals include chemicals which do not fall into the category described above but which may be required for operational reasons and, by virtue of their use, may be intermittently discharged or have the potential to be discharged (e.g., required as a result of maintenance or intervention activities). Examples include subsea control fluids, dyes and well intervention/workover chemicals.

Operational non-process chemicals such as hydraulic fluids required for operation of the PWH HPU, have been introduced and included in this EP.

3.9.4 Maintenance Chemicals

Maintenance chemicals include chemicals which are required for general maintenance or ‘housekeeping’ activities and are critical for overall maintenance of the riser platform and its equipment. These may include paints, degreasers, greases, lubricants and domestic cleaning products. They may also include chemicals required for specialty tasks, such as laboratory testing

and analysis. Maintenance chemicals generally present negligible risk to the environment, as they are not discharged as a result of their use (e.g., paint) or are used intermittently and discharged in low volumes (e.g., domestic cleaning products).

3.9.5 Indicative Chemical Inventories

An indicative list of bulk chemicals commonly used (or planned to be used on the facility) and estimated storage quantities, is summarised in Table 3-13. Other chemicals may be used in the future if chemical requirements change; for example, during start-up of new wells, there may also be temporary well clean-up skid which may include water clarifiers. In addition to the chemicals listed, the riser platform may also maintain other small volumes of various operational chemicals and facility maintenance chemicals as previously described.

Table 3-13: Indicative bulk inventories of chemicals

Material	Storage Means	Storage Capacity
MEG	Hydrate inhibitor storage vessel[1] Transportable ISO container	12 m³ (working volume 10 m³)
Methanol (if required)	Hydrate inhibitor storage vessel [1] Transportable ISO container	Typically, 4–6 m³ ISO containers
Subsea control fluid	Hydraulic power unit storage tank	4 m³
Water clarifier (if required)	Water clarifier storage tank	4 m³
Demulsifier	Demulsifier storage tank	4 m³
Corrosion inhibitor	Corrosion inhibitor storage tank (stainless steel) Lifted from vessels in IBC's and gravity drained into storage tank	28 m³ 4 m³
Subsea control fluid	Hydraulic power unit storage tank for PWH	3 m³

[1] Only a single hydrate inhibitor storage vessel is provided on the platform; however, the utility fluid may vary between methanol and MEG depending on operations requirements.

3.9.6 Environmental Consideration during Selection, Assessment and Approval of Chemicals

As part of Woodside's chemical approval process, operational chemicals required by the PAP are selected and approved in accordance with the Woodside Chemical Selection and Assessment Environment Guideline. This guideline is used to demonstrate that the potential impacts of the chemicals selected are acceptable and ALARP and meet Woodside's corporate requirements (as outlined in Woodside's Environmental Performance Procedure, which requires chemicals to be selected with the lowest practicable environmental impacts and risks, subject to technical constraints). A summary of the environmental requirements of the guideline is outlined below.

3.9.7 Environmental Selection Criteria

The Woodside Chemical Selection and Assessment Environment Guideline follows the principles outlined in the OCNS which manages chemical use and discharge in the United Kingdom (UK) and the Netherlands (background on the OCNS provided is below).

Operational chemicals will be selected/assessed in compliance with the Woodside Chemical Selection and Assessment Environment Guideline, specifically:

- Where operational chemicals with an OCNS rating of Gold/Silver/E/D and no OCNS substitution or product warning are selected, or a substance is considered to pose little or no risk to the environment (PLONOR), no further control is required. (Such chemicals do not represent a significant impact on the environment under standard use scenarios and therefore, are considered ALARP and acceptable).

- If other OCNS rated or non-OCNS rated operational chemicals are selected, the chemical will be assessed as follows:
  - If there is no planned discharge of the operational chemical to the marine environment, written technical verification of the 'no discharge' fate must be provided, and no further assessment is required.
  - If there is planned discharge of the operational chemical to the marine environment, a further assessment/ALARP justification will be conducted.

The ALARP assessment will include consideration of chemical toxicity, biodegradation and bioaccumulation potential, using industry standard classification criteria (CEFAS scheme criteria).

If a product has no specific ecotoxicity, biodegradation or bioaccumulation data available, the following options are considered:

- Environmental data for analogous products can be referred to where chemical ingredients and composition are largely identical.
- Alternatively, environmental data may be referenced for each separate chemical ingredient (if known) within the product.

If no environmental data is available for a chemical or if the environmental data does not meet the acceptability criteria outlined above, potential alternatives for the chemical will be investigated, with preference for options with a Hazard Quotient (HQ) band of Gold or Silver, or are OCNS Group E or D with no substitution or product warnings.

If no more environmentally suitable alternatives are available, further risk reduction measures (e.g., controls related to use and discharge) will be considered for the specific context and implemented where relevant so that the risk is ALARP and acceptable.

Once the further assessment/ALARP justification has been completed, concurrence from the relevant manager that the environmental risk as results of chemical use is ALARP and acceptable is obtained.

3.9.8 Background Overview of the Offshore Chemical Notification Scheme

The OCNS applies the requirements of the Convention for the Protection of the Marine Environment of the North-East Atlantic (OSPAR Convention). The OSPAR Convention is widely accepted as best practice for chemical management.

All chemical substances listed on the OCNS ranked list of registered products have an assigned ranking based on toxicity and other relevant parameters such as biodegradation, and bioaccumulation, in accordance one of two schemes (as shown in Figure 3-9):

- Hazard Quotient Colour Band: Gold, Silver, White, Blue, Orange and Purple (listed in order of increasing environmental hazard), or
- OCNS Grouping: E, D, C, B or A (listed in order of increasing environmental hazard). Applied to inorganic substances, hydraulic fluids and pipeline chemicals only.

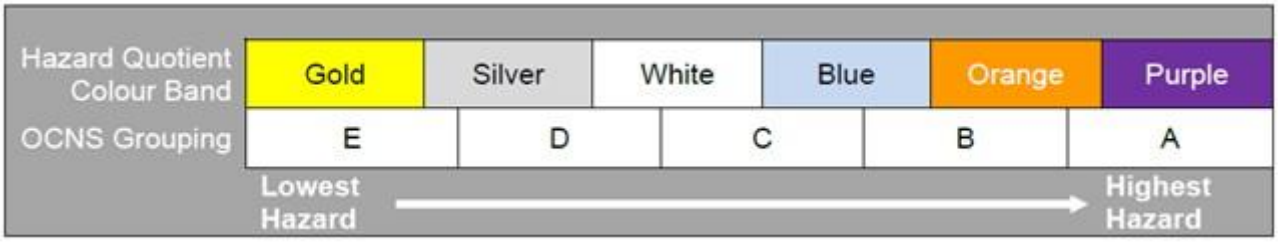

Figure 3-9: Offshore Chemical Notification Scheme ranking

3.10 Subsea Inspection, Maintenance, Monitoring and Repair Activities

3.10.1 Overview

Subsea infrastructure, including the platform substructure, is designed not to require significant intervention. Inspection and maintenance are undertaken to ensure the integrity of the infrastructure and identify problems before they present a risk of loss of containment. Maintaining infrastructure integrity also supports decommissioning planning. Intervention may be required to repair identified problems.

To manage subsea threats (risks) the IMMR process requires an appropriate response to be selected to manage specific equipment risks. This is typically one of: inspection, maintenance, monitoring and repair.

The IMMR process for subsea infrastructure maintains equipment in good condition and repair, for production and to enable future removal.

Subsea activities are typically undertaken from a subsea support vessel or uncrewed surface vessel (USV) and may use an ROV to inspect equipment. For some activities, ROVs may also be deployed from the PLA platform.

Maintenance and repair activities may require the deployment of frames/baskets which are temporarily placed on the seabed. These typically have a perforated base with a seabed footprint of about 15 m². This temporary equipment is removed from field via recovery to subsea support vessels at the completion of IMMR activities. Typical IMMR activities are described below.

3.10.1.1 Inspection

Inspection of subsea infrastructure is the process of physical verification and assessment of components in order to detect changes to the as-installed location and condition by comparison to initial state following installation and previous inspections. Details of typical subsea infrastructure inspections/surveys and indicative frequencies are provided in Table 3-14. Scope and frequency of subsea equipment (operational and redundant) and pipeline inspections are determined using a risk-based inspection (RBI) methodology and associated plans. RBI is commonly used within the industry as a method for determining inspection frequencies (Energy Institute, 2009; DNV, 2019).

During planned inspections, anomalies may be identified by ROV, for example visible hydrates, discharges or bubbling which may indicate fugitive emissions. In accordance with the Subsea and Pipelines Integrity Management Procedure, the anomaly is identified and assessed for scale during the inspection by performing visual bubble estimates or bubble measurements, where it is feasible to do so. The anomaly and its scale are noted in the anomaly/inspection report and recorded in Woodside's centralised Inspection Database. The anomaly is then assessed to determine future monitoring and/or corrective actions to address the anomaly.

Table 3-14: Typical subsea infrastructure inspections and surveys, their purpose and approximate frequencies

Type of Inspection/ Survey	Subsea Infrastructure	Purpose	Approximate Frequency
General visual inspection	All subsea infrastructure	Check general infrastructure integrity.	Varied – every 1 to 8 years
Close visual inspections	All subsea infrastructure (including previously identified anomalies)	Investigate certain subsea infrastructure components, anomaly identification, and estimation of any fugitive emissions and discharges.	Varied – every 2 to 6 years
Cathodic protection	All subsea infrastructure	Check for corrosion and renew sacrificial anodes, if required.	Varied – every 2 to 6 years
Wall thickness surveys	Production and crossover manifolds, flowlines and pipelines	Monitor the condition of subsea infrastructure. (i.e., ultrasonic testing). Typically, only performed if a specific threat is identified through other means.	Typical: Once every 25 years Worst case: Once every 5 years
Acoustic survey (e.g., multibeam echo sounder (MBES), sidescan sonar (SSS)	Pipelines	Identify buckling, movement, scour and seabed features. Low frequency/ intensity signals undertaken on the flowlines.	Varied – every 1 to 6 years
Non-destructive testing (NDT)	Pipeline and manifolds (if required)	Evaluates the properties of material/items using electromagnetic, radio graphic, acoustic resonance technology, ultrasonic, or magnetic equipment.	Typical: Once every 25 years Worst case: Once every 25 years per well
Seabed sampling surveys including minor grabs/cores	NA	Identify benthic fauna, sediment characteristics, determine level of penetration/compaction, etc. Grabs/cores typically disturb 0.1 m² of seabed per sample.	Typical: Once every 25 years Worst case: Once every 5 years
Anode inspections and/or replacement	Production and crossover manifolds, trees, flowlines and pipelines	Samples taken of anode materials for testing.	Typical: Once every 25 years
Marine growth sampling	All subsea infrastructure	Samples taken of marine growth for testing.	Typical: Once every 25 years Worst case: Once every 5 years
Sub bottom profiling	Around subsea components	Low frequency echo sounder undertaken to identify returns of metals under the seabed.	Varied – every 1 to 6 years
Laser surveys	Dimensional check on spools	Used to conduct dimensional checks on spools, etc, and measure proximity.	Varied – every 1 to 6 years

Type of Inspection/ Survey	Subsea Infrastructure	Purpose	Approximate Frequency
Pigging	Export pipeline, flowline	Inspection, maintenance, repair or to facilitate modifications.	Typical – Once every 4 years Worst case – every 2 years

3.10.1.2 Monitoring

Monitoring of subsea infrastructure refers to the process of surveillance of the physical and chemical environment that a subsea system or component is exposed to, in order to determine if and when damage may occur, and (where relevant) predict the rate or extent of that damage. Monitoring activities may include process composition testing, corrosion probes, corrosion mitigation checks, metocean and seismic monitoring, and cathodic protection testing. Other monitoring activities include process monitoring (temperature, pressure, etc), cyclone weather monitoring, and hydraulic fluid usage.

3.10.1.3 Maintenance

Maintenance activities on subsea infrastructure are those required at regular or planned intervals to prevent deterioration or integrity failure of infrastructure. Typical maintenance activities are described in Table 3-15.

Table 3-15: Typical maintenance activities, their purpose and approximate frequencies

Type of maintenance	Subsea infrastructure	Purpose	Approximate Frequency
Cycling of valves via control system	Wells and manifolds	Test functionality of technical integrity valves	Every 6 months for well barriers during operations
Marine growth removal	Production and cross over manifolds and retrieval components (e.g., chokes) and jacket cleaning	Reduce weight or gain visual access	Based on outcomes from visual inspections (Table 3-14) and marine growth trends on regional infrastructure
Flushing of chemical hydraulic fluid lines	Hydraulic fluid lines	For repair scenarios	When required for repair
Leak and pressure testing	All subsea infrastructure	Test integrity of subsea infrastructure	Following installation of subsea infrastructure components after a repair or intervention, prior to return to service
Pigging	Export pipeline	Cleaning of trunkline or liquids management	Typically, every year for cleaning and liquids management; pigging not required at current export rates but would be performed on as needs basis

3.10.1.4 Repair

Repair activities are those required when a subsea system or component is degraded, damaged or has deteriorated to a level outside of acceptance limits as defined by design codes. Damage sustained may not necessarily pose an immediate threat to continued system integrity but may present an elevated level of risk to environment or production reliability. Due to the design of subsea infrastructure and materials used, repairs are undertaken on an as needs basis. The requirements and frequency of these repairs are dictated by the outcome of the inspection and maintenance

regimes described in Table 3-14 and Table 3-15. Typical subsea repair activities, described in the following sections, include.

- subsea choke and/or battery module replacement
- chemical injection throttling valve (CITV) replacement
- subsea control module (SCM) or electrical distribution unit (EDU) replacement
- power and communications router, tree and downhole replacement
- multi-phase flow meter (MPFM) or wet gas flow meter (WGM) replacement
- acoustic sand detector (ASD) replacement
- hydraulic control router (HCR) replacement
- hydraulic flying lead (HFL) replacement
- electrical flying lead (EFL) replacement
- pipeline or spool support with grout bag, mattress, anchors or rock dumping
- spool disconnection and/or replacement
- umbilical jumper replacement and/or relocation
- flowline/pipeline replacement
- scour prevention installation
- cathodic protection system replenishment/repair.

When equipment is replaced, the redundant equipment, may remain in-situ or be removed from the field. The location of redundant subsea infrastructure items is recorded as part of the ROV as left survey and included in a database for Pluto subsea inventory.

3.10.2 Subsea Chemical Usage

Planned chemical discharges may occur during a range of subsea system operation and IMMR activities. The chemicals and volumes released will be specific to each activity. Releases are discussed and provided in the specific activity sections below and, where practical, typical and approximate worst-case volumes provided. Typical volumes are the expected releases associated with the activity following depressurisation and flushing activities.

Operational chemicals to be used within Pluto subsea infrastructure are selected and assessed using Woodside's chemical selection and assessment procedures as detailed in Section 3.9.

Typical chemicals which are used in subsea infrastructure and may be released during IMMR activities include:

- Subsea control fluid – The subsea control fluid presently used in the facility subsea systems is HW443. HW443 is a water-based product.
- Hydrate control – MEG is used for hydrate control. Provision for methanol on an as-needed basis.
- Corrosion inhibitor – Corrosion inhibitor is generally used to manage and prevent corrosion in flowlines, pipelines, pipes, vessels and tanks.
- Water clarifier - Water clarifier is generally added if required to assist with oil and water separation to help reduce elevated oil in water concentration in produced water.
- Demulsifier – Demulsifiers are generally added to assist with reducing water content in the production hydrocarbons.

- Biocide – Biocides are generally used to prevent the bacterial growth in pipelines that may cause corrosion.
- Dye – Chemical dyes are used to identify the source of a leak.
- Acid – Where removal of calcium deposits is required, Woodside typically uses sulphamic (or equivalent) acid. Alternatives such as citric acid may be used.
- Oxygen scavenger – Oxygen scavenger is used to de-oxygenate the flowlines and prevent corrosion and aerobic bacterial growth.
- Grout – The material used in grout, mattresses and rock is typically concrete-based.
- Staurolite products – Staurolite products are used for abrasive/sand blasting to clean and remove marine growth. The main component is staurolite, which is a naturally forming mineral.

3.10.3 Marine Growth Removal

Due to the relatively high rate of marine growth on the NWS, it is often necessary to remove excess growth prior to undertaking many subsea IMMR activities. Marine growth removal is undertaken with a ROV or a diver. The different techniques are described in Table 3-16.

Table 3-16: Marine growth removal techniques

Activity/Equipment	Description
Water jetting	Uses high pressure water to remove marine growth
Brush systems	Uses brushes attached to a ROV to remove marine growth
Acid (typically sulphamic acid)	Dissolving of calcium deposits between interfaces on subsea infrastructure
Sand/abrasive blasting	Additional cleaning to allow close visual inspections

3.10.4 Intervention Isolations

The Woodside Engineering Operating Standard – Subsea Isolation defines a proven isolation to be a valved isolation where the effectiveness of the isolation has been confirmed via vent, bleed, or instrumentation points. An activity specific philosophy/procedure must be developed in line with this standard for each isolation. Isolation testing will result in a planned release of hydrocarbons to the environment.

3.10.5 Pipeline Pigging Operations

Pipeline cleaning pigging currently occurs approximately annually to manage liquid hold-up and solids generation, and as part of the planned inspection programme. Pipeline maintenance and monitoring requirements may increase pipeline pigging frequency with time, to monitor pipeline integrity more closely as the facilities age and/or in response to findings from intelligent pigging campaigns. Liquid hold-up management pigging (to assist flow through to the onshore LNG facility) may be required on an as-needs basis to support flow assurance outcomes.

3.10.6 Sediment Relocation

If sediment builds up around a pipeline or other subsea infrastructure, an ROV-mounted suction pump/dredging unit may be used to relocate the sediment to allow inspection/works to be undertaken. This activity is limited to the relocation of small amounts of sediment material in the immediate vicinity of the subsea infrastructure (i.e., within the existing footprint). Sediment relocation typically results in minor seabed disturbance and some localised turbidity.

3.10.7 Corrosion Protection

The aim of corrosion protection is to preventor limit the chemical reactions that cause corrosion and to manipulate them in such a way that corrosion is avoided or mitigated. Corrosion prevention techniques used are:

- corrosion protection layers to provide a barrier of corrosion-resistant material between the subsea environment and the structural material
- anode skids where an anode is attached to the subsea asset to act as 'sacrificial metal' which is more easily corroded.

Measurements may be undertaken using probes (e.g., electrical resistance probes) to assess the effectiveness of these techniques. If a measurement identifies the corrosion protection layer requires repairs, appropriate remediation options will be investigated.

If additional anode skids are required, they will be placed on the seabed using a support vessel crane. A typical anode skid will have a seabed footprint of approximately 8 m². It is necessary to remove marine growth around the point where the anode skid is to be connected in order to establish good continuity through clamping and/or welding.

Activities may result in some minor disturbance due to placement of skids, removal of marine growth from equipment, sediment relocation, the placement of ROV tool baskets and DP transponders on the seabed.

3.10.8 Span Rectification, Pipeline Protection and Stabilisation

Due to tidal currents or other scouring processes, sections of pipelines, spool flowlines and umbilicals may become unsupported by the seabed (span) and/or become unstable on the seabed. Spanning or instability may expose the component to risk of stress beyond design parameters, increasing risk of failure.

A number of techniques may be used for span rectification or component stabilisation and protection, including grout bags, mattresses, anchors, piling or rock placement. All techniques require the use of a support vessel crane to deploy the material and a ROV so that it is accurately placed on the seabed. In addition, a subsea component may require protection from additional activities (e.g., supply vessel lifts onto the facility and pipeline crossings).

3.10.8.1 Grout Bags

Span rectification typically involves placement of a grout bag with anti-scouring skirts under the spanned component. Grout is pumped into the grout bag from a support vessel via a downline. Once the bag is inflated, it acts as a pillow with the pipe resting on top (Figure 3-10). Typical grout volumes will depend on the size of the span and may vary from 200 kg to greater than 2000 kg.

Figure 3-10: Grout bags in position

3.10.8.2 Mattresses

Mattresses are typically made of concrete and may be used for span rectification or pipeline protection and stabilisation. An example of a mattress over a pipeline is provided in Figure 3-11. Mattresses are typically 3 m by 6 m in size and therefore may disturb 18 m² of the seabed.

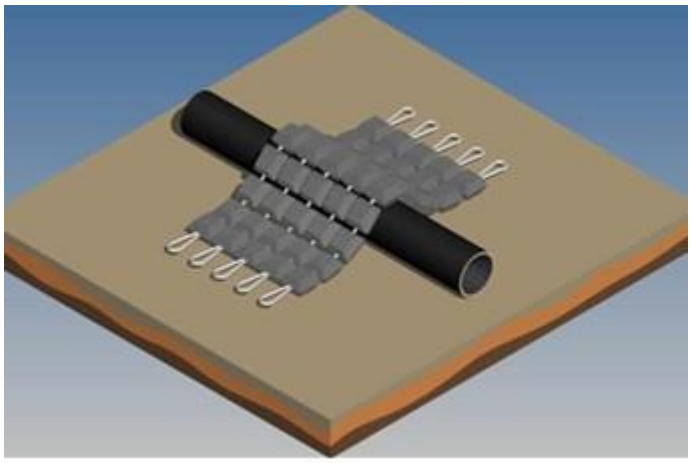

Figure 3-11: Concrete mattress for span rectification or pipeline protection or stabilisation

3.10.8.3 Rock Placement

Rock placement for span rectification is typically small scale and involves the use of one tonne bulker bags filled with rock, with the number of bags varying to suit the application. This activity will cause seabed disturbance due to placement of material on the seabed; however, the area of seabed affected will be small and localised and is unlikely to extend beyond the area originally impacted during the laying of the pipeline.

In addition, the activity may result in some minor disturbance from removal of marine growth, sediment relocation, the placement of ROV tool baskets and DP transponders on the seabed.

3.10.9 Suspension and Preservation of Redundant Equipment

In the event equipment is degraded, damaged or has deteriorated to a level outside of acceptance limits, equipment may be repaired, replaced, or preserved and suspended until decommissioning. A risk assessment will be undertaken considering level of risk to safety, health, and environment or production reliability and will determine if the infrastructure will be repaired, replaced or suspended and preserved.

A typical program to suspend and preserve redundant equipment is as follows:

- Complete an as-found ROV survey of the umbilical/jumper and adjacent infrastructure.
- Remove marine growth, if required.
- Relocate any sediment build-up in the area surrounding infrastructure, if required.
- Flush prior to disconnection.
- Isolate equipment.
- Install caps/flanges.
- Relocate infrastructure to a safe location (if required).

3.10.10 Well Management and Maintenance Activities

The facility subsea well interventions, workovers and well kills require a suitable vessel or MODU to accommodate and support intervention packages. Therefore, these activities do not form part of the scope of this EP. Unloading and clean-up from subsea wells via the facility may be required infrequently. Unloading and clean-up discharges are routed via the process facilities to be cleaned of any remaining chemicals and fluids in the wellbore or reservoir.

3.10.10.1 Well Unloading and Clean-up

Following subsea interventions, workovers and well kills, the well may be unloaded and flowed via the process facilities to be cleaned of any remaining chemicals and fluids in the wellbore or reservoir. During this phase, the products may be processed as follows:

- Gas will be routed into the production process where possible or flared if unsuitable.
- Fluids will be routed to the HP flare knock-out drum which discharges liquids to the closed drain system.
- Wastes (may include fluids and sand/solids) will be managed as appropriate based on composition. Solids will be separated for onshore disposal as required following Woodside's Waste Management Plan for Offshore Facilities. An additional strainer may be placed in the flowlines prior to the main separators to remove any large debris that may be in the wellbore.

3.11 Xena-03 Drilling and Tie-back Activities

3.11.1 Drilling Activities

This EP includes drilling activities for the Xena-03 well in the Xena-03 Operational Area and tie-back to the Pluto facility, in the PAA. Well construction activities are conducted in a number of stages, as described below. Well design will be optimised for ultimate recovery.

Detailed well designs will be submitted to NOPSEMA as part of the Approval to Drill and the accepted Well Operation Management Plan (WOMP), as required under the Offshore Petroleum and Greenhouse Gas Storage (Resource Management and Administration) Regulations 2011.

For clarity, all activities specific to the Xena-03 Drilling and Tie-back campaign will herein be referred to as the Xena-03 Tie-back activities.

3.11.1.1 Cement Unit Test

Upon arrival on location at the Xena-03 Operational Area, the MODU may need to perform a cement unit test, or 'dummy cement job', to test the functionality of the cement unit and the MODU's bulk cement delivery system before performing an actual cement job. This operation is usually performed after a MODU has been out of operation for an amount of time (warm-stack), if maintenance on the cement unit has been performed, or if it is the first time a MODU is being used in-country and commissioning of the cement unit system is required.

A 'dummy cement job' involves mixing a sacrificial cement slurry at surface, and once functionality of the cement unit and delivery system has been confirmed, the slurry is discharged through the usual cement unit discharge line (which may be up to 10 m above the sea level) or through drill pipe below sea level as a cement slurry. The slurry is usually a mix of cement and water; however, may sometimes contain stabilisers or additives. The indicative volume of cement that may be discharged to sea during a cement unit test is approximately 100 bbl.

3.11.1.2 Top Hole Section Drilling

PAP drilling commences with the top-hole section as follows:

- The MODU arrives and establishes position over the well site.

- Top-hole sections are drilled riserless using seawater with pre-hydrated bentonite sweeps/XC polymer sweeps or drilling fluids to circulate drilled cuttings from the wellbore. As a contingency, water-based mud (WBM) may be used in the presence of a shallow gas anomaly.

Once the top hole sections of the well have been drilled, steel tubulars (called conductor or casing) are inserted into the wellbore to form the surface/intermediate casing and secured in place by pumping cement into the annular space above the casing shoe or to surface (seabed), which will involve discharging excess cement at the seabed.

3.11.1.3 Blowout Preventer and Marine Riser Installation

After setting the surface or intermediate casing, a BOP is installed on the wellhead, and the marine riser above it, to provide a physical connection between the well and MODU. This enables a closed circulation system to be maintained, where weighted drilling fluids and cuttings can be circulated from the wellbore back to the MODU, via the riser.

In addition, the BOP provides a means for sealing, controlling and monitoring the well during drilling operations. The BOP components operate using open hydraulic systems, using water-based BOP control fluids.

Each time a BOP pressure and function test schedule is undertaken approximately 3620 L of water-based fluid is released to the marine environment, of this approximately 4% is control fluid additive. BOP operation includes function and pressure testing approximately every 21 days, and a function test (approximately 2665 L) approximately every seven days, excluding the week a pressure test is conducted.

3.11.1.4 Bottom Hole Section Drilling

A closed system (riser in place) is used for drilling bottom hole sections to the planned wellbore total depth (TD). The bottom hole sections will be drilled using water-based mud (WBM) drilling fluids, although contingency non-water-based muds (NWBM) may be used if WBM cannot meet technical requirements (Section 3.11.5).

Protective steel tubulars (casings and liners) are inserted as required. The size, grade, weight, length and inclination of the casing/liner sections within the wellbore are determined by factors such as the geology/subterranean pressures likely to be encountered in the area and any specific information or resource development requirements.

After a string of casing/liner has been installed into the wellbore, it is cemented into place. The casing/liner is then pressure tested. Once the pressure testing is passed, drilling of the next section can resume with the riser in place to circulate drill cuttings and drilling fluids back to the MODU.

Cementing operations can be performed to:

- provide annular isolation between hole sections and structural support of the casing/liner as required.
- set a plug in an existing well to sidetrack.
- plug a well so it can be suspended/abandoned.

Cement is transported as dry bulk to the MODU by the support vessels, mixed as required by the cementing unit on the MODU and pumped by high pressure pumps to the surface cementing head then directed down the well.

3.11.1.5 Formation Evaluation

Formation evaluation is the interpretation of a combination of measurements taken inside a wellbore to detect and quantify hydrocarbon presence in the rock adjacent to the well. ‘Formation evaluation

while drilling' (FEWD) is the process by which the presence and quantity of hydrocarbon in a reservoir is measured according to its response to radioactive and electrical input. It may include extracting small cores, wireline logging, full diameter cores and other down-hole technologies, as required. FEWD tools will be incorporated into the drillstring during development drilling and may include gamma ray, directional deep resistivity, callipers, density-neutron, sonic and tools which can measure formation pressures. Some FEWD tools contain radioactive sources; however, no radioactive material will be released to the environment and radiation fields are not generally detectable outside the tool when the tool is not energised. Therefore, they do not present an environmental risk.

3.11.1.6 Wellbore Clean Out

As required throughout activities with the riser connected, wells will be displaced from one drilling fluid system to another, or from the drilling fluid system to completion brine. A chemical clean out pill or fluids train will be circulated between the two fluids. Brine is typically a filtered brine with <70 NTU or <0.05% total suspended solids (TSS). This results in a brine and seawater discharge after this operation.

Clean out fluids and completion brine will be captured and stored on the MODU and discharged if oil concentration is <1% by volume or returned to shore if discharge requirements cannot be met.

3.11.1.7 Xmas Tree Installation

Before the upper completion is installed into the well, the horizontal xmas tree will be installed from either an installation vessel or directly from the MODU. Due to the subsea well layout, if installation was to occur from an installation vessel, the MODU will be required to reposition away from the drill centre to allow the installation vessel to install the xmas tree. Once the xmas tree has been installed, the tree-to-wellhead interface will be pressure tested to confirm integrity. The MODU BOP will then be reconnected to continue with drilling and completions activities.

The xmas tree will be installed with a preservation mixture in the production and annulus bore.

3.11.1.8 Completions Activities

Once the well has been drilled, well completion activities will be performed which may include the installation of the lower completion, intermediate completion, production tubing and subsea tree. The well is then pressure tested for integrity before well suspension.

The well will be completed with a conventional upper completion. The well will be suspended with two crown plugs installed in the tubing hanger. Crown plugs will be individually pressure tested to verify suspension barriers before removing the BOP.

3.11.1.9 Well Unload

3.11.1.9.1 General Description

During well unloading activities, all completion and reservoir fluids will be directed through the Pluto facility to the onshore LNG plant.

In the event fluids from well unloading cannot be directed to the Pluto facility, they may be flared or discharged to the environment via the well test package onboard the MODU. The base oil column, completion fluid, hydrocarbons and produced/condensed water will be measured, handled, separated, treated for overboard discharge (non-hydrocarbon) and flared/burned (hydrocarbon) through the temporary production system on the MODU. Note that the opportunity to unload to the Pluto facility is Woodside's preferred option, which could eliminate or reduce well unloading to the MODU.

3.11.1.9.2 Produced/Reservoir Water Disposal

If fluids from well unloading are directed to the MODU, the well test water treatment package will be used to treat produced/reservoir water before discharge. Prior to discharging, the fluids are cycled through an onboard filtration system and gauge tank. Water filtration is standard practice for well unloading operations. Fluids that cannot be treated or flared will be sent onshore in tanks for disposal.

3.11.1.9.3 Emissions

If well unloading is performed to the MODU, it is expected that condensate, diesel and methanol in the wellbore will be flared. The flare may be extinguished due to water ingress, lack of fuel (propane), weather impact or equipment failure resulting in cold venting of gas from the flare for several minutes before the flare can be restarted or venting stopped. After the objectives of the well testing and flowback are achieved, the flow is stopped and the well may be cleaned using a brine that can include several chemicals, such as biocide and surfactant.

3.11.2 Drilling Fluid System

In addition to the base fluid, drilling muds contain a variety of chemicals, incorporated into the selected drilling fluid system to meet specific technical requirements (e.g., mud weight required to manage pressure, or for borehole stability). All chemicals selected for use will be assessed under Woodside's internal guidelines so that potential impacts are acceptable, ALARP and meet Woodside's expectation for environmental performance.

3.11.2.1 Water-based Mud System

A water-based drilling fluid system is the preferred option for the Petroleum Activities Program.

In addition to the base fluid, drilling muds contain a variety of chemicals, incorporated into the selected drilling fluid system to meet specific technical requirements (e.g., mud weight required to manage pressure, or for borehole stability). The WBM drilling fluid will either be mixed on the MODU or received pre-mixed, then stored and maintained aboard the MODU. The top hole sections are drilled riserless with seawater containing pre-hydrated gel sweeps. The bottom hole sections may be drilled using WBM in a closed circulation system which enables reuse of the WBM drilling fluids.

WBM drilling fluids that cannot be reused (e.g., due to bacterial deterioration or if they do not meet required drilling fluid properties) or are mixed in excess of required volumes, may be operationally discharged to the ocean under the MODU's Permit to Work (PTW) system.

A number of factors unique to each drilling program will determine the quantities of WBM drilling fluids required and subsequent discharge volumes if no suitable reuse option is available.

3.11.2.2 Mud Pits

There are typically a number of mud pits (tanks) on the MODU that provide a capacity to mix, maintain and store fluids required for drilling activities. The mud pits form part of the drilling fluid circulating system. The mud pits and associated equipment/infrastructure are cleaned out at the end of drilling and completions operations. Mud pit wash residue is discharged overboard with less than 1% oil contamination by volume. Mud pit residue over 1% oil volume is sent to shore for disposal.

3.11.2.3 Drill Cuttings

Drill cuttings generated from the well are expected to range from very fine to very coarse (<1 cm) particle/sediment sizes. Cuttings generated during drilling of the top hole sections are discharged at the seabed. Estimated volumes of drill cuttings that may be discharged during the PAP are presented in Section 6.7.8.

The bottom hole sections are drilled with a marine riser that enables cuttings and drilling fluid to be circulated back to the MODU, where the cuttings are separated from the drilling fluids by the SCE. The SCE comprises, but is not limited to, shale shakers, cuttings dryers and centrifuges. The SCE uses shale shakers to remove coarse cuttings from the drilling mud. After being processed by the shale shakers, the recovered mud from the cuttings may be directed to centrifuges, which are used to remove fine solids (4.5 to 6 µm). The cuttings are usually discharged below the water line and the mud is recirculated into the fluid system.

If contingency NWBM is needed to drill a well section, the cuttings which are separated from the NWBM via the shakers will also pass through a cuttings dryer and associated SCE to reduce the average oil on cuttings for the entire well (only sections using NWBM) to 6.9% wt or less on wet cuttings prior to discharge. Woodside is not planning to use NWBM, and their use is retained as a contingency only. The approval process within Woodside to permit the use of NWBM is described in Section 3.11.5.4.

3.11.2.4 Cement, Barite and Bentonite Discharge

Excess cement, barite and bentonite (dry bulk) after well operations are completed, will either be held onboard and used for subsequent wells, provided to the next operator at the end of the program, or if these options are not feasible, discharged to the marine environment. Toward the end of the campaign, if re-use, transfer or on-sale of the dry bulk stocks becomes not feasible, Woodside will implement stock reduction measures to reduce the volume dry bulk stock requirement, to that necessary for well control, as defined in relevant well control procedures.

Excess cement, barite and bentonite that does not meet technical requirements during the PAP may also be bulk discharged to the environment. Bulk discharges of cement, barite and bentonite may occur as a slurry through the usual cement discharge line or blown as dry bulk and discharged. Woodside requires that mercury and cadmium concentration in stock barite be below 1 mg/kg and 3 mg/kg, respectively. Documentation of heavy metal analysis is planned to be undertaken for all individual batches of barite and used to verify compliance with these concentrations.

3.11.3 Subsea Installation and Pre-commissioning Activities

The subsea installation scope of work will include installing and pre-commissioning the infrastructure summarised in Table 3-17. The PAP includes directly installing infrastructure from the installation vessels in the relevant location. During hook-up and pre-commissioning of the new and existing facilities there is potential for discharges associated with the testing and connection activities of the subsea systems. The pre-commissioning associated with subsea infrastructure generally includes leak testing of the flexibles, subsea control systems verification and function-testing of valves to verify that the electric and hydraulic flying leads are ready for entry into the commissioning phase.

Table 3-17: Subsea installation component summary

Description	Detail	Dimensions (Approximate)
Well (Xena-03)	1 wellhead and xmas tree system	6.0 m (L) × 4.0 m (W) × 6.0 m (H) (typical)
Subsea flowline	10” ID flexible flowline	3000 m
Subsea control	1 electrohydraulic umbilical (EHU)	2500 m
	2 umbilical termination assemblies	4 m × 3m
Stabilisation	~10 concrete mattresses	6 m × 3 m

3.11.3.1 Underwater Acoustic Positioning

Long baseline (LBL) transponders and ultra short baseline transponders (USBL) are commonly used acoustic positioning methods and may be installed on the seabed as required by the installation

activities. The USBL subsea transponder transmits an acoustic pulse back to the vessel receiver, hence providing an accurate positioning of the subsea transponder location. The LBL array provides accurate positioning by measuring ranges to three or more transponders deployed at known locations on the seabed and structures.

These transponders are utilised for the correct positioning of the subsea infrastructure. Transmissions are not continuous but consist of short 'chirps' with a duration that ranges from three to 40 milliseconds. If used, the LBL transponders are installed in stands on the seabed. Both the transponders and stands are recovered after installation. The USBL transponders are mounted on the subsea infrastructure and removed post installation.

Transponders may also be installed in stands on the seabed for vessel positioning. Both transponders and stands shall be removed post installation.

3.11.3.2 Installation of Structures

Subsea structures (i.e., subsea distribution unit, mudmats) are lowered to the seabed using the main crane positioned on an installation vessel to a pre-determined depth before engaging an ROV to guide it to the correct position.

As described above, the structures may be positioned using LBL array or USBL. Additional pre-deployed clump weights or sandbags can potentially be used to provide further assurance that the structures are positioned in the correct location and orientation.

3.11.3.3 Flexible Flowline Initiation/Initiation Anchor Deployment

Commencement of the flowline installation may require using an initiation anchor to pull against in order to provide the required tension to the flexible flowline as it transitions from the installation vessel to the seabed. The initiation anchor, which will be recovered after use, may consist of a clump weight.

Installation aids such as sandbag markers or concrete mattresses may be used for positioning aids or wet storage as required.

3.11.3.4 General Flexible Flowline and Flying Leads Installation

The installation contractor will mobilise an installation vessel to the field to install the flexible flowline and flying leads to the seabed. The installation vessel will operate in DP during installation activities.

The optimum flowline route is selected by considering seabed bathymetry, pre-installation surveys and installation risk management, including dropped object risks.

The indicative installation methodology and principle applied when installing the flowline is as follows:

- The flexible flowline is reeled onto either horizontal or vertical reels.
- VLS are installed on the vessel to lay the flexible flowline.
- During installation, a hydraulically driven centre reel drive is engaged to the reel to rotate the reel in synchronised speed with the VLS.

Installation sequence for flexible flowline is as follows:

- Prepare universal connection system and VLS onboard the vessel.
- Fit applicable subsea components (anodes, bend restrictors) to flexible flowline, perform tests and pre-deployment checks.
- Deploy flexible flowline, ROV guide tail end to initiation point and land out.
- Continue flexible flowline lay as per lay route while monitoring touchdown with ROV.
- Land out second end to final location and disconnect.

The flexible flowline may also be installed using a lighter installation spread on the installation vessel, via a deck-mounted powered reel system in combination with a deployment chute mounted on the side of the installation vessel and temporary installation aids placed on the seabed.

The flying leads are configured into deployment basket(s) and landed on the seabed using a crane. ROVs will complete the final subsea tie-in. Small volumes of MEG and HW443 will be released to subsea environment during HFL removal and installation.

3.11.3.5 Span/Scouring Rectification and Stabilisation

Spans are undulations in the seabed that do not provide sufficient support to the flowline. Spans are generally mitigated by installing structures, such as concrete mattresses, before installing the flowline. Engineering validation will determine if concrete mattresses need to be installed to mitigate spans. The dimensions for each concrete mattress are typically 6 m by 3 m by 0.3 m.

Post-lay span rectification may also be required after flexible flowline installation. This process typically involves placing grout bags under the span section. The empty bag is moved into position using ROV, then filled with grout supplied from a mixing and pumping spread on the vessel via a downline. Typical grout volumes depend on the size of the span and may vary from about 200 kg to 2000 kg per span.

If grout bags are used, the downline recovery time risks exceeding the grout curing time. If grout cures within the downline and pump, the equipment is likely to be rendered unserviceable, as well as the downline not being safely recoverable in the normal way. Therefore, after grouting activities at each span site, the downline and pump will need to be purged using seawater. This results in an amount of grout, approximately equivalent to the downline volume (5 m^3), being discharged to the ocean. This flushing is required once per grout site. The actual number is not known until the line is laid and need for span rectification determined, if any.

Scouring is the movement of seabed sediment (e.g., silt, sand and gravel) from around the base of a subsea structure to further afield due to prevailing hydrodynamic conditions, potentially compromising the integrity of a structure. Scouring is generally mitigated by installing mattresses along the perimeter of the installed structure. Concrete mattresses may be installed pending engineering verification.

Stabilisation is a post-lay activity to ensure that items, such as the flying leads remain at their installed positions, i.e., not being shifted due to strong seabed current. Stabilisation of flying leads is generally mitigated by installing sandbags on top of flying leads at a predetermined distance apart. Sandbags generally come in a standard size with 20 kg to 25 kg weight. Concrete mattresses may be used to stabilise the flexible flowline. Sandbags or concrete mattresses may also be used to provide temporary stability of wet stored items if wet storage proves necessary.

Sandbags or concrete mattresses may be installed for crossings over existing umbilicals or jumpers/flowlines.

3.11.3.6 Pre-commissioning of the Flexible Flowline

Leak testing is performed to test the integrity of subsea infrastructure, test isolations and identify any leaks. Pressure may be applied via a downline from the installation vessel or via ROV. Failure of testing equipment or integrity of the tested infrastructure may lead to a loss of leak test fluids to the marine environment. After the leak testing is completed, the system pressurisation volume may be released to the environment to mitigate the risk of hydrocarbons returning to the installation vessel.

During tie-in and pre-commissioning activities, any subsea connection breakouts will be preserved with chemical sticks. A small amount of chemically treated MEG/water may be discharged to the environment from the structure and tie-in flexible prior to final makeup of the connection. All chemicals used in pre-commissioning activities will be subject to the chemical selection assessment process described in Section 3.9.

3.11.3.6.1 Flooding

The flexible flowline will be installed filled with chemically treated ~50 wt% MEG/water. MEG is used to prevent formation of hydrates during start-up. Topping up of the flowline will occur when the pulling head is removed to install diverless connectors.

3.11.3.6.2 Leak Testing

Leak test/system pressure tests are performed to confirm the integrity of subsea connections and flowline. During leak testing there may be small volumes of test fluids discharged to environment during connection and disconnection of hot stabs.

3.11.3.7 Tie-in of Flowlines at Pluto Manifold

Prior to tie-in of the Xena-03 flowline to the Pluto manifold, verification testing of any leakage from the manifold isolation valves may be undertaken. This testing will verify that suitable isolations for safe tie-in are available, thereby preventing a major hydrocarbon release during tie-in. This verification may result in the release of hydrocarbons to the environment. The hydrocarbons are predominately gas with a small quantity of condensate. Additionally, when the flowline tie-ins take place, a quantity of hydrocarbons may be released. A conservative estimate of hydrocarbons that may be released during the flowline tie-in at the manifold is up to 400 L of condensate and residual gas over a 48-hour period. Water jetting and/ or acid injection may be used to clean the connections on the infrastructure prior to tie-in.

3.11.3.8 Cold Commissioning of Subsea Infrastructure

The commissioning associated with subsea infrastructure prior to the introduction of hydrocarbons (referred to as cold commissioning) generally includes subsea control systems verification and function testing of valves to verify that the hydraulic flying leads (HFLs) and electric flying leads (EFLs) are ready for entry into the start-up phase.

During cold commissioning, an ROV is deployed from the installation vessel (or similar support vessel) to provide visual confirmation of xmas tree valve actuation. This activity is typically less than 12 hours in duration.

3.11.3.9 Wet Storage of Equipment

Wet storage of infrastructure may be required intermittently throughout the duration of subsea installation activities as part of the Petroleum Activities Program. There are two categories of equipment that may require wet storage as part of the Petroleum Activities Program, as summarised in Table 3-18. At completion of Xena-03 Tie-back activities there will be no wet stored infrastructure remaining on the seabed.

Table 3-18: Wet storage that may be required as part of Xena-03 Tie-back activities

Wet Storage Category	Reason for Wet Storage	Typical Equipment	Retrieval Method
Installation aids	To facilitate safe installation of infrastructure	Predominately installation aids (subsea/ROV baskets, clump weights, grout bags and concrete mattresses (if used for temporary stabilisation), etc)	Retrieval will be undertaken using project vessels (Section 3.12) and associated equipment such as cranes, ROV, etc
Subsea installation	Prior to connection of infrastructure, wet storage may be necessary to optimise project schedule and support SIMOPS	Items may include flexible flowline, flying leads and wet parking/deployment frames, etc	Retrieval is not required, as infrastructure will be used for production operations and once connected is no longer considered wet stored

3.11.3.10 Maintenance of Subsea Infrastructure

All subsea structures installed during the PAP have been designed for full removal. The stored items will be removed during the subsea installation activities. Due to the design of equipment, the materials selected and short duration of subsea installation activities, all wet-stored equipment will be in a condition that allows for removal. The as-built survey will confirm that structures installed for production operations are in good condition and repair.

3.11.3.11 Site Surveys

Site surveys will be undertaken at various stages throughout the installation of subsea infrastructure. An initial pre-lay survey will be undertaken by the flexible flowline installation contractor before starting installation activities. The pre-lay survey may be performed by a dedicated pre-lay survey vessel which is typically similar in size to support vessels, or potentially by the installation vessel.

The pre-lay survey is a debris and hazard identification survey and not a full geophysical survey along the pre-determined route or proposed design route. While it is not anticipated that any significant debris may need to be removed before flexible flowline installation, if required, these activities will fall under this EP and will be performed by an installation vessel, a support vessel or similar.

Additional surveys, with an ROV, will be undertaken throughout the installation activities. These surveys will identify the location of all items placed on the seabed (including wet stored items and installed infrastructure). The survey data will be input into a computer program to track all subsea equipment and displayed on the 'survey screen' (comprising an AutoCAD file). This file will be progressively updated throughout the activities as items are placed and removed from the seabed (and in the title).

An as-built survey will be conducted by ROV at the completion of the installation campaign so that installation of equipment is in the designed location. This data will be used to update the 'survey screen' to develop the as-built report, which is considered the inventory of items remaining on the seabed (and in the title). In addition, any material items dropped to the marine environment and not recovered (see Section 6.9.8) will be added to the inventory for the title.

3.11.4 Xena-03 Commissioning (Initial Start-up) Activities

The commissioning (initial start-up) activities of the Xena-03 well and associated subsea infrastructure are planned to commence in 2025. All activities may be subject to rescheduling, including delay, based on operational requirements of the Pluto platform or other production scheduling reasons as well as project schedule changes. Topsides modifications on the Pluto facility are limited to controls updates.

Once hydrocarbons have been introduced into the system, preservation fluids are displaced to the Pluto platform, where they are processed, and wells are cleaned up to maximum rates. Performance testing may be undertaken such as Multi-Rate Testing, simulated ESD of Xena-03 well only, then Pressure Build-up testing. MEG of up to 100%, or a combination of MEG/treated water initially in the Xena-03 flowline arrives at the separator and is discharged via the produced water (PW) discharge route, along with residual completions fluids and fines from the well as part of well clean-up.

3.11.5 Contingent Activities for the Xena-03 Tie-back

The following sections present contingencies that may be required, if operational or technical issues occur during the Petroleum Activities Program. These contingencies have been considered within the relevant impact assessment sections and do not represent significant additional risks or impacts but may generate additional volumes of drilling fluids and cuttings being discharged operationally.

3.11.5.1 Respud

A respud may be required for a number of reasons, such as if the conductor or well head slumps or fails installation criteria (typically during top hole drilling). Re-spudding involves moving the MODU to a suitably close location (e.g., ~50 m from the original location) to recommence drilling. A respud activity would result in repeating top hole drilling (Section 3.11.1).

The environmental aspects of re-spudding are the same as those for drilling and are considered to be adequately addressed by this EP (Section 6.7), with no significant changes to existing environmental risks or any additional environmental risks likely. The net environmental effect will be limited to an increase in the volume of cuttings generated (Section 6.7.8) and increased volumes discharged.

3.11.5.2 Sidetrack

The option of a sidetrack instead of a respud may be required if operational issues are encountered. The environmental aspects of a sidetrack well are the same as those for routine drilling activities, which are considered to be adequately addressed by this EP (Section 6.7), with no significant changes to existing environmental risks or any additional environmental risks likely. The net environmental effect will be limited to an increase in the volume of cuttings generated (Section 6.7.8), potential increase in the use of drilling fluids and the additional emissions (atmospheric and waste) associated with an extended drilling program.

3.11.5.3 Workover

A workover may be performed on the Xena-03 well. A workover or intervention may be required to restore production or integrity due to a failed completion or component in the well. The environmental aspects of a workover operation are the same as those for well completion activities and are considered to be adequately addressed by this EP, with no significant changes to existing environmental risks or any additional environmental risks likely.

3.11.5.4 Non-water-based Mud System

The Xena-03 well is planned to be drilled entirely using WBM, however NWBM may be required for bottom hole sections as a contingency. The decision to use NWBM drilling fluids for the bottom hole sections of a well is based on a variety of technical factors relevant to wellbore conditions, such as well temperature, well shape and depth, reactivity of formation to water and well friction. The technical justification to use NWBM includes environment, health, safety and waste management considerations.

The use of NWBM drilling fluids is subject to a formal written commercial and/or technical justification approved in accordance with the Best Practice – Overburden Drilling Fluids Environmental Requirements. The main ingredient of NWBM is base oil, and similar to a WBM system, a range of standard solid and liquid additives may be added in the pits to alter specific mud properties for each section of the well, dependent on the conditions encountered while drilling.

The NWBM drilling fluid will be primarily mixed onshore (new or reuse of existing stock) and transferred to the MODU by a support vessel, where it is stored and maintained in the mud pits. During drilling operations, the NWBM drilling fluid, like the WBM, is pumped by high pressure pumps down the drill string and out through the drill bit, returning via the annulus between the drill string and the hole/casing back to the MODU via the riser.

The used NWBM pumped back to the MODU contains drill cuttings and is pumped to the solid control equipment (SCE), where the drill cuttings are removed before the NWBM is pumped back to the pits ready for reuse. The technical properties of the NWBM drilling fluids are maintained/altered (e.g., to increase weight) using additives as required when in the mud pits.

The NWBM drilling fluids that cannot be re-used (i.e., do not meet required drilling fluid properties or are mixed in excess of required volumes) are recovered from the mud pits and returned to the shore base for onshore processing, recycling and/or disposal. The mud pits and associated equipment/infrastructure are cleaned when NWBM is no longer required, with wash water treated onboard through SCE before discharge with mud pit washings, or returned to shore for disposal if discharge criteria cannot be achieved (refer to Section 3.5).

3.11.5.5 Well Suspension

During drilling activities, a well may need to be temporarily suspended. Suspension involves establishing suitable barriers, removing the riser and disconnecting the MODU from the well. The BOP may be left in place to act as a barrier. Suspension may be short term (e.g., in the case of a cyclone) or longer term (more than one year). On return to a well after suspension, the MODU reconnects to the well via the riser, and with BOP in place, barriers are removed and drilling and completions activity resumes.

3.11.5.6 Wireline Logging

Wireline contingencies that may be in place for development drilling include gamma ray and casing collar locator for depth correlation, ultrasonic imaging tool and cement bond log to measure cement integrity, formation pressures (XPT), density, neutron and resistivity and punch perforators/tubing cutters suitable for all tubing sizes. Wireline contingency work will be performed with appropriate isolation barriers in place, i.e., an overbalanced fluid column. If wireline work is required to occur in a live well, or where there is a risk of barrier failure, the operation will be performed with full pressure control equipment at the surface.

Some logging tools may contain low activity radiation sources. Radiation fields are not generally detectable outside the tool when the tool is not energised; therefore, they do not present an environmental risk.

3.11.5.7 Well Intervention

An intervention may be performed on the Xena-03 well. Interventions may be performed due to down-hole equipment failure or to address underperformance of a well. Key well intervention methods include wireline and coiled tubing. Potential environmental impacts from intervention activities have been included in this EP, including discharge of suspension fluids and brines and small volume gas releases subsea due to removal of a tree cap which may be in place if the well was previously suspended.

3.11.5.8 Well Abandonment

The PAP covers the drilling and intervention of the Xena-03 well, which is not envisaged to be abandoned until the end of the production field life. For technical reasons, the lower section of a well may need to be abandoned, before side-tracking, or if a respud is required.

Well abandonment activities are conducted in accordance with Woodside's internal standards. Base oil may be used for inflow testing before abandonment, to verify barrier integrity. Base oil would be pumped down the drill string and reverse circulated back to the rig, with fluids collected for disposal onshore. If stored in a mud pit, the base oil and other fluids associated with the test may result in pit wash water contaminated with hydrocarbons. If this is the case, mud pit wash water would be discharged in accordance with requirements in this EP; with a hydrocarbon content <1% by volume.

If required, wells will be abandoned with abandonment cement plugs, including verification of cement plug by tagging and/or pressure testing through a prescribed program. A lower section of a well may also be abandoned before side-tracking.

After abandonment activity, the marine riser and BOP will be removed and every reasonable attempt made to retrieve the wellhead. Conventional wellheads are removed by deploying a cutting device

on drill pipe which then cuts through the casing and conductor, allowing the wellhead to be retrieved to the surface. Backup cutting equipment is sent offshore as a contingency should the primary set of equipment fail. The conductor cutting equipment is very reliable with a high success rate of cutting wellheads.

If these recognised removal techniques are ineffective, the wellhead may be left in-situ. The integrity of the wellbore is not affected by the wellhead assembly remaining in-situ.

3.11.5.9 Wellhead Assembly Left In-situ

If a well is abandoned due to the requirement to respud, the wellhead assembly may be left in-situ if recognised removal techniques are ineffective. Well abandonment activities would be performed as outlined in Section 3.11.5.8 but the well assembly would remain. The integrity of the wellbore is not affected by the wellhead assembly remaining in-situ. The environmental aspects of the wellhead assembly remaining in-situ as a contingent activity are considered to be adequately addressed by this EP (Section 6.7.2) with no significant changes to existing environmental risks or any additional environmental risks likely.

Final decommissioning of the development wellhead assembly and other subsea infrastructure at the end of field life will be subject to a separate EP. Woodside's Decommissioning Framework is discussed further in Section 7.5.

3.11.5.10 Sediment Mobilisation and Relocation

If required, an ROV-mounted suction pump/dredging unit may be used to relocate sediment/cuttings around the wellhead or other infrastructure, to keep the area clear and safe for operations and equipment. This activity has the potential to generate plumes of suspended sediment during pumping and disturb benthic fauna in the immediate area.

3.11.5.11 Venting

During drilling of the well, a kick may occur. A kick is an undesirable influx of formation fluid into the wellbore. To maintain well integrity in this situation, a small volume of greenhouse gas is released to the atmosphere via the degasser, in a well control operation known as 'venting'.

3.11.5.12 Emergency Disconnect Sequence

An emergency disconnect sequence (EDS) may be implemented if the MODU is required to rapidly disengage from the well. The EDS closes the BOP (i.e., shutting in the well) and disconnects the riser to break the conduit between the wellhead/BOP and MODU. Common examples of when this system may be initiated include the movement of the MODU outside of its operating circle (e.g., due to a failure of the DP system) or the movement of the MODU to avoid a vessel collision (e.g., third-party vessel on collision course with the MODU). EDS aims to leave the wellhead and BOP in a secure condition but will result in loss of the drilling fluids/cuttings in the riser after disconnection.

3.12 Vessel-based Activities for the Xena-03 Tie-back

During the Xena-03 Tie-back activities, vessel-based activities will involve the MODU, subsea installation vessels and support vessels such as anchor handling vessels (AHVs).

For power generation, vessels may use diesel-powered generators and/or LNG. All vessels will display navigational lighting and external lighting, as required for safe operations. The MODU and support vessels will be lit to maintain operational safety on a 24-hour basis. Vessel activities while in transit to the PAA are not included in the scope of this EP.

3.12.1 Mobile Offshore Drilling Unit

The Xena-03 well will be drilled by a moored, or hybrid MODU. Contingent well intervention activities may also be performed by a moored or hybrid MODU. Typical specifications for a moored and hybrid MODU are provided in Table 3-19 and Table 3-20, respectively. Moored and hybrid MODU types are collectively referred to as MODU for the remainder of the document unless specific risks for different MODU types have been identified. Due to variabilities such as contractual and operational matters, the MODU used may be subject to change.

Table 3-19: Typical moored MODU specifications for Ocean Apex

Component	Specification Range
Rig Type/Design/Class	Semi-submersible MODU
Accommodation	120 to 200 personnel
Station Keeping	Eight-point or twelve-point mooring system
Bulk Mud and Cement Storage Capacity	283 to 770 m^3
Liquid Mud Storage Capacity	576 to 2500 m^3
Fuel Oil Storage Capacity	966 to 1400 m^3
Drill Water Storage Capacity	3500 m^3

Table 3-20: Typical hybrid MODU specifications for Transocean Endurance

Component	Specification
Rig Type/Design/Class	Semi-submersible MODU
Accommodation	130 persons (maximum persons on board)
Station Keeping	Eight-point or twelve-point mooring system with thrusters for Dynamic Positioning (DP3)
Bulk Mud and Cement Storage Capacity	340 m^3
Liquid Mud Storage Capacity	1445 m^3
Fuel Oil Storage Capacity	2600 m^3
Drill Water Storage Capacity	1508 m^3

3.12.2 Installation Vessels

The PAP subsea installation scopes of work may require various installation vessels, with sufficient capacity to accommodate hardware and equipment such as flowlines, flexible flowlines, umbilicals and the cold commissioning/dewatering spreads.

A typical installation vessel for subsea and flowline installation would be a DP vessel (usually DP2 Class) equipped with a primary differential global surface positioning system (DGPS) and an independent secondary DGPS backup. The specification of a typical subsea installation vessel is provided in Table 3-21.

Installation vessels are typically equipped with various material handling equipment, which includes cranes, winches, remotely operated vehicles (ROVs) and ROV launch and recovery systems, vertical lay system (VLS) with either vertical reel drive or horizontal reel drive (carousel) and cold commissioning spread.

Lifting operations may involve loading and unloading equipment from support and supply vessels onto the installation vessel and subsequently onto the seabed. Cranes are typically equipped with active heave compensation and auto tension, modes and have lifting capacities in excess of lifting loads expected to be encountered during operations.

Table 3-21: Typical DP2 Class subsea installation vessel for Deep Orient

Component	Specification Range
Vessel Type	DP2 Class as a minimum
Crane Capacity	250 T active heave compensation crane as minimum
ROVs	Two Work Class ROVs
Deck Space	Approximately 1900 m²
Deck Strength	Approximately 15 T/m²
Accommodation	Approximately 120 people
Fuel Oil	Approximately 2200 m³
Potable Water	Approximately 800 m³

3.12.3 Support and Other Vessels

During the PAP, the MODU and installation vessel will be supported by other vessels, such as general support vessel(s)and AHVs.

General support vessels are used to transport equipment and materials between the MODU/installation vessel and port (e.g., Dampier, Onslow, Exmouth). When required, a support vessel will perform standby duties at the MODU. During this time, support vessels will make regular trips between the Xena-03 Operational Area to port for routine, non-routine and emergency operations. Subsea Support vessels as described in Section 3.8.2 may also be used.

Support vessels will be using their DP system within the Xena-03 Operational Area. The support vessels are also available to assist in implementing the Oil Pollution First Strike Plan, should an environmental incident occur (e.g., spills).

3.12.4 Subsea Support Vessel for Light Well Intervention Activities

During the Petroleum Activities Program, a subsea support vessel for light well intervention operations may be used as an option for contingent well intervention, subsea installation and other activities. An example of this vessel type is the Sapura Constructor, which is a 117 m long subsea support vessel equipped with a saturation dive system, two Work Class ROVs, well intervention equipment, a helideck, moon pool and accommodation for 120 persons. The final vessel selection, if required, will be subject to commercial and/or operational considerations.

3.12.5 Holding Station: Mooring Installation and Anchor Hold Testing/Soil Analysis

Mooring uses a system of chains/ropes and anchors, which may be pre-laid before the MODU arrives at the location, to maintain position when drilling. Mooring analysis will be undertaken to determine the appropriate mooring system for the PAP. The mooring analysis will identify whether the mooring systems are pre-laid or set by the rig, proof tension values, and if synthetic fibre mooring ropes are required. Pre-laid systems are often selected and designed to withstand higher sea states than the rig's mooring system or to provide additional clearance/protection of subsea infrastructure when deemed necessary in the mooring analysis.

Installation and proof tensioning of anchors involves some disturbance to the seabed. Anchor handling vessels (AHVs) are used in the deployment and recovery of the mooring system.

As part of mooring preparations, anchor hold testing may be conducted at the well locations. Anchor hold testing would be undertaken if Woodside determines that further assurance is required to ensure a robust mooring design.

Anchor hold testing may involve an AHV or similar vessel deploying an anchor at a potential mooring location. The AHV would then tension the anchor to determine its ability to hold, embed and not drag at location. This may have to be repeated several times at each location. An ROV may also be used

to evaluate how deep the anchor has embedded and independently verify the seabed condition. Anchor hold testing activities would occur prior to the MODU arriving on location.

Soil analysis may also be necessary to provide data on composition and rock/substrate strength as input into the mooring design and to verify seabed conditions for anchor holding. Soil analysis could include taking a physical sample of the seabed using ROV or other tools or using measuring devices such as a cone penetrometer. These tests would be carried out up to several months prior to MODU arriving on location and may occur from a support vessel or an AHV.

3.12.6 Holding Station: Rig Anchor Release Mobile Offshore Drilling Unit

The hybrid MODU scenario is such that the MODU is DP capable though predominantly holds station via a pre-laid mooring system. If a hybrid MODU is used to conduct drilling, it will likely have a rig anchor release (RAR) system integrated as a contingency case for cyclone season. A traditional arrangement with no RAR (for lines passing over subsea assets) and rig- or prelay-lines (for lines clear of subsea assets) will likely be used as the base case in non-cyclone seasons.

The moorings are typically pre-laid in an eight-point arrangement, with a RAR device connecting the MODU mooring components with the anchor mooring components. The RAR is an acoustic release connecting link that can be installed in a mooring line to enable a rapid disconnection of a MODU from the mooring system. Each mooring leg would have one RAR installed in the mooring line.

The acoustic release process is instigated from a command unit on the MODU that, when activated, transmits a low frequency signal (9–11 kHz) that is received by the RAR transducer in the mooring line and activates the primary hydraulic actuator. The hydraulic actuator then releases the locking mechanism of the RAR, and the mooring line is disconnected. The MODU then recovers the MODU wire/chain ready for transit (on DP) and the subsea mooring leg remains on the seabed. Anchor lines crossing subsea infrastructure, will be buoyed to maintain clearance from the subsea assets after a disconnection (either on the surface or suspended in the water column).

To reconnect the MODU with the mooring system after a disconnection, the AHV will recover the MODU mooring line (including RAR and the trigger sleeve) from the MODU before connecting to the pre-laid line, which is recovered from the seabed or water column by the AHV using an ROV.

3.12.7 Mobile Offshore Drilling Unit and Support Vessel Activities

A variety of materials are routinely bulk transferred from support vessels to the MODU including drilling fluids (e.g., muds), base fluids, cements and drill water. A range of dedicated bulk transfer stations and equipment are in place to accommodate the bulk transfer of each type of material. There is also a capacity to bulk transfer waste oil from the MODU to the support vessel, for back loading and disposal on shore.

The loading and back-loading of equipment, materials and wastes is one of the most common supporting activities conducted during drilling programs. Loading and back-loading is performed using cranes on the MODU to lift materials in appropriate offshore rated containers (e.g., ISO tanks, skip bins, containers) between the MODU and support vessel.

Seawater is pumped on board and used as a heat exchange medium for cooling machinery engines and high temperature drilling fluid on the MODU. It is subsequently discharged from the MODU at the sea surface at potentially a higher temperature. Alternately, MODUs may use closed loop cooling systems.

Potable water, primarily for accommodation and associated domestic areas, may be generated on vessels using a reverse osmosis plant. This process will produce brine, which is diluted and discharged at the sea surface.

The MODU and support vessels will also discharge deck drainage from open drainage areas, bilge water from closed drainage areas, putrescible waste and treated sewage and grey water. Solid hazardous and non-hazardous wastes generated during the PAP are disposed of onshore by support

vessels. The MODU and support vessels may also take on or discharge ballast water to maintain vessel stability.

3.12.8 Subsea Installation and Support Vessel Activities

An installation vessel may be used for various subsea installation activities such as pre- and post-installation survey, installation of subsea structures, installation of the flowline, installation of interconnecting HFL, EFL and MEG jumper, tie-in to existing infrastructure, and cold commissioning activities. Other support vessels may also be used to transport equipment, hardware and MEG from shore to the installation vessel.

3.12.9 Refuelling

The MODU will be refuelled via support vessels approximately once a month, or as required. Refuelling will occur within the Xena-03 Operational Area and has been included in the risk assessment for this EP. Other fuel transfers that may occur on board the MODU may include refuelling of cranes, helicopters or other equipment as required. As the base case, refuelling of installation vessels is planned to occur outside of the Operational Area during interim mobilisation/demobilisation.

4. DESCRIPTION OF THE EXISTING ENVIRONMENT

4.1 Overview

In accordance with Regulations 21(2) and 21(3) of the Environment Regulations, this section describes the existing environment that may be affected by the activity (planned and unplanned, as described in Section 2.4), including details of the particular relevant values and sensitivities of the environment, which were used for the risk assessment.

The EMBA is the largest spatial extent where unplanned events could have an environmental consequence on the surrounding environment. For this EP, the EMBA is the potential spatial extent of surface and in-water hydrocarbons at concentrations above ecological impact thresholds, for this EP a loss of well integrity (from drilling of Xena-03 and an operational well), potential marine diesel loss of containment release in the offshore area, and a nearshore subsea loss of containment scenario. The ecological impact thresholds used to delineate the EMBA are defined in Section 6.8.2.2.The EMBA also includes any areas that are predicted to experience shoreline contact with hydrocarbons above threshold concentrations.

Woodside recognises that hydrocarbons may be visible beyond the EMBA at lower concentrations than the ecological impact thresholds defined in Section 6.8.2.2. These visible hydrocarbons are not expected to cause ecological impacts. In respect of this, an additional socio-cultural EMBA is defined, as the potential spatial extent within which social-cultural impacts may occur from changes to the visual amenity of the marine environment. Receptors relevant to the socio-cultural EMBA include cultural values and heritage, Commonwealth and State marine protected areas (MPAs), National and Commonwealth Heritage Listed places, areas of tourism and recreation, and commercial and traditional fisheries. The EMBA and socio-economic EMBA are shown in

Figure 4-1 and described in Table 4-1.

The EMBA presented does not represent the predicted coverage of any one hydrocarbon spill or a depiction of a slick or plume at any particular point in time. Rather, the areas are a composite of a large number of theoretical paths, integrated over the full duration of the simulations under various metocean conditions.

Table 4-1: Hydrocarbon spill thresholds used to define the EMBA for surface and in-water hydrocarbons

<table>
<tr><th>Hydrocarbon Type</th><th>EMBA[1]</th><th>Socio-cultural EMBA[1]</th><th>Planning Area for Scientific Monitoring</th></tr>
<tr><td>Surface</td><td>10 g/m²
This represents the minimum oil thickness (0.01 mm) at which ecological impacts (e.g., to birds and marine mammals) are expected to occur.</td><td colspan="2">1 g/m²
This represents a wider area where a visible sheen may be present on the surface and, therefore, the concentration at which socio-cultural impacts to the visual amenity of the marine environment may occur. However, it is below concentrations at which ecological impacts are expected to occur.
This low exposure value also establishes the planning area for scientific monitoring (NOPSEMA Environment bulletin: A652993, April 2019).</td></tr>
<tr><td>Dissolved</td><td colspan="2">50 ppb
This represents potential toxic effects, particularly sublethal effects to highly sensitive species (NOPSEMA Environment bulletin: A652993, April 2019). As dissolved hydrocarbons are within the water column and not visible, impacts to socio-cultural receptors are associated with ecological impacts. Therefore, dissolved hydrocarbons at this threshold also represent the level at which socio-cultural impacts may occur.</td><td rowspan="2">10 ppb
This low exposure value establishes the planning area for scientific monitoring (based on potential for exceedance of water quality triggers) (NOPSEMA Environment bulletin: A652993, April 2019). This area is described in Appendix H: Oil Spill Preparedness and Response Mitigation Assessment.
In the event of a spill, DNP will be notified of AMPs which may be contacted by hydrocarbons at this threshold.</td></tr>
<tr><td>Entrained</td><td colspan="2">100 ppb
This represents potential toxic effects, particularly sublethal effects to highly sensitive species (NOPSEMA Environment bulletin: A652993, April 2019). As entrained hydrocarbons are within the water column and not visible, impacts to socio-cultural receptors are associated with ecological impacts. Therefore, entrained hydrocarbons at this threshold also represent the level at which socio-cultural impacts may occur.</td></tr>
<tr><td>Shoreline</td><td>100 g/m²
This represents the threshold that could impact the survival and reproductive capacity of benthic epifaunal invertebrates living in intertidal habitat.</td><td>10 g/m²
This represents the volume where hydrocarbons may be visible on the shoreline but is below concentrations at which ecological impacts are expected to occur.</td><td>N/A.</td></tr>
</table>

[1] *Further detail, including the source of the thresholds used to define the EMBA in this table, are provided in Section 6.8.2.2*

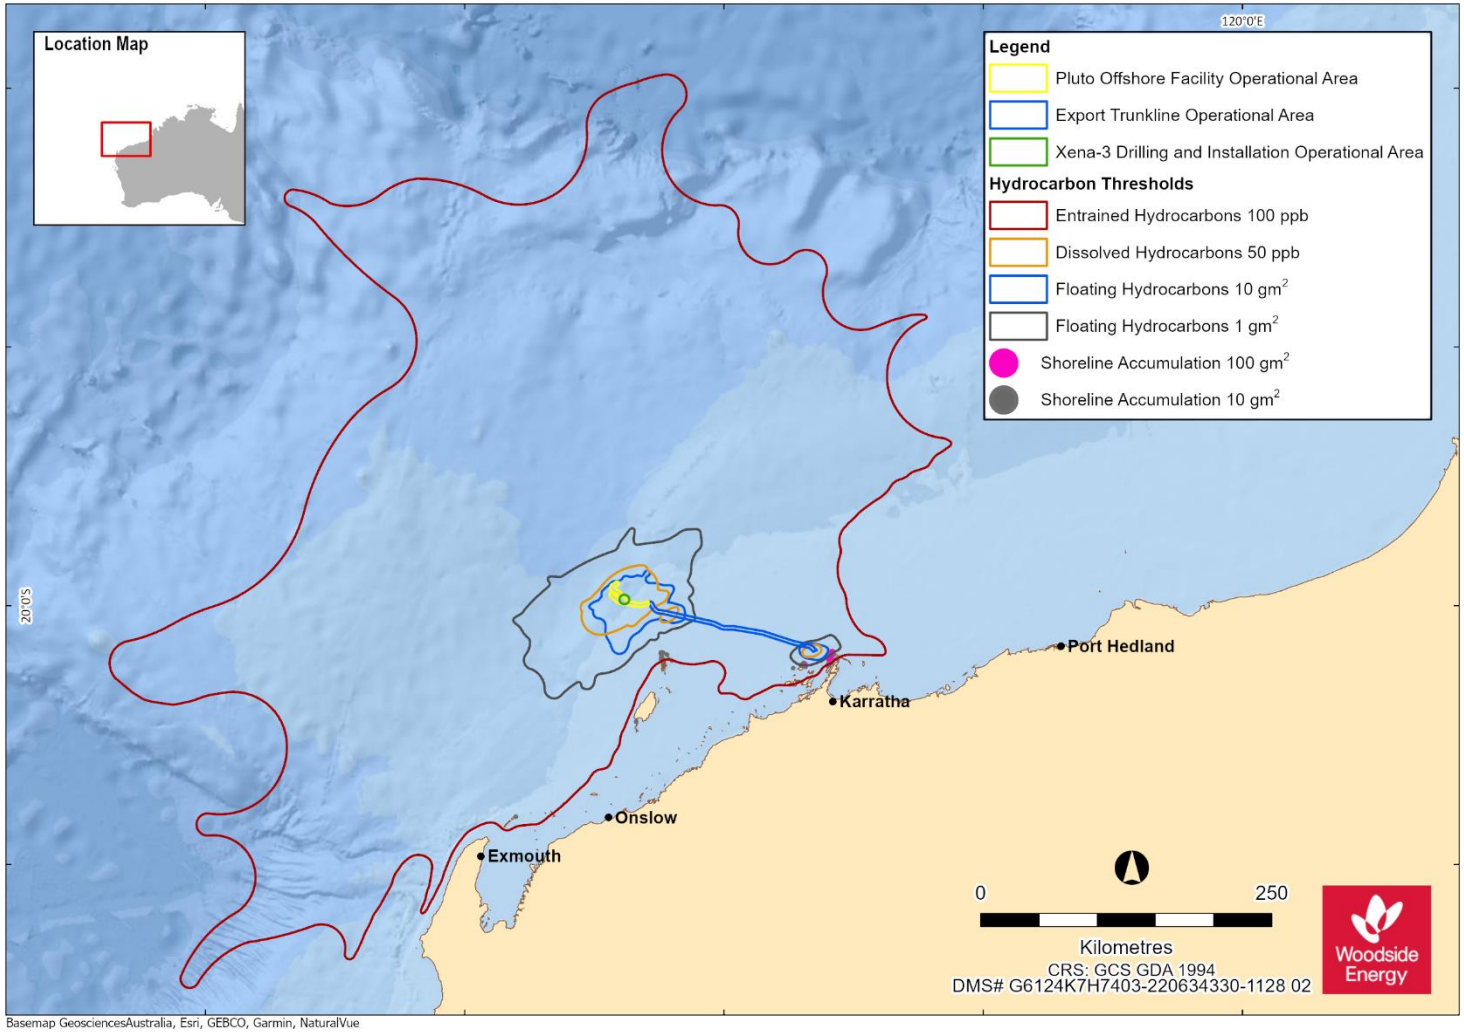

Figure 4-1: EMBA by the Petroleum Activities Program

4.2 Regional Context

The PAA is located in Commonwealth waters within the North-west Marine Region (NWMR), as defined under the Integrated Marine and Coastal Regionalisation of Australia (IMCRA v4.0) (Commonwealth of Australia, 2006). Within the NWMR, the Export Trunkline Operational Area lies within the North West Shelf Province, while the Pluto Facility and Xena-03 drilling and installation Operational Areas lie across the boundary of the North West Shelf Province and the Northwest Province. Woodside's Master EE (Appendix K) summarises the characteristics for the relevant marine bioregions.

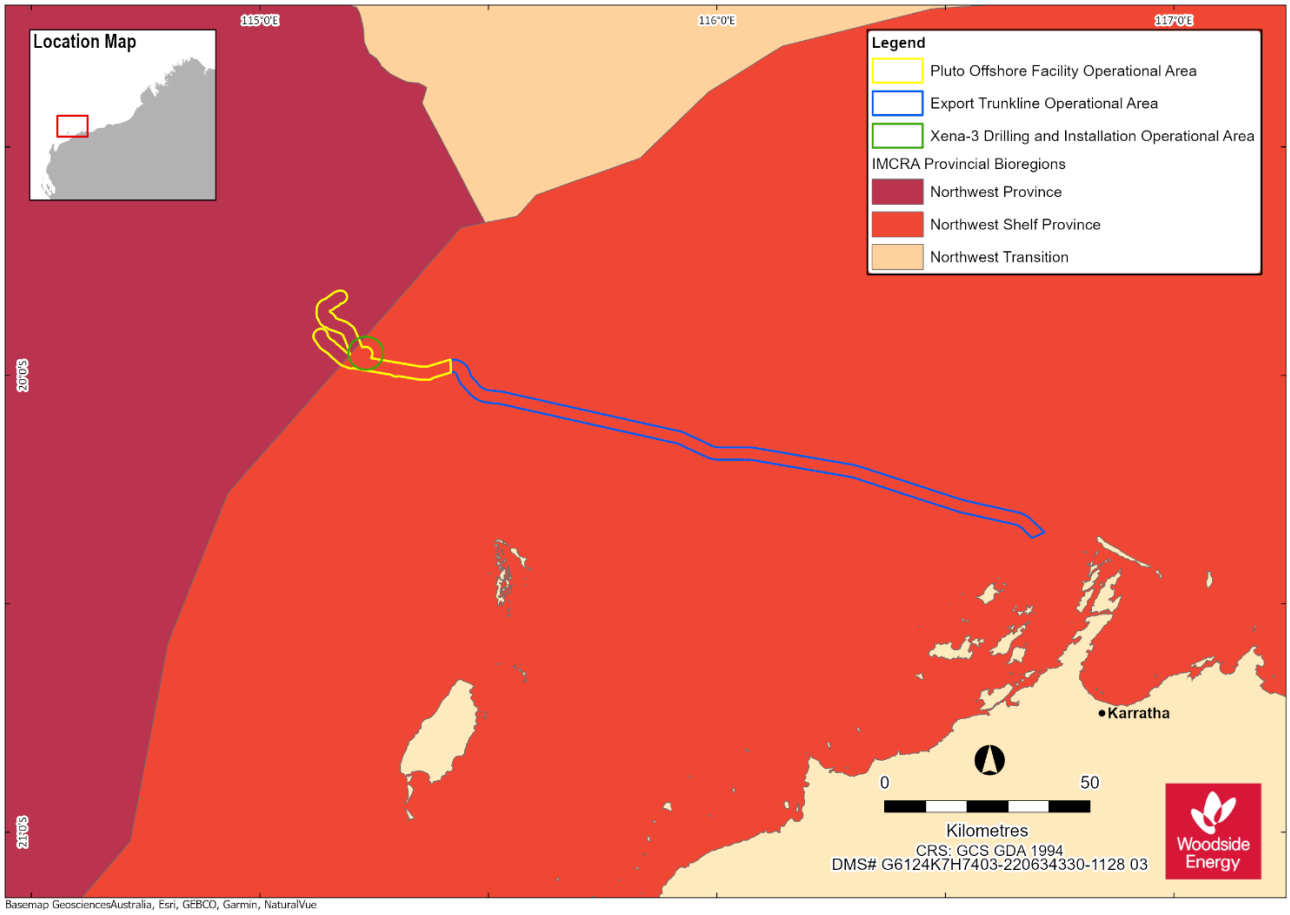

Figure 4-2: Location of the Petroleum Activities Area and relevant marine bioregions

4.3 Matters of National Environmental Significance (EPBC Act)

Table 4-2 and Table 4-3 summarise the MNES overlapping the PAA and EMBA, respectively, according to Protected Matters Search Tool (PMST). It should be noted that the EPBC Act PMST is a general database that conservatively identifies areas in which protected species have the potential to occur. The PMST conducts searches to determine the presence/absence of MNES based on a conservative grid-based search function. Marine areas >30 km from the coast are subject to 32 km × 32 km grid cells to determine the spatial overlap with listed MNES. It is therefore possible that the PMST report (Appendix D) overestimates the presence of MNES within the Operational Area or EMBA. So that any impacts from the Petroleum Activity on MNES are accurately considered, shapefiles (provided by DCCEEW) are also assessed using Geographic Information System software to determine the actual presence and distance to MNES.

Additional information on these MNES is provided in subsequent sections of this chapter and described in detail in Appendix K.

Table 4-2: Summary of MNES identified by the EPBC Act Protected Matters Search Tool as potentially occurring within the PAA

4.4 Physical Environment

The PAA is characterised by both the continental shelf and the continental slope of the NWMR. The export pipeline lies entirely in continental shelf waters from the State waters boundary to the facility. Water depth along the export pipeline is between 40 and 85 m. Water depth at the Pluto offshore facility (at the riser platform) is 85 m and the subsea gathering system extends downslope to depths of ~960 m.

The bathymetry within the continental shelf section of the PAA is generally flat, which is consistent with the broader NWS Province (Baker et al., 2008). Bathymetry around the riser platform is relatively flat and featureless (Woodside, 2006). Across the shelf, the seabed has a gentle (approximately 0.05°) seaward gradient to where it transitions to a steep distal slope approximately 200 to 300 km offshore, in water depths of around 200 m (Dix et al., 2005). The continental slope descends relatively rapidly from the shelf edge to depths greater up to 5,000 m within the Northwest Province (James et al., 2004; Woodside, 2006).

Within the broader Northwest Province, the continental slope comprises seven major geomorphic features, including plateaus, deeps/holes/valleys, terraces, trenches/troughs and canyons (Baker et al., 2008). Key features overlapping the subsea hydrocarbon gathering system section of the facility include:

- a number of canyon systems which trend east-west across the continental slope and have an increased seafloor gradient of up to 80°

- approximately 20 m high cliff-like structures at 1000 m depth where the continental slope meets the abyssal plain
- mudstone outcrops at 900 to 1000 m
- a field of rock pinnacles (2 to 3 m tall and 1 m wide and in an area covering approximately 4 × 1 km) of biogenic origin located at a depth of 300 to 500 m on the continental slope within WA-34-L.

Appendix K provides a summary of the physical characteristics of the environment within the EMBA.

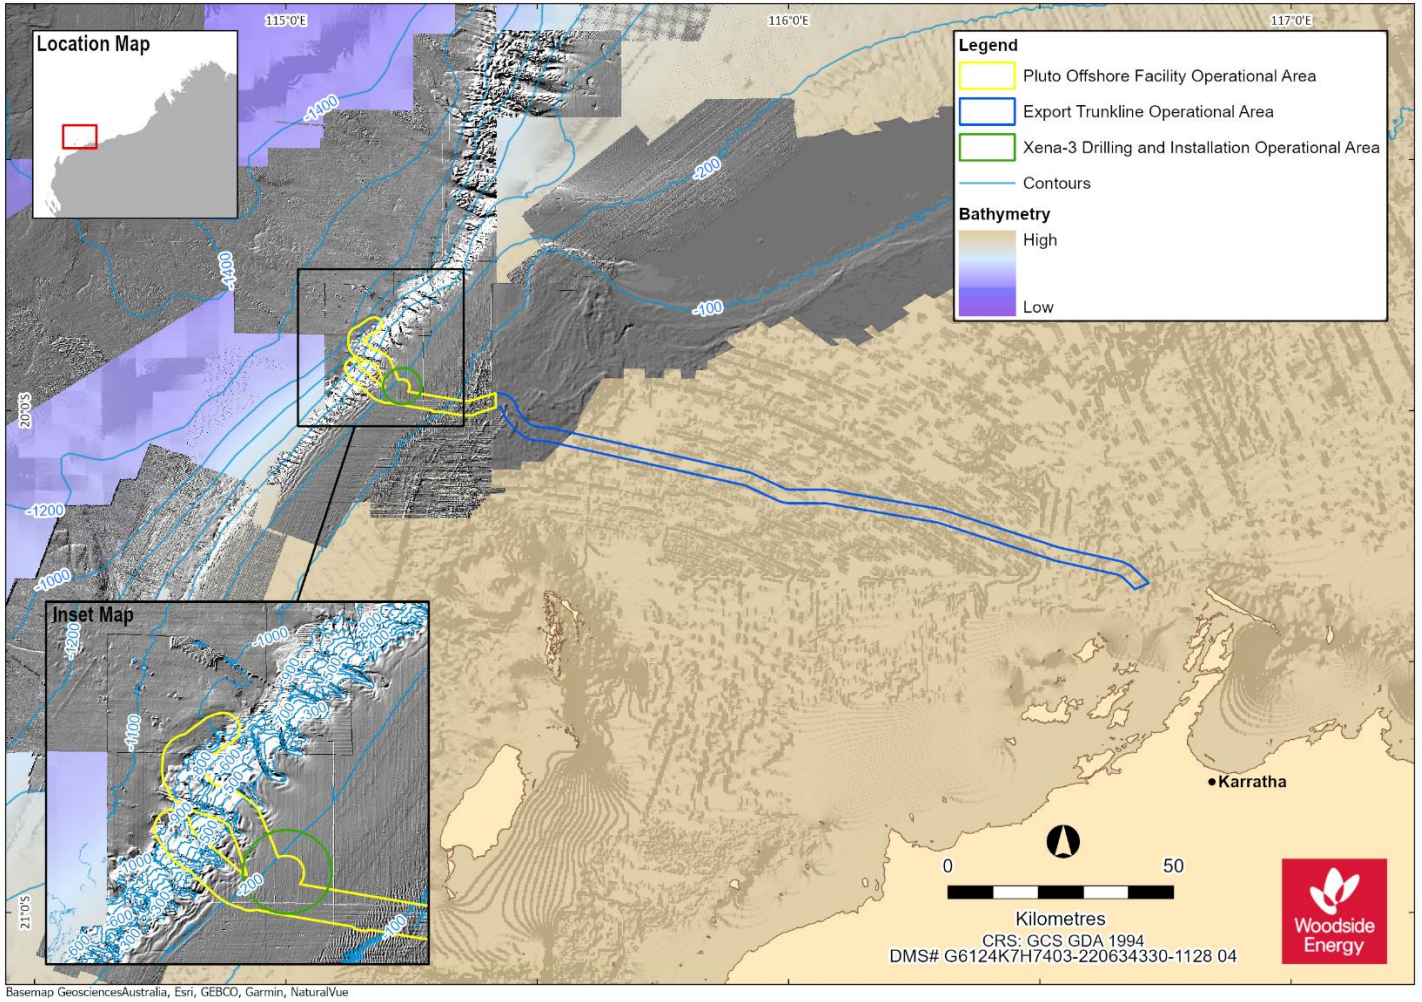

Figure 4-3: Location and bathymetry for the Petroleum Activities Area

4.5 Habitats and Biological Communities

Sediments in the outer NWMR are relatively homogenous and are typically dominated by sands and a small portion of gravel (Baker et al., 2008). Sediments sampled in 2021 around the facility were predominately well sorted, medium to coarse sands with very low TOC content (BMT 2022). Fine sediment size classes (e.g., muds) increase with proximity to the shoreline and the shelf break but are less prominent in the intervening continental shelf (Baker et al., 2008). Carbonate sediments typically account for the bulk of sediment composition, with both biogenic and precipitated sediments present on the outer shelf (Dix et al., 2005). Beyond the shelf break within the NWMR (200 m depth contour), the proportion of fine sediments increases along the continental slope towards the abyssal plain (Baker et al., 2008).

Prior to commissioning of the facility, seabed surveys of the Facility Operational Area were completed. The survey revealed that the seabed around the riser platform comprised soft sediments, with surface layer of sand between 1–4 m thick overlying cemented sands, typical of the region (SKM, 2007; Woodside, 2006). Seabed surveys along the export pipeline route found sediments were predominantly fine sand with variable proportions of coarser sand fractions, silt, shells and shell fragments, coral cemented materials (including calcarenite gravel and cobbles) (SKM, 2006; Woodside, 2006). In 2021, a survey of the benthic habitats around the facility was completed and results showed habitats predominantly comprised of unconsolidated (soft) sand and mud of possible biogenic origins containing shell fragments and a low cover (<20%) of biota that mostly consisted of a mixed community of poriferans (erect, crust, cup-like and massive forms) and cnidarians (sea whips, sea pens, sea fans, soft corals and hydroids) (BMT 2022).

Within WA-34-L on the continental slope, sediments ranged from fine sands to silts, with sediments generally becoming finer with increasing water depth down to 600 m for both slope and canyon transects. Below 600 m, sediment became slightly coarser, but still relatively fine compared to continental shelf sediments (between 150–200 m) (SKM, 2007). This is expected to be characteristic of the sediment across the subsea hydrocarbon gathering system section of the facility.

While the PAA comprises of mainly soft sediments, two Key Ecological Features (KEFs) overlap the Facility Operational Area, including the Ancient Coastline at 125 m Depth Contour KEF and the Continental Slope Demersal Fish Communities KEF (Figure 4-10). The Xena-03 Operational Area also overlaps the Continental Slope Demersal Fish Communities KEF. Areas of hard substrate may be associated with these KEFs, which are considered to support more diverse benthic communities that are characteristic of the wider region. Refer to Section 4.7 and Appendix K for information on the environmental values of KEFs overlapping the PAA and EMBA.

Key habitats and ecological communities within the EMBA are identified in Table 4-4 and described in Appendix K.

Table 4-4: Key sensitive habitats and communities within the EMBA (distance calculated from PAA)

Habitat/Community	Key Locations Within the EMBA
Seabed characteristics	
Ancient Coastline at 125 m depth contour	Several steps and terraces as a result of Holocene Sea level changes occur in the region with the most prominent of these features occurring as an escarpment along the NWMR and Sahul Shelf at a water depth of 125 m, which forms the Ancient Coastline at 125 m depth contour KEF (the Ancient Coastline). The Ancient Coastline KEF overlaps the Facility Operational Area, extending along a line approximated by the 125 m isobath Section 4.7. The Ancient Coastline is not continuous throughout the NWMR and coincides with a well-documented eustatic stillstand at approximately 130 m worldwide (Falkner et al., 2009). Where the Ancient Coastline provides areas of hard substrate, it may contribute to higher diversity and enhanced species richness relative to soft sediment habitat (Falkner et al., 2009). Parts of the Ancient Coastline, represented as rocky escarpment, are considered to provide biologically important habitat in an area predominantly made up of soft sediment. The escarpment type features may also potentially facilitate mixing within the water column due to upwelling, providing a nutrient rich environment. Although the Ancient Coastline adds additional habitat types to a representative system, the habitat types are not unique to the coastline as they are widespread on the upper shelf (Falkner et al., 2009). Detail regarding these features is provided in Section 4.7 and Appendix K.
Continental slope demersal fish communities	The continental slope demersal fish communities in the region have been identified as a KEF of the NWMR (DSEWPaC, 2012) and overlaps the Facility Operational Area and Xena-03 Operational Area. The continental slope between North West Cape and the Montebello Trough has been identified as one of the most diverse slope assemblages in Australian waters, with over 508 fish species and the highest number of endemic species (76) of any Australian slope habitat (DEWHA, 2008). Detail regarding these features is provided in Section 4.7 and Appendix K.
Marine primary producers (distances from the PAA)	
Coral	Rankin Bank (29 km north-east) Montebello Islands State Marine Park (25 km south) Barrow Island State Nature Reserve (43 km south) Dampier Archipelago Island Reserves – Rosemary Island (13 km south) Lowendal Islands (61 km south-west) Muiron Islands (195 km south-west) Ningaloo Coast World Heritage Area (WHA) (incl. Muiron Islands) (195 km south-west)
Seagrass beds and macroalgae	Montebello Islands (25 km south-west) Barrow Island (67 km south-west) Muiron Islands (195 km south-west) Ningaloo Coast (195 km south-west) Exmouth Gulf (225 km south-west)
Mangroves	Montebello Islands (32 km south) Ningaloo Coast (195 km south-west) Exmouth Gulf (225 km south-west)

Habitat/Community	Key Locations Within the EMBA
Other communities and habitats	
Plankton	Plankton within the PAA and EMBA are expected to be representative of the wider NWMR, as detailed in Appendix K Primary productivity of the NWMR appears to be largely driven by offshore influences (as reported by Brewer et al., 2007), with periodic upwelling events and cyclonic influences driving coastal productivity with nutrient recycling and advection. There is a tendency for offshore phytoplankton communities in the NWMR to be characterised by smaller taxa (e.g. bacteria), whereas shelf waters are dominated by larger taxa such as diatoms (Hanson et al., 2007). Within the wider EMBA, peak primary productivity occurs in late summer/early autumn, along the shelf edge of the Ningaloo Reef. It also links to a larger biologically productive period in the area that includes mass coral spawning events, peaks in zooplankton and fish larvae abundance (Department of Conservation and Land Management, 2005) with periodic upwelling throughout the year.
Pelagic and demersal fish populations	Pelagic and demersal fish populations within the PAA and EMBA are expected to be representative of the NWMR (described in Appendix K). The presence of subsea infrastructure with the facility and export pipeline has likely resulted in the development of demersal fish communities that would otherwise not occur within the PAA (McLean et al., 2017). Given continental shelf waters overlap the majority of the Operational Area, pelagic species will also be present. The Continental Slope Demersal Fish Communities KEF and Ancient Coastline at 125 m Depth Contour KEF overlap the Facility Operational Area. These KEFs include areas of hard substrate that are known or likely to support a higher diversity of demersal fish assemblages. Rankin Bank (29 km north-east of the PAA) has also been identified as supporting high demersal fish richness and abundance (Australian Institute of Marine Science, 2014). Further information KEFs is provided in Section 4.7. Fish species in the NWMR (including the PAA and the EMBA) comprise small and large pelagic and demersal species. Small pelagic fish inhabit a range of marine habitats, including inshore and continental shelf waters. They feed on pelagic phytoplankton and zooplankton and represent a food source for a wide variety of predators including large pelagic fish, sharks, seabirds and marine mammals (Mackie et al., 2007). Large pelagic fish in the NWMR include commercially targeted species such as mackerel, wahoo, tuna, swordfish and marlin. Large pelagic fish are typically widespread, found mainly in offshore waters (occasionally on the shelf) and often travel extensively. Detail regarding these features is provided in Appendix K.
Epifauna and infauna	Filter feeders such as sponges, ascidians, soft corals and gorgonians are animals that feed by actively filtering suspended matter and food particles from water by passing the water over specialised filtration structures (DEWHA, 2008). Filter feeders within the EMBA are expected to be representative of the NWMR, with notable areas of high sponge diversity occurring in the Commonwealth Waters of Ningaloo Marine Park and at shoals within the EMBA. Filter feeders generally live in areas that have strong currents and hard substratum and are closely associated with substrate type, with areas of hard substrate typically supporting more diverse epibenthic communities (Heyward et al., 2001a). Conversely, higher diversity infauna is mainly associated with soft unconsolidated sediment and infauna communities are considered widespread and well represented along the continental shelf and upper slopes of the NWMR (Brewer et al., 2007a; Rainer, 1991; SKM, 2007b; Woodside Energy Limited, 2004). A number of targeted surveys investigating epibenthos and infauna within offshore NWSP shelf and slope environments have been carried out by Woodside. Woodside has collected survey data from numerous sampling locations within and surrounding the Operational Area using ROV/video investigations of benthic habitats and infauna and epifauna sampling using sediment grabs and epibenthic sled (SKM, 2007). Elsewhere on the NWSP, surveys have included grab samples of seabed sediments from around North Rankin Complex, Goodwyn A, Angel facilities and their export pipeline routes (SKM, 2007), as well as additional sampling throughout the broader region (SKM, 2007b). In 2021, a survey of the benthic habitats around the Pluto A offshore facility was completed

Habitat/Community	Key Locations Within the EMBA
	and results showed habitats predominantly comprised of unconsolidated (soft) sand and mud of possible biogenic origins containing shell fragments and a low cover (<20%) of biota that mostly consisted of a mixed community of poriferans (erect, crust, cup-like and massive forms) and cnidarians (sea whips, sea pens, sea fans, soft corals and hydroids) (BMT 2022). Benthic grab sampling in the vicinity of the continental slope region of the Operational Area revealed a sparse abundance, high variability and high diversity of infauna dominated by polychaetes with other fauna including nemerteans and sipunculids and crustaceans (mainly amphipods) (SKM, 2007). Higher, albeit low, infauna density was reported at the shelf break (200 m) compared to deeper areas on the continental slope. Epifaunal sled samples to 800 m depth including from inside and outside the canyon systems on the continental slope found deepwater solitary cnidarians were the most common fauna in samples, followed by crustaceans (mostly decapods), bony fish and sponges, with urchins, sea stars and brittle stars also recorded (SKM, 2007). Epifauna, cnidarians and demersal fish were also more common in samples taken at 200 m compared to deeper depths and it was noted other epifauna groups showed some variation in abundance with depth (SKM, 2007). These survey findings at the facility were typical of other surveys in the region which revealed deep water habitats consist primarily of bare unconsolidated carbonate sediments supporting a sparse assemblage of deposit and filter feeding organisms, including glass sponges, urchins, sea cucumbers, sea stars and crustaceans (Mobil, 2011; Heyward et al., 2001; URS, 2010). Only limited areas of deepwater hard substrate have been observed over the continental slope, namely rock pinnacles on the upper continental slope and exposed cliff-like features and relatively soft expanses of mudstone outcrops on the mid continental slope. Benthic fauna is closely associated with substrate type, with areas of hard substrate typically supporting more diverse epibenthic communities (Heyward et al., 2001a). Rock pinnacles possibly formed by the deep-water coral Lophelia spp. (few live specimens were observed with low cover) were found in a small portion of the Pluto reservoir (4 × 1 km area) at a depth of 300–500 m and observed to provide habitat for fish, shrimp, hydroids and anemones (SKM, 2007). Exposed cliff-like features of banded sedimentary rock (approximately 20 m in height) were observed at around 1000 m deep. ROV survey findings showed no epifauna on exposed rock, possibly due to their vertical orientation and water flow which may impede settlement (SKM, 2007). However, anemones and fish were observed in areas on more sloping areas among the cliff-like features where sediment had accumulated. At approximately 900–1000 m, mudstone outcrops were also observed dominated by glass sponges. Discrete areas of hard substrate hosting sessile filter feeding communities may also be associated within the Ancient Coastline at the 125 m Depth Contour KEF, which overlaps the PAA. However, Falkner et al. (2009) concluded the Ancient Coastline may not represent different habitat type compared to the surrounding areas and suggested that associated faunal communities may be similar. Refer to Section 4.7 for additional information on KEFs overlapping the Operational Area and wider EMBA. Filter feeder communities within the PAA are present on the subsea infrastructure and Pluto platform, which provides hard substrate for attachment (Jacobs, 2014). Within the wider EMBA, the NWMR has been identified as a sponge diversity hotspot with a variety of areas of potentially high and unique sponge biodiversity, particularly in the Commonwealth waters of Ningaloo Marine Park (CALM, 2005b; Rees et al., 2004). Detail regarding these features is provided in Appendix K.

4.6 Protected Species

A total of 100 EPBC Act listed species considered to be MNES were identified as potentially occurring within the EMBA, of which a subset of 47 species were identified as potentially occurring within the PAA. The full list of marine species identified from the PMST reports is provided in Appendix C,. The PMST report is produced from a grid-based search, which can cause species outside of the search area to be detected, such as terrestrial species. Species identified in the PMST that are not known to inhabit shorelines, nor rely on the marine environment for their diet, are not included assessed.

Species identified as potentially occurring within the PAA and EMBA, and relevant Biologically Important Areas (BIAs) and Habitat Critical to their Survival (Habitat Critical) are listed in Table 4-4 to Table 4-13. A description of these species is included in Appendix K, which also shows the spatial overlap with relevant BIAs and Habitat Critical areas and the PAA and EMBA.

4.6.1 Fish, Sharks and Rays

A total of eight EPBC-listed Threatened and an additional seven Migratory fish species have been identified to potentially occur within the EMBA, of which 14 occur in the PAA (Table 4-5). For additional detail, the PAA is presented here in two parts: the Export Pipeline Operational Area, and the combined Facility and Xena-03 Drilling Operational Areas. Two threatened species, identified in the PMST were identified to occur within the EMBA, however, are not considered to inhabit shorelines, or rely on the marine environment for their diet, and therefore are not included. There are also 35 EPBC-listed Marine species in the EMBA, which do not have a Threatened or Migratory status and include a variety of pipefish and sea dragons. These species are described in Appendix K.

The PAA overlaps the foraging BIA for the whale shark as outlined in Figure 4-4. The BIAs are detailed further in Appendix K.

Table 4-5: Threatened and Migratory fish, shark and ray species predicted to occur within the PAA and the EMBA

Species Name	Common Name	Threatened Status	Migratory Status	Potential for Interaction		
				Export Pipeline Operational Area	***Facility and Xena-03 Operational Areas***	***EMBA***
Carcharadon carcharias	White shark	Vulnerable	Migratory	Species or species habitat may occur within area	Species or species habitat may occur within area	Species or species habitat known to occur within area
Pristis clavata	Dwarf sawfish	Vulnerable	Migratory	Species or species habitat known to occur within area	Species or species habitat known to occur within area	Species or species habitat known to occur within area
Pristis zijsron	Green sawfish	Vulnerable	Migratory	Species or species habitat known to occur within area	Species or species habitat known to occur within area	Species or species habitat known to occur within area
Pristis pristis	Freshwater sawfish	Vulnerable	Migratory	Species or species habitat may occur within area	Species or species habitat may occur within area	Species or species habitat likely to occur within area
Rhincodon typus	Whale shark	Vulnerable	Migratory	Foraging, feeding or related behaviour known to occur within area	Foraging, feeding or related behaviour known to occur within area	Foraging, feeding or related behaviour known to occur within area
Carcharias taurus	Grey nurse shark	Vulnerable	N/A	Species or species habitat likely to occur within area	Species or species habitat likely to occur within area	Species or species habitat likely to occur within area
Sphyrna lewini	Scalloped hammerhead	Conservation Dependant	N/A	Species or species habitat known to occur within area	Species or species habitat known to occur within area	Species or species habitat known to occur within area
Thunnus maccoyii	Southern bluefin tuna	Conservation Dependent	N/A	Breeding known to occur within area	Breeding known to occur within area	Breeding known to occur within area
Anoxypristis cuspidata	Narrow sawfish	N/A	Migratory	Species or species habitat likely to occur within area	Species or species habitat may occur within area	Species or species habitat known to occur within area

Species Name	Common Name	Threatened Status	Migratory Status	Potential for Interaction		
				Export Pipeline Operational Area	***Facility and Xena-03 Operational Areas***	***EMBA***
Carcharhinus longimanus	Oceanic whitetip shark	N/A	Migratory	Species or species habitat likely to occur within area	Species or species habitat likely to occur within area	Species or species habitat likely to occur within area
Isurus oxyrinchus	Shortfin mako	N/A	Migratory	Species or species habitat likely to occur within area	Species or species habitat likely to occur within area	Species or species habitat likely to occur within area
Isurus paucus	Longfin mako	N/A	Migratory	Species or species habitat likely to occur within area	Species or species habitat likely to occur within area	Species or species habitat likely to occur within area
Manta alfredi	Reef manta ray	N/A	Migratory	Species or species habitat known to occur within area	Species or species habitat likely to occur within area	Species or species habitat known to occur within area
Manta birostris	Giant manta ray	N/A	Migratory	Species or species habitat likely to occur within area	Species or species habitat likely to occur within area	Species or species habitat known to occur within area
Lamna nasus	Porbeagle shark	N/A	Migratory	N/A	N/A	Species or species habitat may occur within area

Table 4-6: Fish, shark and ray BIAs within the PAA and EMBA

Species	BIA Type	Approximate Distance (Closest) and Direction of BIA from PAA (km)
Whale shark	Foraging (northward from Ningaloo along 200 m isobath)	Overlaps the Facility and Xena-03 Operational Areas and Export Pipeline Operational Area
	Foraging (high density prey) (Ningaloo Marine Park and adjacent Commonwealth waters)	228 km south-west (Facility and Xena-03 Operational Areas)

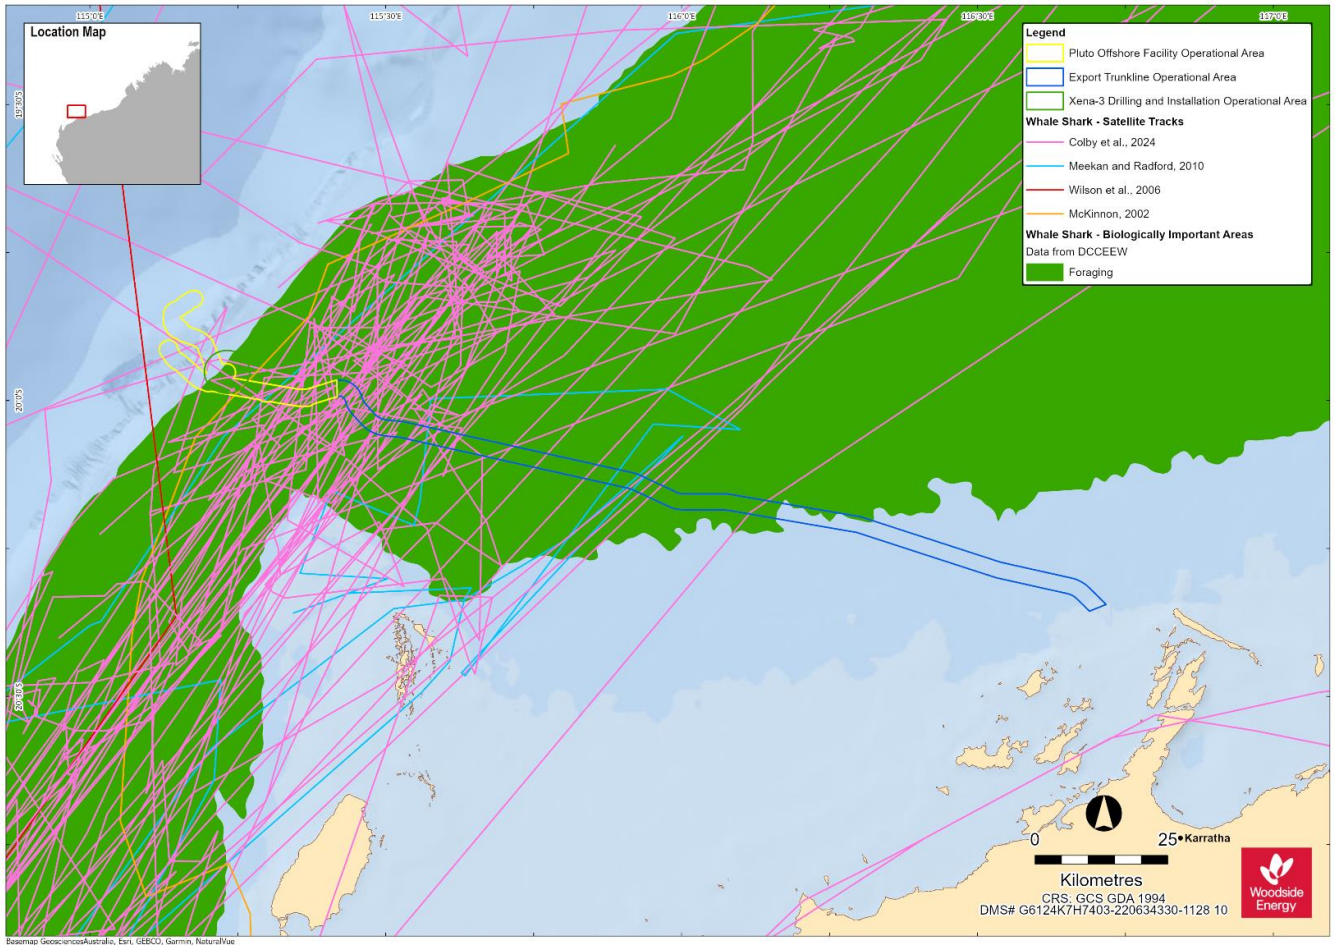

Figure 4-4: Whale shark BIAs overlapping the PAA and satellite tracks of whale sharks tagged between 2002 and 2024 (McKinnon, 2002, Wilson *et al* 2006, Meekan and Radford 2010, Colby *et al* 2024)

4.6.2 Marine Reptiles

All seven EPBC listed marine reptiles are and five of these are also listed Migratory species (Table 4-7). For additional detail, the PAA is presented here in two parts: the Export Pipeline Operational Area, and the combined Facility and Xena-03 Drilling Operational Areas. Two threatened species identified in the PMST were identified to occur within the EMBA, however, are not considered to inhabit shorelines, or rely on the marine environment for their diet, and therefore are not included in Table 4-7.

BIAs for the green turtle, hawksbill turtle and flatback turtle overlap the PAA; the loggerhead turtle only overlaps the Export Pipeline Operational Area as described in Table 4-7 and shown in Figure 4-5.

Habitat critical to the survival of the green turtle, hawksbill turtle, and loggerhead turtle is overlapped by, or adjacent to the PAA as shown in Figure 4-5. An additional 16 EPBC-listed Marine reptiles species occur in the EMBA, which do not have Threatened or Migratory status. The majority of these are sea snake species. These listed Marine species are described in the Appendix K.

Table 4-7: Threatened and Migratory marine reptile species predicted to occur within the PAA and the EMBA

Species Name	Common Name	Threatened Status	Migratory Status	Potential for Interaction		
				Export Pipeline Operational Area	Facility and Xena-03 Operational Areas	EMBA
Caretta caretta	Loggerhead turtle	Endangered	Migratory	Congregation or aggregation known to occur within the area	Species or species habitat known to occur within the area	Breeding known to occur within area
Dermochelys coriacea	Leatherback turtle	Endangered	Migratory	Species or species habitat likely to occur within the area	Species or species habitat likely to occur within the area	Species or species habitat known to occur within area
Chelonia mydas	Green turtle	Vulnerable	Migratory	Congregation or aggregation known to occur with the area	Species or species habitat known to occur within the area	Breeding known to occur within area
Eretmochelys imbricata	Hawksbill turtle	Vulnerable	Migratory	Congregation or aggregation known to occur with the area	Species or species habitat known to occur within the area	Breeding known to occur within area
Natator depressus	Flatback turtle	Vulnerable	Migratory	Congregation or aggregation known to occur with the area	Congregation or aggregation known to occur with the area	Breeding known to occur within area
Aipysurus apraefrontalis	Short-nosed seasnake	Critically Endangered	N/A	Species or species habitat likely to occur within the area	Species or species habitat may occur within the area	Species or species habitat known to occur within area
Aipysurus foliosquama	Leaf-scaled seasnake	Critically Endangered	N/A	Species or species habitat known to occur within the area	N/A	Species or species habitat known to occur within area

Table 4-8: Marine turtle BIAs within the EMBA

Species	BIA Type (Closest Location)	Approximate Distance and Direction of BIA from PAA (km)
Flatback turtle	Internesting Buffer (Montebello Island, Hermite Island, NW Island, Trimouille Island; Dampier Archipelago (islands to the west of the Burrup Peninsula); Intercourse Island; Legendre Island, Huay Island; Delambre Island; Dixon Island; West of Cape Lambert; Thevenard Island – South coast)	Overlaps the Facility Operational Area Overlaps the Xena-03 Operational Area Overlaps the Export Pipeline Operational Area
	Mating (Dampier Archipelago (islands to the west of the Burrup Peninsula); Montebello Island, Hermite Island, NW Island, Trimouille Island; coral reef habitat west of the Montebello group (extends the entire length of Montebello Islands); Barrow Island; Coral reef habitat west of the Montebello group (extends the entire length of the Montebello's)	39 km south-east of the Facility Operational Area 48 km south-east of the Xena-03 Operational Area 10 km south-of the Export Pipeline Operational Area

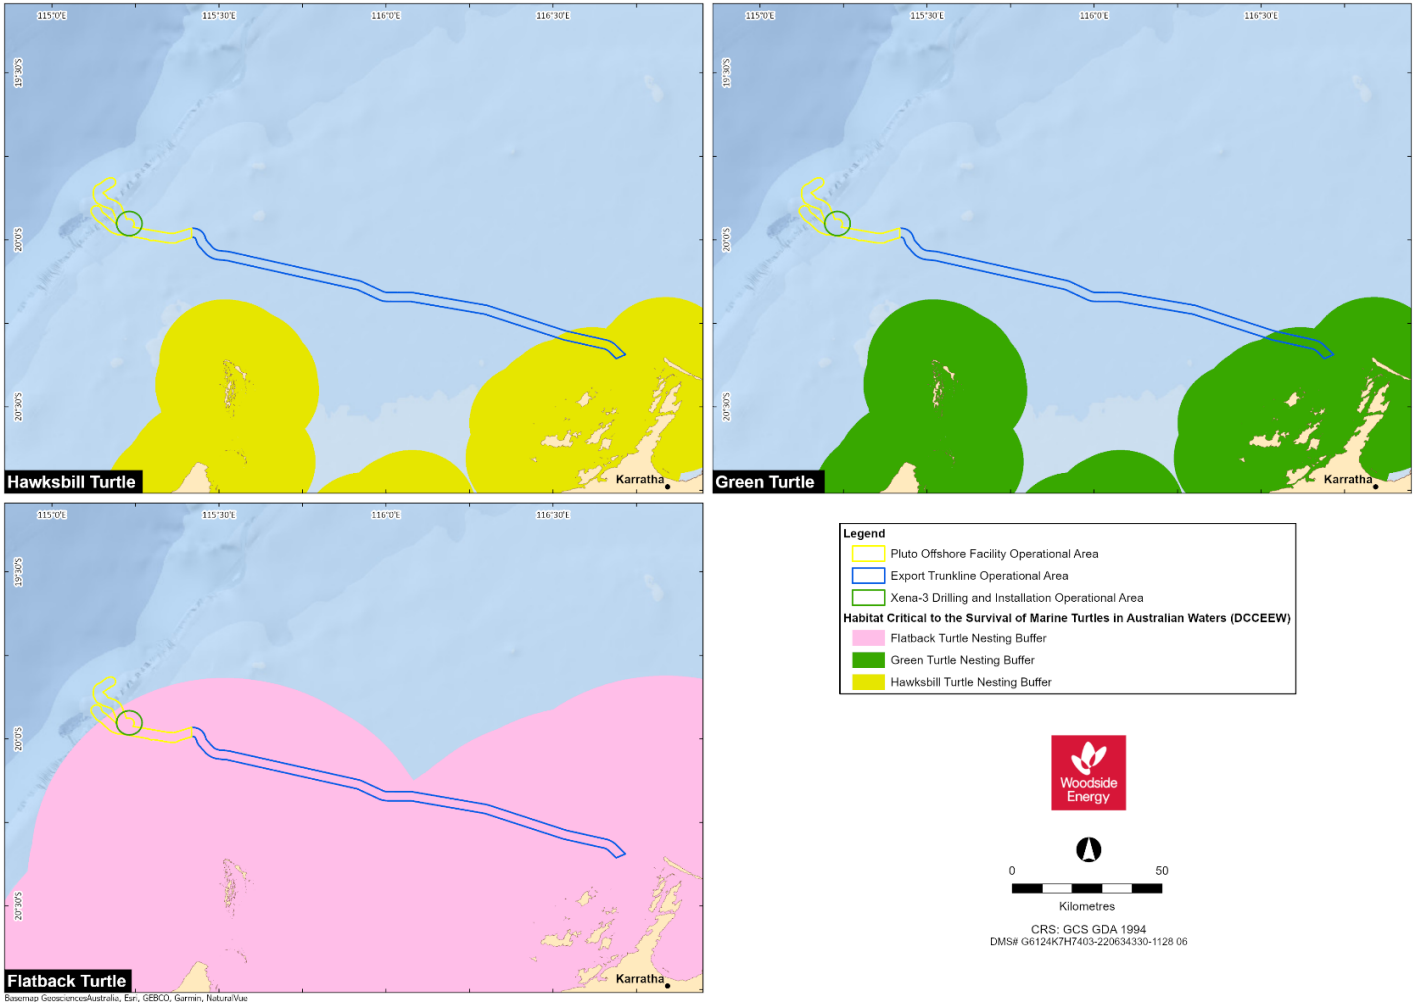

Figure 4-6: Habitat critical to the survival of marine turtles overlapping the PAA

4.6.3 Marine Mammals

A total of four EPBC Listed Threatened and an additional nine Migratory marine mammal species have been identified to potentially occur within the EMBA, of which 11 occur in the PAA (**Error! Reference source not found.**). For additional detail, the PAA is presented here in two parts: the Export Pipeline Operational Area, and the combined Facility and Xena-03 Drilling Operational Areas. Nine threatened species, identified in the PMST were identified to occur within the EMBA, however, are not considered to inhabit shorelines, or rely on the marine environment for their diet, and therefore are not included.

The PAA overlaps with the distribution and migration BIAs for the pygmy blue whale and migration (north and south) BIA for the humpback whale. Two other species of marine mammal species have BIAs within the EMBA and are described in **Error! Reference source not found.**.

Table 4-10: Threatened and Migratory marine mammal species predicted to occur within the PAA and the EMBA

Species Name	Common Name	Threatened Status	Migratory Status	Potential for Interaction		
				Export Pipeline Operational Area	***Facility and Xena-03 Operational Areas***	***EMBA***
Balaenoptera musculus	Blue whale	Endangered	Migratory	Migration route known to occur within the area	Migration route known to occur within the area	Migration route known to occur within area
Balaenoptera physalus	Fin whale	Vulnerable	Migratory	Species or species habitat likely to occur within the area	Species or species habitat likely to occur within the area	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera borealis	Sei whale	Vulnerable	Migratory	Species or species habitat likely to occur within the area	Species or species habitat likely to occur within the area	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera edeni	Bryde's whale	N/A	Migratory	Species or species habitat likely to occur within the area	Species or species habitat likely to occur within the area	Species or species habitat likely to occur within area
Dugong dugon	Dugong	N/A	Migratory	Species or species habitat known to occur within the area	N/A	Breeding known to occur within area
Megaptera novaeangliae	Humpback whale	N/A	Migratory	Breeding known to occur with in the area	Breeding known to occur with in the area	Breeding known to occur within area
Orcaella heinsohni	Australian snubfin dolphin	N/A	Migratory	Species or species habitat may occur within the area	Species or species habitat may occur within the area	Species or species habitat known to occur within area
Orcinus orca	Killer whale	N/A	Migratory	Species or species habitat may occur within the area	Species or species habitat may occur within the area	Species or species habitat may occur within area
Physeter macrocephalus	Sperm whale	N/A	Migratory	Species or species habitat may occur within the area	Species or species habitat may occur within the area	Species or species habitat may occur within area

Species Name	Common Name	Threatened Status	Migratory Status	Potential for Interaction		
				Export Pipeline Operational Area	***Facility and Xena-03 Operational Areas***	***EMBA***
Sousa chinensis	Australian humpback dolphin	N/A	Migratory	Species or species habitat may occur within the area	Species or species habitat may occur within the area	Species or species habitat known to occur within area
Tursiops aduncus (Arafura/Timor Sea populations)	Spotted bottlenose dolphin	N/A	Migratory	Species or species habitat likely to occur within the area	Species or species habitat likely to occur within the area	Species or species habitat known to occur within area
Eubalaena australis	Southern right whale	Endangered	Migratory	N/A	N/A	Species or species habitat likely to occur within area
Balaenoptera bonaerensis	Antarctic minke whale	N/A	Migratory	N/A	N/A	Species or species habitat likely to occur within area

Table 4-11: Marine mammal BIAs within the EMBA

Species	BIA Type	Approximate Distance and Direction from PAA (km)
Dugong	Calving (Exmouth Gulf)	207 km south-west (Facility and Xena-03 Operational Areas)
	Nursing (Exmouth Gulf)	207 km south-west (Facility and Drilling Operational Area)
	Breeding (Exmouth Gulf)	207 km south-west (Facility and Xena-03 Operational Areas)
	Foraging (high density seagrass beds) (Exmouth Gulf)	207 km south-west (Facility and Xena-03 Operational Areas)
Pygmy blue whale	Migration (Augusta to Derby) (Tend to pass along the shelf edge at depths of 500 m to 1000 m; appear close to coast in the Exmouth-Montebello Islands area on southern migration)	Overlaps the Facility and Xena-03 Operational Areas 20 km north-west of the Export Pipeline Operational Area Approximately 17 km from the Pluto Facility
	Distribution	Overlaps the Facility and Xena-03 Operational Areas and Export Pipeline Operational Area
	Foraging (Ningaloo)	232 km south-west (Facility and Xena-03 Operational Areas)
Humpback whale	Migration (north and south) (The migration corridor extends from the coast to out to approximately 100km offshore in the Kimberley region extending south to North-west Cape; from North-west Cape to south of Shark Bay, the migration corridor is reduced to approximately 50 km)	20 km from the Facility and Xena-03 Operational Area Overlaps the Export Pipeline Operational Area Approximately 24 km from the Pluto Facility
Southern right whale	Reproduction (Exmouth Gulf and Ningaloo)	Abuts the EMBA

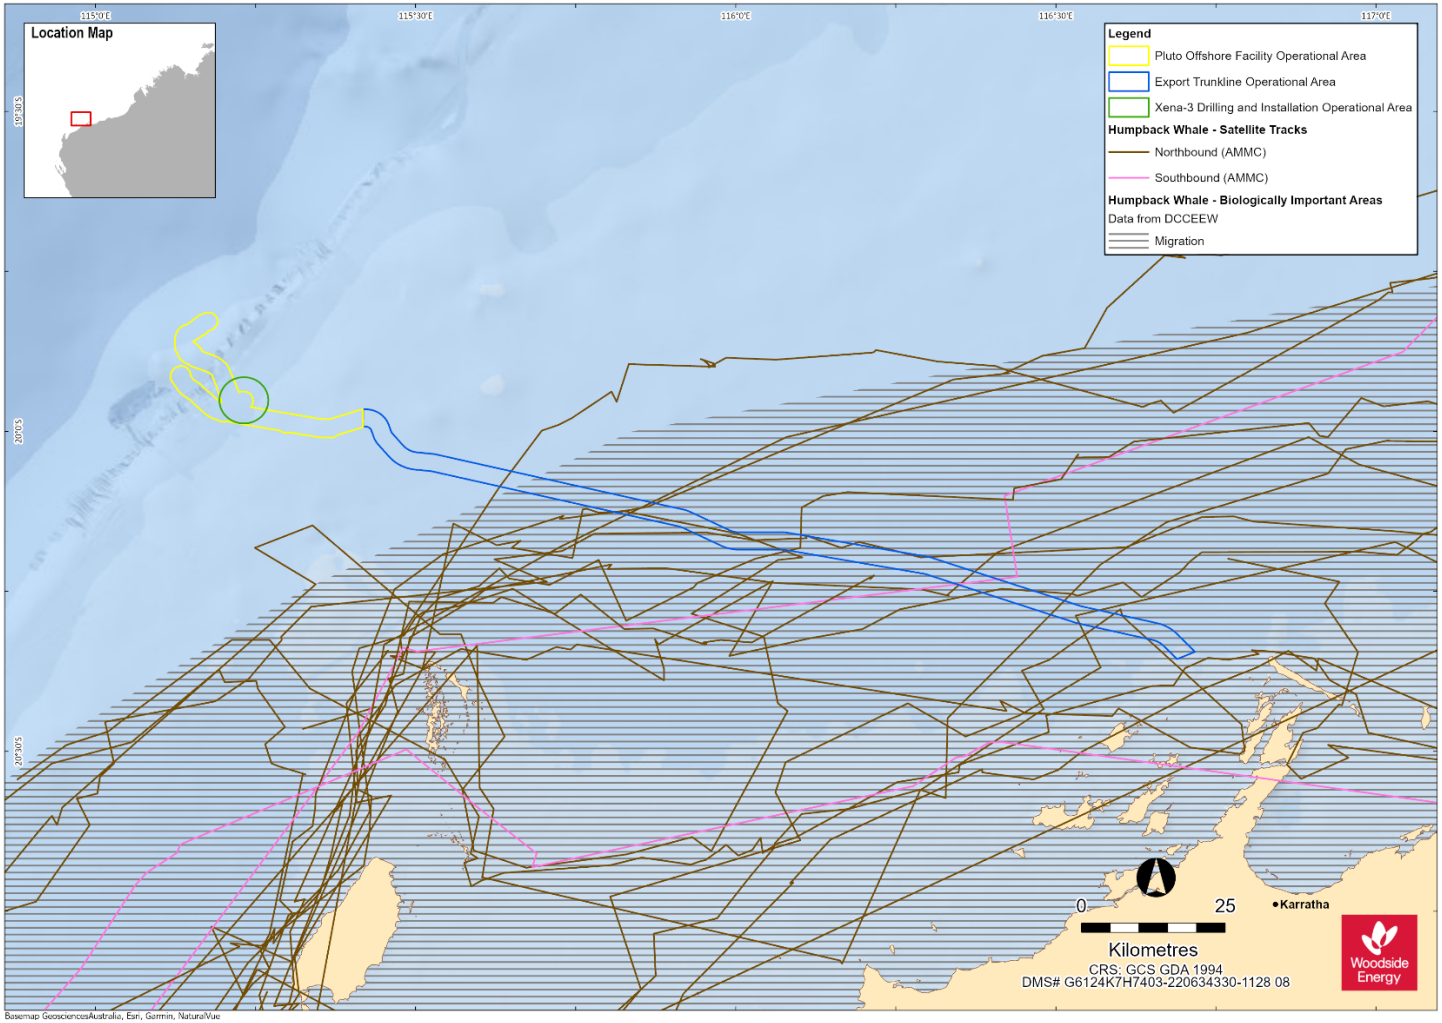

Figure 4-8: Humpback whale BIAs overlapping the PAA and satellite tracks of tagged whales (

4.6.4 Seabirds and Migratory Shorebirds

A total of 17 EPBC-listed Threatened and additional 21 Migratory seabird and shorebird species have been identified to potentially occur within the EMBA, of which 15 occur in the PAA (Table 4-12). For additional detail, the PAA is presented here in two parts: the Export Pipeline Operational Area, and the combined Facility and Xena-03 Drilling Operational Areas. There are 2 migratory bird species (fork-tailed swift and roseate turn) occurring within the Export Pipeline Operational Area that are not present within the Facility and Xena-03 Drilling Operational Areas. An additional 6 EPBC-listed Marine bird species are identified to occur within the EMBA, none of which are listed as Threatened or Migratory.

The PAA overlaps the BIA (Breeding) for the wedge-tailed shearwater. The roseate tern, and fairy tern only overlap the Export Pipeline Operational Area, as shown in Figure 4-9. The lesser crested tern breeding BIA is overlapped by the EMBA. Seabird and Migratory shorebirds which BIAs within the PAA and EMBA are outlined in Table 4-13.

Table 4-12: Threatened and Migratory seabird and Migratory shorebird species predicted to occur within the PAA and the EMBA

Species Name	Common Name	Threatened Status	Migratory Status	Potential for Interaction		
				Export Pipeline Operational Area	***Facility and Xena-03 Operational Areas***	***EMBA***
Calidris ferruginea	Curlew sandpiper	Critically Endangered	Migratory	Species or species habitat may occur within the area	Species or species habitat may occur within the area	Species or species habitat known to occur within area
Numenius madagascariensis	Eastern curlew	Critically Endangered	Migratory	Species or species habitat may occur within the area	Species or species habitat may occur within the area	Species or species habitat known to occur within area
Macronectes giganteus	Southern-giant petrel	Endangered	Migratory	Species or species habitat may occur within the area	Species or species habitat may occur within the area	Species or species habitat may occur within area
Calidris acuminata	Sharp-tailed sandpiper	Vulnerable	Migratory	Species or species habitat may occur within the area	Species or species habitat may occur within the area	Species or species habitat known to occur within area
Calidris canutus	Red knot	Vulnerable	Migratory	Species or species habitat may occur within the area	Species or species habitat may occur within the area	Species or species habitat known to occur within area
Phaethon lepturus fulvus	Christmas Island white-tailed tropicbird	Endangered	N/A	Species or species habitat may occur within the area	Species or species habitat may occur within the area	Species or species habitat may occur within area
Phaethon rubricauda	Red-tailed tropicbird	Endangered	N/A	Species or species habitat likely to occur within area	Species or species habitat likely to occur within area	Species or species habitat known to occur within area
Sternula nereis nereis	Australian fairy tern	Vulnerable	N/A	Breeding known to occur within the area	Foraging, feeding or related behaviour likely to occur within the area	Breeding known to occur within area

Species Name	Common Name	Threatened Status	Migratory Status	Potential for Interaction		
				Export Pipeline Operational Area	***Facility and Xena-03 Operational Areas***	***EMBA***
Actitis hypoleucos	Common sandpiper	N/A	Migratory	Species or species habitat may occur within the area	Species or species habitat may occur within the area	Species or species habitat known to occur within area
Anous stolidus	Common noddy	N/A	Migratory	Species or species habitat may occur within the area	Species or species habitat may occur within the area	Species or species habitat likely to occur within area
Apus pacificus	Fork-tailed swift	N/A	Migratory	Species or species habitat likely to occur within the area	N/A	Species or species habitat likely to occur within area
Ardenna pacifica	Wedge-tailed shearwater[14]	N/A	Migratory	Breeding known to occur within the area	Breeding known to occur within the area	Breeding known to occur within area
Calidris melanotos	Pectoral sandpiper	N/A	Migratory	Species or species habitat may occur within the area	Species or species habitat may occur within the area	Species or species habitat may occur within area
Calonectris leucomelas	Streaked shearwater	N/A	Migratory	Species or species habitat likely to occur within the area	Species or species habitat likely to occur within the area	Species or species habitat likely to occur within area
Fregata ariel	Lesser frigatebird	N/A	Migratory	Species or species habitat likely to occur within the area	Species or species habitat likely to occur within the area	Species or species habitat known to occur within area
Fregata minor	Great frigatebird	N/A	Migratory	Species or species habitat may occur within the area	Species or species habitat may occur within the area	Species or species habitat may occur within area

[14] The wedge-tailed shearwater was not captured in the PMST but will interact with the PAA.

Species Name	Common Name	Threatened Status	Migratory Status	Potential for Interaction

4.7 Key Ecological Features

Two KEFs overlap the PAA (Figure 4-10). KEFs within the PAA and EMBA are identified in Table 4-15 and described in Appendix K. Figure 4-10 shows the spatial overlap with KEFs and the PAA and EMBA.

Table 4-15: KEFs within the PAA and EMBA

Key Ecological Feature	Distance (Closest) and Direction from PAA to KEF (km)
Ancient Coastline at the 125 m Depth Contour	Overlaps (Facility Operational Area)
Continental Slope Demersal Fish Communities	Overlaps (Facility and Xena-03 Operational Areas)
Glomar Shoal KEF	56 km north-east (Export Pipeline Operational Area)
Exmouth Plateau	74 km west (Facility and Xena-03 Operational Areas)
Canyons Linking the Cuvier Abyssal Plain and the Cape Range Peninsula	164 km south-west (Facility and Xena-03 Operational Areas)
Commonwealth Waters Adjacent to Ningaloo Reef	207 km south-west (Facility and Xena-03 Operational Areas)

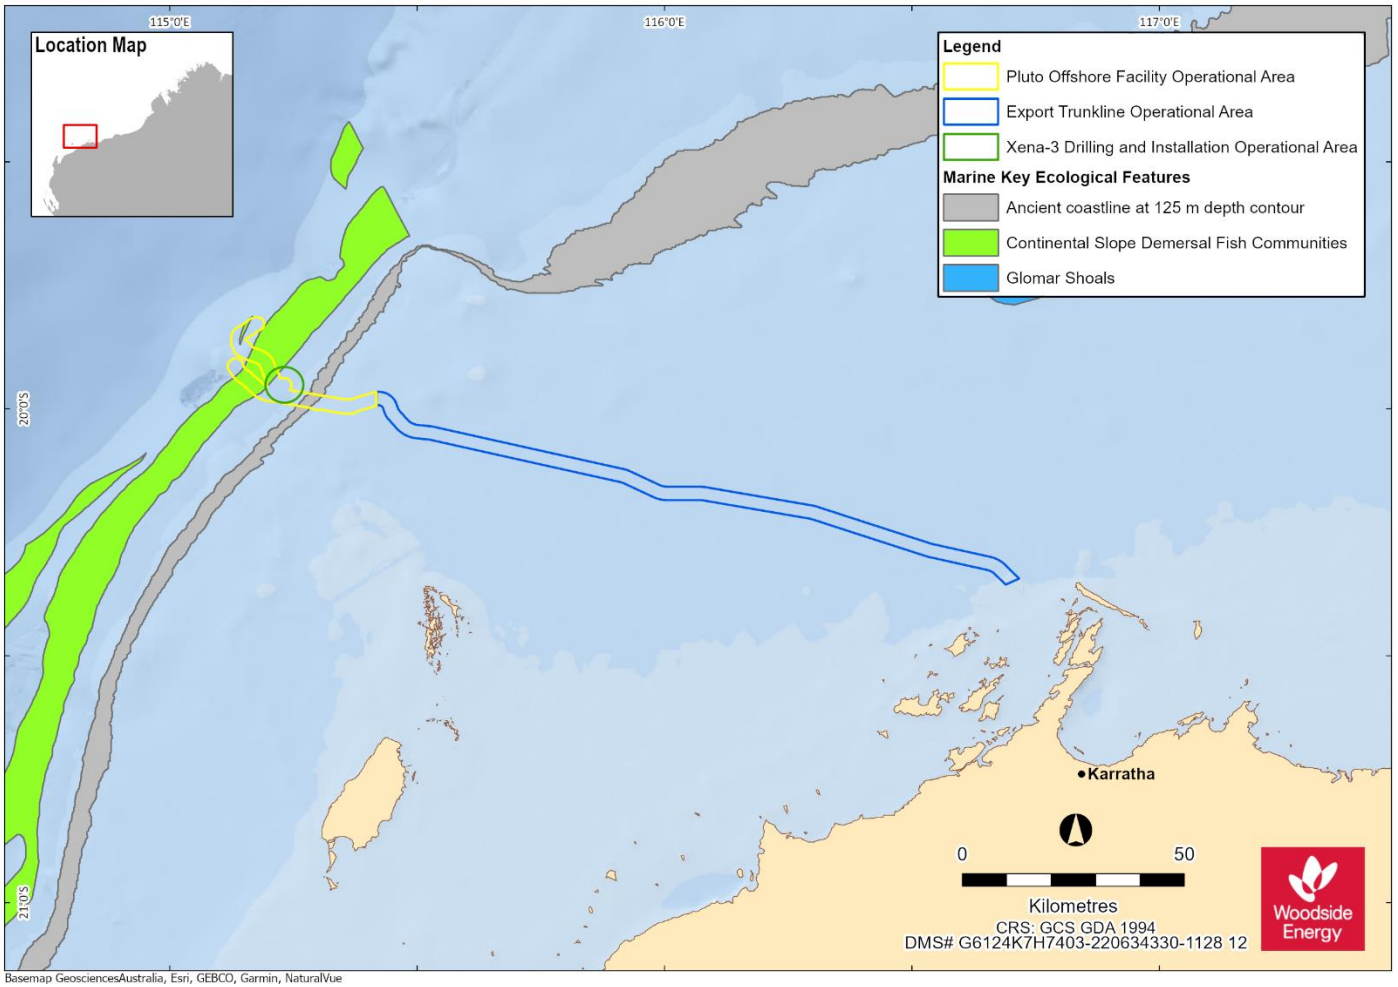

Figure 4-10: KEFs overlapping and near the PAA

4.8 Protected Places

The Montebello Marine Park overlaps the PAA, specifically the Facility and Export Pipeline Operational Areas. The Montebello Marine Park is located offshore of Barrow Island and 80 km west of Dampier extending from the Western Australian State water boundary and is adjacent to the Western Australian Barrow Island and Montebello Islands Marine Parks. This Marine Park covers an area of 3413 km² and water depths from less than 15 m to 150 m. The perimeter of the Montebello Marine Park is 420 m from the Pluto facility.

Protected places within the EMBA are identified in Table 4-16 and presented in Figure 4-11 and Figure 4-12. The Master EE (Appendix K) outlines the values and sensitivities of protected places and other sensitive areas in the EMBA.

Table 4-16: Established protected places and other sensitive areas overlapping the EMBA

**Conservation objectives for IUCN categories include:*

Ia: Strict Nature Reserve

Ib: Wilderness Area

II: National Park

III: Natural Monument or Feature

IV: Habitat/Species Management Area

V: Protected Landscape

VI: Protected area with sustainable use of natural resources – allow human use but prohibits large scale development.

IUCN categories for the marine park are provided and, in brackets, the IUCN categories for specific zones within each Marine Park as assigned under the North-west Marine Parks Network Management Plan 2018 and South-west Marine Parks Network Management Plan 2018.

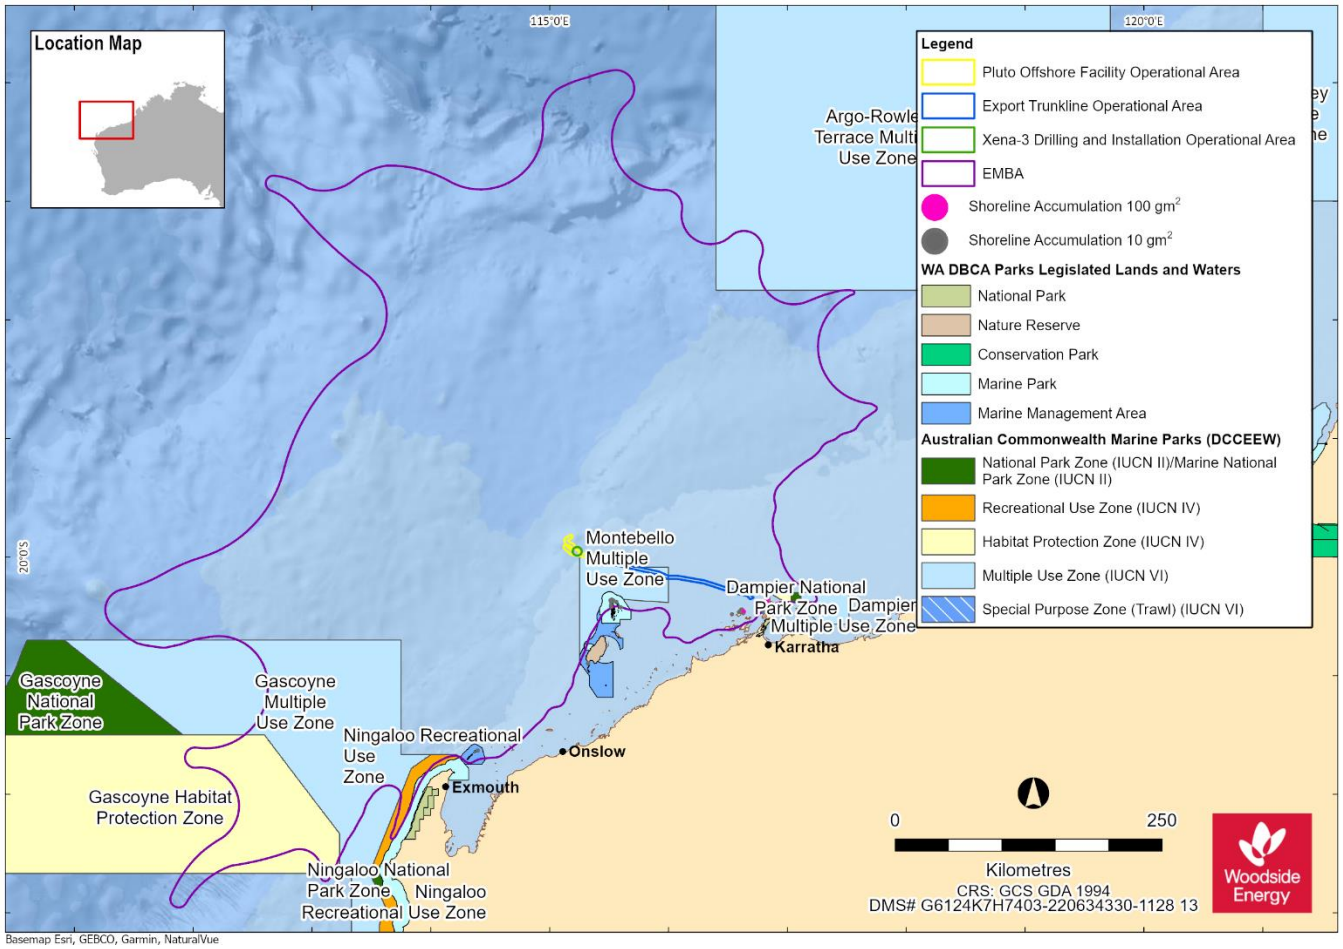

Figure 4-11: Protected areas adjacent to the PAA and EMBA

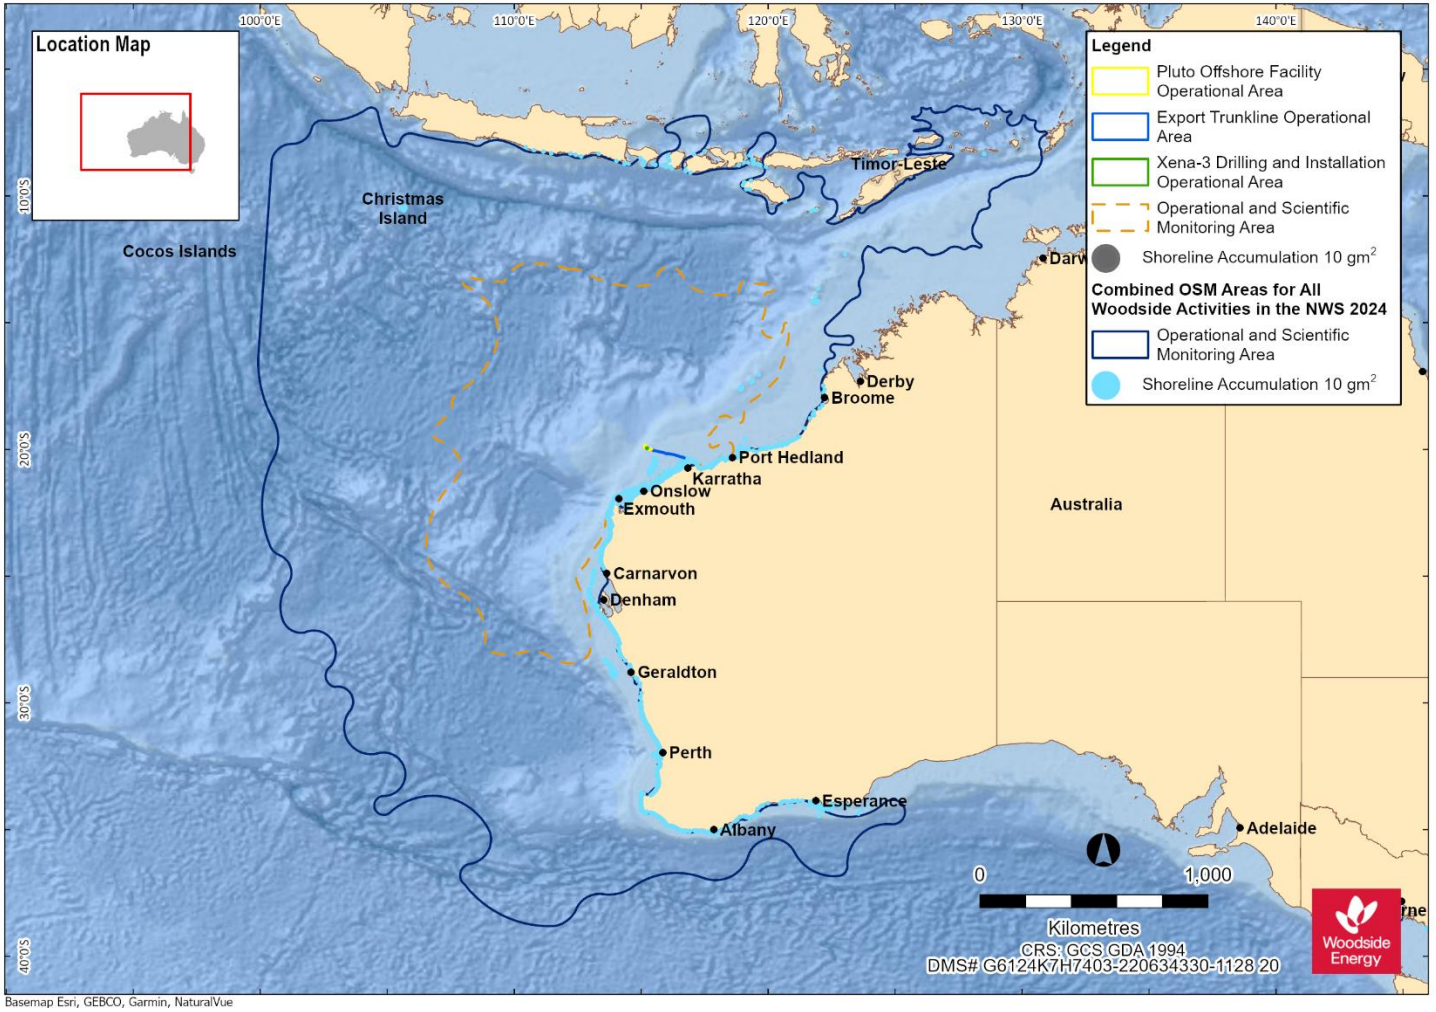

Figure 4-12: Australian Marine Parks adjacent to the PAA, Scientific Monitoring Area and EMBA

4.9 Cultural Features and Heritage Values

4.9.1 Background

Woodside recognises the 'environment' for the purpose of the evaluation required under the Environment Regulations includes:

- the heritage value of places
- the social, economic, and cultural features of the broader environment.

In this section, the heritage value of places within the PAA and EMBA and the cultural features of the PAA and EMBA are described.

In line with The Burra Charter: The Australia ICOMOS Charter for Places of Cultural Significance (Australia ICOMOS, 2013) (Burra Charter) and associated practice notes, Woodside understands heritage value to refer to the cultural significance of a place to an individual or group. A cultural feature, by contrast, is understood to be comparable to the Burra Charter term “fabric” and refer to a place’s elements, fixtures, contents and objects which have cultural values. Although these features are necessarily physical, the place they inhabit or comprise may have tangible or intangible dimensions (Australia ICOMOS, 2013). Woodside has undertaken heritage assessment to identify potential cultural values or features that may be impacted by the PAA. This assessment has not identified heritage places, objects or values that will be impacted by the activities planned under this EP (discussed in Section 6.11). However, Woodside recognises the deep spiritual and cultural connection to the environment[26] that First Nations peoples hold and is committed to ensuring appropriate management through on-going consultation.

4.9.2 First Nations People

Woodside uses established systems managed and maintained by government at State and/or Federal level where possible to identify First Nations groups that may have functions, interests or activities that may be affected by the PAP. Woodside identifies native title representative bodies and nominated representative entities, as well as native title claims, determinations and Indigenous Land Use Agreements (ILUAs) which the EMBA overlaps. Native title claims, determinations and ILUAs are defined under the Native Title Act 1993 (Cth). While acknowledging that cultural features and heritage values may exist outside of the native title framework, Woodside considers this to be the broadest extent over which Indigenous groups have claimed native title rights and interests.

Native title claims are applications made to the Federal Court under the Native Title Act 1993 for a determination or decision about native title in a particular area. A claim is made by a native title claim group which asserts it holds native title rights and interests in an area of land and/or water, according to its traditional laws and customs. By making a claim, the native title claim group seeks a decision that native title exists so that its native title rights and interests are recognised by the common law of Australia. This is called a native title determination. A determination is a decision by a recognised body, such as the Federal Court or High Court of Australia, that native title either does or does not exist in relation to a particular area (National Native Title Tribunal).

A requirement to establishing a positive determination of native title in court is proving that there is an organised society that occupied the land and/or waters at the time of British annexation. The

[26] Definition of ‘Environment’ in Regulation 4 of the OPGGS (Environment) Regulations are defined as:
- ecosystems and their constituent parts, including people and communities
- natural and physical resources
- the qualities and characteristics of locations, places and areas
- the heritage values of places, and includes
- the social, economic and cultural features of the matters mentioned in paragraphs (a), (b), (c) and (d).

requirement of an 'organised society' is set out by Justice Toohey in the historic judgment of Mabo versus Queensland (No 2) [1992] HCA 23; (1992) 175 CLR 1 ('Mabo'). Justice Toohey had the following to say (at 187):

"it is inconceivable that indigenous inhabitants in occupation of land did not have a system by which land was utilized in a way determined by that society. There must, of course, be a society sufficiently organised to create and sustain rights and duties…"

Therefore, Woodside understands that native title rights and interests are held communally by an organised society, that native title claims are understood to represent the area over which First Nations groups are claiming these rights and interests, and that native title determinations provide clarity on where native title rights and interests are found to either exist or not exist. Where native title rights or interests are determined to exist, they will be held by a Registered Native Title Body Corporate (section 57, Native Title Act 1993) in trust or as agent for native title holders.

ILUAs are voluntary agreements between native title parties and other people or bodies about the use and management of land and/or waters and are registered by the Native Title Registrar in the Register of ILUAs. An ILUA can be made over areas where:

- native title has been determined to exist in at least part of the area, or
- a native title claim has been made, or
- where no native title claim has been made.

While registered, ILUAs operate as a contract between the parties, including relevant native title holders (National Native Title Tribunal).

The Native Title Act 1993 provides for a Representative Aboriginal/Torres Strait Islander Body (Native Title Representative Body) to be recognised by the Commonwealth Minister for an area. Native Title Representative Bodies have specialist functions set out in the Native Title Act 1993 within the area for which they are the Native Title Representative Body. However, the functions of a Native Title Representative Body are such that they do not hold details on the cultural features or heritage values of an area and therefore do not inform Woodside's understanding of heritage values or cultural features.

For the activity in this EP, there are no native title claims or determinations, ILUAs overlapping the PAA and therefore also no native title rights or interests and/or cultural values identified over the PAA (Figure 4-13).

There are three native title claims overlapping the EMBA and areas of potential shoreline accumulation. A further two native title claims are coastally adjacent to the EMBA. There are three ILUAs overlapping the in-water EMBA and areas of potential shoreline accumulation. A further 9 ILUAs are coastally adjacent to the EMBA (Figure 4-13).

4.9.3 Coastally Adjacent First Nations Groups

Woodside understands that First Nations groups are keenly aware of the extent of their rights, interests and responsibilities for Country, and these are generally discrete, defined areas, including areas of sea (Smyth, 2007). To identify cultural features and heritage values which may exist outside of native title claim, determination and ILUA areas, Woodside considers native title claims, determinations and ILUAs coastally adjacent to the EMBA to be an instructive means of identifying potentially relevant First Nations groups to be consulted.

Woodside understands from engagement with relevant persons and/ or organisations, that extending a native title group's responsibility to areas which those groups have elected to not include in their claims or ILUAs can have significant cultural consequences for First Nations groups and individuals. This may also, over time, build expectations in the broader First Nations community that a group is

responsible for maintaining environmental values in areas for which they do not hold traditional knowledge. Woodside also acknowledges that a First Nations group's relative proximity to any PAA or EMBA is not necessarily a meaningful indicator of the connection of First Nations groups to the area, and providing advice over such areas can be culturally dangerous. As a result, caution must be used when conducting broader engagement.

A summary of native title claims, determinations and ILUAs overlapping or coastally adjacent to the EMBA is set out in Table 4-17. Claims and determinations have not been differentiated in this table, as it is acknowledged that either of these may indicate the existence of rights and interests.

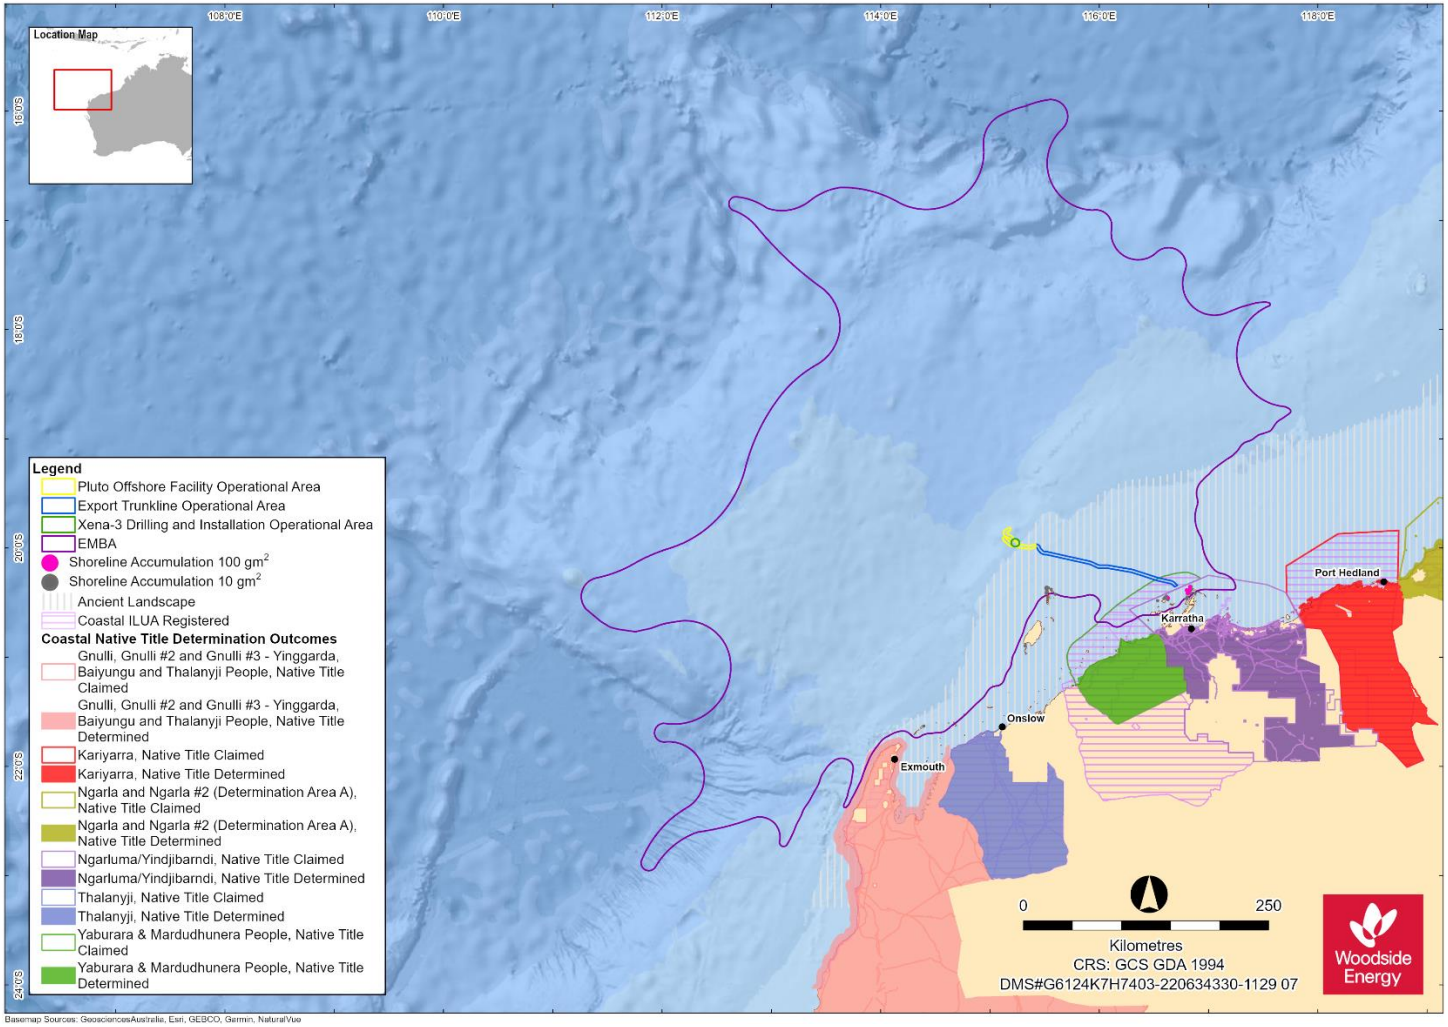

Figure 4-13: PAA and EMBA in relation to Native Title Claims, Determinations and ILUAs

4.9.4 Sea Country Values

Woodside recognises the potential for marine ecosystems to include cultural features as well as environmental values. This is one aspect of the broader concept of "Sea Country", which can be defined as the area of sea over which a First Nations group has interests, cultural value, connection and use. It has been noted that "the saltwater peoples of the north-west are associated with discrete clan estates or tribal areas, often referred to in contemporary Aboriginal English as 'saltwater country' or 'Sea Country'. 'Country' refers to more than just a geographical area: it is shorthand for all the values, places, resources, stories and cultural obligations associated with that geographical area." (Smyth, 2007). It necessarily follows that an impact to marine ecosystems has the potential to impact cultural values where the impact is detectable within Sea Country – the seascape that Traditional Custodians view, interact with or hold knowledge of. The link between environmental protection and cultural heritage protection is illustrated in the Australian Government's Indigenous Protected Areas Program. The Indigenous Protected Areas program provides for "areas of land and sea managed by Indigenous groups as protected areas for biodiversity conservation…IPAs deliver environmental benefits…Managing IPAs also helps Indigenous communities protect the cultural values of their country for future generations…" (NIAA, 2024).

McNiven (2004) suggests that "For those mainland groups whose exploitation of the sea was limited to littoral resources, it is likely that seascapes extended no more than c. 20–30km out to sea, out to the horizon and the limit of human visibility. ... However, in some coastal places, clouds that can be seen well over 100 km out to sea are imbued with spiritual significance. For those groups with elaborate canoe technology, seascapes extend well over the horizon." While there is some evidence of traditional watercraft in Australia's North West, the recorded evidence is limited to travel across inland rivers (e.g., Barber and Jackson, 2011) or travel between coastal islands (Paterson et al., 2019). The process for identifying First Nations groups who may have interests and connection in Sea Country are set out in Section 4.9.4.1. The scope of advice Traditional Custodians were encouraged to provide through project consultation was not limited by reference to any particular boundaries or limits of Sea Country.

Cultural features of coastal areas may include marine species that may travel many thousands of kilometres through areas with similar cultural values to multiple First Nations groups. Some species may travel as far as 5000 km from Antarctica to the Kimberley region of Western Australia (Double et al., 2010, 2012), passing First Nations groups along the entire west coast of Australia. For a further description of whale distribution and whale migration patterns, see Section **Error! Reference source not found.**. For a further description on turtles, see Section 4.6.2.

As set out above, an impact to marine ecosystems has the potential to impact cultural values where the impact is detectable within Sea Country. Woodside considers that impact to cultural values of marine species will be adequately managed in areas of traditional Sea Country, and therefore management of the environmental values will preserve the cultural values of environmental receptors, as assessed in Section 6.

Sea country values have been defined using multiple lines of evidence, including:

- desktop assessment of Sea Country values from publicly available sources
- Indigenous archaeological heritage assessments
- consultation with First Nations groups and individuals.

4.9.4.1 Desktop Assessment of Sea Country Values

4.9.4.1.1 Cultural Features and Heritage Values Identified in Publicly Available Literature

Publicly available sources were assessed for any records of previously identified Sea Country values or cultural features that may overlap with the EMBA or PAA. Where cultural features or Sea Country

values were identified, these are summarised in Table 4-18 according to the First Nations groups (where identified or inferable) who hold these values.

All cultural features and heritage values restricted to onshore locations or inland waters have been excluded in Table 4-18, noting that the closest boundary of the PAA is approximately 13 km to islands of the Dampier Archipelago and 22 km north-west of the coastal mainland, while the boundary of the EMBA is about 6 km from closest landfall with no shoreline contact. Where the geographical extent is not specified or unclear it has been included for completeness.

Table 4-18: Cultural features and heritage values identified in publicly available literature

First Nations Group	Features and Values	Source	Potential for Overlap	
			PAA	***EMBA***
Gnulli (Baiyungu, Thalanyji, Yinggarda)	Feature: resources including marine animals. Value: traditional knowledge holds that ancestors live on the land and in the water. Therefore, people have obligations to access and care for these places (e.g., keeping them clean).	Peck on behalf of the Gnulli Native Title Claim Group v State of Western Australia [2019] FCA 2090	Possible (unspecified) Possible (unspecified)	Possible (unspecified) Possible (unspecified)
	Feature: resources including mangrove crabs, gastropods, shellfish, dugong, turtle.	Morse, 1993	Possible (turtle) No (other resources)	Possible (all)
	Feature: heritage sites in the Ningaloo region include shell middens, artefact scatters, skeletal material/burial sites, camps, meeting places, hunting places and water sources.	Deloitte, 2020	No	Possible (Shoreline accumulation areas on offshore islands)
	Feature: resources including gajalbu (emu), bundgurdi (kangaroo), bardurra (bush turkey), majun (marine turtles), turtle eggs, bilygurumarda (osprey), fish, shellfish and plants.		Possible (turtles, fish) No (other resources)	Possible (turtles, turtle eggs, fish, shellfish) No (other resources)
	Feature: mudflats, mangroves and sand dunes provide a critical breeding ground for marine and terrestrial wildlife.		No	Possible (mangroves)
	Value: the Ningaloo region contains cultural heritage dating back at least 32,000 years, including ceremonial Thalu sites.		No	Possible (unspecified, but likely refers to onshore areas outside the EMBA)
	Value: connection to Country is important to the Traditional Owners' spirituality and religion.		Possible Unspecified	Possible (unspecified, but likely due to location of EMBA)
	Value: caring for Country – "The southern coastal reserves along the Ningaloo Coast are jointly managed by Traditional Owners and the DBCA. The Joint Management Body ensures that the Traditional Owners have an opportunity to make decisions about environmental management and land use". 	Value: a distinct way of life centred around the use of limited water and coastal resources.		No	Possible (unspecified)

4.9.4.1.2 First Nations Archaeological Heritage Assessment

Woodside understands communal cultural connection may exist between Traditional Custodians and land and waters. It is understood from the onshore archaeological record that Aboriginal people have occupied the Australian continent for at least 65,000 years (Clarkson et al., 2017) and in many places maintain a strong continuing connection that is said to extend back in Indigenous cosmology to the beginning of time.

It is understood that the sea level has risen significantly during the 65,000 years of Indigenous occupation, and areas that were once inhabited are now submerged on the continental shelf (Veth et al., 2019; UWA, 2021). Woodside also understands that, at its lowest level during First Nations occupation, sea level was between 125 m (O'Leary et al., 2020; Veth et al., 2019; Williams et al., 2018) and 130 m below current levels (Benjamin et al., 2020; Benjamin et al., 2023; UWA, 2021). Archaeological material preserved on the Ancient Landscape has the potential to provide further information about the earliest periods of human occupation (Veth et al., 2019; UWA, 2021).

Recent archaeological discoveries demonstrate that the now submerged landscape was occupied and inhabited and can retain archaeological material from this time (Benjamin et al., 2020; Benjamin et al., 2023; see Ward et al., 2021 for an opposing view).

In recognition of this, Woodside considers the Ancient Landscape between the mainland and the Ancient Coastline KEF as an area where potential First Nations archaeological material may exist on the seabed, as this covers the full extent of this possible First Nations occupation. Known Indigenous heritage places including archaeological sites may be protected subject to declarations under the Aboriginal and Torres Strait Islander Heritage Protection Act 1984, Underwater Cultural Heritage Act 2018 or EPBC Act 1999. However, these Acts only extend protection to heritage places specified by declaration or otherwise included on a statutory list. Woodside understands that there is no First Nations archaeology known to exist anywhere within Commonwealth waters and no declarations or prescriptions under these Acts are located within the EMBA.

The PAA is located beyond the Ancient Landscape. The EMBA overlaps the ancient landscape, but no impacts to the seabed are anticipated. Archaeological material on the Ancient Landscape is not a relevant matter for the proposed activity as there is no overlap between the PAA or areas of potential seabed disturbance and the Ancient Landscape.

The Department of Planning, Lands and Heritage (DPLH) Aboriginal Heritage Inquiry system was searched for the EMBA, which indicated 55 Registered Aboriginal Sites and Other Heritage Places (Appendix D). The exact location, access, and traditional practices for a number of these sites may not be disclosed and if required, such as in the event of a major oil spill, would involve prioritising further consultation with key contacts within DPLH and relevant local Aboriginal communities.

No sites of significance within the PAA or EMBA were identified by Traditional Custodians during the course of preparing the EP.

Should feedback be received (including any relevant new information on cultural values), it will be assessed and, where appropriate, Woodside will apply its Management of Change and Revision process.

Where Indigenous archaeological material is identified within the EMBA, Woodside will discuss the management of this material with appropriate Traditional Custodian group(s), starting with any adjacent Native Title Body Corporate.

4.9.4.1.3 Consultation Feedback to Inform Existing Environment

First Nations cultural values are communally held. This is reflected in Vision 3 of Dhawura Ngilan that "Aboriginal and Torres Strait Islander heritage is managed according to community ownership" (Heritage Chairs of Australia and New Zealand, 2021). Dhawura Ngilan also specifically notes that "Aboriginal and Torres Strait Islander... intangible knowledge systems, which are held in songlines and language, are endangered. This knowledge is held by Elders and the community..." Through

consultation with relevant persons, Registered Native Title Bodies Corporate have identified or raised topics relating to environmental values of cultural interest. These include a broad interest in the marine fauna.

Additional cultural values and broader interests in the environment are known and have been shared with Woodside in the course of consultation on this activity and other Environment Plans. These cultural values and broader interests that are known to exist within the EMBA are identified below:

The marine ecosystem description (Section 4.5) encompasses the description of the cultural features and Section 4.6 describes turtles and marine cetaceans.

Woodside has committed to ongoing engagement to further understand these values. The Program of Ongoing Engagement with Traditional Custodians provides a mechanism for ongoing dialogue between Woodside and Traditional Custodians. The program enables Woodside to manage uncertainty on the impacts and risks to cultural values which may be identified at any time during Woodside's activities via ongoing dialogue with Traditional Custodians. Should feedback be received (including any relevant new information on cultural values), it will be assessed and, where appropriate, Woodside will apply its Management of Change and Revision process.

A summary of the topics/interests and values raised by First Nations groups through consultation relevant to this PAP or raised in context of general Project activities or other activities are provided in Table 4-19.

Table 4-19: Summary of Sea Country values raised during consultation

First Nations Group / Individuals	Context	Description of Value / Feature / Interest	Potential for Overlap	
			PAA	EMBA
Buurabalayji Thalanyji Aboriginal Corporation	Raised during the course of consultation for another EP	Value: Connection to Sea Country Enduring deep connection to sea country north of Onslow, extending out to Islands off the Pilbara coast such as the Montebello islands, Barrow Island and the Mackerel Islands	Possible	Possible
Kariyarra Aboriginal Corporation	Raised during the course of consultation for another EP	Value: Turtles	Possible	Possible
		Value: Access to Sea Country (1) Accessing Sea Country for fishing, trapping, crabbing catching turtle, hunting dugong, using stingray barbs for spears and collecting shellfish. (2) Visiting offshore islands at low tide	No (all)	Possible (all)
		Value: Marine species resources Resource species of cultural interest to Kariyarra people include marine mammals, fish, molluscs including bivalves, gastropods and cephalopods.	Possible	Possible
		Value: The existence of intangible cultural heritage including the Yinta (associated with Sea Country). From Kariyarra Native Title documents it is clear that Yinta are significant cultural/spiritual sites, often a pool or water source but possibly a hill or other feature. These are, at least generally, associated with creation beings and are	Possible	Possible

First Nations Group / Individuals	Context	Description of Value / Feature / Interest	Potential for Overlap	
			PAA	EMBA
		a core part of cultural rights to land in determining who can use or speak for an area.		
		Interest: Coastal Landforms (Cultural interest)	No	Possible
		Interest: Coastal Native Vegetation (Cultural interest)	No	Possible
		Feature: Cultural interest in cultural heritage sites associated with the coast and the ocean.	Possible	Possible
		Value: Traditional fishing and gathering rights in the ocean	Possible	Possible
		Value: Cultural interest in intangible cultural heritage associated with the coast and the ocean. (1) Presence of mythic snakes	Possible	Possible
		Value: Intergenerational Knowledge In addition to their immediate value as sustenance, the gathering and preparation of these resources are informed by cultural knowledge, and an inability to use these resources may result in a loss of ability to transfer that knowledge to future generations. Direct impact to communities using these resources will inherently occur when the resource disappears, is displaced or suffers a reduction in population. Therefore, these communities may be impacted where there is an impact at the species/population level. Impacts to resource collection would be limited to temporary exclusion in areas where there are hydrocarbons present, including shoreline accumulation. Relevant cultural authorities will be engaged in the event of a spill that may affect them.	Possible	Possible
		Value: Cultural obligations to care for Country, including Sea Country. Value: Secret Habitat Totems associated with Sea Country	Possible	Possible
		Interest: Assertion of sea rights in native title claim area Interpreted as general connection to country, assertion of rights to access country and cultural obligation to care for environmental values of sea country (1) Having duties to look after and protect all KACs Sea Country.	No (based on NT determined area)	Possible

First Nations Group / Individuals	Context	Description of Value / Feature / Interest	Potential for Overlap	
			PAA	EMBA
Murujuga Aboriginal Corporation	Raised during the course of consultation for another EP	Value: Mermaid Sound (1) The ecosystem health of Mermaid Sound	No	Possible
		Value: Whales (1) Whales and other species of totemic importance need to be protected, including their populations, biodiversity, and migration patterns. (2) A whale Thalu is an increase at the totemic site that brings whales into the beach.	Possible (all)	Possible (all)
		Value: Dolphins There are cultural ceremonies associated with communicating with dolphins	Possible	Possible
		Value: Dugongs Dugongs are a food source associated with seagrasses near Gidley Island	Possible	Possible
		Value: Fish Specific mentions of fish included There are Thalu ceremonies associated with increasing fish stocks	Possible	Possible
		Value: Sea Snakes Sea snakes were specifically mentioned as culturally important species	Possible	Possible
		Value: Turtles (1) Flatback, green, hawksbill, loggerhead and leatherback turtles; Songline The Songline associated with the turtle comes from Fortescue to Withnell Bay. This song is sung by four or five tribes for day and night without consuming food or water. (2) Flatback, green, hawksbill, loggerhead and leatherback turtles: They are culturally important species that moves through Mermaid Sound. Turtles are most often seen in shallower areas and where there are seagrasses. (3) Most beaches are nesting sites for turtles, including those on Gidley and Legendre Islands... which also identifies Rosemary Island as the most important hawksbill turtle nesting site in Western Australia.	Possible (1,2) No (3)	Possible (all)

First Nations Group / Individuals	Context	Description of Value / Feature / Interest	Potential for Overlap	
			PAA	EMBA
		Feature: Coral Concerned about coral bleaching because corals are important. Beautiful colours. They also attract a lot of other things. Fish carry coral spawn like bees pollinate flowers. If fish were looked after, the corals would get brighter and brighter (by transmitting nutrients and performing other ecosystem services, fish can be symbiotic with corals). Locations identified during consultation include Withnell Bay; Conzinc Bay; south west of Legendre Island.	No	Possible
		Feature: Seagrass (1) Seagrasses provide protection for animals. (2) Locations identified during consultation include Conzinc Island, between Angel and Gidley Islands.	No	Possible
		Feature: Mangroves (1) Mangroves would have provided shelter, crabbing, digging for shellfish, could be turtle nurseries. Locations identified during consultation include Conzinc Bay north end; Flying Foam Passage; Searipple Passage; north-east bay of West Lewis Island.	No	Possible
		Feature: Macroalgal communities Are important primary production sites, habitats, and food sources (not explicitly identified by elders).	No	Possible
		Feature: Subtidal soft-bottom communities Support invertebrate diversity (not explicitly identified by elders).	No	Possible
		Feature: Intertidal sand and mudflat communities Important primary production sites, support invertebrate diversity and provide food for shorebirds (not explicitly identified by elders).	No	Possible
		Feature: Rocky shores Habitats for intertidal organisms and provide food for shorebirds (not explicitly identified by elders).	No	Possible

First Nations Group / Individuals	Context	Description of Value / Feature / Interest	Potential for Overlap	
			PAA	EMBA
		Feature: Other areas of Mermaid Sound of importance (including Conzinc Bay) (1) Fish traps: There are known fish traps in Conzinc Bay, and others would have or do exist in coastal areas of islands, such as Angel and Gidley Islands. People still use the Conzinc Bay fish traps regularly for catching mangrove jack, trevally and other fish.	No	Possible
		Value: Squid (1) Squidding (harvesting of squid from the ocean) around Conzinc Bay	No (based on specific location)	Possible
		Value: Appropriate cultural authority for Murujuga.	No	Possible
		Interest: Management of onshore heritage sites	No	
		Interest: Submerged Heritage Engage with researchers on options to identify potential submerged heritage.	Possible	Possible
		Value: Songlines The potential impact on Jinna (Songlines) due to the lack of broader-scale bathymetric information for the submerged landscape	Possible	Possible

		unplanned chemical discharges (non-hydrocarbon)		
		Interest: Seabirds "Potential impacts on marine species and natural environment, relevant to the natural environment, relevant to the Applicant's interests, including but not limited to: v. potential impacts on water quality and consequent potential impacts on marine fauna such as whales, dugongs, sharks, rays, and seabirds from the risk of unplanned chemical discharges (non-hydrocarbon)	Possible	Possible
		Interest: Where saltwater and freshwater meet "The places where the saltwater from the sea and the freshwater from the land connect are where the biggest energy lines[1] are, and that connection is a core of creation relevant to a Dreaming story."	No	Possible
		Value: Rock Art "Rocks at Murujuga symbolise stories, the totems (the depicted artwork) - whether representing plants or animals - and tell a story of their history, and how long they've been there."	No	Possible (submerged)
		Value: Bungarra, Eagle, Kangaroo Identified totemic species	No	No
		Interest: Murujuga "When [Individual 2] and [Individual 1] and their people stand on Country they are connected to their songlines through the rocks. As holders of women's lore, [Individual 2] and [Individual 1] put healing energy into the rocks and use that to heal the songlines." "[Individual 2] and [Individual 1] connect to their bloodline, old people and songlines through Country, including the rocks at Murujuga, which are encrypted with ancient stories that keep connection to the bloodline and songlines alive and well."	No	Possible

4.9.4.2 Summary of Cultural Features and Heritage Values

Woodside has developed a robust understanding of cultural features and heritage values relevant to the activity through examination of publicly available information, studies and consultation with relevant persons under Regulation 25.

The cultural features and heritage values identified in Section 4.9.4.1 to Section 4.9.4.2.3 confirm whether there is any potential for these to exist within the PAA or EMBA. As previously described,

topics that have been raised in the context of an interest linked to the natural environment are impact and risk assessed in Section 6.

As cultural features are physical elements of a place, these can generally be assessed for impacts; where a feature is avoided, it is not impacted. Heritage values relate less to what is significant and more to why something is significant; interaction between heritage values and the PAA can only be reliably informed by consultation with Traditional Custodians where they are willing to share the necessary knowledge. Assessment of heritage values beyond cultural features alone is addressed in Section 6.11, subject to these caveats.

Table 4-20: Summary of cultural features and heritage values

Identified Cultural Features and Heritage Values	Context	EP Source		Potential for Overlap	
		Consultation Feedback	Desktop Literature Assessment	PAA	EMBA
Archaeological Heritage and Landscapes					
Coastal/island archaeological sites	Coastal archaeological sites include shell middens, artefact scatters, skeletal material/burial sites, camps, meeting places, hunting places and water sources.	×	✓	No	Possible (shoreline accumulation only)
Petroglyphs	Petroglyphs are a form of rock art. Petroglyphs are a prominent feature particularly at Murujuga where it is found on hard, volcanic rock.	×	✓	No	Possible (submerged)
Fish traps	Stone arrangements constructed in intertidal areas which fill with fish at high tide and trap them at low tide.	×	✓	No	Possible (submerged)
Submerged archaeological sites	The Ancient Landscape extends between 125m and 130m below current sea level. Ancient occupation of this area may have left traces through now submerged archaeological sites.	×	✓	No	Possible
Rivers, waterholes, tidal channels and seeps	Water sources on the Ancient Landscape which may be culturally significant or archeologically prospective. Traditional knowledge retains knowledge of some water sources on the ancient landscape and some submerged waterholes are related to a Kangaroo songline.	×	✓	No	Known to occur
Submerged hills	Hills on the Ancient Landscape which may be culturally significant or archeologically prospective. As sea level rose these hills would have become islands and eventually submerged.	×	✓	No	Possible

Identified Cultural Features and Heritage Values	Context	EP Source		Potential for Overlap	
		Consultation Feedback	Desktop Literature Assessment	PAA	EMBA
Intangible Values					
Songlines	Consultation and publicly available literature talk to songlines associated with ancestral beings that travelled Sea Country. Energy lines were raised in consultation. Energy lines are understood by Woodside to be the same as songlines.	✓	✓	Possible (unspecified)	Possible (unspecified)
Creation/ dreaming sites, sacred sites and ancestral beings	Publicly available literature talks to creation/dreaming and ancestral beings, including water serpents, connected to or originating from the sea generally.	✓	✓	Possible (unspecified)	Possible (unspecified)
Ceremonial sites	Places where ceremony (e.g., Thalu ceremonies) are performed. All identified ceremonial sites are located onshore.	×	✓	No	Possible (unspecified)
Cultural obligations to care for Country	Cultural obligation to care for the environmental values of Sea Country. Exclusion of Traditional Custodians from Sea Country or decision-making processes may inhibit ability to care for Country.	✓	✓	Possible (unspecified)	Possible (unspecified)
Cultural safety	Respecting local Lore and culturally significant areas to protect individuals from cultural harm.	×	✓	No	Possible (unspecified)
Knowledge of Country/customary law and transfer of knowledge	The preservation and transmission of knowledge is dependent on the preservation of the environment generally. Exclusion of Traditional Custodians from Sea Country may inhibit the transfer of knowledge.	✓	✓	Possible (unspecified)	Possible (unspecified)

Identified Cultural Features and Heritage Values	Context	EP Source		Potential for Overlap	
		Consultation Feedback	Desktop Literature Assessment	PAA	EMBA
Connection to Country	Connection to Country is described in publicly available literature as “important to the Traditional owners’ spirituality and religion”. Connection to Country may be damaged where people are displaced or disrupted (e.g. during colonisation) or where there is a loss of technical skills or environmental knowledge.	×	✓	Possible (unspecified)	Possible (unspecified)
Access to Country	Limitations on Traditional Custodians accessing or enjoying areas of Sea Country.	✓	✓	No	No (No limitations on access beyond the PAA)
Kinship systems and totemic species	Traditional Custodians have connection to species through kinship and totemic systems. An individual may have obligation to care for or not consume a species to which they are kin.	✓	✓	Possible	Possible
Resource collection	Fishing, hunting, trapping, crabbing, gathering of marine species including marine mammals, marine reptiles, fish and invertebrates including molluscs.	✓	✓	No	Possible
Marine Ecosystems and Species					
Marine species	Generally raised in consultation and literature as an interest.	✓	✓	Possible	Possible
Marine mammals: whales	Generally raised in consultation and identified in publicly available literature. Thalu species of totemic importance. Linked to songlines and dreaming stories. Humpback whales in particular.	✓	✓	Possible	Possible

Identified Cultural Features and Heritage Values	Context	EP Source		Potential for Overlap	
		Consultation Feedback	Desktop Literature Assessment	PAA	EMBA
Marine mammals: dugongs	Culturally important species. Used as a resource.	✓	✓	No	Possible
Marine reptiles: marine turtles	Culturally important species and migration. There are Thalu ceremonies associated with turtles. Turtles and turtle eggs as a resource.	✓	✓	Possible	Possible
Fish: fish, whale sharks, sharks and rays	Culturally important species. Used as a resource. There are Thalu ceremonies associated with increasing fish stocks. Whale sharks are known as guardians of the sea by the Mayala People. Fish, including bream and sting rays are totemic species. Fish, including sharks and rays raised as a natural environment interest.	✓	✓	Possible	Possible
Cephalopods: squid and octopus	Octopus are a species of totemic importance. Resource.	✓	✓	Possible	Possible
Intertidal communities: bivalves, gastropods, echinoderms, sea urchins, crustaceans	Resource. Bivalve and gastropod shells such as pearl shells, baler shells and trochus shells used in traditional trading practices and in resource collection. Molluscs are collected as a resource.	×	✓	No	Possible

Identified Cultural Features and Heritage Values	Context	EP Source		Potential for Overlap	
		Consultation Feedback	Desktop Literature Assessment	PAA	EMBA
Seabirds	Culturally important species. Birds (including shags, seagulls and osprey) and bird eggs as a resource. Bird feathers also used as a resource. Kestrel is a species of totemic importance.	✓	✓	Possible	Possible
Plankton	Interest only, raised as a natural environment interest.	×	×	Possible	Possible
Benthic habitats: coral and reefs	Publicly available literature identified coral and reefs as culturally important with regard to connection with fish and important for food gathering.	×	✓	No	Possible
Benthic habitats: seagrass	Publicly available literature identified seagrass as a culturally important species, providing for the protection of other marine species (e.g., turtles, dugongs).	×	✓	No	Possible
Benthic habitats: macroalgal communities	Interest only, raised as a natural environment interest.	×	✓	No	Possible
Benthic habitats: epifauna and infauna	Interest only, subtidal soft bottom communities raised as a natural environment interest.	×	✓	No	Yes

Identified Cultural Features and Heritage Values	Context	EP Source		Potential for Overlap	
		Consultation Feedback	Desktop Literature Assessment	PAA	EMBA
Shoreline habitats: mangroves and saltmarsh communities	Mangrove seeds as resource. Critical breeding ground for marine and terrestrial wildlife. Mangroves would have provided shelter, crabbing, digging for shellfish, could be turtle nurseries. Saltmarshes would have provided an environment for crabbing and digging for shellfish. Coastal vegetation, raised as an interest	✓	✓	No	Possible
Shoreline habitats: intertidal sand/ mudflat communities	Interest only, raised as a natural environment interest.	×	✓	No	Possible
Shorelines and coastal landforms	Interest only, raised as a natural environment interest.	✓	×	No	Possible
Estuarine crocodiles	Publicly available literature identified estuarine crocodiles as a culturally important species. Resource.	×	✓	No	Possible
Marine Park/coastal reserves	Interest and responsibility.	×	×	No	Yes
Nearshore and offshore islands	Interest in protection of islands and species that inhabit the islands, including Rosemary Island and Solitary Island. Interest in access to nearshore islands. Offshore islands are culturally significant.	✓	×	No	Yes (Rosemary Island, other islands) No (Solitary Island)

4.9.4.2.1 Further Context: Archaeological Heritage

The PAA is in water depths of 40 to 960 m, some of which overlaps the Ancient Landscape. No coastal areas or islands exist within the PAA. Islands do exist within the EMBA boundary; however, given the EMBA is driven by an unplanned loss of well containment, there is no anticipated impact pathway from this activity to onshore archaeological sites above highest astronomical tide (HAT).

Archaeological sites identified onshore with the potential to exist in intertidal or submerged locations include petroglyphs, fish traps and artefact scatters or burials contained within sand dunes. As archaeological sites, these features have archaeological value which relates to the preservation of their fabric (i.e., the tangible features) and their context (i.e. their location and relationship to other archaeological and natural features). Archaeological sites may also have intangible dimensions (ICOMOS, 2013) cultural value that exist in addition to their archaeological or scientific value and are assessed separately.

Certain landscapes have been identified as archaeologically prospective on the submerged Ancient Landscape, including:

- submerged water sources (rivers, waterholes, tidal channels and seeps) which have an increased likelihood of use or habitation as past generations used the associated resources (UWA, 2021)
- submerged calcarenite ridges younger that human occupation of the continent which may have formed over and protected artefacts in situ (Veth, 2019)
- prominent landscape features (e.g. hills, particularly of igneous rock formations) that may have been foci for cultural activity (UWA, 2021)
- Karst depressions and other “catch points” where artefacts may accumulate following disturbances caused by inundation (UWA, 2021; Nutley, 2022; Nutley, 2023a).

4.9.4.2.2 Further Context: Intangible Cultural Heritage

Cultural knowledge, as expressed through songlines, dreaming, dance and other cultural practices, can be associated with tangible objects and physical sites that are culturally important to First Nations people (Ardler, 2021; Bursill et al., 2007). Intangible cultural heritage can also be embodied in the practices, representations, expressions, knowledge, uses and skills associated with physical sites (UNESCO, 2003). As a result, physical features may have intangible dimensions (ICOMOS, 2013).

In terms of identified cultural features and heritage values related to intangible values, see below some additional context:

- Songlines: Oral Songlines are often described by First Nations people as the law of the land and make up part of the Dreaming (Neale and Kelly, 2020). Songlines are viewed in Western academia as a framework for relating people to land and consist of a series of invisible, interconnected routes along the landscape that mark significant sites for First Nations people (Higgins, 2021). Songlines demonstrate First Nations peoples’ strong connections to land by revealing scared knowledge that is place-specific (Roberts, 2023). The land’s physical features are instrumental in maintaining songlines because this is how ancestral spirits journeyed through, and interacted with, the physical landscape leaving scared knowledge behind. The interconnection between the physical and spiritual is where songlines become intrinsically tied to significant places across Country. As a result, geographical landforms are recorded within songlines and become sacred places. Such landforms can include inter alia: rocks, mountains, rivers, caves and hills (Higgins, 2021). Songlines can become lost, fragmented or broken when there is a loss of Country or forced removal from Country (Neale and Kelly, 2020). Physical sites that have been identified as comprising a component of a songline are important to protect in order to prevent the fragmenting or breaking apart of

songlines and loss of sacred cultural knowledge. No specific details of songlines have been provided by relevant persons during consultation for this activity. The activity is located beyond the Ancient Landscape where prominent landscape features (e.g., rocks, mountains, rivers, caves and hills) would have been visible or used by Traditional Custodians and therefore likely to be incorporated in songlines. In Australia, songlines can stretch thousands of kilometres, making up a complex and organic network of stories containing cultural knowledge of First Nations communities across the land (Neale and Kelly, 2020). Songlines can also extend out to Sea Country and contain cultural knowledge that is tied to geographic features, atmospheric phenomena and marine plants and animals. Often songlines containing references to a seascape or Sea Country make mention of mythical events occurring around marine life, fishing areas, submerged rocks or coral. Songlines that embody seascapes can reflect how a group may relate to, or value, Sea Country; for example, connections to nearby islands that they once inhabited in their songlines (Smyth and Isherwood, 2016). Songlines can also be used as proof of long-standing connection to land and support a legal entitlement to land rights (Higgins, 2021). Examples where songlines contain strong references to Sea Country are more common in Pacific Islander and Torres Strait Islander communities, who often refer to seascapes and skylines in their songlines in order to communicate sacred knowledge that assists in safe navigation of the ocean (Neale and Kelly, 2020).

- Creation/dreaming sites, sacred sites and ancestral beings: The only sources identified by Woodside that contained detailed descriptions of the location of ancestral beings or creation/ dreaming/sacred sites placed these locations or sites on land, islands or within inland water sources such as rivers or pools. It is acknowledged that some ancestral beings are noted to live within or originate from the sea generally, and some creation stories talk to the creation of features from or in the sea. Additionally, places on shore or at sea are (without further information or specificity) assumed to have been created on some level in First Nations cosmology.
- Cultural obligations to care for Country: Caring for Country collectively refers to the cultural obligations of individuals and groups, as well as rituals and ceremonies required for the physical and spiritual health of the environment. In the literature reviewed by Woodside, caring for Country was noted to include, but is not limited to, maintenance of the physical environment and ecosystem. It may also have cultural, spiritual and ritual dimensions such as caring for ancestral beings or ensuring cultural safety. Thalu sites are places where ceremonies are performed to increase, enhance or maintain populations of plants, animals or phenomena. All references to active ceremonial sites were confined to onshore locations, though the values may extend offshore where, for example, a Thalu relates to marine species populations.
- Knowledge of Country/customary law and transfer of knowledge: Knowledge of and familiarity with the features of Sea Country is itself a “value”. The inherent potential for restricted or secret knowledge (or information that is not wished to be shared) makes this difficult to assess even through consultation with Traditional Custodians. However, aspects such as limitations on access to sites or disruption/relocation of First Nations communities may have implications for the preservation of First Nations knowledge. Further, connection to Country may be damaged where people are displaced or disrupted (e.g., during colonisation) or where there is a loss of technical skills or environmental knowledge (McDonald and Phillips, 2021). Transfer of knowledge includes continuing traditional practices to pass on practical skills. This transfer of knowledge may be integral to managing a group’s intangible cultural heritage (UNESCO, 2003).
- Connection to Country: Describes the multi-faceted relationship between First Nations people and the landscape, which is envisioned as having personhood and spirit. It is also an aspect of personal identity for many First Nations people. In the case of Sea Country this can mean identifying as a Saltwater person, where “essence of being a Saltwater person is

ontological… it is about how people relate spiritually to the sea and engage with spiritual forces that created it, the marine flora and fauna and people" (McDonald and Phillips, 2021).

- Access to Country, including Sea Country: Is necessary for the continuation of other values including caring for Country and the transfer of traditional knowledge. Being on Country can be an important way of expressing or maintaining connection to Country (Australian Indigenous HealthInfoNet n.d.). Access is also a value in its own right, as a continuation of traditional Sea Country access and use.
- Cultural Safety: refers to respecting local Lore and culturally significant areas to protect individuals from cultural harm. There are many cultural implications for those (Aboriginal and non-Aboriginal) who do not follow cultural advice or access Country in culturally inappropriate ways. Cultural safety may include observing gender restricted areas, respecting significant places and restricted areas as well as following the advice from those with cultural authority.
- Kinship systems and totemic species: Individuals may have kinship to specific species (Smyth, 2008; Juluwarlu, 2004) and/or a responsibility to care for species (Muller, 2008). Kinship arises from totemic associations within First Nations "skin group" systems. It is forbidden for an individual to kill or eat a species who is from the same "skin group" (Juluwarlu, 2004). They may also have certain obligations linked to the discussion of caring for Country below. It is assumed that marine species may have kinship/totemic relationships to Traditional Custodians, but it is understood that these relationships do not prohibit people outside of that "skin group" from hunting or eating that same species (Juluwarlu, 2004).
- Resource collection: A number of marine species are identified through consultation and literature as important resources, particularly as food sources. In addition to their immediate value as sustenance, the gathering and preparation of these resources is informed by cultural knowledge, and an inability to use these resources may result in a loss of ability to transfer that knowledge to future generations.

4.9.4.2.3 Further Context: Marine Ecosystems and Species

First Nations people have noted through consultation that they have a general interest in environmental management and ecosystem health (i.e., natural environment interest). This was noted in the context of a group/individual seeking further information about potential impacts and risks from the PAP on marine species and benthic communities in the PAA and EMBA. This includes marine mammals, marine reptiles, fish, seabirds, plankton, benthic and shoreline habitats and marine parks, which are described in context of their distribution and populations in Sections 4.6 to 4.8, with further details in Appendix K.

In terms of identified cultural features and heritage values related to marine ecosystems and species summarised in Section 4.9, see below some additional context:

- Marine mammals: Whales, and in particular humpback whales, have been identified through consultation with First Nations people as culturally important species, with totemic importance including their populations, biodiversity, and migration patterns. Cultural ceremonies associated with communicating with dolphins have also been raised by MAC through consultation and dugongs predominantly as a resource. Details pertaining to whales, dugongs and dolphins, their distribution, migration patterns and populations are described in Section **Error! Reference source not found.**, with further details in the Appendix K.
- Marine reptiles: Turtles and sea snakes have been identified through consultation with First Nations people as culturally important species, with turtles identified as a resource. First Nations people that identify marine reptiles as species of totemic importance or integral to songlines may place high cultural value on their protection. No specific marine reptiles-related songlines have been identified as per Section 4.9 that have the potential to interact with the PAA or EMBA. Note the only specific songline related to marine reptiles (turtles) was shared by MAC, and was geographically restricted from Fortescue to Withnell Bay, in Mermaid

Sound (MAC, 2021). Cultural knowledge of turtles at a population level (turtle migration, behaviour and the related marine environment) may all be important in ensuring the continuation of cultural functions and activities that remain valuable to First Nations people (Fijn, 2021:47; Delisle et al., 2018). Details pertaining to marine reptiles, their distribution, and populations are described in Section 4.6.2, with further details in the Appendix K.

- Fish and Cephalopods: Fish and squid have been identified through consultation with First Nations people as a culturally important species, with fish generally being identified as a resource. First Nations may identify cultural values associated with fish species as important to maintaining both tangible (physical cultural sites) and intangible (cultural knowledge) cultural heritage. Tangible cultural heritage associated with fish can include important cultural sites such as midden sites, fish traps and Thalu sites. While the octopus is an important totem to Ngarla People and features in the creation story of Solitary Island. There are increase ceremonies/ rituals for species of squid and octopus to enhance or maintain populations. Thalu are places where these increase ceremonies are performed. Details pertaining to fish and cephalopods are described in Section 4.9, with further details in the Appendix K.
- Seabirds: Seabird eggs have been identified through literature as a culturally significant resource (Smyth, 2007). Details pertaining to seabirds and migratory shorebirds are described in Section **Error! Reference source not found.**, with further details in the Appendix K.
- Benthic habitats: Through consultation, First Nations groups identified benthic habitats as valuable for their ecological values, including corals attracting fish and seagrass providing shelters for fauna, as well as an important resource for dugongs. Additionally, coral is valued by MAC for its aesthetic values. Details pertaining to benthic habitats and communities, including their distribution, with further details in the Appendix K.
- Shoreline habitats: Through consultation, First Nations groups identified shoreline habitats as valuable for their ecological values, including mangroves for providing shelter to marine invertebrates, which are identified resources, and potential nursery for turtles. Literature also notes that mangroves are also valued for the flora and fauna they are associated with and support (Commonwealth of Australia, 2002) and Smyth (2007) reports that mangrove seeds are used as a resource by Ngarda-Ngarli. Details pertaining to shoreline and coastal habitats, including their distribution, with further details in the Appendix K.

4.9.5 Murujuga Cultural Landscape

Murujuga is a significant cultural landscape rich with heritage values, included on Australia's National Heritage list and World Heritage tentative list. It contains one of the largest, densest and most diverse collections of rock art in the world, estimated to contain over a million engravings (petroglyphs) covering a broad range of styles and subjects. The landscape also contains quarries, middens, fish traps, rock shelters, ceremonial sites, artefact scatters, grinding patches and stone arrangements that evidence tens of thousands of years of human occupation. These places are linked through the stories, knowledge and customs that are still held by Traditional Custodians and have significance beyond their archaeological value.

This Cultural Landscape has global significance and is on the UNESCO World Heritage Tentative List. As stated on the UNESCO World Heritage website[27]:

The Traditional Custodians of Murujuga, the Ngarluma, Yindjibarndi, Yaburara, Mardudhunera and Wong-Goo-Tt-Oo groups, collectively referred to as Ngurra-ra Ngarli, have taken the lead in proposing the inclusion of the Murujuga Cultural Landscape on Australia's World Heritage Tentative List. Ngurra-ra Ngarli, represented by the Murujuga Aboriginal Corporation, have prepared this

[27] https://whc.unesco.org/en/tentativelists/6445/

Tentative List Submission in partnership with the Western Australian Government and with the support of the Australian Government.

Murujuga, the Aboriginal traditional name for the Dampier Archipelago and surrounds, including the Burrup Peninsula, is located in the Pilbara region of Western Australia. When the Ngurra-ra Ngarli talk about Murujuga, they talk about Land and Sea Country, which consists of a narrow peninsula of land extending approximately 22 kilometres from the mainland, a group of 42 islands, islets and rocks and the surrounding sea up to 40 kilometres from the port of Dampier (Murujuga Aboriginal Corporation 2016). With more than one million images in an area of more than 37,000 hectares, Murujuga is home to one of the most significant and diverse collections of petroglyphs in the world which documents the transition of an arid maritime cultural landscape through time (McDonald 2015, Mulvaney 2015, McDonald et al. 2018). Murujuga has the densest known concentration of hunter-gatherer petroglyphs anywhere in the world (Jo McDonald Cultural Heritage Management 2011, Australian Heritage Council 2012, Mulvaney 2015).

For the Aboriginal people of the Pilbara region, including the Ngurra-ra Ngarli, the petroglyphs are the work of the Marrga, the ancestral creator beings. They are a permanent reminder of Traditional Lore and retain their spiritual power. On Murujuga, the petroglyphs are an inherited and ongoing responsibility of the Ngurra-ra Ngarli (Jo McDonald Cultural Heritage Management 2011). The songs and mythologies for many of the images, such as Minyuburru (Seven Sisters), the fruit bat and Archaic Face, have important meaning across the whole of the Pilbara region and are central to Ngurra-ra Ngarli culture.

Archaic Faces have a widespread distribution throughout the arid zone of Australia and include a locally developed form on Murujuga (McDonald 2005, Mulvaney 2010, Veth et al. 2011). The Archaic Faces of Murujuga are a permanent reminder of how Traditional Lore should be followed. The presence of the Archaic Faces across the Pilbara region and into the Western Desert demonstrates the importance of the deep time-shared cultural practices, including through the transfer of songs and mythologies between different language groups over thousands of kilometres.

“Some of these carvings are our Lore and Culture. The Lore, it goes from here, right to Uluru, from Uluru into the desert and back again to the West. That’s including the Kimberley and Northern Territory area. It’s still going strong”.

Source: Jakari Togo (Geoffrey Togo), Senior Cultural Ranger (deceased) 2013. Murujuga Cultural Heritage Management Plan (Murujuga Aboriginal Corporation 2016)

There is evidence that suggests that the Ngurra-ra Ngarli first started living and using this part of the Pilbara coastal plain around 50,000 years ago, when the coastline was understood to be about 100 kilometres away. At that time Murujuga was understood to have been wetter and warmer than it is now. The archaeological record of the coastal plain at this time reveals a faunal assemblage no longer found in this part of Australia, such as nail-tailed wallabies and crocodiles. Murujuga’s artists recorded this group of animals in the engraving assemblage. During the last ice age (between 30,000 and 18,000 years ago), when the coastline was understood to be 160 kilometres away, Ngurra-ra Ngarli are understood to have lived in the Murujuga Ranges (McDonald et al. 2018) as well as other desert refugia. Evidence of Ngurra-ra Ngarli living in this landscape is seen in a number of petroglyphs of animals that are now extinct, such as thylacines (Tasmanian Tiger) and a fat-tailed species of kangaroo (Brown 2018; Mulvaney 2013) which are distributed widely across the Pilbara region and into the sandy deserts. More recent petroglyphs depict fish, turtles, dugongs and small marsupials that now live on the islands (McDonald 2015). The variations in petroglyphs and archaeological evidence demonstrate how Ngurra-ra Ngarli are understood to have adapted to the changing environments wrought by sea level rise (McDonald and Berry 2016).

The estimated more than one million petroglyphs of Murujuga demonstrate an extraordinary diversity of style, theme, mode of production and aesthetic repertoire. This art province is an inscribed landscape complete with other archaeological components, such as stone structures, middens and

quarries, and provides a social context and means for interpreting the complexity of the petroglyphs (McDonald and Veth 2009).

The many stone features of Murujuga include standing stones, fish traps, stone arrangements, hunting hides and domestic structures. Some standing stones are thalu sites, places where ceremonies are carried out to increase and manage the social and economic benefits of natural resources (Daniel 1990). On Murujuga, stone feature sites range from single monoliths through to extensive alignments comprising at least three or four hundred standing stones (Vinnicombe 2002). Thalu sites are permanent reminders of the Traditional Lore.

Murujuga is sacred to Ngurra-ra Ngarli, it is a place where everything is connected, through the Ancestral Beings – the land, the sky, the sea, the plants, the animals, the Lore and the spiritual world. This is the belief system that underlies life on Murujuga today (Murujuga Aboriginal Corporation 2016).

National Heritage Place – Dampier Archipelago

The Dampier Archipelago, including Murujuga, was included in the National Heritage List in 2007. Values listed against National Heritage criteria in the gazettal notice include:

- Engravings of a wide range of terrestrial, avian and marine fauna. These provide an "outstanding visual record of the course of Australia's cultural history through the Aboriginal responses to the rise of sea levels at the end of the last Ice Age"
- Engraved "archaic faces" which demonstrate the long contact between Aboriginal societies on the Dampier Archipelago and inland arid Australia
- Diversity in representation of the human form in engravings, including depictions of groups of people "engaged in both mundane and sacred activities"
- Standing stones, stone pits and circular stone arrangements associated with various uses
- Ability to link research on archaeological remains (middens, grinding patches, quarries) and associated rock engravings to "contribute to an understanding of the cultural and economic meaning"

Further details of these values can be found in the publicly available Gazettal[28].

Murujuga National Park Management Plan

Parts of the Burrup Peninsula (4,913 hectares which is approximately 44% of the Burrup Peninsula) is owned by the Murujuga Aboriginal Corporation, leased back to the Western Australian Government and is jointly managed with DBCA as a National Park (DBCA, 2024). The Park and some adjacent areas are managed under the Murujuga National Park management plan 78 (2013, as amended 2023). The Management Plan created by Ngarda-Ngarli and their joint management partners seeks to ensure the protection of the area and to revive Ngarda-Ngarli knowledge, associations and responsibility. The plan acknowledges the coexistence of Woodside production facilities and the Park, identifying its objective to 'To promote effective, integrated and cooperative management between Murujuga National Park and adjacent land managers' (DBCA, 2013, and amendment DBCA & MAC 2023).

In 2007, the Australian Government signed a Conservation Agreement with Woodside Energy Ltd to protect and research the National Heritage values of the Dampier Archipelago. In July 2017, Woodside signed the 'Ngajarli (Deep Gorge) Joint Statement' reaffirming the cooperative commitments made under each of the Conservation Agreements.

It is under the Conservation Agreement that Woodside provides ongoing funding for programmes continuing to support research into, and monitoring of the National heritage values of the park so

[28] https://www.dcceew.gov.au/sites/default/files/env/pages/d53ee213-2f1e-481e-b0f6-85d861a52de2/files/10572701.pdf

that activities are carried out in a manner that is consistent with the Murujuga National Park Management Plan 78 (2013). Further protections and management practices have been integrated into Woodside's Cultural Heritage Management Plans and engagement protocols. Outcomes of funded programs include processes to identify sites with National Heritage values, present and transmit information about the National Heritage values, and manage the National Heritage values so that they are conserved for future generations.

World Heritage Nomination

The United Nations Educational, Scientific and Cultural Organisation (UNESCO) "seeks to encourage the identification, protection and preservation of cultural and natural heritage around the world considered to be of outstanding value to humanity" via the World Heritage List, established under the World Heritage Convention 1972 (UNESCO 2024). The Murujuga Cultural Landscape was nominated to the UNESCO Tentative World Heritage List by the Federal Department of the Environment and Energy in 2020. Inscription on the World Heritage List means that Murujuga's unique cultural, spiritual and archaeological values would be internationally recognised at the highest level.

As stated by the State Department of Biodiversity, Conservation and Attractions, "World Heritage Listing also brings a commitment at local, state and national levels to protect and manage the property for present and future generations." World Heritage listing and industry can occur in parallel, as long as there are no significant impacts on World Heritage values.

As required under the World Heritage framework, the tentative World Heritage Listing of the Murujuga Cultural Landscape submission justifies its Outstanding Universal Values by meeting two of the possible ten selection criteria:

- To represent a masterpiece of human creative genius, with "more than one million images in an area of more than 27,000 hectares, the Murujuga Cultural Landscape has one of the densest known concentration of petroglyphs anywhere in the world," and for the content, age and significance of the petroglyphs
- To bear a unique or at least exceptional testimony to a cultural tradition or to a civilisation which is living or which has disappeared, through the unbroken connection of the Ngarda-Ngarli people to Murujuga "since the world was soft and Ancestral Beings moved over the earth," reflecting both deep-time history and ongoing critical cultural significance.

Further submissions on how the Murujuga Cultural Landscape meets World Heritage criteria can be found on the publicly available UNESCO World Heritage Tentative Listing[29].*Current Condition of Murujuga Cultural Landscape*

The current condition of the Murujuga Cultural Landscape has been assessed from a number of publicly available sources.

The World Heritage Tentative List Submission for Murujuga Cultural Landscape (MAC, DBCA, DEE 2020) notes, with regards to the Statements of Integrity and/or Authenticity:

"Aboriginal cultural landscapes are living landscapes that change as time progresses, where oral tradition is the canon of proof and where changing practices of embodied experience with landscapes grow from generation to generation (Andrews and Buggey 2008).

In the context of Aboriginal cultural landscapes, any test of authenticity, must recognise, expect, and endorse changes (Andrews and Buggey 2008). The archaeological and anthropological evidence for Murujuga is well preserved, with a high degree of authenticity. The exceptionally well-preserved cultural values of Murujuga can be found across an area of more than 37,000 hectares,

[29] https://whc.unesco.org/en/tentativelists/6445/

comprising the majority of the Burrup Peninsula, as well as the surrounding islands of the Dampier Archipelago…

The petroglyphs of Murujuga have been made on the exceptionally hard, dark volcanic rock using stone tool technology. Methods of production included pecking, abrasion, incision and bas-relief. When first produced the very pale grey petroglyphs would have contrasted starkly with the dark red-brown cortex of the rock. With subsequent patination and weathering, this contrast gradually reduces…

Murujuga has a high level of integrity and received enhanced protection and management following its National Heritage listing in 2007. A detailed land-use impact study of Murujuga documented that all 40 islands included in the Dampier Archipelago (including Burrup Peninsula) National Heritage place and approximately 85 per cent of the Burrup Peninsula, retain extremely high integrity (McDonald and Veth 2006a), and contain all the attributes that constitute the potential Outstanding Universal Value of the place…

Within the National Heritage listed area, the petroglyphs are whole and intact (Jo McDonald Cultural Heritage Management 2009, 2011). Although the entirety of Murujuga has not been surveyed and recorded, there are thousands of known sites which demonstrate the potential Outstanding Universal Value of the Murujuga Cultural Landscape…

While industrial development visually compromises some areas of the southern section of the Burrup Peninsula, the topography, with its deeply dissected gorges, valleys and scree slopes, means that a large portion of Murujuga, including the vast majority of its islands retain high visual integrity (Jo McDonald Cultural Heritage Management 2011, Australian Heritage Council 2012). In summary, the Murujuga Cultural Landscape is an intact and representative example of one of the most significant concentrations of human artistic creativity in the world, which survives through the continuity of Ngurra-ra Ngarli cultural and social practices and active management."

The Report "The Potential Outstanding Universal Value of the Dampier Archipelago Site and Threats to that Site - A report by the Australian Heritage Council to the Minister for Sustainability, Environment, Water, Population and Communities" (Australian Heritage Council 2012) found that:

"It is clear that the undisturbed area within the boundaries of the National Heritage Listed place is complete and whole, notwithstanding the proximity of industry"

The Australian Heritage Database listing for the Nationally Heritage Listed Damper Archipelago (including Burrup Peninsula) states:

"Condition: Parts of the area, particularly the Burrup Peninsula, East Intercourse Island and Mid East Intercourse Island, have been subject to industrial development and other impacts such as the construction of towns and work camps. A land use impact assessment, undertaken using aerial photographs from August 2004, estimates that high levels of impact have occurred on 1,643 hectares (or 16.4 square kilometres) on the Burrup Peninsula (McDonald and Veth 2006). A high level of impact in these areas on the Burrup Peninsula has resulted in the destruction of archaeological material and in some cases the relocation of engravings and other stone features. Despite this, the natural and cultural heritage in Dampier Archipelago and its surrounding waters is in good condition" (DCCEEW 2007).

Research to date on the impacts of industrial emissions on rock art has not been conclusive and is summarised in Section 4.9.6.

4.9.6 Summary of Existing Research on Murujuga Petroglyphs and Anthropogenic Air Emissions

Murujuga (Burrup Peninsula), including the Murujuga National Park, is most widely known for its large collection of rock art (petroglyphs). The Traditional Owners of Murujuga have a deep cultural

and spiritual connection to the rock art of the Burrup Peninsula, which provides a record of Aboriginal lore, dreamtime stories, customs, and local knowledge of the land and its resources (MAC, 2019).

The presence of industry on the Burrup Peninsula has been the subject of topics and issues raised by some Relevant Persons during consultation. The topics and issues have centred around emissions associated with industrial activity leading to an accelerated weathering of rocks on which rock art is present which may reduce the visibility or destroy the rock art. This is based on a hypothesis that deposition of compounds such as NOx, SOx and ammonia (NH_3) from anthropogenic industrial sources have the potential to increase the acidity of the rock surface through chemical and/or biological processes and that acidic conditions may then accelerate the weathering of rock patina, eroding or affecting the contrast of the rock art. There have been several independent studies and rock art monitoring initiatives since the mid-2000s, none of which have conclusively demonstrated a causal link between degradation of rock art and industrial activity. There are therefore also no applicable environmental air quality standards or guidelines available that can be applied to engraved rock art (Government of Western Australia, 2023).

Nevertheless, relevant persons have raised through consultation (Appendix F, Table 2) the possibility that emissions from the processing of LNG onshore at Murujuga may have an impact on the preservation of rock art. While these onshore emissions are not within the scope of the PAP, they are assessed in this EP as potential indirect impacts (Section **Error! Reference source not found.**). Research to date on the impacts of industrial emissions on rock art has not been conclusive and is summarised in this section. While these onshore emissions are not within the scope of the PAP, the research related to this topic is summarised in this section and evaluated to consider the potential for indirect impact (Section **Error! Reference source not found.**).

Further research continues to be undertaken by the Murujuga Rock Art Monitoring Program (MRAMP), run by the Traditional Custodians of the petroglyphs, the Murujuga Aboriginal Corporation, and Western Australian Department of Water and Environmental Regulation (DWER). MRAMP is described as “A best practice monitoring and analysis program” by the Western Australian Government which “will provide reliable information on changes and trends in the condition of the rock art and whether the rock art is showing signs of accelerated change… The results from these studies will guide management and protection of the rock art” (Government of Western Australia, 2023). MRAMP will provide the necessary certainty to guide management and protection of the rock art. The MRAMP website also describes the role of MRAS as part of the proposed World Heritage listing for Murujuga:

“The Department of Biodiversity, Conservation and Attractions (DBCA) works with MAC to lead the development of the World Heritage nomination of the Murujuga Cultural Landscape, as well as joint management of the Murujuga National Park. The World Heritage nomination for Murujuga includes a comprehensive and effective management framework that outlines how the potential ‘Outstanding Universal Value’ of the area will be protected, conserved and monitored. As part of this framework, the State Government and MAC will demonstrate how they are working closely together to protect the rock art through the Murujuga Rock Art Strategy and the Murujuga Rock Art Monitoring Program” (Government of Western Australia, 2023).

Refer to Section **Error! Reference source not found.** for more information about the Murujuga cultural heritage management framework.

In the absence of scientific certainty on the level of emissions which theoretically may affect rock art, Pluto LNG Plant (PLP) is applying the best available practicable and efficient technologies to minimise and monitor air emissions from the plant.

It is a condition of the existing EP Act approvals for PLP (Ministerial Statement 757) that the proponent of PLP produce a “Front End Engineering Design Report demonstrating that the proposed works adopt best practice pollution control measures to minimise emissions from the plant”. The WA Department of Environment and Conservation accepted this design demonstration in 2008 prior to facility construction, and the Pluto Air Quality Management Plan (Revision 1) was approved by Office

of the EPA (EPA) on 10 November 2011. An update of the Best Practice Air Emissions Report was prepared for the operation of a second LNG train at PLP and was submitted in July 2019 to the EPA for assessment (Woodside, 2019).

PLP's publicly available Air Quality Management Plan has been reviewed and approved by the Western Australian Environment Protection Authority as meeting the requirement for best available practicable and efficient technologies to be used to minimise and monitor air emissions from the plant (Woodside, 2019). This included an independent peer review assessment which concluded that the design of Pluto Train 2 is consistent with best practice in the context of air emissions control for LNG plants and the minimisation of greenhouse gas emissions (Woodside 2019).

4.9.6.1 Research, Monitoring and Publications

Bednarik (2002) speculated the existence of several possible impact pathways for industrial emissions to impact rock art, including acidification of rain and promotion of microbial activity. Bednarik suggested there was a key indicator for this is identified as colour change in the rock surfaces. Bednarik's speculation led to further studies detailed in this section. The data provided by Bednarik is not sufficient to demonstrate that industrial emissions have negative impacts on the rock art, but did warrant further study.

In 2002, the Western Australian Government established the Burrup Rock Art Monitoring Management Committee (BRAMMC) to assess the possible impacts of industrial emissions on the rock art of Murujuga. Research conducted by the BRAMMC included measurements of colour change as well as air quality, microclimate, dust deposition, mineral spectrometry, microbiological analyses, air dispersion modelling, and laboratory simulations of chemical impacts at contemporary, predicted and 10-times predicted pollutant estimates.

During the course of the BRAMMC studies, several further publications were produced, including:

- MacLeod 2005, which found that acidity of rockfaces on Murujuga is higher than samples kept in museum conditions. The paper does not demonstrate that the museum samples, which have been subject to decades of museum preservation conditions, are representative of the natural pH of Murujuga's rocks nor does it draw any conclusions on the impacts of acidity on rock art preservation.
- Bednarik 2006 and 2007a were editorials, which did not include any original research.
- Bednarik 2007b argued that industrial emissions were impacting rock art but provided no evidence beyond analogy to bird droppings and expert advice that the absence of rock patina near trees was not the result of any known process caused by plants. The data provided by Bednarik is not sufficient to demonstrate that industrial emissions have negative impacts on the rock art but did warrant further study (which was already underway at that time).

In 2009, the BRAMMC reviewed the results of studies conducted under their program and concluded that "there is no scientific evidence to indicate that there is any measurable impact of emissions on the rate of deterioration of the Aboriginal rock art in the Burrup" and recommended that a technical working group be established to continue long-term monitoring.

In 2010, the Burrup Rock Art Technical Working Group (BRATWG) was established. Under the BRATWG, the CSIRO continued to monitor potential colour change on the rock art (Markley et al., 2015). In 2016, an unpublished paper by Black and Diffey concluded, contrary to CSIRO analysis at the time, that colour change was detected in CSIRO data but that "a cause for the colour changes cannot be properly determined" and "the colour changes at the southern [non-control] sites are not readily explained by the concentrations of NOx and SOx compounds in the air."

These criticisms of the statistical methods used by CSIRO prompted the Department of Environment Regulation to commission Data Analysis Australia (DAA) to review the CSIRO research. The DAA report found that "Superficially our analyses and those of Black and Diffey suggest that some changes may have taken place, but… we have substantial doubts about the reliability of the data

and hence any conclusions drawn" and, in relation to the conclusions of Black and Diffey, "it would not be appropriate for the Draft paper to be published in its current form – the findings are based on highly doubtful data rendering any discussion of statistical significance moot" (DAA, 2016). The final CSIRO report includes a reassessment using more robust methods informed by the DAA report. The result of this analysis was "not fully conclusive" (Duffey et al., 2017).

In 2016, the BRATWG commissioned an extreme condition weathering study to investigate the effects of different concentrations of acids on weathered rock surfaces. This study found that the dissolution of chemicals began at lower pH levels than previously estimated (pH 3 for aluminium, manganese and iron), but was recognised as a preliminary study and did not provide definitive results (Ramanaidou et al., 2017). These results cannot be relied on as a meaningful threshold for determining whether rock art is being impacted by emissions.

Since the 2016 BRATWG extreme weathering study, several additional papers have been produced, including:

- Black et al. 2017a provides a review of the conclusions of earlier studies into emissions impacts by the CSIRO, specifically those undertaken with regards to the fumigation of rock samples with acid gasses, emersion of iron-rich rocks in acids, air pollution modelling and colour change. This review concluded that a number of errors and inaccuracies prevent any meaningful conclusion being drawn from the CSIRO data. This review did not demonstrate impacts to rock art from industrial emissions.
- Black et al. 2017b provides a theoretical evaluation of MacLeod 2005 research. It provides no data that links industrial air emissions or subsequent deposition to changes in pH on Murujuga rock surfaces. There are practical limitations that prevent the MacLeod data from being adapted to the paper's purpose, including variation in sample dilution and the arbitrary exclusion of data.
- Black et al. 2018 speculates the existence of several possible impact pathways, including acidification of rain and promotion of microbial activity. The paper recognises, however, that "there is no proof yet that the patina on Murujuga rocks is dissolving" and asserts that "there has not been credible research to determine" whether rock art is being degraded. In drawing conclusions regarding changes in acidity this paper assumes, without evidence, that geological samples which have been subject to decades of preservation in a museum are representative of the natural pH of Murujuga's rocks. The key conclusions of this paper are that further, more robust research is required, and that the precautionary principle should be applied in the interim.
- Gleeson et al. 2018 primarily discusses microbial organisms that may be responsible for the formation of rock varnish. The paper briefly speculates on the possible impacts of industrial emissions but does not purport to provide evidence of impacts to Murujuga's rock art.
- In 2019, the Department of Water and Environmental Regulation (DWER) produced the Murujuga Rock Art Strategy, which built on the research to that date, and according to DWER will establish a world's best practice program to monitor, evaluate and report on factors that could affect the condition of rock art. This will be undertaken in consultation with a team of national and international experts in relevant disciplines and funded by industry including from Woodside. Research by this program is led independently by MAC and DWER working with leading research groups so that results are independent from industry.
- CBG Solutions 2020 repurposes previous pH records from 2003 and 2004 (as a baseline), and data collected between 2017 and 2019 to assess changes in acidity on rock surfaces. The report repurposes historical and inconsistent pH data and acknowledges a number of resulting statistical issues which "makes determination of long-term pH changes problematic". The report states that "there appears to be no detrimental (acidification) impact that can be statistically supported regarding proximity to either the NW Gas plant or to the Pluto plant" and "owing to the many variables that determine the surface pH of the Burrup

rocks and the significant impact of periodic cyclonic heavy rain and the lack of historic data on all the tested sites, it is not possible to claim that there is sufficient evidence for the statement that there is a continuing increase in acidity across Murujuga since measurements commenced in 2003".

- Dorn 2020 discusses competing theories of desert varnish growth and how chemical changes to desert varnish result from human sources, such as lead concentration following the addition of lead to petrol. The chapter predominantly focusses on North America but uncritically restates the conclusions of Black et al. 2017b. Only one other example in the paper, regarding an apparent change in varnish texture from near Los Angeles, appears to have even tangential relevance to industry on Murujuga. Acid fog is proposed as one *possible* cause, but this suggestion is not supported by any provided data and is based on examinations from an area with significantly higher acid gas concentration than Murujuga experiences.
- MacLeod 2020 provides results of a study commissioned by Yara Pilbara Nitrates. This report observes a variability of the relationship between colour difference and pH, with colour difference diminishing with increasing pH at some points, and diminishing with decreasing pH at other points although the final sentence of the report claims "there is unequivocal evidence that the changes in colour contrast are affected by the changes in the mean and in the minimum pH observed on the rock art sites at the reference positions". At several points this report notes that rainfall events – particularly cyclonic events – appear to substantially reduce the acidity. The executive summary states that "there is a clear link between the minimum pH and the amount of sulphate on the rock surfaces, w*hich indicates some of the sulphate comes from anthropogenic sources*" (emphasis added), though the report does not articulate how a link between pH and sulphate contributes to an understanding of sulphate origin. MacLeod (2020) comments in relation to the two sites that are closest to Pluto LNG Plant and Karratha Gas Plant that the observed low sulphate concentrations "strongly supports that these exhaust sources are not resulting in any significant SOx deposition on the rock surfaces".
- MacLeod 2021 provides an update to this previous work which found that pH had increased during the study period, but pH changes were affected by microclimate at each site, including seasonal variations, microbial activity, and localised rainfall events. Any relationship between anthropogenic NOx and SOx emissions and acidity was not established and "just as the mechanisms of adsorption of NOx and SOx onto the moistened rock surfaces are yet to be unequivocally established, the presence of a direct relationship between the concentration of sulphate in the wash solutions with the underlying acidity can be regarded as a de-facto correlation". Once again, the report states that "there is unequivocal evidence that the changes in colour contrast are affected by the changes in the mean and in the minimum pH observed on the rock art sites at the reference positions".
- Also in 2021, MacLeod and Fish (2021) published results of the studies commissioned by Yara Pilbara Nitrates, including that "there is presently no adverse impact on the rock engravings from industrial pollution owing to a lower NOx level than when the studies commenced 14 years ago". This conclusion was critiqued by Smith et al. 2022a, who correctly noted that this conclusion is based on limited data and makes a number of key assumptions without adequate peer-reviewed research.
- Gagan et al. 2022 is an investigation of anthropogenic air-borne sulphur on rock art on limestone in Sulawesi, Indonesia. This is not comparable to the Murujuga petroglyphs as the Murujuga petroglyphs are not on a limestone substrate. The research notes that "the bulk of the damage was present before 1950 CE", for example such as due to biomass burning ~3,500 years ago; current threats include "vandalism and sulphur emissions from diesel-powered traffic and cement-based infrastructure"; and that "the rate of rock art loss may be on the decline".

- Smith et al. 2022a is a review of the Fish and McLeod report; the review does not contain original research and therefore does not further the existing scientific understanding of the subject. Claims that Smith et al. 2022a demonstrate that emissions from industry are impacting rock art are incorrect.
- Smith et al. 2022b does provide evidence of impacts to rock art and attributes these to three sources: mechanical removal and damage, chemical emissions and emitted by industry, and an increased unsympathetic human presence. in the landscape – examples provided include "rock scratching from off-road vehicles and graffiti, broken rocks from inappropriate trampling… rock splitting and discolouration from non-traditional burning practices". Evidence of the first and third of these is apparent and easily demonstrated from the photographic record, yet the paper itself notes that the use of photographic records to assess chemical impacts through colour change are subject to considerable errors including distortion and degradation of early photographs, variable lighting conditions and other factors. The researchers do note that several petroglyphs (numbered 2, 5, 6, 9, 16, 17, 21, 22 and 24) appear to have lightened over time in line with a hypothesis that emissions have played a role in this, while one petroglyph (1) appears to have darkened and at least 13 do not demonstrate any change, including several in close proximity to industry. The paper appropriately notes that further research is required to determine the causes of these perceived changes.
- Neumann et al. 2022 is an important proof-of-concept for analytical techniques, but is clear in its conclusion that "Although our data clearly demonstrate that acidic rain has measurable effects on the varnish surface, including its colour and increased dissolution of Fe and Mn compounds, it should be stressed here that this does not necessarily mean that natural weathering of the petroglyphs is accelerated by anthropogenic pollution."
- Ruffolo et al. 2023 review the formation of "black crusts", accumulation of materials on the surface of stone buildings, in highly polluted urban environments, and intervention strategies to mitigate damage to built heritage from black crusts. The study notes "the research outcomes have established some correlations between black crusts and the surrounding air pollution, leading to them being considered as a "'record'" and also a '"passive sampler'" of past pollution patterns. However, in this case, there is not yet a well-defined procedure to obtain accurate and unambiguous information." This paper does not provide new science applicable to the Murujuga petroglyphs due to its focus on built heritage and urban pollution.

In 2019, DWER released the Murujuga Rock Art Strategy (MRAS), "A monitoring, analysis and decision-making framework to protect Aboriginal rock art located on Murujuga (the Dampier Archipelago and Burrup Peninsula)" (DWER, 2019). The MRAS notes "This strategy builds on the previous work on Murujuga to deliver a scientifically rigorous approach to monitoring, analysis and management that will provide an appropriate level of protection to the rock art. It describes a risk-based approach for the management of impacts to the rock art that is consistent with the State Government's responsibilities under the Environmental Protection Act 1986 (EP Act) and provides the monitoring and analysis to determine whether accelerated change is occurring to the petroglyphs" (DWER 2019).

In regards to previous scientific studies and monitoring, the MRAS states *"In 2002, the Western Australian Government established the Burrup Rock Art Monitoring Management Committee (BRAMMC) in response to concerns about possible adverse impacts on the rock art from industrial air emissions…In 2009, after reviewing the information from these studies and the comments from the international peer reviewers, BRAMMC concluded there was no scientific evidence of any measurable impact of industrial emissions on the rate of deterioration of the Burrup rock art. BRAMMC recommended that no environmental management measures specifically to protect the rock art from air pollution were necessary at that time. BRAMMC recommended that colour contrast and spectral mineralogy monitoring be continued on an annual basis for 10 years and be reviewed after five years; and that a technical working group be established to consider the results*

of monitoring and other studies. BRAMMC also recommended that the monitoring of ambient air quality and rock microbiology be suspended and only recommenced if warranted by a major increase in emissions or if evidence became available indicating further monitoring was required. The Burrup Rock Art Technical Working Group (BRATWG) was established to oversee the colour contrast and spectral mineralogy monitoring program and other studies between September 2010 and June 2016. The then Department of Environment Regulation (DER) managed the monitoring program from the expiry of BRATWG's tenure in June 2016 until the formation of DWER on 1 July 2017" (DWER 2019).

Outcomes of both the BRAMMC and the BRATWG have been discussed above.

The MRAS states that "The successful implementation of the management framework to protect the rock art from anthropogenic emissions will require…a monitoring program that is appropriately designed and implemented to take the necessary measurements, to analyse the data and to report on the integrity or condition of the rock art and change in that condition" (DWER 2019). As described in the MRAS "The Western Australian Government in partnership with MAC and in consultation with international and national experts in relevant disciplines and the Murujuga Rock Art Stakeholder Reference Group, will develop and implement a revised long-term Murujuga Rock Art Monitoring Program" (DWER 2019).

In December 2023, the first interim report of MRAMP was published. An accompanying summary report notes that "Data collected in the first year of observation do not permit any firm conclusions to be drawn about trends in rock surface condition and any relationship to air quality over time" (Government of Western Australia 2023). However, several techniques were considered promising for future analysis, including spectral measurement of rock art condition, geological studies and mineralogical studies. Though requiring more data to draw any conclusions, the report and summary both note that the correlation observed between acid-producing emissions and pH were the *inverse* of predictions if these gases were causing acidification of rock surfaces (that is, higher concentrations of these gases were associated with *less* acidic rock surfaces). Woodside does not consider these results to be definitive and recognises that further work by MRAMP is required. Final results by MRAMP are scheduled for December 2025, with interim Environmental Quality Criteria anticipated to be published in the preceding years. This will provide the necessary certainty to guide management and protection of the rock art for industry on Murujuga.

Produced subsequent to these interim results, Smith 2024 provides the results of laboratory studies on Murujuga rock samples. The methodology for these experiments is not provided. The reported results are that particles of weathering rind begin to detach from the rock samples when the pH of rocks reach 6 or lower—significantly higher than, for example, suggested in Ramanaidou et al 2017. This report also reinterprets results from the MRAMP program (although excluding results from the first campaign of this work from consideration). This reinterpretation requires cautious consideration, noting the MRAMP interim report's caveats that the available data is insufficient for drawing meaningful conclusions. The conclusions of Smith 2024 state that "The rock surfaces of Murujuga have become increasingly acidic due to the nitric and sulphuric dusts emitted *by industry in the area.*" (emphasis added). This causal link is not supported in the report by reference to any other study, and as the report does not provide a clearly stated methodology it is unclear whether this is supported by the laboratory work performed. A correlation may, perhaps, be implied by reference to historic trends reported in reports discussed elsewhere in this section, which have noted methodological issues. Smith 2024 also fails to address, in its reinterpretation of MRAMP data, the preliminary observation that higher levels of acid-producing emissions were found to correlate with less acidic rock surfaces.

Woodside is also aware of a draft paper, [Individual 18] 2024, which reiterates previous conclusions drawn by [Individual 18] but does not provide new science regarding Murujuga's rock art. The paper summarises some of the scientific literature addressing rock art on Murujuga and other locations around the world described above.

On 1 July 2024, a Statutory Declaration by [Individual 19], formerly employed by Murujuga Aboriginal Corporation as Coordinator of the Murujuga Rock Art Strategy and the Monitoring Program (MRAMP) was tabled in the Australian Senate by [Individual 20] which alleges that:

Calibre Ventures Pty Ltd, a third-party private contractor, was in effect managing the MRAMP" (paragraph 10), and

the partnership between MAC and DWER (as it stood in 2023) required "significant changes in the existing management structure, due largely to conflict of interest and related issues", (paragraph 11) and

people in leadership positions at MAC have attempted to unduly influence the outcome of MRAMP (paragraphs 4-5, 24-25 and 34).

[Individual 19] also claimed to record "multiple scientific flaws" (paragraph 13) and "numerous deficiencies" (paragraph 17) with MRAMP, though the nature of these issues is not provided. No such errors are apparent from the MRAMP first interim report, which has been subject to independent peer review (Government of Western Australia 2024).

The CEO of MAC provided comments to media in response to the tabled documents, stating "The claims made in the tabled documents do not stand up to scrutiny. The Murujuga rock art monitoring program is a strong, best-practice program that has been designed with international experts to examine the impact of industrial emissions on Murujuga's petroglyphs" (WA Today, 6 June 2024, article entitled "Leaked letter reveals internal concerns about science on Australia's next world heritage site by Hamish Hastie and Peter Milne, 2024)

The Government of Western Australia maintains that the MRAMP is a "*best practice monitoring and analysis program*" which "*will provide reliable information on changes and trends in the condition of the rock art and whether the rock art is showing signs of accelerated change*" (Government of Western Australia 2024). As a basic principle of managing First Nations cultural heritage, and as reflected in Woodside's First Nations Communities Policy (Woodside, 2022), the involvement of MAC as representatives of Traditional Custodians in this project is also important to ensuring that the broader values of Murujuga are appropriately managed. Further results from the MRAMP are expected periodically until its conclusion in 2025, and relevant findings will be managed through Woodside's Management of Change process.

4.9.7 Historic Sites of Significance

Historic sites of significance and heritage value are found along adjacent foreshores of the NWMR. Heritage places are protected in Western Australia under the Heritage Act 2018. There are no known sites of historic cultural heritage significance within the PAA.

4.9.8 Historic Underwater Heritage

A search of the Australian National Shipwreck Database, which records all known Maritime Cultural Heritage (shipwrecks, aircraft, relics and other underwater cultural heritage) in Australian waters, indicated there are no sites within the PAA; however, a number of shipwrecks exist within the EMBA and detailed in Appendix K.

Table 4-21: Historic shipwrecks within 100 km of the PAA

Shipwreck	Distance from PAA to Shipwreck (km)
Curlew	<1
Marietta	<1
Wild Wave (China)	<1
Vianen	<1
McDermott Derrick Barge No 20	14
Zelma	17
Tanami	28
Trial	28
HMS Plym	36
Tropic Queen	41
Parks Lugger	45

4.9.9 World, National and Commonwealth Heritage Listed Places

No World, National or Commonwealth heritage listed places overlap the PAA. World, National and Commonwealth heritage places within the EMBA are identified in Table 4-22.Appendix K outlines the values and sensitivities of these places.

Table 4-22: World, National and Commonwealth Heritage Listed places within the EMBA

Listed Place	Distance and Direction from PAA to Listed Place (km)
World Heritage Places	
The Ningaloo Coast	208 south-west (Facility and Xena-03 Operational Areas)
National Heritage Places	
The Ningaloo Coast	194 south-west (Facility and Xena-03 Operational Areas)
Dampier Archipelago	9 km south-east (Export Pipeline Operational Area)

4.10 Socio-economic Environment

4.10.1 Commercial Fisheries

Five Commonwealth and 18 State fishery management areas are located within the PAA and EMBA. For additional detail, the PAA is presented here in two parts: the Export Pipeline Operational Area, and the combined Facility and Xena-03 Drilling Operational Areas.

The Annual Fishery Status Reports published by the Australian Bureau of Agricultural and Resource Economics and Sciences (ABARES) were used to identify whether Commonwealth-managed fisheries were active within the PAA and EMBA in the last five years. FishCube data were also requested from the WA Department of Primary Industries and Regional Development (DPIRD) for the most recently available five-year period for each fishery (2019–2023). Data obtained from the catch and effort system (CAES) was analysed to assess the potential for fisheries interaction with the PAA and Petroleum Activities Program. Data was reviewed from the last five years as a subset of past fishing effort. This was deemed an appropriate period to represent potential future fishing effort over the lifecycle of this EP (five years from NOPSEMA acceptance). In addition, any impacts to fish are expected to be temporary in nature (see Section 6) and therefore not to extend beyond the life of the EP.

This information was used to determine relevant fisheries for consultation who may be impacted by the PAP. Table 4-23 provides an assessment of the potential interaction and Appendix K provides

further detail on the fisheries that have been identified through desk-based assessment and consultation (Section 5). One Commonwealth-managed and 10 State-managed fisheries were identified as having a potential interaction with the Petroleum Activities Program, within the PAA (Figure 4-14).

Table 4-23: Commonwealth and State commercial fisheries management areas overlapping the PAA and EMBA and potential for interaction during the PAP

Fishery	PAA/EMBA			Description		
	Facility and Xena-03 Operational Areas	Export Pipeline Operational Area	EMBA	Potential for Interaction During Petroleum Activity Program		
				✖ no spatial overlap	✓ spatial overlap	Blue shading possibility for interaction
Commonwealth Managed Fisheries						
North West Slope Trawl Fishery	✓	✖	✓	The North West Slope Trawl Fishery management area overlaps the Facility and Xena-03 Operational Areas and the EMBA. The fishery operates off north-western Australia from 114°E to 125°E, roughly between the 200 m isobath and the outer boundary of the Australian Fishing Zone (Keller and Curtotti, 2023). Fishing effort commenced in 1985 with vessel numbers between 1 and 6 vessels per year since 2005–2006 (Keller and Curtotti, 2023). Three vessels operated in the 2021–2022 season, decreasing from 4 in 2020–2021 season (Keller and Curtotti, 2023). Woodside considers it a possibility that interactions with the fishery may occur in the Facility and Xena-03 Operational Areas and the EMBA.		
Southern Bluefin Tuna Fishery	✓	✓	✓	The Southern Bluefin Tuna Fishery management area overlaps the PAA and the EMBA. The Southern Bluefin Tuna Fishery spans the Australian Fishing Zone; however, since 1992, the majority of Australian catch has concentrated in south-eastern Australia (Patterson and Dylewski, 2023a). Woodside considers there to be no potential for interaction with this fishery and the Petroleum Activities Program.		
Western Deepwater Trawl Fishery	✖	✖	✓	The Western Deepwater Trawl management area overlaps the EMBA. The fishery operates off the coast between the western boundary off the Southern and Eastern Scalefish and Shark Fishery in the south, and the western boundary of the North West Slope Trawl Fishery in the north (Kell et al., 2023). Fishing effort has been relatively low since 2005–2006, with 1 to 3 vessels active in the fishery since 2004–2005, and 2 active vessels recorded in 2021–2022 (Keller et al., 2023). Woodside considers it a possibility that interactions with the fishery may occur in the EMBA.		

Fishery	PAA/EMBA			Description
	Facility and Xena-03 Operational Areas	Export Pipeline Operational Area	EMBA	Potential for Interaction During Petroleum Activity Program × no spatial overlap ✓ spatial overlap Blue shading possibility for interaction
Western Tuna and Billfish Fishery	✓	✓	✓	The Western Tuna and Billfish Fishery management area overlaps the PAA and the EMBA. However, the majority of Australian catch has concentrated off south-west Western Australia with occasional activity off South Australia (Patterson et al., 2023). Woodside considers there to be no potential for interaction with this fishery and the Petroleum Activities Program.
Western Skipjack Tuna Fishery	✓	✓	✓	The Western Skipjack Tuna Fishery management area overlaps the PAA and the EMBA. The Western Skipjack Tuna Fishery spans the Australian Fishing Zone west of Victoria and the Torres Strait. The Fishery is currently not active, and no fishing has occurred since 2009 (Patterson and Dylewski, 2023b). Woodside considers there to be no potential for interaction with this fishery and the Petroleum Activities Program.
State Managed Fisheries				
Exmouth Gulf Prawn Managed Fishery	×	×	✓	The Exmouth Gulf Prawn Fishery is a prawn trawl fishery operating in Exmouth Gulf. Target species generally <50 m water depth. Fishing effort has been stable in the last 5 years with 6 vessels active during the 2020–2021 and 2021–2022 season (Wilkin et al., 2023a). The fishery management area overlaps with the EMBA. The fishery is limited to the spatial extent within the Exmouth Gulf and Muiron Islands. Woodside considers there to be a potential for interaction with this fishery in the EMBA.
Hermit Crab Fishery	×	✓	✓	The Hermit Crab Fishery management area overlaps the Export Pipeline Operational Area and the EMBA. The Land Hermit Crab Fishery is a shoreline fishery active North of Exmouth, with crabs taken onshore at night by hand. The fishery is active within the Export Pipeline Operational Area, with 60 NM CAES blocks only (DPIRD, 2023) with 2 licences active during the 2021-2022 fishing season (Newman et al., 2023). The activity is likely to occur predominantly in coastal waters outside of the Export Pipeline Operational Area. Woodside considers it a possibility that interactions with the fishery may occur in the Export Pipeline Operational Area and the EMBA.

Fishery	PAA/EMBA			Description
	Facility and Xena-03 Operational Areas	Export Pipeline Operational Area	EMBA	Potential for Interaction During Petroleum Activity Program × no spatial overlap ✓ spatial overlap Blue shading possibility for interaction
Mackerel Managed Fishery	✓	✓	✓	The Mackerel Managed Fishery management area (Area 2) overlaps the PAA and the EMBA (Areas 2 and 3). The fishery is active within the Facility and Xena-03 Operational Areas, and the Export Pipeline Operational Area. FishCube data for the Mackerel Managed Fishery reported less than 3 vessels active during the 2020-2021 season under 10 NM, and up to 6 vessels active over the last 5 years under 60 NM CAES blocks (DPIRD, 2023). The fishery is managed through designated Areas, and extends from coastal waters to the EEZ, in waters northwards of Cape Leeuwin to the NT border. Nominal catch rates in Area 2 (Pilbara) have been generally decreasing since 2004 (Lewis and Watt, 2023). Woodside considers it a possibility that interactions with the fishery may occur within the PAA and the EMBA.
Marine Aquarium Managed Fishery	✓	✓	✓	The Marine Aquarium Managed Fishery management area overlaps the PAA and the EMBA. The Marine Aquarium Fishery is a diver-based fishery and therefore typically restricted to relatively shallow waters. FishCube data for the fishery from within the EMBA is provided at 10 NM and 60 NM CAES blocks reporting a maximum of 4 licences under 10 NM and 7 licences active under 60 NM across the 2017–2023 seasons (DPIRD, 2023). Woodside considers it a possibility that interactions with the fishery may occur within the Export Trunkline Operations Area and the EMBA.
Nickol Bay Prawn Managed Fishery	×	×	✓	The Nickol Bay Prawn Managed Fishery management area overlaps the EMBA. The fishery is active in State waters and the EMBA with fishing effort at 10 NM CAES blocks recording 3 vessels active during the 2021-2022 fishing season, a decrease from 8 vessels in 2021–2022 (Wilkin et al., 2023b). Woodside considers it a possibility that interactions with this fishery may occur within the EMBA.
Onslow Prawn Managed Fishery	✓	✓	✓	The Onslow Prawn Managed Fishery management area overlaps the PAA and the EMBA. The fishery is active within the Export Pipeline Operational Area and EMBA with 60 NM CAES blocks reporting less than 3 vessels active during the 2021–2022 season (DPIRD, 2023). Woodside considers it a possibility that interactions with the fishery may occur in the Export Pipeline Operational Area and EMBA.

Fishery	PAA/EMBA			Description		
	Facility and Xena-03 Operational Areas	Export Pipeline Operational Area	EMBA	Potential for Interaction During Petroleum Activity Program		
				✖ no spatial overlap	✓ spatial overlap	Blue shading possibility for interaction
Pearl Oyster Managed Fishery (Zones 1 and 2)	✓	✓	✓	The Pearl Oyster Managed Fishery management area overlaps the PAA and the EMBA. Fishing effort is mostly focused within coastal waters (10–15 m depth) with a maximum depth of 35 m (Lulofs et al., 2002), collecting wild oysters for use in the aquaculture production of pearls. These are collected from fishing grounds primarily off the coast of Eighty Mile Beach with smaller catches from the Lacepede Islands. Woodside considers there to be no potential for interaction with this fishery and the Petroleum Activities Program.		
Pilbara Line Fishery (Condition)	✓	✓	✓	The Pilbara Line Fishery (Condition) licensees are permitted to operate anywhere within Pilbara waters (Wakefield et al., 2023), overlapping the PAA and the EMBA. The fishery is active in the PAA and the EMBA, with 60 NM CAES blocks reporting up to 5 vessels active across the 2017–2023 seasons (DPIRD, 2023). Fishing effort has decreased form 7 vessels activin in 2020–2021 to 6 vessels active in 2021-2022 (Wakefield et al., 2023). Woodside considers it a possibility that interactions with the fishery may occur within the Facility, Xena-03 and Export Pipeline Operational Area and the EMBA.		
Pilbara Crab Managed Fishery	✓	✓	✓	The Pilbara Crab Managed Fishery management area overlaps the PAA and the EMBA. The fishery operates via trap-based fishery methods up to 50 m and is concentrated around Dampier. The fishery is active in the Export Pipeline Operational Area and the EMBA, with 60 NM CAES blocks reporting less than 3 vessels active across the 2017–2023 seasons (DPIRD, 2023). Fishing effort has remained stable from 2020–2022 with 2 vessels active within the EMBA (Johnston et al., 2023). Woodside considers it a possibility that interactions with the fishery may occur within the Export Pipeline Operational Area and the EMBA.		
Pilbara Trap Managed Fishery	✓	✓	✓	The Pilbara Trap Managed Fishery management area overlaps the PAA and EMBA. The fishery is active within the Facility and Xena-03 Operational Areas, Export Pipeline Operational Area and the EMBA, with 60 MN CAES blocks reporting less than 3 vessels active across the 2017–2023 seasons (DPIRD, 2023). Fishing effort has increased from 7 active vessels during 2020–2021 to 8 vessels active in 2021–2022 (Wakefield et al., 2023). Woodside considers it a possibility that interactions with the fishery may occur within the PAA as well as the EMBA.		

Fishery	PAA/EMBA			Description		
	Facility and Xena-03 Operational Areas	Export Pipeline Operational Area	EMBA	Potential for Interaction During Petroleum Activity Program ✗ no spatial overlap	✓ spatial overlap	Blue shading possibility for interaction
Pilbara Fish Trawl (Interim) Managed Fishery	✗	✓	✓	The Pilbara Fish Trawl (Interim) Managed Fishery management area (Area 1) overlaps the Export Pipeline Operational Area and the EMBA. The fishery is active within the Export Pipeline Operational Area and EMBA with four 10 NM CAES blocks reporting up to four vessels across the 2017–2023 seasons (DPIRD, 2023). Fishing effort within the EMBA has been stable with 2 vessels active between 2018 and 2022 (Wakefield et al., 2023). Woodside considers it a possibility that interactions with the fishery may occur within the EMBA and the Export Pipeline Operational Area.		
Specimen Shell Managed Fishery	✓	✓	✓	The Specimen Shell Managed Fishery management area overlaps the PAA and the EMBA. The fishery is active within the Export Pipeline Operational Area and the EMBA. FishCube data for the fishery is provided at 10 NM and 60 NM CAES blocks reporting less than 3 licences under 10 NM and up to 3 licences under 60 NM CAES blocks active across 2017–2023 seasons (DPIRD, 2023). The fishery is largely diver-based, targeting specimen shells in water depths mostly <30 m. Given the depth of the Export Pipeline Operational Area at its shallowest, it is not likely to interact with the fishery. Woodside considers it a possibility that interactions with the fishery may occur in the Export Pipeline Operational Area and the EMBA.		
West Coast Deep Sea Crustacean Managed Fishery	✓	✓	✓	The West Coast Deep Sea Crustacean Managed Fishery management area overlaps the PAA and the EMBA. The fishery is prohibited to fish landwards of the 150 m isobath, restricting any potential interactions to activities within the Facility and Xena-03 Operational Areas. Most of the commercial crab catch is taken in depth of 500 m to 800 m (WAFIC, 2024). The fishery is active within the EMBA, with 5 vessels active during the 2021–2022 season (Tuffley et al., 2023). Woodside considers it a possibility that interactions with the fishery may occur within the EMBA only.		

Fishery	PAA/EMBA			Description		
	Facility and Xena-03 Operational Areas	Export Pipeline Operational Area	EMBA	Potential for Interaction During Petroleum Activity Program		
				✖ no spatial overlap	✓ spatial overlap	Blue shading possibility for interaction
Western Australian Sea Cucumber Fishery	✓	✓	✓	The Western Australian Sea Cucumber Fishery management area overlaps the PAA and the EMBA. The fishery is active within the EMBA, with 60 NM CAES blocks reporting less than 3 vessels active across the 2017–2019 seasons. The fishery operates as a wader and diver-based fishery in the Kimberley region and therefore would typically be restricted to coastal waters outside of the Export Pipeline Operational Area. Woodside considers it a possibility that interactions with the fishery may occur in the Export Pipeline Operational Area and the EMBA.		
South West Coast Salmon Managed Fishery	✓	✓	✓	The South West Coast Salmon Managed Fishery management area overlaps the PAA and EMBA. Historically, no fishing has occurred north of the Perth Metropolitan Area. Therefore, no effort is reported within the EMBA (Duffy et al., 2023) and Woodside considers there to be no potential for interaction with this fishery within the PAA and EMBA.		
Western Australian Abalone Managed Fishery	✓	✓	✓	The Abalone Fishery management area overlaps the PAA and the EMBA. The fishery operates in shallow coastal waters off the south-west and south coasts of WA (Strain et al., 2023). Given the fishery method (shore-based and hand caught) and water depths of the PAA there are no CAES blocks reporting fishing effort within the PAA. Woodside considers there to be no potential for interactions with the fishery within the EMBA or PAA.		
West Coast Rock Lobster Managed Fishery	✖	✖	✓	The Western Rock Lobster Fishery management area overlaps the EMBA. The fishery mainly operates off the west coast of WA between Shark Bay and Cape Leeuwin (de Lestang and Walsh, 2023). There is no CAES block reporting fishing effort within the EMBA. Woodside considers there to be no potential for interactions with the fishery within the EMBA.		
WA North Coast Shark Fishery	✓	✓	✓	The North Coast Shark Fishing area overlaps the PAA and the EMBA. The northern shark fisheries comprise of the North Coast Shark Fishery in the Pilbara and Western Kimberly (closed since 1998), and the Joint Authority of Northern Shark Fishery in the eastern Kimberly, which has not been active since the 2008–2009 season (AFMA, 2021). Woodside considers there to be no interaction with the fishery and the Petroleum Activities Program.		
Charter Based Commercial Operators						

Fishery	PAA/EMBA			Description		
	Facility and Xena-03 Operational Areas	Export Pipeline Operational Area	EMBA	Potential for Interaction During Petroleum Activity Program ✖ no spatial overlap	✓ spatial overlap	Blue shading possibility for interaction
Tour Operators	✓	✓	✓	Fishing Tour Operators are permitted to operate across WA state waters and are required to report monthly logbook records of client fish catches. The fishery is active within the Facility and Xena-03 Operational Areas and Export Pipeline Operational Area as well as the EMBA. FishCube data indicates fishing effort across the 10 NM and 60 NM CAES blocks overlap the PAA. Fishing effort at 10 NM scale has been consistent over the last 5 years reporting no more than 3 licence holders (DPIRD, 2023). FishCube data provided for 60 NM recorded up to 5 licences active across the 2017–2023 seasons (DPIRD, 2023). Woodside considers interaction with tour operators a possibility within the Facility and Xena-03 Operational Areas, the Export Pipeline Operational Area, and the EMBA.		

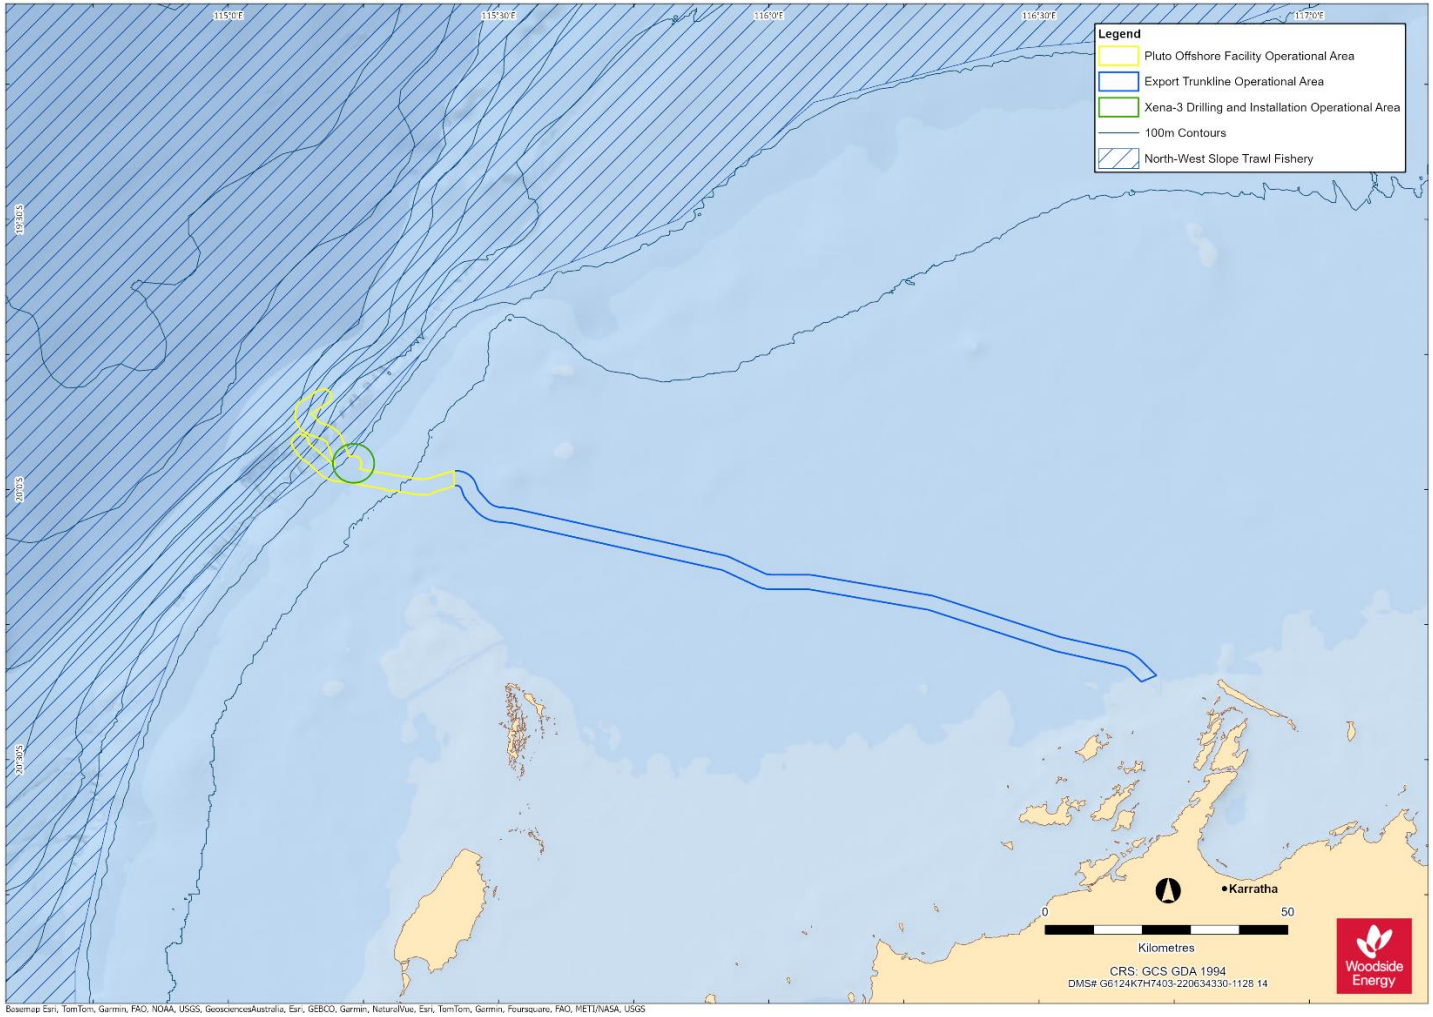

Figure 4-14: Commonwealth managed commercial fisheries overlapping the PAA with a potential for interaction with the PAP

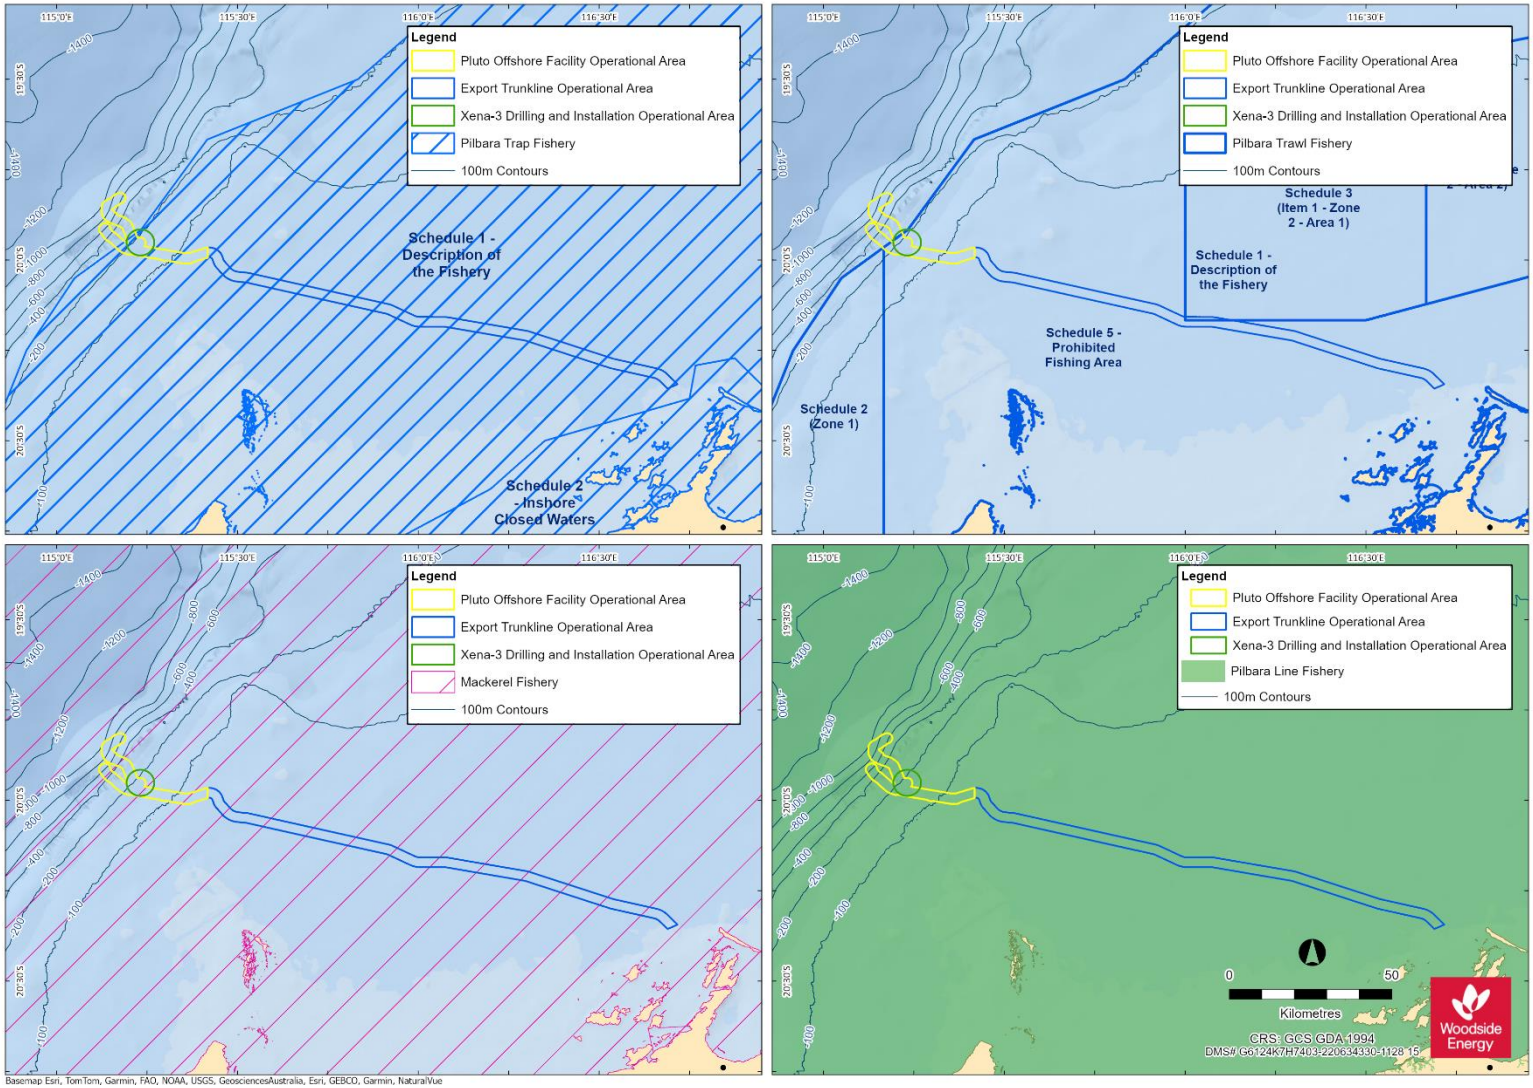

Figure 4-15: State-managed (Western Australia) commercial fisheries overlapping the PAA with a potential for interaction with the PAP

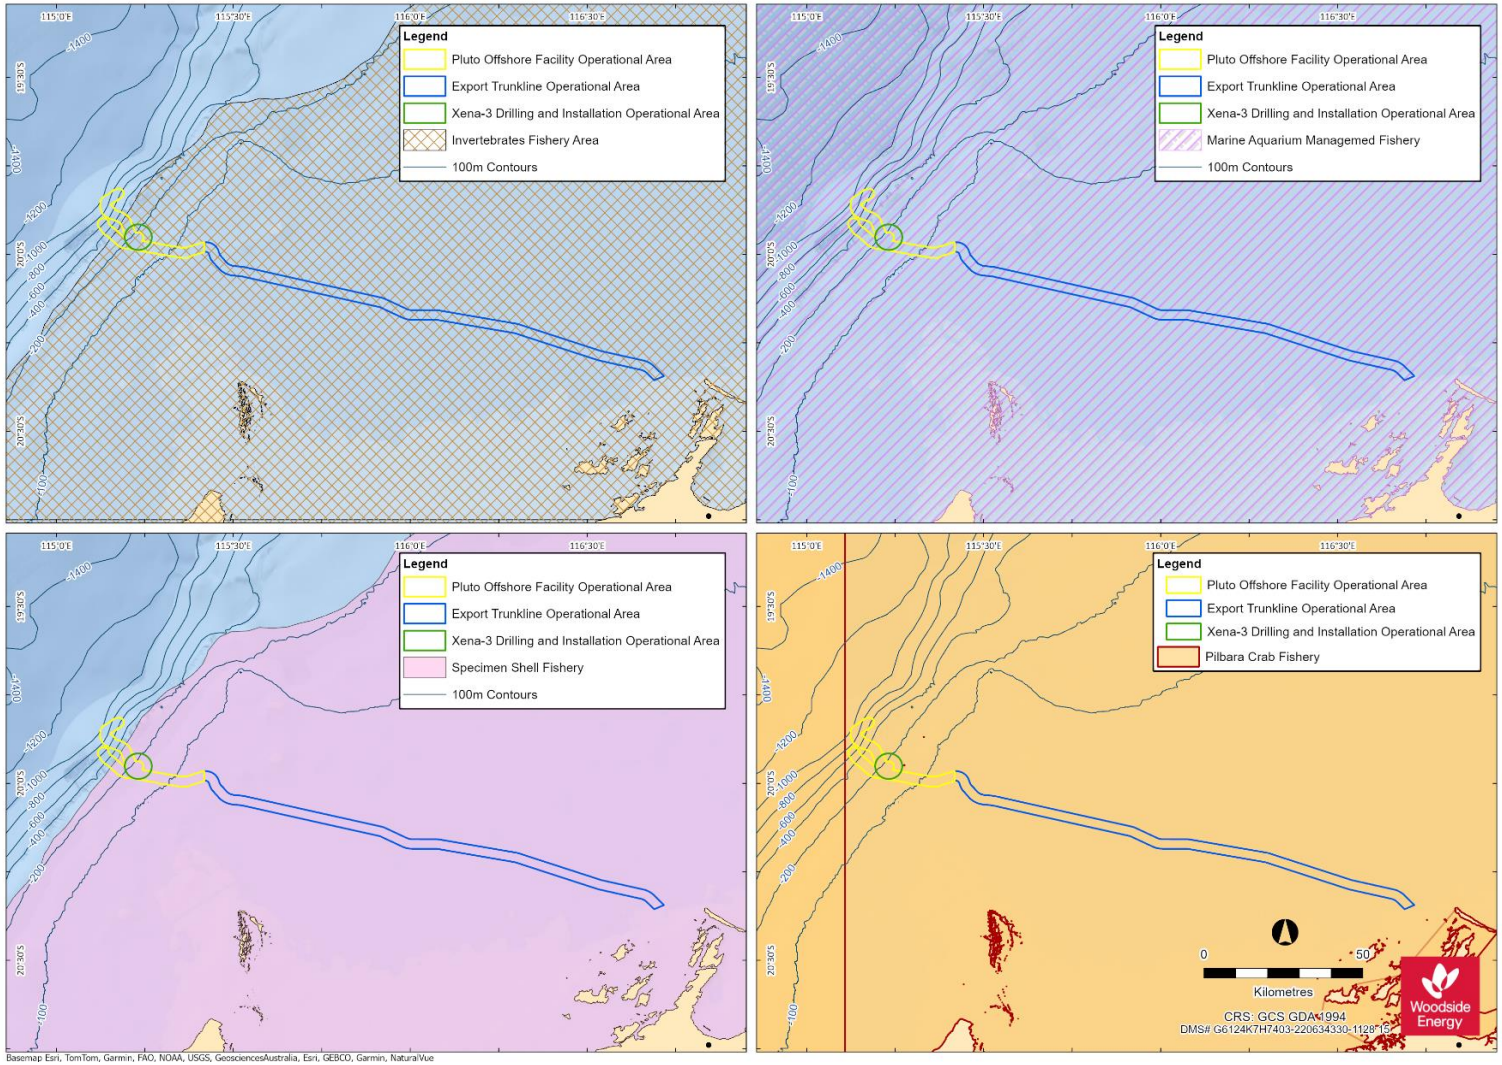

Figure 4-16: State-managed (Western Australia) commercial fisheries overlapping the PAA with a potential for interaction with the PAP

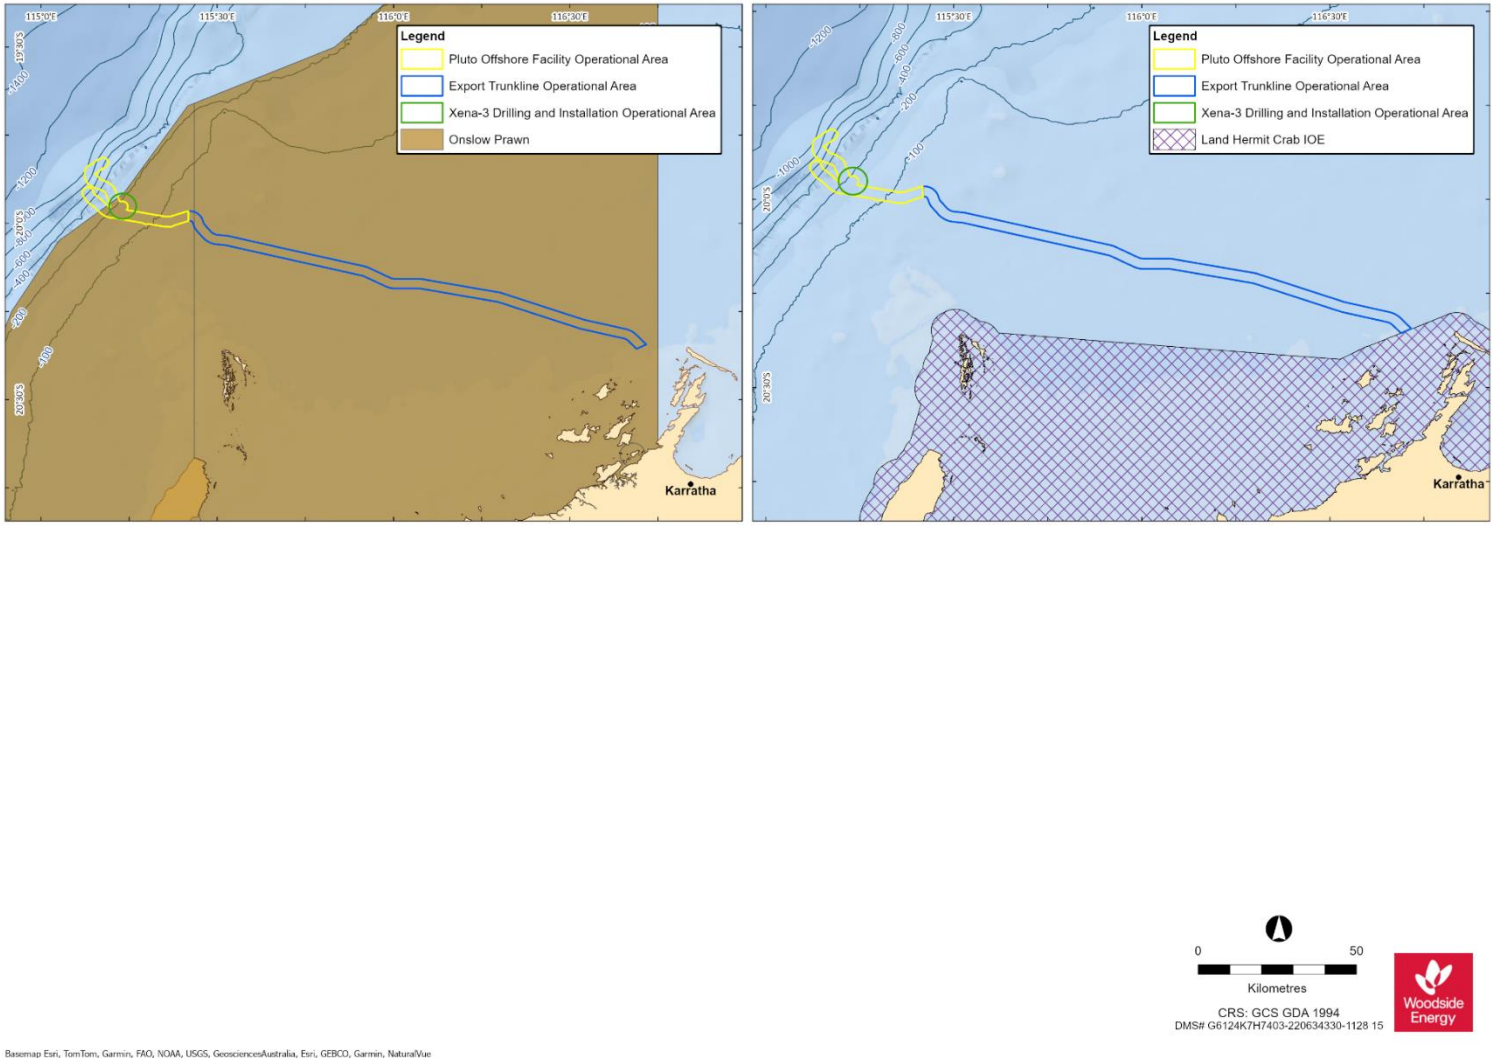

Figure 4-17: State-managed (Western Australia) commercial fisheries overlapping the PAA with a potential for interaction with the PAP

4.10.2 Traditional Fisheries

There are no traditional or customary fisheries within the PAA, as these are typically restricted to shallow coastal waters and/or areas with structures such as reefs. However, it is recognised that Barrow Island, Montebello Islands and Ningaloo Reef, all within the wider EMBA, have a known history of fishing when areas were occupied (as from historical records) (Department of Conservation and Land Management (DCLM), 2005, Department of Environment and Conservation (DEC), 2007). Areas that are covered by registered native title claims are likely to practice Aboriginal fishing techniques at various sections of the Western Australia coastline. Further information on traditional fishing activity that is likely to occur in the EMBA is provided in Appendix K).

4.10.3 Tourism and Recreation

The recreation and tourism industries in the Pilbara are of high social value with approximately 965,000 visitors over the last five years (Tourism Western Australia, 2023). Tourism continued to grow in 2022, with over one million visitors (Tourism Western Australia, 2023). Growth and the potential for further expansion in tourism and recreational activities are recognised for the Pilbara region, with the development of regional centres and a workforce associated with the resources sector (SGS Economics and Planning, 2012).

The PAA is located offshore of the North West tourism region, which includes parts of the Gascoyne, Pilbara, and Kimberley region. Tourism is concentrated in the vicinity of population centres such as Broome, Dampier, Exmouth, Coral Bay, and Shark Bay. The population centre closest to the PAA is the town of Dampier (31 km from the Export Pipeline Operational Area and 157 km from the Facility and Xena-03 Operational Areas). No tourist activities take place specifically within the PAA.

The nearest tourism areas include the Montebello State Marine Park (25 km from the Export Pipeline Operational Area and 34 km from the Facility and Xena-03 Operational Areas) and the Montebello Marine Park, which is located in deeper offshore waters and overlaps the Facility and Export Pipeline Operational Areas. These tourism areas have some charter boat operators taking visitors to islands (Department of Environment and Conservation, 2007). Recreational fishing in the Pilbara and Gascoyne regions is mainly concentrated around the coastal waters and islands and has grown considerably with the expanding regional centres, seasonal tourism and increasing residential and fly in/fly out work force, particularly in the Pilbara region (Fletcher et al., 2017). Some recreational fishing has historically taken place at Rankin Bank (approximately 29 km north-east of the PAA at the closest point). However, due to the distance from access nodes, such as Dampier and Onslow (approximately 31 km south and 180 km southwest from the PAA at the closest point respectively) recreational fishing effort is expected to be restricted to relatively large vessels and hence is considered to be low.

4.10.4 Commercial Shipping

The Australian Maritime Safety Authority (AMSA) has introduced a network of marine fairways across the NWMR off WA to reduce the risk of vessel collisions with offshore infrastructure. Two fairways overlap the Export Pipeline Operational Area, and none overlap with the Facility and Xena-03 Operational Areas (

Figure 4-18). Ports in the region are nodes of increased vessel activities. Active ports within the vicinity of the PAA include:

- Dampier (approximately 30 km south)
- Barrow Island (approximately 85 km south)
- Port Walcott (approximately 160 km south)
- Onslow (approximately 180 km south)

- Port Hedland (approximately 200 km south-east).

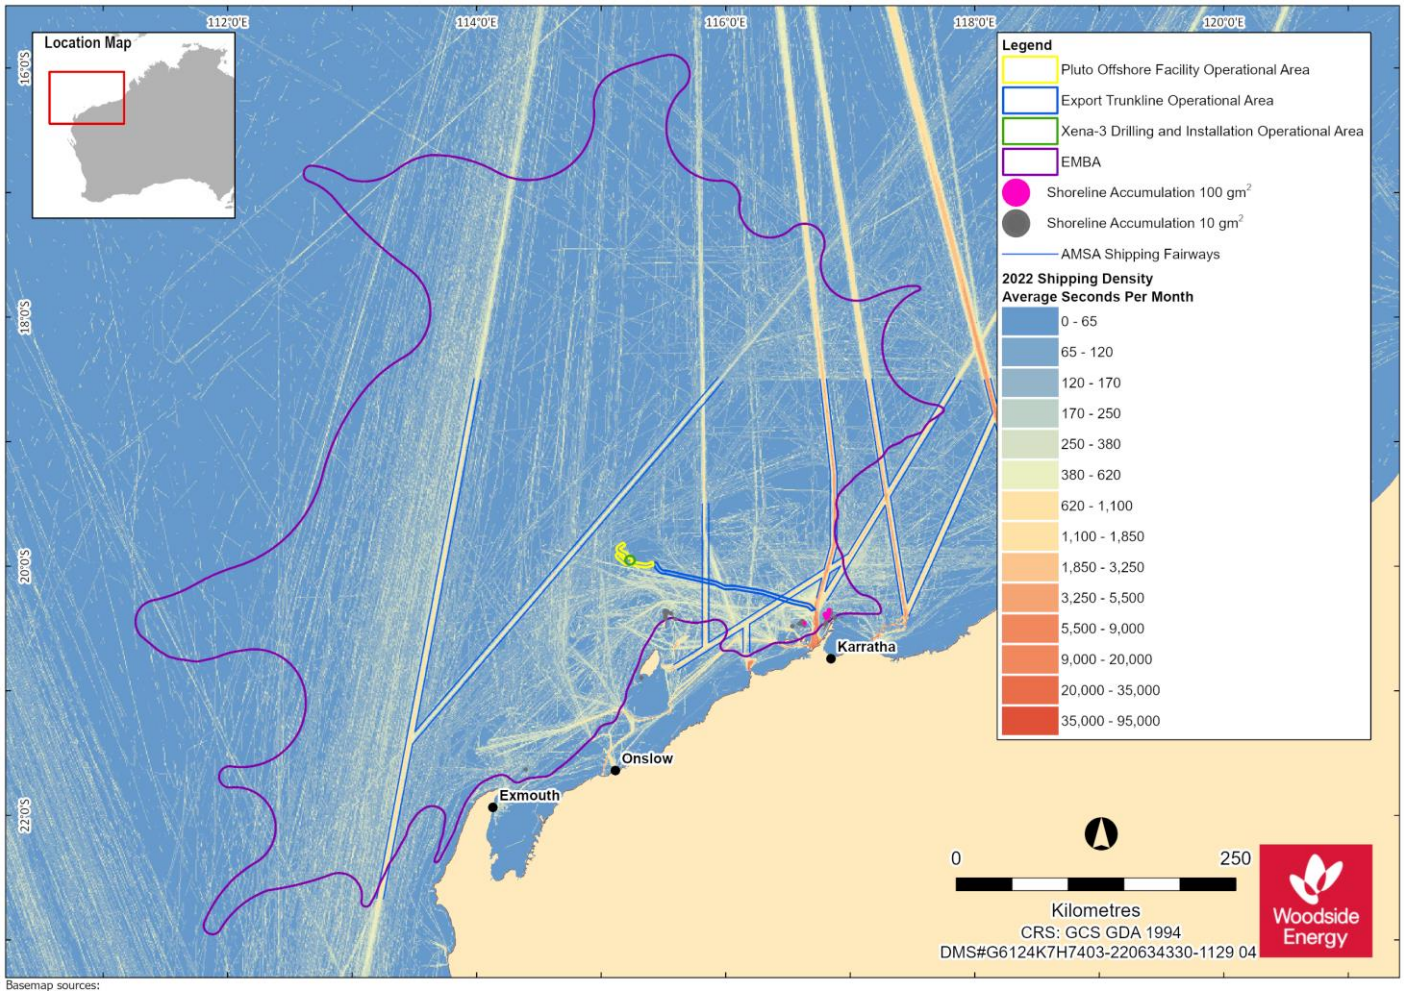

Figure 4-18: Vessel density map for the PAA, derived from AMSA satellite tracking system data (vessels include cargo, LNG tanker, passenger vessels, support vessels, and others/unnamed vessels

4.10.5 Oil and Gas

The PAA is located within an area of established oil and gas operations in the broader NWMR. Table 4-24 details the proximity of other oil and gas facilities within the region to the operational areas within the PAA. Appendix K describes current oil and gas development within the EMBA, also shown in Figure 4-19.

There are also facilities with intersecting subsea infrastructure, including:

- Julimar Brunello production pipeline (Woodside)
- Wheatstone pipeline (Chevron)
- Reindeer offshore gas supply pipeline (Santos)
- Scarborough export trunkline (Woodside).

Table 4-24: Other oil and gas facilities located within 70 km of the PAA

Facility Name and Operator	Distance and Direction from Facility and Xena-03 Operational Areas	Distance and Direction from Export Pipeline Operational Area
Wheatstone platform (Chevron)	5 km north	5 km north
Angel platform (Woodside)	48 km north	48 km north
John Brookes (Santos)	50 km south	57 km south-west
Goodwyn Alpha platform (Woodside)	72 km north-east	51 km north
North Rankin complex (Woodside)	86 km north-east	64 km north
Reindeer wellhead platform (Santos)	109 km east	12 km north
Stag A (Jadestone)	112 km south-east	8 km south
Wandoo B (VOGA)	123 km south-east	12 km south

The PAA overlaps the following titles for which Woodside is not a titleholder:

- WA-48-L: Chevron Australia Pty Ltd is the contact titleholder of production licence WA-48-L.
  - Part of the Facility Operational Area, including the Pluto Platform (WA-1-IL) and part of the Pluto subsea infrastructure within WA-16-PL overlap WA-48-L (Figure 4-19). While the platform and IMMR activities will be undertaken within Woodside operated pipeline and infrastructure licences, the Operational Area includes a radius of 1,500m from the platform and subsea infrastructure, and allows for the movement and positioning of vessels. This means that vessel surface activity may temporarily occur within this adjacent Title during crewed platform activities and some IMMR activities.
  - The Xena-03 well and subsea infrastructure is located in close proximity to WA-48-L. The Xena-03 Operational Area extends 4000 m from the well and into WA-48-L to allow for vessel movement which may temporarily occur within this adjacent title.

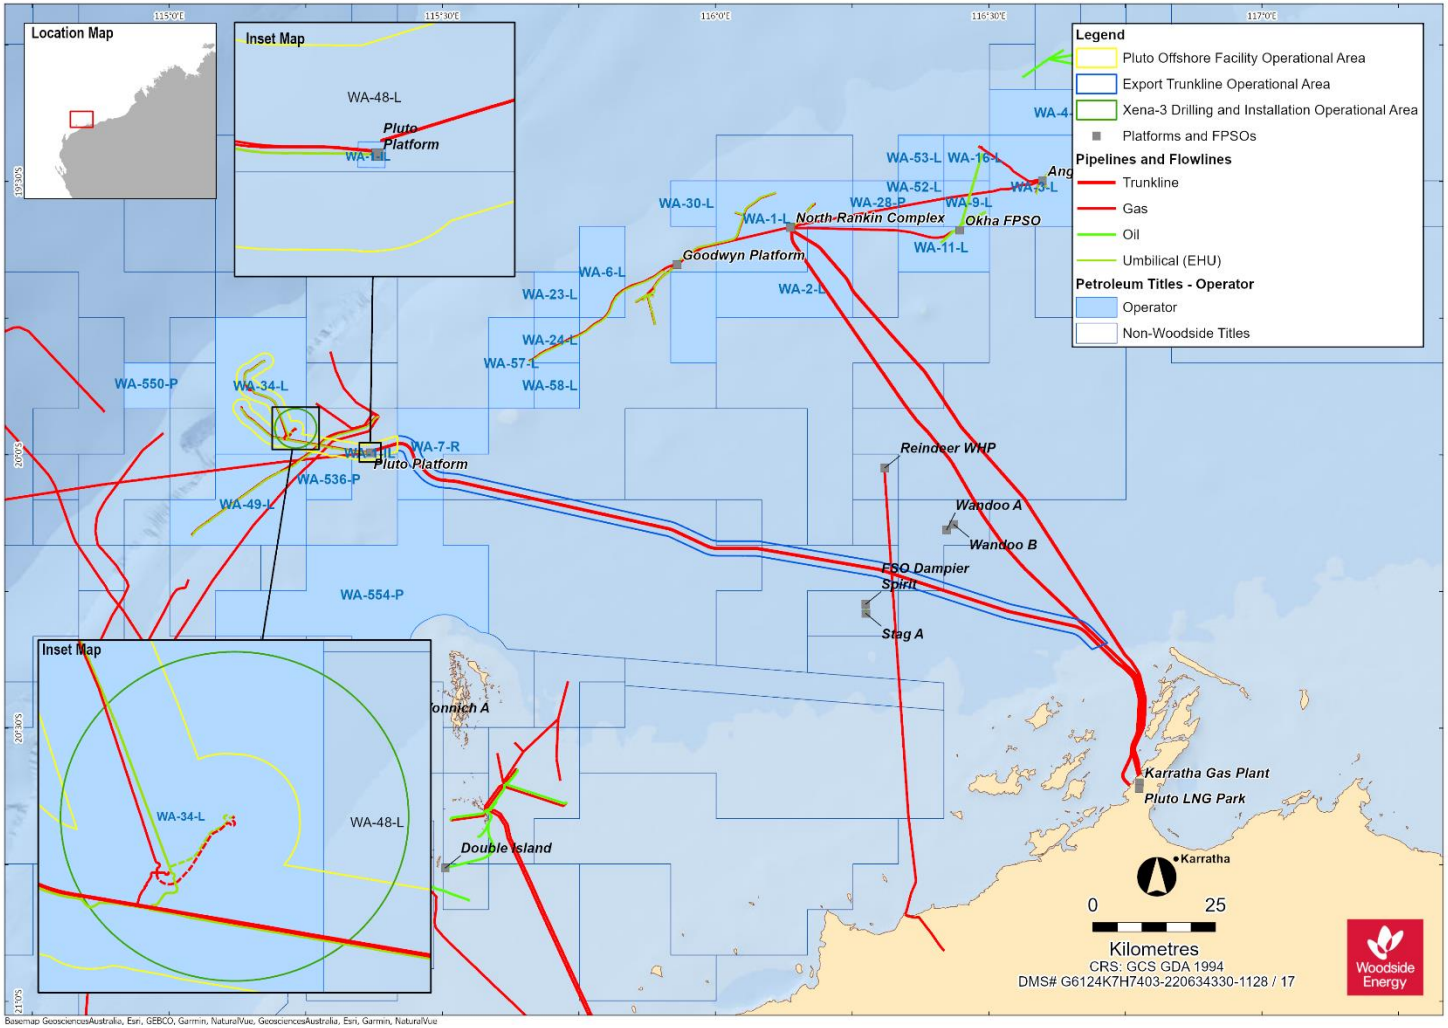

Figure 4-19: Oil and gas facilities located within the EMBA

4.10.6 Submarine Communications Infrastructure

The PAA is located in a region with submarine communications infrastructure. The submarine communications infrastructure located within 50 km of the PAA is listed in Table 4-25.

Table 4-25:Communications Infrastructure located within 50 km of the PAA

Communications Infrastructure (submarine cables)	Distance and direction from PAA to Facility
Woodside Fibre Optic Cable Route	~21 km from the Export Trunkline Operational Area
Scarborough Fibre Optic Cable	~18 km from the Facility Operational Area
Chevron Fibre Optic Cable Route	Intersects Export Trunkline Operational Area in two places

Source: Submarine cable locations sourced from Vocus and Telstra.

4.10.7 Defence

Department of Defence (DoD) areas, facilities and UXOs near the PAA and within the EMBA are outlined in Table 4-26. There are no DoD areas overlapping the PAA. Appendix Kdescribes key DoD areas and facilities.

Table 4-26: Defence areas, facilities and unexploded ordnances overlapping the PAA or EMBA

Defence Area/Facility	Presence	
	PAA	EMBA
UXO SDG096 Sea Dumping: Anchor Island. This site is an area used for the dumping at sea of ordnance and other items.		✓
Potential Depth Charge UXO DEP022: Northwest of Bessieres Island. This site was an area where Depth Charges were used in WWII and where some depth charges failed to function.		✓
Potential Depth Charge UXO DEP027: East of Montebello Islands. This site was an area where Depth Charges were used in WW2 and where some depth charges failed to function.		✓

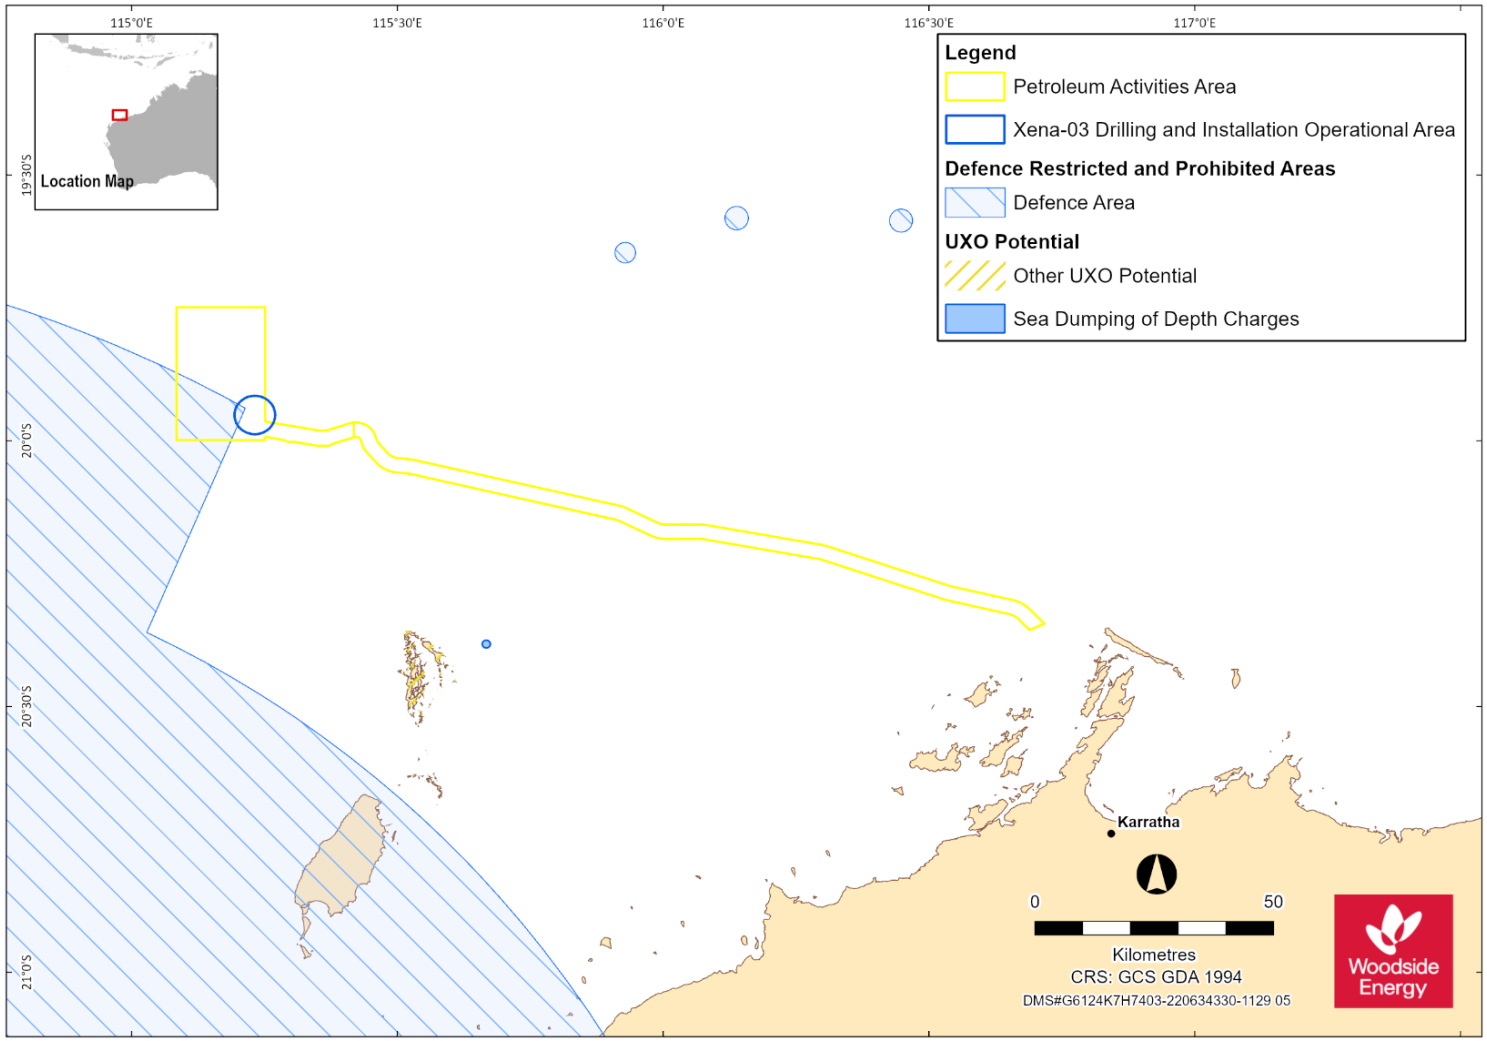

Figure 4-20: Defence areas relative to the PAA

5. CONSULTATION

5.1 Summary

Woodside consults relevant persons in the course of preparing an Environment Plan (EP) in accordance with Regulation 25 of the Environment Regulations. (In this section, references to 'Regulations' are to Regulations of the Environment Regulations, unless otherwise stated).

The consultation process is designed to identify relevant persons and provide them with sufficient information and a reasonable period to allow them to make an informed assessment of the possible consequences of the proposed activity on their functions, interests or activities. This enables Woodside to assess the merits of objections or claims about the adverse impact of each activity to which the EP relates that are received from relevant persons and for Woodside to adopt appropriate measures (if any) in response to those objections or claims so that the activity is carried out in a manner by which the environmental impacts and risks of the activity will be reduced to as low as reasonably practicable (ALARP) and will be of an acceptable level.

Consultation is informed by both the Environment Regulations and the findings of relevant Courts, including the Full Federal Court in the *Santos NA Barossa Pty Ltd v Tipakalippa [2022]* FCAFC 193 (Tipakalippa Appeal) (see Section 5.2 and 5.5.1) and *Munkara v Santos NA Barossa Pty Ltd (No 3) [2024]* FCA 9 (Munkara Case).

For this EP, Woodside has considered both the PAA and the broader EMBA in undertaking consultation (see further discussion in Section 5.2). The broadest extent of the EMBA has been determined by reference to the highly unlikely event of a hydrocarbon release resulting from the activities in the PAA (see Section 4). Consultation beyond the defined EMBA is too remote, would mean persons with interests are not reasonably capable of ascertainment and would mean consultation is not workable (*Tipakalippa* para [88]).

Woodside's consultation methodology is divided into two parts:

- The first part (Section 5.2 to 5.5) provides an overview of Woodside's consultation methodology for its EPs, including how we apply Regulation 25(1) to identify relevant persons.
- The second part (Sections 5.6 and 5.7) details Woodside's approach to accepting feedback and assessment of the merits of each objection or claim about the adverse impact of each activity to which the EP relates, and engaging in ongoing consultation for this EP.

Woodside's consultation record is in Appendix F and includes a summary of the following:

- assessment and identification of relevant persons
- consultation information provided to relevant persons, feedback received, Woodside's assessment of the merits of objections or claims and Woodside's response to relevant persons and other stakeholders Woodside chose to consult
- engagement with persons or organisations that Woodside chose to contact who are not relevant persons for the purposes of Regulation 25(1) (see Section 5.3.4)
- opportunities provided to persons or organisations to participate in consultation.

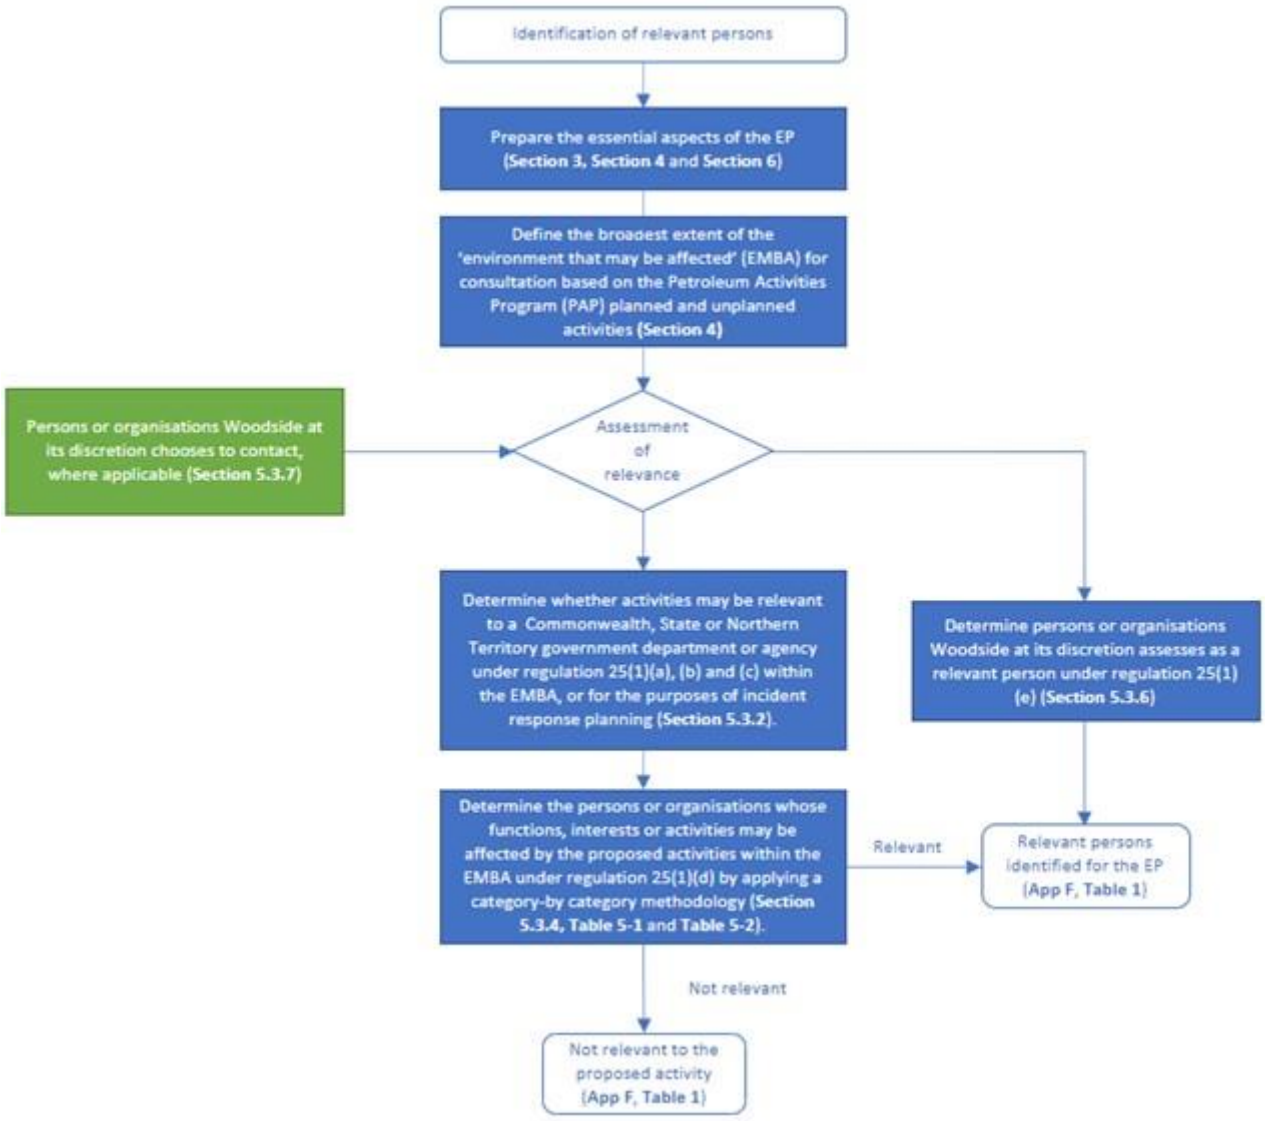

Figure 5-1: Overview of Woodside's methodology to identify relevant persons

5.2 Consultation – General Context

Woodside has a portfolio of quality oil and gas assets and more than 40 years of operating experience. We have a strong history of working with local communities, the relevant regulators and a broad range of persons and organisations, to better understand the potential risks and impacts associated with our proposed activities and to develop appropriate measures to manage them.

The length of time that we have operated in Commonwealth and State waters, and the history of continued engagement with a wide range of persons and organisations, enables Woodside to develop an extensive consultation list to inform its consultation process. This consultation list is not used as a definitive list of persons to consult but, rather, assists Woodside as an input to its understanding of relevant persons with whom to consult on a Petroleum Activities Program. The information in the consultation list has been captured from years of experience: it contains insights relating to the type of information particular persons or organisations want to receive during consultation, the appropriate method of consultation for relevant persons and includes appropriate contact details, which are reviewed and updated periodically.

Woodside acknowledges NOPSEMA's GL2086 - *Consultation in the course of preparing an environment plan* guideline (May 2023) as well as judicial guidance in the *Tipakalippa Appeal* on the intent of consultation, as follows:

- At paragraph 54 of the appeal decision: … *provide a basis for NOPSEMA's considerations of the measures, if any, that a titleholder proposes to take or has taken to lessen or avoid the deleterious effect of its proposed activity on the environment, as expansively defined.*
- At paragraph 89 of the appeal decision: … *its purpose is to ensure that the titleholder has ascertained, understood and addressed all the environmental impacts and risks that might arise from its proposed activity. Consultation facilitates this outcome because it gives the titleholder an opportunity to receive information that it might not otherwise have received from others affected by its proposed activity. Consultation enables the titleholder to better understand how others with an objective stake in the environment in which it proposes to pursue the activity perceive those environmental impacts and risks. As the Regulations expressly contemplate, it enables the titleholder to refine or change the measures it proposes to address those impacts and risks by taking into account the information acquired through the consultations. Objectively, the scheme intends that this is likely to improve the minimisation of environmental impacts and risks from the activity.*

The *Tipakalippa Appeal* and *Munkara Case* have also been further considered in the context of specific methods for consultation with First Nations' relevant persons (Section 5.5.1).

To undertake consultation, Woodside has developed a methodology for identifying relevant persons in accordance with Regulation 25(1) (Section 5). This methodology is consistent with NOPSEMA's Guideline and demonstrates that, to meet the requirements of Regulation 34 (criteria for EP acceptance) when preparing the EP, Woodside understands:

- our planned activities in the PAA, being the area in which our planned activities are proposed to occur (see Section 3.2.1)
- the geographical extent to which the environment may be affected (EMBA) by risks and impacts from our activities (unplanned) (identified in Section 4.1 and assessed in Section 6.8).

Woodside has undertaken consultation in the course of preparing this EP in compliance with Regulation 25, which requires a Titleholder to:

- consult with each of the following (a relevant person):
  - each Commonwealth, State or Northern Territory agency or authority to which the activities to be carried out under the EP may be relevant
  - if the plan relates to activities in the offshore area of a state – the Department of the responsible State Minister
  - if the plan relates to activities in the Principal Northern Territory offshore area – the Department of the responsible Northern Territory Minister
  - a person or organisation whose functions, interests or activities may be affected by the activities to be carried out under the EP
  - any other person or organisation that the titleholder considers relevant (Regulation 25(1)).
- give each relevant person sufficient information to allow the relevant person to make an informed assessment of the possible consequences of the activity on their functions, interests or activities (Regulation 25(2))
- allow a relevant person a reasonable period for the consultation (Regulation 25(3))

- tell each relevant person that the Titleholder consults with, that the relevant person may request that particular information it provides in the consultation not be published and any information subject to such a request is not to be published (Regulation 25(4)).

Further, Woodside seeks to carry out consultation in a manner that:

- is consistent with the principles of ecologically sustainable development (ESDev) set out in section 3A of the EPBC Act – see Section 2
- is intended to reduce the environmental impacts and risks from the activity to ALARP and an acceptable level (Regulation 4)
- is intended to minimise harm to the relevant person and the environment from the proposed petroleum activities and to enable Woodside to consider measures that may be taken to mitigate the potential adverse environmental impacts from the petroleum activity
- is collaborative; Woodside respects that, for a relevant person, consultation is voluntary. Where the relevant person seeks to engage, Woodside engages with the relevant person with the aim of seeking genuine and meaningful two-way dialogue
- provides opportunities for relevant persons to provide feedback throughout the life of the EP through its ongoing consultation process (refer to Section 5.7 and Section 7.12).

An overview of Woodside's consultation approach is outlined at Figure 5-2.

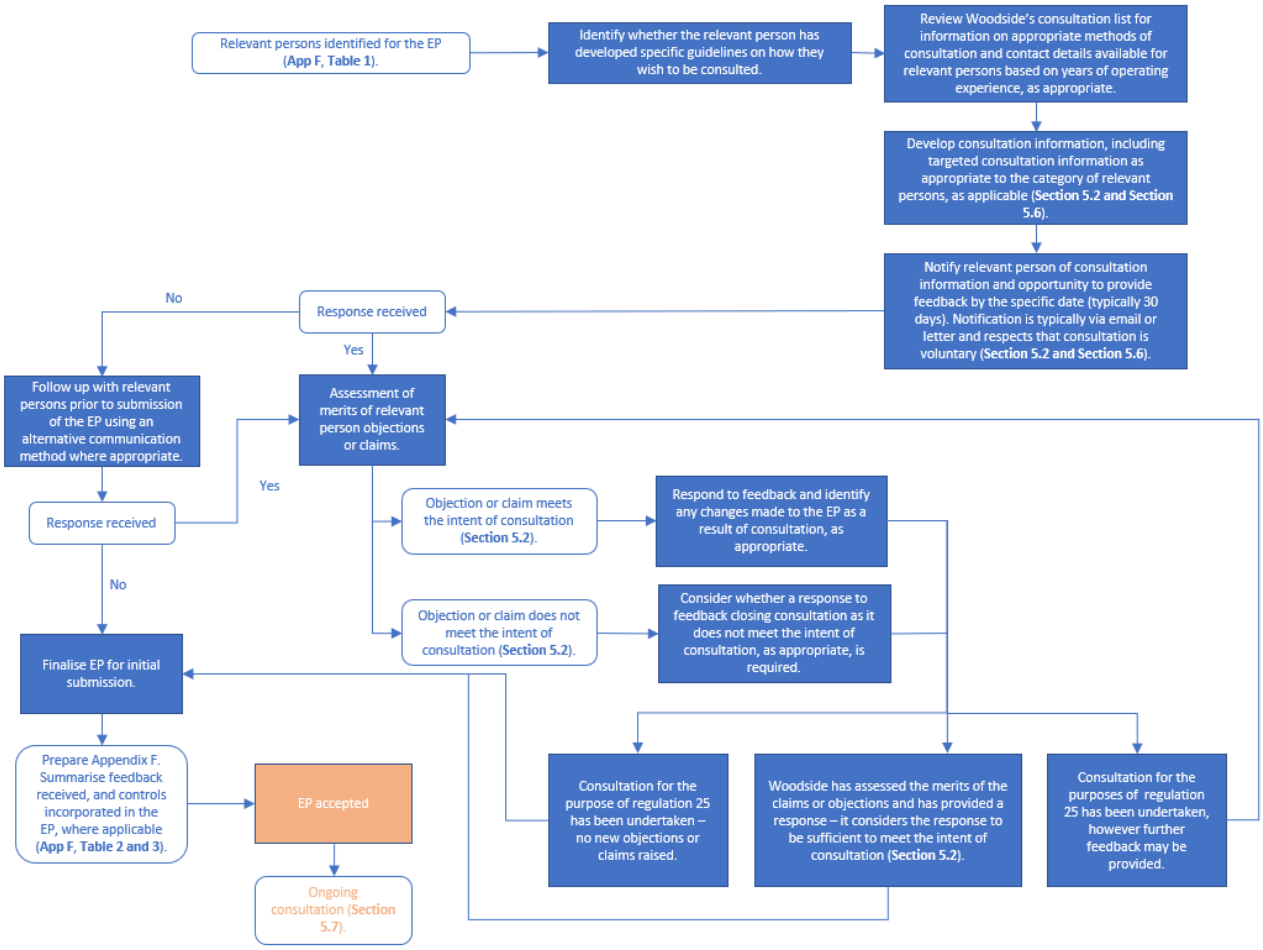

Figure 5-2: Overview of Woodside's consultation approach

The methodology for consultation for this activity has been informed by various guidelines and relevant information for consultation on planned activities, including:

Federal Court:

- Santos NA Barossa Pty Ltd v Tipakalippa [2022] FCAFC 193
- Munkara v Santos NA Barossa Pty Ltd (No 3) [2024] FCA 9.

5.3 Identification of Relevant Persons for Consultation

5.3.1 Regulations 25(1)(a), (b) and (c)

The relevant inquiry for determining relevant persons under Regulations 25(1)(a) and (b) is whether the activities to be carried out under the EP may be relevant to one of the government departments

or agencies in those Regulations. The government departments and agencies relevant to the EP are listed in Appendix F, Table 1. In accordance with Regulation 25(1)(b), Woodside consults with the Department of the relevant State Minister.

5.3.2 Identification of Relevant Persons under Regulations 25(1)(a), (b) and (c)

Woodside's methodology for identifying relevant persons under Regulations 25(1)(a), (b) and (c) is as follows:

- Woodside considers the defined responsibilities of each of the departments and agencies to which the activities to be carried out in the EMBA under the EP may be relevant. This list of relevant departments and agencies is formulated by reference to the responsibilities of the government departments, as set out on their websites, in NOPSEMA's GL1887 – Consultation with Commonwealth agencies with responsibilities in the marine area guideline (January 2024), which describes where the Department is a relevant agency under the Environment Regulations, as well as experience and knowledge that Woodside has gained from years of operating. This list is revised from time to time, for example, for the purposes of accommodating government restructures, renaming of departments, shifting portfolios and/or to account for new agencies that might arise.
- Woodside has categorised government department or agency groups as follows:

– ***Government departments / agencies – marine***	– Agencies with legislated responsibilities for use of the marine environment.
– ***Government departments / agencies – environment***	– Agencies with legislated responsibilities for the protection of the environment.
– ***Government departments / agencies – industry***	– The legislated Department of the responsible Commonwealth, State or Northern Territory Minister for Industry.

- Woodside considers each of the responsibilities of the departments and agencies, determining whether those responsibilities overlap with potential risks and impacts specific to the PAA in the EMBA. The assessment is both activity and location based.
- Woodside acknowledges the roles and responsibilities of government departments and agencies acting on behalf of various industry participants. For example, AMSA – Marine Safety is responsible for the safety of vessels and the seafarers who are operating in the domestic commercial shipping industry; and AHO is responsible for maritime safety and Notices to Mariners. To undertake the PAP in a manner that prevents a substantially adverse effect on the potential displacement of marine users, Woodside therefore consults AMSA – Marine Safety and AHO on its proposed activities. Woodside considers each of the responsibilities of the departments and agencies and determines those that would either be involved in the incident response itself or in relation to the regulatory or decision-making capacity with respect to planning for the unlikely event of a worst-case hydrocarbon release incident response specific to the Operational Area. Feedback received, if any, is assessed in accordance with the intended outcome of consultation.
- The list of government departments and agencies assessed as relevant is set out in Appendix F, Table 1.
- Feedback received, if any, is assessed in accordance with the intended outcome of consultation and summarised at Appendix F, Table 2 and Table 3 as appropriate to the relevance assessment.

Woodside does not consult with departments or agencies with interests that do not overlap with risks and impacts specific to the PAA in the EMBA or would not be involved in incident response planning.

5.3.3 Regulation 25(1)(d)

To identify a relevant person for the purposes of Regulation 25(1)(d), the meaning of "*functions, interests or activities*" needs to be understood. In Regulation 25(1)(d), the phrase "*functions, interests or activities*" should be construed broadly and consistently with the objects of the Environment Regulations (Regulation 4) and the objects of the *EPBC Act* (section 3A).

In developing its methodology for consultation, Woodside acknowledges the guidance below from NOPSEMA's *GL2086 – Consultation in the course of preparing an environment plan guideline* (May 2023):

- functions: refers to a power or duty to do something
- interests: conforms to the accepted concept of 'interest' in other areas of public administrative law and includes any interest possessed by an individual whether or not the interest amounts to a legal right or is a proprietary or financial interest or relates to reputation
- activities: broader than the definition of 'activity' in Regulation 5 of the Environment Regulations and is likely be directed to what the relevant person is already doing.

Woodside's methodology for determining 'relevant persons' for the purpose of Regulation 25(1)(d) includes consideration of:

- whether a person or organisation has functions interests or activities that overlap with the Operational Area or PAA, and EMBA
- whether a person or organisation's functions, interests or activities may be affected by Woodside's proposed planned or unplanned activities.

5.3.4 Identification of Relevant Persons under Regulation 25(1)(d)

Relevant persons under Regulation 25(1)(d) are defined as a person or organisation whose functions, interests or activities may be affected by the activities to be carried out under the EP. In identifying relevant persons, Woodside considers:

- the planned activities to be carried out under the EP (described in Section 3)
- the EMBA by unplanned activities (identified in Section 4 and assessed in Section 6).

To identify relevant persons who fall within Regulation 25(1)(d), Woodside adopts the following methodology and then undertakes consultation with relevant persons.

As a general proposition, Woodside assesses whether a person or organisation is a relevant person having regard to:

- whether a person or organisation has functions, interests or activities that overlap with the Operational Area or PAA, and EMBA
- whether a person or organisation's functions, interests or activities may be affected by Woodside's proposed planned or unplanned activities to be carried out under the EP.

This assessment will include applying judgement, knowledge and considering available, relevant literature.

To assist in identifying the full range of relevant persons, Woodside considers the impacts and risks associated with its proposed activities and considers the broad categories of relevant persons who may be affected by the activities to be carried out under the EP. The broad categories are identified in Table 5-1 and identification methodology applied as set out in Table 5-1.

The list of those persons or organisations assessed as relevant persons or organisations Woodside separately chose to contact is set out in Appendix F, Table 1.

Feedback received, if any, is assessed in accordance with the intended outcome of consultation and applying the categories of relevant persons methodology outlined in Table 5-3, as appropriate.

Feedback from relevant persons is summarised at Appendix F, Table 2. Feedback from persons assessed as "not relevant" but whom Woodside chose to contact, or self-identified and Woodside assessed as "not relevant", are summarised at Appendix F, Table 3.

Table 5-1: Categories of relevant persons

Category	Explanation
Commercial fisheries (Commonwealth and State) and peak representative bodies	Commonwealth or State Commercial Fishery with a fishery management plan recognised under the *Commonwealth Fisheries Management Act 1991* (Cth) and the *Western Australian Fish Resources Management Act 1994* (WA), which may be amended from time to time. Commonwealth peak fishery representative bodies are identified by AFMA. WAFIC is the peak representative body for state fishers in Western Australia.
Recreational marine users and peak representative bodies	Charter boat, tourism and dive operators identified by DPIRD specific to the location of the proposed activity. Representative bodies are the recognised peak organisation(s) for recreational marine users.
Titleholders and operators	Registered holder of an offshore petroleum title or GHG title under the OPGGS Act and associated Regulations.
Peak industry representative bodies	Recognised peak organisation(s) for the oil and gas sector.
Traditional Custodians (individuals and/or groups/entity)	Traditional Custodians are First Nations Australians with cultural rights and interests or cultural functions or who perform cultural activities over particular lands and waters. Where a First Nations person, group or entity self-identifies and asserts cultural rights, functions, interests or activities they will be considered under the definition of Traditional Custodian for the purpose of this EP (as appropriate).
Nominated Representative Corporations	Nominated representative corporations are Traditional Custodians' nominated representative institutions such as Prescribed Bodies Corporate (PBC). PBCs are established under the Native Title Act 1993 (Cth) by Traditional Custodians to represent their entire Traditional Custodian group (defined broadly by reference to descents from an ancestor set who were known to be the Traditional Custodians at the time of European colonisation) and their interests including, among other things, management and protection of cultural values.
Native Title Representative Bodies	A Representative Aboriginal/Torres Strait Islander Bodies (RATSIB) is a regional organisation appointed under the Native Title Act 1993 with prescribed functions, set out in Part 11 of the Native Title Act 1993, which relate to: facilitation and assistance; certification; dispute resolution; notifications; agreement making. They are also known, and referred to here, as Native Title Representative Bodies.
Historical heritage groups or organisations	Legislated or government enlisted groups or organisations responsible for the management of marine heritage.
Local government and recognised local community reference/liaison groups or organisations	Local government body formed under the Local Government Act 1995 (WA) which is responsible for representing the local community. Recognised local community reference or liaison group or organisation in relation to oil and gas matters.
Other non-government groups, organisations or individuals	Non-government organisation with public website material targeting the proposed activity.

Category	Explanation
	Individual who demonstrates the proposed activity could potentially impact their interests, functions or activities.
Research institutes and local conservation groups or organisations	Research institutes are government or private institutions that conduct marine or terrestrial research. Local conservation groups are local non-government organisation that regularly conduct conservation activities focused on the local environment or wildlife.

Table 5-2: Methodology for identifying relevant persons within the environment that may be affected undertaken under Regulation 25(1)(d) – by category

Category	Relevant Person Identification Methodology
Commercial fisheries (Commonwealth and State) and peak representative bodies	Woodside assesses relevance for commercial fisheries (Commonwealth and State) and their representative bodies using the following next steps in its methodology: • Defining the parameters having regard to timing, location and duration of the proposed petroleum activity. • Confirming whether the EMBA overlaps with the fisheries management area (i.e., the spatial area the fishery is legally permitted to fish in) (see Section 4.10.1). • Woodside acknowledges WAFIC's consultation guidance[30], that Titleholders develop separate consultation strategies for significant unplanned events (for example an oil spill) where titleholders can demonstrate the likelihood of such events occurring is extremely low. WAFIC's guidance is that consultation on unplanned events resulting in an emergency scenario should only be undertaken if an incident occurs. • For Commonwealth and State commercial fisheries, Woodside assesses the potential spatial and temporal extent for interaction with the fishery by reviewing AFMA, ABARES and DPIRD FishCube data within the Operational Area and EMBA (see Section 4.10.2). Assessment of relevance: • State commercial fisheries that have been assessed as having a potential for interaction within the Operational Area or EMBA (see Section 4.10.2) are assessed as relevant to the proposed activity. However, to avoid over consulting and as requested in WAFIC's guidance, Woodside only consults individual licence holders based on WAFIC's advice. Woodside also utilises WAFIC's consultation service whereby WAFIC: – directly consults fishery licence holders that are assessed as having a potential for interaction in the Operational Area – consults fisheries that are assessed as having a potential for interaction in the EMBA only in the event of an unplanned emergency scenario. • Commonwealth commercial fisheries that have been assessed as having a potential for interaction within the Operational Area or EMBA (see Section 4.10.1) are assessed as relevant to the proposed activity. • If Woodside has identified that a Commonwealth or State fishery is a relevant person, then Woodside also consults the fisheries relevant representative body. For example, WAFIC represents the interests of State fisheries in Western Australia. If a State fishery is identified as relevant, Woodside would also identify WAFIC as relevant. Recognised Commonwealth fishery representative bodies are identified by AFMA via its website. WAFIC is the only recognised State fishery representative body.
Recreational marine users and peak representative bodies	Woodside assesses relevance for recreational marine users and peak representative bodies using the following next steps in its methodology: • Using Woodside knowledge and operating experience, apply knowledge of recreational marine users in the area. This assessment is both activity and location based.

[30] Consultation Approach for Unplanned Events – WAFIC.

Category	Relevant Person Identification Methodology
	• Define the parameters having regard to timing, location and duration of the proposed petroleum activity. • Assess the potential spatial and temporal extent for interaction with recreational marine users by reviewing DPIRD FishCube data to assess whether there has been activity within the EMBA in the past 5 years. Assessment of relevance: • Recreational marine users that have been active in the past 5 years within the EMBA are assessed as relevant to the proposed activity. Woodside is provided with the contact details of charter, boat tourism and dive operators specific to the region of the EMBA by DPIRD to consult with the relevant persons. • If Woodside has identified recreational marine users as relevant persons, then Woodside also consults identified peak recreational marine user representative bodies. For example, Recfishwest represents the interests of recreational fishers. These representative bodies are identified via Woodside's existing consultation list, which is updated as appropriate via advice from known groups and DPIRD.
Titleholders and Operators	Woodside assesses relevance for other Titleholders and operators using the following steps in its methodology: • Use GPInfo to determine overlap with other Titleholders or Operators permit areas within the EMBA. • Using Woodside knowledge and operating experience, apply knowledge of other operators in the area. • Woodside produces a map showing the outcome of this assessment. Assessment of relevance: • Titleholders and Operators whose permit areas are identified as having an overlap within the EMBA are assessed as relevant.
Peak industry representative bodies	Woodside assesses relevance for peak industry representative bodies using the following steps in its methodology: • Review of peak industry representative bodies responsibilities that Woodside actively participates in, with consideration of overlap between industry focus area and Woodside's proposed activities within the EMBA. • Review of Woodside's existing consultation list. • Website search to identify whether any additional peak industry representative bodies have been created whose responsibilities may overlap with Woodside's proposed activities within the EMBA. Assessment of relevance: • Peak industry representative bodies whose responsibilities are identified as having an overlap with Woodside's proposed activities within the EMBA are assessed as relevant.
Traditional Custodians (individuals and/or groups/entity) and Nominated Representative Corporations	Consistent with its understanding of the matters discussed in Section 4.9, to identify Traditional Custodian groups or individuals, Woodside: • uses existing systems of recognition to identify First Nations groups who overlap or are coastally adjacent to the EMBA (for example, recognition provided under Native Title or cultural heritage legislation, or marine park management plans, or identification by other First Nations groups or entities) • notifies and invites consultation with First Nations people through their nominated representative corporation (for example PBCs); or, in the case of native title and where appropriate, the Native Title Representative Body • requests the nominated representative body to forward the notifications and invitations to consult to their members (members are individual communal rights holders • requests advice as to other First Nations groups or individuals that should be consulted • advertises widely so as to invite self-identification and consultation by First Nations groups and individuals.

Category	Relevant Person Identification Methodology
	Further detail to Woodsides methodology is as follows: • Woodside uses the databases of the National Native Title Tribunal to understand: – whether there are any Native Title Claims (historical or current) or determinations overlapping or coastally adjacent to the EMBA – whether there are any relevant Indigenous Land Use Agreements (ILUA), registered with the National Native Title Tribunal that overlap or are adjacent to the EMBA that may identify Traditional Custodians or representative bodies to contact regarding potential cultural values. • Where there is a positive determination of Native Title, contacting the PBC or, where their representative is a Native Title Representative Body, contacts the Native Title Representative Body. • Where appropriate, contacting the relevant Native Title Representative Body to request a list of any First Nations groups asserting Traditional Custodianship over an area of coastline adjacent to the EMBA. • Review of Commonwealth and State Marine Park Management Plans that overlap the EMBA which may identify Traditional Custodians or representative bodies to contact regarding potential cultural values. • In Victoria, using the Victorian Aboriginal Heritage Council data to determine whether there are any Registered Aboriginal Parties (RAP) appointed under the Aboriginal Heritage Act 2006 (Vic), that overlap or are adjacent to the EMBA. • First Nations groups or individuals are identified by a Traditional Custodian, nominated representative corporation, Native Title Representative Body. • Request to the PBC to distribute Woodside consultation materials through its membership. Woodside is unable to contact this membership through any other means. • Woodside has a number of public notification and information sharing processes by which individual Traditional Custodians can become aware of the proposed activity, its risks and impacts, and self-identify. • Individuals that consider their functions, interests or activities may be affected by a proposed activity are provided an opportunity to self-identify for each EP. Woodside does not presume that self-identification for an activity, covered by another EP, automatically means that an individual/s functions, interests and activities may be affected by other activities where EMBAs overlap. This decision is for the individual to make. The public notification, information sharing, and consultation processes Woodside puts in place enables Traditional Custodians to become aware of proposed activities, assess risks and impacts to their values, and enable individuals to self-identify. Assessment of relevance: • Traditional Custodian groups, entities or individuals and Nominated Representative Corporations who are identified through the above methodology and overlap or are coastally adjacent to the EMBA are assessed as relevant.
Native Title Representative Bodies	Woodside assesses relevance for Native Title Representative Bodies using the following steps in its methodology: • A Representative Aboriginal/Torres Strait Islander Body (RATSIB) is a regional organisation appointed under the Native Title Act 1993 with prescribed functions set out in Part 11 of the Native Title Act 1993, which relate to: facilitation and assistance; certification; dispute resolution; notifications; agreement making. They are also known, and referred to here, as Native Title Representative Bodies. • Review of National Native Title Tribunal RATSIB areas that overlap or are coastally adjacent to the EMBA. Assessment of relevance: • Where the area for which a Native Title Representative Body is recognised under the Native Title Act 1993, overlaps with the EMBA or is coastally adjacent to the EMBA, Woodside will assess the Native Title Representative Body as relevant.

Category	Relevant Person Identification Methodology
Historical heritage groups or organisations	Woodside assesses relevance for groups or organisations whose responsibilities are focused on historical heritage using the following steps in its methodology: • Use the Australasian Underwater Cultural Heritage Database to assess known records Maritime Cultural Heritage sites (shipwrecks, aircraft and relics) within the EMBA (see Section4.9.8). Assessment of relevance: • Where there is a known underwater heritage site (shipwrecks, aircraft and relics) within the EMBA, the relevant group or organisation that manages the site will be assessed as relevant.
Local government and recognised local community reference/liaison groups or organisations	Woodside assesses relevance for local government and recognised local community reference/liaison groups or organisations using the following steps in its methodology: • Review of Woodside maps (developed based on data from the WA Local Government, Sport and Cultural Industries 'My Council' database and WA Local Government Association (WALGA) Local Government Directory maps to assess overlap between the local government's defined area of responsibility and the EMBA. • Woodside hosts regular community reference/liaison group meetings. Members represent a cross-section of the community and local towns interests. Representatives are from community and industry and generally include, Woodside, State Government (for instance relevant Regional Development Commissions), Local Government, Indigenous Groups, Industry representative bodies, community and industry organisations. Woodside considers these reference/liaison groups to be the appropriate recognised representatives of the local community for the oil and gas sector. • Woodside reviews the community reference/liaison group's terms of reference to determine its area of responsibility and overlap with the EMBA. For example, the Exmouth Community Liaison Group's area of responsibility in relation to Woodside's operational, development and planning activities, is defined in the terms of reference as the Exmouth sub-basin. Comparatively, the Karratha Community Liaison Group's area of responsibility is the Pilbara region (i.e., onshore). Assessment of relevance: • The local government whose defined area of responsibility overlaps the EMBA is assessed as relevant. • The community reference/liaison group whose defined area of responsibility overlaps the EMBA is assessed as relevant and consulted collectively via the relevant reference/liaison group.

Category	Relevant Person Identification Methodology
Other non-government groups, organisations or individuals	Woodside assesses relevance for other non-government groups, organisations or individuals using the following steps in its methodology: • Review of Woodside's existing consultation list. • Website search of registered non-government groups or organisations (i.e., registered with an Australian Business Number (ABN) and publicly available contact information) that may have public website and/or social media material specific to the proposed activity at the time of development of the EP. • Organisation has a publicly available statement (or purpose) that clearly describes its collective functions, interests or activities. • Review of current website and/or social media material to identify targeted information which demonstrates functions, interests or activities relevant to the potential risks and impacts associated with planned activities associated with the EMBA. • Review of an organisations/individual's feedback to consider whether their functions, interests or activities within the EMBA may be affected by the activities to be carried out under the Environment Plan. Considering interests outside the EMBA would be considered too remove and contrary to the purpose of Environment Plan consultation. Assessment of relevance: • Registered non-government groups or organisations with current targeted public material specific to the proposed activity at the time of developing the EP and who have demonstrated functions, interests or activities relevant to the potential risks and impacts associated with planned activities in accordance with the intended outcome of consultation will be assessed as relevant. • Individual demonstrates their functions, interests or activities may be impacted will be assessed as relevant.
Research institutes and local conservation groups or organisations	Woodside assesses relevance for research institutes and local conservation groups or organisations using the following steps in its methodology: • Review of Woodside's existing consultation list. • Website search for research institutes that may operate within the EMBA. This assessment is both activity and location based. • Website search for local conservation groups or organisations that regularly conduct conservation activities within the EMBA. Assessment of relevance: • Where there is known research being undertaken by a research institute within the EMBA, the research institute that is conducting the research will be assessed as relevant. • Local environmental conservation groups who regularly conduct conservation activities or have demonstrated conservation functions, interests or activities within the EMBA are assessed as relevant. This assessment is both activity and location based.

5.3.5 Regulation 25(1)(e)

In addition to assessing relevance under Regulation 25(1)(d), Woodside has discretion to categorise any other person or organisation as a relevant person under Regulation 25(1)(e).

5.3.6 Identification of Relevant Persons under Regulation 25(1)(e)

Woodside adopts a case-by-case approach for each EP to assess relevance under Regulation 25(1)(e).

5.3.7 Persons or Organisations Woodside Chooses to Contact

In addition to undertaking consultation with relevant persons under Regulation 25(1), from time to time there are persons or organisations that Woodside chooses to contact in relation to a proposed activity. For example, these are persons or organisations:

- that are 'not relevant' pursuant to Regulation 25(1) but that Woodside has chosen to seek additional guidance from, for example, to inform the correct contact person that Woodside should consult, or engage with
- that are 'not relevant' pursuant to Regulation 25(1) but have been contacted as a result of consultation requirements changing or updated guidance from the Regulator
- where it is unclear what their functions, interests or activities are, or whether their functions, interests or activities may be affected. In this circumstance, engagement is used to inform relevance under Woodside's methodology. Woodside follows the same methodology for assessing a person or organisations relevance as it does during its initial assessment (as described in Figure 5-2 and Section 5.3). The result of Woodside's assessment of relevance during the development of the EP is outlined at Appendix F, Table 1.

5.3.8 Assessment of Relevant Persons for the Proposed Activity

The result of Woodside's assessment of relevant persons in accordance with Regulation 25(1) is outlined at Appendix F, Table 1 and Table 2.

Persons or organisations that Woodside assessed as not relevant but chose to contact at its discretion in accordance with Section 5.3.4, or who self-identified and Woodside assessed as not relevant, are summarised at Appendix F, Table 1 and Table 3.

5.4 Consultation Material and Timing

Regulation 25(2) provides that a titleholder must give each relevant person sufficient information to allow the relevant person to make an informed assessment of the possible consequences of the activity on the functions, interests or activities of the relevant person. Regulation 25(3) provides that the Titleholder must allow a relevant person a reasonable period for the consultation.

As set out in Section 5.2, Woodside notifies relevant persons of the proposed activities, respecting that consultation is voluntary, and collaborates on a consultation approach where further engagement is sought by the relevant person. The consultation process aims to be appropriate for the category of relevant persons and not all persons or organisations will require the same level of engagement. Woodside recognises that the level of engagement is dependent on the nature and scale of the PAA and PAP. Woodside acknowledges published guidance for good practice consultation, relevant to different sectors and disciplines. Woodside's methodology for providing relevant persons with sufficient information as well as a reasonable period of time to provide feedback is set out in this section.

5.4.1 Sufficient Information

Woodside produces a Consultation Information Sheet for each EP. This is provided to relevant persons and organisations and is also available on Woodside's website for interested parties to access and to provide feedback on. The Consultation Information Sheet typically includes:

- a description of the proposed petroleum activity
- the Operational Area or PAA, dependant on the EP
- where the activity will take place
- the timing and duration of the activity

- a location map of the Operational Area or PAA, and EMBA
- a description of the EMBA
- relevant exclusion zones
- a summary of relevant risks and mitigation and management control measures relevant to the proposed petroleum activity.

It also sets out contact details to provide feedback to Woodside.

The level of information necessary to assist a person or organisation to understand the impacts of the proposed activity on their functions, interests or activities may vary and may depend on the degree to which a relevant person is affected. For example, Woodside considers that relevant persons who may be impacted by planned activities in the PAA, as a result of temporary displacement due to exclusion zones, may require more targeted information relevant to their functions, interests or activities. Sufficient information may have been provided to a relevant person even where all documents requested by a relevant person have not been provided. Woodside acknowledges NOPSEMA's brochure titled Consultation on offshore petroleum environment plans information for the community, which advises persons being consulted that they may inform titleholders that they only want to be consulted in the very unlikely event of an oil spill.

Woodside places advertisements in selected local, state and national newspapers. This typically includes:

- the name of the EP Woodside is seeking feedback on
- an overview of the activity
- the consultation feedback date
- the ways in which a person or organisation can provide feedback.

Advertising in the local paper in the area of the activity is also consistent with the public notification process under section 66 of the Native Title Act 1993 for Native Title applications. Woodside typically aligns advertisement feedback timeframes with the timing described below. Feedback received is assessed in accordance with Section 5.3 to determine relevance and evidenced in Appendix F, Table 1 as appropriate.

Woodside uses a range of tools to provide sufficient information to relevant persons, which may include one or more of the following:

- Consultation Information Sheet available on Woodside's website and shared directly with relevant persons
- Summary Consultation Information Sheet, presentations or summaries specific to a particular relevant person group
- subscription available on Woodside's website to receive notification of new Consultation Information Sheets for Woodside EPs
- emails
- letters
- phone calls
- face-to-face meetings (virtual or in person) with presentation slides or handouts as appropriate
- Let's Talk newsletter – digital and hard copy
- maps outlining a person or organisation's defined area of responsibility in relation to the proposed activity, for example a fisheries management area or defence training area

- community meetings, as appropriate
- attendance at on-the-ground community events or planned regional roadshows
- broader awareness campaigns on the how to be involved in the EP consultation process.

Woodside recognises that information may be provided to relevant persons in an iterative manner during the consultation process. Woodside considers that genuine two-way engagement may be demonstrated via information on incorporation of controls, where applicable, being provided to the relevant person so that the relevant persons understand how their input has been considered in the development of the EP.

Woodside communicates with relevant persons in different ways. Woodside recognises that, as part of genuine two-way dialogue, these forms of communication may evolve including, for example, due to changes to organisation representation, as relationships are further established, or a preference for an alternative form of communication is expressed by a person or organisation. There might be limitations in how Woodside can consult with relevant persons.

Typical forms of communications for categories of relevant persons are set out in Table 5-3.

Table 5-3: Forms of communication with relevant persons

Category of Relevant Person	Typically Accepted Form of Communication
Government departments/ agencies – marine	Woodside applies NOPSEMA's guideline for engagement with Commonwealth government departments or agencies GL1887 – Consultation with Commonwealth agencies with responsibilities in the marine area – January 2023 by using email for its consultation unless another form of communication is requested. Other forms of communication, such as phone calls, meetings and/or presentation briefings are used on request.
Government departments/ agencies – environment	
Government departments/ agencies – industry	
Commercial fisheries and peak representative bodies	Commonwealth commercial fisheries: Email is used as the primary form of communication with Commonwealth commercial fisheries in the ordinary course of business. Other forms of communication, such as phone calls, and meetings and/or presentation briefings are used on request. State commercial fisheries and recreational marine users: The Western Australian Department of Primary Industries and Regional Development (DPIRD) has responsibility for managing the Fish Resources Management Act 1994 and Aquatic Resources Management Act 2016, which limits the provision of contact details from the register to the name and business address of licence holders. Alternative forms of communication are at the licence holder's discretion. Other forms of communication, such as phone calls, and meetings and/or presentation briefings are used on request. Peak representative bodies: Email is used as the primary form of communication with commercial fishery and recreational marine user peak representative bodies in the ordinary course of business. Other forms of communication, such as phone calls, and meetings and/or presentation briefings are used on request.
Recreational marine users and peak representative bodies	
Titleholders and Operators	Email is used as the primary form of communication between titleholders and operators in the ordinary course of business. Other forms of communication, such as phone calls, and meetings and/or presentation briefings are used on request.
Peak industry representative bodies	Email is used as the primary form of communication with peak representative bodies in the ordinary course of business. Other forms of communication, such as phone calls, and meetings and/or presentation briefings are used on request.
Traditional Custodians and nominated representative corporations	There are many forms of communication that Woodside uses on a case-by-case basis and as appropriate to or requested by the specific group, such as email, phone calls, meetings and community forums. Other forms of communication are used on request.
Native Title Representative Bodies	There are many forms of communication that Woodside uses on a case-by-case basis and as appropriate to or requested by the specific group, such as email,

Category of Relevant Person	Typically Accepted Form of Communication
	phone calls, meetings and community forums. Other forms of communication are used on request.
Historical heritage groups or organisations	NOPSEMA's guideline (GL1887 – Consultation with Commonwealth agencies with responsibilities in the marine area – January 2023) for engagement with government departments or agencies is used as a reference for Woodside's approach for communicating with historical heritage groups or organisations. Other forms of communication, such as phone calls, and meetings and/or presentation briefings are used on request.
Local government and recognised local community reference/liaison groups or organisations	Local government: NOPSEMA's guideline (GL1887 – Consultation with Commonwealth agencies with responsibilities in the marine area – January 2023) for engagement with local government is used as a reference for Woodside's approach for communicating with historical heritage groups or organisations. Community reference/liaison groups and chambers of commerce: Email and presentations are used as the primary form of communication with local community reference/liaison groups or organisations in the ordinary course of business. Other forms of communication, such as phone calls, and meetings and/or presentation briefings are used on request.
Other non-government groups or organisations	Email is used as the primary form of communication with Other non-government groups or organisations. Other forms of communication, such as phone calls, and meetings and/or presentation briefings are used on request.
Research Institutes and Local conservation groups or organisations	Email is used as the primary form of communication with research institutes and local conservation groups or organisations. Other forms of communication, such as phone calls, and meetings and/or presentation briefings are used on request.

Information which is provided to relevant persons for the purposes of consultation on this EP is summarised at Appendix F, Table 2.

Appendix F, Table 3 sets out the information which is provided to persons or organisations that are not relevant for the purposes of Regulation 25 but which Woodside has chosen to contact.

When engaging in consultation, Woodside notifies relevant persons that, in accordance with Regulation 25(4), the relevant person may request that the titleholder notifies NOPSEMA that particular information the person or organisation provides in the consultation not be published, and that information subject to that request will not be published under the Environment Regulations.

5.4.2 Reasonable Period for Consultation

Woodside seeks to consult in order to support preparation of its EP. Woodside recognises that what constitutes a reasonable period for consultation should be considered on a case-by-case basis, with reference to the nature, scale and complexity of the activity.

Woodside recognises that information may need to be provided to relevant persons in an iterative manner during the consultation process. Woodside considers that genuine two-way engagement may be demonstrated via information on incorporation of controls, where applicable, being provided to the relevant person so that the relevant person understands how their input has been considered in the development of the EP.

Woodside's methodology allows relevant persons a reasonable period for consultation (Regulation 25(3)). A reasonable period for all relevant persons, including Traditional Custodians, to participate in consultation for this EP has been provided.

The consultation period under this EP has satisfied benchmark periods under other relevant legislative processes:

- Regulation 30 sets out a public consultation period of 30 days.

- The Department of Mines, Energy and Petroleum (DEMIRS) "*Guidelines for Consultation with Indigenous People by Mineral Explorers*" directs a period of 21 to 30 days of consultation with traditional owners.
- While repealed, guidance taken from the *Aboriginal Cultural Heritage Act 2021 – Consultation Guidelines* (Government of Western Australia, 2023) suggests that up to 12 weeks may be a reasonable period to allow identification, contact and response from First Nations peoples (subject to any alternative timeframe being agreed through co-design of consultation).

This period of consultation demonstrates that Woodside has provided a "*reasonable period*" for relevant persons to consult in accordance with Regulation 25(3). Commentary in the *Tipakalippa Appeal* judgment limits consultation to a process that must be capable of being discharged within a reasonable time:

"it must be taken to be the regulatory intention that the consultation requirement cannot be one that is incapable of being complied with within a reasonable time..."[31]

Woodside seeks feedback in order to support preparation of its EP. What constitutes a reasonable period for consultation is considered on a case-by-case basis, with reference to the person being consulted and the nature, scale and complexity of the activity.

Woodside's typical approach to providing a reasonable period for consultation is as follows:

- advertising in selected local, state and national newspapers to give persons or organisations the opportunity to understand the activity and identify whether their functions, interests or activities may be affected
- providing consultation materials directly to identified relevant persons as well as persons who are not relevant but Woodside chose to contact and providing a target date for feedback; Woodside acknowledges that feedback may be received from relevant persons following the target date
- acknowledging that the way in which Woodside provides consultation information may vary depending on the relevant person or organisation and, may depend on the degree to which a relevant person or organisation is affected; different consultation processes may be required for relevant persons and organisations depending on the information requirements
- following up with relevant persons prior to EP submission; where possible, Woodside will endeavour to use an alternative method of communication to contact the relevant person
- engaging in two-way dialogue with relevant persons or organisations where feedback is received.

Appendix F, Table 2 and Table 3 sets out a history of ongoing consultation and demonstrates that a reasonable period of consultation has been provided.

Woodside considers that consultation for this EP has closed.

As detailed in Section 5.6, if comments and feedback are received after the EP has been submitted, Woodside will consider those comments and update controls as appropriate and at all stages of the life of the EP as per Woodside's ongoing consultation approach described in Section 5.7.

5.4.3 Discharge of Regulation 25

The Full Federal Court made clear in the *Tipakalippa Appeal* that consultation should be approached in a "*reasonable*", "*pragmatic*" and "*not so literal*" way, so that consultation obligations were capable

[31] Santos NA Barossa Pty Ltd v Tipakalippa [2022] FCAFC 193 at paragraph [136].

of being met by Titleholders (Section 5.5.1).[32] Consultation is a "*real world activity*" and must be capable of reasonable discharge.[33] The Full Federal Court referred to Native Title cases as an illustration that reasonable limits should be applied to consultation efforts to ensure the process is workable.[34]

When the Titleholder demonstrates that it has provided sufficient information and a reasonable period for consultation, then Regulation 25 consultation requirements are met.[35] Meeting these obligations requires evaluative judgement to determine reasonable satisfaction of the consultation obligation and, as such, the Regulator uses its discretion to determine if this criteria are met. The nature of the person being consulted and their function, interest and activity that may be affected, will inform the manner of consultation and the reasonable period to be afforded.[36]

While a Titleholder is required to provide an opportunity to consult, the titleholder is not required to obtain consent to engage in the activity from a person being consulted, or confirmation from a person being consulted, that consultation is complete. The Federal Court has commented that a "reasonable opportunity" for consultation must be afforded to relevant persons.[37] A reasonable opportunity may not be every opportunity requested and is limited to reasonable opportunities to consult.

Woodside has completed steps required to discharge its consultation obligations. Woodside has provided sufficient information and a reasonable period of time to enable relevant persons to make an informed assessment of the possible consequences of the activity on their functions, interests or activities; and sufficient time to provide relevant feedback for Woodside to assess relevant persons objections or claims. Woodside has also provided a reasonable opportunity for there to be genuine two-way dialogue on a person's claims or objections.

Woodside has discharged its duty under Regulation 25 and considers that is complete.

Appendix F, Table 2 and Table 3 of this EP sets out the history of consultation under Regulation 25. To the extent a relevant person says that they have further information to share or claims that consultation under Regulation 25 has not been completed, Appendix F, Table 2 and Table 3 provide reasons why Woodside considers consultation under Regulation 25 has been met, in relation to that relevant person.

5.5 Context of Consultation Approach with First Nations

To comply with Regulation 25, Woodside identifies and consults Traditional Custodians whose functions, interests or activities may be affected by the activities under an EP.

5.5.1 Approach to Methodology − Woodside's Interpretation of Tipakalippa Appeal

Woodside has implemented a consultation methodology consistent with Regulation 25 and guidance provided in the *Tipakalippa Appeal*. Woodside's consultation methodology allows for a sufficiently broad capture of Traditional Custodian relevant persons, provides for informed consultation, follows cultural protocols and allows a reasonable opportunity for consultation with Traditional Custodians whose functions, interests or activities may be affected by the activity described in this EP.

Woodside notes the Full Federal Court discussed several *Native Title Act 1993* (Cth) cases in response to a submission made in that case that a requirement under Regulation 25 to consult "*each and every*" relevant person would be "*unworkable*". The reference to Native Title cases dealt with

[36] Explanatory Statement, Offshore Petroleum and Greenhouse Gas Storage (Environment) Regulations 2023, page 30 and Santos NA Barossa Pty Ltd v Tipakalippa [2022] FCAFC 193 at [153].
[37] Cooper v National Offshore Petroleum Safety and Environmental Management Authority (No 2) [2023] FCA 1158 at paragraph [11]; Santos NA Barossa Pty Ltd v Tipakalippa [2022] FCAFC 193 at [153].

how decision-making processes under the NTA requiring "*all*" members of a group to be contacted for communal approval are interpreted by courts in a "*reasonable*", "*pragmatic*" and "*not so literal*" way,[38] and how obligations to consult "each and every" person under Regulation 25 should be interpreted in a similarly pragmatic way, so that consultation is workable. The reference to NTA authorities was made by analogy:

"It can be seen that the terms of [the native title legislation] are somewhat absolute – "all". However, [the native title legislation] has consistently been construed in a way that is not so literal … The cases concerning [the native title legislation] … have reiterated … that [the native title legislation] does not require that "all" of the members of the relevant claim group be involved in the decision. The key question will be whether a reasonable opportunity to participate in the decision-making process has been afforded by the notice for a relevant meeting."[39]

"We consider the authorities in relation to processes under the NTA to be ***illustrative*** *of how a seemingly rigid statutory obligation to consult persons holding a communal interest may operate in a workable manner"*[40] *(emphasis added).*

"there is no definition of what constitutes "consultation for the purpose of Reg11A [now Regulation 25] ... A titleholder will need to "demonstrate" to NOPSEMA that what it did constituted ***consultation appropriate and adapted*** *to the nature of the interests of the relevant persons"*[41] *(emphasis added).*

The Judgment in the *Tipakalippa Appeal* makes it clear that a Titleholder will have some decisional choice in identifying which person(s) are to be approached, how the information will be given to allow the "*relevant person*" to assess the possible consequence of the proposed activities on their functions, interests or activities, and how the requisite consultation is undertaken.[42] Consultation is not fixed to a rigid process and will be adapted so that it is informed by the relevant person or group. Woodside has met its Regulation 25 requirements through its consultation methodology (Section 5.5.2).

Consistent with the *Tipakalippa Appeal*, Woodside considers NTA-style "*full group*" meetings are not required for there to be compliance with Regulation 25. Nominated representative corporations (such as PBCs established under the NTA) have a designated role of representing the views of their member Traditional Custodians. They have established methods for engaging with their own members. Woodside will not undermine the purpose and authority of nominated representative corporations by requiring full group meetings where the nominated representative corporations have not requested engagement of members via full group meetings. It is not appropriate for titleholders to direct or challenge the nominated representative corporations on how to engage with their members.

Woodside's approach described below demonstrates that sufficient information and a reasonable opportunity is provided to individual Traditional Custodians to provide feedback on Woodside activities beyond the opportunity provided to nominated representative corporations.

5.5.2 Consultation Method

Woodside's First Nations team has experience in engaging and working with First Nations organisations and individuals, including within the Commonwealth Native Title and cultural heritage systems, and state and territory cultural heritage and land rights systems. The team understands the complexities of making information accessible to groups and individuals and engaging in accordance with First Nations groups' established channels of communication and methods of consultation. The

[38] Santos NA Barossa Pty Ltd v Tipakalippa [2022] FCAFC 193 at paragraph [95], [98], [103]-[104] and [109].
[39] Santos NA Barossa Pty Ltd v Tipakalippa [2022] FCAFC 193 at paragraph [98].
[40] Santos NA Barossa Pty Ltd v Tipakalippa [2022] FCAFC 193 at paragraph [96].
[41] Santos NA Barossa Pty Ltd v Tipakalippa [2022] FCAFC 193 at paragraph [104].
[42] Santos NA Barossa Pty Ltd v Tipakalippa [2022] FCAFC 193 at paragraph [47] and [48].

First Nations team exercises its professional judgement and is respectful of long-standing relationships (where in place) when considering consultation with First Nations groups. The First Nations team's approach is also informed by the established systems of recognition for First Nations groups and their nominated representative corporations within particular jurisdictions. For example, the methodology for engaging with First Nations groups in the Northern Territory (not relevant for this EP) tends to centre around engagement through Aboriginal land councils (under the *Aboriginal Land Rights (Northern Territory) Act 1976* (Cth)) as well as community meetings that target clan groups where they do not have PBCs or other nominated representative corporations to represent them.

By contrast, recognition for First Nations groups and their nominated representative corporations in Western Australia falls under the *Native Title Act 1993* (Cth) because the vast majority of the Western Australian coastline is settled under the Native Title regime. This means that the methodology and process for consultation in Western Australia places greater emphasis on, but is not limited to, Native Title Representative Bodies and PBCs.

Native Title determinations provide certainty about the appropriate Traditional Custodian groups that have the cultural authority to speak for country adjacent to the EMBA and help Woodside to identify Traditional Custodian persons and groups asserting Traditional Custodianship. The Judgment in the *Tipakalippa Appeal* endorses methods of consultation with groups of relevant persons that are appropriate and adapted to the characteristics of groups.[43] Woodside's consultation methodology is adapted and appropriate to the recognised systems of communal interests in Western Australia.

In Western Australia (relevant for this EP), Woodside has sought to follow the established, effective and respectful means of communication used by Native Title Representative Bodies and nominated representative corporations (including PBCs) with their respective First Nations communities. Woodside follows these processes for the appropriate broad capture of individuals' awareness of our activities, to self-identify (Section 5.5.4), and to provide feedback to inform the management of environmental impacts and risks.

Using these processes, Woodside communicates information about EPs by:

- Advertising in relevant newspapers – This encourages self-identification, by advertising proposed activities widely through newspapers that have national and intra-state circulation; i.e., Koori Mail, National Indigenous Times, The West Australian.
- Creating carefully considered Consultation Summary Sheets with information developed by an Indigenous member of the First Nations Team to remove jargon and provide relevant information for people to have informed understandings about the activities.
- Direct contact through nominated representative corporations.
- Utilising social media (i.e., Facebook/Instagram), texts and emails – These mediums are the preferred communication methods used by Traditional Custodians throughout Western Australia and, on that basis, used by Native Title Representative Bodies and other government agencies and industry, to engage with Traditional Custodians or call meetings. First Nations woman, Professor Bronwyn Castle, through 10 years of research found "*Social media is an intrinsic part of daily life. The use of Facebook is around 20 per cent higher [among First Nations people] than the national average across all geographical locations*" (Social media mob: being Indigenous online, Professor Bronwyn Carlson (2018)).
- For ongoing consultation post Regulation 25 consultation, Woodside has a Program of Ongoing Engagement with Traditional Custodians which sets out Woodside's commitment to ongoing engagement and support to care for and manage country, including Sea Country. The program was developed in response to Traditional Custodian feedback.

[43] Santos NA Barossa Pty Ltd v Tipakalippa [2022] FCAFC 193 at paragraph [95].[104].[153].

- Woodside has members of its First Nations team who are based in Karratha and Roebourne and who serve as on-Country points of contact for First Nations organisations and individuals. These team members have broad local knowledge and established, on-the-ground relationships within communities. This helps contribute to positive outcomes including encouraging First Nations attendance and involvement at Woodside's information sessions and Community roadshows. Team members on the ground engage in a great deal of preparatory work including by distributing information and providing notice to the community to support First Nations attendance at information sessions and Community roadshows.
- From the commencement of engagement with Traditional Custodians, Woodside seeks direction on how they prefer to be consulted and has consulted accordingly. Consultation processes that are informed by Traditional Custodians and co-designed on a case-by-case basis and includes their direction as to cultural protocols, structure of consultation and who to appropriately consult with (such as elders).
- Holding meetings on country at a place and time agreed with Traditional Custodians and offering and providing financial assistance for meeting expenses (as appropriate).
- Providing information specifically designed to be easily understood, to reach all relevant people, and give a reasonable period of time for those people to make an informed assessment of the possible consequences of the proposed activity on them.

The First Nations team approach to consultation is also consistent with the Federal Court's decision in the *Munkara Case.* The *Munkara Case* notes that the word "*culture*" (and hence the word "*cultural*") has a communal aspect to it. To establish cultural features, it is necessary that the beliefs and values are held by the relevant people as a people. For values, features or beliefs that are expressed by an individual to be "*cultural*" they cannot simply be an individual's belief - the belief must have a communal aspect too, and demonstrate that the "*individual beliefs are broadly representative of the beliefs of other members of the group*"[44]. The phrase "*cultural features*", when applied to "*people*" as constituent parts of an ecosystem, is not directed to idiosyncratic views or beliefs of an individual[45]. When the First Nations team is told that a particular value is cultural by an individual Traditional Owner, that information is taken back to the relevant cultural authority to test its broad acceptance. In the case of gender sensitive information, that information would be restricted to the specific gender within the community.

5.5.3 Identification of Relevant Persons

To undertake consultation, Woodside has developed a methodology for identifying relevant persons, in accordance with Regulation 25(1) (Sections 5.2 and 5.3).

Specific to Woodside's approach for identifying relevant Traditional Custodians, Woodside's First Nations Communities Policy and consultation approach is guided by Traditional Custodians by directing consultations through their nominated representative corporation. This has been implemented by Woodside through consultation with a nominated representative corporation, where that corporation has advised Woodside that it acts as the representative body for a Traditional Custodian group and has requested that Woodside engage with it as the representative body for that Traditional Custodian group.

Woodside asks nominated representative corporations (such as PBCs) and Native Title Representative Bodies to identify individuals that should be consulted, and enables individuals to self-identify in response to national and local advertising, social media and community engagement opportunities (Section 5.5.4). Where there is a nominated representative corporation for an area, unless directed by the nominated representative corporation, Woodside does not directly approach individuals for consultation, because this has the potential to undermine the role of the nominated

[44] Munkara v Santos NA Barossa Pty Ltd (No 3) [2024] FCA 9 at [205].
[45] Munkara v Santos NA Barossa Pty Ltd (No 3) [2024] FCA 9 at [205].

representative corporation. Approaching individuals directly is a practice that is no longer considered acceptable because of divisions it has been shown to cause in communities. In addition to asking for the identification of individuals, Woodside also asks nominated representative corporations to distribute consultation information to whomever the nominated representative corporations deem appropriate, including members of the nominated representative corporations who are communal rights holders.

Having said this, as set out in further detail in Section 5.5.4, individuals are also given the opportunity to self-identify, consult and provide their own feedback on the proposed activity. When approached in this way, Woodside will engage individuals as relevant persons and will also (subject to any confidentiality or cultural restrictions) advise the nominated representative body of the consultation where it relates to cultural values. These methods of consultation are consistent with requirements for notification under the *Native Title Act 1993 (*Cth), such as under the future act provisions (section 29), which requires notification of the Native Title Representative Body, the PBC (or nominated representative) and notification through newspapers. The notification process has been selected as a respectful, practical and pragmatic analogue for consultation with First Nations peoples, rather than requiring members to be notified via a formal authorisation process which seeks, from members, authorisation of agreements and native title/compensation claims under the *Native Title Act 1993* (Cth)[46].

In this consultation, Woodside requested nominated representative corporations to identify any potential individual relevant persons for consultation. Woodside requests nominated representative corporations to distribute consultation materials to their members. However, Woodside recognises that the process is voluntary and that it cannot compel nominated representative corporations (such as PBCs) to do so. Woodside also recognises that it would not be appropriate to seek to audit the nominated representative corporations for compliance with any member consultation request.

5.5.4 Opportunity to Self-identify and Identifying Other Individuals

Woodside requests nominated representative corporations and Native Title Representative Bodies to identify other individuals to consult with or individuals who may seek to self-identify for a proposed activity. Woodside also advertises broadly through Indigenous, national and local advertising, social media and community engagement opportunities to provide individuals with an opportunity to consult. Woodside does not directly approach individuals for consultation, as this undermines the role of the nominated representative corporations (Section 5.5.3). Woodside's approach to providing individual Traditional Custodians the opportunity to self-identify and consult for an EP is as follows:

- Woodside applies the principles of self-determination when consulting with Traditional Custodians by consulting through the Traditional Owners authorised representative entities.
- Recognising the function of nominated representative corporations (such as PBCs) and Native Title Representative Bodies to represent communal interests and manage cultural values, Woodside requests that the information provided to representative entities is provided to their members but Woodside recognises the process is voluntary and Woodside cannot compel them to do so, nor seek to audit the representative entities for compliance with any request.
- Representative entities cannot provide membership details to Woodside due to individual confidentiality requirements.
- Woodside requests advice as to who else Woodside should be consulting but recognises the process is voluntary and cannot compel nominated representative corporations to provide this information.

[46] Santos NA Barossa Pty Ltd v Tipakalippa [2022] FCAFC 193, at [104].

- Modern Indigenous engagement practises rely on the building and maintaining of respectful relationships. To date, most nominated representative corporations have requested the building of that relationship, where one is not already in place.
- While Woodside has, in some cases, approached individual directors and Elders outside of this process due to requirements imposed in EP consultation, this approach is considered inappropriate by modern Indigenous engagement standards, fundamentally undermining the authority of the authorised representative entity and can be detrimental to the relationship.

For this proposed activity, Woodside requested nominated representative corporations (including PBCs) and Native Title Representative Bodies to identify any potential individual relevant persons for consultation, and to distribute consultation materials to their member base. However, Woodside recognises the process is voluntary and it cannot compel them to do so nor seek to audit the representative entities for compliance with any request. Woodside has not been directed to engage individual Traditional Custodians by nominated representative corporations for this proposed activity. Woodside has nevertheless provided reasonable opportunity for individual Traditional Custodians to engage in consultation through appropriate and adapted consultation methods.

5.5.5 Sufficient Information

Woodside recognises that the information sufficient to allow a person or organisation to make an informed assessment of the possible consequences of the proposed activity on their functions, interests or activities may vary and may depend on the degree to which a relevant person is potentially affected.

Woodside produces Consultation Information Sheets for each EP which is provided to relevant persons and organisations for the purpose of seeking feedback on the activity (Section 5.4.1). In response to feedback from Traditional Custodians' feedback on information provisions, Woodside has tailored effective consultation methods for its activities, specifically designed for Traditional Custodians, so that information is provided in a form that is readily accessible and appropriate. The targeted Summary Information Sheet developed and reviewed by Woodside's First Nations Engagement Team and First Nations staff to ensure that content is appropriate to the intended recipients, which is then provided to relevant Traditional Custodian groups. Phone calls are made to provide context to the consultation.

Where face-to-face consultation meetings are requested, Woodside coordinates engagement at the Traditional Custodians location of choice (where practicable) and with their nominated attendees. Key project personnel, environmental and First Nations relations experts are typically present to enable effective communication and prompt response to questions. Materials for these sessions incorporate visual aids such as photos, maps and videos, and plain language suitable for people with a non-technical background.

During consultation, Woodside provides relevant persons with additional information as appropriate in response to requests. There is no requirement to provide relevant persons with all information or documents requested and a titleholder will have provided sufficient information even where it has not provided all information or documents requested.

Woodside has sought to provide sufficient information to individual members of nominated representative corporations (such as PBCs) by providing information to representative bodies and requesting dissemination with members. However, Woodside recognises consultation is voluntary and it cannot compel them to do so, nor would it be appropriate to seek to audit the representative entities for compliance with any request.

5.5.6 Reasonable Period for Consultation

Woodside seeks to consult in order to support preparation of its EP. Woodside recognises that what constitutes a reasonable period for consultation should be considered on a case-by-case basis, with reference to the nature, scale and complexity of the activity (Section 5.4.2).

5.5.7 Discharge of Regulation 25

Woodside's consideration and approach to discharging Regulation 25 for relevant persons is discussed in Section 5.4.3. In addition to this, Woodside has considered the application of Regulation 25 specific to First Nations based on the *Tipakalippa Appeal*.

In relation to Traditional Custodian relevant persons (and all relevant persons), Woodside has discharged its duty under Regulation 25 of the Environment Regulations. Woodside considers that consultation under Regulation 25 is complete.

5.6 Providing Feedback and Assessment of Merit of Objections or Claims

There are a number of ways in which feedback can be provided. Feedback can be provided through the Woodside feedback email or via the Woodside feedback toll free phone line as outlined in the Consultation Information Sheet and the Woodside website. Where appropriate, consultation may also be supported by phone calls or meetings. An EP feedback form is also available on Woodside's website enabling stakeholders to provide feedback on proposed activities, or to request additional information.

Woodside consults widely on its EPs and notes that feedback is received in various forms. Feedback that is considered inappropriate or that puts the environment, health, safety or wellbeing of Woodside employees or operations at risk will not be tolerated. Woodside respects people's rights to protest peacefully and lawfully but actions that put the environment, health, safety or wellbeing of Woodside employees or operations at risk go beyond those boundaries.

Woodside accepts feedback and engages in consultation in order to achieve the aims set out in Section 5.2. Woodside recognises that there are persons and organisations that take a view that Woodside's operations and/or growth projects should be stopped or at least delayed as far as possible. Whilst Woodside assesses the merits of objections or claims received, it acknowledges NOPSEMA's guidance in its brochure entitled Consultation on offshore petroleum environment plans information for the community, which states that relevant persons are free to respond on any matter and raise any concern, however this may not be able to be considered if it is outside the scope or purpose of the EP and approval process, for example, statements of fundamental objection to offshore petroleum activities or information containing personal threats or profanities. Under Regulation 34(g), there is no requirement for a relevant person to agree or confirm that they have been adequately consulted.

Feedback from relevant persons is reviewed and an assessment of the merits is made of information provided as well as objections or claims about the adverse impact of each activity to which the EP relates. This might, for instance, be done through a review of data and literature and for relevance to the nature and scale of the activity outlined in the EP. Consistent with the aim of consultation in Section 5.2, Woodside will consider information received when reviewing and designing measures to put in place to minimise harm to relevant persons and where reasonable or practical to further manage impacts and risks to ALARP and acceptable levels.

Woodside considers feedback during consultation from relevant persons and other persons Woodside chose to contact (see Section 5.3.7). This information is summarised in Appendix F, Table 1 and Table 2 of the EP and includes a statement of Woodside's response, or proposed response, if any, to each objection and claim.

In accordance with Regulation 26(8), sensitive information (if any) in an EP, and the full text of any response by a relevant person to consultation under Regulation 25, must be contained in the sensitive information part of the plan and not anywhere else in the plan.

5.7 Ongoing Consultation

Consultation can continue to occur during the life of an EP, including after an EP has been accepted by NOPSEMA.

As per Woodside's ongoing consultation approach (refer to Section 7.12), feedback and comments received from relevant persons continue to be assessed and responded to, as required, throughout the life of an EP, including during its assessment and once accepted, in accordance with the intended outcome of consultation.

Should consultation feedback be received following the acceptance of an EP that identifies a measure or control that Woodside considers requires implementation or updates to meet the intended outcome of consultation, Woodside will apply its Management of Change and Review process as appropriate (see Section 7.3).

6. ENVIRONMENTAL IMPACT AND RISK ASSESSMENT, PERFORMANCE OUTCOMES, STANDARDS AND MEASUREMENT CRITERIA

6.1 Overview

This section presents the impact and risk analysis and evaluation, EPOs, EPSs and MC for the Petroleum Activities Program, using the methodology described in Section 2. MEEs require a further level of analysis and are assessed separately in Section 6.8.

6.2 Analysis and Evaluation

As required by Regulation 21(5) and 21(6) of the Environment Regulations, the analysis and evaluation demonstrate that the identified risks and impacts associated with the PAP are reduced to ALARP, are of an acceptable level and consider all operations of the activity, including potential emergency conditions.

Impacts and risks identified during the ENVID (including Decision Type, current risk level, acceptability of risk and tools used to demonstrate acceptability and ALARP) have been divided into two broad categories:

- planned (routine and non-routine) activities
- unplanned events (accidents, incidents or emergency situations).

Within these categories, impact and risk assessment groupings are based on environmental aspect[47] (e.g., emissions, physical presence, etc). For all hazardous events considered, the worst credible consequence was assumed.

The ENVID identified 12 impacts and 15 risks associated with the Petroleum Activities Program. Planned activities and unplanned events are summarised in Table 6-1 and Table 6-2.

The analysis and evaluation for the PAP indicate that current environmental risks and impacts associated with the activity are reduced to ALARP and are of an acceptable level, as discussed further in Section 6.

[47] An environmental aspect is an element of the activity that can interact with the environment.

Table 6-1: Environmental impact and risk analysis summary table – planned activities

Aspect	EP Section	Source of Impact	Key Potential Environmental Impacts (Refer to relevant EP section for details)	Controlled Impact Classification	Residual Impact Level (ALARP controls in place)	Acceptability of Impact
Planned Activities (Routine and Non-routine)						
Physical Presence: Interaction with Other Marine Users	6.7.1	Presence of facility, ASV and vessels displacing and/or excluding other users from PSZ during routine and IMMR activities within the PAA, respectively.	Potential isolated social impact resulting from interference with other sea users (e.g., commercial and recreational fishing, and shipping).	F	Socio-economic – No lasting effect (<1 month). Localised impact not significant to area/item of cultural significance.	Broadly Acceptable
		Presence of MODU, AHVs, installation vessels and other support vessels displacing and/or excluding other users during Xena-03 Tie-back activities.				
		Presence of subsea infrastructure interfering with or displacing third party vessels (commercial fishing).				
Physical Presence: Disturbance to the Seabed	6.7.2	Presence of Pluto Facility and subsea infrastructure.	Localised modification of seabed habitat (formation of artificial reef) within PAA.	E	Environment – Slight, short-term impact (<1 year) on species, habitat (but not affecting ecosystem function), physical or biological attributes.	Broadly Acceptable
		Subsea operations, inspection, maintenance and repair activities, including ASV and installation of pig receivers/launchers at the subsea wells.	Potential minor, localised modification of seabed habitat within PAA.	E	Environment – Slight, short-term impact (<1 year) on species, habitat (but not affecting ecosystem function), physical or biological attributes.	
		Presence of redundant infrastructure remaining infield until facility EOFL.	Potential slight, short-term loss or damage to benthic habitats, including benthic communities and marine primary producers.	F	Environment – No lasting effect (<1 month). Localised impact not significant to environmental receptor.	
		Disturbance to seabed from drilling operations.		F	Environment – No lasting effect (<1 month). Localised impact not significant to environmental receptor.	
		Disturbance to seabed from subsea installation of infrastructure (e.g., flowlines, umbilicals, flying leads) as well as rectification and stabilisation activities (e.g. installation of concrete mattresses).		F	Environment – No lasting effect (<1 month). Localised impact not significant to environmental receptor.	
		Disturbance to seabed from ROV operation (including localised sediment relocation from sediment mobilisation techniques and marine growth removal).		E	Environment – Slight, short-term impact (<1 year) on species, habitat (but not affecting ecosystem function), physical or biological attribute.	
		Disturbance to seabed from mooring installation.		E	Environment – Slight, short-term impact (<1 year) on species, habitat (but not affecting ecosystem function), physical or biological attribute.	
		Placement and retrieval of seabed transponders and temporary installation aids.		E	Environment – Slight, short-term impact (<1 year) on species, habitat (but not affecting ecosystem function), physical or biological attribute.	
Acoustic Emissions: Generation of Noise for Facility Operations	6.7.3	Noise generated within the PAA from: • Pluto Facility and associated infrastructure • vessels (ASV and support vessels) • helicopters • subsea IMMR activities.	Potential localised behavioural impacts to marine fauna around and within the PAA.	F	Environment – No lasting effect (<1 month). Localised impact not significant to environmental receptor.	Broadly Acceptable
Acoustic Emissions: Generation of Noise During Xena-03 Tie-Back Activities	6.7.4	Generation of noise from MODU, AHVs and support vessels.	Slight, short-term impacts to marine mammals, reptiles and fish, varying from behavioural responses to physiological impact (TTS).	F	Environment – Slight, short-term impact (<1 year) on species, habitat (but not affecting ecosystem function), physical or biological attributes.	Broadly Acceptable
		Generation of noise from DP systems on support vessels.		F	Environment – Slight, short-term impact (<1 year) on species, habitat (but not affecting ecosystem function), physical or biological attributes.	
		Generation of noise from cutting of well infrastructure and contingency activities.		F	Environment – No lasting effect (<1 month). Localised impact not significant to environmental receptors.	

Aspect	EP Section	Source of Impact	Key Potential Environmental Impacts (Refer to relevant EP section for details)	Controlled Impact Classification	Residual Impact Level (ALARP controls in place)	Acceptability of Impact
Routine and Non-Routine Discharges: Discharge of Hydrocarbons and Chemicals	6.7.5	Discharge of subsea control fluids.	Localised decrease in water quality around subsea system within PAA with no lasting effect.	F	Environment – No lasting effect (<1 month). Localised impact not significant to environmental receptors.	Broadly Acceptable
		Discharge of hydrocarbons remaining in subsea pipework and equipment as a result of subsea intervention works (including pigging).	Slight, short-term decrease in water quality at release location during IMMR activities.	E	Environment – Slight, short-term impact (<1 year) on species, habitat (but not affecting ecosystems function), physical or biological attributes.	
		Discharge of chemicals remaining in subsea pipework and equipment or the use of chemicals for subsea IMMR activities.	Localised decrease in water quality at release location during IMMR activities.	F	Environment – No lasting effect (<1 month). Localised impact not significant to environmental receptors.	
		Discharge of minor fugitive hydrocarbons from subsea equipment.	Potential slight short-term, localised decrease in water quality around subsea system within PAA with no lasting effect.	F	Environment – No lasting effect (<1 month). Localised impact not significant to environmental receptors.	
		Discharge of chemicals (e.g., MEG) during installation and leak testing of new infrastructure.	Localised decrease in water quality at discharge location during installation and leak testing of new infrastructure.	F	Environment – No lasting effect (<1 month). Localised impact not significant to environmental receptors.	
Routine and Non-Routine Marine Wastewater Discharges: Utility Systems and Drains	6.7.6	Discharge of sewage, grey water and putrescible waste from the Pluto Facility, MODU, ASV, installation and support vessels to the marine environment.	Potential localised, short-term decrease in water quality (increased nutrients and biological oxygen demand) at the discharge location.	F	Environment – No lasting effect (<1 month). Localised impact not significant to environmental receptors.	Broadly Acceptable
		Discharge of deck, bilge and drain water from the Pluto Facility, MODU, ASV, installation and support vessels to the marine environment.	Potential localised, short-term decrease in water quality (increased hydrocarbon and chemical concentrations) at the discharge location.	F	Environment – No lasting effect (<1 month). Localised impact not significant to environmental receptors.	
		Discharge of brine and cooling water from the Pluto Facility, MODU, ASV, installation and support vessels to the marine environment.	Negligible, localised increase in salinity at the discharge location.	F	Environment – No lasting effect (<1 month). Localised impact not significant to environmental receptors.	
Routine and Non-routine Discharges: Produced Water	6.7.7	Discharge of produced water during routine and non-routine operations.	Potential slight, short-term, localised decrease in water quality (increased hydrocarbon and chemical concentrations) at discharge location and within mixing zone, with potential impacts to marine fauna (toxicity).	E	Environment – Slight, short-term impact (<1 year) on species, habitat (but not affecting ecosystem function), physical or biological attributes.	Broadly Acceptable
Routine and Non-routine Discharges: Drill Cuttings, Drilling Fluids and Well Removal Fluids	6.7.8	Routine discharge of WBM drill cuttings to the seabed and the marine environment.	Potential slight, short-term toxic effects to marine biota, as well as localised reduction in water quality with potential effects on both water quality and benthic communities.	E	Environment – Slight, short-term impact (<1 year) on species, habitat (but not affecting ecosystem function), physical or biological attributes.	Broadly Acceptable
		Routine discharge of drilling muds (WBM) to the seabed and the marine environment.		D		
		Non-routine discharge of treated NWBM drill cuttings to the marine environment.		D		
		Non-routine discharge of wash water from mud pits and vessel tank wash fluids.		E		
		Routine discharge of well clean-out fluids.		E		
		Non-routine discharge of well annular fluids.		F		
Routine and Non-Routine Discharges: Cement, Cementing Fluids, Subsea Well Fluids, Unused Bulk Product and Subsea Chemicals from Xena-03 Tie-back Activities	6.7.9	Routine discharge of cement and cementing fluids, to the seabed and the marine environment.	Potential slight, short term toxic effects to marine biota, as well as localised reduction in water quality with potential effects on both water quality and benthic communities.	F	Environment – No lasting effect (<1 month). Localised impact not significant to environmental receptors.	Broadly Acceptable
		Routine discharge of subsea well fluids (including BOP and well construction activity control fluids).				
		Produced / reservoir water disposal.				
		Non-routine discharge of unused bulk products at campaign end.				

Aspect	EP Section	Source of Impact	Key Potential Environmental Impacts (Refer to relevant EP section for details)	Controlled Impact Classification	Residual Impact Level (ALARP controls in place)	Acceptability of Impact
Routine and Non-routine Atmospheric (Direct) and GHG Emissions (Direct and Indirect)	6.7.10	Operational flaring, exhaust emissions from fuel combustion, fugitive emissions from the Pluto facility.	Potential short-term localised decrease in air quality, limited to the airshed local to the facility. Potential negligible (de minimis) impact to global atmospheric GHG carbon budgets	F	Environment – No lasting effect (<1 month). Localised impact not significant to environmental receptors.	Broadly Acceptable
		Exhaust emissions from fuel combustion and incinerators on the ASV, MODU, installation and support vessels and helicopters.				
		Contingent MODU flaring (well test non-routine) during well unloading for pressure test and clean up.				
		Contingent venting of gas during drilling (e.g., well kick).				
		Consideration of indirect emissions associated onshore processing, third party transportation, regassification and combustion by end users.				
Routine Atmospheric Emissions: Indirect Emissions associated with Gas Processing Onshore	**Error! Reference source not found.**	Consideration of potential indirect impact from atmospheric emissions associated with onshore processing of Pluto gas.	Negligible, small contribution to cumulative air quality relative to defined air quality criteria. Risk of processing of Pluto gas at onshore facilities adversely impacting rock art on Murujuga is considered to be low, and no impact classification assigned.	F	Environment – No lasting effect (<1 month). Localised air quality impact not significant to environmental receptors.	Broadly Acceptable
Routine Light Emissions: Light Emissions from Facility Operations and Xena-03 Tie-back Activities	6.7.12	Light emissions from the Pluto Facility, ASV, MODU, installation and support vessels.	Negligible, localised potential for behavioural disturbance of species in close proximity to riser platform and vessels.	F	Environment – No lasting effect (<1 month). Localised impact not significant to environmental receptors.	Broadly Acceptable
		Light emissions during flaring.	Negligible, localised potential for behavioural disturbance of species in close proximity to riser platform and vessels.	F	Environment – No lasting effect (<1 month). Localised impact not significant to environmental receptors.	

Table 6-2: Environmental impact and risk analysis summary table – unplanned events (including MEEs)

				Controlled Impact Classification	Residual Impact Level (ALARP controls in place)	Likelihood	Residual Risk Rating	
Unplanned Events (Accidents/Incidents) – MEEs								
Unplanned Hydrocarbon Release: Loss of Well Containment from Operating Wells (MEE-01)	6.8.3	Release of hydrocarbons resulting from subsea loss of well containment.	Potential significant impacts to the marine environment: • medium-term impacts to sensitive nearshore areas of offshore islands and coastal shorelines • disruption to marine fauna, including protected species • potential short-term interference with or displacement of other sea users.	C	Environment – Moderate, medium-term impact (2–10 years) on ecosystem, species, habitat or physical or biological attribute.	1	M	Acceptable if ALARP
Unplanned Hydrocarbon Release: Subsea Equipment Loss of Containment (MEE-02)	6.8.4	Surface or subsea release from flowline, pipeline and riser to the marine environment and atmosphere within PSZ and to mid-point of export pipeline.	Potential significant impacts to the marine environment: • medium-term impacts to sensitive offshore and nearshore areas • disruption to marine fauna, including protected species • potential short-term interference with or displacement of other sea users.	C	Environment – Moderate, medium-term impact (2–10 years) on ecosystem, species, habitat or physical or biological attribute.	1	M	Acceptable if ALARP
		Subsea release from export pipeline to the marine environment and atmosphere between mid-point of export pipeline to shore.		B	Environment – Major, long-term impact (10–50 years) on highly valued ecosystem, species, habitat or physical or biological attribute.	1	M	
Unplanned Hydrocarbon Release: Loss of Structural Integrity (MEE-03)	6.8.5	Marine environment footprint and associated hydrocarbon and chemical release associated with structural collapse of riser platform.	Potential significant impacts to the marine environment: • medium-term impacts to sensitive offshore and nearshore areas • disruption to marine fauna, including protected species • potential short-term interference with or displacement of other sea users.	C	Environment – Moderate, medium-term impact (2–10 years) on ecosystem, species, habitat or physical or biological attribute.	1	M	Acceptable if ALARP
		Surface or subsea release from flowline, pipeline and riser to the marine environment and atmosphere within PSZ (MEE-02) – caused by loss of structural integrity.		C	Environment – Moderate, medium-term impact (2–10 years) on ecosystem, species, habitat or physical or biological attribute.	1	M	
Unplanned Hydrocarbon Release: Loss of Marine Vessel Separation (MEE-04)	6.8.6	Hydrocarbon release of marine diesel to the marine environment from vessel due to collision within the PSZ.	Potential significant impacts to the marine environment: • medium-term impacts to sensitive offshore and nearshore areas • disruption to marine fauna, including protected species • potential short-term interference with or displacement of other sea users.	C	Environment – Moderate, medium-term impact (2–10 years) on ecosystem, species, habitat or physical or biological attribute.	1	M	Acceptable if ALARP
		Hydrocarbon release from pipeline, flowline(s) and riser(s) to the marine environment and atmosphere (MEE-02/03) caused by collision and structural integrity failures.		C	Environment – Moderate, medium-term impact (2–10 years) on ecosystem, species, habitat or physical or biological attribute.	1	M	
		Marine environment footprint and associated hydrocarbon and chemical release associated with platform loss of structural integrity (MEE-03) caused by collision.		C	Environment – Moderate, medium-term impact (2–10 years) on ecosystem, species, habitat or physical or biological attribute.	1	M	
Unplanned Hydrocarbon Release: Loss of Control of Suspended Load from Platform (MEE-05)	6.8.7	Surface or subsea release from flowline, pipeline and riser to the marine environment and atmosphere within PSZ (MEE-02) – caused by loss of control of suspended load.	Potential significant impacts to the marine environment: • medium-term impacts to sensitive offshore and nearshore areas • disruption to marine fauna, including protected species • potential short-term interference with or displacement of other sea users.	C	Environment – Moderate, medium-term impact (2–10 years) on ecosystem, species, habitat or physical or biological attribute.	1	M	Acceptable if ALARP
		Hydrocarbon release from topsides equipment to the marine environment and atmosphere – caused by loss of control of suspended load.	Potential minor, short-term impacts to the marine environment including disruption to marine fauna, including	D	Environment – Minor, short-term impact (1–2 years) to a community or highly valued area/item of cultural significance.	1	M

			protected species, and/or temporary impacts to water quality.					
Unplanned Events (Accidents/Incidents)								
Unplanned Hydrocarbon Release: Loss of Well Integrity During Drilling of Xena-03	6.9.1	Loss of hydrocarbons to marine environment due to loss of well containment during drilling of the Xena-03 well.	Potential significant impacts to the marine environment: • medium-term impacts to sensitive offshore and nearshore areas • disruption to marine fauna, including protected species • potential short-term interference with or displacement of other sea users.	B	Environment – Major, long-term impact (10–50 years) on highly valued ecosystem, species, habitat or physical or biological attribute.	1	M	Acceptable if ALARP
Unplanned Hydrocarbon Release: Pluto-A Topsides Loss of Containment	6.9.2	Hydrocarbon release from Pluto-A topsides equipment to the marine environment and atmosphere.	Potential minor, short-term impacts to the marine environment including disruption to marine fauna, including protected species, and/or temporary impacts to water quality.	D	Environment – Minor, short-term impact (1–2 years) to a community or highly valued area/item of cultural significance.	1	M	Broadly Acceptable
Unplanned Hydrocarbon Release: Vessel Collision during Drilling and Tie-back Activities	6.9.3	Loss of hydrocarbons to marine environment due to a vessel collision during drilling and tie-back of the Xena-03 well.	Potential minor, short-term impacts to the marine environment: • short-term impacts to sensitive offshore and nearshore areas • disruption to marine fauna, including protected species • potential short-term interference with or displacement of other sea users.	C	Environment – Moderate, medium-term impact (2–10 years) on ecosystem, species, habitat or physical or biological attribute.	1	M	Broadly Acceptable
Unplanned Hydrocarbon or Chemical Release: Hydrocarbon Release During Bunkering, Refuelling and Chemical Release During Transfer, Storage and Use, Rupture of Chemical Supply Lines – Pluto Operations	6.9.4	Accidental discharge of marine diesel/hydrocarbons to the marine environment during bunkering and refuelling.	Potential minor, short-term impacts to marine water quality with no lasting effect.	D	Environment - Minor, short-term impact (1–2 years) to a community or highly valued area/item of cultural significance.	2	M	Broadly Acceptable
		Accidental discharge of chemicals to the marine environment from transfer, storage and use, as well as rupture of chemical supply lines.	Potential minor, short-term impacts to marine water quality with no lasting effect	D	Environment - Minor, short-term impact (1–2 years) to a community or highly valued area/item of cultural significance.	1	M	Broadly Acceptable
		Accidental release of MEG from chemical supply lines.	Potential slight, short-term impacts to marine water quality with no lasting effect.	E	Slight, short-term impact (<1 year) on species, habitat (but not affecting ecosystem function), physical or biological attributes.	2	M	Broadly Acceptable
Unplanned Discharges: Tie-back Activities Unplanned Deck and Subsea Spills	6.9.5	Accidental discharge of hydrocarbons or chemicals from the MODU, ASV, installation and support vessel deck activities and equipment, and from subsea ROV hydraulic leaks.	Potential minor, short-term impacts to the marine environment including disruption to marine fauna, including protected species, and/or temporary impacts to water quality.	D	Environment - Minor, short-term impact (1–2 years) to a community or highly valued area/item of cultural significance.	2	M	Broadly Acceptable
Unplanned Discharge: Drilling Fluids	6.9.6	Accidental discharge of project fluids (WBM/NWBM/base oil) and cement to marine environment.	Potential slight, short-term impacts to the marine environment including disruption to marine fauna, including protected species, and/or temporary impacts to water quality.	E	Environment – Slight, short-term impact (< 1 year) on species, habitat (but not affecting ecosystem function), physical or biological attributes.	1	L	Broadly Acceptable
Unplanned Discharges: Hazardous and Non-hazardous Waste Management	6.9.7	Incorrect disposal or accidental discharge of non-hazardous and hazardous waste to the marine environment.	Potential slight, short-term impacts to the marine fauna, and localised temporary impacts to water quality and marine sediments.	E	Environment – No lasting effect (< 1 month). Localised impact not significant to environmental receptors.	2	M	Broadly Acceptable

Physical Presence: Seabed Disturbance from Dropped Objects or Loss of Station Keeping Leading to Anchor Drag	6.9.8	Dropped objects resulting in the disturbance of benthic habitat.	Potential minor, localised impact to benthic habitat as well as potential seabed infrastructure damage.	D	Environment – Minor, short-term impact (1–2 years) to a community or highly valued area/item of cultural significance.	1	L	Broadly Acceptable
		Loss of station keeping of the MODU leading to anchor drag and the disturbance of benthic habitat.		D	Environment – Minor, short-term impact (1–2 years) to a community or highly valued area/item of cultural significance.	1	L	
Physical Presence: Interactions with Marine Fauna	6.9.9	Physical presence of MODU, ASV, installation and support vessels resulting in collision with marine fauna.	Potential injury or death of marine fauna (single animal), including protected species.	E	Environment – Slight, short-term impact (<1 year) on species, habitat (but not affecting ecosystem function), physical or biological attributes.	1	L	Broadly Acceptable
Physical Presence: Introduction of Invasive Marine Species	6.9.10	Invasive species in vessel ballast tanks or on vessels/submersible equipment.	Potential introduction of invasive marine species possibly resulting in an alteration of the localised environment.	E	Environment – Slight, short-term impact (<1 year) on species, habitat (but not affecting ecosystem function), physical or biological attributes.	1	L	Broadly Acceptable

6.2.1 Cumulative Impacts

Woodside has assessed the cumulative impacts of the PAP in relation to other relevant petroleum activities that could realistically result in overlapping temporal and spatial extents. The closest facilities to the Pluto Riser Platform and Pluto Export Pipeline include the Wheatstone platform, 5 km north, and the Stag A platform 8 km south, respectively (Section 4.10.5). However, given the concentration of sources of environmental risks and impacts from the PAP are localised, the potential for cumulative impacts is considered to be low. Cumulative impacts are discussed for sources of risk and impacts where such impacts were deemed to be credible.

6.3 Environmental Performance Outcomes, Standards and Measurement Criteria

Regulation 21(7) of the Environment Regulations requires that an EP includes EPOs, EPSs and MC that address legislative and other controls to manage the environmental risks and impacts of the activity to ALARP and Acceptable levels.

The EPOs, EPSs and MC specified are consistent with legislative requirements and Woodside's standards and procedures. They have been developed based on the Codes and Standards, Good Industry Practices and Professional Judgement outlined in Section 2.6, as part of the acceptability and ALARP justification process.

As defined in Regulation 5 of the Environment Regulations, an EPO "for an activity, means a measurable level of performance required for the management of environmental aspects of the activity to ensure that environmental impacts and risks of the activity will be of an acceptable level".

EPOs are set so that they are consistent with the principles of ESD as defined in the section 3A of the EPBC Act and demonstrated through the acceptability process (described in Section 2.8.2), which is applied to the aspects in Section 6, taking into consideration the principles of ESD. The EPOs for planned activities have been set at a level of environmental performance that is equal to the identified environmental impact.

EPSs and MC are defined to measure environment performance against the EPOs:

- EPSs are statements of performance required of a control measure in order to manage risk and/or impacts to ALARP and an acceptable level. EPSs are used as a basis for environmental performance reporting and demonstrate compliance against the EPOs.
- MCs are outlined defining how environmental performance is measured and sets the criteria to determine whether the EPOs and EPSs have been met during the activity.
- For planned activities, where the activity is undertaken as described and the relevant EPSs are implemented it confirms that the EPOs are being met.

The EPOs, EPSs and MC are presented throughout this section for both operations and Xena-03 Tie-back activities, as relevant. A breach of these EPOs or EPSs constitutes a 'Recordable Incident' under the Environment Regulations (refer to Section 7.13.5).

6.4 Presentation

The analysis and evaluation (ALARP and acceptability), EPOs, EPSs and MC are presented in tabular form throughout this section, as shown in the sample below. Italicised text in this example table denotes the purpose of each part of the table, with reference to the relevant sections of the Regulations and/or this EP.

Context Description of the context for the impact/risk. Regulation 21(1), 21(2) and 21(3)			
MEEs are subject to additional analysis and evaluation as outlined in Section 2.7. ALARP is demonstrated through controls being analysed for selection, based on their independence, and prioritised in accordance with hierarchy of controls, and further analysed to consider the type of effect the control provides.			
ALARP Statement Made on the basis of the environmental risk/impact assessment outcomes, use of the relevant tools appropriate to the Decision Type (Section 2.6.1) and a proportionality assessment. Regulation 34(b).			
Demonstration of Acceptability			
Acceptability Statement Made on the basis of applying the process described in Section 2.8.2 and taking into account internal and external expectations, risk/impact to environmental thresholds and use of environment decision principles. Regulation 34(c)			
EPOs, EPSs and MC			
Environmental Performance Outcomes	***Controls***	***Environmental Performance Standards***	***Measurement Criteria***
EPO No. S: Specific performance that addresses the legislative and other controls that manage the activity, and against which performance by Woodside in protecting the environment will be measured. M: Performance against the outcome will be measured through implementation of the controls via the MC. A: Achievability/feasibility of the outcome demonstrated via discussion of feasibility of controls in ALARP demonstration. Controls are directly linked to the outcome. R: The outcome will be relevant to the source of risk/impact and the potentially impacted environmental value[49] T: The outcome will state the timeframe during which the outcome will apply or by which it will be achieved.	C No. Identified control adopted to ensure that the impacts and risks are continuously reduced to ALARP. Regulation 21(5c).	PS No. Statement of the performance required of a control measure. Regulation 21(7)(a).	MC No. Measurement criteria for determining whether the outcomes and standards have been met. Regulation 21(7)(c).

6.5 Environment Risk/Impacts not Deemed Credible

The ENVID identified a source of environmental risk / impact that was assessed as not being applicable (not credible) within or outside the PAA as a result of the Petroleum Activities Program. It therefore does not form part of this EP. This is described in the following sections for information only.

[49] Where impact/consequence descriptors are capitalised and presented within EPOs in Section 6; performance level corresponds with those aligned with the Woodside Risk Matrix (refer Section 2.6.3).

6.5.1 Shallow/Near-shore Activities

The PAP is located in water depths of approximately between 40 m at the state-waters boundary of the Pluto Export Pipeline and 962 m at the greatest depths of the hydrocarbon gathering system. The closest land is 10 km from the Export Pipeline Operational Area at Legendre Island and 32 km from the Facility and Xena-03 Operational Areas at Montebello Islands. Consequently risks/impacts associated with shallow/near-shore activities such as anchoring and vessel grounding were assessed as not credible.

6.6 Indirect Impacts

For the proposed Petroleum Activities Program, potential 'indirect' environmental impacts and risks are those associated with waste brought onshore, mobilisation/demobilisation of vessels to the PAA, and related to emissions associated with the extraction of Pluto gas for onshore processing and third-party transport, regassification, distribution and use. Due to the nature and scale of these potential indirect environmental impacts and risks which could be reasonably attributed to the PAP, and the regulatory frameworks in place to manage them, Woodside considers the potential indirect impacts and risks from these activities to be inherently managed to ALARP and acceptable in its current state.

However, recognising stakeholder and regulatory interest with the processing of Pluto gas onshore and concern regarding the potential for indirect impacts from atmospheric emissions; and GHG emissions from third party use, further information and evaluation has been provided in Sections 6.7.10 and **Error! Reference source not found.**.

6.7 Planned Activities

6.7.1 Physical Presence: Interaction with Other Marine Users

Context		
Facility Layout and Description – Section ` Support Vessel Operations – Section 3.8 Subsea Inspection, Maintenance and Repair Activities – Section 3.10 Xena-03 Drilling &Tie-back Activities – Section 3.11 Vessel-based Activities for the Xena-03 Tie-back – Section 3.12	Socio-economic Environment – Section 4.10	Consultation – Section 5

Impacts and Risks Evaluation Summary

Presence of MODU, AHVs, installation vessels and other support vessels displacing and/or excluding other users during Xena-03 Tie-back activities							x							
Presence of subsea infrastructure interfering with or displacing third-party vessels (commercial fishing)							x							

Description of Source of Impact

Operations

The facility commenced operation in 2012 and is marked on nautical charts. The riser platform is surrounded by a 500 m radius PSZ, which vessels are prohibited from entering unless authorised by Woodside. The PSZ is a critical safety control intended to reduce the likelihood of interactions between vessels and the platform, which increases safety for both vessels and the facility. Implementation of the PSZ around the riser platform excludes other users from a small area of the sea (approximately 0.079 km²). The riser platform is highly visible under most conditions and is well lit, and the nature of the riser platform (large steel structure) ensures a clear radar return to alert ships fitted with anti-collision radars.

Routine vessel activities (Section 3.8) associated with the Pluto facility to support crewed operations are concentrated within the PSZ (e.g., activities performed by support and resupply vessels at the platform as well as an ASV). Subsea support vessels, or USVs may undertake activities (e.g., IMMR, removal of redundant equipment) within the PAA at any time, including within parts of the PAA which are beyond the PSZ. The duration and location of these activities varies depending on the activity being undertaken.

Planned maintenance campaigns undertaken during routine intervention activities typically occur ten times per year, lasting approximately 14 days per campaign. Vessels required for major projects, including AHV and subsea installation vessels may undertake activities within the PAA as required.

An ASV may be present for up to approximately 90 days during a planned extended maintenance campaign, shutdown maintenance or major project. Whilst such activities are underway, the ASV would be connected to the platform 24 hours per day, seven days per week. An ASV may be used approximately once every 3-6 years.

Subsea infrastructure associated with operations activities may have the potential for interactions with other marine users. The AHO has been notified of the location of all existing subsea infrastructure, for marking on nautical charts. Water depths of the existing subsea infrastructure range between 40 m at the export pipeline state boundary and 180-962 m, at the hydrocarbon gathering system. The Pluto riser platform itself, is located at the edge of the continental shelf at 85 m depth. A number of oil and gas facilities are located in the vicinity of the Operational Areas as are fibre optic cables (Section 4.10.5 and Section 4.10.6).

Presence of MODU, Xena-03 Tie-back activities and associated Subsea Infrastructure

The activity includes mooring system installation, drilling of one well, installation of a wellhead and xmas tree, and connection of the well to the existing Pyxis Hub subsea infrastructure.

Support vessels will be used for MODU mooring system installation activities before the arrival of the MODU, and for retrieval of anchors following completion of drilling when the MODU departs. Each of these phases are intended to last seven to 10 days.

A MODU is planned to be present for approximately 60 days, including mobilisation, demobilisation and contingency activities. When underway, activities will be 24 hours per day, seven days per week. A 500 m safety exclusion zone (SEZ) will be applied to the MODU within the Xena-03 Operational Area for the duration of the drilling activity. A support vessel would be present in proximity to the MODU, which would also be supported periodically by another support vessel to facilitate resupply.

Installation vessels will be used to install, pre-commission and cold commission the flexible flowline, subsea distribution unit, and other subsea infrastructure following completion of drilling of the new well, as described in Section 3.11. This is expected to take approximately three weeks. Installation is expected to be predominantly undertaken by the primary installation vessel (PIV), which will be surrounded by a 500 m SEZ when on-location within the Xena-03 Operational Area. A smaller vessel (IMMR type) may be used to undertake components of the installation activity before or after primary installation has been completed.

Mooring installation, drilling and subsea installation activities are expected to be temporally discrete (i.e., conducted at different times); however, they may overlap. If these activities coincide, a vessel support or PIV type) would be active in the Xena-03 Operational Area while the MODU (supported by two OSVs) is present. A SIMOPS plan would be in place to manage interaction between vessels in the field.

Xena-03 Tie-back activities will include the addition of new infrastructure within the PAA. The proposed Xena-03 wellhead, subsea xmas tree and other subsea infrastructure will remain for the duration of field life. All new infrastructure will be contained within the existing Facility Operational Area.

The AHO will be notified of the Xena-03 well and associated subsea infrastructure locations. Further, once Xena-03 infrastructure is operational, potential interactions with other marine users will be managed as per all other subsea infrastructure associated with Pluto operations.

Impact Assessment

Exclusion and Displacement of Other Users

Interaction with other marine users due to the physical presence of activity-related vessels in the PAP may result in localised changes to the functions, interests or activities of other users.

The duration and extent of potential for interaction will depend on the activity undertaken, and are outlined below:

- Pluto facility operations – ongoing, for the period of the Petroleum Activities Program, limited to the Facility Operational Area. Typically the duration of potential interaction will be 14 days, 10 times a year, but could include a planned extended maintenance campaign, shutdown maintenance or major project involving an ASV and lasting approximately 90 days, which could occur every 3-6 years.
- Xena-03 Tie-back activities – approximately 60 days, limited to the Xena-03 Operational Area.
- IMMR – typically 14 days, throughout the PAA. Frequency varies depending on the type of IMMR activities required which range from once a year to once every 25 years (Table 3-14).

Commercial Fishing

The PAA overlaps four Commonwealth and 15 State managed commercial fisheries management areas. Historical fisheries data indicate that only one Commonwealth fishery and 10 State-managed fisheries have been active within the PAA over the last five years. To identify active fisheries with the potential for interaction, ABARES and FishCube data at the 10 NM and 60 NM CAES reporting blocks overlapping the PAA were identified and fishery effort was assessed (Section 4.10.1).

Routine Operations

The Commonwealth-managed North West Slope Trawl Fishery, and 10 State-managed fisheries are considered to have potential for interaction with activities in the PAA. There is potential to interact with the activity is based on their catch effort drawn from ABARES (Commonwealth) and FishCube (WA State) data. The catch effort is described for each fishery in Table 4-23 in Section 4.10.1.

Fishing activities will be excluded from the PSZ around the platform and from ASV temporary SEZ. As the ASV is located within the facility PSZ potential for cumulative impacts are not credible. Potential impacts to commercial fisheries include loss of commercial catch due to displacement from fishing grounds and potential damage to fishing gear. Fisheries using divers, lines, traps, and pots have little or no potential to interact with subsea infrastructure, hence impacts to such fisheries will be limited to localised displacement from the PSZ and temporary SEZ associated with the ASV. As such, the potential impact is considered to be localised displacement of fishing effort to avoid subsea infrastructure, exclusion zones, and vessels undertaking the petroleum activity

The continued presence of subsea infrastructure over the field life could present a hazard to bottom trawl fisheries due to the risk of equipment entanglement and subsequent equipment damage/loss. The presence of subsea infrastructure could present a hazard to bottom trawl fisheries due to risk of equipment entanglement and subsequent equipment damage/loss. Given the catch effort of commercial fisheries outlined in Table 4-23, anticipated impacts from activities associated with the ongoing presence of infrastructure are assessed as having no lasting effect

Xena-03 Tie-back Activities

During Xena-03 Tie-back activities, additional vessels will be temporarily present in the Xena-03 Operational Area and may restrict the use of the area by the commercial fisheries and tour operators that have been identified as having potential to use the region. Use will particularly be restricted within the 500 m SEZ (temporary) that will be established around the MODU and installation vessel while undertaking drilling and installation activities. The exclusions represent a relatively small area when compared to the extent of the fishery boundaries that overlap. The MODU is planned to be present for approximately 60 days, and the installation vessels for up to three weeks. Potential impacts to commercial fisheries include damage to fishing equipment and physical displacement from some parts of the managed fishery areas for the duration of the Xena-03 Tie-back activities.

Given the distance offshore and previous fishing effort within the Facility Operational Area (discussed above), the Xena-03 Operational Area is not considered to be an area of high commercial fishing activity. Furthermore, the 500 m temporary exclusion zones around the MODU and installation vessel comprise a relatively small area when compared to the extent of the individual fishery boundaries that overlap. As such, any displacement of commercial fisheries due to the Xena-03 Tie-back activities in the Xena-03 Operational Area are not expected to impact commercial fishing activities or the economic viability of the fisheries.

Tourism and Recreation

Tourism and recreation activity in the PAA is expected to be infrequent, with recreational and charter fishing from vessels the only tourism and recreational activities identified as potentially occurring.

The Montebello Islands State Marine Park (~25 km from the PAA), is the closest location for tourism with some charter boat operators taking visitors to these islands. Reported fishing charter catch effort (at 10 NM CAES blocks) within the PAA, is predominantly located along the Export Pipeline. There may be recreational fishing at Rankin Bank, which is ~29 km from the PAA. The Export Pipeline Operational Area is 13 km from the Dampier Archipelago at the state boundary and therefore, low numbers of recreational vessels may be encountered within that nearshore area.

Given the distance from boating facilities, lack of natural attractions and water depth (~85 m) of the Facility Operational Area, very little recreational or charter fishing is expected to occur. In nearshore waters where the Export Pipeline Operational Area has the potential for greater interaction with tourism and recreational activities, given the infrequent and transient nature of IMMR activities and the known presence of current infrastructure, any impacts are not likely to be of significance. Collectively, activities in the PAA are not likely to significantly impact recreational and tourism activities and are expected to be localised with no lasting effect.

Shipping

Commercial shipping occurs in high numbers across the NWS, based on the proximity to key export ports. Commercial shipping traffic comprises vessels, including:

- bulk carriers (e.g., mineral ore, salt) from Port Hedland, Port Walcott and Dampier
- offtake tankers
- support vessels for offshore oil and gas activities
- LNG carriers from Dampier, Barrow Island and Ashburton North.

To reduce the likelihood of interactions between commercial vessels and offshore facilities, AMSA has introduced a series of shipping fairways, within which commercial vessels are advised to navigate. The fairways are not mandatory, but AMSA strongly recommends commercial vessels remain within the fairway when transiting the region. The use of shipping fairways is considered to be good seafaring practice, with AUSREP data from AMSA indicating cargo ships and tankers routinely navigate within the established fairways.

No shipping fairways interact with the Facility and/or Xena-03 operational areas; however, two fairways overlap the Export Pipeline Operational Area:

- A fairway directs north/south-bound vessel traffic from Barrow Island and the southern Montebello Islands.
- A fairway travels parallel to the coast, from Barrow Island to the Dampier Shipping Fairways.

In addition, most vessel activity in the vicinity of the PAA is associated with nodes such as offshore facilities (e.g., Wheatstone) and ports; no such nodes occur within the PAA (aside from the Pluto facility).

The presence of the Pluto riser platform, vessels and subsea infrastructure does not result in impacts to commercial shipping beyond a localised exclusion of shipping traffic from the PSZ and the temporary displacement of commercial shipping from subsea support vessels as a result of vessels undertaking activities in the PAA.

Oil and Gas

Several oil and gas facilities are located within 50 km of the PAA (see Section 4.10.5), the nearest being the Wheatstone platform 5 km north of the Pluto riser platform. Operational history of the facility has shown that interactions with other titleholders has not been an issue to date.

The PAA overlaps WA-48-L which is a production licence held by Chevron Australia Pty Ltd and other (non-Woodside) titleholders with Chevron as operator. No subsea infrastructure associated with the PAP is located in WA-48-L, however, the operational area extends 4000 m from the Xena-03 well and into WA-48-L. The PAA does not overlap any production wells in WA-48-L. All activities on the seabed including drilling will be undertaken within Woodside-operated titles.

Submarine communications infrastructure is also present in the region with the Chevron fibre optic cable intersecting the Export Trunkline Operational Area twice (Section 4.10.6).

Cumulative Impacts

Given the presence of the riser platform, subsea infrastructure and export pipeline as well as support vessels there is the potential for cumulative impacts due to the presence of the Wheatstone platform, subsea infrastructure and support vessels. Additionally, a MODU and support vessels will also be present during Xena-03 Tie-back activities which may incrementally increase cumulative impacts for a shorter period of time ~12 weeks.

Other marine users will be restricted from exclusion zones established around the Pluto riser platform for the duration of this EP and from around the MODU and installation vessels for ~12 weeks. These exclusion zones in combination remain negligible, and partially temporary, relative to the area of overlapping fisheries zones.

Vessel activities in support of both Pluto Facility operations and Xena-03 Tie-back activities are usually of a short duration. Any impacts arising from presence of additional vessels in connection with Xena-03 Tie-back activities are expected to be localised and short-lived with limited, if any, cumulative impacts anticipated.

Demonstration of ALARP

Control Considered	***Control Feasibility (F) and Cost/ Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Legislation, Codes and Standards				
Contract vessels compliant with Marine Orders for safe vessel operations: • Marine Order 21 (Safety of navigation and emergency procedures) 2016 • Marine Order 27 (Safety of navigation and radio equipment) 2016 • Marine Order 30 (Prevention of collisions) 2016. Compliance with Marine Orders 21, 27 and 30 reduces the likelihood of interactions.	F: Yes. CS: Minimal cost. Standard practice.	Marine Orders 21, 27 and 30 are required under Australian Regulations; implementation is standard practice for commercial vessels as applicable to vessel size, type and class.	Control based on legislative requirement – must be adopted.	Yes C 1.1

Implementation of a 500 m PSZ around riser platform reduces the likelihood of interaction of vessels with the facility.	F: Yes. CS: Minimal cost. Standard practice.	The PSZ is a requirement under Australian Regulations and reduces the likelihood of interactions with third parties and the riser platform.	Control based on legislative requirement – must be adopted.	Yes C 1.2
Establishment of a 500 m SEZ around ASV and communicated to marine users.	F: Yes. CS: Minimal cost. Standard practice.	Establishment of a 500 m safety exclusion zone around ASV reduces the likelihood of interaction with other marine users.	Benefits outweigh cost/sacrifice. Control is also standard practice.	Yes C 1.3
Establishment of a 500 m sez around MODU and primary installation vessel and communicated to marine users.	F: Yes. CS: Minimal cost. Standard practice.	Establishment of a 500 m safety exclusion zone around MODU and the primary installation vessel reduces the likelihood of interaction with other marine users.	Benefits outweigh cost/sacrifice. Control is also standard practice.	Yes C 1.4
For Xena-03 Tie-back activities, reasonable attempts at removal of wellhead(s) will be made in the event of a respud.	F: Yes. CS: Additional cost. Standard practice.	In accordance with OPGGS Act Section 572.	Benefits outweigh cost/ sacrifice. Control is also standard practice.	Yes C 1.5
MODU mooring systems (chains/wires and anchors) will be removed.	F: Yes CS: Additional cost. Standard Practice.	In accordance with OPGGS Act Section 572.	Benefits outweigh cost/sacrifice.	Yes C 1.6
Good Practice				
Location of permanent infrastructure shown on AHO marine charts.	F: Yes. CS: Minimal cost. Standard practice.	Include location of Pluto infrastructure on maritime charts.	Benefits outweigh cost/sacrifice.	Yes C 1.7
Consultation undertaken in support of the Petroleum Activities Program, so that marine users are informed and aware.	F: Yes. CS: Minimal cost. Standard practice.	Consultation ensures marine users, including those associated with the activities of adjacent titleholders, are informed and aware.	Benefits outweigh cost/sacrifice.	Yes C 1.8
Notify AHO of activities no less than four working weeks prior to scheduled activity commencement date (during operations, where vessels will be in the PAA, but outside of the PSZ>3 weeks).	F: Yes. CS: Minimal cost. Standard Practice.	Notification of AHO will enable them to issue a Maritime Safety Information Notifications (MSIN) and Notice to Mariners (NTM) thereby reducing the likelihood of unplanned interactions with other vessels.	Benefits outweigh cost/sacrifice.	Yes C 1.9
Notify AMSA ARC least 24-48 hours before operations commence (during operations if vessels are undertaking activities within the PAA for more than three weeks at a time)	F: Yes CS: Minimal cost. Standard Practice.	Communicating the PAP to other marine users ensures they are informed and aware should emergency response be required.	Benefits outweigh cost/sacrifice.	Yes C 1.10

Notify relevant persons for Xena-03 Tie-back activities within the PAP that commence more than a year after EP acceptance.	F: Yes. CS: Minimal cost. Standard practice.	Communicating the PAP to other marine users ensures they are informed and aware, thereby reducing the likelihood of interference with other marine users.	Benefits outweigh cost/ sacrifice. Control is also standard practice.	Yes C 1.11
Notify DoD no less than four weeks before Xena-03 Tie-back activities commence.	F: Yes CS: Additional cost. Standard practice.	In accordance with request made by DoD during consultation.	Benefits outweigh cost/sacrifice.	Yes C 1.12
Notify relevant government departments, fishing industry representative bodies and licence holders of activities prior to commencement and upon completion of the Xena-03 Tie-back activities.	F: Yes. CS: Minimal cost. Standard practice.	Communication of the PAP to other marine users ensures they are informed and aware, thereby reducing the likelihood of interference with other marine users.	Benefits outweigh cost/sacrifice. Control is also standard practice.	Yes C 1.13
Notify AMSA JRCC at least 24-48 hours before operations commence, if vessels are undertaking activities in, or in close proximity to (within 1 km of), shipping lane	F: Yes CS: Minimal. The control will only apply to IMMR activities undertaken within a shipping lane.	Notification of AMSA ensures they are informed and aware, thereby reducing the risk of unplanned interactions within shipping lanes.	Benefits outweigh cost/sacrifice.	Yes C 1.14
Develop a SIMOPS Plan to manage MODU interactions with other facilities/vessels, where multiple campaigns occur within the PAA (i.e., during xmas tree installation). SIMOPS Plan to contain information on: • minimum separation distances • communications • MODU/vessels/ activities involved in SIMOPS • exclusion zone entry and exit processes • ROV operations • helicopter operations • key roles, responsibilities and emergency contacts • PTW arrangements • incident reporting and investigation • management of change.	F: Yes. CS: Minimal cost. Standard practice.	SIMOPS Management Plans between Woodside operated vessels in the PAA will provide for efficient delivery of the activity.	Benefits outweigh cost/sacrifice.	Yes C 1.15

Professional Judgement – Eliminate				
Reducing the PSZ.	F: No. PSZ is mandated by the OPGGS Act and is an SCE; it cannot be reduced. CS: Not assessed, control not feasible.	Not assessed, control not feasible.	Not assessed, control not feasible.	No
Limit the PAP to avoid peak shipping and commercial fishing activities.	F: No. Shipping occurs year-round and cannot be avoided. SIMOPS with fishing seasons cannot be eliminated as exact timings for all activities are not confirmed. CS: Not considered, control not feasible.	Not considered, control not feasible.	Not considered, control not feasible.	No
Professional Judgement – Substitute				
None identified.				
Professional Judgement – Engineered Solution				
Pluto's collision prevention system is implemented to alert marine vessels of the facility location, which reduces the likelihood of adverse interaction with other marine users.	F: Yes. CS: Minimal cost. Standard practice.	Pluto's collision prevention system equipment has the ability to alert marine vessels of the facility location, which reduces the likelihood of adverse interaction with other marine users.	Control is SCE requirement – must be adopted.	Yes C1.16
Over-trawl protection on subsea infrastructure.	F: Yes. Over-trawl protection on subsea infrastructure could be fitted to Pluto subsea infrastructure. CS: Significant additional cost associated with designing and installing trawl protection on subsea infrastructure.	Over-trawl protection on subsea infrastructure could mitigate the potential for commercial fishing trawl gear to damage infrastructure or result in gear loss.	Given the PAA only overlies a small portion of the fisheries management area open to trawl fishing, the cost of installing over-trawl protection is considered grossly disproportionate to the environmental benefit.	No

ALARP Statement:

On the basis of the environmental impact assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the potential impacts of the physical presence of the facility, subsea infrastructure, MODU and project vessels on other users.

Identified controls comprehensively cover all legislative requirements, relevant industry codes, standards and guidelines as well as company requirements.

Efforts towards reducing potential for impacts by identifying additional or alternative controls was a key feature of HAZID/ENVID studies informing this EP. As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.

Demonstration of Acceptability

Acceptability Statement:

The approach to risk assessment and implementation strategy is consistent with Woodside policies, procedures and standards ensuring consistency and reliability in our environmental management practices. The management of risk and potential impacts of the activity to other marine users and values are also consistent with legislative and other regulatory requirements including relevant policy documents, guidelines and conservation plans. This ensures our activities are aligned with national standards and objectives.

Woodside has engaged with Chevron and established an Ingress Agreement between Woodside and Chevron to allow required activities within WA-48-L.

Woodside has comprehensively considered the socio-economic context relevant to the activity allowing us to understand and respect the inherent values and sensitivities of other users of the operational area of the activity. We have assessed, responded to and adopted controls from objections and claims received from relevant persons, ensuring community concerns are addressed in our management strategies of the activity. This includes expectations of AMSA and AHO provided in consultation with relevant persons.

The potential impacts are considered broadly acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the impacts from the physical presence of the PAP to a level that is broadly acceptable; and demonstrates the EPOs are met.

Disturbance to seabed from mooring installation		x	x		x				E					

Placement and retrieval of seabed transponders and temporary installation aids		x	x		x				E					

Description of Source of Impact

Seabed disturbance associated with the PAP can occur during operations and Xena-03 Tie-back activities, including:

- physical presence of the facility and subsea infrastructure (operational and redundant) scour, spans, and flowline movement inherent in design
- subsea IMMR activities
- Xena-03 Tie-back activities.

Pluto Operations

Physical Presence

The physical presence of the Pluto facility provides hard substrate habitats from the surface to the seabed via jackets and risers, as well as along the seabed from pipelines, flowlines and manifolds. The presence of subsea infrastructure and the interaction with hydrodynamic processes may result in localised scouring to the seabed and localised sedimentation of fine substrates around infrastructure. An ASV may be present in the PAA as described in Section 3.8.3. The ASV is not expected to anchor or disturb sediment.

Flowline movement may occur as per design and within integrity margins along the flowline corridors. Normal flowline operational movement occurs due to factors such as flowline buckling, walking and varying metocean conditions. Lateral movement can occur within the flowline corridor. Management of flowline buckling and walking, and scouring around subsea infrastructure may necessitate IMMR activities, as part of integrity management practices.

Subsea IMMR Activities

Woodside may be required to undertake routine subsea IMMR activities within the PAA, to maintain the integrity of subsea infrastructure. IMMR activities identified as impacting the benthic environment include:

- inspections – localised sediment resuspension by ROV
- marine growth removal – localised resuspension of sediment; removal of marine biota from subsea infrastructure and the Pluto facility jacket
- sediment relocation – localised modification of benthic habitat and sediment resuspension
- span rectification, pipeline protection and stabilisation – minor, localised modification of benthic habitat within footprint of area subject to rectification/protection/stabilisation
- flowline and umbilical replacement – minor, localised modification of benthic habitat in the vicinity of the flowline/umbilical
- spool repair/replacement – minor, localised modification of benthic habitat in the vicinity of the spool
- temporary placement of tools on the seabed, such as baskets – minor localised modification of the benthic habitat in the vicinity of the items.
- pig launcher/receiver installation and retrieval – minor, localised modification of benthic habitat and sediment resuspension in the vicinity of the receiver.

The area of benthic habitat predicted to be impacted varies depending on the nature and scale of the IMMR activity, however, no impact is expected beyond the PAA. Span rectification is the IMMR activity with the greatest potential to modify benthic habitats, due to the alteration of the existing soft sediment habitat to hard substrate. Woodside's operational experience on the North West Shelf indicates these activities (e.g., span rectification, pipeline protection and stabilisation) are typically restricted to relatively short (tens of metres) linear sections of pipeline, with areas of up to approximately 200 m² impacted. Refer to MEE-02 Subsea equipment loss of containment which includes controls to limit scour and flowline movement within integrity requirements.

Xena Tie-back Drilling and MODU Operations

Drilling activities may result in intermittent or discontinuous direct physical or mechanical disturbance to the seabed up to an approximate 100 m radial distance around the Xena-03 well location due to the installation of the BOP and conductor. Potential impacts to the seabed from the generation and discharge of cuttings and drilling fluids are considered in Section 6.7.8 and Section 6.7.9 respectively.

Mooring Installation and Anchor Hold Testing

The Xena-03 well may be drilled using a moored or hybrid MODU. Seabed disturbance will result from installation of the MODU anchor mooring system (supported by AHVs), including placement of anchors and chain/wire/fibre lines on the seabed, potential dragging during tensioning, and recovery of anchors. Mooring may require an 8 to 12 point pre-laid mooring system, with RAR and buoyed arrangements an option, depending on the time of year. Although the exact anchoring configurations are not finalised, a semi-submersible MODU with an 8 to 12-point anchoring system

could disturb up to 0.013 km² (13,000 m²), allowing for anchor footprint and disturbance from anchor chains (NERA, 2018).

The area of seabed affected by mooring installation depends upon water depth, currents, size of the vessels and anchors, and length of anchor chain (NERA, 2018). Seabed disturbance from mooring installation and anchor hold testing will result in localised, small scale seabed disturbance relating to the benthic habitats described in Section 4.5.

The planned anchoring activities are to be within the parameters defined in the Anchoring of Vessels and Floating Facilities Environment Plan Reference Case (Department of Industry, Innovation and Science, undated) for all anchoring activities performed by vessels and floating facilities (excluding FPSOs and Floating LNG vessels) during the PAP, including:

- installation of moorings, buoys, equipment or other infrastructure for a period of up to two years
- wet storage on seabed of anchor chains, etc. during activities up to two years
- activities with total areas of seabed disturbance less than 13,000 m²
- locations of water depth greater than 70 m. This boundary is set to exclude areas of sensitive primary producer habitats (e.g., corals, seagrass) that occur in shallower waters.

Subsea Installation Activities

Subsea installation will include the installation of subsea infrastructure (including placement of materials/equipment on the seabed), supporting structures (including wellhead, flowline, flying leads, subsea distribution unit, mudmats) and installation aids (clump weights, concrete mattresses, sandbags). Subsea infrastructure components are described in Section 3.4. The estimated total footprint of the Xena-03 Tie-back is 1405 m², with additional subsea infrastructure including the 500 m flowline, wellhead, EHU, concrete mats and UTAs.

Subsea structures (subsea distribution unit, mudmats) will be deployed to the seabed by the installation vessel's primary crane and guided to final position by ROV. Commencement of the flowline installation generally requires tension to the flowline as it transitions from the installation vessel to the seabed. Therefore, commencement of the flowline installation may start with landing the end of flowline termination head into the manifold connection system or on the seabed attached to the initiation anchor (drag anchor or clump weight/dead anchor). This will cause small, localised and temporary impacts to water quality in the vicinity of flowline landout.

Once the termination end is fully landed, the flowline is to be continuously laid using vertical lay system and at the same time, the ROV monitors the touch-down point on the seabed as well as the flexible lay back radius. Flying leads will be deployed to the seabed in deployment baskets, and final subsea tie-in will be completed using ROVs.

Span Rectification

The optimum flexible flowline route will be selected by considering seabed bathymetry, pre-installation ROV surveys and installation risk management, including dropped object risks and buckling/walking impacts. This reduces the potential for spanning and therefore the need for span rectification, while avoiding potential hard substrate habitats.

Where span rectification is required, concrete mattresses may be positioned at the identified free span location using the vessel crane and ROV. The dimensions for each concrete mattress are expected to be 6 m × 3 m × 0.3 m. Post-lay span rectification may involve placing grout bags (multiple ~25 kg) on the seabed, with the extent of any impact limited to the footprint of the installed flexible flowline.

Scouring

Scouring is the movement of sediment around the base of subsea structures due to prevailing wind conditions. Concrete mattresses may be installed at the Xena-03 UTA if required, to mitigate scouring.

Stabilisation

Stabilisation is a post lay activity so that light items, such as HFL, EFL and flowlines, remain at their installed positions; i.e., not being shifted due to strong seabed current, by installing sand bags on top of HFLs, EFLs and flowlines at a predetermined distance apart. Sandbags generally come in a standard size with 20 kg to 40 kg weight. Concrete mattresses may also be used for stabilisation of some sections of the Xena-03 flexible flowline subject to detailed design.

Crossings

Sandbags or concrete mattresses may be installed for crossings over existing umbilicals or flowlines.

Wet Storage of Equipment

Temporary wet storage of installation aids may be required intermittently during Xena-03 Tie-back activities. Installation aids will be recovered at the completion of the Xena-03 Tie-back activities by ROV and project vessels.

ROV Operations

The use of an ROV during drilling and subsea installation activities may result in temporary seabed disturbance and suspension of sediment as a result of working close to, or occasionally on, the seabed. ROV use close to or on the seabed is limited to that required for effective and safe subsea activities. The footprint of a typical ROV is about 2.5 m × 1.7 m (4.25 m²).

Additionally, an ROV may be used to relocate small amounts of sediment material to create a stable, level surface and reduce the potential for scouring from subsea equipment (e.g., BOP).

Marine Growth Removal

Excess marine growth may need to be removed following return to well after a period of suspended drilling. Removing marine growth is undertaken via a high-pressure water and/or brushes or acid, by ROV.

Underwater Transponders

An array of long base line (LBL) transponders may be installed on the seabed as required to support drilling and subsea installation activities. Transponders may be moored to the seabed either by a clump weight or mounted on a seabed frame. The standard clump weights used, made of cement or steel, will likely weigh about 80 kg. A typical seabed frame is 1.5 m × 1.5 m × 1.5 m in dimension and weighs about 40 kg. On completion of the positioning operation, the array transponders moored by clump weight will be recovered by means of a hydrostatic release and the clump weights removed from the seabed. The transponders mounted on seabed frames will be removed by ROV.

Contingency Activities

Woodside may need to intervene or workover the Xena-03 well. Any seabed disturbance would be the same as those described for drilling operations and MODU operations. In addition, in the event of a respud of the Xena-03 well, the base case would be to remove the wellhead. However, if reasonable attempts at wellhead removal are unsuccessful, a wellhead may remain in situ until the end of field life. If this is the case, it will be recorded in a database and monitored and maintained until decommissioned. If a wellhead is left in-situ, there would be localised seabed disturbance at the wellhead location.

Impact Assessment

Drilling, subsea installation, IMMR activities and physical presence of subsea infrastructure can be categorised into two potential impacts:

- direct physical disturbance of benthic habitat
- indirect disturbance to benthic habitats from sedimentation.

ROVs working well above the seabed do not have an impact on the seabed.

Water and Sediment Quality

Seabed disturbance may include localised and temporary decline in water quality due to increased suspended sediment concentrations and increased sediment deposition caused by drilling, subsea installation and IMMR activities near the seabed. Similarly, removal of marine growth from the Pluto jacket for structural integrity maintenance, carried out on an as required basis, would cause localised temporary decrease in water quality and suspended sediment from water jetting activities.

Each discrete IMMR activity near the seabed is likely to cause a single brief disturbance resulting in a transient plume of suspended sediment. This plume will subsequently be deposited down current as particles settle out. Such localised and short-term events may affect small areas of the seabed and consequently, impact the associated biota (typically sparsely distributed infauna and sessile fauna). Given the expected nature and scale of resuspension resulting from IMMR activities, impacts such as smothering or burial are not expected. Rather, impacts are likely to be restricted to increased ingestion of sediments by filter feeders. Biota in the region are well adapted to periodic turbidity events caused by cyclones and tidal movements. As such, impacts from turbidity caused by IMMR activities are not expected to have any lasting effect on benthic biota.

Benthic Habitats

The Pluto facility is located within deeper offshore waters (~85 m) approximately 152 km north-west of Dampier and includes the riser platform, hydrocarbon gathering system and export pipeline, extending through shallower waters to the state-waters boundary. The benthic habitat within the PAA is predominantly soft sediment (Section 4.5) with sparsely associated epifauna, which is broadly represented throughout the NWSP and NP Provinces.

Benthic communities in the soft sediment seabed are characterised by burrowing infauna such as polychaetes, with biota such as sessile filter feeders occurring on areas of hard substrate (such as subsea infrastructure).

Direct seabed disturbance, including permanent modification of benthic communities, may result as a consequence of IMMR activities, such as span rectification, pipeline protection and stabilisation. These activities typically disturb a small area (typically <200 m²) of soft sediment habitat, which is broadly represented in the PAA and wider NWMR region.

Drilling

Physical impacts from drilling activities (excluding impacts from routine and non-routine discharges such as drill cuttings assessed in Section 6.7.8) are expected to be for the most part confined to sediment burrowing infauna and surface epifauna invertebrates, particularly filter feeders, inhabiting the seabed directly around the Xena-03 well. Impacts from the installation of subsea infrastructure are expected to be confined to sediment burrowing infauna and surface epifauna invertebrates, particularly filter feeders, inhabiting the seabed directly around the installation site. Impacts to these broadly represented communities are expected to be highly localised with no significant impact.

Seabed disturbance will be limited to the wellhead (100 m radial distance), subsea infrastructure and anchoring physical footprint (estimated at up to 0.013 km²); a small proportion of the benthic habitat and associated communities of the PAA will be affected. Marine life such as deep water benthic communities epifauna and infauna (living on and in the sediment dominated habitat), may be impacted from the placement of project infrastructure (i.e., Xena-03 wellhead, flowline and subsea infrastructure), or placement of temporary supporting infrastructure (anchors, installation aids) and equipment (e.g. mud mats) on the seabed. Potential impacts include burial or smothering of benthic biota from localised sediment deposition, particularly to sessile epifauna such as sea pens and infauna (polychaetes); and potential clogging or damage to the physiological functioning of certain biota (sea pens, polychaetes) reliant on external respiratory and feeding structures from elevated suspended sediment load (turbidity). Secondary impacts may include highly localised alterations to epifauna and infauna communities (Newell et al., 1998).

Mooring installation activities (MODU) are likely to result in localised physical modification to a small area of the seabed and disturbance to soft sediment. An anchor must travel a certain horizontal distance before penetrating and embedding into the seabed. The drag length of the anchors may be up to a linear distance of 100 m from the drop location (NERA, 2018). The disturbance footprint extends beyond this distance with the anchor chain. The maximum disturbance radius of each anchor drop will therefore not exceed the drag length, plus the additional length of the anchor chain that comes into contact with the sea floor (4000 m). Following recovery of the anchors, impacts from the disturbance (estimated at up to 0.013 km²) are expected to be localised and short-term, with the underlying conditions present to support re-colonisation and recovery after the activity has been completed (Ingole et al., 2005).

ROV activities associated with IMMR and Xena-03 Tie-back operations, near the seafloor and small amounts of sediment relocation may result in slight and short-term impacts to deepwater biota, detailed above, as a result of elevated turbidity and localised sedimentation. However, elevated turbidity and sedimentation would only be expected to be slight and short-term, and is therefore, not expected to have any consequential impact to environment receptors.

Values and Sensitivities

Ancient Coastline at 125 m Depth Contour

The Facility Operational Area overlaps approximately 9 km² of the 16,190 km² Ancient Coastline, which is about 0.06% of the KEF. The Facility Operational Area represents a 1500 m² buffer around the Pluto subsea infrastructure to facilitate vessel operations; the potential for seabed disturbance is much more localised (i.e., within tens of metres of the subsea infrastructure).

Benthic habitat surveys in the region (including within the Ancient Coastline at 125 m depth contour KEF) indicate that benthic habitats within the KEF are characterised by sand interspersed with areas of rubble and outcroppings of limestone pavement (AIMS, 2014b; RPS, 2011). Such habitats are widely distributed in the NWMR. No significant escarpments, species of conservation significance, emergent features or areas of high biological productivity characteristically associated with the Ancient Coastline at 125 m KEF have been observed in the Facility Operational Area. As noted in Section 4.7, the geomorphic feature associated with this KEF is represented worldwide and represents the coastline during a previous glacial period. These impacts are discussed in relation to filter feeders above. Therefore, potential impacts to this regional-scale KEF are expected to be negligible.

Continental Slope Demersal Fish Communities

The Facility Operational Area and the Xena-03 Operational Area overlap the Continental Slope Demersal Fish Communities KEF. Seabed disturbance will have no adverse environmental impact on this KEF and the presence of the riser platform and subsea infrastructure may provide habitat for demersal fish communities potentially having a low level positive environmental impact.

Montebello Australian Marine Park (IUCN IV)

A small portion of the Pluto Export Pipeline Operational Area overlaps the Montebello Marine Park Multiple Use Zone. The Marine Park includes values associated with the shallow shelf environment; however, no pinnacle or terrace seafloor features are found within the Operational Areas.

Direct loss of sediments in the Marine Park may be possible if IMMR activities include the placement of materials on the seabed. In addition, indirect impacts may occur as a result of sedimentation. These impacts are discussed in relation to soft sediment benthic habitats above.

Cultural Heritage

As described in Section 4.10, the PAA overlaps the Ancient Coastline at 125 m depth contour KEF. The wider Xena-03 Operational Area overlaps the Ancient Coastline KEF, the targeted well location and installation activities for the Xena-03 well are not within the Ancient Coastline KEF. Therefore, there may be the potential that Indigenous Cultural features may exist, and these may potentially be impacted during seabed disturbance resulting from operations and associated activities. While no cultural features have been identified in the PAA, consultations with First Nations groups have been undertaken for the Petroleum Activities Program.

Cumulative Impacts

Seabed disturbance may arise from the Pluto facility, subsea infrastructure and IMMR activities as well as Xena-03 tie-back activities at a localised level limited to well within the PAA. At a regional scale, cumulative impacts also arise from the presence of the Wheatstone platform and associated subsea infrastructure and activities. The activities are expected to incur localised and temporary declines in water quality and modification of soft sediment habitat where

infrastructure has a physical footprint. These impacts are considered to be temporary and, in the case of benthic habitat modification, limited relative to the vast representation of similar habitat in the PAA and surrounds as well as regionally. Cumulative impacts are considered to be localised and temporary, or in the case of physical footprints, to be slight relative to the presence of similar habitat in the PAA and regionally.

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Legislation, Codes and Standards				
For Xena-03 subsea tie-back activities, reasonable attempt(s) at removal of wellhead will be undertaken in the event of a respud and if unable to be removed, is monitored and maintained.	F: Yes. CS: Additional cost. Standard practice.	In accordance with OPGGS Act Section 572.	Benefits outweigh cost/ sacrifice.	Yes Refer to C 1.5
MODU mooring systems (chains/wires and anchors) will be removed.	F: Yes. CS: Additional cost. Standard practice.	In accordance with OPGGS Act Section 572.	Benefits outweigh cost/ sacrifice.	Yes Refer to C 1.6
A ROV survey will be undertaken post maintenance or repair activity, and post Xena-03 Tie-back activities, to confirm all temporary equipment has been removed and to record location of new subsea infrastructure.	F: Yes. CS: Minimal cost ROV as left survey is standard practice.	In accordance with OPGGS Act Section 572 all equipment is removed when no longer in use.	Legislative requirement.	Yes C 2.1
Location of subsea infrastructure and temporary equipment brought into the PAA, is tracked and recorded.	F: Yes. CS: Minimal cost. Standard Practice.	In accordance with OPGGS Act Section 572 the location of equipment is tracked to enable future removal.	Benefits outweigh cost/sacrifice.	Yes C 2.2
Monitoring and maintenance of redundant infrastructure is undertaken in accordance with the IMMR process.	F: Yes. CS: Minimal cost. Standard practice.	Monitoring and maintenance of redundant subsea infrastructure undertaken to enable cost efficient and safe removal and meet Section 572(2) and (3) of the OPGGS Act.	Legislative requirement.	Yes C 2.3
Remove redundant infrastructure as soon as it is no longer used, nor to be used.	F: Yes. CS: Removal of property throughout the operational life where it is incorporated within or located close to live infrastructure introduces	While subsea equipment is in-situ, risks and impacts to the seabed are considered to be low, so only a minor reduction in sediment/habitat disturbance from less infrastructure in the PAA would be achieved.	Cost of standalone retrieval work scopes are considered disproportionate to the benefit gained when considering the risks of retrieval during current	No

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
	additional complexities and HSE risk that can be avoided if removed during EOFL decommissioning.		operations versus risk of extending duration in-situ. Wet-stored subsea infrastructure is also RBI-assessed and managed while preserved to ensure integrity and retrieval options are maintained for potential full removal.	
Good Practice				
Subsea infrastructure will be positioned within planned footprint to reduce seabed disturbance.	F: Yes. CS: Standard practice.	Ensures risks appropriately addressed for seabed disturbance.	Benefits outweigh cost/sacrifice.	Yes C 2.4
Xena-03 Project-specific Basis of Well Design, which includes an assessment of seabed sensitivity.	F: Yes. CS: Minimal cost. Standard practice.	Reduces the likelihood of anchoring occurring in areas of high sensitivity.	Benefits outweigh cost/sacrifice.	Yes C 2.5
Project-specific MODU Mooring Design Analysis.	F: Yes. CS: Additional costs associated with upgraded MODU mooring design.	The mooring design analysis determines the number and spread of anchors required based on sediment type and seabed topography, reducing the likelihood of anchor drag leading to seabed disturbance.	Benefits outweigh cost/sacrifice.	Yes C 2.6
Positioning technology used to place seabed infrastructure within the design footprint to reduce seabed disturbance.	F: Yes. CS: Minimal cost. Standard practice.	Use of positioning technology to position infrastructure on the seabed with accuracy will reduce seabed disturbance.	Benefits outweigh cost/sacrifice.	Yes C 2.7
Wet parked items will be tracked and removed from the seabed (monitoring and maintenance).	F: Yes. CS: Minimal cost. Standard practice.	Ensures inventory of equipment is maintained and no wet parked items are unintentionally left in situ.	Benefits outweigh cost/sacrifice.	Yes C 2.8
Unexpected finds of potential Underwater Cultural Heritage sites/ features, including First Nations UCH are managed in accordance	F: Yes. CS: Cost of implementation.	Allows management of Unexpected Finds in accordance with legislative requirements, (including Underwater Cultural Heritage Guidance for Offshore	Benefits outweigh cost/ sacrifice.	Yes C 30.1

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
with an Unexpected Finds Procedure set out in Section 7.8.		Developments and the guidelines for assessing and managing impacts to underwater cultural heritage(DCCEEW 2024c),, expert advice and community expectations.		
Report any potential UCH finds to relevant stakeholders and authorities in accordance with the Unexpected Finds Procedure, Underwater Cultural Heritage Act 2018 and the ATSIHP Act	F: Yes. CS: Minimal costs associated with reporting process.	Meets legislative requirements and community expectations.	Benefit outweighs cost/ sacrifice.	Yes C 30.2
Relevant vessel crew, USV remote operators and ROV operators will be advised in an induction of the potential to encounter UCH and requirement to follow the Unexpected Finds Procedure	F: Yes. CS: Minimal costs associated with reporting process.	Ensures workforce are suitably aware of legal and process requirements for managing cultural features and heritage values.	Benefits outweigh cost/ sacrifice.	Yes C 30.3
Professional Judgement – Eliminate				
Vessels used for IMMR/ Support Vessels used for Xena-03 Tie-back activities will not anchor under routine operations.	F: Yes. CS: Minimal. Subsea support vessels undertaking IMMR activities typically do not anchor	By not anchoring, the potential impacts to benthic habitat are reduced.	Benefits outweigh cost/sacrifice.	Yes C 2.9
ASV will not anchor under routine operations.	F: Yes. CS: Minimal. ASV undertaking platform support activities typically do not anchor.	By not anchoring, the potential impacts to benthic habitat are reduced.	Benefits outweigh cost/sacrifice.	Yes C 2.10
Pre-lay survey undertaken prior to installation of flowlines.	F: Yes CS: Minimal cost.	May identify potential environmental sensitivities within subsea infrastructure footprint. Given the relatively small footprint and previous observations in the Operational Area, no particularly sensitive benthic habitats are expected to occur. Pre-lay surveys are routinely undertaken for engineering purposes.	Benefits outweigh cost/sacrifice.	Yes C 2.11

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Do not use ROV close to, or on, the seabed.	F: No. The use of ROVs (including work close to or occasionally landed on the seabed) is critical as the ROV is an integral part of IMMR activities. CS: Not assessed, control not feasible.	Not assessed, control not feasible.	Not assessed, control not feasible.	No
Do not complete anchor hold testing for the MODU.	F: No. Anchor hold testing is a requirement for a moored MODU and it is not technically feasible for the MODU to use DP in the water depth of the well location (about 130 m). Woodside has a demonstrated capacity to manage the environmental risks and impacts from mooring to a level that is ALARP and acceptable. CS: Not assessed, control not feasible.	Not assessed, control not feasible.	Not assessed, control not feasible.	No

None identified.				
Professional Judgement – Engineered Solution				
Monitoring and maintenance of subsea infrastructure to manage scour and flowline movement to within integrity envelope.	F: Yes, subsea inspection maintenance and integrity monitoring is undertaken which inherently controls extent of scour and flowline movement. CS: Minimal cost. Standard practice	Monitoring and maintenance of subsea infrastructure confirms benthic seabed disturbance is limited to design flowline corridor.	Control is WMS requirement – must be adopted.	Yes C 2.12 Refer also MEE-02

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Monitoring of seabed surrounding riser platform and subsea infrastructure.	F: Yes. ROV footage collected as part of subsea integrity surveys could be reviewed to observe and detect changed in benthic habitats. CS: Costs associated with the review of collected footage.	Limited environmental benefit (information) gained from monitoring benthic habitats.	Given the sparsely populated infauna habitat and low sensitivity of the environment surrounding the facility and associated subsea infrastructure, any environmental benefit gained is outweighed by costs associated with implementing control.	No
ALARP Statement: On the basis of the environmental impact assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts of seabed disturbance from Xena-03 Tie-back activities and subsea IMMR activities. As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.				
Demonstration of Acceptability				
Acceptability Statement: The impact assessment has determined that, given the adopted controls, seabed disturbance from subsea activities is unlikely to result in a potential impact greater than slight, short-term impact to benthic habitats and marine sediments and water quality. Further opportunities to reduce the impacts have been investigated above. The adopted controls are considered good oil-field practice/industry best practice. The potential impacts are considered broadly acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the impacts of Xena-03 Tie-back activities and subsea IMMR activities to a level that is broadly acceptable; and demonstrate the EPOs are met.

Impacts and Risks Evaluation Summary

Source of Impact	***Environmental Value Potentially Impacted***							***Evaluation***						
	Soil and Groundwater	Marine Sediment	Water Quality	Air Quality (incl Odour)	Ecosystems/Habitat	Species	Socio-economic	Decision Type	Consequence/Impact	Likelihood	Risk Rating	ALARP Tool	Acceptability	Outcome
Noise generated from: • Pluto facility and associated subsea infrastructure • vessels (platform support and supply vessels as well as ASV) • helicopters • subsea IMMR activities (routine and non-routine) and positioning equipment						x		A	F	-	-	LCS GP PJ	Broadly Acceptable	EPO 3a EPO 3b

Description of Source of Impact

The facility and associated subsea infrastructure, platform-related vessel activities (platform support and supply vessels as well as ASV), helicopters, IMMR activities and associated positioning equipment will generate noise both in the air and underwater, due to normal operation of machinery noise, propeller movement, and infrequent routine and non-routine activities. Typical noise levels for these sources are provided in Table 6-3, with more detailed descriptions provided below. This noise will contribute to and can exceed ambient noise levels which range from around 90 dB re 1 µPa sound pressure level (SPL) under very calm, low wind conditions, to 120 dB re 1 µPa SPL under windy conditions (McCauley, 2005).

Sound levels will fluctuate over the course of the PAP and will depend on concurrent vessel activities. Generally, sound associated with operations of the NNC Pluto facility and associated subsea infrastructure will be limited. Short-term increases in sound will occur from time to time associated with platform support and supply vessel operations in the vicinity of the Pluto Facility within the PSZ. It is also anticipated, that an ASV may be required at the Pluto Facility in connection with major maintenance campaigns once every 3-6 years for up to 90 days.

In addition to above-mentioned platform-related vessel activities, IMMR vessel activities may also occur intermittently in the vicinity of subsea infrastructure anywhere within the PAA.

Key acoustic sources associated with the PAP are described below. Table 6-3 presents potential concurrent activities contributing to cumulative underwater noise levels. This has been used to inform the worst-case credible sound propagation scenarios for modelling as well as cumulative impact assessment as a result of concurrent operations.

Table 6-3: Indicative source characteristics of underwater noise associated with the PAP as reported in Jiménez-Arranz et al. (2017) and by McCauley (2005) and McCauley (2002)

Acoustic Noise Sources	Estimated SPL (dB re 1 µPa SPL) @1 m unless otherwise stated	Frequency Range (kHz)
Vessels (Continuous)		
Platform support and supply vessels or USV, ASV using DP	182	Broadband
IMMR Activity Noise (Pulsed)		
Multibeam echo sounder (MBES)	210–247	12–675
Side scan sonar (SSS)	200–234	9–675
Sub-bottom profiler (SBP) (Pinger)	167–212	4–12
SBP (Chirp)	161–205	2–23
SBP (Boomer)	205–225	0.3–6
Wellhead, Flowlines and Subsea Infrastructure (Continuous)		
Wellhead	113	Broadband
Choke valve	155	Broadband
Production platforms		
Riser platform	110–130 @100 m	Broadband (mainly < 100 Hz)

** Range provided was not measured at the noise source; therefore, this should be used as an indicative estimate only and cannot be used to estimate exposure thresholds closer to the source.*

Continuous (Non-impulsive) Noise Sources

Platform Machinery and Flaring

Production platforms have machinery mounted on decks raised above the sea, hence, most noise is transmitted to the marine environment from air (i.e., power generation and operational flaring). Machinery noise on-board the riser platform may be radiated into the underwater environment via the jacket legs and risers, which may act as transducers. Monitoring programs have indicated that underwater noise from platforms is typically very low or not detectable (Jiménez-Arranz et al., 2017; McCauley, 2002).

The flare system will generate noise from combustion. Noise from flaring represents a health and safety risk to personnel, and noise from flaring was considered in the design of the facility to manage the occupational health and safety risks associated with noise (e.g., height specification of flare tower). Noise from flaring is emitted at the top of the flare tower, which has a flare boom length of 87 m. Noise from the tip of the flare is not constrained and will spread spherically in all directions.

Gales (1982) assessed noise from 18 oil and gas platforms, including 11 bottom-standing fixed platforms during production operations (i.e., consistent with the Pluto riser platform). The study found the strongest noise levels were relatively low frequency (<100 Hz, and mostly between 4 and 38 Hz), with sound levels of 110 to 130 dB re 1 µPa @100 m (Gales, 1982). Noise from the platforms was found to be lower than levels recorded from support vessels, with a cumulative increase in overall underwater noise of 20–30 dB from the noise produced by a support vessel operating in the vicinity of an operations platform (Gales, 1982).

Noise emitted from machinery on the riser platform is limited relative to other operating facilities due to its NNC status, smaller size and the lack of processing facilities on the riser platform. Therefore, it is likely that the range provided by Gales (1982) is a conservative estimate. Noise from the riser platform is not expected to significantly increase from operation of the Water Handling Module given the nature and duration of the activity. In summary, noise emissions generated by the facility are expected to be minimal.

Wellheads, Pipelines and Subsea Infrastructure

The noise produced by an operational wellhead was measured by McCauley (2002). The broadband noise level was very low, 113 dB re 1 µPa, which is only marginally above rough sea condition ambient noise. For a number of nearby wellheads, the sources would have to be in very close proximity (<50 m apart) before their signals summed to increase the total noise field (with two adjacent sources only increasing the total noise field by 3 dB). Hence, for multiple wellheads in an area, the broadband noise level in the vicinity of the wellheads would be expected to be of the order of 113 dB re 1 µPa and this would drop very quickly to ambient conditions on moving away from the wellhead, falling to background levels within <200 m from the wellhead.

Based on the measurements of wellhead noise discussed in McCauley (2002), which included noise from flowlines, noise emitted along a flowline or the export pipeline may be expected to be similar to that described for wellheads, with the radiated noise field falling to ambient levels within a hundred metres of the flowline or export pipeline.

Woodside has undertaken acoustic measurements on noise generated by the operation of choke valves associated with the Angel facility (JASCO, 2015) similar to the design employed across Pluto subsea valves. These measurements indicated choke valve noise is continuous, and the frequency and intensity of noise emitted is dependent on the rate of production from the well. Noise intensity at low production rates (16% and 30% choke positions) were approximately 154–155 dB re 1 μPa, with higher production rates (85% and 74% choke positions) resulting in lower noise levels (141–144 dB re 1 μPa). Noise from choke valve operation was broadband in nature, with the majority of noise energy concentrated above 1 kHz.

Vessels and Operations of Dynamic Positioning Systems

The main source of noise from vessels (platform support and supply, ASV and subsea IMMR) relates to the use of DP thrusters (i.e., cavitation from thruster propellers). Thruster noise is typically high intensity and broadband in nature, with sound pressure levels of 137 dB re 1 μPa at 405 m from a typical offshore support vessel holding station in strong currents (McCauley 1998). McCauley (2005) measured underwater broadband noise up to approximately 182 dB re 1 μPa at 1 m (SPL) from a support vessel holding station in the Timor Sea; it is expected that noise levels up to this level may be generated by vessels using DP during the Petroleum Activities Program. Thruster noise from vessels holding station is typically the most intense underwater noise source from vessel activities; other sources of underwater noise from vessels (e.g., main engines when underway, machinery noise transmitted through the hull, etc) are typically considerably lower intensity noise (McCauley, 1998). Note that vessels undertaking the PAP inherently minimise the use of DP, and there is little potential to reduce DP use further.

For planned operations and maintenance activities, vessels are expected to be in the field operating 24 hours per day for approximately 14 days, approximately 10 times per year. However, vessels will be present for longer durations or at a higher frequency during pigging operations, corrective maintenance and interventions, major/shutdown maintenance, contingent manning (refer to Section 3.5.3). For example, the ASV may be utilised for campaigns of approximately 90 days duration once every 3-6 years (Section 3.8.3).

Helicopter Transfers

Helicopter activities occur in the PAA, including landing and take-off on the facility or vessel helidecks. Helicopters land and take-off on the riser platform (which occurs typically twice every 10 weeks during normal operations but may occur more often during unplanned maintenance activities) and potentially on subsea support vessels. Sound emitted from helicopter operations is typically below 500 Hz (Richardson et al., 1995). The peak received level diminishes with increasing helicopter altitude, but the duration of audibility often increases with increasing altitude.

Richardson et al. (1995) reports that helicopter sound is audible in air for four minutes before it passed over underwater hydrophones, but detectable underwater for only 38 seconds at 3 m depth and 11 seconds at 18 m depth. Noise levels reported for a Bell 212 helicopter during fly-over was reported at 162 dB re 1 μPa (SPL) and for Sikorsky-61 is 108 dB re 1 μPa (SPL) at 305 m (Simmonds et al., 2004). Water has a very high acoustic impedance contrast compared to air, and the sea surface is a strong reflector of noise energy (i.e., very little noise energy generated above the sea surface) crosses into and propagates below the sea surface (and vice versa) – the majority of the noise energy is reflected). The angle at which the sound path meets the surface influences the transmission of noise energy from the atmosphere through the sea surface, angles >13° from vertical being almost entirely reflected (Richardson et al., 1995). Given this, and the typical characteristics of helicopter flights within the PAA (duration, frequency, altitude and air speed), the opportunity for underwater noise levels to exceed the behavioural thresholds is not considered credible and is not assessed further.

Impulsive Noise Sources

Subsea Inspection, Monitoring, Maintenance and Repair Activities

MBES and SSS are low-energy, high-resolution geophysical survey instruments that may be required for IMMR every one to six years to identify buckling, movement, scour and seabed features. MBES have operating frequencies ranging from 12 kHz to 700 kHz (Jimenez-Arranz et al., 2017) with peak pressure (PK) source levels between approximately 210 and 245 dB re 1 μPa at 1 m (Jimenez-Arranz et al., 2017; Zykov, 2013; MacGillivray et al., 2013). MBES generate micro-pulses of high frequency sound in a highly focused beam directed towards the seabed, which attenuates rapidly underwater compared to lower frequency sound sources. Due to this directionality and short pulse duration, there is relatively low sound energy and very limited horizontal sound propagation. The high operating frequencies of many MBES are typically above the hearing range of the low frequency (LF) cetacean (7 Hz to 35 kHz; Southall et al. 2019) and high frequency (HF) cetacean (150 Hz to 160 kHz; Southall et al. 2019) species that may occur in the Petroleum Activities Area. The high operating frequencies of MBES are also above the hearing ranges of marine turtles (<2 kHz, Finneran et al., 2017) and the majority of fish species (100 Hz to several kHz; Ladich, 2000; Popper et al., 2014). Additionally, sound sources generated closer to the seabed have a lower received noise level in the horizontal direction due to seafloor scattering and absorption.

Similar to MBES, SSS produce micro-pulses of sound in a focussed swath directed at the seabed. SSS operating frequencies may range between 75 kHz and 900 kHz, with sound energy attenuating rapidly with horizontal distance from the main swath (Jimenez-Arranz et al., 2017; Zykov, 2013). Representative source levels range between 200 and 235 dB re 1 μPa PK at 1 m (Jimenez-Arranz et al., 2017; Zykov, 2013). The high operating frequencies of SSS places the

dominant sound frequencies above the hearing range of most marine fauna species, including LF cetaceans, turtles and fish, although some of the lower frequency devices may be audible to HF cetaceans (MacGillivray et al., 2013; Zykov, 2013).

Sub-bottom profiling may also be undertaken every one to six years to identify features under the seabed. Most commercial SBPs are small, low-powered, high-resolution and shallow-penetrating systems, producing electrical pulses across a range of frequencies (Salgado Kent et al., 2016; Jiménez-Arranz et al., 2017). The instruments proposed for the survey produce pulses of sound between approximately 2 kHz and 30 kHz with source levels between approximately 170 and 230 dB re 1µPa PK at 1 m. Indicative source characteristics for typical acoustic survey equipment are provided in Table 6-3.

Positioning Equipment

An array of long baseline (LBL) and/or ultrashort baseline (USBL) transponders may be used for positioning during IMMR activities. Transponders typically emit pulses of medium frequency sound, generally within the range 21 to 31 kHz. The estimated SPL at source ranges from 180 to 202 dB re 1 µPa SPL at 1 m (Jiménez-Arranz et al., 2017). Transmissions are not continuous but consist of short 'chirps' with a duration that ranges from 3 to 40 milliseconds. Transponders will not emit any sound when on standby, and when required for precise positioning they will emit one chirp every five seconds.

Cumulative Noise Sources

Concurrent activities contributing to cumulative underwater noise from vessel activities during routine operations are outlined in Table 6-4.

As a worst-case scenario, the riser platform, when in crewed mode, may be supported by an ASV (in addition to a platform support vessel and supply vessel) within the PSZ and with IMMR activities underway anywhere in the Facility Offshore Operational Area or Export Pipeline Operational Area. Activities utilising single vessels are not expected to contribute significantly to the cumulative noise footprint, due to their relatively small size, short activity duration and separation distances from other activities.

Table 6-4: Concurrent activities contributing to cumulative underwater vessel noise.

Scenario	Platform Mode	Sources	Location	Duration
1. Platform and subsea infrastructure	Uncrewed	Platform and subsea infrastructure No vessels	Within PSZ and location of wells.	Continuous
	Crewed	Platform and subsea infrastructure	Within PSZ and location of wells	Continuous
		1 x platform support vessel (PSV)	Inside PSZ + Outside PSZ but inside Operational Area	Typically in operation for full 14 days of crewed platform period
		1x supply vessel	Within PSZ	24-48 hrs, 1-2 visits per 15 days of crewed platform period
2. Platform and subsea infrastructure with concurrent IMMR activities	Uncrewed	As per Scenario 1	As per Scenario 1	As per Scenario 1
		IMMR activity (1x subsea support vessel or an USV)	IMMR anywhere in Facility offshore operational area or Export Pipeline operational area	Approximately 2 weeks per activity at the frequencies described in Section 3.10
	Crewed	As per Scenario 1	As per Scenario 1	As per Scenario 1
		IMMR activity (1x subsea support vessel or an USV)	IMMR anywhere in Facility offshore operational area or Export Pipeline operational area	Approximately 2 weeks per activity at the frequencies described in Section 3.10
3. Platform and subsea infrastructure with concurrent IMMR activities and ASV	Crewed	As per Scenario 2	As per Scenario 2	As per Scenario 2
		1x accommodation support vessel (ASV)	Within PSZ	ASV may occur up to 90 days during planned maintenance campaigns

				provisionally planned to occur once every 3-6 years. Requirement for an ASV is not scheduled to occur concurrently with Xena-03 tie-back activities.

Sound Transmission Loss Modelling

Noise modelling was commissioned from JASCO by Woodside for the Julimar Appraisal Drilling and Surveys activities (Julimar South-1 well) (Stroot et al., 2022) and Pyxis Drilling and Subsea Installation activities (Xena-02 well) (Wecker, et al., 2022), which is considered broadly comparable or conservative in terms of anticipated noise emissions from the platform and subsea infrastructure as well as associated platform support and supply vessel activities.

The noise profile of the ASV, should it be utilised within the life of the EP, is considered to be covered by analogue modelling for the Xena02 well of a MODU on DP which has a higher sound source level of ~187.7 dB re 1 μPa^2m^2s). For DP vessel activities, noise modelling of a MODU on DP with a support vessel resupply under DP (8 hr) and support vessel resupply on standby (24 hr) is considered to adequately represent the worst case scenario of activities co-occurring at the Pluto Facility.

For the addition of an IMMR vessel operating concurrent with the crewed mode of the Pluto platform, Woodside recently commissioned a cumulative noise study of 5 FPSOs or support/IMMR vessels which conservatively provides for the ensonified area surrounding a suitable model IMMR vessel, Fugro Etive (Li et al. 2024).

Table 6-5: Summary of the modelled scenario at the Xena (Xena-02) field as a worst-case analogue for DP operations for routine operations within the PSZ for the Pluto platform (source: Wecker et al., 2022 and Stroot et al. 2022)

Scenario Number (Wecker et al. 2022, Stroot et al. 2022)	Concurrent activity scenario (Table 6-12)	Description
5	1 – crewed	Anchored MODU Drilling (24h) + OSV resupply, under DP (8h) + OSV on standby (24h)
N/A	2 – crewed	As per scenario number 5 with the addition of an IMMR vessel located at the Xena-03 well.
10	3 – crewed	MODU under DP, (ASV) (24 hr) + support vessel resupply, under DP (8 hr) + support vessel resupply on standby (24 hr) with the addition of an IMMR vessel located at the Xena-03 well.

Impact Assessment

Receptors

Fauna associated with the PAA is predominantly pelagic species of fish, with migratory species such as turtles, whale sharks and cetaceans potentially present in the area seasonally. Noise interference is a key threat to a number of migratory and threatened cetaceans and marine turtles identified as occurring within the PAA (Section 4.6).

Noise interference is a key threat to a number of migratory and threatened cetaceans and marine turtles identified as potentially occurring within the Facility and Xena-03 Operational Areas, including the pygmy blue whale (PBW).

The Export Pipeline Operational Area extends from the Facility Operational Area, across Commonwealth Waters to the boundary with WA State Waters. The fauna associated with the Export Pipeline Operational Area includes both pelagic and demersal species of fish. Additional migratory species associated with the Export Pipeline Operational Area include migrating humpback whales, and marine turtle aggregation areas near State waters and the coastline (**Section 4.6**). Relevant actions included in recovery plans for these species are outlined in Section 6.10**Error! Reference source not found.**.

The key BIAs within the PAA include:

- PBW migration BIA (overlapping the Facility and Xena-03 Operational Areas, approximately 17 km from the Pluto Facility)

- Humpback whale migration BIA (overlapping the Export Pipeline Operational Area, approximately 24 km from the Pluto Facility)
- Flatback turtle (overlapping all Operational Areas) and Hawksbill turtle (overlapping the Export Pipeline Operational Area) internesting BIAs.
- Whale shark foraging BIA (overlapping all Operational Areas)

In addition, habitat critical to the survival of green and hawksbill turtles also overlap the Export Pipeline Operational Area. Habitat critical to the survival of flatback turtles overlap all Operational Areas.

Two key ecological features overlap the PAA. The Facility and Xena-03 Operational Areas overlap the Continental Slope Demersal Fish Communities and the Facility Operational Area also overlaps the Ancient Coastline at 125 m KEF.

Demersal fish from these KEFs may be impacted by noise emissions. While the Ancient Coastline at 125 m KEF may be associated with outcroppings of hard substrate, no evidence of significant reefs has been found in the Facility Operational Area. Note: some demersal fish are also likely to be associated with subsea infrastructure such as the export pipeline (McLean et al., 2017).

In addition to the KEFs, the Montebello Marine Park Multiple Use Zone also overlaps the Facility and Export Pipeline Operational Areas. The perimeter of the Montebello Marine Park is ~420 m from the Pluto facility. This marine park supports a range of species listed under the EPBC Act. Biologically important areas within this marine park include breeding habitat for seabirds, internesting, foraging, mating, and nesting habitat for marine turtles, a migratory pathway for humpback whales and foraging habitat for whale sharks. Impacts to these values are described below.

Potential Impacts of Noise

Elevated underwater noise can affect marine fauna, including cetaceans, fish, turtles, sharks and rays, in three main ways (Richardson et al., 1995; Simmonds et al., 2004):

- by causing direct physical effects on hearing or other organs. Hearing loss may be temporary (temporary threshold shift (TTS) referred to as auditory fatigue), or permanent threshold shift (PTS) (injury)
- by masking or interfering with other biologically important sounds (including vocal communication, echolocation, signals and sounds produced by predators or prey)
- through disturbance leading to behavioural changes or displacement from important areas (e.g., BIAs). The occurrence and intensity of disturbance is highly variable and depends on a range of factors relating to the animal and situation.

Increasing the distance from the noise source usually results in the level of noise reducing, due primarily to the spreading of the sound energy with distance. The way that the noise spreads (geometrical divergence) depend upon several factors such as water column depth, pressure, temperature gradients, and salinity, as well as surface and bottom conditions.

Cetaceans

Species Sensitivity and Exposure Thresholds

Marine mammals and especially cetaceans rely on sound for important life functions including individual recognition, socialising, detecting predators and prey, navigation and reproduction (Weilgart, 2007; Erbe et al., 2015; Erbe et al., 2018). Underwater noise can affect marine mammals in various ways including interfering with communication (masking), behavioural changes, a shift in the hearing threshold (PTS and TTS), physical damage and stress (Erbe, 2012; Rolland et al., 2012). Frequency-specific hearing sensitivity differs among marine mammals, influencing how they are affected by noise exposure. For the purposes of predicting the effects of noise exposure on different groups of cetaceans, blue whales, humpback whales and other large mysticete (baleen) whales are categorised as low frequency (LF) cetaceans, while odontocetes (toothed whales and dolphins) are categorised as high frequency (HF) or very high frequency (VHF) cetaceans (Southall et al., 2019).

The thresholds that could result in behavioural response for cetaceans is expected to be 120 dB re 1 µPa (SPL) for continuous noise sources, and 160 dB re 1 µPa (SPL) for impulsive noise sources (Table 6-6). These thresholds have been adopted by the United States National Oceanic and Atmospheric Administration (NOAA) (National Marine Fisheries Service [NMFS], 2014, 2018; Southall et al., 2019; NOAA, 2019). The adopted thresholds are based on best data available and published in peer-reviewed literature and represent conservative internationally accepted and applied impact evaluation thresholds.

Table 6-6: Thresholds for permanent and temporary threshold shift and behavioural response onset for low-frequency, high-frequency and very high frequency cetaceans for continuous and impulsive noise

Hearing Group	Impulsive					Continuous		
	PTS Onset		TTS Onset		Behavioural Response	PTS Onset	TTS Onset	Behavioural Response
	SEL24h	PK	SEL24h	PK	SPL	SEL24h	SEL24h	SPL

LF cetaceans	183	219	168	213	160	199	179	120
HF cetaceans	185	230	170	224	160	198	178	120
VHF cetaceans	155	202	140	196	160	173	153	120

Source: NMFS (2014, 2018; Southall, 2019; NOAA, 2019).

SEL24h expressed as dB re 1 µPa².s; Peak pressure (PK) and SPL expressed as dB re 1 µPa.

The Conservation Management Plan for the Blue Whale (BWCMP) (Commonwealth of Australia, 2015a), a recovery plan made under the EPBC Act, defines important areas for PBW and these are also described with reference to BIAs in the National Conservation Values Atlas (NCVA), with particular emphasis placed on foraging areas and migration corridors. As noted above and in Section **Error! Reference source not found.**, the Facility and Xena-03 Operational Areas overlap the pygmy blue whale migration BIA, the perimeter of which is approximately 17 km from the Pluto platform. The nearest foraging BIA (Ningaloo possible foraging area) is approximately 232 km to the south of the PAA. Action Area A.2.3 of the BWCMP states: "Anthropogenic noise in biologically important areas will be managed such that any blue whale continues to utilise the area without injury, and is not displaced from a foraging area". Furthermore, the Guidance on Key Terms within the Blue Whale Conservation Management Plan (DAWE, 2021), underwater noise emissions from the PAP must not:

- result in injury[55] (TTS or PTS) to any pygmy blue whale in BIAs, or
- displace a pygmy blue whale from a foraging BIA.

The following assessment of impacts to cetaceans includes consideration of the requirements of the BWCMP with respect to pygmy blue whales.

The National Recovery Plan for the Southern Right Whale (DCCEEW, 2024a) also identified anthropogenic noise as a threat, however the BIAs and habitat critical to the survival are over 250 km away, well outside the area where behavioural responses are expected to extend from the Operational Area and as such, there is not expected to be any anthropogenic noise from the petroleum activity that could displace or interfere with life cycle activities within, or near, the reproduction or migration BIAs and habitat critical to the survival.

The humpback whale migration BIA overlaps with the Export Pipeline Operational Area. The Pluto facility is located outside the humpback whale migration BIA (platform is ~24 km north-west of the BIA boundary, see **Error! Reference source not found.**).

Predicted Underwater Noise Impacts to Cetaceans

Facility and Support Vessel Noise Impacts

Vessels holding station are considered to be the predominant noise source related to the Petroleum Activities Program. Using thruster noise, McCauley (1998) measured underwater broadband noise equivalent to about 182 dB re 1 µPa (SPL) at 1 m from a support vessel holding station in the Timor Sea. Similar noise levels are expected to be generated by vessels used for the Petroleum Activities Program.

PTS and TTS thresholds for LF cetaceans are 199 dB re 1 µPa2 s (SEL weighted) and 179 dB re 1 µPa2 s (SEL weighted), respectively for continuous noise sources (refer Table 6-6). Typical sound exposures generated by the facility and a support vessel using DP would not exceed the PTS threshold for LF cetaceans and only exceed the TTS threshold at very close ranges to the source, so PTS and TTS in LF cetaceans, such as large baleen whales, is not anticipated.

The thresholds that could result in a behavioural response for cetaceans is expected to be 120 dB re 1 µPa (SPL) for continuous noise sources such as vessels (refer Table 6-6).

With the worst-case inclusion of an ASV (concurrent activity scenario 3), an analogue acoustic modelling scenario by JASCO for a MODU on DP (Wecker et al., 2022) was considered conservative. This modelling indicated that PTS and TTS thresholds for low frequency (LF) cetaceans, such as humpback and pygmy blue whales, may be exceeded at a maximum distance of 0.13 km and 2.66 km, respectively. The TTS threshold for HF and VHF cetaceans is exceeded at 0.13 and 2.63 km, respectively. For PTS, the maximum distance at which the threshold is exceeded for HF and VHF cetaceans is 0.09 km and 0.15 km, respectively.

The radii that represent potential for PTS and TTS onset are based on a 24-hour period of cumulative exposure and therefore represent an unlikely worst-case scenario since, more realistically, cetaceans would not stay in the same location or at the same range for 24-hours. It is not considered credible that individual LF, HF and VHF cetaceans that may pass through the Facility Operational Area during DP vessel operations would experience PTS, given individuals would need to remain within 150 m of the PSZ for a period of 24 hours. TTS onset is also considered highly unlikely given the known movement behaviour of cetaceans including key migrating LF whale species such as the pygmy blue whale and humpback whale transiting through the Facility and Export Pipeline Operational Areas, respectively. The PAA is not known to represent significant foraging/aggregation habitat for cetaceans and individuals are not expected to dwell within the area for extended periods.

The behavioural response threshold may be exceeded from platform-related vessel activities at a maximum of 20.7 km if an ASV is in operation (8.85 km if an ASV is not in use) and may thus overlap slightly with the pygmy blue whale migration BIA which is 17 km from the Pluto facility.

Potential impacts to cetaceans from a single support or IMMR vessels operating concurrently with other noise sources may include behavioural disturbance from DP. In 2024, JASCO modelled cumulative noise sources including the model IMMR vessel, Fugro Etive (Li et al. 2024). The distance from the Fugro Etive at which the behavioural impact threshold for cetaceans was no longer exceeded was ~7.5 km. This result was achieved in conjunction with other vessels and FPSOs in the region and is considered conservative relative to a single vessel planned for IMMR activities.

Cetaceans are capable of moving away from potential noise sources, and there are no constraints to their movement within the PAA. LF cetaceans such as humpback whales and PBW may be seasonally present in the PAA, though limited to individuals infrequently transiting through the area. Interactions between PBW or humpback whales with vessels typically result in avoidance behaviour, with whales generally moving away from vessels (Bauer, 1986; Stamation *et al*., 2010).

Given the migration corridor BIAs for PBW and humpback whales overlap the PAA (pygmy blue whale BIA overlaps the Facility Operational Area and humpback whales BIA overlaps the Export Pipeline Operational Area), there is the potential for these species to be exposed to underwater noise from vessels associated with the PAP when they are present in the region during seasonal migrations. However, as the underwater noise levels that may be generated by DP vessels and IMMR activities are below those resulting in impairment or mortality, only behavioural impacts are credible. Impacts are expected to be limited to localised avoidance of the noise source as there are no physical barriers in or near the operational areas that may prevent cetaceans from moving away from vessels.

Aerial surveys of humpback whales show the majority of humpback whales migrate within continental shelf waters along Western Australia (Double et al., 2010, 2012; Jenner et al., 2001). Humpback whales are expected to transit the Export Pipeline Operational Area during their annual north and south migrations between May and November, where vessel activity will be limited to during intermittent IMMR activities. These activities are relatively short-term and occur relatively infrequently and, therefore, are unlikely to impact humpback whales.

PBW are likely to be present when migrating north between April and August and south between October and December. Tagging studies of PBW showed tagged animals were typically in water depths of >1000 m. PBW are expected to transit the subsea hydrocarbon gathering system section of the facility and are unlikely to occur within proximity to the riser platform.

Mid and high frequency cetaceans are known to show behavioural disturbance at a range of received noise levels (Southall et al., 2007a). Mid- and high frequency cetaceans may exhibit short-term behavioural responses to increased levels of underwater noise, such as avoidance or attraction. This is expected to occur mainly within the Export Pipeline Operational Area during IMMR activities, but is unlikely to significantly impact these species (e.g., spotted bottlenose dolphins).

In the unlikely worst-case event that an IMMR vessel is in use within the PAA whilst an ASV is in operation, the noise profile of the Petroleum Activity Program could be further elevated for a short period of time. The worst-case location for co-timing of an IMMR activity with platform-related vessel activities involving also an ASV, would be if IMMR activities were underway in the Xena-03 Operational Area. In such circumstances, the IMMR activities would overlap with the pygmy blue whale migration BIA with behavioural disturbance from a vessel on DP conservatively being out to about 7.5 km. Depending on the precise location of IMMR activities, it is possible that the ensonified area of the IMMR overlapping the pygmy blue whale migration BIA could intersect the ensonified area overlapping the BIA from platform-related vessel activities (20.7 km radii), as the distance between the Xena-03 location and the Pluto platform is ~15.1 km.

The rare use of an ASV to support major maintenance activities (once every 3-6 years for 90 days) and the risk that an IMMR vessel may occur within the pygmy blue whale migration BIA at the time of biological sensitivity, is unlikely. Given, further, that the overlap of the potential ensonified areas with the pygmy blue whale migration BIA is very small relative to the total extent of the BIA in which individuals would be transiting, any behavioural impacts to cetaceans from concurrent vessel activities are considered to be localised with no lasting effect.

IMMR Activities

Zykov (2013) conducted acoustic modelling for five low energy survey instruments off the coast of California, including MBES, SSS and sub-bottom profiler. All equipment types were modelled in the sandy bottom environment, similar to that of the PAA. Although the bathymetry, salinity, water temperature and sub-seafloor sediment type may differ, given the similarities in equipment type and seafloor habitat, the modelling is considered comparable for the nature and scale of the low energy IMMR survey equipment.

The high operating frequencies of MBES and SSS places the majority of sound frequencies above the auditory range of LF cetaceans. Dolphins and other HF cetaceans, which have peak hearing sensitivity up to 110 kHz, with potential for some limited hearing ability up to approximately 160 kHz (NMFS 2018, Southall et al. 2019), may be able to detect a small amount of the sound energy from some instruments in the lower operating frequency ranges available for MBES and SSS (MacGillivray et al., 2013; Zykov, 2013).

The modelling by Zykov (2013) indicates that the sound emissions from MBES and SSS do not exceed PTS and TTS accumulated sound exposure criteria for LF cetaceans at any distance, and do no– exceed criteria for HF cetaceans beyond 2–3 m horizontal distance from the source, which is not considered to be a credible exposure scenario for mobile marine fauna. Zykov (2013) also estimated the maximum distance at which the unweighted 160 dB re 1 µPa (SPL) behavioural disturbance threshold for impulsive sound was reached was 290 m for MBES and 690 m for SSS. Again, it is emphasised that many MBES and SSS instruments may operate at frequencies outside of the hearing range of cetaceans and so these would not be audible or result in behavioural disturbance. For instruments with frequencies that overlap with the hearing ranges of cetaceans, a significant proportion of the sound energy may still be outside of their hearing ranges, therefore, the perceived sound levels are reduced and the horizontal distances at which behavioural disturbances may occur are less than those inferred by the unweighted 160 dB re 1 µPa (SPL) behavioural disturbance threshold. For example, modelling of weighted SPLs by Zykov (2013) for MBES indicated that the 160 dB re 1 µPa (SPL) behavioural threshold was not exceeded for LF cetaceans at any distance and was limited to approximately 205 m horizontal distance for HF cetaceans. For SSS, the modelling of weighted SPLs indicated that the 160 dB re 1 µPa (SPL) behavioural threshold was exceeded at horizontal distances of 110 m for LF cetaceans and 611 m for HF cetaceans.

Acoustic modelling of sub-bottom profilers by Zykov (2013) and McPherson and Wood (2017) indicates limited horizontal sound propagation outside of the main directional field of sound. The modelling studies also indicate PK and SEL24h thresholds for PTS are not exceeded. The potential for TTS resulting from SEL24h is limited to within a few metres from the moving sound source (Zykov, 2013; McPherson and Wood, 2017), which is not considered to be a credible exposure for mobile marine fauna. Exceedance of the 160 dB re 1 µPa SPL behavioural response threshold for impulsive sound is limited to within a few metres in most instances, or up to a maximum of 50 m depending upon which SBP instrument is used, water depth and the seabed sediment characteristics (Zykov, 2013; McPherson and Wood, 2017).

Potential impacts to cetaceans from MBES, SSS and sub-bottom profiler may, therefore, include behavioural disturbance if in close proximity to the survey instruments, but ranges to disturbance are less than or equivalent to disturbance ranges for the IMMR vessel itself. PTS or TTS are not considered credible, given individuals would need to be directly next to the noise sources for prolonged duration.

Transponders used for positioning during IMMR activities have the potential to cause some temporary behavioural disturbance to cetaceans. The typical frequencies of 21 to 31 kHz produced by the transponders are most audible to HF cetaceans such as toothed whales and dolphins rather than LF cetaceans, and the source levels (180 to 202 dB re 1 µPa at 1 m SPL) rapidly attenuate within a very short distance from the source, such that PTS or TTS are not considered credible. Based on empirical spreading loss estimates measured by Warner and McCrodan (2011), received levels from USBL transponders are expected to exceed the cetacean behavioural response threshold for impulsive sources out to about 42 m.

Transmissions are not continuous but consist of short ‘chirps’ with a duration that ranges from three to 40 milliseconds. Transponders do not emit sound when on standby. When required for general positioning, they emit one chirp every five seconds (estimated to be required for 4 hrs at a time). When required for precise positioning, they emit one chirp every second (estimated to be required for 2 hrs at a time). Due to the short duration chirps, the temporary and intermittent use and the mid frequencies used by positioning equipment, the acoustic noise from the transponders is unlikely to have a substantive effect on the behavioural patterns of cetaceans.

Potential impacts from predicted noise levels from the operating facility, project vessels, and IMMR survey activities are not considered to be ecologically significant at a population level for cetaceans.

Marine Turtles

Species Sensitivity and Exposure Thresholds

The Recovery Plan for Marine Turtles (Commonwealth of Australia, 2017) notes there is limited information available on the impact of noise on marine turtles and that the impact of noise on turtle stocks may vary depending on whether exposure is short (acute) or long-term (chronic). However, turtles have been shown to respond to low frequency sound, with indications that they have the highest hearing sensitivity in the frequency range 100–700 Hz (Bartol and Musick, 2003).

McCauley et al. (2000) observed the behavioural response of caged green and loggerhead turtles to impulsive sound (an approaching seismic airgun). For received levels above 166 dB re 1 µPa SPL, the turtles increased their swimming activity and above 175 dB re 1 µPa they began to behave erratically, which was interpreted as an agitated state. The 166 dB re 1 µPa SPL has been used as the threshold level for a behavioural disturbance response by the US NMFS (NSF, 2011) and is applied to this impact assessment. No quantitative (numerical) thresholds have been developed for behavioural effects from continuous sources (e.g., vessel noise) on marine turtles. However, Popper et al. (2014) propose qualitative impact criteria for near-field, intermediate and far-field exposures (Popper et al., 2014). Finneran et al., (2017) presents thresholds for turtle PTS and TTS for both impulsive and continuous sound exposures.

The thresholds listed in Table 6-7 are considered appropriate for the assessment of effects from impulsive and continuous sound sources during the Petroleum Activities Program.

Table 6-7: Thresholds for permanent and temporary threshold shift and behavioural response onset in marine turtles for continuous and impulsive noise

Hearing group	Impulsive	Continuous

	PTS onset thresholds: SEL24h (dB re 1 µPa².s)	TTS onset thresholds: SEL24h (dB re 1 µPa².s)	Behavioural response (dB re 1 µPa)	PTS onset thresholds: SEL24h (dB re 1 µPa².s)	TTS onset thresholds: SEL24h (dB re 1 µPa².s)	Behavioural response (dB re 1 µPa)
Marine turtles	204	189	166* 175+	220	200	(N) High (I) Moderate (F) Low#

*Source: PTS and TTS thresholds (Finneran et al., 2017), * behavioural response threshold (impulsive) (NSF 2011), + behavioural disturbance threshold (impulsive) (McCauley et al. 2000), # behavioural response threshold (continuous) (Popper et al. 2014).*

Note: The sound units provided in the table above for continuous noise include: relative risk (high, medium and low) is given for marine turtles at three distances from the source defined in relative terms as near (N – tens of metres), intermediate (I – hundreds of metres) and far (F – thousands of metres) (after Popper et al. 2014).

Predicted Underwater Noise Impacts to Turtles

Facility and Support Vessel Noise Impacts

As noted above, vessels holding station are considered to be the predominant noise source related to the Petroleum Activities Program, with source levels of approximately 182 dB re 1 µPa SPL at 1 m from a support vessel holding station considered to be representative of noise levels generated by vessels used for the Petroleum Activities Program.

Although there are no quantitative sound exposure thresholds for impacts on marine turtles resulting from continuous noise sources, the relative risk for behavioural response is expected to be high within tens of metres of the source, medium within hundreds of metres and low within kilometres from the source (refer Table 6-7). PTS and TTS thresholds for turtles are 220 dB re 1 µPa2 s (SEL weighted) and 200 dB re 1 µPa2 s (SEL weighted), respectively (refer Table 6-7). Typical noise levels generated by the facility and a support vessel using DP would not exceed these levels (except at extremely close ranges to the source), and prolonged exposure of transient marine turtles at close range is not considered a credible scenario.

Marine turtles are not expected to be in the area in high numbers even during nesting and internesting periods. Marine turtles are also capable of moving away from potential noise sources, and there are no constraints to their movement within the PAA. Therefore, impacts to marine turtles from project vessels or the platform are expected to be of no lasting effect.

IMMR Activities

As outlined above for cetaceans, Zykov (2013) conducted noise modelling for low energy survey instruments, with the modelling for MBES, SSS and sub-bottom profiler considered comparable for the nature and scale of the low energy IMMR survey equipment. The operating frequencies of MBES (12–700 kHz) and SSS (75–900 kHz) are well above the hearing range of turtles (0.1–2 kHz) and so no disturbance is expected. It is possible that some of the lower frequency sound emitted by sub-bottom profilers (2–30 kHz) may be audible to turtles, but again, a large proportion of the sound energy may be at frequencies that are outside of their normal auditory range. Modelling of impulsive sub-bottom profiler sound emissions by Zykov (2013) and McPherson and Wood (2017) indicates that the 166 dB re 1 µPa (SPL) behavioural disturbance threshold for turtles may only be exceeded within metres or tens of metres of the survey instruments. Therefore, behavioural impacts would be highly localised. PTS or TTS is not considered to be credible given the rapid attenuation of sound close to the source and a large proportion of the sound energy is produced at frequencies outside the peak hearing frequency range of turtles.

Transponders used for positioning during IMMR activities typical operate at frequencies of 21 to 31 kHz which is well outside the peak hearing frequency range of turtles (0.1–2 kHz). Therefore, no impacts are considered credible.

Potential impacts from predicted noise levels from the operating facility, project vessels, and IMMR survey activities are not considered to be ecologically significant at a population level for turtles.

Fish, Sharks and Rays

Species Sensitivity and Exposure Thresholds

Fishes are primarily sensitive to the particle motion component of sound at close range to a sound source, while the presence of the swim bladder results in a varying degree of sensitivity of some fishes to sound pressure (Popper and Hawkins, 2018; Popper et al., 2019). Consequently, fishes are broadly categorised into three groups with respect to their hearing capabilities that are relevant to the types of fishes and sharks that may be present in the Operational Area (Popper et al., 2014):

- Fishes with no swim bladder or other gas chamber (e.g., sharks, mackerels) – Sensitive only to particle motion, not sound pressure changes.
- Fishes with swim bladders, but without a direct connection between the swim bladder and the inner ear (e.g., demersal snappers and emperors) – Hearing primarily involves particle motion with some limited ability to indirectly detect changes in sound pressure.

- Fishes with a swim bladder or other gas volume connected directly to the inner ear (e.g. herrings, sardines, pilchards, shads) – These fishes are able to detect both sound pressure as well as particle motion.

Sound exposure criteria applicable to continuous sound sources are presented in Table 6-8. Popper et al. (2014) propose relative risk criteria (high, moderate, low) for injury, impairment and behavioural effects to fishes at three distance categories, near (N) (tens of metres from the source), intermediate (I) (hundreds of metres from the source), and far (F) (kilometres from the source).

Table 6-8: Impact thresholds to fish, sharks and rays for continuous noise

Receptor	Mortality and potential mortal injury	Impairment			Behaviour
		Recoverable Injury	TTS	Masking	
Fish: no swim bladder	(N) Low (I) Low (F) Low	(N) Low (I) Low (F) Low	(N) Moderate (I) Low (F) Low	(N) High (I) High (F) Moderate	(N) Moderate (I) Moderate (F) Low
Fish: swim bladder not involved in hearing	(N) Low (I) Low (F) Low	(N) Low (I) Low (F) Low	(N) Moderate (I) Low (F) Low	(N) High (I) High (F) Moderate	(N) Moderate (I) Moderate (F) Low
Fish: swim bladder involving hearing	(N) Low (I) Low (F) Low	170 dB SPL for 48-hours	158 dB SPL for 12-hours	(N) High (I) High (F) High	(N) High (I) Moderate (F) Low
Fish eggs and fish larvae	(N) Low (I) Low (F) Low	(N) Low (I) Low (F) Low	(N) Low (I) Low (F) Low	(N) High (I) Moderate (F) Low	(N) Moderate (I) Moderate (F) Low

Note: The sound units provided in the table above include relative risk (high, medium and low) is given for fish (all types) at three distances from the source defined in relative terms as near (N – tens of metres), intermediate (I – hundreds of metres) and far (F – thousands of metres) (after Popper et al., 2014).

Predicted Underwater Noise Impacts to Fish

Facility and Support Vessel Noise Impacts

Vessels holding station using DP are expected to produce sound equivalent to about 182 dB re 1 µPa SPL at 1 m. Modelling undertaken by McPherson et al. (2019) of sound produced by facility and vessel operations found that recoverable injury to some types of fish would only be possible if they remained within a distance of less than 10 m for 48 hours, and TTS if fishes remained within 10 m for at least 12 hours. Pelagic fish are highly mobile, and the types of demersal fishes known to occur in the vicinity of the Pluto facility (e.g., snappers, emperors, cods and groupers) will exhibit some fidelity to the area but are still relatively free-swimming and are not constrained to such close ranges (i.e., 10 m). Therefore, free-swimming fish remaining in close range to sound sources for periods that subject themselves to TTS and injury is not considered to be a credible scenario.

There are no quantitative sound exposure thresholds for impacts on fish, sharks and rays resulting from continuous noise sources. The relative risk for behavioural response is expected to be high within tens of metres of the source, medium within hundreds of metres and low within kilometres from the source (refer Table 6-7). In the context of the riser platform, the largest contribution to operational noise is from the topside and near the surface, with lower sound levels produced from subsea infrastructure such as choke valves. Similarly, sound from the PSV would be at the surface. While some localised behavioural avoidance and masking in the vicinity of the loudest sound sources from the riser platform, choke valves and PSV may occur in some fishes, no lasting effect is anticipated. Fish are also known to habituate to continuous noise sources, which is consistent with fish congregating around operating offshore oil and gas structures.

The foraging BIA for whale shark overlaps the PAA, and the species may be seasonally present (particularly between March and July) Currently, there are no quantitative sound exposure thresholds relevant to whale sharks. It is expected that the potential effects of noise on whale sharks are the same as for other fish species, resulting in minor, localised and temporary behavioural change such as avoidance. Therefore, impacts to whale sharks from support vessels or the platform are expected to have no lasting effect.

Other fauna associated with the PAA includes predominantly pelagic species of fish, with migratory species such as rays transiting through the PAA; these species may be similarly affected by noise from the PAP. Potential impacts from predicted noise levels from the operating facility, support vessels and IMMR survey activities are not considered to be ecologically significant at a population level for fish, sharks and rays.

IMMR Activities

As outlined above, Zykov (2013) conducted noise modelling for low energy survey instruments, with the modelling for MBES, SSS and sub-bottom profiler considered comparable for the nature and scale of the low energy IMMR survey equipment. The operating frequencies of MBES (12 to 700 kHz) and SSS (75 to 900 kHz) are well above the peak hearing ranges of fish (100 Hz to several kHz) and so no disturbance is expected. It is possible that some of the lower frequency sound emitted by sub-bottom profilers (2 to 30 kHz) will be audible to fish, but again, a large proportion of the sound energy may be at frequencies that are outside of their normal auditory range. Therefore, behavioural impacts would be highly localised. PTS or TTS is not considered to be credible given the rapid attenuation of sound close to the source and a large proportion of the sound energy is produced at frequencies outside the peak hearing frequency range of fish.

Transponders used for positioning during IMMR activities typical operate at frequencies of 21 to 31 kHz which is well outside the hearing frequency range of fish. Therefore, no impacts are considered credible.

Potential impacts from predicted noise levels from the Pluto facility, support vessels and IMMR activities are not considered to be ecologically significant at a population level.

Demonstration of ALARP				
Control Considered	**Control Feasibility (F) and Cost/ Sacrifice (CS)**	**Benefit in Impact/Risk Reduction**	**Proportionality**	**Control Adopted**
Legislation, Codes and Standards				
EPBC Regulations 2000 – Part 8 Division 8.1 Interacting with cetaceans, including the following measures[56]: • Support vessels will not travel greater than 6 knots within 300 m of a cetacean (caution zone) and not approach closer than 100 m from a whale. • Support vessels will not approach closer than 50 m for a dolphin and/or 100 m for a whale (with the exception of animals bow riding). • If the cetacean shows signs of being disturbed, support vessels will immediately withdraw from the caution zone at a constant speed of less than 6 knots.	F: Yes. CS: Minimal cost. Standard practice.	Implementation of these controls is primarily intended to reduce the likelihood of a collision with a cetacean, occurring. However, implementation may also provide some reduction in the potential for exposure of these fauna to sound levels in direct proximity to vessels.	Controls based on legislative requirements – must be adopted.	**Yes** **C 3.1**
Department of Parks and Wildlife (2013) Whale shark management with particular reference to Ningaloo Marine Park: • Support vessels will not travel greater than 8 knots within 250 m of a whale shark and not allow the vessel to approach closer than 30 m of a whale shark.	F: Yes. CS: Minimal cost. Standard practice.	Implementation of controls for reduced vessel speed around whale sharks can potentially reduce the underwater noise footprint of a vessel.	Benefits outweigh cost/sacrifice. Good practice.	**Yes** **C 3.2**
Good Practice				

[56] For safety reasons, the distance requirements below are not applied for a vessel holding station or with limited manoeuvrability, e.g., anchor handling, loading, back-loading, bunkering, close standby cover for overside working and emergency situations.

Demonstration of ALARP				
Control Considered	**Control Feasibility (F) and Cost/ Sacrifice (CS)**	**Benefit in Impact/Risk Reduction**	**Proportionality**	**Control Adopted**
Implement adaptive management procedure prior to resupply/IMMR vessel to the riser platform	F: Yes. CS: Schedule delays associated with waiting on pygmy blue whale activity to cease/move on.	Implementation of adaptive management where PBW (or large unidentified whales) are observed means a new noise source (vessel) is not introduced while PBW are sighted. The riser platform is not located in the Pygmy Blue Whale BIA. Limited value in implanting adaptive management procedure outside sensitive areas.	Disproportionate. The cost/sacrifice outweighs the benefit gained.	No
Vary the timing of the PAP to avoid migration periods.	F: No. The PAP occurs continuously over a five-year period, modifying the timing of the PAP is not feasible. CS: Not considered, control not feasible.	Not considered, control not feasible.	Not considered, control not feasible.	No
Management of noise from IMMR activities by varying the timing of the PAP to avoid migration periods.	F: Yes. Migration periods for cetaceans that may occur in the PAA (pygmy blue and humpback whales) are well known. CS: Significant cost and schedule impacts if activities avoid specific timeframes. Increased potential safety and environmental risks due to reduction in maintenance.	The platform is NNC. Maintenance activities including vessel-based activities are not flexible. Avoiding migration periods would reduce the likelihood of impacts to cetaceans. However, given the predicted impacts from noise sources associated with the PAP are considered to be localised with no lasting effect, the overall benefit is minimal.	Disproportionate. The cost/sacrifice outweighs the benefit gained.	No

Demonstration of ALARP				
Control Considered	**Control Feasibility (F) and Cost/ Sacrifice (CS)**	**Benefit in Impact/Risk Reduction**	**Proportionality**	**Control Adopted**
Vessels will not travel greater than 6 knots within 300 m of a turtle (caution zone). If the turtle shows signs of being disturbed, vessels will immediately withdraw from the caution zone at a constant speed of less than 6 knots.	F: Yes CS: Minimal cost. Standard practice.	Implementation of controls for reduced vessel speed around turtles can potentially reduce the underwater noise footprint of a vessel.	Benefits outweigh cost/sacrifice. Good practice.	**Yes** **C 3.3**
Collect data on opportunistic sightings of PBW to gauge presence and behaviour using trained crew.	F: Yes. CS: Time/cost associated with training personnel and person used for observations and in data collection on minimally crewed facility.	Collecting data on pygmy blue whale presence and behaviour is not warranted as the riser platform is located outside the PBW BIA.	Disproportionate. The cost/sacrifice outweighs the benefit gained.	No
Implement a shutdown zone around MBES, SSS and sub-bottom profiler for the following fauna: whales marine turtles whale sharks.	F: Yes. However, as equipment is underwater, effective implementation of zones is challenging from topside observation. CS: Moderate. Requires the provision of a dedicated suitably trained crew member to undertake Marine Fauna Observations.	Limited. The areas of disturbance for these devices are limited and injury, PTS and TTS are not expected to occur. In addition, it is noted that for many MBES and SSS, the frequency range of these devices are outside the estimated frequency hearing range of identified protected species (whales, turtles and whale sharks).	Acoustic MBES, SSS and sub-bottom profiler surveys are infrequently conducted (every 1–6 years) as part of the Petroleum Activities Program. The source levels and frequency range of these devices are mostly outside the estimated frequency hearing range of identified protected species (whales, turtles and whale sharks), so costs are considered disproportionate to benefits.	No
Manage IMMR vessel speed in the HBW and PBW whale BIAs in migration seasons (Apr-Jul & Oct-Jan for PBW and Jun-Sep & Jul-Nov for HBW).	F: Yes, within the limits of navigational safety. CS: Time/cost associated with slower transit speed.	Given the PAA overlaps the pygmy blue whale migration BIA and introduction of vessel noise may present behavioural disturbance risk to migrating pygmy blue whales, reducing vessel speed can result in reduced underwater	Benefit outweighs cost/sacrifice.	Yes C 3.4

Demonstration of ALARP				
Control Considered	**Control Feasibility (F) and Cost/ Sacrifice (CS)**	**Benefit in Impact/Risk Reduction**	**Proportionality**	**Control Adopted**
		noise emissions and overall reduction in potential behavioural disturbance.		
The use of dedicated marine fauna observers (MFOs) on IMMR vessels for the duration of the PAP to watch for whales and provide direction on and monitor compliance with Part 8 of the EPBC Regulations.	F: Yes. However, support vessel bridge crews already maintain a constant watch during operations. CS: Additional cost of MFOs.	Given that support vessel bridge crews already maintain a constant watch during operations and trained crew as MFOs will monitor for pygmy blue whale presence prior to resupply/support vessel moves alongside the MODU and PIV, additional MFOs would not further reduce the likelihood of an individual being within close proximity of the acoustic source during introduction of sounds related to DP or during operations.	Disproportionate. The cost/sacrifice outweighs the benefit gained.	No
Use professional MFOs in lieu of trained crew to observe for pygmy blue whales.	F: Yes. CS: The cost of implementing dedicated MFOs during vessel activities would be tens of thousands of dollars and expose additional personnel to the health and safety risks of working at sea. The cost is grossly disproportionate to the environmental benefit.	The environmental benefit of having dedicated professional MFOs is a potential increase in the likelihood of detecting PBW at the species level, which then permits actions to maintain separation as per the adaptive management procedure. Trained crew will watch for marine fauna during the petroleum activity. Trained crew will implement adaptive management measures if a pygmy blue whale	Disproportionate. The cost/ sacrifice outweighs the benefit gained.	No.

Demonstration of ALARP				
Control Considered	**Control Feasibility (F) and Cost/ Sacrifice (CS)**	**Benefit in Impact/Risk Reduction**	**Proportionality**	**Control Adopted**
		or large unidentified whale is observed. Therefore, while there is an increased likelihood for professional MFOs to detect PBW from other large whale species, the ability to identify marine fauna in comparison with trained crew is negligible.		
Professional Judgement – Eliminate				
Eliminate the use of DP on vessels during the Petroleum Activities Program.	F: No. Both platform and subsea support vessels are required to reliably hold station during the Petroleum Activities Program. Failure to do so may lead to loss of separation between vessels and infrastructure. This would result in unacceptable safety and environmental risk (loss of vessel separation has been identified as an MEE) CS: Not considered, control not feasible.	Not considered, control not feasible.	Not considered, control not feasible.	No
Avoid where practicable, planned IMMR vessel activities, during Pygmy Blue Whale migration (Apr-Jul & Oct-Jan) and humpback whale migration (Jun-Sep & Jul-Nov).	F: Yes CS: Significant increased cost for logistics and restriction of vessel availability due to extensive period (10 months).	Planning to avoid where practicable, planned IMMR activities during PBW migration and humpback whale migration will reduce underwater noise emissions in the PBW and humpback whale	Implementing this control would result in very little benefit, and the cost sacrifice is disproportionate to the benefit gained.	No

Demonstration of ALARP				
Control Considered	**Control Feasibility (F) and Cost/ Sacrifice (CS)**	**Benefit in Impact/Risk Reduction**	**Proportionality**	**Control Adopted**
		migration BIAs and in close proximity to the PBW foraging BIA. However, given the infrequent noise emissions from IMMR vessel(s), the size and extent of the migration BIAs, the extensive period that the whales may be present, and the behaviour of the whales being transitory during migration, it is expected that this would have a very limited benefit, if any, on the migration behaviour of the PBW or humpback whale.		
Professional Judgement – Substitute				
None identified.				
Professional Judgement – Engineered Solution				
Application of bubble curtains to reduce noise propagation.	F: No, Bubble curtain installation and operation in offshore open water not feasible due to technical operation constraints; i.e., water depth/ current.	Not considered, control not feasible.	Not considered, control not feasible.	No
ALARP Statement: On the basis of the environmental impact assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the potential impacts from acoustic emissions from vessels, helicopters, wellheads, pipelines and the Pluto platform (including machinery). As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.

	PBW whale BIAs in migration seasons (Apr-Jul & Oct-Jan for PBW and Jun-Sep & Jul-Nov for HBW).	IMMR vessel speeds in the Operational Area are restricted ≤10kn: • When in the pygmy blue whale migration BIA during PBW migration periods (Apr-Jul & Oct-Jan) • When in the HBW migration BIA during migration periods (Jun-Sep & Jul-Nov).	Operational Area were ≤ 10 knots during whale migration seasons (Apr-Jul & Oct-Jan for PBW and Jun-Sep & Jul-Nov for HBW).

Demonstration of Acceptability
Acceptability Statement: The impact assessment has determined that, given the adopted controls, impacts from acoustic emissions from vessels, helicopters, wellheads, pipelines and the Pluto platform represent a negligible impact/disturbance to marine fauna within the Export Pipeline and Pluto Facility Operational Areas. Further opportunities to reduce the impacts and risks have been investigated above. The impacts are consistent with good oil-field practice/industry best practice. The potential impacts and risks are considered broadly acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the impacts of acoustic emissions to a level that is broadly acceptable and demonstrate the EPOs are met.

6.7.4 Acoustic Emissions: Generation of Noise During Xena-03 Tie-back Activities

Context		
Xena-03 Drilling &Tie-back Activities – Section 3.11 Vessel-based Activities for the Xena-03 Tie-back – Section 3.12	Protected Species – Section 4.6	Consultation – Section 5

Impact Evaluation Summary

Source of Impact	***Environmental Value Potentially Impacted***						***Evaluation***						
	Marine Sediment	Water Quality	Air Quality (incl Odour)	Ecosystems/Habitat	Species	Socio-economic	Decision Type	Consequence/Impact	Likelihood	Risk Rating	ALARP Tools	Acceptability	Outcome
Generation of noise from project vessels (MODU, installation vessels, AHVs and support vessels) during Xena-03 Tie-back activities					x		A	F	-	-	LCS GP PJ	Broadly Acceptable	EPO 4 EPO 3b
Generation of noise from DP systems on project vessels					x			F					
Generation of noise from cutting of well infrastructure and contingency activities					x			F					

Description of Source of Impact

During Xena-03 Tie-back activities, sound will be generated from a number of sources including from vessels involved with installation of the mooring system, the MODU during drilling operations, support vessels, and retrieval of anchors. Noise may also be generated from contingency activities such as respud, sidetrack, well removal and associated underwater acoustic positioning systems. These noise sources will contribute to and have the potential to exceed ambient noise levels which range from around 90 dB re 1 µPa (SPL) under very calm, low wind conditions, to 120 dB re 1 µPa (SPL) under windy conditions (McCauley, 2005).

Vessel Noise

A range of vessels may be used to complete the Xena-03 Tie-back activities, including AHVs, MODU, subsea installation vessels and other support vessels (Section 3.12).

The MODU (hybrid or moored) is expected to be on location for drilling operations for approximately 60 days including mobilisation, demobilisation and contingency. Vessels associated with installation of the mooring system will be on location for up to 10 days prior to arrival of the MODU. Subsea installation and commissioning activities may be on location for up to three weeks. Mooring system anchor retrieval may also take up to 10 days once the MODU departs.

The vessels will generate noise both in the air and underwater, due to the operation of thrusters, engines, propeller movement, etc. Vessels, including the MODU (unless moored/ hybrid), installation vessels, AHVs, general support vessels will use DP where propellers and thrusters are used to hold position, rather than anchoring, unless in an emergency.

MODU Drilling Operations (Moored)

During drilling operations, a moored MODU will produce low-intensity continuous sound. Sound produced from an active MODU is predominantly below 2 kHz, with peak frequencies below 500 Hz.

A range of broadband values, 59 to 185 dB re 1 µPa at 1 m (SPL), have been quoted for various MODUs (Simmonds et al., 2004). McPherson et al. (2021) recorded the source level spectrum of the Ocean Onyx, which is considered

representative of a moored MODU considered for the tie-back campaign. The Ocean Onyx was measured to have a broadband (10 Hz to 31 kHz) source level of 175.4 dB re 1 µPa m while anchored and drilling and is considered representative drilling activity for this EP. The measured source level for the Ocean Onyx is consistent with or slightly higher than levels recorded for other moored MODUs during drilling operations. For example, McCauley (1998) recorded source noise levels for moored MODUs from 149-154 dB re 1 µPa at 1 m while actively drilling (with support vessel on anchor) and Greene (1987) recorded source levels of two moored drillships from 145 to 158 dB re 1 µPa at 1 m during drilling (with support vessels idling nearby). Austin et al. (2018) recorded broadband source levels from MODU operations (excluding DP thrusters) to be 170.7 dB re 1 µPa.

Project Vessels and MODU Operation of DP

Vessels used for the Xena-03 Tie-back activities are detailed in Section 3.12, and are DP capable, as required. As discussed in Section 6.7.3, sound levels and frequencies generated by vessels varies with the size of the vessel, speed, engine type and the activity being undertaken.

Indicative MODU underwater noise measurements were taken for the West Aquarius MODU by JASCO on the Scotian Shelf in Canada (Wecker et al., 2022). The 90th percentile of the broadband radiated sound levels was 186.3 dB re 1 µPa (Martin et al., 2019). This is similar to measurements taken for the Maersk Discoverer drill rig on the North West Shelf (Woodside Energy Limited, 2011), where the system emitted tonal signals between 200 Hz to 1.2 kHz, at a source level between 176 and 185 dB re 1 µPa SPL at 1 m.

Noise levels generated by support vessels on standby is expected to be similar to levels discussed in Section 6.7.3.

Sound Transmission Loss Modelling

Noise modelling was commissioned from JASCO by Woodside for the Julimar Appraisal Drilling and Surveys activities (Julimar South-1 well) (Stroot et al., 2022) and Pyxis Drilling and Subsea Installation activities (Xena-02 well) (Wecker, et al., 2022), which are considered broadly comparable in terms of MODU and vessel activities, and the water depths and seabed substrates at the Xena-03 well location.

For moored MODU scenarios, noise modelling for the Julimar Appraisal Drilling and Surveys activities (Stroot et al., 2022) provides a suitable analogue to the size and type of moored MODU and support vessels planned for use during Xena-03 tie-back activities. A number of moored MODU scenarios were modelled including with an offshore supply vessel (OSV) in ~166 m at the Julimar South-1 well location. Given water depth at the Xena-03 location is 177 m and similar seabed substrate, the modelling of the moored MODU and OSV are regarded as a suitable analogue for similar vessels and activities at the Xena-03 location.

For DP vessel activities, noise modelling for Pyxis Drilling and Subsea Installation activities (Wecker, et al., 2022) provides a similar analogue to the size and type of hybrid MODU and support vessels planned for use during the Xena-03 Tie-back activities. Several DP MODU scenarios were modelled, including with an OSV in ~172 m at the Xena-02 well location. As above, this modelling is considered a suitable analogue for similar vessels and activities at the Xena-03 location.

These scenarios included several permutations of support vessels and the MODU undertaking drilling activities, used to inform the worst-case credible noise propagation scenarios (including concurrent activities).

Table 6-9: Summary of modelled scenarios for drilling activities at the Julimar South-1 well location as an analogue for moored operations (source: Stroot et al., 2022)

Scenario Number	Description
1	Anchored MODU Drilling (24h)
2	Anchored MODU Drilling (24h) + OSV on standby (24h)
3	Anchored MODU Drilling + OSV resupply, under DP (2h)
4	Anchored MODU Drilling (24h) + OSV resupply, under DP (8h)
5	Anchored MODU Drilling (24h) + OSV resupply, under DP (8h) + OSV on standby (24h)

Table 6-10: Summary of modelled scenarios at the Xena (Xena-02) field as an analogue for DP operations (source: Wecker et al., 2022)

Scenario Number	Description
6	MODU under DP, drilling at Xena-02 (24 hr)
7	MODU under DP, drilling at Xena-02 (24 hr) + support vessel resupply, under DP (2 hr)
8	MODU under DP, drilling at Xena-02 (24 hr) + support vessel resupply, under DP (8 hr)
9	MODU under DP, drilling at Xena-02 (24 hr) + support vessel on standby (24 hr)

10	MODU under DP, drilling at Xena-02 (24 hr) + support vessel resupply, under DP (8 hr) + support vessel resupply on standby (24 hr)

Source levels representative of drilling and subsea installation scenarios.

Source levels for relevant vessels that were used to inform the sound transmission loss modelling (Stroot et al., 2022; Wecker et al., 2022) are presented in Table 6-11. The source sounds were applied to the modelling scenarios for drilling and subsea installation activities.

Table 6-11: Vessel source levels used in the acoustic modelling for the Xena-03 Tie-back activities

Vessel	Sound Level (dB re 1 µPa².m2.s)	Reference
Moored MODU	175.4	(Stroot et al., 2022)
MODU under DP	187.7	(Wecker et al., 2022)
OSV stationary under DP (resupply scenario)	187.6	(Stroot et al., 2022)
OSV slow transit	177.8	(Stroot et al., 2022)

Sound Transmission Loss Modelling Scenarios

The acoustic modelling scenarios used in this assessment are presented in Table 6-9 and Table 6-10. Vessel scenarios during Xena-03 Tie-back activities may differ slightly from those modelled from time to time in terms of precise vessel types, proximity and number. However, the magnitude and extent of potential sound propagation and the resultant effects on marine fauna from the modelled worst-case scenario are expected to be comparable to the worst-case scenario or are conservative.

The acoustic modelling studies assessed distances from operations where underwater sound levels were predicted to drop below thresholds corresponding to behavioural response and injury (temporary reduction in hearing sensitivity or TTS and permanent threshold shift or PTS) for marine fauna. The animals considered included marine mammals, turtles, and fish. Due to the variety of species considered, several different thresholds were used for evaluating effects.

The modelling methodologies considered scenario specific source levels and range-dependent environmental properties. Estimated underwater acoustic levels for non-impulsive (continuous) noise sources presented as sound pressure levels (SPL, Lp), and as accumulated sound exposure levels (SEL, LE) as appropriate for different noise effect criteria, behavioural response and injury (TTS and TPS), respectively. In this report, the duration of the SEL accumulation is defined as integrated over a 24-hour period.

The SEL24h is a cumulative metric that reflects the dosimetric impact of noise levels within 24 hours based on the assumption that an animal is consistently exposed to such noise levels at a fixed position. The corresponding SEL24h radii represent an unlikely worst-case scenario. More realistically, marine mammals (as well as pelagic fish and turtles) would not stay in the same location for 24 hours. Therefore, a reported radius for SEL24h criteria does not mean that marine fauna travelling within this radius of the source will be injured, but rather that an animal could be exposed to the sound level associated with injury (TTS or PTS) if it remained in that location for 24 hours.

Contingency Activities (Respud, Sidetrack, Well Removal)

Contingency activities include a well respud or sidetrack and will involve the use of a MODU and vessels, plus drilling operations. Any acoustic emissions generated will be the same as those expected from the planned activities described above.

In the event the wellhead is removed under this EP scope, additional noise from the cutting of the surface casing and conductors is likely to be generated. Underwater noise associated with cutting (diamond wire) of subsea infrastructure is generally indistinguishable above background noise levels at lower frequencies, primarily detected at noise frequencies above 5 kHz (Pangerc et al., 2016). Quijano and McPherson (2021) estimated the source level of a diamond wire saw cutter at 169 dB re 1 µPa at 1 m. The casings and conductors will be cut below the mudline to enable wellhead recovery using either abrasive water jet cutting method, or mechanical cutting method.

Twachtman et al. (2004) concluded that mechanical cutting and abrasive water jetting, as well as diamond wire cutting methods, are generally considered harmless to marine life and the environment. Similarly, Pangerc et al. (2016) found that the sound radiated from the diamond wire cutting of the conductor was not easily discernible above the background noise at the closest recorder located at 100 m from the source. The sound that could be associated with the diamond wire cutting was primarily detectable above the background noise at the higher acoustic frequencies (above around 5 kHz) (Pangerc et. al., 2016) above the hearing range of low frequency cetaceans. Background noise was attributed to surface vessel activity such as DP. Any noise propagating at seabed from either abrasive water jet cutting or mechanical cutting of the wellhead casing and conductors is likely to attenuate to levels at, or close to background ambient levels within <100 m of the source, with ambient levels being significantly elevated by the concurrent presence of a DP vessel immediately above the wellhead location. As such, noise from the cutting of the

casing and conductors will not add to significantly to noise levels for the Xena-03 Tie-back activities and are not assessed further.

Generation of Underwater Noise from Positioning Equipment

An array of long baseline (LBL) and/or ultra-short baseline (USBL) transponders may be installed on the seabed for metrology and positioning. An array of transponders is proposed within a radius of 500 m from the proposed location of the well and will be in place for a period of about three months. During xmas tree installation, ultra-short baseline transponders (USBL) may be installed on the seabed or mounted to the wellhead as required by the subsea installation activities. Transmissions from USBL transponders are similar to LBL transponders.

Transponders typically emit pulses (impulsive noise) of medium frequency sound, generally within the range 21 to 31 kHz. The estimated SPL would be 180 to 206 dB re 1 µPa at 1 m (Jiménez-Arranz et al., 2017). Transmissions are not continuous but consist of short 'chirps' with a duration that ranges from 3 to 40 milliseconds. Transponders will not emit any sound when on standby and are planned to only actively emit sound for about six hours per well. When required for general positioning they will emit one chirp every five seconds (estimated to be required for four hours at a time). When required for precise positioning they will emit one chirp every second (estimated to be required for two hours at a time). An array of transponders will be active whilst the DP MODU is on location.

Rig Anchor Release System

Should a hybrid MODU be used, Rig Anchor Release (RAR) moorings may be installed to allow the DP-capable rig to rapidly disengage from a mooring system. An RAR device will couple each of the moorings to the MODU (eight to 12 devices depending on mooring spread).

RAR devices typically emit pulses (impulsive noise) of low frequency, in the range of 9 to 11 kHz. Transmissions are expected to be limited to short pulses with a duration of minutes, during weekly testing. When activated to release moorings, they are expected to emit pulses of ~two minutes duration for each RAR.

Cumulative Noise Sources

Underwater noise generated during Xena-03 Tie-back activities (~12 weeks) have the potential for cumulative impacts with routine Pluto Facility Operations (Section 6.7.3) with acoustic emissions from routine operations (e.g., machinery, flaring, IMMR activities etc), which may result in slightly elevated acoustic levels.

As described above, Xena-03 Tie-back activities are likely to include AHVs, a MODU and PIV as well as installation and support vessels. SIMOPS with drilling and installation are not planned but are considered as a contingency. During concurrent activities, a number of vessels may be operating. The worst-case credible scenario is considered to be if the MODU, support vessel and installation vessel are required to be in proximity. This is the case used for the following cumulative assessment of potential impacts.

Table 6-12: Concurrent activities considered in the assessment of cumulative underwater vessel noise

Concurrent Activities	Approx. Duration[1]	Vessels	Approximate Distance Between Vessels
MODU drilling Subsea tree installation from installation vessel (or similar activity)	2 days	MODU + supply vessel Installation or IMMR vessel (DP)	<3 km
Pre-commissioning and start-up of Xena-03 tie back Platform operations and supply	5 days	Commissioning (IMMR class) vessel (DP) Platform + DP supply vessel	~11 km

[1] *Relates to period of overlap, not entire duration of activity.*

Impact Assessment

Potential impacts to environmental values

Receptors

The Xena-03 Operational Area is located in waters at ~177 m depth (Section 3.2). The fauna associated with this area will be predominantly pelagic species of fish and cetaceans, with migratory species such as cetaceans, marine turtles and whale sharks occurring in the area seasonally (Section 4.6). Anthropogenic noise interference is a key threat to a number of migratory and threatened cetaceans, marine turtles and whale sharks identified as potentially occurring within the Xena-03 Operational Area.

The migration and distribution BIA for the pygmy blue whale partially overlaps the Xena-03 Operational Area (Section **Error! Reference source not found.**). Migration periods for PBW are April to July and October to January, and some whales can be expected to pass by the Xena-03 Tie-back activities.

The migration BIA for the humpback whale is ~30 km east of the Xena-03 Operational Area with no overlap. The migration period for humpback whale is June to November and the majority of the migrating population will be found further inshore than the Xena-03 Tie-back activities, inside the BIA.

The internesting buffer BIA for the flatback turtle overlaps the Xena-03 Operational Area. Habitat Critical for the flatback turtle is ~10 km from the Xena-03 Operational Area (~12 km from the Xena-03 well location). Given the water depths and distance from shore, the Xena-03 Operational Area does not represent suitable foraging or internesting habitat. Satellite tracking of flatback turtle nesting populations (Barrow Island and mainland sites) indicates this species travels to the east of Barrow Island between nesting events, within WA mainland coastal waters less than 70 m deep (Chevron Australia Pty Ltd, 2015).

The whale shark foraging BIA overlaps with the Xena-03 Operational Area. Peak whale shark numbers are expected in the region from March to July.

The Continental Slope Demersal Fish Communities KEF overlaps the wider Xena-03 Operational Area (Section 4.7) and is recognised for its biodiversity values, including high levels of species endemism (DCCEEW 2023b). The targeted well location is not within the Continental Slope Demersal Fish Communities KEF (Figure 4-10).

The Montebello Marine Park Multiple Use Zone is ~1.75 km from the boundary of the Xena-03 Operational Area, and ~5.8 km from the Xena-03 well. This marine park supports a range of species listed under the EPBC Act. Biologically important areas within this marine park include breeding habitat for seabirds, internesting, foraging, mating, and nesting habitat for marine turtles, a migratory pathway for humpback whales and foraging habitat for whale sharks. Impacts to these values are described below.

Potential Impacts of Noise

Elevated underwater noise can affect marine fauna, including cetaceans, fish, turtles, sharks and rays, in three main ways (Richardson et al., 1995; Simmonds et al., 2004):

- by causing direct physical effects on hearing or other organs; hearing loss may be temporary (temporary threshold shift (TTS) referred to as auditory fatigue), or permanent threshold shift (PTS) (injury)
- by masking or interfering with other biologically important sounds (including vocal communication, echolocation, signals and sounds produced by predators or prey)
- through disturbance leading to behavioural changes or displacement from important areas (e.g., BIAs); the occurrence and intensity of disturbance is highly variable and depends on a range of factors relating to the animal and situation.

Sound Propagation

Increasing the distance from the noise source usually results in the level of noise reducing, due primarily to the spreading of the sound energy with distance. The way the noise spreads (geometrical divergence) depends upon several factors such as water column depth, pressure, temperature gradients, and salinity, as well as surface and bottom conditions.

Cetaceans

Species Sensitivity and Thresholds

Protected species including migratory PBW may be encountered near the Xena-03 Operational Area and therefore could be impacted by acoustic emissions associated with Xena-03 Tie-back activities. Thresholds that could result in a behavioural response, TTS and PTS for cetaceans as a result of continuous and impulsive noise sources are presented in Table 6-13.

Predicted Underwater Noise Impacts to Cetaceans

Results – Modelling of a Moored MODU

A sound transmission loss modelling study was conducted by JASCO for several scenarios at the analogous Julimar South-1 well location (water depth – 166.6 m) as well as a nominated OSV standby location (water depth – 150.2 m), (Stroot et al., 2022). The modelling study indicated that exceedances of the PTS and TTS thresholds for low frequency (LF) cetaceans, such as humpback whale and pygmy blue whale, may occur out to a maximum of 0.07 km and 0.92 km respectively. For HF and VHF cetaceans (toothed whales and dolphins), the maximum distances at which sound levels dropped below PTS and TTS thresholds were 0.21 km and 2.76 km respectively.

During normal operations (the moored MODU drilling with an OSV on standby – Scenario 2), the minimum distance to the TTS threshold is 0.23 km, 0.09 km and 2.57 km for LF, HF and VHF cetaceans respectively. The PTS threshold was only exceeded for VHF for Scenario 2, at a maximum distance of 0.15 km; refer to Table 6-13.

As described above, the PTS and TTS thresholds are based on a cumulative metric that that reflects the dosimetric impact of noise levels over a 24-hour period based on the assumption that an animal is consistently exposed to such noise levels at a fixed position. It is not considered credible that individual LF and HF cetaceans that may pass through the Xena-03 Operational Area during the drilling program would experience PTS or TTS, given individuals

would need to remain within 70 m (PTS) and <1 km (TTS) of the drilling activity for a period of 24 hours. It is also considered highly unlikely that any VHF cetaceans would experience PTS or TTS.

The behavioural response threshold may be exceeded at a maximum of 3.57 km during normal drilling operations, and at a maximum of 8.85 km at times when an additional OSV is present and operating DP. At these distances, the ensonified area of the Pluto facility when in crewed mode (also 8.85 km without an ASV in operation) could slightly overlap as the distance between the Xena-03 well and the Pluto platform is 15.1 km.

Table 6-13: Thresholds for permanent and temporary threshold shift and behavioural response onset thresholds for cetaceans and marine turtles based on Southall et al. (2019) and Finneran et al. (2017)

Hearing Group	Frequency-weighted SEL24h Threshold (LE,24h; dB re 1 µPa²·s)	Scenario 1	Scenario 2	Scenario 3	Scenario 4	Scenario 5
		Rmax (km)	Rmax (km)	Rmax (km)	Rmax (km)	Rmax (km)

Cetaceans	120	1.07	3.57	8.25*		8.85

**Scenario 4 has been omitted from Table 6-13 because Scenario 4 differs to Scenario 3 only by the time duration, and the SPL sound footprints represent the instantaneous sound field, independent on accumulation time. A dash indicates the level was not reached within the limits of the modelled resolution–(20 m).Source: Stroot et al (2022)*

Results – Modelling of a DP MODU

The analogous sound transmission loss modelling study by JASCO for a MODU on DP (Wecker et al., 2022) indicated the PTS and TTS thresholds for low frequency (LF) cetaceans, such as humpback whale and pygmy blue whale, may be exceeded out to a maximum of 0.13 km and 2.66 km respectively across the scenarios modelled. For HF and VHF cetaceans, the maximum distances at which sound levels dropped below PTS and TTS thresholds were 0.15 km (PTS) and 2.63 km respectively. During normal operations (MODU on DP with a support vessel on standby – Scenario 9), the maximum distance at which the TTS threshold is exceeded is 2.17 km, 0.09 km and 2.44 km for LF, HF and VHF cetaceans respectively. For PTS, the maximum distance at which the threshold is exceeded is 0.08 km, 0.02 km and 0.11 km for LF, HF and VHF cetaceans respectively.

As described above, the radii that represent potential for PTS and TTS onset are based on a 24-hour period of exposure and therefore represent an unlikely worst-case scenario since, more realistically, cetaceans would not stay in the same location or at the same range for 24-hours. It is not considered credible that individual LF, HF and VHF cetaceans that may pass through the Xena-03 Operational Area during DP vessel operations, would experience PTS, given individuals would need to remain within 150 m of the drilling activity for a period of 24 hours. TTS onset is also considered highly unlikely given the known movement behaviour of cetaceans including key migrating LF whale species such as the pygmy blue whale transiting through the Xena-03 Operational Area. The Xena-03 Operational Area is not known to represent significant foraging/aggregation habitat for cetaceans and individuals are not expected to dwell within the area for extended periods.

The behavioural response threshold may be exceeded at a maximum of 17.2 km during normal drilling operations and a maximum of 20.7 km at times when an additional support vessel is present and operating DP. At these distances,

the ensonified area would overlap with the location of the Pluto facility 15.1 km away, outside of the pygmy blue whale migration BIA.

Table 6-14: Thresholds for permanent and temporary threshold shift and behavioural response onset thresholds for cetaceans and marine turtles based on Southall et al. (2019) and Finneran et al. (2017)

Impact Assessment

Potential behavioural disturbance to PBW within the distribution range is limited to any overlap with the northbound (April to July) and southbound (October to January) migratory seasons. Migrating humpback whales have shown avoidance behaviours (increased movement rate and dive frequency) when exposed to underwater noise generated by a vessel (Dunlop et al., 2015), and PBW may exhibit similar responses.

There is limited data to indicate that the Xena-03 Operational Area represents an area where opportunistic foraging by PBW occurs. Based on an overlap of three different metrics (occupancy, number of whales in a cell and move persistence), Thums et al. (2022) identified the most important foraging areas for PBW offshore from Western Australia but also recognised such areas are not static but dependent on the interplay of oceanographic and prey dynamics. The included areas encompassed the shelf edge from Ningaloo Reef to the Rowley Shoals, but none of the important foraging areas identified were on the shelf edge or slope offshore from where the Xena-03 Operational Area is located. Hence, it cannot be reasonably predicted that pygmy blue whale foraging is probable in the Xena-03 Operational Area. Furthermore, all of the identified important pygmy blue whale foraging areas identified by Thums et al. (2022) in offshore NW Australian waters are located beyond the maximum range (km) at which the TTS and behavioural impact thresholds for cetaceans are predicted to be exceeded based on modelling presented above.

Humpback whales occur in the region, with the migration BIA ~30 km east of the Xena-03 Operational Area. Aerial surveys of migrating humpback whales in the region showed that the majority of migrating humpbacks occur in the mid- and inner-continental shelf waters, rather than the outer part of the migration BIA (RPS Environment and Planning, 2010). The Xena-03 Operational Area is surrounded by open water, with no restrictions (e.g., shallow waters, embayment's) to an animal's ability to avoid the activities. Behavioural responses by cetaceans (such as PBW and humpback whales) may result in a deviation in course during migration, which is expected to be insignificant in the context of the long distances over which individuals migrate (thousands of kilometres). Cetaceans that are frequently exposed to sounds such as vessel noise may also habituate and adapt to this noise (Richardson et al., 1995; NRCC, 2003). This may be the case for the humpback whale population that regularly passes through areas of significant shipping traffic during their migrations. Furthermore, MODU activities are expected to occur over approximately 50 to 60 days.

Transponders used for positioning have the potential to cause some temporary behavioural disturbance to cetaceans; however, noise levels will be well below injury thresholds. Based on empirical spreading loss estimates measured by Warner and McCrodan (2011), received levels from USBL transponders are expected to exceed the cetacean behavioural response threshold for impulsive sources out to about 42 m. Given the short-duration chirps and the mid frequencies used by positioning equipment, the acoustic noise from a single transponder is unlikely to have any substantial effect on the behavioural patterns of marine fauna. Therefore, potential impacts from transponder noise are likely to be restricted to temporary and localised avoidance behaviour of individuals transiting through the PAA and therefore are considered localised with no lasting effect.

Potential impacts from predicted noise levels from the MODU, project vessels and transponders are not considered to be ecologically significant at a population level.

The National Recovery Plan for the Southern Right Whale (DCCEEW, 2024a) also identified anthropogenic noise as a threat, however the BIAs and habitat critical to the survival are over 250 km away, well outside the area where behavioural responses are expected to extend from the Operational Area and as such, there is not expected to be any anthropogenic noise from the petroleum activity that could displace or interfere with life cycle activities within, or near, the reproduction or migration BIAs and habitat critical to the survival.

Marine Turtles

Species Sensitivity and Thresholds

Turtles have been shown to respond to low frequency sound, with indications that they have the highest hearing sensitivity in the frequency range 100 to 700 Hz (Bartol and Musick, 2003). Lenhardt (1994) observed marine turtles avoiding low-frequency sound.

Acute noise, or temporary exposure to loud noise, may result in the avoidance of important habitats and in some situations physical damage to marine turtles. McCauley et al. (2000) observed the behavioural response of caged sea turtles – green (*Chelonia mydas*) and loggerhead (*Caretta caretta*) – to an approaching seismic airgun. For received levels above 166 dB re 1 µPa, the turtles increased their swimming activity and above 175 dB re 1 µPa (SPL) they began to behave erratically, which was interpreted as an agitated state. No numerical thresholds have been developed for behavioural impacts of continuous sources (e.g., vessel noise) on marine turtles. A Popper et al. (2014) review assessed thresholds for marine turtles and found qualitative results that the risk of behavioural disturbance was high for near field exposure, moderate for intermediate exposure and low for far field exposure (Popper et al., 2014).Sound exposure thresholds and criteria for continuous sound sources (e.g., vessel noise) and impulsive sources (e.g., transponders) applicable to marine turtles are summarised in Table 6-14.

Impact Assessment

Marine turtles may be present in the region, with a flatback turtle internesting BIA, overlapping the Xena-03 Operational Area. Habitat Critical for the flatback turtle is present ~10 km south west of the Xena-03 Operational Area. The Recovery Plan for Marine Turtles (Commonwealth of Australia, 2017) notes there is limited information available on the impact of noise on marine turtles and that the impact of noise on turtle stocks may vary depending on whether exposure is short (acute) or long-term (chronic). However, given the thresholds outlined it is reasonable to expect that marine turtles may demonstrate avoidance or attraction behaviour to the noise generated by the Xena-03 Tie-back activities. Sound transmission loss modelling indicated that the potential for PTS and TTS onset would be limited to within tens of meters of drilling activity, and up to 140 m (TTS) during DP vessel activities. However, marine turtles within the Xena-03 Operational Area are expected to be transient individuals, and unlikely to remain within 140 m of the vessels for 24-hours, and therefore PTS and TTS thresholds are not expected to be reached. Behavioural impacts to marine turtles from continuous noise sources generated by the Xena-03 Tie-back activities are expected to be short-term and localised.

Given the water depths and distance from shore, the Xena-03 Operational Area does not represent suitable foraging or internesting habitat. The defined BIA and Habitat Critical are considered very conservative as they are based on the maximum range of internesting females rather than direct studies that show marine turtles are more likely to remain near their nesting beaches. For example, tracking studies at Barrow and Thevenard islands suggest the majority of internesting flatback turtles remain in shallow water, close (<3 km) to nesting beaches (Whittock et al., 2014). Studies of flatback turtle nesting in the Pilbara region also found that the average distance travelled at each of the beaches ranged between approximately 10 km and 27 km, and typically in water depths of less than 25 m (RPS, 2010; Whittock et al., 2014; Whittock et al., 2016; Waayers and Stubbs, 2016). Hence it is considered highly unlikely that the Xena-03 Operational Area is used by internesting flatback turtles.

Marine turtle presence in general is expected to be infrequent, and potential impacts from predicted noise levels from the project vessels (including MODU and support vessels) are expected to be short-term, intermittent and localised, if they occur and are not considered to be ecologically significant at a population level.

Fish, Sharks and Rays

Species Sensitivity and Thresholds

Fish perceive sound through the ears and the lateral line, which are sensitive to vibration. Some species of teleost or bony fish (e.g., herring) have a structure linking the gas-filled swim bladder and ear, and these species usually have increased hearing sensitivity. These species are considered to be more sensitive to anthropogenic underwater noise sources than species such as cod (Gadus sp.), which do not possess a structure linking the swim bladder and inner

ear. Fish species that either do not have a swim bladder (e.g., elasmobranchs (sharks and rays) and scombrid fish (mackerel and tunas)) or have a much-reduced swim bladder (e.g., flat fish) tend to have a relatively low auditory sensitivity.

Considering these differences in fish physiology, Popper et al. (2014) developed sound exposure guidelines for fish; these are presented in Table 6-15 and are considered appropriate to assess continuous acoustic discharges to fish from the Petroleum Activities Program.

Table 6-15: Impact thresholds to fish, sharks and rays for continuous noise

Receptor	Mortality and Potential Mortal Injury	PTS	TTS	Masking	Behaviour
Fish: no swim bladder	(N) Low (I) Low (F) Low	(N) Low (I) Low (F) Low	(N) Moderate (I) Low (F) Low	(N) High (I) High (F) Moderate	(N) Moderate (I) Moderate (F) Low
Fish: swim bladder not involved in hearing	(N) Low (I) Low (F) Low	(N) Low (I) Low (F) Low	(N) Moderate (I) Low (F) Low	(N) High (I) High (F) Moderate	(N) Moderate (I) Moderate (F) Low
Fish: swim bladder involving hearing	(N) Low (I) Low (F) Low	170 dB rms SPL for 48-hours	158 dB rms SPL for 12-hours	(N) High (I) High (F) High	(N) High (I) Moderate (F) Low
Fish eggs and fish larvae	(N) Low (I) Low (F) Low	(N) Low (I) Low (F) Low	(N) Low (I) Low (F) Low	(N) High (I) Moderate (F) Low	(N) Moderate (I) Moderate (F) Low

Note: The sound units provided in the table above include relative risk (high, moderate and low) is given for fish (all types) at three distances from the source defined in relative terms as near (N – tens of metres), intermediate (I – hundreds of metres) and far (F – thousands of metres) (after Popper et al., 2014).

Impact Assessment

Given the thresholds outlined in Table 6-15, it is reasonable to expect that fish, sharks and rays may demonstrate avoidance or attraction behaviour to the noise generated by the Xena-03 Tie-back activities. However, potential impacts from predicted noise levels from the project vessels (including MODU and support vessels) are not considered to be ecologically significant at a population level.

A number of demersal and pelagic fish species will be present within the Xena-03 Operational Area which overlaps the Continental Slope Demersal Fish Communities KEF. However, given species richness has been shown to correlate with habitat complexity (Gratwicke and Speight, 2005), it is unlikely that the sand/silt sediments that comprise the largest proportion of the Xena-03 Operational Area will support a wide diversity of species.

Maximum-over-depth horizontal distances to PTS and TTS thresholds for fish with a swim bladder involved in hearing as a result of underwater noise from a support vessel are approximately 10 m or less from the source based on modelling from JASCO for the Scarborough field (McPherson et al., 2019). For fish with a swim bladder not involved in hearing, and fish without a swim bladder (including whale sharks) the likelihood of PTS or TTS is low. Based on an intermediate spreading equation to estimate sound propagation loss from the MODU (15Log(R)), noise levels would drop below PTS and TTS thresholds for fish with a swim bladder involved in hearing within 15 m and 78 m respectively. It is expected that potential impact to demersal and pelagic fish and sharks/rays will be limited to a behavioural response. Behavioural responses are expected to be short-lived, with duration of effect less than or equal to the duration of exposure.

Whale sharks do frequent the wider NWS outside their seasonal aggregation period (peak: April and May) within the high-density prey foraging BIA at Ningaloo. The Xena-03 Operational Area overlaps a foraging BIA for whale sharks (Section 4.6.1); however, it is over 200 km from the Ningaloo high density prey foraging BIA and therefore likelihood of whale shark encounters is not considered high but is possible. Acoustic detections of tagged whale sharks at the North Rankin A and GWA platforms during two periods – June to July and October to January – were recorded (Thomson et al., 2021) and supported anecdotal evidence of whale shark presence on NWS. Behavioural disturbance to whale sharks as a result of vessel noise may result in a temporary deviation on their migration route. However, any deviation is considered to be insignificant in the context of the long distances over which whale sharks migrate and normal variation in their movements in the region.

It is reasonable to expect that fish, sharks and rays may demonstrate avoidance or attraction behaviour to the noise generated by the Xena-03 Tie-back activities. However, potential impacts from predicted noise levels from the project vessels (including MODU and support vessels) are not considered to be ecologically significant at a population level.

Cumulative Impacts

As identified above, Xena-03 Tie-back activities will coincide with routine operations of the Pluto facility (but is not planned to be co-timed with major maintenance requiring an ASV) and may result in cumulative impacts from underwater noise emissions. The combined sound fields of the drilling activity and routine facility operations are likely to result in an increase in the maximum range to the behavioural response threshold for LF cetaceans described above (i.e., ~20 km). However, as described above, the Xena-03 Operational Area, in which only temporary activities will occur, is surrounded by open water, with no restrictions (e.g., shallow waters, embayment's) to an animal's ability to avoid the activities. Consequently, if concurrent activities occur and coincide with seasonal migrations, any pygmy blue whales, humpback whales or whale sharks transiting through the area, may deviate, but can continue on their pathway. The intersect of ensonified areas between temporarily concurrent activities within the Xena-03 Operational Area and routine operations at the Pluto facility is likely to affect only a very small area of the pygmy blue whale migration BIA and biologically significant impacts at a population level are not anticipated. Modelling outlined above predicted PTS onset in LF cetaceans within a maximum of 150 m and TTS onset within a maximum of 2.66 km for a combination of three vessels in close proximity. Any cumulative impacts arising from the Pluto Facility Operations will be limited to the duration of Xena-03 Tie-back activities (~12 weeks) and would be discontinuous over this time.

• Project vessels will not travel greater than 8 knots within 250 m of a whale shark and not allow the vessel to approach closer than 30 m of a whale shark.		underwater noise footprint of a vessel.		
Good Practice				
Develop a SIMOPS Plan to manage MODU interactions with other facilities/vessels, where multiple campaigns occur within the PAA (i.e. during xmas tree installation). SIMOPS Plan will contain information on: • minimum separation distances • communications • MODU/vessels/ activities involved in SIMOPS • exclusion zone entry and exit processes • ROV operations • helicopter operations • key roles, responsibilities and emergency contacts • PTW arrangements • incident reporting and investigation management of change.	F: Yes. CS: Minimal cost. Standard practice.	SIMOPS management plans between Woodside operated vessels in the PAA will reduce the acoustic emissions from concurrent vessels.	Benefits outweigh cost/sacrifice.	**Yes** **C 1.15**
Implement adaptive management procedure prior to: • resupply vessel moving alongside the MODU with PIV within the PAA, during daylight hours • MODU departing well location (excludes kedging).	F: Yes. CS: Time/cost associated with person used for observations. Schedule delays associated with waiting on pygmy blue whale activity to cease/move on.	Implementation of adaptive management where PBW (or large unidentified whales) are observed means a new noise source (vessel) is not introduced while PBW are sighted. Restricting the introduction of new noise sources when pygmy blue whale presence is detected could lower likelihood of disturbance to PBW so as to not be inconsistent with the Blue Whale Conservation Management Plan.	Benefits outweigh cost/sacrifice.	**Yes** **C 4.1**

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)[58]***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Vessels will not travel greater than 6 knots within 300m of a turtle (caution zone). If the turtle shows signs of being disturbed, vessels will immediately withdraw from the caution zone at a constant speed of less than 6 knots.	F: Yes CS: Minimal cost. Standard practice.	Implementation of controls for reduced vessel speed around turtles can potentially reduce the underwater noise footprint of a vessel.	Benefits outweigh cost/sacrifice. Good practice.	**Yes** **C 3.3**
Collect data on opportunistic sightings of PBW to gauge presence and behaviour using trained crew.	F: Yes. CS: Time/cost associated with person used for observations and in data collection.	Collecting data on pygmy blue whale presence and behaviour may assist in increasing understanding of their activity in the PAA to inform future activities and support environmental knowledge.	Benefits outweigh cost/sacrifice.	**Yes** **C 4.2**
Implement speed limitations when safe[60] to do so for MODU and PIV within the Xena-03 Operational Area.	F: Yes, within the limits of navigational safety. CS: Time/cost associated with slower transit speed.	Given the Xena-03 Operational Area overlaps the pygmy blue whale migration BIA and introduction of vessel noise may present behavioural disturbance risk to migrating pygmy blue whales, reducing vessel speed can result in reduced underwater noise emissions and overall reduction in potential behavioural disturbance. Additionally, reducing speed to 6 knots is consistent with the EPBC Regs 2000 – Part 8 Division 8.1, interacting with cetaceans, under which project vessels are not to travel greater than 6 knots within 300 m of a cetacean. Application of this speed restriction for the MODU and PIV within the Xena-03 Operational Area is considered to be a precautionary approach to reducing vessel noise and potential disturbance to cetaceans.	Benefit outweighs cost/sacrifice.	**Yes** **C 4.3**

[60] Vessel speeds are at the ultimate discretion of the vessel master, noting speed limitations may be exceeded from time to time to maintain safe navigation.

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)[58]***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Stop or deviate from course[61] if pygmy blue whale (or large unidentified whale) observed during entry of a hybrid MODU and PIV to the Xena-03 Operational Area.	F: Yes. If a whale is observed during mobilisation into the Xena-03 Operational Area, the MODU (if under own propulsion) and PIV could deviate course away from the whale and delay mobilisation. CS: Time/cost associated with deviating and delay to mobilisation into the Xena-03 Operational Area.	Deviating course may reduce potential behavioural disturbance associated with vessel noise.	Benefit outweighs cost/sacrifice.	**Yes** **C 4.4**
Stop or deviate from course if pygmy blue whale (or large unidentified whale) observed during entry of a moored MODU into the Xena-03 Operational Area.	F: No. Stopping or deviating the MODU in an unplanned manner if a pygmy blue whale or large unidentified whale is observed may reduce potential behavioural disturbance associated with vessel noise. However, the action would significantly increase the safety risk profile of the mobilisation activity through reactive interruption of planned course by vessels towing MODU into field. CS: Introduces unacceptable safety risk.	Not considered – introduces unacceptable safety risk.	Not considered – introduces unacceptable safety risk.	No
The use of dedicated marine fauna observers (MFOs) on project vessels for the duration of the PAP to watch for whales and provide direction on and monitor compliance with Part 8 of the EPBC Regulations.	F: Yes. However, support vessel bridge crews already maintain a constant watch during operations. CS: Additional cost of MFOs.	Given that support vessel bridge crews already maintain a constant watch during operations and trained crew as MFOs will monitor for pygmy blue whale presence prior to resupply/support vessel moves alongside the MODU and PIV, additional MFOs would not further reduce the likelihood of an individual being within close proximity of the acoustic source during introduction of sounds	Disproportionate. The cost/sacrifice outweighs the benefit gained.	No

[61] Unless deemed navigationally unsafe by the vessel master.

Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)[58]***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
		related to DP or during operations.		
Implement adaptive management procedure prior to: • hybrid MODU energising (turning on) DP system within the Xena-03 Operational Area.	F: No, a DP assist or thruster assist rig is held into position by a mooring spread and may be supplemented by a thruster assisted mooring system. The DP system will be energised and available for emergency use but not planned for use in regular operations. The system operates such that thrusters engage automatically in response to metocean conditions using feedback (signals) from the mooring system. Therefore, it is not feasible to predict when this will occur and hence, pre-emptively apply adaptive management procedures. CS: N/A.	Not considered, control not feasible.	Not considered, control not feasible.	No
Use professional MFOs in lieu of trained crew to observe for pygmy blue whales.	F: Yes. CS: The cost of implementing dedicated MFOs during vessel activities would be tens of thousands of dollars and expose additional personnel to the health and safety risks of working at sea. The cost is grossly disproportionate to the environmental benefit.	The environmental benefit of having dedicated professional MFOs is a potential increase in the likelihood of detecting PBW at the species level, which then permits actions to maintain separation as per the adaptive management procedure. Trained crew will watch for marine fauna during the petroleum activity. Trained crew will implement adaptive management measures if a pygmy blue whale or large unidentified whale is observed. Therefore, while there is an increased likelihood for professional MFOs to detect PBW from other large whale species, the ability to identify marine fauna in comparison with trained crew is negligible.	Disproportionate. The cost/ sacrifice outweighs the benefit gained.	No
Professional Judgement – Eliminate				

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)[58]***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Remove support vessel on standby at the PAP location.	F: No. Activity support vessel required as per MODU Safety Case, particularly for maintaining the 500 m petroleum safety zone around the MODU/ installation vessel. CS: Introduces unacceptable safety risk.	Not considered, control not feasible.	Not considered, control not feasible.	No
Eliminate generation of noise from the MODU, installation vessel, support vessels or positioning equipment.	F: No. The generation of noise from these sources cannot be eliminated due to operating requirements. Note that vessels operating on DP may be a safety critical requirement. CS: Inability to conduct the Petroleum Activities Program. Loss of project.	Not considered, control not feasible.	Not considered, control not feasible.	No
Professional Judgement – Substitute				
Management of vessel noise by varying the timing of the PAP to avoid migration periods.	F: Yes. Migration periods for cetaceans that may occur in the PAA (pygmy blue and humpback whales) are well known. CS: Significant cost and schedule impacts if activities avoid specific timeframes.	Avoiding migration periods would reduce the likelihood of impacts to cetaceans. However, given the predicted impacts from noise sources associated with the PAP are considered to be localised with no lasting effect, the overall benefit is minimal.	Disproportionate. The cost/sacrifice outweighs the benefit gained.	No
Professional Judgement – Engineered Solution				
Use of additional detection controls (e.g., drones for aerial observations, Passive Acoustic Monitoring for use at night, thermal imaging for use at night) to Identify cetacean presence.	F: Yes. CS: Time/cost associated with additional personnel and technology onboard vessels. Due to distance offshore actual observation times are limited by fuel availability – larger fuel capacity associated with larger aircraft increases cost of the exercise.	May increase likelihood of detection of whales, particularly during periods of poor visibility. Additional detection technologies can be degraded by metocean conditions (e.g., sea state). Additional detection methods would not result in a reduction in the potential consequence level.	Disproportionate. The cost/ sacrifice outweighs the benefit gained. Adequate observations are able to be made from the MODU bridge due to the height and surveillance by trained crew. It is not expected that additional technologies would add significantly more value than this to	No

			warrant deployment.	

ALARP Statement:

On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts and risks of noise emissions from Xena-03 Tie-back activities. As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.

Demonstration of Acceptability

Acceptability Statement

The impact assessment has determined that the generation of noise from project vessels, MODU, and positioning equipment during Xena-03 Tie-back activities is unlikely to result in an impact significance level greater than slight. Relevant recovery plans and conservation advice have been considered during the impact assessment, and the PAP is not considered to be inconsistent with the overall recovery objectives and actions of these recovery plans and conservation advice.

In particular, the Conservation Management Plan for the Blue Whale (Commonwealth of Australia, 2015a) and associated guidance on key terms requires that PBW not be displaced from a foraging area. The nearest recognised foraging BIA is off the Ningaloo Coast, approximately 232 km south-west of the PAA at the closest point. The sound transmission loss modelling studies by JASCO (Stroot et al., 2022; Wecker et al., 2022) predicted that behavioural responses (a conservative surrogate for displacement) could occur up to 8.85 km from the noise source during moored drilling activities or up to 20.7 km from the noise source during DP vessel activities; less than one tenth of the distance to the foraging BIA). Hence, displacement of PBW from this foraging BIA as a result of the Xena-03 Tie-back activities will not occur. The potential impacts are considered broadly acceptable if the adopted controls are implemented and EPO 5 has been applied to demonstrate the activities are not inconsistent with the Blue Whale Conservation Management Plan. Therefore, Woodside considers the adopted controls appropriate to manage the impacts of acoustic emissions to a level that is broadly acceptable and demonstrate the EPOs are met.

Discharge of minor fugitive hydrocarbons from subsea equipment			x		x				F					
Discharge of chemicals, (e.g., MEG), during installation and leak testing of new infrastructure		x	x		x				F					

Description of Source of Impact
Operations

Hydrocarbons and chemicals may be discharged as a result of planned routine and non-routine operations and activities for:

- operational discharges, including:
  - discharge of subsea control fluids – subsea control fluid is used to control valves remotely from the facility; it is an open-loop system, designed to release control fluid from the control system during valve operations (e.g., up to about 6 L per valve actuation)
  - potential non-routine hydraulic or chemical fluid discharge associated with umbilical system losses/weeps
  - discharge of minor fugitive hydrocarbon from wells and subsea equipment (e.g., weeps/seeps/bubbles)
  - discharge of chemicals introduced into subsea infrastructure and the production stream, either as process or non-process chemicals (e.g., corrosion inhibitors, biocides, scale inhibitors); chemicals flow through the production process, with residual hydrophilic chemicals discharged as a component of PW discharged overboard.
- IMMR activities (nominal discharges described in Section 3.10.2), including:
  - discharge of residual hydrocarbons in subsea lines and equipment and small gas releases associated with isolation testing and breaking containment
  - discharge of hydrocarbons associated with pigging activities required as shown in Section 3.10.5
  - discharge of approximately 100–150 L of preservation fluids from flowlines following flushing when the flowlines are cut and plugs installed in either end of the cut section
  - discharge of residual chemicals in subsea lines and equipment, or the use of chemicals; these chemicals are used and discharged intermittently in small volumes. Small quantities of chemicals may remain in the flushed infrastructure, which may be released to the environment after disconnection.

Xena-03 Tie-back Activities

The activities that may result in the discharges of small quantities of flowline and subsea installation preservation and pre-commissioning fluids are:

- discharges during barrier testing
- discharges during disconnection of caps from installed structures (manifold, xmas tree, UTA)
- discharges from flexible flowline and flying leads during tie-in and reconfiguration activities
- discharges from installation vessel's pre-commissioning equipment or subsea infrastructure during leak testing activities
- discharges post leak test, during depressurisation to marine environment.

In addition, there is potential for discharge of minor fugitive hydrocarbons from the suspended Xena-03 well prior to xmas tree installation (e.g., weeps, seeps, bubbles).

Flexible Flowline Fluids

The flexible flowline and subsea distribution unit will be installed filled with a chemically treated mixture of up to 50 wt% MEG/water. The MEG concentration must be fibre-grade (99.9 wt%) before mixing with water. The flexible flowline will not require further flooding post-installation, but pressure test top-up fluid may be required in the event of test failure.

Installation and tie-in of the flexible flowline to the manifold and xmas tree may result in small quantities of fluids within the flowline being released to the environment. These volumes are expected to be small (1 m^3 per tie-in point) as the pressure within the flowline is equal to the hydrostatic pressure and the flowline is uncapped for a short duration during tie-in. Water jetting and/ or acid injection (~400 L acid) may be used to clean the connections on the infrastructure prior to tie-in.

A leak test/system pressure test will be performed to test the integrity of the subsea connections, flowline and flowlines, which may result in ~4 m^3 of MEG/treated potable water and ~0.6 to 1.2 L of treatment chemicals (including corrosion inhibitor, biocide, oxygen scavengers and dye) being released to the environment at the locality of the subsea infrastructure. A contingency secondary leak test may also be required, with similar discharge volumes.

Xmas Tree

The xmas tree will be installed with a preservation mixture in the production and annulus bore. There will be a small discharge of preservation fluid associated with testing after connection to the THS (estimated 100 to 150 L).

Hydrocarbons

Testing of manifold isolations may be undertaken to verify that suitable isolations are available for safe tie-in to the subsea distribution unit and flexible flowline. The testing and tie-in may release gas and condensate (up to 400 L) over a 48-hour period. This testing is required to verify that suitable isolations are available for safe tie-in and cannot reasonably be eliminated. The estimated mass of hydrocarbons is considered to be a worst-case, with the actual release volume expected to be smaller.

Well Unload

During well unloading activities, all completion and reservoir fluids will be directed to the Pluto facility and be handled by the systems onboard the platform, in accordance with Section 3.10.10. All non-hydrocarbon fluids will be discharged overboard with the produced water.

Should well unloading fluids not be directed to the Pluto facility, they may be flared or discharged to the environment via the well test package onboard the MODU. The base oil column, completion fluid, hydrocarbons and produced/condensed water will be measured, handled, separated, treated for overboard discharge (non-hydrocarbon) and flared/burned (hydrocarbon) through the temporary production system on the MODU.

Well Intervention (contingency)

Well intervention activities have been considered within the Petroleum Activities Program, for contingency purposes. During intervention activities, including post xmas tree installation testing and TIV valve operations, local control of the xmas tree may be required. Valve actuation of the trees may be required, which will result in small releases of subsea control fluids to be released to the environment.

All subsea chemicals will be selected, assessed and approved in accordance with a defined framework and set of tools so that the potential impacts are acceptable, ALARP and meet Woodside's expectation for environmental performance, outlined in Section 3.9. This procedure is used to demonstrate that the potential impacts of the chemicals selected are acceptable and ALARP (subject to technical and economic constraints).

Impact Assessment

There is potential for localised water column pollution and adverse effects on marine biota as a result of planned routine and non-routine hydrocarbon and chemical discharges during operations and Xena-03 Tie-back activities. However, planned discharges of hydrocarbons and chemicals are minor and are minimised as far as practicable via flushing of the lines back to the facility during IMMR activities, and unloading wells to host during tie-back activities. Discharge locations during routine operations are either the PW stream, subsea valves (subsea control fluid), at dis/connection points in subsea infrastructure, including during installation of pig receivers or launchers, or via the export pipeline to the onshore process. During tie-back activities, discharges may also occur at connection points and during leak testing.

Water Quality

During operations, subsea control fluids are discharged at relatively small volumes during valve actuations (typically <6 L) and IMMR activities at or near the seabed. On release the subsea control fluids are expected to mix rapidly and dilute in the water column. Pigging activities are infrequent and result in relatively small releases of hydrocarbon.

During Xena-03 Tie-back activities, leak testing and tie in of new infrastructure may result in discharges of small amounts of MEG and hydrotest fluids as described above. Contingency activities, such as well intervention may result in minor discharges of subsea control fluids from the xmas tree, similar to valve actuation releases discussed above. On release, impacts of MEG and hydrotest fluids will be localised to the immediate vicinity of the release location with short-lasting impacts. This is based on the low potential for toxicity and bioaccumulation of MEG, small volumes/rates of discharge and rapid dilution in the marine environment.

Gas and condensate may be released during IMMR activities that break containment of isolated subsea infrastructure or during verification testing of the subsea distribution unit. Hydrocarbons will become dispersed as bubbles in the water column, which will rise to the surface. Methane is the principal component of the gas and is relatively insoluble in water. As such, methane is expected to rise until it reaches the sea surface, where it will be readily dispersed in the atmosphere. The concentration of methane will not be sufficient to form an explosive atmosphere or result in asphyxiation. Water-soluble components of the gas, such as carbon dioxide and sulphur dioxide will dissolve in the seawater as the gas bubbles rise in the water column. These soluble gasses occur naturally and are present in relatively low amounts. No measurable impacts to water quality are expected to occur as a result of the gas release.

The insoluble condensate release during verification testing will be buoyant and rise in the water column. The condensate will be released with gas which will act to disperse the condensate within the water column as it rises to the sea surface. The resulting condensate droplets will rise slowly in the water column and may be transported away from the release location by currents. Upon reaching the sea surface, the condensate will almost entirely evaporate, with a relatively small portion remaining entrained in the water column. Condensate droplets are not expected to reach the surface in sufficient quantities to result in surface slicks above thicknesses that result in biological impacts, although a sheen may be visible. Any condensate reaching the surface will spread and weather rapidly. Soluble hydrocarbons will be distributed in the water column through natural water movement and the buoyancy of the condensate droplets and are expected to drop below concentrations recognised as causing biological impacts within tens to hundreds of metres of the release location.

There is potential for slight, localised decrease in water quality at planned discharge locations and potential impacts on marine biota. Impacts to pelagic fish are expected to be limited to avoidance of the localised area of the discharge and short-term, localised decline in planktonic organisms in the immediate vicinity of the discharge.

Ecosystems

Sediments in the PAA are expected to be broadly consistent with those in the NWS Province (as described in Section 4.5), with filter feeders such as sponges, ascidians, soft corals and gorgonians associated with areas of hard substrate. Subsea control fluids and installation fluids are non-toxic and do not have the potential to bioaccumulate.

Receptors that may be impacted by a condensate release during verification testing are in-water receptors within the vicinity of the release location. These receptors include plankton, pelagic fishes and potentially cetaceans. Potential impacts to these receptors include:

acute toxic effects to planktonic organisms near the release location from soluble hydrocarbons. Only a very small portion of the planktonic community at a bioregional scale would credibly be impacted. Planktonic communities have high turnover rates, and recovery from any impacts would occur rapidly. Given the small volume of soluble hydrocarbons, the planktonic community in the upper part of the water column will not be impacted.

temporary displacement of pelagic fishes. Large-scale oil spills in open water typically do not result in fish kills, and it is assumed that fishes in open water will actively avoid harmful concentrations of hydrocarbons. Given the relatively small volume of hydrocarbons released and the resulting localised impact, it is unlikely that displacement of pelagic fishes will occur.

Given the nature and scale of planned discharges, potential impacts are considered to be slight and short term (expected to recover once routine and non-routine discharges cease).

KEFs

The Ancient Coastline at 125 m Depth Contour and Continental Slope Demersal Fish Communities KEF, overlap the PAA (Figure 4-10). The Continental Slope Demersal Fish Communities KEF overlaps the wider Xena-03 Operational Area and the Pluto Facility Operational Area. No significant escarpments, species of conservation significance, emergent features or areas of high biological productivity characteristically associated with the Ancient Coastline at 125 m KEF have been observed in the PAA. Therefore, potential impacts to these regional-scale KEFs are not expected.

A small portion of the Pluto Export Operational Area overlaps the Ancient Coastline at 125 m Depth Contour KEF. Potential impacts to this KEF would be limited to IMMR activities. Given the infrequent and small volumes of discharges associated with IMMR activities, potential impacts to the KEF are not expected.

Cumulative Impacts

Given the adopted controls, the overall impacts from the discharge of hydrocarbons and chemicals to the marine environment is Slight (E) based on short term (<1 year) on species, habitat (but not affecting ecosystems function), physical or biological attributes.

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Legislation, Codes and Standards				
None identified.				
Good Practice				
Implement Woodside's Chemical Selection and Assessment Environment Guideline: • Where Gold, Silver, E or D OCNS rating (and no OCNS substitution or product warning), chemicals are selected – no further control required. • If chemicals with a different OCNS rating, sub warning or non-OCNS rated	F: Yes. Routinely implemented to the chemical selection process for Woodside facilities. CS: Minimal cost. Standard practice.	Selection and assessment of chemicals in accordance with the Woodside process, reduces environmental impacts associated with planned chemical discharge.	Control is a WMS requirement – must be adopted.	Yes C 5.1

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
chemicals are required, chemicals will be assessed in accordance with the guideline prior to use.				
Subsea infrastructure flushed where practicable prior to disconnection to reduce volume/ concentration of hydrocarbons released to the environment.	F: Yes. Subsea infrastructure has been designed such that much of the hydrocarbon containing elements can be flushed back to the riser platform. CS: Minor. Flushing may prolong the cessation of production required for subsea IMMR activities, leading to reduced production.	Flushing reduces the volumes/ concentration of hydrocarbons released to the environment.	Benefit outweighs cost/sacrifice.	Yes C 5.2
Monitoring subsea control fluid use, investigate material discrepancies, and using control fluid with dye marker to support identification of potential integrity failures. Where fluid losses are unexplained relative to expected usage trends (dependent on operational demand for system activation), potential integrity issues are investigated	F: Yes. The use of control fluid is monitored to maintain adequate fluid in the system. CS: Minimal cost.	Limits the volumes of subsea control fluid discharged to the marine environment.	Benefit outweighs cost/sacrifice.	Yes C 5.3
Implement Woodside Engineering Operating Standard - Subsea Isolation). Proven isolation in place for relevant IMMR activities.	F: Yes CS: Minimal cost. Standard practice.	Maintaining and testing the ability to isolate wells and pipelines will ensure barriers are in place and verified limiting the volume of hydrocarbon released.	Control is a WMS requirement – must be adopted.	Yes C 5.4
For Xena-03 Tie-back activity fluids, six-monthly chemical reviews are performed during active drilling campaigns.	F: Yes. CS: Minimal cost. Standard practice.	More frequent reviews will ensure chemicals selected remain ALARP. During routine operations chemicals are reviewed as the Chemical Selection and Assessment Environment Guideline.	Benefits of increased review frequency outweigh cost/sacrifice.	Yes C 5.5

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
ROV inspection during leak test (during Xena-03 Tie-back activities).	F: Yes. CS: Minimal cost. Standard practice.	A procedure for leak testing work that includes inspection (including by ROV) during testing to identify leakage and trigger activity to stop will reduce likelihood of impacts.	Benefits outweigh cost/sacrifice.	Yes C 5.6
Test subsea manifold isolation valves prior to tie-in.	F: Yes. CS: Minimal cost. Standard practice.	Testing of the isolation valves will provide a valve pass rate to be used to assess isolation requirements and determine the isolations required to confirm to the relevant internal Woodside standards.	Benefits outweigh cost/sacrifice.	Yes C 5.7
Pre-commissioning and flexible flowline subsea installation procedures developed.	F: Yes. CS: Minimal cost. Standard practice.	A procedure for pre-commissioning and subsea installation will reduce likelihood of impacts.	Benefits outweigh cost/sacrifice.	Yes C 5.8
Subsea isolations conform to the relevant internal Woodside standards, which include: • A double block isolation is used. • If it is not practicable to establish a double block isolation, then one effective, proven and monitored barrier (single block isolation) shall be in place, with the following conditions: • It must be possible to isolate the reservoir by remote operation of tree isolation valves. • The residual risks must be shown to be ALARP by a documented isolation risk assessment. • Procedures and response plans for the activity must be developed and implemented and address all applicable hazards	F: Yes. CS: Minimal cost. Standard practice.	Pass rate (≤0.05 kg/s) across valve with proven single block isolation. Conditions for single block isolation reduce the likelihood and consequence of an uncontrolled release.	If valve testing confirms proven barrier (≤0.05 kg/s pass rate), slight environmental impact associated with hydrocarbon release is disproportionate to requirement to shut in the well to achieve double isolation. Benefit for additional conditions for single isolation outweigh cost. Benefit outweighs cost.	Yes C 5.9

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
appropriately, including provision for closing tree isolation valves.				
Monitor and track subsea fugitive hydrocarbon emissions to support identification of potential integrity failures in accordance with the Subsea and Pipelines Integrity Management Procedure.	F: Yes. CS: Minimal cost. Standard practice	Tracks and manages fugitive hydrocarbons discharged to the marine environment, and supports integrity management assessments.	Benefits outweigh cost/sacrifice. The subsea anomaly and its scale is noted in the anomaly/inspection report and recorded in the Company's centralised subsea Inspection Database. The anomaly is then assessed to determine integrity risks, future monitoring, and/or corrective actions.	Yes C 5.10
Professional Judgement – Eliminate				
Reduce volume or not use preservation and pre-commissioning chemicals including MEG.	F: No. Preservation and pre-commissioning fluids are required to verify the structural integrity of the subsea infrastructure and avoidance of hydrate formation. The volumes selected are required to achieve verification. CS: Potential loss of production due to loss of integrity, possibly leading to a larger environmental incident.	Not considered, control not feasible.	Disproportionate. The cost/sacrifice outweighs the benefit gained.	No

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Do not conduct leak testing activities.	F: No. Leak testing activities are required to control the potential for corrosion of the flexible flowlines and to determine if any unacceptable restrictions and/or obstructions exist in the line. CS: Potential loss of production due to loss of integrity, possibly leading to a larger environmental incident.	This would eliminate any potential impacts from the leak testing activities but increases the likelihood of loss of integrity during operation and potentially greater environmental impacts.	Disproportionate. The cost/sacrifice outweighs the benefit gained.	No
Professional Judgement – Substitute				
Installing closed-loop subsea valve control system.	F: Yes. Closed-loop subsea valve control systems can be installed; however, they may not perform as quickly/reliably as open-loop systems. CS: Significant. The design, procurement and retrofitting of a closed-loop valve control system would result in considerable offshore logistics, exposure to safety hazards during installation, and significant financial burden through direct costs and lost production.	The potential consequence of the discharges is ranked as incidental, based on the volume, frequency, location, and types of fluid discharged in an open-ocean environment, and avoiding the discharges would provide little or no environmental benefit.	When considering the negligible effect from the release of control fluids, the risk and costs of retrofitting a closed-loop subsea valve control system is considered to be grossly disproportionate to the environmental benefit.	No
Professional Judgement – Engineered Solution				
Poppetted hydraulic lines in control connections (to minimise release of control/preservation fluids).	F: Yes. CS: Minimal cost. Standard practice	Poppeted connections minimise discharge to marine environment in pressurised hydraulic lines.	Benefits outweigh cost/sacrifice.	Yes C 5.11

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Routing hydrocarbons to vessel during disconnection of subsea infrastructure.	F: Yes. However, to do so would introduce significant safety risks to the vessel crew (fire, explosion, asphyxiation). CS: Significant. Equipping and training crew on-board subsea support vessels to safely route hydrocarbons to the vessel would result in significant additional costs (in addition to the increased safety risk identified above).	Small environmental benefit from preventing low concentration hydrocarbon discharge.	Given the increased safety risk and the very low environmental impact from hydrocarbon releases during subsea IMMR activities, the cost of routing hydrocarbons to the vessel is grossly disproportionate to the environmental benefit.	No
Decreasing the frequency of valve actuation.	F: Yes. However, decreasing the frequency of valve actuation may adversely impact the safe functionality and reliability of valves. Reducing the performance of subsea valves may introduce operability impacts, and increased safety and environmental risk associated with loss of containment events. CS: Minimal cost.	The potential consequence of the discharges is ranked as incidental, based on the volume, frequency, location and types of fluid discharged in an open-ocean environment, and reducing the number of discharges would provide little or no environmental benefit.	Decreasing the frequency of valve actuations would lead to a potential decrease in safe functionality and reliability of valves. When considering the potential safety and environmental risks from such a performance degradation, along with the minor impact from the release of control fluids, the cost of decreasing the frequency of valve actuations is considered to be grossly disproportionate to the environmental benefit.	No
ALARP Statement: On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts of planned routine and non-routine hydrocarbon and chemical discharges. As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.				
Demonstration of Acceptability				
Acceptability Statement: The impact assessment has determined that, given the adopted controls, planned routine and non-routine hydrocarbon and chemical discharge represents a localised short-term impact that is unlikely to result in a potential impact greater than slight short-term effects on water quality, marine sediment or ecosystem habitat. Further				

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
opportunities to reduce the impacts have been investigated above. Fluid discharges from the subsea system during operations, IMMR activities, flexible flowline commissioning and well intervention are routine in the oil and gas industry. The adopted controls are considered good oil-field practice/industry best practice. The potential impacts are considered broadly acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the impacts of planned routine and non-routine hydrocarbon and chemical discharges to a level that is broadly acceptable and demonstrates the EPOs are met.

Discharge of sewage, grey water and putrescible waste from the Pluto facility, MODU, ASV, installation and support vessels to the marine environment			x					A	F	-	-	LCS GP PJ	Broadly Acceptable	EPO 6
Discharge of deck, bilge and drain water from the Pluto facility, MODU, ASV, installation and support vessels to the marine environment			x					A	F	-	-			
Discharge of brine and cooling water from the Pluto facility, MODU, ASV, installation and support vessels to the marine environment			x					A	F	-	-			

Description of Source of Impact

Sewage, Putrescible Waste and Grey Water

No sewage is discharged from the facility when it is uncrewed. When the facility is crewed, the sanitary drainage system is a combined black and grey water system, with black and grey water discharged to the marine environment as untreated, un-macerated waste. Sewage is disposed via a dedicated overboard caisson (7.5 m below LAT). Putrescible waste (principally food scraps) bagged and transported to shore for disposal as domestic waste.

The volume of sewage and greywater generated is estimated to be in the order of 1.8 m^3 per day (based on an average volume of 75 L/person/day), from the facility when crewed. The actual volume of discharge varies depending on personnel requirements on the facility. Refer to Section 3.6.6 for further details.

Treatment systems on the facility may require routine maintenance or repair during operations, requiring infrequent short periods in which sewage is directly discharged overboard.

During maintenance campaigns or major projects, an ASV may be utilised inside the PSZ for periods of approximately 90 days to accommodate crews of around 100 POB. The ASV will discharge sewage, putrescible waste and grey water, managed in accordance with MARPOL requirements.

Vessels may also discharge sewage, grey water and putrescible wastes within the PAA, but outside of the facility PSZ. Sewage on-board operational vessels is routinely treated (either sewage treatment plant or macerator) prior to discharge.

The MODU and project vessels routinely generate/discharge small volumes of treated sewage, putrescible wastes and grey water to the marine environment (impact assessment based on approximate discharge of 15 m^3 per vessel/MODU per day), using an average volume of 75 L/person/day and a maximum of 200 persons on board. However, it is noted that vessels such as the AHV and support vessels will have considerably fewer persons on board.

During tie-back activities the facility will be crewed during the commissioning phase, in addition to the presence of the MODU, installation vessels and other support vessels, resulting in cumulative volumes of sewerage, putrescible waste and grey water over approximately 12 weeks (Section 0).

Drain and Bilge Water

Pluto's hazardous open drains system collects wash water and waste liquids from major process and utility equipment and diesel/chemical storage areas, including plated area deck drains, drain tundishes and equipment drip trays in hazardous areas. Drainage into the hazardous open drains system discharges into two collection tanks (working volume 11.6 m^3 and 10.7 m^3), which are periodically pumped to a waste oil storage tank (capacity 4 m^3) then transported onshore for disposal. The transfer of liquids from the PLA open drain collection tank to the waste oil storage tank is a manual operation only undertaken while the facility is crewed. Pump-out from the module open drain collection tank can be remotely operated to decant to the PLA open drain collection tank.

The non-hazardous area open drains system collects liquids from areas designated as non-hazardous. It is segregated from all other drainage systems to eliminate the risk of hydrocarbon vapour transmission from hazardous to non-hazardous areas. Water and any contamination are routed to the non-hazardous area open drains collection tank, which is 2 m^3 (with max capacity of 2.6 m^3). The collected liquids are manually drained to the hazardous area open drains collection tank during every facility campaign maintenance visit.

The MODU, ASV, installation and support vessels routinely generate and discharge relatively small volumes of bilge water. Bilge tanks receive fluids from many parts of the vessel, including machinery spaces. Bilge water can contain water, oil, detergents, solvents, chemicals, particles and other liquids, solids or chemicals. The MODU and vessels may also discharge drainage water from decks directly overboard or via deck drainage systems; deck drainage may also contain traces of chemicals. Water sources could include rainfall events and/or from deck activities such as cleaning/wash-down of equipment/decks.

Cooling Water and Brine

No brine water is produced on the facility as potable water is supplied from onshore. Additionally, no seawater cooling is undertaken on the facility.

Potable water, primarily for accommodation and associated domestic areas, may be generated on the MODU, ASV, installation and support vessels using a reverse osmosis (RO) plant. This process will produce brine, which is diluted and discharged at the sea surface.

During the distillation process, relatively small volumes of reject brine is produced and discharged. Reject brine discharge is typically 20 to 50 percent higher in salinity than the intake seawater (depending on the desalination process used) and may contain low concentrations of scale inhibitors and biocides, which are used to avoid fouling of pipework (Woodside, 2014).

Models developed by the US EPA (Frick et al., 2001) for temporary brine discharges from vessels assuming no ocean current (i.e., 0 m/s) found that brine discharges from the surface dilute 40–fold at 4 m from the source. This modelling can be used as an indicator for predicting horizontal attenuation and diffusion of reject brine; and suggests that the salinity concentration drops below environmental impact thresholds within 4 m of the discharge point.

Seawater is pumped on board and used as a heat exchange medium for the cooling of machinery engines and high temperature drilling fluid on the MODU. Seawater is drawn up from the ocean, where it is subsequently de-oxygenated and sterilised by electrolysis (by release of chlorine from the salt solution) and then circulated as coolant for various equipment through the heat exchangers (in the process transferring heat from the machinery), prior to discharge to the ocean. It is subsequently discharged from the MODU to the sea surface at potentially a higher temperature. Cooling water is often treated with additives including scale inhibitors and biocide to avoid fouling of pipework. Scale inhibitors and biocide are usually used at low dosages, and are usually consumed in the inhibition process, so there is little or no residual chemical concentration remaining upon discharge. In addition, the scale inhibitors and brine are selected and assessed using the Woodside chemical selection process.

Alternatively, MODUs may utilise closed-loop cooling systems. In these systems, fresh water is used in a closed circuit to cool down the engine room machinery, and then further cooled by sea water in a seawater cooler. Seawater used for cooling purposes would be routinely discharged at a temperature expected to be less than 70°C and rates ~50 m^3/d.

Impact Assessment

Sewage, Putrescible Waste and Grey Water

The environmental impact associated with ocean disposal of sewage, grey water and putrescible waste is eutrophication. Eutrophication occurs when the addition of nutrients, such as nitrates and phosphates, causes adverse changes to the ecosystem, such as oxygen depletion and phytoplankton blooms. Other contaminants of concern occurring in these discharges may include ammonia, E. coli, faecal coliform, volatile and semi-volatile organic compounds, phenol, hydrogen sulphide, metals, surfactants and phthalates.

No significant impacts from planned (routine and non-routine) discharges to the marine environment are anticipated, given the minor volumes involved, the localised mixing zone (as indicated by dilution modelling at the facility and high level of dilution into the open water marine environment of the PAA. This is supported by historical water quality and sewage discharge monitoring undertaken by Woodside around the nearby Goodwyn Alpha platform. The Goodwyn Alpha platform is approximately 72 km northeast of the PAA; therefore, conditions are comparable. Water quality monitoring around the Goodwyn Alpha platform (which is a crewed platform) indicates there was no detectable decrease in oxygen saturation, nutrients or increase in oxygen demand at the Goodwyn Alpha platform (BMT Oceanica, 2015a). In addition, monitoring of sewage discharges demonstrated that a 10 m^3 sewage discharge reduces to approximately 1% of its original concentration within 50 m of the discharge location (Woodside, 2008).

The tieback is expected to take up to 12 weeks including mobilisation, demobilisation and contingency with subsea installation and pre-commissioning. MODU and installation and support vessel routine discharges are expected to be intermittent in nature for the duration of the tie-back activity. Therefore, impacts to water quality within the PAA are expected to be localised with no lasting effect due to the small mass, relative to daily turnover, the assimilative capacity of the receiving environment, intermittent nature of discharges, and the variable discharge location due to project vessel movement.

Although the NWS Province is characterised as a low nutrient environment (DEWHA, 2008), studies of adjacent shelf water have found the area to be “a highly productive ecosystem in which nutrients and organic matter are rapidly recycled” (Furnas and Mitchell, 1999). The estimated daily loading from sewage and putrescible waste (Facility ~1.8 m^3 per day; MODU/project vessels ~15 m^3 per day) is not significant in comparison to the daily turnover of nutrients in the area. Furthermore, installation and support vessels are typically moving when in the PAA, which facilitates mixing of sewage, putrescible wastes and grey water when discharged.

The impact of nutrients associated with discharge of sewage, grey-water and putrescible waste is considered to have a localised impact with no lasting effect due to the small mass, relative to daily turnover, and the assimilative capacity of the receiving environment.

Drain and Bilge Water

Drain water from the facility and bilge and deck drainage water from the MODU and installation and support vessels are expected to mix rapidly in the marine environment upon discharge. Deck drainage and treated bilge may contain a range of chemicals, oil, grease and solid material. This particulate matter can cause an increase in the turbidity of the receiving waters close to the point of discharge. The addition of these substances into the marine environment will result in a change ambient water quality; however, these discharges will disperse and dilute rapidly, with concentrations significantly dropping with distance from the discharge point. The PAA is located more than 12 nm from land exceeding the exclusion zones required by Marine Order 96 (Marine pollution prevention – sewage) 2018 and Marine Order 95 (Marine pollution prevention – garbage) 2013.

No significant impacts from the planned routine discharges are anticipated, because of the minor quantities involved, the expected localised mixing zone and high level of dilution into the open water marine environment of the PAA. Based on the detailed evaluation and low levels of potential contaminants, the magnitude of potential impact of a change in water quality is considered highly localised with no lasting effects.

Cooling Water and Brine

The key physicochemical stressors that are associated with reject brine and cooling water discharge from MODU and project vessels include salinity, pH, temperature and chemical toxicity.

The potential impacts on water quality due to cooling water discharge include chlorine toxicity and increased water temperatures. Woodside undertook modelling of continuous wastewater discharges (including cooling water) for its Torosa South-1 drilling program in the Scott Reef complex (Woodside, 2014). This study predicted that discharge water temperature decreases quickly as it mixes with the receiving waters, with the discharge water temperature being <1°C above ambient within 100 m (horizontally) of the discharge point, and 10 m vertically (Woodside, 2014). As such, any potential impacts to water quality are expected to occur within approximately 100 m of the source of the discharge, where concentrations are highest.

Reject brine will sink through the water column, owing to the 20% to 50% increase in salinity (Frick et al., 2001), where it will be rapidly mixed with receiving waters and dispersed by ocean currents, decreasing in salinity rapidly as distance from source increases.

The scale inhibitors used in the prevention of fouling within cooling systems are typically low in molecular weight and phosphorous compounds that are water-soluble and only have acute toxicity to marine organisms approximately two orders of magnitude higher than typically used in the water phase (Black et al., 1994). The biocides typically used in the industry are highly reactive and degrade rapidly (Black et al., 1994).

Based on the detailed risk evaluation, the magnitude of the potential impact of a change in water quality from routine and non-routine brine and cooling water discharges is assessed as having no lasting effect on the receiving environment.

Cumulative Impacts

Given the activities that may be conducted during the Petroleum Activities Program, there is the potential for cumulative impacts from routine discharges of sewage, putrescible waste, grey water, PW, bilge water or drain water, due to:

- periodic, repeated discharges at the same location (riser platform) over the course of the PAP
- cumulative discharges from differing point sources (riser platform and various vessels, e.g. ASV, MODU, installation vessels).

Because of the nature of these routine discharges, normal operations are unmanned (and therefore no discharges), the localised spatial extent of impacts and the well mixed receiving environment, the cumulative impacts from these discharges are not considered to result in impacts more than slight short-term impact (i.e., Environment Impact – E). Given the highly localised nature of the impacts of routine discharges, no cumulative impacts are expected from similar discharges from other production facilities (e.g., Wheatstone), Xena-03 drilling and tieback activities, or support vessels.

		from food wastes, and limits topsides maintainable equipment in line with NNC philosophy.		disposal pathway not installed.
Professional Judgement – Substitute				
None identified.				
Professional Judgement – Engineered Solution				
Treating or macerating sewage from Pluto facility prior to overboard discharge.	F: Yes. CS: Significant. Installation of a sewage treatment system onboard the facility would require design, procurement and installation costs.	Little reduction in impacts due to eutrophication as the facility is NNC and therefore, sewage discharges are low volume and intermittent.	Sewage discharge is inherently controlled (substituted) for the riser platform by pursuing a NNC design philosophy and maintaining this position through efficient operation and maintenance practices. Installation would require considerable retrofit costs and topsides piping modifications. This would Increase maintenance load not in line with key safety principles required for the NNC facility. Installation of maintainable items for limited benefit inherently increases manning durations and associated sewage discharges. Compared to caisson discharge at depth, further treatment via treatment system/ maceration would deliver only a negligible reduction in environmental impact, with the sacrifice considered to be grossly disproportionate to the environmental benefit.	No
Facility open hazardous and diesel drain system integrity maintained to contain potential spilled liquid hydrocarbon in areas as appropriate to safe integrated facility design.	F: Yes. CS: Minimal cost. Standard practice.	The open hazardous drain and diesel drain systems are maintained to support appropriate disposal of environmentally hazardous liquids.	Benefits outweigh cost/sacrifice.	Yes C 6.3

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)[65]***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
ALARP Statement: On the basis of the environmental impact assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts of discharge of sewage, putrescible waste, grey water, bilge water, drain water, cooling water and brine from the Pluto Offshore facility, MODU, ASV, installation and support vessels. As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.				
Demonstration of Acceptability				
Acceptability Statement: The impact assessment has determined that, given the adopted controls, routine and non-routine discharges of sewage, putrescible waste, grey water, bilge water, drain water, cooling water and brine from the Pluto Offshore facility, MODU, ASV, installation and support vessels are not expected to result in potential impacts greater than localised contamination not significantly above background levels outside a localised mixing zone. Further opportunities to reduce the impacts have been investigated above. The adopted controls are considered good oil-field practice/industry best practice and meet legislative requirements under Marine Orders 91, 95 and 96. The potential impacts and risks are considered broadly acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the impacts and risks of these discharges to a level that is broadly acceptable and demonstrate the EPOs are met.

Description of Source of Impact

Produced water (PW) is condensed water (water vapour within gas/condensate that condenses when brought to the surface) or formation water (derived from a water reservoir below the hydrocarbon formation) or a combination of both.

Separation of produced water from reservoir fluids is not 100%-effective and therefore, PW often contains small amounts of naturally occurring contaminants including dispersed oil, dissolved organic compounds (aliphatic and aromatic hydrocarbons, organic acids and phenols), inorganic compounds (e.g., soluble inorganic chemicals or dissolved metals) and residual process chemicals (including MEG or methanol on a non-routine basis) as well as production chemicals such as water clarifier, demulsifier, and corrosion inhibitor. Non-routine PW discharge operations are required during intermittent activities such as production restarts and water cut well restarts.

A description of the PW system and expected operating scenarios has been provided in Section 3.5. Intermittent PW discharge operations occurred at low flow rates (scenario 2) during 2024, with commissioning primarily occurring through April and May. During 2024, there were 204 days with PW discharge occurring, averaging 87 m^3/day with 95% of daily totals less than 207 m^3/day. A total of 11 days through the year saw discharges between 200 m^3/d and maximum recorded of 500 m^3/d which were mostly associated with non-routine commissioning and optimisation activities. The overall flow-weighted average OIW concentration performance through the year achieved 25.6 mg/L.

As wells cut water volumes of PW are expected to increase. It is difficult to anticipate with high confidence when wells will begin to cut water from each reservoir or how much water will be produced however the estimated profile is shown below in Figure 6-1. The graph shows the 10% predicted low PW rates (blue), the predicted 50% PW rates (orange) and the 90% high WP rates (grey) illustrating the range expected.

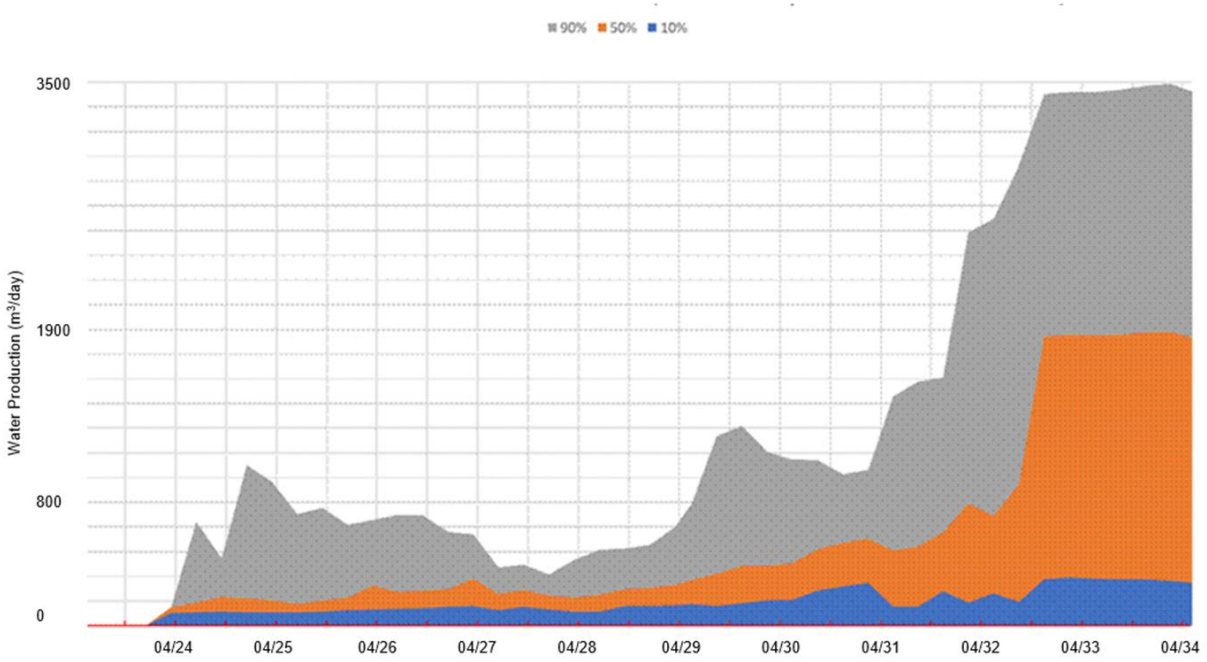

Figure 6-1: Predicted probabilistic PW profile.

Monitoring and Management Framework

Overview

This section describes the monitoring and management framework which Woodside has developed to support the monitoring of PW discharges from offshore assets. The monitoring and management framework comprises of:

- baseline monitoring (prior to discharge)
- operational monitoring of OIW
- initial monitoring following commissioning (in progress)
- routine monitoring.

Further details are provided in Section 7.2.3 which describes Woodside's Offshore Marine Discharge Adaptive Management Plan (OMDAMP). The monitoring and management of produced water will be implemented in accordance with the OMDAMP which details guidelines (ANZG 2018) for water and sediment quality monitoring including chemical assessments (metals, BTEX, PAH, phenols, organic acids, TPH and TRH), and ecotoxicity testing.

Operational Monitoring

Oil in Water

OIW monitoring during routine operations is undertaken via an online analyser prior to discharge. Online analyser information is sent via transmitter instantaneously and reported to the control system and is also captured within the process historian database (PHD). The control system facilitates visibility in the Central Control Room (either from local central control room at PLP or remote central control room in Perth), for manual or automated process control changes to be made, and/or annunciate alarms (e.g., high oil-in-water specification). PHD information is available onshore for analysis and trending. During each planned intervention visit, on an approximately five-weekly basis or up to ten campaigns per year, operators manually sample PW and undertake manual analyser QC checks either at the onshore lab or on the facility.

Any discrepancies that are identified between instrument readings outside of expected tolerance or known causes are investigated to determine the cause. As discussed in the Section 3.5.5.2, two analysers have been installed on the facility. If an analyser is faulty or breaks down, any anomalies that are identified are investigated to determine the cause and may be addressed by corrective maintenance during the next intervention visit.

Oil in water verification

At low flow rates (< 800 m^3/day), the online analysers are unable to be calibrated to the full range of operation due to fluctuations in flow rate and equipment turn down (minimum flow velocity) limitations. During this initial stage, overboard discharge is limited to small volumes of condensed water (~100 m^3/day) which has low concentrations of

OIW, and intermittent intervals of higher flow produced formation water (up to 800 m^3/day) from well trials, process optimisation and early well watering events. These intervals of short-term higher flow produced formation water introduce higher OIW concentrations which require active OIW management (e.g. recalibration of online analysers, manual sampling) to accurately determine OIW concentrations if significant fluctuations in flow rate and process performance occur.

During the initial monitoring, a suite of sampling and testing (chemical characterisation, whole effluent testing (WET testing), settling velocity and particle size distribution) was collected to verify overboard discharge stream characteristics are within anticipated composition used for impact assessment. This verification will continue to inform management and monitoring activities as part of the initial produced water characterisation (see initial monitoring – produced water).

Loss of Signal Management

If there is a loss of signal from both OIW analysers, operators attempt to troubleshoot remotely and monitor process stability for changes. If analysers cannot be restored and there are no observable changes to a stable operating process, low water cut, and high confidence of compliance with OIW standards, the next intervention visit will include reinstatement of the analyser operation if the next planned intervention is within seven days. If the next planned intervention is greater than seven days away, a 'reactive intervention' visit takes place to repair the analysers. Similarly, if analysers cannot be restored and there are no observable changes to a stable operating process, low water cut, and high confidence of compliance with OIW standards the reactive intervention visit will be performed within seven days.

If there is a lack of certainty around results risking OIW measurements exceeding criteria for more than 12 consecutive hours, and a risk of OIW exceedance (24-hour rolling average) is anticipated, the asset may undertake a 'reactive intervention visit' via helicopter to verify results. A react visit if required is deployed to the platform within 48 hours, if weather and time-of-day allow. A Standard Operating Procedure for loss of signal is in place, with decision criteria to allow clear interpretation and facilitation of compliance with OIW standards.

High OIW Management

If the analyser is online and the OIW measurement exceeds criteria for more than 12 consecutive hours, an Operational Risk Assessment will be performed to determine if the high OIW could have occurred as a result of faulty equipment. If the risk of OIW exceedance (24-hour rolling average) is anticipated, the asset may undertake a 'reactive intervention visit' via helicopter to verify results, manually intervene to manage discharge operations, and support through additional manual sampling. The asset will manage discharges to prevent impacts beyond the mixing zone boundary through well management and monitoring of process stability in conjunction with OIW analysers and sampling.

Baseline Monitoring – Water and Sediments

As per EPBC Act condition requirements for the Pluto Gas condensate field (EPBC 2006/2968, condition 1(c) ii), Woodside completed a pre-discharge monitoring program in 2021 which included water, sediment, biological and physical monitoring. The assessment determined that pre-discharge of PW conditions (sediment and water quality) met the ANZG (2018) default guideline values (DGV) and that benthic habitats present were typical of the Northwest Shelf in similar depths (BMT, 2022). The only exception to meeting the ANZG DGVs was copper (0.33 µg/L) in waters which exceeded the 99% DGV (0.3 µg/L) at sites both inside the mixing zone and reference sites. It was also noted that zinc in receiving waters had concentrations (5.75 µg/L) measured approaching the ANZG 99% DGV (previously 7 µg/L recently revised to 3.3 µg/L) at sites both inside the mixing zone and reference sites (BMT, 2022).

Initial Monitoring

Post commissioning initial samples of PW are being collected to characterise the discharge stream and potential effluent toxicity (first sample event completed August 2024). The first sample included settling velocity and particle size distribution, chemical characterisation and WET testing. A further three chemical characterisation and single species toxicity testing events are scheduled to develop a comprehensive understanding of the discharge stream characteristics during discharge. Only one event has been completed to date due to the facility not discharging.

PW samples should represent normal operations, so sampling should only be undertaken during periods of normal production for the facility. Sampling should, as far as reasonably practicable, provide a representative sample. Representative samples are taken at a time when as many formation water-producing wells are online as reasonably practicable with a consideration of chemicals that may be present in the discharge stream.

Initial monitoring includes the following:

- Chemical characterisation to identify if toxicants with the potential to bioaccumulate exceed the ANZG recommended DGV at end of pipe. If toxicants with the potential to bioaccumulate are predicted to exceed DGV's at end of pipe, further investigations are required as described in the Offshore Marine Discharges Management Plan (OMDAMP).
- Chemical characterisation of the PW identify toxicants with the potential to drive changes in WET results.
- WET testing to verify 99% species protection safe dilutions (as per SSD (species sensitivity distribution)) for comparison with the approved mixing zone dilutions.

- Sedimentation and particle size distribution analysis to ascertain the potential for contaminants to flocculate or precipitate and settle out of solution and impact sediment quality. If an exceedance in water quality occurs, the results of these studies will inform if non routine sediment sampling is required.

Results from the August 2024 sample are described in the “Impact Assessment” section below.

Routine Monitoring

Produced water is monitored and managed in accordance with the OMDAMP (see Section 7.2.3). The OMDAMP details routine monitoring assessment against guideline values (ANZG 2018), analytical methods and management actions if a guideline value is exceeded. The trigger values are applied through a risk-based approach that is intended to capture uncertainty around the level of impact by staging monitoring and management responses according to the degree of risk of environmental impact. This approach provides a level of confidence that management responses are not triggered too early (i.e. when there is no actual impact) or too late after significant or irreversible damage to the surrounding ecosystem (EPA 2016). Changes in discharge contaminants and PW toxicity can be detected early and can indicate the potential for an impact prior to an impact occurring allowing for timely management. WET testing confirms if there is a potential for impact on biota. Chemical characterisation is undertaken to understand toxicants that may be driving toxicity in the WET test and used as an indicator to assess whether the discharge has changed significantly from the last WET test.

WET tests are undertaken on a broad range of taxa of ecological relevance. A minimum of eight toxicity tests are carried out with each PW sample during WET testing. Specific toxicity tests are listed in the OMDAMP which include a range of mainly tropical, Australian marine species and are selected based on their ecological relevance, known sensitivity to contaminants, availability of robust test protocols and known reproducibility and sensitivity as test species for assessing PW in marine environments. Tests can be exchanged over time if tests are not available, or become obsolete, however, preference would be for tests that mimic the receiving environment as closely as possible (i.e. for most facilities this would be tropical, marine water tests) (Warne et al. 2018). The dilutions required to protect 99% and 95% of species is calculated using the ANZG (2018) statistical distribution methodology on the results of direct toxicity assessment using sub-lethal chronic endpoints. The protection of 99% of species maintains a high level of ecological and conservation value at the boundary of the approved mixing zone and is considered appropriate to account for the uncertainty in composition and proximity to the Montebello Marine Park Multiple User Zone. The approved mixing zone boundary is defined below.

Given the proximity of the discharge point to the Montebello Marine Park Multiple Use Zone (~420 m south from the facility) the PW mixing zone has potential to extend into the Montebello Marine Park Multiple Use Zone. The approved mixing zone boundary has been defined to achieve 99% species protection safe dilutions at the boundary of the MUZ.

Table 6-16 Trigger values and frequency of routine monitoring

Routine Monitoring	Trigger Value	Frequency
Chemical characterisation: End of pipe sample – physio chemical and toxicants	Results that are predicted to be higher than the 99% DGV at boundary of the approved mixing zone and are above the results from the earlier toxicity year[1] or above the toxicity year when no guideline was available.	Annual
	Results that are predicted to be higher than the 99% DGV at the AMP boundary (416 m) and are above the results from the earlier toxicity year[2] or above the toxicity year when no guideline was available.	Annual
WET testing	The 99% species protection safe dilutions derived from earlier toxicity year are not predicted to be achieved at boundary of the approved mixing zone.	Three yearly (calendar year), Conducted in parallel with annual chemical characterisation
	The 99% species protection safe dilutions derived from earlier toxicity year[2] are not predicted to be achieved at the AMP boundary.	
Review of continuous operational monitoring results	Increases in the average monthly OIW concentration by 5 mg/L total over six consecutive months or by 10 mg/L total over two consecutive months.	Monthly

Discharge volume	Monthly mean discharge volume (m³/day) is equal to or less than modelled flow rates used to define approved mixing zone based on earlier toxicity year[1].	Monthly
	Monthly mean discharge volume (m³/day) is equal to or less than modelled flow rates used to confirm 99% species protection based on earlier toxicity year[2] can be met at the AMP boundary.	Monthly

Note: 1 earlier toxicity year means the GWA design WET test (2,000 dilutions).

2 earlier toxicity year means the year in which the most recent WET test occurred.

Results of chemical characterisation and WET testing are compared against OMDAMP trigger values Table 6-16). Exceedances of trigger values require further investigation, including multiple lines of evidence. If further investigations confirm the trigger value has been exceeded, a review of single species testing is conducted[66], plus additional WET testing if required. Monitoring is conducted in accordance with the OMDAMP and where appropriate routine monitoring triggers, methodologies and standards applied (e.g. requirements for WET testing) to ensure consistency and comparability of data.

Approved mixing zone

The mixing zone extends 1300 m from the facility, except to the south, where it only extends to the Montebello marine park multiple user zone boundary (416 m from the facility)., How this mixing zone is derived is described under 'Potential Impacts to Biological Indicators' below.

Impact Assessment

Potential impacts of PW discharge include:

- changes to water quality
- toxicity to biota
- changes to sediment quality.

The maximum discharge rate is 3,500 m³/day. Since commencement of discharge PW discharge rates varied fluctuating typically between 20 m³/day – 200 m³/day significantly less than the maximum rate. As the total volume of PW is expected to increase as the fields age, the environmental impacts have been assessed against maximum discharge rates and the expected 50% probabilistic discharge of 1,900 m³/day (Figure 6-2).

Potential Impacts to Water Quality

Potential impacts to water quality are to be assessed through chemical characterisation of the end of pipe discharge. Variability in the chemical composition is managed via the Monitoring and Management Framework and the OMDAMP (Section 7.2.3).

Chemical Characterisation of PW (Physio-chemical Parameters and Toxicants in Water)

Initial monitoring of undiluted PW collected end of pipe commenced in August 2024, post commissioning, during an overboard discharge flowrate of 168 m³/day. Chemical characterisation, WET testing settling velocity and particle size distribution were undertaken. Samples were analysed for key physio-chemical parameters and toxicants. In most cases results are below the limit of reporting and ANZG DGVs as presented in Table 6-17.

Table 6-17: Pluto initial monitoring chemical characterisation - Metals.

Metal and Metalloid (mg/L)	ANZG 99% DGV [a]	ANZG 95% DGV	Initial monitoring (August 2024) end of pipe)

a 99% species protection DGV (ANZG 2018) ranking of reliability is shown in parenthesis.

b No DGV or low reliability DGV only available.

c ANZG recommends 99% DGV for application for slightly to moderately disturbed ecosystems (to protect key species from chronic toxicity or due to bioaccumulating nature).

The composition of PW may also consist of phenols and hydrocarbon components such as volatile aromatic compounds (benzene, toluene, ethylbenzene, xylenes (BTEX)) and polycyclic aromatic hydrocarbons (PAHs). The initial chemical characterisation of the PW discharge stream at the end of pipe found concentrations of PAHs below the 95% DGVs, BTEX concentrations required <10 dilutions to achieve PNEC and phenols only required 5 dilutions to achieve PNEC.

PW may include low levels of naturally occurring radionuclides (NORMs). In particular, uranium 238 and thorium 232 decay chains and the longer-lived radionuclides lead 210, polonium 210, radium 226 (Ra-226) and radium 228 (Ra-228) (Coleman and West, 2000). These radionuclides can occur in produced water either in solution or as fine mineral suspended solids (OSPAR Commission, 2009).

Valeur and Petersen (2013) assessed the ecological hazard related to NORMs in PW discharged to the marine environment. They concluded that NORMs have a strong affinity for particulate matter and discharged NORMs would be adsorbed onto fine grained sediments and particulate matter relatively soon after introduction to the marine environment. In high energy environments, NORMs associated particles would settle and resuspend numerous times until they eventually settle in low energy environments in deep parts of the sea that serve as accumulation areas for fine grained sediments. Over time these particles would be buried beneath the benthic mixing layer of the seabed where they will become isolated from the biosphere and are unlikely to exceed background levels.

The average concentration of radioactivity (mainly K-40) in surface waters is 13.6 Bq/kg water (Walker and Rose 1990). Currently there are no ANZG (2018) guidelines or international guidance for concentrations of radionuclides in marine water. In the event that meter readings indicate an increased risk of NORMs as reported in the NORMs facility register on the facility, the treated PW will be tested for NORMs (Ra-226 and 228).

Residual Process Chemicals

Residual process chemicals may be present in the PW stream. Process chemicals are subject to Woodside's chemical selection and approval process. The largest chemical by volume is MEG. MEG is rated OCNS Group E (lowest hazard) and is considered PLONOR. Corrosion inhibitor required for the operation of the PW module and subsea system is assessed as having a CHARM assessment calculation rating of Gold. Chemicals will decrease the water quality in the immediate area of the release (i.e. surface waters at the release location); however, the consequence is expected to be temporary and localised due to dilution in the open ocean mixing environment, distance from sensitive receptors and relatively low discharge volumes.

Impact

Potential impacts to water quality are expected to be localised to the immediate vicinity of the platform and a small area of the AMP if maximum discharge rates (3,500 m^3/day) were to be realised (Figure 6-2). Potential impacts to water quality are limited to the immediate vicinity of the platform at expected probabilistic discharge rates (1,900 m^3/day) (**Error! Reference source not found.**) with a Negligible (F) effect on water quality in both scenarios. .

Potential Impacts to Biological Indicators

Chemical characterisation and WET testing of the PW has been completed to establish actual toxicity and to verify the required dilutions are being achieved within the approved mixing zone.

WET Testing

Most treated PW has low to moderate toxicity (Neff et al., 2011), with actual toxicity of discharge dependant on the chemical constituents of the PW and any added process chemicals, the level of treatment and dilution with condensed water prior to release, and the dilution of the discharge as it mixes with seawater. Most hydrocarbons in PW are

considered non-specific narcotic toxins with additive toxicities; therefore, the toxicity of a PW will, in part, depend on the total concentration and range of bioavailable hydrocarbons (Neff, 2002).

WET testing is undertaken to allow for interactions between toxicants and consider toxicants that cannot readily be measured or are not known to be present in the sample. For the WET testing a range of tropical and temperate Australian marine species are selected based on their ecological relevance, known sensitivity to contaminants, availability of robust test protocols, and known reproducibility and sensitivity as test species (ANZG, 2018).

Woodside has extensive operational experience with PW characterisation from gas condensate facilities on the North West Shelf of Western Australia. During design of the PW handling module, the then available suite of Woodside PW WET testing results guided the conservative selection of the GWA species protection safe dilutions as 1:2000 – which is the basis for Pluto QSRA studies and informing the approved mixing zone (2019 Environment Plan). Actual 99% and 95% species protection safe dilutions have been provided from initial monitoring WET testing as shown in Table 6-18.

Recent WET testing data collected in 2022 and 2023 from existing operating facilities (Table 6-18) was reviewed, to verify a reasonable level of conservatism is included in the impact assessment to ensure 99% species protection safe dilutions will be met at the approved mixing zone boundary and at the Montebello Marine Park multiple user zone boundary. Results from Pluto's first WET testing sampling in August 2024 verify the assumptions made during the impact assessment that sufficient dilutions are being achieved prior to the approved mixing zone boundary for 3,500 m^3/day. Suitable dilutions are not achieved at the AMP boundary for maximum discharge rates of 3, 500 m^3/day but are met at the expected discharge flow rate of 1,900 m^3/day.

Table 6-18: Actual 99% and 95% species protection level safe dilutions at Woodside's current PW discharging facilities

Facility	Year	99% Safe Dilutions	95% Safe Dilutions
Pluto A	2024	1:1,112	1:260
Angel	2022	1:417	1:278
Goodwyn Alpha	2023	1:1,388	1:205
North Rankin	2020	1:1,428	1:435
Okha FPSO	2023	1:157	1:110

Determination of Approved Mixing Zone

The principal aim of the modelling was to quantify the likely extents of the near-field and far-field mixing zones and therefore the potential impact of the PW to the marine environment. Three modelling methods were integrated to simulate the potential dispersion, an oceanic hydrodynamic model (HDROMAP) for current data, a near-field discharge model (PDS surface discharge model), and a far-field advection and dispersion model (MUDMAP) (APASA, 2017). The dispersion of contaminants will depend, initially, on the geometry and hydrodynamics of the discharge itself, where the induced momentum and buoyancy effects dominate over background processes. This region is generally referred to as the near-field zone and is characterised by variations over short time and space scales. As the discharge mixes with the ambient waters, the momentum and buoyancy signatures are eroded, and the background, or ambient, processes become dominant.

The far-field modelling expands on the near-field work by allowing the time-varying nature of currents to be included, and the potential for recirculation of the plume back to the discharge location to be assessed. The near-field simulations consider steady-state unidirectional currents, while the far-field simulations account for currents that vary in speed and direction over time and space, far field modelling represents minimum dilutions achieved 95% of the time. Validation of the current data used for the modelling was performed using infield current measurements located approximately 30 km to the southwest of the Pluto riser platform location, two-point current measurements nearest to the surface, at depths of approximately 10 m and 70 m were used to evaluate the modelled current data. The outcome of the comparison was good agreement at all current speeds, and the modelled data product was suitable for PW discharge modelling. Validation of tidal predictions was performed using the model output and independent predictions of tides. All comparisons demonstrated that the model produces a very good match to the known tidal behaviour for a wide range of tidal amplitudes and clearly represents the varying diurnal and semi-diurnal nature of the tidal signal.

The dilution modelling results are based on the maximum design flow rates of 3500 m^3/day representing the worst-case load to the environment. At lower actual discharge rates, dilutions levels are predicted to be achieved far closer to the discharge point than those predicted by the design-case modelling due to reduced loading to the environment.

Once initial monitoring of the discharge has been completed, the mixing zone boundary will be assessed to ensure it is adequately conservative. Once sufficient PW flows are achieved, the assessment of the mixing zone boundary will

be completed by a field survey to collect in-situ plume measurements and analysis of plume dilutions and mixing characteristics (including water quality monitoring at the approved mixing boundary).

Near Field

Modelling indicated that, irrespective of the season, given the elevation of the discharge above the water surface, the plume will initially plunge downward into the water column creating a turbulent mixing zone. Once the initial jet momentum ceased, the plume would remain sufficiently buoyant to rise to the surface to continue to mix with ambient waters, though at a slower rate. As a result of the mixing during the initial plunge and buoyant rise, the salinity and temperature of the discharge plume are predicted to reach background level over a short distance.

During low current speeds, the discharge will plunge the deepest (~11.5 m below sea level) and resurface close to the riser platform. Under medium and high current, the plunge depth becomes progressively shallower (approximately 7.5 and 5.5 m below sea level, respectively) due to the increasing deflection of the plume as it enters the water. Under all current conditions, the plume is predicted to resurface and remain in the upper layer of the water column (5 to 10 m).

Far Field

The far field modelling for all simulations indicated that the discharge plume would drift horizontally with the currents prevailing in the near surface layer while undergoing vertical and horizontal dispersion. Variable and patchy concentrations were predicted within the plume, attributed to large variation in current flows past the discharge point. The annual dilutions are provided below in Figure 6-2.

Generally, the overall plume footprints were observed to vary between season, with a noticeable north to north-westerly drift during the summer months and a south to south-westerly drift during the winter months. In the transitional months, more variation in the transport patterns was evident.

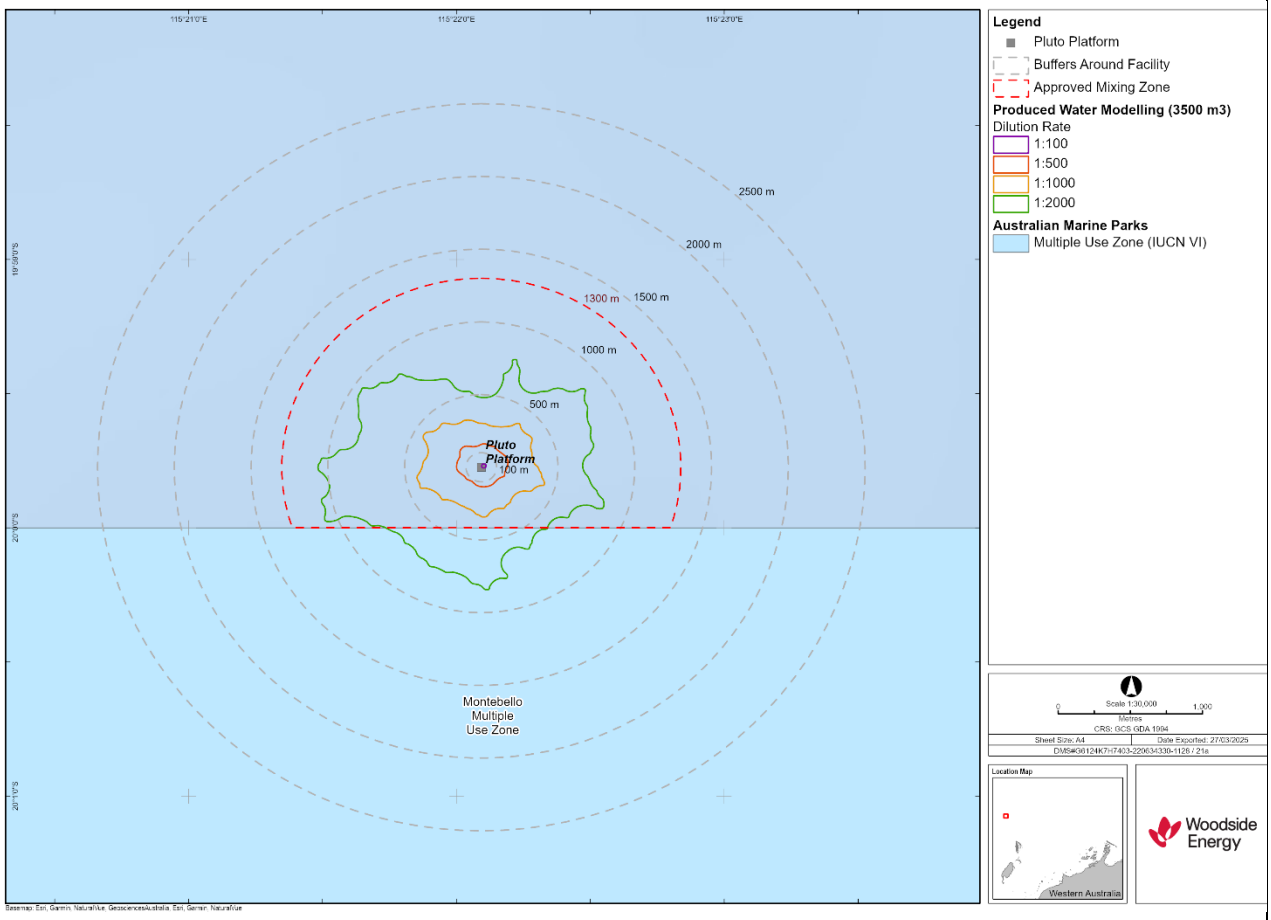

Figure 6-2: Annual dilution contours for a 3,500 m³/day discharge from the Pluto riser platform

Modelling shows 99% species protection safe dilutions used for design (2,000 dilutions) can be achieved at maximum discharge rates (3,500 m^3/day) in all conditions at 1,300 m. However, 99% species protection safe dilutions (both 2,000 dilutions used for design and actual Pluto 2024 WET value of 1,112) cannot be achieved at the AMP boundary.

Additional modelling was undertaken for a lower discharge rate of 1,900 m^3/day (RPS, 2023). Modelling indicated that, irrespective of season, the plume will plunge deepest (~12.8 m) and resurface close to the platform during low current speeds, Under medium and high currents, the plunge depth becomes progressively shallower (~6.9 m and ~4.2 m, respectively) due to the increasing deflection of the plume as it enters the water. Under all current conditions, the

plume is predicted to resurface and remain in the upper layer of the water column (5-10 m). The overall plume footprints were observed to vary between months, with a noticeable easterly and westerly drift during the summer months and a south to south-westerly drift during the winter months. In the transitional months, more variation in the transport patterns was evident. The annual dilutions are provided below in **Error! Reference source not found.**.

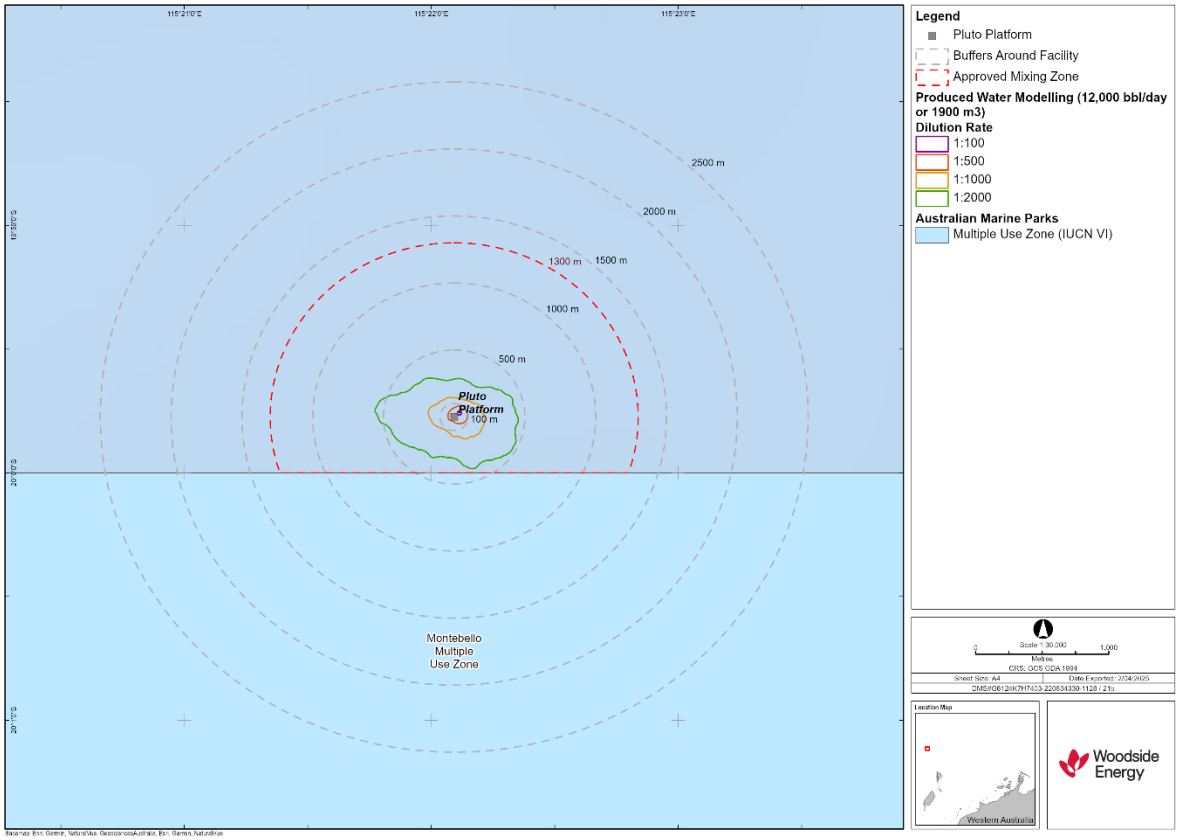

Figure 6-3: Annual dilution contours for 1,900 m^3/day discharge from the Pluto riser platform.

Modelling of a 1,900 m^3/day discharge indicates while the design 99% species protection safe dilutions (2000) cannot be met at the AMP boundary if GWA PW toxicity was encountered, requiring species protection level safe dilutions as 1:2000. The actual Pluto 2024 WET value of 1,112 dilutions achieves 99% species protection levels by 300 m in all conditions.

Bioaccumulation

Bioaccumulation refers to the amount of a substance taken up by an organism through all routes of exposure (water, diet, inhalation, epidermal). The Bioaccumulation Factor is the ratio of the steady-state tissue concentration and the steady-state environmental concentration (assuming uptake is from food and water). The test developed to measure the ability of a substance to bioaccumulate, namely, the octanol-water partition (P_{ow}), is based on the preferential partitioning of lipophilic organic compounds into the octanol phase. Partitioning into octanol can be correlated with the attraction for such compounds to the fatty tissue (lipid) of organisms.

Initial monitoring of BTEX in PW discharged from the facility was 3.2 mg/L (Worley 2025). Bioaccumulation of BTEX compounds has been observed to occur in the laboratory, only at concentrations far in excess of that discharged from facilities on the NWS (for example refer to Berry, 1980); hence it is unlikely that BTEX would bioaccumulate at the exposure concentrations that may be experienced by biota around the Pluto facility.

In contrast to BTEX compounds, PAH compounds have high P_{ow} values indicative of the potential for bioaccumulation (Vik et al., 1996). Neff and Sauer (1996) compiled available literature for laboratory and field studies investigating the bioaccumulation of PAHs. The bioaccumulation values for PAHs in marine organisms collected near PW discharges in the Gulf of Mexico reported by Neff and Saur (1996) indicate that the highest bioaccumulation factor was in the tissues of bivalve molluscs and the lowest in the muscle tissue of fish.

The most comprehensive field study assessing bioaccumulation of hydrocarbons and metals from PW discharged into offshore waters is that by Neff et al. (2011). At the request of the United States Environmental Protection Agency (USEPA), the Gulf of Mexico Offshore Operators Committee sponsored a study of bioconcentration of selected PW chemicals by marine invertebrates and fish around several offshore production facilities discharging more than 731 m^3 per day of PW to outer continental shelf waters of the western Gulf of Mexico (by comparison Pluto discharges will be up to 3500 m^3/day). The target chemicals identified by USEPA included five metals (As, Cd, Hg, 226^{Ra} and 228^{Ra}),

three volatile monocyclic aromatic hydrocarbons (MAH) – benzene, toluene and ethylbenzene – and four semi-volatile organic chemicals – phenol, fluorene, benzo(a)pyrene and di (2 ethylhexyl) phthalate. Additional MAH (m-, p-, and o-xylenes) and a full suite of 40 parent and alkyl PAH and dibenzothiophenes were also analysed by Neff et al. (2011) in PW, ambient water, and tissues at some platforms.

Concentrations of MAH, PAH and phenol as determined by Neff et al. were orders of magnitude higher in PW than in ambient seawater. There was no evidence of MAH or phenol being bioconcentrated. All MAH and phenol were either not detected (>95% of tissue samples) or were present at trace concentrations in all invertebrate and fish tissue samples. Concentrations of several petrogenic PAHs, including alkyl naphthalene's and alkyl dibenzothiophenes, were slightly, but significantly, higher in some bivalve molluscs, but not fish, from discharging than from non-discharging platforms. These PAH could have been derived from PW discharges or from tar balls or small fuel spills. Concentrations of individual and total PAH in mollusc, crab and fish tissues were well below concentrations that might be harmful to the marine animals or to humans who might collect them for food at offshore platforms (Neff et. al., 2011).

Mercury in the marine environment exists mainly as complexes of mercury (II) and as organomercurials (Hart 1982). Of particular concern is inorganic forms of mercury (of relatively low toxicity and availability to bioconcentrate) that may be converted by bacteria in situ into organomercury complexes (particularly methylmercury), which are more toxic and tend to bioaccumulate (Mason et at 2012). Neff et al (2011) attempted to measure bioaccumulation of four metals (arsenic, barium, cadmium, and mercury), by two species of bivalve molluscs from platform legs and five species of fish collected within 100 m of produced water discharging and non-discharging platforms in the Gulf of Mexico. The study found no difference in metal concentrations between impact and control sites. Potential impacts to biota from heavy metals would be localised to the immediate vicinity of the facility. Therefore, based on outcomes from studies (Neff et al 2011) and given the size of the mixing zone and the wide distribution of most species potential impacts would be limited to individuals and not impact on populations. It is expected that bioaccumulation is unlikely to result in increased levels of BTEX in biota surrounding the riser platform; however, there may be an elevation in PAH levels. Given the similarity of the chemical characterisation of PW discharges from Woodside facilities to those elsewhere in the world including those in the Gulf of Mexico (Rob Phillips Consulting, 2016), the results from Neff et al. (2011) can be used to infer the very low potential for adverse bioaccumulation effects to marine organisms, or to humans, if they were to consume any affected fish, molluscs or crabs found on upper near-surface legs of the facility.

The potential environmental impact associated with bioaccumulation of PW constituents in the water column is considered to be slight and a localised effect on a small number of non-threatened species in waters immediately surrounding the facility. The potential risk to fisheries is further reduced to ALARP as a result of negligible exposure given the PSZ that prohibits fishing from or near the platform. Given the nature of the PW discharge from the riser platform, the potential for bioaccumulation of PW contaminants (particularly BTEX) is considered to be minor and restricted to sessile organisms growing on the legs of the platform.

Marine Fauna

Given that PW will be managed to achieve 99% species protection safe dilutions at the AMP boundary and at the approved mixing zone boundary, potential for impacts to marine fauna are limited to a localised area in proximity to the facility. In addition, toxicants are expected to rapidly diluted and are not considered to cause acute toxicity. Therefore, impacts would be limited to fish communities associated with the facility exposed to water quality changes. While transiting cetaceans, whale sharks or turtles may pass through the plume they are not anticipated to spend long durations within the mixing zone and no impacts are expected.

Plankton

A change in water quality as a result of PW discharges has the potential to result in the injury or death of planktonic species within the water column through toxicity effects. Early life stages of fish (embryos, larvae) and other plankton would be the most susceptible organisms to exposure from hydrocarbons and chemicals in the discharges, as they are omnipresent and are therefore likely to be exposed to the plume. Impacts are predicted to be limited to within 1300 m of the platform and impacts are expected to be slight. These types of organisms are known to have high levels of natural mortality and a rapid replacement rate (UNEP, 1985). Plankton is generally abundant in the upper layers of the water column and is the basis of the marine food web, so localised impacts in any one location are unlikely to have long-lasting impacts on plankton populations at a regional level. Reproduction by survivors or migration from unaffected areas is likely to rapidly replenish losses (Volkman et al., 2004).

Impacts to Australian Marine Parks, KEFs and Biologically Important Areas

The facility is located y ~420 m from the boundary of the Multiple Use Zone (IUCN Category VI) of the Montebello Marine Park. This zone is managed to allow ecologically sustainable use while conserving ecosystems, habitats and native species (Section 4.8). The 1,300 approved mixing zone (predicted for GWA PW toxicity and 3,500 m^3/day discharge rate) overlaps <0.05% (1.6 km^2 of the 3,412 km^2) of the Multiple Use Zone however a 99% species protection safe dilution has been adopted at the marine park boundary. This is predicted to be achievable at 1,900 m^3/day or less adopting the PLA 2024 WET testing results. The management objective is to ensure long-term protection and maintenance of biological diversity with a sustainable flow of natural products and services to meet community needs. Potential to impact the values of the Montebello Marine Park are not expected and are considered below.

Table 6-19 Values of the Montebello Marine Park

Value	Potential Impact
Ancient Coastline at the 125 m depth contour	The KEF is located approximately 6.5 km from the PW discharge point and is outside of the approved mixing zone. Modelling predicts the PW will form a buoyant plume extending less than 1,300 m from the discharge point, therefore, no contact and no impacts to biological indicators associated with the KEF are expected from the plume.
Species including species listed as threatened, migratory, marine or cetacean under the EPBC Act	A number of threatened migratory, marine or cetacean species may be present in the approved mixing zone (Section 4.6). Given that PW will be managed to achieve 99% species protection dilutions at the boundary potential for impacts to marine fauna are not predicted. Given the minor reduction in water quality and small area of impact and noting while transiting cetaceans, or whale sharks (noting that there are no BIAs or critical habitats within the mixing zone) may pass through the plume they are not anticipated to spend long durations within the mixing zone and no impacts are expected As such, the magnitude for fish, whale sharks, rays, cetaceans has been identified as no lasting effect (F).
BIA flatback turtle internesting buffer around the Montebello Islands (Oct to Mar)	The Montebello Islands, located approximately 41 km from the PW discharge, are the nearest emergent land and potential nesting habitat (minor) for flatback turtles. During internesting turtles remain close to the nesting beach or rookery (DOEE, 2017). Typically, internesting habitat is located immediately seaward of designated nesting habitat (DOEE, 2017). The approved mixing zone is within the Pilbara flatback turtle 60 km internesting buffer zone (October–March) however given the approved mixing zone is over 40 km from the nearest nesting beach internesting turtles are not anticipated to remain in the approved mixing zone for prolonged periods of time or in large numbers. Chronic discharge is identified as a moderate risk threat in the Recovery Plan for Marine Turtles for the Pilbara flatback population (DOEE, 2017). Given the localised area of impact, 99% species protection safe dilutions at the boundary of the marine park and the distance to nesting habitat the magnitude for marine reptiles has been identified as no lasting effect (F).
BIA foraging for whale sharks along the 200 m isobath, with seasonally high use (Apr to Jun)	The 200 m isobath is located about 17 km outside the approved mixing zone. Given the localised area of impact and that whale sharks are transiting the area, no impacts are expected.
BIA breeding habitat for seabirds	There is no nesting habitat within the approved mixing zone, therefore aggregations of breeding birds are unlikely to be present in the approved mixing zone. Foraging areas are located outside the approved mixing zone. No impacts are expected to this value.
BIA pygmy blue whale migration corridor (northern migration Apr to Aug; southern migration Oct to Jan) from Indonesian Waters to southwest Australia	The pygmy blue whale migration is thought to follow deep oceanic routes (DEWHA, 2008). In the NWMR, PBW migrate along the 500 m to 1000 m depth contour on the continental slope where they are likely to opportunistically feed on ephemeral krill aggregations (DEWHA, 2008). Given the BIA is located outside the approved mixing zone and that PW forms a surface buoyant plume, no impacts are expected to this value.
Cultural values	Cultural and spiritual values have been identified in Section 4.9 and assessed in Section 6.11.
Heritage values	No international, Commonwealth or national listings apply to the Montebello Marine Park currently. The Western Australia Barrow Island and the Montebello–Barrow Island Marine Conservation Reserves are outside of the approved mixing zone and therefore are not predicted to be impacted. Two historic shipwrecks, the Trial and Tanami, are located about 30 km outside of the approved mixing zone and PW forms a surface buoyant plume, therefore no impacts are expected to this value.

The Montebello Marine Park special protection zone for benthic habitat and sanctuary zone boundaries are located approximately 36 km to the south of the riser platform. As such, there are no impacts anticipated in these zones.

There are no impacts anticipated to the values of the Montebello Marine Park (including natural, cultural, heritage and socio-economic values). Wider water quality and sediment impacts are considered in respective sections above. Discharges are monitored and managed to achieve a 99% species protection safe dilution via the OMDAMP at the AMP boundary.

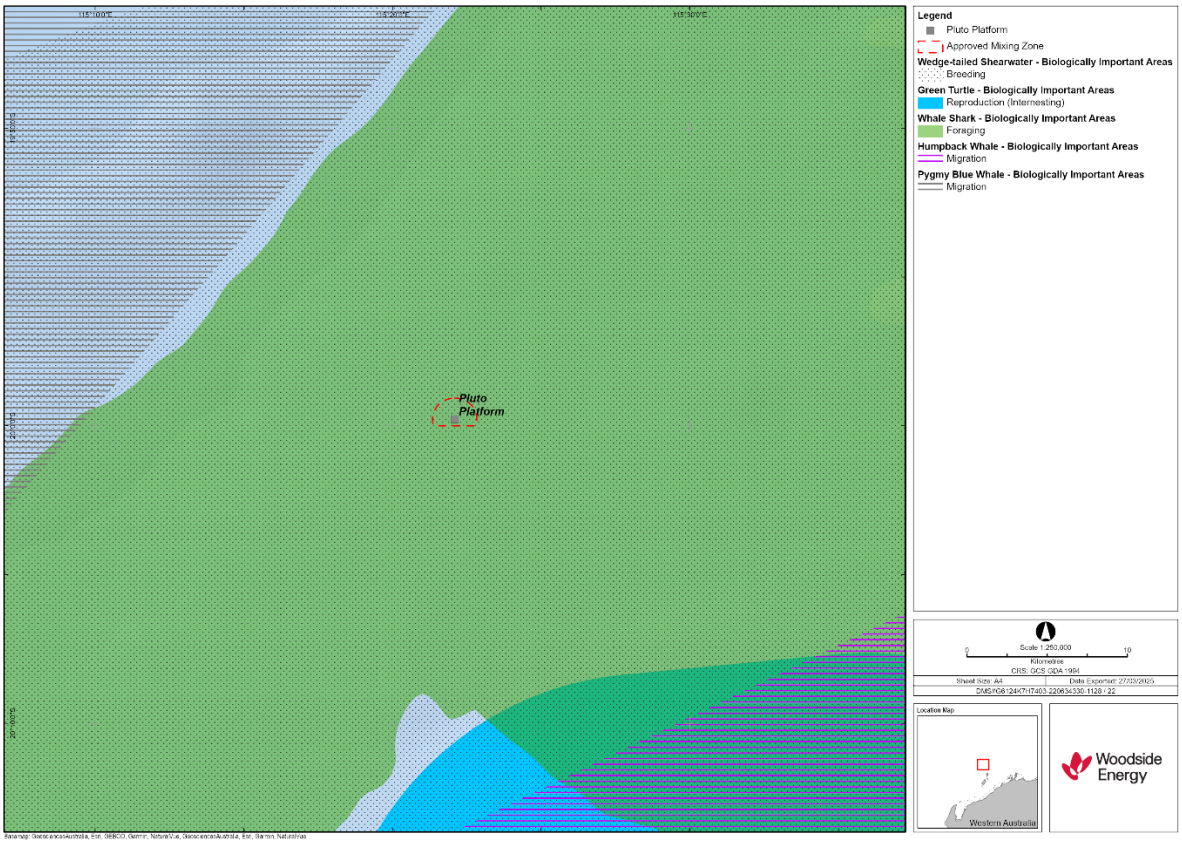

Figure 6-5: Biologically Important Areas

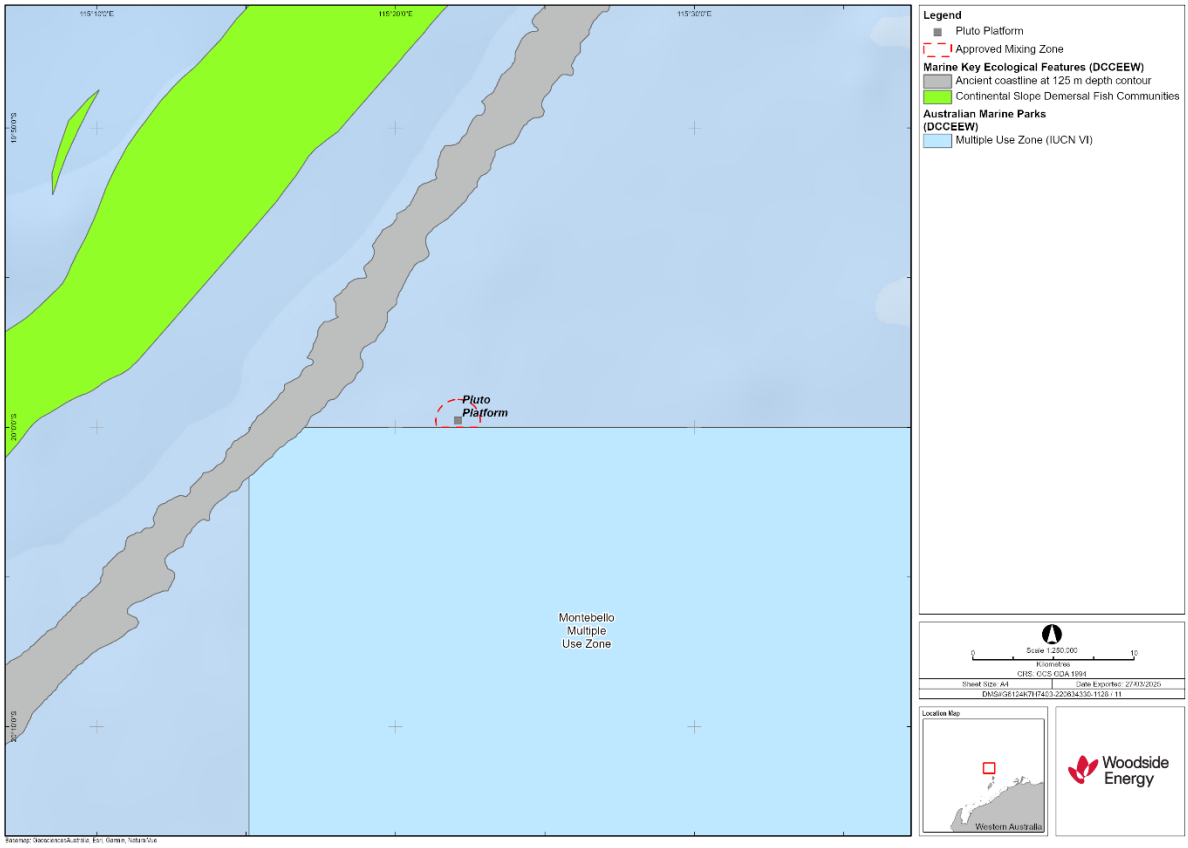

Figure 6-6: Key ecological features

Potential Impacts to Sediment Quality

Potential impacts to sediment quality were assessed through sediment surveys and supported by the results of sedimentation and flocculation studies and potential impacts to water quality through annual produced water chemical characterisation assessments.

Toxicants in Sediments

Accumulation of PW contaminants in sediments depends primarily on the volume and concentration of particulates in PW discharges or constituents that sorb onto seawater particulates the area over which those particulates could settle onto the seabed (dominated by current speeds and water depths) and re-suspension, bioturbation and microbial decay of those particulates in the water column and on the seabed.

Baseline sediment surveys were completed to prior to the discharge of PW from the riser platform. Sediments within the 1300 m mixing zone and adjacent reference areas (5000 m) had no toxicants which exceeded the ANZG 2018 DGV (BMT 2022). In 2021, a survey of the benthic habitats around the facility was completed and results showed habitats predominantly comprised of unconsolidated (soft) sand and mud of possible biogenic origins containing shell fragments and a low cover (<20%) of biota that mostly consisted of a mixed community of poriferans (erect, crust, cup-like and massive forms) and cnidarians (sea whips, sea pens, sea fans, soft corals and hydroids) (BMT 2022), which is broadly represented throughout the NWS Province (Section 4.2). Benthic communities of soft sediment are characterised by burrowing infauna such as polychaetes, with biota such as sessile filter feeders occurring on areas of hard substrate (such as subsea infrastructure). Benthic grab sampling in the vicinity of the continental slope region of the Operational Area revealed a sparse abundance, high variability and high diversity of infauna dominated by polychaetes with other fauna including nemerteans and sipunculids and crustaceans (mainly amphipods) (SKM, 2007). Higher, albeit still low, infauna density was reported at the shelf break (200 m) compared to deeper areas on the continental slope.

Within the approved mixing zone potential impacts to sediment quality are considered to be very low risk. If they occurred, it would be limited to localised impacts to benthic communities. The potential extent of such impacts is extremely small in relation to the extent of the soft sediment habitats that are broadly represented within the Operational Area and the wider NWS Province. As such, impacts to benthic communities are expected to be localised with no lasting effect. There is no history of drilling with oil-based muds at the riser platform.

The PW plume is predicted to be buoyant, due to lower salinity and/or higher temperature than surrounding seawater. Therefore, potential contaminants in the PW discharge may be introduced into sediments around the riser platform through precipitation of soluble contaminants and flocculation and sedimentation of the particles in the PW plume. Studies into potential sediment accumulation from PW discharge have been undertaken by Woodside (Jacobs, 2016). The study found that the PW at all facilities had very small amounts of solid material, with very little potential of settling or flocculation due to the very small particle sizes.

The initial chemical characterisation and sedimentation monitoring in August 2024 included particle size distribution analysis to confirm potential for sedimentation. The analysis showed that 48% of particles from PW discharge are <5 µm and 95% <40 µm. Based on these characteristics sedimentation from PW is not expected to occur at the facility. Dr Graeme Hubbert categorised particulate behaviour based on oceanographic experience and mathematical calculations using settling rates and resuspension velocities for various particle sizes. He determined that particles of a size 1 to 5 µm would never permanently settle out of the water column, and that particles of a size 5 to 40 µm would not permanently settle out of the water column, unless they were in very deep water (>5,000 m) or in areas where hydrodynamic conditions were very weak and did not continuously resuspend the particles.

It is anticipated PW will not impact sediment quality to an unacceptable level; however, this will be verified via initial chemical characterisation monitoring and results considered and managed by the OMDAMP. Should initial routine monitoring indicate the potential for impact to sediment quality, it will be necessary to undertake further investigations. This may include additional chemical characterisation, sedimentation studies, non-routine sediment sampling and/or bioavailability testing.

Non-Routine PW Discharges Impact Assessment

Non-routine PW discharge operations are required during intermittent activities such as production restarts and water cut well restarts. Operations requires flexibility to allow for OIW elevation while the wells are started up and flow rates vary while the system is optimised. It is expected that within 7 days of sequentially managing the system, the process will allow for effective OIW separation with OIW concentrations reflective of steady-state conditions. During restarts at reduced discharge rates, OIW may be elevated for up to 7 days.

The complexities involved in the restart process are hydrate and integrity management requirements, and liquids and pressure management across the integrated production system to prevent potential flaring and onshore LNG plant cascade impacts, as well as managing chemical interactions and effectiveness. In order to provide the required flexibility during production restarts the following OIW levels are applied (whilst maintaining a monthly average consistent with operational criteria):

- <100 mg/L 24-hour rolling average (ra), with flow constrained to less than 800 m^3/d (ra), and.

- <50 mg/L 24-hour rolling average, with flow constrained to less than 1,900 m^3/d (ra).

To assess the short-term non-routine OIW discharges with varied initial OIW concentration assumptions, the OSPAR (2014) dispersed oil concentration of 70 µg/L is used as the PNEC for the non-routine activity dispersion modelling (RPS, 2023). Dispersion modelling developed a series of tables of the dilutions achieved based on the volume of discharge and the distance from the facility that the dilutions are achieved. Using these tables the distance required to achieve PNEC based on the discharge volume can be determined and activities managed to ensure that impacts are managed to ALARP and acceptable levels. Additional modelling was undertaken in 2024 (RPS, 2024a-e) to assess the potential impact of possible lower-rate discharges, including those during non-routine activities such as production system restarts, and water cut well start-ups. These intermittent activities have potential for short term variations in OIW specification which require system flexibility to optimise and stabilise the PW process, and hence may see short periods of elevated OIW concentration, and will be managed to not exceed 50 mg/L and 100 mg/L 24-hour rolling average criteria, corresponding to discharge rates constrained well below the design basis (3,500m^3/day) – limited to 1,900 m^3/day and 795 m^3/d respectively. Non-routine modelling dispersion outcomes at these reduced rates validate that OIW PNEC values are predicted to be achieved for non-routine activities well within the defined mixing zone, and prior to the AMP boundary.

Production Restarts

There is the potential for the facility to experience high OIW during production restarts. Wells that have been shut in are required to be MEG and corrosion inhibitor dosed to maintain pipeline integrity, this may in part cause emulsions to form and OIW management issues. Wells that are either condensed water or have less associated produced water are expected to experience similar high OIW issues.

During production restart events, the modelled discharge rate of ~800 m^3/day with the additional controls, and non-routine discharge criteria of up to 100 mg/L 24-hour rolling average (see Demonstration of ALARP table below) with lower-than-design discharge rates it is expected that OIW predicted-no-effect-concentrations (PNEC) of 70 µg/L (requires 1,429 dilutions) will be readily achieved for the duration of the activity within an approximate 200–425 m radius of discharge (worse-case), and well before the AMP boundary(**Error! Reference source not found.**).

Water Cut Well Restarts

Water cut wells that have been shut in for extended periods of time, may have varied produced water profiles on restart which can impact process stability until stable rates are achieved. It is expected that this can take a number of days for water rates to plateau from each individual water cut well when restarted.

During water cut well restart events and production restarts once sustained water rates occur across the field, a modelled discharge rate of 1,900 m^3/day) with the additional controls, and non-routine discharge criteria of up to 50 mg/L 24-hour rolling average (see Demonstration of ALARP table below) with lower-than-design discharge rates it is expected that OIW PNEC of 70 µg/L (requires 715 dilutions) will be readily achieved for the duration of the activity within an approximate 300 m radius of discharge, and well before the AMP boundary..

Based on modelling and the non-routine short duration of elevated OIW, the non-routine discharge during production restarts and restarts of water cut wells is considered to have a short term, temporary and localised impact to water quality, and not predicted to result in impacts beyond the approved mixing zone, or beyond the AMP boundary.

(and no OCNS substitution or product warning), chemicals are selected – no further control required. • If chemicals with a different OCNS rating, sub warning or non-OCNS rated chemicals are required, chemicals will be assessed in accordance with the guideline prior to use.		environment by assessing chemicals for environmental acceptability. Planned discharges are required for the safe execution of activities and therefore no reduction in likelihood can occur.		
Monitoring of OIW concentrations in accordance with PARCOM 1997/16 Annex 3 methodology. Limiting average PW OIW during routine operations to less than 30 mg/L (over a 24-hr rolling average (ra.)). During non-routine production restart and water cut well re-start activities: • limit PW OIW to less than 100 mg/L 24hr rolling average (<800 m3/day ra.), for up to 7 days following re-starts, OR • limit PW OIW to a 50 mg/L 24-hr rolling average (1,900 m3/day ra.), for up to 7 days following restarts. PW OIW is limited to a 30 mg/L monthly rolling average for all activities.	F: Yes. CS: Monitoring and implementation costs. Standard practice. The 30 mg/L 24-hour rolling average limit is a legacy of the former Environment Regulations 29 and 29A repealed in 2014. Reduction of this limit is not considered feasible or practicable. The current limit is effective in managing potential impact of PW discharge. Short-term non-routine criteria support ensuring PW operations achieve environmental outcomes (EPO) with ALARP management of start-up constraints which could otherwise resulting in frequent flaring, system upsets, and/or addition of process chemicals for integrity management (potentially adversely affecting overall outcomes and OIW separation performance).	Limiting OIW concentrations within PW reduces impacts to the environment.	The adoption of a limit ensures that PW OIW is controlled. Short-term, non-routine criterial with volume and duration constraints ensure PNEC values are predicted to be achieved for non-routine activities well within the defined mixing zone, and prior to the Montebello Marine Park multiple use zone boundary, whilst ensuring system stability, safety and integrity and reducing potential flaring emissions and chemical discharges.	**Yes** **C 7.1**

Implement Monitoring and Management Framework for PW discharges, including: • monitoring of PW discharge volume • chemical characterisation (including BTEX, PAH's, Organic Acids, metals and glycol) • WET testing timing of annual/ triennial sampling to be representative aiming to detect change, considering when the reservoir cuts formation water.	F: Yes. CS: Monitoring costs. Standard practice.	The OMDAMP provides for detection of significant changes to the PW discharge characteristics (i.e., volumes, OIW concentration, chemical characterisation) that may cause an increased impact or risk to the marine environment. Monitoring is designed to detect if 95% or 99% species protection is achieved at the approved mixing zone boundary and AMP boundary. Through the implementation of the OMDAMP, potential risks to the environment are reduced.	Woodside has developed the OMDAMP based on operational experience from relevant offshore assets. The OMDAMP considers risk-based adaptive management measures.	**Yes** **C 7.4**
Online monitoring and/or procedural controls in place to monitor and control PW discharge volume and OIW concentrations and prevent discharge of PW with high OIW concentrations through OIW analyser, or off spec/outage procedures. Process performance monitored by OIW concentration analyser and volume meter(s).	F: Yes. CS: Minimal cost. Standard practice.	The OIW analysers and flow meter provides optimal process control and safeguarding to monitor, control and prevent discharge of PW with high OIW concentration to the environment.	Online monitoring control is WMS requirement – must be adopted.	**Yes.** **C 7.5**
The online analyser is calibrated with a manual sample in accordance with Offshore Laboratory Determination of Oil in Water Standard Operating Procedure.	F: Yes. CS: Monitoring and implementation costs. Standard practice.	Calibration of equipment to maintain quality control.	Calibrations undertaken at appropriate frequency to maintain quality control and in line with procedures.	**Yes.** **C 7.6**

Control Considered	***Control Feasibility (F) and Cost/ Sacrifice (CS)[67]***	***Benefit in Impact/ Risk Reduction***	***Proportionality***	***Control Adopted***
Professional Judgement – Eliminate				
Reinjecting PW into reservoirs.	F: No. Some technical risk associated with reservoir uncertainty and ultimate reservoir recovery. Economically not feasible. CS: Significant. The reinjection of PW would require significant modification to the PLA facility, including drilling of injection wells. This would require considerable design and construction costs. Previous studies indicate a cost in excess of $400 million CAPEX for a PW reinjection solution on-board the Pluto facility. ***Benefit in Impact Reduction*** The environmental impacts in the approved mixing zone around the facility would be eliminated. Long term biological impacts from PW that are outside of the acceptable limits of change (i.e., impacts to ecosystem integrity from contaminant accumulation in sediment and bioaccumulation effects over time) are prevented by the PW Monitoring and Management Framework. ***Proportionality*** As part of the possible solutions for managing PW from the Pluto operations, Woodside examined the potential for reinjection of PW. Woodside did not identify a suitable reservoir, and such an option would require additional drilling activities to be undertaken. Reinjection is not feasible unless a suitable reservoir is identified. It is not feasible to reinject into a previous Pluto appraisal well, or future shut-in well because this would further accelerate the production of PW from the reservoir and reduce the overall recoverable volume from the reservoir. Given the limited space available on the platform, subsea separation would be required, this is novel technology with limited operational experience. Drilling and Subsea work activities to establish a reliable PW reinjection well and subsea infrastructure also introduce significant complexity, risk and cost. Together the significant technological and operational risks, associated environmental impact (drilling and subsea construction, greenhouse gas emissions associated with 7–15 MW based on known historical requirements for Enfield–Laverda) is considered significantly disproportionate to the potential slight environmental impact improvement. As such, no further engineering design or screening studies reporting is considered reasonably practicable. It is not necessary to conduct a reservoir-by-reservoir analysis to understand these costs. For Type B impacts, it is appropriate to consider case specific drivers to ALARP management. The lack of a suitable reservoir contrasts with Woodside's facilities that historically reinject PW. At Nganhurra, for example, water re-injection was required to maintain reservoir pressure for production and was a key part of the FDP to optimise overall field recovery. As PW alone was not sufficient to maintain reservoir pressure, seawater was used to make up the balance. Therefore, given the significant economic benefits associated with reinjection at NGA, the ALARP outcome is different from NGA to Pluto. The reinjection of PW would also introduce additional sources of environmental risks and impacts, such as those associated with drilling injection wells (e.g., drill cuttings) and maintaining injection capability (e.g., increased greenhouse gas emissions from power generation for pumps, increased chemical usage, etc). Given the localised, slight non-significant impact of PW discharges, and the considerable costs involved in developing a PW reinjection			No

	capability for the Pluto facility, implementation risks and environmental impacts (greenhouse gas, chemical use), the costs are grossly disproportionate to the potential environmental benefit gained.			
Professional Judgement – Substitute				
None identified.				
Professional Judgement – Engineered Solution				
Chemical injection of water clarifier, demulsifier to reduce OIW concentration, if required.	F: Potentially feasible. CS: Moderate. Initial cost of modifying production system to include chemical dosing point. Ongoing cost of chemical procurement.	Potential minor reduction in OIW concentration; however, does not reduce the overall consequence rating. Further, this results in additional chemical load, and lifecycle environmental footprint associated with packaging, logistics, waste management and potential process upsets.	Benefits outweigh cost/sacrifice.	**Yes** **C 7.7**
Secondary treatment stage (HIGF) to reduce OIW concentration.	F: Yes. Process design adopts an HIGF unit. CS: Moderate. Integrated in to process design. Ongoing cost of maintenance.	Installation of a secondary treatment stage (HIGF) has been provided on the NNC facility to ensure OIW remains below 30 mg/L (24-hr rolling average) during routine operations.	As part of the possible solutions for managing PW from the Pluto operations, Woodside examined the potential for installation of various secondary treatment technologies. The HIGF was identified as the optimal secondary treatment stage in order to maximise OIW separation prior to discharge overboard during routine operations.	**Yes** **C 7.2**
Permanently installed tertiary treatment stage for contingent use to reduce OIW concentration. Filters are used during non-routine activities and to support elevated OIW response procedures.	F: Yes. Coalescing filters are provided in the PWH design as a contingency tertiary treatment stage for use during process upsets and non-routine activities to maintain acceptable OIW concentrations. CS: Moderate cost. Integrated in to the process design. Use is a high cost activity associated with	Installation of a tertiary treatment stage has been provided on the NNC facility to ensure OIW can be managed to below criteria during process upsets or non-routine activities, and to minimise the requirement for unplanned	As part of the facility design - possible solutions for managing PW from the Pluto operations, Woodside examined the potential for installation of various treatment technologies Coalescing filters have been installed as a mitigation measure for process upsets and to support non-routine activities only. Long	**Yes** **C 7.3**

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/ Sacrifice (CS)[67]***	***Benefit in Impact/ Risk Reduction***	***Proportionality***	***Control Adopted***
	maintenance change-out and filter costs. Manual change-out frequency has limitation due to NNC facility.	intervention visits to the platform.	term continuous running of the filters results may result in high cost and increase health and safety handling and exposure risks. The filters have been designed such that a variable flow can be slipstreamed through them from 0 – 100%, providing maximum operator flexibility for remote troubleshooting to prevent the need for a react visit to the platform, therefore these filters provide an ALARP solution to managing non-routine and process upset OIW discharge requirements, while minimising the safety risk on the NNC platform.	
Facility modification to adopt alternate secondary treatment stage technologies to further reduce OIW concentration. For example: • Macroporous Polymer Extraction (MPPE) • Centrifuges / Hydrocyclones • Membrane/ adsorption media filtration	F: No, MPPE, centrifuges/ hydro cyclones and membrane/media filtration typically require high operator intervention, operations and maintenance requirements not conducive to the NNC facility philosophy. PLA platform has limited space, and weight constraints, as well as ancillary considerations such as power generation and no heating circuits. These limit the ability for a number of these alternate technologies to be installed or operated considering provision for sufficient sparing and/or filter handling and waste management/ handling.	Alternate secondary and tertiary options have potential to be effective on suitable facilities to reduce OIW with certain hydrocarbon characteristics. In PLA and PWH's context, feasible options are limited – thus there is limited environmental benefit available compared to the in-place systems, with HIGF, and contingent coalescing filtration system installed. Further operational optimisation is expected from the in-place system as water rates stabilise above the current minimum turndown.	Additional systems pose significant space, weight, utility modifications and requirement for extended crewed operations (to execute the modification and ongoing operation) – Hence a large upgrade, new platform, or extended crewed operation and costs are not proportionate to the impact reduction, especially considering likely periods of reduced PW discharge rates within the design basis for the facility.	No

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/ Sacrifice (CS)[67]***	***Benefit in Impact/ Risk Reduction***	***Proportionality***	***Control Adopted***
	CS: Modification of the PWH and PLA facility would require extended periods of crewed offshore operations, and significant design and execution costs. A number of options would require significant facility layout modification and operational crewed operations and maintenance support.			
Professional Judgement – Procedures and Administration				
Routine in situ monitoring beyond the requirements of Woodside's OMDAMP.	F: Yes. CS: Increasing the frequency of field-based monitoring would result in additional offshore demand on resources, safety hazards and costs associated with an offshore environmental monitoring program, such as vessel activities, logistics, manual labour, analytical laboratory and service provider costs.	In situ monitoring following release is not an effective control to manage the nature of PW discharges and results no impact reduction. Increases to in situ monitoring beyond the adaptive management approach outlined in the OMDAMP does not follow good application of the hierarchy of controls and results in disproportionate sacrifice with regard to execution risks and costs for limited gain.	Long-term monitoring of water and sediment characteristics at the Woodside facilities indicate the PW discharge is not detectable beyond the approved mixing zone. No sediment contamination has been detected. PW separation process design, optimisation, monitoring and surveillance offer the primary controls, with discharge OIW analysis in place to detect performance variations. Further, Woodside maintains a routine OIW monitoring program for the PW stream (including adaptive management via the OMDAMP, which assesses the need for in situ monitoring). The work undertaken to date provides Woodside with a sound understanding of the nature and scale of the environmental impacts from PW discharge, which would not be further improved by	No

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/ Sacrifice (CS)[67]***	***Benefit in Impact/ Risk Reduction***	***Proportionality***	***Control Adopted***
			increasing the frequency of in situ monitoring. The execution risks and cost of implementing this control is grossly disproportionate to the environmental benefit.	
Annual review of routine monitoring results and determine requirement for non-routine sediment quality monitoring as per OMDAMP.	F: Yes. CS: Monitoring and implementation costs. Standard practice.	Review of monitoring results to determine if additional monitoring is required does not reduce environmental impact but provide necessary assurance that impact continues to be appropriately defined.	Additional risk-based monitoring is proportional to the additional cost of implementation and part of the OMDAMP.	**Yes** **C 7.8**
Review of continuous improvement measures to determine if 30 mg/ L OIW limit can be reduced further.	F: Yes. CS: Minimal cost.	Following commissioning and start-up and operating in steady state data will be available to support whether a reduction in the OIW limit is feasible. Reducing the OIW may result in a small reduction in environmental impact to water quality in the immediate vicinity of the facility.	Although the reduction in environmental impact may be small a review of the limit once operating does not incur any large cost and demonstrates continual improvement and ALARP. It should be noted that regardless of the limit the system will be operated to the lowest practicable OIW concentration that can be achieved based on system design and functionality.	**Yes** **C 7.9**
In-situ plume measurement and analysis of plume dilution and mixing characteristics (including monitoring at approved mixing boundary).	F: Yes, once sufficient PW discharge rates are achieved. CS: Monitoring and implementation costs. Incrementally increases vessel activities within the 500 m PSZ adjacent to the facility with applicable SIMOPS management requirements.	In-situ plume studies confirm the validity of the predicted mixing zone and dilutions from the model. This provides confidence in the ongoing application of the model outputs to understand dilutions of the PW. By using the measured WET testing and chemical	Additional cost is proportionate to the environmental benefit to validate model conservatism used to bound impact assessment. The initiation of this control at Pluto is precautionarily applied from 800 m^3/d rate (23% design capacity) to ensure validation of potential uncertainty of up to 100% of predicted dilutions (in	**Yes** **C 7.10**

Control Considered	***Control Feasibility (F) and Cost/ Sacrifice (CS)[67]***	***Benefit in Impact/ Risk Reduction***	***Proportionality***	***Control Adopted***
		characterisation results and applying the verified model dilutions as well as water quality monitoring at the approved mixing zone boundary confirms that the EPO has been met.	the absolute worst case) model results predicted at the Montebello Marine Park Multiple Use Zone boundary (416 m). i.e. 3719 worst case dilutions are predicted (averaging >20,000), which is significantly higher than observed WET testing PNEC 1112, 1429 non-routine, or conservative assumption of 2000 dilutions required.	

Risk Based Analysis

Application of Woodside's Risk Management Procedures and implementation of the OMDAMP ensures the routine assessment of PW impacts, identification of changes to discharges, systematic assessment of risks and ongoing assessment/monitoring of discharge streams to reduce risk to ALARP, that includes:

- ongoing hazard identification, risk assessment and the identification of control measures
- ongoing PW discharge monitoring.

Company Values

Corporate values require all personnel at Woodside to comply with appropriate policies, standards, procedures and processes while being accountable for their actions and holding others to account in line with the Woodside Values. As detailed above, the PAP will be undertaken in line with these policies, standards and procedures that include suitable controls to manage PW discharge.

Societal Values

Due to the Petroleum Activities Program's proximity to sensitive receptors and potential uncertainty around PW discharges, the PW discharge consequence rating presents a Decision Type B in accordance with the decision support framework described in Section 2.6.1. Consultation was undertaken for this program to identify the views and concerns of relevant stakeholders, as described in Section 5.

Woodside has sent an Activity Factsheet to all identified relevant stakeholders regarding the PAP (Section 5 and Appendix F), no specific concerns around PW discharge were identified through this process.

ALARP Statement

Based on the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts of PW discharge. Woodside has undertaken extensive PW process studies, trials (emulsions) and risk-based analysis (PW discharge modelling) to inform the evaluation and assessment of environmental impacts and risks. Woodside also implements a risk-based adaptive OMDAMP. The outcomes of the modelling studies and process engineering have been considered in determining the ALARP position.

As no reasonable additional/alternative controls are currently identified that would further reduce the impacts and risks without grossly disproportionate sacrifice, the impacts are considered ALARP.

Demonstration of Acceptability

To assess and determine the acceptable limits of impacts from PW discharges, Woodside has considered the following criteria, appropriate guidelines, principles of Ecologically Sustainable Development, Company Values and Societal Values.

Other Requirements (includes Laws, Polices, Standards and Conventions)

The adopted controls and acceptability assessment has considered regulatory guidance, in particular WA EPA (2016) Technical Guidance: Protecting the Quality of Western Australia's Marine Environment and the ANZG (2018)

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/ Sacrifice (CS)[67]***	***Benefit in Impact/ Risk Reduction***	***Proportionality***	***Control Adopted***

guidelines. Both sources of Regulatory Guidance provide that environmental values should be identified, and levels of ecological protection should then be set. To ensure ecosystem health is maintained overall, the cumulative size of the areas where lower levels of ecological protection apply should be proportionally small compared to the areas designated high and maximum. The ANZG (2018) guidelines similarly provide guidance that levels of protection should be identified, based on the environmental values to be protected. The Monitoring and Management Framework aligns to the levels of protection described by both WA EPA (2016) Technical Guidance and the ANZG 2018 guidelines through the acceptable limits of change.

The level of ecological protection provided to sensitive receptors is consistent with the North-west Network Management Plan (2018). By monitoring and managing to the 99% species protection safe dilutions, there can be high confidence that any potential for impacts will be detected and managed via the OMDAMP.

The Minamata Convention 2013 (ratified by Australia in 2021) requires measures to be in place to control releases containing mercury or mercury compounds. Each of these measures, with information on how each measure is met for discharges of PW from the facility is provided below:

- *Release limit values to control, and where feasible, reduce releases*. DGV related to mercury are in place and described above.
- *The use of best available techniques and best environmental practices to control releases*. Monitoring via the annual chemical characterisation and OMDAMP provides adaptive management to ensure best environmental practices.
- *A multi pollutant control strategy for mercury releases*. The monitoring framework implemented includes full chemical characterisation and WET testing of discharge stream, which allows understanding of holistic toxicity of the effluent considering all contaminants and potential additive effects.

Principles of Ecologically Sustainable Development

Woodside has established several research projects to understand the marine environments in which we operate, notably in the Exmouth Region and the Kimberley Region, including Rankin Bank, Glomar Shoals, Enfield Canyon and Scott Reef. Woodside's corporate values require that we consider the environment and communities in which we operate when making decisions.

These principles of ESD were considered for this aspect:

- Integration Principle
  - the existing environment (Section 4) has been described consistent with the definition within Regulation 5 of the Environment Regulations (i.e. includes ecological, socioeconomic, and cultural features), and any relevant values and sensitivities have been included within this impact analysis; therefore, the impact assessment process inherently includes economic, environmental and social considerations.
  - Feedback, objections and claims from Relevant Persons were considered, see Appendix F.
- Precautionary Principle
  - the impact consequence rating for this aspect is slight, therefore, potential for serious or irreversible environmental damage is not expected.
  - although serious or irreversible environmental damage is not predicted to occur, there is some scientific uncertainty associated with the produced water composition however it is not expected to change the consequence level and PW will be monitored and managed as per the adopted control measures.
- Intergenerational Principle
  - the acceptable levels were developed consistent with the principles of ESD, including that the environmental impacts and risks of the offshore project will not forego the health, diversity, or productivity of the environment for future generations.
  - as described above, the predicted environmental impact spatially limited to an area around the facility, which is not considered as having the potential to affect ecological integrity. By maintaining ecological integrity the discharge of PW is not considered to have the potential affect intergenerational equity.
- Biodiversity Principle
  - the existing environment identifies and describes relevant MNES, as defined in Regulation 7(3) of the Environment Regulations; any relevant values and sensitivities are included within this impact analysis.
  - as described above, the predicted environmental impact are spatially limited to an area around the facility, which is not considered as having the potential to affect ecological integrity. By maintaining ecological integrity the discharge of PW is not considered to have the potential affect biological diversity.

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/ Sacrifice (CS)[67]***	***Benefit in Impact/ Risk Reduction***	***Proportionality***	***Control Adopted***
Woodside looks after the communities and environments where we operate. Risks are inherent in petroleum activities; however, through sound management, systematic application of policies, standards, procedures and processes, Woodside considers that despite this potential impact, the extremely low impact of PW is acceptable. The proposed activity has been assessed and considered in accordance with Australian IUCN Reserve Management Principles, conditions of the class approval (Section 1.9), objectives of the IUCN category VI zone (Section 1.9), the North West Marine Park Management Plan and the values of the Montebello Marine Park. Discharge of PW is acceptable providing that 99% species protection safe dilutions are met at the Montebello Marine Park Multiple User Zone boundary. This removes potential to adversely impact on biodiversity, ecological integrity, social amenity or human health. Activities will not be conducted in a manner inconsistent with the objectives of the respective zones of the Australian Marine Park (AMPs), the principles of the IUCN Area categories or the values of the AMPs. ***Internal Context*** The PAP is consistent with Woodside corporate policies, standards, procedures, and processes as outlined in the Demonstration of ALARP and Environmental Performance Outcomes, including: • Woodside Environment and Biodiversity Policy (Appendix A) • Woodside Risk Management Policy • Woodside Environmental Performance Procedure (which specifies maximum mixing zones and minimum sampling requirements). Woodside corporate values include working sustainably, with respect to the environment and communities in which we operate, listening to internal and external stakeholders (below) and considering HSE when making decisions. ***External Context*** Woodside recognises that its licence to operate from a regulator and societal perspective is based on historical performance, complying with appropriate policies, standards and procedures, and understanding the expectations of external stakeholders. External stakeholder consultation was undertaken with relevant stakeholders (Section 5), prior to the PAP and feedback was incorporated into this EP where appropriate. In particular, the Director of National Parks (DNP) was consulted as part of the five-yearly update for this document. In addition, Woodside undertook additional consultation (2022) specific to PW discharge monitoring and management and other activities including baseline data collection on sediment quality during the engagement process. By providing PW monitoring and control measures that are commensurate with the risk rating, location and sensitivity of the receiving environment (including social and aesthetic values), Woodside believes this addresses broad societal concerns to an acceptable level. ***Acceptability Statement:*** Routine and non-routine discharges of PW have been evaluated as representing potential slight, localised, short-term impacts to water quality, marine sediment, marine fauna and habitat. As per Section 2.6.1, Woodside considers 'high order impacts' (Decision Type B impacts such as PW discharge) as acceptable if ALARP is demonstrated using good industry practice, consideration of company and societal values and RBA, if legislative requirements are met and societal concerns are accounted for, and the alternative control measures are grossly disproportionate to the benefit gained. In addition, acceptability is assessed against the above criteria. The adopted controls are considered good oil-field practice/industry best practice, are consistent with WA EPA (2016), ANZG (2018) and Woodside's internal requirements. Further opportunities to reduce the impacts have been investigated (refer ALARP demonstration) and considered to be grossly disproportionate to the benefit gained. Woodside considers the adopted controls appropriate to manage the impacts of PW discharge to an acceptable level.				

EPOs, EPSs and MCs For Pluto Facility Operations			
Environmental Performance Outcomes	***Controls***	***Environmental Performance Standards***	***Measurement Criteria***
EPO 7 No impact to the environment outside of the Approved Mixing Zone from planned discharge of produced water.	**C 5.1** Implement Woodside's Chemical Selection and Assessment Environment Guideline: • Where Gold, Silver, E or D OCNS rating (and no OCNS substitution or product warning), chemicals are selected – no further control required. • If chemicals with a different OCNS rating, sub warning or non-OCNS rated chemicals are required, chemicals will be assessed in accordance with the guideline prior to use.	**PS 5.1** All chemicals intended or likely to be discharged to the marine environment will be assessed and approved prior to use in accordance with the Chemical Selection and Assessment Environment Guideline (described in Section 3.9) to ensure the impacts associated with use are ALARP and acceptable.	**MC 5.1.1** Chemical assessment register demonstrates the chemical selection, assessment and approval process for selected chemicals is followed.
	C 7.1 Monitoring of OIW concentrations in accordance with PARCOM 1997/16 Annex 3 methodology. **C 7.2** Continuous reservoir management during routine operations; i.e., changing the relative contribution to facility production of each well, including choking back high OIW wells, to maintain OIW concentrations below Performance Standard. **C 7.3** Adopting a tertiary and secondary treatment stage to reduce OIW concentration.	**PS 7.1** Limiting average PW OIW during routine operations to less than 30 mg/L (over a 24 hr rolling average. During non-routine production restart and water cut well re-start activities: • limit PW OIW to less than 100 mg/L 24 hr rolling average (<800 m3/day ra.), for the first 7 days following re-starts, OR • limit PW OIW to a 50 mg/L 24 hr rolling average (<1,900 m3/day ra.), for up to 7 days. PW OIW is limited to a 30 mg/L monthly rolling average for all activities. Tertiary coalescing filter separation will be used for all non-routine activities where this aligns with achieving beneficial OIW concentration objectives.	**MC 7.1.1** Records demonstrate OIW rolling average limits are not exceeded during routine and non-routine (production restart and water cut well restarts) activities.

	C 7.4 Implementation of the OMDAMP including: • monitoring of PW discharge volume • chemical characterisation (including mercury) • WET testing triennial sampling to be representative aiming to detect change.	**PS 7.4.1** No impact to the environment from PW discharge outside of the approved mixing zone based on multiple lines of evidence.	**MC 7.4.1** Records show routine monitoring has been conducted. Settling velocity and particle size distribution analysis is proposed as part of the initial monitoring of representative discharge to confirm potential for sediment impacts. Results of these studies will inform if non-routine sediment sampling is required prior to the next routine monitoring event. Further investigations have identified no potential to impact environment from PW outside of acceptable limit.
	C 7.5 Online monitoring and/or procedural controls in place to monitor and control PW discharge volume and OIW concentrations and prevent discharge of PW with high OIW concentrations through OIW analyser, operating procedures, and off-spec/outage procedures.	**PS 7.5.1** Instrumentation integrity will be managed in accordance with SCE Management Procedures (Section 7.4) and SCE Technical Performance Standard(s) to prevent environmental risk related to Damage to SCEs for: • P31 – Environmental Emissions Monitoring and Controls, to: • provide means of detecting environmental releases, emissions and discharges to prevent MEEs from manifesting over time, and/or assure compliance monitoring and reporting equipment • ensure monitoring data is available to control PW discharge volume and OIW concentrations; to prevent discharge of PW with high OIW concentrations.	**MC 1.16.1** Records demonstrate implementation of SCE Technical Performance Standard(s) and Management of Hardware Controls in the Operate Phase Procedure (Section 7.4.2), in order to achieve the functional objective of the control. Records may include implementation and maintain/assure and manage-change information summarised in Section 7.4.2

		PS 7.5.2 Online monitoring and/or procedural controls in place to monitor and control PW discharge volume and OIW concentrations, and prevent discharge of PW with high OIW concentrations by implementing; procedures that includes response measures in the event of: • increasing or off-spec PW OIW readings • loss of signal for two OIW analysers.	**MC 7.5.1** Records demonstrate online and/or manual OIW monitoring, operating procedures in place, and implemented.
	C 7.6 The online analyser is calibrated with a manual sample in accordance with Offshore Laboratory Determination of Oil in Water Standard Operating Procedure.	**PS 7.6** Complete calibrations of online analyser and manual OIW sampling equipment in accordance with Offshore Laboratory Determination of Oil in Water Standard Operating Procedure.	**MC 7.4.1** Records demonstrate manual sampling and calibration undertaken during commissioning activities as appropriate.
	C 7.7 Chemical injection of water clarifier, demulsifier to reduce OIW concentration.	**PS 7.7** PW is chemically treated as required so that OIW is limited to a 30 mg/L 24-hour rolling average.	**MC 7.7.1** Records demonstrate OIW rolling average limits are not exceeded during routine activities.
	C 7.8 Annual review of routine monitoring results and determine requirement for non-routine sediment quality monitoring as per OMDAMP.	**PS 7.8** Complete review of routine monitoring results and determine if contaminants with the potential to impact sediments have increased and whether non routine sediment quality monitoring should be undertaken to determine extent of impacts	**MC 7.8** Records show annual review has been conducted as described.
	C 7.9 Review of continuous improvement measures to determine if 30 mg/ L OIW limit can be reduced further.	**PS 7.9** Complete review to determine whether OIW limit can be reduced in the next five-year revision of the EP.	**MC 7.9** Records show review has been conducted as described.

	C 7.10 In-situ plume measurement and analysis of plume dilution and mixing characteristics (including monitoring at approved mixing boundary) to verify dilutions are achieved.	**PS 7.10** Complete plume verification (once flow is greater than 800 m^3/day average discharge rate for at least eight consecutive weeks) including: • obtain background measurements of surface and sub surface temperature and salinity levels surrounding facility • tracking the plume (using a dye or similar) to quantify the horizontal and vertical plume dilutions achieved under different current conditions. • water quality sampling at approved mixing zone boundary to measure potential contaminant concentrations.	**MC 7.10** Technical report confirms predicted model outputs or mixing zone boundary updated (if required).

6.7.8 Routine and Non-routine Discharges: Drill Cuttings, Drilling Fluids and Well Removal Fluids

Context

Impact Evaluation Summary

Source of Impact	***Environmental Value Potentially Impacted***							***Evaluation***						
	Soil and Groundwater	Marine Sediment	Water Quality	Air Quality (incl Odour)	Ecosystems/Habitat	Species	Socio-economic	Decision Type	Consequence/Impact	Likelihood	Risk Rating	ALARP Tools	Acceptability	Outcome
Routine discharge of WBM drill cuttings to the seabed and the marine environment		x	x		x			A	E	-	-	GP PJ	Broadly Acceptable	**EPO 8**
Routine discharge of drilling muds (WBM) to the seabed and the marine environment		x	x		x				E					
Non-routine discharge of treated NWBM drill cuttings to the marine environment		x	x		x				D					
Non-routine discharge of wash water from mud pits and vessel tank wash fluids		x	x		x				E					
Routine discharge of well clean-out fluids		x	x		x				E					
Non-routine discharge of well annular fluids		x	x		x				F					

Description of Source of Impact

Drilling Operations

The PAP will involve the drilling of the Xena-03 well, drilled over a period of approximately 60 days (including mobilisation, demobilisation and contingency). Drilling activities generate drill cuttings, require cementing of the casing, and require the use of a range of fluids. Throughout the drilling program several different fluids are to be run through the closed circulation system, including, but not limited to, drilling fluids (water-based muds and non-water-based muds), sea water, and kill-weight brine.

Routine drilling discharges will include:

- drill cuttings
- drilling fluids direct to seabed (WBMs only), retained on cuttings and bulk discharge of mud pits (WBMs only)
- Non-routine drilling discharges may include:
- drill cuttings and fluids generated due to respud or side tracking
- WBM, swarf and cement cuttings
- well abandonment and use of fluids (subsea control, completions and well annular fluids).

Drilling activities are described in Section 3.11.1. The well will be drilled as a series of sections, as detailed in Section 3.11.1. The top hole section of the well will be drilled without a riser in place (i.e., riserless drilling). Drill cuttings and unrecoverable WBMs are discharged at the seabed for the top-hole sections, which are drilled riserless

(i.e., no closed loop with the MODU). This results in a localised area of sediment deposition (known as a cuttings pile) around and in proximity to the well site influenced by prevailing seabed currents.

Upon drilling of the top hole section, a casing will be cemented in place, a BOP installed and a riser put in place between the BOP and the MODU. The riser remains in place during drilling of the bottom hole sections and facilitates the circulation of drilling fluids and cuttings between the well bore and the MODU. This enables cuttings and drilling fluids to be circulated back to the MODU, where the cuttings are separated from the drilling fluids by the solids control equipment (SCEt) and typically re-used in the closed loop system between the well bore and the MODU. The cuttings (with adhered residual fluids) are, in typical circumstances, discharged below the water line, with their fate and dispersion determined by cuttings particle size and the density of the unrecoverable fluids. In contrast the fluids are recirculated into the fluid system where there are a number of mud pits (tanks) on the MODU that provide a capacity to mix, maintain and store fluids required for drilling activities. The mud pits form part of the drilling fluid circulating system and may be discharged at the end of specific well sections, where there is a requirement to change the drilling fluid system or the drilling fluid cannot be re-used (due to deterioration/contamination). Bulk discharge of this type is only permitted for WBMs.

Base oil may be used for inflow testing prior to abandonment of the well, to verify barrier integrity. Base oil would be pumped down the drill string and reverse circulated back to the rig, with fluids collected for disposal onshore. If stored in a mud pit, the base oil and other fluids associated with the test may result in pit wash water contaminated with hydrocarbons. If this is the case, mud pit wash water would be discharged in accordance with requirements in this EP, with a hydrocarbon content <1% by volume. Well abandonment activities are conducted in accordance with Woodside's internal standards.

Drill Cuttings and Fluids

As described above, the primary discharges used as the basis of the impact assessment for this PAP are as follows:

- Drill cuttings: drilling generates drill cuttings due to the breakup of solid material from within the borehole. The resultant drill cuttings are basically rock particles of various shapes, with sizes typically ranging from very fine to very coarse.
- Drilling fluids: serve many purposes including maintaining borehole stability and hydrostatic pressure, reducing friction and cleaning/ cooling of the drill bit, in addition to acting as a medium to carry cuttings from the well bore and return them to the surface at seabed or on the MODU. There are two main types of drilling fluids as follows:
  - WBMs consists mainly of fresh water or seawater with the addition of chemical and mineral additives to aid in its function. Drilling additives typically used may include chlorides (e.g., sodium, potassium), bentonite (clay), cellulose polymers, guar gum, barite or calcium carbonate. These additives are either completely inert in the marine environment, naturally occurring benign materials, or readily biodegradable organic polymers with a very fast rate of biodegradation in the marine environment. Bentonite and guar gum are listed as 'E' category fluids under the OCNS and is included on the Oslo Paris (OSPAR) Commission PLONOR (chemicals that 'pose little or no risk to the environment') list (OSPAR Commission, 2021). WBMs can be discharged to sea as fluids retained on cuttings and as bulk discharge from mud pits.

For the purposes of this impact assessment, the indicative dimensions, discharge locations and approximate drill cuttings and drilling fluid volumes provided in Table 6-20 represent the estimated discharges for the Xena-03 Tie-back activities.

Table 6-20: Estimated discharge of cuttings and volumes of drilling fluids used for Xena-03 Tie-back activities

Well Section Width (Inches)	Cuttings ~volume (m^3)	Drilling Fluid Type	Drilling Fluid ~ volume (m^3)	Hole Section	Discharge Point
42	72	Seawater1 with pre-hydrated bentonite (PHB) sweeps/XC polymer	157	Top hole	Seabed
26	569	Seawater1 with pre-hydrated bentonite (PHB) sweeps/XC polymer	752		
17.5	304	WBM	920	Production hole #1	Surface

	13.5 or 12.25	163	WBM	327	Production hole #2	
	9.875	15	WBM	2640	Reservoir section	
Total planned activities		***591 m³***		***5573 m³***		
Indicative Contingent Activities – NWBM. If NWBM required, these volumes will replace WBM volumes for production hole #2	13.5 or 12.25	163	NWBM	670 (retained fluid on cuttings)	Production hole #2	Surface
Indicative Contingent Activities – one top-hole respud	42" + 26" + 17.5" sections	534	Seawater1 with PHB sweeps/XC polymer for 42"/26" sections. WBM for 17.5" sections.	3030	Top hole + production hole #1	As above for each section
Indicative Contingent Activities – sidetrack one section (WBM or NWBM, not both)	~12.5 - 13.5" section	163	WBM	1590	Production hole #2	Surface
	~12.25 - 13.5" section	163	NWBM	670	Production hole #2	Surface

[1] Seawater volume is not included in the estimated 'drilling fluid volume'.

Subsea – Displacement, Completion and Well-bore Cleanout Fluids

Reservoir drilling and completion fluids are usually brines (i.e. a mixture of seawater or formation water) with additives that can include:

- chlorides (often sodium, potassium or calcium)
- bromides
- hydrate inhibitor (monoethylene glycol (MEG))
- biocide
- oxygen scavenger.

They are designed to have the proper density and flow characteristics to be compatible with the reservoir formation. Completion fluids are used to run well completions, and during wellbore clean up and flowback during drilling.

Wellbore and casing clean-up are required at various stages of the drilling operations so that the contents of the well are free of contaminants before the next stage of drilling. A chemical wellbore cleanout fluid train may be used to remove residual fluids from the wellbore. The wellbore cleanout fluid is usually brine (similar to completion fluid) that can include several chemicals, such as biocide and surfactant. During the clean-up process, fluids are circulated back to the MODU.

Cleanout fluids and completion brine will be captured and stored on the MODU and discharged if oil concentration is less than 1% by volume or returned to shore if discharge requirements cannot be met. Discharge volume would be ~400 m³.

Contingent Drilling Activities

Non-water-based Muds

NWBM are not planned to be used but may be required as a contingency during drilling should the offset history, geohazards assessment and borehole stability studies indicate that NWBM is required to manage well stability to safe levels. Where NWBM is needed to drill a well section, the cuttings from the NWBM drilling fluid system will also pass through a cuttings dryer to reduce the average residual oil on cuttings (OOC) for the well (only sections using NWBM) to ALARP, prior to discharge. In the event of SCE failures, cuttings may be discharged without having passed through the dryer; however, this will only occur for a short duration while the drill string is being moved to a safe location in the

well and existing cuttings are circulated out of hole. A decision will then be made on the case for drilling ahead without the failed SCE, while still meeting residual OOC discharge limits. Drilling ahead while SCE breakdown assessment and repairs occur is a contingent activity subject to additional controls; however, the standard mode of operation for the management of cuttings to ALARP is to treat cuttings through a dryer. An OOC discharge limit of <6.9% on wet cuttings will be averaged over well sections drilled with NWBM for the well.

Should NWBM be used, mud pit residue may be discharged to the sea where the residue contains <1% oil volume. Where the mud pit residue exceeds 1% by volume, the residue will be retained and disposed of onshore.

Base oil and chemicals used in NWBM are assessed in accordance with the Chemical Selection and Assessment Environment Guideline.

Respud

It is unlikely the well would be required to respud. If required, the most likely scenario is that the decision to respud is made during drilling of the top hole section of the well; therefore, the incremental increase in cuttings and fluids discharges is associated with the repeat drilling of the same top hole sections for the respudded well with the same associated discharges. A respud once drilling of the bottom hole sections has commenced is far less likely, given the time and effort already committed to the well. However, if this was to occur, the associated discharges would also be a repeat of the discharges required to re-drill the same sections of the respudded well.

Permanent Plugging Program and Removal of Well Infrastructure

If required as a contingency activity, the base case for permanently plugging the well includes the use of WBM and wet cement and will produce well annulus fluids (residual hydrocarbons and residual produced formation water). These fluids/cuttings will be generated during the well bore clean-out, drilling of existing cement barriers, installation of permanent abandonment barriers, circulation of the annulus and washing out of the mud pit.

Potential additional activities that may be required as part of the PAP includes milling, which will produce metal swarf, drilled cement and formation rock. All of the downhole plugging for permanent abandonment activities are conducted through the marine riser. This is a closed system, meaning there are no planned discharges directly to sea during these activities. Planned discharges of the above fluids are only planned to occur after they have been received on the MODU.

The following describes the source of impact with respect to discharge of clean-up fluids, well kill fluids, grit and flocculent only. See Section 6.7.9 for cement, cementing fluids and subsea control fluids. For the purposes of this impact assessment, the indicative dimensions, discharge locations and approximate volumes are provided in Table 6-21.

Table 6-21: Estimated discharges of solids and volumes of drilling fluids used for contingency plugging and well infrastructure removal

Description	Discharge Point	Discharge	Approximate Solids Discharged (m^3)	Approximate Fluid Discharged (m^3)	Potential Additional Solids (m^3)	Potential Additional Fluid Discharge (m^3)
Drill out cement plug	Below sea level	WBM and cement cuttings	2	1	0	0
Kill well	Below sea level	Well kill fluid	0	0	0	Discharged if oil concentration is less than 1% by volume or returned to shore if discharge requirements cannot be met
End of well discharge	Below sea level	WBM, brine, mud pit and vessel tank was fluids	0	600	0	0

Milling (potential activity using WBM)	Below sea level	WBM, swarf, cement and formation rock	0	0	2 (swarf) 3 (cement) 3.5 (formation rock)	1600
Milling (potential activity using NWBM)	Below sea level	NWBM, swarf, cement and formation rock	0	0	2 (swarf) 3 (cement) 3.5 (formation rock)	5
Mechanical cutting	Within the well, below the mudline	Metal and cement cuttings from well infrastructure and lubrication for the cutting tool	0	0	Negligible volumes may be released to surface sediments if cut is made at or close to the mudline	
ABWJ cutting	Within the well, below the mudline	Flocculant and grit	4 tonnes (planned to be released within the well, above the top permanent plug with small volumes entering sediments at cutting depth)	250 L (planned to be released within the well, above the top permanent plug with small volumes entering sediments at cutting depth)	Small volumes may be released to surface sediments if cut is made at or close to the mudline	

Drilled Cement

Indicative volumes of drilled cement for the well are outlined in Table 6-21. The shallow cement plug will preferentially be drilled out with WBM. The drilling fluids will pass through shakers to remove the cement cuttings from the drilling fluid before discharging the cement cuttings.

Well Annular Fluids

Well annular fluids refer to the fluids that remain in the wellbore, or annular spaces between the casing. They may consist of weighted drilling fluid and cement-contaminated mud, seawater, barite, cement polymer, and may include small amounts of hydrocarbon. Upon wellhead removal small volumes (~1.5 m^3) of fluid exchange between the annular spaces and the ocean may occur. The exchange will not be instantaneous as the annular spaces are small and the fluids are typically heavier than seawater. In the unlikely event routine wellhead removal techniques are unsuccessful, this fluid exchange is expected to occur over time following sufficient corrosion of the wellhead.

The small volumes and non-instantaneous nature of the release of the well annular fluids is expected to result in rapid dilution to a no-effect concentration within metres of the release location.

Well Bore Clean-out and Well Kill Fluids

If permanent plugging activities are required, the well will generally be displaced from well kill brine to viscosified brine, or cleaned, which may include residual annulus fluid. A chemical clean-out pill or fluids train will be circulated between the two fluids. This will result in a discharge of fluids in accordance with Woodside's internal guidelines to ensure the potential impacts of the chemicals selected are acceptable.

Should there be clean-up brine contaminated with base oil or NWBM, it will be captured and stored on the MODU for discharge if oil concentration is less than 1% by volume, or returned to shore if discharge requirements cannot be met.

If well kill fluid fails to be bullhead pumped into the well, reservoir fluids may need to be bled off at the MODU through well control equipment (dedicated bleed off/well test spread). In this event, well control equipment will be used to separate the well kill fluids from the hydrocarbons and direct the hydrocarbons to be flared, vented or incinerated, depending on a number of factors including the volume, weather conditions, and safety requirements as documented in relevant procedures for this activity. The well kill fluids will be captured and stored on the MODU and discharged overboard if oil concentration is less than 1% by volume or returned to shore if discharge requirements cannot be met.

Milling

If permanent plugging activities are required, there is a potential additional activity where the well casing needs to be milled out (up to 100 m). This will produce milled swarf (2 m³), drilled cement cuttings (~3 m³) and formation rock (~3.5 m³) and will preferentially be completed using WBM. There may be instances where NWBM is required for operational purposes to manage well stability to safe levels. The solids from the WBM or NWBM drilling fluid system (including the swarf, drilled cement cuttings and formation rock) will also pass through the shakers, to separate these solids before discharging them. Given the small volumes of solids and only limited drilling into formation rock, no oil on cuttings (OOC) discharge limits have been applied, as would be the case for a drilling activity. The estimated volume of solids discharged with residual NWBM on them is expected to be about 5 m³ (per 100 m milled interval).

Removal (Cutting) of Well Infrastructure (Contingency)

The planned cutting depth for removal of the wellhead is approximately 3–5 m below the mudline. Discharges from cutting of well infrastructure using either an abrasive water jet cutting method of a mechanical cutting tool are therefore expected to be confined predominately within the well and settle on the top of the permanent plug. During final cut through the conductor pipe, small amounts of flocculant and grit will be released below the mudline to sediments immediately surrounding the well.

Should cutting at a shallower depth be required, these discharges may be released to the seabed surface. For the mechanical cutting tool, discharges will be limited to small quantities of metal and cement cuttings from the infrastructure itself as well as small quantities of lubricant. For the abrasive water jet cutting method, discharges include a small amount of grit and flocculant. Depending on the cutting depth, pressure from the jet cutting could push some of the material up to the seabed surface causing localised smothering of benthic communities as well as create localised and temporary increases in turbidity around the well.

Impact Assessment

Potential impacts to environmental values

Routine and non-routine drilling-related discharges may result in the impacts of:

- change in water quality
- change in seabed sediment quality
- change in seabed habitat
- injury/mortality to marine fauna (benthic communities).

Some fluids are discharged at the sea surface (or just below); and some are discharged at the seabed. Due to water depth at the drilling location (177 m), this will determine the exposure pathway, and hence potential impacts and receptors.

Drill Cuttings and Retained Fluids

Water Quality and Planktonic Communities

Drill cuttings and retained drilling fluid discharges are expected to increase turbidity and TSS levels above ambient concentrations above the seabed (top-hole well section) or in the upper surface layers (bottom-hole well sections with discharge below the water line from the MODU). Drill cuttings discharge will be generally intermittent and of short duration (over a total period of about 15 days) during drilling of the well.

Top-hole well section drill cuttings and drilling fluids (WBM) will be discharged at the seabed. The coarser material (drill cuttings) will deposit on the seabed and the finer sediment material (the WBM) will cause localised elevated TSS in the water column above the seabed surrounding the well. This reduction in water quality will be temporary (limited to the operational discharges during drilling) and subject to rapid dispersion and dilution by prevailing seabed currents.

During bottom-hole well sections, when drill cuttings with retained drilling fluids (WBM) are discharged below the water line (from the MODU), the larger particles, representing about 90% of the mass of the solids, form a plume that drops out of suspension in the water column rapidly and, deposits on the seabed. About 10% of the mass of the solids (the fines predominately composed of drilling fluid) form a plume in the upper surface layer (depending on the depth of discharge from the MODU) that will be transported by prevailing currents away from the MODU and is diluted rapidly in the receiving waters (Neff, 2005, 2010). There is a large body of knowledge indicating a discharge of cuttings with adhered fluids diluting rapidly, finding that within 100 m of the discharge point, a drilling cuttings and fluid plume released at the surface will have diluted by a factor of at least 10,000. Further to that, Neff (2005) states that in well-mixed oceans waters, the plume is diluted by more than 100-fold within 10 m of the discharge site.

Dispersion of the cuttings plume is influenced by a number of factors: particle sized distribution of the cuttings and fluids, operational discharge events and rates and metocean conditions such as ocean current speed. The case studies described in Neff (2005) used WBMs and surface current speeds of 0.15–0.3 m/s. As currents in the PAA are expected to be within this range, and WBMs (bulk discharge) will contribute the largest input to elevated TSS/turbidity during drilling discharges, the dispersion extent as determined by Neff (2005) is considered representative for Xena-03 tie-back activities.

Using the widely accepted dilution factor of 10,000 (Neff, 2005), cuttings (and adhered fluids) are expected to reach 100 mg/L TSS within 100 m of the MODU. Using a conservative ocean current speed of 0.1 m/s, these discharges are expected to disperse to 100 mg/L within ~16 minutes.

Given the generally low concentration of TSS outside the immediate vicinity of the discharge point, due to rapid dispersion of sediment and the short period of intermittent discharge, the plume is not expected to have more than a very highly localised reduction in water quality and area of potential ecological impact. It is not predicted to impact productivity of the water column.

The combination of low toxicity and rapid dilution of unrecoverable NWBMs discharged in association with drill cuttings are of little risk of direct toxicity to water-column biota (Neff et al., 2000).

Injury/mortality to planktonic species may occur due to a change in water quality following discharges of drill cuttings and fluids. Impacts to these organisms can be as a product of both physical and chemical alterations of water quality, predominantly in the water column.

As outlined above, using the widely accepted dilution factor of 10,000 (Neff, 2005), cuttings (and adhered fluids) are expected to reach 100 mg/L TSS within 100 m of the MODU over a period of ~16 minutes. Minimal impact to plankton (phytoplankton, zooplankton and meroplankton (larvae of invertebrates and fish) is therefore expected from the discharge of drill cuttings. Neff (2010) explains that the lack of toxicity and low bioaccumulation potential of the drilling muds means that the effects of the discharges are highly localised and are not expected to spread through the food web (of which planktonic species are the basis).

Impacts to zooplankton from turbidity are associated with variations in predator prey dynamics, which favours planktonic feeders over visual feeders (Gophen, 2015), while impacts to phytoplankton occur due to decreases in available light, therefore reducing productivity (Dokulil, 1994).

Jenkins and McKinnon (2006) reported that levels of suspended sediments greater than 500 mg/L are likely to produce a measurable impact upon larvae of most fish species, and that levels of 100 mg/L will affect the larvae of some species if exposed for periods greater than 96 hours. Jenkins and McKinnon (2006) also indicated that levels of 100 mg/L may affect the larvae of several marine invertebrate species, and that fish eggs and larvae are more vulnerable to suspended sediments than older life stages. However, dilution estimates (e.g., Hinwood et al., 1994; Neff, 2005) suggest suspended sediment concentrations caused by the discharge of drill cuttings will be well below the levels required to cause an effect on fish or invertebrate larvae (i.e., predicted levels are well below a 96-hour exposure at 100 mg/L, or instantaneous 500 mg/L exposure), beyond the immediate vicinity of the discharge.

Due to the low levels of planktonic productivity in the offshore area, plankton populations on a regional scale are not expected to be affected by drilling or well abandonment activities. In addition, due to the open nature of the marine environment of the PAA and associated environmental conditions (i.e., windy, strong currents, etc), the content and dispersive nature of drilling muds within the marine environment and the high population replenishment of these organisms, it is expected that impacts to plankton species will be limited to within tens of metres of the discharge point and return to previous conditions within a relatively short period of time. On this basis, the impacts to plankton from routine and non-routine discharges during drilling activities is slight.

Sediment Quality and Benthic Communities

Accumulation of drill cuttings, grit and flocculent on the seabed causes changes in the physical properties of the seabed sediment such as the particle size distribution (PSD), the introduction of contaminants (metals such as barium) from retained drilling fluids (WBM) and associated ecological effects.

The discharge of drill cuttings and unrecoverable fluids at the seabed during riserless top hole drilling results in a localised area of sediment deposition (known as a cuttings pile) surrounding the well site. The cuttings pile distribution may reflect prevailing seabed currents and spread predominately downstream of the well site but overall extent from the well site is typically tens of metres. The dimensions of the cuttings pile depend on several factors, including volume (approximately 641 m^3 of top hole cuttings) and composition of cuttings, and oceanographic conditions at the discharge location. The top hole well section drill cuttings and retained drilling fluids (WBM) to seabed have the greatest impact to sediment quality and modification of the habitat in proximity to the well, as the solids tend to clump and settle rapidly around the discharge point (Neff, 2010).

Indicative components of the WBM system outlined in Section 3.11.2 have a low toxicity. Bentonite and chemicals from the family of XC polymers (xanthan gum or similar) are listed as ‘E’ category fluids under the OCNS and considered to ‘pose little or no risk to the environment’. Metals such as barium from these additives will be present in the drilling fluid, primarily as insoluble mineralised salts, and consequently are not released in significant amounts to the pore water of marine sediments and have low bioavailability to those benthic fauna which may come into contact with the discharged barite (Crecelius et al., 2007; Neff, 2008). The XC polymer and bentonite sweeps have very low toxicities and are considered by OSPAR to pose little or no risk to the environment.

As described above, the bottom hole sections are drilled after the riser is fitted. Cuttings and unrecoverable fluids are discharged below the water line at the MODU site, resulting in drill cuttings and retained drilling fluids rapidly dispersing through the water column. The larger cuttings particles will drop out of suspension and deposit in proximity to the well site (tens to hundreds of metres distance) with potential for localised spreading downstream, while the finer fluid particles will remain in suspension and will be transported further away from the well site, rapidly diluting and eventually depositing over a larger area (hundreds of metres to several kilometres) downstream of the well site. Drill

cuttings from the bottom-hole sections will be smaller in volume (approximately 482 m³, Table 6-20) and as determined by surface discharge, depth of seabed and time to reach seabed, result in an extended area of deposition, but a much thinner cuttings pile depth (IOGP, 2016). The fines associated with the retained drilling fluids or mud pit bulk discharge of WBM will settle over a greater extended distance as a thin, undetectable veneer on the seabed. Predicted impacts for bottom hole cuttings are generally confined to a maximum of 500 m from the discharge point (IOGP, 2016). The final deposition of drill cuttings and drilling fluids is largely determined by seabed depth and the time to drop out of suspension within the water column and deposit on the seabed. This leads to the coarser cuttings material being deposited at a location offset but closest to the well site in an area downstream and a distance of up to several hundreds of metres, with associated ecological effects within this area and the fines (predominately drilling fluids) dispersed over a greater distance from the discharge site, typically several kilometres but with no associated ecological effects.

Benthic organisms below the cuttings pile will be buried and smothered; however, the cuttings pile is expected to be recolonised over time. Ecological impacts to benthic biota are predicted when sediment deposition is equal to or greater than 6.5 mm in thickness (IOGP, 2016). This amount of sediment deposition from top hole and bottom hole cuttings is expected to be confined to within a few hundred metres around the well location, although this depends on the nature of the cuttings, the water depth and currents of the receiving environment (IOGP, 2016). A conservative radius of 500 m representing a zone of potential ecological impact has been applied to each well location for this impact assessment. Mobile benthic fauna, such as demersal fish, may be temporarily displaced from where cuttings discharges accumulate. Furthermore, ecological impacts are not expected for mobile benthic fauna such as crabs and shrimps or pelagic and demersal fish, given their mobility (IOGP, 2016). Balcom et al. (2012) concluded that impacts associated with discharging cuttings and base fluids are minimal, with impacts highly localised to the area of the discharge deposition on the seabed. Changes to benthic communities are normally not severe. Organic enrichment can occur, leading to anoxic conditions in the surface sediments and a loss of infauna species that have a low tolerance to low oxygen concentrations, and to a lesser extent chemical toxicity near the well location. These impacts are highly localised with short-term recovery that may include changes in community composition with the replacement of infauna species that are hypoxia-tolerant (IOGP, 2016). Recovery of affected benthic infauna, epifauna and demersal communities is expected to occur, given the short duration of sediment deposition and the widely represented benthic and demersal community composition.

It is acknowledged that transport of fines (associated with the drilling fluids) will disperse beyond the zone of potential ecological impact but there are no associated ecological effects expected beyond this zone (500 m distance from each well site). Low levels of sediment deposition away from the immediate area of each well site would represent a thin layer of settled drill cuttings and drilling fluids, which will likely be naturally reworked into surface sediment layers through bioturbation (US Environmental Protection Agency, 2000). Metals such as barium from the drilling fluid additives are used as a tracer of dispersion and are typically detected beyond the zone of ecological impact but as discussed for sediment quality (above), the insoluble mineralised salts (the source of barium) have low bioavailability to benthic biota.

Impacts associated with routine and non-routine drilling discharges will be largely limited to an area surrounding the well. The low sensitivity of the benthic communities/habitats within and in the vicinity of the PAA, combined with the low toxicity of WBMs and residual NWBMs, no bulk discharges of NWBM and the highly localised nature and scale of predicted physical impacts to seabed biota, affirm that any predicted impact is considered likely but of a slight environmental consequence.

Australian Marine Parks and KEFs

The Xena-03 Operational Area overlaps the Continental Slope Demersal Fish Communities KEF (Section 4.7) and is located ~1.75 km from the boundary of the Multiple Use Zone (IUCN Category VI) of the Montebello Marine Park. This zone is managed to allow ecologically sustainable use while conserving ecosystems, habitats and native species (Section 4.8). While drill cuttings will be discharged within the KEF, the highly localised turbidity and sediment deposition effects will not affect demersal fish communities, beyond temporary avoidance behaviour for some individual fish. Within the conservatively applied zone of potential ecological impact (500 m radius) burial or smothering of epifauna and infauna will be largely confined to close proximity to the wellhead. Recovery of affected benthic infauna, epifauna and demersal fish communities is expected to occur, given the short duration of sediment deposition and the widely represented benthic and demersal community composition. The small portion of the overall KEF area that overlaps the Xena-03 Operational Area, in combination with the predicted recovery of the affected benthic communities, affirms that any predicted impact is considered to be a slight, short-term effect. Given that the Xena-03 wellhead location is ~5.8 km from the boundary of the Multiple Use Zone, potential for drilling discharges to impact the values of the Montebello Marine Park is not expected.

Cultural Heritage

The Xena-03 Operational Area is located further offshore than the Ancient Coastline at 125 m depth contour KEF (Section 4.7). The Xena-03 Tie-back activities do not pose a risk to Indigenous Cultural features on the Ancient Landscape between the mainland and the Ancient Coastline KEF.

Drilling Fluids (Bulk Discharge)

WBM may be bulk discharged at the end of specific well sections, as described above, where there is a requirement to change the drilling fluid system, or the drilling fluid cannot be re-used (due to deterioration/contamination). A small

quantity of WBM and NWBM residue (<1%) may also be discharged at the sea surface while cleaning the mud pits, typically at the conclusion of drilling activities or when changing between mud types.

Discharge of WBM will result in a buoyant plume of fine materials that will rapidly dilute and decrease in turbidity levels immediately away from the discharge point. WBM samples collected by Jones et al. (2021) from the mud pits just before discharge during the Greater Western Flank-2 drilling campaign were ~90% silt sized (<62.5 µm) with a mean diameter of 12 µm (gel-polymer) and 33 µm (KCl-polymer). Total suspended solid (TSS) levels in the gel-polymer mud and KCl-polymer mud were 257 g/L and 245 g/L respectively. Jones et al. (2021) used an ROV to observe mud pit discharges and reported the discharge to exit the discharge outlet as a jet of material in a distinctive cloud-like plume descending rapidly to the seabed and growing in diameter with increasing depth.

The subsea plume can be expected to disperse over a wide area (up to several kilometres), with no discernible sediment deposition on the seabed and no physical or biological impacts, particularly given the water depth at the drilling location (176 m). Impacts beyond the 500 m zone of ecological impact for the well as described for drill cuttings and retained fluids discharge is not expected.

Subsea – Displacement, Completion and Well-bore Cleanout Fluids

Discharges such as displacement, completion and wellbore cleanout fluids are typically inert and of low toxicity. These fluids are mostly brine, with a small proportion of chemical additives such as surfactants, biocide, corrosion inhibitor, oxygen scavenger, MEG and guar gum. The volume of one wellbore and subsequent discharge volume would be ~400 m^3. Any change to water quality is expected to be localised and temporary. Rapid dilution due to prevailing ocean currents in the open water environment would lead to any changes in water quality such as low toxicity contaminants being temporary (only for the duration of the discharge) and reducing water quality within a short distance of the discharge location.

Removal (Cutting) of Well Infrastructure (Contingency)

The planned cutting depth is approximately 3–5 m below the mudline, therefore discharges from cutting of well infrastructure using either an abrasive water jet cutting method of a mechanical cutting tool are expected to be confined predominately within the well and settle on the top of the permanent plug. During final cut through the conductor pipe, small amounts of flocculent and grit will be released below the mudline to sediments immediately surrounding the well.

Should cutting at a shallower depth be required, however, these discharges may be released to the seabed surface. For the mechanical cutting tool, discharges will be limited to small quantities of metal and cement cuttings from the infrastructure itself as well as small quantities of lubricant. For the abrasive water jet cutting method, discharges include a small amount of grit and flocculent. Depending on the cutting depth, pressure from the jet cutting could push some of the material up to the seabed surface causing localised smothering of benthic communities as well as create localised and temporary increases in turbidity around the well. All chemicals used for infrastructure removal are assessed in accordance with the Woodside Chemical Selection and Assessment Environment Guideline.

Cumulative Impacts

The seabed around the Xena-03 well is in close proximity to other wells and hence the discharge of drill cuttings and drilling fluids from the well may result in cumulative impacts. The benthic habitats and communities that may be impacted by the discharge of drill cuttings and fluids are widely represented in the region and not of high conservation value. The area within which cumulative impacts may occur is relatively small and would be substantially smaller than the area impacted directly by drill cuttings and fluids discharges. Other aspects of the PAP that may impact upon benthic habitats will be localised around the Xena-03 wellhead and subsea infrastructure; hence the potential area impacts by cumulative impacts from other aspects is very small. Recovery is expected to occur through natural processes. Hence cumulative impacts will be slight and of no lasting effect (i.e., Environment Impact – F).

Summary of Potential Impacts to Environmental Values

Given the adopted controls, it is considered that routine discharges of drill cuttings and drilling fluids described will not result in a potential impact greater than slight, short-term impact (less than one year) on species, habitat (but not affecting ecosystems function), physical or biological attributes (i.e., Environment Impact – E).

Good Practice				
Implement Woodside's Chemical Selection and Assessment Environment Guideline: • Where Gold/Silver/E/D OCNS rating (and no OCNS substitution or product warning), chemicals are selected – no further control required. • If chemicals with a different OCNS rating, sub warning or non-OCNS rated chemicals are required chemicals will be assessed in accordance with the guideline prior to use.	F: Yes. Routinely implemented to the chemical selection process for Woodside facilities. CS: Minimal cost. Standard practice.	Selection and assessment of chemicals in accordance with the Woodside process, reduces environmental impacts associated with planned chemical discharge.	Control is a WMS requirement – must be adopted.	Yes C 5.1
For Xena-03 Tie-back activities fluids, six-monthly chemical reviews are performed during active drilling campaigns.	F: Yes. CS: Minimal cost. Standard practice.	Regular reviews will ensure chemicals selected for drilling fluids remain ALARP.	Benefits outweigh cost/sacrifice.	Yes C 5.5
Written NWBM justification process followed.	F: Yes. CS: Minimal cost. Standard practice.	The written justification takes onboard the technical need for NWBM use, receiving environment, cost and additional controls that may be required. By undertaking formal assessment, the potential impacts are well understood, allowing for development of control measures to reduce the consequence of NWBM use. This provides an overall environmental benefit.	Benefits outweigh cost/sacrifice.	Yes C 8.1
NWBM base oils selected based on expected toxicity.	F: Yes. CS: Minimal cost.	By selecting a base oil with lower toxicity, the consequence of the release on the environment is reduced.	Benefits outweigh cost/sacrifice.	Yes C 8.2
Backload bulk NWBM or maintain on rig for re-use.	F: Yes. CS: Minimal cost. Standard practice.	By restricting the volume of NWBM for overboard discharge, the consequence of	Benefits outweigh cost/sacrifice.	Yes C 8.3

		the release on the environment is reduced. Although no change in likelihood is provided, the decrease in consequence results in an environmental benefit.		
Bulk operational discharges conducted under MODU's Permit to Work (PTW) system (to operate discharge valves/pumps).	F: Yes. CS: Minimal cost. Standard practice.	The MODU's PTW may slightly reduce the volumes of bulk discharges occurring, but it is unlikely to be significant given that bulk discharges are often operationally required and cannot be eliminated.	Benefits outweigh cost/sacrifice.	Yes C 8.4
Displacement, brine, workover or intervention fluids contaminated with hydrocarbons will be treated prior to discharge or containment. If discharge specification not met, the fluid will be returned to shore.	F: Yes. CS: Minimal cost. Standard practice.	Ensuring <1% oil content will provide a small reduction in consequence when fluids are discharged to the environment.	Benefits outweigh cost/sacrifice.	Yes C 8.5
SCEt used to treat NWBM cuttings prior to discharge.	F: Yes. CS: Minimal – more frequent cuttings sampling and testing.	Achieving average oil on cuttings (sections using NWBM only) discharge limit of 6.9% or less oil on wet cuttings will have a small reduction in consequence.	Benefits outweigh cost/sacrifice.	Yes C 8.6
In event of SCE failure (including auger) while drilling with NWBM, the initial action will be to cease drilling and determine whether to repair SCE or drill ahead until next practicable opportunity to trip out of the hole. If cuttings are discharged during dryer or auger failure, measurement of OOC to occur more frequently from shakers.	F: Yes. CS: Cost and schedule implications due to cessation of drilling.	Ceasing of drilling in the event of equipment failure will allow for time to assess feasibility of drilling ahead while still meeting residual OOC discharge requirements.	Benefits outweigh cost/sacrifice.	Yes C 8.7

Control Considered	***Control Feasibility (F) and Cost/ Sacrifice (CS)[68]***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
	– deck congestion due to large footprint of the plant.			
Time restricted discharge of WBM and/or cuttings to align with tide/current or other oceanographic events.	F: Yes. CS: Disruption to drilling operations in having to stop drilling at time when discharge of WBM and/or cuttings might not be permitted. Additional mud storage volume required.	Given the offshore location, oceanographic changes are unlikely to significantly affect the dispersion of cuttings and therefore no environmental benefit would be gained.	Disproportionate. The cost/sacrifice outweighs the benefit gained – no hard coral or other photosensitive benthic communities in the vicinity of the well to rationalise phased/ timed discharge.	No
ALARP Statement: On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts and risks of drill cuttings and fluids discharges to the marine environment. As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.				
Demonstration of Acceptability				
Acceptability Statement: The impact assessment has determined that, given the adopted controls, routine discharges of drilling cuttings and fluids to the marine environment are unlikely to result in a potential impact greater than slight, short-term impact (less than one year) on species, habitat (but not affecting ecosystems function), cultural heritage, physical or biological attributes. Further opportunities to reduce the impacts and risks have been investigated above. The adopted controls are considered good oil-field practice/industry best practice. The potential impacts and risks are considered broadly acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the impacts and risks of these discharges to a level that is broadly acceptable and demonstrates the EPO has been met.

Description of Source of Impact

Cement, Cementing Fluids, Grout, Subsea Well Fluids and Unused Bulk Products at End of Drilling Campaign

Cementing Fluids, Cement and Grout

Cementing fluids, including cementing mix water, may require discharge to the marine environment under various scenarios during drilling and tie-back activities for the Xena-03 well.

At the commencement of the drilling campaign there may be a requirement to run a cement unit test to ensure the functionality of the cement unit and the cement bulk delivery system prior to performing an actual cement job. This test would result in a small volume of approximately 10 m^3 of cement slurry being discharged at the sea surface. The slurry is usually a mix of cement and water however may contain stabilisers or chemical additives.

When cementing the conductor and surface casings after top hole sections of a well have been drilled, cement must be circulated to the seabed to ensure structural integrity of the well. Excess cement is pumped so that structural integrity is achieved. If the hole is completely in-gauge and there are no downhole losses while pumping the cement, a maximum volume of 80 m^3 is estimated to be circulated to the seabed at the well location, which forms a thin concrete film on the seabed in close proximity to the well.

Wherever possible, the cement line flush volumes are included in the planned cement jobs. After each cement job, leftover cement slurry in the cement pump unit and the surface lines is flushed and discharged to the sea to prevent clogging of the lines and equipment. This is estimated at about 10 m^3 discharged. In the unlikely event a respud event is required it would result in additional cement jobs. Also, in the rare event that the cement products become contaminated, the entire volume (~180 m^3) may need to be discharged to sea.

Cement spacers can be used as part of the cementing process, within the well casing, to assist with cleaning of the casing sections prior to cement flow through. The spacers may consist of either seawater or a mixture of seawater and dye. The dye is used to provide a pre-indicator of cement overflow to the seabed surface, to ensure adequate cement height.

If grout bags are used, after grouting activities at each span site, the downline and pump will need to be purged using seawater. This will result approximately 5 m^3 (downline volume) of grout discharged to the ocean. This flushing is required once per grout site.

Subsea Fluids – Blow Out Preventors (BOP) and Well Construction Activity Control Fluids

Subsea fluids are likely to be released during drilling, including the release of BOP control fluids. Subsea control fluids are water-based hydraulic control fluids used in control systems on the subsea trees and BOPs. The BOP is required, by legislation, to be regularly function tested when subsea.

Subsea control fluids will be discharged during function testing of the BOP on installation and pressure testing.

The BOP is function-tested during assembly and maintenance and during operation on the seabed, as described in Section 3.11. As part of this testing, small volumes of BOP control fluid (generally consisting of water mixed with a glycol based detergent or equivalent water-based anti-corrosive additive) are released to the marine environment.

Each time a pressure and function test is undertaken approximately 3620 L of water-based fluid is released to the marine environment, of this approximately 4% is control fluid additive. BOP operation includes function and pressure testing approximately every 21 days, and a function test (approx. 2665 L) approximately every seven days, excluding the week a pressure test is conducted.

Subsea Fluids – Displacement Fluids

As required throughout activities with the riser connected, the well will be displaced from one drilling fluid system to another. A chemical clean-out pill or fluids train will be circulated between the different fluids. This will result in a discharge of operational fluids in accordance with the Woodside internal guidelines.

Produced/Reservoir Water

If well unloading activities were to occur, a temporary production system water filtration treatment package will be used to treat produced/reservoir water before discharge. Prior to discharging, the fluids are cycled through an oilbond filtration system and gauge tank. Water filtration is standard practice for well unloading operations and the produced water will be treated to meet 30 ppm OIW. Fluids that cannot be treated or flared will be sent onshore in tanks for disposal.

Non-Routine Discharge of Unused Dry Bulk Products at the End of the Drilling Campaign:

Adequate stocks of dry bulk product are required to be stored on the MODU for the duration of the drilling activity for safe operations and well control purposes, as defined in the Woodside Well Control Bridging Document. Approximate quantities typically required are:

- cement: approximately 100 tonnes
- barite: approximately 120 tonnes
- bentonite: approximately 120 tonnes.

At the end of the drilling activity and prior to demobilisation, Woodside is contractually obliged to remove the dry bulk product from the MODU. A number of options for removing excess product from the MODU exist, with the last option being to discharge to the marine environment. Woodside has developed a process to assess all safe and technically feasible options for the excess product before a decision is made to discharge overboard. This includes considering the following options, as described below and illustrated in Figure 6-7:

- Retain products on the MODU to be used for subsequent Woodside drilling activities where the activity is not the last in the Woodside MODU sequence.
- Retain products on the MODU to be used by the next titleholder who has the MODU on hire.
- Transfer to another Woodside contracted MODU operating in the region.
- Transfer to another titleholder-contracted MODU operating in the region.
- Return to shore for onshore storage and/or disposal if a facility is available that is both safe and technically feasible to transfer dry bulk products to.
- Discharge to the marine environment as a slurry as a last resort, if it is concluded that no other options outlined in Figure 6-7 are feasible and that concentrations of mercury and cadmium in barite are <1 mg/kg and <3 mg/kg, respectively.

Woodside's base plan is to retain dry bulk products on board the MODU at the end of the campaign, either for reuse by Woodside (if a subsequent Woodside drilling activity is contracted after the petroleum activity), or transfer the dry bulks to the next titleholder who has the MODU on hire. At the time this EP was written it was not yet confirmed whether Woodside would be contracting the MODU for subsequent petroleum activities or if there was another titleholder who planned to contract it.

If there are no available options to leave the dry bulk products on the MODU, Woodside would look to transfer excess dry bulk product to another MODU operating in the region, either for Woodside use or for another titleholder. MODU schedules and regional activities are closely monitored to identify these transfer opportunities early, allowing sufficient time to coordinate transfer arrangements. At the time this EP was written, it was not yet confirmed if there was another MODU to transfer dry bulk product to, and this opportunity typically presents towards the end of a drilling activity. Woodside has a proven record of transferring dry bulk materials for reuse between operators and offshore facilities within these timeframes.

The backload of dry bulks to shore at the end of the campaign has been explored with Woodside's fluids providers. However, current onshore infrastructure does not support the safe transfer of bulk product at high pressure. When the MODU receives bulk product from a shore base, it involves the pneumatic transfer of product from a lower pressure container/tank to the higher pressure MODU or supply vessel container/tank. However, transfer of bulk product from the MODU to shore would involve the transfer of that material, which is powder, from a high pressure to low pressure mobile tank. These high to low pressure transfers of dry powder carry safety risk as the pressure differential between the two systems can result in an uncontrolled, or rapid fluid flow causing pressure build up, beyond safe limits. Dry bulk products can be transported from shore when initially processed given the manufacturing locations have necessary infrastructure to package bulks in bags for transportation and sale, including bagging machines. These dry bulk products cannot be returned to shore in this same manner. Once the product is transported offshore, it is stored in tanks under high pressure conditions. To return product to shore in the same manner it is initially transported from manufacturing location, the product would need to be high-pressure transferred from the MODU or support vessel tanks to bags, which is not considered to be feasible.

During the PAP Woodside will continue exploring the feasibility of installing appropriate infrastructure including pressure release valves and other transfer equipment to enable safe transfer of dry bulk product to shore.

If reuse of excess bulks for subsequent activities in the region is not possible and no feasible options for safe transfer of dry bulk product are identified by completion of the campaign, excess dry bulk will be discharged to the marine environment in the form of a slurry. This will only occur if it can be demonstrated that there are no other options identified in Figure 6-7. Use and discharge of all chemicals and products will be conducted in line with Woodside's internal guidelines (Section 3.9).

Dry bulk materials generally pose little or no risk to the environment (PLONOR)[69], though barite may contain traces of heavy metals, such as mercury and cadmium. Woodside requires that concentrations of mercury and cadmium in barite be <1 mg/kg and <3 mg/kg, respectively. This conforms to the American Petroleum Institute (API) specification for drilling barite. Heavy metal analysis is conducted on individual batches of stock barite prior to mobilisation offshore. This sampling confirms that heavy metals of concern (cadmium and mercury) are within limits prescribed by API standards.

[69] Barite (as barium sulphate) is on the OSPAR List of Substances Used and Discharged Offshore which are Considered to Pose Little or No Risk to the Environment (PLONOR). The list is available at: https://www.cefas.co.uk/media/p3sbu3bn/ospar-list-of-substances-used-and-discharged-offshore-which-are-considered-to-pose-little-or-no-risk-to-the-environment-plonor-update-2021.pdf.

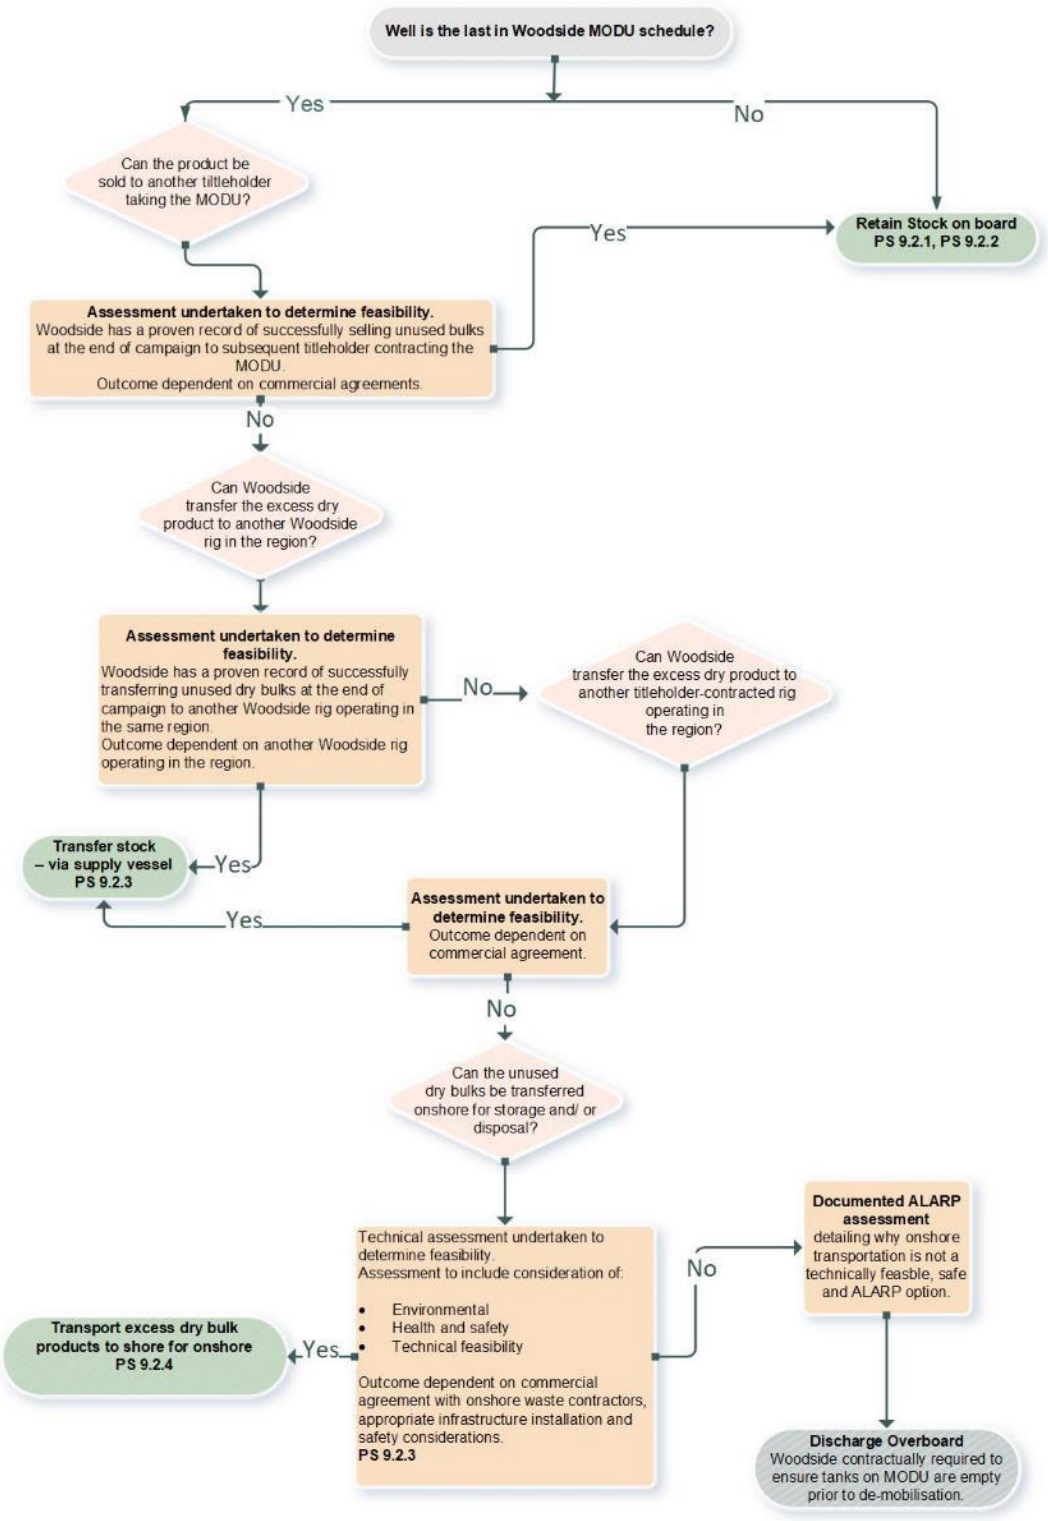

Figure 6-7: Management process for excess bulk product

Impact Assessment

Potential Impacts to Environmental Values

Pelagic and benthic habitats and communities in the Xena-03 Operational Area are considered to be of low sensitivity and reflective of the wider NWMR. No known regionally significant benthic or infauna habitat occur in the area. The

Continental Slope Demersal Fish Communities KEF overlaps the Xena-03 Operational Area (Section 4.7); however, the targeted well location is not located within the KEF. Impacts to values and sensitivities of this KEF are not expected due to the location of the well, small physical footprint of the discharges, coupled with the low toxicity of cementing and subsea fluids used for the Petroleum Activities Program. The likelihood of any significant impact to marine biota is subsequently considered to be low.

Cement and Grout

Sediment Quality and Benthic Communities

Impacts of cement and grout on the marine environment are predominantly associated with localised burial of benthic biota in the direct physical footprint of deposition. Cement operations and grout discharge during drilling involve routine and non-routine discharges that can result in turbidity in the water column. Reduction in water quality will be temporary (limited to the cement operational discharges during drilling) and subject to rapid dispersion and dilution by prevailing currents. Modelling of cement discharges for another offshore project (BP Azerbaijan, 2013) was used because it provides an appropriate, but conservative, comparison of the potential extent of exposure from this activity. In this study, two hours after the start of discharge, plume concentrations were determined to be between 5 and 50 ppm with the horizontal and vertical extents of the plume ~150 m and 10 m, respectively (BP Azerbaijan, 2013). Five hours after ceasing the discharge, modelling indicates that the plume will have dispersed to concentrations <5 ppm.

Cement is the most common material currently used in artificial reefs around the world and is inert. The potential for toxicity is associated with chemical additives that may be added to cement mixtures. Therefore, the toxicity associated with the discharge of cement is limited to the subsurface release of cement (not discharge of slurrified or dry cement). Once the cement has hardened, chemical additives are locked into the cement (Terrens et al., 1998) and not expected to pose any toxicological risk to benthic biota from leaching or direct contact. Most cement discharges that will occur during the drilling activities will be at the seabed during cementing of the casing. Once overspill from cementing activities hardens, the physical sediment properties of the area directly adjacent to the well (10–50 m) will be permanently altered (Terrens et.al., 1998). The potential disturbance area is an estimated 0.007 km^2. Cement discharges at the seabed will overlap with the highest deposition of drill cuttings and drilling fluids. The highly localised physical footprint at the well site is not expected to affect the overall diversity or ecosystem function of the benthic communities of the area.

The potential impacts to benthic communities caused by smothering from a surface release of cement or a seabed release of grout are expected to be significantly less, due to small volumes, intermittent nature of these discharges, and high potential for dispersal by ocean currents. This impact on soft sediment communities is not expected to affect the diversity or ecosystem function in this area and is only considered a short-term impact.

Australian Marine Parks and KEFs

The Xena-03 Operational Area overlaps the Continental Slope Demersal Fish Communities KEF and is located ~1.75 km from the boundary of the Multiple Use Zone (IUCN Category VI) of the Montebello Marine Park. The targeted Xena-03 well location is ~2.5 km from the Continental Slope Demersal Fish Communities KEF and ~5.8 km from the boundary of the Multiple Use Zone. The potential for interaction is limited to a surface release of cement within the overlapping KEF. However, as described above, the surface release of cement or the seabed release of grout will be highly localised around the well location. Recovery of affected demersal fish communities is expected to occur, given the small volume and dispersion, and the widely represented benthic and demersal community composition. The small portion of the overall KEF area that overlaps the Xena-03 Operational Area, in combination with the predicted recovery of the affected benthic communities, affirms that any predicted impact is considered to be a slight, short-term effect. Given that any cement or grout releases to the marine environment will be highly localised to the well location and the distance from the well location to the Multiple Use Zone boundary, potential impact to the values of the Montebello Marine Park is not expected.

Cultural Heritage

The targeted Xena-03 well location (~176 m) and Xena-03 Operational Area is not located within the Ancient Coastline at 125 m depth contour KEF, which extends from the 115–130 m isobath (Section 4.7). The targeted well location is ~4.5 km from the Ancient Coastline at 125 m depth contour KEF, The Xena-03 Tie-back activities do not pose a risk to Indigenous cultural features on the Ancient Landscape between the mainland and the Ancient Coastline KEF.

Cementing Fluids, Subsea Well Fluids (BOP Control Fluids and Well Displacement Fluids) and Other Unused Bulk Products

All chemicals that may be operationally released or discharged to the marine environment by the PAP are evaluated using a defined framework and set of tools to ensure the potential impacts of the chemicals selected are acceptable, ALARP and meet Woodside's expectation for environmental performance. Therefore, any chemicals selected and potentially released are expected to be of low toxicity and biodegradable. Additionally, where cements have been mixed in excess and cannot be reused or returned to shore, these will be turned into a slurry. As chemicals have initially been chosen based on the environmental performance and based on an ALARP assessment, additional dilution prior to discharge further reduces the environment impact to water quality, sediment quality and marine benthic and/or infauna communities. Given the minor quantities of routine and non-routine planned discharges, short

discharge durations and the low toxicity and high dispersion in the open, offshore environment, any impacts on the marine environment are expected to be slight and short-term.

Summary of Potential Impacts to Environmental Values

The overall impact significance level for routine and non-routine discharges of cement, cementing fluids, subsea well fluids and unused bulk product is E based on slight, short-term impact (less than one year) on species, habitat (but not affecting ecosystems function), physical or biological attributes.

		often operationally required and cannot be eliminated.		
Displacement, brine, workover or intervention fluids contaminated with hydrocarbons will be treated prior to discharge or contained. If discharge specification not met the fluid will be returned to shore.	F: Yes. CS: Minimal cost. Standard practice.	Ensuring <1% oil content will provide a small reduction in consequence when fluids are discharged to the environment.	Benefits outweigh cost/sacrifice.	Yes C 8.5
During well unloading and completions activities, if PW is not flared, it will be processed through the well test water treatment package prior to discharge to the environment.	F: Yes. CS: Minimal cost. Standard practice.	Reduced toxicity to the marine environment when discharged.	Benefits outweigh cost/ sacrifice.	Yes C 9.1
Professional Judgement – Eliminate				
Do not use BOP control fluids.	F: No. BOP and xmas tree control fluids are critical to the operation of the BOP and xmas trees. CS: Not considered, control not feasible.	Not considered, control not feasible.	Not considered, control not feasible.	No
Excess dry bulk products will be managed as per Figure 6-7.	F: Yes. However, the cement may not meet the required technical specifications, and hence not be usable. CS: Minor administrative costs associated with coordinating reuse opportunities. Cost savings associated with the re-use or on sell of the dry bulk products. Moderate cost associated with onshore transportation and/ or disposal, if deemed feasible.	Reusing bulk products or identifying an opportunity for it to be returned to shore may eliminate any environmental impacts associated with discharge to the marine environment, where these options are safe and technically feasible. Furthermore, following the process outlined in Figure 6-7 confirms that discharge to the marine environment only occurs when there are no other safe or technically feasible options and therefore when ALARP.	Benefits outweigh cost/sacrifice.	Yes C 9.2

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost /Sacrifice (CS)[70]***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Sampling/analysis of stock barite to ensure acceptable levels of heavy metals (i.e., concentrations of mercury and cadmium in barite are <1 mg/kg and <3 mg/kg, respectively).	F: Yes. CS: Minimal cost. Standard practice.	Barite may contain heavy metal such as cadmium and mercury, depending on its geological origin. Limiting the concentrations of cadmium and mercury is consistent with industry good practice. Limiting cadmium and mercury concentrations in barite reduces the environmental risk from discharges of barite to the environment.	Benefits outweigh cost/sacrifice.	Yes C 9.3
Professional Judgement – Substitute				
No additional controls identified.				
Professional Judgement – Engineered Solution				
No additional controls identified.				
ALARP Statement: On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts and risks of cement, cementing fluids, subsea well fluids and unused bulk products. As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.				

Demonstration of Acceptability
Acceptability Statement: The impact assessment has determined that, given the adopted controls, cement, cementing fluids, subsea well fluids and unused bulk products discharges are unlikely to result in an impact greater than slight, short-term impact (less than one year) on species, habitat (but not affecting ecosystems function), physical or biological attributes. Further opportunities to reduce the impacts have been investigated above. The adopted controls are considered good practice. When considering the broader acceptability of the potential impacts consideration has been given to the legislative context, including International Conventions such as the Minamata Convention. Woodside has undertaken an assessment of the PAP and the Minamata Convention (including measures in Article 9(5), and considers that the PAP is not inconsistent with the Minamata Convention. The potential impacts are considered broadly acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the impacts of these discharges to a level that is broadly acceptable and demonstrates the EPO will be met.

Description of Source of Impact

Air emissions generated during the PAP can be classified into two categories:

- Atmospheric pollutants (non-greenhouse gas emissions) are gases and particulates from an activity, or piece of machinery, which have a recognised adverse effect on human health and/or flora and fauna. The main emissions responsible for these effects include carbon monoxide (CO), oxides of nitrogen (NOx), sulphur

dioxide (SO2), particulate matter less than 10 microns (PM10), non-methane volatile organic compounds (VOCs) including BTEX (benzene, toluene, ethylbenzene and xylenes).

- Greenhouse gas (GHG) emissions. GHG emissions refers to those gases within the atmosphere that absorb long-wave radiation, and thus trap heat reflected from the earth's surface. The main gases associated with this effect include carbon dioxide (CO2), methane (CH4) and nitrous oxide (N2O). Other GHGs include perfluorocarbons (PFCs), hydrofluorocarbons (HFCs) and sulphur hexafluoride (SF6). There are considered to be both direct and indirect GHG emissions.

In this section, atmospheric emissions estimates are developed in line with the National Pollutant Inventory (NPI) emission estimation techniques (EET). GHG emissions are estimated using the National Greenhouse and Energy Reporting (NGER) Measurement Determination 2008 (Cth). The following section has been separated into Direct Emissions (Scope 1 and 2) and Indirect Emissions (Scope 3), aligned with the definitions of the GHG Protocol Corporate Standard (GHG Protocol 2015) and NGERS.

The main sources of GHG emissions associated with the PAP are shown in Table 3-7. GHG emissions sources that are not part of the PAP (e.g. GHG emissions from the onshore processing of Pluto gas) are included for consideration as indirect emissions. In the context of this EP, GHG emissions are classified as direct and indirect emissions, as shown in Table 3-7.

The GHG Protocol 2015 defines indirect GHG emissions as *emissions that are a consequence of the activities of the reporting entity but occur at sources owned or controlled by another entity*. For the purposes of this EP, the "reporting entity" is the Pluto offshore facility and therefore, onshore processing and support vessel/helicopter operations are considered indirect emissions sources.

Climate change is caused by the net global concentration of greenhouse gases in the atmosphere. Human-caused climate change is a consequence of more than a century of net GHG emissions from energy use, land use change, lifestyle patterns of consumption, and production (IPCC 2023). The IPCC has stated that observed increases in GHG concentrations since 1750 leading to climate change are unequivocally caused by human activities and that there is a near linear relationship between cumulative anthropogenic CO_2 emissions and the global warming they cause (IPCC 2023).

Direct Atmospheric and Greenhouse Gas Emissions – Pluto Operations

Direct atmospheric emissions from the Pluto facility during the PAP include emissions from flaring, equipment and generators, fugitives and process vents. Direct emissions and combustion products typically include CO_2, water vapour, NO_x, SO_2, methane, refrigerant gases, particulates and VOCs.

The emissions estimates presented provide a conservative estimate of activities and operations over the next five-year period of the Pluto Facility Operations EP. Direct GHG emissions are estimated to average up to approximately 37,700 t CO_2-e p.a during this period based on facility design values, and consideration for potential maintenance activities and system reliability upsets. Of this, approximately 2,220 t CO_2-e p.a. are predicted to be from methane. This is around 6% of the total.

Variance within the period may occur, due to a number of factors such as reservoir and production system performance outcomes, planned activities including shutdowns and maintenance activities and unplanned reliability events. Emissions estimates below are provided as a reasonable estimate to inform an impact and risk assessment associated with activities requiring emissions to air. Historical emissions are lower than this due to high Pluto-system reliability, limited flaring, and recent installation of the PWH.

Greenhouse gas emissions associated from Xena-03 drilling and tie-back activities is estimated to be approximately 13,300 t CO_2-e.

Atmospheric Emissions – Flaring: Historical Emissions, Prior to Water Handling Module

Prior to the PWH start up, flaring has been the largest source of combustion emissions from the riser platform. The combustion of hydrocarbon gas by flaring is an essential practice, primarily for safety requirements. Operational flaring is comprised of two elements:

- normal operational flaring typically associated with flare system purge and pilot and process flows from produced water separation system
- non-routine flaring that may result from activities such as planned shutdowns, ESD testing and pigging, and unplanned shutdowns and ESDs, production restarts, equipment outage/failures, subsea flowline depressurisation and well remediation activities.

During flaring, the burnt gas generates mainly water vapour and CO2. Gas flaring has the potential to increase the volumes of GHGs emitted to the atmosphere. Flaring also consumes natural gas, a non-renewable resource. The efficiency of the facility flare is estimated to be approximately 98%. Incomplete combustion under certain scenarios may also generate dark smoke.

During normal operations, approximately 540 tonnes of gas are flared per year due to purging and maintenance of a pilot (based on data between 2020 and 2024).

Atmospheric Emissions – Flaring: Water Handling Module Normal Operations

Additional sources have been routed to flare as a result of recent commencement of PWH operations with sources from the produced water degasser and the horizontal induced gas flotation (HIGF) processes. Following full ramp-up of PWH operations, combined continuous low-pressure flows to flare are estimated to result in approximately 3500 tonnes flaring per annum.

Atmospheric Emissions – Intermittent Flaring Required to Operate the Water Handling Module and Integrated Subsea System

It is estimated that intermittent flaring may total approximately 4500 tonnes of gas per year associated with operation of the PWH and integrated subsea system. Flaring will vary as a result of production rates and non-routine activities, outages and shutdowns, and is key to safe operation of the facility and integrity management of the subsea system (particularly pressure management in case of upset to prevent hydrate formation) as outlined in Section 3.7.1.

Atmospheric Emissions – Flaring: Non-routine Flowline Pigging

Flaring to facilitate round-trip pigging of the flowlines is an integral part of operation and maintenance of the facility and occurs as required (approximately once every four years). Non-routine flowline pigging is expected to result in approximately 8300 tonnes of flaring in order to transport flowline pig(s) through the subsea flowline system.

Atmospheric Emissions – Fuel Consumption

Diesel for fuel combustion has been used for the operation of the crane, and survival craft, and main power generation prior to the installation of the water handing module. Diesel usage on the facility (excluding support vessels) between 2016 and 2023 ranged between 202 tonnes and 632 tonnes. The 2016–2017 period (330 tonnes) represented a typical NNC year, while the 2022–2023 period reflects an increased diesel use year as a result of ongoing topside modifications and continuous crewing of the NNC facility associated with the tie-in of the PWH.

Operation of the PWH requires power generation and fuel usage. To accommodate this, installation of the Water Handling Module during 2023 also included installation of a gas engine generator as the main source of power on PLA. Two existing diesel engine generators remain on the platform for backup power generation. When the PWH is operating at design flow rates, the gas engine generator is expected to consume a maximum estimated 147 kg/hr (1286 t/y fuel gas). Diesel use will continue for operation of diesel generators as backup and certain peak demand needs, as well as the crane and survival craft. Since achieving operation of the Water Handling Module gas engine, and completion of crewed offshore project activities, annual emissions from diesel combustion have decreased.

The current arrangement for power generation is:

- gas engine generator
- diesel engine generators.

Grid Stability Module (contingent power supply)

There are several operating conditions that will use various arrangements for power generation as outlined in Table 6-22. Emissions estimates from these different modes and sources are summarised in Table 6-23 and Table 6-24.

Table 6-22: Power generation configuration list

No.	Scenarios	Configuration
1	Uncrewed normal production	Gas Engine Generator priority: • 1 generator online • 2 generators offline standby • 1 grid stability module online
2	Flowline depressurised	Gas Engine Generator priority: • 2 generators online • 1 generator offline standby • 1 grid stability module online
3	Production recovery	
4	Start-up (warm-up) production recovery from ESD

6	Campaign maintenance	
7	Campaign maintenance, UPS discharge test	
8	Shutdown maintenance	

Emissions Estimates

The following sections provide direct emissions estimates associated with annual fuel combustion for power generation, routine and non-routine flaring, and fugitives required in the operation of the Pluto offshore facility.

Table 6-23: Estimated annual atmospheric emissions consumed in operations for power generation

Emission Type	Estimated Annual Emissions from Diesel Combustion	Estimated Total Annual Emissions from Gaseous Fuel Combustion[1]
Source/Fuel	330	1286
CO_2 (t/yr)	1032	3558
CH4 (tCO_2-e/yr)	1	7
N2O (tCO_2-e/yr)	3	2
Total CO_2-e (t/yr)	1036	3567
NO_x (t/yr)	5	120
SO_x (t/yr)	0	0
VOCs (t/yr)	2	3
PM10 (t/yr)	2	0
CO (t/yr)	5	16

[1] Based on combustion of 1286 tonnes of fuel gas required for gas engine generator operation at design capacity.

Table 6-24: Estimated annual atmospheric emissions from routine and non-routine flaring sources

Activity	Routine	Non-routine	
	Routine operations flared gas combustion	Flaring during shutdown, blowdown and start-up events (includes blowdown, warm-up, and infrequent flowline depressurisation)	Estimated emissions from flared gas combustion required for infrequent flowline pigging
Total Gas (t/yr)	3957	4532	8300
CO_2 (t/yr)	10,684	12,236	22,410
CH_4 (tCO_2-e/yr)	526	603	1104
N_2O (tCO_2-e/yr)	103	118	216
Total CO_2-e (t/yr)	11,313	12,957	23,730
NO_x (t/yr)	6	7	12
SO_x (t/yr)	n/a (NPI EETM)		
VOCs (t/yr)	59	68	25
PM10 (t/yr)	n/a (NPI EETM)		
CO (t/yr)	34	39	72

Non-Routine Venting of Process Hydrocarbons via Flare System

During normal operations, hydrocarbon gas is flared via the flare system. The system is maintained to effectively combust hydrocarbons as a critical component for the safe operation of the facility. In the unlikely event that the flare is extinguished or unavailable (such as following a major shutdown prior to system ramp-up or cyclonic wind impact), the hydrocarbon gas discharged via the flare system may initially not be combusted during the period required to maintain safety purge flows to the flare system and intervention to re-establish flare ignition. This may result in the short term (days) low-rate contingent release of hydrocarbon gas to the atmosphere. Intermittent non-routine venting from the riser platform represents only a minor source of atmospheric emissions and is not considered to pose a risk beyond the routine air emissions described in this section.

Fugitive Emissions

Fugitive emissions can occur from pressurised equipment and are inherent in design. Fugitive emissions may occur due to infrequent operational activities or unintentional equipment leaks. Sources can include valves, flanges, pump seals, relief valves, vents, sampling connections, process drains, open-ended lines, casing, tanks, produced water and other potential leak sources from pressurised equipment. Fugitive emissions are quantified and reported as requirements set under the National Greenhouse and Energy Reporting Scheme (NGERS). Fugitive methane

emissions are anticipated to be around 6% of total GHG emissions, which is a very small GHG contributor at Pluto-A as safe operation of the facility relies on the effective containment of hydrocarbons.

This is a conservative estimate based on NGER emissions factors assigned to a shallow water platform, and an upper end estimate of associated methane emissions from PW discharges and conservative flare estimates. The amount of routine and non-routine fugitive methane emissions is considered to be small, and is inherently controlled by design and operations/maintenance practices. The facility has limited topsides processing and relatively few potential leak-points, is well-maintained using good practice operations and maintenance tightness validation. Furthermore, the facility is monitored with safety gas detection systems, and produced water discharges are processed through a degasser to remove associated entrained methane. Facility safety-related controls, produced water operations and implementation strategy measures provide proportional management of potential fugitive emissions for PLA. Potential unplanned hydrocarbon releases to the atmosphere associated with accidents, incidents and emergency situations are described in Sections 6.7 and 6.8). The National Greenhouse and Energy Reporting (Measurement) Determination 2008 estimates fugitive emissions based on typical 'shallow water offshore platforms' to be 1777 t CO_2-e/yr of methane and 7 t CO_2-e/yr of carbon dioxide (with very minor variations depending on facility gas composition). Fugitive emissions associated with produced water production at the PWH maximum design rate is estimated to be up to approximately 1140 t CO_2-e/yr based on accepted NGERs methodologies. Discrete relatively small volumes of packed gases and charged systems, including non-ozone depleting refrigerant gases, are used across the facility and vessels which have potential for small volume leaks (typically less than 100 kg per isolatable inventory). Such gases are used in the HVAC and refrigerant systems on the facility and vessels.

The facility is fitted with several portable fire extinguishing units utilising CO_2. The facility does not have any gaseous fire extinguishing systems containing synthetic GHGs or ozone depleting substances.

Historical Emissions

An historical 5-year emissions summary is provided in Table 6-25 which support the conservative representation of forecast emissions envelope presented above. Historical data illustrates Pluto offshore facility emissions through a period with stable and optimised Pluto-system reliability, includes offshore PWH construction and crewed offshore maintenance campaigns, and commencement of commissioning of the PWH gas engine and produced water handling system. Only a limited duration of wet-flowline operational mode, and very low produced water discharge ramp-up occurred during this period (early 2024).

Table 6-25: 5-year Pluto offshore GHG (NGERS) emissions summary (Direct)

Source	Pluto Offshore GHG Emissions Summary (NGERS)				
Financial year	FY2020	FY2021	FY2022	FY2023	FY2024
Flared Gas (t)	527	1,227	559	710	1,854

Indirect Emissions

Tie-back Activities: MODU, Vessel and Helicopter Operations

Atmospheric emissions during tie-back activities are generated by installation and support vessels from internal combustion engines (including all equipment and generators) and incineration activities (including onboard incinerators) during the PAP for standard operations, excluding drilling waste.

Atmospheric emissions generated during these operations will include SO_x, NO_x, particulates and VOCs. SOx and particulate matter emissions are heavily influenced by the fuel used and its relative sulphur content, MGO usually having a lower sulphite content than marine diesel oil (MDO) or heavy fuel oil (HFO).

NO_2 emissions from routine MODU power generation for an offshore project were modelled previously by another operator (BP Azerbaijan, 2013). NO_2 was the focus of the modelling, on account of the larger predicted emission volumes compared to the other atmospheric emissions, and the potential for NO_2 to impact on human health (as a proxy for environmental receptors). The model demonstrated that atmospheric emissions generated by MODU operations may increase ambient NO_2 concentrations by 1 µg/m³ (0.001 ppm) within 10 km of the source and 0.1 µg/m³ (0.0001 ppm) within 40 km of the source. This represents an increase of 2% over typical background concentrations within 40 km, with air quality remaining well below the WHO air quality guideline for NO_2 of 40 µg/m³ annual mean. As NO_2 is the main emission that poses a threat to receptor health, it is considered conservative to use the above studies to justify potential impacts to receptors. As such, studies into the attenuation of other gasses emitted are not evaluated.

A moored MODU may be used for the drilling campaign resulting in less fuel needed for station keeping, however a hybrid MODU may be used. Other vessels required for the PAP (e.g. installation vessels) may use DP to conduct installation or intervention activities. Based on fuel consumption information from the DPS-1 MODU on previous Woodside drilling campaigns and the expected activity duration plus mobilisation, it is estimated that a hybrid MODU will consume approximately 44 t/d of fuel when compared to similar scenarios. Based on the information available it is expected that up to approximately 2640 tonnes of fuel may be used from MODU activities (60 total days for the drilling and completions of the single well). Other DP vessels associated with the subsea installation and contingent well intervention activities may use up to 315 t (based on 21 days and a rate of 15 t/day). GHG emissions from the MODU, vessel and helicopter operations are expected to be approximately 8042 t CO_2-e.

Support vessels, refuelling vessel and helicopters will support the Petroleum Activities Program, although emissions produced will be substantially less than those produced by the MODU/installation vessels. Total fuel consumption for support vessel activities (based on four general offshore supply vessels on standby at 2.5 t/day) is expected to be up to 1669 tCO_2-e for anchor handling, drilling activities, subsea installation, well start-up and contingent well intervention activities. Helicopter operations during drilling activities may consume up to 84 tCO_2-e, based on ~1.5 t/day. The potential for multiple helicopter runs has been considered in GHG emissions summations.

Well Kick

During drilling of the well and contingent well intervention activities, a kick may occur. A kick is an undesirable influx of formation fluid into the wellbore. The resultant effect would be a release of a small volume of GHGs via the degasser to the atmosphere during well control operations, known as ‘venting’. Venting is required to ensure well integrity is maintained in the event of a kick thereby avoiding an emergency condition. The total estimated, expected volume of GHG emissions from well kicks and venting is estimated to be approximately 378 tCO_2-e.

Well Flowback (Flaring) and Contingency Activities (Venting)

The preferred well unloading method for the tie-back activities is to direct all fluids to the onshore LNP plant via the Pluto facility. However, if this activity is not practicable, contingent well unloading to the MODU may result in gas, condensate, base oil and methanol in the wellbore to be flared and efficiently burned. The flare may be extinguished due to water ingress, lack of pilot (propane), weather impact or equipment failure resulting in cold venting of gas from the flare for several minutes. After the objectives of the well testing and flowback are achieved, the flow is stopped and the well may be cleaned using a brine that can include several chemicals, such as biocide and surfactant. Across approximately 48 hours a volume of ~31 mmscf of gas, 534 bbl condensate may be flared, or 1918 tCO_2-e.

Mud Degassing

Methane emissions may be released during the period of intersection with the reservoir. Small amounts of gases such as methane may dissolve in drilling fluids and be released to the atmosphere as fluids are degassed and recirculated. These emissions have been estimated using American Petroleum Institute factors and are negligible over the activity.

Venting of Residual Gas

During well intervention activities there are several scenarios that may cause small amounts of gas to be vented directly to atmosphere in an intrinsically safe manner via the choke manifold onboard the WIV. Due to the small quantities of gas, it is not viable to flare this gas. These sources of direct gas emissions include:

- Riser disconnect – Riser will be disconnected at the end of well intervention activities. Pressurised gas will be vented to the atmosphere.
- Wireline tool string and tool change – During the well intervention activities, it is estimated that there will be three to five tool changes per well requiring intervention. Tool changes will cause a small quantity of venting to the atmosphere via the wireline lubricator.
- Surface returns – Small volumes of hydrocarbon gas from annular spaces will be cold vented via a choke manifold in a controlled and safe manner from the WIV.

Table 6-26: Greenhouse gas emissions and sources associated with tie-back activities

Source	GHG Emissions (t CO_2-e)
Anchor Handling Activities	
Anchor Handling Operations	273
Support Vessel (Anchor Handling)	136
MODU Activities	
MODU Operations	7140
Support Vessel (MODU Operations)	818
Helicopter Operations	84
Subsea Installation Activities	
Primary Installation Vessel Operations	858
Support Vessel (PIV Operations)	286
Well Start-up and Performance Testing	
Support Vessel	286
Contingent Scenarios – Intervention/IMMR Activities	
Intervention Vessel/IMMR Vessel	858
Support Vessel Operations	143
Contingent Flaring	4
Well Kick and Flowback	1918
Vented Per Well	378
Venting – Riser Disconnect (~1800 PSI)	176
Venting – Tool Change (5 changes)	<1
Venting – Surface Returns	<1
Venting – Removal of Tree Cap	<1

Greenhouse Gas and Atmospheric Emissions associated with Support Vessels and Helicopters

Indirect GHG and atmospheric emissions will be generated by various support vessels, and helicopters supporting Pluto. Vessel emissions include those from internal combustion engines and fugitives. Incinerators may be used onboard vessels to dispose of flammable domestic wastes such as cardboard. Incinerators are typically used infrequently, with wastes generally segregated and transported to shore for disposal.

The figures provided below are estimates of key vessel and helicopter emissions. Atmospheric and GHG emissions from support vessels vary depending on the nature of activities being undertaken; for example, travelling or “steaming”

to a destination at low speed uses less fuel and generates lower atmospheric and GHG emissions than high speed steaming. Emissions generated during safety related vessel standby activities, holding station using DP during loading and unloading of materials to the facility or undertaking subsea IMMR work also vary. PLA is not expected to require routine vessel support except on occasion when an intervention visit is required (planned or reactive maintenance). This is estimated to occur as frequently as eight times per year.

Vessel Masters control day to day operations that determine support vessel emissions. Woodside has the potential to influence fleet level approaches to support vessel emissions through contracting activities. Refrigerant gases are used onboard supply vessels in small quantities.

Expected annual GHG emissions for vessel and helicopter activities have been estimated to be:

- 827 tCO_2-e for support vessels, based on MDO consumption
- 1035 tCO_2-e for IMMR vessels, based on MDO consumption
- 80 tCO_2-e for helicopters, based on Jet A1 fuel consumption.

Indirect emissions from these sources are expected to be relatively constant throughout the EP period.

Greenhouse Gas Emissions associated with Accommodation Support Vessels

Accommodation support vessels generate emissions dependent on several factors, including sea state conditions, size of the vessel, environmental conditions as well as crewing and activity requirements. It is expected that fuel requirements depend on these factors, ranging from ~6 to ~48 tonnes per day. Estimated ASV GHG emissions is approximately 12,760 tCO_2-e for ASVs, based on a 90-day campaign.

GHG Emissions Associated with Processing Onshore and Product End-use Associated with Pluto

Indirect emissions associated with Pluto Operations result from hydrocarbon processing (onshore), third party transport of products, regassification, distribution and combustion by end users. Key influences impacting indirect GHG associated with Pluto production include:

- Total production – indirect emissions are proportional to total production, which varies reservoir, well and production system performance, maintenance and shutdown activities, and well tie-backs and technical and commercial operating requirements.
- Composition of produced gas – such as variability due to technical constraints, inert gas optimisation, and separation of reservoir CO_2.

Downstream feed gas and product demands – the proportion of hydrocarbons attributed to Pluto sold as LNG, condensate, domestic gas and other products varies. Each product requires differing amounts of energy to process to the point of sale and varies based on reservoir composition, field contribution and commercial reasons.

End location, and use of sold products by third parties varies with national and international pathways for valuable energy and resource produces. Wide potential for end use of sold products can result in variable emissions intensities.

For the purposes of framing potential indirect emissions, the total assumed GHG emissions associated with annual production and from transport and customer combustion are estimated in Table 6-27. Estimates are conservatively framed, as they do not include possible abatement or offsets applied voluntarily or through regulatory mechanisms in Australia and across the value chain and product lifecycle, including international. Indirect atmospheric emissions (non-GHG) are discussed in Section **Error! Reference source not found.**.

Table 6-27: Estimated direct and potential indirect GHG emissions associated with Pluto offshore activity production

Source of Emissions	Annual Estimated Emissions (MtCO2-e)	Total Possible Emissions for EP Period (MtCO2-e)
Direct Emissions		
Pluto offshore operations (including fuel, flaring and fugitives)	0.038	0.189
Indirect Emissions		
Project vessels, MODU and helicopters during XNA03 drilling, installation, hook-up and commissioning	0.013	0.013
Vessels and helicopters during operations	0.002	0.01
Onshore hydrocarbon processing[1]	2.36	9.52
Third-party transport of products, regassification, distribution and end use[2]	23.1	91.3

[1] *Estimated onshore processing emissions envelope based on potential positive reservoir and production outcomes, processed through onshore PLP and KGP LNG facilities. Typical of most oil and gas activities, reservoir performance carries a wide uncertainty range, and production varies with market demand and downstream processing performance. The annual estimated emissions presented in Table 6-27 represent the year with highest expected production/GHG emissions in the duration of the five years prior to acceptance of this EP. Total emissions presented do not consider net reduction by way of voluntary and regulatory abatement/offsets.*

[2] *Source: EcoInvent 3.5 database and National Greenhouse and Energy Reporting (Measurement) Determination 2008. EcoInvent v3.5 represents a large collection of inventory data, used as an approximation of third-party lifecycle LNG use for cargos delivered to China. It has been recognised as emission factor source for the European Union Renewable Energy Direction greenhouse gas methodology and is aligned to the principles of the NGERS methodology. Total emissions presented do not consider potential third-party net reduction by way of voluntary and regulatory abatement/offsets.*

The precise shape and pace of the energy transition is uncertain. It is expected to vary across countries because they have different starting points, development requirements, resources and capabilities. However, the scale of the transition is clearer, as it will take many trillions of dollars, invested over decades. Today, Woodside has a portfolio of oil and gas assets. We are also diversifying our portfolio by investing in new energy products and lower carbon services that can avoid or reduce customer emissions. We see an ongoing role for gas from the Pluto facility to support our customers' plans to secure their energy needs, while they reduce their emissions.

Impact/Risk Assessment

Air Quality

Facility, tie-back activities and vessel routine and non-routine emissions, predominantly flaring, have the potential to result in localised, temporary reduction in air quality, generation of dark smoke and contribution to GHG emissions. Potential impacts of emissions depend on the nature of the emissions, as well as the location and nature of the receiving environment.

Facility design (including the rapidly dispersive characteristics of the gas turbine exhausts, flare and other emissions), the estimated level of pollutants in the emissions, and the absence of elevated background ambient levels have been considered in estimating the potential for interaction with human and environmental sensitivities. The PAA is in a remote offshore location, with no expected adverse interaction with populated areas or sensitive environmental receptors associated with air emissions.

The PAA overlaps the breeding BIA for the wedge-tailed shearwater, roseate tern, and fairy tern (see Section **Error! Reference source not found.**); as such, these seabirds may occur near to the facility airshed. Birds (including migratory birds) are also known to opportunistically roost on the riser platform. Given the highly dispersed nature of facility air emissions, no adverse impacts to birds are anticipated due to air emissions.

Potential impacts are expected to be temporary, localised air quality changes, limited to the airshed local to the riser platform. Air emission impacts are not expected to have direct or cumulative impacts on sensitive environmental receptors, or above National Environmental Protection (Ambient Air Quality) measures and are expected to disperse well before reaching the nearest populated area (Dampier).

The flare and potential black smoke resulting from emissions may impact visual amenity. The offshore location of the Platform is not directly visible from the nearest landfall (Montebello Islands, 43 km south). Hence, no impacts to visual amenity for residential communities are expected. Visual amenity impairment to tourism activities is not expected.

Management and Abatement

Woodside's requirements for GHG emissions in the operate phase is applied to continue the identification and evaluation of emission reduction opportunities. These include application of the Emissions and Energy Management Procedure (Section 7.2.11) and the Production Optimisation and Opportunity Management Procedure (POOMP) (Section 7.2.11.1) to enable continued reduction of direct GHG emissions to ALARP. This includes a system of continual review and improvement of key emissions sources from the Pluto facility (which includes the Pluto offshore operations), and ongoing identification, screening and implementation of opportunities to reduce emissions.

During operate phase, Woodside's Flare Management Framework and Woodside's methane Management strategy will also be implemented. This includes setting of annual flare and emissions targets for the asset, and annual execution of asset-specific Methane Action Plans, with discrete activities consistent with the principles of OGMP2.0 and OGCI's Aiming for Zero Methane emissions initiative to reduce emissions to ALARP.

Net-Emissions limits under the Federal Safeguard Mechanism (SGM)[71]

[71] Further information about the SGM and SGM Baselines can be found at the Clean Energy Regulator website: https://cer.gov.au/schemes/safeguard-mechanism and https://cer.gov.au/schemes/safeguard-mechanism/safeguard-baselines

The Federal Safeguard Mechanism (SGM)[72] requires Australia's highest greenhouse gas emitting facilities to reduce or limit their emissions in line with Australia's emission reduction targets of 43% below 2005 levels by 2030 and net zero by 2050. Direct and indirect GHG emissions associated with onshore processing of gas at the Pluto facility, as well as indirect emissions associated with the transportation and end use of gas within Australian safeguard facilities are subject to the SGM, and net emissions from these sources must be kept below a specified limit or baseline.

Safeguard facilities that exceed their baseline must manage their excess emissions, such as by surrendering Australian Carbon Credit Units (ACCUs) or Safeguard Mechanism Credits (SMCs), which are representative of one tonne of CO2-e per credit, so that net emissions are brought in line with the baseline. So that sufficient credits are available and that there is a means to comply, safeguard facilities that exceed their baseline are able to buy Government-held ACCUs from the Clean Energy Regulator via the Cost Containment Measure implemented as part of recent reforms.

Safeguard Mechanism (SGM) obligations for the Pluto facility will be met by emissions abatement via operational controls as first preference. Options to manage residual net emissions in excess of baseline include surrendering ACCUs or SMCs, applying to become a trade-exposed baseline-adjusted facility, applying to borrow baseline from the following year or applying for a multi-year monitoring period. Surrendered carbon credits may be generated from Woodside projects, purchased from the market or purchased from the Government through the Cost-Containment Mechanism.

NGERS requires Woodside to report on GHG emissions and energy use from activities which are under its operational control and includes continued reporting for the Pluto offshore and onshore facility in accordance with its requirements under the NGERS Act.

Carbon Management – Business Context

Woodside established a Carbon Business in 2018 in order to develop a portfolio of carbon credits and skills and expertise in managing carbon credit integrity. Total expenditure to date has been split between approximately one-third on origination of new Woodside projects, and the remainder on purchase of credits. In the future, focus is expected to shift towards project origination.

Woodside recognises that assessing integrity of carbon credits and managing a diverse portfolio of credits is important. In addition to regulatory requirements associated with the SGM, management of carbon credits is informed by current and emerging external frameworks such as the Integrity Council for the Voluntary Carbon Market's Core Carbon Principles, the Investor Group on Climate Change's guidance, and the Oxford Principles for Net Zero Aligned Offsetting. More information on Woodside's approach and management of carbon credits can be found in section 3.4 of the 2023 Climate Transition Action Plan.

Woodside Climate Targets

Woodside is targeting a reduction of net equity Scope 1 and 2 GHG emissions of 15% by 2025 and 30% by 2030, with an aspiration of net zero by 2050 or sooner. The net equity Scope 1 and 2 emissions reduction targets are relative to a starting base of 6.32 MtCO2-e which is representative of the gross annual average equity Scope 1 and 2 GHG emissions over 2016-2020. This starting base may be adjusted (up or down) for potential equity changes in producing or sanctioned assets with a final investment decision prior to 2021. Net equity emissions include the utilisation of carbon credits as offsets.

The targets mean that total portfolio net equity Scope 1 and 2 emissions for the 12 month period ending December 2025 are targeted to be 15% lower than the starting base, and that net equity Scope 1 and 2 emissions for the 12 months period ending 31 December 2030 are targeted to be 30% lower than the starting base.

There is no direct mapping of these corporate level Scope 1 targets to Pluto operations. Abatement of these emissions may come from other facilities with more cost-effective or impactful abatement opportunities, or from offsets. Meeting these targets may mean additional net voluntary abatement beyond that required by the SGM described above.

Data on broader GHG emissions, such as Scope 3 emissions and progress against corporate targets and commitments, will be published as part of Woodside's annual disclosures.

Other regulatory framework for management of Indirect GHG emissions from onshore processing

As described above, indirect GHG emissions will be generated by the onshore processing of gas from the Pluto facility. Onshore processing facilities are also subject to GHG emissions management frameworks and relevant Regulatory approvals.

Ministerial Statement 757 required the development of a Greenhouse Gas Abatement Program for Pluto (Pluto GGAP), prior to the commencement of construction, in order to:

- ensure that the plant is designed and operated in a manner which achieves reductions in GHG emissions as far as practicable

[72] Further information about the SGM and SGM Baselines can be found at the Clean Energy Regulator website: https://cer.gov.au/schemes/safeguard-mechanism and https://cer.gov.au/schemes/safeguard-mechanism/safeguard-baselines

- provide for onshore GHG emissions reductions over time
- ensure that through the use of best practice, the total net GHG emissions and/or GHG emissions per unit of product from the project are minimised.

The Pluto GGAP for the initial Pluto train 1 development was updated to incorporate Pluto train 2 and included interim and long term emission reduction targets approved by the Minister for Environment in August 2021. Ministerial Statement 1208, issued in August 2023, updates the Greenhouse Gas Abatement conditions from Ministerial Statement 757 and includes net GHG emission limits reflected in the approved Pluto GGAP targets in addition to ongoing review and reporting of GHG emissions and updates to the Pluto GGAP. The Pluto GGAP Revision 3A is currently applicable and in-force under MS1208 and is subject to annual compliance reporting provided to the WA EPA and published on the Woodside website – Pluto LNG Environmental Compliance Reporting[73].

On 15 October 2024, the WA State Government released its updated greenhouse gas emissions policy for major projects (State policy) assessed by the EPA. Recognizing reforms that strengthened the Commonwealth SGM in 2023, the State policy describes that conditions to reduce net greenhouse gas emissions will no longer be applied to major proposals assessed under Part IV of the Environmental Protection Act 1986 where the proposals are subjected to alternative regulatory measures such as the current SGM.

In November 2024, the EPA updated its Environmental Factor Guideline: Greenhouse Gas Emissions with consideration of 'rapidly evolving' climate science and policy and the updated State Policy. In its updated guideline, the EPA states that 'emission reductions required under the SGM are now likely to represent an "as far as practicable" reduction of, and in most cases meet its factor expectation for, covered emissions.'

The WA Minister for Environment has recently requested the EPA to inquire into and report on the matter of changing the implementation conditions relating to the management of GHG emissions at Pluto. It is anticipated that Ministerial Statement 1208 will be amended to align with conditions of other major projects, recognizing the SGM declining baseline, and other conditions such as those outlined for Ministerial Statement 1233 (summarised below), to achieve the EPA's objective to minimise the risk of environmental harm associated with climate change by reducing GHG emissions as far as practicable. For Pluto, the trajectory of net GHG emission limits under the SGM is substantially lower than the net GHG limits currently specified in Ministerial Statement 1208.

Following EPA assessment of the North West Shelf Project Extension Proposal, which allows for continued operation of the NWS Project and processing of third party gas at KGP, Ministerial Statement 1233 was issued in December 2024, approving the proposal with conditions relating to the management of GHG emissions (Condition 2-1 to 2-5). The GHG conditions require:

- notifying the relevant state government department if implementation of the proposal will not be or is not expected to be regulated under Safeguard legislation and of the implications of any changes to Federal Safeguard Legislation including obligations to reduce net Scope 1 GHG emissions.
- within 12 months of publication of the Ministerial Statement, and thereafter at five yearly intervals, to carry out a review of best practice design and operational measures that could be implemented to reduce GHG emissions, and provide to the relevant state government department a report which:
  - identifies practicable and reasonable options to reduce GHG emissions from the proposal
  - explains the assessment of both technical and economic feasibility of these options, and identifies which are considered feasible
  - includes an independent peer-review report of this options analysis
  - considers reasonably practicable options for reductions in scope 3 emissions

These measures, which include ongoing compliance with the Federal SGM baseline in accordance with Australia's GHG abatement targets, and an approach which ensures emissions reduction opportunities are periodically reviewed, ensure that portion of indirect GHG emissions associated with processing of Pluto gas at KGP are ALARP and acceptable.

Management and Abatement for Third Party Consumption (inc. Transport, Regasification, Distribution, Combustion) (Indirect)

Woodside continues to pursue a range of management and abatement measures relevant to GHG emissions associated with third party consumption of gas from Pluto. These are appropriate and practicable given that Woodside does not have operational control over third party GHG emissions. Examples of initiatives we are involved with are given below; involvement may change over time.

<u>Reduce</u>

Methane Guiding Principles: Woodside joined the Methane Guiding Principles in 2018. The MGP focuses on priority areas for action to reduce methane emissions across the natural gas supply chain.

Completed activities under the MGP include:

[73] https://www.woodside.com/what-we-do/operations/pluto-lng/pluto-lng-environmental-compliance-reporting

- led the “Global Midstream initiative” which encourages MGP members to engage and collaborate with supply chain and share best practises for methane reduction
- sponsored the first technical workshop of the Australian Energy Producers methane taskforce
- presented and participated in panels at the Global Methane Summit and International Gas Union conference

ASEAN Methane Leadership Programme: Woodside joined in 2023 and initiated an Australian methane programme through the Australian Climate Leaders Coalition. These programmes allow Woodside to share expertise with other companies in the natural gas value chain to help them reduce emissions of methane to near-zero74

IPIECA Scope 3 Emissions Taskforce: Providing members the opportunity to convene and disseminate knowledge and good practice in the area of Scope 3 emissions, including categorisation, value chain emission analysis, Scope 3 measurement and reporting and engagement along the value chain

OGMP 2.0: Woodside joined OGMP 2.0 in 2024. The OGMP 2.0 is the United Nations Environment Programme’s flagship oil and gas reporting and abatement programme. OGMP 2.0 is the only comprehensive, measurement-based reporting framework for the oil and gas industry that improves the accuracy and transparency of methane emissions reporting. This is key to prioritising methane abatement actions in the sector.

Woodside shares examples of emissions reduction initiatives being implemented on its assets with the Operator of non-operated assets at governance forums and joint venture technical committee meetings. Examples have included sharing knowledge about methane measurement (such as drone observation surveys), reduction opportunities such as thermal oxidisers at the Wheatstone asset, and approach to workforce engagement on decarbonisation and identification of opportunities.

Woodside also supports customers[75] to reduce their emissions via the investment in new energy products and lower carbon services, including the progression of corporate Scope 3 targets that apply across Woodside’s portfolio including:

- Scope 3 Investment Target[76]: Woodside has a Scope 3 investment target aiming to invest $5 billion in new energy products and lower carbon services by 2030[77]
- Scope 3 Emissions Abatement Target[76]: Woodside has a Scope 3 emissions abatement target, to indicate the potential abatement impact of these products and services upon customer Scope 1 or 2 emissions. This target it to take final investment decisions on new energy products and lower carbon services by 2030, with total abatement capacity of 5 Mtpa CO2-e[78]

Substitute

Promoting and marketing the role of LNG in displacing higher carbon intensity fuels (IEA, 2019): Woodside continues to advocate LNG as a means for customers to reduce their Scope 1 and 2 emissions, in accordance with the customer nations’ NDCs (see section below). The Pluto joint venture partnerships and investment by Kansai Electric Power and MidOcean demonstrates a long term recognition of the contribution of Pluto gas to meeting global energy demand. Further, evidence of the effectiveness of this strategy is the recent buy into the Scarborough project by Japan LNG (10% – 8 August 2023) and JERA (15.1% – 23 February 2024) with associated potential LNG offtake and collaboration on opportunities in new energy.

Advocate

Advocacy for stable policy frameworks that reduce carbon emissions: Woodside aligns its advocacy to support the goals of the Paris Agreement. A list of speeches and submissions to international and domestic audiences which contain climate related content or positions in 2023 is presented in the Woodside Climate Transition Action Plan, section 6.1.

Monitor and Report

[74] OGMP, 2023. “Implementation Plan Guidance”, p. 2 https://ogmpartnership.com/wp-content/uploads/2023/02/OGMP-2.0-Implementation-Plan-Guidance_2.pdf. OGMP provides the OGCI collective average target for upstream operations as an example of ‘near zero’ emissions intensity

[75] The customers for these products and services may be the same as the customers of our oil and gas business, directly substituting their energy for new products or directly abating the associated emissions. There may also be customers of the new products and services, without also being customers of oil and gas

[76] Scope 3 targets are subject to commercial arrangements, commercial feasibility, regulatory and Joint Venture approvals, and third party activities (which may or may not proceed). Individual investment decisions are subject to Woodside’s investment targets. Not guidance. Potentially includes both organic and inorganic investment. Timing refers to financial investment decision, not start-up/operations.

[77] Includes pre-RFSU spend on new energy products and lower carbon services that can help our customers decarbonise by using these products and services. It is not used to fund reductions of Woodside’s net equity Scope 1 and 2 emissions which are managed separately through asset decarbonisation plans.

[78] Includes binding and non-binding opportunities in the portfolio, subject to commercial arrangements, commercial feasibility, regulatory and Joint Venture approvals, and third party activities (which may or may not proceed). Individual investment decisions are subject to Woodside’s investment targets. Not guidance.

Monitor and report on the global energy outlook: This will be achieved via the release of Woodside's annual disclosures.

Detailed Impact/Risk Assessment

Assessment of Potential Climate Change Impacts

Climate change is caused by the net global concentration of greenhouse gases in the atmosphere. Human-caused climate change is a consequence of more than a century of net GHG emissions from energy use, land use change, lifestyle patterns of consumption, and production (IPCC 2023). The IPCC has stated that observed increases in GHG concentrations since 1750 leading to climate change are unequivocally caused by human activities and that there's a near linear relationship between cumulative anthropogenic CO_2 emissions and the global warming they cause (IPCC 2023). This relationship implies that reaching net zero anthropogenic CO2 emissions is a requirement to stabilize human-induced global temperature increase at any level, but that limiting global temperature increase to a specific level would imply limiting cumulative CO2 emissions to within a carbon budget (IPCC 2023)

As stated by the IPCC, "it is unequivocal that human influence has warmed the atmosphere, ocean and land. Widespread and rapid changes in the atmosphere, ocean, cryosphere and biosphere have occurred". These impacts are summarised in the below section *Climate Change – Global and Australian Context.*

The Paris Agreement

The Paris Agreement is an international treaty on climate change, signed in 2016. It includes the goal to hold "the increase in the global average temperature to well below 2°C above pre-industrial levels and to pursue efforts to limit the temperature increase to 1.5°C."

Carbon budgets "refer to the total net amount of carbon dioxide that can still be emitted by human activities while limiting global warming to a specified level" (IPCC 2023). A number of factors influence the calculation of remaining carbon budgets, such as the level of global warming chosen, probability, contribution of other greenhouse gases, how much global warming has already occurred due to historical emissions. The remaining carbon budget to limit global warming to 1.5°C and 2°C was 500 GtCO2 and 1350 GtCO2 respectively, as calculated from 2020 (IPCC 2023).

Since 2020, a portion of this global carbon budget has been consumed by ongoing global CO2 emissions. The Global Carbon Budget, an initiative of the Global Carbon Project of the University of Exeter "tracks the trends in global carbon emissions and sinks and is a key measure of progress towards the goals of the Paris Agreement." It is recognised by being presented at the UNFCC's Conference of Parties (COP) sessions. The last Global Carbon Budget in 2024 estimated that the remaining carbon budget for cumulative global GHG emissions to limit global warming to 1.5°C, and 2°C were 235 GtCO2, and 1110 GtCO2 respectively at January 2025 (50% likelihood).

Greenhouse gas emissions associated with Pluto are estimated to be up to 180 Mt CO2-e till EOFL, of which approximately 17 Mt CO2-e may originate from extraction and processing in Australia. Peak projected annual extraction and processing GHG of approximately 2.4 Mt CO2-e would represent ~0.5% of national Australian emissions (440.6 Mt CO2-e during FY2024) (DCCEEW, 2024b), and an estimated ~0.5% of annualised average Australian carbon budget (of 437.7 MT CO2-e average over the ten year period between 2021-2030, (DCCEEW, 2024b)) to meet Australia's GHGs emissions reduction commitments. These emissions will not materially or substantially contribute to either Australia's GHG emissions or global GHG emissions and are considered de minimis. Further, net emissions associated with Pluto in Australia are set to be lower than these totals - with ongoing abatement via implementation of the NGERS Safeguard Mechanism which sets out an abatement trajectory consistent with achieving Australia's emission reduction targets of 43% below 2005 levels by 2030 and net zero by 2050 (DCCEEW, 2023e).

Federally, the Australian domestic policy response to its Paris Agreement commitments is contained in multiple pieces of Commonwealth legislation (for example, Australian Registry of Emissions Units Act 2011 (Cth); Carbon Credits (Carbon Farming Initiative) Act 2011 (Cth); Climate Change Act 2022 (Cth); National Greenhouse and Energy Reporting Act 2007 (Cth); National Greenhouse and Energy Reporting (Safeguard Mechanism) Rule 2015 (Cth); Offshore Electricity Infrastructure Act 2011 (Cth); Renewable Energy (Electricity) Act 2000 (Cth)). There are also climate change policies at State level. Policies and mechanisms of this kind will serve as Woodside's primary means of managing GHG. As recent Court decisions have noted, current domestic environmental protection and assessment mechanisms are ill-suited for considering climate change impacts.

The Federal Safeguard Mechanism (SGM) described in the Management and Abatement section above is the key piece of legislation that implements the Australian Government's policy for reducing emissions at Australia's largest industrial facilities. The SGM sets legislated limits. known as baselines, on the net greenhouse gas emissions of these facilities. These emissions limits will decline, predictably and gradually. Through these limits, the Australian Government aims to help achieve Australia's emission reduction targets, as committed in Australia's Nationally Determined Contribution (NDC) to the Paris Agreement of 43% below 2005 levels by 2030 and net zero by 2050.

Climate Related Scenarios

Detailed Impact/Risk Assessment

The use of fossil fuels for energy currently accounts for around three quarters of anthropogenic GHG emissions (IEA 2021). This means that efforts to meet climate change goals must include changes to the way that the world produces and consumes energy. These changes are referred to as the "energy transition".

The precise shape and pace of the energy transition is uncertain. It is expected to vary in different countries because they have different starting points, development requirements, resources and capabilities. However, the scale of the transition is clearer. It will take many trillions of dollars, invested over decades. The International Renewable Energy Agency estimates it will require $115 trillion of cumulative investment by 2050 (IRENA 2022).

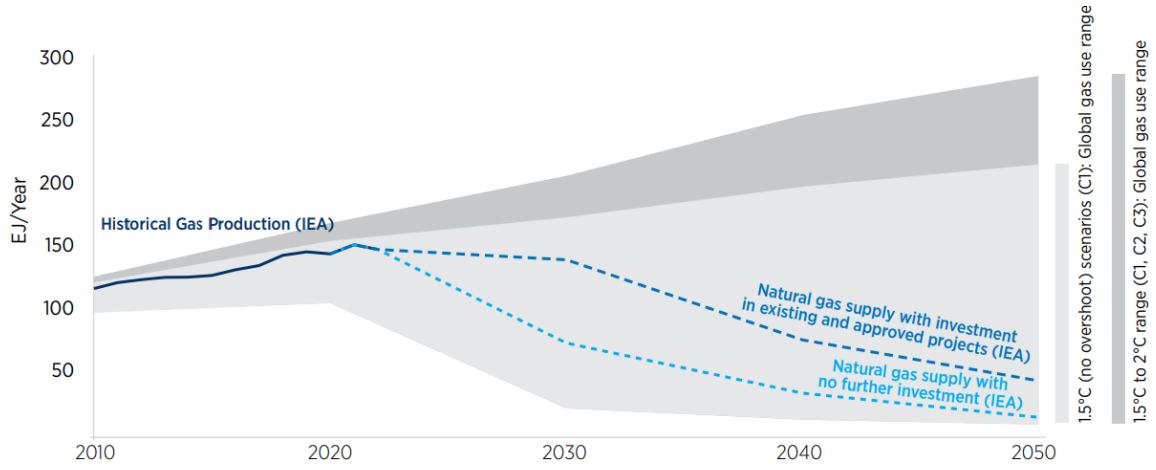
During 2022, the world experienced what the IEA has called the "first truly global energy crisis" (UNFCCC 2022). This crisis has seen higher energy prices and in some cases constraints on access to energy supply, impacting both businesses and households. The energy crisis has led to a renewed focus on energy security and has reconfirmed that the energy transition needs to be carefully managed if it is to be fair, inclusive and ultimately successful.

Gas from Pluto is understood to have an ongoing role in supporting customers' plans to secure their energy needs, while they reduce their emissions. Current uses of gas include power generation[79], heating and chemical feedstock.

In 2021, the IEA published its Net Zero by 2050: A Roadmap for the Global Energy Sector report (the NZE Scenario) (IEA 2021). The report is clear that "the route mapped out here is a path, not necessarily the path", and Woodside recognises that this is one scenario out of many. A range of pathways are considered by the IPCC.

Even in the NZE Scenario, investment in oil and gas development does not cease. The IEA estimates the need for an average $365 billion of upstream oil and gas investment every year until 2030, and $171 billion every year thereafter to 2050 is required in the NZE Scenario. The IEA cautions that "The fact that no new oil and natural gas fields are required in the NZE does not mean that limiting investment in new fields will lead to the energy transition outcomes in the NZE. If demand remains at higher levels, reduced investment would result in a shortfall in supply in the years ahead, and this would lead to higher and more volatile prices.

A range of climate pathways which limit global warming to either 1.5°C or 2°C have been published in addition to the NZE Scenario Figure 6-8 shows the range of potential global gas consumption in these scenarios, along with forecast supply with and without new investment.



[79] Electricity generation fueled with natural gas typically releases about half the lifecycle amount of greenhouse gases compared to electricity generation fueled with coal (IEA 2019). Additionally, natural gas fired electricity generation offers a flexible means of providing support to batteries and help stabilize the power grid during periods of reduced renewable energy production (e.g. at night, and when the wind is calm)

Detailed Impact/Risk Assessment

Figure 6-8: Forecast global gas use in climate pathways that limit warming to 1.5°C and 2ºC, with expected supply[808182]

Woodside notes that the IEA has published two special reports, Emissions from Oil and Gas Operations in Net Zero Transitions and The Oil and Gas Industry in Net Zero Transitions (IEA 2023). Combined, these reports note that oil and gas operations currently account for around 15% of total energy related emissions globally, identify and advocate for opportunities for oil and gas producers to abate these emissions, and analyse broader implications for the sector through the energy transition which includes the need for increased investment in clean energy. This EP demonstrates that management and abatement measures applied reduce GHG emissions associated with the project to acceptable and ALARP levels. Through meeting requirements of the Federal SGM, direct GHG emissions and those created by onshore processing at Pluto are aligned with Australia's emission reduction targets under the Paris Agreement. Further, Woodside's Scope 3 targets demonstrate how Woodside's products and services can help our customers avoid or reduce their Scope 1 or 2 emissions and therefore reduce life cycle (Scopes 1, 2 and 3) emissions intensity of Woodside's portfolio.

Woodside notes that the IEA makes the following statements in their World Energy Outlook 2024 on LNG demand in their Stated Policies Scenario (STEPS), Announced Pledges Scenario (APS) and Net Zero Emissions by 2050 Scenario (NZE):

- In the STEPS, LNG demand increases by more than 2.5% per year over the 2023-2035 period, which is faster than overall natural gas demand but far less rapid than the average 6% per year LNG growth rate between 2013 and 2022. Around 270 bcm of new LNG supply is currently under construction, and this will lead to a near-doubling of capacity in the United States and Qatar, which are set to dominate supply in 2035, together accounting for around 50% of global LNG trade in the STEPS by this date. This increased supply concentration is likely to put a spotlight on possible security of supply risks that might arise from extreme weather in the Gulf of Mexico and from disruption in the Middle East.
- Due to an upward adjustment to projected natural gas demand growth to 2030, LNG demand growth in the STEPS is higher than in the WEO-2023, reaching more than 700 bcm by 2035. However, this pace of growth does not keep pace with export capacity additions. As a result, a 130 bcm surplus emerges by 2030, bringing prices down in key importing regions like the European Union, China and Japan to a range between USD 6.5- 8.5 per million British thermal units (MBtu). This makes it difficult for some exporters to fully recover their long-run marginal cost of supply during this period.
- This LNG surplus narrows in subsequent years as LNG demand growth continues in the 2030s, and a supply gap emerges in 2040. By 2050, around 175 bcm of additional LNG export capacity is required in the STEPS to cover both demand growth and retiring capacity. This additional supply mainly comes from the Middle East, East Africa and North America. In the APS, projects currently under construction are sufficient to meet LNG demand: this peaks at 650 bcm in 2030, and no supply gap emerges. In the NZE Scenario, demand can be met in aggregate from projects existing today, without any need for additional LNG from projects currently under construction: this has a profound effect on gas prices in importing regions, which fall to around USD 5/MBtu by 2030.

Japan and Korea have significant energy- and carbon-intensive industry sectors which account for approximately 30% of GDP for each. Most energy used in industry is imported, which creates a priority for energy security during energy transitions. In the APS, energy supplies in Japan and Korea are underpinned by a variety of sources over the next decade as they pivot to increased use of clean energy sources – including renewables, nuclear and low emissions fuels – to reduce emissions and secure supply. Although the share of fossil fuels in power generation decreases through to 2035 and beyond, natural gas continues to provide stable and flexible power for both countries in light of

[80] Charts utilise IPCC ranges for oil and gas usage in scenarios that have a 50% or greater probability of limiting warming to 1.5°C with no or limited overshoot (C1), a 50% or greater probability of returning warming to 1.5°C after a high overshoot (C2), a 67% or greater probability of limiting warming to 2°C (C3) from AR6-WG3. IPCC data representing outlooks for Primary Energy Oil and Primary Energy Gas was sourced from AR6 Scenarios Database

[81] Data points sourced from the IPCC includes 2010, 2020, 2030, 2040 and 2050. Historical data from the IEA is provided on an annualised basis. Forward looking data from the IEA includes 2030, 2040, 2050. Woodside has used interpolation of the IEA and IPCC data points in intervening years. This is a work derived by Woodside Energy Ltd from IEA material and Woodside Energy Ltd is solely liable and responsible for this derived work. The derived work is not endorsed by the IEA in any manner. IEA data was converted to exajoules using conversion factors obtained from the IEA report; The Oil and Gas Industry in Net Zero Transitions, IEA 2023. IEA and IPCC scenarios are not predictions or forecasts and are representative of views of the future. Woodside's approach to analysing and assessing future energy market conditions is based on qualitative and quantitative factors and may vary from any one scenario presented by the IEA or IPCC.

[82] IEA, 2023. "The Oil and Gas Industry in Net Zero Transitions", https://www.iea.org/reports/the-oil-and-gas-industry-in-net-zero-transitions, License: CC BY 4.0.

Detailed Impact/Risk Assessment

limited domestic supply options or interconnections with neighbouring countries. Natural gas is projected to remain an important energy source, accounting for nearly 12% of the power mix in 2035 in the APS, though gas-fired power drops to just 3% by 2050.

It is acknowledged that information related to climate related scenarios and the energy transition are subject to change, through mechanisms such as ongoing work by the IPCC and other agencies. Woodside will stay abreast of such changes and apply change management processes as described in Section 7.3.2.

Gas's Role in Energy System

The IEA identifies that there are strong macroeconomic drivers for growth in natural gas consumption in emerging markets and developing economies in Asia over the next decade, at least partially driven by coal to gas switching which "helps countries with net-zero emissions targets accelerate the transition away from coal, even if renewables are the major source of emissions reductions" (IEA 2023).

In the 2019 report The Role of Gas in Today's Energy Transition, the IEA indicates that electricity generation fuelled with natural gas typically releases about half the lifecycle amount of greenhouse gases compared to electricity generation fuelled with coal (IEA 2019). Additionally, natural gas-fired electricity generation offers a flexible means of providing support to batteries and helps stabilise the power grid during periods of decreased renewable energy production (e.g. at night or when the wind is calm).

The same IEA report states that "beating coal on environmental grounds sets a low bar for natural gas, given there are lower emissions and lower cost alternatives to both fuels". However, as shown in **Error! Reference source not found.** there is ongoing demand for gas in Paris aligned scenarios regardless of the presence or trajectory of renewable energy development.

The IPCC has noted Carbon intensity (from fossil fuel combustion and industrial processes) decreased, with large regional variations, over 2010-2019 "mainly due to fuel switching from coal to gas, reduced expansion of coal capacity, and increased use of renewables" (IPCC 2023).

Global energy demand is expected to increase. Since the availability of gas can support the reduction of more carbo-intensive firming fuel sources such as coal, rather than displacing renewable energy, it cannot be assumed that emissions associated with customer consumption of Pluto gas would be entirely additive to global atmospheric emissions.

While the US market is not expected to be customers for Pluto gas, it serves as a relevant example. In an article titled *Natural gas is now stronger than ever in the United States power sector*, the IEA states "the switch from coal to gas and uptake of renewables has lowered emissions in the US power sector… In this period, gas-fired generation more than doubled while coal-fired generation was cut by half" (IEA 2023)

Asia has more than half of the world's people and is growing. Across Asia many countries are still heavily reliant on coal which accounts for approximately 50% of the total energy supply in the Asia Pacific (IEA 2020).

Gas also provides important input to industry, with industrial uses of gas including:

- A feedstock for ammonia and methanol production, which are used for fertiliser and consumer goods manufacturing, among other processes that fuel economic growth and an increasing population
- A source of hydrogen production for the refining and chemical industries
- A source of heat for high-temperature industrial processes, such as producing aluminium, ceramics, cement, glass and steel. Due to its high energy density and controllable combustion characteristics, gas is particularly suitable for generating high temperature heat which may not be achievable through direct electrification (International Gas Union 2023).

Woodside currently expects that natural gas will continue to have a role in the energy transition.

Consideration of likely customer markets and associated energy mixes is important to understand the context of emissions from third party consumption of Pluto gas. Pluto includes joint venture partnerships and is geographically positioned to provide LNG to Asian markets, which also enables lower shipping emissions. The strong demand for Pluto gas, including from customer nations who have publicly stated that they intend to use LNG as part of their approach to meeting their Paris commitments (see the next section below), some of which already receive LNG from the Pluto facility, indicate that it is possible for Pluto gas to have a role in reducing global emissions.

The International Energy Agency (IEA) forecasts suggest that most future gas demand in Asia is China, India, Japan, Korea and other developing regions. These regions are existing or likely customer markets for the purpose of evaluating the role of gas from Pluto in existing energy mixes. This does not preclude the sale of gas from Pluto to other customers.

Customer Markets' Nationally Determined Contributions (NDCs)/commitments

The emissions associated with the consumption of Pluto gas along with other feed sources in customer markets will be considered under domestic and international emissions control frameworks. Anticipated and existing customers of gas from Pluto are in countries that are parties to the Paris Agreement. Under the Paris Agreement and global GHG accounting conventions, each country is responsible for accounting for, reporting and reducing emissions that

Detailed Impact/Risk Assessment

physically occur in its jurisdiction. As described in the *Management and Abatement* section above, Woodside will seek to minimise these emissions as appropriate to our level of control.

The Paris Agreement requires countries to publish Nationally Determined Contributions to the goals of the Agreement. GHG emissions associated with customer use in countries that have ratified the Paris Agreement are considered under relevant national plans, summarised along with other policies below:

- **Japan:** "Japan aims to reduce its greenhouse gas emissions by 46 percent in fiscal year 2030 from its fiscal year 2013 levels, setting an ambitions target which is aligned with the long-term goal of achieving net zero by 2050." Japan also published an "Outline of Strategic Energy Plan" in October 2021. This plan assumes that LNG, while reducing from 37% in 2019, still makes up 20% of Japan's electricity generation mix in 2030.
- **The People's Republic of China:** "China would scale up its NDCs by adopting more vigorous policies and measures, and aims to have CO2 emissions peak before 2030 and achieve carbon neutrality before 2060." It goes on to state that "energy storage and gas-powered electricity will be stepped up rapidly"
- **Republic of Korea**: "The Republic of Korea is seeking to dramatically phase down coal-fired power generation while ramping up renewable power. Aged coal power plants will be shut down or shift their fuels from coal to Liquefied Natural Gas (LNG)."

Woodside's analysis of the NDCs and key policy documents of key customer nations is that LNG has an important role in supporting their decarbonisation plans under the Paris Agreement. If the introduction or continuation of Pluto LNG into the global energy market serves to reduce GHG emissions elsewhere, then in Woodside's view the full volume of GHG emissions associated with the project are not expected to be additive to global GHG concentrations.

Gas' Role in Australia's Energy Market

Domestic users of Pluto gas are expected to be subject to Australia's GHG framework which reflect Australia's NDCs, such as the Federal SGM which applies to Australia's largest industrial facilities.

The primary product from the Pluto facility is LNG. However, Pluto also contributes to the WA domestic gas network through production of pipeline domestic gas, and trucked LNG over road networks.

The emissions intensity of gas-fuelled electricity generation can be compared to other fuels data published by the Clean Energy Regulator (CER 2024). This includes data for designated generation facilities only, which according to the CER are facilities "where the principal activity is electricity production." This data is summarised in Table 6-24.

Table 6-28: Comparative emissions intensity of different energy sources in Western Australia, 2022-2023 financial year

Primary Fuel	Total Generation (million MWh)	Scope 1 and 2 Emissions (MtCO2e)	Emissions Intensity (tCO2e/MWh)
Natural Gas	13.89	7.95	0.57
Coal	6.23	5.33	0.86
Oil, Diesel	0.10	0.06	0.65
Solar, Wind, Hydro	3.79	0.00	0.00
Other	0.10	0.01	0.08
Total	24.10	13.35	0.55

Table 6-28 shows that the GHG emissions intensity of gas-fuelled electricity generation in WA is approximately 30% lower than coal-fuelled electricity generation, and comparable to that of the total aggregated electricity generation. This may continue to change, for example as the portion of electricity generated from zero-carbon sources increases.

As stated by the Australian Energy market Operator,

[the 2023 data shows] strong growth in electricity demand, driven by electrification, electric vehicle uptake, and new energy-intensive industries including green hydrogen production. Several of these trends lead to reduced gas consumption. However, increases in expected electricity consumption, coupled with the phased closure of state-owned coal power stations has a corresponding impact on modelled use of gas-powered generation to support the transition to a majority-renewables power system

and

Pressures associated with future coal supply and the planned retirements of coal-fired generation, are expected to increase the reliance of the South West Integrated System gas powered generation (GPG) fleet, and GPG is expected to play an important role, along with renewables, storage and supporting transmissions infrastructure, in ensuring the reliability in the SWIS as the energy transition continues. (AEMO 2023)

Detailed Impact/Risk Assessment

Continuing operations of Pluto will deliver more gas to the WA market, at a time when WA is predicted to face supply shortages. According to 2022 WA Gas Statement of Opportunities report by Australian Energy Market Operator (AEMO) it is forecast there will be insufficient gas supply to meet WA demand. Pluto will continue to help to address the anticipated forecast supply gap in the WA domestic gas market.

Pluto Contribution to Global Greenhouse Gas Concentrations

Pluto operations creates Scope 1 GHG emissions from the PAP and Scope 3 emissions associated with onshore processing at Pluto LNG. There are also Scope 3 GHG emissions from customer use associated with the XNA03 project and other support services. These are estimated in the *Description of Source* section above.

The remaining carbon budget to limit global warming to 1.5°C and 2°C was 500 GtCO2 and 1350 GtCO2 respectively, as calculated from 2020 (IPCC 2023).

Since 2020, a portion of this global carbon budget has been consumed by ongoing global CO2 emissions. The Global Carbon Budget, an initiative of the Global Carbon Project of the University of Exeter "tracks the trends in global carbon emissions and sinks and is a key measure of progress towards the goals of the Paris Agreement." The University of Exeter presented at the UNFCC's Conference of Parties (COP) sessions. The last Global Carbon Budget in 2024 estimated that the remaining carbon budget for cumulative global GHG emissions to limit global warming to 1.5°C, and 2°C were 235 GtCO2, and 1110 GtCO2 respectively (50% likelihood).

As described above, LNG can have a role in displacing higher carbon intensity fuels and lowering carbon intensity of existing energy mixes, and key customer nations have stated that LNG has an important role in supporting their decarbonisation plans under the Paris Agreement. If the continuation of Pluto LNG into the global energy market serves to reduce GHG emissions elsewhere, then the full volume of GHG emissions associated with the project may not be additive to global GHG concentrations.

To facilitate a comparison against carbon budgets, a hypothetical scenario where GHG emissions associated with the Pluto facility are treated as entirely additive is considered. This scenario is not expected to eventuate due to the reasons described above. The estimated Pluto GHG emissions over the expected remaining life of the development are compared with remaining carbon budgets expected to achieve the goals of the Paris Agreement below. Additionally, no allowance is given for future abatement of GHG emissions associated with the project (such as through future abatement opportunities or future policy requirements), or changes to the carbon budgets which are known to be estimates only. As described above, the carbon budgets are developed based on CO_2 only however the comparison below conservatively considers all GHG emissions from the project normalised as CO_2-e, the vast majority of which are CO_2.

Emissions associated with onshore processing of Pluto gas is also subject to GHG frameworks which are expected to reduce the estimate from the gross figure used, such as the Federal SGM.

Table 6-29: Comparison of potential lifecycle GHG emissions associated with the Pluto offshore operations to global carbon budgets, assuming they are additive

Source	Estimated GHG Emissions over the potential remaining field-life ($MtCO_2$-e)	Proportion of remaining global carbon budget – achieving 1.5°C (235 $GtCO_2$)	Proportion of remaining global carbon budget – achieving 2°C (1110 $GtCO_2$)
Direct + Vessels and Helicopters	0.3	0.00%	0.00%
Onshore hydrocarbon processing	17	0.01%	0.00%
Third party transport of products, regasification, distribution and end use	163	0.07%	0.01%
Total	180	0.08%	0.02%

Assuming the scenario in which all GHG emissions associated with potential remaining Pluto field life are additive to global GHG gas concentrations, which they may not be, Pluto's contribution to the global carbon budget required to meet the goals of the Paris Agreement is de minimis.

Climate Change – Global and Australian Context

Climate change is caused by the net global concentration of greenhouse gases in the atmosphere. Noting that human-caused climate change is a consequence of more than a century of net GHG emissions from energy use, land

Detailed Impact/Risk Assessment

use change, lifestyle patterns of consumption, and production (IPCC 2023), the following contextual evaluation of Climate Change impacts is provided.

Climate science is a rapidly evolving field in which new observations continue to deepen understanding of the current and potential impacts of global warming, and the possible pathways for mitigation and adaptation.

The CSIRO State of the Climate 2024 Report (CSIRO, 2024) draws on the latest national and international climate research, encompassing observations, analyses and future projections to describe year-to-year variability and longer-term changes in Australia's climate. Key points from this report on measured warming trends and forecast trajectories include the following:

- Australia's climate has warmed by an average of 1.51 ± 0.23 °C since national records began in 1910.
- Sea surface temperatures have increased by an average of 1.08 °C since 1900.
- The warming has led to an increase in the frequency of extreme heat events over land and in the oceans.
- Mass coral bleaching is a stress response of corals occurring primarily due to elevated ocean temperature, with five bleaching events associated with marine heatwaves occurring on the Great Barrier Reef over the past 10 years: in 2016, 2017, 2020, 2022 and 2024. In 2016, bleaching was associated with then record high sea surface temperatures, which in turn led to the largest recorded mass bleaching to date on the Great Barrier Reef.
- The 2022 event was the first time that mass bleaching occurred on the Reef during a La Niña year. Accumulated thermal stress during the 2024 event was higher than in 2016, although the full impact in terms of bleaching is still being assessed.
- In 2022 bleaching was also observed on some reefs on Australia's west coast, including Ningaloo Reef. This was due to warm ocean temperatures, driven by the 2021–2022 La Niña. The region's previous severe marine heatwave was driven by the 2010–2011 La Niña, which resulted in bleaching being recorded for the first time on Ningaloo and the closure of several Western Australian fisheries.
- In the south-west of Australia there has been a decrease of around 16% in April to October rainfall since 1970. Across the same region, May to July rainfall has seen the largest reduction, by around 20% since 1970.
- In the south-east of Australia, there has been a decrease of around 9% in April to October rainfall since 1994.
- Heavy short-term rainfall events are becoming more intense.
- There has been a decrease in streamflow at most gauges across Australia since 1970.
- There has been an increase in rainfall and streamflow across parts of northern Australia since the 1970s.
- There has been an increase in extreme fire weather, and a longer fire season, across large parts of the country since the 1950s.
- There has been a decrease in the number of tropical cyclones observed in the Australian region since at least 1982.
- Snow depth, snow cover and number of snow days have decreased in alpine regions since the late 1950s.
- Oceans around Australia are becoming more acidic, with changes happening faster in recent decades.
- Sea levels are rising around Australia, including more frequent extreme high levels that increase the risk of inundation and damage to coastal infrastructure and communities.
- The CSIRO report states that in the coming decades, Australia will experience ongoing changes to its weather and climate which are projected to include:
- Continued increase in air temperatures, with more heat extremes and fewer cold extremes.
- Continued decrease, on average, in cool season rainfall across many regions of southern and eastern Australia, which will likely lead to more time in drought.
- More intense short-duration heavy rainfall events even in regions where the average rainfall decreases or stays the same.
- Continued increase in the number of dangerous fire weather days and a longer fire season for much of southern and eastern Australia.
- Further sea level rise and continued warming and acidification of the oceans around Australia.
- Increased and longer-lasting marine heatwaves that will affect marine environments such as kelp forests and increase the likelihood of more frequent and severe bleaching events in coral reefs around Australia, including the Great Barrier Reef and Ningaloo Reef.
- Fewer tropical cyclones, but with higher intensity on average, and greater impacts when they occur through higher rain rates and higher sea level.

Detailed Impact/Risk Assessment

- Reduced average snow depth in alpine regions, but with variations from year to year.

The IPCC is the United Nations body for assessing the science related to climate change and finalised the Sixth Assessment Report (AR6) in 2023. This consists of three Working Group contributions and a Synthesis Report. A summary of outcomes of the working group's contributions comprises a range of matters, which amongst others include:

- The AR6 Working Group I (AR6-WG1) report stated that it is unequivocal that there is human-induced warming. It also stated that increased atmospheric carbon dioxide (CO2) levels, generated by human activity, are the largest driver of warming over the longer term, and that there are a range of factors, including emissions of methane, which increase warming in the short-term.
- The AR6 Working Group II (AR6-WG2) report stated that human-induced climate change, including more frequent and intense extreme events, has caused widespread adverse impacts and related losses and damages to nature and people, beyond natural climate variability. It stated that global warming, reaching 1.5°C in the near-term, would cause unavoidable increases in multiple climate hazards and present multiple risks to ecosystems and humans. The report noted that societal choices and actions implemented in the next decade will determine the extent to which medium- and long-term pathways will deliver climate resilient development.
- The AR6 Working Group III (AR6-WG3) report provided an updated global assessment of climate change mitigation progress and pledges and examined the sources of global emissions. It explained developments in emissions reduction and mitigation efforts and assessed the impact of national climate pledges in relation to long-term emissions goals. More than 2000 quantitative emissions pathways were submitted to the IPCC, of which 1202 scenarios included sufficient information for assessing the associated warming. The report found that there are many pathways in the literature that likely limit global warming to 2°C with no overshoot, or to 1.5°C with limited overshoot. These variations occur because, while climate science is able to calculate a 'carbon budget' of net emissions before any particular temperature outcome is reached, the allocation of this budget between different human activities requires additional judgements about for example technology, economics, consumer preferences and policy choices.
- The AR6 Working Group I (AR6-WGI) report states "[climate change is a global phenomenon, but manifests differently in different regions" (IPCC 2021b). IPCC projections for climate change in Australia from the AR6 Working Group II (AR6-WGII) report include:
- further climate change is inevitable, with the rate and magnitude largely dependent on the emission pathway (very *high confidence*)[83]
- ongoing warming is projected, with more hot days and fewer cold days (*very high confidence*)
- further sea level rise, ocean warming, and ocean acidification are projected (*very high confidence*)
- less winter and spring rainfall is projected in southern Australia, with more winter rainfall in Tasmania, less autumn rainfall in southwestern Victoria and less summer rainfall in western Tasmania (*medium confidence*), with uncertain rainfall changes in northern Australia
- more extreme fire weather is projected in southern and eastern Australia (*high confidence*)
- increased drought frequency is projected for southern and eastern Australia (*medium confidence*)
- increased heavy rainfall intensity is projected, with fewer tropical cyclones and a greater proportion of severe cyclones (*medium confidence*) (Lawrence et al., 2022).
- The AR6-WGII also contains information about projected impacts to health and well-being for the Australasian region including, amongst others:
- detrimental effects on human health due to heat stress, changing rainfall patterns including floods and drought climate-sensitive air pollution (including that caused by wildfires) (high confidence) and vector-borne diseases (medium confidence)
- vulnerability to detrimental effects of climate change will vary with socioeconomic conditions (high confidence) (Lawrence et al. 2022).

For further information related to Woodside's approach to climate change, please see Section 5.3 'Managing Physical Risk' and Section 6.3 'A Just Transition' of Woodside's Climate Transition Action Plan and 2023 Progress Report.

The AR6-WGII report identified nine key climate risks for the Australasian region:

[83] A level of confidence is expressed using five qualifiers: very low, low, medium, high, and very high. For a given evidence and agreement statement, different confidence levels can be assigned, but increasing levels of evidence and degrees of agreement are correlated with increasing confidence (Lawrence et al., 2022).

Detailed Impact/Risk Assessment

- loss and degradation of coral reefs and associated biodiversity and ecosystem service values in Australia due to ocean warming and marine heatwaves (very high confidence)
- loss of alpine biodiversity in Australia due to less snow (high confidence)
- transition or collapse of alpine ash, snow gum woodland, pencil pine and northern jarrah forests in southern Australia due to hotter and drier conditions with more fires (high confidence)
- loss of kelp forests in southern Australia due to ocean warming, marine heatwaves, and overgrazing by climate-driven range extensions of herbivore fish and urchins (high confidence)
- loss of natural and human systems in low-lying coastal areas due to sea level rise (high confidence)
- disruption and decline in agricultural production and increased stress in rural communities in south-western, southern and eastern mainland Australia due to hotter and drier conditions (high confidence)
- increase in heat-related mortality and morbidity for people and wildlife in Australia due to heatwaves (high confidence)
- cascading, compounding and aggregate impacts on cities, settlements, infrastructure, supply-chains and services due to wildfires, floods, droughts, heatwaves, storms and sea level rise (high confidence)
- inability of institutions and governance systems to manage climate risks (high confidence) (Lawrence et al., 2022).

An earlier report by Australia's Biodiversity and Climate Change Advisory Group summarised the potential impacts of climate change to marine and terrestrial species, habitats and ecosystems across Australia (Steffen et al., 2009). The 2009 report identified examples of observed changes in Australia's biota that were considered consistent with the emerging climate change 'signal', as genetic constitution, geographic ranges, lifecycles, populations, ecotonal boundaries, ecosystems, and disturbance regimes (Steffen et al., 2009). The report also stated:

"Biodiversity is one of the most vulnerable sectors to climate change".

"Australia's biodiversity is not distributed evenly over the continent but is clustered in a small number of hotspots with exceptionally rich biodiversity", and that these "include the Great Barrier Reef, south-west Western Australia, the Australian Alps, the Queensland Wet Tropics and the Kakadu wetlands".

Further, it was stated that *"many of the most important impacts of climate change on biodiversity will be the indirect ones at the community and ecosystem levels, together with the interactive effects with existing stressors (Steffen et al., 2009).* Future climate change (e.g., increased temperature and decreased, but more variable, rainfall) has the potential to have a range of impacts on ecological factors and threaten biodiversity in the Australian Mediterranean ecosystem (CSIRO, 2017).

Extensive modelling and monitoring studies over the last twenty years provide considerable evidence that global climate change is already affecting and will continue to affect species (Hoegh-Guldberg et al., 2018); however, these impacts are likely to be highly species-dependent and spatially variable. The most frequently observed and cited ecological responses to climate change include species distributions shifting towards the poles, upwards in elevation and shifts in phenology (earlier and later autumn life-history events) (M. Dunlop et al., 2012). Climate change may not only change species distribution patterns but also life-history traits such as migration patterns, reproductive seasonality and sex ratios (Steffen et al., 2009).

Impacts of climate change such as altering temperature, rainfall patterns and fire regimes, are likely to lead to changes in vegetation structure across all terrestrial ecosystems within Australia (M. Dunlop et al., 2012; Steffen et al., 2009). Increases in fire regimes will impact Australian ecosystems altering composition structure, habitat heterogeneity and ecosystem processes. Changes in climate variability, as well as averages, could also be important drivers of altered species interactions, both endemic and invasive species (M. Dunlop et al., 2012). Climate change could result in significant ecosystem shifts, as well as alterations to species ranges and abundances within those ecosystems (Hoegh-Guldberg et al., 2018).

The 'loss of climatic habitat caused by anthropogenic emissions of greenhouse gases' has been listed as a key threatening process under the EPBC Act (DCCEEW, 2021). The threatening process consists of reductions in the bioclimatic range within which a given species or ecological community exists due to emissions induced by human activities of greenhouse gases (DCCEEW, 2021). The process is considered to have a continental distribution, including both terrestrial and marine areas. Ecosystems in which the process occurs include: alpine habitats, coral reefs, wetlands and coastal ecosystems, polar communities, tropical forests, temperate forests, and arid and semi-arid environments (DCCEEW, 2021).

Coral reefs were recognised by both IPCC and the Australian Government as being at risk of climate change (Lawrence et al., 2022; DCCEEW, 2021). Protected coral reef areas in Australia include those within World Heritage listed sites, such as Ningaloo Coast, Shark Bay, or the Great Barrier Reef. Climate change has been identified as a threat for each of these World Heritage areas, with potential risks to coral reef as well as other environmental values (such as marine fauna) within these ecosystems (IUCN, 2020b, 2020c, 2020a).

Detailed Impact/Risk Assessment
Climate variability and change has been identified as a threat to some EPBC Act protected species, including marine turtles, whales, seabirds and migratory shorebirds: • The Recovery Plan for Marine Turtles in Australia (CoA 2017) states that "[climate change is of particular concern to marine turtles because it is likely to have impacts across their entire range and at all life stages. Climate change is expected to cause changes in dispersal patterns, food webs, species range, primary sex ratios, habitat availability, reproductive success and survivorship". • The Conservation Management Plan for the Blue Whale (CoA 2015a) states: [climate change is expected to cause changes in migratory timing and destinations, population range, breeding schedule, reproductive success and survival of baleen whales, including blue whale species and subspecies". • The Wildlife Conservation Plan for Seabirds (CoA 2022) states that "[consequences to seabirds could include negative impacts from an increase in extreme weather events, reduced or changed prey abundance and distribution, and decrease in nesting habitat". • The Wildlife Conservation Plan for Migratory Shorebirds (CoA 2015) states that '[such changes have the potential to affect migratory shorebirds and their habitats by reducing the extent of coastal and inland wetlands or through a poleward shift in the range of many species". The Recovery Plan for the Southern Right Whale (DCCEEW, 2024a) states that 'modelling the links between krill and whale population dynamics with climate change, including changes in ocean temperature, primary productivity, and sea ice, suggests future ocean conditions are likely to have a negative impact on krill populations and in association the baleen whale species that feed on them.' The North-west Marine Parks Network Management Plan 2018 (DNP, 2018) identifies climate change as a pressure that may impact marine park values. The management plan states that "[t]he impacts of climate change on the marine environment are complex and may include changes in sea temperature, sea level, ocean acidification, sea currents, increased storm frequency and intensity, species range extensions or local extinctions, all of which have the potential to impact on marine park values" (DNP, 2018). Within the Marine Bioregional Plan for the NWMR (DSEWPaC, 2012), pressures related to climate change are assessed as 'of potential concern' for species of marine turtle, inshore dolphins, sawfish, sea snakes, whale shark, dugong, and seabird and shorebird, as well as the KEFs and shipwrecks known to occur in the NWMR.
Summary of Assessment Outcomes
Overall Impact Significance Level: Pluto offshore operations (Direct and Indirect) GHG emissions cause a small reduction of global carbon budgets estimated to meet goals of the Paris Agreement – assigned an Impact level of Negligible (F). Climate change impacts cannot be attributed to any one activity as they are instead the result of global GHG emissions, minus global GHG sinks, that have accumulated in the atmosphere since the industrial revolution started. They do not take into account the net impact of each project or activity. Even discounting the role gas can play towards customer commitments and plans to decarbonise through the energy transition, emissions associated with Pluto are expected to have a de minimis impact to global carbon budgets estimated to meet goals of the Paris Agreement. Pluto offshore operations and downstream processing facilities will also comply with the Federal Safeguard Mechanism Baseline, aligning with Australia's carbon management framework and implementation of the Paris Agreement.

XNA03 Drilling: Well control bridging document (WCBD) for alignment of Woodside and the MODU Contractor in order to manage the equipment and procedures for preventing and handling a well kick.	F: Yes. CS: Standard practice. Required by Woodside standards.	Implementing equipment and procedures in the well control bridging document will reduce the volume of gas vented in the event of a well kick.	Benefits outweigh cost/sacrifice.	Yes C 10.8
Good Practice				
Forecast, measure, monitor and or estimate facility fuel and flare emissions (in accordance with NGERS and WMS procedures named in Section 7.2.11.2) to inform optimisation management practices and minimise environmental impact of emissions.	F: Yes. CS: Minimal cost. Standard practice.	Minimises environmental impact of emissions through planning, ongoing review, governance and optimisation. It combines with good operating practice to maximise production and reduce flaring emissions (Pluto) and fuel emissions at the LNG plant to manage cost, which improves energy intensity (e.g. cleaner production), optimising emissions from the project. Fuel and flared gas are potential product streams, as such, Woodside applies routine short and long term optimisation and opportunity management framework to identify and prioritise enhancement opportunities. On Pluto to date this has been limited to reduced flaring (e.g. flare purge rates); however overall system efficiencies (such as well and composition optimisation) and LNG Plant opportunities are also considered in this process. Annual flare and emissions target setting and monthly review of performance is completed for Pluto. The LNG Plant also applies flare and emissions target setting and tracking for emissions management. Daily production meetings allow for optimisation as an integrated production system, considering impacts of variables such as maintenance activities and temperature influence on production rates.	Control is WMS requirement – must be adopted.	Yes 10.9
Contracting strategy and evaluation for hire of support vessels includes consideration of	F: Yes. CS: Fuel cost over the 5-year contract is considered in the	Minimises costs and emissions through eco-efficiency approach recognising cost of fuel and	Control effectively allocates a cost to emissions to	Yes C 10.10

vessel emissions parameters and low carbon/alternate fuels.	evaluation of responses, allowing for competitive consideration of low carbon alternatives.	carbon emissions over the contract term	recognise that higher emitting fuel sources with other lower operating costs do not represent overall best value.	
XNA03 Drilling: Well unloading acceptance criteria that define the well objectives will be established.	F: Yes. CS: Standard practice.	Eliminates unnecessary flared volumes and corresponding emissions (light and GHG).	Benefits outweigh cost/sacrifice.	Yes C 10.11
XNA03 Drilling: Assess opportunities to eliminate well flowback flaring to MODU. The assessment will consider factors such as: • HSE considerations • well performance • proof of completions success • solids and liquids handling • potential eventual other impacts to the topsides.	F: To be decided. The decision on whether to unload to the MODU or Pluto will be based on technical study outcomes. CS: Cost effective but introduces additional risks to the production facility (i.e. risk of equipment and subsea system failures due to solids).	Minimises environmental impact through the reduction of GHG emissions. Well flowback may be avoided entirely. In this case the wells are instead flowed back to the eventual host facility (the Pluto Facility), resulting in a small increase to expected bean-up flaring for the well but resulting in a net overall flaring decrease.	Benefits potentially outweigh cost/sacrifice.	Yes C 10.12
Development and implement a Pluto integrated facility Methane Action Plan which will detail: • Inventorisation and planned measurement activities to align with the principles of OGMP2.0 reporting framework levels and timelines;	F: Yes CS: Cost, and facility modification safety and reliability risks associated with implementation of commitments.	Methane management activities are aligned with environmental, social, and governance expectations, and Woodside's approach to methane emissions management including and consistent with the principles of OGMP 2.0, and Near-Zero, and is consistent with industry-recognised practices, delivering appropriate and proportional identification and reduction efforts for methane emissions, considering the nature and scale of the facility. Pluto integrated facility management Methane Action	Control is committed – will be adopted	Yes C 10.14

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/ Sacrifice (CS)[84]***	***Benefit in Impact Reduction***	***Proportionality***	***Control Adopted***
• Proportional identification and evaluation of methane opportunities as part of GHG optimisation and opportunity management practices • Includes controls and monitoring activities at the Pluto offshore facility for direct methane GHG emissions		Plan (in-place during 2025) will include: • Development and maintenance of a methane inventory (offshore and onshore processing) • Progress measurement projects to align with OGMP2.0 reporting framework levels and timelines – focussing on onshore processing methane emissions as the material OGMP2.0 facility. – Indicative projects for the action plan for Pluto LNG facility monitoring includes direct measurement surveys of combustion system and vent streams, safety and operational gas detection, leak surveys, metering upgrades, and testing of emergent technology for flare gas combustion efficiency. • Identify and evaluate opportunities for methane emissions mitigation based on a methane inventory using appropriate valuation assumptions to identify NPV positive projects (to contribute optimisation practices (Section 7.2.11.1)) These management measures at Pluto align with Woodside's corporate approach to methane emissions management as appropriate including current OGMP 2.0 requirements to progress proportional identification and reduction efforts for methane for the integrated Pluto facility, and considers the design, very low contribution, non-material and not-normally crewed nature of the PLA platform.		
Implement relevant methane management activities at Pluto offshore platform	F: Yes CS: Cost associated with offshore deployment and logistics. Some offshore activities can be accommodated, however	Methane management activities at PLA which supports the integrated Pluto facility methane and GHG optimisation (C 10.14 above) includes:	Process safety-driven gas detection, maintenance and operations is good industry	**C 10.17**

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/ Sacrifice (CS)[84]***	***Benefit in Impact Reduction***	***Proportionality***	***Control Adopted***
	PLA platform is designed to be operated with minimal crewing, thus minimising risk exposure to personnel. The operations and maintenance strategy has a focus on reducing personnel exposure to hazards associated with offshore operations while maintaining the integrity and operability of the facilities. The strategy depends on effective management of all workforce groups and all activities on the PLA platform to maximise efficiency and ensure offshore scopes are selected with the appropriate risk-based lens. Disproportionate utilisation of offshore crewing for very minor or low-probability of material environmental benefit is not ALARP. Given PLA's very low methane emissions, and existing controls in place; potential GHG footprint of incremental offshore work scopes, maintenance hours and associated logistics risk GHG emissions from vessel support and helicopter loads exceeding any low-probability identification and remediation of residual low rate fugitive emissions. Further, due to its small emissions footprint, the Pluto-A offshore facility is classed as a non-material facility under the OGMP 2.0 Framework. LDAR via fixed gas detection is considered industry standard practice, which is expected to detect material methane leaks and maintain platform safety. Operational LDAR for fugitive methane leaks using either handheld equipment or top-down /	• Operational gas detection, fixed and mobile, to identify hydrocarbon leak sources, predominantly methane. Continuous fixed gas detection (as a component of the PLA Safety Case) and operator inspections upon platform arrival, detect and enable repair of material methane emissions. Regular visitation (approx. 10 visits per year) aids in facilitating observation, inspection and maintenance of methane-containing systems. • Safety-driven LDAR - start-up leaks checks following crewed turnarounds with break-of-containment activities can reduce methane emissions. Baseline Pluto PWH module commissioning leak testing and remediation (two small fugitives identified) was completed during 2024. Post-shutdown start-up infrared and portable gas detection identify leaks for evaluation and repair. Benefits likely outweigh minor cost/sacrifice. • CCTV monitoring of the flare ignition from Pluto PROC CCR to reduce incomplete combustion in flaring. Includes thermal imaging for strong flame indication to support timely reignition (Refer flare monitoring and ignition equipment standards). • Pluto produced water system designed and operated with secondary treatment HIGF which includes low-pressure flash gas operations to remove hydrocarbons including entrained methane from offshore discharged produced water. PW discharge metered • Pluto offshore methane inventory developed in 2025 - reviewed annually.	practice with gas detection control based on legislative requirements (e.g. Safety Case) – thus, must be adopted. Flare monitoring and ignition controls (refer engineered solution), and produced water separation HIGF system installed, and metered per Section 6.7.7). Routine leak survey beyond OGMP 2.0 requirements is proposed at PLA to verify scale of methane emissions against the NGER estimate methane assumption in the EP, incrementally increasing short-term offshore crewing to support EP acceptability.	

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/ Sacrifice (CS)[84]***	***Benefit in Impact Reduction***	***Proportionality***	***Control Adopted***
	remote sensing, e.g., via drone is feasible.	• Conduct routine methane leak surveys on Pluto offshore platform, beginning in 2026 and three-yearly[85] thereafter to: – Verify NGERS-based methane estimates • Identify opportunities for mitigation, actioned in accordance with optimisation management practices (Section 7.2.11.1).		
Woodside supports customers[86] to reduce their emissions via the investment in new energy products and lower carbon services, including the progression of corporate Scope 3 targets that apply across Woodside's portfolio including the following: • Scope 3 Investment Target[87]: Woodside has a Scope 3 investment target aiming to invest $5 billion in new energy products and lower carbon services (non LNG) by 2030[88]. • Scope 3 Emissions Abatement Target[8787]:	F: Yes CS: Cost as reflected in target	Supports customers to reduce their scope 1 and 2 emissions	Proportional at a Woodside corporate level	Yes C 10.15

[85] Frequency is deemed appropriate based on facility methane risk, NGER estimate and other controls in place. Appropriateness of frequency will be verified following 2026 survey.
[86] The customers for these products and services may be the same as the customers of our oil and gas business, directly substituting their energy for new products or directly abating the associated emissions. They may also be customers of the new products and services, without also being customers of oil and gas.
[87] Scope 3 targets are subject to commercial arrangements, commercial feasibility, regulatory and Joint Venture approvals, and third party activities (which may or may not proceed). Individual investment decisions are subject to Woodside's investment targets. Not guidance. Potentially includes both organic and inorganic investment. Timing refers to financial investment decision, not start-up/operations.
[88] Includes pre-RFSU spend on new energy products and lower carbon services that can help our customers decarbonise by using these products and services. It is not used to fund reductions of Woodside's net equity Scope 1 and 2 emissions which are managed separately through asset decarbonisation plans.

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/ Sacrifice (CS)[84]***	***Benefit in Impact Reduction***	***Proportionality***	***Control Adopted***
• Woodside has a Scope 3 emissions abatement target, to indicate the potential abatement impact of these products and services upon customer Scope 1 or 2 emissions. This target is to take final investment decisions on new energy products and lower carbon services by 2030, with total abatement capacity of 5 Mtpa CO2 -e[89].				
Woodside will work with the natural gas value chain to reduce emissions in third party systems (e.g. regasification and distribution),	F: Yes CS: Minimal cost associated with collaboration and advocacy	Supports customers to reduce their scope 1 and 2 emissions	Proportional at a Woodside corporate level	Yes **C 10.16**
Professional Judgement – Elimination				
Eliminate flaring by venting un-combusted hydrocarbons.	F: No. Routine hydrocarbon venting is not considered good industry practice, as unburnt methane poses potential for greater environment impact compared to combustion emissions. The ability to flare hydrocarbons is a key safety feature on the facility. Removing the ability to flare hydrocarbons may result in unacceptable safety risks on the facility. CS: Not assessed, control not feasible.	Not assessed, control not feasible.	Not assessed, control not feasible.	No

[89] Includes binding and non-binding opportunities in the portfolio, subject to commercial arrangements, commercial feasibility, regulatory and Joint Venture approvals, and third party activities (which may or may not proceed). Individual investment decisions are subject to Woodside's investment targets. Not guidance.

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/ Sacrifice (CS)[84]***	***Benefit in Impact Reduction***	***Proportionality***	***Control Adopted***
Eliminate flaring by reinjecting un-combusted hydrocarbons.	F: No. Routine hydrocarbon reinjection, as opposed to transport to onshore facilities, would not be consistent with the approved Pluto Field Development Plan (FDP) which seeks to optimise hydrocarbon recovery while fulfilling gas supply commitments. As such, gas reinjection would not meet concept screening criteria to warrant option evaluation. CS: Not assessed, control not feasible.	Not assessed, control not feasible.	Not assessed, control not feasible.	No
XNA03 Drilling: Do not vent during well kick.	F: No. Venting is a critical safety activity required in the event of a kick to reduce pressure build up. CS: Not considered, control not feasible.	Not considered, control not feasible.	Not considered, control not feasible.	No
Professional Judgement – Substitution				
Fuel for energy generation on the riser platform is selected for lowest indirect emissions generation practicable: Fuel gas used in preference to diesel for power generation.	F: Yes, fuel gas is the primary fuel source, with diesel as back up fuel used during peak power demand periods and when gas production is shut down. CS: Cost effective.	Gas turbines reduce CO_2 emissions for a given unit of power and reduces spill risk associated with diesel bunkering activities.	Cost effective. Minimises fuel bunkering risks.	Yes. Solution permanently implemented. This improvement was made as part of the recent PW-handling module upgrades, with gas engine commissioned in 2023.
Professional Judgement – Engineered Solution				
Maintain flare tip integrity, flame monitoring (CCTV) and ignition system to support efficiency of combustion and minimise venting,	F: Yes. CS: Minimal cost. Standard practice.	Flare tip integrity, flame monitoring (CCTV) and ignition system functionality minimises potential for venting, incomplete combustion waste products and smoke emissions. Managed via	Control is WMS requirement – must be adopted.	Yes C 10.13

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/ Sacrifice (CS)[84]***	***Benefit in Impact Reduction***	***Proportionality***	***Control Adopted***
incomplete combustion waste products and smoke emissions (equipment within scope of P31).		P31 - Emissions Monitoring and Controls. Minimises environmental emissions through reduction of frequency and duration of potential unplanned venting. Monitoring of the flare is conducted via CCTV (including thermal optical detection) from the PROC CCR. In the event that the flare is extinguished the flare can be reignited remotely or locally via the reignition panel. Note PLA historically operates with a stable flare flame and does not experience flameout events during normal operations.		
Installation of flare gas recovery systems to reduce emissions entering the atmosphere from flaring.	F: Yes CS: Significant additional cost associated with the design and installation of flare gas recovery systems, including significant retrofitting of multiple stages of compression systems, coupled with associated ancillaries, valving and piping, platform modification and weight considerations. The safe addition of required rotating equipment also poses significant production sacrifice and potential domestic gas supply impacts due to the initial design layout, space and safety constraints.	Small to negligible environmental benefit from reducing atmospheric emissions from flaring. The environmental benefit gained from the recovery of flaring emissions would be limited to only a portion of flare system flows due to process safety constraints and flare system operation over a wide design envelope (associated with flow and pressure variations and related flowline integrity management). Furthermore, required retrofitting of multiple stages of compressions (e.g. for LP/HP streams) would offset any environmental benefits through increased power generation emissions. The retrofitting interaction with the safety critical flare system and continued operation and maintenance of gas compression would also increase the NNC platform safety risks.	Given the increased safety risk and the very low, if any, environmental benefit provided when increased power generation emissions are taken into consideration, the installation of flare gas recovery systems is considered grossly disproportionate to the environmental benefit it would provide.	No

Discussion of ALARP

Atmospheric Emissions

On the basis of the environmental risk assessment outcomes and the use of the relevant tools appropriate to decision type A, Woodside considers the adopted controls appropriate to manage the impacts of Pluto facility, tie-back activities and vessel atmospheric emissions. As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.

GHG Emissions

Risk Based Analysis

Application of Woodside's Risk Management Procedures, implementation of the GHG Emissions and Energy Management Procedure and Production Optimisation and Opportunity Management Procedure reduces GHG emissions risk to ALARP (Section 7.2). This includes a system of continual review and improvement of key

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/ Sacrifice (CS)[84]***	***Benefit in Impact Reduction***	***Proportionality***	***Control Adopted***

emissions sources from the Pluto assets as an integrated system, including the Pluto-A offshore platform; e.g., installation of a gas engine on PLA which replaces the primary method of power generation from diesel to gas. Further opportunities are implemented at the Pluto LNG Plant to reduce indirect emissions associated with production from Pluto offshore fields.

Societal Values

Consultation was undertaken for this program to identify the views and concerns of relevant persons, as described in Section 5 and Appendix F Consultation Summary Tables. Some stakeholders expressed strong views on GHG emissions associated with Pluto operations, which were responded to accordingly. This included provision of further information on direct and indirect GHG emissions, discussion of controls and Woodside's corporate position, targets and controls via the 2024 Climate Transition Action Plan and 2023 Progress Report (Woodside, 2024).

ALARP Statement:

On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type (i.e., Decision Type A and B for direct and indirect emissions respectively), Woodside considers the adopted controls appropriate to manage GHG emissions from the Pluto facility and indirect emissions sources that Woodside can practicably influence, including support vessels, during the five year term of this EP. The adopted controls meet legislative requirements, including:

- Marine Order 97 for support vessels
- NGERS and NPI reporting for direct emissions attributed to Pluto
- National Greenhouse and Energy Reporting (Safeguard Mechanism) Rule 2015.

Indirect GHG emissions from onshore processing at PLP are managed under the Pluto Greenhouse Gas Abatement Program, and at Karratha Gas Plant (KGP) are managed under MS1233 GHG Conditions. These require comprehensive reporting and independent auditing of emissions and emission intensities to ensure compliance with contemporary greenhouse gas standards and to maintain transparency and accountability. GHG emissions data available to Woodside is used to derive onshore hydrocarbon processing estimates allocated to the processing of Pluto gas - for example data made publicly available under state Ministerial Statements 757 (Pluto) and 1233 (KGP). It is noted that MS 757/1208 may be amended to alter GHG conditions, however precedent exists that contemporised conditions (such as MS1233) retain requirements for the publication of such data.

The Federal Safeguard Mechanism (SGM)[90] requires Australia's highest greenhouse gas emitting facilities to reduce or limit their emissions in line with Australia's emission reduction targets of 43% below 2005 levels by 2030 and net zero by 2050. Direct GHG emissions from the Pluto Offshore Facility, indirect emissions associated with onshore processing of gas from Pluto as well as indirect emissions associated with the transportation and end use of gas within Australian safeguard facilities are subject to the SGM, and net emissions from these sources must be kept below a specified limit or baseline.

Safeguard facilities that exceed their baseline must manage their excess emissions, such as by surrendering acceptable quality offsets suitably classified as Australian Carbon Credit Units (ACCUs) or Safeguard Mechanism Credits (SMCs) which is the other eligible compliance unit. Each are representative of one tonne of CO2-e per credit, so that net emissions under the scheme are brought in line with the baseline. So that sufficient credits are available and that there is a means to comply, safeguard facilities that exceed their baseline are able to buy Government-held ACCUs from the Clean Energy Regulator via the Cost Containment Measure implemented as part of recent reforms.

Safeguard Mechanism (SGM) obligations for the Pluto facility as defined under SGM will be met by emissions abatement via operational controls as first preference (described above). Options to manage residual net emissions in excess of baseline include surrendering ACCUs or SMCs, applying to become a trade-exposed baseline-adjusted facility, applying to borrow baseline from the following year or applying for a multi-year monitoring period. Surrendered carbon credits may be generated from Woodside projects, purchased from the market or purchased from the Government through the Cost-Containment Mechanism. Woodside is implementing programs at a corporate level to manage indirect emissions associated with customer use of gas from Pluto.

As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, GHG emissions from the Pluto facility and indirect emissions sources that Woodside may practicably influence are considered ALARP.

[90] Further information about the SGM and SGM Baselines can be found at the Clean Energy Regulator website: https://cer.gov.au/schemes/safeguard-mechanism and https://cer.gov.au/schemes/safeguard-mechanism/safeguard-baselines.

Demonstration of Acceptability

Atmospheric Emissions

Given the adopted controls, atmospheric emissions represent a negligible impact that is unlikely to result in greater than isolated impacts with close proximity of the Pluto facility, in an unpopulated area approximately 160 km northwest of the nearest community receptor, Dampier. The adopted controls are considered good oil-field practice/industry good practice and meet requirements of Australia Marine Orders and National Pollutant Inventory reporting.

The potential impacts and risks are considered broadly acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the impacts and risks of atmospheric emissions to a level that is broadly acceptable.

Greenhouse Gas Emissions

To assess and determine that impacts from GHG emissions will be of an acceptable level, Woodside considered corporate commitments, principles of Ecologically Sustainable Development, Company Values and Societal Values.

Principles of Ecologically Sustainable Development

Giving consideration to economic development that safeguards the welfare of future generations, Pluto offshore operations is considered to align with the following core objectives of ESD by:

- Integration Principle
  - the existing environment (Section 4) has been described consistent with the definition within Regulation 5 of the Environment Regulations (i.e. includes ecological, socioeconomic, and cultural features), and any relevant values and sensitivities have been included within this impact analysis; therefore, the impact assessment process inherently includes economic, environmental and social considerations
  - indirect GHG emissions associated with Pluto will be managed to ALARP and an acceptable level through the implementation of the controls detailed in this section.
  - Feedback, objections and claims from Relevant Persons were considered, see Appendix F
- Precautionary Principle
  - there is some scientific uncertainty associated with the projection of climate change trends, the predicted and observed environmental effects of climate change, and the changing regulatory and social requirements and/or expectations
  - Woodside has committed to management and mitigation measures for GHG emissions to ensure that Pluto continues to manage GHG emissions to an ALARP and acceptable level
- Intergenerational Principle
  - continue to provide LNG as a source of fuel for global markets and pursue the development of new energy products and lower carbon services with reference to the UN Sustainable Development Goal 7, Affordable and Clean Energy
  - gas having the potential to contribute to an incremental reduction in global GHG emissions by displacing more carbon intensive power generation (e.g., coal), firming up renewables, or in hard-to-abate sectors
  - Woodside considers that this development is aligned with its goals for supporting the energy transition and is compatible with the Paris Agreement goal to hold “the increase in the global average temperature to well below 2°C above pre-industrial levels and to pursue efforts to limit the temperature increase to 1.5°C.”
- Biodiversity Principle
  - the existing environment (Section 4) identifies and describes relevant MNES, as defined in Regulation 7(3) of the Environment Regulations; any relevant values and sensitivities are included in the contextual evaluation of climate change.
  - As described above the estimated GHG emissions associated with Pluto will have a de minimis contribution the net atmospheric global GHG concentrations and therefore are not expected to affect biodiversity.

Woodside looks after the communities and environments where we operate. Risks are inherent in petroleum activities; however, through sound management, systematic application of policies, standards, procedures and processes

Internal Context

The PAP is consistent with Woodside corporate polices, culture, processes, standards, structure and systems as outlined in the Demonstration of ALARP and Environmental Performance Outcomes, including:

- Woodside Environment and Biodiversity Policy (Appendix A)
- Woodside Risk Management Policy (Appendix A)
- Woodside Climate Policy (Appendix A)

- Woodside Climate Transition Action Plan and Progress Report
- Woodside being a signatory to the Aiming for Zero Methane Emissions Initiative, the Oil and Gas Methane Partnership 2.0 and the World Bank's Zero Routine Flaring by 2030 Initiative for oil projects, which are voluntary, international multi stakeholder partnerships between industry and non-industry organisations.
  - Deployment is applied consistent with OGMP2.0 principles on a risk-based approach for the most effective deployment of resources and effort to identify and reduce streams which make the most proportional difference - with a methane management strategy for the integrated Pluto facilities, including offshore at PLA.
- WMS requirements such as the GHG emissions and Energy Management Procedure, Production Optimisation and Opportunity Management Procedure (Section 7.2). This is achieved by implementing tools to identify, evaluate, implement and review emissions reductions projects.

External Context

GHG emissions are a global concern, and as such Woodside has undertaken an impact assessment of GHG associated with the Pluto facility and identified key measures to manage GHG emissions to an acceptable level.

According to Wood Mackenzie Energy Research Consultancy, LNG from Woodside operated facilities is amongst the lowest carbon intensity in the world delivered into North Asia[91].

The global consensus on climate change led to the implementation of the Paris Agreement. The aim of the Paris Agreement, as stated in the Article 2.1(a) is to hold the increase in global average temperature to well below 2°C above pre-industrial levels. The Agreement also aims to pursue efforts to limit the temperature increase to 1.5°C above pre-industrial levels, recognising that this would significantly reduce the risks and impacts of climate change.

Paris Agreement text extract[92]:

"Article 2

1. This Agreement, in enhancing the implementation of the Convention, including its objective, aims to strengthen the global response to the threat of climate change, in the context of sustainable development and efforts to eradicate poverty, including by:

(a) Holding the increase in the global average temperature to well below 2°C above pre-industrial levels and pursuing efforts to limit the temperature increase to 1.5°C above pre-industrial levels, recognising this would significantly reduce the risks and impacts of climate change;

This was reaffirmed in December 2023 in the COP28 decision text on the First global stocktake[93]. The text further recognised that the transition away from fossil fuels in energy systems is to be done in a just, orderly and equitable manner accelerating action in this critical decade, so as to achieve net zero by 2050 in keeping with the science[94]. It also recognises transitional fuels can play a role in facilitating the energy transition while ensuring energy security[95].

The Paris Agreement establishes a framework where countries make nationally determined contributions to manage and reduce their own emissions.

Australia has ratified the Paris Agreement and has set a target to reduce emissions by 43% below 2005 levels by 2030 and to reach net-zero emissions by 2050. Australia's emissions projections under a 'with additional measures' scenario is projected to be 42.6% below 2005 levels by 2030, the next waypoint to net zero emissions by 2050 (DCCEEW 2024b)

Pluto offshore (direct GHG) and indirect onshore third-party processing facilities are also subject to complying with the Federal Safeguard Mechanism (SGM) to manage net emissions under the scheme in line with Australia's emission reduction targets of 43% below 2005 levels by 2030 and net zero by 2050.

Australia's Long-Term Emissions Reduction Plan (DISER, 2021) presents Australia's whole-of-economy plan to achieving net zero emissions by 2050 with priority technologies estimated to achieve 85% reduction and yet-to-be identified emerging technologies abating the remainder. The plan identified LNG as a critical transition fuel and expects growth in the sector with higher use in 2030 than it is today but acknowledging that growth will depend on the preferences of customers and the pace of international action (DISER, 2021).

Climate science has drawn a link between cumulative emissions of greenhouse gases and global temperature levels. The link between cumulative emissions and temperature levels allows a carbon budget to be calculated. This is the

[94] FCCC/PA/CMA/2023L.17 (Draft decision distributed 13 December 2023) First global stocktake text extracts https://unfccc.int/sites/default/files/resource/cma2023_L17_adv.pdf (Section II, Subsection A, Clause 28 (d)).
[95] FCCC/PA/CMA/2023L.17 (Draft decision distributed 13 December 2023) First global stocktake text extracts https://unfccc.int/sites/default/files/resource/cma2023_L17_adv.pdf (Section II, Subsection A, Clause 29).

remaining amount of net emissions (i.e., all global sources of emissions minus all global sinks of emissions) that can occur before today's concentration of greenhouse gases increases to the concentration associated with potential temperature outcomes.

Assuming the scenario in which all GHG emissions associated with Pluto are additive to global GHG gas concentrations, which they may not be, the activity's contribution to the carbon budget required to meet the goals of the Paris Agreement is de minimis.

However, the distribution of this carbon budget across different human activities requires additional judgements about a wider range of social, economic and technological factors and consumer and policy choices. Strategies to achieve emissions reductions include transitioning from fossil fuels without CCS to very-low- or zero-carbon energy sources, such as renewables or fossil fuels with CCS, demand side measures and improving efficiency, reducing non-CO2 emissions, and deploying carbon dioxide removal (CDR) methods to counterbalance residual greenhouse gas emissions. Pathways to limit warming therefore show different combinations of sectoral mitigation strategies consistent with a given warming level.

As a result, the demand for oil and gas in climate-related scenarios that could limit global warming to 1.5°C or 2°C is uncertain. For example, in the AR6-WG3 report, the IPCC stated that in pathways that limit warming to 1.5°C (with a greater than 50% probability and with no or limited overshoot) the potential global use of gas in 2050 ranges from 30% above 2019 levels to 85% below them with a median 45% decline.

Woodside considers our role in providing energy as core to our contribution to a just energy transition. UNSD Goal 7 is to "ensure access to affordable, reliable, sustainable and modern energy for all". The Pluto Facility will provide an incremental volume of hydrocarbons to Australian and international markets during its estimated remaining field life. Woodside considers that this development is aligned with the goals for supporting the energy transition and is compatible with the Paris Agreement goal.

Woodside is a signatory to several global initiatives which are complementary to our corporate approach to methane emissions management, which include OGMP 2.0 (2024), Oil and Gas Climate Initiative Aiming for Zero Methane Emissions (OGCI Near-Zero) and the Methane Guiding Principles (MGP, 2022), which are voluntary, international multi-stakeholder partnerships between industry and non-industry organisations. The OGMP 2.0 is the United Nations Environment Programme's flagship oil and gas reporting and abatement programme. OGMP 2.0 is a comprehensive, measurement-based reporting framework for the oil and gas industry that improves the accuracy and transparency of methane emissions reporting. This is key to prioritising methane abatement actions in the sector. Woodside is actioning these commitments at Pluto in line with the control measures C.10.14.

External context – stakeholder expectations and feedback

GHG emissions associated with the project, and the impacts of climate change, were noted as a material issue for relevant persons consulted in the course of preparing this EP. All feedback, claims or objections from Relevant Persons has been appropriately responded to and addressed (see Appendix F), and controls proposed have been assessed in the EP.

Other Requirements (Includes Laws, Polices, Standards and Conventions)

Legislation and other requirements considered relevant for this aspect, and a demonstration of how these requirements are met, are described below.

Requirement	Demonstration
Marine Order 97 Gives effect to Annex VI of MARPOL 73/78	The requirements of Marine Order 97 are incorporated into the key control measures.
National Greenhouse and Energy Reporting (NGER) scheme Annual GHG reporting for facilities	The requirements of NGER reporting scheme are incorporated into the key control measures.
National Greenhouse and Energy Reporting (Safeguard Mechanism) Rule 2015	The requirements of NGER Safeguard Mechanism are incorporated into the key control measures.
National Pollutant Inventory (NPI) Reporting Annual air pollutant reporting	The requirements of annual NPI reporting are incorporated into the key control measures.
Conservation Management Plan for the Blue Whale 2015–2025 Management action A3.1: Continue to meet Australia's international commitments to reduce greenhouse gas emissions and regulate the krill fishery in Antarctica Conservation Advice Balaenoptera borealis Sei Whale	As described above, the predicted atmospheric and GHG emissions from the Pluto Facility are considered de minimis, with no link to climate change impacts on Australian or International receptors. Therefore, the Pluto Facility is not considered to be inconsistent with the Conservation Management Plan for the Blue Whale 2015–2025 (CoA, 2015a), Conservation Advice for Sei Whale (TSSC, 2015a),

Conservation action: Continue to meet Australia's international commitments to reduce greenhouse gas emissions and regulate the krill fishery in Antarctica Conservation Advice Balaenoptera physalus Fin Whale Conservation action: Continue to meet Australia's international commitments to reduce greenhouse gas emissions and regulate the krill fishery in Antarctica National Recovery Plan for the Southern Right Whale action area A3.1: Continue to meet Australia's international commitments to address causes of climate change, including greenhouse gas emissions Recovery Plan for Marine Turtles in Australia Management action A2.1: Continue to meet Australia's international commitments to address the causes of climate change	Conservation Advice for Fin Whale (TSSC, 2015b), National Recovery Plan for the Southern Right Whale (DCCEEW, 2024a). Recovery Plan for Marine Turtles in Australia (CoA, 2017).

Acceptability Statement: Greenhouse Gas Emissions

As per Section 2.6.1 Decision Type B, GHG emissions are acceptable if "ALARP" is demonstrated using good industry practice and risk-based analysis, if legislative requirements are met and societal concerns are accounted for and the alternative control measures are grossly disproportionate to the benefit gained. In addition, acceptability is assessed against the above criteria. Further opportunities to reduce the impacts have been investigated (refer ALARP demonstration discussion). The potential impacts are considered acceptable if ALARP is demonstrated.

Indirect GHG emissions associated with the Pluto facility are managed to an acceptable level by meeting (where they exist) legislative requirements, industry codes and standards, applicable company requirements, and industry guidelines, and these have been adopted as key controls.

Even discounting the role gas can play towards customer commitments and plans to decarbonise through the energy transition, emissions associated with the project are negligible in the context of existing and future predicted global GHG emissions. As described above, even in the hypothetical scenario when taken to be wholly additive, the GHG emissions created by and associated with the project represent a de minimis contribution to the carbon budgets estimated to achieve the goals of the Paris Agreement. Further, the Project will comply with the relevant Australian carbon management framework, for example the Federal SGM. The impact on national and international emission reduction targets is therefore acceptable.

		management practices (Section 7.2.11.1).	
EPO 10d Woodside will support customers to reduce their GHG emissions.	**C 10.15** Woodside supports customers[97] to reduce their emissions via the investment in new energy products and lower carbon services, including corporate targets that apply across Woodside's portfolio including the following: • Scope 3 Investment Target[98] Invest $5 billion in new energy products and lower carbon services (non LNG) by 2030[99]. Scope 3 Emissions Abatement Target[98] • Take final investment decisions on new energy products and lower carbon services by 2030, with total abatement capacity of 5 Mtpa CO2 -e[100].	**PS 10.15.1** Woodside will progress its Scope 3 investment and emissions targets, aligned with stated timeframes	**MC 10.15.1** Progress against targets reported in the relevant annual Woodside disclosures to relevant industry standards and/or requirements. This includes an estimate of abated emissions from currently sanctioned projects.

[97] The customers for these products and services may be the same as the customers of our oil and gas business, directly substituting their energy for new products or directly abating the associated emissions. They may also be customers of the new products and services, without also being customers of oil and gas.
[98] Scope 3 targets are subject to commercial arrangements, commercial feasibility, regulatory and Joint Venture approvals, and third party activities (which may or may not proceed). Individual investment decisions are subject to Woodside's investment targets. Not guidance. Potentially includes both organic and inorganic investment. Timing refers to financial investment decision, not start-up/operations.
[99] Includes pre-RFSU spend on new energy products and lower carbon services that can help our customers decarbonise by using these products and services. It is not used to fund reductions of Woodside's net equity Scope 1 and 2 emissions which are managed separately through asset decarbonisation plans.
[100] Includes binding and non-binding opportunities in the portfolio, subject to commercial arrangements, commercial feasibility, regulatory and Joint Venture approvals, and third party activities (which may or may not proceed). Individual investment decisions are subject to Woodside's investment targets. Not guidance.

Routine Atmospheric Emissions – Indirect Emissions from Gas Processing Onshore

Description of Source of Impact/Risk

Background

The processing of gas from Pluto at onshore processing facilities will result in the release of atmospheric emissions. These emissions, and their potential indirect effects, have been raised by stakeholders as a concern and as such are evaluated within the Pluto Facility Operations EP.

This section provides contextual evaluation of consideration for potential indirect impacts, particularly the potential for atmospheric emissions associated with the PAA to cause a reduction in ambient air quality impacting human health and the potential to contribute to accelerated weathering of rock art on the Burrup Peninsula and within the Dampier Archipelago (i.e., Murujuga). These potential indirect impacts cannot be considered in isolation as they are the result of cumulative airshed conditions generated from various sources.

Murujuga Rock Art Strategy

The WA State Government (DWER) has established a Murujuga Rock Art Strategy (MRAS) in partnership with MAC as the Traditional Owners and custodians of Murujuga.

DWER has primary responsibility for the day-to-day implementation of the strategy in partnership with MAC. This includes working with MAC to oversee the development and implementation of a world's best practice monitoring and

analysis program that will determine whether the rock art on Murujuga is subject to accelerated change (for further information see Murujuga Rock Art | Western Australian Government (www.wa.gov.au).

The results from studies underway will guide management and protection of Murujuga rock art, with State environmental protection and heritage legislation in place as the applicable regulatory framework.

The MRAS states that:

"The data currently available from previous monitoring projects does not allow for a conclusive answer on whether anthropogenic emissions are impacting Murujuga's rock art. The Murujuga Rock Art Strategy is therefore essential to fill these gaps in knowledge.

Although it is not known whether the rock art is being impacted currently, there are feasible impact pathways by which emissions from industrial activities and other local sources could cause accelerated weathering of the rock art. The strategy is examining these potential pathways and the condition of the rock art to understand whether change is occurring, and whether there is a need to set a future limit on emissions to ensure accelerated weathering does not occur."

As a causal link between industrial air emissions and anthropogenic-induced change to rock art on Murujuga has not been established, nor sources and potential pathways defined, it is not yet practicable to attribute impact and risk level posed by the Pluto Offshore Operations PAA. The scientific uncertainty that persists is addressed by an adaptive and precautionary management framework in place by way of the MRAS and the associated Murujuga Rock Art Monitoring Program (MRAMP), together with the State Environmental Protection Act 1986 (WA) and associated regulatory framework, approvals and licences.

Onshore Processing Emission Context

Gas from Pluto is transported to shore through the trunkline to be processed at the Pluto LNG Facility. A portion of annual gas supply from Pluto offshore may also be processed at the KGP LNG train 4 and 5 via the interconnector pipeline. Products from Pluto gas are then sold as LNG and delivered to customers via ship or road or distributed to customers via pipeline for domestic consumption for purposes such as heating, electricity generation or industrial processes such as the production of LNG, ammonia, urea or hydrogen.

This section relates to atmospheric emissions that are associated with the processing of gas exported from Pluto to onshore facilities. While the operation of these onshore processing facilities is outside the scope of this EP, the atmospheric emissions associated with processing Pluto gas at these facilities is addressed in this section. The processing facilities addressed in this section are considered as the primary recipients of Pluto gas, being the Pluto LNG facility, and a smaller portion of gas supplied to KGP.

Source of Atmospheric Emissions from Onshore Processing

The principal atmospheric emissions from onshore processing in terms of potential for air quality impacts arise from the combustion of gas in fuel turbine generators and compressors as well as gas conditioning process vents at onshore facilities. Gas processing and liquefaction can also result in flaring of some gas and incidental venting of un-combusted gas. The most significant by-products of gas combustion, flaring and venting of gas will include oxides of nitrogen (NOx), carbon monoxide (CO), methane and non-methane volatile organic compounds (VOCs) including BTEX (benzene, toluene, ethylbenzene and xylenes).

Ozone is not typically emitted directly from gas consumption or processing but is formed through anthropogenic sources via chemical reactions between oxides of nitrogen and other emissions such as VOCs and CO in the presence of ultraviolet light. Ventilation readily disperses CO emissions relative to criteria. There may also be traces of particulate matter (PM) and sulphur dioxide (SO_2), but such emissions are generally considered negligible from the onshore processing of Pluto gas, due to the fact it has a very low sulphur content and absence of products that are precursors to the formation of particulate pollution. Emissions of PM from the consumption of gas from Pluto is negligible in comparison to background and other industrial sources.

Sources of Emissions within the Murujuga Airshed

Potential indirect impacts from processing of gas from Pluto could arise via a contribution to the cumulative effect of all emissions in the airshed. The Murujuga airshed encompasses the entire Burrup Peninsula and includes the population centres of Dampier and Karratha and surrounding areas. Industrial facilities that currently release or have approval to emit into the Murujuga airshed include:[101]

- Woodside Operated North West Shelf Venture's Karratha Gas Plant (KGP)
- Woodside Operated Pluto LNG Facility
- Yara Pilbara Fertilisers Pty Ltd Ammonia Plant
- Yara Pilbara Nitrates Pty Ltd Technical Ammonium Nitrate Production Facility (TANPF)
- Perdaman Urea Project

- Pilbara Iron Yurralyi Maya Power Station
- Santos Devil Creek Power Station
- ATCO Karratha Power Station
- EDL West Kimberley Power Plant (Maitland LNG Plant).

Atmospheric Emissions into the Murujuga Airshed from Onshore Processing of Gas from Pluto

Emissions associated with onshore processing of gas from Pluto are emitted and combined with similar emissions from natural sources and other industrial activities in proximity of the Murujuga region. Assessment of potential impacts considers cumulative impacts within the airshed rather than estimating emissions influence associated with processing gas from Pluto in isolation. Further, estimating ground level concentrations of atmospheric constituents as related to human health and deposition relies on complex non-linear photochemical modelling, underpinned by biochemical and physical forcing systems such as regional meteorological forcing model.

Therefore, impact assessment is based on a cumulative airshed modelling inclusive of contribution from onshore processing of Pluto gas, and other material sources.

In 2021, DWER commissioned Ramboll Australia Pty Ltd to undertake a *Study of the Cumulative Impacts of Air Emissions in the Murujuga Airshed*[102](Ramboll 2022) which considered a "complete emission inventory" including air emissions from existing and proposed future industries, shipping, and aggregated sources in the Pilbara region. The study used the CAMx atmospheric emission model, which includes atmospheric photochemistry to evaluate concentrations of a range of pollutants including NOx, ozone, SOx, CO, VOCs, and particulates across two modelling domains. The detailed 1.33 km grid encompasses the Dampier Archipelago, as far East as Wickham and as far West as 40 Mile Beach. Predicted ground level concentrations were evaluated at Karratha, Dampier, Hearson Cove and Ngajarli (Deep Gorge) and compared with relevant criteria in the National Environment Protection Measure (NEPM) air quality standards. Deposition rates were also predicted.

Emission estimates in the Ramboll 2022 study were based on a range of sources, including publicly available datasets, engineering design estimates (maximum and averages) and facility level monitoring data which match the selected year's meteorological data. The scenarios investigated as part of this study included:

A baseline scenario reflecting 2014 sources, including all industrial, mobile, domestic and commercial as well as natural sources. This covers onshore gas processing at steady state operational capacity at Pluto Train 1 and KGP Gas Plants. The year 2014 was selected due to typical meteorology (Ramboll 2022). A comparison of modelled data with real-world air quality monitoring data was undertaken, which "indicated reasonable agreement with the measurements at Burrup Road, Dampier, and Karratha"

A future scenario that considered the above scenario as a basis, but included proposed future additional industrial emissions sources in 2030. This scenario included operation of Pluto Train 1, Pluto Train 2, KGP and Perdaman onshore facilities and other future projects producing at capacity.

Assumptions regarding non-industrial emissions considered in these scenarios were based on a range of sources (Ramboll 2022):

- Mobile sources:
  - Commercial shipping and boating, with data sourced from the maritime automatic identification system (AIS) which also identifies vessel type, enabling application of USEPA default specifications for engines. Recreational boating
  - vehicles, which included data from an ABS survey of motor vehicle use scaled down the region, vehicle registration information and traffic and road network data from Main Roads WA
  - aircraft, which applied techniques from NPI to data supplied by airports and public sources such as aircraft operator website and tracking tools
  - railways, based on public data on fuel consumption per tonne of minerals delivered and mine site production rates. All rail lines in the region are operated by mining companies
  - Domestic and commercial sources:
  - estimates of population (with growth for future scenario),
  - other sources such as solvent and aerosol use (per capita data), bitumen road construction (materials usage), service stations (applying population data to service station locations), domestic fuel burning (from previous surveys) and others
- Natural sources such as vegetation, dust, bushfires and oceanic sources which came from other models

Both the baseline and 2030 scenarios included operation of onshore processing facilities at capacity which covers the portion associated with ongoing processing of Pluto gas.

[102] Study of the Cumulative Impacts of Air Emissions in the Murujuga Airshed: https://www.wa.gov.au/system/files/2023-03/Study-of-the-cumulative-impacts-of-air-emissions-in-the-Murujuga-airshed.pdf.

Specific assumptions for individual emission sources were provided by all regional parties in confidence to DWER or were otherwise estimated by Ramboll based on sources such as NPI for operating facilities, and as such are not published in the report. Woodside provided inputs to the Ramboll 2022 study in response to DWER's data request, and these are aligned with scenario descriptions and assumptions described in North West Shelf Project Extension Environmental Review Document (ERD) Appendix E Air Quality Impact Assessment[103] (Jacobs, 2019), Section 4, Scenarios 3 and 4 with existing, approved and referred facilities operating – which included (amongst others):

- Airshed baseline
- NWS Extension Project with NO_x improvement opportunities
- Expansion of Pluto (Train 2fed by Scarborough gas
- Perdaman Urea project
- Methanol facility proposal.

Ramboll used tools such as the EPA's Proposal Search Tool and related assessment documentation (such as Environment Document Review or Works Approvals) to provide data on future proposed developments. The model performance was validated at a number of locations using real-world air quality monitoring data provided by DWER and industrial operators in the region.

This indicated that NOx loads to the airshed from NO2 concentrations predicted by the model were "similar ranges at Karratha, but the model is biased high at Burrup Road and Dampier" which indicates that modelled outcomes at these locations on Murujuga are conservative. It also indicates that assumptions for model inputs are appropriate.

The Jacobs 2019 assumptions were developed with "reasonable and conservative emission estimates" for the purposes of completing a robust risk and impact assessment of industrial sources are, such as inclusive of elevated flare rates (Jacobs 2019 81). This 2030 projection is the "Future Burrup Strategic Industrial Area state (existing, approved and referred) with proposed emission reductions in place" referred to in Table 6-5 of the NWS Project Extension ERD . The Jacobs 2019 report drew on an earlier aggregated air emissions inventory for the Pilbara region developed by SKM (2003) for sources such as biogenic emissions, vegetation sources and other natural sources, and other previous modelling studies. The Jacobs 2019 model outputs were compared with real-world air quality monitoring results from multiple locations, which indicated that the model was "performing well in terms of being able to accurately predict a variety of statistical results for NO2. as measured by Woodside at the Burrup, Dampier and Karratha monitoring stations" In addition to validating model performance, this also demonstrates that the assumptions used for existing emissions sources were appropriate.

Ramboll 2022 estimated that NOx loads to the Murujuga airshed (1.33 km grid encompassing Dampier Archipelago, Murujuga, Karratha and Roebourne) from industrial sources were estimated to be 13,937 tonnes per year and are forecast to reduce to 12,052 tonnes per year by 2030, when calculated over a 1.33 km grid. A significant contribution to this cumulative airshed reduction is associated with commitments by the NWSJV to reduce NO_x emissions from the Karratha Gas Plant by 40% by 2030. Ramboll (2022) did not predict NO_x air concentrations in excess of current air quality standards in any modelled scenario.

The assumptions for Murujuga airshed NO_x emissions underpinning Ramboll (2022) are suitably conservative for reviewing relative contribution of KGP and Pluto for the onshore processing of Pluto gas using information provided by the respective facilities as described below:

Table 6-30: Comparison of modelled NOx emission assumptions with recent reported information

	Pluto		**KGP**	
	NOx emission rate annual avg (g/s)	*Source/comment*	*NOx emission rate annual avg (g/s)*	*Source/comment*
Baseline Scenario (2014)	34.1 g/s (Train 1)	Jacobs 2019	281.1	Jacobs 2019
Current	29.1 g/s (Train 1 - 15% below modelled baseline)	Reported NPI data, 2022/23 period (with consistent multi-year history)	248.7 (12% below modelled baseline)	Reported NPI data, 2022/23 period (with consistent multi-year history)
Future emissions scenario assumptions	35.6 (Train 1) + 33.59 g/s (Train 2)	Pluto Expansion estimates – Jacobs 2019	149.2 g/s (40% reduction commitment)	NWS Extension ERD commitment (Table 6-9, p 106)

[103] NWS Extension Environment Review Document Appendices: https://www.woodside.com/docs/default-source/current-consultation-activities/australian-activties/north-west-shelf-project-extension---appendices.pdf.

The current trajectory of aggregated emissions in the Murujuga airshed indicates that the future emissions scenario assumptions considered by Ramboll 2022 were conservative because:

- Assumptions for Pluto Train 1 and Train 2 include conservatisms as set out in the Jacobs report. Assumptions for Train 2 equipment are based on vendor specified performance, which is a conservative basis for emission estimation. This performance will be measured and validated in accordance with Condition 38 of the Pluto Train 2 Works Approval[104] which will include a summary of the environmental performance of equipment against design specifications and the Pluto AQMP (which is consistent with Jacobs 2019). Validation is also covered in section 5 of the Pluto AQMP
- KGP has commenced the NOx reduction committed in the NWS Extension ERD[105] (see Table 6-29on pg. 106) with one LNG train planned to be taken offline between late 2024 and mid 2025 (Woodside 2024)
- Emissions estimates for the Perdaman urea project in Jacobs 2019 are 8.93 g/s. It is acknowledged that the current Perdaman Urea Project Air Quality Management Plan (2021) references an Air Quality Impact Assessment (Jacobs 2020) which estimates 'based on engineering and other data" total NOx emissions for the plant of 11.7 g/s. This increase is 0.7% of the Ramboll future scenario and therefore negligible in context of the broader airshed
- It is Woodside's understanding that the proposed Methanol plant is no longer proceeding[106], which for context was expected to contribute 28.05 g/s (Jacobs 2019[81]).

Woodside is not aware of any reason why the future emissions scenario assumptions for contribution to the Murujuga airshed from non-Woodside sources are not appropriate. Any potential future development not considered in this scenario would be required to undergo its own assessment process under regulatory frameworks (described below). Further, the MRAS/MRAMP is expected to identify any ongoing or future trends in air quality which could potentially impact rock art.

The Ramboll 2022 study found that "SO_2, NO_2, $PM_{2.5}$, PM_{10}, CO and NH_3 peak ground level concentrations are centered at industrial facilities near or on the Burrup Peninsula, showing that industrial sources and shipping contribute to emissions in the area, but with total air concentrations for these compounds remaining below current air quality standards except for $PM_{2.5}$ and PM_{10}." The report also noted that the governing driver for particulate matter concentrations was dust, rather than industrial emissions. As stated in the report "There are no accepted or commonly applied standards for assessing deposition of acidic air pollutants on land surfaces or on sensitive receptors such as the Burrup Peninsula rock art. While this assessment report provides results for acidic deposition, no assessment, or commentary is provided about the potential impacts on areas of sensitivity such as the rock art."

Some recommendations are provided in the Ramboll 2022 report related to potential improvements in accuracy regarding terrain datasets, modelling approach for dust and treatment of plumes in the model grid, and uncertainty related to emissions estimates including NPI data. However, "significant effort was made to obtain the most accurate information available with particular focus on sources located near or on the Burrup peninsula" and the comparison of modelled emissions with latest data shown in Table 6-30 indicates that conservatism exists in assumptions. The NWS Project Extension ERD Air Quality Impact Assessment compared measured ground level concentrations of NO_2 from 2009-2015 with NEPM criteria and found no exceedances. The report states that there was "no currently accepted or commonly applied standards for assessing deposition of air pollutants on land surfaces, such as Burrup Peninsula rock art" and the report does not provide any assessment or commentary on potential impacts to rock art.

Applying expected NOx emission rates from Table 6-28 and multi-year NPI reporting history; peak NOx emissions associated with processing of Pluto gas at Pluto and a 1/5th proportion supply of Train 4 or Train 5 capacity at KGP are conservatively estimated to be approximately 1,200 t/yr.

Based on the estimated total regional airshed emissions used in Ramboll (2022) and NO_x contribution to the airshed outlined within the Pluto Air Quality Management Plan (approved in accordance with Ministerial Statement 757), it is estimated that NO_x emissions associated with the processing of Pluto gas via the Pluto LNG facility, and an approximate 1/5th proportion supply of Train 4 or Train 5 capacity at KGP accounts for approximately 12% currently, declining to less than 6% of the total estimated 2030 NO_x load in the Murujuga region. Conservatively applying these estimate over the potential remaining field life results in a total NOx emission estimate of approximately 8,000 t.

Where Pluto gas is processed at KGP, it proportionally displaces other sources of gas processed at this facility (as assumed in the Ramboll (2022) model, which did not need to account for the source of gas); Pluto gas therefore does not result in a net increase in KGP or total airshed NO_x, relative to those presented in the Ramboll 2030 projections.

[104] https://www.der.wa.gov.au/our-work/licences-and-works-approvals/lwa-available-for-public-appeal/item/download/12092_8dfe908804d6cc7505eb20a79d09f08f

[105] https://www.woodside.com/docs/default-source/current-consultation-activities/australian-activties/north-west-shelf-project-extension---environmental-review-document.pdf?sfvrsn=a8b10277_4

Continued processing of gas from Pluto is therefore not anticipated to cause an increase of NO_x within the Murujuga airshed beyond historic maximum levels; which, as described in Section 4.9.6 has resulted in no scientifically conclusive evidence for anthropogenic change to rock art on Murujuga. The reduction in future NO_x load within the Murujuga air-shed presented in the Ramboll 2022 study is reflective of commitments made by third party proponents that are publicly disclosed either in Ministerial Statements or Air Quality Management Plans.

Existing Regulatory Framework

Facilities associated with the onshore processing of LNG are not subject to the Offshore Petroleum and Greenhouse Gas Storage (Environment) Regulations 2023 (Cth). Assessment and management of these emissions is required pursuant to various State and Commonwealth legislative frameworks. Impacts associated with atmospheric emissions are subject to an appropriate level of independent assessment by regulatory agencies and management measures are in place which are sufficient to ensure the environment performance outcome of this PAP can be achieved.

A summary of the relevant legislation, approvals and governance measures in place to manage atmospheric emissions from onshore processing facilities such as Pluto LNG facility, NWS Karratha Gas Plant and Perdaman Urea facility are outlined below.

Environmental Protection (EP) Act 1986 (WA)

The EP Act is the principal legislation in WA that provides for "the prevention, control and abatement of pollution and environmental harm" and for "the conservation, preservation, protection, enhancement and management of the environment".

The object of the EP Act is to protect the environment of Western Australia, having regard to a number of principles, including:

- the precautionary principle, which holds that where there are threats of serious or irreversible damage, lack of full scientific certainty should not be used as a reason for postponing measures to prevent environmental degradation. In the application of the precautionary principle, decisions are to be guided by:
  - careful evaluation to avoid, where practicable, serious or irreversible damage to the environment
  - an assessment of the risk-weighted consequences of various options
- the principle of intergenerational equity, which holds that the present generation should ensure that the health, diversity and productivity of the environment is maintained or enhanced for the benefit of future generations
- the principle of waste minimisation, which holds that all reasonable and practicable measures should be taken to minimise the generation of waste and its discharge into the environment
- principles relating to improved valuation, pricing and incentive mechanisms, which include the 'polluter pays principle' whereby those who generate pollution and waste should bear the costs of containment, avoidance or abatement.

Assessment of Proposals under Pt IV of the EP Act

In Western Australia, it is the role of the independent Environment Protection Authority (EPA) to assess proposals against the requirements of the EP Act and EPA objectives.

Section 15 of the Act establishes the objectives of the EPA (Authority): It is the objective of the Authority to use its best endeavours to protect the environment; and to prevent, control and abate pollution and environmental harm. The object and principles guide the overall application of the powers of the Act. The principles are matters to which the EPA is required to have regard as a condition of the valid exercise of its powers to assess and report on proposals and schemes under the Act. The EPA only recommends that the Minister approve a proposal if it can be demonstrated the proposal is aligned with the Act including any relevant objectives.

Under the EPA's Air Quality Environmental Factor Guideline, the EPA has an objective to *maintain air quality and minimise emissions so that environmental values are protected*[107] (Air Quality Objective). The Air Quality Environmental Factor Guideline identifies that this objective recognises the fundamental link between good air quality and the environmental values it supports. It also recognises the principle of waste minimisation as set out in the EP Act. In the context of this factor and objective, the EPA recognises that maintaining good air quality and minimising emissions protects human health and amenity, as well as the broader environment. When considering the significance of potential impacts to air quality, the EPA may have regard to the various matters outlined in Section 5 of the Statement of Environmental Principles, Factors and Objectives[108], including the Air Quality Objective.

Applicable assessments by the EPA and subsequent decisions by the Minister for Environment under Part IV of the EP Act include Ministerial Statement (MS) 757 for the Pluto LNG Facility, and MS 536 for LNG trains 4 and 5 at the Karratha Gas Plant (KGP). MS 1233 was also recently issued for the North West Shelf (NWS) Project Extension, published in December 2024, which allows for continued operation of the NWS Project and processing of third party gas at KGP. Further information regarding conditions of implementation is detailed in sections below.

[107] EFG – Air Quality - 03.04.2020.pdf (epa.wa.gov.au).
[108] Statement of environmental principles, factors, objectives and aims of EIA (epa.wa.gov.au).

Environment Protection and Biodiversity Conservation Act 1999 (Cth)

The EPBC Act is the Australian Government's key piece of environmental legislation providing for the protection of the environment and the conservation of biodiversity. The EPBC Act requires approval for activities with a significant impact on a number of matters of national environmental significance, including, for example, National Heritage places and listed threatened species or endangered communities.

The Pluto LNG Development Draft Public Environment Report (EPBC Referral 2006/2968) included evaluation of air emissions within the context of presence of rock art and monitoring studies being undertaken at the time (e.g. BRAMMC/CSIRO discussed in Section 4.9.6). Commonwealth ministerial approval of EPBC 2006/2968 was granted in October 2007.

The NWS Project Extension (a proposal to extend operation of the NWS Project beyond 2030) has been assessed under the EPBC Act by the WA EPA under an accredited process (Refer EPA Report 1727). The controlling provision for the proposed action is 'National heritage places', and the Project is subject to assessment by accredited assessment under Part IV of the EP Act at the level of Public Environment Review. The Commonwealth Minister for the Environment will make an approval decision once the State process has completed.

Aboriginal Heritage

Aboriginal sites are of cultural heritage importance to both the Aboriginal and wider community. The Aboriginal Heritage Act 1972 (AH Act) is the principal legislation providing for the preservation of Aboriginal sites and objects in WA. All Aboriginal heritage sites or places to which s.5 of the AH Act applies are protected, whether or not they are registered with the Department of Planning, Lands and Heritage (DPLH). It is an offence under the AH Act to excavate, destroy, damage, conceal or in any way alter any Aboriginal site unless the consent of the Registrar or the Minister for Aboriginal Affairs is first obtained.

Approvals under Pt V of the EP Act

DWER regulates certain premises through a works approval and licensing process to prevent, control, abate and mitigate pollution and environmental harm, under Part V of the EP Act.

Woodside currently holds the following licences for facilities operated on the Burrup Peninsula:

- Pluto Liquefied Natural Gas (LNG) Project (L8752/2013/2)[109]
- Woodside Onshore Gas Treatment Plant (KGP) (L5491/1984/18)[110]

The above-mentioned licences specify air emission limits for individual emission points, NOx concentration in Pluto turbine exhausts is limited to 100 mg/m^3 over a stack test average period not less than 30 minutes; and at KGP 350 mg/m^3 for trains 1, 2 and 3 and 100 mg/m^3 for trains 4 and 5. Monitoring of emissions points is required at the facilities annually and quarterly (respectively). Woodside is required under these licences to submit an Annual Audit Compliance Report identifying compliance with the conditions of the licences ensuring emissions remain within acceptable levels. Copies of the Annual Audit Compliance Reports are available on the DWER's website.

Other Regulatory Measures in Place for Management of Atmospheric Emissions

National Environmental Protection (Ambient Air Quality) Measure (Cth)

The National Environment Protection Council (NEPC), comprising Commonwealth, State, and Territory Ministers, finalised the NEPM (Ambient Air Quality), on 26 June 1998. The National Environment Protection Council Act 1994 (Cth) allows the National Environment Protection Council to make National Environment Protection Measures (NEPMs). NEPMs are a special set of national objectives designed to assist in protecting or managing particular aspects of the environment. The NEPM [Ambient Air Quality] outlines ambient air quality monitoring protocol that allows for the adequate protection of human health and well-being.

National Environment Protection (National Pollutant Inventory) Measure 1998 (Cth)

The National Pollutant Inventory (NPI) is a public database that provides information on 93 selected air pollutants and their emissions, produced as a result of industry, transport, commercial premise, and household activities, and emitted to air, land, and water in Australia. The NPI is a Commonwealth Government initiative and each state and territory is responsible for implementing the program. The objective of the NPI is to inform the community about emissions to water, air, and land and acceptable emissions levels. It also provides information for policy and decision making, environmental planning and management, and minimising waste.

The Woodside operated facilities on the Burrup Peninsula have been reporting emission data to the NPI from the NWS Project since the 1998/1999 reporting period and Pluto since the commencement of operations in 2012. Other facilities located on the Burrup Peninsula including Yara Pilbara Fertilisers Pty Ltd have reported since 2005. Emissions data is publicly available on the Australian Government Department of Climate Change, Energy, the Environment and Water (DCCEEW) website: https://www.dcceew.gov.au/environment/protection/npi

Other Relevant Frameworks and Programs

Murujuga National Park Management Plan

As outlined in Section 4.9.5, Murujuga National Park management plan objectives are achieved through measures which include Conservation Agreements, funding and support, and Cultural Heritage Management Plans (Section 6.11). It is under the Conservation Agreement that Woodside continues to support research into, and monitoring of the National Heritage values of the Park and conducts its activities in a manner not inconsistent with the Murujuga National Park management plan.

Program: Murujuga Rock Art (Western Australian Government)

The Western Australian Government publish on their Aboriginal heritage conservation website a summary of their Murujuga Rock Art Program, the partnership with Murujuga Aboriginal Corporation, and the Murujuga Rock Art Strategy. The description of the program is provided in the box below, courtesy of Govt of Western Australia Website: https://www.wa.gov.au/service/aboriginal-affairs/aboriginal-heritage-conservation/program-murujuga-rock-art.

Program Murujuga Rock Art

Background

Murujuga (which means 'hip bone sticking out' in the Ngarluma-Yaburara language) comprises the Burrup Peninsula and the Dampier Archipelago 1,300 km north of Perth, Western Australia. The Government of Western Australia (State Government) recognises Murujuga as a unique ecological and archaeological area containing one of the largest collections of Aboriginal engraved rock art in the world.

Murujuga is also home to industry that contributes to the local, state and national economy and employment. Concerns the rock art could be damaged by industrial air emissions have led to several independent scientific studies and rock art monitoring initiatives since the mid 2000s.

Murujuga Rock Art Strategy

The purpose of the Murujuga Rock Art Strategy (MRAS) is to protect the Aboriginal rock art by providing a long-term framework that builds on previous work to deliver an improved approach to monitoring, analysis and management.

The Murujuga Rock Art Strategy will be reviewed at least every five years. This will ensure it remains current, supports appropriate governance arrangements, and that the best scientific knowledge and management practices are used to protect the rock art.

Scope

The department has primary responsibility for the day-to-day implementation of the strategy in partnership with MAC. This includes working with MAC to oversee the development and implementation of a world's best practice monitoring and analysis program that will determine whether the rock art on Murujuga is subject to accelerated change.

The scope of this strategy is to:

- *establish an environmental quality management framework, including the derivation and implementation of environmental quality criteria*
- *develop and implement a robust program of monitoring and analysis to determine whether change is occurring to the rock art on Murujuga*
- *identify and commission scientific studies to support the implementation of the monitoring and analysis program and management*
- *establish governance arrangements to ensure that:*
  - *monitoring, analysis and reporting are undertaken in such a way as to provide confidence to Traditional Owners, the community, industry scientists and other stakeholders about the integrity, robustness, repeatability and reliability of the monitoring data and results*
  - *government is provided with accurate and appropriate recommendations regarding the protection of the rock art, consistent with legislative responsibilities*
- *develop and implement a communication strategy in consultation with stakeholders.*

The consultation summary report summarises the comments received on the draft strategy. The consultation ran from September 2017 to May 2018. There were 27 written submissions received.

Monitoring Program [Murujuga Rock Art Monitoring Program – MRAMP]

A best practice monitoring and analysis program commenced in 2020. It will provide reliable information on changes and trends in the condition of the rock art and whether the rock art is showing signs of accelerated change.

The program includes:

- *installation of air quality monitoring stations across Murujuga*
- *regular field measurements of selected rock art panels using a variety of methods*
- *detailed laboratory investigation of rock samples, including the microorganisms living on the rock surface.*

The results from these studies will guide management and protection of the rock art. Reports produced as part of the monitoring program are regularly published in the Murujuga Rock Art Strategy document collection.

The monitoring program is overseen by the department and MAC, in consultation with national and international subject matter experts, a panel of independent peer reviewers and stakeholders.

MAC has developed the Murujuga Research Protocols as a set of governing principles and guidelines to ensure research is conducted in a respectful and culturally appropriate manner.

[continues over…]

[…continued]

The monitoring program is being implemented by Calibre Group and experts from Curtin University until early 2026. Curtin University has also developed a training program for MAC Rangers to build their skills and knowledge in monitoring and analysis techniques. Once Rangers are qualified, MAC will be well placed to implement the monitoring from 2026 onwards.

Conceptual models of the rock art system were published in 2021 to share the current understanding of the system and interactions that are likely to be occurring. These models inform the development of the monitoring studies plans and the development of an environmental quality management framework.

The monitoring studies data collection and analysis plan, published in April 2022, is crucial to the design of the Murujuga Rock Art Monitoring Program, and the scope and quality of the science to monitor, evaluate and report on changes and trends in the integrity of the rock art on Murujuga.

The first Monitoring Studies Technical Report was published in December 2023, following an independent peer review process. View the Summary Monitoring Studies Report. View all reports from the Murujuga Rock Art Monitoring Program.

Key Milestones and Status:

Year	***Program Key Milestone and Status***
2020-2021	• *Review weathering/alteration/degradation processes that have the potential to cause change in the rock art (**completed**).* • *Deliver a stakeholder workshop (**completed**).* • *Develop conceptual models and a monitoring studies plan (**completed**).* • *Determine optimal monitoring sites (**completed**).* • *Peer-review conceptual model and monitoring studies plan (**completed**).*
2022	• *Gain MAC and the department's approval of the monitoring studies plan (**completed**).* • *Obtain State Government commitment to funding dedicated MAC Ranger positions and to support training and capacity building for MAC (**announced May 2022**).* • *Complete fieldwork and laboratory monitoring studies (**2022 studies completed**).* • *Commence Ranger training needs analysis, Ranger training and capacity building (**completed**).*
2023	• *Continue fieldwork and laboratory monitoring studies (**2023 fieldwork completed**).* • *Procure and install air quality monitoring stations (**completed**).* • *Continue of Ranger training and capacity building (**completed**).* • *Develop report on monitoring studies Mar 2022–Mar 2023 (peer reviewed) (**completed**).* • *Deliver a stakeholder workshop (**completed**).*
2024	• *Continue fieldwork and laboratory monitoring studies.* • *Report on monitoring studies April 2023–April 2024 (peer reviewed).* • *Design ongoing monitoring program.* • *Develop interim Environmental Quality Criteria (EQC) based on field and laboratory (chamber) studies.* • *Implement the ongoing monitoring program.* • *Commence reporting against interim EQC.* • *Continue Ranger training and capacity building (Curtin University micro credentials).* • *Develop Environmental Monitoring Programme Regulations under the Environmental Protection Act 1986.* • *Perform independent review of the Murujuga Rock Art Strategy.*

[continues over…]

[…continued]

Key Milestones and Status:

Year	*Program Key Milestone and Status*
2025	• *Report on monitoring studies April 2024–April 2025 (peer reviewed).* • *Design final monitoring program.* • *Develop final EQC.* • *Report on monitoring program 2024–2025.* • *Commence progressive handover monitoring and reporting program to Murujuga Aboriginal Corporation (with support from the department).* • *Perform independent review of the monitoring program.*
2026 (and beyond)	• *Perform ongoing monitoring program, managed by the Murujuga Aboriginal Corporation and the Department of Water and Environmental Regulation.* • *Perform ongoing monitoring and reporting against final EQC.*

Stakeholder Reference Group:

The Murujuga Rock Art Stakeholder Reference Group is an advisory group that was established by the previous Minister for Environment, Hon. Stephen Dawson MLC, in September 2018. The group facilitates engagement between the Murujuga Aboriginal Corporation (MAC) and key government, industry and community representatives on the development and implementation of the strategy.

Professor Stephen van Leeuwen is the independent chair of the stakeholder reference group, which meets on a quarterly basis. Visit the document collection to read summaries of meetings and community forums.

The Terms of Reference are reviewed regularly in consultation with MAC and the Independent Chair to ensure the group remains effective in achieving its purpose.

[end]

Murujuga Rock Art Monitoring Program

In recognising the high level of stakeholder concern and scientific uncertainty regarding the links between anthropogenic emissions and risks to rock art (see Appendix F), in 2019 the Department of Water and Environmental Regulation (DWER) produced the Murujuga Rock Art Strategy[111] (MRAS), which builds on the research to date, and according to DWER will establish a world's best practice program to monitor, evaluate and report on factors that could affect the condition of Murujuga rock art. This is being undertaken in consultation with the Murujuga Aboriginal Corporation, a team of national and international experts in relevant disciplines and is funded by industry, including Woodside. The MRAS describes a risk-based approach for the management of impacts to the rock art that is consistent with the State Government's responsibilities under the EP Act.

A program being executed as part of the MRAS is the Murujuga Rock Art Monitoring Program (MRAMP) which will monitor, evaluate, and report on changes and trends in the integrity of the rock art, specifically to determine whether anthropogenic emissions are accelerating the natural weathering, alteration, or degradation of the rock art. This will enable timely and appropriate management responses by the Western Australian Government, industry and other stakeholders to emerging issues and risks. The following extract from the WA Government website MRAS website outlines this. (Govt of Western Australia (December 2023) https://www.wa.gov.au/service/aboriginal-affairs/aboriginal-heritage-conservation/program-murujuga-rock-art#frequently-asked-questions).

[111] https://www.wa.gov.au/system/files/2020-07/DWER-Murujuga-rock-art-strategy.pdf.

How Will the Murujuga Rock Art Strategy Provide Protection for the Rock Art?

The initial studies will allow the scientific team to determine the levels of various air emissions that may cause accelerated weathering of the rock art. These levels will not necessarily be identified during the field studies on Murujuga Country, in which case they will be informed by laboratory tests.

The research will inform an environmental quality management framework. Specifically, the levels of air emissions at which accelerated weathering is deemed to occur will be used to inform environmental quality criteria. The ongoing monitoring program, administered by MAC and the department, will gather data and ensure that emissions do not exceed the criteria. Industry will also be regulated to ensure their emissions will not cause the criteria to be exceeded.

There are two types of environmental quality criteria under the framework: environmental quality standards and environmental quality guidelines. Guidelines provide early warning of potential environmental effects, while standards indicate where the level of risk is no longer acceptable, triggering a management response to prevent environmental harm. In the case of the rock art, an exceedance of the standard means there is a high risk of permanent loss or damage to the rock art.

While environmental quality criteria have been used successfully in other contexts, it is important to remember that there are no environmental quality standards or guidelines values currently available anywhere in the world that can be applied to engraved rock art.

[… and…]

What is the Connection with World Heritage Listing?

The World Heritage nomination for Murujuga includes a comprehensive and effective management framework that outlines how the potential 'Outstanding Universal Value' of the area will be protected, conserved and monitored. As part of this framework, the State Government and MAC will demonstrate how they are working closely together to protect the rock art through the Murujuga Rock Art Strategy and the Murujuga Rock Art Monitoring Program.

The DBCA website has more information on the World Heritage nomination.

In recent EPA assessment reports for industrial facilities on the Burrup Peninsula, the EPA has recommended a condition mandating relevant facilities to comply with air quality standards such as those derived from the MRAMP.

In the EPA's North West Shelf Project Extension Assessment Report 1727 (EPA Report 1727), the EPA recommends the 'Air Quality Outcome' for recommended condition 3 be 'to ensure that no air emissions from the proposal have an adverse impact accelerating the weathering of rock art within Murujuga beyond natural rates.'

Recommended condition 3-3 states that if the Minister notifies the proponent in writing of one or more air quality standards to be met (including standards derived from the results of the Murujuga Rock Art Monitoring Program) and the proponent complies with all those standards, and any amendments to the standards the proponent is taken to have achieved the Air Quality Outcome.

EPA Report 1727[112] specifies that the proponent is to achieve compliance with any detailed air quality standards to ensure that there are no adverse impacts accelerating the weathering of rock art within Murujuga beyond natural rates. The EPA expects that this will include environmental quality objectives and environmental quality standards derived from the results of the MRAMP. Ministerial Statement 1233[113] was subsequently issued for the North West Shelf Project Extension, published in December 2024, adopting the above mentioned EPA recommended conditions relating to air quality. The Ministerial Statement for the Perdaman Urea Project (MS 1180) includes the same air quality outcome condition that is proposed in EPA Report 1727 and MS 1233.

The Pluto LNG Facility has a Cultural Heritage Management Plan and Air Quality Management Plan (AQMP) (required under Ministerial Statement 757). Statements and commitments made by Woodside within the North West Shelf Air Quality Management Plan and the Pluto LNG Facility Air Quality Management Plan commit to manage potential impacts to Aboriginal rock art on the Burrup Peninsula in accordance with the MRAS and as a member of the Murujuga Rock Art Stakeholder Reference Group. Woodside actively supports the implementation of the Murujuga Rock Art Strategy through membership of the Murujuga Rock Art Reference Group and provides funding associated with the Murujuga Rock Art Monitoring Program. Woodside also supports the coordinated approach for an atmospheric deposition monitoring program to be established under the Strategy, and currently provides data to the program from the Woodside Atmospheric and Ambient Air Quality Monitoring Programs.

[112] North West Shelf Project Extension Proposal (epa.wa.gov.au).

[113] https://www.epa.wa.gov.au/sites/default/files/1MINSTAT/1727%20Statement%201233%20for%20publishing%20North%20West%20Shelf_0.pdf

Onshore Facility Air Emission Design Mitigations

Under the regulatory Conditions and Part IV Air Quality Management Plans of onshore processing facilities on the Burrup, operators are required to implement a number of controls and risk management practices related to air emissions, including the demonstration of best practice design, and monitoring and abatement programs.

Condition 11-1 of Ministerial Statement 757 required the development of an Assessment of Best Practice for Minimising Emissions to Air from Major Plant (Best Practice Report) for the Pluto LNG Facility and condition 11-2 required the development of the Pluto LNG Facility Air Quality Management Plan to demonstrate that best available practicable and efficient technologies are used to minimise and monitor air emissions from the plant. This demonstration was required to meet the requirements of the Minister for the Environment on advice of the EPA prior to Woodside applying for and obtaining a Works Approval to construct the Pluto LNG facility. In 2019, these reports were updated to include Pluto Train 2 and subject to an independent peer review commissioned by the EPA, before being approved by the Minister for Environment in 2020 on advice of the EPA.

Best practice technologies to minimise air emissions implemented in Pluto LNG design and operation include:

- dry Low NO_x emissions control systems on gas turbines
- specification of activated methyldiethanolamine (aMDEA) in the acid gas removal system to reduce co-absorption of benzene, toluene and xylene (BTX) and other hydrocarbons.
- installation of a regenerative thermal oxidiser on the acid gas removal unit
- flare design integrated smokeless flaring technologies implemented for the storage and loading flare system, cold dry flare, warm wet flare and common spare flare.
- Best practice technologies to minimise air emissions implemented in Pluto LNG Train 2 design and operation are also included associated with facility expansion to process Scarborough gas.

The Pluto Ministerial Statement 757 requires the Pluto Air Quality Management Plan to include:

- targets and standards
- an emissions monitoring programme to cover specified pollutant compounds
- an ambient air monitoring programme and a nitrogen deposition monitoring programme
- provisions for annual reporting

Annual compliance reporting against these requirements is provided to the WA EPA and published on the Woodside website – Pluto LNG Environmental Compliance Reporting114.

Point source emissions monitoring under the Pluto Air Quality Management Plan focusses on validating emissions performance during operations against targets (50 mg/Nm3 and 70 mg/Nm3) which are lower than Licenced emissions limits. Any target excursions are investigated through Woodside's management system investigation practices, and actions taken toward rectification back within the target values, with emissions above target and responses summarised in annual reporting.

The NWS Extension Environment Review Document115 details how the most recent LNG trains (Trains 4 and 5) constructed at the existing North West Shelf Project are already equipped with lower NOx technology for gas turbines. KGP's Ministerial Statement 536116 (February 2000) applicable for the construction and operation of Train 4 and Train 5 included the requirement to install low-NOx burners on new gas equipment.

In addition, EPA Report 1727 includes recommended conditions requiring the minimisation of air emissions from the NWS Project Extension proposal by the adoption of practicable technologies, and, as a minimum, a substantial reduction of both total NO_x and VOC emissions from the proposal baseline by 31 December 2030.

Ministerial Statement 1233[117] (MS 1233) issued for the North West Shelf Project Extension, published in December 2024, requires that:

…no air emissions from the proposal have an adverse impact accelerating the weathering of rock art within Murujuga beyond natural rates.

MS 1233 contains a number of conditions related to air quality and NOx emissions, including but not limited to:

- Within 12 months of issue of MS 1233, the Air Quality Management Plan must be revised in consultation with Murujuga Key Stakeholders

[114] https://www.woodside.com/what-we-do/operations/pluto-lng/pluto-lng-environmental-compliance-reporting
[115] https://www.epa.wa.gov.au/sites/default/files/PER_documentation2/NWS%20Project%20Extension%20-%20Environmental%20Review%20Document.pdf.
[116] https://www.epa.wa.gov.au/sites/default/files/1MINSTAT/Ministerial%20Statement%20536.pdf
[117] https://www.epa.wa.gov.au/sites/default/files/1MINSTAT/1727%20Statement%201233%20for%20publishing%20North%20West%20Shelf_0.pdf

- Compliance with all air quality objectives and standards, including, if applicable, those derived from the results of the MRAMP
- At a minimum, reduce NOx emissions to 3065 tpa by 31 December 2030, corresponding to a 60% reduction
- Include provisions for adoption of continuous or predictive emission monitoring technologies on each stack of LNG processing trains by 30 June 2030
- Identification of best practice design and operational measures and efficient technologies implemented or to be implemented:
  - Specifying when each measure will be implemented
  - Methodology for determination of effectiveness of the measure in minimising air emissions
  - Independent Peer Review Report assessing these measures against international and Australian industry best practice

Monitoring data and compliance reporting is required to be provided to the WA EPA and made public.

The existing NWS Air Quality Management Plan includes the following management actions:

- MA4: Adopt practicable and efficient technologies to reduce air emissions. The AQMP states that Woodside has identified and evaluated credible opportunities to achieve a long term reduction in air emissions and commits to a 40% [updated to 60% in MS1233 Condition] reduction in NOx emissions from a baseline set between 2013 and 2018. Measures which the NWS has or is considering include implementation of technology such as water injection, dry-low NOx, ultra dry-low NOx, selective catalytic reduction (SCR) systems on turbines, or ceasing operation of older non-DLN equipment with proportionally higher NOx emissions.
- MA5: Implement an adaptive management plan addressing the potential impact to rock art from industrial emissions. This is described in the AQMP, stating that since it is difficult to set appropriate management actions given the current lack of scientific understanding of the impacts of air emissions on petroglyphs, actions will be monitored, reviewed, evaluated and updated considering a range of factors including outcomes from MRAS.

Should credible scientific evidence emerge that industrial emissions are causing accelerated weathering of Murujuga rock art as an outcome of MRAMP, the impact profile of onshore atmospheric emissions may change. In this eventuality, sufficient provisions exist in the relevant onshore regulatory frameworks as described above to ensure that onshore atmospheric emissions are limited to acceptable levels, which may require review of controls currently in place at onshore processing facilities to manage potential impacts (for example under section 2 of MS1233 for NWS, or section 10 of the Pluto AQMP). In such a case whereby impact is attributed to the onshore process of Pluto gas, EP change management process would apply (Section 7.3.2) as required by Regulation 39. It is not feasible to pre-emptively lay out a planned response to such an outcome because there is a broad range of potential findings, severity of change, mechanism timeframes, attribution considerations, and outcomes from stakeholder engagement. However, potential options are available to reduce NOx emissions in this context and to achieve the 60% reduction in NOx emissions at NWS required under MS1233, which may include:

- Retrofitting NOx reduction technology such as DLN (or other technologies as noted above under description of NWS AQMP MA4) on, or ceasing operation of older non-DLN equipment at KGP which emits proportionally higher NOx concentration, noting that Pluto gas is not processed into LNG through these older trains in any case
- Implementation of further NOx reduction measures or technologies which may no longer be considered disproportionate in context of a proven impact pathway, such as water injection, dry-low NOx, ultra dry-low NOx.

Both Pluto LNG Facility and NWS Karratha Gas Plant are also subject to cultural heritage management obligations detailed in MS757 and MS1233 respectively – further described in Section 6.11.

Detailed Impact Assessment

Indirect Emissions from Gas Processing Onshore – Assessment of Potential Impacts

Contribution to Accelerated Weathering of Murujuga Rock Art

The Dampier Archipelago, including the Burrup Peninsula and surrounds, traditionally referred to as Murujuga (which means 'Hip Bone Sticking Out' in the Ngarluma-Yaburara language) is located in the Pilbara region of WA. With more than one million images, Murujuga is home to one of the largest, densest and most diverse collections of rock art in the world.[118]

[118] https://www.wa.gov.au/system/files/2020-07/DWER-Murujuga-rock-art-strategy.pdf.

The presence of industry on the Burrup Peninsula has generated concerns from some stakeholders that these emissions may lead to an accelerated weathering of rocks on which rock art is present which may reduce the visibility or destroy the rock art. Research to date on the impacts of emissions on rock art has not been conclusive, and there are currently no set air quality thresholds for the protection of rock art.

As outlined in Section 4.9.6, industrial emissions on the Burrup Peninsula are subject to extensive scientific studies to understand any potential pathway to impact on rock art, including wet and dry deposition which may alter the pH of rocks as well as the supply of nutrients which may promote microbial activity, the metabolic by-products of which may interact with rock surfaces.

The history of research on this subject, set out in more detail in Section 4.9.6, may be broadly divided into four periods. The earliest period, from 2002 to 2009, aligns with the studies conducted by the Burrup Rock Art Monitoring Management Committee (BRAMMC) but also includes work conducted by others, primarily Bednarik who identified potential impact pathways through acid formation and microbial impacts. During this period MacLeod (2005) also took some comparative pH samples between in-situ rocks and museum samples. None of this parallel work established that industrial emissions were impacting rock art, or the levels of emissions at which impacts may be expected to occur. This period concluded with the 2009 BRAMMC report which stated that “there is no scientific evidence to indicate that there is any measurable impact of emissions on the rate of deterioration of the Aboriginal rock art in the Burrup” (BRAMMC, 2009) but recommended the establishment of the Burrup Rock Art Technical Working Group (BRATWG) to conduct ongoing monitoring.

The second period of research aligns with this monitoring from 2010 to 2017. A significant component of this monitoring involved the monitoring of rock art colour. In 2016, Black and Diffey produced an unpublished paper critiquing the statistical methods applied by the CSIRO, which led to a review by Data Analysis Australia (DAA) which also raised “substantial doubts about the reliability of the data”. A final report from the CSIRO adapted its statistical methods to respond where possible to the conclusions from DAA but the results were described as “not fully conclusive”. Also, during this period, the BRATWG also commissioned an extreme condition weathering study which found that the dissolution of chemicals began at lower pH levels than previously estimated, however this work was only preliminary and should not be relied upon in setting thresholds for potential impacts.

The third research period, although overlapping with the conclusion of the BRATWG and initial years of the MRAS and MRAMP, is marked by the absence of any results from a coordinated, well-resourced research program and instead comprises a number of independent studies between 2017 and 2023. As a result, it is difficult to characterise these studies consistently. Some (Black et al., 2017a; Dorn, 2020; Smith, 2022a) critiqued or re-stated conclusions of previous studies. Black et al. 2017b repurposes historic pH data and concludes that “theoretical evaluation using electrochemical equilibrium principles” indicates impacts to rock art will result from a decreased pH since pre-industrial times; CGB Solutions’ 2020 analysis of historic pH and contemporary measurements found that pH was not decreasing and that any correlation between acidity and LNG production sites could not be statistically supported. Both studies suffer from significant issues with the available data.

Other studies (Black et al., 2018; Gleeson et al., 2018) discuss possible impact pathways but stop short of drawing conclusions on whether impacts to rock art are resulting from industrial emissions. Smith et al. (2022b) does hypothesise that industrial emissions may be responsible for some reported impacts but acknowledges that the methodologies applied are subject to considerable errors that prevent a definitive conclusion being drawn. A series of studies by MacLeod (2020, 2021, MacLeod and Fish, 2021) report on the results of monitoring conducted for Yara Pilbara Nitrates. The outcomes of these reports are inconsistent. Solo reports by MacLeod (2020, 2021) both state that “There is unequivocal evidence that the changes in colour contrast are affected by the changes in the mean and in the minimum pH observed on the rock art sites at the reference positions”, though the results include increased acidity correlating in some places with increased contrast and elsewhere with decreased contrast. MacLeod and Fish (2021) then state that “there is presently no adverse impact on the rock engravings from industrial pollution owing to a lower NO_x level than when the studies commenced 14 years ago”. This conclusion is critiqued by Smith et al. (2022a).

As noted in the MRAMP conceptual model, “while many of these studies form useful datasets to include in subsequent analyses, in general these studies have been inconclusive or failed to show any significant impact of anthropogenic impact on the rock art or chemical/biological species composition and abundance (Commonwealth of Australia, 2018). Nor have they produced any definitive relationships to inform a conceptual impact model, which is instead reliant on fundamental scientific studies in other regions to inform the likely processes occurring at Murujuga (e.g., Dorn, 2020[119]).”

In December 2023, the first interim report of MRAMP[120] was published (refer to Section 4.9.6), marking the start of a fourth period of research. The report states that results remain inconclusive with regards to whether industrial air emissions are resulting in anthropogenic change to rock art and recommends that further scientific studies are required. The MRAMP report noted that while some spatial trends in electrochemical parameters (such as pH) and rock surface elemental composition have been found, more work is required to determine causal relationships for these trends (as relationships were not as expected). Spatial trends were also identified as appearing for several

[119] https://www.wa.gov.au/system/files/2023-12/murujuga-rock-art-monitoring-program-conceptual-models.pdf.
[120] https://www.wa.gov.au/system/files/2023-12/murujuga-rock-art-monitoring-program-monitoring-studies-repo2023.pdf.

measured air pollutants such as NO_2 that are generally consistent with earlier air quality modelling by Ramboll (Ramboll 2022).

The MRAMP monitoring report outlined that similar trends exist for the pH measurements taken in March–April 2022 and the measured NO_2 levels generally. This relationship was the reverse of what would be expected to confirm the acid deposition hypothesis in previous literature as MRAMP found pH values in March–April 2022 were highest where NO_2 concentrations are highest; whereas with acid deposition, pH is expected to be lower where NO_2 is higher, as NO_2 is often a precursor to the formation of nitric acid, which has a low pH. Neutral pH is around 7, with low pH indicating potentially acidic conditions. The results in the MRAMP monitoring report have been reinterpreted by Smith (2024) in addition to original research but fails to address this unexpected correlation. Smith (2024) claims that "the damaging impact of acidic emissions on the rock surfaces is not in doubt" but does not provide adequate detail on the original research to allow its reliability to be considered, nor does it provide reason to question the conclusions of the MRAMP report, which stress that the available data is insufficient to draft any meaningful conclusions.

Throughout this ongoing period of research, new information will continue to be considered and responded to. However, the resourcing, scope and expertise available to MRAMP make it by far the most significant source of research on the cultural impacts of industrial emissions on Murujuga. MRAMP is also co-managed by MAC and emphasises Indigenous decision making and management, aligned with international guidance and standards, including the United Nations Declaration on the Rights of Indigenous Peoples and ICOMOS Charter for the Protection and Management of the Archaeological Heritage. For these reasons, the results of the MRAMP are prioritised in understanding the potential for emission to impact Murujuga's rock art.

The contribution of emissions from processing of Pluto gas to the Murujuga airshed is relatively small over the remaining life of Pluto Offshore Operations. Further, there is inconclusive evidence for any causal link between industrial air emissions and anthropogenic change to rock art on Murujuga. Given this, and that downstream facilities are subject to separate regulatory assessment outcomes, the risk of processing of Pluto gas at onshore facilities adversely impacting rock art on Murujuga is considered to be low, and no impact classification is able to be assigned. Woodside will continue to monitor the outcomes of MRAMP (as per C 11.1) and update or change manage the EP accordingly (Section 7.3)

Potential Impacts to Human Health

It is recognised that gaseous emissions causing a reduction in ambient air quality have the potential to impact human health as regulated by the NEPM. Both the Pluto LNG Facility and NWS Project Air Quality Management Plans have modelled and assessed the potential impacts of industrial emissions on human health in accordance with the requirements of Western Australian regulatory requirements and international standards (e.g., World Health Organisation). Ambient air quality monitoring programs are in place which demonstrate that current air pollution levels were well below standards set to protect human health and well-being.[121] The magnitude of emissions from processing Pluto gas are insufficient to lead to the exceedance of any relevant health criteria on the Burrup Peninsula or surrounding region.

Both Pluto LNG facility and the NWS Project have committed to maintaining an ongoing air quality monitoring program that is in place to monitor the ambient ground-level concentrations of relevant gases on the Burrup Peninsula, with comparisons being made against the NEPM standards and reported to DWER.

Ambient air quality monitoring results from Pluto and NWS Project will be summarised in the relevant facilities' Annual Environment Report, including any observed exceedances of ambient air quality standards.

As part of the NWS Extension proposal, the EPA assessed the residual impact to human health and amenity from the proposal's nitrogen dioxide (NO_2), SO_2, NH_3, ozone (O_3), and particulate (as PM_{10} and $PM_{2.5}$) emissions at sensitive receptors both in isolation and in a cumulative context with other existing and future emission sources. Predicted ground level concentrations (GLCs) at Dampier, Karratha, Hearson Cove, and Deep Gorge (Ngajarli) remain below applicable current and future proposed air quality criteria at 'standard operating conditions' and 'worst case' cumulative impact scenarios, with the exception of annual PM_{10} and $PM_{2.5}$ GLCs at Hearson Cove and Deep Gorge (Ngajarli), which slightly exceed the applicable criteria due to high levels of natural background dust. Subject to recommended conditions, the impact of the proposal was considered as being consistent with the EPA's objective for air quality in respect of human health.

Noting the absence of any current impacts to human health from industrial activity on Murujuga and presence of a comprehensive regulatory regime including monitoring program, the risk of processing of Pluto gas to human health is assessed as Negligible (F) based on slight effect to overall cumulative air quality in context of defined air quality criteria.

Control Considered	**Control Feasibility (F) and Cost/ Sacrifice (CS)**	**Benefit in Impact/Risk Reduction**	**Proportionality**	**Control Adopted**
sources (via. EP Act Part V Licencing) • Implementation of Part IV conditions. • Requirement to assess and implement NOx reduction measures, (e.g. Pluto Best Practice Report, NWS AQMP MA4) This includes implementation of potential EQMF developed as an outcome of MRAS; and measures such as NOx concentration limits at emissions point sources under EP Act Part V licences, and implementation of Part IV conditions. The NWS AQMP also requires MA5 development of an adaptive management plan to address the potential impact to rock art from industrial emissions.		KGP of 60% by 2030, and identification and implementation of best practice (with peer review). Pluto MS 757 required an Assessment of Best Practice for Minimising Emissions to Air from Major Plant. Further information on these requirements is described above, under Onshore Facility Air Emission Design Mitigations		
Implement the PAP in a manner that is not inconsistent with the objectives of the Murujuga National Park Management Plan 78, through execution of the Conservation Agreement and Deep Gorge Joint Statement.	F: Yes CS: Significant potential cost. Legal requirement.	Legal requirement to carry out activities not inconsistent with the Murujuga National Park Management Plan.	Control based on legislative requirements – must be adopted.	**Yes** C11.3
Good Practice				
Forecast, measure, monitor and or estimate facility fuel and flare emissions (in accordance with NGERS and WMS procedures named in Section 7.2.11.2) to inform optimisation management practices and minimise environmental impact of emissions.	F: Yes. CS: Minimal cost. Standard practice.	Minimises environmental impact of emissions through planning, ongoing review, governance and optimisation. It combines with good operating practice to maximise production and reduce flaring emissions (Pluto) and fuel emissions at the LNG plant to manage cost, which improves energy intensity (e.g. cleaner production),	Control is WMS requirement – must be adopted.	Yes **C 10.9**

Demonstration of ALARP				
Control Considered	**Control Feasibility (F) and Cost/ Sacrifice (CS)**	**Benefit in Impact/Risk Reduction**	**Proportionality**	**Control Adopted**
		optimising emissions from the project. Fuel and flared gas are potential product streams, as such, Woodside applies routine short and long term optimisation and opportunity management framework to identify and prioritise enhancement opportunities. On Pluto to date this has been limited to reduced flaring (e.g. flare purge rates); however overall system efficiencies (such as well and composition optimisation) and LNG Plant opportunities are also considered in this process. Annual flare and emissions target setting and monthly review of performance is completed for Pluto. The LNG Plant also applies flare and emissions target setting and tracking for emissions management. Daily production meetings allow for optimisation as an integrated production system, considering impacts of variables such as maintenance activities and temperature influence on production rates.

Selective Catalytic Reduction (SCR) at onshore processing facilities[122].	F: Potentially; subject to sufficient space and technical integration and safety requirements. Installation of SCR on gas turbines to reduce NOx emissions is proven in the power industry. Woodside is not aware of any instances where this has been retrofitted to mechanical drive turbines such as those used in LNG trains. CS: Substantial cost and significant business disruption. The installation of SCR systems introduces material new hazards to facilities, including the need to import significant amounts of ammonia daily,	SCR technology converts NOx to other compounds using a catalyst and gaseous reagent, usually ammonia or urea. If feasible, the installation of SCR on existing turbines could deliver a material reduction in NOx emissions from onshore processing.	Not proportional based on current impact profile. SCR was not selected for Pluto Train 1 nor recent Train 2, however the design was subject to peer review and EPA assessment with regard to best practice emission controls. Retrofitting on operational processing facilities carries significant cost, safety considerations and complexity.	No

	and potentially introduces risks associated with ammonia emissions while operating (which are also being monitored for potential impact to rock art). New gas fired boilers would be required to replace lost ability to extract heat from best-practice exhaust waste-heat recovery systems.			

ALARP Statement:

On the basis of the environmental risk assessment outcomes and the use of the relevant tools appropriate to decision type B for indirect emissions from gas processing onshore, Woodside considers the adopted controls appropriate to manage the risk.

Air emissions from onshore processing at Pluto LNG Facility are managed under Ministerial Statement 757.

Air emissions from onshore processing at the NWS Project have been assessed and approved in accordance with Ministerial Statement 536 (and others). Air emissions from onshore processing at the NWS Project Extension (i.e., an extension of the life of the NWSV beyond 2030) have been assessed by the EPA under Assessment Report 1727, and approved by Ministerial Statement 1233. Both facilities are subject to the provisions of Commonwealth and State legislation to ensure unacceptable environmental impacts are avoided.

The assessment in the ALARP table reflects the current status of controls related to routine atmospheric emissions, in the context that there is currently no scientific consensus that anthropogenic emissions are accelerating weathering of Murujuga rock art. These current controls are considered to appropriately implement a risk-weighted precautionary principle.

As described above, established programs and frameworks such as MRAS/MRAMP are designed to investigate theorised impact pathways and determine whether impact is occurring. Should credible scientific evidence emerge that anthropogenic emissions associated with processing of Pluto gas are causing accelerated weathering of Murujuga rock art as an outcome of MRAMP, the impact profile of onshore atmospheric emissions may change. In this eventuality, sufficient provisions exist in the relevant onshore regulatory frameworks to ensure that onshore atmospheric emissions are limited to acceptable levels, which may require review of controls currently in place at onshore processing facilities to manage potential impacts.

As no reasonable additional/alternative controls were identified that would further reduce the impacts without being grossly disproportionate the impacts and risks are considered ALARP.

Societal Values

Consultation was undertaken for this program to identify the views and concerns of relevant stakeholders. Industrial air emissions on the Burrup Peninsula are being managed by the EPA as part of the EP Act Part IV assessment process and DWER as part of their EP Act Part V process and via the MRAS. It is important to note that operators of the Pluto LNG Facility and Northwest Shelf Karratha Gas Plant have both made public commitments to supporting the outcomes of MRAS.

Atmospheric emissions associated with onshore processing of Pluto gas and potential for impact of those emissions on rock art was noted as a material issue for relevant persons consulted in the course of preparing this EP. All

Control Considered	**Control Feasibility (F) and Cost/ Sacrifice (CS)**	**Benefit in Impact/Risk Reduction**	**Proportionality**	**Control Adopted**
feedback, claims or objections from relevant persons has been appropriately responded to, addressed (see Appendix F and controls proposed have been assessed in the EP. ***Summary of ALARP Statement:*** On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type (i.e., Decision Type B for indirect emissions), the adopted controls are appropriate to manage the indirect impacts of air emissions related with processing Pluto gas onshore. The adopted controls meet NEPM, EP Act Part IV and Part V legislative requirements, and include application of precautionary measures to protect environmental cultural heritage values. As no reasonable additional/alternative controls were identified that would further reduce the impacts without being grossly disproportionate sacrifice, the impacts and risks are considered ALARP.				

Demonstration of Acceptability
Acceptability Criteria and Assessment
Acceptability Statement: Indirect Atmospheric Emissions The impact assessment concludes that indirect atmospheric emissions from the onshore processing of Pluto gas contribute only a minor portion to the overall industrial emission airshed load on the Burrup Peninsula. Atmospheric emissions within the Murujuga airshed from both Pluto LNG, NWS Project Extension have undergone independent assessment by the WA and agencies and have been considered acceptable, and are subject to management conditions. Woodside supports the ongoing management of heritage values under listings; Murujuga Cultural Landscape, Murujuga National Park and Dampier Archipelago (Including Burrup Peninsula) National Heritage Place. Planned activities under the PAP are not inconsistent with relevant heritage legislation, management plans and agreements under which these values are protected. Based on the implemented controls and the inconclusive evidence for any causal link between industrial air emissions and anthropogenic change to rock art, uncertainty and precaution are addressed by the existing State regulatory processes including the MRAS, which can apply adaptive management and mitigation measures as further scientific knowledge of potential pathways and indirect links to rock art are established. Ongoing reduction of NOx emissions to the Murujuga airshed is required and regulated under EP Act Ministerial Conditions. Therefore, based on application of a risk-weighted precautionary principle and adaptive management in the airshed, impacts from indirect air emissions as a result of onshore processing of Pluto gas are considered Negligible and of an ALARP and Acceptable level.

Light emissions during flaring						x		A	F	-	-			EPO 12c

Description of Source of Impact

Operations

When the riser platform is not crewed, lighting is limited to essential navigational and aviation requirements to communicate the presence of the riser platform and vessels to other marine users (i.e., navigation lights). Navigational lights are located on the facility's tallest structures (i.e., crane boom). Helideck lighting is provided to assist helicopter landings.

When crewed, which is generally ten times per year for approximately 14 days at a time, the platform and support vessels have adequate lighting to allow safe working conditions during 24-hour operations. Lights are not normally directed outwards away from work areas except when necessary for safe operations outboard, such as lifting operations, and deployment/retrieval of equipment from IMMR activities. A relatively small quantity of gas is required to be continuously flared associated with purge and pilot of the flare system and produced water treatment system low pressure gas streams that are not able to be recovered to the process. Intermittent flaring may occur during facility shutdowns/blowdown, pigging, restart, flowline depressurisation for subsea system integrity management and in case of emergency.

The distance to the horizon at which components of the facility will be directly visible can be estimated using the formula below:

$$horizon\ distance\ = 3.57 \times \sqrt{height}$$

Where horizon distance is the distance to the horizon at sea level in kilometres and height is the height above sea level of the light source in metres. Using this formula, the approximate distances at which the production deck and flare tower top will be visible at sea level are (based on the weather deck height above sea level of 47.4 m and flare tower height of 44 m – given an angle of 30°):

- weather deck: approximately 25 km from riser platform
- flare tower tip: approximately 34 km from riser platform.

The ASV has the majority of its lighting sources located on the main accommodation decks below the bridge at heights extending from ~47 m to ~100 m above sea level (while at operating draft). Therefore, the majority of the lighting is approximately at, or below, the level of the most significant light source on the riser platform (the flare tower tip). Accordingly, cumulative light from the ASV and riser platform will not be visible beyond approximately 36 km from the facilities.

IMMR activities

In addition to lighting to allow safe operations, and to meet mandatory navigational requirements, during IMMR activities underwater lighting is generated for short periods while ROVs/AUVs are in use. Given the typical intensity of ROV/AUV lights and inspection tools and the attenuation of light in seawater, light from these sources will be localised to the vicinity of the ROV/AUV, operating in close proximity to subsea infrastructure. During IMMR activities, vessels generally move slowly over the subsea infrastructure and are in the Operational Area for short periods of time.

Whilst subsea support vessel light inventories may vary, they are not considered to be greater than those of a trailer suction hopper dredge (TSHD) or pipelay vessel which have been previously modelled for Woodside activities (PENV 2022). These vessels were used as conservative analogues for IMMR activities in the Petroleum Activities Program. For evaluating the impact of Artificial Light at Night (ALAN) on marine turtles, PENV developed an approach based on the visibility of the full moon. Modelling undertaken indicated that light emissions were predicted to reduce to ambient levels (0.01, or 1%, radiance of a full moon) at 5.7 km and 3.2 km from a representative pipelay vessel and TSHD, respectively (PENV 2022).

Xena-03 Tie-back Activities

The MODU and project vessels will have external lighting to support safe navigation and safe operations at night. This lighting typically consists of bright white (i.e. metal halide, halogen, fluorescent) lights, and is not dissimilar to lighting used for other offshore activities, including fishing and shipping. Lighting is required for the safe operation of the MODU and project vessels cannot be reasonably eliminated.

The extent of potential impact for this activity is restricted to the line of sight for each source emitting light. Based on other previous work undertaken by Woodside this is about 30 km from the MODU during drilling activities and 30 km from vessels (Woodside, 2014). For contingent well flowback, specifically flaring, the distance at which the flare will be visible is expected to be less than 50 km from the source, and potentially around a further 10 km during emergency flaring (Woodside Energy Limited, 2011). Contingent well flowback activities would be intermittent and of a short duration, where alternate options for reservoir fluids during well unloading activities cannot be achieved (i.e., directed to the onshore LNG plant via the Pluto Facility).

Whilst the line of sight may extend tens of kilometres from the source, the light density (measured in Lux – which represents the intensity of light that arrives at or leaves a surface, as perceived by the human eye) rapidly decreases as distance increases from the source of the light. Monitoring undertaken as a part of Woodside's 2014 study indicated that light density (from navigational lighting) attenuated to below 1.00 Lux and 0.03 Lux at distances of 300 m and 1.4 km, respectively, from the source (a MODU). Light densities of 1.00 and 0.03 Lux are comparable to natural light densities experienced during deep twilight and during a quarter moon. Navigational lighting from vessels is less than lighting on a MODU. Therefore, light emissions from the MODU and installation vessel are expected to be below 1.00 Lux within 300 m from the source during Xena-03 Tie-back activities.

Cumulative light sources

Cumulative increases in light levels will occur during Xena-03 tie-back activities and commissioning/maintenance visits where the facility will be crewed and may also be utilising an ASV (up to 90 days per campaign). There will be additional lighting for safe operations of the MODU and installation and support vessels present in these periods. These scenarios will be short term (~12 weeks for tie-back activities).

Light emissions associated with routine operations will also arise from flaring at the riser platform, IMMR activities and vessel lighting from several nearby platforms including Wheatstone, Reindeer and Goodwyn (see Section 4.10.5) that are located within 50 km of Pluto. These activities combined may result in slightly elevated ambient light levels.

Impact Assessment

Lighting from the facility, MODU, ASV, project and support vessels may appear from direct unshielded light sources or through skyglow. Where direct light falls upon the ocean, this area of light is referred to as light spill. Skyglow is the diffuse glow caused by light that is screened from view, but through reflection and refraction creates a glow in the atmosphere. The distance at which direct light and skyglow may be visible from the source is dependent on the lighting on the facility / vessel and environmental conditions.

Receptors that have important habitat present within a 20 km buffer of artificial light sources were considered as having potential for interaction, based on recommendations of the National Light Pollution Guidelines for Wildlife Including Marine Turtles, Seabirds and Migratory Shorebirds (NLPG). The 20 km threshold provides a precautionary limit based on observed effects of sky glow on marine turtle hatchlings (15 to 18 km) and fledgling seabirds grounded in response to artificial light 15 km away (Commonwealth of Australia, 2020).

- The breeding BIA for the Wedge-tailed shearwater and the foraging BIA for the whale shark overlaps all three Operational Areas.

- The following turtle BIAs overlap operational areas:
- Flatback turtle internesting buffer (all three Operational Area)
- Green turtle internesting buffer (Export Pipeline Operational Area)
- Hawksbill turtle internesting buffer (Export Pipeline Operational Area)
- Loggerhead turtle internesting buffer (Export Pipeline Operational Area)
- Habitat critical to the survival of the flatback turtle overlap all three Operational Areas. The habitat critical to the survival of the green and hawksbill turtle both overlap the Export Pipeline Operational Area.
- Other marine turtle BIAs within 20 km of the PAA include:
- Flatback turtle foraging, mating, nesting and migration BIA (Export Pipeline Operational Area)
- Green turtle interesting buffer, foraging, mating, nesting and migration BIA (Export Pipeline Operational Area)
- Hawksbill turtle foraging, mating, nesting and migration BIA (Export Pipeline Operational Area)
- Loggerhead turtle nesting BIA (Export Pipeline Operational Area)
- Given that lighting from flaring may be visible up to 36 km from the riser platform, species with BIAs outside of 20 km and within 36 km of the Facility Operational Area and Xena-03 Operational Area were also identified. Although the NLPG suggest that impact to these species is unlikely beyond 20 km from the source, an assessment of these species has been included for completeness:
- Green turtle habitat critical to the survival (Facility Operational Area)
- Green turtle foraging, mating and nesting BIA (Facility Operational Area)
- Loggerhead turtle internesting buffer (Facility Operational Area)

Light emissions can affect fauna in two main ways:

- Behaviour: many organisms are adapted to natural levels of lighting and the natural changes associated with the day and night cycle as well as the phase of the moon. Artificial lighting has the potential to create a constant level of light at night that can override these natural levels and cycles.
- Orientation: organisms such as marine turtles and birds may use lighting from natural sources to orient themselves in a certain direction at night. In instances where an artificial light source is brighter than a natural source, the artificial light may act to override natural cues, leading to disorientation.

Vessel operations will take place within the PAA located in an open water, offshore environment, about 30 km from the nearest emergent islands (Montebello Islands). A number of BIAs overlap the PAA and EPBC Act listed fauna may transit through (refer to Section 4.6).

Light pollution is identified as a key threat to species of marine turtles and seabirds identified as occurring within the PAA (Section 6.10). Relevant conservation actions outlined in recovery plans and Wildlife Conservation Management plans for these species are also outlined in Section 6.10..

Seabirds

Artificial lighting can attract and disorient seabird species resulting in species behavioural changes (e.g., circling light sources or disrupted foraging), injury or mortality near the light source as a result of collision (Longcore and Rich, 2004; Gaston et al., 2014). All seabird species active at night are vulnerable to artificial light as it can disrupt their ability to orient towards the sea (Commonwealth of Australia, 2020). The potential for bird interactions is dependent upon their ability to perceive the dominant wavelengths in the spectral composition of a light source (PENV, 2023). Species with a nocturnal component to their behaviour and life history, such as procellariforms (including wedge-tailed shearwaters), are at greater risk of negative impacts from artificial light sources at night. The bulk of the literature concerning impacts of lighting upon procellariforms relates to the synchronised mass exodus of fledgling seabirds from their nesting sites (Deppe et al., 2017; Raine et al., 2007; Rodriguez et al., 2017a; Rodriguez et al., 2017b), with fewer investigating the impacts of light at sea. Diurnal seabird species, such as terns, noddies and boobies, in contrast to procellariforms, are less vulnerable to impacts resulting from nocturnal behaviours. However, the presence of lit facilities can result in localised alteration of foraging behaviours such as extended foraging durations. When Seabirds and shorebirds interact with bright light sources which could alter migratory pathways and/or nocturnal roosting behaviours when artificial light spill occurs over the habitat (PENV, 2023).

The breeding BIA for the wedge-tailed shearwater overlaps all three Operational areas, with the breeding period occurring from August to April. Adult shearwaters are vulnerable to artificial lighting during the breeding cycle, when returning to and leaving the nesting colony to maintain nesting sites or forage.

Facility and Xena-03 Operational Areas

Artificial light at night can alter foraging and migratory behaviours of avian species and lead to disorientation, grounding or death. Foraging wedge tailed shearwaters may be attracted to artificial light sources to feed upon fish drawn to the light; however, the species feeds predominantly during the day in association with pelagic predators (Catry et al., 2009; Whittow, 1997). The majority of foraging trips are short, with single day foraging trips significantly more common than any other length trip, with birds returning to nesting/roosting sites between trips (Congdon et al., 2005). As the Facility and Xena-03 Operational Areas are offshore and away from islands or other emergent features

(the distance to nearest landfall at the Montebello Islands from the riser platform is 43 km), any presence of seabirds or shorebirds is considered likely to be of a transient nature only. As such, the numbers of wedge-tailed shearwaters present in the Facility Operational Area or Xena-03 Operational Area at night is expected to be low relative to daylight hours, and any potential changes to behaviour would only affect a relatively low number of birds. Given the species' global distribution and primarily diurnal foraging behaviour, impacts to wedge-tailed shearwaters from artificial lighting are considered to be negligible.

Export Pipeline Operational Area

The nearest potential seabird roosting habitat on natural emergent land, the Dampier Archipelago, lie approximately 10 km from the Export Pipeline Operational Area (at the perimeter to state waters).

The breeding BIAs for the roseate tern and fairy tern overlap the Export Pipeline Operational Area, with breeding occurring in June to March for the Australian fairy tern, and breeding varying throughout the year for the roseate tern.

Adult shearwaters are vulnerable to artificial lighting in the breeding cycle, when returning to and leaving the nesting colony to maintain nesting sites or forage. Foraging wedge-tailed shearwaters may be attracted to sources of light emissions to feed on fish drawn to the light, however the species reportedly feeds predominately during the day (Catry et al. 2009). Artificial light can also impact behaviour and adult nest attendance, or confuse shearwater species, resulting in injury or mortality as a result of birds colliding with structures (Cianchetti-Benedetti et al. 2018; Rodriguez et al. 2017a and b). Fledglings of burrow-nesting seabirds, and to a lesser extent adults, are attracted to and then grounded (i.e., forced to land) by lights when they fly at night with the most affected seabirds being petrels and shearwaters (Procellariiformes) (Rodriguez et al. 2017). Shearwater fledglings are predominately impacted by onshore lighting sources, which can override sea finding cues and attract fledglings further inland, preventing them from reaching the sea (Mitkus et al. 2016; Telfer et al., 1987). Fledglings leave the nesting colony for the sea at night and the main fledgling period for shearwaters in Western Australia is reportedly April (Advisian, 2022). Reported mass groundings and mortalities are associated with formerly uninhabited islands and the risk of light pollution from tourism and urban sprawl, and generally occur during adverse weather conditions. This is probably because of the potential for clouds, mist and rain to increase light pollution levels (Kyba et al., 2011), however recent research is revealing added complexity including moon phase, wind strength and direction (see Commonwealth of Australia, 2020b for review).

Potential for overlap of IMMR activities, near the State waters boundary, with the wedge-tailed shearwater fledgling exodus from islands of the Dampier Archipelago in April is possible. However, given the localised vessel light emissions predicted and existing light sources in the marine waters in the area, vessels are expected to move at varying speeds and the expected, generally benign weather conditions in this region, the potential for wedged-tailed shearwater fledglings leaving burrows at night to collide, ground or become disoriented are considered unlikely. Artificial light from the PAP is not predicted to disrupt critical breeding behaviours within important nesting habitat or displace seabirds from nesting habitat.

The magnitude of impact to seabirds and migratory shorebirds in the Export Pipeline Operational Area from artificial light emissions is expected to be localised and temporary and only contribute negligibly to the incremental increase of vessel lighting in a region that already experiences considerable vessel traffic.

Riser Platform

Large numbers of migratory seabirds have been observed opportunistically roosting on the facility. If maintenance, process safety and/or health risks are identified associated with the presence of birds, it may be necessary to deter them from roosting on the riser platform by installing bird proofing/exclusion devices. The installation of bird proofing poses the potential risk of entanglement for individual birds. There have been no reported bird injuries or deaths at the facility, and consequently future adverse interactions are considered highly unlikely with no lasting effects on populations or impacts to critical habitat anticipated. If deterrents are installed birds will be likely to relocate to previous ranges (i.e. rather than landing on the platform), therefore no lasting effect is anticipated. The risk associated with collision from seabirds attracted to the light is considered to be low, given that lighting will be limited, except during intermittent periods when the riser platform is crewed and during support, IMMR and Xena-03 Tie-back activities.

Migratory shorebirds may be present in or fly through the offshore region of the riser platform between July and December, and again between March and April as they complete migrations between Australia and offshore locations (Commonwealth of Australia, 2015). The risk associated with collision from seabirds or migratory shorebirds attracted to artificial lighting is considered to be low, impacts are expected to be limited to localised behavioural disturbance to isolated individuals, with no displacement from important habitat.

The most vulnerable life stages for seabirds and migratory shorebirds are nesting adults or fledglings. Nesting or fledgling seabirds and migratory shorebirds are vulnerable to artificial lighting within 20 km of the nesting location (Commonwealth of Australia, 2020). For shearwater species, fledglings are predominantly impacted by onshore lighting sources, which can override sea finding cues and attract fledglings further inland, preventing them from reaching the sea (Mitkus et al., 2018). Artificial light can also impact important behaviour of nesting adults (e.g., adult nest attendance, maintaining nest sites) or confuse shearwater species, resulting in injury or mortality as a result of birds colliding with structures (Cianchetti-Benedetti et al., 2018; Rodriguez et al., 2017). As the riser platform is 43 km from the nearest emergent land, impacts to adult nesting or fledgling seabirds and migratory shorebirds are not expected. No nesting activity has been identified on the Pluto facility. Artificial light from the platform as well as

support, IMMR and Xena-03 tie-back activities are not predicted to disrupt critical breeding behaviours within important nesting habitat or displace seabirds from nesting habitat.

Marine Turtles

The following turtle BIAs overlap operational areas:

- Flatback turtle internesting buffer (all three Operational Area)
- Green turtle internesting buffer (Export Pipeline Operational Area)
- Hawksbill turtle internesting buffer (Export Pipeline Operational Area)
- Loggerhead turtle internesting buffer (Export Pipeline Operational Area)

Habitat critical to the survival of the flatback turtle overlap all three Operational Areas. The habitat critical to the survival of the green and hawksbill turtle both overlap the Export Pipeline Operational Area.

Other marine turtle BIAs within 20 km of the PAA include:

- Flatback turtle foraging, mating, nesting and migration BIA (Export Pipeline Operational Area)
- Green turtle interesting buffer, foraging, mating, nesting and migration BIA (Export Pipeline Operational Area)
- Hawksbill turtle foraging, mating, nesting and migration BIA (Export Pipeline Operational Area)
- Loggerhead turtle nesting BIA (Export Pipeline Operational Area)

Given that lighting from flaring may be visible up to 36 km from the riser platform, species with BIAs outside of 20 km and within 36 km of the Facility Operational Area and Xena-03 Operational Area were also identified. Although the NLPG suggest that impact to these species is unlikely beyond 20 km from the source, an assessment of these species has been included for completeness:

- Green turtle habitat critical to the survival (Facility Operational Area)
- Green turtle foraging, mating and nesting BIA (Facility Operational Area)
- Loggerhead turtle internesting buffer (Facility Operational Area)

Green turtle foraging, mating and nesting BIA as well as habitat critical to the survival are located approximately 36 km from the Facility Operational Area. The loggerhead turtle interesting BIA is located approximately 24 km from the Facility Operational Area and 37 km from the Xena-03 Tie-back Operational Area. Lighting from flaring may be visible up to 36 km away, however, the locations of flaring will be more distant than the estimated distance from the perimeter of the operational area. Whilst internesting loggerhead turtles may come within the light footprint from flaring at the riser platform, light is not thought to be an important cue for individuals that may move through the offshore area around the riser platform or Xena-03 tie-back activities. Adult turtles migrating through these Operational Areas may temporarily alter their normal behaviour if attracted to flaring from these facilities and activities.

Hatchlings

Light pollution is listed as a key threat to all marine turtle species, with advice to minimise light. The nearest potential nesting site in relation to the Facility and Xena-03 Operational Area is the Montebello Islands, approximately 43 km from the Xena-03 Tie-back and Pluto Facility Operational Areas. Given this, platform lighting and the tip of the flare tower will not be directly visible from this potential nesting site.

Light emissions reaching turtle nesting beaches is widely considered detrimental owing to interference with important nocturnal activities including choice of nesting sites and orientation/navigation to the sea by post-nesting females and hatchlings (Lorne and Salmon, 2007; Salmon, 2003; Tuxbury and Salmon, 2005).

Turtle hatchlings emerge from the nest and orient towards the sea. After entering the water, hatchlings use a combination of cues (wave direction and currents) to orient and travel into offshore waters. Impacts to the sea-finding behaviour of hatchlings are more common for light sources behind a beach, as lighting offshore will orient emerging hatchlings towards the sea. Artificial light at close distances can also impact hatchling dispersal once they are in the water. Light spill may ‘entrap’ hatchling swimming behaviour, reducing the success of their seaward dispersion and potentially increasing their exposure to predators via silhouetting (Salmon et al., 1992).

Sky glow, particularly from flaring on the riser platform, is also unlikely to be visible at the closest nesting locations and is unlikely to cause behavioural impacts. In any case, the light source is located directly offshore in the same direction that emerging hatchlings would be heading in during normal sea-finding behaviour, meaning that no significant misorientation or disorientation would occur.

The weather deck is approximately 47 m above sea level, with the highest point of the facility (the top of the flare tower) reaching approximately 91 m above sea level. The distance to visible horizon is ~34 km, i.e., anything beyond this distance is below the horizon and direct light would not be visible. Therefore, direct light from facility will not reach any nesting location. Sky glow (particularly from flaring) is also unlikely to be visible at the closest nesting locations resulting in no behavioural impact (i.e., not biologically relevant). Even in the scenarios where these areas may be affected, the light source is located directly offshore in the same direction that emerging hatchlings would be heading in during normal sea-finding behaviour, meaning that no disorientation impacts would occur.

The maximum likely height for a derrick on a MODU contracted for the PAP is ~50 m and subsequently have a lesser visible reach than the facility flare tower. External lighting on vessels is typically lower than the facility lights, with vessel lighting usually reduced to improve night vision of bridge crew.

During IMMR activities vessels may come within 10 km of turtle nesting beaches, mainly within the Dampier Archipelago when operating in the Export Pipeline Operational Area. Modelling predicted that light emissions would reduce to 0.01, or 1% radiance of a full moon (equivalent to the light output of the first quarter moon) within 5.7 km (PV) and 3.2 km (TSHD) (PENV 2022). At this level, light or light glow is visible but impact on hatchling behaviour is considered unlikely (i.e., not biologically relevant) (Aube et al., 2005).

There is potential for behavioural impacts to marine turtles to occur (greater than 0.1 full moon equivalent) within 1.8 km (PV) and 0.7 km (TSHD) (PENV 2022), but behavioural impacts are more likely (greater than radiance of one full moon) within 0.6 km (PV) and 0.2 km (TSHD) (PENV 2022).

Given that hatchlings' distribution is likely to be governed by currents, any hatchlings dispersed by water currents to within 1.8 km of an IMMR vessel risking entrapment by lighting, would be very limited.

Given the distance from the nearest nesting location to the Operational Area (10 km at the closest point) and the short term, infrequent nature of IMMR activities, any impacts to isolated hatchlings offshore are expected to be minor and temporary.

Adults

Artificial lighting may affect the location that turtles emerge to the beach, the success of nest construction, whether nesting is abandoned, and even the seaward return of adults (Salmon et al., 1995a, 1995b; Salmon and Witherington, 1995). However, such lighting is typically from residential and industrial development overlapping the coastline, rather than offshore from nesting beaches. It is acknowledged that the Facility Operational Area and Xena-03 Operational Area overlaps a 40 km internesting buffer BIA for flatback turtles and that marine turtles may occur in low densities in this area. However, no impacts to nesting flatback turtles will occur due to light generated within this section of the PAA given the riser platform's NNC status and the distance to the nearest landfall.

Within the Export Pipeline Operational Area, a higher abundance of turtles may be present. The Export Pipeline Operational Area overlaps internesting buffer BIAs for green, hawksbill and loggerhead turtles and is within 10 km of the nearest nesting beaches in the Dampier Archipelago. Although light from IMMR vessels may be visible from these beaches, nesting females are not considered highly vulnerable to disorientation from offshore artificial light (Pendoley, 2020). It is also highly unlikely that the PAP would cause disruption to sea-finding behaviour post nesting as the light source is located directly offshore in the same direction that females would be heading during normal sea-finding behaviour and IMMR activities requiring vessels have short durations and are very infrequent. As such, vessel light sources will not discourage females from nesting, or affect nest site selection, and therefore are not expected to displace females from nesting habitat. Given also the short-term and infrequent occurrence of IMMR activities, no impacts to nesting turtles of these species are expected to occur

Fish

Lighting from the presence of the facility, MODU, project and support vessels may result in the localised aggregation of fish. These aggregations of fish are considered localised and temporary and any long-term changes to fish species composition or abundance is considered highly unlikely. This localised increase in fish extends to those comprising the whale shark's diet which has a foraging BIA that intersects majority of the PAA. However, given that a large proportion of the diet comprises krill and other planktonic larvae, it is unlikely a light source would lead to a significant increase in whale shark abundance in the vicinity of the facility or vessels. Similarly, any localised impacts to marine fish are not expected to impact on any commercial fishers in the area.

Cumulative Impacts

There is potential for overlap when the Pluto facility becomes staffed during commissioning and tie-back activities where cumulative light emissions would occur from lighting required for safe operations from the facility, MODU and project vessels. As outlined above, these scenarios will be short term. The cumulative impact is likely to be minor, due to the low light intensities of the vessel navigational lighting, MODU and facility lighting, short and intermittent nature of the impact, and is not anticipated to adversely affect any sensitive receptors.

Cumulative light impacts have the potential to occur from flaring, IMMR activities and project vessel lighting from several nearby gas platforms; however, negligible detrimental impact to biological communities is expected.

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/Sacrifice (CS)[124]***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Legislation, Codes and Standards				
None identified.				
Good Practice				
Implement a Seabird Management Plan that includes: • standardisation and maintenance of record keeping and reporting of seabird interactions • procedures on seabird intervention, care and management • regulatory reporting requirements for seabirds (unintentional death of or injury to seabirds that constitute MNES). • A scalable adaptive management process should negative light impacts to nocturnal seabirds be detected.	F: Yes. CS: Minimal.	Potential for slight reduction in the likelihood of seabird attraction to vessels and facility resulting in a reduced likelihood of bird strikes.	Potential benefits outweigh cost/sacrifice.	Yes C 12.1
Lighting limited to the minimum required for navigational and safety requirements, with the exception of emergency events.	F. Yes. Lighting is typically appropriate for navigation and safety.	Given the potential impacts to turtles during this activity is insignificant, implementation of this control would not result in a reduction in consequence.	While the control does not result in significant reduction of impacts, it is good practice and not at significant cost.	Yes C 12.2
Well unloading acceptance criteria that define the well objectives will be established.	F: Yes. CS: Standard practice.	Eliminates unnecessary flared volumes and corresponding emissions (light and GHG).	Benefits outweigh cost/sacrifice.	Yes C 10.11

[124] Qualitative measure.

Lighting modifications (shielding, directional lighting) to minimise over water light spill and light emissions during peak turtle hatchling season (Dec to Mar).	F: Yes, lighting is able to be modified on the facility and vessel(s). CS: Financial cost of changes and time associated with implementing these.	Reducing light spill over water and overall light glow from a vessel can reduce the likelihood that hatchling behaviour will be influenced.	The cost/sacrifice outweighs benefit gained. Due to the short-term and infrequent nature of IMMR activities and the minimum distance of the Export Pipeline Operational Area from nearest nesting beaches (10 km) the benefits of implementing this control are expected to be minimal.	No
IMMR vessel crew will be trained in light reduction measures when operating within 20 km of islands between December and April (peak turtle hatchling emergence period is Dec-Mar, with the wedge-tailed shearwater fledgling emergence in Apr).	F: Yes. CS: Minimal cost/sacrifice.	Reducing overall light emissions from the IMMR activities can reduce light glow and potentially lower the area over which vessel lighting may impact turtle and wedge-tailed shearwater fledglings' behaviour. Given distance of the Operational Area from known turtle nesting beaches, a reduction in consequence from implementation of this control is not expected, however is possibly beneficial for wedge-tailed shearwater fledglings.	While the control does not result in significant reduction of potential impacts, it is good practice to raise awareness.	Yes 12.3
Professional Judgement – Eliminate				
No external lighting during Petroleum Activities Program.	F: No. Light management is consistent with that required to provide a safe working environment on-board the facility and support vessels. Lighting is required to enable monitoring of the platform from Pluto CCR. CS: Not considered, control not feasible.	Not considered, control not feasible.	Not considered, control not feasible.	No
Variation of the timing of the tie-back activities to avoid peak turtle internesting periods (December to January).	F: Yes CS: Significant cost and schedule impact due to delays in securing vessels/MODU for specific timeframes.	Not considered, control not feasible.	Not considered, control not feasible.	No

Substitute external lighting with light sources designed to minimise impacts to seabirds, shorebirds and marine turtles as outlined in the NLPG, considered for the riser platform, MODU, ASV, installation and support vessels including IMMR vessels: • Use flashing/ intermittent lights instead of fixed beam. • Use motion sensors to turn lights on only when needed. • Use luminaires with spectral content appropriate for the species present. • Avoid high intensity light of any colour.	F: Yes. Replacement of external lighting with lighting appropriate for turtles and seabirds is technically feasible, although is not considered to be practicable. CS: Significant cost sacrifice. The retrofitting of all external lighting on the facilities, etc, would result in considerable cost and time expenditure. Considerable logistical effort to source sufficient inventory of the range of light types.	Given the potential impacts to turtles, nesting seabirds and fledglings during this activity are insignificant, implementation of this control would not result in a reduction in consequence. Potential for minor reduction in impact to individual foraging seabirds that may transit the PAA.	Grossly disproportionate. Implementation of the control requires considerable cost sacrifice for minimal environmental benefit. The cost/sacrifice outweighs the benefit gained.	No
No flaring during Petroleum Activities Program.	F: No. The ability to flare hydrocarbons is a safety and integrity critical requirement for the facility. Note, Woodside is committed to reducing flaring and has developed annual internal facility flare targets against which progress is monitored (see Section 7.2.11.2). CS: Not considered, control not feasible.	Not considered, control not feasible.	Not considered, control not feasible.	No
Variation of the timing of the PAP to avoid IMMR activities during peak turtle internesting periods (October to February).	F: Yes. It is possible to avoid peak turtle hatchling emergence periods, through scheduling. CS: Significant cost and schedule impact due to delays in securing vessels for specific timeframes	Implementation of this control would not result in a reduction in consequence due to the distance of the Export Pipeline Operational Area from turtle nesting beaches.	The cost/sacrifice outweighs benefit gained.	No
Subsea support vessel activities which require direction of floodlights outside vessel(s) will preferentially occur during daylight hours	F: Yes. CS: Cost implication and delay of required IMMR activities.	Reducing light spill onto the water can reduce hatchling attraction to vessel(s). Given the distance of the Export Pipeline Operational Area	Implementation would be disproportionate to the risk reduction. While the control may reduce light spill, any IMMR	No

for IMMR operations in December and April (peak turtle hatchling emergence period is Dec-Mar, with the wedge-tailed shearwater fledgling exodus in Apr).		from known turtle nesting beaches and wedge-tailed shearwater rookeries, a reduction in consequence from implementation of this control is not expected.	activity is expected to be short in duration and infrequent.

Professional Judgement – Engineered Solution				
IMMR vessels to use block-out blinds / curtains on accommodation windows at night between December and April (peak turtle hatchling emergence period is Dec-Mar, with the wedge-tailed shearwater fledgling exodus in Apr).	F: Yes. Installing block-out blinds / curtains is technically feasible. CS: Minimal cost/sacrifice. Accommodation modules on vessels usually have window treatments for crew comfort.	Reducing light emissions from the vessel at night can reduced light glow and the area over which light may impact turtle hatchling emergence and wedge-tailed shearwater fledgling exodus.	Benefits outweigh minimal cost/ sacrifice of implementation.	Yes C 12.4

ALARP Statement:

On the basis of the environmental impact assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the potential impacts from routine light emissions from the facility, MODU and vessels to be ALARP. As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.

Demonstration of Acceptability

Acceptability Statement:

The impact assessment has determined that, given the adopted controls, routine light emissions from external lighting on Pluto facility, MODU, ASV, installation and support vessels represent a localised impact /disturbance to marine fauna within the PAA, the majority of which will occur in the Facility Operational Area and Xena-03 Operational Area.

The PAA overlaps with the whale shark foraging BIA as well as BIAs for the loggerhead turtle, green turtle, hawksbill turtle, and flatback turtle, and Habitat Critical to the green turtle, hawksbill turtle, and loggerhead turtle. The PAA also overlaps the breeding BIA for the wedge-tailed shearwater, roseate tern, and fairy tern. Conservation advice and the NLPG were taken into consideration during the impact evaluation. The PAP is deemed consistent with the conservation advice and guideline.

Further opportunities to reduce the impacts have been investigated above. The potential impacts are consistent with good oil-field practice/industry best practice and are considered to be broadly acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the impacts of light emissions to a level that is broadly acceptable and demonstrate the EPOs are met.

6.8 Unplanned Activities (Accidents, Incidents, Emergency Situations) – Major Environmental Events

For Woodside's production facilities, an analysis is undertaken to identify, classify and analyse major environmental events (MEEs), as described in Section 2.7. This extra level of rigour is applied so that sufficient controls for operational activities are in place for risks with potential Major and above environment event related consequences as per Woodside's Risk Matrix.

MEEs are evaluated against credible worst-case scenarios that may occur when all controls are absent or have failed. The risks considered in this section have therefore been identified as MEEs due to the potential for significant consequence. These sources of risk are subject to additional consideration in accordance with the process described in Section 2.6.4. Risks associated with the PAP that have been classified as MEEs are summarised in Section 6.8.1 and include a range of hydrocarbon spills. The quantitative spill risk assessment methodology used to assess the potential consequence of credible spills is outlined in Section 6.8.2. Credible hydrocarbon spills that have not been classified as MEEs have also been assessed in Section 6.8. Risks that do not meet the MEE definition, although screened out of the MEE process, are still evaluated for ALARP and risk acceptability using the methodology described in Section 2.8. These include credible hydrocarbon spills during drilling and tie-back activities, which are not classified as MEEs for the following reasons:

- Drilling and subsea installation activities are performed outside of operations asset controls and ownership. Ownership is only handed over in cold commissioning when the asset gains control of subsea systems and well control, as such a different set of controls and safety systems are used in the lead up to pre-commissioning.
- The vessel safety case contains safety systems that prevent the occurrence of hydrocarbon spills during drilling and subsea installation.
- Hydrocarbon spills assessed for the drilling and subsea installation phase align with vessel safety case risk assessments and mitigation to reflect controls proportionate to the short duration elevated risk activities.

Drilling and subsea installation activities conclude with the hand over to the asset along with the subsequent risk and consequence from the activities.

6.8.1 Major Environmental Events Overview

Section 2.7 outlines the process for additional analysis and evaluation of MEEs. The bowtie output for each MEE identified has been provided in Table 6-31.

Table 6-31: Major environmental events for the Pluto facility operations

No.	Hazard	Top Event
MEE-01	Hydrocarbons in reservoirs, wells, wellheads and xmas trees	Well loss of containment
MEE-02	Hydrocarbons in subsea equipment (pipelines, flowlines and risers)	Subsea equipment loss of containment
MEE-03	Hydrocarbons in subsea and topsides equipment	Loss of structural integrity
MEE-04	Hydrocarbons in subsea and topsides equipment and marine vessels	Loss of marine vessel separation with platform
MEE-05	Hydrocarbons in subsea and topsides equipment	Loss of control of suspended load from platform

Each section includes a summary of the hazard description, hazard management, emergency response, ALARP summary and a list of SCE barriers identified on the bowties. Each group of SCEs is listed under Technical Performance Standards, with consistent naming conventions used across

Woodside's process safety management processes (e.g., pipeline integrity SCEs are captured as P09 – Pipeline Systems).

Section 6.8.8 presents the generic SCE Failure and Human Error bowties that illustrate the causes, outcomes and controls/barriers in place to manage potential common cause event (CCE) failure mechanisms for MEE controls associated with generic SCE equipment failure (CCE-01), and also human error (CCE-02). Controls and specific measures are listed for both bowties. Human Error is managed via the WMS and the generic Human Error bowtie is included in the MEE section for completeness.

ALARP is demonstrated through controls and barriers being analysed for selection based on their independence, prioritised in accordance with the hierarchy of controls where controls further up the hierarchy take precedence over controls further down, and further analysed to consider the type of effect the control provides. ALARP controls presented for MEE bowties are labelled in accordance with Type of Effect classifications presented.

Woodside has developed a tailored ALARP position for hydrocarbon spill response, including EPOs, EPSs and MC for preparedness and response. The response arrangements are a mitigative control that applies to all MEEs where a hydrocarbon release may credibly occur. The hydrocarbon spill response arrangements are described in Section 7.

Table 6-32: Barrier hierarchy and type of effect

Type of Effect	Legend	Description
Elimination (Technical)		Elimination controls form the 'first line of defence'. They eliminate the underlying hazard and therefore are the most effective category of control measure. If practicable, they should be selected in preference to any other type, as their existence removes the need for any other controls (e.g., a corrosion-resistant metal could replace the original material of construction).
Elimination (Administration)		
Prevention (Technical)		Prevention controls are intended to remove certain causes of incidents or reduce their likelihood. The corresponding hazard remains, but the frequency of incidents involving the hazard is lowered (e.g., introduction of regular maintenance programs can prevent the development of events involving the hazard). Where hazards and causes could not be 'eliminated', controls are required to prevent them from leading to unwanted events and consequences.
Prevention (Administration)		
Detection (Technical)		Detection controls are those that identify a potentially hazardous scenario (e.g., a change in operating parameters), allowing initiation of procedures or systems to prevent the cause occurring. Controls that detect the occurrence of events are often critical to being able to respond with other control measures that reduce the propagation of the events. Detection controls themselves often provide no actual control other than the awareness of the need to respond.
Detection (Administration)		
Reduction/Control (Technical)		Reduction controls are intended to limit the scale and consequence of incidents. They include systems that detect incidents and take some action (e.g., to reduce the rate of leakage of a toxic gas) and also aspects such as inter-unit separation that prevent escalation of fire and explosion incidents. As there is always potential for controls to fail, additional measures are required to limit the scale and severity of any unwanted event or outcome that may arise, by providing the ability to intervene and limit the propagation of the events.
Reduction/Control (Administration)		
Mitigation (Technical)		Mitigation controls take effect in response to an incident. They include controls that lessen the significance or damage caused by an

Type of Effect	Legend	Description
Mitigation (Administration)		unwanted event. Such controls only take effect after the hazardous event and outcomes occur. Mitigation controls are generally those designed to protect personnel against the consequences of a hazard or to aid in recovering from the effects of the hazard.

6.8.2 Quantitative Spill Risk Assessment Methodology

As part of the risk identification process, Woodside identified the range of credible hydrocarbon spill scenarios that may occur during the PAP. Scenarios that have been classified as MEEs are assessed in Sections 6.8.3 to 6.8.7. Scenarios that are not classified as MEEs are assessed in Section 6.9.

Quantitative hydrocarbon spill modelling was undertaken by RPS, on behalf of Woodside, using a three-dimensional (3D) hydrocarbon spill trajectory and weathering model, SIMAP (Spill Impact Mapping and Analysis Program), which is designed to simulate the transport, spreading and weathering of specific hydrocarbon types under the influence of changing meteorological and oceanographic forces.

A stochastic modelling scheme was followed in this study, whereby SIMAP was applied to repeatedly simulate the defined credible spill scenarios using different samples of current and wind data. These data samples were selected randomly from an historic time-series of wind and current data representative of the study area. Results of the replicate simulations were then statistically analysed and mapped to define contours of percentage probability of contact at identified thresholds around the hydrocarbon release point.

The model simulates surface releases and uses the unique physical and chemical properties of a hydrocarbon type to calculate rates of evaporation and viscosity change, including the tendency to form oil in water emulsions. Moreover, the unique transport and dispersion of surface slicks and in water components (entrained and dissolved) are modelled separately. Thus, the model can be used to understand the wider potential consequences of a spill, including direct contact of hydrocarbons due to surface slicks (floating hydrocarbon) and exposure of organisms to entrained and dissolved aromatic hydrocarbons in the water column.

During each simulation, the SIMAP model records the location (by latitude, longitude and depth) of each of the particles (representing a given mass of hydrocarbons) on or in the water column, at regular time steps. For any particles that contact a shoreline, the model records the accumulation of hydrocarbon mass that arrives on each section of shoreline over time, less any mass that is lost to evaporation and/or subsequent removal by current and wind forces.

The collective records from all simulations are then analysed by dividing the study region into a 3D grid. For surface hydrocarbons (floating oil), the sum of the mass in all hydrocarbon particles located within a grid cell, divided by the area of the cell, provides hydrocarbon concentration estimates in that grid cell at each model output time interval. For entrained and dissolved aromatic hydrocarbon particles, concentrations are calculated at each time step by summing the mass of particles within a grid cell and dividing by the volume of the grid cell. The process is also subject to the application of spreading filters that represent the expected mass distribution of each distinct particle. The concentrations of hydrocarbons calculated for each grid cell, at each time step, are then analysed to determine whether concentration estimates exceed defined threshold concentrations.

Hydrocarbon spill modelling assessments undertaken by RPS undergo initial sensitivity modelling to determine appropriate time to add to the simulation after the cessation of the spill. The amount of time following the spill is based on the time required for the modelled concentrations to practically drop below threshold concentrations anywhere in the model domain in the test cases. This assessment is done by post-processing the sensitivity test results and analysing time-series of median and maximum concentrations in the water and on the surface.

6.8.2.1 Hydrocarbon Characteristics

The characteristics of the hydrocarbons used as the basis for the modelling studies and subsequently to inform the assessment of credible hydrocarbon spills is summarised in Table 6-33. Additional detail on the characteristics of these hydrocarbons is also provided below.

Table 6-33: Characteristics of the hydrocarbon types used for modelling and ecotoxicological studies

Hydrocarbon Type	Density (g/cm3) at 15°C	Viscosity (cP) at 15°C	Component	Volatile (%)	Semi-volatile (%)	Low Volatility (%)	Residual (%)	Aromatics (%)
			Boiling Point (°C)	<180	180-265	265-380	>380	Of Whole Oil <380

** at 25°C*

6.8.2.1.1 Pluto Condensate (PLA02 Operations)

Pluto condensate (applicable to PLA02 Operations) is a mixture of volatile and persistent hydrocarbons with high proportions of volatile and semi-volatile components. In favourable conditions, about 68% of the oil mass should evaporate within the first 12 hours (boiling point

<180°C); a further 18.48% should evaporate within the first 24 hours (180°C < boiling point < 265°C); and a further 10.05% should evaporate over several days (265°C < boiling point < 380°C). About 2.5% of the oil is shown to be persistent. The aromatic content of the oil is about 9.83% (RPS Group, 2024b).

Soluble, aromatic, hydrocarbons contribute to approximately 9.83% mass of the total oil. A further 10.05% has low volatility and a further 18.48% is semi-volatile. These compounds dissolve more slowly but tend to persist in soluble form for longer. Discharge onto the water surface will favour the process of evaporation over dissolution under calm sea conditions, but increased entrainment of oil and dissolution of soluble compounds can be expected under breaking wave conditions (RPS Group, 2024b).

The mass balance forecast for the constant-wind case shows that approximately 85% of the oil is predicted to evaporate within 24 hours. Under calm conditions, most of the remaining oil on the water surface will weather at a slower rate due to being comprised of the longer-chain compounds with higher boiling points. Evaporation of the residual compounds will slow significantly, and they will then be subject to more gradual decay through biological and photochemical processes (RPS Group, 2024b).

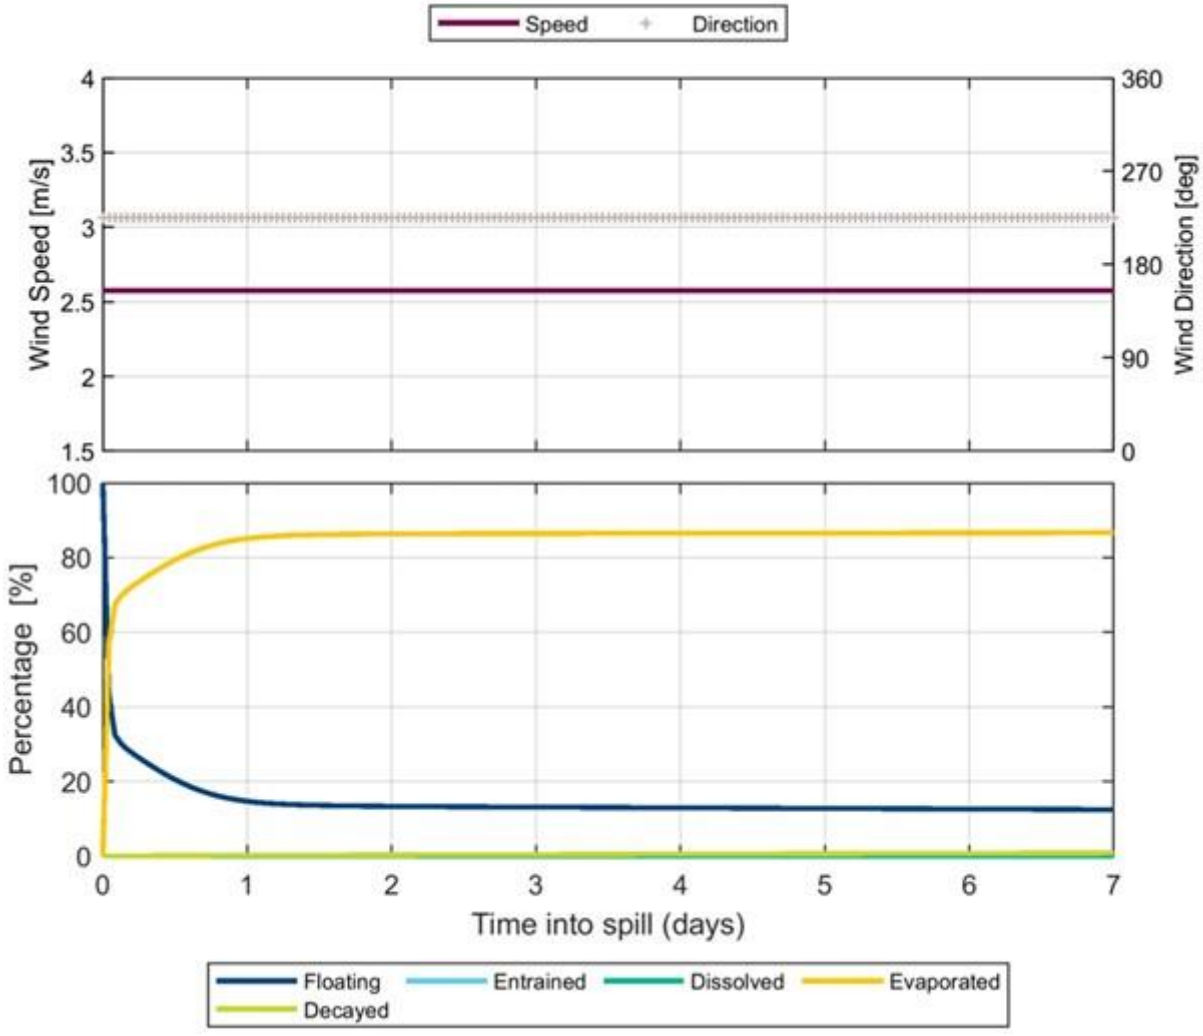

Figure 6-9: Proportional mass balance plot representing the weathering of Pluto condensate spilled onto the water surface as a one-off instantaneous release (50 m³) and subject to a constant 5 kn (2.6 m/s) wind at 27°C water temperature and 25°C air temperature

Under the variable-wind case, where the winds are of greater strength on average, entrainment of Pluto condensate into the water column is predicted to increase. Approximately 24 hours after the spill, around 16% of the oil mass is forecast to have entrained and a further 82% is forecast to have evaporated, leaving only a small proportion of the oil floating on the water surface (<0.1%). The residual compounds will tend to remain entrained beneath the surface under conditions that generate wind waves (approximately >6 m/s) (RPS Group, 2024b).

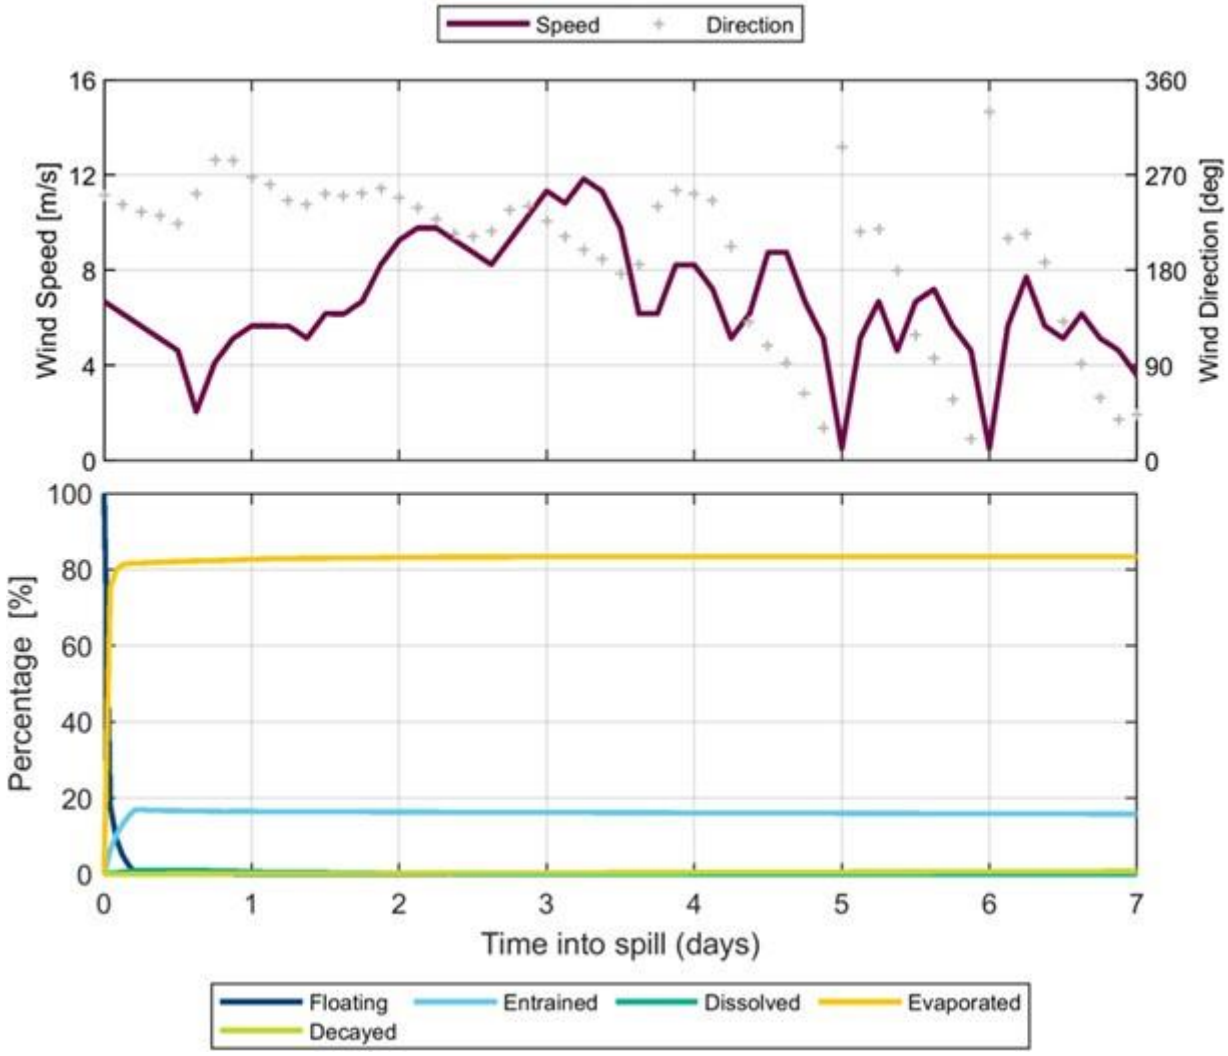

Figure 6-10: Proportional mass balance plot representing the weathering of Pluto condensate spilled onto the water surface as a one-off instantaneous release (50 m³) and subject to variable wind at 27°C water temperature and 25°C air temperature

6.8.2.1.2 Pluto Condensate (Trunkline Operations)

Pluto condensate is a mixture of volatile and persistent hydrocarbons with high proportions of volatile and semi-volatile components. In favourable conditions, about 76% of the oil mass should evaporate within the first 12 hours (boiling point <180°C); a further 14% should evaporate within the first 24 hours (180°C < boiling point < 265°C); and a further 9.5% should evaporate over several days (265°C < boiling point < 380°C). About 0.5% of the oil is shown to be persistent (RPS Group, 2024c, 2024d).

Around 76% of the oil is highly soluble and highly volatile. A further 14% is semi-volatile, and a further 9.5% has low volatility. These compounds dissolve more slowly but tend to persist in soluble form

for longer. Discharge onto the water surface will favour the process of evaporation over dissolution under calm sea conditions, but increased entrainment of oil and dissolution of soluble compounds can be expected under breaking wave conditions (RPS Group, 2024c, 2024d).

The mass balance forecast for the constant low-wind case for Pluto shows that approximately 90% of the oil should evaporate within 24 hours. Under calm conditions, most of the remaining oil on the water surface will weather at a slower rate due to being comprised of the longer-chain compounds with higher boiling points. Evaporation of the residual compounds will slow significantly, and they will then be subject to more gradual decay through biological and photochemical processes (RPS Group, 2024c, 2024d).

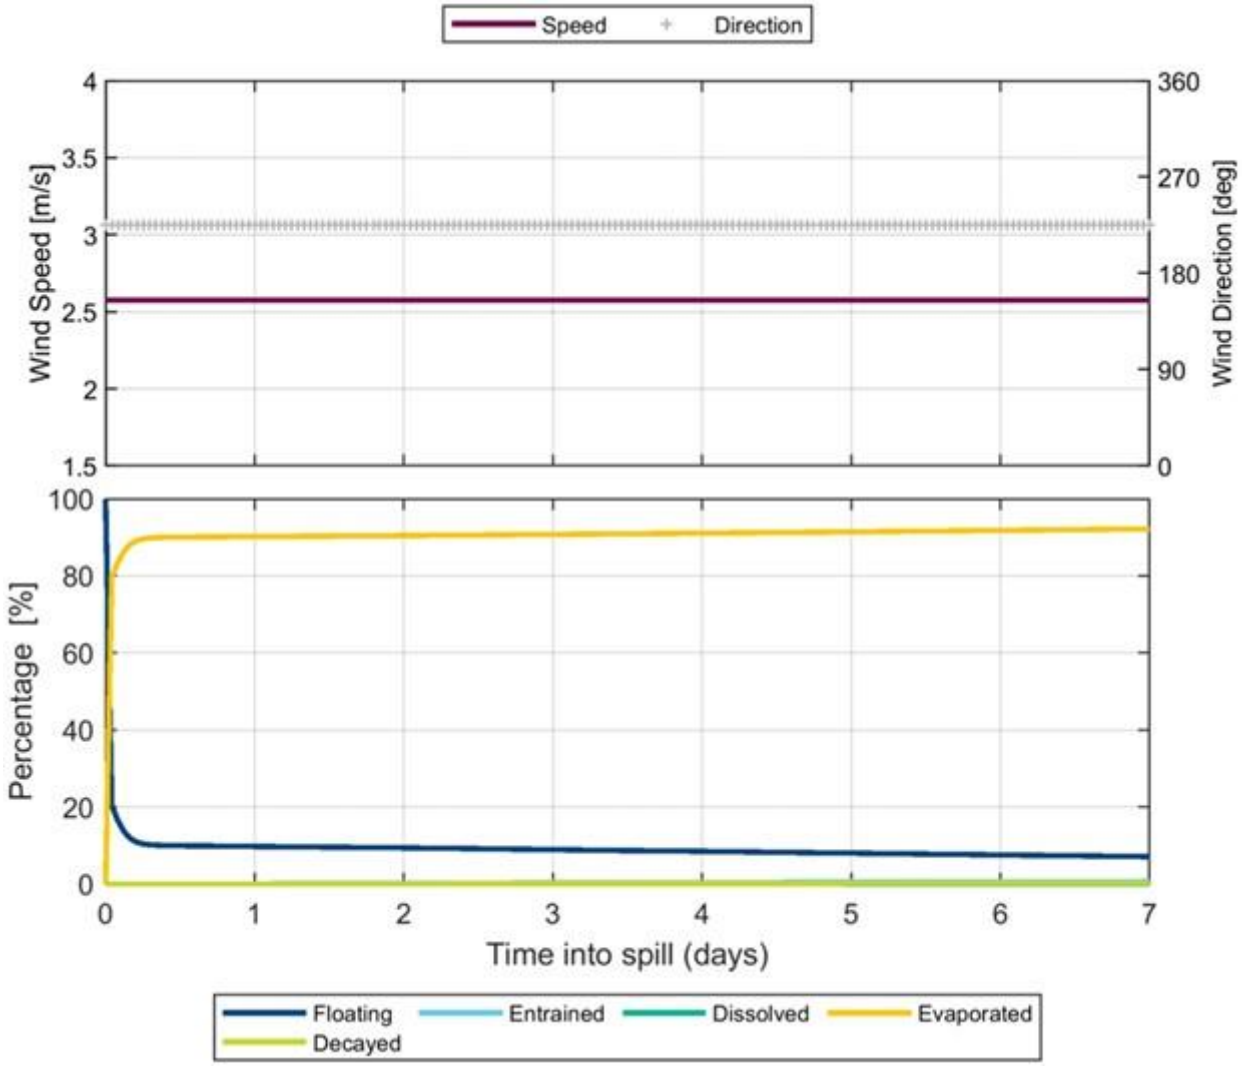

Figure 6-11: Proportional mass balance plot representing the weathering of Pluto condensate spilled onto the water surface as a one-off instantaneous release (50 m³) and subject to a constant 5 kn (2.6 m/s) wind at 27°C water temperature and 25°C air temperature

Under the variable-wind case, where the winds are of greater strength on average, entrainment of Pluto Condensate into the water column is predicted to increase. Approximately 24 hours after the spill, around 12% of the oil mass is predicted to have entrained and a further 87% is predicted to have evaporated, leaving only a small proportion of oil floating on the water surface (<1%). The residual compounds will tend to remain entrained beneath the surface under conditions that generate wind waves (approximately >6 m/s) (RPS Group, 2024c, 2024d).

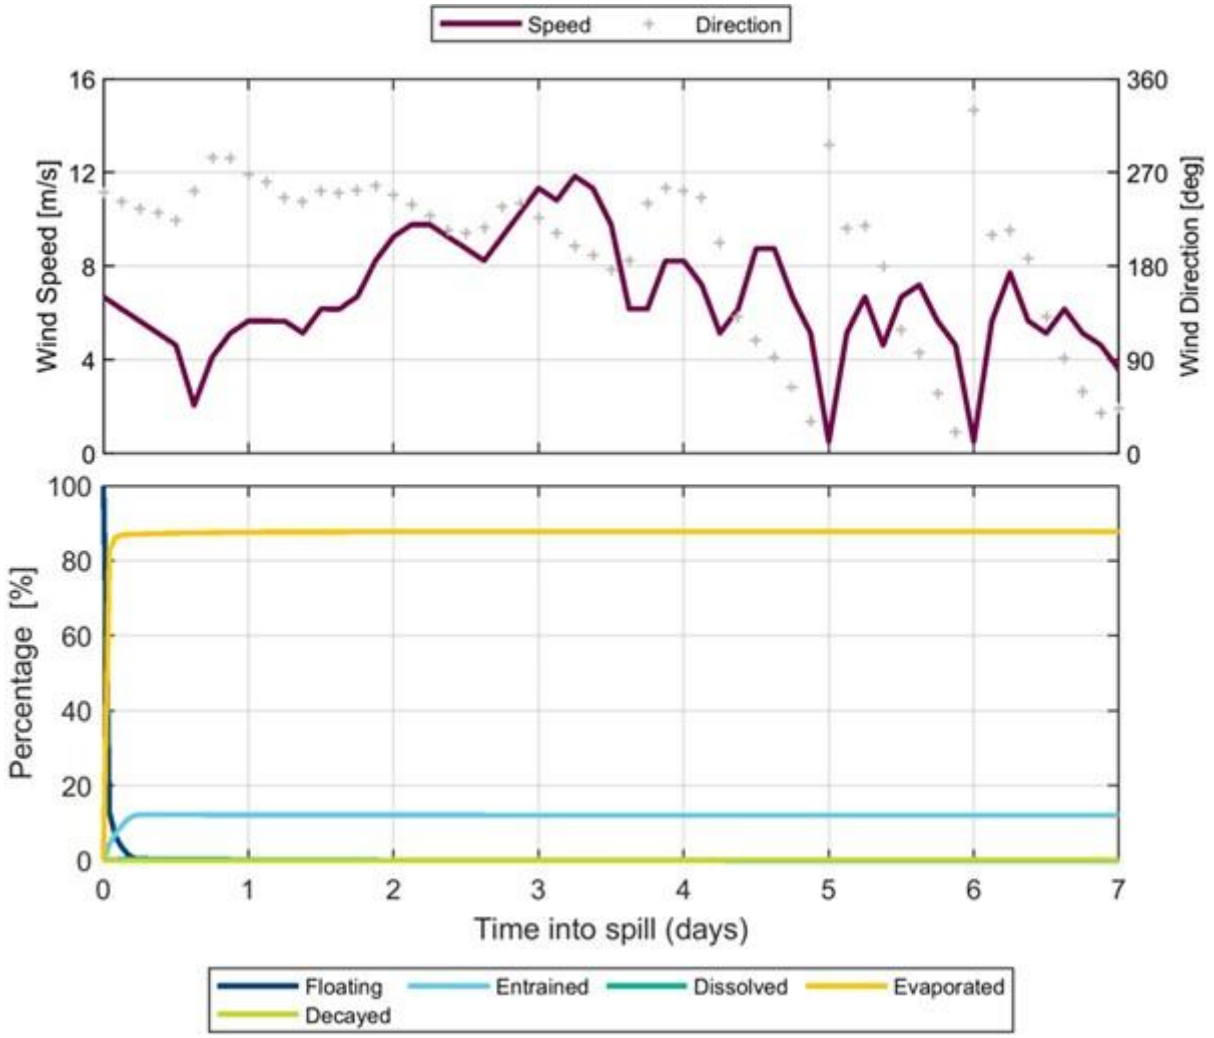

Figure 6-12: Proportional mass balance plot representing the weathering of Pluto condensate spilled onto the water surface as a one-off instantaneous release (50 m³) and subject to variable wind at 27°C water temperature and 25°C air temperature

6.8.2.1.3 Condensate – Eris-1 and Pluto Analogues (Surface and Seabed)

Eris-1 and Pluto analogues condensate (Eris-1), applicable for Xena-03 hydrocarbon QSRA, is a mixture of hydrocarbon compounds that would condense from the gas-phase on exposure to the lower pressures and temperatures of ambient conditions. As these conditions would differ, the hydrocarbon characteristics of the condensate at the surface and the seabed have both been accounted for.

Eris-1 condensate released at the surface is a mixture of volatile and persistent hydrocarbons with high proportions of volatile and semi-volatile components. In favourable conditions, about 15% of the oil mass should evaporate within the first 12 hours (boiling point <180°C); a further 48.43% should evaporate within the first 24 hours (180°C < boiling point < 265°C); and a further 26.6% should evaporate over several days (265°C < boiling point < 380°C). About 10% of the oil is shown to be persistent. The aromatic content of the oil is about 9.85% (RPS Group, 2024a).

Soluble, aromatic, hydrocarbons contribute approximately 9.85% by mass of the whole oil. Around 14.97% is highly soluble and highly volatile. A further 48.43% is semi-volatile and a 26.6% has a low volatility. These compounds dissolve more slowly but tend to persist in soluble form for longer. Discharge onto the water surface will favour the process of evaporation over dissolution under calm

sea conditions, but increased entrainment of oil and dissolution of soluble compounds can be expected under breaking wave conditions (RPS Group, 2024a).

The mass balance forecast for the constant wind case for the Eris-1 condensate (surface) shows that approximately 64% of the oil should evaporate within 24 hours. Under calm conditions, the majority of the remaining oil on the water surface will weather at a slower rate due to being comprised of the longer-chain compounds with higher boiling points. Evaporation of the residual compounds will slow significantly, and they will then be subject to more gradual decay through biological and photochemical processes (RPS Group, 2024a).

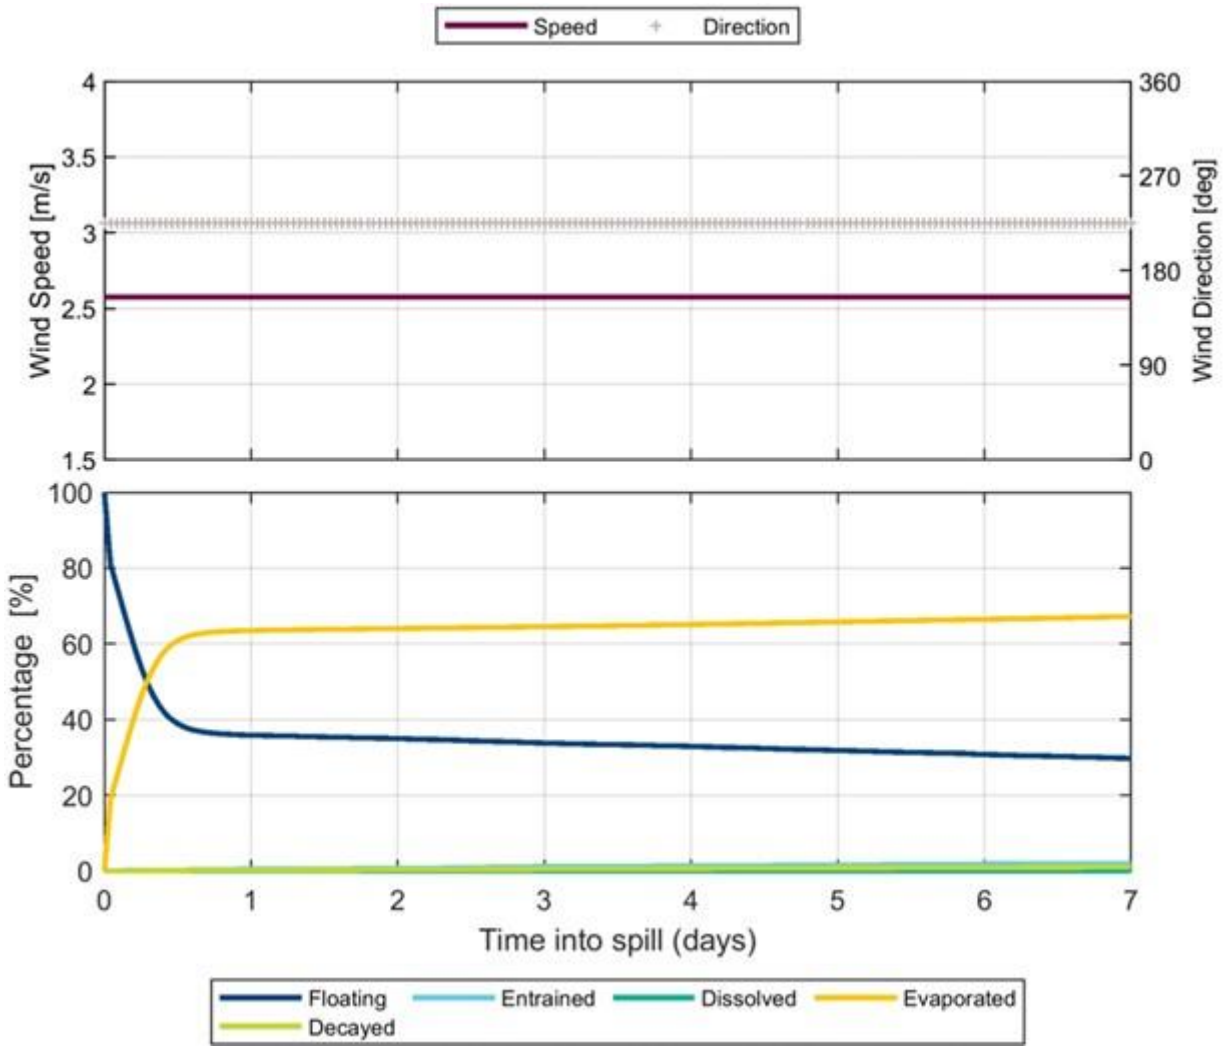

Figure 6-13: Proportional mass balance plot representing the weathering of Eris-1 condensate spilled onto the water surface as a one-off instantaneous release (50 m³) and subject to a constant 5 kn (2.6 m/s) wind at 27°C water temperature and 25°C air temperature

Under the variable-wind case, where the winds are of greater strength on average, entrainment of Eris-1 condensate (surface) into the water column is predicted to increase. Approximately 24 hours after the spill, around 54% of the oil mass is expected to have entrained and a further 43% is forecasted to have evaporated, leaving only a small proportion of oil floating on the water surface (<15). The residual compounds will tend to remain entrained beneath the surface under conditions that generate wind waves (approximately >6 m/s) (RPS Group, 2024a).

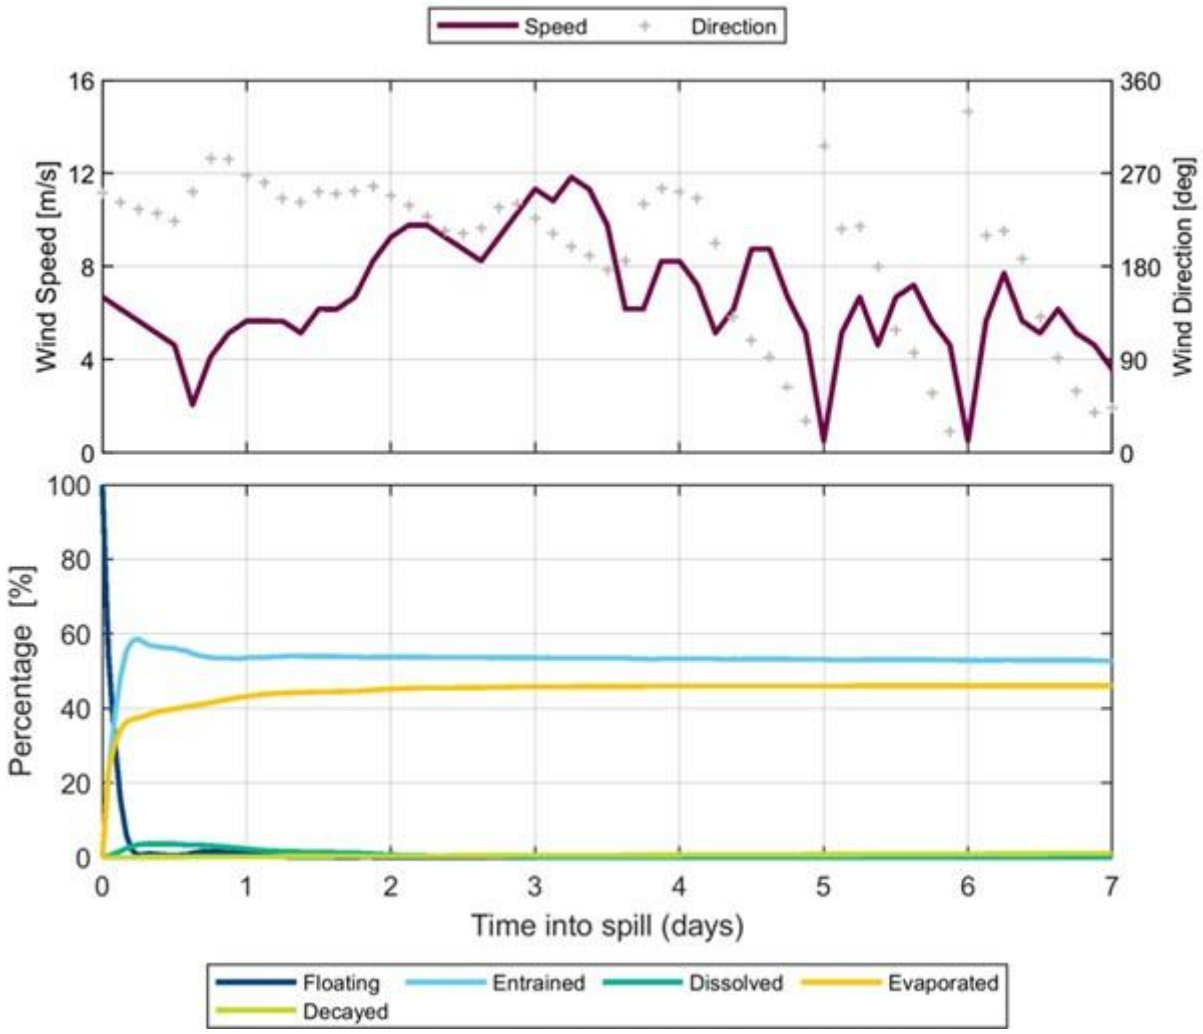

Figure 6-14: Proportional mass balance plot representing the weathering of Xena fluid spilled onto the water surface as a one-off instantaneous release (50 m³) and subject to variable wind at 27°C water temperature and 25°C air temperature

6.8.2.1.4 Marine Diesel

Marine diesel, 'marine gas oil' (MGO) is a mixture of volatile and persistent hydrocarbons with low proportions of highly volatile and residual components. Modelling for marine diesel used information for a comparable MGO. In favourable conditions, about 6% of the oil mass should evaporate within the first 12 hours (boiling point <180°C); a further 34.6% should evaporate within the first 24 hours (180°C < boiling point < 265°C); and a further 54.4% should evaporate over several days (265°C < boiling point < 380°C). About 5% of the oil is shown to be persistent. The aromatic content of the oil is about 3% (RPS Group, 2024e).

The mass balance forecast for the constant-wind case for MGO shows that about 38% of the oil is predicted to evaporate within 24 hours. Under these calm conditions the majority of the remaining oil on the water surface weathers at a slower rate due to comprising the longer-chain compounds with higher boiling points. Evaporation of the residual compounds slows significantly and is then subject to more gradual decay through biological and photochemical processes (RPS Group, 2024e).

Under the more realistic variable-wind case, where the winds are of greater strength, entrainment of MGO into the water column is indicated to be significant. About 24 hours after the spill, around 74%

of the oil mass is forecast to have entrained and a further 26% is forecast to have evaporated, leaving only a small proportion of the oil floating on the water surface (<1%). The residual compounds tend to remain entrained beneath the surface under conditions that generate wind waves (about >6 m/s).

The increased level of entrainment in the variable-wind case results in a higher percentage of biological and photochemical degradation. Given the large proportion of entrained oil and the tendency for it to remain mixed in the water column, the remaining hydrocarbons decay and/or evaporate over time scales of several weeks to a few months. This long weathering duration extends the area of potential effect (RPS Group, 2024e).

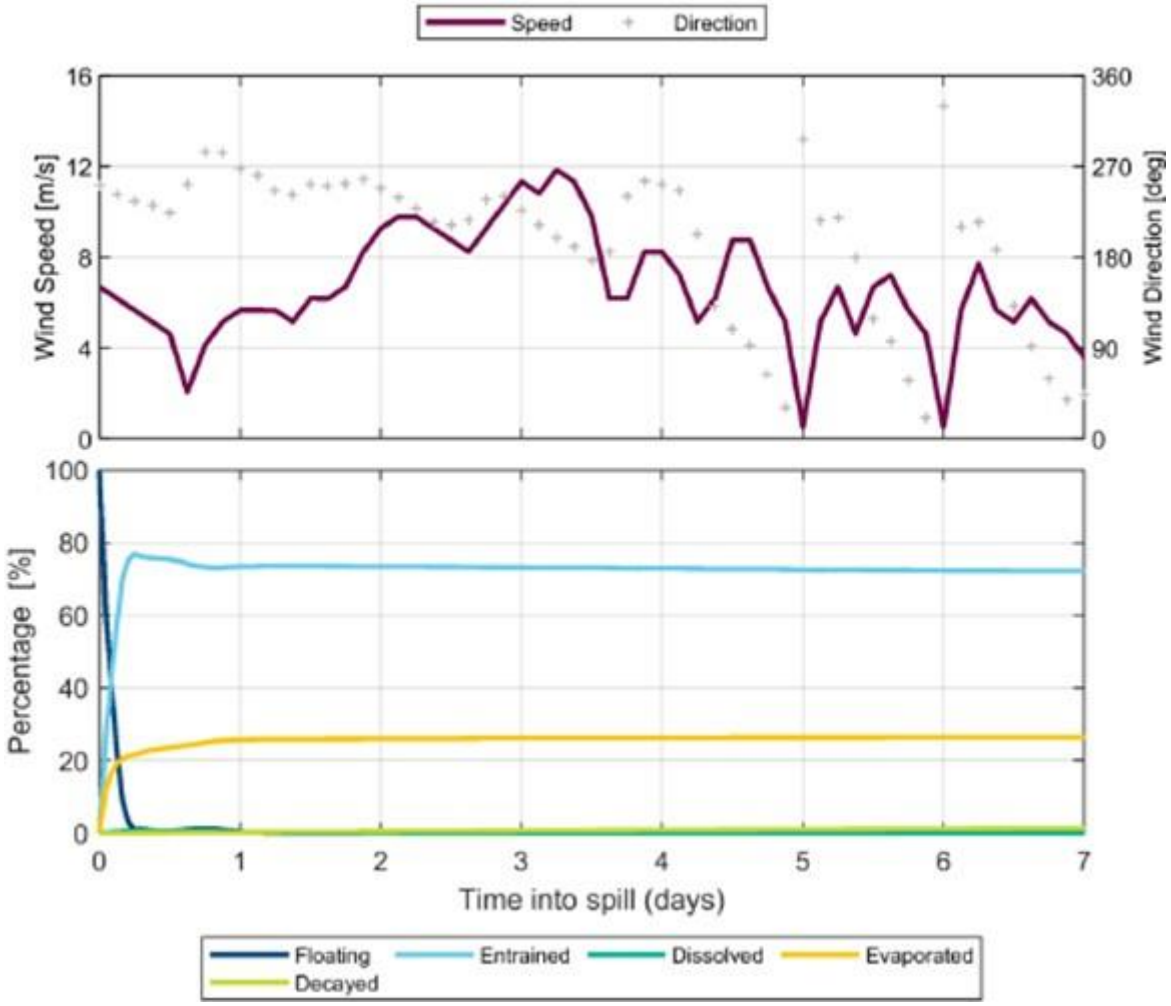

Figure 6-15: Proportional mass balance plot representing the weathering of marine gas oil spilled onto the water surface as a one-off release (50 m³ over one hour) and subject to variable wind at 27°C water temperature and 25°C air temperature

6.8.2.2 EMBA and Hydrocarbon Contact Thresholds

The outputs of the quantitative hydrocarbon spill modelling are used to assess the environmental consequence by delineating which areas of the marine environment could be exposed to hydrocarbon levels exceeding selected hydrocarbon threshold concentrations (Table 6-34), if a credible hydrocarbon spill scenario occurred. The summary of the locations where hydrocarbon thresholds could be exceeded by any of the simulations modelled is defined as the EMBA. The EMBA covers a larger area than the area that is likely to be affected during any single spill event, as the model was run for a variety of weather and metocean conditions, and the EMBA represents the

total extent of all the locations where hydrocarbon thresholds could be exceeded from all modelling runs.

As the weathering of different fates of hydrocarbons (surface, entrained and dissolved) differs due to the influence of the metocean mechanism of transportation, a different EMBA is presented for each hydrocarbon fate. Together, these EMBA have defined the spatial extent for the existing environment described in Section 4.

The spill modelling outputs are presented as areas that meet threshold concentrations for surface, entrained and dissolved hydrocarbons for the modelled scenarios. Surface spill concentrations are expressed as grams per square metre (g/m²), with entrained and dissolved aromatic hydrocarbon concentrations expressed as parts per billion (ppb). A conservative approach to selecting thresholds was taken by adopting the guideline impact thresholds (NOPSEMA, 2019) for surface, entrained, dissolved and accumulated hydrocarbons to define the EMBA for condensate spills from a loss of well control and marine diesel spills. An additional threshold has been included to define the boundary within which socio-cultural impacts may occur, based on visible surface oil (1 g/m²) impacting on the visual amenity of the marine environment. Each of these hydrocarbon thresholds are presented in Table 6-34 and described in the sub-sections below.

Table 6-34: Summary of thresholds applied to the quantitative hydrocarbon spill risk modelling results

Hydrocarbon Type	EMBA				Socio-cultural EMBA	
	Dissolved Hydrocarbon (ppb)	Entrained Hydrocarbon (ppb)	Surface Hydrocarbon (g/m²)	Accumulated Shoreline Hydrocarbon (g/m²)	Surface Hydrocarbon (g/m²)	Accumulated Shoreline Hydrocarbon (g/m²)
Condensate	50	100	10	100	1	10
Marine Gas Oil	50	100	10	100	1	10

6.8.2.2.1 Surface Hydrocarbon Threshold Concentrations

The spill modelling outputs defined the EMBA for surface hydrocarbons resulting from a spill (presence on surface waters) using a threshold of ≥10 g/m². This threshold is used to define an area within which ecological impacts to the marine environment may occur from surface hydrocarbons. It represents the minimum oil thickness (0.01 mm) at which ecological impacts (e.g. to birds and marine mammals) are expected to occur.

Thresholds for registering biological impacts resulting from contact of surface slicks have been estimated by different researchers at about 10–25 g/m² (French et al., 1999; Koops et al., 2004; National Oceanic and Atmospheric Administration, 1996). Potential impacts of surface slick concentrations in this range for floating hydrocarbons may include harm to seabirds through ingestion from preening of contaminated feathers, or the loss of the thermal protection of their feathers. The 10 g/m² threshold is the reported level of oiling to instigate impacts to seabirds and is also applied to other wildlife, though it is recognised that 'unfurred' animals, where hydrocarbon adherence is less, may be less vulnerable. 'Oiling' at this threshold is taken to be of a magnitude that can cause a response from the most vulnerable wildlife such as seabirds. Due to weathering processes, surface hydrocarbons will have a lower toxicity due to change in their composition over time.

A lower concentration of 1 g/m^2 is used to define an area within which social-cultural impacts to the visual amenity of the marine environment may occur. The surface threshold of ≥1 g/m² is based on the relationship between film thickness and appearance (Bonn Agreement oil appearance code,

2015), and represents a 'rainbow sheen' appearance. This threshold is considered below levels which would cause ecological impacts, and instead represents potential for visual amenity impacts. This threshold area is used to inform the 'socio-cultural EMBA'.

6.8.2.2.2 Accumulated Hydrocarbon Threshold Concentrations

Owens et al (1994) define accumulated hydrocarbon <100 g/m² to have an appearance of a stain on shorelines. French-McCay (2009) defines accumulated hydrocarbons ≥100 g/m² to be the threshold that could impact the survival and reproductive capacity of benthic epifaunal invertebrates living in intertidal habitat. A threshold of ≥100 g/m² has been adopted as the threshold for shoreline accumulation and has been included in the EMBA.

A lower concentration of 10 g/m^2 is used to define an area within which social-cultural impacts to the visual amenity along the shoreline may occur.

6.8.2.2.3 Entrained Hydrocarbon Threshold Concentrations

This threshold is used to define an area within which ecological impacts to the marine environment may occur from entrained hydrocarbons. Therefore, it may also be associated with socio-cultural impacts.

Entrained hydrocarbons present a number of possible mechanisms for toxic exposure to marine organisms. The entrained hydrocarbon droplets may contain soluble compounds, hence have the potential for generating elevated concentrations of dissolved aromatic hydrocarbons (e.g. if mixed by breaking waves against a shoreline). Physical and chemical effects of the entrained hydrocarbon droplets have also been demonstrated through direct contact with organisms; for example, through physical coating of gills and body surfaces, and accidental ingestion (National Research Council, 2005).

The entrained threshold has been selected to be consistent with the NOPSEMA Oil Spill Modelling Guidance Bulletin (NOPSEMA, 2019). An entrained threshold of 100 ppb is considered to be appropriate given the oil characteristics for informing potential impacts to receptors.

6.8.2.2.4 Dissolved Aromatic Hydrocarbon Threshold Concentrations

Dissolved hydrocarbons present a narcotic effect resulting from uptake into the tissues of marine organisms. This effect is additive, increasing with exposure concentration or with time of exposure (French-McCay, 2002; National Resource Council, 2005). The dissolved aromatic threshold of 50 ppb has been selected as a medium level threshold to approximate the potential toxic effects, particularly sublethal effects to sensitive species, as consistent with the NOPSEMA Oil Spill Modelling Guidance Bulletin (NOPSEMA, 2019).

6.8.2.2.5 Scientific Monitoring

A planning area for scientific monitoring is also described in the Oil Spill Preparedness and Response Mitigation Assessment (Appendix H). This planning area has been set with reference to the low exposure entrained value of 10 ppb detailed in the NOPSEMA (2019) bulletin Oil Spill Modelling.

A scientific monitoring program may be activated following a release event with the potential to contact sensitive environmental receptors. This would consider receptors at risk (ecological and socio-economic) and in particular, any identified pre-emptive baseline areas (PBAs), for the worst-case credible spill scenario or other identified unplanned hydrocarbon releases associated with the operational activities.

6.8.3 Unplanned Hydrocarbon Release: Loss of Well Containment from Operating Wells (MEE-01)

Context		
Reservoir and Wells – Section 3.4.2	Physical Environment – Section 4.4 Habitats and Biological Communities – Section 4.5 Protected Species – Section 4.6 Protected Places – Section 4.8 Socio-economic and Cultural – Section 4.9	Consultation – Section 5

Impacts and Risks Evaluation Summary

Source of Risk	***Environmental Value Potentially Impacted***							***Evaluation***						
	Soil and Groundwater	Marine Sediment	Water Quality	Air Quality (incl Odour)	Ecosystems/Habitat	Species	Socio-economic	Decision Type	Consequence	Likelihood	Risk Rating	ALARP Tool	Acceptability	Outcome
Release of hydrocarbons resulting from subsea well loss of containment		x	x	x	x	x	x	B	C	1	M	LCS GP PJ RBA CV SV	Acceptable if ALARP	EPO 13

Description of Source of Risk

During operations, the facility will receive hydrocarbons via the Pluto flowline from wells in the Pluto, Xena and Pyxis fields, as described in Section 3.

Loss of well containment can lead to an uncontrolled release of reservoir hydrocarbons and well fluids to the environment. Woodside has identified a loss of well containment (LOWC) as the scenario with the worst-case credible environmental outcome as a result of this event. A loss of well containment during operations could occur due to a variety of causes, including:

- internal corrosion
- external corrosion
- erosion
- overpressure of the annuli
- fatigue
- loss of control of suspended load from vessel (operating near subsea wells) (MEE-04; Section 6.8.6)
- loss of well system structural integrity.

A number of common failure causes due to human error and SCC failures are presented in the generic Human Error and SCE Failure bowties in Section 6.8.8.

The LOWC scenario that may occur during the drilling and any MODU-based well test of Xena-03 is considered separately in Section 6.9.1.

Loss of Well Control – Credible Scenario

The PAP includes production from a series of subsea wells (Section 3.4.2). To assess the potential consequences, a worst credible hydrocarbon release scenario has been defined for a Pluto well (PLA02). The Pluto well scenario is based on a loss of containment from a well which represents the overall characteristics of the Pluto reservoir and is a high producing well, thus representing a worst credible volume release and potential environmental impact, for current Pluto, Pyxis and Xena wells. Future wells (PLA08 and XNA03) were considered but the existing PLA02 scenario is considered to be worst case.

The LOWC was assumed to have a release duration of 77 days. This duration is based on the estimated time required to successfully drill an intervention well (refer to Appendix H for additional discussion of relief well timing). The characteristic of the release scenario is summarised in Table 6-35. The characteristics of Pluto condensate was used as the basis in the modelling the LOWC scenario (RPS, 2024b); refer to Sections 6.8.2 and 6.8.2.2 for additional information on modelling methods, hydrocarbon characteristics and environmental impact thresholds.

Table 6-35: Summary of worst-case loss of well containment hydrocarbon release scenarios

Scenario	Hydrocarbon	Average Rate (m^3/day)	Duration (days)	Depth (m)	Latitude	Longitude	Total Condensate Release Volume (Sm^3)
Scenario 2: Well blowout at seabed PLA02	Pluto Condensate	4848	77	829	19° 54' 48.266" S	115° 7' 54.151" E	59,459

Decision Type, Risk Analysis and ALARP Tools

Woodside implements industry standard practice in well design and construction. In the company's recent history, it has not experienced any well integrity events that have resulted in significant releases or significant environmental impacts. Woodside has never experienced a worst-case loss of well containment in its operational history.

Decision Type

Decision Type B has been applied to this risk under the Guidance on Risk Related Decision Making (Oil and Gas UK, 2014). This reflects the complexity of the risk, the higher potential consequence and stakeholder implications should the event be realised. To align with this decision type, a further level of analysis has been applied using risk-based tools including the bowtie methodology (described in Section 2.7.3) and hydrocarbon spill trajectory modelling. Company and societal values were also considered in the demonstration of ALARP and acceptability, considered through internal reviews, and stakeholder consultation (Section 5).

The release of hydrocarbons as a result of well loss of containment is considered a major environment event (MEE-01). The hazard associated with this MEE is hydrocarbons in reservoirs, wells, wellheads and xmas trees tied back to the facility.

Quantitative Spill Risk Assessment

Spill modelling of the worst-case credible loss of well containment spill scenario was undertaken by RPS, to determine the fate of hydrocarbons released based on the assumptions. Modelling was undertaken over all seasons to address year-round operations (RPS, 2024b). This is considered to provide a conservative estimate of the EMBA and the potential impacts from the identified worst-case credible release volumes for all loss of well containment scenarios.

Hydrocarbon Characteristics

Hydrocarbon characteristics of Pluto condensate are provided and described in more detail in Section 6.8.2.

Subsea Plume Dynamics

The subsea loss of well containment scenario would result in a buoyant plume of hydrocarbons, which has been modelled using the OILMAP-Deep numerical model.

Table 6-36: Near-field subsurface discharge model parameters for loss of well containment scenario

Scenario	Hydrocarbon	Rate (m^3/hr)	Duration (days)	Depth (m)
Well blowout at seabed (PLA02)	Pluto condensate	202	77	829

Likelihood

In accordance with the Woodside Risk Matrix, a worst-case loss of well containment has been defined as a 'highly unlikely' event as it 'has occurred once or twice in the industry' (experience-based likelihood) and aligns with a frequency of a '1 in 10,000 to 1 in 100,000 year' event. Information to support this likelihood determination is outlined below.

The blowout likelihood was evaluated using Blowout and Well release Frequencies based on SINTEF offshore blowout database as analysed in the IOGP, 2019 Study "Risk Assessment Data Directory Blowout Frequencies – Report 434-02" (September 2019). This uses data from 1980 to 2014 to determine likelihood for well blowouts and releases. For a gas well, the IOGP study calculated gas blowout frequency during production as 7.20 × 10-5 per year per well.

Given consideration for up to 13 subsea gas wells and using SINTEF/IOGP database, blowout during production occurs with a frequency of 9.36E-04 per year which gives a likelihood level of 2 “Unlikely” on the Woodside Risk Matrix. An order of magnitude reduction has been taken to reduce the likelihood of significant environmental impacts to Level 1 “Highly Unlikely”, for the following reasons:

SINTEF and Lloyds data presented in the IOGP 2019 Blowout Frequencies study considers Production well integrity events between 1980 and 2011, with some additional data from the North Sea between 2011 and 2014. Frequencies are informed by incidents which occurred in Gulf of Mexico, which occurred prior to standards improvement following the Macondo event. Similarly, improvements in standards have been achieved in the North Sea compared to the pre-Macondo era. External causes are excluded for subsea production wells, as causes discussed appears to only be relevant to dry-tree/platform wells.

For the international blowout incidents analysed, these are expected to have resulted in varied release outcomes with varied flow and environmental consequence outcomes – not all are aligned with a worst case unconstrained full-bore blowout, from the highest flowing well, nor necessarily required a relief well to remediate (which is the basis for this risk assessment)

Woodside have adopted international best practice – the O&G UK Well Lifecycle Integrity Guidelines (post-Macondo industry improvements). Woodside continue to apply a rigorous well integrity management program (refer WOMP) as required under WMS and Australian Regulations, including verification, and testing of key barriers including SSSVs.

Additionally, when considering likelihood from an ‘experience’ perspective, and considering the significant environmental consequence likelihood as the outcome of a blowout event; historical blowouts resulting in major impacts to the environment have not occurred “many times in industry”. Hence, alignment with Highly Unlikely likelihood classification is deemed appropriate.

Consequence

The spatial extent and fate (including weathering) of the spilled hydrocarbon were considered during the impact assessment for a worst-case loss of well containment (presented in the following section). These considerations were informed primarily by the outputs from the numerical modelling studies undertaken by RPS (2024b), available information on environmental sensitivities that may credibly be impacted in the event of a worst-case spill, and relevant literature and studies considering the effects of hydrocarbon exposure.

Consequence Assessment

Environment that May Be Affected

Surface Hydrocarbons

Hydrocarbon spill modelling for surface hydrocarbons indicated that concentrations equal to or greater than the 10 g/m² ecological threshold could potentially be found, in the form of slicks, up to 20 km (south-west) from the release location. There is minimal surface hydrocarbon contact with receptors for the worst-case scenario. The probability of films arriving at receptors were <1%.

Entrained Hydrocarbons

Entrained oil concentrations equal to or greater than the 100 ppb ecological thresholds are predicted to be found up to 420 km (south-west) from the release location. A number of receptors were predicted to be contacted by entrained hydrocarbons. The greatest probabilities of contact by entrained hydrocarbons were at Gascoyne MP (2%) and Montebello MP (71%).

Dissolved Hydrocarbons

Dissolved aromatic hydrocarbon concentrations equal to or greater than the 50 ppb ecological threshold are predicted to be found up to 80 km (south-west) from the release location. The greatest probabilities of contact by dissolved hydrocarbons were at Montebello MP (3%).

Accumulated Hydrocarbons

A number of receptors were predicted to potentially receive shoreline hydrocarbons in the spill modelling. The hydrocarbon contact is expected to be minimal for all receptors for the worst-case scenario. The probability of shoreline accumulation on receptors at all thresholds were <1%.

Summary of Potential Impacts to Environmental Values

The combined EMBA for loss of well containment within which all other credible hydrocarbon spill EMBAs are contained, i.e. the sensitive receptors and their locations that may be exposed to hydrocarbons (surface, entrained, dissolved and accumulated) at or above the set threshold concentrations in the unlikely event of a loss of well containment during the PAP are outlined in Section 4. The potential biological and ecological impacts of an unplanned hydrocarbon release as a result of a LOWC during the PAP are discussed in the following sections.

Table 6-37: EMBA– key receptor locations and sensitivities potentially contacted above impact thresholds by the loss of well containment scenario with summary hydrocarbon spill contact ≥ 1% probability

[125] Worst case probability

Open Water Environment (Near Spill Area)
Air Quality A hydrocarbon release during a loss of well containment has the potential to result in localised, temporary reduction in air quality and contribution of greenhouse gases to the global concentration of these gases in the atmosphere. Potential impacts from reduced air quality are expected to be minor, short-term and predominantly localised due to rapid entrainment and dissolution of gas bubbles into the water column. There is potential for human health effects for workers in the immediate vicinity of atmospheric emissions that potentially reach the surface. The ambient concentrations of methane and VOCs released from diffuse sources is difficult to accurately quantify, although the behaviour and fate is predictable in open offshore environments as rapidly dissolved in deep waters, and it is dispersed rapidly by meteorological factors such as wind and temperature. Methane and VOC emissions from a hydrocarbon release in such environments are rapidly degraded in the atmosphere by reaction with photochemically-produced hydroxyl radicals. Due to the unlikely occurrence of a loss of well containment; the temporary nature of any methane or VOC emissions (from either gas surfacing or weathering of liquid hydrocarbons from a loss of well containment); the predicted behaviour and fate of methane and VOCs in open offshore environments; and the significant distance from the PAA to the nearest sensitive air shed (town of Dampier, about 157 km away), the potential impacts are expected to be minor and short-term.
Water Quality Water quality would be affected in the offshore environment within the EMBA due to hydrocarbon contamination from entrained, dissolved and surface hydrocarbons. Due to the weathering processes of the hydrocarbons, impacts to water quality are anticipated to be minor long term and/or significant short term as a result of hydrocarbon contamination above background levels.
Marine Sediment Quality Studies of hydrocarbon concentrations in deep sea sediments in the vicinity of a catastrophic well blowout indicate hydrocarbon from the blowouts can be incorporated into marine sediments (Romero et al., 2015). Proposed mechanisms for hydrocarbon contamination of sediments include sedimentation of hydrocarbons and direct contact between submerged plumes and the seabed (Romero et al., 2015). In the event of a major hydrocarbon release at the seabed, modelling indicates that a pressurised release of condensate would atomise into droplets that would be transported into the water column to the surface. As a result, the extent of potential impacts to the seabed area at and surrounding the release site would be confined to a localised footprint. Marine sediment quality would be reduced as a consequence of hydrocarbon contamination for a small area within the immediate release site for a long to medium term.
Benthic Fauna Communities In the event of a loss of well containment at the seabed, the spill modelling predicted hydrocarbon droplets would be entrained in a gas plume, transporting them through the water column and to the sea surface. As a result, the low sensitivity benthic communities associated with the unconsolidated, soft sediment habitat within the PAA are generally not expected to be exposed to released hydrocarbons. A localised area of impact relating to the hydrocarbon plume at the point of release is however predicted, which would result in a small area of seabed and any associated epifauna and infauna being exposed to hydrocarbons. Impacts to benthic communities within the PAA would subsequently be limited to the immediate area around the release site and may include lethal or sub-lethal impacts. Within the offshore waters of the EMBA, impacts to benthic fauna on the seafloor are not anticipated as hydrocarbons are not expected to gravitate toward the seafloor (as described above). Benthic fauna at geomorphic features located within the water column such as shoals and banks are not predicted to be impacted by dissolved and/or entrained hydrocarbons above the ecological thresholds. Offshore features such as Rankin Bank support benthic communities; however, the modelling indicated that hydrocarbon contact would only occur at low thresholds below the ecological threshold. Notably, given the depths of offshore benthic communities such as Rankin Bank, the potential for impacts to benthic communities is considered to be significantly reduced given hydrocarbons will primarily feature in the upper water column.
The Ancient Coastline at 125 m Depth Contour and Continental Slope Demersal Fish Communities KEFs overlap the PAA (Figure 4-10). The Continental Slope Demersal Fish Communities KEF overlaps the Pluto Facility Operational Area. Other KEFs that overlap and are in proximity to the combined EMBA are listed in Section 4.7. These KEFs and geomorphic features may host relatively diverse or abundant fish assemblages compared to the otherwise relatively featureless continental shelf habitats of the NWMR. Impacts to KEFs are discussed below. In summary, impacts to these features are considered to be unlikely. Indirect impacts due to decreased habitat quality at these KEFs to pelagic and demersal fish communities are, therefore, considered unlikely. Impacts to pelagic fish (associated with receptors such as the Rankin Bank) from hydrocarbons are described herein. The values of these KEFs are described in further details within the Appendix K). Fish mortalities are rarely observed to occur as a result of hydrocarbon spills (International Tanker Owners Pollution Federation, 2011b). This has generally been attributed to the possibility that pelagic fish are able to detect and avoid

surface waters underneath hydrocarbon spills by swimming into deeper water or away from the spill affected areas. Fish that have been exposed to dissolved aromatic hydrocarbons are capable of eliminating the toxicants once placed in clean water. Hence individuals exposed to a spill are likely to recover (King et al., 1996). Where fish mortalities have been recorded historically, the spills (resulting from the groundings of the tankers Amoco Cadiz in 1978 and the Florida in 1969) have occurred in sheltered bays.

Laboratory studies have shown that adult fish are able to detect hydrocarbons in water at very low concentrations, and large numbers of dead fish have rarely been reported after hydrocarbon spills (Hjermann et al., 2007). This suggests that juvenile and adult fish are capable of avoiding water contaminated with high concentrations of hydrocarbons. However, sub-lethal impacts to adult and juvenile fish may be possible, given long-term exposure (days to weeks) to polyaromatic hydrocarbon (PAH) concentrations (Hjermann et al., 2007). While modelling of the loss of well containment indicates the potential EMBA for dissolved hydrocarbons is relatively extensive, no time-integrated exposure metrics were modelled; given the oceanographic environment within the EMBA, PAH exposures in the order of weeks for pelagic fish are not considered credible.

The effects of exposure to oil on the metabolism of fish appears to vary according to the organs involved, exposure concentrations and route of exposure (waterborne or food intake). Oil reduces the aerobic capacity of fish exposed to aromatics in the water and to a lesser extent affects fish consuming contaminated food (Cohen et al., 2005). The liver, a major detoxification organ, appears to be the organ where anaerobic activity is most impacted, probably increasing anaerobic activity to facilitate the elimination of ingested oil from the fish (Cohen et al., 2005).

Fish are perhaps most susceptible to the effects of spilled oil in their early life stages, particularly during egg and planktonic larval stages, which can become entrained in spilled oil. Contact with oil droplets can mechanically damage feeding and breathing apparatus of embryos and larvae (Fodrie and Heck, 2011). The toxic hydrocarbons in water can result in genetic damage, physical deformities and altered developmental timing for larvae and eggs exposed to even low concentrations over prolonged timeframes (days to weeks) (Fodrie and Heck, 2011). More subtle, chronic effects on the life history of fish as a result of exposure of early life stages to hydrocarbons include disruption to complex behaviours such as predator avoidance, reproductive and social behaviour (Hjermann et al. 2007). Prolonged exposure of eggs and larvae to weathered concentrations of hydrocarbons in water has also been shown to cause immunosuppression and allows expression of viral diseases (Hjermann et al., 2007). PAHs have also been linked to increased mortality and stunted growth rates of early life history (pre-settlement) of reef fishes, as well as behavioural impacts that may increase predation of post-settlement larvae (Johansen et al., 2017). However, the effect of a hydrocarbon spill on a population of fish in an area with fish larvae and/or eggs, and the extent to which any of the adverse impacts may occur, depends greatly on prevailing oceanographic and ecological conditions at the time of the spill and its contact with fish eggs or larvae. Hydrocarbons above ecological thresholds although not predicted to, may subsequently impact populations located near to the release location for the worst-case spill scenario, with lethal impacts not considered likely in this offshore environment. No significant escarpments, species of conservation significance, emergent features or areas of high biological productivity characteristically associated with the Continental Slope Demersal Fish Communities KEF have been observed in the PAA. Therefore, potential impacts to these regional-scale KEFs are not expected.

Protected Places

Receptors

The modelling of the worst-case LOWC indicated that Australian Marine Parks may be impacted by entrained (Gascoyne and Montebello Marine Park) and dissolved (Montebello Marine Park) hydrocarbons. No AMPs were predicted to potentially be contacted by surface hydrocarbons in the event of a worst-case spill scenario (RPS, 2024b).

Impacts

The Montebello Marine Park is the closest AMP to the PAA (overlapped by the facility Operational Area) predicted to be contacted by hydrocarbons. Impacts to this AMP are discussed below. Impacts to the natural, cultural, heritage and socio-economic values of the other three AMPs predicted to be contacted by hydrocarbons in a worst-case spill scenario are expected to be similar, however, of lower severity and duration due to their being at least 100 km further from the PAA.

Montebello Marine Park

The Montebello Marine Park comprises an area of about 3413 km², all of which is zoned as a Multiple Use Zone (IUCN VI). The AMP ranges in water depths from less than 15 m up to 150 m.

The Montebello Marine Park is significant as it contains habitats, species and ecological communities' representative of the Northwest Shelf Province. It overlaps with The Ancient Coastline at the 125m Depth Contour KEF (see 'Key Ecological Features' above for a discussion of impacts to KEFs). The AMP provides connectivity between the deeper waters of the continental shelf and slope, and the adjacent Barrow Island and Montebello Islands State Marine Parks. A prominent seafloor feature in the AMP is Trial Rocks, which consists of two close coral reefs that are emergent at low tide. There is subsequently potential for impacts to shallow coral reef communities at Tryal Rocks, as discussed in the section 'Marine Primary Producers – Coral Reef' above. The specific values of the AMP and associated impacts are summarised here.

Natural values – The AMP includes diverse benthic and pelagic fish communities and ancient coastline thought to be an important seafloor feature (KEF) and a migratory pathway for humpback whales (BIA). The AMP supports a range of species, including those listed as threatened, migratory, marine and/or cetacean under the EPBC Act. BIAs within the AMP include breeding habitat for seabirds, internesting, foraging, mating and nesting habitat for marine turtles, a migratory pathway for humpback whales and foraging habitat for whale sharks. Impacts to the relevant species and BIAs are discussed in the sections above.

Cultural values – There is limited information about the cultural significance of this AMP; however, it is noted that Sea Country is valued for Indigenous cultural identity, health and wellbeing. Across Australia, Indigenous people have been sustainably using and managing their Sea Country for tens of thousands of years. Potential impacts to cultural values of the AMP will closely tie in with the impacts to the natural values of the Marine Park, as addressed above and below; and range from moderate mid-term potential impacts to major long-term potential impacts.

Heritage values – There are no World, National or Commonwealth heritage listings that apply to the AMP. Two historic shipwrecks are located within the Marine Park. Impacts to shipwrecks are discussed below under 'Cultural Heritage'.

Social and economic values – Tourism, commercial fishing, mining and recreation are important activities in the AMP. These activities contribute to the wellbeing of regional communities and the prosperity of the nation. Impacts to tourism and recreation within the AMP are discussed with regard to offshore and nearshore waters in the sections 'Tourism and Recreation' below.

A worst-case hydrocarbon spill scenario has the potential to result in impacts to these AMPs that range from moderate, medium-term to major, long-term, with the consequence severity dependent on the actual timing, duration and extent of a spill.

Key Ecological Features

KEFs located within the combined EMBA are listed in Section 4.7 (described in the Master EE(Appendix K)).

The modelling for the worst-case LOWC (MEE-01) predicted an overlap of entrained hydrocarbons above the ecological threshold with the offshore features of:

- Ancient Coastline at the 125 m Depth Contour KEF
- Continental Slope Demersal Fish Communities KEF
- Glomar Shoals KEF.

The Ancient Coastline, Glomar Shoals and Continental Slope Demersal Fish Communities are KEFs primarily defined by seabed geomorphological features and have been classified as KEFs in recognition of the potential for increased biological productivity and, therefore, ecological significance. Potential impacts to these KEFs include the direct and indirect impacts to benthic fauna/habitats and associated impacts to demersal fish populations described in the sections above.

In-water hydrocarbon exposure (entrained and dissolved) is only predicted to occur within the upper 0–10 m of the water column, therefore, benthic values of these KEFs are not anticipated to be impacted following a LOWC.

Notably, other than some small outcrops of hard substrate, no features indicative of the Ancient Coastline have been identified within the portion of this KEF overlapping the PAA (as per Section 4.7) These KEFs cover extensive areas (as listed in Appendix K) and, should impacts to receptors within the KEFs (e.g., benthic communities) occur, these would be anticipated to be short lived with no permanent impacts to the KEF.

Protected Species

A number of cetaceans were identified as potentially occurring within the PAA and the combined EMBA (see Section 4). In the event of a worst-case LOWC, surface, entrained and dissolved hydrocarbons exceeding environmental impact threshold concentrations may drift across habitat for oceanic cetacean species and the migratory routes and/or BIAs of cetaceans considered to be MNES (e.g., humpback whale and pygmy blue whale north and southbound migrations).

Cetaceans that have direct physical contact with surface, entrained or dissolved aromatic hydrocarbons may suffer surface fouling, ingestion of hydrocarbons (including from prey, water and sediments), aspiration of oily water or droplets and inhalation of toxic vapours (Deepwater Horizon Natural Resource Damage Assessment Trustees, 2016). This may result in the irritation of sensitive membranes such as the eyes, mouth, digestive and respiratory tracts and organs, impairment of the immune system, neurological damage (Helm et al., 2015), reproductive failure, adverse health effects (e.g., lung disease, poor body condition) and, potentially, mortality (Deepwater Horizon Natural Resource Damage Assessment Trustees, 2016).

Given cetaceans maintain thick skin and blubber, external exposure to hydrocarbons is more likely to result in irritation to the more exposed skin and eyes. Entrained hydrocarbons may also be ingested, particularly by baleen whales which feed by filtering large volumes of water. Fresh hydrocarbons (i.e., typically in the vicinity of the release location) may have a higher potential to cause toxic effects when ingested, while weathered hydrocarbons are considered to be less likely to result in toxic effects.

Given the non-persistent nature of the relevant hydrocarbons, such as Pluto condensate, and the relatively small floating hydrocarbon release of the worst-case LOWC EMBA (RPS Group, 2024a, 2024b), the area where potential impacts from inhalation and physical contact with surface slicks may occur would primarily be localised around the

release location and impacts would most likely be expected to be limited to individuals that contact the slick, as discussed above. The modelling for surface hydrocarbons above the ecological threshold did not overlap any cetacean BIAs beyond those that are found within the PAA: the EIO pygmy blue whale migration and distribution BIA and the humpback whale migration (north and south) BIA.

There is a small overlap of the southern right whale migration and reproduction BIAs in proximity to the North West Cape with entrained and dissolved oil exceeding thresholds, however no floating oil is present in this area and no hydrocarbons are predicted to enter the Exmouth Gulf, which is used as a resting area by humpback whales during the southern migration and a reproduction area by the Southern Right Whale.

In a review of the impacts of large-scale hydrocarbon spills on cetaceans, it was found that exposure to oil from the Deepwater Horizon resulted in increased mortality to cetaceans in the Gulf of Mexico (DHNRDT, 2016), and long-term population level impacts to killer whales were linked to the Exxon Valdez tanker spill (Matkin et al., 2008). Given the nature of the condensate (compared with crude oil from these two spills) and relatively small nature of the surface slick, such exposure impacts to cetaceans may not eventuate.

Geraci (1988) has identified behavioural disturbance (i.e., avoiding spilled hydrocarbons) in some instances for several species of cetacean, suggesting that cetaceans have the ability to detect and avoid surface slicks. However, observations during spills have also recorded larger whales (both mysticetes and odontocetes) and smaller delphinids traveling through and feeding in oil slicks. During the Deepwater Horizon spill cetaceans were routinely seems swimming in surface slicks offshore (and nearshore) (Aichinger Dias et al., 2017).

Suitable habitat for oceanic toothed whales (e.g. sperm whales) and dolphins (e.g., long-snouted spinner dolphin) is broadly distributed throughout the NWMR and, as such, while these species may be present within the combined EMBA, impacts from a spill are unlikely to affect an entire population. Notably, there are no known aggregation areas or BIAs for dolphins or whales within the PAA.

East Indian Ocean (EIO) Pygmy Blue Whale and Humpback Whale

EIO PBW and humpback whales are known to migrate seasonally through the worst-case LOWC EMBA. A migration and distribution BIA for the pygmy blue whale overlaps the PAA and Facility and Xena-03 Operational Areas. A major spill event in June through to November would coincide with the humpback whale migration through the waters off the Pilbara, North West Cape and Shark Bay (outside the EMBA). A major spill in April to July or October to January would coincide with EIO pygmy blue whale migration (Double et al., 2010). Both the pygmy blue and humpback whales are baleen whales and are therefore most likely to be significantly impacted by toxic effects of the oil which can be engulfed during feeding. However, feeding during migrations is typically low level and opportunistic, with most feeding for both species occurring in the Southern Ocean (Thums et al., 2022). Subsequently the risk of ingestion of hydrocarbons through feeding is low.

Migrations of both pygmy blue whales and humpback whales are protracted through time and space (i.e., the whole population will not be within the worst-case LOWC EMBA at any one time), and as such, a hydrocarbon loss of containment is not considered likely to affect an entire population.

Dugong

There are no BIAs or known areas of aggregation in the offshore waters of either the combined EMBA or worst-case LOWC for the dugong. The BIAs are only found in nearshore waters, which is assessed below.

Summary

A worst-case hydrocarbon spill scenario has the potential to result in moderate, medium-term impacts to offshore cetacean species, with consequence severity dependent on the actual timing, duration and extent of a spill in relation to species' migratory movements and distributions.

Marine Turtles

Five of the six marine turtle species were identified as potentially occurring within the combined EMBA of all spill scenarios, with a number of BIAs and Habitat Critical areas also identified. A flatback turtle internesting BIA intersects the PAA and the Facility and Xena-03 Operational Areas (see Section 4.6.2).

Modelling for the worst-case LOWC (MEE-01) predicted a low probability of overlap by entrained hydrocarbons within a number of BIAs, including the green turtle, hawksbill, and flat back turtle internesting buffer (RPS, 2024b). The modelling predicted no exposure to shorelines at any exposure threshold. Therefore, impacts to Habitat Critical areas are not anticipated following a LOWC.

Adult marine turtles exhibit no avoidance behaviour when they encounter hydrocarbon spills (National Oceanic and Atmospheric Administration, 2010). Contact with surface slicks or entrained hydrocarbon can therefore result in hydrocarbon adherence to body surfaces (Gagnon and Rawson, 2010), causing irritation of mucous membranes in the nose, throat and eyes leading to inflammation and infection (National Oceanic and Atmospheric Administration, 2010). Oiling can also irritate and injure skin, which is most evident on pliable areas such as the neck and flippers (Lutcavage et al., 1995). A stress response associated with this exposure pathway includes an increase in the production of white blood cells and even a short exposure to hydrocarbons may affect the functioning of their salt glands (Lutcavage et al., 1995).

Hydrocarbons in surface waters may also impact turtles when they surface to breathe and inhale toxic vapours. Their breathing pattern, involving large 'tidal' volumes and rapid inhalation before diving, results in direct exposure to petroleum vapours which are the most toxic component of the hydrocarbon spill (Milton and Lutz 2003). This can lead

to lung damage and congestion, interstitial emphysema, inhalant pneumonia and neurological impairment (National Oceanic and Atmospheric Administration, 2010).

Given the hydrocarbon is expected to weather rapidly when released to the environment, relatively fresh entrained hydrocarbons (which are typically relatively close to the release location) are considered to have the greatest potential for impact. Given the non-persistent nature of the hydrocarbons and the relatively small floating hydrocarbon EMBA, the area where potential impacts from inhalation may occur would be localised around the release location. There is also minimal surface hydrocarbon contact with the marine turtle BIAs and Habitat Critical areas listed in Section 4.6.2.

Due to the offshore location and water depths within the PAA, this area is unlikely to represent important habitat for marine turtles. There are also no known areas of aggregation (i.e., BIAs, Habitat Critical) for marine turtles within the PAA.

The LOWC EMBA only overlapped the outer edges of a few marine turtle internesting BIAs, with no overlap of Habitat Critical areas for marine turtles (RPS, 2024b). Marine turtles are, therefore, likely to be present in the offshore waters of the EMBA, particularly as they are a migratory species which often travel large distances during migration periods. Important areas of aggregation for foraging, nesting and mating are typically associated with nearshore islands along the Pilbara and Gascoyne coastlines, as opposed to offshore waters.

Summary

In the event of a LOWC, there is potential that surface, entrained and dissolved hydrocarbons exceeding environmental impact threshold concentrations will be present in offshore waters. Therefore, a hydrocarbon spill may disrupt a portion of marine turtle populations for the green, flatback, hawksbill, loggerhead and/or leatherback turtle. However, there is considered to be no threat to overall population viability given the non-persistent nature of predicted hydrocarbons.

Sea Snakes

A number of sea snake species which are listed Marine under the EPBC Act were identified by the PMST as potentially occurring within the combined EMBA. Two critically endangered species were identified as known to occur within the EMBA, the short-nosed sea snake and the leaf-scaled sea snake.

Impacts to seasnakes from direct contact with hydrocarbons are likely to result in similar physical effects to those recorded for marine turtles and may include potential damage to the dermis and irritation to mucus membranes of the eyes, nose and throat (International Tanker Owners Pollution Federation, 2011a). They may also be impacted when they return to the surface to breathe and inhale the toxic vapours associated with the hydrocarbons, resulting in damage to their respiratory system. Oiling of the sensory and respiratory areas on the body of the snake is shown to prevent the mouth from opening and obstructing the nares and airway which can interfere with feeding and result in asphyxiation. Oiling of the outer body surface has shown to inhibit their movements which can lead to overexertion and drowning. Sea snakes are also capable of transcutaneous oxygen uptake, therefore oiling to the surface of their cutaneous layer can compromise this ability (Yaghmour et al., 2022).

In general, sea snakes frequent the waters of the continental shelf area around offshore islands and potentially submerged shoals (water depths <100 m) (impacts described below). However, it is acknowledged that sea snakes may be present in the PAA and within the EMBA. Their abundance is not expected to be high, given the water depth and offshore environment.

In summary, a hydrocarbon spill may have a minor disruption to some individuals in the offshore environment. Population level impacts to sea snake species are not, however, considered credible.

Sharks and Rays

A number of shark and ray species were identified as potentially occurring within the PAA and/or combined EMBA (see Section 4.6.1). Two foraging BIAs for the whale shark overlap the combined EMBA: foraging (northward from Ningaloo along the 200 m isobath; PAA, combined EMBA) and foraging (high prey density – Ningaloo Marine Park; EMBA). Whale sharks are, therefore, likely to transit the open offshore waters within the EMBA whilst they migrate to and from Ningaloo Reef between July and November. Modelling for the worst-case LOWC scenario (MEE-01) predicted exposure to only one of the whale shark foraging BIA: foraging (northward from Ningaloo along the 200 m isobath) (RPS, 2024b).

Other listed Threatened pelagic species identified in the PMST report as potentially occurring within the combined EMBA include the white shark and grey nurse shark. There are no known areas of aggregation for these species in the offshore waters of the combined EMBA.

Impacts to sharks and rays may occur through direct contact with hydrocarbons and contaminate the tissues and internal organs either through direct contact or via the food chain (i.e., consumption of prey). As gill breathing organisms, sharks and rays may be vulnerable to toxic effects of dissolved hydrocarbons (entering the body via the gills) and entrained hydrocarbons (coating of the gills inhibiting gas exchange). In the offshore environment, it is probable that pelagic shark species, such as the whale shark, are able to detect and avoid surface waters underneath hydrocarbon spills by swimming into deeper water or away from the affected areas.

Impacts to whale sharks from a hydrocarbon spill will depend on the timing of the spill, however; whale sharks as a pelagic species are expected to demonstrate avoidance behaviour and population level impacts are not anticipated.

Seabirds

A number of EPBC Act listed Threatened and/or Migratory seabird and shorebird species were identified by the PMST as potentially occurring within the PAA and/or combined EMBA (see Section **Error! Reference source not found.**). The EMBA for the worst-case LOWC (MEE-01) also predicted exposure to a number of seabird BIAs, including the wedge-tailed shearwater roseate tern breeding and foraging BIAs.

Seabirds and migratory shorebirds are particularly vulnerable to contact with floating hydrocarbons, which may mat their feathers. This may lead to hypothermia from loss of insulation and ingestion of hydrocarbons when preening to remove hydrocarbons; both impacts may result in mortality (Hassan and Javed, 2011). Notably, the credible loss of well containment scenarios result in a relatively small floating hydrocarbon EMBA which is primarily centred around the release location. Subsequently, the potential for seabird exposure to floating hydrocarbons is considered to be low. Migratory shorebirds are considered unlikely to interact with spilled hydrocarbons as they are not expected to stop over within the offshore waters surrounding the PAA during their migrations between mainland/island areas. Many seabirds and migratory shorebirds forage over extensive areas (some hundreds of kilometres out to sea) so individuals may be present. Seabirds which are roosting or resting on the Pluto platform may also be impacted, however; these would be individuals and not populations.

Seabirds which plunge dive to feed on prey may contact entrained or dissolved hydrocarbons, most likely through ingestion of prey which are contaminated. Impacts to prey abundance as a result of hydrocarbons may also indirectly impact individuals.

There are several breeding BIAs for seabirds and migratory shorebirds that overlap with the combined EMBA and breeding BIAs within the LOWC EMBA, which are associated with breeding and nesting at locations along the Gascoyne and Pilbara coastlines (including near-shore islands). The outer edge of a breeding BIA for the wedge-tailed shearwater overlaps with the PAA, and another is less than a kilometre away. It is likely that individual birds may, therefore, transit the PAA.

However, the EMBA for the worst-case LOWC predicted no impact to shorelines at any thresholds, therefore impacts to breeding sites are not anticipated in the event of a LOWC.

Given the relatively low area of floating hydrocarbons and the lack of key aggregation areas for migratory shorebirds and seabirds within the PAA, impacts at the population level are not anticipated. Individual animals may, however, be impacted with potential fatalities occurring from oiling.

Nearshore Waters (Mainland and Islands)

The combined EMBA overlaps the nearshore waters of a few shorelines and islands. However, the modelling for the LOWC scenario EMBA (MEE-01), predicted no shoreline, entrained or dissolved hydrocarbons (at or above the defined ecological thresholds) to potentially contact shallow, nearshore waters of identified islands and mainland coastlines. Therefore, impacts to nearshore waters is not predicted from a MEE-01 scenario.

Submerged Shoals and Banks

The combined EMBA overlaps a few submerged shoals and banks (Section 4.5). However, the modelling for the LOWC scenario EMBA (MEE-01) did not predict entrained or dissolved hydrocarbons (at or above the defined ecological threshold) to contact any submerged shoals and banks. Therefore, impacts are not anticipated for a MEE-01 scenario at these receptors.

All Settings

Coral Reefs

Receptors

There are no coral reef habitats located within the PAA. The closest coral reef habitats exist at Rankin Bank, Muiron Islands, the Montebello Islands, Barrow Island, Dampier Archipelago, Lowendal Island and numerous receptors associated with Ningaloo Reef, including the reef itself (see Section 4.5).

As discussed in ‘Benthic Fauna’, no dissolved or entrained hydrocarbons above the ecological threshold are anticipated to contact these known coral habitat areas for MEE-01. Therefore, impacts to coral reef habitats at these features are not anticipated during this scenario.

Modelling for the vessel separation scenario (MEE-04) also predicted low probability of hydrocarbon contact at the Montebello Shoals, Outtrim Patches and Tryal Rocks.

Productivity Primary production by plankton (supported by sporadic upwelling events in the offshore waters of the NWS) is an important component of the primary marine food web. Planktonic communities are generally mixed, including phytoplankton (cyanobacteria and other microalgae) and secondary consuming zooplankton, such as crustaceans (e.g., copepods), and the eggs and larvae of fish and invertebrates (meroplankton). Plankton exposure to hydrocarbons in the water column can result in changes in species composition with declines or increases in one or more species or taxonomic groups (Batten et al., 1998). Phytoplankton may also experience decreased rates of photosynthesis (Tomajka, 1985). For zooplankton, direct effects of contamination may include toxicity, suffocation, changes in behaviour, or environmental changes that make them more susceptible to predation. Impacts on plankton communities are likely to occur in areas where entrained or dissolved aromatic hydrocarbon threshold concentrations are exceeded, but communities are expected to recover relatively quickly (within weeks or months). This is due to high population turnover with copious production within short generation times that also buffers the potential for long-term (i.e., years) population declines (International Tanker Owners Pollution Federation, 2011a). Therefore, any impacts to exposed planktonic communities present within the EMBA are anticipated to be short-term.
Filter Feeders Hydrocarbon exposure to offshore filter feeding communities may occur, however, due to the hydrocarbon modelling predicting no contact above the ecological threshold and the anticipated depth of the entrained and dissolved aromatic hydrocarbons. See discussion above on potential impacts. Nearshore filter feeders that are present in shallower water <20 m are unlikely to be impacted by entrained hydrocarbon based on the predicted modelling. The released hydrocarbons are predicted to be weathered and less likely to result in toxic effects in comparison to fresh hydrocarbons (i.e., typically in the vicinity of the release location) before they reach any potential filter feeder community. Therefore, impacts such as localised, long-term effects to community structure and habitat are not predicted.
Seagrass Beds, Macroalgae and Mangroves No primary macroalgal/seagrass communities identified within the worst-case LOWC EMBA (RPS, 2024b). Therefore, these communities not predicted to be exposed to hydrocarbons above the ecological threshold.

Summary of Potential Impacts to Socio-economic Values	
Setting	***Receptor Group***
All Settings	***Cultural Features and Heritage Values*** Through consultation and review of available literature (Section 4.9), Woodside understands that Sea Country, including marine ecosystems and species, archaeological heritage and heritage sites, marine parks, as well as intangible cultural heritage may be impacted in the event of a hydrocarbon release from a loss of well containment. Cultural features and heritage values that have the potential to be impacted include: Marine Ecosystems and Species: Marine ecosystems may hold both cultural and environmental value to Traditional Custodians (see Section 4.9), with cultural and environmental values intrinsically linked (DCCEEW, 2023; MAC, 2021 as cited in Woodside, 2023a). It necessarily follows that an impact to marine ecosystems has the potential to impact cultural features where the impact is detectable within Sea Country – the seascape which Traditional Custodians view, interact with or hold knowledge of. The EMBA is known to include habitat for culturally important species such as whales, whale sharks, turtles, dugongs, plankton and seagrass (Sections 4.6 and 4.9). In the event of a worst-case release of hydrocarbons, individual fauna may be directly impacted or impacted through temporary degradation of their habitats; however, no population level impacts as expected. Impacts are not expected to occur to ecologically significant proportions of the populations of the species, nor expected to result in a decrease of the quality of the habitat such that the extent of these species is likely to decline. As such, cultural values and intangible cultural heritage associated with these species are expected to be maintained. Heritage Sites: The combined EMBA overlaps a number of native features and heritage values (see Section 4.9) Any oil (combined EMBA – not applicable to MEE01) that reaches the shoreline has potential to impact on indigenous heritage places along the coastline. In the unlikely event of a hydrocarbon release, shoreline accumulation may affect sensitive artefacts or areas, which could damage their heritage value. Marine Parks: The combined EMBA overlaps a number of AMPs under the North-West Marine Parks Network Management Plan 2018 and a few State Marine Parks. Management Plans for these parks recognise cultural values of Indigenous groups (Section 4.9). Due to the low

	maximum concentrations predicted to reach any marine park, it is not anticipated that their values will be compromised. Intangible Cultural Heritage: Impacts may occur to intangible cultural values such as songlines; creation/dreaming sites, sacred sites, ancestral beings; cultural obligations to care for Country; knowledge of Country/customary law and transfer of knowledge; connection to Country; Access to Country; kinship systems and totemic species, resource collection. Related intangible cultural heritage may include the transmission of cultural knowledge about whales and whale behaviour, including birthing areas, whale communication and migratory patterns. Such cultural knowledge may be associated with various cultural functions and activities that support the social and economic life of a community (Fijn, 2021). Inter-generational transmission of cultural knowledge (including songlines) relating to marine reptiles may be impacted where changes results in reduced sightings (e.g., through population decline, changes to migration routes or changes to migration seasonality). This transfer of knowledge may be integral to managing a group's intangible cultural heritage (UNESCO, 2003). In the unlikely event of a hydrocarbon release, intangible cultural heritage values may be impacted.
Offshore Waters	***Fisheries – Commercial*** Please refer to Section 4.10.1 for a list of the fisheries occurring within the EMBA, and for those considered to have potential for impact with the PAP. A worst-case hydrocarbon spill, as modelled for this EP, is not considered likely to cause significant direct impacts on the target species of these commercial fisheries, as discussed below. Refer to above sections for a discussion of impacts to spawning. Fish exposure to hydrocarbon can result in 'tainting' of their tissues. Even very low levels of hydrocarbons can impart a taint or 'off' flavour or smell in seafood. Tainting is reversible through the process of depuration which removes hydrocarbons from tissues by metabolic processes, although it is dependent upon the magnitude of the hydrocarbon contamination. Fish have a high capacity to metabolise these hydrocarbons while crustaceans (such as prawns) have a comparably reduced ability (Yender et al., 2002). Seafood safety is a concern associated with spill incidents. Therefore, actual or potential contamination of seafood can affect commercial and recreational fishers and can impact seafood markets long after any actual risk to seafood from a spill has subsided (Yender et al., 2002). A major hydrocarbon spill would result in the establishment of an exclusion zone around the spill affected area. There would also be a temporary prohibition on fishing activities for a period. Subsequently, there is potential for economic impacts to the affected commercial fishing operators. Additionally, hydrocarbon can foul fishing equipment such as traps and trawl nets, requiring cleaning or replacement. Impact to fishers would subsequently be dependent on the extent of the spill and resulting exclusion zone and may cause economic impacts due to fishing bans, damaged equipment and/or consumer perception of seafood safety. These impacts would not be expected to be long term or affect the viability of the fishery.
	Tourism and Recreation Tourism would likely be adversely affected if a visible surface slick entered areas of tourism activity. Spill modelling predicted low probability of hydrocarbon contact to the closest tourism area, such as the Montebello MP, Rankin Bank, and the Dampier AMP. These areas have some seasonal charter boat operators and recreational fishing activities, mainly concentrated around the islands. Recreational fishers predominantly target tropical species, such as emperor, snapper, grouper, mackerel, trevally and other game fish. Recreational angling activities include shore-based fishing, private boat and charter boat fishing, with the peak in activity between April and October (Smallwood et al., 2011). Impacts on species that are recreationally fished are described above under 'Commercial Fisheries' and 'Pelagic and Demersal Fish'. In the event of a major spill, tourists and recreational users may also avoid areas due to perceived impacts, including after the hydrocarbon spill has dispersed. There is also the potential for stakeholder perception that this remote environment will be contaminated over a larger area and for the longer term resulting in a prolonged period of tourism decline. Oxford Economics (2010) assessed the duration of hydrocarbon spill in relation to tourism impacts and found that on average, it took 12 to 28 months to return to baseline visitor spending. There is likely to be significant impacts to the tourism industry, wider service industry (hotels, restaurants and their supply chain) and local communities in terms of economic loss as a result of spill impacts to tourism. Recovery and return of tourism to pre-spill levels will depend on the size of the spill, effectiveness of the spill clean-up and change in any public misconceptions regarding the spill (Oxford Economics, 2010).

	However, based on the low levels of tourism and recreation at these locations (compared to other locations such as the Ningaloo Coast), and the low probability of hydrocarbons above the socio-economic thresholds contacting these areas impacts are not expected to be significant.
	Offshore Oil and Gas Infrastructure Surface hydrocarbons from a worst-case spill may affect production from existing offshore petroleum facilities (e.g., platforms and FPSOs). For example, facility water intakes for cooling and fire hydrants could be shut off which could in turn lead to the temporary cessation of production activities. Spill exclusion zones established to manage the spill could also prohibit activity support vessel access as well as tankers approaching facilities on the NWS. However, no petroleum operations are located within the spill EMBA that would likely be affected. The closest oil and gas operation is the Wheatstone platform (operated by Chevron). Other nearby facilities include the Woodside-operated Angel platform, GWA and the Santos operated John Brookes platform (Section 4.10.5). Operation of these facilities is unlikely to be affected in the event of a worst-case loss of well containment.

MEE-01 Well Loss of Containment – Risk Analysis
A bowtie risk analysis was undertaken to assess MEE-01; refer to the below figures for bowtie diagrams that were an output of Woodside's risk analysis process.

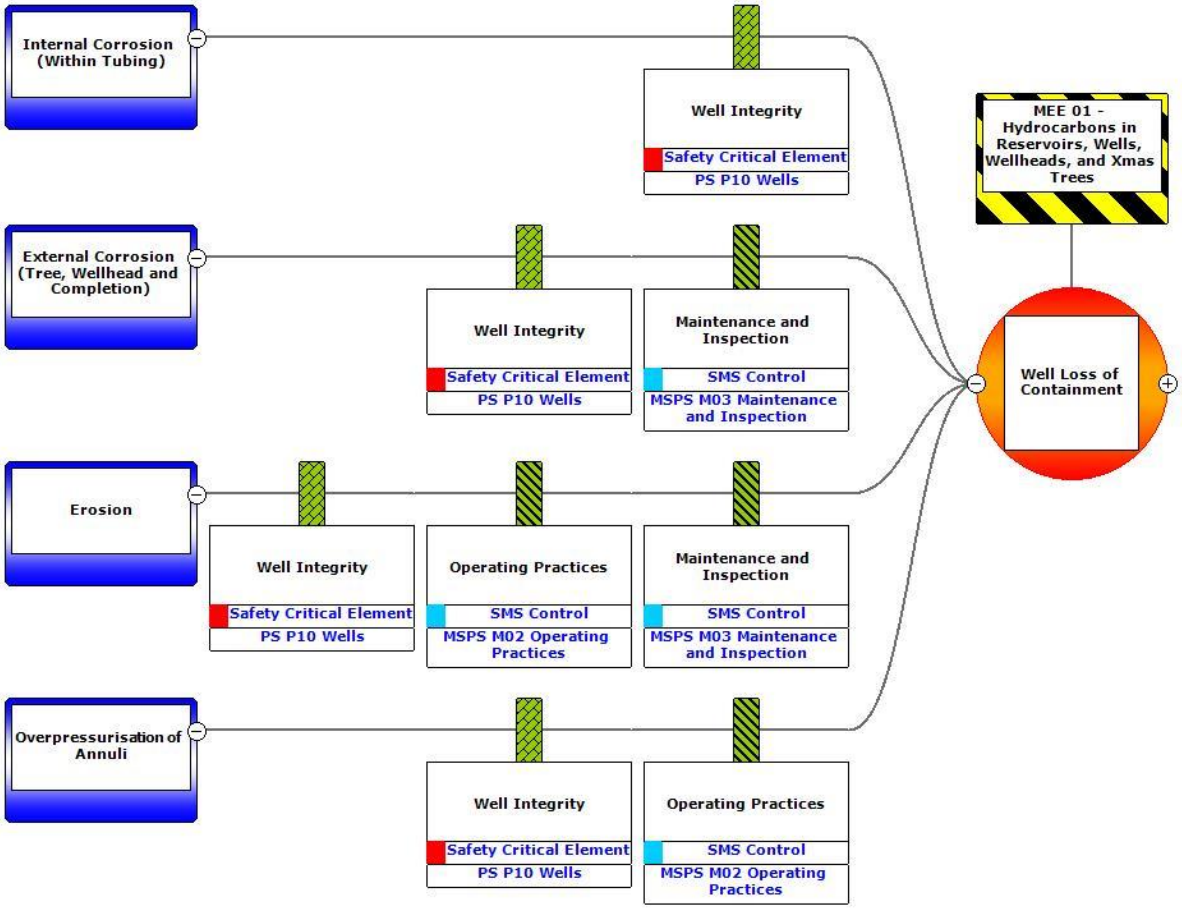

Figure 6-16: MEE-01 Wells loss of containment (Causes 1–4)

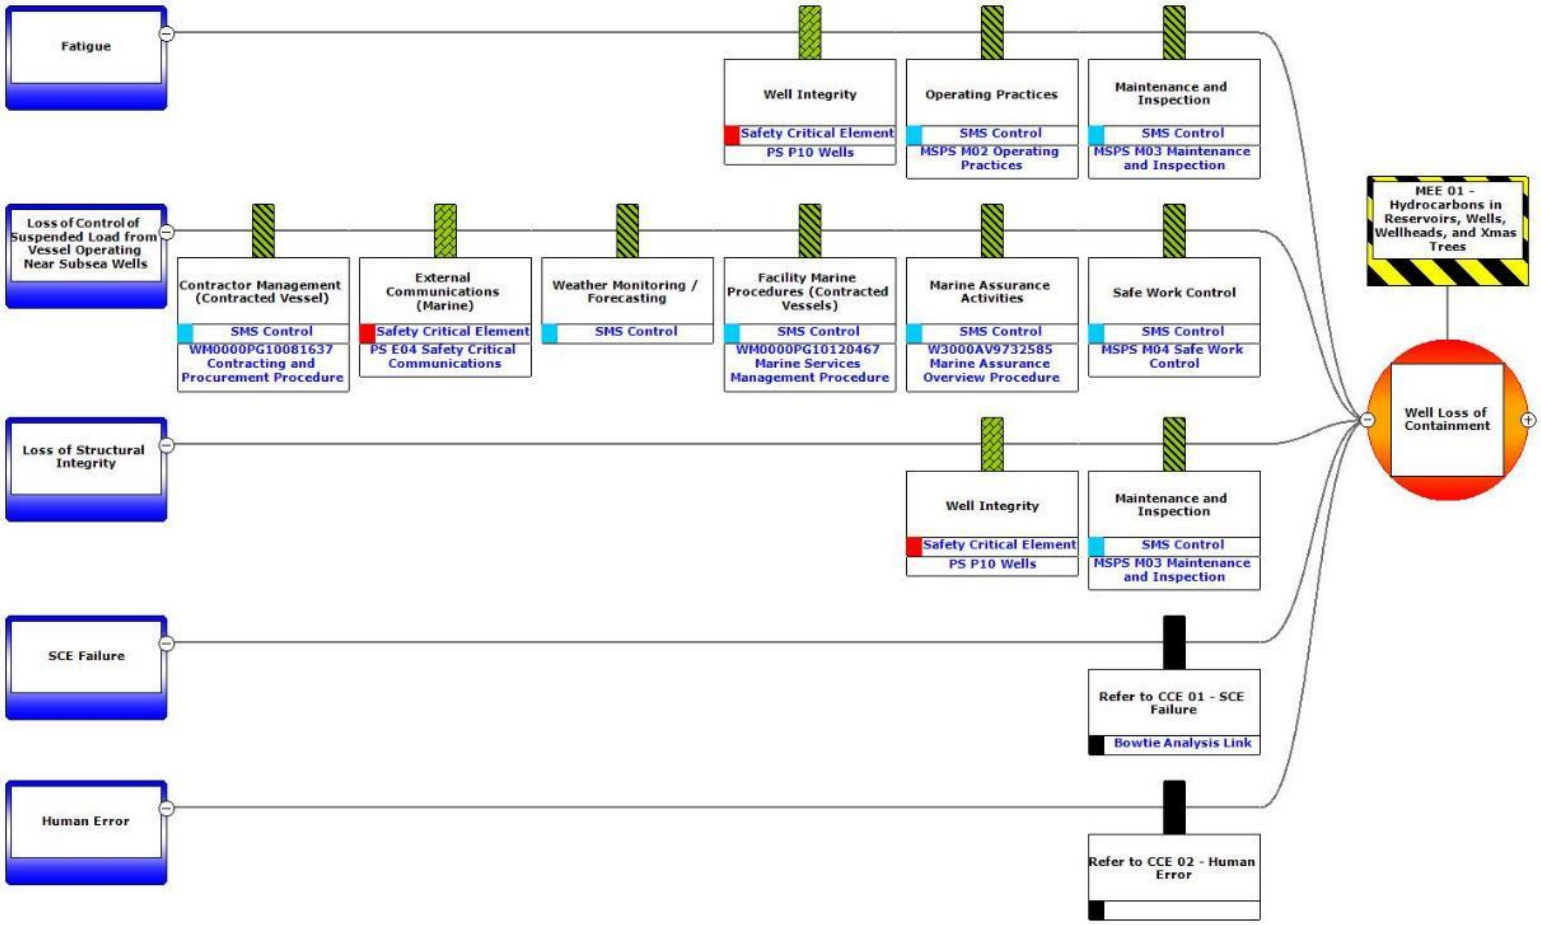

Figure 6-17: MEE-01 Wells loss of containment (Causes 5–9)

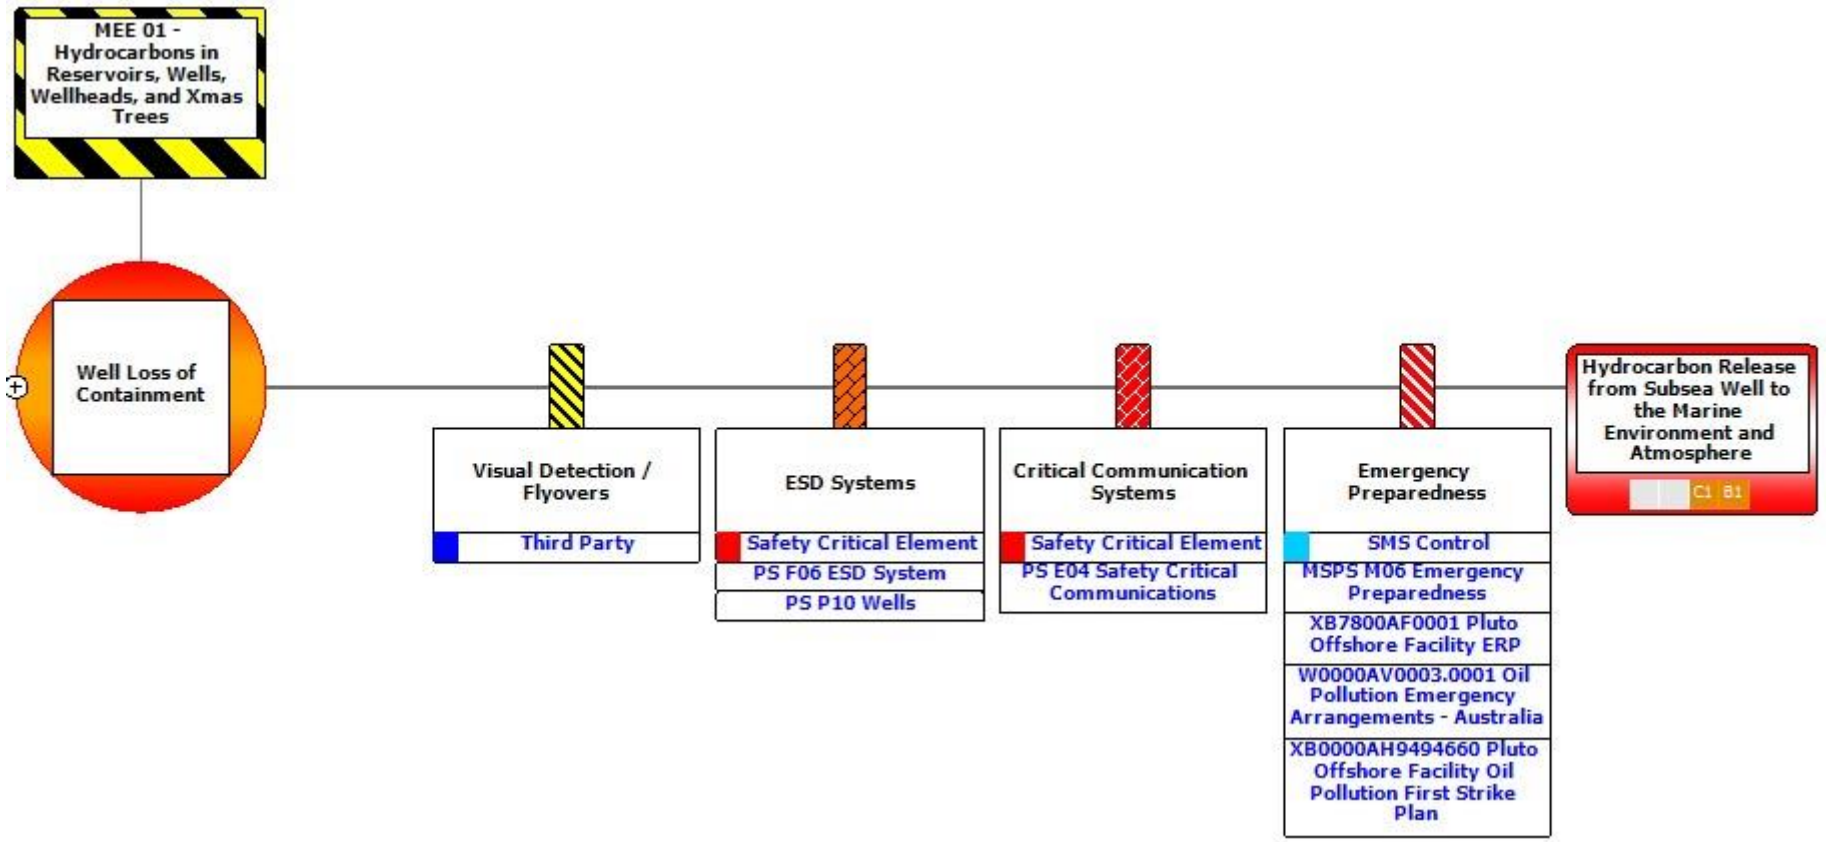

Figure 6-18: MEE-01 Wells loss of containment (outcomes)

MEE-01 Loss of Well Containment – Demonstration of ALARP ALARP Control Measures				
Hierarchy	***Control/Barrier***	***SCE/Management System Reference***	***Type of Effect***	***Control Adopted***

Risk Based Analysis

For risks identified as MEEs, a detailed risk-based Bowtie Analysis (as outlined in Section 2.7.3) has been used to identify, analyse and demonstrate that controls in place reduce the risk associated with each MEE to ALARP. Controls have been selected following hierarchy of control principles and consider independence of each barrier and their type of effect in controlling the hazardous event.

Application of Woodside's Risk Management Procedures and implementation of the WOMP ensures the continuous identification of hazards, systematic assessment of risks, and ongoing assessment of alternative control measures to reduce risk to ALARP, which includes:

- ongoing hazard identification, risk assessment and the identification of control measures
- ongoing integrity management of hardware control measures in accordance with the operational performance standards which define requirements to be suitably maintained, such that they retain effectiveness, functionality, availability and survivability
- well integrity codes and standards.

For each SCE, detailed requirements for equipment functionality, availability, reliability and survivability are incorporated into SCE Performance Standards which also include the relevant assurance tasks (e.g., inspection, maintenance, testing and monitoring requirements) to ensure technical integrity.

Bowtie analysis was undertaken to assess MEE-01, with review of well integrity formal safety and design studies.

Company Values

Woodside's corporate values require all personnel to comply with appropriate policies, standards, procedures and processes while being accountable for their actions and holding others to account in line with Our Values. As detailed above, the PAP is undertaken in line with these policies, standards and procedures that include suitable controls to prevent loss of well containment, and response should a loss of well containment occur.

Societal Values

Due to the Petroleum Activities Program's proximity to sensitive receptors (e.g. Barrow Island, Ningaloo Coast) and the potential extent of the wider EMBA, a major hydrocarbon spill could have impacts to a community. However, due to the low maximum concentrations predicted to reach sensitive receptors, it is not anticipated that their values will be compromised. Therefore, the LOWC risk rating presents a Decision Type B in accordance with the decision support framework described in Section 2.6.1. Extensive consultation was undertaken for this program to identify the views and concerns of relevant persons, as described in Section 5.

Woodside has sent an Activity Factsheet to all identified relevant persons regarding the PAP (Section 5). Woodside has consulted with AMSA and the WA Department of Transport (DoT) on spill response strategies. A copy of the Oil Pollution First Strike Plan was provided to AMSA and DoT.

ALARP Statement:

On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts and risks of a very low likelihood unplanned hydrocarbon release as a result of a loss of well containment.

The principle of inherent safety and environmental protection is based on prevention of the MEE through design of well integrity, ensuring the wells are operated within their design envelope through operating practices, and assurance through maintenance and inspection. If hydrocarbon loss of containment occurs, mitigation measures are in place to minimise the consequence, by limiting the inventory which can be released and implementing remediation.

The controls in place for prevention and mitigation of MEEs are specified and assured through implementing the WOMP, SCE management procedures including performance standards for SCEs, and Management System Performance Standards (MSPSs) for Safety Critical Management System Controls.

The application of Woodside Risk Management Procedures and implementation of the WOMP ensures the continuous identification of hazards, systematic assessment of risks and ongoing assessment of alternative control measures to reduce risk to ALARP, which includes:

- ongoing hazard identification, risk assessment and the identification of control measures
- ongoing integrity management of hardware control measures in accordance with the technical performance standards which define requirements to be suitably maintained, such that they retain effectiveness, functionality, availability and survivability
- well integrity codes and standards.

MEE-01 Loss of Well Containment – Demonstration of ALARP ALARP Control Measures				
Hierarchy	***Control/Barrier***	***SCE/Management System Reference***	***Type of Effect***	***Control Adopted***
Given the controls in place to prevent and control loss of containment events and mitigate their consequences, it is considered that MEE risk associated with loss of well containment is managed to ALARP.				

Demonstration of Acceptability

Acceptability Statement:

Loss of well containment has been evaluated as having a 'moderate' risk rating, based on a C consequence level and a 'highly unlikely' likelihood. As per Section 2.6.3, Woodside considers C+ consequence risks as acceptable if ALARP is demonstrated using good industry practice, consideration of company and societal values and risk based analysis, if legislative requirements are met and societal concerns are accounted for and the alternative control measures are grossly disproportionate to the benefit gained.

Acceptability is demonstrated with regard to the considerations below.

Principles of Ecologically Sustainable Development

Woodside is a proud Australian company that is here for the long term. Woodside has a strong history of exploration and development of oil and gas reserves in the north west of Western Australia with an excellent environmental record, while providing revenue to State and Commonwealth Governments, returns to shareholders, jobs and support to local communities. Titles for oil and gas exploration are released based on commitments to explore with the aim of uncovering and developing resources. It is under the lease agreement that Woodside has determined the potential to develop the hydrocarbon fields for which acceptance of this EP is sought under the Environment Regulations.

Woodside has established a number of research projects in order to understand the marine environments in which they operate, notably in the Exmouth Region and the Kimberley Region, including Rankin Bank, Glomar Shoal, Enfield Canyon and Scott Reef. Where scientific data does not exist, Woodside assumes a pristine natural environment exists, and therefore implements all practicable steps to prevent damage. Woodside's corporate values (Appendix A) require that we consider the environment and communities in which we operate when making decisions.

Woodside looks after the communities and environments in which it operates. Risks are inherent in petroleum activities; however, through sound management and systematic application of policies, standards, procedures and processes, Woodside considers that despite this risk, the extremely low likelihood of loss of well containment is acceptable.

Internal Context

The PAP is consistent with Woodside corporate policies, standards, procedures, processes and training requirements as outlined in the Demonstration of ALARP and EPOs, including:

- Woodside Environment and Biodiversity Policy (Appendix A)
- Woodside Risk Management Policy (Appendix A)
- the SCE Performance Standards developed and implemented for the facility.

Hydrocarbon spill preparedness and response strategies are considered applicable to the nature and scale of the risk, and associated impacts of the response are reduced to ALARP (Section 2.8.1).

Woodside corporate values include working sustainably with respect to the environment and communities in which we operate, listening to internal and external stakeholders and considering HSE when making decisions. Consultation, outlined below, has been undertaken prior to the Petroleum Activities Program.

External Context – Societal Values

Woodside recognises that its licence to operate from a regulatory and societal perspective is based on historical performance, complying with appropriate policies, standards and procedures, and understanding the expectations of external stakeholders. External stakeholder consultation, outlined below, has been undertaken prior to the Petroleum Activities Program:

- Woodside has consulted with AMSA and WA DoT on spill response strategies. A copy of the Oil Pollution First Strike Plan was provided to AMSA and DoT.
- Other relevant persons were consulted (Section 5) and their feedback incorporated into this EP where appropriate.
- By providing hydrocarbon spill response measures that are commensurate with the risk rating, location and sensitivity of the receiving environment (including social and aesthetic values), Woodside believes this addresses societal concerns to an acceptable level.

Other Requirements (includes Laws, Policies, Standards and Conventions)

The PAP is consistent with laws, policies, standards and conventions, including:

- accepted Safety Case (as per the requirements of the OPGGS (Safety) Regulations 2009
- Mutual Aid MoU for relief well drilling is in place
- accepted WOMP as per the requirements of the OPPGS (Resource Management and Administration) Regulations 2011
- notification of reportable and recordable incidents to NOPSEMA, if required, in accordance with Section 7.13.5.

The PAP is consistent with the objectives in the Ningaloo management plans (Management Plan for Ningaloo Marine Park and Muiron Islands Marine Management Areas, Ningaloo Marine Park Management Plan) in relation to water quality, coral, shoreline and intertidal, macroalgal, seagrass, mangroves, seabirds and social and economic values.

6.8.4 Unplanned Hydrocarbon Release: Subsea Equipment Loss of Containment (MEE-02)

Context		
Flowline and Riser System – Section 3.4.3 Pipeline and 6-inch Chemical Supply Line – Section 3.4.5 Subsea Infrastructure – Section 3.4.6	Physical Environment – Section 4.4 Habitats and Biological Communities – Section 4.5 Protected Species – Section 4.6 Protected Places – Section 4.8 Socio-economic Environment – Section 4.9	Consultation – Section 5

Impacts and Risks Evaluation Summary

Source of Risk	***Environmental Value Potentially Impacted***							***Evaluation***						
	Soil and Groundwater	Marine Sediment	Water Quality	Air Quality (incl Odour)	Ecosystems/Habitat	Species	Socio-economic	Decision Type	Consequence	Likelihood	Risk Rating	ALARP Tool	Acceptability	Outcome
Surface or subsea release from flowline, pipeline and riser to the marine environment and atmosphere within PSZ and to mid-point of export pipeline		x	x	x	x	x	x	B	C	1	M	LCS GP PJ RBA CV SV	Acceptable if ALARP	EPO 14
Subsea release from export pipeline to the marine environment and atmosphere between mid-point of export pipeline to shore		x	x	x	x	x	x	B	B	1	M			

Description of Source of Risk

A loss of containment from subsea equipment, including the export pipeline may result in the release of large volumes of hydrocarbon inventory to the environment. The worst-case scenario is based on a release (such as a major rupture or failure) and assumes depressurisation and release of the pipeline inventory prior to and following activation of the emergency shut down systems. Due to the potential consequence of a worst-case subsea equipment loss of containment, this risk is considered to be an MEE (MEE-02).

The potential hazard sources that could instigate a loss of containment from the export pipeline are:

- internal corrosion
- external corrosion
- erosion (for flowlines)
- overpressure
- equipment fatigue and mechanical failures
- pipeline stability and freespans
- anchor impact/dragging

- loss of control of suspended load from supply/ support boat.

Escalation from other MEEs can cause subsea equipment loss of containment:

- loss of structural integrity (MEE-03)
- loss of marine vessel separation (MEE-04)
- loss of control of suspended load from facility lifting operations (MEE-05).

The potential for subsea loss of containment events within the PSZ to escalate due to fire and/or explosion events is considered in Section 6.8.5 Loss of Structural Integrity (MEE-03).

A number of common failure causes due to human error and SCC failures are presented in the generic Human Error and SCE Failure bowties in Section 6.8.8

Subsea Export Pipeline Loss of Containment – Credible Scenarios

The credible worst-case hydrocarbon release caused by subsea loss of containment is a release from the export pipeline.

Woodside evaluated three locations for a loss of containment of the export pipeline, as the location will influence the potential environmental consequence. These included:

- A seabed loss of containment of hydrocarbons from the export pipeline approximately 29 km shorewards along the pipeline from Pluto A. The approximate mid-point location was identified as the point closest to offshore sensitive environmental receptors (i.e., Montebello Islands).
- A seabed loss of containment of hydrocarbons from the export pipeline at the State waters 3nm boundary to consider potential near-shore impacts.
- A surface loss of containment of hydrocarbons from the export pipeline at the riser platform. However, based on the predicted annualised probability and previous modelling studies, the subsea scenario (1) was predicted to be the worst-case scenario within the PSZ, and therefore a surface scenario was not modelled.

The characteristics of the release scenarios modelled are summarised in Table 6-38.

Refer to Section 6.8.2 for additional information on modelling methods and environmental impact, thresholds and hydrocarbon characteristics.

Table 6-38: Summary of worst-case subsea pipeline loss of containment release scenarios

Scenario	Hydrocarbon	Duration (hrs)	Depth (m)	Latitude	Longitude	Total Condensate Release Volume (Sm^3)
Scenario 3: Loss of containment of the export pipeline 29 km from Pluto A	Pluto condensate	8	78	20° 3’ 55.1” S	115° 36’ 1.1” E	472
Scenario 4: Loss of containment of the export pipeline at the State Waters boundary	Pluto condensate	8	41	20° 21’ 0.81” S	116° 42’ 12.41” E	662

Decision Type, Risk Analysis and ALARP Tools

Woodside has a good history of implementing industry standard practice in subsea system design and construction. In the company’s recent history, it has not experienced any pipeline integrity events that have resulted in significant releases or significant environmental impacts. The facility has never experienced a worst-case loss of pipeline and riser containment in its operational history.

Prevention and Mitigation

The main measures in place to prevent and mitigate consequences of a subsea equipment loss of containment event are:

- pipeline design and integrity management
- sand management systems
- process control and emergency shutdown systems
- operating practices
- maintenance and inspection

- emergency and hydrocarbon spill response.

Decision Type

Decision Type B has been applied to this risk under the Guidance on Risk Related Decision Making (Oil and Gas UK, 2014). This reflects the complexity of the risk, the higher potential consequence and stakeholder implications should the event be realised. To align with this decision type, a further level of analysis has been applied using risk based tools, including the bowtie methodology (described in Section 2.7.3) and hydrocarbon spill trajectory modelling (described in Section 6.8.2). Company and societal values were also considered in the demonstration of ALARP and acceptability, considered through internal reviews and stakeholder consultation (Section 5).

The release of hydrocarbons as a result of subsea equipment loss of containment is considered a major environment event (MEE-02). The hazard associated with this MEE is hydrocarbons in subsea infrastructure tied to or originating from the facility.

Quantitative Spill Risk Assessment

Spill modelling of each of the subsea loss of containment credible spill scenarios was undertaken by RPS (2024c, 2024d), on behalf of Woodside, to determine the fate of hydrocarbon released in each scenario based on the assumptions outlined in Section 6.8.2. Modelling was undertaken over all seasons to address year-round operations. This is considered to provide a conservative estimate of the EMBA, and the potential impacts from the identified worst-case credible release volumes for all subsea loss containment scenarios.

Hydrocarbon Characteristics

Refer to Section 6.8.2 for a discussion of Pluto condensate characteristics.

Subsea Plume Dynamics

The loss of subsea containment scenarios will result in a buoyant plume of hydrocarbons, which has been modelled using the OILMAP-Deep numerical model for Scenarios 3A and 7 (summarised in Table 6-39 and Table 6-40, respectively).

Table 6-39: Near-field subsurface discharge model parameters, OILMAP deep model, for the loss of containment of the export pipeline at 29 km from Pluto A for hour 1

	Parameter	Scenario 3
Inputs	Release depth (m below sea level)	78
	Oil density (g/cm³) (at 15°C)	0.733
	Oil viscosity (cP) (at 15°C)	0.58
	Oil temperature (°C)	95
	Gas:oil ratio (m³/m³) [scf/bbl]	9264/52,016
	Oil flow rate (m³/hr)	2444
	Hole diameter (m) [in]	1.2 [47.2]
Outputs	Plume diameter (m)	10
	Plume height (m above seabed	78
	Plume initial rise velocity (m/s)	33
	Plume terminal rise velocity (m/s)	27
Predicted oil droplet size distribution	20% droplets of size (µm)	2586
	20% droplets of size (µm)	3776
	20% droplets of size (µm)	4908
	20% droplets of size (µm)	6380
	20% droplets of size (µm)	9316

Table 6-40: Near-field subsurface discharge model parameters, OILMAP deep model, for the loss of containment of export pipeline at State Waters boundary for 1 hour

	Parameter	Scenario 4
Inputs	Release depth (m below sea level)	41
	Oil density (g/cm³) (at 15°C)	0.733
	Oil viscosity (cP) (at 15°C)	0.58
	Oil temperature (°C)	95
	Gas:oil ratio (m³/m³) [scf/bbl]	7495/42,082
	Oil flow rate (m³/hr)	3063
	Hole diameter (m) [in]	1.2 [47.2]
Outputs	Plume diameter (m)	5.3
	Plume height (m above seabed	41
	Plume initial rise velocity (m/s)	50.9
	Plume terminal rise velocity (m/s)	41.8
Predicted Oil Droplet Size Distribution	20% droplets of size (µm)	2024
	20% droplets of size (µm)	2956
	20% droplets of size (µm)	3842
	20% droplets of size (µm)	4994
	20% droplets of size (µm)	7293

Likelihood

In accordance with the Woodside Risk Matrix, given prevention and mitigation measures in place, worst case subsea loss of containment likelihood has been assessed as 1 (Highly Unlikely).

Subsea loss of containment full bore export pipeline loss of containment events where the zone of contact potentially includes shoreline impact or impact on nearshore Marine Parks/Reserves with low associated probability: Formal safety studies indicate the frequency of this event is calculated to be 3.03E-05, or 1 in 33,000 years. This means with outcome mitigation factored in, the likelihood is considered 1 “Highly Unlikely”.

For full bore loss of containment releases from the export riser or pipeline at any point within the platform PSZ, consequences for the worst-case credible spill where the zone of contact does not include predicted shoreline impact or impact on nearshore Marine Parks/Reserves; Likelihood is estimated to be 3.6E-05 per year, or 1 in 27,470 years.

Similarly, for releases at the platform location from the production flowlines or risers; the frequency of this event is estimated to be 9.8E-05, or 1 in 10,200 years. Therefore, both scenarios have consequences and likelihood considered as 1 “Highly Unlikely”.

Consequence

The spatial extent and fate (including weathering) of the spilled hydrocarbon were considered during the impact assessment for a worst-case subsea or riser loss of containment (presented in the following section). These considerations were informed primarily by the outputs from the numerical modelling studies undertaken by RPS (2024c, 2024d), available information on environmental sensitivities that may credibly be impacted in the event of a worst-case spill and relevant literature and studies considering the effects of hydrocarbon exposure.

Consequence Assessment

Environment that May Be Affected

Scenario 3 – Loss of Containment of the Export Pipeline at 29 km from Pluto A

Surface Hydrocarbons

The hydrocarbon spill modelling indicated that concentrations of floating hydrocarbons equal to or greater than the 10 g/m² threshold could potentially be found, in the form of slicks, approximately 10 km north-west, from the release location. The only receptor modelled with a probability of contact at the ecological threshold (10 g/m²) was Montebello AMP (90%).

Dissolved Hydrocarbons

Dissolved aromatic hydrocarbon concentrations equal to or greater than the 50 ppb threshold are predicted to be found up to around 10 km south-west from the release location. The only receptor modelled with a probability of contact at the ecological threshold (50 ppb) was Montebello AMP (2%).

Entrained Hydrocarbons

Entrained oil concentrations equal to or greater than the 100 ppb threshold are predicted to be found up to 110 km south-west from the release location. The only receptors modelled with a probability of contact at the ecological threshold (100 ppb) was Montebello AMP (47%) and Tryal Rocks (1%).

Accumulated Hydrocarbons

No shoreline accumulation at the ecological threshold, at or above 100 g/m², was predicted.

Scenario 4 – Loss of Containment of the Export Pipeline at the State Waters 3 nm Boundary

Surface Hydrocarbons

The hydrocarbon spill modelling indicated that concentrations of floating hydrocarbons equal to or greater than the 10 g/m² threshold could potentially be found, in the form of slicks, up to 12 km south-west from the release location. However, no receptors are predicted to be contacted by surface hydrocarbons at or above ecological thresholds.

Dissolved Hydrocarbons

Dissolved aromatic hydrocarbon concentrations equal to or greater than the 50 ppb threshold are predicted to be found up to around 10 km south-west from the release location. However, no receptors are predicted to be contacted by dissolved hydrocarbons at ecological thresholds.

Entrained Hydrocarbons

Entrained oil concentrations equal to or greater than the 100 ppb threshold are predicted to be found up to 80 km south-west from the release location.

Receptors with the highest probability of contact at the ecological threshold (100 ppb) include Dampier AMP (23%), Cape Bruguieres (3%), Dampier Archipelago (16%), Cohen Island (7%), Enderby Island (1%), Gidley Island (1%), Goodwyn Island (1%), Keast Island (5%), Kendrew Island (6%), Legendre Island (13%), Malus Island (1%), Rosemary Island (7%), Courtenay Shoal (1%), Hammersley Shoal (8%) and the Madeline Shoals (25%).

Accumulated Hydrocarbons

Shoreline accumulation was predicted at or above 100 g/m² was predicted for Cape Bruguieres (1%), Dampier Archipelago (2%), Cohen Island (2%), Keast Island (1%), Legendre Island (1%), and Rosemary Island (1%)

Any impacts to biological and physical receptors within this area are addressed within the impact discussion for MEE-01 (Section 6.8.3).

Summary of Potential Impacts to Environmental Values

The credible worst-case hydrocarbon spill scenario that may arise from MEE-02 may impact upon a range of environmental receptors. Potential impacts of a hydrocarbon spill to the open water environment and receptors have been assessed within the worst-case spill scenario, MEE-01; refer to Section 6.8.3 for a description of potential impacts.

However, the spill scenario that may arise from MEE-02 is the only scenario predicted to impact the shorelines at or above relevant thresholds. Therefore, potential impacts to nearshore waters (including mainlands and islands) have been assessed below.

Table 6-41: Environment that may be affected – key receptor locations and sensitivities potentially contacted above impact thresholds by the export pipeline and riser loss of containment scenarios with summary hydrocarbon spill contact ≥ 1% probability

Environmental Setting	Receptor	Environmental, Social, Cultural, Heritage and Economic Aspects Presented as per the Environmental Risk Definitions (Woodside's Risk Management Procedure)																												Probability of Hydrocarbon Contact and Fate (%)

Nearshore Waters (Mainland and Islands)

Marine Sediment Quality

The EMBA modelled for MEE-02 scenarios (RPS, 2024c, 2024d) overlapped the nearshore waters of a few shorelines and islands. Specifically, the modelling for the export pipeline release near State Waters 3 nm boundary was the only scenario to predict hydrocarbon accumulation above the ecological threshold at any shoreline. Low probabilities (<2%) of hydrocarbon accumulation were predicted at a few nearshore receptors, such as the Dampier Archipelago, Cape Bruguieres, Keast Island, Cohen Island, Legendre Island, and Rosemary Island. Therefore, hydrocarbon contact from this scenario may lead to reduced marine sediment quality by several processes, such as adherence to sediment and deposition on shores or seabed habitat.

Protected Species

Cetaceans

Evaluation of the extent of the spill EMBA modelled for MEE-02 demonstrated an overlap with areas where cetaceans are known to occur, including the BIAs for a number of species. The potential impacts of hydrocarbon exposure upon cetaceans have already been assessed within the offshore environment evaluation above.

No additional BIAs beyond those already assessed were identified within the EMBA modelled for MEE-02.

Marine Turtles

Marine turtles are known to utilise nearshore waters and shorelines for foraging and breeding activities (including internesting), with significant nesting beaches along the WA mainland coast and nearshore islands in locations (such as the Dampier Archipelago and Montebello Island).

The combined EMBA overlaps a number of marine turtle BIAs. The modelling for the LOC from the export pipeline scenario in MEE-02 predicted low probabilities of contact by shoreline hydrocarbons above the ecological threshold at a number of these nearshore shorelines; including Dampier Archipelago (2%), Legendre Island (1%) and Rosemary Island (1%).

In addition, a number of islands and the nearshore waters of these marine turtle habitat areas are also shown to be exposed to entrained hydrocarbons exceeding the threshold concentrations modelled for MEE-02.

Seasonal timings for breeding, nesting and hatchling dispersal for each marine turtle species is provided in Section 4.6.5, as are the known BIAs and habitat critical areas.

The potential impacts of exposure within the offshore environment have been previously discussed within Section 6.8.3. In the nearshore environment, turtles can ingest hydrocarbons when feeding and/or can be indirectly affected by loss of a food source (e.g., seagrass due to dieback from hydrocarbon exposure) (Gagnon and Rawson, 2010). In addition, hydrocarbon exposure can impact on turtles during the breeding season at nesting beaches. Contact with gravid adult females or with hatchlings may occur on nesting beaches (accumulated hydrocarbons) or in nearshore waters (entrained hydrocarbons) where hydrocarbons are predicted to make shoreline contact. Males waiting in nearshore areas to mate with adult females may also be impacted by entrained hydrocarbons.

Marine turtles aggregating near nesting beaches within the spill EMBA during the mating and nesting seasons are most vulnerable to hydrocarbons, due to greater turtle densities and the possible disruption to important life cycle behaviours. Potential impacts may occur at the population level due to the presence of a high number of breeding individuals and hatchlings (during hatchling dispersal) and may impact on overall population viability of marine turtle species. However, given the volatile nature of the hydrocarbons, population level impacts are not anticipated to occur.

Sea Snakes

Impacts to sea snakes for the mainland and island nearshore waters from direct contact with hydrocarbons may occur and may include potential damage to the dermis and irritation to mucous membranes of the eyes, nose and throat (ITOPF, 2011a). Due to the time to impact in the nearshore environment, the hydrocarbons are considered to be weathered and less likely to result in toxic effects in comparison to fresh hydrocarbons (i.e., typically in the vicinity of the release location).

Sharks and Rays

Whale sharks and manta rays generally transit along the nearshore coastline in these areas and are vulnerable to surface, entrained and dissolved aromatic hydrocarbon spill impacts, with both taxa having similar modes of feeding. Whale sharks and manta rays (reef manta ray and giant manta ray) are known to frequent Ningaloo Reef (forming feeding aggregations from March through July) and the nearshore waters of the Muiron Islands (located 228 km south-west of the PAA).

Impacts from hydrocarbon exposure occurring within the nearshore waters of their main foraging areas, such as Ningaloo Reef, has been assessed in more detail below as the spill EMBA for MEE-04 is more relevant for this assessment.

Seabirds

There is the potential for seabirds, and resident/non-breeding overwintering shorebirds that use the nearshore waters for foraging and resting to be exposed to hydrocarbons above ecological impact thresholds within the EMBA modelled for MEE-02. Impacts may include both lethal or sub-lethal effects, as discussed below and above in the offshore environment assessment.

Although breeding oceanic seabird species can travel long distances to forage in offshore waters, most breeding seabirds tend to forage in nearshore waters near to their breeding colony, resulting in intensive feeding by higher seabird densities in these areas during the breeding season and making these areas particularly sensitive in the event of a spill.

Migratory shorebirds may be exposed to stranded hydrocarbons when foraging or resting in intertidal habitats, however, direct oiling is typically restricted to relatively small portion of birds, and such oiling is typically restricted to the birds' feet. Unlike seabirds, shorebird mortality due to hypothermia from matted feathers is relatively uncommon (Henkel et al., 2012). Indirect impacts, such as reduced prey availability, may occur (Henkel et al., 2012).

As mentioned, predicted surface hydrocarbons are relatively restricted to the release location, with only low probabilities of sporadic shoreline contact at certain locations. Shoreline hydrocarbon contact above ecological thresholds may occur at the Dampier Archipelago, Cape Bruguieres and a number of islands, including Cohen Island, Keast Island, Legendre and Rosemary Island during a MEE-02 scenario. Impacts may, therefore, occur at the population level for species breeding at these locations should a spill occur during the relevant species breeding seasons.

Impacts are likely to occur through the ingestion of contaminated fish (nearshore waters) or invertebrates (intertidal foraging grounds such as beaches, mudflats and reefs) which have been exposed to surface, shoreline, entrained or dissolved hydrocarbons within the combined EMBA. Ingestion of contaminated prey can also lead to internal injury to sensitive membranes and organs (International Petroleum Industry Environmental Conservation Association, 2004). Whether the toxicity of ingested hydrocarbons is lethal or sub-lethal will depend on the weathering stage and its inherent toxicity. Exposure to hydrocarbons may have longer term effects, with impacts to population numbers due to decline in reproductive performance and malformed eggs and chicks, affecting survivorship and loss of adult birds. Seabirds also typically nest above the high-water mark, meaning nesting areas would not be expected to be directly impacted.

Notably, the nearest receptor to the release location that is predicted to receive shoreline hydrocarbons above threshold concentrations is the Dampier Archipelago. Shoreline hydrocarbons were modelled to take a minimum of 21 hours to arrive at this location (RPS, 2024d). Hydrocarbons will be weathered after this period and toxic impacts unlikely to occur. Birds utilising the nearshore waters and intertidal areas for foraging and resting at locations of shoreline contact may, therefore, suffer sub-lethal and less likely, lethal impacts.

Submerged Shoals and Banks

Protected Species

Marine Turtles

While there are no shoal, bank or reef features within the PAA, there is the potential for marine turtles to be present at submerged shoals and banks within the spill EMBA modelled for MEE-02; with modelling predicted relatively low probabilities of contact by entrained hydrocarbons at Madeleine Shoals (25%), Courtenay Shoal (1%), Hammersley Shoal (8%) and Tryal Rocks (1%). Shoals and banks may, at times, be foraging habitat for marine turtles, given the coral and filter feeding biota associated with these areas.

Notably, there are no known key aggregation areas (i.e., BIAs or habitat critical areas) for marine turtles associated with these submerged receptors (see Section 4.6.2 for further details on key areas).

Impacts to marine turtles at submerged shoals and banks in offshore marine environments have been discussed above. Marine turtles would be expected to be foraging, resting and breathing at the surface at these geomorphic features. Ingestion of hydrocarbons while foraging through prey is also possible.

Marine turtles that may be present at these submerged shoals and banks within the EMBA may be impacted by entrained hydrocarbons present at concentrations greater than the relevant thresholds. Impacts would be expected to be limited to the individuals that may be transiting these areas. Subsequently, impacts at the population level are not anticipated for any of the five marine turtle species that may frequent shoals and banks within the EMBA.

Sea Snakes

It is likely that sea snakes will be present at submerged shoals and banks within the EMBA modelled for MEE-2. While there are no known areas of aggregation for sea snakes within the extended combined EMBA (see Section 4.6.2), individual sea snakes may be impacted by hydrocarbons predicted at and near to their habitat preferences (see Section 4.6.2).

The potential impacts to sea snakes following exposure to hydrocarbons have been discussed above.

Sea snake species in Australia generally show strong habitat preferences (Heatwole and Cogger, 1993); species that have preferred habitats associated with submerged shoals and oceanic atolls may be disproportionately affected by a hydrocarbon spill affecting such habitat. However, population level impacts are not anticipated.

Sharks and Rays

Pelagic sharks and rays may frequent submerged shoals and banks to feed within the EMBA modelled for MEE-02. Some species may also exhibit site fidelity to these geomorphic features. There is the potential for resident shark and ray populations to be impacted directly from hydrocarbon contact or indirectly through contaminated prey or loss of habitat.

Species which are resident to or exhibit site-fidelity to impacted shoals or banks may experience sub-lethal impacts and/or become displaced. Indirect impacts through ingestion of prey that has been exposed to hydrocarbons and/or the loss of marine flora habitats may also impact sharks and rays.

Pelagic sharks and rays are expected to move away from areas affected by spilled hydrocarbons. Impacts to such species are expected to be limited to behavioural responses/displacement. Shark and ray species that have associations with submerged shoals and banks may or may not be displaced/exhibit behavioural avoidance in response to such habitat being contacted by spilled hydrocarbons. Such species may be more susceptible to a reduction in habitat quality resulting from a hydrocarbon spill. It is expected that there will be no impacts at the population level

All Settings

Coral

Modelling for the pipeline export scenario (MEE-02) was predicted to contact known coral reef habitats above the ecological threshold. The modelling predicted low probability of entrained hydrocarbons to contact the Dampier Archipelago (16%).

Impacts

Exposure to entrained hydrocarbons (≥100 ppb) or dissolved aromatic hydrocarbons (≥50 ppb) has the potential to result in lethal or sub-lethal toxic effects to corals and other sensitive sessile benthos within the upper water column, including upper reef slopes (subtidal corals), reef flat (intertidal corals) and lagoonal (back reef) coral communities. Mortality in a number of coral species is possible and this would result in the reduction of coral cover and change in the composition of coral communities. Sub-lethal effects to corals may include polyp retraction, changes in feeding, bleaching (loss of zooxanthellae), increased mucous production resulting in reduced growth rates and impaired reproduction (Negri and Heyward, 2000).

This could result in impacts to the shallow water fringing coral communities/reefs of the nearshore islands.

Shoreline Accumulation

A very low probability of shoreline contact (<2%) above the ecological threshold was predicted at a few receptors for the MEE-02 scenario at the State Waters 3 nm boundary, including Cape Bruguieres, Dampier Archipelago, Cohen Island, Rosemary Island, Keast Island, Legendre Island.

Shallow coral habitats (i.e. nearshore and intertidal waters) are most vulnerable to hydrocarbons through coating by direct contact with surface slicks during periods when corals are tidally-exposed at spring low tides. Water soluble hydrocarbon fractions associated with surface slicks are known to cause high coral mortality (Shigenaka, 2001) via direct physical contact of hydrocarbon droplets to sensitive coral species (such as the branching coral species).

There is, therefore, potential for lethal impacts due to the physical hydrocarbon coating of sessile benthos (including by entrained hydrocarbons), with likely significant mortality of corals (adults, juveniles and established recruits) at the small spill affected areas. These impacts are particularly applicable to branching corals which are reported to be more sensitive than massive corals (Shigenaka, 2001).

Recruitment/Spawning

In the unlikely event of a spill occurring at the time of coral spawning at potentially affected coral locations or in the general peak period of biological productivity, there is the potential for a significant reduction in successful fertilisation and coral larval survival due to the sensitivity of coral early life stages to hydrocarbons (Negri and Heyward, 2000). Such impacts are likely to result in the failure of recruitment and settlement of new population cohorts. In addition, some non-coral species may be affected via direct contact with entrained and dissolved aromatic hydrocarbons, resulting in sub-lethal impacts and in some cases mortality. This is with particular reference to the early life-stages of coral reef animals (reef attached fishes and reef invertebrates), which can be relatively sensitive to hydrocarbon exposure. Coral reef fish are site attached, have small home ranges and as reef residents they are at higher risk from hydrocarbon exposure than non-resident, more wide-ranging fish species. The exact impact on resident coral communities (which may include fringing reefs of the offshore islands) will be entirely dependent on actual hydrocarbon concentration, duration of exposure and water depth of the affected communities. Coral cover, structure and composition may be reduced in hydrocarbon impacted areas, manifested by loss of corals and associated sessile biota.

Recovery of impacted reef areas from a range of stressors typically relies on coral larvae from neighbouring coral communities that have either not been affected or only partially impacted. For example, there is evidence that Ningaloo Reef corals and fish are partly self-seeding (Underwood, 2009) with the supply of larvae from locations within Ningaloo Reef of critical importance to the healthy maintenance of the coral communities. Recovery at other coral reef areas, may not be aided by a large supply of larvae from other reefs, with levels of recruits after a

disturbance event only returning to previous levels after the numbers of reproductive corals had also recovered (Gilmour et al., 2013).

The hydrocarbon modelling for the MEE-02 scenarios predicted only low probability of contact from entrained hydrocarbons at the Dampier Archipelago, Outtrim Patches, Submerged Shoals, and Tryal Rocks. Therefore, a worst-case scenario of an export pipeline release near the State Waters boundary may cause impacts to coral reefs with the EMBA, with the potential to cause long-term effects.

Productivity

The potential impacts to plankton and offshore productivity following exposure to entrained hydrocarbons have been discussed above.

Filter Feeders

Nearshore filter feeders that are present in shallower water <20 m may potentially be impacted by entrained hydrocarbon based on the predicted modelling.

However, the released hydrocarbons are predicted to be weathered and less likely to result in toxic effects in comparison to fresh hydrocarbons (i.e., typically in the vicinity of the release location) before they reach any potential filter feeder community. Therefore, impacts such as localised, long-term effects to community structure and habitat, are not predicted.

Seagrass Beds, Macroalgae and Mangroves

The primary macroalgal/seagrass communities identified within the combined EMBA including those along the Ningaloo Coast (patchy and low cover associated with the shallow limestone lagoonal platforms), Muiron Islands (associated with limestone pavements), and the Barrow and Montebello Island groups are not predicted to be exposed to hydrocarbons above the ecological threshold based on the modelling.

The seagrass and macroalgal beds that may be found at other areas of lower coverage, such as the Dampier Archipelago, may be susceptible to impacts from entrained hydrocarbons from a worst-case release near the State Water boundary (MEE-02). Toxicity effects can also occur due to absorption of soluble fractions of hydrocarbons into tissues (Runcie et al., 2010). The potential for toxicity effects of entrained hydrocarbons may be reduced by weathering processes that should serve to lower the content of soluble aromatic components before contact occurs. Furthermore, given the non-persistent nature of the hydrocarbons, however, no significant effects to seagrass and macroalgal habitats are expected to occur.

Mangrove habitats and associated mud flats and salt marsh at Ningaloo Coast (small habitat areas) and the Montebello Islands were not predicted to be exposed to entrained hydrocarbons. Therefore, impacts are not expected to occur.

Summary of Potential Impacts to Socio-economic Values	
Setting	***Receptor Group***
Nearshore Island and Mainland Coastal Areas (Nearshore Waters)	***Fisheries – Commercial*** A few State-managed fisheries have been identified to overlap with the EMBA. Any impacts to these fisheries would include possible direct mortality or sub-lethal impacts to the target species, as well as indirect financial and reputational impacts from possible fishing exclusion zones and perceived health impacts by the community/consumers as a result of the spill event. Impacts to fish stocks would depend on the time of the year the spill event was to occur, and the maturity of the fishery. Impacts are, however, expected to be restricted to mid-term for both direct and indirect impacts. Fishing activities may be hampered if fisheries are restricted from entry to an affected area, however the area potentially affected represents a very small part of available fishery zones and the short duration that diesel would persist limits the potential for significant impacts.
	Fisheries – Traditional Although no designated traditional fisheries have been identified within the PAA or EMBA, it is recognised that Indigenous communities' fish in the shallow coastal and nearshore waters of Ningaloo Reef and, therefore, may be impacted if a worst-case hydrocarbon spill were to occur. Impacts would be similar to those identified for commercial fishing, in the form of a potential fishing exclusion zone and possible contamination/tainting of fish stocks.

	Tourism and Recreation Tourism would likely be adversely affected if a visible surface slick entered areas of tourism activity. Spill modelling predicted low probability of hydrocarbon contact to the closest tourism area, such as the Montebello MP and Dampier AMP and archipelago. These areas have some seasonal charter boat operators and fishing activities, mainly concentrated around the islands. The Dampier Archipelago was predicted to have low probability of shoreline contact by MEE-02 scenario. This area experiences seasonal charter boats and recreational fishing. In the event of an export pipeline release near the State Waters 3 nm boundary, there could be restricted access to this area for a period of days to weeks, until natural weathering or tides and currents remove the hydrocarbon.

MEE-02 Subsea Equipment Loss of Well Containment – Risk Analysis
A bowtie risk analysis was undertaken to assess MEE-02; refer to the below figures for bowtie diagrams which were an output of Woodside's risk analysis process.

Risk Based Analysis

For risks identified as MEEs, a detailed risk-based Bowtie Analysis (as outlined in Section 2.7.3) has been used to identify, analyse and demonstrate that controls in place reduce the risk associated with each MEE to ALARP. Controls have been selected following hierarchy of control principles and consider independence of each barrier and their type of effect in controlling the hazardous event.

Application of Woodside's Risk Management Procedures and implementation of the Pluto A Operations Safety Case and Pluto Export Pipeline Safety Case ensures the continuous identification of hazards, systematic assessment of risks and ongoing assessment of alternative control measures to reduce risk to ALARP, which includes:

ongoing hazard identification, risk assessment and the identification of control measures

ongoing integrity management of hardware control measures in accordance with the operational performance standards which define requirements to be suitably maintained, such that they retain effectiveness, functionality, availability and survivability.

For each SCE, detailed requirements for equipment functionality, availability, reliability and survivability are incorporated into SCE Performance Standards which also include the relevant assurance tasks (e.g., inspection, maintenance, testing and monitoring requirements) to ensure technical integrity.

Bowtie analysis was undertaken to assess MEE-02, with review of formal safety assessments and subsea system design studies.

Company Values

Corporate values require all personnel at Woodside to comply with appropriate policies, standards, procedures and processes while being accountable for their actions and holding others to account in line with Our Values. As detailed above, the PAP is undertaken in line with these policies, standards and procedures that include suitable controls to prevent subsea flowline and riser loss of containment, and response should a loss of containment occur.

Societal Values

Due to the Petroleum Activities Program's proximity to sensitive receptors (e.g., Montebello Islands) and the potential extent of the wider EMBA, the pipeline and riser loss of containment risk rating presents a Decision Type B in accordance with the decision support framework described in Section 2.6.1. Consultation was undertaken for this program to identify the views and concerns of relevant persons, as described in Section 5.

Woodside has sent an Activity Factsheet to all identified relevant persons regarding the PAP (Section 5). Woodside has consulted with AMSA and WA DoT on spill response strategies. A copy of the Oil Pollution First Strike Plan was provided to AMSA and DoT.

MEE-02 Subsea Equipment Loss of Well Containment – Demonstration of ALARP ALARP Control Measures				
Hierarchy	***Control/Barrier***	***SCE/Management System Reference***	***Type of Effect***	***Control Adopted***

ALARP Statement:

On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts and risks of a very low likelihood unplanned hydrocarbon release as a result of a pipeline and riser loss of containment.

The principle of inherent safety and environmental protection is based on the prevention of the MEE through design of pipelines and risers, ensuring the export pipeline and risers are operated within their design envelope through operating practices, and assurance through maintenance and inspection. If hydrocarbon loss of containment occurs, mitigation measures are in place to minimise the consequence by limiting the inventory which can be released and implementing remediation.

The controls in place for prevention and mitigation of MEEs are specified and assured through implementing the Safety Cases and SCE management procedures, including performance standards for SCEs and MSPSs for Safety Critical Management System Controls.

The application of Woodside's Risk Management Procedures ensures the continuous identification of hazards, systematic assessment of risks and ongoing assessment of alternative control measures to reduce risk to ALARP, which includes:

- ongoing hazard identification, risk assessment and the identification of control measures
- ongoing integrity management of hardware control measures in accordance with the technical performance standards which define requirements to be suitably maintained, such that they retain effectiveness, functionality, availability and survivability.

Given the controls in place to prevent and control loss of containment events and mitigate their consequences, it is considered that MEE risk associated with a pipeline and riser loss of containment is managed to ALARP.

Demonstration of Acceptability

Acceptability Statement

Subsea equipment loss of containment has been evaluated as having a 'moderate' level of risk rating.

Subsea loss of containment events are risk assessed as Highly Unlikely, potential "C – Moderate" consequence for offshore events.

Export pipeline mid-point to shore section loss of containment events are risk assessed as Highly Unlikely, potential "B – Major" consequence.

As per Section 2.6.3, Woodside considers 'moderate' risk ratings as broadly acceptable if the adopted controls are implemented. Due to the consequence associated with MEE-02, Decision Type B has been applied, and ALARP is demonstrated using good industry practice, consideration of company and societal values and risk-based analysis, if legislative requirements are met and societal concerns are accounted for and the alternative control measures are grossly disproportionate to the benefit gained.

Acceptability is demonstrated with regard to the oil spill risk considerations as described in Section 6.8.3 (MEE-01) (the considerations include principles of Ecologically Sustainable Development, internal context, external context and other requirements (includes laws, policies, standards and conventions)).

On the basis of the environmental impact assessment outcomes and Woodside's criteria for acceptability outlined in Section 2.8.2, this is considered an acceptable level of risk.

Surface or subsea release from flowline, pipeline and riser to the marine environment and atmosphere within PSZ (MEE-02) – caused by loss of structural integrity		x	x	x	x	x	x	B	C	1	M			

Description of Source of Risk

Extreme environmental conditions or other causes which result in an exceedance of the design criteria and a catastrophic failure of the facility and individual equipment (e.g., cranes, flare tower) has been identified as a potential MEE (MEE-03). Catastrophic structural failure of the facility could lead to the release of hydrocarbons to the environment.

The identified causes, including escalation from other MEEs, include:

- internal corrosion
- external corrosion
- equipment failure
- extreme weather (cyclone, high waves)
- seismic events/seabed instability
- fire/overpressure event (escalation of loss of containment event).

Escalation from other MEEs can also cause loss of structural integrity:

- loss of marine vessel separation (refer to MEE-04, Section 6.8.6)
- loss of control of suspended load from facility lifting operations (refer to MEE-05).

A number of common failure causes due to human error and SCC failures are presented in the generic Human Error and generic SCE Failure bowties in Section 6.8.8.

There is a possibility of riser platform collapse ('slow' or 'rapid') caused by the extreme loads induced by strong winds and extreme waves. Extreme weather may induce fracture of pipework due to vibration/fatigue and loosen/dislodge objects/projectiles causing impact to equipment/pipework and subsequently, resulting in a loss of containment.

Structural damage to the platform resulting from the causes listed above could be minor or could in the most extreme situation result in total loss of the platform. The type of structural failure considered is restricted to major structural damage (e.g., catastrophic collapse of the jacket or release of hydrocarbons on or adjacent to the platform). Such events are beyond the design basis for the platform.

Loss of Structural Integrity – Credible Scenarios

A loss of structural integrity could result in a significant release of hydrocarbons. A loss of structural integrity may result in credible hydrocarbon spill scenarios consistent with:

- subsea equipment loss of containment (MEE-02)
- loss of marine vessel separation (MEE-04)
- topsides loss of containment (one or more storage inventories) through to total loss of platform hydrocarbon/chemical inventory (bound by MEE-04 impact assessment) (Section 6.8.4).

The worst-case credible spill scenarios associated with these MEEs/sources of risk are discussed in the relevant sections above, with impacts dependent on the extent of structural damage, volume of hydrocarbons released (including cumulative volumes from tanks/vessels), the associated weather conditions, and effectiveness of mitigation and response measures.

Decision Type, Risk Analysis and ALARP Tools

Woodside has a good history of implementing industry standard practice in structural design, construction and operation. In the company's 60-year history, it has not experienced any loss of structural integrity events that have resulted in significant releases or significant environmental impacts.

Decision Type

Decision Type B has been applied to this risk under the Guidance on Risk Related Decision Making (Oil and Gas UK, 2014). This reflects the complexity of the risk, the higher potential consequence and stakeholder implications should the event be realised. To align with this decision type, a further level of analysis has been applied using risk-based tools including the bowtie methodology (described in Section 2.7.3) and hydrocarbon spill trajectory modelling. Company and societal values were also considered in the demonstration of ALARP and acceptability, considered through internal reviews, and stakeholder consultation (Section 5).

The potential release of hydrocarbons from a loss of structural integrity is considered an MEE (MEE-03). The hazard associated with this MEE is hydrocarbons in pipelines, risers, process and non-process hydrocarbon and chemical inventories and potentially the physical riser platform/jacket structure itself.

Quantitative Spill Risk Assessment

Credible worst-case stochastic spill modelling for the scenarios associated with MEE-02 Subsea system loss of containment and MEE-04 Loss of marine vessel separation (diesel loss of containment) has been undertaken. Results of these modelling studies have been used to inform the consequence assessment for these MEEs; these assessments are applicable to bounding the worst-case consequence assessment for a loss of structural integrity event. A "C" Moderate consequence is assigned to worst-case releases from the riser platform location for both MEE-02 subsea system loss of containment, and a conservatively assessed MEE-04 diesel loss of containment scenario, which bounds the worst-case impact potential for cumulative topsides hydrocarbon, chemicals and marine vessel loss of containment in case of a structural collapse.

Likelihood

Formal safety studies inform an assessed frequency of total platform collapse estimated to be 1.08E-04 per year, or 1 in 9285 years considering seismic factors, weather events and vessel collision risk. Once the low likelihood of cumulative instantaneous release to result in worst-case environmental consequence is considered, together with prevention and mitigation factors – the likelihood is assessed as "Highly Unlikely" in accordance with the Woodside Risk Matrix.

Consequence

The spatial extent and fate (including weathering) of the spilled hydrocarbon was considered during the impact assessment for a loss of structural integrity. These considerations were informed primarily by the outputs from the stochastic modelling studies undertaken by RPS (2024c, 2024e), available information on environmental sensitivities that may credibly be impacted in the event of a worst-case spill, and relevant literature and studies considering the effects of hydrocarbon exposure.

Consequence Assessment

Environment that May Be Affected

As discussed above, the potential impacts from hydrocarbon release caused by a loss of structural integrity are analogous to those which would result from:

- loss of containment from subsea equipment (within PSZ) (MEE-02)
- loss of marine vessel separation (MEE-04)
- topsides loss of containment (one or more storage inventories) through to total loss of platform hydrocarbon/chemical inventory (bound by MEE-04 impact assessment) (Section 6.8.4).

The potential impacts associated with these impacts are therefore discussed in the above-mentioned sections.

Seabed Disturbance

In the event of loss of structural integrity, there is the potential for collapse of the riser platform leading to an incremental increase of the facility's footprint on the seabed. The potential area that would be affected can conservatively be defined as the existing facility footprint plus 100 m in all directions, that is approximately 300 m by 350 m (0.105 km^2). The benthic habitats surrounding the riser platform have been subject to historical disturbance (e.g., facility construction and operation) and are considered to be of low ecological value (although it is acknowledged the facility provides artificial hard substrate which has formed the basis of relatively high biodiversity communities at this location when compared to the surrounding seabed). Subsequently, the physical disturbance to the seabed resulting from the collapse of the riser platform would be localised but may result in long-term disturbance to benthic communities.

The riser platform could also act as a source of environmental contaminants due to material on board the platform (e.g., chemical/hydrocarbon inventories, corrosion of structural materials, debris). The potential for contamination would diminish over time, as the structure degrades. Depending on the nature of the loss of structural integrity, complete or partial salvage of the riser platform may not be feasible. These structures are expected to be colonised by marine organisms, and a reef habitat will develop over time on the structures.

While the PAA overlaps the Continental Slope Demersal Fish Communities KEF and Ancient Coastline at 125 m Depth Contour KEF, neither of these are in close proximity to the riser platform.

MEE-03 Loss of Structural Integrity – Risk Analysis

A bowtie risk analysis was undertaken to assess MEE-03; refer to the below figures for bowtie diagrams that were an output of Woodside's risk analysis process.

MEE-03 Loss of Structural Integrity – Demonstration of ALARP ALARP Control Measures				
Hierarchy	***Control/Barrier***	***SCE/Management System Reference***	***Type of Effect (Refer to Table 6-32)***	***Control Adopted***
Risk Based Analysis				

For risks identified as MEEs, a detailed risk-based Bowtie Analysis (as outlined in Section 2.7.3) has been used to identify, analyse and demonstrate that controls in place reduce the risk associated with each MEE to ALARP. Controls have been selected following hierarchy of control principles and consider independence of each barrier and their type of effect in controlling the hazardous event.

Application of Woodside's Risk Management Procedures and implementation of the Pluto-A Operations Safety Case ensures the continuous identification of hazards, systematic assessment of risks and ongoing assessment of alternative control measures to reduce risk to ALARP, which includes:

- ongoing hazard identification, risk assessment and the identification of control measures
- ongoing integrity management of hardware control measures in accordance with the operational performance standards which define requirements to be suitably maintained, such that they retain effectiveness, functionality, availability and survivability.

For each SCE, detailed requirements for equipment functionality, availability, reliability and survivability are incorporated into SCE Performance Standards which also include the relevant assurance tasks (e.g., inspection, maintenance, testing and monitoring requirements) to ensure technical integrity.

Bowtie analysis was undertaken to assess MEE-03, with review of formal safety assessment studies.

ALARP Statement:

On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts and risks of a very low likelihood of a loss of structural integrity.

The principle of inherent safety and environmental protection is based on the prevention of the MEE through design of the facility, ensuring the equipment is operated within the design envelope through operating practices, and assurance through maintenance and inspection. If a loss of structural integrity occurs, mitigation measures are in place to minimise the consequence by limiting the inventory which can be released and implementing remediation.

The controls in place for prevention and mitigation of MEEs are specified and assured through implementing the Pluto A Operations Safety Case, SCE management procedures including performance standards for SCEs, and MSPSs for Safety Critical Management System Controls.

The application of Woodside Risk Management Procedures and implementation of the Pluto A Operations Safety Case ensures the continuous identification of hazards, systematic assessment of risks and ongoing assessment of alternative control measures to reduce risk to ALARP.

Given the controls in place to prevent and control loss of containment events and mitigate their consequences, alongside procedural control of facility operations, it is considered that MEE risk associated a loss of structural integrity is managed to ALARP.

Demonstration of Acceptability

Acceptability Statement:

A loss of structural integrity has been evaluated as having a 'Moderate' risk rating (including the consideration of applicable MEEs). As per Section 2.6.1, Woodside considers 'Moderate' (B0) risk ratings as acceptable if managed to ALARP. Due to the consequence associated with MEE-03, Decision Type B has been applied, and ALARP is demonstrated using good industry practice and risk-based analysis, if legislative requirements are met and societal concerns are accounted for, and the alternative control measures are grossly disproportionate to the benefit gained.

Acceptability is demonstrated with regard to the oil spill risk considerations as described in Section 6.8.3 (MEE-01) (the considerations include principles of Ecologically Sustainable Development, internal context, external context and other requirements (includes laws, policies, standards and conventions)).

On the basis of the environmental impact assessment outcomes and Woodside's criteria for acceptability outlined in Section 2.8.2, this is considered an acceptable level of risk.

Description of Source of Risk

A loss of marine vessel separation between a vessel and the facility, or between vessels may result in a loss of hydrocarbon containment from the facility and/or the release of fuel from the vessel. A loss of marine vessel separation with PLA has been identified as a potential MEE (MEE-04). Loss of marine vessel separations can arise from:

- visiting vessel collisions associated with platform support vessels, IMMR and accommodation vessels – ships that are visiting the riser platform can accidentally collide with the platform or each other during approach to, or manoeuvring alongside, the platform
- errant passing vessel collision – ships that are not visiting the riser platform (i.e., passing vessels) can, for one reason or another, move off-course and collide with the platform
- vessel operations during adverse weather.

The different collision hazards involve significantly different sized vessels and collision speeds; hence, differing impact energies and consequences have been assessed.

Visiting Vessels

Visiting vessels are defined as those which are routinely used to service the facility. Operating procedures dictate how vessels are operated, loaded and unloaded, but it will generally occur so that the prevailing winds move the vessel away from the facility. The primary causes of visiting vessel collisions are failure to follow safe procedures and communication errors between the marine vessels and riser platform operations. These errors could be worsened by:

- vessel station keeping failures
- vessel operations in adverse weather conditions.

A number of common failure causes due to human error and SCC failures are presented in the generic Human Error and SCE Failure bowties in Section 6.8.8.

Errant Passing Vessels

Errant passing vessels are defined as third party vessels that enter the riser platform's 500 m PSZ, but do not call at the riser platform (i.e., not support vessels). The collision can be powered or drifting. Either has the potential to cause significant damage to the riser platform.

The causes of errant passing vessel collisions include:

- failure of propulsion or steering systems
- adverse weather conditions resulting in poor visibility
- rough seas
- human error.

Woodside implements a range of control measures to mitigate the risk of errant vessel collision. In addition to the potential for large hydrocarbon releases following impact by a vessel with the riser platform, powered collisions from large passing vessels or tankers could have sufficient impact energy to breach both skins of the vessel to the extent that there is a loss of containment of cargo or fuel oil with the potential for significant loss of inventory and consequent environmental impact. This is not within the control of Woodside so is not assessed further.

Loss of Vessel Separation – Credible Hydrocarbon Spill Scenario

The loss of marine vessel separation is considered a Major Environment Event (MEE-04). The hazards associated with this MEE is loss of containment of hydrocarbons in subsea equipment, process and non-process hydrocarbon inventories and potentially fuel stored in vessels (such as platform support/IMMR vessels).

A loss of marine vessel separation could result in a significant release of process hydrocarbons. Hydrocarbon releases may result in a spill to the marine environment as described in Section 6.8.4 (MEE-02 Subsea equipment loss of containment, surface scenario) caused due to mechanical integrity impacts to structures, which include flowline/export pipeline riser systems. Escalation events could interact with MEE-03 Loss of structural integrity (Section 6.8.5) topsides inventories. In addition, vessel cargo, including diesel inventory, could be spilled if the cause of the loss of platform integrity was a collision from a support vessel or other in-field vessel.

Worst case hydrocarbon release scenarios for a subsea equipment loss of containment (MEE-02) that could result from loss of marine vessel separation in the PSZ is discussed in Section 6.8.4. Relevant trajectory modelling as applicable to these scenarios is also discussed above.

A loss of vessel separation may lead to the accidental release of marine diesel from the fuel tanks on the vessel(s) involved. For a vessel collision to result in the worst-case scenario of a hydrocarbon spill potentially impacting an environmental receptor, several factors must align as follows:

- Vessel interaction must result in a collision.
- The collision must have enough force to penetrate the vessel hull.
- The collision must be in the exact location of the fuel tank.
- The fuel tank must be full, or at least of volume that is higher than the point of penetration.

The probability of the chain of events described above aligning, to result in a breach of fuel tanks resulting in a spill that could potentially affect the marine environment is considered highly unlikely. Given the offshore location of the PAA, vessel grounding in relation to the PAP is not considered a credible risk.

A collision between a platform, subsea support vessel or ASV with a third-party vessel (i.e. commercial shipping, other petroleum related vessels and commercial fishing vessels) was considered the only credible event that could release a significant quantity of marine diesel to the environment. This was assessed as being credible but highly unlikely, given the platform support vessels typically operate in the Operational Area, the presence of vessels within the Operational Area is typically temporary (e.g., while undertaking IMMR activities), vessels undertaking the PAP typically operate of low speeds or are stationary, the standard vessel operations and equipment in place to prevent collision at sea, and the construction and placement of storage tanks. For marine vessels, credible spill volume assumptions are taken as the volume of the largest fuel tank in line with AMSA guidelines [Technical Guidelines for Preparing Contingency Plans for Marine and Coastal Facilities]. The largest tank of a platform support or subsea support vessel is unlikely to exceed 105 m^3. However, non-routine vessel activities may be required with larger tank inventories such as ASV with segregated tank inventories of ~300 m^3, with combined capacity of ~1800 m^3. For the purposes of understanding the characteristics of a marine diesel release from a large vessel, a loss of 1000 m^3 of marine diesel to sea-surface within the PSZ has been selected as being representative of a worst-case spill scenario.

Decision Type, Risk Analysis and ALARP Tools

Woodside has not experienced any loss of marine vessel separation events that have resulted in significant environmental impacts. The facility has never experienced a worst-case loss of containment due to loss of vessel separation in its operational history.

Decision Type

Decision Type B has been applied to this risk under the Guidance on Risk Related Decision Making (Oil and Gas UK, 2014). This reflects the complexity of the risk, the higher potential consequence and stakeholder implications should the event be realised. To align with this decision type, a further level of analysis has been applied using risk-based tools, including the Bowtie Methodology (described in Section 2.7.3) and hydrocarbon spill trajectory modelling. Company and societal values were also considered in the demonstration of ALARP and acceptability, considered through internal reviews, and stakeholder consultation (Section 5).

Quantitative Spill Risk Assessment

Credible worst-case hydrocarbon spill scenarios: subsea equipment loss of containment (MEE-02) applies to a loss of vessel separation (MEE-04) causing structural failures, with PLA facility location noted to be further away (offshore) from key receptors modelled in a mid-point export pipeline loss of containment scenario. Refer to the Section 6.8.4 for a discussion of this credible worst-case spill scenario.

Spill modelling of the worst-case credible loss of marine diesel from a vessel spill scenario was undertaken by RPS (2024e) on behalf of Woodside. Modelling of a diesel fuel tank loss of containment described in Table 6-42 was undertaken over all seasons to address possible year-round vessel operations. This is considered to provide a conservative estimate of the EMBA and the potential impacts from the identified worst-case credible release volumes for marine diesel loss of containment scenarios.

Table 6-42: Summary of worst-case vessel fuel tank loss of containment during operations scenario

Scenario	Hydrocarbon	Duration (minutes)	Depth (m)	Latitude	Longitude	Total Hydrocarbon Release Volume (m^3)
Scenario 5: Vessel fuel tank loss of containment	Marine gas oil	60	Surface	19° 59’ 46.5” S	115° 22’ 5.6” E	1000

Hydrocarbon Characteristics

See Section 6.8.2 for a description of marine diesel.

Likelihood

In accordance with the Woodside Risk Matrix, a likelihood of 'highly unlikely' event as it 'has occurred once or twice in the industry' (experience-based likelihood) and aligns with a frequency of '1 in 10,000 to 1 in 100,000 years' has been assigned to the events of:

- hydrocarbon release from subsea equipment to the marine environment and atmosphere
- marine environment footprint and associated hydrocarbon and chemical release associated with structural collapse of riser platform.
- surface release from vessel fuel tank.

Consequence

The spatial extent and fate (including weathering) of the spilled hydrocarbon was considered during the impact assessment for MEE-02 (Section 6.8.4), and separate diesel modelling scenario. These considerations were informed primarily by the outputs from the stochastic modelling studies undertaken by RPS (2024c, 2024e), available information on environmental sensitivities that may credibly be impacted in the event of a worst-case spill (Sections 6.8.3 and 6.8.4), and relevant literature and studies considering the effects of hydrocarbon exposure.

Consequence Assessment

Environment that May Be Affected

As discussed above, the potential impacts from a hydrocarbon release caused by a loss of vessel separation include those which would result from:

- subsea equipment loss of containment (MEE-02 – Scenario 3)
- loss of structural integrity
- Scenario 5 – loss of containment of the marine diesel within the PSZ.

The potential impacts are –discussed in the above-mentioned sections and below.

Scenario 5 – Loss of Containment of the Marine Diesel Within the PSZ

Surface Hydrocarbons

The hydrocarbon spill modelling indicated that concentrations of floating hydrocarbons equal to or greater than the 10 g/m2 threshold could potentially be found, in the form of slicks, up to 50 km north and north-east from the release location. Receptors with the highest probability of contact at the ecological threshold include Montebello AMP with a 24% probability.

Entrained Hydrocarbons

Entrained oil concentrations equal to or greater than the 100 ppb threshold are predicted to be found up to 400 km south-west from the release location.

Receptors with the highest probability of contact at the ecological threshold (>100 ppb) include Gascoyne AMP (4%), Montebello AMP (57.5%) and Tryal Rocks (1.5%). Several other sensitive receptors are predicted to be contacted at concentrations equal to or greater than 100 ppb with probabilities of 0.5–2% (Table 6-43).

Dissolved Hydrocarbons

Dissolved aromatic hydrocarbon concentrations equal to or greater than the 50 ppb threshold are predicted to be found up to around 26 km south-west from the release location. Receptors with the highest probability of contact at the ecological threshold (>50 ppb) include Montebello AMP (19.5%).

Accumulated Hydrocarbons

The modelling predicted no shoreline hydrocarbon accumulated at any receptor above the ecological threshold.

Summary of Potential Impacts to Environmental Values

The credible worst-case hydrocarbon spill scenario that may arise from MEE-04 may impact upon a range of environmental receptors; refer to Table 6-43 for a summary of receptors identified by the stochastic spill modelling studies. Potential impacts of a hydrocarbon spill to the open water environment and receptors have been assessed within the worst-case spill scenario, MEE-01; refer to Section 6.8.3 for a description of potential impacts.

The modelling for the spill scenario that may arise from MEE-04 predicted some low-probability entrained hydrocarbons that may also impact the environment and receptors within the nearshore waters above the relevant thresholds that were not located within the EMBAs modelled for either the worst-case spill scenario; MEE-01 or MEE-02 assessed above. Therefore, the potential impacts have been assessed further below.

Table 6-43: Environment that may be affected – key receptor locations and sensitivities potentially contacted above impact thresholds by loss of vessel marine diesel inventory at the Pluto Alpha Petroleum Safety Zone for threshold ≥0.5%

Nearshore Waters (Mainland and Islands)

Marine Sediment Quality

The EMBA modelled for MEE-04 scenario overlaps the nearshore waters of a few shorelines and islands (RPS, 2024e).

Low probabilities (<2%) of entrained hydrocarbons were predicted to contact a few nearshore receptors, such as the Ningaloo Coast, Montebello Islands and Shoals, Barrow Island and Muiron Island. Therefore, hydrocarbon contact from this scenario may lead to reduced marine sediment quality by several processes, such as adherence to sediment and deposition seabed habitat.

No shorelines were predicted to be exposed to either shoreline accumulation or floating surface hydrocarbons at any threshold (RPS, 2024e).

Protected Species

Cetaceans and Dugongs

Coastal populations of small cetaceans (e.g., the spotted dolphin) and dugongs are known to reside or frequent nearshore waters along the WA coastline and nearshore islands, including the Exmouth Gulf, Ningaloo Coast and at the Muiron Islands, Montebello and Barrow Island groups, and the Pilbara Southern Island Groups. The general impacts of hydrocarbons on cetaceans have been assessed above.

Evaluation of the extent of the spill EMBA modelled for MEE-04 demonstrated an overlap with areas where cetaceans are known to occur, including the BIAs for a number of species. In addition to the BIAs that overlap the PAA, the EMBA overlaps with the dugong calving, breeding, foraging (high density seagrass beds) and nursing BIAs, the OIE pygmy blue whale foraging BIA (see Section 4.6).

OIE Pygmy Blue Whale

The pygmy blue whale foraging area in the Ningaloo Coast is within the EMBA modelled for the vessel separation scenario (due to contact with entrained hydrocarbons at 100 ppb); however, it is about 232 km south-west of the PAA and the EMBA is not representative of any one hydrocarbon spill. The likelihood of impacts occurring within this BIA are, therefore, considered low.

Dugong

Impacts (in addition to those noted above) include ingestion of hydrocarbons by dugongs that feed on oiled seagrass and indirect impacts to dugongs should seagrass habitats be damaged by a hydrocarbon spill. As noted for the pygmy blue whale foraging BIA, the spill EMBA modelled for MEE-04 scenario only overlaps a small northern portion of the Exmouth Gulf and it is considered a low likelihood that the dugong BIAs (and associated seagrass meadows) located there and along the Ningaloo Coast (BIAs for calving, nursing, breeding and foraging) would be impacted by a hydrocarbon spill. No surface or shoreline hydrocarbons are predicted within the Exmouth Gulf or associated dugong BIAs within this EMBA.

Summary

A hydrocarbon spill following a vessel separation may impact coastal cetaceans through site displacement and damage to food source, however, due to the non-persistent nature of the hydrocarbon, it is not predicted to result in impacts on overall population viability of either dugongs or coastal cetaceans.

Marine Turtles

Marine turtles are known to use nearshore waters and shorelines for foraging and breeding activities (including internesting), with significant nesting beaches along the WA mainland coast and nearshore islands in locations (such as the Dampier Archipelago and Montebello Island).

The combined EMBA overlaps a number of marine turtle BIAs. The modelling for MEE-04 scenario predicted exposure by to entrained hydrocarbons exceeding the relevant exposure thresholds at a number of islands and the nearshore waters of these marine turtle habitat areas.

The modelling for MEE-04 predicted no hydrocarbon exposure to any shorelines at any threshold. Therefore, impacts to nesting individuals are not expected following a release of hydrocarbons in the event of a vessel separation.

The potential impacts of hydrocarbon exposure within the nearshore environment have been assessed above. Marine turtles aggregating near nesting beaches within the EMBA for MEE-04 during the mating and nesting seasons are most vulnerable to hydrocarbons, due to greater turtle densities and the possible disruption to important life cycle behaviours.

Potential impacts may occur at the population level due to the presence of a high number of breeding individuals and hatchlings (during hatchling dispersal) and may impact on overall population viability of marine turtle species. However, given the volatile nature of the hydrocarbons population level impacts are not anticipated to occur.

Sea Snakes

The potential impacts of hydrocarbon exposure within the nearshore environment upon sea snakes has been assessed above.

Sharks and Rays

Whale sharks and manta rays (reef manta ray and giant manta ray) are known to frequent Ningaloo Reef (forming feeding aggregations March through July) and the nearshore waters of the Muiron Islands (located 228 km south-west of the PAA). Whale sharks and manta rays generally transit along the nearshore coastline in these areas and are vulnerable to surface, entrained and dissolved aromatic hydrocarbon spill impacts, with both taxa having similar modes of feeding.

Whale sharks are versatile feeders, filtering large amounts of water over their gills, catching planktonic and nektonic organisms (Jarman and Wilson, 2004). Whale sharks at Ningaloo Reef have been observed using two different feeding strategies, including passive sub-surface ram-feeding and active surface feeding (Taylor, 2007). Passive feeding consists of swimming slowly at the surface with the mouth wide open. During active feeding, sharks swim high in the water with the upper part of the body above the surface with the mouth partially open (Taylor, 2007). These feeding methods would result in the potential for individuals that are present in worse affected spill areas to ingest potentially toxic amounts of entrained or dissolved aromatic hydrocarbons into their body. Large amounts of ingested hydrocarbons may affect their endocrine and immune system in the longer term.

The presence of hydrocarbons may also cause displacement of whale sharks from important feeding and resting areas at Ningaloo Reef, potentially disrupt migration and aggregations to these areas in subsequent seasons. Whale sharks may also be affected indirectly by entrained or dissolved aromatic hydrocarbons through the contamination of their prey. The preferred food of whale sharks are planktonic organisms which are abundant in the coastal waters of Ningaloo Reef in late summer/autumn, driving the annual arrival and aggregation of whale sharks in this area. If a worse-case spill event were to occur during the spawning season, this important food supply (in worse spill affected areas of the reef) may be diminished or contaminated. The contamination of their food supply and the subsequent ingestion of this prey by the whale shark may also result in long term impacts as a result of bioaccumulation.

There is the potential for other coastal shark species (e.g., dwarf, narrow and/or green sawfish) to be impacted directly from hydrocarbon contact and/or indirectly through contaminated prey or loss of habitat. Excluding sawfish, which may exhibit high site fidelity, it is most likely that shark species (as mobile animals) will move away from spill affected areas and suffer minimal direct impact.

A spill reaching the Ningaloo coastline during key aggregation periods and impacting important whale shark foraging areas may have severe impacts to the local whale shark population, including possible mortality of individuals and impacts to life cycle habitats such as migration patterns. Most species of shark and ray (including whale sharks) are, however, expected to move away from spill affected areas with minimal impacts.

Seabirds

The potential impacts of hydrocarbon exposure within the nearshore environment upon seabirds has been assessed above. The modelling for the EMBA for MEE-04 predicted no shoreline accumulation of hydrocarbons at any thresholds. As mentioned above, the area exposed to surface hydrocarbons is also relatively restricted to the release site, therefore impacts to rafting or foraging individuals are anticipated to be low.

Submerged Shoals and Banks

Protected Species

Marine Turtles

Modelling for the MEE-04 spill scenario predicted a very low probability of overlap of submerged shoals and banks by the EMBA, including Montebello Shoals (0.5%), Outtrim Patches (1%), and Tryal Rocks (1.5%). Shoals and banks may, at times, be foraging habitat for marine turtles, given the coral and filter feeding biota associated with these areas.

Notably, there are no known key aggregation areas (i.e., BIAs or habitat critical areas) for marine turtles associated with these submerged receptors (see Section 4.6.2 for further details on key areas).

Impacts to marine turtles at submerged shoals and banks in offshore marine environments have been discussed above in Section 6.8.3. Marine turtles would be expected to be foraging, resting and breathing at the surface at these geomorphic features. Ingestion of hydrocarbons while foraging through prey is also possible.

Marine turtles that may be present at these submerged shoals and banks within the EMBA may be impacted by entrained hydrocarbons present at concentrations greater than the relevant thresholds. Impacts would be expected to be limited to the individuals that may be transiting these areas. Subsequently, impacts at the population level are not anticipated for any of the five marine turtle species that may frequent shoals and banks within the EMBA.

Sea Snakes

It is likely that sea snakes will be present at submerged shoals and banks within the EMBA modelled for MEE-2. While there are no known areas of aggregation for sea snakes within the extended combined EMBA (see Section 4.6.2), individual sea snakes may be impacted by hydrocarbons predicted at and near to their habitat preferences (see Section 4.6.2).

The potential impacts to sea snakes following exposure to hydrocarbons have been discussed above.

Sharks and Rays
Pelagic sharks and rays may frequent submerged shoals and banks to feed within the EMBA modelled for MEE-04. The potential impacts to sharks and rays following exposure to entrained hydrocarbons have been discussed above.
All Settings
Coral
The potential impacts to coral and coral recruitment / spawning following exposure to entrained hydrocarbons have been discussed above.
Productivity
The potential impacts to plankton and offshore productivity following exposure to entrained hydrocarbons have been discussed above.
Seagrass Beds, Macroalgae and Mangroves
The potential impacts to seagrass beds, macroalgae and mangroves following exposure to entrained hydrocarbons have been discussed above.

Summary of Potential Impacts to Socio-economic Values	
Setting	***Receptor Group***
Nearshore Island and Mainland Coastal Areas (Nearshore Waters)	***Fisheries – Commercial*** The potential impacts to commercial fisheries following exposure to hydrocarbons have been discussed above.
	Fisheries – Traditional Although no designated traditional fisheries have been identified within the PAA or EMBA, it is recognised that Indigenous communities' fish in the shallow coastal and nearshore waters of Ningaloo Reef and therefore may be impacted if a worst-case hydrocarbon spill were to occur. Impacts would be similar to those identified for commercial fishing, in the form of a potential fishing exclusion zone and possible contamination/tainting of fish stocks.
	Tourism and Recreation Tourism would likely be adversely affected if a visible surface slick entered areas of tourism activity. Spill modelling predicted low probability of hydrocarbon contact to the closest tourism area, such as the Montebello MP and Dampier AMP and archipelago. These areas have some seasonal charter boat operators and fishing activities, mainly concentrated around the islands. Modelling also predicted low probabilities of entrained hydrocarbon exposure at areas such as the Ningaloo Coast located over 200 km south of the PAA. These areas experience high levels of seasonal tourism and recreational activities. Impacts would be temporary exclusion of these activities within the exposed areas. No long-term impacts are expected due to the distance and weathering and fate of the hydrocarbons exposed to prior to reaching these areas.

MEE-04 Loss of Marine Vessel Separation – Risk Analysis
A bowtie risk analysis was undertaken to assess MEE-04; refer to the below figures for bowtie diagrams which were an output of Woodside's risk analysis process.

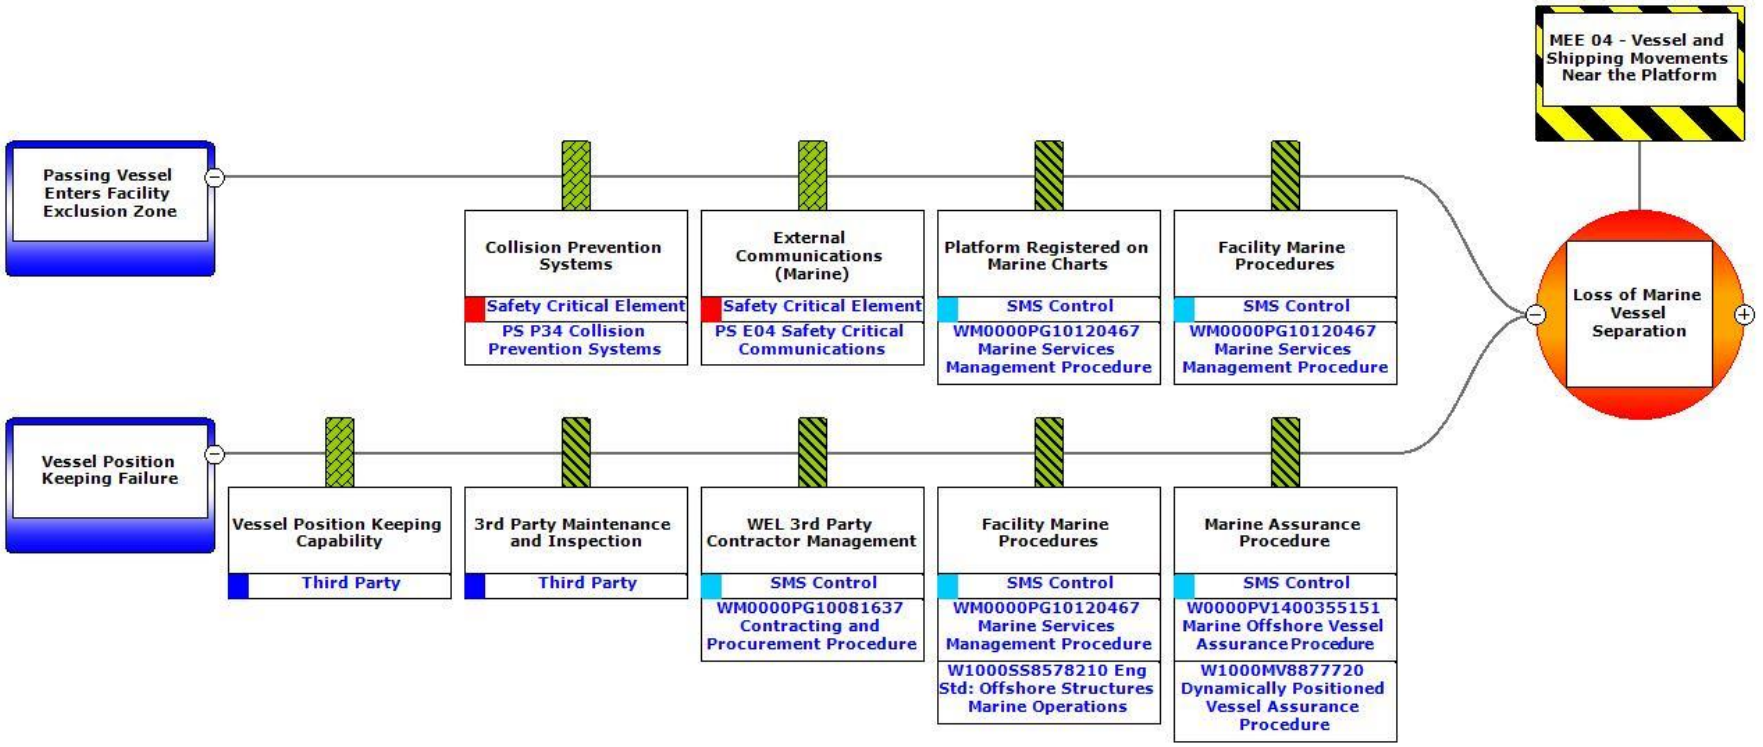

Figure 6-27: MEE-04 Loss of vessel separation (Causes 1–2)

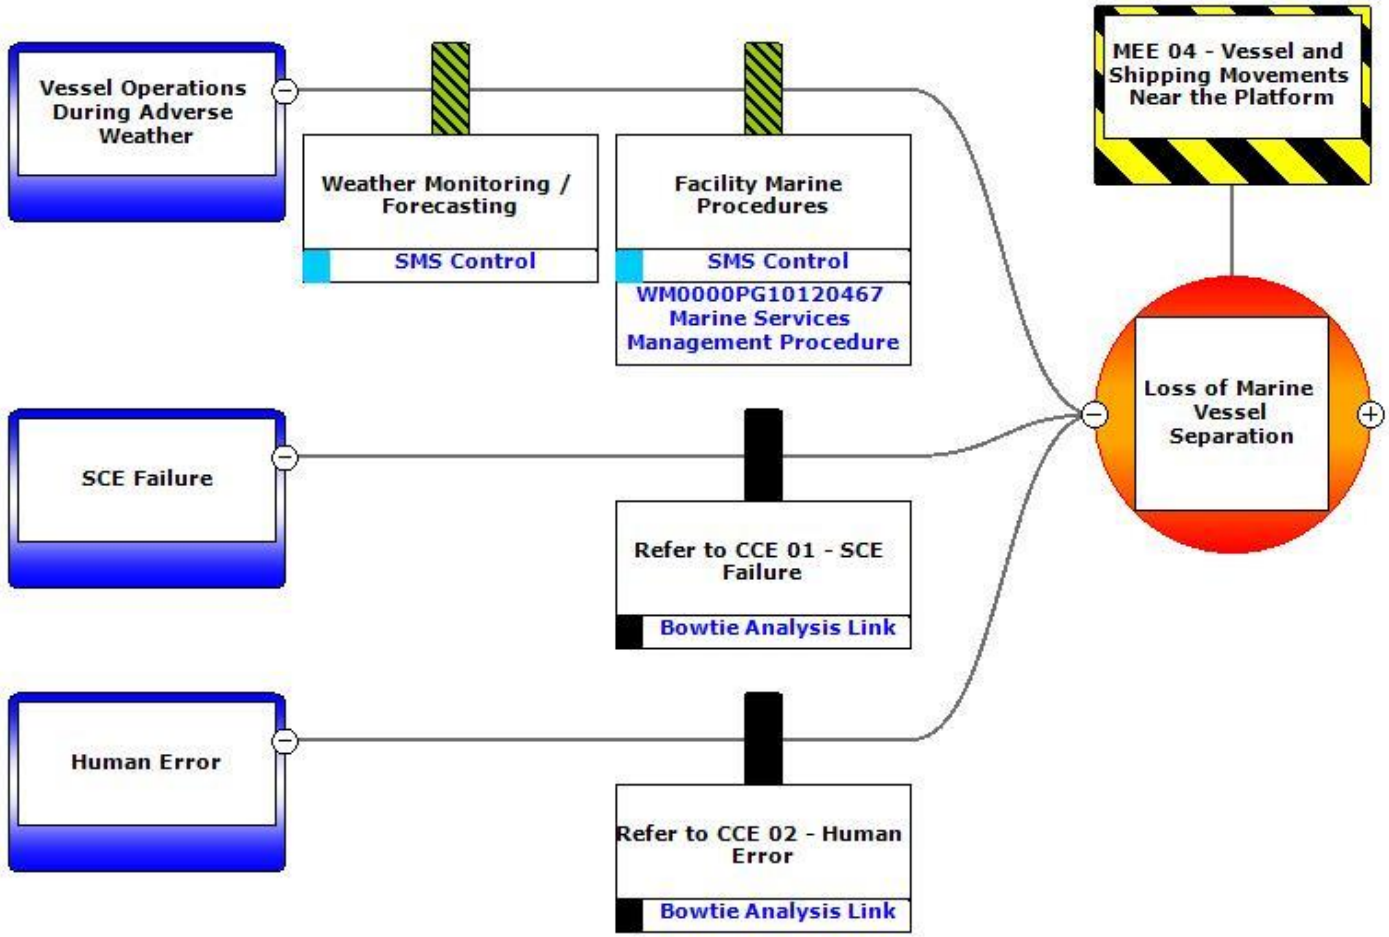

Figure 6-28: MEE 04 Loss of marine vessel separation (Causes 3–5)

MEE-04 Loss of Marine Vessel Separation – Demonstration of ALARP ALARP Control Measures				
Hierarchy	***Control/Barrier***	***SCE/Management System Reference***	***Type of Effect***	***Control Adopted***

Risk Based Analysis

For risks identified as MEEs, a detailed risk-based bowtie analysis (as outlined in Section 2.7.3) has been used to identify, analyse and demonstrate that controls in place reduce the risk associated with each MEE to ALARP. Controls have been selected following hierarchy of control principles and consider independence of each barrier and their type of effect in controlling the hazardous event.

Application of Woodside's Risk Management Procedures and implementation of the Pluto A Operations Safety Case and Pluto Export Pipeline Safety Case ensures the continuous identification of hazards, systematic assessment of risks and ongoing assessment of alternative control measures to reduce risk to ALARP, which includes:

- ongoing hazard identification, risk assessment and the identification of control measures
- ongoing integrity management of hardware control measures in accordance with the operational performance standards which define requirements to be suitably maintained, such that they retain effectiveness, functionality, availability and survivability.

For each SCE, detailed requirements for equipment functionality, availability, reliability and survivability are incorporated into SCE Performance Standards which also include the relevant assurance tasks (e.g., inspection, maintenance, testing and monitoring requirements) to ensure technical integrity.

Bowtie analysis was undertaken to assess MEE-04, with review of formal safety assessment studies.

ALARP Statement:

On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts and risks of a remote likelihood unplanned hydrocarbon release as a result of a loss of marine vessel separation.

The principle of inherent safety and environmental protection is based on the prevention of the MEE through design of the facility jacket and pipeline, flowline and riser integrity and ensuring controls are assurance through maintenance and inspection, and safe operating practices applied. If hydrocarbon loss of containment occurs, mitigation measures are in place to minimise the consequence by limiting the inventory which can be released and implementing remediation.

The controls in place for prevention and mitigation of MEEs are specified and assured through implementing the Pluto A Operations Safety Case(s), SCE management procedures including technical performance standards for SCEs and MSPSs for Safety Critical Procedures.

The application of Woodside Risk Management Procedures, and implementation of the Pluto Subsea Pipeline and Pluto A Operations Safety Cases ensures the continuous identification of hazards, systematic assessment of risks and ongoing assessment of alternative control measures to reduce risk to ALARP, which includes:

- ongoing hazard identification, risk assessment and the identification of control measures
- ongoing integrity management of hardware control measures in accordance with SCE technical performance standards which define requirements to be suitably maintained, such that they retain effectiveness, functionality, availability and survivability.

Given the controls in place to prevent and control loss of containment events and mitigate their consequences, it is considered that MEE risk associated with Loss of Marine Vessel Separation at the riser platform is managed to ALARP.

Demonstration of Acceptability

Acceptability Statement

Loss of marine vessel separation has been evaluated as having a 'moderate' level of risk rating. Woodside considers 'moderate' risk ratings as broadly acceptable if the adopted controls are implemented. Due to the consequence associated with MEE-04, Decision Type B has been applied, and ALARP is demonstrated using good industry practice, consideration of company and societal values and risk-based analysis, if legislative requirements are met and societal concerns are accounted for and the alternative control measures are grossly disproportionate to the benefit gained.

Acceptability is demonstrated with regard to the oil spill risk considerations as described in Section 6.8.3 (MEE-01) (the considerations include principles of Ecologically Sustainable Development, internal context, external context and other requirements (includes laws, policies, standards and conventions)).

EPOs, EPSs and MC for Pluto Facility Operations			
Environmental Performance Outcomes	***Controls***	***Environmental Performance Standards***	***Measurement Criteria***
EPO 16 No release of hydrocarbons to the marine environment due to loss of marine vessel separation associated with the Petroleum Activities Program.	**C 16.1** Maintaining collision warning systems and navigational aids to alert facility of a potential collision with marine vessels, and to alert marine vessels of facility location so they may take timely action to avoid the facility and hence reduce likelihood of collision.	**PS 16.1** Integrity will be managed in accordance with SCE Management Procedures (Section 7.4) and SCE Technical Performance Standard(s) to prevent environment risk related damage to SCEs for: • P34 – Collision prevention systems, to: • alert facility of a potential collision with marine vessels • alert marine vessels of facility location so they may take timely action to avoid the facility and hence reduce likelihood of collision.	**MC 2.11.1** Records demonstrate implementation of SCE Technical Performance Standard(s) and Management of Hardware Controls in the Operate Phase Procedure (Section 7.4.2), in order to achieve the functional objective of the control. Records may include implementation and maintain/assure and manage-change information summarised in Section 7.4.2

Hydrocarbon release from topsides equipment to the marine environment and atmosphere – caused by loss of control of suspended load		x	x	x		x		A	D	1	M			

Description of Source of Risk

Lifting activities on the riser platform can take place from the platform crane between supply vessels and laydown areas, or between laydown areas. Lifting operations performed using the platform or visiting vessel cranes could potentially lead to dropped objects, impacting assets (topsides equipment, subsea infrastructure) inside the riser platform 500 m PSZ, potentially leading to a hydrocarbon loss of containment from topsides and/or subsea infrastructure. Loss of suspended load has been identified as an MEE (MEE-05). A loss of suspended load may arise from:

- lifting equipment failure
- facility lifting operations
- adverse weather.

A number of common failure causes due to human error and SCC failures are presented in the generic Human Error and SCE Failure bowties in Section 6.8.8.

Loss of Control of Suspended Load – Credible Scenarios

The identified outcome of this MEE is a loss of containment of hydrocarbons due to impact of a dropped object on topsides equipment or subsea pipelines resulting in a release of the hydrocarbon inventory to the atmosphere or the marine environment.

Decision Type, Risk Analysis and ALARP Tools

Woodside has a good history of implementing industry standard practice in subsea system design and construction. In the company's recent history, it has not experienced any loss of suspended load events that have resulted in significant releases or significant environmental impacts.

Decision Type

Decision Type B has been applied to this risk under the Guidance on Risk Related Decision Making (Oil and Gas UK, 2014). This reflects the complexity of the risk, the higher potential consequence and stakeholder implications should the event be realised. To align with this decision type, a further level of analysis has been applied using risk-based tools including the bowtie methodology (described in Section 2.7.3) and hydrocarbon spill trajectory modelling. Company and societal values were also considered in the demonstration of ALARP and acceptability, considered through internal reviews, and stakeholder consultation (Section 5).

A loss of control of a suspended load is considered an MEE (MEE-05). The hazard associated with this MEE is the hydrocarbon inventory of flowlines and risers, or topsides process and non-process hydrocarbons.

Quantitative Spill Risk Assessment

The credible worst-case hydrocarbon scenario for MEE-02 is considered to apply to a loss of control of suspended load, as they may credibly arise from damage to hydrocarbon containing subsea infrastructure within the 500 m PSZ. A quantitative spill risk assessment was not conducted for the topsides loss of containment scenario due to the relatively small credible release volume. Potential escalation events are considered and previously discussed in Section 6.8.5 Loss of Structural Integrity.

Likelihood

In accordance with the Woodside Risk Matrix a likelihood rating of "Highly Unlikely" is assigned for potential environmental consequences from loss of containment events caused by dropped objects. Formal safety assessment studies considered the frequency of dropped objects from platform into sea with potential impaction to flowline or export pipeline being limited to 1.0E-05 per year, or 1 in 100,000 years. This aligns with an experience-based likelihood assessment as it 'has occurred once or twice in the industry' and is considered appropriate also for hydrocarbon release from topsides equipment to the marine environment and atmosphere, due to the nature of topsides infrastructure, containment storage design and locations, and lifting protocols in place.

Consequence

The spatial extent and fate (including weathering) of the spilled hydrocarbons were considered during the impact assessment for a loss of control of suspended load. These considerations were informed primarily by the outputs from the numerical modelling studies undertaken by RPS, available information on environmental sensitivities that may credibly be impacted in the event of a worst-case spill, and relevant literature and studies considering the effects of hydrocarbon exposure. Refer to Section 6.8.4 (MEE-02) and Section 6.9.2 for a description of the consequence potentially resulting from subsea and topsides loss of containment scenarios, respectively – as applicable worse-case outcomes from loss of control of suspended load events.

Benthic Disturbance

In the unlikely event of an object being dropped into the marine environment, potential environmental effects would be limited to slight physical impacts on benthic communities. In most cases, objects will be able to be recovered and therefore these impacts will also be temporary in nature. However, there may be instances where objects are unable to be recovered due to health and safety, operational constraints or other factors such as the difficulty of recovering dropped objects at depth. When dropped objects are unable to be recovered, the impact will continue to be slight but permanent.

MEE-05 Loss of Control of Suspended Load from Platform – Risk Analysis

A bowtie risk analysis was undertaken to assess MEE-05; refer to the below figures for bowtie diagrams that were an output of Woodside's risk analysis process.

Risk Based Analysis

For risks identified as MEEs, a detailed risk-based Bowtie Analysis (as outlined in Section 2.7.3) has been used to identify, analyse and demonstrate that controls in place reduce the risk associated with each MEE to ALARP. Controls have been selected following hierarchy of control principles and consider independence of each barrier and their type of effect in controlling the hazardous event.

Application of Woodside's Risk Management Procedures and implementation of the Pluto A Operations Safety Case and Pluto Export Pipeline Safety Case ensures the continuous identification of hazards, systematic assessment of risks and ongoing assessment of alternative control measures to reduce risk to ALARP, which includes:

- ongoing hazard identification, risk assessment and the identification of control measures
- ongoing integrity management of hardware control measures in accordance with the operational performance standards which define requirements to be suitably maintained, such that they retain effectiveness, functionality, availability and survivability.

For each SCE, detailed requirements for equipment functionality, availability, reliability and survivability are incorporated into SCE Performance Standards which also include the relevant assurance tasks (e.g., inspection, maintenance, testing and monitoring requirements) to ensure technical integrity.

A bowtie analysis quantitative spill risk assessment was undertaken to assess MEE-05.

Company Values

Refer to Section 6.8.4 for a discussion of company values in relation to the pipeline and riser loss of containment scenario.

Societal Values

Refer to Section 6.8.4 for a discussion of societal values in relation to the pipeline and riser loss of containment scenario.

ALARP Statement:

On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts and risks of a highly unlikely likelihood unplanned hydrocarbon release as a result of a loss of control of suspended load.

The principle of inherent safety and environmental protection is based on the prevention of the MEE through design of structural integrity and impact protection, and lifting equipment and standards ensuring the systems are operated within their design envelope through operating practices and assurance through maintenance and inspection. If hydrocarbon loss of containment occurs, mitigation measures are in place to minimise the consequence by limiting the inventory which can be released and implementing remediation.

The controls in place for prevention and mitigation of MEEs are specified and assured through implementing the Safety Case(s) and SCE management procedures, including technical performance standards for SCEs and MSPSs for Safety Critical Procedures.

The application of Woodside Risk Management Procedures, and implementation of the Pluto Export Pipeline and Pluto A Operations Safety Cases ensures the continuous identification of hazards, systematic assessment of risks and ongoing assessment of alternative control measures to reduce risk to ALARP, which includes:

- ongoing hazard identification, risk assessment and the identification of control measures
- ongoing integrity management of hardware control measures in accordance with the SCE technical performance standards which define requirements to be suitably maintained, such that they retain effectiveness, functionality, availability and survivability.

Given the controls in place to prevent and control loss of containment events and mitigate their consequences, alongside procedural control of facility operations, it is considered that MEE risk associated with a loss of control of suspended load is managed to ALARP.

MEE-05 Loss of Control of Suspended Load from Platform – Demonstration of ALARP ALARP Control Measures				
Hierarchy	***Control/Barrier***	***SCE/Management System Reference***	***Type of Effect***	***Control Adopted***
Demonstration of Acceptability				
Acceptability Statement: Loss of suspended load has been evaluated as having a 'moderate' level of risk rating. As per Section 2.2.1., Woodside considers 'moderate' risk ratings as broadly acceptable if the adopted controls are implemented. Due to the consequence associated with MEE-05, Decision Type B has been applied, and ALARP is demonstrated using good industry practice, consideration of company and societal values and risk-based analysis, if legislative requirements are met and societal concerns are accounted for and the alternative control measures are grossly disproportionate to the benefit gained. Acceptability is demonstrated with regard to the oil spill risk considerations as described in Section 6.8.3 (MEE-01) (the considerations include principles of Ecologically Sustainable Development, internal context, external context and other requirements (includes laws, policies, standards and conventions).

Pluto: Major Environment Event Datasheet	
MEE Number	All
Hazard Description	Generic Human Errors

Hazard Description

Hazard Overview and Scope

There are a number of causes of human errors which contribute to MEEs, or which can result in failure or degradation of the barriers in place to protect against MEEs. These are presented in the following bowtie pages and include:

- task issues; e.g., poor task design; time pressures, task complexity
- poor physical interfaces/working environment
- provision of inappropriate tools for the task
- communication errors; i.e., poor-quality information, lack of clarity in instructions
- operator failings; e.g., competence, fitness, impairment or fatigue
- organisational issues; e.g., peer pressure, poor safety culture, inadequate supervision, lack of clarity on roles and expectations.

The generic Human Error bowtie illustrates the causes, outcomes and the barriers in place for these failure mechanisms. Human Errors are managed solely via the WMS (no SCEs) and the bowtie is included in this section for completeness. Refer to Section 7 Implementation Strategy for applicable WMS procedures.

Xena-03 Drilling and Tie-back Activities – Section 3.11	Physical Environment – Section 4.4 Habitats and Biological Communities – Section 4.5 Protected Species – Section 4.6 Protected Places – Section 4.8 Socio-economic Environment – Section 4.9	Consultation – Section 5

Impacts and Risks Evaluation Summary

Source of Risk	***Environmental Value Potentially Impacted***						***Evaluation***						
	Marine Sediment	Water Quality	Air Quality (incl Odour)	Ecosystems/Habitat	Species	Socio-economic	Decision Type	Consequence / Impact	Likelihood	Risk Rating	ALARP Tools	Acceptability	Outcome
Loss of hydrocarbons to marine environment due to loss of well containment during drilling of the Xena-03 well	x	x	x	x	x	x	B	B	1	M	LCS GP PJ RBA CV SV	Acceptable if ALARP	EPO 18

Description of Source of Risk

Woodside has identified a subsea well blowout as the scenario with the worst-case credible environmental outcome as a result of loss of well containment (LOWC) during drilling of the Xena-03 well. A LOWC is an uncontrolled release of reservoir hydrocarbon and/or other well fluids to the environment. A blowout is an incident where formation fluid flows out of the well or between formation layers after all the predefined technical well barriers (e.g. the blow out preventer [BOP]) or activation of the same has failed. Woodside has identified one well blowout scenario:

- well blowout – full reservoir open to flow in the 9-7/8" hole section.

The LOWC MEE scenario from all Pluto wells during operations is considered separately.

Industry Experience

A risk assessment by AMSA of oil spills in Australian ports and waters (Det Norske Veritas, 2011) concluded that:

- overall national exceedance frequency for oil spills from offshore drilling in Australia is 0.033 for spills >1 tonne/year decreasing to 0.008 for spills >100 tonnes/year
- probability of a blow-out from a well intervention is 1 x 10-4 (0.0001, or 0.01%), considerably lower than drilling activities (International Association of Oil and Gas Producers, 2010).

Woodside has a good history of implementing industry standard practice in well design and construction. In the company's history, it has not experienced any well containment events that have resulted in significant releases or significant environmental impacts.

Credible Scenario – Loss of Well Containment

The credible worst-case scenario to be considered during drilling of the Xena-03 well is an uncontrolled subsea release to environment lasting <64 days. This timeframe has been selected because:

- the Mutual Aid Memorandum of Understanding informed a likely relief well drilling and response time following the Montara well loss of containment in 2009 (77 days)
- internal Woodside guidelines and procedures indicate that appropriate modelling and response times for well based spill scenarios is reservoir-specific, and reliant on drilling times.

Quantitative Hydrocarbon Spill Modelling – Loss of Well Containment During Drilling at Xena-03

Spill modelling was undertaken by RPS (2024a), on behalf of Woodside, to determine the fate of hydrocarbon released from the loss of well containment scenario, based on the Xena condensate characteristics. The modelled release rate provided assumes the worst-case scenario for the largest oil volume release. Modelling considered metocean conditions throughout the year; this was done to inform the determination of consequence of loss of well control during intervention at any time of the year.

Table 6-44: Summary of modelled credible scenario – well blowout

Loss of Well Integrity	
Total discharge[126] at surface	5 days 1880 Sm^3
Total discharge at seabed	59 days 44,751 Sm^3
Water depth	178 m
Fluid	Eris-1 (and Pluto analogues) condensate

Subsea Plume dynamics

The well blowout surface/subsea release that has been modelled forecasts the size of the hydrocarbon droplets that would be released from the well as determined by the OILMAP model. The results of the OILMAP simulation predict that the discharge will generate a cone of rising gas that will entrain the oil droplets and ambient sea water up to the water surface. In the first week, the mixed plume is initially forecast to jet towards the water surface with a vertical velocity of around 12.3 m/s, gradually slowing and increasing in plume diameter as more ambient water is entrained. The diameter of the central cone of rising water and oil at the point of surfacing is predicted to be about 23 m.

Given the discharge velocity and turbulence generated by the expanding gas plume, the release is predicted to generate droplet sizes ranging from approximately 2500 µm to 12,884 µm. The results suggest that beyond the immediate vicinity of the blowout, the majority of the released hydrocarbons will be present in the upper layers of the ocean, with the potential for oil to form floating slicks under sufficiently calm local wind conditions.

The ongoing nature of the release combined with the potential for the plume to breach the water surface may present other hazards, including conditions that may lead to high local concentrations of atmospheric volatiles. These issues should be considered when evaluating the practicality of the response operations at or near the blowout site.

Consequence Assessment

Potential Impacts Overview

EMBA

Quantitative hydrocarbon spill modelling results have been used to define the EMBA (Section 4.1) (see RPS, 2024a for further details).

Surface Hydrocarbons

In the event of the loss of well containment scenario occurring, surface hydrocarbons at or above 1 g/m^2 and 10 g/m^2 are forecast to potentially occur up to 100 km and 25 km respectively from the release site. Floating oil concentrations greater than 10 g/m^2 are predicted to contact Montebello AMP at 2% probability.

Entrained Hydrocarbons

Entrained hydrocarbons at concentrations equal to or greater than the 100 ppb threshold are predicted to be found up to 600 km from the release site. Contact by entrained hydrocarbons at concentrations equal to or greater than 100 ppb is predicted to be greatest at Montebello AMP with 81% probability of hydrocarbon contact and worst-case entrained

[126] The discharge volumes are predicted using reservoir modelling software packages that consider a number of factors (well design, reservoir properties and environmental conditions such as water depth, temperature and pressure) to provide a production profile over the oil spill modelling period.

concentration of 1960 ppb. Several other sensitive receptors are predicted to be contacted at concentrations equal to or greater than 100 ppb include Tryal Rocks (4%), Argo-Rowley Terrace MP (1%), and Gascoyne MP (5%).

Dissolved Hydrocarbons

Dissolved aromatic hydrocarbons at concentrations equal to or greater than the 50 ppb thresholds are predicted to be found up to around 45 km from the release site. Contact by dissolved aromatic hydrocarbons at concentrations equal to or greater than 50 ppb is predicted to be at the Montebello AMP (5%), with a worst-case dissolved concentration of 454 ppb.

Accumulated Hydrocarbons

Shoreline oil concentrations above 10 g/m² are predicted to contact Muiron Islands with 18% probability. No shoreline oil impact is predicted at 100 g/m².

Table 6-45: Key receptor locations and sensitivities potentially contacted above impact thresholds by the loss of well containment scenario during drilling of Xena-03 with summary hydrocarbon spill contact with ≥ 1% probability (table cell values correspond to probability of contact [%])

Summary of Potential Impacts to Environmental Values

The potential impacts of spilled hydrocarbons to species (protected and otherwise), marine primary producers, other habitats and communities, water quality, marine sediment quality, air quality, protected areas and socio-economic values are described in Section 6.8.3. Potential impacts specific the loss of well containment during drilling of the Xena-03 well are summarised below.

Marine Mammals

A range of cetaceans were identified as potentially occurring within the Xena-03 Operational Area and wider EMBA (Section **Error! Reference source not found.**). In the event of a LOWC during drilling of Xena-03, surface, entrained, and dissolved hydrocarbons exceeding environmental impact threshold concentrations may drift across habitat for cetacean species. Migratory routes and BIAs of cetaceans considered to be MNES may be affected, including humpback whales and PBW (northbound and southbound migrations). As described in Section **Error! Reference source not found.**, cetaceans that have direct physical contact with surface, entrained, or dissolved aromatic hydrocarbons may suffer surface fouling, ingestion of hydrocarbons (from prey, water and sediments), aspiration of oily water or droplets, and inhalation of toxic vapours (Deepwater Horizon Natural Resource Damage Assessment Trustees [DHNRDT], 2016).

PBW and humpback whales are known to migrate seasonally through the Xena-03 Operational Area, the PAA and the modelled EMBA. Pygmy blue whale migration BIA intersects the Xena-03 Operational Area. A major spill in May to November would coincide with humpback whale migration through the waters off the Pilbara and North West Cape (Section **Error! Reference source not found.**). A major spill in April–August or October would coincide with pygmy blue whale migration (Section 4.6.5). Both pygmy blue and humpback whales are baleen whales, so are most likely to be significantly impacted by toxic effects when feeding. However, feeding during migrations is low level and opportunistic, with most feeding for both species occurring in the Southern Ocean. Fresh hydrocarbons (i.e., typically in the vicinity of the release location) may have a higher potential to cause toxic effects when ingested, while weathered hydrocarbons are considered to be less likely to result in toxic effects. As such, the risk of ingestion of hydrocarbons is low. Pygmy blue whale and humpback whale migrations are protracted through time and space (i.e., the whole population will not be within the EMBA), and as such, a spill from the loss of well integrity is unlikely to affect an entire population.

Coastal populations of small cetaceans and dugongs are known to reside or frequent nearshore waters, including the Ningaloo Coast, Muiron Islands, Montebello/Barrow Islands and Pilbara Southern Island Group which may be potentially impacted by entrained or dissolved hydrocarbons exceeding threshold concentrations in the event of a loss of well containment. The Exmouth Gulf is a known humpback whale aggregation area on the annual southern migration (September to December), as well as overlapping foraging, breeding, nursing and calving BIAs for dugongs (~207 km south of the Xena-03 Operational Area).; therefore, migratory humpbacks moving into the Gulf, or more residential dugongs, may be exposed to entrained or dissolved hydrocarbons above thresholds levels. However, entrained and dissolved hydrocarbons concentrations above the threshold are not expected within Exmouth Gulf itself. No hydrocarbon contact at or above threshold concentrations for the ecological EMBA is expected for Camden Sound, an important calving area for humpback whales.

The potential impacts of exposure are discussed above. However, nearshore populations of cetaceans and dugongs are known to exhibit site fidelity and are often resident populations. Therefore, avoidance behaviour may have greater impacts to population functioning. Nearshore dolphin species (e.g., spotted bottlenose dolphins) may exhibit higher site fidelity than oceanic species, although Geraci (1988) observed relatively little impacts beyond behavioural disturbance. Additional potential environment impacts may also include the potential for dugongs to ingest hydrocarbons when feeding on oiled seagrass stands, or indirect impacts to dugongs due to loss of this food source due to dieback in worst-affected areas.

In summary, a LOWC during drilling of Xena-03 has the potential to result in major long-term impacts to cetacean species and dugongs, with consequence severity dependent on the actual timing, duration and extent of a spill in relation to species' migratory movements and distributions.

Marine Reptiles

The Xena-03 Operational Area is unlikely to represent an important habitat for marine turtles as there is an absence of potential nesting or foraging habitat (i.e., no emergent islands, reef habitat or shallow shoals) and the water is deep (70–130 m). There is the potential for marine turtles to be present at submerged shoals within the EMBA, such as Rankin Bank and Glomar Shoals, however these receptors have a low probability of being contacted by dissolved hydrocarbons only above the threshold concentration (<1%).

An internesting BIA for the flatback turtle overlaps the Xena-03 Operational Area (Section 4.6.2). However, there are significant nesting and foraging sites along the mainland coast and islands of the region, including the Montebello Islands, and a number of BIAs and habitat critical for the survival of marine turtles overlap the EMBA (Section 4.6.2). In particular, the internesting BIAs and habitat critical to the survival of a species for green, loggerhead and hawksbill turtles extend for ~20 km from known nesting locations, and for ~60 km for flatback turtles. It is noted that the drilling of the Xena-03 well is proposed to be undertaken in Q2 2025, indicating species may be present, however avoids the peak nesting period (October to January) (refer to Section 4.6.5). Oil from an ongoing loss of containment could be present during nesting season for all hawksbill, flatback and green turtles depending on the timing of a spill. No floating or accumulated hydrocarbons above ecological threshold concentrations are predicted at shoreline locations,

although the nearshore waters of these turtle habitat areas have a low probability (1 to 2%) of contact with dissolved and/or entrained hydrocarbons.

In summary, a LOWC during drilling of Xena-03 has the potential to result in major long-term impacts to offshore foraging and nesting marine turtles, with consequence severity dependent on the actual timing, duration and extent of a spill in relation to species' migratory movements and distributions.

In general, sea snakes are found in continental shelf waters around offshore islands and potentially submerged shoals (water depths <100 m. Sea snakes may be present in the wider EMBA at the submerged shoals, Rankin Bank and Glomar Shoals, as well as the submerged reefs and shoals of Barrow Island and southern Pilbara islands. Sea snakes may also be present in nearshore waters of the mainland and islands which, along with submerged reefs and shoals, have the potential to be contacted by entrained and/or dissolved hydrocarbons above the threshold concentrations. Their abundance is not expected to by high given the water depth and offshore environment. However, sea snake species in Australia generally show strong habitat preferences (Heatwole and Cogger, 1993); species that have preferred habitats associated with submerged shoals may be disproportionally affects by a hydrocarbon spill affecting such habitat.

Therefore, a loss of well containment during drilling of Xena-03 may have a minor disruption to some individuals in the offshore environment. Population level impacts to sea snake species are not, however, considered credible.

Fish, Sharks and Rays

Shark and ray species may occasionally transit through the area and may potentially be exposed to hydrocarbons from a loss of well containment during drilling of the Xena-03 well, including species such as whale sharks and manta rays. Whale sharks may transit offshore open waters when migrating to and from Ningaloo Reef, where they aggregate for feeding from March to July. Both the Xena-03 Operational Area and the EMBA overlap the whale shark foraging BIA identified in Section 4.6.1. Should sharks or rays be present in offshore waters near the PAA during the spill, direct impacts may occur if foraging within surface slicks or in the upper 20 to 30 m of the water column containing entrained hydrocarbons and dissolved aromatics. Contamination of their food supply and the subsequent ingestion of this prey may also result in long term impacts as a result of bioaccumulation. Impacts are predicted to be limited to a small number of animals given the absence of key habitat and the low numbers of animals that may transit through the area during the short period when spilled hydrocarbons are present.

Seabirds and Migratory Shorebirds

Offshore waters of the PAA are potential foraging grounds for seabirds associated with the coastal roosting and nesting habitat (e.g., Ningaloo, Muiron Islands and the Barrow/Montebello Islands). A breeding BIA for the wedge-tailed shearwater overlaps the Xena-03 Operational Area. Foraging and breeding BIAs for a number of seabirds and migratory shorebirds overlap with the EMBA (Section **Error! Reference source not found.**). A hydrocarbon spill may result in surface slicks disrupting a significant portion of the foraging habitat for seabirds, including foraging BIAs, which are generally associated with breeding habitats. Seabird distributions are typically concentrated around islands, so hydrocarbons near nesting/roosting areas may result in increased numbers of seabirds being impacted, with many species of seabirds, such as the wedge-tailed shearwater and the various species of tern, foraging relatively close to breeding islands/colonies. Potential impacts on seabirds and shorebirds are expected to be major and long-term in the unlikely event of a loss of well control. However, given the volatile and non-persistent nature of the hydrocarbons and lack of shoreline accumulation predicted, the extent of impacts is not expected to result in a threat to the overall viability of seabird or shorebird populations in the wider region.

Other Habitats, Species and Communities

There is potential for plankton communities to be impacted where entrained hydrocarbon threshold concentrations are exceeded due to a loss of well containment during drilling of the Xena-03 well. A range of lethal and sublethal impacts may occur to plankton exposed to entrained or dissolved hydrocarbons within the EMBA. Communities are expected to recover quickly (weeks/months) due to high population turnover (ITOPF, 2011). It is therefore considered that any potential impacts would be low magnitude and temporary in nature.

Pelagic fish populations in the open water offshore environment of the EMBA are highly mobile and have the ability to move away from a marine diesel spill. It is therefore unlikely that fish populations would be exposed to widespread hydrocarbon contamination. Pelagic fish populations are distributed over a wide geographical area so impacts on populations or species level are considered to be limited. Combined with these factors and the rapid dispersion of condensate, it is considered that any potential impacts will be minor.

Other communities (e.g., demersal fish, benthic infauna and epifauna) and key sensitivities (e.g., KEFs identified in Section 4.7) occur within the EMBA and may potentially be exposed to entrained hydrocarbons from a loss of well containment.

Water Quality

It is likely that water quality will be reduced at the release location of the spill; however, such impacts to water quality would be temporary and localised in nature due to the rapid dispersion and weathering of condensate. The potential impact is therefore expected to be low.

Protected Areas

Entrained and/or dissolved hydrocarbons at or exceeding the 100 ppb and 50 ppb threshold, respectively, have a low probability of contacting the Argo-Rowley Terrace AMP, Montebello AMP, Gascoyne AMP and Ningaloo AMP and

WHA. Entrained and dissolved hydrocarbons are only predicted within the surface waters of the deep open waters of these protected areas, with no contact to seabed habitats or to shoreline contact. Potential impacts to water quality and the natural values (e.g., mobile protected species) in these areas would be temporary and localised in nature due to the rapid dispersion and weathering of the condensate, as described above. Visible surface hydrocarbons (at or exceeding 1 g/m² are not predicted to reach any protected areas.

Socio-economic

A spill resulting from a loss of well containment during drilling of the Xena-03 well is considered unlikely to cause significant direct impacts on the target species fished by Commonwealth State active fisheries identified in Section 4.10.1 which overlap with the EMBA. The fisheries management areas that overlap with the EMBA are predominantly for demersal fish species (demersal finfish and crustaceans) that inhabit waters in the range of >60 to 200 m depth, or pelagic species which are highly mobile. Therefore, a spill from a loss of well control is expected to only result in negligible impacts, considering that hydrocarbons are confined to the upper layers of the water column beyond the immediate area of the spill. Visible surface hydrocarbons at or exceeding 1 g/m² may also occur up to 100 km from the release site, which may result in fouling of fishing gear and a perception of impacts to fish stocks by fisheries stakeholders and the public. There is the potential that a fishing exclusion zone would be applied in the area of the spill, which would put a temporary ban on fishing activities and therefore potentially lead to subsequent economic impacts on commercial fishing operators if they were planning to fish within the area of the spill. Such measures would likely be in place for less than a week and would not result in widespread or long term impacts to fishing activities.

Cultural Heritage

There are a number of historic shipwrecks identified within the EMBA, but none identified within 50 km of the PAA (Section 4.10).

The modelling results do not predict surface slicks contacting the identified wrecks, and the majority of entrained hydrocarbons are expected to occur close to the surface. However, shipwrecks in the subtidal zone could be exposed to entrained and dissolved hydrocarbons. Marine life that shelter and take refuge in and around these wrecks may be affected by in-water toxicity of dispersed hydrocarbons. The consequences of such hydrocarbon exposure may include large fish species moving away and resident fish species and sessile benthos such as hard corals exhibiting sub-lethal and lethal impacts (which may range from physiological issues to mortality).

Within the wider EMBA are several designated heritage places (Section 4.10). These places are also covered by other designations such as WHA. Potential impacts are discussed in the sections above.

Summary of Potential Impacts to Environmental Values

In the highly unlikely event of a major hydrocarbon spill due to a loss of well containment during drilling of the Xena-03 well, the EMBA includes AMPs as well as other sensitive marine environments and associated receptors of the Muiron Islands, Ningaloo Coast, Rankin Bank, Montebello/Barrow Islands and the Pilbara Southern Islands Group. Long term impacts may occur at these locations, including socio-cultural effects as a result of a major spill of condensate from drilling activities within the PAA.

Given the adopted controls, the overall risk rating for an unplanned hydrocarbon due to a loss of well containment during drilling of the Xena-03 well is Moderate based on a Major consequence (long-term impact (10–50 years) on highly valued ecosystem, species, habitat or physical or biological attributes, or to a community, social infrastructure or highly valued area/item of cultural significance), and a remote likelihood.

Risk Based Analysis				
A quantitative spill risk assessment was performed (refer Section 6.8.2).				
Company Values				
Woodside's corporate values require all personnel to comply with appropriate policies, standards, procedures and processes while being accountable for their actions and holding others to account in line with Our Values. As detailed above, the PAP will be performed in line with these policies, standards and procedures that include suitable controls to prevent loss of well integrity, and response should a loss of well integrity occur.				
Societal Values				
Due to the Petroleum Activities Program's potential extent of the EMBA, the loss of well integrity current risk rating presents a Decision Type B, in accordance with the decision support framework described in Section 2.6.1. Consultation was conducted for this program to identify the views and concerns of relevant persons, as described in Section 5. Woodside has consulted with AMSA and WA DoT on spill response strategies. A copy of the Oil Pollution First Strike Plan was provided to AMSA and DoT.				
ALARP Statement On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type (i.e., Decision Type B, Section 2.6.1), Woodside considers the adopted controls appropriate to manage the risks and consequences of a highly unlikely unplanned hydrocarbon release as a result of a loss of well integrity. As no reasonable additional/alternative controls were identified that would further reduce the risks and consequences without grossly disproportionate sacrifice, the risks and consequences are considered ALARP.				

Demonstration of Acceptability

Acceptability Criteria and Assessment

Loss of well integrity during drilling of the Xena-03 well was evaluated and the risk was rated as high due to the scale of potential environmental impacts. However, the loss of well integrity occurring is considered highly unlikely. As outlined in Section 2.6.1, Woodside considers the current risk ratings for a Decision Type B to be acceptable, if ALARP is demonstrated using good industry practice, consideration of company and societal values and RBA, if legislative requirements are met and societal concerns are accounted for, and the alternative control measures are grossly disproportionate to the benefit gained.

Principles of Ecologically Sustainable Development

The impact and risk evaluation has taken into account the relevant principles of ESDev:

- Decision-making processes should effectively integrate both long-term and short-term economic, environmental, social and equitable considerations.
- The principle of inter-generational equity: the present generation should ensure that the health, diversity and productivity of the environment is maintained or enhanced for the benefit of future generations.
- The conservation of biological diversity and ecological integrity should be a fundamental consideration in decision-making.

Internal Context

The PAP is consistent with Woodside corporate policies, culture, processes, standards, structure and systems as outlined in the Demonstration of ALARP and Environmental Performance Outcomes, including:

- Woodside Environment and Biodiversity Policy
- Engineering Standards – Well Barriers
- Well Acceptance Criteria Procedure
- Global, Wells and Seismic – Well Control Procedure
- Woodside Engineering Standard – Rig Equipment
- Source Control Emergency Response Planning Guideline (SCERP Guidelines).

Oil spill preparedness and response strategies are considered applicable to the nature and scale of the risk and associated impacts of the response are reduced to ALARP.

Monitoring and Evaluation (operational monitoring) as a key response in the highly unlikely event of a hydrocarbon release will assess and track the extent of the hydrocarbon contact and revise the predicted extent of impact.

In addition, the Planning Area for scientific monitoring can be re-assessed in the unlikely event of hydrocarbon release with consideration of the conservation values and social-cultural values of state and commonwealth protected areas (including AMPs), National and Commonwealth Heritage Listed places; tourism and recreation; and fisheries. The post-response SMP will consider assessment and monitoring in line with the affected receptors such as habitat and species, AMPs and fisheries. Woodside corporate values include working sustainably with respect to the environment and communities in which we operate, listening to internal and external stakeholders, and considering HSE when making decisions. consultation, outlined below, has been performed prior to the Petroleum Activities Program.

External Context

During consultation with relevant persons, DoT requested to be consulted on spill risks with a potential to impact State Waters (Section 5). Woodside has also consulted with AMSA on spill response strategies. IA copy of the Oil Pollution First Strike Plan was provided to AMSA and DoT. No additional queries or concerns relating to a loss of well integrity hydrocarbon spill risk during drilling of the Xena-03 well were raised during consultation.

Other Requirements

Impact assessment has been informed by risk-based analysis, including hydrocarbon spill modelling. The proposed control measures are consistent with industry legislation, codes and standards, good practice and professional judgement, including:

- API Standard 53 for Subsea BOP Function Testing.
- AEP (Australian Energy Producers) Memorandum of Understanding: Mutual Assistance for relief well drilling is in place. Woodside develops an activity SCERP, including the Relief Well Plan, which is signed off by the Drilling Engineering Manager and maintains a list of rigs that are currently operating in Australia.
- OPGGS (Resource Management and Administration) Regulations 2011 mandate to have an accepted WOMP and application to permanently plug for abandonment of the wells.
- NOPSEMA will be notified of reportable and recordable incidents, if required (Section 7). A Mutual Aid MoU for relief well drilling is in place and the Woodside Head of Projects/Region (Global Wells and Seismic) maintains a list of rigs that are currently operating in WA.

The EMBA overlaps a number of BIAs for threatened and migratory species, as well as a number of State and Commonwealth MPAs and the Ningaloo Coast WHA. The residual risk of accidental hydrocarbon release from loss of

well integrity during drilling of the Xena-03 well is not inconsistent with the relevant objectives and actions of any applicable recovery plans or threat abatement plans. Regard has been given to relevant conservation advice and wildlife conservation plans during the assessment of potential impacts. The PAP is not considered to be inconsistent with the overall recovery objectives and actions of these recovery plans and conservation advice.

Acceptability Statement:

The impact assessment has determined that an accidental hydrocarbon release as a result of a loss of well integrity represents a moderate current risk rating and may result in major, long-term impacts (10–50 years) on highly valued ecosystems, species, habitat or physical or biological attributes. A number of BIAs for protected species overlap with the BIA and EMBA. Relevant recovery plans and conservation advice have been considered during the impact assessment, and the PAP is not considered to be inconsistent with the overall recovery objectives and actions of these recovery plans and conservation advice.

The likelihood of a loss of well integrity during drilling of the Xena-03 well occurring is highly unlikely, given the adopted controls. The adopted controls are considered consistent with industry legislation, codes and standards, and professional judgement and a risk-based assessment has been conducted to better understand the potential consequences and plan oil spill response. The adopted controls also meet the requirements and expectations of Australian Marine Orders, AMSA and AHO identified during impact assessment and consultation. As demonstrated in Section 6.10, the potential impacts of hydrocarbon release from loss of well integrity is not inconsistent with the relevant objectives and actions of any applicable recovery plans or threat abatement plans. Regard has been given to relevant conservation advice during the assessment of potential risks.

On the basis of the environmental impact assessment outcomes and Woodside's criteria for acceptability outlined in Section 2.8.2, this is considered an acceptable level of risk.

	C 18.4 An approved SCERP shall exist prior to drilling the well, including feasibility and any specific considerations for relief well kick.	**PS 18.4** The SCERP is in place to ensure feasibility of responding to a source control incident.	**MC 18.4.1** An approved Source Control Emergency Response Plan.
	C 10.6 Subsea BOP installed and tested during drilling operations. The BOP shall include: • one annular preventer • two pipe rams (excluding the test rams) • a minimum of two sets of shear rams, one of which must be capable of sealing • deadman functionality • the capability of ROV intervention • independent power systems.	**PS 10.6** Subsea BOP specification, installation and testing compliant with internal Woodside Standards and international requirements (API Standard 53 5th Edition) as agreed by Woodside and MODU contractor.	**MC 10.6.1** Records demonstrate that BOP and BOP control system specifications and testing were in accordance with minimum standards for the expected drilling conditions as agreed by Woodside and MODU contractor.
	C 2.6 Project-specific MODU Mooring Design Analysis.	**PS 2.6** Seabed disturbance from MODU mooring limited to that required to ensure adequate MODU station holding capacity.	**MC 2.6.1** Records demonstrate Mooring Design Analysis approved and implemented during anchor deployment.
	Detailed preparedness and response performance outcomes, standards and measurement criteria for the PAP are presented in Appendix H.		

6.9.2 Unplanned Hydrocarbon Release: Pluto-A Topsides Loss of Containment

Context		
Topsides – Section 3.4.1 Process Description – Section 3.5.4 Hydrocarbon and Chemical Inventories and Selection – Section 3.9	Physical Environment – Section 4.4 Protected Species – Section 4.6	Consultation – Section 5

Impacts and Risks Evaluation Summary

Source of Risk	***Environmental Value Potentially Impacted***							***Evaluation***						
	Soil and Groundwater	Marine Sediment	Water Quality	Air Quality (incl Odour)	Ecosystems/Habitat	Species	Socio-economic	Decision Type	Consequence/Impact	Likelihood	Risk Rating	ALARP Tool	Broadly Acceptable Acceptability	Outcome
Hydrocarbon release from Pluto-A topsides equipment to the marine environment and atmosphere			x	x		x	x	A	D	1	M	LCS GP PJ		EPO 19

Description of Source of Risk

The facility has a range of topsides process and non-process equipment. A loss of containment from the topsides includes hydrocarbon inventories that could be released to the environment from high pressure process gas equipment and piping manifolds, and non-process hydrocarbon and chemical inventories.

Hazards that could lead to loss of containment from the topsides are:

- corrosion
- erosion
- material defect
- welding defect
- piping/equipment repair/defect
- vibration fatigue failure
- equipment overpressure
- uncontrolled transfer.

Escalation from MEEs can cause topsides loss of containment, specifically:

- loss of structural integrity (MEE-03) (Section 6.8.5)
- loss of marine vessel separation (MEE-04) (Section 6.8.6)
- loss of control of suspended load from facility lifting operations (MEE-05) (Section 6.8.7).

A number of common failure causes due to human error and SCC failures are presented in the generic Human Error and SCE Failure bowties in Section 6.8.8.

Topsides Loss of Containment – Credible Scenarios

Topsides process and non-process hydrocarbon inventories, and therefore, worst case credible spill scenarios, are relatively low for PLA riser platform in comparison to other offshore facilities, due to reservoir composition and the integrated Pluto Development design, including NNC offshore philosophy, meaning limited offshore processing and storage inventory. The maximum credible process-hydrocarbon loss scenario includes the loss of the potential condensate inventory within process vessels such as the production separator and produced water/condensate separator and cooler with potential ~30 m^3 condensate inventory. The maximum potential non-process hydrocarbons loss of containment scenario on the topsides is associated with the largest diesel storage inventory in the crane

pedestal storage tank (80 m³). While a number of hydrocarbon release scenarios were determined to constitute MEEs, the consequence assessment for a topsides loss of containment determined this source of risk is not an MEE.

Other smaller condensate and hydrocarbon inventories also present on the topsides (Section 3.4.1). Smaller volumes of stored diesel, hydraulic and lube oils and waste oil may also be released in case of loss of containment. While a number of hydrocarbon release scenarios were determined to constitute MEEs, the consequence assessment for a topsides loss of containment determined this source of risk is not an MEE.

Quantitative Hydrocarbon Risk Assessment

Spill modelling was performed by RPS, on behalf of Woodside to determine the fate of marine diesel (modelled as marine gas oil) released from loss of marine vessel separation within the PAA (RPS, 2024e) – as described in Section 6.8.6. The modelling assessed the extent of a marine diesel spill volume of 1000 m³ for all seasons, using an historic sample of wind and current data for the region. The results of the modelling can be used to demonstrate that a marine diesel spill within the PAA has an EMBA that is not predicted to include any shoreline contact or accumulation at impact thresholds. A total of 200 replicate simulations were modelled over an annual period (50 per quarter). As stated above, the largest topsides loss of containment diesel storage tank volume is 80 m³; therefore, the modelling of 1000 m³ is considered conservative for Topsides loss of containment scenarios. Historical spill risk assessment modelling undertaken for a smaller diesel spill (105 m³ released in under ten minutes) at the Greater Western Flank Project (GWF) location near the GWA facility, located 75 km north-east of the facility (APASA, 2016) also provides as an approximate analogue for the topside loss of containment scenario – which indicated floating hydrocarbons may occur above threshold criteria up to 10 km from the release site.

Hydrocarbon Characteristics

Marine diesel oil (MDO) is a mixture of both volatile and persistent hydrocarbons. Modelling conducted on a comparable marine gas oil (MGO) more typical of vessel fuel. Predicted weathering of marine diesel, based on typical conditions in the region, indicates that around 72% of the oil mass is forecast to have entrained and a further 24% is forecast to have evaporated over the first 24 hours (RPS, 2024e). After this time, the majority of the remaining hydrocarbon is entrained into the upper water column, leaving only a small proportion of the oil floating on the water surface (<1%). Given the large proportion of entrained oil and the tendency for it to remain mixed in the water column, the remaining hydrocarbons will decay and/or evaporate over time scales of several weeks to a few months, thereby extending the area of potential effect.

Given the environmental conditions experienced in the PAA, marine gas oil is expected to undergo rapid spreading and this, together with evaporative loss, is likely to result in a rapid dissipation of the spill. Marine gas oil distillates tend not to form emulsions at the temperatures found in the region. The characteristics of the marine gas oil are given in Section 6.8.2.

Consequence Assessment

Consequences associated with hydrocarbon release due to a topsides loss of containment event are similar, however, substantially more localised than consequences presented in this EP for diesel loss of containment events detailed in Section 6.8.6 Unplanned Hydrocarbon Release: Loss of Marine Vessel Separation (MEE-04) and Section 6.9.3 Unplanned Hydrocarbon Release: Vessel Collision During Drilling and Tie-back Activities

Once released to the open offshore setting around the riser platform (refer to Section 4), the potential for impacts to environmental receptors is limited to those in the open ocean, up to 10 km from the riser platform.

Given the density of the hydrocarbon, this decrease in water quality will be restricted to the top few metres of the water column. As such, impacts to demersal or benthic receptors (e.g., Ancient Coastline or continental slope demersal fish KEFs) are not considered credible.

Water Quality

There may be a minor short-term decrease in water quality in the immediate vicinity of the release location. The soluble fraction of condensate may cause acute toxic effects to planktonic organisms. Given the short generation times and high productivity of planktonic communities, this impact would be localised and have no lasting effect on planktonic species populations.

Air Quality

A topsides release of Pluto condensate may be potentially accompanied by release of a limited volume of methane and ethane released to atmosphere. The gas plume is expected to mix and disperse rapidly in the atmosphere. Hence, it has limited potential to impact fauna in the vicinity of the release location. Impacts, such as asphyxiation, would be highly localised and of no lasting effect to species populations.

Marine Fauna

A range of marine species may be present around the riser platform, such as cetaceans, marine turtles, whale sharks, fishes and birds. These species are widely distributed relative to the potential EMBA that would result from a topsides loss of containment (due to the relatively small volume of hydrocarbons compared to the scenarios considered in Section 6.8.6). Many large marine fauna in the region are migratory and are seasonally present in the PAA, which reduces the likelihood of exposure. Air breathing marine species may be impacted by the reduction in air quality (refer above); however, the potential for this impact is very limited. Marine fauna at or near the sea surface may be contacted by liquid-phase hydrocarbons, resulting in oiling. This may lead to impacts such as irritation of sensitive

mucous membranes (e.g., eyes, mouth and digestive tract), matting of feathers (leading to inability to fly and loss of insulation) or clogging of filtering structures (e.g., gills). Pelagic and site-attached fish (i.e., those resident around risers and jackets) may be exposed to spilled hydrocarbons, but are expected to avoid areas of high concentrations. Depending on the degree of exposure and the sensitivity of the receptor, these impacts may lead to injury or death. Mortality of larger fauna is not expected to occur. No impacts to ecosystem function are expected. Given the volatile nature of the hydrocarbons and the relatively small release volume, the potential for these impacts is largely constrained to the initial 12 hours immediately after the release. Hence, the potential impacts to species would be localised and of no lasting effect to species populations.

Socio-economic

Slight, short-term impacts may occur to other marine users (e.g., commercial fisheries); however, as the worst case marine diesel spill would weather rapidly, and there is already no fishing within PSZ and limited fishing within the PAA it is unlikely that there would be any significant impact to commercial fishers.

Summary

Given the adopted controls, the overall risk rating for an unplanned hydrocarbon due to a Pluto-A topsides loss of containment is Moderate based on a Minor consequence (short-term impact (one to two years) on species, habitat (but not affecting ecosystem function), physical or biological attribute, or to a community or highly valued area/item of cultural significance community), and a highly unlikely likelihood.

Demonstration of ALARP

While the loss of topsides containment does not constitute an MEE, it is considered to be a potential MAE in the Pluto A Operations Safety Case. As such, this source of risk is managed under the SCE management system (Section 7.4) for the facility. Specific measures and controls presented below are drawn from this management system.

Control Considered	Control Feasibility (F) and Cost/ Sacrifice (CS)	Benefit in Impact/Risk Reduction	Proportionality	Control Adopted
Legislation, Codes and Standards				
Offshore Petroleum and Greenhouse Gas Storage (Safety) Regulations 2009: Accepted Safety Case for the facility.	F: Yes. CS: Minimal cost. Standard practice.	Offshore Petroleum and Greenhouse Gas Storage (Safety) Regulations 2009: Accepted the Pluto A Operations Safety Case to: • identify hazards that have the potential to cause an MAE • detail assessment of MAE risks • describe the physical barriers SCEs and the safety management systems identified as being required to reduce the risk to personnel associated with an MAE to ALARP, thus contributing to management of associated potential environmental consequences of MAEs.	Control based on legislative requirements – must be adopted.	Yes C 14.4
Good Practice				
Incident reports are raised for unplanned releases within event reporting system.	F: Yes. CS: Minimal cost. Standard practice.	Good practice that operators identify, report and learn from unplanned release events. Supports compliance with regulatory reporting requirements.	Control based on Woodside standard and regulatory requirements – must be adopted.	Yes C 13.5

Professional Judgement – Elimination				
None identified beyond those integrated within PLA facility design.				
Professional Judgement – Substitute				
None identified beyond those integrated within PLA facility design.				
Professional Judgement – Engineered Solution				
Facility open hazardous and diesel drain system integrity maintained to contain potential spilled liquid hydrocarbon in areas as appropriate to safe integrated facility design.	F: Yes. The riser platform has been designed with an integral drains system (as practicable to suit NNC facility safety design requirements) to prevent escalation associated with hazardous inventories and support the appropriate containment of environmentally hazardous liquids. CS: Inherent feature of riser platform design ALARP. Some safety philosophy sacrifice.	Reduces the likelihood of environmental harm by: • limiting escalation of an incident following loss of containment, fire and/or explosion by removing or containing flammable liquid from hazardous areas supporting appropriate containment and disposal of environmentally hazardous liquids.	Benefits outweigh cost/sacrifice.	Yes C 6.3
Maintaining Safety Instrumented System (Safety Instrumented Functions and ESD actions) and valves to detect and respond to pre-defined initiating conditions, and/or initiating responses that put the process plant, equipment, and the wells in a safe condition to prevent or mitigate the effects of an MEE.	F: Yes. CS: Minimal cost. Standard practice.	Safety instrumented systems reduce the risk of topsides loss of containment by detecting and responding to pre-defined conditions and/or initiate responses that put the process plant and equipment in a safe condition so as to prevent or mitigate the effects of an MAE/MEE.	Benefits outweigh cost/sacrifice.	Yes C 13.3
Maintain topsides hydrocarbon-containing infrastructure integrity (P01 – Pressure Vessels, P04 Tanks).	F: Yes. CS: Minimal cost. Standard practice.	Reduces the likelihood of topsides loss of containment through inspection and assurance of key hydrocarbon containing vessels/tanks.	Benefits outweigh cost/sacrifice.	Yes C 19.1
Emergency Response				
Mitigation – Emergency and Hydrocarbon Spill Response	Standard practice to implementing management systems to maintain: • Pluto Offshore Facility Emergency Response Plan • Pluto Offshore Facility Oil Pollution First Strike Plan • Oil Pollution Emergency Arrangements – Australia. Refer to Appendix H: Oil Spill Preparedness and Response Mitigation Assessment for discussion around the ALARP assessment of controls related to hydrocarbon spill response.			

ALARP Statement:

The controls for the Topsides loss of containment are based on the controls similar to those identified for MEE-03, MEE-04 and MEE-05 (Sections 6.8.5 to 0) and are supported by specific measures presented in Section 7.2. On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the risks of a topsides loss of containment. As no reasonable additional/alternative controls were identified that would further reduce the consequences and risks without grossly disproportionate sacrifice, the risks are considered ALARP.

Demonstration of Acceptability

Acceptability Statement:

The consequence assessment has determined that, given the adopted controls, a highly unlikely worst case hydrocarbon release from topside loss of containment represent a Moderate risk rating. Consequences are unlikely to result in a consequence greater than Minor, short-term impacts. Further opportunities to reduce the risks have been investigated above. The adopted controls are considered good oil-field practice/industry best practice and consistent with the safety case. The potential risks are considered broadly acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the risks of process hydrocarbon release from loss of containment to a level that is broadly acceptable.

Loss of hydrocarbons to marine environment due to a vessel collision during drilling and tie-back of the Xena-03 well		x		x	x	x	A	C	1	M	LCS GP PJ	Broadly Acceptable	EPO 20

Description of Source of Risk

Background

The temporary presence of the MODU, AHVs, installation and support vessels in the Xena-03 Operational Area during Xena-03 Tie-back activities will result in a navigational hazard within the immediate area.

Spill scenarios involving the MODU are not considered likely for a hydrocarbon release given the collision points, vessel speeds and locations of the vessel tanks. MODU fuel tanks are located in the MODU pontoons, typically located on the inner sides of pontoons and can be over 10 m below the waterline.

The installation vessel is expected to have a total fuel capacity of 2200 m^3, with the largest tank holding approximately 340 m^3 (Section 3.12.2). AHVs and other support vessels for the Xena-03 Tie-back activities are likely to have multiple isolated marine diesel tanks distributed throughout the hull of the vessel, typically ranging from 22 to 105 m^3.

In the unlikely event of a vessel collision involving the installation vessel or a support vessel during the Xena-03 Tie-back activities, the vessel will have the capability to pump marine diesel from a ruptured tank to a tank with spare volume in order to reduce the potential volume of fuel released to the environment. It is noted that a hydrocarbon spill from a loss of vessel separation during operational activities is assessed in Section 6.8.6.

Industry Experience

Registered vessels or foreign flag vessels in Australian waters are required to report events to the Australian Transport Safety Bureau (ATSB), AMSA or Australian Search and Rescue (AusSAR).

From a review of the ATSB marine safety and investigation reports, one vessel collision occurred in 2011/12 that resulted in a spill of 25–30 L of hydrocarbon into the marine environment as a result of a collision between a tug and support vessel off Barrow Island. Two other vessel collisions occurred in 2010, one in the port of Dampier, where a support vessel collided with a barge being towed. Minor damage was reported and no significant injury to personnel or pollution occurred. The second 2010 vessel collision involved a vessel under pilot control in port connecting with a vessel alongside a wharf, causing it to sink. No reported pollution resulted from the sunken vessel. These incidents demonstrate the likelihood of only minor volumes of hydrocarbons being released during the highly unlikely event of a vessel collision.

From 2010 to 2011, the ATSB's annual publication defines the individual safety action factors identified in marine accidents and incidents: 42% related to navigation action (2011). Of those, 15% related to poor communication and

42% related to poor monitoring, checking and documentation (ATSB, 2011). The majority of these related to the grounding instances.

Credible Scenario

For a vessel collision to result in the worst-case scenario of a hydrocarbon spill potentially impacting an environmental receptor, several factors must align as follows:

- The identified causes of vessel interaction must result in a collision.
- The collision must have enough force to penetrate the vessel hull.
- The collision must be in the exact location of the fuel tank.
- The fuel tank must be full, or at least of volume which is higher than the point of penetration.

The environmental risk analysis and evaluation identified and assessed a range of potential scenarios that could result in a loss of vessel structural integrity, resulting in damage to fuel storage tank(s) and a loss of marine diesel to the marine environment. Spill scenarios involving the MODU are not considered likely for a hydrocarbon release given collision points, vessel speeds and locations of the vessel tanks. Instead, the most credible scenarios are associated with the collision of an installation vessel with a support vessel in the event that one should be used within the field.

In summary, it is not a credible scenario that the total storage volume of the MODU, installation and support vessels would be damaged or lost, as fuel is stored in more than one tank and stored within the hull, behind the bilge tanks, below the waterline.

The last scenario considered was a collision between a project vessel with a third-party vessel (i.e. other petroleum related vessel or commercial fishing vessel). This was assessed as being credible but highly unlikely, given the standard vessel operations and equipment in place to prevent collision at sea, the standby role of a support vessel (low vessel speed) and its operation in close proximity to the MODU (exclusion areas), and the construction and placement of storage tanks. Potential spill volumes for these scenarios are summarised in Table 6-46. Given the offshore location of the PAA, vessel grounding is not considered a credible risk.

Table 6-46: Summary of credible hydrocarbon spill scenario as a result of vessel collision

Scenario	Hydrocarbon Volumes	Preventative and Mitigation Controls	Credibility
Loss of containment from MODU as a result of vessel collision	Submerged marine diesel tanks up to an individual capacity of 500 m³.	Fuel tanks are located on the inside of pontoons and protected by location below water line, protection from other tanks; e.g., bilge tanks. The draught of vessel and location of tanks in terms of water line prevent the tanks from being breached.	Not credible Due to location of tanks.
Breach of support vessel fuel tanks due to support vessel – other vessel collision including commercial, shipping/fisheries.	Activity support vessel has multiple marine diesel tanks typically ranging between 22–105 m³ each.	Typically, double wall, tanks which are located midship (not bow or stern). Vessels are not anchored and steam at low speeds when relocating within the PAA or providing stand-by cover. Normal maritime procedures would apply during such vessel movements.	Credible Activity support vessel – other vessel collision could potentially result in the release from a fuel tank.
Breach of installation vessel fuel tanks due to collision with another vessel including commercial shipping/fisheries.	The installation vessel has multiple isolated tanks, largest volume of a single tank is unlikely to exceed 500 to 1000 m³.	Tank locations midship (not bow or stern). Installation vessel will be holding station during installation activities or steaming at low speeds when relocating within the PAA.	Credible – Worst Case Installation vessel – third party vessel collision could potentially result in the release from a fuel tank.

Quantitative Hydrocarbon Risk Assessment

Spill modelling was performed by RPS, on behalf of Woodside to determine the fate of marine diesel (modelled as marine gas oil) released from a collision within the PAA (RPS, 2024e). The modelling assessed the extent of a marine diesel spill volume of 1000 m³ for all seasons, using an historic sample of wind and current data for the region. The results of the modelling can be used to demonstrate that a marine diesel spill within the PAA has an EMBA that is not

predicted to include any shoreline contact or accumulation at impact thresholds. A total of 200 replicate simulations were modelled over an annual period (50 per quarter). As stated above, the largest tank volume on an installation vessel is expected to be 500 m³; therefore, the modelling of 1000 m³ is considered conservative for a vessel collision scenario during drilling and tie-back activities.

Hydrocarbon Characteristics

Marine diesel oil (MDO) is a mixture of both volatile and persistent hydrocarbons. Modelling conducted on a comparable marine gas oil (MGO) more typical of vessel fuel. Predicted weathering of marine diesel, based on typical conditions in the region, indicates that around 72% of the oil mass is forecast to have entrained and a further 24% is forecast to have evaporated over the first 24 hours (RPS, 2024e). After this time the majority of the remaining hydrocarbon is entrained into the upper water column, leaving only a small proportion of the oil floating on the water surface (<1%). Given the large proportion of entrained oil and the tendency for it to remain mixed in the water column, the remaining hydrocarbons will decay and/or evaporate over time scales of several weeks to a few months, thereby extending the area of potential effect.

Given the environmental conditions experienced in the PAA, marine gas oil is expected to undergo rapid spreading and this, together with evaporative loss, is likely to result in a rapid dissipation of the spill. Marine gas oil distillates tend not to form emulsions at the temperatures found in the region. The characteristics of the marine gas oil are given in Table 6-47.

Table 6-47: Characteristics of the marine gas oil

Hydrocarbon Type	Initial Density (g/cm³) at 25 ºC	Viscosity (cP @ 25 ºC)	Component BP (ºC)	Volatiles %<180	Semi Volatiles % 180 to 265	Low Volatility (%) 265 to 380	Residual (%) >380
				Non-Persistent			Persistent
Marine gas oil	0.829	4.0	% of total	6	34.6	54.4	5

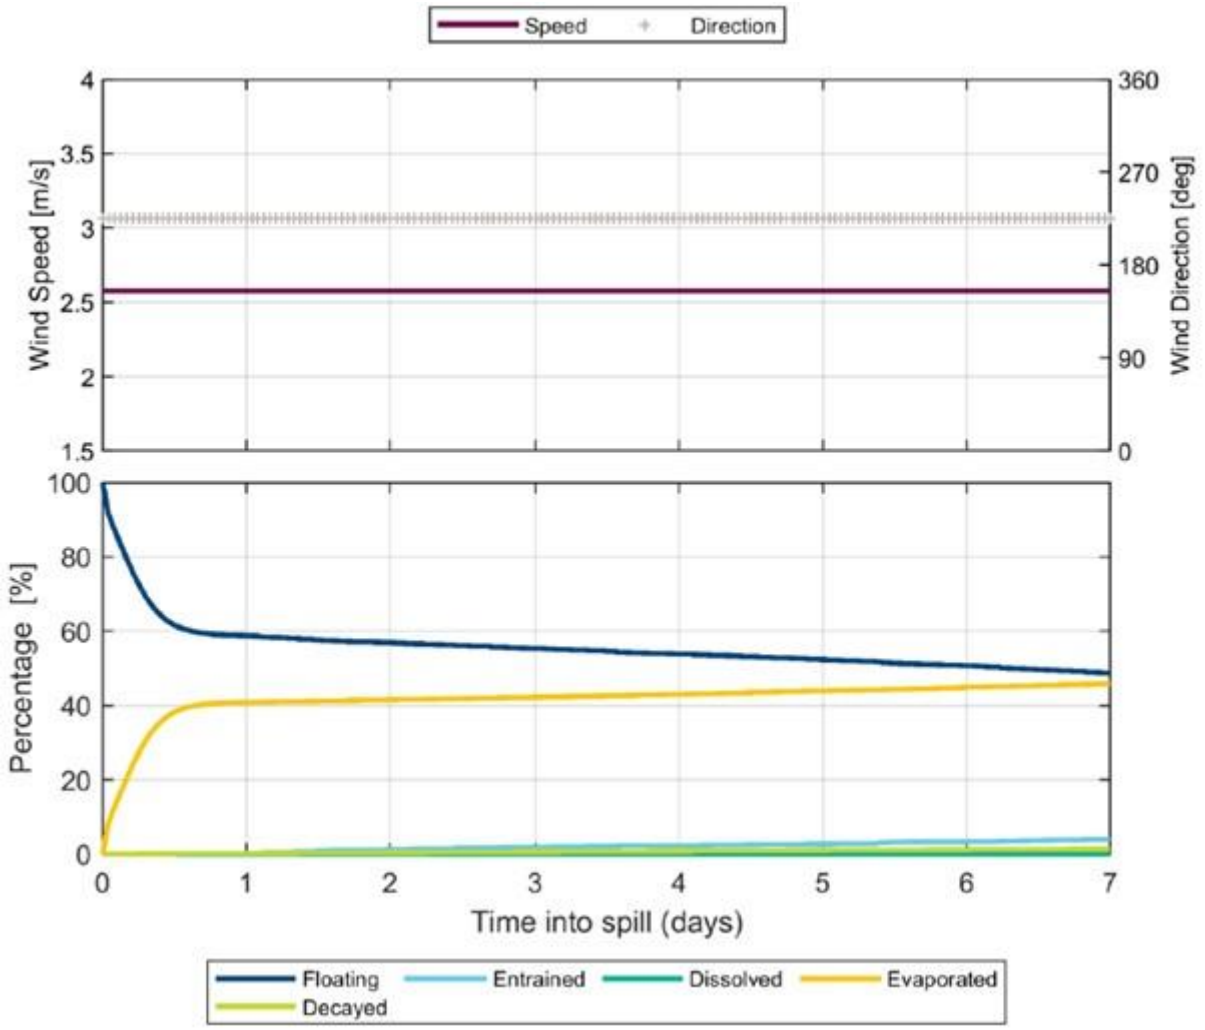

Figure 6-39: Proportional mass balance plot representing the weathering of MGO spilled onto the water surface as a one-off release (50 m³) and subject to a constant 5 kn (2.6 m/s) wind at 27°C water temperature and 25°C air temperature (RPS Group, 2024e)

Consequence Assessment

Environment that May Be Affected

In the event of a 1000 m³ release of marine diesel spill due to vessel collision during drilling and tie-back activities, the modelling predicts a low probability of receptors being contacted by entrained hydrocarbons >100 ppb or dissolved aromatic hydrocarbons >50 ppb (RPS, 2024e).

The greatest likelihood of contact is at the Montebello AMP (24% probability for surface hydrocarbons, 57.5% probability for entrained and 19.5% for dissolved). All other sensitive locations identified are predicted to have a 0.5% probability or less of contact at threshold concentrations. Further, entrained hydrocarbons reaching these environments will be highly weathered, with the volatile and water soluble (often the most toxic) components expected to have dissipated. No surface hydrocarbons above 10 g/m² are predicted to contact sensitive receptors and no shoreline oiling above 100 g/m² is predicted (RPS, 2024e).

Potential Impacts to Environmental Value(s)

The potential impacts from a hydrocarbon release caused by a vessel separation (Pluto Operations) are discussed in Section 6.8.6 (MEE-04). Taking into consideration that the EMBA derived from hydrocarbon spill modelling for a marine diesel spill (during drilling and operations) will fall within the EMBA of the spill from a loss of well containment outlined in Section 6.9.1; moreover, given the expected maximum fuel tank size of the installation vessel (350 m³) is much lower than the modelled scenario (1000 m³), this assessment is considered to be conservative. A summary of the potential environmental impacts specific to a vessel collision scenario during drilling and tie-back activities are provided below.

Water Quality

There may be a short-term decrease in water quality in the immediate vicinity of the release location. Given the localised area of the potential EMBA and the rapid dispersion, dilution and weathering of a marine diesel spill, it is expected that any potential impacts will be minor and temporary in nature.

Marine Sediment Quality

Low probabilities (<2%) of entrained hydrocarbons were predicted to contact a few nearshore receptors, such as the Ningaloo Coast, Montebello Islands and Shoals, Barrow Island and Muiron Islands. No shorelines were predicted to be exposed to either shoreline accumulation or floating surface hydrocarbons at any threshold (RPS, 2024e). However, hydrocarbon contact from this scenario may lead to reduced marine sediment quality by processes such as adherence to sediment and deposition seabed habitat away from shoreline areas.

Protected Species

Cetaceans

As identified in Section 4, protected species including migrating PBW may be encountered near the PAA, and therefore could be impacted in close proximity to the marine diesel spill location, where the volatile, water soluble and most toxic components of the diesel may be present. However, the window for exposure to hydrocarbons with the potential for any toxicity effects in these waters would be limited to a few days following the spill. Potential impacts may include behavioural impacts (e.g., avoidance of impacted areas), sub-lethal biological effects (e.g., skin irritation, irritation from ingestion or inhalation, reproductive failure) and, in rare circumstances, organ or neurological damage leading to death. Given the absence of critical habitats or aggregation areas, cetaceans in the area are expected to be transient, and impacts are expected to be limited to individuals or small groups of animals. Impact on the overall population viability of cetaceans are not predicted.

There is also the potential for migrating humpback whales, dugongs and coastal dolphin populations to be exposed in nearshore waters, however, the low concentrations and advanced degree of weathering of hydrocarbons in these nearshore waters is not expected to result in any discernible sublethal or lethal impacts to cetaceans.

Marine Turtles

The EMBA modelled for a release of hydrocarbons following a vessel collision overlaps with BIAs for marine turtle internesting habitat, as identified in Section 4.6.2. Turtle internesting habitats, such as those in waters adjacent to the Dampier Archipelago Islands, are predicted to have very limited or no exposure to surface or dissolved hydrocarbons above their respective impact threshold concentrations. Some marine turtles in these areas may be exposed to patchy occurrences of entrained hydrocarbons, which would be in an advanced state of weathering with reduced toxicity. Low concentrations are only capable of causing sublethal impacts to the most sensitive marine organisms and no lethal or sub-lethal impacts to marine turtles are expected in the BIAs. The potential for lethal and sub-lethal impacts to marine turtles is limited to small numbers of transient individuals that may be present in offshore waters near the release location.

Seabirds

Seabirds may also be exposed to marine diesel on the sea surface or upper water column, if resting or foraging in waters near to the release in the event of a marine diesel spill during drilling and tie-back activities. Impacts may include mortality due to oiling of feathers or the ingestion of hydrocarbons. However, due to the limited spatial extent of a marine diesel spill and limited window for exposure, population level impacts are not expected.

Other Species

Other protected species that may occasionally transit through the area and may potentially be exposed to a marine diesel spill during drilling and tie-back activities, include shark and ray species such as whale sharks and manta rays. Should sharks or rays be present in offshore waters near the PAA during the spill, direct impacts may occur if foraging within surface slicks or in the upper 20 to 30 m of the water column containing entrained hydrocarbons and dissolved aromatics. Contamination of their food supply and the subsequent ingestion of this prey may also lead to long term impacts as a result of bioaccumulation. Impacts are again predicted to be limited to a small number of animals, given the absence of key habitat and the high population turnover of prey (ITOPF, 2011). It is therefore considered that any potential impacts would be low magnitude and temporary in nature.

Pelagic fish populations in the open water offshore environment of the EMBA are highly mobile and have the ability to move away from a marine diesel spill. The spill-affected area would be confined to the surface layer and upper 20 to 30 m of the water column. It is therefore unlikely that fish populations would be exposed to widespread hydrocarbon contamination. Pelagic fish populations are distributed over a wide geographical area so impacts on populations or species level are considered to be negligible. Combined with these factors and the rapid dispersion of marine diesel, it is considered that any potential impacts will be minor.

Other communities (e.g., demersal fish, benthic infauna and epifauna) and key sensitivities (e.g., KEFs identified in Section 4.7) occur within the combined EMBA, however will not be directly exposed or impacted by a marine diesel spill as hydrocarbons are confined to the upper layers of the water column (0–10 m).

Protected Areas

Entrained hydrocarbons at or exceeding the 100 ppb threshold have a low probability of contacting the Montebello AMP, Gascoyne AMP, and Ningaloo MPWHA in the event of a vessel collision during drilling and tie-back activities

(RPS, 2024e). Entrained hydrocarbons are only predicted within the surface waters of the deep open waters of these protected areas, with no contact to seabed habitats or to shoreline contact. Potential impacts to water quality and the natural values (e.g., mobile protected species) in these areas would be temporary and localised in nature due to the rapid dispersion and weathering of the marine diesel, as described above. Dissolved and visible surface hydrocarbons (at or exceeding 1 g/m²) are not predicted to reach any other protected areas.

Socio-economic

A marine diesel spill is considered unlikely to cause significant direct impacts on the target species fished by the Commonwealth and State active fisheries identified in Section 4.10.1 which overlap with the combined EMBA. The fisheries that operate within the EMBA predominantly target demersal fish species (demersal finfish and crustaceans) that inhabit waters in the range of >60–200 m depth, or pelagic species which are highly mobile. Therefore, a marine diesel spill is expected to only result in negligible impacts, considering that hydrocarbons are confined to the upper layers of the water column (0–10 m). There is the potential that a fishing exclusion zone would be applied in the area of the spill, which would put a temporary ban on fishing activities and therefore potentially lead to subsequent economic impacts on commercial fishing operators if they were planning to fish within the area of the spill. Such measures would likely be in place for less than a week and would not result in widespread or long-term impacts to fishing activities.

Demonstration of ALARP

Given the adopted controls, the overall risk rating for an unplanned hydrocarbon release resulting from a vessel collision during drilling and tie-back activities is Moderate based on a Minor consequence (short term impact: one to two years), to the high value receptors (marine fauna, AMPs, KEFs and commercial fishing), and a highly unlikely likelihood.

Control Considered	Control Feasibility (F) and Cost/Sacrifice (CS)[129]	Benefit in Impact/Risk Reduction	Proportionality	Control Adopted
Legislation, Codes and Standards				
Contract vessels complying with Marine Orders for safe vessel operations: • Marine Order 21 (Safety of navigation and emergency procedures) 2016 • Marine Order 27 (Safety of navigation and radio equipment) 2016 • Marine Order 30 (Prevention of collisions) 2016.	F: Yes. CS: Minimal cost. Standard practice.	Legislative requirements to be followed, reduces the likelihood of interference with other marine users resulting in a collision.	Controls based on legislative requirements – must be adopted.	Yes C 1.1
Establishment of a 500 m sez around MODU and primary installation vessel and communicated to marine users.	F: Yes. CS: Minimal cost. Standard practice.	Establishment of a 500 m safety exclusion zone around MODU and the primary installation vessel reduces the likelihood of interaction with other marine users.	Benefits outweigh cost/sacrifice. Control is also standard practice.	Yes C 1.4
Arrangements supporting the activities in the Xena-03 Tie-back Oil Pollution First Strike Plan (per Section 7.14) will be tested to ensure the Xena-03 Tie-Back Oil Pollution First	F: Yes. CS: Minimal cost. Standard practice.	Legislative requirement based on vessel class. Unlikely to have a significant reduction in consequence.	Controls based on legislative requirements – must be adopted.	Yes C 18.2

[129] Qualitative measure.

Strike Plan can be implemented as planned.				
Good Practice				
Support vessel on standby as required during the PAP to assist in third-party vessel interactions. When a support vessel is designated for standby it will undertake actions to prevent unplanned interactions, such as: • Maintain a 24-hour radio watch on designated radio channel(s). • Undertake continuous surveillance and warn the MODU/ installation vessel of any approaching vessels reaching the 500 m safety exclusion zone. Surveillance shall be conducted by a combination of: • visual lookout – radar watch – other electronic systems available including Automatic Identification System (AIS) – monitoring any additional/ agreed radio communications channels – all other means available. • While complying with the International Regulations for Preventing Collisions at Sea (COLREGS), approach any vessel attempting to transit through the 500 m zone and contact vessel by all available means. • Monitor and advise the MODU if: • MODU navigation signals are defective. • visibility becomes restricted • any buoys in the area are not holding position or are not working as expected.	F: Yes. CS: Minimal cost – support vessels available routinely in PAA during Petroleum Activities Program. Standard practice.	Given the legislative controls in place, use of a support vessel, as defined in the One Marine Charterers Instructions, will provide a small reduction in likelihood of a collision with a third-party vessel.	Benefits outweigh cost/sacrifice.	Yes C 20.1

Notify AHO of activities no less than four working weeks prior to scheduled activity commencement date.	F: Yes. CS: Minimal cost. Standard practice.	Notification of AHO will enable them to issue a Maritime Safety Information Notifications (MSIN) and Notice to Mariners (NTM) thereby reducing the likelihood of unplanned interactions with other vessels.	Benefits outweigh cost/sacrifice. Control is also Standard Practice.	Yes C 1.9
Notify AMSA ARC least 24-48 hours before operations commence.	F: Yes. CS: Minimal cost. Standard practice.	Communicating the PAP to other marine users ensures they are informed and aware should emergency response be required.	Benefits outweigh cost/sacrifice. Control is also Standard Practice.	Yes C 1.10
Notify DoD no less than four weeks before Xena-03 Tie-back activities commence.	F: Yes. CS: Additional cost. Standard practice.	In accordance with request made by DoD during consultation.	Benefits outweigh cost/sacrifice.	Yes C 1.12
Notify relevant government departments, fishing industry representative bodies and licence holders of activities prior to commencement and upon completion of the Xena-03 Tie-back activities	F: Yes. CS: Minimal cost. Standard practice.	Communication of the PAP to other marine users ensures they are informed and aware, thereby reducing the likelihood of interference with other marine users.	Benefits outweigh cost/sacrifice. Control is also standard practice.	Yes C 1.13
Develop a SIMOPS Plan to manage MODU interactions with other facilities/vessels, where multiple campaigns occur within the PAA (i.e. during xmas tree installation). SIMOPS Plan will contain information on: • minimum separation distances • communications • MODU/vessels/ activities involved in SIMOPS • exclusion zone entry and exit processes • ROV operations • helicopter operations • key roles, responsibilities and emergency contacts • PTW arrangements • incident reporting and investigation management of change.	F: Yes. CS: Minimal cost. Standard practice.	SIMOPS Plan contains detail such as communications requirements, exclusion zones and entry/exit requirements and roles and responsibilities – which can help reduce likelihood of vessel collision.	Benefits outweigh cost/sacrifice. Control is also standard practice.	Yes C 1.15
Mitigation: Oil Spill Response	Refer to Appendix H.			

Professional Judgement – Eliminate				
Eliminate use of vessels.	F: No. The use of vessels is required to conduct the Petroleum Activities Program. CS: Not considered, control not feasible.	Not considered, control not feasible.	Not considered, control not feasible.	No
Professional Judgement – Substitute				
No additional controls identified.				
Professional Judgement – Engineered Solution				
No additional controls identified.				
ALARP Statement: On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type (i.e., Decision Type A, Section 2.6.1), Woodside considers the adopted controls appropriate to manage the risks and consequences of an unplanned loss of hydrocarbon as a result of a vessel collision during drilling and tie-back activities. As no reasonable additional/alternative controls were identified that would further reduce the risks and consequences without grossly disproportionate sacrifice, the risks and consequences are considered ALARP.				
Demonstration of Acceptability				
Acceptability Statement: The impact assessment has determined that an accidental hydrocarbon release as a result of a vessel collision during drilling and tie-back activities represents a moderate current risk rating and is unlikely to result in a risk consequence greater than Minor. Relevant recovery plans and conservation advice have been considered during the impact assessment, and the PAP is not considered to be inconsistent with the overall recovery objectives and actions of these recovery plans and conservation advice. The adopted controls are considered consistent with industry legislation, codes and standards, good practice and professional judgement and meet the requirements and expectations of Australian Marine Orders, AMSA and AHO identified during impact assessment and consultation. The potential risks and consequences are considered acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the risks and consequences of a loss of vessel structural integrity to a level that is broadly acceptable.

Accidental release of MEG from chemical supply lines			x		x	x	x	A	E	2	M			

Description of Source of Risk

Operations: Marine Diesel Bunkering and Refuelling

Marine diesel fuel is transferred to the facility (during crewed visits) and ASV by bunkering. Two key scenarios for the loss of containment of marine diesel during bunkering operations were identified:

- Partial or total failure of a bulk transfer hose or fittings during bunkering, due to operational stress or other integrity issues could spill marine diesel to the deck and/or into the marine environment. This would be less than 200 L, based on the likely volume of a bulk transfer hose (assuming a failure of the dry break and complete loss of hose volume).
- Partial or total failure of a bulk transfer hose or fittings during bunkering or refuelling, combined with a failure in procedure to shutoff fuel pumps, for a period of up to five minutes, resulting in approximately 8 m^3 marine diesel loss to the deck and/or into the marine environment.

Mechanisms are available to capture potential topsides diesel spillage from process/piping associated with the PLA bunkering station and manual fuel transfers, enabling drainage flow to be routed inboard to the open drains collections tank when the facility is crewed and during specific activities. The diesel unloading stations have isolation and vent valves to allow draining of bunkering hoses between uses.

Diesel system storage and use risks are covered in Section 6.9.2 Topsides Loss of Containment.

Chemical Transfer, Bunkering, Storage and Use

Transfer and Bunkering

Operational process chemicals are transferred to the facility in a dedicated MEG supply line, or transportable containers. Operational non-process and facility maintenance chemicals, such as subsea control fluid, cleaning products, paint and degreaser, are typically transferred to the facility in containers.

Spills have the potential to occur during transfer to the facility (e.g., transport or lifting incidents). Given the small volumes being handled, the worst credible release volumes are relatively small (e.g., the typical largest chemical transfer is via transportable 4–6 m^3 ISO containers of MEG, corrosion inhibitor and water clarifier).

Installation of the PWH provided equipment to facilitate chemical bunkering of corrosion inhibitor and water clarifier – however, this is not used – with a long-term isolation in place.

MEG loss of containment risks associated with supply and distribution is discussed below.

Storage and Use

Spills of chemicals (including non-process hydrocarbons stored in transportable containers) can originate from stored hydrocarbons/chemicals or equipment on the platform, vessel decks or subsea (refer to Section 6.7.5 for an assessment of the impacts of planned routine and non-routine chemical discharges).

The chemical planned to be stored in the largest volume on the riser platform is corrosion inhibitor (28 m^3 stainless steel tank associated with the PWH). Therefore, the worst-case credible chemical spill scenario could result in up to 28 m^3 of corrosion inhibitor being discharged from the riser platform if all controls were to fail.

Selection of operational chemicals and those used during IMR activities is undertaken in accordance with the Woodside Chemical Selection and Assessment Environment Guideline.

Operational process chemicals are typically stored in dedicated vessels which have similar controls of those related to mitigating hydrocarbon releases; e.g., permanent piping to the process, isolatable by valves, open drain systems and collection tanks, and assurance through risk-based inspection in accordance with the Maintenance and Inspection regimes under the Maintain Assets Process (Section 7.2.1.2).

The riser platform and support vessels also store other non-process chemicals and hydrocarbons, in various volumes. Operational non-process chemicals and facility maintenance chemicals present on the riser platform and support vessels are typically held in low quantities (usually less than 50 L).

Chemical storage areas are typically set up in cabinets, or bunded storage areas to contain any releases to deck from transportable containers (e.g., ISOs, IBCs, barrels, drums). Releases from equipment are predominantly from the failure of hoses or minor leaks from process components, or spills during decant or refuelling of equipment, which can either be located within bunded/drained areas or outside of bunded/drained areas (e.g., over grating on cranes).

Subsea Support Vessels undertaking IMR activities may also store quantities of chemicals for subsea use. Subsea chemical selection process and use is described in Section 3.9. Accidental releases of small quantities of subsea chemicals may occur (e.g. deck spills). Operational experience indicates potential volumes of such spills is small (<20 L).

ROV hydraulic fluid is supplied through hoses containing approximately 20 L of fluid. Hydraulic lines to the ROV arms and other tooling may become caught resulting in minor leaks to the marine environment. Small volume hydraulic leaks may occur from equipment operating via hydraulic controls subsea (subsea control fluid). These include the diamond wire cutter, bolt tensioning equipment, ROV tooling, etc.

Six-inch and Four-inch Chemical Supply Lines

MEG may be released from 6-inch chemical supply and 4-inch chemical supply lines due to a rupture of the lines. Subsea umbilicals transport production chemicals such as corrosion inhibitor for distribution to wells and manifolds. The worst-case credible spill scenario has been determined to be a loss of containment of lean MEG from the 6inch chemical supply line due to a rupture caused by external impact (such as a vessel's anchor). If a rupture occurs the likely volume to be released to the marine environment is 35 m^3 through the depressurisation of the MEG pipeline from its operating pressure of 25 MPag to seabed pressure. Additional MEG losses may occur if:

- there are severe tidal movements around the rupture location causing sea water ingress into the chemical supply line and displacing the MEG to the marine environment, or
- there is a downward flow of MEG due to gravity, dependent on the location of the rupture.

In the unlikely event that there is a continuous leak which does not trigger alarms due to flow differential between onshore and offshore, MEG release could be in the order of 30 m^3/day resulting in a worst-case release of 420 m^3, over two weeks, until detection based on consumption trends.

Surface Spill (Hydrocarbons/Chemicals)

Small diesel spills will rapidly spread on the water surface, with the diesel expected to evaporate and disperse rapidly (National Oceanic and Atmospheric Administration (NOAA), 2006). Woodside has commissioned RPS APASA to model several small marine diesel spills, including surface spill volumes of 8 m^3 in the offshore waters of northwest WA. The results of these models have indicated that exposure to surface hydrocarbons above the 10 g/m^2 threshold is limited to the immediate vicinity of the release site, with little potential to extend beyond 1 km. Based on these

modelling results, the potential impacts of the credible marine diesel and chemical spill scenarios described above are reasonably expected to occur within 1 km of the release location.

The impact assessment assumes this release location to be the riser platform, as this is where all platform-based and most vessel-based spills will potentially occur. Given the nature and scale of the risk, along with the relatively low sensitivity of the receiving environment, no additional modelling studies were considered necessary to inform the impact assessment of unplanned discharges of hydrocarbons or chemicals during transfer, storage and use.

Hydrocarbon Characteristics

Refer to Section 6.8.2 for a description of the characteristics of marine diesel, including detail on the predicted fate and weathering of a spill to the marine environment.

Consequence Assessment

Marine Diesel

Given the low viscosity of marine diesel, along with the high portion of volatile components, a spill of up 8 m^3 of marine diesel during transfer, storage or use would spread and weather rapidly. Environmental receptors at risk would be restricted to those in the vicinity (<1 km from the release location).

Consequences to marine environmental receptors are assessed as consistent with diesel loss of containment impacts described in Section 6.9.2, however, with an order of magnitude lower volume potential, and hence spatial extent.

Given the adopted controls, the overall risk rating for an unplanned bunkering loss of containment is Moderate based on a Minor consequence (short-term impact (one to two years) on species, habitat (but not affecting ecosystem function), physical or biological attribute, or to a community or highly valued area/item of cultural significance community), and an Unlikely likelihood.

Chemicals and Non-process Hydrocarbons

MEG is considered PLONOR; however, very high concentrations of MEG (>50%) may cause irritation to sensitive areas of larger marine fauna (e.g., eyes, gills). Woodside undertook ecotoxicity testing on the lean Pluto MEG (90% monoethylene glycol, ~10% demineralised water and 0.05% corrosion inhibitor). Seven tests, comprised of five different species representing five different taxonomic groups (algae, echinoderm, crustacea, molluscs and fish), were used. The toxicity of the MEG was found to be low, 240 mg/L for 99% species protection and 780 mg/L for 95% species protection (SKM, 2014). MEG is water soluble and will dilute rapidly in the marine environment to low concentrations. Impacts may occur as described above if marine fauna are within the mixing zone when the MEG is released. However, given MEG's low toxicity impacts, it is unlikely there would be any measurable effects on marine species resident in the vicinity of the release. The maximum credible spill of MEG is expected to mix rapidly with the local receiving environment with short term environmental impact.

Accidental releases of chemicals (including corrosion inhibitor) or non-process hydrocarbons decrease the water quality in the immediate area of the release; however, the worst-case loss of containment consequences are expected to be minor with a short-term impact given the water depths, the open ocean mixing environment, distance from sensitive receptors and relatively low credible release volumes. Depending on the chemical released the toxicity and/or potential to bioaccumulate may potentially result in impacts to pelagic fish or other marine species in the vicinity of the discharge.

Potential impacts to plankton from an accidental chemical spill may include acute toxicity resulting in mortality of planktonic organisms. Given the rapid turnover of plankton communities and nature and scale of the credible releases, these impacts will be short-lived (hours to days). Impacts to fish are expected to be of no lasting effect, as fish species are mobile and expected to avoid the area affected by an accidental chemical spill. Impacts to air-breathing fauna such as cetaceans, birds and marine turtles, are expected to be restricted to irritation of sensitive membranes such as the eyes, mouth, and digestive system.

Slight, short-term impacts may occur to other marine users (e.g., commercial fisheries); however, as there is limited fishing within the PAA, it is unlikely there would be any significant impact to commercial fishers.

Summary of Potential Impacts to Environmental Values

Given the adopted controls, the overall risk rating for an unplanned hydrocarbon or chemical release to the marine environment resulting from bunkering, transfer, storage and use is Moderate based on a maximum of Minor consequence (short-term impact: one to two years) to species, habitat (but not affecting ecosystems function), physical and biological attributes, or to a community or highly valued area/item of cultural significant, and an Unlikely likelihood.

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/ Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Legislation, Codes and Standards				
Contract vessels complying with Marine Orders for safe vessel operations: • Marine Order 91 (Marine pollution prevention – oil) Marine Orders 91 (pollution prevention) reduce the potential impact of marine wastewater discharges on water quality.	F: Yes. CS: Minimal cost. Standard practice.	Marine Orders required under Australian Regulations; implementation is standard practice for commercial vessels as applicable to vessel size, type and class.	Controls based on legislative requirements – must be adopted.	Yes C 6.1
Helicopter fuel storage areas are bunded or secondarily contained when they are not being handled/moved temporarily in accordance with the Australian Government Civil Aviation Safety Authority CAAP 92-4(0) 'Guidelines for the development and operation of offshore helicopter landing sites, including vessels.	F: Yes. CS: Minimal cost. Standard practice.	Reduced the likelihood of an unplanned release during helicopter operations. The consequence is unchanged.	Controls based on legislative requirements – must be adopted.	Yes C 21.1
Implementation of bunkering procedures to reduce the risk of a hydrocarbon release as a result of a bunkering incident.	F: Yes. CS: Minimal cost. Standard practice.	Reduced the likelihood of an unplanned release.	Benefits outweigh cost/sacrifice.	Yes C 21.2
Good Practice				
Implement Woodside's Chemical Selection and Assessment Environment Guideline: • Where Gold, Silver, E or D OCNS rating (and no OCNS substitution or product warning), chemicals are selected – no further control required. • If chemicals with a different OCNS rating, sub warning or non-OCNS rated chemicals are required, chemicals will be assessed in accordance with the guideline prior to use.	F: Yes. Routinely implemented to the chemical selection process for Woodside facilities. CS: Minimal cost. Standard practice.	Selection and assessment of chemicals in accordance with the Woodside process, reduces environmental impacts associated with planned chemical discharge.	Control is a WMS requirement – must be adopted.	Yes C 5.1
Incident reports are raised for unplanned releases within event reporting system.	F: Yes. CS: Minimal cost. Standard practice.	Good practice that operators identify, report and learn from unplanned release events. Supports compliance with	Control based on Woodside standard and regulatory requirements.	Yes C 13.5

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/ Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
		regulatory reporting requirements.		
PLA bunkering equipment controls: • All bulk transfer hoses shall be pressure-rated at purchase to reduce the risk of accidental hydrocarbon release during bunkering. • There shall be dry-break couplings on fuel hoses. • There shall be an adequate number of appropriately stocked, located and maintained spill kits.	F: Yes. CS: Minimal cost. Standard practice.	By ensuring the appropriate equipment is in place, tested and maintained appropriately, the likelihood of a spill occurring is reduced. Although no significant reduction in consequence could result, the overall risk is reduced.	Benefits outweigh cost/sacrifice	Yes C 21.3
Contractor procedures include requirements to be implemented during vessel bunkering/refuelling operations, including: • A completed PTW and/or job safety analysis (JSA) shall be implemented for the hydrocarbon bunkering/refuelling operation. • Visually monitoring of gauges, hoses, fittings and the sea surface during the operation. • Hoses will be checked before starting. • Bunkering/refuelling will commence in daylight hours. If the transfer is to continue into darkness, the JSA risk assessment must consider lighting and the ability to determine if a spill has occurred. • Hydrocarbons shall not be transferred in marginal weather conditions.	F: Yes. CS: Minimal cost. Standard practice.	By ensuring the appropriate equipment is in place, tested and maintained appropriately, the likelihood of a spill occurring is reduced. Although no significant reduction in consequence could result, the overall risk is reduced.	Benefits outweigh cost/sacrifice.	Yes C 21.4
Chemicals and diesel stored safely to prevent the release to the marine environment.	F: Yes. CS: Minimal cost. Standard practice.	Reduces risk of unplanned chemical/diesel release.	Benefits outweigh cost/sacrifice.	Yes C 21.5
Monitoring and maintenance of subsea infrastructure to ensure integrity management (MEG lines inspected during hydrocarbon system ROV inspection).	F: Yes. CS: Minimal cost. Standard practice.	Good practice to inspect integrity of MEG pipeline.	Benefit outweighs cost/sacrifice.	Yes C 21.6

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/ Sacrifice (CS)***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Monitoring MEG use, investigating material discrepancies, and monitoring flow discrepancy to support identification of potential integrity failures (instruments in scope of P31).	F: Yes. The use of MEG is monitored to maintain adequate fluid in the system. CS: Minimal cost.	Chemical inventory monitoring and surveillance limits the volumes of MEG potentially discharged to the marine environment.	Benefit outweighs cost/sacrifice.	Yes C 21.7
Professional Judgement – Substitute				
None identified.				
Professional Judgement – Substitute				
None identified.				
Professional Judgement – Engineered Solution				
Facility open hazardous and diesel drain system integrity maintained to contain potential spilled liquid hydrocarbon in areas as appropriate to safe integrated facility design.	F: Yes. The riser platform has been designed with an integral drains system (as practicable to suit NNC facility safety design requirements) to prevent escalation associated with hazardous inventories and support the appropriate containment of environmentally hazardous liquids. CS: Inherent feature of riser platform design to ALARP. Some safety philosophy sacrifice.	The drains system can support the appropriate segregation and containment of environmentally hazardous liquids in case of unplanned loss of containment before it reaches the environment.	Benefit outweighs cost/sacrifice.	Yes C 6.3
Emergency Response				
Mitigation – Emergency and Hydrocarbon Spill Response.	Standard practice to implementing management systems to maintain: • Pluto Offshore Facility Emergency Response Plan • Pluto Offshore Facility Oil Pollution First Strike Plan • Oil Pollution Emergency Arrangements – Australia. Refer to Appendix H: Oil Spill Preparedness and Response Mitigation Assessment for discussion around the ALARP assessment of controls related to hydrocarbon spill response			

ALARP Statement:

On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts of accidental spills of hydrocarbons from bunkering/refuelling, chemicals transfer, storage, and use, and accidental release of 6-inch MEG chemical supply line and 4-inch chemical supply lines. As no reasonable additional/alternative controls were identified that would further reduce the consequences and risks without grossly disproportionate sacrifice, the risks are considered ALARP

Demonstration of Acceptability
Acceptability Statement: The consequence assessment has determined that, given the adopted controls, accidental spills during bunkering/refuelling, or spills from storage, transfer and use and from a release of 6-inch MEG chemical supply line and 4-inch chemical supply lines represent a moderate risk rating that is unlikely to result in a consequence greater than Minor, short-term impacts. Further opportunities to reduce the risks have been investigated above. The adopted controls are considered good oil-field practice/industry best practice and meet requirements of Australian Marine Orders. The potential risks are considered broadly acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the risks of bunkering/refuelling, and storage, transfer and use, and the release of 6-inch MEG chemical supply line and 4-inch chemical supply lines to a level that is broadly acceptable.

Description of Source of Risk

Marine Diesel Bunkering/Refuelling

Bunkering of marine diesel between the MODU and project vessels, as well as the possible refuelling of cranes and other equipment, may take place on the MODU.

Three credible scenarios for the loss of containment of marine diesel during bunkering operations have been identified:

- Partial or total failure of a bulk transfer hose or fittings during bunkering, due to operational stress or other integrity issues could spill marine diesel to the deck and/or into the marine environment. This would be in the order of less than 200 L, based on the likely volume of a bulk transfer hose (assuming a failure of the dry break and complete loss of hose volume).
- Partial or total failure of a bulk transfer hose or fittings during bunkering, combined with a failure in procedure to shutoff fuel pumps, for a period of up to fifteen minutes, resulting in approximately 24 m³ marine diesel lost to the deck and/or into the marine environment.
- Partial or total failure of a bulk transfer hose or fittings during helicopter refuelling could spill aviation jet fuel to the helicopter deck and/or into the marine environment. All helicopter refuelling activities are closely supervised and leaks on the helideck are considered to be easily detectable. In the event of a leak, transfer would cease immediately. The credible volume of such a release during helicopter refuelling would be in the order of <100 L.

Quantitative Spill Risk Assessment

Small diesel spills rapidly spread on the water surface, with the diesel expected to evaporate and disperse rapidly (National Oceanic and Atmospheric Administration (NOAA), 2006). Woodside commissioned RPS to model several small marine diesel spills in the offshore waters of northwest WA. The results of these models have indicated that exposure to surface hydrocarbons above the 10 g/m² threshold is limited to the immediate vicinity of the release site, with little potential to extend beyond 1 km. Therefore, it is considered that exposure to threshold concentrations from a 24 m³ surface spill from MODU bunkering activities would be well within the EMBA for the vessel collision scenario detailed in Section 6.9.3. Given this, the offshore location of the Xena-03 Operational Area, and the fact that the same hydrocarbon type is involved for both scenarios, specific modelling for a 24 m³ marine diesel release was not undertaken for this Petroleum Activities Program.

Hydrocarbon Characteristics

Refer to Section 6.9.3 for a description of the characteristics of marine diesel (comparable characteristics for marine gas oil used in the modelling), including detail on the predicted fate and weathering of a spill to the marine environment.

Chemical Spills – Deck and Subsea

MODU, Installation Vessel and ROV Operations

Deck spills can result from spills from stored chemicals or equipment. Installation vessels typically store chemicals in various volumes (20 L, 205 L; up to approximately 4000–6000 L). Storage areas are typically set up with effective primary and secondary bunding to contain any deck spills. Releases from equipment are predominantly from the failure of hydraulic hoses, which can either be located within bunded areas or outside of bunded or deck areas (e.g., over water on cranes). Helicopter refuelling may also take place within the PAA, on the helipad of the MODU and project vessels.

Chemicals that will be used and may be accidentally released include:

- non process chemicals (maintenance and cleaning chemicals)
- non process hydrocarbons; i.e., hydraulic fluids used in machinery (including cranes, winches, ROVs), small volumes of fuel
- drilling and well fluids
- pre-commissioning chemicals used for leak testing (MEG/treated water mixture).

Non-Process Chemicals

Non-process chemicals, such as wash chemicals, cleaning chemicals, maintenance and solvents, are generally held onboard in low quantities (typically <50 L containers) and are located within chemical cabinets or bunded storage areas on the project vessels and MODU. Non-process chemical spills may result from human error or damage to a chemical container during handling. Spills are generally captured by the drain system and routed to a holding tank for treatment or disposal onshore. In the event that a spill is not contained on deck or within a bunded area, there would be a release to the marine environment of an estimated up to 50 L.

Non-Process Hydrocarbons

Woodside's operational experience demonstrates that non-process hydrocarbon spills are most likely to originate from hydraulic hoses and are typically less than 100 L, with an approximate average volume <10 L.

Non-process hydrocarbons (hydraulic fluids) are used in hydraulic-powered machinery, such as winches, cranes and ROVs, and are hydrocarbon-based with added chemical component additives. Unplanned discharges are predominantly due to failure of hydraulic hoses or minor leaks from process components, or spills during periodic refuelling of hydraulic hoses. Spills or leaks from hydraulic hoses are usually very small volumes (~1 L) and are typically contained within a bunded or drained area under the equipment mounted on deck. These small on-deck spills are unlikely to reach the marine environment. A burst hydraulic hose on an extended crane could potentially result in hydraulic fluid being sprayed in a fine jet out over the water. However, this would only result in a small volume (~25 L) being released, due to the small capacity of hydraulic hoses.

Subsea leaks or spills can result from a loss of containment of fluids from subsea equipment including the BOP or ROVs. Subsea chemical use is described in Section 3.9. Typically, subsea spills during Woodside drilling activities generally do not exceed 26 L.

The ROV hydraulic fluid is supplied through hoses containing approximately 20 L of fluid. Hydraulic lines to the ROV arms and other tooling may become caught resulting in minor leaks to the marine environment. Small volume hydraulic leaks may occur from equipment operating via hydraulic controls subsea (subsea control fluid).

Hydraulic fluids are medium oils of light to moderate viscosity. They have a relatively rapid spreading rate and will dissipate quickly, particularly in high sea states. Lubricating oils may also be held onboard, typically stored with the non process chemicals and held in low quantities. These hydrocarbons are more viscous, so in the event of an unplanned discharge, the spreading rate of a slick of these oils would be slightly slower.

Contingency Activities

Wireline Operations

Minor unplanned leaks of hydrocarbons or chemicals during wireline activities with a live well include leaks such as:

- leaks from the lubricator, stuffing box and hose or fitting failure, which are expected to be less than 10 L (0.01 m^3)
- loss of containment – fluids – surface holding tanks
- backloading of raw slop fluids in an IBC
- stuffing box leak/under pressure
- draining of lubricator contents
- excess grease/lubricant leaking from the grease injection head
- wind-blown lubricant dripping from cable/on deck
- lubricant used to lubricate hole.

Consequence Assessment

Marine Diesel

Given the low viscosity of marine diesel, along with the high portion of volatile components, a surface spill of marine diesel during transfer, storage or use would spread and weather rapidly. Environmental receptors at risk would be restricted to those in the vicinity (<1 km from the release location). The biological consequences of a small volume diesel spill on identified open water sensitive receptors relate to the potential for minor consequences to megafauna, plankton and fish populations (surface and water column biota). Impacts to plankton may include acute toxicity resulting in mortality of planktonic organisms. Given the rapid turnover of plankton communities, these impacts will be short-lived (hours to days). Impacts to fish are expected to be of no lasting effect, as fish species are mobile and expected to avoid the area affected by a marine diesel spill incident. Impacts to larger fauna such as cetaceans and marine turtles may be light fouling, potentially resulting in irritation of sensitive membranes such as the eyes, mouth and digestive system (Helm et al., 2015). Mortality of larger fauna is not expected to occur. No impacts to ecosystem function are expected.

Hydrocarbons may extend into the Multiple Use Zone of the Montebello Marine Park and impacts would be as described above for open ocean receptors. No impacts are predicted to Continental Slope Demersal Fish Communities and the Ancient Coastline at 125 m Depth Contour KEFs. Although they do overlap the operational area, they are outside the predicted spill impact zone.

Slight, short-term impacts may occur to other marine users (e.g., commercial fisheries); however, as there is already no fishing within the PSZ and limited fishing within the Xena-03 Operational Area, it is unlikely that there would be any significant impact to commercial fishers.

Accidental spills of hydrocarbons or chemicals from the MODU, installation vessel and support vessels will decrease the water quality in the immediate area of the spill; however, the impacts are expected to be temporary and very localised due to dispersion and dilution in the open ocean environment.

Given the offshore/open water location, receptors such as marine fauna may be affected if they come in direct contact with a release (i.e., by traversing the immediate spill area). In the event that marine fauna come into contact with a release, they could suffer fouling, ingestion, inhalation of toxic vapours, irritation of sensitive membranes in the eyes, mouth, digestive and respiratory tracts, and organ or neurological damage. Cetaceans may exhibit avoidance behaviour patterns and, given they are smooth skinned, hydrocarbons and other chemicals are not expected to adhere. Given the small area of the potential spill and the dilution and weathering of any spill, the likelihood of ecological impacts to marine fauna (protected species), other communities and habitats is expected to have no lasting effect.

No impacts on socio-economic receptors are expected due to the low levels of fishing activity in the Xena-03 Operational Area, the small volumes of hydrocarbons/chemicals that could be accidentally spilled, and the localised and temporary nature of the impacts.

Summary of Potential Impacts to Environmental Values

Given the adopted controls, it is considered that hydrocarbon spills to the marine environment from bunkering will not result in a potential impact greater than minor, short term local impacts on species, habitat (but not affecting ecosystems function), physical and biological attributes (i.e., Consequence – D). Further, other hydrocarbon and chemical spills to the marine environment from deck/subsea is expected to have no lasting effect (<1 month), localised impact not significant to environmental receptor (i.e., Consequence – F).

onboard MODU/ project vessels.	CS: Project delays if required chemicals not on board. Increases the risks associated with transportation and lifting operations.	drilling activities to occur.		
ALARP Statement: On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the risks and consequences of unplanned release of chemicals and hydrocarbons from bunkering, deck and subsea spills during Xena-03 Tie-back activities. As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.				

Demonstration of Acceptability
Acceptability Statement: The consequence assessment has determined that, given the adopted controls, accidental spills during bunkering/refuelling from Xena-03 Tieback activities represent a moderate risk rating that is unlikely to result in a consequence greater than Minor, short-term impacts. Other accidental hydrocarbon or chemical spills to Deck/subsea during Xena-03 Tieback activities represent a low risk rating that is unlikely to result in potential impact greater than localised, minor and temporary disruption to a small proportion of the population and no impact on critical habitat or activity. Further opportunities to reduce the risks have been investigated above. The adopted controls are considered good oil-field practice/industry best practice and meet requirements of Australian Marine Orders. The potential risks are considered broadly acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the risks of unplanned hydrocarbon or chemical release from bunkering, deck and subsea spills to a level that is broadly acceptable.

Description of Source of Risk

Drilling Fluids – Transfers

A project vessel will undertake bulk transfer of drilling muds or base oil to the MODU, if and when required during tie-back activities. Failure of a transfer hose or fittings during a transfer or backload, as a result of an integrity or fatigue issue, could result in a spill of mud or base oil to either the bunded deck or into the marine environment.

The most likely spill volume of mud is likely to be less than 0.2 m² based on the volume of the transfer hose and the immediate shutoff of the pumps by personnel involved in the bulk transfer process. However, the worst-case credible spill scenario could result in up to 8 m³ of mud being discharged. This scenario represents a complete failure of the bulk transfer hose combined with a failure to follow procedures requiring transfer activities to be monitored, coupled with a failure to immediately shut off pumps (e.g., mud pumped through a failed transfer hose for a period of about five minutes).

Drilling Fluids – Slip Joint Packer Failure

The slip joint packer enables compensation for the dynamic movement of the MODU (heave) in relation to the static location of the BOP. A partial or total failure of the slip joint packer could result in a loss of mud to the marine environment. The likely causes of this failure include a loss of pressure in the pneumatic (primary) system combined with loss of pressure in the back up (hydraulic) system.

Catastrophic sequential failure of both slip joint packers (pneumatic and hydraulic) would trigger the alarm and result in a loss of the volume of fluid above the slip joint (conservatively 1.5 m³) plus the volume of fluid lost in the one minute (maximum) taken to shut down the pumps. At a flow rate of 3800 L (1000 gallons) per minute this volume would equate to an additional 3.8 m². In total, it is expected that this catastrophic failure would result in a loss of 5.3 m².

Failure of either of the slip joint packers at a rate not large enough to trigger the alarms could result in an undetected loss of 20 bbl (3 m³) maximum assuming a loss rate of 10 bbl/hr and that MODU personnel would likely walk past the moon pool at least every two hours.

Loss of a drilling chemical container or drum during transfer from the supply vessel to the MODU may occur due to crane operator error or machinery failure. The maximum container that could be lost is an intermediate bulk container (IBC) which can hold 1 m³ of chemicals. In the event that an IBC or drum is lost to the marine environment and cannot be recovered the contents will discharge, either immediately or over a period depending on the damage to the drum or container.

NWBM Drilling Fluid System

The selection of a NWBM drilling fluid system (if required) will be based on Woodside processes; however, for the purposes of this risk assessment, an example base oil (Saraline 185V) has been used. Saraline 185V is a mixture of

volatile to low volatility hydrocarbons. Predicted weathering of base oil, based on typical conditions in the region, indicates that about 50% by mass is predicted to evaporate over the first day or two. At this time, most of the remainder could be entrained into the water column. In calm conditions, entrained hydrocarbons are likely to resurface with up to 100% able to evaporate over time.

Table 6-48: Characteristics of the non-water-based mud base oil

Oil Type	Initial Density (kg/m³)	Viscosity (cP @ 20 °C)	Volatiles (%) <180	Semi Volatiles (%) 180–265	Low Volatility (%) 265–380	Residual (%) >380	Aromatic (%) of Whole Oil <380 °C BP
Base oil (Saraline 185V)			***Non-Persistent***		***Persistent***		
	0.7760	2.0 @ 40°C	8.5	41.1	50.4	0	0

Cement

Bulk cement is transferred as powder from the supply vessel to the MODU prior to being mixed into a slurry in the cement unit. Additives are required to form a cement slurry; these are transferred to the MODU in drums from the supply vessel to the MODU. Unplanned discharge to the marine environment may occur due to crane operator error or machinery failure resulting in loss of a drum of cement additive, which cannot be recovered. Cement additives are typically stored in drums <100 litres.

Contingency Activities

Activation of the Emergency Disconnect Sequence

The EDS is an emergency system that provides a rapid means of shutting in the well (i.e., BOP closed) and disconnecting the MODU from the BOP. The EDS could be manually activated due to an identified threat to the safety of the MODU, including loss of MODU station keeping resulting from loss of multiple moorings, potential collision by a third-party vessel or a loss of well control. During operations, this could result in a subsurface release of a combination of WBM and/or NWBM and solids at the seabed and a release of base fluid. The volume of material released depends on the water depth and, hence, the length of the riser (i.e. the entire riser volume would be lost). The base oil of the NWBM would remain in an emulsion with the other components of the mud system. Approximately 103 m³ of base oil could be released in the event of the riser being disconnected when drilling with NWBM.

Consequence Assessment

Potential Impacts to Environmental Values

Some drilling fluids/cement may be spilt at the sea surface (e.g., transfer failure) and some in the water column potentially close to the seabed (e.g., in the event of an EDS or Slip Joint Packer Failure). Due to water depth in the PAA (70–130 m), this will determine the exposure pathway, and hence potential impacts and receptors.

Water Quality

NWBM is made up of a number of components including base oil, which generally has a high volatile to semi-volatile fraction. If released to the marine environment at surface, this generally evaporates within the first 48 hours, with the remaining fraction being on the sea surface and weathering at a slower rate. As a result of this volatility, combined with the worst-case credible spill scenario volumes (8 m³, during bulk transfer from supply vessel to MODU), and based on Woodside's experience of modelling base oil, it is considered there would be an extremely small footprint area associated with any release. Therefore, any surface oil would be confined to open waters with a minor surface slick that would not reach any sensitive receptors. Therefore, impacts on water quality would be minor and temporary in nature. The material safety datasheet for Saraline 185V indicates that it is readily biodegradable, non-toxic in the water column and has low sediment toxicity (Shell, 2014). Marine fauna may be affected if they come in direct contact with a release (i.e., by traversing the immediate spill area), but due to the small footprint of such a spill, it is anticipated that any impacts would be negligible and temporary in nature.

WBM is made up of a number of components including a variety of chemicals, incorporated into the selected drilling fluid system to meet specific technical requirements. If released to the marine environment at surface, there would be an extremely small impact footprint area associated with a release. Any release would be confined to the open waters of the Operational Area that would not reach any sensitive receptors. Components of the WBM would settle out in the water column and be subject to dilution. Given the low toxicity of WBM and its planned discharge during drilling, any impacts on water quality would be slight and temporary in nature.

The EMBA associated with the release of NWBM from the activation of the EDS would be small and limited to deeper water seabed surrounding the well site (the release point). The environmental consequence of such a release would include a highly localised area at the discharge location. Lethal impacts to the underlying infauna may occur but are considered unlikely, and recolonisation would occur over time. Elevated hydrocarbon and metal concentrations in the localised area of deposition would also occur, with reduction over time. It is likely that any impacts to water and sediment quality and low-sensitivity deeper water benthos would be short term, localised and a full recovery expected.

All chemicals that may be operationally released or discharged to the marine environment by the PAP are evaluated using a defined framework and set of tools to ensure the potential impacts of the chemicals selected are acceptable, ALARP and meet Woodside's expectation for environmental performance. Therefore, any chemicals selected and potentially released are expected to be of low toxicity and biodegradable.

Base oil has a high volatile to semi-volatile fraction. A surface spill would typically evaporate within 48 hours, with the remaining portion to weather at a slow rate. The example base oil, Saraline 185V, is readily biodegradable, non-toxic in the water column and has low sediment toxicity (Shell, 2014). Due to its volatility, and small worst-case credible spill scenario, there would be a very localised footprint unlikely to reach any sensitive receptors.

Given the occasional nature of unplanned chemical discharge, the small volumes, and the offshore location of the PAA, the change to water quality resulting from unplanned discharge of chemicals will not be substantial.

Therefore, any potential impact of a change in water and sediment quality and low-sensitivity deeper water benthos would be short-term and localised, with a full recovery expected. Receptor sensitivity of water quality is low (low value, open ocean), and therefore the consequence of a release of hydrocarbons/chemicals on water and sediment quality would be no lasting effect (F).

Marine Fauna

Injury or Mortality to Marine Fauna

As a result of a change in water quality, further impacts to receptors may occur, which may include injury or mortality to marine fauna resulting from exposure to toxins in the released drilling fluids. Neff (2010) explains that the lack of toxicity and low bioaccumulation potential of the drilling muds means that the effects of the discharges are highly localised and are not expected to spread through the food web (of which planktonic species are the basis). Given that surface discharges are rapidly dispersed, potential impacts would be highly localised and temporary.

Local increases in turbidity from cement spills may affect zooplankton with variations in predator prey dynamics, which favours planktonic feeders over visual feeders (Gophen, 2015), while impacts to phytoplankton may occur due to decreases in available light, therefore reducing productivity (Dokulil, 1994). The magnitude of potential impact to marine fauna is no lasting effect, which results in a consequence of Slight (E) based on the high receptor sensitivity.

Suspended sediment levels greater than 500mg/L are likely to produce a measurable impact on larvae of most fish species, and levels of 100 mg/L may affect the larvae of some species if exposed for periods greater than 96 hours (Jenkins and McKinnon, 2006). In addition, levels of 100 mg/L may affect the larvae of several marine invertebrate species. Dilution estimates (e.g. Hinwood et al., 1994; Neff, 2005) would suggest that suspended sediment concentrations from unplanned cement discharge, loss of drilling mud from slip joint packer failure, or activation of the EDS, would dilute rapidly with instantaneous exposures of 500 mg/L unlikely and exposure times of 100 mg/L well below 96 hours.

Due to the low levels of planktonic productivity in the offshore area, the fact that the Xena-03 Operational Area (70 to 130 m depth) is outside of the highly productive shelf break situated on the 200 m isobath, plankton populations on a regional scale are not expected to be adversely affected by drill and project fluid spills. In addition, due to the open nature of the marine environment of the Xena-03 Operational Area and associated environmental conditions (windy, strong currents, etc), the content and dispersive nature of drilling muds within the marine environment and the high population replenishment of these organisms, it is expected that impacts to plankton species will be limited to within tens of metres of the discharge point and return to previous conditions within a relatively short period of time. On this basis, the risk to plankton from unplanned discharges during Xena-03 Tie-back activities is low and would result in consequences no greater than slight, short-term effects.

Seafloor Receptors (Benthic Communities and Cultural Heritage Sites)

The impact area associated with release of NWBM from activation of the EDS would be small, limited to the seabed surrounding the well. Base fluids for NWBM are designed to be biodegradable in offshore marine sediments. Biodegradation can result in a low oxygen (anoxic) environment resulting in changes in benthic community structure. NWBMs are designed to be low in toxicity and are not readily bioavailable, based on their physical/chemical properties, for bioaccumulation to infauna and epifauna. Deleterious impacts to the infauna may still occur to a limited extent, together with increased hydrocarbon and metal concentrations in the area of deposition. The ability for the infauna communities to recolonise following a small localised disturbance within the Xena-03 Operational Area would mean impacts are short-term and slight.

Drill cuttings from unplanned loss of used drilling fluids would increase turbidity and TSS levels above ambient, where coarser material will deposit on the seabed and finer sediment material (WBM) will temporarily cause elevated TSS above the seabed surrounding the well. This would rapidly disperse and dilute with the prevailing seabed currents.

Accumulation of drill cuttings, grit and flocculent on the seabed causes changes in the physical properties of the seabed sediment such as the particle size distribution (PSD), the introduction of contaminants (metals such as barium) from retained drilling fluids (WBM) and associated ecological effects.

Impacts associated with unplanned drill and project fluid discharges will be largely limited to an area surrounding the well. The low sensitivity of the benthic communities/habitats within and in the vicinity of the Xena-03 Operational Area, combined with the low toxicity of WBMs and residual NWBMs, insoluble mineralised salts (the source of barium) having low bioavailability to benthic biota, and the highly localised nature and scale of predicted physical impacts to seabed biota, affirm that any predicted impact is considered likely but of a short-term environmental consequence.

Cultural Heritage
As described in Section 4.10, the Xena-03 Operational Area is located further offshore than the Ancient Coastline at 125 m depth contour KEF. Seabed disturbance resulting from Xean-03 Tie-back activities does not pose a threat to Indigenous Cultural features of the Ancient Landscape.
Summary of Potential Impacts to Environmental Values
Given the adopted controls, it is considered that unplanned discharges of drilling fluids or cement to the marine environment will not result in a potential impact greater than slight and short-term impacts on species, habitat (but not affecting ecosystems function), physical and biological attributes (i.e., Environment Impact – E).

Yes C 6.2
Incident reports are raised for unplanned releases within event reporting system.	F: Yes. CS: Minimal cost. Standard practice.	Good practice that operators identify, report and learn from unplanned release events. Supports compliance with regulatory reporting requirements.	Control based on Woodside standard and regulatory requirements.	Yes C 13.5
Professional Judgement – Eliminate				
No additional controls identified.				
Professional Judgement – Substitute				
Only use WBM during drilling.	F: Not feasible. While the base case is to use WBM, a contingent NWBM drilling fluid system is required for safety and technical reasons; therefore, option to use must be maintained. CS: Not considered, control not feasible.	Not considered, control not feasible.	Not considered, control not feasible.	No
Professional Judgement – Engineered Solution				
Use a MODU which may have a larger tank storage capacity for WBM. As such, there would be fewer bulk transfer movements.	F: Not feasible. The use of a MODU with greater storage capacity cannot be confirmed. CS: Significant cost and schedule delay would occur if the MODU was limited to greater storage capacity.	Not considered, control not feasible.	Not considered, control not feasible.	No
ALARP Statement: On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts and risks of unplanned release of project fluids. As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.				

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/ Sacrifice (CS)[131]***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Demonstration of Acceptability				
Acceptability Statement: The impact assessment has determined that, given the adopted controls, unplanned discharges of drilling fluids represent a low current risk rating that is unlikely to result in a potential impact greater than minor and/or temporary contamination above background levels and/or national/international quality standards and/or known biological effect concentrations on a localised scale. Further opportunities to reduce the risks and consequences have been investigated above. The adopted controls are considered good oil-field practice/industry best practice. The potential risks and consequences are considered broadly acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the risks and consequences of an unplanned discharge of NWBM/base oil or WBM to a broadly acceptable level.

Incorrect disposal or accidental discharge of non-hazardous and hazardous waste to the marine environment		x	x			x		A	E	2	M	LCS GP	Broadly Acceptable	EPO 24

Description of Source of Risk

Non-hazardous and Hazardous Waste

Normal operations on the facility, the MODU and support vessels generate a variety of hazardous and non-hazardous wastes. These materials could potentially impact the marine environment, if incorrectly disposed of, lost overboard or discharged in significant quantities.

Non-hazardous wastes include domestic and industrial wastes such as paper and cardboard, aluminium cans, bottles, polystyrene, organics and scrap steel. Hazardous wastes include recovered solvents, excess or spent chemicals, oil contaminated materials (e.g., sorbents, filters and rags), batteries and used lubricating oils and potentially material containing NORMs. Sand and sludges may be periodically generated during process and vessel maintenance. Many waste streams are only generated on the riser platform and support vessels during deployment of personnel to the facility for IMMR activities.

Equipment (small hand-held tools) and Personal Protective Equipment (PPE) may be accidentally lost overboard. Equipment that has been recorded as being lost on other similar facilities and vessels has primarily been windblown or dropped overboard and has included things such as hardhats, gloves, safety glasses and small tools or materials. Equipment (small hand-held tools) and PPE are not classified as waste as per the Woodside Offshore Facilities Waste Management Plan and are not included any further in this risk assessment. Equipment (small hand-held tools) and PPE lost overboard are recorded, investigated and corrective actions tracked as per requirements in Section 7.10.3 and Section 7.13.4. Loss of hazardous and non-hazardous wastes have occurred during backloading activities, periods of adverse weather and incorrect waste storage.

All waste materials not suitable for discharge to the environment, including hazardous wastes (i.e., liquid and solid wastes), generated during the PAP are transported to shore for disposal or recycling by Woodside's licenced waste contractor.

Material generated onshore from pigging of the export pipeline has been tested in accordance with the relevant procedures and determined not to be classified as NORMs; therefore, NORMs are not expected to be encountered.

Consequence Assessment

The potential impacts of hazardous or non-hazardous solid waste/equipment accidentally discharged to the marine environment include contamination of the environment as well as secondary impacts relating to potential contact of marine fauna with wastes. This could result in entanglement or ingestion and lead to injury and death of individual animals. The temporary or permanent loss of waste materials into the marine environment is not likely to have a significant environmental impact, based on the location of the PAA, the types, size and frequency of wastes that could occur, and species present.

Water and Sediment Quality

Hazardous solid wastes, such as paint cans, oily rags, etc, can cause localised contamination of the water and sediment through a release of toxins and chemicals. Given likely small volumes of any unplanned solid waste discharge, and the occasional nature of the event, these would result in temporary and highly localised changes to the water quality.

In the unlikely event of an object being dropped into the marine environment, potential environmental effects would be limited to slight physical impacts on benthic communities. In most cases, objects will be able to be recovered and therefore these impacts will also be temporary in nature. However, there may be instances where objects are unable to be recovered due to health and safety, operational constraints or other factors such as the difficulty of recovering dropped objects at depth. When dropped objects are unable to be recovered, the impact will continue to be slight but permanent.

Seabirds and Migratory Shorebirds, Fish, Marine Reptiles and Marine Mammals

The unplanned discharge of solid wastes can result in mortality to fauna, either through contamination or physical injury depending on the nature of the waste. Marine fauna, including fish, seabirds and shorebirds, marine mammals and marine reptiles may be impacted through ingestion or entanglement of waste or through exposure to toxic chemicals. Ingestion or entanglement of marine fauna has the potential for physical harm which may limit feeding/foraging behaviours and thus can result in mortalities. Injury and fatality to vertebrate marine life caused by ingestion of, or entanglement in, harmful marine debris was listed as a key threatening process under the EPBC Act in August 2003 (DoEE, 2018). The Threat Abatement Plan for the impacts of marine debris on the vertebrate wildlife of Australia's coasts and oceans (DoEE, 2018) identifies EPBC Act-listed species for which there are scientifically documented adverse impacts resulting from marine debris. Marine turtles and seabirds in particular may be at risk from plastics which may cause entanglement or be mistaken for food (e.g., DoEE, 2018; Commonwealth of Australia, 2017) and ingested causing damage to internal tissues and potentially preventing feeding activities. In the worst instance this could have a lethal effect to an individual. Marine debris has been identified as a threat in the Recovery Plan for Marine Turtles in Australia (2017–2027).

Impacts to species including fish, birds, marine mammals and marine reptiles from the unplanned discharge of solid waste is unlikely given low occurrence of unplanned discharges. Significant impacts are unlikely to occur at an individual level and will not occur at a population level, nor result in the decrease of the quality of the habitat such that the extent of these species is likely to decline.

The temporary or permanent loss of waste materials into the marine environment is not likely to have a significant environmental impact, based on the nature and scale of activities that may generate wastes, the types, size and frequency of wastes that could occur.

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/ Sacrifice (CS)***	***Benefit in Impact/ Risk Reduction***	***Proportionality***	***Control Adopted***
ALARP Statement: On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts and risks of accidental discharge of non-hazardous and hazardous wastes. As no reasonable additional/alternative controls were identified that would further reduce the impacts and risks without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.				

Demonstration of Acceptability
Acceptability Statement: The consequence assessment has determined that, given the adopted controls, the accidental discharge of non-hazardous waste and hazardous waste represents a low risk rating and is unlikely to result in a consequence greater than localised impacts to water quality, marine sediment and marine species with no lasting effects. Woodside, across its operations (including this facility), has a well-established waste management culture which underpins a strong performance and limits the potential for accidental releases to the marine environment. Opportunities to reduce waste management impacts and risks are employed through standard practices such as job planning, implementation of Waste Management Plans and job hazard analysis practices. The adopted controls are considered good oil-field practice/industry best practice and meet requirements of Australian Marine Orders. The potential impacts and risks are considered broadly acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the impacts and risks of accidental discharge of non-hazardous and hazardous waste to a level that is broadly acceptable.

Loss of station keeping of the MODU leading to anchor drag and the disturbance of benthic habitat	x			x		x							

Description of Source of Risk

The primary cause for unplanned seabed disturbance during the PAP is through dropped objects from the riser platform and support vessel operations or from installation of the Xena-03 mooring system, the MODU, subsea installation and support vessels. Additional unplanned disturbance to the seabed may occur from a loss of station keeping and subsequent anchor drag during MODU operations if a moored MODU is used. An assessment of the risks of loss of control of suspended loads from the platform, and waste/objects lost to sea is presented in Sections 0 and 6.9.7 and is not considered further here.

Dropped Objects

There is the potential for objects to be dropped overboard from the riser platform and support vessel operations or from installation of the Xena-03 mooring system, the MODU, installation and support vessels to the marine environment. Objects that have been dropped during previous offshore activities include small numbers of personal protective gear (e.g., glasses, gloves, hard hats), small tools (e.g., spanners) hardware fixtures (e.g., riser hose clamp) and drill equipment (e.g., drill pipe); however, there is also potential for larger equipment to also be dropped during the activity, particularly during recovery of infrastructure from the seabed. The spatial extent in which dropped objects can occur is restricted to the PAA.

Anchor Drag

The Xena-03 well may be drilled using a moored or hybrid MODU. If a moored MODU is used for drilling the Xena-03 well, it will be secured on station by an 8- to 12-point pre-laid mooring system deployed to the seabed, as dictated by the mooring analysis. High energy weather events such as cyclones, occurring while the MODU is on station, can lead to excessive loads on the mooring lines, resulting in failure (either anchor(s) dragging or mooring lines parting). A failure of mooring integrity may lead to the mooring lines and anchors attached to the MODU being trailed across the seabed. If mooring failure is sufficient, the MODU may move off station, increasing the likelihood of anchor drag across the seafloor. A hybrid MODU that uses DP in conjunction with a pre-laid mooring system to hold station, may be used to conduct the drilling. In this scenario, there may be an opportunity to disconnect the RAR (see Section 3.12), which would allow the rig to avoid the cyclone and for the anchor drag risk to be reduced.

For a moored MODU, personnel on-board are typically evacuated during cyclones. Woodside implements a risk-based assessment process to aid in decision-making for cyclone evacuations, with the well suspended prior to MODU

evacuation. Support vessels also demobilise from the PAA during the passage of a cyclone. While the MODU is temporarily abandoned, the position of the MODU is monitored remotely for any deviation. Support vessels and MODU personnel return to the Xena-03 Operational Area as soon as safe to do so after a cyclone evacuation. Operational experience indicates cyclone evacuations typically last for seven days.

Industry statistics from the North Sea show that a single mooring line failure for MODUs is the most common failure mechanism (33 × 10-4 per line per year), followed by a double mooring line failure (11 × 10-4 per line per year) (Petroleumstilsynet, 2014). Note that single and double mooring line failures do not typically result in the loss of station keeping. If partial or complete mooring failures are sufficient to result in a loss of station keeping, industry experience indicates that MODUs may drift considerable distances from their initial position (Offshore: Risk and Technology Consulting Inc., 2002). Partial mooring failures leading to a loss of station keeping resulted in smaller MODU displacements, due to the remaining anchors dragging along the seabed when compared to complete mooring failures; complete mooring failures resulted in a freely drifting MODU (Offshore: Risk and Technology Consulting Inc., 2002). NOPSEMA has recorded four cases of anchor drag due to loss of MODU holding station during cyclone activity between 2004 and 2015 (NOPSEMA, 2015). Seabed disturbance area size from anchor drag will depend on the extent of the drag.

Consequence Assessment

Potential Impacts to Environmental Values

In the unlikely event of an object being dropped into the marine environment or failed mooring, potential environmental effects would be limited to minor physical impacts on benthic communities. In most cases, objects will be able to be recovered and therefore these impacts will also be temporary in nature. However, there may be instances where objects are unable to be recovered due to health and safety, operational constraints or other factors such as the difficulty of recovering dropped objects at depth. When dropped objects are unable to be recovered, the impact will continue to be minor but permanent.

KEFs and Cultural Heritage

The temporary or permanent loss of dropped objects into the marine environment and mooring failure is likely to result in a minor impact only, as the benthic communities associated with the Pluto Facility and Xena-03 Operational Areas are of low sensitivity and are broadly represented throughout the NWMR. As described in Section 4.7, the Ancient Coastline at 125 m overlaps with the Pluto Facility Operational Area, and the Continental Slope Demersal Fish Communities KEF overlaps the Pluto Facility and Xena-03 Operational Areas. Benthic communities in these Operational Areas are representative of the deepwater soft sediment habitats reported in the wider region, and is likely to consist of soft sediment seabed habitat, characterised by sparse, widely represented epifauna and infauna (Woodside, 2004; Brewer et al., 2007).

Given the nature and scale of risks and consequences from dropped objects and mooring failure, slight impacts are expected to seabed sensitivities within the Pluto Facility and Xena-03 Operational Areas. Further, considering the types, size, scale and frequency of dropped objects that could occur, it is unlikely that a dropped object would have a significant impact on any benthic community.

The operational areas overlap a small proportion of the KEFs. Any unplanned seabed disturbance within the KEFs would be minor and relatively small compared to the size of the KEFs. Given the location of the MODU, and likely anchor placement locations outside of the KEFs, impacts from anchor drag are likely to be further reduced. On this basis, the risk to the KEFs from unplanned seabed disturbance during Facility Operations and Xena-03 Tie-back Activities is low and would result in consequences no greater than minor, short-term impacts.

Epifauna and Infauna

As a result of a change in water quality and change in habitat, injury or mortality to marine fauna resulting from an increase in turbidity may occur. Given a change to water quality is unlikely, the only receptors that would potentially be at risk of unplanned seabed disturbance are bottom dwelling species including epifauna and infauna. Benthic communities, including epifauna and infauna may be impacted by the dropped objects, or the drag of anchors on the seabed. If not recovered, dropped objects may result in the permanent loss of a small area under the object. Over time, these hard substrates are expected to be colonised by sessile benthic biota (e.g., sponges, gorgonians), which is consistent with other small areas of hard substrate throughout the region.

If anchor drag occurs, habitat impact will span the extent of the drag area, leading to a localised change in communities; however, substantial adverse effect is not anticipated, given the sparse marine life that are well represented elsewhere in the region.

Given generally sparse benthic communities in the operational areas, no threatened or migratory benthic species or ecological communities were identified, and those epifauna and infauna communities observed are likely to be well represented elsewhere in the region, impacts are expected to be restricted to a localised proportion of epifauna and infauna communities.

On this basis, the risk to epifauna and infauna from unplanned seabed disturbance during Xena-03 Tie-back activities is low and would result in consequences no greater than minor, short-term impacts.

Summary of Potential Impacts to Environmental Values(s)
Given the adopted controls, the predicted small footprint of a dropped object and the highly unlikely nature of anchor drag, it is considered that unplanned seabed disturbance will result in Minor, short-term impact (one to two years) on species, habitat (but not affecting ecosystems), physical or biological attributes, and cultural heritage, with an overall risk rating of Moderate.

ALARP Statement: On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts and risks of unplanned seabed disturbance. As no reasonable additional/alternative controls were identified that would further reduce the impacts without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.				

[138] For the purposes of this control/performance standard, “material” is defined as unplanned releases of environmentally hazardous or non-hazardous solid object/waste events with an environmental consequence of > F.

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/ Sacrifice (CS)[137]***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Demonstration of Acceptability				
Acceptability Statement: The impact assessment has determined that disturbance to seabed from dropped objects from the Pluto Facility Operations and the Xena-03 Tie-back activities, including a loss of station keeping of the MODU, represents a moderate current risk rating and is unlikely to result in a risk consequence greater than Minor. The adopted controls are considered industry good practice. The potential risks and consequences are considered broadly acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the risks of seabed disturbance from dropped objects/anchor drag to an acceptable level.

Physical presence of the Pluto Facility, MODU, ASV, installation and support vessels resulting in collision with marine fauna						x		A	E	1	L	LCS PJ	Broadly Acceptable	EPO 26

Description of Source of Risk

Activities associated with the PAP will require vessels IMMR activities, support operations and supply/transport as well as for tie-back activities. The type and number of vessels in the PAA at any one time, and the duration of presence, will differ depending on the activities being undertaken.

Vessels operating in and around the PAA may present a potential hazard to cetaceans and other protected marine fauna such as whale sharks and marine reptiles. Vessel movements can result in collisions between the vessel (hull and propellers) and marine fauna, potentially resulting in superficial injury, serious injury that may affect life functions (e.g., movement and reproduction) and mortality. The frequency and severity of impacts due to collisions vary greatly due to vessel type, vessel operation (specific activity, speed), physical environment (e.g., water depth), and the type of marine fauna potentially present and their behaviours.

Consequence Assessment

Marine Mammals, Reptiles and Sharks

The likelihood of vessel/whale collision being lethal is influenced by vessel speed; the greater the speed at impact, the greater the risk of mortality (Jensen and Silber, 2004; Laist et al., 2001). Vanderlaan and Taggart (2007) found that the chance of lethal injury to a large whale as a result of a vessel strike increases from about 20% at 8.6 knots to 80% at 15 knots. According to the data of Vanderlaan and Taggart (2007), it is estimated that the risk is less than 10% at a speed of four knots. Vessel–whale collisions at this speed are uncommon and, based on reported data contained in the US NOAA database (Jensen and Silber, 2004), there are only two known instances of collisions when the vessel was travelling at less than six knots. Both of these were from whale watching vessels that were deliberately placed among whales.

Support vessels undertaking the PAP within the PAA are likely to be travelling less than eight knots (and will often be stationary). Therefore, the risk of a vessel collision with protected species resulting in death is inherently low. No known key aggregation areas (resting, breeding or feeding) are located within or immediately adjacent to the PAA.

The PAA overlaps two recognised BIAs for cetaceans; the pygmy blue whale migration and distribution BIA and the humpback whale migration BIA (the humpback whale is considered to be at risk due to relatively slow movement and proportion of time spent at or near the sea surface) (refer to Section **Error! Reference source not found.**). Both humpback whales and PBW are only expected to be present during their seasonal migrations. Refer to Table 4-14 for information on migration timing.

Whale sharks are at risk from vessel strikes when feeding at the surface. Whale sharks may traverse offshore NWS waters including the PAA during their migrations to and from Ningaloo Reef, and a BIA for foraging whale sharks

overlaps the PAA. However, given the main aggregation area for whale sharks is approximately 340 km off the coast of Ningaloo (designated as a foraging BIA with high density prey) (Section 4.6.1), it is expected that whale shark presence within the PAA would not comprise significant numbers, and their presence would be transitory and of a short duration. There are no constraints preventing whale sharks from moving away from vessels to avoid injury (e.g. shallow water or shorelines).

Vessel strikes have also been identified as a threat to marine turtles; however, no explicit management actions are listed in relevant conservation advices or recovery plans (Table 4-3). The typical response from turtles on the surface to the presence of vessels is to dive (a potential "startle" response), which decreases the risk of collisions (Hazel et al., 2007). As with cetaceans, the risk of collisions between turtles and vessels increases with vessel speed (Hazel et al., 2007). Given the low speeds of vessels undertaking the Petroleum Activities Program, along with the expected low numbers of turtles within the Facility and Xena-03 Operational Areas, interactions between vessels and turtles are considered to be highly unlikely.

The facility section of the PAA overlaps a flatback internesting buffer BIA which extends for 40 km around a nesting BIA at the Montebello Islands and Dampier Archipelago during their summer nesting period. Given the water depth around the facility (between approximately 85 and 960 m) and absence of potential nesting or significant foraging habitat for turtles (i.e., no emergent islands, reef habitat or shallow shoals/banks), the Facility Operational Area is unlikely to represent important habitat for marine turtles.

The Export Pipeline Operational Area also overlaps the aforementioned flatback turtle internesting buffer BIA, as well as internesting BIAs for green, hawksbill and loggerhead turtles. The BIAs for flatback, green and hawksbill turtles have also been designated as habitat critical to the survival of the species in the Recovery plan for marine turtles in Australia 2017–2027 (Commonwealth of Australia, 2017); however, these areas are likely to hold the same significance as the existing BIAs with slightly differing spatial areas. The export pipeline lies in water depths of 40 to 85 m. No potential nesting or significant foraging habitat for turtles (i.e., no emergent islands, reef habitat or shallow shoals/banks) overlap the Export Pipeline Operational Area.

Given there are significant nesting sites along the mainland coast and islands in proximity to the Export Pipeline Operational Area, turtles are likely to transit this area. Individuals may also infrequently forage in some areas of the export pipeline (i.e., flatback turtles), although not in significant numbers given the lack of suitable habitat and distance from emergent land. As vessels are likely to only operate within the PAA infrequently during IMMR activities and when the facility is crewed, interactions with vessels during the PAP are highly unlikely. Given vessels will be moving at low speeds while in the PAA, turtles are likely to avoid collisions with vessels by diving or swimming away from the area. It is not deemed credible that vessel movement associated with the PAP could have a significant impact on marine fauna populations given (1) the low presence of transiting individuals, (2) avoidance behaviour commonly displayed by marine fauna, and (3) low operating speed of the activity support vessels (generally less than eight knots or stationary, unless operating in an emergency). Activities are considered unlikely to result in a consequence greater than slight, short-term disruption to individuals or a small proportion of the population, and no impact on critical habitat or fauna activity.

ALARP Statement: On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the risk of interactions with marine fauna. As no reasonable additional/alternative controls were identified that would further reduce the impacts and risks without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.				

Demonstration of Acceptability

Acceptability Statement:

The consequence assessment has determined that, given the adopted controls, interaction with marine fauna represents a low risk rating that is unlikely to result in a consequence greater than slight, short-term disruption to individuals or a small proportion of the population, and no impact on critical habitat or activity. Further opportunities to reduce the impacts and risks have been investigated above. The adopted controls are considered good oil-field practice/industry best practice and meet the requirements of Part 8 (Division 8.1) of the EPBC Regulations 2000. The management of interactions with marine fauna is consistent with the objectives of approved conservation advice and recovery plans for marine fauna, including cetaceans and whale sharks, where human interference has been identified as a threat.

EPOs, EPSs and MC for Xena-03 Tie-back Activities			
Environmental Performance Outcomes	***Controls***	***Environmental Performance Standards***	***Measurement Criteria***
EPO 26 No injury of, or mortality to, EPBC Act 1999 and listed marine fauna as a result of the Petroleum Activities Program.	**C 3.1** EPBC Regulations 2000 – Part 8 Division 8.1 Interacting with cetaceans, including the following measures[142]: • Project vessels will not travel greater than 6 knots within 300 m of a cetacean (caution zone) and not approach closer than 100 m from a whale. • Project vessels will not approach closer than 50 m for a dolphin and/or 100 m for a whale (with the exception of animals bow riding). • If the cetacean shows signs of being disturbed, support vessels will immediately withdraw from the caution zone at a constant speed of less than 6 knots.	**PS 3.1** Vessels will comply with the EPBC Regulations 2000 – Part 8 Division 8.1 (Regulation 8.05 and 8.06) Interacting with cetaceans to manage the risk of fauna collision.	**MC 3.1.1** Records demonstrate no breaches with EPBC Regulations 2000 – Part 8 Division 8.1 Interacting with cetaceans and Woodside Marine Charterers Instructions. **MC 3.1.2** Records demonstrate reporting cetacean ship strike incidents to DCCEEW.

The potential impacts and risks are considered broadly acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the impacts and risks of vessel collision with marine fauna to a level that is broadly acceptable.

Invasive species in vessel ballast tanks or on vessels/ submersible equipment					x	x	x	A	E	1	L	LCS GP PJ	Broadly Acceptable	EPO 27

Description of Source of Risk

During the Petroleum Activities Program, vessels will be transiting to and from the PAA, potentially including traffic mobilising from beyond Australian waters. Vessels include those servicing and supporting Pluto operations (Section 3.8) as well as the MODU, ASV, IMMR vessel, installation vessels or general support vessels (Section 3.12). Vessels may be sourced from the local area (Dampier, Port Hedland, etc) or from further afield, depending on the type of vessel required and availability. In addition, infrequent import of materials (e.g., spares) from international suppliers may be required. Vessels arriving from international waters typically call into Dampier, where quarantine clearance including ballast log reviews is conducted in accordance with Biosecurity Act 2015.

All vessels are inherently subject to some level of marine fouling. Organisms attach to the vessel hull, particularly in areas where organisms can find a good surface (e.g., seams, strainers and unpainted surfaces) or where turbulence is lowest (e.g., niches, sea chests). Organisms can also be drawn into ballast tanks during on-boarding of ballast water as cargo is unloaded or to balance vessels under load. Biofouling organisms can become established in an area through the release of propagules (e.g., eggs or larvae), or by attaching to substrate after becoming detached from the host vessel.

Non-indigenous Marine Species (NIMS) have been introduced into a region beyond their natural biogeographic range and have the ability to survive, reproduce and establish founder populations. Not all NIMS introduced into an area thrive or cause demonstrable impacts. Indeed, the majority of NIMS around the world are relatively benign and few have spread widely beyond sheltered ports and harbours. Only a subset of NIMS that become abundant and impact on social/cultural, human health, economic and/or environmental values can be considered Invasive Marine Species (IMS).

During the Petroleum Activities Program, vessel activities that have the potential to lead to the introduction of IMS are:

- discharge of ballast water from vessels
- vessel interactions with the facility
- cross contamination between vessels (e.g., when vessels need to be alongside each other).

Consequence Assessment

IMS have historically been introduced and translocated around Australia by a variety of human means including biofouling and ballast water. Species of concern are those that:

- are not native to the region
- are likely to survive and establish in the region
- are able to spread by human mediated or natural means.

Species of concern vary from one region to another, depending on various environmental factors such as water temperature, salinity, nutrient levels and habitat type. These factors dictate their survival and invasive capabilities.

Introducing IMS into the local marine environment may alter the ecosystem, as IMS have characteristics that make them superior (in a survival and/or reproductive sense) to indigenous species. They may prey upon local species (which had previously not been subject to this kind of predation and therefore not have evolved protective measures against the attack), they may outcompete indigenous species for food, space or light and can also interbreed with local species, creating hybrids such that the endemic species is lost.

IMS have also proven economically damaging to areas where they have been introduced and established. Such impacts include direct damage to assets (fouling of vessel hulls and infrastructure) and depletion of commercially harvested marine life (e.g., shellfish stocks). IMS have proven particularly difficult to eradicate from areas, once established. If the introduction is captured early, eradication may be effective but is likely to be expensive, disruptive and, depending on the method of eradication, harmful to other local marine life.

Despite the potential high consequence of the establishment of a marine pest within a high value environment as a result of introduction, unlike coastal or sheltered nearshore waters, the deep offshore open waters of the PAA are not conducive to the settlement and establishment of IMS (Geiling, 2016), due to the lack of light or suitable habitat to sustain growth or survival. Table 6-49 provides an assessment of the IMS impacts and risks associated with the Petroleum Activity Program.

Epifauna and Infauna

Epifauna and infauna are susceptible to impacts from IMS due to the risk of changes to the ecosystem dynamics such as competition for resources and predation.

Two KEFs also overlap the PAA: the Ancient Coastline at 125 m Depth Contour KEF and the Continental Slope Demersal Fish Communities KEF.

Discrete areas of hard substrate hosting sessile filter feeding communities such as sponges and gorgonians may be associated within the Ancient Coastline at the 125 m Depth Contour KEF, of which 9.1 km² overlaps the PAA. However, no areas of hard substrate characteristic of this KEF have been identified within the PAA (Jacobs, 2014).

Filter feeder communities within the PAA are present on the subsea infrastructure and Pluto platform, which provides hard substrate for attachment (Jacobs, 2014).

Vessels have the potential to introduce IMS into the PAA, however, the deep offshore open waters of the PAA (70 to 130 m) are not conducive to the settlement and establishment of IMS. Furthermore, the PAA are away from shorelines and/or critical habitat. The likelihood of IMS being introduced and establishing viable populations within the PAA or immediate surrounds is considered unlikely, with the potential settlement on subsea infrastructure not expected. Accordingly, impact to epifauna/infauna in the PAA is not considered credible. Receptor sensitivity for epifauna and infauna is low, leading to a Slight (E) risk consequence.

Industry, Shipping, Defence

The establishment of IMS has the potential to cause changes to the functions, interests or activities of other users through indirect impact such as changes to fisheries target species resulting in economic and social implications, or due to compromised reputation to the oil and gas industry.

Given the low likelihood of IMS translocation to, and colonisation of environments within the PAA, project activities will not result in establishment of IMS, and as such not adversely affect other marine user activities in the region.

Based on the impact evaluation, the magnitude of potential impacts of a change to the functions, interests or activities of other users is slight. Receptor sensitivity for industry, shipping and defence is medium, leading to a Slight (E) risk consequence. The likelihood of the risk event occurring is Remote, therefore the risk is assessed as Low.

Summary of Potential Impacts to Environment Values

In support of Woodside's assessment of the impacts and risks of IMS introduction associated with the Petroleum Activities Program, a risk and impact evaluation of the different aspects of marine pest translocation associated with the activity was conducted.

Given the adopted controls, the overall risk rating for unplanned introduction of invasive marine species is Low based on a Slight consequence (short-term impact (<1 year) on species, habitat (but not affecting ecosystem function), physical or biological attribute, or to a community or area/item of cultural significance community), and a highly unlikely likelihood.

Table 6-49: Assessment of the impacts and risks of invasive marine species introduction associated with the Petroleum Activity Program

IMS Introduction Aspect	Credibility of Introduction	Consequence of Introduction	Likelihood
Transfer of IMS from infected vessel to PAA and establishment on the seafloor or subsea infrastructure.	Not Credible The deep offshore open waters of the PAA away from shorelines and/or critical habitat, more than 12 nm from a shore and in waters 40–85 m deep, are not conducive to the settlement and establishment of IMS.		
Transfer of IMS from infected vessel to and subsequent establishment on the Pluto platform.	Credible There is potential for the transfer of marine pests to occur.	If IMS were to establish this would potentially result in fouling of intakes (depending on the pest introduced) and would likely result in the quarantine of the Pluto facility until eradication could occur (through cleaning and treatment of infected areas), which would be costly to undertake. Minor (D) – Reputation and Brand Such introduction would be expected to have Minor (D) impact to Woodside's reputation and brand, and close scrutiny of asset level operations or future proposals. Slight (E) – Environment Environmental consequence of introduction of IMS to the Pluto platform is considered Slight (E), localised and would relate to habitat directly on the facility.	Highly Unlikely (1) Interactions between the Pluto facility and support vessels is limited during the petroleum activity program, with a 500 m safety exclusion zone being adhered too. Spread of marine pests via ballast water or spawning in these open ocean environments is considered Highly Unlikely (1).
Introduced to PAA and establishment on a project vessel.	Credible There is potential for the transfer of marine pests between project vessels within the PAA.	Environment – Not Credible The translocation of IMS from a colonised MODU or project vessel to shallower environments via natural dispersion is not considered credible given the distances of the PAA from nearshore environments (i.e., greater than 12 nm/50 m water depth). There is therefore no credible environmental risk and the assessment is	Remote (0) Interactions between project vessel will be limited during the Petroleum Activities Program, with minimum 500 m safety exclusion zones being adhered to around the MODU and installation vessel, and interactions limited short periods of time alongside (i.e., during backloading, bunkering activities). There is also no direct contact (i.e., they are not

		limited to Woodside's reputation. Reputation – E If IMS were to establish on a project vessel (i.e., MODU, installation vessel, activity project vessels) this could potentially impact the vessel operationally through the fouling of intakes, result in translocation of an IMS into the PAA and, depending on the species, potentially transfer of an IMS to other project vessels, which would likely result in the quarantine of the vessel until eradication could occur (through cleaning and treatment of infected areas), which would be costly to perform. Such introduction would be expected to have slight impact to Woodside's reputation, particularly with Woodside's contractors, and would likely have a reputational impact on future proposals.	tied up alongside) during these activities. Spread of marine pests via ballast water or spawning in these open ocean environments is also considered remote.
Transfer of IMS from infected vessel to and subsequent establishment on riser platform, then transfer of IMS to a secondary vessel from the facility.	Not Credible Risk is considered so remote that it is not credible for the purposes of the Petroleum Activity Program. The transfer of a marine pest from an infected activity vessel to the facility is considered highly unlikely given the offshore open ocean environment. For a marine pest to then establish into a mature spawning population on the facility and then transfer to another support vessel is not considered credible (i.e., beyond the Woodside risk matrix). The facility is located in an offshore, open ocean, deep environment. Support vessels only spend short periods of time alongside the riser platform (i.e., during backloading or bunkering activities).		

	There is also no direct contact (i.e., they are not tied up alongside) during these activities. It is also noted that Woodside has been conducting marine vessel movements between the facility and WA ports (such as Dampier) for a long period of time, and no IMS has been detected in these ports (Department of Fisheries, 2017).		

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/ Sacrifice (CS)***	***Benefit in Impact/ Risk Reduction***	***Proportionality***	***Control Adopted***
Legislation, Codes and Standards				
On arrival in Australia, all vessels will manage their ballast water using one of the approved ballast water management options, as specified in the Australian Ballast Water Management Requirements.	F: Yes. CS: Minimal cost. Standard practice.	Reduction in the likelihood that ballast water will host IMS.	Controls based on legislative requirements under the Biosecurity Act 2015 – must be adopted.	Yes C 27.1
Internationally sourced project vessels will manage their biosecurity risk associated with biofouling as specified in the Australian Biofouling Management Requirements.	F: Yes. CS: Minimal cost. Standard practice.	Reduces the likelihood of transfer of marine pests between vessels within the PAA. No change in consequence would occur.	Controls based on legislative requirements under the Biosecurity Act 2015 – must be adopted.	Yes C 27.2
Good Practice				
Woodside's IMS risk assessment process[144] will be applied to the MODU, and all vessels and relevant immersible equipment undertaking the Petroleum Activities Program. Assessment will consider these risk factors: For MODU and project vessels: • vessel/MODU/ type • recent IMS inspection and cleaning history,	F: Yes. CS: Minimal cost. Good practice implemented across all Woodside Operations.	Identifies potential risks and additional controls implemented accordingly. In doing so, the likelihood of transferring marine pests between project vessels within the PAA is reduced. No change in consequence would occur.	Benefits outweigh cost/sacrifice.	Yes C 27.3

[144] Qualitative measure
45 Woodside's IMS risk assessment process was developed with regard to the national biofouling management guidelines for the petroleum production and exploration industry and guidelines for the control and management of a ships' biofouling to minimise the transfer of invasive aquatic species (IMO Guidelines, 2011).

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/ Sacrifice (CS)***	***Benefit in Impact/ Risk Reduction***	***Proportionality***	***Control Adopted***
including for internal niches • out-of-water period before mobilisation • age and suitability of antifouling coating at mobilisation date • internal treatment systems and history • origin and proposed area of operation • number of stationary/slow speed periods >7 days • region of stationary or slow periods • type of activity – contact with seafloor. For immersible equipment: • region of deployment since last thorough clean, particularly coastal locations • duration of deployments • duration of time out of water since last deployment • transport conditions during mobilisation • post-retrieval maintenance regime. Based on the outcomes of each IMS risk assessment, management measures commensurate with the risk (such as treating internal systems, IMS inspections or cleaning) will be implemented to minimise the likelihood of IMS being introduced.				
Diver based monitoring of the riser platform for IMS.	F: Potentially. Diver based surveys are technically feasible for the facility but are not approved under the in-force Safety Case. CS: Significant. IMS inspections of in-water assets typically require	Riser platform monitoring does not prevent the potential for translocation (i.e., only as a mitigation measure). Detection may facilitate subsequent development of options to manage	Disproportionate. Interactions between the facility and support/subsea vessels posing IMS translocation risk is limited, and the vessels involved will have been managed through the implementation of	No

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/ Sacrifice (CS)***	***Benefit in Impact/ Risk Reduction***	***Proportionality***	***Control Adopted***
	vessel logistics and diver-based inspection teams to reliably detect IMS. This is a costly, time-consuming process that would likely require facility simultaneous operational constraints, and invariably introduces a series of significant safety risks in a hazardous offshore environment. Monetary cost of IMS survey for facility-sized infrastructure would be comparable to safe diver campaign arrangements in the order of $200,000/day plus mob/demob costs. Costs of ROV to support survey are in the order of $150,000/day plus mob/demob costs (based on subsea ROV hire costs). Health and safety exposure includes those of personnel while conducting diver-based surveys – four days of two to three people (based on subsea ROV surveys of similar size), as well as offshore vessel and facility simultaneous operations hazards.	IMS. Subsequent success may be limited due to structure complexity and hazardous environment.	Woodside's Invasive Marine Species Management Plan (IMSMP) (C 13.2), a verified process which provides Woodside confidence in the verification of EPO 13. Consequently, any additional benefit gained through the implementation of this control is considered disproportionate, given material execution safety risks and controls already adopted (and noting already incurred cost through implementation of IMSMP (i.e., inspections and cleaning where risk warrants)), and the unlikely likelihood of a translocation event.	
Professional Judgement – Elimination				
Not using MODU and project vessels.	F: No. No alternative to the use of vessels during the PAP was identified, given vessels must be used to undertake the Petroleum Activities Program. There is no feasible means to eliminate the source of risk.	Not assessed, control not feasible.	Not assessed, control not feasible.	No

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/ Sacrifice (CS)***	***Benefit in Impact/ Risk Reduction***	***Proportionality***	***Control Adopted***
	CS: Not assessed, control not feasible.			
No discharge of ballast water during the Petroleum Activities Program.	F: No. Ballast water discharges are critical for maintaining vessel stability. Given the nature of the Petroleum Activities Program, the use of ballast (including the potential discharge of ballast water) is considered to be a safety critical requirement. CS: Not assessed, control not feasible.	Not assessed, control not feasible.	Not assessed, control not feasible.	No
Professional Judgement – Substitute				
Sourcing vessels based in Australia only.	F: Potentially. Limiting activities to only use local project vessels could potentially pose a significant risk in terms of time and duration of sourcing a vessel, as well as the ability of the local vessels to perform the required tasks. For example, there are limited installation vessels based in Australian waters. While the project will attempt to source project vessels locally it is not always possible. Availability cannot always be guaranteed when considered competing Oil and Gas activities in the region. In addition, sourcing Australian based vessels only will cause increases in cost due to pressures of vessel availability. CS: Significant cost and schedule impacts due to restrictions of vessel hire opportunities.	Sourcing vessels from within Australian will reduce the likelihood of IMS from outside Australian waters, however, it does not reduce the likelihood of introduction of species native to Australia but alien to the PAA and NWMR, or of IMS that have established elsewhere in Australia. The consequence is unchanged.	Disproportionate. Sourcing vessels from Australian waters may result in a reduction in the likelihood of IMS introduction to the PAA; however, the potential cost of implementing this control is grossly disproportionate to the minor environmental gain (or reducing an already remote likelihood of IMS introduction) potentially achieved by using only Australian based vessels, consequently this risk is considered not reasonably practicable.	No

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/ Sacrifice (CS)***	***Benefit in Impact/ Risk Reduction***	***Proportionality***	***Control Adopted***
Inspecting all vessels for IMS.	F: Yes. Approach to inspect vessels is feasible. CS: Significant cost and schedule impacts. Thorough inspections require vessels to be removed from the sea (e.g., slipped or dry docked) and examined by an IMS expert. This process incurs significant financial and schedule sacrifices. Timely vessel-based support is integral to the safe and efficient operation of the facility and subsea infrastructure.	Reduction in the likelihood that a vessel will host IMS.	Disproportionate. The cost/sacrifice is grossly disproportionate to the benefit gained.	No
Professional Judgement – Engineered Solution				
None identified.				
ALARP Statement: On the basis of the environmental risk assessment outcomes and use of the relevant tools appropriate to the decision type, Woodside considers the adopted controls appropriate to manage the impacts and risks of IMS introduction and establishment. As no reasonable additional/alternative controls were identified that would further reduce the impacts and risks without grossly disproportionate sacrifice, the impacts and risks are considered ALARP.				
Demonstration of Acceptability				
Acceptability Statement: The risk assessment has determined that, given the adopted controls, introduction of IMS represent a moderate risk rating that has a remote likelihood to result in an environmental consequence greater than major long-term impact on marine communities within the PAA. Further opportunities to reduce the impacts and risks have been investigated above. The adopted controls are considered good oil-field practice/industry best practice and meet Australian legislative requirements, including the Biosecurity Act 2015. The potential impacts and risks are considered broadly acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the impacts and risks of invasive marine species to an acceptable level.

EPO 27 No introduction and establishment of IMS into the PAA as a result of the Petroleum Activities Program.	**C 27.1** All vessels will manage their ballast water using one of the approved ballast water management options, as specified in the Australian Ballast Water Management Requirements.	**PS 27.1** Compliance with Australian Ballast Water Management Requirements (as defined under the Biosecurity Act 2015) (aligned with the International Convention for the Control and Management of Ships' Ballast Water and	**MC 27.1.1** Ballast water exchange records maintained by vessels which verify compliance against Ballast Water Management requirements.

EPOs, EPSs and MC for Pluto Operations and Xena-03 Tie-back Activities			
Environmental Performance Outcomes	***Controls***	***Environmental Performance Standards***	***Measurement Criteria***
		Sediments) to prevent the introduction of IMS.	
	C 27.2 Internationally sourced project vessels will manage their biosecurity risk associated with biofouling as specified in the Australian Biofouling Management Requirements.	**PS 27.2** Compliance with Australian Biofouling Management Requirements.	**MC 27.2.1** Records of implementation of biofouling management measure and pre-arrival reporting.
	C 27.3 Woodside's IMS risk assessment process[145] will be applied to all vessels and relevant immersible equipment undertaking the Petroleum Activities Program. Assessment will consider these risk factors: For all vessels: • vessel/MODU/ type • recent IMS inspection and cleaning history, including for internal niches • out-of-water period before mobilisation • age and suitability of antifouling coating at mobilisation date • internal treatment systems and history • origin and proposed area of operation • number of stationary/slow speed periods >7 days • region of stationary or slow periods • type of activity – contact with seafloor. For immersible equipment: • region of deployment since last thorough clean, particularly coastal locations • duration of deployments	**PS 27.3** Before entering the PAA, all vessels and relevant immersible equipment are determined to be low risk of introducing IMS of concern and maintain this low risk status to mobilisation.	**MC 27.3.1** Records of IMS Vessel Risk Assessments maintained for all vessels and relevant immersible equipment, as required by the management plan. **MC 27.3.2** Records maintained of management measures which have been implemented where identified through the IMS Vessel Risk Assessment process.

[140] Woodside's IMS risk assessment process was developed with regard to the national biofouling management guidelines for the petroleum production and exploration industry and guidelines for the control and management of a ships' biofouling to minimise the transfer of invasive aquatic species (IMO Guidelines, 2011).

EPOs, EPSs and MC for Pluto Operations and Xena-03 Tie-back Activities			
Environmental Performance Outcomes	***Controls***	***Environmental Performance Standards***	***Measurement Criteria***
	• duration of time out of water since last deployment • transport conditions during mobilisation • post-retrieval maintenance regime. Based on the outcomes of each IMS risk assessment, management measures commensurate with the risk (such as treating internal systems, IMS inspections or cleaning) will be implemented to minimise the likelihood of IMS being introduced.		

6.9.11 Physical Presence (Unplanned): Interaction with Live Infrastructure

Context		
Project Vessels – Section 3.12 Subsea, Inspection, Maintenance and Repair Activities – Section 3.10 Support Vessel Operations – Section 3.8 Xena-03 Drilling and Tie-back Activities – Section 3.11 Vessel-based Activities for the Xena-03 Tie-back – Section 3.12	Socio-economic Environment – Section 4.10	Consultation – Section 5

Impact Evaluation Summary

Source of Risk	***Environmental Value Potentially Impacted***						***Evaluation***						
	Marine Sediment	Water Quality	Air Quality (incl Odour)	Ecosystems/Habitat	Species	Socio-economic	Decision Type	Consequence/Impact	Likelihood	Risk Rating	ALARP Tools	Acceptability	Outcome
Interaction with live infrastructure from dropped objects						X	A	E	1	L	LCS GP	Broadly Acceptable	EPO 28
Interaction with live infrastructure from anchor drag						X							

Description of Source of Impact

There is existing live subsea infrastructure in the PAA, which includes components of the Woodside Julimar Brunello Production Pipeline, Chevron Wheatstone Pipeline, Santos Reindeer Offshore Gas Supply Pipeline and Woodside Scarborough Export Pipeline. During the PAP, activities may be conducted that present a risk of dropped objects or anchor drag over the nearby live infrastructure.

Dropped Objects

There is the potential for objects to be dropped overboard from the MODU and project vessels to the marine environment. Objects that have been dropped during previous offshore activities include small numbers of personal protective gear (e.g., glasses, gloves, hard hats), small tools (e.g., spanners), hardware fixtures (e.g., riser hose clamp) and drill equipment (e.g., drill pipe). However, there is potential for larger equipment to be dropped during the activity, particularly during recovery of infrastructure from the seabed. The spatial extent in which dropped objects can occur is restricted to the PAA.

Anchor Drag

A moored/ hybrid MODU may be used for drilling the wells, secured on station by an 8- to 12-point mooring system deployed to the seabed, as dictated by the mooring analysis. High energy weather events such as cyclones, occurring while the MODU is on station, can lead to excessive loads on the mooring lines, resulting in failure (either anchor(s) dragging or mooring lines parting). A failure of mooring integrity may lead to the mooring lines and anchors attached to the MODU being trailed across the seabed and over live infrastructure.

For a moored MODU, personnel on-board are typically evacuated during cyclones. Woodside implements a risk-based assessment process to aid in decision making for cyclone evacuations, with the well suspended prior to MODU evacuation. Support vessels also demobilise from the PAA during the passage of a cyclone. While the MODU is temporarily abandoned, the position of the MODU is monitored remotely for any deviation. Support vessels and MODU personnel return to the PAA as soon as safe to do so after a cyclone evacuation. Operational experience indicates cyclone evacuations typically last for seven days.

Industry statistics from the North Sea show that a single mooring line failure for MODUs is the most common failure mechanism (33 × 10-4 per line per year), followed by a double mooring line failure (11 × 10-4 per line per year) (Petroleumstilsynet, 2014). Note that single and double mooring line failures do not typically result in the loss of

station keeping. If partial or complete mooring failures are sufficient to result in a loss of station keeping, industry experience indicates that MODUs may drift considerable distances from their initial position (Offshore: Risk and Technology Consulting Inc., 2002). Partial mooring failures leading to a loss of station keeping resulted in smaller MODU displacements, due to the remaining anchors dragging along the seabed when compared to complete mooring failures; complete mooring failures resulted in a freely drifting MODU (Offshore: Risk and Technology Consulting Inc., 2002).

NOPSEMA has recorded four cases of anchor drag due to loss of MODU holding station during cyclone activity between 2004 and 2015 (NOPSEMA, 2015).

Impact Assessment

Potential Impacts to Environmental Values

Interactions with Other Marine Users

In the unlikely event of an object being dropped on, or anchors dragging over, live infrastructure there is potential impacts to the infrastructure and the Operators of that infrastructure.

If interactions with live infrastructure were to occur, Woodside would notify the relevant operations team in accordance with the SIMOPS plan. This would trigger responses from the Operator to assess and respond to any damage caused in accordance with the relevant operations EP for the live infrastructure. Under Regulation 56 of the Environment Regulations, a titleholder may refer NOPSEMA to information previously given to NOPSEMA for another purpose under the OPGGS Act, the Environment Regulations or any other Regulations made under the Act, to comply with a requirement on the titleholder under the Environment Regulations to give NOPSEMA information or include information in a document. In accordance with Regulation 56, NOPSEMA is referred to the relevant operations EPs submitted by the Operators of the live infrastructure, and accepted by NOPSEMA, for the detail of the Operators' assessment and response in such a scenario. Potential impacts therefore include time and costs associated with inspecting the infrastructure and time and costs associated with any associated repair, which are expected to be slight and short-term in nature.

Potential Subsequent Loss of Containment

In the unlikely event of an object being dropped on, or anchors dragging over, live infrastructure, and in the further unlikely event of a severe interaction with the infrastructure, there is a possibility that live infrastructure could be ruptured releasing hydrocarbons into the marine environment in such a scenario. In accordance with Regulation 56, NOPSEMA is referred to the relevant operations EPs submitted by the Operators of the live infrastructure, and accepted by NOPSEMA, for the detail of potential impacts, receptors and the extent of the environment that may be affected in such a scenario, being:

- Julimar Operations EP (NOPSEMA Doc A771970, https://docs.nopsema.gov.au/A771970)
- Wheatstone Project Start-up and Operations EP (NOPSEMA Doc: A853704, https://docs.nopsema.gov.au/A853704)
- Reindeer Wellhead Platform and Offshore Gas Supply Pipeline Operations (NOPSEMA Doc: A738138, https://docs.nopsema.gov.au/A738138)
- Scarborough Seabed Intervention and Trunkline Installation (NOPSEMA Doc. A1027151, https://docs.nopsema.gov.au/A1027151).

As detailed in this section above and below, this EP addresses the risks and impacts (interaction with live infrastructure) that arise from the activities under this EP (interaction from dropped objects and interaction from anchor drag). This EP also contains controls to prevent such an event from occurring that are within the operational control of this EP. As detailed in this section, the operational control, maintenance and incident response associated with the live infrastructure and/or loss of containment from the live infrastructure is not within the operational control of this EP. As detailed below, the risks and impacts of the activities under this EP are managed to ALARP and an acceptable level by implementing the SIMOPS plan and notifying the relevant Operators in the instance of an interaction with live infrastructure to allow the relevant Operator's detailed response strategies under the relevant operations EPs to be triggered, if required. In the event of a loss of containment caused by an interaction with live infrastructure Woodside will follow direction from the relevant Operator and will respond as per the relevant Operator's requirements. In accordance with Regulation 56, NOPSEMA is referred to the relevant operations EPs submitted by the Operators of the live infrastructure, and accepted by NOPSEMA, for the detail of the operational control, maintenance and incident response associated with the live infrastructure and/or loss of containment from the live infrastructure.

Demonstration of ALARP				
Control Considered	***Control Feasibility (F) and Cost/ Sacrifice (CS)[146]***	***Benefit in Impact/Risk Reduction***	***Proportionality***	***Control Adopted***
Good Practice				
The MODU/PIV work procedures for lifts, bulk transfers and cargo loading, which require: • The security of loads shall be checked prior to commencing lifts. • Loads shall be covered if there is a risk of loss of loose materials. • Lifting operations shall be conducted using the PTW and JSA systems to manage the specific risks of that lift, including consideration of weather and sea state.	F: Yes. CS: Minimal cost. Standard practice.	Reduces the likelihood of an object being dropped during lifts, bulk transfers and cardo loading.	Benefits outweigh cost/sacrifice.	Yes C 25.1
Specifications and requirements for station keeping equipment (mooring systems), require that: • systems are tested and inspected in accordance with API RP 21 • systems have sufficient capability such that a failure of any single component will not cause progressive failure of the remaining anchoring arrangement.	F: Yes. CS: Minimal cost. Standard practice.	Reduces the likelihood of mooring failure leading to uncontrolled anchor drag.	Benefit outweighs cost/sacrifice.	Yes C 25.3
Project-specific Mooring Design Analysis.	F: Yes. CS: Minimal cost. Standard practice.	By ensuring that a mooring analysis report is undertaken, the likelihood of mooring failure occurring is reduced. The mooring design analysis report specifically considers proximity to live infrastructure and manages potential impacts on that infrastructure accordingly.	Benefit outweighs cost/sacrifice.	Yes C 2.6

[146] Qualitative measure.

Mooring system is tested to recommended tension as per API RP 2SK.	F: Yes. CS: Minimal cost. Standard practice	Reduces the likelihood of anchor drag.	Benefit outweighs cost/sacrifice.	Yes C 25.4
Professional Judgement – Eliminate				
No additional controls identified.				
Professional Judgement – Substitute				
No additional controls identified.				
Professional Judgement – Engineered Solution				
MODU tracking equipment operational when the MODU unmanned.	F: Yes. CS: Minimal cost. Standard practice.	Although no reduction in consequence would occur, the overall risk is reduced as the location of the MODU would be known at all times and the appropriate response could be deployed in the event of a loss of station keeping.	Benefit outweighs cost/sacrifice.	Yes C 28.1
Develop a SIMOPS Plan to manage MODU interactions with other facilities/vessels, where multiple campaigns occur within the PAA (i.e. during xmas tree installation). SIMOPS Plan will contain information on: • minimum separation distances • communications • MODU/vessels/ activities involved in SIMOPS • exclusion zone entry and exit processes • ROV operations • helicopter operations • key roles, responsibilities and emergency contacts • PTW arrangements • incident reporting and investigation • management of change.	F: Yes. CS: Minimal cost. Standard practice.	SIMOPS Plan contains detail such as communications requirements, exclusion zones and entry/exit requirements and roles and responsibilities – which can help reduce likelihood of interactions with live infrastructure, it also contains notification protocols in the event of an interaction with live infrastructure. The SIMOPS plan also requires notification in the event of an incident or interaction with infrastructure thus triggering response strategies in the relevant operations EPs. The detailed response is in the Operations EP and the implementation of that would be triggered by the SIMOPS plan and Woodside will support the response according to the other Operator's requests.	Benefits outweigh cost/sacrifice. Control is also Standard Practice.	Yes C 1.15
ALARP Statement: Woodside considers the adopted controls appropriate to manage the risks of a significant dropped object or anchor drag interacting with live infrastructure within the PAA. As no reasonable additional/alternative controls were identified that would further reduce the risks and consequences without disproportionate sacrifice, the risks and consequences are considered ALARP.				

Demonstration of Acceptability			
Acceptability Statement: The impact assessment has determined that interaction with live infrastructure from dropped objects or a loss of station keeping of the MODU represents a low current risk rating and is unlikely to result in a risk consequence greater than slight. The adopted controls are considered industry good practice. The potential risks and consequences are considered broadly acceptable if the adopted controls are implemented. Therefore, Woodside considers the adopted controls appropriate to manage the risks of seabed disturbance from dropped objects/anchor drag to an acceptable level.			
EPOs, EPSs and MC for Xena-03 Tie-back Activities			
Outcomes	***Controls***	***Standards***	***Measurement Criteria***
EPO 28 No interaction with live infrastructure as a result of the Petroleum Activities Program.	**C 1.15** Develop a SIMOPS Plan to manage MODU interactions with other facilities/vessels, where multiple campaigns occur within the PAA (i.e. during xmas tree installation). SIMOPS Plan will contain information on: • minimum separation distances • communications • MODU/vessels/ activities involved in SIMOPS • exclusion zone entry and exit processes • ROV operations • helicopter operations • key roles, responsibilities and emergency contacts • PTW arrangements • incident reporting and investigation management of change.	**PS 1.15** MODU and applicable vessels compliant with SIMOPS Plan.	**MC 1.15.1** Records demonstrate implementation of SIMOPS Management Plan when MODU working in vicinity of other facilities/vessels, i.e. during xmas tree installation.
	C 2.6 Project-specific MODU Mooring Design Analysis.	**PS 2.6** Seabed disturbance from MODU mooring limited to that required to ensure adequate MODU station holding capacity.	**MC 2.6.1** Records demonstrate Mooring Design Analysis approved and implemented during anchor deployment.
	C 25.1 The MODU/installation vessel work procedures for lifts, bulk transfers and cargo loading, which require: • the security of loads shall be checked prior to commencing lifts • loads shall be covered if there is a risk of loss of loose materials. • Lifting operations shall be conducted using the PTW and JSA systems to manage the specific risks of that lift,	**PS 25.1** All lifts conducted in accordance with applicable MODU/installation vessel work procedures to limit potential for dropped objects.	**MC 25.1.1** Records show lifts conducted in accordance with the applicable MODU/installation vessel work procedures.

	including consideration of weather and sea state.		
	C 25.3 Specification and requirements for station keeping equipment (mooring systems) require that: • systems are tested and inspected in accordance with API RP 21 • systems have sufficient capability such that a failure of any single component will not cause progressive failure of the remaining anchoring arrangement.	**PS 25.3** MODU mooring system tested and in place to ensure no complete mooring failure.	**MC 25.3.1** Records demonstrate mooring system tests and inspection.
	C 25.4 Mooring system is tested to recommended tension as per API RP 2SK.	**PS 25.4** Monitoring compliant with ISO 19901-7:2013.	**MC 25.4.1** Records confirm mooring system is tested to recommended tension as per API RP 2SK.
	C 28.1 MODU tracking equipment operational when the MODU unmanned.	**PS 28.1** Tracking of the MODU is possible when the MODU is unmanned.	**MC 28.1.1** Records show the moored MODU has functional tracking equipment for instances when MODU is unmanned.

6.10 Recovery Plan and Threat Abatement Plan Assessment

This section describes the assessment that Woodside has undertaken to demonstrate that the PAP is not inconsistent with any relevant recovery plans or threat abatement plans. For the purposes of this assessment, the relevant Part 13 statutory instruments (recovery plans and threat abatement plans) are:

- Recovery Plan for Marine Turtles in Australia 2017–2027 (Commonwealth of Australia, 2017).
- Conservation Management Plan for the Blue Whale 2015–2025 (Commonwealth of Australia, 2015a).
- National Recovery Plan for the Southern Right Whale (DCCEEW, 2024a)
- Recovery Plan for the Grey Nurse Shark (Carcharias taurus) 2014 (Commonwealth of Australia, 2014)
- Sawfishes and River Sharks Multispecies Recovery Plan (Commonwealth of Australia, 2015b).
- Threat Abatement Plan for the impacts of marine debris on the vertebrate wildlife of Australia's coasts and oceans 2018 (Commonwealth of Australia, 2018).

Table 6-50 lists the objectives and (where relevant) the action areas of these plans, and also describes whether these objectives/action areas are applicable to government, the Titleholder, and/or the Petroleum Activities Program. For those objectives/action areas applicable to the Petroleum Activities Program, the relevant actions of each plan have been identified, and an evaluation has been conducted as to whether impacts and risks resulting from the activity are not inconsistent with that action.

The assessment of potential impacts and risks to PBW from underwater noise emissions has taken into account the definitions of terminology in the CMP, as described in the DAWE and NOPSEMA guidance released in September 2021. Similarly, the assessment against relevant actions in the CMP in Table 6-52 has been undertaken in the context of the definitions included in the guidance note.

Table 6-50: Identification of applicability of recovery plan and threat abatement plan objectives and action areas

EPBC Act Part 13 Statutory Instrument	Applicable to:		
	Government	***Titleholder***	***Petroleum Activities Program***
Marine Turtle Recovery Plan			
Long-term Recovery Objective: Minimise anthropogenic threats to allow for the conservation status of marine turtles to improve so they can be removed from the EPBC Act threatened species list	Y	Y	Y
Interim Recovery Objectives			
Current levels of legal and management protection for marine turtle species are maintained or improved, both domestically and throughout the migratory range of Australia's marine turtles	Y		
The management of marine turtles is supported	Y		
Anthropogenic threats are demonstrably minimised	Y	Y	Y
Trends in nesting numbers at index beaches and population demographics at important foraging grounds are described	Y	Y	
Action Areas			
A. Assessing and addressing threats			
A1. Maintain and improve efficacy of legal and management protection	Y		
A2. Adaptatively manage turtle stocks to reduce risk and build resilience to climate change and variability	Y	Y	Y
A3. Reduce the impacts of marine debris	Y	Y	Y
A4. Minimise chemical and terrestrial discharge	Y	Y	Y
A5. Address international take within and outside Australia's jurisdiction	Y		
A6. Reduce impacts from terrestrial predation	Y		
A7. Reduce international and domestic fisheries bycatch	Y		
A8. Minimise light pollution	Y	Y	Y
A9. Address the impacts of coastal development/infrastructure and dredging and trawling	Y	Y	
A10. Maintain and improve sustainable Indigenous management of marine turtles	Y		
B. Enabling and measuring recovery			

EPBC Act Part 13 Statutory Instrument	Applicable to:		
	Government	***Titleholder***	***Petroleum Activities Program***
B1. Determine trends in index beaches	Y	Y	
B2. Understand population demographics at key foraging grounds	Y		
B3. Address information gaps to better facilitate the recovery of marine turtle stocks	Y	Y	Y
Blue Whale Conservation Management Plan			
Long-term recovery objective: Minimise anthropogenic threats to allow for their conservation status to improve so that they can be removed from the EPBC Act threatened species list	Y	Y	Y
Interim Recovery Objectives			
The conservation status of blue whale populations is assessed using efficient and robust methodology	Y		
The spatial and temporal distribution, identification of biologically important areas, and population structure of blue whales in Australian waters is described	Y	Y	Y
Current levels of legal and management protection for blue whales are maintained or improved and an appropriate adaptive management regime is in place	Y		
Anthropogenic threats are demonstrably minimised	Y	Y	Y
Action Areas			
A. Assessing and addressing threats			
A.1: Maintain and improve existing legal and management protection	Y		
A.2: Assessing and addressing anthropogenic noise	Y	Y	Y
A.3: Understanding impacts of climate variability and change	Y	Y	Y
A.4: Minimising vessel collisions	Y	Y	Y
B. Enabling and Measuring Recovery			
B.1: Measuring and monitoring population recovery	Y		
B.2: Investigating population structure	Y		
B.3: Describing spatial and temporal distribution and defining biologically important habitat	Y	Y	Y

EPBC Act Part 13 Statutory Instrument	Applicable to:		
	Government	***Titleholder***	***Petroleum Activities Program***
Southern Right Whale Recovery Plan			
Long-term vision: increase population to a level that the conservation status has improved and the species no longer qualifies for listing as threatened under any of the EPBC Act listing criteria	Y	Y	Y
Interim Recovery Objectives			
• Current levels of Commonwealth and State legislative and management protection for southern right whales are implemented, maintained, or improved, so threats continue to be managed and reduced over the life of the plan	Y		
• Anthropogenic threats are managed consistent with ecologically sustainable principles to facilitate recovery of southern right whales	Y	Y	Y
• Population dynamics, including demographics, distribution, residency, and coastal movement across the species range are monitored and quantified using robust, standardised, best-practice methodology to assess population recovery	Y		
• The population structure in Australian waters is clearly characterised to evaluate the degree to which the western and eastern populations are separate populations and inform the degree of connectivity with other southern right whale populations	Y		
• Capability of First Nation Australians, research, citizen science, and general community groups is improved to assist in addressing recovery actions of southern right whales in Australia	Y		
Action Areas			
<u>Assess and address key threats</u>			
A1: Maintain, implement and improve efficacy of current legislative and management protection for southern right whales	Y		
A2: Address habitat degradation impacts from coastal and offshore marine infrastructure developments within the species' range	Y	Y	Y
A3: Understand impacts of climate variability and anthropogenic climate change on the species biology and population recovery	Y	Y	Y
A4: Manage and mitigate the threat of entanglements from commercial active or discarded fishing gear throughout the species' range in Australian waters	Y		
A5: Assess, manage and mitigate impacts from anthropogenic underwater noise	Y	Y	Y

EPBC Act Part 13 Statutory Instrument	Applicable to:		
	Government	***Titleholder***	***Petroleum Activities Program***
A6: Manage, minimise and mitigate the threat of vessel strike	Y	Y	Y
Measure Recovery			
B1: Measure and monitor population demographic and recovery	Y		
B2: Characterise population structure	Y		
B3: Determine migratory paths and offshore distribution	Y		
B4: Improve capability of First Nation Australians, research, citizen science, and general community groups to assist management of southern right whales	Y		
Grey Nurse Shark Recovery Plan			
Overarching Objective			
To assist the recovery of the grey nurse shark in the wild, throughout its range in Australian waters, with a view to: • improving the population status, leading to future removal of the grey nurse shark from the threatened species list of the EPBC Act • ensuring that anthropogenic activities do not hinder the recovery of the grey nurse shark in the near future, or impact on the conservation status of the species in the future	Y	Y	Y
Specific Objectives			
Develop and apply quantitative monitoring of the population status (distribution and abundance) and potential recovery of the grey nurse shark in Australian waters	Y		
Quantify and reduce the impact of commercial fishing on the grey nurse shark through incidental (accidental and/or illegal) take, throughout its range	Y		
Quantify and reduce the impact of recreational fishing on the grey nurse shark through incidental (accidental and/or illegal) take, throughout its range	Y		
Where practicable, minimise the impact of shark control activities on the grey nurse shark	Y		
Investigate and manage the impact of ecotourism on the grey nurse shark	Y		
Manage the impact of aquarium collection on the grey nurse shark	Y		
Improve understanding of the threat of pollution and disease to the grey nurse shark	Y	Y	Y

EPBC Act Part 13 Statutory Instrument	Applicable to:		
	Government	***Titleholder***	***Petroleum Activities Program***
Continue to identify and protect habitat critical to the survival of the grey nurse shark and reduce the impact of threatening processes within these areas	Y	Y	
Continue to develop and implement research programs to support the conservation of the grey nurse shark	Y	Y	
Promote community education and awareness in relation to grey nurse shark conservation and management	Y		
Sawfish and River Sharks Recovery Plan			
Primary Objective			
To assist the recovery of sawfish and river sharks in Australian waters with a view to: • improving the population status leading to the removal of the sawfish and river shark species from the threatened species list of the EPBC Act • ensuring that anthropogenic activities do not hinder recovery in the near future, or impact on the conservation status of the species in the future	Y	Y	Y
Specific Objectives			
Reduce and, where possible, eliminate adverse impacts of commercial fishing on sawfish and river shark species	Y		
Reduce and, where possible, eliminate adverse impacts of recreational fishing on sawfish and river shark species	Y		
Reduce and, where possible, eliminate adverse impacts of Indigenous fishing on sawfish and river shark species	Y		
Reduce and, where possible, eliminate the impact of illegal, unregulated and unreported fishing on sawfish and river shark species	Y		
Reduce and, where possible, eliminate adverse impacts of habitat degradation and modification on sawfish and river shark species	Y	Y	Y
Reduce and, where possible, eliminate any adverse impacts of marine debris on sawfish and river shark species noting the linkages with the Threat Abatement Plan for the Impact of Marine Debris on Vertebrate Marine Life	Y	Y	Y
Reduce and, where possible, eliminate any adverse impacts of collection for public aquaria on sawfish and river shark species	Y		
Improve the information base to allow the development of a quantitative framework to assess the recovery of, and inform management options for, sawfish and river shark species	Y		
Develop research programs to assist conservation of sawfish and river shark species	Y	Y	

EPBC Act Part 13 Statutory Instrument	Applicable to:		
	Government	***Titleholder***	***Petroleum Activities Program***
Improve community understanding and awareness in relation to sawfish and river shark conservation and management	Y		
Marine Debris Threat Abatement Plan			
Objectives			
Contribute to long-term prevention of the incidence of marine debris	Y	Y	
Understand the scale of impacts from marine plastic and microplastic on key species, ecological communities and locations	Y	Y	Y
Remove existing marine debris	Y		
Monitor the quantities, origins, types and hazardous chemical contaminants of marine debris, and assess the effectiveness of management arrangements for reducing marine debris	Y		
Increase public understanding of the causes and impacts of harmful marine debris, including microplastic and hazardous chemical contaminants, to bring about behaviour change	Y		

Table 6-51: Assessment against relevant actions of the Marine Turtle Recovery Plan

Part 13 Statutory Instrument	Relevant Action Areas/Objectives	Relevant Actions	Evaluation	EPO, Controls and PS
Marine Turtle Recovery Plan	**Action Area A2:** Adaptively manage turtle stocks to reduce risk and build resilience to climate change and variability	**Action:** Continue to meet Australia's international commitments to address the causes of climate change.	Refer Section 6.7.10 **Not inconsistent assessment**: This PAP contributes to Australia meeting international commitments to address the causes of climate change primarily via compliance with Marine Order 97, the National Greenhouse and Energy Reporting Scheme (NGERS) and National Greenhouse and Energy Reporting (Safeguard Mechanism) Rule 2015.	EPO 10a, 10b, 10c, 10d, 10e C10.1, 10.2, 10.3, 10.9, 10.10, 10.14, 10.13, 10.15, 10.16 PS 10.1, 10.2, 10.3, 10.9.1, 10.9.2, 10.9.3, 10.10, 10.14, 10.15.1, 10.16.1
	Action Area A3: Reduce the impacts from marine debris	Action: Support the implementation of the Marine Debris Threat Abatement Plan (TAP) Priority actions at stock level: • G-NWS – Understand the threat posed to this stock by marine debris • LH-WA – Determine the extent to which marine debris is impacting loggerhead turtles • F-Pil – no relevant actions	Not inconsistent assessment: The assessment of the accidental release of solid hazardous and non-hazardous wastes has considered the potential risks to marine turtles. Controls have been implemented to reduce the likelihood of accidental release of solid wastes for the duration of the petroleum activities program.	EPO 24 C 24.1 , 24.2, 24.3, 24.4, 24.6 PS 24.1, 24.2, 24.3, 24.4, 24.6
	Action Area A4: Minimise chemical and terrestrial discharge	Action: Ensure spill risk strategies and response programs adequately include management for marine turtles and their habitats, particularly in reference to 'slow to recover habitats'; e.g., nesting habitat, seagrass meadows or coral reefs Priority actions at stock level: • G-NWS – Ensure that spill risk strategies and response programs include management for turtles and their habitats • LH-WA and F-Pil – Ensure that spill risk strategies and response programs include management for turtles and their habitats, particularly in reference to slow to recover habitats; e.g., seagrass meadows or corals	Not inconsistent assessment: The assessment of accidental release of chemicals/hydrocarbons has considered the potential risks to marine turtles. Spill risk strategies and response program include management measures for turtles and their nesting habitats.	Detailed oil spill preparedness and response performance outcomes, standards and measurement criteria for the PAP are present in Sections 6.8 and 6.9.

Part 13 Statutory Instrument	Relevant Action Areas/Objectives	Relevant Actions	Evaluation	EPO, Controls and PS
	Action Area A8: Minimise light pollution	Action: Artificial light within or adjacent to habitat critical to the survival of marine turtles will be managed such that marine turtles are not displaced from these habitats Priority actions at stock level: • G-NWS – as above • LH-WA – no relevant actions • F-Pil – Manage artificial light from onshore and offshore sources to ensure biologically important behaviours of nesting adults and emerging/dispersing hatchlings can continue	Not inconsistent assessment: The assessment of light emissions has considered the potential impacts to marine turtles. Internesting, mating, foraging or migrating turtles are not impacted by light from offshore vessels. Based on the frequency and nature of IMMR activities, the impacts to adult turtles moving through the PAA from vessel lighting are expected to be localised and temporary with no lasting effect.	EPO 12a, b, c C 12.1, 12.2, C 10.11 PS 12.1, 12.2, 10.11
	Action Area B1: Determine trends at index beaches	Action: Maintain or establish long-term monitoring programs at index beaches to collect standardised data critical for determining stock trends, including data on hatchling production Priority actions at stock level: • G-NWS – Continue long-term monitoring of index beaches • LH-WA – Continue long-term monitoring of nesting and foraging populations • F-Pil – no relevant actions	Not inconsistent assessment: Woodside contributes to Action Area B1 via its support of the Ningaloo Turtle Program1.	N/A
	Action Area B3: Address information gaps to better facilitate the recovery of marine turtle stocks	Action: Understand the impacts of anthropogenic noise on marine turtle behaviour and biology Priority actions at stock level: • G-NWS – Given this is a relatively accessible stock that is likely to be exposed to anthropogenic noise – Investigate the impacts of anthropogenic noise on turtle behaviour and biology and extrapolate findings from the North West Shelf stock to other stocks • LH-WA – no relevant actions • F-Pil – no relevant actions	Not inconsistent assessment: The assessment of acoustic emissions has considered the potential impacts to marine turtles. Noise related to the PAP is not expected to result in behavioural response, injury or mortality of individuals, or any other lasting effect.	EPO 3a, 3b, 4 C 3.3, 3.4, 4.1, 4.3, PS 3.3, 3.4, 4.1, 4.3,

Part 13 Statutory Instrument	Relevant Action Areas/Objectives	Relevant Actions	Evaluation	EPO, Controls and PS
Assessment Summary The Marine Turtle Recovery Plan has been considered during the assessment of impacts and risks, and the PAP is not considered to be inconsistent with the relevant actions of this plan.				

Table 6-52: Assessment against relevant actions of the Blue Whale Conservation Management Plan

Part 13 Statutory Instrument	Relevant Action Areas/Objectives	Relevant Actions	Evaluation	EPO, Controls and PS
Blue Whale Conservation Management Plan	Action Area A.2: Assessing and addressing anthropogenic noise.	Action 2: Assessing the effect of anthropogenic noise on blue whale behaviour Action 3: Anthropogenic noise in biologically important areas will be managed such that any blue whale continues to use the area without injury, and is not displaced from a foraging area	Not inconsistent assessment: The assessment of acoustic emissions has considered the potential impacts to pygmy blue whales. Acoustic emissions from project vessels will not cause injury to any pygmy blue whale. There are no known or possible foraging areas for PBW within or adjacent to the PAA. If the PAP within the PAA overlaps with an individual northbound or southbound migration, they may deviate slightly from the migratory route but will continue on their migration.	EPO 3a, 3b, 4 C 3.1, 3.2, 3.4, 4.1, 4.2 4.3, 4.4 PS 3.1, 3.2, 3.4, 4.1, 4.2 4.3, 4.4
	Action Area A.3: Understanding impacts of climate variability and change	**Action 1:** Continue to meet Australia's international commitments to reduce greenhouse gas emissions and regulate the krill fishery in Antarctica.	Refer Section 6.7.10 **Not inconsistent assessment**: This PAP contributes to Australia meeting international commitments to reducing greenhouse gas emissions primarily via compliance with Marine Order 97, the National Greenhouse and Energy Reporting Scheme (NGERS) and National Greenhouse and Energy Reporting (Safeguard Mechanism) Rule 2015. The Regulation of the krill fishery in Antarctica is not applicable to Woodside or this EP.	EPO 10a, 10b, 10c, 10d, 10e C10.1, 10.2, 10.3, 10.9, 10.10, 10.14, 10.13, 10.15, 10.16 PS 10.1, 10.2, 10.3, 10.9.1, 10.9.2, 10.9.3, 10.10, 10.14, 10.15.1, 10.16.1
	Action Area A.4: Minimising vessel collisions	Action 3: Ensure the risk of vessel strikes on blue whales is considered when assessing actions that increase vessel traffic in areas where blue whales occur and, if required, appropriate mitigation measures are implemented	Not inconsistent assessment: The assessment of vessel collision with marine fauna has considered the potential risks to pygmy blue whales. If the PAP within the PAA overlaps with an individual northbound or southbound migration, they may deviate slightly from the migratory route, but will continue on their migration. Vessel collisions with PBW are highly unlikely to occur, given the low operating speed of support vessels.	EPO 26 C 3.1 PS 3.1

Part 13 Statutory Instrument	Relevant Action Areas/Objectives	Relevant Actions	Evaluation	EPO, Controls and PS
	Action Area B.3: Describing spatial and temporal distribution and defining biologically important habitat	Action 2: Identify migratory pathways between breeding and feeding grounds Action 3: Assess timing and residency within Biologically Important Areas	Not inconsistent assessment: Woodside contributes to Action Area B3 via its support of targeted research initiatives (e.g., satellite tracking of pygmy blue whale migratory movements).	N/A
Assessment Summary The Blue Whale Conservation Management Plan has been considered during the assessment of impacts and risks, and the PAP is not considered to be inconsistent with the relevant actions of this plan.				

Table 6-53: Assessment against relevant actions of the Southern Right Whale Recovery Plan

Part 13 Statutory Instrument	Relevant Action Areas/Objectives	Relevant Actions	Evaluation	EPO, Controls and PS
National Recovery Plan for the Southern Right Whale	A2: Address habitat degradation impacts from coastal and offshore marine infrastructure developments within the species' range	Action 1: Coastal and offshore development actions are assessed according to principles of ecological sustainable development to ensure the risk of injury, auditory impairment and/or disturbance to southern right whales is maintained. Action 3: Current information on species' occurrence, particularly in HCTS, BIAs and historic high use areas, are used to inform planning, assessment, and decision-making on marine infrastructure development actions.	Not inconsistent assessment: This EP assesses the potential impacts of the petroleum activity do not result in the risk of injury, auditory impairment and/or disturbance to southern right whales, particularly within the HCTS and BIAs that are located over 250 km from the Operational Areas.	N/A

Part 13 Statutory Instrument	Relevant Action Areas/Objectives	Relevant Actions	Evaluation	EPO, Controls and PS
	Action Area A.3: Understand impacts of climate variability and anthropogenic climate change on the species biology and population recovery.	**Action 1:** Continue to meet Australia's international commitments to address causes of climate change, including greenhouse gas emissions.	Refer Section 6.7.10 **Not inconsistent assessment**: This PAP contributes to Australia meeting international commitments to address causes of climate change, including greenhouse gas emissions, primarily via compliance with Marine Order 97, the National Greenhouse and Energy Reporting Scheme (NGERS) and National Greenhouse and Energy Reporting (Safeguard Mechanism) Rule 2015.	EPO 10a, 10b, 10c, 10d, 10e **C10.1, 10.2, 10.3, 10.9, 10.10, 10.14, 10.13, 10.15, 10.16** **PS 10.1, 10.2, 10.3, 10.9.1, 10.9.2, 10.9.3, 10.10, 10.14, 10.15.1, 10.16.1**
	A5: Assess, manage, and mitigate impacts from anthropogenic underwater noise	Action 2: Actions within and adjacent to southern right whale BIAs and HCTS should demonstrate that it does not prevent any southern right whale from utilising the area or cause auditory impairment Action 3: Actions within and adjacent to southern right whale BIAs and HCTS should demonstrate that the risk of behavioural disturbance is minimised Action 4: Ensure environmental assessments associated with underwater noise generating activities include consideration of national policy (e.g., EPBC Act Policy Statement 2.1) and guidelines related to managing anthropogenic underwater noise and implement appropriate mitigation measures to reduce risks to southern right whales to the lowest possible level Action 5: Quantify risks of anthropogenic underwater noise to southern right whales, including studies aimed to measure physiological effects, behavioural disturbance, and changes to acoustic communication (e.g., masking of vocalisations) to whales	Not inconsistent assessment: The assessment of acoustic emissions has considered the potential impacts to southern right whales. The nearest BIAs and HCTS for the southern right whale being over 250 km from the Operational Areas therefore it is not expected that noise from the petroleum activity program will impact the southern right whales.	N/A

Part 13 Statutory Instrument	Relevant Action Areas/Objectives	Relevant Actions	Evaluation	EPO, Controls and PS
	A6: Manage, minimise and mitigate the threat of vessel strike	Action 1: Assess risk of vessel strike to southern right whales in BIAs Action 3: Ensure environmental impact assessments and associated plans consider and quantify the risk of vessel strike and associated potential cumulative risks in BIAs and HCTS	Not inconsistent assessment: The assessment of vessel collision with marine fauna has considered the potential risks to southern right whales. The nearest BIAs and HCTS for the southern right whale being over 250 km from the Operational Areas; therefore, it is not expected that there is a risk of vessel strike.	N/A
Assessment Summary The National Recovery Plan for the Southern Right Whale has been considered during the assessment of impacts and risks, and the PAP is not considered to be inconsistent with the relevant actions of this plan.				

Table 6-54: Assessment against relevant actions of the Grey Nurse Shark Recovery Plan

Part 13 Statutory Instrument	Relevant Action Areas/Objectives	Relevant Actions	Evaluation	EPO, Controls and PS
Grey Nurse Shark Recovery Plan	Objective 7: Improve understanding of the threat of pollution and disease to the grey nurse shark	Action 7.1: Review and assess the potential threat of introduced species, pathogens and pollutants	Not inconsistent assessment: This EP includes an assessment of the impacts from accidental release of solid wastes as well as planned discharges of drilling waste on marine species.	N/A.
			Not inconsistent assessment: The assessment of accidental release of chemicals / hydrocarbons has considered the potential risks to grey nurse sharks. Spill risk strategies and response program include management measures, as identified and required.	Detailed oil spill preparedness and response performance outcomes, standards and measurement criteria for the PAP are present in Sections 6.8 and 6.9.
Assessment Summary The Grey Nurse Shark Recovery Plan has been considered during the assessment of impacts and risks, and the PAP is not considered to be inconsistent with the relevant actions of this plan.				

Table 6-55: Assessment against relevant actions of the Sawfish and River Shark Recovery Plan

Part 13 Statutory Instrument	Relevant Action Areas/Objectives	Relevant Actions	Evaluation	EPO, Controls and PS
Sawfish and River Shark Recovery Plan	Objective 5: Reduce and, where possible, eliminate adverse impacts of habitat degradation and modification on sawfish and river shark species	Action 5c: Identify risks to important sawfish and river shark habitat and measures needed to reduce those risks	Not inconsistent assessment: The assessment of accidental release of chemicals/hydrocarbons has considered the potential risks to sawfish and river shark. Spill risk strategies and response program include management measures, as identified and required.	Detailed oil spill preparedness and response performance outcomes, standards and measurement criteria for the PAP are present in Appendix H
	Objective 6: Reduce and, where possible, eliminate any adverse impacts of marine debris on sawfish and river shark species noting the linkages with the Threat Abatement Plan for the Impact of Marine Debris on Vertebrate Marine Life	Action 6a: Assess the impacts of marine debris including ghost nets, fishing gear and plastics on sawfish and river shark species	Not inconsistent assessment: The assessment of the accidental release of solid hazardous and non-hazardous wastes has considered the potential risks to sawfish. Controls have been implemented to reduce the likelihood of accidental release of solid wastes for the duration of the petroleum activities program.	N/A
Assessment Summary The Sawfish and River Shark Recovery Plan has been considered during the assessment of impacts and risks, and the PAP is not considered to be inconsistent with the relevant actions of this plan.				

Table 6-56: Assessment against relevant actions of the Marine Debris Threat Abatement Plan

Part 13 Statutory Instrument	Relevant Action Areas/Objectives	Relevant Actions	Evaluation	EPO, Controls and PS
Marine Debris TAP	Objective 2: Understand the scale of marine plastic and microplastic impact on key species, ecological communities and locations	Action 2.04: Build understanding related to plastic and microplastic pollution	Not inconsistent assessment: The assessment of the accidental release of solid hazardous and non-hazardous wastes has considered the potential risks to the marine environment. Controls have been implemented to reduce the likelihood of accidental release of solid wastes for the duration of the petroleum activities program.	N/A
Assessment Summary The Marine Debris TAP has been considered during the assessment of impacts and risks, and the PAP is not considered to be inconsistent with the relevant actions of this plan.				

6.11 First Nations Cultural Features and Heritage Values Assessment

As described in Section 4.9, the identification of cultural features and heritage values of the environment as well as the social, economic and cultural features important to First Nation's people is integral to understanding the environment and any potential impacts and risks to the environment.

In line with Woodside's First Nations Communities Policy (December 2023), Woodside seeks to avoid damage or disturbance to cultural heritage (including intangible heritage) and, if avoidance is not possible, minimise and mitigate the impacts, in consultation with First Nation communities and Traditional Custodians. Mitigation can include any measure or control aimed at ensuring the viability of the intangible cultural heritage and its intergenerational transmission. This can include reducing impacts and risks to environmental features that are associated with intangible cultural heritage (UNESCO, 2003; ICOMOS, 2013).

It is important to note that not all topics raised by First Nations groups and individuals through consultation are considered values for the purpose of the cultural features and heritage values impact assessment below. A number of topics were raised in the context of a general interest in environmental management and ecosystem health (i.e., natural environment interest), where the group/individual was seeking further information about potential impacts and risks from the PAP on a receptor. As these interests relate to the maintenance of the natural environment, these are adequately addressed through impact and risk assessments and not further assessed in Table 6-57.

Table 6-57: First Nations cultural features and heritage values assessment

Aspect	Cultural Features and Heritage Values
Description of Source Impact/ Risk	***Physical Presence of Vessels*** The PAP involves operation of the Pluto Facility and the drilling and tie-back of one new production well (Xena-03). The MODU will be present within the Xena-03 Operational Area for ~60 days to drill the Xena-03 well. When underway, activities will be 24 hours per day, seven days per week. Subsea installation vessels will be used to install and cold commission the flowlines and subsea infrastructure following the completion of drilling the new well. This is expected to take approximately three weeks. Temporary exclusion zones will be established around the MODU. ***Acoustic Emissions from Vessels*** MODUs, installation vessels and support vessels (including ASV and AHVs) undertaking the PAP will generate noise both in the air and underwater. During drilling operations, the MODU will produce low-intensity continuous sound. In addition, the PAP will be supported by DP capable vessels. These noises will contribute to and can exceed ambient noise levels which range from around 90 dB re 1 µPa (root square mean sound pressure level (RMS SPL)) under very calm, low wind conditions, to 120 dB re 1 µPa (RMS SPL) under windy conditions. ***Unplanned Hydrocarbon Release from Loss of Well Containment (Basis of EMBA)*** For each source of risk, the credible worst-case scenario in conjunction with impact thresholds is used to determine the spatial extent of the EMBA. The worst-case unplanned event is considered to be an unplanned hydrocarbon release. The stochastic modelling approach to determining the EMBA involves numerous simulations covering a range of metocean conditions representing currents and winds that typically prevail over the course of a year. The EMBA is generated from a composite of outcomes of each simulation and therefore covers a larger area than the area that could be affected during any one single spill event. In the event of a spill, the area that would be affected would be much smaller than the EMBA. The EMBA is driven by the distribution of entrained hydrocarbon above ecological thresholds and hence although Islands such as Barrow and Montebello Islands, and mainland coastlines are within the EMBA, these are not expected to be affected unless there is shoreline contact above thresholds. While the EMBA is driven by predictions of entrained hydrocarbons, the scenario associated with the most significant consequence involves shoreline contact, which is predicted from the scenario of subsea equipment loss of containment.
