[197] The ability to adjust schedules is dependent on the type of activity and any schedule drivers (e.g. safe operating [metocean] conditions, vessel or equipment availability, integrity management for IMR, etc.).

[198] The development, spatial extent, and use of any management zones (e.g. observation, action, shut-down) will be commensurate with the sound source and risk being managed.

[199] These in-field decisions to adjust an activity are the responsibility of the Vessel Master (or equivalent), and would only be implemented where it is considered operationally safe and technically feasible.

[200] In-field observations of actual whale feeding are difficult to detect, so indicators of probable foraging (e.g. aggregating in a particular area) may be used as a proxy (Ref. 369). The type of indicator, or ability to detect actual feeding behaviours, may change over the life of the Development with advancement in science and technology.

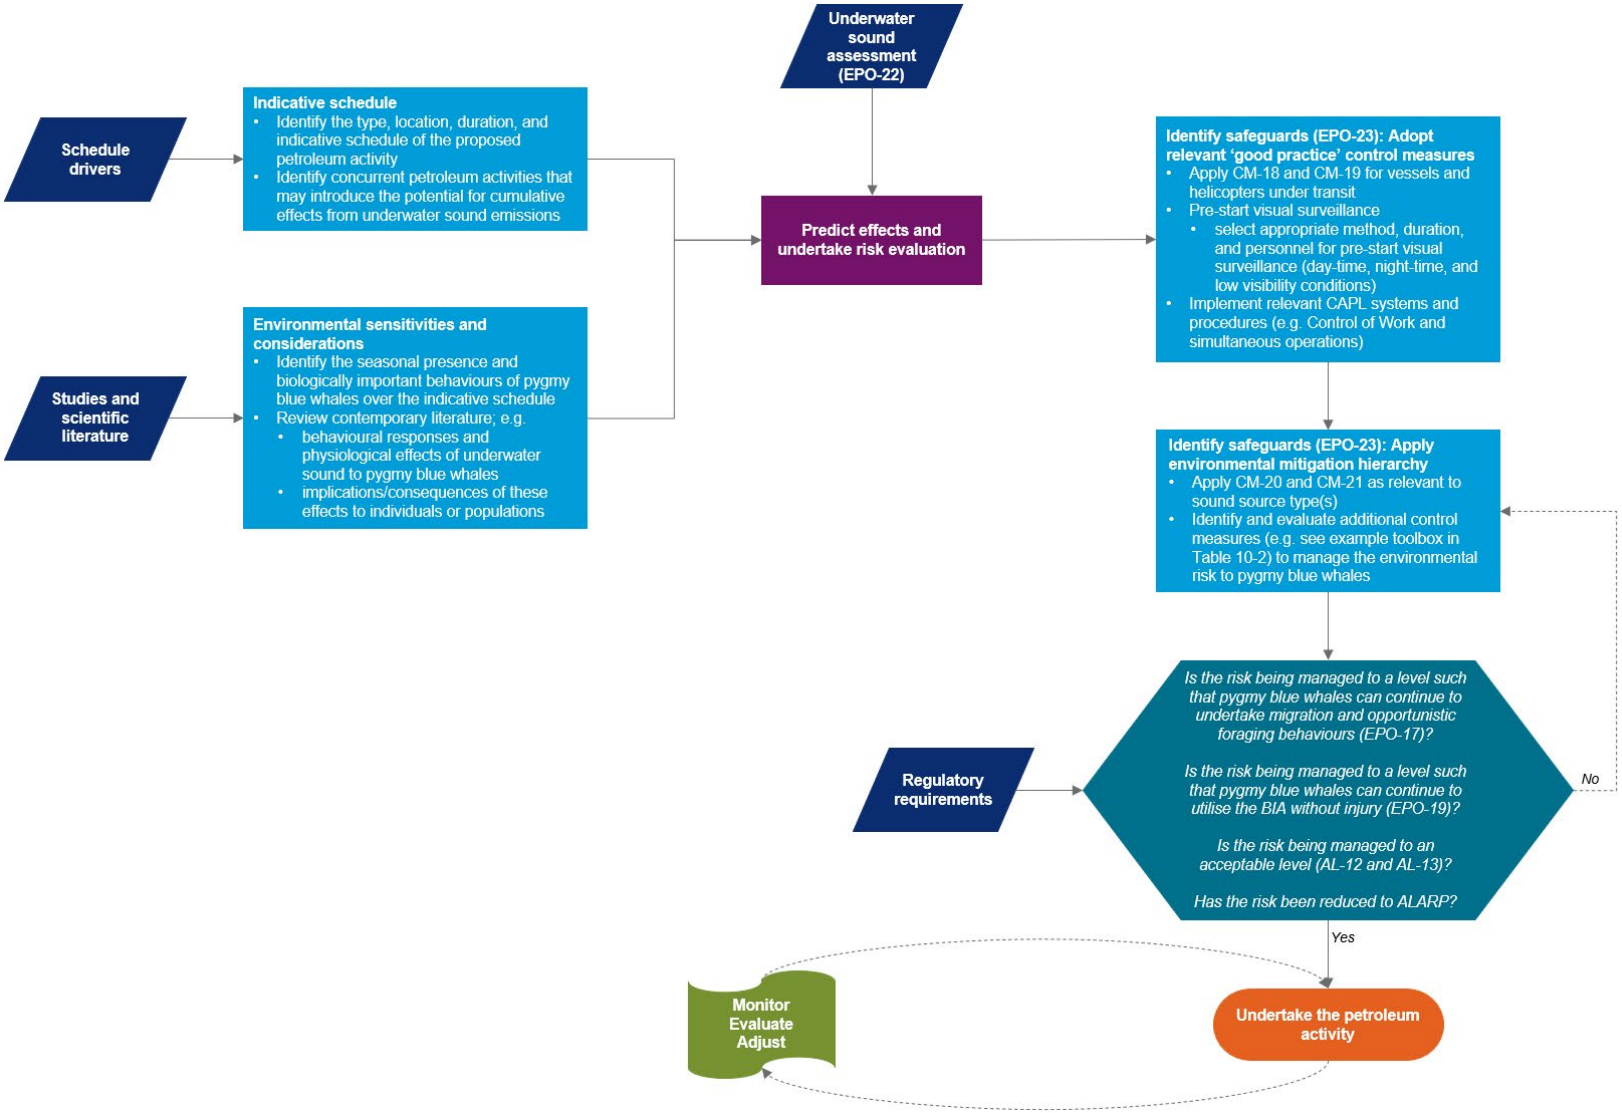

Figure 10-4: Expanded overview of 'plan' with application of the environmental mitigation hierarchy

10.4.5 implementation of the framework in EPs

It is intended that this adaptive management framework for pygmy blue whales is applied to the subsequent suite of EPs required for the Development. As each EP is developed, this framework may be refined and revised (e.g. to incorporate new science, technology, regulatory requirements, etc.), and changes will be described in the EPs.

10.5 environmental monitoring and reporting

10.5.1 environmental monitoring

Monitoring will be undertaken to demonstrate that CAPL complies with regulatory requirements specified in the OPP and subsequent EPs. The goals of monitoring activities are to:

- monitor discharges and emissions
- identify changes to the environment as a result of Development activities
- provide continuous review of procedures and activities.

Monitoring programs will be described in detail in subsequent EPs. The OSMP will be included with subsequent EPs and will describe a program of monitoring to determine the extent, severity, and persistence of environmental impacts from emergency conditions and emergency response activities undertaken by CAPL.

10.5.2 incident reporting

Part 5 of the OPGGS(E)R requires the reporting of incidents in subsequent EPs.

A reportable incident, as defined under the OPGGS(E)R is an incident relating to the activity that

> 'has caused, or has the potential to cause, moderate to significant environmental damage.'

NOPSEMA will be notified of all reportable incidents as per regulations 47, 48, and 49.

Environmental incident reporting requirements are covered in the II&R Execution Manual (Ref. 498) outlined in Section 10.3.7.

Other reporting requirements are shown in Table 10-3.

Table 10-3: Other incident reporting requirements

Reporting requirement	Reporting to	Timing
An oil/gas pollution incident that occurs within a marine park or is likely to impact on a marine park. The notification should include: • titleholder details • time and location of the incident (including name of marine park likely to be affected) • proposed response arrangements as per the OPEP (e.g. dispersant, containment, etc.)	DNP (24-hour) Marine Compliance Duty Officer • Phone: 0419 293 465. • Email: marine.compliance@environment.gov.au	As soon as practicable

Reporting requirement	Reporting to	Timing
• confirmation of providing access to relevant monitoring and evaluation reports when available • contact details for the response coordinator.		
Death or injury to individual(s) from an EPBC Act Listed Species as a result of the petroleum activities	Report injury to or mortality of EPBC Act listed threatened or migratory species to DCCEEW or equivalent: • Phone: +61 2 6274 1111 • Email: EPBC.Permits@environment.gov.au	Within 7 business days of observation
Vessel collision with marine megafauna	DCCEEW: • https://data.marinemammals.gov.au/report/shipstrike	As soon as practicable
Presence of any suspected IMP or disease	DPIRD: • Email: biosecurity@fish.wa.gov.au • Phone: FishWatch 24-hour hotline: 1800 815 507	Within 24 hours of confirmation

10.5.3 routine environmental reporting

Regulation 51 of the OPGGS(E)R requires environmental performance reporting for activities described in subsequent EPs, including recordable incidents. These are summarised in Table 10-4.

Table 10-4: Routine external reporting requirements

Reporting requirement	Description	Reporting to	Timing
Environmental performance	A report detailing environmental performance of the activity detailed in an EP	NOPSEMA submissions@nopsema.gov.au Phone: 1300 674 472	Annually
Recordable incident	Report includes details of recordable incidents (if any) that have occurred during the petroleum activity for the previous month		Monthly

10.6 implementing requirements of the OPP in subsequent EPs

NOPSEMA's Offshore Project Proposal Content Requirements (Ref. 16) states that EPOs must be consistent with the principles of ESD and demonstrate that the environmental impacts and risks of the project will be managed to an acceptable level.

Control measures detail how EPOs will be achieved and are provided in subsequent EPs. EPs must have EPSs set with appropriate measurement criteria to monitor the performance of the control measures and determine whether the EPOs and EPSs have been met during the activity.

The impact and risk assessments in this OPP are based on conservative assumptions of Development activities, as understood at the time of writing. Evaluations in subsequent EPs will revalidate levels of impact and risk and acceptability, as needed.

This implementation strategy will have further detail added in subsequent EPs. The strategy will ensure control measures are effective in reducing the environmental impacts and risks of the activity to ALARP and acceptable levels, and that EPOs and EPSs are continually met.

11 acronyms, abbreviations and definitions

Table 11-1 defines the acronyms, abbreviations and terminology used in this document.

Table 11-1: Acronyms and abbreviations

Acronym / abbreviation	Definition
~	Approximately
″	Inch
<	Less / fewer than
>	Greater / more than
≥	Greater / more than or equal to
µg	Microgram
µm	Micrometre. 1 µm = 10^{-6} metre = 0.000001 metre or one millionth of a metre.
µPa	Micropascal
3D	Three-dimensional
AASM	Airgun Array Source Model
ABARES	Australian Bureau of Agricultural and Resource Economics and Sciences
ABU	Australian Business Unit
ACAP	Agreement on the Conservation of Albatrosses and Petrels
ACCU	Australian carbon credit unit
ACHIS	Aboriginal Cultural Heritage Inquiry System
AFMA	Australian Fisheries Management Authority
AHO	Australian Hydrographic Office
AIMS	Australian Institute of Marine Science
ALARP	As low as reasonably practicable
AMP	Australian Marine Park
AMSA	Australian Maritime Safety Authority
ANZG	Australian and New Zealand Guidelines for Fresh and Marine Water Quality
API	American Petroleum Institute
APS	Announced Pledges Scenario
AR6	Sixth Assessment Report (AR6) of the United Nations Intergovernmental Panel on Climate Change (IPCC)
AUV	Autonomous underwater vehicle
barg	Bar gauge
BC Act	Western Australian *Biodiversity Conservation Act 2016*
BCH	Benthic habitat and community
bcm	Billion cubic metres
BIA	Biologically important area
BOP	Blowout preventer
BRS	Commonwealth Bureau of Rural Sciences

Acronym / abbreviation	Definition
BTEX	Benzene, toluene, ethylbenzene, and xylene
C&D	Chrysaor and Dionysus
CALM Act	Western Australian *Conservation and Land Management Act 1984*
CAMBA	China Australia Migratory Birds Agreement
CAPEX	Capital expenditure
CAPL	Chevron Australia Pty Ltd
CCS	Carbon capture and storage
CDU	Controls Distribution Unit. For the distribution of hydraulics, electrical power, chemicals and communications; refers to new units in the backfill fields that will be termination points for the umbilicals from the FCS or existing subsea infrastructure and where the umbilicals split to link components such as production manifolds.
CEFAS	Centre for Environment, Fisheries and Aquaculture Science (UK)
CER	Clean Energy Regulator
CH_4	Methane
CIA	Cumulative impact assessment
cm	Centimetre
CM	Control measure
CO	Carbon monoxide
CO_2	Carbon dioxide
CO_2-e	Carbon dioxide equivalent
CoW	Control of Work
cP	Centipoise
CSIRO	Commonwealth Scientific and Industrial Research Organisation
Cth	Commonwealth of Australia (Australian Government)
DA	Development area
DAFF	Department of Agriculture, Fisheries and Forestry
DAWE	Former Commonwealth Department of Agriculture, Water and the Environment (now DCCEEW)
dB	decibel
DBCA	Department of Biodiversity, Conservation and Attractions (WA)
DC	Drill Centre. Refers to a central location from which several subsea wells are drilled. Some fields have more than one DC.
DCCEEW	Commonwealth Department of Climate Change, Energy, the Environment and Water
DEMIRS	Western Australian Department of Energy, Mines, Industry Regulation and Safety
DGV	Default guideline value
DISER	Department of Industry, Science, Energy and Resources (Cth) (now DISR)
DISR	Department of Industry, Science and Resources (Cth)
DNP	Director of National Parks

Acronym / abbreviation	Definition
DoT	Department of Transport (WA)
DP	Dynamic positioning
DPIRD	Department of Primary Industries and Regional Development (WA)
DWER	Department of Water and Environmental Regulation (WA)
e.g.	For example
EEZ	Exclusive economic zone
EFL	Electrical flying lead
EIS	Environmental Impact Statement
EMBA	Environment that may be affected
EP	Environment Plan
EP Act	Western Australian *Environmental Protection Act 1986*
EPBC 2003/1294	Gorgon Gas Development/Barrow Island
EPBC 2005/2184	Jansz Feed Gas Pipeline
EPBC 2008/4178	Gorgon Gas Development Revised
EPBC 2011/5942	Gorgon Fourth Train Expansion
EPBC Act	Commonwealth *Environment Protection and Biodiversity Conservation Act 1999*
EPO	Environmental performance outcome
EPRS	Emergency pipeline repair system
EPS	Environmental performance standard
ERMP	Environmental Review and Management Programme
ERO	Emergency Response Organisation
ESD	Ecologically sustainable development
FCGT	Flood, clean, gauge and testing
FCS	Field control station
Feed Gas Pipeline	Pipeline system from the Gorgon and Jansz–Io gas wells to the Gas Treatment Plant
FPSO	Floating production storage and offloading
G&E	Geryon and Eurytion
g/m^2	Grams per square metre
GEC	Global Energy and Climate
GES	Greater East Spar
GFP	Gorgon Foundation Project
GHG	Greenhouse gas
GHGMP	Greenhouse Gas Management Plan
GS2	Gorgon Stage 2
Gt	Gigatonne
GTP	Gas treatment plant
GWL	Global warming level

Acronym / abbreviation	Definition
ha	Hectare
HFL	Hydraulic flying lead
Hg	Mercury
HGs(s)	Mercury (II) sulfide
HSE	Health, safety, and environment
HWM	High water mark
HWU	Hydraulic workover unit
Hz	Hertz
i.e.	That is
IChEMS	Industrial Chemicals Environmental Management Standard
IEA	International Energy Agency
II&R	Incident investigation and reporting
IMCRA	Integrated Marine and Coastal Regionalisation of Australia
IMO	International Maritime Organization
IMP	Invasive marine pest
IMR	Inspection, maintenance and repair
IMS	Incident management system
in	inch
IPCC	Intergovernmental Panel on Climate Change
ISO	International Organization for Standardization
IUCN	International Union for Conservation of Nature
JAMBA	Japan Australia Migratory Birds Agreement
J-IC	Jansz–Io Compression
KEF	Key ecological feature
kg	Kilogram
kHz	Kilohertz
km	Kilometre
kV	Kilovolt
L	Litre
LC_{50}	Lethal concentration with the potential to result in a 50% mortality of a sample population
LGM	Last glacial maximum
LNG	Liquefied natural gas
LOC	Loss of containment
LOWC	Loss of well control
lux	A standard for measuring light; equal to the amount of visible light per square metre incident on a surface. 1 lux = 1 lumen/square metre
m	Metre
m^3	For liquids: Cubic metres

Acronym / abbreviation	Definition
	For gases: Standard cubic metres (Sm^3) measured at 0 barg
MARPOL	The International Convention for the Prevention of Pollution From Ships, 1973 as modified by the Protocol of 1978; also known as MARPOL 73/78.
MASS	Marine Autonomous Surface Ship
MBES	Multibeam echo sounder
MDO	Marine diesel oil
MEG	Monoethylene glycol
MFE	Mass flow excavation
mg	Milligram
MGO	Marine gas oil
mm	Millimetre
MM	Million
MMscf/d	Million standard cubic feet per day (of gas). 1 MMscf/d = 1180 Sm^3/h (standard cubic metres per hour)
MNES	Matters of national environmental significance
MODU	Mobile offshore drilling unit
MOPU	Mobile operational production unit
MoU	Memorandum of Understanding
MPTS	Midline pipeline termination structure
MS 1002	Ministerial Statement 1002 – Gorgon Gas Development Fourth Train Expansion Proposal
MS 1198	Ministerial Statement 1198 – Gorgon Gas Development Revised and Expanded Proposal
MS 748	Ministerial Statement 748 –Gorgon Gas Development Barrow Island Nature Reserve
MS 1136	Ministerial Statement 1136 – Gorgon Gas Development Revised and Expanded Proposal Barrow Island Nature Reserve
MS 769	Ministerial Statement 769 – Jansz Feed Gas Pipeline – Barrow Island Nature Reserve
MS 800	Ministerial Statement 800 – Gorgon Gas Development Revised and Expanded Proposal Barrow Island Nature Reserve
MS 865	Ministerial Statement 865 – Gorgon Gas Development Revised and Expanded Proposal Barrow Island Nature Reserve
MS 965	Ministerial Statement 965 – Gorgon Gas Development – Barrow Island
Mt	Million tonnes
Mtpa	Million tonnes per annum
N/A	Not applicable
NADF	Nonaqueous drilling fluids
NCVA	National conservation values atlas
NDC	Nationally determined contribution
NEPM	National Environmental Protection Measure
NGER Act	Commonwealth *National Greenhouse and Energy Reporting Act 2007*

Acronym / abbreviation	Definition
NIS	Non-indigenous species
nm	Nautical mile
NMVOC	Non-methane volatile organic compound
NNM	Not normally manned
NO	Nitric oxide
NO_2	Nitrogen dioxide
NOPSEMA	National Offshore Petroleum Safety and Environment Management Authority
NOPTA	National Offshore Petroleum Titles Administrator
NORM	Naturally occurring radioactive material
NO_x	Nitrous oxides
NTGAC	Nganhurra Thanardi Garrbu Aboriginal Corporation
NWMR	North-west Marine Region
NWS	North West Shelf (of Western Australia)
NWSTF	North West Slope Trawl Fishery
NZE	Net Zero Emissions by 2050 Scenario
NZS	New Zealand Standard
O_3	Ozone
OCNS	Offshore Chemical Notification Scheme
OCV	Offshore construction vessel
ODS	Ozone-depleting substance
OE	Operational Excellence
OEMS	Operational Excellence Management System
OHS	Occupational health and safety
OPEP	Oil Pollution Emergency Plan
OPGGS Act	Commonwealth *Offshore Petroleum and Greenhouse Gas Storage Act 2006*
OPGGS(E)R	Commonwealth *Offshore Petroleum and Greenhouse Gas Storage (Environment) Regulations 2009*
OPP	Offshore Project Proposal
OSMP	Operational and Scientific Monitoring Plan
OSV	Offshore support vessel
P&A	Plug and abandonment
PAH	Polycyclic aromatic hydrocarbon
PCPT	Piezocone penetration test
PER	Public environmental review
Pipeline termination structure	For the commingling of production fluids; may refer to existing GFP infrastructure or a new pipeline termination structure in the backfill fields
PLEM	Pipeline end manifold
PLET	Pipeline end termination

Acronym / abbreviation	Definition
PLONOR	Pose little or no risk
PLV	Pipelay vessel
PM	Particulate matter
$PM_{2.5}$	Particulate matter with a diameter of 2.5 micrometres or less
PNEC	Predicted no-effect concentration
POB	Personnel on board
ppb	Parts per billion
ppm	Parts per million
Production pipeline	For the transport of production fluids; refers to the existing Jansz and Gorgon Feed Gas Pipelines associated with the GFP.
PSU	Practical Salinity Units
PSZ	Petroleum safety zone
PTS	Permanent threshold shift
RNTBC	Registered Native Title Body Corporate
ROKAMBA	Republic of Korea Migratory Birds Agreement
ROV	Remotely operated vehicle
RTM	Response Time Model
SBP	Sub-bottom profiler
SCSt	Subsea compression station
SIMAP	Spill Impact Mapping and Analysis Program
SMC	Safeguard Mechanism credit
SNA	Safe navigation area
SO	Sulfur monoxide
SO_2	Sulfur oxides
SO_3	Sulfur trioxide
SoE	State of the Environment
SOLAS	International Convention for the Safety of Life at Sea 1974
SOPEP	Ship Oil Pollution Emergency Plan
SPL	Sound pressure levels
SSPLR	Subsea pig launcher receiver
SSS	Side-scan sonar
STEPS	Stated Policies Scenario
STFL	Steel tube flying lead
t	Tonne
TEC	Threatened ecological community
TJ	Terajoules
TLP	Tension-leg platform
TSS	Total suspended solids

Acronym / abbreviation	Definition
TTS	Temporary threshold shift
UCH	Underwater cultural heritage
UCH Act	*Underwater Cultural Heritage Act 2018* (Cth)
Umbilical	For the transfer of electricity; electrohydraulic umbilicals incorporate hydraulic power, electric power and a fibre-optic control link.
UN SDG	United Nations Sustainable Development Goal
UNFCCC	United Nations Framework Convention on Climate Change
UXO	Unexploded ordnance
VSP	Vertical seismic profiling
WA	Western Australia
WAFIC	Western Australian Fishing Industry Council Inc
WBF	Water-based fluid
WDTF	Western Deep Trawl Fishery
WEO	World Energy Outlook
WHP	Wellhead platform
WOMP	Well operations management plan
WTBF	Western Tuna and Billfish Fishery
WTR	West Tryal Rocks

Executive Summary

Chevron Australia Pty Ltd (CAPL) are developing an Offshore Project Proposal (OPP) to work towards approvals for the development of several new fields to tie-in existing Gorgon Development infrastructure (Gorgon Foundation Project) in the Greater Gorgon area (collectively known as Gorgon Gas Development: Backfill Fields; GBF) which will include the installation of multiple subsea facilities such as flowlines, umbilicals, and drill centres/well infrastructure sites. To inform the OPP and support future environmental approvals, CAPL commissioned Advisian Pty Ltd to characterise the marine benthic environment within the GBF project area, which is defined as a 5 km buffer around all indicative subsea infrastructure. The final flowlines and umbilical routes have not been identified yet by CAPL however, survey sites are focused on indicative flowline and umbilical routes, tie-in locations and proposed drill centres. The scope of works included: 1) the development of a preliminary benthic habitat map to identify areas of significance (such as Key Ecological Features; KEFs) and notable benthic features and identify survey sites for field verification; and 2) to undertake an environmental survey of benthic habitat, sediment, benthic infauna, marine water, and fish assemblages within the GBF project area.

Prior to the field survey, a preliminary benthic habitat map spanning 500 m from all potential benthic disturbance footprints was generated using all available geophysical data provided by CAPL, which included multibeam echo sounder, backscatter, sidescan sonar, 3D seismic, and geotechnical sediment data. Images were processed and enhanced where possible to identify geomorphic habitat types. The map identified eight broad habitats within the GBF project area, and identified three KEFs (elements of the Commonwealth marine environment that are considered to be of regional importance; DCCEEW, 2022) that intersect with some of the GBF project area: 'Exmouth Plateau', 'Continental Slope Demersal Fish Communities', and 'Ancient Coastline at 125 m depth contour' (hereafter 'Ancient Coastline'). From this map, sampling sites were identified for ground-truthing based on the geomorphic attributes, the presence of benthic features within these KEFs, and areas with data deficiency and other points of interest. Following the completion of in field ground-truthing, the project operational area was expanded from 500 m to a 5 km radius around all potential subsea facilities, and was further mapped using all available desktop resources. No ground truthing of benthic habitats was undertaken within the expanded operational area footprint.

The field survey was completed between the 26th April and 11th May 2022 on board Skandi Singapore (DOF Subsea Pty Ltd). Benthic habitat and fish survey data were collected along transects using a remotely operated vehicle (ROV). The ROV had a forward-facing high definition (HD) camera to collect video footage for habitat mapping and fish assemblages, and a downward-facing HD camera that captured still images and video footage for benthic cover. The vessel position and ROV were tracked using survey grade positioning equipment. The ROV was also used to deploy all sampling equipment to the seafloor including push corers for the collection of sediments and benthic infauna, Niskin bottles for water sampling above the seabed, and a water quality probe to measure conductivity, temperature, and depth throughout the water column. Surface water samples were also collected from the vessel. All sediment samples were analysed for hydrocarbons, total metals/metalloids, particle size distribution, total organic carbon (TOC) and moisture content. All water samples were analysed for hydrocarbons, dissolved and total metals, dissolved organic carbon (DOC), TOC, total dissolved solids (TDS) and nutrients.

Benthic habitat mapping following ground-truthing confirmed that a mixture of habitat types were present within the proposed GBF project area. Where the GBF project area intersects with the Exmouth

Plateau KEF, the benthic habitat is dominated by irregular seabed with bioturbation, irregular and smooth seabed floor with bare substrates, and mounds on the seafloor of bare substrate. In the Exmouth Plateau KEF that lies within the GBF project area, two large discrete scarps with 3-dimensional hard structure (i.e., rock) cross through the indicative flowline from east to west, likely providing biota with suitable habitat. Where the GBF project area crosses with the Continental Slope Demersal Fish Communities KEF, irregular and smooth seabed with bare substrates and discrete depressions of bare substrate, and scarps with bare substrate were the most dominant benthic features. Topographically complex rock reefs and scarps were also present traversing through the GBF project area between ~400–800 m depths that were colonised by cnidarians, echinoderms, sponges, and a mixture of these biotic groups. Mapping of the GBF project area that lies within the Ancient Coastline KEF shows that the benthic habitat consisted of smooth seabed with bioturbation and appeared devoid of non-cryptic biota.

Benthic habitat mapping of low slope areas (defined as areas within the GBF project area containing proposed infrastructure located outside of KEFs in the lower slope and Kangaroo Syncline areas) showed a mixture of low structural habitats present within the Chandon DC-1 to JMT corridor. The benthic habitat within the Jansz to Geryon and Eurytion corridors comprised smooth seabed with bioturbation and irregular seabed with bare substrate, with intermittent mounds with bare substrate and scattered patches of depressions over bare substrate. The benthic habitats within the Chrysaor and Dionysus to Gorgon corridor are predominantly characterised by smooth and irregular seabed with either bare substrate or bioturbation.

Benthic habitat mapping around proposed drill centres and tie in locations that are located outside a KEF and not in a low slope area, which include Jansz DC2, G & E DC-1, Semele DC-1, Semele DC-2, BCH40 and WTR DC-1, were of low structural complexity and dominated by smooth seabed with bioturbation. Ground truthing transects at each of these locations did not reveal any epifaunal communities.

The benthic cover at 14 proposed drill centres and tie-in locations showed that bare sediment with no biota was the dominant benthic category. Gorgon M1 was the only site with bioturbation and very low cover of cnidarians[1].

For fish assemblages, Ancient Coastline KEF recorded a total of 18,011 individuals from 13 fish taxa compared to the Exmouth Plateau (165 individuals from 14 taxa), Continental Slope Demersal Fish Communities (165 individuals from 14 taxa) and out of KEF area (11,800 individuals belonging to 28 taxa). The fish assemblage across most KEFs were by dominated trevallies such as *Seriola dumerili* (Carangidae), *Carcharhinus* sp1 (Carcharhinidae), an unidentified anguilliform fish, and an unidentified baitfish species. The crustacean assemblage was greatest in the Exmouth Plateau KEF and outside of KEF areas, comprising of 228 individuals from seven taxa and 236 total individual crustaceans from seven taxa, respectively. Prawns were the most dominant crustacean taxa found across all KEFs.

[1] Note: this revision (Rev 6) of the Gorgon Backfill Fields Benthic Survey Report has been updated to correct a transcription error presented in the previous revisions of this Report. The correction resulted in the reassignment of one abiotic category from low relief sand/mud with boulders (rocks >255 mm), to the same category without boulders for the affected transects in Section 4.2. This revision has been updated to correct a classification error resulting in the reassignment of one abiotic category from <1% cover low relief sand/mud with boulders at Chandon DC-1 T2 to the same category without boulders and with bioturbation. Note that the occasional presence of boulders in low relief sand/mud have minimal role in habitat provision for biotic assemblages.

Of the four geomorphic features (plateau slope, trench/trough slope, slope, and deep/hole/valley slope), the slope geomorphic features had the largest number of individual fish species (30,033) belonging to 37 taxa followed by the deep/hole/valley slope with 187 individuals from 16 fish taxa. Between 110 and 236 individual crustaceans were recorded across all geomorphic features with the exception for slope which only recorded five individuals.

A total of 922 invertebrate individuals from 26 taxa were recorded across all sites. The invertebrate assemblage included feather stars, jellyfish, sea cucumbers, sea stars, sea urchins and squids.

For sediment samples located within proposed drill centres and tie in locations, concentrations of all hydrocarbons were below the laboratory limit of reporting (LOR). Concentrations of all metals and metalloids were all below their relevant ANZG (2018) default guideline values (DGVs), with the exception of nickel. TOC concentrations were relatively low across all samples. Sediments primarily consisted of well-sorted clays and silts that were odourless and contained the occasional small shell fragments. A total of five individual benthic infauna belonging to three families were collected across four sites.

No hydrocarbons were detected in water samples collected from the surface and near the seabed across the GBF project area. Concentrations of all dissolved and total metals in water samples met the relevant DGVs except for dissolved cobalt and copper. Measurable levels of DOC, TOC, TDS, and nutrients were detected in the water samples. Water profiles were consistent across the sites and showed a gradual decrease in temperature and conductivity with increasing depth while salinity was relatively consistent with depth. At the deeper sites, three water masses were identified in the water column: low salinity surface waters (upper ~180 m), higher salinity mid-waters (~185–250 m) and low salinity bottom waters (~250–1310 m depth).

Overall, the benthic environment is characteristic of the North Carnarvon Basin and the North West Shelf region and is typical of an undisturbed tropical offshore environment (Heyward et al., 2001; Falkner et al., 2009; Williams et al., 2010). This survey did not find any benthic communities and habitats of regional significance.

Acronyms and Abbreviations

Acronym/abbreviation	Definition
°C	Degrees Celsius
2D	Two dimensional
3D	Three dimensional
AAIW	Antarctic Intermediate Water
ANZG	Australian and New Zealand Guidelines
BCH	Benthic communities and habitats
BS	Backscatter
BTEX	Benzene, toluene, ethylbenzene, and xylenes
CATAMI	Collaborative and Automated Tools for Analysis of Marine Imagery
CoC	Chain of custody
CTD	Conductivity, temperature, and depth
C & D	Chryasor and Dionysus
DC	Drill centre
DGV	Default guideline value
DEM	Digital elevation model
DistLM	Distance-based linear modelling

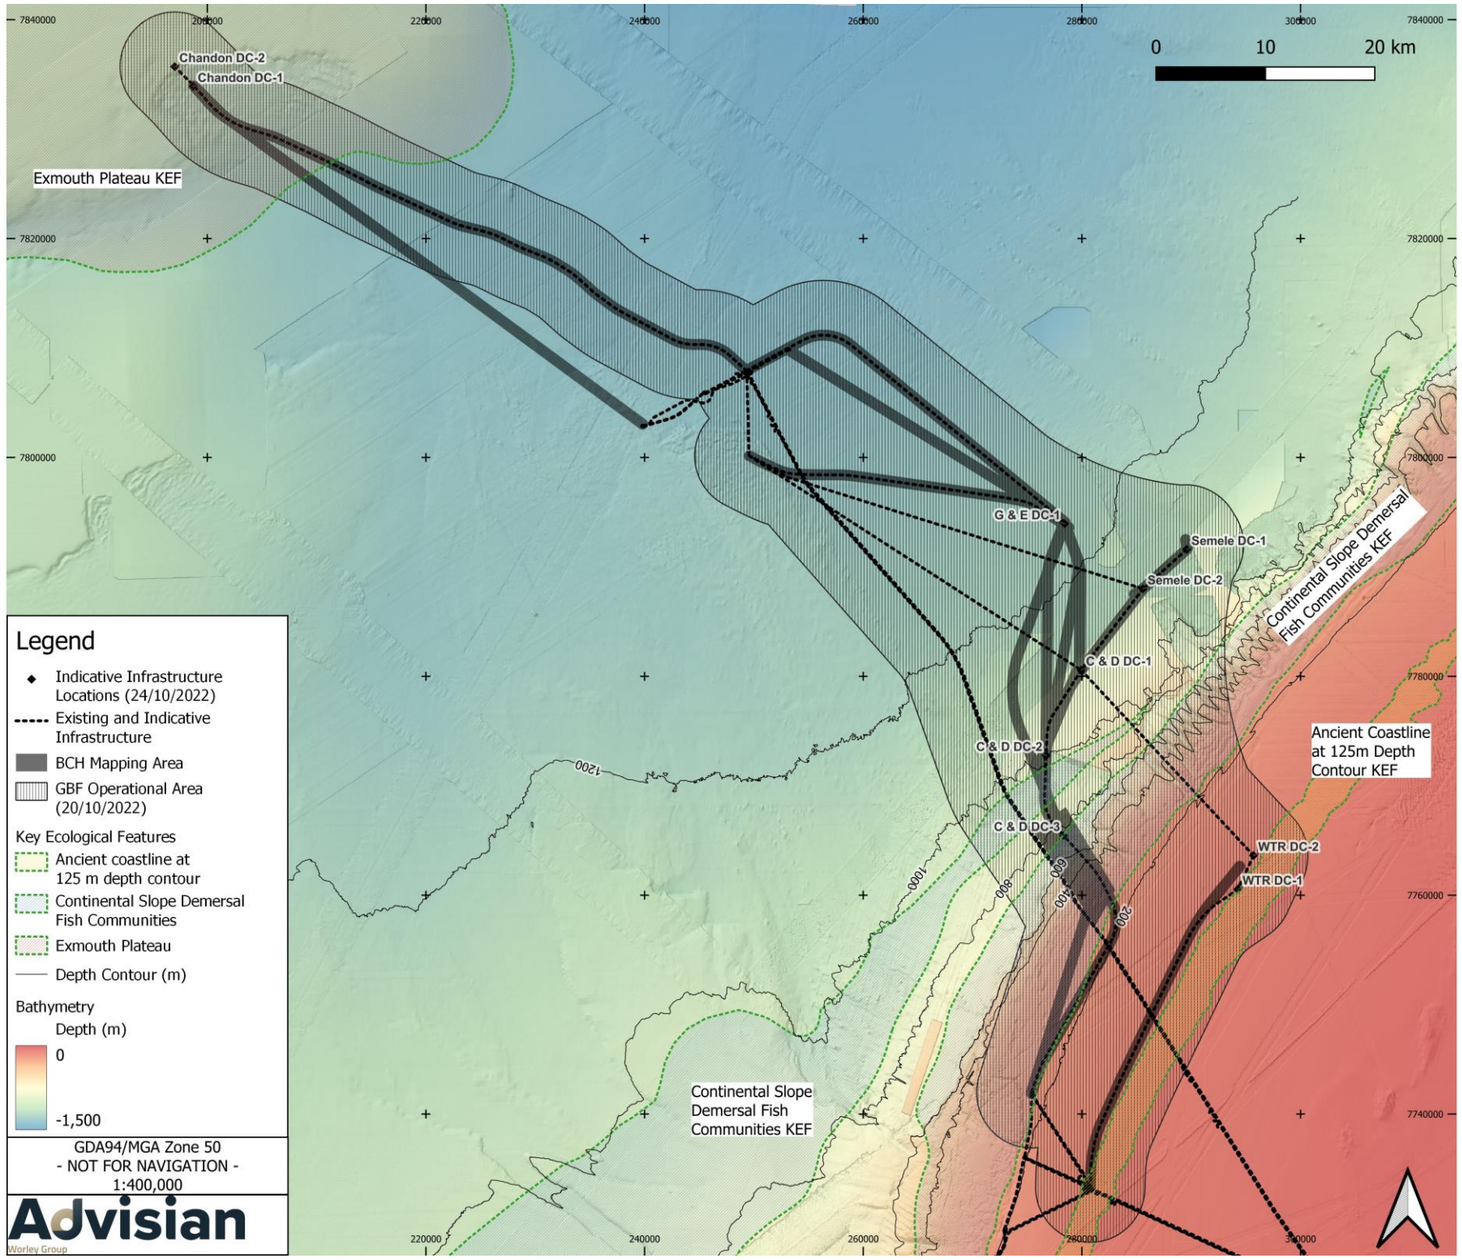
TMS	Tether management system
TN	Total nitrogen
TOC	Total organic carbon
TP	Total phosphorus
TPI	Topographic Position Index
TRH	Total recoverable hydrocarbons
TSW	Tropical Surface Water
WTR	West Tryal Rocks



1 Introduction

1.1 Background

Chevron Australia Pty Ltd (CAPL) are developing an Offshore Project Proposal (OPP) to work towards approvals for the development of several new fields to tie-in existing Gorgon Development infrastructure (Gorgon Foundation Project) in the Greater Gorgon area: Geryon, Eurytion, Chandon, Semele, Chrysaur, Dionysus and West Tryal Rocks (WTR) (hereafter; collectively known as Gorgon Gas Development: Backfill Fields, GBF; Figure 1-1). The fields are located between ~60–130 km north-west of Barrow Island, Western Australia, in water depths ranging from 150 m (WTR) to 1,300 m (Chandon). Multiple subsea facilities such as flowlines, umbilicals and drill centres/well infrastructure sites may be required for the development of each field. Although the final flowlines and umbilical routes have not been identified yet by CAPL, the study sites are focused on indicative flowline and umbilical routes, tie-in locations and indicative drill centres.

The GBF project area spans three Key Ecological Features[2] (KEF) of the Commonwealth marine environment; from the Exmouth Plateau in the west, to the Continental Slope Demersal Fish Communities, and Ancient Coastline at 125 m depth contour (hereafter Ancient Coastline) (Figure 1-1). These KEFs are likely to be relatively topographically complex and support a range of benthic habitats and organisms such as soft deep-sea coral, sea fans (gorgonians), sponges as well as regionally significant stocks of demersal fishes. To inform the OPP and support future environmental approvals, CAPL commissioned Advisian Pty Ltd (Advisian) to characterise the marine benthic environment within the GBF project area.

[2] Key Ecological Features are elements of the Commonwealth marine environment that are considered to be of regional importance for either a region's biodiversity or its ecosystem function and integrity (DCCEEW, 2022).

Notes:
1. BCH = Benthic communities and habitat, GBF = Gorgon Backfill Fields, KEF = Key Ecological Feature, WTR = West Tryal Rocks
2. The GBF operational area has been expanded to a 5 km radius around the GBF project area post-field survey, as further discussed in Section 3.4

Figure 1-1 Overview of Gorgon Backfill Fields project area with conceptual subsea facilities in relation to Key Ecological Features of the area

1.2 Project Location and Geomorphology

To better understand the geomorphic characteristics of the GBF project area, which is defined as a 500 m radius around the proposed drill centres and tie-in locations, and a 500 m buffer around all associated subsea flowlines, CAPL and Advisian undertook a desktop study to develop a preliminary benthic habitat map. To develop this map, CAPL provided Advisian all available geophysical data to classify the habitat type based on discernible physical geomorphic or other notable benthic features. This map was then used to identify and inform targeted survey sites where information within the GBF project area may have been lacking. Refer to Section 2 for more details.

The primary geomorphic features in the GBF project area include the continental shelf, the upper, middle, and lower continental slope, the Kangaroo Syncline, and the Exmouth Plateau. The continental shelf is generally defined as extending from the nearshore environment to the shelf break at approximately 200 m water depth. The shelf features varied terrain including both modern sedimentary deposits and the remains of low sea level shoreline features (Geoscience Australia, 2022). The shallower continental slope deposits comprise mixed sediments, including both modern terrigenous (river derived) and carbonate (biogenic) materials, as well as the often-coarse preserved remains of ancient sediments [relict intraclasts] (James et al., 2004). The continental slope is characterised by complex and often steep submarine canyon systems, smooth sedimentary fans, and abrupt landslide scars.

The deep-water area separating Barrow Island from the Exmouth Plateau is known as the Kangaroo Syncline. This area includes mostly featureless seabed and the remains of older landslide deposits and sedimentary fans. The majority of the GBF project area is within this deeper area (800–1350 m) and is typically dominated by hemipelagic-pelagic sandy muds (high carbonate foraminiferal and nannofossil 'ooze'), which mantles all but the steepest of seabed features. Rates of sediment deposition and disturbance are low in these environments and even highly pronounced seabed features can be very old and may be draped with many metres of pelagic sediments (Hengesh et al., 2013).

The Exmouth Plateau is located in the Northwest Province and covers an area of approximately 49,310 km^2 (Heap and Harris, 2008). The plateau is an ancient, stranded section of continental crust that now resides in water depths typically greater than 1000 m. The plateau has associated lower continental slope features including landslide scars. The seascape is generally considered not unique in the regional context however it is believed that the expansive surface and large size may modify deep water flow and generate internal tides (Brewer et al., 2007). The Exmouth Plateau has been described as an area of low habitat heterogeneity, however, is considered to be an important area of biodiversity for offshore communities (DSEWPaC, 2012).

The GBF project area also intersects through three KEFs at different locations: proposed Chandon drill centre and associated flowline/umbilical corridors are located within the Exmouth Plateau KEF; flowlines in the Chrysaor and Dionysus fields are within Continental Slope Demersal Fish Communities KEF; and flowlines stemming from Gorgon GMT to WTR DC-1 in the WTR field are located within the Ancient Coastline KEF (Figure 1-1). The Exmouth Plateau KEF is recognised for its biodiversity values, with unique seafloor features ecological properties of regional significance, which apply to both the benthic and pelagic habitats within this KEF (DSEWPaC, 2012). The Continental Slope Demersal Fish Communities is an area on the Australian continental slope with a high diversity of demersal fish assemblages and high levels of endemism (DSEWPaC, 2012). This KEF has documented more than 500 fish species, 76 of which are endemic, making it the most diverse continental slope bioregion in Australia (Last et al., 2005). Demersal fish species occupy two distinct demersal community types, or

biomes, associated with the upper slope (water depth of 225–500 m) and the mid-slope (750–1000 m). The Ancient Coastline is an area of hard substrate (i.e., rock escarpments) that may be associated with enhanced species richness and higher diversity relative to surrounding areas of predominantly soft sediment. Likely fauna associated with the hard substrate of the ancient coastline include sponges, molluscs, echinoderms, corals, and crinoids (DSEWPaC, 2012).

1.3 Project Objective and Scope

The primary objective of this project was to describe the marine benthic environment (benthic habitats and communities; BCH) within the GBF project area. Secondary, we used the field mobilisation to broadly characterise other elements of the GBF project area, including marine water and sediment quality, demersal fish and benthic infaunal assemblages.

The scope of work included:

1. Development of a preliminary benthic habitat map based on assessment of geomorphic features to identify areas of significance (such as KEFs) and notable benthic features within the GBF project area and identify survey sites for field verification
2. Complete a visual benthic survey within identified survey sites to:
    a) verify the presence/absence of prominent and/or complex seabed features and other BCH across the GBF project area to further inform the preliminary habitat map
    b) describe and quantify BCH across a subset of representative sites
    c) opportunistically describe demersal fishes and identify fish and habitat associations within surveyed areas
3. Broadly characterise the water and sediment quality and composition within the GBF project area.
4. Describe the benthic infaunal assemblages within a subset of representative sites

This report presents the results of the field survey and includes both preliminary and refined benthic habitat assessment and mapping.

2 Preliminary Benthic Habitat Mapping Methods and Results

2.1 Data Acquisition

A preliminary benthic habitat map within the GBF project area was developed prior to the field survey to classify key benthic and geomorphic features of the seabed, and identify areas with insufficient information to describe the existing environment. To support the development of this map, all available geophysical data was provided by CAPL (Table 2-1), which included data collected from shipborne and underwater vehicles:

- Multibeam echo sounder (MBES) data, which provided a medium to high resolution 3-dimensional (3D) bathymetric terrain model of the seabed, from which morphological features were identified. Bathymetric grids of 2 m, 3 m, 5 m, 10 m, and 20 m resolution were supplied.
- Backscatter (BS) data, which is a product derived from MBES outputs that represents the strength of the acoustic signal returning from the seabed. This allows an assessment of seabed textural qualities (e.g., hardness or roughness) which can help in identifying features not otherwise visible in the bathymetry data.
- Sidescan Sonar (SSS) data, which is similar to BS however, it typically has higher resolution, allowing identification of fine-scale objects and textures, but lower spatial accuracy.
- 3D Seismic data, which comprises an acoustic reflection that can be processed to create a bathymetric terrain model similar to MBES.
- Geotechnical sediment data, including the results of 349 sediment descriptions as well as qualitative sediment assessments from SSS data.

Table 2-1 Details of the available geophysical data within the Gorgon Backfill Fields project area

Data Type	Number of Files	Grid Cell Resolution (m)	Areas Covered
MBES data	31	2, 3, 5, 10, 20	Most of the study area
BS data	6	1, 2, 3, 5	Same area as MBES
SSS data	69	0.2, 0.3, 0.5	Various narrow track lines covering less than 50% of the study area
3D Seismic data	3	10, 20, 25	Most of the study area

Note:
1. BS = Backscatter, MBES = multibeam echo sounder, SSS = sidescan sonar

2.2 Image Processing

MBES imagery was processed into a number of derivative products, to delineate seabed features at a variety of scales. Quantitative bathymetric analysis techniques were used to split the project area into multiple polygons for final interpretation. Bathymetric terrain derivatives were calculated using the powerful software tool SAGA GIS (System for Automated Geoscientific Analyses). These included:

- Shaded relief bathymetry: a 'sun shading' software rendering process was applied to the bathymetry dataset, which enhances textural features that are large enough to be captured by the mapping and processing equipment used (Yokoyama et al., 2002).
- Topographic roughness: roughness was computed by subtracting the minimum depth from the maximum depth value in a defined-neighbourhood around a central pixel. The neighbourhood is defined as the 8 nearest cells to a central pixel. Roughness is equal to the maximum depth displacement in a 3 by 3 grid of digital elevation model (DEM) cells around a central point. Given how roughness is calculated, it is always given as a value greater than or equal to zero. Values of zero or those close to zero indicate flat areas, whereas larger roughness values indicate increasingly steep or complex terrain (Riley et al., 1999).
- Topographic Position Index (TPI): the TPI algorithm compares a DEM cell value to the mean value of its neighbours. The mean value is calculated based on the shape selected by the user. Positive values represent features typically higher than surrounding features, negative values represent lower features, and values near zero are either flat or areas of constant slope (Watkins, 2020).
- Quantitative Seabed Slope (°): slope was defined as the ratio of rise to run over the defined-neighbourhood area. In geospatial data, slope is defined as the steepness of a surface or its inclination and is always positive. It should be noted that slope cannot differentiate between a mound and a depression, or a ridge and a valley (Evans, 1979; Florinsky, 2009).
- BS/SSS: indicates the strength of the returning signal as received by the vessel-mounted MBES or SSS system. This can indicate much finer scale textural and hardness information relating to the seabed. Note that only a derived image of BS was provided, which limits the potential classification techniques which can be applied. Images were locally stretched in order to maximise the resolving capability. High BS (typically white) indicates a harder/rougher seabed, whereas low BS (typically black) typically indicates a softer/smoother seabed.

2.3 Data Coverage and Quality

Data reliability buffers were applied that represent the distribution of the source data. A combination of MBES and SSS imagery with a resolution ranging from 0.2–10 m were considered more reliable, spatially accurate and of higher confidence, whereas 3D seismic/MBES combination with a resolution range of 10–25 m was considered of moderate (adequate) confidence.

2.4 Classification of Habitat

Due to the high spatial variability and availability of data types, no fully automated classification techniques could be implemented. However, using the derived terrain and textural feature layers, physical seabed features could be recognized and manually interpreted according to the following documented techniques:

- Morphological features (Dove et al., 2020)
- Terrain feature segmentation (Watkins, 2020)
- Sedimentary bedforms (Ashley, 1990)
- Shelf and slope classification (Butler et al., 2017, James et al., 2004)
- Submarine landslide interpretation (Hengesh et al., 2013)
- Debris fans (Posamentier and Walker, 2006)

- Habitat mapping surrogacy assumptions (McArthur et al., 2010)
- Habitat mapping assumptions (EPA, 2016)
- Submarine canyons (Huang et al., 2014, 2018)
- Collaborative and Automated Tools for Analysis of Marine Imagery (CATAMI) classification scheme (Althaus et al., 2015).

Using the shaded relief, slope, TPI, roughness and backscatter information, seabed features were visually assessed for any discernible physical geomorphic or other notable benthic features. Assessments were made for potential sediment type, presence of rock or subsurface rock, relief, slope and sedimentary bedforms according to the CATAMI classification scheme (Althaus et al., 2015; Table 2-2). These features were nested within common boundaries in order to allow geographic information system (GIS) polygon attribution. Additionally, a morphological descriptor nested with the CATAMI scheme was also provided (Table 2-3). On-screen delineation of polygon boundaries was undertaken at a scale of 1:5000 using a desktop GIS software package.

Table 2-2 Collaborative and Automated Tools for Analysis of Marine Imagery classification scheme with feature descriptors

CATAMI	Feature Descriptors
Substrate Type 1 (S1)	Consolidated/ Hard (CAAB 82 001001) Unconsolidated/ Soft (CAAB 82 001005)
Substrate Type 2 (S2)	Fine sand/ mud (CAAB 82001015 + 82001016 Undifferentiated) Coarse sand (CAAB 82 001014) Pebble/ Gravel (CAAB 82001006)
Substrate Type 3 (S3)	Veneer Rock (CAAB 82 001002)
Relief Type 1 (R1)	Flat (CAAB 82 003001), Roughness <0.05 Low / Moderate (CAAB 82 003002) High (CAAB 82 003005), Roughness >0.1
Relief Type 2 (R2)	Low <1 m (CAAB 82 003003) Moderate 1-3 m (CAAB 82 003004) High >3 m (CAAB 82 003006) Wall (CAAB 82 003007) Other
Bedform Type 1 (B1)	None (CAAB 82 002001) 2D (CAAB 82 002002) 3D (CAAB 82 002006) Other
Bedform Type 2 (B2)	Ripples <10 cm (CAAB 82 002003) Waves >10 cm (CAAB 82 002004)

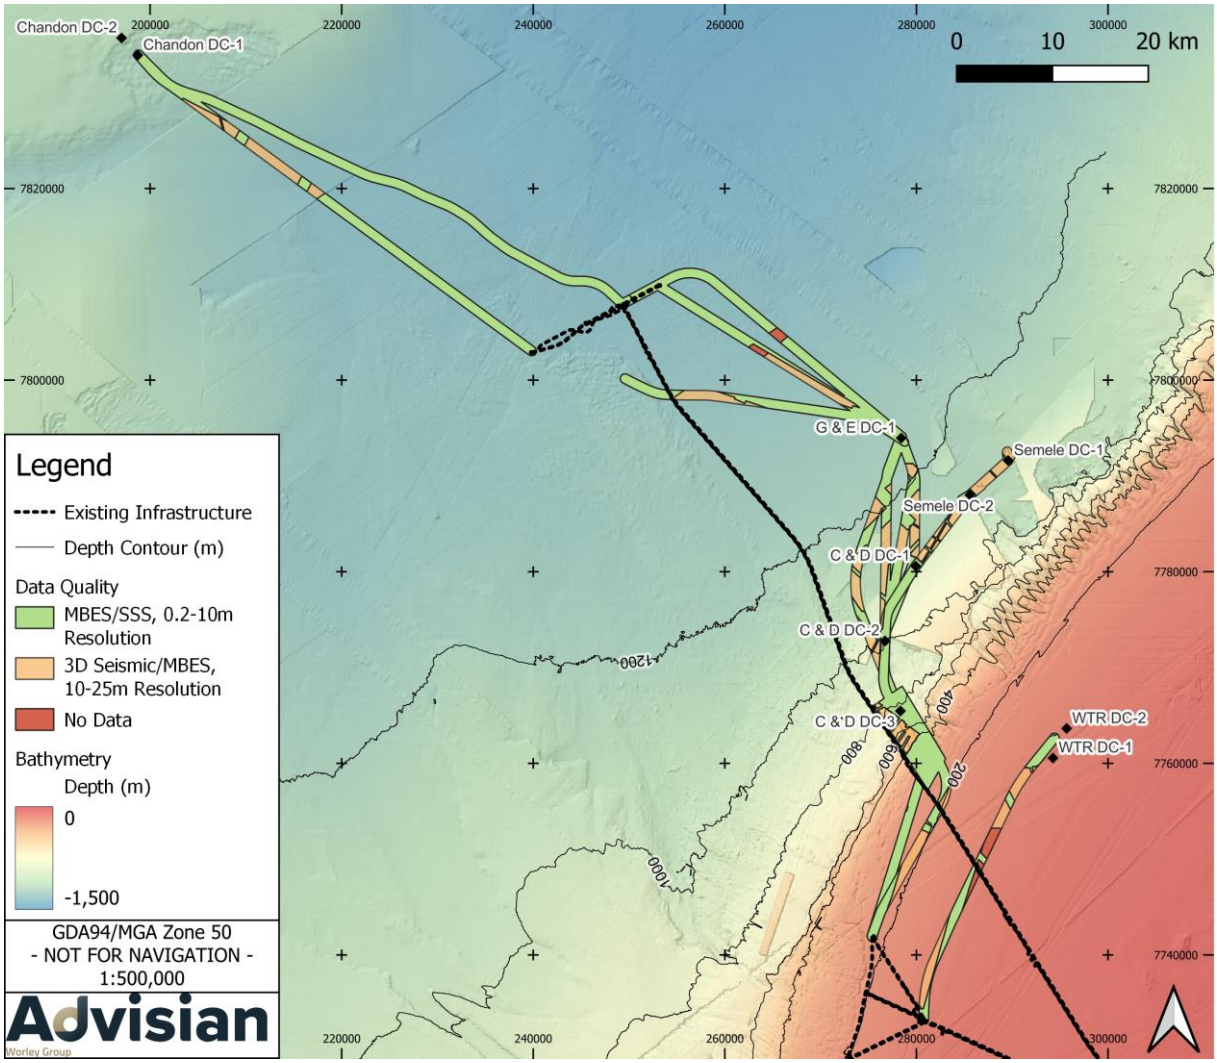
CATAMI	Feature Descriptors
	Large waves >0.75 m Very large waves >5 m Irregular
Bedform Type 3 (B3)	Small <10 m Medium 10–50 m Large 50–100 m Very large >100 m

Table 2-3 Attribute table (final substrate descriptor relating to Collaborative and Automated Tools for Analysis of Marine Imagery classification)

Morphological Descriptor	Description	Bathymetry	Slope/Topographic Position	Relative BS/SSS	CATAMI (S1/S2/S3/R1/R2/B1/B2/B3)
Bare seabed	Featureless sedimentary terrain	Smooth, no identifiable features, fine or coarse sediment	Typically, less than 2°, no topographic features	Low, no discernible feature	S1: UNCONSOLIDATED S2: FINE SAND-MUD, COARSE S3: N/A R1: FLAT R2: N/A B1-3: N/A
Mostly bare seabed	Mostly flat sediment terrain with very minor features	Smooth with rare identifiable but unmappable regular bedforms or mounds. Fine or coarse sediment	Typically, less than 2°, very minor topographic features	Low, rare, and small discernible features	S1: UNCONSOLIDATED S2: FINE SAND-MUD, COARSE S3: N/A R1: FLAT R2: N/A B1-3: N/A
Irregular Seabed	Mostly flat sediment terrain with minor features which may be derived from underlying geology	Smooth with identifiable, regular but small bedforms or mounds. Fine or coarse sediment	Typically, less than 2°, minor topographic features	Low, rare, and small discernible features	S1: UNCONSOLIDATED S2: FINE SAND-MUD, COARSE S3: N/A R1: LOW-MOD R2: LOW B1: OTHER B2: IRREGULAR B3: N/A

Morphological Descriptor	Description	Bathymetry	Slope/Topographic Position	Relative BS/SSS	CATAMI (S1/S2/S3/R1/R2/B1/B2/B3)
Rock Veneer	Area of buried bedrock/rocks or cemented sediments with very low sediment input (Starved). Also known as low profile reef	Uneven, rugged, and irregular features, often angular or linear. Fine or coarse sediment	Typically, less than 2°, highly variable but low-profile topographic features. Signs of subsurface structure must be apparent	Varied, mostly high	S1: UNCONSOLIDATED S2: FINE SAND-MUD, COARSE S3: VENEER R1: LOW-MODERATE R2: LOW or MODERATE B1: OTHER B2: IRREGULAR B3: N/A
Mound	Locally elevated Sediment or Rock Veneer feature which comprising rubble, geological or biological in origin	Bathymetric features measurable in profile. Isolated, smooth-edged feature. No structure indicating active sand wave or dune	Varied but smooth slope. TPI index high	Varies depending on incidence angle, typically very high	S1: UNCONSOLIDATED S2: FINE SAND-MUD, COARSE S3: VENEER R1: LOW-MODERATE or HIGH R2: MODERATE or HIGH B1: OTHER B2: IRREGULAR B3: N/A
Rock Reef	Bedrock or other consolidated material outcrop	Rough bathymetric features measurable in profile	Varied complex slope. TPI index high	High/variable	S1: CONSOLIDATED S2: N/A S3: ROCK R1: LOW-MODERATE or HIGH R2: MODERATE or HIGH B1: OTHER

Morphological Descriptor	Description	Bathymetry	Slope/Topographic Position	Relative BS/SSS	CATAMI (S1/S2/S3/R1/R2/B1/B2/B3)
					B2: IRREGULAR B3: N/A
Depression / Scour	Local depression which may be geological or biological in origin (Linear Scour or Pockmark)	Bathymetric features measurable in profile (low)	Varied slope. TPI index low	Varies depending on incidence angle	S1: UNCONSOLIDATED S2: FINE SAND-MUD, COARSE S3: VENEER or N/A R1: LOW-MODERATE or HIGH R2: LOW or MODERATE or HIGH B1: OTHER B2: IRREGULAR B3: N/A
Scarp	Bedrock or other consolidated material outcrop, subject to landslide erosion	Rough bathymetric features measurable in profile	Typically, greater than 15°, may have steep sides	Varies depending on incidence angle	S1: CONSOLIDATED S2: N/A S3: ROCK R1: LOW-MODERATE or HIGH R2: MODERATE or HIGH B1: OTHER B2: IRREGULAR B3: N/A
Bedforms/Ripples/ Ribbons (Small, Medium 2 or 3 dimensional, Irregular)	Active or once active sediment bedforms indicating wave or current action on the seabed	May be visible bathymetric features or may only occur in backscatter if small	Varied, wavelength and amplitude measured in profile (Ashley, 1990)	Varies depending on incidence angle. Typically, low	S1: UNCONSOLIDATED S2: FINE SAND-MUD, COARSE S3: N/A R1: LOW-MODERATE or HIGH



Morphological Descriptor	Description	Bathymetry	Slope/Topographic Position	Relative BS/SSS	CATAMI (S1/S2/S3/R1/R2/B1/B2/B3)
					R2: MODERATE or HIGH B1: 2D or 3D B2: ANY B3: ANY

Note:
1. N/A = not applicable

2.5 Results

2.5.1 Mapping Confidence

A total of 31,053 hectares (ha) of benthic habitat was initially mapped within the GBF project area, which spanned 500 m from all preliminary indicative subsea infrastructure. Of this, 23,600 ha was mapped with high confidence based on the MBES and SSS imagery classification, and 6,721 ha was mapped with moderate confidence using 3D seismic/MBES imagery (Figure 2-1). The remaining 733 ha was classified as low confidence as there were no data available (Figure 2-1). Areas with no data included small sections along the proposed Geryon and Eurytion (G & E) to Jansz corridors, and sections along the proposed WTR corridor (Figure 2-1).

Note:

1. C & D = Chrysaor and Dionysus, DC = drill centre, G & E = Geryon and Eurytion, MBES = multibeam echo sounder, SSS = sidescan sonar, WTR = West Tryal Rocks

Figure 2-1 Mapping confidence within the Gorgon Backfill Fields project area

2.5.2 Preliminary Habitat Mapping

Preliminary mapping of seabed geomorphology identified a total of eight broad geomorphic feature types, including mostly bare sediments, bedforms, irregular seabed, mounds, depression/scours, rock veneer, rock reef and scarp (Figure 2-2). Areas mapped with no polygons reflect data gaps where mapping could not be completed (Figure 2-2). The GBF project area is dominated by bare and irregular bare seabed, which comprised over 75% of the mapped area. Rock reef or areas that potentially feature exposed bedrock comprised ~10%.

Most of the GBF project area is dominated by recent or ancient landslide features. These features include incipient failure ridges and depressions on the shelf edge, a series of very steep escarpments (head scarps), signs of large translational and rotational mass movements, chaotic debris accumulations, isolated blocks, and distal debris fans with associated soft sediment 'crevasse' structures. Many areas have their morphology determined by rocky outcrops or rock debris. However, as pelagic marine sediment is known to cover most of the area, it is likely that all but the steepest areas may comprise a mosaic of outcrop or sediment cover.

The edge of the Exmouth Plateau KEF was mapped, showing sediment covered landslide features. Geomorphic habitats intersected with the Continental Slope Demersal Fish Communities KEF, forming highly complex and sometimes steep terrain. No Ancient Coastline KEF features were detected within the GBF project area. The Ancient Coastline KEF is known to exist in shallower water, particularly from the 60–80 m depth range (DSEWPaC, 2012).

No canyon features were observed in the GBF project area; however, these are known to occur close to the area in the Continental Shelf transition zone. Coarse sediment could not be detected with the available data, however, patches of high SSS anomaly on the shelf edge may indicate the presence of coarse material. Furthermore, the available SSS and high resolution MBES data was highly variable, meaning that the quality varied making interpretation harder in some cases, and fine scale features will have been missed in many areas.

The preliminary habitat map was reviewed by Advisian and CAPL marine environmental specialists to determine field survey sampling sites for further ground-truthing, which were based on the spatial representation of all geomorphic attributes throughout the GBF project area, the presence of benthic features within KEFs, and areas with data deficiency and other points of interest.

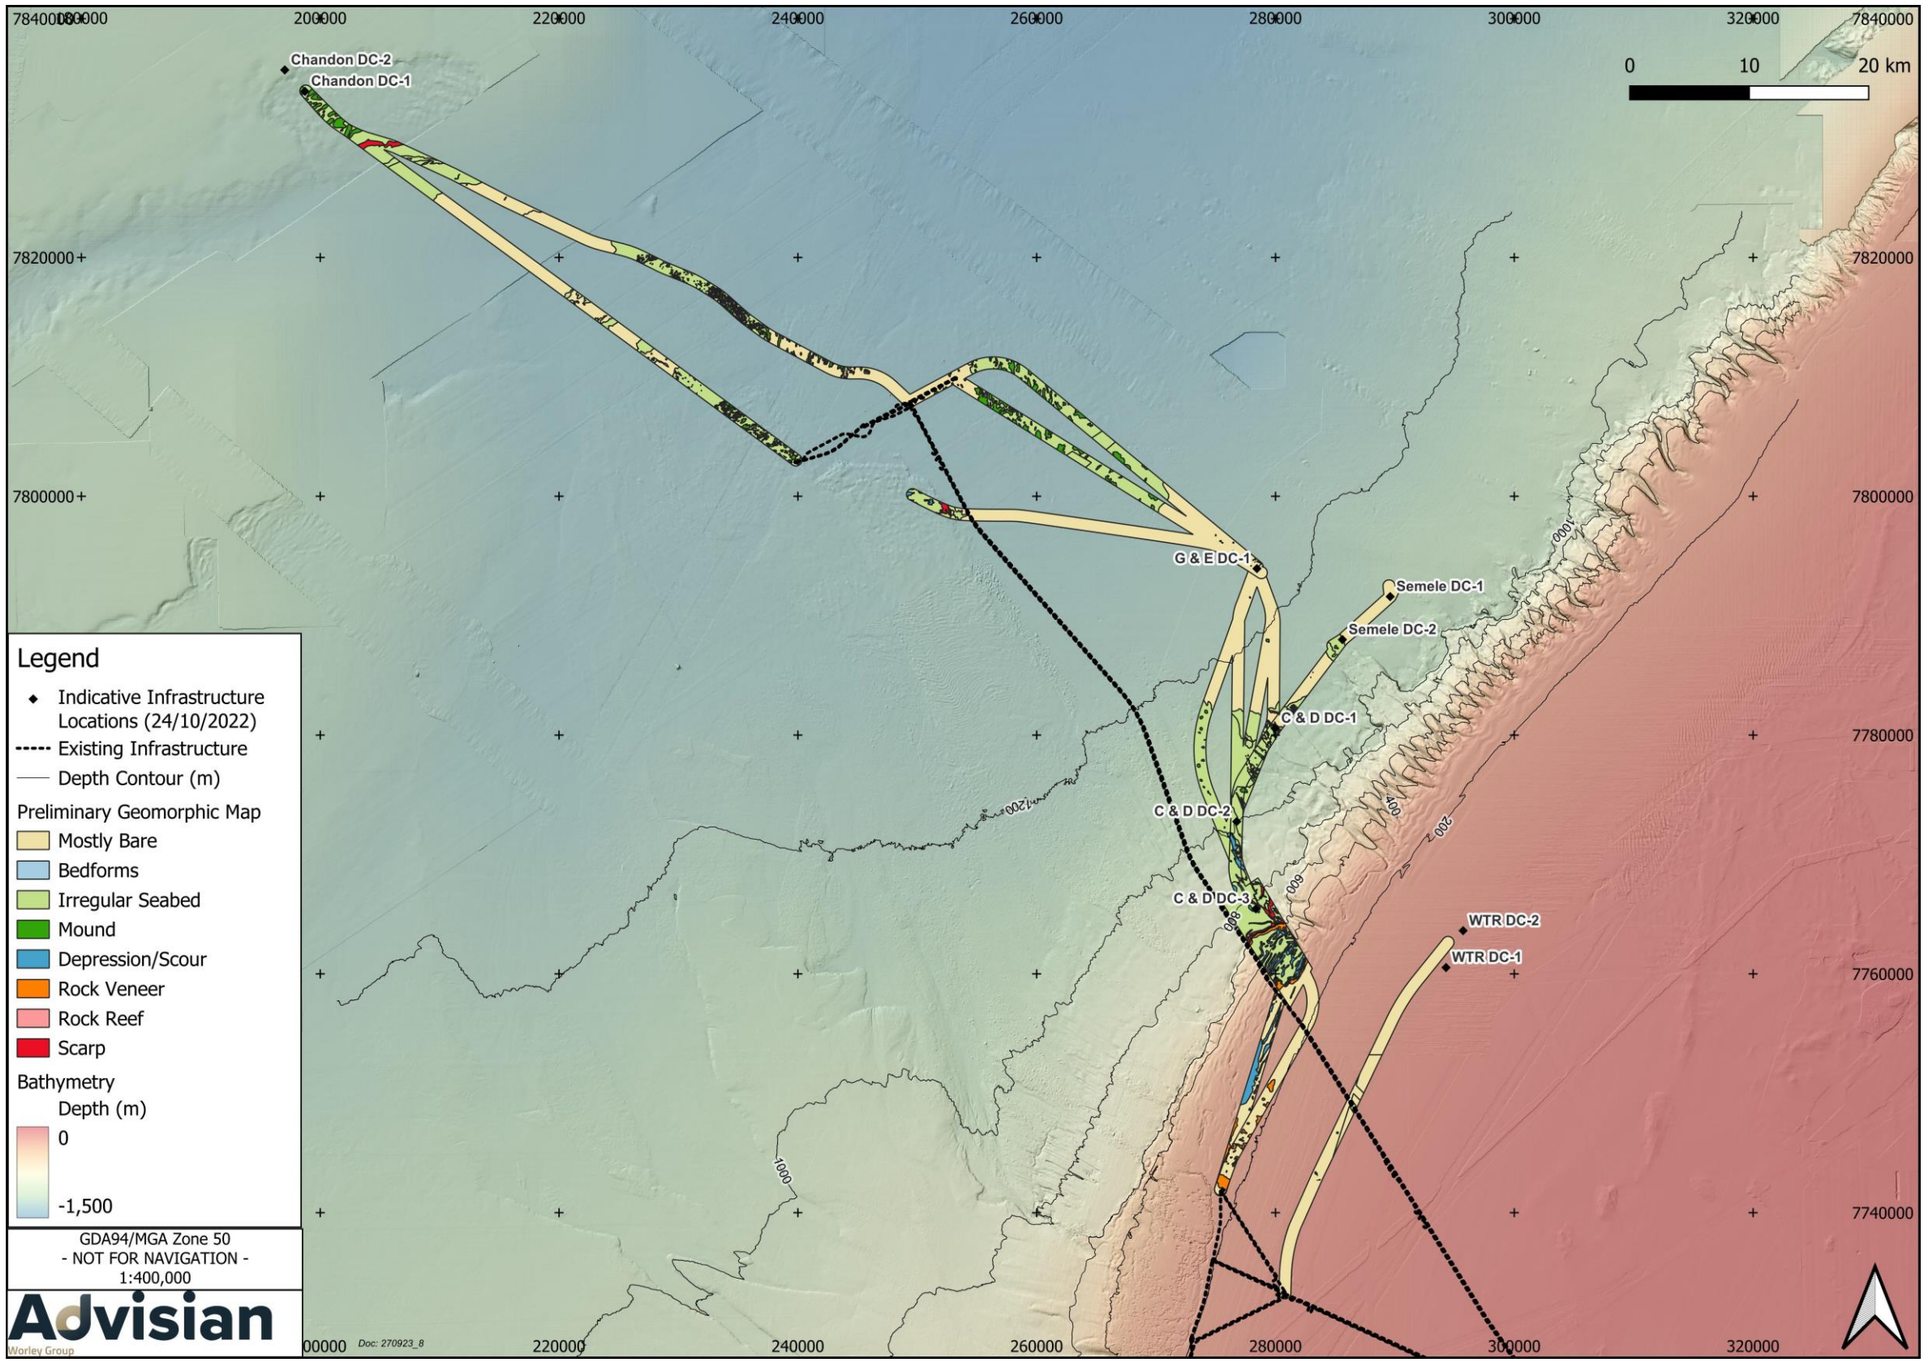


Figure 2-2 Preliminary benthic habitat maps based on assessment of geomorphic features within the Gorgon Backfill Fields project area

3 Field Survey Methods

3.1 Field Survey Scope

The main objective of this field survey was to investigate the physical and biological characteristics of the seabed features in the identified survey sites. Advisian delivered this scope in partnership with DOF Subsea under CAPL. Advisian led the scientific scope and DOF Subsea provided the vessel Skandi Singapore, the marine survey equipment for positioning of the vessel, and the remotely operated vehicle (ROV). DOF Subsea and CAPL were responsible for communicating with Barrow Island central control room to coordinate and approve permits (e.g., Permit to Work) to operate and undertake the field sampling program in GBF.

The primary field survey components and environmental monitoring parameters are summarised in Table 3-1.

Table 3-1 Summary of field survey monitoring parameters

Field Survey Component	Monitoring Parameters
Habitat Mapping	• Qualitative description of benthic habitats across a large project scale
Marine Benthic Survey	• Quantitative description of benthic cover and type at a subset of GBF project area
Fish Assemblage Survey	• Abundance, composition and size of fish assemblages and their association with key habitat types and other environmental variables • Description of mobile invertebrates and epifauna
Sediment Quality	• Hydrocarbons, metals, particle size distribution (PSD), total organic carbon (TOC) and moisture content
Benthic Infauna	• Benthic infauna composition
Water Quality	• Hydrocarbons, metals, TOC, dissolved organic carbon (DOC), total dissolved solids (TDS), nutrients • Water column profiling to describe physical water quality parameters (temperature, salinity, conductivity, and depth)

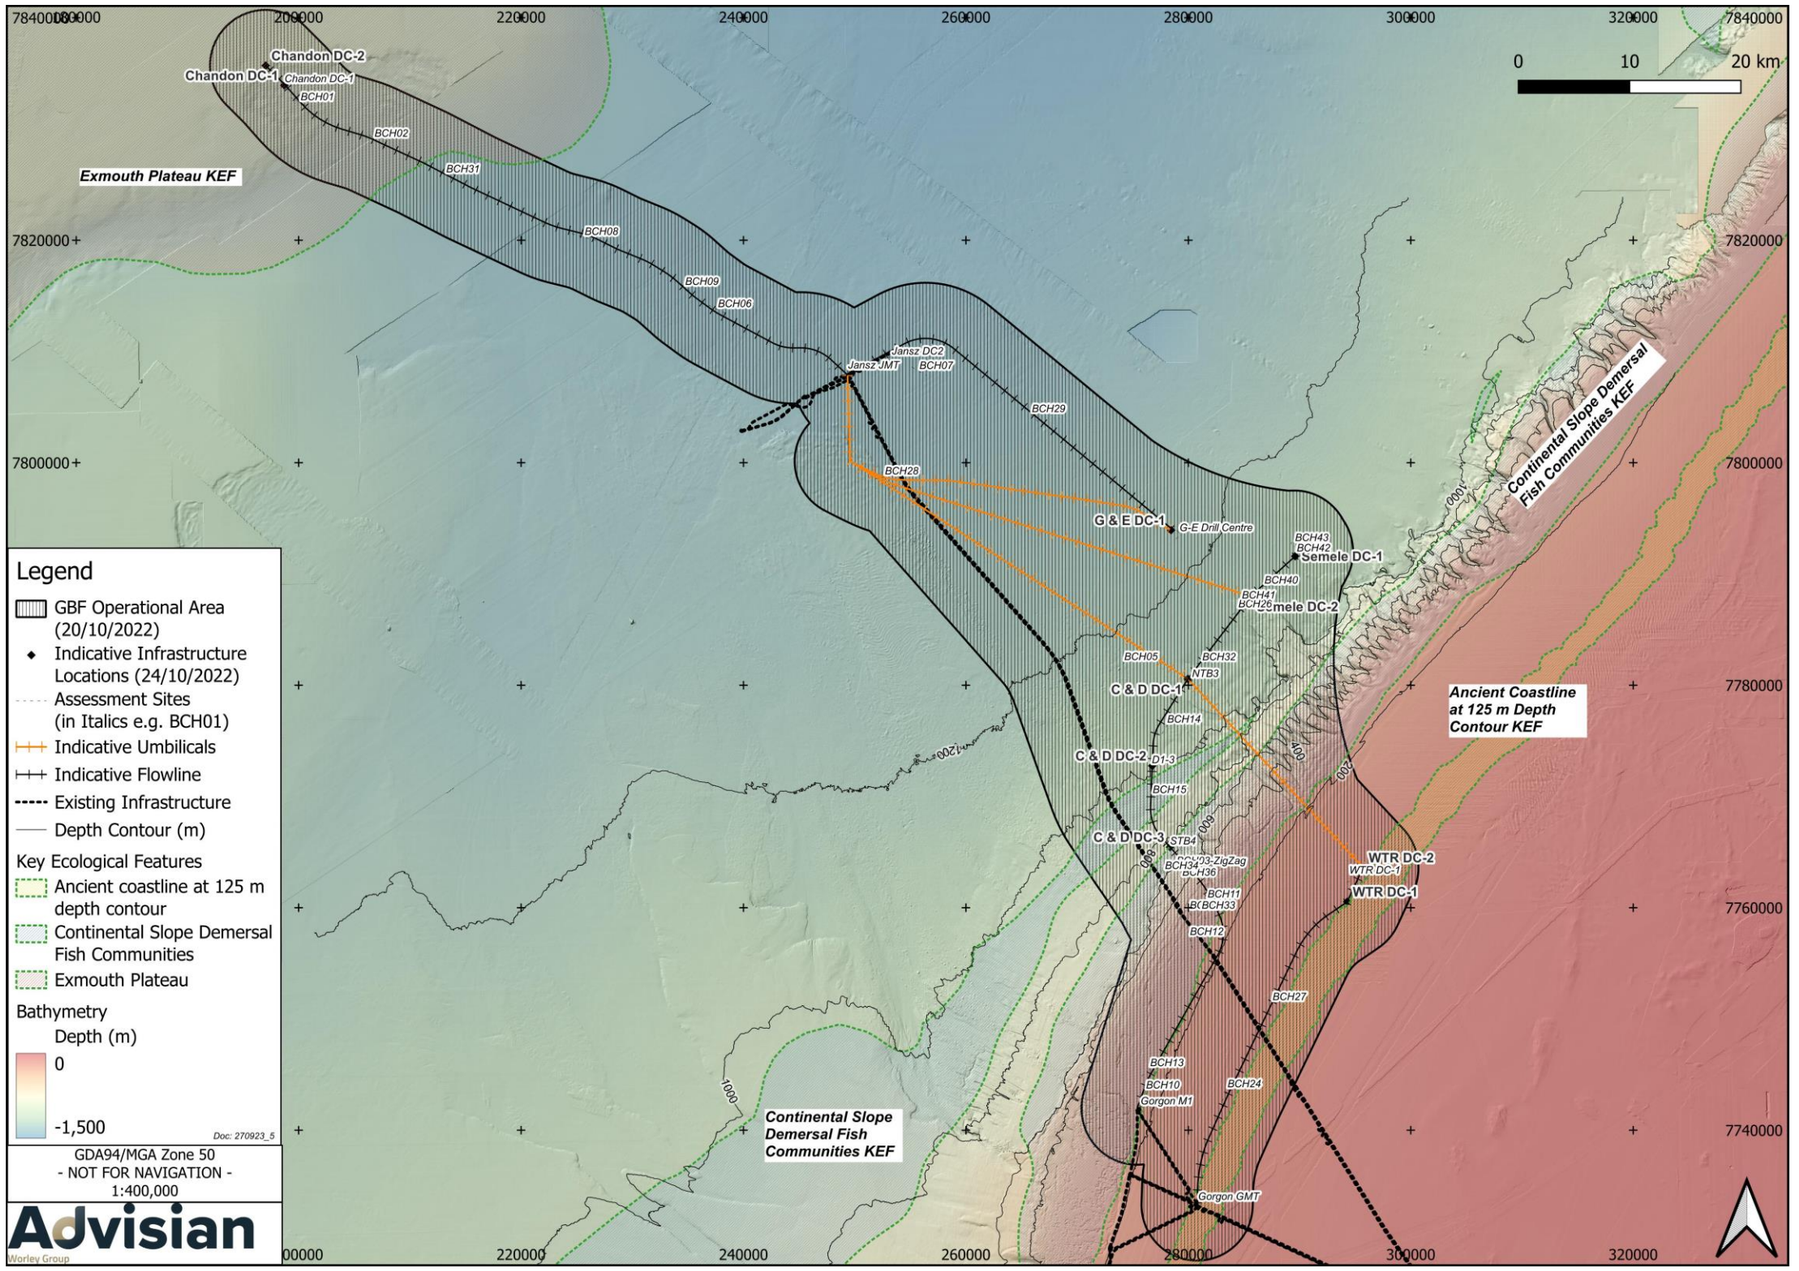
3.2 Permits

In order to collect sediment infauna, Advisian applied for an Instrument of Exemption from the Department of Primary Industries and Regional Development (DPIRD) in line with the Fish Resources Management Act 1994 and Regulations, Section 7, and Regulation 6. Advisian were granted this permit by DPIRD on 26 April 2022 (Appendix A).

3.3 Survey Schedule

The field survey was completed between the 26th April and 11th May 2022. Table 3-2 details the field schedule for high level activities completed during the GBF field survey. Further details on field survey timing can be found in the Field Survey Summary Report (Advisian, 2022a).

Table 3-2 Field survey schedule



Date	Activity
26 April 2022	Mobilised to Dampier and boarded the Skandi Singapore vessel Transit to survey sites
27 April 2022	ROV test dives and calibrations
28 April – 3 May 2022	Complete benthic habitat survey at sites BCH16, BCH19, BCH17, Gorgon M1, BCH10, BCH13, BCH21, BCH23, BCH30, BCH18, BCH22, BCH25, BCH12, BCH04, BCH11, BCH03 and C&D DC3 (and water and sediment quality samples)
4 May 2022	Complete benthic habitat survey and water and sediment quality sites (where applicable) for sites BCH15, C & D DC-2, BCH14, NTB3 and BCH05 Freight chemical samples
5 –10 May 2022	Complete benthic habitat survey and water and sediment quality sites (where applicable) for sites G & E DC-1, BCH29, BCH18, BCH07, Jansz DC2, Jansz JMT, BCH28, BCH06, BCH09, BCH08, BCH02, BCH01, Chandon DC-1, BCH31, Semele DC-2, Semele DC-1, BCH42, BCH40, BCH43, BCH41, BCH32, WTR DC-1, BCH27, BCH33, BCH34, BCH35, BCH36, BCH24, Gorgon BMT
10 May 2022	Scope completed
11 May 2022	Pack equipment, freight samples Demobilise from Dampier

3.4 Survey Locations

Following the development of a preliminary benthic habitat map (Section 2.5), survey sites (Figure 3-1) for benthic habitat mapping, sediment and water quality sampling were selected based on:

- the spatial representation of all geomorphic attributes throughout the GBF project area (drill centres and associated well infrastructure, and flowlines/umbilical corridors)
- the presence of benthic features within KEFs
- areas with data deficiency and other points of interest
- to understand the composition of sediment at potential drill centres and tie-in locations
- to understand background concentrations of marine water quality near proposed infrastructure locations.

In response to an increase in project operational area post-field survey, the originally proposed 500 m radius around proposed manifold and tie-in locations and associated flowlines has been expanded to a 5 km radius around the GBF project area (as per Figure 1-1). Classification and mapping procedures for benthic habitats that fall within the 5 km operational buffer area is described in Section 3.6.5, and the distribution of benthic habitats within the 5 km operational buffer area are presented in Sections 4.1.1 and 4.1.2.

Note:
1. BCH = Benthic communities and habitat, C & D = Chrysaor and Dionysus, DC = drill centre, G & E = Geryon and Eurytion, GBF = Gorgon Backfill Fields, KEF = Key Ecological Features, WTR = West Tryal Rocks

Figure 3-1 Gorgon Backfill Fields project area with survey sites for benthic habitat mapping, sediment, and water quality sampling

3.5 Project Equipment

3.5.1 Remotely Operated Vehicle

A work class ROV (TRITON XLX) was provided and operated by DOF Subsea and used to deploy all sampling equipment to the seafloor (habitat and fish survey cameras, water quality profiler, sediment, and infauna corers, and Niskin bottles) (Figure 3-2). The ROV was deployed while connected to a tether management system (TMS). Once the ROV was near the seabed, the ROV was detached from the TMS and was flown at approximately 1.5 m above the seabed at approximately 0.7 knots (1.3 km/h) while recording video footage of benthic habitat and fish assemblages. This speed ensured adequate image quality was captured.

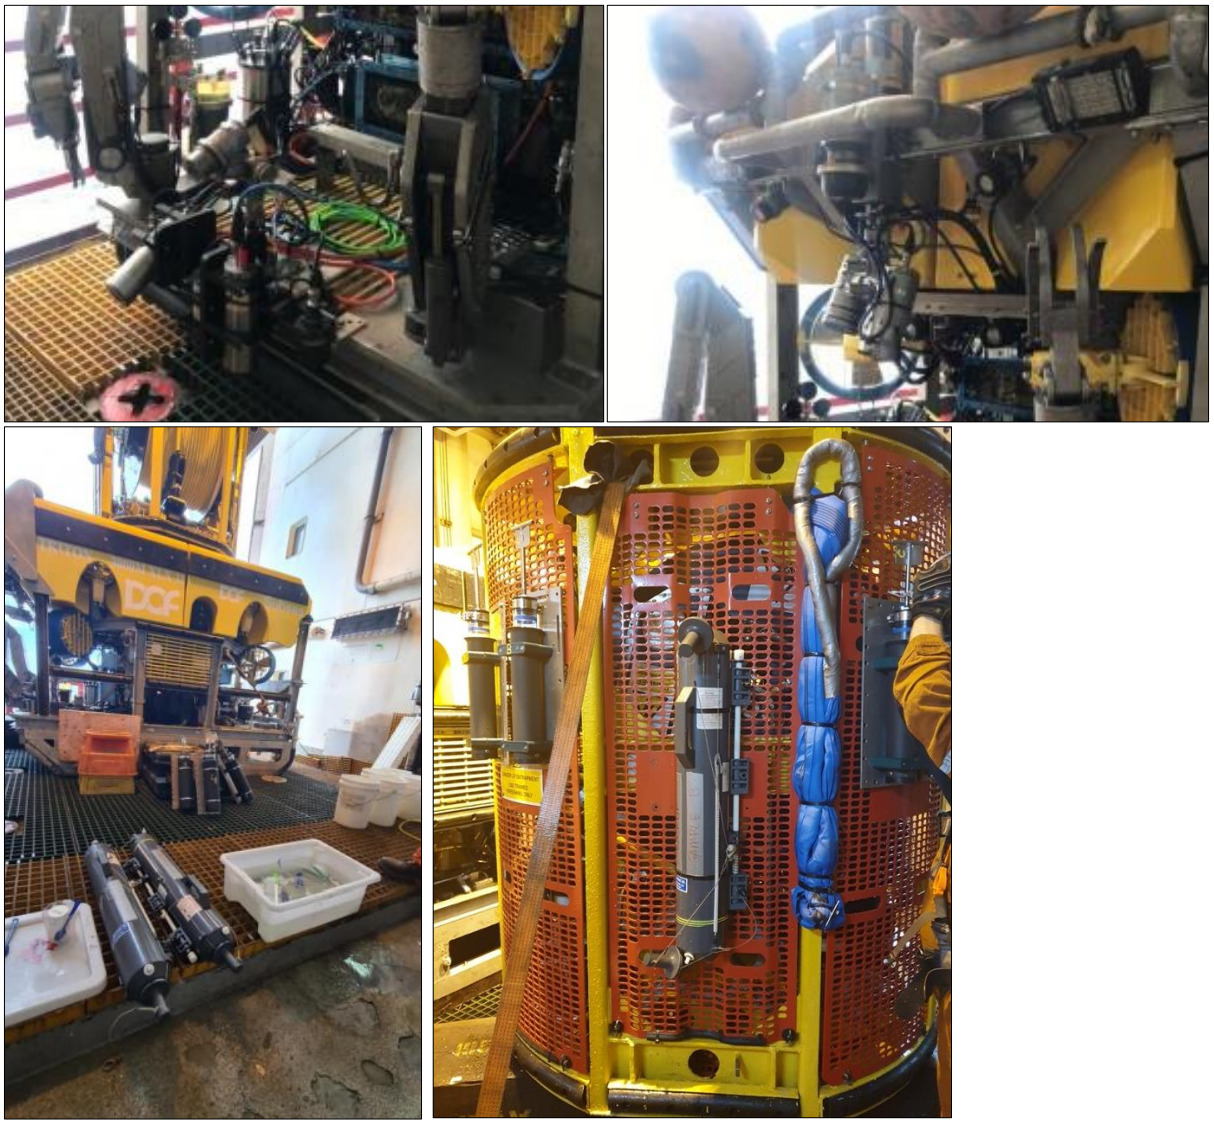


Figure 3-2 Remotely operated vehicle and tether management system with cameras, sediment corers and Niskin bottles attached

3.5.2 Habitat Mapping and Fish Survey Cameras

The ROV utilised the forward-facing high-definition (HD) camera (30° angle) for the collection of video footage for habitat mapping and demersal fish assemblages, and a downward facing camera (90° angle) for collection of marine benthic survey data (Table 3-3). The ROV pan and tilt HD camera captured suitable additional footage and provided a backup in the event of failure of the primary forward-facing camera. Two sets of cameras were also included as redundancy in case of equipment failure. All camera systems were controlled from the surface with a live feed ensuring correct operating and capture of the required data. All cameras were powered from the surface through the ROV tether.

Table 3-3 Camera systems mounted on the remotely operated vehicle

Camera	Tasks
1 x forward-facing camera (~30º)	• Capture benthic habitat and demersal fish data • Subsea HD wide angle camera Kongsberg/Imenco OE14-504 (1080i/720p 50 frames per second; fps) • External lighting system –Imenco SeaLED 300 (15,000 lumens) was added to the ROV for illumination (camera pan/tilt/zoom/altitude and set to forward and approximately 30° tilt)
1 x downward facing camera (~90º)	• Capture 'still' images of benthic habitat for percent cover • 1CAM Mk5 camera (stills/4K/1080p 60 fps) • Lighting system – Aquorea Mk2 LED/strobe mounted away from camera • Laser scale
ROV Pan & Tilt (HD video)	• General ROV navigation

Note:
1. HD = High definition, ROV = remotely operated vehicle

3.5.3 Sediment Sampling Push Corers

Raytech push corers were used for the collection of marine sediments. Each push corer was comprised of a Perspex core tube with T-bar handle, a one-way valve, and the corer housing (Table 3-4).

Sets of push cores were attached to the ROV TMS and transported to the seabed. Using the ROV manipulator arm, a core was removed from its holster style housing and pushed into the sediment while holding on to the T-bar handle (Figure 3-3). The one-way valve at the top of the chamber allowed water to escape during the capture of sediment. The sample was retained in the corer by suction as the corer was withdrawn from the sediment. The core containing sediment sample was then returned to the housing, which has a tapered, rubber plug at the base of the housing to retain the sample in the corer. Once the ROV surfaced, the T-bar and valve were removed and the core with its rubber plug was removed from the housing with.

Cores of two different internal diameters were used: 60 and 100 mm. Specifications of the push corers are provided in Table 3-4.

Table 3-4 Push corer specifications

Corer internal diameter (mm)	Total length (mm)	Insertion into sediment (mm)	Maximum volume of sediment retrieved (ml)	~Weight of wet sediment (kg)	Weight of corer empty (kg)	Weight of holster and mount (kg)	Weight of corer full (kg) in holster
60	575	355	1,003	1.73	1.5	2	5.23
100	575	355	2,788	4.8	2	3	9.8

Figure 3-3 Raytech push corer and attachment plate (left) and milk crate style carrier (right)

3.5.4 Niskin Bottles

Niskin bottles were used for the collection of surface and near-bottom water samples (Figure 3-4). For the collection of water at depth, one 10 L externally sprung Niskin bottle was attached vertically to the TMS (Figure 3-2) and activated by the ROV manipulator arm to secure containment of the sample at the target location. A second 10 L Niskin bottle was attached to the ROV to provide redundancy in case of failure to collect a water sample from the primary unit mounted to the TMS. All near-bottom water sampling was undertaken prior to sediment sampling to ensure the seabed was not disturbed and a clean water sample was collected.

Surface waters were sampled at each location using a 10 L Niskin bottle deployed over the side of the vessel using a davit arm. Once the Niskin bottle settled approximately 1 m below the surface, the activating weight was dropped to release the springs and close the bottle.

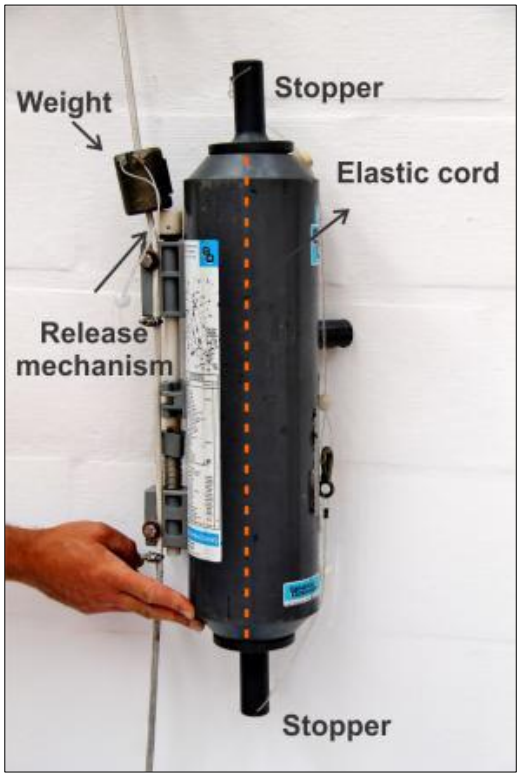

Figure 3-4 Niskin bottle (VLIZ 2022)

3.5.5 Water Quality Profiler

A calibrated Valeport Midas SVX2 water quality probe was used to collect physico-chemical profiles of the water column, specifically conductivity (MilliSiemens per centimetre; mS/cm), temperature (°C), depth (meters; m, below sea level) (CTD), and salinity (Practical Salinity Unit; PSU) (Figure 3-5). The probe was attached to the ROV and logged data on the downcast (surface to seabed) and upcast (seabed to surface) for each dive, in addition to transects along the bottom (just above the seabed). Specifications of the probe are provided in the PEP (Advisian, 2022b).

Figure 3-5 Valeport water quality probe for physico-chemical sampling parameters

3.5.6 Subsea Positioning

The vessel was equipped with a differential global positioning system, and an ultra-short baseline acoustic positioning system was placed on the ROV to track its position during sampling operations. A

hand-held global positioning system (GPS) was used as a secondary GPS in verification of vessel location in relation to each sampling site.

3.6 Benthic Habitat Survey

3.6.1 Survey Sites

Benthic habitat transects were positioned across predicted geomorphic transition zones (i.e., an area where a shift in geomorphic features is apparent) to capture highly variable environments, which are typically attributed with diverse benthic habitats and epifaunal communities. This approach also enabled the validation of predicted benthic habitat boundaries. Seabed imagery for benthic habitat mapping was collected at a total of 39 sites within the originally proposed GBF project area (500 m radius around proposed drill centres, tie-in locations and associated subsea flowlines) (Figure 3-1; Table 3-5), as this smaller footprint represented areas of most-likely benthic disturbance at the time of field mobilisation. At each benthic survey site, video footage was collected along ~2 km-long transects using the ROV, capturing a total of approximately 45.4 km of benthic imagery across the Project area.

Of these 39 sites, 14 sites were identified within more discrete disturbance areas (i.e., proposed drill centres and tie-in locations will be subject to localized disturbance through drilling installation activities; Table 3-5). Within each of the 14 survey sites, five haphazard transects of variable length (ranging from 102–570 m) were surveyed to allow quantitative assessment of benthic cover (%) at these sites. These data were also used to inform habitat mapping objectives. Haphazard transects were positioned by applying a random point generator across the spatial extent of each site that had been adjusted to existing seabed infrastructure (Figure 3-6).

Table 3-5 Benthic habitat mapping and benthic cover survey sites

Notes:
1. Within these sites, a set of 5 haphazard transects were collected to allow quantitative assessment of the BCH
2. BCH = Benthic communities and habitat, DC = drill centre, WTR = West Tryal Rocks

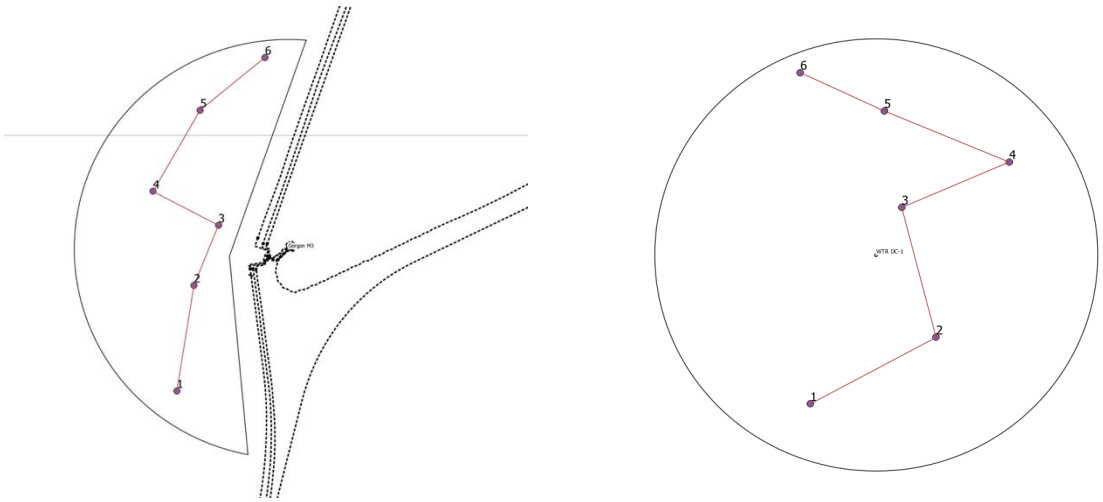

Figure 3-6 Nominal sampling layout for haphazard transects around tie-in locations (left) and proposed drill centres (right)

3.6.2 Benthic Habitat Data Collection

Video footage was collected along the transects outlined in Table 3-5. A video log was maintained throughout the recording. The video log was used to note the start and end times of each transect, as well as for scientific notes such as key physical and biological attributes, and biota (including semi-quantitative descriptions where appropriate). These video logs were used to aid the classification of data. All video footage was stored on external hard drives by the ROV operator and transferred daily to backup hard drives for transport back to Advisian.

3.6.3 Video Classification

Classification of benthic habitat (39 sites) and benthic cover (14 sites) was conducted according to a set of standardised classification categories based on the CATAMI classification scheme (Table 3-6; CATAMI, 2014; Althaus et al., 2015) developed with CAPL. Analysis and classification of video footage for benthic habitat was completed using TransectMeasure (SeaGIS, 2022a) by a marine scientist experienced in image classification. Following classification, the time and classification log were merged with the position and time log to provide a single file with a classification for every position where valid video footage was obtained. Example images of benthic habitat and biotic categories extracted from the video images are provided in Appendix B.

Analysis and classification of video footage (5 x 50 m transects) for benthic cover was also undertaken using TransectMeasure (SeaGIS, 2022a). TransectMeasure was set to randomly pause, enabling 20 images to be extracted per transect (n=100). Ten random points were generated on each image (n = 200/transect) and each point was classified based on the CATAMI classification scheme (Table 3-6).

Table 3-6 Habitat classification categories applied to image analysis for benthic habitat mapping and benthic cover

Habitat Categories	Biota Categories
Relief/Slope	**Biota**
Low (<1 m)	Sponges
Moderate (<3 m)	Cnidaria
High (>3 m)	Echinoderms
Wall	Sponges, Cnidaria
Substrate	Sponges, Echinoderms
Unconsolidated (soft)	Cnidaria, Echinoderms
Consolidate (hard)	Mixed biota (all 3)
Substrate size/appearance	
Sand/mud (<2 mm)	
Sand/mud (<2 mm) and occasional boulders	
Cobbles	
Boulders	
Rock (Outcropping bedrock)	
Modifier	
Bare	
Biota only

Ripples (<10 cm height) with biota and sparse veneer with biota	
Veneer with biota	
Unknown	

3.6.4 Video Quality Assurance and Quality Control Assessment

Following completion of the video classification, a quality assurance and quality control (QA/QC) assessment was performed by Advisian personnel to determine confidence in video analysis

techniques. Each video analyser was assigned 5% of processed video transects to re-process and note errors. The video QA/QC assessment is detailed in Appendix C.

3.6.5 Classification and Mapping Procedures

To characterise the benthic habitat and potential occurrence of significant BCH in areas away from ground truthing transects (between 500 m and 5 km from the proposed subsea facilities), a predictive mapping approach known as supervised classification was adopted. Supervised classification techniques use an artificial intelligence algorithm to statistically compare specific attributes of multiple raster layers of known sites of interest. Supervised classification is a 'bottom up' approach (Brown et al., 2011) whereby the *in-situ* ground truthing transects are used to inform the organization and segmentation of the broad scale environmental data, and is applied at the same taxonomic level as the ground truthing data.

For this study, the video footage captured by the ROV is used to verify the distribution of epibenthic BCH of interest (e.g., bare seabed, cnidaria, sponges, or a combination of categories). The verified BCH is then spatially linked with characteristics of the seabed terrain derived from the 3D seismic data to build a predictive model of a large component of the mapping area.

3.6.5.1 Bathymetric Derivatives

A 25 m cell size bathymetric digital terrain model derived from 3D seismic data was available for a large proportion of the GBF project area (including the entire escarpment area) and was free of data artefacts. A series of 'derivative' terrain layers were created to extract additional information about the type of seabed terrain that most commonly support the observed BCH. The derivatives calculated for each cell included:

- Depth: depth in metres of the seabed for every cell, with implications for water pressure and light penetration.
- Roughness: derived from the bathymetric dataset by subtracting the minimum depth from the maximum depth value in a defined-neighbourhood around a central pixel (Riley et al., 1999). The neighbourhood is defined as the eight nearest cells to a central pixel (a 3 m x 3 m area). Values of zero or close to zero indicate flat areas, whereas larger roughness values indicate increasingly complex terrain. For this study, roughness was a good proxy for the complex terrain associated with rocky outcrops on the seabed. Smaller scale sediment ripples can also appear to have high seabed roughness values; however, ripples were not a common seabed characteristic in the GBF project area.
- Slope: slope is the ratio of rise to run over a defined neighbourhood area. For this study, the seabed away from the coastline was typically very flat, and slopes greater than five degrees were rare and often indicative of interesting features. Higher slopes are often associated with seabed features that are important for ecological habitats such as reef edges and drop offs.
- Aspect: the facing direction of the local neighbourhood area of seabed, defined as slope orientation in degrees clockwise from north, with implications for exposure to oceanic currents (Florinsky, 2016).
- Relative TPI (two scales): the TPI distinguishes topographic features such as a hilltops, valley bottoms, exposed ridges, flat plains, and slopes. It is calculated by comparing the elevation of each pixel above or below its surrounding neighbours. The number of neighbours compared (i.e., the scale of the neighbourhood) is of critical importance, therefore two scales were calculated and

incorporated. Smaller neighbourhood sizes are better at detecting small-scale features whereas larger neighbourhood sizes better detect large features (Guisan et al., 1999; Wilson and Gallant, 2000).

- Total Curvature: measured 3D curvature of the local topographic surface (Wilson, 2018).
- Morphometric Protection Index: analyses the immediate surrounding of each cell up to a given distance and evaluates how the relief protects it, describing canyon or pinnacle reef environments (Olaya, 2002).

These seabed terrain indices were calculated for the GBF project area, and merged in a desktop GIS software package to directly 'stack' all pixel values into an n-dimensional multiband raster image.

3.6.5.2 Criteria for likelihood of biota presence

Acoustic backscatter data, which is a product derived from MBES outputs, relates to seafloor micro-topography (or roughness) and volume heterogeneity (sediment grain-size and sediment composition). It has been used as a qualitative indicator of the nature of the substrate, whereby high backscatter is received from hard and rough materials such as rocky reefs, whereas lower backscatter might be expected from smooth, soft, muddy bottoms.

All sediment habitats that appeared as flat and featureless soft sandy substrates (smooth and irregular seabed, bare substrate, mound, veneer of sand) lack the overt visual complexity of more ecologically enigmatic habitats such as coral reefs and seagrass meadows, and are likely to provide a less diverse and/or lower benthic assemblage than other habitat types. As such, these habitats are assigned a 'low' likelihood of biota presence.

Raised geomorphic features (depression/scour, reef mosaic, rock reef, scarp) typically offer structural complexity (e.g., fissures, holes, caves and overhangs) with a hard surface to an otherwise flat bare substrate for marine life to attach to, potentially supporting extensive communities and providing refuge to epibenthic and encrusting biota. Therefore, these structures are primarily assigned a 'high' likelihood of biota presence. However, due to the varying degree of soft sediment coverage and other environmental factors within raised or otherwise apparent consolidated geomorphic features, these locations may also be represented to have a 'low' likelihood of biota presence and/or classified as a bare substrate.

3.6.6 Model Training

The ground truthing habitat layer was compiled into a GIS for integration with the supervised classification algorithm. For each training dataset point, a single consistent and unified class was attributed, which included:

- Bare seabed (including areas that support mobile echinoderms)
- Cnidaria
- Sponges
- Sponges and Cnidaria.

Using spatial analysis techniques, the 'training' dataset was linked to the corresponding terrain characteristics. This dataset was used to train the random forest classifier for habitat prediction.

A random forest classifier known as an ensemble machine learning method, was employed to predict the distribution of habitats across the GBF project area. The classifier was trained on the small dataset of biota types and their locations using the derivative terrain layers as predictor variables. The random forest approach was chosen for its ability to handle complex and non-linear relationships, robustness to noise, and resistance to overfitting. This technique was only applied to the 'slope break' component of the GBF project area as this was the only region with available high quality bathymetry dataset. Areas in deeper waters (the 1200 m contour that defined the outer limit) with no biota recorded in the ground truthing survey were not included. Supervised data classification was undertaken in a Python-based software implementation Dzetsaka (Karasiak, 2016). Once imported, the seven composite bands (the derivative terrain layers outlined in Section 3.6.5.1) were overlain with the habitat-attributed training dataset, and were analysed to determine the spectral statistics relevant to each habitat layer. The classification was then run on the entire dataset, allowing the program to assess the band spectral values for each pixel cell. For the dominant habitat classification, the algorithm assigns one of the four main habitat types to each cell: bare seabed, cnidaria, sponges, and sponges and cnidaria. For the presence-absence assessment, the cells are attributed to either 1 (unknown), 2 (known to be absent) or 3 (known to be present).

For validation and error assessment, a 'bootstrap' subset of data was withheld from the training dataset; 90% of original data pixels were used to train the model, and the remaining 10% dataset was used by the model to evaluate its own performance.

3.6.6.1 Results of the Model Training

The results show that the BCH are likely to be found along areas with very steep escarpments (Figure 3-7), which coincides with the observational data. The overall accuracy of the self-assessment model, which is a comparison of the 10% training pixels withheld from the classification with classified pixels in the same location, was 92% (Kappa statistic of 98.7%), suggesting a strong correlation, and a Cohens Kappa value of 0.48, indicating a moderate correlation between the datasets and a low probability of the influence of random chance (de Raadt, A et al., 2021).

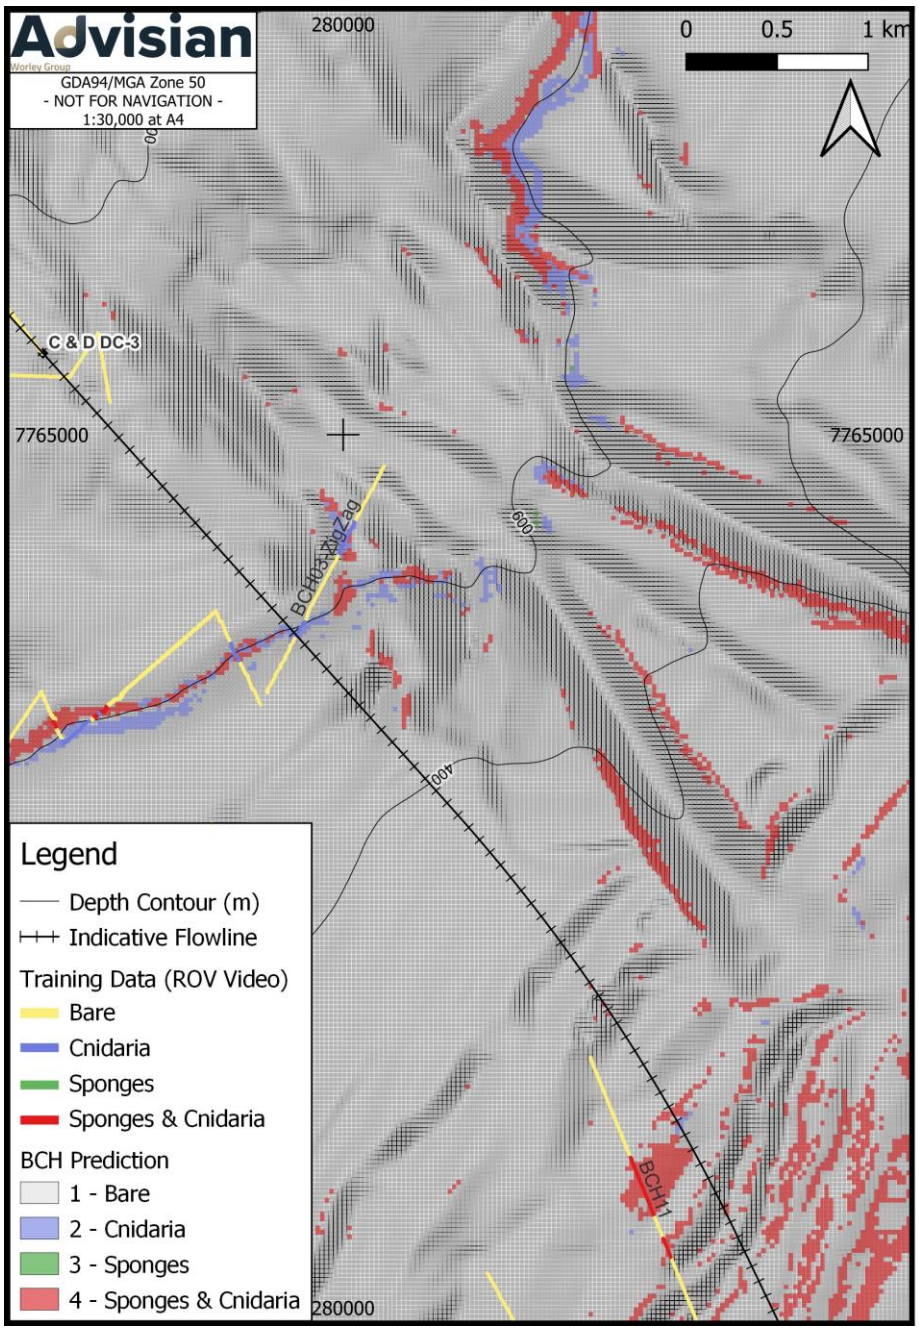

Figure 3-7 Example of a supervised classification map of the East Scarp-Tryal area within the Gorgon Backfill Fields project area

3.7 Fish Assemblage Surveys

3.7.1 Survey Sites

A total of 11 sites were examined to describe and compare the fish and crustacean assemblages (Table 3-7). Of these sites, two sites were located within the Exmouth Plateau KEF, four sites were within the Continental Slope Demersal Fish Communities KEF, and one site was located within the Ancient

Coastline KEF, while the remaining four sites were located outside any KEFs (Table 3-7). The sites also covered four geomorphic features (Heap & Harris, 2008) including plateau slope, deep/hole/valley slope, trench/tough slope, and slope (Table 3-7).

Table 3-7 Fish survey sites

Field	Site Name	Key Ecological Feature	Geomorphic Feature	Survey Date	Easting	Northings	Depth Range (m)
Chandon	BCH01	Exmouth Plateau	Plateau slope	7/05/2022	198899	7833791	1,100–1,200
	BCH02	Exmouth Plateau	Plateau slope	7/05/2022	200918	7832022	1,200–1,300
Chrysaor and Dionysus (C & D)	C &D DC-3	Outside of any KEF	Trench/ tough slope	3/05/2022	278747	7765155	700–800
	BCH04	Continental Slope Demersal Fish Communities	Slope	3/05/2022	280271	7759126	200–400
	BCH11	Continental Slope Demersal Fish Communities	Slope	3/05/2022	281368	7761555	200–300
	BCH12	Continental Slope Demersal Fish Communities	Slope	1/05/2022	280344	7756362	200–300
	BCH33	Continental Slope Demersal Fish Communities	Slope	9/05/2022	281572	7758993	200–300
Semele	NTB3	Outside of any KEF	Deep/hole/ valley slope	4/05/2022	280281	7780314	1,100–1,200
WTR	WTR DC-1	Outside of any KEF	Slope	9/05/2022	294288	7762283	100–200
	BCH24	Outside of any KEF	Slope	10/05/2022	283879	7744470	100–200
	Gorgon GMT	Ancient Coastline	Slope	10/05/2022	280989	7733571	100–200

Note:
1. BCH = Benthic communities and habitat, C & D = Chrysaor and Dionysus, DC = drill centre, KEF = Key Ecological Feature, WTR = West Tryal Rocks

3.7.2 Fish Assemblage Data Collection

Video footage was collected along the transects outlined in Table 3-7 using the forward-facing HD camera (30° angle) on the ROV (Section 3.5.2).

3.7.3 Fish Species Classification System

Classification of the video footage was completed using EventMeasure Stereo (SeaGIS, 2022b). Each fish, crustacean and other mobile invertebrate that was encountered along each transect was identified to the lowest taxonomic resolution possible and enumerated as outlined in Goetze et al. (2019). Any fish that re-entered the field of view was not re-counted.

3.7.4 Statistical Treatment and Analysis

Due to the varying transects lengths collected at each site, the length of all transects were standardised to 200 m to allow for a robust statistical analysis and is a similar length to other studies conducted in the North West Shelf (Saunders et al., 2021). For six transects along three sites (C & D DC-3, NTB3 and Gorgon GMT), transects lengths ranged from 112 and 198 m and as such, the entire transect was used for analyses. For transects greater than 200 m, the first 200 m section of the transect was selected for statistical analysis. Where transect lengths were greater than 400 m, the transect was split into multiple replicate 200 m lengths with a 10 m gap to separate the transects.

To determine whether there are any differences between the fish and crustacean assemblages among water masses, among KEFs, and among the geomorphic features, three different statistical designs were used, each comprising of a two-factor design:

Design one – Water mass

- Water mass = fixed factor with three levels: Tropical Surface Water (TSW), Southern Indian Central Water (SICW), Antarctic Intermediate Water (AAIW)
- Site = random factor nested within water mass, varying levels depending on replication

Design two – KEFs

- KEF = fixed factor with four levels: Exmouth Plateau, Continental Slope Demersal Fish Communities, Ancient Coastline, and Outside of any KEF
- Site = random factor nested within KEF, varying levels depending on replication

Design three – Geomorphic features

- Geomorphic feature = fixed factor with four levels: slope, trench/trough, deep/hole/valley, plateau
- Site = random factor nested within geomorphic feature, varying levels depending on replication.

All statistical analyses, including post-hoc tests on significant factors, were undertaken using non-parametric analysis of variance (PERMANOVA) in the software package PRIMER with PERMANOVA+ (Primer-E Ltd, Version 7.0.18; Anderson, 2008; Clarke & Gorley, 2015). Fish assemblage data were fourth root transformed and crustacean assemblage data were square root transformed prior to analysis to down-weigh the contribution of dominant species and allow rarer groups to play a part in the analyses. The Bray-Curtis dissimilarity measure was used on the multivariate dataset prior to analysis with PERMANOVA.

Results of multivariate analysis (fish and crustacean assemblages) were presented graphically using a non-parametric multidimensional scaling (nMDS) plot to visualise any patterns in two-dimensional space. Vectors were overlaid on the nMDS plot to illustrate the strength and direction of the Pearson's correlation (>0.5) of individual taxa to the dataset.

To investigate the effect of depth on the composition of the multivariate fish and crustacean assemblages, a distance-based linear modelling (DistLM) was completed. For this analysis, depth was the explanatory variable, and the fish or crustacean assemblages were the dependent variables.

Data were not transformed prior to univariate analyses of number of fish and crustaceans, and number of fish taxa and crustacean taxa. Euclidean distance was used as a dissimilarity measure for univariate

analyses. Results were presented using bar graphs of means and standard errors (SE) to illustrate patterns among the factors of interest.

Refer to Appendix D for more details on the methodology of fish assemblages.

3.8 Sediment Sampling

Sediment sampling comprised of two separate assessments: sediment characterisation (chemistry and composition) and benthic infauna. Sample collection for both types of assessments were completed simultaneously using ROV-operated push corers.

3.8.1 Sediment Sample Collection

Sediment quality sampling sites were selected to understand the chemistry and composition of sediment at potential drill centres and tie-in locations. These sites were sampled to characterise the sediment quality prior to any disturbance or potential contamination arising from development activities (e.g., drilling and cutting disposal), providing a broad-level baseline understanding of project area.

Sediment samples were collected using push corers operated by the ROV manipulator arm (Section 3.5.3). At each site (Table 3-8), three replicate sediment cores (of 100 mm internal diameter) were collected and analysed for sediment chemistry, and two replicate sediment cores (60 mm internal diameter) were collected for benthic infauna (Table 3-9). This approach was a reduction in effort compared with the PEP (Advisian, 2022a) due to time constraints encountered in the field. A total of 30 samples for chemistry (excluding QA/QC samples; Section 3.8.4) from ten sites (Table 3-8) were collected. For benthic infauna, a total of 28 samples (14 sites with two replicate samples collected from each site) were collected.

Table 3-8 Sediment sampling sites

Field	Site Name	Survey Date	Easting	Northings	Depth Range (m)
Chandon	Chandon DC-1	7/05/2022	198899	7833791	1,100–1,200
Chrysaor and Dionysus	C & D DC-3	3/05/2022	278747	7765155	700–800
	C & D DC-2	4/05/2022	276899	7772322	1,000–1,100
Geryon and Eurytion	G & E DC-1	5/05/2022	278876	7793169	1,200–1,300

Note:
1. C & D = Chrysaor and Dionysus, DC = drill centre, G & E = Geryon and Eurytion, WTR = West Tryal Rocks

Table 3-9 Sediment samples for each core size

Parameters	Corer Size	Core Sample Depth	Sample Sites per Location	Replicate Samples
Sediment chemistry and composition	100 mm	5 cm	1	3
Benthic infauna	60 mm	10 cm	1	2

3.8.2 Sediment Chemistry Sample Processing and Labelling

All sediment samples were processed and preserved according to Australian and New Zealand Standards (AS/NZS 5667.1:1998) and the requirements of the analytical laboratories. On the recovery of samples to the surface, each core was deposited into core trays, assessed for physical properties (e.g., odour, sediment grain size and the presence of organic matter, marine organisms, shells, and other relevant features), and photographed with the relevant site identification prior to sample processing. All sampling equipment including the push corers and core trays, were washed with laboratory grade decontamination solution (Decon 90), and rinsed thoroughly with clean seawater. Field personnel wore disposable sterile nitrile gloves at all times during the sampling process which were changed between sampling collections at each site.

For the analysis of sediment chemistry and composition (PSD), the top 5 cm of sediment sample from each of three replicate cores were extracted and homogenised in a glass bowl until the texture and colour was uniform. The sediment sample was then placed into laboratory supplied containers (Table 3-10) and labelled with the date and time of sampling, field location and site number (sample unique identifier). All samples were stored in a refrigerator and each sample was recorded on a field sheet.

Chain of custody (CoC) documentation was used for all stages of the sample processing and storage. Field sheets and data tracking sheets were used to ensure all sites were sampled and samples were properly stored, labelled, preserved, and delivered to the laboratories within the recommended holding times. However, due to the remote location of sampling sites, recommended holding times for the analyses of some analytes (TRH, BTEX and moisture content) were exceeded for sites WTR DC-1 and Semele 4. Such exceedances should be taken into consideration when interpreting the results. CoC tables are presented in Appendix E.

3.8.3 Sample Analysis

Sediment samples were analysed using standard laboratory methods at ALS Environmental (Perth), a National Association of Testing Authorities (NATA) accredited laboratory. Samples were analysed for hydrocarbons (total recoverable hydrocarbons [TRH], benzene, toluene, ethylbenzene and xylenes [BTEX], and polycyclic aromatic hydrocarbons [PAHs]), total metals/metalloids, PSD, TOC, and moisture content (Table 3-10). Sediment concentrations were compared to Australian and New Zealand Guidelines (ANZG; ANZG, 2018) default guideline values (DGVs), and upper guideline values (GV-High) if required.

Table 3-10 Chemical and physical analysis of sediment samples

Parameter	ALS Limit of Reporting (LOR) as per Quote EP/246/22 (mg/kg)[1]	Container, Preservation and Holding Time (as per ALS Methods)

TOC (%)	0.02%	150ml Soil Glass Jar – Unpreserved Chilled <6°C Holding Time: 28 days
Moisture (%)		*250ml Soil Glass Jar – Unpreserved Chilled <6°C Holding Time: 14 days

Notes:
1. Value in parentheses for total metals is the ANZG (2018) default guideline value (DGV), and guideline value high (GV-High)
2. Asterisks (*) denotes a shared laboratory container
3. BTEX = Benzene, toluene, ethylbenzene and xylenes, PAH = polycyclic aromatic hydrocarbons, PSD = particle size distribution, TOC = total organic carbon, TRH = total recoverable hydrocarbons

3.8.4 Quality Assurance and Quality Control Analysis

As part of the NATA requirements, the following QA/QC samples were collected in the field to ensure data integrity:

- Sediment field blanks were used to test for potential contamination of sediment samples during the sampling process. The blank sample consisted of acid washed and heated soil to remove organic content. The blank sample was processed using the same methods and equipment as the actual sediment samples and was analysed for hydrocarbons. A field blank was collected at sites G & E DC-1 and WTR DC-1.
- Duplicate sediment samples (two extra cores) were collected at sites Semele BCH2 and WTR DC-1 to test for inter-laboratory variability. Two independent samples (i.e., two separate grabs) were collected at the same location and were analysed by the secondary laboratory (ALS on the east coast of Australia) for metals and moisture content.
- Triplicate sediment samples were collected at site WTR DC-1 to test for intra-laboratory variability. Three independent samples (i.e., three separate grabs) were collected at the same location and were analysed by the primary laboratory for metals and moisture content.

The accuracy of sediment analyses was determined by quantifying the differences between the concentrations of analytes in the duplicate and triplicate samples. The relative percent difference (RPD) was calculated for duplicate samples and the relative standard deviation (RSD) was calculated for the triplicate sample using the methods outlined in the National Assessment Guidelines for Dredging (Commonwealth of Australia, 2009). The RPD and RSD calculations are determined as follows:

$$\text{RPD (\%)} = \frac{\text{(difference between replicates) x 100}}{\text{(average of the replicates)}}$$

$$\text{RSD (\%)} = \frac{\text{(standard deviation of replicates)x 100}}{\text{(average of replicates)}}$$

Values for RPD and RSD greater than 50% may signify that sediments are either heterogenous, or greatly differ in grain size. RPD/RSD calculations were not completed where one or more of the replicates were below the laboratory limit of reporting (LOR).

In addition to the field QA/QC samples, laboratory analyses included quality control testing of sediment samples to include:

- 5% method blanks (one analysed within each process lot of 20 samples)
- 10% laboratory duplicates (two analysed within each process lot of 20 samples)
- 5% laboratory control samples (one analysed within each process lot of 20 samples)
- 5% matrix spikes (one analysed within each process lot of 20 samples).

All QA/QC samples were analysed within laboratory holding times and in accordance with NATA quality control procedures (Appendix I). QA/QC samples were not required for benthic infauna samples.

3.8.5 Benthic Infauna Collection and Processing

Sediment samples for infauna were collected using methods similar to Hook et al. (2016) in which the top 10 cm of sediment sample from both cores were used. If the sample contained less than 10 cm, the depth of sample was noted on the field sheet and the whole sample was used. Samples were sieved on site to 1 mm, placed into a calico bag and were preserved in 100% ethanol before transporting to the laboratory. CoC documentation was used for all stages of the sample processing and storage.

Benthic infauna samples were processed by Benthic Australia. Laboratory processing of sediment samples for benthic infauna included:

- Sample sorting – the separation of biological material from sediment, shell-hash, and other non-living biological material retained by sieving. Rose Bengal may be added to stain the biological material and facilitate the sorting process.
- Species identification and enumeration – the accurate identification (using stereomicroscopy) of all invertebrates found in a sample to the lowest reliable taxonomic level and the counting of invertebrate numbers in each taxonomic category.

Invertebrates were identified to the lowest reliable taxonomic level using appropriate standard identification guides and keys for the taxonomic groups. After sorting, identification and counting, invertebrates were stored in 70% isopropyl alcohol.

3.9 Water Sampling

3.9.1 Water Sample Collection

Sampling sites for water quality were selected to ensure sufficient spatial representation across the GBF project area whilst still maintaining alignment with planned ROV benthic survey deployment locations. Sampling for water ensured a high-level baseline dataset was obtained prior to any disturbance or potential contamination arising from development activities (e.g., drilling and cutting disposal), and allows for valid comparisons in the unlikely event of a discharge or spill event(s).

Replicate water samples were collected from the surface and near the seabed at each site (n = 4 per site; Table 3-11) using a Niskin bottle (Section 3.5.4). Samples were collected from approximately 1 m below the surface using a Niskin bottle deployed over the side of the vessel, and from near the seabed (~5–10 m above) from ROV-activated Niskin bottles attached to the ROV TMS. At site Jansz JMT, the second Niskin bottle attached to the ROV was not loaded and only one of two water samples from near the seabed was collected. As such, a total of 31 samples (excluding QA/QC samples; Section 3.9.4) from eight sites (Table 3-11) were collected.

Table 3-11 Water quality sampling sites

Field	Site Name	Survey Date	Number of Surface Samples	Number of Near Seabed Samples	Facility / BCH Transect	Easting	Northings	Depth Range (m)
Chandon	Jansz JMT	5/05/2022	1	2	Tie in	249098	7807831	1,300–1,400
	Chandon DC-1	7/05/2022	2	2	Proposed Drill Centre	198899	7833791	1,100–1,200

Field	Site Name	Survey Date	Number of Surface Samples	Number of Near Seabed Samples	Facility / BCH Transect	Easting	Northings	Depth Range (m)
Chrysaor and Dionysus	C & D DC-3	3/05/2022	2	2	Proposed Drill Centre	278747	7765155	700–800
Geryon and Eurytion	G & E DC-1	5/05/2022	2	2	Proposed Drill Centre	278876	7793169	1,200–1,300
	BCH28	6/05/2022	2	2	BCH Transect	253595	7798894	1,200–1,300
Semele	NTB3	4/05/2022	2	2	Proposed Drill Centre	280281	7780314	1,100–1,200

	Gorgon GMT	10/05/2022	2	2	Tie in	280989	7733571	100–200

Note:

1. BCH = Benthic communities and habitat, C & D Chrysaor and Dionysus, DC = drill centre, G & E = Geryon and Eurytion, WTR = West Tryal Rocks

3.9.2 Water Chemistry Sample Processing and Labelling

All water samples were processed and preserved according to Australian and New Zealand Standards (AS/NZS 5667.1:1998) and the requirements of the analytical laboratories. For all samples, water from the Niskin bottle was emptied directly into the laboratory containers in order to decrease chance of contamination (Table 3-12). All sampling equipment including the Niskin bottles, were washed with Decon 90 and rinsed thoroughly with clean seawater. Field personnel wore disposable sterile nitrile gloves at all times during the sampling process which were changed between sampling collections at each site. Filtering of water samples was completed by the laboratory, where required. All sample containers were labelled with the date and time of sampling, field location and site number (sample unique identifier). All samples were stored in a refrigerator and each sample was recorded on a field sheet.

CoC documentation was used for all stages of the sample processing and storage (Appendix E). Field sheets and data tracking sheets were used to ensure all water sampling sites were sampled and samples were properly stored, labelled, preserved, and delivered to the laboratories within the recommended holding times. However, due to the remote location of sampling sites, recommended holding times for the analyses of some analytes were exceeded for some samples, including TRH and TDS for surface and seabed water samples at NTB3, and TDS for surface and seabed water samples at C & D DC-3. Such exceedances should be taken into consideration when interpreting the results.

3.9.3 Sample Analysis

Water samples were analysed using standard laboratory methods at ALS Environmental (Perth), a NATA-accredited laboratory. Samples were analysed for hydrocarbons (TRH, BTEX, PAHs), total and dissolved metals, DOC, TOC, TDS, total phosphorus (TP) and total nitrogen (TN) (Table 3-12). Concentrations were compared to ANZG (2018) DGVs for 99% species protection.

2. °C = Celsius degrees, BTEX = benzene, toluene, ethylbenzene and xylenes, DOC = dissolved organic carbon, LOR = limit of reporting, PAH = polycyclic aromatic hydrocarbons, TDS = total dissolved solids, TOC = total organic carbon, TN = total nitrogen, TP = total phosphorus, TRH = total recoverable hydrocarbons

3.9.4 Quality Assurance and Quality Control Analysis

As part of the NATA requirements, the following QA/QC samples were collected in the field to ensure data integrity:

- Duplicate water samples were collected to test for inter-laboratory variability. Two independent samples (i.e., two separate grabs) were collected at the same location and were analysed by the secondary laboratory (ALS on the east coast of Australia) for dissolved and total metals, TN, TP, DOC, TOC, and TDS. Duplicate samples were collected from near the seabed at G & E DC-1, near the seabed at Gorgon GMT, and surface sample at WTR DC-1.
- Equipment water blanks were processed while at site WTR DC-1 to test for potential contaminants in the sampling equipment. Water blank samples were used on the four Niskin bottles (one attached to the ROV and another to the TMS, and two on the surface) and were analysed by the primary laboratory for dissolved and total metals, hydrocarbons and TN, TP, DOC, TOC, and TDS.

Similar to sediment samples, laboratory analyses included quality control testing of water samples to include 5% method blanks, 10% laboratory duplicates, 5% laboratory control samples, and 5% matrix spikes. All QA/QC samples were analysed within laboratory holding times and in accordance with NATA quality control procedures (Appendix I).

3.10 Water Profiling

3.10.1 Data Acquisition and Presentation

Profiles of the water column were collected by the water quality profiler attached to the ROV (Section 3.5.5). CTD measurements were collected at 35 sites, as presented in Table 3-13. After all sites were completed, the water quality profiler was removed from the ROV, and data downloaded to a laptop. Salinity was calculated by the CTD processing software using EOS-80 (Practical Salinity) equations.

Table 3-13 Summary of CTD sampling sites, start/end times, depth, and up/down cast

Field	Site Name	Upcast (U)/ Downcast (D)	Survey Date	Start Time	End Time	Depth (m)

	BCH27	D	9/5/2022	10:40	12:27	141
	Gorgon GMT	D	10/5/2022	05:17	05:26	136

Note:
1. BCH = Benthic communities and habitat, C & D Chrysaor and Dionysus, DC = drill centre, G & E = Geryon and Eurytion, WTR = West Tryal Rocks

Data are presented as profiles of temperature, salinity, and conductivity against depth for each site. Additionally, temperature-salinity plots were presented for the deepest site at each field to evaluate localised water masses that may be present in the area. Outliers in the water column profiles were removed.

Depth profiles were also recorded by the ROV (recorded as altitude) during each deployment (transect) in the GBF project area.

4 Results

4.1 Benthic Habitat

The overall distribution of benthic habitats within the GBF project area (within the 5 km operational area buffer) is presented in Figure 4-1. The overall benthic habitat map is split into seven maps to show the fine scale seabed features with higher resolution. The seven maps include the 1) Exmouth Plateau area (Figure 4-2), 2) North Jansz area (Figure 4-3), 3) Jansz area (Figure 4-4), 4) North East Semele area (Figure 4-5), 5) North Gorgon area (Figure 4-6), 6) East Scarp-Tryal area (Figure 4-7) and Figure 4-8, and 7) South Gorgon area (Figure 4-9).

These maps presented have been developed using a supervised classification approach, whereby the ROV imagery has been used to verify the distribution of BCH and inform the organisation and segmentation of the broadscale geophysical environmental data. The mapped classification categories presented herein are derived from nested CATAMI scheme (see examples in Appendix B) and have been grouped to represent the appropriate taxonomic level for assessment across a broad scale project area.

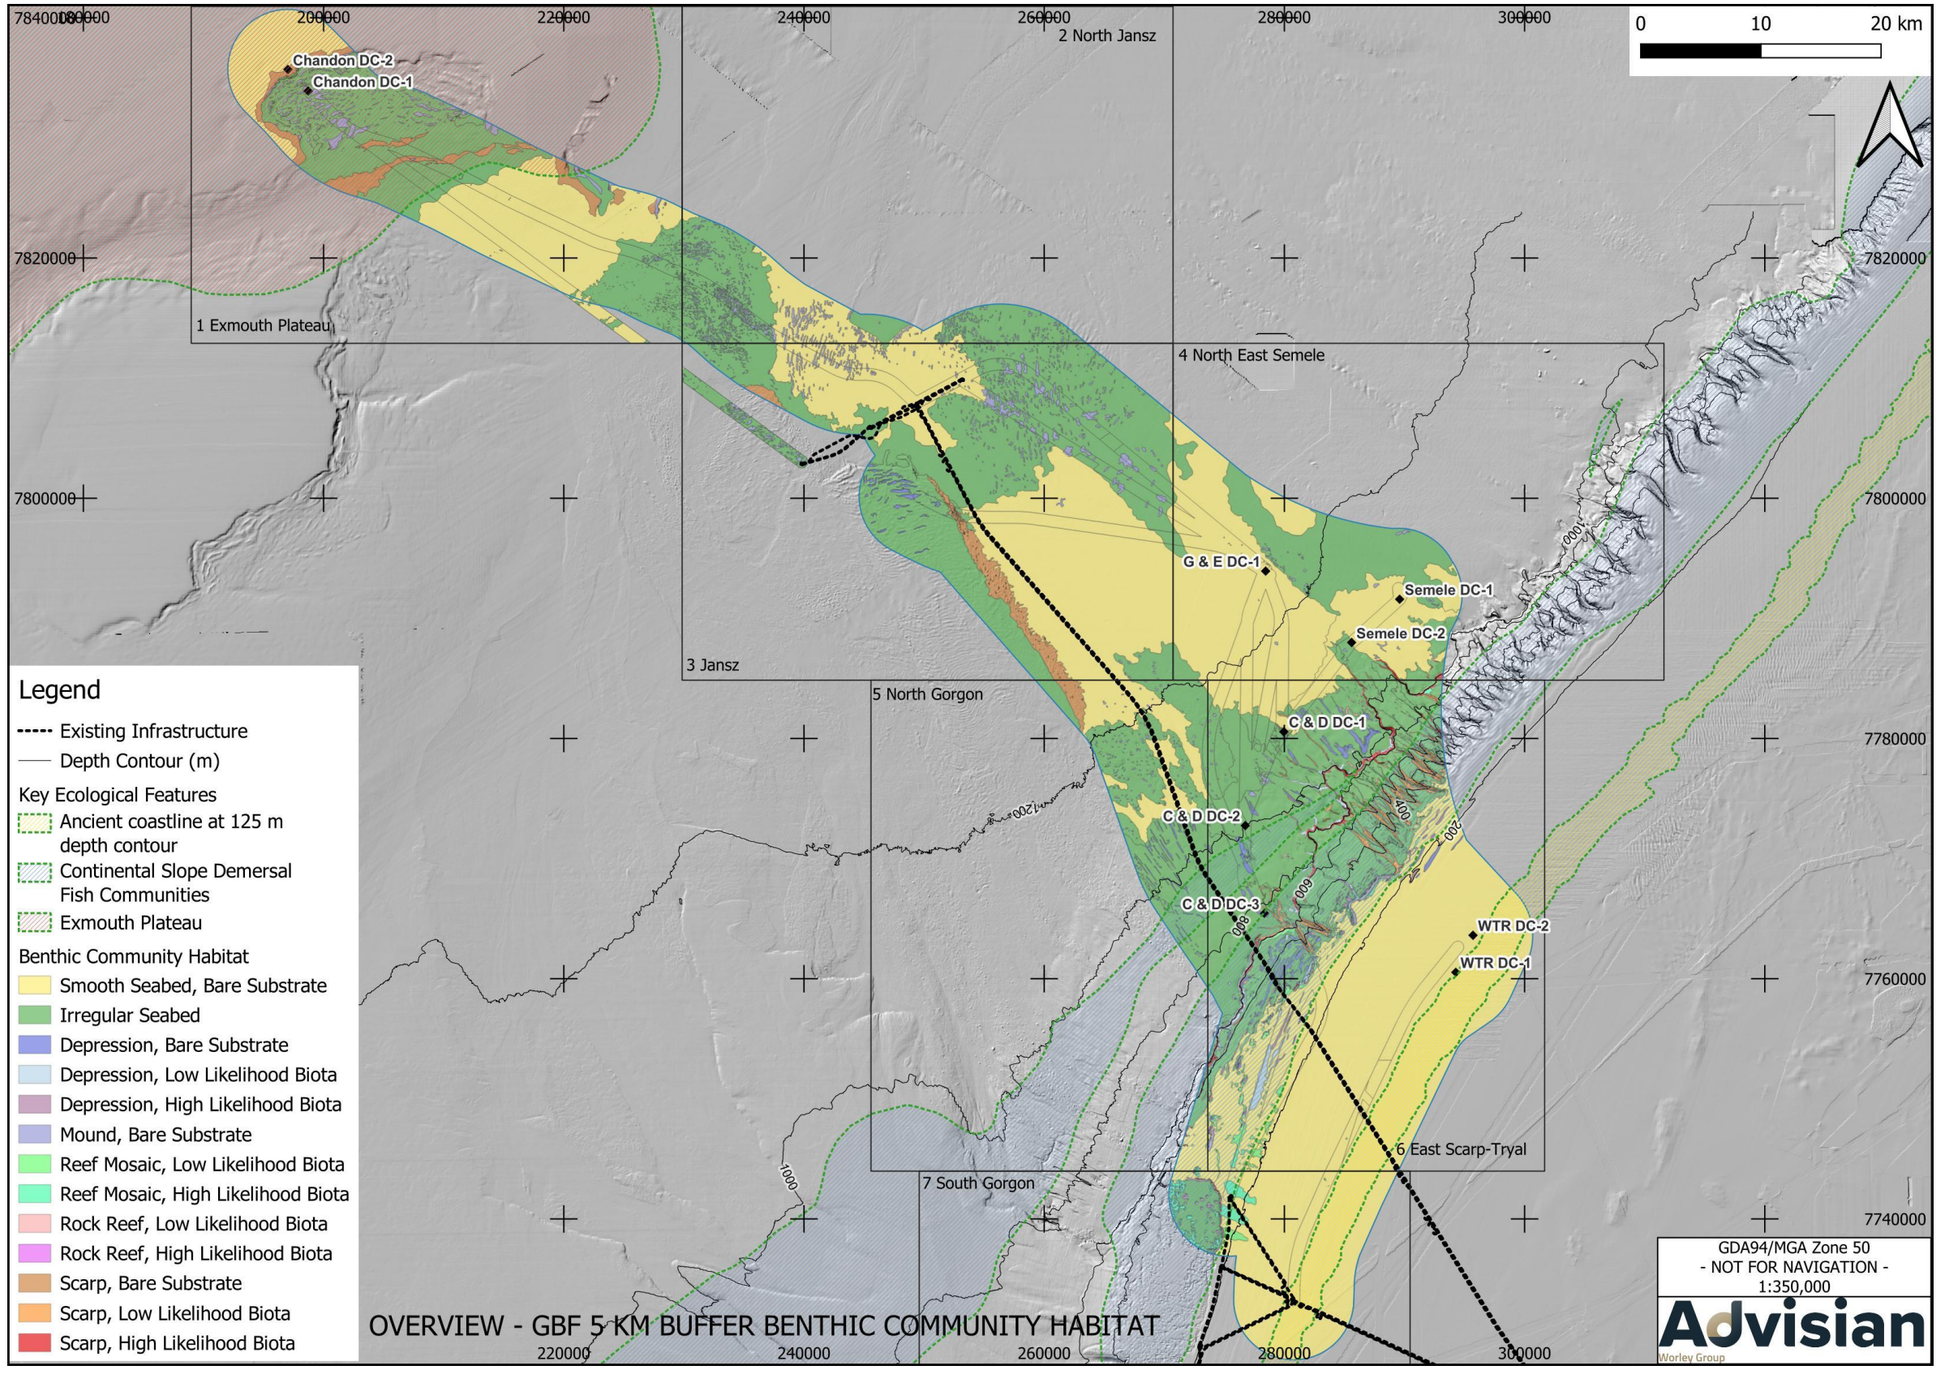

Figure 4-1 Overall distribution of benthic habitats within the Gorgon Backfill Fields project area, subdivided into seven broad areas (1 Exmouth Plateau, 2 North Jansz, 3 Jansz, 4 North East Semele, 5 North Gorgon, 6 East Scarp-Tryal, and 7 South Gorgon areas)

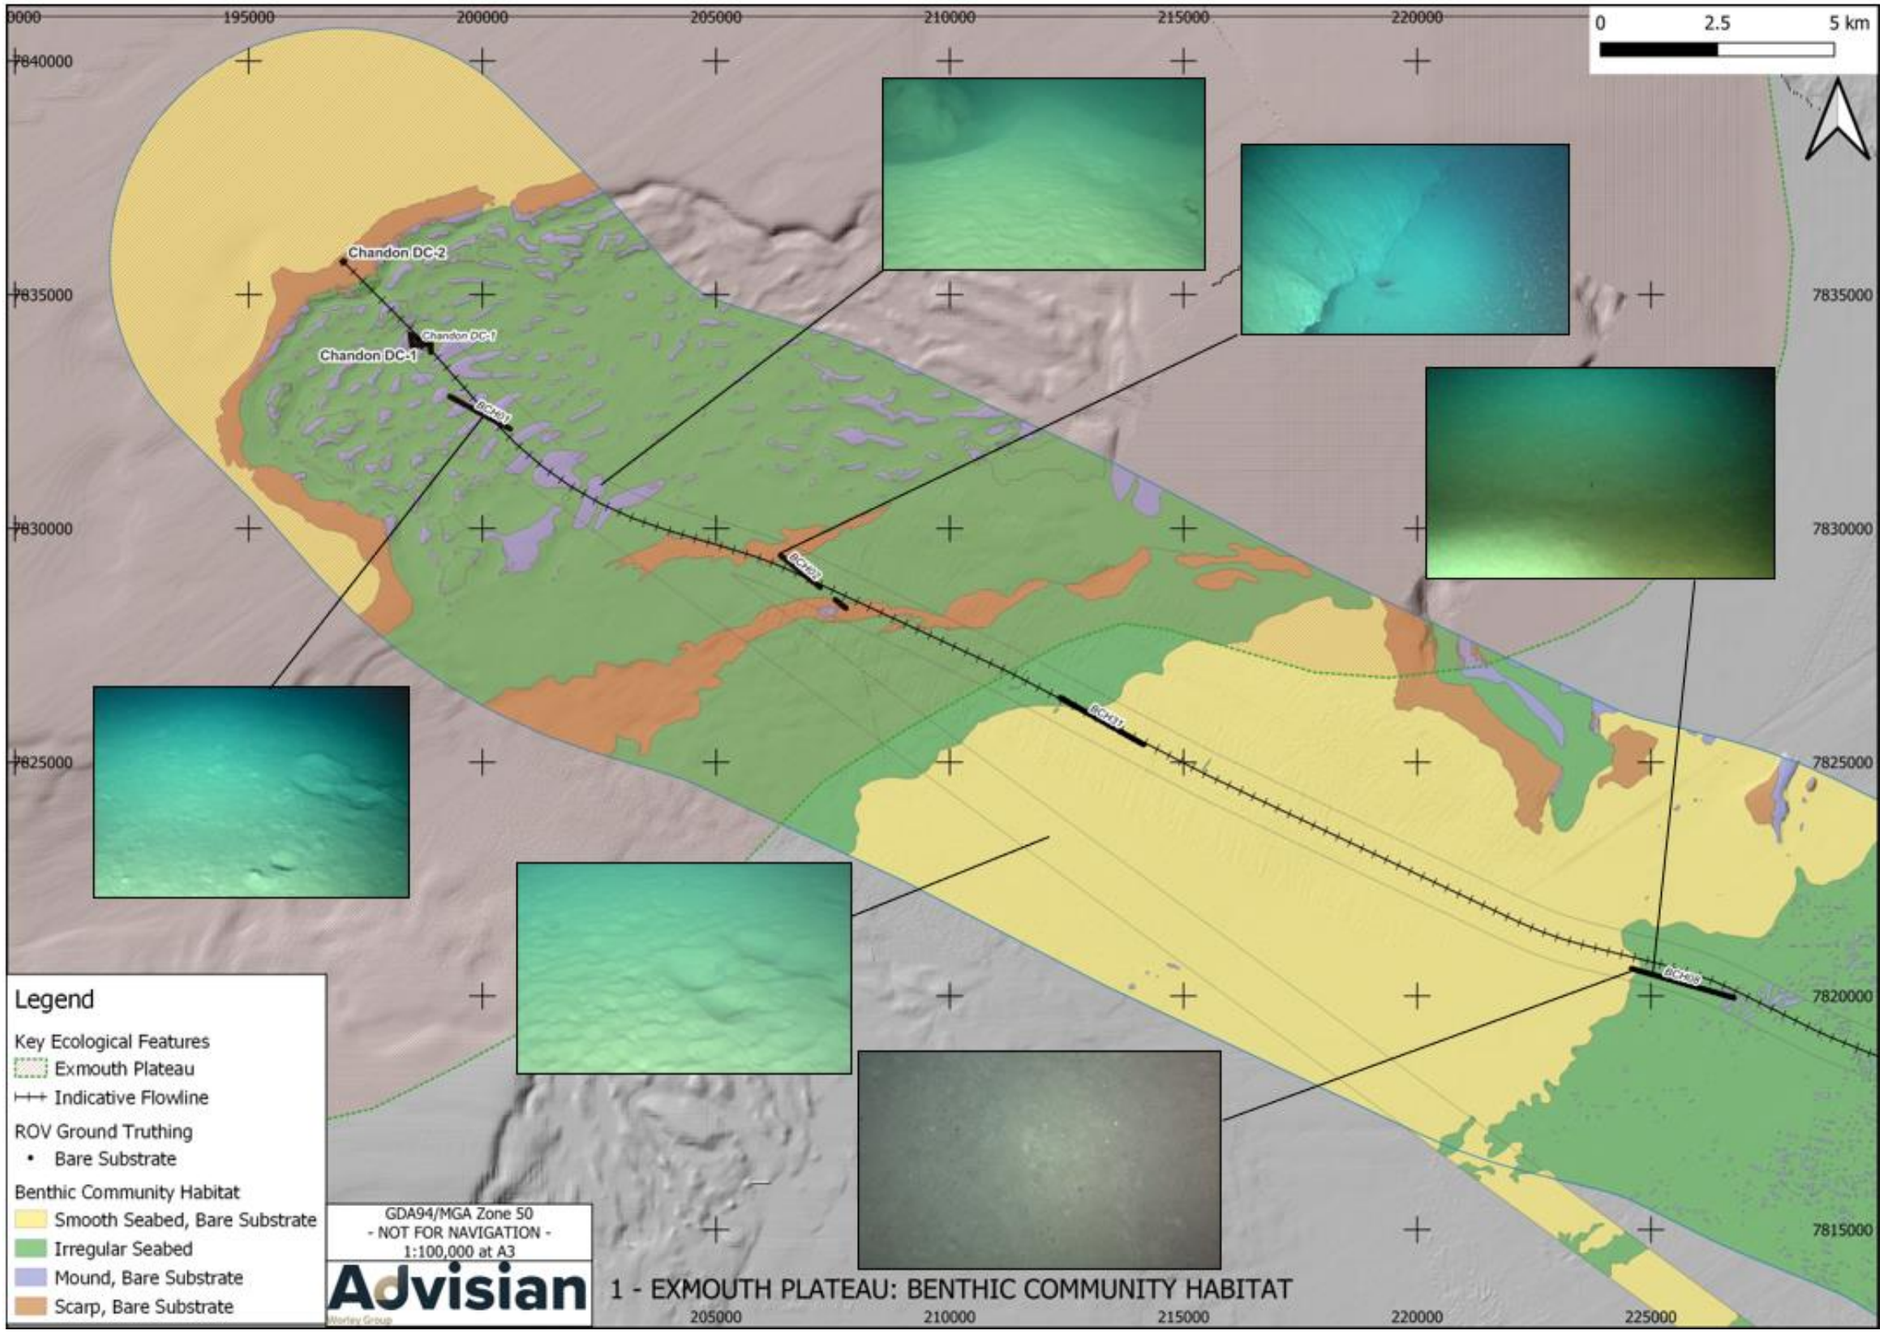

Figure 4-2 Distribution of benthic habitats within the Exmouth Plateau area of Gorgon Backfill Fields project area, with representative images of the benthic communities and habitats. Note – insert images of predictive mapped areas are taken from nearby ROV ground-truthing locations showing the same geomorphic characteristics

Note – insert images of predictive mapped areas are taken from nearby ROV ground-truthing locations showing the same geomorphic characteristics

4.1.1 Benthic Communities and Habitats at Key Ecological Features

The distribution of benthic habitats in the Exmouth Plateau KEF is presented in Figure 4-2. Mapping shows the Exmouth Plateau KEF is dominated by mixed habitats comprising irregular seabed with bioturbation, irregular and smooth seabed floor with bare substrates, and mounds on the seafloor of bare substrate. The seabed immediately surrounding the proposed Chandon drill centre (Chandon DC-1), out to ~5 km east and west, and approximately 6 km along the proposed associated flowline comprise of bioturbated irregular seabed and large patches of depressions over bare substrate (as seen in BCH01). Little to no biota is predicted to occur in these bare substrates. In the Exmouth Plateau KEF that lies within the GBF project area, three large discrete scarps with bare substrate are present. Of these scarps, two scarps approximately 5.5 km and 2.5 km from the KEF border, cross through the indicative flowline from east to west, likely representing the edge of the Exmouth Plateau. The third scarp that runs from east to west and is ~500 m wide, is located ~1.4 km north of Chandon DC-1. Given that scarps or steep slopes may comprise of 3D hard structure (i.e., rock) and other structural features, the presence of biota is more likely, although not detected along the transect in this area (BCH02) due to the variable distribution across these habitats. The Exmouth Plateau is predominantly bare substrate, comprised of little to no biota. This is complemented by further ground-truthing in Figure 4-13. Aside from the mixture of sandy habitats with relatively low structural complexity, few ground-truthing transects were acquired along raised geomorphic features including scarps to validate the preliminary benthic habitat map in the Exmouth Plateau KEF. Therefore, the mapping product outlining scarps with bare substrate should be interpreted with a moderate level of certainty.

Mixed benthic habitats comprising irregular and smooth seabed of bare substrates, discrete depressions over bare substrate and scarps with bare substrate are the most dominant benthic features in the Continental Slope Demersal Fish Communities KEF (Figure 4-6, Figure 4-7 and Figure 4-9). A mixture of habitats is present along the proposed flowline route from benthic transect BCH15 to the proposed C & D DC-3 drill centre, including irregular seabed with bioturbation and bare substrate, depressions with bioturbation, and patches of scarps with bare substrate. Larger scarps (in relation to the scarp adjacent to the proposed C & D DC-3 drill centre) are mostly evident north, south and east of C & D DC-3 within the GBF project area which appear to follow changes in depth contours (Figure 4-7). A mixture of habitats and benthic communities extend along the indicative flowline from the proposed C & D DC-3 drill centre to the Gorgon M1 tie in location (Figure 4-4), including the presence of a continuous south-west to north-east scarp with low and high likelihood of biota, discrete patches of depressions over bare substrate, and reef mosaic adjacent to the scarps with a low likelihood of biota. Sections of rock reef mosaic that cross through the indicative flowline is colonised by sponges and cnidarians as identified in benthic transects BCH03 – ZIGZAG and BCH11 within the KEF (Figure 4-7). Topographically complex scarps in a south-west to north-east orientation with low and high likelihood of biota are present traversing through the GBF project area within the Continental Slope Demersal Fish Communities KEF between ~400–800 m depths. Ground-truthing transects (BCH34, BCH03 – ZIGZAG, BCH04, BCH11 and BCH33) verified the presence of cnidarians, echinoderms, sponges, and a mixture of these biotic groups along these scarps (Figure 4-3 and Figure 4-8) in varying percent cover (from low [<10%] to high cover [>80%]). Patches of reef mosaic with a low likelihood of biota, and rock reef and depressions with a high likelihood of biota are present to the west of the C & D DC-3 to Gorgon M1 corridor, which are likely to support sponges and cnidarians, as verified by benthic habitat transects BCH13 and BCH10 (Figure 4-7 and Figure 4-9). A scarp orientated north to south with a high likelihood of biota is present ~650 m west of Gorgon M1 tie in location and runs parallel to existing subsea infrastructure (Figure 4-9). The extensive field observations (ground-truthing transects) collected at and adjacent to indicative infrastructure locations confirmed the habitat

complexity and topographical heterogeneity present in the Continental Slope Demersal Fish Communities KEF as identified in the preliminary benthic habitat map. As such, the mapping products of this KEF can be inferred with a high level of confidence.

Mapping of the GBF project area (proposed flowline/umbilical corridors) that lie within the Ancient Coastline KEF only captures the existing infrastructure and Gorgon GMT proposed tie-in location (Figure 4-9). The benthic habitat at Gorgon GMT and the GBF project area within this KEF only consists of smooth seabed with bioturbation and bare substrate and appears to be devoid of biota, as further evidenced by ground-truthing (Figure 4-7 and Figure 4-9). This is also supported by ground truthing in Figure 4-13. However, the BCH distribution maps of the GBF project area within the Ancient Coastline KEF should be considered with moderate confidence, due to the limited and varying (low to high resolution) geophysical data available for the KEF, and the relatively small number of ground-truthing transects collected within the GBF project area of this KEF.

4.1.2 Benthic Communities and Habitats at Low Slope Areas

Low slope areas are defined as areas within the GBF project area that contain the proposed flowlines and umbilical corridors situated outside of KEFs in the lower slope and Kangaroo Syncline areas, and are characterised by low structural complexity/rugosity and carbonate and clay muds. These include benthic habitat transects collected along BCH31 and BCH08 (Figure 4-2), BCH09 and BCH06 (Figure 4-3) within the Chandon DC-1 to JMT corridor, BCH07, BCH28 and BCH29 (Figure 4-4) in the Jansz to Geryon and Eurytion (G & E) corridors, and BCH26 (Figure 4-5) BCH05, BCH14, BCH32 and proposed NTB3 drill centre (Figure 4-7) within the Chrysaor and Dionysus (C & D) to Gorgon corridor.

A mixture of habitats was present along the Chandon to JMT corridor however all were of low structural complexity: irregular and/or smooth seabed either with bioturbation or bare substrate, and scattered patches of depression over bare substrate. No epifaunal communities were noted during ground-truthing transects across this area (Figure 4-2, Figure 4-3 and Figure 4-4). These habitats of low structural complexity extend out to the boundary of the GBF project area, with the exception of scarps with bare substrate which are present between benthic habitat transects BCH31 and BCH08, and approximately 1.8 km north from the proposed flowline (Figure 4-2).

Benthic habitats along the proposed flowline and umbilical routes from Jansz DC2 to G & E DC-1 comprises smooth seabed with bioturbation and irregular seabed with bare substrate with intermittent mounds with bare substrate, and scattered patches of depressions over bare substrate (Figure 4-4). Geomorphic feature mapping identified a continuous scarp with bare substrate near the Jansz Field Control Station (FCS), orientated north to south and parallel to existing subsea infrastructure (Figure 4-4). Small patches along the scarp are identified as areas with low likelihood of biota (Figure 4-4). Despite this, the ground-truthing transect of this area (benthic transect BCH28) did not identify the presence of epifauna due to a thick coverage of sediment. Scarps are often located in or adjacent to deep-sea currents, which are exposed to increased bottom stress and significant sediment movement, resulting in a thin or thick veneer of sand over consolidated substrate that could compromise reef growth and the presence of epifauna. This showcases the dynamic nature of biotic and abiotic habitats. Therefore, there are some uncertainties in the BCH distribution maps around scarps of this area as a result of natural and localised sediment transport processes.

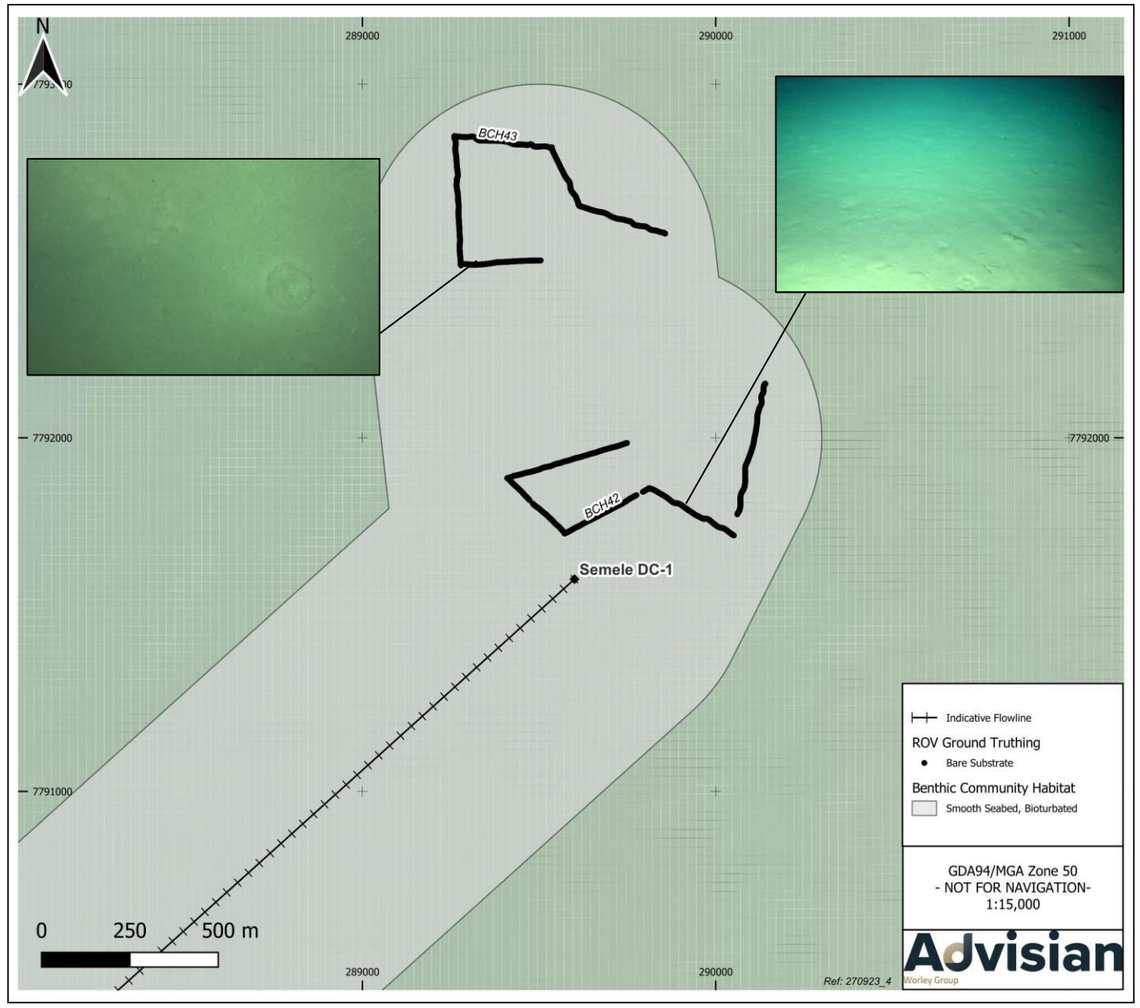
The benthic habitats within the low slope area of the C & D to Gorgon corridor are predominantly characterised by smooth and irregular seabed with either bare substrate or bioturbation. Along the Semele to C & D corridor, scarps orientated north to south are located ~500 m south of the proposed

flowline near benthic habitat transect BCH26, with a low and high likelihood of biota (Figure 4-5). Seabed areas of depressions with bare substrate and high likelihood of biota are present along BCH05, BCH14 and BCH32 that extend further out within the GBF project area (Figure 4-7). The acquisition of several ground-truthing transects, particularly along indicative flowline locations, have validated the presence of benthic biota and therefore, the BCH maps for this area can be interpreted with a high level of confidence.

Scarps orientated south-west to north-east with bare substrate are situated ~60 m north and ~1 km south of the proposed NTB3 drill centre that crosses through the indicative flowlines (Figure 4-7). As verified with ground-truthing, no epifauna were identified on the scarps with bare substrate (Figure 4-7). The scarp located north of the proposed NTB3 drill centre extends further out within the GBF project area in a south-easterly direction (Figure 4-5). The benthic habitat surrounding the proposed C & D drill centre (C & D DC-2), which is situated outside of the Continental Slope Demersal Fish Communities KEF on the northern border, consists primarily of irregular seabed with bare substrate.

4.1.3 Benthic Communities and Habitats at Proposed Drill Centres

The type of BCH present in proposed drill centres that are located within a KEF (Chandon DC-1 in the Exmouth Plateau KEF; and C & D DC-2 and C & D DC-3 within the Continental Slope Demersal Fish Communities KEF) are described in Section 4.1.1 Similarly, benthic habitat mapping of the proposed NTB3 drill centre that is situated in a low slope area, is described in Section 4.1.2



The benthic habitats immediately surrounding the Jansz DC2 tie-in (Figure 4-10) is characterised as low structural complexity, with smooth seabed with bioturbation and isolated patches of mounds with bioturbation. Similarly, the G & E DC-1 is primarily comprised of smooth seabed with bioturbation and scattered patches of bedforms with bare substrate to the north and north-east of the proposed drill centre (Figure 4-10). Ground truthing transects at each of these locations did not reveal any notable epifaunal communities.

The benthic habitat around the proposed drill centres Semele DC-1 and Semele DC-2, and benthic habitat transect BCH40 (Figure 4-11) and associated flowlines is of low structural complexity and dominated by smooth seabed with bioturbation. Irregular seabed with bioturbation and a mound with bare substrate is present around BCH41 (Figure 4-5). Ground truthing transects at each of these locations did not reveal any epifaunal communities.

Similarly to the proposed Semele drill centre sites, low structural complexity is present at WTR DC-1 and comprises only of smooth seabed with bioturbation (Figure 4-12) and no presence of biota. The ground-truthing transects collected around the proposed drill centres confirm the lack of complex seafloor structures as identified in the preliminary habitat map, and therefore, the BCH maps at the proposed drill centres can be interpreted with a high level of confidence.

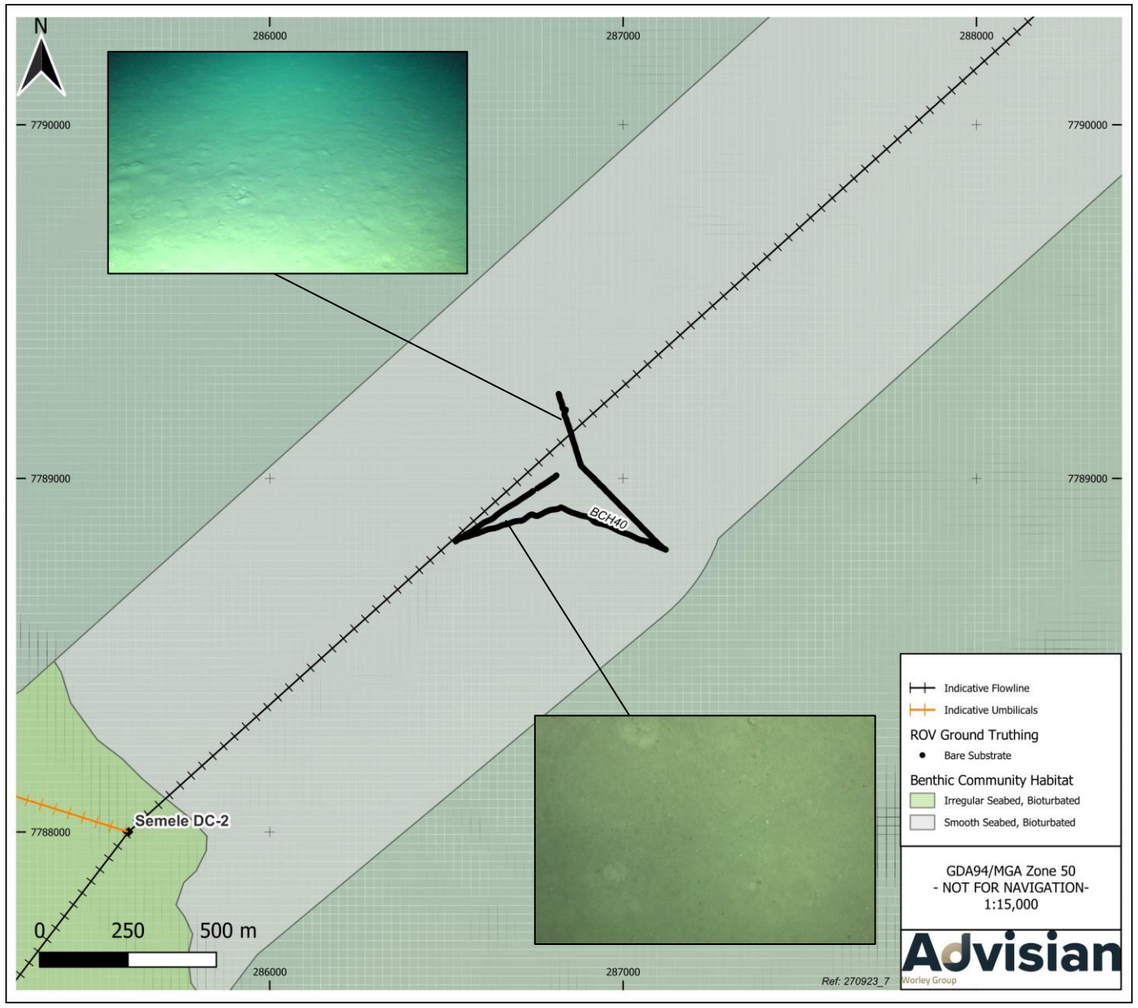

Figure 4-11 Distribution of benthic habitats within BCH42 and BCH43 (left) and BCH40 (right) with representative images of the benthic communities and habitats observed within the ROV transects

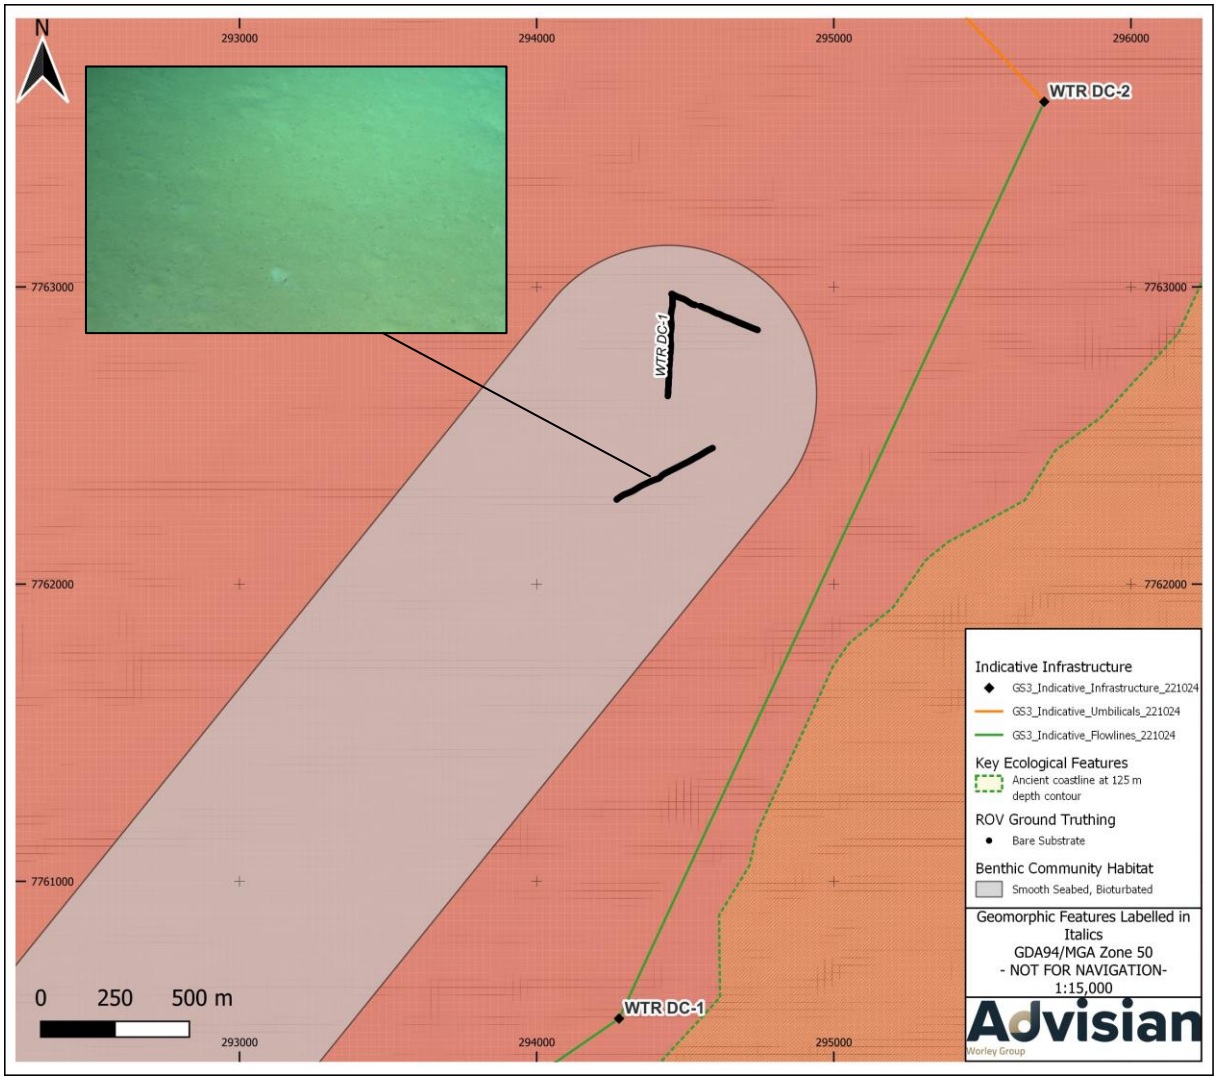

Figure 4-12 Distribution of benthic habitats within WTR DC-1 with a representative image of the benthic communities and habitats observed within the ROV transects

4.2 Benthic Cover

Across the 12 sites that are proposed drill centres and tie-in locations, and 2 benthic habitat transect sites, bare sediment (soft unconsolidated sand/mud <2 mm) with no biota was the dominant benthic category. Along one or more transects at sites Chandon DC-1, Semele DC-1, BCH42 and BCH43, bioturbation in bare sediment was observed in small quantities (with a range of 0.5–39% cover; (Figure 4-13). Bioturbation with cnidarians was only observed at site Gorgon M1 where they contributed to 1% of the overall cover (Figure 4-13). Overall, the proposed drill centre & tie-in locations are considered to be relatively devoid of epifauna.

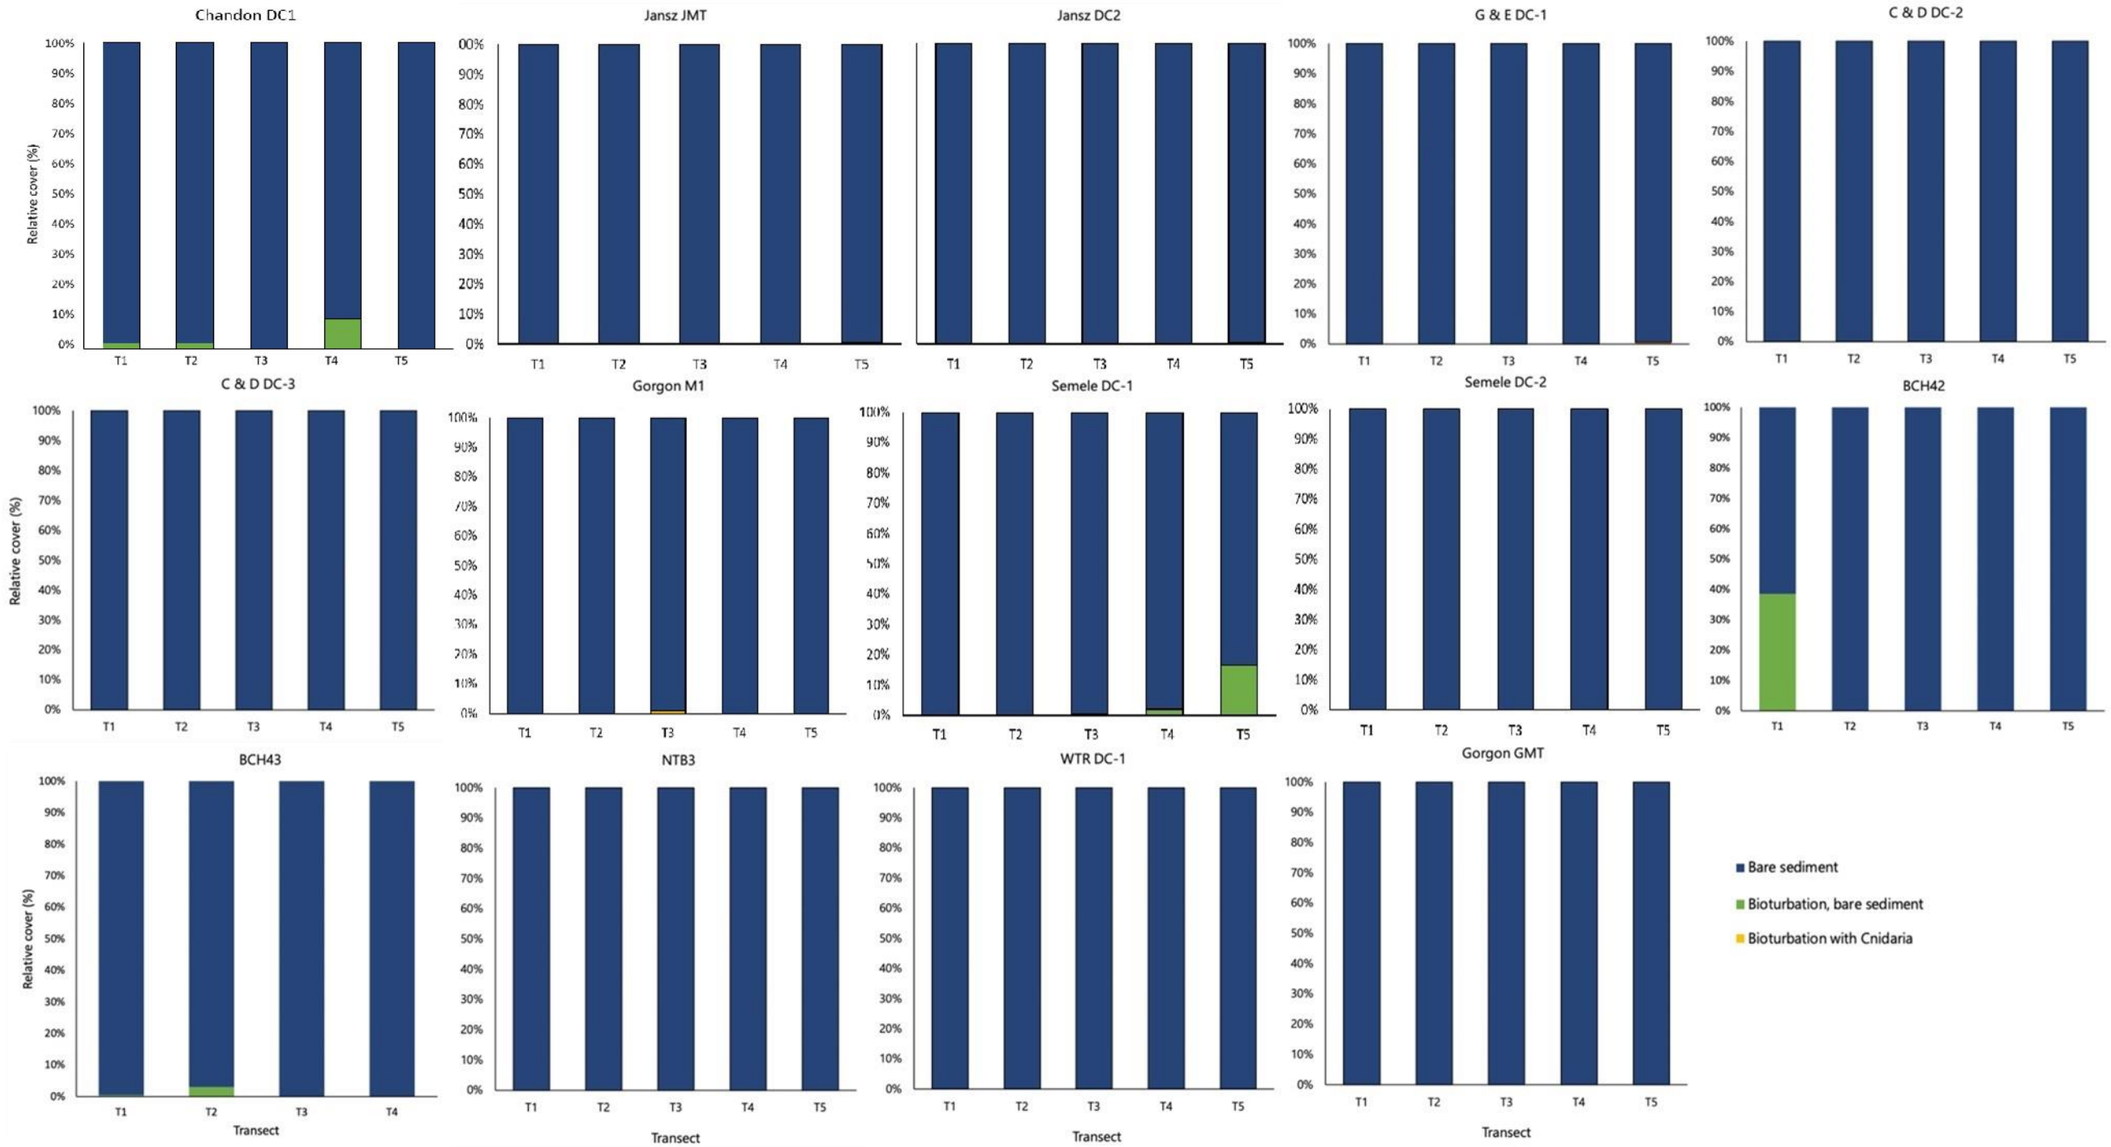

Figure 4-13 Benthic cover (%) along transects

4.3 Fish Assemblage

Refer to the Fish Report presented in Appendix D for more details on the results.

4.3.1 General Description of Fish and Crustacean Assemblages at Key Ecological Features

In the Exmouth Plateau KEF, a total of 165 individual fish from 14 taxa were identified. The fish assemblage was dominated by an unidentified anguilliform fish and *Bathypterois* sp1 (family Ipnopidae), together representing over 65% of the total number of individual fish recorded. Other abundant taxa included *Aldrovandia* sp1 and *Aldrovandia* sp2 (Halosauridae), and *Macrouridae* sp2 (Macrouridae, rat tails). The crustacean assemblage in the Exmouth Plateau KEF consisted of 228 individuals from seven taxa. A species of red prawn was the most dominant crustacean taxa representing over 81% of the total number of individuals, followed by a pink prawn and an orange prawn.

Within the Continental Slope Demersal Fish Communities KEF, a total of 468 fish belonging to 25 taxa were recorded. The fish assemblage was dominated by Trevallies (Carangidae) with four species from three genera accounting for 256 of the individuals observed. The five most abundant fish taxa were *Decapterus kurroides*, *Decapterus* sp1 and *Seriola dumerili* (Carangidae), an unidentified bait fish, and *Synodontidae* sp2 (Synodontidae). Only one site (BCH04) in this KEF recorded crustaceans. At this site, a total of three crustaceans from three taxa (two from infraorder Anomura, and one from infraorder Achelata) were recorded.

The Ancient Coastline KEF recorded a total of 18,011 individuals from 13 fish taxa. The fish assemblage was dominated by Trevallies (Carangidae) with three species representing 14,231 of the total individuals. The most abundant fish taxa were *Carangoides* sp1 and *Seriola dumerili* (Carangidae), an unidentified baitfish, *Carcharhinus* sp1 (Carcharhinidae), and *Rachycentron canadum* (Rachycentridae). Only one crustacean (unidentified prawn species) was recorded at Gorgon GMT.

At the four sites (C & D DC-3, NTB3, WTR DC-1 and BCH24) outside of KEF areas, a total of 11,800 individual fish belonging to 28 taxa were identified. The five most abundant taxa were *Trachurus novaezelandiae* and *Seriola dumerili* (Carangidae), an unidentified baitfish species, an unidentified anguilliform fish species, and *Carcharhinus* sp1 (Carcharhinidae). 11,007 of the total individual fish were recorded at site BCH24, which was dominated by *Trachurus novaezelandiae* (78% of total individuals) and an unidentified baitfish species (21% of total individuals). There were 236 total individual crustaceans recorded from seven taxa, with all sites dominated by a red prawn species. The red prawn species accounted for 66 of the 107 total individuals observed in site NTB3, whereas only one unidentified prawn species identified at site WTR DC-1

4.3.2 General Description of Fish and Crustacean Assemblages at Geomorphic Features

The fish and crustacean assemblages at the plateau slope, which contains the same two sites as the Exmouth Plateau KEF (BCH01 and BCH02), is described in Section 4.3.1.

The trench/trough slope contained 59 individual fish from 14 taxa. The fish assemblage was distinguished by Macrouridae species, Halosauridae species, and an unidentified anguilliform species (eel-like fish), which accounted for 82% of the total recorded individuals. The four most abundant taxa

were the unidentified anguilliform species (28 individuals), *Macrouridae* sp4 (eight individuals) and *Macrouridae* sp2 (Macrouridae; four individuals), and *Synaphobranchus* sp1 (Synaphobranchidae; four individuals). The crustacean assemblage in the trench/trough slope geomorphic feature consisted of 128 individuals belonging to five taxa. The assemblage was dominated by a red prawn species, which made up 80% of the total individuals and was also the most abundant taxa for each transect in site C & D DC-3. The other abundant crustacean species included a dark prawn species, a second red prawn species, and an orange prawn species.

The slope geomorphic feature comprised of seven sites (BCH04, BCH11, BCH12, BCH33, WTR DC-1, BCH24 and Gorgon GMT), where a total of 30,033 individual fish species belonging to 37 taxa were recorded. The fish assemblage was dominated by Trevallies (Carangidae) with 23,208 individuals from seven taxa. The five most abundant species were *Carangoides* sp1, *Trachurus novaezelandiae* and *Seriola dumerili* (Carangidae), an unidentified baitfish species, and Carcharhinus sp1 (Carcharhinidae), which together accounted for 98% of the total individuals. Only three sites in this geomorphic feature contained crustaceans: WTR DC-1, BCH04 and Gorgon GMT. The crustacean assemblage consisted of five total individuals recorded from four taxa.

In the deep/hole/valley slope geomorphic feature, there were 16 fish taxa and a total of 187 individuals recorded. The fish assemblage was dominated by an unidentified anguilliform fish species, representing 54% of the individuals observed, followed by *Aldrovandia* sp1, *Aldrovandia* sp2, and *Aldrovandia affinis* (Halosauridae), and *Macrouridae* sp1 (Macrouridae). The crustacean assemblage consisted of 110 total individuals recorded from four taxa. The assemblage was dominated by a red prawn species which accounted for 70% of the total individuals across the NTB3 site.

4.3.3 General Description of Invertebrate Assemblage

A total of 922 invertebrate individuals from 26 taxa were recorded across all sites. The invertebrate assemblage included one feather star (Cormatulida) species, four jellyfish (Scyphozoa) species, seven sea cucumber (Holothuroidea) species, seven sea star (Asteroidea) species, six sea urchin (Echinoidea) species and one squid (Cephlapod) species. The assemblage was dominated by a brown jellyfish species which accounted for 69% of the total number of individuals and were mostly recorded at site BCH24.

4.3.4 Comparison of Fish and Crustacean Assemblages Between Water Masses

The deeper water fish assemblages of the AAIW mass were significantly different ($p<0.001$) to the shallower water fish assemblages in both the SICW and the TSW water masses (Figure 4-14). The AAIW were characterised by species including two *Aldrovandia* spp. (Halosauridae), a Macrouridae species, a species of unidentified anguilliform fish, and a Bathypterois species (Ipnopidae) (Figure 4-14). A greater abundance of *Trachurus novaezelandiae* (Carangidae), an unidentified bait fish, and whaler shark *Carcharhinus* sp1 were observed at the TSW, whereas the SICW water mass was characterised by a high abundance of *Seriola dumerilii* (Carangidae) and *Carcharhinus plumbeus* (Figure 4-14).

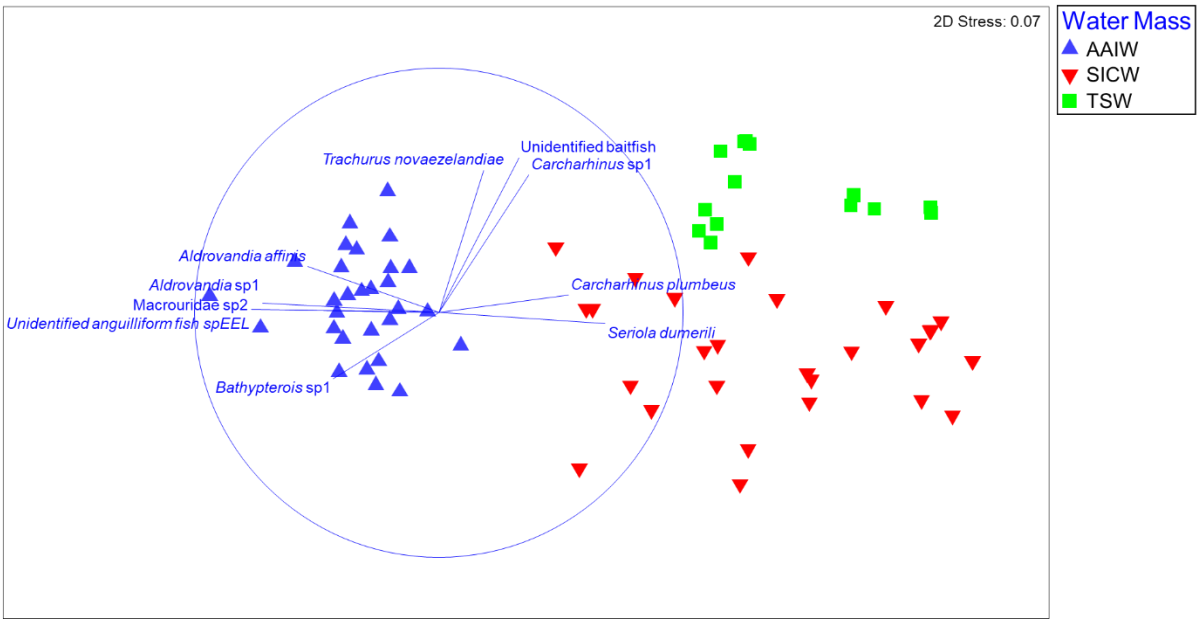

Figure 4-14 Non-metric multidimensional scaling plot illustrating the differences in fish assemblages among the Antarctic Intermediate Water (AAIW), Southern Indian Central Water (SICW) and Tropical Surface Water (TSW) masses

A greater mean number of fish per transect were identified in the TSW mass (1684 ± 358 no. fish) compared to SICW and AAIW (118 ± 38 and 16 ± 2 no. fish, respectively). There was no significant difference ($p>0.05$) in the mean number of fish taxa per transect between water masses. On average each transect had ~four and six fish taxa.

The crustacean assemblages of the deeper AAIW mass were significantly different ($p<0.001$) to the shallower assemblages in the SICW and the TSW water masses. The most strongly correlated taxa to the AAIW mass were all prawns.

The mean number of crustaceans and mean number of taxa were both significantly greater in the AAIW (27 ± 3 no. crustaceans; 3 ± 0.2 no. taxa) than SICW (0.1 ± 0.1 no. crustaceans; 0.1 ± 0.1 no. taxa) and TSW (0.1 ± 0.1 no. crustaceans; 0.1 ± 0.1 no. taxa).

4.3.5 Comparison of Fish and Crustacean Assemblages Among Key Ecological Features

The fish assemblages of the Continental Slope Demersal Fish Communities KEF were significantly different to the fish assemblages at the Exmouth Plateau KEF and outside any KEFs ($p<0.05$; Figure 4-15a). This difference was primarily driven by two *Aldrovandia* spp. (Halosauridae), a Macrouridae species, an unidentified anguilliform fish, and a Bathypterois (Ipnopidae) species (Figure 4-15a).

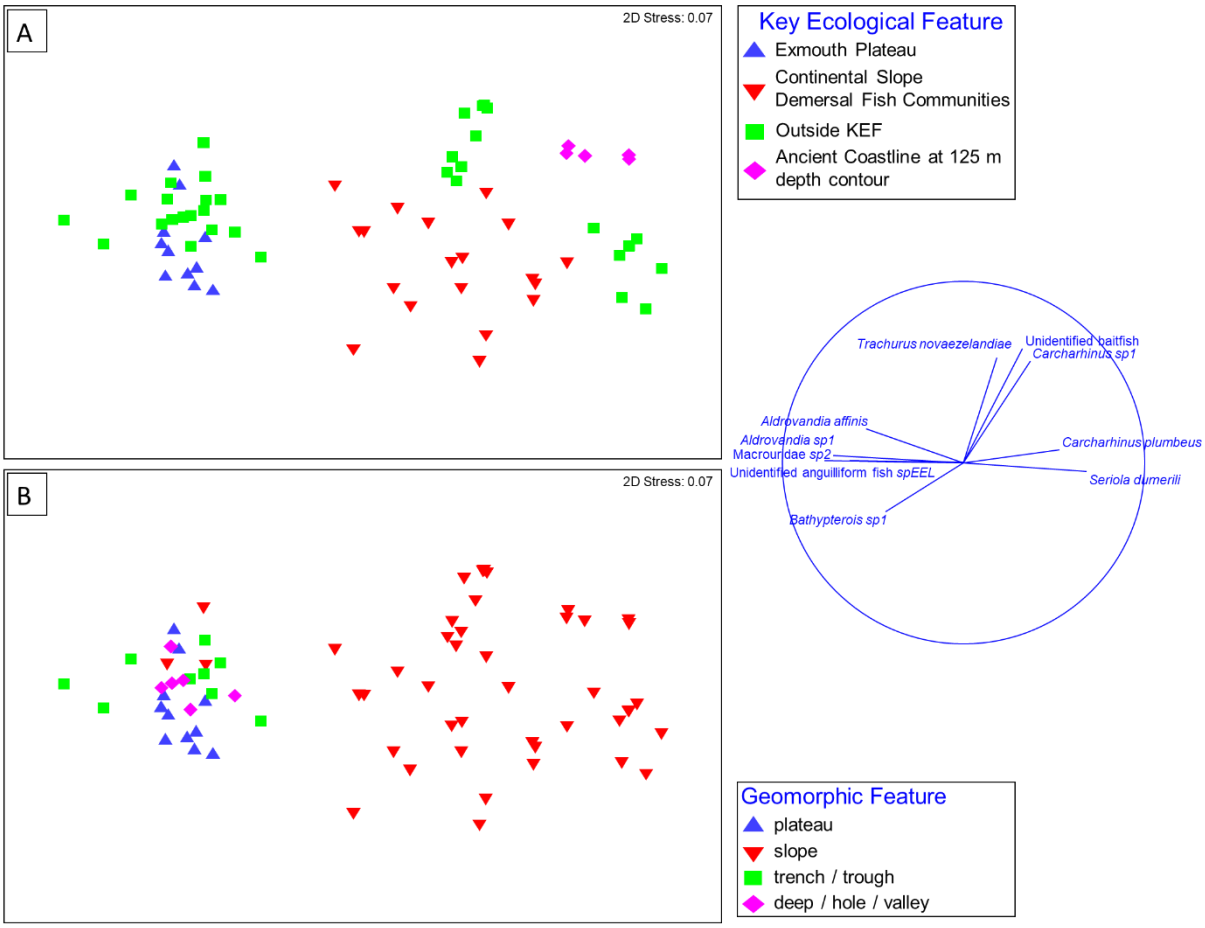

Figure 4-15 Non-metric multidimensional scaling plot illustrating the differences in fish assemblages among a) Key Ecological Features, and b) geomorphic features

The Ancient Coastline KEF had a greater mean number of fish per transect (3021 ± 150 no. fish) compared to Continental Slope Demersal Fish Communities KEF (25 ± 5 no. fish), Exmouth Plateau (13 ± 1 no. fish) and outside of KEF (322 ± 108 no. fish). There was no significant difference in the mean number of fish taxa between KEFs. Between five and nine fish taxa were recorded at each KEF.

The crustacean assemblage of the Exmouth Plateau KEF was significantly different ($p = 0.05$) to that of the Continental Slope Demersal Fish Communities KEF and the Ancient Coastline KEF. The crustacean assemblage of the Continental Slope Demersal Fish Communities KEF was also different to the crustacean assemblage at areas outside any KEF. Both the Exmouth Plateau and outside any KEF, which are located in deeper waters, were primarily driven by all prawn taxa.

The mean number of crustaceans and mean number of taxa were statistically greater in the Exmouth Plateau (17 ± 2 no. crustaceans; 3 ± 0.4 no. taxa) and outside any KEF (16 ± 4 no. crustaceans; 2 ± 0.3 no. taxa) compared to Ancient Coastline (0.2 ± 0.2 no. crustaceans; 0.2 ± 0.2 no. taxa) and Continental Slope Demersal Fish Communities KEFs (0.2 ± 0.1 no. crustaceans; 0.2 ± 0.1 no. taxa).

4.3.6 Comparison of Fish and Crustacean Assemblages Among Geomorphic Features

The fish assemblage of the slope geomorphic feature was significantly different ($p<0.05$) to the plateau, trench/trough, and deep/hole/valley slope, and was driven by shallower fish species such as *Trachurus novaezelandiae* (Carangidae), unidentified baitfish, *Carcharhinus* sp1, *Carcharhinus plumbeus* (Carcharhinidae), and *Seriola dumerili* (Carangidae; Figure 4-15b).

The mean number of fish was higher on the slope (598 ± 156 no. fish) than any other geomorphic features (plateau: 13 ± 1 no. fish; trench/trough: 12 ± 2 no. fish; deep/hole/valley: 27 ± 5 no. fish), however, there were large variations in the number of fish among samples. There was no significant difference in the mean number of fish taxa between geomorphic features. Between five and seven fish taxa were recorded at each geomorphic feature.

The crustacean assemblage of the shallower water slope geomorphic feature was significantly different ($p = 0.001$) compared to the other deeper water geomorphic features, in which deeper waters was the primary driven by the crustacean taxa.

Although not statistically significant, the mean number of crustaceans was lower in the slope geomorphic feature (3 ± 2 no. crustaceans) and highest at the trench/trough (41 ± 6 no. crustaceans), while deep/hole/valley and plateau were similar (15 ± 2 and 17 ± 2 no. crustaceans). The mean number of crustacean taxa was significantly lower in the slope (0.4 ± 0.2 no. taxa) compared to the deep/hole/valley (3 ± 0.3 no. taxa), plateau (3 ± 0.4 no. taxa), and trench/trough (3 ± 0.3 no. taxa) geomorphic features.

4.3.7 Composition of Fish and Crustacean Assemblages

For both fish and crustacean assemblages, water depth was an important predictor of the multivariate composition of assemblages. The DistLM analysis for fish assemblages showed that depth alone explained 27% of the variation in the fish assemblage composition ($R^2 = 0.27177$, pseudo $F_{(1,69)} = 25.751$, $p<0.001$). for the crustacean assemblages, water depth explained 73% of the variation in the assemblage composition ($R^2 = 0.72716$, pseudo-$F_{(1,69)} = 183.9$, $p<0.001$).

4.4 Sediment Chemistry

Laboratory reports for sediment samples are presented in Appendix F. Photos of the sediment cores are provided in Appendix G.

4.4.1 Hydrocarbons

Concentrations of hydrocarbons (TRH, BTEX and PAHs) in all sediment samples were below the laboratory LOR.

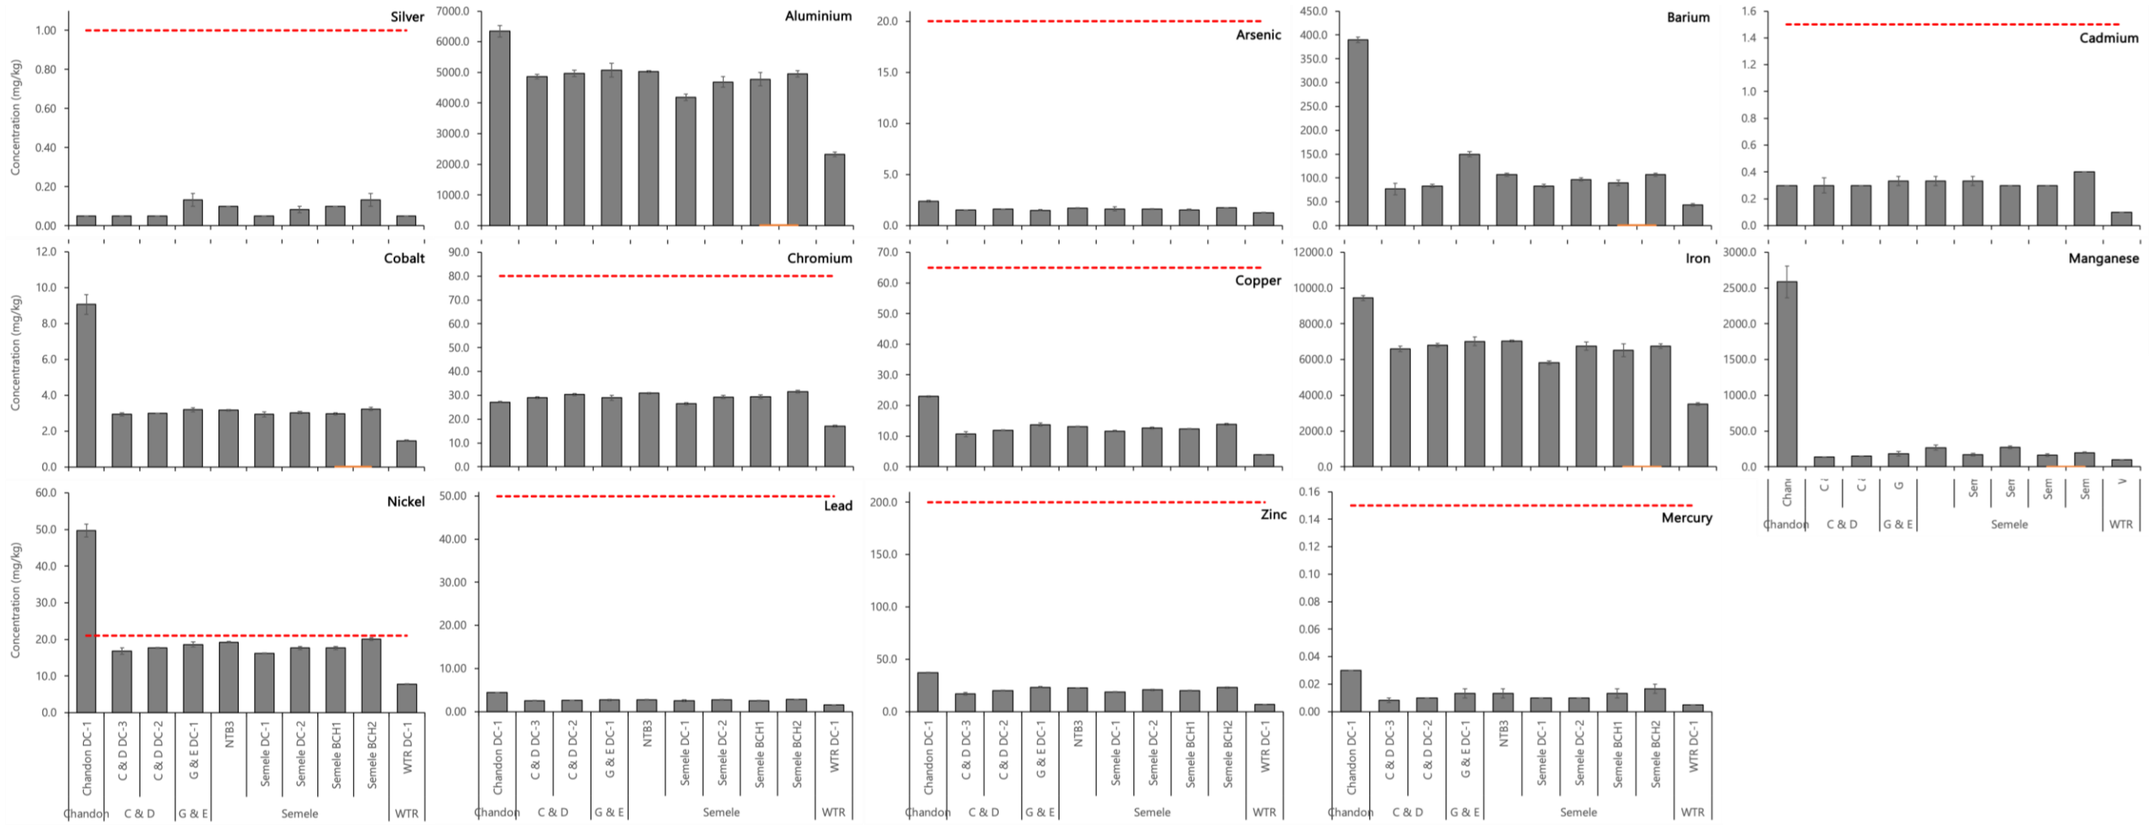
4.4.2 Metals and Metalloids

Concentrations of all metals and metalloids in sediment samples located within proposed drill centres and tie-in locations all met their relevant ANZG (2018) DGVs[3], with the exception of nickel (Table 4-1,

[3] There are no ANZG (2018) DGVs for aluminium, barium, cobalt, iron, and manganese.

Figure 4-16). Total nickel in all three replicate samples collected from Chandon DC-1 exceeded the ANZG (2018) DGV of 21 mg/kg however, were below the GV-High values (Table 4-1, Figure 4-16). Nickel concentrations across the remaining sites were slightly below the ANZG (2018) DGV (Table 4-1, Figure 4-16).

Concentrations of other total metals (aluminium, arsenic, barium, cobalt, copper, iron, manganese, lead, zinc and mercury) in sediments at Chandon DC-1 were slightly higher compared to the other sites (Table 4-1, Figure 4-16). Slightly higher metal concentrations at Chandon DC-1 may be linked to the higher content of clay-sized fraction sediments (see Section 4.4.3). It is also possible that these higher concentrations of metals are linked to sample contamination during the collection of or sub-sampling of cores (see Section 4.4.5), as the sample location is far beyond any industrial infrastructure and operational areas. Site WTR DC-1 also had notably and consistently lower concentrations for all metals (Table 4-1, Figure 4-16).



Concentrations of mercury were not detected in any replicate sediment samples collected at C & D DC-3, WTR DC-1, and WTR DC-2. Concentrations of silver were also absent in replicate sediment samples collected at Chandon DC-1, C & D DC-3, C & D DC-2, Semele DC-1 and WTR DC-1 (Table 4-1, Figure 4-16).

With the exception of elevated concentrations of some metals in sediments at Chandon DC-1 and the consistently lower concentrations of all metals at WTR DC-1 likely attributed to the particle size distributions found in each survey site (see Section 4.4.3), there were no other discernible trends in for metal concentrations across the sites.

Table 4-1 Total metal concentrations (mean ± SE) in sediment samples

Field and Site Name	Parameter (mg/kg)	Silver	Aluminium	Arsenic	Barium	Cadmium	Cobalt	Chromium	Copper	Iron	Manganese	Nickel	Lead	Zinc	Mercury

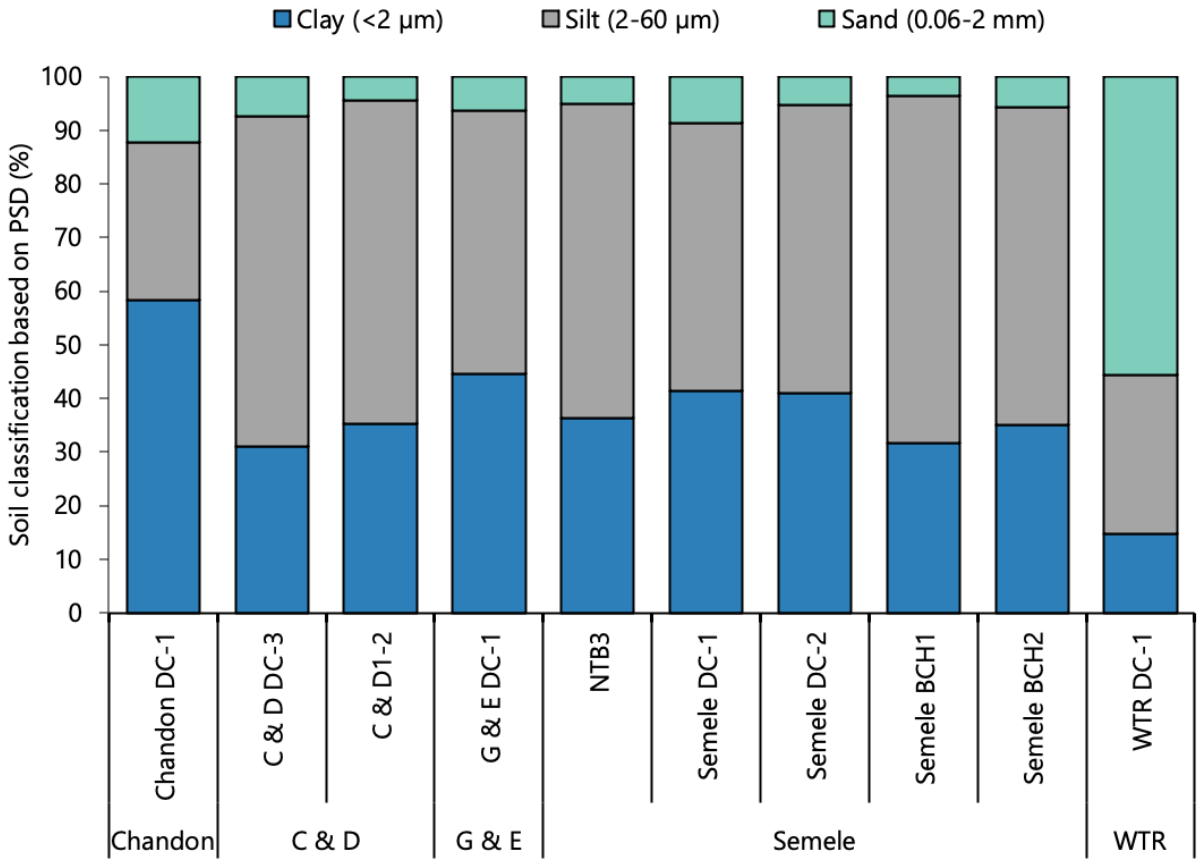
Notes:
1. DGV and GV-High values derived from ANZG (2018)
2. For ease of identification, concentrations above the DVG (ANZG, 2018) are shown in **bold**
3. All metal data are the average of three replicate sediment samples
4. BCH = Benthic communities and habitat, C & D = Chrysaor and Dionysus, DC = drill centre, DGV = default guideline value, G & E = Geryon and Eurytion, GV-High = guideline value high, LOR = limit of reporting, WTR = West Tryal Rocks



Notes:
1. If results were below the LOR, half the LOR was used for graphing purposes
2. Red dashed line denotes the ANZG (2018) DGV value; no ANZG (2018) DGV value exists for aluminium, barium, cobalt, iron, and manganese
3. BCH = Benthic communities and habitat, C & D = Chrysaor and Dionysus fields, DC = drill centre, G & E = Geryon and Eurytion fields, WTR = West Tryal Rocks

Figure 4-16 Total metal concentrations (mean ± SE) in sediment samples

4.4.3 Particle Size Distribution

Sediment samples were comprised of well-sorted silts and clay, brown in colour, odourless and with occasional small (>2 mm) shell fragments. No anoxic layer was present in any of the samples. There was no visible biota or vegetation recovered from these samples.

All samples were predominantly comprised of clays (<2 µm), silts (2–60 µm) and sands (0.06–2 mm) (Figure 4-17). All sites with the exception of WTR DC-1 and Chandon DC-1, were dominated by silt fraction ranging from 29 to 65%, while clay-sized fractions ranged from 31 to 58% (Figure 4-17). Sediments at WTR DC-1 were dominated by sand (56%) and clay (58%) was the dominant sediment fraction at Chandon DC-1, whereas all other sites comprised of <13% sand (Figure 4-17).

Note:
1. BCH = Benthic communities and habitat, C & D = Chrysaor and Dionysus fields, DC = drill centre, G & E = Geryon and Eurytion fields, PSD = particle size distribution, WTR = West Tryal Rocks

Figure 4-17 Sediment particle size distribution across the Gorgon Backfill Fields project sites

4.4.4 Other Parameters

There is no ANZG (2018) guideline value for TOC in sediments. TOC concentrations were low, ranging from 0.51 to 1.36% (Table 4-2). Higher TOC concentrations were detected at C & D DC-2, G & E DC-1, and sites within the Semele field, while sediments at WTR DC-1 had lower TOC content (Table 4-2).

Lower TOC concentrations in sediments at WTR DC-1 may be attributed to the higher sand content (refer to Section 4.4.3).

Moisture content of sediment samples was generally consistent across the sites, ranging from 40.5 to 61.3% (Table 4-2).

Table 4-2 Sediment total organic carbon and moisture content across the Gorgon Backfill Fields project sites

Field and Site Name	Parameter (mg/kg)	TOC (%)	Moisture (%)
	LOR	–	–
	DGV	–	–
	GV-High	–	–
Chandon	Chandon DC-1	0.81 ± 0.08	61.3 ± 0.52
Chrysaor and Dionysus	C & D DC-3	1.10 ± 0.01	55.4 ± 1.03
	C & D DC-2	1.36 ± 0.20	56.3 ± 0.69
Geryon and Eurytion	G & E DC-1	1.24 ± 0.05	57.5 ± 1.18
Semele	NTB3	1.26 ± 0.03	58.7 ± 0.32
	Semele DC-1	1.30 ± 0.08	58.0 ± 1.05
	Semele DC-2	1.27 ± 0.08	59.0 ± 0.20
	Semele BCH1	1.34 ± 0.05	57.7 ± 0.57
	Semele BCH2	1.23 ± 0.04	61.1 ± 0.25
WTR	WTR DC-1	0.51 ± 0.01	40.5 ± 0.84

Notes:
1. DGV = Default guideline value, GV-High = guideline value high, LOR = limit of reporting, TOC = total organic carbon
2. C & D = Chrysaor and Dionysus fields, DC = drill centre, G & E = Geryon and Eurytion fields, WTR = West Tryal Rocks

4.4.5 Quality Assurance and Quality Control Assessment

Intra-laboratory duplicates analysed for metals and moisture content were within acceptable limits of their assigned RPD (30%), indicating that the sediment samples were relatively homogeneous and/or small to no differences in laboratory methods for sample preparation and analysis. Intra-laboratory triplicates analysed for metals were within their RSD with the exception of cadmium that exceeded its assigned RSD. Variability between triplicate samples may be caused by heterogeneity between samples and/or differences in laboratory methods for sample preparation and analysis. The concentrations of cadmium in sediments should be noted as uncertain rather than precise measurements. A breakdown of the QA/QC assessment for sediment samples is provided in Appendix I.

Concentrations of hydrocarbons (TRH and BTEX) in the sediment field blanks were below the laboratory LOR suggesting there was no contamination during the sediment sampling process.

The results of laboratory quality control testing of sediment samples (method blanks, laboratory duplicates, laboratory control samples, and matrix spikes) are presented in Appendix F.

4.5 Benthic Infauna

A total of five individual benthic infauna belonging to three families across three phyla (Sipuncula, Annelida, and Mollusca) were collected from all the sediment sites (Table 3-8). Semele DC-1 and Semele DC-2 had one and two individual Sipunculids or marine worms, respectively, while Semele BCH1 had one individual mollusc (Aplacophora family). One polychaete worm (Annelida) was identified in WTR DC-1.

The benthic infauna laboratory results provided by Benthic Australia are included in Appendix J.

4.6 Water Chemistry

Laboratory reports for water samples are presented in Appendix H.

4.6.1 Hydrocarbons

Concentrations of hydrocarbons (TRH, BTEX and PAHs) in all water samples were all below the laboratory LOR.

4.6.2 Metals

Concentrations of all dissolved metals in water samples met their relevant ANZG (2018) DGVs for 99% species protection[4], with the exception of copper and cobalt (Table 4-3, Figure 4-18). Dissolved copper was at the 99% DGV of 0.3 µg/L for either one or both replicate samples from the surface at BCH38 and WTR DC-1 and from near the seabed at NTB3, whereas dissolved copper exceeded the DGV in both replicate samples collected from the surface at Chandon DC-1 and Gorgon GMT (Table 4-3). All samples were below the 95% species protection guideline value of 1.3 µg/L. It is possible that there may have been a copper source from the vessel during the sampling process that led to the contamination of the samples, particularly those collected from surface waters.

Dissolved cobalt concentrations in one replicate water sample near the seabed at Gorgon GMT exceeded the 99% DGV of 0.05 µg/L (Table 4-3). Furthermore, one surface sample at Gorgon GMT had higher total lead concentrations than other sites; however, these exceedances may be due to contamination during the sampling process, as the remaining samples at these sites have low or below laboratory LOR concentrations.

Concentrations for dissolved and/or total aluminium, arsenic, barium, iron, manganese, nickel, lead, and zinc were detected in either surface and/or near seabed water samples (Figure 4-19), while cadmium, silver and chromium VI concentrations in surface and seabed water samples were all below laboratory LOR.

Dissolved and total barium concentrations were notably higher in water samples near the seabed at all of the deeper sites (all sites with the exception of WTR DC-1 and Gorgon GMT; see Table 3-5 for depths). There were no other discernible trends observed for dissolved nor total metal concentrations across the sites.

[4] There are no ANZG (2018) 99% default guideline values for aluminium, arsenic, barium, iron, and manganese.

Table 4-3 Dissolved and total mean concentrations in water samples

Field and Site Name		Parameter (µg/L)	Silver	Aluminium	Arsenic	Barium	Cadmium	Cobalt	Copper	Iron	Manganese	Nickel	Lead	Zinc	Chromium III	Chromium VI

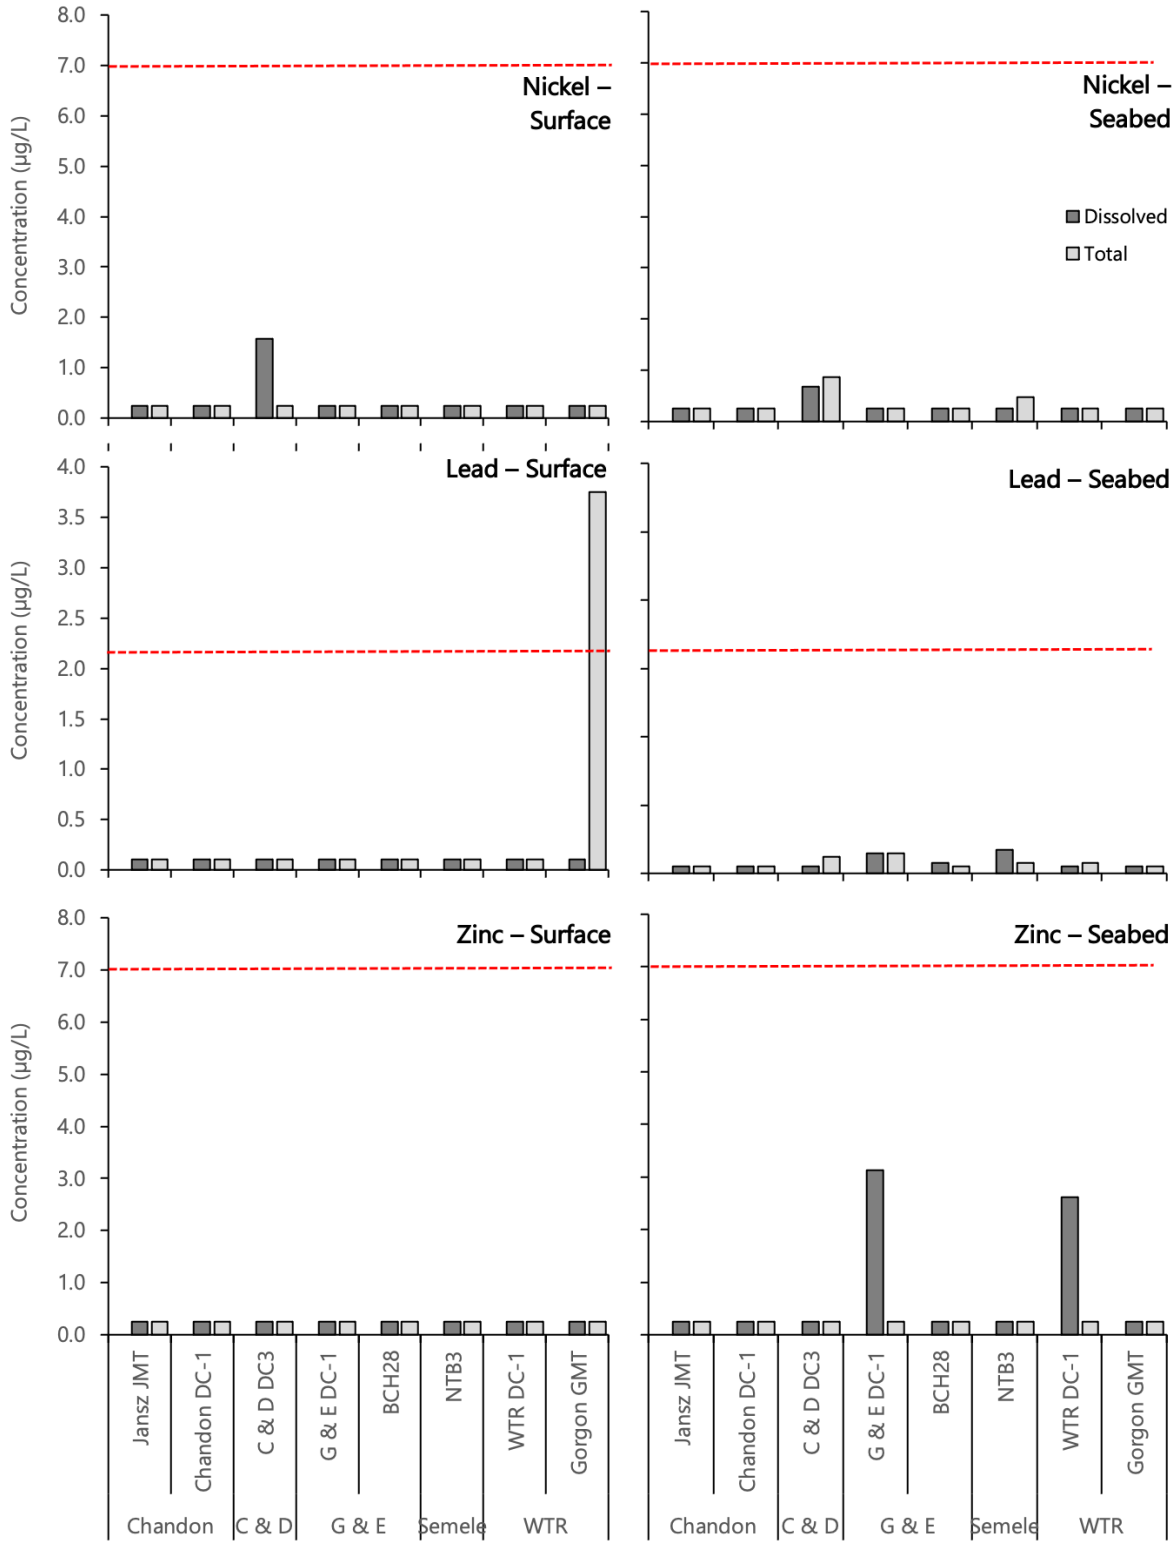

Figure 4-19 Dissolved (dark grey) and total (light grey) metal concentrations in water samples across the Gorgon Backfill Fields project sites. Red dashed line denotes the ANZG (2018) default guideline values 99% species protection

4.6.3 Other Parameters

Average DOC and TOC concentrations ranged from 0.5 to 2.0 mg/L and 0.5 to 2.0 mg/L, respectively. Average DOC concentrations were between 1.5 and 2.5-fold higher in surface waters compared to water samples collected from near the seabed at Jansz JMT, Chandon DC-1, C & D DC-3 and NTB3. Concentrations of TOC were on average higher in surface waters than near the seabed at Chandon DC-1 and C & D DC-3, whereas TOC concentrations were higher near the seabed at shallower sites WTR DC-1 and Gorgon GMT (100–200 m depth).

TDS ranged from 37,000 to 39,900 mg/L from surface and seabed samples across all sampling sites (Table 4-4). Across most sites (with the exception of Jansz JMT, Chandon DC-1 and Gorgon GMT), average TDS concentration were slightly higher in surface waters. TP and TN in surface and seabed water samples ranged 0.01 to 0.12 mg/kg, and 0.10 to 0.75 mg/kg, respectively (Table 4-4). At all sites, water samples near the seabed had higher mean TP concentrations (between 1.2 to 10-fold) compared to surface samples. A similar trend to TP concentration was observed for mean TN concentrations, whereby TN concentration were between 2 to 3-fold higher in water samples near the seabed compared to surface samples at all sites except for sites within the WTR field.

Table 4-4 Other parameter concentrations in water samples

Field and Site Name		Parameter (mg/L)	DOC	TOC	TDS	TP	TN

4.6.4 Quality Assurance and Quality Control Assessment

Intra-laboratory duplicates analysed for metals and moisture content were within their assigned RPD of 30% for all samples with the exception of total manganese in Gorgon GMT near the seabed that exceeded its RPD (31.5%). Variability between duplicates can be caused by heterogeneity between splits and/or differences in laboratory methods for sample preparation and analysis. As such, the concentrations for manganese in seabed water samples should be recognised as uncertain rather than precise measurements. A breakdown of the QAQC assessment for samples is provided in Appendix I.

Blank water samples collected from the Niskin bottles contained measurable concentrations of TDS, dissolved barium, copper, manganese and zinc, total aluminium, barium, copper, iron, manganese, lead and zinc, DOC, TOC, TRHs (all fractions) and BTEX (except for benzene and ethylbenzene). The concentrations of these parameters suggest the likelihood of contamination during the water sampling process and as such, these parameters at site WTR DC-1 should be recognised as uncertain rather than precise measurements.

The results of laboratory quality control testing of water samples (method blanks, laboratory duplicates, laboratory control samples, and matrix spikes) are presented in Appendix H.

4.7 Water Quality Profiles

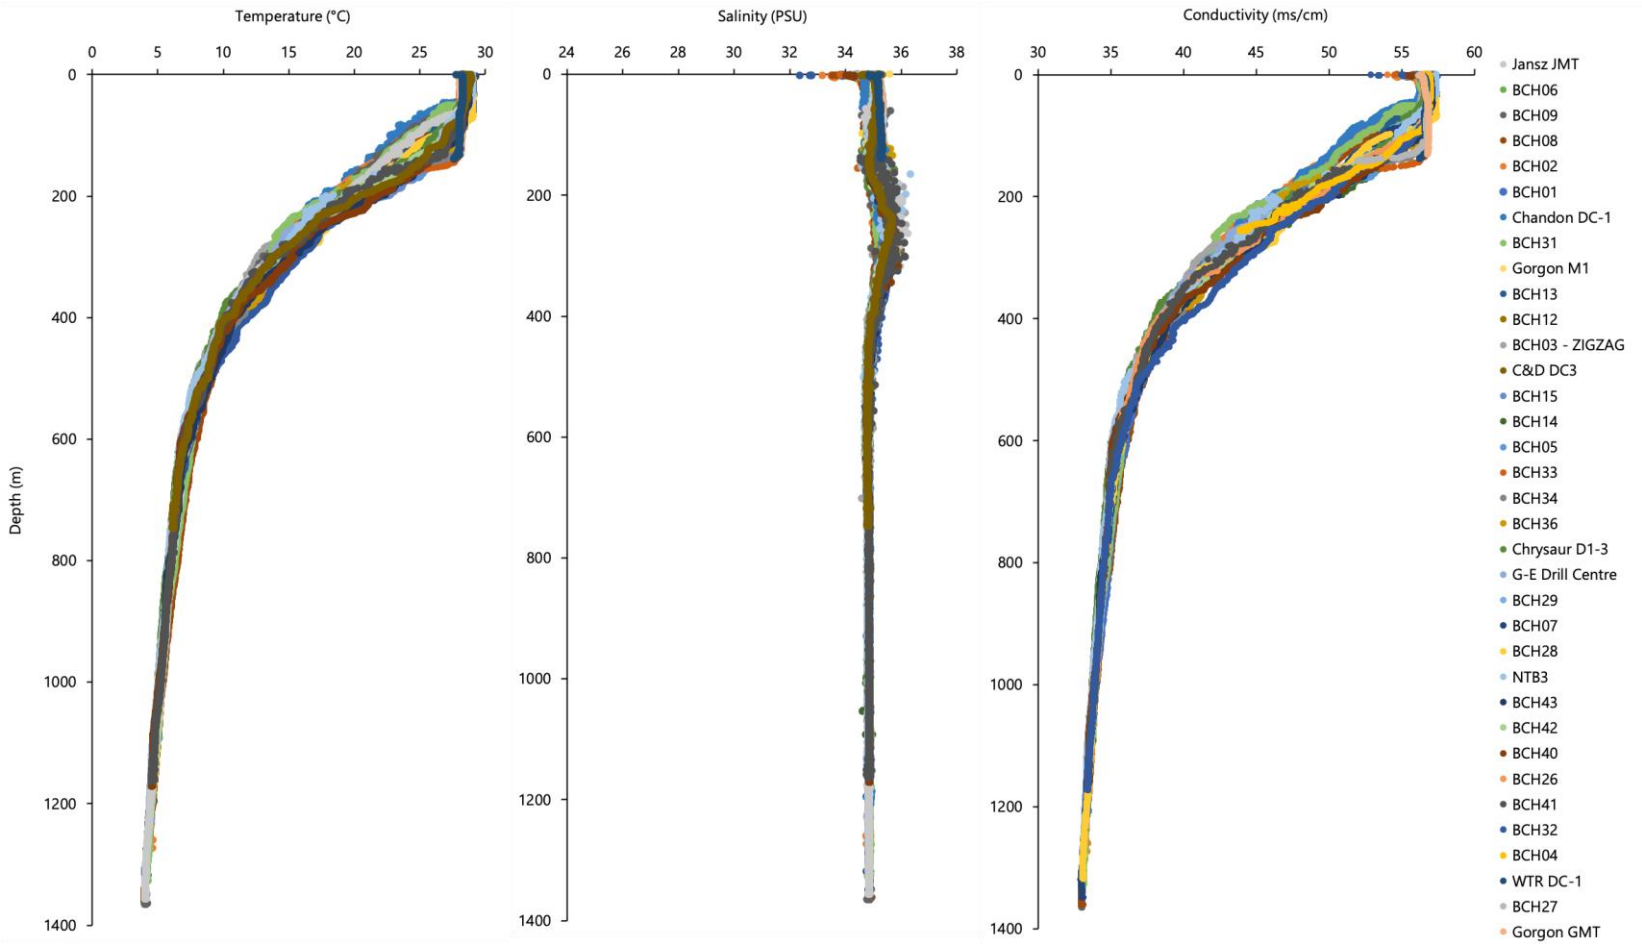
Depth profiles of each transect site recorded by the ROV are presented in Appendix K.

Warmer temperatures were seen in the top 50 m of water across all sampling sites, ranging from 27.7°C to 29.2°C, and gradually decreased in temperature with increasing depth (Figure 4-20). Water temperatures dropped to minimum of ~3.9–4.2°C in depths ~1,350 m (Figure 4-20).

Salinity was relatively consistent with depth, ranging from 32.3 to 36.3 PSU (Figure 4-20). Conductivity showed a similar trend to temperature, in which conductivity ranged from 52.9 to 57.4 mS/cm between the surface and 50 m, and gradually declined with depth, reaching a minimum of ~33.1 mS/cm at ~1,350 m (Figure 4-20).

For the temperature-salinity plots, the water quality profiles for the deepest site at each field indicated that the ocean environment around the sampling sites are relatively consistent across the GBF project area and are typical for the region. Across the five fields (Chandon, C & D, G & E, Semele and WTR), three separate water masses can be identified in Figure 4-21:

- Low salinity surface water ranging from 34.6–35.3 PSU with a temperature range of ~18–28°C; upper ~180 m of water column
- Higher salinity mid-waters with a salinity and temperature range of 35.4–36 PSU and 15–20°C, respectively; centred between 185 and 250 m depth
- Lower salinity bottom waters with a salinity and temperature range of 34.7–35.4 PSU ~3.5–15°C, respectively; between 250 to ~1,310 m depth.



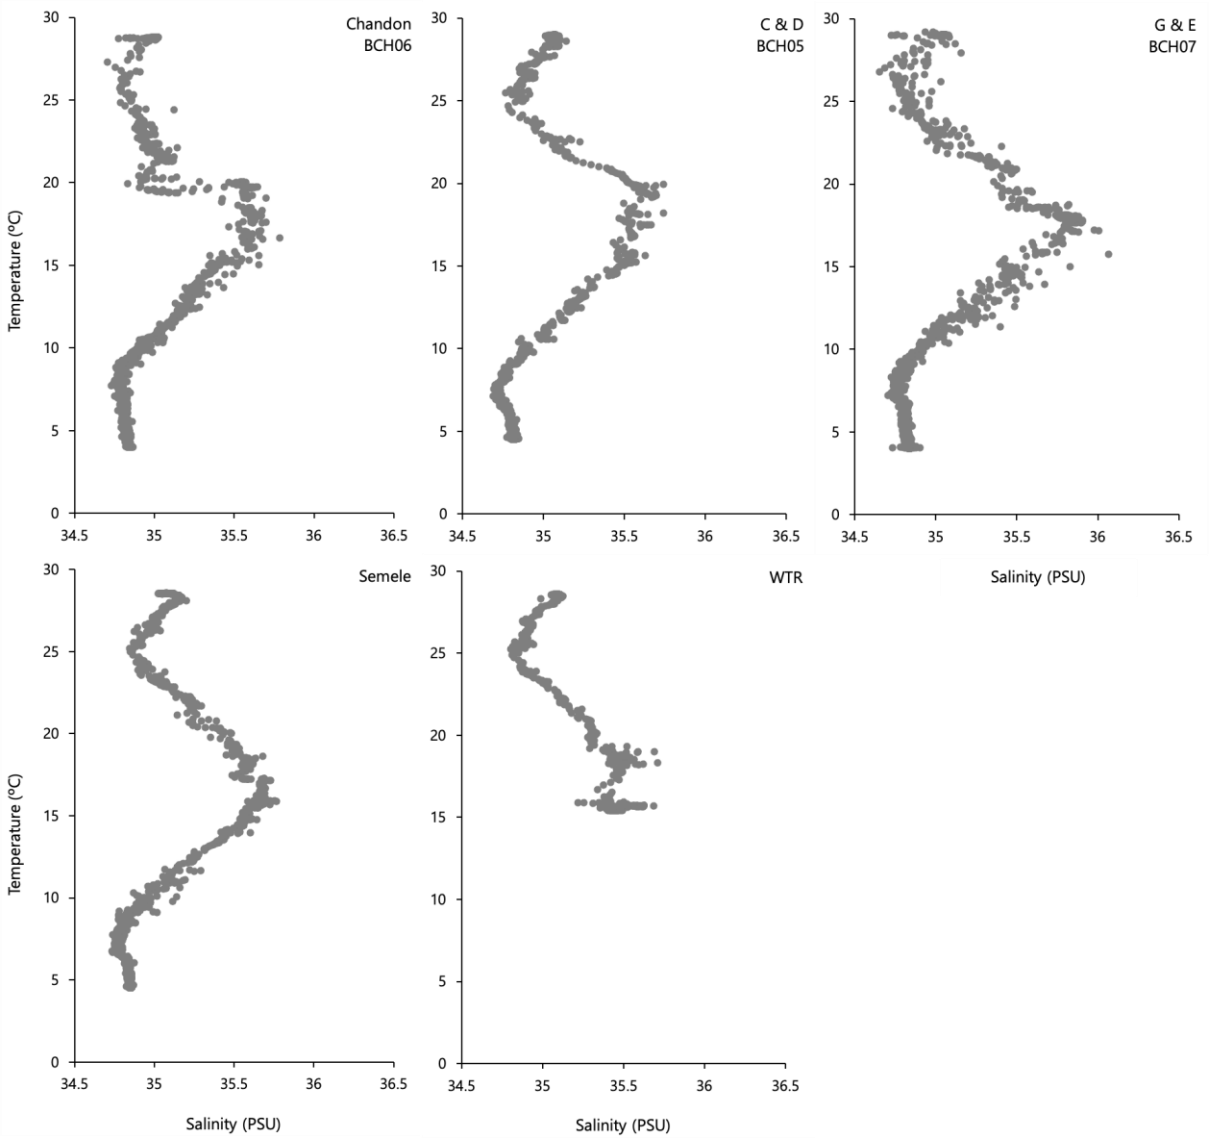


Figure 4-20 Water quality profiles at all sampling sites within the Gorgon Backfill Fields project area

Note:
1. BCH = Benthic communities and habitat, C & D = Chrysaor and Dionysus, G & E = Geryon and Eurytion, PSU = practical salinity unit, WTR = West Tryal Rocks

Figure 4-21 Temperature-salinity measured at the deepest sites at each field (Chandon, Chrysaor and Dionysus, Geryon and Eurytion, Semele, and WTR)

5 Discussion and Conclusion

To inform the OPP and support future environmental approvals for the development of several new fields in the GBF, Advisian were commissioned by CAPL to characterise the marine benthic environment within the GBF project area. Specifically, the objectives of this study were to develop a validated benthic habitat map of the project area based on assessment of geomorphic features and BCH, describe the demersal fish assemblages associated with areas of interest, and to broadly characterise the water and sediment quality of the GBF project area.

5.1 Benthic Habitat Mapping

There was a strong positive correlation between the preliminary and final benthic habitat maps following the ground-truthing survey, meaning that the available geophysical data (SSS, MBES and 3D seismic) allowed for a good interpretation of the key benthic and geomorphic features of the seabed across the wider area without further ground-truthing effort.

The GBF project area, which is a 5 km radius from proposed or indicative subsea infrastructure, sits along the continental slope located between the continental shelf and the abyssal plain/deep ocean floor in the Exmouth Plateau in water depths ranging from 100 to 1,300 m (Heap et al., 2005; Falkner et al., 2009). Overall, the distribution of benthic habitat within the GBF project area comprises mostly a mixture of flat sediment terrain with bioturbation or bare sediment, and isolated areas of high structural complexity, typical of the Northern Carnarvon Basin (Falkner et al., 2009; Geoscience Australia, 2022). The mapped benthic habitats were representative of known regional and local habitats and no new benthic habitats or communities to the bioregion were observed.

The benthic habitat in shallower waters (<200 m) within and surrounding Gorgon GMT consisted of mostly smooth seabed with bioturbation and no epibenthic biota observed. Located within the Ancient Coastline KEF, the region is identified as having unique seafloor features comprising areas of hard substrate that may provide areas for higher diversity and enrich species richness compared to soft sediment areas (DSEWPaC, 2012; DCCEEW, 2022). However, at the Gorgon GMT survey site, minimal topographic seabed features (e.g., consolidated substrate) were observed (Puotinen and Currey-Randall, 2020; Currey-Randall et al., 2021), which may indicate a layer of soft substrate over consolidated hard substrate that is unlikely to provide significant habitat to biota. Furthermore, the positioning of existing Gorgon GMT facilities on which this survey site boundary was based, would have likely targeted seabed areas of low structural complexity.

Between 200 m and 1000 m depths within the Continental Slope Demersal Fish Communities KEF, a diversity of benthic habitats were present along the seabed, including irregular and smooth seabed, depressions, reef mosaics and discrete fault scarps. The topographically complex scarps that traverse through the GBF project area are indicative of extensive canyon systems (Geoconsult, 2005; Advisian, 2019) formed by the gradual erosion of the continental slope. These scarps which are adjacent to the proposed C & D DC-3 drill centre and sections along its associated flowline routes to Gorgon M1, hosts typical deep-sea benthic biota. These biota were sparsely distributed and limited to isolated individual biota including sponges, echinoderms, and cnidarians, which resemble benthic compositions previously found along continental slope seabed habitats at depths of 700–1,000 m (Heyward et al., 2001; Williams et al., 2010; Advisian, 2019).

The benthic habitat along the Chandon to JMT and Jansz DC2 to G & E DC-1 corridors, which are situated between 1,000 m and 1,400 m in low slope areas, consisted primarily of relatively flat terrain.

Isolated fault scarps with bare substrates are present around the proposed NTB3 drill centre and its associated flowline routes heading north (to benthic transects near Semele and G & E DC-1). It is probable that these scarps are steep and affect deep sea currents, transport of marine propagules and water temperatures, which in turn determine the composition of marine biotic assemblages present. Unlike the scarps within the Continental Slope Demersal Fish Communities KEF which have shown to provide high structural complexity in shallower (200–1000 m) waters, scarps in deeper waters may not provide suitable habitat for marine biota including invertebrates.

In deeper waters (1,200–1,300 m) within the Exmouth Plateau KEF, two large fault scarps ~7 km and ~11 km from Chandon DC-1 are positioned west to east and cross through the indicative flowline route. These scarps however, are devoid of epibenthic fauna as observed in the ground-truthing videos. The remaining benthic habitats were relatively uniform and dominated by irregular seabed with bioturbation or bare substrate and have a low likelihood of providing epibiota with significant habitat. Similar to the low slope areas, deep water areas of complex bathymetry appear to support sparse to no biota (Advisian, 2019). It is probable that the spatial distribution of benthic biota across different benthic habitats depends on several factors such as water temperature, sediment characteristics, food availability, depth, and the nature of the underlying substrate. Furthermore, the seabed sediments are likely to host benthic infauna such as polychaetes, however, larger sediment grab samples instead of cores are required to verify their presence (e.g., Gardline, 2009; Section 5.5) given that no benthic infauna were collected within the Exmouth Plateau KEF during this survey.

5.2 Benthic Cover

Based on the distribution of benthic habitats mapped and the percent cover of benthic habitats in each proposed drill centre and tie-in locations and 2 benthic habitat transects, bare sediment (soft unconsolidated sand/mud) with no biota was the dominant benthic category with greatest benthic cover. These results are comparable to previous studies of the Exmouth Plateau (Falkner et al., 2009), Continental Slope Demersal Fish Communities (DSEWPaC, 2012) and Ancient Coastline (Currey-Randall et al., 2021) that identified soft sediments (sand and mud/silt) as the dominant substrate type in deeper waters with less than 15% benthos cover.

Of the 12 sites examined that consists of proposed drill centres and tie-in locations and 2 benthic habitat transects, the only biota present were cnidarians (over bioturbated sediments) that were detected at Gorgon M1, albeit at a very low percent cover. The presence of biota may suggest that unconsolidated soft sand/mud may only be present as a veneer over the top of consolidated hard substrate. Although higher or rougher topographic features were not identified in any of the captured still images, habitat mapping of C & D DC-3 and NTB3 proposed drill centres suggests that consolidated and steep scarps are present and may support benthic communities.

5.3 Fish Assemblage

Distinct fish and crustacean assemblages were found across the GBF project area which were strongly influenced by water depth. Shallower and warmer sites located in the TSW mass within the Ancient Coastline KEF had a greater number of fish recorded than other sites, with a mean of 3000 fish per transect in the Ancient Coastline KEF and 1700 fish per transect across all sites in the TSW mass. These shallower sites were characterised by sharks and Carangidae such as *Trachurus novaezelandiae* (yellowtail scad). The fish assemblages of the deeper continental slope were mostly dominated by Carangidae, Macrouridae (rat tails), Halosauridae (halosaurs) and unidentified anguilliform (eel-like) fishes. This zone was characterised by the SICW mass and included the slope geomorphic feature and

the Continental Slope Demersal Fish Communities KEF. Although there were large differences in the number of fish observed across the GBF project area among water masses, KEFs and geomorphic features, the average diversity of fishes remained consistent across the sites. Furthermore, while the deeper sites had lower numbers of fishes, the number of fish taxa was the same as the shallower sites.

The patterns of assemblage composition, abundance and number of taxa identified in both the fish and crustaceans sampled support that there is a different fauna associated with the deeper waters of greater than 800 m depth and the AAIW mass. A similar pattern was suggested by Saunders et al. (2021) and has previously been reported (Last et al., 2009). This change in fauna is likely linked to the AAIW, as the cold deep-water and lower saline current has a strong influence on the distribution of fish communities as seen in the south-west region between the Great Australian Bight and north of the Ningaloo Reef where its core fluctuates with depth from 875 m at 27.50°S to 520 m around 21.50°S (Williams et al., 1996; 2001; Woo & Pattiaratchi, 2008). A recent survey in a similar area covered water depths between 360 and 870 m and identified that a similar faunal break occurred between 700 and 800 m water depth (Saunders et al., 2021). A break between mid-slope and shelf-break fish assemblages at water depths of between 700 and 900 m was also reported by Williams et al. (2001) in the North West Cape.

5.4 Sediment Chemistry

The quality of sediments at proposed drill centre and tie-in locations met the ANZG (2018) environmental guidelines at all sites and for all parameters tested, except for nickel which only exceeded at Chandon DC-1. All other sediment sampling sites also contained detectable concentrations of nickel just below ANZG (2018) DGV. Given that this was a baseline study, and no previous activities have occurred in the proposed drill centres and tie-in locations, the detection of nickel across a range of depths (from 100 m at WTR DC-1 to 1300 m at G & E DC-1) is indicative of naturally occurring nickel in sediments.

The presence of nickel may be linked to the sediments' composition (PSD) and organic matter content (Munksgaard and Parry, 2002). The sediments at all sites were mainly composed of clays and silts with TOC concentrations below 1%, suggesting that there has been no enrichment of organic matter in these sediments. However, the high binding capacity of finer-sized particles (clays and silt fractions) will likely result in higher concentrations of naturally occurring nickel in sediments. This is evident in all sediment samples except for sediments in WTR DC-1 which is dominated by sand-size fractions.

The sediments in the Exmouth Plateau are of lithogenic origin consisting of high carbonate content (>55%; McLoughlin and Young, 1985) and largely comprise of sandy mud and muddy sand while larger-size sediment fractions are common in shallower depths along the Northern Carnarvon Basin (Baker et al., 2008). In summary, sediments are generally in a pristine condition, as expected given the absence of anthropogenic activities.

5.5 Benthic Infauna

Despite the limited number of individuals collected, the benthic infauna found were primarily in both deep-sea sediments (1100–1200 m) around proposed drill centres Semele DC-1, Semele DC-2, and Semele BCH1, and shallower seabed (100–200 m) at WTR DC-1. The benthic infauna collected in this study, which included marine worms, a mollusc and polychaete worm, is similar to previous seabed surveys in the north-west shelf region (Heyward et al., 2001; Falkner et al., 2009; Advisian, 2019) whereby polychaetes and crustaceans are the dominant epibenthic and infaunal invertebrates of soft

sediment habitats. Although few individuals were collected in this study, other surveys in the North West Shelf region have also recorded a sparse distribution of epifaunal and infaunal benthic biota, with abundances ranging from one to 47 individuals (Heyward et al., 2001; Advisian, 2019).

The sediments around the proposed drill centres were free of hydrocarbons, had low concentrations of metals and TOC content, indicating that these sediments used by the infauna are free of contaminants and there was no evidence of enrichment of organic matter. The quantity and distribution of infauna found in this survey suggests that other factors such as sediment type, depth, temperature, and food supply to the benthos (Basford et al., 1990; Künitzer et al., 1992; Levin and Gage, 1998) may be affecting the type and quantity of infauna inhabiting the area. Of the five individuals collected, four of the benthic infauna were found in sediments consisting of high silt and clay content, whereas one individual biota was collected in a shallower area with sediments dominated by sand. It is possible that homogeneous sediments provide less niches and support a lower diversity of benthic infauna than heterogeneous sediment (e.g., Gray, 1974). This survey did not find any endemic benthic infauna.

It is possible that the low number of benthic infauna collected in this survey may also be due to the sampling equipment. Compared to traditional box corers, push corers capture a smaller surface area of seabed that may have missed benthic infaunal communities of low density. Furthermore, it is possible that the standard sieve size of 1 mm (Hook et al., 2016) used may have lost smaller-sized individuals (<1 mm), particularly in deep-ocean sediments where lower organism densities and potentially smaller infauna sizes may occur (Gage et al., 2002).

5.6 Water Chemistry

A range of water quality parameters were collected across a range of sites within the GBF project area to understand background conditions. With the exception of dissolved copper and cobalt, metal and hydrocarbon concentrations in water samples were either below laboratory LORs, or below available 99% species protection DGVs, which is typical of an undisturbed tropical offshore environment.

Copper is a natural and essential trace element required by many marine organisms but in high concentrations is one of the most toxic trace metals in seawater (Mackey, 1984; ANZG, 2018). The natural presence of copper in surface water samples may vary in concentrations over time, in response to physical oceanographic effects such as tide and wind and/or seasonal differences (Wenziker et al., 2006). Copper is also released into the water column during physical and chemical weathering of the underlying geology (OzCoasts, 2013). However, the elevated levels of copper detected in some seawater samples may also suggest an alternative copper source such as wind-blown dust, fossil fuel burns, survey vessel discharges and antifouling paints may have contaminated the samples during the sampling process (Richon & Tagliabue, 2019). It is possible that some contamination occurred during sampling, with anomalous results for cobalt and lead being detected in some samples.

Nutrient concentrations across the GBF project area were consistently low across the sampling sites. Surface waters had lower concentrations of nutrients than bottom waters. These results are consistent with nutrient concentrations reported in previous studies in deep-water environments in the North West Shelf (Holloway et al., 1985; URS, 2007; Gardline, 2009), which are influenced by the Indonesian Throughflow. Given that slightly higher concentrations of nutrients were evident near the seafloor compared to the sea surface, it is likely that there are no physical processes such as upwelling (wave or current-induced) of deeper waters occurring in the region (Mackey, 1984).

5.7 Water Quality Profiles

Water quality profiles were consistent between sites, with a warm and low salinity surface layer (to ~180 m depth) overlying a broad thermocline/subsurface salinity maximum (between 185–250 m depth), followed by the colder, lower salinity waters of the deeper ocean (~250–1,350 m). The CTD data collected within the GBF project area allowed the identification of tropical surface waters corresponding with the southward-flowing Leeuwin Current and the deeper south Indian central water mass along with the subsurface Leeuwin Undercurrent which moves equator-ward along the Western Australian coast at deeper depths. Similar water mass structures have been identified in the Gascoyne region (Woo & Pattiaratchi, 2008; Pattiaratchi & Woo, 2009, BMT Oceanica, 2016). Oceanic processes such as currents in the water column can be used to understand the type and distribution of seabed habitat.

5.8 Conclusion

This survey report details the existing marine benthic environment and geomorphological seabed features within the GBF project area. In line with the scope of works, a preliminary benthic habitat map was developed based on assessment of geomorphic features derived from sonar and seismic survey data, and a visual benthic survey was completed to validate BCH. Further to this, we described the demersal fish and habitat associations across areas of interest, and broadly characterised the water and sediment quality and infaunal assemblages of the project area.

Overall, the benthic environment is characteristic of the North Carnarvon Basin and the North West Shelf region and is dominated by mixture of benthic habitats of low topographic features with few benthic biota. Sections of seabed between 200 m and 1000 m depths within the Continental Slope Demersal Fish Communities KEF and Exmouth Plateau KEF was comprised of topographically complex scarps with sparse benthic biota that are typically found in deeper waters (>200 m). Though these benthic habitats are well represented regionally, further consideration of the most suitable placement of subsea facilities may be warranted as the project matures to minimise potential impacts to the BCH within the GBF project area (i.e., along scarp and reef mosaic habitats with low and high likelihood of biota).

Water and sediment samples collected from within the GBF project area were free from contaminants and typical of an undisturbed tropical offshore environment. Although there were a few exceedances of some metal concentrations in water and sediment samples compared to ANZG (2018) guideline values, these concentrations could either be a result of contamination during the sampling process, or reflect natural background levels given the absence of anthropogenic activities in the area.

Appendix A
Exemption from Fish Resources Management Act 1994 and Regulations, Section 7, and Regulation 6

Office use only
EXEMPTION NUMBER:

Fish Resources Management Act 1994
Section 7(2)(e)

INSTRUMENT OF EXEMPTION

I, Nathan Harrison, Director, Aquatic Resource Management, as delegate of the Minister for Fisheries pursuant to Section 7(2) (e) of the *Fish Resources Management Act 1994*, do HEREBY EXEMPT the persons specified in **Schedule 1** from the provisions of the *Fish Resources Management Act 1994* and associated subsidiary legislation which would otherwise prevent those persons from lawfully pursuing the activity specified in **Schedule 2**, using the methods specified in **Schedule 3**, for the area and period specified in **Schedule 4**, subject to the conditions specified in **Schedule 5**.

Schedule 1
Persons

Persons exempted	Exemption holder
Luca.Chiaroni +61 498 014 575 Luca.Chiaroni@Advisian.com And Employees of Worley Services Pty Ltd	Applicant: Worley Services Pty Ltd, trading as Advisian Address: Level 14, 240 St Georges Terrace, Perth, 6000 Telephone No: (08) 9485 3811

Schedule 2
Activity and Purpose

Marine Benthic Survey of the Greater Gorgon Area. This project performs habitat mapping and marine benthic surveys for seven new fields in the Greater Gorgon area on the Northwest Shelf.

Schedule 3
Fishing Methods

A key component of the baseline program is a sediment quality survey sampling and testing for metals, nutrients, and total organic carbon. Sediment samples will be collected via Push Cores to a depth of 40 cms.

Although some sediment infauna will be obtained through sediment push core samples, fish or other biota are an incidental catch. It is expected that the total biomass collected from the survey will be less than 10 kgs.

Schedule 4
Area and Period

Marine Benthic Survey Surveys will be conducted within the Greater Gorgon area located in the Northern Carnarvon Basin Surveys. The fields are located around 130 km northwest of Barrow Island, Western Australia (WA), in water depths ranging from 150 m to 1300 m. The study area covers an area of approximately

2000 square kilometres. Sediment samples will be conducted within these new fields indicated in Figure 1

From the date of signing until 10 October 2022.

Locations to be sampled

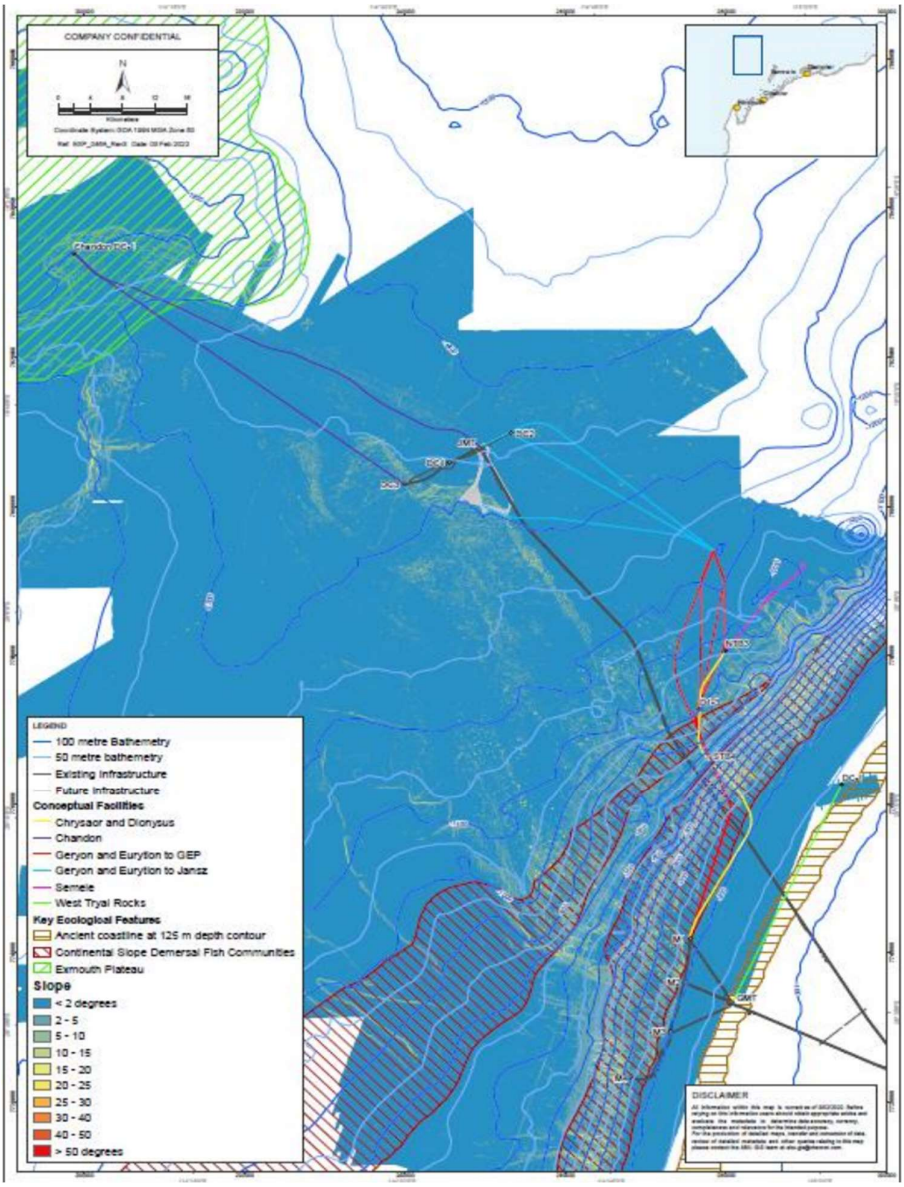

Figure 1: Overview of the greater Gorgon survey area

Schedule 5

Conditions

1. The exemption holder must advise the Department by calling FishWatch 1**800 815 507** at least 12 hours prior to commencing every sampling trip under the exemption, of:

    a) the Exemption holder's full name;
    b) the Exemption holder's contact numbers;
    c) the nearest Office of the Department;
    d) the location of the Exemption and the proposed place and time of landing of any fish retained under the authority of this Exemption;
    e) the Exemption number;
    f) the Exemption start date and time;
    g) the Exemption end date and time;
    h) the name and registration of any vessels/s and the registration of any vehicle/s used to transport any fish retained under the authority of this Exemption;
    i) the species and number of fish intended to be collected under the authority of this Exemption; and
    j) the Call date and time.

2. The exemption holder must ensure the Department is notified via FishWatch **1800 815 507** of any changes to the nomination information, including collection trip cancelations or variations to the date or time.

3. The person(s) exempt **(Schedule 1)** must carry a copy of this Exemption when they are carrying out the activities provided for by this Exemption or when transporting any species collected under this Exemption. The exemption holder must also retain the call reference number (provided by the call centre upon making the prior nomination to fish). A copy of the Exemption must be made available for inspection by a Fisheries and Marine Officer on request.

4. Where any vessel and / or vehicle is being used to take fish and / or samples pursuant to this exemption, the persons specified in **Schedule 1,** must ensure that these vehicles:

    a. be made visibly identifiable as belonging to the client or the persons specified in **Schedule 1;** and
    b. display a sign that is at least 600mm x 600mm, with a minimum character size of 50 mm, stating "Operating under Exemption No." along with the Exemption Number.

5. Where any fishing gear is being used to take fish and / or samples pursuant to this exemption, the persons specified in **Schedule 1,** must ensure that the fishing gear is visibly identifiable as belonging to those specified in **Schedule 1,** along with the Exemption Number, by attaching either marked surface floats or waterproof tags.

6. The persons specified in **Schedule 1,** must only use the sampling methods described in **Schedule 3** while operating under the authority of this Exemption.

7. No other fishing activities, other than those under the authority of this Exemption, are to be undertaken during any sampling trip.

8. The exemption holder must obtain any additional approvals or permissions to complete the activities specified under this Exemption should it be prohibited by other Western Australian or Commonwealth legislation.

9. The Director Aquatic Resource Management can at his discretion revoke this Exemption at any time.

10. If a fish or fish sample is removed from the collection site, it must be disposed of on land, in municipal waste, and not be returned to the marine environment or any water body.

11. Any person specified in **Schedule 1,** must not fish or collect samples, under the authority of this exemption, in any marine protected areas; including State Marine Nature Reserves, Marine Park Sanctuary Zones, Fish Habitat Protection Areas or Reef Observation Areas, without the specific written permission of the Department of Biodiversity, Conservation and Attractions Manager, Marine Science and the Department of Primary Industries and Regional Development's Director, Aquatic Resource Management or Director, Aquatic Science and Assessment.

12. All samples taken pursuant to this exemption, must only be transported in vessels or vehicles described as required under **Condition 1. (h).**

13. Any collected specimen or by-catch that are displaying invasive characteristics or are suspected or recognised invasive aquatic species identified in the Fish Resources Management Regulations 1995 (Schedule 5, Noxious Fish), and/or in the current version of the Western Australian Prevention List for Introduced Marine Pests, Department of Fisheries, found on the DPIRD website must not be returned to the water.

    http://www.fish.wa.qov.au/Documents/biosecurity/noxious fish list.pdf
    http://www.fish.wa.gov.au/Documents/biosecurity/epa introduced marine pests

    Noting these lists may be amended from time to time.

14. Any specimens retained in accordance with **Condition 13** must be humanely euthanized and kept in a sealed plastic bag or container, separate from any other fish and either kept on ice or refrigerated (but not frozen), until further advice is obtained from DPIRD.

15. The holder of the Exemption must report to the DPIRD via FISHWATCH (ph 1800 815 507) or by email at aquatic.biosecurity@dpird.wa.gov.au, within 24 hours following the:
    a) Initial detection of:
        a. a listed noxious fish

b. a suspected or recognised invasive aquatic species not previously known from the sampled waters; or
c. an introduced aquatic pest, or
d. a disease, and

b) Subsequent analysis and confirmation of fish/species identified in **Condition 13** above or by any other further investigation.

Nathan Harrison
DIRECTOR, AQUATIC RESOURCE MANAGEMENT
as delegate of Minister for Fisheries

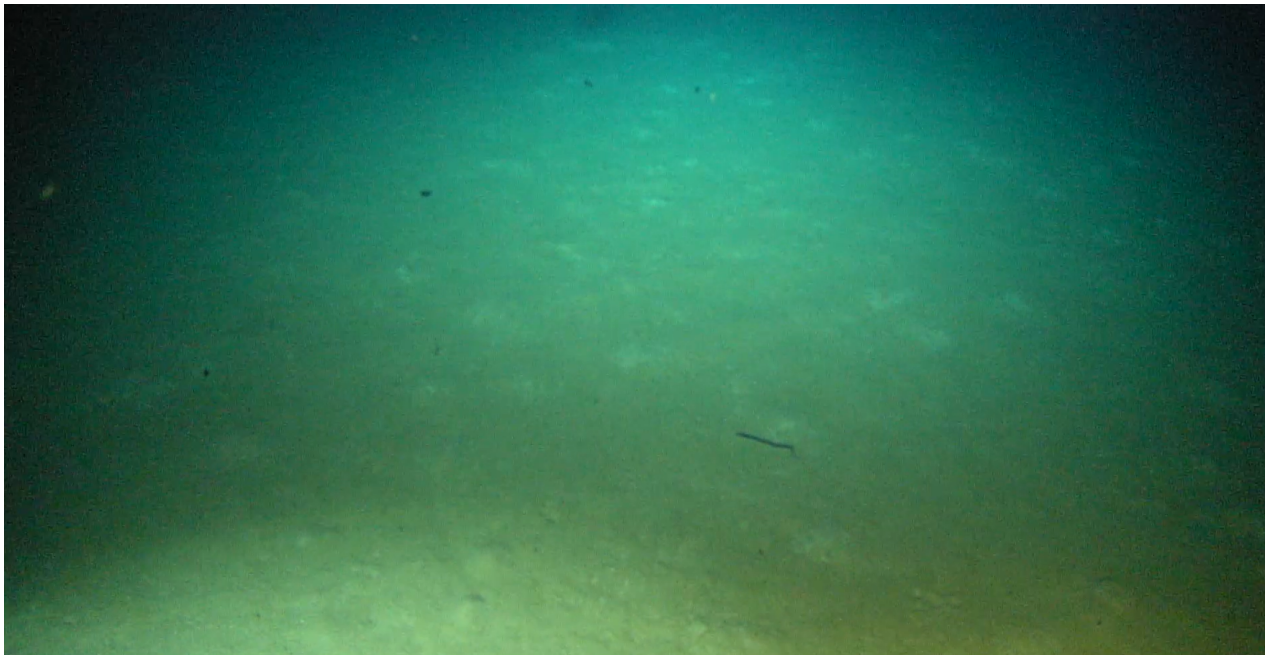
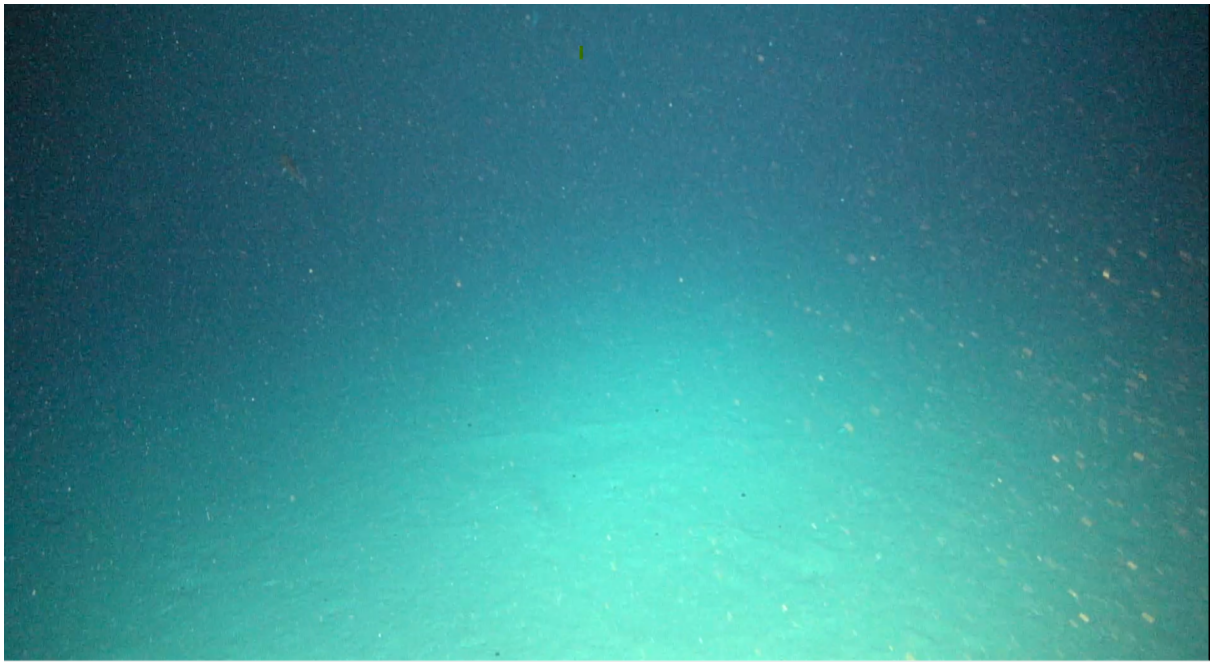
Appendix B
Benthic Habitat Categories and Example Images (Based on CATAMI Classifications)

Substrate descriptor



Morphological Descriptor	Description	Bathymetry	Slope/Topographic Position	Relative Backscatter/ Sidescan
Bedforms	Active or once active sediment bedforms indicating wave or current action on the seabed.	May be visible bathymetric features, or may only occur in backscatter if small.	Varied, wavelength and amplitude measured in profile (Ashley 1990).	Varies depending on incidence angle. Typically, low.
Depression-Scour	Local depression which may be geological or biological in origin (Scour or Pockmark).	Bathymetric features measurable in profile (low).	Varied slope. TPI index low.	Varies depending on incidence angle.
Irregular Seabed	Mostly flat sediment terrain with minor features which may be derived from underlying geology.	Smooth with identifiable, regular but small bedforms or mounds. Fine or coarse sediment.	Typically, less than 2°, minor topographic features.	Low, rare, and small discernible features.
Mostly Bare	Mostly flat sediment terrain with very minor features.	Smooth with rare identifiable but unmappable regular bedforms or mounds. Fine or coarse sediment.	Typically, less than 2°, very minor topographic features.	Low, rare, and small discernible features.
Mound	Locally elevated Sediment or Rock Veneer feature which comprising rubble, geological or biological in origin.	Bathymetric features measurable in profile. Isolated, smooth edged feature. No structure indicating active sand wave or dune.	Varied but smooth slope. TPI index high.	Varies depending on incidence angle, typically very high.
Rock Reef	Bedrock or other consolidated material outcrop.	Rough bathymetric features measurable in profile.	Varied complex slope. TPI index high.	High/variable.
Rock Veneer	Area of buried bedrock/rocks or cemented sediments with very low sediment input (Starved). Also known as low profile reef.	Uneven, rugged, and irregular features, often angular or linear. Fine or coarse sediment.	Typically, less than 2°, highly variable low profile topographic features. Signs of subsurface structure must be apparent.	Varied, mostly high.
Scarp	Bedrock or other consolidated material outcrop, subject to landslide erosion.	Rough bathymetric features measurable in profile.	Typically, greater than 15°, may have steep sides	Varies depending on incidence angle.

The images below are classified according to the CATAMI scheme (table below) and are intended as representative examples of this habitat classification.



Habitat and Biota Categories

Habitat Categories	Biota Categories
Relief/Slope	**Biota**
Flat	Sponges
Low (<1 m)	Cnidaria
Moderate (<3 m)	Echinoderms
High (>3 m)	Sponges, Cnidaria
Wall	Sponges, Echinoderms
Substrate	Cnidaria, Echinoderms
Unconsolidated (soft)	Mixed biota (all 3)
Consolidate (hard)	
Substrate size/appearance	
Sand/mud (<2 mm)	
Sand/mud (<2 mm) and occasional boulders	
Cobbles	
Boulders	
Rock (Outcropping bedrock)	
Modifier	
Bare	
Biota only	
Bioturbation and bare	
Bioturbation and occasional veneer only	
Bioturbation with biota and occasional veneer	
Ripples (<10 cm height) and bare	
Ripples (<10 cm height) with biota and sparse veneer with biota	
Veneer with biota

Appendix C Video Analysis Quality Assurance and Quality Control

Appendix C Video analysis QAQC

Throughout the benthic habitat video analysis Advisian marine scientists analysed 631 AVI video files in Transect Measure (SeaGIS 2021) software using agreed CATAMI habitat classifications. A video QAQC process was preformed after the initial analysis, where 5% of analysed videos were re-analysed by a different Advisian scientist (Table 1-1). Each QAQC video was re-analysed using the Transect Measure function which assigns a random video frame within a video file. Each random frame was checked using the CATAMI habitat classifications to determine if the appropriate habitat classification had been assigned during that video timestamp. Throughout the re-analysis of 31 QAQC videos none required to be corrected.

Table 1-1 TransectMeasure video analysis QAQC checks.

QAQC Number	File name	Frame	Time (HMS)	Original Classification	QAQC Classification Check

1. Introduction

Chevron Australia Pty Ltd (CAPL) are developing an Offshore Project Proposal (OPP) to work towards approvals for the development of several new fields to tie-in existing Gorgon Development infrastructure (Gorgon Foundation Project) in the Greater Gorgon area: Geryon, Eurytion, Chandon, Semele, Chrysaur, Dionysus and West Tryal Rocks (WTR) (hereafter; collectively known as Gorgon Gas Development: Backfill Fields, GBF; Figure 1). The fields are located between ~60–130 km north-west of Barrow Island, Western Australia, in water depths ranging from 150 m (WTR) to 1,300 m (Chandon). Multiple subsea facilities such as flowlines, umbilicals and drill centres/well infrastructure sites may be required for the development of each field. Although the final flowlines and umbilical routes have not been identified yet by CAPL, the study sites are focused on indicative flowline and umbilical routes, tie-in locations and indicative drill centres.

The GBF project area spans three Key Ecological Features (KEF) of the Commonwealth marine environment; from the Exmouth Plateau in the west, to the Continental Slope Demersal Fish Communities, and Ancient Coastline at 125 m depth contour (Figure 1). These KEFs are likely to be relatively topographically complex and support a range of benthic habitats and organisms such as soft deep-sea coral, sea fans (gorgonians), sponges as well as regionally significant stocks of demersal fishes. To inform the OPP and support future environmental approvals, CAPL commissioned Advisian Pty Ltd (Advisian) to characterise the marine benthic environment within the GBF project area. Curtin University were commissioned to describe fish and crustacean assemblages within the GBF project area.

In northwest Western Australia, the marine region is recognised as a biodiversity hotspot (Fox and Beckley, 2005), and supports economically important industries, including commercial fisheries (Gaughan and Santoro, 2020) and oil and gas (Bond et al., 2018; McLean et al., 2018). The shallow water fish assemblages in this area are relatively well studied, however, a substantial amount of these industries operate in the deep sea (Armstrong et al., 2012), and the deeper marine habitats and their associated biodiversity are relatively understudied and poorly understood in this region (Currey-Randall et al., 2021). This is because sampling in deep water is expensive and logistically challenging (Saunders et al., 2021; Wellington et al. 2021), and previous studies have relied on extractive and destructive techniques such as trawling (Williams et al. 2001). Research on deep-water ecosystems using non-invasive methods, such as remotely operated vehicles (ROVs) (Schramm et al., 2020; Sward et al., 2019), is important as these ecosystems are vulnerable to anthropogenic impacts (Rogers, 2015)

and they provide structurally diverse and ecologically important habitats for marine species, many of which may not have been described (Appeltans et al., 2012).

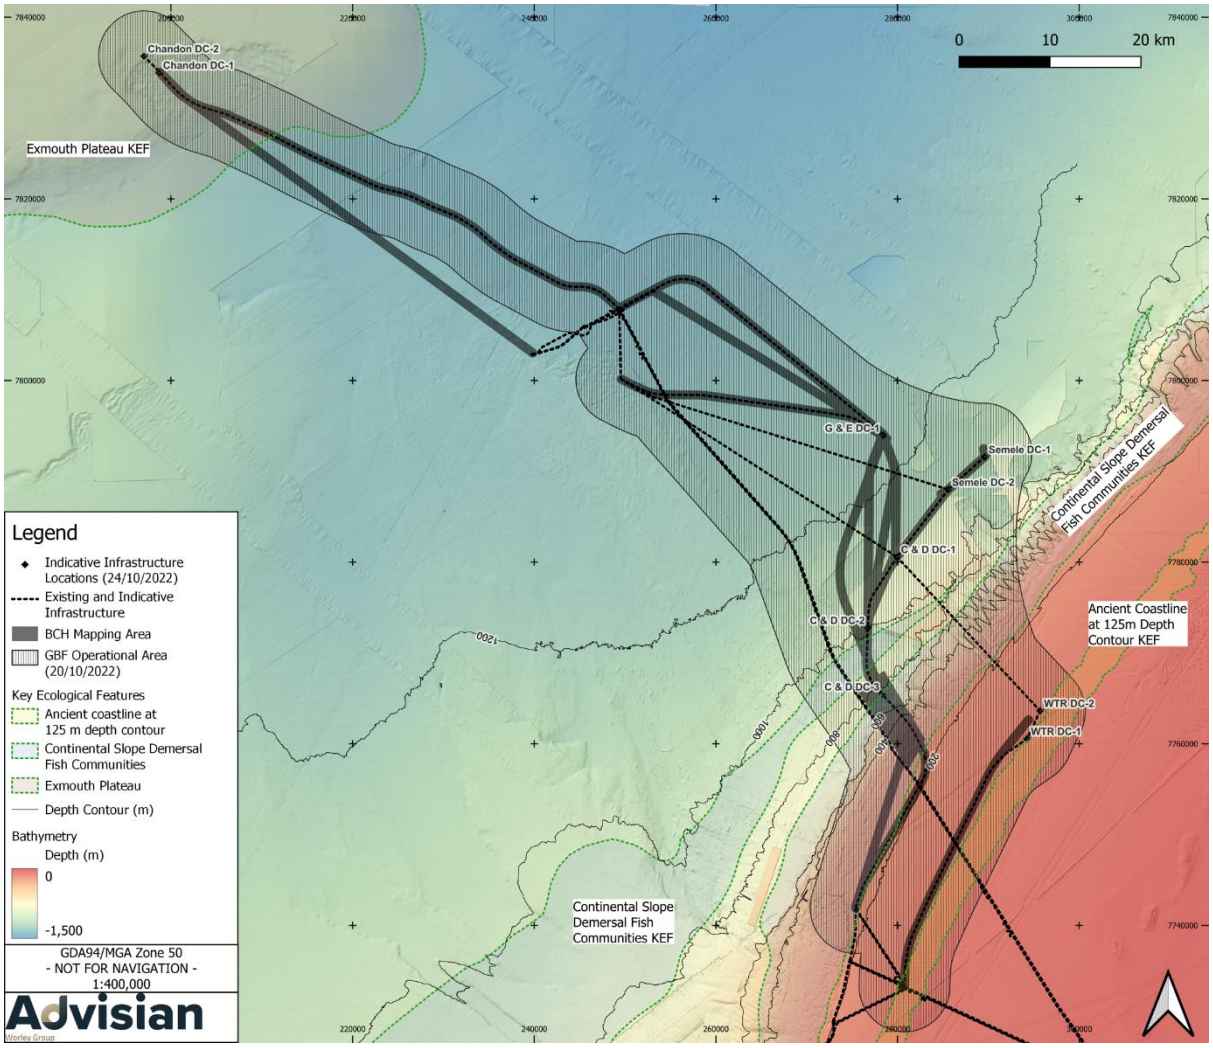

Figure 1. Context map illustrating existing and indicative infrastructure locations, the mapping area and the locations of the Key Ecological Features (KEFs). Map supplied by Advisian Pty. Ltd.

Key ecological features (KEFs) are areas in the marine ecosystem of regional importance as they are recognised as having high biodiversity or significant ecosystem function (Falkner et al., 2009). In northwest Western Australia, there are 13 KEFs, however, there is limited information on the faunal diversity and habitat structure in these areas, particularly those located in deeper water (Currey-Randall et al., 2021). The KEFs in the study area are the Exmouth Plateau, Continental Slope Demersal Fish Communities, and Ancient Coastline at 125 m depth contour, which are some of the least studied KEFs in Australia (Hayes et al., 2015). As the pressures on the marine environment intensify, the function and biodiversity of the ecosystems associated with KEFs need to be described and understood to manage and mitigate these impacts (Saunders et al., 2021).

The deep sea marine environments in this region are diverse and can be characterised by their geomorphic features (Heap and Harris, 2008), which may be associated with distinctive biological assemblages (Last et al., 2010). In the deeper waters of northwest Western Australia which encompass the study area, the geomorphic features (GFs) of interest are: 1) Plateaus; 2) Trench/troughs; 3) Deep/hole/valleys; and 4) Slopes. Plateaus are defined as areas of high elevation bordered by closely spaced contours of increasing depth, while trenches and troughs can be defined by an elongate depression of V-shaped/flat bottom contours of increasing depth, bordered on both sides by more closely spaced contours of decreasing depth (Heap and Harris, 2008). Deep/hole/valley features are concave or tapered depressions bordered by closely enclosed contours and laterally converging contours of increasing depth (Heap and Harris, 2008).

The aims of this study are:

1) To describe the fish and crustacean assemblages in a regional and environmental context.
2) To describe and compare the fish and crustacean assemblages within the KEFs.
3) To describe and compare the fish and crustacean assemblages within each Geomorphic Feature.

2. Methods

Study Site

The survey was conducted off the north-west coast of Western Australia. The survey encompassed a large area of seabed located between 55 and 185 km to the north-west of Barrow Island in water depths ranging from approximately 130 m to approximately 1270 m. The survey area encompassed three KEFs. These features were the Ancient coastline at 125 m depth contour, the Continental Slope Demersal Fish Communities, and the Exmouth Plateau. The survey also covered four Geomorphic areas (Figure 3). These were the continental slope, trench/trough, deep/hole/valley, and plateau GFs. Each site was classified according to the KEF and GF in which it was situated (Appendix Table 1).

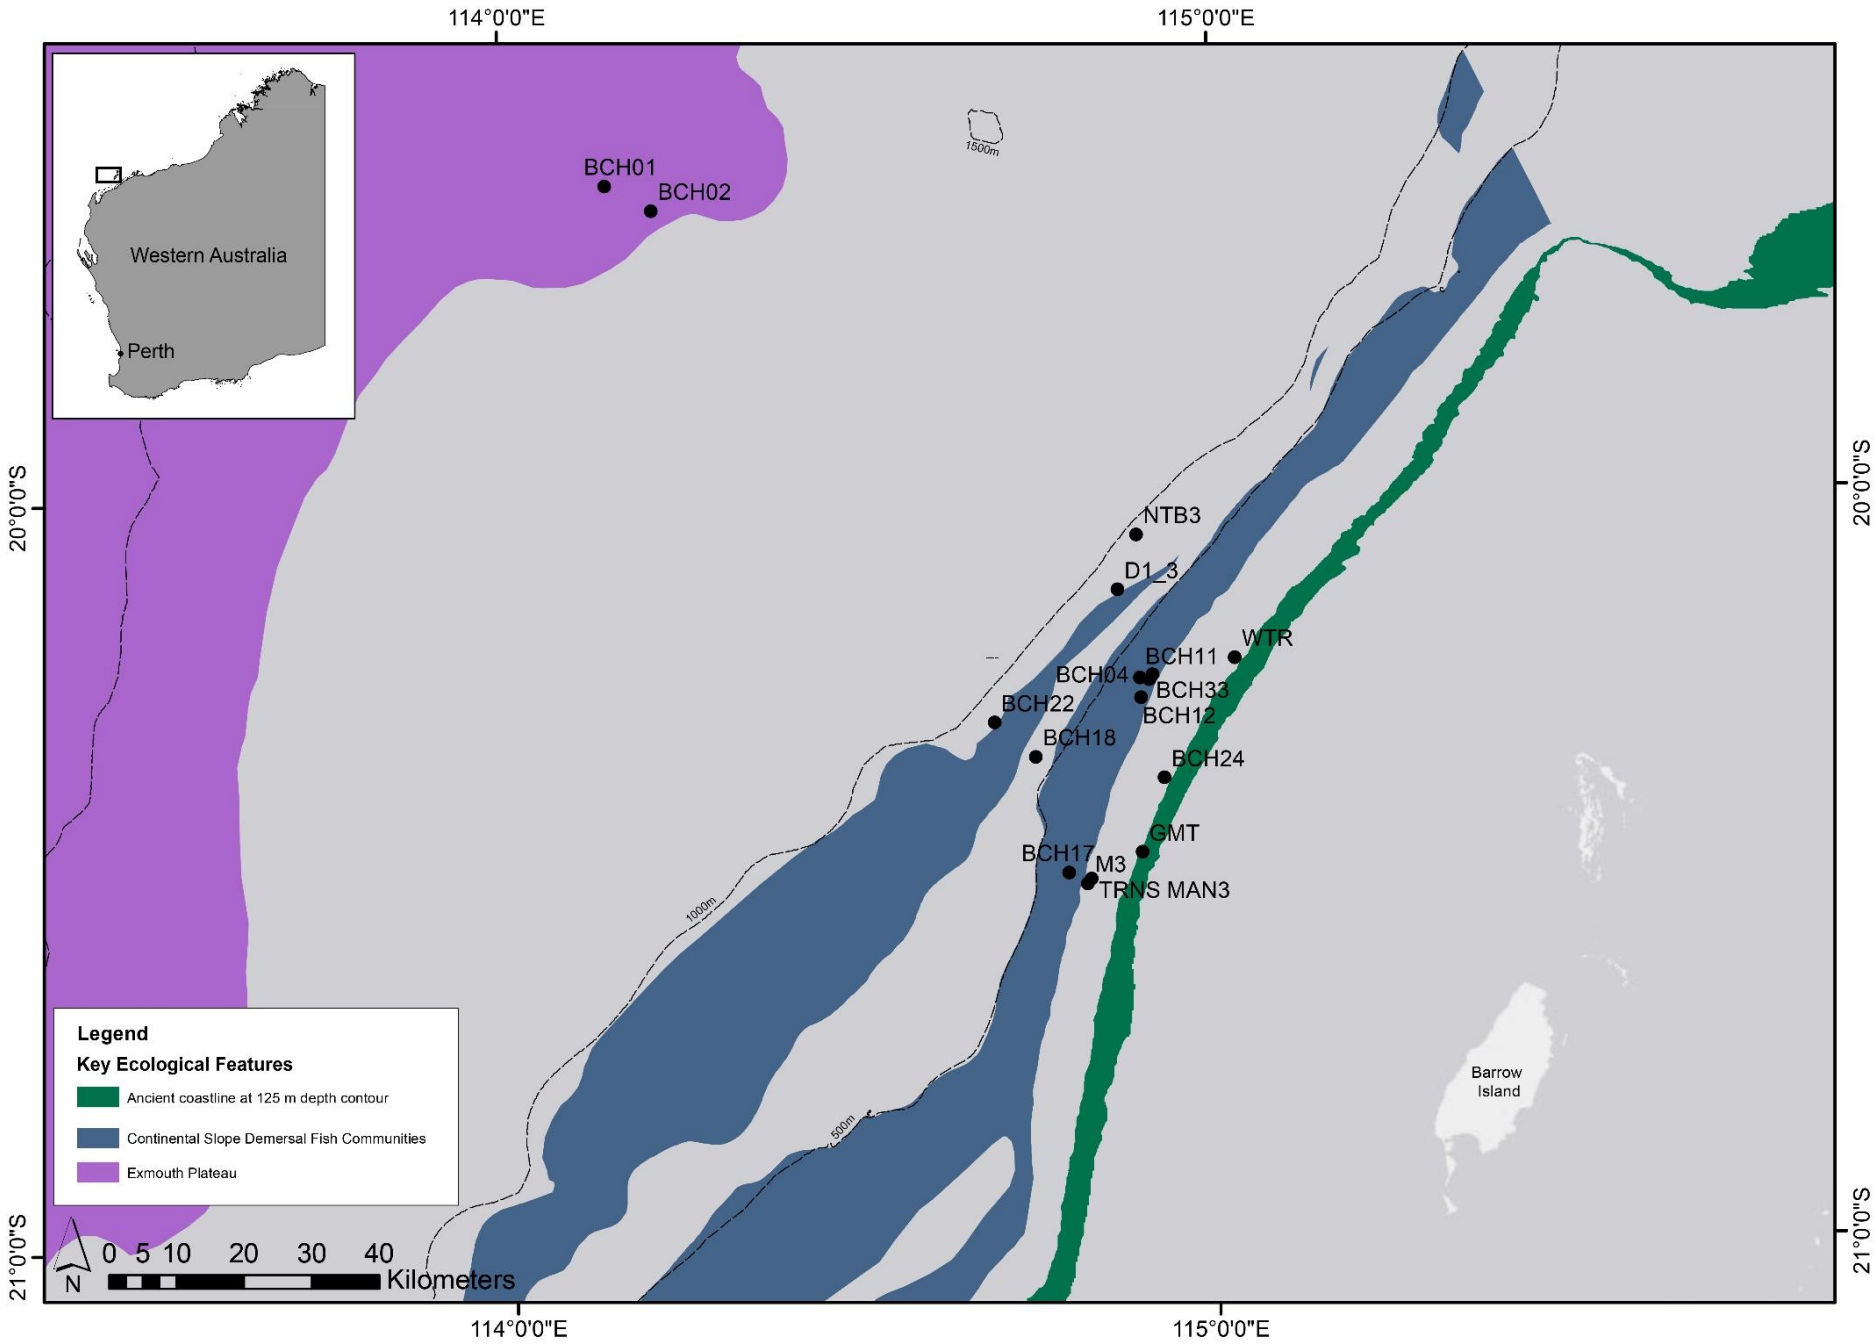

Figure 2. Context map illustrating the survey sites overlaid upon a map of the Key Ecological Features (KEFs) (Falkner et al., 2009). The inset illustrates the location of the study area off the coast of Western Australia.

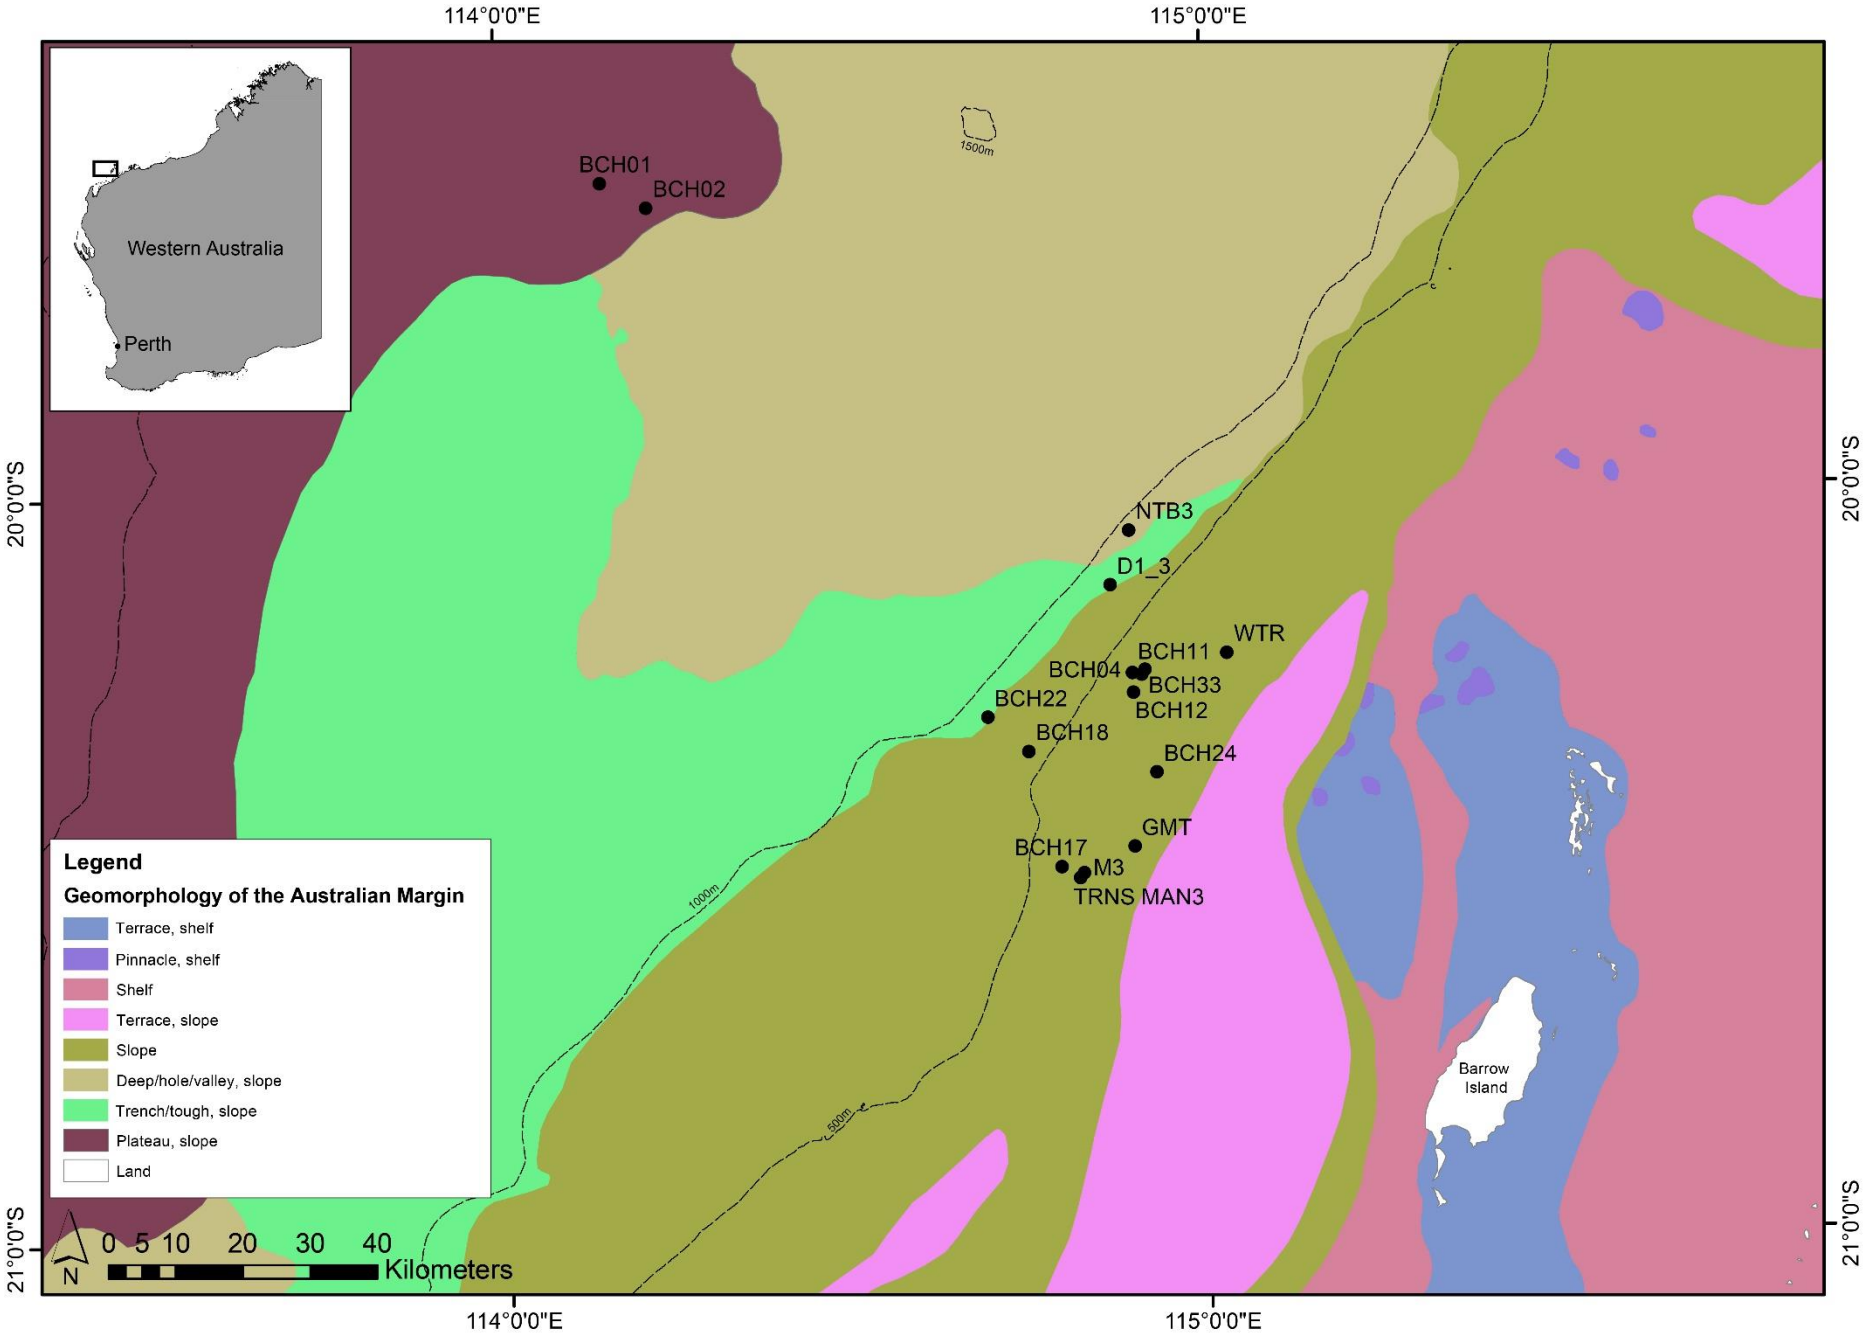

Figure 3. Context map illustrating the survey sites overlaid upon a map of the Geomorphology of the Australian Margin, or Geomorphic features (GFs) (Heap and Harris, 2008). The inset illustrates the location of the study area off the coast of Western Australia.

Video collection and analysis

Video transects were collected using a working class Remotely Operated Vehicle (ROV), fitted with a forward and slightly downward facing high definition video camera and flood lighting.

Video footage was analysed using the EventMeasure Stereo software (SeaGIS 2022). Identifications were made of fish, crustaceans and other mobile invertebrate species. An extensive reference library of images and videos in combination with taxonomic literature (for example Poore et al., 2008; Last & Stevens, 2009; Swainston, 2010; Flynn & Pogonoski, 2012) and online resources (for example Froese & Pauly, 2022; CSIRO, 2022) were used to aid species identification. In many cases identification to species level was not possible. In such cases species were identified to the lowest taxonomic resolution that was possible and the species was labelled with a descriptive annotation. In some cases, it was consistently difficult to observe identifying features, the taxa were very small, or the footage collected was not of a quality that allowed identification of taxa to a low taxonomic resolution. In these cases a conservative approach was taken and these were classified according to morphological descriptions. This was often the case for crustaceans and other mobile invertebrates. When identifying the decapod crustaceans, there were a number of species observed which could have been classified as either Dendrobranchiata (prawns) or Caridea (true shrimp). The only way to distinguish between this suborder and infraorder is by gill structure, which can't be inferred from the video. Therefore we took a conservative approach to identification and these decapod crustaceans are referred to as 'prawn' species differentiated by morphology, for example, Red prawn sp1. By taking this approach diversity could be measured, even where positive identification to low taxonomic level was not possible.

Using the EventMeasure software each fish or mobile invertebrate individual that was encountered along each transect was identified and counted following the principles outlined in Goetze et al. (2019). Where a fish could be positively identified as re-entering the field of view immediately after leaving the field of view it was not re-counted. However, in most cases each individual encountered was recorded.

Initial species identifications were made by analysts with experience in the identification of deep-water Australian fish and crustacean species. Identifications were made in a collaborative environment where difficult identifications could be discussed between analysts. Once analysed another experienced analyst made a secondary species identification check. As it was difficult to describe many of the organisms to a low taxonomic resolution, a particular emphasis was placed on consistent application of identifications and naming conventions.

Environmental situation.

The environmental situation was characterised from Conductivity, Temperature and Depth (CTD) data that were collected for most sites. For each transect site the CTD data for Salinity (PSU) and temperature (°C) were taken as the mean of the last minute (60 observations) of the CTD cast. If a CTD cast was not recorded at a specific site the values were taken from the nearest cast with the most similar depth (Appendix Table 1). The salinity, temperature and depth data were used to characterise the oceanographic conditions and identify the water mass in which each site was located following Woo and Pattiaratchi (2008).

Standardisation of transect length for statistical analysis.

The surveys conducted at each site were of varying transect lengths. To allow robust statistical analysis a standard transect length of 200 m was chosen. This transect length was selected as it is similar to the 250 m length used in similar surveys (Saunders et al., 2021) and only six of the transect sites had a sampled length that was less than 200 m. At transects sites with a sampled length that was less than

200 m the whole length of transect was used. These transect sites and their respective lengths are outlined in Table 1. Because so few transects were less than 200 m in length, and the length of most of these was close to 200 m no multiplication factor or standardisation factor was applied to the abundance data. This allowed the same statistical approach to be used for analysis of the abundance based data (fish/crustacean assemblage data, number of fish/crustaceans) and diversity data (number of fish/crustacean taxa).

Table 1. The transect sites with a total length of less than 200 m

Transect site	Transect length (m)
Chrysaor Central D1_3 T4	189
Dionysus NTB3 T2	112
Dionysus NTB3 T3	191
Gorgon GMT T2	198
Gorgon GMT T3	141
Gorgon GMT T4	172

At transect sites that had a length greater than 200 m, the first 200 m section of the transect were selected for statistical analysis. At sites where the length sampled was greater than 400 m the transect was broken up into multiple replicate 200 m lengths with a 10 m gap to separate transects. These transects sites and their respective number of replicate 200 m transects are listed in Table 2. This approach resulted in a total of 71 replicate transects across the survey area.

Statistical analysis

All statistical analysis was conducted using PRIMER version 7 (Clarke & Gorley 2015) and the PERMANOVA + add in for PRIMER (Anderson et al 2008). Fish and crustacean assemblage data were visually assessed for dominant taxa using shade plots. The data were transformed to reduce the influence of any single dominant taxa. Fish assemblage data was fourth root transformed, and the crustacean assemblage data were square root transformed for statistical analysis. A Bray-Curtis similarity matrix was constructed on the transformed data and this was used for further multivariate statistical analysis.

To investigate the effect of depth on the composition of the multivariate fish and crustacean assemblages a Distance based Linear Model (DistLM) was constructed. For this analysis depth was the explanatory variable, and the fish or crustacean assemblages were the dependent variables.

To address the three aims of the study three different statistical designs were used. These were to assess differences in the fish and crustacean assemblages among water masses, among the KEFs, and among the GFs. For each analysis site was nested within the factor of interest as a random factor. The replicate transects were allocated sites according to their location, Figure 3, Appendix Table 1). Transect Trans Man 3 was allocated to site M3 for statistical analysis as this transect was directly adjoining site M3 (Appendix Table 1).

The statistical designs for each test were:

Water Mass

Factor 1 Water Mass, Fixed, three levels; Tropical Surface Water (TSW), Southern Indian Central Water (SICW), Antarctic Intermediate Water (AAIW).

Factor 2 Site, Random, nested within Water Mass, varying levels depending upon replication

Key Ecological Features

Factor 1 KEF, Fixed, four levels; Ancient Coastline at 125 m depth contour, Continental Slope Demersal Fish Communities, Exmouth Plateau, and Outside any KEF.

Factor 2 Site, Random, nested within KEF, varying levels depending upon replication

Geomorphic Features

Factor 1 Geomorphic Feature, Fixed, four levels; slope, trench/trough, deep/hole/valley, plateau.

Factor 2 Site, Random, nested within Geomorphic Feature, varying levels depending upon replication

Non-metric Multidimensional Scaling (nMDS) plots were used to illustrate patterns in the fish and crustacean assemblages according to each of the factors of interest. Vectors were overlaid that illustrate the strength and direction of the Pearson's correlation of individual taxa to the data. Taxa with a correlation of greater than 0.5 are illustrated.

Post-hoc pairwise tests in PERMANOVA were done when statistically significant differences between levels of the factors of interest were detected. Post-hoc pairwise tests were also done where visual differences among means were apparent on the plots, or where the P value of the test for a factor of interest approached the convention of 0.05. This approach to testing for differences was taken following the precautionary principle because of the variable numbers of replicate samples between the levels of the factors of interest. Where the numbers of unique permutations was low Monte-Carlo (MC) bootstrapping was used to calculate the P value.

Univariate tests of the number of fish, number of fish taxa, number of crustaceans, and number of crustacean taxa were carried out according to the same statistical design. For these univariate tests the data were not transformed, and a Euclidean distance resemblance matrix was used. Plots of means and standard errors were used to illustrate patterns among the factors of interest.

3. Results

Environmental situation

The CTD data collected at sampling depth revealed three distinct temperature and salinity regimes (Figure 4). Following Woo and Pattiaratchi (2008) three water masses were identified through the relationship between temperature and salinity (Figure 4B). These were the same three water masses identified in Saunders et al. (2021). The shallowest sites, in water depths less than 150m, were characterised by high temperatures (~28 °C) and salinities of 35.3 PSU (Figure 4). This was identified as the Tropical Surface Water (TSW) water mass. The sites sampled in between 200 and 270 m water depth were characterised by a higher salinity (35.39 – 35.46 PSU) and a water temperature between 15 and 19 °C (Figure 4). These were classified as Southern Indian Central Water (SICW). The deepest sites, at 800 m or greater water depth had cold temperatures (less than 6 °C) and salinity less than 34.8 PSU (Figure 4). This was Antarctic Intermediate Water (AAIW) (Woo and Pattiaratchi, 2008).

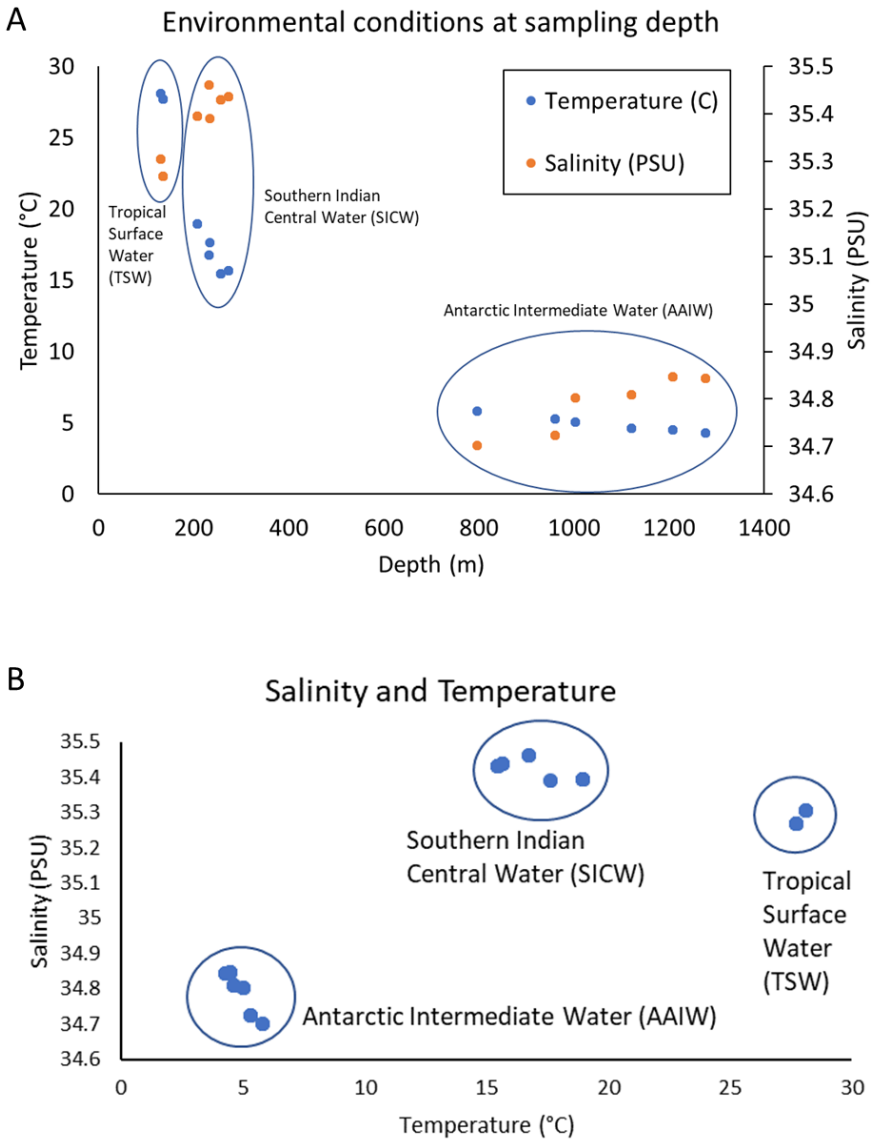

Figure 4. Environmental conditions at sampling depths. A illustrates the change in both Temperature and Salinity with depth. B illustrates the relationship between Salinity and Temperature. Circles indicate groupings of samples by the three identified water masses.

General descriptions of the survey areas

Key Ecological Feature (KEF)

Continental Slope Demersal Fish Communities

Within the Continental Slope Demersal Fish Communities KEF, a total of 4.11 km of transect was analysed, where 28 fish taxa were recorded with a total of 519 fish. The fish assemblage was dominated by Trevallies (Carangidae), with 4 species from 3 genera accounting for 271 of the individuals observed. The five most abundant fish taxa were *Decapterus* sp1, *Seriola dumerili*, an unidentified bait fish, *Decapterus kurroides,* and Synodontidae sp2 (Table 3). Five transect sites were located within the Continental Slope Demersal Fish Communities KEF. These were BCH04, BCH11, BCH12, BCH17, and BCH33. The transect length at these sites was 867 m, 932 m, 412 m, 1280 m, and 619 m respectively. At BCH04 the most abundant fish taxa were an unidentified bait fish, Synodontidae sp2, and *Decapterus* sp1, accounting for 82 of the 105 individuals recorded on the transect (Appendix Table 2). The most abundant taxa at BCH11 were *Seriola dumerili*, *Decapterus* sp1, and Synodontidae sp2, which accounted for over 93% of the total recorded individuals at the site (Appendix Table 2). *Decapterus* sp1 and Synodontidae sp2 were also the most abundant taxa at BCH17, whereas site BCH12 was dominated by *Decapterus kurroides* (Appendix Table 2). BCH33 had a large number of an unidentified anguilliform fish taxa and an abundance of Synodontidae sp3 and *Pristipomoides typus* (Appendix Table 2). Images of each of these most abundant fish taxa are presented in Appendix 1 Table 28.

Table 3. Most abundant fish taxa in the Continental Slope Demersal Fish Communities KEF transects

Family	Taxa	Number of individuals
Carangidae	*Decapterus kurroides*	63
	Decapterus sp1	103
	Seriola dumerili	91
Synodontidae	Synodontidae sp2	52
N/A	unidentified bait fish	69

Only two of the five sites in Continental Slope Demersal Fish Communities KEF recorded crustaceans; BCH04 and BCH17. At these sites, a total of 5 crustaceans were recorded, with each being different taxa. Two were from the infraorder Anomura, one from the infraorder Brachyura, one from the infraorder Achelata, and one unknown (Table 4). Images of the ten most abundant crustacean taxa across the survey area are presented in Appendix 1 Table 29.

Table 4. Crustacean taxa in the Continental Slope Demersal Fish Communities KEF transects

Infraorder	Family	Taxa	Number of individuals
Anomura	Galatheidae	Galatheidae sp. G	1
Brachyura	Homolidae	Homolidae spH	1
Achelata	Ibacinae	*Ibacus* spI	1
Anomura	Parapaguridae	Parapaguridae spPP	1
unknown	N/A	Red prawn sp7	1

Ancient Coastline at 125 m depth contour

The Ancient Coastline at 125 m depth contour KEF sites recorded 13 fish taxa with a total of 18,011 individuals along 1.03 km of transect. The fish assemblage was dominated by Trevallies (Carangidae), with three species representing 14,231 of the total individuals. The most abundant fish taxa were *Carangoides* sp1, an unidentified baitfish, *Seriola dumerili*, *Carcharhinus* sp1, and *Rachycentron canadum* (Table 5). The five transects which make up the Ancient Coastline at 125 m depth contour KEF were all located at the Gorgon GMT site, with transect lengths of 269 m, 198 m, 141 m, 172 m, and 247 m, respectively. At transect 1 (T1) the most abundant fish taxa were an unidentified baitfish species and *Carangoides* sp1 which together made up 3,451 of the 3,591 total observed number of fish (Appendix Table 2). *Carangoides* sp1 represented more than 95% of the total observed fish individuals in T2, with the next most abundant taxa being *Seriola dumerili* (Appendix Table 2). T3 and T5 were also dominated by *Carangoides* sp1, representing more than 94% and 97% of the total fish respectively, with *Seriola dumerili* as the next most abundant taxa in T3, and *Carcharhinus* sp1 in T5 (Appendix Table 2). *Carangoides* sp1 was also the most abundant taxa in T4, with unidentified bait fish the second most abundant taxa recorded in the transect (Appendix Table 2). Images of each of these most abundant fish taxa are presented in Appendix 1 Table 28.

Table 5. Most abundant fish taxa in the Ancient Coastline at 125m depth contour KEF transects

Family	Taxa	Number of individuals
Carangidae	*Carangoides* sp1	13,835
	Seriola dumerili	381
Carcharhinidae	*Carcharhinus* sp1	189
Rachycentridae	*Rachycentron canadum*	45
N/A	unidentified baitfish	3,454

Only one crustacean was recorded in the Ancient Coastline at 125m depth contour KEF, at the Gorgon GMT T1 site; an unidentified prawn species (Appendix Table 3).

Exmouth Plateau

The Exmouth Plateau KEF was represented by two sites; BCH01 and BCH02, which recorded a total of 165 individuals from 14 taxa in 2.57 km of transect. The lengths of the transect at each site were 1437 m and 1129 m respectively. The fish assemblage was dominated by an unidentified anguilliform fish and *Bathypterois* sp1, together representing over 65% of the total number of individual fish recorded. Other abundant taxa included *Aldrovandia* sp1, *Aldrovandia* sp2, and Macrouridae sp2 (Table 6). At BCH01, *Bathypterois* sp1 was the most abundant taxa with 30 of the total 73 individual fish, with the second most abundant taxa being an unidentified anguilliform fish (Appendix Table 2). The same two taxa were also the most abundant at the BCH02 site, but the unidentified anguilliform fish was by far the most dominant, representing almost 60% of the total recorded individual fish for the transect (Appendix Table 2). Images of each of these most abundant fish taxa are presented in Appendix 1 Table 28.

Table 6. Most abundant fish taxa in the Exmouth Plateau KEF transects

Family	Taxa	Number of individuals
N/A	unidentified anguilliform fish	70
Ipnopidae	*Bathypterois* sp1	38
Halosauridae	*Aldrovandia* sp1	11
	Aldrovandia sp2	7
Macrouridae	Macrouridae sp2	8

The crustacean assemblage for the Exmouth Plateau KEF consisted of seven taxa with a total of 228 individuals recorded. Red prawn sp7 was the most dominant crustacean taxa representing over 81% of the total number of individuals. The next most abundant species was pink prawn sp9 and orange prawn sp8 (Table 7). At BCH01, red prawn sp7 dominated the site with 107 of the recorded 128 total individuals, with pink prawn sp9 the next most abundant taxa with 9 individuals (Appendix Table 3). Similarly, red prawn sp7 and pink prawn sp9 at BCH02 accounted for 78% and 14% of the total number of individuals recorded respectively (Appendix Table 3). Images of the ten most abundant crustacean taxa across the survey area are presented in Appendix 1 Table 29.

Table 7. Most abundant crustacean taxa in the Exmouth Plateau KEF transects

Taxa	Number of individuals
Red prawn sp7	185
Pink prawn sp9	23
Orange Prawn sp8	9

Sites outside the KEFs

There were 21 sites outside of the KEF areas, with a total of 9.05 km of transect analysed, with transect lengths ranging from 112 m to 1242 m (Table 8). These sites recorded a total of 15,828 individual fish from 41 taxa. The five most abundant taxa from these sites were *Trachurus novaezelandiae, Seriola dumerili,* an unidentified baitfish species, an unidentified anguilliform fish species, and *Carcharhinus* sp1 (Table 9). 11,007 of the total individual fish were recorded at the BCH24 site, which was dominated by *Trachurus novaezelandiae* (78% of total individuals) and an unidentified baitfish species (21% of total individuals; Appendix Table 3). The Gorgon M3 sites were dominated by *Seriola dumerili* (99% of total individuals), whereas the WTR DC-1 sites had a high abundance of the unidentified baitfish species and *Trachurus novaezelandiae* (Appendix Table 2). Site BCH18 had an unidentified anguilliform fish species as its most abundant taxa, followed by Macrouridae sp2, while the TRNS MAN3 to T3 transect was dominated by *Seriola dumerili* (Appendix Table 2). The other sites (BCH22, Chrysaor Central D1_3 transects and Dionysus NTB3 transects) are summarised in their Geomorphic Feature (GF) sections. Images of each of these most abundant fish taxa are presented in Appendix 1 Table 28.

Table 9. Most abundant fish taxa in the sites outside of the KEF areas

Family	Taxa	Number of individuals
Carangidae	*Trachurus novaezelandiae*	8720
	Seriola dumerili	3858
Carcharhinidae	*Carcharhinus* sp1	101
N/A	unidentified baitfish	2685
N/A	unidentified anguilliform fish	155

Crustaceans were recorded in half of the sites outside the KEF areas; BCH18 and BCH22, the Chrysaor Central D1_3 transects, the Dionysus NTB3 transects, and at WTR DC-1 T1. A total of 694 individuals were recorded from 12 taxa, with all sites dominated by red prawn sp7 (Appendix Table 3). Red prawn sp7 accounted for 122 of the 143 total individuals observed on the BCH18 transect, whereas at WTR DC-1 T1 there was only one crustacean recorded; an unidentified prawn species (Appendix Table 3). The crustacean assemblages at the other sites (the Chrysaor Central D1_3 transects and the Dionysus NTB3 transects) are summarised in the GF section below.

General descriptions of the survey areas.

Geomorphic Feature (GF)

Deep/hole/valley

In the Deep/hole/valley GF there were 16 fish taxa and a total of 187 individuals recorded from 1.26 km of transect. The fish assemblage was dominated by an unidentified anguilliform fish species, representing 54% of the individuals observed. The next most abundant taxa were *Aldrovandia* sp1, followed by Macrouridae sp1, *Aldrovandia* sp2, and *Aldrovandia affinis* (Table 10). The four transects which make up the Deep/hole/valley GF were all located at the Dionysus NTB3 site. The first transect (T1) was dominated by the unidentified anguilliform fish species, accounting for 48 of the 70 recorded individuals (Appendix Table 2). This was similar for T2 and T4, with the unidentified anguilliform fish species most abundant in both transects and the 3 *Aldrovandia* species accounting for the vast majority of the remaining taxa recorded (Appendix Table 2). T3 again had the unidentified anguilliform fish as the most abundant taxa but was followed by Macrouridae sp1 and *Aldrovandia* sp1 (Appendix Table 2). Images of each of these most abundant fish taxa are presented in Appendix 1 Table 28.

Table 10. Most abundant fish taxa in the Deep/hole/valley GF transects

Family	Taxa	Number of individuals
N/A	unidentified anguilliform fish	101
Halosauridae	*Aldrovandia* sp1	19
	Aldrovandia sp2	8
	Aldrovandia affinis	7
Macrouridae	Macrouridae sp2	11

The crustacean assemblage in the Deep/hole/valley GF consisted of 110 individuals recorded from four taxa. The assemblage was dominated by red prawn sp7 which accounted for almost 71% of the total individuals across the sites (Table 11). The first transect (T1) had the highest number of individuals recorded, with the red prawn species as the most abundant taxa, representing 71% of the total number of individuals, with orange prawn sp8 as the next most abundant taxa (Appendix Table 3). T2 and T3 also had red prawn sp7 as the most abundant taxa, representing 83% and 71% of total individuals respectively, and both had a second red prawn, sp11 as the next most abundant taxa (Appendix Table 3). Red prawn sp7 again was the most abundant taxa in T4, followed by orange prawn sp8 and a second red prawn sp11 (Appendix Table 3).

Table 11. Crustacean taxa in the Deep/hole/valley GF transects

Taxa	Number of individuals
Red prawn sp7	78
Red prawn sp11	16
Orange prawn sp8	14
Pink prawn sp9	2

Slope

The Slope GF was made up of 22 sites with a total of 10.78 km of transect analysed, where 51 fish taxa were recorded with a total of 34,042 individuals. The fish assemblage was dominated by Trevallies (Carangidae) with 27,086 individuals from seven taxa. The five most abundant species were *Carangoides* sp1, *Trachurus novaezelandiae*, *Seriola dumerili*, an unidentified baitfish species, and *Carcharhinus* sp1, which together accounted for 98% of the total individuals (Table 12). The 22 sites in the Slope GF were BCH04, BCH11, BCH12, BCH17, BCH18, BCH24 and BCH33, the 5 Gorgon GMT transects, the 5 Gorgon M3 transects, the 4 WTR DC-1 transects, and the TRNS MAN3 to T3 site. Images of each of these most abundant fish taxa are presented in Appendix 1 Table 28.

Table 12. Most abundant fish taxa in the Slope GF transects

Family	Taxa	Number of individuals
Carangidae	*Carangoides* sp1	13,835
	Trachurus novaezelandiae	8,720
	Seriola dumerili	4,330
Carcharhinidae	*Carcharhinus* sp1	290
N/A	unidentified baitfish	6,208

Only five sites in the Slope GF contained crustaceans; BCH04, BCH17, BCH18 Gorgon GMT T1, and WTR DC-1 T1. The crustacean assemblage consisted of 150 individuals recorded from 11 taxa. Of these, 143 (95% of the total individuals) crustaceans were recorded from the BCH18 transect, which was dominated by two red prawn species, red prawn sp7 and red prawn sp11 (Appendix Table 3).

Plateau

The plateau GF contains the same two sites as the Exmouth plateau KEF (BCH01 and BCH02), so the fish and crustacean assemblages for this GF have been summarised above.

Trench/Trough

The Trench/Trough GF contained 129 individual fish from 17 taxa, recorded from 2.15 km of transect. The fish assemblage was distinguished by Macrouridae species, Halosauridae species, and an unidentified anguilliform species, which accounted for almost 88% of the total recorded individuals. The five most abundant taxa were the unidentified anguilliform species, *Aldrovandia* sp1, Macrouridae sp1, Macrouridae sp2, and Macrouridae sp4 (Table 13). Five transect sites were located in the Trench/Trough GF; BCH22 and the four Chrysaor Central D1_3 transects. Of the total individual fish, 70 were recorded at the BCH22 site, where the most abundant taxa was *Aldrovandia* sp1, followed by Macrouridae sp2 (Appendix Table 2). At the Chrysaor Central D1_3 sites, each transect had 9-18 total individual fish recorded, with the unidentified anguilliform species being the most abundant taxa for each site (Appendix Table 2). Images of each of these most abundant fish taxa are presented in Appendix 1 Table 28.

Table 13. Most abundant fish taxa in the Trench/Trough GF transects

Family	Taxa	Number of individuals
N/A	unidentified anguilliform fish	39
Halosauridae	*Aldrovandia* sp1	18
Macrouridae	Macrouridae sp1	7
	Macrouridae sp2	17
	Macrouridae sp4	17

The crustacean assemblage in the Trench/Trough GF consisted of eight taxa with 440 total individuals recorded. The assemblage was dominated by red prawn sp7, which made up almost 85% of the total individuals. The other abundant crustacean species included a dark prawn species (Dark prawn sp10), red prawn sp11, orange prawn sp8, and pink prawn sp9 (Table 14). Of the recorded crustaceans, 312 were found at the BCH22 site, which had red prawn sp7 as the most abundant taxa, representing almost 87% of the total individuals on that transect (Appendix Table 3). At the Chrysaor Central D1_3 sites T1-T4, the same red prawn species was also the most abundant taxa for each transect, representing 80%, 72%, 89%, and 75% of the total number of individuals on each respective transect (Appendix Table 3).

Table 14. Crustacean taxa in the Trench/Trough GF transects

Taxa	Number of individuals
Red prawn sp7	373
Dark prawn sp10	35
Red prawn sp11	12
Orange prawn sp8	10
Pink prawn sp9	6

Invertebrates

A total of 1,093 invertebrate individuals from 31 taxa were recorded across all sites. The invertebrate assemblage included 1 feather star (Cormatulida) species, 7 jellyfish (Scyphozoa) species, 7 sea cucumber (Holothuroidea) species, 8 sea star (Asteroidea) species, 7 sea urchin (Echinoidea) species and 1 squid (Cephlapod) species (Appendix Table 4). The assemblage was dominated by a brown jellyfish species (spJB) which accounted for 54% of the total number of individuals and were almost all recorded at site BCH22 (Appendix Table 4). The next most abundant taxa were *Peniagone* spPG, a purple sea cucumber species, Phormosomatidae spPH, and a purple sea urchin species (Table 15). Images of the ten most abundant invertebrate taxa are presented in Appendix 1 Table 30.

Table 15. Most abundant invertebrate taxa across all sites

Family	Taxa	Number of individuals
N/A	Brown jellyfish spJB	590
Elpidiidae	*Peniagone* spPG	83
N/A	Purple sea cucumber spSCP	64
Phormosomatidae	Phormosomatidae spPH	63
N/A	Purple sea urchin spSUBP	55

Statistical analysis

Fish assemblage

Across the whole survey area depth was an important predictor of the multivariate composition of the fish assemblage. A DistLM analysis found that depth alone explained 27% of the variation in the fish assemblage composition. (R^2 = 0.27177, Pseudo $F_{(1,69)}$ = 25.751, P<0.001).

Tests of differences in fish assemblage composition between water masses.

There was a significant difference in the fish assemblages of each of the three water masses (Table 16, Figure 5). The deeper water fish assemblages of the AAIW mass were different to the shallower water fish assemblages in both the SICW and the TSW water masses (Table 17). While some species were shared, the fish assemblage composition of the SICW and the TSW were also significantly different to one another (Table 19). The deeper waters of the AAIW were characterised by species that were correlated toward the left of the nMDS plot (Figure 5). These taxa included two *Aldrovandia* spp. (Halosauridae), a Macrouridae species, a species of Unidentified anguilliform fish, and a *Bathypterois* species (Ipnopidae). The fish assemblages of the TSW were separated from those of the SICW by a greater abundance of *Trachurus novaezelandiae* (Carangidae), an unidentified bait fish, and whaler shark *Carcharhinus* sp1 (Figure 5). The SICW water mass was characterised by a high abundance of *Seriola dumerilii* (Carangidae) and *Carcharhinus plumbeus*.

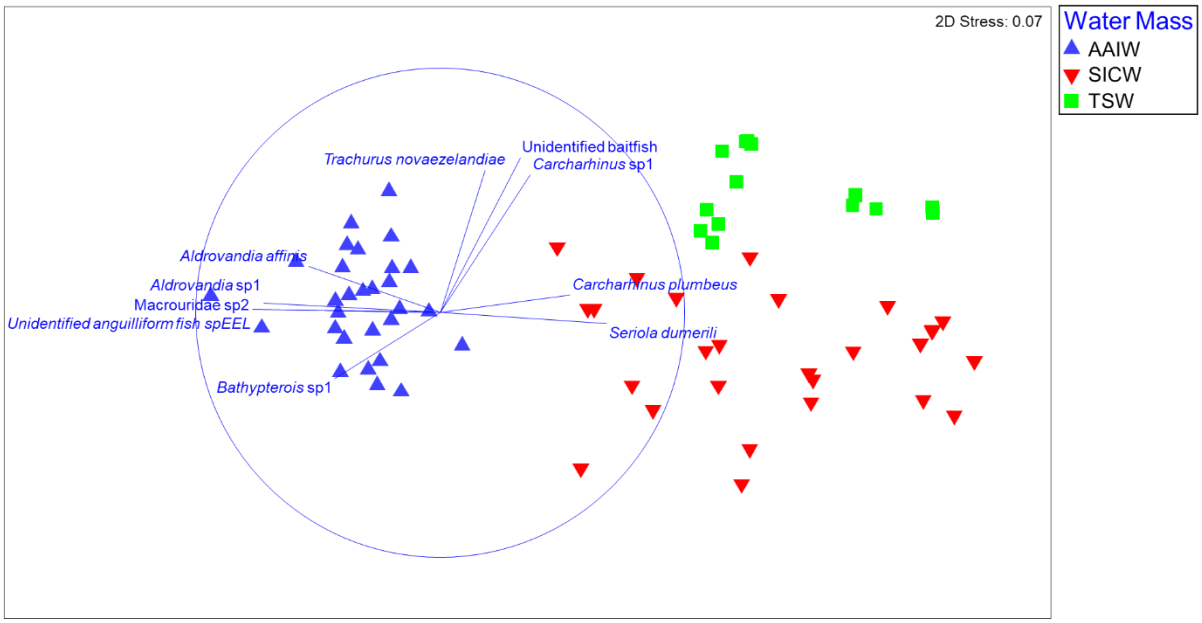

Figure 5. Non-metric Multidimensional Scaling Plot illustrating the difference in the multivariate composition of the fish assemblages among the Antarctic Intermediate Water (AAIW), Southern Indian Central Water (SICW) and Tropical Surface Water (TSW) masses. The length and direction of the vectors illustrated in blue indicates the strength and direction of the correlation of the named taxa to the data.

Table 17. Post-hoc pairwise tests for differences in the multivariate Fish Assemblage composition between water masses. Statistically significant contrasts at α=0.05 are highlighted in bold.

Fish assemblage post-hoc comparisons between water masses			
Groups	t	P(perm)	perms
AAIW, SICW	2.79	**0.002**	9921
AAIW, TSW	2.93	**0.006**	8939
SICW, TSW	1.43	**0.040**	9435

The mean number of fish per transect was much greater in the TSW mass than in either the SICW or the AIW masses (Figure 6). Despite this, there was no statistically significant difference in the mean number of fish taxa per transect between water masses (Figure 7). On average each transect had between four and six fish taxa.

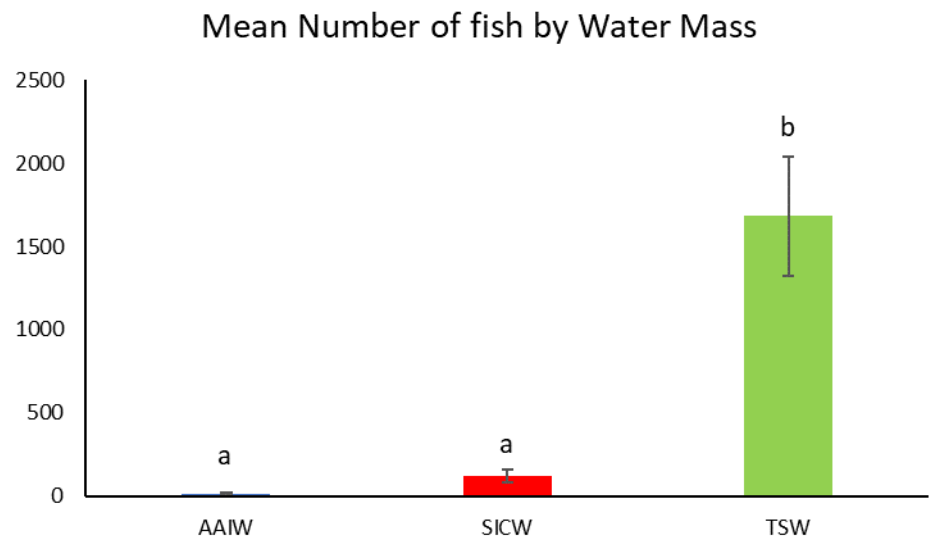

Figure 6. The mean (+- 1SE) number of fish per transcent within each water mass. Letters above bars indicate statistically similar means at α = 0.05.

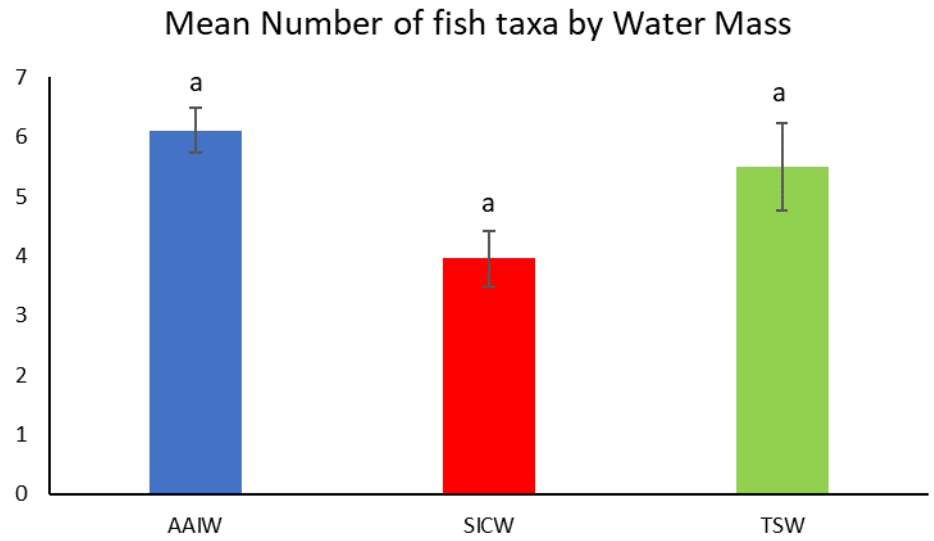

Figure 7. The mean (+- 1SE) number of fish taxa per transcent within each water mass. Letters above bars indicate statistically similar means at α = 0.05.

Tests of differences in Fish assemblages among Key Ecological Features

There was a significant difference in the composition of the multivariate fish assemblage among the KEFs (Table 18). The fish assemblages of the Continental Slope Demersal Fish Communities KEF was different to those found at the Exmouth Plateau KEF and outside any KEFs (Table 19). This difference was driven by a number of fish species that were correlated toward the left of the nMDS plot (Figure 8a) in the direction of the deeper water samples from the Exmouth Plateau KEF and areas outside any KEF. These taxa included two *Aldrovandia* spp. (Halosauridae), a Macrouridae species, a species of Unidentified anguilliform fish, and a *Bathypterois* (Ipnopidae) species.

There was no statistically significant difference in the total number of fish among KEFs (Table 18). However, the P value of 0.054 is very close to the convention of α = 0.05, so post-hoc pairwise tests on the KEFs were done to confirm whether any differences did exist between KEFs. There was a much greater mean number of fish per transect at the Ancient Coastline at 125m depth contour KEF than at any of the other KEFs (Figure 9). In contrast, there was no statistically significant difference in the mean number of fish taxa between KEFs. Similar numbers of fish taxa were recorded at each KEF (Figure 10).

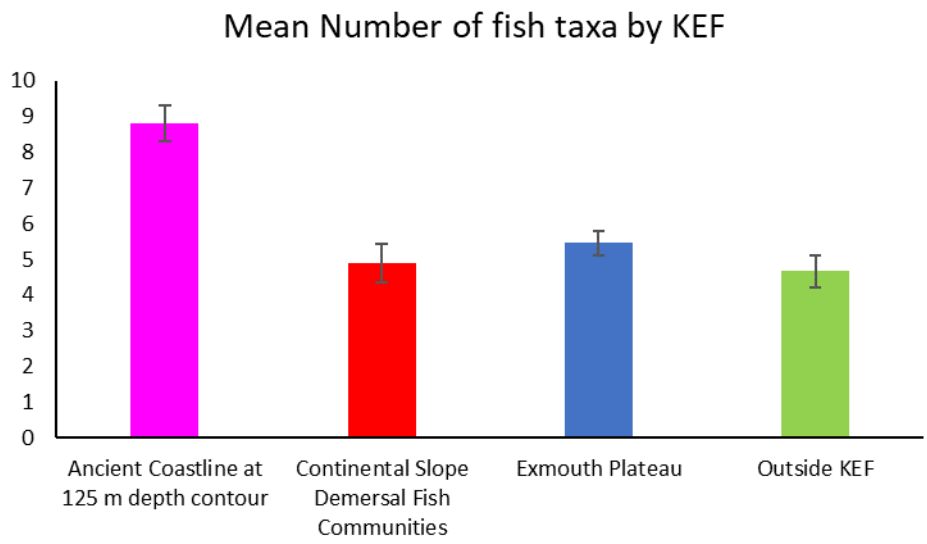

Figure 10. The mean (+- 1SE) number of fish taxa per transect within each Key Ecological Feature (KEF).

Tests of differences in Fish assemblages among Geomorphic Features

There was a significant difference in the composition of the multivariate fish assemblage among the GFs (Table 20Table 18). The fish assemblage of the slope GF was different to the plateau GF and the trench / trough GF (Table 21). This difference was driven by a number of fish species that were correlated toward the right of the nMDS plot (Figure 8b) in the direction of the shallower water slope samples. These taxa included *Trachurus novaezelandiae* (Carangidae), Unidentified baitfish, *Carcharhinus* sp1, *Carcharhinus plumbeus* (Carcharhinidae), and *Seriola dumerilii* (Carangidae) (Figure 8b).

There was no statistically significant difference in the total number of fish or the number of fish taxa per transect among GFs (Table 20). Qualitatively, the mean number of fish appeared higher on the slope GF than any other GFs (Figure 11), but there was a lot of variation in the number of fish associated with the slope among samples which is indicated by the large error bar (Figure 11). There was a similar number of fish taxa recorded among the GFs (Figure 12).

Crustaceans

Across the whole survey area depth was a very important predictor of the multivariate composition of the crustacean assemblage. A DistLM analysis found that depth alone explained 73% of the variation in the crustacean assemblage composition (R^2 = 0.72716, Pseudo $F_{(1,69)}$ = 183.9, P<0.001).

Tests of differences in crustacean assemblage composition between water masses.

There was a significant difference in the crustacean assemblages of the three water masses (Figure 13, Table 22). Crustaceans were predominantly found in the deeper AAIW mass, and so the crustacean assemblage here was different to the shallower water SICW and the TSW water masses, which were not significantly different (Table 23). The abundance of all crustacean species was greater in the

deeper waters of the AAIW, and correlated toward the right side of the nMDS plot (Figure 13). The most strongly correlated taxa were all prawns (Figure 13).

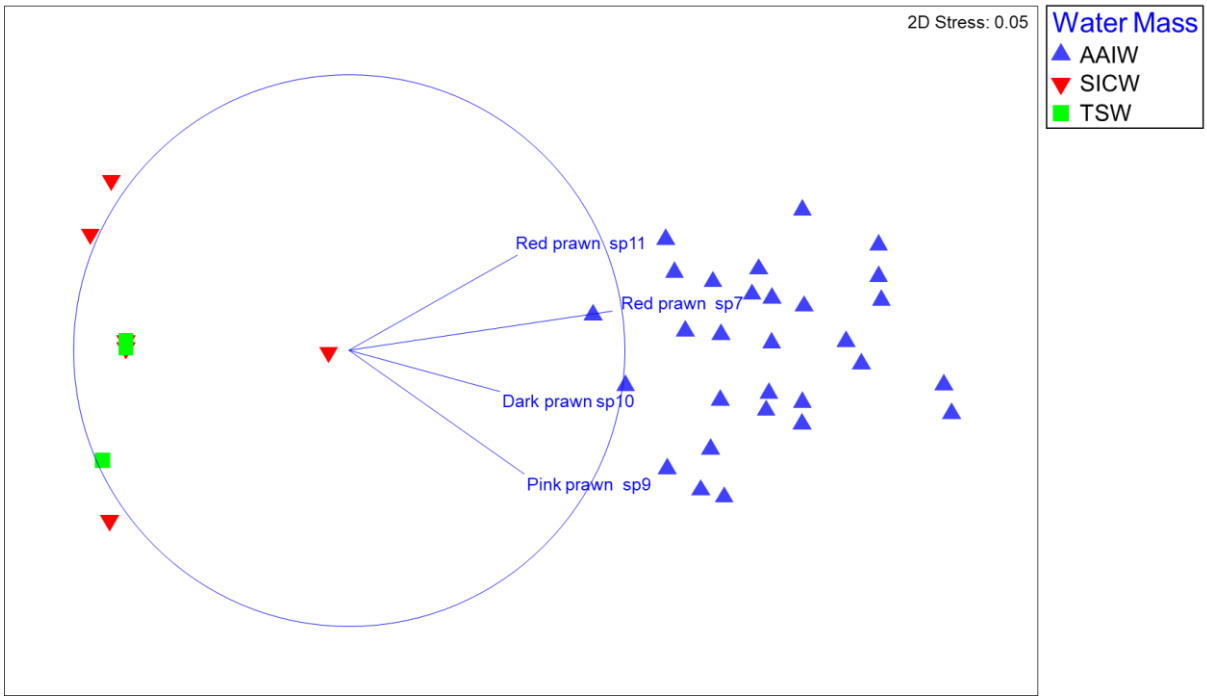

Figure 13. Non-metric Multidimensional Scaling Plot illustrating the difference in the multivariate composition of the crustacean assemblages among water masses. The length and direction of the vectors illustrated in blue indicates the strength and direction of the correlation of the named taxa to the data.

AAIW, TSW	6.08	**0.005**	8828
SICW, TSW	1.51	0.058	1193

The mean number of crustaceans, and the mean number of crustacean taxa were both significantly greater in the Antarctic Intermediate Water mass than either the Southern Indian Central or the Tropical Surface water masses (Table 22, Figure 14, Figure 15.). There was an average of 27 individual crustaceans and 3 crustacean taxa per transect in the AAIW water mass. The number of crustaceans and the number of crustacean taxa were similarly low in both the AAIW and the TSW water masses (Figure 14, Figure 15)

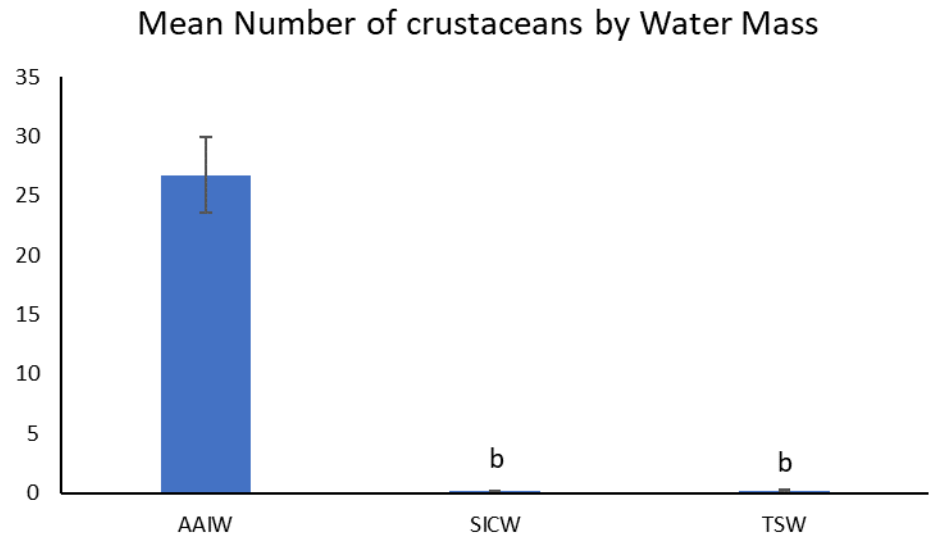

Figure 14. The mean (+- 1SE) number of crustaceans per transect within each water mass. Letters above bars indicate statistically similar means at α = 0.05.

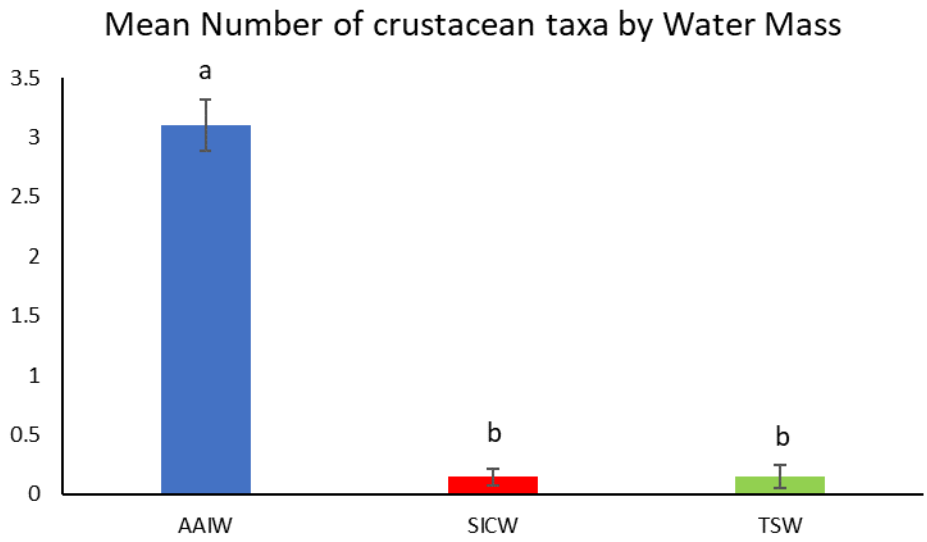

Figure 15. The mean (+- 1SE) number of crustacean taxa per transect within each water mass. Letters above bars indicate statistically similar means at α = 0.05.

Tests of differences in Crustacean assemblages among Key Ecological Features

There was not a statistically significant difference in the composition of the multivariate crustacean assemblage among the KEFs (Table 24). However, the P value of 0.057 is very close to the convention of α = 0.05, so post-hoc pairwise tests on the KEFs were done to confirm whether any differences did exist (Table 25). The crustacean assemblage of the Exmouth Plateau KEF was significantly different to that of the Continental Slope Demersal Fish Communities KEF and the Ancient Coastline at 125 m depth contour KEF (Table 25). The crustacean assemblage of the Continental Slope Demersal Fish Communities KEF was also different to the crustacean assemblage at areas Outside any KEF. These differences were driven by the crustacean taxa that were all correlated toward the right of the nMDS plot (Figure 16Figure 8a) in the direction of the deeper water samples from the Exmouth Plateau KEF and deeper areas outside any KEF. These taxa were all Prawn taxa.

There was no overall statistically significant difference in the total number of crustaceans among GFs (Table 24). However, qualitatively there was a greater number of crustaceans and crustacean taxa at the Exmouth Plateau and Outside KEFs than elsewhere. So post-hoc pairwise tests on the KEFs were done to confirm whether any differences did exist between KEFs.

There was a greater mean number of crustaceans, and a greater mean number of crustacean taxa at the Exmouth Plateau KEF than at the Ancient Coastline and Continental Slope Demersal Fish Communities KEFs (Figure 17, Figure 18). The mean number of crustaceans and number of crustacean taxa per transect Outside any KEF was also high, and statistically similar to the Exmouth Plateau KEF (Figure 17, Figure 18). However, there was variability within the Outside KEF samples, and the mean number of crustaceans was statistically similar to the mean number of crustaceans within the Ancient Coastline KEF (Figure 17). Similarly, the mean number of crustacean taxa Outside KEF was statistically similar to the number of crustacean taxa at both the Ancient Coastline and Continental Slope Demersal Fish KEFs (Figure 17, Figure 18).

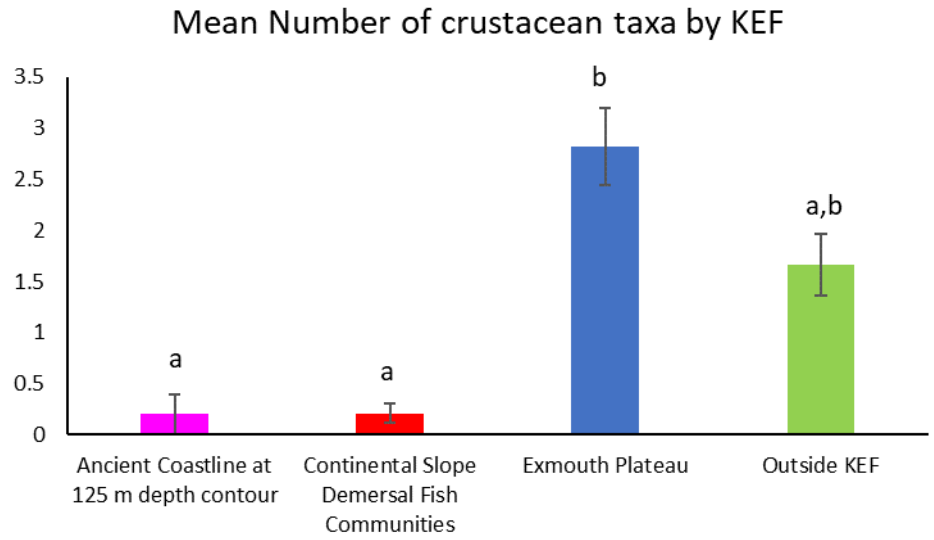

Figure 18. The mean (+- 1SE) number of crustacean taxa per transect within each Key Ecological Feature. Letters above bars indicate statistically similar means at α = 0.05.

Tests of differences in Crustacean assemblages among Geomorphic Features

There was a significant difference in the composition of the multivariate crustacean assemblage among the GFs (Table 26Table 20Table 18). The crustacean assemblage of the slope GF was different to the plateau GF, the trench / trough GF, and the Deep / hole / valley GF (Table 27). The crustacean assemblages of the plateau GF, the trench / trough GF, and the Deep / hole / valley GF were statistically similar (Table 27). The difference between the slope GF and the other GFs was driven by the crustacean taxa that were all correlated toward the right of the nMDS plot (Figure 16Figure 8b) in the direction of the deeper water samples and away from the shallower water samples of the slope GF.

There was no statistically significant difference in the total number of crustaceans per transect among GFs (Table 26). Qualitatively, the mean number of crustaceans appeared lowest on the slope GF and highest at the trench / trough GFs (Figure 19). Post-hoc pairwise tests confirmed that the mean number of crustaceans per transect was higher in the trench / trough GF than the slope GF (Figure 19). However, these were both statistically similar to the deep / hole / valley GF and the plateau GFs (Figure 19).

There was a statistically significant difference in the mean number of crustacean taxa per transect among the GFs (Table 26, Figure 20). The number of crustacean taxa at the trench / trough GF was higher than at the plateau or slope GFs (Figure 20). The number of crustacean taxa per transect in the plateau GF was also greater than at the slope GF (Figure 20). The mean number of crustacean taxa per transect at the deep / hole / valley GF was statistically similar to all the other GFs (Figure 20).

Table 26. Results of multivariate and univariate PERMANOVA tests for differences among Geomorphic Features (GFs) for the Crustacean Assemblage, the Total Number of Crustacean, and the Number of Crustacean Taxa.

Crustacean assemblage

4. Discussion

Distinct fish and crustacean assemblages were recorded across the survey area. These were strongly influenced by water depth, and the three water masses that were identified. Most notably, almost all crustaceans and crustacean taxa were recorded at the deeper sites in the AAIW mass. There was also a clear distinction in the fish assemblages, with the deeper sites being characterised by Macrouridae (rat tails), Halosauridae (halosaurs) and unidentified anguilliform (eel like) fishes. The shallower sites of the TSW mass and the Ancient Coastline at 125 m contour KEF were characterised by sharks and Carangidae such as *Trachurus novaezelandiae* (yellowtail scad). These shallower areas had a much greater number of fish recorded than elsewhere, with a mean of 3,000 fish per transect in the Ancient Coastline at 125 m contour KEF, and 1,700 fish per transect across all sites in the TSW. The fish assemblages of the deeper continental slope were also dominated by Carangidae, but here different taxa including two species of scad, *Decapterus kurroides* and *Decapterus* sp1, and *Seriola dumerili* (amberjack) were recorded. This zone was characterised by the SICW mass and included the slope GF and the Continental Slope Demersal Fish Communities KEF. Although there were large differences in the number of fish observed across the survey area among water masses, KEFs and GFs, the average diversity of fishes remained consistent across the survey area. While the deeper sites had lower numbers of fishes, the number of fish taxa was the same as at the shallower sites.

There were differences in patterns of assemblage composition, abundance and number of taxa in both the fish and crustaceans sampled that were associated with the deeper waters of greater than 800 m depth and the AAIW mass. A similar pattern was described by Saunders et al. (2021) and has previously been reported (Last et al., 2011). This faunal break can be attributed to the influence of the AAIW (Williams et al., 2001). This deep-water current is cold and has a lower salinity than the shallower water masses identified in this survey. The AAIW has a strong influence on the distribution of fish communities in the south-west region between the Great Australian Bight and north of the Ningaloo Reef. The depth of the AAIW fluctuates from 875 m at 27.50°S to 520 m around 21.50°S (Williams et al., 1996; 2001; Woo and Pattiaratchi, 2008). There was a break in the water depth of the samples collected during this survey, with no samples collected between 280 and 800 m water depth. Therefore the transition zone between water masses could not be identified. A recent survey in a similar area covered water depths between 360 and 870 m and identified that a similar faunal break occurred between 700 and 800 m water depth (Saunders et al., 2021). A break between mid-slope and shelf-break fish assemblages at water depths of between 700 and 900 m was also reported by Williams et al. (2001) in the northern area of their survey, which is a similar location to this one.

There were some limitations associated with the survey method that are likely to have influenced the fish and crustacean data that was recorded. The identification of many of the individuals observed was difficult because of the small size, distance from the camera, and the slight downward facing camera angle. For this reason, a conservative approach was taken where there was uncertainty in the identification, and many taxa were pooled to higher taxonomic groups. In particular, the group of unidentified anguilliform fishes and unidentified baitfish are likely to include multiple taxa. This could be partially mitigated by mounting video cameras lower down on the ROV platform, and facing directly forward, although this set up was used in Saunders et al. (2021) and similar issues with identification were encountered. In addition, some of the shallower sites sampled had very high abundances of fish, particularly *Decapterus* spp. (scads). Following the established procedure (Goetze et al., 2019) all fish encountered along a transect were counted, unless they could be positively identified as having been already counted, and to have re-entered the transect. Therefore, it's possible that the abundances of these species may be inflated due to re-counts of the same individual. With a single video camera

recording it is not possible to define the transect width and height, which could also lead to inflated numbers. A stereo-video system (Saunders et al., 2021) would overcome this issue by allowing the transect dimensions to be defined, and the three-dimensional position of each fish within the transect to be identified.

Appendix F Laboratory Reports for Sediment Samples

ALS Environmental

CERTIFICATE OF ANALYSIS

Work Order	: **EB2215235**	Page	: 1 of 5
Client	: **ADVISIAN PTY LTD**	Laboratory	: Environmental Division Brisbane
Contact	: MARK WESTERA	Contact	: Customer Services EB
Address	: LEVEL 4 600 MURRAY STREET WEST PERTH WA, AUSTRALIA	Address	: 2 Byth Street Stafford QLD Australia 4053
Telephone	: ----	Telephone	: +61 7 3243 7222
Project	: Gorgon Benthic Survey 2022	Date Samples Received	: 27-May-2022 10:00
Order number	: 1	Date Analysis Commenced	: 01-Jun-2022
C-O-C number	: ----	Issue Date	: 09-Jun-2022 13:38
Sampler	: Luca Chiaroni, Stephanie Watts		
Site	: ----		
Quote number	: EP/246/22		
No. of samples received	: 4		
No. of samples analysed	: 4		

Accreditation No. 825
Accredited for compliance with
ISO/IEC 17025 - Testing

This report supersedes any previous report(s) with this reference. Results apply to the sample(s) as submitted, unless the sampling was conducted by ALS. This document shall not be reproduced, except in full.

This Certificate of Analysis contains the following information:

- General Comments
- Analytical Results
- Surrogate Control Limits

Additional information pertinent to this report will be found in the following separate attachments: Quality Control Report, QA/QC Compliance Assessment to assist with Quality Review and Sample Receipt Notification.

Signatories

This document has been electronically signed by the authorized signatories below. Electronic signing is carried out in compliance with procedures specified in 21 CFR Part 11.

Signatories	*Position*	*Accreditation Category*
Kim McCabe	Senior Inorganic Chemist	Brisbane Inorganics, Stafford, QLD
Timothy Creagh	2IC Organic Chemist	Brisbane Organics, Stafford, QLD

General Comments

The analytical procedures used by ALS have been developed from established internationally recognised procedures such as those published by the USEPA, APHA, AS and NEPM. In house developed procedures are fully validated and are often at the client request.

Where moisture determination has been performed, results are reported on a dry weight basis.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis.

Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

When sampling time information is not provided by the client, sampling dates are shown without a time component. In these instances, the time component has been assumed by the laboratory for processing purposes.

Where a result is required to meet compliance limits the associated uncertainty must be considered. Refer to the ALS Contract for details.

Key : CAS Number = CAS registry number from database maintained by Chemical Abstracts Services. The Chemical Abstracts Service is a division of the American Chemical Society.
LOR = Limit of reporting
^ = This result is computed from individual analyte detections at or above the level of reporting
ø = ALS is not NATA accredited for these tests.
~ = Indicates an estimated value.

- EG048G (Hexavalent Chromium by Alkaline Digestion): Some samples were diluted due to matrix interference. LOR adjusted accordingly.
- EP080: Where reported, Total Xylenes is the sum of the reported concentrations of m&p-Xylene and o-Xylene at or above the LOR.
- EG005T (Total Metals by ICP-AES): EB2215171-003 shows poor matrix spike recovery due to sample heterogeneity. This has been confirmed by visual inspection.
- EG005T (Total Metals by ICP-AES): EB2215331-031 shows poor duplicate results due to sample heterogeneity. This has been confirmed by visual inspection.
- EG005T (Total Metals by ICP-AES): EB2215331-033 shows poor matrix spike recovery due to sample heterogeneity. This has been confirmed by visual inspection.
- EG005T (Total Metals by ICP-AES): EB2215290-003 shows poor duplicate results due to sample heterogeneity. This has been confirmed by visual inspection.
- EG048G (Hexavalent Chromium by Alkaline Digestion): Sample EB2215235_001 (SEMELE WELL-4_1_3) shows poor matrix spike recovery due to matrix interferences.

ALS Environmental

CERTIFICATE OF ANALYSIS

Work Order	: **EB2215199**	Page	: 1 of 4
Client	: **ADVISIAN PTY LTD**	Laboratory	: Environmental Division Brisbane
Contact	: MARK WESTERA	Contact	: Customer Services EB
Address	: LEVEL 4 600 MURRAY STREET WEST PERTH WA, AUSTRALIA	Address	: 2 Byth Street Stafford QLD Australia 4053
Telephone	: ----	Telephone	: +61 7 3243 7222
Project	: Gorgon Benthic Survey 2022	Date Samples Received	: 30-May-2022 13:54
Order number	: 1	Date Analysis Commenced	: 01-Jun-2022
C-O-C number	: ----	Issue Date	: 09-Jun-2022 08:49
Sampler	: Luca Chiaroni, Stephanie Watts		
Site	: ----		
Quote number	: EP/246/22		
No. of samples received	: 2		
No. of samples analysed	: 2		

Accreditation No. 825
Accredited for compliance with
ISO/IEC 17025 - Testing

This report supersedes any previous report(s) with this reference. Results apply to the sample(s) as submitted, unless the sampling was conducted by ALS. This document shall not be reproduced, except in full.

This Certificate of Analysis contains the following information:

- General Comments
- Analytical Results

Additional information pertinent to this report will be found in the following separate attachments: Quality Control Report, QA/QC Compliance Assessment to assist with Quality Review and Sample Receipt Notification.

Signatories

This document has been electronically signed by the authorized signatories below. Electronic signing is carried out in compliance with procedures specified in 21 CFR Part 11.

Signatories	*Position*	*Accreditation Category*
Ankit Joshi	Senior Chemist - Inorganics	Sydney Inorganics, Smithfield, NSW
Kim McCabe	Senior Inorganic Chemist	Brisbane Inorganics, Stafford, QLD
Matt Frost	Assistant Laboratory Manager	Brisbane Organics, Stafford, QLD

General Comments

The analytical procedures used by ALS have been developed from established internationally recognised procedures such as those published by the USEPA, APHA, AS and NEPM. In house developed procedures are fully validated and are often at the client request.

Where moisture determination has been performed, results are reported on a dry weight basis.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis.

Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

When sampling time information is not provided by the client, sampling dates are shown without a time component. In these instances, the time component has been assumed by the laboratory for processing purposes.

Where a result is required to meet compliance limits the associated uncertainty must be considered. Refer to the ALS Contract for details.

Key : CAS Number = CAS registry number from database maintained by Chemical Abstracts Services. The Chemical Abstracts Service is a division of the American Chemical Society.
LOR = Limit of reporting
^ = This result is computed from individual analyte detections at or above the level of reporting
ø = ALS is not NATA accredited for these tests.
~ = Indicates an estimated value.

- EK061G (Total Kjeldahl Nitrogen as N) / EK067G (Total Phosphorus as P): Some samples were diluted due to matrix interference. LOR adjusted accordingly.
- **Metals analysis will be conducted by ALS Sydney, NATA accreditation no. 825, site no 10911.**
- EG093: Samples containing high levels of sulfate may precipitate barium under the acidic conditions of this method and may therefore bias results low.

Analytical Results

General Comments

The analytical procedures used by ALS have been developed from established internationally recognised procedures such as those published by the USEPA, APHA, AS and NEPM. In house developed procedures are fully validated and are often at the client request.

Where moisture determination has been performed, results are reported on a dry weight basis.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis.

Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

When sampling time information is not provided by the client, sampling dates are shown without a time component. In these instances, the time component has been assumed by the laboratory for processing purposes.

Where a result is required to meet compliance limits the associated uncertainty must be considered. Refer to the ALS Contract for details.

Key : CAS Number = CAS registry number from database maintained by Chemical Abstracts Services. The Chemical Abstracts Service is a division of the American Chemical Society.
LOR = Limit of reporting
^ = This result is computed from individual analyte detections at or above the level of reporting
ø = ALS is not NATA accredited for these tests.
~ = Indicates an estimated value.

- EP080: Where reported, Total Xylenes is the sum of the reported concentrations of m&p-Xylene and o-Xylene at or above the LOR.
- EP002, EP005: It has been noted that the result for Dissolved Organic Carbon is greater than the result for Total Organic Carbon for samples #002, 010, 011 & 013-018 however the difference is within the limits of experimental variation.
- EG093 and EG093-LL: It is recognised that some total analyte concentrations are less than dissolved for various samples. However, the difference is within experimental variation of the methods.
- EG093-LL: Dissolved and Total Cu results for sample EP2205671 -018 has been confirmed by re-preparation and re-analysis.
- EK061G/EK067G (TKN/TP): LOR for samples EP2205671-001, -006, -013, -014, -017 and -018 raised due to the high amount of TDS present.
- EG093: Samples containing high levels of sulfate may precipitate barium under the acidic conditions of this method and may therefore bias results low.

Client	: **ADVISIAN PTY LTD**	Laboratory	: Environmental Division Perth
Contact	: MARK WESTERA	Contact	: Customer Services EP
Address	: LEVEL 4 600 MURRAY STREET WEST PERTH WA, AUSTRALIA	Address	: 26 Rigali Way Wangara WA Australia 6065
Telephone	: ----	Telephone	: +61-8-9406 1301
Project	: Gorgon Benthic Survey 2022	Date Samples Received	: 12-May-2022 09:00
Order number	: 1	Date Analysis Commenced	: 13-May-2022
C-O-C number	: ----	Issue Date	: 20-May-2022 17:21
Sampler	: Luca Chiaroni, STEPHANIE WATTS		
Site	: ----		
Quote number	: EP/246/22		
No. of samples received	: 12		
No. of samples analysed	: 12		

Accreditation No. 825
Accredited for compliance with
ISO/IEC 17025 - Testing

This report supersedes any previous report(s) with this reference. Results apply to the sample(s) as submitted, unless the sampling was conducted by ALS. This document shall not be reproduced, except in full.

This Certificate of Analysis contains the following information:

- General Comments
- Analytical Results
- Surrogate Control Limits

Additional information pertinent to this report will be found in the following separate attachments: Quality Control Report, QA/QC Compliance Assessment to assist with Quality Review and Sample Receipt Notification.

Signatories

This document has been electronically signed by the authorized signatories below. Electronic signing is carried out in compliance with procedures specified in 21 CFR Part 11.

Signatories	*Position*	*Accreditation Category*
Canhuang Ke	Inorganics Supervisor	Perth Inorganics, Wangara, WA
Chris Lemaitre	Laboratory Manager (Perth)	Perth Inorganics, Wangara, WA
David Viner	SENIOR LAB TECH	Perth Organics, Wangara, WA
Mark Kinnin	Laboratory Technician	Perth Inorganics, Wangara, WA

General Comments

The analytical procedures used by ALS have been developed from established internationally recognised procedures such as those published by the USEPA, APHA, AS and NEPM. In house developed procedures are fully validated and are often at the client request.

Where moisture determination has been performed, results are reported on a dry weight basis.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis.

Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

When sampling time information is not provided by the client, sampling dates are shown without a time component. In these instances, the time component has been assumed by the laboratory for processing purposes.

Where a result is required to meet compliance limits the associated uncertainty must be considered. Refer to the ALS Contract for details.

Key : CAS Number = CAS registry number from database maintained by Chemical Abstracts Services. The Chemical Abstracts Service is a division of the American Chemical Society.
LOR = Limit of reporting
^ = This result is computed from individual analyte detections at or above the level of reporting
ø = ALS is not NATA accredited for these tests.
~ = Indicates an estimated value.

- EP080: Where reported, Total Xylenes is the sum of the reported concentrations of m&p-Xylene and o-Xylene at or above the LOR.
- EP002, EP005: It is noted that the results for Dissolved Organic Carbon are greater than the results for Total Organic Carbon for samples #002 & 007, however the results are within the limits of experimental variation.
- EG093 and EG093-LL: It is recognised that some total analyte concentrations are less than dissolved for various samples. However, the difference is within experimental variation of the methods.
- EK061G/EK067G (TKN/TP): LOR for samples EP2205756-009, -010, -011 and -012 raised due to the high amount of TDS present.
- EG094: Positive metals results for samples EP2205756-005 to -008 have been confirmed by re-preparation and re-analysis.
- EG094 and EG094-LL: It is recognised that total Cu, Zn concentrations are less than dissolved for samples EP2205756-005 to -008. However, the difference is within experimental variation of the methods.
- EG093: Samples containing high levels of sulfate may precipitate barium under the acidic conditions of this method and may therefore bias results low.

Appendix I Assessment of QAQC samples

Assessment of Quality Control Samples

Comparisons were made of the laboratory test results for the duplicate samples with the original samples and the Relative Percentage Difference (RPD) calculated as difference/average in order to assess the accuracy of the sampling and laboratory test procedures. The comparisons between the duplicates and the original samples indicate acceptable RPDs when they comply with criteria which are commonly set at:

- Less than 30% for inorganics (metals) and 50% for organics (hydrocarbons and PAHs);
- Less than five times the Laboratory LOR; and,

Where analyte values resulted as < LOR, half the LOR was used to calculate the RPD.

This data validation criteria and process is based off the National Environment Protection Measure (NEPM).

Both water and sediment hydrocarbons (PAH's, BTEXN), values at all sites resulted below the LOR therefore they have all conformed to the above criteria (RPD = 0%), and therefore have not been included or displayed in the tables.

The RPD% for the majority of intra-laboratory and inter-laboratory duplicates had concentrations that complied with the criteria set for acceptable RPDs. Only two exceedances were noted. These included the duplicate sample for (dissolved) iron in water from G-E DC_Seabed (RPD% = 33.33%), and the intra-laboratory samples for (total) manganese in water from Gorgon GMT_Seabed (RPD% = 31.48%).

The RSD% for the majority of replicates had concentrations that complied with the criteria set for acceptable RSDs. Only one exceedance was noted. The replicate samples for cadmium from WTR DC-2 (RSD% = 43.30%) displayed an exceedance.

The RPD/RSD results for the metals were all below 50%. The heterogeneity observed in the duplicate and replicate samples was not deemed significant enough to diminish confidence in the sampling technique or laboratory results. Therefore, it is considered that sampling techniques and laboratory analysis were appropriate.

Table 1 1 Calculated intra-laboratory and replicate RPDs for sediment metal concentrations

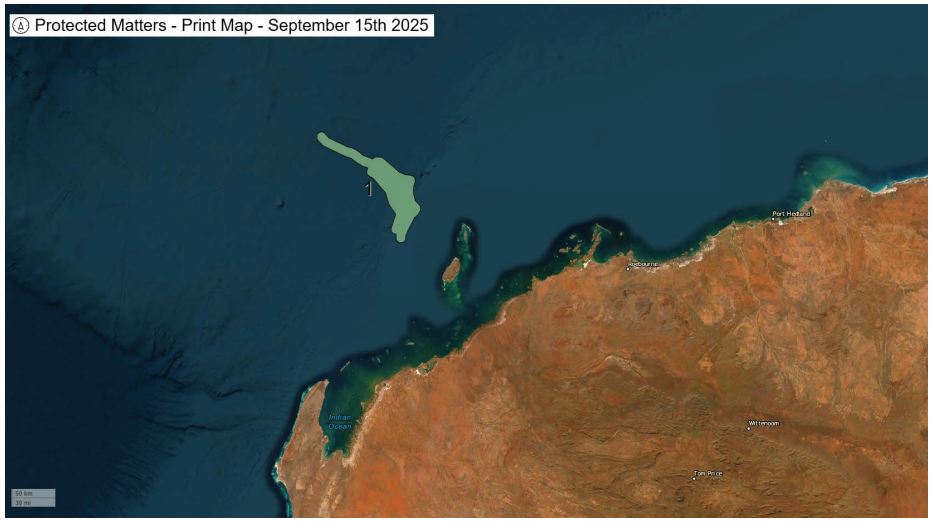
DEVELOPMENT AREA



EPBC Act Protected Matters Report

This report provides general guidance on matters of national environmental significance and other matters protected by the EPBC Act in the area you have selected. Please see the caveat for interpretation of information provided here.

Report created: 15-Sep-2025

Summary
Details
- Matters of NES
- Other Matters Protected by the EPBC Act

Summary

Matters of National Environment Significance

This part of the report summarises the matters of national environmental significance that may occur in, or may relate to, the area you nominated. Further information is available in the detail part of the report, which can be accessed by scrolling or following the links below. If you are proposing to undertake an activity that may have a significant impact on one or more matters of national environmental significance then you should consider the Administrative Guidelines on Significance.

World Heritage Properties:	None
National Heritage Places:	None
Wetlands of International Importance (Ramsar	None
Great Barrier Reef Marine Park:	None
Commonwealth Marine Area:	2
Listed Threatened Ecological Communities:	None
Listed Threatened Species:	26
Listed Migratory Species:	43

Other Matters Protected by the EPBC Act

This part of the report summarises other matters protected under the Act that may relate to the area you nominated. Approval may be required for a proposed activity that significantly affects the environment on Commonwealth land, when the action is outside the Commonwealth land, or the environment anywhere when the action is taken on Commonwealth land. Approval may also be required for the Commonwealth or Commonwealth agencies proposing to take an action that is likely to have a significant impact on the environment anywhere.

The EPBC Act protects the environment on Commonwealth land, the environment from the actions taken on Commonwealth land, and the environment from actions taken by Commonwealth agencies. As heritage values of a place are part of the 'environment', these aspects of the EPBC Act protect the Commonwealth Heritage values of a Commonwealth Heritage place. Information on the new heritage laws can be found at https://www.dcceew.gov.au/parks-heritage/heritage

A permit may be required for activities in or on a Commonwealth area that may affect a member of a listed threatened species or ecological community, a member of a listed migratory species, whales and other cetaceans, or a member of a listed marine species.

Commonwealth Lands:	None
Commonwealth Heritage Places:	None
Listed Marine Species:	69
Whales and Other Cetaceans:	30
Critical Habitats:	None
Commonwealth Reserves Terrestrial:	None
Australian Marine Parks:	None
Habitat Critical to the Survival of Marine Turtles:	1

Extra Information

This part of the report provides information that may also be relevant to the area you have

State and Territory Reserves:	None
Regional Forest Agreements:	None
Nationally Important Wetlands:	None
EPBC Act Referrals:	45
Key Ecological Features (Marine):	3
Biologically Important Areas:	5
Bioregional Assessments:	None
Geological and Bioregional Assessments:	None

Details

Matters of National Environmental Significance

Commonwealth Marine Area [Resource Information]

Approval is required for a proposed activity that is located within the Commonwealth Marine Area which has, will have, or is likely to have a significant impact on the environment. Approval may be required for a proposed action taken outside a Commonwealth Marine Area but which has, may have or is likely to have a significant impact on the environment in the Commonwealth Marine Area.

Feature Name
Commonwealth Marine Areas (EPBC Act)
Commonwealth Marine Areas (EPBC Act)

Listed Threatened Species [Resource Information]

Status of Conservation Dependent and Extinct are not MNES under the EPBC Act.
Number is the current name ID.

Scientific Name	Threatened Category	Presence Text
BIRD		
Calidris acuminata Sharp-tailed Sandpiper [874]	Vulnerable	Species or species habitat may occur within area
Calidris canutus Red Knot, Knot [855]	Vulnerable	Species or species habitat may occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Species or species habitat may occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat may occur within area
Phaethon lepturus fulvus Christmas Island White-tailed Tropicbird, Golden Bosunbird [26021]	Endangered	Species or species habitat may occur within area
Phaethon rubricauda westralis Red-tailed Tropicbird (Indian Ocean), Indian Ocean Red-tailed Tropicbird [91824]	Endangered	Species or species habitat may occur within area
Sternula nereis nereis Australian Fairy Tern [82950]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
MAMMAL		
Balaenoptera borealis Sei Whale [34]	Vulnerable	Species or species habitat likely to occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Migration route known to occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Species or species habitat likely to occur within area
Orcaella heinsohni Australian Snubfin Dolphin [81322]	Vulnerable	Species or species habitat may occur within area
Sousa sahulensis Australian Humpback Dolphin [87942]	Vulnerable	Species or species habitat may occur within area
REPTILE		
Aipysurus apraefrontalis Short-nosed Sea Snake, Short-nosed Seasnake [1115]	Critically Endangered	Species or species habitat may occur within area
Caretta caretta Loggerhead Turtle [1763]	Endangered	Species or species habitat known to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Species or species habitat known to occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Species or species habitat likely to occur within area

Scientific Name	Threatened Category	Presence Text
Eretmochelys imbricata		
Hawksbill Turtle [1766]	Vulnerable	Species or species habitat known to occur within area
Natator depressus		
Flatback Turtle [59257]	Vulnerable	Congregation or aggregation known to occur within area
SHARK		
Carcharias taurus (west coast population)		
Grey Nurse Shark (west coast population) [68752]	Vulnerable	Species or species habitat likely to occur within area
Carcharodon carcharias		
White Shark, Great White Shark [64470]	Vulnerable	Species or species habitat may occur within area
Pristis clavata		
Dwarf Sawfish, Queensland Sawfish [68447]	Vulnerable	Species or species habitat known to occur within area
Pristis pristis		
Largetooth Sawfish, Freshwater Sawfish, River Sawfish, Leichhardt's Sawfish, Northern Sawfish [60756]	Endangered	Species or species habitat may occur within area
Pristis zijsron		
Green Sawfish, Dindagubba, Narrowsnout Sawfish [68442]	Vulnerable	Species or species habitat known to occur within area
Rhincodon typus		
Whale Shark [66680]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Sphyrna lewini		
Scalloped Hammerhead [85267]	Conservation Dependent	Species or species habitat likely to occur within area

Listed Migratory Species [Resource Information]		
Scientific Name	Threatened Category	Presence Text
null		
Balaenoptera omurai		
Omura's Whale [87136]		Species or species habitat likely to occur within area
Migratory Marine Birds		
Anous stolidus		
Common Noddy [825]		Species or species habitat may occur within area
Calonectris leucomelas		
Streaked Shearwater [1077]		Species or species habitat likely to occur within area
Fregata ariel		
Lesser Frigatebird, Least Frigatebird [1012]		Species or species habitat likely to occur within area
Macronectes giganteus		
Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Species or species habitat may occur within area
Phaethon lepturus		
White-tailed Tropicbird [1014]		Species or species habitat may occur within area
Phaethon rubricauda		
Red-tailed Tropicbird [994]		Species or species habitat may occur within area
Migratory Marine Species		
Anoxypristis cuspidata		
Narrow Sawfish, Knifetooth Sawfish [68448]		Species or species habitat may occur within area
Balaenoptera bonaerensis		
Antarctic Minke Whale, Dark-shoulder Minke Whale [67812]		Species or species habitat likely to occur within area
Balaenoptera borealis		
Sei Whale [34]	Vulnerable	Species or species habitat likely to occur within area
Balaenoptera edeni		
Bryde's Whale [35]		Species or species habitat likely to occur within area
Balaenoptera musculus		
Blue Whale [36]	Endangered	Migration route known to occur within area

Scientific Name	Threatened Category	Presence Text
Balaenoptera physalus Fin Whale [37]	Vulnerable	Species or species habitat likely to occur within area
Carcharhinus longimanus Oceanic Whitetip Shark [84108]		Species or species habitat likely to occur within area
Carcharias taurus Grey Nurse Shark [64469]		Species or species habitat likely to occur within area
Carcharodon carcharias White Shark, Great White Shark [64470]	Vulnerable	Species or species habitat may occur within area
Caretta caretta Loggerhead Turtle [1763]	Endangered	Species or species habitat known to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Species or species habitat known to occur within area
Crocodylus porosus Salt-water Crocodile, Estuarine Crocodile [1774]		Species or species habitat may occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Species or species habitat likely to occur within area
Eretmochelys imbricata Hawksbill Turtle [1766]	Vulnerable	Species or species habitat known to occur within area
Isurus oxyrinchus Shortfin Mako, Mako Shark [79073]		Species or species habitat likely to occur within area
Isurus paucus Longfin Mako [82947]		Species or species habitat likely to occur within area

Scientific Name	Threatened Category	Presence Text
Megaptera novaeangliae Humpback Whale [38]		Breeding known to occur within area
Mobula alfredi as Manta alfredi Reef Manta Ray, Coastal Manta Ray [90033]		Species or species habitat likely to occur within area
Mobula birostris as Manta birostris Giant Manta Ray [90034]		Species or species habitat likely to occur within area
Natator depressus Flatback Turtle [59257]	Vulnerable	Congregation or aggregation known to occur within area
Orcaella heinsohni Australian Snubfin Dolphin [81322]	Vulnerable	Species or species habitat may occur within area
Orcinus orca Killer Whale, Orca [46]		Species or species habitat may occur within area
Physeter macrocephalus Sperm Whale [59]		Species or species habitat may occur within area
Pristis clavata Dwarf Sawfish, Queensland Sawfish [68447]	Vulnerable	Species or species habitat known to occur within area
Pristis pristis Largetooth Sawfish, Freshwater Sawfish, River Sawfish, Leichhardt's Sawfish, Northern Sawfish [60756]	Endangered	Species or species habitat may occur within area
Pristis zijsron Green Sawfish, Dindagubba, Narrowsnout Sawfish [68442]	Vulnerable	Species or species habitat known to occur within area
Rhincodon typus Whale Shark [66680]	Vulnerable	Foraging, feeding or related behaviour known to occur within area

Scientific Name	Threatened Category	Presence Text
Sousa sahulensis as Sousa chinensis		
Australian Humpback Dolphin [87942]	Vulnerable	Species or species habitat may occur within area
Tursiops aduncus (Arafura/Timor Sea populations)		
Spotted Bottlenose Dolphin (Arafura/Timor Sea populations) [78900]		Species or species habitat may occur within area
Migratory Wetlands Species		
Actitis hypoleucos		
Common Sandpiper [59309]		Species or species habitat may occur within area
Calidris acuminata		
Sharp-tailed Sandpiper [874]	Vulnerable	Species or species habitat may occur within area
Calidris canutus		
Red Knot, Knot [855]	Vulnerable	Species or species habitat may occur within area
Calidris ferruginea		
Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area
Calidris melanotos		
Pectoral Sandpiper [858]		Species or species habitat may occur within area
Numenius madagascariensis		
Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat may occur within area
Pandion haliaetus		
Osprey [952]		Species or species habitat may occur within area

Other Matters Protected by the EPBC Act

Listed Marine Species [Resource Information]

Scientific Name	Threatened Category	Presence Text
Bird		
Actitis hypoleucos		
Common Sandpiper [59309]		Species or species habitat may occur within area
Anous stolidus		
Common Noddy [825]		Species or species habitat may occur within area
Calidris acuminata		
Sharp-tailed Sandpiper [874]	Vulnerable	Species or species habitat may occur within area
Calidris canutus		
Red Knot, Knot [855]	Vulnerable	Species or species habitat may occur within area overfly marine area
Calidris ferruginea		
Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area overfly marine area
Calidris melanotos		
Pectoral Sandpiper [858]		Species or species habitat may occur within area overfly marine area
Calonectris leucomelas		
Streaked Shearwater [1077]		Species or species habitat likely to occur within area
Fregata ariel		
Lesser Frigatebird, Least Frigatebird [1012]		Species or species habitat likely to occur within area
Macronectes giganteus		
Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Species or species habitat may occur within area
Numenius madagascariensis		
Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat may occur within area
Pandion haliaetus		
Osprey [952]		Species or species habitat may occur within area

Scientific Name	Threatened Category	Presence Text
Phaethon lepturus		
White-tailed Tropicbird [1014]		Species or species habitat may occur within area
Phaethon lepturus fulvus		
Christmas Island White-tailed Tropicbird, Golden Bosunbird [26021]	Endangered	Species or species habitat may occur within area
Phaethon rubricauda		
Red-tailed Tropicbird [994]		Species or species habitat may occur within area
Fish		
Acentronura larsonae		
Helen's Pygmy Pipehorse [66186]		Species or species habitat may occur within area
Bulbonaricus brauni		
Braun's Pughead Pipefish, Pug-headed Pipefish [66189]		Species or species habitat may occur within area
Campichthys tricarinatus		
Three-keel Pipefish [66192]		Species or species habitat may occur within area
Choeroichthys brachysoma		
Pacific Short-bodied Pipefish, Short-bodied Pipefish [66194]		Species or species habitat may occur within area
Choeroichthys latispinosus		
Muiron Island Pipefish [66196]		Species or species habitat may occur within area
Choeroichthys suillus		
Pig-snouted Pipefish [66198]		Species or species habitat may occur within area
Corythoichthys flavofasciatus		
Reticulate Pipefish, Yellow-banded Pipefish, Network Pipefish [66200]		Species or species habitat may occur within area
Cosmocampus banneri		
Roughridge Pipefish [66206]		Species or species habitat may occur within area

Scientific Name	Threatened Category	Presence Text
Doryrhamphus dactyliophorus		
Banded Pipefish, Ringed Pipefish [66210]		Species or species habitat may occur within area
Doryrhamphus excisus		
Bluestripe Pipefish, Indian Blue-stripe Pipefish, Pacific Blue-stripe Pipefish [66211]		Species or species habitat may occur within area
Doryrhamphus janssi		
Cleaner Pipefish, Janss' Pipefish [66212]		Species or species habitat may occur within area
Doryrhamphus multiannulatus		
Many-banded Pipefish [66717]		Species or species habitat may occur within area
Doryrhamphus negrosensis		
Flagtail Pipefish, Masthead Island Pipefish [66213]		Species or species habitat may occur within area
Festucalex scalaris		
Ladder Pipefish [66216]		Species or species habitat may occur within area
Filicampus tigris		
Tiger Pipefish [66217]		Species or species habitat may occur within area
Halicampus brocki		
Brock's Pipefish [66219]		Species or species habitat may occur within area
Halicampus grayi		
Mud Pipefish, Gray's Pipefish [66221]		Species or species habitat may occur within area
Halicampus nitidus		
Glittering Pipefish [66224]		Species or species habitat may occur within area
Halicampus spinirostris		
Spiny-snout Pipefish [66225]		Species or species habitat may occur within area

Scientific Name	Threatened Category	Presence Text
Haliichthys taeniophorus Ribboned Pipehorse, Ribboned Seadragon [66226]		Species or species habitat may occur within area
Hippichthys penicillus Beady Pipefish, Steep-nosed Pipefish [66231]		Species or species habitat may occur within area
Hippocampus angustus Western Spiny Seahorse, Narrow-bellied Seahorse [66234]		Species or species habitat may occur within area
Hippocampus histrix Spiny Seahorse, Thorny Seahorse [66236]		Species or species habitat may occur within area
Hippocampus kuda Spotted Seahorse, Yellow Seahorse [66237]		Species or species habitat may occur within area
Hippocampus planifrons Flat-face Seahorse [66238]		Species or species habitat may occur within area
Hippocampus spinosissimus Hedgehog Seahorse [66239]		Species or species habitat may occur within area
Hippocampus trimaculatus Three-spot Seahorse, Low-crowned Seahorse, Flat-faced Seahorse [66720]		Species or species habitat may occur within area
Micrognathus micronotopterus Tidepool Pipefish [66255]		Species or species habitat may occur within area
Phoxocampus belcheri Black Rock Pipefish [66719]		Species or species habitat may occur within area
Solegnathus hardwickii Pallid Pipehorse, Hardwick's Pipehorse [66272]		Species or species habitat may occur within area
Solegnathus lettiensis Gunther's Pipehorse, Indonesian Pipefish [66273]		Species or species habitat may occur within area
Solenostomus cyanopterus Robust Ghostpipefish, Blue-finned Ghost Pipefish, [66183]		Species or species habitat may occur within area
Syngnathoides biaculeatus Double-end Pipehorse, Double-ended Pipehorse, Alligator Pipefish [66279]		Species or species habitat may occur within area
Trachyrhamphus bicoarctatus Bentstick Pipefish, Bend Stick Pipefish, Short-tailed Pipefish [66280]		Species or species habitat may occur within area
Trachyrhamphus longirostris Straightstick Pipefish, Long-nosed Pipefish, Straight Stick Pipefish [66281]		Species or species habitat may occur within area
Reptile		
Aipysurus apraefrontalis Short-nosed Sea Snake, Short-nosed Seasnake [1115]	Critically Endangered	Species or species habitat may occur within area
Aipysurus duboisii Dubois' Sea Snake, Dubois' Seasnake, Reef Shallows Sea Snake [1116]		Species or species habitat may occur within area
Aipysurus laevis Olive Sea Snake, Olive-brown Sea Snake [1120]		Species or species habitat may occur within area
Aipysurus mosaicus as Aipysurus eydouxii Mosaic Sea Snake [87261]		Species or species habitat may occur within area
Caretta caretta Loggerhead Turtle [1763]	Endangered	Species or species habitat known to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Species or species habitat known to occur within area

Scientific Name	Threatened Category	Presence Text
Crocodylus porosus Salt-water Crocodile, Estuarine Crocodile [1774]		Species or species habitat may occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Species or species habitat likely to occur within area
Emydocephalus annulatus Eastern Turtle-headed Sea Snake [1125]		Species or species habitat may occur within area
Ephalophis greyae as Ephalophis greyi Mangrove Sea Snake [93738]		Species or species habitat may occur within area
Eretmochelys imbricata Hawksbill Turtle [1766]	Vulnerable	Species or species habitat known to occur within area
Hydrophis czeblukovi Fine-spined Sea Snake [59233]		Species or species habitat may occur within area
Hydrophis elegans Elegant Sea Snake, Bar-bellied Sea Snake [1104]		Species or species habitat may occur within area
Hydrophis kingii as Disteira kingii Spectacled Sea Snake [93511]		Species or species habitat may occur within area
Hydrophis major as Disteira major Olive-headed Sea Snake [93512]		Species or species habitat may occur within area
Hydrophis ornatus Spotted Sea Snake, Ornate Reef Sea Snake [1111]		Species or species habitat may occur within area
Hydrophis peronii as Acalyptophis peronii Horned Sea Snake [93509]		Species or species habitat may occur within area
Hydrophis platura as Pelamis platurus Yellow-bellied Sea Snake [93746]		Species or species habitat may occur within area
Hydrophis stokesii as Astrotia stokesii Stokes' Sea Snake [93510]		Species or species habitat may occur within area
Natator depressus Flatback Turtle [59257]	Vulnerable	Congregation or aggregation known to occur within area

Whales and Other Cetaceans [Resource Information]

Current Scientific Name	Status	Type of Presence
Mammal		
Balaenoptera acutorostrata Minke Whale [33]		Species or species habitat may occur within area
Balaenoptera bonaerensis Antarctic Minke Whale, Dark-shoulder Minke Whale [67812]		Species or species habitat likely to occur within area
Balaenoptera borealis Sei Whale [34]	Vulnerable	Species or species habitat likely to occur within area
Balaenoptera edeni Bryde's Whale [35]		Species or species habitat likely to occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Migration route known to occur within area
Balaenoptera omurai Omura's Whale [87136]		Species or species habitat likely to occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Species or species habitat likely to occur within area

Current Scientific Name	Status	Type of Presence
Delphinus delphis Common Dolphin, Short-beaked Common Dolphin [60]		Species or species habitat may occur within area
Feresa attenuata Pygmy Killer Whale [61]		Species or species habitat may occur within area
Globicephala macrorhynchus Short-finned Pilot Whale [62]		Species or species habitat may occur within area
Grampus griseus Risso's Dolphin, Grampus [64]		Species or species habitat may occur within area
Kogia breviceps Pygmy Sperm Whale [57]		Species or species habitat may occur within area
Kogia sima Dwarf Sperm Whale [85043]		Species or species habitat may occur within area
Lagenodelphis hosei Fraser's Dolphin, Sarawak Dolphin [41]		Species or species habitat may occur within area
Megaptera novaeangliae Humpback Whale [38]		Breeding known to occur within area
Mesoplodon densirostris Blainville's Beaked Whale, Dense-beaked Whale [74]		Species or species habitat may occur within area
Orcaella heinsohni Australian Snubfin Dolphin [81322]	Vulnerable	Species or species habitat may occur within area
Orcinus orca Killer Whale, Orca [46]		Species or species habitat may occur within area

Current Scientific Name	Status	Type of Presence
Peponocephala electra Melon-headed Whale [47]		Species or species habitat may occur within area
Physeter macrocephalus Sperm Whale [59]		Species or species habitat may occur within area
Pseudorca crassidens False Killer Whale [48]		Species or species habitat likely to occur within area
Sousa sahulensis Australian Humpback Dolphin [87942]	Vulnerable	Species or species habitat may occur within area
Stenella attenuata Spotted Dolphin, Pantropical Spotted Dolphin [51]		Species or species habitat may occur within area
Stenella coeruleoalba Striped Dolphin, Euphrosyne Dolphin [52]		Species or species habitat may occur within area
Stenella longirostris Long-snouted Spinner Dolphin [29]		Species or species habitat may occur within area
Steno bredanensis Rough-toothed Dolphin [30]		Species or species habitat may occur within area
Tursiops aduncus Indian Ocean Bottlenose Dolphin, Spotted Bottlenose Dolphin [68418]		Species or species habitat may occur within area
Tursiops aduncus (Arafura/Timor Sea populations) Spotted Bottlenose Dolphin (Arafura/Timor Sea populations) [78900]		Species or species habitat may occur within area
Tursiops truncatus s. str. Bottlenose Dolphin [68417]		Species or species habitat may occur within area

Current Scientific Name	Status	Type of Presence
Ziphius cavirostris		
Cuvier's Beaked Whale, Goose-beaked Whale [56]		Species or species habitat may occur within area

Habitat Critical to the Survival of Marine Turtles		[Resource Information]

Key Ecological Features [Resource Information]

Key Ecological Features are the parts of the marine ecosystem that are considered to be important for the biodiversity or ecosystem functioning and integrity of the Commonwealth Marine Area.

Name	Region
Ancient coastline at 125 m depth contour	North-west
Continental Slope Demersal Fish Communities	North-west

Name	Region
Exmouth Plateau	North-west

Biologically Important Areas		[Resource Information]
Scientific Name	Behaviour	Presence
Marine Turtles		
Natator depressus		
Flatback Turtle [59257]	Internesting buffer	Known to occur
Seabirds		
Ardenna tenuirostris		
Short-tailed Shearwater [84292]	Breeding	Known to occur
Sharks		
Rhincodon typus		
Whale Shark [66680]	Foraging	Known to occur
Whales		
Balaenoptera musculus brevicauda		
Pygmy Blue Whale [81317]	Migration	Known to occur
Megaptera novaeangliae		
Humpback Whale [38]	Migration (north and south)	Known to occur

Caveat

1 PURPOSE

This report is designed to assist in identifying the location of matters of national environmental significance (MNES) and other matters protected by the Environment Protection and Biodiversity Conservation Act 1999 (Cth) (EPBC Act) which may be relevant in determining obligations and requirements under the EPBC Act.

The report contains the mapped locations of:

- World and National Heritage properties;
- Wetlands of International and National Importance;
- Commonwealth and State/Territory reserves;
- distribution of listed threatened, migratory and marine species;
- listed threatened ecological communities; and
- other information that may be useful as an indicator of potential habitat value.

2 DISCLAIMER

This report is not intended to be exhaustive and should only be relied upon as a general guide as mapped data is not available for all species or ecological communities listed under the EPBC Act (see below). Persons seeking to use the information contained in this report to inform the referral of a proposed action under the EPBC Act should consider the limitations noted below and whether additional information is required to determine the existence and location of MNES and other protected matters.

Where data is available to inform the mapping of protected species, the presence type (e.g. known, likely or may occur) that can be determined from the data is indicated in general terms. It is the responsibility of any person using or relying on the information in this report to ensure that it is suitable for the circumstances of any proposed use. The Commonwealth cannot accept responsibility for the consequences of any use of the report or any part thereof. To the maximum extent allowed under governing law, the Commonwealth will not be liable for any loss or damage that may be occasioned directly or indirectly through the use of, or reliance on the contents of this report.

3 DATA SOURCES

Threatened ecological communities

For threatened ecological communities where the distribution is well known, maps are generated based on information contained in recovery plans, State vegetation maps and remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

Threatened, migratory and marine species

Threatened, migratory and marine species distributions have been discerned through a variety of methods. Where distributions are well known and if time permits, distributions are inferred from either thematic spatial data (i.e. vegetation, soils, geology, elevation, aspect, terrain, etc.) together with point locations and described habitat; or modelled (MAXENT or BIOCLIM habitat modelling) using point locations and environmental data layers.

Where little information is available for a species or large number of maps are required in a short time-frame, maps are derived either from 0.04 or 0.02 decimal degree cells; by an automated process using polygon capture techniques (static two kilometre grid cells, alpha-hull and convex hull); or captured manually or by using topographic features (national park boundaries, islands, etc.).

In the early stages of the distribution mapping process (1999-early 2000s) distributions were defined by degree blocks, 100K or 250K map sheets to rapidly create distribution maps. More detailed distribution mapping methods are used to update these distributions when time permits.

4 LIMITATIONS

The following species and ecological communities have not been mapped and do not appear in this report:

- threatened species listed as extinct or considered vagrants;
- some recently listed species and ecological communities;
- some listed migratory and listed marine species, which are not listed as threatened species; and
- migratory species that are very widespread, vagrant, or only occur in Australia in small numbers.

The following groups have been mapped, but may not cover the complete distribution of the species:

- listed migratory and/or listed marine seabirds, which are not listed as threatened, have only been mapped for recorded breeding sites; and
- seals which have only been mapped for breeding sites near the Australian continent

The breeding sites may be important for the protection of the Commonwealth Marine environment.

Refer to the metadata for the feature group (using the Resource Information link) for the currency of the information.

Acknowledgements

This database has been compiled from a range of data sources. The department acknowledges the following custodians who have contributed valuable data and advice:

EPBC Act Protected Matters Report

This report provides general guidance on matters of national environmental significance and other matters protected by the EPBC Act in the area you have selected. Please see the caveat for interpretation of information provided here.

Report created: 15-Sep-2025

Summary
Details
- Matters of NES
- Other Matters Protected by the EPBC Act
- Extra Information

Summary

Matters of National Environment Significance

This part of the report summarises the matters of national environmental significance that may occur in, or may relate to, the area you nominated. Further information is available in the detail part of the report, which can be accessed by scrolling or following the links below. If you are proposing to undertake an activity that may have a significant impact on one or more matters of national environmental significance then you should consider the Administrative Guidelines on Significance.

World Heritage Properties:	1
National Heritage Places:	1
Wetlands of International Importance (Ramsar	None
Great Barrier Reef Marine Park:	None
Commonwealth Marine Area:	4
Listed Threatened Ecological Communities:	None
Listed Threatened Species:	63
Listed Migratory Species:	69

Other Matters Protected by the EPBC Act

This part of the report summarises other matters protected under the Act that may relate to the area you nominated. Approval may be required for a proposed activity that significantly affects the environment on Commonwealth land, when the action is outside the Commonwealth land, or the environment anywhere when the action is taken on Commonwealth land. Approval may also be required for the Commonwealth or Commonwealth agencies proposing to take an action that is likely to have a significant impact on the environment anywhere.

The EPBC Act protects the environment on Commonwealth land, the environment from the actions taken on Commonwealth land, and the environment from actions taken by Commonwealth agencies. As heritage values of a place are part of the 'environment', these aspects of the EPBC Act protect the Commonwealth Heritage values of a Commonwealth Heritage place. Information on the new heritage laws can be found at https://www.dcceew.gov.au/parks-heritage/heritage

A permit may be required for activities in or on a Commonwealth area that may affect a member of a listed threatened species or ecological community, a member of a listed migratory species, whales and other cetaceans, or a member of a listed marine species.

Commonwealth Lands:	5
Commonwealth Heritage Places:	2
Listed Marine Species:	119
Whales and Other Cetaceans:	33
Critical Habitats:	None
Commonwealth Reserves Terrestrial:	None
Australian Marine Parks:	13
Habitat Critical to the Survival of Marine Turtles:	4

Extra Information

This part of the report provides information that may also be relevant to the area you have

State and Territory Reserves:	30
Regional Forest Agreements:	None
Nationally Important Wetlands:	1
EPBC Act Referrals:	217
Key Ecological Features (Marine):	7
Biologically Important Areas:	37
Bioregional Assessments:	None
Geological and Bioregional Assessments:	None

Erythrotriorchis radiatus Red Goshawk [942]	Endangered	Species or species habitat may occur within area
Falco hypoleucos Grey Falcon [929]	Vulnerable	Species or species habitat known to occur within area
Limnodromus semipalmatus Asian Dowitcher [843]	Vulnerable	Species or species habitat known to occur within area
Limosa lapponica menzbieri Northern Siberian Bar-tailed Godwit, Russkoye Bar-tailed Godwit [86432]	Endangered	Species or species habitat known to occur within area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Species or species habitat may occur within area
Malurus leucopterus edouardi White-winged Fairy-wren (Barrow Island), Barrow Island Black-and-white Fairy-wren [26194]	Vulnerable	Species or species habitat likely to occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat known to occur within area
Papasula abbotti Abbott's Booby [59297]	Endangered	Species or species habitat may occur within area
Pezoporus occidentalis Night Parrot [59350]	Critically Endangered	Species or species habitat may occur within area

Scientific Name	Threatened Category	Presence Text
Phaethon lepturus fulvus		
Christmas Island White-tailed Tropicbird, Golden Bosunbird [26021]	Endangered	Species or species habitat may occur within area
Phaethon rubricauda westralis		
Red-tailed Tropicbird (Indian Ocean), Indian Ocean Red-tailed Tropicbird [91824]	Endangered	Species or species habitat known to occur within area
Pterodroma mollis		
Soft-plumaged Petrel [1036]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Rostratula australis		
Australian Painted Snipe [77037]	Endangered	Species or species habitat likely to occur within area
Sternula albifrons		
Little Tern [82849]	Vulnerable	Breeding known to occur within area
Sternula nereis nereis		
Australian Fairy Tern [82950]	Vulnerable	Breeding known to occur within area
Thalassarche carteri		
Indian Yellow-nosed Albatross [64464]	Vulnerable	Species or species habitat may occur within area
Thalassarche cauta		
Shy Albatross [89224]	Endangered	Species or species habitat may occur within area
Thalassarche impavida		
Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Species or species habitat may occur within area
Thalassarche melanophris		
Black-browed Albatross [66472]	Vulnerable	Species or species habitat may occur within area
Thalassarche steadi		
White-capped Albatross [64462]	Vulnerable	Species or species habitat may occur within area
Tringa nebularia		
Common Greenshank, Greenshank [832]	Endangered	Species or species habitat likely to occur within area
CRUSTACEAN		
Kumonga exleyi		
Cape Range Remipede [86875]	Vulnerable	Species or species habitat likely to occur within area
FISH		
Milyeringa justitia		
Barrow Cave Gudgeon [86867]	Endangered	Species or species habitat known to occur within area
Milyeringa veritas		
Cape Range Cave Gudgeon, Blind Gudgeon [66676]	Vulnerable	Species or species habitat known to occur within area
Ophisternon candidum		
Blind Cave Eel [66678]	Vulnerable	Species or species habitat known to occur within area
MAMMAL		
Balaenoptera borealis		
Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera musculus		
Blue Whale [36]	Endangered	Migration route known to occur within area
Balaenoptera physalus		
Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Bettongia lesueur Barrow and Boodie Islands subspecies		
Boodie, Burrowing Bettong (Barrow and Boodie Islands) [88021]	Vulnerable	Species or species habitat known to occur within area
Dasyurus hallucatus		
Northern Quoll, Digul [Gogo-Yimidir], Wijingadda [Dambimangari], Wiminji [Martu] [331]	Endangered	Species or species habitat known to occur within area

Scientific Name	Threatened Category	Presence Text
Eubalaena australis		
Southern Right Whale [40]	Endangered	Species or species habitat likely to occur within area
Isoodon auratus barrowensis		
Golden Bandicoot (Barrow Island) [66666]	Vulnerable	Species or species habitat known to occur within area
Lagorchestes conspicillatus conspicillatus		
Spectacled Hare-wallaby (Barrow Island) [66661]	Vulnerable	Species or species habitat known to occur within area
Lagorchestes hirsutus Central Australian subspecies		
Mala, Rufous Hare-Wallaby (Central Australia) [88019]	Endangered	Translocated population known to occur within area
Macroderma gigas		
Ghost Bat [174]	Vulnerable	Species or species habitat likely to occur within area
Orcaella heinsohni		
Australian Snubfin Dolphin [81322]	Vulnerable	Species or species habitat known to occur within area
Osphranter robustus isabellinus		
Barrow Island Wallaroo, Barrow Island Euro [89262]	Vulnerable	Species or species habitat likely to occur within area
Petrogale lateralis lateralis		
Black-flanked Rock-wallaby, Moororong, Black-footed Rock Wallaby [66647]	Endangered	Species or species habitat known to occur within area
Rhinonicteris aurantia (Pilbara form)		
Pilbara Leaf-nosed Bat [82790]	Vulnerable	Species or species habitat known to occur within area
Sousa sahulensis		
Australian Humpback Dolphin [87942]	Vulnerable	Species or species habitat known to occur within area
PLANT		
Minuria tridens		
Minnie Daisy [13753]	Vulnerable	Species or species habitat known to occur within area
REPTILE		
Aipysurus apraefrontalis		
Short-nosed Sea Snake, Short-nosed Seasnake [1115]	Critically Endangered	Species or species habitat known to occur within area
Aipysurus foliosquama		
Leaf-scaled Sea Snake, Leaf-scaled Seasnake [1118]	Critically Endangered	Species or species habitat known to occur within area
Caretta caretta		
Loggerhead Turtle [1763]	Endangered	Breeding known to occur within area
Chelonia mydas		
Green Turtle [1765]	Vulnerable	Breeding known to occur within area
Ctenotus zastictus		
Hamelin Ctenotus [25570]	Vulnerable	Species or species habitat known to occur within area
Dermochelys coriacea		
Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Foraging, feeding or related behaviour known to occur within area
Eretmochelys imbricata		
Hawksbill Turtle [1766]	Vulnerable	Breeding known to occur within area
Liasis olivaceus barroni		
Pilbara Olive Python [66699]	Vulnerable	Species or species habitat likely to occur within area
Natator depressus		
Flatback Turtle [59257]	Vulnerable	Breeding known to occur within area
SHARK		
Carcharias taurus (west coast population)		
Grey Nurse Shark (west coast population) [68752]	Vulnerable	Congregation or aggregation known to occur within area
Carcharodon carcharias		
White Shark, Great White Shark [64470]	Vulnerable	Species or species habitat known to occur within area
Centrophorus uyato		
Little Gulper Shark [68446]	Conservation Dependent	Species or species habitat likely to occur within area

Scientific Name	Threatened Category	Presence Text
Pristis clavata Dwarf Sawfish, Queensland Sawfish [68447]	Vulnerable	Species or species habitat known to occur within area
Pristis pristis Largetooth Sawfish, Freshwater Sawfish, River Sawfish, Leichhardt's Sawfish, Northern Sawfish [60756]	Endangered	Species or species habitat likely to occur within area
Pristis zijsron Green Sawfish, Dindagubba, Narrowsnout Sawfish [68442]	Vulnerable	Species or species habitat known to occur within area
Rhincodon typus Whale Shark [66680]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Sphyrna lewini Scalloped Hammerhead [85267]	Conservation Dependent	Species or species habitat known to occur within area

Listed Migratory Species [Resource Information]

Scientific Name	Threatened Category	Presence Text
null		
Balaenoptera omurai Omura's Whale [87136]		Species or species habitat likely to occur within area
Migratory Marine Birds		
Anous stolidus Common Noddy [825]		Species or species habitat likely to occur within area
Apus pacificus Fork-tailed Swift [678]		Species or species habitat likely to occur within area
Ardenna carneipes Flesh-footed Shearwater, Fleshy-footed Shearwater [82404]		Species or species habitat likely to occur within area
Ardenna pacifica Wedge-tailed Shearwater [84292]		Breeding known to occur within area
Calonectris leucomelas Streaked Shearwater [1077]		Species or species habitat likely to occur within area
Fregata ariel Lesser Frigatebird, Least Frigatebird [1012]		Species or species habitat known to occur within area
Fregata minor Great Frigatebird, Greater Frigatebird [1013]		Species or species habitat may occur within area
Hydroprogne caspia Caspian Tern [808]		Breeding known to occur within area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Species or species habitat may occur within area
Onychoprion anaethetus Bridled Tern [82845]		Breeding known to occur within area
Phaethon lepturus White-tailed Tropicbird [1014]		Species or species habitat known to occur within area
Phaethon rubricauda Red-tailed Tropicbird [994]		Species or species habitat known to occur within area
Sterna dougallii Roseate Tern [817]		Breeding known to occur within area
Sternula albifrons Little Tern [82849]	Vulnerable	Breeding known to occur within area
Thalassarche carteri Indian Yellow-nosed Albatross [64464]	Vulnerable	Species or species habitat may occur within area
Thalassarche cauta Shy Albatross [89224]	Endangered	Species or species habitat may occur within area

Scientific Name	Threatened Category	Presence Text
Thalassarche impavida		
Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Species or species habitat may occur within area
Thalassarche melanophris		
Black-browed Albatross [66472]	Vulnerable	Species or species habitat may occur within area
Thalassarche steadi		
White-capped Albatross [64462]	Vulnerable	Species or species habitat may occur within area
Migratory Marine Species		
Anoxypristis cuspidata		
Narrow Sawfish, Knifetooth Sawfish [68448]		Species or species habitat known to occur within area
Balaenoptera bonaerensis		
Antarctic Minke Whale, Dark-shoulder Minke Whale [67812]		Species or species habitat likely to occur within area
Balaenoptera borealis		
Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera edeni		
Bryde's Whale [35]		Species or species habitat likely to occur within area
Balaenoptera musculus		
Blue Whale [36]	Endangered	Migration route known to occur within area
Balaenoptera physalus		
Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Carcharhinus longimanus		
Oceanic Whitetip Shark [84108]		Species or species habitat likely to occur within area
Carcharias taurus		
Grey Nurse Shark [64469]		Congregation or aggregation known to occur within area

Scientific Name	Threatened Category	Presence Text
Carcharodon carcharias		
White Shark, Great White Shark [64470]	Vulnerable	Species or species habitat known to occur within area
Caretta caretta		
Loggerhead Turtle [1763]	Endangered	Breeding known to occur within area
Chelonia mydas		
Green Turtle [1765]	Vulnerable	Breeding known to occur within area
Crocodylus porosus		
Salt-water Crocodile, Estuarine Crocodile [1774]		Species or species habitat may occur within area
Dermochelys coriacea		
Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Foraging, feeding or related behaviour known to occur within area
Dugong dugon		
Dugong [28]		Breeding known to occur within area
Eretmochelys imbricata		
Hawksbill Turtle [1766]	Vulnerable	Breeding known to occur within area
Eubalaena australis as Balaena glacialis australis		
Southern Right Whale [40]	Endangered	Species or species habitat likely to occur within area
Isurus oxyrinchus		
Shortfin Mako, Mako Shark [79073]		Species or species habitat likely to occur within area
Isurus paucus		
Longfin Mako [82947]		Species or species habitat likely to occur within area
Lamna nasus		
Porbeagle, Mackerel Shark [83288]		Species or species habitat may occur within area
Megaptera novaeangliae		
Humpback Whale [38]		Breeding known to occur within area

Scientific Name	Threatened Category	Presence Text
Mobula alfredi as Manta alfredi		
Reef Manta Ray, Coastal Manta Ray [90033]		Species or species habitat known to occur within area
Mobula birostris as Manta birostris		
Giant Manta Ray [90034]		Species or species habitat known to occur within area
Natator depressus		
Flatback Turtle [59257]	Vulnerable	Breeding known to occur within area
Orcaella heinsohni		
Australian Snubfin Dolphin [81322]	Vulnerable	Species or species habitat known to occur within area
Orcinus orca		
Killer Whale, Orca [46]		Species or species habitat may occur within area
Physeter macrocephalus		
Sperm Whale [59]		Species or species habitat may occur within area
Pristis clavata		
Dwarf Sawfish, Queensland Sawfish [68447]	Vulnerable	Species or species habitat known to occur within area
Pristis pristis		
Largetooth Sawfish, Freshwater Sawfish, River Sawfish, Leichhardt's Sawfish, Northern Sawfish [60756]	Endangered	Species or species habitat likely to occur within area
Pristis zijsron		
Green Sawfish, Dindagubba, Narrowsnout Sawfish [68442]	Vulnerable	Species or species habitat known to occur within area
Rhincodon typus		
Whale Shark [66680]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Sousa sahulensis as Sousa chinensis		
Australian Humpback Dolphin [87942]	Vulnerable	Species or species habitat known to occur within area
Tursiops aduncus (Arafura/Timor Sea populations)		
Spotted Bottlenose Dolphin (Arafura/Timor Sea populations) [78900]		Species or species habitat known to occur within area
Migratory Terrestrial Species		
Hirundo rustica		
Barn Swallow [662]		Species or species habitat may occur within area
Motacilla cinerea		
Grey Wagtail [642]		Species or species habitat may occur within area
Motacilla flava		
Yellow Wagtail [644]		Species or species habitat may occur within area
Migratory Wetlands Species		
Actitis hypoleucos		
Common Sandpiper [59309]		Species or species habitat known to occur within area
Calidris acuminata		
Sharp-tailed Sandpiper [874]	Vulnerable	Species or species habitat known to occur within area
Calidris canutus		
Red Knot, Knot [855]	Vulnerable	Species or species habitat known to occur within area
Calidris ferruginea		
Curlew Sandpiper [856]	Critically Endangered	Species or species habitat known to occur within area
Calidris melanotos		
Pectoral Sandpiper [858]		Species or species habitat may occur within area
Charadrius leschenaultii		
Greater Sand Plover, Large Sand Plover [877]	Vulnerable	Species or species habitat known to occur within area
Charadrius veredus		
Oriental Plover, Oriental Dotterel [882]		Species or species habitat may occur within area

Scientific Name	Threatened Category	Presence Text
Glareola maldivarum		
Oriental Pratincole [840]		Species or species habitat may occur within area
Limnodromus semipalmatus		
Asian Dowitcher [843]	Vulnerable	Species or species habitat known to occur within area
Limosa lapponica		
Bar-tailed Godwit [844]		Species or species habitat known to occur within area
Numenius madagascariensis		
Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat known to occur within area
Pandion haliaetus		
Osprey [952]		Breeding known to occur within area
Thalasseus bergii		
Greater Crested Tern [83000]		Breeding known to occur within area
Tringa nebularia		
Common Greenshank, Greenshank [832]	Endangered	Species or species habitat likely to occur within area

Commonwealth Lands [Resource Information]

The Commonwealth area listed below may indicate the presence of Commonwealth land in this vicinity. Due to the unreliability of the data source, all proposals should be checked as to whether it impacts on a Commonwealth area, before making a definitive decision. Contact the State or Territory government land department for further information.

Commonwealth Land Name	State
Defence	
Defence - EXMOUTH VLF TRANSMITTER STATION [50123]	WA
Defence - EXMOUTH VLF TRANSMITTER STATION [50122]	WA
Defence - LEARMONTH - AIR WEAPONS RANGE [50193]	WA
Defence - LEARMONTH RADAR SITE - VLAMING HEAD EXMOUTH [50001]	WA

Ningaloo Marine Area - Commonwealth Waters	WA	Listed place

Listed Marine Species [Resource Information]

Scientific Name	Threatened Category	Presence Text
Bird		
Actitis hypoleucos		
Common Sandpiper [59309]		Species or species habitat known to occur within area
Anous stolidus		
Common Noddy [825]		Species or species habitat likely to occur within area
Apus pacificus		
Fork-tailed Swift [678]		Species or species habitat likely to occur within area overfly marine area
Ardenna carneipes as Puffinus carneipes		
Flesh-footed Shearwater, Fleshy-footed Shearwater [82404]		Species or species habitat likely to occur within area
Ardenna pacifica as Puffinus pacificus		
Wedge-tailed Shearwater [84292]		Breeding known to occur within area
Bubulcus ibis as Ardea ibis		
Cattle Egret [66521]		Species or species habitat may occur within area overfly marine area
Calidris acuminata		
Sharp-tailed Sandpiper [874]	Vulnerable	Species or species habitat known to occur within area
Calidris canutus		
Red Knot, Knot [855]	Vulnerable	Species or species habitat known to occur within area overfly marine area

Scientific Name	Threatened Category	Presence Text
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat known to occur within area overfly marine area
Calidris melanotos Pectoral Sandpiper [858]		Species or species habitat may occur within area overfly marine area
Calonectris leucomelas Streaked Shearwater [1077]		Species or species habitat likely to occur within area
Chalcites osculans as Chrysococcyx osculans Black-eared Cuckoo [83425]		Species or species habitat known to occur within area overfly marine area
Charadrius leschenaultii Greater Sand Plover, Large Sand Plover [877]	Vulnerable	Species or species habitat known to occur within area
Charadrius veredus Oriental Plover, Oriental Dotterel [882]		Species or species habitat may occur within area overfly marine area
Chroicocephalus novaehollandiae as Larus novaehollandiae Silver Gull [82326]		Breeding known to occur within area
Fregata ariel Lesser Frigatebird, Least Frigatebird [1012]		Species or species habitat known to occur within area
Fregata minor Great Frigatebird, Greater Frigatebird [1013]		Species or species habitat may occur within area
Glareola maldivarum Oriental Pratincole [840]		Species or species habitat may occur within area overfly marine area

Scientific Name	Threatened Category	Presence Text
Haliaeetus leucogaster White-bellied Sea-Eagle [943]		Species or species habitat known to occur within area
Hirundo rustica Barn Swallow [662]		Species or species habitat may occur within area overfly marine area
Hydroprogne caspia as Sterna caspia Caspian Tern [808]		Breeding known to occur within area
Larus pacificus Pacific Gull [811]		Breeding known to occur within area
Limnodromus semipalmatus Asian Dowitcher [843]	Vulnerable	Species or species habitat known to occur within area overfly marine area
Limosa lapponica Bar-tailed Godwit [844]		Species or species habitat known to occur within area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Species or species habitat may occur within area
Merops ornatus Rainbow Bee-eater [670]		Species or species habitat may occur within area overfly marine area
Motacilla cinerea Grey Wagtail [642]		Species or species habitat may occur within area overfly marine area
Motacilla flava Yellow Wagtail [644]		Species or species habitat may occur within area overfly marine area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat known to occur within area

Scientific Name	Threatened Category	Presence Text
Onychoprion anaethetus as Sterna anaethetus		
Bridled Tern [82845]		Breeding known to occur within area
Onychoprion fuscatus as Sterna fuscata		
Sooty Tern [90682]		Breeding known to occur within area
Pandion haliaetus		
Osprey [952]		Breeding known to occur within area
Papasula abbotti		
Abbott's Booby [59297]	Endangered	Species or species habitat may occur within area
Phaethon lepturus		
White-tailed Tropicbird [1014]		Species or species habitat known to occur within area
Phaethon lepturus fulvus		
Christmas Island White-tailed Tropicbird, Golden Bosunbird [26021]	Endangered	Species or species habitat may occur within area
Phaethon rubricauda		
Red-tailed Tropicbird [994]		Species or species habitat known to occur within area
Pterodroma mollis		
Soft-plumaged Petrel [1036]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Rostratula australis as Rostratula benghalensis (sensu lato)		
Australian Painted Snipe [77037]	Endangered	Species or species habitat likely to occur within area overfly marine area
Sterna dougallii		
Roseate Tern [817]		Breeding known to occur within area
Sternula albifrons as Sterna albifrons		
Little Tern [82849]	Vulnerable	Breeding known to occur within area
Sternula nereis as Sterna nereis		
Fairy Tern [82949]		Breeding known to occur within area

Scientific Name	Threatened Category	Presence Text
Thalassarche carteri		
Indian Yellow-nosed Albatross [64464]	Vulnerable	Species or species habitat may occur within area
Thalassarche cauta		
Shy Albatross [89224]	Endangered	Species or species habitat may occur within area
Thalassarche impavida		
Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Species or species habitat may occur within area
Thalassarche melanophris		
Black-browed Albatross [66472]	Vulnerable	Species or species habitat may occur within area
Thalassarche steadi		
White-capped Albatross [64462]	Vulnerable	Species or species habitat may occur within area
Thalasseus bengalensis as Sterna bengalensis		
Lesser Crested Tern [66546]		Breeding known to occur within area
Thalasseus bergii as Sterna bergii		
Greater Crested Tern [83000]		Breeding known to occur within area
Tringa nebularia		
Common Greenshank, Greenshank [832]	Endangered	Species or species habitat likely to occur within area overfly marine area
Fish		
Acentronura larsonae		
Helen's Pygmy Pipehorse [66186]		Species or species habitat may occur within area
Bhanotia fasciolata		
Corrugated Pipefish, Barbed Pipefish [66188]		Species or species habitat may occur within area
Bulbonaricus brauni		
Braun's Pughead Pipefish, Pug-headed Pipefish [66189]		Species or species habitat may occur within area

Scientific Name	Threatened Category	Presence Text
Campichthys galei Gale's Pipefish [66191]		Species or species habitat may occur within area
Campichthys tricarinatus Three-keel Pipefish [66192]		Species or species habitat may occur within area
Choeroichthys brachysoma Pacific Short-bodied Pipefish, Short-bodied Pipefish [66194]		Species or species habitat may occur within area
Choeroichthys latispinosus Muiron Island Pipefish [66196]		Species or species habitat may occur within area
Choeroichthys suillus Pig-snouted Pipefish [66198]		Species or species habitat may occur within area
Corythoichthys amplexus Fijian Banded Pipefish, Brown-banded Pipefish [66199]		Species or species habitat may occur within area
Corythoichthys flavofasciatus Reticulate Pipefish, Yellow-banded Pipefish, Network Pipefish [66200]		Species or species habitat may occur within area
Corythoichthys intestinalis Australian Messmate Pipefish, Banded Pipefish [66202]		Species or species habitat may occur within area
Corythoichthys schultzi Schultz's Pipefish [66205]		Species or species habitat may occur within area
Cosmocampus banneri Roughridge Pipefish [66206]		Species or species habitat may occur within area
Doryrhamphus dactyliophorus Banded Pipefish, Ringed Pipefish [66210]		Species or species habitat may occur within area
Doryrhamphus excisus Bluestripe Pipefish, Indian Blue-stripe Pipefish, Pacific Blue-stripe Pipefish [66211]		Species or species habitat may occur within area
Doryrhamphus janssi Cleaner Pipefish, Janss' Pipefish [66212]		Species or species habitat may occur within area
Doryrhamphus multiannulatus Many-banded Pipefish [66717]		Species or species habitat may occur within area
Doryrhamphus negrosensis Flagtail Pipefish, Masthead Island Pipefish [66213]		Species or species habitat may occur within area
Festucalex scalaris Ladder Pipefish [66216]		Species or species habitat may occur within area
Filicampus tigris Tiger Pipefish [66217]		Species or species habitat may occur within area
Halicampus brocki Brock's Pipefish [66219]		Species or species habitat may occur within area
Halicampus dunckeri Red-hair Pipefish, Duncker's Pipefish [66220]		Species or species habitat may occur within area
Halicampus grayi Mud Pipefish, Gray's Pipefish [66221]		Species or species habitat may occur within area
Halicampus nitidus Glittering Pipefish [66224]		Species or species habitat may occur within area
Halicampus spinirostris Spiny-snout Pipefish [66225]		Species or species habitat may occur within area

Scientific Name	Threatened Category	Presence Text
Haliichthys taeniophorus Ribboned Pipehorse, Ribboned Seadragon [66226]		Species or species habitat may occur within area
Hippichthys penicillus Beady Pipefish, Steep-nosed Pipefish [66231]		Species or species habitat may occur within area
Hippocampus angustus Western Spiny Seahorse, Narrow-bellied Seahorse [66234]		Species or species habitat may occur within area
Hippocampus histrix Spiny Seahorse, Thorny Seahorse [66236]		Species or species habitat may occur within area
Hippocampus kuda Spotted Seahorse, Yellow Seahorse [66237]		Species or species habitat may occur within area
Hippocampus planifrons Flat-face Seahorse [66238]		Species or species habitat may occur within area
Hippocampus spinosissimus Hedgehog Seahorse [66239]		Species or species habitat may occur within area
Hippocampus trimaculatus Three-spot Seahorse, Low-crowned Seahorse, Flat-faced Seahorse [66720]		Species or species habitat may occur within area
Lissocampus fatiloquus Prophet's Pipefish [66250]		Species or species habitat may occur within area
Micrognathus micronotopterus Tidepool Pipefish [66255]		Species or species habitat may occur within area
Nannocampus subosseus Bonyhead Pipefish, Bony-headed Pipefish [66264]		Species or species habitat may occur within area

Scientific Name	Threatened Category	Presence Text
Phoxocampus belcheri Black Rock Pipefish [66719]		Species or species habitat may occur within area
Solegnathus hardwickii Pallid Pipehorse, Hardwick's Pipehorse [66272]		Species or species habitat may occur within area
Solegnathus lettiensis Gunther's Pipehorse, Indonesian Pipefish [66273]		Species or species habitat may occur within area
Solenostomus cyanopterus Robust Ghostpipefish, Blue-finned Ghost Pipefish, [66183]		Species or species habitat may occur within area
Stigmatopora argus Spotted Pipefish, Gulf Pipefish, Peacock Pipefish [66276]		Species or species habitat may occur within area
Syngnathoides biaculeatus Double-end Pipehorse, Double-ended Pipehorse, Alligator Pipefish [66279]		Species or species habitat may occur within area
Trachyrhamphus bicoarctatus Bentstick Pipefish, Bend Stick Pipefish, Short-tailed Pipefish [66280]		Species or species habitat may occur within area
Trachyrhamphus longirostris Straightstick Pipefish, Long-nosed Pipefish, Straight Stick Pipefish [66281]		Species or species habitat may occur within area
Mammal		
Dugong dugon Dugong [28]		Breeding known to occur within area
Reptile		
Aipysurus apraefrontalis Short-nosed Sea Snake, Short-nosed Seasnake [1115]	Critically Endangered	Species or species habitat known to occur within area
Aipysurus duboisii Dubois' Sea Snake, Dubois' Seasnake, Reef Shallows Sea Snake [1116]		Species or species habitat may occur within area

Scientific Name	Threatened Category	Presence Text
Aipysurus foliosquama Leaf-scaled Sea Snake, Leaf-scaled Seasnake [1118]	Critically Endangered	Species or species habitat known to occur within area
Aipysurus laevis Olive Sea Snake, Olive-brown Sea Snake [1120]		Species or species habitat may occur within area
Aipysurus mosaicus as Aipysurus eydouxii Mosaic Sea Snake [87261]		Species or species habitat may occur within area
Aipysurus pooleorum Shark Bay Sea Snake [66061]		Species or species habitat may occur within area
Aipysurus tenuis Brown-lined Sea Snake, Mjoberg's Sea Snake [1121]		Species or species habitat may occur within area
Caretta caretta Loggerhead Turtle [1763]	Endangered	Breeding known to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Breeding known to occur within area
Crocodylus porosus Salt-water Crocodile, Estuarine Crocodile [1774]		Species or species habitat may occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Foraging, feeding or related behaviour known to occur within area
Emydocephalus annulatus Eastern Turtle-headed Sea Snake [1125]		Species or species habitat may occur within area
Ephalophis greyae as Ephalophis greyi Mangrove Sea Snake [93738]		Species or species habitat may occur within area
Eretmochelys imbricata Hawksbill Turtle [1766]	Vulnerable	Breeding known to occur within area

Scientific Name	Threatened Category	Presence Text
Hydrelaps darwiniensis Port Darwin Sea Snake, Black-ringed Mangrove Sea Snake [1100]		Species or species habitat may occur within area
Hydrophis czeblukovi Fine-spined Sea Snake [59233]		Species or species habitat may occur within area
Hydrophis elegans Elegant Sea Snake, Bar-bellied Sea Snake [1104]		Species or species habitat may occur within area
Hydrophis kingii as Disteira kingii Spectacled Sea Snake [93511]		Species or species habitat may occur within area
Hydrophis macdowelli as Hydrophis mcdowelli MacDowell's Sea Snake, Small-headed Sea Snake, [75601]		Species or species habitat may occur within area
Hydrophis major as Disteira major Olive-headed Sea Snake [93512]		Species or species habitat may occur within area
Hydrophis ornatus Spotted Sea Snake, Ornate Reef Sea Snake [1111]		Species or species habitat may occur within area
Hydrophis peronii as Acalyptophis peronii Horned Sea Snake [93509]		Species or species habitat may occur within area
Hydrophis platura as Pelamis platurus Yellow-bellied Sea Snake [93746]		Species or species habitat may occur within area
Hydrophis stokesii as Astrotia stokesii Stokes' Sea Snake [93510]		Species or species habitat may occur within area
Natator depressus Flatback Turtle [59257]	Vulnerable	Breeding known to occur within area

Whales and Other Cetaceans		[Resource Information]
Current Scientific Name	Status	Type of Presence
Mammal		

Current Scientific Name	Status	Type of Presence
Balaenoptera acutorostrata Minke Whale [33]		Species or species habitat may occur within area
Balaenoptera bonaerensis Antarctic Minke Whale, Dark-shoulder Minke Whale [67812]		Species or species habitat likely to occur within area
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera edeni Bryde's Whale [35]		Species or species habitat likely to occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Migration route known to occur within area
Balaenoptera omurai Omura's Whale [87136]		Species or species habitat likely to occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Delphinus delphis Common Dolphin, Short-beaked Common Dolphin [60]		Species or species habitat may occur within area
Eubalaena australis Southern Right Whale [40]	Endangered	Species or species habitat likely to occur within area
Feresa attenuata Pygmy Killer Whale [61]		Species or species habitat may occur within area
Globicephala macrorhynchus Short-finned Pilot Whale [62]		Species or species habitat may occur within area

Current Scientific Name	Status	Type of Presence
Grampus griseus Risso's Dolphin, Grampus [64]		Species or species habitat may occur within area
Indopacetus pacificus Longman's Beaked Whale [72]		Species or species habitat may occur within area
Kogia breviceps Pygmy Sperm Whale [57]		Species or species habitat may occur within area
Kogia sima Dwarf Sperm Whale [85043]		Species or species habitat may occur within area
Lagenodelphis hosei Fraser's Dolphin, Sarawak Dolphin [41]		Species or species habitat may occur within area
Megaptera novaeangliae Humpback Whale [38]		Breeding known to occur within area
Mesoplodon densirostris Blainville's Beaked Whale, Dense-beaked Whale [74]		Species or species habitat may occur within area
Mesoplodon ginkgodens Gingko-toothed Beaked Whale, Gingko-toothed Whale, Gingko Beaked Whale [59564]		Species or species habitat may occur within area
Orcaella heinsohni Australian Snubfin Dolphin [81322]	Vulnerable	Species or species habitat known to occur within area
Orcinus orca Killer Whale, Orca [46]		Species or species habitat may occur within area
Peponocephala electra Melon-headed Whale [47]		Species or species habitat may occur within area

Current Scientific Name	Status	Type of Presence
Physeter macrocephalus Sperm Whale [59]		Species or species habitat may occur within area
Pseudorca crassidens False Killer Whale [48]		Species or species habitat likely to occur within area
Sousa sahulensis Australian Humpback Dolphin [87942]	Vulnerable	Species or species habitat known to occur within area
Stenella attenuata Spotted Dolphin, Pantropical Spotted Dolphin [51]		Species or species habitat may occur within area
Stenella coeruleoalba Striped Dolphin, Euphrosyne Dolphin [52]		Species or species habitat may occur within area
Stenella longirostris Long-snouted Spinner Dolphin [29]		Species or species habitat may occur within area
Steno bredanensis Rough-toothed Dolphin [30]		Species or species habitat may occur within area
Tursiops aduncus Indian Ocean Bottlenose Dolphin, Spotted Bottlenose Dolphin [68418]		Species or species habitat likely to occur within area
Tursiops aduncus (Arafura/Timor Sea populations) Spotted Bottlenose Dolphin (Arafura/Timor Sea populations) [78900]		Species or species habitat known to occur within area
Tursiops truncatus s. str. Bottlenose Dolphin [68417]		Species or species habitat may occur within area
Ziphius cavirostris Cuvier's Beaked Whale, Goose-beaked Whale [56]		Species or species habitat may occur within area

Nationally Important Wetlands [Resource Information]

Wetland Name	State
Cape Range Subterranean Waterways	WA

EPBC Act Referrals [Resource Information]

Title of referral	Reference	Referral Outcome	Assessment Status
3D Seismic Survey in the Carnarvon Bsin on the North West Shelf	2002/778		Completed
Babylon 3D Marine Seismic Survey, Commonwealth Waters, nr Exmouth WA	2013/7081		Completed
Browse to North West Shelf Development, Indian Ocean, WA	2018/8319		Approval
DAVROS MC 3D marine seismic survey northwaet of Dampier, WA	2013/7092		Completed
Deep Water Northwest Shelf 2D Seismic Survey	2007/3260		Completed
Development of Mutineer and Exeter petroleum fields for oil production, Permit	2003/1033		Completed
Gorgon Gas Development	2003/1294		Post-Approval

Title of referral	Reference	Referral Outcome	Assessment Status
Ningaloo Lighthouse Development, 17km north west Exmouth, Western Australia	2020/8693		Post-Approval
Offshore Dredge Spoil Disposal - Mardie Project	2024/10054		Referral Decision
Optimised Mardie Project ? Additional Triodia Grassland Habitat Clearing	2024/10094		Referral Decision
Optimised Mardie Solar Salt Project	2022/9169		Post-Approval
Project Highclere Cable Lay and Operation	2022/09203		Completed
Action clearly unacceptable			
Highlands 3D Marine Seismic Survey	2012/6680	Action Clearly Unacceptable	Completed
Controlled action			
'Van Gogh' Petroleum Field Development	2007/3213	Controlled Action	Post-Approval
Balmoral South Iron Ore Mine	2008/4236	Controlled Action	Post-Approval
Binowee Iron Ore Project	2001/366	Controlled Action	Proposed Decision
Construct and operate LNG & domestic gas plant including onshore and offshore facilities - Wheatston	2008/4469	Controlled Action	Post-Approval
Develop Jansz-Io deepwater gas field in Permit Areas WA-18-R, WA-25-R and WA-26-	2005/2184	Controlled Action	Post-Approval
Development of Angel gas and condensate field, North West Shelf	2004/1805	Controlled Action	Post-Approval
Development of Browse Basin Gas Fields (Upstream)	2008/4111	Controlled Action	Completed
Development of Coniston/Novara fields within the Exmouth Sub-basin	2011/5995	Controlled Action	Post-Approval
Development of Stybarrow petroleum field incl drilling and facility installation	2004/1469	Controlled Action	Post-Approval
Echo-Yodel Production Wells	2000/11	Controlled Action	Post-Approval

Title of referral	Reference	Referral Outcome	Assessment Status
Controlled action			
Enfield full field development	2001/257	Controlled Action	Post-Approval
Equus Gas Fields Development Project, Carnarvon Basin	2012/6301	Controlled Action	Completed
Eramurra Industrial Salt Project	2021/9027	Controlled Action	Assessment Approach
Eramurra Industrial Salt Project, near Karratha, WA	2019/8448	Controlled Action	Completed
Gorgon Gas Development 4th Train Proposal	2011/5942	Controlled Action	Post-Approval
Gorgon Gas Revised Development	2008/4178	Controlled Action	Post-Approval
Greater Enfield (Vincent) Development	2005/2110	Controlled Action	Post-Approval
Greater Gorgon Development - Optical Fibre Cable, Mainland to Barrow Island	2005/2141	Controlled Action	Completed
Light Crude Oil Production	2001/365	Controlled Action	Post-Approval
Mardie Project, 80 km south west of Karratha, WA	2018/8236	Controlled Action	Post-Approval
Mauds Landing Marina	2000/98	Controlled Action	Completed
Pluto Gas Project	2005/2258	Controlled Action	Completed
Pluto Gas Project Including Site B	2006/2968	Controlled Action	Post-Approval
Proposed West Pilbara Iron Ore Project	2009/4706	Controlled Action	Post-Approval
Pyrenees Oil Fields Development	2005/2034	Controlled Action	Post-Approval
Simpson Development	2000/59	Controlled Action	Completed
Simpson Oil Field Development	2001/227	Controlled Action	Post-Approval
The Scarborough Project - FLNG & assoc subsea infrastructure, Carnarvon Basin	2013/6811	Controlled Action	Post-Approval

Title of referral	Reference	Referral Outcome	Assessment Status
Controlled action			
Vincent Appraisal Well	2000/22	Controlled Action	Post-Approval
Yardie Creek Road Realignment Project	2021/8967	Controlled Action	Assessment Approach

Key Ecological Features [Resource Information]

Key Ecological Features are the parts of the marine ecosystem that are considered to be important for the biodiversity or ecosystem functioning and integrity of the Commonwealth Marine Area.

Name	Region
Ancient coastline at 125 m depth contour	North-west
Canyons linking the Cuvier Abyssal Plain and the Cape Range Peninsula	North-west
Commonwealth waters adjacent to Ningaloo Reef	North-west
Continental Slope Demersal Fish Communities	North-west
Exmouth Plateau	North-west
Glomar Shoals	North-west
Mermaid Reef and Commonwealth waters surrounding Rowley Shoals	North-west

Biologically Important Areas [Resource Information]

Scientific Name	Behaviour	Presence
Dugong		

Scientific Name	Behaviour	Presence
Dugong dugon Dugong [28]	Breeding	Known to occur
Dugong dugon Dugong [28]	Calving	Known to occur
Dugong dugon Dugong [28]	Foraging (high density seagrass beds)	Known to occur
Dugong dugon Dugong [28]	Nursing	Known to occur
Marine Turtles		
Caretta caretta Loggerhead Turtle [1763]	Internesting buffer	Known to occur
Caretta caretta Loggerhead Turtle [1763]	Nesting	Known to occur
Chelonia mydas Green Turtle [1765]	Aggregation	Known to occur
Chelonia mydas Green Turtle [1765]	Basking	Known to occur
Chelonia mydas Green Turtle [1765]	Foraging	Known to occur
Chelonia mydas Green Turtle [1765]	Internesting	Known to occur
Chelonia mydas Green Turtle [1765]	Internesting buffer	Known to occur
Chelonia mydas Green Turtle [1765]	Mating	Known to occur
Chelonia mydas Green Turtle [1765]	Nesting	Known to occur

Scientific Name	Behaviour	Presence
Eretmochelys imbricata Hawksbill Turtle [1766]	Foraging	Known to occur
Eretmochelys imbricata Hawksbill Turtle [1766]	Internesting	Known to occur
Eretmochelys imbricata Hawksbill Turtle [1766]	Internesting buffer	Known to occur
Eretmochelys imbricata Hawksbill Turtle [1766]	Mating	Known to occur
Eretmochelys imbricata Hawksbill Turtle [1766]	Nesting	Known to occur
Natator depressus Flatback Turtle [59257]	Aggregation	Known to occur
Natator depressus Flatback Turtle [59257]	Foraging	Known to occur
Natator depressus Flatback Turtle [59257]	Internesting	Known to occur
Natator depressus Flatback Turtle [59257]	Internesting buffer	Known to occur
Natator depressus Flatback Turtle [59257]	Mating	Known to occur
Natator depressus Flatback Turtle [59257]	Nesting	Known to occur
Seabirds		
Ardenna tenuirostris Short-tailed Shearwater [84292]	Breeding	Known to occur
Fregata ariel Lesser Frigatebird [1012]	Breeding	Known to occur
Phaethon lepturus White-tailed Tropicbird [1014]	Breeding	Known to occur

Scientific Name	Behaviour	Presence
Sterna dougallii		
Roseate Tern [817]	Breeding	Known to occur
Sternula albifrons sinensis		
Little Tern [82850]	Resting	Known to occur
Sternula nereis		
Fairy Tern [82949]	Breeding	Known to occur
Thalasseus bengalensis		
Lesser Crested Tern [66546]	Breeding	Known to occur
Sharks		
Rhincodon typus		
Whale Shark [66680]	Foraging	Known to occur
Rhincodon typus		
Whale Shark [66680]	Foraging (high density prey)	Known to occur
Whales		
Balaenoptera musculus brevicauda		
Pygmy Blue Whale [81317]	Foraging	Known to occur
Balaenoptera musculus brevicauda		
Pygmy Blue Whale [81317]	Migration	Known to occur
Megaptera novaeangliae		
Humpback Whale [38]	Migration (north and south)	Known to occur
Megaptera novaeangliae		
Humpback Whale [38]	Resting	Known to occur

Caveat

1 PURPOSE

This report is designed to assist in identifying the location of matters of national environmental significance (MNES) and other matters protected by the Environment Protection and Biodiversity Conservation Act 1999 (Cth) (EPBC Act) which may be relevant in determining obligations and requirements under the EPBC Act.

The report contains the mapped locations of:

- World and National Heritage properties;
- Wetlands of International and National Importance;
- Commonwealth and State/Territory reserves;
- distribution of listed threatened, migratory and marine species;
- listed threatened ecological communities; and
- other information that may be useful as an indicator of potential habitat value.

2 DISCLAIMER

This report is not intended to be exhaustive and should only be relied upon as a general guide as mapped data is not available for all species or ecological communities listed under the EPBC Act (see below). Persons seeking to use the information contained in this report to inform the referral of a proposed action under the EPBC Act should consider the limitations noted below and whether additional information is required to determine the existence and location of MNES and other protected matters.

Where data is available to inform the mapping of protected species, the presence type (e.g. known, likely or may occur) that can be determined from the data is indicated in general terms. It is the responsibility of any person using or relying on the information in this report to ensure that it is suitable for the circumstances of any proposed use. The Commonwealth cannot accept responsibility for the consequences of any use of the report or any part thereof. To the maximum extent allowed under governing law, the Commonwealth will not be liable for any loss or damage that may be occasioned directly or indirectly through the use of, or reliance on the contents of this report.

3 DATA SOURCES

Threatened ecological communities

For threatened ecological communities where the distribution is well known, maps are generated based on information contained in recovery plans, State vegetation maps and remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

Threatened, migratory and marine species

Threatened, migratory and marine species distributions have been discerned through a variety of methods. Where distributions are well known and if time permits, distributions are inferred from either thematic spatial data (i.e. vegetation, soils, geology, elevation, aspect, terrain, etc.) together with point locations and described habitat; or modelled (MAXENT or BIOCLIM habitat modelling) using point locations and environmental data layers.

Where little information is available for a species or large number of maps are required in a short time-frame, maps are derived either from 0.04 or 0.02 decimal degree cells; by an automated process using polygon capture techniques (static two kilometre grid cells, alpha-hull and convex hull); or captured manually or by using topographic features (national park boundaries, islands, etc.).

In the early stages of the distribution mapping process (1999-early 2000s) distributions were defined by degree blocks, 100K or 250K map sheets to rapidly create distribution maps. More detailed distribution mapping methods are used to update these distributions when time permits.

4 LIMITATIONS

The following species and ecological communities have not been mapped and do not appear in this report:

- threatened species listed as extinct or considered vagrants;
- some recently listed species and ecological communities;
- some listed migratory and listed marine species, which are not listed as threatened species; and
- migratory species that are very widespread, vagrant, or only occur in Australia in small numbers.

The following groups have been mapped, but may not cover the complete distribution of the species:

- listed migratory and/or listed marine seabirds, which are not listed as threatened, have only been mapped for recorded breeding sites; and
- seals which have only been mapped for breeding sites near the Australian continent

The breeding sites may be important for the protection of the Commonwealth Marine environment.

Refer to the metadata for the feature group (using the Resource Information link) for the currency of the information.

Acknowledgements

This database has been compiled from a range of data sources. The department acknowledges the following custodians who have contributed valuable data and advice:

-Office of Environment and Heritage, New South Wales

EPBC Act Protected Matters Report

This report provides general guidance on matters of national environmental significance and other matters protected by the EPBC Act in the area you have selected. Please see the caveat for interpretation of information provided here.

Report created: 15-Sep-2025

Summary
Details
- Matters of NES
- Other Matters Protected by the EPBC Act
- Extra Information

Caveat
Acknowledgements

Summary

Matters of National Environment Significance

This part of the report summarises the matters of national environmental significance that may occur in, or may relate to, the area you nominated. Further information is available in the detail part of the report, which can be accessed by scrolling or following the links below. If you are proposing to undertake an activity that may have a significant impact on one or more matters of national environmental significance then you should consider the Administrative Guidelines on Significance.

World Heritage Properties:	2
National Heritage Places:	2
Wetlands of International Importance (Ramsar	None
Great Barrier Reef Marine Park:	None
Commonwealth Marine Area:	4
Listed Threatened Ecological Communities:	None
Listed Threatened Species:	63
Listed Migratory Species:	69

Other Matters Protected by the EPBC Act

This part of the report summarises other matters protected under the Act that may relate to the area you nominated. Approval may be required for a proposed activity that significantly affects the environment on Commonwealth land, when the action is outside the Commonwealth land, or the environment anywhere when the action is taken on Commonwealth land. Approval may also be required for the Commonwealth or Commonwealth agencies proposing to take an action that is likely to have a significant impact on the environment anywhere.

The EPBC Act protects the environment on Commonwealth land, the environment from the actions taken on Commonwealth land, and the environment from actions taken by Commonwealth agencies. As heritage values of a place are part of the 'environment', these aspects of the EPBC Act protect the Commonwealth Heritage values of a Commonwealth Heritage place. Information on the new heritage laws can be found at https://www.dcceew.gov.au/parks-heritage/heritage

A permit may be required for activities in or on a Commonwealth area that may affect a member of a listed threatened species or ecological community, a member of a listed migratory species, whales and other cetaceans, or a member of a listed marine species.

Commonwealth Lands:	7
Commonwealth Heritage Places:	2
Listed Marine Species:	119
Whales and Other Cetaceans:	33
Critical Habitats:	None
Commonwealth Reserves Terrestrial:	None
Australian Marine Parks:	13
Habitat Critical to the Survival of Marine Turtles:	4

Extra Information

This part of the report provides information that may also be relevant to the area you have

State and Territory Reserves:	39
Regional Forest Agreements:	None
Nationally Important Wetlands:	2
EPBC Act Referrals:	222
Key Ecological Features (Marine):	7
Biologically Important Areas:	40
Bioregional Assessments:	None
Geological and Bioregional Assessments:	None

Details

Matters of National Environmental Significance

World Heritage Properties [Resource Information]

Name	State	Legal Status
Murujuga Cultural Landscape	WA	Declared property
The Ningaloo Coast	WA	Declared property

National Heritage Places [Resource Information]

Name	State	Legal Status
Indigenous		
Dampier Archipelago (including Burrup Peninsula)	WA	Listed place
Natural		
The Ningaloo Coast	WA	Listed place

Commonwealth Marine Area [Resource Information]

Approval is required for a proposed activity that is located within the Commonwealth Marine Area which has, will have, or is likely to have a significant impact on the environment. Approval may be required for a proposed action taken outside a Commonwealth Marine Area but which has, may have or is likely to have a significant impact on the environment in the Commonwealth Marine Area.

Feature Name
Commonwealth Marine Areas (EPBC Act)
Commonwealth Marine Areas (EPBC Act)
Commonwealth Marine Areas (EPBC Act)
Commonwealth Marine Areas (EPBC Act)

Listed Threatened Species [Resource Information]

Status of Conservation Dependent and Extinct are not MNES under the EPBC Act.
Number is the current name ID.

Scientific Name	Threatened Category	Presence Text
BIRD		
Aphelocephala leucopsis Southern Whiteface [529]	Vulnerable	Species or species habitat may occur within area
Calidris acuminata Sharp-tailed Sandpiper [874]	Vulnerable	Species or species habitat known to occur within area
Calidris canutus Red Knot, Knot [855]	Vulnerable	Species or species habitat known to occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat known to occur within area
Charadrius leschenaultii Greater Sand Plover, Large Sand Plover [877]	Vulnerable	Species or species habitat known to occur within area
Erythrotriorchis radiatus Red Goshawk [942]	Endangered	Species or species habitat may occur within area
Falco hypoleucos Grey Falcon [929]	Vulnerable	Species or species habitat known to occur within area
Limnodromus semipalmatus Asian Dowitcher [843]	Vulnerable	Species or species habitat known to occur within area
Limosa lapponica menzbieri Northern Siberian Bar-tailed Godwit, Russkoye Bar-tailed Godwit [86432]	Endangered	Species or species habitat known to occur within area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Species or species habitat may occur within area
Malurus leucopterus edouardi White-winged Fairy-wren (Barrow Island), Barrow Island Black-and-white Fairy-wren [26194]	Vulnerable	Species or species habitat likely to occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat known to occur within area
Papasula abbotti Abbott's Booby [59297]	Endangered	Species or species habitat may occur within area

Scientific Name	Threatened Category	Presence Text
Pezoporus occidentalis Night Parrot [59350]	Critically Endangered	Species or species habitat may occur within area
Phaethon lepturus fulvus Christmas Island White-tailed Tropicbird, Golden Bosunbird [26021]	Endangered	Species or species habitat may occur within area
Phaethon rubricauda westralis Red-tailed Tropicbird (Indian Ocean), Indian Ocean Red-tailed Tropicbird [91824]	Endangered	Species or species habitat known to occur within area
Pterodroma mollis Soft-plumaged Petrel [1036]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Rostratula australis Australian Painted Snipe [77037]	Endangered	Species or species habitat likely to occur within area
Sternula albifrons Little Tern [82849]	Vulnerable	Breeding known to occur within area
Sternula nereis nereis Australian Fairy Tern [82950]	Vulnerable	Breeding known to occur within area
Thalassarche carteri Indian Yellow-nosed Albatross [64464]	Vulnerable	Species or species habitat may occur within area
Thalassarche cauta Shy Albatross [89224]	Endangered	Species or species habitat may occur within area
Thalassarche impavida Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Species or species habitat may occur within area
Thalassarche melanophris Black-browed Albatross [66472]	Vulnerable	Species or species habitat may occur within area
Thalassarche steadi White-capped Albatross [64462]	Vulnerable	Species or species habitat may occur within area
Tringa nebularia Common Greenshank, Greenshank [832]	Endangered	Species or species habitat likely to occur within area
CRUSTACEAN		
Kumonga exleyi Cape Range Remipede [86875]	Vulnerable	Species or species habitat likely to occur within area
FISH		
Milyeringa justitia Barrow Cave Gudgeon [86867]	Endangered	Species or species habitat known to occur within area
Milyeringa veritas Cape Range Cave Gudgeon, Blind Gudgeon [66676]	Vulnerable	Species or species habitat known to occur within area
Ophisternon candidum Blind Cave Eel [66678]	Vulnerable	Species or species habitat known to occur within area
MAMMAL		
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Migration route known to occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Bettongia lesueur Barrow and Boodie Islands subspecies Boodie, Burrowing Bettong (Barrow and Boodie Islands) [88021]	Vulnerable	Species or species habitat known to occur within area

Scientific Name	Threatened Category	Presence Text
Dasyurus hallucatus		
Northern Quoll, Digul [Gogo-Yimidir], Wijingadda [Dambimangari], Wiminji [Martu] [331]	Endangered	Species or species habitat known to occur within area
Eubalaena australis		
Southern Right Whale [40]	Endangered	Species or species habitat likely to occur within area
Isoodon auratus barrowensis		
Golden Bandicoot (Barrow Island) [66666]	Vulnerable	Species or species habitat known to occur within area
Lagorchestes conspicillatus conspicillatus		
Spectacled Hare-wallaby (Barrow Island) [66661]	Vulnerable	Species or species habitat known to occur within area
Lagorchestes hirsutus Central Australian subspecies		
Mala, Rufous Hare-Wallaby (Central Australia) [88019]	Endangered	Translocated population known to occur within area
Macroderma gigas		
Ghost Bat [174]	Vulnerable	Species or species habitat likely to occur within area
Orcaella heinsohni		
Australian Snubfin Dolphin [81322]	Vulnerable	Species or species habitat known to occur within area
Osphranter robustus isabellinus		
Barrow Island Wallaroo, Barrow Island Euro [89262]	Vulnerable	Species or species habitat likely to occur within area
Petrogale lateralis lateralis		
Black-flanked Rock-wallaby, Moororong, Black-footed Rock Wallaby [66647]	Endangered	Species or species habitat known to occur within area
Rhinonicteris aurantia (Pilbara form)		
Pilbara Leaf-nosed Bat [82790]	Vulnerable	Species or species habitat known to occur within area
Sousa sahulensis		
Australian Humpback Dolphin [87942]	Vulnerable	Species or species habitat known to occur within area
PLANT		
Minuria tridens		
Minnie Daisy [13753]	Vulnerable	Species or species habitat known to occur within area
REPTILE		
Aipysurus apraefrontalis		
Short-nosed Sea Snake, Short-nosed Seasnake [1115]	Critically Endangered	Species or species habitat known to occur within area
Aipysurus foliosquama		
Leaf-scaled Sea Snake, Leaf-scaled Seasnake [1118]	Critically Endangered	Species or species habitat known to occur within area
Caretta caretta		
Loggerhead Turtle [1763]	Endangered	Breeding known to occur within area
Chelonia mydas		
Green Turtle [1765]	Vulnerable	Breeding known to occur within area
Ctenotus zastictus		
Hamelin Ctenotus [25570]	Vulnerable	Species or species habitat known to occur within area
Dermochelys coriacea		
Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Foraging, feeding or related behaviour known to occur within area
Eretmochelys imbricata		
Hawksbill Turtle [1766]	Vulnerable	Breeding known to occur within area
Liasis olivaceus barroni		
Pilbara Olive Python [66699]	Vulnerable	Species or species habitat likely to occur within area
Natator depressus		
Flatback Turtle [59257]	Vulnerable	Breeding known to occur within area
SHARK		
Carcharias taurus (west coast population)		
Grey Nurse Shark (west coast population) [68752]	Vulnerable	Congregation or aggregation known to occur within area

Scientific Name	Threatened Category	Presence Text
Carcharodon carcharias White Shark, Great White Shark [64470]	Vulnerable	Species or species habitat known to occur within area
Centrophorus uyato Little Gulper Shark [68446]	Conservation Dependent	Species or species habitat likely to occur within area
Pristis clavata Dwarf Sawfish, Queensland Sawfish [68447]	Vulnerable	Species or species habitat known to occur within area
Pristis pristis Largetooth Sawfish, Freshwater Sawfish, River Sawfish, Leichhardt's Sawfish, Northern Sawfish [60756]	Endangered	Species or species habitat likely to occur within area
Pristis zijsron Green Sawfish, Dindagubba, Narrowsnout Sawfish [68442]	Vulnerable	Species or species habitat known to occur within area
Rhincodon typus Whale Shark [66680]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Sphyrna lewini Scalloped Hammerhead [85267]	Conservation Dependent	Species or species habitat known to occur within area

Listed Migratory Species		[Resource Information]
Scientific Name	Threatened Category	Presence Text
null		
Balaenoptera omurai Omura's Whale [87136]		Species or species habitat likely to occur within area
Migratory Marine Birds		
Anous stolidus Common Noddy [825]		Species or species habitat likely to occur within area
Apus pacificus Fork-tailed Swift [678]		Species or species habitat likely to occur within area
Ardenna carneipes Flesh-footed Shearwater, Fleshy-footed Shearwater [82404]		Species or species habitat likely to occur within area
Ardenna pacifica Wedge-tailed Shearwater [84292]		Breeding known to occur within area
Calonectris leucomelas Streaked Shearwater [1077]		Species or species habitat likely to occur within area
Fregata ariel Lesser Frigatebird, Least Frigatebird [1012]		Species or species habitat known to occur within area
Fregata minor Great Frigatebird, Greater Frigatebird [1013]		Species or species habitat may occur within area
Hydroprogne caspia Caspian Tern [808]		Breeding known to occur within area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Species or species habitat may occur within area
Onychoprion anaethetus Bridled Tern [82845]		Breeding known to occur within area
Phaethon lepturus White-tailed Tropicbird [1014]		Species or species habitat known to occur within area
Phaethon rubricauda Red-tailed Tropicbird [994]		Species or species habitat known to occur within area
Sterna dougallii Roseate Tern [817]		Breeding known to occur within area
Sternula albifrons Little Tern [82849]	Vulnerable	Breeding known to occur within area

Scientific Name	Threatened Category	Presence Text
Thalassarche carteri		
Indian Yellow-nosed Albatross [64464]	Vulnerable	Species or species habitat may occur within area
Thalassarche cauta		
Shy Albatross [89224]	Endangered	Species or species habitat may occur within area
Thalassarche impavida		
Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Species or species habitat may occur within area
Thalassarche melanophris		
Black-browed Albatross [66472]	Vulnerable	Species or species habitat may occur within area
Thalassarche steadi		
White-capped Albatross [64462]	Vulnerable	Species or species habitat may occur within area
Migratory Marine Species		
Anoxypristis cuspidata		
Narrow Sawfish, Knifetooth Sawfish [68448]		Species or species habitat known to occur within area
Balaenoptera bonaerensis		
Antarctic Minke Whale, Dark-shoulder Minke Whale [67812]		Species or species habitat likely to occur within area
Balaenoptera borealis		
Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera edeni		
Bryde's Whale [35]		Species or species habitat likely to occur within area
Balaenoptera musculus		
Blue Whale [36]	Endangered	Migration route known to occur within area
Balaenoptera physalus		
Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area

Scientific Name	Threatened Category	Presence Text
Carcharhinus longimanus		
Oceanic Whitetip Shark [84108]		Species or species habitat likely to occur within area
Carcharias taurus		
Grey Nurse Shark [64469]		Congregation or aggregation known to occur within area
Carcharodon carcharias		
White Shark, Great White Shark [64470]	Vulnerable	Species or species habitat known to occur within area
Caretta caretta		
Loggerhead Turtle [1763]	Endangered	Breeding known to occur within area
Chelonia mydas		
Green Turtle [1765]	Vulnerable	Breeding known to occur within area
Crocodylus porosus		
Salt-water Crocodile, Estuarine Crocodile [1774]		Species or species habitat may occur within area
Dermochelys coriacea		
Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Foraging, feeding or related behaviour known to occur within area
Dugong dugon		
Dugong [28]		Breeding known to occur within area
Eretmochelys imbricata		
Hawksbill Turtle [1766]	Vulnerable	Breeding known to occur within area
Eubalaena australis as Balaena glacialis australis		
Southern Right Whale [40]	Endangered	Species or species habitat likely to occur within area
Isurus oxyrinchus		
Shortfin Mako, Mako Shark [79073]		Species or species habitat likely to occur within area
Isurus paucus		
Longfin Mako [82947]		Species or species habitat likely to occur within area

Scientific Name	Threatened Category	Presence Text
Lamna nasus Porbeagle, Mackerel Shark [83288]		Species or species habitat may occur within area
Megaptera novaeangliae Humpback Whale [38]		Breeding known to occur within area
Mobula alfredi as Manta alfredi Reef Manta Ray, Coastal Manta Ray [90033]		Species or species habitat known to occur within area
Mobula birostris as Manta birostris Giant Manta Ray [90034]		Species or species habitat known to occur within area
Natator depressus Flatback Turtle [59257]	Vulnerable	Breeding known to occur within area
Orcaella heinsohni Australian Snubfin Dolphin [81322]	Vulnerable	Species or species habitat known to occur within area
Orcinus orca Killer Whale, Orca [46]		Species or species habitat may occur within area
Physeter macrocephalus Sperm Whale [59]		Species or species habitat may occur within area
Pristis clavata Dwarf Sawfish, Queensland Sawfish [68447]	Vulnerable	Species or species habitat known to occur within area
Pristis pristis Largetooth Sawfish, Freshwater Sawfish, River Sawfish, Leichhardt's Sawfish, Northern Sawfish [60756]	Endangered	Species or species habitat likely to occur within area
Pristis zijsron Green Sawfish, Dindagubba, Narrowsnout Sawfish [68442]	Vulnerable	Species or species habitat known to occur within area

Scientific Name	Threatened Category	Presence Text
Rhincodon typus Whale Shark [66680]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Sousa sahulensis as Sousa chinensis Australian Humpback Dolphin [87942]	Vulnerable	Species or species habitat known to occur within area
Tursiops aduncus (Arafura/Timor Sea populations) Spotted Bottlenose Dolphin (Arafura/Timor Sea populations) [78900]		Species or species habitat known to occur within area
Migratory Terrestrial Species		
Hirundo rustica Barn Swallow [662]		Species or species habitat likely to occur within area
Motacilla cinerea Grey Wagtail [642]		Species or species habitat may occur within area
Motacilla flava Yellow Wagtail [644]		Species or species habitat may occur within area
Migratory Wetlands Species		
Actitis hypoleucos Common Sandpiper [59309]		Species or species habitat known to occur within area
Calidris acuminata Sharp-tailed Sandpiper [874]	Vulnerable	Species or species habitat known to occur within area
Calidris canutus Red Knot, Knot [855]	Vulnerable	Species or species habitat known to occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat known to occur within area
Calidris melanotos Pectoral Sandpiper [858]		Species or species habitat likely to occur within area

Scientific Name	Threatened Category	Presence Text
Charadrius leschenaultii		
Greater Sand Plover, Large Sand Plover [877]	Vulnerable	Species or species habitat known to occur within area
Charadrius veredus		
Oriental Plover, Oriental Dotterel [882]		Species or species habitat may occur within area
Glareola maldivarum		
Oriental Pratincole [840]		Species or species habitat may occur within area
Limnodromus semipalmatus		
Asian Dowitcher [843]	Vulnerable	Species or species habitat known to occur within area
Limosa lapponica		
Bar-tailed Godwit [844]		Species or species habitat known to occur within area
Numenius madagascariensis		
Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat known to occur within area
Pandion haliaetus		
Osprey [952]		Breeding known to occur within area
Thalasseus bergii		
Greater Crested Tern [83000]		Breeding known to occur within area
Tringa nebularia		
Common Greenshank, Greenshank [832]	Endangered	Species or species habitat likely to occur within area

Other Matters Protected by the EPBC Act

Commonwealth Lands [Resource Information]

The Commonwealth area listed below may indicate the presence of Commonwealth land in this vicinity. Due to the unreliability of the data source, all proposals should be checked as to whether it impacts on a Commonwealth area, before making a definitive decision. Contact the State or Territory government land department for further information.

Commonwealth Land Name	State
Defence	
Defence - EXMOUTH VLF TRANSMITTER STATION [50122]	WA
Defence - EXMOUTH VLF TRANSMITTER STATION [50123]	WA
Defence - LEARMONTH - AIR WEAPONS RANGE [50193]	WA

Listed Marine Species [Resource Information]

Scientific Name	Threatened Category	Presence Text
Bird		
Actitis hypoleucos		
Common Sandpiper [59309]		Species or species habitat known to occur within area
Anous stolidus		
Common Noddy [825]		Species or species habitat likely to occur within area
Apus pacificus		
Fork-tailed Swift [678]		Species or species habitat likely to occur within area overfly marine area
Ardenna carneipes as Puffinus carneipes		
Flesh-footed Shearwater, Fleshy-footed Shearwater [82404]		Species or species habitat likely to occur within area
Ardenna pacifica as Puffinus pacificus		
Wedge-tailed Shearwater [84292]		Breeding known to occur within area
Bubulcus ibis as Ardea ibis		
Cattle Egret [66521]		Species or species habitat may occur within area overfly marine area

Scientific Name	Threatened Category	Presence Text
Calidris acuminata Sharp-tailed Sandpiper [874]	Vulnerable	Species or species habitat known to occur within area
Calidris canutus Red Knot, Knot [855]	Vulnerable	Species or species habitat known to occur within area overfly marine area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat known to occur within area overfly marine area
Calidris melanotos Pectoral Sandpiper [858]		Species or species habitat likely to occur within area overfly marine area
Calonectris leucomelas Streaked Shearwater [1077]		Species or species habitat likely to occur within area
Chalcites osculans as Chrysococcyx osculans Black-eared Cuckoo [83425]		Species or species habitat known to occur within area overfly marine area
Charadrius leschenaultii Greater Sand Plover, Large Sand Plover [877]	Vulnerable	Species or species habitat known to occur within area
Charadrius veredus Oriental Plover, Oriental Dotterel [882]		Species or species habitat may occur within area overfly marine area
Chroicocephalus novaehollandiae as Larus novaehollandiae Silver Gull [82326]		Breeding known to occur within area
Fregata ariel Lesser Frigatebird, Least Frigatebird [1012]		Species or species habitat known to occur within area

Scientific Name	Threatened Category	Presence Text
Fregata minor Great Frigatebird, Greater Frigatebird [1013]		Species or species habitat may occur within area
Glareola maldivarum Oriental Pratincole [840]		Species or species habitat may occur within area overfly marine area
Haliaeetus leucogaster White-bellied Sea-Eagle [943]		Species or species habitat known to occur within area
Hirundo rustica Barn Swallow [662]		Species or species habitat likely to occur within area overfly marine area
Hydroprogne caspia as Sterna caspia Caspian Tern [808]		Breeding known to occur within area
Larus pacificus Pacific Gull [811]		Breeding known to occur within area
Limnodromus semipalmatus Asian Dowitcher [843]	Vulnerable	Species or species habitat known to occur within area overfly marine area
Limosa lapponica Bar-tailed Godwit [844]		Species or species habitat known to occur within area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Species or species habitat may occur within area
Merops ornatus Rainbow Bee-eater [670]		Species or species habitat may occur within area overfly marine area
Motacilla cinerea Grey Wagtail [642]		Species or species habitat may occur within area overfly marine area

Scientific Name	Threatened Category	Presence Text
Motacilla flava		
Yellow Wagtail [644]		Species or species habitat may occur within area overfly marine area
Numenius madagascariensis		
Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat known to occur within area
Onychoprion anaethetus as Sterna anaethetus		
Bridled Tern [82845]		Breeding known to occur within area
Onychoprion fuscatus as Sterna fuscata		
Sooty Tern [90682]		Breeding known to occur within area
Pandion haliaetus		
Osprey [952]		Breeding known to occur within area
Papasula abbotti		
Abbott's Booby [59297]	Endangered	Species or species habitat may occur within area
Phaethon lepturus		
White-tailed Tropicbird [1014]		Species or species habitat known to occur within area
Phaethon lepturus fulvus		
Christmas Island White-tailed Tropicbird, Golden Bosunbird [26021]	Endangered	Species or species habitat may occur within area
Phaethon rubricauda		
Red-tailed Tropicbird [994]		Species or species habitat known to occur within area
Pterodroma mollis		
Soft-plumaged Petrel [1036]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Rostratula australis as Rostratula benghalensis (sensu lato)		
Australian Painted Snipe [77037]	Endangered	Species or species habitat likely to occur within area overfly marine area

Scientific Name	Threatened Category	Presence Text
Sterna dougallii		
Roseate Tern [817]		Breeding known to occur within area
Sternula albifrons as Sterna albifrons		
Little Tern [82849]	Vulnerable	Breeding known to occur within area
Sternula nereis as Sterna nereis		
Fairy Tern [82949]		Breeding known to occur within area
Thalassarche carteri		
Indian Yellow-nosed Albatross [64464]	Vulnerable	Species or species habitat may occur within area
Thalassarche cauta		
Shy Albatross [89224]	Endangered	Species or species habitat may occur within area
Thalassarche impavida		
Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Species or species habitat may occur within area
Thalassarche melanophris		
Black-browed Albatross [66472]	Vulnerable	Species or species habitat may occur within area
Thalassarche steadi		
White-capped Albatross [64462]	Vulnerable	Species or species habitat may occur within area
Thalasseus bengalensis as Sterna bengalensis		
Lesser Crested Tern [66546]		Breeding known to occur within area
Thalasseus bergii as Sterna bergii		
Greater Crested Tern [83000]		Breeding known to occur within area
Tringa nebularia		
Common Greenshank, Greenshank [832]	Endangered	Species or species habitat likely to occur within area overfly marine area
Fish		
Acentronura larsonae		
Helen's Pygmy Pipehorse [66186]		Species or species habitat may occur within area

Scientific Name	Threatened Category	Presence Text
Bhanotia fasciolata Corrugated Pipefish, Barbed Pipefish [66188]		Species or species habitat may occur within area
Bulbonaricus brauni Braun's Pughead Pipefish, Pug-headed Pipefish [66189]		Species or species habitat may occur within area
Campichthys galei Gale's Pipefish [66191]		Species or species habitat may occur within area
Campichthys tricarinatus Three-keel Pipefish [66192]		Species or species habitat may occur within area
Choeroichthys brachysoma Pacific Short-bodied Pipefish, Short-bodied Pipefish [66194]		Species or species habitat may occur within area
Choeroichthys latispinosus Muiron Island Pipefish [66196]		Species or species habitat may occur within area
Choeroichthys suillus Pig-snouted Pipefish [66198]		Species or species habitat may occur within area
Corythoichthys amplexus Fijian Banded Pipefish, Brown-banded Pipefish [66199]		Species or species habitat may occur within area
Corythoichthys flavofasciatus Reticulate Pipefish, Yellow-banded Pipefish, Network Pipefish [66200]		Species or species habitat may occur within area
Corythoichthys intestinalis Australian Messmate Pipefish, Banded Pipefish [66202]		Species or species habitat may occur within area
Corythoichthys schultzi Schultz's Pipefish [66205]		Species or species habitat may occur within area
Cosmocampus banneri Roughridge Pipefish [66206]		Species or species habitat may occur within area
Doryrhamphus dactyliophorus Banded Pipefish, Ringed Pipefish [66210]		Species or species habitat may occur within area
Doryrhamphus excisus Bluestripe Pipefish, Indian Blue-stripe Pipefish, Pacific Blue-stripe Pipefish [66211]		Species or species habitat may occur within area
Doryrhamphus janssi Cleaner Pipefish, Janss' Pipefish [66212]		Species or species habitat may occur within area
Doryrhamphus multiannulatus Many-banded Pipefish [66717]		Species or species habitat may occur within area
Doryrhamphus negrosensis Flagtail Pipefish, Masthead Island Pipefish [66213]		Species or species habitat may occur within area
Festucalex scalaris Ladder Pipefish [66216]		Species or species habitat may occur within area
Filicampus tigris Tiger Pipefish [66217]		Species or species habitat may occur within area
Halicampus brocki Brock's Pipefish [66219]		Species or species habitat may occur within area
Halicampus dunckeri Red-hair Pipefish, Duncker's Pipefish [66220]		Species or species habitat may occur within area
Halicampus grayi Mud Pipefish, Gray's Pipefish [66221]		Species or species habitat may occur within area

Scientific Name	Threatened Category	Presence Text
Halicampus nitidus Glittering Pipefish [66224]		Species or species habitat may occur within area
Halicampus spinirostris Spiny-snout Pipefish [66225]		Species or species habitat may occur within area
Haliichthys taeniophorus Ribboned Pipehorse, Ribboned Seadragon [66226]		Species or species habitat may occur within area
Hippichthys penicillus Beady Pipefish, Steep-nosed Pipefish [66231]		Species or species habitat may occur within area
Hippocampus angustus Western Spiny Seahorse, Narrow-bellied Seahorse [66234]		Species or species habitat may occur within area
Hippocampus histrix Spiny Seahorse, Thorny Seahorse [66236]		Species or species habitat may occur within area
Hippocampus kuda Spotted Seahorse, Yellow Seahorse [66237]		Species or species habitat may occur within area
Hippocampus planifrons Flat-face Seahorse [66238]		Species or species habitat may occur within area
Hippocampus spinosissimus Hedgehog Seahorse [66239]		Species or species habitat may occur within area
Hippocampus trimaculatus Three-spot Seahorse, Low-crowned Seahorse, Flat-faced Seahorse [66720]		Species or species habitat may occur within area
Lissocampus fatiloquus Prophet's Pipefish [66250]		Species or species habitat may occur within area
Micrognathus micronotopterus Tidepool Pipefish [66255]		Species or species habitat may occur within area
Nannocampus subosseus Bonyhead Pipefish, Bony-headed Pipefish [66264]		Species or species habitat may occur within area
Phoxocampus belcheri Black Rock Pipefish [66719]		Species or species habitat may occur within area
Solegnathus hardwickii Pallid Pipehorse, Hardwick's Pipehorse [66272]		Species or species habitat may occur within area
Solegnathus lettiensis Gunther's Pipehorse, Indonesian Pipefish [66273]		Species or species habitat may occur within area
Solenostomus cyanopterus Robust Ghostpipefish, Blue-finned Ghost Pipefish, [66183]		Species or species habitat may occur within area
Stigmatopora argus Spotted Pipefish, Gulf Pipefish, Peacock Pipefish [66276]		Species or species habitat may occur within area
Syngnathoides biaculeatus Double-end Pipehorse, Double-ended Pipehorse, Alligator Pipefish [66279]		Species or species habitat may occur within area
Trachyrhamphus bicoarctatus Bentstick Pipefish, Bend Stick Pipefish, Short-tailed Pipefish [66280]		Species or species habitat may occur within area
Trachyrhamphus longirostris Straightstick Pipefish, Long-nosed Pipefish, Straight Stick Pipefish [66281]		Species or species habitat may occur within area
Mammal		
Dugong dugon Dugong [28]		Breeding known to occur within area
Reptile		

Scientific Name	Threatened Category	Presence Text
Aipysurus apraefrontalis Short-nosed Sea Snake, Short-nosed Seasnake [1115]	Critically Endangered	Species or species habitat known to occur within area
Aipysurus duboisii Dubois' Sea Snake, Dubois' Seasnake, Reef Shallows Sea Snake [1116]		Species or species habitat may occur within area
Aipysurus foliosquama Leaf-scaled Sea Snake, Leaf-scaled Seasnake [1118]	Critically Endangered	Species or species habitat known to occur within area
Aipysurus laevis Olive Sea Snake, Olive-brown Sea Snake [1120]		Species or species habitat may occur within area
Aipysurus mosaicus as Aipysurus eydouxii Mosaic Sea Snake [87261]		Species or species habitat may occur within area
Aipysurus pooleorum Shark Bay Sea Snake [66061]		Species or species habitat may occur within area
Aipysurus tenuis Brown-lined Sea Snake, Mjoberg's Sea Snake [1121]		Species or species habitat may occur within area
Caretta caretta Loggerhead Turtle [1763]	Endangered	Breeding known to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Breeding known to occur within area
Crocodylus porosus Salt-water Crocodile, Estuarine Crocodile [1774]		Species or species habitat may occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Foraging, feeding or related behaviour known to occur within area

Scientific Name	Threatened Category	Presence Text
Emydocephalus annulatus Eastern Turtle-headed Sea Snake [1125]		Species or species habitat may occur within area
Ephalophis greyae as Ephalophis greyi Mangrove Sea Snake [93738]		Species or species habitat may occur within area
Eretmochelys imbricata Hawksbill Turtle [1766]	Vulnerable	Breeding known to occur within area
Hydrelaps darwiniensis Port Darwin Sea Snake, Black-ringed Mangrove Sea Snake [1100]		Species or species habitat may occur within area
Hydrophis czeblukovi Fine-spined Sea Snake [59233]		Species or species habitat may occur within area
Hydrophis elegans Elegant Sea Snake, Bar-bellied Sea Snake [1104]		Species or species habitat may occur within area
Hydrophis kingii as Disteira kingii Spectacled Sea Snake [93511]		Species or species habitat may occur within area
Hydrophis macdowelli as Hydrophis mcdowelli MacDowell's Sea Snake, Small-headed Sea Snake, [75601]		Species or species habitat may occur within area
Hydrophis major as Disteira major Olive-headed Sea Snake [93512]		Species or species habitat may occur within area
Hydrophis ornatus Spotted Sea Snake, Ornate Reef Sea Snake [1111]		Species or species habitat may occur within area
Hydrophis peronii as Acalyptophis peronii Horned Sea Snake [93509]		Species or species habitat may occur within area

Scientific Name	Threatened Category	Presence Text
Hydrophis platura as Pelamis platurus Yellow-bellied Sea Snake [93746]		Species or species habitat may occur within area
Hydrophis stokesii as Astrotia stokesii Stokes' Sea Snake [93510]		Species or species habitat may occur within area
Natator depressus Flatback Turtle [59257]	Vulnerable	Breeding known to occur within area

Whales and Other Cetaceans [Resource Information]

Current Scientific Name	Status	Type of Presence
Mammal		
Balaenoptera acutorostrata Minke Whale [33]		Species or species habitat may occur within area
Balaenoptera bonaerensis Antarctic Minke Whale, Dark-shoulder Minke Whale [67812]		Species or species habitat likely to occur within area
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera edeni Bryde's Whale [35]		Species or species habitat likely to occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Migration route known to occur within area
Balaenoptera omurai Omura's Whale [87136]		Species or species habitat likely to occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Delphinus delphis Common Dolphin, Short-beaked Common Dolphin [60]		Species or species habitat may occur within area
Eubalaena australis Southern Right Whale [40]	Endangered	Species or species habitat likely to occur within area
Feresa attenuata Pygmy Killer Whale [61]		Species or species habitat may occur within area
Globicephala macrorhynchus Short-finned Pilot Whale [62]		Species or species habitat may occur within area
Grampus griseus Risso's Dolphin, Grampus [64]		Species or species habitat may occur within area
Indopacetus pacificus Longman's Beaked Whale [72]		Species or species habitat may occur within area
Kogia breviceps Pygmy Sperm Whale [57]		Species or species habitat may occur within area
Kogia sima Dwarf Sperm Whale [85043]		Species or species habitat may occur within area
Lagenodelphis hosei Fraser's Dolphin, Sarawak Dolphin [41]		Species or species habitat may occur within area
Megaptera novaeangliae Humpback Whale [38]		Breeding known to occur within area
Mesoplodon densirostris Blainville's Beaked Whale, Dense-beaked Whale [74]		Species or species habitat may occur within area

Current Scientific Name	Status	Type of Presence
Mesoplodon ginkgodens Gingko-toothed Beaked Whale, Gingko-toothed Whale, Gingko Beaked Whale [59564]		Species or species habitat may occur within area
Orcaella heinsohni Australian Snubfin Dolphin [81322]	Vulnerable	Species or species habitat known to occur within area
Orcinus orca Killer Whale, Orca [46]		Species or species habitat may occur within area
Peponocephala electra Melon-headed Whale [47]		Species or species habitat may occur within area
Physeter macrocephalus Sperm Whale [59]		Species or species habitat may occur within area
Pseudorca crassidens False Killer Whale [48]		Species or species habitat likely to occur within area
Sousa sahulensis Australian Humpback Dolphin [87942]	Vulnerable	Species or species habitat known to occur within area
Stenella attenuata Spotted Dolphin, Pantropical Spotted Dolphin [51]		Species or species habitat may occur within area
Stenella coeruleoalba Striped Dolphin, Euphrosyne Dolphin [52]		Species or species habitat may occur within area
Stenella longirostris Long-snouted Spinner Dolphin [29]		Species or species habitat may occur within area
Steno bredanensis Rough-toothed Dolphin [30]		Species or species habitat may occur within area

Current Scientific Name	Status	Type of Presence
Tursiops aduncus Indian Ocean Bottlenose Dolphin, Spotted Bottlenose Dolphin [68418]		Species or species habitat likely to occur within area
Tursiops aduncus (Arafura/Timor Sea populations) Spotted Bottlenose Dolphin (Arafura/Timor Sea populations) [78900]		Species or species habitat known to occur within area
Tursiops truncatus s. str. Bottlenose Dolphin [68417]		Species or species habitat may occur within area
Ziphius cavirostris Cuvier's Beaked Whale, Goose-beaked Whale [56]		Species or species habitat may occur within area

Key Ecological Features [Resource Information]

Key Ecological Features are the parts of the marine ecosystem that are considered to be important for the biodiversity or ecosystem functioning and integrity of the Commonwealth Marine Area.

Name	Region
Ancient coastline at 125 m depth contour	North-west
Canyons linking the Cuvier Abyssal Plain and the Cape Range Peninsula	North-west
Commonwealth waters adjacent to Ningaloo Reef	North-west
Continental Slope Demersal Fish Communities	North-west
Exmouth Plateau	North-west
Glomar Shoals	North-west
Mermaid Reef and Commonwealth waters surrounding Rowley Shoals	North-west

Biologically Important Areas [Resource Information]

Scientific Name	Behaviour	Presence
Dugong		
Dugong dugon Dugong [28]	Breeding	Known to occur
Dugong dugon Dugong [28]	Calving	Known to occur
Dugong dugon Dugong [28]	Foraging (high density seagrass beds)	Known to occur
Dugong dugon Dugong [28]	Nursing	Known to occur
Marine Turtles		
Caretta caretta Loggerhead Turtle [1763]	Internesting buffer	Known to occur
Caretta caretta Loggerhead Turtle [1763]	Nesting	Known to occur
Chelonia mydas Green Turtle [1765]	Aggregation	Known to occur
Chelonia mydas Green Turtle [1765]	Basking	Known to occur
Chelonia mydas Green Turtle [1765]	Foraging	Known to occur
Chelonia mydas Green Turtle [1765]	Internesting	Known to occur
Chelonia mydas Green Turtle [1765]	Internesting buffer	Known to occur
Chelonia mydas Green Turtle [1765]	Mating	Known to occur
Chelonia mydas Green Turtle [1765]	Migration corridor	Known to occur
Chelonia mydas Green Turtle [1765]	Nesting	Known to occur

Scientific Name	Behaviour	Presence
Eretmochelys imbricata Hawksbill Turtle [1766]	Foraging	Known to occur
Eretmochelys imbricata Hawksbill Turtle [1766]	Internesting	Known to occur
Eretmochelys imbricata Hawksbill Turtle [1766]	Internesting buffer	Known to occur
Eretmochelys imbricata Hawksbill Turtle [1766]	Mating	Known to occur
Eretmochelys imbricata Hawksbill Turtle [1766]	Migration corridor	Known to occur
Eretmochelys imbricata Hawksbill Turtle [1766]	Nesting	Known to occur
Natator depressus Flatback Turtle [59257]	Aggregation	Known to occur
Natator depressus Flatback Turtle [59257]	Foraging	Known to occur
Natator depressus Flatback Turtle [59257]	Internesting	Known to occur

1 PURPOSE

This report is designed to assist in identifying the location of matters of national environmental significance (MNES) and other matters protected by the Environment Protection and Biodiversity Conservation Act 1999 (Cth) (EPBC Act) which may be relevant in determining obligations and requirements under the EPBC Act.

The report contains the mapped locations of:

- World and National Heritage properties;
- Wetlands of International and National Importance;
- Commonwealth and State/Territory reserves;
- distribution of listed threatened, migratory and marine species;
- listed threatened ecological communities; and
- other information that may be useful as an indicator of potential habitat value.

2 DISCLAIMER

This report is not intended to be exhaustive and should only be relied upon as a general guide as mapped data is not available for all species or ecological communities listed under the EPBC Act (see below). Persons seeking to use the information contained in this report to inform the referral of a proposed action under the EPBC Act should consider the limitations noted below and whether additional information is required to determine the existence and location of MNES and other protected matters.

Where data is available to inform the mapping of protected species, the presence type (e.g. known, likely or may occur) that can be determined from the data is indicated in general terms. It is the responsibility of any person using or relying on the information in this report to ensure that it is suitable for the circumstances of any proposed use. The Commonwealth cannot accept responsibility for the consequences of any use of the report or any part thereof. To the maximum extent allowed under governing law, the Commonwealth will not be liable for any loss or damage that may be occasioned directly or indirectly through the use of, or reliance on the contents of this report.

3 DATA SOURCES

Threatened ecological communities

For threatened ecological communities where the distribution is well known, maps are generated based on information contained in recovery plans, State vegetation maps and remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

Threatened, migratory and marine species

Threatened, migratory and marine species distributions have been discerned through a variety of methods. Where distributions are well known and if time permits, distributions are inferred from either thematic spatial data (i.e. vegetation, soils, geology, elevation, aspect, terrain, etc.) together with point locations and described habitat; or modelled (MAXENT or BIOCLIM habitat modelling) using point locations and environmental data layers.

Where little information is available for a species or large number of maps are required in a short time-frame, maps are derived either from 0.04 or 0.02 decimal degree cells; by an automated process using polygon capture techniques (static two kilometre grid cells, alpha-hull and convex hull); or captured manually or by using topographic features (national park boundaries, islands, etc.).

In the early stages of the distribution mapping process (1999-early 2000s) distributions were defined by degree blocks, 100K or 250K map sheets to rapidly create distribution maps. More detailed distribution mapping methods are used to update these distributions when time permits.

4 LIMITATIONS

The following species and ecological communities have not been mapped and do not appear in this report:

- threatened species listed as extinct or considered vagrants;
- some recently listed species and ecological communities;
- some listed migratory and listed marine species, which are not listed as threatened species; and
- migratory species that are very widespread, vagrant, or only occur in Australia in small numbers.

The following groups have been mapped, but may not cover the complete distribution of the species:

- listed migratory and/or listed marine seabirds, which are not listed as threatened, have only been mapped for recorded breeding sites; and
- seals which have only been mapped for breeding sites near the Australian continent

The breeding sites may be important for the protection of the Commonwealth Marine environment.

Refer to the metadata for the feature group (using the Resource Information link) for the currency of the information.

Acknowledgements

This database has been compiled from a range of data sources. The department acknowledges the following custodians who have contributed valuable data and advice:

TERMS AND ABBREVIATIONS

°	Degrees
‘	Minutes
“	Seconds
µm	Micrometre (unit of length; 1 µm = 0.001 mm)
Actionable oil	Oil which is thick enough for the effective use of mitigation strategies
AMP	Australian Marine Park
AMSA	Australian Maritime Safety Authority
ANZECC	Australian and New Zealand Environment and Conservation Council
API	American Petroleum Institute gravity. A measure of how heavy or light a petroleum liquid is compared to water.
ARMCANZ	Agriculture and Resource Management Council of Australia and New Zealand
ASTM	American Society for Testing and Materials
bbl	Barrel (unit of volume; 1 bbl = 0.159 m3)
bbl/d	Barrels per day
Bonn Agreement	An agreement for cooperation in dealing with pollution of the North Sea by oil and other harmful substances, 1983, includes: Governments of the Kingdom of Belgium, the Kingdom of Denmark, the French Republic, the Federal Republic of Germany, the Republic of Ireland, the Kingdom of the Netherlands, the Kingdom of Norway, the Kingdom of Sweden, the United Kingdom of Great Britain and Northern Ireland and the European Union.
BP	Boiling point. The temperature at which the vapor pressure of the liquid is equal to the pressure exerted on it by the surrounding atmosphere
BTEX	Benzene, Toluene, Ethylbenzene, and Xylenes
°C	degree Celsius (unit of temperature)
CFSR	Climate Forecast System Reanalysis
cm	Centimetre (unit of length)
cP	Centipoise (unit of dynamic viscosity)
Decay	The process where oil components are changed either chemically or biologically (biodegradation) to another compound. It includes breakdown to simpler organic carbon compounds by bacteria and other organisms, photo-oxidation by solar energy, and other chemical reactions.
Dynamic viscosity	The dynamic viscosity of a fluid expresses its resistance to shearing flows, where adjacent layers move parallel to each other with different speeds.
Floating oil exposure	Contact by floating oil on the sea surface at concentrations equal to or exceeding defined threshold concentrations. The consequence will vary depending on the threshold and the receptors
g/m^2	Grams per square meter (unit of surface area density)
GODAE	Global Ocean Data Assimilation Experiment
HYCOM	Hybrid Coordinate Ocean Model. A data-assimilative, three-dimensional ocean model
HYDROMAP	Advanced ocean/coastal tidal model used to predict tidal water levels, current speed and current direction.
IAA	Impact Assessment Area
IBRA	Interim Biogeographic Regionalisation for Australia

IMCRA	Integrated Marine and Coastal Regionalisation of Australia
ITOPF	International Tanker Owners Pollution Federation Limited
KEF	Key Ecological Feature
km	Kilometre (unit of length)
km^2	Square Kilometres (unit of area)
Knots	unit of speed (1 knot = 0.514 m/s)
LOWC	Loss of well control
m	Meter (unit of length)
m^3	Cubic meter (unit of volume)
m/s	Meter per Second (unit of speed)
MAHs	Monoaromatic Hydrocarbons
MNP	Marine National Park
MP	Marine Park
NASA	National Aeronautics and Space Administration (USA)
NCEP	National Centres for Environmental Prediction (USA)
nm	Nautical mile
NOAA	National Oceanic and Atmospheric Administration (USA)
NOPSEMA	National Offshore Petroleum Safety and Environmental Management Authority
NP	National Park
NR	Nature Reserve
PAH	Polynuclear Aromatic Hydrocarbons
Pour Point	The pour point of a liquid is the temperature below which the liquid loses its flow characteristics
ppb	Parts per billion (concentration)
psu	Practical salinity nits
RSB	Reefs, Shoals and Banks
scf	Standard cubic feet (defined as one cubic foot of gas at 15.56 °C and at normal sea level air pressure)
Shoreline contact	Arrival of oil at or near shorelines at on-water concentrations equal to or exceeding defined threshold concentrations. Shoreline contact is judged for floating oil arriving within a 2 km buffer zone from any shoreline as a conservative measure
SIMAP	Spill Impact Model Application Package. SIMAP is designed to simulate the fate and effects of spilled hydrocarbons for surface or subsea releases
Single Oil spill modelling	Oil spill modelling involving a computer simulation of a single hypothetical oil spill event subject to a single sequence of wind, current and other sea conditions over time. Single oil spill modelling, also referred to as “deterministic modelling” provides a simulation of one possible outcome of a given spill scenario, subject to the metocean conditions that are imposed. Single oil spill modelling is commonly used to consider the fate and effects of ‘worst-case’ oil spill scenarios that are carefully selected in consideration of the nature and scale of the offshore petroleum activity and the local environment (NOPSEMA, 2017). Because the outcomes of a single oil spill simulation can only represent the outcome of that scenario under one sequence of metocean conditions, worst-case conditions are often identified from stochastic modelling. It is impossible to calculate the likelihood of any outcome from a single oil spill simulation. Single oil spill modelling is generally used for response planning, preparedness planning and for supporting oil spill response operations in the event of an actual spill

SRTM	Shuttle Radar Topography Mission
Stochastic oil spill modelling	Stochastic oil spill modelling is created by overlaying and statistically analysing the outcomes of many single oil-spill simulations of a defined spill scenario, where each simulation was subject to a different sequence of metocean conditions, selected objectively (typically by random selection) from a long sequence of historic conditions for the study area. Analysis of this larger set of simulations provides a more accurate indication of the environment that maybe affected (EMBA) and indicates which locations are more likely to be affected (as well as other statistics). Stochastic oil spill modelling avoids biases that affect single oil spill modelling (due to the reliance on only one possible sequence of conditions). However, when interpreting stochastic modelling, which is based on a wide range of potential conditions that might happen to occur, it is essential to understand that calculations will encompass a much larger area than could be affected in any single spill event, where a more limited set of conditions will occur. Consequently, it is misleading to imply that the region derived from stochastic modelling indicate the outcomes expected from a single spill event (NOPSEMA, 2017) Stochastic modelling is generally used for risk assessment and preparedness planning by indicating locations that could be exposed and may require response or subsequent impact assessment
TOPEX/Poseidon	A joint satellite mission between NASA and CNES to map ocean surface topography using an array of satellites equipped with detailed altimeters
USA	United States of America
US CG	United States Coast Guard
US EPA	United States Environmental Protection Agency
World Ocean Atlas	A collection of objectively analysed, quality controlled physicochemical parameters (e.g. temperature, salinity, oxygen, phosphate, silicate, and nitrate) based on profile data from the World Ocean Database (NCEI, 2021) established by NOAA's National Centers for Environmental Information (NCEI)
WGS 1984	World Geodetic System 1984 (WGS84); reference coordinate system

EXECUTIVE SUMMARY

Background

Chevron Australia Pty Ltd (Chevron) is the operator of the Greater Gorgon area, which includes the West Tryal Rocks (WTR) field situated within the Northern Carnarvon Basin in Permit area WA-5-R northwest of Barrow Island off the north-west coast of Western Australia. RPS was commissioned via Xodus on behalf of Chevron to undertake an oil spill modelling to support environmental approvals.

The oil spill modelling study was conducted to assess the seasonal risk and potential exposure to the surrounding waters and contact to the shorelines from the following hypothetical scenario:

- **Scenario:** A 1,500 m^3 surface release of marine diesel oil (MDO) over 24 hours resulting from a containment loss following a vessel collision.

The potential risk of exposure to the surrounding waters and contact to shorelines was assessed for three distinct seasons; (i) summer (September to the following March), (ii) the transitional periods (April and August) and (iii) winter (May to July). This approach assists with identifying the environmental values and sensitivities that would be at risk of exposure on a seasonal basis.

One of the purposes for the modelling is to define the 'outer boundaries' of the environment that may be affected (EMBA) in the unlikely event of hydrocarbon release. Therefore, the modelling does not take into consideration any of the spill prevention, mitigation and response capabilities that would be implemented in response to the spill.

Methodology

The modelling study was carried out in stages. Firstly, a ten-year current dataset (2010–2019) that includes the combined influence of large-scale ocean and nearshore tidal currents was developed. Secondly, the currents, local winds and detailed hydrocarbon characteristics were used as inputs in the three-dimensional oil spill model (SIMAP) to simulate the drift, spread, weathering and fate of the spilled oil.

As spills can occur during any set of wind and current conditions, modelling was conducted using a stochastic (or probabilistic) approach, which involved running per scenario 100 spill simulations per season, with each simulation having the same spill information (spill volume, duration and composition of hydrocarbons) but randomly selected start time. This ensured that each spill trajectory was subjected to varying wind and current conditions.

Hydrocarbon Properties

Marine Diesel Oil Properties

The MDO has an API of 37.60, a density of 829 kg/m^3 (at 25ºC) and a low viscosity value of 4.0 cP. When exposed to the atmosphere at local temperatures, about 6.0% of the MDO volatile components should evaporate within the first 12 hours (BP < 180°C); a further 34.6% of the semi-volatiles should evaporate within the first 24 hours (180°C < BP < 265°C); and low volatile portion (54.4%) should evaporate over a longer period (265°C < BP < 380°C). Additionally, 5.0% of the MDO is shown to be persist in the marine environment for much longer periods and be subject to relatively slow degradation.

Key Findings

- The maximum distance from the release location to the low (≥ 1 g/m^2), moderate (≥ 10 g/m^2) and high (≥ 50 g/m^2) threshold for floating condensate was 167.0 northeast (summer), 59.6 km south-southwest (winter) and 17.6 km north-northeast (summer), respectively.

- Excluding the receptors that the release location resides within, the Humpback Whale - Migration BIA and Continental Slope Demersal Fish Communities KEF were the only receptors predicted to be exposed during all three seasons at the low and moderate floating oil thresholds. The probabilities of low and moderate exposure at the Humpback Whale - Migration BIA ranged between 16–22% and 3–4%,whilst the probabilities of low and moderate exposure to the Continental Slope Demersal Fish Communities KEF ranged between 35–54% and 4–13%, respectively. The minimum times before exposure at the low threshold for the Humpback Whale - Migration BIA and Continental Slope Demersal Fish Communities KEF were 0.54 days (winter) and 0.38 days (transitional), respectively.

- The probability of accumulation on any shoreline at, or above, the low threshold (≥ 10 g/m^2) was greatest during winter at 9%, while the minimum time before shoreline accumulation was 6.50 days and the maximum volume of oil ashore above the low threshold was 35.1 m3. No high (≥ 1,000 g/m2) shoreline threshold accumulation was predicted in the modelling results.

- In the surface (0-10 m) depth layer, a total of 14, 12, and 14 BIAs were predicted to be exposed to dissolved hydrocarbons at, or above, the low threshold during summer, transitional and winter, respectively. Excluding the 4 BIAs, the highest probabilities of exposure for the low threshold during summer, transitional and winter were predicted as 6%, 6% and 14%, respectively for the Humpback Whale - Migration BIA.

- In the surface (0-10 m) depth layer, a total of 29 BIAs were predicted to be exposed at, or above, the low threshold during all 3 seasons. Excluding the 4 BIAs (that the release location resides within, the highest probabilities of exposure for the low threshold were predicted for the Humpback Whale - Migration during all seasons (42%, 59% and 71% for summer, transitional and winter, respectively).

- During all 3 seasons, 3 AMPs were predicted to be exposed at the low entrained hydrocarbon threshold, with the highest probabilities predicted at the Gascoyne AMP (21% summer, 22% transitional and 37% winter). Furthermore, during seasonal conditions the Gascoyne, Montebello and Ningaloo AMP were also predicted to be exposed to entrained hydrocarbons at the high threshold.

1 INTRODUCTION

Chevron Australia Pty Ltd (Chevron) is the operator of the Greater Gorgon area, which includes the West Tryal Rocks (WTR) field situated within the Northern Carnarvon Basin in Permit area WA-5-R northwest of Barrow Island off the north-west coast of Western Australia.

As part of the planned development for the WTR field, Xodus on behalf of Chevron had commissioned RPS to undertake a comprehensive oil spill modelling study to support environmental approvals. The modelling study assessed the seasonal risk and potential exposure to the surrounding waters and contact to the shorelines from the following hypothetical scenario:

- **Scenario:** A 1,500 m^3 surface release of marine diesel oil (MDO) over 24 hours resulting from a containment loss following a vessel collision.

The release location is presented in Table 1.1 and illustrated in Figure 1.1.

The potential risk of exposure to the surrounding waters and contact to shorelines was assessed for three distinct seasons; (i) summer (September to the following March), (ii) the transitional periods (April and August) and (iii) winter (May to July). This approach assists with identifying the environmental values and sensitivities that would be at risk of exposure on a seasonal basis.

One of the purposes for the modelling is to define the 'outer boundaries' of the environment that may be affected (EMBA) in the unlikely event of hydrocarbon release. Therefore, the modelling does not take into consideration any of the spill prevention, mitigation and response capabilities that would be implemented in response to the spill.

The spill modelling was performed using an advanced three-dimensional trajectory and fates model; Spill Impact Mapping Analysis Program (SIMAP). The SIMAP model calculates the transport, spreading, entrainment and evaporation of spilled hydrocarbons over time, based on the prevailing wind and current conditions and the physical and chemical properties.

The hydrocarbon spill model, the method and analysis applied herein uses modelling algorithms which have been peer reviewed and published in international journals. Further, RPS warrants that this work meets and exceeds the American Society for Testing and Materials (ASTM) Standard F2067-13 "*Standard Practice for Development and Use of Oil Spill Models*".

2 SCOPE OF WORK

The scope of work included the following components:

1. Generate ten years (2010 to 2019 (inclusive)) of wind and current data. The three-dimensional current data includes the combined influence of ocean and tidal currents;

2. Include the wind data, current data and condensate properties characteristics into the three-dimensional oil spill model; SIMAP, to model the movement, spreading, entrainment, weathering and potential shoreline accumulation over time;

3. For each scenario run 100 simulations per season (i.e. 300 simulations total), with each simulation having the same spill information (location, volume, duration and condensate properties) but randomly varying start times. This ensured that each spill simulation was subjected to unique wind and current conditions;

4. Combine the results from the 100 spill simulations to assess the exposure to waters and shoreline accumulation based upon the NOPSEMA thresholds for each scenario; and

5. From the 300 simulations modelled per scenario, identify and present the “worst case” deterministic runs, which can be used to inform response planning based on the following criteria:

    a. Largest swept area of floating hydrocarbon above 10 g/m^2

    b. Largest swept area of floating hydrocarbon above 50 g/m^2

    c. Largest volume of oil ashore

    d. Longest length of shoreline with accumulation above 100 g/m^2

    e. Largest area of entrained hydrocarbons above 100 ppb

    f. Largest area of dissolved hydrocarbons above 50 ppb

3 REGIONAL CURRENTS

The study area is located within the Northern Carnarvon Basin, on the North West Shelf, a waterbody bordered by the Indian Ocean and Timor Sea. The North West Shelf is characterised by complex geomorphological features such as shoals, valleys and terraces and is dominated by high-amplitude tides and seasonally-dependant wind driven currents (DEWHA, 2007).

Although the Indonesian Throughflow and Holloway current generate south-westerly flows all year-round, warm and less saline waters originating from the tropics can generate internal gyres that typically migrate through the area and result in large variation in the speed and direction of local currents. The Holloway current generally intensifies during April to July due to increased wind forcing.

A comprehensive description of the circulation patterns of the North West Shelf is provided in a review by Condie and Andrewartha (2008) and a schematic of the ocean currents along the Northwest Australian continental shelf is shown in Figure 3.1.

While, tidal currents are generally weaker in the deeper waters, its influence is greatest along the near shore and around islands. Therefore, to accurately account for the movement of an oil spill, which can move between the offshore and near shore region, ocean and tidal currents were combined as part of the study.

Figure 3.2 and Figure 3.3 present summer and winter current trends within the Carnarvon Basin and the North West Shelf.

3.1 Tidal Currents

Tidal current data was generated using RPS's advanced ocean/coastal model, HYDROMAP. The HYDROMAP model has been thoroughly tested and verified through field measurements throughout the world over the past 38 years (Isaji & Spaulding, 1984; Isaji, et al., 2001; Zigic, et al., 2003). HYDROMAP tidal current data has been used as input to forecast (in the future) and hindcast (in the past) pollutant spills in Australian waters and forms part of the Australian National Oil Spill Emergency Response System operated by AMSA (Australian Maritime Safety Authority).

HYDROMAP employs a sophisticated sub-gridding strategy, which supports up to six levels of spatial resolution, halving the grid cell size as each level of resolution is employed. The sub-gridding allows for higher resolution of currents within areas of greater bathymetric and coastline complexity, and/or of particular interest to a study.

The numerical solution methodology follows that of Davies (1977a and 1977b) with further developments for model efficiency by Owen (1980) and Gordon (1982). A more detailed presentation of the model can be found in Isaji and Spaulding (1984) and Isaji et al. (2001).

3.1.1 Grid Setup

The tidal model domain has been sub-gridded to a resolution of 500 m for shallow and coastal regions, starting from an offshore (or deep water) resolution of 8 km. The finer grids were allocated in a step-wise fashion to resolve flows more accurately along the coastline, around islands and over regions with more complex bathymetry. Figure 3.4 shows the tidal model grid resolutions.

A combination of datasets was used and merged to describe the shape of the seabed within the grid domain (Figure 3.5). These included spot depths and contours which were digitised from nautical charts released by the hydrographic offices as well as Geoscience Australia database and depths extracted from the Shuttle Radar Topography Mission (SRTM30_PLUS) Plus dataset (see Becker et al., 2009).

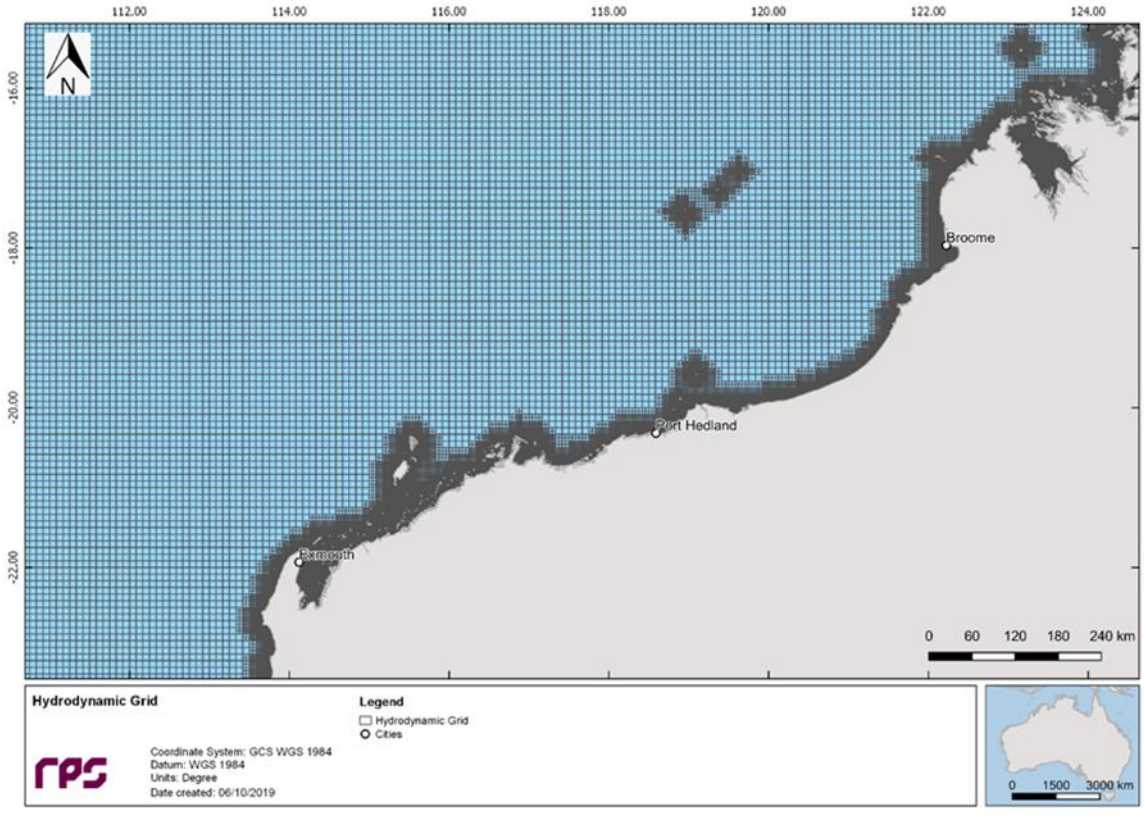

Figure 3.4 Zoomed in view of the model grid used to generate the tidal currents for the study region. Higher resolution areas are shown by the denser mesh.

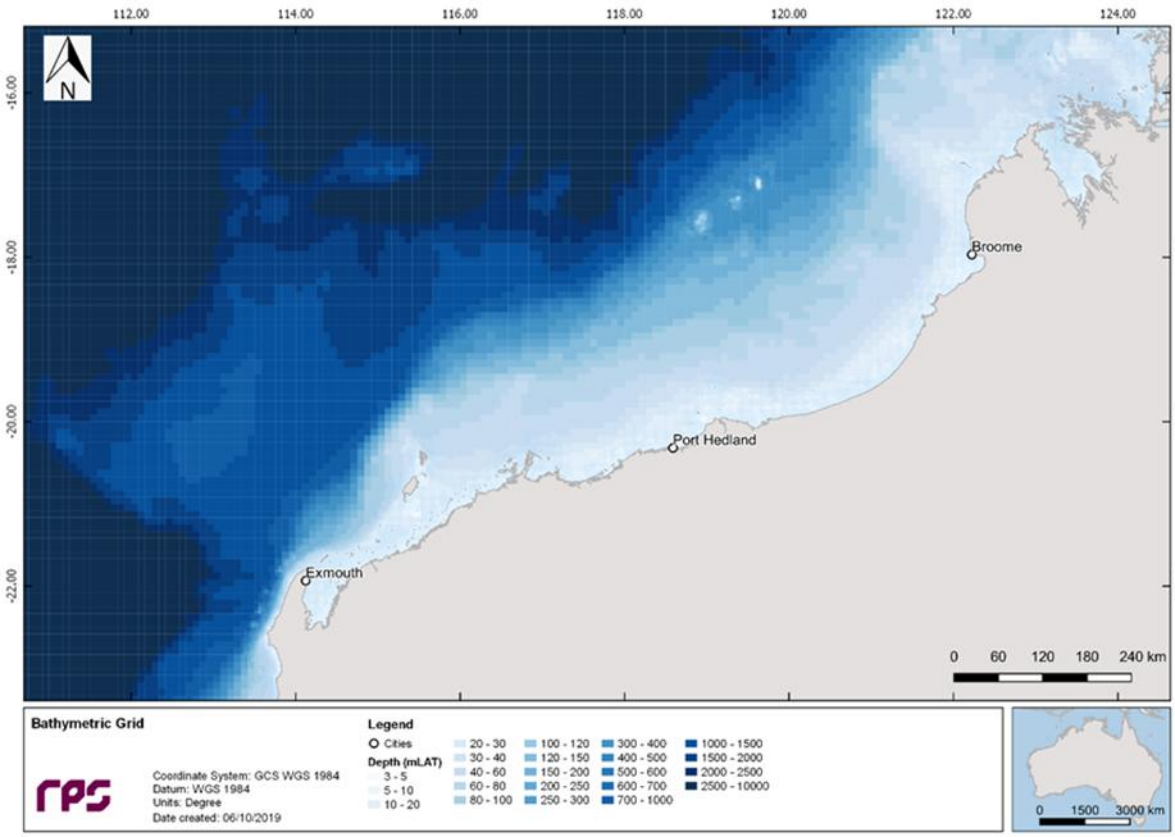

Figure 3.5 Bathymetry defined throughout the tidal model domain.

3.1.2 Tidal Conditions

The ocean boundary data for the regional model was obtained from satellite measured altimetry data (TOPEX/Poseidon 7.2) which provided estimates of the eight dominant tidal constituents at a horizontal scale of approximately 0.25 degrees. The eight major tidal constituents used were K_2, S_2, M_2, N_2, K_1, P_1, O_1 and Q_1. Using the tidal data, surface heights were firstly calculated along the open boundaries, at each time step in the model.

The TOPEX/Poseidon satellite data has a global resolution of 0.25 degrees and is produced and quality controlled by NASA (National Aeronautics and Space Administration). The satellites equipped with two highly accurate altimeters and capable of taking sea level measurements with an accuracy of ± 5 cm measured oceanic surface elevations (and the resultant tides) for over 13 years (1992–2005). In total, these satellites carried out 62,000 orbits of the planet.

The TOPEX/Poseidon tidal data has been widely used amongst the oceanographic community, being included in more than 2,100 research publications (e.g. Andersen, 1995; Ludicone et al., 1998; Matsumoto et al., 2000; Kostianoy et al., 2003; Yaremchuk and Tangdong, 2004; Qiu and Chen 2010). As such the TOPEX/Poseidon tidal data is considered suitably accurate for this study.

3.2 Ocean Currents

Data describing the flow of ocean currents was obtained from HYCOM (Hybrid Coordinate Ocean Model, (Chassignet et al., 2007), which is operated by the HYCOM Consortium, sponsored by the National Ocean Partnership Program (NOPP), as part of the U.S. Global Ocean Data Assimilation Experiment (GODAE). HYCOM is a data-assimilative, three-dimensional ocean model that is run as a hindcast (for a past period), assimilating time-varying observations of sea surface height, sea surface temperature and in-situ temperature and salinity measurements (Chassignet et al., 2009). The HYCOM predictions for drift currents are produced at a horizontal spatial resolution of approximately 8.25 km (1/12th of a degree) over the region, at a frequency of every 3 hours. HYCOM uses isopycnal layers in the open, stratified ocean, but uses the layered continuity equation to make a dynamically smooth transition to a terrain following coordinate in shallow coastal regions, and to z-level coordinates in the mixed layer and/or unstratified seas.

For this study, the HYCOM hindcast currents were obtained for the years 2010 to 2019 (inclusive).

3.3 Surface Currents

Table 3.1 presents the predicted average and maximum monthly surface current speeds at the release location.

The month average surface current speeds ranged between 0.16 m/s (November) and 0.26 m/s (May). Additionally, the maximums ranged between 0.54 m/s (November) and 2.18 m/s (March). The general current directions were towards the southwest. Figure 3.6 and Figure 3.7 present the monthly and total current rose distributions, respectively.

Note the convention for defining current direction throughout this report is the direction the current flows towards. Each branch of the current rose distribution represents the currents flowing to that direction, with north to the top of the diagram. The branches are divided into segments of different colour, which represent the current speed ranges for each direction. Speed intervals of 0.1 m/s are typically used in these current roses. The length of each coloured segment within a branch is proportional to the frequency of currents flowing within the corresponding speed and direction.

Table 3.1 Predicted monthly average and maximum surface current speeds close to the release location. Data derived by combining the HYCOM ocean data and HYDROMAP high resolution tidal data from 2010-2019 (inclusive).

Season	Month	Average current speed (m/s)	Maximum current speed (m/s)	General direction (towards)
Summer	January	0.23	1.93	Northeast and Southwest
	February	0.21	1.07	Northeast and Southwest
	March	0.22	2.18	Southwest
Transitional	April	0.24	1.20	Southwest
Winter	May	0.26	0.95	Southwest
	June	0.26	0.90	Southwest
	July	0.21	1.08	Southwest
Transitional	August	0.19	0.78	Southwest
Summer	September	0.19	1.03	Northeast and Southwest
	October	0.18	0.63	Northeast and Southwest
	November	0.16	0.54	Variable
	December	0.20	0.80	Southwest
Minimum		**0.16**	**0.54**	
Maximum		**0.26**	**2.18**

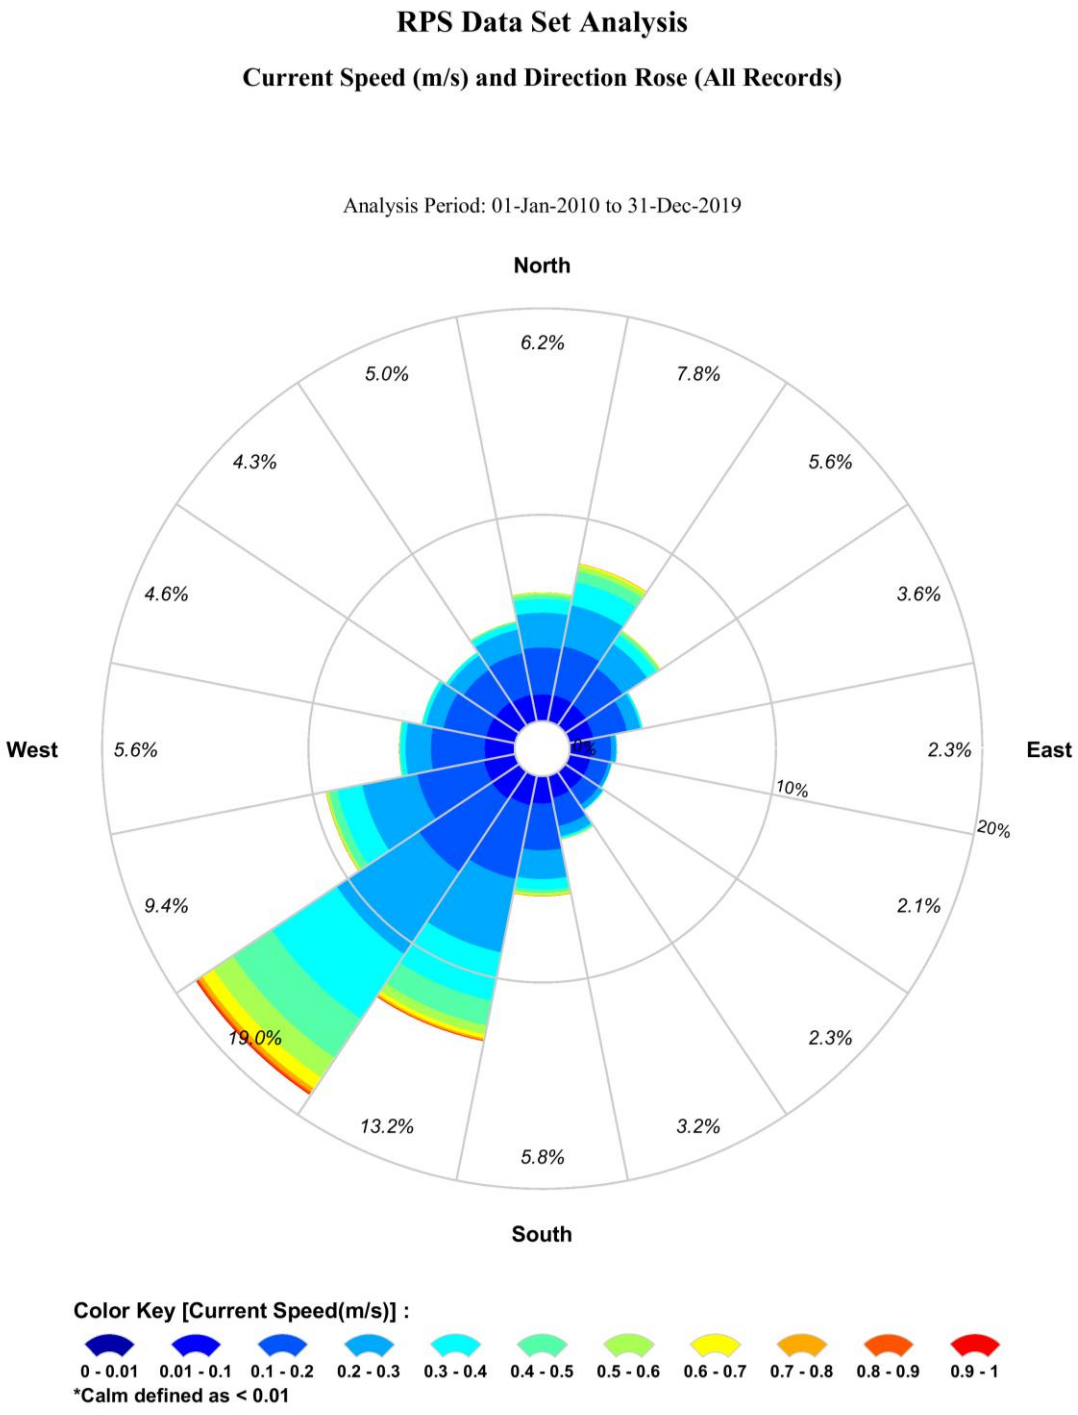

Figure 3.7 Total surface current rose plot at the release location, derived from the 2010 to 2019 modelled dataset.

4 WIND DATA

To account for the influence of the wind on the floating oil, wind data from 2010 to 2019 (inclusive) was sourced from the National Centre for Environmental Prediction (NCEP) Climate Forecast System Reanalysis (CFSR; see Saha et al., 2010). The CFSR wind model includes observations from many data sources; surface observations, upper-atmosphere air balloon observations, aircraft observations and satellite observations. The model is capable of accurately representing the interaction between the earth's oceans, land and atmosphere. The gridded wind data output is available at ¼ of a degree resolution (~33 km) and 1-hourly time intervals. Figure 4.1 shows the spatial resolution of the wind field used as input into the oil spill model.

Table 4.1 shows the monthly average and maximum winds derived from the CFSR node closest to the release location. The model wind data demonstrated that this region typically experiences moderate winds all year round and although the monthly average wind speeds remain under 15 knots. The maximum wind speed was 49 knots (July). Winds typically blow from the southwest during the summer months, while winds are typically easterly during the winter months.

Figure 4.2 and Figure 4.3 illustrates the monthly and total wind rose distributions nearby the release location, respectively.

Note that the atmospheric convention for defining wind direction, that is, the direction the wind blows from, is used to reference wind direction throughout this report. Each branch of the rose represents wind coming from that direction, with north to the top of the diagram. Sixteen directions are used. The branches are divided into segments of different colour, which represent wind speed ranges from that direction. Speed ranges of 5 knot intervals are typically used in these wind roses. The length of each segment within a branch is proportional to the frequency of winds blowing within the corresponding range of speeds from that direction.

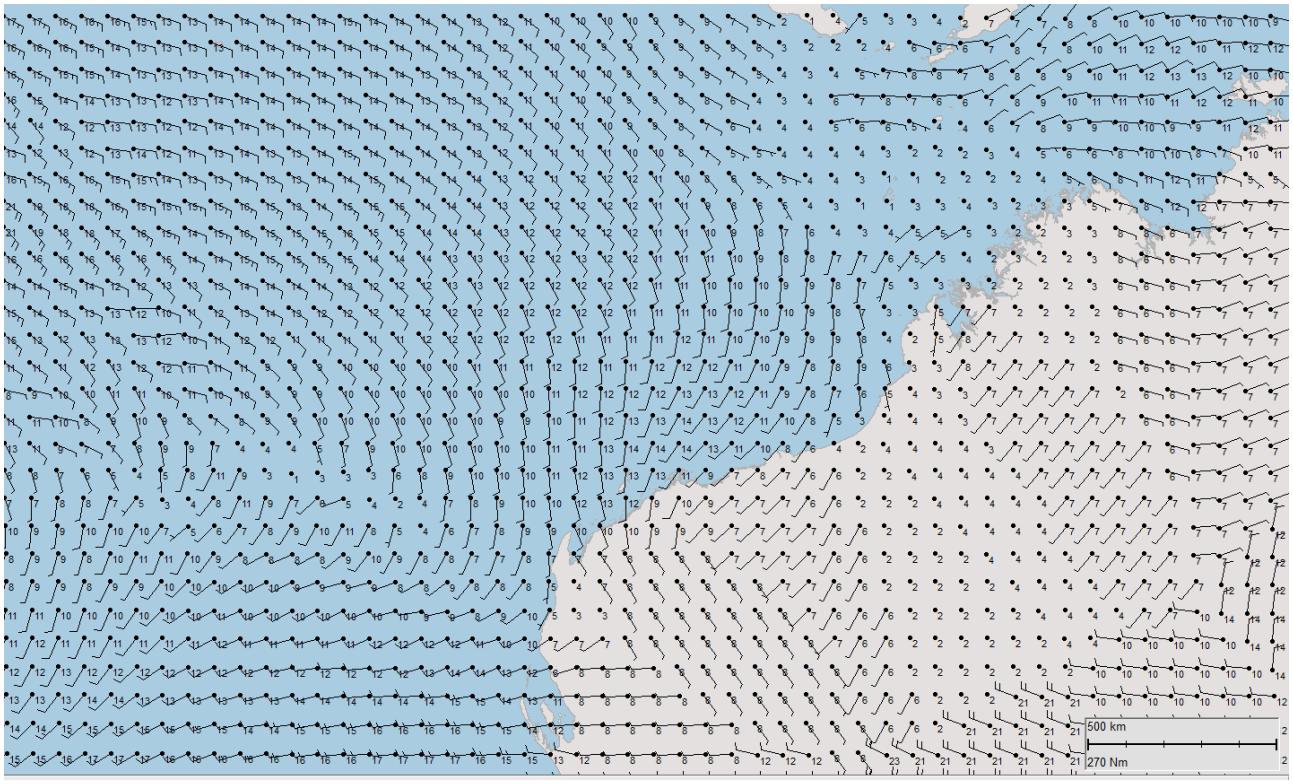

Figure 4.1 Spatial resolution of the CFSR modelled wind data used as input into the oil spill model. Note, for ease viewing only every second wind vector is displayed on the map.

Table 4.1 Predicted average and maximum winds for the wind node closest to the release location. Data derived from CFSR hindcast model 2010 to 2019 (inclusive).

Season	Month	Average wind (knots)	Maximum wind (knots)	General direction (from)
Summer	January	13	41	Southwest
	February	11	46	Southwest
	March	10	35	Southwest
Transitional	April	10	38	Variable
Winter	May	12	40	East
	June	14	31	East
	July	13	49	East to South
Transitional	August	11	31	South
Summer	September	12	27	South-Southwest
	October	13	28	Southwest
	November	13	25	Southwest
	December	12	29	Southwest
Minimum		**10**	**25**	
Maximum		**14**	**49**

5 WATER TEMPERATURE AND SALINITY

The monthly depth-varying water temperature and salinity profiles nearest to the release location was obtained from the HYbrid Coordinate Ocean Model (see Section 3.2 Ocean Currents).

The three-dimensional salinity and temperature datasets are used in the oil spill model domain to inform the weathering, movement, and evaporative loss of hydrocarbon spills in the surface and subsurface layers.

Table 5.1 shows that the monthly average sea surface temperatures ranged from 24.2°C (September) to 29.6°C (March), whilst salinity remained relatively consistent throughout the year, ranging between 34.6–35.3 psu.

Figure 5.1 the vertical profile of sea temperature and salinity nearby the release location.

Table 5.1 Monthly average sea surface temperature and salinity near the release location in the 0-5 m depth layer.

Month	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sept	Oct	Nov	Dec
Temperature (°C)	27.8	28.6	29.6	28.7	27.9	27.0	25.3	24.5	24.2	25.0	27.3	27.0
Salinity (psu)	35.1	34.9	35.0	35.1	35.2	35.3	34.9	34.8	34.9	34.9	34.6	34.9

6 OIL SPILL MODEL – SIMAP

Modelling of the fate of oil was performed using the Spill Impact Mapping Analysis Program (SIMAP). SIMAP is designed to simulate the fate and effects of spilled hydrocarbons for both the surface and subsurface releases (Spaulding et al. 1994; French et al. 1999; French-McCay, 2003, 2004; French-McCay et al. 2004).

SIMAP has been used to predict the weathering and fate of oil spills during and after major incidents including: Montara (Australia) well blowout August 2009 in the Timor Sea (Asia-Pacific ASA, 2010); Macondo (USA) well blowout April 2010 in the Gulf of Mexico; Bohai Bay (China) oil spill August 2011; and the pipeline oil spill July 2013 in the Gulf of Thailand.

The SIMAP model calculates the transport, spreading, entrainment, evaporation and decay of surface hydrocarbon slicks as well as the entrained and dissolved oil components in the water column, either from surface slicks or from oil discharged subsea. The movement and weathering of the spilled oil is calculated for specific oil types. Input specifications for oil mixtures include the density, viscosity, pour point, distillation curve (volume lost versus temperature) and the aromatic/aliphatic component ratios within given boiling point ranges.

SIMAP is a three-dimensional model that allows for various response actions to be modelled including oil removal from skimming, burning, or collection booms, and surface and subsurface dispersant application.

The SIMAP oil spill model includes advanced weathering algorithms, specifically focussed on unique oils that tend to form emulsions and/or tar balls. The weathering algorithms are based on five years of extensive research conducted in response to the Deepwater Horizon oil spill in the Gulf of Mexico (French et al., 2015).

Biodegradation is included in the oil spill model. In the model, SIMAP, degradation is calculated for the surface slick, deposited oil on the shore, the entrained oil and dissolved constituents in the water column, and oil in the sediments. For surface oil, water column oil and sedimented oil a first order degradation rate is specified. Biodegradation rates are relatively high for hydrocarbons in dissolved state or in dispersed small droplets.

6.1 Stochastic Modelling

Stochastic oil spill modelling is created by overlaying a great number (often 100 hundred) simulated hypothetical oil spills (Figure 6.1). Stochastic modelling involves running numerous individual oil spill simulations using a range of prevailing wind and current conditions that are historically representative of the season and location of where the spill event may occur.

For the stochastic modelling presented herein, **100 spills** were simulated per season using the same spill information (release location, spill volume, duration and condensate properties) but with varied start dates and times corresponding to the period represented by the available wind and current data. During each simulation, the model records whether any grid cells are exposed to any hydrocarbon concentrations, the concentrations involved and the elapsed time before exposure. For each scenario the results of all 100 condensate spill simulations were analysed to determine the following seasonal statistics for every grid cell:

- Exposure load (concentrations and volumes);
- Minimum time before exposure;
- Probability of contact above defined concentrations;
- Volume of condensate that may strand on shorelines from any single simulation;
- Concentration that might occur on sections of individual shorelines;
- Exposure (instantaneous and/or over a specified duration) to dissolved hydrocarbons in the water column; and

- Exposure (instantaneous and/or over a specified duration) to entrained hydrocarbons in the water column.

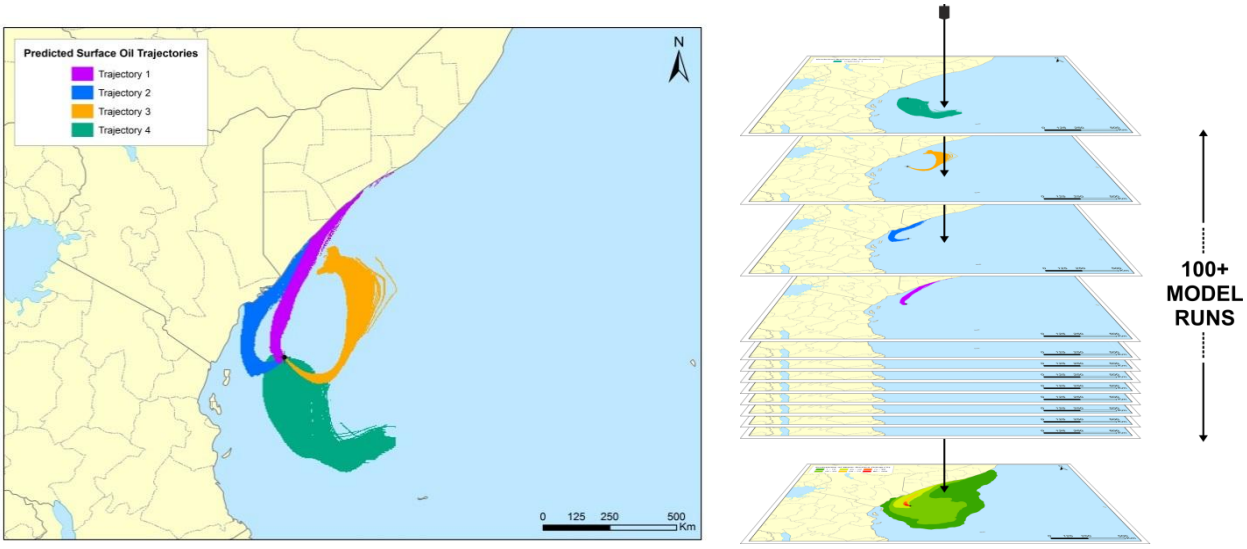

Figure 6.1 Predicted movement of four single oil spill simulations by SIMAP for the same scenario (left image). All model runs are overlain (shown as the stacked runs on the right) and the number of times that trajectories contact a given location at a concentration is used to calculate the probability (Source: NOPSEMA, 2018).

6.2 Floating, Shoreline and In-Water Thresholds

The thresholds and their relationship to exposure for the sea surface, shoreline and water column (entrained and dissolved hydrocarbons) are presented in Sections 6.2.1 to 6.2.3. Supporting justifications of the adopted thresholds applied during the study and additional context relating to the area of influence are also provided. It is important to note that the thresholds herein are based on NOPSEMA (2019).

6.2.1 Floating Oil Exposure Thresholds

The modelling results can be presented to any levels; therefore, thresholds have been specified (based on scientific literature) to record floating oil exposure to the sea-surface at meaningful levels only, described in the following paragraphs.

The low threshold to assess the potential for floating oil exposure, was 1 g/m^2, which equates approximately to an average thickness of 1 µm, referred to as visible oil. Oil of this thickness is described as rainbow sheen in appearance, according to the Bonn Agreement Oil Appearance Code (Bonn Agreement, 2009; AMSA, 2014) (see Table 6.1). Figure 6.2 shows photographs highlighting the difference in appearance between a silvery sheen, rainbow sheen and metallic sheen. This threshold is considered below levels which would cause environmental harm and it is more indicative of the areas perceived to be affected due to its visibility on the sea surface and potential to trigger temporary closures of areas (i.e. fishing grounds) as a precautionary measure. Table 6.1 provides a description of the appearance in relation to exposure zone thresholds used to classify the zones of floating oil exposure.

Ecological impact has been estimated to occur at 10 g/m^2 (a film thickness of approximately 10 µm or 0.01 mm) according to French et al. (1996) and French-McCay (2009) as this level of fresh oiling has been observed to mortally impact some birds through adhesion of oil to their feathers, exposing them to secondary effects such as hypothermia. The appearance of oil at this average thickness has been described as a metallic sheen (Bonn Agreement, 2009). Concentrations above 10 g/m^2 is also considered the lower actionable threshold, where oil may be thick enough for containment and recovery as well as dispersant treatment (AMSA, 2015).

Scholten et al. (1996) and Koops et al. (2004) indicated that at oil concentrations on the sea surface of 25 g/m^2 (or greater), would be harmful for all birds that have landed in an oil film due to potential contamination of their feathers, with secondary effects such as loss of temperature regulation and ingestion of oil through preening. The appearance of oil at this thickness is also described as metallic sheen (Bonn Agreement, 2009). For this study the high exposure threshold was set to 50 g/m^2 and above based on NOPSEMA (2019). This threshold can also be used to inform response planning.

Table 6.2 defines the thresholds used to classify the zones of floating oil exposure reported herein.

Table 6.1 The Bonn Agreement Oil Appearance Code.

Code	Description Appearance	Layer Thickness Interval (g/m^2 or µm)	Litres per km^2
1	Sheen (silvery/grey)	0.04 – 0.30	40 – 300
2	Rainbow	0.30 – 5.0	300 – 5,000
3	Metallic	5.0 – 50	5,000 – 50,000
4	Discontinuous True Oil Colour	50 – 200	50,000 – 200,000
5	Continuous True Oil Colour	≥ 200	≥ 200,000

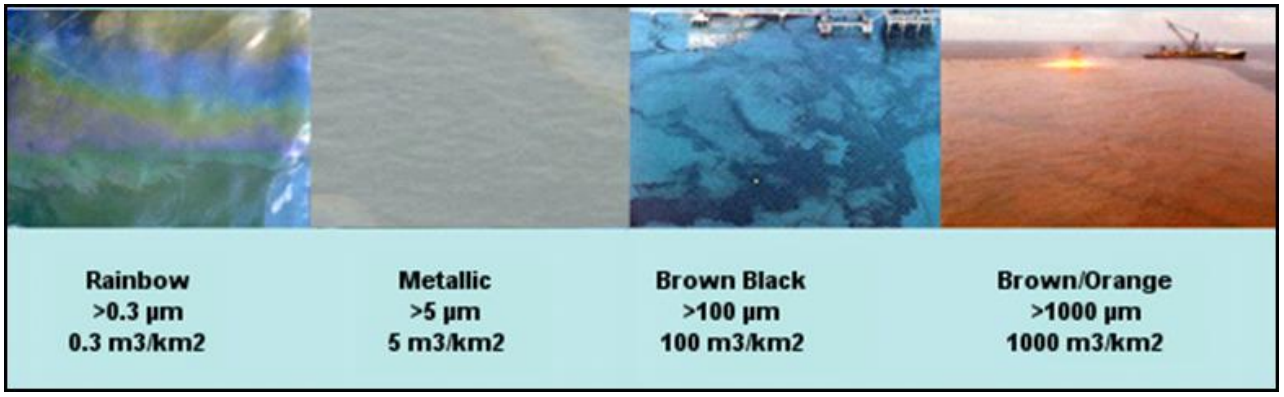

Figure 6.2 Photographs showing the difference between oil colour and thickness on the sea surface (source: adapted from Oil Spill Solutions, 2015).

Table 6.2 Floating oil exposure thresholds used in this report (in alignment with NOPSEMA, 2019).

Threshold level	Floating oil (g/m^2)	Description
Low	1	Approximates range of socioeconomic effects and establishes planning area for scientific monitoring
Moderate	10	Approximates lower limit for harmful exposures to birds and marine mammals
High	50*	Approximates surface oil slick and informs response planning

* 50 g/m^2 also used to define the threshold for actionable floating oil.

6.2.2 Shoreline Accumulation Thresholds

There are many different types of shorelines, ranging from cliffs, rocky beaches, sandy beaches, mud flats and mangroves, and each of these influences the volume of oil that can remain stranded ashore and its thickness before the shoreline saturation point occurs. For instance, a sandy beach may allow oil to percolate through the sand, thus increasing its ability to hold more oil ashore over tidal cycles and various wave actions than an equivalent area of water; hence oil can increase in thickness onshore over time. A sandy beach shoreline was assumed as the default shoreline type for the modelling herein, as it allows for the highest carrying capacity of oil (of the available open/exposed shoreline types). Hence the results contained herein would be indicative of a worst-case scenario, where the highest volume of oil may be stranded on the shoreline (when compared to other shoreline types, such as exposed rocky shores).

In previous risk assessment studies, French-McCay et al. (2005a; 2005b) used a threshold of 10 g/m^2 to assess the potential for shoreline accumulation. This is a conservative threshold used to define regions of socio-economic impact, such as triggering temporary closures of adjoining fisheries or the need for shore clean-up on beaches or man-made features/amenities (breakwaters, jetties, marinas, etc.). It would equate to approximately 2 teaspoons of hydrocarbon per square meter of shoreline accumulation. The appearance is described as a stain/film. On that basis, the 10 g/m^2 shoreline accumulation threshold has been selected to define the zone of potential “low shoreline accumulation”.

French et al. (1996) and French-McCay (2009) define a shoreline oil accumulation threshold of 100 g/m^2, or above, would potentially harm shorebirds and wildlife (furbearing aquatic mammals and marine reptiles on or along the shore) based on studies for sub-lethal and lethal impacts. This threshold has been used in previous environmental risk assessment studies (see French-McCay, 2003; French-McCay et al., 2004, French-McCay et al., 2011; 2012; NOAA, 2013). Additionally, a shoreline concentration of 100 g/m^2, or above, is the minimum limit that the oil can be effectively cleaned according to the AMSA (2015) guideline. This threshold equates to approximately ½ a cup of oil per square meter of shoreline accumulation. The appearance is described as a thin oil coat. Therefore, 100 g/m^2 has been selected to define the zone of potential “moderate shoreline accumulation”.

Observations by Lin & Mendelssohn (1996) demonstrated that loadings of more than 1,000 g/m^2 of hydrocarbon during the growing season would be required to impact marsh plants significantly. Similar thresholds have been found in studies assessing hydrocarbon impacts on mangroves (Grant et al., 1993; Suprayogi & Murray 1999). Hence, 1,000 g/m^2 has been selected to define the zone of potential “high shoreline accumulation”. It equates to approximately 1 litre of hydrocarbon per square meter of shoreline accumulation. The appearance is described as a hydrocarbon cover.

It is worth noting that the shoreline accumulation thresholds derived from extensive literature review (outlined in Table 6.3) agree with the commonly used threshold values for oil spill modelling specified in NOPSEMA (2019).

Table 6.3 Thresholds used to assess shoreline accumulation.

Threshold level	Shoreline accumulation (g/m^2)	Description
Low (socioeconomic/sublethal)	10	Predicts potential for some socio-economic impact
Moderate	100*	Loading predicts area likely to require clean-up effort
High	> 1,000	Loading predicts area likely to require intensive clean-up effort

* 100 g/m^2 also used to define the threshold for actionable shoreline oil.

6.2.3 In-water Exposure Thresholds

Oil is a mixture of thousands of hydrocarbons of varying physical, chemical, and toxicological characteristics, and therefore, demonstrate varying fates and impacts on organisms. As such, for in-water exposure, the SIMAP model provides separate outputs for dissolved and entrained hydrocarbons from oil droplets. The consequences of exposure to dissolved and entrained components will differ because they have different modes and magnitudes of effect.

Entrained hydrocarbon concentrations were calculated based on oil droplets that are suspended in the water column, though not dissolved. The composition of this oil would vary with the state of weathering (oil age) and may contain soluble hydrocarbons when the oil is fresh. Calculations for dissolved hydrocarbons specifically calculates oil components which are dissolved in water, which are known to be the primary source of toxicity exerted by oil.

6.2.3.1 Dissolved Hydrocarbons

Laboratory studies have shown that dissolved hydrocarbons exert most of the toxic effects of oil on aquatic biota (Carls et al., 2008; Nordtug et al., 2011; Redman, 2015). The mode of action is a narcotic effect, which is positively related to the concentration of soluble hydrocarbons in the body tissues of organisms (French-McCay, 2002). Dissolved hydrocarbons are taken up by organisms directly from the water column by absorption through external surfaces and gills, as well as through the digestive tract. Thus, soluble hydrocarbons are termed “bioavailable”.

Hydrocarbon compounds vary in water-solubility and the toxicity exerted by individual compounds is inversely related to solubility, however bioavailability will be modified by the volatility of individual compounds (Nirmalakhandan & Speece, 1988; Blum & Speece, 1990; McCarty, 1986; McCarty et al., 1992a, 1992b; Mackay et al., 1992; McCarty & Mackay, 1993; Verhaar et al., 1992, 1999; Swartz et al., 1995; French-McCay, 2002; McGrath & Di Toro, 2009). Of the soluble compounds, the greatest contributor to toxicity for water-column and benthic organisms are the lower-molecular-weight aromatic compounds, which are both volatile and soluble in water. Although they are not the most water-soluble hydrocarbons within most oil types, the polynuclear aromatic hydrocarbons (PAHs) containing 2-3 aromatic ring structures typically exert the largest narcotic effects because they are semi-soluble and not highly volatile, so they persist in the environment long enough for significant accumulation to occur (Anderson et al., 1974, 1987; Neff & Anderson, 1981; Malins & Hodgins, 1981; McAuliffe, 1987; NRC, 2003). The monoaromatic hydrocarbons (MAHs), including the BTEX compounds (benzene, toluene, ethylbenzene, and xylenes), and the soluble alkanes (straight chain hydrocarbons) also contribute to toxicity, but these compounds are highly volatile, so that their contribution will be low when oil is exposed to evaporation and higher when oil is discharged at depth where volatilisation does not occur (French-McCay, 2002).

French-McCay (2002) reviewed available toxicity data, where marine biota was exposed to dissolved hydrocarbons prepared from oil mixtures, finding that 95% of species and life stages exhibited 50% population mortality (LC_{50}) between 6 and 400 ppb total PAH concentration after 96 hrs exposure, with an average of 50 ppb. Hence, concentrations lower than 6 ppb total PAH value should be protective of 97.5% of species and life stages even with exposure periods of days (at least 96 hours). Early life-history stages of fish appear to be more sensitive than older fish stages and invertebrates.

Exceedances of 10, 50 or 400 ppb over a 1 hour timestep (see Table 6.4) was applied to indicate increasing potential for sub-lethal to lethal toxic effects (or low to high), based on NOPSEMA (2019).

6.2.3.2 Entrained Hydrocarbons

Entrained hydrocarbons consist of oil droplets that are suspended in the water column and insoluble. As such, insoluble compounds in oil cannot be absorbed from the water column by aquatic organisms, hence are not bioavailable through absorption of compounds from the water. Exposure to these compounds would require routes of uptake other than absorption of soluble compounds. The route of exposure of organisms to whole oil alone include direct contact with tissues of organisms and uptake of oil by direct consumption, with potential for biomagnification through the food chain (NRC, 2003).

The 10 ppb threshold represents the very lowest concentration and corresponds generally with the lowest trigger levels for chronic exposure for entrained hydrocarbons in the ANZECC & ARMCANZ (2000) water quality guidelines. Due to the requirement for relatively long exposure times (> 24 hours) for these concentrations to be significant, they are likely to be more meaningful for juvenile fish, larvae and planktonic organisms that might be entrained (or otherwise moving) within the entrained plumes, or when entrained hydrocarbons adhere to organisms or trapped against a shoreline for periods of several days or more.

This exposure zone is not considered to be of significant biological impact and is therefore outside the adverse exposure zone. This exposure zone represents the area contacted by the spill. This area does not define the area of influence as it is considered that the environment will not be affected by the entrained hydrocarbon at this level.

Thresholds of 10 ppb and 100 ppb were applied over a 1 hour time exposure (Table 6.4), to cover the range of thresholds outlined in the ANZECC & ARMCANZ (2000) water quality guidelines, the incremental change for greater potential effect and is per NOPSEMA (2019).

A complicating factor that should be considered when assessing the consequence of dissolved and entrained oil distributions is that there will be some areas where both physically entrained oil droplets and dissolved hydrocarbons co-exist. Higher concentrations of each will tend to occur close to the source where sea conditions can force mixing of relatively unweathered oil into the water column, resulting in more rapid dissolution of soluble compounds.

Table 6.4 Dissolved and entrained hydrocarbon exposure values assessed over a 1-hour time step, as per NOPSEMA (2019).

Threshold level	Dissolved hydrocarbon concentration (ppb)	Entrained hydrocarbon concentrations (ppb)
Low	10	10
Moderate	50	-
High	400	100

7 HYDROCARBON PROPERTIES

7.1 Marine Diesel Oil Properties

The marine diesel oil (MDO) physical properties and boiling point distributions are presented in Table 7.1 and Table 7.2, respectively.

The MDO has an API of 37.60, a density of 829 kg/m^3 (at 25ºC) and a low viscosity value of 4.0 cP. When exposed to the atmosphere at local temperatures, about 6.0% of the MDO volatile components should evaporate within the first 12 hours (BP < 180°C); a further 34.6% of the semi-volatiles should evaporate within the first 24 hours (180°C < BP < 265°C); and low volatile portion (54.4%) should evaporate over a longer period (265°C < BP < 380°C). Additionally, 5.0% of the MDO is shown to be persist in the marine environment for much longer periods and be subject to relatively slow degradation.

The oil is categorised as a group II oil (light-persistent) based on categorisation and classification derived from AMSA (2015) guidelines. The classification is based on the specific gravity of hydrocarbons in combination with relevant boiling point ranges.

The actual fate of released oil in the marine environment will depend greatly on the amount of oil that remains on the surface or is entrained in the water column.

Table 7.1 Physical properties of marine diesel oil.

Characteristic	Marine Diesel Oil
Density (kg/m^3)	829 (at 25°C)
API	37.60
Dynamic viscosity (cP)	4.0 (at 25°C)
Pour point (°C)	-14
Hydrocarbon property category	Group II
Hydrocarbon property classification	Light-persistent

Table 7.2 Boiling point ranges of marine diesel oil.

Oil Type	Component	Volatile (%)	Semi-volatile (%)	Low volatility (%)	Residual (%)
	Boiling point (°C)	<180 C_4 to C_{10}	180-265 C_{11} to C_{15}	265-380 C_{16} to C_{20}	>380 >C_{20}
Marine Diesel Oil	% of total	6.0	34.6	54.4	5.0

7.2 Marine Diesel Oil Weathering Characteristics

7.2.1 Overview

A series of weathering tests were conducted to illustrate the potential behaviour of this diesel when exposed to idealised and representative environmental conditions:

- Instantaneous 50 m^3 surface release under calm wind conditions (constant 5 knots), 27°C water temperature and currents.

- Instantaneous 50 m^3 surface release under variable moderate wind conditions, 27°C water temperature and currents.

The first case is indicative of weathering rates under calm conditions that would not generate entrainment, while the second case would be more representative of the moderate winds experienced over the region. Both scenarios provide examples of potential behaviour during periods of a spill event once the diesel reaches the surface.

7.2.2 Results

The mass balance forecast for the calm-wind case (Figure 7.1) shows that 36.1% of the diesel is predicted to evaporate within 24 hours. Majority of the remaining diesel on the water surface will weather at a slower rate due to being comprised of the longer-chain compounds with higher boiling points. Evaporation of the residual compounds will slow significantly, and they will then be subject to more gradual decay through biological and photochemical processes.

Under the variable-wind case (Figure 7.2), where the winds are of greater strength on average, entrainment of diesel into the water column is predicted to increase. Approximately 24 hours after the spill, 80.5% of the diesel is forecast to have entrained and a further 15.0% is forecast to have evaporated, leaving only a small proportion floating on the water surface (<1%). The residual compounds will tend to remain entrained beneath the surface under conditions that generate wind waves (approximately >6 m/s).

The increased level of entrainment in the variable-wind case will result in a higher percentage of biological and photochemical degradation, where the decay of the floating slicks and diesel droplets in the water column occurs at an approximate rate of 2.90% per day with an accumulated total of 20.3% after 7 days, in comparison to a rate of 0.37% per day and an accumulated total of 2.60% after 7 days in the constant-wind case. Given the proportion of entrained MDO and the tendency for it to remain mixed in the water column, the remaining hydrocarbons will decay over time scales of several weeks.

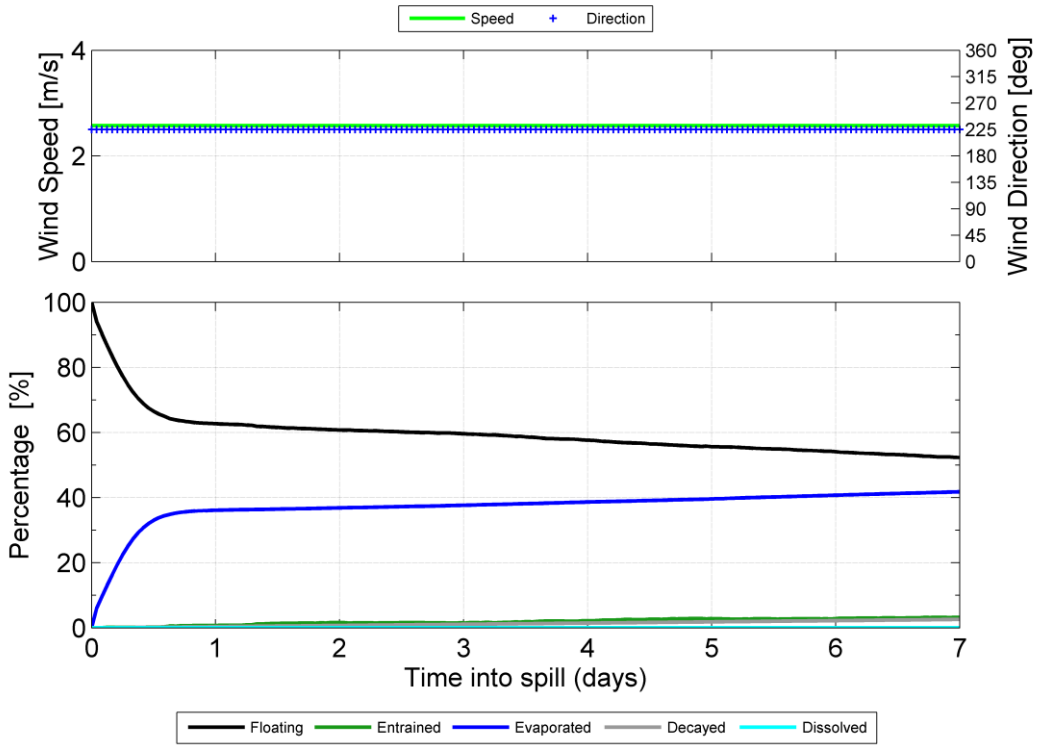

Figure 7.1 Proportional mass balance plot representing the weathering of marine diesel oil spilled onto the water surface as a one-off instantaneous release and subject to a constant 5 knots (2.6 m/s) wind at 27°C water temperature.

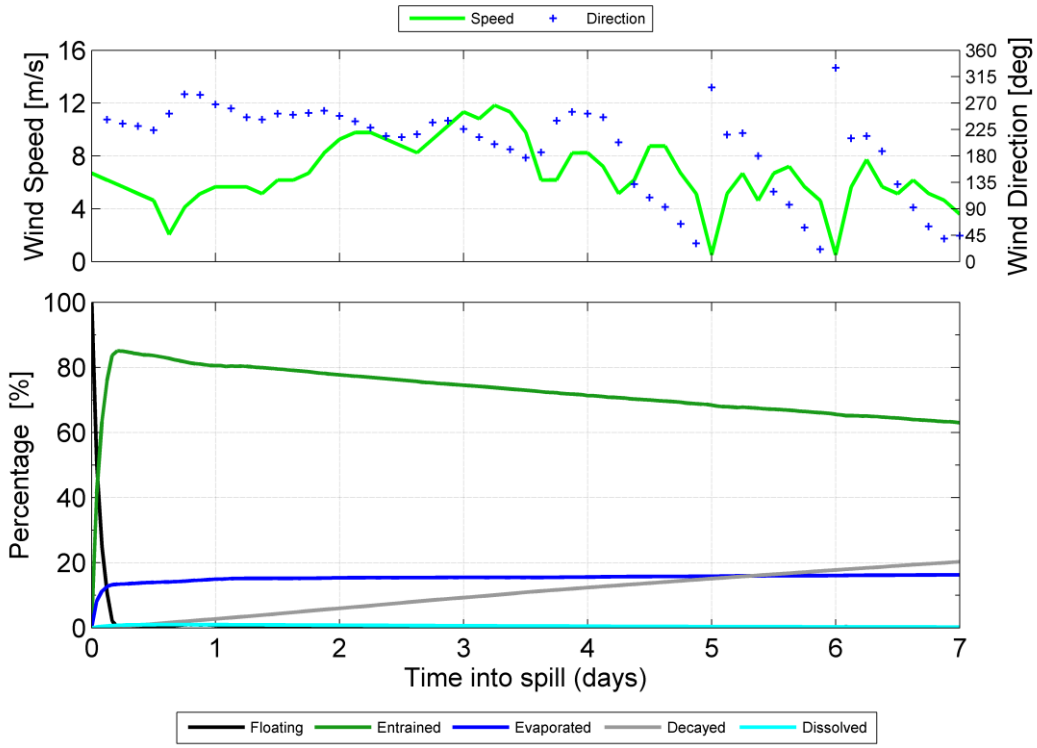

Figure 7.2 Proportional mass balance plot representing the weathering of marine diesel oil spilled onto the water surface as a one-off instantaneous release and subject to variable wind at 27°C water temperature.

8 MODEL SETTINGS

Table 8.1 provides a summary of the oil spill model settings.

Table 8.1 Summary of the oil spill model settings used in this assessment.

	Scenario
Location	WTR Well 5
Number of spill simulations with randomly selected start times	100 per season (300 total)
Spill volume (m^3) [bbl]	1,500 [238.5]
Condensate type	MDO
Release type (depth)	Surface
Release duration (days)	1
Simulation length (days)	60
Model period	Summer (September to the following March) Transitional (April and August) Winter (May to July)
Floating oil (NOPSEMA) thresholds	1 g/m^2, low exposure 10 g/m^2, moderate exposure 50 g/m^2, high exposure
Shoreline accumulation (NOPSEMA) thresholds	10 g/m^2, low exposure 100 g/m^2, moderate exposure 1,000 g/m^2, high exposure
Dissolved hydrocarbon (NOPSEMA) thresholds	10 ppb over 1 hour, low exposure 50 ppb over 1 hour, moderate exposure 400 ppb over 1 hour, high exposure
Entrained hydrocarbon (NOPSEMA) thresholds	10 ppb over 1 hour, low exposure 100 ppb over 1 hour, high exposure

9 PRESENTATION AND INTERPRETATION OF MODEL RESULTS

The results from the modelling study are presented in a number of tables and figures, which aim to provide an understanding of the predicted sea-surface and water column (subsurface) exposure and shoreline accumulation (if predicted).

9.1 Stochastic Analysis

9.1.1 Statistics

The statistics are based on the following principles:

- The ***greatest distance travelled by a spill trajectory*** – is determined by a) recording the maximum and b) second greatest distance travelled (or 99th percentile) by a single trajectory, within a scenario, from the release location to the identified exposure thresholds.
- The ***probability of oil exposure to a receptor*** – is determined by recording the number of spill trajectories to reach a specified sea surface or subsea threshold within a receptor polygon, divided by the total number of spill trajectories within that scenario.
- The ***minimum time before oil exposure to a receptor*** – is determined by ranking the elapsed time before sea surface exposure, at a specified threshold, to grid cells within a receptor polygon and recording the minimum value.
- The ***probability of oil accumulation at a receptor*** – is determined by recording the number of spill trajectories to reach a specified shoreline accumulation threshold within a receptor polygon, divided by the total number of spill trajectories within that scenario.
- The ***maximum potential oil accumulation within a receptor*** – is determined by identifying the maximum loading to any grid cell within a receptor polygon, for a scenario.
- The ***dissolved and entrained hydrocarbon exposure*** – is determined by recording the maximum instantaneous concentrations at each grid cell assessed over a 1-hour time step.

9.2 Deterministic Trajectories

The deterministic results for both scenarios are based on the following criteria:

a. Largest volume of oil ashore;

b. Minimum time before shoreline accumulation above 10 g/m^2;

c. Longest length of shoreline accumulation above 10 g/m^2;

d. Largest swept area of floating oil above 1 g/m2;

e. Largest area of entrained hydrocarbons above 10 ppb; and

f. Largest area of dissolved hydrocarbons above 10 ppb.

9.3 Receptors

A range of environmental receptors and shorelines were assessed for floating oil exposure, shoreline contact and water column exposure (entrained and dissolved hydrocarbons) as part of the study (see Figure 9.1 to Figure 9.11). Receptor categories (see Table 9.1) include sections of shorelines and offshore islands. All other sensitive receptors other than submerged reefs, shoals and banks (RSB) were sourced from http://www.environment.gov.au/. Risks of exposure were separately calculated for each sensitive receptor area and have been tabulated.

Table 9.2 summarises the receptors that the location resides within.

Table 9.1 Summary of receptors used to assess floating oil, shoreline and in-water exposure to hydrocarbons.

10 RESULTS: WEST TRYAL ROCKS VESSEL COLLISION

This scenario examined a 1,500 m^3 surface release of MDO over 24 hours, from a vessel collision. A total of 300 spill simulations were run for each of the three seasons (i.e. 100 spills per season) and tracked for 60 days.

Section 10.1 presents the seasonal (or stochastic) analysis results, while Section 10.2 presents the deterministic results.

10.1 Stochastic Analysis

10.1.1 Floating MDO Exposure

Table 10.1 summarises the maximum distances from the release location to floating oil exposure zones for each season.

The maximum distance from the release location to the low (≥ 1 g/m^2), moderate (≥ 10 g/m^2) and high (≥ 50 g/m^2) threshold was 167.0 northeast (summer), 59.6 km south-southwest (winter) and 17.6 km north-northeast (summer), respectively.

Table 10.2 summarises the potential floating oil exposure to individual receptors during each season.

The Offshore Area IAA, Flatback Turtle - Internesting Buffer, Pygmy Blue Whale – Distribution, Wedge-tailed Shearwater - Breeding, Whale Shark – Foraging BIAs, Pilbara (offshore) IMCRA, and the Ancient coastline at 125 m depth contour KEF, which the release location resides within (see Section 10.3), and the Humpback Whale - Migration BIA and Continental Slope Demersal Fish Communities KEF were the only receptors predicted to be exposed during all three seasons at the low and moderate thresholds. With the exception of the Humpback Whale - Migration BIA and Continental Slope Demersal Fish Communities KEF, the probabilities for the low and moderate thresholds was 100% for all seasons for these receptors. The probabilities of low and moderate exposure at the Humpback Whale - Migration BIA ranged between 16–22% and 3–4%, whilst the probabilities of low and moderate exposure to the Continental Slope Demersal Fish Communities KEF ranged between 35–54% and 4–13%, respectively. The minimum times before low exposure for the Humpback Whale - Migration BIA and Continental Slope Demersal Fish Communities KEF were 0.54 days (winter) and 0.38 days (transitional), respectively.

Figure 10.1 to Figure 10.3 present the zones of floating oil exposure for each season.

Table 10.1 Maximum distances and directions travelled from the release location to floating oil exposure for each season and threshold, following a vessel collision at WTR Well 5. The results were calculated from 100 spill trajectories per season.

Season	Distance and direction	Zones of potential floating oil exposure		
		Low	Moderate	High
Summer	Max. distance from release site (km)	167.0	52.1	17.6
	Max. distance from release site (km) (99th percentile)	154.0	43.4	17.1
	Direction	Northeast	South	North-northeast
Transitional	Max. distance from release site (km)	134.4	46.6	17.3
	Max. distance from release site (km) (99th percentile)	91.6	43.7	16.7
	Direction	West-northwest	South-southwest	South-southwest
Winter	Max. distance from release site (km)	158.6	59.6	9.8
	Max. distance from release site (km) (99th percentile)	86.3	53.3	9.5
	Direction	South-southwest	South-southwest	North

10.1.2 Shoreline Accumulation

Table 10.3 presents a summary of the predicted shoreline accumulation during summer, transitional and winter seasons. The probability of accumulation on any shoreline at, or above, the low threshold (≥ 10 g/m^2) was greatest during winter at 9%, while the minimum time before shoreline accumulation was 6.50 days and the maximum volume of oil ashore was 35.1 m^3.

No high (≥ 1,000 g/m^2) shoreline threshold accumulation was predicted in the modelling results.

Table 10.4 to Table 10.6summarises the shoreline accumulation on individual receptors for each season.

During summer conditions, 23 shoreline receptors were predicted to record oil accumulation at, or above, the low threshold with the greatest probability predicted for Ningaloo Coast World Heritage Area IAA (4%). In comparison, during transitional and winter conditions, 9 and 22 shoreline receptors, respectively, were predicted to record accumulation. During transitional conditions the greatest probability for low threshold accumulation was 3% predicted for South Muiron Island and Ningaloo Coast World Heritage Area IAA, and the Muiron Islands IAA and shoreline. Additionally, during the winter conditions the greatest probability for low threshold accumulation was 7% and was predicted for the Ningaloo Coast World Heritage Area IAA.

The maximum potential shoreline accumulation is presented for each season in Figure 10.4 to Figure 10.6.

Table 10.3 Summary of oil accumulation across all shorelines for each season and threshold, following a vessel collision at WTR Well 5. The results were calculated from 100 spill trajectories per season.

Shoreline Statistics	Summer	Transitional	Winter
Probability of accumulation on any shoreline (%)	6	4	9
Absolute minimum time for visible oil to shore (days)	8.04	16.33	6.50
Maximum volume of hydrocarbons ashore (m^3) above the low threshold	35.1	1.7	7.2
Average volume of hydrocarbons ashore (m^3) above the low threshold	1.9	< 0.1	0.2
Maximum length of the shoreline at **10 g/m^2** (km)	51.0	6	14
Average shoreline length (km) at **10 g/m^2** (km)	21.7	4.3	6.2
Maximum length of the shoreline at **100 g/m^2** (km)	24	-	2

10.1.3 Water Column Exposure

10.1.3.1 Dissolved Hydrocarbons

Table 10.7 summarises the seasonal probability of exposure to individual receptors from dissolved hydrocarbons in the 0-10 m depth layer, at the low (≥ 10 ppb), moderate (≥ 50 ppb) and high (≥ 400 ppb) exposure thresholds.

In the surface (0-10 m) depth layer, a total of 14, 12, and 14 BIAs were predicted to be exposed at, or above, the low threshold during summer, transitional and winter, respectively. Excluding the 4 BIAs that the release location resides within (Flatback Turtle - Internesting Buffer, Pygmy Blue Whale - Distribution, Wedge-tailed Shearwater - Breeding and Whale Shark – Foraging) , the highest probabilities of exposure for the low threshold during summer, transitional and winter were predicted as 6%, 6% and 14%, respectively for the Humpback Whale - Migration BIA.

A total of 3, 2 and 2 AMPs were predicted to be exposed to dissolved hydrocarbons at, or above the low threshold during summer, transitional and winter, respectively with the highest probability predicted at the Montebello AMP of 3% during summer and transitional.

Additionally, 4, 3 and 4 IAAs and 2, 3 and 3 IMCRAs were predicted to be exposed to dissolved hydrocarbons at, or above the low threshold during summer, transitional and winter, respectively.

Furthermore, 4 (summer) and 3 (transitional) and 5 (winter) KEFs were predicted to be exposed to dissolved hydrocarbons at, or above the low threshold.

Figure 10.7 to Figure 10.9 presents the zones of potential instantaneous dissolved hydrocarbon exposure for the 0-10 m depth layer for the summer, transitional and winter periods, respectively.

Table 10.7 Predicted probability and maximum dissolved hydrocarbon exposure to individual receptors in the 0-10 m depth layer following a vessel collision at WTR Well 5. The results were calculated from 100 spill simulations per season.

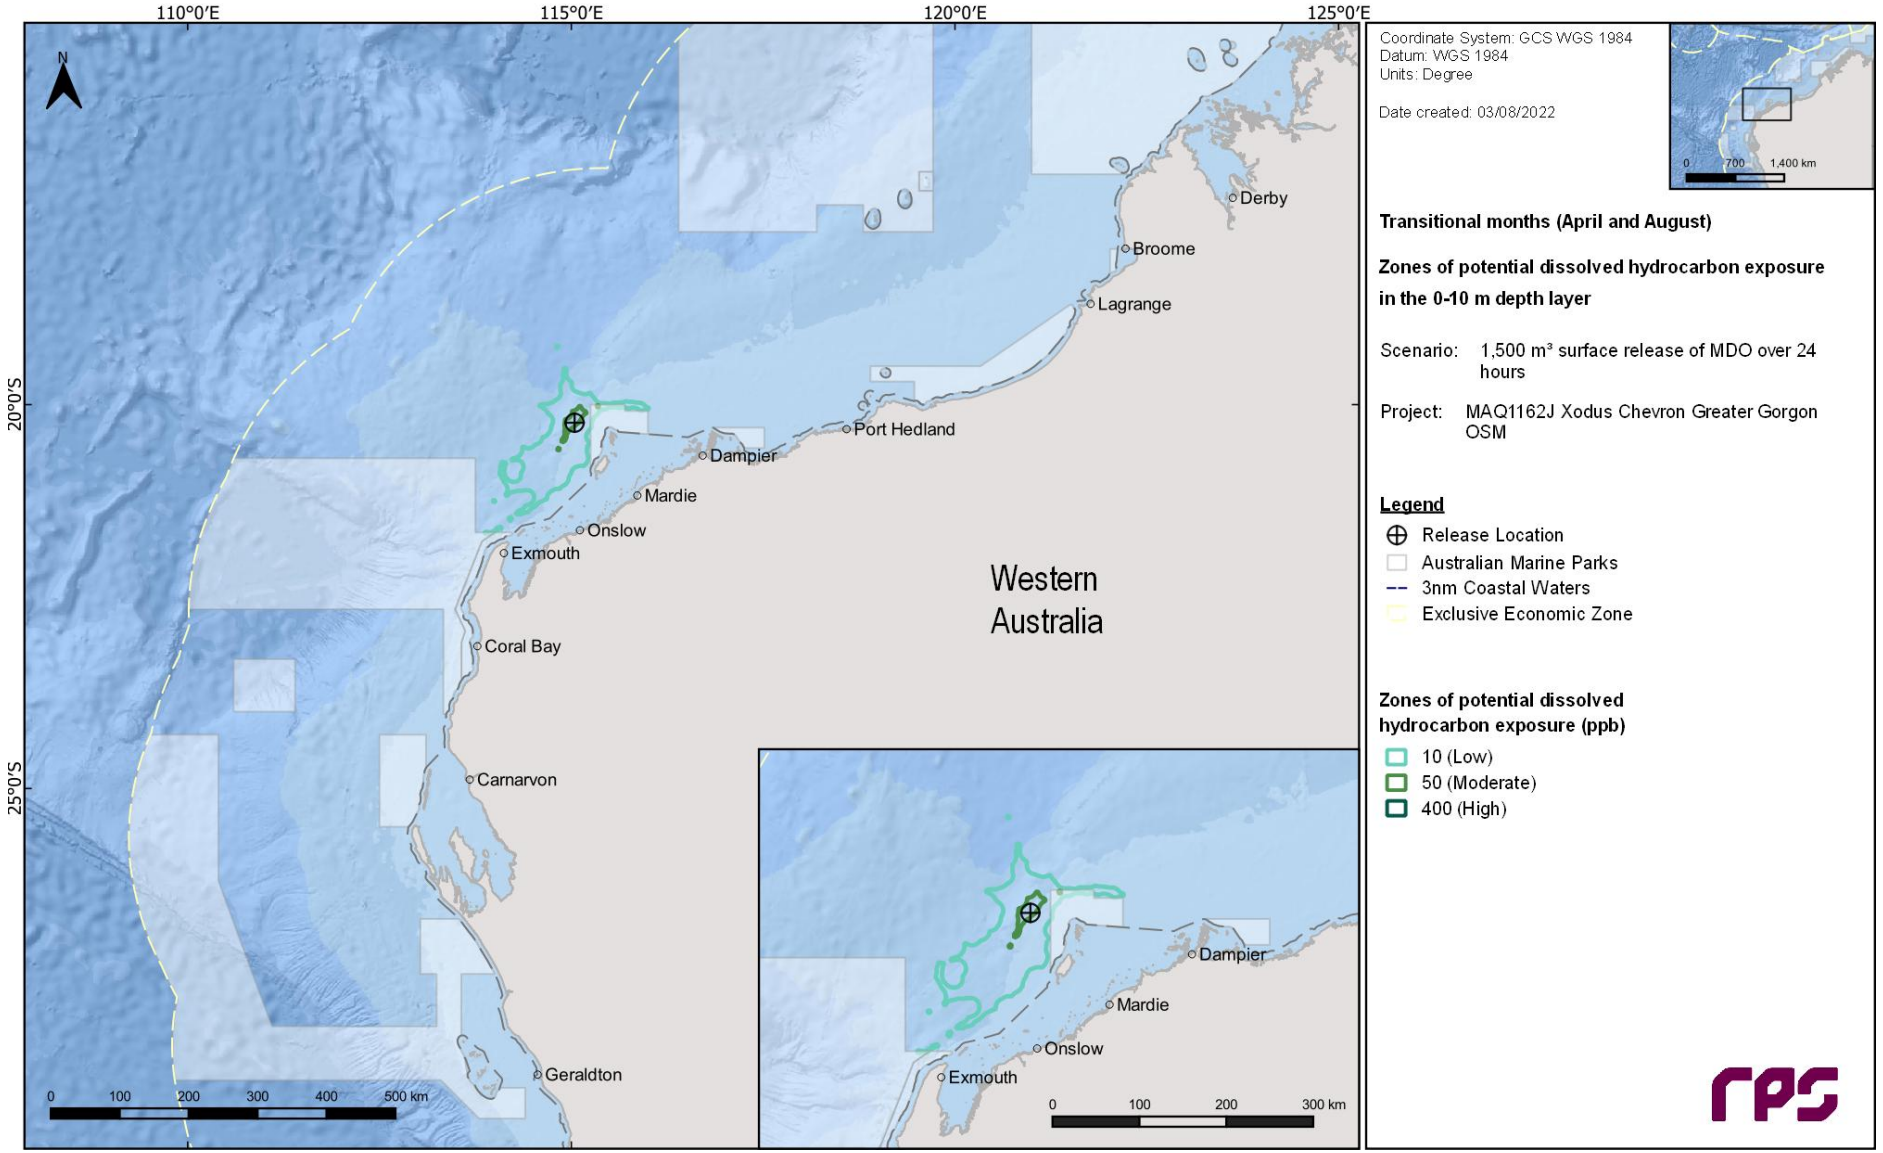

Figure 10.8 Zones of potential dissolved hydrocarbon exposure at 0-10 m following a vessel collision at WTR Well 5 during transitional (April and August) wind and current conditions. The results were calculated from 100 spill simulations.

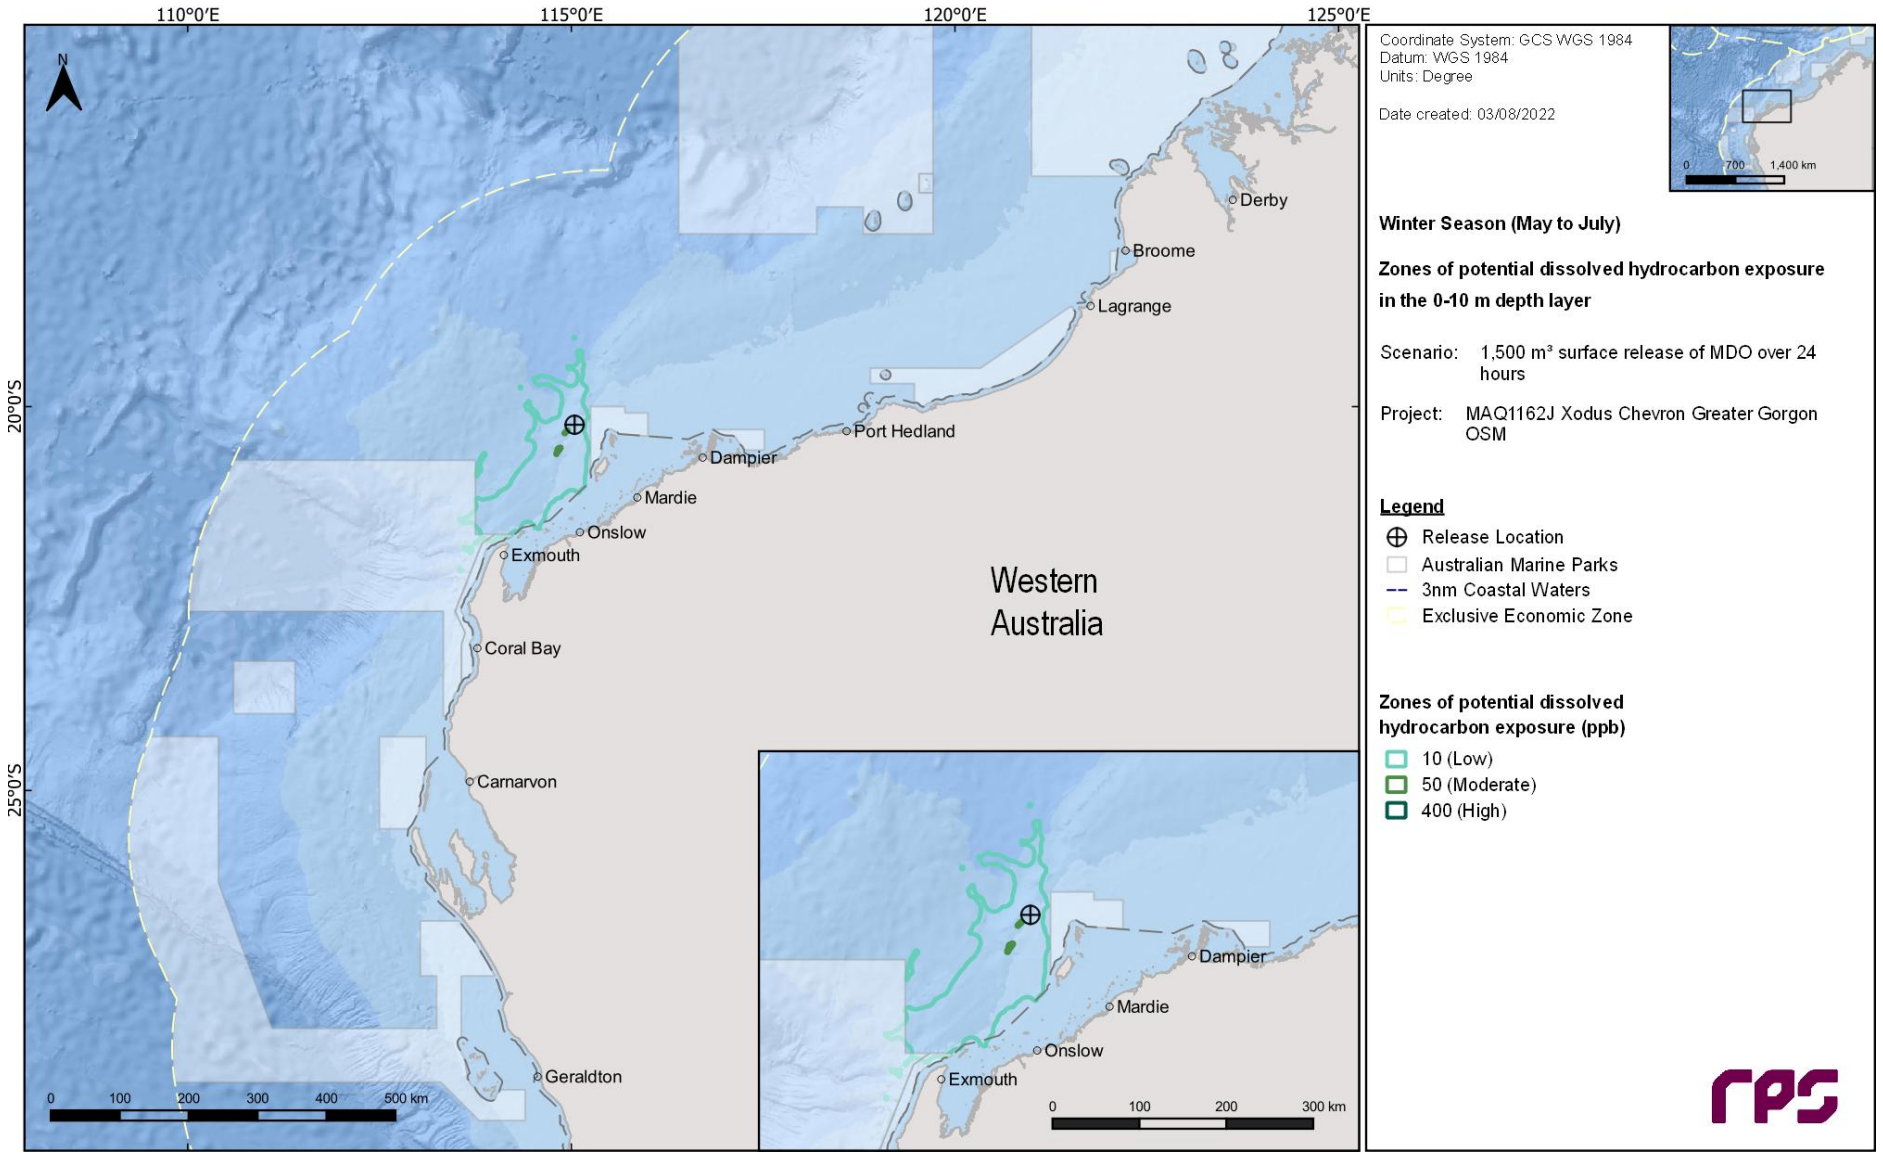

Figure 10.9 Zones of potential dissolved hydrocarbon exposure at 0-10 m following a vessel collision at WTR Well 5 during winter (May to July) wind and current conditions. The results were calculated from 100 spill simulations.

10.1.3.2 Entrained Hydrocarbons

Table 10.8 summarises the probability and minimum time before exposure to receptors from entrained hydrocarbons in the 0-10 m depth layer, for each season, at the low (≥ 10 ppb) and high (≥ 100 ppb) thresholds.

In the surface (0-10 m) depth layer, a total of 29 BIAs were predicted to be exposed at, or above, the low threshold during all 3 seasons. Excluding the 4 BIAs that the release location resides within (Flatback Turtle - Internesting Buffer, Pygmy Blue Whale - Distribution, Wedge-tailed Shearwater - Breeding and Whale Shark – Foraging) , the highest probabilities of exposure to low entrained hydrocarbons were predicted for the Humpback Whale - Migration during all seasons (42%, 59% and 71% for summer, transitional and winter, respectively).

During all 3 seasons, 3 AMPs were predicted to be exposed at the low threshold, with the highest probabilities predicted at the Gascoyne AMP (21% summer, 22% transitional and 37% winter). Furthermore, during seasonal conditions the Gascoyne, Montebello and Ningaloo AMP were also predicted to be exposed to entrained hydrocarbons at the high threshold.

During summer, transitional and winter conditions, 8, 5 and 6 KEFs were predicted to be exposed by entrained hydrocarbons at the low threshold, respectively. Probabilities of exposure ranged between 1–100%, 13–95% and 12–100%, for summer, transitional and winter, respectively. Excluding the KEF that the release location resides within (Ancient coastline at 125 m depth contour), the KEF with the greatest probability of low exposure for each season was the Continental Slope Demersal Fish Communities KEF (58%, 54% and 68% for summer, transitional and winter, respectively).

Additionally, 24, 22 and 24 IAA (including the Offshore IAA that the release site is located within), were predicted to be exposed to entrained hydrocarbons at low threshold. Excluding the Offshore IAA, the probabilities for each season ranged between 1–21%, 1–22% and 1–37% under summer, transitional and winter conditions, respectively, with the maximum probabilities occurring at the Gascoyne IAA during all seasons.

Furthermore, 17, 22 and 23 RBS receptors were predicted to be exposed to entrained hydrocarbons at the low threshold during summer, transitional and winter, respectively. The maximum probabilities for low threshold exposure during summer, transitional and winter were predicted for Rankin Bank (17%), Rankin Bank (8%) and Outtrim Patches (13%), respectively.

Figure 10.10 to Figure 10.12 illustrate the extent of the predicted entrained hydrocarbon exposure for the low and high thresholds in the 0-10 m depth layer for each season.

Table 10.8 Predicted probability and maximum entrained hydrocarbon exposure to individual receptors in the 0-10 m depth layer following a vessel collision at WTR Well 5. The results were calculated from 100 spill simulations per season.

10.2 Deterministic Analysis

The deterministic analysis presented below, are based on simulations that resulted in the largest swept area of floating MDO above 10 g/m^2 (see Section 10.2.1), largest swept area of floating MDO above 50 g/m^2 (see Section 10.2.2), largest volume of oil ashore and longest length of shoreline accumulation above 100 g/m^2 (see Section 10.2.3), the largest area of entrained hydrocarbons above 100 ppb (see Section 10.2.4), and the largest area of dissolved hydrocarbons above 50 ppb (see Section 10.2.5).

Table 10.9 presents a summary of all deterministic analysis criteria and the corresponding floating oil, shoreline accumulation, entrained and dissolved hydrocarbon values at the assessed thresholds.

Table 10.9 Summary of the deterministic analysis following a vessel collision at WTR Well 5.

Variable	Threshold	Deterministic Analysis Criteria					
		Largest swept area of floating MDO above 10 g/m^2	Largest swept area of floating MDO above 50 g/m^2	Largest volume of oil ashore	Longest length of shoreline accumulation above 100 g/m^2	Largest area of entrained hydrocarbons above 100 ppb	Largest area of dissolved hydrocarbons above 50 ppb

10.2.1 Deterministic Case: Largest swept area of floating oil above 10 g/m^2

The deterministic simulation that resulted in the largest swept area of floating oil above 10 g/m^2 (moderate threshold) was identified as run number 60 during the winter period.

Figure 10.13 presents the extent of the predicted floating oil exposure zones on the sea surface (swept area) and shoreline accumulation over the entire 60-day simulation.

Figure 10.14 displays the time series of the swept area of low (≥ 1 g/m^2), moderate (≥ 10 g/m^2) and high (≥ 50 g/m^2) floating oil over the 60-day simulation.

Figure 10.15 presents the fates and weathering for the corresponding simulation and Table 10.10 summarises peak volumes and times of occurrence for each oil phase and volumes at the end of the 60-day simulation.

Table 10.10 Summary of peak volumes and times of occurrence for each oil phase and the volumes at the conclusion of the simulation (day 60), for the simulation with the largest swept area of floating oil above 10 g/m^2 following a vessel collision at WTR Well 5.

Exposure Metrics	Peak Volume	Day of Occurrence	Volume at day 60
Surface (m^3)	900	1	0
Entrained (m^3)	488	4	62
Dissolved (m^3)	1	4	0
Evaporation (m^3)	1,057	58	1,057
Decay (m^3)	371	60	371
Ashore (m^3)	0	0	0

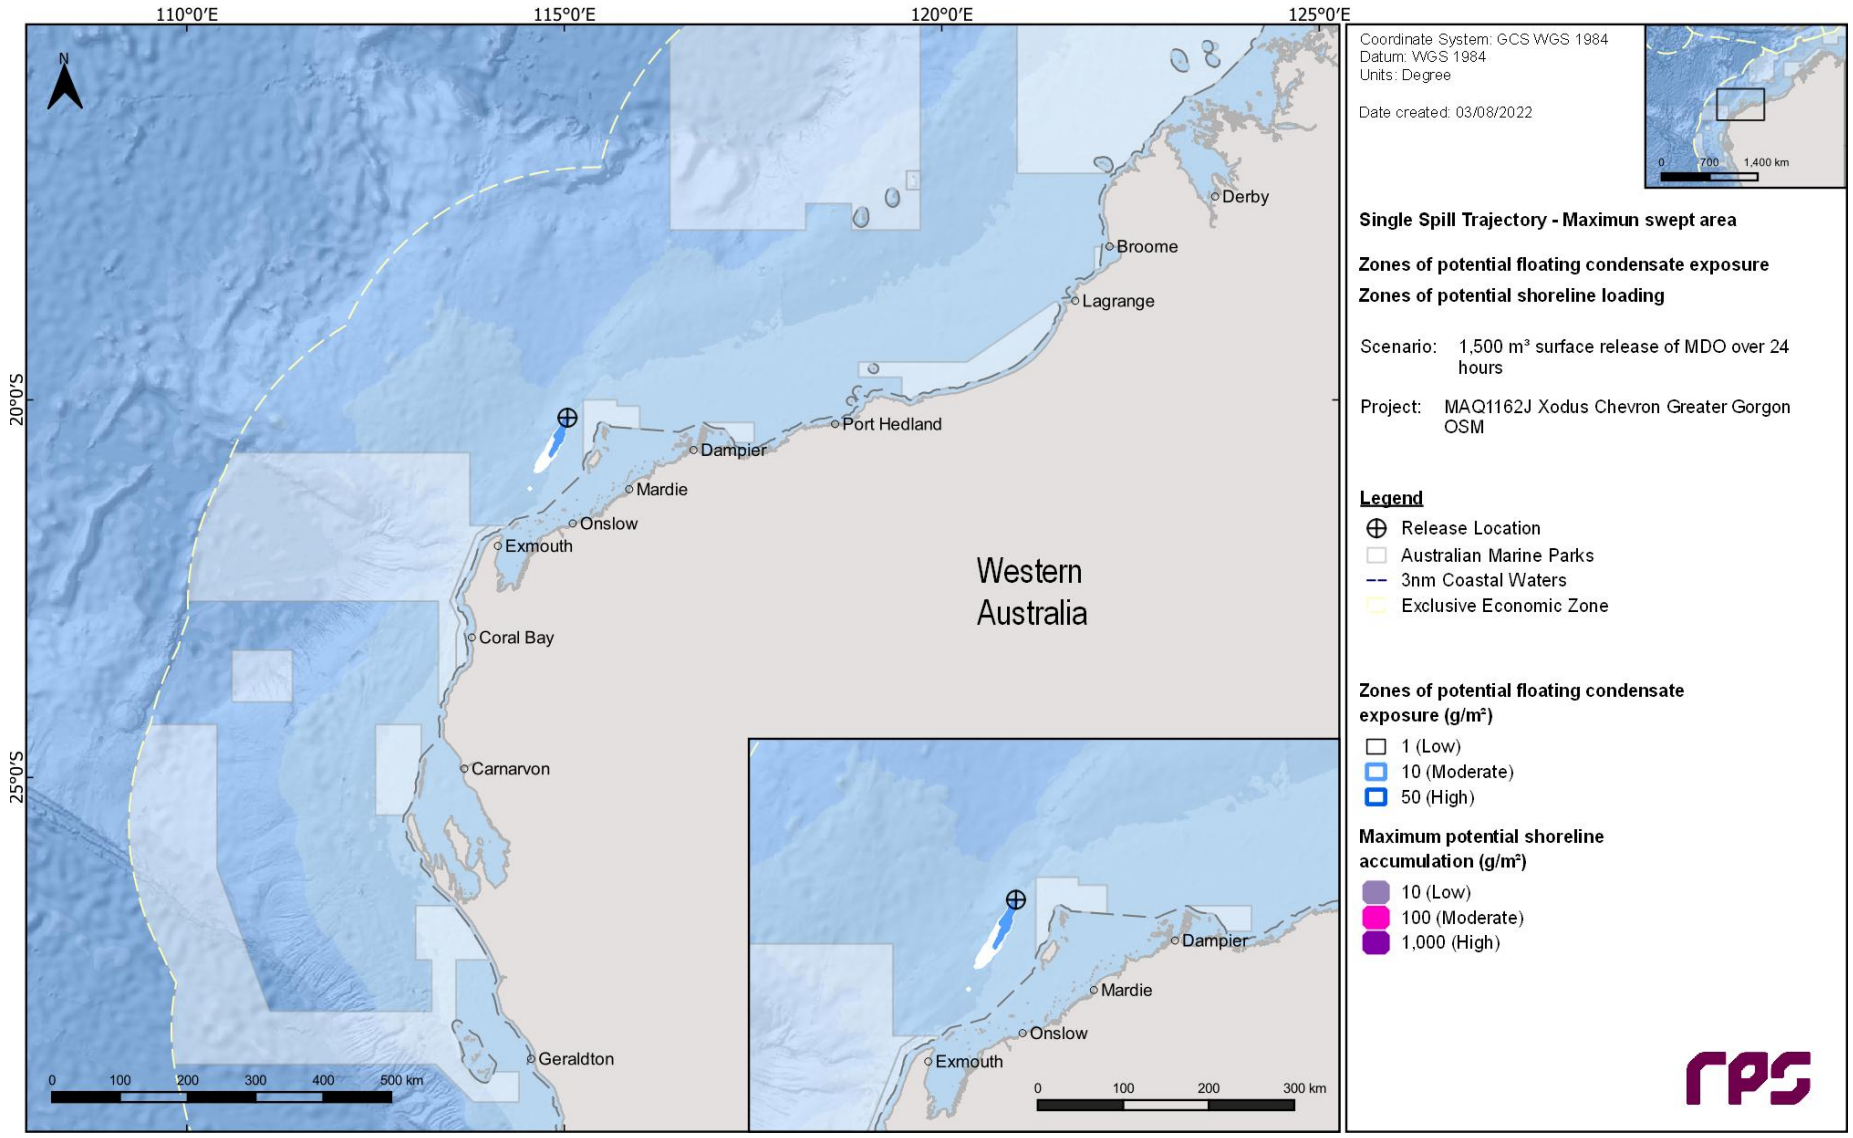

Figure 10.13 Zones of potential floating oil exposure and shoreline accumulation over the entire 60 days, for the simulation with the largest swept area of floating oil above 10 g/m² following a vessel collision at WTR Well 5.

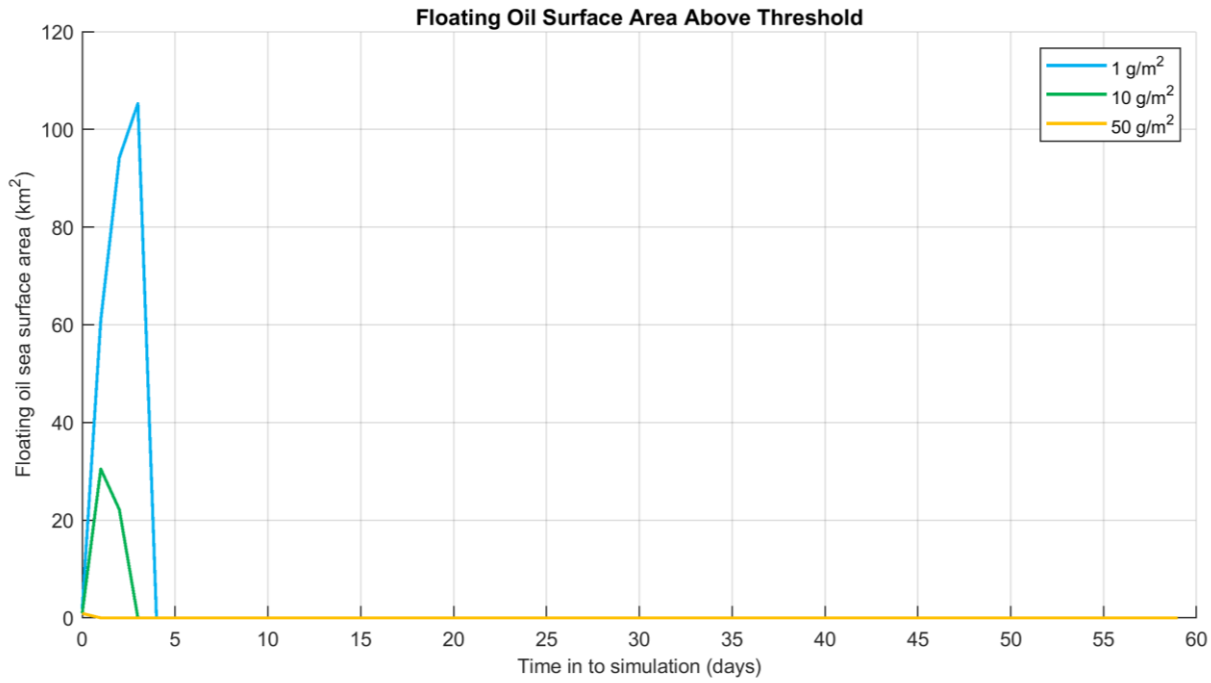

Figure 10.14 Predicted area of floating oil exposure for each threshold, for the simulation with the largest swept area of floating oil above 10 g/m^2 following a LOWC at WTR Well 5.

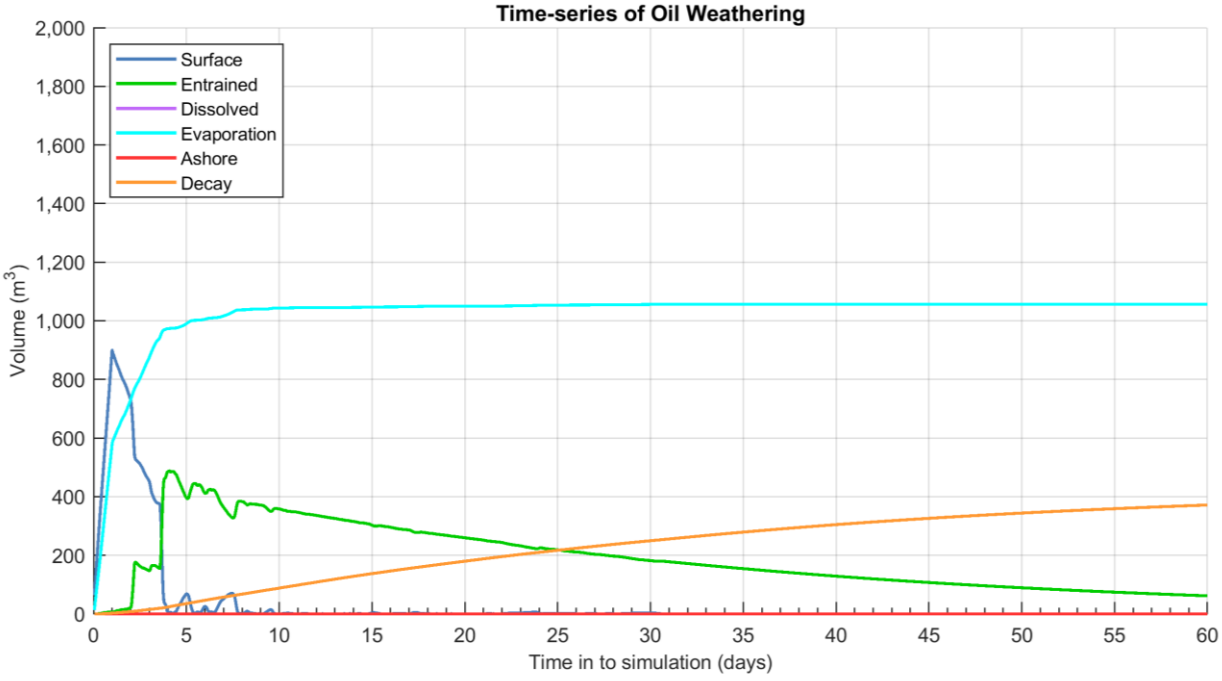

Figure 10.15 Predicted weathering and fates for the simulation with the largest swept area of floating oil above 10 g/m^2 following a vessel collision at WTR Well 5.

10.2.2 Deterministic Case: Largest swept area of floating oil above 50 g/m^2

The deterministic simulation that resulted in the largest swept area of floating oil above 50 g/m^2 (high threshold) was identified as run number 64 during the transitional period.

Figure 10.16 presents the extent of the predicted floating oil exposure zones on the sea surface (swept area) and shoreline accumulation over the entire 60-day simulation.

Figure 10.17 displays the time series of the swept area of low (≥ 1 g/m^2), moderate (≥ 10 g/m^2) and high (≥ 50 g/m^2) floating oil over the 60-day simulation.

Figure 10.18 presents the fates and weathering for the corresponding simulation and Table 10.11 summarises peak volumes and times of occurrence for each oil phase and volumes at the end of the 60-day simulation.

Table 10.11 Summary of peak volumes and times of occurrence for each oil phase and the volumes at the conclusion of the simulation (day 60), for the simulation with the largest swept area of floating oil above 50 g/m^2 following a vessel collision at WTR Well 5.

Exposure Metrics	Peak Volume	Day of Occurrence	Volume at day 60
Surface (m^3)	932	1	0
Entrained (m^3)	745	3	83
Dissolved (m^3)	1	5	0
Evaporation (m^3)	866	59	866
Decay (m^3)	553	60	553
Ashore (m^3)	0	0	0

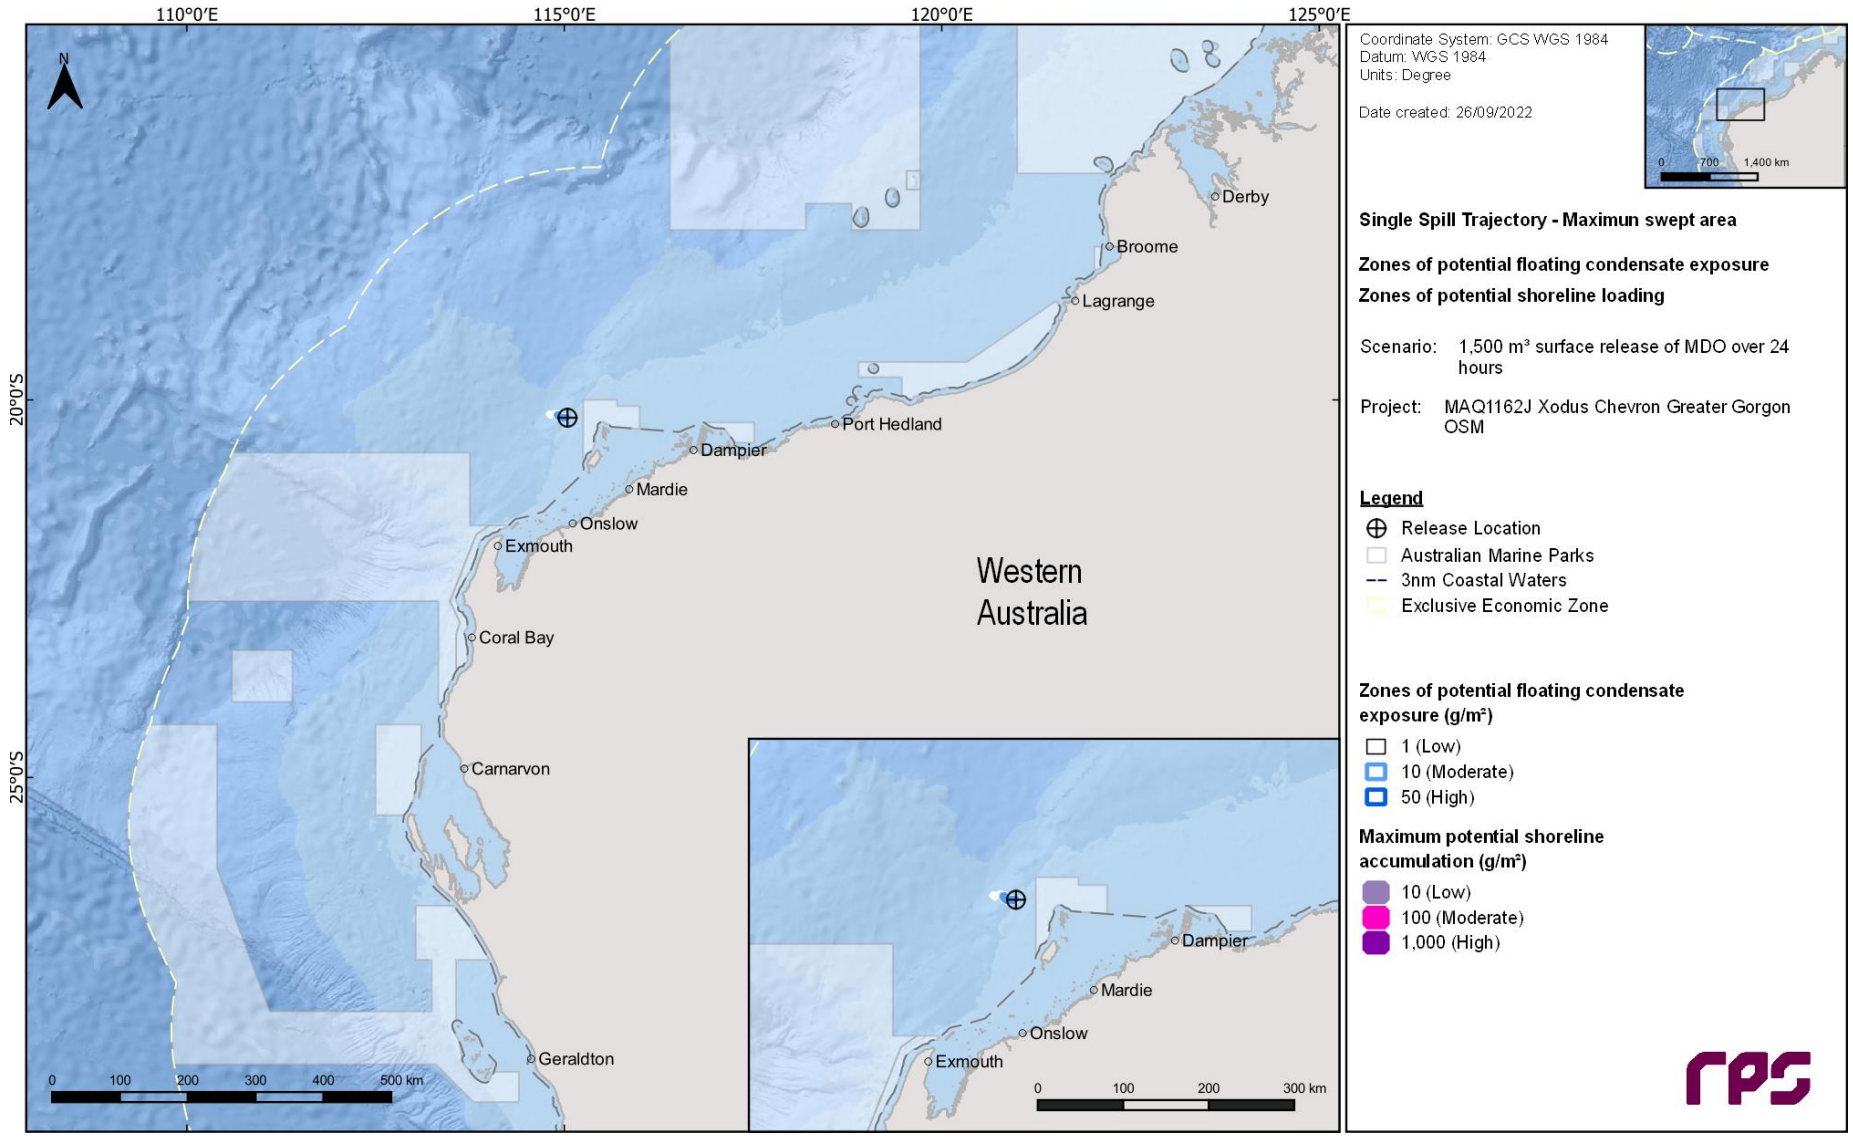

Figure 10.16 Zones of potential floating oil exposure and shoreline accumulation over the entire 60 days, for the simulation with the largest swept area of floating oil above 50 g/m² following a vessel collision at WTR Well 5.

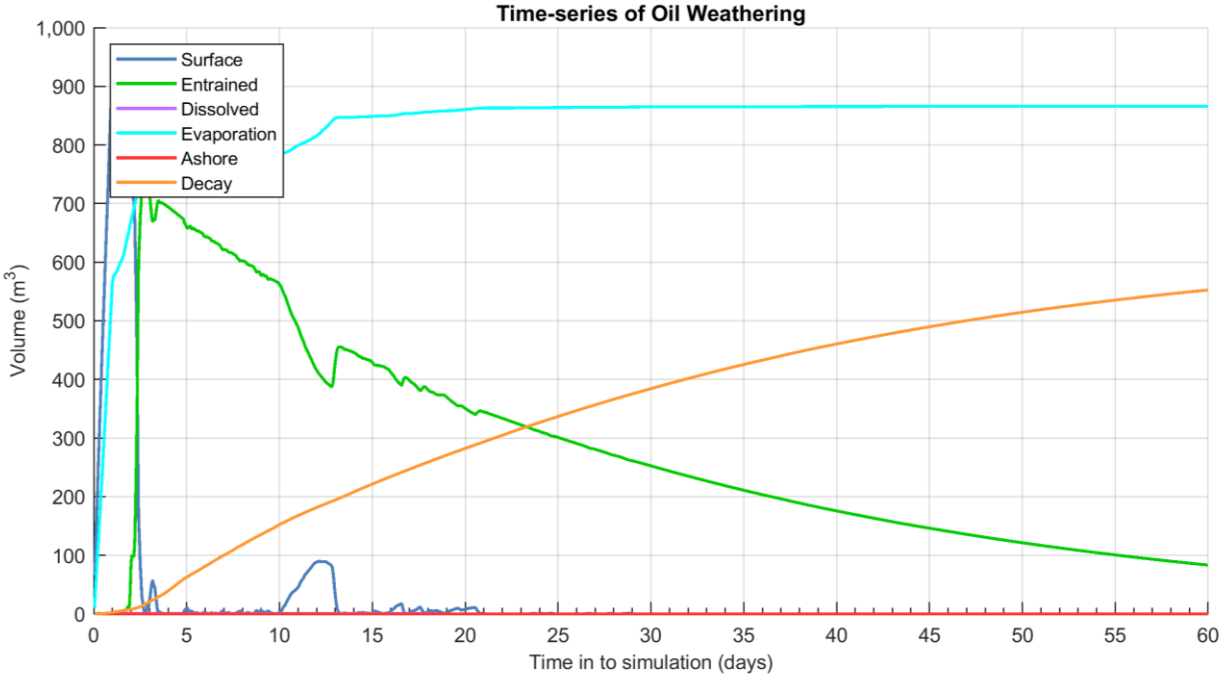

Figure 10.18 Predicted weathering and fates for the simulation with the largest swept area of floating oil above 50 g/m^2 following a vessel collision at WTR Well 5.

10.2.3 Deterministic Case: Largest volume of oil ashore and longest length of shoreline accumulation above 100 g/m^2

The deterministic simulation that resulted in the largest volume of oil ashore and the longest length of shoreline accumulation above 100 g/m^2 (moderate threshold) was identified as run number 41 during the summer period.

Figure 10.19 presents the extent of the predicted floating oil exposure zones on the sea surface (swept area) and shoreline accumulation over the entire 60-day simulation.

Figure 10.20 displays the time series of the volume of oil accumulating on shorelines at the low (≥ 10 g/m^2), moderate (≥ 100 g/m^2) and high (≥ 1,000 g/m^2) thresholds over the 60-day simulation

Figure 10.21 displays the time series of length of shoreline oil accumulation at the low (≥ 10 g/m^2), moderate (≥ 100 g/m^2) and high (≥ 1,000 g/m^2) thresholds over the 60-day simulation.

Figure 10.22 presents the fates and weathering graph for the corresponding single spill trajectory and Table 10.12 summarises the peak volumes and times of occurrence for each oil phase and volumes at the end of the simulation.

Table 10.12 Summary of peak volumes and times of occurrence for each oil phase and the volumes at the conclusion of the simulation (day 60), for the simulation that resulted in the largest volume of oil ashore and the longest length of shoreline accumulation above 100 g/m^2 following a vessel collision at WTR Well 5.

Exposure Metrics	Peak Volume	Day of Occurrence	Volume at day 60
Surface (m^3)	738	1	<1
Entrained (m^3)	854	2	106
Dissolved (m^3)	1	5	-
Evaporation (m^3)	703	60	706
Decay (m^3)	679	60	684
Ashore (m^3)	35	17	3

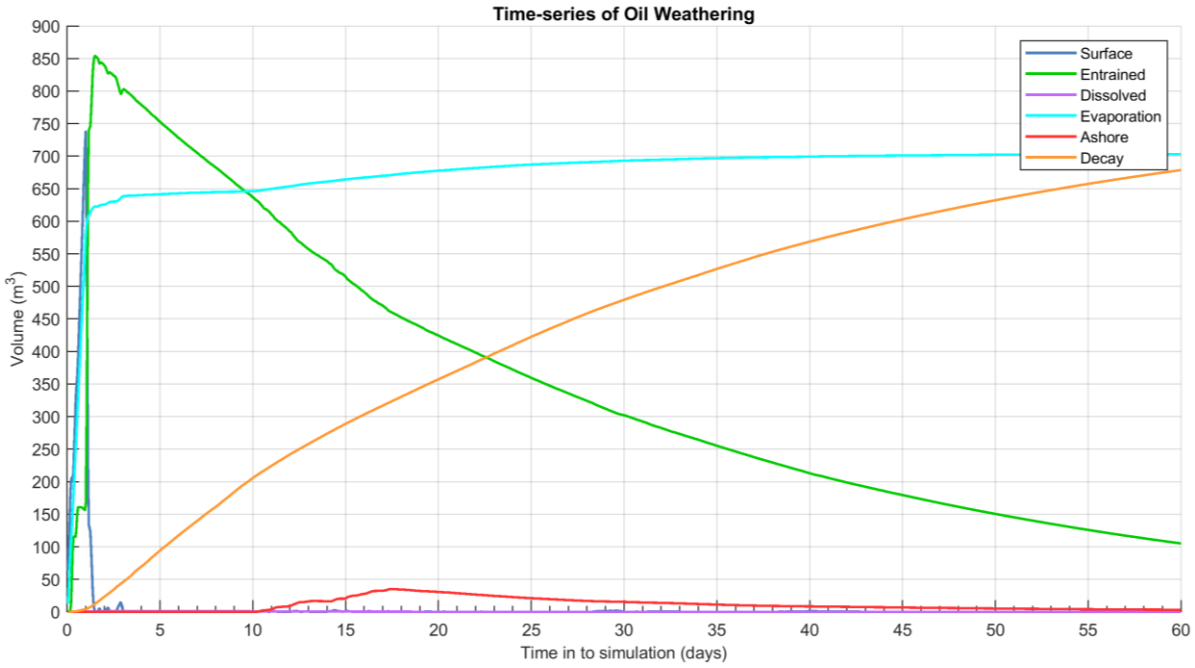

Figure 10.22 Predicted weathering and fates for the simulation that resulted largest volume of oil ashore and the longest length of shoreline with accumulation above 100 g/m^2 following a vessel collision at WTR Well 5.

10.2.4 Deterministic Case: Largest area of entrained hydrocarbons above 100 ppb

The deterministic simulation that resulted in the largest area of entrained hydrocarbons above 100 ppb (high threshold) was identified as run number 31 during transitional period.

Figure 10.23 presents the extent of the predicted entrained hydrocarbon exposure zones over the entire 60-day simulation.

Figure 10.24 displays the time series of the area of entrained hydrocarbons at the low (≥ 10 ppb) and high (≥ 100 ppb) thresholds over the 60-day simulation.

Figure 10.25 presents the fates and weathering for the corresponding single spill trajectory and Table 10.13 summarises the peak volumes and times of occurrence for each oil phase and volumes at the end of the simulation.

Table 10.13 Summary of peak volumes and times of occurrence for each oil phase and the volumes at the conclusion of the simulation (day 60), for the simulation with the largest area of entrained hydrocarbons above 100 ppb following a vessel collision at WTR Well 5.

Exposure Metrics	Peak Volume	Day of Occurrence	Volume at day 60
Surface (m^3)	247	0	0
Entrained (m^3)	954	1	104
Dissolved (m^3)	3	2	0
Evaporation (m^3)	656	60	656
Decay (m^3)	727	60	727
Ashore (m^3)	0	0	0

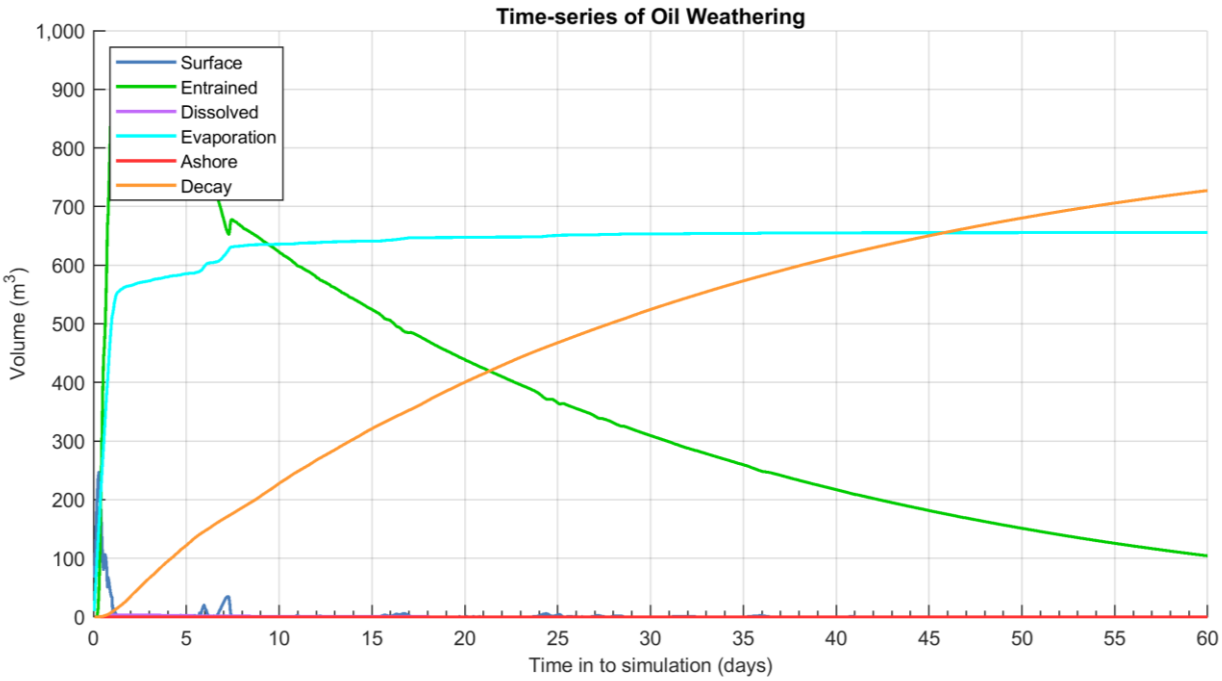

Figure 10.25 Predicted weathering and fates graph for the simulation with the largest area of entrained hydrocarbons above 100 ppb following a vessel collision at WTR Well 5.

10.2.5 Deterministic Case: Largest area of dissolved hydrocarbons above 50 ppb

The deterministic simulation that resulted in the largest area of dissolved hydrocarbons above 50 ppb (moderate threshold) was identified as run number 96 during the winter period.

Figure 10.26 presents the extent of the predicted dissolved hydrocarbon exposure zones over the entire 60-day simulation.

Figure 10.27 displays the time series of the area of dissolved hydrocarbons at the low (≥ 10 ppb), moderate (≥50 ppb) and high (≥ 100 ppb) thresholds over the 60-day simulation.

Figure 10.28 presents the fates and weathering for the corresponding single spill trajectory and Table 10.14 summarises the peak volumes and times of occurrence for each oil phase and volumes at the end of the simulation.

Table 10.14 Summary of peak volumes and times of occurrence for each oil phase and the volumes at the conclusion of the simulation (day 60), for the simulation with the largest area of dissolved hydrocarbons above 50 ppb following a vessel collision at WTR Well 5.

Exposure Metrics	Peak Volume	Day of Occurrence	Volume at day 60
Surface (m^3)	78	0	0
Entrained (m^3)	1,049	1	84
Dissolved (m^3)	8	1	0

Condensate Properties 4
Key Findings 5
Loss of Well Control 5

1 INTRODUCTION 6

2 SCOPE OF WORK 8

3 REGIONAL CURRENTS 9
3.1 Tidal Currents 11
3.1.1 Grid Setup 11
3.1.2 Tidal Conditions 12
3.2 Ocean Currents 13
3.3 Surface Currents 13

4 WIND DATA 16

5 WATER TEMPERATURE AND SALINITY 20

6 SUBSEA PLUME MODEL – OILMAP DEEP 22

7 OIL SPILL MODEL – SIMAP 24
7.1 Stochastic Modelling 24
7.2 Floating, Shoreline and In-Water Thresholds 25
7.2.1 Floating Oil Exposure Thresholds 25
7.2.2 Shoreline Accumulation Thresholds 27
7.2.3 In-water Exposure Thresholds 28

8 HYDROCARBON PROPERTIES 30
8.1 Condensate Properties 30
8.2 Condensate Weathering Characteristics 31
8.2.1 Overview 31
8.2.2 Results 31

9 MODEL SETTINGS 33

10 PRESENTATION AND INTERPRETATION OF MODEL RESULTS 34
10.1 Stochastic Analysis 34
10.1.1 Statistics 34
10.2 Deterministic Trajectories 34
10.3 Receptors 35

11 RESULTS: WEST TRYAL ROCKS LOSS OF WELL CONTROL 44
11.1 Stochastic Analysis 44
11.1.1 Floating Condensate Exposure 44
11.1.2 Shoreline Accumulation 51
11.1.3 Water Column Exposure 62
11.2 Deterministic Analysis 85
11.2.1 Deterministic Case: Largest swept area of floating condensate above 10 g/m^2 87
11.2.2 Deterministic Case: Largest swept area of floating condensate above 50 g/m^2 90
11.2.3 Deterministic Case: Largest volume of oil ashore 93
11.2.4 Deterministic Case: Longest length of shoreline with accumulation above 100 g/m^2 96

11.2.5 Deterministic Case: Largest area of entrained hydrocarbons above 100 ppb 99
11.2.6 Deterministic Case: Largest area of dissolved hydrocarbons above 50 ppb 102

TERMS AND ABBREVIATIONS

°	Degrees
‘	Minutes
“	Seconds
µm	Micrometre (unit of length; 1 µm = 0.001 mm)
Actionable oil	Oil which is thick enough for the effective use of mitigation strategies
AMP	Australian Marine Park
AMSA	Australian Maritime Safety Authority
ANZECC	Australian and New Zealand Environment and Conservation Council
API	American Petroleum Institute gravity. A measure of how heavy or light a petroleum liquid is compared to water.
ARMCANZ	Agriculture and Resource Management Council of Australia and New Zealand
ASTM	American Society for Testing and Materials
bbl	Barrel (unit of volume; 1 bbl = 0.159 m3)
bbl/d	Barrels per day
Bonn Agreement	An agreement for cooperation in dealing with pollution of the North Sea by oil and other harmful substances, 1983, includes: Governments of the Kingdom of Belgium, the Kingdom of Denmark, the French Republic, the Federal Republic of Germany, the Republic of Ireland, the Kingdom of the Netherlands, the Kingdom of Norway, the Kingdom of Sweden, the United Kingdom of Great Britain and Northern Ireland and the European Union.
BP	Boiling point. The temperature at which the vapor pressure of the liquid is equal to the pressure exerted on it by the surrounding atmosphere
BTEX	Benzene, Toluene, Ethylbenzene, and Xylenes
°C	degree Celsius (unit of temperature)
CFSR	Climate Forecast System Reanalysis
cm	Centimetre (unit of length)
cP	Centipoise (unit of dynamic viscosity)
Decay	The process where oil components are changed either chemically or biologically (biodegradation) to another compound. It includes breakdown to simpler organic carbon compounds by bacteria and other organisms, photo-oxidation by solar energy, and other chemical reactions.
Dynamic viscosity	The dynamic viscosity of a fluid expresses its resistance to shearing flows, where adjacent layers move parallel to each other with different speeds.
Floating oil exposure	Contact by floating oil on the sea surface at concentrations equal to or exceeding defined threshold concentrations. The consequence will vary depending on the threshold and the receptors
g/m^2	Grams per square meter (unit of surface area density)
GODAE	Global Ocean Data Assimilation Experiment
HYCOM	Hybrid Coordinate Ocean Model. A data-assimilative, three-dimensional ocean model
HYDROMAP	Advanced ocean/coastal tidal model used to predict tidal water levels, current speed and current direction.
IAA	Impact Assessment Area
IBRA	Interim Biogeographic Regionalisation for Australia

IMCRA	Integrated Marine and Coastal Regionalisation of Australia
ITOPF	International Tanker Owners Pollution Federation Limited
KEF	Key Ecological Feature
km	Kilometre (unit of length)
km^2	Square Kilometres (unit of area)
Knots	unit of speed (1 knot = 0.514 m/s)
LOWC	Loss of well control
m	Meter (unit of length)
m^3	Cubic meter (unit of volume)
m/s	Meter per Second (unit of speed)
MAHs	Monoaromatic Hydrocarbons
MNP	Marine National Park
MP	Marine Park
NASA	National Aeronautics and Space Administration (USA)
NCEP	National Centres for Environmental Prediction (USA)
nm	Nautical mile
NOAA	National Oceanic and Atmospheric Administration (USA)
NOPSEMA	National Offshore Petroleum Safety and Environmental Management Authority
NP	National Park
NR	Nature Reserve
PAH	Polynuclear Aromatic Hydrocarbons
Pour Point	The pour point of a liquid is the temperature below which the liquid loses its flow characteristics
ppb	Parts per billion (concentration)
psu	Practical salinity nits
RSB	Reefs, Shoals and Banks
scf	Standard cubic feet (defined as one cubic foot of gas at 15.56 °C and at normal sea level air pressure)
Shoreline contact	Arrival of oil at or near shorelines at on-water concentrations equal to or exceeding defined threshold concentrations. Shoreline contact is judged for floating oil arriving within a 2 km buffer zone from any shoreline as a conservative measure
SIMAP	Spill Impact Model Application Package. SIMAP is designed to simulate the fate and effects of spilled hydrocarbons for surface or subsea releases
Single Oil spill modelling	Oil spill modelling involving a computer simulation of a single hypothetical oil spill event subject to a single sequence of wind, current and other sea conditions over time. Single oil spill modelling, also referred to as “deterministic modelling” provides a simulation of one possible outcome of a given spill scenario, subject to the metocean conditions that are imposed. Single oil spill modelling is commonly used to consider the fate and effects of ‘worst-case’ oil spill scenarios that are carefully selected in consideration of the nature and scale of the offshore petroleum activity and the local environment (NOPSEMA, 2017). Because the outcomes of a single oil spill simulation can only represent the outcome of that scenario under one sequence of metocean conditions, worst-case conditions are often identified from stochastic modelling. It is impossible to calculate the likelihood of any outcome from a single oil spill simulation. Single oil spill modelling is generally used for response planning, preparedness planning and for supporting oil spill response operations in the event of an actual spill

SRTM	Shuttle Radar Topography Mission
Stochastic oil spill modelling	Stochastic oil spill modelling is created by overlaying and statistically analysing the outcomes of many single oil-spill simulations of a defined spill scenario, where each simulation was subject to a different sequence of metocean conditions, selected objectively (typically by random selection) from a long sequence of historic conditions for the study area. Analysis of this larger set of simulations provides a more accurate indication of the environment that maybe affected (EMBA) and indicates which locations are more likely to be affected (as well as other statistics). Stochastic oil spill modelling avoids biases that affect single oil spill modelling (due to the reliance on only one possible sequence of conditions). However, when interpreting stochastic modelling, which is based on a wide range of potential conditions that might happen to occur, it is essential to understand that calculations will encompass a much larger area than could be affected in any single spill event, where a more limited set of conditions will occur. Consequently, it is misleading to imply that the region derived from stochastic modelling indicate the outcomes expected from a single spill event (NOPSEMA, 2017) Stochastic modelling is generally used for risk assessment and preparedness planning by indicating locations that could be exposed and may require response or subsequent impact assessment
TOPEX/Poseidon	A joint satellite mission between NASA and CNES to map ocean surface topography using an array of satellites equipped with detailed altimeters
USA	United States of America
US CG	United States Coast Guard
US EPA	United States Environmental Protection Agency
World Ocean Atlas	A collection of objectively analysed, quality controlled physicochemical parameters (e.g. temperature, salinity, oxygen, phosphate, silicate, and nitrate) based on profile data from the World Ocean Database (NCEI, 2021) established by NOAA's National Centers for Environmental Information (NCEI)
WGS 1984	World Geodetic System 1984 (WGS84); reference coordinate system

EXECUTIVE SUMMARY

Background

Chevron Australia Pty Ltd (Chevron) is the operator of the Greater Gorgon area, which includes the West Tryal Rocks (WTR) field situated within the Northern Carnarvon Basin in Permit area WA-5-R northwest of Barrow Island off the north-west coast of Western Australia. RPS was commissioned to undertake an oil spill modelling to support environmental approvals.

The oil spill modelling study was conducted to assess the seasonal risk and potential exposure to the surrounding waters and contact to the shorelines from the following two hypothetical scenario:

- **Scenario 1:** A 4,302 stb/day (684.0 m^3/day) subsea release of condensate over 90 days (totalling 387,180 stb or 61,555 m^3) resulting from a loss of well control (LOWC);

The potential risk of exposure to the surrounding waters and contact to shorelines was assessed for three distinct seasons; (i) summer (September to the following March), (ii) the transitional periods (April and August) and (iii) winter (May to July). This approach assists with identifying the environmental values and sensitivities that would be at risk of exposure on a seasonal basis.

One of the purposes for the modelling is to define the 'outer boundaries' of the environment that may be affected (EMBA) in the unlikely event of hydrocarbon release. Therefore, the modelling does not take into consideration any of the spill prevention, mitigation and response capabilities that would be implemented in response to the spill.

Methodology

The modelling study was carried out in stages. Firstly, a ten-year current dataset (2010–2019) that includes the combined influence of large-scale ocean and nearshore tidal currents was developed. Secondly, the currents, local winds and detailed hydrocarbon characteristics were used as inputs in the three-dimensional oil spill model (SIMAP) to simulate the drift, spread, weathering and fate of the spilled oil.

As spills can occur during any set of wind and current conditions, modelling was conducted using a stochastic (or probabilistic) approach, which involved running per scenario 100 spill simulations per season, with each simulation having the same spill information (spill volume, duration and composition of hydrocarbons) but randomly selected start time. This ensured that each spill trajectory was subjected to varying wind and current conditions.

Hydrocarbon Properties

Condensate Properties

West Tryal Rocks condensate has an API of 41.2, a density of 817 kg/m^3 (at 15ºC) and a low viscosity value of 5.9 cP. When exposed to the atmosphere at local temperatures, about 31.1% of the condensate volatile components should evaporate within the first 12 hours (BP < 180°C); a further 29.9% of the semi-volatiles should evaporate within the first 24 hours (180°C < BP < 265°C); and low volatile portion (~19.4%) should evaporate over a longer period (265°C < BP < 380°C). Additionally, 19.6% of the condensate is shown to be persist in the marine environment for much longer periods and be subject to relatively slow degradation. The process of evaporation will be greater than under calm sea conditions, but increased entrainment can be expected under stronger winds due to the presence of small breaking waves (whitecaps).

This condensate has a low asphaltene content (< 0.05%), which is one indicator for a very low propensity for the mixture to take up water to form water-in-oil emulsion over the weathering cycle. The soluble aromatic hydrocarbons contribute approximately 3.2% by mass of the whole oil, which is contained in the volatile fractions, which are highly soluble.

Key Findings

Loss of Well Control

- The maximum distance from the release location to the low (≥ 1 g/m^2), moderate (≥ 10 g/m^2) and high (≥ 50 g/m^2) threshold was 251.7 West-southwest (summer), 45.9 km North-northwest (transitional) and 5.2 km West-northwest (transitional) and West-southwest (winter), respectively.

- Other than the receptors that the release location resides within (Section 10.3), the Montebello AMP, Flatback Turtle - Nesting and Humpback Whale - Migration BIAs, Barrow & Montebello Islands IAA and the Continental Slope Demersal Fish Communities KEF were the only receptors predicted to be exposed during all three seasons at the low and moderate thresholds. Accordingly, the probabilities for the low and moderate thresholds was 100% for all seasons for the receptors that the release location resides within. The probabilities of low and moderate exposure at the Flatback Turtle - Nesting ranged between 91–95% and 17–25%, whilst the probabilities of low and moderate exposure at Humpback Whale - Migration ranged between 97–100% and 6–32%, respectively. The minimum times before low exposure for the Flatback Turtle - Nesting BIA and Humpback Whale - Migration BIA were 1.08 days and 0.71 days during summer conditions, respectively.

- The probability of accumulation on any shoreline at, or above, the low threshold (≥ 10 g/m^2) was greatest during summer at 59%, while the minimum time before shoreline accumulation was 6.5 days and the maximum volume of oil ashore was 128 m^3. No high (≥ 1,000 g/m^2) shoreline threshold accumulation was predicted in the modelling results.

- During summer conditions, 82 shoreline receptors were predicted to record condensate accumulation at, or above, the low threshold with the greatest probability predicted for Barrow & Montebello Islands IAA (38%). In comparison, during transitional and winter conditions, 40 and 42 shoreline receptors, respectively, were predicted to record accumulation, with the greatest probability during transitional season occurring at the Ningaloo Coast World Heritage Area IAA and the Muiron Islands (30%) and at the Ningaloo Coast World Heritage Area IAA only during winter (30%).

- In the surface (0-10 m) depth layer, a total of 14, 20, and 10 BIAs were predicted to be exposed at, or above, the low threshold during summer, transitional and winter, respectively. Excluding the 4 BIAs that the release location resides within (Flatback Turtle - Internesting Buffer, Pygmy Blue Whale - Distribution, Wedge-tailed Shearwater - Breeding and Whale Shark – Foraging), the highest probabilities of exposure to low dissolved hydrocarbons were predicted as 7% for Humpback Whale - Migration during summer, 12% Humpback Whale - Migration during transitional, and 4% for Flatback Turtle – Nesting and Humpback Whale - Migration during winter conditions.

- In the surface (0-10 m) depth layer, a total of 44, 39 and 40 BIAs were predicted to be exposed at, or above, the low threshold during summer, transitional and winter respectively. Excluding the 4 BIAs that the release location resides within, the highest probabilities of exposure to low entrained hydrocarbons were predicted for the Flatback Turtle - Nesting (98% during summer and 100% during transitional and winter) and Humpback Whale - Migration BIAs (100% during all seasons).

- During summer, 9 AMPs were predicted to be exposed at the low threshold, compared to 7 AMPs during transitional and winter periods. The highest probabilities predicted were at the Gascoyne AMP (96% summer, 100% transitional and 98% winter). Furthermore, during seasonal conditions the Gascoyne, Montebello and Ningaloo AMP were also predicted to be exposed to entrained hydrocarbons at the high threshold

1 INTRODUCTION

Chevron Australia Pty Ltd (Chevron) is the operator of the Greater Gorgon area, which includes the West Tryal Rocks (WTR) field situated within the Northern Carnarvon Basin in Permit area WA-5-R northwest of Barrow Island off the north-west coast of Western Australia.

As part of the planned development for the WTR field, Chevron commissioned RPS to undertake a comprehensive oil spill modelling study to support environmental approvals. The modelling study assessed the seasonal risk and potential exposure to the surrounding waters and contact to the shorelines from the two following hypothetical scenarios:

- **Scenario 1:** A 4,302 stb/day (684.0 m^3/day) subsea release of condensate over 90 days (totalling 387,180 stb or 61,555 m^3) resulting from a loss of well control (LOWC);

The release location is presented in Table 1.1 and illustrated in Figure 1.1.

The potential risk of exposure to the surrounding waters and contact to shorelines was assessed for three distinct seasons; (i) summer (September to the following March), (ii) the transitional periods (April and August) and (iii) winter (May to July). This approach assists with identifying the environmental values and sensitivities that would be at risk of exposure on a seasonal basis.

One of the purposes for the modelling is to define the 'outer boundaries' of the environment that may be affected (EMBA) in the unlikely event of hydrocarbon release. Therefore, the modelling does not take into consideration any of the spill prevention, mitigation and response capabilities that would be implemented in response to the spill.

The spill modelling was performed using an advanced three-dimensional trajectory and fates model; Spill Impact Mapping Analysis Program (SIMAP). The SIMAP model calculates the transport, spreading, entrainment and evaporation of spilled hydrocarbons over time, based on the prevailing wind and current conditions and the physical and chemical properties.

The hydrocarbon spill model, the method and analysis applied herein uses modelling algorithms which have been peer reviewed and published in international journals. Further, RPS warrants that this work meets and exceeds the American Society for Testing and Materials (ASTM) Standard F2067-13 "*Standard Practice for Development and Use of Oil Spill Models*".

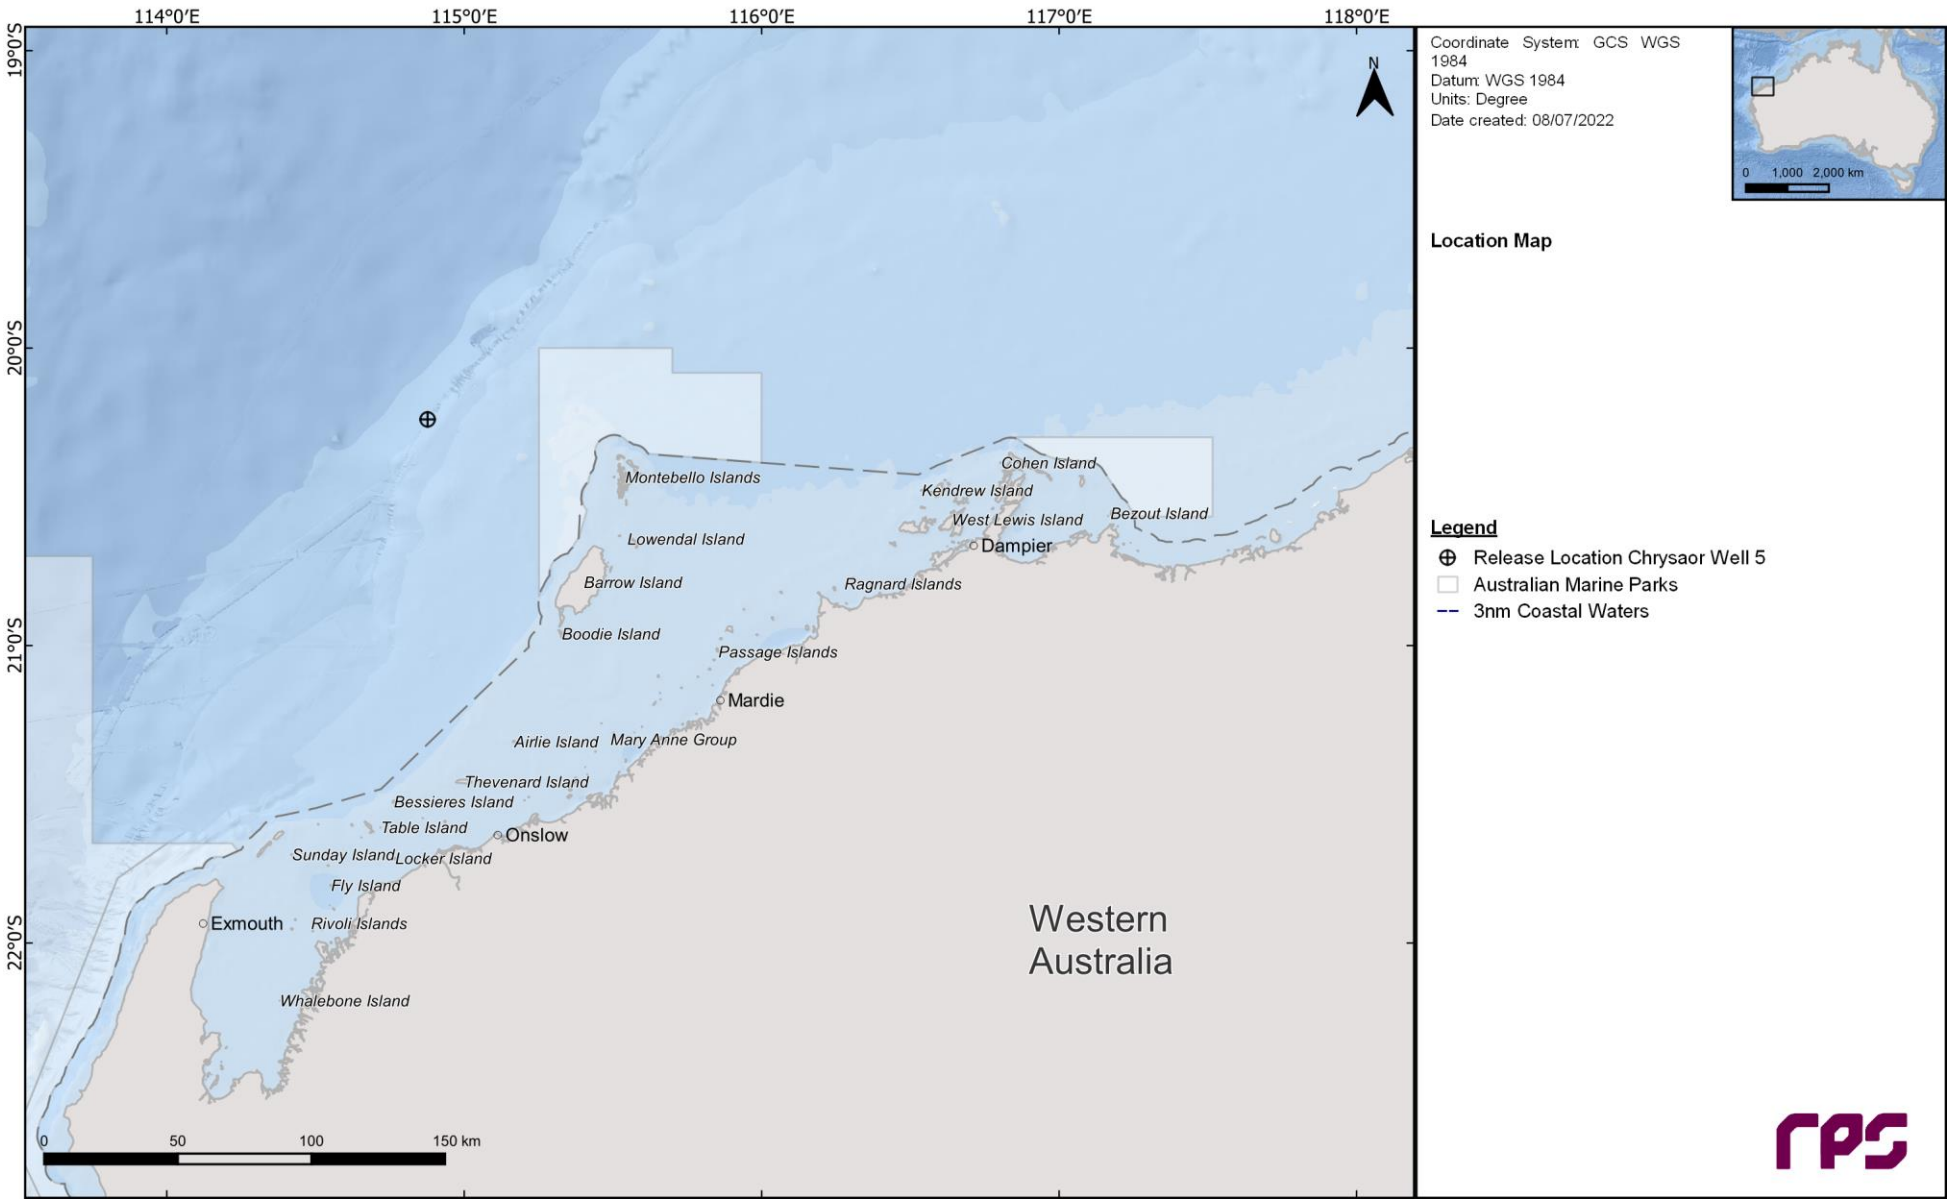

Figure 1.1 West Tryal Rocks hydrocarbon spill modelling release location.

2 SCOPE OF WORK

The scope of work included the following components:

1. Generate ten years (2010 to 2019 (inclusive)) of wind and current data. The three-dimensional current data includes the combined influence of ocean and tidal currents;

2. Include the wind data, current data and condensate properties characteristics into the three-dimensional oil spill model; SIMAP, to model the movement, spreading, entrainment, weathering and potential shoreline accumulation over time;

3. For each scenario run 100 simulations per season (i.e. 300 simulations total), with each simulation having the same spill information (location, volume, duration and condensate properties) but randomly varying start times. This ensured that each spill simulation was subjected to unique wind and current conditions;

4. Combine the results from the 100 spill simulations to assess the exposure to waters and shoreline accumulation based upon the NOPSEMA thresholds for each scenario; and

5. From the 300 simulations modelled per scenario, identify and present the “worst case” deterministic runs, which can be used to inform response planning based on the following criteria:

    a. Largest swept area of floating hydrocarbon above 10 g/m^2

    b. Largest swept area of floating hydrocarbon above 50 g/m^2

    c. Largest volume of oil ashore

    d. Longest length of shoreline with accumulation above 100 g/m^2

    e. Largest area of entrained hydrocarbons above 100 ppb

    f. Largest area of dissolved hydrocarbons above 50 ppb

3 REGIONAL CURRENTS

The study area is located within the Northern Carnarvon Basin, on the North West Shelf, a waterbody bordered by the Indian Ocean and Timor Sea. The North West Shelf is characterised by complex geomorphological features such as shoals, valleys and terraces and is dominated by high-amplitude tides and seasonally-dependant wind driven currents (DEWHA, 2007).

Although the Indonesian Throughflow and Holloway current generate south-westerly flows all year-round, warm and less saline waters originating from the tropics can generate internal gyres that typically migrate through the area and result in large variation in the speed and direction of local currents. The Holloway current generally intensifies during April to July due to increased wind forcing.

A comprehensive description of the circulation patterns of the North West Shelf is provided in a review by Condie and Andrewartha (2008) and a schematic of the ocean currents along the Northwest Australian continental shelf is shown in Figure 3.1.

While, tidal currents are generally weaker in the deeper waters, its influence is greatest along the near shore and around islands. Therefore, to accurately account for the movement of an oil spill, which can move between the offshore and near shore region, ocean and tidal currents were combined as part of the study.

Figure 3.2 and Figure 3.3 present summer and winter current trends within the Carnarvon Basin and the North West Shelf.

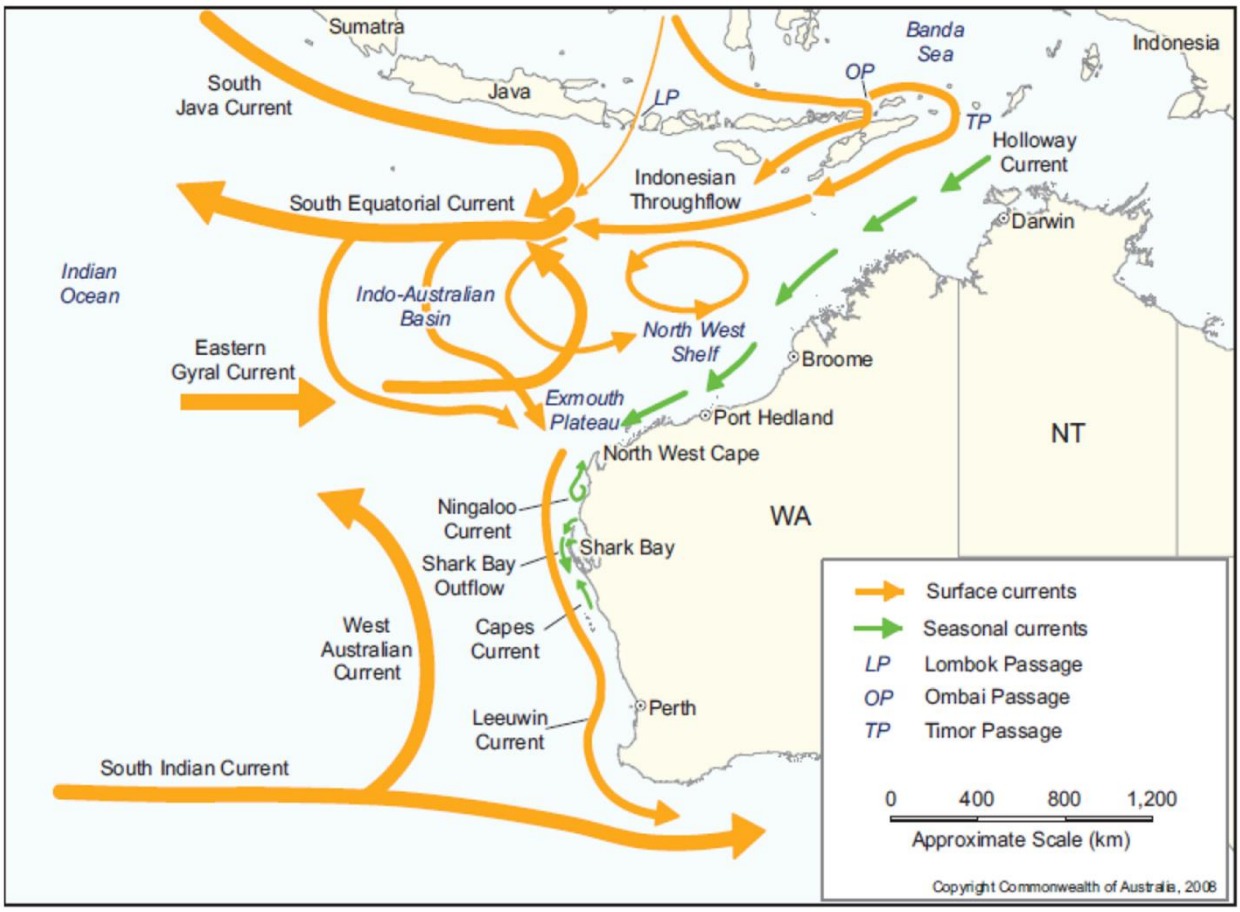

Figure 3.1 Schematic of ocean currents along the northwest Australian continental shelf. Image adapted from DEWHA (2008).

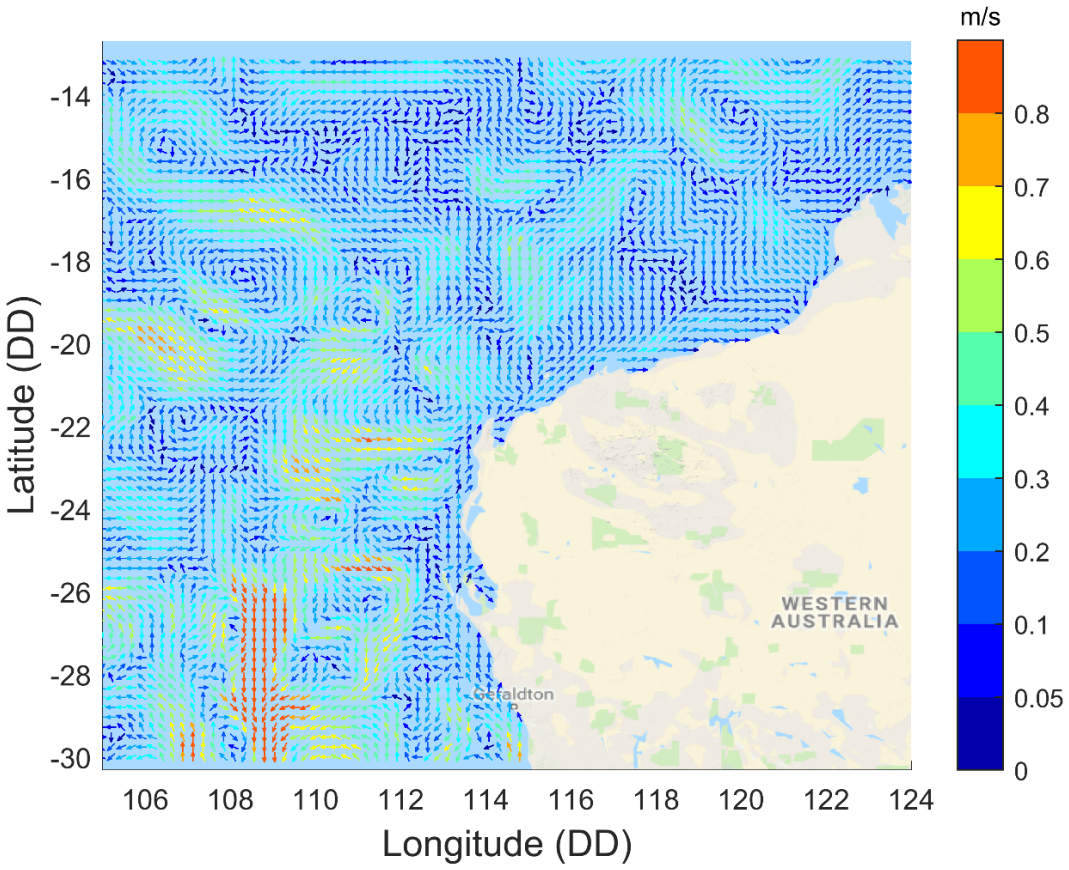

Figure 3.2 Typical ocean current circulation pattern during the summer months.

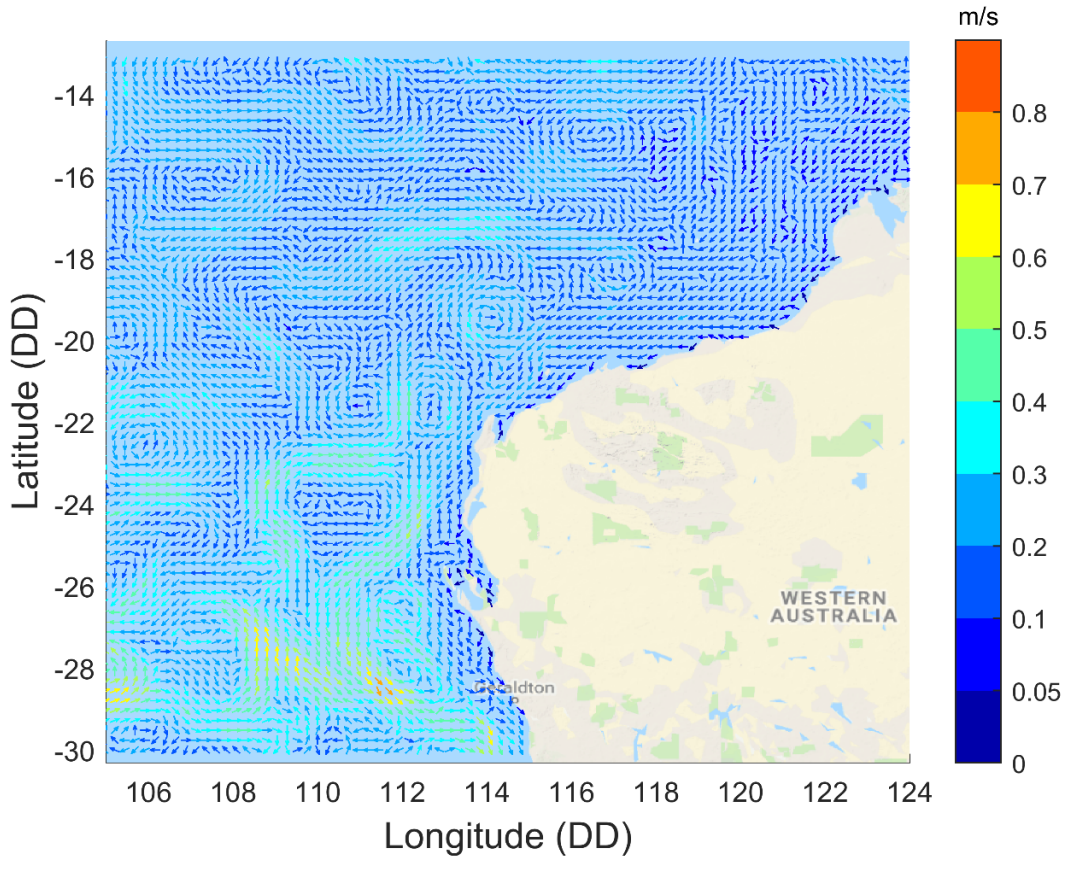

Figure 3.3 Typical ocean current circulation pattern during the winter months.

3.1 Tidal Currents

Tidal current data was generated using RPS's advanced ocean/coastal model, HYDROMAP. The HYDROMAP model has been thoroughly tested and verified through field measurements throughout the world over the past 38 years (Isaji & Spaulding, 1984; Isaji, et al., 2001; Zigic, et al., 2003). HYDROMAP tidal current data has been used as input to forecast (in the future) and hindcast (in the past) pollutant spills in Australian waters and forms part of the Australian National Oil Spill Emergency Response System operated by AMSA (Australian Maritime Safety Authority).

HYDROMAP employs a sophisticated sub-gridding strategy, which supports up to six levels of spatial resolution, halving the grid cell size as each level of resolution is employed. The sub-gridding allows for higher resolution of currents within areas of greater bathymetric and coastline complexity, and/or of particular interest to a study.

The numerical solution methodology follows that of Davies (1977a and 1977b) with further developments for model efficiency by Owen (1980) and Gordon (1982). A more detailed presentation of the model can be found in Isaji and Spaulding (1984) and Isaji et al. (2001).

3.1.1 Grid Setup

The tidal model domain has been sub-gridded to a resolution of 500 m for shallow and coastal regions, starting from an offshore (or deep water) resolution of 8 km. The finer grids were allocated in a step-wise fashion to resolve flows more accurately along the coastline, around islands and over regions with more complex bathymetry. Figure 3.4 shows the tidal model grid resolutions.

A combination of datasets was used and merged to describe the shape of the seabed within the grid domain (Figure 3.5). These included spot depths and contours which were digitised from nautical charts released by the hydrographic offices as well as Geoscience Australia database and depths extracted from the Shuttle Radar Topography Mission (SRTM30_PLUS) Plus dataset (see Becker et al., 2009).

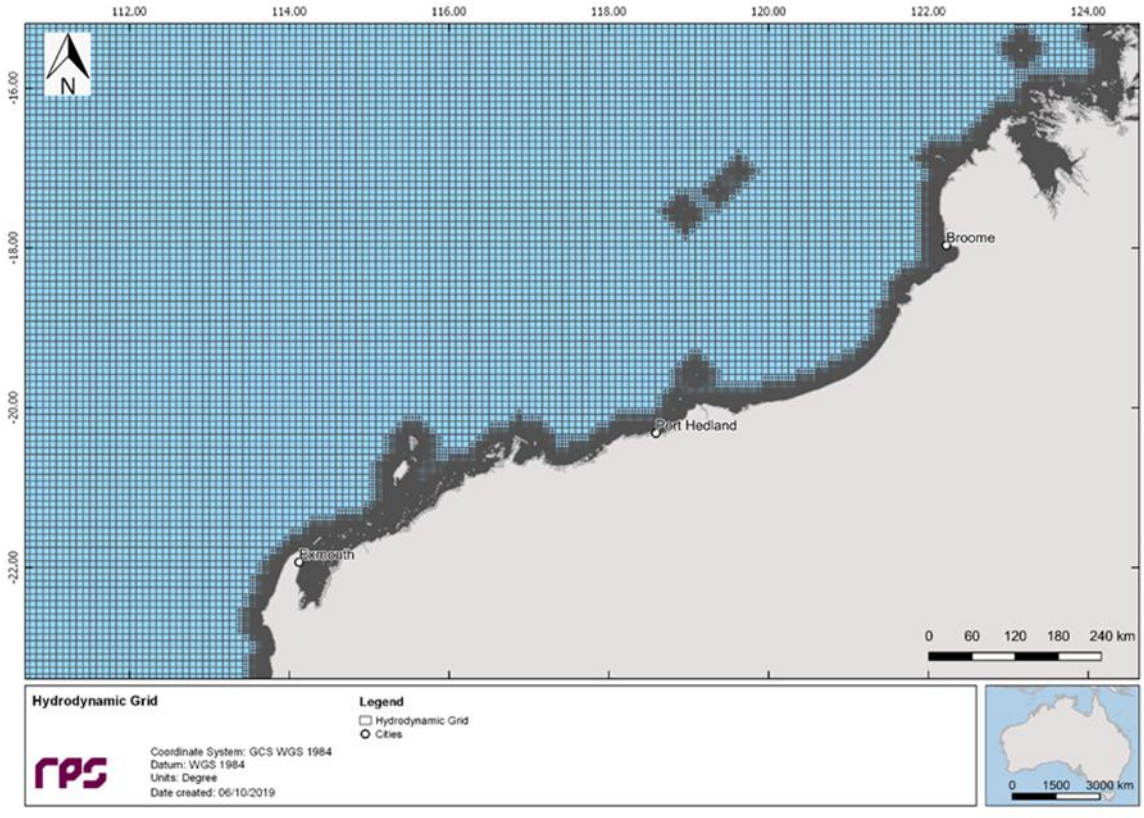

Figure 3.4 Zoomed in view of the model grid used to generate the tidal currents for the study region. Higher resolution areas are shown by the denser mesh.

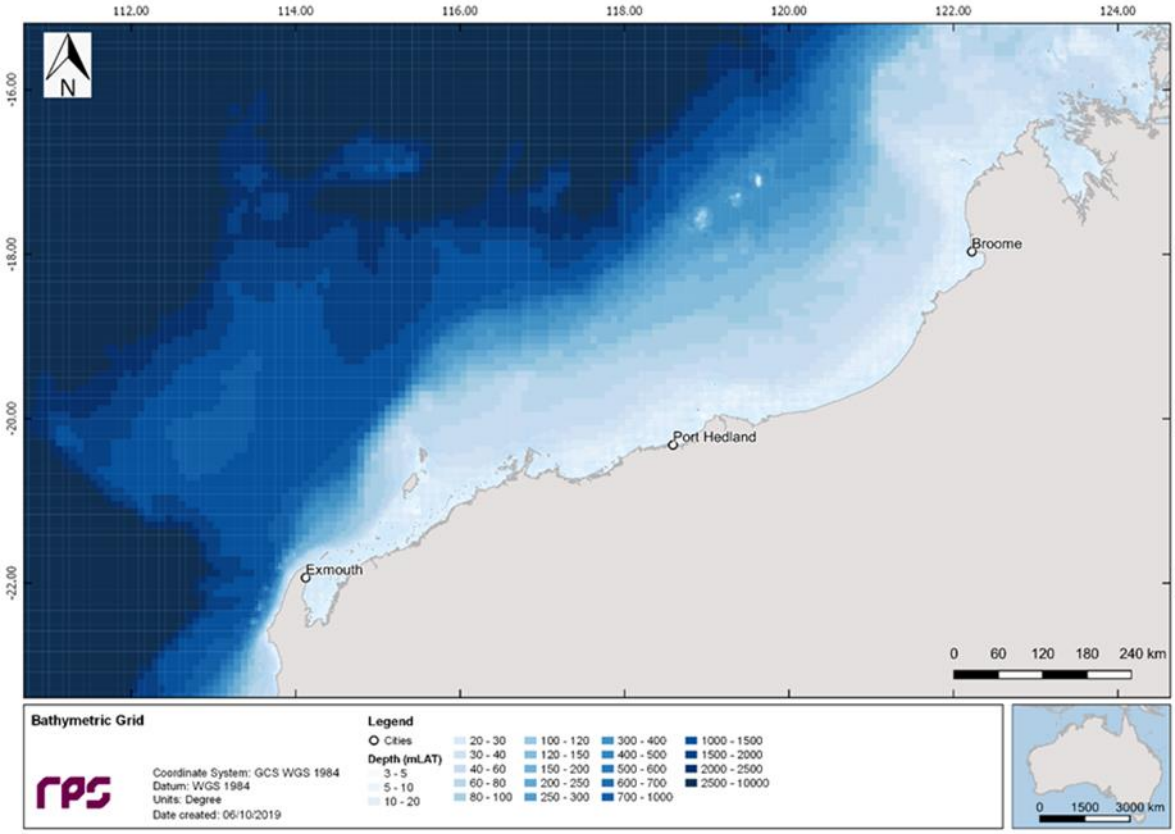

Figure 3.5 Bathymetry defined throughout the tidal model domain.

3.1.2 Tidal Conditions

The ocean boundary data for the regional model was obtained from satellite measured altimetry data (TOPEX/Poseidon 7.2) which provided estimates of the eight dominant tidal constituents at a horizontal scale of approximately 0.25 degrees. The eight major tidal constituents used were K_2, S_2, M_2, N_2, K_1, P_1, O_1 and Q_1. Using the tidal data, surface heights were firstly calculated along the open boundaries, at each time step in the model.

The TOPEX/Poseidon satellite data has a global resolution of 0.25 degrees and is produced and quality controlled by NASA (National Aeronautics and Space Administration). The satellites equipped with two highly accurate altimeters and capable of taking sea level measurements with an accuracy of ± 5 cm measured oceanic surface elevations (and the resultant tides) for over 13 years (1992–2005). In total, these satellites carried out 62,000 orbits of the planet.

The TOPEX/Poseidon tidal data has been widely used amongst the oceanographic community, being included in more than 2,100 research publications (e.g. Andersen, 1995; Ludicone et al., 1998; Matsumoto et al., 2000; Kostianoy et al., 2003; Yaremchuk and Tangdong, 2004; Qiu and Chen 2010). As such the TOPEX/Poseidon tidal data is considered suitably accurate for this study.

3.2 Ocean Currents

Data describing the flow of ocean currents was obtained from HYCOM (Hybrid Coordinate Ocean Model, (Chassignet et al., 2007), which is operated by the HYCOM Consortium, sponsored by the National Ocean Partnership Program (NOPP), as part of the U.S. Global Ocean Data Assimilation Experiment (GODAE). HYCOM is a data-assimilative, three-dimensional ocean model that is run as a hindcast (for a past period), assimilating time-varying observations of sea surface height, sea surface temperature and in-situ temperature and salinity measurements (Chassignet et al., 2009). The HYCOM predictions for drift currents are produced at a horizontal spatial resolution of approximately 8.25 km (1/12th of a degree) over the region, at a frequency of every 3 hours. HYCOM uses isopycnal layers in the open, stratified ocean, but uses the layered continuity equation to make a dynamically smooth transition to a terrain following coordinate in shallow coastal regions, and to z-level coordinates in the mixed layer and/or unstratified seas.

For this study, the HYCOM hindcast currents were obtained for the years 2010 to 2019 (inclusive).

3.3 Surface Currents

Table 3.1 presents the predicted average and maximum monthly surface current speeds at the release location.

The month average surface current speeds ranged between 0.16 m/s (November) and 0.26 m/s (May). Additionally, the maximums ranged between 0.54 m/s (November) and 2.18 m/s (March). The general current directions were towards the southwest. Figure 3.6 and Figure 3.7 present the monthly and total current rose distributions, respectively.

Note the convention for defining current direction throughout this report is the direction the current flows towards. Each branch of the current rose distribution represents the currents flowing to that direction, with north to the top of the diagram. The branches are divided into segments of different colour, which represent the current speed ranges for each direction. Speed intervals of 0.1 m/s are typically used in these current roses. The length of each coloured segment within a branch is proportional to the frequency of currents flowing within the corresponding speed and direction.

Table 3.1 Predicted monthly average and maximum surface current speeds close to the release location. Data derived by combining the HYCOM ocean data and HYDROMAP high resolution tidal data from 2010-2019 (inclusive).

Season	Month	Average current speed (m/s)	Maximum current speed (m/s)	General direction (towards)
Summer	January	0.23	1.93	Northeast and Southwest
	February	0.21	1.07	Northeast and Southwest
	March	0.22	2.18	Southwest
Transitional	April	0.24	1.20	Southwest
Winter	May	0.26	0.95	Southwest
	June	0.26	0.90	Southwest
	July	0.21	1.08	Southwest
Transitional	August	0.19	0.78	Southwest
Summer	September	0.19	1.03	Northeast and Southwest
	October	0.18	0.63	Northeast and Southwest
	November	0.16	0.54	Variable
	December	0.20	0.80	Southwest
Minimum		**0.16**	**0.54**	
Maximum		**0.26**	**2.18**

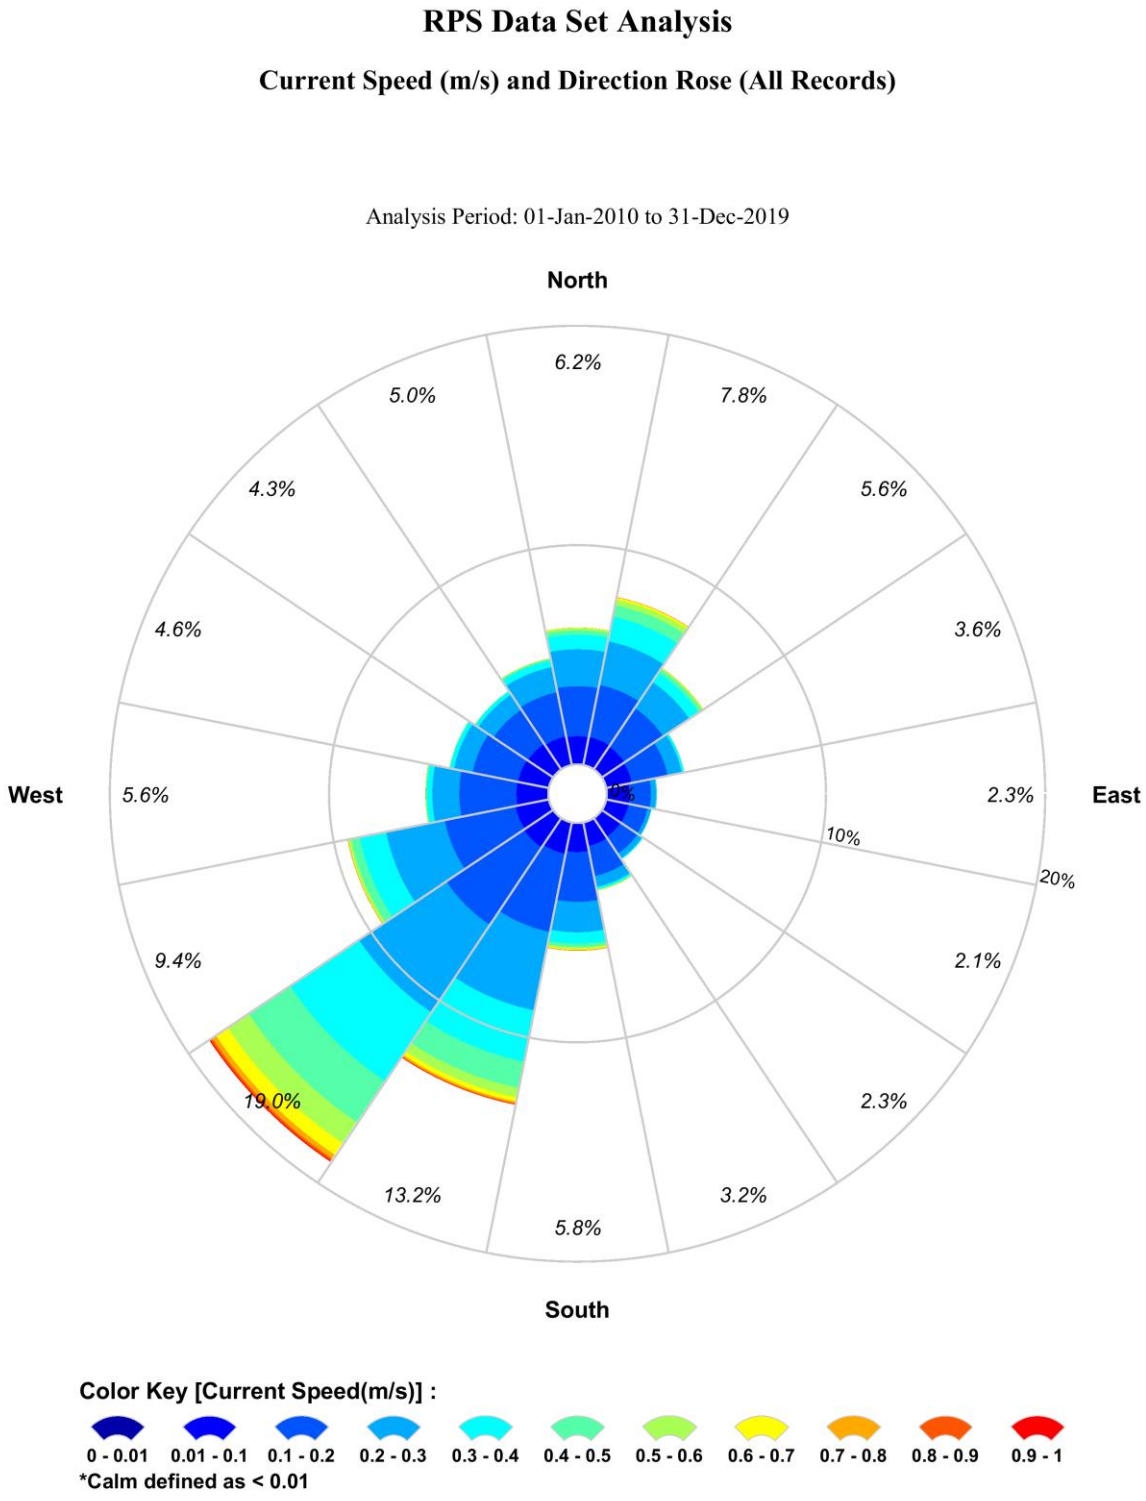

Figure 3.7 Total surface current rose plot at the release location, derived from the 2010 to 2019 modelled dataset.

4 WIND DATA

To account for the influence of the wind on the floating oil, wind data from 2010 to 2019 (inclusive) was sourced from the National Centre for Environmental Prediction (NCEP) Climate Forecast System Reanalysis (CFSR; see Saha et al., 2010). The CFSR wind model includes observations from many data sources; surface observations, upper-atmosphere air balloon observations, aircraft observations and satellite observations. The model is capable of accurately representing the interaction between the earth's oceans, land and atmosphere. The gridded wind data output is available at ¼ of a degree resolution (~33 km) and 1-hourly time intervals. Figure 4.1 shows the spatial resolution of the wind field used as input into the oil spill model.

Table 4.1 shows the monthly average and maximum winds derived from the CFSR node closest to the release location. The model wind data demonstrated that this region typically experiences moderate winds all year round and although the monthly average wind speeds remain under 15 knots. The maximum wind speed was 49 knots (July). Winds typically blow from the southwest during the summer months, while winds are typically easterly during the winter months.

Figure 4.2 and Figure 4.3 illustrates the monthly and total wind rose distributions nearby the release location, respectively.

Note that the atmospheric convention for defining wind direction, that is, the direction the wind blows from, is used to reference wind direction throughout this report. Each branch of the rose represents wind coming from that direction, with north to the top of the diagram. Sixteen directions are used. The branches are divided into segments of different colour, which represent wind speed ranges from that direction. Speed ranges of 5 knot intervals are typically used in these wind roses. The length of each segment within a branch is proportional to the frequency of winds blowing within the corresponding range of speeds from that direction.

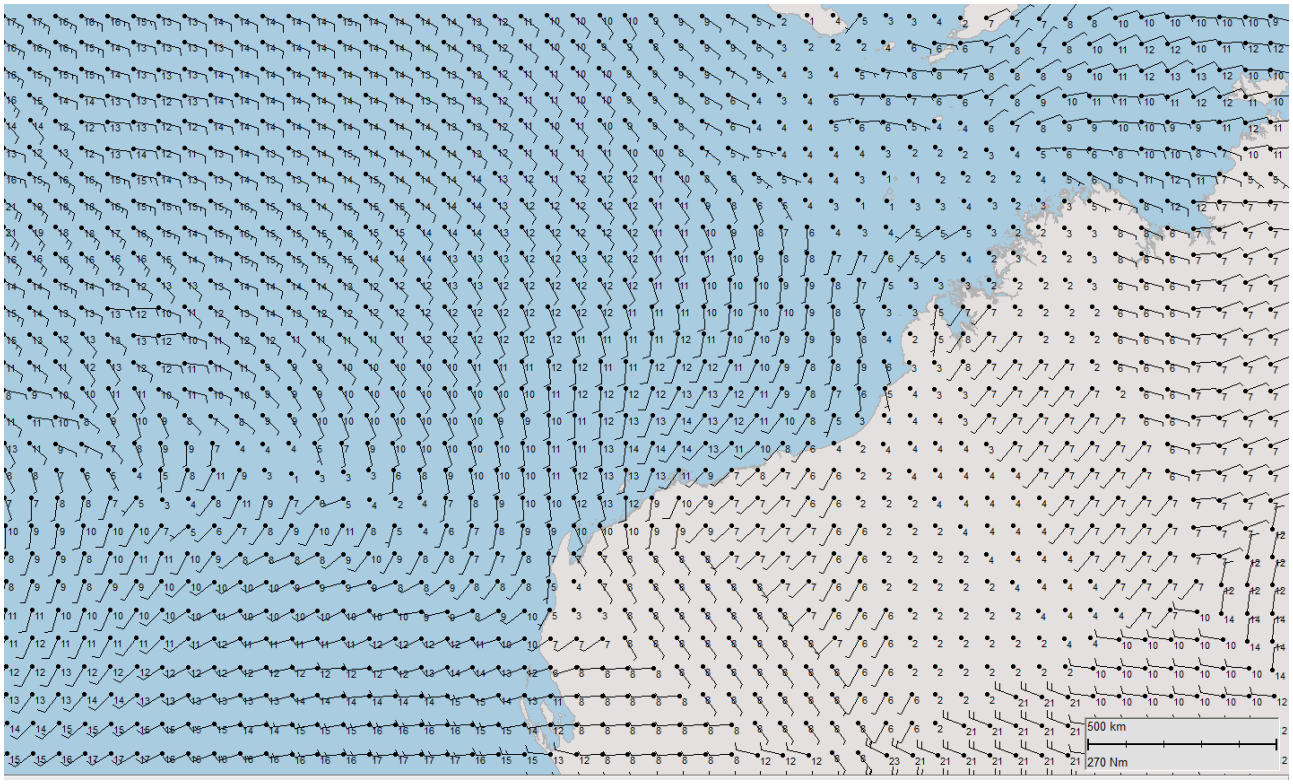

Figure 4.1 Spatial resolution of the CFSR modelled wind data used as input into the oil spill model. Note, for ease viewing only every second wind vector is displayed on the map.

Table 4.1 Predicted average and maximum winds for the wind node closest to the release location. Data derived from CFSR hindcast model 2010 to 2019 (inclusive).

Season	Month	Average wind (knots)	Maximum wind (knots)	General direction (from)
Summer	January	13	41	Southwest
	February	11	46	Southwest
	March	10	35	Southwest
Transitional	April	10	38	Variable
Winter	May	12	40	East
	June	14	31	East
	July	13	49	East to South
Transitional	August	11	31	South
Summer	September	12	27	South-Southwest
	October	13	28	Southwest
	November	13	25	Southwest
	December	12	29	Southwest
Minimum		**10**	**25**	
Maximum		**14**	**49**

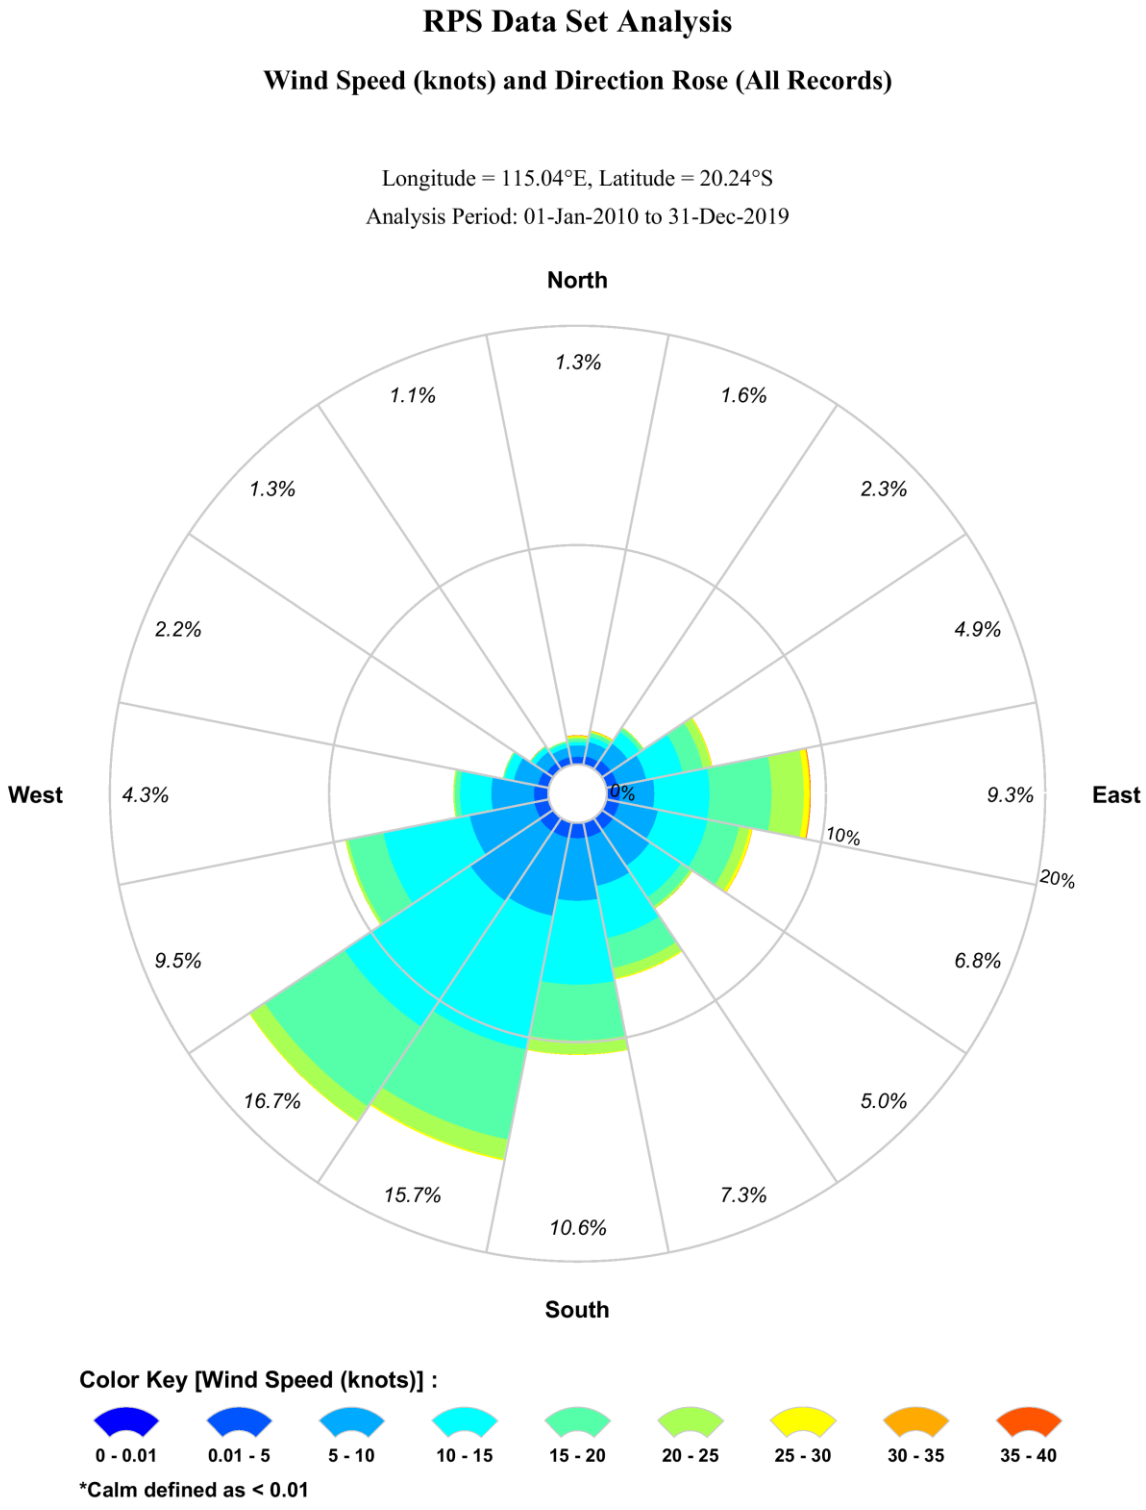

Figure 4.3 Total wind rose distributions adjacent to the release location, derived from the 2010 to 2019 modelled dataset.

5 WATER TEMPERATURE AND SALINITY

The monthly depth-varying water temperature and salinity profiles nearest to the release location was obtained from the HYbrid Coordinate Ocean Model (see Section 3.2 Ocean Currents).

The three-dimensional salinity and temperature datasets are used in the oil spill model domain to inform the weathering, movement, and evaporative loss of hydrocarbon spills in the surface and subsurface layers.

Table 5.1 shows that the monthly average sea surface temperatures ranged from 24.2°C (September) to 29.6°C (March), whilst salinity remained relatively consistent throughout the year, ranging between 34.6–35.3 psu.

Figure 5.1 the vertical profile of sea temperature and salinity nearby the release location.

Table 5.1 Monthly average sea surface temperature and salinity near the release location in the 0-5 m depth layer.

Month	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sept	Oct	Nov	Dec
Temperature (°C)	27.8	28.6	29.6	28.7	27.9	27.0	25.3	24.5	24.2	25.0	27.3	27.0
Salinity (psu)	35.1	34.9	35.0	35.1	35.2	35.3	34.9	34.8	34.9	34.9	34.6	34.9

6 SUBSEA PLUME MODEL – OILMAP DEEP

The LOWC scenario is a high-pressure release of mostly gas and condensate and where gas is released with condensate, the buoyancy of the expanding gas cloud will entrain ambient seawater and propel the droplets towards the surface at a faster rate than would occur from the relative buoyancy of the condensate alone. Furthermore, the turbulence generated by such an intense discharge will tend to break the condensate up into droplets of various sizes.

To define the near-field plume dynamics, the subsea blowout model, OILMAP-DEEP, was applied. The model simulates the plume rise dynamics in two phases, the initial jet phase and the buoyant plume phase. The initial jet phase governs the plume dynamics directly above the subsurface release location and is predominately driven by the exit velocity. During this phase, the condensate droplet size and distribution is calculated. Next, the rise dynamics are dominated by the buoyant nature of the plume until the termination of the plume phase (known as the trapping depth). At this point, the results from OILMAP-DEEP (including plume trapping depth, plume diameter and droplet size distribution) are integrated into the far-field model SIMAP to simulate the rise and dispersion of the condensate droplets.

More details on the OILMAP-DEEP model, can be found in Spaulding et al. (2015). The model has been validated against observations from Deepwater Horizon as well as small and large-scale laboratory studies on subsurface oil releases (Brandvik et al., 2013, 2014; Belore, 2014; Spaulding et al., 2015; Li et al., 2017).

Table 6.1 presents the input parameters for the OILMAP-DEEP model and key results related to the near-field plume dynamics. The results indicated that the mixture of gas and condensate rose through the water column (whilst gradually losing momentum) to a trapping depth of less than 1 m below mean sea level. The modelling predicted droplets ranging in size from 175 to 756 µm.

Figure 6.1 illustrates the various stages of an example blowout plume.

Table 6.1 Input data and key results for the subsea plume modelling.

Input Variable	Value
Scenario	Loss of Well Control
Well name	WTR Well 5
Water depth (m)	150
Tubing diameter (inch) [m]	7 5/8 [0.194]
Condensate rate (stb/day)	4,302
Gas rate (MMscf/day)	310
Gas to condensate ratio (scf/bbl)	72,060
Formation water flow rate (stb/day)	0
Operating pressure (psia)	6,220
Key results	
Plume execution depth (m BMSL)	<1
Droplet sizes (µm)	175 to 756

7 OIL SPILL MODEL – SIMAP

Modelling of the fate of oil was performed using the Spill Impact Mapping Analysis Program (SIMAP). SIMAP is designed to simulate the fate and effects of spilled hydrocarbons for both the surface and subsurface releases (Spaulding et al. 1994; French et al. 1999; French-McCay, 2003, 2004; French-McCay et al. 2004).

SIMAP has been used to predict the weathering and fate of oil spills during and after major incidents including: Montara (Australia) well blowout August 2009 in the Timor Sea (Asia-Pacific ASA, 2010); Macondo (USA) well blowout April 2010 in the Gulf of Mexico; Bohai Bay (China) oil spill August 2011; and the pipeline oil spill July 2013 in the Gulf of Thailand.

The SIMAP model calculates the transport, spreading, entrainment, evaporation and decay of surface hydrocarbon slicks as well as the entrained and dissolved oil components in the water column, either from surface slicks or from oil discharged subsea. The movement and weathering of the spilled oil is calculated for specific oil types. Input specifications for oil mixtures include the density, viscosity, pour point, distillation curve (volume lost versus temperature) and the aromatic/aliphatic component ratios within given boiling point ranges.

SIMAP is a three-dimensional model that allows for various response actions to be modelled including oil removal from skimming, burning, or collection booms, and surface and subsurface dispersant application.

The SIMAP oil spill model includes advanced weathering algorithms, specifically focussed on unique oils that tend to form emulsions and/or tar balls. The weathering algorithms are based on five years of extensive research conducted in response to the Deepwater Horizon oil spill in the Gulf of Mexico (French et al., 2015).

Biodegradation is included in the oil spill model. In the model, SIMAP, degradation is calculated for the surface slick, deposited oil on the shore, the entrained oil and dissolved constituents in the water column, and oil in the sediments. For surface oil, water column oil and sedimented oil a first order degradation rate is specified. Biodegradation rates are relatively high for hydrocarbons in dissolved state or in dispersed small droplets.

7.1 Stochastic Modelling

Stochastic oil spill modelling is created by overlaying a great number (often 100 hundred) simulated hypothetical oil spills (Figure 7.1). Stochastic modelling involves running numerous individual oil spill simulations using a range of prevailing wind and current conditions that are historically representative of the season and location of where the spill event may occur.

For the stochastic modelling presented herein, **100 spills** were simulated per season using the same spill information (release location, spill volume, duration and condensate properties) but with varied start dates and times corresponding to the period represented by the available wind and current data. During each simulation, the model records whether any grid cells are exposed to any hydrocarbon concentrations, the concentrations involved and the elapsed time before exposure. For each scenario the results of all 100 condensate spill simulations were analysed to determine the following seasonal statistics for every grid cell:

- Exposure load (concentrations and volumes);
- Minimum time before exposure;
- Probability of contact above defined concentrations;
- Volume of condensate that may strand on shorelines from any single simulation;
- Concentration that might occur on sections of individual shorelines;
- Exposure (instantaneous and/or over a specified duration) to dissolved hydrocarbons in the water column; and

- Exposure (instantaneous and/or over a specified duration) to entrained hydrocarbons in the water column.

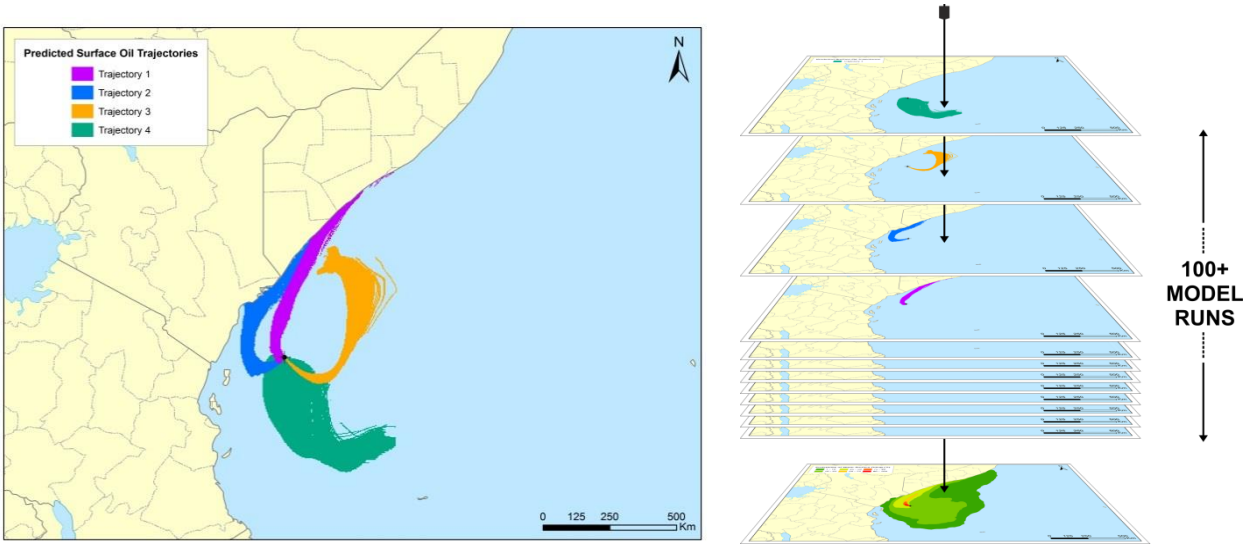

Figure 7.1 Predicted movement of four single oil spill simulations by SIMAP for the same scenario (left image). All model runs are overlain (shown as the stacked runs on the right) and the number of times that trajectories contact a given location at a concentration is used to calculate the probability (Source: NOPSEMA, 2018).

7.2 Floating, Shoreline and In-Water Thresholds

The thresholds and their relationship to exposure for the sea surface, shoreline and water column (entrained and dissolved hydrocarbons) are presented in Sections 7.2.1 to 7.2.3. Supporting justifications of the adopted thresholds applied during the study and additional context relating to the area of influence are also provided. It is important to note that the thresholds herein are based on NOPSEMA (2019).

7.2.1 Floating Oil Exposure Thresholds

The modelling results can be presented to any levels; therefore, thresholds have been specified (based on scientific literature) to record floating oil exposure to the sea-surface at meaningful levels only, described in the following paragraphs.

The low threshold to assess the potential for floating oil exposure, was 1 g/m^2, which equates approximately to an average thickness of 1 µm, referred to as visible oil. Oil of this thickness is described as rainbow sheen in appearance, according to the Bonn Agreement Oil Appearance Code (Bonn Agreement, 2009; AMSA, 2014) (see Table 7.1). Figure 7.2 shows photographs highlighting the difference in appearance between a silvery sheen, rainbow sheen and metallic sheen. This threshold is considered below levels which would cause environmental harm and it is more indicative of the areas perceived to be affected due to its visibility on the sea surface and potential to trigger temporary closures of areas (i.e. fishing grounds) as a precautionary measure. Table 7.1 provides a description of the appearance in relation to exposure zone thresholds used to classify the zones of floating oil exposure.

Ecological impact has been estimated to occur at 10 g/m^2 (a film thickness of approximately 10 µm or 0.01 mm) according to French et al. (1996) and French-McCay (2009) as this level of fresh oiling has been observed to mortally impact some birds through adhesion of oil to their feathers, exposing them to secondary effects such as hypothermia. The appearance of oil at this average thickness has been described as a metallic sheen (Bonn Agreement, 2009). Concentrations above 10 g/m^2 is also considered the lower actionable threshold, where oil may be thick enough for containment and recovery as well as dispersant treatment (AMSA, 2015).

Scholten et al. (1996) and Koops et al. (2004) indicated that at oil concentrations on the sea surface of 25 g/m^2 (or greater), would be harmful for all birds that have landed in an oil film due to potential contamination of their feathers, with secondary effects such as loss of temperature regulation and ingestion of oil through preening. The appearance of oil at this thickness is also described as metallic sheen (Bonn Agreement, 2009). For this study the high exposure threshold was set to 50 g/m^2 and above based on NOPSEMA (2019). This threshold can also be used to inform response planning.

Table 7.2 defines the thresholds used to classify the zones of floating oil exposure reported herein.

Table 7.1 The Bonn Agreement Oil Appearance Code.

Code	Description Appearance	Layer Thickness Interval (g/m^2 or µm)	Litres per km^2
1	Sheen (silvery/grey)	0.04 – 0.30	40 – 300
2	Rainbow	0.30 – 5.0	300 – 5,000
3	Metallic	5.0 – 50	5,000 – 50,000
4	Discontinuous True Oil Colour	50 – 200	50,000 – 200,000
5	Continuous True Oil Colour	≥ 200	≥ 200,000

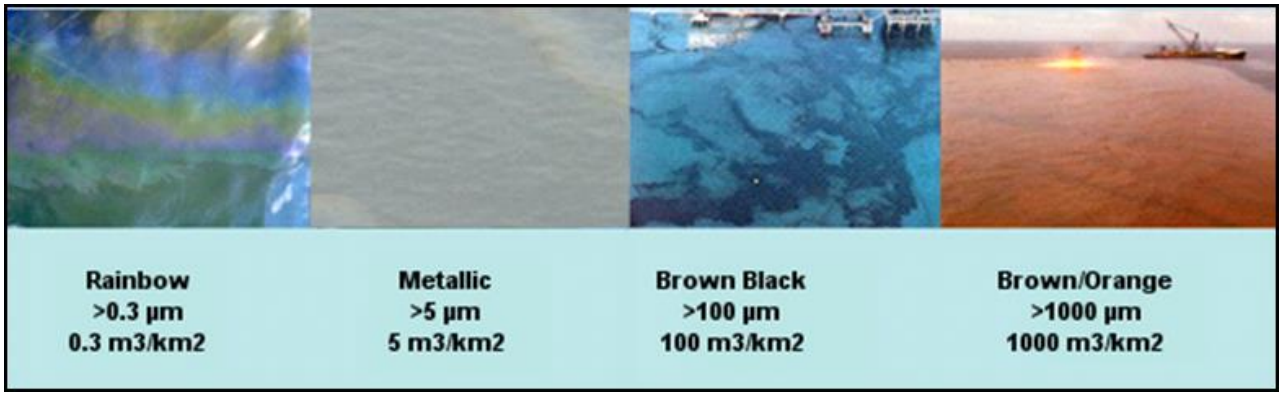

Figure 7.2 Photographs showing the difference between oil colour and thickness on the sea surface (source: adapted from Oil Spill Solutions, 2015).

Table 7.2 Floating oil exposure thresholds used in this report (in alignment with NOPSEMA, 2019).

Threshold level	Floating oil (g/m^2)	Description
Low	1	Approximates range of socioeconomic effects and establishes planning area for scientific monitoring
Moderate	10	Approximates lower limit for harmful exposures to birds and marine mammals
High	50*	Approximates surface oil slick and informs response planning

* 50 g/m^2 also used to define the threshold for actionable floating oil.

7.2.2 Shoreline Accumulation Thresholds

There are many different types of shorelines, ranging from cliffs, rocky beaches, sandy beaches, mud flats and mangroves, and each of these influences the volume of oil that can remain stranded ashore and its thickness before the shoreline saturation point occurs. For instance, a sandy beach may allow oil to percolate through the sand, thus increasing its ability to hold more oil ashore over tidal cycles and various wave actions than an equivalent area of water; hence oil can increase in thickness onshore over time. A sandy beach shoreline was assumed as the default shoreline type for the modelling herein, as it allows for the highest carrying capacity of oil (of the available open/exposed shoreline types). Hence the results contained herein would be indicative of a worst-case scenario, where the highest volume of oil may be stranded on the shoreline (when compared to other shoreline types, such as exposed rocky shores).

In previous risk assessment studies, French-McCay et al. (2005a; 2005b) used a threshold of 10 g/m^2 to assess the potential for shoreline accumulation. This is a conservative threshold used to define regions of socio-economic impact, such as triggering temporary closures of adjoining fisheries or the need for shore clean-up on beaches or man-made features/amenities (breakwaters, jetties, marinas, etc.). It would equate to approximately 2 teaspoons of hydrocarbon per square meter of shoreline accumulation. The appearance is described as a stain/film. On that basis, the 10 g/m^2 shoreline accumulation threshold has been selected to define the zone of potential “low shoreline accumulation”.

French et al. (1996) and French-McCay (2009) define a shoreline oil accumulation threshold of 100 g/m^2, or above, would potentially harm shorebirds and wildlife (furbearing aquatic mammals and marine reptiles on or along the shore) based on studies for sub-lethal and lethal impacts. This threshold has been used in previous environmental risk assessment studies (see French-McCay, 2003; French-McCay et al., 2004, French-McCay et al., 2011; 2012; NOAA, 2013). Additionally, a shoreline concentration of 100 g/m^2, or above, is the minimum limit that the oil can be effectively cleaned according to the AMSA (2015) guideline. This threshold equates to approximately ½ a cup of oil per square meter of shoreline accumulation. The appearance is described as a thin oil coat. Therefore, 100 g/m^2 has been selected to define the zone of potential “moderate shoreline accumulation”.

Observations by Lin & Mendelssohn (1996) demonstrated that loadings of more than 1,000 g/m^2 of hydrocarbon during the growing season would be required to impact marsh plants significantly. Similar thresholds have been found in studies assessing hydrocarbon impacts on mangroves (Grant et al., 1993; Suprayogi & Murray 1999). Hence, 1,000 g/m^2 has been selected to define the zone of potential “high shoreline accumulation”. It equates to approximately 1 litre of hydrocarbon per square meter of shoreline accumulation. The appearance is described as a hydrocarbon cover.

It is worth noting that the shoreline accumulation thresholds derived from extensive literature review (outlined in Table 7.3) agree with the commonly used threshold values for oil spill modelling specified in NOPSEMA (2019).

Table 7.3 Thresholds used to assess shoreline accumulation.

Threshold level	Shoreline accumulation (g/m^2)	Description
Low (socioeconomic/sublethal)	10	Predicts potential for some socio-economic impact
Moderate	100*	Loading predicts area likely to require clean-up effort
High	> 1,000	Loading predicts area likely to require intensive clean-up effort

* 100 g/m^2 also used to define the threshold for actionable shoreline oil.

7.2.3 In-water Exposure Thresholds

Oil is a mixture of thousands of hydrocarbons of varying physical, chemical, and toxicological characteristics, and therefore, demonstrate varying fates and impacts on organisms. As such, for in-water exposure, the SIMAP model provides separate outputs for dissolved and entrained hydrocarbons from oil droplets. The consequences of exposure to dissolved and entrained components will differ because they have different modes and magnitudes of effect.

Entrained hydrocarbon concentrations were calculated based on oil droplets that are suspended in the water column, though not dissolved. The composition of this oil would vary with the state of weathering (oil age) and may contain soluble hydrocarbons when the oil is fresh. Calculations for dissolved hydrocarbons specifically calculates oil components which are dissolved in water, which are known to be the primary source of toxicity exerted by oil.

7.2.3.1 Dissolved Hydrocarbons

Laboratory studies have shown that dissolved hydrocarbons exert most of the toxic effects of oil on aquatic biota (Carls et al., 2008; Nordtug et al., 2011; Redman, 2015). The mode of action is a narcotic effect, which is positively related to the concentration of soluble hydrocarbons in the body tissues of organisms (French-McCay, 2002). Dissolved hydrocarbons are taken up by organisms directly from the water column by absorption through external surfaces and gills, as well as through the digestive tract. Thus, soluble hydrocarbons are termed “bioavailable”.

Hydrocarbon compounds vary in water-solubility and the toxicity exerted by individual compounds is inversely related to solubility, however bioavailability will be modified by the volatility of individual compounds (Nirmalakhandan & Speece, 1988; Blum & Speece, 1990; McCarty, 1986; McCarty et al., 1992a, 1992b; Mackay et al., 1992; McCarty & Mackay, 1993; Verhaar et al., 1992, 1999; Swartz et al., 1995; French-McCay, 2002; McGrath & Di Toro, 2009). Of the soluble compounds, the greatest contributor to toxicity for water-column and benthic organisms are the lower-molecular-weight aromatic compounds, which are both volatile and soluble in water. Although they are not the most water-soluble hydrocarbons within most oil types, the polynuclear aromatic hydrocarbons (PAHs) containing 2-3 aromatic ring structures typically exert the largest narcotic effects because they are semi-soluble and not highly volatile, so they persist in the environment long enough for significant accumulation to occur (Anderson et al., 1974, 1987; Neff & Anderson, 1981; Malins & Hodgins, 1981; McAuliffe, 1987; NRC, 2003). The monoaromatic hydrocarbons (MAHs), including the BTEX compounds (benzene, toluene, ethylbenzene, and xylenes), and the soluble alkanes (straight chain hydrocarbons) also contribute to toxicity, but these compounds are highly volatile, so that their contribution will be low when oil is exposed to evaporation and higher when oil is discharged at depth where volatilisation does not occur (French-McCay, 2002).

French-McCay (2002) reviewed available toxicity data, where marine biota was exposed to dissolved hydrocarbons prepared from oil mixtures, finding that 95% of species and life stages exhibited 50% population mortality (LC_{50}) between 6 and 400 ppb total PAH concentration after 96 hrs exposure, with an average of 50 ppb. Hence, concentrations lower than 6 ppb total PAH value should be protective of 97.5% of species and life stages even with exposure periods of days (at least 96 hours). Early life-history stages of fish appear to be more sensitive than older fish stages and invertebrates.

Exceedances of 10, 50 or 400 ppb over a 1 hour timestep (see Table 7.4) was applied to indicate increasing potential for sub-lethal to lethal toxic effects (or low to high), based on NOPSEMA (2019).

7.2.3.2 Entrained Hydrocarbons

Entrained hydrocarbons consist of oil droplets that are suspended in the water column and insoluble. As such, insoluble compounds in oil cannot be absorbed from the water column by aquatic organisms, hence are not bioavailable through absorption of compounds from the water. Exposure to these compounds would require routes of uptake other than absorption of soluble compounds. The route of exposure of organisms to whole oil alone include direct contact with tissues of organisms and uptake of oil by direct consumption, with potential for biomagnification through the food chain (NRC, 2003).

The 10 ppb threshold represents the very lowest concentration and corresponds generally with the lowest trigger levels for chronic exposure for entrained hydrocarbons in the ANZECC & ARMCANZ (2000) water quality guidelines. Due to the requirement for relatively long exposure times (> 24 hours) for these concentrations to be significant, they are likely to be more meaningful for juvenile fish, larvae and planktonic organisms that might be entrained (or otherwise moving) within the entrained plumes, or when entrained hydrocarbons adhere to organisms or trapped against a shoreline for periods of several days or more.

This exposure zone is not considered to be of significant biological impact and is therefore outside the adverse exposure zone. This exposure zone represents the area contacted by the spill. This area does not define the area of influence as it is considered that the environment will not be affected by the entrained hydrocarbon at this level.

Thresholds of 10 ppb and 100 ppb were applied over a 1 hour time exposure (Table 7.4), to cover the range of thresholds outlined in the ANZECC & ARMCANZ (2000) water quality guidelines, the incremental change for greater potential effect and is per NOPSEMA (2019).

A complicating factor that should be considered when assessing the consequence of dissolved and entrained oil distributions is that there will be some areas where both physically entrained oil droplets and dissolved hydrocarbons co-exist. Higher concentrations of each will tend to occur close to the source where sea conditions can force mixing of relatively unweathered oil into the water column, resulting in more rapid dissolution of soluble compounds.

Table 7.4 Dissolved and entrained hydrocarbon exposure values assessed over a 1-hour time step, as per NOPSEMA (2019).

Threshold level	Dissolved hydrocarbon concentration (ppb)	Entrained hydrocarbon concentrations (ppb)
Low	10	10
Moderate	50	-
High	400	100

8 HYDROCARBON PROPERTIES

8.1 Condensate Properties

West Tryal Rocks condensate physical properties and boiling point distributions were provided by Chevron and are presented in Table 8.1 and Table 8.2, respectively.

West Tryal Rocks condensate has an API of 41.2, a density of 789 kg/m^3 (at 15ºC) and a low viscosity value of 5.9 cP. When exposed to the atmosphere at local temperatures, about 31.1% of the condensate volatile components should evaporate within the first 12 hours (BP < 180°C); a further 29.9% of the semi-volatiles should evaporate within the first 24 hours (180°C < BP < 265°C); and low volatile portion (~19.4%) should evaporate over a longer period (265°C < BP < 380°C). Additionally, 19.6% of the condensate is shown to be persist in the marine environment for much longer periods and be subject to relatively slow degradation.

This condensate has a low asphaltene content (< 0.05%), which is one indicator for a very low propensity for the mixture to take up water to form water-in-oil emulsion.

Soluble, aromatic hydrocarbons contribute approximately 3.2% by mass of the whole oil, which is contained in the volatile fractions, which are highly soluble. The process of evaporation will be greater under calm sea conditions, but increased entrainment can be expected under stronger winds due to the presence of small breaking waves (whitecaps).

The actual fate will depend greatly on the amount that reaches the surface, either through the initial release or by resurfacing.

Table 8.1 Physical properties of West Tryal Rocks condensate.

Characteristic	West Tryal Rocks Condensate
Density (kg/m^3)	817 (at 15°C)
API	41.2
Dynamic viscosity (cP)	5.9 (at 15°C)
Pour point (°C)	0
Surface tension (dyne/cm)	23
Hydrocarbon property category	Group II
Hydrocarbon property classification	Light-persistent

Table 8.2 Boiling point ranges of West Tryal Rocks condensate.

Oil Type	Component	Volatile (%)	Semi-volatile (%)	Low volatility (%)	Residual (%)
	Boiling point (°C)	<180 C_4 to C_{10}	180-265 C_{11} to C_{15}	265-380 C_{16} to C_{20}	>380 >C_{20}
West Tryal Rocks Condensate	% of total	31.1	29.9	19.4	19.6
	% of aromatics	3.2	0.0	0.0	0.0

8.2 Condensate Weathering Characteristics

8.2.1 Overview

A series of weathering tests were conducted to illustrate the potential behaviour of this condensate when exposed to idealised and representative environmental conditions:

- Instantaneous 50 m^3 surface release under calm wind conditions (constant 5 knots), 27°C water temperature and currents.
- Instantaneous 50 m^3 surface release under variable moderate wind conditions, 27°C water temperature and currents.

The first case is indicative of weathering rates under calm conditions that would not generate entrainment, while the second case would be more representative of the moderate winds experienced over the region. Both scenarios provide examples of potential behaviour during periods of a spill event once the condensate reaches the surface.

8.2.2 Results

The mass balance forecast for the calm-wind case (Figure 8.1) shows that 61.1% of the condensate is predicted to evaporate within 24 hours. Majority of the remaining condensate on the water surface will weather at a slower rate due to the low volatile components. Evaporation of the residual compounds will slow significantly, and they will then be subject to more gradual decay through biological and photochemical processes.

Under the variable-wind case (Figure 8.2), where the winds are of greater strength on average, entrainment of West Tryal Rocks condensate into the water column is predicted to increase. Approximately 24 hours after the spill, 51.6% of the condensate mass is forecast to have entrained and a further 45.1% is forecast to have evaporated, leaving only a small proportion of the condensate floating on the water surface (1.5%). The residual compounds will tend to remain entrained beneath the surface under conditions that generate wind waves (approximately >6 m/s).

The increased level of entrainment in the variable-wind case will result in a higher percentage of biological and photochemical degradation, where the decay of the floating slicks and condensate droplets in the water column occurs at an approximate rate of 1.66% per day with an accumulated total of 11.6% after 7 days, in comparison to a rate of 0.22% per day and an accumulated total of 1.59% after 7 days in the constant-wind case. Given the proportion of entrained condensate and the tendency for it to remain mixed in the water column, the remaining hydrocarbons will decay over time scales of several weeks.

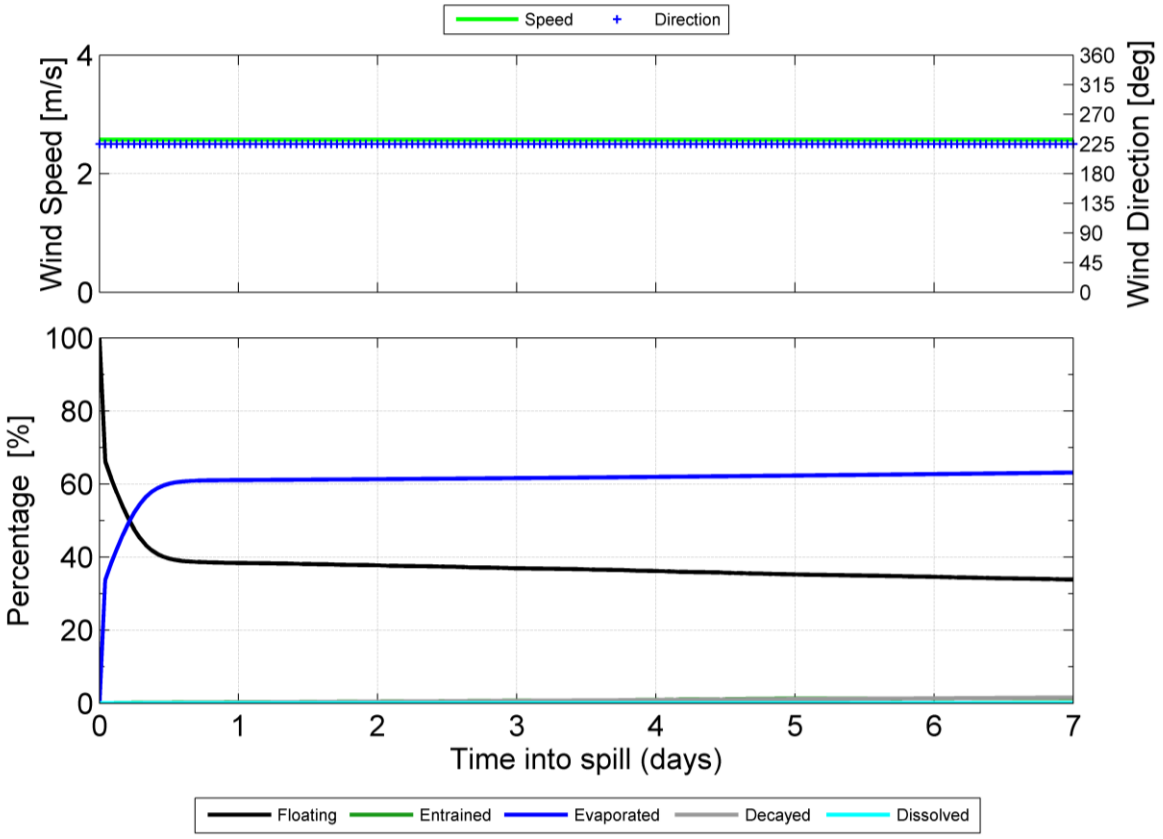

Figure 8.1 Proportional mass balance plot representing the weathering of West Tryal Rocks condensate spilled onto the water surface as a one-off instantaneous release and subject to a constant 5 knots (2.6 m/s) wind at 27°C water temperature.

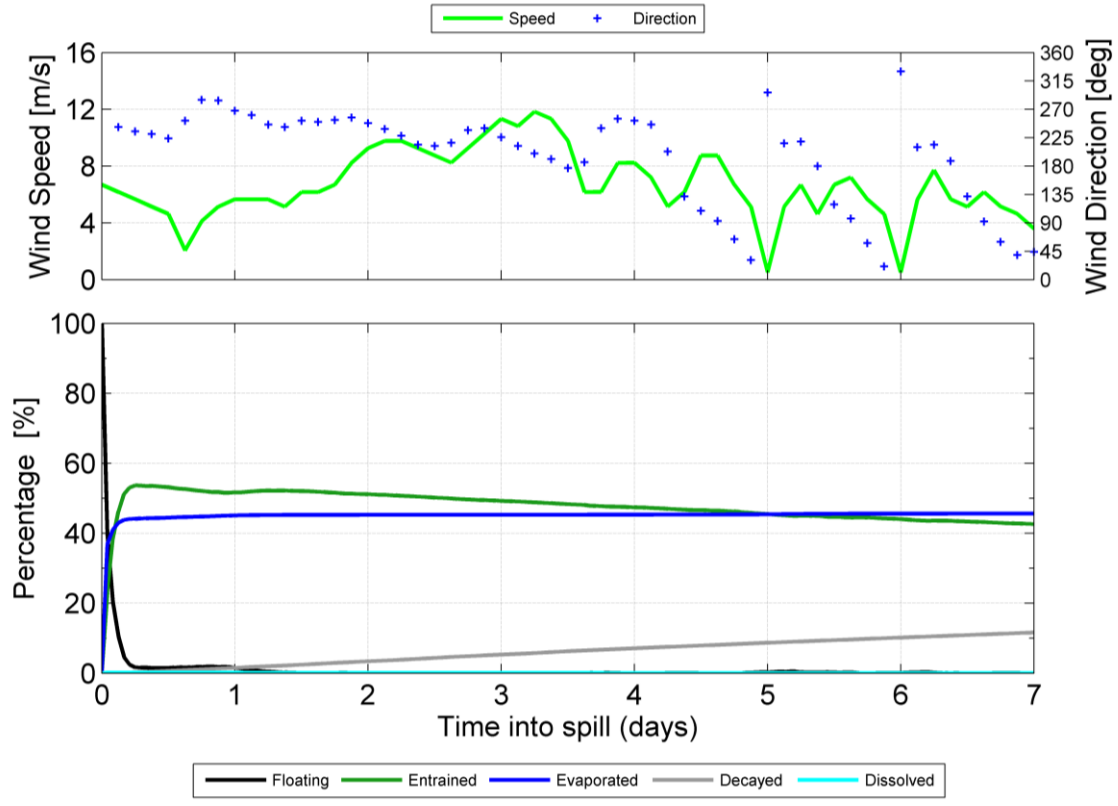

Figure 8.2 Proportional mass balance plot representing the weathering of West Tryal Rocks condensate spilled onto the water surface as a one-off instantaneous release and subject to variable wind at 27°C water temperature.

9 MODEL SETTINGS

Table 9.1 provides a summary of the oil spill model settings.

Table 9.1 Summary of the oil spill model settings used in this assessment.

	Scenario 1
Location	WTR Well 5
Number of spill simulations with randomly selected start times	100 per season (300 total)
Spill volume (m^3) [bbl]	61,555 [387,180]
Condensate type	West Tryal Rocks condensate
Release type (depth)	Subsea (150 m)
Release duration (days)	90
Simulation length (days)	104
Model period	Summer (September to the following March) Transitional (April and August) Winter (May to July)
Floating oil (NOPSEMA) thresholds	1 g/m^2, low exposure 10 g/m^2, moderate exposure 50 g/m^2, high exposure
Shoreline accumulation (NOPSEMA) thresholds	10 g/m^2, low exposure 100 g/m^2, moderate exposure 1,000 g/m^2, high exposure
Dissolved hydrocarbon (NOPSEMA) thresholds	10 ppb over 1 hour, low exposure 50 ppb over 1 hour, moderate exposure 400 ppb over 1 hour, high exposure
Entrained hydrocarbon (NOPSEMA) thresholds	10 ppb over 1 hour, low exposure 100 ppb over 1 hour, high exposure

10 PRESENTATION AND INTERPRETATION OF MODEL RESULTS

The results from the modelling study are presented in a number of tables and figures, which aim to provide an understanding of the predicted sea-surface and water column (subsurface) exposure and shoreline accumulation (if predicted).

10.1 Stochastic Analysis

10.1.1 Statistics

The statistics are based on the following principles:

- The ***greatest distance travelled by a spill trajectory*** – is determined by a) recording the maximum and b) second greatest distance travelled (or 99th percentile) by a single trajectory, within a scenario, from the release location to the identified exposure thresholds.
- The ***probability of oil exposure to a receptor*** – is determined by recording the number of spill trajectories to reach a specified sea surface or subsea threshold within a receptor polygon, divided by the total number of spill trajectories within that scenario.
- The ***minimum time before oil exposure to a receptor*** – is determined by ranking the elapsed time before sea surface exposure, at a specified threshold, to grid cells within a receptor polygon and recording the minimum value.
- The ***probability of oil accumulation at a receptor*** – is determined by recording the number of spill trajectories to reach a specified shoreline accumulation threshold within a receptor polygon, divided by the total number of spill trajectories within that scenario.
- The ***maximum potential oil accumulation within a receptor*** – is determined by identifying the maximum loading to any grid cell within a receptor polygon, for a scenario.
- The ***dissolved and entrained hydrocarbon exposure*** – is determined by recording the maximum instantaneous concentrations at each grid cell assessed over a 1-hour time step.

10.2 Deterministic Trajectories

The deterministic results for both scenarios are based on the following criteria:

a. Largest swept area of floating hydrocarbon above 10 g/m^2
b. Largest swept area of floating hydrocarbon above 50 g/m^2
c. Largest volume of oil ashore
d. Longest length of shoreline with accumulation above 100 g/m^2
e. Largest area of entrained hydrocarbons above 100 ppb
f. Largest area of dissolved hydrocarbons above 50 ppb

10.3 Receptors

A range of environmental receptors and shorelines were assessed for floating oil exposure, shoreline contact and water column exposure (entrained and dissolved hydrocarbons) as part of the study (see Figure 10.1 to Figure 10.11). Receptor categories (see Table 10.1) include sections of shorelines and offshore islands. All other sensitive receptors other than submerged reefs, shoals and banks (RSB) were sourced from http://www.environment.gov.au/. Risks of exposure were separately calculated for each sensitive receptor area and have been tabulated.

Table 10.2 summarises the receptors that the location resides within.

Table 10.1 Summary of receptors used to assess floating oil, shoreline and in-water exposure to hydrocarbons.

11 RESULTS: WEST TRYAL ROCKS LOSS OF WELL CONTROL

This scenario examined a 387,180 bbl (or 61,555 m^3) subsea release of condensate over 90 days, from a LOWC. A total of 300 spill simulations were run for each of the three seasons (i.e. 100 spills per season) and tracked for 104 days.

Section 11.1 presents the seasonal (or stochastic) analysis results, while Section 11.2 presents the deterministic results.

11.1 Stochastic Analysis

11.1.1 Floating Condensate Exposure

Table 11.1 summarises the maximum distances from the release location to floating condensate exposure zones for each season.

The maximum distance from the release location to the low (≥ 1 g/m^2), moderate (≥ 10 g/m^2) and high (≥ 50 g/m^2) threshold was 251.7 West-southwest (summer), 45.9 km North-northwest (transitional) and 5.2 km West-northwest (transitional) and West-southwest (winter), respectively.

Table 11.2 summarises the potential floating condensate exposure to individual receptors during each season.

The Offshore Area IAA, Flatback Turtle - Internesting Buffer, Pygmy Blue Whale – Distribution, Wedge-tailed Shearwater - Breeding, Whale Shark – Foraging BIAs, Pilbara (offshore) IMCRA, and the Ancient coastline at 125 m depth contour KEF, which the release location resides within (see Section 10.3), and the Montebello AMP, Flatback Turtle - Nesting and Humpback Whale - Migration BIAs, Barrow & Montebello Islands IAA and the Continental Slope Demersal Fish Communities KEF were the only receptors predicted to be exposed during all three seasons at the low and moderate thresholds. The probabilities for the low and moderate thresholds was 100% for all seasons for the receptors which the release location resides within. The probabilities of low and moderate exposure at the Flatback Turtle - Nesting BIA ranged between 91–95% and 17–25%, whilst the probabilities of low and moderate exposure at the Humpback Whale - Migration BIA ranged between 97–100% and 6–32%, respectively. The minimum times before low exposure for the Flatback Turtle - Nesting BIA and Humpback Whale - Migration BIA were 1.08 days and 0.71 days during summer conditions, respectively. Furthermore, the probability of exposure at the low threshold for the Montebello AMP and Continental Slope Demersal Fish Communities KEF was 77%, 60% and 59% during summer, transitional and winter conditions and 100%, 100% and 100% during summer, transitional and winter conditions, respectively. The corresponding minimum time before low exposure Montebello AMP and Continental Slope Demersal Fish Communities KEF was 1.21 days (winter) and 0.46 days (transitional and winter).

Figure 11.1 to Figure 11.3 present the zones of floating condensate exposure for each season.

Table 11.1 Maximum distances and directions travelled from the release location to floating condensate exposure for each season and threshold, following a subsea LOWC at WTR Well 5. The results were calculated from 100 spill trajectories per season.

Season	Distance and direction	Zones of potential floating condensate exposure		
		Low	Moderate	High
Summer	Max. distance from release site (km)	251.7	45.9	4.9
	Max. distance from release site (km) (99th percentile)	107.5	39.1	4.9
	Direction	West-southwest	North-northwest	North
Transitional	Max. distance from release site (km)	177.1	42.8	5.2
	Max. distance from release site (km) (99th percentile)	127.7	37.5	5.2
	Direction	North	Northeast	West-northwest
Winter	Max. distance from release site (km)	169.7	43.5	5.2
	Max. distance from release site (km) (99th percentile)	114	37.1	5.2
	Direction	Northeast	Northeast	West-southwest

*The release location resides within the receptor boundaries.

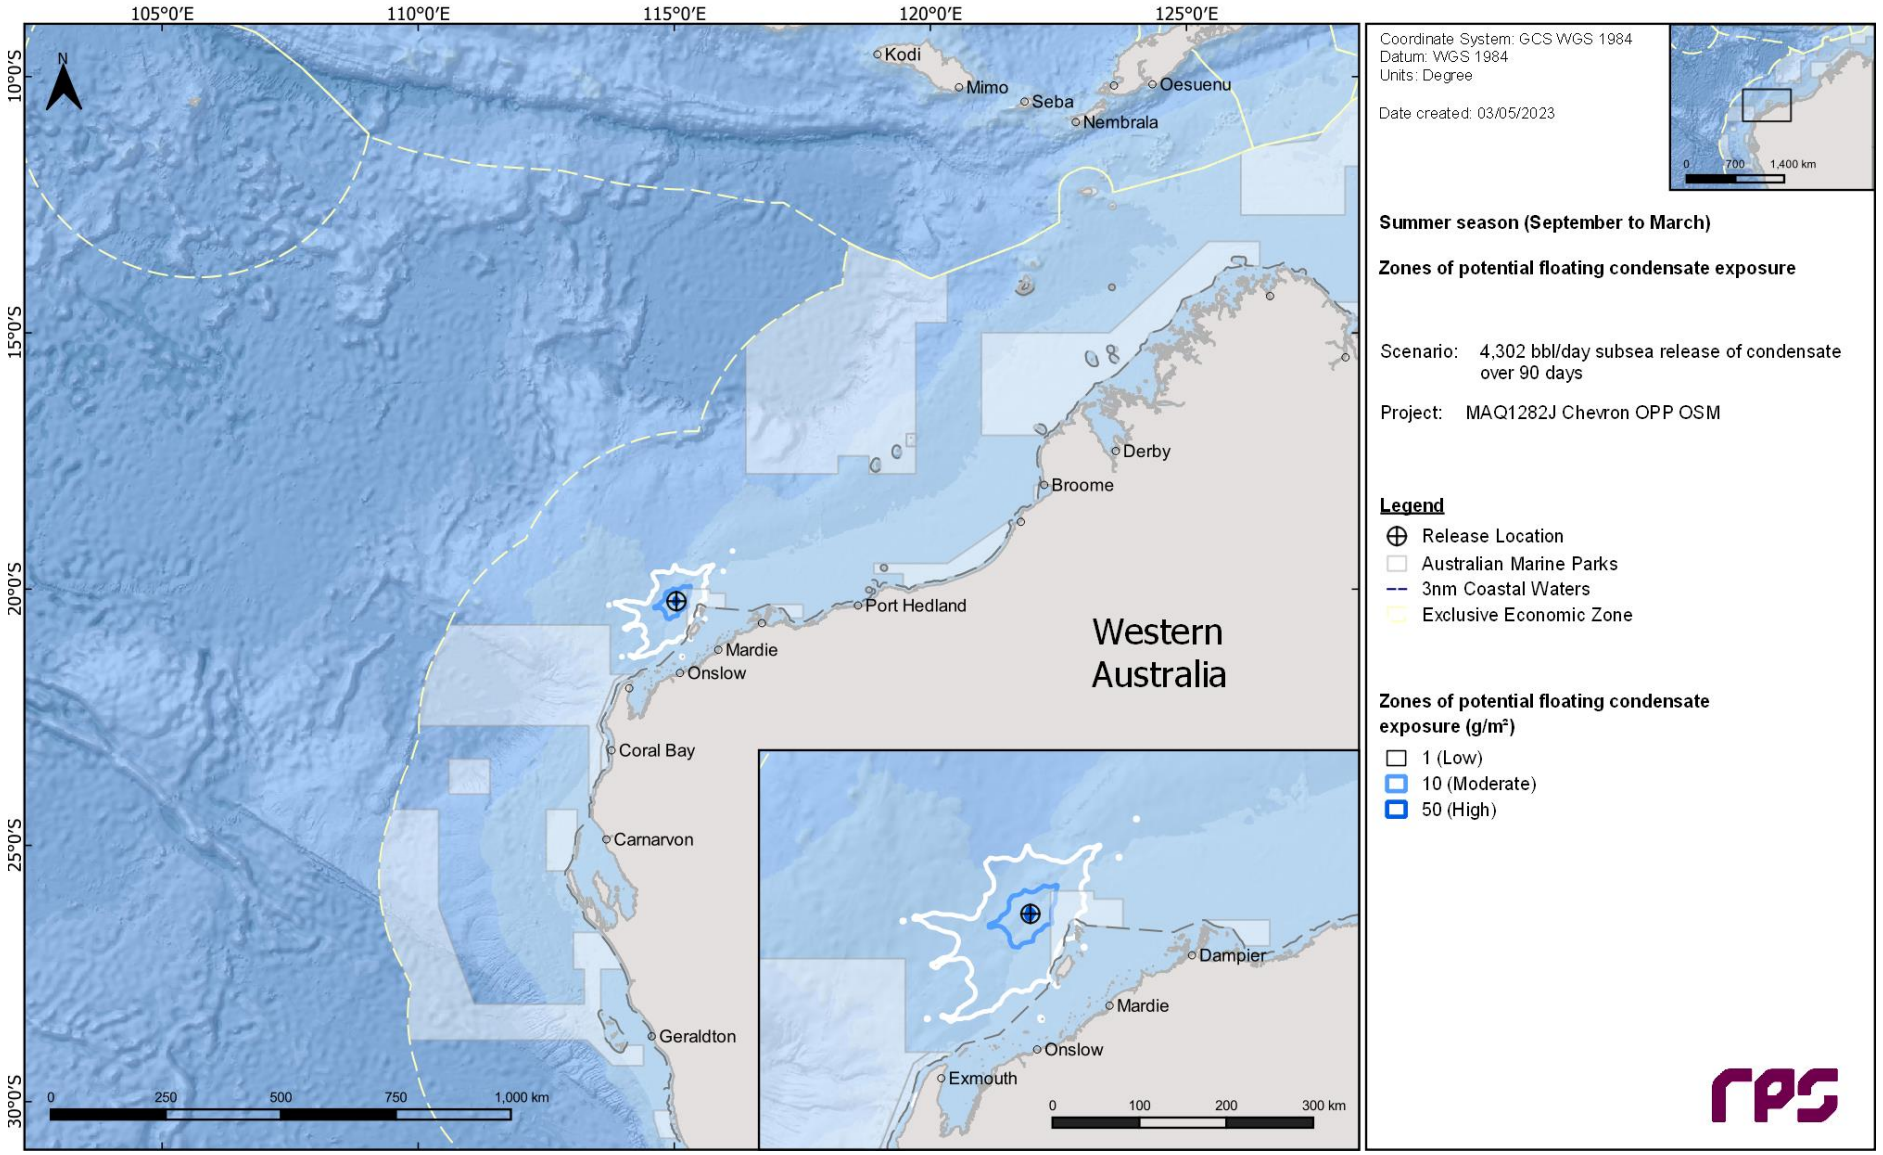

Figure 11.1 Zones of potential floating condensate exposure following a subsea LOWC at WTR Well 5 during summer (September to the following March) wind and current conditions. The results were calculated from 100 spill simulations.

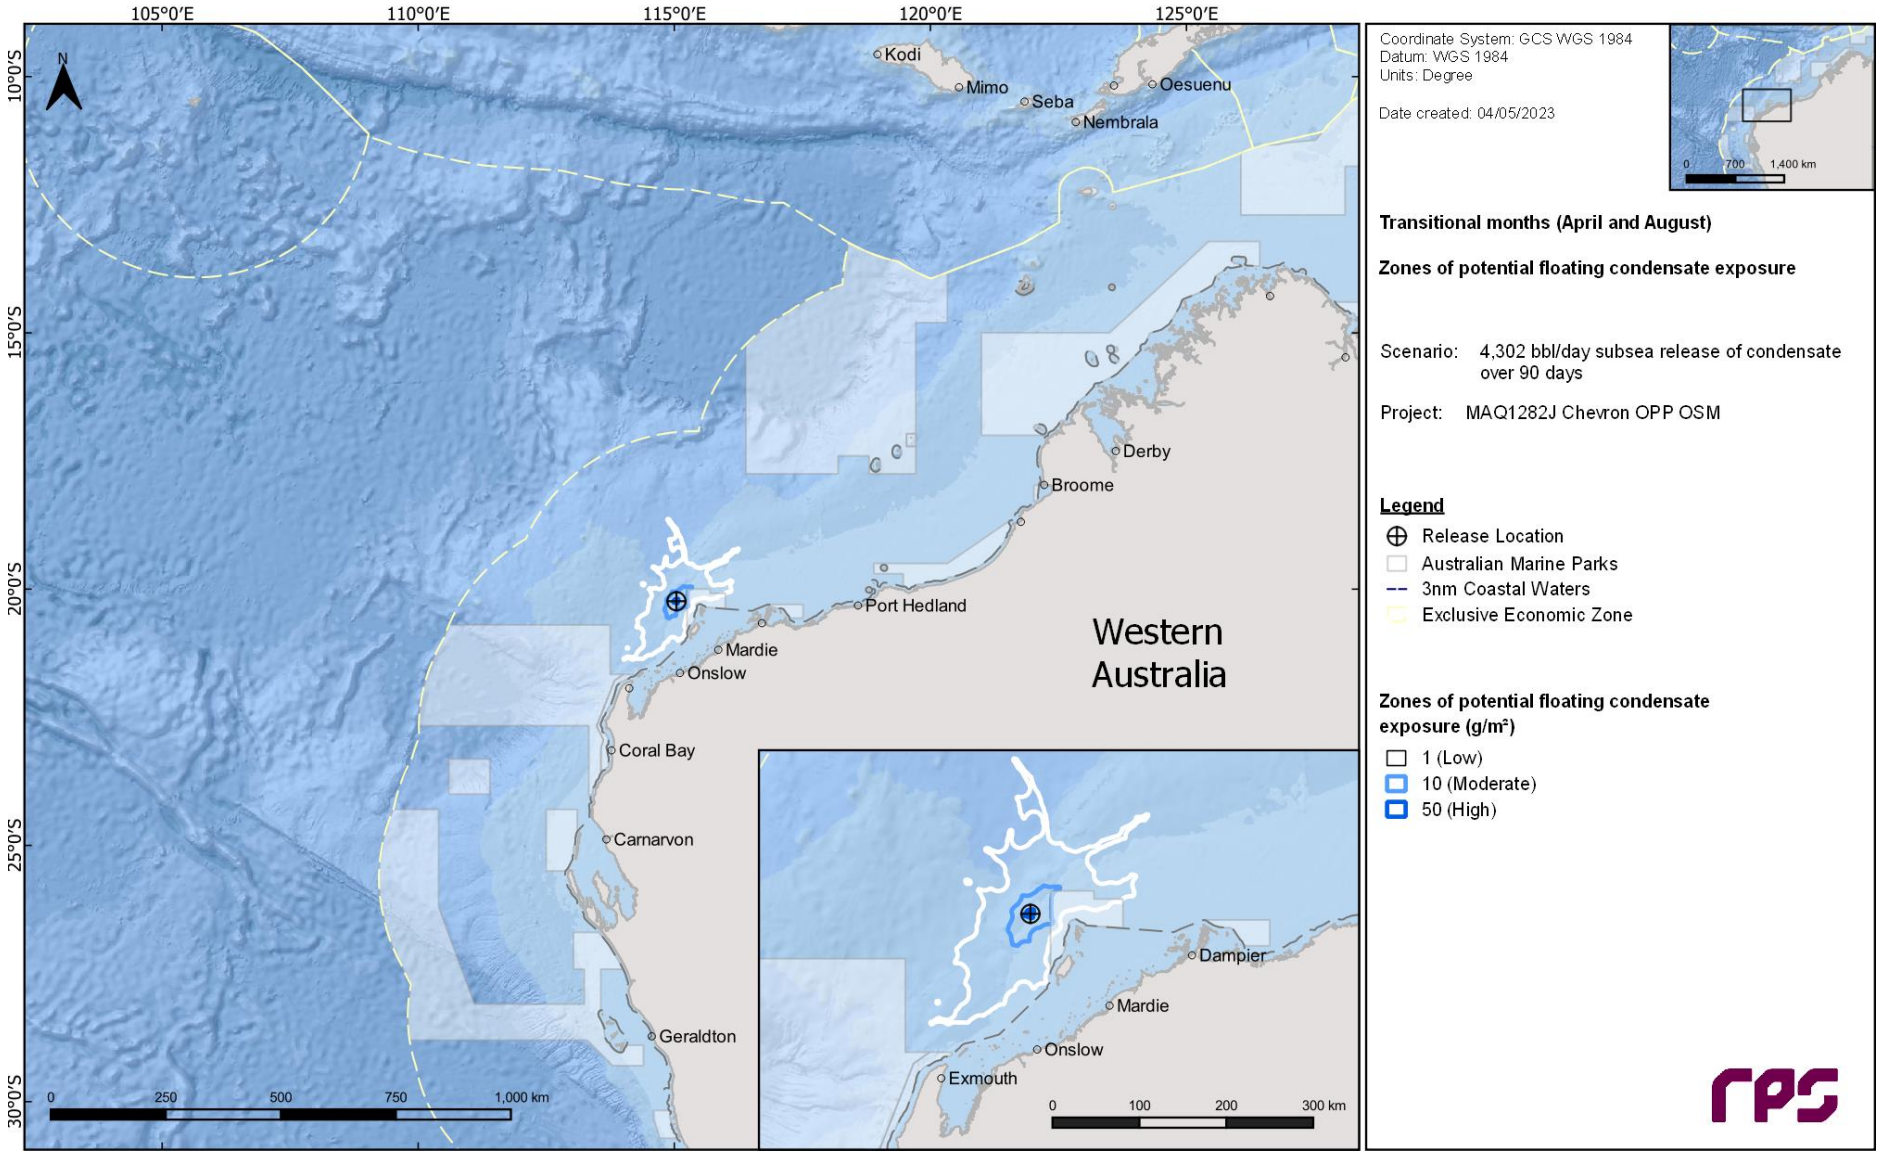

Figure 11.2 Zones of potential floating condensate exposure following a subsea LOWC at WTR Well 5 during transitional (April and August) wind and current conditions. The results were calculated from 100 spill simulations.

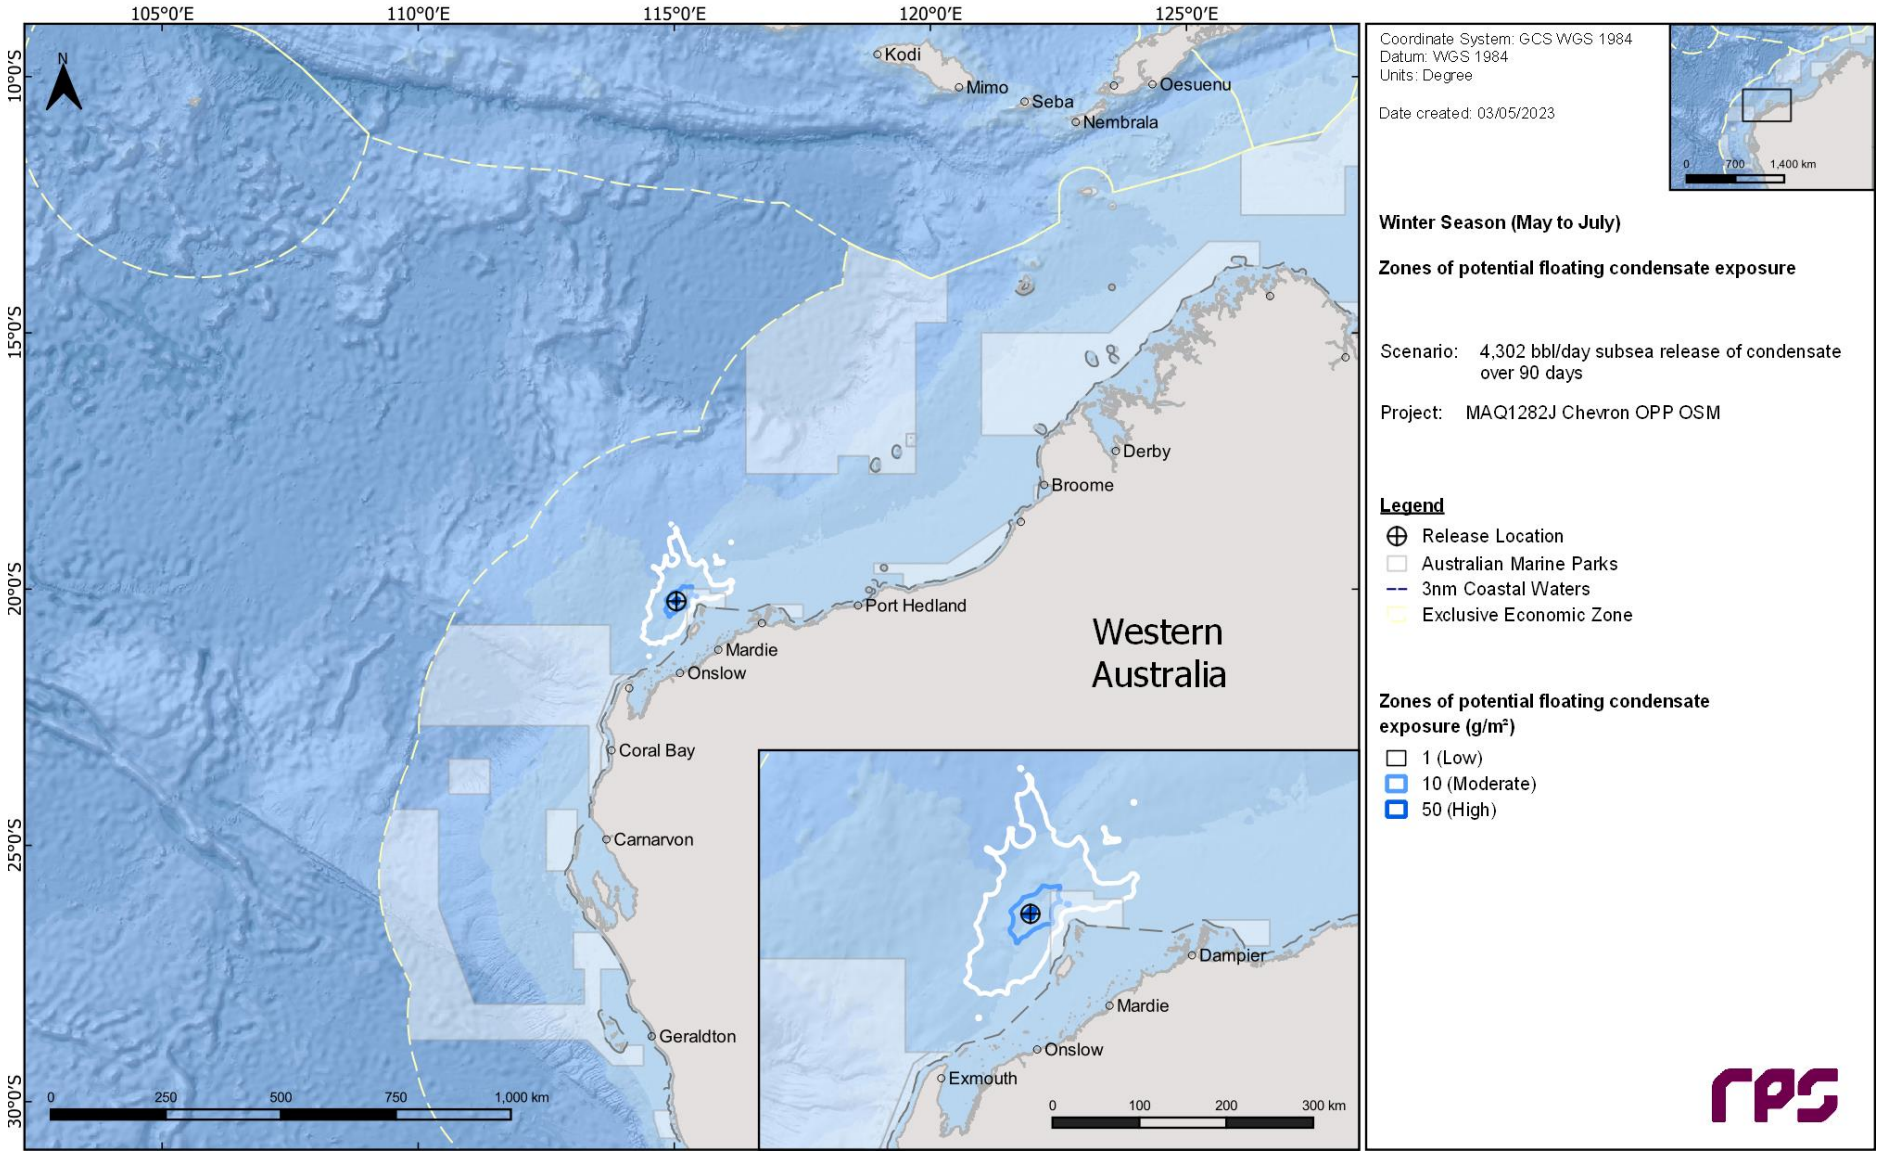

Figure 11.3 Zones of potential floating condensate exposure following a subsea LOWC at WTR Well 5 during winter (May to July) wind and current conditions. The results were calculated from 100 spill simulations.

11.1.2 Shoreline Accumulation

Table 11.3 presents a summary of the predicted shoreline accumulation during summer, transitional and winter seasons. The probability of accumulation on any shoreline at, or above, the low threshold (≥ 10 g/m^2) was greatest during summer at 59%, while the minimum time before shoreline accumulation was 6.5 days and the maximum volume of oil ashore was 128 m^3.

No high (≥ 1,000 g/m^2) shoreline threshold accumulation was predicted in the modelling results.

Table 11.4 to Table 11.6 summarises the shoreline accumulation on individual receptors for each season.

During summer conditions, 82 shoreline receptors were predicted to record condensate accumulation at, or above, the low threshold with the greatest probability predicted for Barrow & Montebello Islands IAA (38%). In comparison, during transitional and winter conditions, 40 and 42 shoreline receptors, respectively, were predicted to record accumulation, with the greatest probability during transitional season occurring at the Ningaloo Coast World Heritage Area IAA and the Muiron Islands (30%) and at the Ningaloo Coast World Heritage Area IAA only during winter (30%).

The maximum potential shoreline accumulation is presented for each season in Figure 11.4 to Figure 11.6.

Table 11.3 Summary of oil accumulation across all shorelines for each season and threshold, following a subsea LOWC at WTR Well 5. The results were calculated from 100 spill trajectories per season.

Shoreline Statistics	Summer	Transitional	Winter
Probability of accumulation on any shoreline (%)	59	38	45
Absolute minimum time for visible oil to shore (days)	6.5	7.75	10.79
Maximum volume of hydrocarbons ashore (m^3) above the low threshold	128	27.5	4.8
Average volume of hydrocarbons ashore (m^3) above the low threshold	27.1	3.2	1.6
Maximum length of the shoreline at **10 g/m^2** (km)	155	39	13
Average shoreline length (km) at **10 g/m^2** (km)	47.2	9.2	4.9
Maximum length of the shoreline at **100 g/m^2** (km)	38	7	-
Average shoreline length (km) at **100 g/m^2** (km)	12.6	4.7	-
Maximum length of the shoreline at **1,000 g/m^2** (km)	-	-	-
Average shoreline length (km) at **1,000 g/m^2** (km)	-	-	-

Table 11.4 Summary of shoreline condensate accumulation to individual receptors, following a LOWC at WTR Well 5. The results were calculated from 100 spill trajectories days during summer (September to the following March) wind and current conditions.

11.1.3 Water Column Exposure

11.1.3.1 Dissolved Hydrocarbons

Table 11.7 summarises the seasonal probability of exposure to individual receptors from dissolved hydrocarbons in the 0-10 m depth layer, at the low (≥ 10 ppb), moderate (≥ 50 ppb) and high (≥ 400 ppb) exposure thresholds.

In the surface (0-10 m) depth layer, a total of 14, 20, and 10 BIAs were predicted to be exposed at, or above, the low threshold during summer, transitional and winter, respectively. Excluding the 4 BIAs that the release location resides within (Flatback Turtle - Internesting Buffer, Pygmy Blue Whale - Distribution, Wedge-tailed Shearwater - Breeding and Whale Shark – Foraging) (see Section 10.3), the highest probabilities of exposure to low dissolved hydrocarbons were predicted as 7% for Humpback Whale - Migration during summer, 12% Humpback Whale - Migration during transitional, and 4% for Flatback Turtle – Nesting and Humpback Whale - Migration during winter conditions.

A total of 2, 3 and 1 AMPs were predicted to be exposed to dissolved hydrocarbons at, or above the low threshold during summer, transitional and winter, respectively with the highest probability predicted at the Montebello AMP (3%) during transitional and winter.

Additionally, 3, 4 and 2 IAAs and 3, 3 and 2 IMCRAs were predicted to be exposed to dissolved hydrocarbons at, or above the low threshold during summer, transitional and winter, respectively.

Furthermore, 3 (summer), 4 (transitional) and 2 (winter) KEFs were predicted to be exposed to dissolved hydrocarbons at, or above the low threshold.

Figure 11.7 to Figure 11.9 presents the zones of potential instantaneous dissolved hydrocarbon exposure for the 0-10 m depth layer for the summer, transitional and winter periods, respectively.

The same maps for the 10-20 m depth layer are presented in Figure 11.10 to Figure 11.12.

Table 11.7 Predicted probability and maximum dissolved hydrocarbon exposure to individual receptors in the 0-10 m depth layer following a subsea LOWC at WTR Well 5. The results were calculated from 100 spill simulations per season.

11.1.3.2 Entrained Hydrocarbons

Table 11.8 summarises the probability and minimum time before exposure to receptors from entrained hydrocarbons in the 0-10 m depth layer, for each season, at the low (≥ 10 ppb) and high (≥ 100 ppb) thresholds.

In the surface (0-10 m) depth layer, a total of 44, 39 and 40 BIAs were predicted to be exposed at, or above, the low threshold during summer, transitional and winter respectively. Excluding the 4 BIAs (Flatback Turtle - Internesting Buffer, Pygmy Blue Whale - Distribution, Wedge-tailed Shearwater - Breeding and Whale Shark – Foraging) that the release location resides within (see Section 10.3), the highest probabilities of exposure to low entrained hydrocarbons were predicted for the Flatback Turtle - Nesting (98% during summer and 100% during transitional and winter) and Humpback Whale - Migration BIAs (100% during all seasons).

During summer, 9 AMPs were predicted to be exposed at the low threshold, compared to 7 AMPs during transitional and winter periods. The highest probabilities predicted were at the Gascoyne AMP (96% summer, 100% transitional and 98% winter). Furthermore, during seasonal conditions the Gascoyne, Montebello and Ningaloo AMP were also predicted to be exposed to entrained hydrocarbons at the high threshold.

During summer, transitional and winter conditions, 9, 10 and 11 KEFs were predicted to be exposed by entrained hydrocarbons at the low threshold, respectively. Probabilities of exposure ranged between 9–100%, 4–100% and 2–100%, for summer, transitional and winter, respectively. Excluding the KEF that the release location resides within (Ancient coastline at 125 m depth contour), the KEF with the greatest probability of low exposure for each season was the Continental Slope Demersal Fish Communities KEF (100% during all seasons).

Additionally, 60, 35 and 32 IAA (including the Offshore IAA that the release site is located within), were predicted to be exposed to entrained hydrocarbons at low threshold. Excluding the Offshore IAA, the probabilities for each season ranged between 1–96%, 1–100% and 7–99% under summer, transitional and winter conditions, respectively, with the maximum probabilities occurring at the Gascoyne IAA during summer and transitional and at Barrow & Montebello Islands IAA during winter.

Furthermore, 70, 29 and 35 RSB receptors were predicted to be exposed to entrained hydrocarbons at the low threshold during summer, transitional and winter, respectively. The maximum probabilities for low threshold exposure were predicted for Rankin Bank (73% and 58% for summer and transitional respectively) and Rosily Shoals (73% for winter).

Figure 11.13 to Figure 11.15 illustrate the extent of the predicted entrained hydrocarbon exposure for the low and high thresholds in the 0-10 m depth layer for each season.

The same maps for the 10-20 m depth layer are presented in Figure 11.16 to Figure 11.18.

Table 11.8 Predicted probability and maximum entrained hydrocarbon exposure to individual receptors in the 0-10 m depth layer following a subsea LOWC at WTR Well 5. The results were calculated from 100 spill simulations per season.

Receptor		Summer					Transitional					Winter				
		Maximum exposure to entrained hydrocarbons (ppb)	Probability of exposure to entrained hydrocarbons (%)		Minimum time before exposure to entrained hydrocarbons (Days)		Maximum exposure to entrained hydrocarbons (ppb)	Probability of exposure to entrained hydrocarbons (%)		Minimum time before exposure to entrained hydrocarbons (Days)		Maximum exposure to entrained hydrocarbons (ppb)	Probability of exposure to entrained hydrocarbons (%)		Minimum time before exposure to entrained hydrocarbons (Days)

11.2 Deterministic Analysis

The deterministic analysis presented below, are based on simulations that resulted in the largest swept area of floating condensate above 10 g/m^2 (see Section 11.2.1), the largest swept area of floating condensate above 50 g/m^2 (see Section 11.2.2), largest volume of oil ashore (see Section 11.2.3), longest length of shoreline accumulation above 100 g/m^2 (see Section 11.2.4), the largest area of entrained hydrocarbons above 100 ppb (see Section 11.2.5), and the largest area of dissolved hydrocarbons above 50 ppb (see Section 11.2.6).

Table 11.9 presents a summary of all deterministic analysis criteria and the corresponding floating condensate, shoreline accumulation, entrained and dissolved hydrocarbon values at the assessed thresholds.

Interpretation of the deterministic analysis result table and timeseries plots:

The summary deterministic analysis results presented in the table below should be interpreted as **maximum values**, representing the total volume or swept area exposed by floating or in-water hydrocarbons throughout the entire simulation duration. In this particular case, the simulation showed that a maximum of 3,033 km^2 was exposed to floating oil above the low threshold over a period of 104 days.

However, it's important to note that the timeseries plots present **peak values** at specific points in time. For example, when considering shoreline volume, the peak value in the timeseries plot does not account for oil that may have reached the shore earlier in the simulation but was subsequently lost through evaporation or other weathering processes.

Continuing with the previous example, the timeseries plot indicates that the peak floating oil swept area above the low threshold reached 220 km^2. This value represents the highest swept area recorded at a single point in time during the simulation.

Table 11.9 Summary of the deterministic analysis following a subsea LOWC at WTR Well 5.

Variable	Threshold	Deterministic Analysis Criteria					
		Largest swept area of floating condensate above 10 g/m^2	Largest swept area of floating condensate above 50 g/m^2	Largest volume of oil ashore	Longest length of shoreline accumulation above 100 g/m^2	Largest area of entrained hydrocarbons above 100 ppb	Largest area of dissolved hydrocarbons above 50 ppb
Season		Summer	Summer	Summer	Summer	Summer	Summer
Run Number		38	31	4	70	60	82
Floating Oil (km^2)	1 g/m^2	3,033	3,481	2,760	3,129	2,356	1,046

11.2.1 Deterministic Case: Largest swept area of floating condensate above 10 g/m^2

The deterministic simulation that resulted in the largest swept area of floating condensate above 10 g/m^2 was identified as run number 38 during the summer period.

Figure 11.19 presents the extent of the predicted floating oil exposure zones on the sea surface (swept area) and shoreline accumulation over the entire 104-day simulation.

Figure 11.20 displays the time series of the swept area of low (≥ 1 g/m^2), moderate (≥ 10 g/m^2) and high (≥ 50 g/m^2) floating condensate over the 104-day simulation.

Figure 11.21 presents the fates and weathering for the corresponding simulation and Table 11.10 summarises peak volumes and times of occurrence for each oil phase and volumes at the end of the 104-day simulation.

Table 11.10 Summary of peak volumes and times of occurrence for each oil phase and the volumes at the conclusion of the simulation (day 104), for the simulation with the largest swept area of floating condensate above 10 g/m^2 following a subsea LOWC at WTR Well 5.

Exposure Metrics	Peak Volume	Day of Occurrence	Volume at day 104
Surface (m^3)	1,165	9	1
Entrained (m^3)	9,458	90	6,965
Dissolved (m^3)	3	84	0
Evaporation (m^3)	40,477	101	40,477
Decay (m^3)	14,039	104	14,039
Ashore (m^3)	62	30	30

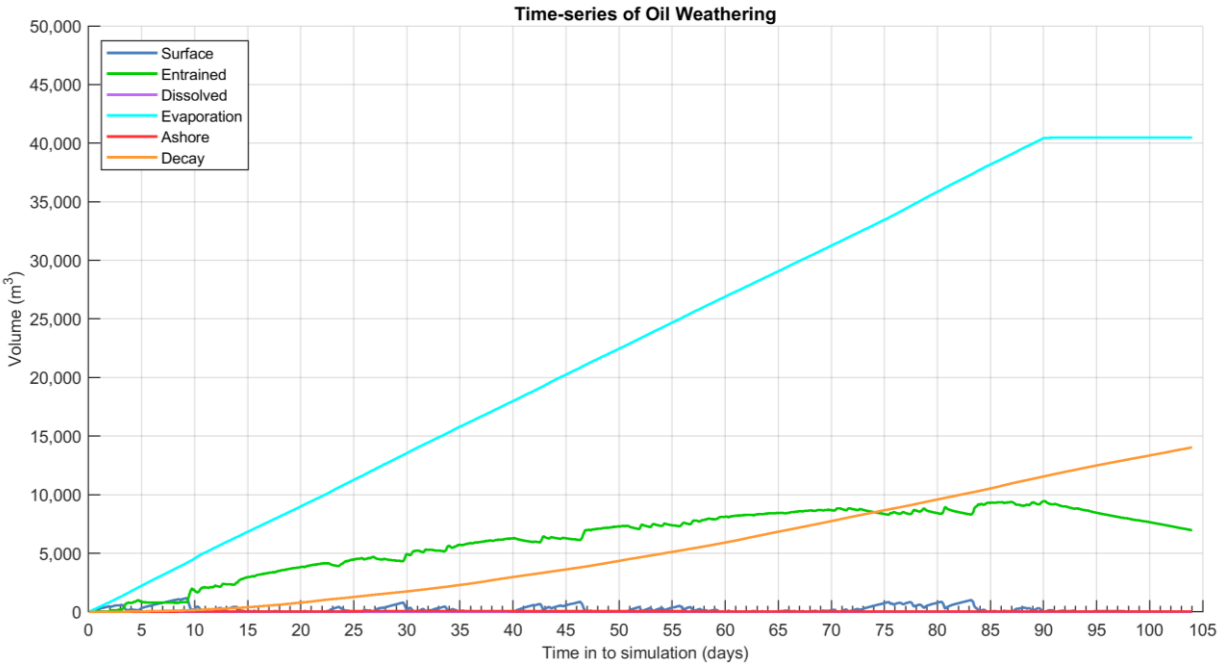

Figure 11.21 Predicted weathering and fates for the simulation with the largest swept area of floating condensate above 10 g/m² following a subsea LOWC at WTR Well 5.

11.2.2 Deterministic Case: Largest swept area of floating condensate above 50 g/m^2

The deterministic simulation that resulted in the largest swept area of floating condensate above 50 g/m^2 was identified as run number 31 during the summer period.

Figure 11.19 presents the extent of the predicted floating oil exposure zones on the sea surface (swept area) and shoreline accumulation over the entire 104-day simulation.

Figure 11.20 displays the time series of the swept area of low (≥ 1 g/m^2), moderate (≥ 10 g/m^2) and high (≥ 50 g/m^2) floating condensate over the 104-day simulation.

Figure 11.21 presents the fates and weathering for the corresponding simulation and Table 11.10 summarises peak volumes and times of occurrence for each oil phase and volumes at the end of the 104-day simulation.

Table 11.11 Summary of peak volumes and times of occurrence for each oil phase and the volumes at the conclusion of the simulation (day 104), for the simulation with the largest swept area of floating condensate above 50 g/m^2 following a subsea LOWC at WTR Well 5.

Exposure Metrics	Peak Volume	Day of Occurrence	Volume at day 104
Surface (m^3)	889	60	4
Entrained (m^3)	9,630	90	7,103
Dissolved (m^3)	3	53	0
Evaporation (m^3)	40,650	103	40,650
Decay (m^3)	13,751	104	13,751
Ashore (m^3)	4	101	4

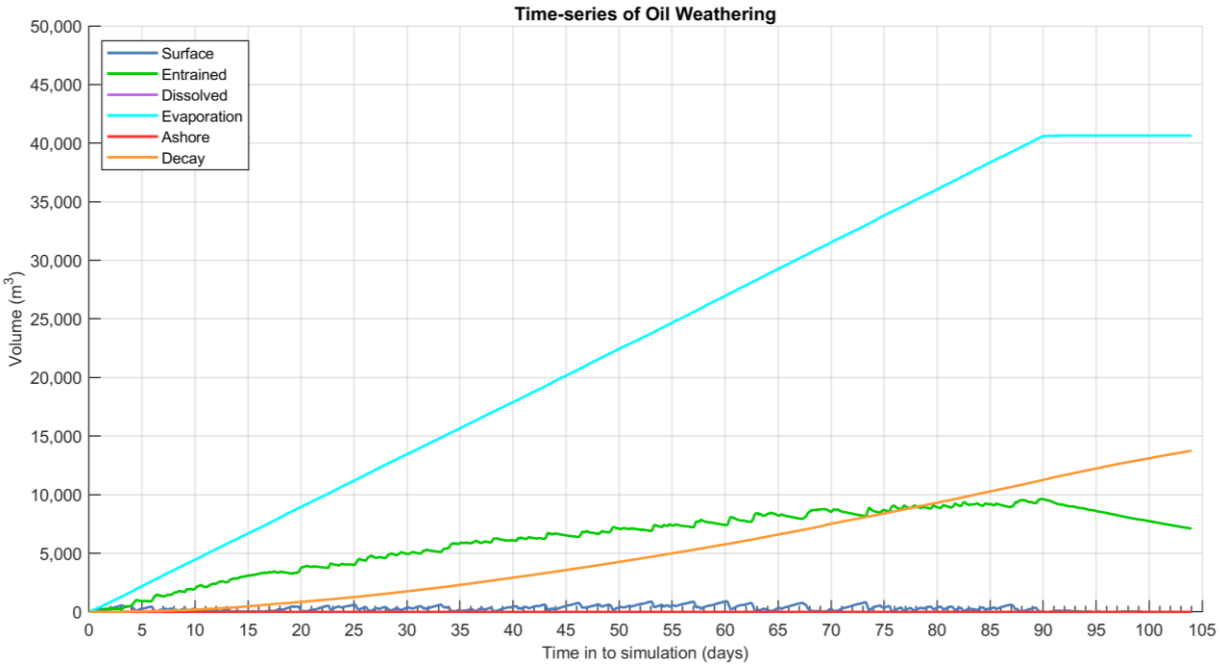

Figure 11.24 Predicted weathering and fates for the simulation with the largest swept area of floating condensate above 50 g/m² following a subsea LOWC at WTR Well 5.

11.2.3 Deterministic Case: Largest volume of oil ashore

The deterministic simulation that resulted in the largest volume of oil ashore was identified as run number 4 during the summer period.

Figure 11.25 presents the extent of the predicted floating oil exposure zones on the sea surface (swept area) and shoreline accumulation over the entire 104-day simulation.

Figure 11.26 displays the time series of the volume of oil accumulating on shorelines at the low (≥ 10 g/m^2), moderate (≥ 100 g/m^2) and high (≥ 1,000 g/m^2) thresholds over the 104-day simulation.

Figure 11.27 presents the fates and weathering graph for the corresponding single spill trajectory and Table 11.12 summarises the peak volumes and times of occurrence for each oil phase and volumes at the end of the simulation.

Table 11.12 Summary of peak volumes and times of occurrence for each oil phase and the volumes at the conclusion of the simulation (day 104), for the simulation with the largest volume of oil ashore following a subsea LOWC at WTR Well 5.

Exposure Metrics	Peak Volume	Day of Occurrence	Volume at day 104
Surface (m^3)	1,211	72	20
Entrained (m^3)	8,831	88	6,539
Dissolved (m^3)	3	73	0
Evaporation (m^3)	40,583	104	40,583
Decay (m^3)	14,257	104	14,257
Ashore (m^3)	128	91	113

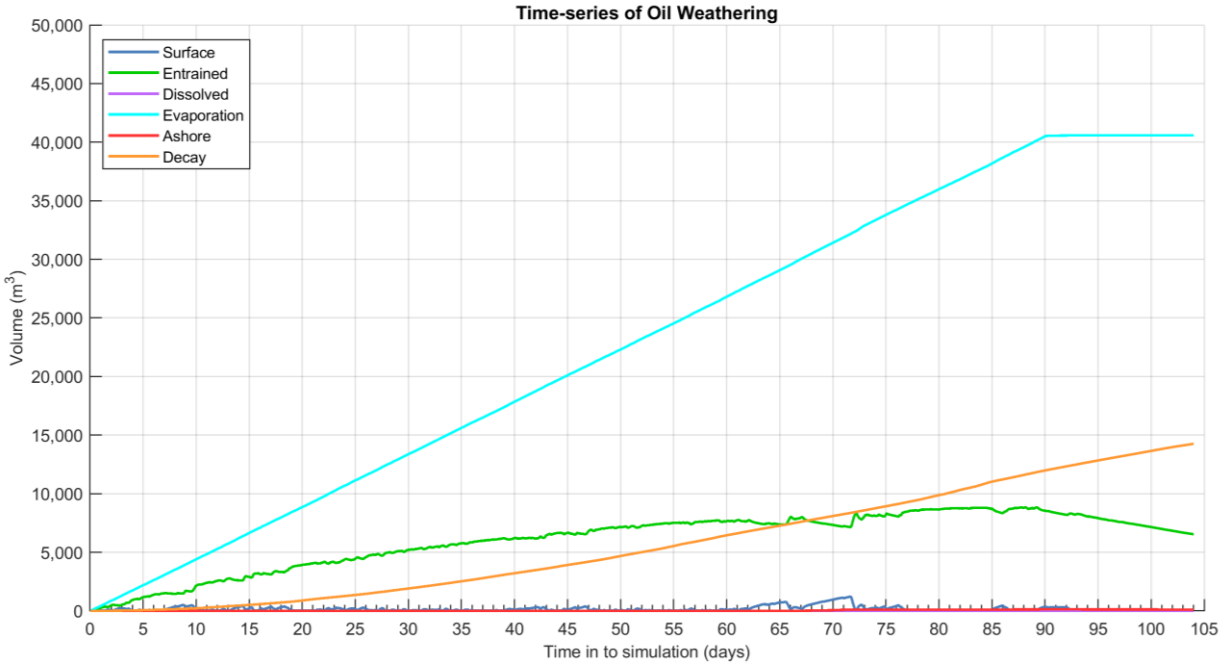

Figure 11.27 Predicted weathering and fates for the simulation with largest volume of oil ashore following a subsea LOWC at WTR Well 5.

11.2.4 Deterministic Case: Longest length of shoreline with accumulation above 100 g/m^2

The deterministic simulation that resulted in the longest length of shoreline with accumulation above 100 g/m^2 (moderate threshold) was identified as run number 70 during the summer period.

Figure 11.28 presents the extent of the predicted floating oil exposure zones on the sea surface (swept area) and shoreline accumulation over the entire 104-day simulation.

Figure 11.29 displays the time series of the length of shoreline with accumulation above the low (≥ 10 g/m^2), moderate (≥ 100 g/m^2) and high (≥ 1,000 g/m^2) thresholds over the 104-day simulation.

Figure 11.30 presents the fates and weathering graph for the corresponding single spill trajectory and Table 11.13 summarises the peak volumes and times of occurrence for each oil phase and volumes at the end of the simulation.

Table 11.13 Summary of peak volumes and times of occurrence for each oil phase and the volumes at the conclusion of the simulation (day 104), for the simulation with the longest length of shoreline accumulation above 100 g/m^2 following a subsea LOWC at WTR Well 5.

Exposure Metrics	Peak Volume	Day of Occurrence	Volume at day 104
Surface (m^3)	1,212	41	1
Entrained (m^3)	9,282	90	6,916
Dissolved (m^3)	3	38	0
Evaporation (m^3)	40,452	104	40,452
Decay (m^3)	14,065	104	14,065
Ashore (m^3)	121	60	80

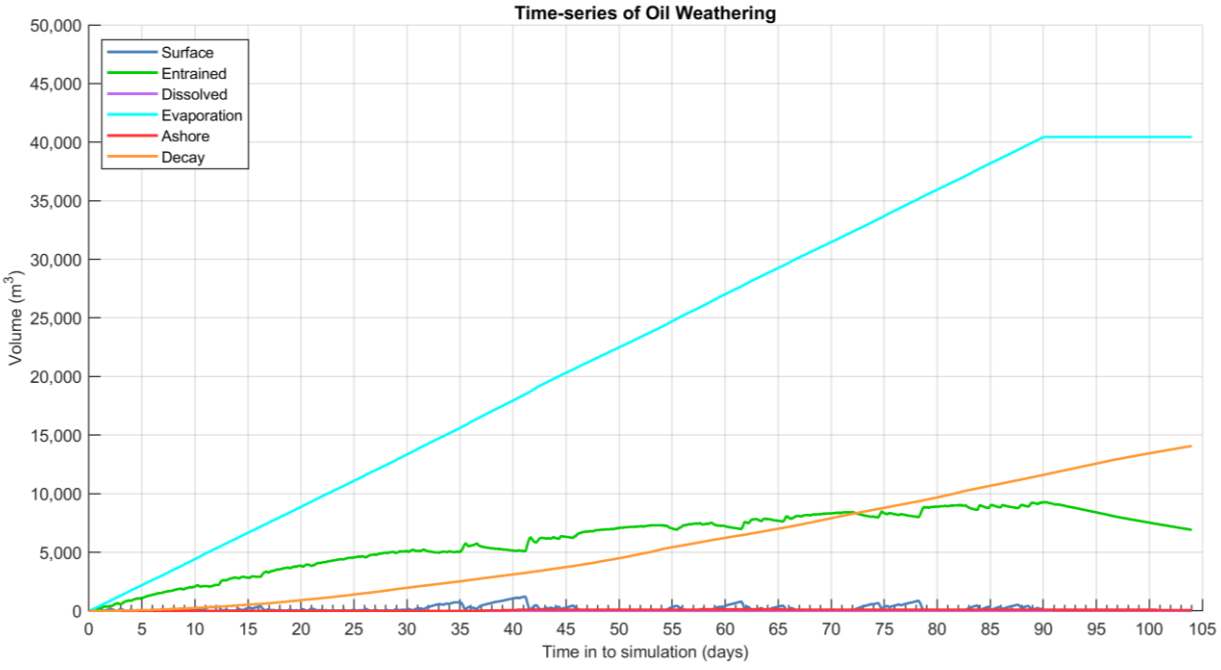

Figure 11.30 Predicted weathering and fates for the simulation with the longest length of shoreline with accumulation above 100 g/m^2 following a subsea LOWC at WTR Well 5.

11.2.5 Deterministic Case: Largest area of entrained hydrocarbons above 100 ppb

The deterministic simulation that resulted in the largest area of entrained hydrocarbons above 100 ppb (high threshold) was identified as run number 60 during the summer period.

Figure 11.31 presents the extent of the predicted entrained hydrocarbon exposure zones over the entire 104-day simulation.

Figure 11.32 displays the time series of the area of entrained hydrocarbons at the low (≥ 10 ppb) and high (≥ 100 ppb) thresholds over the 104-day simulation.

Figure 11.33 presents the fates and weathering for the corresponding single spill trajectory and Table 11.14 summarises the peak volumes and times of occurrence for each oil phase and volumes at the end of the simulation.

Table 11.14 Summary of peak volumes and times of occurrence for each oil phase and the volumes at the conclusion of the simulation (day 104), for the trajectory with the largest area of entrained hydrocarbons above 100 ppb following a subsea LOWC at WTR Well 5.

Exposure Metrics	Peak Volume	Day of Occurrence	Volume at day 104

TERMS AND ABBREVIATIONS

°	Degrees
‘	Minutes
“	Seconds
µm	Micrometre (unit of length; 1 µm = 0.001 mm)
Actionable oil	Oil which is thick enough for the effective use of mitigation strategies
AMP	Australian Marine Park
AMSA	Australian Maritime Safety Authority
ANZECC	Australian and New Zealand Environment and Conservation Council
API	American Petroleum Institute gravity. A measure of how heavy or light a petroleum liquid is compared to water.
ARMCANZ	Agriculture and Resource Management Council of Australia and New Zealand
ASTM	American Society for Testing and Materials
bbl	Barrel (unit of volume; 1 bbl = 0.159 m^3)
bbl/d	Barrels per day
Bonn Agreement	An agreement for cooperation in dealing with pollution of the North Sea by oil and other harmful substances, 1983, includes: Governments of the Kingdom of Belgium, the Kingdom of Denmark, the French Republic, the Federal Republic of Germany, the Republic of Ireland, the Kingdom of the Netherlands, the Kingdom of Norway, the Kingdom of Sweden, the United Kingdom of Great Britain and Northern Ireland and the European Union.
BP	Boiling point. The temperature at which the vapor pressure of the liquid is equal to the pressure exerted on it by the surrounding atmosphere
BTEX	Benzene, Toluene, Ethylbenzene, and Xylenes
°C	degree Celsius (unit of temperature)
CFSR	Climate Forecast System Reanalysis
cm	Centimetre (unit of length)
cP	Centipoise (unit of dynamic viscosity)
Decay	The process where oil components are changed either chemically or biologically (biodegradation) to another compound. It includes breakdown to simpler organic carbon compounds by bacteria and other organisms, photo-oxidation by solar energy, and other chemical reactions.
Dynamic viscosity	The dynamic viscosity of a fluid expresses its resistance to shearing flows, where adjacent layers move parallel to each other with different speeds.
Floating oil exposure	Contact by floating oil on the sea surface at concentrations equal to or exceeding defined threshold concentrations. The consequence will vary depending on the threshold and the receptors
g/m^2	Grams per square meter (unit of surface area density)
GODAE	Global Ocean Data Assimilation Experiment
HYCOM	Hybrid Coordinate Ocean Model. A data-assimilative, three-dimensional ocean model
HYDROMAP	Advanced ocean/coastal tidal model used to predict tidal water levels, current speed and current direction.
IAA	Impact Assessment Area
IBRA	Interim Biogeographic Regionalisation for Australia

IMCRA	Integrated Marine and Coastal Regionalisation of Australia
ITOPF	International Tanker Owners Pollution Federation Limited
KEF	Key Ecological Feature
km	Kilometre (unit of length)
km^2	Square Kilometres (unit of area)
Knots	unit of speed (1 knot = 0.514 m/s)
LOWC	Loss of well control
m	Meter (unit of length)
m^3	Cubic meter (unit of volume)
m/s	Meter per Second (unit of speed)
MAHs	Monoaromatic Hydrocarbons
MNP	Marine National Park
MP	Marine Park
NASA	National Aeronautics and Space Administration (USA)
NCEP	National Centres for Environmental Prediction (USA)
nm	Nautical mile
NOAA	National Oceanic and Atmospheric Administration (USA)
NOPSEMA	National Offshore Petroleum Safety and Environmental Management Authority
NP	National Park
NR	Nature Reserve
PAH	Polynuclear Aromatic Hydrocarbons
Pour Point	The pour point of a liquid is the temperature below which the liquid loses its flow characteristics
ppb	Parts per billion (concentration)
psu	Practical salinity nits
RSB	Reefs, Shoals and Banks
scf	Standard cubic feet (defined as one cubic foot of gas at 15.56 °C and at normal sea level air pressure)
Shoreline contact	Arrival of oil at or near shorelines at on-water concentrations equal to or exceeding defined threshold concentrations. Shoreline contact is judged for floating oil arriving within a 2 km buffer zone from any shoreline as a conservative measure
SIMAP	Spill Impact Model Application Package. SIMAP is designed to simulate the fate and effects of spilled hydrocarbons for surface or subsea releases
Single Oil spill modelling	Oil spill modelling involving a computer simulation of a single hypothetical oil spill event subject to a single sequence of wind, current and other sea conditions over time. Single oil spill modelling, also referred to as “deterministic modelling” provides a simulation of one possible outcome of a given spill scenario, subject to the metocean conditions that are imposed. Single oil spill modelling is commonly used to consider the fate and effects of ‘worst-case’ oil spill scenarios that are carefully selected in consideration of the nature and scale of the offshore petroleum activity and the local environment (NOPSEMA, 2017). Because the outcomes of a single oil spill simulation can only represent the outcome of that scenario under one sequence of metocean conditions, worst-case conditions are often identified from stochastic modelling. It is impossible to calculate the likelihood of any outcome from a single oil spill simulation. Single oil spill modelling is generally used for response planning, preparedness planning and for supporting oil spill response operations in the event of an actual spill

SRTM	Shuttle Radar Topography Mission
Stochastic oil spill modelling	Stochastic oil spill modelling is created by overlaying and statistically analysing the outcomes of many single oil-spill simulations of a defined spill scenario, where each simulation was subject to a different sequence of metocean conditions, selected objectively (typically by random selection) from a long sequence of historic conditions for the study area. Analysis of this larger set of simulations provides a more accurate indication of the environment that maybe affected (EMBA) and indicates which locations are more likely to be affected (as well as other statistics). Stochastic oil spill modelling avoids biases that affect single oil spill modelling (due to the reliance on only one possible sequence of conditions). However, when interpreting stochastic modelling, which is based on a wide range of potential conditions that might happen to occur, it is essential to understand that calculations will encompass a much larger area than could be affected in any single spill event, where a more limited set of conditions will occur. Consequently, it is misleading to imply that the region derived from stochastic modelling indicate the outcomes expected from a single spill event (NOPSEMA, 2017) Stochastic modelling is generally used for risk assessment and preparedness planning by indicating locations that could be exposed and may require response or subsequent impact assessment
TOPEX/ Poseidon	A joint satellite mission between NASA and CNES to map ocean surface topography using an array of satellites equipped with detailed altimeters
USA	United States of America
US CG	United States Coast Guard
US EPA	United States Environmental Protection Agency
World Ocean Atlas	A collection of objectively analysed, quality controlled physicochemical parameters (e.g. temperature, salinity, oxygen, phosphate, silicate, and nitrate) based on profile data from the World Ocean Database (NCEI, 2021) established by NOAA's National Centers for Environmental Information (NCEI)
WGS 1984	World Geodetic System 1984 (WGS84); reference coordinate system

EXECUTIVE SUMMARY

Background

Chevron Australia Pty Ltd (Chevron) is the operator of the Greater Gorgon area, which includes the Geryon and Eurytion (G&E) fields situated within the Northern Carnarvon Basin in Permit area WA-22-R and WA-39-L, respectively, northwest of Barrow Island off the north-west coast of Western Australia. Chevron commissioned RPS to undertake an oil spill modelling to support environmental approvals.

The oil spill modelling study was conducted to assess the seasonal risk and potential exposure to the surrounding waters and contact to the shorelines from the following hypothetical scenario:

- **Scenario:** A 3,506 stb/day (557.47 m^3/day) subsea release of condensate over 90 days (totalling 315,540 stb or 50,165 m^3) from a loss of well control (LOWC).

The potential risk of exposure to the surrounding waters and contact to shorelines was assessed for three distinct seasons; (i) summer (September to the following March), (ii) the transitional periods (April and August) and (iii) winter (May to July). This approach assists with identifying the environmental values and sensitivities that would be at risk of exposure on a seasonal basis.

One of the purposes for the modelling is to define the 'outer boundaries' of the environment that may be affected (EMBA) in the unlikely event of hydrocarbon release. Therefore, the modelling does not take into consideration any of the spill prevention, mitigation and response capabilities that would be implemented in response to the spill.

Methodology

The modelling study was carried out in stages. Firstly, a 10-year current dataset (2010–2019) that includes the combined influence of large-scale ocean and nearshore tidal currents was developed. Secondly, the currents, local winds and detailed hydrocarbon characteristics were used as inputs in the three-dimensional oil spill model (SIMAP) to simulate the drift, spread, weathering and fate of the spilled oil.

As spills can occur during any set of wind and current conditions, modelling was conducted using a stochastic (or probabilistic) approach, which involved running 100 spill simulations per season, with each simulation having the same spill information (spill volume, duration and composition of hydrocarbons) but randomly selected start time. This ensured that each spill trajectory was subjected to varying wind and current conditions.

Condensate Properties

Geryon condensate has an API of 42.67, a density of 810 kg/m^3 (at 15ºC) and a low viscosity value of 5.2 cP. When exposed to the atmosphere at local temperatures, about 31.5% of the condensate volatile components should evaporate within the first 12 hours (BP < 180°C); a further 27.1% of the semi-volatiles should evaporate within the first 24 hours (180°C < BP < 265°C); and low volatile portion (~31.7%) should evaporate over a longer period (265°C < BP < 380°C). Additionally, 9.7% of the condensate is shown to be persist in the marine environment for much longer periods and be subject to relatively slow degradation.

This condensate has a low asphaltene content (< 0.5%), indicating a very low propensity for the mixture to take up water to form water-in-oil emulsion over the weathering cycle. The soluble aromatic hydrocarbons contribute approximately 2.9% by mass of the whole oil, which is contained in the volatile fractions, which are highly soluble.

Key Findings

- The maximum distance from the release location to the low (≥ 1 g/m^2) and moderate (≥ 10 g/m^2) thresholds was 132.6 km south (summer) and 60.4 km southeast (winter), respectively. No exposure was predicted at the high (≥ 50 g/m^2) threshold.

- The Offshore Area IAA, Pygmy Blue Whale - Distribution and Wedge-tailed Shearwater - Breeding BIAs, which the release location resides within, were the only receptors predicted to be exposed during all three seasons at the low and moderate thresholds. The probabilities for the low threshold was 100% for all seasons for these receptors. Probabilities of moderate exposure for these rectors ranged between 51% (all receptors; summer) and 82% (Pygmy Blue Whale - Distribution (BIA) and Offshore Area IAA); winter). Additionally, the Flatback Turtle - Internesting Buffer and Whale Shark - Foraging BIAs were also predicted to be exposed at the low threshold during summer (7% and 1%), transitional (13% and 6%) and winter (15% and 13%), respectively. The minimum time before low exposure for the Flatback Turtle - Internesting Buffer and Whale Shark - Foraging BIAs was 5.79 days during summer conditions. Furthermore, the probability of exposure at the low threshold for the Continental Slope Demersal Fish Communities (KEF) was 96%, 80% and 84% during summer, transitional and winter, respectively. The corresponding minimum time before low exposure at the Continental Slope Demersal Fish Communities (KEF) was 1.88 days (summer).

- The probability of shoreline accumulation on any shoreline at, or above, the low threshold (≥ 10 g/m^2) was greatest during summer at 23%, while the minimum time before shoreline accumulation was 7.46 days and the maximum volume of oil ashore 23.2 m^3. Additionally, no shoreline accumulation was predicted during transitional conditions, nor was there any high (≥ 1,000 g/m^2) shoreline threshold accumulation predicted during any seasonal conditions modelled.

- During summer conditions, condensate had accumulated on 38 shoreline receptors at, or above, the low threshold with the greatest probability predicted for Barrow & Montebello Islands IAA and Barrow Island Group (15%). In comparison, during winter conditions, condensate was predicted to accumulate on 4 shoreline receptors and each with an 8% probability.

- No dissolved hydrocarbon exposure was predicted for this scenario at, or above, the low reporting threshold (≥10 ppb) during any of the seasons modelled.

- In the 0-10 m depth layer, a total of 40, 22 and 22 BIAs were predicted to be exposed at, or above, the low threshold during summer, transitional and winter conditions respectively. Excluding the Pygmy Blue Whale - Distribution and Wedge-tailed Shearwater – Breeding BIAs which the release location resides within, the highest probabilities of exposure were predicted for Humpback Whale - Migration BIA (95% summer, 91% transitional and 87% winter). Additionally, within the same depth layer, during summer, transitional and winter conditions, 8, 7 and 7 KEFs were predicted to be exposed at the low threshold, respectively. Probabilities ranged between 2–100%, 2–100% and 3–100% for summer, transitional and winter, respectively.

- In the 0-10 m depth layer, a total of 50, 17 and 15 IAA (including the Offshore IAA that the release site is located within), were predicted to be exposed to entrained hydrocarbons at low threshold during summer, transitional and winter conditions, respectively. Excluding the Offshore IAA, the probabilities for each season ranged between 1–92%, 1–97% and 1–86% under summer, transitional and winter conditions, respectively with the maximum probabilities occurring at the Gascoyne IAA during all seasons. Furthermore, 59, 5 and 4 RSB receptors were predicted to be exposed to entrained hydrocarbons at the low threshold during summer, transitional and winter conditions, respectively. Maximum summer, transitional and winter probabilities of 23% for Rankin Bank, 6% for Rankin Bank and Outtrim Patches and 14% for Outtrim Patches, respectively, were predicted.

1 INTRODUCTION

Chevron Australia Pty Ltd (Chevron) is the operator of the Greater Gorgon area, which includes the Geryon and Eurytion (G&E) fields situated within the Northern Carnarvon Basin in Permit area WA-22-R and WA-39-L, respectively, northwest of Barrow Island off the north-west coast of Western Australia.

As part of the planned development for the G&E fields, Chevron commissioned RPS to undertake a comprehensive oil spill modelling study to support environmental approvals. The modelling study assessed the seasonal risk and potential exposure to the surrounding waters and contact to the shorelines from the following hypothetical scenario:

- **Scenario:** A 3,506 stb/day (557.47 m^3/day) subsea release of condensate over 90 days (totalling 315,540 stb or 50,165 m^3) from a loss of well control (LOWC).

The release location used for the oil spill assessment is presented in Table 1.1 and illustrated in Figure 1.1.

The potential risk of exposure to the surrounding waters and contact to shorelines was assessed for three distinct seasons; (i) summer (September to the following March), (ii) the transitional periods (April and August) and (iii) winter (May to July). This approach assists with identifying the environmental values and sensitivities that would be at risk of exposure on a seasonal basis.

One of the purposes for the modelling is to define the 'outer boundaries' of the environment that may be affected (EMBA) in the unlikely event of hydrocarbon release. Therefore, the modelling does not take into consideration any of the spill prevention, mitigation and response capabilities that would be implemented in response to the spill.

The spill modelling was performed using an advanced three-dimensional trajectory and fates model; Spill Impact Mapping Analysis Program (SIMAP). The SIMAP model calculates the transport, spreading, entrainment and evaporation of spilled hydrocarbons over time, based on the prevailing wind and current conditions and the physical and chemical properties.

The hydrocarbon spill model, the method and analysis applied herein uses modelling algorithms which have been peer reviewed and published in international journals. Further, RPS warrants that this work meets and exceeds the American Society for Testing and Materials (ASTM) Standard F2067-13 "*Standard Practice for Development and Use of Oil Spill Models*".

2 SCOPE OF WORK

The scope of work included the following components:

1. Generate 10-years (2010 to 2019 (inclusive)) of wind and current data. The three-dimensional current data includes the combined influence of ocean and tidal currents;

2. Include the wind data, current data and condensate properties characteristics into the three-dimensional oil spill model; SIMAP, to model the movement, spreading, entrainment, weathering and potential shoreline accumulation over time;

3. Run 100 simulations for each season (i.e. 300 simulations total), with each simulation having the same spill information (location, volume, duration and condensate properties) but randomly varying start times. This ensured that each spill simulation was subjected to unique wind and current conditions;

4. Combine the results from the 100 spill simulations to assess the exposure to waters and shoreline accumulation based upon the NOPSEMA thresholds; and

5. From the 300 simulations modelled, identify and present the “worst case” deterministic runs, which can be used to inform response planning based on the following criteria:
    a. Largest swept area of floating hydrocarbon above 10 g/m^2
    b. Largest swept area of floating hydrocarbon above 50 g/m^2
    c. Largest volume of oil ashore
    d. Longest length of shoreline accumulation above 100 g/m^2
    e. Largest area of entrained hydrocarbons above 100 ppb
    f. Largest area of dissolved hydrocarbons above 50 ppb

As there was no floating hydrocarbons at or above 50 g/m^2 and no dissolved hydrocarbon exposure at or above 50 ppb, for any of the 300 simulations, the deterministic results are presented based on criteria a, c, d and e only.

3 REGIONAL CURRENTS

The study area is located within the Northern Carnarvon Basin, on the North West Shelf, a waterbody bordered by the Indian Ocean and Timor Sea. The North West Shelf is characterised by complex geomorphological features such as shoals, valleys and terraces and is dominated by high-amplitude tides and seasonally-dependant wind driven currents (DEWHA, 2007).

Although the Indonesian Throughflow and Holloway current generate south-westerly flows all year-round, warm and less saline waters originating from the tropics can generate internal gyres that typically migrate through the area and result in large variation in the speed and direction of local currents. The Holloway current generally intensifies during April to July due to increased wind forcing.

A comprehensive description of the circulation patterns of the North West Shelf is provided in a review by Condie and Andrewartha (2008) and a schematic of the ocean currents along the Northwest Australian continental shelf is shown in Figure 3.1.

While, tidal currents are generally weaker in the deeper waters, its influence is greatest along the near shore and around islands. Therefore, to accurately account for the movement of an oil spill, which can move between the offshore and near shore region, ocean and tidal currents were combined as part of the study.

Figure 3.2 and Figure 3.3 present summer and winter current trends within the Carnarvon Basin and the North West Shelf.

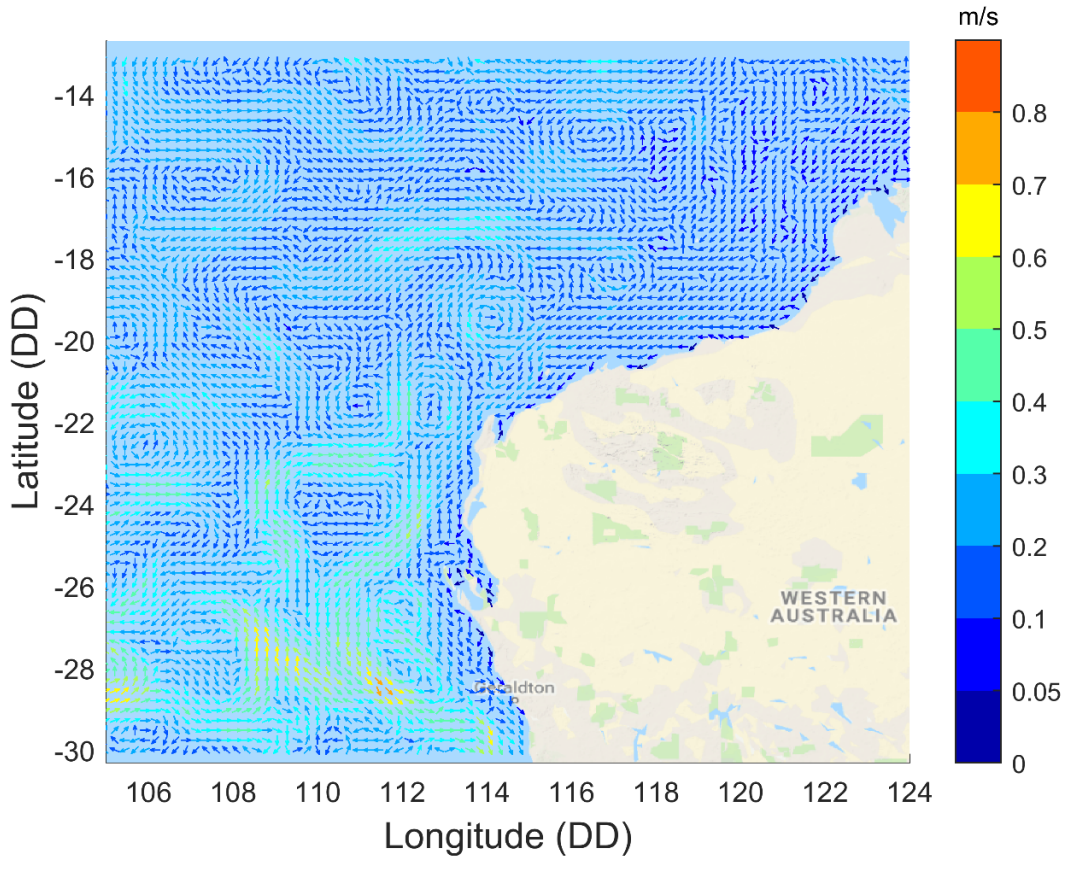

Figure 3.3 Typical ocean current circulation pattern during the winter months.

3.1 Tidal Currents

Tidal current data was generated using RPS's advanced ocean/coastal model, HYDROMAP. The HYDROMAP model has been thoroughly tested and verified through field measurements throughout the world over the past 38 years (Isaji & Spaulding, 1984; Isaji, et al., 2001; Zigic, et al., 2003). HYDROMAP tidal current data has been used as input to forecast (in the future) and hindcast (in the past) pollutant spills in Australian waters and forms part of the Australian National Oil Spill Emergency Response System operated by AMSA (Australian Maritime Safety Authority).

HYDROMAP employs a sophisticated sub-gridding strategy, which supports up to six levels of spatial resolution, halving the grid cell size as each level of resolution is employed. The sub-gridding allows for higher resolution of currents within areas of greater bathymetric and coastline complexity, and/or of particular interest to a study.

The numerical solution methodology follows that of Davies (1977a and 1977b) with further developments for model efficiency by Owen (1980) and Gordon (1982). A more detailed presentation of the model can be found in Isaji and Spaulding (1984) and Isaji et al. (2001).

3.1.1 Grid Setup

The tidal model domain has been sub-gridded to a resolution of 500 m for shallow and coastal regions, starting from an offshore (or deep water) resolution of 8 km. The finer grids were allocated in a step-wise fashion to resolve flows more accurately along the coastline, around islands and over regions with more complex bathymetry. Figure 3.4 shows the tidal model grid resolutions.

A combination of datasets was used and merged to describe the shape of the seabed within the grid domain (Figure 3.5). These included spot depths and contours which were digitised from nautical charts released by the hydrographic offices as well as Geoscience Australia database and depths extracted from the Shuttle Radar Topography Mission (SRTM30_PLUS) Plus dataset (see Becker et al., 2009).

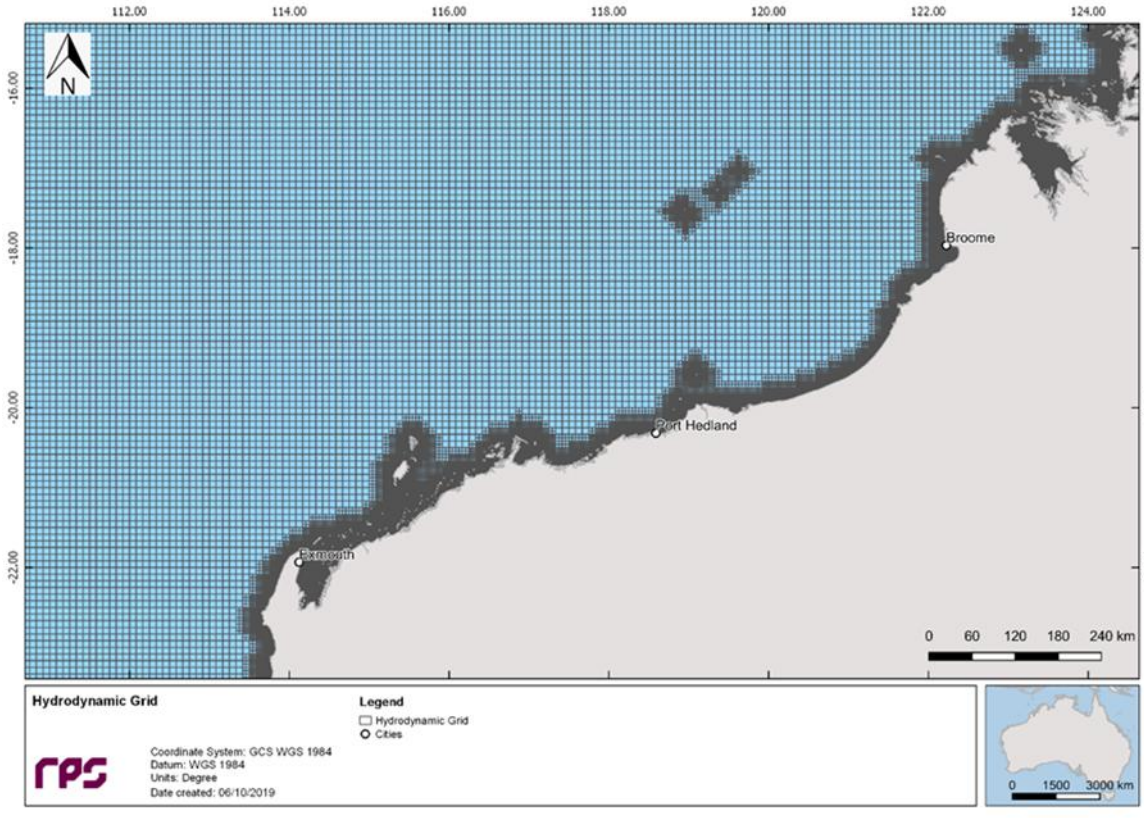

Figure 3.4 Zoomed in view of the model grid used to generate the tidal currents for the study region. Higher resolution areas are shown by the denser mesh.

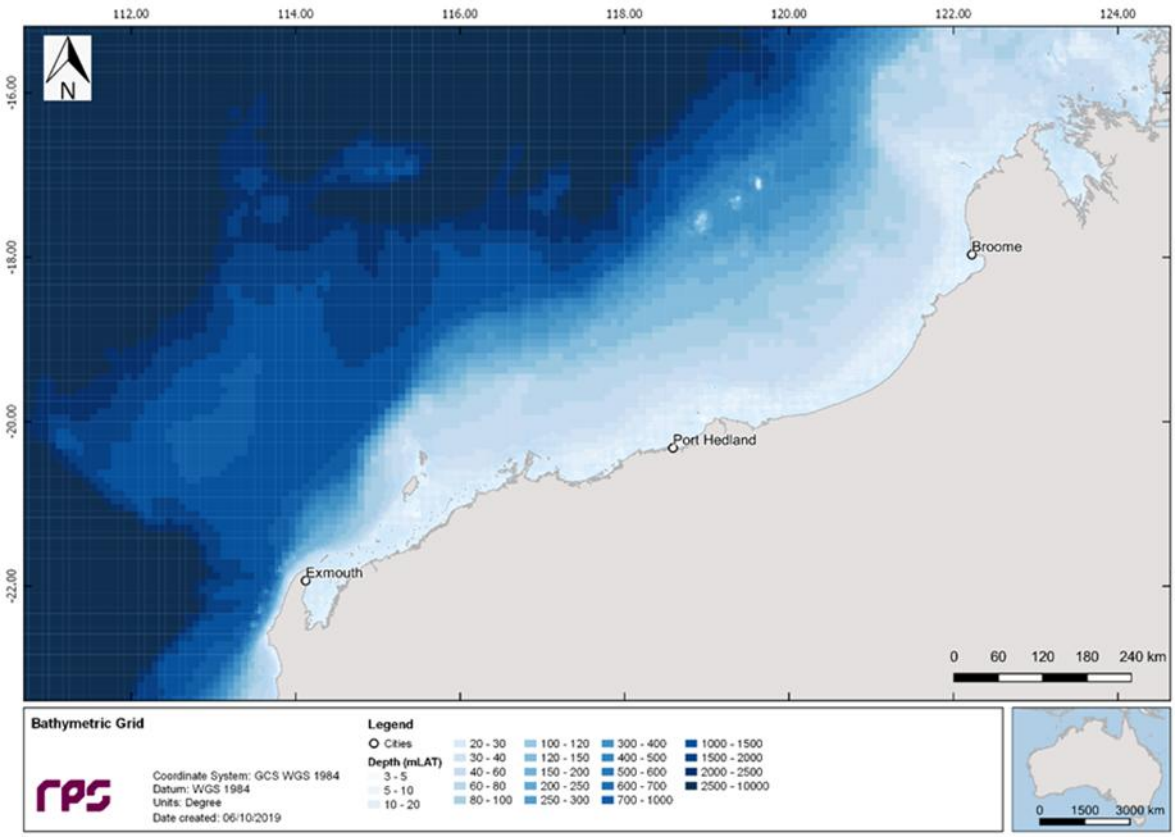

Figure 3.5 Bathymetry defined throughout the tidal model domain.

3.1.2 Tidal Conditions

The ocean boundary data for the regional model was obtained from satellite measured altimetry data (TOPEX/Poseidon 7.2) which provided estimates of the eight dominant tidal constituents at a horizontal scale of approximately 0.25 degrees. The eight major tidal constituents used were K_2, S_2, M_2, N_2, K_1, P_1, O_1 and Q_1. Using the tidal data, surface heights were firstly calculated along the open boundaries, at each time step in the model.

The TOPEX/Poseidon satellite data has a global resolution of 0.25 degrees and is produced and quality controlled by NASA (National Aeronautics and Space Administration). The satellites equipped with two highly accurate altimeters and capable of taking sea level measurements with an accuracy of ± 5 cm measured oceanic surface elevations (and the resultant tides) for over 13 years (1992–2005). In total, these satellites carried out 62,000 orbits of the planet.

The TOPEX/Poseidon tidal data has been widely used amongst the oceanographic community, being included in more than 2,100 research publications (e.g. Andersen, 1995; Ludicone et al., 1998; Matsumoto et al., 2000; Kostianoy et al., 2003; Yaremchuk and Tangdong, 2004; Qiu and Chen 2010). As such the TOPEX/Poseidon tidal data is considered suitably accurate for this study.

3.2 Ocean Currents

Data describing the flow of ocean currents was obtained from HYCOM (Hybrid Coordinate Ocean Model, (Chassignet et al., 2007), which is operated by the HYCOM Consortium, sponsored by the National Ocean Partnership Program (NOPP), as part of the U.S. Global Ocean Data Assimilation Experiment (GODAE). HYCOM is a data-assimilative, three-dimensional ocean model that is run as a hindcast (for a past period), assimilating time-varying observations of sea surface height, sea surface temperature and in-situ temperature and salinity measurements (Chassignet et al., 2009). The HYCOM predictions for drift currents are produced at a horizontal spatial resolution of approximately 8.25 km (1/12th of a degree) over the region, at a frequency of every 3 hours. HYCOM uses isopycnal layers in the open, stratified ocean, but uses the layered continuity equation to make a dynamically smooth transition to a terrain following coordinate in shallow coastal regions, and to z-level coordinates in the mixed layer and/or unstratified seas.

For this study, the HYCOM hindcast currents were obtained for the years 2010 to 2019 (inclusive).

3.3 Surface Currents

Table 3.1 presents the predicted average and maximum monthly surface current speeds at the release location.

The month average surface current speeds ranged between 0.19 m/s (February, November and December) and 0.25 m/s (June). Additionally, the monthly maximums ranged between 0.62 m/s (November) and 1.53 m/s (January). The general surface current directions were towards the southwest. Figure 3.6 and Figure 3.7 present the monthly and total surface current rose distributions, respectively.

Note the convention for defining current direction throughout this report is the direction the current flows towards. Each branch of the current rose distribution represents the currents flowing to that direction, with north to the top of the diagram. The branches are divided into segments of different colour, which represent the current speed ranges for each direction. Speed intervals of 0.1 m/s are typically used in these current roses. The length of each coloured segment within a branch is proportional to the frequency of currents flowing within the corresponding speed and direction.

Table 3.1 Predicted monthly average and maximum surface current speeds close to the release location. Data derived by combining the HYCOM ocean data and HYDROMAP high resolution tidal data from 2010-2019 (inclusive).

Season	Month	Average current speed (m/s)	Maximum current speed (m/s)	General direction (towards)
Summer	January	0.20	1.53	Variable
	February	0.19	1.11	Variable
	March	0.21	1.35	Southwest
Transitional	April	0.23	1.02	Southwest
Winter	May	0.23	0.78	Southwest
	June	0.25	0.84	Southwest
	July	0.23	0.90	Southwest
Transitional	August	0.21	0.79	Variable
Summer	September	0.22	0.83	Northeast and Southwest
	October	0.19	0.63	Northeast and Southwest
	November	0.19	0.62	Southwest
	December	0.19	0.71	Southwest
Minimum		**0.19**	**0.62**	
Maximum		**0.25**	**1.53**	

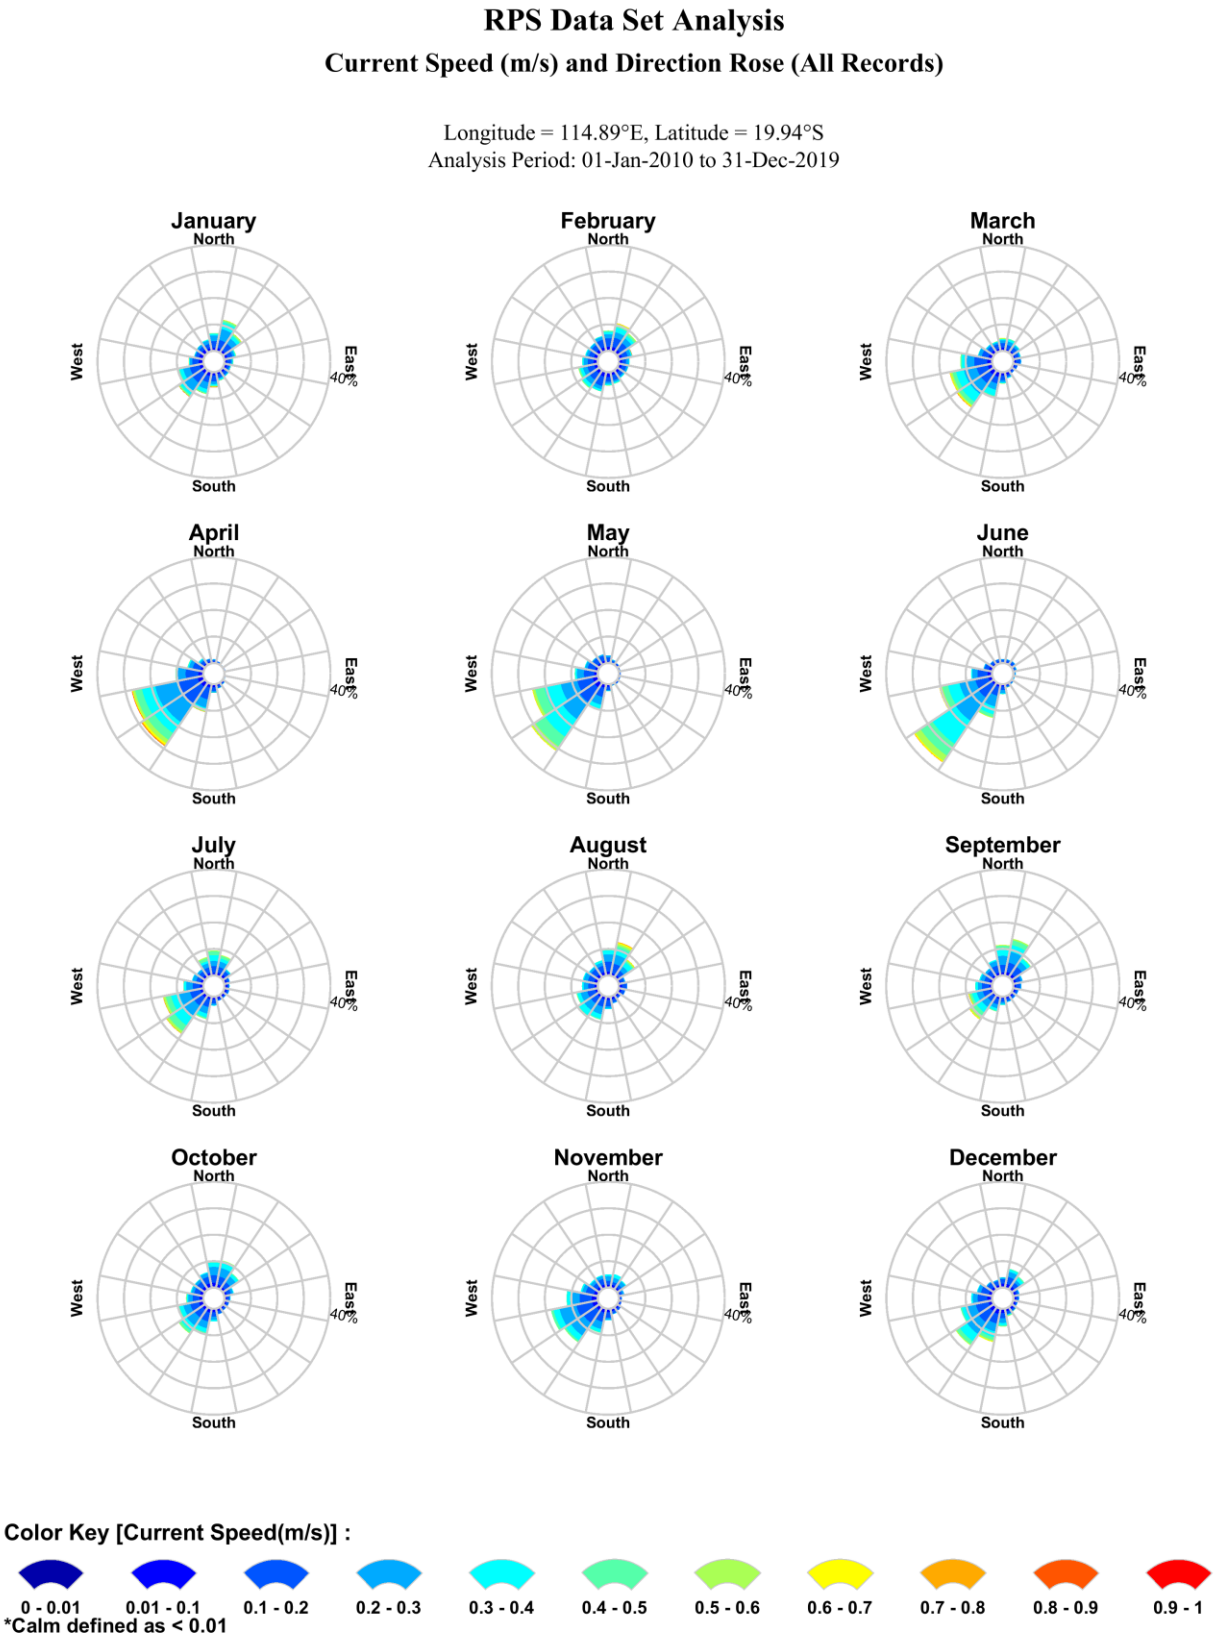

Figure 3.6 Monthly surface current rose distributions at the release location, derived from the 2010 to 2019 modelled dataset.

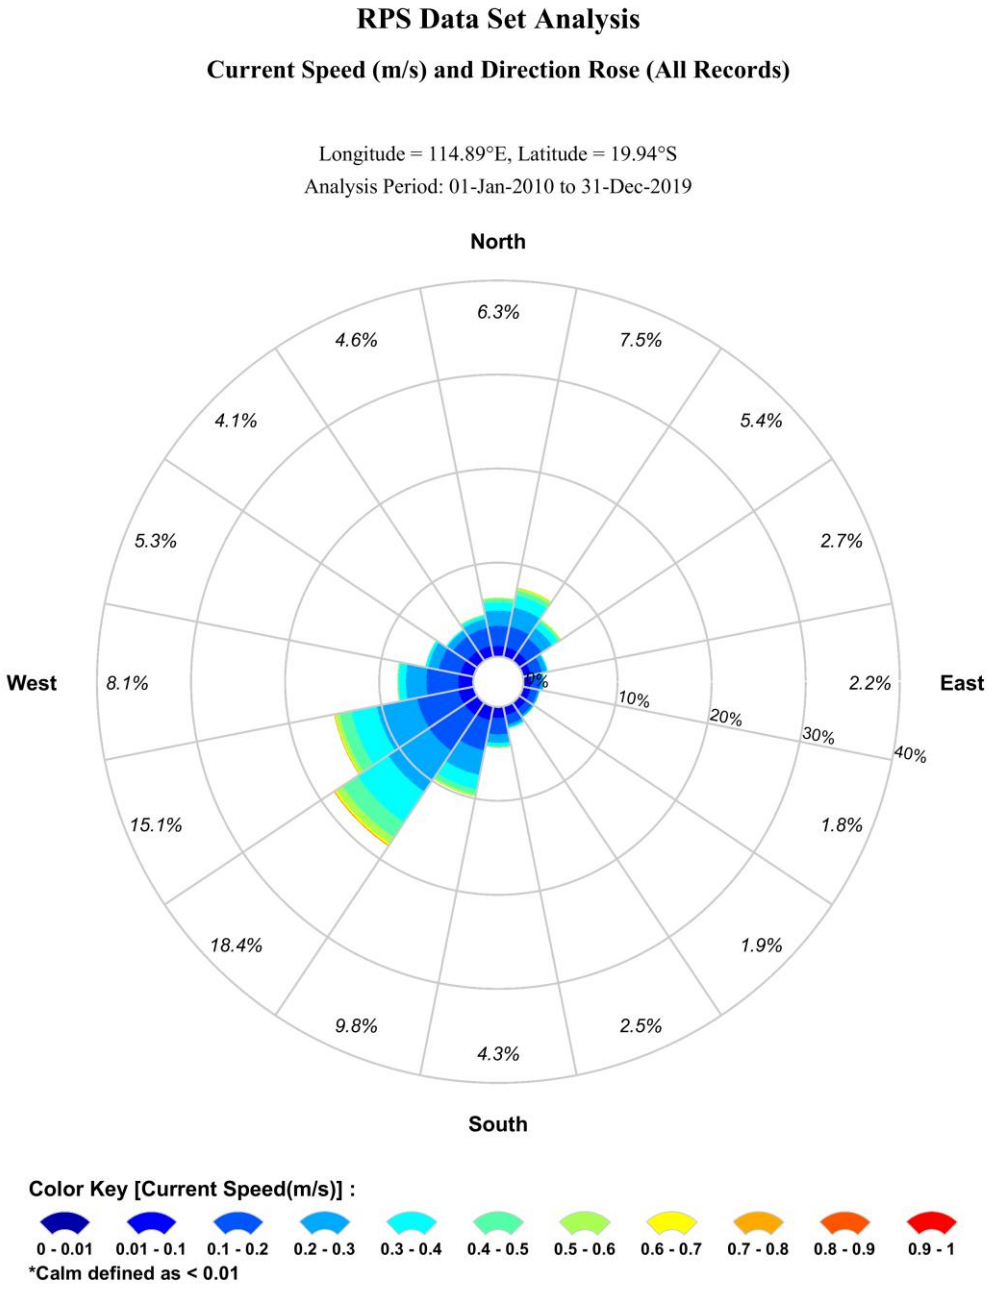

Figure 3.7 Total surface current rose plot at the release location, derived from the 2010 to 2019 modelled dataset.

4 WIND DATA

To account for the influence of the wind on the floating oil, wind data from 2010 to 2019 (inclusive) was sourced from the National Centre for Environmental Prediction (NCEP) Climate Forecast System Reanalysis (CFSR; see Saha et al., 2010). The CFSR wind model includes observations from many data sources; surface observations, upper-atmosphere air balloon observations, aircraft observations and satellite observations. The model is capable of accurately representing the interaction between the earth's oceans, land and atmosphere. The gridded wind data output is available at ¼ of a degree resolution (~33 km) and 1-hourly time intervals. Figure 4.1 shows the spatial resolution of the wind field used as input into the oil spill model.

Table 4.1 shows the monthly average and maximum winds derived from the CFSR node closest to the release location. The model wind data demonstrated that this region typically experiences moderate winds all year round and although the monthly average wind speeds remain under 15 knots. The maximum wind speed was 45 knots (July). Winds typically blow from the southwest during the summer months, while winds are typically easterly during the winter months.

Figure 4.2 and Figure 4.3 illustrates the monthly and total wind rose distributions nearby the release location, respectively.

Note that the atmospheric convention for defining wind direction, that is, the direction the wind blows from, is used to reference wind direction throughout this report. Each branch of the rose represents wind coming from that direction, with north to the top of the diagram. Sixteen directions are used. The branches are divided into segments of different colour, which represent wind speed ranges from that direction. Speed ranges of 5 knot intervals are typically used in these wind roses. The length of each segment within a branch is proportional to the frequency of winds blowing within the corresponding range of speeds from that direction.

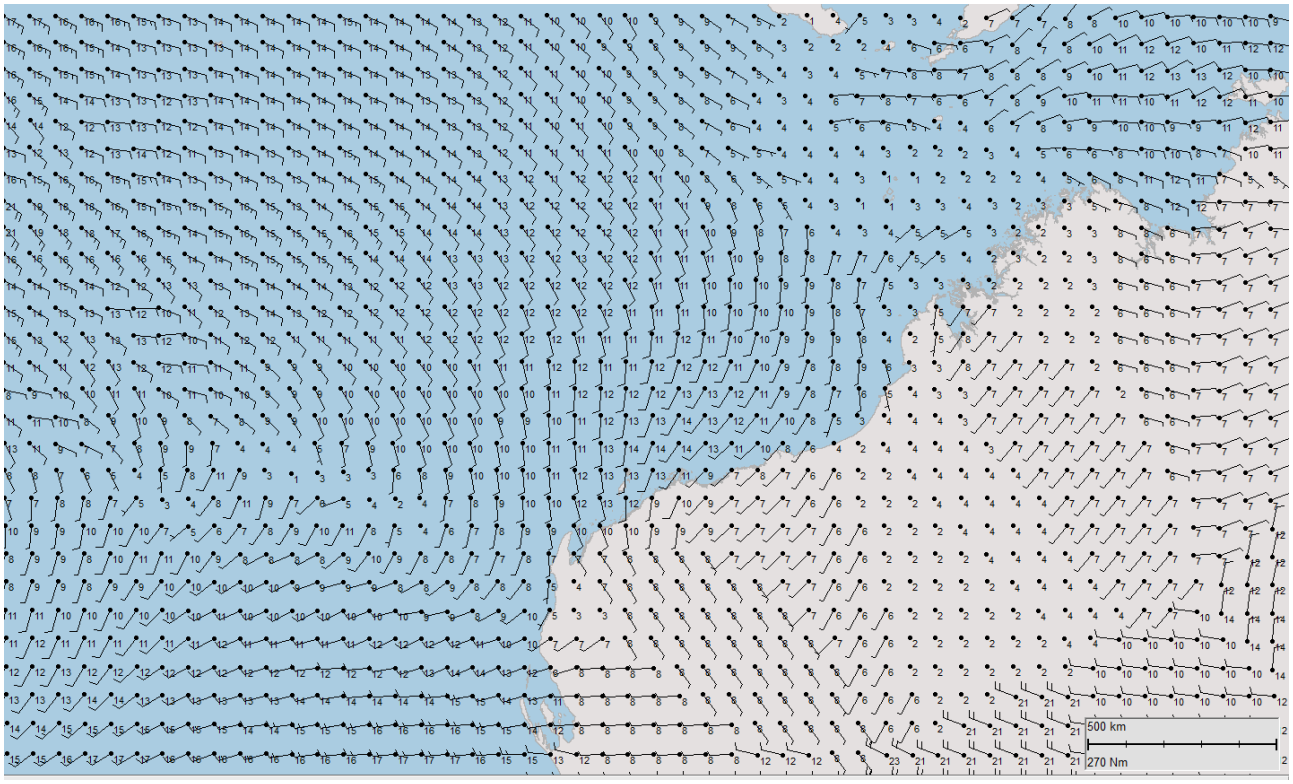

Figure 4.1 Spatial resolution of the CFSR modelled wind data used as input into the oil spill model. Note, for ease viewing only every second wind vector is displayed on the map.

Table 4.1 Predicted average and maximum winds for the wind node closest to the release location. Data derived from CFSR hindcast model 2010 to 2019 (inclusive).

Season	Month	Average wind (knots)	Maximum wind (knots)	General direction (from)
Summer	January	13	42	Southwest
	February	11	43	Southwest
	March	10	35	Southwest
Transitional	April	10	37	Variable
Winter	May	12	39	East
	June	14	30	East
	July	13	45	East to South
Transitional	August	11	30	Variable
Summer	September	12	27	South-Southwest
	October	13	26	South-Southwest
	November	13	25	South-Southwest
	December	12	30	Southwest
Minimum		**10**	**25**	
Maximum		**14**	**45**

5 WATER TEMPERATURE AND SALINITY

The monthly depth-varying water temperature and salinity profiles nearest to the release location was obtained from HYCOM (see Section 3.2 Ocean Currents).

The three-dimensional salinity and temperature datasets are used in the oil spill model domain to inform the weathering, movement, and evaporative loss of hydrocarbon spills in the surface and subsurface layers.

Table 5.1 shows that the monthly average sea surface temperatures ranged from 24.1°C (September) to 29.6°C (March), whilst salinity remained relatively consistent throughout the year, ranging between 34.5–34.9 psu.

Figure 5.1 the vertical profile of sea temperature and salinity nearby the release location.

Table 5.1 Monthly average sea surface temperature and salinity near the release location in the 0-5 m depth layer.

Month	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sept	Oct	Nov	Dec
Temperature (°C)	27.8	28.6	29.6	28.9	27.8	26.9	25.4	24.4	24.1	24.9	27.2	27.0
Salinity (psu)	34.9	34.6	34.6	34.5	34.7	34.8	34.6	34.7	34.7	34.7	34.7	34.7

6 SUBSEA PLUME MODEL – OILMAP DEEP

The LOWC scenario is a high-pressure release of mostly gas and condensate and where gas is released with condensate, the buoyancy of the expanding gas cloud will entrain ambient seawater and propel the droplets towards the surface at a faster rate than would occur from the relative buoyancy of the condensate alone. Furthermore, the turbulence generated by such an intense discharge will tend to break the condensate up into droplets of various sizes.

To define the near-field plume dynamics, the subsea blowout model, OILMAP-DEEP, was applied. The model simulates the plume rise dynamics in two phases, the initial jet phase and the buoyant plume phase. The initial jet phase governs the plume dynamics directly above the subsurface release location and is predominately driven by the exit velocity. During this phase, the condensate droplet size and distribution is calculated. Next, the rise dynamics are dominated by the buoyant nature of the plume until the termination of the plume phase (known as the trapping depth). At this point, the results from OILMAP-DEEP (including plume trapping depth, plume diameter and droplet size distribution) are integrated into the far-field model SIMAP to simulate the rise and dispersion of the condensate droplets.

More details on the OILMAP-DEEP model, can be found in Spaulding et al. (2015). The model has been validated against observations from Deepwater Horizon as well as small and large-scale laboratory studies on subsurface oil releases (Brandvik et al., 2013, 2014; Belore, 2014; Spaulding et al., 2015; Li et al., 2017).

Table 6.1 presents the input parameters for the OILMAP-DEEP model and key results related to the near-field plume dynamics. The results indicated that the mixture of gas and condensate rose through the water column (whilst gradually losing momentum) to a trapping depth of approximately 688 m below mean sea level. After this point the condensate droplets would rise due to their own buoyancy. The modelling predicted droplets ranging in size from 151 to 654 µm.

Figure 6.1 illustrates the various stages of an example blowout plume.

Table 6.1 Input data and key results for the subsea plume modelling.

Input Variable	Value
Scenario	Loss of Well Control
Well name	GER FL2
Water depth (m)	1,100
Tubing diameter (inch) [m]	7 5/8 [0.194]
Condensate rate (stb/day)	3,506
Gas rate (MMscf/day)	551
Gas to condensate ratio (scf/bbl)	157,159
Formation water flow rate (stb/day)	0
Operating pressure (psia)	4,670
Key results	
Plume execution depth (m BMSL)	688
Droplet sizes (µm)	151 to 654

7 OIL SPILL MODEL – SIMAP

Modelling of the fate of oil was performed using the Spill Impact Mapping Analysis Program (SIMAP). SIMAP is designed to simulate the fate and effects of spilled hydrocarbons for both the surface and subsurface releases (Spaulding et al. 1994; French et al. 1999; French-McCay, 2003, 2004; French-McCay et al. 2004).

SIMAP has been used to predict the weathering and fate of oil spills during and after major incidents including: Montara (Australia) well blowout August 2009 in the Timor Sea (Asia-Pacific ASA, 2010); Macondo (USA) well blowout April 2010 in the Gulf of Mexico; Bohai Bay (China) oil spill August 2011; and the pipeline oil spill July 2013 in the Gulf of Thailand.

The SIMAP model calculates the transport, spreading, entrainment, evaporation and decay of surface hydrocarbon slicks as well as the entrained and dissolved oil components in the water column, either from surface slicks or from oil discharged subsea. The movement and weathering of the spilled oil is calculated for specific oil types. Input specifications for oil mixtures include the density, viscosity, pour point, distillation curve (volume lost versus temperature) and the aromatic/aliphatic component ratios within given boiling point ranges.

SIMAP is a three-dimensional model that allows for various response actions to be modelled including oil removal from skimming, burning, or collection booms, and surface and subsurface dispersant application. The SIMAP oil spill model includes advanced weathering algorithms, specifically focussed on unique oils that tend to form emulsions and/or tar balls. The weathering algorithms are based on five years of extensive research conducted in response to the Deepwater Horizon oil spill in the Gulf of Mexico (French et al., 2015).

Biodegradation is included in the oil spill model. In the model, SIMAP, degradation is calculated for the surface slick, deposited oil on the shore, the entrained oil and dissolved constituents in the water column, and oil in the sediments. For surface oil, water column oil and sedimented oil a first order degradation rate is specified. Biodegradation rates are relatively high for hydrocarbons in dissolved state or in dispersed small droplets.

7.1 Stochastic Modelling

Stochastic oil spill modelling is created by overlaying a great number (often 100 hundred) simulated hypothetical oil spills (Figure 7.1). Stochastic modelling involves running numerous individual oil spill simulations using a range of prevailing wind and current conditions that are historically representative of the season and location of where the spill event may occur.

For the stochastic modelling presented herein, **100 spills** were simulated per season using the same spill information (release location, spill volume, duration and condensate properties) but with varied start dates and times corresponding to the period represented by the available wind and current data. During each simulation, the model records whether any grid cells are exposed to any hydrocarbon concentrations, the concentrations involved and the elapsed time before exposure. For each scenario the results of all 100 condensate spill simulations were analysed to determine the following seasonal statistics for every grid cell:

- Exposure load (concentrations and volumes);
- Minimum time before exposure;
- Probability of contact above defined concentrations;
- Volume of condensate that may strand on shorelines from any single simulation;
- Concentration that might occur on sections of individual shorelines;
- Exposure (instantaneous and/or over a specified duration) to dissolved hydrocarbons in the water column; and
- Exposure (instantaneous and/or over a specified duration) to entrained hydrocarbons in the water column.

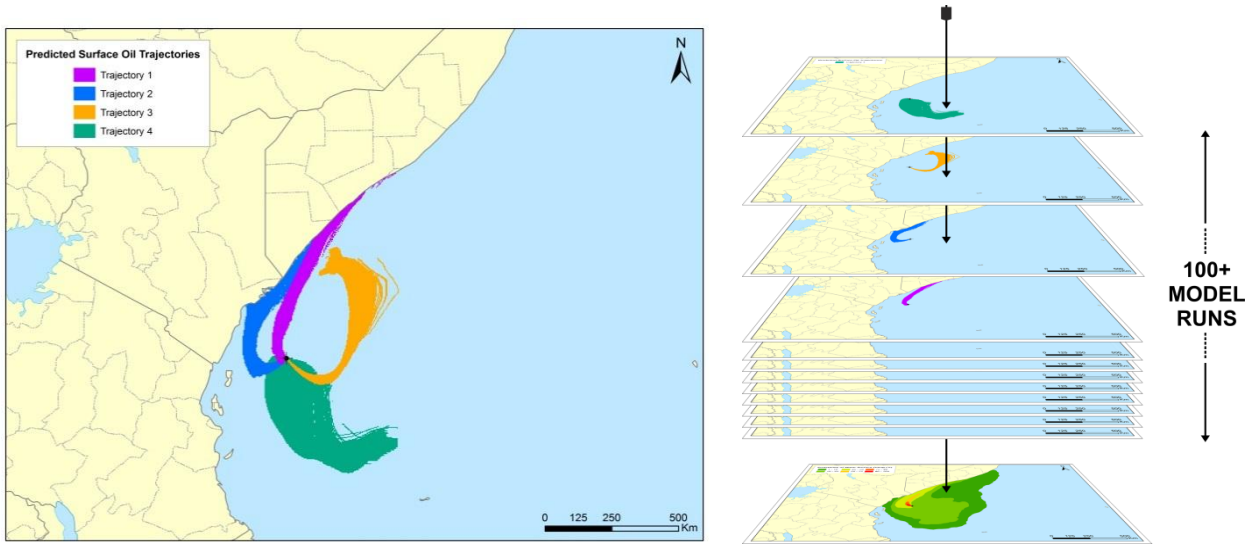

Figure 7.1 Predicted movement of four single oil spill simulations by SIMAP for the same scenario (left image). All model runs are overlain (shown as the stacked runs on the right) and the number of times that trajectories contact a given location at a concentration is used to calculate the probability (Source: NOPSEMA, 2018).

7.2 Floating, Shoreline and In-Water Thresholds

The thresholds and their relationship to exposure for the sea surface, shoreline and water column (entrained and dissolved hydrocarbons) are presented in Sections 7.2.1 to 7.2.3. Supporting justifications of the adopted thresholds applied during the study and additional context relating to the area of influence are also provided. It is important to note that the thresholds herein are based on NOPSEMA (2019).

7.2.1 Floating Oil Exposure Thresholds

The modelling results can be presented to any levels; therefore, thresholds have been specified (based on scientific literature) to record floating oil exposure to the sea-surface at meaningful levels only, described in the following paragraphs.

The low threshold to assess the potential for floating oil exposure, was 1 g/m^2, which equates approximately to an average thickness of 1 µm, referred to as visible oil. Oil of this thickness is described as rainbow sheen in appearance, according to the Bonn Agreement Oil Appearance Code (Bonn Agreement, 2009; AMSA, 2014) (see Table 7.1). Figure 7.2 shows photographs highlighting the difference in appearance between a silvery sheen, rainbow sheen and metallic sheen. This threshold is considered below levels which would cause environmental harm and it is more indicative of the areas perceived to be affected due to its visibility on the sea surface and potential to trigger temporary closures of areas (i.e. fishing grounds) as a precautionary measure. Table 7.1 provides a description of the appearance in relation to exposure zone thresholds used to classify the zones of floating oil exposure.

Ecological impact has been estimated to occur at 10 g/m^2 (a film thickness of approximately 10 µm or 0.01 mm) according to French et al. (1996) and French-McCay (2009) as this level of fresh oiling has been observed to mortally impact some birds through adhesion of oil to their feathers, exposing them to secondary effects such as hypothermia. The appearance of oil at this average thickness has been described as a metallic sheen (Bonn Agreement, 2009). Concentrations above 10 g/m^2 is also considered the lower actionable threshold, where oil may be thick enough for containment and recovery as well as dispersant treatment (AMSA, 2015).

Scholten et al. (1996) and Koops et al. (2004) indicated that at oil concentrations on the sea surface of 25 g/m^2 (or greater), would be harmful for all birds that have landed in an oil film due to potential

contamination of their feathers, with secondary effects such as loss of temperature regulation and ingestion of oil through preening. The appearance of oil at this thickness is also described as metallic sheen (Bonn Agreement, 2009). For this study the high exposure threshold was set to 50 g/m^2 and above based on NOPSEMA (2019). This threshold can also be used to inform response planning.

Table 7.2 defines the thresholds used to classify the zones of floating oil exposure reported herein.

Table 7.1 The Bonn Agreement Oil Appearance Code.

Code	Description Appearance	Layer Thickness Interval (g/m^2 or µm)	Litres per km^2
1	Sheen (silvery/grey)	0.04 – 0.30	40 – 300
2	Rainbow	0.30 – 5.0	300 – 5,000
3	Metallic	5.0 – 50	5,000 – 50,000
4	Discontinuous True Oil Colour	50 – 200	50,000 – 200,000
5	Continuous True Oil Colour	≥ 200	≥ 200,000

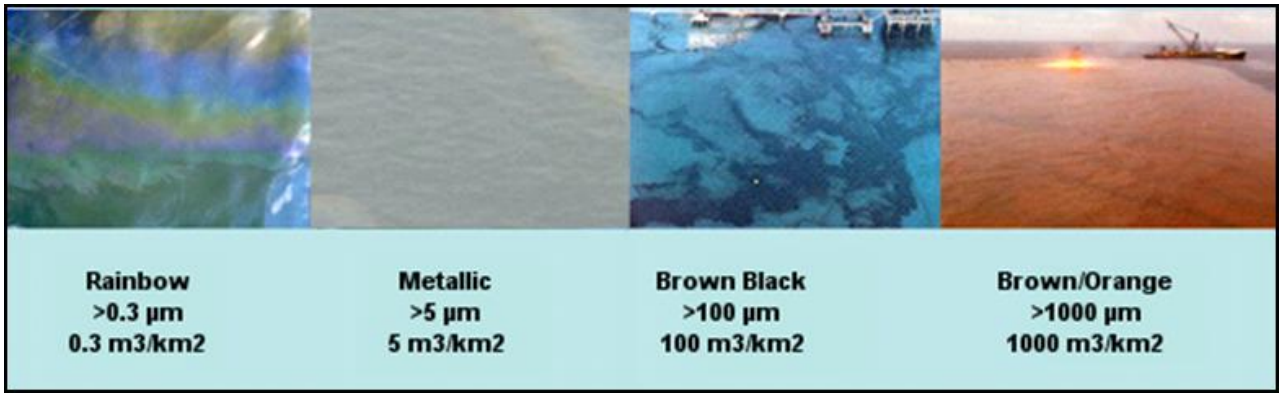

Figure 7.2 Photographs showing the difference between oil colour and thickness on the sea surface (source: adapted from Oil Spill Solutions, 2015).

Table 7.2 Floating oil exposure thresholds used in this report (in alignment with NOPSEMA, 2019).

Threshold level	Floating oil (g/m^2)	Description
Low	1	Approximates range of socioeconomic effects and establishes planning area for scientific monitoring
Moderate	10	Approximates lower limit for harmful exposures to birds and marine mammals
High	50*	Approximates surface oil slick and informs response planning

* 50 g/m^2 also used to define the threshold for actionable floating oil.

7.2.2 Shoreline Accumulation Thresholds

There are many different types of shorelines, ranging from cliffs, rocky beaches, sandy beaches, mud flats and mangroves, and each of these influences the volume of oil that can remain stranded ashore and its thickness before the shoreline saturation point occurs. For instance, a sandy beach may allow oil to percolate through the sand, thus increasing its ability to hold more oil ashore over tidal cycles and various

wave actions than an equivalent area of water; hence oil can increase in thickness onshore over time. A sandy beach shoreline was assumed as the default shoreline type for the modelling herein, as it allows for the highest carrying capacity of oil (of the available open/exposed shoreline types). Hence the results contained herein would be indicative of a worst-case scenario, where the highest volume of oil may be stranded on the shoreline (when compared to other shoreline types, such as exposed rocky shores).

In previous risk assessment studies, French-McCay et al. (2005a; 2005b) used a threshold of 10 g/m^2 to assess the potential for shoreline accumulation. This is a conservative threshold used to define regions of socio-economic impact, such as triggering temporary closures of adjoining fisheries or the need for shore clean-up on beaches or man-made features/amenities (breakwaters, jetties, marinas, etc.). It would equate to approximately 2 teaspoons of hydrocarbon per square meter of shoreline accumulation. The appearance is described as a stain/film. On that basis, the 10 g/m^2 shoreline accumulation threshold has been selected to define the zone of potential "low shoreline accumulation".

French et al. (1996) and French-McCay (2009) define a shoreline oil accumulation threshold of 100 g/m^2, or above, would potentially harm shorebirds and wildlife (furbearing aquatic mammals and marine reptiles on or along the shore) based on studies for sub-lethal and lethal impacts. This threshold has been used in previous environmental risk assessment studies (see French-McCay, 2003; French-McCay et al., 2004, French-McCay et al., 2011; 2012; NOAA, 2013). Additionally, a shoreline concentration of 100 g/m^2, or above, is the minimum limit that the oil can be effectively cleaned according to the AMSA (2015) guideline. This threshold equates to approximately ½ a cup of oil per square meter of shoreline accumulation. The appearance is described as a thin oil coat. Therefore, 100 g/m^2 has been selected to define the zone of potential "moderate shoreline accumulation".

Observations by Lin & Mendelssohn (1996) demonstrated that loadings of more than 1,000 g/m^2 of hydrocarbon during the growing season would be required to impact marsh plants significantly. Similar thresholds have been found in studies assessing hydrocarbon impacts on mangroves (Grant et al., 1993; Suprayogi & Murray 1999). Hence, 1,000 g/m^2 has been selected to define the zone of potential "high shoreline accumulation". It equates to approximately 1 litre of hydrocarbon per square meter of shoreline accumulation. The appearance is described as a hydrocarbon cover.

It is worth noting that the shoreline accumulation thresholds derived from extensive literature review (outlined in Table 7.3) agree with the commonly used threshold values for oil spill modelling specified in NOPSEMA (2019).

Table 7.3 Thresholds used to assess shoreline accumulation.

Threshold level	Shoreline accumulation (g/m^2)	Description
Low (socioeconomic/sublethal)	10	Predicts potential for some socio-economic impact
Moderate	100*	Loading predicts area likely to require clean-up effort
High	> 1,000	Loading predicts area likely to require intensive clean-up effort

* 100 g/m^2 also used to define the threshold for actionable shoreline oil.

7.2.3 In-water Exposure Thresholds

Oil is a mixture of thousands of hydrocarbons of varying physical, chemical, and toxicological characteristics, and therefore, demonstrate varying fates and impacts on organisms. As such, for in-water exposure, the SIMAP model provides separate outputs for dissolved and entrained hydrocarbons from oil droplets. The consequences of exposure to dissolved and entrained components will differ because they have different modes and magnitudes of effect.

Entrained hydrocarbon concentrations were calculated based on oil droplets that are suspended in the water column, though not dissolved. The composition of this oil would vary with the state of weathering (oil age) and may contain soluble hydrocarbons when the oil is fresh. Calculations for dissolved hydrocarbons

specifically calculates oil components which are dissolved in water, which are known to be the primary source of toxicity exerted by oil.

7.2.3.1 Dissolved Hydrocarbons

Laboratory studies have shown that dissolved hydrocarbons exert most of the toxic effects of oil on aquatic biota (Carls et al., 2008; Nordtug et al., 2011; Redman, 2015). The mode of action is a narcotic effect, which is positively related to the concentration of soluble hydrocarbons in the body tissues of organisms (French-McCay, 2002). Dissolved hydrocarbons are taken up by organisms directly from the water column by absorption through external surfaces and gills, as well as through the digestive tract. Thus, soluble hydrocarbons are termed “bioavailable”.

Hydrocarbon compounds vary in water-solubility and the toxicity exerted by individual compounds is inversely related to solubility, however bioavailability will be modified by the volatility of individual compounds (Nirmalakhandan & Speece, 1988; McCarty, 1986; McCarty et al., 1992a, 1992b; Mackay et al., 1992; McCarty & Mackay, 1993; Verhaar et al., 1992, 1999; Swartz et al., 1995; French-McCay, 2002; McGrath & Di Toro, 2009). Of the soluble compounds, the greatest contributor to toxicity for water-column and benthic organisms are the lower-molecular-weight aromatic compounds, which are both volatile and soluble in water. Although they are not the most water-soluble hydrocarbons within most oil types, the polynuclear aromatic hydrocarbons (PAHs) containing 2-3 aromatic ring structures typically exert the largest narcotic effects because they are semi-soluble and not highly volatile, so they persist in the environment long enough for significant accumulation to occur (Anderson et al., 1974, 1987; Neff & Anderson, 1981; Malins & Hodgins, 1981; McAuliffe, 1987; NRC, 2003). The monoaromatic hydrocarbons (MAHs), including the BTEX compounds (benzene, toluene, ethylbenzene, and xylenes), and the soluble alkanes (straight chain hydrocarbons) also contribute to toxicity, but these compounds are highly volatile, so that their contribution will be low when oil is exposed to evaporation and higher when oil is discharged at depth where volatilisation does not occur (French-McCay, 2002).

French-McCay (2002) reviewed available toxicity data, where marine biota was exposed to dissolved hydrocarbons prepared from oil mixtures, finding that 95% of species and life stages exhibited 50% population mortality (LC_{50}) between 6 and 400 ppb total PAH concentration after 96 hrs exposure, with an average of 50 ppb. Hence, concentrations lower than 6 ppb total PAH value should be protective of 97.5% of species and life stages even with exposure periods of days (at least 96 hours). Early life-history stages of fish appear to be more sensitive than older fish stages and invertebrates.

Exceedances of 10, 50 or 400 ppb over a 1 hour timestep (see Table 7.4) was applied to indicate increasing potential for sub-lethal to lethal toxic effects (or low to high), based on NOPSEMA (2019).

7.2.3.2 Entrained Hydrocarbons

Entrained hydrocarbons consist of oil droplets that are suspended in the water column and insoluble. As such, insoluble compounds in oil cannot be absorbed from the water column by aquatic organisms, hence are not bioavailable through absorption of compounds from the water. Exposure to these compounds would require routes of uptake other than absorption of soluble compounds. The route of exposure of organisms to whole oil alone include direct contact with tissues of organisms and uptake of oil by direct consumption, with potential for biomagnification through the food chain (NRC, 2003).

The 10 ppb threshold represents the very lowest concentration and corresponds generally with the lowest trigger levels for chronic exposure for entrained hydrocarbons in the ANZECC & ARMCANZ (2000) water quality guidelines. Due to the requirement for relatively long exposure times (> 24 hours) for these concentrations to be significant, they are likely to be more meaningful for juvenile fish, larvae and planktonic organisms that might be entrained (or otherwise moving) within the entrained plumes, or when entrained hydrocarbons adhere to organisms or trapped against a shoreline for periods of several days or more.

This exposure zone is not considered to be of significant biological impact and is therefore outside the adverse exposure zone. This exposure zone represents the area contacted by the spill. This area does not define the area of influence as it is considered that the environment will not be affected by the entrained hydrocarbon at this level.

Thresholds of 10 ppb and 100 ppb were applied over a 1 hour time exposure (Table 7.4), to cover the range of thresholds outlined in the ANZECC & ARMCANZ (2000) water quality guidelines, the incremental change for greater potential effect and is per NOPSEMA (2019).

A complicating factor that should be considered when assessing the consequence of dissolved and entrained oil distributions is that there will be some areas where both physically entrained oil droplets and dissolved hydrocarbons co-exist. Higher concentrations of each will tend to occur close to the source where sea conditions can force mixing of relatively unweathered oil into the water column, resulting in more rapid dissolution of soluble compounds.

Table 7.4 Dissolved and entrained hydrocarbon exposure values assessed over a 1-hour time step, as per NOPSEMA (2019).

Threshold level	Dissolved hydrocarbon concentration (ppb)	Entrained hydrocarbon concentrations (ppb)
Low	10	10
Moderate	50	-
High	400	100

8 CONDENSATE PROPERTIES

8.1 Properties

As a conservative approach, Chevron had chosen Geryon condensate for the purposes of the modelling and hence provided physical properties and boiling point distributions, which are presented in Table 8.1 and Table 8.2, respectively.

Geryon condensate has an API of 42.67, a density of 810 kg/m^3 (at 15ºC) and a low viscosity value of 5.2 cP. When exposed to the atmosphere at local temperatures, about 31.5% of the condensate volatile components should evaporate within the first 12 hours (BP < 180°C); a further 27.1% of the semi-volatiles should evaporate within the first 24 hours (180°C < BP < 265°C); and low volatile portion (~31.7%) should evaporate over a longer period (265°C < BP < 380°C). Additionally, 9.7% of the condensate is shown to be persist in the marine environment for much longer periods and be subject to relatively slow degradation.

This condensate has a low asphaltene content (< 0.5%), indicating a very low propensity for the mixture to take up water to form water-in-oil emulsion over the weathering cycle.

Soluble, aromatic hydrocarbons contribute approximately 2.9% by mass of the whole oil. For this condensate they are all contained in the volatile fractions, which are highly soluble. Discharges onto the water surface will favour the process of evaporation over dissolution under calm sea conditions, but increased entrainment of oil and dissolution of soluble compounds can be expected under stronger wind periods with the presence of small breaking waves (whitecaps).

Table 8.1 Physical properties of Geryon condensate.

Characteristic	Geryon Condensate
Density (kg/m^3)	810.0 (at 15°C)
API	42.67
Dynamic viscosity (cP)	5.2 (at 15°C)
Pour point (°C)	-20
Surface tension (dyne/cm)	19
Hydrocarbon property category	Group II
Hydrocarbon property classification	Light-persistent

Table 8.2 Boiling point ranges of Geryon condensate.

Oil Type	Component	Volatile (%)	Semi-volatile (%)	Low volatility (%)	Residual (%)
	Boiling point (°C)	<180 C_4 to C_{10}	180-265 C_{11} to C_{15}	265-380 C_{16} to C_{20}	>380 >C_{20}
Geryon Condensate	% of total	31.5	27.1	31.7	9.7
	% of aromatics	2.9	0	0	0

8.2 Weathering Characteristics

8.2.1 Overview

A series of weathering tests were conducted to illustrate the potential behaviour of this condensate when exposed to idealised and representative environmental conditions:

- Instantaneous 50 m^3 surface release under calm wind conditions (constant 5 knots), 27°C water temperature and currents.
- Instantaneous 50 m^3 surface release under variable moderate wind conditions, 27°C water temperature and currents.

The first case is indicative of weathering rates under calm conditions that would not generate entrainment, while the second case would be more representative of the moderate winds experienced over the region. Both scenarios provide examples of potential behaviour during periods of a spill event once the condensate reaches the surface.

8.2.2 Results

The mass balance forecast for the calm-wind case (Figure 8.1) shows that 58.8% of the condensate is predicted to evaporate within 24 hours. Majority of the remaining condensate on the water surface will weather at a slower rate due to the low volatile components. Evaporation of the residual compounds will slow significantly, and they will then be subject to more gradual decay through biological and photochemical processes.

Under the variable-wind case (Figure 8.2), where the winds are of greater strength on average, entrainment of Geryon condensate into the water column is predicted to increase. Approximately 24 hours after the spill, 20.9% of the condensate mass is forecast to have entrained and a further 18.3% is forecast to have evaporated, leaving only a small proportion of the condensate floating on the water surface (<0.3%). The residual compounds will tend to remain entrained beneath the surface under conditions that generate wind waves (approximately >6 m/s).

The increased level of entrainment in the variable-wind case will result in a higher percentage of biological and photochemical degradation, where the decay of the floating slicks and condensate droplets in the water column occurs at an approximate rate of ~0.64% per day with an accumulated total of ~4.5% after 7 days, in comparison to a rate of <0.15% per day and an accumulated total of 1.04% after 7 days in the constant-wind case. Given the proportion of entrained condensate and the tendency for it to remain mixed in the water column, the remaining hydrocarbons will decay over time scales of several weeks.

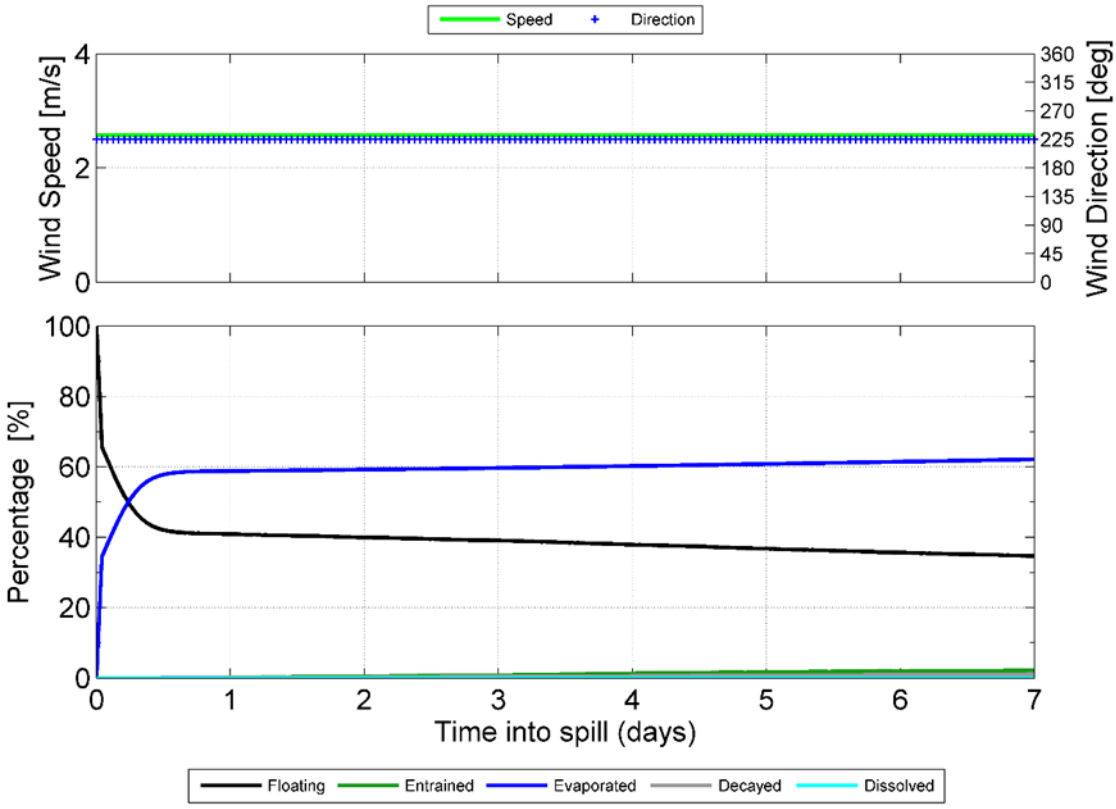

Figure 8.1 Proportional mass balance plot representing the weathering of Geryon condensate spilled onto the water surface as a one-off instantaneous release and subject to a constant 5 knots (2.6 m/s) wind at 27°C water temperature.

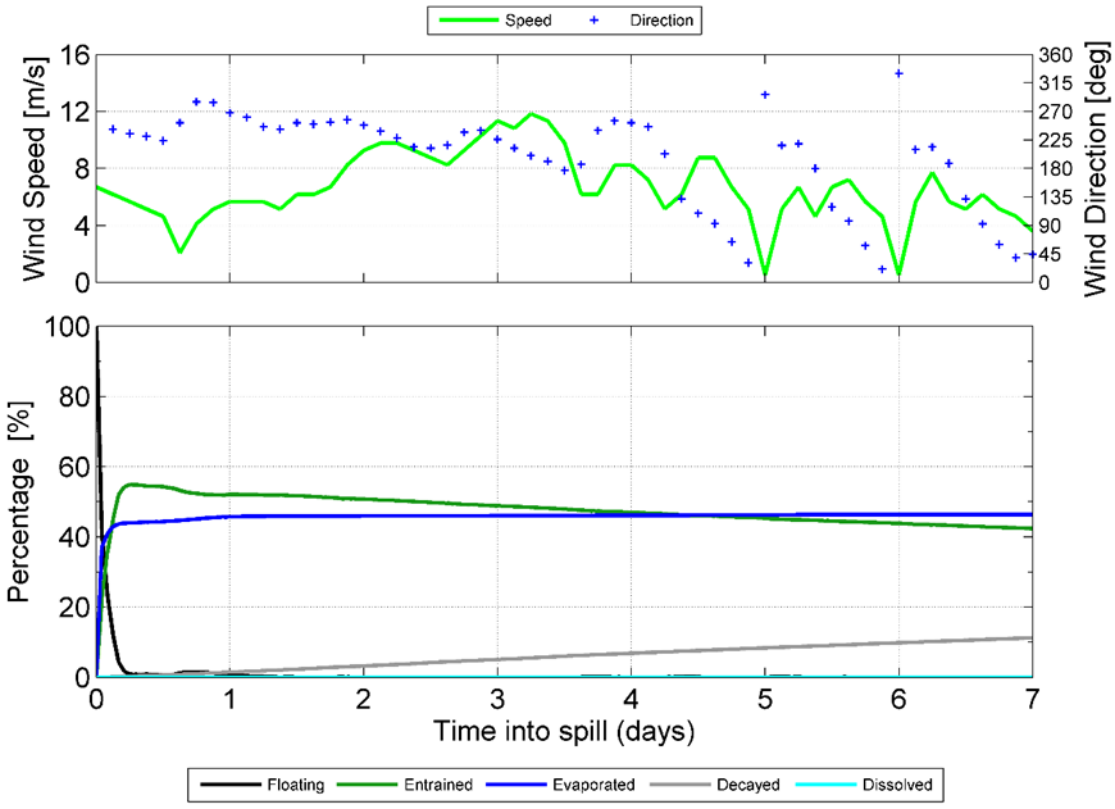

Figure 8.2 Proportional mass balance plot representing the weathering of Geryon condensate spilled onto the water surface as a one-off instantaneous release and subject to variable wind at 27°C water temperature.

9 MODEL SETTINGS

Table 9.1 provides a summary of the oil spill model settings.

Table 9.1 Summary of the oil spill model settings used in this assessment.

	Scenario
Location	GER FL 2
Number of spill simulations with randomly selected start times	100 per season (300 total)
Spill volume (m^3) [bbl]	50,165 [315,540]
Condensate type	Geryon condensate
Release type (depth)	Subsea (1,100 m)
Release duration (days)	90
Simulation length (days)	104
Model period	Summer (September to the following March) Transitional (April and August) Winter (May to July)
Floating oil (NOPSEMA) thresholds	1 g/m^2, low exposure 10 g/m^2, moderate exposure 50 g/m^2, high exposure
Shoreline accumulation (NOPSEMA) thresholds	10 g/m^2, low exposure 100 g/m^2, moderate exposure 1,000 g/m^2, high exposure
Dissolved hydrocarbon (NOPSEMA) thresholds	10 ppb over 1 hour, low exposure 50 ppb over 1 hour, moderate exposure 400 ppb over 1 hour, high exposure
Entrained hydrocarbon (NOPSEMA) thresholds	10 ppb over 1 hour, low exposure 100 ppb over 1 hour, high exposure

10 PRESENTATION AND INTERPRETATION OF MODEL RESULTS

The results from the modelling study are presented in a number of tables and figures, which aim to provide an understanding of the predicted sea-surface and water column (subsurface) exposure and shoreline accumulation (if predicted).

10.1 Stochastic Analysis

10.1.1 Statistics

The statistics are based on the following principles:

- The ***greatest distance travelled by a spill trajectory*** – is determined by a) recording the maximum and b) second greatest distance travelled (or 99th percentile) by a single trajectory, within a scenario, from the release location to the identified exposure thresholds.
- The ***Probability of condensate exposure to a receptor*** – is determined by recording the number of spill trajectories to reach a specified sea surface or subsea threshold within a receptor polygon, divided by the total number of spill trajectories within that scenario.
- The ***Minimum time before condensate exposure to a receptor*** – is determined by ranking the elapsed time before sea surface exposure, at a specified threshold, to grid cells within a receptor polygon and recording the minimum value.
- The ***probability of oil accumulation at a receptor*** – is determined by recording the number of spill trajectories to reach a specified shoreline accumulation threshold within a receptor polygon, divided by the total number of spill trajectories within that scenario.
- The ***maximum potential oil accumulation within a receptor*** – is determined by identifying the maximum loading to any grid cell within a receptor polygon, for a scenario.
- The ***dissolved and entrained hydrocarbon exposure*** – is determined by recording the maximum instantaneous concentrations at each grid cell assessed over a 1-hour time step.

10.2 Deterministic Trajectories

The deterministic results in Section 11.2 are based on the following criteria:

a. Largest swept area of floating hydrocarbon above 10 g/m^2
b. Largest swept area of floating hydrocarbon above 50 g/m^2
c. Largest volume of oil ashore
d. Longest length of shoreline accumulation above 100 g/m^2
e. Largest area of entrained hydrocarbons above 100 ppb
f. Largest area of dissolved hydrocarbons above 50 ppb

As there was no dissolved hydrocarbon exposure at or above 50 ppb, for any of the 300 simulations, there is no deterministic results presented.

10.3 Receptors

A range of environmental receptors and shorelines were assessed for floating oil exposure, shoreline contact and water column exposure (entrained and dissolved hydrocarbons) as part of the study (see Figure 10.1 to Figure 10.10). Receptor categories (see Table 10.1) include sections of shorelines and offshore islands. All other sensitive receptors other than submerged reefs, shoals and banks (RSB) were sourced from http://www.environment.gov.au/. Risks of exposure were separately calculated for each sensitive receptor area and have been tabulated.

Table 10.2 summarises the receptors that the location resides within.

Table 10.1 Summary of receptors used to assess floating oil, shoreline and in-water exposure to hydrocarbons.

11 RESULTS: GERYON-EURYTION LOSS OF WELL CONTROL

This scenario examined a 315,540 stb (or 50,165 m^3) subsea release of condensate over 90 days, following a LOWC. A total of 300 spill simulations were run for each of the three seasons (i.e. 100 spills per season) and tracked for 104 days.

Section 11.1 presents the seasonal (or stochastic) analysis results, while Section 11.2 presents the deterministic results.

11.1 Stochastic Analysis

11.1.1 Floating Condensate Exposure

Table 11.1 summarises the maximum distances from the release location to floating condensate exposure zones for each season. The maximum distance from the release location to the low (≥ 1 g/m^2) and moderate (≥ 10 g/m^2) thresholds was 132.6 km south (summer) and 60.4 km southeast (winter), respectively.

No exposure was predicted at the high (≥ 50 g/m^2) threshold.

Table 11.2 summarises the potential floating condensate exposure to individual receptors during each season.

The Offshore Area IAA, Pygmy Blue Whale - Distribution and Wedge-tailed Shearwater - Breeding BIAs, which the release location resides within (see Section 10.3), were the only receptors predicted to be exposed during all three seasons at the low and moderate thresholds. The probabilities for the low threshold was 100% for all seasons for these receptors. Probabilities of moderate exposure for these rectors ranged between 51% (all receptors; summer) and 82% (Pygmy Blue Whale - Distribution (BIA) and Offshore Area IAA); winter). Additionally, the Flatback Turtle - Internesting Buffer and Whale Shark - Foraging BIAs were also predicted to be exposed at the low threshold during summer (7% and 1%), transitional (13% and 6%) and winter (15% and 13%), respectively. The minimum time before low exposure for the Flatback Turtle - Internesting Buffer and Whale Shark - Foraging BIAs was 5.79 days during summer conditions. Furthermore, the probability of exposure at the low threshold for the Continental Slope Demersal Fish Communities (KEF) was 96%, 80% and 84% during summer, transitional and winter, respectively. The corresponding minimum time before low exposure at the Continental Slope Demersal Fish Communities (KEF) was 1.88 days (summer).

Figure 11.1 to Figure 11.3 present the zones of floating condensate exposure for each season.

Table 11.1 Maximum distances and directions travelled from the release location to floating condensate exposure for each season and threshold, following a subsea LOWC at GER FL2. The results were calculated from 100 spill trajectories per season.

Season	Distance and direction	Zones of potential floating condensate exposure		
		Low	Moderate	High
Summer	Max. distance from release site (km)	132.6	59.1	-
	Max. distance from release site (km) (99th percentile)	114.1	59.1	-
	Direction	South	Southeast	-
Transitional	Max. distance from release site (km)	129.2	59.9	-
	Max. distance from release site (km) (99th percentile)	105.5	59.9	-
	Direction	South	Southeast	-

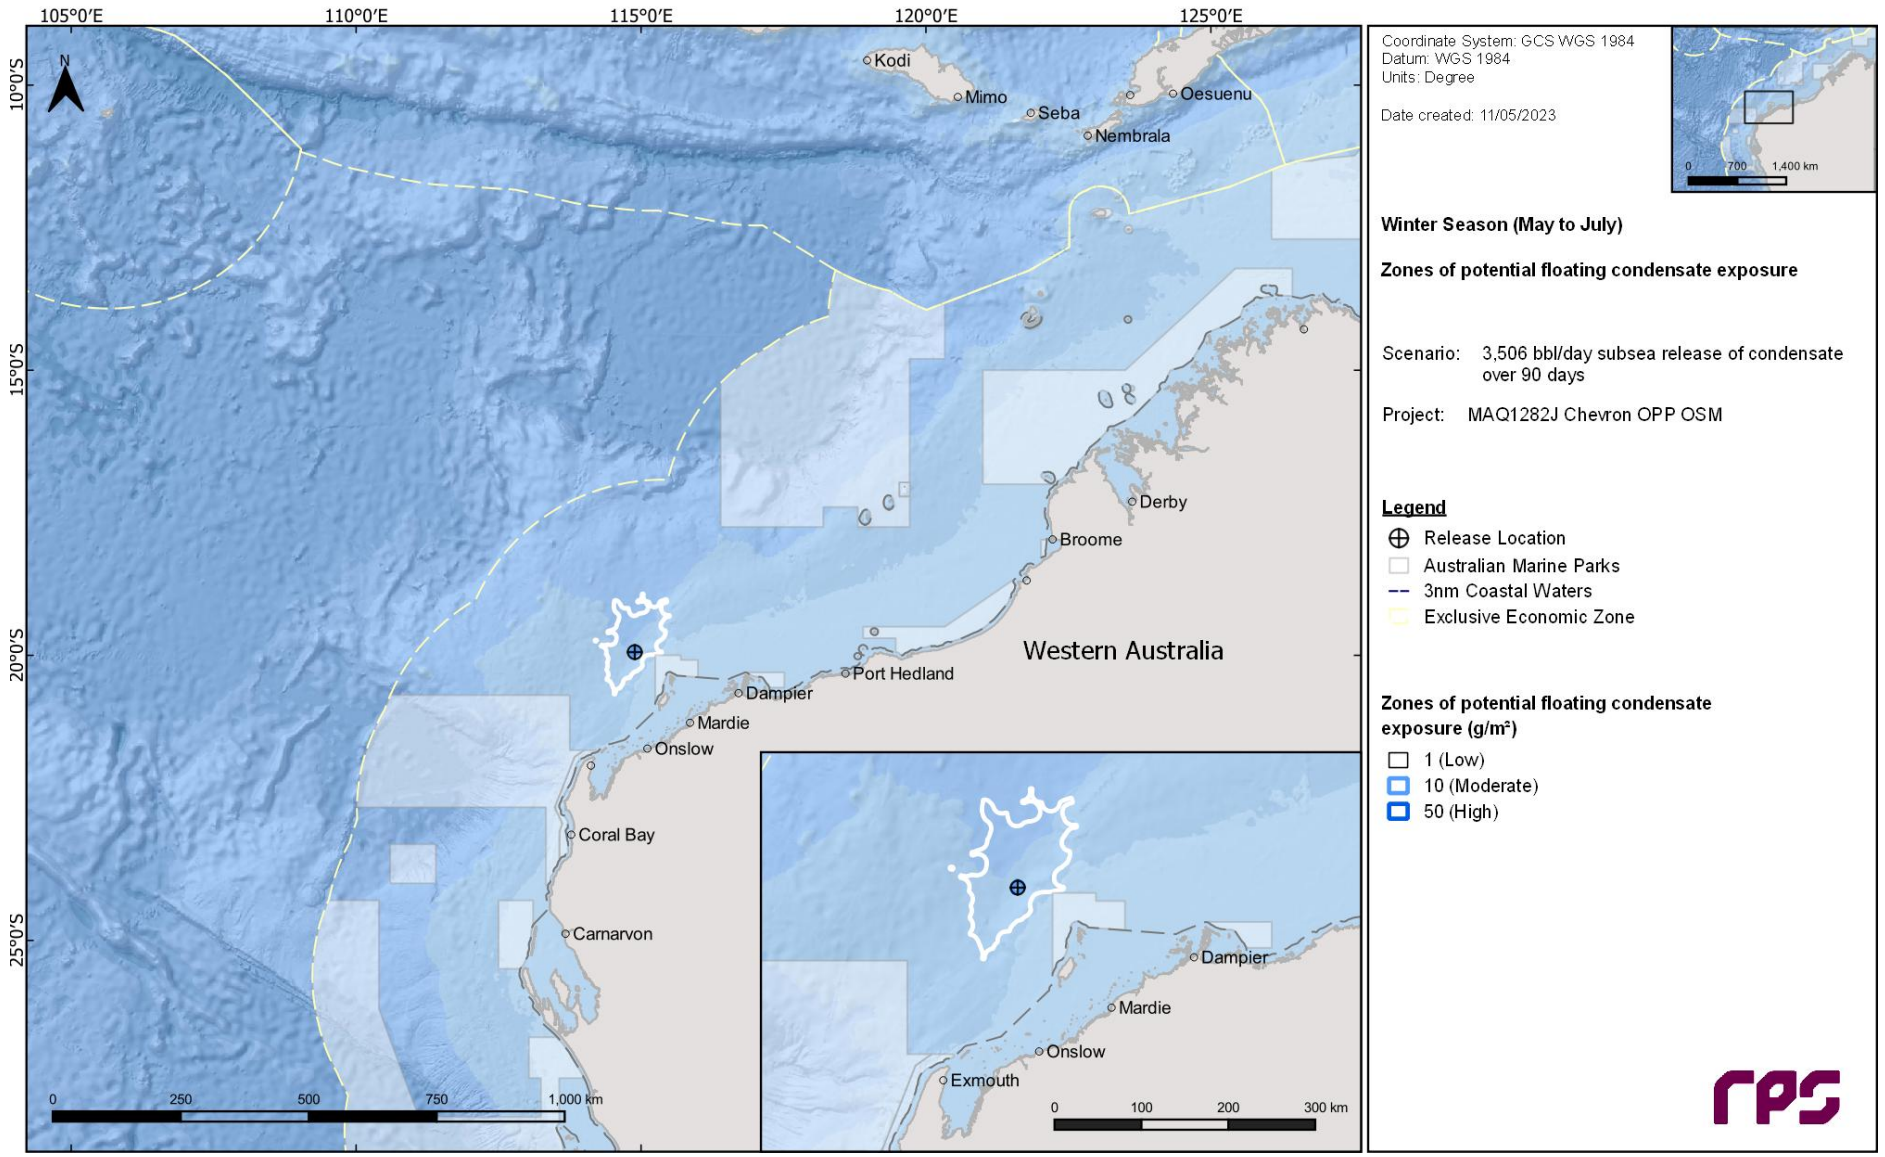

Figure 11.3 Zones of potential floating condensate exposure following a subsea LOWC at GER FL2 during winter (May to July) wind and current conditions. The results were calculated from 100 spill simulations.

11.1.2 Shoreline Accumulation

Table 11.3 presents a summary of the predicted shoreline accumulation during summer, transitional and winter seasons. The probability of shoreline accumulation on any shoreline at, or above, the low threshold (≥ 10 g/m^2) was greatest during summer at 23%, while the minimum time before shoreline accumulation was 7.46 days and the maximum volume of oil ashore was 23.2 m^3. No shoreline accumulation was predicted during transitional conditions.

Additionally, no high (≥ 1,000 g/m^2) shoreline threshold accumulation was predicted in the modelling results.

Table 11.4 and Table 11.5 summarises the shoreline accumulation on individual receptors for the summer and winter season.

During summer conditions, condensate had accumulated on 38 shoreline receptors at, or above, the low threshold with the greatest probability predicted for Barrow & Montebello Islands IAA and Barrow Island Group (15%). In comparison, during winter conditions, condensate was predicted to accumulate on 4 shoreline receptors and each with an 8% probability.

The maximum potential shoreline accumulation is presented for the summer and winter season in Figure 11.4 and Figure 11.5.

Table 11.3 Summary of condensate accumulation across all shorelines for each season and threshold, following a subsea LOWC at GER FL2. The results were calculated from 100 spill trajectories per season.

Shoreline Statistics	Summer	Transitional	Winter
Probability of accumulation on any shoreline (%)	23	-	8
Absolute minimum time for visible oil to shore (days)	7.46	-	43.75
Maximum volume of hydrocarbons ashore (m^3)	23.2	-	1.9
Average volume of hydrocarbons ashore (m^3)	9.4	-	0.8
Maximum length of the shoreline at **10 g/m^2** (km)	79	-	7
Average shoreline length (km) at **10 g/m^2** (km)	31.4	-	4.9
Maximum length of the shoreline at **100 g/m^2** (km)	2	-	-
Average shoreline length (km) at **100 g/m^2** (km)	1.1	-	-
Maximum length of the shoreline at **1,000 g/m^2** (km)	-	-	-
Average shoreline length (km) at **1,000 g/m^2** (km)	-	-	-

Table 11.4 Summary of shoreline condensate accumulation to individual receptors, following a LOWC at GER FL2. The results were calculated from 100 spill trajectories days during summer (September to the following March) wind and current conditions.

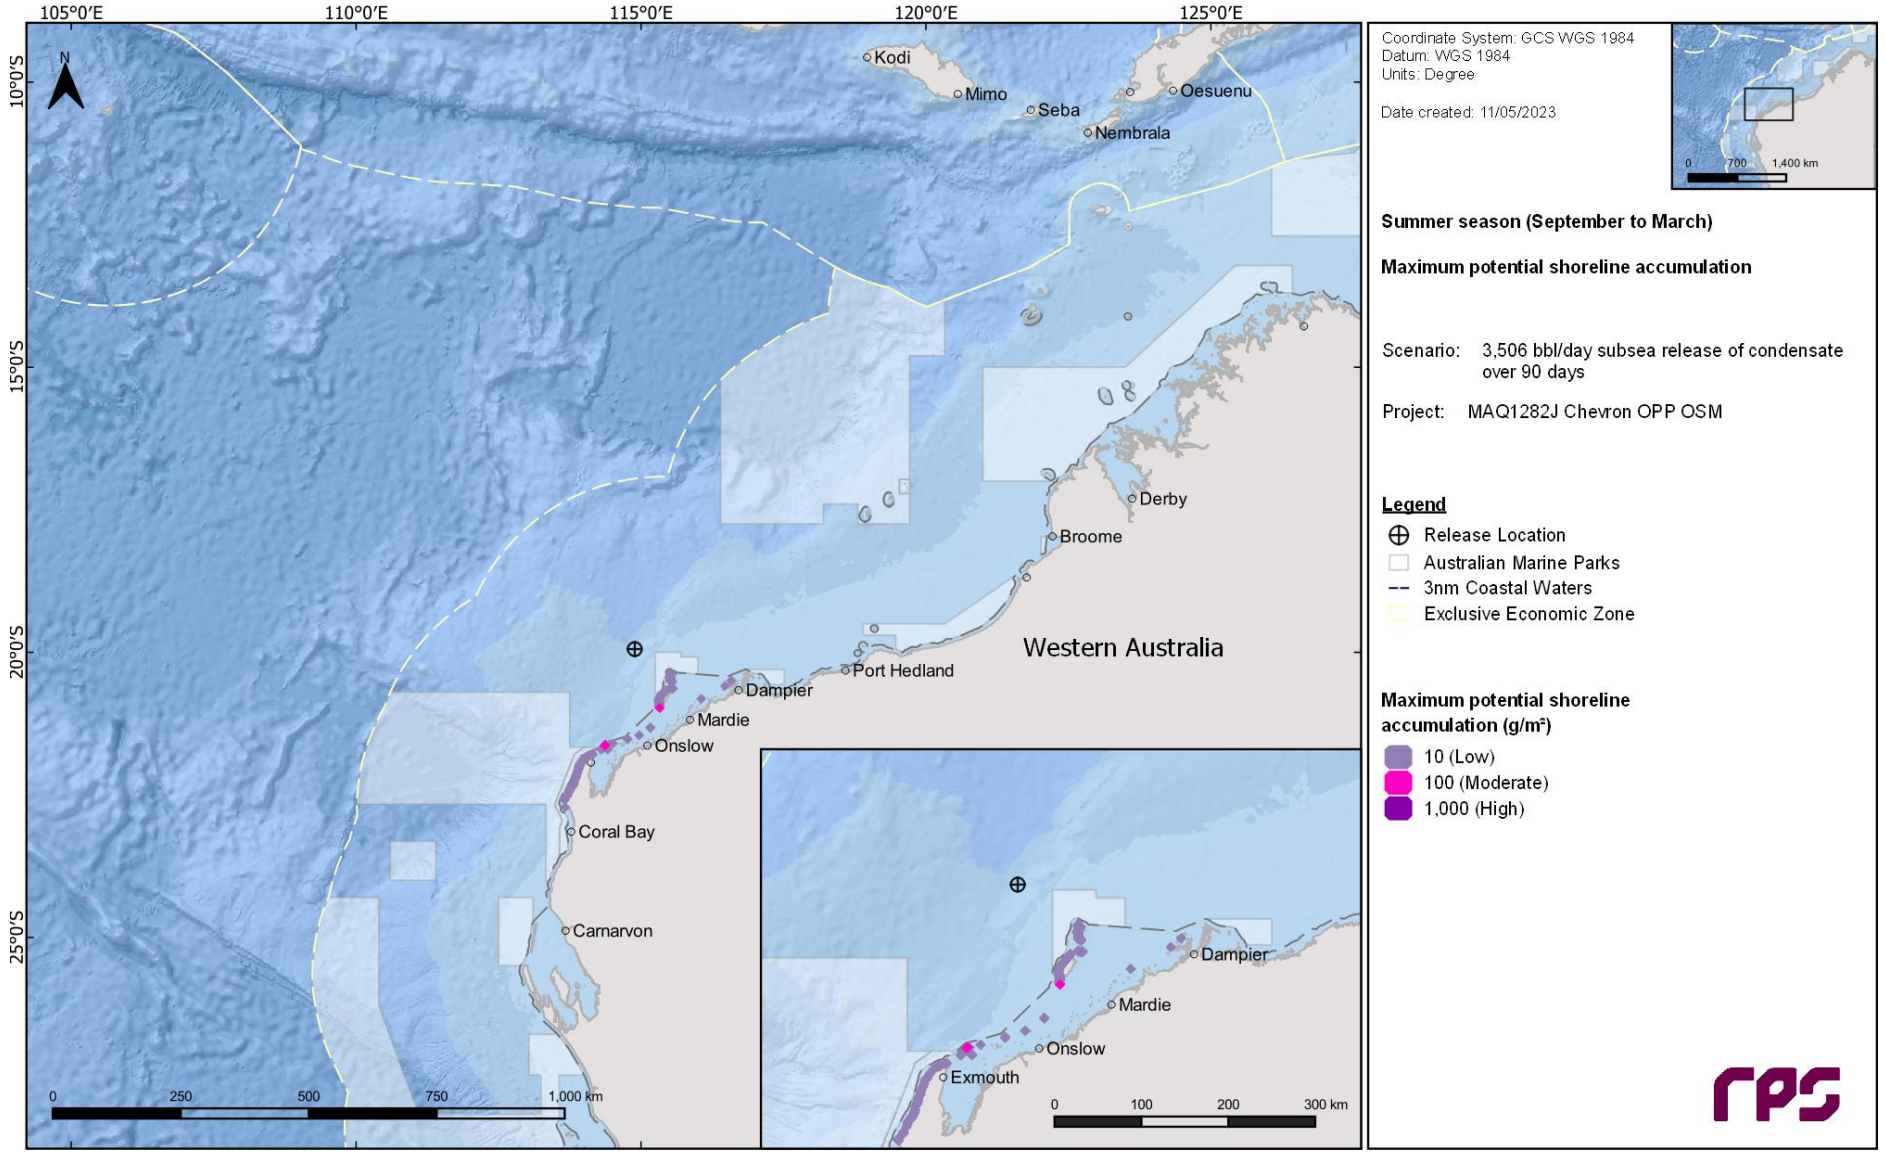

Figure 11.4 Maximum potential shoreline accumulation following a subsea LOWC at GER FL2 during summer (September to the following March) wind and current conditions. The results were calculated from 100 spill simulations.

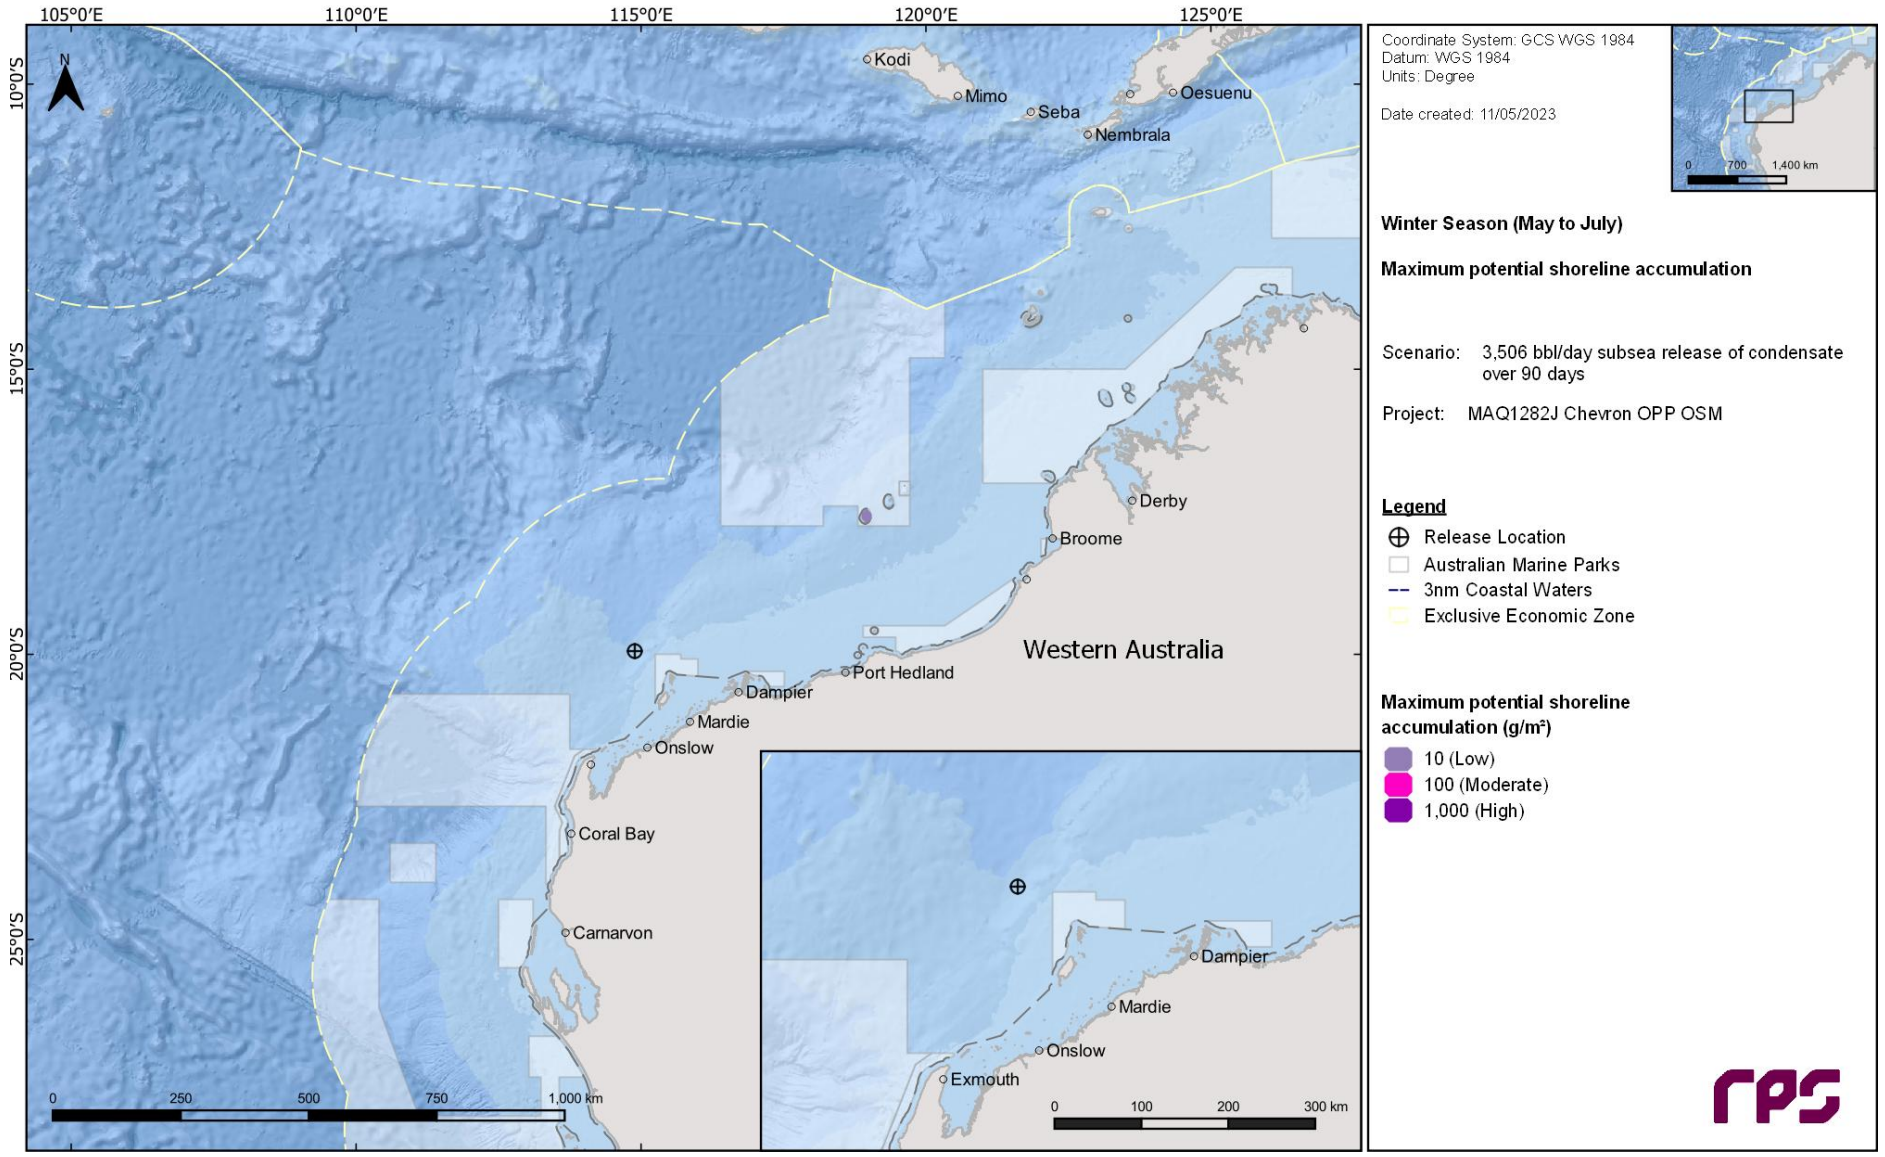

Figure 11.5 Maximum potential shoreline accumulation following a subsea LOWC at GER FL2 during winter (May to July) wind and current conditions. The results were calculated from 100 spill simulations.

11.1.3 Water Column Exposure

11.1.3.1 Dissolved Hydrocarbons

No dissolved hydrocarbon exposure was predicted for this scenario above the low reporting threshold (≥10 ppb) during any of the seasons modelled. Consequently, no results are reported.

11.1.3.2 Entrained Hydrocarbons

Table 11.6 summarises the probability and minimum time before exposure to receptors from entrained hydrocarbons in the 0-10 m depth layer, for each season, at the low (≥ 10 ppb) and high (≥ 100 ppb) thresholds.

A total of 40, 22 and 22 BIAs were predicted to be exposed at, or above, the low threshold during summer, transitional and winter conditions respectively. Excluding the Pygmy Blue Whale - Distribution and Wedge-tailed Shearwater – Breeding BIAs which the release location resides within, the highest probabilities of exposure were predicted for Humpback Whale - Migration BIA (95% summer, 91% transitional and 87% winter).

During summer and transitional conditions, 7 AMPs were predicted to be exposed at, or above the low threshold, and 6 AMPs under winter conditions. The highest probabilities predicted were at the Gascoyne AMP (92% summer, 97% transitional and 86% winter). Furthermore, the Gascoyne AMP during all seasons (3% summer, 6% transitional and 5% winter) and the Montebello AMP during summer (4%) were predicted to be exposed to entrained hydrocarbons at the high threshold.

During summer, transitional and winter conditions, 8, 7 and 7 KEFs were predicted to be exposed at the low threshold, respectively. Probabilities ranged between 2–100%, 2–100% and 3–100% for summer, transitional and winter, respectively.

Additionally, 50, 17 and 15 IAA (including the Offshore IAA that the release site is located within), were predicted to be exposed to entrained hydrocarbons at low threshold during summer, transitional and winter conditions, respectively. Excluding the Offshore IAA, the probabilities for each season ranged between 1–92%, 1–97% and 1–86% under summer, transitional and winter conditions, respectively with the maximum probabilities occurring at the Gascoyne IAA during all seasons.

Furthermore, 59, 5 and 4 RSB receptors were predicted to be exposed to entrained hydrocarbons at the low threshold during summer, transitional and winter conditions, respectively. Maximum summer, transitional and winter probabilities of 23% for Rankin Bank, 6% for Rankin Bank and Outtrim Patches and 14% for Outtrim Patches, respectively, were predicted.

Figure 11.6 to Figure 11.8 illustrate the extent of the predicted entrained hydrocarbon exposure for the low and high thresholds in the 0-10 m depth layer for each season.

The same maps for the 10-20 m depth layer are presented in Figure 11.9 to Figure 11.11.

Table 11.6 Predicted probability and maximum entrained hydrocarbon exposure to individual receptors in the 0-10 m depth layer following a subsea LOWC at GER FL2. The results were calculated from 100 spill simulations per season.

Receptor		Summer					Transitional					Winter

11.2 Deterministic Analysis

The deterministic analysis presented below, are based on simulations that resulted in the largest swept area of floating condensate above 10 g/m^2 (see Section 11.2.1), largest volume of oil ashore (see Section 11.2.2), longest length of shoreline accumulation above 100 g/m^2 (see Section 11.2.2) and the largest area of entrained hydrocarbons above 100 ppb (see Section 11.2.4).

Table 11.7 presents a summary of all deterministic analysis criteria and the corresponding floating condensate, shoreline accumulation, entrained and dissolved hydrocarbon values at the assessed thresholds.

Note that there was no floating hydrocarbons at or above 50 g/m^2 and no dissolved hydrocarbon exposure at or above 50 ppb for any of the 300 simulations.

Interpretation of the deterministic analysis result table and timeseries plots:

The summary deterministic analysis results presented in the table below should be interpreted as **maximum values**, representing the total volume or swept area exposed by floating or in-water hydrocarbons throughout the entire simulation duration. In this particular case, the simulation showed that a maximum of 932 km^2 was exposed to floating oil above the low threshold over a period of 104 days.

However, it's important to note that the timeseries plots present **peak values** at specific points in time. For example, when considering shoreline volume, the peak value in the timeseries plot does not account for oil that may have reached the shore earlier in the simulation but was subsequently lost through evaporation or other weathering processes.

Continuing with the previous example, the timeseries plot indicates that the peak floating oil swept area above the low threshold reached 68 km^2. This value represents the highest swept area recorded at a single point in time during the simulation.

Table 11.7 Summary of the deterministic analysis following a subsea LOWC at GER FL2.

Variable	Threshold	Deterministic Analysis Criteria			
		Largest swept area of floating condensate above 10 g/m^2	Largest volume of oil ashore	Longest length of shoreline accumulation above 100 g/m^2	Largest area of entrained hydrocarbons above 100 ppb
Season		Winter	Summer	Summer	Summer
Run Number		64	40	51	15
Floating Oil (km^2)	**1 g/m^2**	932.0	804.6	856.3	914.5
	10 g/m^2	**22.2**	6.5	4.6	3.7
	50 g/m^2	-	-	-	-
Shoreline Length (km)	**10 g/m^2**	-	50	76	55
	100 g/m^2	-	1	**2**	-
	1,000 g/m^2	-	-	-	-
Minimum Time (days)		-	73.9	12.5	59.0
Maximum Volume (m^3)		-	**23.2**	22	13
Entrained Area (km^2)	**10 ppb**	140,946	152,629	129,032	144,042
	100 ppb	2,598	8,677	5,635	**8,847**
Dissolved Area (km^2)	**10 ppb**	-	-	-	-
	50 ppb	-	-	-	-
	400 ppb	-	-	-	-
Start Date		20 June 2011	6 October 2010	6 December 2010	21 October 2010

11.2.1 Deterministic Case: Largest swept area of floating condensate above 10 g/m^2

The deterministic simulation that resulted in the largest swept area of floating condensate above 10 g/m^2 (moderate threshold) was identified as run number 64 during the winter period.

Figure 11.12 presents the extent of the predicted floating oil exposure zones on the sea surface (swept area) and shoreline accumulation over the entire 104-day simulation.

Figure 11.13 displays the time series of the swept area of low (≥ 1 g/m^2), moderate (≥ 10 g/m^2) and high (≥ 50 g/m^2) floating condensate over the 104-day simulation.

Figure 11.14 presents the fates and weathering for the corresponding simulation and Table 11.8 summarises the peak volumes and times of occurrence for each oil phase and volumes at the end of the 104-day simulation.

Table 11.8 Summary of peak volumes and times of occurrence for each oil phase and the volumes at the conclusion of the simulation (day 104), for the simulation with the largest swept area of floating condensate above 10 g/m^2 following a subsea LOWC at GER FL2.

Exposure Metrics	Peak Volume	Day of Occurrence	Volume at day 104
Surface (m^3)	442	52.42	1
Entrained (m^3)	4,828	90.00	2,999
Dissolved (m^3)	7	81.46	0
Evaporation (m^3)	33,388	103.54	33,388
Decay (m^3)	14,140	104.00	14,140
Ashore (m^3)	0	0.04	0

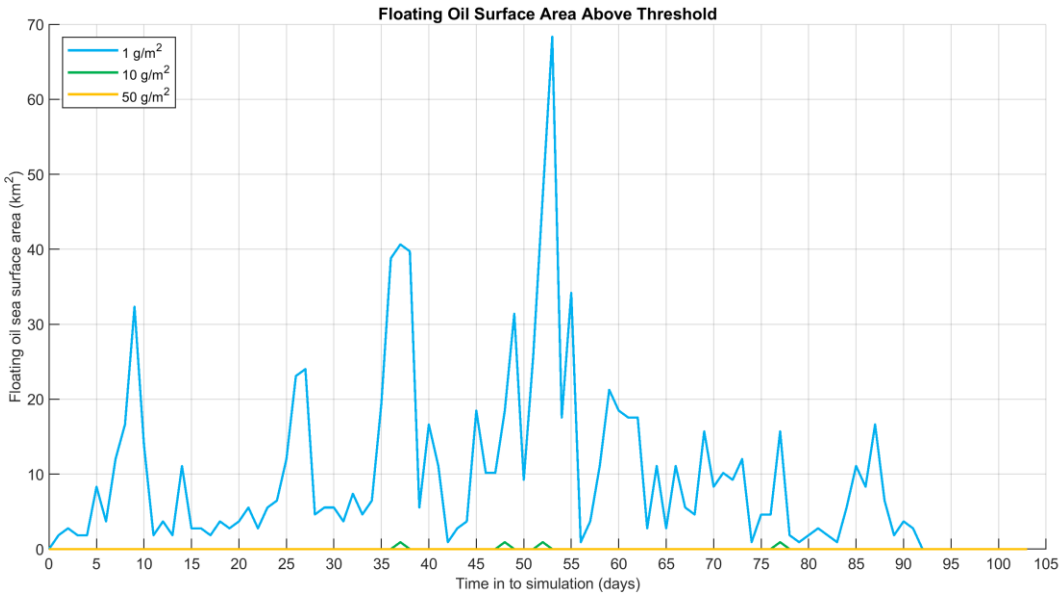

Figure 11.13 Predicted area of floating condensate exposure for each threshold, for the simulation with the largest swept area of floating condensate above 10 g/m^2 following a LOWC at GER FL2.

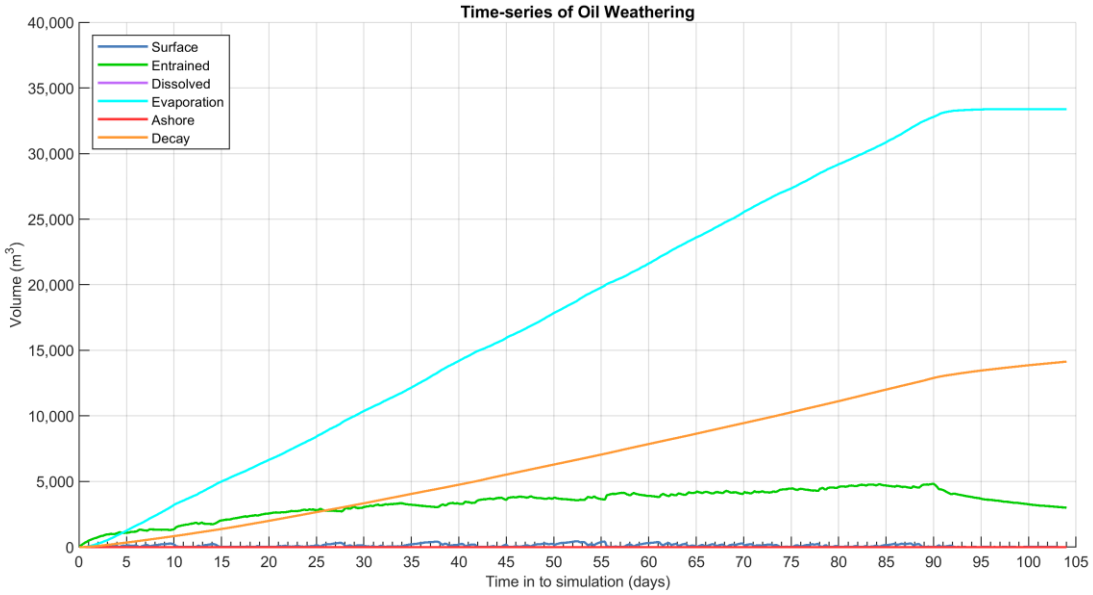

Figure 11.14 Predicted weathering and fates for the simulation with the largest swept area of floating condensate above 10 g/m^2 following a LOWC at GER FL2.

11.2.2 Deterministic Case: Largest volume of oil ashore

The deterministic simulation that resulted in the largest volume of oil ashore was identified as run number 40, during the summer season.

Figure 11.15 presents the extent of the predicted floating oil exposure zones on the sea surface (swept area) and shoreline accumulation over the entire 104-day simulation.

Figure 11.16 displays the time series of the volume of oil accumulating on shorelines at the low (≥ 10 g/m^2), moderate (≥ 100 g/m^2) and high (≥ 1,000 g/m^2) thresholds over the 104-day simulation.

Figure 11.17 presents the fates and weathering graph for the corresponding single spill trajectory and Table 11.9 summarises the peak volumes and times of occurrence for each oil phase and volumes at the end of the 104-day simulation.

Table 11.9 Summary peak volumes and times of occurrence for each oil phase and the volumes at the conclusion of the simulation (day 104), for the simulation with the largest volume of oil ashore following a subsea LOWC at GER FL2.

Exposure Metrics	Peak Volume	Day of Occurrence	Volume at day 104
Surface (m^3)	277	14	3
Entrained (m^3)	4,975	89	3,112
Dissolved (m^3)	7	69	0
Evaporation (m^3)	32,924	104	32,924
Decay (m^3)	14,469	104	14,469
Ashore (m^3)	23.2	94	19

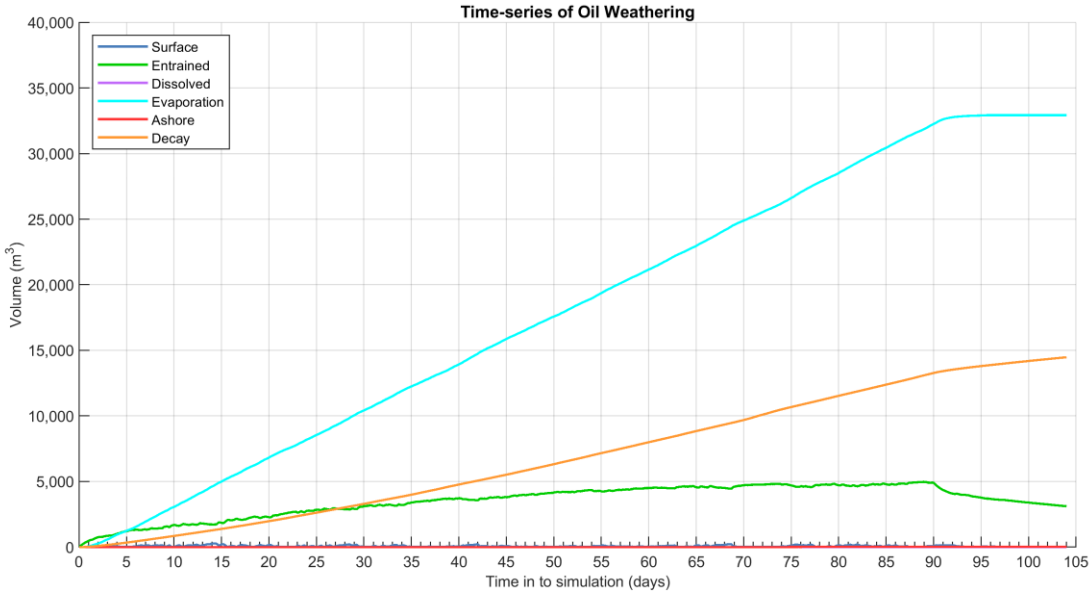

Figure 11.17 Predicted weathering and fates for the simulation with the largest volume of oil ashore following a LOWC at GER FL2.

11.2.3 Deterministic Case: Longest length of shoreline with accumulation above 100 g/m^2

The deterministic simulation that resulted in the longest length of shoreline with accumulation above 100 g/m^2 (moderate threshold) was identified as run number 51 during the summer period.

Figure 11.15 presents the extent of the predicted floating oil exposure zones on the sea surface (swept area) and shoreline accumulation over the entire 104-day simulation.

Figure 11.16 displays the time series of the length of shoreline with accumulation above the low (≥ 10 g/m^2), moderate (≥ 100 g/m^2) and high (≥ 1,000 g/m^2) thresholds over the 104-day simulation.

Figure 11.17 presents the fates and weathering graph for the corresponding single spill trajectory and Table 11.9 summarises the peak volumes and times of occurrence for each oil phase and volumes at the end of the 104-day simulation.

Table 11.10 Summary peak volumes and times of occurrence for each oil phase and the volumes at the conclusion of the simulation (day 104), for the simulation with the longest length of shoreline with accumulation above 100 g/m^2 following a subsea LOWC at GER FL2.

Exposure Metrics	Peak Volume	Day of Occurrence	Volume at day 104
Surface (m^3)	227	55	1
Entrained (m^3)	4,738	89	3,015
Dissolved (m^3)	7	74	0
Evaporation (m^3)	33,548	104	33,548
Decay (m^3)	13,938	104	13,938
Ashore (m^3)	22	82	21

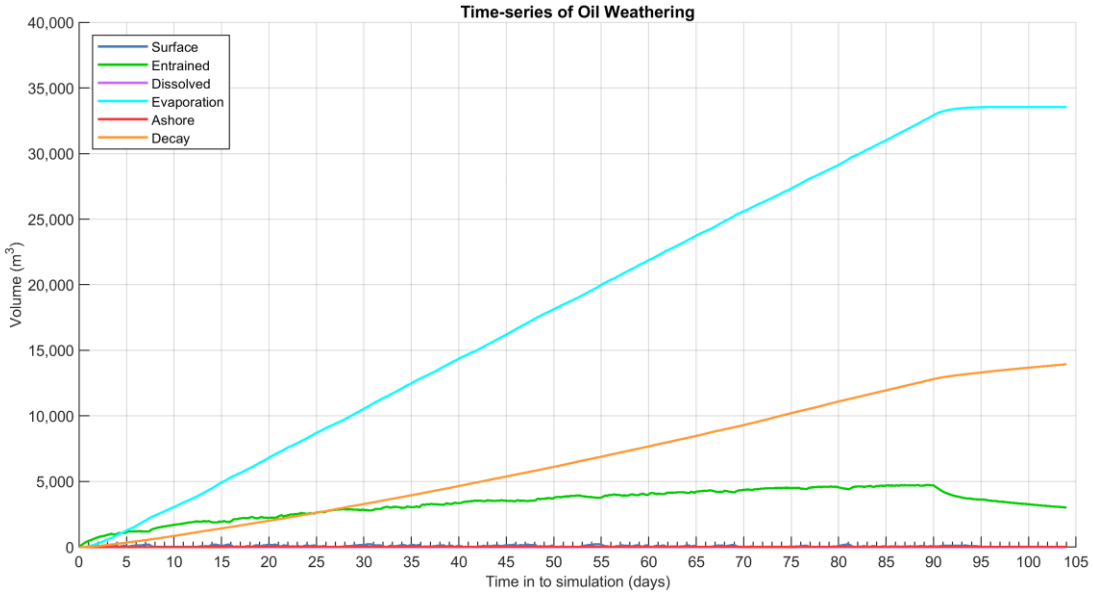

Figure 11.20 Predicted weathering and fates for the simulation with the longest length of shoreline with accumulation above 100 g/m^2 following a LOWC at GER FL2.

11.2.4 Deterministic Case: Largest area of entrained hydrocarbons above 100 ppb

The deterministic simulation that resulted in the largest area of entrained hydrocarbons above 100 ppb (low threshold) was identified as run number 15 during the summer period.

Figure 11.21 presents the extent of the predicted entrained hydrocarbon exposure zones over the entire 104-day simulation.

Figure 11.22 displays the time series of the area of entrained hydrocarbons at the low (≥10 ppb) and high (≥100 ppb) thresholds over the 104-day simulation.

Figure 11.23 presents the fates and weathering for the corresponding single spill trajectory and Table 11.11 summarises the peak volumes and times of occurrence for each oil phase and volumes at the end of the 104-day simulation.

Table 11.11 Summary of the peak volumes and times of occurrence for each oil phase and the volumes at day 104, for the simulation with the largest area of entrained hydrocarbons above 100 ppb following a subsea LOWC at GER FL2.

Exposure Metrics	Peak Volume	Day of Occurrence	Volume at day 104
Surface (m^3)	216	54	3
Entrained (m^3)	4,869	89	3,072
Dissolved (m^3)	7	54	0
Evaporation (m^3)	33,018	103	33,018
Decay (m^3)	14,419	104	14,419
Ashore (m^3)	18	80	16

TERMS AND ABBREVIATIONS

°	Degrees
‘	Minutes
“	Seconds
µm	Micrometre (unit of length; 1 µm = 0.001 mm)
Actionable oil	Oil which is thick enough for the effective use of mitigation strategies
AMP	Australian Marine Park
AMSA	Australian Maritime Safety Authority
ANZECC	Australian and New Zealand Environment and Conservation Council
API	American Petroleum Institute gravity. A measure of how heavy or light a petroleum liquid is compared to water.
ARMCANZ	Agriculture and Resource Management Council of Australia and New Zealand
ASTM	American Society for Testing and Materials
bbl	Barrel (unit of volume; 1 bbl = 0.159 m3)
bbl/d	Barrels per day
Bonn Agreement	An agreement for cooperation in dealing with pollution of the North Sea by oil and other harmful substances, 1983, includes: Governments of the Kingdom of Belgium, the Kingdom of Denmark, the French Republic, the Federal Republic of Germany, the Republic of Ireland, the Kingdom of the Netherlands, the Kingdom of Norway, the Kingdom of Sweden, the United Kingdom of Great Britain and Northern Ireland and the European Union.
BP	Boiling point. The temperature at which the vapor pressure of the liquid is equal to the pressure exerted on it by the surrounding atmosphere
BTEX	Benzene, Toluene, Ethylbenzene, and Xylenes
°C	degree Celsius (unit of temperature)
CFSR	Climate Forecast System Reanalysis
cm	Centimetre (unit of length)
cP	Centipoise (unit of dynamic viscosity)
Decay	The process where oil components are changed either chemically or biologically (biodegradation) to another compound. It includes breakdown to simpler organic carbon compounds by bacteria and other organisms, photo-oxidation by solar energy, and other chemical reactions.
Dynamic viscosity	The dynamic viscosity of a fluid expresses its resistance to shearing flows, where adjacent layers move parallel to each other with different speeds.
Floating oil exposure	Contact by floating oil on the sea surface at concentrations equal to or exceeding defined threshold concentrations. The consequence will vary depending on the threshold and the receptors
g/m^2	Grams per square meter (unit of surface area density)
GODAE	Global Ocean Data Assimilation Experiment
HYCOM	Hybrid Coordinate Ocean Model. A data-assimilative, three-dimensional ocean model
HYDROMAP	Advanced ocean/coastal tidal model used to predict tidal water levels, current speed and current direction.
IAA	Impact Assessment Area
IBRA	Interim Biogeographic Regionalisation for Australia

IMCRA	Integrated Marine and Coastal Regionalisation of Australia
ITOPF	International Tanker Owners Pollution Federation Limited
KEF	Key Ecological Feature
km	Kilometre (unit of length)
km^2	Square Kilometres (unit of area)
Knots	unit of speed (1 knot = 0.514 m/s)
LOWC	Loss of well control
m	Meter (unit of length)
m^3	Cubic meter (unit of volume)
m/s	Meter per Second (unit of speed)
MAHs	Monoaromatic Hydrocarbons
MNP	Marine National Park
MP	Marine Park
NASA	National Aeronautics and Space Administration (USA)
NCEP	National Centres for Environmental Prediction (USA)
nm	Nautical mile
NOAA	National Oceanic and Atmospheric Administration (USA)
NOPSEMA	National Offshore Petroleum Safety and Environmental Management Authority
NP	National Park
NR	Nature Reserve
PAH	Polynuclear Aromatic Hydrocarbons
Pour Point	The pour point of a liquid is the temperature below which the liquid loses its flow characteristics
ppb	Parts per billion (concentration)
psu	Practical salinity nits
RSB	Reefs, Shoals and Banks
scf	Standard cubic feet (defined as one cubic foot of gas at 15.56 °C and at normal sea level air pressure)
Shoreline contact	Arrival of oil at or near shorelines at on-water concentrations equal to or exceeding defined threshold concentrations. Shoreline contact is judged for floating oil arriving within a 2 km buffer zone from any shoreline as a conservative measure
SIMAP	Spill Impact Model Application Package. SIMAP is designed to simulate the fate and effects of spilled hydrocarbons for surface or subsea releases
Single Oil spill modelling	Oil spill modelling involving a computer simulation of a single hypothetical oil spill event subject to a single sequence of wind, current and other sea conditions over time. Single oil spill modelling, also referred to as “deterministic modelling” provides a simulation of one possible outcome of a given spill scenario, subject to the metocean conditions that are imposed. Single oil spill modelling is commonly used to consider the fate and effects of ‘worst-case’ oil spill scenarios that are carefully selected in consideration of the nature and scale of the offshore petroleum activity and the local environment (NOPSEMA, 2017). Because the outcomes of a single oil spill simulation can only represent the outcome of that scenario under one sequence of metocean conditions, worst-case conditions are often identified from stochastic modelling. It is impossible to calculate the likelihood of any outcome from a single oil spill simulation. Single oil spill modelling is generally used for response planning, preparedness planning and for supporting oil spill response operations in the event of an actual spill

SRTM	Shuttle Radar Topography Mission
Stochastic oil spill modelling	Stochastic oil spill modelling is created by overlaying and statistically analysing the outcomes of many single oil-spill simulations of a defined spill scenario, where each simulation was subject to a different sequence of metocean conditions, selected objectively (typically by random selection) from a long sequence of historic conditions for the study area. Analysis of this larger set of simulations provides a more accurate indication of the environment that maybe affected (EMBA) and indicates which locations are more likely to be affected (as well as other statistics). Stochastic oil spill modelling avoids biases that affect single oil spill modelling (due to the reliance on only one possible sequence of conditions). However, when interpreting stochastic modelling, which is based on a wide range of potential conditions that might happen to occur, it is essential to understand that calculations will encompass a much larger area than could be affected in any single spill event, where a more limited set of conditions will occur. Consequently, it is misleading to imply that the region derived from stochastic modelling indicate the outcomes expected from a single spill event (NOPSEMA, 2017) Stochastic modelling is generally used for risk assessment and preparedness planning by indicating locations that could be exposed and may require response or subsequent impact assessment

EXECUTIVE SUMMARY

Background

Chevron Australia Pty Ltd (Chevron) is the operator of the Greater Gorgon area, which includes the Chrysaor and Dionysus (C&D) fields situated within the Northern Carnarvon Basin in Permit area WA-15-R northwest of Barrow Island off the north-west coast of Western Australia.

Chevron commissioned RPS to undertake an oil spill modelling to support environmental approvals. The study assessed the seasonal risk and potential exposure to the surrounding waters and contact to the shorelines from the following hypothetical scenario:

- **Scenario:** A 1,308 stb/day (207.9 m^3/day) subsea release of condensate over 90 days (totalling 117,720 stb or 18,715 m^3) from a loss of well control (LOWC).

The potential risk of exposure to the surrounding waters and contact to shorelines was assessed for three distinct seasons; (i) summer (September to the following March), (ii) the transitional periods (April and August) and (iii) winter (May to July). This approach assists with identifying the environmental values and sensitivities that would be at risk of exposure on a seasonal basis.

One of the purposes for the modelling is to define the 'outer boundaries' of the environment that may be affected (EMBA) in the unlikely event of hydrocarbon release. Therefore, the modelling does not take into consideration any of the spill prevention, mitigation and response capabilities that would be implemented in response to the spill.

Methodology

The modelling study was carried out in stages. Firstly, a ten-year current dataset (2010–2019) that includes the combined influence of large-scale ocean and nearshore tidal currents was developed. Secondly, the currents, local winds and detailed hydrocarbon characteristics were used as inputs in the three-dimensional oil spill model (SIMAP) to simulate the drift, spread, weathering and fate of the spilled oil.

As spills can occur during any set of wind and current conditions, modelling was conducted using a stochastic (or probabilistic) approach, which involved running 100 spill simulations per season, with each simulation having the same spill information (spill volume, duration and composition of hydrocarbons) but randomly selected start time. This ensured that each spill trajectory was subjected to varying wind and current conditions.

Condensate Properties

Chrysaor condensate physical properties and boiling point distributions were provided by Chevron. The condensate has an API of 40.2, a density of 824 kg/m^3 (at 15ºC) and a low viscosity value of 5.6 cP. When exposed to the atmosphere at local temperatures, about 23.8% of the condensate volatile components should evaporate within the first 12 hours (BP < 180°C); a further 33.0% of the semi-volatiles should evaporate within the first 24 hours (180°C < BP < 265°C); and low volatile portion (~32.9%) should evaporate over a longer period (265°C < BP < 380°C). Additionally, 10.3% of the condensate is shown to be persist in the marine environment for longer period and be subject to relatively slow degradation.

This condensate has a low asphaltene content (< 0.5%), which is one indicator for a very low propensity to take up water to form water-in-oil emulsion. Soluble aromatic hydrocarbons contribute approximately 3.0% by mass of the whole oil (contained in the volatile fraction).

Key Findings

- The maximum distance from the release location to the low (≥ 1 g/m^2) and moderate (≥ 10 g/m^2) thresholds was 82.0 km west (summer) and 4.3 km northeast (transitional and winter), respectively. No exposure was predicted at the high (≥ 50 g/m^2) threshold.

- The Offshore Area IAA, Pygmy Blue Whale - Distribution and Wedge-tailed Shearwater - Breeding BIAs, and the Continental Slope Demersal Fish Communities KEF, which the release location resides within, were the only receptors predicted to be exposed during all three seasons at the low and moderate thresholds. The probabilities for the low threshold were 100% for all seasons for these receptors. Probabilities of moderate exposure for these receptors ranged between 89% (all receptors; summer) and 99% (all receptors; winter). Additionally, the Flatback Turtle - Internesting Buffer BIA was also predicted to be exposed at the low threshold during summer (95%), transitional (100%) and winter (97%), respectively. The minimum time before low exposure for the Flatback Turtle - Internesting Buffer BIA was 0.67 days during summer conditions. Furthermore, the probability of exposure at the low threshold for the Pilbara (offshore) IMCRA and Ancient coastline at 125 m depth contour (KEF) was 88%, 84% and 89% during summer, transitional and winter conditions and 31%, 27% and 41% summer, transitional and winter conditions, respectively. The corresponding minimum time before low exposure at the Pilbara (offshore) IMCRA and Ancient coastline at 125 m depth contour FEF was 0.88 days (summer) and 2.21 days (winter).

- The probability of accumulation on any shoreline at, or above, the low threshold (≥ 10 g/m^2) was greatest during summer at 32%, while the minimum time before shoreline accumulation was 4.29 days and the maximum volume of oil ashore was 32.0 m^3.

- During summer conditions, condensate had accumulated on 56 shoreline receptors at, or above, the low threshold with the greatest probability predicted for Barrow & Montebello Islands and Ningaloo Coast World Heritage Area IAAs (22%). In comparison, during transitional and winter conditions, condensate had accumulated on 6 and 4 shoreline receptors, respectively. The greatest probabilities of shoreline accumulation occurred at Muiron Islands, Ningaloo Coast World Heritage Area and North Muiron Island, all 3% probability during transitional season and at Muiron Islands, Ningaloo Coast World Heritage Area and South Muiron Island, all 1% probability during winter.

- No dissolved hydrocarbon exposure was predicted for this scenario at or above the low reporting threshold (≥10 ppb) during any of the seasons modelled.

- In the 0-10 m depth layer, a total of 38, 12 and 11 IAA (including the Offshore IAA that the release site is located within), were predicted to be exposed to entrained hydrocarbons at low threshold. Excluding the Offshore, the probabilities for each season ranged between 1–80%, 1–82% and 1–87% under summer, transitional and winter conditions, respectively, with the maximum probabilities occurring at the Gascoyne IAA during all seasons. Furthermore, 46, 5 and 2 RSB receptors were predicted to be exposed to entrained hydrocarbons at the low threshold with maximum seasonal probabilities of 36%, 18% and 26% for Rankin Bank, during summer, transitional and winter, respectively.

1 INTRODUCTION

Chevron Australia Pty Ltd (Chevron) is the operator of the Greater Gorgon area, which includes the Chrysaor and Dionysus (C&D) fields situated within the Northern Carnarvon Basin in Permit area WA-15-R northwest of Barrow Island off the north-west coast of Western Australia.

As part of the planned development for the C&D fields, Chevron commissioned RPS to undertake a comprehensive oil spill modelling study to support environmental approvals. The modelling study assessed the seasonal risk and potential exposure to the surrounding waters and contact to the shorelines from the following hypothetical scenario:

- **Scenario:** A 1,308 stb/day (207.9 m^3/day) subsea release of condensate over 90 days (totalling 117,720 stb or 18,715 m^3) from a loss of well control (LOWC).

The release location used for the oil spill assessment is presented in Table 1.1 and illustrated in Figure 1.1.

The potential risk of exposure to the surrounding waters and contact to shorelines was assessed for three distinct seasons; (i) summer (September to the following March), (ii) the transitional periods (April and August) and (iii) winter (May to July). This approach assists with identifying the environmental values and sensitivities that would be at risk of exposure on a seasonal basis.

One of the purposes for the modelling is to define the 'outer boundaries' of the environment that may be affected (EMBA) in the unlikely event of hydrocarbon release. Therefore, the modelling does not take into consideration any of the spill prevention, mitigation and response capabilities that would be implemented in response to the spill.

The spill modelling was performed using an advanced three-dimensional trajectory and fates model; Spill Impact Mapping Analysis Program (SIMAP). The SIMAP model calculates the transport, spreading, entrainment and evaporation of spilled hydrocarbons over time, based on the prevailing wind and current conditions and the physical and chemical properties.

The hydrocarbon spill model, the method and analysis applied herein uses modelling algorithms which have been peer reviewed and published in international journals. Further, RPS warrants that this work meets and exceeds the American Society for Testing and Materials (ASTM) Standard F2067-13 "*Standard Practice for Development and Use of Oil Spill Models*".

2 SCOPE OF WORK

The scope of work included the following components:

1. Generate ten years (2010 to 2019 (inclusive)) of wind and current data. The three-dimensional current data includes the combined influence of ocean and tidal currents;

2. Include the wind data, current data and condensate properties characteristics into the three-dimensional oil spill model; SIMAP, to model the movement, spreading, entrainment, weathering and potential shoreline accumulation over time;

3. Run 100 simulations for each season (i.e. 300 simulations total), with each simulation having the same spill information (location, volume, duration and condensate properties) but randomly varying start times. This ensured that each spill simulation was subjected to unique wind and current conditions;

4. Combine the results from the 100 spill simulations to assess the exposure to waters and shoreline accumulation based upon the NOPSEMA thresholds; and

5. From the 300 simulations modelled, identify and present the “worst case” deterministic runs, which can be used to inform response planning based on the following criteria:
    a. Largest swept area of floating hydrocarbon above 10 g/m^2
    b. Largest swept area of floating hydrocarbon above 50 g/m^2
    c. Largest volume of oil ashore
    d. Longest length of shoreline accumulation above 100 g/m^2
    e. Largest area of entrained hydrocarbons above 100 ppb
    f. Largest area of dissolved hydrocarbons above 50 ppb

As there was no floating hydrocarbons at or above 50 g/m^2 and no dissolved hydrocarbon exposure at or above 50 ppb, for any of the 300 simulations, the deterministic results are presented based on criteria a, c, d and e only.

3 REGIONAL CURRENTS

The study area is located within the Northern Carnarvon Basin, on the North West Shelf, a waterbody bordered by the Indian Ocean and Timor Sea. The North West Shelf is characterised by complex geomorphological features such as shoals, valleys and terraces and is dominated by high-amplitude tides and seasonally-dependant wind driven currents (DEWHA, 2007).

Although the Indonesian Throughflow and Holloway current generate south-westerly flows all year-round, warm and less saline waters originating from the tropics can generate internal gyres that typically migrate through the area and result in large variation in the speed and direction of local currents. The Holloway current generally intensifies during April to July due to increased wind forcing.

A comprehensive description of the circulation patterns of the North West Shelf is provided in a review by Condie and Andrewartha (2008) and a schematic of the ocean currents along the Northwest Australian continental shelf is shown in Figure 3.1.

While, tidal currents are generally weaker in the deeper waters, its influence is greatest along the near shore and around islands. Therefore, to accurately account for the movement of an oil spill, which can move between the offshore and near shore region, ocean and tidal currents were combined as part of the study.

Figure 3.2 and Figure 3.3 present summer and winter current trends within the Carnarvon Basin and the North West Shelf.

3.1 Tidal Currents

Tidal current data was generated using RPS's advanced ocean/coastal model, HYDROMAP. The HYDROMAP model has been thoroughly tested and verified through field measurements throughout the world over the past 38 years (Isaji & Spaulding, 1984; Isaji, et al., 2001; Zigic, et al., 2003). HYDROMAP tidal current data has been used as input to forecast (in the future) and hindcast (in the past) pollutant spills in Australian waters and forms part of the Australian National Oil Spill Emergency Response System operated by AMSA (Australian Maritime Safety Authority).

HYDROMAP employs a sophisticated sub-gridding strategy, which supports up to six levels of spatial resolution, halving the grid cell size as each level of resolution is employed. The sub-gridding allows for higher resolution of currents within areas of greater bathymetric and coastline complexity, and/or of particular interest to a study.

The numerical solution methodology follows that of Davies (1977a and 1977b) with further developments for model efficiency by Owen (1980) and Gordon (1982). A more detailed presentation of the model can be found in Isaji and Spaulding (1984) and Isaji et al. (2001).

3.1.1 Grid Setup

The tidal model domain has been sub-gridded to a resolution of 500 m for shallow and coastal regions, starting from an offshore (or deep water) resolution of 8 km. The finer grids were allocated in a step-wise fashion to resolve flows more accurately along the coastline, around islands and over regions with more complex bathymetry. Figure 3.4 shows the tidal model grid resolutions.

A combination of datasets was used and merged to describe the shape of the seabed within the grid domain (Figure 3.5). These included spot depths and contours which were digitised from nautical charts released by the hydrographic offices as well as Geoscience Australia database and depths extracted from the Shuttle Radar Topography Mission (SRTM30_PLUS) Plus dataset (see Becker et al., 2009).

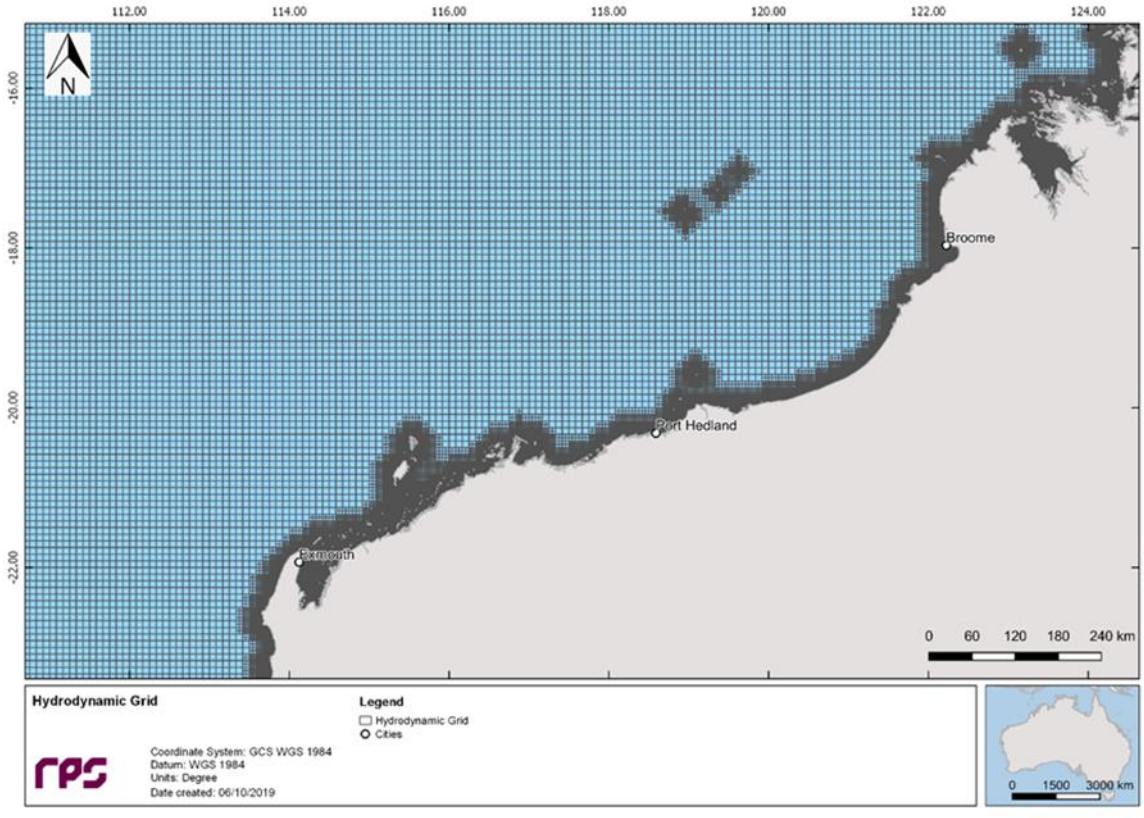

Figure 3.4 Zoomed in view of the model grid used to generate the tidal currents for the study region. Higher resolution areas are shown by the denser mesh.

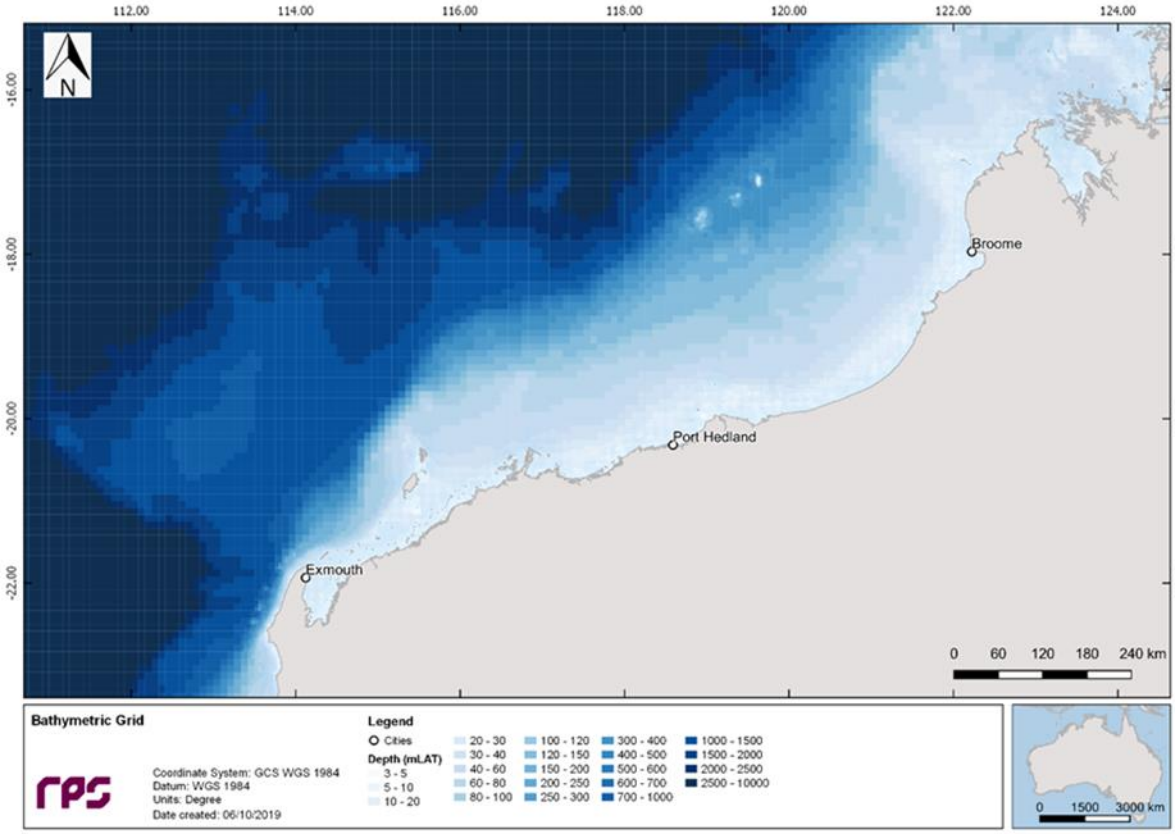

Figure 3.5 Bathymetry defined throughout the tidal model domain.

3.1.2 Tidal Conditions

The ocean boundary data for the regional model was obtained from satellite measured altimetry data (TOPEX/Poseidon 7.2) which provided estimates of the eight dominant tidal constituents at a horizontal scale of approximately 0.25 degrees. The eight major tidal constituents used were K_2, S_2, M_2, N_2, K_1, P_1, O_1 and Q_1. Using the tidal data, surface heights were firstly calculated along the open boundaries, at each time step in the model.

The TOPEX/Poseidon satellite data has a global resolution of 0.25 degrees and is produced and quality controlled by NASA (National Aeronautics and Space Administration). The satellites equipped with two highly accurate altimeters and capable of taking sea level measurements with an accuracy of ± 5 cm measured oceanic surface elevations (and the resultant tides) for over 13 years (1992–2005). In total, these satellites carried out 62,000 orbits of the planet.

The TOPEX/Poseidon tidal data has been widely used amongst the oceanographic community, being included in more than 2,100 research publications (e.g. Andersen, 1995; Ludicone et al., 1998; Matsumoto et al., 2000; Kostianoy et al., 2003; Yaremchuk and Tangdong, 2004; Qiu and Chen 2010). As such the TOPEX/Poseidon tidal data is considered suitably accurate for this study.

3.2 Ocean Currents

Data describing the flow of ocean currents was obtained from HYCOM (Hybrid Coordinate Ocean Model, (Chassignet et al., 2007), which is operated by the HYCOM Consortium, sponsored by the National Ocean Partnership Program (NOPP), as part of the U.S. Global Ocean Data Assimilation Experiment (GODAE). HYCOM is a data-assimilative, three-dimensional ocean model that is run as a hindcast (for a past period), assimilating time-varying observations of sea surface height, sea surface temperature and in-situ temperature and salinity measurements (Chassignet et al., 2009). The HYCOM predictions for drift currents are produced at a horizontal spatial resolution of approximately 8.25 km (1/12th of a degree) over the region, at a frequency of every 3 hours. HYCOM uses isopycnal layers in the open, stratified ocean, but uses the layered continuity equation to make a dynamically smooth transition to a terrain following coordinate in shallow coastal regions, and to z-level coordinates in the mixed layer and/or unstratified seas.

For this study, the HYCOM hindcast currents were obtained for the years 2010 to 2019 (inclusive).

3.3 Surface Currents

Table 3.1 presents the predicted average and maximum monthly surface current speeds at the release location.

The month average surface current speeds ranged between 0.16 m/s (November) and 0.27 m/s (June). Additionally, the maximums ranged between 0.55 m/s (November) and 1.76 m/s (January). The general current directions were towards the southwest. Figure 3.6 and Figure 3.7 present the monthly and total current rose distributions, respectively.

Note the convention for defining current direction throughout this report is the direction the current flows towards. Each branch of the current rose distribution represents the currents flowing to that direction, with north to the top of the diagram. The branches are divided into segments of different colour, which represent the current speed ranges for each direction. Speed intervals of 0.1 m/s are typically used in these current roses. The length of each coloured segment within a branch is proportional to the frequency of currents flowing within the corresponding speed and direction.

Table 3.1 Predicted monthly average and maximum surface current speeds close to the release location. Data derived by combining the HYCOM ocean data and HYDROMAP high resolution tidal data from 2010-2019 (inclusive).

Season	Month	Average current speed (m/s)	Maximum current speed (m/s)	General direction (towards)
Summer	January	0.21	1.76	North and Southwest
	February	0.19	1.08	Variable
	March	0.21	1.73	Southwest
Transitional	April	0.22	1.02	Southwest
Winter	May	0.24	0.78	Southwest
	June	0.27	0.81	Southwest
	July	0.20	0.90	Southwest
Transitional	August	0.18	0.60	Southwest
Summer	September	0.19	0.93	Northeast and Southwest
	October	0.20	0.75	Northeast and Southwest
	November	0.16	0.55	Southwest
	December	0.21	0.74	Southwest
Minimum		**0.16**	**0.55**	
Maximum		**0.27**	**1.76**	

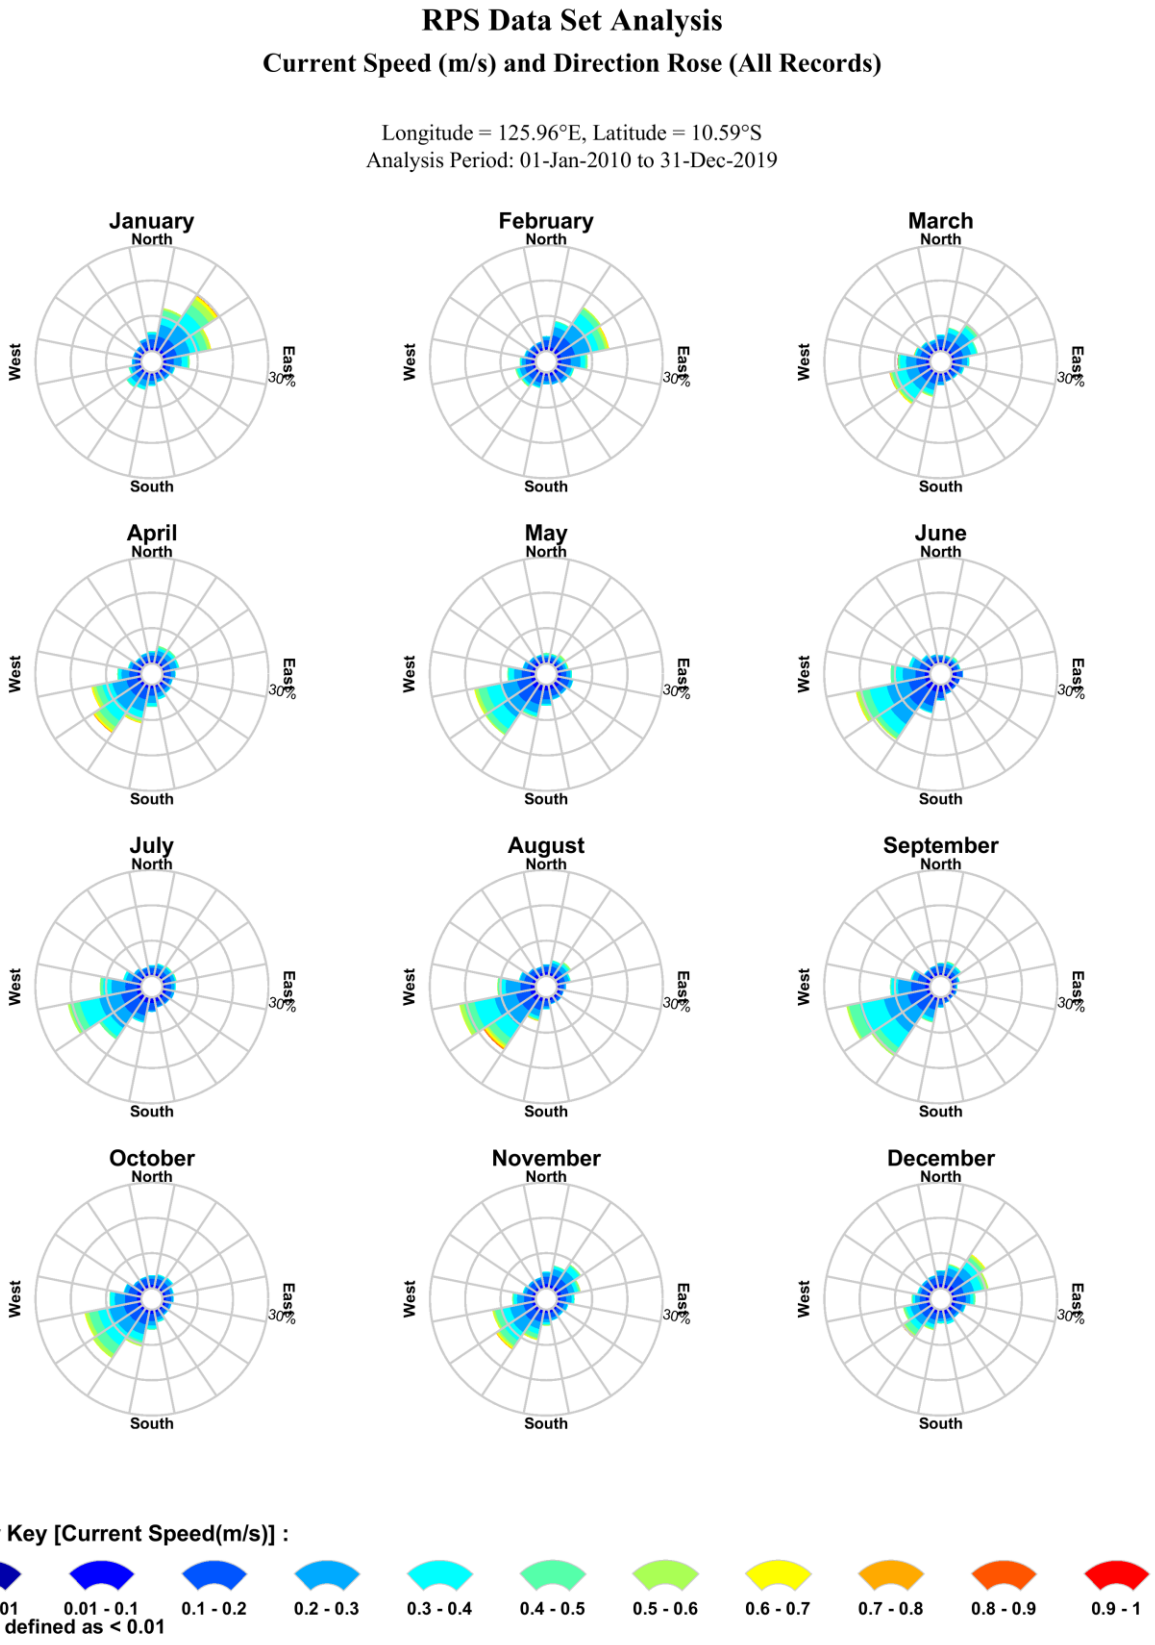

Figure 3.6 Monthly surface current rose distributions at the release location, derived from the 2010 to 2019 modelled dataset.

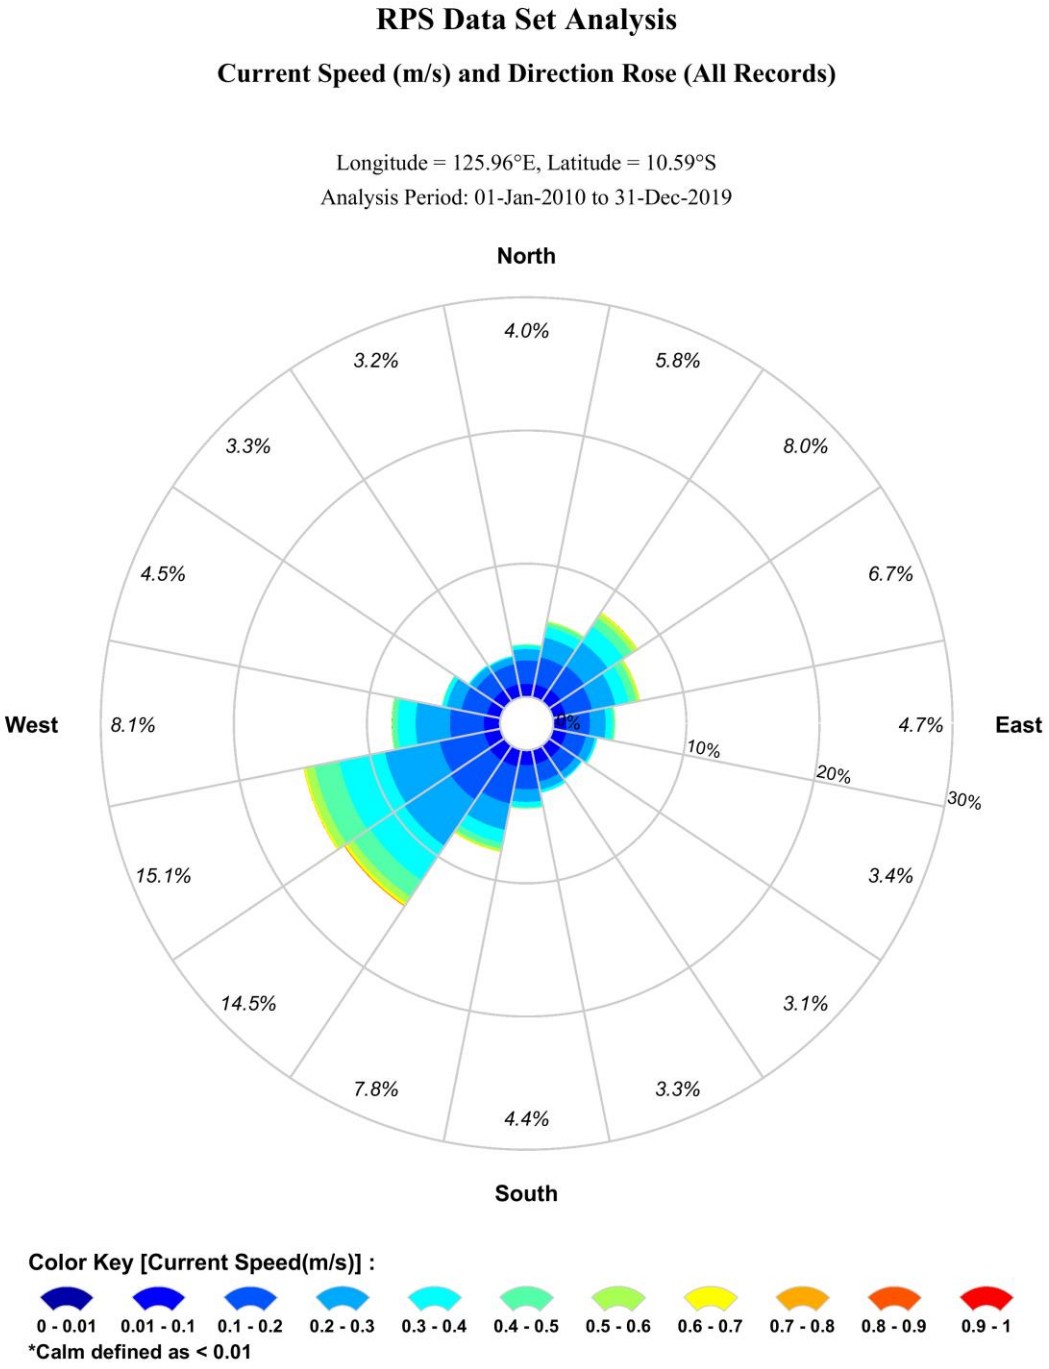

Figure 3.7 Total surface current rose plot at the release location, derived from the 2010 to 2019 modelled dataset.

4 WIND DATA

To account for the influence of the wind on the floating oil, wind data from 2010 to 2019 (inclusive) was sourced from the National Centre for Environmental Prediction (NCEP) Climate Forecast System Reanalysis (CFSR; see Saha et al., 2010). The CFSR wind model includes observations from many data sources; surface observations, upper-atmosphere air balloon observations, aircraft observations and satellite observations. The model is capable of accurately representing the interaction between the earth's oceans, land and atmosphere. The gridded wind data output is available at ¼ of a degree resolution (~33 km) and 1-hourly time intervals. Figure 4.1 shows the spatial resolution of the wind field used as input into the oil spill model.

Table 4.1 shows the monthly average and maximum winds derived from the CFSR node closest to the release location. The model wind data demonstrated that this region typically experiences moderate winds all year round and although the monthly average wind speeds remain under 15 knots. The maximum wind speed was 48 knots (July). Winds typically blow from the southwest during the summer months, while winds are typically easterly during the winter months.

Figure 4.2 and Figure 4.3 illustrates the monthly and total wind rose distributions nearby the release location, respectively.

Note that the atmospheric convention for defining wind direction, that is, the direction the wind blows from, is used to reference wind direction throughout this report. Each branch of the rose represents wind coming from that direction, with north to the top of the diagram. Sixteen directions are used. The branches are divided into segments of different colour, which represent wind speed ranges from that direction. Speed ranges of 5 knot intervals are typically used in these wind roses. The length of each segment within a branch is proportional to the frequency of winds blowing within the corresponding range of speeds from that direction.

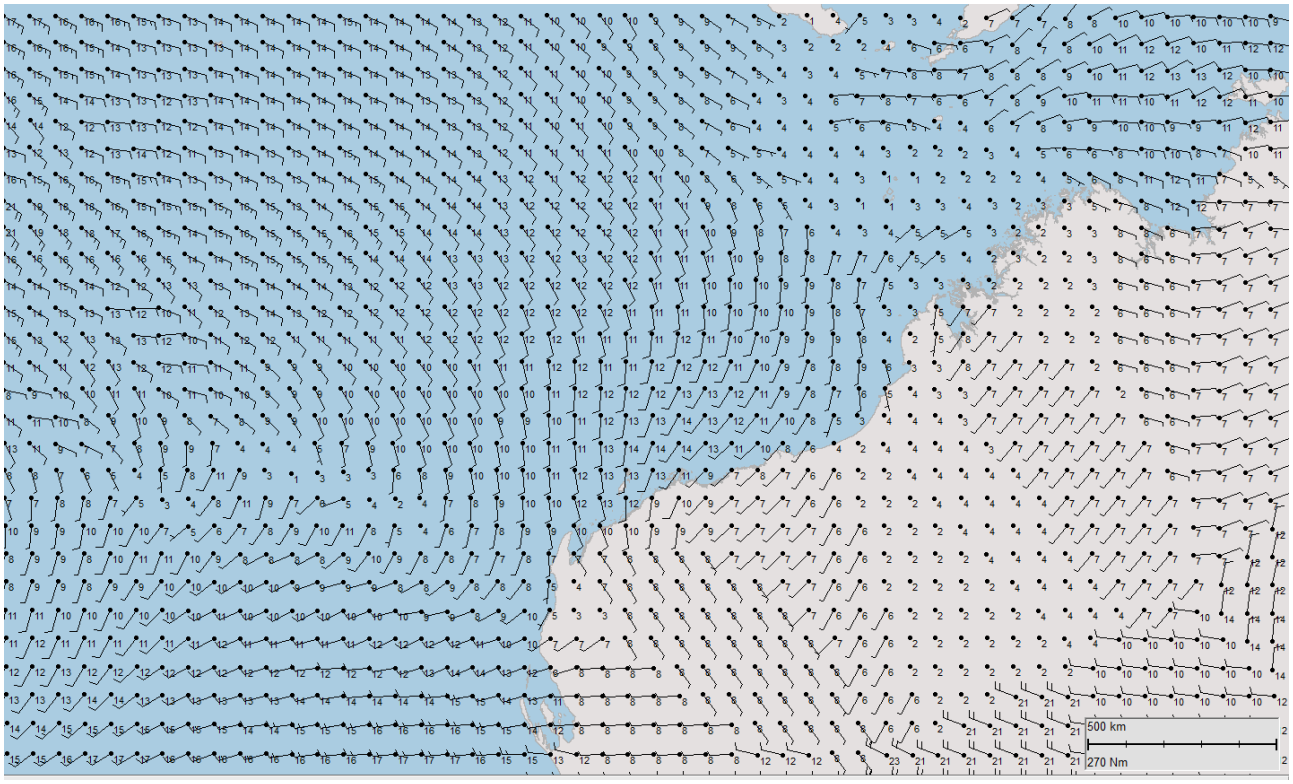

Figure 4.1 Spatial resolution of the CFSR modelled wind data used as input into the oil spill model. Note, for ease viewing only every second wind vector is displayed on the map.

Table 4.1 Predicted average and maximum winds for the wind node closest to the release location. Data derived from CFSR hindcast model 2010 to 2019 (inclusive).

Season	Month	Average wind (knots)	Maximum wind (knots)	General direction (from)
Summer	January	13	45	Southwest
	February	11	46	Southwest
	March	10	34	Southwest
Transitional	April	10	39	Variable
Winter	May	12	43	East
	June	14	29	East
	July	13	48	East to South
Transitional	August	11	30	Variable

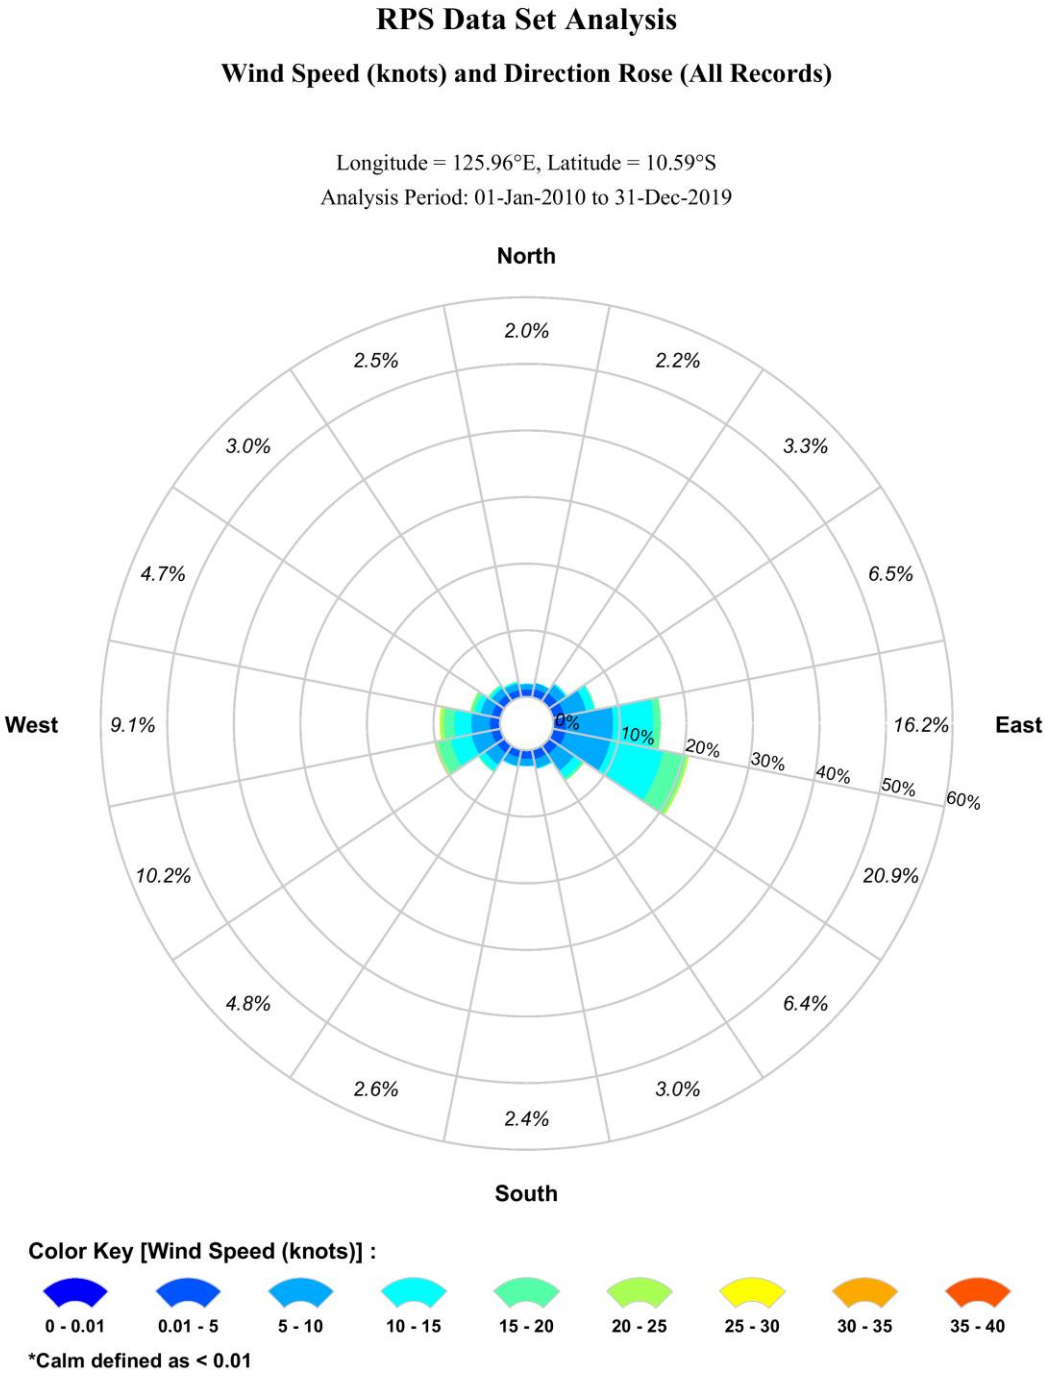

Figure 4.3 Total wind rose distributions adjacent to the release location, derived from the 2010 to 2019 modelled dataset.

5 WATER TEMPERATURE AND SALINITY

The monthly depth-varying water temperature and salinity profiles nearest to the release location was obtained from the HYbrid Coordinate Ocean Model (see Section 3.2 Ocean Currents).

The three-dimensional salinity and temperature datasets are used in the oil spill model domain to inform the weathering, movement, and evaporative loss of hydrocarbon spills in the surface and subsurface layers.

Table 5.1 shows that the monthly average sea surface temperatures ranged from 24.1°C (September) to 29.6°C (March), whilst salinity remained relatively consistent throughout the year, ranging between 34.5–34.9 psu.

Figure 5.1 the vertical profile of sea temperature and salinity nearby the release location.

Table 5.1 Monthly average sea surface temperature and salinity near the release location in the 0-5 m depth layer.

Month	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sept	Oct	Nov	Dec
Temperature (°C)	27.8	28.6	29.6	28.9	27.8	26.9	25.4	24.4	24.1	24.9	27.2	27.0
Salinity (psu)	34.9	34.6	34.6	34.5	34.7	34.8	34.6	34.7	34.7	34.7	34.7	34.7

6 SUBSEA PLUME MODEL – OILMAP DEEP

The LOWC scenario is a high-pressure release of mostly gas and condensate and where gas is released with condensate, the buoyancy of the expanding gas cloud will entrain ambient seawater and propel the droplets towards the surface at a faster rate than would occur from the relative buoyancy of the condensate alone. Furthermore, the turbulence generated by such an intense discharge will tend to break the condensate up into droplets of various sizes.

To define the near-field plume dynamics, the subsea blowout model, OILMAP-DEEP, was applied. The model simulates the plume rise dynamics in two phases, the initial jet phase and the buoyant plume phase. The initial jet phase governs the plume dynamics directly above the subsurface release location and is predominately driven by the exit velocity. During this phase, the condensate droplet size and distribution is calculated. Next, the rise dynamics are dominated by the buoyant nature of the plume until the termination of the plume phase (known as the trapping depth). At this point, the results from OILMAP-DEEP (including plume trapping depth, plume diameter and droplet size distribution) are integrated into the far-field model SIMAP to simulate the rise and dispersion of the condensate droplets.

More details on the OILMAP-DEEP model, can be found in Spaulding et al. (2015). The model has been validated against observations from Deepwater Horizon as well as small and large-scale laboratory studies on subsurface oil releases (Brandvik et al., 2013, 2014; Belore, 2014; Spaulding et al., 2015; Li et al., 2017).

Table 6.1 presents the input parameters for the OILMAP-DEEP model and key results related to the near-field plume dynamics. The results indicated that the mixture of gas and condensate rose through the water column (whilst gradually losing momentum) to a trapping depth of approximately 492 m below mean sea level. After this point the condensate droplets would rise due to their own buoyancy, which range in size from 366 to 1,583 µm.

Figure 6.1 illustrates the various stages of an example blowout plume.

Table 6.1 Input data and key results for the subsea plume modelling.

Input Variable	Value
Scenario	Loss of Well Control
Well name	Chrysaor Well 5
Water depth (m)	800
Tubing diameter (inch) [m]	7 5/8 [0.194]
Condensate rate (stb/day)	1,308
Gas rate (MMscf/day)	239
Gas to condensate ratio (scf/bbl)	182,722
Formation water flow rate (stb/day)	0
Operating pressure (psia)	5,097
Key results	
Plume execution depth (m BMSL)	492
Droplet sizes (µm)	366 to 1,583

7 OIL SPILL MODEL – SIMAP

Modelling of the fate of oil was performed using the Spill Impact Mapping Analysis Program (SIMAP). SIMAP is designed to simulate the fate and effects of spilled hydrocarbons for both the surface and subsurface releases (Spaulding et al. 1994; French et al. 1999; French-McCay, 2003, 2004; French-McCay et al. 2004).

SIMAP has been used to predict the weathering and fate of oil spills during and after major incidents including: Montara (Australia) well blowout August 2009 in the Timor Sea (Asia-Pacific ASA, 2010); Macondo (USA) well blowout April 2010 in the Gulf of Mexico; Bohai Bay (China) oil spill August 2011; and the pipeline oil spill July 2013 in the Gulf of Thailand.

The SIMAP model calculates the transport, spreading, entrainment, evaporation and decay of surface hydrocarbon slicks as well as the entrained and dissolved oil components in the water column, either from surface slicks or from oil discharged subsea. The movement and weathering of the spilled oil is calculated for specific oil types. Input specifications for oil mixtures include the density, viscosity, pour point, distillation curve (volume lost versus temperature) and the aromatic/aliphatic component ratios within given boiling point ranges.

SIMAP is a three-dimensional model that allows for various response actions to be modelled including oil removal from skimming, burning, or collection booms, and surface and subsurface dispersant application.

The SIMAP oil spill model includes advanced weathering algorithms, specifically focussed on unique oils that tend to form emulsions and/or tar balls. The weathering algorithms are based on five years of extensive research conducted in response to the Deepwater Horizon oil spill in the Gulf of Mexico (French et al., 2015).

Biodegradation is included in the oil spill model. In the model, SIMAP, degradation is calculated for the surface slick, deposited oil on the shore, the entrained oil and dissolved constituents in the water column, and oil in the sediments. For surface oil, water column oil and sedimented oil a first order degradation rate is specified. Biodegradation rates are relatively high for hydrocarbons in dissolved state or in dispersed small droplets.

7.1 Stochastic Modelling

Stochastic oil spill modelling is created by overlaying a great number (often 100 hundred) simulated hypothetical oil spills (Figure 7.1). Stochastic modelling involves running numerous individual oil spill simulations using a range of prevailing wind and current conditions that are historically representative of the season and location of where the spill event may occur.

For the stochastic modelling presented herein, **100 spills** were simulated per season using the same spill information (release location, spill volume, duration and condensate properties) but with varied start dates and times corresponding to the period represented by the available wind and current data. During each simulation, the model records whether any grid cells are exposed to any hydrocarbon concentrations, the concentrations involved and the elapsed time before exposure. For each scenario the results of all 100 condensate spill simulations were analysed to determine the following seasonal statistics for every grid cell:

- Exposure load (concentrations and volumes);
- Minimum time before exposure;
- Probability of contact above defined concentrations;
- Volume of condensate that may strand on shorelines from any single simulation;
- Concentration that might occur on sections of individual shorelines;
- Exposure (instantaneous and/or over a specified duration) to dissolved hydrocarbons in the water column; and

- Exposure (instantaneous and/or over a specified duration) to entrained hydrocarbons in the water column.

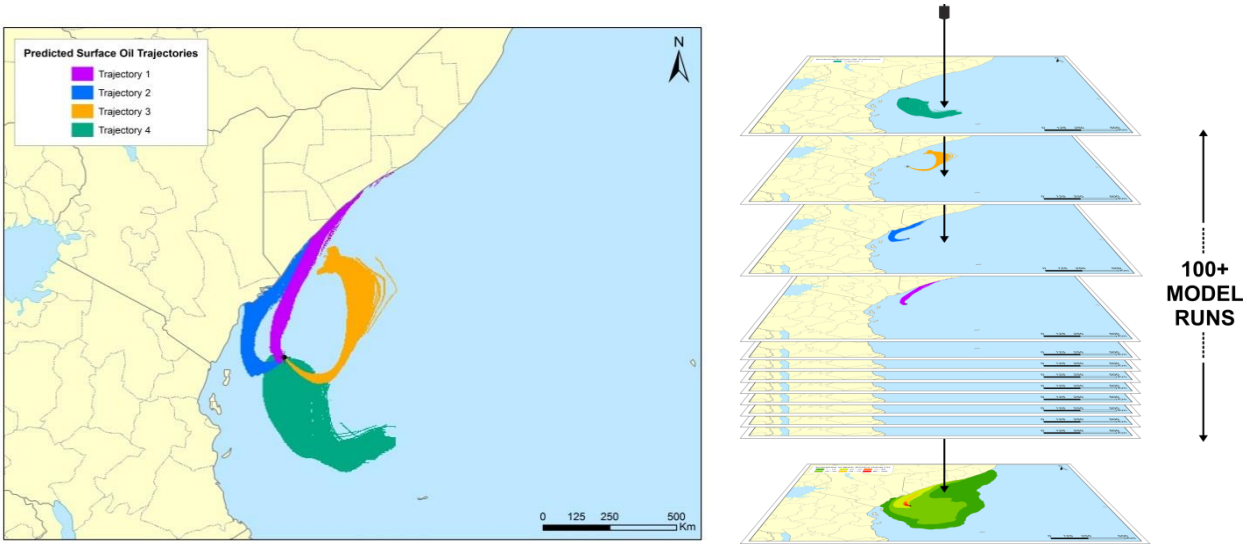

Figure 7.1 Predicted movement of four single oil spill simulations by SIMAP for the same scenario (left image). All model runs are overlain (shown as the stacked runs on the right) and the number of times that trajectories contact a given location at a concentration is used to calculate the probability (Source: NOPSEMA, 2018).

7.2 Floating, Shoreline and In-Water Thresholds

The thresholds and their relationship to exposure for the sea surface, shoreline and water column (entrained and dissolved hydrocarbons) are presented in Sections 7.2.1 to 7.2.3. Supporting justifications of the adopted thresholds applied during the study and additional context relating to the area of influence are also provided. It is important to note that the thresholds herein are based on NOPSEMA (2019).

7.2.1 Floating Oil Exposure Thresholds

The modelling results can be presented to any levels; therefore, thresholds have been specified (based on scientific literature) to record floating oil exposure to the sea-surface at meaningful levels only, described in the following paragraphs.

The low threshold to assess the potential for floating oil exposure, was 1 g/m^2, which equates approximately to an average thickness of 1 µm, referred to as visible oil. Oil of this thickness is described as rainbow sheen in appearance, according to the Bonn Agreement Oil Appearance Code (Bonn Agreement, 2009; AMSA, 2014) (see Table 7.1). Figure 7.2 shows photographs highlighting the difference in appearance between a silvery sheen, rainbow sheen and metallic sheen. This threshold is considered below levels which would cause environmental harm and it is more indicative of the areas perceived to be affected due to its visibility on the sea surface and potential to trigger temporary closures of areas (i.e. fishing grounds) as a precautionary measure. Table 7.1 provides a description of the appearance in relation to exposure zone thresholds used to classify the zones of floating oil exposure.

Ecological impact has been estimated to occur at 10 g/m^2 (a film thickness of approximately 10 µm or 0.01 mm) according to French et al. (1996) and French-McCay (2009) as this level of fresh oiling has been observed to mortally impact some birds through adhesion of oil to their feathers, exposing them to secondary effects such as hypothermia. The appearance of oil at this average thickness has been described as a metallic sheen (Bonn Agreement, 2009). Concentrations above 10 g/m^2 is also considered the lower actionable threshold, where oil may be thick enough for containment and recovery as well as dispersant treatment (AMSA, 2015).

Scholten et al. (1996) and Koops et al. (2004) indicated that at oil concentrations on the sea surface of 25 g/m^2 (or greater), would be harmful for all birds that have landed in an oil film due to potential contamination of their feathers, with secondary effects such as loss of temperature regulation and ingestion of oil through preening. The appearance of oil at this thickness is also described as metallic sheen (Bonn Agreement, 2009). For this study the high exposure threshold was set to 50 g/m^2 and above based on NOPSEMA (2019). This threshold can also be used to inform response planning.

Table 7.2 defines the thresholds used to classify the zones of floating oil exposure reported herein.

Table 7.1 The Bonn Agreement Oil Appearance Code.

Code	Description Appearance	Layer Thickness Interval (g/m^2 or µm)	Litres per km^2
1	Sheen (silvery/grey)	0.04 – 0.30	40 – 300
2	Rainbow	0.30 – 5.0	300 – 5,000
3	Metallic	5.0 – 50	5,000 – 50,000
4	Discontinuous True Oil Colour	50 – 200	50,000 – 200,000
5	Continuous True Oil Colour	≥ 200	≥ 200,000

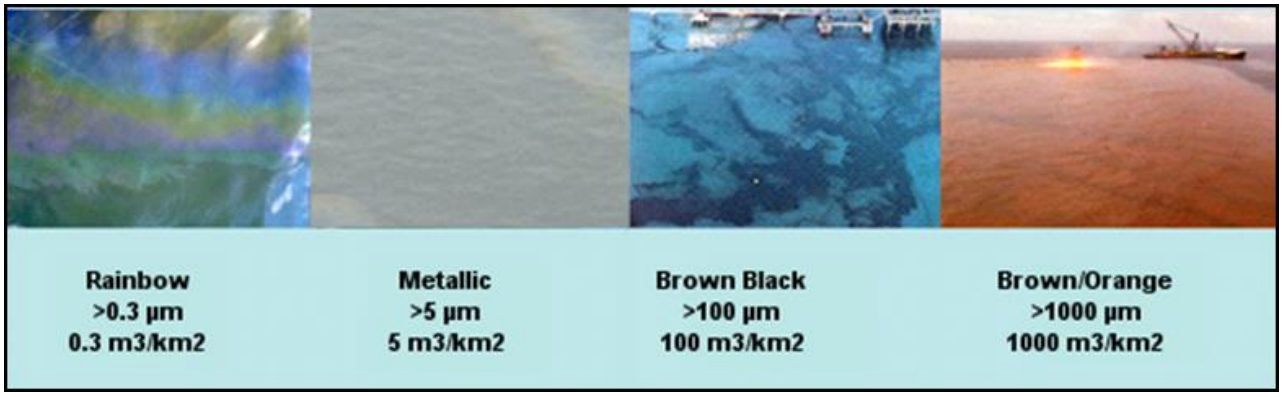

Figure 7.2 Photographs showing the difference between oil colour and thickness on the sea surface (source: adapted from Oil Spill Solutions, 2015).

Table 7.2 Floating oil exposure thresholds used in this report (in alignment with NOPSEMA, 2019).

Threshold level	Floating oil (g/m^2)	Description
Low	1	Approximates range of socioeconomic effects and establishes planning area for scientific monitoring
Moderate	10	Approximates lower limit for harmful exposures to birds and marine mammals
High	50*	Approximates surface oil slick and informs response planning

* 50 g/m^2 also used to define the threshold for actionable floating oil.

7.2.2 Shoreline Accumulation Thresholds

There are many different types of shorelines, ranging from cliffs, rocky beaches, sandy beaches, mud flats and mangroves, and each of these influences the volume of oil that can remain stranded ashore and its thickness before the shoreline saturation point occurs. For instance, a sandy beach may allow oil to percolate through the sand, thus increasing its ability to hold more oil ashore over tidal cycles and various wave actions than an equivalent area of water; hence oil can increase in thickness onshore over time. A sandy beach shoreline was assumed as the default shoreline type for the modelling herein, as it allows for the highest carrying capacity of oil (of the available open/exposed shoreline types). Hence the results contained herein would be indicative of a worst-case scenario, where the highest volume of oil may be stranded on the shoreline (when compared to other shoreline types, such as exposed rocky shores).

In previous risk assessment studies, French-McCay et al. (2005a; 2005b) used a threshold of 10 g/m^2 to assess the potential for shoreline accumulation. This is a conservative threshold used to define regions of socio-economic impact, such as triggering temporary closures of adjoining fisheries or the need for shore clean-up on beaches or man-made features/amenities (breakwaters, jetties, marinas, etc.). It would equate to approximately 2 teaspoons of hydrocarbon per square meter of shoreline accumulation. The appearance is described as a stain/film. On that basis, the 10 g/m^2 shoreline accumulation threshold has been selected to define the zone of potential “low shoreline accumulation”.

French et al. (1996) and French-McCay (2009) define a shoreline oil accumulation threshold of 100 g/m^2, or above, would potentially harm shorebirds and wildlife (furbearing aquatic mammals and marine reptiles on or along the shore) based on studies for sub-lethal and lethal impacts. This threshold has been used in previous environmental risk assessment studies (see French-McCay, 2003; French-McCay et al., 2004, French-McCay et al., 2011; 2012; NOAA, 2013). Additionally, a shoreline concentration of 100 g/m^2, or above, is the minimum limit that the oil can be effectively cleaned according to the AMSA (2015) guideline. This threshold equates to approximately ½ a cup of oil per square meter of shoreline accumulation. The appearance is described as a thin oil coat. Therefore, 100 g/m^2 has been selected to define the zone of potential “moderate shoreline accumulation”.

Observations by Lin & Mendelssohn (1996) demonstrated that loadings of more than 1,000 g/m^2 of hydrocarbon during the growing season would be required to impact marsh plants significantly. Similar thresholds have been found in studies assessing hydrocarbon impacts on mangroves (Grant et al., 1993; Suprayogi & Murray 1999). Hence, 1,000 g/m^2 has been selected to define the zone of potential “high shoreline accumulation”. It equates to approximately 1 litre of hydrocarbon per square meter of shoreline accumulation. The appearance is described as a hydrocarbon cover.

It is worth noting that the shoreline accumulation thresholds derived from extensive literature review (outlined in Table 7.3) agree with the commonly used threshold values for oil spill modelling specified in NOPSEMA (2019).

Table 7.3 Thresholds used to assess shoreline accumulation.

Threshold level	Shoreline accumulation (g/m^2)	Description
Low (socioeconomic/sublethal)	10	Predicts potential for some socio-economic impact
Moderate	100*	Loading predicts area likely to require clean-up effort
High	> 1,000	Loading predicts area likely to require intensive clean-up effort

* 100 g/m^2 also used to define the threshold for actionable shoreline oil.

7.2.3 In-water Exposure Thresholds

Oil is a mixture of thousands of hydrocarbons of varying physical, chemical, and toxicological characteristics, and therefore, demonstrate varying fates and impacts on organisms. As such, for in-water exposure, the SIMAP model provides separate outputs for dissolved and entrained hydrocarbons from oil droplets. The consequences of exposure to dissolved and entrained components will differ because they have different modes and magnitudes of effect.

Entrained hydrocarbon concentrations were calculated based on oil droplets that are suspended in the water column, though not dissolved. The composition of this oil would vary with the state of weathering (oil age) and may contain soluble hydrocarbons when the oil is fresh. Calculations for dissolved hydrocarbons specifically calculates oil components which are dissolved in water, which are known to be the primary source of toxicity exerted by oil.

7.2.3.1 Dissolved Hydrocarbons

Laboratory studies have shown that dissolved hydrocarbons exert most of the toxic effects of oil on aquatic biota (Carls et al., 2008; Nordtug et al., 2011; Redman, 2015). The mode of action is a narcotic effect, which is positively related to the concentration of soluble hydrocarbons in the body tissues of organisms (French-McCay, 2002). Dissolved hydrocarbons are taken up by organisms directly from the water column by absorption through external surfaces and gills, as well as through the digestive tract. Thus, soluble hydrocarbons are termed “bioavailable”.

Hydrocarbon compounds vary in water-solubility and the toxicity exerted by individual compounds is inversely related to solubility, however bioavailability will be modified by the volatility of individual compounds (Nirmalakhandan & Speece, 1988; Blum & Speece, 1990; McCarty, 1986; McCarty et al., 1992a, 1992b; Mackay et al., 1992; McCarty & Mackay, 1993; Verhaar et al., 1992, 1999; Swartz et al., 1995; French-McCay, 2002; McGrath & Di Toro, 2009). Of the soluble compounds, the greatest contributor to toxicity for water-column and benthic organisms are the lower-molecular-weight aromatic compounds, which are both volatile and soluble in water. Although they are not the most water-soluble hydrocarbons within most oil types, the polynuclear aromatic hydrocarbons (PAHs) containing 2-3 aromatic ring structures typically exert the largest narcotic effects because they are semi-soluble and not highly volatile, so they persist in the environment long enough for significant accumulation to occur (Anderson et al., 1974, 1987; Neff & Anderson, 1981; Malins & Hodgins, 1981; McAuliffe, 1987; NRC, 2003). The monoaromatic hydrocarbons (MAHs), including the BTEX compounds (benzene, toluene, ethylbenzene, and xylenes), and the soluble alkanes (straight chain hydrocarbons) also contribute to toxicity, but these compounds are highly volatile, so that their contribution will be low when oil is exposed to evaporation and higher when oil is discharged at depth where volatilisation does not occur (French-McCay, 2002).

French-McCay (2002) reviewed available toxicity data, where marine biota was exposed to dissolved hydrocarbons prepared from oil mixtures, finding that 95% of species and life stages exhibited 50% population mortality (LC_{50}) between 6 and 400 ppb total PAH concentration after 96 hrs exposure, with an average of 50 ppb. Hence, concentrations lower than 6 ppb total PAH value should be protective of 97.5% of species and life stages even with exposure periods of days (at least 96 hours). Early life-history stages of fish appear to be more sensitive than older fish stages and invertebrates.

Exceedances of 10, 50 or 400 ppb over a 1 hour timestep (see Table 7.4) was applied to indicate increasing potential for sub-lethal to lethal toxic effects (or low to high), based on NOPSEMA (2019).

7.2.3.2 Entrained Hydrocarbons

Entrained hydrocarbons consist of oil droplets that are suspended in the water column and insoluble. As such, insoluble compounds in oil cannot be absorbed from the water column by aquatic organisms, hence are not bioavailable through absorption of compounds from the water. Exposure to these compounds would require routes of uptake other than absorption of soluble compounds. The route of exposure of organisms to whole oil alone include direct contact with tissues of organisms and uptake of oil by direct consumption, with potential for biomagnification through the food chain (NRC, 2003).

The 10 ppb threshold represents the very lowest concentration and corresponds generally with the lowest trigger levels for chronic exposure for entrained hydrocarbons in the ANZECC & ARMCANZ (2000) water quality guidelines. Due to the requirement for relatively long exposure times (> 24 hours) for these concentrations to be significant, they are likely to be more meaningful for juvenile fish, larvae and planktonic organisms that might be entrained (or otherwise moving) within the entrained plumes, or when entrained hydrocarbons adhere to organisms or trapped against a shoreline for periods of several days or more.

This exposure zone is not considered to be of significant biological impact and is therefore outside the adverse exposure zone. This exposure zone represents the area contacted by the spill. This area does not define the area of influence as it is considered that the environment will not be affected by the entrained hydrocarbon at this level.

Thresholds of 10 ppb and 100 ppb were applied over a 1 hour time exposure (Table 7.4), to cover the range of thresholds outlined in the ANZECC & ARMCANZ (2000) water quality guidelines, the incremental change for greater potential effect and is per NOPSEMA (2019).

A complicating factor that should be considered when assessing the consequence of dissolved and entrained oil distributions is that there will be some areas where both physically entrained oil droplets and dissolved hydrocarbons co-exist. Higher concentrations of each will tend to occur close to the source where sea conditions can force mixing of relatively unweathered oil into the water column, resulting in more rapid dissolution of soluble compounds.

Table 7.4 Dissolved and entrained hydrocarbon exposure values assessed over a 1-hour time step, as per NOPSEMA (2019).

Threshold level	Dissolved hydrocarbon concentration (ppb)	Entrained hydrocarbon concentrations (ppb)
Low	10	10
Moderate	50	-
High	400	100

8 CONDENSATE PROPERTIES

8.1 Properties

As a conservative approach, Chevron had chosen Chrysaor condensate for the purposes of the modelling and hence provided physical properties and boiling point distributions, which are presented in Table 8.1 and Table 8.2, respectively.

Chrysaor condensate has an API of 40.20, a density of 824 kg/m^3 (at 15ºC) and a low viscosity value of 5.6 cP. When exposed to the atmosphere at local temperatures, about 23.8% of the condensate volatile components should evaporate within the first 12 hours (BP < 180°C); a further 33.0% of the semi-volatiles should evaporate within the first 24 hours (180°C < BP < 265°C); and low volatile portion (~32.9%) should evaporate over a longer period (265°C < BP < 380°C). Additionally, 10.3% of the condensate is shown to be persist in the marine environment for longer period and be subject to relatively slow degradation.

This condensate has a low asphaltene content (< 0.05%), which is one indicator for a very low propensity to take up water to form water-in-oil emulsion.

Soluble, aromatic hydrocarbons contribute approximately 3.0% by mass of the whole oil. For this condensate they are all contained in the volatile fractions, which are highly soluble. Discharges onto the water surface will favour the process of evaporation over dissolution under calm sea conditions, but increased entrainment of oil and dissolution of soluble compounds can be expected under stronger wind periods with the presence of small breaking waves (whitecaps).

The actual fate of released oil in the marine environment will depend greatly on the amount of oil that reaches the surface, either through the initial release or by rising after discharge in the water column.

Table 8.1 Physical properties of Chrysaor condensate.

Characteristic	Chrysaor Condensate
Density (kg/m^3)	824 (at 15°C)
API	40.20
Dynamic viscosity (cP)	5.6 (at 15°C)
Pour point (°C)	-9
Surface tension (dyne/cm)	19
Hydrocarbon property category	Group II
Hydrocarbon property classification	Light-persistent

Table 8.2 Boiling point ranges of Chrysaor condensate.

Oil Type	Component	Volatile (%)	Semi-volatile (%)	Low volatility (%)	Residual (%)
	Boiling point (°C)	<180 C_4 to C_{10}	180-265 C_{11} to C_{15}	265-380 C_{16} to C_{20}	>380 >C_{20}
Chrysaor Condensate	% of total	23.8	33.0	32.9	10.3
	% of aromatics	3.0	0	0	0

8.2 Weathering Characteristics

8.2.1 Overview

A series of weathering tests were conducted to illustrate the potential behaviour of this condensate when exposed to idealised and representative environmental conditions:

- Instantaneous 50 m^3 surface release under calm wind conditions (constant 5 knots), 27°C water temperature and currents.
- Instantaneous 50 m^3 surface release under variable moderate wind conditions, 27°C water temperature and currents.

The first case is indicative of weathering rates under calm conditions that would not generate entrainment, while the second case would be more representative of the moderate winds experienced over the region. Both scenarios provide examples of potential behaviour during periods of a spill event once the condensate reaches the surface.

8.2.2 Results

The mass balance forecast for the calm-wind case (Figure 8.1) shows that 57.0% of the condensate is predicted to evaporate within 24 hours. Majority of the remaining condensate on the water surface will weather at a slower rate due to the low volatile components. Evaporation of the residual compounds will slow significantly, and they will then be subject to more gradual decay through biological and photochemical processes.

Under the variable-wind case (Figure 8.2), where the winds are of greater strength on average, entrainment of Chrysaor condensate into the water column is predicted to increase. Approximately 24 hours after the spill, 58.7% of the condensate mass is forecast to have entrained and a further 39.1% is forecast to have evaporated, leaving only a small proportion of the condensate floating on the water surface (0.5%). The residual compounds will tend to remain entrained beneath the surface under conditions that generate wind waves (approximately >6 m/s).

The increased level of entrainment in the variable-wind case will result in a higher percentage of biological and photochemical degradation, where the decay of the floating slicks and condensate droplets in the water column occurs at an approximate rate of ~1.9% per day with an accumulated total of ~13% after 7 days, in comparison to a rate of 0.16% per day and an accumulated total of 1.09% after 7 days in the constant-wind case. Given the proportion of entrained condensate and the tendency for it to remain mixed in the water column, the remaining hydrocarbons will decay over time scales of several weeks.

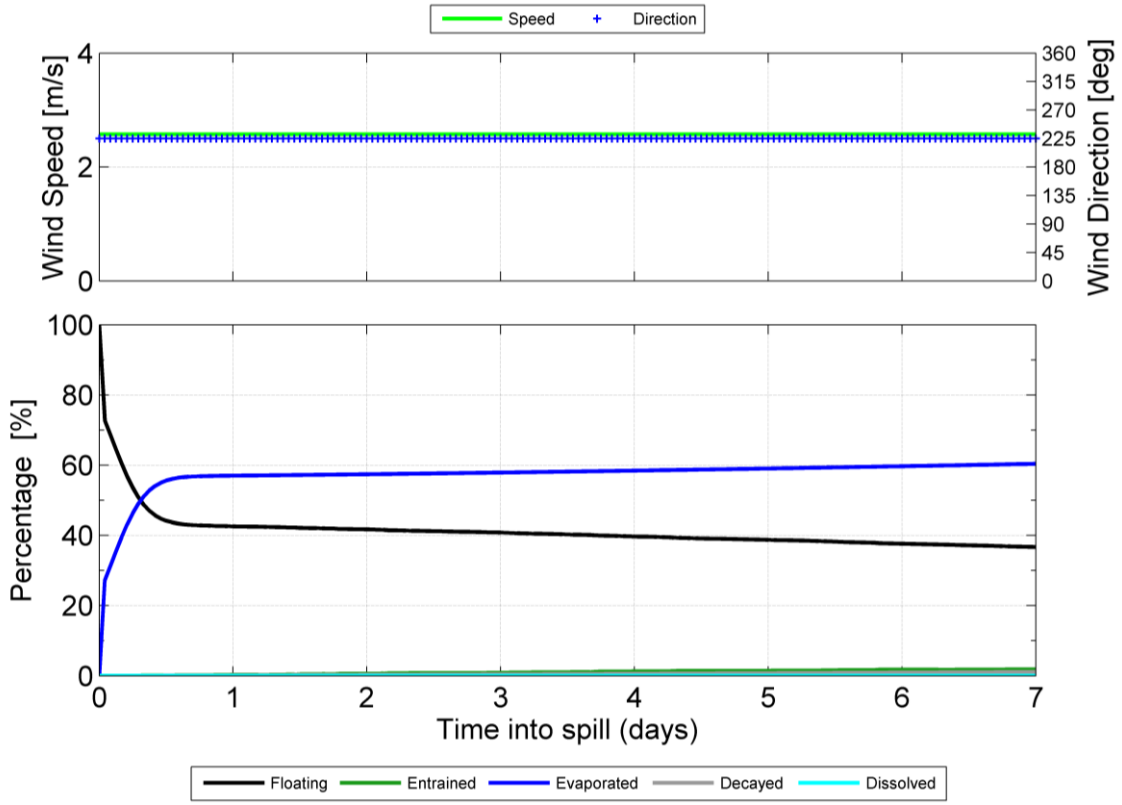

Figure 8.1 Proportional mass balance plot representing the weathering of Chrysaor condensate spilled onto the water surface as a one-off instantaneous release and subject to a constant 5 knots (2.6 m/s) wind at 27°C water temperature and 25°C air temperature.

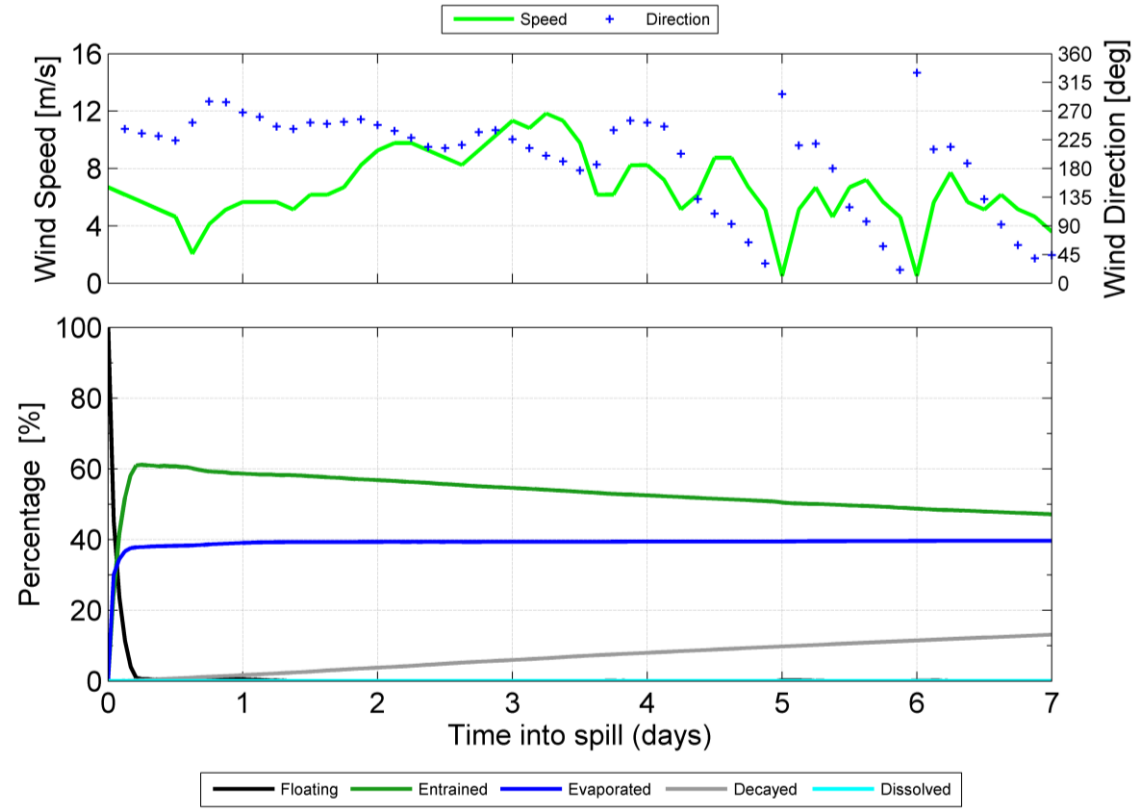

Figure 8.2 Proportional mass balance plot representing the weathering of Chrysaor condensate spilled onto the water surface as a one-off instantaneous release and subject to variable wind at 27°C water temperature and 25°C air temperature.

9 MODEL SETTINGS

Table 9.1 provides a summary of the oil spill model settings.

Table 9.1 Summary of the oil spill model settings used in this assessment.

	Scenario
Location	Chrysaor Well 5
Number of spill simulations with randomly selected start times	100 per season (300 total)
Spill volume (m^3) [bbl]	18,715 [117,720]
Condensate type	Chrysaor condensate
Release type (depth)	Subsea (800 m)
Release duration (days)	90
Simulation length (days)	104
Model period	Summer (September to the following March) Transitional (April and August) Winter (May to July)
Floating oil (NOPSEMA) thresholds	1 g/m^2, low exposure 10 g/m^2, moderate exposure 50 g/m^2, high exposure
Shoreline accumulation (NOPSEMA) thresholds	10 g/m^2, low exposure 100 g/m^2, moderate exposure 1,000 g/m^2, high exposure
Dissolved hydrocarbon (NOPSEMA) thresholds	10 ppb over 1 hour, low exposure 50 ppb over 1 hour, moderate exposure 400 ppb over 1 hour, high exposure
Entrained hydrocarbon (NOPSEMA) thresholds	10 ppb over 1 hour, low exposure 100 ppb over 1 hour, high exposure

10 PRESENTATION AND INTERPRETATION OF MODEL RESULTS

The results from the modelling study are presented in a number of tables and figures, which aim to provide an understanding of the predicted sea-surface and water column (subsurface) exposure and shoreline accumulation (if predicted).

10.1 Stochastic Analysis

10.1.1 Statistics

The statistics are based on the following principles:

- The ***greatest distance travelled by a spill trajectory*** – is determined by a) recording the maximum and b) second greatest distance travelled (or 99th percentile) by a single trajectory, within a scenario, from the release location to the identified exposure thresholds.
- The ***Probability of condensate exposure to a receptor*** – is determined by recording the number of spill trajectories to reach a specified sea surface or subsea threshold within a receptor polygon, divided by the total number of spill trajectories within that scenario.
- The ***Minimum time before condensate exposure to a receptor*** – is determined by ranking the elapsed time before sea surface exposure, at a specified threshold, to grid cells within a receptor polygon and recording the minimum value.
- The ***probability of oil accumulation at a receptor*** – is determined by recording the number of spill trajectories to reach a specified shoreline accumulation threshold within a receptor polygon, divided by the total number of spill trajectories within that scenario.
- The ***maximum potential oil accumulation within a receptor*** – is determined by identifying the maximum loading to any grid cell within a receptor polygon, for a scenario.
- The ***dissolved and entrained hydrocarbon exposure*** – is determined by recording the maximum instantaneous concentrations at each grid cell assessed over a 1-hour time step.

10.2 Deterministic Trajectories

The deterministic results in Section 11.2 are based on the following criteria:

a. Largest swept area of floating hydrocarbon above 10 g/m^2
b. Largest swept area of floating hydrocarbon above 50 g/m^2
c. Largest volume of oil ashore
d. Longest length of shoreline accumulation above 100 g/m^2
e. Largest area of entrained hydrocarbons above 100 ppb
f. Largest area of dissolved hydrocarbons above 50 ppb

As there was no dissolved hydrocarbon exposure at or above 50 ppb, for any of the 300 simulations, the deterministic results are presented based on criteria's a - e.

10.3 Receptors

A range of environmental receptors and shorelines were assessed for floating oil exposure, shoreline contact and water column exposure (entrained and dissolved hydrocarbons) as part of the study (see Figure 10.1 to Figure 10.10). Receptor categories (see Table 10.1) include sections of shorelines and offshore islands. All other sensitive receptors other than submerged reefs, shoals and banks (RSB) were sourced from http://www.environment.gov.au/. Risks of exposure were separately calculated for each sensitive receptor area and have been tabulated.

Table 10.2 summarises the receptors that the location resides within.

Table 10.1 Summary of receptors used to assess floating oil, shoreline and in-water exposure to hydrocarbons.

Receptor Category	Acronym	Hydrocarbon Exposure Assessment

11 RESULTS: CHRYSAOR–DIONYSUS LOSS OF WELL CONTROL

This scenario examined a 117,720 stb (or 18,715 m^3) subsea release of condensate over 90 days, following a LOWC. A total of 300 spill simulations were run for each of the three seasons (i.e. 100 spills per season) and tracked for 104 days.

Section 11.1 presents the seasonal (or stochastic) analysis results, while Section 11.2 presents the deterministic results.

11.1 Stochastic Analysis

11.1.1 Floating Condensate Exposure

Table 11.1 summarises the maximum distances from the release location to floating condensate exposure zones for each season. The maximum distance from the release location to the low (≥ 1 g/m^2) and moderate (≥ 10 g/m^2) thresholds was 82.0 km west (summer) and 4.3 km northeast (transitional and winter), respectively.

No exposure was predicted at the high (≥ 50 g/m^2) threshold.

Table 11.2 summarises the potential floating condensate exposure to individual receptors during each season.

The Offshore Area IAA, Pygmy Blue Whale - Distribution and Wedge-tailed Shearwater - Breeding BIAs, and the Continental Slope Demersal Fish Communities KEF, which the release location resides within, were the only receptors predicted to be exposed during all three seasons at the low and moderate thresholds. The probabilities for the low threshold were 100% for all seasons for these receptors. Probabilities of moderate exposure for these receptors ranged between 89% (all receptors; summer) and 99% (all receptors; winter). Additionally, the Flatback Turtle - Internesting Buffer BIA was also predicted to be exposed at the low threshold during summer (95%), transitional (100%) and winter (97%), respectively. The minimum time before low exposure for the Flatback Turtle - Internesting Buffer BIA was 0.67 days during summer conditions. Furthermore, the probability of exposure at the low threshold for the Pilbara (offshore) IMCRA and Ancient coastline at 125 m depth contour (KEF) was 88%, 84% and 89% during summer, transitional and winter conditions and 31%, 27% and 41% summer, transitional and winter conditions, respectively. The corresponding minimum time before low exposure at the Pilbara (offshore) IMCRA and Ancient coastline at 125 m depth contour FEF was 0.88 days (summer) and 2.21 days (winter).

Figure 11.1 to Figure 11.3 present the zones of floating condensate exposure for each season.

Table 11.1 Maximum distances and directions travelled from the release location to floating condensate exposure for each season and threshold, following a subsea LOWC at Chrysaor Well 5. The results were calculated from 100 spill trajectories per season.

Season	Distance and direction	Zones of potential floating condensate exposure		
		Low	Moderate	High
Summer	Max. distance from release site (km)	82.0	2.6	-
	Max. distance from release site (km) (99th percentile)	45.4	2.6	-
	Direction	West	Southwest	-
Transitional	Max. distance from release site (km)	73.5	4.3	-
	Max. distance from release site (km) (99th percentile)	60.5	4.3	-
	Direction	North-northeast	Northeast	-
Winter	Max. distance from release site (km)	70.3	4.3	-
	Max. distance from release site (km) (99th percentile)	58.5	4.3	-
	Direction	East-northeast	Northeast	-

Table 11.2 Summary of the potential floating condensate exposure to individual receptors, following a LOWC at Chrysaor Well 5. The results were calculated from 100 spill trajectories per season.

*The release location resides within the receptor boundaries.

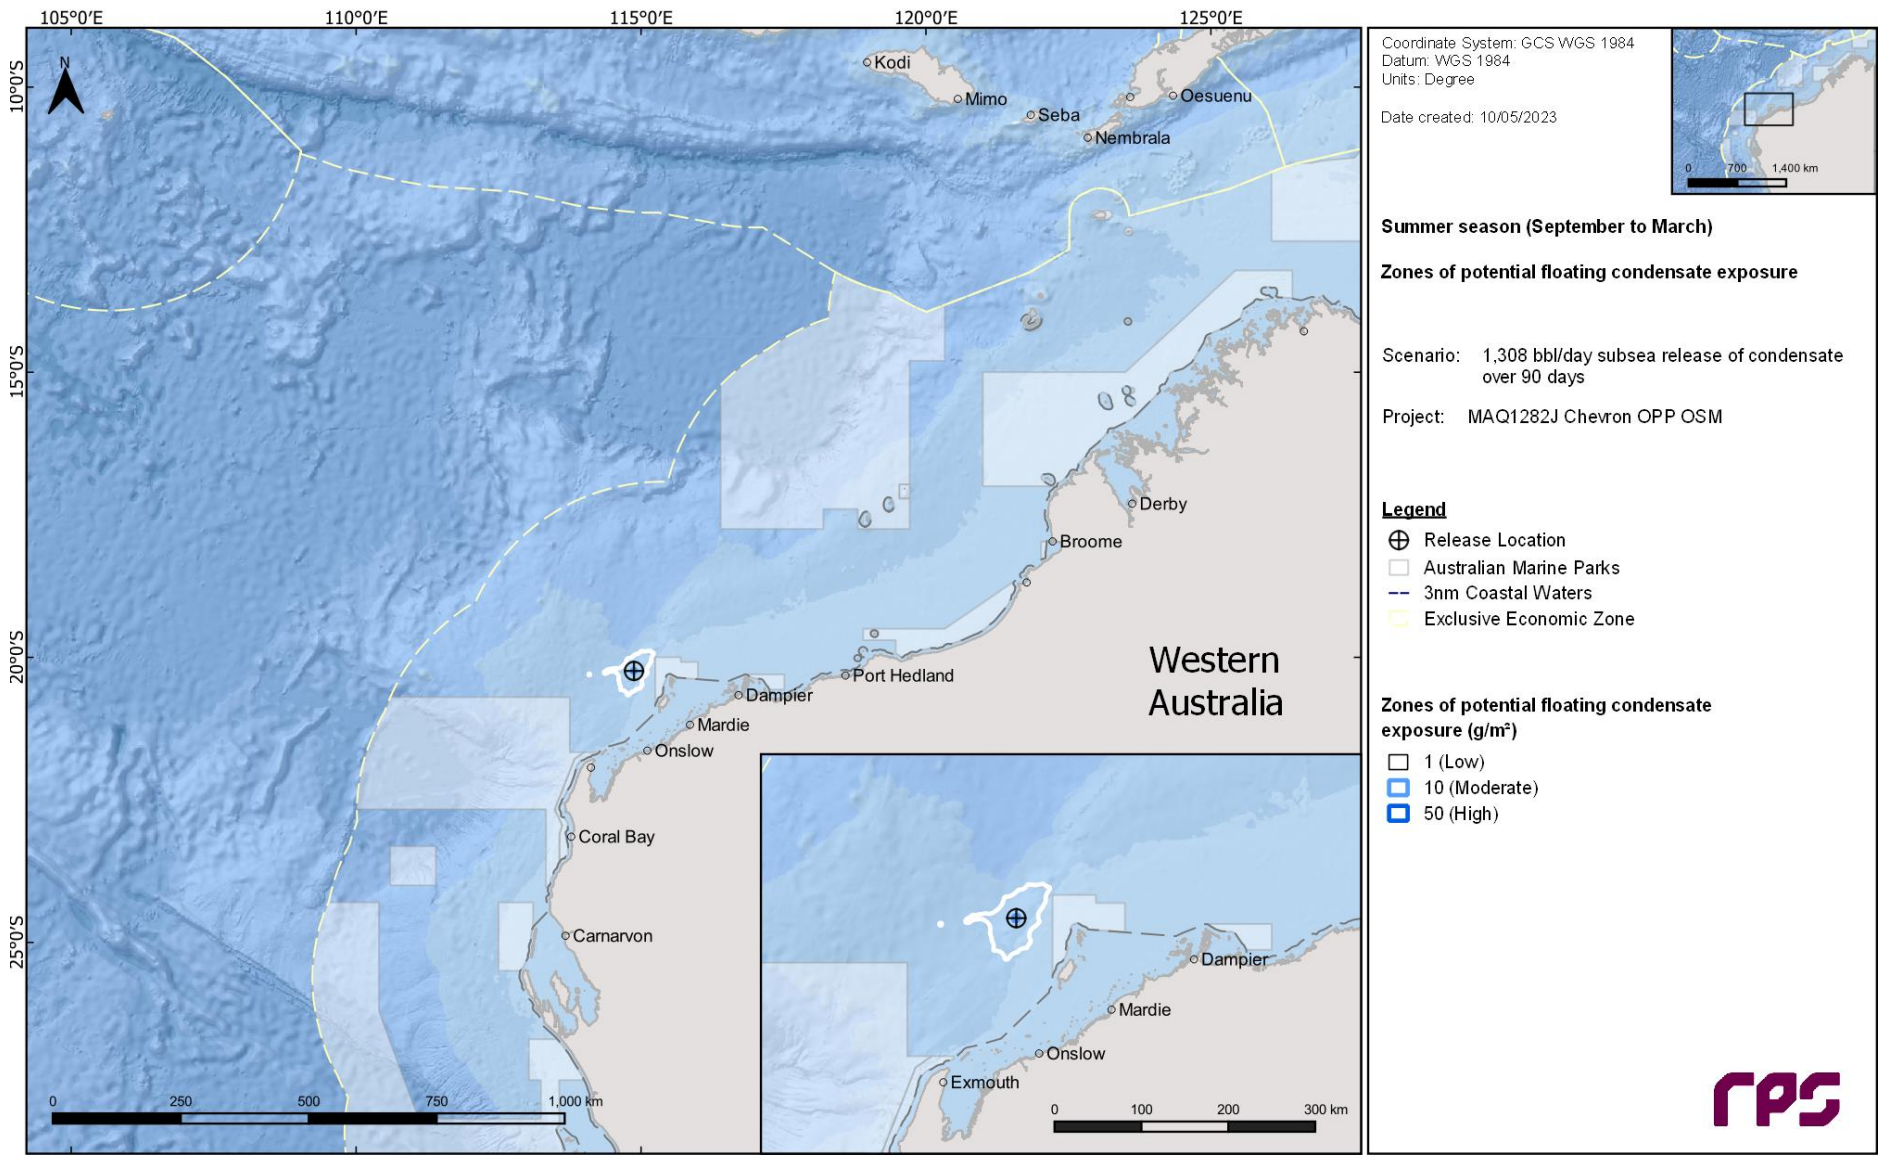

Figure 11.1 Zones of potential floating condensate exposure following a subsea LOWC at Chrysaor Well 5 during summer (September to the following March) wind and current conditions. The results were calculated from 100 spill simulations.

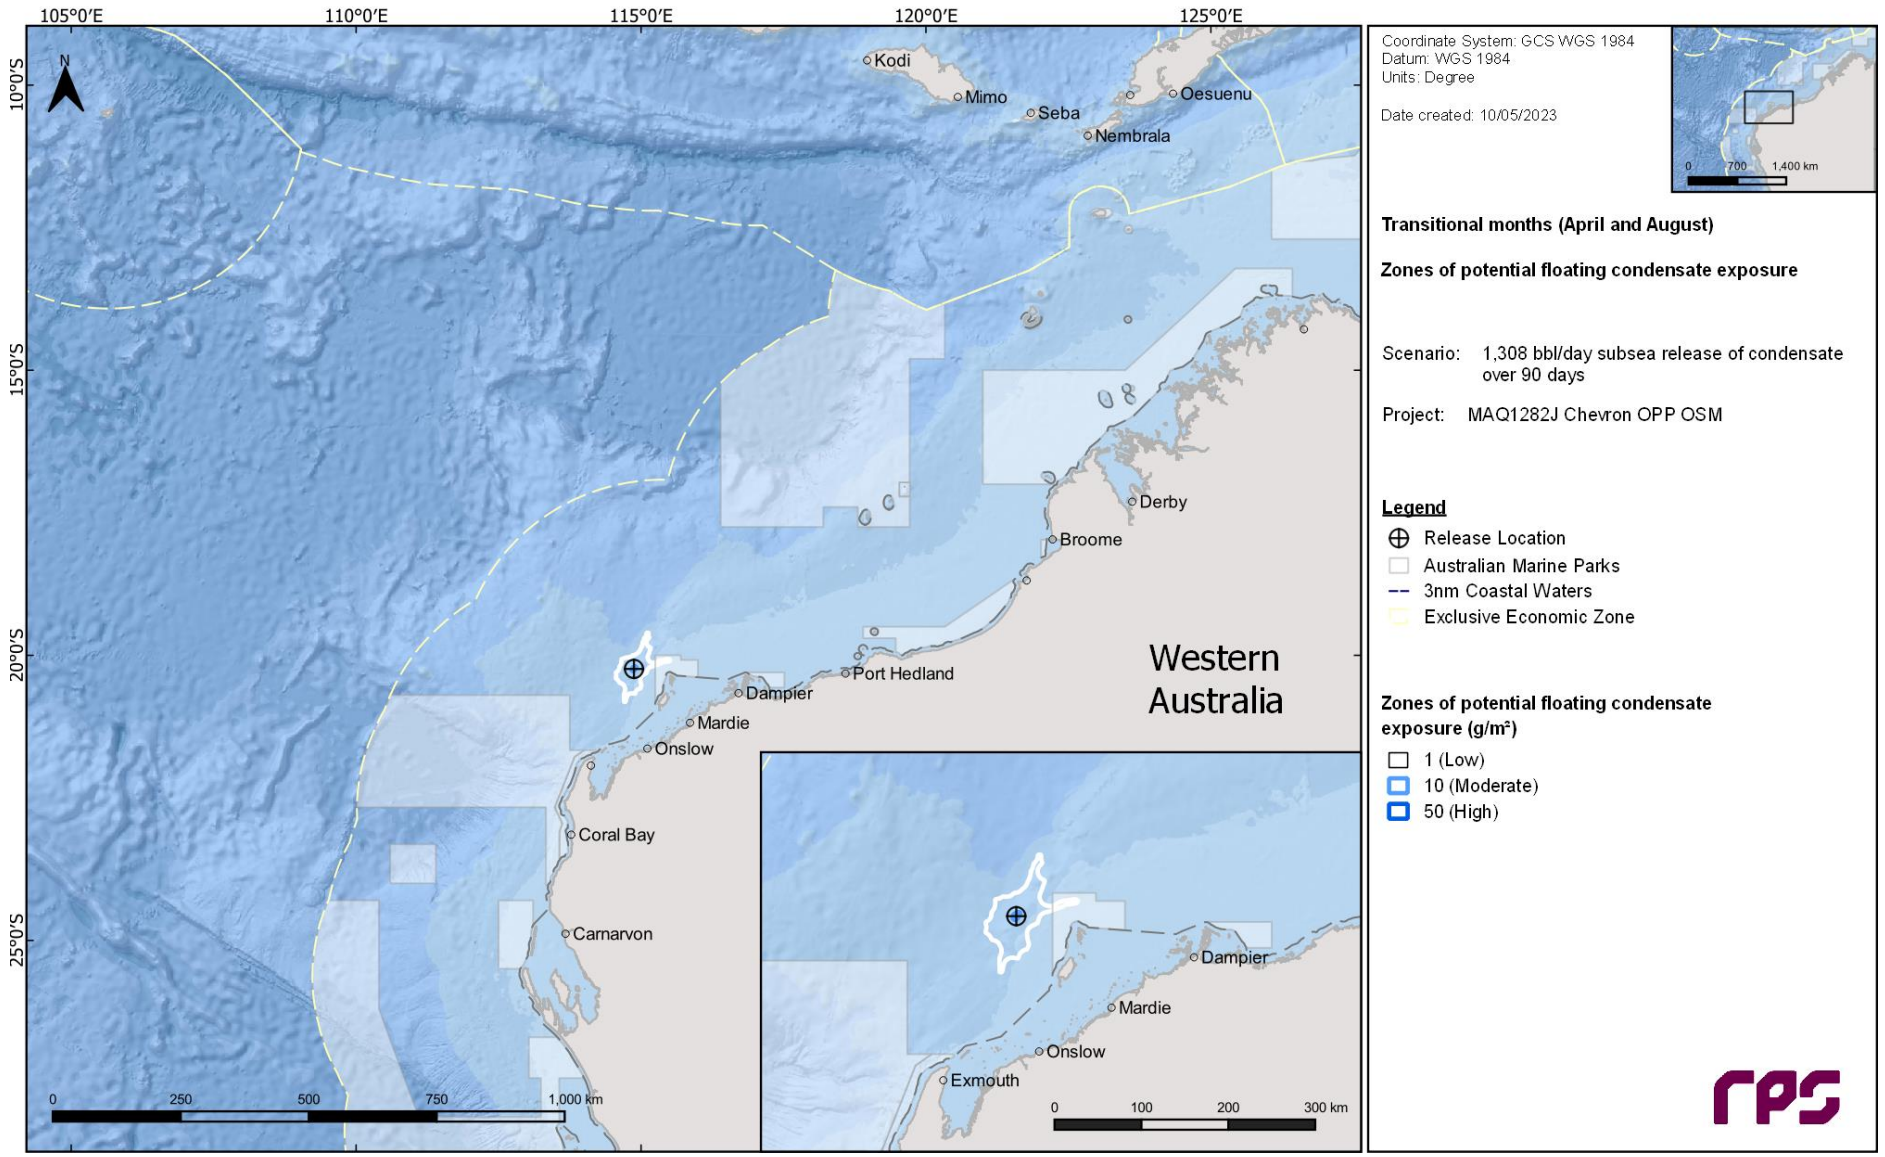

Figure 11.2 Zones of potential floating condensate exposure following a subsea LOWC at Chrysaor Well 5 during transitional (April and August) wind and current conditions. The results were calculated from 100 spill simulations.

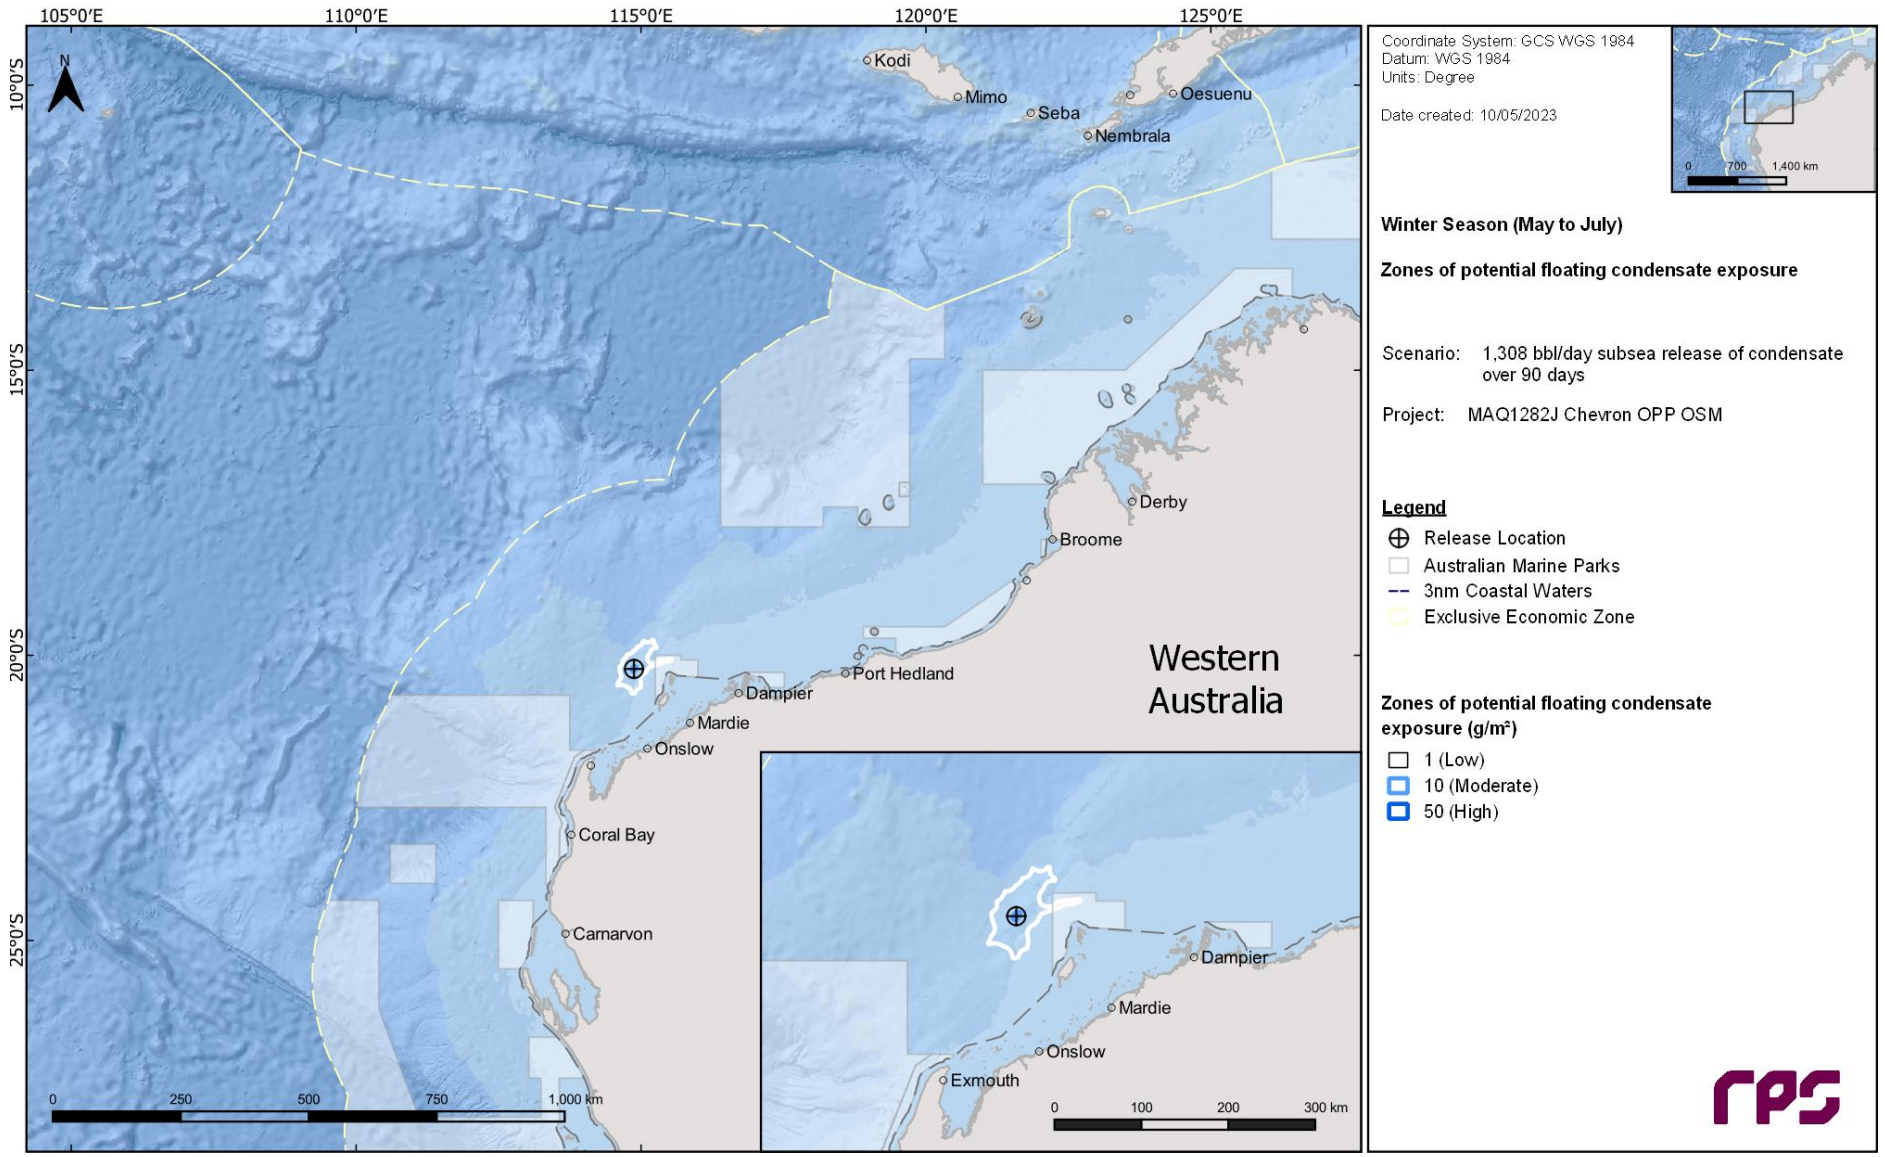

Figure 11.3 Zones of potential floating condensate exposure following a subsea LOWC at Chrysaor Well 5 during winter (May to July) wind and current conditions. The results were calculated from 100 spill simulations.

11.1.2 Shoreline Accumulation

Table 11.3 presents a summary of the predicted shoreline accumulation during summer, transitional and winter seasons. The probability of accumulation on any shoreline at, or above, the low threshold (≥ 10 g/m^2) was greatest during summer at 32%, while the minimum time before shoreline accumulation was 4.29 days and the maximum volume of oil ashore was 32.0 m^3.

No high (≥ 1,000 g/m^2) shoreline threshold accumulation was predicted in the modelling results.

Table 11.4 to Table 11.6 summarises the shoreline accumulation on individual receptors for each season.

During summer conditions, condensate had accumulated on 56 shoreline receptors at, or above, the low threshold with the greatest probability predicted for Barrow & Montebello Islands and Ningaloo Coast World Heritage Area IAAs (22%). In comparison, during transitional and winter conditions, condensate had accumulated on 6 and 4 shoreline receptors, respectively. The greatest probabilities of shoreline accumulation occurred at Muiron Islands, Ningaloo Coast World Heritage Area and North Muiron Island, all 3% probability during transitional season and at Muiron Islands, Ningaloo Coast World Heritage Area and South Muiron Island, all 1% probability during winter.

The maximum potential shoreline accumulation is presented for each season in Figure 11.4 to Figure 11.6.

Table 11.3 Summary of condensate accumulation across all shorelines for each season and threshold, following a subsea LOWC at Chrysaor Well 5. The results were calculated from 100 spill trajectories per season.

Shoreline Statistics	Summer	Transitional	Winter
Probability of accumulation on any shoreline (%)	32	3	1
Absolute minimum time for visible oil to shore (days)	4.29	18.83	36.42
Maximum volume of hydrocarbons ashore (m^3)	32.0	1.2	0.8
Average volume of hydrocarbons ashore (m^3)	9.2	0.2	0.2
Maximum length of the shoreline at **10 g/m^2** (km)	131	2	2
Average shoreline length (km) at **10 g/m^2** (km)	38.8	1.7	2
Maximum length of the shoreline at **100 g/m^2** (km)	5	-	-
Average shoreline length (km) at **100 g/m^2** (km)	2.7	-	-
Maximum length of the shoreline at **1,000 g/m^2** (km)	-	-	-
Average shoreline length (km) at **1,000 g/m^2** (km)	-	-	-

Table 11.4 Summary of shoreline condensate accumulation to individual receptors, following a LOWC at Chrysaor Well 5. The results were calculated from 100 spill trajectories days during summer (September to the following March) wind and current conditions.

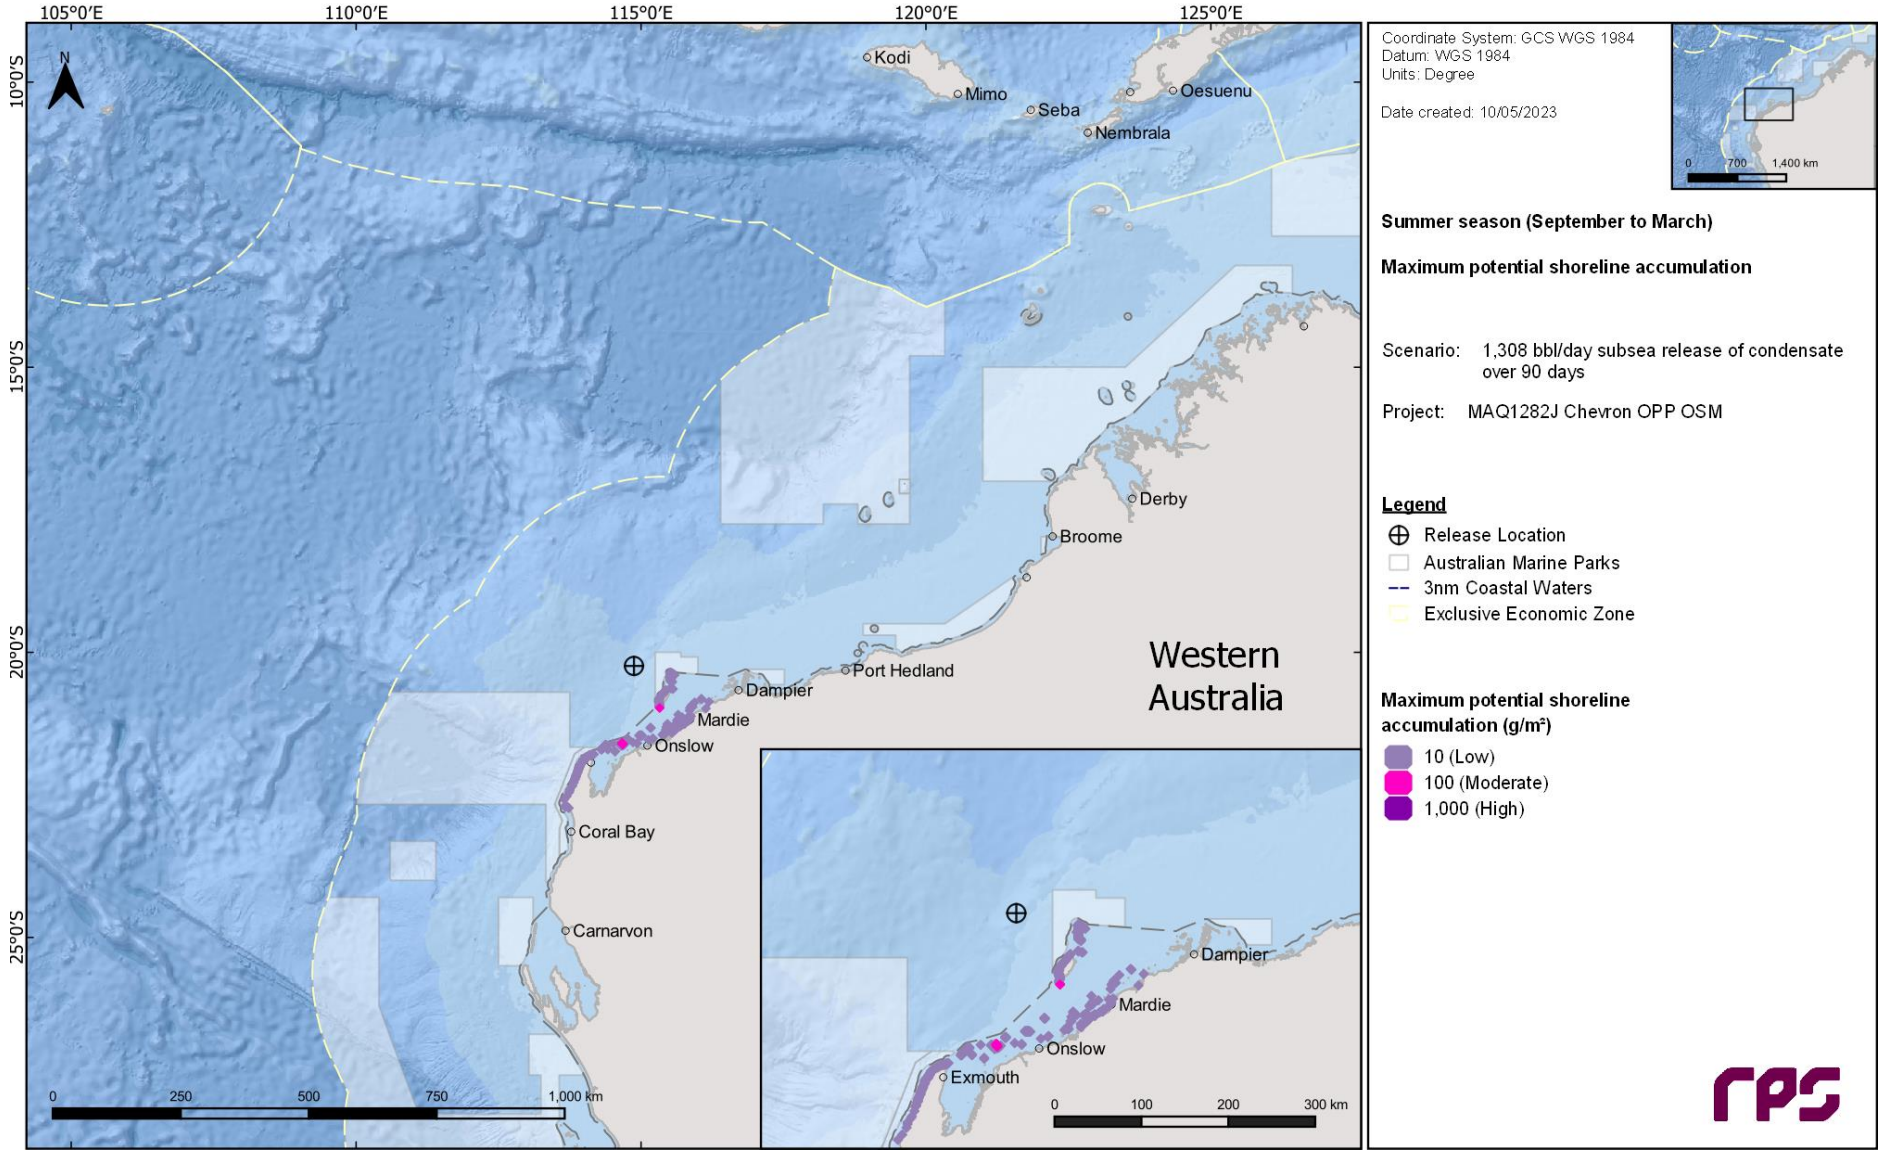

Figure 11.4 Maximum potential shoreline accumulation following a subsea LOWC at Chrysaor Well 5 during summer (September to the following March) wind and current conditions. The results were calculated from 100 spill simulations.

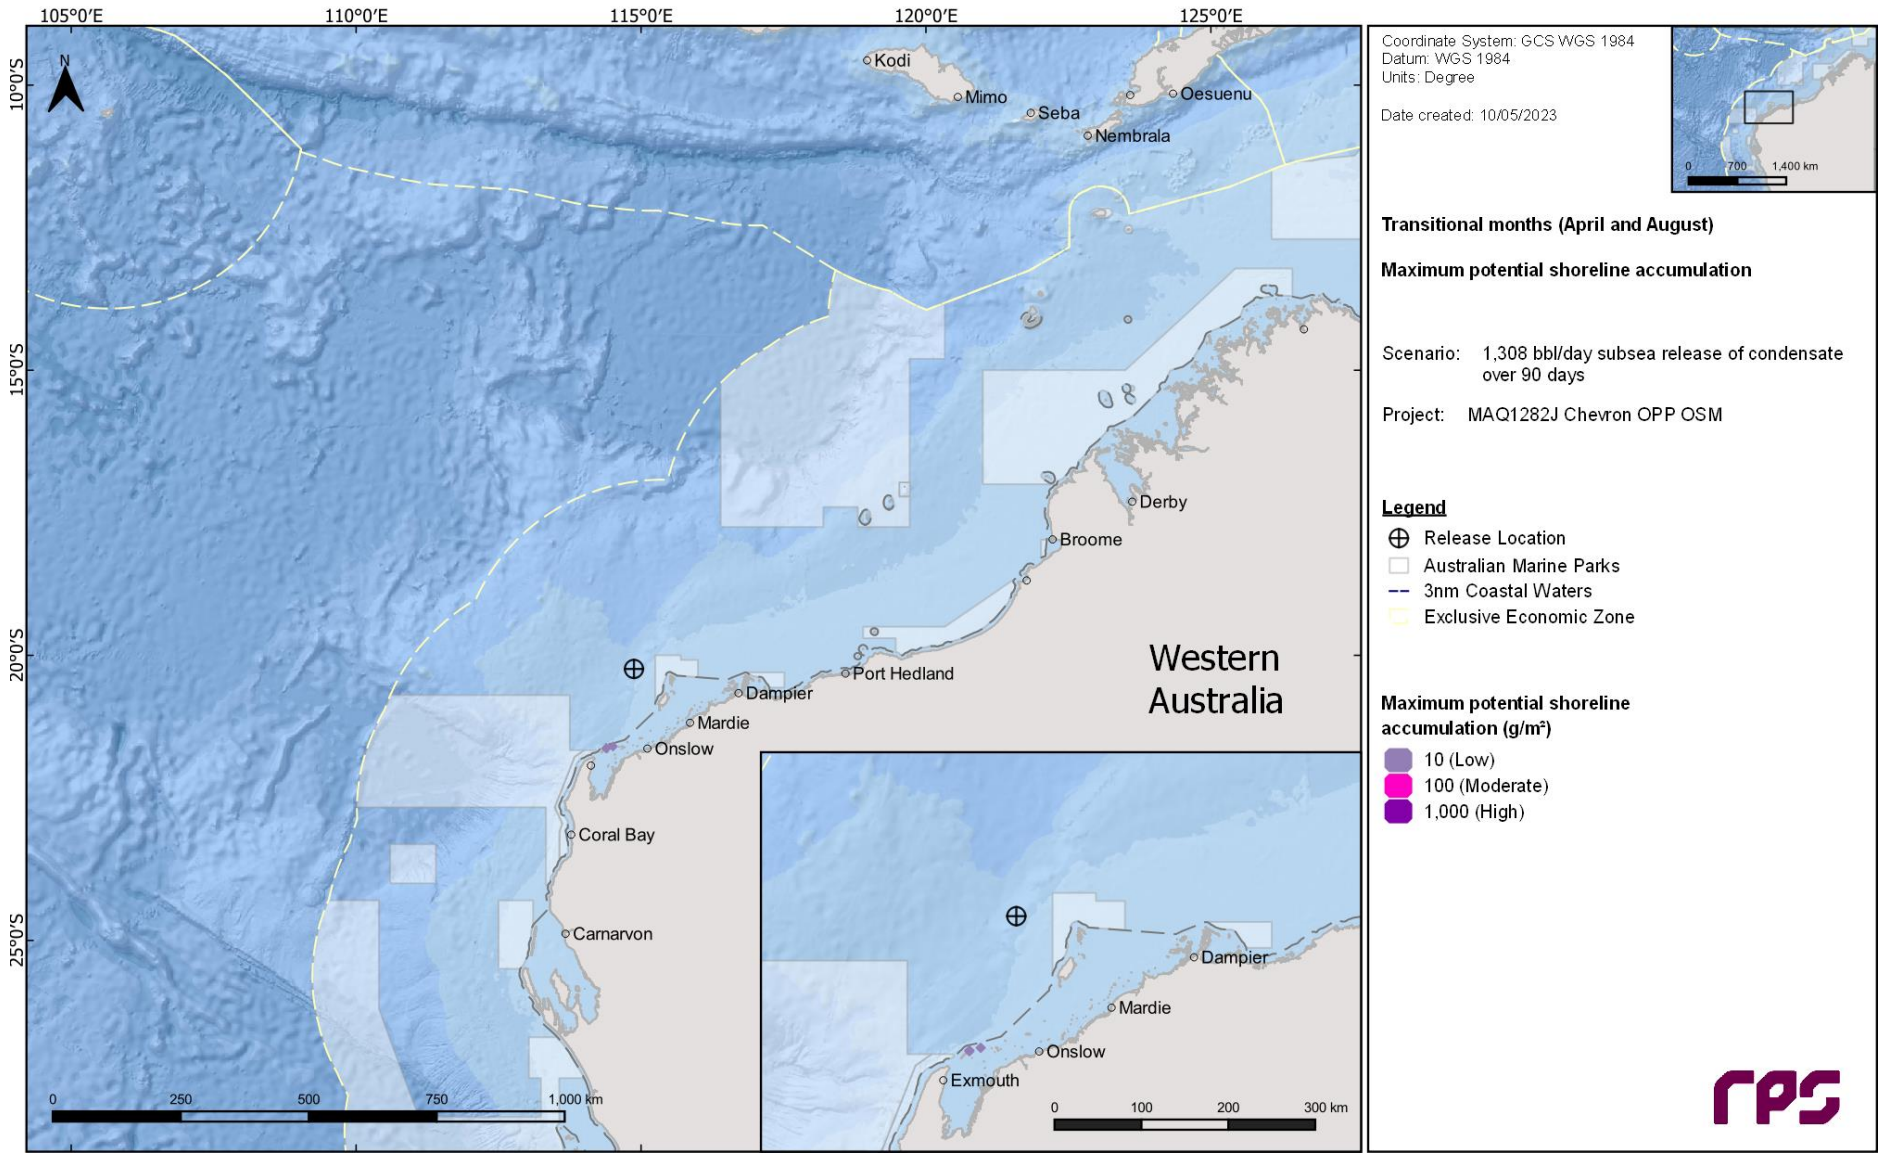

Figure 11.5 Maximum potential shoreline accumulation following a subsea LOWC at Chrysaor Well 5 during transitional (April and August) wind and current conditions. The results were calculated from 100 spill simulations.

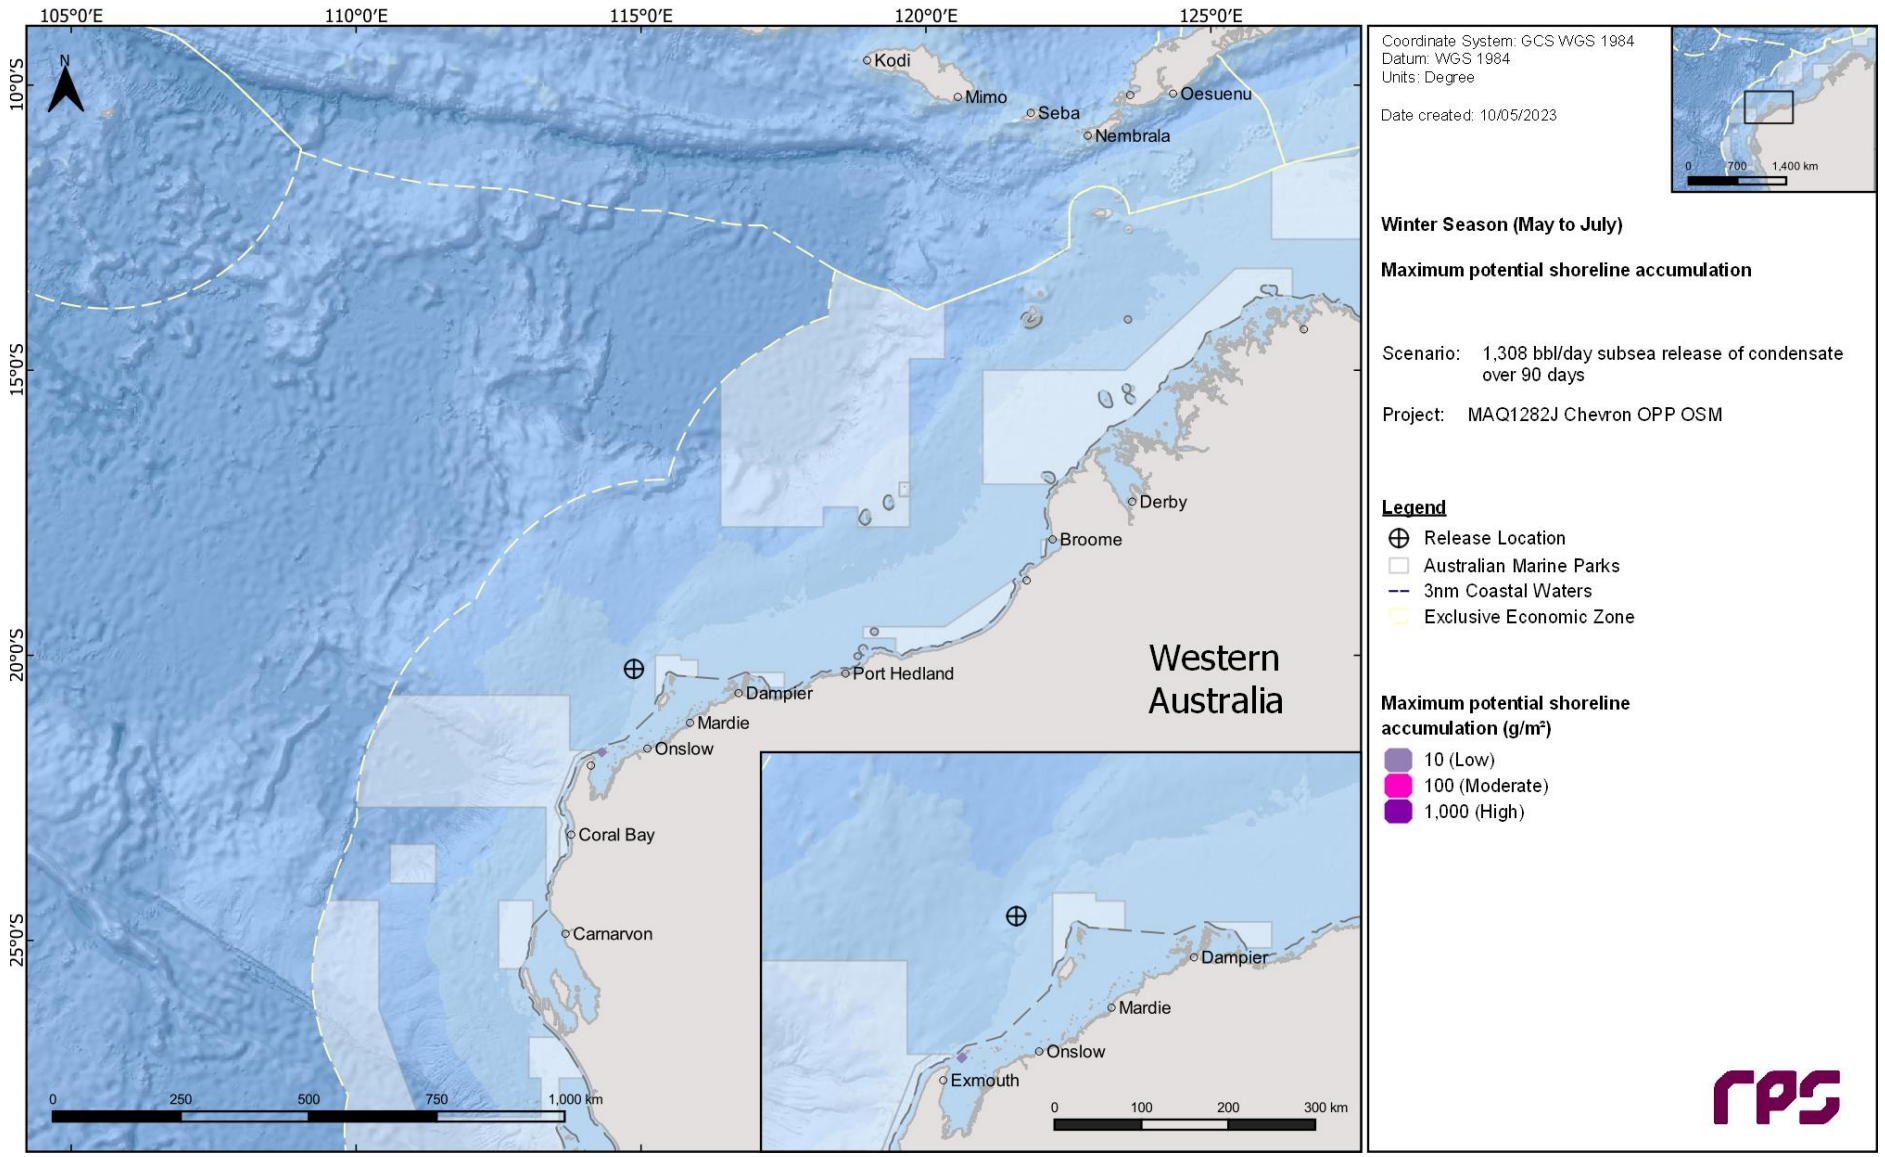

Figure 11.6 Maximum potential shoreline accumulation following a subsea LOWC at Chrysaor Well 5 during winter (May to July) wind and current conditions. The results were calculated from 100 spill simulations.

11.1.3 Water Column Exposure

11.1.3.1 Dissolved Hydrocarbons

No dissolved hydrocarbon exposure was predicted for this scenario above the low reporting threshold (≥10 ppb) during any of the seasons modelled. Consequently, no results are reported.

11.1.3.2 Entrained Hydrocarbons

Table 11.7 summarises the probability and minimum time before exposure to receptors from entrained hydrocarbons in the 0-10 m depth layer, for each season, at the low (≥ 10 ppb) and high (≥ 100 ppb) thresholds.

A total of 35 BIAs were predicted to be exposed at, or above, the low threshold during summer, compared to 20 during transitional and winter. Excluding the Pygmy Blue Whale - Distribution and Wedge-tailed Shearwater – Breeding BIAs which the release location resides within, the highest probabilities of exposure were predicted for the Flatback Turtle - Internesting Buffer and Humpback Whale - Migration BIAs at 100% during all seasons.

During summer conditions, 6 AMPs were predicted to be exposed at, or above the low threshold, and 5 AMPs under transitional and winter conditions. The highest probabilities predicted were at the Gascoyne AMP (80% summer, 82% transitional and 87% winter). Furthermore, the Montebello AMP was predicted to be exposed to entrained hydrocarbons at the high threshold during summer (3%), transitional (6%) and winter (3%), respectively.

During summer, transitional and winter conditions, 7, 5 and 5 KEFs were predicted to be exposed by at the low threshold, respectively. Probabilities ranged between 5–100%, 16–100% and 18–100%, for each season, respectively. Excluding the KEF that the release location resides within (Continental Slope Demersal Fish Communities), the ancient coastline at 125 m depth contour KEF recorded the highest probability of exposure for all three seasons (98%, 100% and 95% during summer, transitional and winter, respectively).

Additionally, 38, 12 and 11 IAA (including the Offshore IAA that the release site is located within), were predicted to be exposed to entrained hydrocarbons at low threshold. Excluding the Offshore, the probabilities for each season ranged between 1–80%, 1–82% and 1–87% under summer, transitional and winter conditions, respectively, with the maximum probabilities occurring at the Gascoyne IAA during all seasons.

Furthermore, a total of 46, 5 and 2 RSB receptors were predicted to be exposed to entrained hydrocarbons at the low threshold with maximum seasonal probabilities of 36%, 18% and 26% for Rankin Bank, during summer, transitional and winter, respectively.

Figure 11.7 to Figure 11.9 illustrate the extent of the predicted entrained hydrocarbon exposure for the low and high thresholds in the 0-10 m depth layer for each season.

The same maps for the 10-20 m depth layer are presented in Figure 11.10 to Figure 11.12.

Table 11.7 Predicted probability and maximum entrained hydrocarbon exposure to individual receptors in the 0-10 m depth layer following a subsea LOWC at Chrysaor Well 5. The results were calculated from 100 spill simulations per season.

Receptor		Summer					Transitional					Winter

11.2 Deterministic Analysis

The deterministic analysis presented below, are based on simulations that resulted in the largest swept area of floating condensate above 10 g/m^2 (see Section 11.2.1), largest volume of oil ashore (see Section 11.2.2), longest length of shoreline accumulation above 100 g/m^2 (see Section 11.2.2) and the largest area of entrained hydrocarbons above 100 ppb (see Section 11.2.4).

Table 11.8 presents a summary of all deterministic analysis criteria and the corresponding floating condensate, shoreline accumulation and entrained hydrocarbon values at the assessed thresholds.

Note there was no floating hydrocarbons at or above 50 g/m^2 and no dissolved hydrocarbon exposure at or above 50 ppb for any of the 300 simulations.

Interpretation of the deterministic analysis result table and timeseries plots:

The summary deterministic analysis results presented in the table below should be interpreted as **maximum values**, representing the total volume or swept area exposed by floating or in-water hydrocarbons throughout the entire simulation duration. In this particular case, the simulation showed that a maximum of 481 km^2 was exposed to floating oil above the low threshold over a period of 104 days.

However, it's important to note that the timeseries plots present **peak values** at specific points in time. For example, when considering shoreline volume, the peak value in the timeseries plot does not account for oil that may have reached the shore earlier in the simulation but was subsequently lost through evaporation or other weathering processes.

Continuing with the previous example, the timeseries plot indicates that the peak floating oil swept area above the low threshold reached 27 km^2. This value represents the highest swept area recorded at a single point in time during the simulation.

Table 11.8 Summary of the deterministic analysis following a subsea LOWC at Chrysaor Well 5.

Variable	Threshold	Deterministic Analysis Criteria			
		Largest swept area of floating condensate above 10 g/m^2	Largest volume of oil ashore	Longest length of shoreline accumulation above 100 g/m^2	Largest area of entrained hydrocarbons above 100 ppb
Season		Transitional	Summer	Summer	Transitional
Run Number		78	80	46	55
Floating Oil (km^2)	1 g/m^2	481	322	294	251
	10 g/m^2	**7**	4	2	2

11.2.1 Deterministic Case: Largest swept area of floating condensate above 10 g/m^2

The deterministic simulation that resulted in the largest swept area of floating condensate above 10 g/m^2 (moderate threshold) was identified as run number 78 during the transitional period.

Figure 11.13 presents the extent of the predicted floating condensate exposure zones on the sea surface (swept area) and shoreline accumulation over the entire 104-day simulation.

Figure 11.14 displays the time series of the swept area of low (≥ 1 g/m^2), moderate (≥ 10 g/m^2) and high (≥ 50 g/m^2) floating condensate over the 104-day simulation.

Figure 11.15 presents the fates and weathering for the corresponding simulation and Table 11.9 summarises the peak volumes and times of occurrence for each oil phase and volumes at the end of the 104-day simulation.

Table 11.9 Summary of peak volumes and times of occurrence for each oil phase and the volumes at the conclusion of the simulation (day 104), for the simulation that resulted in the largest swept area of floating condensate above 10 g/m^2 following a subsea LOWC at Chrysaor Well 5.

Exposure Metrics	Peak Volume	Day of Occurrence	Volume at day 104
Surface (m^3)	175	55	2
Entrained (m^3)	1,679	90	1,161
Dissolved (m^3)	2	48	0
Evaporation (m^3)	14,634	104	14,634
Decay (m^3)	3,015	104	3,015
Ashore (m^3)	0	0	0

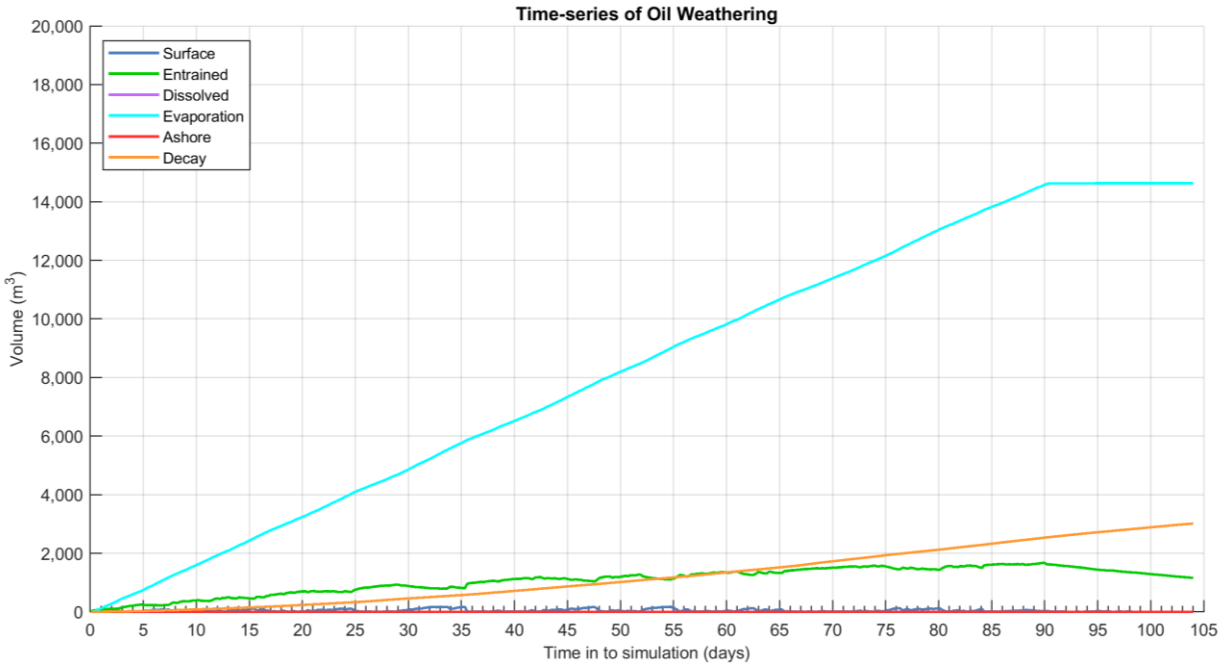

Figure 11.15 Predicted weathering and fates for the simulation with the largest swept area of floating condensate above 10 g/m^2 following a LOWC at Chrysaor Well 5.

11.2.2 Deterministic Case: Largest volume of oil ashore

The deterministic simulation that resulted in the largest volume of oil ashore was identified as run number 80, during the summer season.

Figure 11.16 presents the extent of the predicted floating condensate exposure zones on the sea surface (swept area) and shoreline accumulation over the entire 104-day simulation.

Figure 11.17 displays the time series of the volume of oil accumulating on shorelines at the low (≥ 10 g/m^2), moderate (≥ 100 g/m^2) and high (≥ 1,000 g/m^2) thresholds over the 104-day simulation.

Figure 11.18 presents the fates and weathering graph for the corresponding single spill trajectory and Table 11.10 summarises the peak volumes and times of occurrence for each oil phase and volumes at the end of the 104-day simulation.

Table 11.10 Summary peak volumes and times of occurrence for each oil phase and the volumes at the conclusion of the simulation (day 104), for the simulation with the largest volume of oil ashore following a subsea LOWC at Chrysaor Well 5.

Exposure Metrics	Peak Volume	Day of Occurrence	Volume at day 104
Surface (m^3)	130	75	0
Entrained (m^3)	1,668	88	1,153
Dissolved (m^3)	2	59	0
Evaporation (m^3)	14,494	104	14,494
Decay (m^3)	3,138	104	3,138
Ashore (m^3)	32	103	31

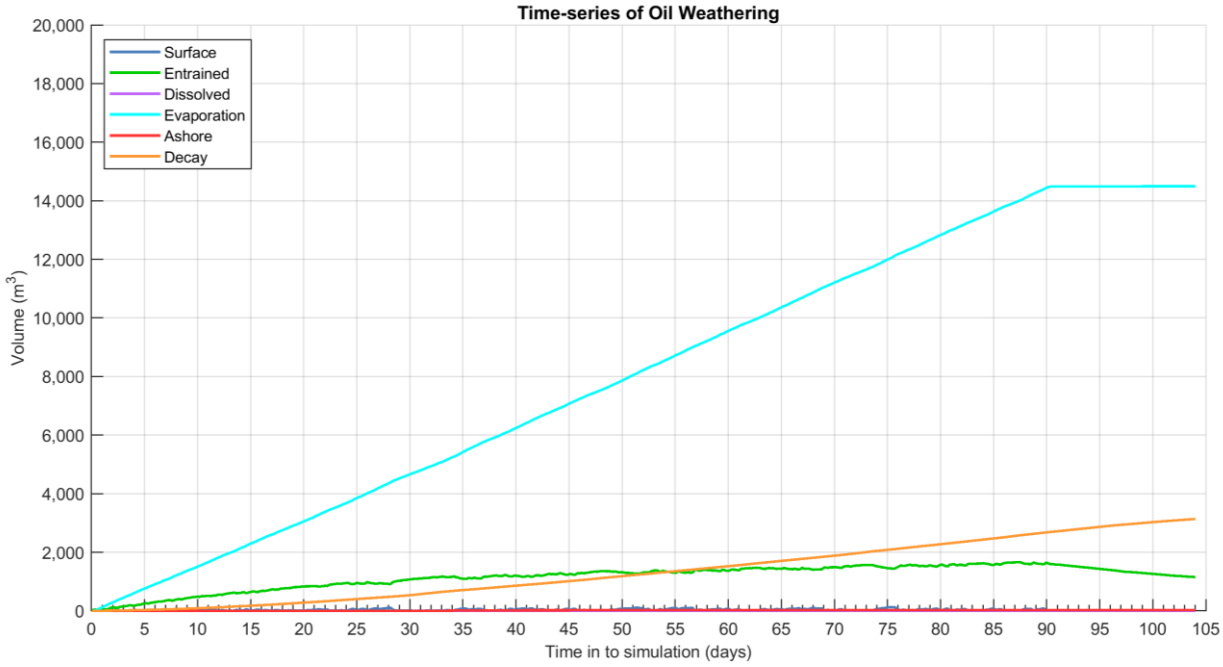

Figure 11.18 Predicted weathering and fates for the simulation with the largest volume of oil ashore following a LOWC at Chrysaor Well 5.

11.2.3 Deterministic Case: Longest length of shoreline with accumulation above 100 g/m^2

The deterministic simulation that resulted in the longest length of shoreline with accumulation above 100 g/m^2 (moderate threshold) was identified as run number 46 during the summer period.

Figure 11.16 presents the extent of the predicted floating condensate exposure zones on the sea surface (swept area) and shoreline accumulation over the entire 104-day simulation.

Figure 11.17 displays the time series of the length of shoreline with accumulation above the low (≥ 10 g/m^2), moderate (≥ 100 g/m^2) and high (≥ 1,000 g/m^2) thresholds over the 104-day simulation.

Figure 11.18 presents the fates and weathering graph for the corresponding single spill trajectory and Table 11.10 summarises the peak volumes and times of occurrence for each oil phase and volumes at the end of the 104-day simulation.

Table 11.11 Summary peak volumes and times of occurrence for each oil phase and the volumes at the conclusion of the simulation (day 104), for the simulation with the longest length of shoreline with accumulation above 100 g/m^2 following a subsea LOWC at Chrysaor Well 5.

Exposure Metrics	Peak Volume	Day of Occurrence	Volume at day 104
Surface (m^3)	134	23	8
Entrained (m^3)	1,788	82	1,219
Dissolved (m^3)	2	33	0
Evaporation (m^3)	14,203	104	14,203
Decay (m^3)	3,357	104	3,357
Ashore (m^3)	29	101	29

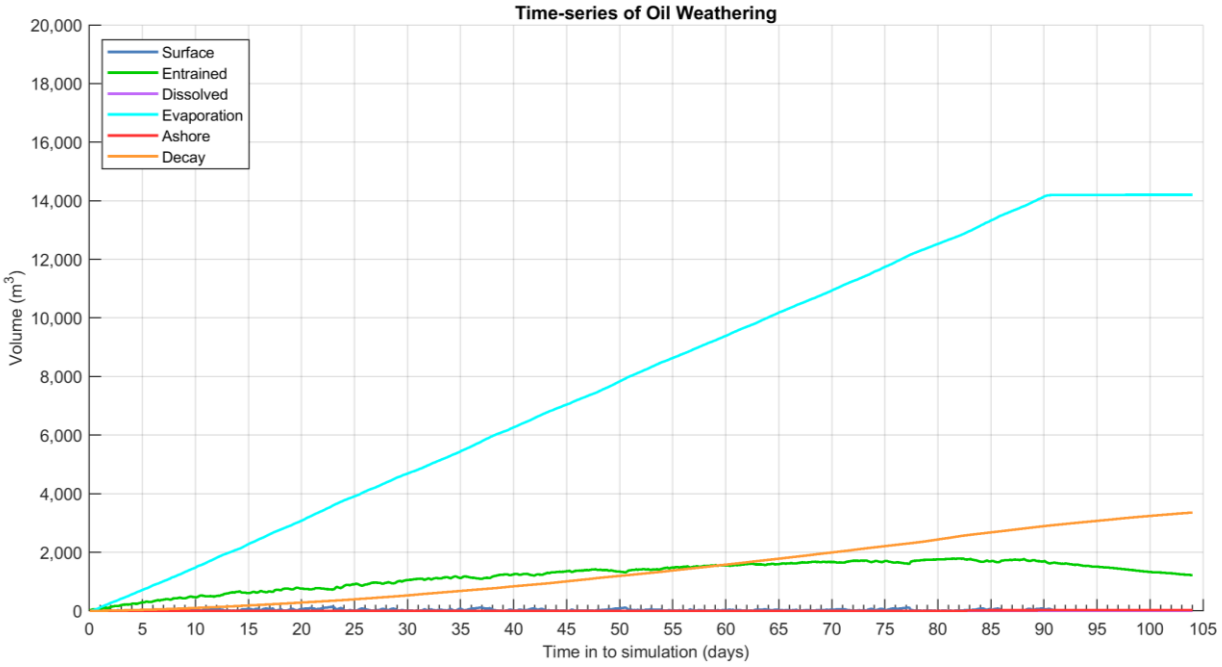

Figure 11.21 Predicted weathering and fates for the simulation with the longest length of shoreline with accumulation above 100 g/m² following a LOWC at Chrysaor Well 5.

11.2.4 Deterministic Case: Largest area of entrained hydrocarbons above 100 ppb

The deterministic simulation that resulted in the largest area of entrained hydrocarbons above 100 ppb (moderate threshold) was identified as run number 55 during the transitional period.

Figure 11.22 presents the extent of the predicted entrained hydrocarbon exposure zones over the entire 104-day simulation.

Figure 11.23 displays the time series of the area of entrained hydrocarbons at the low (≥10 ppb) and high (≥100 ppb) thresholds over the 104-day simulation.

Figure 11.24 presents the fates and weathering for the corresponding single spill trajectory and Table 11.12 summarises the peak volumes and times of occurrence for each oil phase and volumes at the end of the 104-day simulation.

Table 11.12 Summary of the peak volumes and times of occurrence for each oil phase and the volumes at day 104, for the trajectory with the largest area of entrained hydrocarbons above 100 ppb following a subsea LOWC at Chrysaor Well 5.

Exposure Metrics	Peak Volume	Day of Occurrence	Volume at day 104
Surface (m^3)	113	38	8

Terms and Abbreviations **1**

Executive Summary **4**
Background 4
Methodology 4
Condensate Properties 4
Key Findings 5

1 INTRODUCTION **6**

2 SCOPE OF WORK **8**

3 REGIONAL CURRENTS **9**
3.1 Tidal Currents 11
3.1.1 Grid Setup 11
3.1.2 Tidal Conditions 12
3.2 Ocean Currents 13
3.3 Surface Currents 13

4 WIND DATA **16**

5 WATER TEMPERATURE AND SALINITY **20**

6 SUBSEA PLUME MODEL – OILMAP DEEP **22**

7 OIL SPILL MODEL – SIMAP **24**
7.1 Stochastic Modelling 24
7.2 Floating, Shoreline and In-Water Thresholds 25
7.2.1 Floating condensate exposure Thresholds 25
7.2.2 Shoreline Accumulation Thresholds 27
7.2.3 In-water Exposure Thresholds 28

8 CONDENSATE PROPERTIES **30**
8.1 Properties 30
8.2 Weathering Characteristics 31
8.2.1 Overview 31
8.2.2 Results 31

9 MODEL SETTINGS **33**

10 PRESENTATION AND INTERPRETATION OF MODEL RESULTS **34**
10.1 Stochastic Analysis 34
10.1.1 Statistics 34
10.2 Deterministic Trajectories 34
10.3 Receptors 35

11 RESULTS: SEMELE LOSS OF WELL CONTROL **43**
11.1 Stochastic Analysis 43
11.1.1 Floating Condensate Exposure 43
11.1.2 Shoreline Accumulation 48
11.1.3 Water Column Exposure 60
11.2 Deterministic Analysis 76
11.2.1 Deterministic Case: Largest swept area of floating condensate above 10 g/m^2 77
11.2.2 Deterministic Case: Largest volume of condensate ashore 80
11.2.3 Deterministic Case: Longest length of shoreline with accumulation above 100 g/m^2 83
11.2.4 Deterministic Case: Largest area of entrained hydrocarbons above 100 ppb 86

TERMS AND ABBREVIATIONS

°	Degrees
‘	Minutes
“	Seconds
µm	Micrometre (unit of length; 1 µm = 0.001 mm)
Actionable oil	Oil which is thick enough for the effective use of mitigation strategies
AMP	Australian Marine Park
AMSA	Australian Maritime Safety Authority
ANZECC	Australian and New Zealand Environment and Conservation Council
API	American Petroleum Institute gravity. A measure of how heavy or light a petroleum liquid is compared to water.
ARMCANZ	Agriculture and Resource Management Council of Australia and New Zealand
ASTM	American Society for Testing and Materials
bbl	Barrel (unit of volume; 1 bbl = 0.159 m3)
bbl/d	Barrels per day
Bonn Agreement	An agreement for cooperation in dealing with pollution of the North Sea by oil and other harmful substances, 1983, includes: Governments of the Kingdom of Belgium, the Kingdom of Denmark, the French Republic, the Federal Republic of Germany, the Republic of Ireland, the Kingdom of the Netherlands, the Kingdom of Norway, the Kingdom of Sweden, the United Kingdom of Great Britain and Northern Ireland and the European Union.
BP	Boiling point. The temperature at which the vapor pressure of the liquid is equal to the pressure exerted on it by the surrounding atmosphere
BTEX	Benzene, Toluene, Ethylbenzene, and Xylenes
°C	degree Celsius (unit of temperature)
CFSR	Climate Forecast System Reanalysis
cm	Centimetre (unit of length)
cP	Centipoise (unit of dynamic viscosity)
Decay	The process where oil components are changed either chemically or biologically (biodegradation) to another compound. It includes breakdown to simpler organic carbon compounds by bacteria and other organisms, photo-oxidation by solar energy, and other chemical reactions.
Dynamic viscosity	The dynamic viscosity of a fluid expresses its resistance to shearing flows, where adjacent layers move parallel to each other with different speeds.
Floating condensate exposure	Contact by floating oil on the sea surface at concentrations equal to or exceeding defined threshold concentrations. The consequence will vary depending on the threshold and the receptors
g/m^2	Grams per square meter (unit of surface area density)
GODAE	Global Ocean Data Assimilation Experiment
HYCOM	Hybrid Coordinate Ocean Model. A data-assimilative, three-dimensional ocean model
HYDROMAP	Advanced ocean/coastal tidal model used to predict tidal water levels, current speed and current direction.
IAA	Impact Assessment Area

IBRA	Interim Biogeographic Regionalisation for Australia
IMCRA	Integrated Marine and Coastal Regionalisation of Australia
ITOPF	International Tanker Owners Pollution Federation Limited
KEF	Key Ecological Feature
km	Kilometre (unit of length)
km^2	Square Kilometres (unit of area)
Knots	unit of speed (1 knot = 0.514 m/s)
LOWC	Loss of well control
m	Meter (unit of length)
m^3	Cubic meter (unit of volume)
m/s	Meter per Second (unit of speed)
MAHs	Monoaromatic Hydrocarbons
MNP	Marine National Park
MP	Marine Park
NASA	National Aeronautics and Space Administration (USA)
NCEP	National Centres for Environmental Prediction (USA)
nm	Nautical mile
NOAA	National Oceanic and Atmospheric Administration (USA)
NOPSEMA	National Offshore Petroleum Safety and Environmental Management Authority
NP	National Park
NR	Nature Reserve
PAH	Polynuclear Aromatic Hydrocarbons
Pour Point	The pour point of a liquid is the temperature below which the liquid loses its flow characteristics
ppb	Parts per billion (concentration)
psu	Practical salinity nits
RSB	Reefs, Shoals and Banks
scf	Standard cubic feet (defined as one cubic foot of gas at 15.56 °C and at normal sea level air pressure)
Shoreline contact	Arrival of oil at or near shorelines at on-water concentrations equal to or exceeding defined threshold concentrations. Shoreline contact is judged for floating oil arriving within a 2 km buffer zone from any shoreline as a conservative measure
SIMAP	Spill Impact Model Application Package. SIMAP is designed to simulate the fate and effects of spilled hydrocarbons for surface or subsea releases
Single Oil spill modelling	Oil spill modelling involving a computer simulation of a single hypothetical oil spill event subject to a single sequence of wind, current and other sea conditions over time. Single oil spill modelling, also referred to as “deterministic modelling” provides a simulation of one possible outcome of a given spill scenario, subject to the metocean conditions that are imposed. Single oil spill modelling is commonly used to consider the fate and effects of ‘worst-case’ oil spill scenarios that are carefully selected in consideration of the nature and scale of the offshore petroleum activity and the local environment (NOPSEMA, 2017). Because the outcomes of a single oil spill simulation can only represent the outcome of that scenario under one sequence of metocean conditions, worst-case conditions are often identified from stochastic modelling. It is impossible to calculate the likelihood of any outcome

	from a single oil spill simulation. Single oil spill modelling is generally used for response planning, preparedness planning and for supporting oil spill response operations in the event of an actual spill
SRTM	Shuttle Radar Topography Mission
Stochastic oil spill modelling	Stochastic oil spill modelling is created by overlaying and statistically analysing the outcomes of many single oil-spill simulations of a defined spill scenario, where each simulation was subject to a different sequence of metocean conditions, selected objectively (typically by random selection) from a long sequence of historic conditions for the study area. Analysis of this larger set of simulations provides a more accurate indication of the environment that maybe affected (EMBA) and indicates which locations are more likely to be affected (as well as other statistics). Stochastic oil spill modelling avoids biases that affect single oil spill modelling (due to the reliance on only one possible sequence of conditions). However, when interpreting stochastic modelling, which is based on a wide range of potential conditions that might happen to occur, it is essential to understand that calculations will encompass a much larger area than could be affected in any single spill event, where a more limited set of conditions will occur. Consequently, it is misleading to imply that the region derived from stochastic modelling indicate the outcomes expected from a single spill event (NOPSEMA, 2017) Stochastic modelling is generally used for risk assessment and preparedness planning by indicating locations that could be exposed and may require response or subsequent impact assessment
TOPEX/Poseidon	A joint satellite mission between NASA and CNES to map ocean surface topography using an array of satellites equipped with detailed altimeters
USA	United States of America
US CG	United States Coast Guard
US EPA	United States Environmental Protection Agency
World Ocean Atlas	A collection of objectively analysed, quality controlled physicochemical parameters (e.g. temperature, salinity, oxygen, phosphate, silicate, and nitrate) based on profile data from the World Ocean Database (NCEI, 2021) established by NOAA's National Centers for Environmental Information (NCEI)
WGS 1984	World Geodetic System 1984 (WGS84); reference coordinate system

EXECUTIVE SUMMARY

Background

Chevron Australia Pty Ltd (Chevron) is the operator of the Greater Gorgon area, which includes the Semele field situated within the Northern Carnarvon Basin in Permit area WA-15-R, northwest of Barrow Island off the north-west coast of Western Australia.

Chevron commissioned RPS to undertake an oil spill modelling to support environmental approvals. The oil spill modelling study was conducted to assess the seasonal risk and potential exposure to the surrounding waters and contact to the shorelines from the following hypothetical scenario:

- **Scenario:** A 2,441 stb/day (388.1 m^3/day) subsea release of condensate over 90 days (totalling 219,690 stb or 34,927 m^3) from a loss of well control (LOWC).

The potential risk of exposure to the surrounding waters and contact to shorelines was assessed for three distinct seasons; (i) summer (September to the following March), (ii) the transitional periods (April and August) and (iii) winter (May to July). This approach assists with identifying the environmental values and sensitivities that would be at risk of exposure on a seasonal basis.

One of the purposes for the modelling is to define the 'outer boundaries' of the environment that may be affected (EMBA) in the unlikely event of hydrocarbon release. Therefore, the modelling does not take into consideration any of the spill prevention, mitigation and response capabilities that would be implemented in response to the spill.

Methodology

The modelling study was carried out in stages. Firstly, a ten-year current dataset (2010–2019) that includes the combined influence of large-scale ocean and nearshore tidal currents was developed. Secondly, the currents, local winds and detailed hydrocarbon characteristics were used as inputs in the three-dimensional oil spill model (SIMAP) to simulate the drift, spread, weathering and fate of the spilled oil.

As spills can occur during any set of wind and current conditions, modelling was conducted using a stochastic (or probabilistic) approach, which involved running 100 spill simulations per season, with each simulation having the same spill information (spill volume, duration and composition of hydrocarbons) but randomly selected start time. This ensured that each spill trajectory was subjected to varying wind and current conditions.

Condensate Properties

Semele condensate has an API of 41.9, a density of 816 kg/m^3 (at 15ºC) and a viscosity value of 6.7 cP at 15 ºC. When exposed to the atmosphere at local temperatures, about 33% of the condensate volatile components should evaporate within the first 12 hours (BP < 180°C); a further 32.5% of the semi-volatiles should evaporate within the first 24 hours (180°C < BP < 265°C); and low volatile portion (27.9%) should evaporate over a longer period (265°C < BP < 380°C). The remaining 6.5% of the condensate would persist in the marine environment for much longer periods and be subject to relatively slow degradation. The process of evaporation will be greater than under calm sea conditions, but increased entrainment can be expected under stronger winds due to the presence of small breaking waves (whitecaps).

This condensate has a low asphaltene content (< 0.05%), which is one indicator for a very low propensity to take up water to form water-in-oil emulsion. For this condensate, the aromatic hydrocarbons contribute 3.9% and are all contained in the volatile fractions, which are highly soluble.

Key Findings

- The maximum distance from the release location to the low (≥ 1 g/m^2) and moderate (≥ 10 g/m^2) thresholds was 144.5 km southwest (summer) and 2.2 km west southwest (winter and transitional), respectively. No exposure was predicted at the high (≥ 50 g/m^2) threshold. No exposure was predicted at the high (≥ 50 g/m^2) threshold.

- The Offshore Area IAA, Pygmy Blue Whale – Distribution BIA and Wedge-tailed Shearwater – Breeding BIA which the release location resides within, were the only receptors predicted to be exposed during all three seasons at the low and moderate thresholds. The probability for the low threshold was 100% for all seasons for these receptors. Probabilities of moderate exposure for these receptors ranged between 6% (summer) and 18% (transitional).

- The probability of accumulation on any shoreline at, or above, the low threshold (≥ 10 g/m^2) was greatest during summer at 27%, while the minimum time before shoreline accumulation was 13.7 days and the maximum volume of condensate ashore above the low threshold was 29.0 m^3.

- No high (≥ 1,000 g/m^2) shoreline threshold accumulation was observed in the modelling results.

- During summer conditions, condensate had accumulated on 62 shoreline receptors at, or above, the low threshold with the greatest probability predicted for Barrow & Montebello Islands IAA (19%). In comparison, during transitional and winter conditions condensate had accumulated on 10 and 4 shoreline receptors, respectively. During transitional conditions, the greatest probabilities had occurred at Cunningham Island (Imperieuse Reef), Argo-Rowley Terrace IAAs and Imperieuse Reef, all 3% probability. While for the winter season, the same three receptors recorded a 9% probability.

- There were several receptors exposed at or above the low threshold for dissolved hydrocarbons (≥ 10 ppb) during summer and winter, however they were all 1% occurrence.

- In the 0-10 m depth layer, a total of 34, 22 and 21 BIAs were shown to be exposed at or above the low threshold during summer, transitional and winter seasons respectively. Excluding the receptors that the release location resides within, the highest probabilities of exposure were shown for the Flatback Turtle – Internesting Buffer BIA during summer (100%), transitional (97%) and winter (90%) conditions.

- Across the three seasons, 6 Australian Marine Parks (AMP) were predicted to be exposed at, or above the low threshold for entrained hydrocarbons, with the highest probabilities predicted at the Gascoyne AMP (81% summer, 82% transitional and 74% winter).

- A total of 6 KEFs were shown to be exposed by entrained hydrocarbons at the low threshold, including the Continental Slope Demersal Fish Communities KEF that the release site is located within. Excluding that receptor, probabilities of exposure ranged between 6–80%, 1–92% and 1–80%, for summer, transitional and winter, respectively.

- A total of 37 IAAs were shown to be exposed to entrained hydrocarbons at low threshold.

1 INTRODUCTION

Chevron Australia Pty Ltd (Chevron) is the operator of the Greater Gorgon area, which includes the Semele field situated within the Northern Carnarvon Basin in Permit area WA-15-R, northwest of Barrow Island off the north-west coast of Western Australia.

As part of the planned development for the Semele field, Chevron commissioned RPS to undertake a comprehensive oil spill modelling study to support environmental approvals. The modelling study assessed the seasonal risk and potential exposure to the surrounding waters and contact to the shorelines from the following hypothetical scenario:

- **Scenario:** A 2,441 stb/day (388.1 m^3/day) subsea release of condensate over 90 days (totalling 219,690 stb or 34,927 m^3) from a loss of well control (LOWC).

The release location used for the oil spill assessment is presented in Table 1.1 and illustrated in Figure 1.1.

The potential risk of exposure to the surrounding waters and contact to shorelines was assessed for three distinct seasons; (i) summer (September to the following March), (ii) the transitional periods (April and August) and (iii) winter (May to July). This approach assists with identifying the environmental values and sensitivities that would be at risk of exposure on a seasonal basis.

One of the purposes for the modelling is to define the 'outer boundaries' of the environment that may be affected (EMBA) in the unlikely event of hydrocarbon release. Therefore, the modelling does not take into consideration any of the spill prevention, mitigation and response capabilities that would be implemented in response to the spill.

The spill modelling was performed using an advanced three-dimensional trajectory and fates model; Spill Impact Mapping Analysis Program (SIMAP). The SIMAP model calculates the transport, spreading, entrainment and evaporation of spilled hydrocarbons over time, based on the prevailing wind and current conditions and the physical and chemical properties.

The hydrocarbon spill model, the method and analysis applied herein uses modelling algorithms which have been peer reviewed and published in international journals. Further, RPS warrants that this work meets and exceeds the American Society for Testing and Materials (ASTM) Standard F2067-13 "*Standard Practice for Development and Use of Oil Spill Models*".

2 SCOPE OF WORK

The scope of work included the following components:

1. Generate ten years (2010 to 2019 (inclusive)) of wind and current data. The three-dimensional current data includes the combined influence of ocean and tidal currents;

2. Include the wind data, current data and condensate properties characteristics into the three-dimensional oil spill model; SIMAP, to model the movement, spreading, entrainment, weathering and potential shoreline accumulation over time;

3. Run 100 simulations for each season (i.e. 300 simulations total), with each simulation having the same spill information (location, volume, duration and condensate properties) but randomly varying start times. This ensured that each spill simulation was subjected to unique wind and current conditions;

4. Combine the results from the 100 spill simulations to assess the exposure to waters and shoreline accumulation based upon the NOPSEMA thresholds; and

5. From the 300 simulations modelled, identify and present the “worst case” deterministic runs, which can be used to inform response planning based on the following criteria:
    a. Largest swept area of floating hydrocarbon above 10 g/m^2
    b. Largest swept area of floating hydrocarbon above 50 g/m^2
    c. Largest volume of condensate ashore
    d. Longest length of shoreline accumulation above 100 g/m^2
    e. Largest area of entrained hydrocarbons above 100 ppb
    f. Largest area of dissolved hydrocarbons above 50 ppb

As there was no floating hydrocarbons at or above 50 g/m^2 and no dissolved hydrocarbon exposure at or above 50 ppb, for any of the 300 simulations, the deterministic results are presented based on criteria a, c, d and e only.

3 REGIONAL CURRENTS

The study area is located within the Northern Carnarvon Basin, on the North West Shelf, a waterbody bordered by the Indian Ocean and Timor Sea. The North West Shelf is characterised by complex geomorphological features such as shoals, valleys and terraces and is dominated by high-amplitude tides and seasonally-dependant wind driven currents (DEWHA, 2007).

Although the Indonesian Throughflow and Holloway current generate south-westerly flows all year-round, warm and less saline waters originating from the tropics can generate internal gyres that typically migrate through the area and result in large variation in the speed and direction of local currents. The Holloway current generally intensifies during April to July due to increased wind forcing.

A comprehensive description of the circulation patterns of the North West Shelf is provided in a review by Condie and Andrewartha (2008) and a schematic of the ocean currents along the Northwest Australian continental shelf is shown in Figure 3.1.

While, tidal currents are generally weaker in the deeper waters, its influence is greatest along the near shore and around islands. Therefore, to accurately account for the movement of an oil spill, which can move between the offshore and near shore region, ocean and tidal currents were combined as part of the study.

Figure 3.2 and Figure 3.3 present summer and winter current trends within the Carnarvon Basin and the North West Shelf.

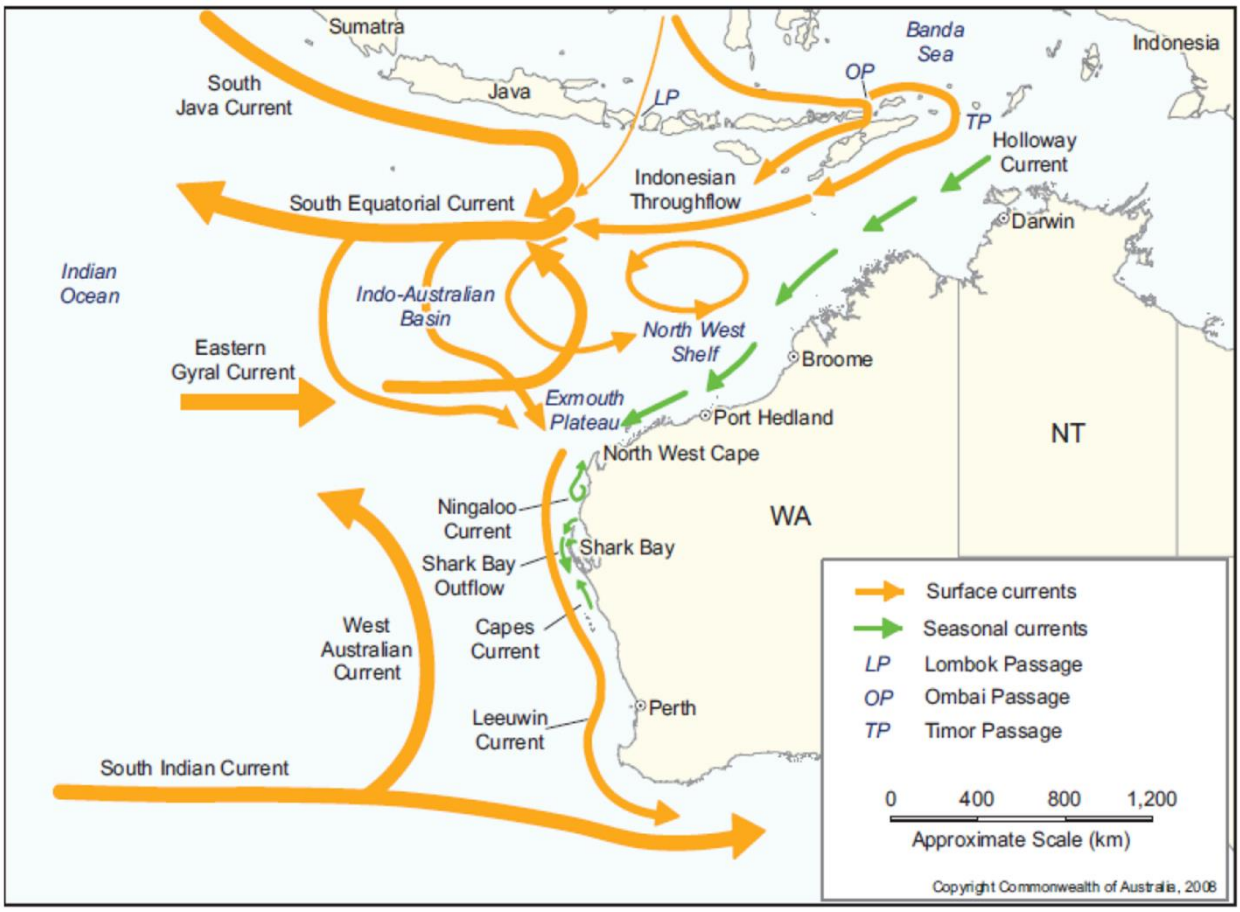

Figure 3.1 Schematic of ocean currents along the northwest Australian continental shelf. Image adapted from DEWHA (2008).

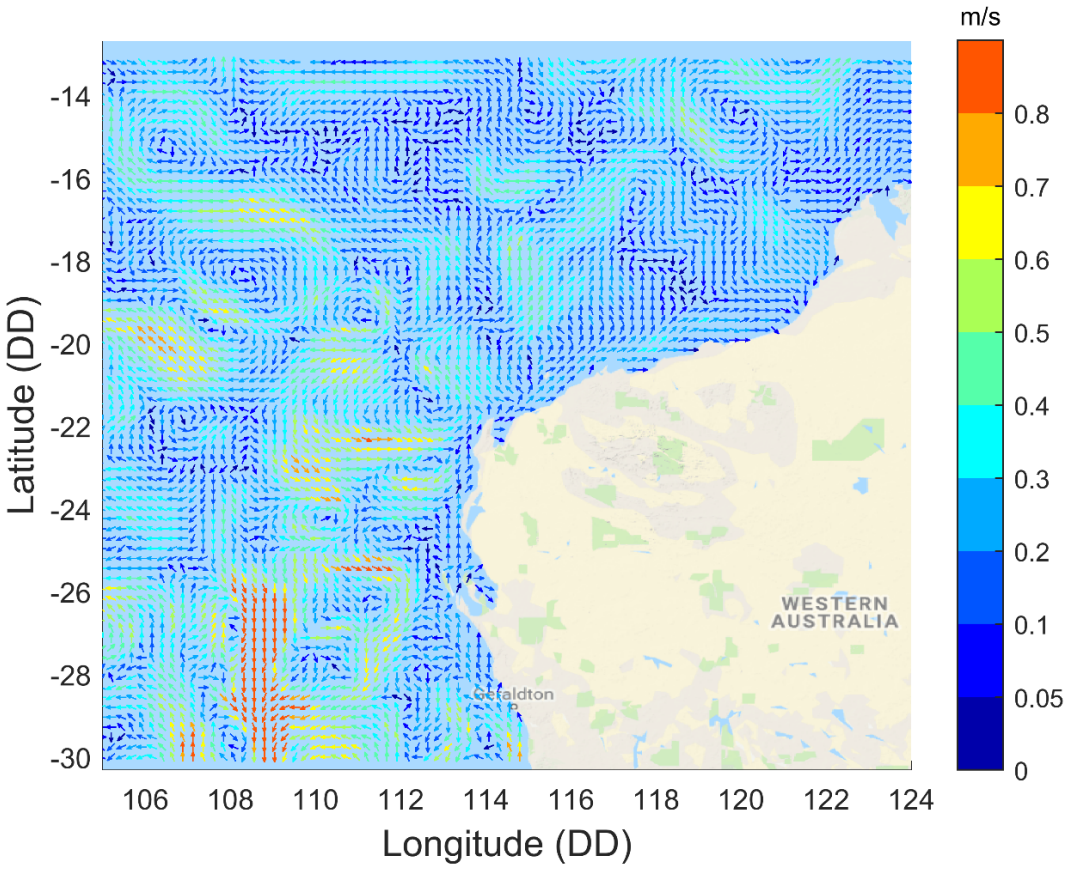

Figure 3.2 Typical ocean current circulation pattern during the summer months.

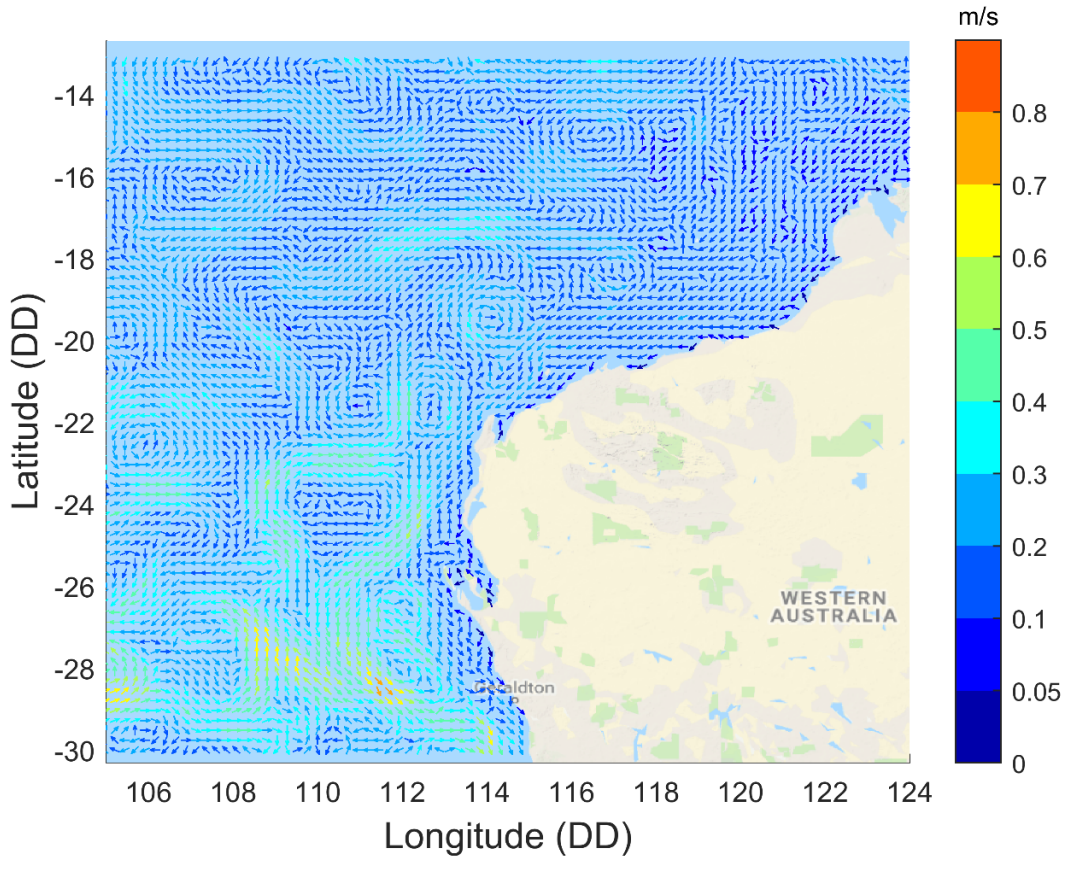

Figure 3.3 Typical ocean current circulation pattern during the winter months.

3.1 Tidal Currents

Tidal current data was generated using RPS's advanced ocean/coastal model, HYDROMAP. The HYDROMAP model has been thoroughly tested and verified through field measurements throughout the world over the past 38 years (Isaji & Spaulding, 1984; Isaji, et al., 2001; Zigic, et al., 2003). HYDROMAP tidal current data has been used as input to forecast (in the future) and hindcast (in the past) pollutant spills in Australian waters and forms part of the Australian National Oil Spill Emergency Response System operated by AMSA (Australian Maritime Safety Authority).

HYDROMAP employs a sophisticated sub-gridding strategy, which supports up to six levels of spatial resolution, halving the grid cell size as each level of resolution is employed. The sub-gridding allows for higher resolution of currents within areas of greater bathymetric and coastline complexity, and/or of particular interest to a study.

The numerical solution methodology follows that of Davies (1977a and 1977b) with further developments for model efficiency by Owen (1980) and Gordon (1982). A more detailed presentation of the model can be found in Isaji and Spaulding (1984) and Isaji et al. (2001).

3.1.1 Grid Setup

The tidal model domain has been sub-gridded to a resolution of 500 m for shallow and coastal regions, starting from an offshore (or deep water) resolution of 8 km. The finer grids were allocated in a step-wise fashion to resolve flows more accurately along the coastline, around islands and over regions with more complex bathymetry. Figure 3.4 shows the tidal model grid resolutions.

A combination of datasets was used and merged to describe the shape of the seabed within the grid domain (Figure 3.5). These included spot depths and contours which were digitised from nautical charts released by the hydrographic offices as well as Geoscience Australia database and depths extracted from the Shuttle Radar Topography Mission (SRTM30_PLUS) Plus dataset (see Becker et al., 2009).

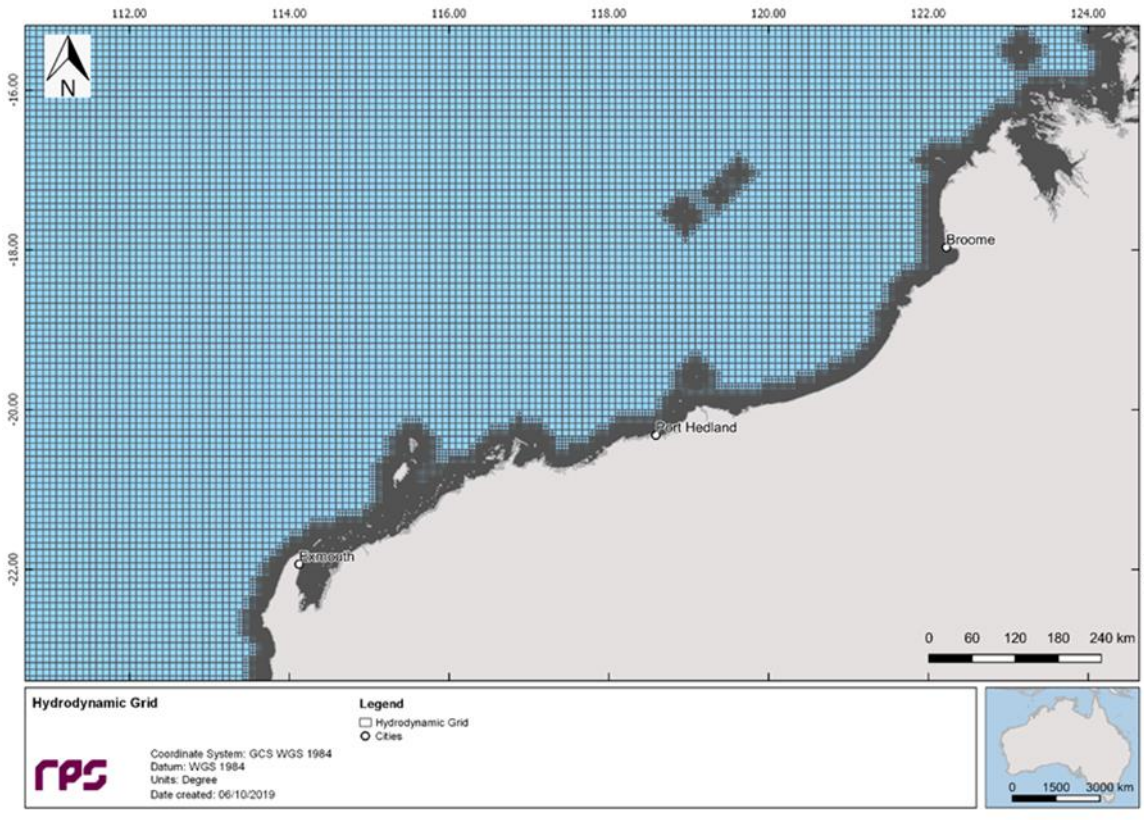

Figure 3.4 Zoomed in view of the model grid used to generate the tidal currents for the study region. Higher resolution areas are shown by the denser mesh.

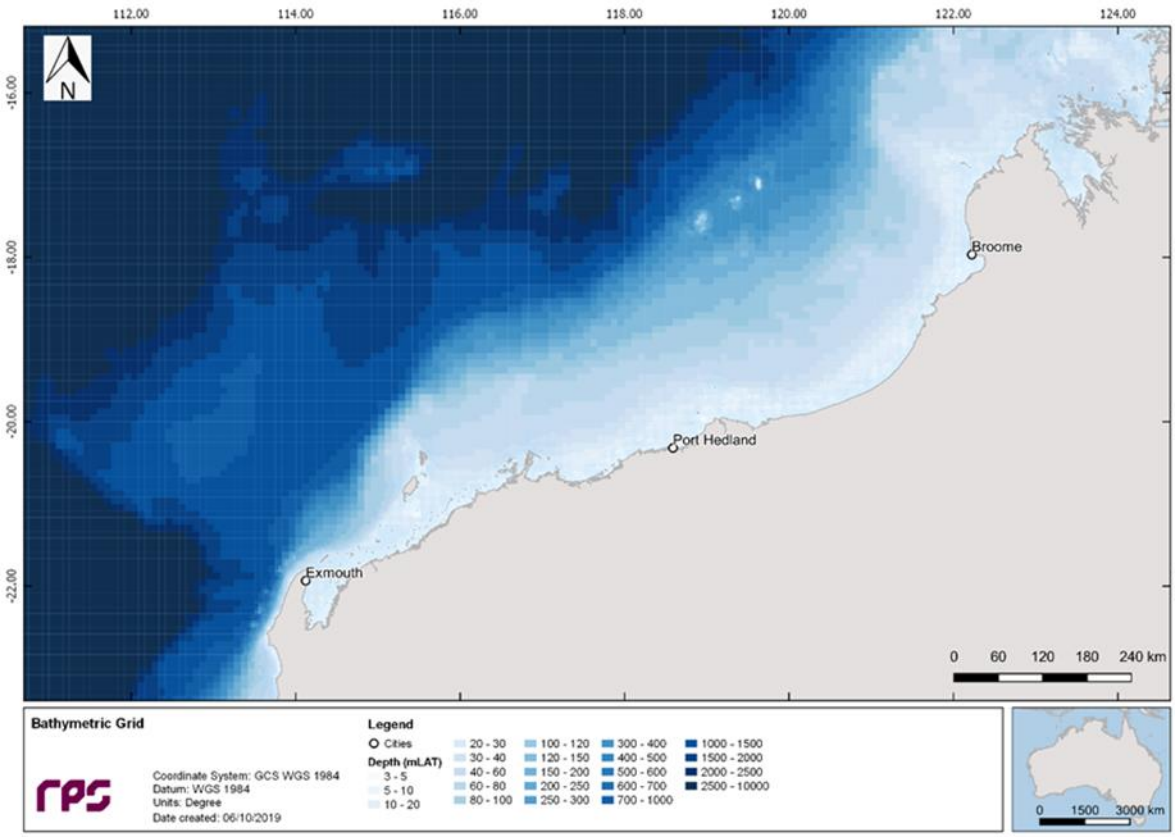

Figure 3.5 Bathymetry defined throughout the tidal model domain.

3.1.2 Tidal Conditions

The ocean boundary data for the regional model was obtained from satellite measured altimetry data (TOPEX/Poseidon 7.2) which provided estimates of the eight dominant tidal constituents at a horizontal scale of approximately 0.25 degrees. The eight major tidal constituents used were K_2, S_2, M_2, N_2, K_1, P_1, O_1 and Q_1. Using the tidal data, surface heights were firstly calculated along the open boundaries, at each time step in the model.

The TOPEX/Poseidon satellite data has a global resolution of 0.25 degrees and is produced and quality controlled by NASA (National Aeronautics and Space Administration). The satellites equipped with two highly accurate altimeters and capable of taking sea level measurements with an accuracy of ± 5 cm measured oceanic surface elevations (and the resultant tides) for over 13 years (1992–2005). In total, these satellites carried out 62,000 orbits of the planet.

The TOPEX/Poseidon tidal data has been widely used amongst the oceanographic community, being included in more than 2,100 research publications (e.g. Andersen, 1995; Ludicone et al., 1998; Matsumoto et al., 2000; Kostianoy et al., 2003; Yaremchuk and Tangdong, 2004; Qiu and Chen 2010). As such the TOPEX/Poseidon tidal data is considered suitably accurate for this study.

3.2 Ocean Currents

Data describing the flow of ocean currents was obtained from HYCOM (Hybrid Coordinate Ocean Model, (Chassignet et al., 2007), which is operated by the HYCOM Consortium, sponsored by the National Ocean Partnership Program (NOPP), as part of the U.S. Global Ocean Data Assimilation Experiment (GODAE). HYCOM is a data-assimilative, three-dimensional ocean model that is run as a hindcast (for a past period), assimilating time-varying observations of sea surface height, sea surface temperature and in-situ temperature and salinity measurements (Chassignet et al., 2009). The HYCOM predictions for drift currents are produced at a horizontal spatial resolution of approximately 8.25 km (1/12th of a degree) over the region, at a frequency of every 3 hours. HYCOM uses isopycnal layers in the open, stratified ocean, but uses the layered continuity equation to make a dynamically smooth transition to a terrain following coordinate in shallow coastal regions, and to z-level coordinates in the mixed layer and/or unstratified seas.

For this study, the HYCOM hindcast currents were obtained for the years 2010 to 2019 (inclusive).

3.3 Surface Currents

Table 3.1 presents the predicted average and maximum monthly surface current speeds at the release location.

The month average surface current speeds ranged between 0.18 m/s (November) and 0.26 m/s (June). Additionally, the maximums ranged between 0.57 m/s (November) and 1.63 m/s (January). The general current directions were predominately southwest and then northeast throughout the year. Figure 3.6 and Figure 3.7 present the monthly and total current rose distributions, respectively.

Note the convention for defining current direction throughout this report is the direction the current flows towards. Each branch of the current rose distribution represents the currents flowing to that direction, with north to the top of the diagram. The branches are divided into segments of different colour, which represent the current speed ranges for each direction. Speed intervals of 0.1 m/s are typically used in these current roses. The length of each coloured segment within a branch is proportional to the frequency of currents flowing within the corresponding speed and direction.

Table 3.1 Predicted monthly average and maximum surface current speeds close to the release location. Data derived by combining the HYCOM ocean data and HYDROMAP high resolution tidal data from 2010-2019 (inclusive).

Season	Month	Average current speed (m/s)	Maximum current speed (m/s)	General direction (towards)
Summer	January	0.21	1.63	Northeast and Southwest
	February	0.19	1.09	Northeast and Southwest
	March	0.21	1.50	Southwest
Transitional	April	0.23	1.02	Southwest
Winter	May	0.24	0.78	Southwest
	June	0.26	1.01	Southwest
	July	0.22	0.98	Southwest
Transitional	August	0.19	0.60	Northeast and Southwest
Summer	September	0.20	0.87	Northeast and Southwest
	October	0.20	0.67	Northeast and Southwest
	November	0.18	0.57	Southwest
	December	0.20	0.69	Southwest
Minimum		**0.18**	**0.57**	
Maximum		**0.26**	**1.63**	

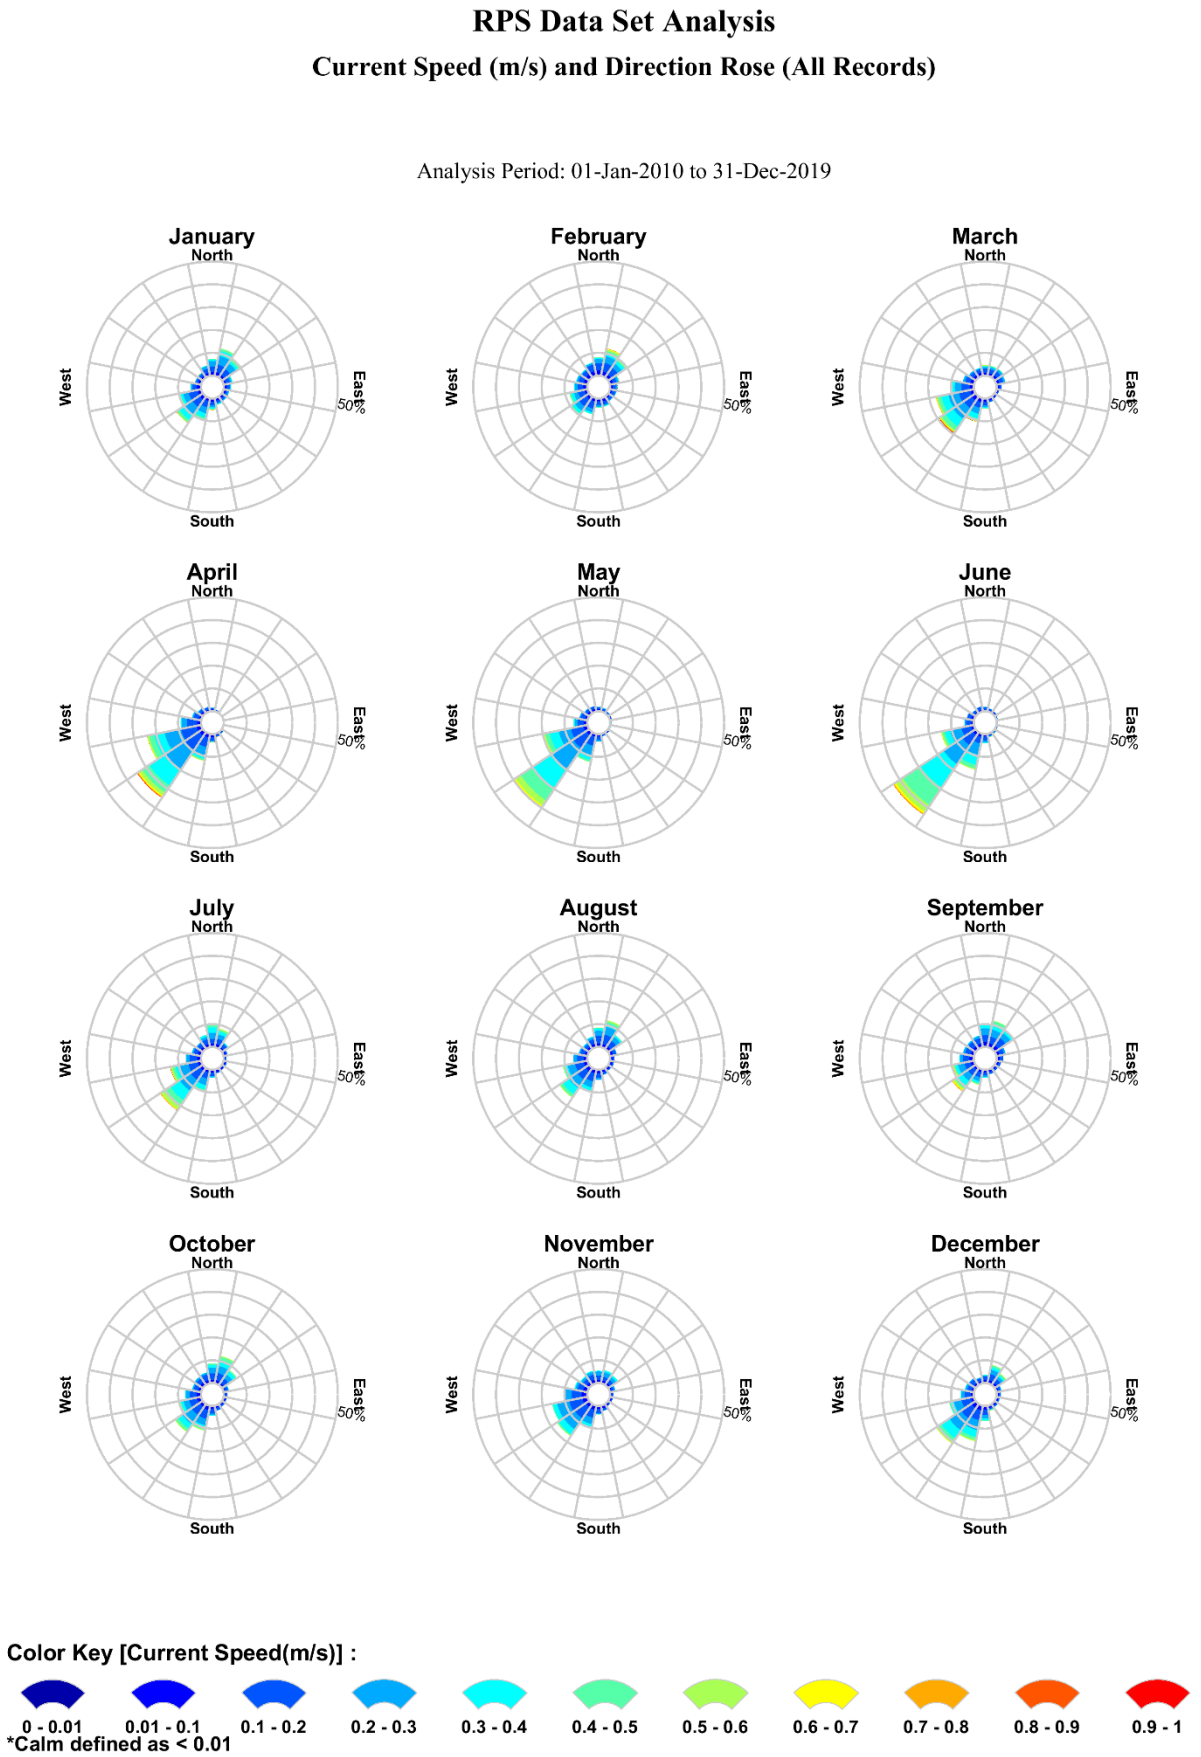

Figure 3.6 Monthly surface current rose distributions at the release location, derived from the 2010 to 2019 modelled dataset.

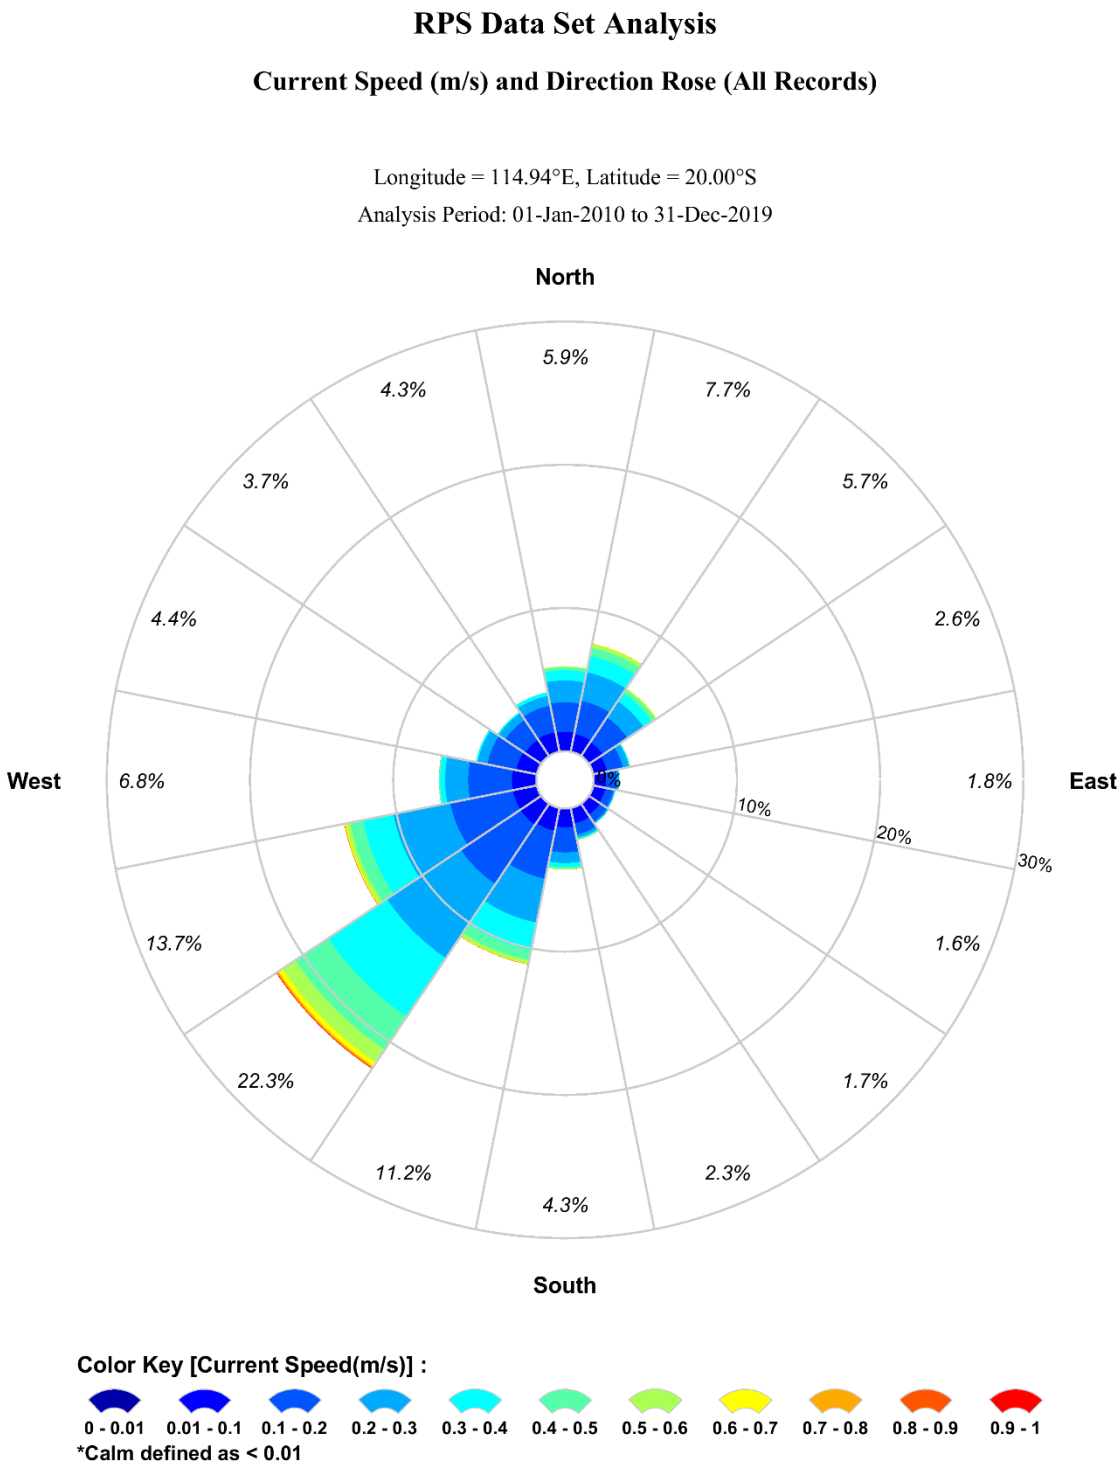

Figure 3.7 Total surface current rose plot at the release location, derived from the 2010 to 2019 modelled dataset.

4 WIND DATA

To account for the influence of the wind on the floating oil, wind data from 2010 to 2019 (inclusive) was sourced from the National Centre for Environmental Prediction (NCEP) Climate Forecast System Reanalysis (CFSR; see Saha et al., 2010). The CFSR wind model includes observations from many data sources; surface observations, upper-atmosphere air balloon observations, aircraft observations and satellite observations. The model is capable of accurately representing the interaction between the earth's oceans, land and atmosphere. The gridded wind data output is available at ¼ of a degree resolution (~33 km) and 1-hourly time intervals. Figure 4.1 shows the spatial resolution of the wind field used as input into the oil spill model.

Table 4.1 shows the monthly average and maximum winds derived from the CFSR node closest to the release location. The model wind data demonstrated that this region typically experiences moderate winds all year round and although the monthly average wind speeds remain under 15 knots. The maximum wind speed was 46 knots (February). Winds typically blow from the southwest during the summer months, while winds are typically easterly during the winter months.

Figure 4.2 and Figure 4.3 illustrates the monthly and total wind rose distributions nearby the release location, respectively.

Note that the atmospheric convention for defining wind direction, that is, the direction the wind blows from, is used to reference wind direction throughout this report. Each branch of the rose represents wind coming from that direction, with north to the top of the diagram. Sixteen directions are used. The branches are divided into segments of different colour, which represent wind speed ranges from that direction. Speed ranges of 5 knot intervals are typically used in these wind roses. The length of each segment within a branch is proportional to the frequency of winds blowing within the corresponding range of speeds from that direction.

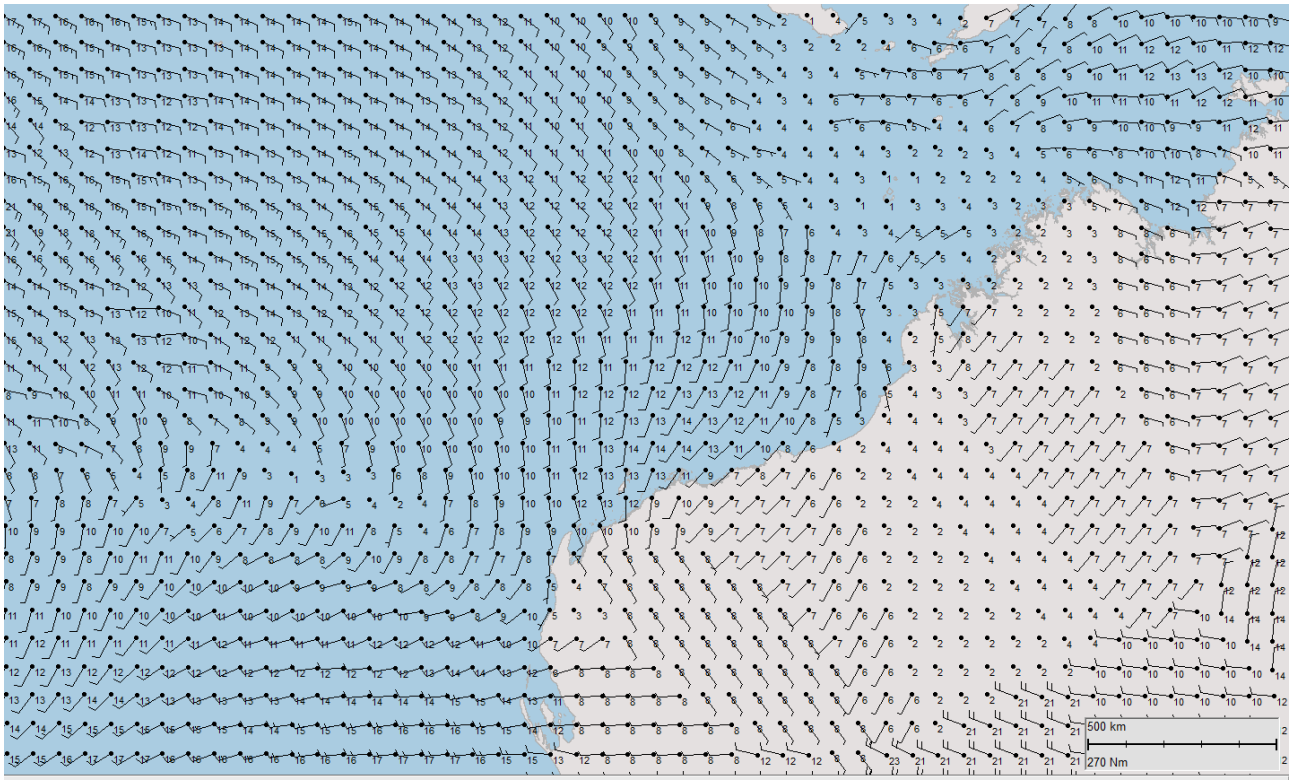

Figure 4.1 Spatial resolution of the CFSR modelled wind data used as input into the oil spill model. Note, for ease viewing only every second wind vector is displayed on the map.

Table 4.1 Predicted average and maximum winds for the wind node closest to the release location. Data derived from CFSR hindcast model 2010 to 2019 (inclusive).

Season	Month	Average wind (knots)	Maximum wind (knots)	General direction (from)
Summer	January	13	45	Southwest
	February	11	46	Southwest
	March	10	34	Southwest
Transitional	April	10	39	South
Winter	May	12	43	East

5 WATER TEMPERATURE AND SALINITY

The monthly depth-varying water temperature and salinity profiles nearest to the release location was obtained from the HYbrid Coordinate Ocean Model (see Section 3.2 Ocean Currents).

The three-dimensional salinity and temperature datasets are used in the oil spill model domain to inform the weathering, movement, and evaporative loss of hydrocarbon spills in the surface and subsurface layers.

Table 5.1 shows that the monthly average sea surface temperatures ranged from 24.3°C (September) to 29.5°C (March), whilst salinity remained relatively consistent throughout the year, ranging between 34.6–35.1 psu.

Figure 5.1 the vertical profile of sea temperature and salinity nearby the release location.

6 SUBSEA PLUME MODEL – OILMAP DEEP

The LOWC scenario is a high-pressure release of mostly gas and condensate and where gas is released with condensate, the buoyancy of the expanding gas cloud will entrain ambient seawater and propel the droplets towards the surface at a faster rate than would occur from the relative buoyancy of the condensate alone. Furthermore, the turbulence generated by such an intense discharge will tend to break the condensate up into droplets of various sizes.

To define the near-field plume dynamics, the subsea blowout model, OILMAP-DEEP, was applied. The model simulates the plume rise dynamics in two phases, the initial jet phase and the buoyant plume phase. The initial jet phase governs the plume dynamics directly above the subsurface release location and is predominately driven by the exit velocity. During this phase, the condensate droplet size and distribution is calculated. Next, the rise dynamics are dominated by the buoyant nature of the plume until the termination of the plume phase (known as the trapping depth). At this point, the results from OILMAP-DEEP (including plume trapping depth, plume diameter and droplet size distribution) are integrated into the far-field model SIMAP to simulate the rise and dispersion of the condensate droplets.

More details on the OILMAP-DEEP model, can be found in Spaulding et al. (2015). The model has been validated against observations from Deepwater Horizon as well as small and large-scale laboratory studies on subsurface oil releases (Brandvik et al., 2013, 2014; Belore, 2014; Spaulding et al., 2015; Li et al., 2017).

Table 6.1 presents the input parameters for the OILMAP-DEEP model and key results related to the near-field plume dynamics. The results indicated that the mixture of gas and condensate rose through the water column (whilst gradually losing momentum) to a trapping depth of approximately 424 m below mean sea level. After this point the condensate droplets would rise due to their own buoyancy, which are predicted to range in size from 115 to 496 µm.

Figure 6.1 illustrates the various stages of an example blowout plume.

Table 6.1 Input data and key results for the subsea plume modelling.

Input Variable	Value
Scenario	Loss of Well Control
Well name	Semele Well 5
Water depth (m)	800
Tubing diameter (inch) [m]	7 5/8 [0.194]
Condensate rate (stb/day)	2,441
Gas rate (MMscf/day)	428
Gas to condensate ratio (scf/bbl)	175,338
Formation water flow rate (stb/day)	0
Operating pressure (psia)	4,646
Key results	
Plume execution depth (m BMSL)	424
Droplet sizes (µm)	115 to 496

7 OIL SPILL MODEL – SIMAP

Modelling of the fate of oil was performed using the Spill Impact Mapping Analysis Program (SIMAP). SIMAP is designed to simulate the fate and effects of spilled hydrocarbons for both the surface and subsurface releases (Spaulding et al. 1994; French et al. 1999; French-McCay, 2003, 2004; French-McCay et al. 2004).

SIMAP has been used to predict the weathering and fate of oil spills during and after major incidents including: Montara (Australia) well blowout August 2009 in the Timor Sea (Asia-Pacific ASA, 2010); Macondo (USA) well blowout April 2010 in the Gulf of Mexico; Bohai Bay (China) oil spill August 2011; and the pipeline oil spill July 2013 in the Gulf of Thailand.

The SIMAP model calculates the transport, spreading, entrainment, evaporation and decay of surface hydrocarbon slicks as well as the entrained and dissolved oil components in the water column, either from surface slicks or from oil discharged subsea. The movement and weathering of the spilled oil is calculated for specific oil types. Input specifications for oil mixtures include the density, viscosity, pour point, distillation curve (volume lost versus temperature) and the aromatic/aliphatic component ratios within given boiling point ranges.

SIMAP is a three-dimensional model that allows for various response actions to be modelled including oil removal from skimming, burning, or collection booms, and surface and subsurface dispersant application.

The SIMAP oil spill model includes advanced weathering algorithms, specifically focussed on unique oils that tend to form emulsions and/or tar balls. The weathering algorithms are based on five years of extensive research conducted in response to the Deepwater Horizon oil spill in the Gulf of Mexico (French et al., 2015).

Biodegradation is included in the oil spill model. In the model, SIMAP, degradation is calculated for the surface slick, deposited oil on the shore, the entrained oil and dissolved constituents in the water column, and oil in the sediments. For surface oil, water column oil and sedimented oil a first order degradation rate is specified. Biodegradation rates are relatively high for hydrocarbons in dissolved state or in dispersed small droplets.

7.1 Stochastic Modelling

Stochastic oil spill modelling is created by overlaying a great number (often 100 hundred) simulated hypothetical oil spills (Figure 7.1). Stochastic modelling involves running numerous individual oil spill simulations using a range of prevailing wind and current conditions that are historically representative of the season and location of where the spill event may occur.

For the stochastic modelling presented herein, **100 spills** were simulated per season using the same spill information (release location, spill volume, duration and condensate properties) but with varied start dates and times corresponding to the period represented by the available wind and current data. During each simulation, the model records whether any grid cells are exposed to any hydrocarbon concentrations, the concentrations involved and the elapsed time before exposure. For each scenario the results of all 100 condensate spill simulations were analysed to determine the following seasonal statistics for every grid cell:

- Exposure load (concentrations and volumes);
- Minimum time before exposure;
- Probability of contact above defined concentrations;
- Volume of condensate that may strand on shorelines from any single simulation;
- Concentration that might occur on sections of individual shorelines;
- Exposure (instantaneous and/or over a specified duration) to dissolved hydrocarbons in the water column; and
- Exposure (instantaneous and/or over a specified duration) to entrained hydrocarbons in the water column.

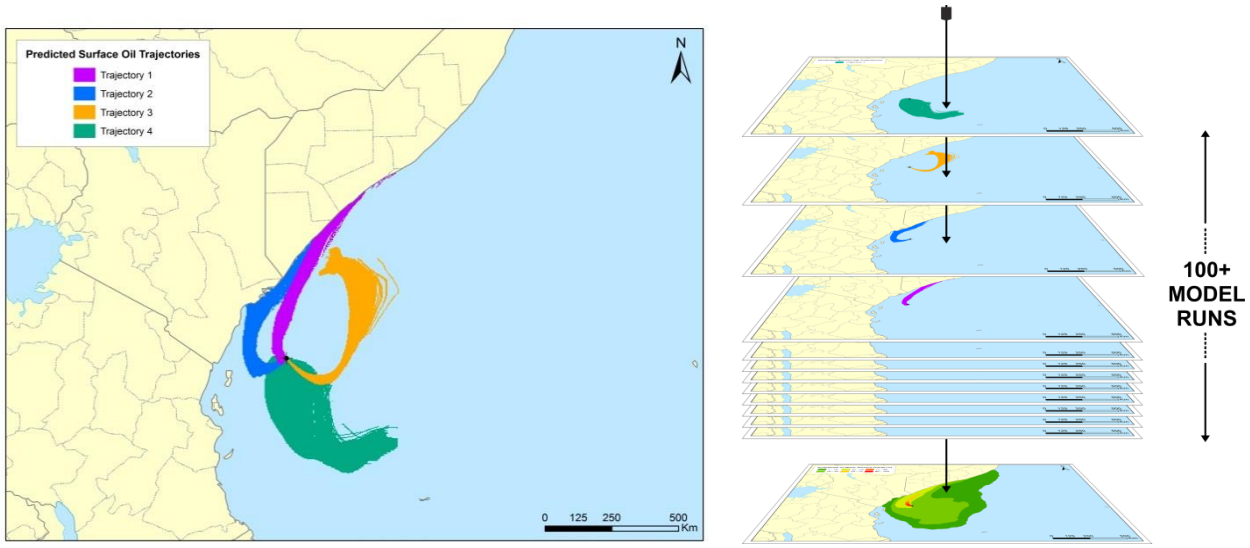

Figure 7.1 Predicted movement of four single oil spill simulations by SIMAP for the same scenario (left image). All model runs are overlain (shown as the stacked runs on the right) and the number of times that trajectories contact a given location at a concentration is used to calculate the probability (Source: NOPSEMA, 2018).

7.2 Floating, Shoreline and In-Water Thresholds

The thresholds and their relationship to exposure for the sea surface, shoreline and water column (entrained and dissolved hydrocarbons) are presented in Sections 7.2.1 to 7.2.3. Supporting justifications of the adopted thresholds applied during the study and additional context relating to the area of influence are also provided. It is important to note that the thresholds herein are based on NOPSEMA (2019).

7.2.1 Floating condensate exposure Thresholds

The modelling results can be presented to any levels; therefore, thresholds have been specified (based on scientific literature) to record floating condensate exposure to the sea-surface at meaningful levels only, described in the following paragraphs.

The low threshold to assess the potential for floating oil exposure, was 1 g/m^2, which equates approximately to an average thickness of 1 µm, referred to as visible oil. Oil of this thickness is described as rainbow sheen in appearance, according to the Bonn Agreement Oil Appearance Code (Bonn Agreement, 2009; AMSA, 2014) (see Table 7.1). Figure 7.2 shows photographs highlighting the difference in appearance between a silvery sheen, rainbow sheen and metallic sheen. This threshold is considered below levels which would cause environmental harm and it is more indicative of the areas perceived to be affected due to its visibility on the sea surface and potential to trigger temporary closures of areas (i.e. fishing grounds) as a precautionary measure. Table 7.1 provides a description of the appearance in relation to exposure zone thresholds used to classify the zones of floating oil exposure.

Ecological impact has been estimated to occur at 10 g/m^2 (a film thickness of approximately 10 µm or 0.01 mm) according to French et al. (1996) and French-McCay (2009) as this level of fresh oiling has been observed to mortally impact some birds through adhesion of oil to their feathers, exposing them to secondary effects such as hypothermia. The appearance of oil at this average thickness has been described as a metallic sheen (Bonn Agreement, 2009). Concentrations above 10 g/m^2 is also considered the lower actionable threshold, where oil may be thick enough for containment and recovery as well as dispersant treatment (AMSA, 2015).

Scholten et al. (1996) and Koops et al. (2004) indicated that at oil concentrations on the sea surface of 25 g/m^2 (or greater), would be harmful for all birds that have landed in an oil film due to potential contamination of their feathers, with secondary effects such as loss of temperature regulation and ingestion

of oil through preening. The appearance of oil at this thickness is also described as metallic sheen (Bonn Agreement, 2009). For this study the high exposure threshold was set to 50 g/m^2 and above based on NOPSEMA (2019). This threshold can also be used to inform response planning.

Table 7.2 defines the thresholds used to classify the zones of floating condensate exposure reported herein.

Table 7.1 The Bonn Agreement Oil Appearance Code.

Code	Description Appearance	Layer Thickness Interval (g/m^2 or µm)	Litres per km^2
1	Sheen (silvery/grey)	0.04 – 0.30	40 – 300
2	Rainbow	0.30 – 5.0	300 – 5,000
3	Metallic	5.0 – 50	5,000 – 50,000
4	Discontinuous True Oil Colour	50 – 200	50,000 – 200,000
5	Continuous True Oil Colour	≥ 200	≥ 200,000

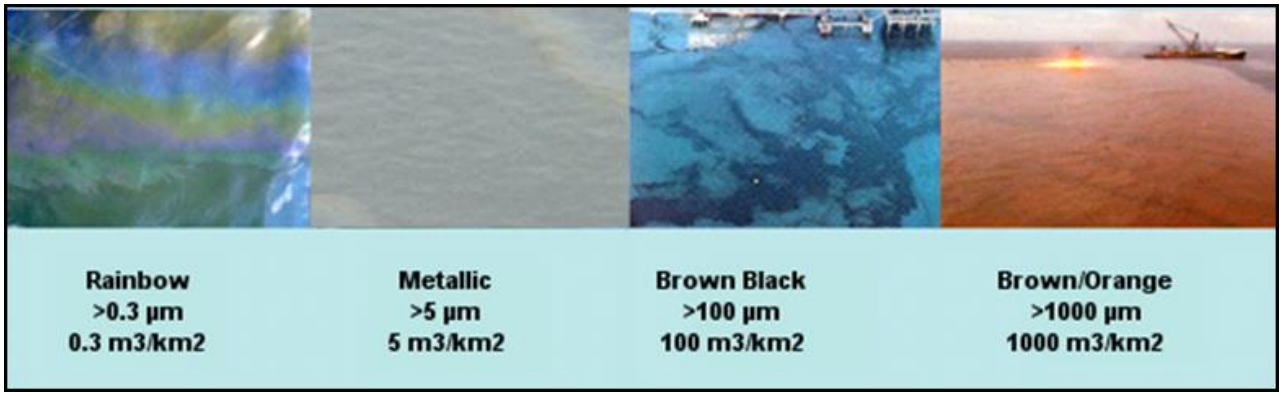

Figure 7.2 Photographs showing the difference between oil colour and thickness on the sea surface (source: adapted from Oil Spill Solutions, 2015).

Table 7.2 Floating condensate exposure thresholds used in this report (in alignment with NOPSEMA, 2019).

Threshold level	Floating oil (g/m^2)	Description
Low	1	Approximates range of socioeconomic effects and establishes planning area for scientific monitoring
Moderate	10	Approximates lower limit for harmful exposures to birds and marine mammals
High	50*	Approximates surface oil slick and informs response planning

* 50 g/m^2 also used to define the threshold for actionable floating oil.

7.2.2 Shoreline Accumulation Thresholds

There are many different types of shorelines, ranging from cliffs, rocky beaches, sandy beaches, mud flats and mangroves, and each of these influences the volume of oil that can remain stranded ashore and its thickness before the shoreline saturation point occurs. For instance, a sandy beach may allow oil to percolate through the sand, thus increasing its ability to hold more oil ashore over tidal cycles and various wave actions than an equivalent area of water; hence oil can increase in thickness onshore over time. A sandy beach shoreline was assumed as the default shoreline type for the modelling herein, as it allows for the highest carrying capacity of oil (of the available open/exposed shoreline types). Hence the results contained herein would be indicative of a worst-case scenario, where the highest volume of oil may be stranded on the shoreline (when compared to other shoreline types, such as exposed rocky shores).

In previous risk assessment studies, French-McCay et al. (2005a; 2005b) used a threshold of 10 g/m^2 to assess the potential for shoreline accumulation. This is a conservative threshold used to define regions of socio-economic impact, such as triggering temporary closures of adjoining fisheries or the need for shore clean-up on beaches or man-made features/amenities (breakwaters, jetties, marinas, etc.). It would equate to approximately 2 teaspoons of hydrocarbon per square meter of shoreline accumulation. The appearance is described as a stain/film. On that basis, the 10 g/m^2 shoreline accumulation threshold has been selected to define the zone of potential “low shoreline accumulation”.

French et al. (1996) and French-McCay (2009) define a shoreline oil accumulation threshold of 100 g/m^2, or above, would potentially harm shorebirds and wildlife (furbearing aquatic mammals and marine reptiles on or along the shore) based on studies for sub-lethal and lethal impacts. This threshold has been used in previous environmental risk assessment studies (see French-McCay, 2003; French-McCay et al., 2004, French-McCay et al., 2011; 2012; NOAA, 2013). Additionally, a shoreline concentration of 100 g/m^2, or above, is the minimum limit that the oil can be effectively cleaned according to the AMSA (2015) guideline. This threshold equates to approximately ½ a cup of oil per square meter of shoreline accumulation. The appearance is described as a thin oil coat. Therefore, 100 g/m^2 has been selected to define the zone of potential “moderate shoreline accumulation”.

Observations by Lin & Mendelssohn (1996) demonstrated that loadings of more than 1,000 g/m^2 of hydrocarbon during the growing season would be required to impact marsh plants significantly. Similar thresholds have been found in studies assessing hydrocarbon impacts on mangroves (Grant et al., 1993; Suprayogi & Murray 1999). Hence, 1,000 g/m^2 has been selected to define the zone of potential “high shoreline accumulation”. It equates to approximately 1 litre of hydrocarbon per square meter of shoreline accumulation. The appearance is described as a hydrocarbon cover.

It is worth noting that the shoreline accumulation thresholds derived from extensive literature review (outlined in Table 7.3) agree with the commonly used threshold values for oil spill modelling specified in NOPSEMA (2019).

Table 7.3 Thresholds used to assess shoreline accumulation.

Threshold level	Shoreline accumulation (g/m^2)	Description
Low (socioeconomic/sublethal)	10	Predicts potential for some socio-economic impact
Moderate	100*	Loading predicts area likely to require clean-up effort
High	> 1,000	Loading predicts area likely to require intensive clean-up effort

* 100 g/m^2 also used to define the threshold for actionable shoreline oil.

7.2.3 In-water Exposure Thresholds

Oil is a mixture of thousands of hydrocarbons of varying physical, chemical, and toxicological characteristics, and therefore, demonstrate varying fates and impacts on organisms. As such, for in-water exposure, the SIMAP model provides separate outputs for dissolved and entrained hydrocarbons from oil droplets. The consequences of exposure to dissolved and entrained components will differ because they have different modes and magnitudes of effect.

Entrained hydrocarbon concentrations were calculated based on oil droplets that are suspended in the water column, though not dissolved. The composition of this oil would vary with the state of weathering (oil age) and may contain soluble hydrocarbons when the oil is fresh. Calculations for dissolved hydrocarbons specifically calculates oil components which are dissolved in water, which are known to be the primary source of toxicity exerted by oil.

7.2.3.1 Dissolved Hydrocarbons

Laboratory studies have shown that dissolved hydrocarbons exert most of the toxic effects of oil on aquatic biota (Carls et al., 2008; Nordtug et al., 2011; Redman, 2015). The mode of action is a narcotic effect, which is positively related to the concentration of soluble hydrocarbons in the body tissues of organisms (French-McCay, 2002). Dissolved hydrocarbons are taken up by organisms directly from the water column by absorption through external surfaces and gills, as well as through the digestive tract. Thus, soluble hydrocarbons are termed “bioavailable”.

Hydrocarbon compounds vary in water-solubility and the toxicity exerted by individual compounds is inversely related to solubility, however bioavailability will be modified by the volatility of individual compounds (Nirmalakhandan & Speece, 1988; Blum & Speece, 1990; McCarty, 1986; McCarty et al., 1992a, 1992b; Mackay et al., 1992; McCarty & Mackay, 1993; Verhaar et al., 1992, 1999; Swartz et al., 1995; French-McCay, 2002; McGrath et al., 2009). Of the soluble compounds, the greatest contributor to toxicity for water-column and benthic organisms are the lower-molecular-weight aromatic compounds, which are both volatile and soluble in water. Although they are not the most water-soluble hydrocarbons within most oil types, the polynuclear aromatic hydrocarbons (PAHs) containing 2-3 aromatic ring structures typically exert the largest narcotic effects because they are semi-soluble and not highly volatile, so they persist in the environment long enough for significant accumulation to occur (Anderson et al., 1974, 1987; Neff & Anderson, 1981; Malins & Hodgins, 1981; McAuliffe, 1987; NRC, 2003). The monoaromatic hydrocarbons (MAHs), including the BTEX compounds (benzene, toluene, ethylbenzene, and xylenes), and the soluble alkanes (straight chain hydrocarbons) also contribute to toxicity, but these compounds are highly volatile, so that their contribution will be low when oil is exposed to evaporation and higher when oil is discharged at depth where volatilisation does not occur (French-McCay, 2002).

French-McCay (2002) reviewed available toxicity data, where marine biota was exposed to dissolved hydrocarbons prepared from oil mixtures, finding that 95% of species and life stages exhibited 50% population mortality (LC_{50}) between 6 and 400 ppb total PAH concentration after 96 hrs exposure, with an average of 50 ppb. Hence, concentrations lower than 6 ppb total PAH value should be protective of 97.5% of species and life stages even with exposure periods of days (at least 96 hours). Early life-history stages of fish appear to be more sensitive than older fish stages and invertebrates.

Exceedances of 10, 50 or 400 ppb over a 1 hour timestep (see Table 7.4) was applied to indicate increasing potential for sub-lethal to lethal toxic effects (or low to high), based on NOPSEMA (2019).

7.2.3.2 Entrained Hydrocarbons

Entrained hydrocarbons consist of oil droplets that are suspended in the water column and insoluble. As such, insoluble compounds in oil cannot be absorbed from the water column by aquatic organisms, hence are not bioavailable through absorption of compounds from the water. Exposure to these compounds would require routes of uptake other than absorption of soluble compounds. The route of exposure of organisms to whole oil alone include direct contact with tissues of organisms and uptake of oil by direct consumption, with potential for biomagnification through the food chain (NRC, 2003).

The 10 ppb threshold represents the very lowest concentration and corresponds generally with the lowest trigger levels for chronic exposure for entrained hydrocarbons in the ANZECC & ARMCANZ (2000) water quality guidelines. Due to the requirement for relatively long exposure times (> 24 hours) for these concentrations to be significant, they are likely to be more meaningful for juvenile fish, larvae and planktonic organisms that might be entrained (or otherwise moving) within the entrained plumes, or when entrained hydrocarbons adhere to organisms or trapped against a shoreline for periods of several days or more.

This exposure zone is not considered to be of significant biological impact and is therefore outside the adverse exposure zone. This exposure zone represents the area contacted by the spill. This area does not define the area of influence as it is considered that the environment will not be affected by the entrained hydrocarbon at this level.

Thresholds of 10 ppb and 100 ppb were applied over a 1 hour time exposure (Table 7.4), to cover the range of thresholds outlined in the ANZECC & ARMCANZ (2000) water quality guidelines, the incremental change for greater potential effect and is per NOPSEMA (2019).

A complicating factor that should be considered when assessing the consequence of dissolved and entrained oil distributions is that there will be some areas where both physically entrained oil droplets and dissolved hydrocarbons co-exist. Higher concentrations of each will tend to occur close to the source where sea conditions can force mixing of relatively unweathered oil into the water column, resulting in more rapid dissolution of soluble compounds.

Table 7.4 Dissolved and entrained hydrocarbon exposure values assessed over a 1-hour time step, as per NOPSEMA (2019).

Threshold level	Dissolved hydrocarbon concentration (ppb)	Entrained hydrocarbon concentrations (ppb)
Low	10	10
Moderate	50	-
High	400	100

8 CONDENSATE PROPERTIES

8.1 Properties

Semele condensate physical properties and boiling point distributions were provided by Chevron and are presented in Table 8.1 and Table 8.2, respectively.

Semele condensate has an API of 41.9, a density of 816 kg/m^3 (at 15ºC) and a viscosity value of 6.7 cP at 15 ºC. When exposed to the atmosphere at local temperatures, about 33% of the condensate volatile components should evaporate within the first 12 hours (BP < 180°C); a further 32.5% of the semi-volatiles should evaporate within the first 24 hours (180°C < BP < 265°C); and low volatile portion (27.9%) should evaporate over a longer period (265°C < BP < 380°C). The remaining 6.5% of the condensate would persist in the marine environment for much longer periods and be subject to relatively slow degradation.

This condensate has a low asphaltene content (< 0.05%), which is one indicator for a very low propensity for the mixture to take up water to form water-in-oil emulsion.

Soluble aromatic hydrocarbons contribute approximately 3.9% by mass of the whole oil, which is contained in the volatile fractions and are highly soluble. The process of evaporation will be grater under calm sea conditions, but increased entrainment can be expected under stronger winds due to the presence of small breaking waves (whitecaps).

The actual fate will depend greatly on the amount that reaches the surface, either through the initial release or by resurfacing.

Table 8.1 Physical properties of Semele condensate.

Characteristic	Semele Condensate
Density (kg/m^3)	816 (at 15°C)
API	41.9
Dynamic viscosity (cP)	6.7 (at 15°C)
Pour point (°C)	-9
Surface tension (dyne/cm)	22
Hydrocarbon property category	Group I
Hydrocarbon property classification	Non-persistent

Table 8.2 Boiling point ranges of Semele condensate.

Oil Type	Component	Volatile (%)	Semi-volatile (%)	Low volatility (%)	Residual (%)
	Boiling point (°C)	<180 C_4 to C_{10}	180-265 C_{11} to C_{15}	265-380 C_{16} to C_{20}	>380 >C_{20}
Semele Condensate	% of total	33.0	32.5	27.9	6.5
	% of aromatics	3.9	0	0	0

8.2 Weathering Characteristics

8.2.1 Overview

A series of weathering tests were conducted to illustrate the potential behaviour of this condensate when exposed to idealised and representative environmental conditions:

- Instantaneous 50 m^3 surface release under calm wind conditions (constant 5 knots), 27°C water temperature and currents.
- Instantaneous 50 m^3 surface release under variable moderate wind conditions, 27°C water temperature and currents.

The first case is indicative of weathering rates under calm conditions that would not generate entrainment, while the second case would be more representative of the moderate winds experienced over the region. Both scenarios provide examples of potential behaviour during periods of a spill event once the condensate reaches the surface.

8.2.2 Results

The mass balance forecast for the calm-wind case (Figure 8.1) shows that 66% of the condensate is predicted to evaporate within 24 hours. The majority of the remaining condensate on the water surface will weather at a slower rate due to the low volatile components. Evaporation of the residual compounds will slow significantly, and they will then be subject to more gradual decay through biological and photochemical processes.

Under the variable-wind case (Figure 8.2), where the winds are of greater strength on average, entrainment of Semele condensate into the water column was shown to increase. Approximately 24 hours after the spill, 49% of the condensate mass was shown to entrain and a further 49% had evaporated, leaving only a small portion of the condensate floating on the water surface (<0.8%). The residual compounds will tend to remain entrained during conditions that generate wind-waves (approximately >6 m/s).

The increased level of entrainment in the variable-wind case would result in a higher percentage of biological and photochemical degradation, where the decay of the floating slicks and condensate droplets in the water column occurs at an approximate rate of ~1.5% per day with an accumulated total of ~11.5% after 7 days, in comparison to a rate of ~0.1% per day and an accumulated total of ~0.7% after 7 days in the constant-wind case. Given the portion of entrained condensate and the tendency for it to remain mixed in the water column, the remaining hydrocarbons will decay over time scales of several weeks.

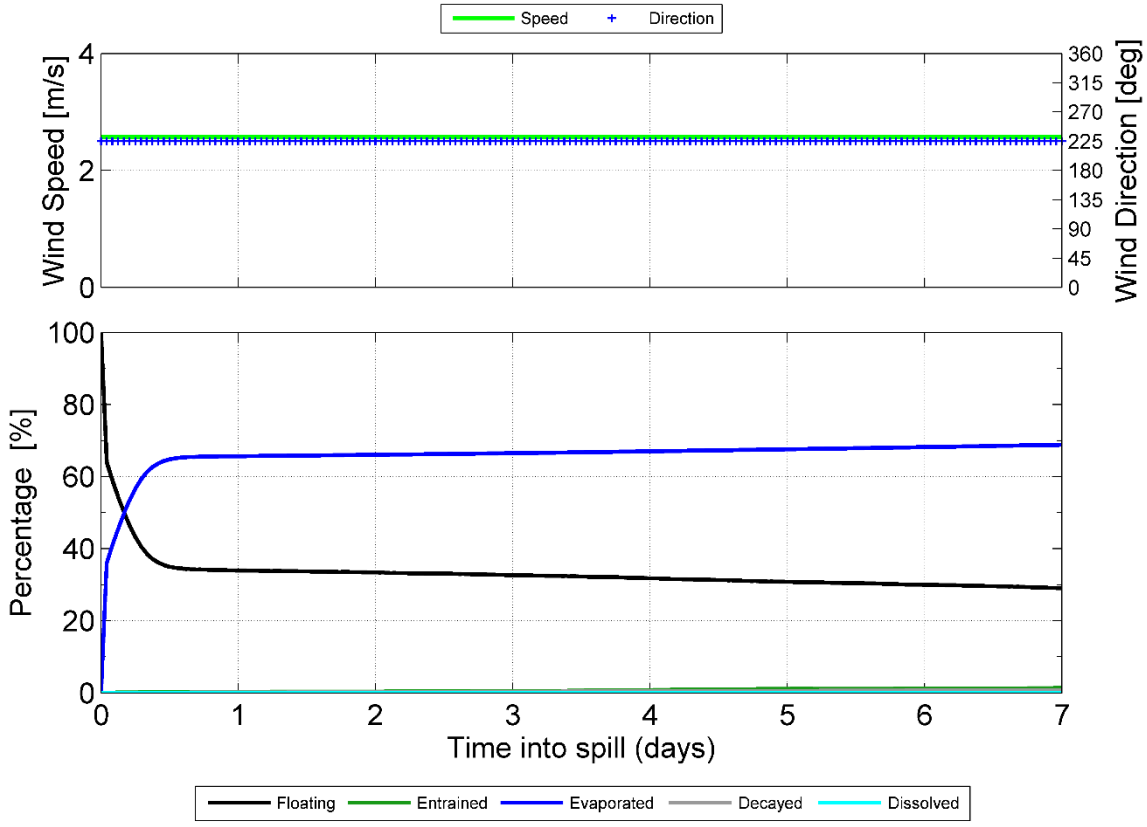

Figure 8.1 Proportional mass balance plot representing the weathering of Semele condensate spilled onto the water surface as a one-off instantaneous release and subject to a constant 5 knots (2.6 m/s) wind at 27°C water temperature.

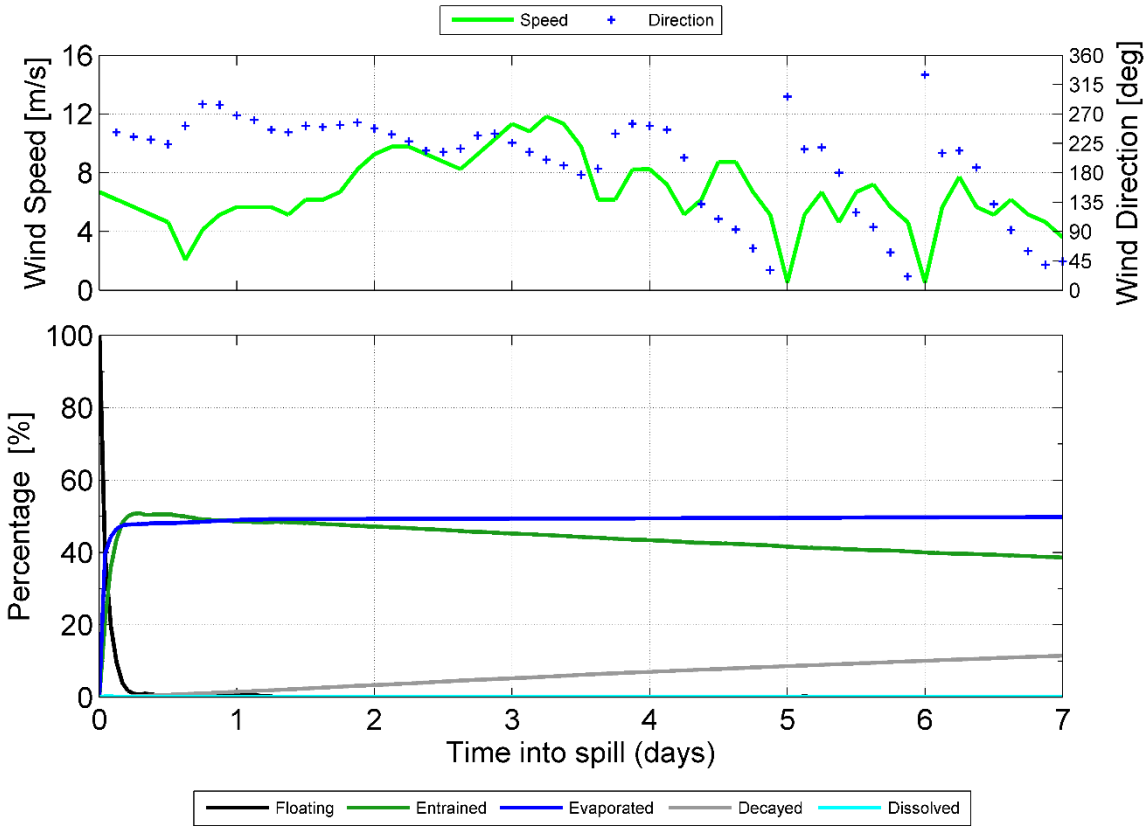

Figure 8.2 Proportional mass balance plot representing the weathering of Semele condensate spilled onto the water surface as a one-off instantaneous release and subject to variable wind at 27°C water temperature.

9 MODEL SETTINGS

Table 9.1 provides a summary of the oil spill model settings.

Table 9.1 Summary of the oil spill model settings used in this assessment.

	Scenario
Location	Semele Well 5 (Semele)
Number of spill simulations with randomly selected start times	100 per season (300 total)
Spill volume (m^3) [bbl]	34,927 [219,690]
Condensate type	Semele condensate
Release type (depth)	Subsea (800 m)
Release duration (days)	90
Simulation length (days)	104
Model period	Summer (September to the following March) Transitional (April and August) Winter (May to July)
Floating oil (NOPSEMA) thresholds	1 g/m^2, low exposure 10 g/m^2, moderate exposure 50 g/m^2, high exposure
Shoreline accumulation (NOPSEMA) thresholds	10 g/m^2, low exposure 100 g/m^2, moderate exposure 1,000 g/m^2, high exposure
Dissolved hydrocarbon (NOPSEMA) thresholds	10 ppb over 1 hour, low exposure 50 ppb over 1 hour, moderate exposure 400 ppb over 1 hour, high exposure
Entrained hydrocarbon (NOPSEMA) thresholds	10 ppb over 1 hour, low exposure 100 ppb over 1 hour high exposure

10 PRESENTATION AND INTERPRETATION OF MODEL RESULTS

The results from the modelling study are presented in a number of tables and figures, which aim to provide an understanding of the predicted sea-surface and water column (subsurface) exposure and shoreline accumulation (if predicted).

10.1 Stochastic Analysis

10.1.1 Statistics

The statistics are based on the following principles:

- The ***greatest distance travelled by a spill trajectory*** – is determined by a) recording the maximum and b) second greatest distance travelled (or 99th percentile) by a single trajectory, within a scenario, from the release location to the identified exposure thresholds.
- The ***Probability of condensate exposure to a receptor*** – is determined by recording the number of spill trajectories to reach a specified sea surface or subsea threshold within a receptor polygon, divided by the total number of spill trajectories within that scenario.
- The ***Minimum time before condensate exposure to a receptor*** – is determined by ranking the elapsed time before sea surface exposure, at a specified threshold, to grid cells within a receptor polygon and recording the minimum value.
- The ***probability of oil accumulation at a receptor*** – is determined by recording the number of spill trajectories to reach a specified shoreline accumulation threshold within a receptor polygon, divided by the total number of spill trajectories within that scenario.
- The ***maximum potential oil accumulation within a receptor*** – is determined by identifying the maximum loading to any grid cell within a receptor polygon, for a scenario.
- The ***dissolved and entrained hydrocarbon exposure*** – is determined by recording the maximum instantaneous concentrations at each grid cell assessed over a 1-hour time step.

10.2 Deterministic Trajectories

The deterministic results in Section 11.2 are based on the following criteria:

a. Largest swept area of floating hydrocarbon above 10 g/m^2
b. Largest swept area of floating hydrocarbon above 50 g/m^2
c. Largest volume of condensate ashore
d. Longest length of shoreline accumulation above 100 g/m^2
e. Largest area of entrained hydrocarbons above 100 ppb; and
f. Largest area of dissolved hydrocarbons above 50 ppb

10.3 Receptors

A range of environmental receptors and shorelines were assessed for floating oil exposure, shoreline contact and water column exposure (entrained and dissolved hydrocarbons) as part of the study (see Figure 10.1 to Figure 10.10). Receptor categories (see Table 10.1) include sections of shorelines and offshore islands. All other sensitive receptors other than submerged reefs, shoals and banks (RSB) were sourced from http://www.environment.gov.au/. Risks of exposure were separately calculated for each sensitive receptor area and have been tabulated.

Table 10.2 summarises the receptors that the location resides within.

Table 10.1 Summary of receptors used to assess floating oil, shoreline and in-water exposure to hydrocarbons.

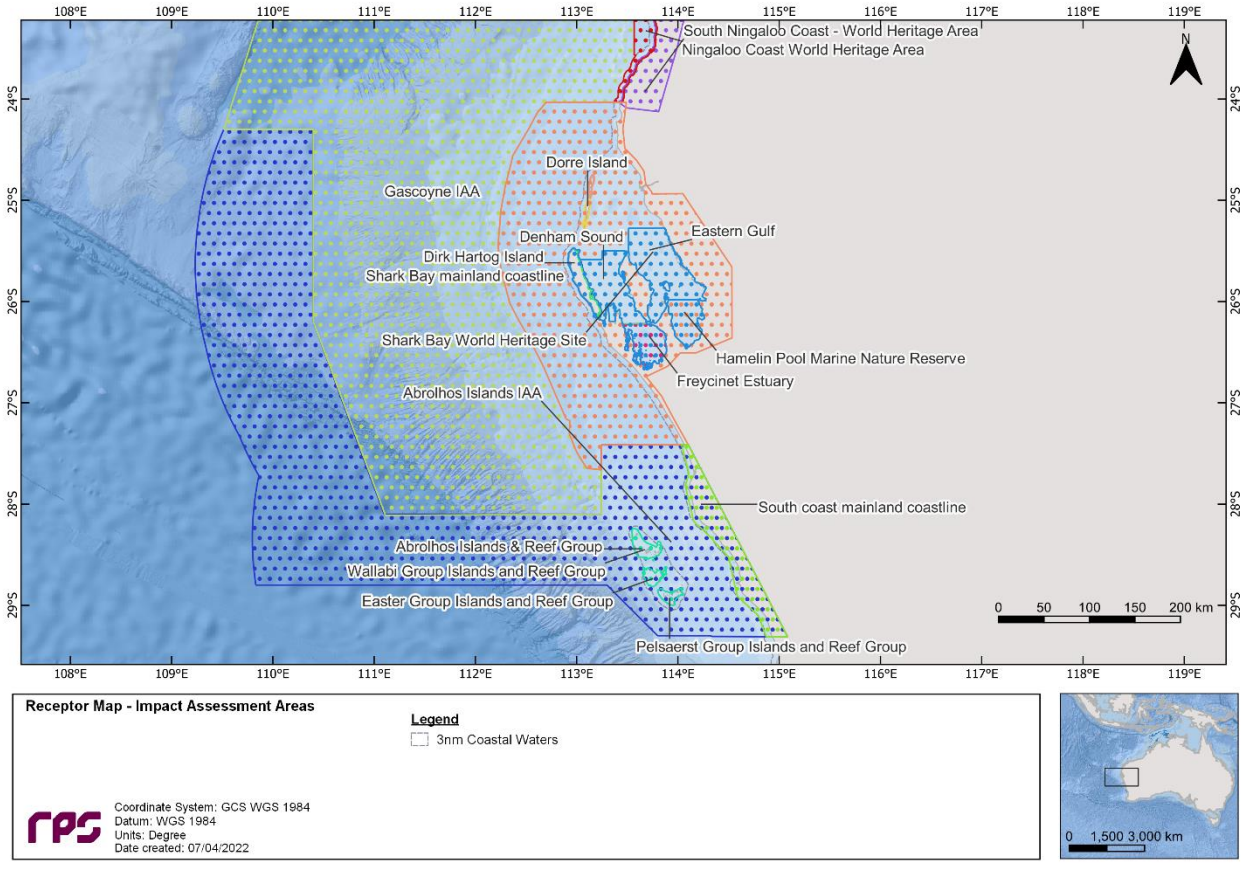

Figure 10.10 Receptor maps for Impact Assessment Areas (3 of 3).

11 RESULTS: SEMELE LOSS OF WELL CONTROL

This scenario examined a 219,690 bbl subsea release of condensate over 90 days, following a LOWC. A total of 300 spill simulations were run across the three seasons; summer, winter and transitional (i.e. 100 spills per season) and tracked for 104 days.

Section 11.1 presents the seasonal (or stochastic) analysis results, while Section 11.2 presents the deterministic results.

11.1 Stochastic Analysis

11.1.1 Floating Condensate Exposure

Table 11.1 summarises the maximum distances from the release location to floating condensate exposure zones for each season.

The maximum distance from the release location to the low (≥ 1 g/m^2) and moderate (≥ 10 g/m^2) thresholds was 144.5 km southwest (summer) and 2.2 km west southwest (winter and transitional), respectively. No exposure was predicted at the high (≥ 50 g/m^2) threshold.

Table 11.2 summarises the potential floating condensate exposure to individual receptors during each season.

The Offshore Area IAA, Pygmy Blue Whale – Distribution BIA and Wedge-tailed Shearwater – Breeding BIA which the release location resides within, were the only receptors predicted to be exposed during all three seasons at the low and moderate thresholds. The probability for the low threshold was 100% for all seasons for these receptors. Probabilities of moderate exposure for these receptors ranged between 6% (summer) and 18% (transitional).

Figure 11.1 to Figure 11.3 present the zones of floating condensate exposure for each season.

Table 11.1 Maximum distances and directions travelled from the release location to floating condensate exposure for each season and threshold, following a subsea LOWC at Semele Well 5. The results were calculated from 100 spill trajectories per season.

Season	Distance and direction	Zones of potential floating condensate exposure		
		Low	Moderate	High
Summer	Max. distance from release site (km)	144.5	1.4	-
	Max. distance from release site (km) (99th percentile)	80.6	1.4	-
	Direction	Southwest	Southwest	-
Transitional	Max. distance from release site (km)	134.6	2.2	-
	Max. distance from release site (km) (99th percentile)	73.9	2.2	-
	Direction	North-northeast	West-southwest	-
Winter	Max. distance from release site (km)	103.2	2.2	-
	Max. distance from release site (km) (99th percentile)	74.1	2.2	-
	Direction	Northeast	West-southwest	-

Table 11.2 Summary of the potential floating condensate exposure to individual receptors, following a LOWC at Semele Well 5. The results were calculated from 100 spill trajectories per season.

*The release location resides within the receptor boundaries.

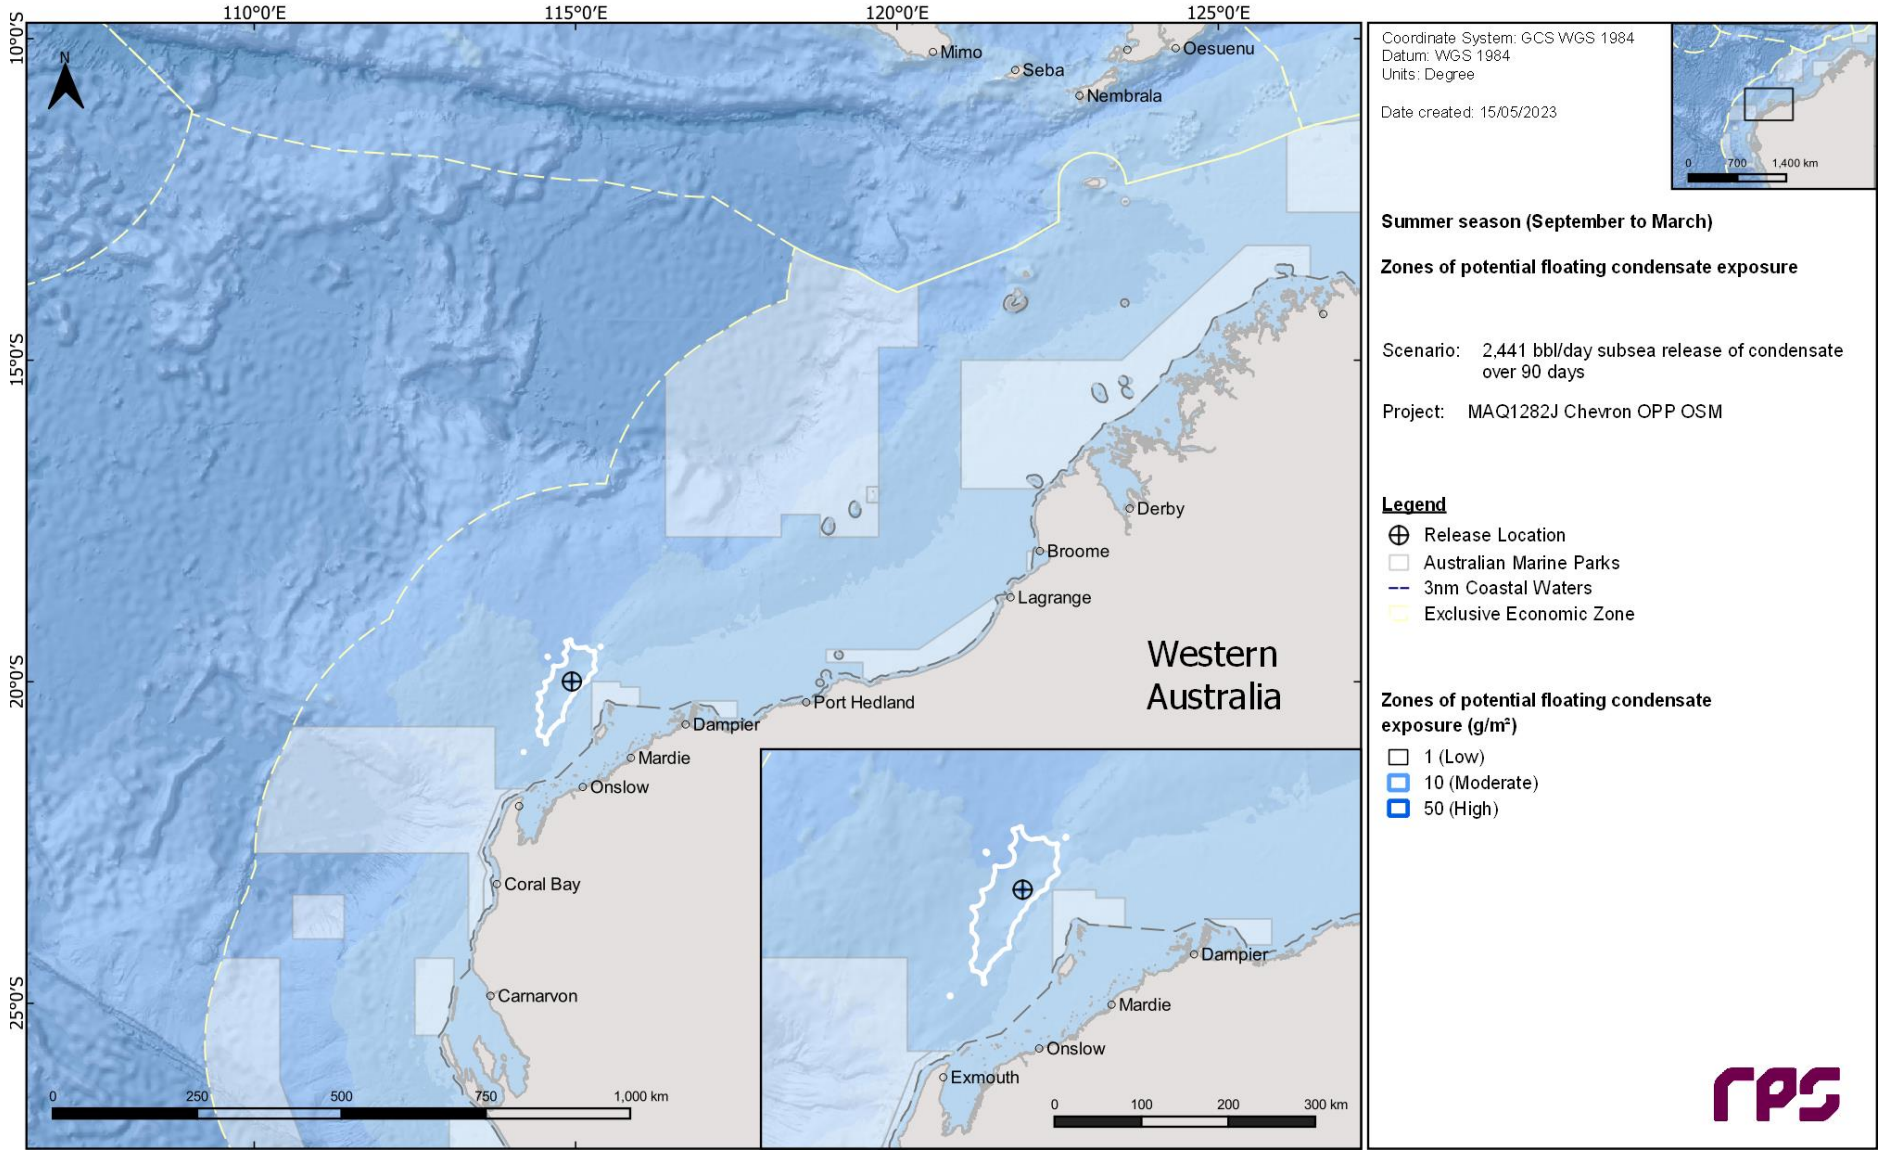

Figure 11.1 Zones of potential floating condensate exposure following a subsea LOWC at Semele Well 5 during summer (September to the following March) wind and current conditions. The results were calculated from 100 spill simulations.

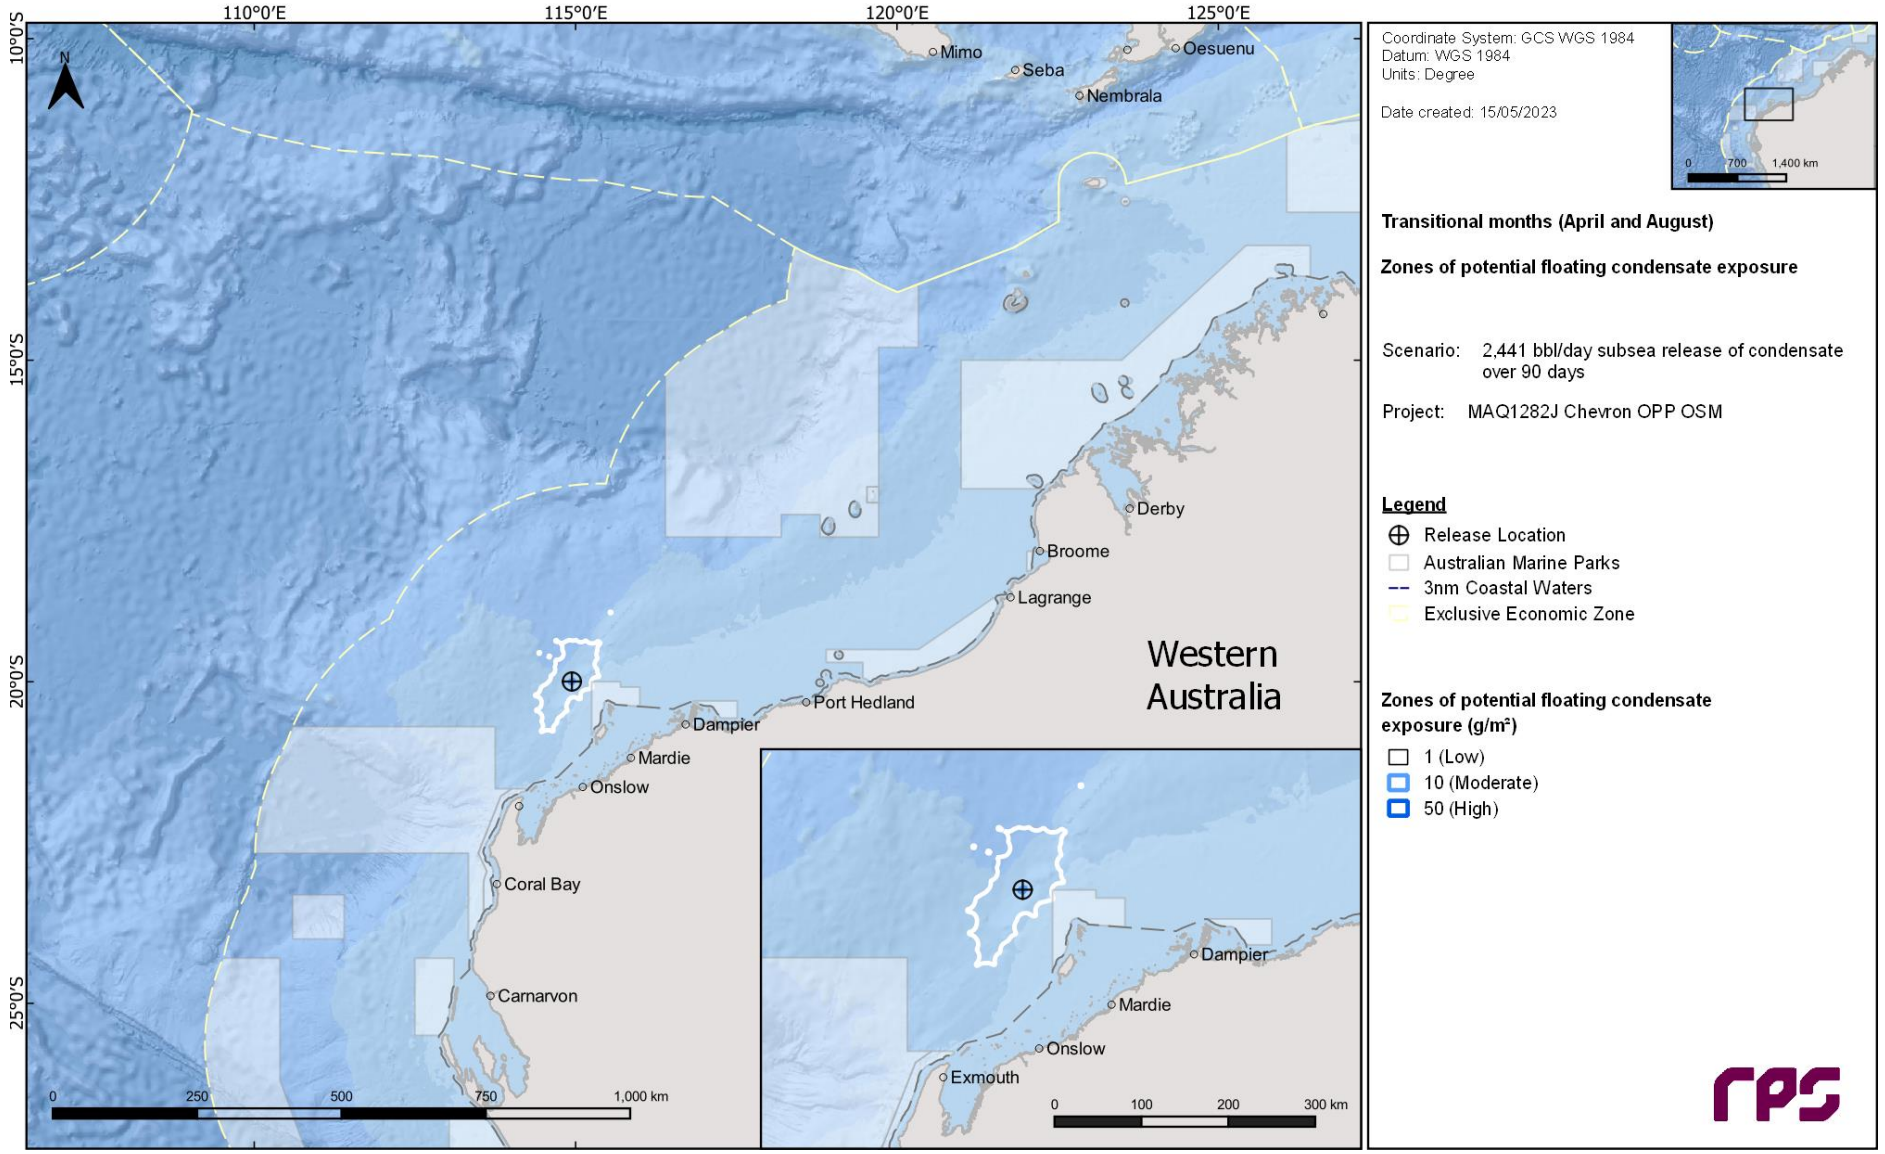

Figure 11.2 Zones of potential floating condensate exposure following a subsea LOWC at Semele Well 5 during transitional (April and August) wind and current conditions. The results were calculated from 100 spill simulations.

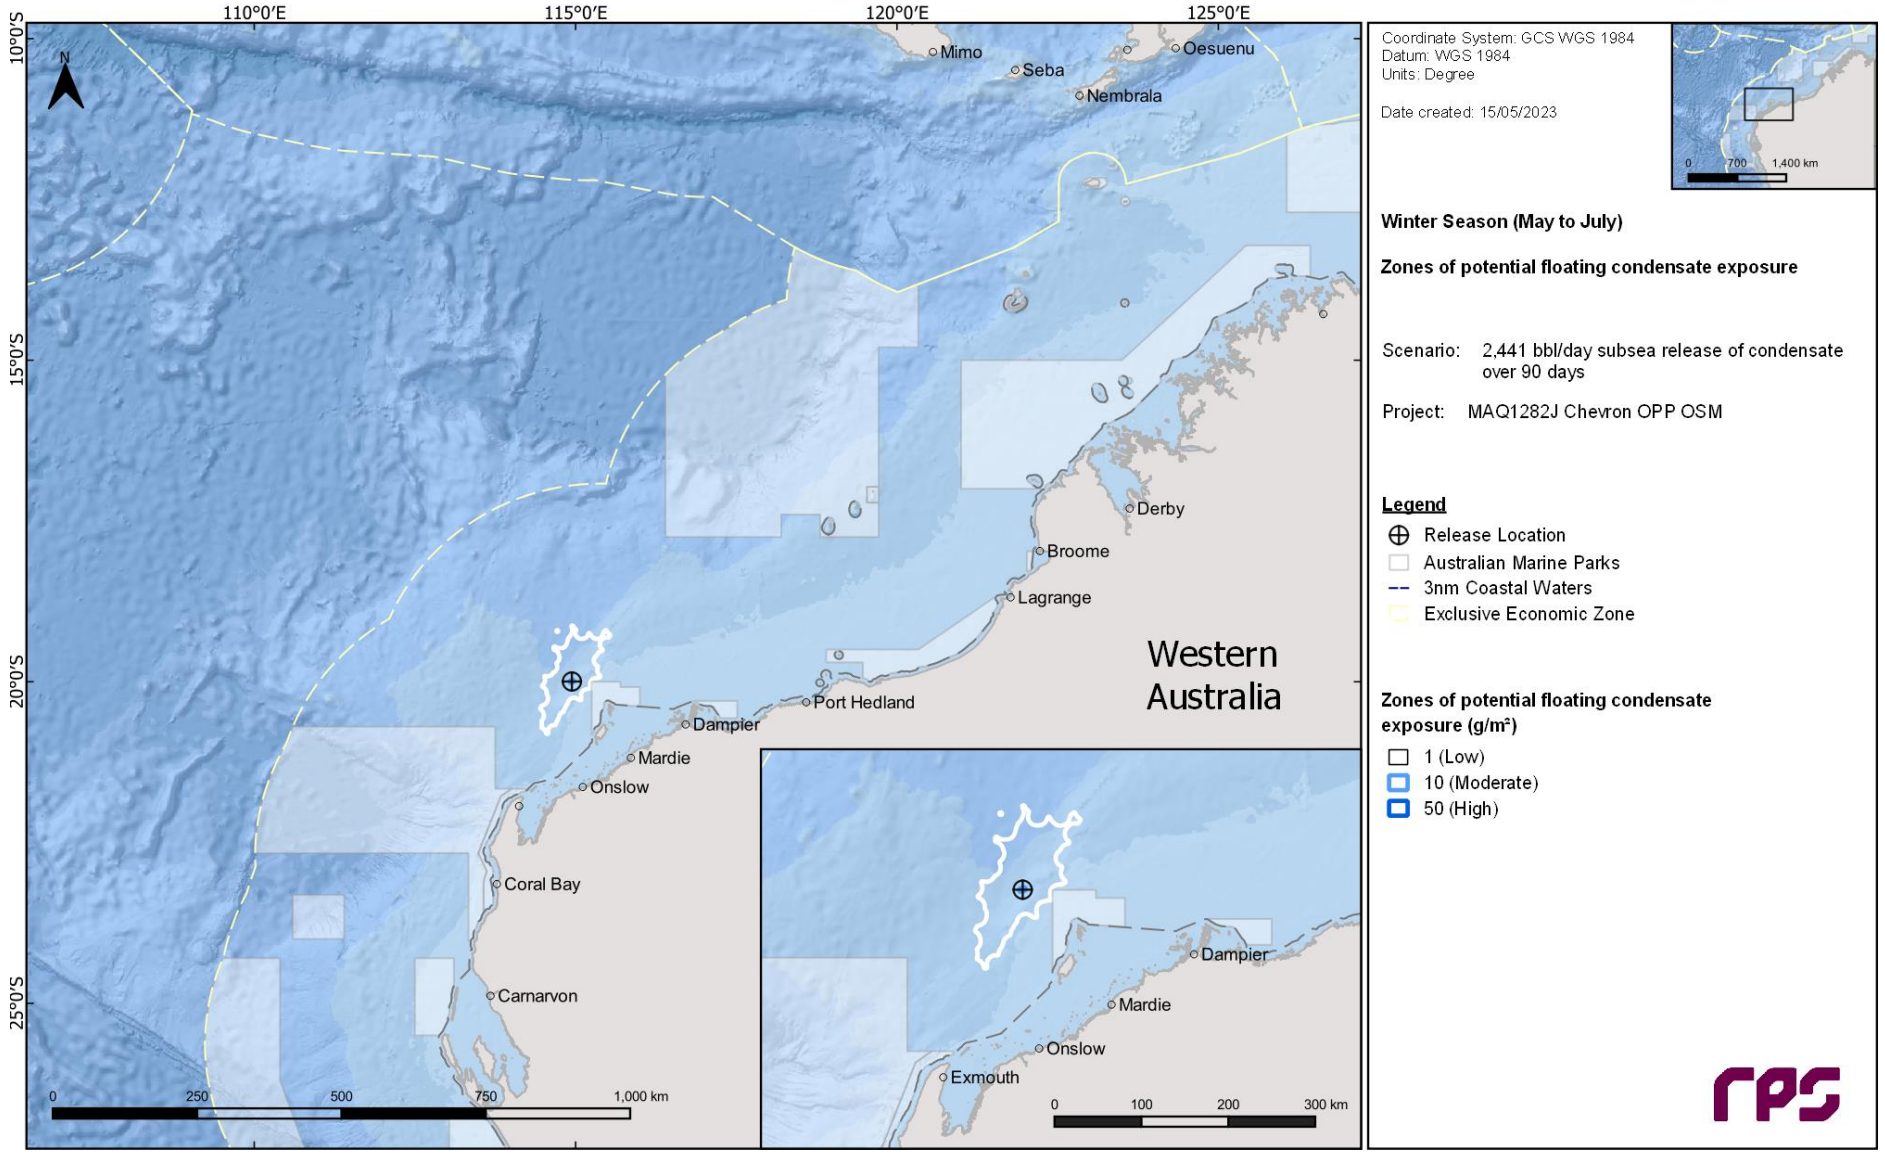

Figure 11.3 Zones of potential floating condensate exposure following a subsea LOWC at Semele Well 5 during winter (May to July) wind and current conditions. The results were calculated from 100 spill simulations.

11.1.2 Shoreline Accumulation

Table 11.3 presents a summary of the predicted shoreline accumulation during summer, transitional and winter seasons. The probability of accumulation on any shoreline at, or above, the low threshold (≥ 10 g/m^2) was greatest during summer at 27%, while the minimum time before shoreline accumulation was 13.7 days and the maximum volume of condensate ashore above the low threshold was 29.0 m^3.

No accumulation at the high (≥ 1,000 g/m^2) shoreline threshold was observed.

Table 11.4 to Table 11.6 summarises the shoreline accumulation on individual receptors for each season.

During summer conditions, condensate had accumulated on 62 shoreline receptors at, or above, the low threshold with the greatest probability predicted for Barrow & Montebello Islands IAA (19%). In comparison, during transitional and winter conditions condensate had accumulated on 10 and 4 shoreline receptors, respectively. During transitional conditions, the greatest probabilities had occurred at Cunningham Island (Imperieuse Reef), Argo-Rowley Terrace IAAs and Imperieuse Reef, all 3% probability. While for the winter season, the same three receptors recorded a 9% probability.

The maximum potential shoreline accumulation is presented for each season in Figure 11.4 to Figure 11.5.

Table 11.3 Summary of oil accumulation across all shorelines for each season and threshold, following a subsea LOWC at Semele Well 5. The results were calculated from 100 spill trajectories per season.

Shoreline Statistics	Summer	Transitional	Winter
Probability of accumulation on any shoreline (%)	27	4	9
Absolute minimum time for visible oil to shore (days)	13.7	29.0	45.4
Maximum volume of hydrocarbons ashore (m^3) above the low threshold	29.0	2.1	2.4
Average volume of hydrocarbons ashore (m^3) above the low threshold	6.9	0.3	0.5
Maximum length of the shoreline at **10 g/m^2** (km)	142	8	7
Average shoreline length (km) at **10 g/m^2** (km)	35.2	5	4.9
Maximum length of the shoreline at **100 g/m^2** (km)	2.9	-	-
Average shoreline length (km) at **100 g/m^2** (km)	2.1	-	-
Maximum length of the shoreline at **1,000 g/m^2** (km)	-	-	-
Average shoreline length (km) at **1,000 g/m^2** (km)	-	-	-

Table 11.4 Summary of shoreline oil accumulation to individual receptors, following a LOWC at Semele Well 5. The results were calculated from 100 spill trajectories days during summer (September to the following March) wind and current conditions.

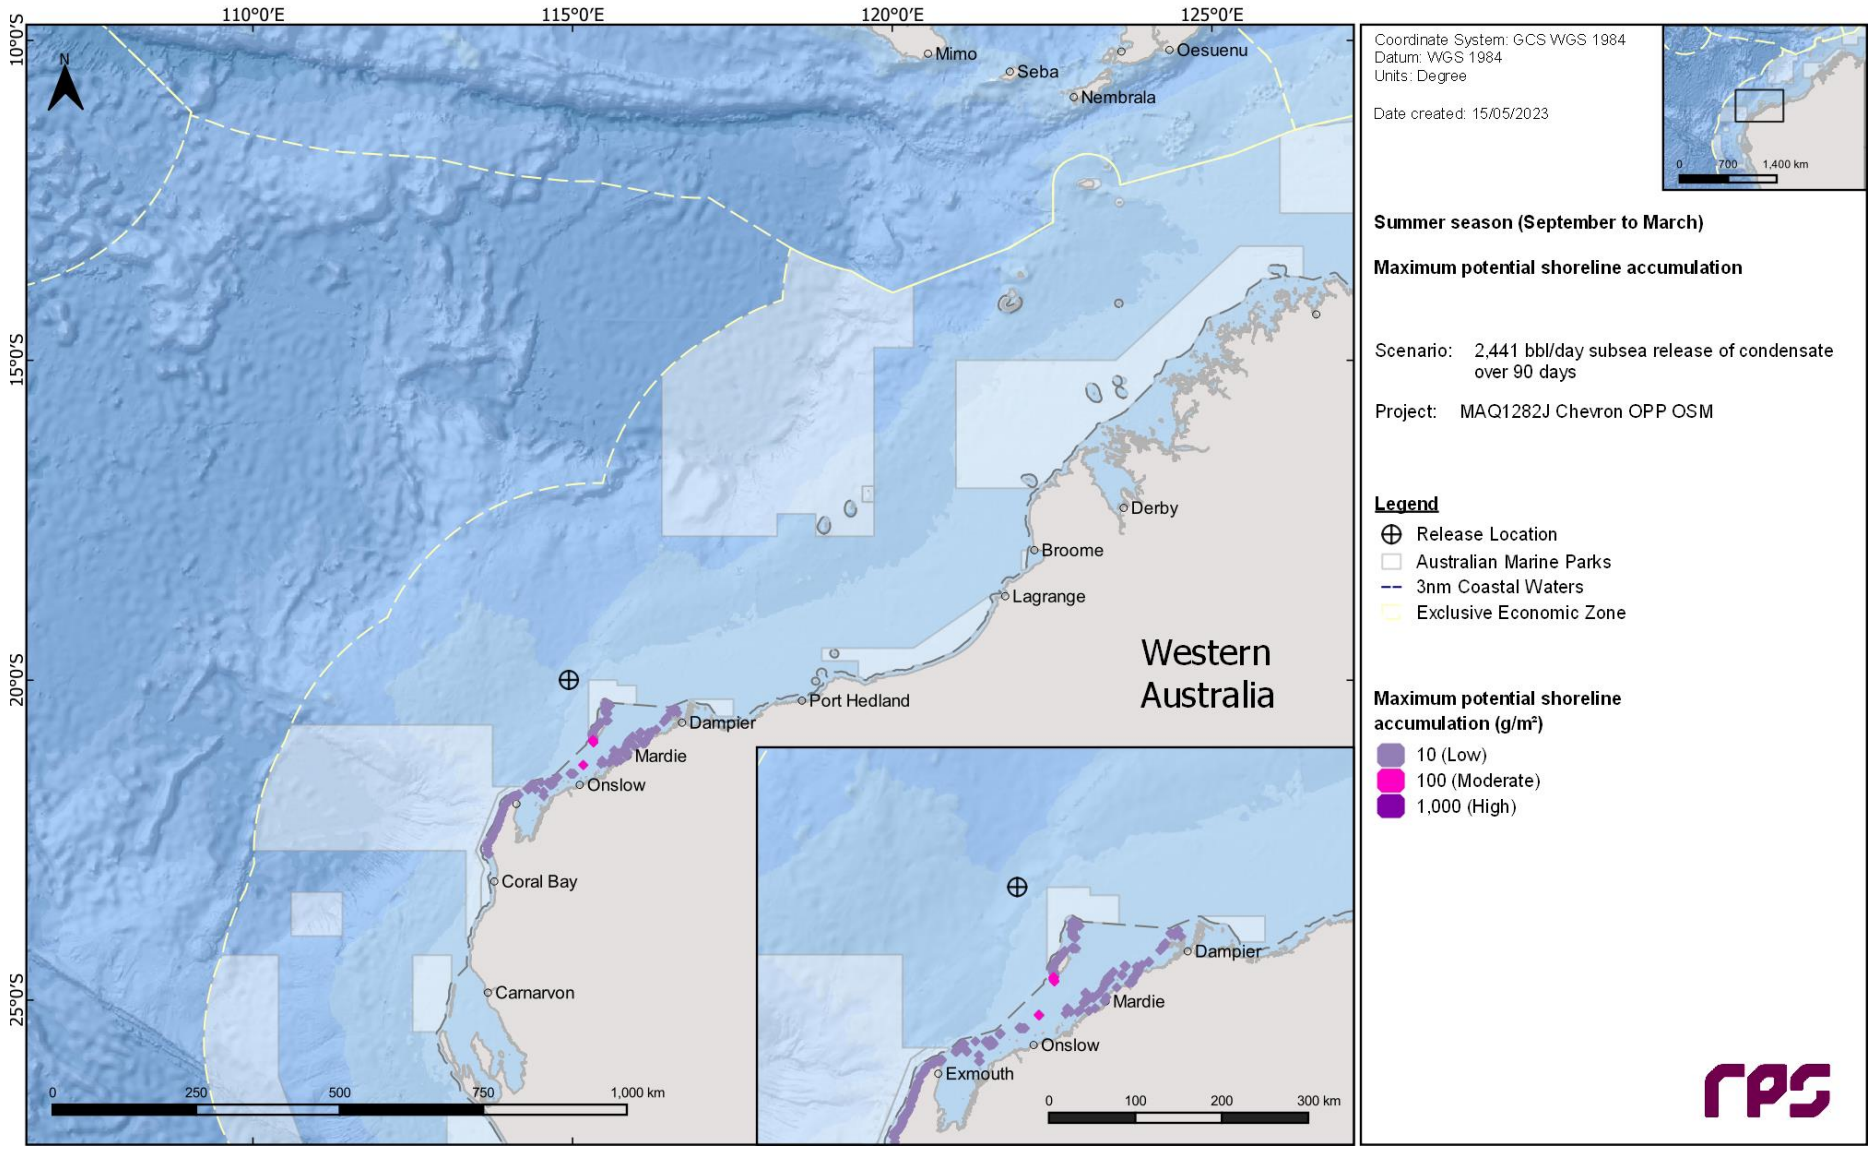

Figure 11.4 Maximum potential shoreline accumulation following a subsea LOWC at Semele Well 5 during summer (September to the following March) wind and current conditions. The results were calculated from 100 spill simulations.

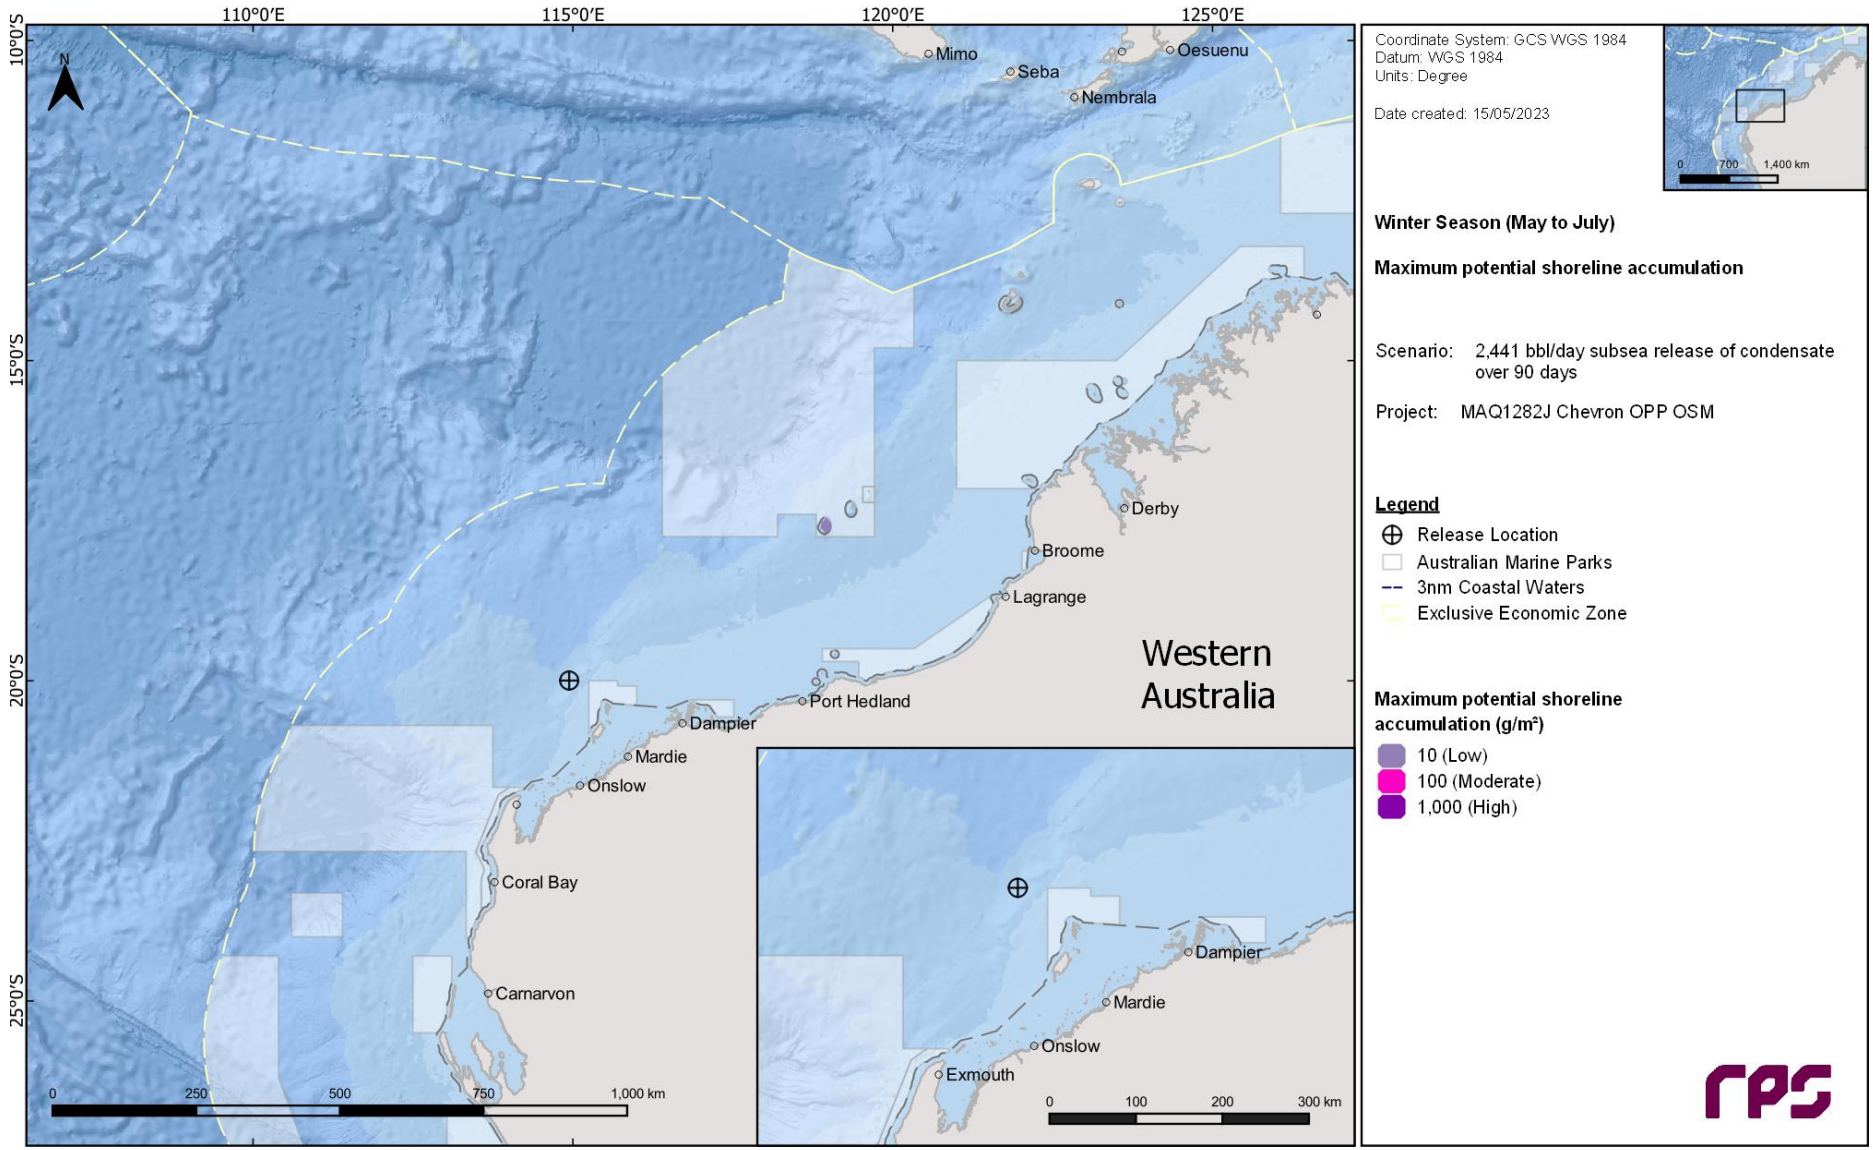

Figure 11.5 Maximum potential shoreline accumulation following a subsea LOWC at Semele Well 5 during winter (May to July) wind and current conditions. The results were calculated from 100 spill simulations.

11.1.3 Water Column Exposure

11.1.3.1 Dissolved Hydrocarbons

Table 11.7 summarises the maximum instantaneous exposure to dissolved hydrocarbons and the probability for individual receptors in the 0-10 m depth layer.

There were several receptors exposed at or above the low threshold during summer and winter, however they were all 1% occurrence.

Figure 11.6 to Figure 11.7 illustrate the extent of the predicted dissolved hydrocarbon exposure in the 0-10 m depth layer for each season.

Table 11.7 Predicted probability and maximum dissolved hydrocarbon exposure to individual receptors in the 0-10 m depth layer following a subsea LOWC at Semele Well 5. The results were calculated from 100 spill simulations per season.

Receptor		Summer							Transitional							Winter						
		Maximum exposure to dissolved hydrocarbons (ppb)	Probability of exposure to dissolved hydrocarbons (%)			Minimum time before exposure to dissolved hydrocarbons (Days)			Maximum exposure to dissolved hydrocarbons (ppb)	Probability of exposure to dissolved hydrocarbons (%)			Minimum time before exposure to dissolved hydrocarbons (Days)			Maximum exposure to dissolved hydrocarbons (ppb)	Probability of exposure to dissolved hydrocarbons (%)			Minimum time before exposure to dissolved hydrocarbons (Days)

*The release location resides within the receptor boundaries.

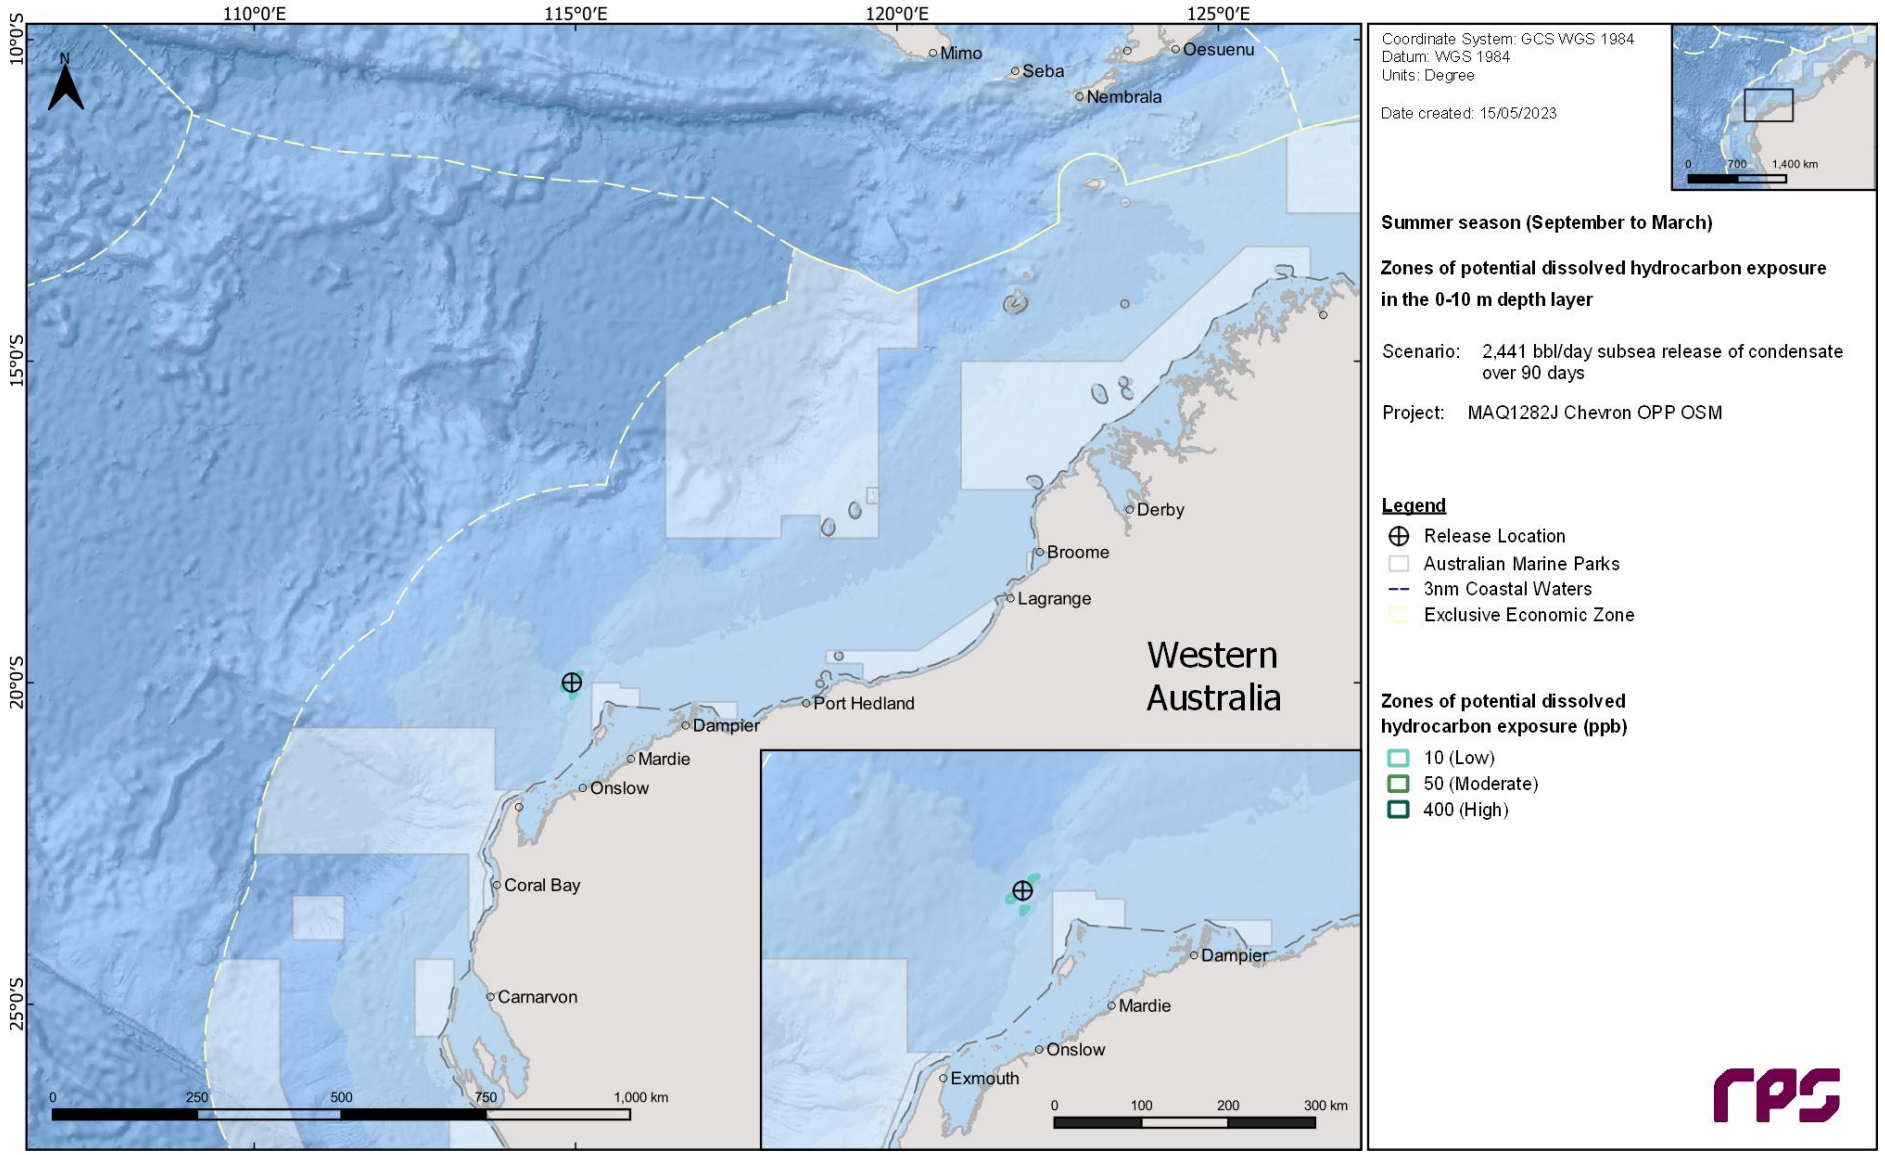

Figure 11.6 Zones of potential dissolved hydrocarbon exposure at 0-10 m during summer (September to the following March) wind and current conditions. The results were calculated from 100 spill simulations.

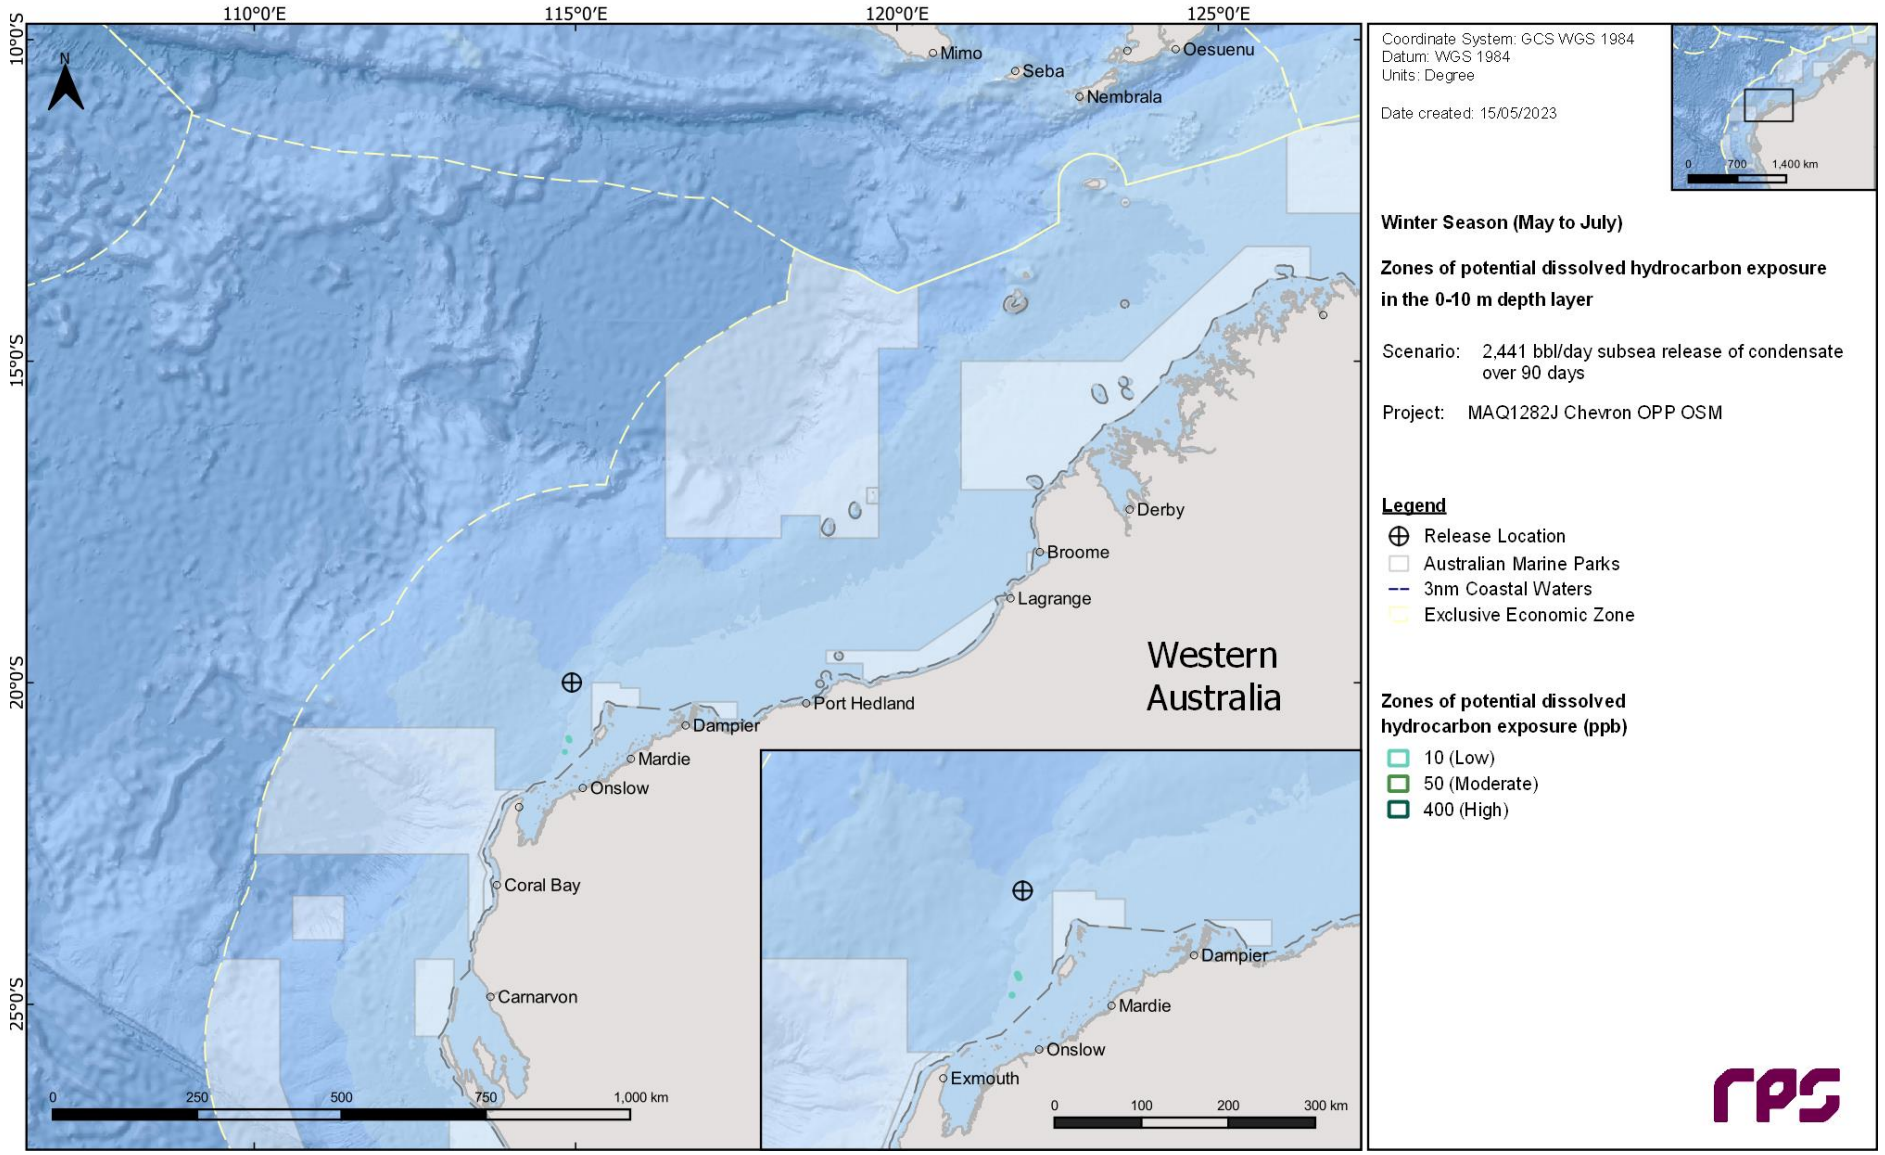

Figure 11.7 Zones of potential dissolved hydrocarbon exposure at 0-10 m following a subsea LOWC at Semele Well 5 during winter (May to July) wind and current conditions. The results were calculated from 100 spill simulations.

11.1.3.2 Entrained Hydrocarbons

Table 11.8 summarises the maximum exposure to entrained hydrocarbons and the probability for individual receptors in the 0-10 m depth layer, for each season, at the low (≥ 10 ppb) and high (≥ 100 ppb) thresholds.

A total of 34, 22 and 21 BIAs were shown to be exposed at or above the low threshold during summer, transitional and winter seasons respectively. Excluding the receptors that the release location resides within, the highest probabilities of exposure were shown for the Flatback Turtle – Internesting Buffer BIA during summer (100%), transitional (97%) and winter (90%) conditions.

Across the three seasons, 6 AMPs were predicted to be exposed at, or above the low threshold, with the highest probabilities predicted at the Gascoyne AMP (81% summer, 82% transitional and 74% winter).

A total of 6 KEFs were shown to be exposed by entrained hydrocarbons at the low threshold, including the Continental Slope Demersal Fish Communities KEF that the release site is located within. Excluding that receptor, probabilities of exposure ranged between 6–80%, 1–92% and 1–80%, for summer, transitional and winter, respectively.

Additionally, 37 IAA, were shown to be exposed to entrained hydrocarbons at low threshold.

Furthermore, 36 RSBs were shown to be exposed to entrained hydrocarbons at the low threshold.

Figure 11.8 to Figure 11.10 illustrate the extent of the predicted entrained hydrocarbon exposure for the low and high thresholds in the 0-10 m depth layer for each season.

The same maps for the 10-20 m depth layer are presented in Figure 11.11 to Figure 11.13.

Table 11.8 Predicted probability and maximum entrained hydrocarbon exposure to individual receptors in the 0-10 m depth layer following a subsea LOWC at Semele Well 5. The results were calculated from 100 spill simulations per season.

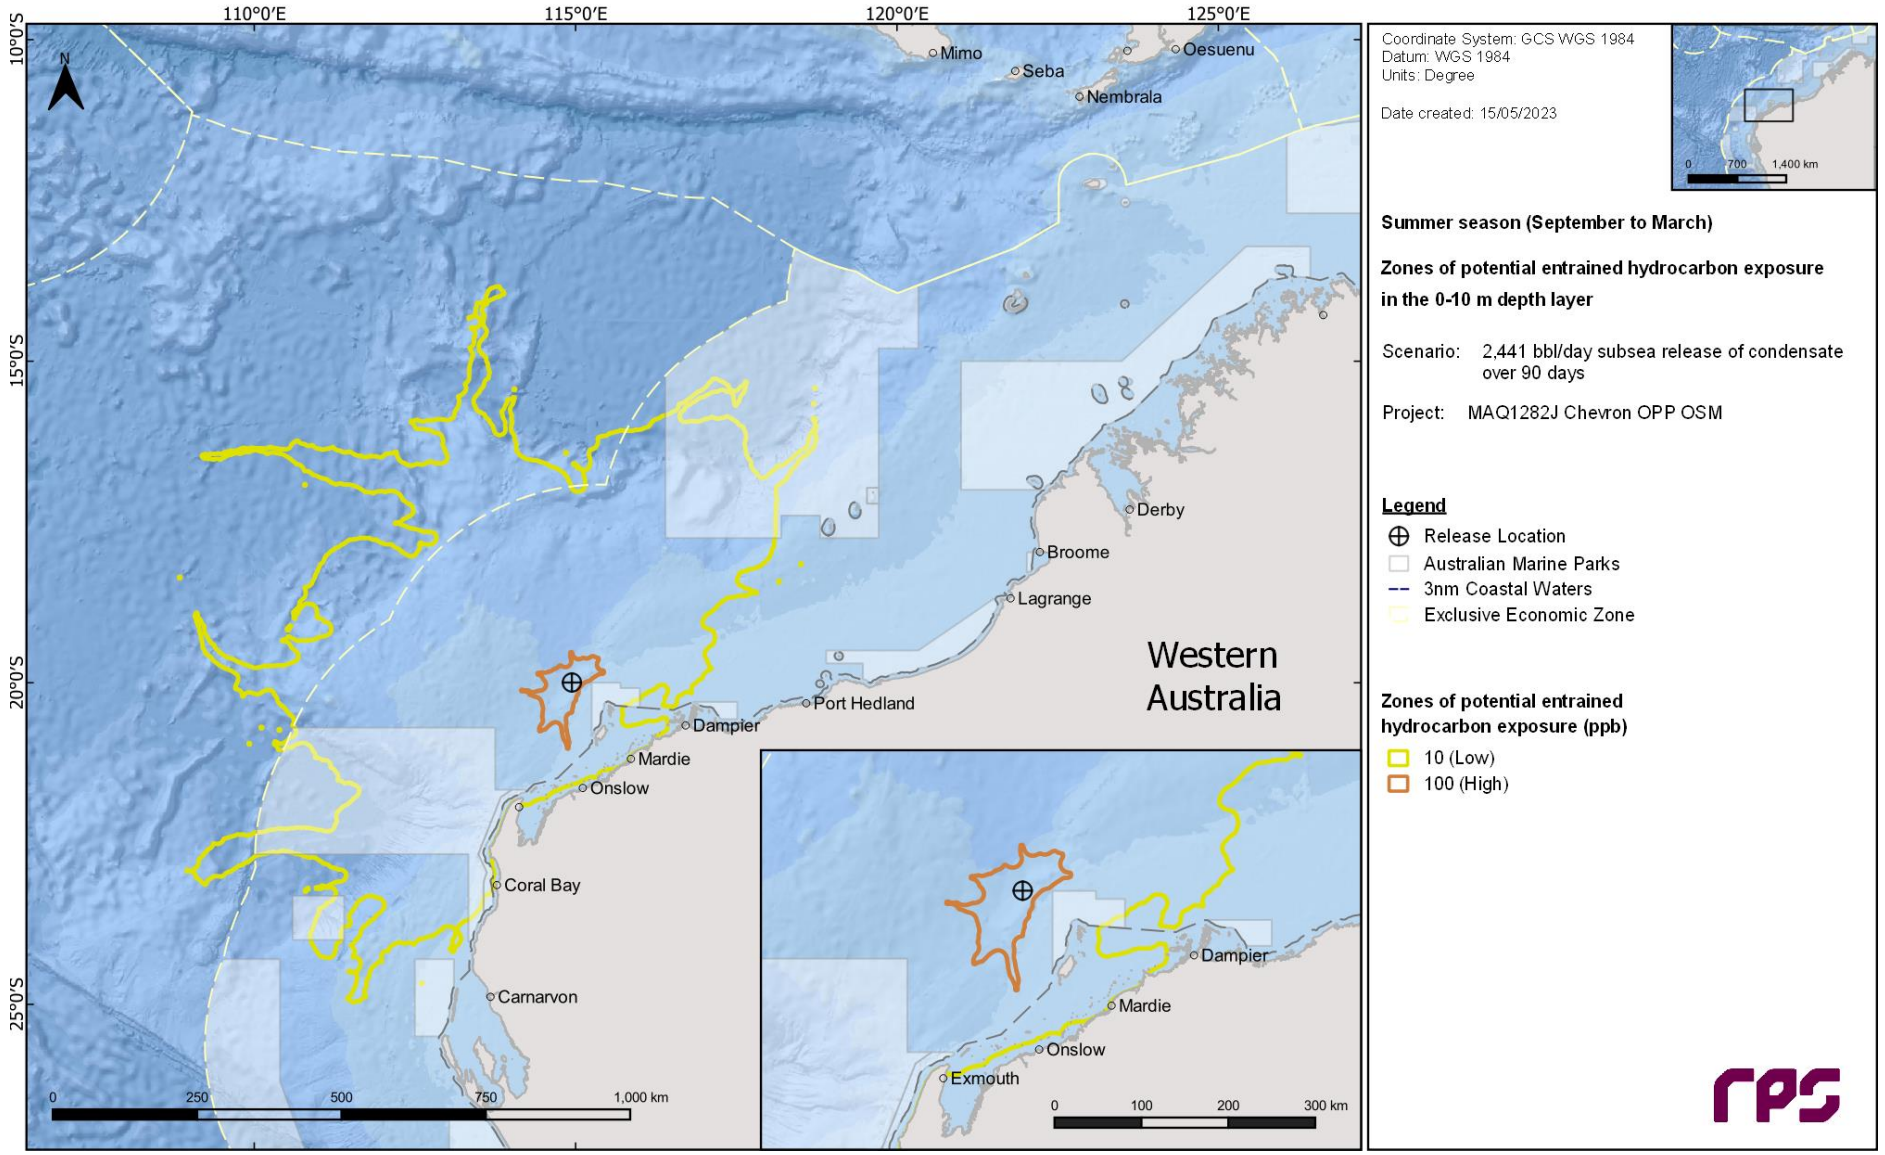

Figure 11.8 Zones of potential entrained hydrocarbon exposure at 0-10 m during summer (September to the following March) wind and current conditions. The results were calculated from 100 spill simulations.

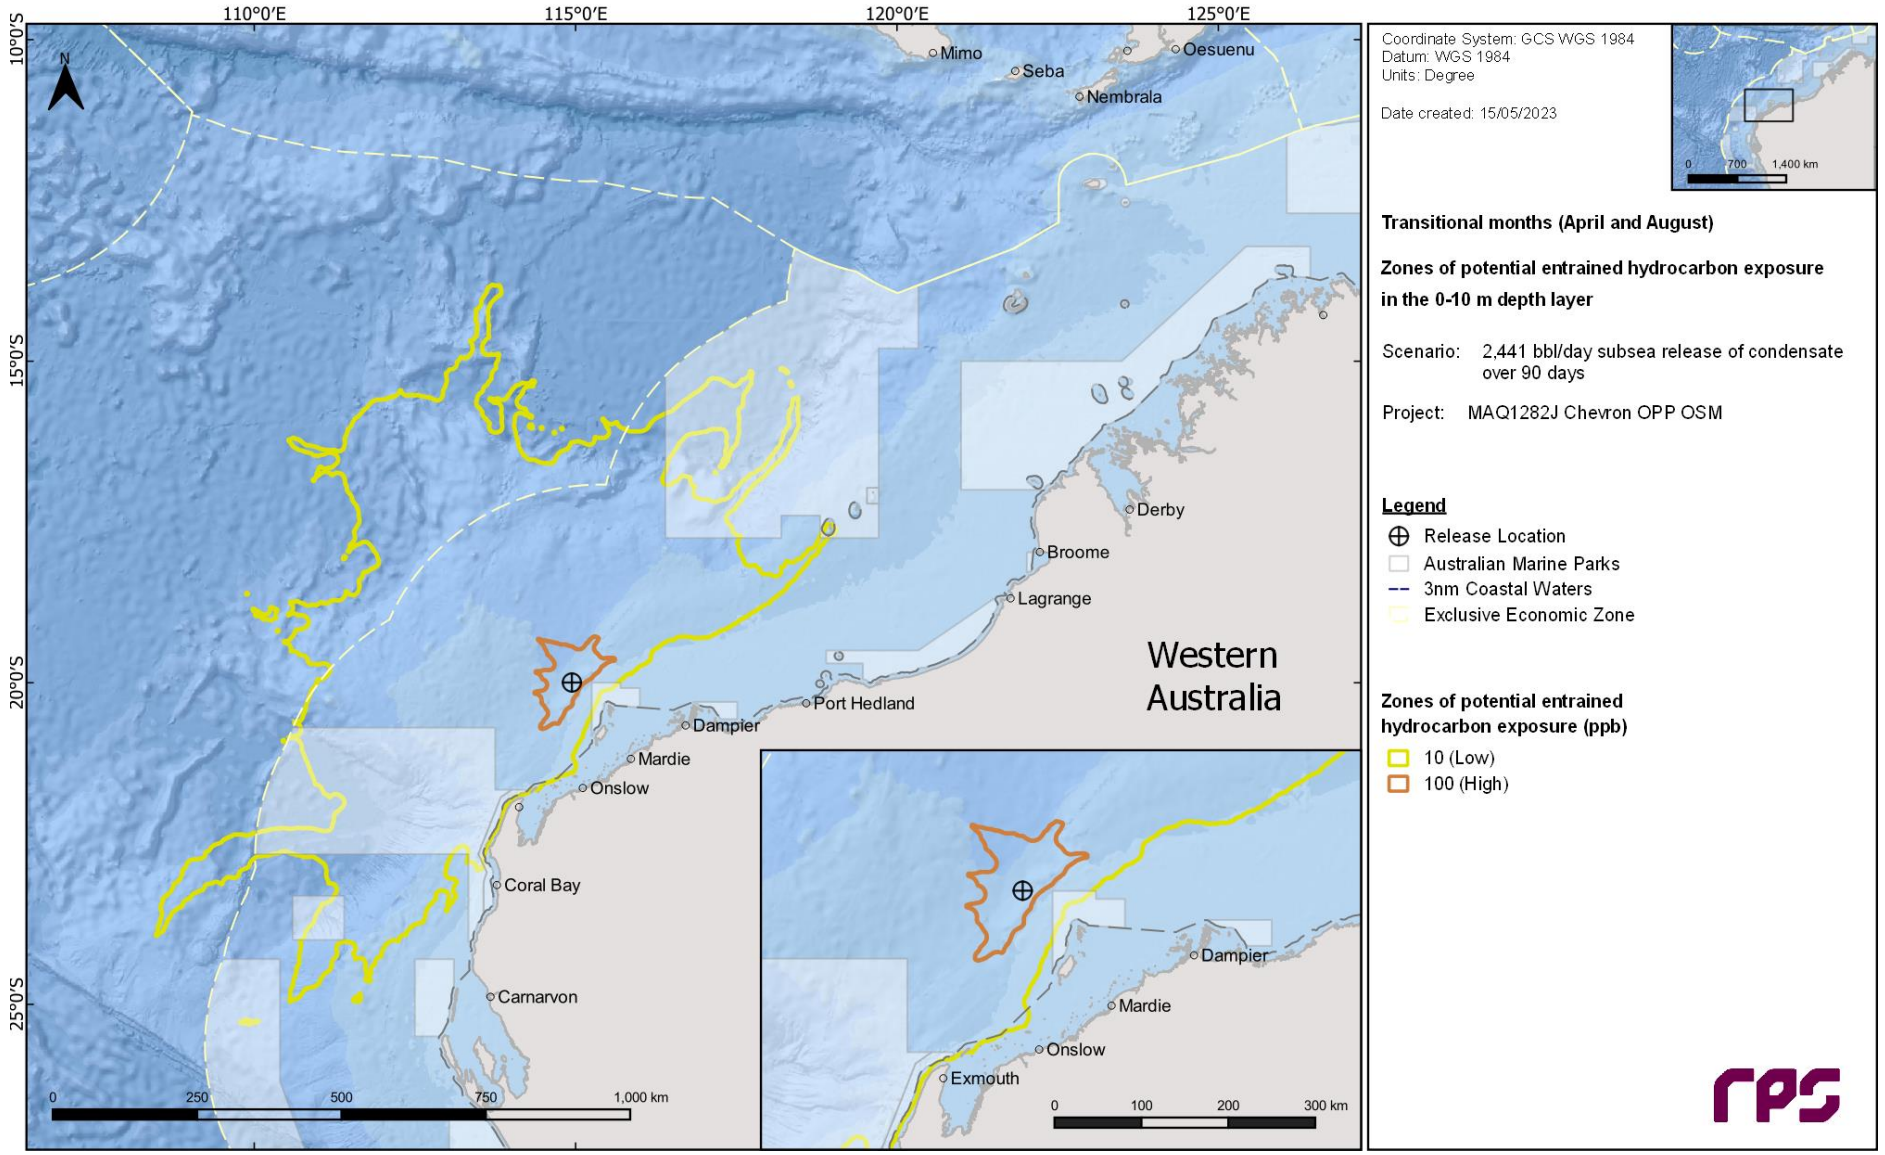

Figure 11.9 Zones of potential entrained hydrocarbon exposure at 0-10 m following a subsea LOWC at Semele Well 5 during transitional (April and August) wind and current conditions. The results were calculated from 100 spill simulations.

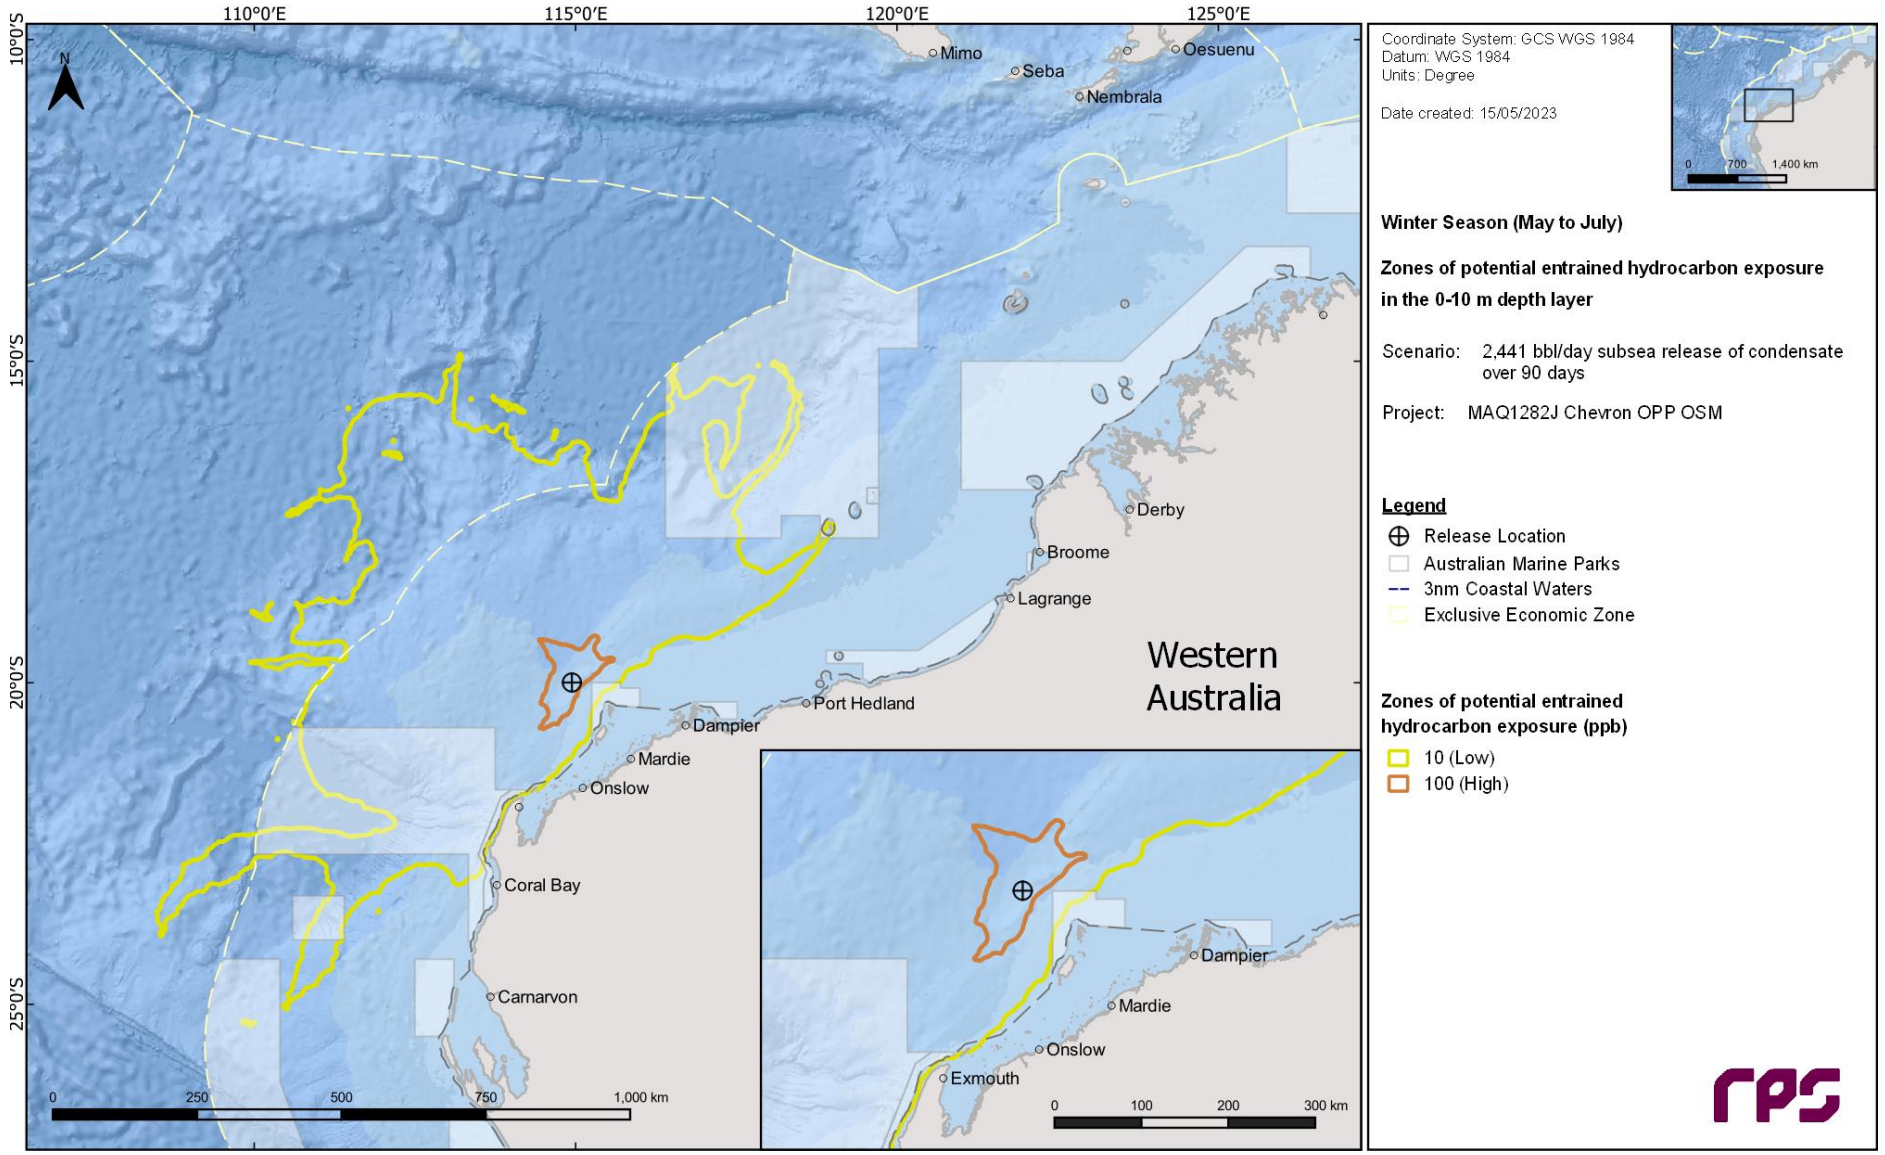

Figure 11.10 Zones of potential entrained hydrocarbon exposure at 0-10 m following a subsea LOWC at Semele Well 5 during winter (May to July) wind and current conditions. The results were calculated from 100 spill simulations.

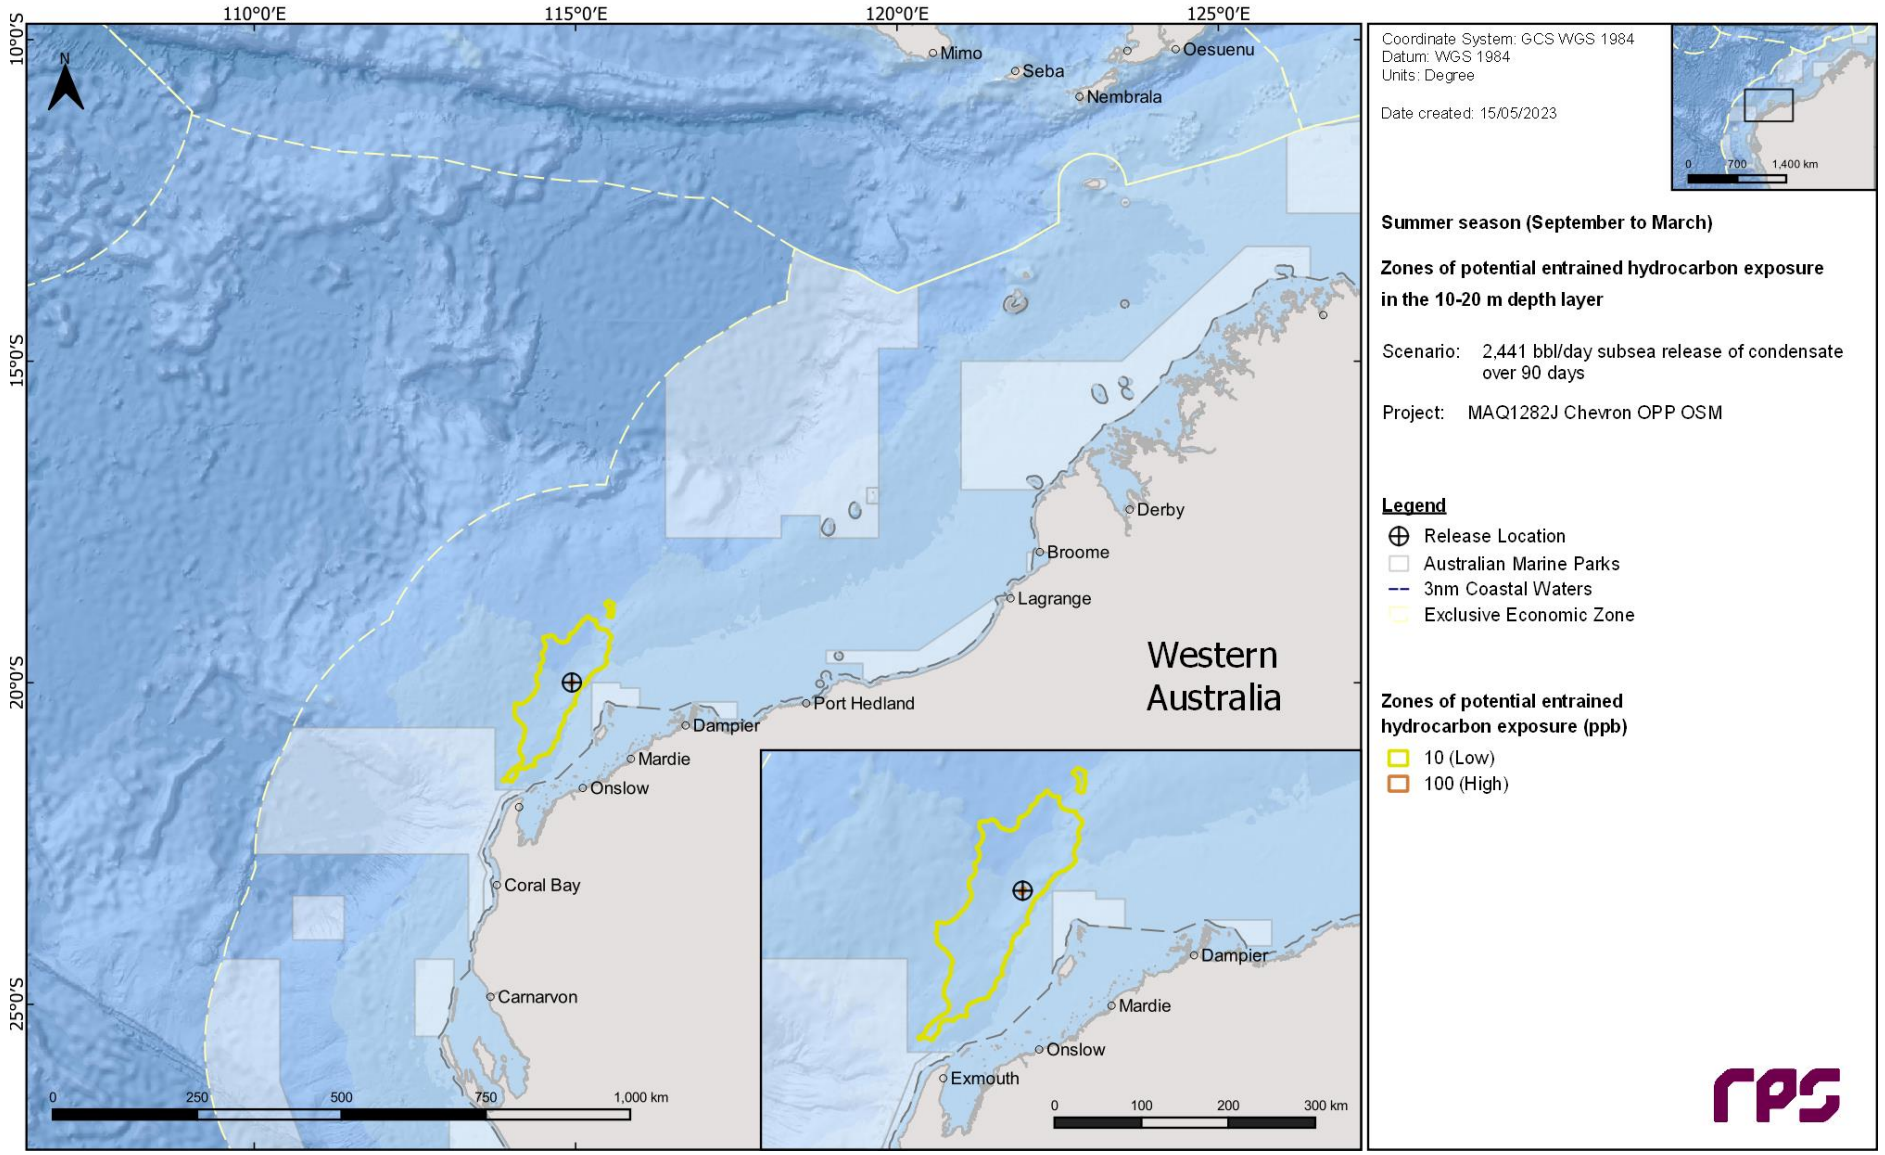

Figure 11.11 Zones of potential entrained hydrocarbon exposure at 10-20 m during summer (September to the following March) wind and current conditions. The results were calculated from 100 spill simulations.

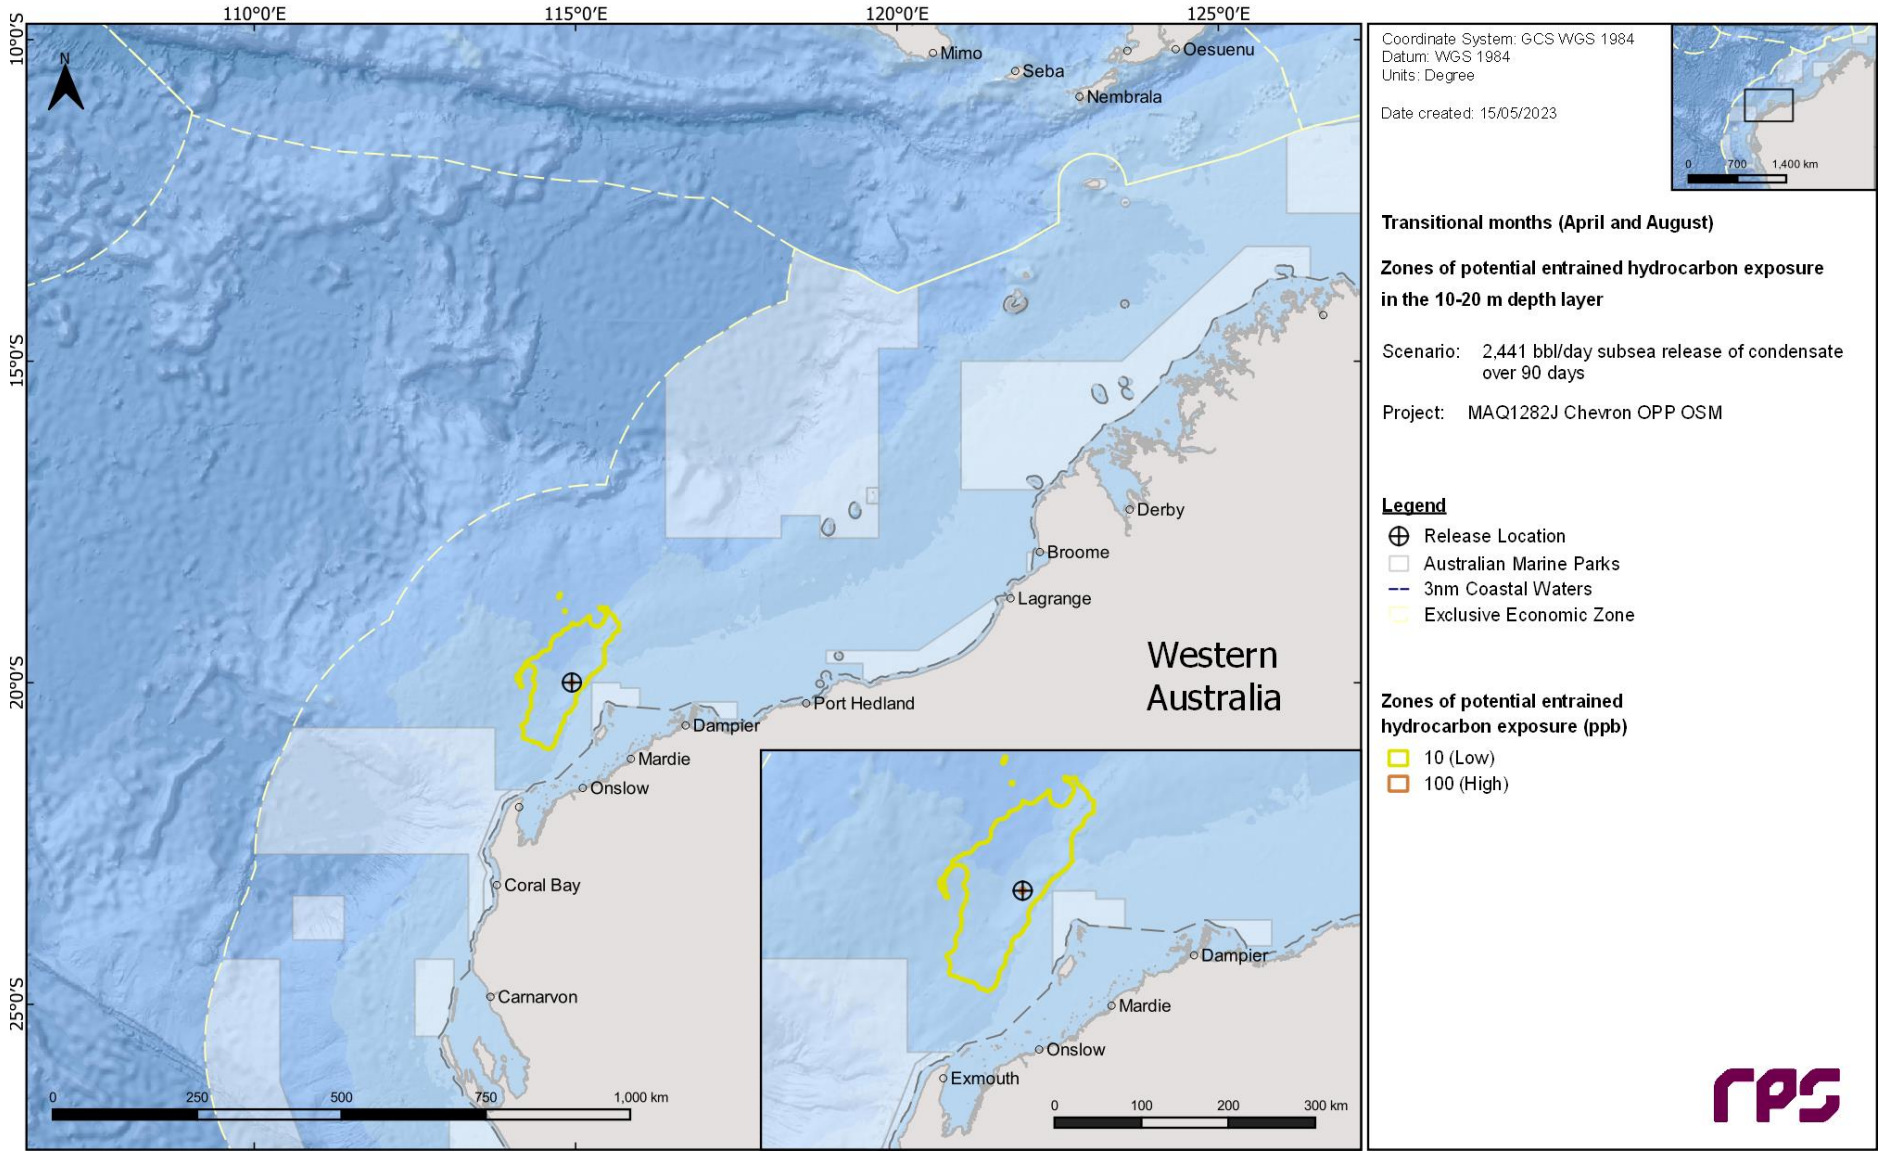

Figure 11.12 Zones of potential entrained hydrocarbon exposure at 10-20 m following a subsea LOWC at Semele Well 5 during transitional (April and August) wind and current conditions. The results were calculated from 100 spill simulations.

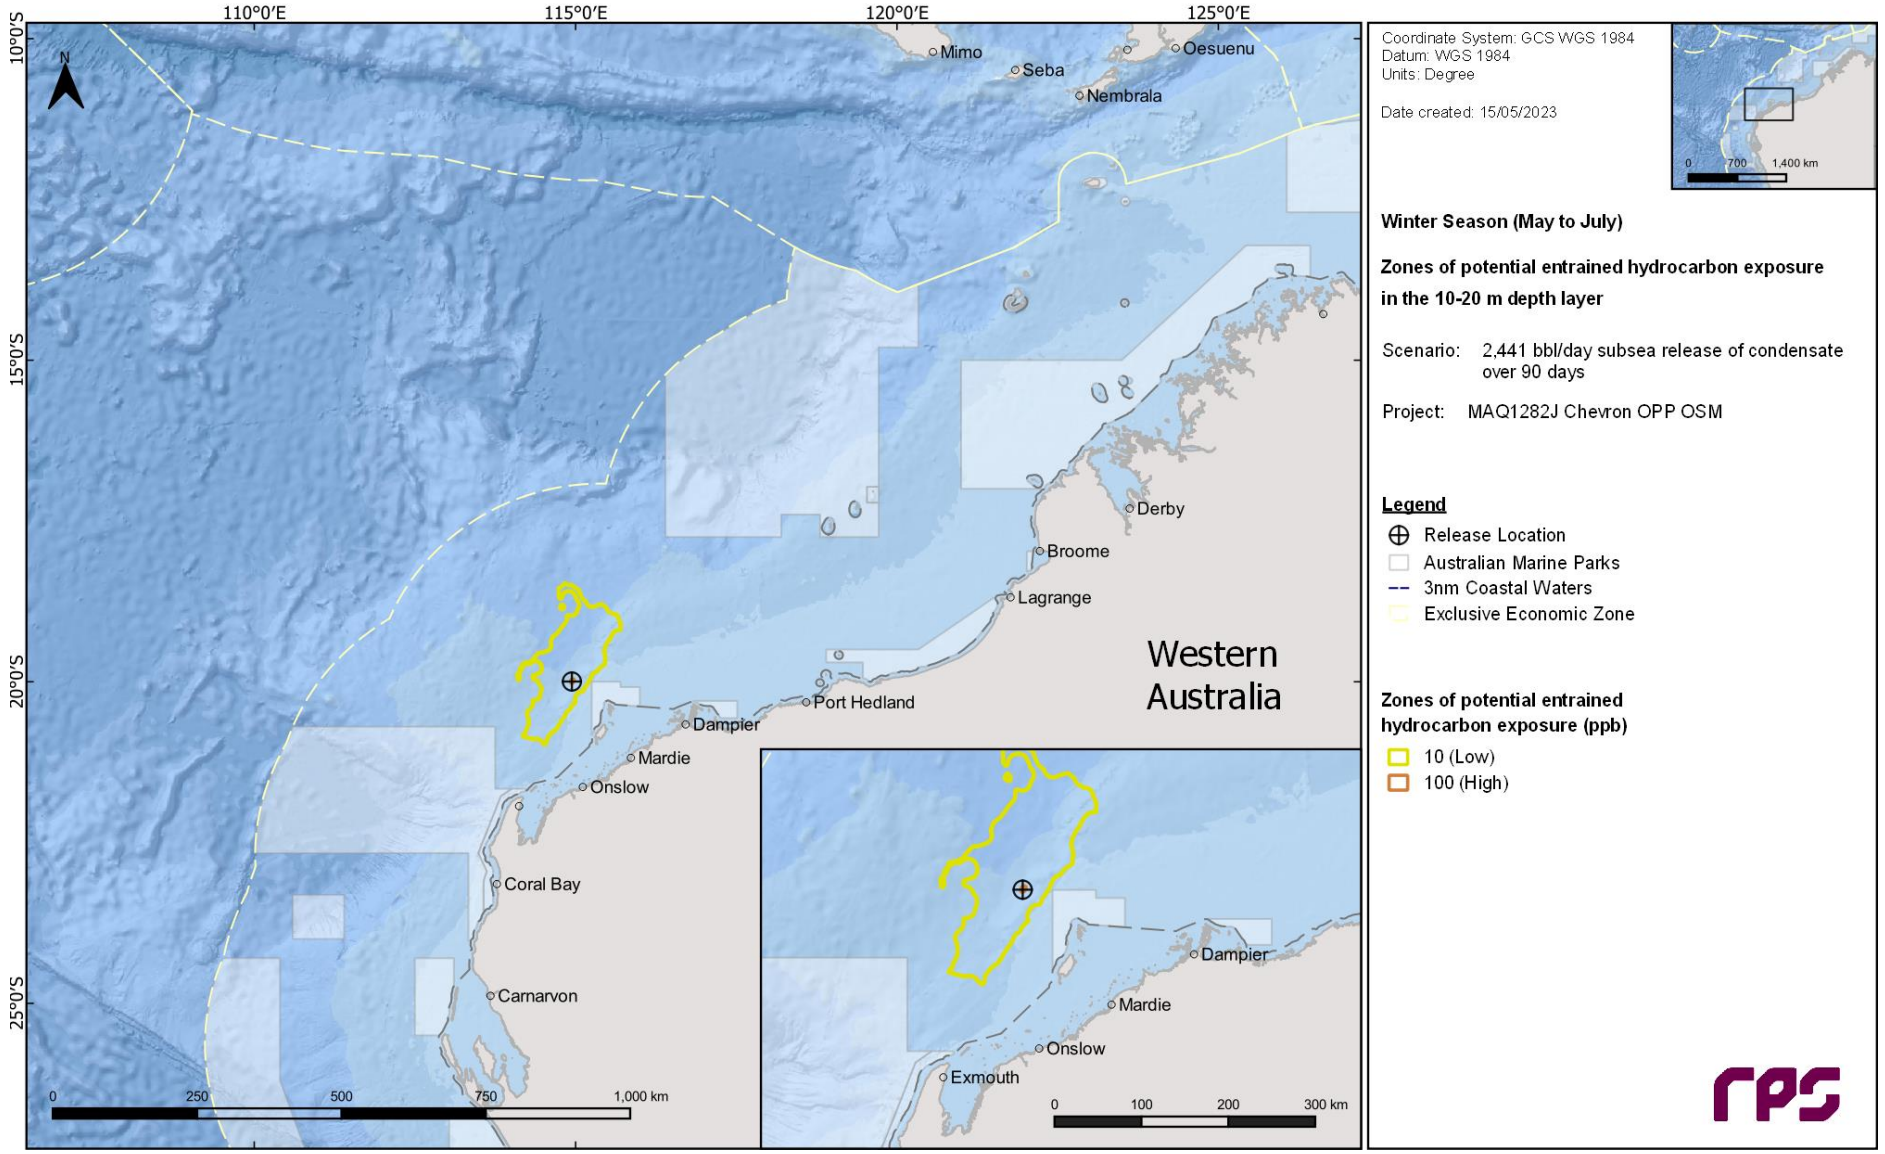

Figure 11.13 Zones of potential entrained hydrocarbon exposure at 10-20 m following a subsea LOWC at Semele Well 5 during winter (May to July) wind and current conditions. The results were calculated from 100 spill simulations.

11.2 Deterministic Analysis

The deterministic analysis presented below, are based on simulations that resulted in the largest swept area of floating condensate above 10 g/m^2 (see Section 11.2.1), and the largest volume of condensate ashore (see Section 11.2.2), the longest length of shoreline with accumulation above 100 g/m2 (see Section 11.2.3) and the largest area of entrained hydrocarbons above 100 ppb (see Section 11.2.4).

Table 11.9 presents a summary of all deterministic analysis criteria and the corresponding values at the assessed thresholds.

Note that there was no floating hydrocarbons at or above 50 g/m^2 and no dissolved hydrocarbon exposure at or above 50 ppb for any of the 300 simulations.

Interpretation of the deterministic analysis result table and timeseries plots:

The summary deterministic analysis results presented in the table below should be interpreted as **maximum values**, representing the total volume or swept area exposed by floating or in-water hydrocarbons throughout the entire simulation duration. In this particular case, the simulation showed that a maximum of 564 km^2 was exposed to floating oil above the low threshold over a period of 104 days.

However, it's important to note that the timeseries plots present **peak values** at specific points in time. For example, when considering shoreline volume, the peak value in the timeseries plot does not account for oil that may have reached the shore earlier in the simulation but was subsequently lost through evaporation or other weathering processes.

Continuing with the previous example, the timeseries plot indicates that the peak floating oil swept area above the low threshold reached 36 km^2. This value represents the highest swept area recorded at a single point in time during the simulation.

Table 11.9 Summary of the deterministic analysis following a subsea LOWC at Semele Well 5.

Variable	Threshold	Deterministic Analysis Criteria			
		Largest swept area of floating condensate above 10 g/m^2	Largest volume of condensate ashore	Longest length of shoreline with accumulation above 100 g/m^2	Largest area of entrained hydrocarbons above 100 ppb
Season		Winter	Summer	Summer	Winter
Run Number		43	18	8	48
Floating Oil (km^2)	1 g/m^2	564	489	814	598

11.2.1 Deterministic Case: Largest swept area of floating condensate above 10 g/m^2

The deterministic simulation that resulted in the largest swept area of floating condensate above 10 g/m^2 (moderate threshold) was identified as run number 43 during the winter period.

Figure 11.14 presents the extent of the predicted floating condensate exposure zones on the sea surface (swept area) and shoreline accumulation over the entire 104-day simulation.

Figure 11.15 displays the time series of the swept area of low (≥ 1 g/m^2), moderate (≥ 10 g/m^2) and high (≥ 50 g/m^2) floating condensate over the 104-day simulation.

Figure 11.16 presents the fates and weathering for the corresponding simulation and Table 11.10 summarises the peak volumes and times of occurrence for each oil phase and volumes at the end of the 104-day simulation.

Table 11.10 Summary of peak volumes and times of occurrence for each oil phase and the volumes at the conclusion of the simulation (day 104), for the simulation with the largest swept area of floating condensate above 10 g/m^2 following a subsea LOWC at Semele Well 5.

Exposure Metrics	Peak Volume	Day of Occurrence	Volume at day 104
Surface (m^3)	325	43	1
Entrained (m^3)	2,703	90	1,561
Dissolved (m^3)	61	78	2
Evaporation (m^3)	23,577	104	23,577
Decay (m^3)	9,937	104	9,937
Ashore (m^3)	0	0	0

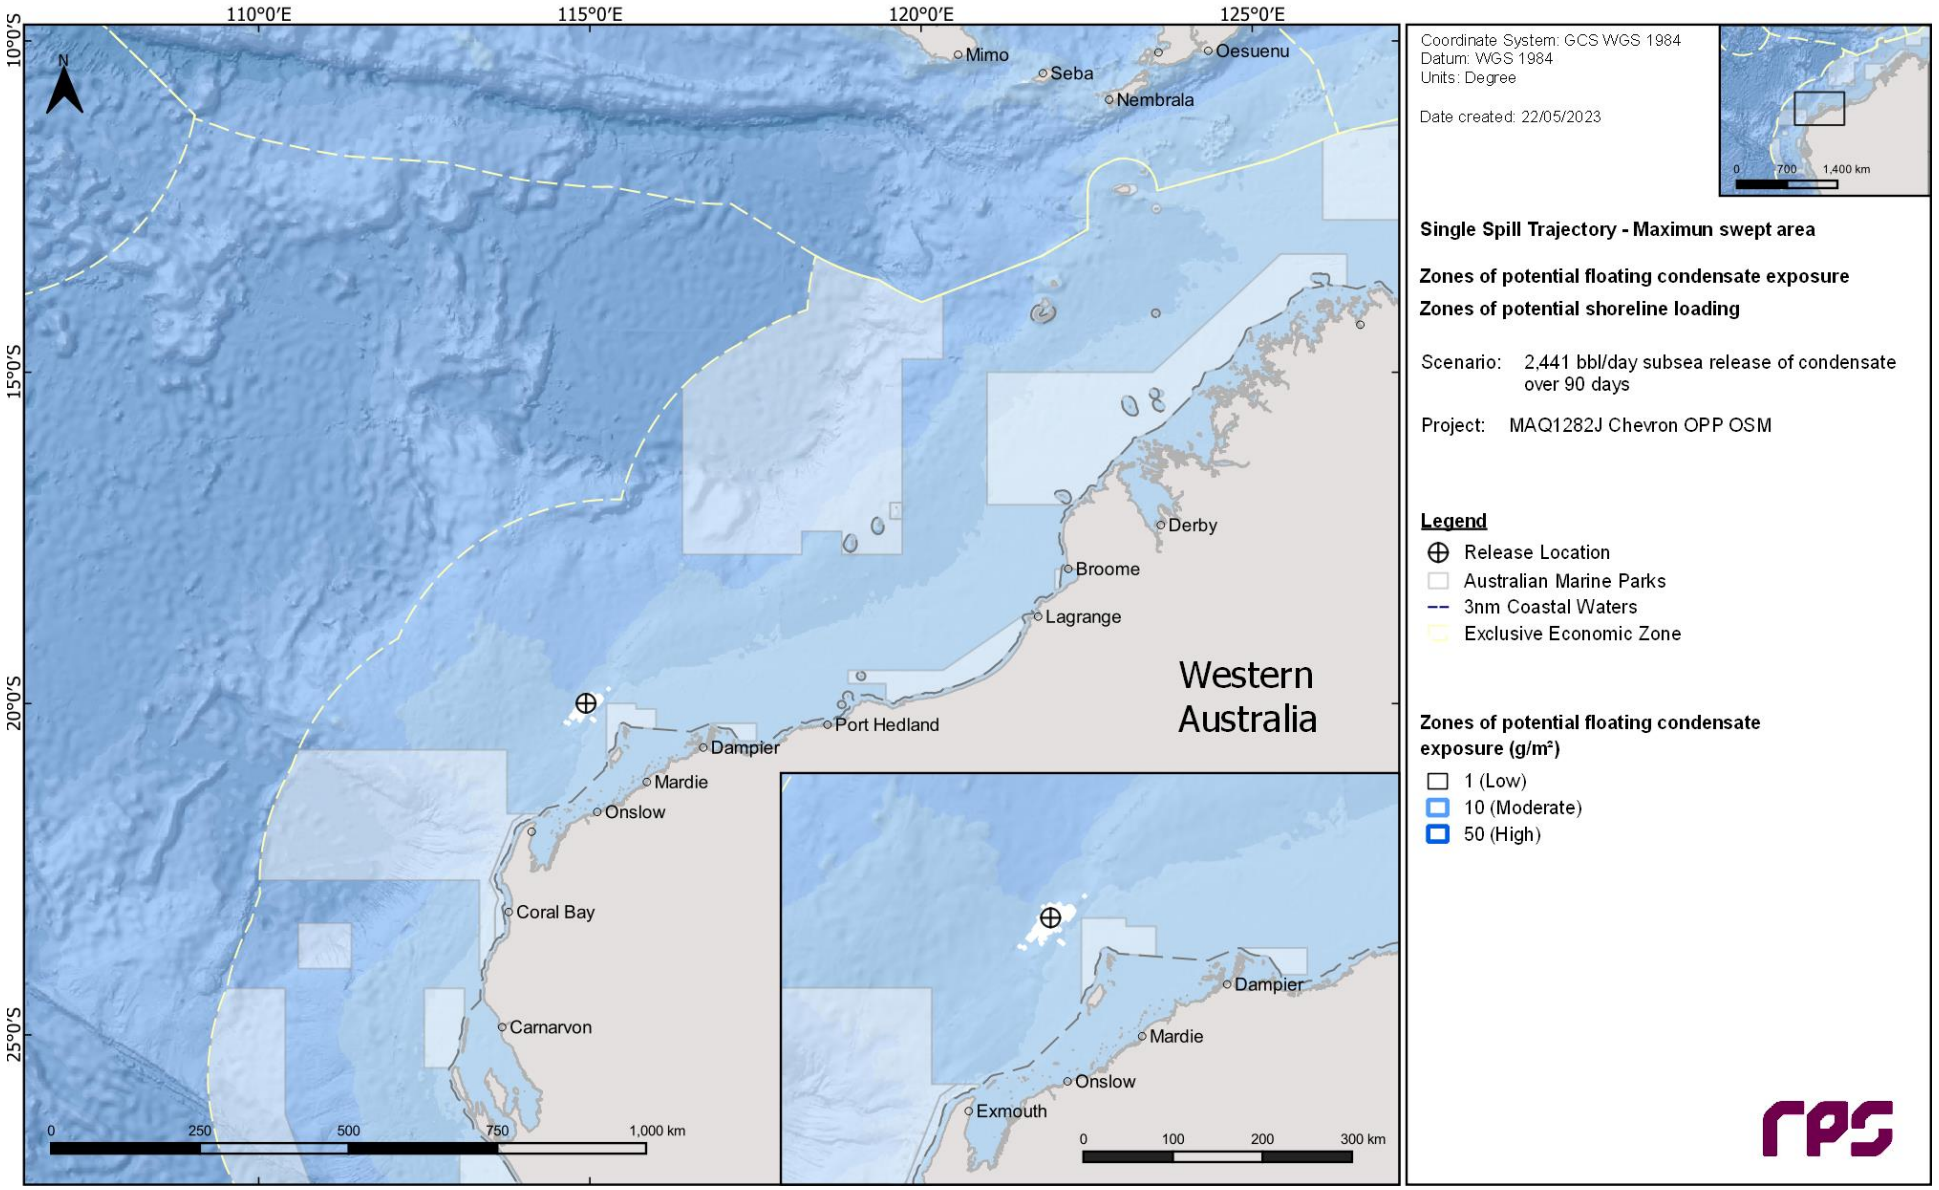

Figure 11.14 Zones of potential floating condensate exposure and shoreline accumulation over the entire 104 days, for the simulation with the largest swept area of floating condensate above 10 g/m² following a LOWC at Semele Well 5.

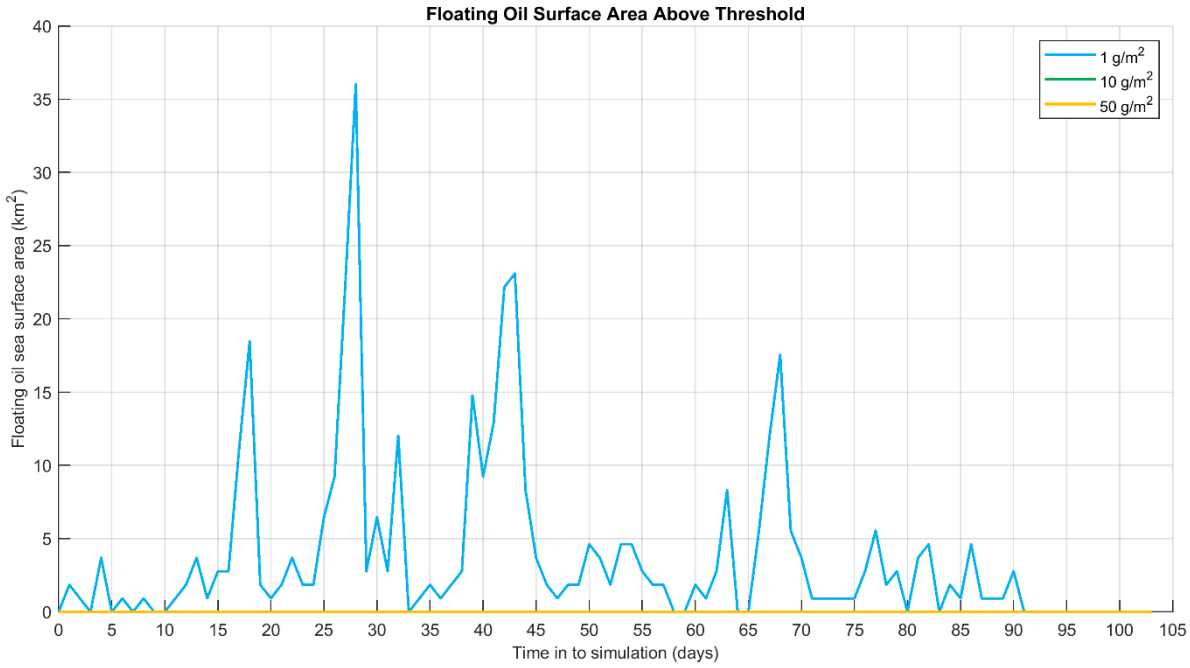

Figure 11.15 Predicted area of floating condensate exposure for each threshold, for the simulation with the largest swept area of floating condensate above 10 g/m^2 following a LOWC at Semele Well 5.

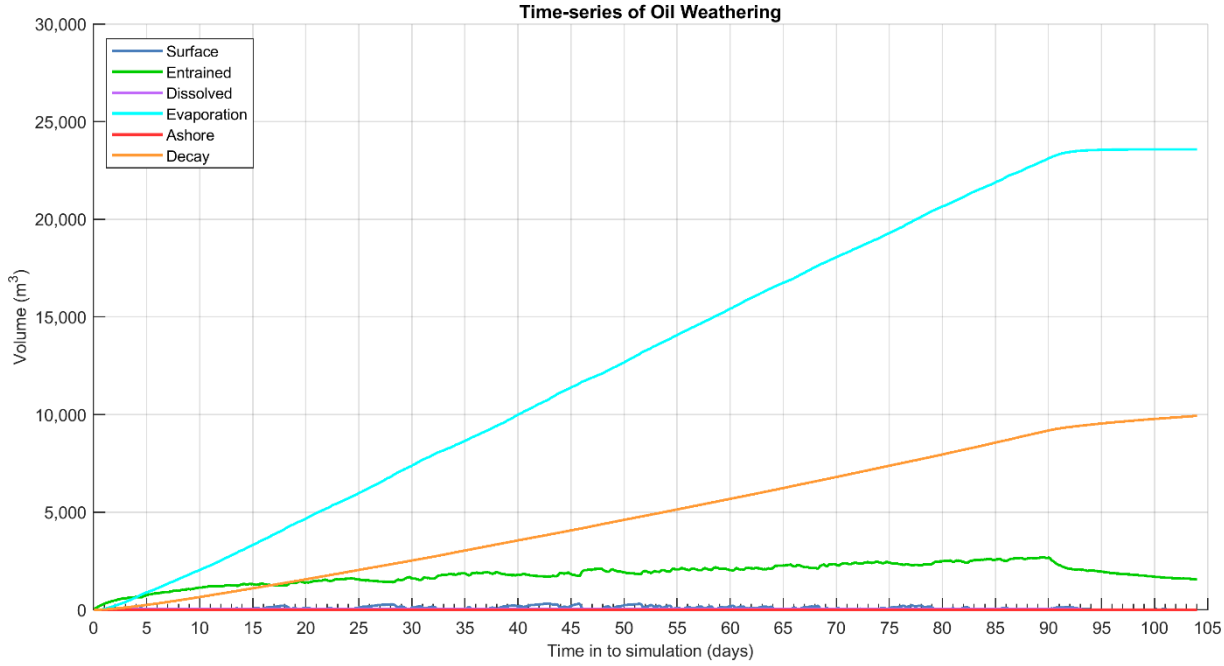

Figure 11.16 Predicted weathering and fates for the simulation with the largest swept area of floating condensate above 10 g/m^2 following a LOWC at Semele Well 5.

11.2.2 Deterministic Case: Largest volume of condensate ashore

The deterministic simulation that resulted in the largest volume of condensate ashore was identified as run number 18, during the summer season.

Figure 11.17 presents the extent of the predicted floating condensate exposure zones on the sea surface (swept area) and shoreline accumulation over the entire 104-day simulation.

Figure 11.18 displays the time series of the volume of oil accumulating on shorelines at the low (≥ 10 g/m^2), moderate (≥ 100 g/m^2) and high (≥ 1,000 g/m^2) thresholds over the 104-day simulation.

Figure 11.19 presents the fates and weathering graph for the corresponding single spill trajectory and Table 11.11 summarises the peak volumes and times of occurrence for each oil phase and volumes at the end of the 104-day simulation.

Table 11.11 Summary peak volumes and times of occurrence for each oil phase and the volumes at the conclusion of the simulation (day 104), for the simulation with the largest volume of condensate ashore following a subsea LOWC at Semele Well 5.

Exposure Metrics	Peak Volume	Day of Occurrence	Volume at day 104
Surface (m^3)	196	75	1
Entrained (m^3)	2,518	87	1,458
Dissolved (m^3)	61	52	2
Evaporation (m^3)	23,753	104	23,753
Decay (m^3)	9,826	104	9,826
Ashore (m^3)	43	103	43

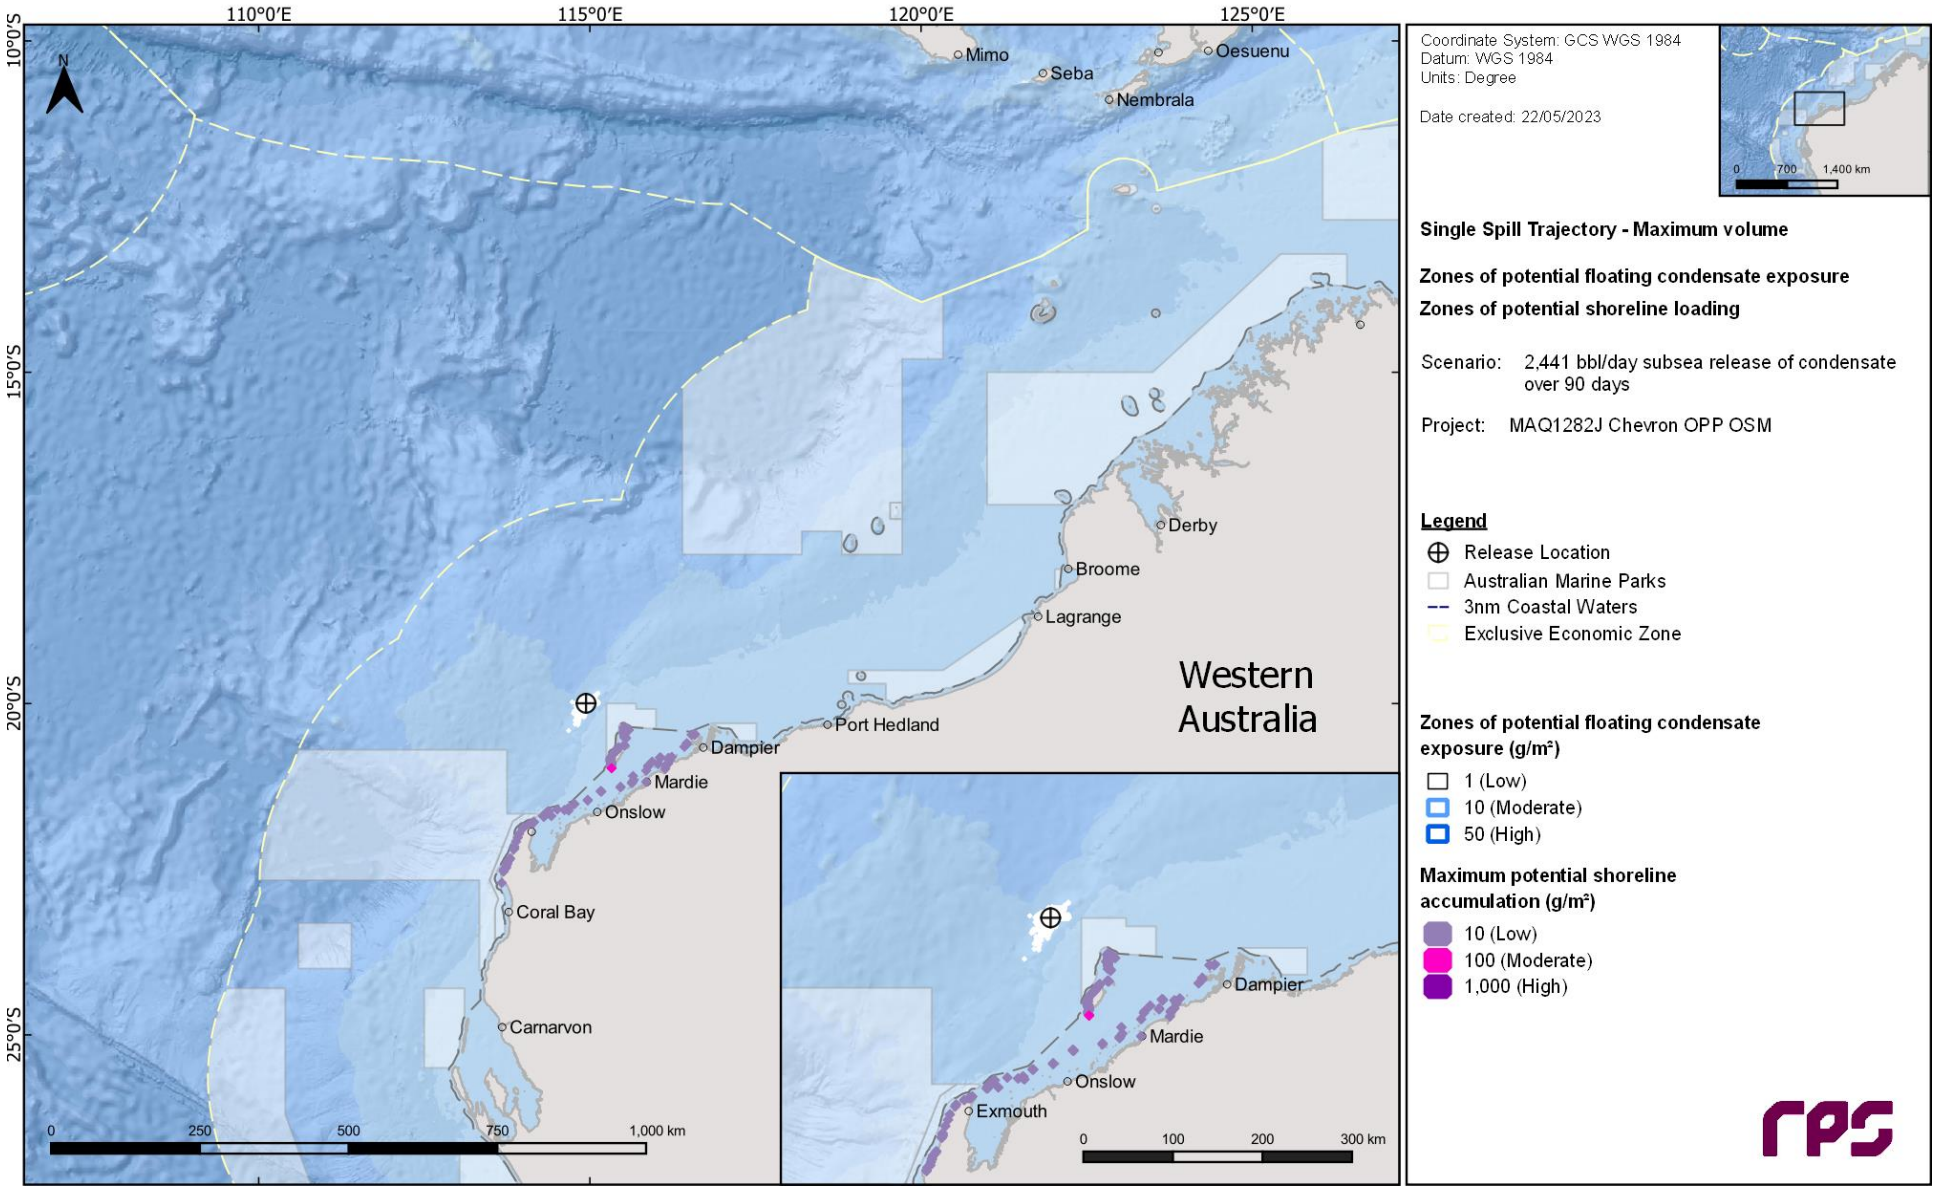

Figure 11.17 Zones of potential floating condensate exposure over the entire 104 days, for the simulation with the largest volume of condensate ashore following a LOWC at Semele Well 5.

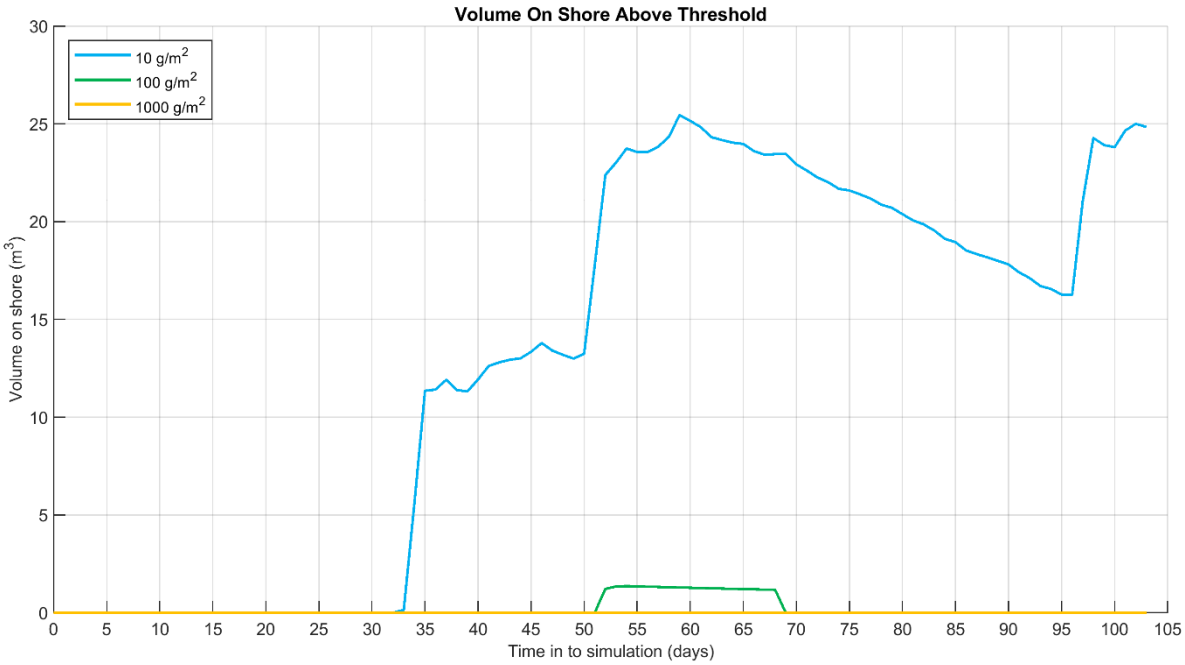

Figure 11.18 Time series of the volume of condensate ashore at each threshold for the simulation with the largest volume ashore following a LOWC at Semele Well 5.

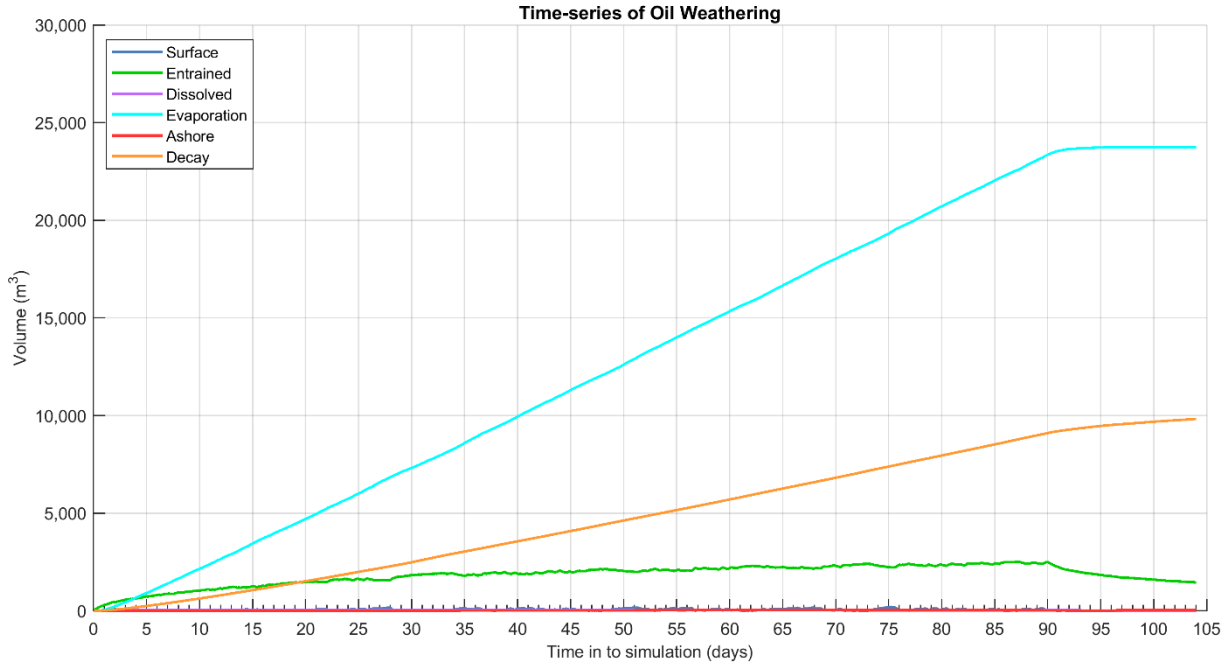

Figure 11.19 Predicted weathering and fates for the simulation with the largest volume of condensate ashore following a LOWC at Semele Well 5.

11.2.3 Deterministic Case: Longest length of shoreline with accumulation above 100 g/m^2

The deterministic simulation that resulted in the longest length of shoreline with accumulation above 100 g/m^2 (moderate threshold) was identified as run number 8 during the summer period.

Figure 11.17 presents the extent of the predicted floating condensate exposure zones on the sea surface (swept area) and shoreline accumulation over the entire 104-day simulation.

Figure 11.18 displays the time series of the length of shoreline with accumulation above the low (≥ 10 g/m^2), moderate (≥ 100 g/m^2) and high (≥ 1,000 g/m^2) thresholds over the 104-day simulation.

Figure 11.19 presents the fates and weathering graph for the corresponding single spill trajectory and Table 11.11 summarises the peak volumes and times of occurrence for each oil phase and volumes at the end of the 104-day simulation.

Table 11.12 Summary peak volumes and times of occurrence for each oil phase and the volumes at the conclusion of the simulation (day 104), for the simulation with the longest length of shoreline with accumulation above 100 g/m^2 following a subsea LOWC at Semele Well 5.

Exposure Metrics	Peak Volume	Day of Occurrence	Volume at day 104
Surface (m^3)	274	22	35
Entrained (m^3)	2,525	82	1,399
Dissolved (m^3)	61	73	2
Evaporation (m^3)	24,037	104	24,037
Decay (m^3)	9,599	104	9,599
Ashore (m^3)	19	42	10

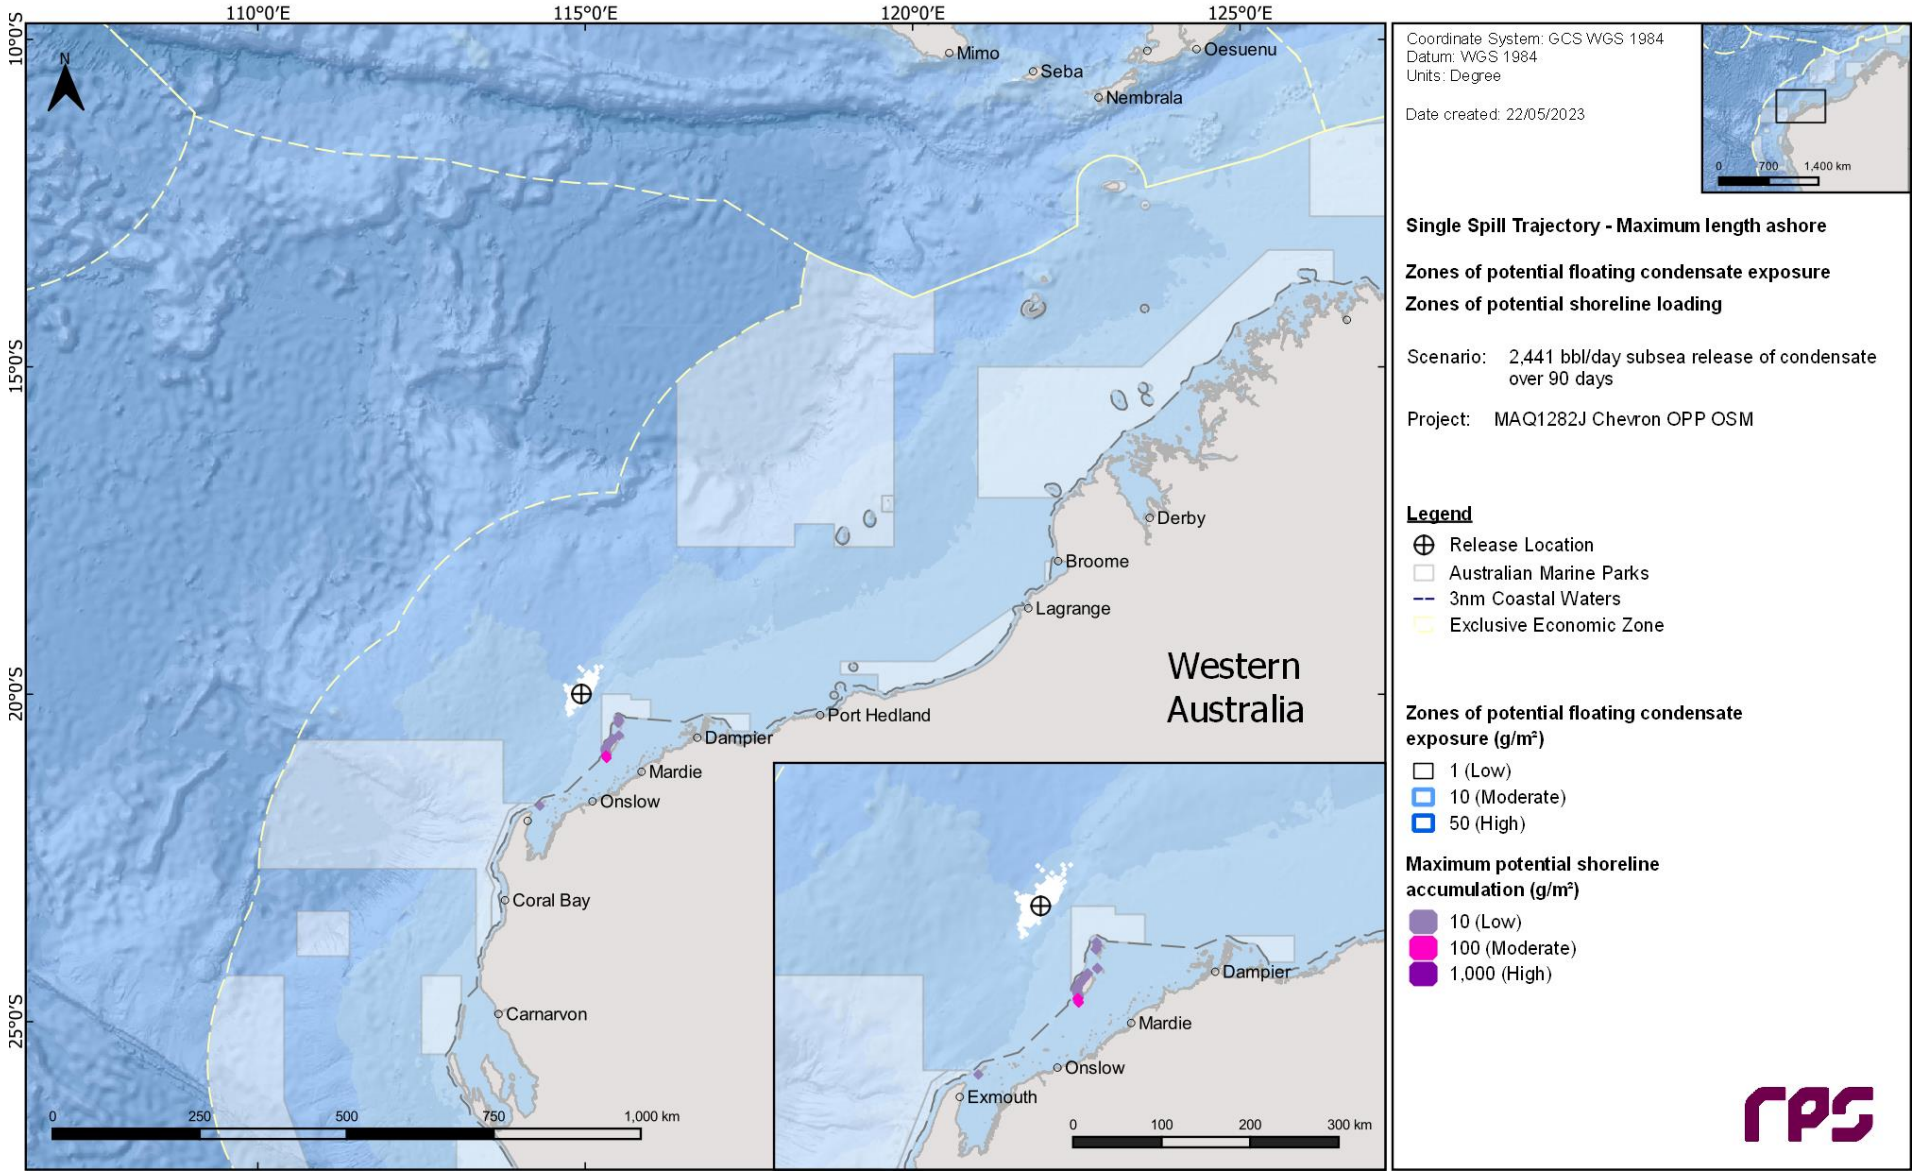

Figure 11.20 Zones of potential floating condensate exposure over the entire 104 days, for the simulation with the longest length of shoreline with accumulation above 100 g/m^2 following a LOWC at Semele Well 5.

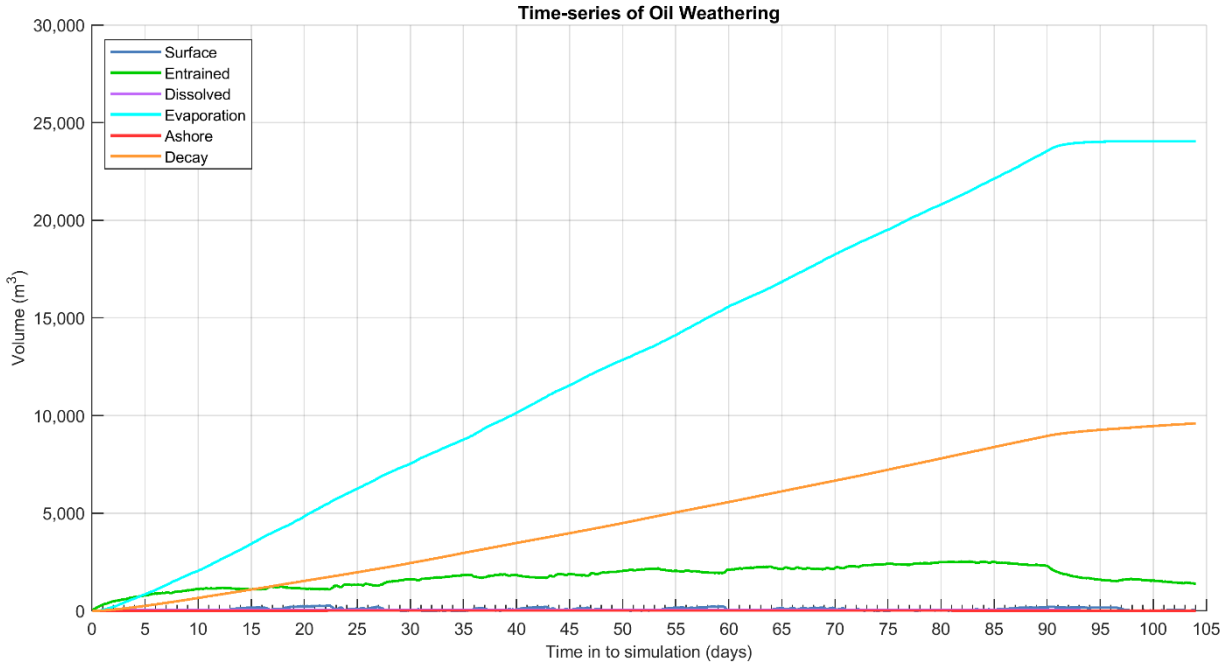

Figure 11.22 Predicted weathering and fates for the simulation with the longest length of shoreline with accumulation above 100 g/m² following a LOWC at Semele Well 5.

11.2.4 Deterministic Case: Largest area of entrained hydrocarbons above 100 ppb

The deterministic simulation that resulted in the largest area of entrained hydrocarbons above 100 ppb (high threshold) was identified as run number 48 during the winter period.

Figure 11.23 presents the extent of the predicted entrained hydrocarbon exposure zones over the entire 104-day simulation.

Figure 11.24 displays the time series of the area of entrained hydrocarbons at the low (≥10 ppb) and high (≥100 ppb) thresholds over the 104-day simulation.

Figure 11.25 presents the fates and weathering for the corresponding single spill trajectory and Table 11.13 summarises the peak volumes and times of occurrence for each oil phase and volumes at the end of the 104-day simulation.

Table 11.13 Summary of peak volumes and times of occurrence for each oil phase and the volumes at the conclusion of the simulation (day 104), for the simulation with the largest area of entrained hydrocarbons above 100 ppb following a subsea LOWC at Semele Well 5.

Exposure Metrics	Peak Volume	Day of Occurrence	Volume at day 104
Surface (m^3)	244	15	7
Entrained (m^3)	2,860	87	1,701
Dissolved (m^3)	61	37	2
Evaporation (m^3)	23,134	104	23,134
Decay (m^3)	10,246	104	10,246
Ashore (m^3)	0	43	0

°	Degrees
‘	Minutes
“	Seconds
µm	Micrometre (unit of length; 1 µm = 0.001 mm)
Actionable oil	Oil which is thick enough for the effective use of mitigation strategies

AMP	Australian Marine Park
AMSA	Australian Maritime Safety Authority
ANZECC	Australian and New Zealand Environment and Conservation Council
API	American Petroleum Institute gravity. A measure of how heavy or light a petroleum liquid is compared to water.
ARMCANZ	Agriculture and Resource Management Council of Australia and New Zealand
ASTM	American Society for Testing and Materials
bbl	Barrel (unit of volume; 1 bbl = 0.159 m3)
bbl/d	Barrels per day
Bonn Agreement	An agreement for cooperation in dealing with pollution of the North Sea by oil and other harmful substances, 1983, includes: Governments of the Kingdom of Belgium, the Kingdom of Denmark, the French Republic, the Federal Republic of Germany, the Republic of Ireland, the Kingdom of the Netherlands, the Kingdom of Norway, the Kingdom of Sweden, the United Kingdom of Great Britain and Northern Ireland and the European Union.
BP	Boiling point. The temperature at which the vapor pressure of the liquid is equal to the pressure exerted on it by the surrounding atmosphere
BTEX	Benzene, Toluene, Ethylbenzene, and Xylenes
°C	degree Celsius (unit of temperature)
CFSR	Climate Forecast System Reanalysis
cm	Centimetre (unit of length)
cP	Centipoise (unit of dynamic viscosity)
Decay	The process where oil components are changed either chemically or biologically (biodegradation) to another compound. It includes breakdown to simpler organic carbon compounds by bacteria and other organisms, photo-oxidation by solar energy, and other chemical reactions.
Dynamic viscosity	The dynamic viscosity of a fluid expresses its resistance to shearing flows, where adjacent layers move parallel to each other with different speeds.
Floating condensate exposure	Contact by floating oil on the sea surface at concentrations equal to or exceeding defined threshold concentrations. The consequence will vary depending on the threshold and the receptors
g/m^2	Grams per square meter (unit of surface area density)
GODAE	Global Ocean Data Assimilation Experiment
HYCOM	Hybrid Coordinate Ocean Model. A data-assimilative, three-dimensional ocean model
HYDROMAP	Advanced ocean/coastal tidal model used to predict tidal water levels, current speed and current direction.

IAA	Impact Assessment Area
IBRA	Interim Biogeographic Regionalisation for Australia
IMCRA	Integrated Marine and Coastal Regionalisation of Australia
ITOPF	International Tanker Owners Pollution Federation Limited
KEF	Key Ecological Feature
km	Kilometre (unit of length)
km^2	Square Kilometres (unit of area)
Knots	unit of speed (1 knot = 0.514 m/s)
LOWC	Loss of well control
m	Meter (unit of length)
m^3	Cubic meter (unit of volume)
m/s	Meter per Second (unit of speed)
MAHs	Monoaromatic Hydrocarbons
MNP	Marine National Park
MP	Marine Park
NASA	National Aeronautics and Space Administration (USA)
NCEP	National Centres for Environmental Prediction (USA)
nm	Nautical mile
NOAA	National Oceanic and Atmospheric Administration (USA)
NOPSEMA	National Offshore Petroleum Safety and Environmental Management Authority
NP	National Park
NR	Nature Reserve
PAH	Polynuclear Aromatic Hydrocarbons
Pour Point	The pour point of a liquid is the temperature below which the liquid loses its flow characteristics
ppb	Parts per billion (concentration)
psu	Practical salinity nits
RSB	Reefs, Shoals and Banks
scf	Standard cubic feet (defined as one cubic foot of gas at 15.56 °C and at normal sea level air pressure)
Shoreline contact	Arrival of oil at or near shorelines at on-water concentrations equal to or exceeding defined threshold concentrations. Shoreline contact is judged for floating oil arriving within a 2 km buffer zone from any shoreline as a conservative measure
SIMAP	Spill Impact Model Application Package. SIMAP is designed to simulate the fate and effects of spilled hydrocarbons for surface or subsea releases
Single Oil spill modelling	Oil spill modelling involving a computer simulation of a single hypothetical oil spill event subject to a single sequence of wind, current and other sea conditions over time. Single oil spill modelling, also referred to as “deterministic modelling” provides a simulation of one possible outcome of a given spill scenario, subject to the metocean conditions that are imposed. Single oil spill modelling is commonly used to consider the fate and effects of ‘worst-case’ oil spill scenarios that are carefully selected in consideration of the nature and scale of the offshore petroleum activity and the local environment (NOPSEMA, 2017). Because the outcomes of a single oil spill simulation can only represent the outcome of that scenario under one sequence of metocean conditions, worst-case conditions are often identified from stochastic modelling. It is impossible to calculate the likelihood of any outcome from a

	single oil spill simulation. Single oil spill modelling is generally used for response planning, preparedness planning and for supporting oil spill response operations in the event of an actual spill
SRTM	Shuttle Radar Topography Mission
Stochastic oil spill modelling	Stochastic oil spill modelling is created by overlaying and statistically analysing the outcomes of many single oil-spill simulations of a defined spill scenario, where each simulation was subject to a different sequence of metocean conditions, selected objectively (typically by random selection) from a long sequence of historic conditions for the study area. Analysis of this larger set of simulations provides a more accurate indication of the environment that maybe affected (EMBA) and indicates which locations are more likely to be affected (as well as other statistics). Stochastic oil spill modelling avoids biases that affect single oil spill modelling (due to the reliance on only one possible sequence of conditions). However, when interpreting stochastic modelling, which is based on a wide range of potential conditions that might happen to occur, it is essential to understand that calculations will encompass a much larger area than could be affected in any single spill event, where a more limited set of conditions will occur. Consequently, it is misleading to imply that the region derived from stochastic modelling indicate the outcomes expected from a single spill event (NOPSEMA, 2017) Stochastic modelling is generally used for risk assessment and preparedness planning by indicating locations that could be exposed and may require response or subsequent impact assessment
TOPEX/ Poseidon	A joint satellite mission between NASA and CNES to map ocean surface topography using an array of satellites equipped with detailed altimeters
USA	United States of America
US CG	United States Coast Guard
US EPA	United States Environmental Protection Agency
World Ocean Atlas	A collection of objectively analysed quality controlled physicochemical parameters (e.g. temperature, salinity, oxygen, phosphate, silicate, and nitrate) based on profile data from the World Ocean Database (NCEI, 2021) established by NOAA's National Centers for Environmental Information (NCEI)
WGS 1984	World Geodetic System 1984 (WGS84); reference coordinate system

EXECUTIVE SUMMARY

Background

Chevron Australia Pty Ltd (Chevron) is the operator of the Greater Gorgon area, which includes the Chandon field situated within the Northern Carnarvon Basin in Permit area WA-53-R, northwest of Barrow Island off the north-west coast of Western Australia.

Chevron commissioned RPS to undertake an oil spill modelling to support environmental approvals. The study assessed the seasonal risk and potential exposure to the surrounding waters and contact to the shorelines from the following hypothetical scenario:

- **Scenario:** A 5,214 stb/day (829 m^3/day) subsea release of condensate over 90 days (totalling 469,260 stb or 74,604 m^3) from a loss of well control (LOWC).

The potential risk of exposure to the surrounding waters and contact to shorelines was assessed for three distinct seasons; (i) summer (September to the following March), (ii) the transitional periods (April and August) and (iii) winter (May to July). This approach assists with identifying the environmental values and sensitivities that would be at risk of exposure on a seasonal basis.

One of the purposes for the modelling is to define the 'outer boundaries' of the environment that may be affected (EMBA) in the unlikely event of hydrocarbon release. Therefore, the modelling does not take into consideration any of the spill prevention, mitigation and response capabilities that would be implemented in response to the spill.

Methodology

The modelling study was carried out in stages. Firstly, a ten-year current dataset (2010–2019) that includes the combined influence of large-scale ocean and nearshore tidal currents was developed. Secondly, the currents, local winds and detailed hydrocarbon characteristics were used as inputs in the three-dimensional oil spill model (SIMAP) to simulate the drift, spread, weathering and fate of the spilled oil.

As spills can occur during any set of wind and current conditions, modelling was conducted using a stochastic (or probabilistic) approach, which involved running 100 spill simulations per season, with each simulation having the same spill information (spill volume, duration and composition of hydrocarbons) but randomly selected start time. This ensured that each spill trajectory was subjected to varying wind and current conditions.

Condensate Properties

Chandon condensate physical properties and boiling point distributions were provided by Chevron. The condensate has an API of 47.80, a density of 789 kg/m^3 (at 15ºC) and a viscosity value of 2.6 cP at 15 ºC. When exposed to the atmosphere at local temperatures, about 45.9% of the condensate volatile components should evaporate within the first 12 hours (BP < 180°C); a further 26.3% of the semi-volatiles should evaporate within the first 24 hours (180°C < BP < 265°C); and low volatile portion (22.4%) should evaporate over a longer period (265°C < BP < 380°C). The remaining 5.4% of the condensate would persist in the marine environment for much longer periods and be subject to relatively slow degradation. The process of evaporation will be greater than under calm sea conditions, but increased entrainment can be expected under stronger winds due to the presence of small breaking waves (whitecaps).

This condensate has a low asphaltene content (< 0.05%), which is one indicator for a very low propensity to take up water to form water-in-oil emulsion. For this condensate, the aromatic hydrocarbons contribute 2.5% and are all contained in the volatile fractions, which are highly soluble.

Key Findings

- The maximum distance from the release location to the low (≥ 1 g/m^2) and moderate (≥ 10 g/m^2) thresholds was 102.9 km south (transitional) and 5.2 km west (transitional and winter), respectively. No exposure was predicted at the high (≥ 50 g/m^2) threshold.

- Other than the receptors that the release location resides within (Offshore Area Impact Assessment Area (IAA), Pygmy Blue Whale – Distribution Biologically Important Area (BIA) and Exmouth Plateau Key Ecological Feature (KEF)), the Wedge-tailed Shearwater – Breeding BIA was the only other receptor to exposed above the low threshold, but only for the transitional season and a 1% probability.

- No shoreline accumulation at or above the low (≥ 10 g/m^2) shoreline contact threshold was recorded for any of the spill simulations.

- There was no exposure to any other receptors by dissolved hydrocarbons in the 0-10 m depth layer, other than those that the release location resides within, being Offshore Area IAA and Pygmy Blue Whale – Distribution BIA.

- In the 0-10 m depth layer, a total of 16 BIAs were shown to be exposed to entrained hydrocarbons at, or above, the low threshold (≥10 ppb) during all 3 seasons. Across the three seasons, 5 Australian Marine Parks (AMPs) were predicted to be exposed at, or above the low threshold, with the highest probabilities predicted at the Gascoyne AMP (63% summer, 65% transitional and 68% winter). Furthermore, during summer conditions the Gascoyne AMP was shown to be exposed to entrained hydrocarbons at the high threshold above 100 ppb (5%). Additionally, 5 KEFs were shown to be exposed to entrained hydrocarbons at or above the low threshold. Furthermore, the Rankin Bank was shown to be exposed to entrained hydrocarbons at the low threshold only during the summer season.

1 INTRODUCTION

Chevron Australia Pty Ltd (Chevron) is the operator of the Greater Gorgon area, which includes the Chandon field situated within the Northern Carnarvon Basin in Permit area WA-53-R, northwest of Barrow Island off the north-west coast of Western Australia.

As part of the planned development for the Chandon field, Chevron commissioned RPS to undertake a comprehensive oil spill modelling study to support environmental approvals. The modelling study assessed the seasonal risk and potential exposure to the surrounding waters and contact to the shorelines from the following hypothetical scenario:

- **Scenario:** A 5,214 stb/day (829 m^3/day) subsea release of condensate over 90 days (totalling 469,260 stb or 74,604 m^3) from a loss of well control (LOWC).

The release location used for the oil spill assessment is presented in Table 1.1 and illustrated in Figure 1.1.

The potential risk of exposure to the surrounding waters and contact to shorelines was assessed for three distinct seasons; (i) summer (September to the following March), (ii) the transitional periods (April and August) and (iii) winter (May to July). This approach assists with identifying the environmental values and sensitivities that would be at risk of exposure on a seasonal basis.

One of the purposes for the modelling is to define the 'outer boundaries' of the environment that may be affected (EMBA) in the unlikely event of hydrocarbon release. Therefore, the modelling does not take into consideration any of the spill prevention, mitigation and response capabilities that would be implemented in response to the spill.

The spill modelling was performed using an advanced three-dimensional trajectory and fates model; Spill Impact Mapping Analysis Program (SIMAP). The SIMAP model calculates the transport, spreading, entrainment and evaporation of spilled hydrocarbons over time, based on the prevailing wind and current conditions and the physical and chemical properties.

The hydrocarbon spill model, the method and analysis applied herein uses modelling algorithms which have been peer reviewed and published in international journals. Further, RPS warrants that this work meets and exceeds the American Society for Testing and Materials (ASTM) Standard F2067-13 "*Standard Practice for Development and Use of Oil Spill Models*".

2 SCOPE OF WORK

The scope of work included the following components:

1. Generate ten years (2010 to 2019 (inclusive)) of wind and current data. The three-dimensional current data includes the combined influence of ocean and tidal currents;

2. Include the wind data, current data and condensate properties characteristics into the three-dimensional oil spill model; SIMAP, to model the movement, spreading, entrainment, weathering and potential shoreline accumulation over time;

3. Run 100 simulations for each season (i.e. 300 simulations total), with each simulation having the same spill information (location, volume, duration and condensate properties) but randomly varying start times. This ensured that each spill simulation was subjected to unique wind and current conditions;

4. Combine the results from the 100 spill simulations to assess the exposure to waters and shoreline accumulation based upon the NOPSEMA thresholds; and

5. From the 300 simulations modelled, identify and present the “worst case” deterministic runs, which can be used to inform response planning based on the following criteria:
    a. Largest swept area of floating hydrocarbon above 10 g/m^2
    b. Largest swept area of floating hydrocarbon above 50 g/m^2
    c. Largest volume of oil ashore
    d. Longest length of shoreline accumulation above 100 g/m^2
    e. Largest area of entrained hydrocarbons above 100 ppb
    f. Largest area of dissolved hydrocarbons above 50 ppb

As there was no floating hydrocarbons at or above 50 g/m^2, no dissolved hydrocarbon exposure at or above 50 ppb, and no shoreline accumulation at or above any threshold, for any of the 300 simulations, the deterministic results are presented based on criteria a, and e only.

3 REGIONAL CURRENTS

The study area is located within the Northern Carnarvon Basin, on the North West Shelf, a waterbody bordered by the Indian Ocean and Timor Sea. The North West Shelf is characterised by complex geomorphological features such as shoals, valleys and terraces and is dominated by high-amplitude tides and seasonally-dependant wind driven currents (DEWHA, 2007).

Although the Indonesian Throughflow and Holloway current generate south-westerly flows all year-round, warm and less saline waters originating from the tropics can generate internal gyres that typically migrate through the area and result in large variation in the speed and direction of local currents. The Holloway current generally intensifies during April to July due to increased wind forcing.

A comprehensive description of the circulation patterns of the North West Shelf is provided in a review by Condie and Andrewartha (2008) and a schematic of the ocean currents along the Northwest Australian continental shelf is shown in Figure 3.1.

While, tidal currents are generally weaker in the deeper waters, its influence is greatest along the near shore and around islands. Therefore, to accurately account for the movement of an oil spill, which can move between the offshore and near shore region, ocean and tidal currents were combined as part of the study.

Figure 3.2 and Figure 3.3 present summer and winter current trends within the Carnarvon Basin and the North West Shelf.

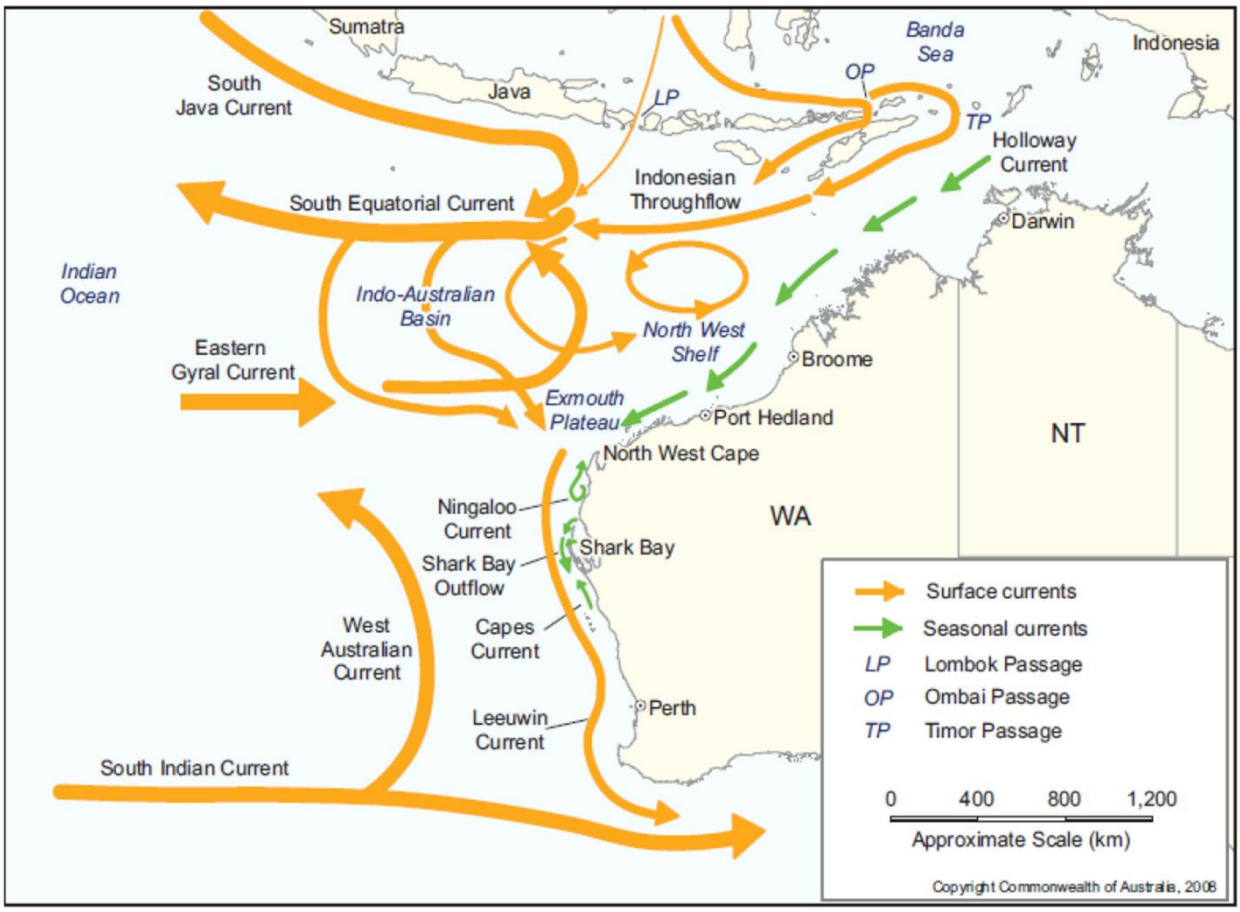

Figure 3.1 Schematic of ocean currents along the northwest Australian continental shelf. Image adapted from DEWHA (2008).

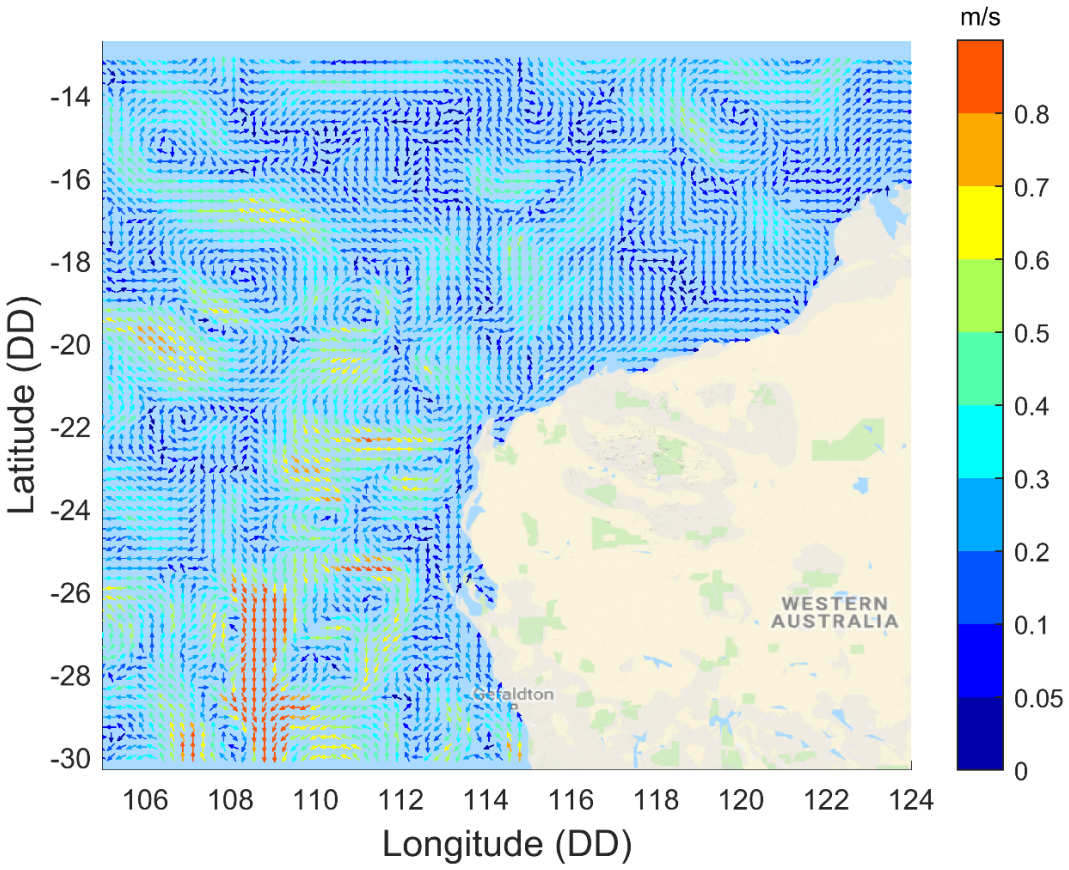

Figure 3.2 Typical ocean current circulation pattern during the summer months.

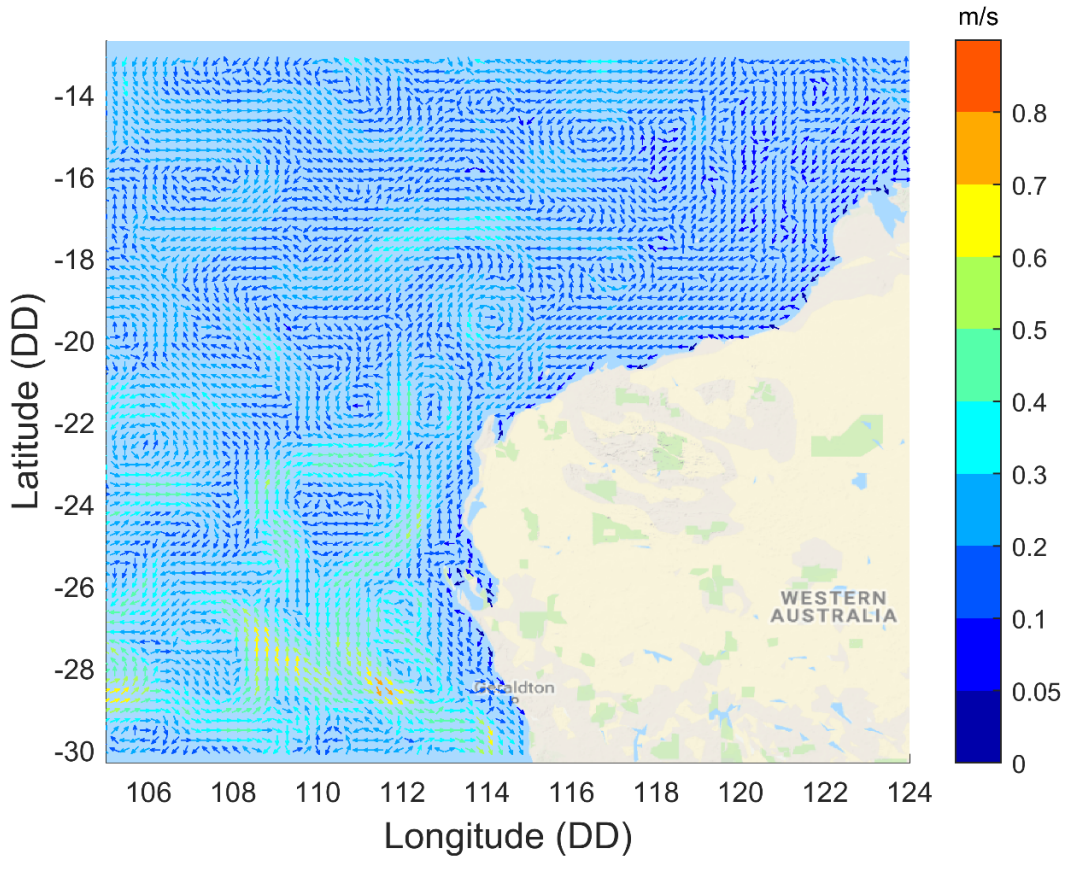

Figure 3.3 Typical ocean current circulation pattern during the winter months.

3.1 Tidal Currents

Tidal current data was generated using RPS's advanced ocean/coastal model, HYDROMAP. The HYDROMAP model has been thoroughly tested and verified through field measurements throughout the world over the past 38 years (Isaji & Spaulding, 1984; Isaji, et al., 2001; Zigic, et al., 2003). HYDROMAP tidal current data has been used as input to forecast (in the future) and hindcast (in the past) pollutant spills in Australian waters and forms part of the Australian National Oil Spill Emergency Response System operated by AMSA (Australian Maritime Safety Authority).

HYDROMAP employs a sophisticated sub-gridding strategy, which supports up to six levels of spatial resolution, halving the grid cell size as each level of resolution is employed. The sub-gridding allows for higher resolution of currents within areas of greater bathymetric and coastline complexity, and/or of particular interest to a study.

The numerical solution methodology follows that of Davies (1977a and 1977b) with further developments for model efficiency by Owen (1980) and Gordon (1982). A more detailed presentation of the model can be found in Isaji and Spaulding (1984) and Isaji et al. (2001).

3.1.1 Grid Setup

The tidal model domain has been sub-gridded to a resolution of 500 m for shallow and coastal regions, starting from an offshore (or deep water) resolution of 8 km. The finer grids were allocated in a step-wise fashion to resolve flows more accurately along the coastline, around islands and over regions with more complex bathymetry. Figure 3.4 shows the tidal model grid resolutions.

A combination of datasets was used and merged to describe the shape of the seabed within the grid domain (Figure 3.5). These included spot depths and contours which were digitised from nautical charts released by the hydrographic offices as well as Geoscience Australia database and depths extracted from the Shuttle Radar Topography Mission (SRTM30_PLUS) Plus dataset (see Becker et al., 2009).

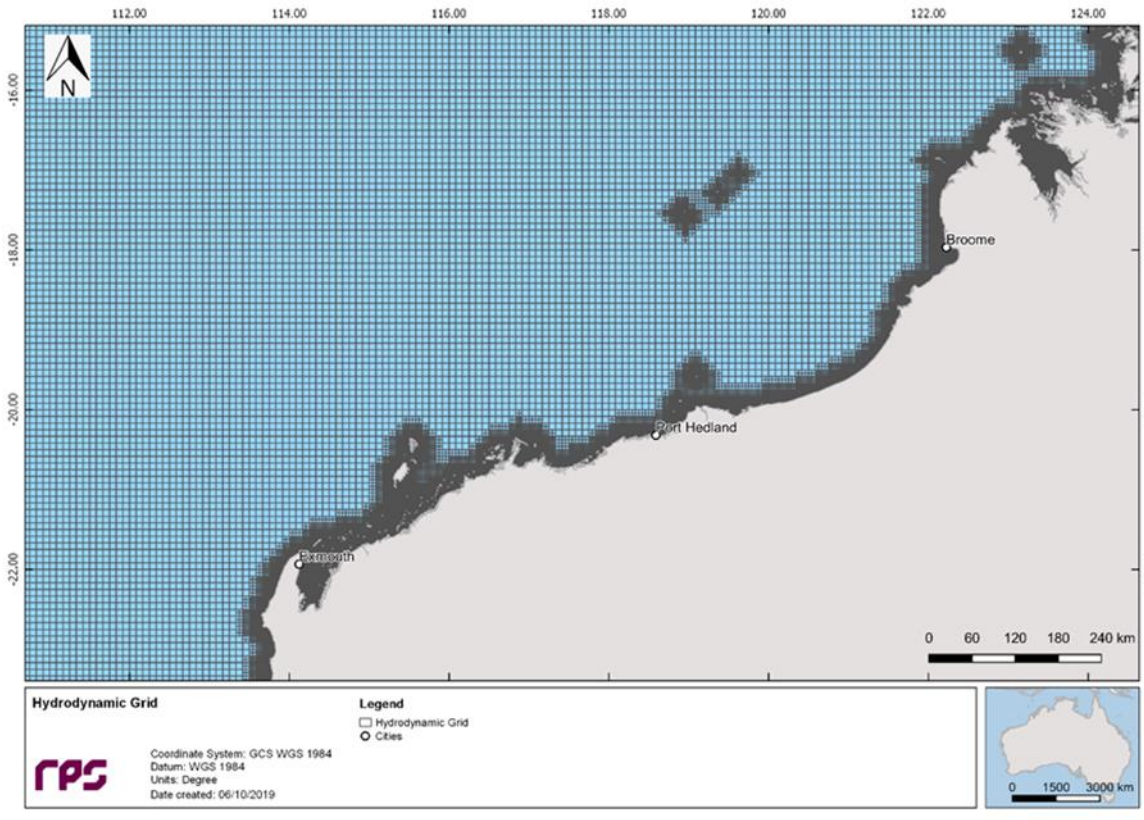

Figure 3.4 Zoomed in view of the model grid used to generate the tidal currents for the study region. Higher resolution areas are shown by the denser mesh.

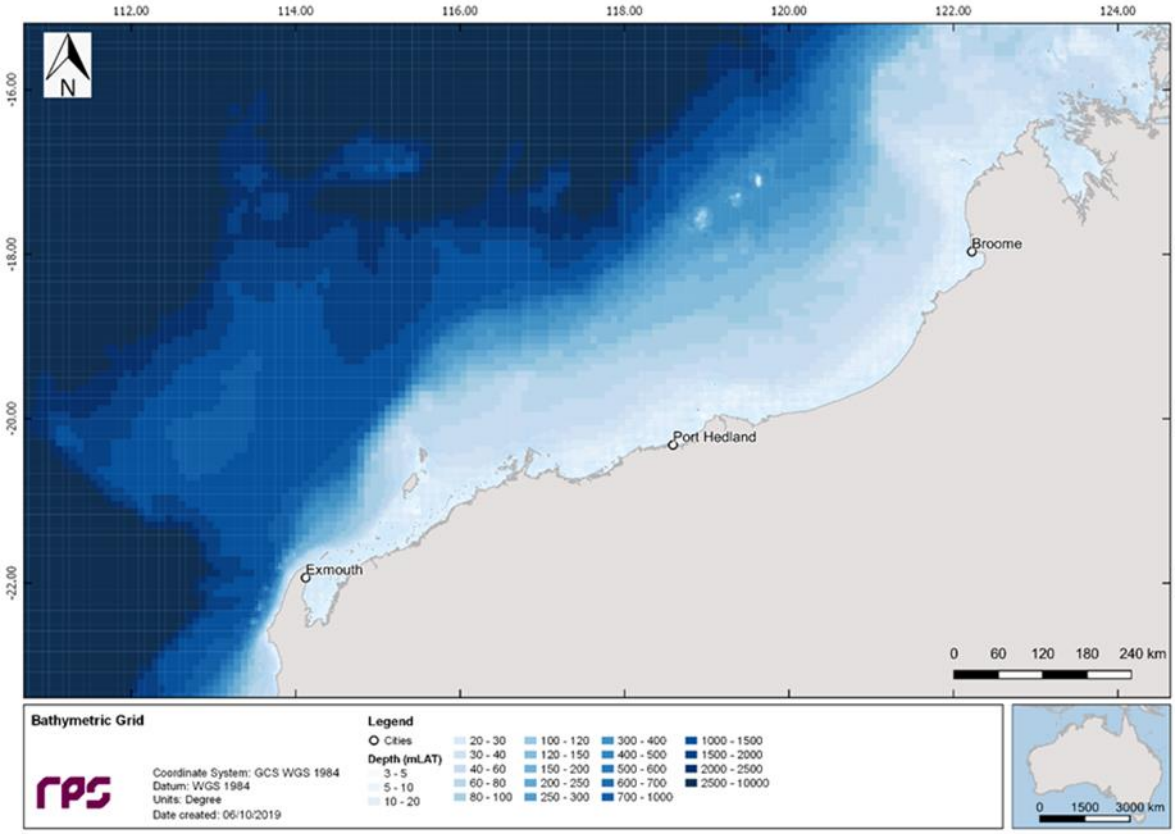

Figure 3.5 Bathymetry defined throughout the tidal model domain.

3.1.2 Tidal Conditions

The ocean boundary data for the regional model was obtained from satellite measured altimetry data (TOPEX/Poseidon 7.2) which provided estimates of the eight dominant tidal constituents at a horizontal scale of approximately 0.25 degrees. The eight major tidal constituents used were K_2, S_2, M_2, N_2, K_1, P_1, O_1 and Q_1. Using the tidal data, surface heights were firstly calculated along the open boundaries, at each time step in the model.

The TOPEX/Poseidon satellite data has a global resolution of 0.25 degrees and is produced and quality controlled by NASA (National Aeronautics and Space Administration). The satellites equipped with two highly accurate altimeters and capable of taking sea level measurements with an accuracy of ± 5 cm measured oceanic surface elevations (and the resultant tides) for over 13 years (1992–2005). In total, these satellites carried out 62,000 orbits of the planet.

The TOPEX/Poseidon tidal data has been widely used amongst the oceanographic community, being included in more than 2,100 research publications (e.g. Andersen, 1995; Ludicone et al., 1998; Matsumoto et al., 2000; Kostianoy et al., 2003; Yaremchuk and Tangdong, 2004; Qiu and Chen 2010). As such the TOPEX/Poseidon tidal data is considered suitably accurate for this study.

3.2 Ocean Currents

Data describing the flow of ocean currents was obtained from HYCOM (Hybrid Coordinate Ocean Model, (Chassignet et al., 2007), which is operated by the HYCOM Consortium, sponsored by the National Ocean Partnership Program (NOPP), as part of the U.S. Global Ocean Data Assimilation Experiment (GODAE). HYCOM is a data-assimilative, three-dimensional ocean model that is run as a hindcast (for a past period), assimilating time-varying observations of sea surface height, sea surface temperature and in-situ temperature and salinity measurements (Chassignet et al., 2009). The HYCOM predictions for drift currents are produced at a horizontal spatial resolution of approximately 8.25 km (1/12th of a degree) over the region, at a frequency of every 3 hours. HYCOM uses isopycnal layers in the open, stratified ocean, but uses the layered continuity equation to make a dynamically smooth transition to a terrain following coordinate in shallow coastal regions, and to z-level coordinates in the mixed layer and/or unstratified seas.

For this study, the HYCOM hindcast currents were obtained for the years 2010 to 2019 (inclusive).

3.3 Surface Currents

Table 3.1 presents the predicted average and maximum monthly surface current speeds at the release location.

The month average surface current speeds ranged between 0.16 m/s (November) and 0.23 m/s (February). Additionally, the maximums ranged between 0.55 m/s (November) and 1.36 m/s (January). The general current directions were quite variable throughout the year. Figure 3.6 and Figure 3.7 present the monthly and total current rose distributions, respectively.

Note the convention for defining current direction throughout this report is the direction the current flows towards. Each branch of the current rose distribution represents the currents flowing to that direction, with north to the top of the diagram. The branches are divided into segments of different colour, which represent the current speed ranges for each direction. Speed intervals of 0.1 m/s are typically used in these current roses. The length of each coloured segment within a branch is proportional to the frequency of currents flowing within the corresponding speed and direction.

Table 3.1 Predicted monthly average and maximum surface current speeds close to the release location. Data derived by combining the HYCOM ocean data and HYDROMAP high resolution tidal data from 2010-2019 (inclusive).

Season	Month	Average current speed (m/s)	Maximum current speed (m/s)	General direction (towards)
Summer	January	0.22	1.36	Northeast
	February	0.23	0.97	Variable
	March	0.18	0.57	Westerly
Transitional	April	0.21	1.15	Westerly
Winter	May	0.22	0.90	Westerly
	June	0.21	0.60	Northwest
	July	0.20	0.90	Westerly
Transitional	August	0.17	0.59	North
Summer	September	0.19	0.93	Variable
	October	0.20	0.74	Northwest
	November	0.16	0.55	Variable
	December	0.21	0.73	North
Minimum		**0.16**	**0.55**	
Maximum		**0.23**	**1.36**	

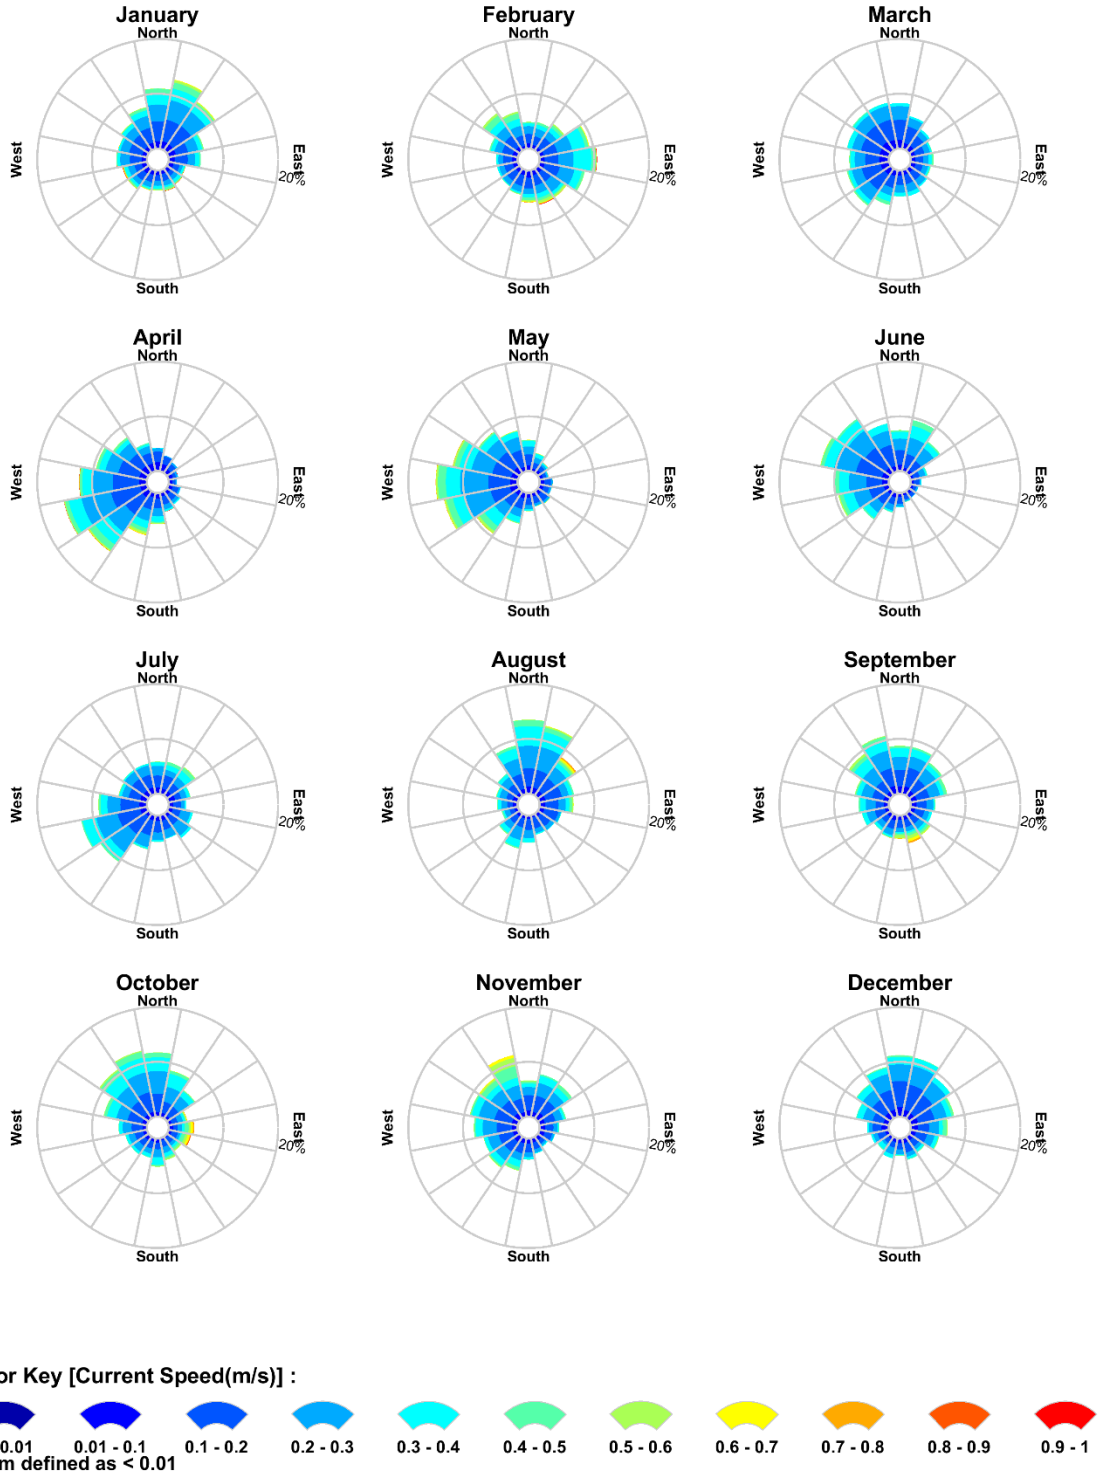

Figure 3.6 Monthly surface current rose distributions at the release location, derived from the 2010 to 2019 modelled dataset.

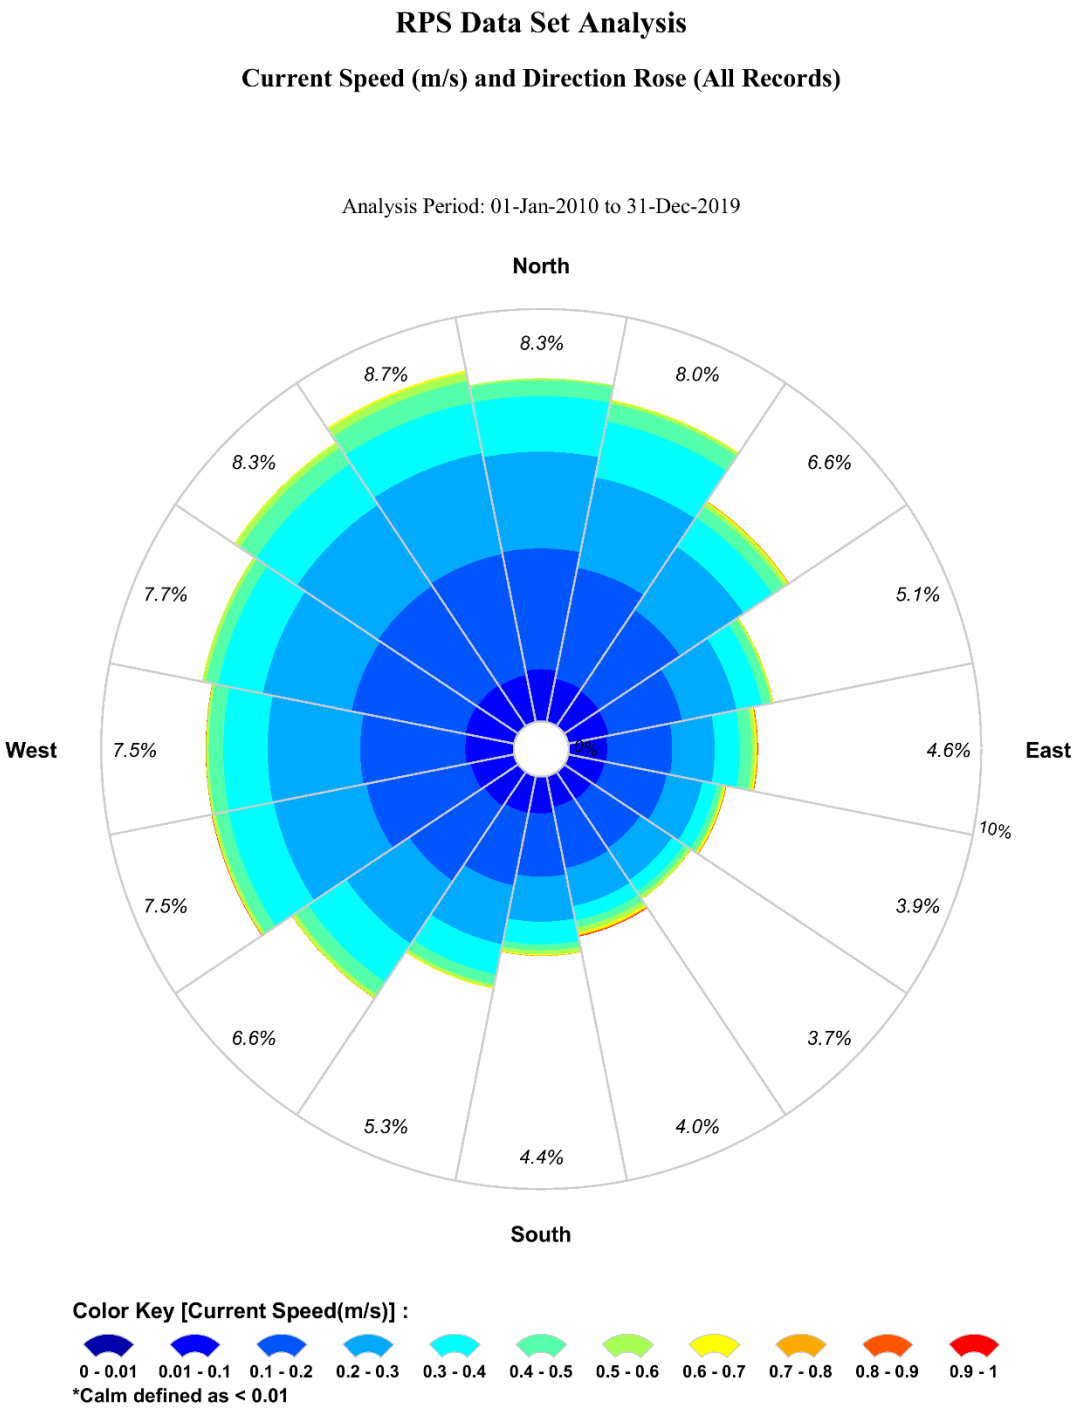

Figure 3.7 Total surface current rose plot at the release location, derived from the 2010 to 2019 modelled dataset.

4 WIND DATA

To account for the influence of the wind on the floating oil, wind data from 2010 to 2019 (inclusive) was sourced from the National Centre for Environmental Prediction (NCEP) Climate Forecast System Reanalysis (CFSR; see Saha et al., 2010). The CFSR wind model includes observations from many data sources; surface observations, upper-atmosphere air balloon observations, aircraft observations and satellite observations. The model is capable of accurately representing the interaction between the earth's oceans, land and atmosphere. The gridded wind data output is available at ¼ of a degree resolution (~33 km) and 1-hourly time intervals. Figure 4.1 shows the spatial resolution of the wind field used as input into the oil spill model.

Table 4.1 shows the monthly average and maximum winds derived from the CFSR node closest to the release location. The model wind data demonstrated that this region typically experiences moderate winds all year round and although the monthly average wind speeds remain under 15 knots. The maximum wind speed was 45 knots (July). Winds typically blow from the southwest during the summer months, while winds are typically easterly during the winter months.

Figure 4.2 and Figure 4.3 illustrates the monthly and total wind rose distributions nearby the release location, respectively.

Note that the atmospheric convention for defining wind direction, that is, the direction the wind blows from, is used to reference wind direction throughout this report. Each branch of the rose represents wind coming from that direction, with north to the top of the diagram. Sixteen directions are used. The branches are divided into segments of different colour, which represent wind speed ranges from that direction. Speed ranges of 5 knot intervals are typically used in these wind roses. The length of each segment within a branch is proportional to the frequency of winds blowing within the corresponding range of speeds from that direction.

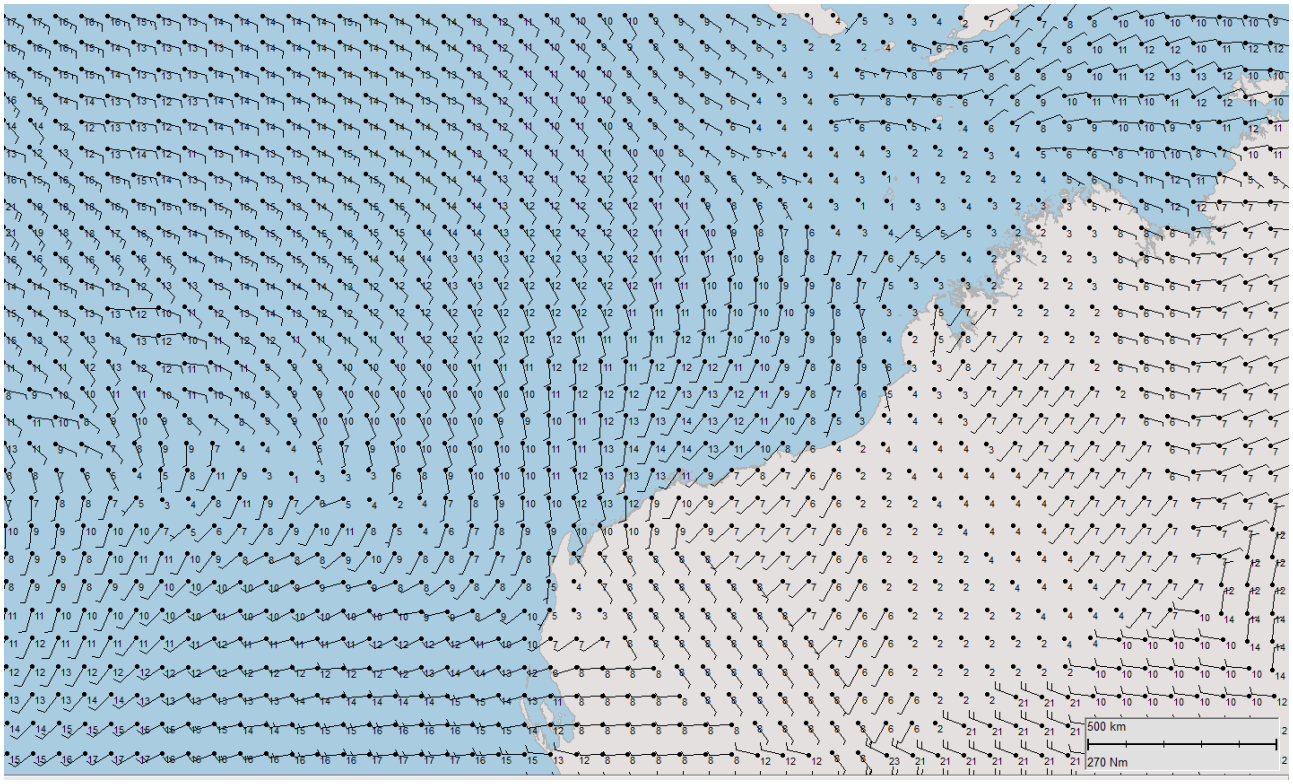

Figure 4.1 Spatial resolution of the CFSR modelled wind data used as input into the oil spill model. Note, for ease viewing only every second wind vector is displayed on the map.

Table 4.1 Predicted average and maximum winds for the wind node closest to the release location. Data derived from CFSR hindcast model 2010 to 2019 (inclusive).

Season	Month	Average wind (knots)	Maximum wind (knots)	General direction (from)
Summer	January	13	44	Southwest
	February	11	36	Southwest
	March	10	33	Southwest
Transitional	April	11	42	South
Winter	May	12	37	East
	June	14	30	East
	July	13	45	Southeast
Transitional	August	11	30	Southeast

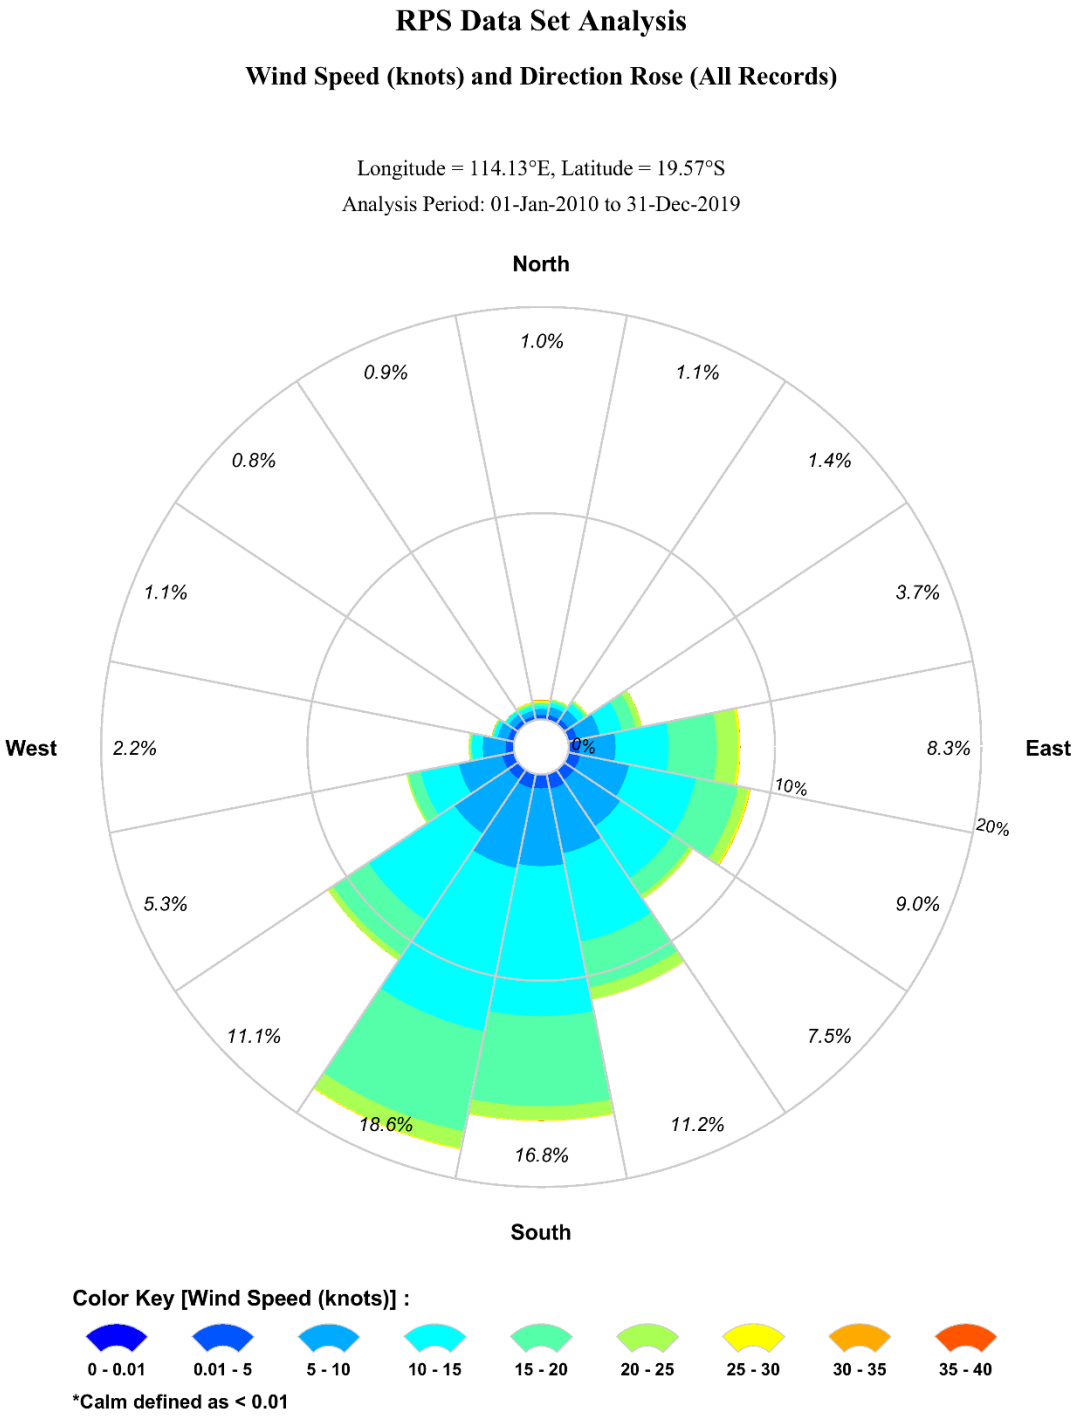

Figure 4.3 Total wind rose distributions adjacent to the release location, derived from the 2010 to 2019 modelled dataset.

5 WATER TEMPERATURE AND SALINITY

The monthly depth-varying water temperature and salinity profiles nearest to the release location was obtained from the HYbrid Coordinate Ocean Model (see Section 3.2 Ocean Currents).

The three-dimensional salinity and temperature datasets are used in the oil spill model domain to inform the weathering, movement, and evaporative loss of hydrocarbon spills in the surface and subsurface layers.

Table 5.1 shows that the monthly average sea surface temperatures ranged from 24.3°C (September) to 29.4°C (March), whilst salinity remained relatively consistent throughout the year, ranging between 34.5–34.9 psu.

Figure 5.1 the vertical profile of sea temperature and salinity nearby the release location.

Table 5.1 Monthly average sea surface temperature and salinity near the release location in the 0-5 m depth layer.

Month	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sept	Oct	Nov	Dec
Temperature (°C)	28.3	28.8	29.4	28.9	27.7	26.2	25.3	24.5	24.3	24.9	26.8	27.3
Salinity (psu)	34.9	34.6	34.6	34.5	34.7	34.8	34.6	34.7	34.7	34.7	34.7	34.7

6 SUBSEA PLUME MODEL – OILMAP DEEP

The LOWC scenario is a high-pressure release of mostly gas and condensate and where gas is released with condensate, the buoyancy of the expanding gas cloud will entrain ambient seawater and propel the droplets towards the surface at a faster rate than would occur from the relative buoyancy of the condensate alone. Furthermore, the turbulence generated by such an intense discharge will tend to break the condensate up into droplets of various sizes.

To define the near-field plume dynamics, the subsea blowout model, OILMAP-DEEP, was applied. The model simulates the plume rise dynamics in two phases, the initial jet phase and the buoyant plume phase. The initial jet phase governs the plume dynamics directly above the subsurface release location and is predominately driven by the exit velocity. During this phase, the condensate droplet size and distribution is calculated. Next, the rise dynamics are dominated by the buoyant nature of the plume until the termination of the plume phase (known as the trapping depth). At this point, the results from OILMAP-DEEP (including plume trapping depth, plume diameter and droplet size distribution) are integrated into the far-field model SIMAP to simulate the rise and dispersion of the condensate droplets.

More details on the OILMAP-DEEP model, can be found in Spaulding et al. (2015). The model has been validated against observations from Deepwater Horizon as well as small and large-scale laboratory studies on subsurface oil releases (Brandvik et al., 2013, 2014; Belore, 2014; Spaulding et al., 2015; Li et al., 2017).

Table 6.1 presents the input parameters for the OILMAP-DEEP model and key results related to the near-field plume dynamics. The results indicated that the mixture of gas and condensate rose through the water column (whilst gradually losing momentum) to a trapping depth of approximately 753 m below mean sea level. After this point the condensate droplets would rise due to their own buoyancy, which are predicted to range in size from 135 to 548 µm.

Figure 6.1 illustrates the various stages of an example blowout plume.

Table 6.1 Input data and key results for the subsea plume modelling.

Input Variable	Value
Scenario	Loss of Well Control
Well name	Chandon Well 1
Water depth (m)	1,100
Tubing diameter (inch) [m]	7 5/8 [0.194]
Condensate rate (stb/day)	5,214
Gas rate (MMscf/day)	356
Gas to condensate ratio (scf/bbl)	68,278
Formation water flow rate (stb/day)	0
Operating pressure (psia)	4,296
Key results	
Plume execution depth (m BMSL)	753
Droplet sizes (µm)	135 to 584

7 OIL SPILL MODEL – SIMAP

Modelling of the fate of oil was performed using the Spill Impact Mapping Analysis Program (SIMAP). SIMAP is designed to simulate the fate and effects of spilled hydrocarbons for both the surface and subsurface releases (Spaulding et al. 1994; French et al. 1999; French-McCay, 2003, 2004; French-McCay et al. 2004).

SIMAP has been used to predict the weathering and fate of oil spills during and after major incidents including: Montara (Australia) well blowout August 2009 in the Timor Sea (Asia-Pacific ASA, 2010); Macondo (USA) well blowout April 2010 in the Gulf of Mexico; Bohai Bay (China) oil spill August 2011; and the pipeline oil spill July 2013 in the Gulf of Thailand.

The SIMAP model calculates the transport, spreading, entrainment, evaporation and decay of surface hydrocarbon slicks as well as the entrained and dissolved oil components in the water column, either from surface slicks or from oil discharged subsea. The movement and weathering of the spilled oil is calculated for specific oil types. Input specifications for oil mixtures include the density, viscosity, pour point, distillation curve (volume lost versus temperature) and the aromatic/aliphatic component ratios within given boiling point ranges.

SIMAP is a three-dimensional model that allows for various response actions to be modelled including oil removal from skimming, burning, or collection booms, and surface and subsurface dispersant application.

The SIMAP oil spill model includes advanced weathering algorithms, specifically focussed on unique oils that tend to form emulsions and/or tar balls. The weathering algorithms are based on five years of extensive research conducted in response to the Deepwater Horizon oil spill in the Gulf of Mexico (French et al., 2015).

Biodegradation is included in the oil spill model. In the model, SIMAP, degradation is calculated for the surface slick, deposited oil on the shore, the entrained oil and dissolved constituents in the water column, and oil in the sediments. For surface oil, water column oil and sedimented oil a first order degradation rate is specified. Biodegradation rates are relatively high for hydrocarbons in dissolved state or in dispersed small droplets.

7.1 Stochastic Modelling

Stochastic oil spill modelling is created by overlaying a great number (often 100 hundred) simulated hypothetical oil spills (Figure 7.1). Stochastic modelling involves running numerous individual oil spill simulations using a range of prevailing wind and current conditions that are historically representative of the season and location of where the spill event may occur.

For the stochastic modelling presented herein, **100 spills** were simulated per season using the same spill information (release location, spill volume, duration and condensate properties) but with varied start dates and times corresponding to the period represented by the available wind and current data. During each simulation, the model records whether any grid cells are exposed to any hydrocarbon concentrations, the concentrations involved and the elapsed time before exposure. For each scenario the results of all 100 condensate spill simulations were analysed to determine the following seasonal statistics for every grid cell:

- Exposure load (concentrations and volumes);
- Minimum time before exposure;
- Probability of contact above defined concentrations;
- Volume of condensate that may strand on shorelines from any single simulation;
- Concentration that might occur on sections of individual shorelines;
- Exposure (instantaneous and/or over a specified duration) to dissolved hydrocarbons in the water column; and
- Exposure (instantaneous and/or over a specified duration) to entrained hydrocarbons in the water column.

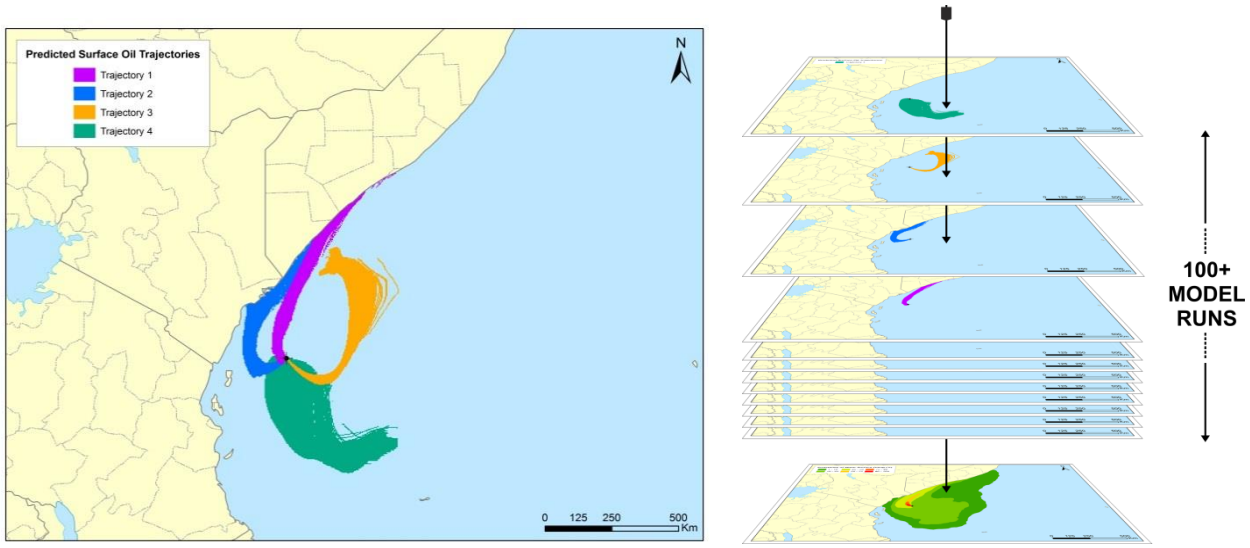

Figure 7.1 Predicted movement of four single oil spill simulations by SIMAP for the same scenario (left image). All model runs are overlain (shown as the stacked runs on the right) and the number of times that trajectories contact a given location at a concentration is used to calculate the probability (Source: NOPSEMA, 2018).

7.2 Floating, Shoreline and In-Water Thresholds

The thresholds and their relationship to exposure for the sea surface, shoreline and water column (entrained and dissolved hydrocarbons) are presented in Sections 7.2.1 to 7.2.3. Supporting justifications of the adopted thresholds applied during the study and additional context relating to the area of influence are also provided. It is important to note that the thresholds herein are based on NOPSEMA (2019).

7.2.1 Floating condensate exposure Thresholds

The modelling results can be presented to any levels; therefore, thresholds have been specified (based on scientific literature) to record floating condensate exposure to the sea-surface at meaningful levels only, described in the following paragraphs.

The low threshold to assess the potential for floating oil exposure, was 1 g/m^2, which equates approximately to an average thickness of 1 µm, referred to as visible oil. Oil of this thickness is described as rainbow sheen in appearance, according to the Bonn Agreement Oil Appearance Code (Bonn Agreement, 2009; AMSA, 2014) (see Table 7.1). Figure 7.2 shows photographs highlighting the difference in appearance between a silvery sheen, rainbow sheen and metallic sheen. This threshold is considered below levels which would cause environmental harm and it is more indicative of the areas perceived to be affected due to its visibility on the sea surface and potential to trigger temporary closures of areas (i.e. fishing grounds) as a precautionary measure. Table 7.1 provides a description of the appearance in relation to exposure zone thresholds used to classify the zones of floating oil exposure.

Ecological impact has been estimated to occur at 10 g/m^2 (a film thickness of approximately 10 µm or 0.01 mm) according to French et al. (1996) and French-McCay (2009) as this level of fresh oiling has been observed to mortally impact some birds through adhesion of oil to their feathers, exposing them to secondary effects such as hypothermia. The appearance of oil at this average thickness has been described as a metallic sheen (Bonn Agreement, 2009). Concentrations above 10 g/m^2 is also considered the lower actionable threshold, where oil may be thick enough for containment and recovery as well as dispersant treatment (AMSA, 2015).

Scholten et al. (1996) and Koops et al. (2004) indicated that at oil concentrations on the sea surface of 25 g/m^2 (or greater), would be harmful for all birds that have landed in an oil film due to potential contamination of their feathers, with secondary effects such as loss of temperature regulation and ingestion

of oil through preening. The appearance of oil at this thickness is also described as metallic sheen (Bonn Agreement, 2009). For this study the high exposure threshold was set to 50 g/m^2 and above based on NOPSEMA (2019). This threshold can also be used to inform response planning.

Table 7.2 defines the thresholds used to classify the zones of floating condensate exposure reported herein.

Table 7.1 The Bonn Agreement Oil Appearance Code.

Code	Description Appearance	Layer Thickness Interval (g/m^2 or µm)	Litres per km^2
1	Sheen (silvery/grey)	0.04 – 0.30	40 – 300
2	Rainbow	0.30 – 5.0	300 – 5,000
3	Metallic	5.0 – 50	5,000 – 50,000
4	Discontinuous True Oil Colour	50 – 200	50,000 – 200,000
5	Continuous True Oil Colour	≥ 200	≥ 200,000

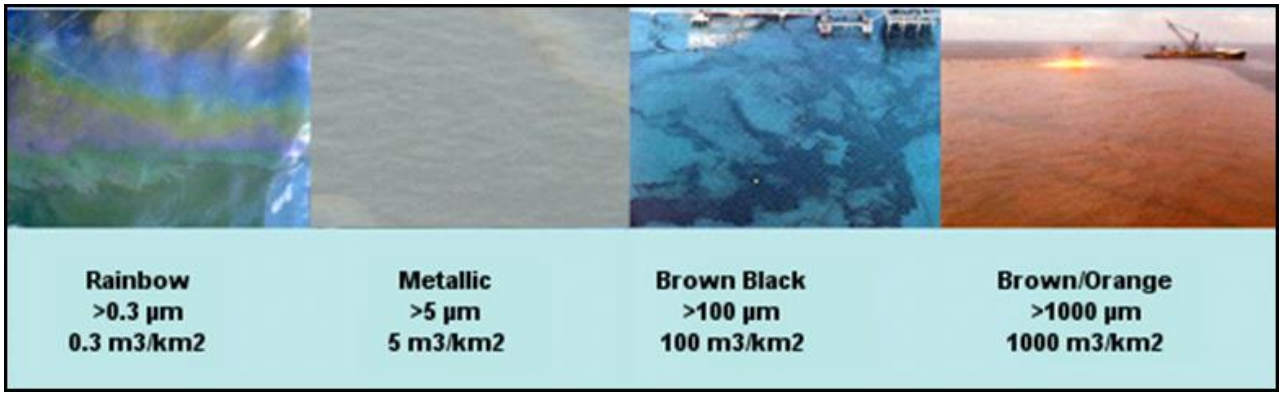

Figure 7.2 Photographs showing the difference between oil colour and thickness on the sea surface (source: adapted from Oil Spill Solutions, 2015).

Table 7.2 Floating condensate exposure thresholds used in this report (in alignment with NOPSEMA, 2019).

Threshold level	Floating oil (g/m^2)	Description
Low	1	Approximates range of socioeconomic effects and establishes planning area for scientific monitoring
Moderate	10	Approximates lower limit for harmful exposures to birds and marine mammals
High	50*	Approximates surface oil slick and informs response planning

* 50 g/m^2 also used to define the threshold for actionable floating oil.

7.2.2 Shoreline Accumulation Thresholds

There are many different types of shorelines, ranging from cliffs, rocky beaches, sandy beaches, mud flats and mangroves, and each of these influences the volume of oil that can remain stranded ashore and its thickness before the shoreline saturation point occurs. For instance, a sandy beach may allow oil to percolate through the sand, thus increasing its ability to hold more oil ashore over tidal cycles and various wave actions than an equivalent area of water; hence oil can increase in thickness onshore over time. A sandy beach shoreline was assumed as the default shoreline type for the modelling herein, as it allows for the highest carrying capacity of oil (of the available open/exposed shoreline types). Hence the results contained herein would be indicative of a worst-case scenario, where the highest volume of oil may be stranded on the shoreline (when compared to other shoreline types, such as exposed rocky shores).

In previous risk assessment studies, French-McCay et al. (2005a; 2005b) used a threshold of 10 g/m^2 to assess the potential for shoreline accumulation. This is a conservative threshold used to define regions of socio-economic impact, such as triggering temporary closures of adjoining fisheries or the need for shore clean-up on beaches or man-made features/amenities (breakwaters, jetties, marinas, etc.). It would equate to approximately 2 teaspoons of hydrocarbon per square meter of shoreline accumulation. The appearance is described as a stain/film. On that basis, the 10 g/m^2 shoreline accumulation threshold has been selected to define the zone of potential "low shoreline accumulation".

French et al. (1996) and French-McCay (2009) define a shoreline oil accumulation threshold of 100 g/m^2, or above, would potentially harm shorebirds and wildlife (furbearing aquatic mammals and marine reptiles on or along the shore) based on studies for sub-lethal and lethal impacts. This threshold has been used in previous environmental risk assessment studies (see French-McCay, 2003; French-McCay et al., 2004, French-McCay et al., 2011; 2012; NOAA, 2013). Additionally, a shoreline concentration of 100 g/m^2, or above, is the minimum limit that the oil can be effectively cleaned according to the AMSA (2015) guideline. This threshold equates to approximately ½ a cup of oil per square meter of shoreline accumulation. The appearance is described as a thin oil coat. Therefore, 100 g/m^2 has been selected to define the zone of potential "moderate shoreline accumulation".

Observations by Lin & Mendelssohn (1996) demonstrated that loadings of more than 1,000 g/m^2 of hydrocarbon during the growing season would be required to impact marsh plants significantly. Similar thresholds have been found in studies assessing hydrocarbon impacts on mangroves (Grant et al., 1993; Suprayogi & Murray 1999). Hence, 1,000 g/m^2 has been selected to define the zone of potential "high shoreline accumulation". It equates to approximately 1 litre of hydrocarbon per square meter of shoreline accumulation. The appearance is described as a hydrocarbon cover.

It is worth noting that the shoreline accumulation thresholds derived from extensive literature review (outlined in Table 7.3) agree with the commonly used threshold values for oil spill modelling specified in NOPSEMA (2019).

Table 7.3 Thresholds used to assess shoreline accumulation.

Threshold level	Shoreline accumulation (g/m^2)	Description
Low (socioeconomic/sublethal)	10	Predicts potential for some socio-economic impact
Moderate	100*	Loading predicts area likely to require clean-up effort
High	> 1,000	Loading predicts area likely to require intensive clean-up effort

* 100 g/m^2 also used to define the threshold for actionable shoreline oil.

7.2.3 In-water Exposure Thresholds

Oil is a mixture of thousands of hydrocarbons of varying physical, chemical, and toxicological characteristics, and therefore, demonstrate varying fates and impacts on organisms. As such, for in-water exposure, the SIMAP model provides separate outputs for dissolved and entrained hydrocarbons from oil droplets. The consequences of exposure to dissolved and entrained components will differ because they have different modes and magnitudes of effect.

Entrained hydrocarbon concentrations were calculated based on oil droplets that are suspended in the water column, though not dissolved. The composition of this oil would vary with the state of weathering (oil age) and may contain soluble hydrocarbons when the oil is fresh. Calculations for dissolved hydrocarbons specifically calculates oil components which are dissolved in water, which are known to be the primary source of toxicity exerted by oil.

7.2.3.1 Dissolved Hydrocarbons

Laboratory studies have shown that dissolved hydrocarbons exert most of the toxic effects of oil on aquatic biota (Carls et al., 2008; Nordtug et al., 2011; Redman, 2015). The mode of action is a narcotic effect, which is positively related to the concentration of soluble hydrocarbons in the body tissues of organisms (French-McCay, 2002). Dissolved hydrocarbons are taken up by organisms directly from the water column by absorption through external surfaces and gills, as well as through the digestive tract. Thus, soluble hydrocarbons are termed “bioavailable”.

Hydrocarbon compounds vary in water-solubility and the toxicity exerted by individual compounds is inversely related to solubility, however bioavailability will be modified by the volatility of individual compounds (Nirmalakhandan & Speece, 1988; Blum & Speece, 1990; McCarty, 1986; McCarty et al., 1992a, 1992b; Mackay et al., 1992; McCarty & Mackay, 1993; Verhaar et al., 1992, 1999; Swartz et al., 1995; French-McCay, 2002; McGrath et al., 2009). Of the soluble compounds, the greatest contributor to toxicity for water-column and benthic organisms are the lower-molecular-weight aromatic compounds, which are both volatile and soluble in water. Although they are not the most water-soluble hydrocarbons within most oil types, the polynuclear aromatic hydrocarbons (PAHs) containing 2-3 aromatic ring structures typically exert the largest narcotic effects because they are semi-soluble and not highly volatile, so they persist in the environment long enough for significant accumulation to occur (Anderson et al., 1974, 1987; Neff & Anderson, 1981; Malins & Hodgins, 1981; McAuliffe, 1987; NRC, 2003). The monoaromatic hydrocarbons (MAHs), including the BTEX compounds (benzene, toluene, ethylbenzene, and xylenes), and the soluble alkanes (straight chain hydrocarbons) also contribute to toxicity, but these compounds are highly volatile, so that their contribution will be low when oil is exposed to evaporation and higher when oil is discharged at depth where volatilisation does not occur (French-McCay, 2002).

French-McCay (2002) reviewed available toxicity data, where marine biota was exposed to dissolved hydrocarbons prepared from oil mixtures, finding that 95% of species and life stages exhibited 50% population mortality (LC_{50}) between 6 and 400 ppb total PAH concentration after 96 hrs exposure, with an average of 50 ppb. Hence, concentrations lower than 6 ppb total PAH value should be protective of 97.5% of species and life stages even with exposure periods of days (at least 96 hours). Early life-history stages of fish appear to be more sensitive than older fish stages and invertebrates.

Exceedances of 10, 50 or 400 ppb over a 1 hour timestep (see Table 7.4) was applied to indicate increasing potential for sub-lethal to lethal toxic effects (or low to high), based on NOPSEMA (2019).

7.2.3.2 Entrained Hydrocarbons

Entrained hydrocarbons consist of oil droplets that are suspended in the water column and insoluble. As such, insoluble compounds in oil cannot be absorbed from the water column by aquatic organisms, hence are not bioavailable through absorption of compounds from the water. Exposure to these compounds would require routes of uptake other than absorption of soluble compounds. The route of exposure of organisms to whole oil alone include direct contact with tissues of organisms and uptake of oil by direct consumption, with potential for biomagnification through the food chain (NRC, 2003).

The 10 ppb threshold represents the very lowest concentration and corresponds generally with the lowest trigger levels for chronic exposure for entrained hydrocarbons in the ANZECC & ARMCANZ (2000) water quality guidelines. Due to the requirement for relatively long exposure times (> 24 hours) for these concentrations to be significant, they are likely to be more meaningful for juvenile fish, larvae and planktonic organisms that might be entrained (or otherwise moving) within the entrained plumes, or when entrained hydrocarbons adhere to organisms or trapped against a shoreline for periods of several days or more.

This exposure zone is not considered to be of significant biological impact and is therefore outside the adverse exposure zone. This exposure zone represents the area contacted by the spill. This area does not define the area of influence as it is considered that the environment will not be affected by the entrained hydrocarbon at this level.

Thresholds of 10 ppb and 100 ppb were applied over a 1 hour time exposure (Table 7.4), to cover the range of thresholds outlined in the ANZECC & ARMCANZ (2000) water quality guidelines, the incremental change for greater potential effect and is per NOPSEMA (2019).

A complicating factor that should be considered when assessing the consequence of dissolved and entrained oil distributions is that there will be some areas where both physically entrained oil droplets and dissolved hydrocarbons co-exist. Higher concentrations of each will tend to occur close to the source where sea conditions can force mixing of relatively unweathered oil into the water column, resulting in more rapid dissolution of soluble compounds.

Table 7.4 Dissolved and entrained hydrocarbon exposure values assessed over a 1-hour time step, as per NOPSEMA (2019).

Threshold level	Dissolved hydrocarbon concentration (ppb)	Entrained hydrocarbon concentrations (ppb)
Low	10	10
Moderate	50	-
High	400	100

8 CONDENSATE PROPERTIES

8.1 Properties

Chandon condensate physical properties and boiling point distributions were provided by Chevron and are presented in Table 8.1 and Table 8.2, respectively.

Chandon condensate has an API of 47.80, a density of 789 kg/m^3 (at 15ºC) and a viscosity value of 2.6 cP at 15 ºC. When exposed to the atmosphere at local temperatures, about 45.9% of the condensate volatile components should evaporate within the first 12 hours (BP < 180°C); a further 26.3% of the semi-volatiles should evaporate within the first 24 hours (180°C < BP < 265°C); and low volatile portion (22.4%) should evaporate over a longer period (265°C < BP < 380°C). The remaining 5.4% of the condensate would persist in the marine environment for much longer periods and be subject to relatively slow degradation.

This condensate has a low asphaltene content (< 0.05%), which is one indicator for a very low propensity for the mixture to take up water to form water-in-oil emulsion.

Soluble aromatic hydrocarbons contribute approximately 2.5% by mass of the whole oil, which is contained in the volatile fractions and are highly soluble. The process of evaporation will be grater under calm sea conditions, but increased entrainment can be expected under stronger winds due to the presence of small breaking waves (whitecaps).

The actual fate will depend greatly on the amount that reaches the surface, either through the initial release or by resurfacing.

Table 8.1 Physical properties of Chandon condensate.

Characteristic	Chandon Condensate
Density (kg/m^3)	789 (at 15°C)
API	47.8
Dynamic viscosity (cP)	2.6 (at 15°C)
Pour point (°C)	<-20
Surface tension (dyne/cm)	21
Hydrocarbon property category	Group I
Hydrocarbon property classification	Non-persistent

Table 8.2 Boiling point ranges of Chandon condensate.

Oil Type	Component	Volatile (%)	Semi-volatile (%)	Low volatility (%)	Residual (%)
	Boiling point (°C)	<180 C_4 to C_{10}	180-265 C_{11} to C_{15}	265-380 C_{16} to C_{20}	>380 >C_{20}
Chandon Condensate	% of total	45.9	26.3	22.4	5.4
	% of aromatics	2.5	0	0	0

8.2 Weathering Characteristics

8.2.1 Overview

A series of weathering tests were conducted to illustrate the potential behaviour of this condensate when exposed to idealised and representative environmental conditions:

- Instantaneous 50 m^3 surface release under calm wind conditions (constant 5 knots), 27°C water temperature and currents.
- Instantaneous 50 m^3 surface release under variable moderate wind conditions, 27°C water temperature and currents.

The first case is indicative of weathering rates under calm conditions that would not generate entrainment, while the second case would be more representative of the moderate winds experienced over the region. Both scenarios provide examples of potential behaviour during periods of a spill event once the condensate reaches the surface.

8.2.2 Results

The mass balance forecast for the calm-wind case (Figure 8.1) shows that 72% of the condensate is predicted to evaporate within 24 hours. The majority of the remaining condensate on the water surface will weather at a slower rate due to the low volatile components. Evaporation of the residual compounds will slow significantly, and they will then be subject to more gradual decay through biological and photochemical processes.

Under the variable-wind case (Figure 8.2), where the winds are of greater strength on average, entrainment of Chandon condensate into the water column was shown to increase. Approximately 24 hours after the spill, 38% of the condensate mass was shown to entrain and a further 60% had evaporated, leaving only a small portion of the condensate floating on the water surface (<0.3%). The residual compounds will tend to remain entrained during conditions that generate wind-waves (approximately >6 m/s).

The increased level of entrainment in the variable-wind case would result in a higher percentage of biological and photochemical degradation, where the decay of the floating slicks and condensate droplets in the water column occurs at an approximate rate of ~1.1% per day with an accumulated total of ~8.6% after 7 days, in comparison to a rate of <0.1% per day and an accumulated total of 0.7% after 7 days in the constant-wind case. Given the portion of entrained condensate and the tendency for it to remain mixed in the water column, the remaining hydrocarbons will decay over time scales of several weeks.

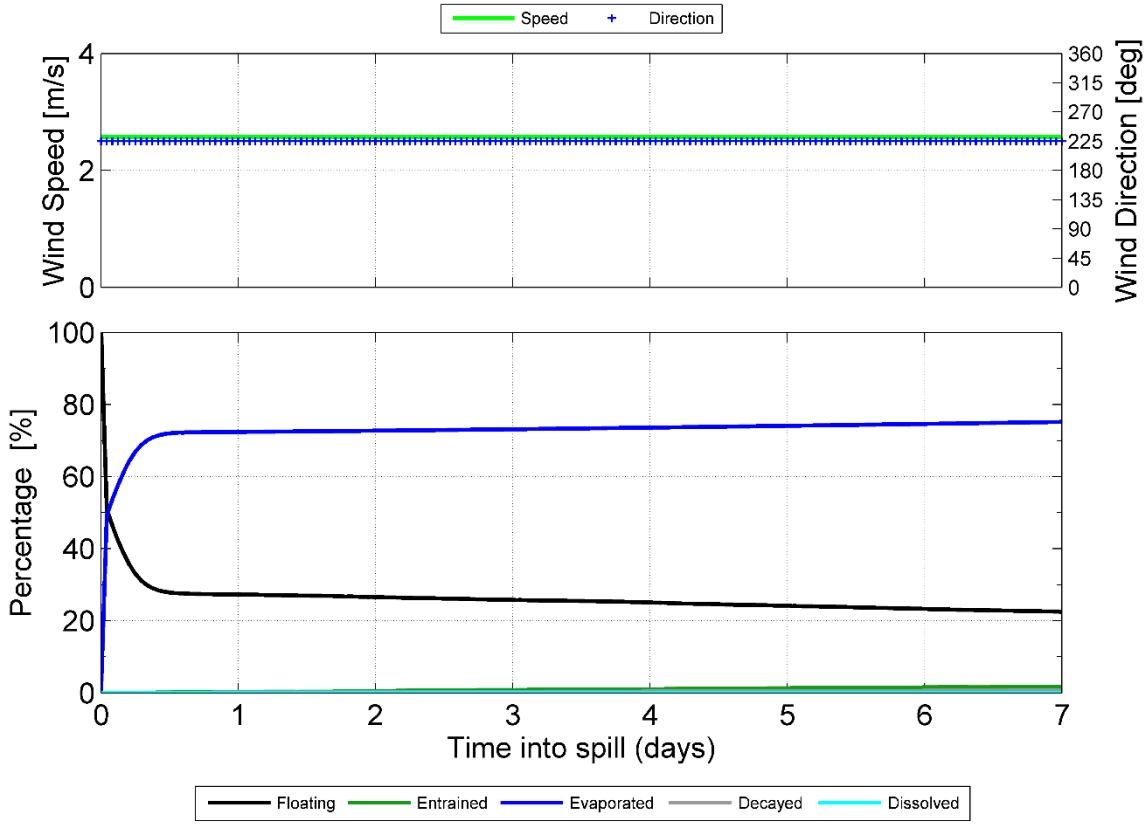

Figure 8.1 Proportional mass balance plot representing the weathering of Chandon condensate spilled onto the water surface as a one-off instantaneous release and subject to a constant 5 knots (2.6 m/s) wind at 27°C water temperature.

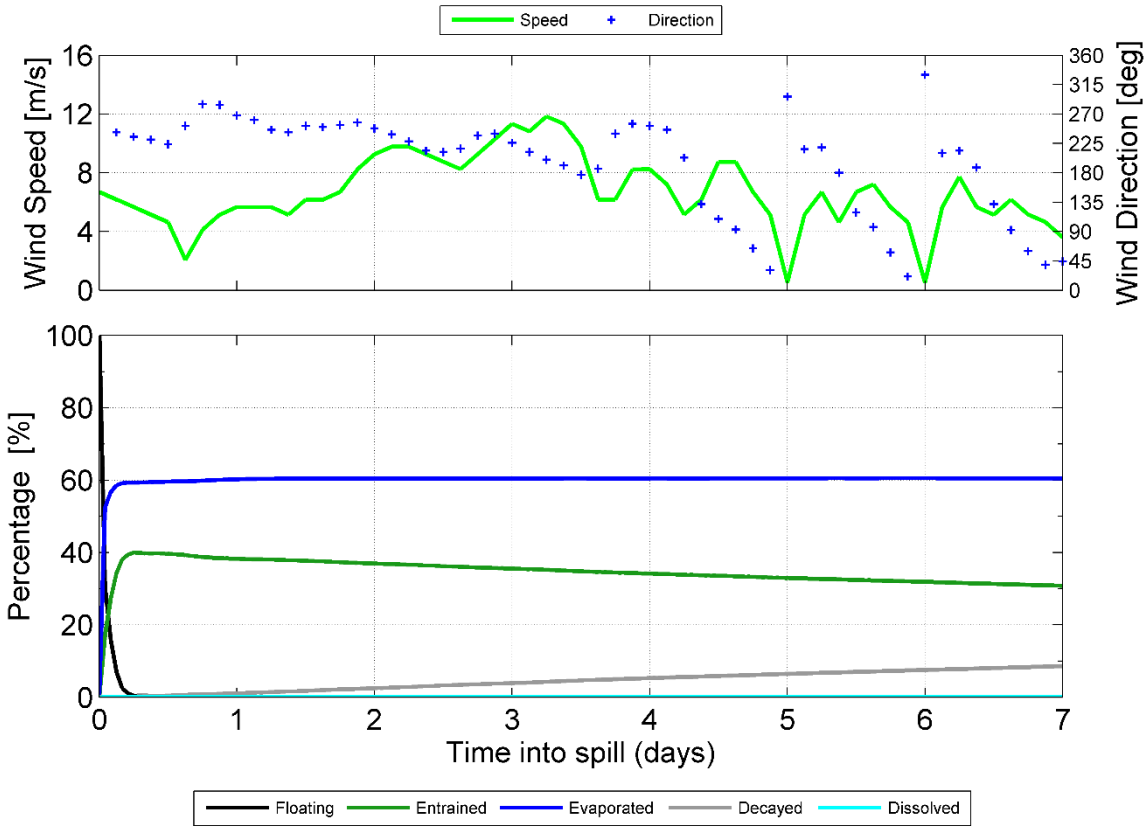

Figure 8.2 Proportional mass balance plot representing the weathering of Chandon condensate spilled onto the water surface as a one-off instantaneous release and subject to variable wind at 27°C water temperature.

9 MODEL SETTINGS

Table 9.1 provides a summary of the oil spill model settings.

Table 9.1 Summary of the oil spill model settings used in this assessment.

	Scenario
Location	Chandon Well 1 (Chandon)
Number of spill simulations with randomly selected start times	100 per season (300 total)
Spill volume (m^3) [bbl]	74,604 [469,260]
Condensate type	Chandon condensate
Release type (depth)	Subsea (1,100 m)
Release duration (days)	90
Simulation length (days)	104
Model period	Summer (September to the following March) Transitional (April and August) Winter (May to July)
Floating oil (NOPSEMA) thresholds	1 g/m^2, low exposure 10 g/m^2, moderate exposure 50 g/m^2, high exposure
Shoreline accumulation (NOPSEMA) thresholds	10 g/m^2, low exposure 100 g/m^2, moderate exposure 1,000 g/m^2, high exposure
Dissolved hydrocarbon (NOPSEMA) thresholds	10 ppb over 1 hour, low exposure 50 ppb over 1 hour, moderate exposure 400 ppb over 1 hour, high exposure
Entrained hydrocarbon (NOPSEMA) thresholds	10 ppb over 1 hour, low exposure 100 ppb over 1 hour high exposure

10 PRESENTATION AND INTERPRETATION OF MODEL RESULTS

The results from the modelling study are presented in a number of tables and figures, which aim to provide an understanding of the predicted sea-surface and water column (subsurface) exposure and shoreline accumulation (if predicted).

10.1 Stochastic Analysis

10.1.1 Statistics

The statistics are based on the following principles:

- The ***greatest distance travelled by a spill trajectory*** – is determined by a) recording the maximum and b) second greatest distance travelled (or 99th percentile) by a single trajectory, within a scenario, from the release location to the identified exposure thresholds.
- The ***Probability of condensate exposure to a receptor*** – is determined by recording the number of spill trajectories to reach a specified sea surface or subsea threshold within a receptor polygon, divided by the total number of spill trajectories within that scenario.
- The ***Minimum time before condensate exposure to a receptor*** – is determined by ranking the elapsed time before sea surface exposure, at a specified threshold, to grid cells within a receptor polygon and recording the minimum value.
- The ***probability of oil accumulation at a receptor*** – is determined by recording the number of spill trajectories to reach a specified shoreline accumulation threshold within a receptor polygon, divided by the total number of spill trajectories within that scenario.
- The ***maximum potential oil accumulation within a receptor*** – is determined by identifying the maximum loading to any grid cell within a receptor polygon, for a scenario.
- The ***dissolved and entrained hydrocarbon exposure*** – is determined by recording the maximum instantaneous concentrations at each grid cell assessed over a 1-hour time step.

10.2 Deterministic Trajectories

The deterministic results in Section 11.2 are based on the following criteria:

a. Largest swept area of floating hydrocarbon above 10 g/m^2
b. Largest swept area of floating hydrocarbon above 50 g/m^2
c. Largest volume of oil ashore
d. Longest length of shoreline accumulation above 100 g/m^2
e. Largest area of entrained hydrocarbons above 100 ppb
f. Largest area of dissolved hydrocarbons above 50 ppb

As there was no floating hydrocarbons at or above 50 g/m^2, no dissolved hydrocarbon exposure at or above 50 ppb, and no shoreline accumulation at or above any threshold, for any of the 300 simulations, the deterministic results are presented based on criteria a, and e only.

10.3 Receptors

A range of environmental receptors and shorelines were assessed for floating oil exposure, shoreline contact and water column exposure (entrained and dissolved hydrocarbons) as part of the study (see Figure 10.1 to Figure 10.10). Receptor categories (see Table 10.1) include sections of shorelines and offshore islands. All other sensitive receptors other than the submerged reefs, shoals and banks (RSB) were sourced from http://www.environment.gov.au/. Risks of exposure were separately calculated for each sensitive receptor area and have been tabulated.

Table 10.2 summarises the receptors that the location resides within.

Table 10.1 Summary of receptors used to assess floating oil, shoreline and in-water exposure to hydrocarbons.

11 RESULTS: CHANDON LOSS OF WELL CONTROL

This scenario examined a 469,260 stb (or 74,604 m^3) subsea release of condensate over 90 days, following a LOWC. A total of 300 spill simulations were run for each of the three seasons; summer (i.e. 100 spills per season) and tracked for 104 days.

Section 11.1 presents the seasonal (or stochastic) analysis results, while Section 11.2 presents the deterministic results.

11.1 Stochastic Analysis

11.1.1 Floating Condensate Exposure

Table 11.1 summarises the maximum distances from the release location to floating condensate exposure zones for each season. The maximum distance from the release location to the low (≥ 1 g/m^2) and moderate (≥ 10 g/m^2) thresholds was 102.9 km south (transitional) and 5.2 km west (transitional and winter), respectively.

No exposure was predicted at the high (≥ 50 g/m^2) threshold.

Table 11.2 summarises the potential floating condensate exposure to individual receptors during each season.

The Offshore Area IAA, Pygmy Blue Whale – Distribution BIA and Exmouth Plateau KEF, which the release location resides within, were the only receptors predicted to be exposed during all three seasons at the low and moderate thresholds. The probabilities for the low threshold was 100% for all seasons for these receptors. Probabilities of moderate exposure for these receptors ranged between 27% (winter) and 37% (summer and transitional).

Figure 11.1 to Figure 11.3 present the zones of floating condensate exposure for each season.

Table 11.1 Maximum distances and directions travelled from the release location to floating condensate exposure for each season and threshold, following a subsea LOWC at Chandon Well 1. The results were calculated from 100 spill trajectories per season.

Season	Distance and direction	Zones of potential floating condensate exposure		
		Low	Moderate	High
Summer	Max. distance from release site (km)	91.0	3.7	-
	Max. distance from release site (km) (99th percentile)	60.4	3.7	-
	Direction	West-northwest	North-northeast	-
Transitional	Max. distance from release site (km)	102.9	5.2	-
	Max. distance from release site (km) (99th percentile)	64.5	5.2	-
	Direction	Southwest	West	-
Winter	Max. distance from release site (km)	88.0	5.2	-
	Max. distance from release site (km) (99th percentile)	61.0	5.2	-
	Direction	West-northwest	West	-

Table 11.2 Summary of the potential floating condensate exposure to individual receptors, following a LOWC at Chandon Well 1. The results were calculated from 100 spill trajectories per season.

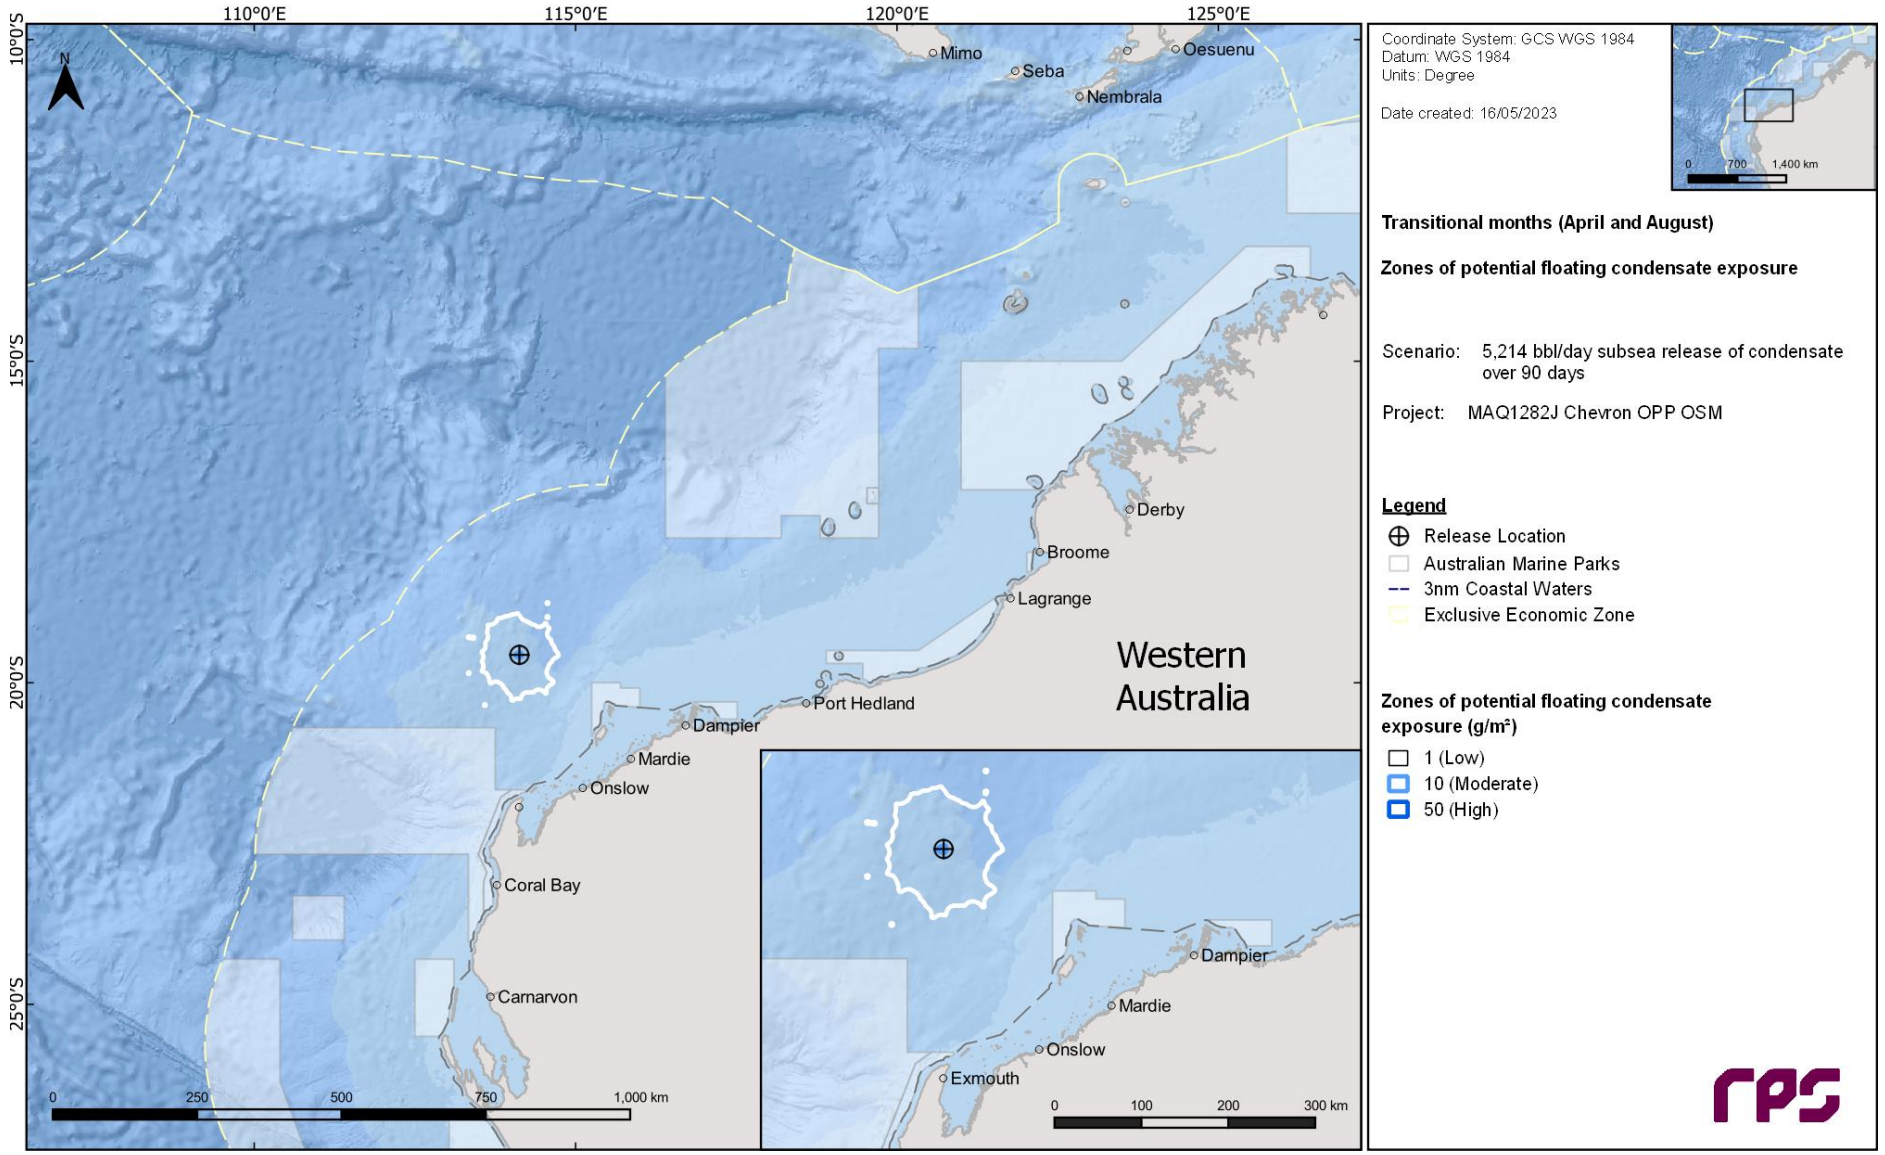

Figure 11.2 Zones of potential floating condensate exposure following a subsea LOWC at Chandon Well 1 during transitional (April and August) wind and current conditions. The results were calculated from 100 spill simulations.

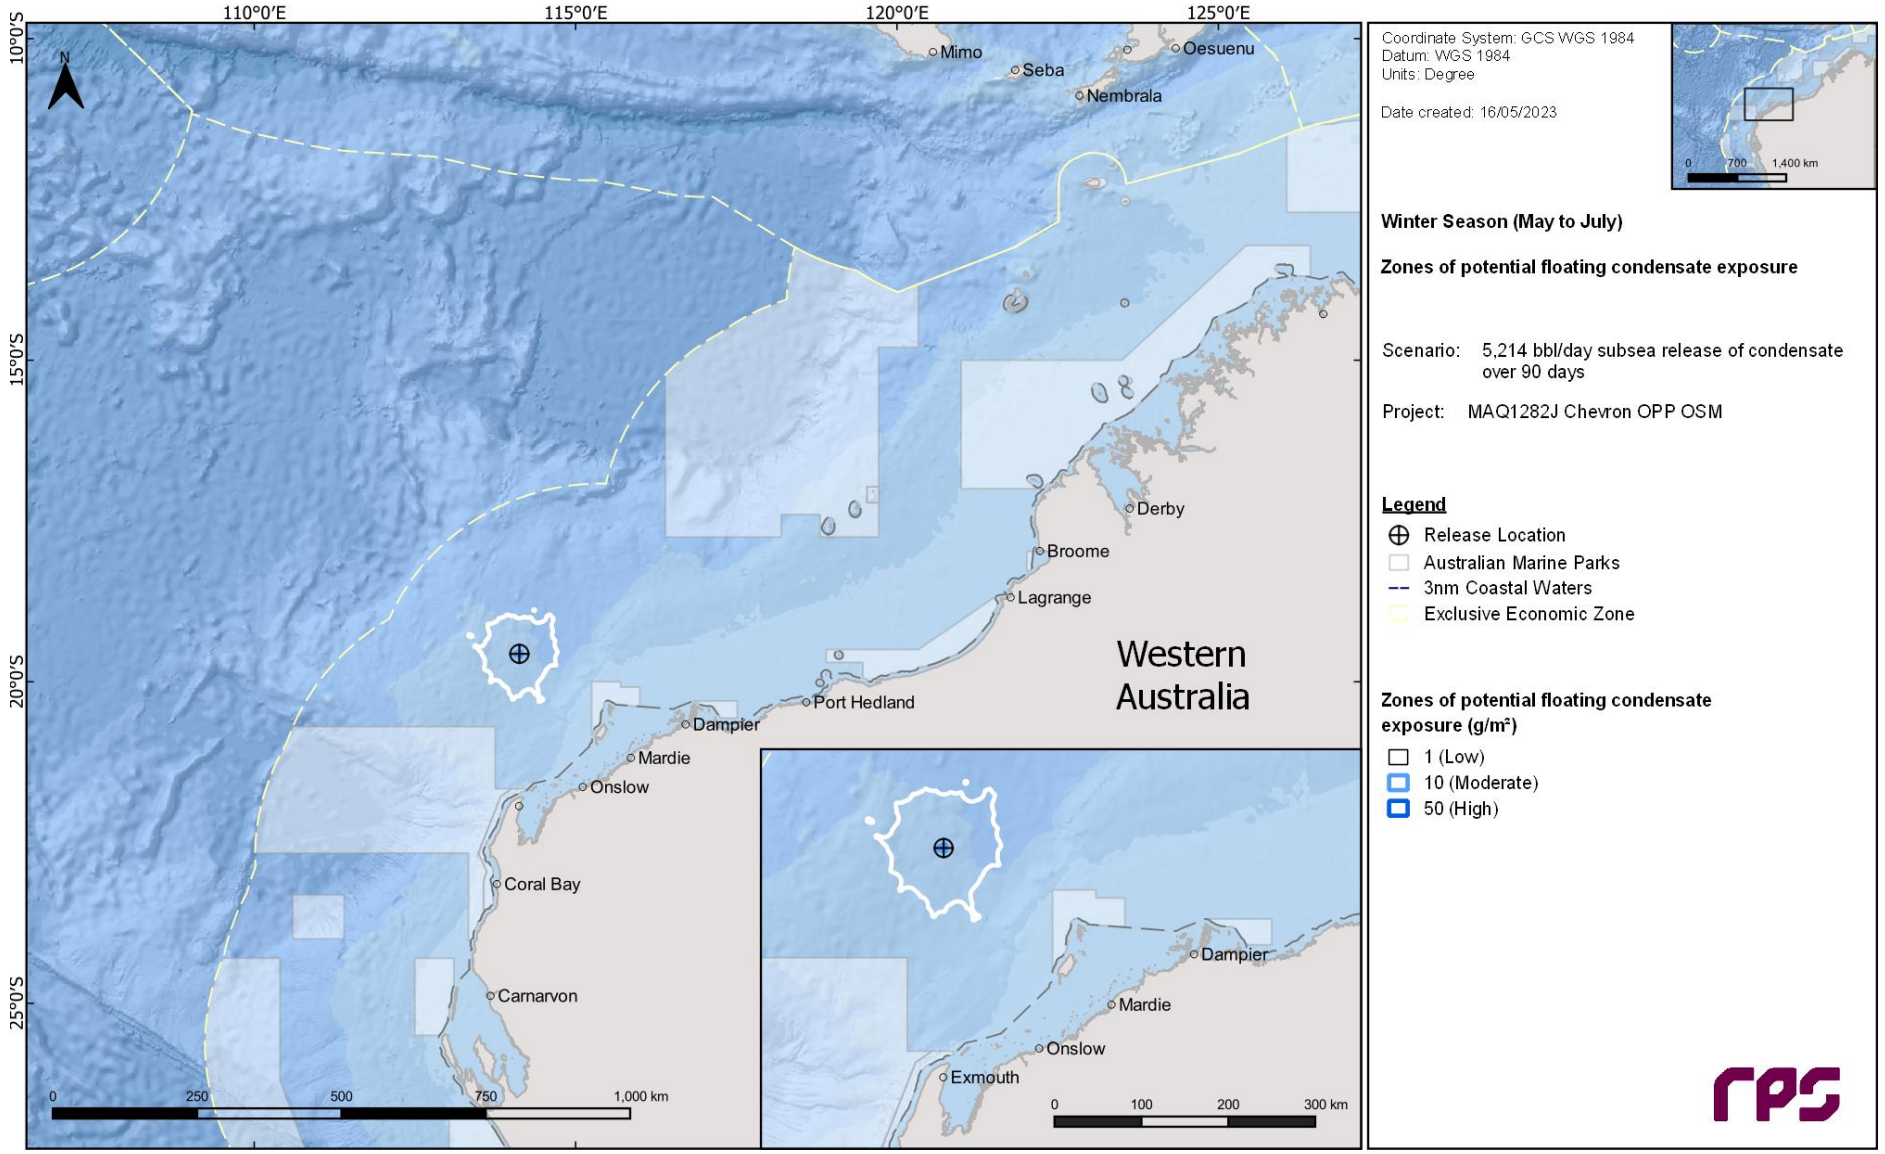

Figure 11.3 Zones of potential floating condensate exposure following a subsea LOWC at Chandon Well 1 during winter (May to July) wind and current conditions. The results were calculated from 100 spill simulations.

11.1.2 Shoreline Accumulation

No shoreline accumulation was predicted for this scenario above the low reporting threshold (≥10 g/m$_2$) during any of the seasons modelled. Consequently, no results are reported.

11.1.3 Water Column Exposure

11.1.3.1 Dissolved Hydrocarbons

Table 11.3 summarises the maximum exposure to dissolved hydrocarbons and the probability for individual receptors in the 0-10 m depth layer.

The Offshore Area IAA and Pygmy Blue Whale – Distribution BIA, which the release location resides within, were the only receptors to be exposed at or above the low threshold exclusively in summer with 1% probability.

Figure 11.4 to Figure 11.5 illustrate the extent of the predicted dissolved hydrocarbon exposure in the 0-10 m depth layer for each season.

Table 11.3 Predicted probability and maximum dissolved hydrocarbon exposure to individual receptors in the 0-10 m depth layer following a subsea LOWC at Chandon Well 1. The results were calculated from 100 spill simulations per season.

11.1.3.2 Entrained Hydrocarbons

Table 11.4 summarises the probability and minimum time before exposure to receptors from entrained hydrocarbons in the 0-10 m depth layer, for each season, at the low (≥ 10 ppb) and high (≥ 100 ppb) thresholds.

A total of 16 BIAs were shown to be exposed at or above the low threshold during summer, compared to 11 and 8 during transitional and winter seasons respectively. Excluding the Pygmy Blue Whale - Distribution BIA, which the release location resides within, the highest probabilities of exposure were predicted for the Wedge-tailed Shearwater - Breeding BIA during summer (60%), transitional (61%) and winter (57%) conditions.

During summer, 5 AMPs were predicted to be exposed at, or above the low threshold, whilst only 3 were predicted to be exposed at the same threshold during transitional and winter conditions. The highest probabilities predicted occurred at the Gascoyne AMP (63% summer, 65% transitional and 68% winter). Furthermore, during summer conditions the Gascoyne AMP was shown to be exposed to entrained hydrocarbons at the high threshold (5%).

A total of 5 KEFs were shown to be exposed by entrained hydrocarbons at the low threshold, including the Exmouth Plateau KEF that the release site is located within. Excluding the Exmouth Plateau, probabilities of exposure ranged between 1–50%, 8–53% and 7–50%, for summer, transitional and winter, respectively.

Additionally, 6 IAA's (including the Offshore IAA that the release site is located within), were shown to be exposed to entrained hydrocarbons at low threshold during summer season, compared to 3 during transitional and winter seasons. Excluding the Offshore IAA, the probabilities for each season ranged between 1–63%, 7–65% and 4–68% under summer, transitional and winter conditions, respectively.

Furthermore, the Rankin Bank RSB was shown to be exposed to entrained hydrocarbons at the low threshold only during the summer conditions and an 8% probability.

Figure 11.6 to Figure 11.8 illustrate the extent of the predicted entrained hydrocarbon exposure for the low and high thresholds in the 0-10 m depth layer for each season.

The same maps for the 10-20 m depth layer are presented in Figure 11.9 to Figure 11.11.

Table 11.4 Predicted probability and maximum entrained hydrocarbon exposure to individual receptors in the 0-10 m depth layer following a subsea LOWC at Chandon Well 1. The results were calculated from 100 spill simulations per season.

11.2 Deterministic Analysis

The deterministic analysis presented below, are based on simulations that resulted in the largest swept area of floating condensate above 10 g/m^2 (see Section 11.2.1), and the largest area of entrained hydrocarbons above 100 ppb (see Section 11.2.2).

Table 11.5 presents a summary of all deterministic analysis criteria and the corresponding values at the assessed thresholds.

Interpretation of the deterministic analysis result table and timeseries plots:

The summary deterministic analysis results presented in the table below should be interpreted as **maximum values**, representing the total volume or swept area exposed by floating or in-water hydrocarbons throughout the entire simulation duration. In this particular case, the simulation showed that a maximum of 793 km^2 was exposed to floating oil above the low threshold over a period of 104 days.

However, it's important to note that the timeseries plots present **peak values** at specific points in time. For example, when considering shoreline volume, the peak value in the timeseries plot does not account for oil that may have reached the shore earlier in the simulation but was subsequently lost through evaporation or other weathering processes.

Continuing with the previous example, the timeseries plot indicates that the peak floating oil swept area above the low threshold reached 40 km^2. This value represents the highest swept area recorded at a single point in time during the simulation.

Table 11.5 Summary of the deterministic analysis following a subsea LOWC at Chandon Well 1.

Variable	Threshold	Deterministic Analysis Criteria	
		Largest swept area of floating condensate above 10 g/m^2	Largest area of entrained hydrocarbons above 100 ppb
Season		Transitional	Winter
Run Number		41	57
Floating Oil (km^2)	**1 g/m^2**	793	1,012
	10 g/m^2	**10**	-
	50 g/m^2	-	-
Shoreline Length (km)	**10 g/m^2**	-	-
	100 g/m^2	-	-
	1,000 g/m^2	-	-
Minimum Time (days)		-	-
Maximum Volume (m^3)		-	-
Entrained Area (km^2)	**10 ppb**	98,614	99,261
	100 ppb	3,030	**6,094**
Dissolved Area (km^2)	**10 ppb**	9	-
	50 ppb	-	-
	400 ppb	-	-
Start Date		28 April 2015	25 June 2011

11.2.1 Deterministic Case: Largest swept area of floating condensate above 10 g/m^2

The deterministic simulation that resulted in the largest swept area of floating condensate above 10 g/m^2 (moderate threshold) was identified as run number 41 during the transitional period.

Figure 11.12 presents the extent of the predicted floating condensate exposure zones on the sea surface (swept area) and shoreline accumulation over the entire 104-day simulation.

Figure 11.13 displays the time series of the swept area of low (≥ 1 g/m^2), moderate (≥ 10 g/m^2) and high (≥ 50 g/m^2) floating condensate over the 104-day simulation.

Figure 11.14 presents the fates and weathering for the corresponding simulation and Table 11.6 summarises the peak volumes and times of occurrence for each oil phase and volumes at the end of the 104-day simulation.

Table 11.6 Summary of peak volumes and times of occurrence for each oil phase and the volumes at the conclusion of the simulation (day 104), for the simulation with the largest swept area of floating condensate above 10 g/m^2 following a subsea LOWC at Chandon Well 1.

Exposure Metrics	Peak Volume	Day of Occurrence	Volume at day 104
Surface (m^3)	234	52	0
Entrained (m^3)	5,305	90	2,817
Dissolved (m^3)	84	82	3
Evaporation (m^3)	47,176	104	47,176
Decay (m^3)	25,177	104	25,177
Ashore (m^3)	0	0	0

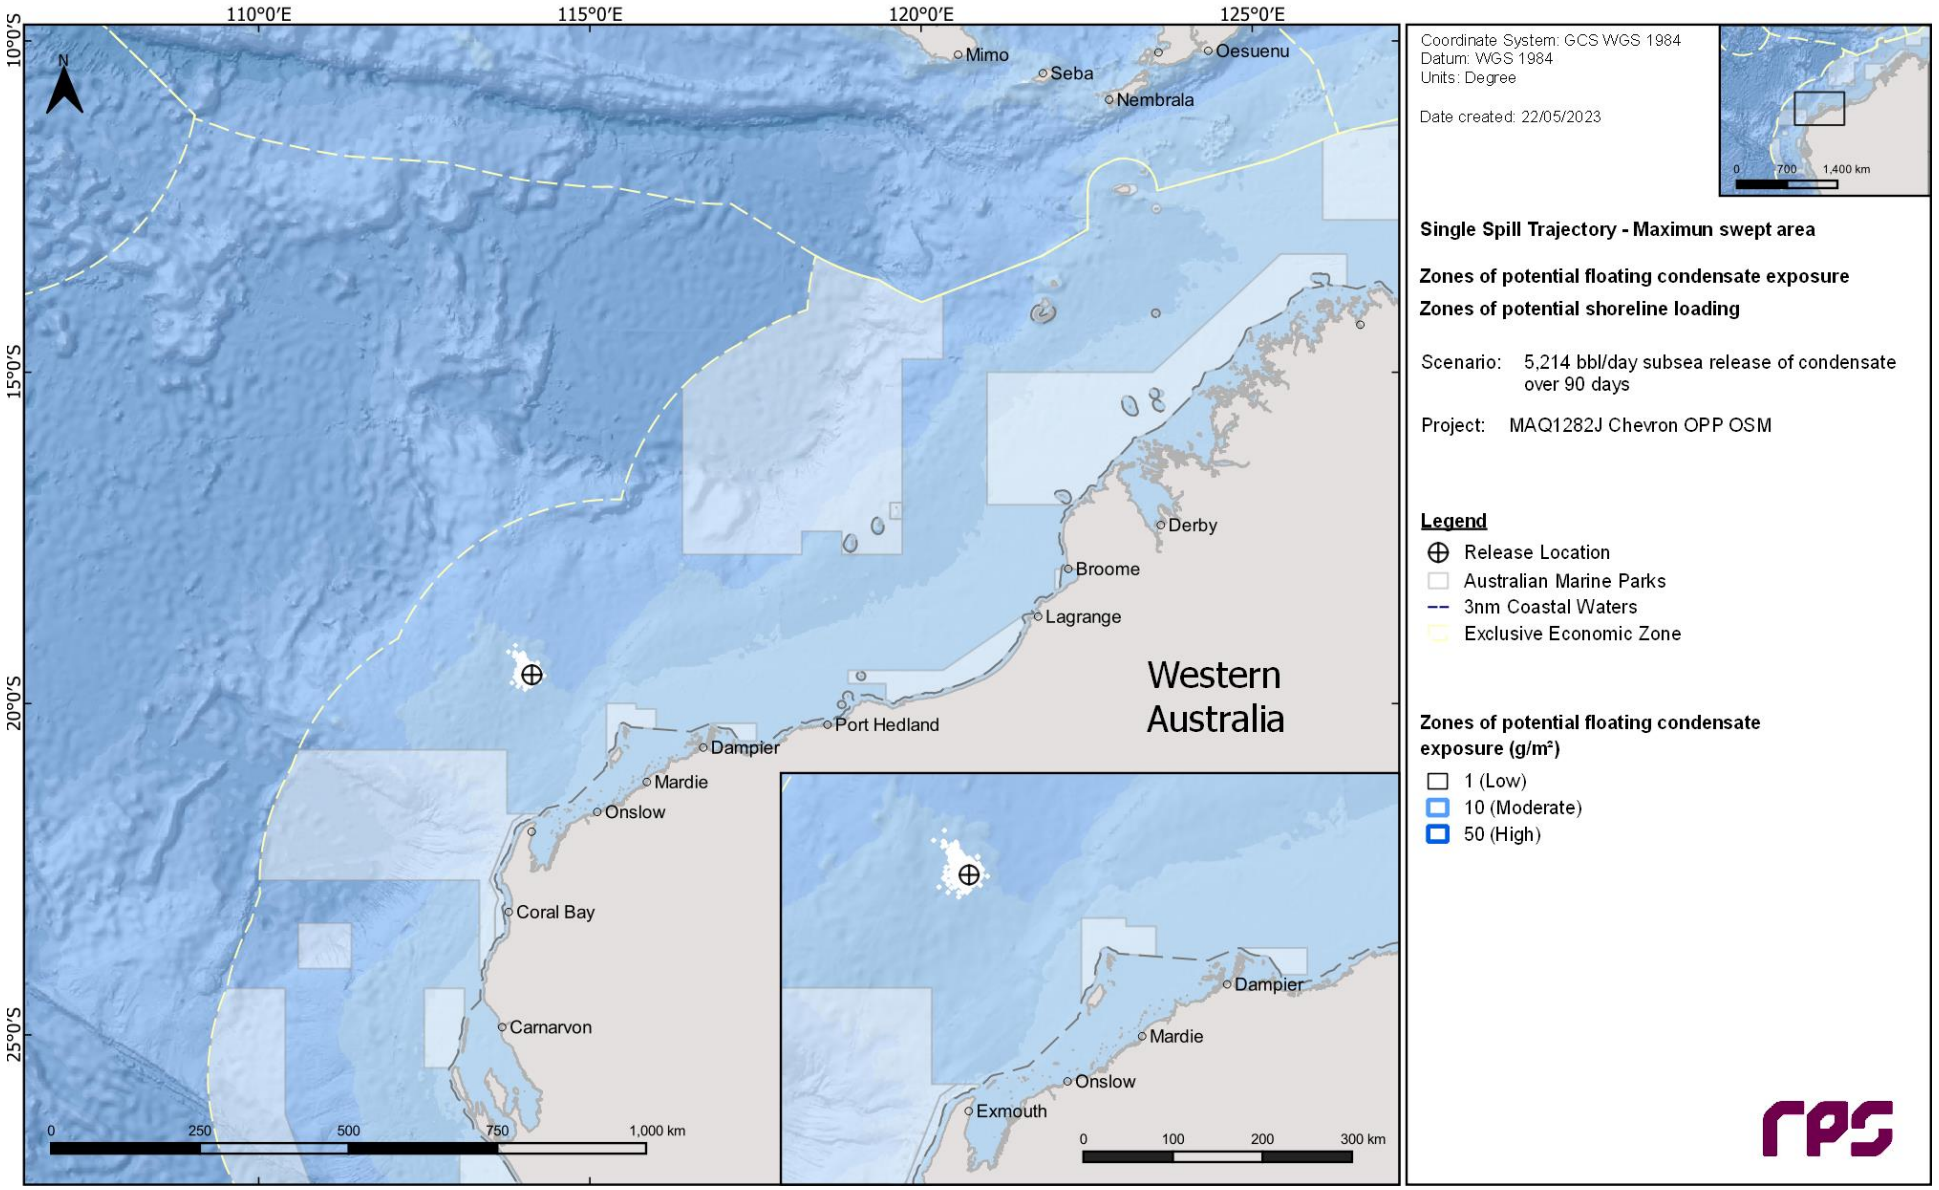

Figure 11.12 Zones of potential floating condensate exposure and shoreline accumulation over the entire 104 days, for the simulation with the largest swept area of floating condensate above 10 g/m² following a LOWC at Chandon Well 1.

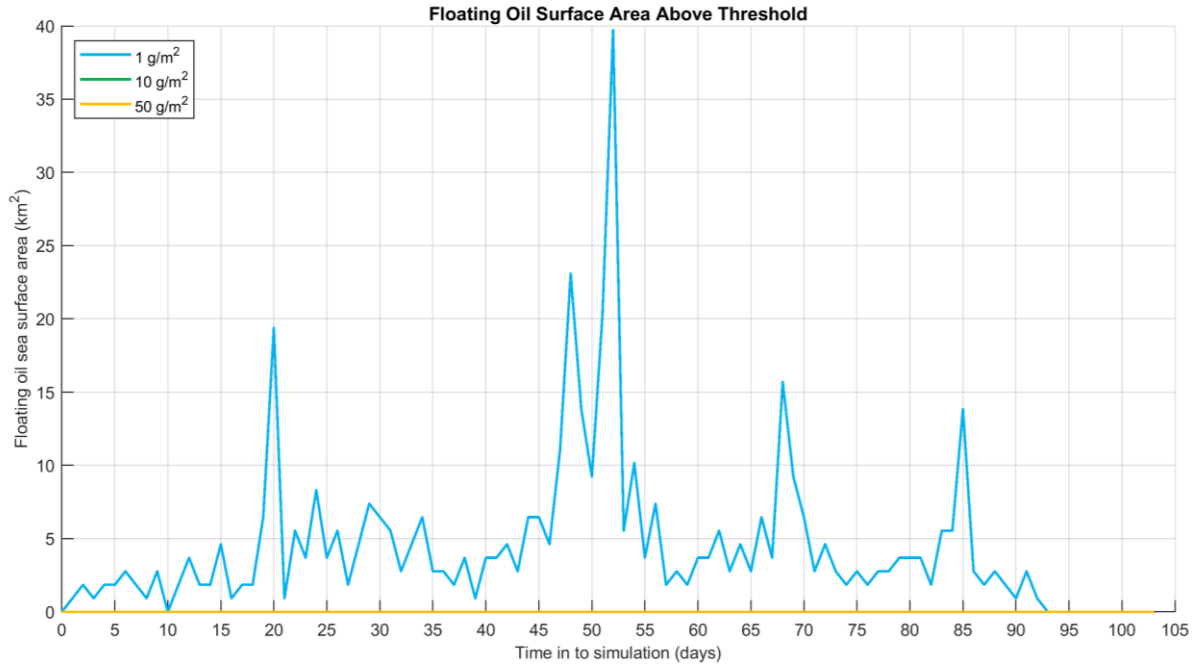

Figure 11.13 Predicted area of floating condensate exposure for each threshold, for the simulation with the largest swept area of floating condensate above 10 g/m^2 following a LOWC at Chandon Well 1.

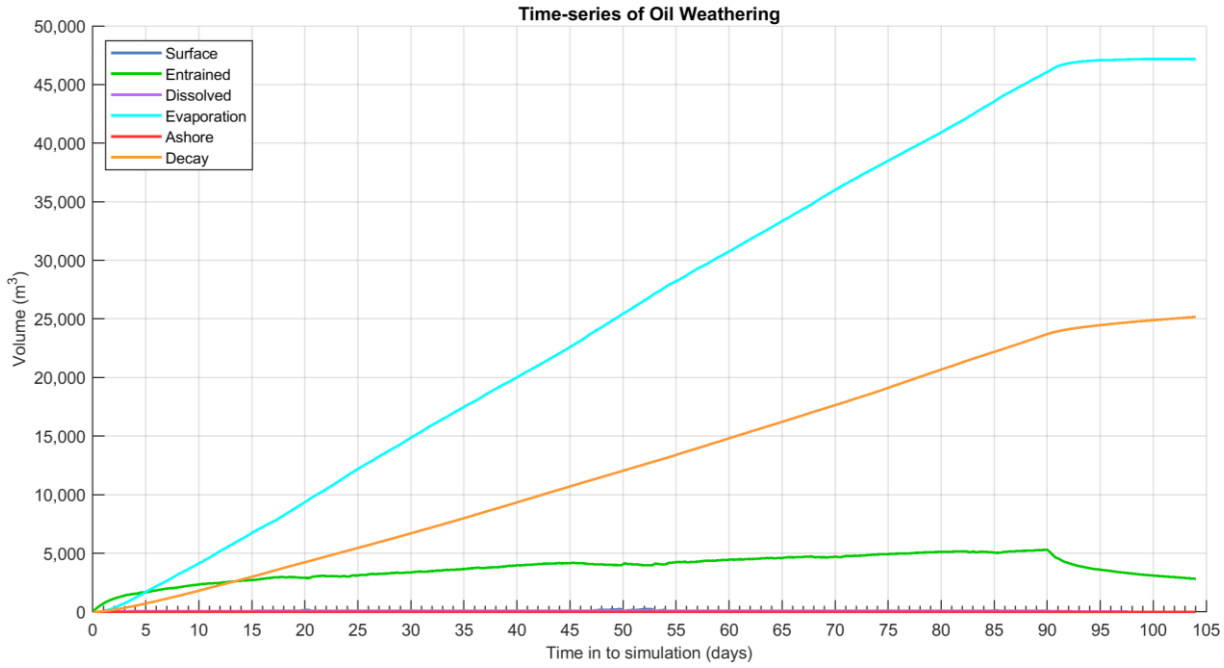

Figure 11.14 Predicted weathering and fates for the simulation with the largest swept area of floating condensate above 10 g/m^2 following a LOWC at Chandon Well 1.

11.2.2 Deterministic Case: Largest area of entrained hydrocarbons above 100 ppb

The deterministic simulation that resulted in the largest area of entrained hydrocarbons above 100 ppb (high threshold) was identified as run number 57 during the winter period.

Figure 11.15 presents the extent of the predicted entrained hydrocarbon exposure zones over the entire 104-day simulation.

Figure 11.16 displays the time series of the area of entrained hydrocarbons at the low (≥10 ppb) and high (≥100 ppb) thresholds over the 104-day simulation.

Figure 11.17 presents the fates and weathering for the corresponding single spill trajectory and Table 11.7 summarises the peak volumes and times of occurrence for each oil phase and volumes at the end of the 104-day simulation.

Table 11.7 Summary of peak volumes and times of occurrence for each oil phase and the volumes at the conclusion of the simulation (day 104), for the simulation with the largest area of entrained hydrocarbons above 100 ppb following a subsea LOWC at Chandon Well 1.

Exposure Metrics	Peak Volume	Day of Occurrence	Volume at day 104
Surface (m^3)	298	51	0
Entrained (m^3)	5,025	89	2,684
Dissolved (m^3)	84	68	3
Evaporation (m^3)	47,918	104	47,918
Decay (m^3)	24,575	104	24,575
Ashore (m^3)	0	0	0

Executive Summary

JASCO Applied Sciences (JASCO) undertook a modelling study of underwater sound levels associated with vessel activities and vertical seismic profiling (VSP) for the construction of the Chevron Gorgon Gas Development: Backfill Fields ('the Development'). This study considers representative noise sources in five representative areas across the Development (Areas 1 to 5). The five nominal areas were designated based upon bathymetry and proximity to each other to assist with the study. Some activities in Area 1, and all activities within Areas 2, 3 and 4 are within the pygmy blue whale migratory Biologically Important Area (BIA). Vessel activities comprise continuous non-impulsive noise sources, while VSP is an impulsive noise source.

Acoustic Modelling – Vessel Noise

The modelling study considers 36 individual vessel activity scenarios across the five Areas:

- Area 1 – Exmouth Plateau, furthest offshore
  - Scenario 1 - Drillship under dynamic positioning (DP)
  - Scenario 2 – Drillship under DP with an Offshore Support Vessel (OSV) (for 8 hours)
  - Scenario 3 – Pipelay under DP
  - Scenario 4 – Pipelay under DP with one resupply vessel
  - Scenario 5 – Pipelay under DP with one resupply vessel and one OSV
  - Scenario 6 – Inspection, Maintenance and Repair (IMR) vessel under DP
  - Scenario 7 – Offshore Construction Vessel (OCV) under DP
  - Scenario 8 – OCV under DP with three support vessels
- Area 2 – Between the Exmouth Plateau and the continental slope
  - Scenario 9 - Drillship under dynamic positioning (DP)
  - Scenario 10 – Drillship under DP with an OSV (for 8 hours)
  - Scenario 11 – Pipelay under DP
  - Scenario 12 – Pipelay under DP with one resupply vessel
  - Scenario 13 – Pipelay under DP with one resupply vessel and one OSV
  - Scenario 14 – IMR vessel under DP
  - Scenario 15 – OCV under DP
  - Scenario 16 – OCV under DP with three support vessels
- Area 3 – Immediately offshore of the continental slope
  - Scenario 17 - Drillship under dynamic positioning (DP)
  - Scenario 18 – Drillship under DP with an OSV (for 8 hours)
  - Scenario 19 – Pipelay under DP
  - Scenario 20 – Pipelay under DP with one resupply vessel
  - Scenario 21 – Pipelay under DP with one resupply vessel and one OSV
  - Scenario 22 – IMR vessel under DP
  - Scenario 23 – OCV under DP
  - Scenario 24 – OCV under DP with three support vessels
- Area 4 – Continental slope
  - Scenario 25 – Pipelay under DP
  - Scenario 26 – Pipelay under DP with one resupply vessel
  - Scenario 27 – Pipelay under DP with one resupply vessel and one OSV

  - Scenario 28 – IMR vessel under DP
- Area 5 – Continental shelf
  - Scenario 29 - Drillship under dynamic positioning (DP)
  - Scenario 30 – Drillship under DP with an OSV (for 8 hours)
  - Scenario 31 – Pipelay under DP
  - Scenario 32 – Pipelay under DP with one resupply vessel
  - Scenario 33 – Pipelay under DP with one resupply vessel and one OSV
  - Scenario 34 – IMR vessel under DP
  - Scenario 35 – OCV under DP
  - Scenario 36 – OCV under DP with three support vessels

Further to the 36 individual vessel activity scenarios, four combined scenarios have also been modelled, which consist of multiple vessel activities. The four combined scenarios consider the aggregate contribution of noise emissions from concurrent vessel activities, namely:

- Scenario 37 – Scenario 5 and 18 (Area 1 Pipelay with resupply vessel and OSV + Area 3 Drillship with OSV)
- Scenario 38 – Scenario 8, 14, and 18 (Area 1 OCV with three support vessels + Area 2 IMR vessel + Area 3 Drillship with OSV)
- Scenario 39 – Scenario 18 and 33 (Area 3 Drillship with OSV, Area 5 Pipelay with resupply vessel and OSV)
- Scenario 40 – Scenario 30 and 33 (Area 5 Drillship with OSV, Area 5 Pipelay with resupply vessel and OSV)

The study assessed distances from vessel activities where underwater sound levels reached thresholds corresponding to various levels of potential impact to marine fauna. The animals considered here included marine mammals, turtles, and fish. Due to the variety of species considered, there are several different thresholds for evaluating effects, including: mortality, injury, temporary reduction in hearing sensitivity, and behavioural disturbance. The modelling methodology considered scenario specific source levels and range-dependent environmental properties. Estimated underwater acoustic levels for non-impulsive (continuous) noise sources presented as sound pressure levels (SPL, L_p), and as accumulated sound exposure levels (SEL, L_E) as appropriate for different noise effect criteria. In this report, the duration of the SEL accumulation is defined as integrated over a 24 h period.

The SEL_{24h} is a cumulative metric that reflects the dosimetric impact of noise levels within 24 hours based on the assumption that an animal is consistently exposed to such noise levels at a fixed position. The corresponding SEL_{24h} radii represent an unlikely worst-case scenario. More realistically, marine mammals (as well as fish and turtles) would not stay in the same location for 24 hours. Therefore, a reported radius for SEL_{24h} criteria does not mean that marine fauna travelling within this radius of the source will be injured, but rather that an animal could be exposed to the sound level associated with impairment if it remained in that location for 24 hours.

Maps are provided in the report to assist with contextualising tabulated distances. The key results of this acoustic modelling study are summarised in Tables 1–5.

In Areas 1, 2, 3 and 5, the OCV with construction support vessels resulted in the longest distances to effect thresholds (Table 1). The 120 dB SPL marine mammal behavioural effect zone from construction activities with support vessels featured a radius of 15.7 km in Area 1, 15.4 km in Area 2, 14.0 km in Area 3, and 17.3km in Area 5. Construction activities were not modelled in Area 4, and in this Area the pipelay vessel with two support vessels resulted in the longest distances to effect

thresholds (120 dB marine mammal behavioural effect radii of 18.3 km). In every modelled Area, and for each activity, additional support vessels generated larger distances to effect thresholds (Table 1).

The smallest horizontal distances to effect thresholds were associated with scenarios that modelled a single IMR vessel; the largest marine mammal behavioural response zone for the IMR vessel was 3.76 km and the largest low-frequency (LF) cetacean TTS zone was 0.63 km (both in Area 5) (Table 1).

Offshore activities over deep water in Areas 1 and 2 generally featured smaller effect zones than equivalent activities in Areas 3, 4 and 5 where the continental shelf environment was conducive to effective sound propagation downslope (Table 1).

To consider the aggregate contribution of noise emissions from the four combined scenarios, ensonified areas were examined for Scenarios 37 – 40, rather than maximum radii. In the combined scenarios, only Scenario 40 resulted in overlapping ensonified areas such that the two behavioural effect zones of the drilling and pipelay activities combined into one larger area (with 12.9% greater ensonified area compared to the two individual scenarios) (Table 2). The SEL_{24h} areas for Scenario 40, and all effect areas for Scenarios 37, 38 and 39, did not result in merged effect zones and the percentage change in ensonified areas therefore remained low (<5%) (Table 2). The lack of change in ensonified area for Scenarios 37, 38 and 39 was primarily due to the distances between concurrent activities being larger than the sum of the effect radii of the individual activities. While the modelled sound fields presented here are specific to the modelled site locations, the effect radii provide some guidance to the spacing between individual scenarios that will result in overlapping, or merged, effect zones.

Table 1. Summary of maximum (R_{max}) horizontal distances (in km) from all scenarios considered to the marine mammal behavioural response criterion of 120 dB re 1 µPa (SPL) and frequency-weighted LF-cetacean SEL_{24h} TTS and PTS thresholds (179 and 199 dB re 1 µPa²·s, respectively) based on Southall et al. (2019).

Scenario Number	Description	Marine Mammal Behavioural Response [a]	LF-cetacean TTS [b]	LF-cetacean PTS [c]
		R_{max} (km)	R_{max} (km)	R_{max} (km)
1	Area 1, Drillship	5.62	0.78	0.08

Acoustic Modelling – Vertical Seismic Profiling

In addition to vessel noise modelling, the modelling study also considers Vertical Seismic Profiling (VSP) at three sites with a maximum of 300 shots over a 24 hour period. The three VSP locations were identified by Chevron to be representative of the range of water depths across the Development area. Site A lies on the Continental Shelf (Area 5) in the shallowest water (142.6 m), Site B is situated in Area 3, above the Continental Slope, with a water depth of 923.7 m, and Site C is situated in the deepest water, 1153 m, in Area 1.

As VSP is an impulsive noise source, the noise effect criteria are different to those in the vessel scenarios.

Of the three modelled sites, Site A generally resulted in the largest maximum horizontal distances to noise effect criteria thresholds.

Marine mammals:

The results for marine mammal injury applied the criteria from Southall et al. (2019), which requires two metrics (PK and SEL_{24h}) to be considered when assessing marine mammal PTS and TTS, with the longest distance associated with either metric being required to be applied. Table 3 summarises the maximum distances for TTS and PTS, along with the relevant metric associated with the maximum distance for the VSP results. The maximum distance where the NOAA (2019) marine mammal behavioural response criterion of 160 dB re 1 µPa (SPL) is also presented in Table 3.

Table 3. Summary of maximum (R_{max}) horizontal distances (in km) from any modelled site to behavioural response thresholds and temporary threshold shift (TTS) and permanent threshold shift (PTS) for marine mammals.

Hearing group	Modelled distance to effect threshold (R_{max} km)		
	Behavioural response [a]	Impairment: TTS [b]	Impairment: PTS [b]
Low-frequency (LF) cetaceans	2.37	3.20[c]	0.48[c]
High-frequency (HF) cetaceans		–	–
Very high-frequency (VHF) cetaceans		0.13[d]	0.06[d]

Noise exposure criteria: [a] NOAA (2019) and [b] Southall et al. (2019)
[c] Longest distance to threshold from SEL_{24h} results
[d] Longest distance to threshold from PK results
A dash indicates the threshold was not reached within the limits of the modelling resolution (20 m).

Sea turtles:

- The PK sea turtle injury criteria of 232 dB re 1 µPa for PTS and 226 dB re 1 µPa for TTS from Finneran et al. (2017) was not exceeded at a distance longer than 20 m from the acoustic centre of the source.
- The maximum distance to the SEL_{24h} metrics for PTS and TTS (Finneran et al. 2017) of 204 dB re 1 μPa^2s for PTS and 189 dB re 1 μPa^2s for TTS (summarised in Table 4) was 0.03 km for PTS onset and 0.24 km for TTS onset for the 750 in^3 seismic source. As is the case with marine mammals, a reported radius for SEL_{24h} criteria does not mean that sea turtles travelling within this radius of the source will be injured, but rather that an animal could be exposed to the sound level associated with either PTS or TTS if it remained in that location for 24 hours.
- The maximum distances to the behavioural response criteria for sea turtles of 166 dB re 1 µPa (SPL) and the 175 dB re 1 µPa (SPL) threshold for behavioural disturbance (McCauley et al. 2000) were 1.03 km and 0.27 km, respectively for the 750 in^3 seismic source (summarised in Table 4).

Table 4. Summary of maximum horizontal distances (in km) from any modelled site to behavioural response thresholds and temporary threshold shift (TTS) and permanent threshold shift (PTS) for marine turtles.

Hearing group	Behavioural response[1]	Behavioural disturbance[1]	Impairment: TTS[2]	Impairment: PTS[2]
Sea Turtles	1.03 (SPL)	0.27 (SPL)	0.24 (SEL_{24h})	0.03 (SEL_{24h})

Noise exposure criteria: [1] McCauley et al. (2000), and [2] Finneran et al. (2017)

Fish, fish eggs, and fish larvae:

This modelling study assessed the ranges for quantitative criteria based on Popper et al. (2014) and considered both PK and SEL_{24h} metrics associated with mortality and potential mortal injury as well as impairment in the following groups:

- Fish without a swim bladder (also appropriate for sharks in the absence of other information),
- Fish with a swim bladder that do not use it for hearing,
- Fish that use their swim bladders for hearing, and
- Fish eggs and fish larvae.

Table 5 summarises the maximum distances to effect criteria for fish, fish eggs, and fish larvae along with the relevant metric for both modelled locations.

Table 5. Summary of maximum fish, fish eggs, and larvae injury and temporary threshold shift (TTS) onset distances for any modelled site, for single impulse and 24 h sound exposure level (SEL_{24h}) modelled scenarios.

Relevant hearing group	Effect criteria	Water column	
		Metric associated with longest distance to criteria	R_{max} (km)
Fish: No swim bladder	Recoverable injury	–	–
	TTS	SEL_{24h}	0.57
Fish: Swim bladder not involved in hearing and Swim bladder involved in hearing	Recoverable injury	SEL_{24h}	0.05
	TTS	SEL_{24h}	0.57
Fish eggs, and larvae	Injury	SEL_{24h}	0.05

A dash indicates the threshold was not reached within the limits of the modelling resolution (20 m).

Benthic invertebrates:

To assist with assessing the potential effects on crustaceans from VSP operations, the following results were determined:

- The sound level of 202 dB re 1 µPa PK-PK from Payne et al. (2008), which is representative of no effects, was considered for seafloor sound levels; the sound level was reached at 60.8 m from the acoustic centre of the VSP array.
- Sound levels of 209–212dB re 1 µPa PK-PK from Day et al. (2016b) and 213 dB re 1 µPa from Day et al. (2016a), which are related to impairment in crustaceans, was considered; the level was not reached for any VSP modelling site at a depth of 5 cm above the seafloor.

Animal Movement Modelling

A more realistic representation of the potential exposures for migrating pygmy blue whales in the migration BIA was undertaken using animal movement modelling ('animat modelling') for five of the vessel scenarios, with the results presented separately below. While acoustic modelling inherently assumes static animals, the JASCO Animal Simulation Model Including Noise Exposure (JASMINE) combines modelled sound fields with realistic animal movements to predict how animals might be impacted through sound exposure. The exposure ranges account for animats sampling the sound field vertically and horizontally based on species-specific diving and movement parameters. JASMINE provides a framework for understanding and predicting sound exposure for species of interest and for calculating ranges to relevant regulatory thresholds. The distribution of distances to the source of simulated animals ('animats') predicted to be exposed to sound levels above relevant thresholds was used to calculate the horizontal distance that includes 95% of the animat distances that exceeded a given effect threshold ($ER_{95\%}$). Within the $ER_{95\%}$, there is generally some proportion of animats that do not exceed the threshold criteria. This occurs for several reasons, including the spatial and temporal characteristics of the sound field and the way in which the animats are exposed to the sound field over time, both vertically and horizontally. The probability that an animat within the $ER_{95\%}$ was exposed above threshold was also computed (P_{exp}) to provide additional context. Due to insufficient density data availability, the modelling results are not related to real-world density estimates for pygmy blue whales within the BIA.

Animat modelling was undertaken for a total of nine scenarios to provide an overview of the construction activities across the range of bathymetric and geological variation within the Development footprint.

The animat modelling study considered six individual vessel activity scenarios across four Areas:

- Scenario 8 – Construction (with three support vessels) in Area 1.
- Scenario 14 – IMR vessel under DP in Area 2.
- Scenario 18 – Drillship under DP with an offshore support vessel (OSV) (for 8 hours) in Area 3.
- Scenario 21 – Pipelay (with two support vessels) in Area 3.
- Scenario 30 – Drillship under DP with an offshore support vessel (OSV) (for 8 hours) in Area 5.
- Scenario 33 – Pipelay under DP with one resupply vessel and one OSV in Area 5.

Further to the six individual vessel activity scenarios, three combined scenarios have also been modelled, which consist of multiple vessel activities:

- Scenario 38 – Construction (with three support vessels) in Area 1, IMR in Area 2, and drilling (with OSV) in Area 3.
- Scenario 39 – Drilling (with OSV) in Area 3 and pipelay (with two support vessels) in Area 5.
- Scenario 40 – Drilling (with OSV) in Area 5 and pipelay (with two support vessels) in Area 5.

The key results of the animat modelling are outlined below and summarised Table 6.

- In general, exposure ranges from animal movement modelling for PTS and TTS criteria (Southall et al. 2019) are typically shorter than those predicted using acoustic propagation modelling because of the shorter time ('dwell time') to accumulate sound energy of the moving animats. In this study, there were no exposures above PTS threshold for any of the pygmy blue whale scenarios. The maximum $ER_{95\%}$ for TTS of 0.04 km with a corresponding exposure probability for animats travelling within that range of 67%.
- Exposure ranges ($ER_{95\%}$) for single exposure metrics, such as the SPL behavioural response criteria, are generally comparable to the predicted acoustic ranges. In this study, exposure ranges

were slightly lower than the R_{max} acoustic ranges based on the vertical distribution of the sound field.

- Unrestricted animat seeding resulted in exposures above the SPL behavioural response threshold (NOAA (2019)) for all considered scenarios. Of these, the maximum $ER_{95\%}$ to the threshold was 12.4 km. The probability of an animat within the $ER_{95\%}$ being exposed above the threshold was 99%.

Table 6. Summary of animat simulation results for the marine mammal behavioural response criterion of 120 dB re 1 µPa (SPL) and frequency-weighted LF-cetacean SEL_{24h} PTS and TTS thresholds for pygmy blue whales with unrestricted and restricted seeding. Maximum exposure ranges show $ER_{95\%}$ (km) first and probability of exposure of animats travelling within the $ER_{95\%}$ (P_{exp} (%)) in parentheses. A dash (-) indicates that no animat was exposed above the threshold.

Scenario Number	Description	Behavioural response (SPL)[2]	LF-cetacean TTS (SEL_{24h})[1]	LF-cetacean PTS (SEL_{24h})[1]
8	Area 1, OCV with 3 support vessels	12.4 (99%)	0.04 (67%)	–
14	Area 2, IMR vessel	0.73 (88%)	0.02 (87%)	–
18	Area 3, Drillship with OSV	3.02 (73%)	0.02 (76%)	–
21	Area 3, Pipelay vessel with resupply and support OSVs	5.03 (73%)	0.02 (91%)	–
30	Area 5, Drillship with OSV	8.03 (>99%)	0.02 (80%)	–
33	Area 5, Pipelay vessel with resupply vessel and support OSV	9.56 (>99%)	0.02 (77%)	–
38	Area 1, OCV with 3 support vessels + Area 2, IMR vessel + Area 3, drillship with OSV	12.3 (50%)	0.03 (61%)	–
39	Area 3, drillship with OSV + Area 5, pipelay vessel with 2 OSVs	9.47 (63%)	0.02 (77%)	–
40	Area 5, drillship with OSV + Area 5, pipelay vessel with 2 OSVs	9.55 (98%)	0.02 (79%)	–

[1] Southall et al. (2019) criteria for marine fauna.
[2] NOAA (2019) recommended unweighted behavioural criteria for marine mammals.

1. Introduction

JASCO Applied Sciences (JASCO) undertook a modelling study of underwater sound levels associated with vessel activities and vertical seismic profiling (VSP) for the construction of the Chevron Gorgon Gas Development: Backfill Fields, incorporating site-specific environmental parameters that affect the propagation of underwater sound. The modelling study considers 36 individual vessel scenarios (Scenarios 1–36) across five representative areas (Areas 1–5) within the Development footprint (Figure 1), four combined vessel scenarios incorporating multiple individual scenarios (Scenarios 37–40) (Section 1.1.1), and three VSP scenarios (Scenarios A, B and C) (Section 1.1.2). Vessel activities comprise continuous non-impulsive noise sources, while VSP is an impulsive noise source. The vessels considered within the study are nominal vessels representing the type and class of vessel likely to be used for the Development.

The modelling study predicted the distances from construction activities at which underwater sound levels reached noise effect thresholds and criteria for marine mammals, sea turtles and fish. The corresponding marine mammal thresholds include levels associated with behavioural response, permanent threshold shift (PTS) and temporary threshold shift (TTS), and the marine mammal functional hearing groups considered were low, high, and very-high-frequency cetaceans. Estimated underwater acoustic levels associated with vessel scenarios are presented as sound pressure levels (SPL, L_p), and accumulated sound exposure levels (over 24 hours) (SEL_{24h}, $L_{E,24h}$), as appropriate for non-impulsive (continuous) noise sources. Estimated underwater acoustic levels associated with VSP scenarios are presented as SEL_{24h}, for multiple pulses (5, 10, 25, 50, 100, 150, 200, 250, 300) over a 24 hour period, as well as single-impulse (i.e., per-pulse) metrics, including SPL, per-pulse sound exposure levels (SEL, L_E), zero-to-peak pressure levels (PK, L_{pk}), peak-to-peak pressure levels (PK-PK, $L_{pk\text{-}pk}$), as appropriate for impulsive noise sources.

The representative areas within the Development footprint are as follows:

- Area 1 – Exmouth Plateau, furthest offshore
- Area 2 – Between the Exmouth Plateau and the continental slope
- Area 3 – Immediately offshore of the continental slope
- Area 4 – Continental slope
- Area 5 – Continental shelf

The modelled vessel activity sites within each area are shown in Figure 1.

Some activities in Area 1, and all activities within Areas 2, 3, and 4 lie within the pygmy blue whale (*Balaenoptera musculus brevicauda*) migratory Biologically Important Area (BIA). Therefore, the acoustic modelling results for some vessel scenarios were used in conjunction with animal movement modelling ('animat modelling') simulations to predict the distance at which migrating pygmy blue whales are expected to be exposed above threshold criteria for PTS, TTS, and behavioural response. Sound exposure distribution estimates are determined by moving large numbers of simulated animals (animats) through a modelled time-evolving sound field, computed using specialised sound source and sound propagation models. This approach provides the most realistic prediction of the maximum expected SPL and SEL_{24h} for comparison against the relevant thresholds. Animal movement modelling was undertaken for nine vessel scenarios (Section 1.1.3) to provide an overview of the construction activities across the range of bathymetric and geological variation within the Development footprint.

This report is structured as follows: the remainder of Section 1 provides details on the scenarios considered for modelling, Section 2 explains the metrics used to represent underwater acoustic fields and the effect criteria considered. Sections 3.1 to 3.4 detail the methodology for predicting the source levels and modelling the sound propagation, including the specifications of the considered sound sources and the environmental parameters. Section 3.5 details the methodology for animat modelling of pygmy blue whales. Section 4.1 presents the acoustic results as tabulated ranges to thresholds,

Sections 4.2.1 and 0 provide sound level contour maps, and Section 4.3 includes animal movement modelling results. The acoustic and animat modelling results are then discussed in Section 5.

1.1. Details of Modelling Scenarios

1.1.1. Vessel Noise Sources

This acoustic and exposure study considered the sound-producing activities associated with thirty individual vessel scenarios (outlined in Table 7), each describing a unique combination of sound sources.

Table 7. Summary of modelled scenarios

Scenario	Associated Site(s)	Area	Scenario description
1	1	1 – Exmouth Plateau, furthest offshore	Drillship under DP
2	1 + 2		Drillship under DP + Offshore Support Vessel (OSV) under DP 8hr
3	3		Pipelay vessel under DP
4	3 + 4		Pipelay vessel + resupply vessel, both under DP
5	3 + 4 + 5		Pipelay vessel + resupply vessel + OSV, all under DP
6	6		IMR vessel under DP
7	7		Offshore Construction Vessel (OCV) under DP
8	7 + 8 + 9 + 10		OCV + 3 support vessels, all under DP
9	11	2 – Between the Exmouth Plateau and the continental slope	Drillship under DP
10	11 + 12		Drillship under DP + OSV under DP 8hr
11	13		Pipelay vessel under DP
12	13 + 14		Pipelay vessel + resupply vessel, both under DP
13	13 + 14 + 15		Pipelay vessel + resupply vessel + OSV, all under DP
14	16		IMR vessel under DP
15	17		OCV under DP
16	17 + 18 + 19 + 20		OCV + 3 support vessels, all under DP
17	21	3 – Immediately offshore of the continental slope	Drillship under DP
18	21 + 22		Drillship under DP + OSV under DP 8hr
19	23		Pipelay vessel under DP
20	23+24		Pipelay vessel + resupply vessel, both under DP
21	23+24+25		Pipelay vessel + resupply vessel + OSV, all under DP
22	26		IMR vessel under DP
23	27		OCV under DP
24	27+28+29+30		OCV + 3 support vessels, all under DP
25	31	4 – Continental slope	Pipelay vessel under DP
26	31+32		Pipelay vessel + resupply vessel, both under DP
27	31+32+33		Pipelay vessel + resupply vessel + OSV, all under DP
28	34		IMR vessel under DP
29	35	5 – Continental shelf	Drillship under DP
30	35+36		Drillship under DP + OSV under DP 8hr
31	37		Pipelay vessel under DP
32	37+38		Pipelay vessel + resupply vessel, both under DP
33	37+38+39		Pipelay vessel + resupply vessel + OSV, all under DP
34	40		IMR vessel under DP
35	41		OCV under DP
36	41+42+43+44		OCV + 3 support vessels, all under DP

Scenarios 1 and 2, 9 and 10, 17 and 18, and 29 and 30 represent the operation of a drillship (nominally, the *Dhirubhai Deepwater KG2*), with and without the addition of an Offshore Support Vessel (OSV), respectively, across Area 1, 2, 3 and 5. The drillship has been assumed to operate continuously (24 h), under dynamic positioning (DP) in a static location. The OSV has been modelled using a representative generic vessel, the *MMA Leeuwin*, which has been considered on DP attendance alongside the drillship for 8 hours per day.

Scenarios 3–5, 11–13, 19–21, 25–27, and 31–33 represent the operation of a pipelay vessel in each of the five Areas with none, one, or two support vessels, respectively. The *Allseas Solitaire* has been considered as a representative pipelay vessel. Scenarios with one support vessel include a resupply vessel (nominally *Allseas Alegria*) alongside the pipelay vessel, and scenarios with two support vessels include the resupply vessel and a generic OSV (again represented by the *MMA Leeuwin*) alongside the pipelay vessel. All vessels are assumed to operate under DP for 24 h per day, travelling at 0.3 km per day along the supplied track-lines.

Scenarios 6, 14, 22, 28 and 34 represent the activities of an Inspection, Maintenance and Repair (IMR) vessel, which has been represented by the *Skandi Hercules*. This vessel is modelled in each of the five Areas for 24 h per day under static DP.

Scenarios 7, 15, 23 and 35 represent the operation of an Offshore Construction Vessel (OCV) (nominally the *Skandi Africa*) in Areas 1, 2, 3 and 5, respectively. Scenarios 8, 16, 24 and 36 represent the OCV with the addition of three support vessels; a tug (represented by *Mermaid Sound*), and two OSVs (represented by *MMA Chieftain* and *MMA Coral)*. In these scenarios, all vessels are assumed to operate statically under DP for 24 h per day.

Figure 1 displays an overview of the modelling area showing the locations of the modelled sites within their respective Areas, the pygmy blue whale BIA (and the humpback whale migratory BIA for reference), and the regional bathymetry.

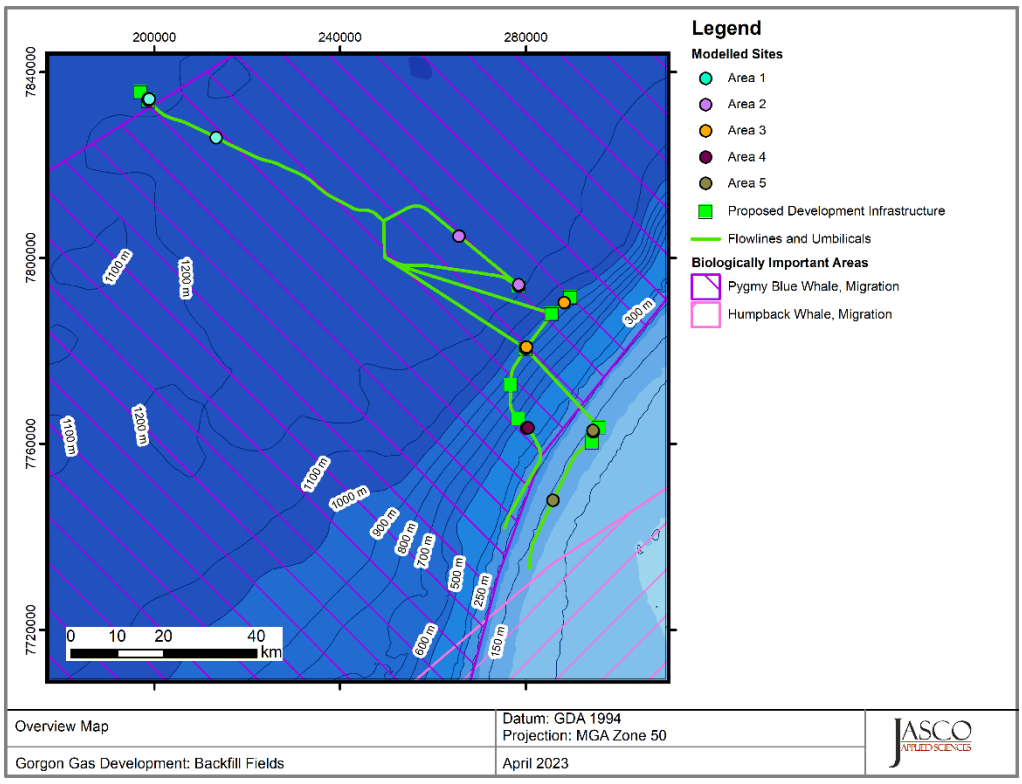

Figure 1. Overview map of the Chevron 'Gorgon Gas Development: Backfill Fields' showing the modelled vessel activity site locations within each representative Development area.

The 36 scenarios outlined in Table 7 comprise a total of 44 acoustic modelling sites that were selected to represent the extent of the construction activities, and these are listed in Table 8. Detailed maps illustrating the site locations within each of the five Areas are included as Figures 2 to 6.

Table 8. Location details for the vessel acoustic modelling sites

Site	Area	Vessel Type	Latitude (S)	Longitude (E)	MGA[1] Zone 50		Water Depth (m)
					X (m)	Y (m)

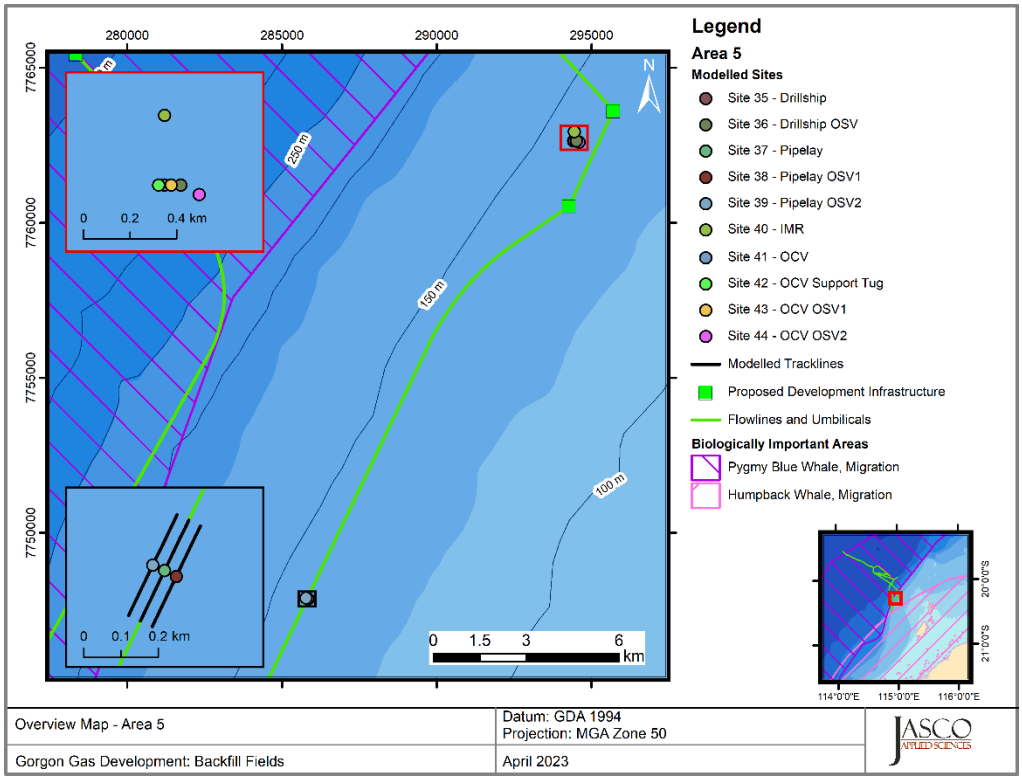

Figure 6. Overview map of Area 5 modelled sites for the Chevron 'Gorgon Gas Development: Backfill Fields' construction scenarios with two zoom inserts focusing on the stationary modelled sites (red, top left) and the modelled pipelay tracklines (black, bottom left).

In addition to the 36 individual vessel scenarios, four combined scenarios have also been modelled, which consider the aggregate contribution of noise emissions from concurrent works. The four combined scenarios are summarised in Table 9.

Table 9. Summary of modelled combined scenarios.

Combined scenario	Associated individual scenarios	Associated sites	Scenario description
37	5, 18	3, 4, 5, 21, 22	Area 1, pipelay vessel with 2 support vessels + Area 3, drillship with OSV
38	8, 14, 18	7, 8, 9, 10, 16, 21, 22	Area 1, OCV with 3 support vessels + Area 2, IMR vessel + Area 3, drillship with OSV
39	18, 33	21, 22, 37, 38, 39	Area 3, drillship with OSV + Area 5, pipelay vessel with 2 support vessels
40	30, 33	35, 36, 37, 38, 39	Area 5, drillship with OSV + Area 5, pipelay vessel with 2 support vessels

1.1.2. Vertical Seismic Profiling Acoustic Source

The modelling study considers three VSP scenarios occurring at three sites as shown in Figure 7 and detailed in Table 10. The three VSP locations were identified by Chevron to be representative of the range of water depths across the Development area. Site A lies on the Continental Shelf (Area 5) in the shallowest water (142.6 m), Site B is situated in Area 3, above the Continental Slope, with a water depth of 923.7 m, and Site C is situated in the deepest water, 1153 m, in Area 1.

Table 10. Location details for VSP acoustic modelling sites

Site	Area	Latitude (S)	Longitude (E)	MGA[1] Zone 50		Water depth (m)
				X (m)	Y (m)	
A	5	20° 13' 20.9892" S	115° 1' 56.172" E	294424.9	7762676	142.6
B	3	20° 3' 33.3684" S	114° 53' 45.3372" E	279947.4	7780574	923.7
C	1	19° 34' 0.822" S	114° 7' 42.5784" E	198714	7833915	1153

[1] Map Grid of Australia (MGA)

The proposed VSP array has a total volume of 750 in^3 in a delta cluster configuration. A set of nine aggregate exposure (SEL_{24h}) scenarios were modelled at each VSP location with 5, 10, 25, 50, 100, 200, 250, and 300 shots over 24 hours to realistically represent a range of potential operations.

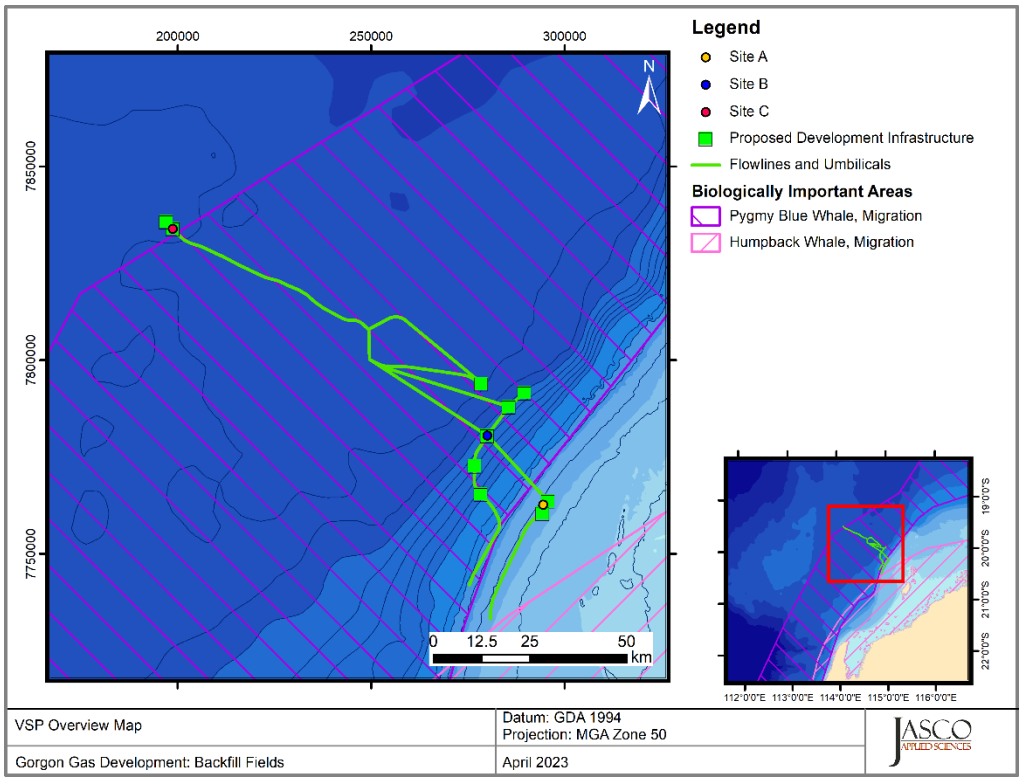

Figure 7. VSP Overview Map.

1.1.3. Animal Movement Modelling

Animal movement modelling simulations were run for migrating pygmy blue whales for vessel Scenarios 8, 14, 18, 21, 30, 33, 38, 39 and 40, as summarised in Table 7 and Table 9. Each of the animat simulations were run for a representative 24 h duration. The simulation area was selected to encompass a buffer of approximately 30 km from either modelled site, in any direction, based on the maximum acoustic range. Figure 8 shows an overview of the animat modelling simulation extents, along with the scenario locations and the pygmy blue whale BIA.

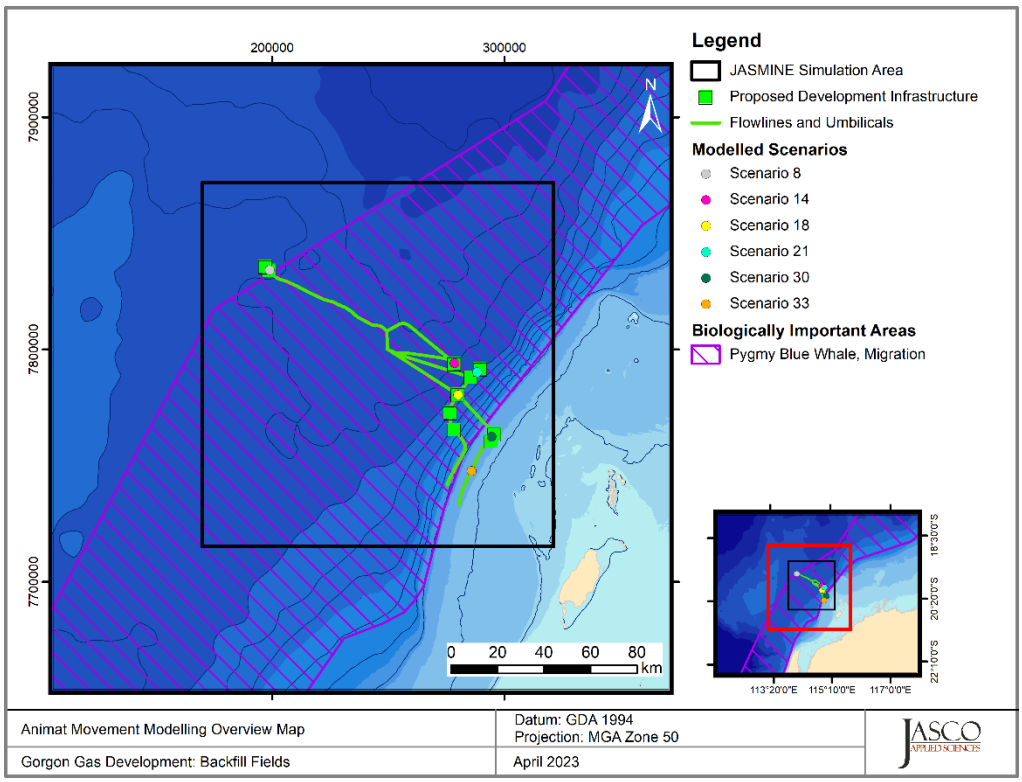

Figure 8. Overview map of the Chevron 'Gorgon Gas Development: Backfill Fields' construction scenarios, showing the animat movement modelling simulation extents along with the scenario locations and the pygmy blue whale BIAs.

2. Noise Effect Criteria

To assess the potential effects of a sound-producing activity, it is necessary to first establish exposure criteria and associated thresholds for which sound levels may be expected to have an adverse effect on animals. Whether acoustic levels might injure or disturb marine fauna is an active research topic. Since 2007, several expert groups have developed SEL-based assessment approaches for evaluating auditory injury, with key works including Southall et al. (2007), Finneran and Jenkins (2012), Popper et al. (2014), United States National Marine Fisheries Service (NMFS 2018) and Southall et al. (2019). The number of studies that investigate the level of behavioural disturbance to marine fauna by anthropogenic sound has also increased substantially.

Two sound level metrics, SPL and SEL, are commonly used to evaluate non-impulsive noise and its effects on marine life. In this report, the duration of the SEL accumulation is defined as integrated over a 24-hour period. The acoustic metrics in this report reflect the ANSI and ISO standards for acoustic terminology, ANSI S1.1 (S1.1-2013) and ISO 18405:2017 (2017).

The following thresholds and guidelines for this study were chosen because they represent the best available science:

1. Marine mammals:
    a. Peak pressure levels (PK; L_{pk}) and frequency–weighted accumulated sound exposure levels (SEL; $L_{E,24h}$) from Southall et al. (2019) for the onset of permanent threshold shift (PTS) and temporary threshold shift (TTS) in marine mammals for non–impulsive and impulsive sources.
    b. Marine mammal behavioural thresholds based on the current interim U.S. National Oceanic and Atmospheric Administration (NOAA) (2019) unweighted criterion for marine mammals of 120 dB re 1 µPa (SPL; L_p) and 160 dB re 1 µPa (SPL; L_p) for non–impulsive and impulsive sound sources.
2. Fish, fish eggs, and larvae:
    a. Sound exposure guidelines for fish, fish eggs, and larvae (Popper et al. 2014).
3. Sea turtles:
    a. Frequency–weighted accumulated sound exposure levels (SEL; $L_{E,24h}$) from Finneran et al. (2017) for the onset of PTS and TTS in turtles for non–impulsive and impulsive sound sources.
    b. Sea turtle behavioural response threshold of 166 dB re 1 µPa (SPL; L_p) for impulsive noise, along with a sound level associated with behavioural disturbance 175 dB re 1 µPa (SPL; L_p) (McCauley et al. 2000).
4. Invertebrates:
    a. Peak-peak pressure levels (PK-PK; $L_{pk\text{-}pk}$) and particle acceleration (ms^{-2}) at the seafloor to help assess effects of noise on crustaceans through comparing to results in Day et al. (2016a), Day et al. (2019), Day et al. (2016b), Day et al. (2017) and Payne et al. (2008).

Section 2.1, along with Appendix A.3 and A.4, expand on the thresholds, guidelines, and sound levels for marine mammals.

2.1. Marine Mammals

Cetaceans represent a potentially sensitive receptor group of marine mammals and were the focus of this assessment. The criteria applied in this study to assess possible effects of non-impulsive noise sources on marine mammals are summarised in Table 11, with impulsive noise criteria summarised in Table 12.

2.1.1. Injury and Hearing Sensitivity Changes

There are two categories of auditory threshold shifts or hearing loss: permanent threshold shift (PTS), a physical injury to an animal's hearing organs; and temporary threshold shift (TTS), a temporary reduction in an animal's hearing sensitivity as the result of receptor hair cells in the cochlea becoming fatigued.

To assist in assessing the potential for effect on marine mammals, this report applies the criteria recommended by Southall et al. (2019), considering both PTS and TTS (see Table 11). Appendix A.3 provides more information about the Southall et al. (2019) criteria, with frequency weighting explained in detail in Appendix A.4.

2.1.2. Behavioural Response

The NMFS noise criterion was selected for this assessment because it represents the most commonly applied behavioural response criterion by regulators. Whilst the newly published Southall et al. (2021) provides recommendations and discusses the nuances of assessing behavioural response, the authors of the study do not present new numerical thresholds for onset of behavioural responses for marine mammals, so the previously established guidelines from the US National Oceanic and Atmospheric Administration (NOAA) (2019) have been used. Accordingly, behavioural responses were assumed to occur in areas ensonified above an unweighted SPL of 120 dB re 1 µPa for continuous noise sources (Table 11), and 160 dB re 1 µPa for impulsive noise sources (Table 12) (NOAA 2019). Appendix A.3 provides more information about the development of this criteria.

Table 11. Criteria for effects of non-impulsive noise exposure, including vessel noise, for marine mammals: Unweighted SPL and SEL_{24h} thresholds.

Hearing group	NOAA (2019)	Southall et al. (2019)	
	Behaviour	PTS onset thresholds (received level)	TTS onset thresholds (received level)
	SPL (Lp; dB re 1 µPa)	Weighted SEL24h (LE,24h; dB re 1 µPa2·s)	Weighted SEL24h (LE,24h; dB re 1 µPa2·s)
Low-frequency (LF) cetaceans	120	199	179
High-frequency (HF) cetaceans		198	178
Very High-frequency (VHF) cetaceans		173	153

L_p denotes sound pressure level period and has a reference value of 1 µPa.
L_E denotes cumulative sound exposure over a 24 h period and has a reference value of 1 $\mu Pa^2 \cdot s$.

Table 12. Criteria for effects of impulsive noise exposure for marine mammals: Unweighted sound pressure level (SPL), 24 h sound exposure level (SEL_{24h}), and peak (PK) thresholds.

Hearing group	NOAA (2019)	Southall et al. (2019)			
	Behaviour	PTS onset thresholds [a] (received level)		TTS onset thresholds [a] (received level)	
	SPL (L_p; dB re 1 µPa)	Weighted SEL_{24h} ($L_{E,24h}$; dB re 1 µPa²·s)	PK (L_{pk}; dB re 1 µPa)	Weighted SEL_{24h} ($L_{E,24h}$; dB re 1 µPa²·s)	PK (L_{pk}; dB re 1 µPa)
Low-Frequency (LF) cetaceans	160	183	219	168	213
High-frequency (HF) cetaceans		185	230	170	224
Very high-frequency (VHF) cetaceans		155	202	140	196
Otariid seals		183	232	168	226

[a] Dual metric acoustic thresholds for impulsive sounds: Use whichever results in the largest isopleth for calculating PTS onset. If a non-impulsive sound has the potential of exceeding the peak sound pressure level thresholds associated with impulsive sounds, these thresholds should also be considered.

L_p denotes sound pressure level period.

$L_{pk,flat}$ denotes peak sound pressure is flat weighted or unweighted.

L_E denotes cumulative sound exposure over a 24 h period.

2.2. Fish, Sea Turtles, Fish Eggs, and Fish Larvae

In 2006, the Working Group on the Effects of Sound on Fish and Sea Turtles was formed to continue developing noise exposure criteria for fish and sea turtles, work begun by a NOAA panel two years earlier. The Working Group developed guidelines with specific thresholds for different levels of effects for several species groups (Popper et al. 2014). The guidelines define quantitative thresholds for three types of immediate effects:

- Mortality, including injury leading to death,
- Recoverable injury, including injuries unlikely to result in mortality, such as hair cell damage and minor haematoma, and
- TTS.

Masking and behavioural effects can be assessed qualitatively, by assessing relative risk rather than by specific sound level thresholds. However, as these depend upon activity-based subjective ranges, these effects are not addressed in this report and are included in Section 2.2.1 for completeness only. Because the presence or absence of a swim bladder has a role in hearing, fish's susceptibility to injury from noise exposure depends on the species and the presence and possible role of a swim bladder in hearing. Thus, different thresholds were proposed for fish without a swim bladder (also appropriate for sharks and applied to whale sharks in the absence of other information), fish with a swim bladder not used for hearing, and fish that use their swim bladders for hearing. The criteria for fish, fish eggs, fish larvae and sea turtles are presented below.

2.2.1. Fish, Eggs, and Larvae

Table 13 lists the relevant effects thresholds from Popper et al. (2014) for non-impulsive noise. Some evidence suggests that fish sensitive to acoustic pressure show a recoverable loss in hearing sensitivity, or injury when exposed to high levels of noise (Scholik and Yan 2002, Amoser and Ladich 2003, Smith et al. 2006); this is reflected in the SPL thresholds for fish with a swim bladder involved in hearing.

Table 13. Criteria for non-impulsive (vessel and drilling) noise exposure for fish and sea turtles, adapted from Popper et al. (2014).

Type of animal	Mortality and Potential mortal injury	Impairment			Behaviour
		Recoverable injury	TTS	Masking	
Fish: No swim bladder (particle motion detection)	(N) Low (I) Low (F) Low	(N) Low (I) Low (F) Low	(N) Moderate (I) Low (F) Low	(N) High (I) High (F) Moderate	(N) Moderate (I) Moderate (F) Low
Fish: Swim bladder not involved in hearing (particle motion detection)	(N) Low (I) Low (F) Low	(N) Low (I) Low (F) Low	(N) Moderate (I) Low (F) Low	(N) High (I) High (F) Moderate	(N) Moderate (I) Moderate (F) Low
Fish: Swim bladder involved in hearing (primarily pressure detection)	(N) Low (I) Low (F) Low	170 dB SPL for 48 h	158 dB SPL for 12 h	(N) High (I) High (F) High	(N) High (I) Moderate (F) Low
Sea turtles	(N) Low (I) Low (F) Low	(N) Low (I) Low (F) Low	(N) Moderate (I) Low (F) Low	(N) High (I) High (F) Moderate	(N) High (I) Moderate (F) Low
Fish eggs and fish larvae	(N) Low (I) Low (F) Low	(N) Low (I) Low (F) Low	(N) Low (I) Low (F) Low	(N) High (I) Moderate (F) Low	(N) Moderate (I) Moderate (F) Low

Sound pressure level dB re 1 µPa.
Relative risk (high, moderate, low) is given for animals at three distances from the source defined in relative terms as near (N), intermediate (I), and far (F).

Impulsive noise from airguns (i.e., from VSP) was assessed in this study based on the relevant effects thresholds from Popper et al. (2014) listed in Table 14. In general, whether an impulsive sound adversely effects fish behaviour depends on the species, the state of the individual exposed, and other factors.

The SEL metric integrates noise intensity over some period of exposure. Because the period of integration for regulatory assessments is not well defined for sounds that do not have a clear start or end time, or for very long-lasting exposures, an exposure evaluation time must be defined. Southall et al. (2007) defines the exposure evaluation time as the greater of 24 h or the duration of the activity. Popper et al. (2014) recommend a standard period of the duration of the activity; however, the publication also includes caveats about considering the actual exposure times if fish move. Integration times in this study for VSP operations have been applied over the total number of impulses per day.

Table 14. Criteria for impulsive noise exposure for fish, adapted from Popper et al. (2014).

Type of animal	Mortality and Potential mortal injury	Impairment			Behaviour
		Recoverable injury	TTS	Masking	
Fish: No swim bladder (particle motion detection)	> 219 dB SEL_{24h} or > 213 dB PK	> 216 dB SEL_{24h} or > 213 dB PK	>> 186 dB SEL_{24h}	Pile driving: (N) Moderate (I, F) Low Seismic: (N, I, F) Low	(N) High (I) Moderate (F) Low
Fish: Swim bladder not involved in hearing (particle motion detection)	210 dB SEL_{24h} or > 207 dB PK	203 dB SEL_{24h} or > 207 dB PK	>> 186 dB SEL_{24h}	Pile driving: (N) Moderate (I, F) Low Seismic: (N, I, F) Low	(N) High (I) Moderate (F) Low
Fish: Swim bladder involved in hearing (primarily pressure detection)	207 dB SEL_{24h} or > 207 dB PK	203 dB SEL_{24h} or > 207 dB PK	186 dB SEL_{24h}	Pile driving: (N, I) High (F) Moderate Seismic: (N, I) Low (F) Moderate	(N, I) High (F) Moderate
Fish eggs and fish larvae	> 210 dB SEL_{24h} or > 207 dB PK	(N) Moderate (I) Low (F) Low	(N) Moderate (I) Low (F) Low	Pile driving: (N) Moderate (I, F) Low Seismic: (N, I, F) Low	(N) Moderate (I, F) Low

Peak sound pressure level dB re 1 µPa; SEL_{24h} dB re 1µPa^2·s.
All criteria are presented as sound pressure even for fish without swim bladders since no data for particle motion exist.
Relative risk (high, moderate, low) is given for animals at three distances from the source defined in relative terms as near (N), intermediate (I), and far (F).

2.2.2. Sea Turtles

There is a paucity of data regarding responses of turtles to acoustic exposure, and no studies of hearing loss due to exposure to loud sounds. Popper et al. (2014) suggested thresholds for onset of mortal injury (including PTS) and mortality for sea turtles and, in absence of taxon-specific information, adopted the levels for fish that do not hear well (suggesting that this likely would be conservative for sea turtles) (Table 13). Finneran et al. (2017) presented revised thresholds for turtle injury, considering frequency weighted SEL, which have been applied in this study for vessels (Table 15). Their rationale is that sea turtles have best sensitivity at low frequencies and are known to have poor auditory sensitivity (Bartol and Ketten 2006, Dow Piniak et al. 2012). Accordingly, TTS and PTS thresholds for turtles are likely more similar to those of fishes than to marine mammals (Popper et al. 2014).

Table 15. Acoustic effects of non-impulsive noise on sea turtles, weighted SEL_{24h}, Finneran et al. (2017).

PTS onset thresholds* (received level)	TTS onset thresholds* (received level)
220	200

[a] L_E, cumulative sound exposure over a 24 h period, with a reference value of 1 µPa^2·s.

McCauley et al. (2000) observed the behavioural response of caged sea turtles (green (*Chelonia mydas*) and loggerhead (*Caretta caretta*)) to an approaching seismic airgun. For received levels above 166 dB re 1 µPa (SPL), the sea turtles increased their swimming activity, and above 175 dB re 1 µPa they began to behave erratically, which was interpreted as an agitated state. The Recovery Plan for Marine Turtles in Australia (Department of the Environment and Energy et al. 2017) acknowledges the 166 dB re 1 µPa SPL reported (McCauley et al. 2000) as the level that may result in a behavioural response to marine turtles. The 175 dB re 1 µPa level from McCauley et al. (2000) is recommended as a criterion for behavioural disturbance. These thresholds are shown in Table 16.

Table 16. Acoustic effects of impulsive noise on sea turtles: Unweighted sound pressure level (SPL), 24 h sound exposure level (SEL_{24h}), and peak pressure (PK) thresholds.

Effect type	Criterion	SPL (L_p; dB re 1 µPa)	Weighted SEL_{24h} ($L_{E,24h}$; dB re 1 µPa²·s)	PK (L_{pk}; dB re 1 µPa)
Behavioural response	McCauley et al. (2000)	166	NA	
Behavioural disturbance		175		
PTS onset thresholds [a] (received level)	Finneran et al. (2017)	NA	204	232
TTS onset thresholds [a] (received level)			189	226

[a] Dual metric acoustic thresholds for impulsive sounds: Use whichever results in the largest isopleth for calculating PTS and TTS onset. If a non-impulsive sound has the potential of exceeding the peak sound pressure level thresholds associated with impulsive sounds, these thresholds should also be considered.

L_p denotes sound pressure level period and has a reference value of 1 µPa.

$L_{pk,flat}$ denotes peak sound pressure is flat weighted or unweighted and has a reference value of 1 µPa.

L_E denotes cumulative sound exposure over a 24 h period and has a reference value of 1 µPa²s.

2.3. Invertebrates

Research is ongoing into the relationship between sound and its effects on crustaceans, including the relevant metrics for both effect and impact. Available literature suggests particle motion, rather than sound pressure, is a more important factor for crustacean and bivalve hearing. Water depth and seismic source size are related to the particle motion levels at the seafloor, with larger arrays and shallower water being related to higher particle motion levels, more likely relevant to effects on crustaceans and bivalves. Information is only available to define levels for assessment for impulsive sources.

At the seafloor interface, crustaceans and bivalves are subject to particle motion stimuli from several acoustic or acoustically induced waves. These include the particle motion associated with an impinging sound pressure wave in the water column (the incident, reflected, and transmitted portions), substrate acoustic waves, and interface waves of the Scholte type. However, it is unclear which aspect(s) of these waves is/are most relevant to the animals, either when they normally sense the environment or their physiological responses to loud sounds so there is not enough information to establish similar criteria and thresholds as done for marine mammals and fish. Including recent research, such as Day et al. (2016b), current literature does not clearly define an appropriate metric or identify relevant levels (pressure or particle motion) for an assessment. This includes the consideration of what particle motion levels lead to a behavioural response, or mortality. Therefore, at this stage, we cannot propose authoritative thresholds to inform the impact assessment. However, levels can be determined for pressure metrics presented in literature to assist the assessment.

The pressure and acceleration examples provided in Day et al. (2016a)) indicate that the acceleration and pressure signals occurred simultaneously, which was interpreted as an indication that the waterborne sounds were responsible for the accelerations measured by the geophones. For clarity, it is important to distinguish that the acceleration from waterborne sound energy is not ground roll,

which Day et al. (2016a) correctly define as the sound that propagates along the interface at a speed lower than the shear wave speed of the sediment. However, the report subsequently uses ground roll for all further discussions of particle acceleration. While Day et al. (2016a) discuss that they chose the simplest measure of ground roll, it should have been referred to as “the acceleration from waterborne sound energy”, or ‘waterborne acceleration’ for short.

For crustaceans, a PK-PK sound level of 202 dB re 1 µPa (Payne et al. 2008) is considered to be associated with no effect, and it was therefore applied in this assessment. Additionally for context related to different levels of potential impairment, the PK-PK sound levels determined for crustaceans in Day et al. (2016b), 209–212 dB re 1 µPa and 213 dB re 1 µPa from Day et al. (2019), are also included.

3. Methods

The modelled sites have been split into five representative Areas to capture the variability of the marine environment across the Development footprint (refer to Figure 1 and the wide regional bathymetry in Appendix B.1.1). Area 1 is furthest from shore and the modelled sites are located in water depths of 1,149 m to 1,292 m. The modelled drilling, IMR and construction activities in Area 1 (Scenarios 1, 2, 6, 7 and 8) lie outside of the pygmy blue whale BIA. The modelled pipelaying activities in Area 1 (Scenarios 3, 4 and 5) lie within the pygmy blue whale BIA.

All activities in Areas 2 to 4 lie within the pygmy blue whale BIA. The water depths of modelled sites in Area 2 range from 1208 m to 1328 m. Area 3 is located over the foot of the continental slope; the water depths of modelled sites in Area 3 range from 918 m to 974 m. Area 4 considers modelled sites directly above the continental shelf, in 400 m of water. The water depth of the modelled sites for Area 4 was chosen based on a sensitivity analysis of seven slope locations of varying water depth; the chosen location resulted in the largest ranges to considered isopleth criteria.

Finally, Area 5 represents vessel activities on the continental shelf, in water depths of 141m to 145 m. Area 5 activities are located outside of the pygmy blue whale BIA.

To allow for operational flexibility, the sound speed profile implemented within the modelling was selected through a sensitivity analysis considering all months of the year. The month of August was found to be the most favourable for sound propagation, resulting in the largest ranges to considered isopleths criteria. As such, August was selected as the conservative choice for modelling. Additional detail can be found in Appendix B.1.2.

Geoacoustics information for Areas 1, 2, 3 and 4 were taken from Duncan and Erbe (2019) as provided by the client. For Area 1, the seabed geoacoustic model was characterised by 5 m of silt overlaying a 200 m thick package of silt and sand sediments underlain by a sedimentary rock half space. Areas 2 and 3 were modelled with a geoacoustic profile characterised by ~300m thick package of silt and sand sediments underlain by a sedimentary rock half space. Area 4 utilised a ‘Slope’ geoacoustic profile characterised by 50 m of silt overlaying a 150 m thick package of silt and sand sediments underlain by a sedimentary rock half space. Area 5, on the continental shelf, was adjacent to drill core site obtained during IODP Cruise 356 (Gallagher et al. 2017). The geoacoustic profile from the sampled core was therefore utilised during modelling of sites in Area 5; a 450 m thick package of unconsolidated sediments underlain by a sedimentary rock half space. Further details on the associated geoacoustic properties used in this modelling study are provided in Appendix B.1.3.

The following sections provide a high-level description of the inputs used for this underwater noise modelling study. The sections are divided into subsections detailing the source inputs for the different vessels (Section 3.1) and VSP activities (Section 3.2), with Sections 3.3 and 3.4 providing details on the applied modelling techniques and model configuration information. Section 3.5 provides details on the animal movement modelling methodology.

3.1. Vessel Noise Sources

Underwater sound that radiates from vessels is produced mainly by propeller and thruster cavitation, with a smaller fraction of noise produced by sound transmitted through the hull, such as by engines, gearing, and other mechanical systems. Sound levels tend to be the highest when thrusters are used to position the vessel and when the vessel is transiting at high speeds. A vessel's sound signature depends on the vessel's size, power output, propulsion system (e.g., conventional propellers vs. Voith Schneider propulsion), and the design characteristics of the given system (e.g., blade shape and size). A vessel produces broadband noise emissions with most of the energy emitted below a few kilohertz. Sound from onboard machinery, particularly sound below 200 Hz, dominates the sound spectrum before cavitation begins (Spence et al. 2007).

For the modelled vessels, Figures 9 to 11 present summary plots of considered source spectra for comparison purposes; additional detail on the sources is provided in Sections 3.1.1 to 3.1.4.

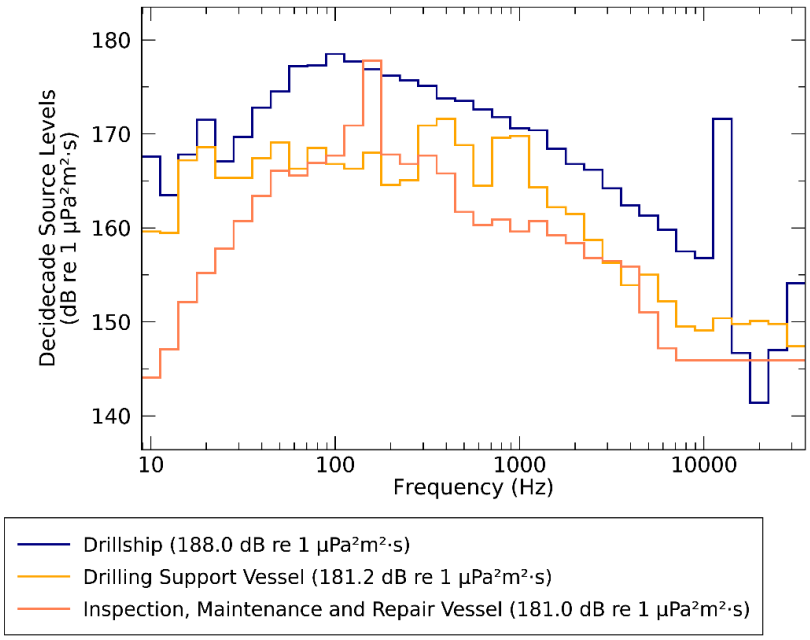

Figure 9. Energy source level (ESL) spectra (in decidecade frequency-band) for the three sound sources associated with Scenarios 1, 2, 6, 9, 10, 14, 17, 18, 22, 28, 29, 30, and 34: the drillship; the drillship support vessel (drillship OSV); and Inspection, Maintenance and Repair (IMR) vessel. All vessels are modelled under dynamic positioning.

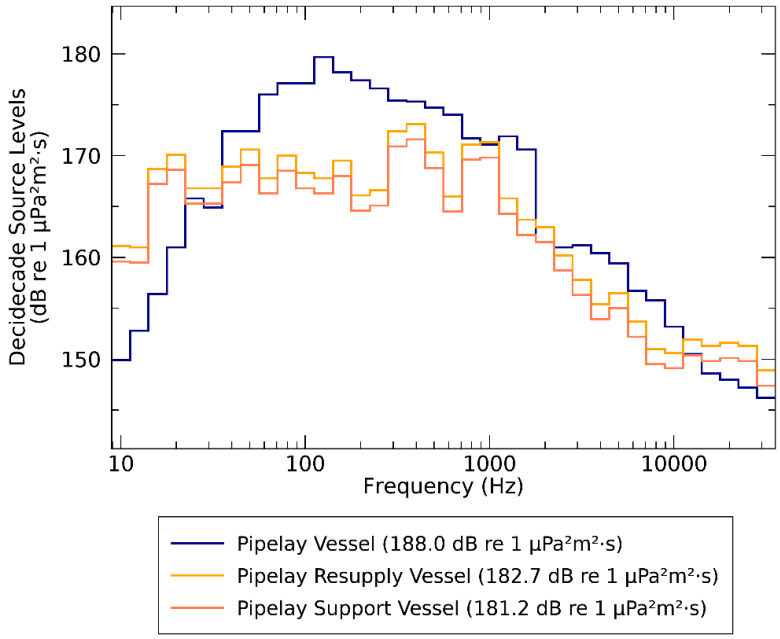

Figure 10. Energy source level (ESL) spectra (in decidecade frequency-band) for the three sound sources associated with Scenarios 3-5, 11-13, 19-21, 25-27, and 31-33: the pipelay vessel; the pipelay resupply vessel (pipelay OSV 1); and the pipelay support vessel (pipelay OSV 2). All vessels are modelled under dynamic positioning.

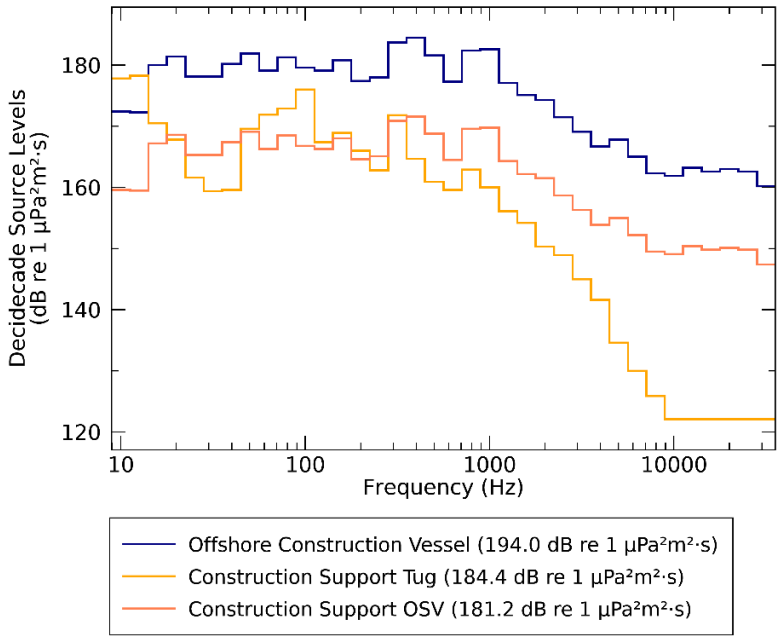

Figure 11. Energy source level (ESL) spectra (in decidecade frequency-band) for the sound sources associated with Scenarios 7, 8, 15, 16, 23, 24, 35, and 36 the offshore construction vessel (OCV), OCV support tug, and OCV support vessels (OSV), of which there are two. All vessels are modelled under dynamic positioning.

Each vessel considered here was modelled as a single source, with source levels detailed in the legends of Figures 9 to 11. Apart from the drillship and pipelay vessels, which have been modelled with source depths equal to their drafts (per the location of their thrusters), all source depths were based on the approximate location of noise emissions using a depth of 0.7 × ship draft, which aligns with current international standards, ISO 17208-1 (2016).

The following sections (Sections 3.1.1 to 3.1.4) detail the example vessels identified by Chevron as suitable representative vessels for the type/class of vessels that would be required to undertake the operations.

3.1.1. Drilling

3.1.1.1. Drillship

The vessel nominated as a representative drillship for this modelling study is the *Dhirubhai Deepwater KG2* (Figure 12). This vessel has an overall length, beam and draft of 228 m, 42 m, and 11.9 m, respectively. The thrusters of this vessel are located at the extent of its draft, and this vessel has been modelled with a source depth of 11.9 m.

Figure 12. *Dhirubhai Deepwater KG2*, the representative drillship.

As there are currently no publicly available underwater sound measurements of the *Dhirubhai Deepwater KG2*, measurements obtained for a similar vessel, the *Stena IceMAX*, have been used as a proxy. The *Stena IceMAX* is an identical size to the *Dhirubhai Deepwater KG2*. Underwater noise measurements of the *Stena IceMAX* were obtained from MacDonnell (2017). The broadband (10 Hz to 31 kHz) source level of this vessel has been modelled as 188.0 dB re 1 $\mu Pa^2m^2 \cdot s$, with the spectral shape for this vessel also available from MacDonnell (2017) (Figure 9).

3.1.1.2. Drilling Offshore Support Vessel (OSV)

In some drilling scenarios, the drillship has been modelled with an offshore support vessel (OSV) alongside under DP for 8 hours. We have considered the *MMA Leeuwin* as a generic OSV in this capacity. The average broadband (10 Hz to 31 kHz) source level of the *MMA Leeuwin* undertaking DP exercises has been measured as 181.2 dB re 1 $\mu Pa^2m^2 \cdot s$ (Esso and ExxonMobil 2021). A publicly available spectral shape of another generic OSV, the *Siem Sapphire* (McPherson et al. 2021), has been scaled to the *MMA Leeuwin* broadband source level (Figure 9). The source depth of the *MMA Leeuwin* has been modelled as 70% of the vessel draft (draft of 6.5 m, resulting in a source depth of 4.6 m), per ISO 17208-1 (2016).

3.1.2. Inspection, Maintenance and Repair (IMR)

The multi-purpose vessel, *Skandi Hercules*, has been nominated as a representative IMR vessel for this Development. This vessel has a length of 110 m, beam of 24 m, and draft of 7.8 m (source depth of 5.5 m). This vessel has been modelled using sound measurements from the similarly sized construction vessel, *Deep Orient*, which has a publicly available broadband source level and source spectra (Quijano and McPherson 2021). The broadband (10 Hz to 31 kHz) source level has been modelled as 181.0 dB re 1 $\mu Pa^2m^2 \cdot s$ (Figure 9).

3.1.3. Pipelay

3.1.3.1. Pipelay Vessel

The *Allseas Solitaire* (Figure 13) has been considered as a representative pipelay vessel in each of the five modelling Areas. This vessel has a length of 368 m (including stinger), beam of 41 m, and draft of 14.5 m (source depth of 14.5 m as thrusters are located at extent of draft).

Figure 13. *Allseas Solitaire*, the representative pipelay vessel

Underwater noise levels related to the *Allseas Solitaire* are publicly available from Tougaard and Griffiths (2020).

The broadband (10 Hz to 31 kHz) source level of the *Allseas Solitaire* is reported in Table 3.1 by Tougaard and Griffiths (2020) for several measurement occasions. This study considers a broadband source level of 188.0 dB re 1 $\mu Pa^2m^2 \cdot s$, which is the median level of those supplied in the referenced table. The source spectra for the *Allseas Solitaire* was also obtained from Tougaard and Griffiths (2020) (Figure 10).

3.1.3.2. Pipelay Resupply Offshore Support Vessel (OSV)

A pipelay resupply OSV has been modelled alongside the pipelay vessel in Scenarios 4, 5, 12, 13, 20, 21, 26, 27, 32 and 33. The resupply vessel has been represented by the *Allseas Alegria*, an OSV, which has an overall length of 83 m, beam of 19 m and draft of 6.3 m (source depth of 4.4m).

As there are no publicly available measurements of the source level of the *Allseas Alegria*, the source level of the OSV *MMA Leeuwin* (Esso and ExxonMobil 2021) was scaled up to correspond with a suitable source level for the *Allseas Alegria*. The overall power of the *MMA Leeuwin* is 4,960 kw, while the *Allseas Alegria* has an overall power of 7000 kW, hence the need to scale up the publicly available source level. The broadband (10 Hz to 31 kHz) source level of the *Allseas Alegria* has been modelled as 182.7 dB re 1 $\mu Pa^2m^2 \cdot s$. As per the drilling OSV (Section 3.1.1.2), the spectra for this vessel has been represented *via* scaling the spectra of the *Siem Sapphire* (McPherson et al. 2021) (Figure 10).

3.1.3.3. Pipelay Offshore Support Vessel (OSV)

In addition to the pipelay resupply OSV, a second concurrent support OSV has been considered alongside the pipelay vessel in Scenarios 5, 13, 21, 27 and 33. This vessel was specified as a generic OSV and is identical to the drilling OSV specified in Section 3.1.1.2.

3.1.4. Construction

3.1.4.1. Offshore Construction Vessel (OCV)

An offshore construction vessel (OCV) is considered in Scenarios 7, 8, 15, 16, 23, 24, 35 and 36. A representative vessel of this vessel class has been considered as the *Skandi Africa.* This vessel has an overall length of 161 m, a beam of 32 m, and a draft of 9.3 m (resulting in a source depth of 6.5 m) (Figure 14). In this modelling study, the *Skandi Africa* has been represented by the OSV *Siem Sapphire*, which is a similarly sized (91m long, 22m beam, 8.0m draft) vessel, with similar installed power (21,100 kW for the *Skandi Africa*, 22,840 kW for the *Siem Sapphire*). The publicly available source level and spectra of the *Siem Sapphire* (McPherson et al. 2021) have been scaled down slightly (based on installed power) to represent the *Skandi Africa*, resulting in a broadband (10 Hz to 31 kHz) source level of 194.0 dB re 1 $\mu Pa^2m^2 \cdot s$ (Figure 11).

3.1.4.2. Construction Support Tug

In Scenarios 8, 16, 24 and 36, the OCV has been considered with support from three other vessels in close proximity. The first of these is a support tug, which has been represented by the *Mermaid Sound*. The *Mermaid Sound* has a length of 50 m, a beam of 13.4 m, and a draft of 4.9 m (resulting in a source depth of 3.4 m). As there are no publicly available measurements of the sound produced by the *Mermaid Sound*, this vessel has been directly represented by another Tug, the *Katun*. The source level and spectra of the *Katun* has been measured by JASCO Applied Sciences (Hannay et al. 2004). The broadband (10 Hz to 31 kHz) source level has been modelled as 184.4 dB re 1 $\mu Pa^2m^2 \cdot s$ (Figure 11).

3.1.4.3. Construction Offshore Support Vessels (OSV 1 and OSV 2)

In addition to the Support Tug, Scenarios 8, 16, 24 and 36 also include two construction support OSVs modelled alongside the OCV. The two OSVs have been represented by the *MMA Chieftain* and the *MMA Coral*. Both OSVs are 70 m long, with drafts of 6.1 m (source depths modelled as 4.3 m). The beam of the *MMA Chieftain* is 16 m, and the beam of the *MMA Coral* is 17 m.

For modelling purposes, both OSVs have been represented with the source level associated with the *MMA Leeuwin*, a similarly sized OSV, which was measured while undertaking comparable activities (Esso and ExxonMobil 2021). The broadband (10 Hz to 31 kHz) source level of each OSV has therefore been modelled as 181.2 dB re 1 $\mu Pa^2m^2 \cdot s$. As per the other OSVs considered in this modelling study, the spectra for these two vessels has been represented *via* scaling the spectra of the *Siem Sapphire* (McPherson et al. 2021) (Figure 11).

Figure 14. *Skandi Africa*, the representative Offshore Construction Vessel.

3.2. Vertical Seismic Profiling Acoustic Source

The pressure signature of the individual airguns and the composite decidecade band point-source equivalent directional levels (i.e., source levels) of the 750 in^3 Vertical Seismic Profiling (VSP) source suspended at a depth of 5 m were modelled with JASCO's Airgun Array Source Model (AASM; Appendix C). A set of nine aggregate exposure (SEL_{24h}) scenarios were modelled at each VSP location with 5, 10, 25, 50, 100, 200, 250 and 300 shots over 24 hours to realistically represent a range of potential operations.

3.2.1. Acoustic Source Model

AASM accounts for the notional pressure signatures of each source element with respect to the effects of surface-reflected signals on bubble oscillations and inter-bubble interactions, the surface-reflected signal (known as surface ghost) is not included in the far-field source signatures. The acoustic propagation models account for those surface reflections, which are a property of the propagating medium rather than the source. AASM considers:

- Array layout;
- Volume, depth, and firing pressure of each airgun; and
- Interactions between different airguns in the array.

3.3. Geometry and Modelled Regions

JASCO's Marine Operations Noise Model (MONM-BELLHOP; see Appendix B.2.2) was used to predict the acoustic field at frequencies of 10 Hz to 25 kHz for all vessels. To supplement the MONM results, high-frequency results for propagation loss were modelled using Bellhop (Porter and Liu 1994) for frequencies from 1.26 to 25 kHz . The MONM and BELLHOP results were combined to produce results for the full frequency range of interest. The sound field modelling calculated propagation losses up to 100 km from the source, with a horizontal separation of 20 m between receiver points along the modelled radials. The sound fields were modelled with a horizontal angular resolution of $\Delta\theta$ = 2.5° for a total of N = 144 radial planes. Receiver depths were chosen to span the entire water column over the modelled areas, from 2 m to a maximum of 3250 m, with step sizes that increased with depth.

To produce the maps of received sound level isopleths, and to calculate distances to specified sound level thresholds, the maximum-over-depth level was calculated at each sampling point within the modelled region. The radial grids of maximum-over-depth levels were then resampled (by linear triangulation) to produce a regular Cartesian grid. The contours and threshold ranges were calculated from these grids of the modelled acoustic fields.

3.4. Accumulated SEL

In this study, the sound sources were considered to be continuously operating with new sound energy constantly being introduced to the environment. The reported source levels are usually in terms of sound pressure levels (SPL), representing the average instantaneous acoustic level of a considered source. The evaluation of the cumulative sound field (i.e., in terms of SEL_{24h}) depends on the number of seconds of operation during the accumulation period.

For all stationary sources, the SPL modelling results were converted to SEL by the duration of the measurement, which is appropriate for a non-impulsive noise source. As SEL was assessed over 24 h and for a stationary vessel over a day, the conversion from SPL was obtained by increasing the levels by $10*\log_{10}(T)$, where T is 86400 (the number of seconds in 24 h). For scenarios where a vessel was transiting along a track a similar adjustment to the SPL was applied, however the time factor was determined based on the step size along the track and the vessel's speed, see Appendix B.4 for details.

3.5. Animal Movement and Exposure Modelling

The JASCO Animal Simulation Model Including Noise Exposure (JASMINE) was used to predict the exposure of animats to sound arising from the vessel activity scenarios (Tables 7 and 9). JASMINE integrates the predicted sound field with biologically meaningful movement rules for each marine mammal species (pygmy blue whales for the current analysis) that results in an exposure history for each animat in the model. An overview of the exposure modelling process using JASMINE is shown in Figure 15.

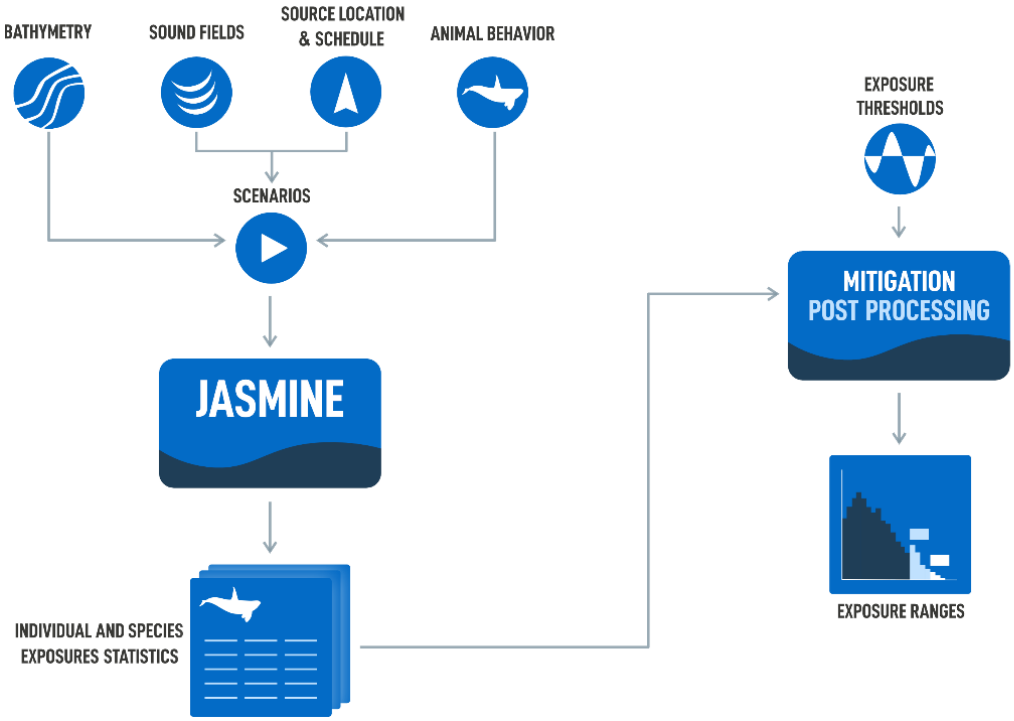

Figure 15. Exposure modelling process overview.

In JASMINE, the sound received by the animats is determined by the proposed vessel activities. As illustrated in Figure 16, animats are programmed to behave like the marine animals that may be present in an area. The parameters used for forecasting realistic behaviours (e.g., diving and foraging depth, swim speed, surface times) are determined and interpreted from marine mammal studies (e.g., tagging studies) where available, or reasonably extrapolated from related or comparable species. For cumulative metrics, an individual animat's sound exposure levels are summed over a 24 h duration to determine its total received energy, and then compared to the relevant threshold criteria. For single-exposure metrics, the maximum exposure is evaluated against threshold criteria for each 24 h period. For additional information on JASMINE, see Appendix D.

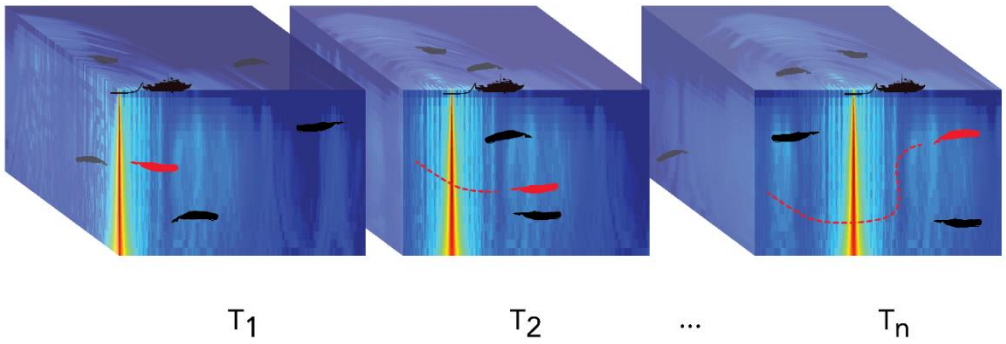

Figure 16. Depiction of animats in a moving sound field. Example animat (red) shown moving with each time step (T_n). The acoustic exposure of each animat is determined by where it is in the sound field, and its exposure history is accumulated as the simulation steps through time.

The exposure criteria for non-impulsive sounds (described in Section 2) were used to determine the number of animats that exceeded thresholds. To generate statistically reliable probability density functions, model simulations were run with animat sampling densities of 4 animats/km^2. Due to insufficient density data availability, the modelling results are not related to real-world density estimates for pygmy blue whales within the BIA. To evaluate PTS, TTS and behavioural response, exposure results were obtained using detailed behavioural information for migrating pygmy blue whales (described in Section 3.5.2). The simulation was run for a representative period of 24 h to coincide with the acoustic modelling effort. A subset of acoustic modelling scenarios was considered for animal movement modelling. Animat scenarios included acoustic modelling Scenarios 8, 19, 32, 33 and 34 (see Tables 7 and 9). Due to their locations within or close to the migratory pygmy blue whale BIA, all considered scenarios were run for migrating pygmy blue whales restricted to the BIA as well as unrestricted.

Despite the Development's proximity to the humpback whale BIA, animal movement modelling was not considered for humpback whales as the acoustic footprints of the corresponding vessel activities did not reach the BIA.

Figure 17 shows an example animat track (generated for information purposes only and not related to the results presented in this report) with associated received levels from a stationary point source. The top panel displays the animat track relative to the point source, and the bottom panel displays the accumulation of SEL_{24h} for TTS and PTS criteria. At approximately 50 seconds, the animat is exposed so that the TTS threshold is exceeded, and at approximately 700 seconds the animat is exposed so that the PTS threshold is exceeded.

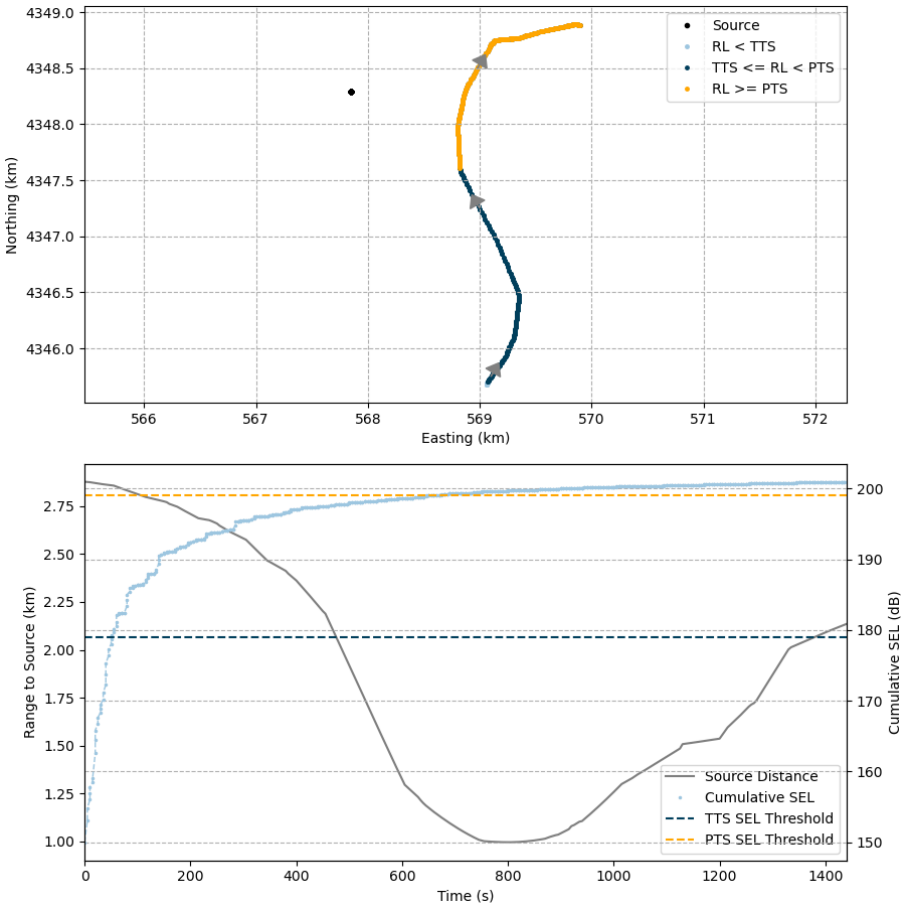

Figure 17. Animat track from an example simulation showing northward movement over a 1400 s duration. The upper panel shows a plan view of both a stationary point source and a foraging animat. Animat steps are coloured to indicate whether the accumulated sound energy at that point has exceeded either TTS or PTS threshold criteria. The lower panel shows horizontal distance in kilometres to the source (grey line; left y-axis) and cumulative 24-h SEL ($L_{E,24h}$, dB re 1 µPa²·s; right y-axis) as a function of time. Note that this example does not use data from the current study.

3.5.1. Exposure-based Radial Distance Estimation

The results from the animal movement and exposure modelling provided a way to estimate radial distances to effect thresholds. The distance to the closest point of approach (CPA) for each of the animats was recorded. The $ER_{95\%}$ (95% Exposure Range) is the horizontal distance that includes 95% of the animat CPAs that exceeded a given effect threshold (Figure 18). Within the $ER_{95\%}$, there is generally some proportion of animats that do not exceed threshold criteria. This occurs for several reasons, including the spatial and temporal characteristics of the sound field and the way in which animats sample the sound field over time, both vertically and horizontally. The sound field varies as a function of range, depth, and azimuth based on a variety of factors such as bathymetry, sound speed profile, and geoacoustic parameters. The way the animats sample the sound field depends upon species-typical swimming and diving characteristics (e.g., swim speed, dive depth, surface intervals, and reversals). Furthermore, even within a particular species definition, these characteristics vary with behavioral state (e.g., feeding, migrating). As this results in some animats not exceeding threshold criteria even within the $ER_{95\%}$, the probability that an animat within that distance was exposed above threshold within the $ER_{95\%}$ was also computed (P_{exp}) to provide additional context.

Acoustic ranges are reported for both $R_{95\%}$ and R_{max}, however, exposure ranges are reported for $ER_{95\%}$ only since, statistically, ER_{max} is not defined. JASMINE is a Monte Carlo simulation, and the results are probabilistic in nature. This is in contrast with acoustic modelling, where there is a specific maximum isopleth range for a given source/environment setup.

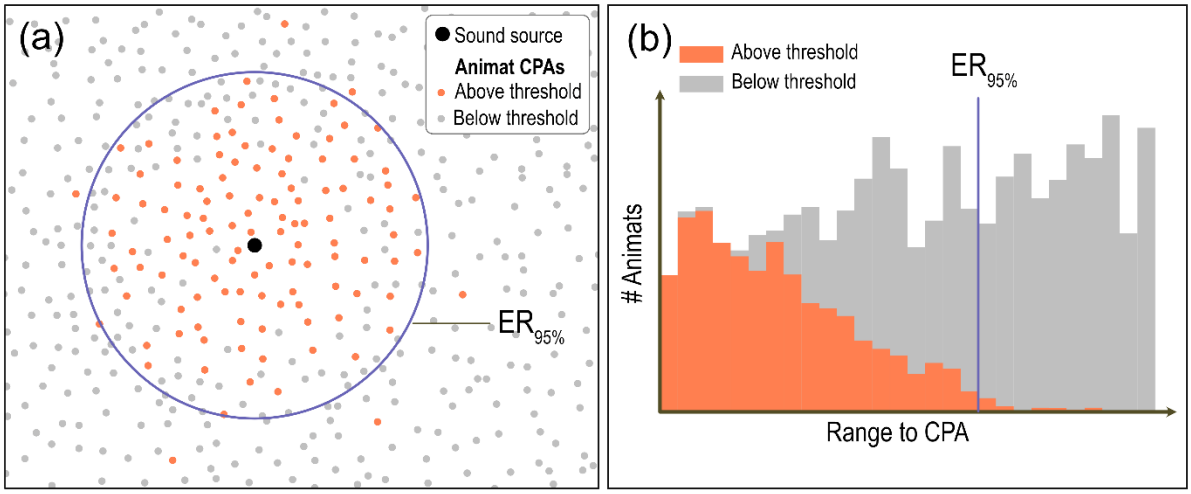

Figure 18. Example distribution of animat closest points of approach (CPAs). Panel (a) shows the horizontal distribution of animats near a sound source. Panel (b) shows the distribution of distances to animat CPAs. The 95% exposure range ($ER_{95\%}$) is indicated in both panels.

3.5.2. Pygmy Blue Whale Behaviour

Animal movement modelling scenarios are located within or adjacent to the migration BIA for pygmy blue whales, therefore migration was the only behavioural profile considered. The north-bound migration was selected for modelling because previous work (McPherson 2022) showed that this behavioural profile resulted in more conservative PTS and TTS exposure range estimates. Detailed information on pygmy blue whales was derived from a range of sources that used multi-sensor tags to record fine-scale dive and movement behaviour (Owen et al. 2016, AIMS unpublished data 2021), as well as satellite tags to record travel speed (Thums and Ferreira 2021).

Multi-sensor tags typically record the depth of an animal along with various movement parameters such as swim speed and their body's orientation. Owen et al. (2016) equipped a sub-adult pygmy blue whale with a multi-sensor tag off Western Australia. They identified dives for the tagged animal as migratory, feeding, or exploratory (i.e., no lunges recorded which would indicate feeding). Pygmy blue whales in the simulation area are presumed to be migrating, and so feeding was not included in the model. Exploratory dives were considered to be part of migratory behaviour, and so the two dive types were modelled together such that the animats were migrating 95% of the time and engaged in exploratory dives 5% of the time (Owen et al. 2016).

Using data from Owen et al. (2016), the approximate length of a bout of exploratory dives could be determined, as well as the average (± SD) depth of this dive type. The speed of travel for both dive behaviours was calculated from data presented in Thums and Ferreira (2021), who analysed data from satellite tags deployed on pygmy blue whales in the Northwest Marine Region. All remaining parameters were calculated from two multi-sensor tags deployed on pygmy blue whales off Western Australia (AIMS unpublished data 2021).

The behaviour of migrating pygmy blue whales was modelled to reflect animats transiting through the modelling area on a 45° track for the northward migration. This represents the animals migrating along the west coast of Australia to their breeding grounds in Indonesia (Double et al. 2014, Thums and Ferreira 2021).

4. Results

4.1. Vessel Activities – Acoustic Modelling Tabulated Results

Tables 17 to 21 present the maximum and 95% distances (defined in Appendix B.3) to SPL levels for each of the five Areas.

To consider the aggregate contribution of noise emissions from the four combined scenarios, ensonified areas were examined for Scenarios 37 – 40, rather than maximum radii. Tables 22 and 23 present the ensonified areas for the four combined scenarios and compare the total ensonified area to the summed areas of the corresponding individual scenarios. The changes in ensonified areas are presented as km^2 and as percentage change.

Tables 24 to 28 present the maximum distances to frequency-weighted SEL_{24h} thresholds, as well as total ensonified areas. Tables 29 and 30 present the changes in ensonified areas for the combined scenarios compared to their corresponding individual scenarios.

For the results below, the distances to isopleths/thresholds were reported from either the centroid of several sources, from the most dominant single source, or from a track. When an isopleth completely envelopes multiple sources the centroid was used, and when several closed isopleths exist the most dominant source was used. Maps are provided in Section 4.2 to assist with contextualising tabulated distances.

Table 17. SPL: Maximum (R_{max}) and 95% ($R_{95\%}$) horizontal distances (in km) to sound pressure level (SPL) for Area 1. A dash indicates the threshold is not reached within the limits of the modelled resolution (20 m). Scenario descriptions are given in Table 7.

4.2. Vessel Activities - Sound Field Maps and Graphs

Maps of the estimated sound fields, threshold contours, and isopleths of interest for SPL and SEL_{24h} sound fields are presented for the vessel activity scenarios. The SPL results for individual and combined scenarios are presented in Figures 19 to Figure 58 (Section 4.2.1), whilst the SEL_{24h} results for individual scenarios are presented in Figures 59 to 92 (Section 4.2.2). SEL_{24h} results for combined scenarios are not illustrated as these effect zones remain identical to their corresponding individual scenarios.

4.2.1. Instantaneous SPL Sound Level Contour Maps

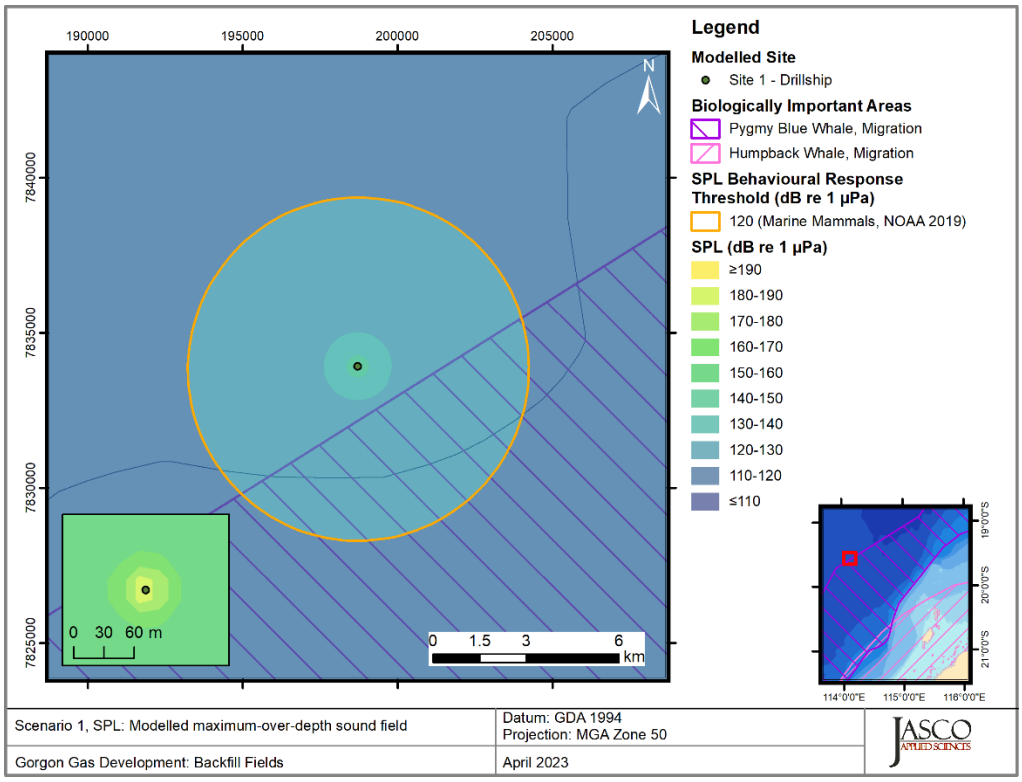

Figure 19. *Scenario 1, Area 1 Drillship, SPL*: Sound level contour map showing the unweighted maximum-over-depth sound field in 10 dB steps, and the isopleth for behavioural response threshold for marine mammals.

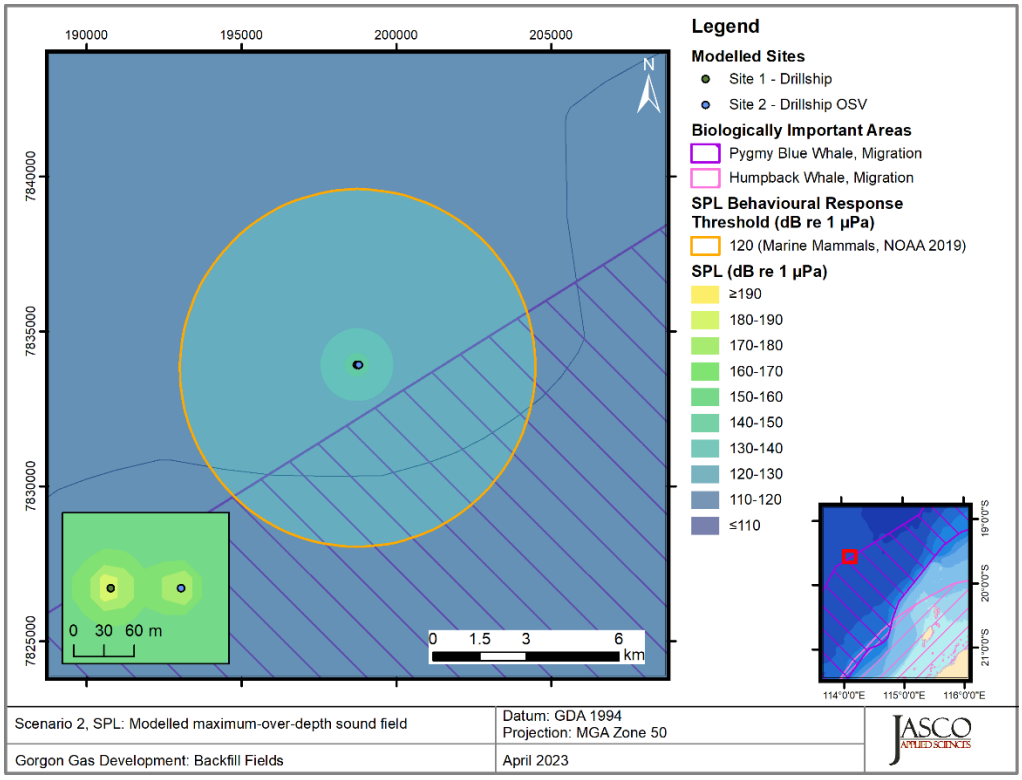

Figure 20. *Scenario 2, Area 1 Drillship with OSV, SPL*: Sound level contour map showing the unweighted maximum-over-depth sound field in 10 dB steps, and the isopleth for behavioural response threshold for marine mammals.

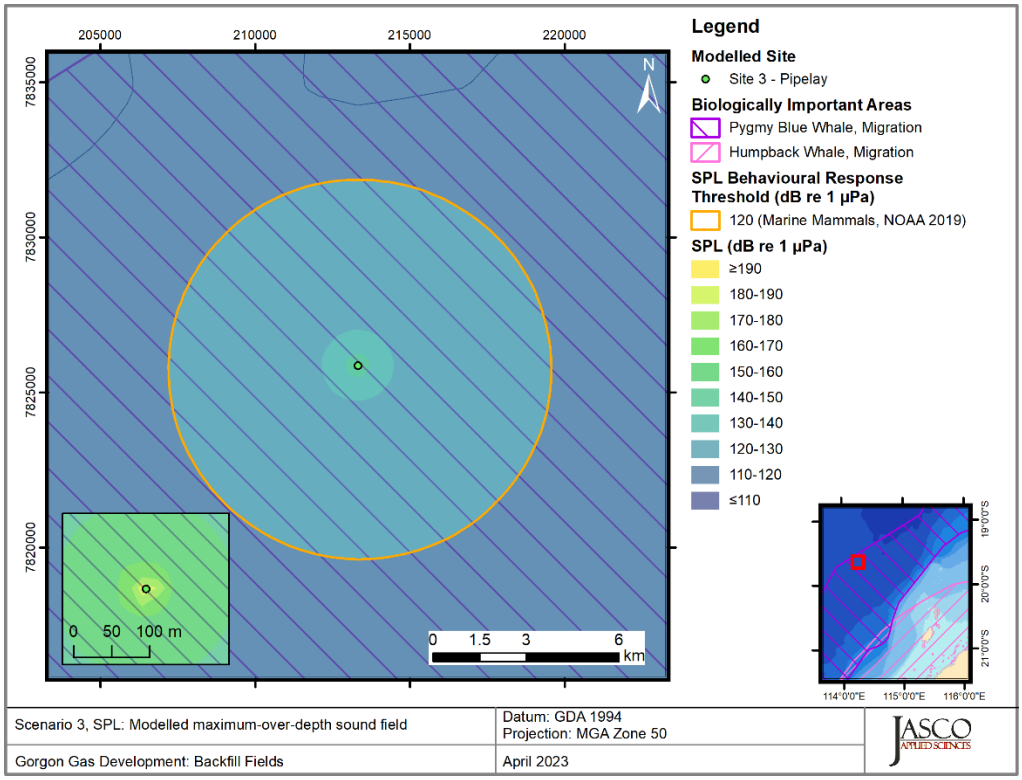

Figure 21. *Scenario 3, Area 1 Pipelay vessel, SPL*: Sound level contour map showing the unweighted maximum-over-depth sound field in 10 dB steps, and the isopleth for behavioural response threshold for marine mammals.

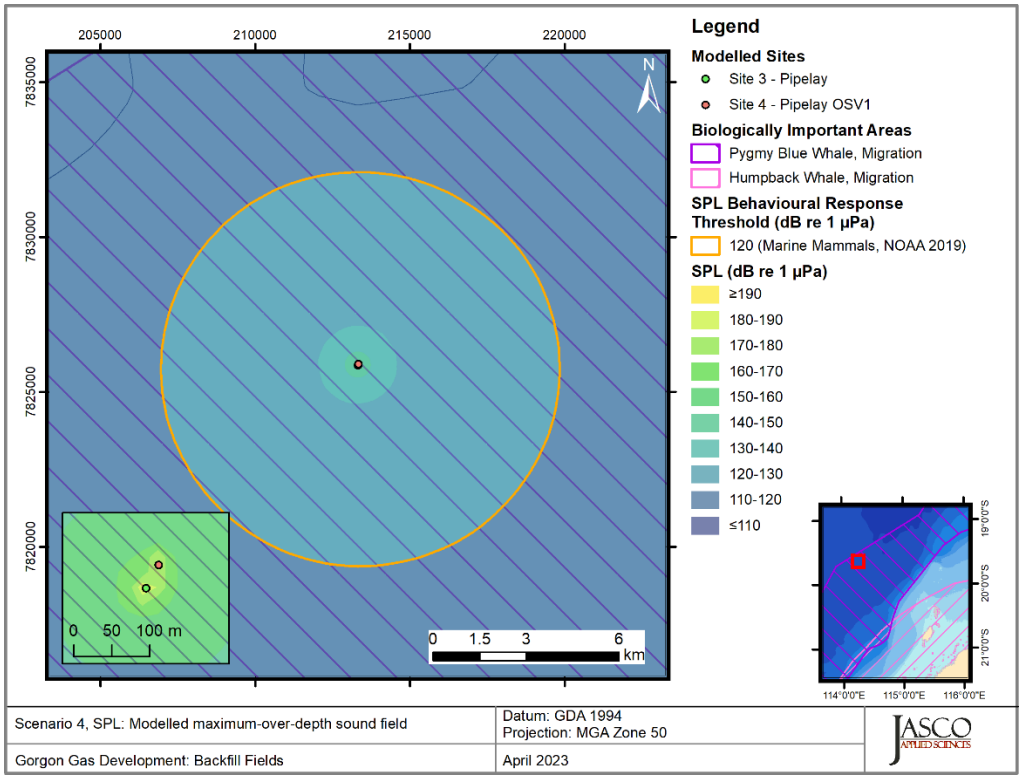

Figure 22. *Scenario 4, Area 1 Pipelay vessel with resupply OSV, SPL*: Sound level contour map showing the unweighted maximum-over-depth sound field in 10 dB steps, and the isopleth for behavioural response threshold for marine mammals.

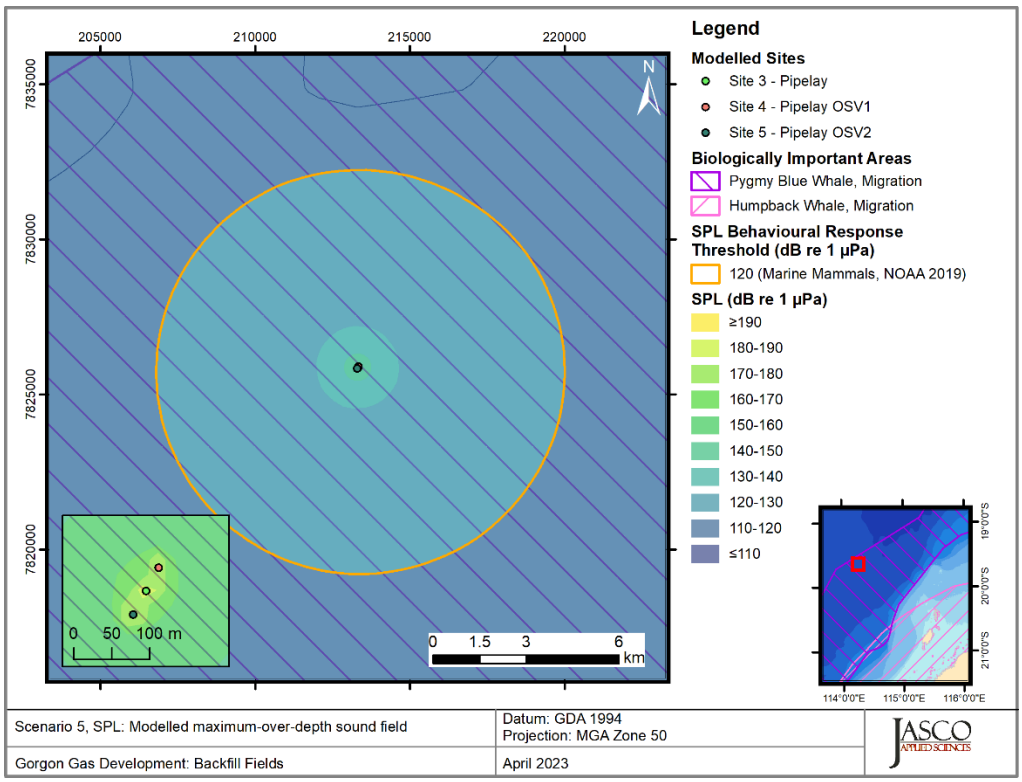

Figure 23. *Scenario 5, Area 1 Pipelay vessel with resupply OSV and support OSV, SPL*: Sound level contour map showing the unweighted maximum-over-depth sound field in 10 dB steps, and the isopleth for behavioural response threshold for marine mammals.

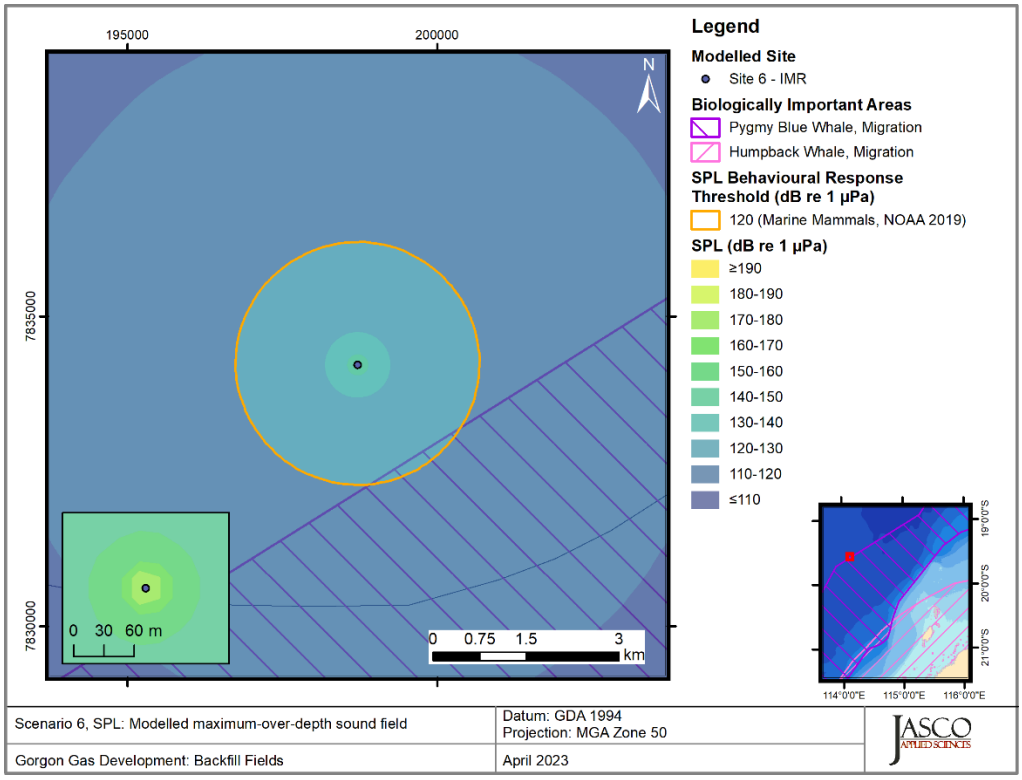

Figure 24. *Scenario 6, Area 1 IMR vessel, SPL*: Sound level contour map showing the unweighted maximum-over-depth sound field in 10 dB steps, and the isopleth for behavioural response threshold for marine mammals.

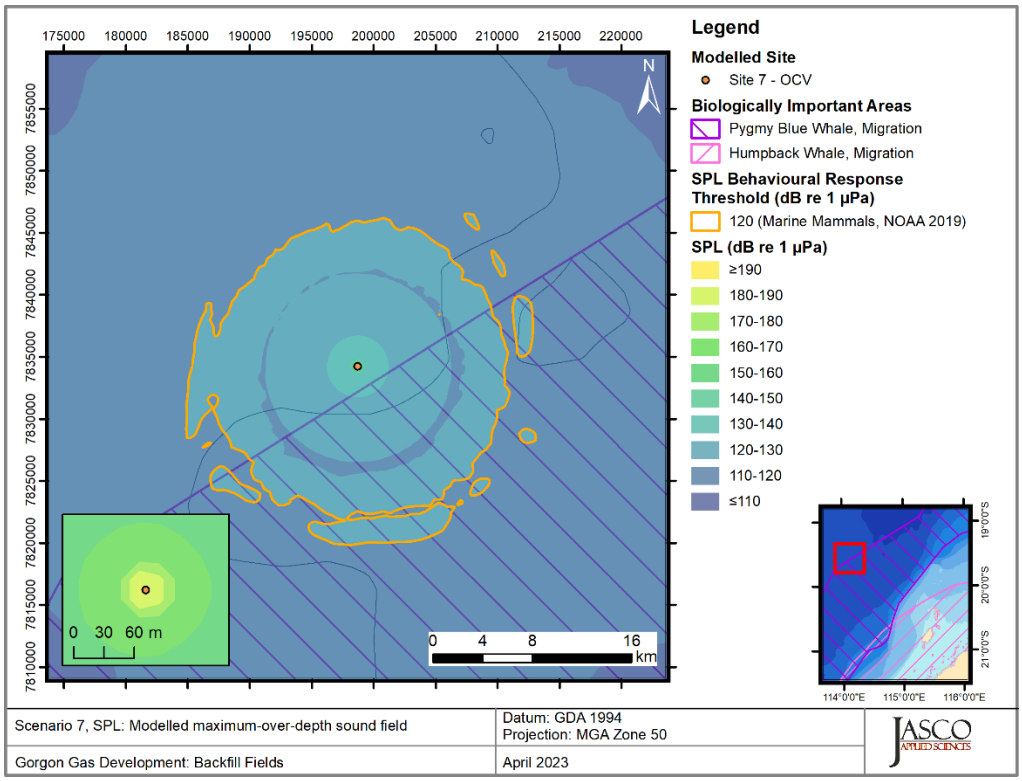

Figure 25. *Scenario 7, Area 1 OCV, SPL*: Sound level contour map showing the unweighted maximum-over-depth sound field in 10 dB steps, and the isopleth for behavioural response threshold for marine mammals.

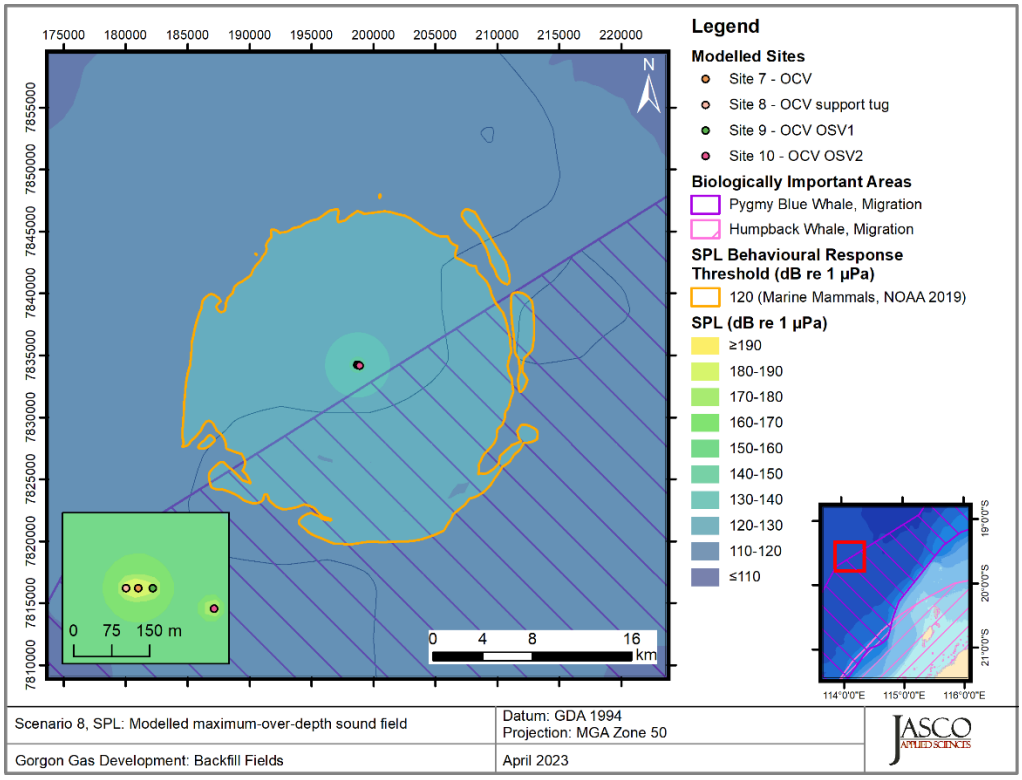

Figure 26. *Scenario 8, Area 1 OCV with three support vessels, SPL*: Sound level contour map showing the unweighted maximum-over-depth sound field in 10 dB steps, and the isopleth for behavioural response threshold for marine mammals.

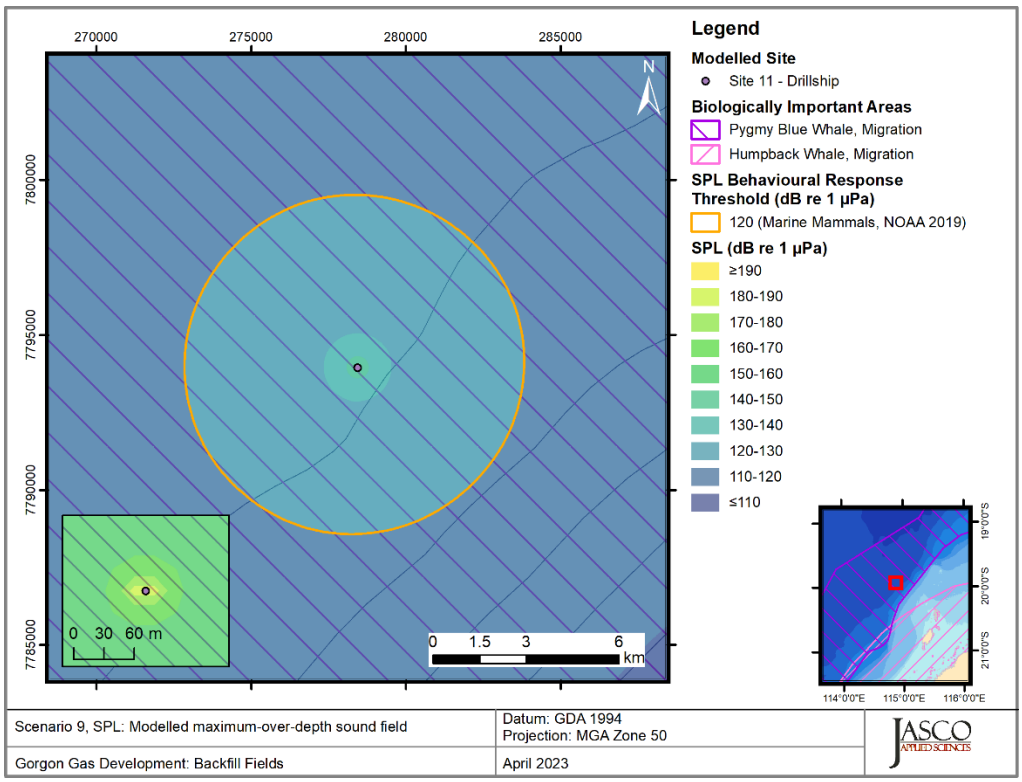

Figure 27. *Scenario 9, Area 2 Drillship, SPL*: Sound level contour map showing the unweighted maximum-over-depth sound field in 10 dB steps, and the isopleth for behavioural response threshold for marine mammals.

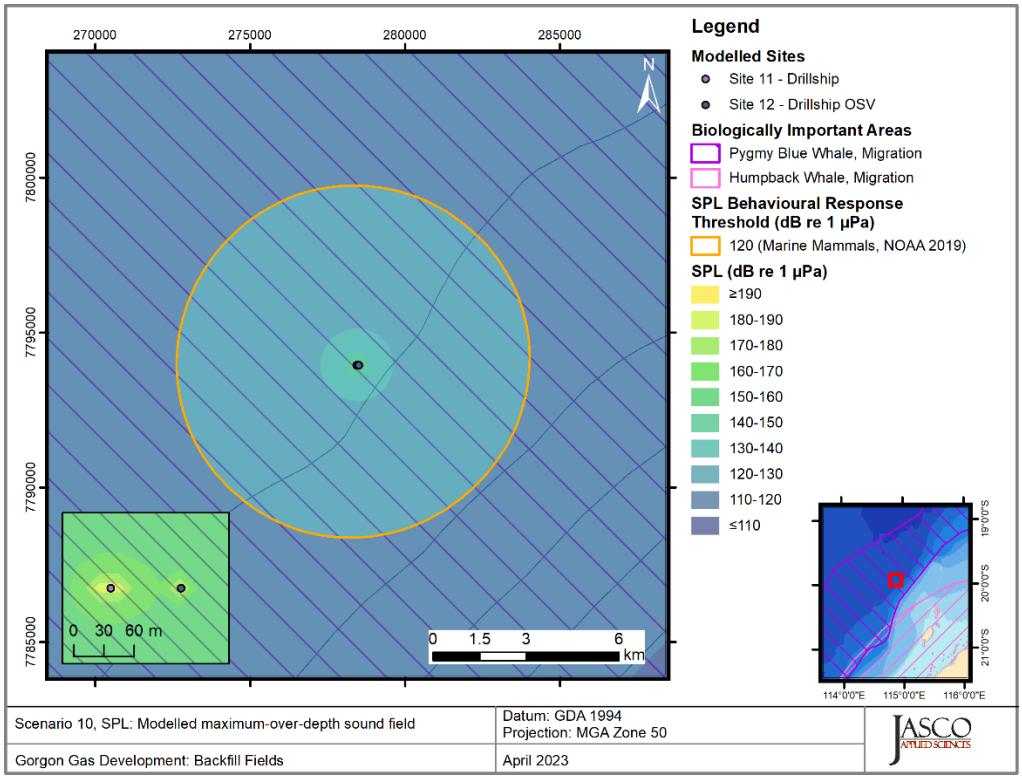

Figure 28. *Scenario 10, Area 2 Drillship with OSV, SPL*: Sound level contour map showing the unweighted maximum-over-depth sound field in 10 dB steps, and the isopleth for behavioural response threshold for marine mammals.

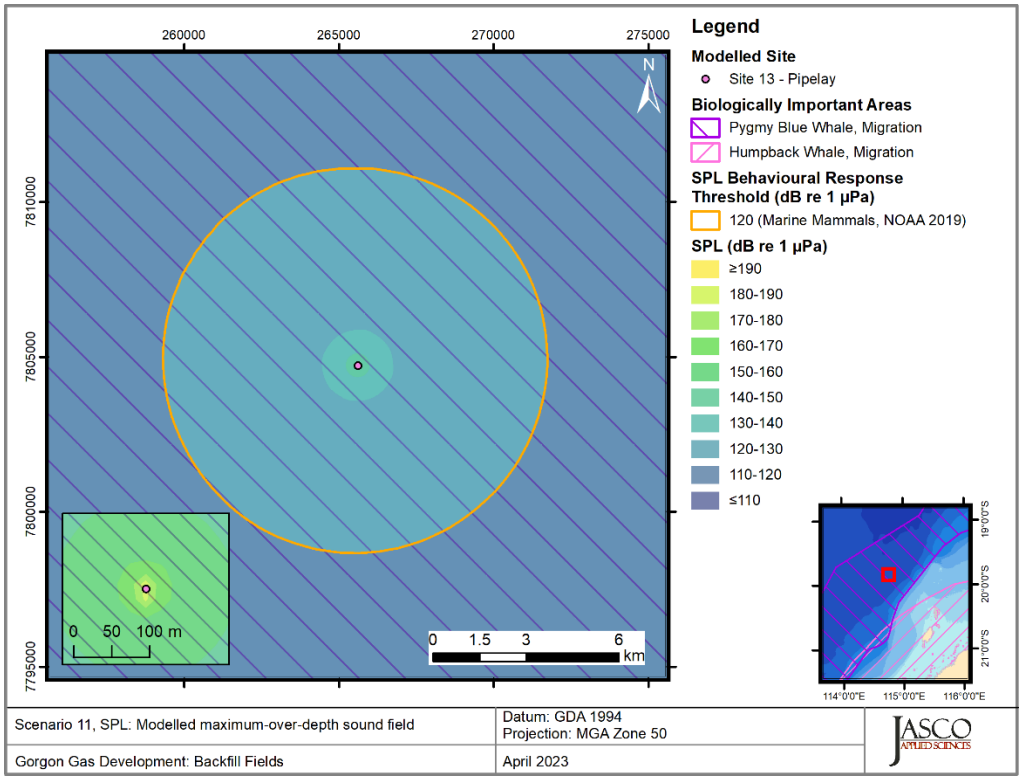

Figure 29. *Scenario 11, Area 2 Pipelay vessel, SPL*: Sound level contour map showing the unweighted maximum-over-depth sound field in 10 dB steps, and the isopleth for behavioural response threshold for marine mammals.

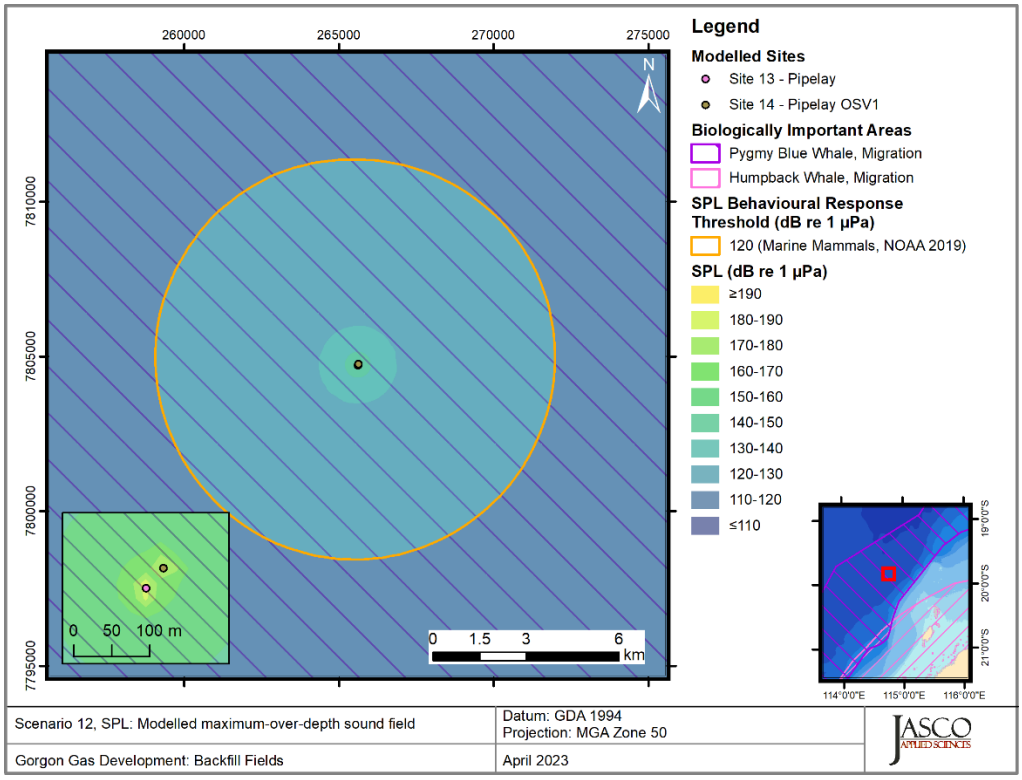

Figure 30. *Scenario 12, Area 2 Pipelay vessel with resupply OSV, SPL*: Sound level contour map showing the unweighted maximum-over-depth sound field in 10 dB steps, and the isopleth for behavioural response threshold for marine mammals.

Thresholds omitted here were either not reached or were not long enough to display graphically.

4.3. Vertical Slice Plots

Vertical slice plots (Figures 95 to 99) are provided to illustrate the underwater propagation of the most significant noise source in each of the five Areas. In Areas 1, 2, 3 and 5, the most significant noise is the OCV; as the OCV was not modelled in Area 4, the pipelay vessel is illustrated.

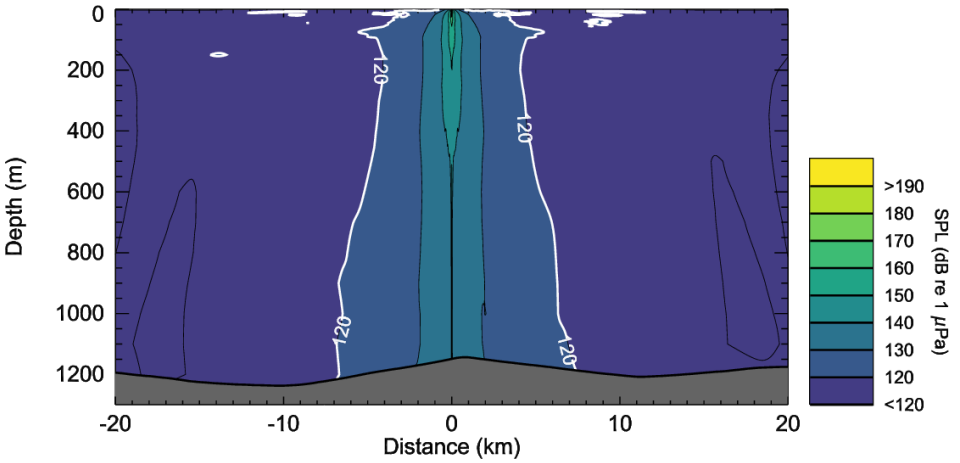

Figure 95. Vertical slice plot of Sound Pressure Levels (SPLs) for the OCV in Area 1 (Site 7).

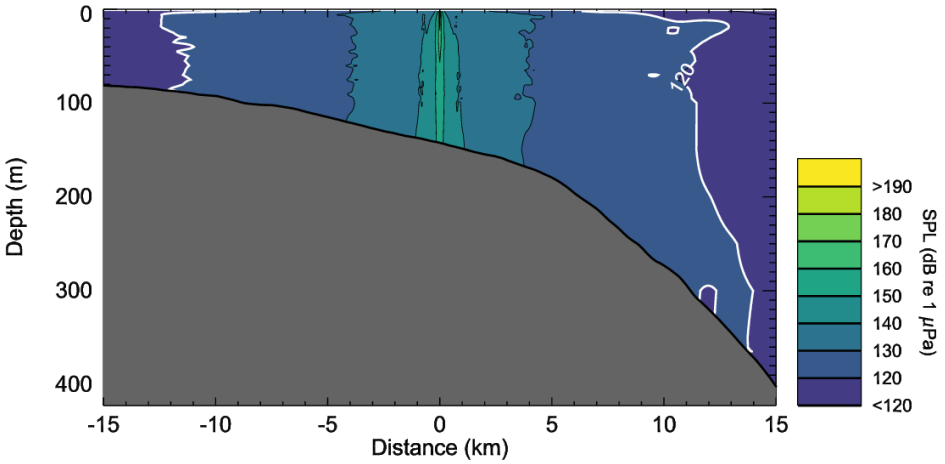

Figure 99. Vertical slice plot of Sound Pressure Levels (SPLs) for the OCV in Area 5 (Site 41).

4.4. VSP Tabulated Results and Maps

4.4.1. Acoustic Source Levels and Directivity

AASM (Section 3.2.1) was used to predict the horizontal and vertical overpressure signatures and corresponding power spectrum levels for the seismic source at the well centre, with results provided in Appendix C along with the horizontal directivity plots.

Table 31 shows the PK and per-pulse SEL source levels in the horizontal-plane broadside (perpendicular to the sagittal plane of the array), endfire (parallel to the sagittal plane of the array), and vertical directions. The vertical source level that accounts for the "surface ghost" (the out of phase reflected pulse from the water surface) is also presented to make it easier to compare the output of other seismic source models.

Appendix C.3 shows the broadside, endfire, and vertical overpressure signature and corresponding power spectrum levels for the source. The signature consists of a strong primary peak, related to the initial release of high-pressure air, followed by a series of pulses associated with bubble oscillations. Most energy was produced at frequencies below 300 Hz. Frequency-dependent peaks and nulls in the spectrum result from interference among airguns in the source and correspond with the volumes and relative locations of the airguns to each other.

Table 31. Far-field source level specifications for the 750 in^3 Vertical Seismic Profiling (VSP) array, for a 5 m source depth. Source levels are for a point-like acoustic source with equivalent far-field acoustic output in the specified direction. Sound level metrics are per-pulse and unweighted.

Direction	Peak source pressure level ($L_{S,pk}$; dB re 1 µPa m)	Per-pulse source SEL ($L_{S,E}$; dB 1 µPa²m²s)	
		10–2000 Hz	2000–25000 Hz
Broadside	239.2	214.5	168.8
Endfire	239.4	214.5	165.8
Vertical	239.2	214.5	173.6
Vertical (surface affected source level)	239.3	216.1	176.6

4.4.2. Per-Pulse Sound Fields

This section presents the per-pulse sound fields in terms of maximum-over-depth SPL, SEL, PK, and seafloor PK and PK-PK. The different metrics are presented for the following reasons:

- Per-pulse SEL sound fields (Table 32) are used as inputs into the 24 h SEL scenario and to provide context for the range to 160 dB re 1 µPa²·s, relevant for the EPBC Act Policy Statement 2.1 (DEWHA 2008).
- SPL sound fields (Table 33) were used to determine the distances to marine mammal and turtle behavioural thresholds (see Sections 2.1 and 2.2).
- PK metrics within the water column (Table 34) are relevant to thresholds and guidelines for marine mammals, sea turtles, fish, fish eggs and larvae (as well as plankton; see Sections 2.1 and 2.2).
- PK metrics at the seafloor (Table 35) are relevant to guidelines for fish, fish eggs and larvae (Section 2.2).
- PK-PK metrics at the seafloor (Table 36) are relevant to sound levels used in assessing effect on benthic invertebrates (see Section 2.3).

The SPL sound fields, and distances to relevant isopleths can be visualised on the contour maps presented in Section 4.4.4.1.

Table 32. Maximum (R_{max}) and 95% ($R_{95\%}$) horizontal distances (in km) from the 750 in^3 Vertical Seismic Profiling (VSP) array to modelled maximum-over-depth unweighted per-pulse sound exposure level (SEL) isopleths.

An asterisk indicates that the sound level was not reached.

4.4.3. Multiple Pulse Sound Fields

This section presents the sound fields in terms of SEL accumulated over 24 h of activity, for the modelled scenarios (Table 10). A set of nine aggregate exposure (SEL_{24h}) scenarios were modelled at each VSP location with 5, 10, 25, 50, 100, 200, 250 and 300 shots over 24 hours to realistically represent a range of potential operations Frequency-weighted SEL_{24h} sound fields were used to estimate the maximum and 95% distances (R_{max} and $R_{95\%}$; calculated as detailed in B.3) to marine mammals and turtle PTS and TTS thresholds (listed in Table 37), and to estimate maximum distance and the area to injury and TTS guidelines for fish (Table 14). (Southall et al. 2019)

Table 37. *VSP, multiple-pulse SEL, Site A*: Maximum-over-depth distances (in km) to frequency-weighted SEL_{24h} based PTS and TTS thresholds for marine mammals (Southall et al. 2019) and sea turtles (Finneran et al. 2017) from Vertical Seismic Profiling (VSP) operations, assuming different numbers of impulses during a 24 h period.

Hearing group	Threshold for SEL_{24h} ($L_{E,24h}$; dB re 1 µPa²·s)	Distance R_{max} (km)								
		Number of impulses								
		5	10	25	50	100	150	200	250	300

4.4.4. Sound Field Maps

Maps of the estimated sound fields, threshold contours, and isopleths of interest for the VSP operations are presented for Sites A-C. The per-pulse SPL sound fields are presented as contour maps in Figures 100–102. The SEL_{24h} sound fields are presented as contour maps in Figures 103–105 for 300 impulses per day. This figure presents the unweighted SEL_{24h} in 10 dB steps, as well as the isopleths corresponding to thresholds or guidelines for which R_{max} is greater than 20 m, the modelling resolution.

4.4.4.1. Maximum-over-depth Per-Pulse Sound Fields

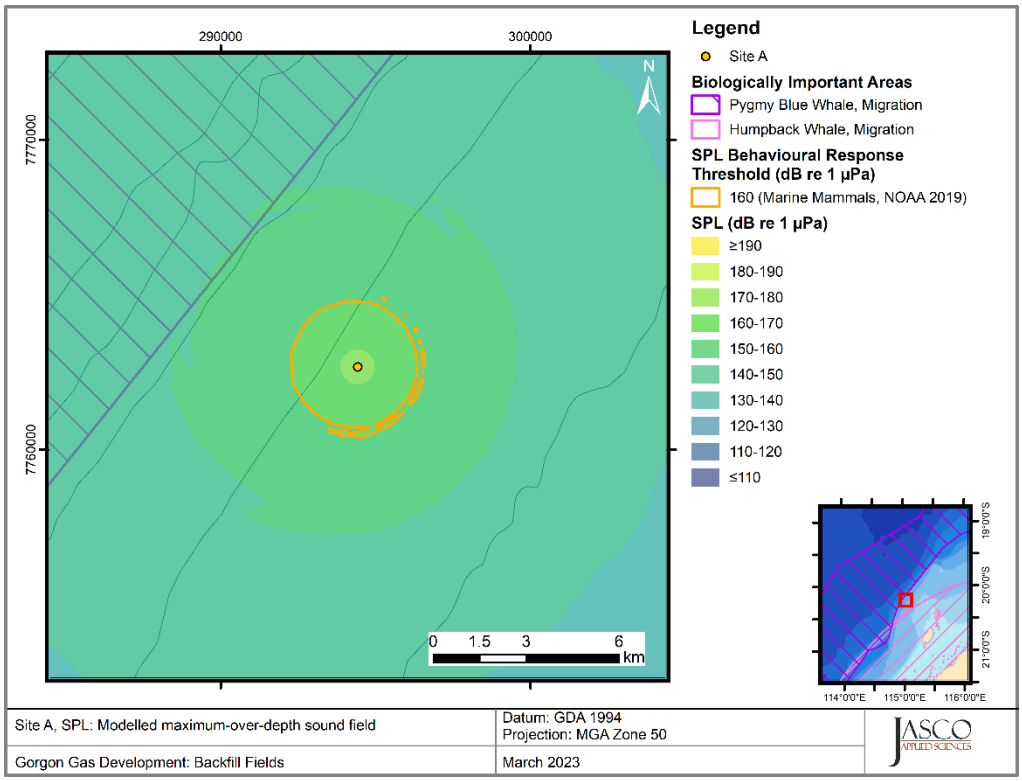

Figure 100. *VSP, Site A, SPL*: Sound level contour map showing the unweighted maximum-over-depth sound field in 10 dB steps, and the isopleth of behavioural response thresholds for marine mammals and turtles.

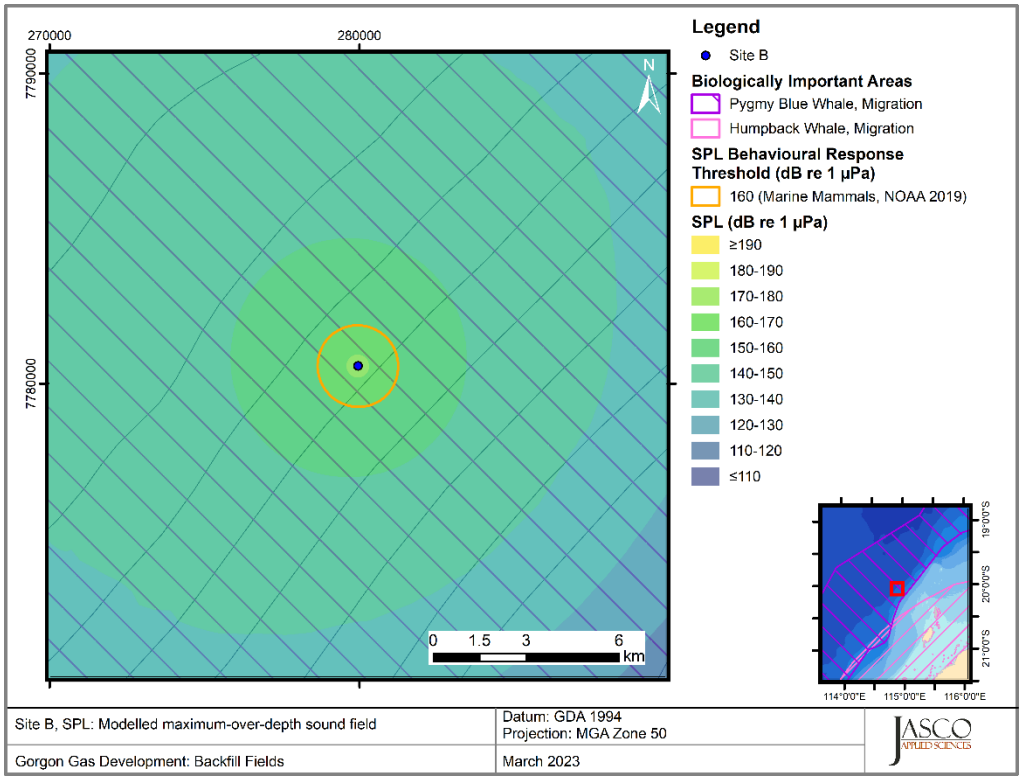

Figure 101. *VSP, Site B, SPL*: Sound level contour map showing the unweighted maximum-over-depth sound field in 10 dB steps, and the isopleth of behavioural response thresholds for marine mammals and turtles.

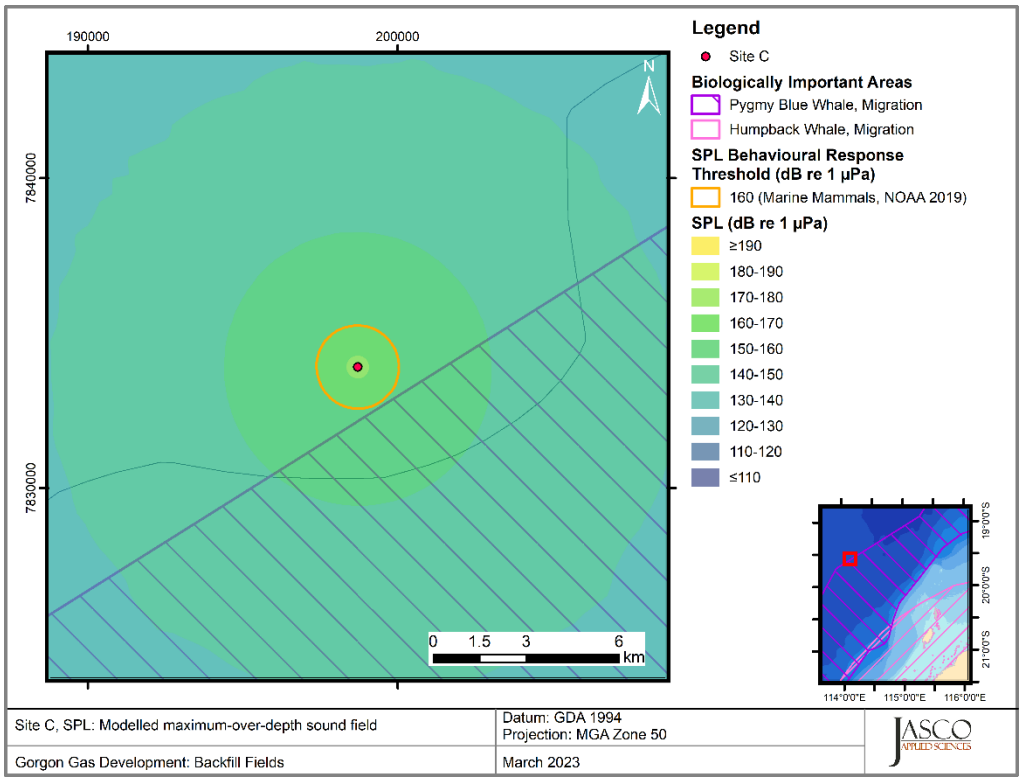

Figure 102. *VSP, Site C, SPL*: Sound level contour map showing the unweighted maximum-over-depth sound field in 10 dB steps, and the isopleth of behavioural response thresholds for marine mammals and turtles.

4.4.4.2. Accumulated Multi-Pulse Sound Fields

Thresholds for permanent threshold shift (PTS) and some thresholds for TTS were either not reached or were small enough such that they could not be displayed on a map. Refer to the radii tables in Section 4.4.3 for distances.

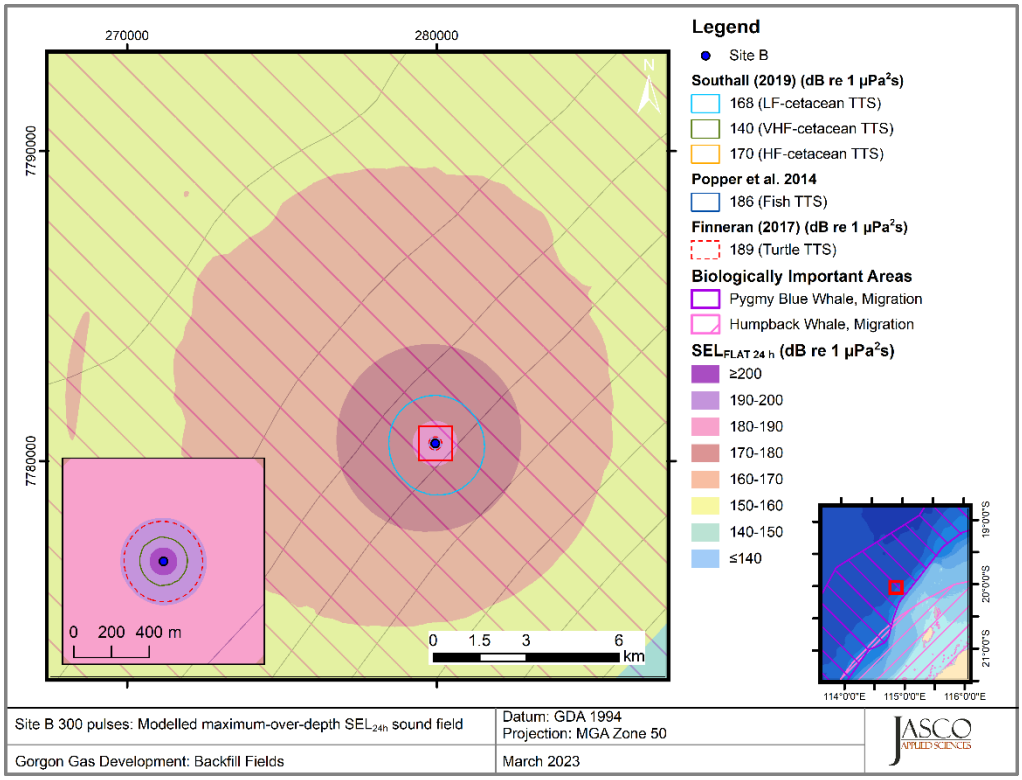

Figure 104. *VSP, Site B, multiple-pulse SEL, 300 impulses*: Sound level contour map showing unweighted maximum-over-depth SEL_{24h} results, along with isopleths for temporary threshold shift (TTS) thresholds.

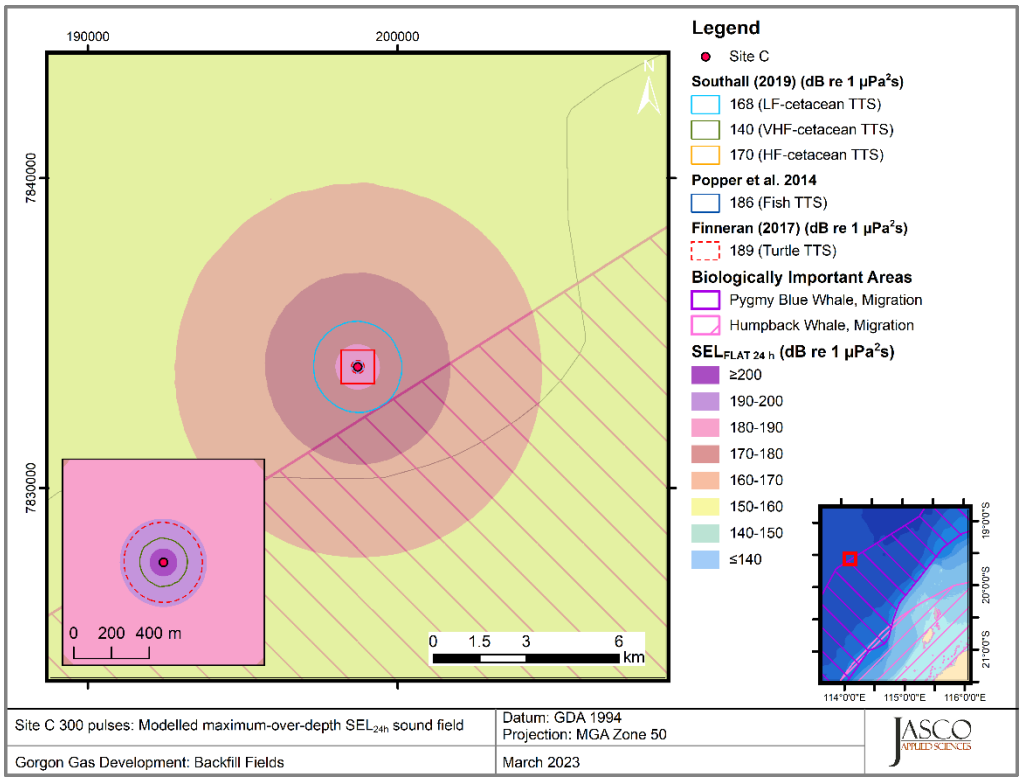

Figure 105. *VSP, Site C, multiple-pulse SEL, 300 impulses*: Sound level contour map showing unweighted maximum-over-depth SEL_{24h} results, along with isopleths for temporary threshold shift (TTS) thresholds.

4.5. Animal Movement Exposure Ranges

Table 45 shows results for scenarios with unrestricted animat seeding. Results include $ER_{95\%}$ exposure ranges calculated for the 120 dB behavioural response threshold and SEL_{24h} thresholds for both TTS and PTS, and the probability of an animat being exposed above the threshold within the $ER_{95\%}$.

Section 4.5.1 includes histograms of CPA ranges to SEL_{24h} TTS, and the behavioural response threshold for pygmy blue whales with BIA-restricted and unrestricted animat seeding where exposures above threshold occurred. Note that no pygmy blue whale animats were exposed above threshold for PTS for any of the scenarios. Additionally, no pygmy blue whale animats were exposed above threshold for TTS for Scenarios 8, 30, 33 and 40 with BIA-restricted animat seeding. Due to the lack of exposures in these scenarios, no histograms of CPA ranges are presented for these cases.

Table 43. Summary of animat simulation results for north-bound migrating pygmy blue whales with animats restricted to the BIA. The 95th percentile exposures ranges ($ER_{95\%}$) in km and probability of animats being exposed above threshold within the $ER_{95\%}$ (P_{exp} (%)) are provided. Dashes indicate no animats were exposed above threshold.

5. Discussion and Conclusion

This modelling study predicted underwater sound levels associated with the construction of the Chevron Gorgon Gas Development: Backfill Fields. The modelled sound-emitting activities were vessel activities and vertical seismic profiling (VSP). The modelling study considered 36 individual vessel activity scenarios (Scenarios 1–36) across five Areas, four combined scenarios incorporating multiple individual vessel scenarios (Scenarios 37–40), and three VSP scenarios (Scenarios A, B, and C). Maximum, 95th percentile ranges (R_{max} and $R_{95\%}$) and ensonified area were computed to PTS, TTS, and behavioural response thresholds. The animal movement and exposure analysis combined species-typical movements for migrating pygmy blue whales with modelled sound fields to estimate both exposure range ($ER_{95\%}$) along with the probability of exposure within the calculated exposure ranges for five vessel activity scenarios.

5.1. Acoustic Modelling – Vessel Scenarios

Table 47 summarises the maximum horizontal distances to behavioural (unweighted SPL) and physiological effects (LF cetacean weighted TTS and PTS) thresholds across all 36 modelled individual vessel activity scenarios. LF cetaceans are summarised due to the proximity of the pygmy blue whale BIA; maximum horizontal distances to physiological effects thresholds for other hearing groups (HF and VHF cetaceans and turtles) are included in Section 4.1.

Table 47. Summary of maximum (R_{max}) horizontal distances (in km) from all scenarios considered to the marine mammal behavioural response criterion of 120 dB re 1 µPa (SPL) and frequency-weighted LF-cetacean SEL_{24h} TTS and PTS thresholds (179 and 199 dB re 1 µPa²·s, respectively) based on Southall et al. (2019).

Scenario Number	Description	Marine Mammal Behavioural Response [a]	LF-cetacean TTS [b]	LF-cetacean PTS [c]

36	Area 5, OCV with 3 support vessels	17.3	4.58	0.21

Noise exposure criteria: [a] NOAA (2019) and [b] Southall et al. (2019).
A dash indicates the level was not reached within the limits of the modelled resolution (20 m)

The smallest horizontal distances to effect thresholds were associated with scenarios that modelled a single IMR vessel; the largest behavioural response zone for the IMR vessel was 3.76 km and the largest low-frequency (LF) cetacean TTS zone was 0.63 km (both in Area 5) (Table 47).

For the results tables presented in Section 4.1, where a dash is used in place of a horizontal distance, these thresholds may or may not be reached. Due to the discretely sampled 20 m calculation grids of the modelled sound fields, distances to these levels could not be estimated for practicable computational purposes. It is likely that SPL isopleths could be reached at distances between the source and the modelled horizontal resolution (20 m); however, distances to injurious accumulated SEL thresholds may not be reached at any range due the species-specific frequency weighing functions. Additionally, if close-to-source radii are comparable to the dimensions of the modelled vessel then they may only be reached within close proximity to a vessel, if at all.

The modelled individual vessel activity scenarios aimed to demonstrate the iterative effect of adding additional support vessels to each vessel activity (i.e. drilling, pipelaying and construction). In every modelled Area, and for each activity, additional support vessels generated larger distances to effect thresholds (Table 47).

In Areas 1, 2, 3 and 5, the OCV with construction support vessels resulted in the longest distances to effect thresholds (Table 1). The 120 dB SPL marine mammal behavioural effect zone from construction activities with support vessels featured a radius of 15.7 km in Area 1, 15.4 km in Area 2, 14 km in Area 3, and 17.3km in Area 5. Construction activities were not modelled in Area 4, and in this Area the pipelay vessel with two support vessels resulted in the longest distances to effect thresholds (120 dB marine mammal behavioural effect radii of 18.3 km).

It should be noted that in Scenarios 18, 20, 21 and 27 (drilling and pipelay in Areas 3 and 4), successive reflections between the seabed and the sea-surface result in convergence zones, which when combined with a high vessel source level, is evident as ‘sound islands’ for low level isopleths like the marine mammal behavioural threshold of 120 dB re 1 µPa (SPL) for non-impulsive sound sources. These are apparent in Figures 36, 38, 39, and 45. Modelled sites that resulted in sound ‘islands’ can be distinguished in Tables 19 and 20 by comparing the R_{max} effect distance with the $R_{95\%}$ effect distance, with the latter being notably smaller.

Furthermore, the successive reflections resulting from the underwater propagation environment caused some SEL_{24h} thresholds to be exceeded more than once. The very-high frequency (VHF) cetacean TTS threshold (153 dB, weighted) was exceeded more than once in Scenarios 1, 2, 9, 10, 17, 18, 20, 27, 29 and 30 (Figures 59, 60, 67, 68, 75, 76, 78, 85, 87, and 88), and the LF cetacean TTS threshold was exceeded more than once in Scenarios 31 and 32 (Figures 89 and 90). The reported effect radii for these scenarios relate to the longest exceedance distance.

Offshore activities over deep water in Areas 1 and 2 generally featured smaller effect zones than equivalent activities in Areas 3, 4 and 5 where the continental shelf environment was more conducive to effective sound propagation. For sources located above the continental slope, significant amounts of energy can be reflected from the seabed in such a way that this energy can propagate downslope and be trapped in the deep sound channel where it can propagate for larger distances (for example, see Figure 98). Effect zones in Areas 3 and 4 clearly demonstrated more favourable propagation conditions in an offshore direction, with less acoustic energy propagating onto the continental shelf (refer to Figures 39 and 45).

In addition to the 36 individual modelled scenarios, four combined scenarios were also modelled, which incorporated concurrent combinations of individual vessel activity scenarios across the five Areas. Table 48 summarises the percentage change in area ensonified above threshold levels between the corresponding individual vessel activity scenarios and the combined scenarios where the individual vessel activities occur concurrently.

Table 48. Summary of percentage change in ensonified area between corresponding individual scenarios and combined scenarios based on the marine mammal behavioural response criterion of 120 dB re 1 µPa (SPL) and frequency-weighted LF-cetacean SEL_{24h} TTS thresholds based on Southall et al. (2019).

Scenario number	Description	Marine Mammal behavioural response [a]	LF-cetacean TTS [b]	LF-cetacean PTS [c]
		Percentage change in ensonified area (km^2) from individual to combined scenarios (%)	Percentage change in ensonified area (km^2) from individual to combined scenarios (%)	Percentage change in ensonified area from individual scenarios to combined (%)
37	Area 1, pipelay vessel with 2 OSVs + Area 3, drillship with OSV	+0.37	-0.18	*
38	Area 1, OCV with 3 support vessels + Area 2, IMR vessel + Area 3, drillship with OSV	+3.21	0	*
39	Area 3, drillship with OSV + Area 5, pipelay vessel with 2 OSVs	+4.04	0	*
40	Area 5, drillship with OSV + Area 5, pipelay vessel with 2 OSVs	+12.9	+2.80	*

Noise exposure criteria: [a] NOAA (2019) and [b] Southall et al. (2019).
* Percentage change associated with area difference less than the modelled resolution (0.0013 km^2)

Only Scenario 40 resulted in overlapping ensonified areas such that the two behavioural effect zones of the drilling and pipelay activities combined into one larger area (with 12.9% greater ensonified area compared to the two individual scenarios. The SEL_{24h} areas for Scenario 40, and all areas for Scenarios 37, 38 and 39, did not result in merged effect zones and the percentage change in ensonified areas therefore remained low (<5%) (Figures 55, 56, and 57). The lack of change in ensonified area for Scenarios 37, 38 and 39 was primarily due to the distances between concurrent activities being larger than the sum of the effect radii of the individual activities.

The pipelaying activities modelled here were located in the centre of flowlines in order to provide a nominal location along the track. At either end of the flowlines, the pipelay vessel and its support vessels will be closer to activities being conducted at specific infrastructure, such as construction or drilling. While the modelled sound fields presented here are specific to the modelled site locations, the effect radii summarised in Section 4.1 provide some guidance to the spacing between individual scenarios that will result in overlapping, or merged, effect zones.

The sound speed profile (Appendix B.1.2) was derived from data from the U.S. Naval Oceanographic Office's Generalized Digital Environmental Model V 3.0 (GDEM; Teague et al. 1990, Carnes 2009). The profile was defined by considering the Development location and was generally consistent with an open ocean deep water profile and it was applied to all modelled sites. This type of sound speed profile is characterised by decreasing sound speed due to decreases in temperature below the sea surface, however at some water depths, sound speeds increase as density increases due to hydrostatic overburden (Jensen et al. 2011). The profile had a minimum sound speed at approximately 800–1000 m water depth, which defines the sound channel axis and is the approximate centre of the deep sound channel. For energy trapped within the deep sound channel or duct, upward travelling energy would be refracted downward and downward travelling energy would be refracted upwards. When acoustic energy becomes trapped in the deep sound channel, it propagates very large distances with little loss within the ocean interior.

5.2. Acoustic Modelling - VSP Scenarios

The VSP produces generally symmetric sound fields across all three sites, as observed in Figures 100–105. Tables 32–42 show that modelling at Site A generally resulted in the largest ranges to considered effect criteria. Site A is the shallowest site and is located above a more reflective seabed than the other considered sites, fine sand sediments compared to silty sediments. These two factors likely contributed to the larger radii at Site A compared to Sites B and C. Sites B and C have very similar distances to thresholds despite the differing seabed characteristics. Whilst the water depths at these sites do differ by about 230 m, they are both located in water approximately 1000 m deep and the radii to effects criteria are therefore likely characterised by similar propagation mechanisms.

Marine mammals:

Marine mammal injury criteria, from Southall et al. (2019), requires two metrics (PK and SEL_{24h}) to be considered for impulsive noise when assessing marine mammal PTS and TTS with the longest distance associated with either metric required to be applied. In this study, the longest horizontal distances to the low-frequency cetacean PTS and TTS thresholds were associated with the SEL_{24h} metric (0.48 km and 3.20 km, respectively), while the longest horizontal distances to the very-high-frequency cetacean PTS and TTS thresholds were associated with the PK metric (0.06 km and 0.13 km, respectively).

The maximum distance to the NOAA (2019) marine mammal behavioural response criterion of 160 dB re 1 µPa (SPL) was 2.37 km, which was associated with Site A. The corresponding distances at Sites B and C were 1.33 km and 1.35 km, respectively.

Sea turtles:

For sea turtles, the maximum distance to the SEL_{24h} metrics of 204 dB re 1 μPa^2s for PTS and 189 dB re 1 μPa^2s for TTS was 0.03 km for PTS onset and 0.24 km for TTS onset for the 750 in^3 seismic source (Finneran et al. 2017). As is the case with marine mammals, a reported radius for SEL_{24h} criteria does not mean that sea turtles travelling within this radius of the source will be injured, but rather that an animal could be exposed to the sound level associated with either PTS or TTS if it remained in that location for 24 hours.

The PK sea turtle injury criteria of 232 dB re 1 µPa for PTS and 226 dB re 1 µPa for TTS from Finneran et al. (2017) was not exceeded at a distance longer than 20 m from the acoustic centre of the source.

The maximum distances to the behavioural response criteria for sea turtles of 166 dB re 1 µPa (SPL) and the 175 dB re 1 µPa (SPL) threshold for behavioural disturbance were 1.03 km and 0.27 km, respectively for the 750 in^3 seismic source (McCauley et al. 2000).

Fish, fish eggs, and fish larvae:

The effects of sound exposure on fish were considered in relation to both PK and SEL_{24h} metrics associated with mortality, potential mortal injury and impairment, based on quantitative criteria from Popper et al. (2014) for the following groups:

- Fish without a swim bladder (also appropriate for sharks in the absence of other information),
- Fish with a swim bladder that do not use it for hearing,
- Fish that use their swim bladders for hearing, and
- Fish eggs and fish larvae.

Table 49 summarises the maximum distances to effect criteria for fish, fish eggs, and fish larvae along with the relevant metric across all three modelled locations. The mortality and recoverable injury distances were comparable across the three sites, but the distance to the TTS threshold was longest at Site A.

Table 49. Summary of maximum fish, fish eggs, and larvae injury and temporary threshold shift (TTS) onset distances for any modelled site, for single impulse and 24 h sound exposure level (SEL_{24h}) modelled scenarios.

Relevant hearing group	Effect criteria	Water column	
		Metric associated with longest distance to criteria	R_{max} (km)
Fish: No swim bladder	Recoverable injury	–	–
	TTS	SEL_{24h}	0.57
Fish: Swim bladder not involved in hearing and Swim bladder involved in hearing	Recoverable injury	SEL_{24h}	0.05
	TTS	SEL_{24h}	0.57
Fish eggs, and larvae	Injury	SEL_{24h}	0.05

A dash indicates the threshold was not reached within the limits of the modelling resolution (20 m).

Benthic invertebrates:

The maximum radius of ensonified areas where sound levels exceeded 202 dB re 1 µPa PK-PK (Payne et al. 2008) was 60.8 m from Site A; in this area crustaceans may be negatively affected by sound. This threshold was not exceeded at Sites B or C. Sound levels of 209 to 213 dB re 1 µPa PK-PK (Day et al. (2016a); Day et al (2016b)), which are related to crustacean impairment, were also considered in this study; these levels were not reached for any VSP modelling site at a depth of 5 cm above the seafloor.

5.3. Animal Movement Modelling

The estimated sound fields produced by source and propagation models for the planned construction of the Chevron Gorgon Gas Development were incorporated into an animat sound exposure model for migrating pygmy blue whales to estimate the radial distance within which 95% of the exposure exceedances occur ($ER_{95\%}$), along with the probability that an animat with the closest point of approach within that distance would be exposed above the relevant threshold (P_{exp}).

For the exposure analysis, a subset of acoustic modelling scenarios (see Table 7) were run with BIA-restricted and unrestricted animat seeding. Scenarios 8 and Scenarios 30, 33 and 40 are located approximately 1.6 and 5.5 km outside of the migratory BIA for pygmy blue whales, respectively, whereas Scenarios 14, 18 and 21 fully, and Scenarios 38 and 39 partially overlap with the BIA (Figure 8).

Sections 5.3.1 and 5.3.2 summarise the PTS, TTS and behavioural exposure range results, with Table 50 summarising the maximum exposure range results for pygmy blue whales not restricted to their corresponding BIAs.

Table 50. Summary of animat simulation results for PTS, TTS, and SPL behavioural response criteria for pygmy blue whales with unrestricted seeding Exposure ranges show $ER_{95\%}$ (km) first and probability of exposure of animats travelling within the $ER_{95\%}$ (P_{exp} (%)) in parentheses. A dash (-) indicates that no animat was exposed above the threshold.

Scenario Number	Species	Behavioural response (SPL)[4]	TTS (SEL_{24h})[3]	PTS (SEL_{24h})[3]
		120[2]	179[1]	199[1]
8	Pygmy blue whale	12.4 (99%)	0.04 (67%)	–
14		0.73 (88%)	0.02 (87%)	–
18		2.76 (77%)	0.02 (76%)	–
21		5.03 (73%)	0.02 (91%)	–
30		8.03 (>99%)	0.02 (80%)	–
33		9.56 (>99%)	0.02 (77%)	–
38		12.3 (50%)	0.03 (61%)	–
39		9.47 (63%)	0.02 (77%)	–
40		9.55 (98%)	0.02 (79%)	–

[1] LF-weighted SEL_{24h} ($L_{E,24h}$; dB re 1 $\mu Pa^2 \cdot s$)
[2] SPL (L_p; dB re 1 µPa)
[3] Southall et al. (2019) criteria for marine fauna.
[4] NOAA (2019) recommended unweighted behavioural threshold for marine mammals.

5.3.1. Behavioural Effects

Exposure ranges for single exposure metrics, such as the SPL behavioural response criteria, are typically comparable to the predicted acoustic ranges. Acoustic ranges are conservatively calculated using the maximum-over-depth sound fields while exposure ranges account for animats sampling the sound field vertically based on species-specific diving parameters, so exposure ranges are often slightly lower than acoustic ranges.

For all considered scenarios with unrestricted animat seeding, the $ER_{95\%}$ to behavioural threshold ranged from 0.73–12.4 km for pygmy blue whales, with P_{exp} varying between 50 and >99%. Overall, ranges were longest for Scenarios 8 and 38.

The different site locations within the scenarios and their impact on exposure ranges are also visible in the histograms showing the CPA ranges to the behavioural response threshold for BIA-restricted pygmy blue whale animats (see Section 4.5.1).

Scenario 21 is located within the migratory BIA for pygmy blue whales and therefore, shows no significant difference between the BIA-restricted and the unrestricted animat seeding simulations (see Figures 108 and 109).
Scenario 39 includes Sites 21 and 22, which are both located within the migratory BIA for pygmy blue whales, and Sites 37 to 39, which are located approximately 5.5 km outside of the BIA. Figure 111 shows CPA ranges to the behavioural response threshold with a high frequency of exposure ranges within the 5 – 6 km bins, which is the closest any animats can come to Sites 37 to 39 of Scenario 39. Any exposure ranges below that are associated with exposures to Sites 21 and 22 as these ones are located within the BIA.
A similar argument can be applied to the CPA ranges for BIA-restricted animats for Scenario 38 (Figure 111).Furthermore, the closest distance between the modelled sites from Scenario 8, Sites 7 to 10, and the BIA is approximately 1.6 km, which explains why minimum CPA ranges for BIA-restricted animats are within the 1.5 to 2 km bin (see Figure 107). A similar argument applies to the CPA ranges for BIA-restricted animats for Scenario 40 (see Figure 115), where the BIA is located approximately 5.5 km from the associated modelled sites.

Due to the main lobe of acoustic energy extending to larger ranges as depth increases, the animat determined exposure ranges were slightly lower than the static acoustic ranges for all considered scenarios, as expected based on the vertical distribution of the sound field. Migrating pygmy blue whales are expected to spend most of their time in a behavioural mode where most dives reach less than 60 m in depth. Figure 116 shows a vertical slice beginning at the source location and extending towards deeper water at an azimuth of 315°. This plot shows how migrating pygmy blue whales sample the upper portion of the water column, which is quieter, and results in exposure ranges that are shorter than acoustic ranges at this location.

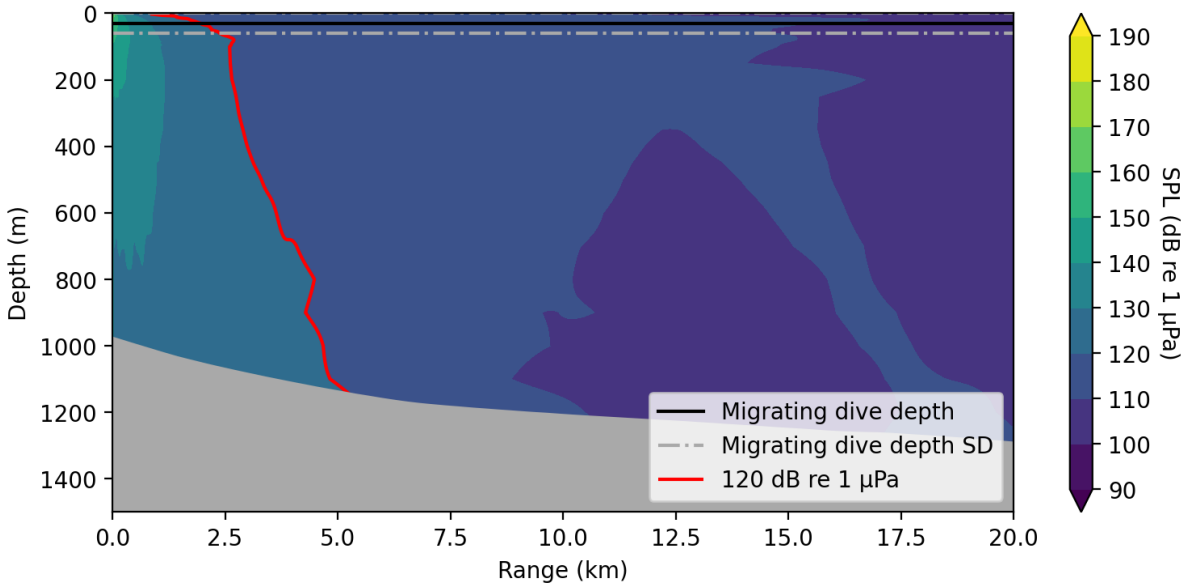

Figure 116. *Scenario 21, Site 23:* Example SPL vertical from the pipelay vessel at an azimuth of 315°. The 120 dB behavioural response threshold is highlighted in red, and the migrating pygmy blue whale dive depth (mean and one standard deviation) is indicated by horizontal lines.

5.3.2. PTS and TTS

Exposure ranges from animal movement modelling for PTS and TTS criteria are typically shorter than those predicted using acoustic propagation modelling because of the generally shorter time (‘dwell time’) to accumulate sound energy of the moving animats. In this analysis, there were no PTS exposures predicted for any of the pygmy blue whale simulations. Unrestricted seeding of animats resulted in a maximum $ER_{95\%}$ for TTS of 0.04 km with a corresponding exposure probability for animats travelling within that range of 67%.

Exposure ranges are, in general, slightly longer for TTS and PTS for unrestricted vs BIA-restricted scenarios because unrestricted animats have more opportunities to be exposed to sound fields closer to the source and for a longer time, which effectively lengthens their dwell time. This is the case for this study. Restricting animats to the migratory BIA for pygmy blue whales resulted in no exposures above TTS for Scenarios 8, 30, 33 and 40. The maximum $ER_{95\%}$ for TTS was 0.02 km with a corresponding exposure probability for animats travelling within the range of 87%.

5.4. Conclusion

This modelling study considered underwater sound levels associated with vessel activities and VSP for the construction of the Chevron Gorgon Gas Development: Backfill Fields. The modelling study considered 30 individual vessel activity scenarios across five representative Areas of the Development, four combined vessel scenarios, and scenarios at three VSP sites. The modelling study predicted the distances from operations at which underwater sound levels reached noise effect thresholds and criteria for marine mammals, sea turtles and fish.

The greatest horizontal distances were associated with the OCV with construction support vessels in Areas 1, 2, 3 and 5, which resulted in a 120 dB SPL marine mammal behavioural effect radius of up to 17.3 km. In Area 4, where construction was not modelled, the pipelay vessel with two support vessels resulted in the longest distances to effect thresholds (120 dB SPL marine mammal behavioural effect radii 18.3 km in Area 4). The smallest horizontal distances to effect thresholds were associated with scenarios that modelled a single IMR vessel.

In the combined vessel scenarios, the lack of change in ensonified area for Scenarios 37, 38 and 39 was primarily due to the distances between concurrent activities being larger than the sum of the effect radii of the individual activities. Only Scenario 40 resulted in overlapping ensonified areas such that the two behavioural effect zones of the drilling and pipelay activities in Area 5 combined into one larger area (with 12.9% greater ensonified area compared to the two individual scenarios). While the modelled sound fields presented here are specific to the modelled site locations, the effect radii summarised in Section 4.1 provide some guidance to the spacing between individual scenarios that will result in overlapping, or merged, effect zones.

The VSP results demonstrated that the greatest distances to noise-effect thresholds were generally associated with Site A, the shallowest site, rather than Sites B and C. It is likely that the shallow water depth at Site A resulted in sound reflecting from the seabed. The longest horizontal distances to the low-frequency cetacean PTS and TTS thresholds were 0.48 km and 3.20 km, respectively. The maximum distance to the 160 dB re 1 µPa (SPL) marine mammal behavioural response criterion was 2.37 km, which was associated with Site A. The corresponding distances at Sites B and C were 1.33 km and 1.35 km, respectively. For sea turtles, behavioural disturbance could occur up to 1.03 km from the VSP acoustic centre, with PTS and TTS maximum distances of 0.03 km and 0.24 km, respectively. All effect zones for fish were less than 0.6 km. Crustaceans may be affected within 60.8 m of Site A, but levels were not predicted to exceed effect thresholds at Sites B or C.

The JASCO Animal Simulation Model Including Noise Exposure (JASMINE) was used to predict sound exposure for migrating pygmy blue whales in their migration BIA. The exposure ranges predicted using animat modelling are significantly more realistic than the acoustic modelling outlined above, due to the incorporation of species-specific realistic movements. In this study, there were no exposures above PTS threshold for any of the pygmy blue whale scenarios. The maximum $ER_{95\%}$ to TTS threshold was 0.04 km. 67% of pygmy blue whale animats that travelled within this distance were exposed above the TTS threshold. All scenarios resulted in the exposure of pygmy blue whale animats above the SPL behavioural response threshold NOAA (2019). Of these, the maximum $ER_{95\%}$ to the threshold was 12.4 km pygmy blue whales (Scenario 8 – OCV under DP with three support vessels). The probability of exposure for animats that travelled within this range was 99%.

Glossary

1/3-octave

One third of an octave. *Note*: A 1/3-octave is approximately equal to one decidecade (1/3 oct ≈ 1.003 ddec).

absorption

The conversion of sound energy to heat energy. Specifically, the reduction of sound pressure amplitude due to particle motion energy converting to heat in the propagation medium.

acoustic noise

Sound that interferes with an acoustic process.

acoustic self-noise

Sound at a receiver caused by the deployment, operation, or recovery of a specified receiver, and its associated platform (ISO 18405:2017).

agent-based modelling

A computer simulation of autonomous agents (sometimes called animats) acting in an environment, used to assess the agents' experience of the environment and/or their effect on the environment. See also animal movement modelling.

ambient sound

Sound that would be present in the absence of a specified activity (ISO 18405:2017). It is usually a composite of sound from many sources near and far, e.g., shipping vessels, seismic activity, precipitation, sea ice movement, wave action, and biological activity.

animal movement modelling

Simulation of animal movement based on behavioural rules for the purpose of predicting an animal's experience of an environment. A type of agent-based modelling.

attenuation

The gradual loss of acoustic energy from absorption and scattering as sound propagates through a medium. Attenuation depends on frequency—higher frequency sounds are attenuated faster than lower frequency sounds.

audiogram

A graph or table of hearing threshold as a function of frequency that describes the hearing sensitivity of an animal over its hearing range.

auditory frequency weighting

The process of applying an auditory frequency-weighting function. An example for marine mammals are the auditory frequency-weighting functions published by Southall et al. (2007).

auditory frequency-weighting function

Frequency-weighting function describing a compensatory approach accounting for a species' (or functional hearing group's) frequency-specific hearing sensitivity.

background noise

Combination of ambient sound, acoustic self-noise, and, where applicable, sonar reverberation (ISO 18405:2017) that is detected, measured, or recorded with a signal.

bandwidth

A range within a continuous band of frequencies. Unit: hertz (Hz).

broadband level

The total level measured over a specified frequency range. If the frequency range is unspecified, the term refers to the entire measured frequency range.

cavitation

A rapid formation and collapse of vapor cavities (i.e., bubbles or voids) in water, most often caused by a rapid change in pressure. Fast-spinning vessel propellers typically cause cavitation, which creates a lot of noise.

cetacean

Member of the order Cetacea. Cetaceans are aquatic mammals and include whales, dolphins, and porpoises.

compressional wave

A mechanical vibration wave in which the direction of particle motion is parallel to the direction of propagation. Also called a longitudinal wave. In seismology/geophysics, it's called a primary wave or P-wave. Shear waves in the seabed can be converted to compressional waves in water at the water-seabed interface.

conductivity-temperature-depth (CTD)

Measurement data of the ocean's conductivity, temperature, and depth; used to compute sound speed profiles and salinity.

continuous sound

A sound whose sound pressure level remains above the background noise during the observation period and may gradually vary in intensity with time, e.g., sound from a marine vessel.

critical band

The auditory bandwidth within which background noise strongly contributes to masking of a single tone. Unit: hertz (Hz).

critical ratio level

The difference between the sound pressure level of a masked tone, which is barely audible, and the spectral density level of the background noise at similar frequencies, referenced to 1 Hz. Unit: decibel (dB).

decade

Logarithmic frequency interval whose upper bound is ten times larger than its lower bound (ISO 80000-3:2006). For example, one decade up from 1000 Hz is 10,000 Hz, and one decade down is 100 Hz.

decibel (dB)

Unit of level used to express the ratio of one value of a power quantity to another on a logarithmic scale. Especially suited to quantify variables with a large dynamic range.

decidecade

One tenth of a decade. Approximately equal to one third of an octave (1 ddec ≈ 0.3322 oct), and for this reason sometimes referred to as a 1/3-octave.

decidecade band

Frequency band whose bandwidth is one decidecade. *Note*: The bandwidth of a decidecade band increases with increasing centre frequency.

delphinid

Member of the family of oceanic dolphins (Delphinidae), composed of approximately 35 extant species, including dolphins, porpoises, and killer whales.

energy source level

A property of a sound source equal to the sound exposure level measured in the far field plus the propagation loss from the acoustic centre of the source to the receiver position. Unit: decibel (dB). Reference value: 1 $\mu Pa^2\,m^2\,s$.

ensonified

Exposed to sound.

equal-loudness-level contour

Curve that shows, as a function of frequency, the sound pressure level required to produce a given loudness for a listener having normal hearing, listening to a specified kind of sound in a specified manner (ANSI S1.1-2013).

far field

The zone where, to an observer, sound originating from an array of sources (or a spatially distributed source) appears to radiate from a single point.

frequency

The rate of oscillation of a periodic function measured in cycles per unit time. The reciprocal of the period. Unit: hertz (Hz). Symbol: f. 1 Hz is equal to 1 cycle per second.

frequency weighting

The process of applying a frequency-weighting function.

frequency-weighting function

The squared magnitude of the sound pressure transfer function (ISO 18405:2017). For sound of a given frequency, the frequency-weighting function is the ratio of output power to input power of a specified filter, sometimes expressed in decibels. Examples include the following:

- *Auditory frequency-weighting function*: compensatory frequency-weighting function accounting for a species' (or functional hearing group's) frequency-specific hearing sensitivity.
- *System frequency-weighting function*: frequency-weighting function describing the sensitivity of an acoustic recording system, which typically consists of a hydrophone, one or more amplifiers, and an analog-to-digital converter.

functional hearing group

Category of animal species when classified according to their hearing sensitivity, hearing anatomy, and susceptibility to sound. For marine mammals, initial groupings were proposed by Southall et al. (2007), and revised groupings are developed as new research/data becomes available. Revised groupings proposed by Southall et al. (2019) include low-frequency cetaceans, high-frequency cetaceans, very high-frequency cetaceans, phocid carnivores in water, other carnivores in water, and sirenians. See auditory frequency-weighting functions, which are often applied to these groups. Example hearing groups for fish include species for which the swim bladder is involved in hearing, species for which the swim bladder is not involved in hearing, and species without a swim bladder (Popper et al. 2014).

geoacoustic

Relating to the acoustic properties of the seabed.

harmonic

A sinusoidal sound component that has a frequency that is an integer multiple of the frequency of a sound to which it is related. For a sound with a fundamental frequency of f, the harmonics have frequencies of $2f$, $3f$, $4f$, etc.

hearing threshold

For a given species or functional hearing group, the sound level for a given signal that is barely audible (i.e., that would be barely audible for a given individual in the presence of specified background noise during a specific percentage of experimental trials).

hertz (Hz)

Unit of frequency defined as one cycle per second. Often expressed in multiples such as kilohertz (1 kHz = 1000 Hz).

high-frequency (HF) cetaceans

See functional hearing group. *Note*: The mid- and high-frequency cetaceans groups proposed by Southall et al. (2007) were renamed high- and very-high-frequency cetaceans, respectively, by Southall et al. (2019).

hydrophone

An underwater sound pressure transducer. A passive electronic device for recording or listening to underwater sound.

hydrostatic pressure

The pressure at any given depth in a static liquid that is the result of the weight of the liquid acting on a unit area at that depth, plus any pressure acting on the surface of the liquid. Unit: pascal (Pa).

impulsive sound

Qualitative term meaning sounds that are typically transient, brief (less than 1 s), broadband, with rapid rise time and rapid decay. They can occur in repetition or as a single event. Sources of impulsive sound include, among others, explosives, seismic airguns, and impact pile drivers.

isopleth

A line drawn on a map through all points having the same value of some specified quantity (e.g., sound pressure level isopleth).

knot (kn)

Unit of vessel speed equal to 1 nautical mile per hour.

level

A measure of a quantity expressed as the logarithm of the ratio of the quantity to a specified reference value of that quantity. For example, a value of sound pressure level with reference to 1 μPa^2 can be written in the form *x* dB re 1 μPa^2.

low-frequency (LF) cetaceans

See functional hearing group.

masking

Obscuring of sounds of interest by other sounds at similar frequencies.

median

The 50th percentile of a statistical distribution.

mid-frequency (MF) cetaceans

See functional hearing group. *Note*: The mid-frequency cetaceans group proposed by Southall et al. (2007) was renamed high-frequency cetaceans by Southall et al. (2019).

monopole source level (MSL)

A source level that has been calculated using an acoustic model that accounts for the effect of the sea-surface and seabed on sound propagation, assuming a point source (monopole). Often used to quantify source levels of vessels or industrial operations from measurements. See also radiated noise level.

Monte Carlo simulation

A method of investigating the distribution of a non-linear multi-variate function by random sampling of its input variable distributions.

multiple linear regression

A statistical method that seeks to explain the response of a dependent variable using multiple explanatory variables.

M-weighting

A set of auditory frequency-weighting functions proposed by Southall et al. (2007).

mysticete

Member of the Mysticeti, a suborder of cetaceans. Also known as baleen whales, mysticetes have baleen plates (rather than teeth) that they use to filter food from water (or from sediment as for grey whales). This group includes rorquals (Balaenopteridae, such as blue, fin, humpback, and minke whales), right and bowhead whales (Balaenidae), and grey whales (*Eschrichtius robustus*).

***N* percent exceedance level**

The sound level exceeded *N* % of the time during a specified time interval. See also percentile level.

non-impulsive sound

Sound that is not an impulsive sound. Not necessarily a continuous sound.

octave

The interval between a sound and another sound with double or half the frequency. For example, one octave above 200 Hz is 400 Hz, and one octave below 200 Hz is 100 Hz.

odontocete

Member of Odontoceti, a suborder of cetaceans. These whales, dolphins, and porpoises have teeth (rather than baleen plates). Their skulls are mostly asymmetric, an adaptation for their echolocation. This group includes sperm whales, killer whales, belugas, narwhals, dolphins, and porpoises.

otariid

Member of the family Otariidae, one of the three groupings of pinnipeds (along with phocids and walrus). These eared seals, commonly called fur seals and sea lions, are adapted to semi-aquatic life; they use their large fore flippers for propulsion underwater and can walk on all four limbs on land.

otariid pinnipeds underwater (OW)

See functional hearing group.

other marine carnivores in water (OCW)

See functional hearing group.

parabolic equation method

A computationally efficient solution to the acoustic wave equation that is used to model propagation loss. The parabolic equation approximation omits effects of backscattered sound (which are negligible for most ocean-acoustic propagation problems), simplifying the computation of propagation loss.

particle acceleration, particle displacement, particle motion, particle velocity

See sound particle acceleration, sound particle displacement, sound particle motion, sound particle velocity.

peak sound pressure level (PK), zero-to-peak sound pressure level

The level (L_{pk}) of the squared maximum magnitude of the sound pressure (p_{pk}^2) in a stated frequency band and time window. Defined as $L_{\mathrm{pk}} = 10log_{10}(p_{\mathrm{pk}}^2/p_0^2) = 20log_{10}(p_{pk}/p_0)$. Unit: decibel (dB). Reference value (p_0^2) for sound in water: 1 μPa^2.

peak-to-peak sound pressure

The difference between the maximum and minimum sound pressure over a specified frequency band and time window. Unit: pascal (Pa).

percentile level

The sound level not exceeded *N* % of the time during a specified time interval. The *N*th percentile level is equal to the (100−*N*) % exceedance level. See also N percent exceedance level.

permanent threshold shift (PTS)

An irreversible loss of hearing sensitivity caused by excessive noise exposure. Considered auditory injury. Compare with temporary threshold shift.

phocid

Member of the family Phocidae, one of the three groupings of pinnipeds (along with otariids and walrus). These true/earless seals are more adapted to in-water life than are otariids, which have more terrestrial adaptations. Phocids use their hind flippers to propel themselves underwater.

phocid pinnipeds underwater (PW), phocid carnivores in water (PCW)

See functional hearing group.

pinniped

Member of the superfamily Pinnipedia, which is composed of phocids (true seals or earless seals), otariids (eared seals or fur seals and sea lions), and walrus.

point source

A source that radiates sound as if from a single point.

propagation loss (PL)

Difference between a source level (SL) and the level at a specified location, $\mathrm{PL}(x) = \mathrm{SL} - L(x)$. Unit: decibel (dB). See also transmission loss.

radiated noise level (RNL)

A source level that has been calculated assuming sound pressure decays geometrically with distance from the source, with no influence of the sea-surface or seabed. Often used to quantify source levels of vessels or industrial operations from measurements. See also monopole source level.

received level

The level of a given field variable measured (or that would be measured) at a given location.

reference value

Standard value of a quantity used for calculating underwater sound level. The reference value depends on the quantity for which the level is being calculated:

Quantity	Reference value
Sound pressure	p_0^2 = 1 µPa^2 or p_0 = 1 µPa
Sound exposure	E_0 = 1 µPa^2 s
Sound particle displacement	δ_0^2 = 1 pm^2
Sound particle velocity	u_0^2 = 1 nm^2/s^2
Sound particle acceleration	a_0^2 = 1 µm^2/s^4

sensation level

Difference between the sound pressure level and hearing threshold at a specified frequency. Unit: decibel (dB).

shear wave

A mechanical vibration wave in which the direction of particle motion is perpendicular to the direction of propagation. Also called a secondary wave or S-wave. Shear waves propagate only in solid media, such as sediments or rock. Shear waves in the seabed can be converted to compressional waves in water at the water-seabed interface.

sirenians (SI)

Members of the order Sirenia, which includes several manatee species and the dugong. See also functional hearing group.

sound

A time-varying disturbance in the pressure, stress, or material displacement of a medium propagated by local compression and expansion of the medium. In common meaning, a form of energy that propagates through media (e.g., water, air, ground) as pressure waves.

sound exposure

Time integral of squared sound pressure over a stated time interval in a stated frequency band. The time interval can be a specified time duration (e.g., 24 h) or from start to end of a specified event (e.g., a pile strike, an airgun pulse, a construction operation). Unit: pascal squared second (Pa^2 s). Symbol: E.

sound exposure level (SEL)

The level (L_E) of the sound exposure (E) in a stated frequency band and time window: $L_E = 10\log_{10}(E/E_0)$ (ISO 18405:2017). Unit: decibel (dB). Reference value (E_0) for sound in water: 1 μPa^2 s.

sound exposure spectral density

Distribution as a function of frequency of the time-integrated squared sound pressure per unit bandwidth of a sound having a continuous spectrum (ISO 18405:2017). Unit: pascal squared second per hertz (Pa^2 s/Hz).

sound field

Region containing sound waves.

sound intensity

Product of the sound pressure and the sound particle velocity (ISO 18405:2017). The magnitude of the sound intensity is the sound energy flowing through a unit area perpendicular to the direction of propagation per unit time. Unit: watt per metre squared (W/m^2). Symbol: I.

sound particle acceleration

The rate of change of sound particle velocity. Unit: metre per second squared (m/s^2). Symbol: a.

sound particle motion

Movement caused by the action of sound of the smallest volume of a medium that represents its mean physical properties. Important for determining effects of underwater noise on fishes and invertebrates because their hearing organs sense particle motion rather than sound pressure.

sound particle displacement

Displacement of a material element caused by the action of sound, where a material element is the smallest element of the medium that represents the medium's mean density (ISO 18405:2017). Unit: metre (m). Symbol: δ.

sound particle velocity

The velocity of a particle in a material moving back and forth in the direction of the pressure wave. Unit: metre per second (m/s). Symbol: u.

sound pressure

The contribution to total pressure caused by the action of sound (ISO 18405:2017). Unit: pascal (Pa). Symbol: p.

sound pressure level (SPL), rms sound pressure level

The level (L_p) of the time-mean-square sound pressure (p_{rms}^2) in a stated frequency band and time window: $L_p = 10\log_{10}(p_{\mathrm{rms}}^2/p_0^2) = 20\log_{10}(p_{rms}/p_0)$, where rms is the abbreviation for root-mean-square. Unit: decibel (dB). Reference value (p_0^2) for sound in water: 1 µPa^2. SPL can also be expressed in terms of the root-mean-square (rms) with a reference value of p_0 = 1 µPa. The two definitions are equivalent.

sound speed profile

The speed of sound in the water column as a function of depth below the water surface.

soundscape

The characterization of the ambient sound in terms of its spatial, temporal, and frequency attributes, and the types of sources contributing to the sound field (ISO 18405:2017).

source level (SL)

A property of a sound source equal to the sound pressure level measured in the far field plus the propagation loss from the acoustic centre of the source to the receiver position. Unit: decibel (dB). Reference value: 1 µPa^2 m^2.

spectrogram

A visual representation of acoustic amplitude over time and frequency. A spectrogram's resolution in the time and frequency domains should generally be stated as it determines the information content of the representation.

spectrum

Distribution of acoustic signal content over frequency, where the signal's content is represented by its power, energy, mean-square sound pressure, or sound exposure.

surface duct

The upper portion of a water column within which the gradient of the sound speed profile causes sound to refract upward and therefore reflect repeatedly off the surface resulting in relatively long-range sound propagation with little loss.

temporary threshold shift (TTS)

Reversible loss of hearing sensitivity caused by noise exposure. Compare with permanent threshold shift.

thermocline

A depth interval near the ocean surface that experiences larger temperature gradients than the layers above and below it due to warming or cooling by heat conduction from the atmosphere and by warming from the sun.

transmission loss (TL)

The difference between a specified level at one location and that at a different location: $\mathrm{TL}(x_1,x_2) = L(x_1) - L(x_2)$ (ISO 18405:2017). Unit: decibel (dB). See also propagation loss.

unweighted

Term indicating that no frequency-weighting function is applied.

very high-frequency (VHF) cetaceans

See functional hearing group.

wavelength

Distance over which a wave completes one cycle of oscillation. Unit: metre (m). Symbol: λ.

Appendix A. Acoustic Metrics

This section describes in detail the acoustic metrics, impact criteria, and frequency weighting relevant to the modelling study.

A.1. Pressure Related Acoustic Metrics

Underwater sound pressure amplitude is measured in decibels (dB) relative to a fixed reference pressure of p_0 = 1 µPa. Because the perceived loudness of sound, especially pulsed sound such as from seismic airguns, pile driving, and sonar, is not generally proportional to the instantaneous acoustic pressure, several sound level metrics are commonly used to evaluate sound and its effects on marine life. Here we provide specific definitions of relevant metrics used in the accompanying report. Where possible, we follow International Organization for Standardization definitions and symbols for sound metrics (e.g., ISO 2017, ANSI S1.1-2013).

The sound pressure level (SPL or L_p; dB re 1 µPa) is the root-mean-square (rms) pressure level in a stated frequency band over a specified time window (T; s). It is important to note that SPL always refers to an rms pressure level and therefore not instantaneous pressure:

$$L_p = 10 \log_{10} \left(\frac{1}{T} \int_T g(t)\, p^2(t)\, dt \Big/ p_0^2 \right) \text{ dB} \qquad \text{(A-1)}$$

where $g(t)$ is an optional time weighting function. In many cases, the start time of the integration is marched forward in small time steps to produce a time-varying SPL function.

The sound exposure level (SEL or L_E; dB re 1 µPa²·s) is the time-integral of the squared acoustic pressure over a duration (T):

$$L_E = 10 \log_{10} \left(\int_T p^2(t)\, dt \Big/ T_0 p_0^2 \right) \text{ dB} \qquad \text{(A-2)}$$

where T_0 is a reference time interval of 1 s. SEL continues to increase with time when non-zero pressure signals are present. It is a dose-type measurement, so the integration time applied must be carefully considered for its relevance to impact to the exposed recipients.

SEL can be calculated over a fixed duration, such as the time of a single event or a period with multiple acoustic events. When applied to pulsed sounds, SEL can be calculated by summing the SEL of the N individual pulses. For a fixed duration, the square pressure is integrated over the duration of interest. For multiple events, the SEL can be computed by summing (in linear units) the SEL of the N individual events:

$$L_{E,N} = 10 \log_{10} \left(\sum_{i=1}^{N} 10^{\frac{L_{E,i}}{10}} \right) \text{ dB}\,. \qquad \text{(A-3)}$$

If applied, the frequency weighting of an acoustic event should be specified, as in the case of weighted SEL (e.g., $L_{E,LFC,24h}$; Appendix A.4). The use of fast, slow, or impulse exponential-time-averaging or other time-related characteristics should also be specified.

A.2. Decidecade Band Analysis

The distribution of a sound's power with frequency is described by the sound's spectrum. The sound spectrum can be split into a series of adjacent frequency bands. Splitting a spectrum into 1 Hz wide bands, called passbands, yields the power spectral density of the sound. This splitting of the spectrum into passbands of a constant width of 1 Hz, however, does not represent how animals perceive sound.

Because animals perceive exponential increases in frequency rather than linear increases, analysing a sound spectrum with passbands that increase exponentially in size better approximates real-world scenarios. In underwater acoustics, a spectrum is commonly split into decidecade bands, which are one tenth of a decade wide. A decidecade is sometimes referred to as a "1/3 octave" because one tenth of a decade is approximately equal to one third of an octave. Each decade represents a factor 10 in sound frequency. Each octave represents a factor 2 in sound frequency. The centre frequency of the ith band, $f_c(i)$, is defined as:

$$f_c(i) = 10^{\frac{i}{10}} \text{ kHz} \tag{A-4}$$

and the low (f_{lo}) and high (f_{hi}) frequency limits of the ith decade band are defined as:

$$f_{lo,i} = 10^{\frac{-1}{20}} f_c(i) \quad \text{and} \quad f_{hi,i} = 10^{\frac{1}{20}} f_c(i) \tag{A-5}$$

The decidecade bands become wider with increasing frequency, and on a logarithmic scale the bands appear equally spaced (Figure A-1). The acoustic modelling spans from band 10 (f_c (10) = 10 Hz) to band 44 ($f_c(44)$ = 25 kHz).

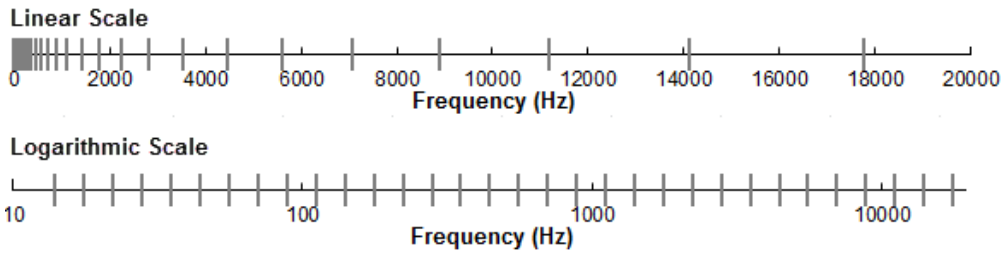

Figure A-1. Decidecade frequency bands (vertical lines) shown on a linear frequency scale and a logarithmic scale.

The sound pressure level in the ith band ($L_{p,i}$) is computed from the spectrum $S(f)$ between $f_{lo,i}$ and $f_{hi,i}$:

$$L_{p,i} = 10\, log_{10} \int_{f_{lo,i}}^{f_{hi,i}} S(f)\, df \text{ dB} \tag{A-6}$$

Summing the sound pressure level of all the bands yields the broadband sound pressure level:

$$\text{Broadband SPL} = 10 \log_{10} \sum_i 10^{\frac{L_{p,i}}{10}} \text{ dB} \tag{A-7}$$

Figure A-2 shows an example of how the decidecade band sound pressure levels compare to the sound pressure spectral density levels of an ambient sound signal. Because the decidecade bands are wider than 1 Hz, the decidecade band SPL is higher than the spectral levels at higher frequencies. Acoustic modelling of decidecade bands requires less computation time than 1 Hz bands and still resolves the frequency-dependence of the sound source and the propagation environment.

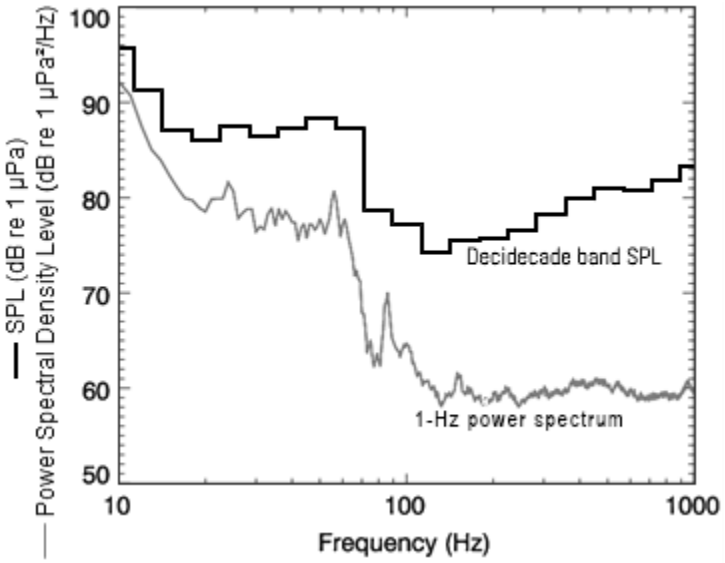

Figure A-2. Sound pressure spectral density levels and the corresponding decidecade band sound pressure levels of example ambient noise shown on a logarithmic frequency scale.Because the decidecade bands are wider with increasing frequency, the decidecade band SPL is higher than the power spectrum.

A.3. Marine Mammal Noise Effect Criteria

It has been long recognised that marine mammals can be adversely affected by underwater anthropogenic noise. For example, Payne and Webb (1971) suggest that communication distances of fin whales are reduced by shipping sounds. Subsequently, similar concerns arose regarding effects of other underwater noise sources and the possibility that impulsive sources—primarily airguns used in seismic surveys—could cause auditory injury. This led to a series of workshops held in the late 1990s, conducted to address acoustic mitigation requirements for seismic surveys and other underwater noise sources (NMFS 1998, ONR 1998, Nedwell and Turnpenny 1998, HESS 1999, Ellison and Stein 1999). In the years since these early workshops, a variety of thresholds have been proposed for auditory injury, impairment, and disturbance. The following sections summarise the recent development of thresholds; however, this field remains an active research topic.

A.3.1. Injury and Hearing Sensitivity Changes

In recognition of shortcomings of the SPL-only based auditory injury criteria, in 2005 NMFS sponsored the Noise Criteria Group to review literature on marine mammal hearing to propose new noise exposure criteria. Some members of this expert group published a landmark paper (Southall et al. 2007) that suggested assessment methods similar to those applied for humans. The resulting recommendations introduced dual auditory injury criteria for impulsive sounds that included peak pressure level thresholds and SEL_{24h} thresholds, where the subscripted 24h refers to the accumulation period for calculating SEL. The peak pressure level criterion is not frequency weighted whereas SEL_{24h} is frequency weighted according to one of four marine mammal species hearing groups: low-, mid- and high-frequency cetaceans (LF, MF, and HF cetaceans, respectively) and Pinnipeds in Water (PINN). These weighting functions are referred to as M-weighting filters (analogous to the A-weighting filter for humans; see Appendix A.4). The SEL_{24h} thresholds were obtained by extrapolating measurements of onset levels of Temporary Threshold Shift (TTS) in belugas by the amount of TTS required to produce Permanent Threshold Shift (PTS) in chinchillas. The Southall et al. (2007) recommendations do not specify an exchange rate, which suggests that the thresholds are the same regardless of the duration of exposure (i.e., it implies a 3 dB exchange rate).

As of present, a definitive approach is still not apparent. There is consensus in the research community that an SEL-based method is preferable, either separately or in addition to an SPL-based approach to assess the potential for injuries. In August 2016, after substantial public and expert input into three draft versions and based largely on the above-mentioned literature (NOAA 2013, 2015, 2016), NMFS finalised technical guidance for assessing the effect of anthropogenic sound on marine mammal hearing (NMFS 2016). The guidance describes auditory injury criteria with new thresholds and frequency weighting functions for the five hearing groups described by Finneran and Jenkins (2012). The latest revision to this work was published in 2018 (NMFS 2018). Southall et al. (2019) revisited the interim criteria published in 2007. All noise exposure criteria in NMFS (2018) and Southall et al. (2019) are identical (for impulsive and non-impulsive sounds); however, the mid-frequency cetaceans from NMFS (2018) are classified as high-frequency cetaceans in Southall et al. (2019), and high-frequency cetaceans from NMFS (2018) are classified as very-high-frequency cetaceans in Southall et al. (2019).

A.3.2. Behavioural Response

Numerous studies on marine mammal behavioural responses to sound exposure have not resulted in consensus in the scientific community regarding the appropriate metric for assessing behavioural reactions. However, it is recognised that the context in which the sound is received affects the nature and extent of responses to a stimulus (Southall et al. 2007, Ellison and Frankel 2012, Southall et al. 2016, Southall et al. 2021).

A.3.2.1. Non-Impulsive Noise

NMFS currently uses step function (all-or-none) threshold of 120 dB re 1 µPa SPL (unweighted) for non-impulsive sounds to assess and regulate noise-induced behavioural impacts on marine mammals (NOAA 2019). The 120 dB re 1 µPa threshold is associated with continuous sources and was derived based on studies examining behavioural responses to drilling and dredging, referring to Malme et al. (1983), Malme et al. (1984), and Malme et al. (1986), which were considered in Southall et al. (2007). Malme et al. (1986) found that playback of drillship noise did not produce clear evidence of disturbance or avoidance for levels below 110 dB re 1 µPa (SPL), possible avoidance occurred for exposure levels approaching 119 dB re 1 µPa. Malme et al. (1984) determined that measurable reactions usually consisted of rather subtle short-term changes in speed and/or heading of the whale(s) under observation. It has been shown that both received level and proximity of the sound source is a contributing factor in eliciting behavioural reactions in humpback whales (Dunlop et al. 2017, Dunlop et al. 2018).

A.3.2.2. Impulsive Noise

For impulsive noise, NMFS currently uses step function thresholds of 160 dB re 1 µPa SPL (unweighted) to assess and regulate noise-induced behavioural impacts for marine mammals (NOAA 2018, NOAA 2019). The threshold for impulsive sound is derived from the High-Energy Seismic Survey (HESS) panel (HESS 1999) report that, in turn, is based on the responses of migrating mysticete whales to airgun sounds (Malme et al. 1984)For impulsive noise, NMFS currently uses step function thresholds of 160 dB re 1 µPa SPL (unweighted) to assess and regulate noise-induced behavioural impacts for marine mammals (NOAA 2018, NOAA 2019). The threshold for impulsive sound is derived from the High-Energy Seismic Survey (HESS) panel (HESS 1999) report that, in turn, is based on the responses of migrating mysticete whales to airgun sounds (Malme et al. 1984). The HESS team recognised that behavioural responses to sound may occur at lower levels, but significant responses were only likely to occur above a SPL of 140 dB re 1 µPa. Southall et al. (2007) found varying responses for most marine mammals between a SPL of 140 and 180 dB re 1 µPa, consistent with the HESS (1999) report, but lack of convergence in the data prevented them from suggesting explicit step functions.

A.4. Marine Mammal Frequency Weighting

The potential for noise to affect animals depends on how well the animals can hear it. Noises are less likely to disturb or injure an animal if they are at frequencies that the animal cannot hear well. An exception occurs when the sound pressure is so high that it can physically injure an animal by non-auditory means (i.e., barotrauma). For sound levels below such extremes, the importance of sound components at particular frequencies can be scaled by frequency weighting relevant to an animal's sensitivity to those frequencies (Nedwell and Turnpenny 1998, Nedwell et al. 2007).

A.4.1. Marine Mammal Frequency Weighting Functions

In 2015, a US Navy technical report by Finneran (2015) recommended new auditory weighting functions. The overall shape of the auditory weighting functions is similar to human A-weighting functions, which follows the sensitivity of the human ear at low sound levels. The new frequency-weighting function is expressed as:

$$G(f) = K + 10\log_{10}\left[\left(\frac{(f/f_{lo})^{2a}}{\left[1+(f/f_{lo})^{2}\right]^{a}\left[1+(f/f_{hi})^{2}\right]^{b}}\right)\right] \quad \text{(A-8)}$$

Finneran (2015) proposed five functional hearing groups for marine mammals in water: low-, mid- and high-frequency cetaceans (LF, MF, and HF cetaceans, respectively), phocid pinnipeds, and otariid pinnipeds. The parameters for these frequency-weighting functions were further modified the following year (Finneran 2016) and were adopted in NOAA's technical guidance that assesses acoustic impacts on marine mammals (NMFS 2018), and in the latest guidance by Southall (2019). The updates did not affect the content related to either the definitions of frequency-weighting functions or the threshold values. Table A-1 lists the frequency-weighting parameters for each hearing group relevant to this assessment, and Figure A-3 shows the resulting frequency-weighting curves.

Table A-1. Parameters for the auditory weighting functions used in this project as recommended by Southall et al. (2019).

Hearing group	a	b	flo (Hz)	fhi (kHz)	*K* (dB)
Low-frequency cetaceans (baleen whales)	1.0	2	200	19,000	0.13
High-frequency cetaceans (most dolphins, plus sperm, beaked, and bottlenose whales)	1.6	2	8,800	110,000	1.20
Very-high-frequency cetaceans (true porpoises, *Kogia*, river dolphins, *Cephalorhynchus* spp., *Lagenorhynchus cruciger* and *L. australis*)	1.8	2	12,000	140,000	1.36

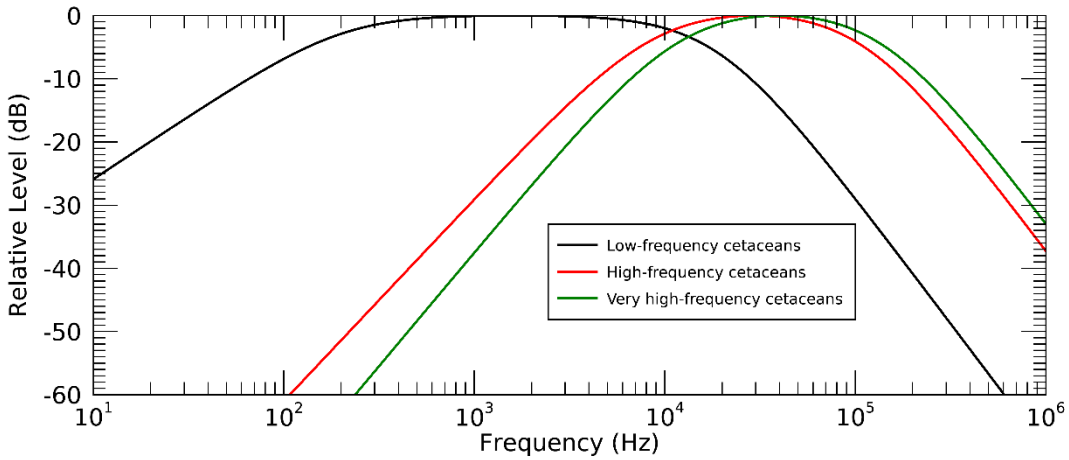

Figure A-3. Auditory weighting functions for functional marine mammal hearing groups used in this project as recommended by Southall et al. (2019).

Appendix B. Methods and Parameters

B.1. Environmental Parameters

B.1.1. Bathymetry

Bathymetry throughout the modelled area was extracted from the Australian Bathymetry and Topography Grid, a 9 arc-second grid rendered for Australian waters (Whiteway 2009). Bathymetry data were re-gridded and combined onto a Map Grid of Australia (MGA) coordinate projection (Zone 50) with a regular grid spacing of 200 × 200 m (Figure B-1).

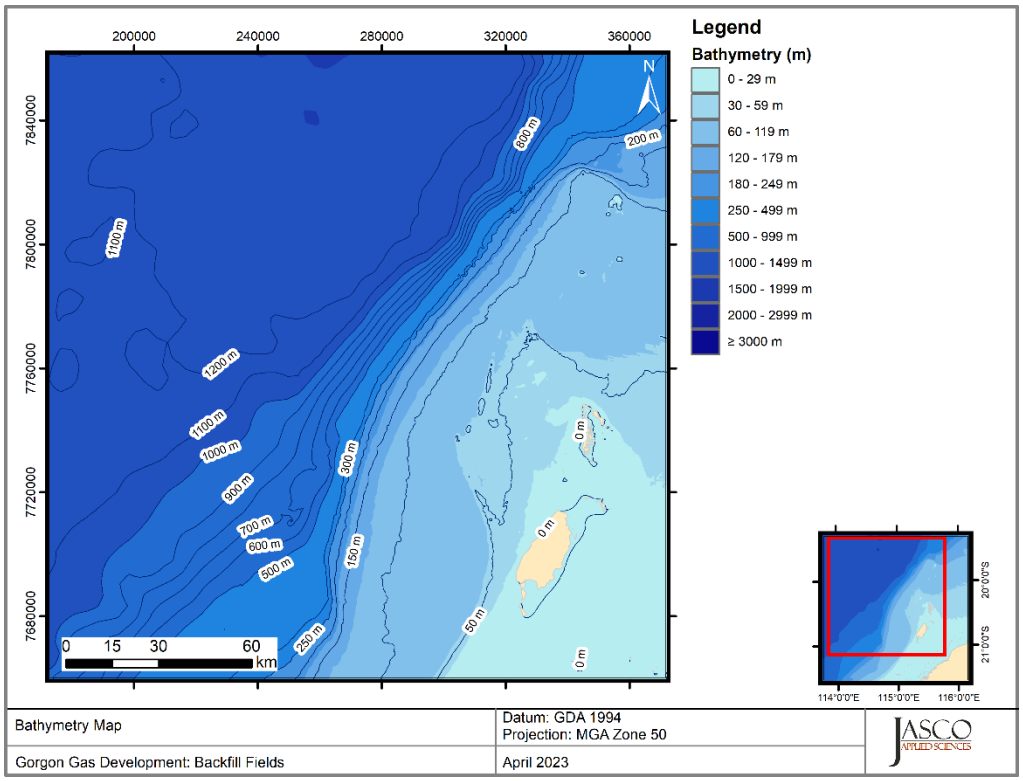

Figure B-1. Bathymetry in the modelled area.

B.1.2. Sound Speed Profile

The sound speed profile in the area was derived from temperature and salinity profiles from the US Naval Oceanographic Office's Generalized Digital Environmental Model V 3.0 (GDEM; Teague et al. 1990, Carnes 2009). GDEM provides an ocean climatology of temperature and salinity for the world's oceans on a latitude-longitude grid with 0.25° resolution, with a temporal resolution of one month, based on global historical observations from the US Navy's Master Oceanographic Observational Data Set (MOODS). The climatology profiles include 78 fixed depth points to a maximum depth of 6800 m (where the ocean is that deep). The GDEM temperature-salinity profiles were converted to sound speed profiles according to Coppens (1981).

Mean monthly sound speed profiles were derived from the GDEM profiles at distances less than 100 km around a representative modelled site. To allow for operational flexibility, the sound speed profiles considered for modelling of operations were selected through a sensitivity analysis considering all months, as shown in Figure B-2. The month of August was found to be the most favourable for sound propagation and this profile was considered in the modelling.

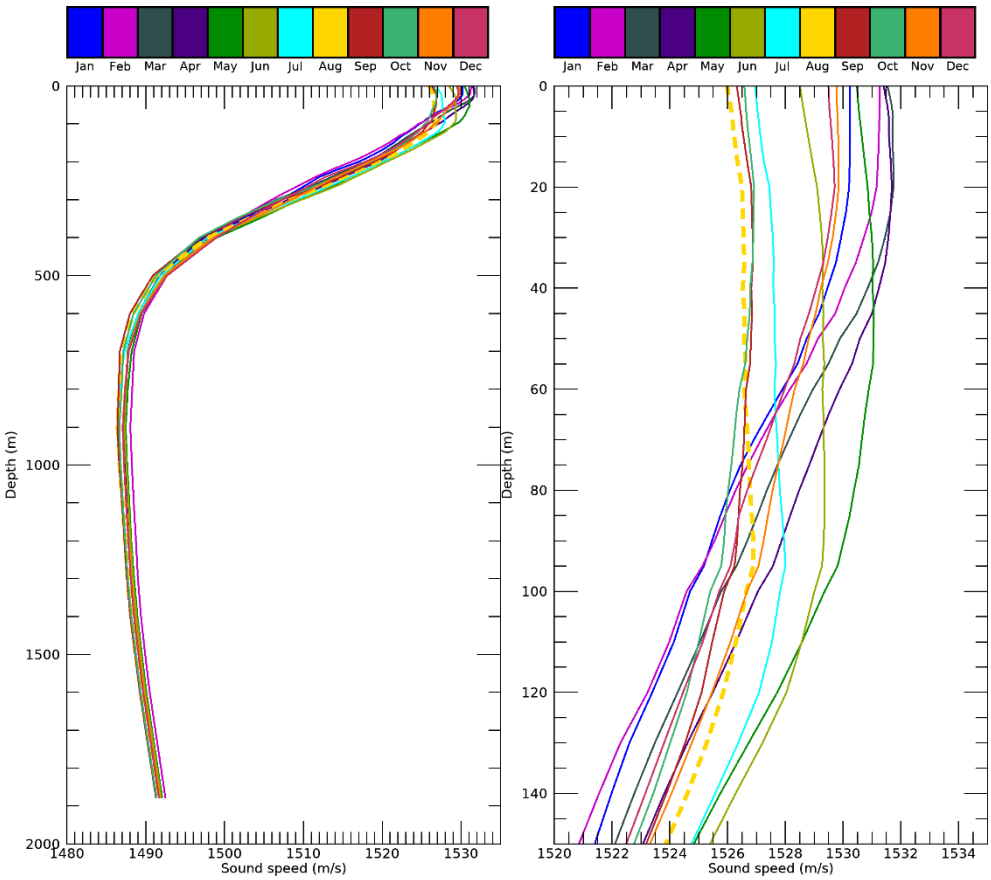

Figure B-2. Sound speed profiles per month for the modelled area: (Left) full profile and (right) top 150 m. The dashed profile indicates the profile considered in the modelling (August).

B.1.3. Geoacoustics

The propagation model used in this study considers five geoacoustic areas, which determine how sound is reflected from the seabed, as well as how it is transmitted, reflected, and absorbed into the sediment layers.

For Areas 1 to 4, information on seabed geology was provided by the client in the form of a geohazards assessment report (Duncan and Erbe 2019). Based on the information provided in that report, the seabed in the study area was divided into four geoacoustic regions.

1. Kangaroo Syncline – The region in water depths greater than 1200 m, close enough to the continental shelf to have potentially been affected by debris flows, as described by Duncan and Erbe (2019).
2. Exmouth Plateau and surrounding area – The Exmouth plateau and the region in water depths greater than 1200 m, considered unlikely to be impacted by debris flow events.
3. Continental Slope – The top of the continental slops was taken as the 200 m bathymetry contour. The bottom of the slope was taken as the 1200 m bathymetry contour, except in the vicinity of the saddle leading to the Exmouth plateau where the 1000 m contour was used.
4. Continental Shelf – Water depths less than 200 m.
5. For the purposes of this modelling study, Area 1 was situated in the Exmouth Plateau, Areas 2 and 3 were situated in the Kangaroo Syncline Area, and Area 4 was situated in the Continental Slope region. The composition of the seabed in each of these regions is summarised in Tables B-1 to B-3.

Table B-1. Geoacoustic profile for the Exmouth Plateau sites (Area 1). Each parameter varies linearly within the stated range. The compressional wave is the primary wave and the shear wave is the secondary wave.

Depth below seafloor (m)	Material	Density (g/cm^3)	Compressional wave		Shear wave	
			Speed (m/s)	Attenuation (dB/λ)	Speed (m/s)	Attenuation (dB/λ)
0–5	Carbonate silt	1.70	1561-1566	1.0	130	2.5
5-205	Sedimentary transition layer	1.96	1580-1766	1.0		
>205	Sedimentary rock halfspace	2.40	3400	0.1		

Table B-2. Geoacoustic profile for the Kangaroo Syncline sites (Areas 2 and 3). Each parameter varies linearly within the stated range. The compressional wave is the primary wave and the shear wave is the secondary wave.

Depth below seafloor (m)	Material	Density (g/cm^3)	Compressional wave		Shear wave	
			Speed (m/s)	Attenuation (dB/λ)	Speed (m/s)	Attenuation (dB/λ)
0–5	Carbonate silt	1.70	1561-1566	1.0	270	2.5
5-15	45 ky bp debris flow	1.90	1636-1645	1.0		
15-20	Post MTC1 transitional	1.92	1650-1700	1.0		
20-120	Mass transport complex	1.95	1710-1803	0.8		
120-320	Sedimentary transition layer	1.96	1790-1980	1.0		
>320	Sedimentary rock halfspace	2.40	3400	0.1		

Table B-3. Geoacoustic profile for the Continental Slope sites (Area 4). Each parameter varies linearly within the stated range. The compressional wave is the primary wave and the shear wave is the secondary wave.

Depth below seafloor (m)	Material	Density (g/cm³)	Compressional wave		Shear wave	
			Speed (m/s)	Attenuation (dB/λ)	Speed (m/s)	Attenuation (dB/λ)
0–50	Carbonate silt	1.70	1565-1611	1.0	259	2.5
50-200	Sedimentary transition layer	1.96	1620-1759	1.0		
>200	Sedimentary rock halfspace	2.40	3400	0.1		

Area 5, on the Continental Shelf, was located in close proximity to a coring location sampled during IODP Cruise 356 Gallagher et al. (2017). The core information was used to estimate the thickness of the un-lithified sediment and the average sediment lithology. The geoacoustic properties were then calculated using the grain-shearing sediment model of Buckingham (2005) based on the information from Gallagher et al. (2017). The core information indicated a loose sediment layer approximately 450 m thick overlaying the bedrock estimated as cemented calcarenite (Table B-4) (the parameters for calcarenite were taken from Duncan et al. (2013)).

Table B-4. Geoacoustic profile for Continental Shelf sites (Area 5). Each parameter varies linearly within the stated range. The compressional wave is the primary wave and the shear wave is the secondary wave.

Depth below seafloor (m)	Predicted lithology	Density (g/cm³)	Compressional wave		Shear wave	
			Speed (m/s)	Attenuation (dB/λ)	Speed (m/s)	Attenuation (dB/λ)
0-3	Silty Sand	1.66-1.67	1539-1650	0.24-0.68	200.0	3.65
3-10		1.67-1.69	1650-1740	0.68-0.96		
10-50	Increasingly consolidated sand-silt-clay	1.75-1.78	1704-1872	0.80-1.26		
50-100		1.78	1872-1979	1.26-1.51		
100-450		1.78-1.96	1979-2382	1.51-2.04		
>450	Well-cemented sand/calcarenite	2.20	2600	0.12		

B.2. Sound Propagation Models

B.2.1. Propagation Loss

The propagation of sound through the environment was modelled by predicting the acoustic propagation loss—a measure, in decibels, of the decrease in sound level between a source and a receiver some distance away. Geometric spreading of acoustic waves is the predominant way by which propagation loss occurs. Propagation loss also happens when the sound is absorbed and scattered by the seawater, and absorbed scattered, and reflected at the water surface and within the seabed. Propagation loss depends on the acoustic properties of the ocean and seabed; its value changes with frequency.

If the acoustic energy source level (ESL), expressed in dB re 1 $\mu Pa^2 \cdot s\ m^2$, and propagation loss (PL), in units of dB, at a given frequency are known, then the received level (RL) at a receiver location can be calculated in dB re 1 $\mu Pa^2 \cdot s$ by:

$$RL = SL - PL. \tag{B-1}$$

B.2.2. MONM-BELLHOP

Long-range sound fields were computed using JASCO's Marine Operations Noise Model (MONM). While other models may be more accurate for steep-angle propagation in high-shear environment, MONM is well suited for effective longer-range estimation. This model computes sound propagation at frequencies of 10 Hz to 1 kHz via a wide-angle parabolic equation solution to the acoustic wave equation (Collins 1993) based on a version of the U.S. Naval Research Laboratory's Range-dependent Acoustic Model (RAM), which has been modified to account for a solid seabed (Zhang and Tindle 1995). MONM computes sound propagation at frequencies > 1 kHz via the BELLHOP Gaussian beam acoustic ray-trace model (Porter and Liu 1994).

The parabolic equation method has been extensively benchmarked and is widely employed in the underwater acoustics community (Collins et al. 1996). MONM accounts for the additional reflection loss at the seabed, which results from partial conversion of incident compressional waves to shear waves at the seabed and sub-bottom interfaces, and it includes wave attenuations in all layers. MONM incorporates the following site-specific environmental properties: a bathymetric grid of the modelled area, underwater sound speed as a function of depth, and a geoacoustic profile based on the overall stratified composition of the seafloor.

MONM computes acoustic fields in three dimensions by modelling propagation loss within two-dimensional (2-D) vertical planes aligned along radials covering a 360° swath from the source, an approach commonly referred to as N×2-D. These vertical radial planes are separated by an angular step size of $\Delta\theta$, yielding N = 360°/$\Delta\theta$ number of planes (Figure B-3).

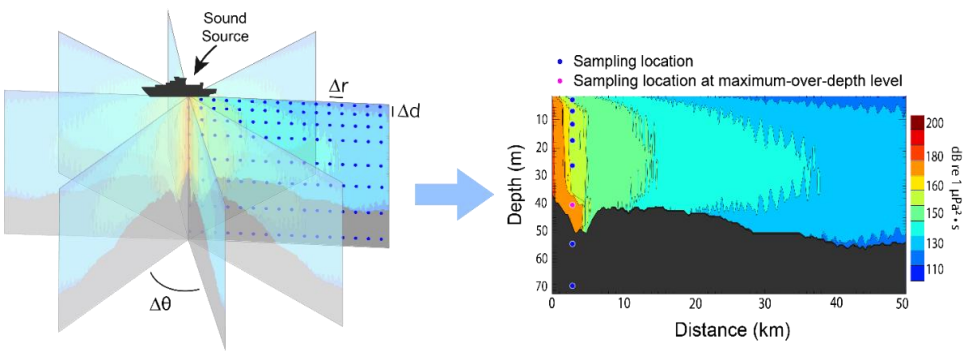

Figure B-3. The N×2-D and maximum-over-depth modelling approach used by MONM.

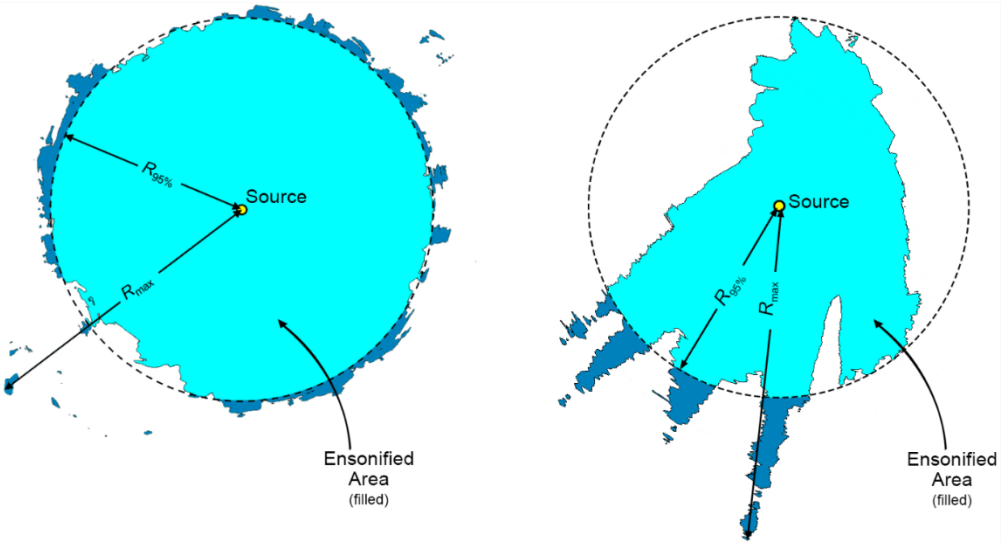

MONM treats frequency dependence by computing acoustic propagation loss at the centre frequencies of decidecade bands. Sufficiently many decidecade frequency-bands, starting at 10 Hz, are modelled to include most of the acoustic energy emitted by the source. At each centre frequency, the propagation loss is modelled within each of the N vertical planes as a function of depth and range from the source. The decidecade received per-second SEL are computed by subtracting the band propagation loss values from the directional source level in that frequency band. Composite broadband received per-second SEL are then computed by summing the received decidecade levels.

The received 1-s SEL sound field within each vertical radial plane is sampled at various ranges from the source, generally with a fixed radial step size. At each sampling range along the surface, the sound field is sampled at various depths, with the step size between samples increasing with depth below the surface. The step sizes are chosen to provide increased coverage near the depth of the source and at depths of interest in terms of the sound speed profile. For areas with deep water, sampling is not performed at depths beyond those reachable by marine mammals. The received per-second SEL at a surface sampling location is taken as the maximum value that occurs over all samples within the water column, i.e., the maximum-over-depth received per-second SEL. These maximum-over-depth per-second SEL are presented as colour contours around the source.

B.3. Estimating Range to Thresholds Levels

Sound level contours were calculated based on the underwater sound fields predicted by the propagation models, sampled by taking the maximum value over all modelled depths above the sea floor for each location in the modelled region. The predicted distances to specific levels were computed from these contours. Two distances relative to the source are reported for each sound level: 1) R_{max}, the maximum range to the given sound level over all azimuths, and 2) $R_{95\%}$, the range to the given sound level after the 5% farthest points were excluded (see examples in Figure B-4).

The $R_{95\%}$ is used because sound field footprints are often irregular in shape. In some cases, a sound level contour might have small protrusions or anomalous isolated fringes. This is demonstrated in the image in Figure B-4(a). In cases such as this, where relatively few points are excluded in any given direction, R_{max} can misrepresent the area of the region exposed to such effects, and $R_{95\%}$ is considered more representative. In strongly asymmetric cases such as shown in Figure B-4(b), on the other hand, $R_{95\%}$ neglects to account for significant protrusions in the footprint. In such cases R_{max} might better represent the region of effect in specific directions. Cases such as this are usually associated with bathymetric features affecting propagation. The difference between R_{max} and $R_{95\%}$ depends on the source directivity and the non-uniformity of the acoustic environment.

(a) (b)

Figure B-4. Sample areas ensonified to an arbitrary sound level with R_{max} and $R_{95\%}$ ranges shown for two different scenarios. (a) Largely symmetric sound level contour with small protrusions. (b) Strongly asymmetric sound level contour with long protrusions. Light blue indicates the ensonified areas bounded by $R_{95\%}$; darker blue indicates the areas outside this boundary which determine R_{max}.

B.4. Estimating Sound Field from Moving Vessels

During vessel transit, new sound energy is constantly being introduced to the environment. The noise footprint for the transiting vessels considered in this report were estimated by modelling the 1-s SEL for the vessel at one location, and by translating and summing these footprints along the vessel transit routes. The vessel locations along the tracks were spaced uniformly, with an approximate step of $\Delta s \approx 100$ m for all scenarios with a track.

The SEL sound field at any given point along the path is dependent upon the duration of exposure, which with a fixed footprint spacing depends upon the speed of the vessel during each segment of the transit. The 1-s SEL footprint at each vessel location (i) were therefore scales based on the speed of the vessel following:

$$\mathrm{SEL}_i = \mathrm{SEL}_{1s} + 10\log_{10}\left(\frac{\Delta s}{v}\right). \qquad \text{(B-2)}$$

where v represents the vessel speed in m/s.

The present method acceptably reflects large-scale sound propagation features, primarily dependent on water depth, which dominate the cumulative field and is thus considered to provide a meaningful estimate of the SEL_{24h} field.

B.5. Model Validation Information

Predictions from JASCO's propagation models (MONM, FWRAM, and VSTACK) have been validated against experimental data from a number of underwater acoustic measurement programs conducted by JASCO globally, including the United States and Canadian Artic, Canadian and southern United States waters, Greenland, Russia and Australia (Hannay and Racca 2005, Aerts et al. 2008, Funk et al. 2008, Ireland et al. 2009, O'Neill et al. 2010, Warner et al. 2010, Racca et al. 2012a, Racca et al. 2012b, Matthews and MacGillivray 2013, Martin et al. 2015, Racca et al. 2015, Martin et al. 2017a, Martin et al. 2017b, Warner et al. 2017, MacGillivray 2018, McPherson et al. 2018, McPherson and Martin 2018).

In addition, JASCO has conducted measurement programs associated with a significant number of anthropogenic activities that have included internal validation of the modelling (including McCrodan et al. 2011, Austin and Warner 2012, McPherson and Warner 2012, Austin and Bailey 2013, Austin et al. 2013, Zykov and MacDonnell 2013, Austin 2014, Austin et al. 2015, Austin and Li 2016, Martin and Popper 2016).

Appendix C. VSP Source

C.1. Airgun Array Source Model

The source levels and directivity of the seismic source were predicted with JASCO's Airgun Array Source Model (AASM). AASM includes low- and high-frequency modules for predicting different components of the seismic source spectrum. The low-frequency module is based on the physics of oscillation and radiation of airgun bubbles, as originally described by Ziolkowski (1970), that solves the set of parallel differential equations that govern bubble oscillations. Physical effects accounted for in the simulation include pressure interactions between airguns, port throttling, bubble damping, and generator-injector (GI) gun behaviour discussed by Dragoset (1984), Laws et al. (1990), and Landrø (1992). A global optimisation algorithm tunes free parameters in the model to a large library of airgun source signatures.

While airgun signatures are highly repeatable at the low frequencies, which are used for seismic imaging, their sound emissions have a large random component at higher frequencies that cannot be predicted using a deterministic model. Therefore, AASM uses a stochastic simulation to predict the high-frequency (800−25,000 Hz) sound emissions of individual airguns, using a data-driven multiple-regression model. The multiple-regression model is based on a statistical analysis of a large collection of high quality seismic source signature data recently obtained from the Joint Industry Program (JIP) on Sound and Marine Life (Mattsson and Jenkerson 2008). The stochastic model uses a Monte-Carlo simulation to simulate the random component of the high-frequency spectrum of each airgun in an array. The mean high-frequency spectra from the stochastic model augment the low-frequency signatures from the physical model, allowing AASM to predict airgun source levels at frequencies up to 25,000 Hz.

AASM produces a set of "notional" signatures for each array element based on:

- Array layout
- Volume, operating depth, and firing pressure of each airgun
- Interactions between different airguns in the array

These notional signatures are the pressure waveforms of the individual airguns at a standard reference distance of 1 m; they account for the interactions with the other airguns in the array. The signatures are summed with the appropriate phase delays to obtain the far-field source signature of the entire array in all directions. This far-field array signature is filtered into decidecade bands to compute the source levels of the array as a function of frequency band and azimuthal angle in the horizontal plane (at the source depth), after which it is considered a directional point source in the far field.

A seismic array consists of many sources and the point source assumption is invalid in the near field where the array elements add incoherently. The maximum extent of the near field of an array (R_{nf}) is:

$$R_{\mathrm{nf}} < \frac{l^2}{4\lambda} \qquad \text{(C-1)}$$

where λ is the sound wavelength and l is the longest dimension of the array (Lurton 2002, §5.2.4). For example, a seismic source length of l = 21 m yields a near-field range of 147 m at 2 kHz and 7 m at 100 Hz. Beyond this R_{nf} range, the array is assumed to radiate like a directional point source and is treated as such for propagation modelling.

The interactions between individual elements of the array create directionality in the overall acoustic emission. Generally, this directionality is prominent mainly at frequencies in the mid-range between tens of hertz to several hundred hertz. At lower frequencies, with acoustic wavelengths much larger

than the inter-airgun separation distances, the directionality is small. At higher frequencies, the pattern of lobes is too finely spaced to be resolved and the effective directivity is less.

C.2. VSP Source Parameters

The layout of the seismic source is provided in Figure C-1. Details of the airgun parameters are provided in Table C-1. In the context of this source geometry the broadside direction is perpendicular to the sagittal plane of the array and the endfire direction is parallel to the sagittal plane of the array.

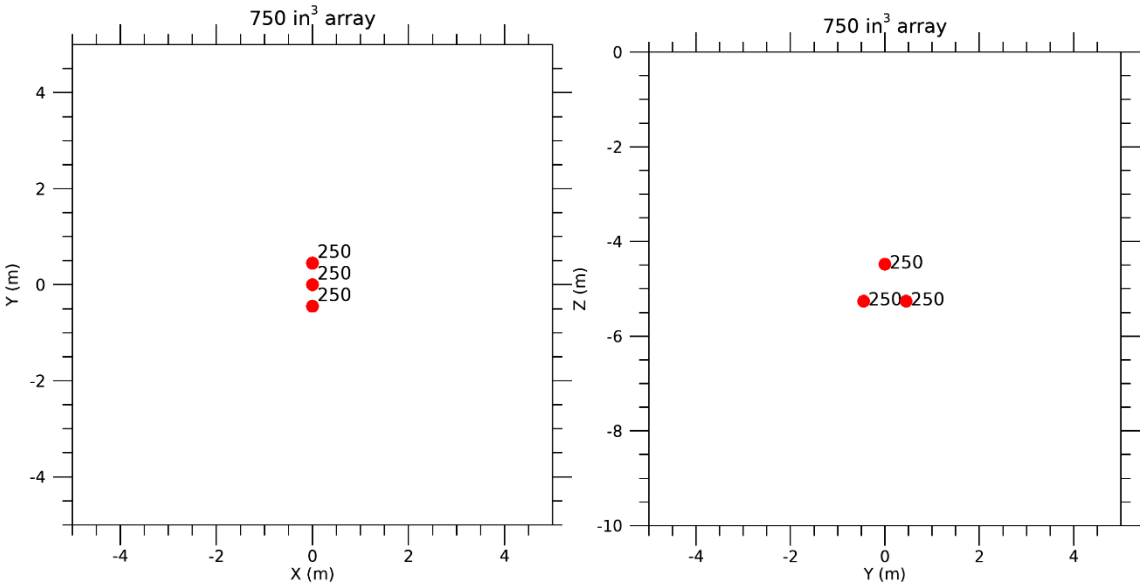

Figure C-1. (Left) Plan and (right) side layouts of the modelled 750 in³ seismic source array Operational depth is 5 m. The labels indicate the firing volume (in cubic inches) for each airgun. Also see Table C-1.

Table C-1. Layout of the modelled 750 in³ seismic source array. Operational depth is 5 m. Firing pressure for all guns is 2000 psi. Also see Figure C-1.

Gun	x (m)	y (m)	z (m)	Volume (in³)
1	0.0	0.0	4.48	250
2	0.0	0.45	5.26	250
3	0.0	−0.45	5.26	250

C.3. Array Source Levels and Directivity

Figure C-2 shows the broadside (perpendicular to the sagittal plane), endfire (parallel to the sagittal plane), and vertical overpressure signature and corresponding power spectrum levels for the 750 in^3 array (see Appendix C.2). Horizontal decidecade band source levels shown as a function of band centre frequency and azimuth (Figure C-3) indicate that this array is mainly isotropic.

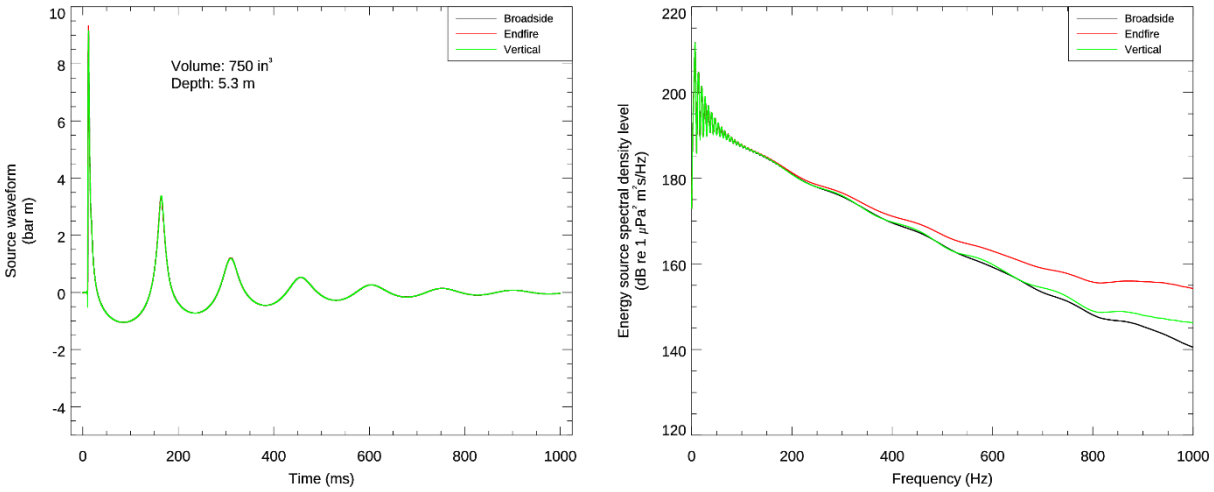

Figure C-2. Predicted source level details for the 750 in^3 array at a 5 m operational depth. (Left) the overpressure signature and (right) the power spectrum for horizontal (broadside and endfire) and vertical directions.

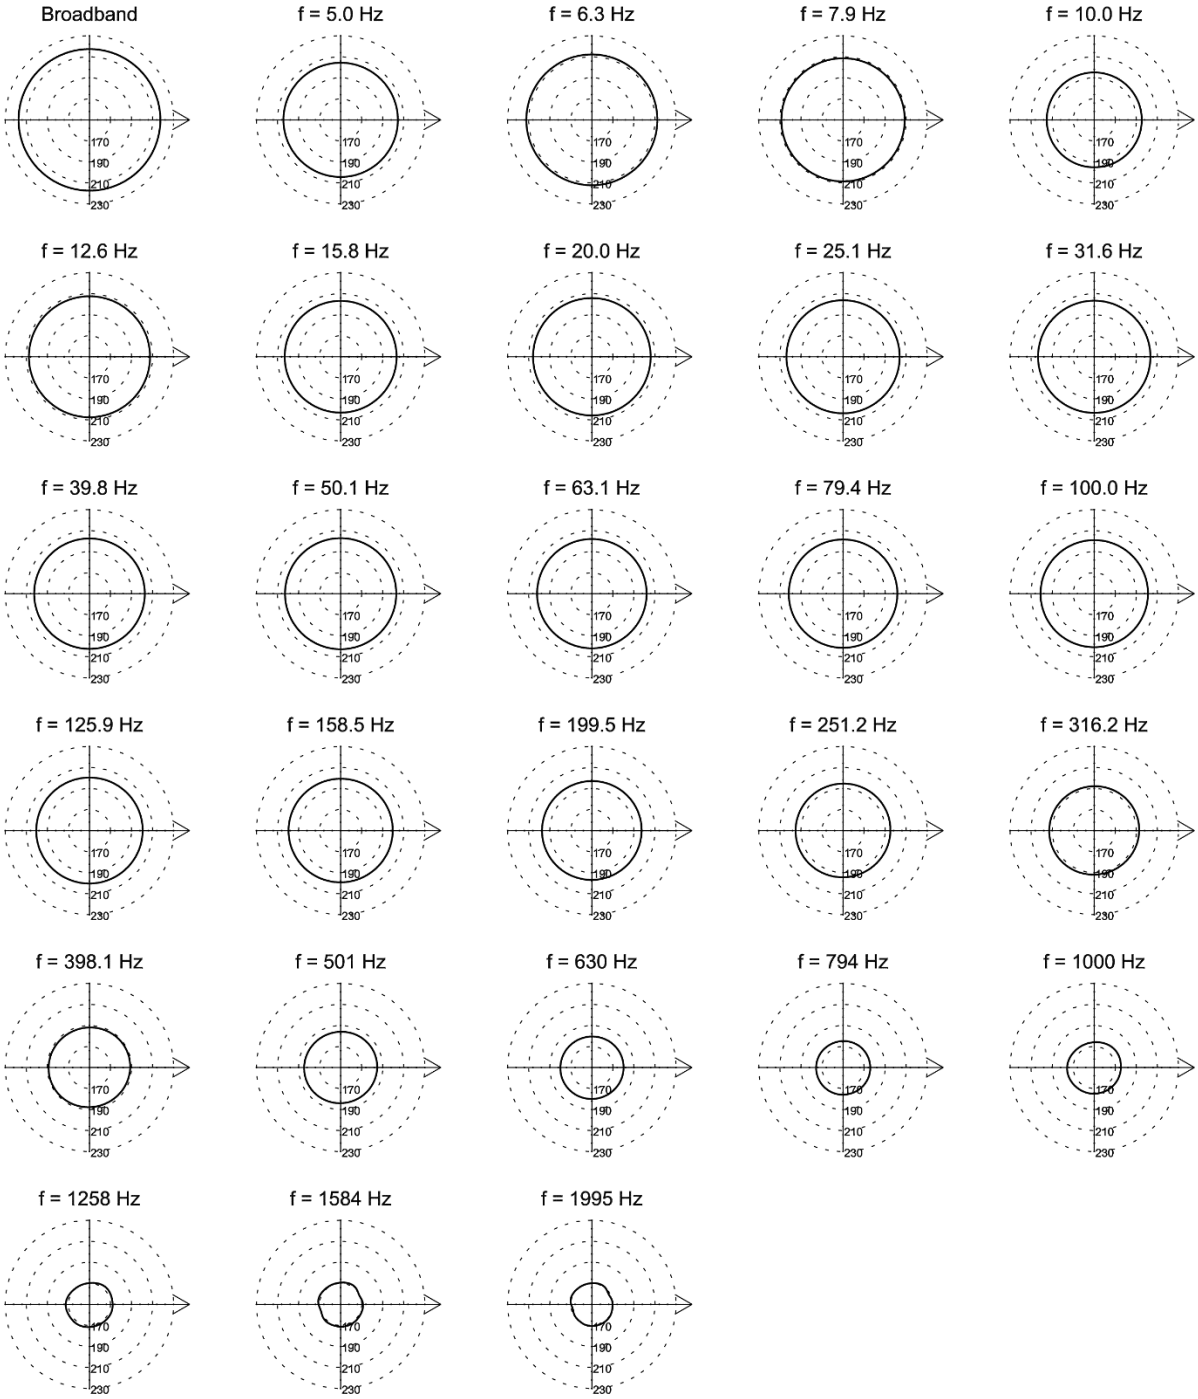

Figure C-3. Directionality of the predicted horizontal source levels for the 750 in^3 seismic source array, 10 Hz to 2 kHz. Source levels (in dB re 1 $\mu Pa^2 \cdot s\ m^2$) are shown as a function of azimuth for the centre frequencies of the decidecade bands modelled, shown above the plots. The endfire axis (i.e., axis parallel to the sagittal plane) is to the right. Operational depth is 5 m.

Appendix D. Animal Movement and Exposure Modelling

Animal movement and exposure modelling considers the movement of both sound sources and animals over time. Acoustic source and propagation modelling are used to generate 3-D sound fields that vary as a function of distance to source, depth, and azimuth. Sound sources are modelled at representative sites and the resulting sound fields are assigned to source locations using the minimum Euclidean distance. The sound received by an animal at any given time depends on its location relative to the source. Because the true locations of the animals within the sound fields are unknown, realistic animal movements are simulated using repeated random sampling of various behavioural parameters. The Monte Carlo method of simulating many animals within the operations area is used to estimate the sound exposure history of the population of simulated animals (animats).

Monte Carlo methods provide a heuristic approach for determining the probability distribution function (PDF) of complex situations, such as animals moving in a sound field. The probability of an event's occurrence is determined by the frequency with which it occurs in the simulation. The greater the number of random samples, in this case the more simulated animats, the better the approximation of the PDF. Animats are randomly placed, or seeded, within the simulation boundary at a specified density (animats/km^2). Higher densities provide a finer PDF estimate resolution but require more computational resources. To ensure good representation of the PDF, the animat density is set as high as practical allowing for computation time. Typically, the animat density is much higher than the real-world density to ensure good representation of the PDF. The resulting PDF can be scaled using the real-world density if it is available.

Several models for marine mammal movement have been developed (Ellison et al. 1987, Frankel et al. 2002, Houser 2006). These models use an underlying Markov chain to transition from one state to another based on probabilities determined from measured swimming behaviour. The parameters may represent simple states, such as the speed or heading of the animal, or complex states, such as likelihood of participating in foraging, play, rest, or travel. Attractions and aversions to variables like anthropogenic sounds and different depth ranges can be included in the models.

The JASCO Animal Simulation Model Including Noise Exposure (JASMINE) was based on the open-source marine mammal movement and behaviour model (3MB, Houser 2006) and used to predict the exposure of animats to sound arising from the anthropogenic activities. Animats are programmed to behave like the species likely to be present in the survey area. The parameters used for forecasting realistic behaviours (e.g., diving, foraging, aversion, surface times, etc.) are determined and interpreted from marine species studies (e.g., tagging studies) where available, or reasonably extrapolated from related species. An individual animat's modelled sound exposure levels are summed over the total simulation duration to determine its total received energy, and then compared to the assumed threshold criteria.

JASMINE uses the same animal movement algorithms as 3MB (Houser, 2006), but has been extended to be directly compatible with JASCO's Marine Operations Noise Model (MONM) and Full Waveform Range-dependent Acoustic Model acoustic field predictions, for inclusion of source tracks, and importantly for animats to change behavioural states based on time and space dependent modelled variables such as received levels for aversion behaviour, although aversion was not considered in this study.

D.1. Animal Movement Parameters

JASMINE uses previously measured behaviour to forecast behaviour in new situations and locations. The parameters used for forecasting realistic behaviour are determined (and interpreted) from marine species studies (e.g., tagging studies). Each parameter in the model is described as a probability distribution. When limited or no information is available for a species parameter, a Gaussian or uniform distribution may be chosen for that parameter. For the Gaussian distribution, the user determines the mean and standard deviation of the distribution from which parameter values are drawn. For the uniform distribution, the user determines the maximum and minimum distribution from which parameter values are drawn. When detailed information about the movement and behaviour of a species are available, a user-created distribution vector, including cumulative transition probabilities, may be used (referred to here as a vector model; Houser 2006). Different sets of parameters can be defined for different behaviour states. The probability of an animat starting out in or transitioning into a given behaviour state can in turn be defined in terms of the animat's current behavioural state, depth, and the time of day. In addition, each travel parameter and behavioural state has a termination function that governs how long the parameter value or overall behavioural state persists in simulation.

The parameters used in JASMINE describe animal movement in both the vertical and horizontal planes. The parameters relating to travel in these two planes are briefly described below.

Travel sub-models

- **Direction**– determines an animat's choice of direction in the horizontal plane. Sub-models are available for determining the heading of animats, allowing for movement to range from strongly biased to undirected. A random walk model can be used for behaviours with no directional preference, such as feeding and playing. In a random walk, all bearings are equally likely at each parameter transition time step. A correlated random walk can be used to smooth the changes in bearing by using the current heading as the mean of the distribution from which to draw the next heading. An additional variant of the correlated random walk is available that includes a directional bias for use in situations where animals have a preferred absolute direction, such as migration. A user-defined vector of directional probabilities can also be input to control animat heading. For more detailed discussion of these parameters, see Houser (2006) and Houser and Cross (1999).
- **Travel rate**–defines an animat's rate of travel in the horizontal plane. When combined with vertical speed and dive depth, the dive profile of the animat is produced.

Dive sub-models

- **Ascent rate**–defines an animat's rate of travel in the vertical plane during the ascent portion of a dive.
- **Descent rate**–defines an animat's rate of travel in the vertical plane during the descent portion of a dive.
- **Depth**–defines an animat's maximum dive depth.
- **Reversals**–determines whether multiple vertical excursions occur once an animat reaches the maximum dive depth. This behaviour is used to emulate the foraging behaviour of some marine mammal species at depth. Reversal-specific ascent and descent rates may be specified.
- **Surface interval**–determines the duration an animat spends at, or near, the surface before diving again.

D.2. Exposure Integration Time

The interval over which acoustic exposure (L_E) should be integrated and maximal exposure (L_p) determined is not well defined. Both Southall et al. (2007) and the NMFS (2018) recommend a 24 h baseline accumulation period, but state that there may be situations where this is not appropriate (e.g., a high-level source and confined population). Resetting the integration after 24 h can lead to overestimating the number of individual animals exposed because individuals can be counted multiple times during an operation. The type of animal movement engine used in this study simulates realistic movement using swimming behaviour collected over relatively short periods (hours to days) and does not include large-scale movement such as migratory circulation patterns. For this study, a representative 24-hour period was simulated.

Ideally, a simulation area is large enough to encompass the entire range of a population so that any animal that could approach the source during an operation is included. However, there are limits to the simulation area, and computational overhead increases with area. For practical reasons, the simulation area is limited. In the simulation, every animat that reaches a border is replaced by another animat entering at the opposing border—e.g., an animat crossing the northern border of the simulation is replaced by one entering the southern border at the same longitude. When this action places the animat in an inappropriate water depth, the animat is randomly placed on the map at a depth suited to its species definition. The exposures of all animats (including those leaving the simulation and those entering) are kept for analysis. This approach maintains a consistent animat density and allows for longer integration periods with finite simulation areas.

D.3. Seeding Density and Scaling

Seeding density refers to the spatial sample rate, in units of animats/km^2, used in the simulation. It is not related to the real-world animal density, but rather is a model parameter that controls the how samples are drawn from the model space. The minimum required seeding density for any given project depends on several factors such as bathymetry, source characteristics, and the behavioural profile of the animats, with the main constraint being computation time and resources. Seeding density is adjusted as needed based on model conditions specific to a project or project area.

In the present study, the exposure criteria for continuous sounds were used to determine the number of animats exceeding exposure thresholds. To generate statistically reliable probability density functions, all simulations were seeded with an animat density of 4 animat/km^2 over the entire simulation area. Due to insufficient density data availability, the modelling results are not related to real-world density estimates for pygmy blue whales within the BIA.

1 introduction

1.1 project overview

Chevron Australia Pty Ltd (CAPL) is proposing to undertake the Backfill Fields Development which comprises the construction, installation, operation, and decommissioning of seven backfill gas fields (Chandon, Chrysaor and Dionysus (C&D), Geryon and Eurytion (G&E), Semele, and West Tryal Rocks [WTR]) in the Greater Gorgon Area. The Backfill Fields Development is a subsea tieback development to existing Gorgon Foundation Project infrastructure. The intent of the Backfill Fields Development is to maintain gas supply to the existing Gas Treatment Plant (GTP) on Barrow Island to sustain current production rates of domestic gas and liquified natural gas (LNG).

1.2 purpose

The purpose of this Technical Note is to provide an overview of the methods used to estimate greenhouse gas (GHG) emissions for the Backfill Fields Development. The GHG emissions inventory has been developed to support the environmental impact and risk assessment within the Gorgon Gas Development: Backfill Fields Offshore Project Proposal (OPP; Ref. 1) which is required under the *Offshore Petroleum and Greenhouse Gas Storage Act 2006* (Cth) and Offshore Petroleum and Greenhouse Gas Storage (Environment) Regulations 2023 (Cth) (OPGGS(E)R).

1.2.1 regulatory context

The National Offshore Petroleum Safety and Environmental Management Authority's (NOPSEMA's) decisions regarding petroleum activities are made in accordance with the OPGGS(E)R. As per regulation 7(5)(b) an OPP must include "an evaluation of all the impacts and risks, appropriate to the nature and scale of each impact or risk"[1].

NOPSEMA's decisions are also guided by other relevant Commonwealth legislation including the *Environment Protection and Biodiversity Conservation 1999* (EPBC Act). Specifically, NOPSEMA's decision making guideline for OPPs (Ref. 2) refers to an evaluation of relevant indirect impacts, having regard to the EPBC Act Policy Statement—'Indirect consequences' of an action: Section 527E of the EPBC Act (hereafter referred to as the EPBC Indirect Consequences Policy Statement; Ref. 3).

Section 527E of the EPBC Act defines the 'impact' of an action as follows:

> "(1) For the purposes of this Act, an event or circumstance is an ***impact*** of an action taken by a person if:
>
> (a) the event or circumstance is a direct consequence of the action; or
>
> (b) for an event or circumstance that is an indirect consequence of the action – subject to subsection (2), the action is a substantial cause of that event or circumstance.
>
> (2) For the purposes of paragraph (1)(b), if:

[1] Under the OPPGS(E)R an environmental impact of an activity means "any change to the environment, whether adverse or beneficial, that wholly or partially results from the activity".

(a) a person (the ***primary person***) takes an action (the ***primary action***); and

(b) as a consequence of the primary action, another person (the ***secondary person***) takes another action (the ***secondary action***); and

(c) the secondary action is not taken at the direction or request of the primary person; and

(d) an event or circumstance is a consequence of the secondary action;

then that event or circumstance is an ***impact*** of the primary action only if:

(e) the primary action facilities, to a major extent, the secondary action; and

(f) the secondary action is:

(i) within the contemplation of the primary person; or

(ii) a reasonably foreseeable consequence of the primary action; and

(g) the event or circumstance is:

(i) within the contemplation of the primary person; or

(ii) a reasonably foreseeable consequence of the secondary action."

1.3 scope

The GHG emissions inventory within this Technical Note is applicable to the petroleum activities comprising the Backfill Fields Development (as described in Section 4 of the OPP). Note: Unplanned events (including major repairs and responding to emergency events) are considered out of scope of the emissions inventory.

GHG emissions that constitute 'direct consequences' as well as GHG emissions that may constitute 'indirect consequences' of the Backfill Fields Development (in accordance with the EPBC Indirect Consequences Policy Statement [Ref. 3]) have been included in this inventory. In this Technical Note GHG emissions have been categorised based on the following definitions:

- **BFF GHG emissions**—these are GHG emissions that are a direct consequence of planned petroleum activities that comprise the Backfill Fields Development (as described in Section 4 of the OPP) from sources within the Development Area (DA) in Commonwealth waters
- **BFF gas processing GHG emissions**—these are GHG emissions from sources outside of the DA associated with CAPL's operation of the Gorgon Gas Development facilities (as outlined MS 800)[2] and that are an indirect consequence of the Backfill Fields Development
- **BFF secondary GHG emissions**—these are transport (shipping) and third-party end use GHG emissions that are a reasonably foreseeable consequence of the Backfill Fields Development from sources outside the DA .

Note: The GHG emissions from gas processing on Barrow Island and the transport and third-party end use for the Gorgon Gas Development have been

[2] This includes emissions from operation of the Gorgon GTP for the processing of LNG and domestic gas, as well as emissions from Barrow Island support operations. This is consistent with the presentation of GHG emissions for the Gorgon Gas Development in existing environment approvals (e.g. Ref. 4; Ref. 5; Ref. 6).

previously described and assessed within existing environmental approvals (e.g. Ref. 4; Ref. 5; Ref. 6; see also Section 1.3.1).

The Gorgon Gas Development, as described in existing environmental approvals, incorporates gas resources from the Greater Gorgon Area, and as such, the GHG emission estimates for the Gorgon Gas Development inherently incorporate emissions associated with the processing, transport and end use of gas resources from the Greater Gorgon Area. Therefore, a proportion of these previously described and assessed emissions for the Gorgon Gas Development are the **BFF gas processing GHG emissions** and **BFF secondary GHG emissions** associated with the seven gas fields of the Backfill Fields Development. These proportions of the overall Gorgon Gas Development's emissions have been included in this GHG emissions inventory to inform the evaluation of impacts and risks associated with the Backfill Fields Development in the OPP.

1.3.1 existing environmental approvals

GHG emissions occurring as a consequence of the Gorgon Gas Development have existing primary environmental approvals under the EPBC Act and the *Environmental Protection Act 1986* (WA) (EP Act), including:

- the three-train Revised and Expanded Gorgon Gas Development (Ref. 4) which was approved with conditions (EPBC 2008/4178 and MS 800 [as amended from time to time[3]])
  - the GHG emissions estimated for the three-train proposal were subsequently revised within the Fourth Train Expansion Proposal (Ref. 5) which was approved with conditions (EPBC 2011/5942 and MS 1002) and within the Gorgon Gas Development and Jansz Feed Gas Pipeline: Greenhouse Gas Abatement Program (Ref. 7) which was approved by the Ministers delegate of the WA Environmental Protection Authority in May 2015
  - the Gorgon GTP Greenhouse Gas Management Plan [GHGMP] (Ref. 6) was developed to to satisfy the requirements of condition 27 of MS 800 (as amended by MS 1198) and also included a revised estimate of secondary GHG emissions for the Gorgon Gas Development; this plan was approved by the Ministers delegate of the WA Environmental Protection Authority in February 2024
- the Development of Jansz–Io Deepwater Gas Field which was approved with conditions (EPBC 2005/2184)
- the Jansz Feed Gas Pipeline which was approved with conditions (MS 769).

Therefore, any Gorgon Gas Development gas processing GHG emissions should be considered in the context of the revised estimate for the three-train Revised and Expanded Gorgon Gas Development (i.e. average annual emissions of ~9.47 Mtpa CO_2-e[4]). Similarly, any secondary GHG emissions should be considered within the context of the revised estimate for a representative year of three-train production (~49.8 Mtpa CO_2-e[4]).

[3] Since the Revised and Expanded Gorgon Gas Development was approved, further changes to the Gorgon Gas Development have been made and/or approved and are now also part of the Gorgon Gas Development. These include MS 865, MS 965, MS 1136, and MS 1198.

[4] These GHG emissions estimates do not take into consideration any potential GHG emissions mitigations, reduction, or offset opportunities that may be undertaken.

The majority of GHG emissions associated with the Backfill Fields Development relate to gas processing, transport and third-party end use of Gorgon Gas Development products as already assessed under these primary approvals. For the purpose of this Backfill Fields Development GHG emissions inventory, a proportion of the overall Gorgon Gas Development gas processing, transport and third-party end use GHG emissions have been included (see Sections 2.2 and 2.3 of this Technical Note).

For a detailed description of primary environmental approvals and relevant GHG emission estimates refer to Section 8.3.6 of the OPP.

Note: The fields proposed to be developed as part of the Backfill Fields Development (as described in the OPP) are not contingent on the additional LNG train (i.e. fourth-train) or the additional Feed Gas Pipeline System that were described within the Gorgon Gas Development Fourth Train Expansion Proposal (Ref. 5). The Backfill Fields Development (as described in the OPP) has been designed as a subsea tieback development to the existing Gorgon Foundation Project infrastructure (i.e. it will utilise the two existing Feed Gas Pipeline Systems and existing domestic gas and three-train LNG capacity at the Gorgon GTP).

1.4 limitations

As the Backfill Fields Development is in early planning phase, this GHG emissions inventory is based on conservative assumptions about design, vessel/equipment requirements, activity durations, reservoir recovery and gas supply forecasts, to support the environmental impact and risk assessment in the OPP. The GHG estimates presented in this inventory are based on the data and assumptions as described in this Technical Note (Section 2).

Estimates of GHG emissions will be refined for each field (or co-developed fields) development during of the subsequent Environment Plans (EPs). The GHG emissions estimates provided in EPs will be based on more detailed field development designs and incorporate contemporary data and/or calculation methods available at the time. Therefore, there may be differences between estimates presented in this GHG emissions inventory prepared to support the OPP and those presented in later EPs for the Backfill Fields Development.

2 GHG emissions inventory

The below GHG emissions inventory for the Backfill Fields Development does not take into consideration any potential GHG emissions mitigations, reduction, or offset opportunities that may be undertaken for the Gorgon Gas Development or by third-parties. For example, there are regulatory GHG emission reduction requirements for the Gorgon Gas Development (e.g. Commonwealth Safeguard Mechanism and environmental approval conditions under the EP Act (WA)), or similarly any actions taken by third-parties in respect to transport or end use of products (see Section 3.2).

2.1 BFF GHG emissions

2.1.1 sources

The following activities have been identified as **BFF GHG emissions** sources for planned petroleum activities for the Backfill Fields Development:

- fuel combustion by vessels, mobile offshore drilling units (MODUs), and helicopters within the Development Area (DA)
- flaring and cold venting from the MODU within the DA
- fugitive emissions.

Any equipment (e.g. remotely operated vehicles, multibeam echo sounders, etc.) used during vessel-based activities are powered by the vessel itself, and as such these do not represent an additional emission source to that already accounted for by the vessel.

Fugitive emissions may occur from the Backfill Fields Development subsea hydrocarbon system in Commonwealth waters; however, these would represent a minor contribution to the overall GHG emissions inventory. Fugitive emissions for the Gorgon Gas Development are estimated based on product throughput (as per accepted National Greenhouse and Energy Reporting [NGER] scheme methodology), and therefore, any offshore component for the Backfill Fields Development cannot easily be separated. As such, fugitive emissions estimates for the Backfill Fields Development are incorporated into the **BFF gas processing GHG emissions** inventory in (Section 2.2).

2.1.2 calculation methods

2.1.2.1 combustion of liquid fuels

The emissions calculation for the combustion of liquid fuels for transport energy purposes uses Method 1 under section 2.41 of the *National Greenhouse and Energy Reporting (Measurement) Determination 2008* (Cth) (NGER Measurement Determination):

$$E_{ij} = \frac{Q_i \times EC_i \times EF_{ijoxec}}{1{,}000}$$

where:

- $\mathbf{E_{ij}}$ is the emissions of gas type (j), being carbon dioxide (CO_2), methane (CH_4) or nitrous oxide (N_2O), released from the combustion of fuel type (i) measured in tonnes CO_2-e (t CO_2-e)

- **Q_i** is the quantity of fuel type (i) combusted for transport energy purposes measured in kilolitres (kL)
- **EC_i** is the energy content (EC) factor of fuel type (i)
- **EF_{ijoxec}** is the emission factor (EF) for each gas type (j) measured in kilograms (kg) CO_2-e per gigajoule (GJ) of fuel type (i)

The relevant energy content and emission factors are shown in Table 2-1.

Table 2-1: Energy content and emission factors

Fuel type and activity	Energy content	Emission factor		
		CO_2	CH_4	N_2O
Diesel oil combustion for transport energy purposes[5]	38.6 GJ/kL	69.9 kg CO_2-e/GJ	0.1 kg CO_2-e/GJ	0.4 kg CO_2-e/GJ
Kerosene combustion for transport energy purposes[5,6]	36.8 GJ/kL	69.6 kg CO_2-e/GJ	0.01 kg CO_2-e/GJ	0.6 kg CO_2-e/GJ
Natural gas flaring[7]	N/A	2.80 t CO_2-e/t gas	0.933 t CO_2-e/t gas	0.026 t CO_2-e/t gas

2.1.2.2 flaring

The emissions calculation for flaring of natural gas uses Method 1 under section 3.4.4 of the NGER Measurement Determination:

$$E_{ij} = Q_i \times EF_{ij}$$

where:

- **E_{ij}** is the fugitive emissions of gas type (j) from a fuel type (i) flared measured in t CO_2-e
- **Q_i** is the quantity of fuel type (i) flared measured in tonnes (t)
- **EF_{ij}** is the EF for gas type (j) measured in t CO_2-e emissions per tonne of the fuel type (i) flared.

The relevant emission factors are shown in Table 2-1.

2.1.2.3 cold venting

The emissions calculation for venting of natural gas is adapted from Equations 3-2 and 6-2 from API's Compendium of Greenhouse Gas Emissions Methodologies (Ref. 8):

$$E_x = V \times F_x \times \frac{MW_x}{molar\ volume\ conversion}$$

[5] Energy content and emission factors for transport energy purposes sourced from Division 4.1 of Schedule 1.

[6] Of the aviation fuel types listed in the NGER Measurement Determination, kerosene was used for calculation purposes as this has higher energy content and emission factors relative to other aviation fuel types (e.g. gasoline).

[7] Emission factors for flaring sourced from Section 3.44 of NGER Measurement Determination.

$$E(CO_2e) = \sum (E_x \times GWP_x)$$

where:

- **E_x** is emissions of gas type (x), being CO_2 or CH_4, measured in mass (tonnes)[8]
- **V** is the vent volume at standard temperature and pressure (STP) conditions, measured in standard cubic feet (sfc) or standard cubic metres (Sm^3)
- **F_x** is the molar fraction of gas type (x) in the vent gas stream
- **MW_x** is the molecular weight of gas type (x)
- **molar volume conversion** is the conversion from molar volume to mass (379.3 scf/lb-mole or 23.685 Sm^3/kg-mole at STP conditions)
- **E(CO_2e)** is the emissions measured in t CO_2-e
- **GWP_x** is the global warming potential of gas type (x) measured in t CO_2-e.

The relevant molecular weights and global warming potentials (GWPs) are shown in Table 2-2.

Table 2-2: Molecular weights and global warming potentials

Molecular weight[9]		Global warming potential[10]	
CO_2	CH_4	CO_2	CH_4
44.01	16.04	1	28

2.1.3 data inputs and assumptions

Table 2-3 provides a summary of the assumptions regarding sources (e.g. numbers and/or types of vessels) and durations that were used when developing this GHG emissions inventory.

Table 2-3: Summary of data inputs and assumptions for BFF direct GHG emission calculations

Phase	Inputs and assumptions
Surveys	Surveys, each of which may take ~3–4 weeks (Section 4.3.1 of OPP), may be undertaken at various times during the life of the Development. **Geophysical surveys**: • geophysical surveys may be required during the life of the Backfill Fields Development to supplement pre-existing geophysical data; however, the number and spatial and extent of these surveys is not yet known • for calculation purposes have allowed for: – drilling ▪ duration of pre-installation surveys estimated at 4 weeks per field or co-developed field (i.e. 140 days for all fields) – pipelay and subsea structures ▪ duration of pre-pipelay/pre-installation surveys estimated at 4 weeks per field or co-developed field (i.e. 140 days for all fields) ▪ duration of post-pipelay/post-installation surveys estimated at 4 weeks per field or co-developed field (i.e. 140 days for all fields)

[8] Conversion factors for units of mass 1 tonne = 1,000 kg = 2,204.62 lbs (sourced from Table 3-4 in Ref. 8).

[9] Molecular weight sourced from Table 3-7 in Ref. 8.

[10] GWPs sourced from Table 3-1 in Ref. 8.

Phase	Inputs and assumptions
	▪ as-built surveys incorporated into main installation phase calculations – decommissioning ▪ duration of pre-decommissioning surveys estimated at 4 weeks per field or co-developed field (i.e. 140 days for all fields) ▪ duration of as-left surveys estimated at 4 weeks per field or co-developed field (i.e. 140 days for all fields) – one IMR vessel present within the DA for full duration of survey – fuel consumption for an IMR vessel based on reported fuel consumption during campaigns for existing CAPL-operated assets **Geotechnical surveys**: • geotechnical surveys may be required during the life of the Backfill Fields Development to supplement pre-existing geotechnical data; however, the number and spatial and extent of these surveys is not yet known • for calculation purposes have allowed for: – estimated duration at 4 weeks per field or co-developed field (i.e. 140 days for all fields) – one IMR vessel present within the DA for full duration of survey – fuel consumption for an IMR vessel based on reported fuel consumption during campaigns for existing CAPL-operated assets **Environmental surveys**: • environmental surveys may be required during the life of the Backfill Fields Development; however, the number and spatial and extent of these surveys is not yet known • for calculation purposes have allowed for: – duration of tangible underwater cultural heritage surveys estimated at 4 weeks; assumed at WTR only (due to water depth <130 m) – duration of pre-construction surveys estimated at 4 weeks per field or co-developed field (i.e. 140 days for all fields) – duration of post-decommissioning surveys estimated at 4 weeks per field or co-developed field (i.e. 140 days for all fields) • one IMR vessel present within the DA for full duration of survey • fuel consumption for an IMR vessel based on reported fuel consumption during campaigns for existing CAPL-operated assets
Drilling	**Production well drilling**: • duration of drilling activities is expected to take up to 24 months per field or co-developed field (Section 4.3.2 of OPP) – 24 months (2 years) = 730 days per field or co-developed field – i.e. 3,650 days for all 40 wells • MODU assumed to be present within the DA for full duration of drilling campaigns – the type of MODU has not yet been selected for the field developments – for calculation purposes have conservatively assumed a drillship using dynamic positioning (DP) – fuel consumption for DP drillship based on reported fuel consumption during the GS2 campaigns • conservatively assumed use of two offshore support vessels (OSVs) present within the DA for the duration of the drilling campaigns – fuel consumption for drilling OSVs based on reported fuel consumption during the GS2 campaigns • helicopter flight frequency is estimated to be ~5 flights per week for the MODU (Section 4.3.6.3 of OPP) – i.e. 24 months (104 weeks) = 520 flights per field or co-developed field

Phase	Inputs and assumptions
	– duration within the DA assumed to be one-hour per flight – estimated hourly fuel consumption based on data from existing CAPL-operated assets **Well flowback**: • wells may be subject to flowback at the end of well completions; and if well flowback occurs then flaring may be required (Section 4.3.2.9 of OPP) • based on typical rates and durations on previous CAPL campaigns, the estimated volume of natural gas flared during well flowback is ~60 MMscf per well flared over one day – using an approximate conversion factor of 1 MMscf = 21 tonnes (Ref. 9), then ~1,260 tonnes natural gas flared for each of the 40 wells • while it is acknowledged that unforeseen circumstances may cause flaring to be repeated (Section 4.3.2.9 of OPP); given that well flowback is not required to be undertaken at every well during a drilling campaign, an allowance of the equivalent of ~60 MMscf over one day for each of the 40 wells is considered sufficient to estimate GHG emissions for both initial and any contingency repeated flaring required **Well suspension**: • wells may be suspended after drilling; and if suspension occurs small volumes of natural gas may be vented (Section 4.3.2.6 of OPP) • the estimated volume of natural gas vented is ~0.5 MMscf per well (based on a typical volume within the landing string) • for calculation purposes have conservatively assumed gas composition is 90% CH_4 and 10% CO_2 (based on approximate maximum molar proportions of each gas constituent across the backfill fields as per Table 4-4 of OPP)
Installation and commissioning	**Pipelay installation**: • duration of pipelay activities is estimated at ~3–6 months per field or co-developed field (Section 4.3.3.3 of the OPP); for the purpose of the calculation a 6 month duration has been used – this duration accounts for use of both construction support (e.g. pre-lay works, pipeline crossings, excavation and trenching, as-built surveys, post-lay works) and pipelay installation (e.g. flowlines, pipelines, pipeline termination structure, as-laid surveys) – for calculation purposes have conservatively assume use of one light construction vessel (LCV) and one OSV, and one pipelay vessel (PLV) and one pipe supply vessel (PSV) for each of the campaigns (183 days each) – fuel consumption for LCV, OSV, PLV and PSV based on reported fuel consumption during the GS2 campaigns • rock stabilisation is not planned, but may be required as a contingency (Sections 4.3.3.2 and 4.3.3.5 of OPP) – for calculation purposes have conservatively estimated duration of rock-dumping activities ~2 months (61 days) per field or co-developed field with one rock-dumping vessel for duration of campaign ▪ further assumed rock stabilisation only relevant to field developments occurring on the continental shelf and/or scarp (i.e. WTR and C&D) – fuel consumption for rock-dumping vessel based on reported fuel consumption during the Gorgon umbilical campaign **Subsea structures installation**: • duration of subsea structure installation activities is estimated at ~4 months per field or co-developed field (Section 4.3.3.4 of the OPP) – i.e. 4 months (0.33 years) = 122 days per field or co-developed field

Phase	Inputs and assumptions
	• assumed use of one heavy construction vessel (HCV) and one LCV for full duration of subsea structures campaigns • fuel consumption for HCV and LCV based on reported fuel consumption during the GS2 campaigns **Pre-commissioning**: • duration of pre-commissioning activities is estimated at ~2 months per field or co-developed field (Section 4.3.3.6 of the OPP) – i.e. 2 months (0.17 years) = 61 days per field or co-developed field • assumed use of one LCV for full duration of pre-commissioning campaigns • fuel consumption for LCV based on reported fuel consumption during the GS2 campaign **Commissioning and start-up**: • duration of commissioning and start-up is estimated at ~3 months per field or co-developed field (Section 4.3.3.8 of the OPP) – i.e. 3 months (0.25 years) = 92 days per field or co-developed field – assumed use of one LCV for full duration of pre-commissioning campaigns – fuel consumption for LCV based on reported fuel consumption during the GS2 campaign • during commissioning dry methane gas will be used to pressurise the production flowlines, which may result in a controlled subsea release of this methane gas (Section 4.3.3.7 of OPP) – gas dispersion studies indicate that for all deepwater fields no surface expression of gas is expected to occur (Ref. 10) – for the shallower WTR field, some of the gas released may rise to the surface and release to the atmosphere ▪ based on the size of the production flowline and assuming the full volume is released to atmosphere (i.e. worst-case with no dissolution), the maximum methane gas release is estimated at 6,000 Sm^3 **Helicopter support during installation and commissioning**: • duration of installation and commissioning activities is estimated at ~12–15 months per field or co-developed field; for the purpose of the calculation a 15 month duration has been used • helicopter flight frequency is estimated to be ~15–16 flights per week for the largest construction vessels (Section 4.3.6.3 of OPP); for the purpose of the calculation a 16 flights/week has been used – i.e. 15 months (65 weeks) = 1040 flights per field or co-developed field – duration within the DA assumed to be one-hour per flight • estimated hourly fuel consumption based on data from existing CAPL-operated assets
Operations	**IMR—inspections (subsea hydrocarbon system)**: • frequency of inspection activities is risk-based (Section 4.3.4.2 of OPP) • duration of inspection activities estimated to be up to ~280 days per year (based on estimates for existing Gorgon and Jansz subsea hydrocarbon system [Ref. 11] and scaled proportionately) – indicative commencement of operations for the Backfill Fields Development is late-2028 (Table 4-2 of OPP) – indicative cessation of operations is mid-2066 (consistent with the Gorgon GTP GHGMP; Ref. 6) – i.e. 38 years @ 280 days per year = 10,640 days • one IMR vessel present within the DA for full duration of inspection activities

Phase	Inputs and assumptions
	• fuel consumption for an IMR vessel based on reported fuel consumption during campaigns for existing CAPL-operated assets **IMR—minor maintenance and repairs**: • frequency of maintenance and repair activities depends on the results of inspections (Section 4.3.4.3 of OPP) – if minor maintenance and minor repair is required, the duration could be up to ~6 months per event (Section 4.3.4.3 of OPP) • given these types of activities are typically triggered by inspection findings rather than specifically being scheduled, the following conservative allowance has been provided for calculation purposes – 85 days[11] of minor maintenance and repair activities per year – i.e. 38 years @ 85 days per year = 3,230 days • one IMR vessel present within the DA for full duration of inspection activities • fuel consumption for an IMR vessel based on reported fuel consumption during campaigns for existing CAPL-operated assets **Helicopter support during IMR**: • not generally required for shorter IMR campaign work, however, has been carried as a contingency allowance – estimated at 2 flights per fortnight (i.e. 52 flights per year) – 38 years @ 52 flights per year = 1,976 flights • duration within the DA assumed to be one-hour per flight • estimated hourly fuel consumption based on data from existing CAPL-operated assets. **IMR—well intervention**: • intervention on a single well may be required once a year; however, intervention activities may be more or less frequent depending on well performance (Section 4.3.4.5 of OPP) • duration of well intervention activities estimated to be ~50 days per well (based on estimates for existing Gorgon and Jansz wells; Ref. 13) – i.e. 38 years @ 50 days per year = 1,900 days • MODU or a well intervention vessel present within the DA for full duration of well intervention campaign – for calculation purposes have conservatively assumed use of a semi-submersible well intervention vessel on DP – estimated daily fuel consumption for well intervention vessel based on reported fuel consumption during campaigns for existing CAPL-operated assets • conservatively assumed use of two OSVs present within the DA for the duration of the well intervention campaigns – fuel consumption for drilling OSVs based on reported fuel consumption during the GS2 campaigns – OSVs based on reported fuel consumption during the GS2 campaigns • flaring may be required as part of well intervention (Section 4.3.4.5 of OPP) – volume of natural gas flared assumed to be the same as for well flowbacks (~60 MMscf per well flared over one day) – using an approximate conversion factor of 1 MMscf = 21 tonnes (Ref. 9), then ~1,260 tonnes natural gas flared per year for 38 years

[11] This allowance for minor maintenance and repairs, in conjunction with the allowance for inspections, equates to an IMR vessel in-field 365 days per year. This is considered to provide a conservation allowance for routine IMR activities during operations.

Phase	Inputs and assumptions
	• if well suspension/de-suspension is required, venting may occur (Section 4.3.4.5 of OPP) – given well suspension is a contingency activity during both drilling and operations phases of the Backfill Fields Development, GHG emissions have only been estimated once (under the drilling phase) as part of this inventory **Temporary contingency power supply**: • if planned umbilical power supply is unavailable, temporary contingency options will be used to ensure power is available (Section 4.2.5.1 of OPP) • duration of temporary power supply estimated to be up to ~200 days per event (based on estimates for existing Gorgon and Jansz subsea hydrocarbon system [Ref. 11]) – as this is a contingency activity for the Backfill Fields Development, an allowance for the use of temporary power supply once for each field or co-developed field has been included for calculation purposes – i.e. 5 fields/co-developed fields @ 200 days each = 1,000 days • one IMR vessel present within the DA for full duration of temporary power supply activities • fuel consumption for an IMR vessel based on reported fuel consumption during campaigns for existing CAPL-operated assets • helicopter flight frequency is estimated to be 2 flights per fortnight – i.e. ~30 flights for each contingency power campaign (150 flights for all fields/co-developed fields) – duration within the DA assumed to be one-hour per flight – estimated hourly fuel consumption based on data from existing CAPL-operated assets.
Decommissioning	**Well plug and abandonment (P&A)**: • duration of P&A activities estimated to be ~60 days per well (based on estimates for existing Gorgon and Jansz wells; Ref. 13) – i.e. 2,400 days for all 40 wells • MODU or a well intervention vessel present within the DA for full duration of P&A campaign – for calculation purposes have conservatively assumed use of a semi-submersible well intervention vessel on DP – estimated daily fuel consumption for well intervention vessel based on reported fuel consumption during campaigns for existing CAPL-operated assets • conservatively assumed use of two OSVs present within the DA for the duration of the P&A campaigns – fuel consumption for drilling OSVs based on reported fuel consumption during the GS2 campaigns – OSVs based on reported fuel consumption during the GS2 campaigns • flaring and venting may be required during well P&A (Section 4.3.5.8 of OPP) – the estimated volume of natural gas flared during P&A is ~1.5 MMscf per well; using an approximate conversion factor of 1 MMscf = 21 tonnes (Ref. 9), then ~31.5 tonnes natural gas flared for each of the 40 wells – the estimated volume of natural gas cold vented during P&A is ~0.5 MMscf per well – for venting calculation purposes have conservatively assumed gas composition is 90% CH_4 and 10% CO_2 (based on approximate maximum molar proportions of each gas constituent across the backfill fields as per Table 4-4 of OPP)

Phase	Inputs and assumptions
	• helicopter flight frequency is estimated to be ~5 flights per week for the MODU (Section 4.3.6.3 of OPP) – i.e. 60 days (~8.6 weeks) = ~43 flights per well – duration within the DA assumed to be one-hour per flight – estimated hourly fuel consumption based on data from existing CAPL-operated assets **Removal of all subsea property:** • given the unknowns in removal method (including availability of new technologies) and timing, the estimate of GHG emissions for the removal of all subsea property is assumed to the same as the pipelay and subsea structure installation

2.1.4 results

Based on the sources, methods, and inputs and assumptions described above, the estimate of total **BFF GHG emissions** over the life of the Backfill Fields Development[12] has been estimated at ~3.075 Mt CO_2-e (Table 2-4).

The proportion of estimated GHG emissions generated during each phase of the Backfill Field Development varies, with the highest proportions associated with drilling, operations, and decommissioning (Figure 2-1).

Table 2-4: Estimated total BFF GHG emissions over the life of the Backfill Fields Development

Phase	Estimated total BFF GHG emissions over the life of the Backfill Fields Development[12] (Mt CO_2-e)
Surveys	0.034
Drilling	0.855
Installation and commissioning	0.367
Operations	1.007
Decommissioning	0.812
Total	**3.075**

[12] Where 'life of the Backfill Fields Development' is represented as FY2027–FY2070 (44 years). This period is based on indicative commencement of drilling activities for the first of the backfill fields (refer to Table 4-2 of the OPP) and the indicative end of life of the Backfill Fields Development (consistent with that for the overall Gorgon Gas Development; refer to Section 4.1.4 of the OPP).

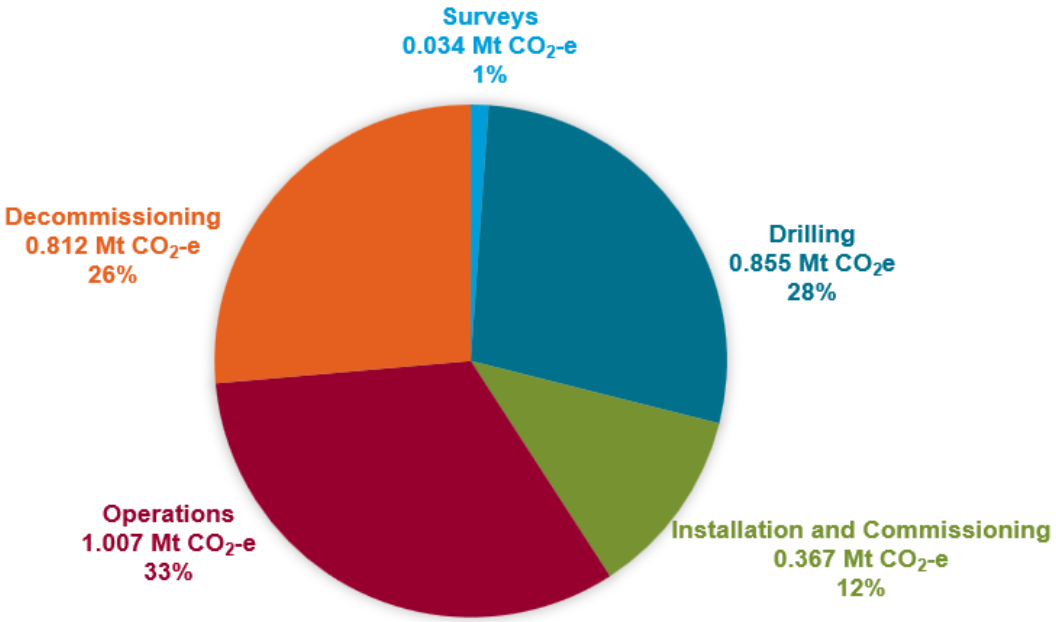

Figure 2-1: Estimated total BFF GHG emissions over the life of the Backfill Fields Development

2.2 BFF gas processing GHG emissions

The purpose of the Backfill Fields Development is to maintain gas supply to the existing Gorgon GTP on Barrow Island (part of the approved Gorgon Gas Development and constructed as part of the Gorgon Foundation Project). Therefore, in having regard to the EPBC Indirect Consequences Policy Statement (Ref. 3), the processing of the gas from the seven backfill fields at the GTP on Barrow Island has been assessed as an indirect consequence of the Backfill Fields Development.

All gas processing GHG emissions from the Gorgon Gas Development have been previously described and assessed in existing primary and secondary environmental approvals (e.g. Ref. 4; Ref. 5; Ref. 6; Ref. 12; see also Section 1.3.1). The detailed methods and assumptions for estimating these Gorgon Gas Development GHG emissions are not repeated here; however as described in the previous approvals the estimates were prepared based on methods consistent with the NGER Act and its supporting determinations and technical guidelines (Ref. 5). The estimated gas processing GHG estimate for the three-train Gorgon Gas Development was an average annual of ~9.47 Mtpa CO_2-e. No change to previously approved gas processing GHG emissions is being sought under the Backfill Fields Development OPP in relation to the overall Gorgon Gas Development GHG emissions.

As gas from the Backfill Fields Development will not be the only feed gas supply for the Gorgon GTP, a proportion of production and hence a proportion of GHG emissions from the overall Gorgon Gas Development will be substantially caused by the Backfill Fields Development. Therefore, this GHG emissions inventory has been prepared to estimate the proportion of the Gorgon Gas Development's gas processing GHG emissions associated with the Backfill Fields Development.

The portion of gas processing GHG emissions attributable to the Backfill Fields Development has been estimated by considering the proportion of production forecast from the seven backfill fields, as a subset of the total Gorgon Gas

Development production forecast[13] over the indicative operational life of the Backfill Fields Development[14]. The estimated total **BFF gas processing GHG emissions** over the operational life of the Backfill Fields Development is ~107.8 Mt CO_2-e. When converted to an annual average over the operational life of the Backfill Fields Development this equates to an estimate of ~2.8 Mtpa CO_2-e[15].

2.3 BFF secondary GHG emissions

With regard to the EPBC Indirect Consequences Policy Statement (Ref. 3), the transport and third-party end use of LNG, condensate and domestic gas products following processing at the existing Gorgon GTP on Barrow Island (part of the approved Gorgon Gas Development) have been assessed as reasonably foreseeable 'secondary actions' and the associated GHG emissions as reasonably foreseeable direct consequences of those 'secondary actions'. Accordingly, they are 'indirect consequences' of the Backfill Fields Development.

All secondary GHG emissions from the Gorgon Gas Development have been described and assessed in existing primary and secondary environmental approvals (e.g. Ref. 5; Ref. 6; Ref. 12; Ref. 14; see also Section 1.3.1). The estimated secondary GHG emissions for the Gorgon Gas Development is ~49.8 Mtpa CO_2-e for a representative production year (15.6 Mt net LNG) during three-train operations[16].

As described in the approved Gorgon GTP GHGMP (Ref. 6), contemporary guidance on estimating emissions was applied to develop the revised estimate of the Gorgon Gas Development's secondary GHG emissions using the following key documents and inputs:

- emissions from transport
  - estimated from shipping fuel consumption scaled for a representative year of production
  - emissions factors sourced from IMO Resolution MEPC.245(66) (Ref. 15) and 100-year GWPs (Ref. 8)

[13] Forecast production rates were based on information available at the time of development of the Backfill Fields Development OPP and Gorgon GTP GHGMP, and may be subject to change as modelling improves or business decisions change.

[14] Where 'operational life of the Backfill Fields Development' is represented as FY2029–FY2066 (38 years). This period is based on indicative ready for start-up for the first of the backfill fields (refer to Table 4-2 of the OPP) and the indicative date of the start of decommissioning (consistent with the Gorgon GTP GHGMP; Ref. 6).

[15] This annual average is a long-term estimate based on the 'operational life of the Gorgon Gas Development' represented as FY2029–FY2066 (38 years). However, as the forecast production takes into consideration lower production in the latter years of the Gorgon Gas Development, the annual average for **BFF gas processing GHG emissions** over a 'nominal period of three-train operations' represented as FY2029–FY2050 (22 years) is estimated at ~4.4 Mtpa CO_2-e, being higher than the long-term operational life estimate.

[16] The annual average for Gorgon Gas Development's secondary GHG emissions over the remainder of the life of the Gorgon Gas Development is expected to be lower than this estimate for a representative production year. The estimated long-term annual average based on the 'remainder of the life of the Gorgon Gas Development' represented as FY2029–FY2066, is ~38.3 Mtpa CO_2-e. This period is based on indicative ready for start-up date for the first of the backfill fields (refer to Table 4-2 of the OPP) and the indicative date of the start of decommissioning (consistent with the Gorgon GTP GHGMP; Ref. 6). This long-term estimate uses the same method, emission factors, and GWPs as the representative year three-train estimate, but incorporates forecast production rates over the remainder of the life of the Gorgon Gas Development (from the onset of the backfill fields in FY2029). As different source fields are utilised and forecast production rates are projected to decline as the project progresses towards end of life, emissions are expected to be lower in future years. The forecast production rates were based on information available at the time and may be subject to change as modelling improves or business decisions change.

- emissions from third-party use of products
  - calculated in alignment with methods in Category 11 of IPIECA's *Estimating Petroleum Industry Value Chain (Scope 3) Greenhouse Gas Emissions* (Ref. 16), including product quantity and fuel-specific higher heating values, and the CO_2, CH_4 and N_2O combustion emissions factors for each fuel type
  - evaluation based upon production data from a representative year (15.6 Mt net LNG), applying API compendium methodologies, factors and 100-year GWPs (Ref. 8; Ref. 17).

As additional context for the inputs and assumptions used to develop the Gorgon Gas Development's secondary GHG emissions estimate:

- LNG is the predominant product (by tonne) produced by the Gorgon Gas Development (with smaller tonnages of condensate and domestic gas); therefore, the LNG related transport and third-party end use represent the greatest proportion of emissions
- for LNG carriers the fuel consumption estimate was based on reported boil off gas (as a percentage per loaded tonne of LNG) from operational data
  - the use of a proportion per loaded tonne removes the effect on destination from this calculation (see also Section 8.3.7 in the OPP for a discussion on customer markets)
- GHG emission estimates for LNG carriers also included allowances for methane slip (Ref. 18)
- for condensate transport the fuel consumption estimate was based on reported fuel type and consumption from operational data
- the emissions from use of products are based on quantity of product (LNG, condensate, domestic gas) and emission factors; the location of where products are used does not affect the quantification of this GHG emissions estimate.

This above approach corresponds to total secondary GHG emissions and does not take into account any potential GHG emissions mitigations and/or reductions opportunities associated with shipping or undertaken by the end user.

As per the treatment of **BFF gas processing GHG emissions**, the **BFF secondary GHG emissions** presented in the inventory represent a proportion of the overall Gorgon Gas Development secondary GHG emissions.

The estimated total **BFF secondary GHG emissions** over the operational life of the Backfill Fields Development[14] is ~600.7 Mt CO_2-e. When converted to an annual average over the operational life of the Backfill Fields Development[14] this equates to an estimate of ~15.8 Mtpa CO_2-e[17].

[17] This annual average is a long-term estimate based on the 'operational life of the Gorgon Gas Development' represented as FY2029–FY2066 (38 years). However, as the forecast production takes into consideration lower production in the latter years of the Gorgon Gas Development, the annual average for **BFF secondary GHG emissions** over a 'nominal period of three-train operations' represented as FY2029–FY2050 (22 years) is estimated to be ~24.7 Mtpa CO_2-e, being higher than the long-term operational life estimate.

3 summary

3.1 GHG emissions inventory

The estimated total GHG emissions for the Backfill Fields Development are summarised in Table 3-1. A long-term annual average value is also presented in Table 3-1; this annual average is based on the estimated total divided by the life (or operational life) of the Backfill Fields Development. Actual annual GHG emissions will vary year to year based on activities/phases and production rates at the given time.

These estimated total GHG emissions have been used to inform the environmental impact and risk assessment in the OPP. However, it is recognised that there are emission reduction requirements and/or targets in place for both the Gorgon Gas Development and customer markets (see Section 3.2).

Table 3-1: Estimated total and annual average GHG emissions for the Backfill Fields Development

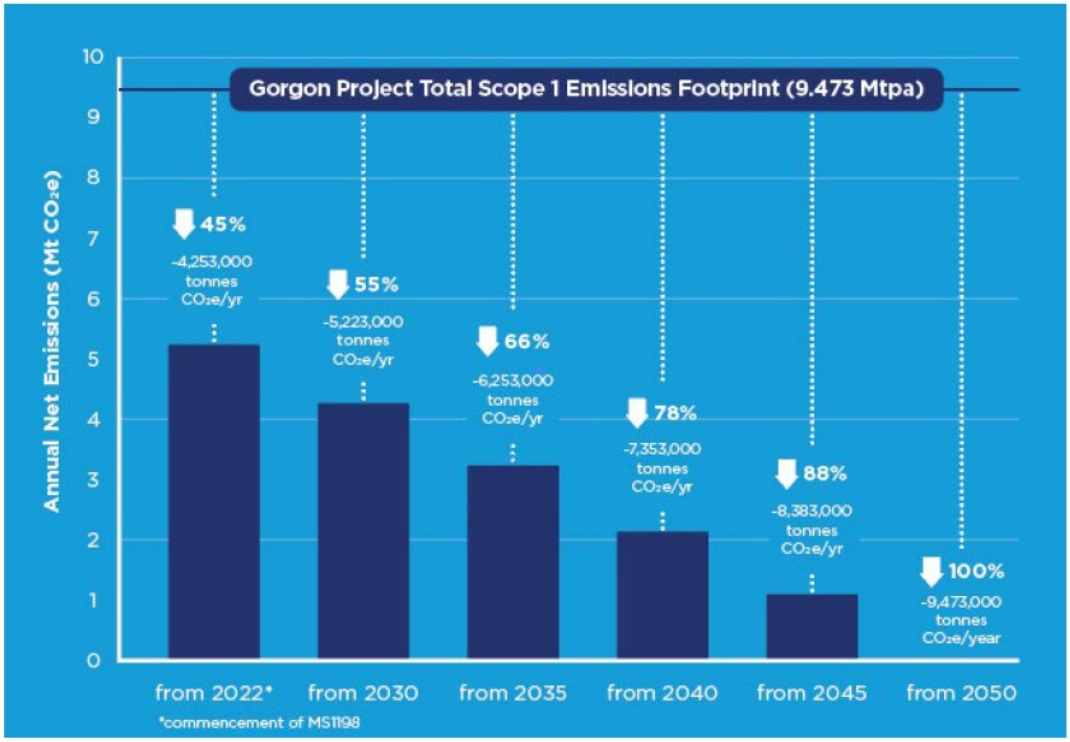
Emission source	Emission location	Jurisdiction for GHG emissions management	Estimated total[18] GHG emissions for the Backfill Fields Development[19] (Mt CO_2-e)	Estimated annual average[18] GHG emissions for the Backfill Fields Development[19] (Mtpa CO_2-e)
BFF GHG emissions				
Fuel combustion (MODU, vessels)	Development Area (Commonwealth waters)	Australia	2.64	0.06
Fuel combustion (helicopters)			0.04	0.001
Flaring (MODU)			0.37	0.01
Cold venting (MODU)			0.02	0.0004
BFF gas processing GHG emissions				
Gas processing at the GTP[20]	Barrow Island (State onshore, State waters)	Australia	107.8	2.8
Purchased electricity[21]	N/A	N/A	0	0
BFF secondary GHG emissions				
Transport and third-party end use (LNG, condensate, and domestic gas)	Western Australia (domestic gas)	Australia	600.7	15.8
	Subject to consumer location (LNG, condensate)	Subject to consumer location		
		Total	**711.6**	**18.7**

[18] All estimated GHG emissions presented in this table do not take into consideration any potential GHG emissions mitigations, reduction, or offset opportunities that may be undertaken (see Section 3.2).

[19] For **BFF GHG emissions** this refers to the 'life of the Backfill Fields Development' as represented by FY 2027–FY 2070 (44 years). However, for **BFF gas processing GHG emissions** and **BFF secondary GHG emissions** this refers to the 'operational life of the Backfill Fields Development') as represented by FY 2029–FY 2066 (38 years).

[20] This includes emissions from operation of the Gorgon GTP for the processing of LNG and domestic gas, as well as emissions from Barrow Island support operations.

[21] There is no purchased electricity associated with the Gorgon Gas Development. All electricity is generated on Barrow Island (including any power required for subsea operations) and any associated emissions are therefore already incorporated into the 'gas processing at the GTP' emissions estimate.



3.2 GHG emissions management

The Backfill Fields Development, as part of the overarching Gorgon Gas Development, is subject to legislated emission reduction requirements. At the time of writing this Technical Note, these requirements include:

- implementation of Reservoir Carbon Dioxide Injection System requirements as per condition 26 of MS 1198 under EP Act (WA) approvals
- implementation of Greenhouse Gas Management Plan requirements as per condition 27 of MS 1198 under EP Act (WA) approvals, including the Net GHG Emissions reductions as set by condition 27.1 (Figure 3-1)
- declining facility baselines under the Commonwealth Safeguard Mechanism
  - this is currently set a 4.9% each financial year from FY2024 to FY2030
  - from FY2031 the decline rates will be set for each year in 5-year blocks by the Department of Climate Change, Energy the Environment and Water.

Both sets of regulatory requirements have GHG emissions from the Gorgon Gas Development on a trajectory to net zero by 2050.

Customer markets for the Gorgon Gas Development are discussed in Section 8.3.7 of the OPP. GHG emissions associated with transport and third-party end use of products will be managed under the respective regulatory regimes of these markets. As described in the OPP, all customer markets with long-term sales agreements in place currently have GHG emission reduction targets in place.

Source: Gorgon GTP GHGMP (Ref. 6).

Figure 3-1: Net GHG Emissions targets (per condition 27.1 of MS 1198) and associated percent reduction in emissions from the 3-train Revised and Expanded Gorgon Gas Development GHG emissions estimate

4 acronyms and abbreviations

Table 4-1 defines the acronyms and abbreviations used in this document.

Table 4-1: Acronyms and abbreviations

Acronym / abbreviation	Definition

Terminology

ID: ACH on the Register is assigned a unique ID by the Department of Planning, Lands and Heritage using the format: ACH-00000001. For ACH on the former Register the ID numbers remain unchanged and use the new format. For example the ACH ID of the place Swan River was previously '3536' and is now 'ACH-00003536'.

Access and Restrictions:

- **Boundary Reliable (Yes/No):** Indicates whether to the best knowledge of the Department, the location and extent of the ACH boundary is considered reliable.
- **Boundary Restricted = No:** Represents the actual location of the ACH as understood by the Department..
- **Boundary Restricted = Yes:** To preserve confidentiality the exact location and extent of the place is not displayed on the map. However, the shaded region (generally with an area of at least 4km²) provides a general indication of where the ACH is located. If you are a landowner and wish to find out more about the exact location of the place, please contact the Department of Planning, Lands and Heritage.
- **Culturally Sensitive = No:** Availability of information that the Department of Planning, Lands and Heritage holds in relation to the ACH is not restricted in any way.
- **Culturally Sensitive = Yes:** Some of the information that the Department of Planning, Lands and Heritage holds in relation to the ACH is restricted if it is considered culturally sensitive information. This information will only be made available if the Department of Planning, Lands and Heritage receives written approval from the people who provided the information. To request access please contact via https://achknowledge.dplh.wa.gov.au/ach-enquiry-form.
- **Culturally Sensitive Nature:**
  - **No Gender / Initiation Restrictions:** *Anyone* can view the information.
  - **Men only:** Only *males* can view restricted information.
  - **Women only:** Only *females* can view restricted information.

Status:

- **Register:** Aboriginal cultural heritage places that are assessed as meeting Section 5 of the *Aboriginal Heritage Act 1972*.
- **Lodged:** Information which has been received in relation to an Aboriginal cultural heritage place, but is yet to be assessed under Section 5 of the *Aboriginal Heritage Act 1972*.
- **Historic:** Aboriginal heritage places assessed as not meeting the criteria of Section 5 of the *Aboriginal Heritage Act 1972*. Includes places that no longer exist as a result of land use activities with existing approvals.

Place Type: The type of Aboriginal cultural heritage place. For example an artefact scatter place or engravings place.
Legacy ID: This is the former unique number that the former Department of Aboriginal Sites assigned to the place.

Disclaimer

Aboriginal heritage holds significant value to Aboriginal people for their social, spiritual, historical, scientific, or aesthetic importance within Aboriginal traditions, and provides an essential link for Aboriginal people to their past, present and future. In Western Australia Aboriginal heritage is protected under the Aboriginal Heritage Act 1972.

All Aboriginal cultural heritage in Western Australia is protected, whether or not the ACH has been reported or exists on the Register.

The information provided is made available in good faith and is predominately based on the information provided to the Department of Planning, Lands and Heritage by third parties. The information is provided solely on the basis that readers will be responsible for making their own assessment as to the accuracy of the information. If you find any errors or omissions in our records, including our maps, it would be appreciated if you provide the details to the Department via https://achknowledge.dplh.wa.gov.au/ach-enquiry-form and we will make every effort to rectify it as soon as possible.

- Culturally Sensitive Nature:
  - No Gender / Initiation Restrictions: Anyone can view the information.
  - Men only: Only males can view restricted information.
  - Women only: Only females can view restricted information.

Status:

- Register: Aboriginal cultural heritage places that are assessed as meeting Section 5 of the Aboriginal Heritage Act 1972.
- Lodged: Information which has been received in relation to an Aboriginal cultural heritage place, but is yet to be assessed under Section 5 of the Aboriginal Heritage Act 1972.
- Historic: Aboriginal heritage places assessed as not meeting the criteria of Section 5 of the Aboriginal Heritage Act 1972. Includes places that no longer exist as a result of land use activities with existing approvals.

Place Type: The type of Aboriginal cultural heritage place. For example an artefact scatter place or engravings place.
Legacy ID: This is the former unique number that the former Department of Aboriginal Sites assigned to the place.

Disclaimer

Aboriginal heritage holds significant value to Aboriginal people for their social, spiritual, historical, scientific, or aesthetic importance within Aboriginal traditions, and provides an essential link for Aboriginal people to their past, present and future. In Western Australia Aboriginal heritage is protected under the *Aboriginal Heritage Act 1972*.

All Aboriginal cultural heritage in Western Australia is protected, whether or not the ACH has been reported or exists on the Register.

The information provided is made available in good faith and is predominately based on the information provided to the Department of Planning, Lands and Heritage by third parties. The information is provided solely on the basis that readers will be responsible for making their own assessment as to the accuracy of the information. If you find any errors or omissions in our records, including our maps, it would be appreciated if you provide the details to the Department via https://achknowledge.dplh.wa.gov.au/ach-enquiry-form and we will make every effort to rectify it as soon as possible.

Terminology

ID: ACH on the Register is assigned a unique ID by the Department of Planning, Lands and Heritage using the format: ACH-00000001. For ACH on the former Register the ID numbers remain unchanged and use the new format. For example the ACH ID of the place Swan River was previously '3536' and is now 'ACH-00003536'.

Access and Restrictions:

- **Boundary Reliable (Yes/No):** Indicates whether to the best knowledge of the Department, the location and extent of the ACH boundary is considered reliable.
- **Boundary Restricted = No:** Represents the actual location of the ACH as understood by the Department..
- **Boundary Restricted = Yes:** To preserve confidentiality the exact location and extent of the place is not displayed on the map. However, the shaded region (generally with an area of at least 4km²) provides a general indication of where the ACH is located. If you are a landowner and wish to find out more about the exact location of the place, please contact the Department of Planning, Lands and Heritage.
- **Culturally Sensitive = No:** Availability of information that the Department of Planning, Lands and Heritage holds in relation to the ACH is not restricted in any way.
- **Culturally Sensitive = Yes:** Some of the information that the Department of Planning, Lands and Heritage holds in relation to the ACH is restricted if it is considered culturally sensitive information. This information will only be made available if the Department of Planning, Lands and Heritage receives written approval from the people who provided the information. To request access please contact via https://achknowledge.dplh.wa.gov.au/ach-enquiry-form.
- **Culturally Sensitive Nature:**
  - **No Gender / Initiation Restrictions:** *Anyone* can view the information.
  - **Men only:** Only *males* can view restricted information.
  - **Women only:** Only *females* can view restricted information.

Status:

- **Register:** Aboriginal cultural heritage places that are assessed as meeting Section 5 of the *Aboriginal Heritage Act 1972*.
- **Lodged:** Information which has been received in relation to an Aboriginal cultural heritage place, but is yet to be assessed under Section 5 of the *Aboriginal Heritage Act 1972*.
- **Historic:** Aboriginal heritage places assessed as not meeting the criteria of Section 5 of the *Aboriginal Heritage Act 1972*. Includes places that no longer exist as a result of land use activities with existing approvals.

Place Type: The type of Aboriginal cultural heritage place. For example an artefact scatter place or engravings place.
Legacy ID: This is the former unique number that the former Department of Aboriginal Sites assigned to the place.

Terminology

ID: ACH on the Register is assigned a unique ID by the Department of Planning, Lands and Heritage using the format: ACH-00000001. For ACH on the former Register the ID numbers remain unchanged and use the new format. For example the ACH ID of the place Swan River was previously '3536' and is now 'ACH-00003536'.

Access and Restrictions:

- Boundary Reliable (Yes/No): Indicates whether to the best knowledge of the Department, the location and extent of the ACH boundary is considered reliable.
- Boundary Restricted = No: Represents the actual location of the ACH as understood by the Department..
- Boundary Restricted = Yes: To preserve confidentiality the exact location and extent of the place is not displayed on the map. However, the shaded region (generally with an area of at least 4km²) provides a general indication of where the ACH is located. If you are a landowner and wish to find out more about the exact location of the place, please contact the Department of Planning, Lands and Heritage.
- Culturally Sensitive = No: Availability of information that the Department of Planning, Lands and Heritage holds in relation to the ACH is not restricted in any way.
- Culturally Sensitive = Yes: Some of the information that the Department of Planning, Lands and Heritage holds in relation to the ACH is restricted if it is considered culturally sensitive information. This information will only be made available if the Department of Planning, Lands and Heritage receives written approval from the people who provided the information. To request access please contact via https://achknowledge.dplh.wa.gov.au/ach-enquiry-form.
- Culturally Sensitive Nature:
  - No Gender / Initiation Restrictions: Anyone can view the information.
  - Men only: Only males can view restricted information.
  - Women only: Only females can view restricted information.

Status:

- Register: Aboriginal cultural heritage places that are assessed as meeting Section 5 of the Aboriginal Heritage Act 1972.
- Lodged: Information which has been received in relation to an Aboriginal cultural heritage place, but is yet to be assessed under Section 5 of the Aboriginal Heritage Act 1972.
- Historic: Aboriginal heritage places assessed as not meeting the criteria of Section 5 of the Aboriginal Heritage Act 1972. Includes places that no longer exist as a result of land use activities with existing approvals.

Place Type: The type of Aboriginal cultural heritage place. For example an artefact scatter place or engravings place.
Legacy ID: This is the former unique number that the former Department of Aboriginal Sites assigned to the place.

Disclaimer

Aboriginal heritage holds significant value to Aboriginal people for their social, spiritual, historical, scientific, or aesthetic importance within Aboriginal traditions, and provides an essential link for Aboriginal people to their past, present and future. In Western Australia Aboriginal heritage is protected under the Aboriginal Heritage Act 1972.

All Aboriginal cultural heritage in Western Australia is protected, whether or not the ACH has been reported or exists on the Register.

The information provided is made available in good faith and is predominately based on the information provided to the Department of Planning, Lands and Heritage by third parties. The information is provided solely on the basis that readers will be responsible for making their own assessment as to the accuracy of the information. If you find any errors or omissions in our records, including our maps, it would be appreciated if you provide the details to the Department via https://achknowledge.dplh.wa.gov.au/ach-enquiry-form and we will make every effort to rectify it as soon as possible.

Terminology

ID: ACH on the Register is assigned a unique ID by the Department of Planning, Lands and Heritage using the format: ACH-00000001. For ACH on the former Register the ID numbers remain unchanged and use the new format. For example the ACH ID of the place Swan River was previously '3536' and is now 'ACH-00003536'.

Access and Restrictions:

- Boundary Reliable (Yes/No): Indicates whether to the best knowledge of the Department, the location and extent of the ACH boundary is considered reliable.
- Boundary Restricted = No: Represents the actual location of the ACH as understood by the Department..
- Boundary Restricted = Yes: To preserve confidentiality the exact location and extent of the place is not displayed on the map. However, the shaded region (generally with an area of at least 4km²) provides a general indication of where the ACH is located. If you are a landowner and wish to find out more about the exact location of the place, please contact the Department of Planning, Lands and Heritage.
- Culturally Sensitive = No: Availability of information that the Department of Planning, Lands and Heritage holds in relation to the ACH is not restricted in any way.
- Culturally Sensitive = Yes: Some of the information that the Department of Planning, Lands and Heritage holds in relation to the ACH is restricted if it is considered culturally sensitive information. This information will only be made available if the Department of Planning, Lands and Heritage receives written approval from the people who provided the information. To request access please contact via https://achknowledge.dplh.wa.gov.au/ach-enquiry-form.
- Culturally Sensitive Nature:
  - No Gender / Initiation Restrictions: Anyone can view the information.
  - Men only: Only males can view restricted information.
  - Women only: Only females can view restricted information.

Status:

- Register: Aboriginal cultural heritage places that are assessed as meeting Section 5 of the Aboriginal Heritage Act 1972.
- Lodged: Information which has been received in relation to an Aboriginal cultural heritage place, but is yet to be assessed under Section 5 of the Aboriginal Heritage Act 1972.
- Historic: Aboriginal heritage places assessed as not meeting the criteria of Section 5 of the Aboriginal Heritage Act 1972. Includes places that no longer exist as a result of land use activities with existing approvals.

Place Type: The type of Aboriginal cultural heritage place. For example an artefact scatter place or engravings place.
Legacy ID: This is the former unique number that the former Department of Aboriginal Sites assigned to the place.

Coordinates

Map coordinates are based on the GDA 2020 Datum.

appendix g response to public comments

Appendix Table G-1: Response to public comments on Revision 2[1] of the Backfill Fields OPP

ID	Stakeholder	Source	Comments received (in general terms)	Titleholder response	Changes to OPP
1	Individual #1	NOPSEMA public comment submission	*Matter*: Supportive of proposed Development. *Objection or claim*: No objection or claim raised.	Chevron Australia Pty Ltd (CAPL) welcomes the support for the proposed Backfill Fields Development (the Development).	CAPL considers no amendments to the OPP are necessary.
2	Individual #2	NOPSEMA public comment submission	*Matter*: Comments were received citing concerns of potential adverse impacts to the marine environment. *Objection or claim*: 2A—The proposed Development would result in disruption and/or damage to the environment at the development site.	In developing the Backfill Fields Offshore Project Proposal (OPP), and in accordance with the requirements of the Offshore Petroleum and Greenhouse Gas Storage (Environment) Regulations 2023 (Cth) (OPGGS(E)R), CAPL has identified and evaluated the environmental impacts and risks associated with both planned activities and unplanned events associated with the petroleum activities within scope of the Development, including identifying environmental performance outcomes (EPOs) and control measures to demonstrate that these petroleum activities can be managed to an acceptable level. The definition of environment under the OPGGS(E)R is broad and includes ecological, socioeconomic, and cultural components. These elements have been incorporated into the description of environment (**Section 6**). An initial screening of environmental aspects was undertaken to identify potential interactions between the proposed Development and the environment (**Table 7-2**). Potential impacts and risks arising from these aspects were then identified (**Table 7-3**). Detailed evaluations of the potential impacts and risks are provided in **Section 8**. The spatial extent of the environment that may be affected (EMBA) from planned activities and unplanned events (except for major hydrocarbon spill events) associated with the Development occurs within, or within the vicinity of, the Development Area (DA) (i.e. an area offshore from Barrow Island in Commonwealth waters, as shown in **Figure 4-2** of the OPP). Detailed	CAPL considers that the OPP sufficiently addresses the matters contained within the public comment relating to the environmental impacts and risks associated with the Development, and as such no amendments to the OPP have been made.

[1] Revision 2 of the Backfill Fields Development OPP was released for public comment between 09 August and 01 November 2024. During the subsequent Stage 2 assessment phase by NOPSEMA further changes to the OPP have been made. Any references to components of the OPP (including figures, environmental performance outcomes and control measures) are as per the updated revisions of the OPP.

ID	Stakeholder	Source	Comments received (in general terms)	Titleholder response	Changes to OPP
				environmental impact and risks assessments for the following aspects have been provided: • seabed disturbance (**Section 8.1**) • air emissions (**Section 8.2**) • light emissions (**Section 8.4**) • underwater sound emissions (**Section 8.5**) • planned discharges (MODU and vessel operations, subsea operations, drilling operations) (**Sections 8.6**, **8.7**, **8.8**) • unplanned interactions from physical presence of Development (other marine users, marine fauna) (**Sections 8.9**, **8.10**) • unplanned introduction of invasive marine species (**Section 8.11**) • unplanned releases (solid waste, minor loss of containment) (**Sections 8.12**, **8.13**) The highest consequence level of all the potential impacts from the above aspects was a 4 (moderate) associated with seabed disturbance. The highest residual risk level of all the potential risks from the above aspects was 6 (moderate) associated with underwater sound emissions. These aspects, and potential impacts or risks, are not dissimilar to those managed by CAPL (and other petroleum operators) for existing petroleum operations. To manage the impacts and risks associated with these aspects, CAPL has defined EPOs that set a level of environmental performance and identified preventative and/or mitigative control measures to ensure that the impacts and risks can be managed to an acceptable level. As such, CAPL consider that the potential for disruption and/or damage to the environment at the Development site can be managed to an acceptable level in alignment with regulatory requirements for an offshore project[2].	
			Objection or claim:	The risk of disruption and/or damage to the Exmouth and Onslow oceanic system is only associated with the risk of an unplanned major hydrocarbon spill event (and not directly from other	

[2] Where 'offshore project' is defined under regulation 5 of the OPGGS(E)R, as "one or more activities that are undertaken for the purpose of the recovery of petroleum, other than on an appraisal basis, including any conveyance of recovered petroleum by pipeline (whether or not the activity is undertaken for other purposes)".

ID	Stakeholder	Source	Comments received (in general terms)	Titleholder response	Changes to OPP
			2B—The proposed Development would result in disruption and/or damage to the Exmouth and Onslow oceanic system.	Development activities). The risk assessments for these two aspects are presented in **Section 8.14** and **Section 8.15**). The EMBA from unplanned major hydrocarbon spill events is much broader than the DA and extends towards the Onslow and Exmouth area (as shown in **Figure 6-1** and **Figure 6-2** of the OPP[3]). CAPL used oil spill modelling to inform its assessment of impacts and risks associated with these unplanned release of hydrocarbon events. The oil spill modelling (full modelling reports are included in **Appendix C**) indicated that for the Onslow and Exmouth area: • no exposure to surface (floating) oil above the ≥10 mg/L ecological threshold; some potential exposure above the visible (≥1 mg/L) threshold may occur in offshore waters • some potential shoreline accumulation (above the visible 10 g/m^2 and ecological 100 g/m^2 thresholds) may occur on some of the Pilbara inshore islands or along the western coast of the North West Cape • no exposure to dissolved hydrocarbons above the 50 ppb threshold • some potential exposure to entrained hydrocarbons above the 100 ppb threshold in waters offshore from Onslow and Exmouth • the probability of exposure varied due to the location and type of spill event. Some of the key environmental sensitivities within the vicinity of the Onslow and Exmouth area are Ningaloo (including the reef system, marine parks, World Heritage Area) and the Pilbara inshore islands, which were both specifically addressed within the impact and risk assessments in **Section 8.14** and **Section 8.15.** To manage the impacts and risks associated with an unplanned hydrocarbon release, CAPL has identified both preventative (e.g.**CM-16, CM-31, CM-32, CM-33, CM-43. CM-45, CM-46**) and mitigative (e.g. **CM-22, CM-44**) control measures to ensure that the impacts and risks can be managed to an acceptable level. As such, CAPL consider that the potential for	

[3] Note: The EMBA shown in these figures is based on the outcomes of stochastic oil spill modelling and is not representative of a single spill event.

ID	Stakeholder	Source	Comments received (in general terms)	Titleholder response	Changes to OPP
				disruption and/or damage to the to the Exmouth and Onslow oceanic system can be managed to an acceptable level in alignment with regulatory requirements for an offshore project.	
3	Individual #3	NOPSEMA public comment submission	*Matter*: Supportive of proposed Development. *Objection or claim*: No objection or claim raised.	CAPL welcomes the support for the proposed Development.	CAPL considers no amendments to the OPP are necessary.
4	Individual #4	NOPSEMA public comment submission	*Matter*: Comments were received citing concerns of potential adverse impacts to the marine environment and marine fauna. *Objection or claim*: 4A—The proposed Development is within whale migration routes and these animals must be protected.	In developing the Backfill Fields OPP, and in accordance with the requirements of the OPGGS(E)R, CAPL has identified and evaluated the environmental impacts and risks associated with both planned activities and unplanned events associated with the petroleum activities within scope of the Development, including identifying EPOs and control measures to demonstrate that these petroleum activities can be managed to an acceptable level. The presence of cetaceans and any identified biologically important areas (BIAs) within the EMBA are described within **Section 6.3.3.1**. The very southern extent of the DA extends into the "migration (north and south)" BIA for humpback whales (**Figure 6-14**). Petroleum activities occurring within vicinity of this BIA include the development of West Tryal Rocks [WTR] and tie-in activities to existing Gorgon infrastructure (i.e. activities associated with the development of the Chrysaor and Dionysus [C&D] and WTR gas fields). The DA more broadly intersects with the "migration" BIA for pygmy blue whales (**Figure 6-16**). Petroleum activities occurring within or within vicinity of this BIA include the development of all gas fields (Chandon, Geryon and Eurytion [G&E], C&D, Semele, WTR). The presence of humpback whales within the Jansz region has been recorded from July to October (**Table 6-18**). Pygmy blue whale presence within the Jansz region has been recorded from late-March to mid-September (peak late-May to June) during northern migration, and from early-October to late-January (peak late-November and early-December) for the southern migration (**Table 6-18**). The gas fields will be developed over multiple campaigns with the G&E development indicatively scheduled to commence from late-2026 (**Section 4.14**). Detailed breakdown	CAPL considers that the OPP sufficiently addresses the matters contained within public comment relating to the environmental impacts and risks associated with the Development, and as such no amendments to the OPP have been made.

ID	Stakeholder	Source	Comments received (in general terms)	Titleholder response	Changes to OPP
				of activity timings is not available at this stage of the Development but will be included in subsequent Environment Plans (EPs). The potential for petroleum activities to occur throughout the year has been carried into the impact and risk assessments presented in the OPP. The screening for potential impacts and risks associated with the Development (**Table 7-3**) identified the following aspects as relevant to marine mammals (including cetaceans): • underwater sound emissions • planned discharges (drilling operations) • unplanned interactions from physical presence of Development (marine fauna) • unplanned releases (minor loss of containment) • unplanned hydrocarbon release (vessel collision, hydrocarbon system). Marine mammals form part of the detailed impact and risk assessment for each of the above aspects within **Section 8**. The highest residual risk level of all the potential risks from the above aspects was 6 (moderate) associated with underwater sound emissions. To mitigate the impacts and risks associated with this aspect, CAPL has set EPOs and identified preventative and/or mitigative control measures to ensure that the impacts and risks can be managed to an acceptable level. For underwater sound, there is also an adaptive management EPO and control measures (**EPO-23, CM-20 and CM-21**) that have been included which requires consideration of appropriate acoustic management controls to be further considered during the development of the subsequent EPs to ensure that the risks from underwater sound have been reduced to as low as reasonably practicable and can be managed to acceptable levels. There are also EPOs (**EPO-17**, **EPO-18**, **EPO-19**) in place to ensure that the risks from the petroleum activity are not inconsistent with the requirements for the Conservation Management Plan for the Blue Whale. As such, CAPL considers that the potential for impacts and risks to whale species, and specifically within migration routes, can be managed to an acceptable level in alignment with regulatory requirements for an offshore project.	

ID	Stakeholder	Source	Comments received (in general terms)	Titleholder response	Changes to OPP
			Objection or claim: 4B—The proposed Development would impact the ocean and this environment must be protected.	Regarding the claim raised about impacts to the ocean, please refer to the response provided above to Item 2. CAPL considers that the potential impacts and risks to the ocean can be managed to an acceptable level in alignment with regulatory requirements for an offshore project.	
5	Individual #5	NOPSEMA public comment submission	*Matter*: Supportive of proposed Development. *Objection or claim*: No objection or claim raised.	CAPL welcomes the support for the proposed Development.	CAPL considers no amendments to the OPP are necessary.
6	Individual #6	CAPL consultation hub (website) submission	*Matter*: A comment was received citing "marine environment and whale migration". *Objection or claim*: No objection or claim has been defined due to lack of context in comment received.	CAPL attempted to contact the individual via email and phone following receipt of the comment asking if they wanted to discuss the Development, or if further information was required, to try and understand the context of the submission and if there were any objections or claims. No response from the individual was received on either attempt of contact. However, regarding the marine environment and whale migration, responses to comments on similar matters are provided above in Item 2 and Item 4.	CAPL considers no amendments to the OPP are necessary.
7	Individual #7	NOPSEMA public comment submission	*Matter*: Supportive of proposed Development. *Objection or claim*: No objection or claim raised.	CAPL welcomes the support for the proposed Development.	CAPL considers no amendments to the OPP are necessary.
8	Conservation Council of WA (CCWA)	NOPSEMA public comment submission	*Matter*: Comments were received citing that the description of the proposed Development is not always consistent. *Objection or claim*: 8A—Number of wells is reported as both seven and forty.	CAPL are unable to find reference to 7 wells in the OPP. However, CAPL can confirm that the Development comprises: • 7 backfill fields (Chandon, Geryon, Eurytion, Chrysaor, Dionysus, Semele, WTR) (**Sections 1.1**, **4.1**) • a maximum of 40 production wells across all fields (**Section 4.2.2**) – with a maximum of 8 wells per field or co-developed fields (i.e. a maximum of 8 wells in each of Chandon, G&E, C&D, Semele, and WTR) (**Section 4.2.2**)	CAPL considers no amendments to the OPP are necessary.

ID	Stakeholder	Source	Comments received (in general terms)	Titleholder response	Changes to OPP
				• the wells are distributed between 10 drill centres (2 in Chandon, 1 in G&E, 3 in C&D, 2 in Semele, and 1 in WTR) (**Section 4.1.3**, **4.2.2**).	
			Matter: Comments were received citing concerns that the Development is near multiple sensitive environmental receptors. *Objection or claim*: 8B—The Development has the potential to produce impacts to ecologically significant communities (specifically the Commonwealth Montebello Marine Park, ancient coastline at 125 m dept contour key ecological feature [KEF], the continental slope demersal fish communities KEF, and the Exmouth Plateau KEF) from: • seabed disturbance • light pollution • noise pollution • hydrocarbon spills • wastewater discharge • drilling by-products.	The presence of KEFs within the EMBA are identified in **Section 6.3.6.1;** specifically, the DA intersects with a small proportion of each of the following KEFs: • ancient coastline at 125 m depth contour (activities associated with the development of WTR) • continental slope demersal fish communities (activities associated with the development of C&D) • Exmouth Plateau (activities associated with the development of Chandon). The values of the ancient coastline and Exmouth Plateau KEFs are listed as 'unique seafloor features with ecological properties of regionally significance' (**Table 6-20**). Parts of the ancient coastline KEF, particularly rocky escarpments, are thought to provide biologically important habitat in areas otherwise dominated by soft sediments (**Table 6-20**). The Exmouth Plateau KEF is likely to be an important area of biodiversity for communities adapted to deep-water conditions (**Table 6-20)**.However, findings from a benthic survey within the DA undertaken in 2022 found that • benthic habitats within the ancient coastline KEF were predicted to be comprised of smooth seabed with bioturbation and bare substrate and appeared to be devoid of epibenthic biota (**Section 6.3.1.1.1**; **Table 6-20).** • the survey did identify two discrete scarp features within the Exmouth Plateau KEF in an area that intersects with the indicative flowline route for Chandon; however, no epibenthic fauna were detected (**Section 6.3.1.1.1**; **Table 6-20)**. The values of the continental slope demersal fish communities KEF are listed as high level of endemism with a diversity of fish assemblages (**Table 6-20**). However, fish assemblage surveys (undertaken as part of the 2022 benthic survey) found that there was no significant difference in the mean number of fish taxa identified within the proportion of the DA that intersected with this demersal fish assemblages KEF compared to where the DA	In response this submission CAPL has revised the OPP to include an evaluation of risks to the values of the Commonwealth Montebello Marine Park from light emissions (**Section 8.4**) and underwater sound (**Section 8.5**). The aspect–receptor screening in **Table 7-3** has been updated to reflect the addition of AMPs for light emissions and underwater sound. **Table 7-3** has also been updated to reflect all relevant receptors that were evaluated within the planned discharges MODU and vessel aspect.

ID	Stakeholder	Source	Comments received (in general terms)	Titleholder response	Changes to OPP
				intersected the other two (ancient coastline and Exmouth Plateau) KEFs (**Table 6-20**). The screening for potential impacts and risks associated with the Development (**Table 7-3**) identified the following aspects as relevant to KEFs: • seabed disturbance • planned discharges (subsea operations, drilling operations) • unplanned introduction of invasive marine species • unplanned releases (solid wastes) • unplanned hydrocarbon release (vessel collision, hydrocarbon system). KEFs form part of the detailed impact and risk assessments for each of the above aspects within **Section 8**. The highest residual risk level of all the potential risks from the above aspects was 7 (low) associated with seabed disturbance. To mitigate the impacts and risks associated with these aspects, CAPL has set EPOs and identified preventative and/or mitigative control measures to ensure that the impacts and risks can be managed to an acceptable level. As such, CAPL considers that the potential for impacts and risks to KEFs can be managed to an acceptable level in alignment with regulatory requirements for an offshore project. The presence of Australian Marine Parks (AMPs) within the EMBA are identified in **Section 6.5.1**. There are no AMPs that intersect with the DA, the closest AMP is Montebello Marine Park which is ~16 km south-east of the DA. The original (Revision 2 of the OPP) screening for potential impacts and risks associated with the Development (**Table 7-3**) identified the following aspects as relevant to AMPs: • unplanned hydrocarbon release (vessel collision, hydrocarbon system). AMPs form part of the detail impact and risk assessment for each of the above aspects within **Sections 8.14** and **8.15**. The highest residual risk level of all the potential risks from the above aspects was 9 (very low). To manage the impacts and risks associated with these aspects, CAPL has identified preventative	

ID	Stakeholder	Source	Comments received (in general terms)	Titleholder response	Changes to OPP
				and/or mitigative control measures to ensure that the impacts and risks can be managed to an acceptable level. As such, CAPL considers that the potential for impacts and risks to AMPs from unplanned hydrocarbon releases can be managed to an acceptable level in alignment with regulatory requirements for an offshore project. The screening for potential impacts and risks associated with the Development (**Table 7-3**) identified the following receptors as relevant to light emissions: • physical environment (ambient light) • marine fauna (seabirds and shorebirds, fish, marine reptiles) • heritage (First Nations cultural values). Given light emission sources from the Development typically occur above the water surface (e.g. from vessels), the fish species associated with the continental slope demersal fish communities KEF were not considered to be exposed to light emissions due to their demersal (i.e. seafloor) habitat (**Section 8.4.3**). With respect to the other two KEFs, as described above, the ancient coastline and Exmouth Plateau KEFs are seafloor features and as such were not considered relevant receptors for light emissions. CAPL has reviewed the maximum flaring and navigational/operational light extents used in the impact and risk assessment and has identified that the spatial extent for flaring does extend to within the boundary of the Commonwealth Montebello Marine Park. CAPL revised **Section 8.4** to include: • a new figure (**Figure 8-22**) showing flaring and light extents in relation to AMPs • identification and evaluation of the risk for changes to the values and sensitivities of Australian Marine Parks. CAPL have also updated the screening table (**Table 7-3**) to identify AMPs as a relevant receptor for the light emissions aspect.	

ID	Stakeholder	Source	Comments received (in general terms)	Titleholder response	Changes to OPP
				The screening for potential impacts and risks associated with the Development (**Table 7-3**) identified the following receptors as relevant to underwater sound: • physical environment (ambient sound) • marine fauna (fish, marine reptiles, marine mammals) • heritage (First Nations cultural values). Although fish may potentially be impacted by underwater sound, the area of influence is localised and is not expected to result in a change in the viability of the population of commercially important species or the continental slope demersal fish communities KEF (**Section 8.5.5**). With respect to the other two KEFs—as described above the ancient coastline and Exmouth Plateau KEFs are seafloor features and as such were not considered relevant receptors for underwater sound. CAPL has reviewed the maximum horizontal extents used in the impact and risk assessment and has identified that the spatial extent to the behavioral response threshold for marine mammals from non-impulsive sound does extend to within the boundary of the Commonwealth Montebello Marine Park. CAPL has revised **Section 8.5** to include: • a new figure (**Figure 8-28**) showing marine mammal maximum horizontal distance for behavioural response in relation to AMPs • identified and evaluated a risk for changes to the values and sensitivities of Australian Marine Parks. CAPL have also updated the screening table (**Table 7-3**) to identify AMPs as a relevant receptor for the underwater sound aspect. No further comment was provided in the submission regarding wastewater discharges. CAPL has interpreted this comment to be in relation to planned discharges from MODUs and vessels (which include sewage and greywater discharges). The screening for potential impacts and risks associated with the Development (**Table 7-3**) identified the following receptors as relevant to planned discharges from MODUs and vessels: • physical environment (water quality).	

ID	Stakeholder	Source	Comments received (in general terms)	Titleholder response	Changes to OPP
				This table has been updated to capture all receptors that were included in the impact and risk assessment (**Section 8.6**), which also incorporated: • marine fauna (seabirds and shorebirds, fish, marine reptiles, marine mammals) and fish assemblages associated with KEFs. Given planned discharges from the MODU and vessels occur in surface waters, the fish species associated with the continental slope demersal fish communities KEF were not considered to be exposed due to their demersal (i.e. seafloor) habitat (**Section 8.6.2**). Planned discharges are expected to dilute and disperse within open ocean environments. Given the distance between the DA and the Montebello Marine Park, no exposure to planned discharges from MODUs and vessels is expected to occur (and therefore AMPs are not a relevant receptor for this aspect).	
			Objection or claim: 8C—A full survey of the Development Area and EMBA is necessary.	The description of environment (**Section 6**) was developed based on several sources of information, including studies specifically undertaken by CAPL. Field surveys were undertaken at sites within the DA to provide information on: • benthic habits • fish assemblages • water and sediment quality. The survey report has been provided in full (**Appendix A**) with key results provided in the relevant parts of **Section 6** and used to inform the impact and risk assessments in **Section 8**. Soundscape monitoring has also been undertaken by CAPL as part of the J-IC project. Findings from the monitoring have been incorporated into **Section 6.3.3.1**. A full survey of the EMBA is not considered practicable or necessary. Available literature has been used to provide a description of the values and sensitivities within the EMBA as appropriate to the nature and scale of the potential impacts and risks to this broader area. Further, in the event of an unplanned hydrocarbon spill, operational and scientific monitoring (**CM-44**; **Sections 8.14** and **8.15**) would be implemented which would	In response to this submission CAPL has revised the OPP to include a summary of the J-IC soundscape monitoring in **Section 6.3.3.1** (marine fauna), Section 6.3.3.1.1 (humpback whales) and **Section 6.3.3.1.2** (pygmy blue whales).

ID	Stakeholder	Source	Comments received (in general terms)	Titleholder response	Changes to OPP
				capture information on the environment at risk from the particular unplanned release event.	
			Matter: Comments were received citing concerns of potential adverse impacts from seabed disturbance associated with the Development. *Objection or claim*: 8D—The Development will disturb 18,850,329 m^2 of seabed, and will impact benthic communities and marine fauna.	As described in **Section 8.1.1.7** the 'long-term disturbance area' of 18.85 km^2 was developed based on a combination of the following allowances: • 30 m wide lay corridor along production flowlines, MEG pipelines, and umbilicals • 250 m radius around DCs and GFP tie-in locations • additional 50% contingency. CAPL considered this a conservative approach to defining the area in which all subsea infrastructure associated with the Development will be installed. That is, all infrastructure footprints will occur within this long-term disturbance area; but the actual infrastructure footprint is likely to be less than this total maximum area (e.g. individual pieces of subsea infrastructure will be placed within the 250 m radius around a GFP tie-in location, but infrastructure would not necessarily cover the full extent of this area). The screening for potential impacts and risks associated with the Development (**Table 7-3**) identified the following receptors as relevant to seabed disturbance: • physical environment (water quality) • benthic habitats and communities • marine fauna (fish) • KEFs • heritage (First Nations cultural values). That is, both benthic communities and marine fauna form part of the detailed impact and risk assessment for seabed disturbance within **Section 8.1**. The highest consequence level of potential impacts associated with seabed disturbance was 4 (moderate), and the highest residual risk level from all potential risks was 7 (low). These potential impacts or risks are not dissimilar to those managed by CAPL (and other petroleum operators) for existing petroleum operations. To manage the impacts and risks associated with seabed disturbance from the Development,	CAPL considers that the OPP sufficiently addresses the matters contained within public comment relating to the environmental impacts and risks associated with seabed disturbance from the Development, and as such no amendments to the OPP have been made.

ID	Stakeholder	Source	Comments received (in general terms)	Titleholder response	Changes to OPP
				CAPL has identified EPOs and preventative control measures to ensure that the impacts and risks can be managed to an acceptable level (**Section 8.1.4**). As such, CAPL considers that the potential for impacts and risks to benthic habitat and associated marine fauna from seabed disturbance can be managed to an acceptable level in alignment with regulatory requirements for an offshore project.	
			Matter: Comments were received citing concerns of potential adverse impacts from light emissions associated with the Development. *Objection or claim*: 8E—The Development will produce light emissions that may impact EPBC-listed marine turtles and birds within respective BIAs or areas identified as habitat critical to survival (HCTS).	The screening for potential impacts and risks associated with the Development (**Table 7-3**) identified the following receptors as relevant to light emissions: • physical environment (ambient light) • marine fauna (seabirds and shorebirds, fish, marine reptiles) • AMPs • heritage (First Nations cultural values). That is, both marine turtles, seabirds and shorebirds were identified as relevant environmental values and sensitivities and were included in the detailed impact and risk assessment for light emissions within **Section 8.4**. The spatial extent used to describe the potential area that may be exposed to light emissions from flaring was based on 42.4 km radius buffer around the DCs (**Section 8.4.2.2**). This distance is based on visible light, which does not necessarily imply a measurable change in ambient light that would have a biological impact to marine fauna. The spatial extent used to describe the potential area that may be exposed to light emissions from navigational/operational lighting on a MODU was 12.6 km radius buffer around the DCs (**Section 8.4.2.3**), and from vessels was based on a 5.2 km radius buffer around the entire DA (**Section 8.4.2.3**). These distances were derived from analogue light monitoring and/or modelling studies. CAPL considered the use of these distances as a conservative approach to defining a spatial extent to be used to identify potential environmental values and sensitives that may be at risk. Note: The actual areas exposed to light emissions will be dependent on location of vessels/MODUs at the time of each activity. Further, where flaring is required, this activity is of limited duration (~1 day per well).	CAPL considers that the OPP sufficiently addresses the matters contained within the public comment relating to the environmental risks to marine fauna associated with light emissions to from the Development, and as such no amendments to the OPP have been made.

ID	Stakeholder	Source	Comments received (in general terms)	Titleholder response	Changes to OPP
				The intersection between these potential light extents and the BIAs and HCTS for marine turtles, seabirds and shorebirds are illustrated in the following figures in the OPP: • flatback turtle—overlap between the flaring and navigational/operational light extents and an internesting buffer BIA and interesting HCTS (**Figure 8-11**) • hawksbill turtle— overlap between the flaring extent and an internesting buffer BIA and internesting HCTS (**Figure 8-13**) • loggerhead turtle—overlap between flaring extent and an internesting buffer BIA (**Figure 8-15**) • green turtle—overlap between the flaring extent and an internesting buffer BIA and internesting HCTS (**Figure 8-16**) • wedge-tailed shearwater—overlap between the flaring and navigational/operational light extents and a breeding BIA (**Figure 8-18**) • fairy tern and lesser crested tern—overlap between the flaring extent and a breeding BIA (**Figure 8-19**, **Figure 8-20**). Neither the navigational/operational lighting extent or the flaring light extent occurs within nearshore or coastal areas (i.e. areas used for nesting/breeding are not predicted to be exposed to light sources from the Development) (**Section 8.4.3**). The residual risk level from risks of behavior changes to marine turtles was 10 (very low), and to seabirds and shorebirds was 9 (very low). These potential impacts or risks are not dissimilar to those managed by CAPL (and other petroleum operators) for existing petroleum operations. To manage the impacts and risks associated with light emissions from the Development, CAPL has identified EPOs and preventative control measures to ensure that the impacts and risks can be managed to an acceptable level (**Section 8.4.5**). As such, CAPL consider that the potential for impacts and risks to marine fauna from light emissions can be managed to an acceptable level in alignment with regulatory requirements for an offshore project.	
			Objection or claim: 8F—The risk of impacts to marine turtles from light emissions may be increased by concurrent activities.	The predicted light extents from flaring and navigation/operational lighting in relation to marine turtle BIAs and/or HCTS are shown in **Figure 8-11** to **Figure 8-17** (for flatback, hawksbill, loggerhead, and green turtles). The predicted	In response to this submission CAPL has revised the OPP to include an

ID	Stakeholder	Source	Comments received (in general terms)	Titleholder response	Changes to OPP
				extent does not reach nearshore or coastal areas (i.e. areas used for nesting or preferred internesting habitat). In recognition that concurrent light emissions may occur from multiple vessels present within a single campaign or from concurrent campaigns, the risk evaluations for marine turtles (and other receptors) have been revised in **Section 8.4.3**. Given the spatial extent of the light emissions and their location to habitats used by marine turtles, no increase in residual risk was predicted to occur from concurrent light emissions.	evaluation of concurrent light emissions for all receptors within **Section 8.4** (light emissions).
			Objection or claim: 8G—The assessment and management of potential impacts and risks from light emissions should be thorough and align with National Light Pollution Guidelines for Wildlife.	The National Light Pollution Guidelines for Wildlife were determined as relevant to the Development in **Section 2.2**, and these were taken into consideration within the light emissions impact and risk assessment in **Section 8.4**. The guidelines were also assessed within the 'determination of acceptability' (**Section 8.4.4**) that demonstrated that the Development is not considered to be inconsistent with the guidelines. To capture further consideration of the mitigation and management tools within the guidelines, an adaptive management EPO (**EPO-16**) control measure (**CM-17**) has been included in the OPP. This adaptive management approach requires consideration of the National Light Pollution Guidelines for Wildlife at the EP stage when activity-specific controls can be considered to support the demonstration that impacts and risks have been reduced to as low as reasonably practicable (ALARP) and acceptable levels.	In response to this submission CAPL has revised the OPP to include an additional EPO (**EPO-16**) and control measure (**CM-17**) in **Section 8.4** (light emissions) regarding consideration of the mitigation toolboxes within the National Light Pollution Guidelines for Wildlife during the subsequent EPs for the Development.
			Objection or claim: 8H—The proponent should avoid generating artificial light emissions during peak nesting periods for several bird and turtle species protected under Part 3 of the EPBC Act.	As described above, neither the navigational/operational lighting extent nor the flaring light extent occurs within nearshore or coastal areas (i.e. areas used for seabird, shorebird, or marine turtle nesting, or the preferred internesting habitat for marine turtles) are not predicted to be exposed to light sources from the Development. Further, the mitigation and management tools within the National Light Pollution Guidelines (which includes consideration of management actions during peak nesting seasons) has been incorporated into the new control measure (**CM-17**).	CAPL considers that the OPP sufficiently addresses the matters contained within the public comment relating to control measures for activities during peak bird or turtle nesting seasons, and as such no further amendments to the

ID	Stakeholder	Source	Comments received (in general terms)	Titleholder response	Changes to OPP
					OPP have been made.
			Matter: Comments were received citing concerns of potential adverse impacts from underwater sound emissions associated with the Development. *Objection or claim*: 8I—The Development will produce underwater sound emissions that may impact EPBC-listed sharks and whales within respective BIAs, and these risks should be assessed. 8J—Acoustic modelling for the Development indicates that behavioural changes, temporary temporal shift (TTS) and permanent temporal shift (PTS) in cetaceans, and TTS in some fish, may occur which presents an unacceptable risk to EPBC-listed threatened species.	The screening for potential impacts and risks associated with the Development (**Table 7-3**) identified the following receptors as relevant to underwater sound: • physical environment (ambient sound) • marine fauna (fish, marine reptiles, marine mammals) • AMPs • heritage (First Nations cultural values). That is, both EPBC-listed sharks and whales were identified as relevant environmental values and sensitivities and were included in the detailed impact and risk assessment for underwater sound within **Section 8.5**. As described in **Sections 8.5.3** and **8.5.4** (summary of modelling results) and **Section 8.5.5** (risk evaluation), the risk of TTS to fish from non-impulsive sounds and impulsive sounds is the order of tens of meters from the sound source. Given the transient and highly mobile nature of sharks (including the EPBC-listed whale shark) the risk of TTS onset was considered to be low (7) to very low (9). As described in **Section 8.5.3** and **8.5.4** (summary of modelling results) and **Section 8.5.5** (risk evaluation), the risk of TTS or PTS to cetaceans from impulsive and non-impulsive sounds was considered low (7) and very low (10) respectively. For low frequency cetaceans (such as the pygmy blue whale) the distances from the sound source that were predicted to be ensonifed above the relevant effect criteria were in the order of tens of meters when considering animat modelling (i.e. incorporating animal movement into acoustic modelling) for low frequency cetaceans. The risk of a behavioural response by cetaceans to either impulsive (e.g. vertical seismic profile [VSP]) or non-impulsive (e.g. from thrusters on a vessel) sounds is considered credible (**Sections 8.5.3, 8.5.4, 8.5.5**). The maximum horizontal distance associated with impulsive sounds was ~2.37 km, and up to ~18.3 km for non-impulsive sounds. These potential ensonified areas overlap with migration BIAs for humpback and pygmy blue	CAPL considers that the OPP sufficiently addresses the matters contained within the public comment relating to the environmental risks to EPBC-listed cetaceans and fish associated with underwater sound emissions from the Development, and as such no amendments to the OPP have been made.

ID	Stakeholder	Source	Comments received (in general terms)	Titleholder response	Changes to OPP
				whales (**Figure 8-27**, **Figure 8-32**). The residual risk level from risks of behavioral changes to cetaceans was 7 (low) for non-impulsive sounds and 9 (very low) for impulsive sounds. Note: Where VSP activities are required, these are of a limited (~1 day per well) duration during the drilling campaigns. These potential risks are not dissimilar to those managed by CAPL (and other petroleum operators) for existing petroleum operations. To manage the risks associated with underwater sound emissions from the Development, CAPL has identified adaptive management EPOs and control measures (including **EPO-23**, **CM-20**, and **CM-21)** which requires acoustic mitigation measures to be further assessed during EPs to ensure that the risks are being reduced to ALARP and managed to an acceptable level. There are also EPOs in place (e.g. **EPO-19**) to ensure that the petroleum activity is not inconsistent with the Conservation Management Plan for Blue Whales (**Section 8.5.7**). As such, CAPL consider that the potential for risks to marine fauna from underwater sound emissions can be managed to an acceptable level in alignment with regulatory requirements for an offshore project.	
			Objection or claim: 8K—Information on migratory routes for southern right whales and dugongs are needed to support risk assessment of sound emissions.	The southern right whale and dugong are not expected to be present within the DA (**Table 6-8**, **Section 6.3.3.1**), and therefore are not predicted to be within ensonified areas from underwater sound emissions associated with the Development. The description of the southern right whale (**Section 6.3.3.1.3**) has been revised to clarify that the distribution range extends north to Exmouth/Ningaloo Reef area in WA (this is within the Hydrocarbon Ecological and Social EMBAs, but not within the DA). Indicative migration paths to/from the Exmouth region have also been shown on a new figure (**Figure 6-18**). The description of the dugong (**Section 6.3.3.1.4**) has been revised to incorporate additional information about dugong habitat. Dugongs habitat preference for seagrass meadows typically restricts them to shallow waters where light penetration allows seagrass to grow. No change has been made to the underwater sound impact and risk assessment (**Section 8.5**) of the OPP.	In response to this submission CAPL has revised the OPP to include additional information within the descriptions of the southern right whale (**Section 6.3.3.1.3**) and dugong (**Section 6.3.3.1.4**).

			Objection or claim: 8L—Further information is required on potential desensitisation of fishes to impulsive sounds associated with seismic airguns.	VSP uses a small (e.g. ~750 in^3) airgun array as an acoustic source; this differs from the larger airgun arrays used in traditional seismic surveys (e.g. for exploration or reservoir management purposes). Traditional seismic surveys are not within the scope of the OPP. The journal article referenced in the submission[4] describes a Norwegian study in which two fish species (Atlantic cod [*Gadus morhua*] and saithe [*Pollachius virens*]) were captured and placed within a sea cage, and then exposed to pulses from a small (40 in^3) airgun over a 3-day period. Results from the study showed some initial behavioural responses (e.g. reduced heart rate, changes to swimming depth and horizonal position), but did not indicate a startle response or long-term alterations to physiology or behaviour. An experimental seismic survey[5] was conducted on the North West Shelf that measured the composition, abundance, behavior, and movement of commercially important demersal fishes. This study was based on exposure to a 3D seismic source (2,600 in^3) over a 5-day period in 50–80 m water depths. The study found that the seismic survey did not alter fish abundance or behavior in multiple before-after-control-impact and dose–response experimental frameworks. The potential risk of behavioural changes to fish from VSP (impulsive sound) is evaluated within **Section 8.5.5**, and is considered appropriate to the nature and scale of the sound source. The residual risk level from impulsive sound on fish was determined as 9 (very low). Use of impulsive sound, and the potential impacts or risks, are not dissimilar to those managed by CAPL (and other petroleum operators) for existing petroleum operations. To manage the impacts and risks associated with these aspects, CAPL has identified EPOs and preventative control measures to ensure that the impacts and risks can be managed to an acceptable level. These include adaptive management EPOs and control measures (**EPO-23**, **CM-20** which requires consideration of activity-specific control measures to ensure that the risks are being reduced to ALARP and managed to an acceptable level. . As such, CAPL consider that the potential for impacts to fish from impulsive sound sources associated with the Development can be managed to an acceptable level in alignment with regulatory requirements for an offshore project.	CAPL considers that the OPP sufficiently addresses the matters contained within the public comment relating to the environmental risks to fish from impulsive sound sources associated with the Development, and as such no amendments to the OPP have been made.

ID	Stakeholder	Source	Comments received (in general terms)	Titleholder response	Changes to OPP
			Objection or claim: 8M—Where data gaps exist about marine fauna and the effect of underwater sound, the precautionary principle should be applied.	The Precautionary Principle is applied as part of the demonstration of principles of ecologically sustainable development (ESD): "if there are threats of serious or irreversible environmental damage, lack of full scientific certainty should not be used as a reason for postponing measures to prevent environmental degradation". The 'determination of acceptability' table within **Section 8.5.6** demonstrates how the principles of ESD, and the Precautionary Principle, have been applied to the underwater sound impact and risk assessment.	CAPL considers no amendments to the OPP are necessary.
			Objection or claim: 8N—EPBC Act Policy Statement 2.1 provides guidance for control measures for consideration by the Development.	EPBC Act Policy Statement 2.1 was prepared for managing the risks of seismic surveys on cetaceans, i.e. the Policy was developed for use with larger traditional seismic surveys, not for the smaller airguns used as part of VSP. The EPBC Act Policy Statement 2.1 was determined as relevant to the Development in **Section 2.2** in that it provides an existing framework for minimising acoustic injury and disturbances to cetaceans from impulsive sound sources. Note: the scope of the OPP does not include seismic surveys. To manage the impacts and risks associated with impulsive sounds (i.e. VSP), CAPL has included adaptive management EPOs and control measures (**EPO-23**, **CM-20**) which requires consideration of activity-specific control measures to ensure that the risks are being reduced to ALARP and managed to an acceptable level. The types of controls that may be considered include those within the Policy.	CAPL considers no amendments to the OPP are necessary.
			Matter: Comments were received citing concerns of potential adverse impacts from	Unplanned hydrocarbon spill scenarios resulting in a release of marine fuel (**Section 8.14**) or gas/condensate (**Section 8.15**) have been identified in the OPP. The worst-case scenarios for each hydrocarbon type were identified:	CAPL considers no amendments to the OPP are necessary.

Effects of sound exposure from a seismic airgun on heart rate, acceleration and depth use in free-swimming Atlantic cod and saithe. *Conservation Physiology*, 7(1). https://doi.org/10.1093/conphys/coz020.

[5] Meekan, M., Speed, C., McCauley, R., Fisher, R., Birt, M., Currey-Randall, L., Semmens, J., Newman, S., Cure, K., Stowar, M., Vaughan, B., and Parsons, M. 2021. A large-scale experiment finds no evidence that a seismic survey impacts a demersal fish fauna. *Proceedings of the National Academy of Sciences*, 118 (30) e2100869118, https://doi.org/10.1073/pnas.2100869118.

ID	Stakeholder	Source	Comments received (in general terms)	Titleholder response	Changes to OPP
			unplanned hydrocarbon spills associated with the Development. *Objection or claim*: 8O—An unplanned spill from the Development has the potential to produce widespread reduction in water quality and sub-lethal to lethal toxicity impacts to marine wildlife, presenting an unacceptable risk to the Australian marine environment.	• marine fuel—vessel collision event • condensate—loss of effective well control (LOWC) event. Oil spill modelling was undertaken for one vessel spill scenario (at WTR as this site is the closest field to shore and represents the worst-case unplanned hydrocarbon release location for hydrocarbon exposure to sensitive receptors (including shorelines; **Section 8.14.2**), and five LOWC events (one at each of Chanon, G&E, C&D, Semele, and WTR; **Section 8.15.2**). A stochastic spill modelling approach (300 simulations under differing metocean conditions) was applied for each of the modelled scenarios. The results from all six sets of oil spill modelling were used to develop the boundaries for the Hydrocarbon Ecological and Social EMBAs (**Section 6.1**, **Figure 6-1**, **Figure 6-2**) and inform the respective risk assessments (**Sections 8.14.3**, **8.15.3**). The highest residual risk level of all the potential risks from the unplanned hydrocarbon release aspects was 8 (low). To manage the impacts and risks associated with an unplanned hydrocarbon release, CAPL has identified both preventative (e.g. **CM-16, CM-31, CM-32, CM-33, CM-43. CM-45, CM-46**) and mitigative (e.g. **CM-22, CM-44**) control measures to ensure that the impacts and risks can be managed to an acceptable level. As such, CAPL considers that the potential for reduced water quality and sub-lethal to lethal impacts on marine fauna can be managed to an acceptable level in alignment with regulatory requirements.	
			Objection or claim: 8P—Given the high-risk to the surrounding environment from an unplanned hydrocarbon spill, a clean-up contingency plan is critically important.	An oil pollution emergency response plan is required as part of the implementation strategy of the EP, as per regulation 22(8) of the OPGGS(E)R. This requirement is reflected in a control measure (**CM-44**) of the OPP. Oil spill response planning is undertaken for the EPs so that the oil spill scenarios, risk assessments, and response planning are undertaken at an activity-specific level. This is aligned with NOPSEMA's Oil Pollution Risk Management guidance note[6].	CAPL considers no amendments to the OPP are necessary.

[6] NOPSEMA. (2024). *Guidance Note: Oil Pollution Risk Management*. Document No. N-04750-GN1488 A382148.

ID	Stakeholder	Source	Comments received (in general terms)	Titleholder response	Changes to OPP
			Matter: Comments were received citing concerns of potential cumulative impacts from the Development in conjunction with other marine activities. *Objection or claim*: 8Q—The impacts from the Development should be assessed in the context of other heavy industrial activity within the North-west Marine Region, to determine the cumulative impact of the activities.	Regulation 13(4)(c) of the OPGGS(E)R requires the identification and evaluation of environmental impacts and risks of the petroleum activities that are part of the proposed Development. NOPSEMA's decision making guideline[7] and content requirements guidance[8] for OPPs both clarify that environmental impacts and risks include cumulative impacts. To address this requirement, a cumulative impact assessment was undertaken (**Section 9**). This cumulative impact assessment identified and evaluated potential cumulative impacts to environmental values and sensitivities that may occur from: • interactions occurring between multiple aspects of the Development • interactions occurring between the Development and third-party activities. The third-party activities included those known to occur within the same vicinity as the proposed Development, including commercial shipping, commercial shipping, and other petroleum activities. The outcomes of the cumulative impact assessment (**Section 9.2**) demonstrated that the EPOs and adopted control measures already in place (within **Section 8**) were also appropriate for the management of any potential cumulative impact. CAPL consider that the potential for cumulative impacts associated with the Development (including those associated with interactions with other industrial activities in the area) have been identified, evaluated, and can be managed to an acceptable level in alignment with regulatory requirements for an offshore project.	CAPL considers no amendments to the OPP are necessary.
			Matter: Comments were received citing concerns that the Development produces significant greenhouse gas (GHG) emissions	The proposed Development comprises the development of seven backfill gas fields in the Greater Gorgon Area that will tie-in to existing Gorgon Foundation Project (GFP) infrastructure. The GFP has primary environmental approvals in place via the *Environment Protection and Biodiversity Conservation Act 1999*	In response to this submission CAPL has revised the OPP to introduce terminology

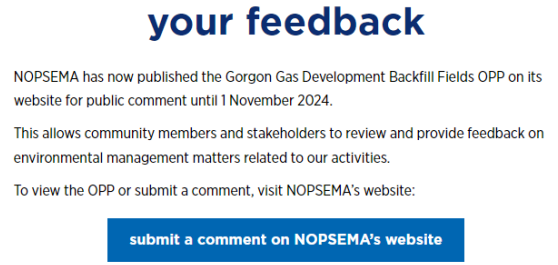
ID	Stakeholder	Source	Comments received (in general terms)	Titleholder response	Changes to OPP
			Objection or claim: 8R—Over its life, the Development will produce approximately 214.7 Mt CO_2-e of GHG emissions (comprising 3.7 Mt CO_2-e of direct emissions and 211 Mt CO_2-e of indirect emissions) and therefore the Development represents an unacceptable source of GHG emissions, when urgent reductions are needed to avoid catastrophic climate change. 8S—The Development's current GHG emissions are incompatible with the IPCC 1.5°C pathway and net zero commitments, and therefore presents unacceptable risk of climate change impacts. 8T—The Development's GHG emissions were not easily identified in the OPP; this information should be made clear to facilitate consultation and assessment.	(Cth) (EPBC Act) and *Environmental Protection Act 1986* (WA) (EP Act), and these primary approvals included assessment and acceptance of GHG emissions associated with the GFP (**Sections 1.2** and **8.3.6**). This OPP is the primary environmental approval, being sought under the *Offshore Petroleum and Greenhouse Gas Storage Act 2006* (Cth) for the Development. For clarity, the GHG emissions identified in the OPP are as follows[9]: • BFF direct GHG emissions – estimate of ~3.07 Mt CO_2-e over the life of the Development (**Section 8.3.4.2**, **Appendix E**) – the proportion of GHG emissions generated during each phase of the Development varies, with the highest proportions associated with drilling, operations and decommissioning (**Figure 8-1**) – CAPL are seeking primary environmental approval associated with these 'BFF direct GHG emissions' by means of the OPP. • BFF gas processing GHG emissions – estimate of ~107.8 Mt CO_2-e over the operational life of the Development (**Section 8.3.4.3**, **Appendix E**) – this is a subset of the total Gorgon Gas Development gas processing emissions already described and assessed under previous approvals • BFF secondary GHG emissions associated with transport and third-party end of use of products – estimate of ~600.7 Mt CO2-e over the operational life of the Development (**Section 8.3.4.4**, **Appendix E**) – these 'GFP secondary GHG emissions' are third-party GHG emissions that are a reasonably foreseeable consequence of the Development – as per the treatment of BFF gas processing GHG emissions, the BFF secondary GHG emissions represent a proportion of	(**Section 8.3.1**) and assessment boundary (**Section 8.3.2**) concepts at the beginning of GHG section. An additional control measure (**CM-10**) has also been included in **Section 8.3.15**. In addition to changes in response to the submission, CAPL has also revised **Section 8.3** of the OPP to include additional information regarding national strategies, legislative and policy framework, corporate context, and projected domestic and global energy trends to support the potential impact and risk evaluations and demonstration of acceptability.

[9] Note: The GHG Inventory (Appendix E) for the Development was revised during Stage 2 OPP assessment, and a new Technical Note has now replaced the previous report that was released during the public comment period. The revised inventory provides additional clarity on the sources of emissions, and the inputs and assumptions used to generate the GHG emissions estimate.

ID	Stakeholder	Source	Comments received (in general terms)	Titleholder response	Changes to OPP
				the overall Gorgon Gas Development secondary GHG emissions. The proposed Development is not increasing the processing capacity or the duration of the Gorgon Gas Development, it is a backfill development that will maintain gas supply to the GTP on Barrow Island (**Section 1.1**), and as such no additional quantity of gas production, or GHG emissions from the GTP, transportation or end-use is associated with the Development that was not already accounted for by existing GFP approvals (**Sections 8.3.3** and **8.3.4**, and **Appendix E**). As presented within the risk evaluation (**Section 8.3.13**) the BFF direct GHG emissions (~3.07 Mt CO_2-e or annual average of ~0.07 Mtpa CO_2-e over the life of the Development) represents ~0.016% of Australia's national annual emissions. These emissions also represent a potential ~0.0002–0.0006% reduction in the total remaining global carbon budget (as described in the outcomes of the IPCC AR6 WGI) for a 50% likelihood to limit global warming to 1.5 °C, and 2.0 °C respectively. This decrease is *de minimis*. The combined BFF GHG emissions and BFF gas processing GHG emissions represent a potential ~0.01–0.02% reduction in the remaining global carbon budget (as estimated to remain at the beginning of 2020) for a 50% likelihood to limit global warming to 1.5–2°C. The BFF secondary GHG emissions (i.e. those emissions from transport and third-party use of products from the Development, represent ~0.04–0.12% of the remaining global carbon budget (as estimated to remain at the beginning of 2020) for a 50% likelihood to limit global warming to 1.5–2°C. To manage the potential impacts and risks associated with GHG emissions, CAPL has identified EPOs and preventative and mitigative control measures (**Section 8.3.15**) to ensure that the impacts and risks associated with the Development can be managed to an acceptable level (as defined within **Section 7.6** of the OPP). GHG emissions associated with the Development are also managed under other legislative requirements, in particular the Commonwealth's Safeguard Mechanism scheme and State primary environmental approvals:	

ID	Stakeholder	Source	Comments received (in general terms)	Titleholder response	Changes to OPP
				• The 'Gorgon Operations Facility' is registered with the Clean Energy Regulator (CER) as a facility under both the National Greenhouse and Energy Reporting (NGER) and Safeguard Mechanism schemes. The scope of the Gorgon Operations Facility includes GHG emissions from both the GTP and associated facilities on Barrow Island, as well as from any activities or facilities in Commonwealth waters. Under the 2023 reforms to the Safeguard Mechanism, an annual decline rate (currently 4.9%) is applied to a facilities baseline (**Section 8.3.5.3**). • The Gorgon GTP Plant Greenhouse Gas Management Plan (GHGMP) is applicable to all GHG emissions from the current operational GFP facilities (as outlined in MS 800[10]), including the three LNG processing trains, domestic gas unit, and Carbon Dioxide Injection System. The GHGMP was developed to satisfy the requirements of condition 27 of MS 800 (as amended by MS 1198), which specifies limits for Net GHG Emissions[11] in 5-yearly intervals, decreasing to net zero by 1 July 2025 (**Section 8.3.6.1**). • Reservoir CO_2 emissions are managed via condition 26 of MS 800 (as amended by MS 1198) and the Safeguard Mechanism • under MS 800 at least 80% of Reservoir CO_2 is injected underground, and offsets acquired for the quantity of Reservoir CO_2 that is not injected underground • under the Safeguard Mechanism reforms new gas fields that supply extant facilities are required to meet zero net reservoir CO_2 emissions. The OPP has been revised to include these other legislative requirements within an EPO (**EPO-11**) and control measure (**CM-10**). As such, CAPL consider that the potential for impacts and risks from the GHG emissions associated with the Development can	

[10] Ministerial Statement 800 (MS 800), as amended by MS 1198, are approval conditions associated with the primary environmental approval for the GFP under the EP Act (WA).



[11] Net GHG Emissions and Reservoir CO_2 and are defined within MS 1198.

				be managed to an acceptable level in alignment with regulatory requirements for an offshore project. In any subsequent Environment Plan, CAPL is required to include details of the control measures that will be used to reduce the impacts and risks of the petroleum activity to ALARP and an acceptable level.	
			Matter: Comments were received citing concerns that the Development lacks an adequate decommissioning plan. *Objection or claim*: 8U—The Development needs a comprehensive decommissioning strategy prior to the end of field life, and this should be available to the public. 8V—The Proponent should remove all property to ensure that the area is left safe, stable and non-polluting. 8W—If infrastructure is not completely removed, there must be ongoing maintenance and monitoring by the Proponent to ensure long-term stability of the infrastructure. 8X—A decommissioning bond sufficient to complete full decommissioning and rehabilitation should be held to protect the Australian government from decommissioning liability.	The overview of CAPL's approach to decommissioning planning (**Section 4.3.5.1**) and description of decommissioning activities (**Sections 4.3.5.2** to **4.3.5.8**) are appropriate to this early-stage of an offshore project. To provide further clarity around decommissioning planning, and how the level of information and detail changes as the Development progresses, additional descriptive material has been incorporated into the introduction of **Section 4.3.5**, including that finalised details of decommissioning activities will be specified in the EP phase. In alignment with requirements under the OPGGS(E)R, relevant persons will be consulted during the preparation of EPs (**Section 3.3**) and the full-text EPs will become public upon submission to NOPSEMA for assessment. Additional clarification around regulatory obligations including other relevant legislation (e.g. *Environment Protection (Sea Dumping) Act 1981* (Cth)) and CAPL's obligations under section 270 of the OPGGS Act for title surrender have also been included in **Section 4.3.5.1**. These criteria under section 270 include the obligation to 'make good' the seabed before the title can be surrendered. Obligations under section 572 of the OPGGS Act regarding the inspection and maintenance of property to ensure full removal can be achieved (unless an alternative arrangement has been accepted by NOPSEMA) is described within existing material in **Sections 4.3.5.1** and **4.3.5.2**. An EPO (**EPO-06**) had also been adopted in the OPP requiring legislative requirements to be met during decommissioning. There is no formal requirement under the OPGGS Act for a titleholder to hold a bond to cover projected decommissioning costs. As described above, and in the OPP, decommissioning is the responsibility of titleholders and section 572 must be met during activities, and criteria under section 270 met before a title can be surrendered at the end of activities. Further, the	In response to this submission CAPL has revised the OPP to include an additional information within the descriptions of the decommissioning phase of the Development (**Section 4.3.5**).

ID	Stakeholder	Source	Comments received (in general terms)	Titleholder response	Changes to OPP
				OPGGS Act was amended to include provisions for enhanced remedial directions (commonly referred to as trailing liability provisions). These amendments came into effect in March 2022, and apply to all titles as they existed on or after 1 January 2021. Trailing liability is designed to ensure that the costs and liabilities associated with decommissioning will be borne by the petroleum industry and do not become the responsibility of government or the Australian community[12].	
			Matter: Comments were received citing concerns that access to the Development's consultation documents is inadequate. *Objection or claim*: 8W—The Proposal documents were not provided on the Proponent's public comment page.	Under regulation 9 of the OPGGS(E)R, it is NOPSEMA's responsibility to publish the OPP and a notice inviting public written comments on their website. The Gorgon Gas Development: Backfill Fields OPP was uploaded to NOPSEMA's Offshore Project Proposals website, with a link to both a PDF version of the full Backfill Fields OPP and NOPSEMA's Consultation and Public Comment webpage (which also had a link to the full OPP as well as instructions for submission of written comments). The OPGGS(E)R specify a period of at least 4 weeks is given for comment; the public comment period for the Backfill Fields OPP was 12 weeks (9 August to 1 November 2024). NOPSEMA's information paper on public comment on OPPs[13] states that the "proponent for the OPP is also requested to promote availability of, and invite comment on, the OPP its website and in a national, state and regional newspapers". The proposed Development was first listed on CAPL's Consultation Hub website during June 2023 as part of the Phase 1 early consultation activities (**Section 3.1**). At the commencement of the NOPSEMA public comment period, CAPL's main website homepage was updated to include a feature box advertising the public comment period, linking directly to the NOPSEMA consultation webpage (see images below).	CAPL has revised **Section 3.2** of the OPP to reflect the NOPSEMA public comment period, advertising by CAPL to support the public comment period, and summary of comments received (this table).

ID	Stakeholder	Source	Comments received (in general terms)	Titleholder response	Changes to OPP
				 The Development's activity information page was also updated at the commencement of the NOPSEMA public comment period to provide a link to the NOPSEMA consultation webpage that had links to a PDF version of the full OPP and details on how to provide written submissions to NOPSEMA (see image below).  In addition to providing a weblink connecting the CAPL consultation page to the NOPSEMA public comment submission page, the following actions were also undertaken by CAPL to promote the NOPSEMA public comment process: • half-page adverts were placed in the following national, state and regional newspapers – The West, and The Australian (12 August 2024) – Pilbara News, Midwest Times, and North West Telegraph (14 August 2024) – National Indigenous Times (27 August 2024) – Business News (2 September 2024) • prominent advertisements were placed in local Onslow and Karratha Chamber of Commerce newsletters, local Facebook	

ID	Stakeholder	Source	Comments received (in general terms)	Titleholder response	Changes to OPP
				discussion boards and a CAPL LinkedIn post, all including a direct link to the NOPSEMA consultation webpage • directly notified stakeholders identified during Phase 1 consultation (**Section 3.1**) with a link to the NOPSEMA consultation webpage for the formal public comment period. These actions are consistent with the Phase 2 public consultation process (**Section 3.2**) described in the OPP and with NOPSEMA's request within their information paper. As such, CAPL consider that while a copy of the OPP was not directly available on their own webpage, that sufficient actions and advertising was taken to direct stakeholders to the NOPSEMA consultation webpage. As the public comment period is a NOPSEMA driven process, this was considered the most efficient way for stakeholders to access all the information they required in the one location.
